

SOCIETY FOR NEUROSCIENCE
ABSTRACTS

VOLUME 20, PART 2

**24TH ANNUAL MEETING
MIAMI BEACH, FLORIDA
NOVEMBER 13–18, 1994**

1994 © Society for Neuroscience

Made in the United States of America.

International Standard Book Numbers:

Part 1 ISBN 0-916110-43-5

Part 2 ISBN 0-916110-44-3

Both parts ISSN 0190-5295

Library of Congress Catalog Card Number 75-7761

Proper citation form for this volume:

Soc. Neurosci. Abstr., Vol. 20, Part 2, p. xxx, 1994.

Abstracts in Session Order*	
Wednesday, November 16–Friday, November 18.....	931
Key Word Index	1786
Author Index	1979

* 10,332 volunteer abstracts, 17 symposia abstracts, 17 history of neuroscience abstracts, and 39 teaching of neuroscience abstracts.

1994 Program Committee

Irwin B. Levitan, Ph.D.

Chairperson

Brandeis University

Leslie G. Ungerleider, Ph.D.

Incoming Chairperson

National Institute of Mental Health, NIH

Jocelyne Bachevalier, Ph.D.

University of Texas School of Medicine

Andrew G. Bulloch, Ph.D.

University of Calgary Health Science Center

Marc G. Caron, Ph.D.

Duke University Medical Center

Catherine E. Carr, Ph.D.

University of Maryland

Raymond J. Dingledine, Ph.D.

Emory University School of Medicine

Stephen S. Easter, Ph.D.

University of Michigan

Judith S. Eisen, Ph.D.

University of Oregon

Michael E. Goldberg, M.D.

National Eye Institute, NIH

Mark W. Hamblin, M.D., Ph.D.

University of Washington

VA Medical Center, Seattle

David M. Katz, Ph.D.

Case Western Reserve University

School of Medicine

Darcy B. Kelley, Ph.D.

Columbia University

Jean M. Lauder, Ph.D.

University of North Carolina

School of Medicine

Amy B. MacDermott, Ph.D.

Columbia University

College of Physicians and Surgeons

Charles B. Nemeroff, M.D., Ph.D.

Emory University School of Medicine

Mary L. Oster-Granite, Ph.D.

University of California, Riverside

Marcus E. Raichle, M.D.

Washington University School of Medicine

John L.R. Rubenstein, M.D., Ph.D.

University of California, San Francisco

Clifford B. Saper, M.D., Ph.D.

Beth Israel Hospital

Gary Charles Schoenwolf, Ph.D.

University of Utah School of Medicine

S. Murray Sherman, Ph.D.

SUNY, Stony Brook

Roger P. Simon, M.D.

University of Pittsburgh School of Medicine

Barry E. Stein, Ph.D.

Bowman Gray School of Medicine

Wake Forest University

W. Thomas Thach, Jr., M.D.

Washington University School of Medicine

R. Suzanne Zukin, Ph.D.

Albert Einstein College of Medicine

Larry R. Squire, Ph.D., *ex officio*

VA Medical Center, San Diego

Carla J. Shatz, Ph.D., *ex officio*

University of California, Berkeley

Lynn T. Landmesser, Ph.D., *ex officio*

Case Western Reserve University

School of Medicine

CHRONOLOGICAL LIST OF SESSIONS

(See page xiv for Thematic List of Sessions.)

Session Number & Title	Page
---------------------------	------

SUNDAY, NOVEMBER 13

Panel—3:00 p.m.

1. Panel on Responsible Conduct in ScienceNo Abstract

Decade of the Brain Lecture—8:00 p.m.

2. Consolidating the Gains in Brain
Chaired by: F.E. BLOOMNo Abstract

MONDAY, NOVEMBER 14

Symposia—8:00 a.m.

3. Molecular Mechanisms of Axon Guidance
Chaired by: M. TESSIER-LAVIGNE1
4. Genes With Triplet Repeats in Neuropsychiatric Illness
Chaired by: C.A. ROSS1

Presidential Special Lecture—10:00 a.m.

5. Cell Death in Development and Disease
H.R. HORVITZNo Abstract

Special Lecture—11:15 a.m.

6. Molecular Studies of Physiological Functions of
Glutamate Receptors
S. NAKANISHINo Abstract

Slide Sessions—8:00 a.m.

7. Basal ganglia and thalamus I1
8. Genetic models3
9. Cognition: imaging I5
10. Subcortical visual pathways: LGN I7
11. Transplantation I9
12. Catecholamines11
13. GABA receptors: molecular biology I13
14. Pain15
15. Stress: neurotransmitter and endocrine studies16
16. Catecholamine receptors I18
17. Cerebellum20
18. Circuitry and pattern generation I22
19. Mental illness24
20. Peptide receptor structure and function I26

Poster Sessions—8:00 a.m.

21. Genesis of neurons and glia I28
22. Neurotransmitter systems and channels: amino acids31
23. Neurotrophic factors: receptors and cellular
mechanisms I34
24. Neurotrophic factors: receptors and cellular
mechanisms II37
25. Neurotrophic factors: receptors and cellular
mechanisms III40
26. Neurotrophic factors: receptors and cellular
mechanisms IV43
27. Motor system I45

Session Number & Title	Page
---------------------------	------

28. Aging process: cerebral cortex, hippocampus, basal
ganglia, and hypothalamus47
29. Gene structure and function I50
30. Gene structure and function II53
31. Presynaptic mechanisms: vesicles57
32. Presynaptic mechanisms: calcium60
33. Sodium channels I63
34. Calcium channels I67
35. Calcium channels II70
36. Potassium channels I74
37. Acetylcholine: anatomy/imaging77
38. Acetylcholine: lesions79
39. Acetylcholine: molecular biology80
40. Acetylcholine: regulation81
41. Anatomical localization of peptides and their
receptors83
42. Neurotransmitters in invertebrates I86
43. Hypothalamic-pituitary-gonadal regulation: GnRH I90
44. Hypothalamic-pituitary-gonadal regulation: steroid
hormones92
45. Hypothalamic-pituitary-gonadal regulation: pituitary95
46. Neuroendocrine regulation: neuropeptides98
47. Neuroendocrine regulation: estradiol100
48. Neural-immune interactions: neurotransmitter
mechanisms101
49. Neural-immune interactions: neural regulation of
immune function104
50. Cardiovascular regulation: system physiology106
51. Cardiovascular regulation: system pharmacology108
52. Regulation of autonomic functions:
reproductive tract111
53. Regulation of autonomic functions: urinary tract112
54. Sensory systems: spinal cord I115
55. Subcortical somatosensory pathways: thalamus117
56. Subcortical somatosensory pathways: brainstem and
spinal cord119
57. Somatosensory cortex and thalamocortical
relationships I122
58. Pain pathways I125
59. Pain modulation: pharmacology I128
60. Retina and photoreceptors I131
61. Subcortical visual pathways: LGN II133
62. Auditory systems: central physiology—brainstem136
63. Olfactory senses: peripheral mechanisms138
64. Oculomotor: superior colliculus141
65. Oculomotor: cortex, thalamus, pretectum143
66. Spinal cord and brainstem: response to injury146
67. Brain metabolism and blood flow: imaging
techniques147
68. Learning and memory: pharmacology—
acetylcholine149
69. Learning and memory: pharmacology—
monoamines152
70. Biological rhythms: sleep I155
71. Biological rhythms: suprachiasmatic nucleus158
72. Biological rhythms: limbic system and reproduction160
73. Neuroethology: bird song I162
74. Neuroethology: bird song II164

CHRONOLOGICAL LIST OF SLIDE AND POSTER SESSIONS

Session Number & Title	Page
75. Neuroethology: general	167
76. Genetic models: learning, memory, and epilepsy	169
77. Degenerative disease: Alzheimer's: cognitive function imaging and cognitive function	171
78. Degenerative disease: Alzheimer's: neuropharmacology and neurotransmitters—cholinergic systems	173
79. Degenerative disease: Parkinson's—model and transplantation	174
80. Ischemia: models	178
81. Ischemia: treatment I	181
82. Ischemia: treatment II	184
83. Ischemia: treatment III	188
84. Trauma: treatment	191
85. Trauma: models	194
86. Neuromuscular disease: muscle	198
87. Neuromuscular disease: neurons	199
(History and Teaching Posters will be posted the entire week.)	
88. History of neuroscience	200
89. Teaching of neuroscience: laboratory courses and exercises	203
90. Teaching of neuroscience: computer programs	206
91. Teaching of neuroscience: curriculum development	208
Symposia—1:00 p.m.	
92. Neuroscience Implications of Inborn Errors of Metabolism <i>Chaired by: A. DIAMOND</i>	210
93. Molecular Mechanisms Controlling K ⁺ Channel Diversity and Distribution in the Nervous System <i>Chaired by: J.M. NERBONNE</i>	210
History of Neuroscience Lecture—1:00 p.m.	
94. Evolving Concepts of Function of the Neocortex V.B. MOUNTCASTLE	No Abstract
Special Lecture—4:15 p.m.	
95. The Molecular Biology and Biophysics of Prions Causing CNS Degeneration S. PRUSINER	No Abstract
Slide Sessions—1:00 p.m.	
96. Excitatory amino acids: pharmacology I	210
97. Process outgrowth I	212
98. Development of visual cortex I	214
99. Retina and photoreceptors II	217
100. Gene structure and function III	219
101. Drugs of abuse: cocaine	221
102. Ischemia: miscellaneous	223
103. Psychotherapeutic drugs: antipsychotics and antidepressants	225
104. Behavioral pharmacology I	227
105. Invertebrate learning and behavior I	229
106. Osmoregulation and cardiovascular regulation	231
107. Oculomotor: saccades	233
108. Excitatory amino acid receptors I	235
109. Neurotrophic factors: receptors and cellular mechanisms V	237
Poster Sessions—1:00 p.m.	
110. Cell migration and differentiation I	239

Session Number & Title	Page
111. Cell migration and differentiation II	243
112. Neuronal death I	245
113. Neuronal death II	246
114. Neuronal death III	249
115. Pattern formation, compartments, and boundaries I	252
116. Motor system II	256
117. Development of chemical senses	258
118. Transplantation II	259
119. Long-term potentiation: physiology I	263
120. Excitatory amino acids: excitotoxicity I	266
121. Excitatory amino acids: excitotoxicity II	269
122. Excitatory amino acids: excitotoxicity III	271
123. Excitatory amino acids: anatomy and physiology I	274
124. Excitatory amino acids: anatomy and physiology II	276
125. Catecholamines: tyrosine hydroxylase and other synthesizing enzymes	279
126. Catecholamines: dopamine release	282
127. Serotonin: behavior	287
128. Serotonin	288
129. Uptake and transporters: serotonin	292
130. Neural-immune interactions: cytokine expression in neural tissues	295
131. Cardiovascular regulation: system organization	296
132. Cardiovascular regulation: dorsal vagal complex	299
133. Respiratory regulation: generation and modulation of respiratory pattern	302
134. Sensory systems: spinal cord II	305
135. Pain modulation: pharmacology II	308
136. Visual cortex: striate I	310
137. Visual cortex: striate II	312
138. Extrastriate visual cortex: functional organization I	315
139. Visual psychophysics and behavior I	317
140. Auditory systems: central physiology—midbrain and thalamus	319
141. Auditory systems: central physiology—cortex I	322
142. Auditory systems: central physiology—cortex II	325
143. Olfactory senses: olfactory bulb	327
144. Olfactory senses: central processing and behavior	329
145. Basal ganglia and thalamus II	331
146. Control of posture and movement I	334
147. Control of posture and movement II	337
148. Limbic system and hypothalamus I	340
149. Limbic system and hypothalamus II	343
150. Limbic system and hypothalamus III	345
151. Limbic system and hypothalamus IV	348
152. Cognition: imaging II	352
153. Learning and memory: systems and functions I	356
154. Learning and memory: systems and functions II	360
155. Learning and memory: systems and functions III	363
156. Motivation and emotion: non-primates	365
157. Motivation and emotion: primates including humans	367
158. Motivation and emotion: self-stimulation	368
159. Neuroethology: electric fish	370
160. Stress: neuroendocrine and <i>c-fos</i> studies	372
161. Hormonal control of reproductive behavior: steroid receptors	375
162. Monoamines and behavior: serotonin	377
163. Neuropeptides and behavior: CCK, TRH, and vasopressin	380
164. Psychotherapeutic drugs: antidepressants and anxiolytics	383

Session Number & Title	Page
165. Aging I	386
166. Aging II	389
167. Aging III	392
168. Developmental disorders: toxins, autoimmunity, and autism	394
169. Epilepsy: basic mechanisms I	396
170. Epilepsy: basic mechanisms—circuitry I	398
171. Epilepsy: basic mechanisms—circuitry II	401
172. Epilepsy: basic mechanisms—genetic models	404
173. Epilepsy: basic mechanisms—kainate and pilocarpine models	407
174. Epilepsy: basic mechanisms—kindling	409
175. Degenerative disease: Parkinson's—neurochemistry	411
176. Degenerative disease: other—diabetes, EAE, and viruses	414
177. Ischemia: white matter	417
178. Trauma: cord	418
179. Trauma: white matter	421
180. Trauma: miscellaneous	422
88. History of neuroscience	200
89. Teaching of neuroscience: laboratory courses and exercises	203
90. Teaching of neuroscience: computer programs	206
91. Teaching of neuroscience: curriculum development	208

Animals in Research Panel—5:30 p.m.

181. Two Aspects of Animal Research: (1) Current Public Attitudes Toward Animal Research; (2) A New Strategy by the Animal Rights Movement: Targeting Perceived Parallels Between the Exploitation of Women and the Exploitation of Animals	No Abstract
---	-------------

Presidential Symposium—8:00 p.m.

182. The Biology of Memory: From Synapses to Systems Genes, Synapses, and the Molecular Switch for Long-term Memory	
E.R. KANDEL	No Abstract
Brain Substrates of Basic Associative Learning	
R.F. THOMPSON	No Abstract
Traces of Recognition	
M. MISHKIN	No Abstract
Neuromodulatory Systems and Regulation of Memory Storage	
J.L. MCGAUGH	No Abstract

TUESDAY, NOVEMBER 15

Symposia—8:00 a.m.

183. New Approaches to Understanding Dendrites <i>Chaired by:</i> D. JOHNSTON	427
184. The Amygdala: From Circuits and Synapses to Emotional Memory <i>Chaired by:</i> J. LEDOUX	427

Special Lecture—11:15 a.m.

185. Membrane Receptors and Ion Channels: Electron Crystallographic Studies of Their Design and Action N. UNWIN	No Abstract
---	-------------

Session Number & Title	Page
Slide Sessions—8:00 a.m.	
186. Extrastriate visual cortex: functional organization II	427
187. Learning and memory: systems and functions IV	429
188. Neuronal death IV	431
189. Cognition: imaging III	433
190. Second messengers I	435
191. Degenerative disease: Alzheimer's—beta amyloid I	437
192. Degenerative disease: Alzheimer's: cognitive function—visual and motor skills	439
193. Neurotrophic factors: biological effects I	441
194. Motor systems: cortex	443
195. Long-term potentiation: physiology II	445
196. Peptides: biosynthesis and metabolism	447
197. Biological rhythms	449
198. Excitatory amino acids: excitotoxicity IV	451
199. Presynaptic mechanisms I	453

Poster Sessions—8:00 a.m.

200. Genesis of neurons and glia II	455
201. Hormones and development I	459
202. Hormones and development II	462
203. Development of visual cortex II	464
204. Successful axonal regeneration	467
205. Transplantation III	470
206. Membrane composition and surface macromolecules: synapses and glia	474
207. Acetylcholine receptors: muscarinic signal transduction	476
208. Acetylcholine receptors: muscarinic molecular biology	477
209. Acetylcholine receptors: muscarinic pharmacology	479
210. Excitatory amino acid receptors II	481
211. Excitatory amino acid receptors III	483
212. Excitatory amino acid receptors: metabotropic receptors	486
213. Excitatory amino acid receptors: localization	489
214. Excitatory amino acid receptors: expression and splice variants	492
215. GABA receptors: function—modulation	495
216. GABA receptors: function I	500
217. GABA receptors: function II	502
218. GABA receptors: development	506
219. GABA receptors: molecular biology II	508
220. Peptide receptor structure and function II	511
221. Anatomical localization of peptides and their receptors: peptides	514
222. Anatomical localization of peptides and their receptors: regulated expression of peptides	519
223. Catecholamine receptors II	520
224. Catecholamine receptors III	523
225. Catecholamines: noradrenergic systems— neuronal circuitry	526
226. Neurotransmitters in invertebrates II	531
227. Uptake and transporters: acetylcholine	533
228. Second messengers: G protein-mediated	535
229. Second messengers: protein kinase C—calcium	538
230. Respiratory regulation: developmental mechanisms	542
231. Respiratory regulation: transmitter mechanisms	544
232. Pain pathways II	547
233. Pain: dorsal horn physiology	550
234. Pain: dorsal horn pharmacology	553
235. Pain modulation: pharmacology III	556

CHRONOLOGICAL LIST OF SLIDE AND POSTER SESSIONS

Session Number & Title	Page	Session Number & Title	Page
236. Retina and photoreceptors III	559	274. Neurotoxicity	641
237. Basal ganglia and thalamus III	561	275. Catecholamine receptors IV	643
238. Basal ganglia and thalamus IV	563	276. Hypothalamic-pituitary-adrenal axis regulation I	645
239. Vestibular: vestibuloocular reflex in humans	566	277. Degenerative disease: Alzheimer's—tau protein	647
240. Vestibular: pharmacology	569	278. Excitatory amino acids: excitotoxicity V	649
241. Control of posture and movement III	571	279. Postsynaptic mechanisms I	651
242. Brain metabolism and blood flow: basic mechanisms I	574		
243. Cognition I	576	Poster Sessions—1:00 p.m.	
244. Invertebrate learning and behavior II	578	280. Cell lineage and determination I	653
245. Ingestive behaviors I	583	281. External influences on neuritic outgrowth	656
246. Ingestive behaviors II	586	282. Process outgrowth and GAP-43	659
247. Hormonal control of reproductive behavior: other I	589	283. Peripheral axon guidance	661
248. Drugs of abuse: cocaine—behavior	592	284. Axon guidance: regeneration	663
249. Drugs of abuse: cocaine—cell biology	594	285. Neurotrophic factors: biological effects II	665
250. Drugs of abuse: cocaine—development	596	286. Neurotrophic factors: biological effects III	668
251. Drugs of abuse: cocaine—peripheral effects	600	287. Neurotrophic factors: biological effects IV	671
252. Degenerative disease: Alzheimer's—beta amyloid II	601	288. Neurotrophic factors: biological effects V	675
253. Degenerative disease: Alzheimer's—beta amyloid III	604	289. Neurotrophic factors: biological effects VI	678
254. Degenerative disease: Alzheimer's: neuropathology and neurotransmitters—cholinergic systems	608	290. Neuronal death V	681
255. Ischemia: inflammation	610	291. Neuronal death VI	684
256. Ischemia: gene transcription	613	292. Neuronal death VII	688
257. Ischemia: molecular	614	293. Pattern formation, compartments, and boundaries II	690
258. Ischemia: neonatal	617	294. Glia: differentiation and cell biology	692
259. Ischemia: nerve	618	295. Sequelae to central injury	696
260. Neuromuscular disease: ALS	619	296. Molecular correlates of central injury	697
261. Mental illness: schizophrenia I	620	297. Staining, tracing, and imaging techniques I	699
88. History of neuroscience	200	298. Staining, tracing, and imaging techniques II	702
89. Teaching of neuroscience: laboratory courses and exercises	203	299. Neuroglia and myelin I	705
90. Teaching of neuroscience: computer programs	206	300. Membrane composition and surface macromolecules: membrane lipids and receptors	708
91. Teaching of neuroscience: curriculum development	208	301. Synaptic structure and function I	710
		302. Long-term potentiation: physiology III	713
Symposia—1:00 p.m.		303. Sodium channels II	717
262. Cytokines and Neural Development <i>Chaired by:</i> J.A. KESSLER	624	304. Potassium channels II	719
263. Autonomic Integration in the Control of Food Intake <i>Chaired by:</i> T.H. MORAN	624	305. Potassium channels III	723
		306. Ion channels: cell function I	726
Special Lecture—1:00 p.m.		307. Excitatory amino acids: pharmacology, metabotropic receptors	729
264. Evolutionary Origins of Neocortex: Reshuffling Neuromeres to Make a New Deck? H. KARTEN	No Abstract	308. Excitatory amino acids: pharmacology II	731
		309. Excitatory amino acid receptors IV	733
Presidential Special Lecture—4:15 p.m.		310. Excitatory amino acid receptors V	737
265. Transient and Enduring Effects of Experience: Functional Studies of Visual and Motor Cortex L.G. UNGERLEIDER	No Abstract	311. Excitatory amino acid receptors: topology	740
		312. Excitatory amino acid receptors: posttranslational modification	741
Slide Sessions—1:00 p.m.		313. Opioid receptors: molecular biology	744
266. Visual cortex: striate III	624	314. Opioid receptors: sigma receptors	746
267. Uptake and transporters	626	315. Opioid receptors: physiology	748
268. Calcium channels III	629	316. Opioids: anatomy and physiology I	750
269. Formation and specificity of synapses I	631	317. Somatosensory cortex and thalamocortical relationships II	753
270. Gene structure and function IV	633	318. Pain: central mechanisms	756
271. Degenerative disease: Alzheimer's—beta amyloid IV	635	319. Pain: peripheral mechanisms	759
272. Hypothalamic-pituitary-gonadal regulation: GnRH II	637	320. Pain: models of nociception	761
273. Epilepsy: basic mechanisms II	639	321. Pain modulation: pharmacology IV	764
		322. Retina and photoreceptors IV	767
		323. Subcortical visual pathways: thalamus and midbrain	770
		324. Extrastriate visual cortex: parietal areas I	772
		325. Invertebrate sensory systems I	774
		326. Invertebrate sensory systems II	777
		327. Basal ganglia and thalamus V	780
		328. Basal ganglia and thalamus VI	783

Session Number & Title	Page
329. Spinal cord and brainstem: functional neurophysiology	786
330. Spinal cord and brainstem: cellular neurophysiology	789
331. Control of posture and movement IV	792
332. Learning and memory: physiology I	795
333. Learning and memory: physiology II	800
334. Learning and memory: physiology III	804
335. Learning and memory: physiology IV	808
336. Motivation and emotion: biochemistry and pharmacology	811
337. Invertebrate learning and behavior III	814
338. Ingestive behaviors III	817
339. Monoamines and behavior: catecholamines I	820
340. Monoamines and behavior: catecholamines II	824
341. Monoamines and behavior: catecholamines III	827
342. Monoamines and behavior: catecholamines IV	830
343. Genetic models: transgenics, trisomics, and mutants	831
344. Neuro-oncology: cell biology	834
88. History of neuroscience	200
89. Teaching of neuroscience: laboratory courses and exercises	203
90. Teaching of neuroscience: computer programs	206
91. Teaching of neuroscience: curriculum development	208
 The Grass Foundation Lecture—8:00 p.m.	
345. In Your Ear: Transduction, Tuning, and Transmission by Hair Cells J. HUDSPETH	No Abstract

WEDNESDAY, NOVEMBER 16

Symposia—8:00 a.m.

346. Early Development and Regionalization of the Mouse Brain <i>Chaired by:</i> S.S. EASTER, JR.	836
347. Molecular Plasticity in Epilepsy and Ischemia <i>Chaired by:</i> Y. BEN-ARI	836

Presidential Special Lecture—11:15 a.m.

348. Adaptation and Exaptation in the Evolution of the Human Brain S.J. GOULD	No Abstract
--	-------------

Slide Sessions—8:00 a.m.

349. Visual cortex: striate IV	836
350. Extrastriate visual cortex: functional organization III	839
351. Acetylcholine receptors: nicotinic	840
352. Cardiovascular regulation	842
353. Trauma	844
354. Long-term potentiation: physiology IV	846
355. Degenerative disease: Alzheimer's—beta amyloid V	848
356. Peptides: physiological effects I	850
357. Control of posture and movement V	852
358. Neurotrophic factors: biological effects VII	855
359. Oculomotor: vestibuloocular reflex and smooth pursuit I	857
360. Drugs of abuse: alcohol I	859
361. Neuroendocrine regulation: other	860

362. Potassium channels IV	863
 Poster Sessions—8:00 a.m.	
363. Formation and specificity of synapses II	865
364. Hormones and development III	868
365. Glia: microglia and ensheathing cells	872
366. Cerebral cortex and limbic system I	875
367. Transplantation IV	878
368. Aging process: genes and receptor	881
369. Neuroglia and myelin II	883
370. Synaptic structure and function II	887
371. Presynaptic mechanisms II	889
372. Postsynaptic mechanisms II	890
373. Long-term potentiation: physiology V	894
374. Calcium channels IV	898
375. Calcium channels V	901
376. Peptide receptor structure and function III	905
377. Catecholamine receptors V	908
378. Neurotransmitters in invertebrates III	912
379. Storage, secretion, and metabolism	915
380. Uptake and transporters: GABA, glycine, and other amino acids	918
381. Uptake and transporters: catecholamines	920
382. Uptake and transporters: glutamate	925
383. Second messengers: phospholipase C, phospholipase A2	927
384. Receptor modulation up- and down-regulation I	931
385. Hypothalamic-pituitary-adrenal axis regulation: stress studies	935
386. Hypothalamic-pituitary-adrenal axis regulation II	938
387. Hypothalamic-pituitary-gonadal regulation: GnRH release	941
388. Neuroendocrine regulation: glucocorticoids	944
389. Neural-immune interactions: stress and other behavioral models	945
390. Neural-immune interactions: hormonal regulation of immune function	949
391. Neural-immune interactions: responses to immunologic challenge	951
392. Neural-immune interactions: cytokine effects on the nervous system	954
393. Respiratory regulation: chemoreceptive mechanisms	956
394. Respiratory regulation: effects of hypoxia or hypercapnia	958
395. Somatic and visceral afferents: visceral afferents	959
396. Pain modulation: pharmacology V	962
397. Retina and photoreceptors V	965
398. Auditory, vestibular, and lateral line: hair cells	967
399. Auditory systems: cochlea	971
400. Auditory systems: central anatomy I	972
401. Auditory systems: central anatomy II	975
402. Gustatory and related chemical senses	978
403. Motor cortex: cortical physiology	981
404. Motor cortex: anatomy	984
405. Motor cortex: cingulate and prefrontal cortex	986
406. Basal ganglia and thalamus VII	987
407. Basal ganglia and thalamus VIII	990
408. Control of posture and movement VI	992
409. Comparative neuroanatomy: sex, evolution, and the forebrain	996
410. Brain metabolism and blood flow: nitric oxide	998
411. Cognition II	1000

CHRONOLOGICAL LIST OF SLIDE AND POSTER SESSIONS

Session Number & Title	Page
412. Cognition III	1003
413. Learning and memory: systems and functions V	1007
414. Learning and memory: systems and functions VI	1010
415. Learning and memory: systems and functions VII	1014
416. Learning and memory: pharmacology—excitatory amino acids	1017
417. Learning and memory: pharmacology—others I	1020
418. Neuroethology: invertebrates	1024
419. Drugs of abuse: CNS stimulants—toxicity	1026
420. Drugs of abuse: CNS stimulants—behavior	1029
421. Degenerative disease: Alzheimer's—mechanisms of cellular injury I	1032
422. Degenerative disease: Alzheimer's—tau phosphorylation and neurofibrillary degeneration	1034
423. Ischemia: mechanisms I	1038
424. Ischemia: mechanisms II	1041
425. Ischemia: apoptosis	1043
426. Neurotoxicity: EAA I	1044
427. Neurotoxicity: EAA II	1048
428. Neuro-oncology: therapy I	1050
88. History of neuroscience	200
89. Teaching of neuroscience: laboratory courses and exercises	203
90. Teaching of neuroscience: computer programs	206
91. Teaching of neuroscience: curriculum development	208
Symposia—1:00 p.m.	
429. Toward a Neurobiology of Visual Consciousness <i>Chaired by: C. KOCH</i>	1051
430. Developmental Control of Electrical Excitability <i>Chaired by: A.B. RIBERA</i>	1051
Special Lecture—1:00 p.m.	
431. The Role of Local Signals in the Control of CNS Neuronal Development M.E. HATTEN	No Abstract
Special Lecture—4:15 p.m.	
432. Potassium Channels L. JAN	No Abstract
Slide Sessions—1:00 p.m.	
433. Second messengers II	1051
434. Extrastriate visual cortex: inferior temporal areas	1053
435. Degenerative disease: Alzheimer's—beta amyloid VI	1055
436. Hypothalamic-pituitary-gonadal regulation	1057
437. Regional localization of receptors and transmitters I	1060
438. Ischemia: mechanisms III	1061
439. Axon guidance I	1063
440. Receptor modulation up- and down-regulation II	1066
441. Neuropeptides and behavior: CRF and oxytocin	1068
442. Glia and other non-neuronal cells	1070
443. Invertebrate learning and behavior IV	1071
444. Learning and memory: systems and functions VIII	1073
445. Degenerative disease: other I	1075
Poster Sessions—1:00 p.m.	
446. Cell lineage and determination II	1077
447. Process outgrowth in retina and retinal prosection sites	1079

Session Number & Title	Page
448. Process outgrowth and second messengers	1081
449. Axon guidance in the visual system	1084
450. Formation and specificity of synapses III	1086
451. Neurotrophic factors: biological effects VIII	1090
452. Neurotrophic factors: biological effects IX	1093
453. Neurotrophic factors: biological effects X	1096
454. Neurotrophic factors: biological effects XI	1099
455. Neurotrophic factors: biological effects XII	1103
456. Development of the auditory and vestibular systems ...	1106
457. Development of visual cortex III	1108
458. Transplant- and prosthesis-assisted regeneration	1110
459. Neuroglia and myelin III	1112
460. Cytoskeleton transport and membrane targeting: axon and dendrite cytoskeleton	1115
461. Synaptic structure and function III	1117
462. Presynaptic mechanisms III	1119
463. Ligand-gated ion channels I	1122
464. Ligand-gated ion channels: alcohol modulation	1125
465. Acetylcholine receptors: nicotinic development	1127
466. Acetylcholine receptors: nicotinic molecular biology ..	1128
467. Acetylcholine receptors: nicotinic pharmacology	1134
468. Acetylcholine receptors: nicotinic function	1139
469. Excitatory amino acids: pharmacology III	1141
470. Excitatory amino acids: pharmacology IV	1143
471. Peptides: biosynthesis, metabolism, and biochemical characterization I	1146
472. Peptides: biosynthesis and processing	1149
473. Catecholamines: measurements, spect, lesions— immediate early genes	1152
474. Serotonin receptors: 5-HT3	1156
475. Serotonin receptors: effector mechanisms	1157
476. Serotonin receptors: molecular biology	1159
477. Serotonin receptors: regulation	1161
478. Regional localization of receptors and transmitters II ...	1165
479. Regional localization of receptors and transmitters III ..	1168
480. Second messengers: kinases and phosphatases	1171
481. Neuroendocrine regulation: magnocellular system	1175
482. Neuroendocrine regulation: other II	1177
483. Thermoregulation and fever	1180
484. Cardiovascular regulation: medullary reticular responses	1181
485. Subcortical visual pathways: midbrain	1184
486. Basal ganglia and thalamus IX	1187
487. Vestibular: vestibuloocular reflex physiology	1190
488. Oculomotor: vestibuloocular reflex and smooth pursuit II	1193
489. Oculomotor: clinical studies	1195
490. Control of posture and movement VII	1197
491. Circuitry and pattern generation II	1200
492. Muscle: force, frequency, and fatigue	1204
493. Learning and memory: systems and functions IX	1205
494. Learning and memory: systems and functions X	1210
495. Learning and memory: systems and functions XI	1214
496. Biological rhythms: sleep II	1218
497. Biological rhythms: lesions pathologies	1219
498. Biological rhythms: molecular regulation	1220
499. Ingestive behaviors IV	1221
500. Ingestive behaviors V	1223
501. Hormonal control of reproductive behavior: mating	1226
502. Drugs of abuse: behavior I	1229
503. Drugs of abuse: behavior II	1231
504. Drugs of abuse: metabolism—pharmacology	1235

Session Number & Title	Page
505. Developmental disorders: cortical injury models	1237
506. Epilepsy: anticonvulsant drugs—AMPA and NMDA receptor	1239
507. Degenerative disease: Alzheimer's- beta amyloid VII	1241
508. Degenerative disease: Alzheimer's- beta amyloid VIII	1245
509. Degenerative disease: Alzheimer's: neuropathology and neurotransmitters—other systems	1248
510. Degenerative disease: Alzheimer's—cellular mechanisms of degeneration	1251
511. Degenerative disease: other—neurotoxic effects and Huntington's	1254
512. Infectious disease	1257
513. Mental illness: schizophrenia II	1260
88. History of neuroscience	200
89. Teaching of neuroscience: laboratory courses and exercises	203
90. Teaching of neuroscience: computer programs	206
91. Teaching of neuroscience: curriculum development	208
Social Issues Roundtable—4:00 p.m.	
514. Health Care Economics and the Brain <i>Sponsored by: Social Issues Committee of the Society for Neuroscience</i> S.F. WITSELSON, Chairperson	No Abstract

THURSDAY, NOVEMBER 17

Symposia—8:00 a.m.

515. Structure, Function, and Regulation of Glutamate Receptors <i>Chaired by: R.L. HUGANIR</i>	1263
516. General Anesthetic Effects on Somatomotor Processing <i>Chaired by: P. MASON</i>	1263

Warner-Lambert Lecture—11:15 a.m.

517. Ins and Outs of Programmed Cell Death M. RAFF	No Abstract
---	-------------

Slide Sessions—8:00 a.m.

518. Brain metabolism and blood flow: general	1264
519. Serotonin receptors	1266
520. Regeneration	1268
521. Cognition: human I	1270
522. Degenerative disease: Alzheimer's—mechanisms of degeneration	1272
523. Cell lineage and determination III	1274
524. Neurotransmitters: neurotransmitter interactions	1276
525. Extrastriate visual cortex: parietal areas II	1278
526. Neurotransmitters in invertebrates IV	1280
527. Axon guidance II	1282
528. Ingestive behaviors VI	1284
529. Drugs of abuse: amphetamines and CNS stimulants	1287
530. Learning and memory: systems and functions XII	1289

Poster Sessions—8:00 a.m.

531. Process outgrowth and adhesion molecules	1291
532. Process outgrowth and cytoskeleton	1292

Session Number & Title	Page
533. Mechanisms of axon guidance	1294
534. Formation and specificity of synapses IV	1297
535. Neurotransmitter systems and channels: other transmitters	1299
536. Neurotrophic factors: expression and regulation I	1302
537. Neurotrophic factors: expression and regulation II	1305
538. Neurotrophic factors: expression and regulation III	1308
539. Neurotrophic factors: expression and regulation IV	1310
540. Neurotrophic factors: expression and regulation V	1311
541. Neurotrophic factors: expression and regulation VI	1313
542. Molecular and pharmacological correlates of development	1315
543. Cerebral cortex and limbic system II	1319
544. Retinal development	1322
545. Influences on axonal regeneration	1324
546. Transplantation V	1327
547. Cytoskeleton transport and membrane targeting: axoplasmic transport and synapses	1331
548. Blood-brain barrier	1333
549. Presynaptic mechanisms IV	1336
550. Presynaptic mechanisms V	1338
551. Long-term potentiation: physiology VI	1340
552. Peptide receptor structure and function IV	1344
553. Peptides: physiological effects II	1347
554. Peptides: physiological effects III	1350
555. Catecholamine receptors VI	1353
556. Second messengers: NO, CO, and gene regulation	1357
557. Behavioral pharmacology II	1360
558. Behavioral pharmacology: dopamine	1363
559. Cardiovascular regulation: pre- and postganglionic control	1366
560. Regulation of autonomic functions: cardiovascular	1368
561. Regulation of autonomic functions: CNS pathways and transmitters	1371
562. Regulation of autonomic functions: gastrointestinal	1375
563. Respiratory regulation: human studies	1378
564. Somatic and visceral afferents: thermoreception	1379
565. Somatic and visceral afferents: anatomy and physiology of mechanoreception	1380
566. Somatosensory cortex and thalamocortical relationships III	1383
567. Somatosensory cortex and thalamocortical relationships IV	1386
568. Pain modulation: pharmacology VI	1389
569. Retina and photoreceptors VI	1392
570. Motor cortex: biophysics, models, plasticity	1394
571. Motor cortex: human studies	1396
572. Oculomotor: brainstem and muscle	1398
573. Oculomotor: performance and modeling of saccades	1400
574. Oculomotor: blinking, vengeance, and torsion	1403
575. Control of posture and movement VIII	1405
576. Control of posture and movement IX	1409
577. Circuitry and pattern generation III	1411
578. Association cortex and thalamocortical relations	1414
579. Comparative neuroanatomy: sensory systems	1417
580. Comparative neuroanatomy: chemical anatomy	1419
581. Brain metabolism and blood flow: basic mechanisms II	1421
582. Cognition IV	1423
583. Neural plasticity I	1426
584. Neural plasticity II	1429

CHRONOLOGICAL LIST OF SLIDE AND POSTER SESSIONS

Session Number & Title	Page
585. Neural plasticity III	1431
586. Neural plasticity IV	1435
587. Biological rhythms: SCN, activation, and anatomy	1438
588. Biological rhythms: pineal and melatonin	1440
589. Stress: neurochemistry and behavior I	1442
590. Stress: neurotransmitter studies	1444
591. Hormonal control of reproductive behavior: parental/aggressive	1447
592. Epilepsy: human studies and animal models I	1449
593. Epilepsy: human studies and animal models II	1452
594. Epilepsy: human studies and animal models III	1454
595. Epilepsy: human studies and animal models— morphological changes	1456
596. Epilepsy: human studies and animal models— kindling	1458
597. Degenerative disease: Alzheimer's— beta amyloid IX	1461
88. History of neuroscience	200
89. Teaching of neuroscience: laboratory courses and exercises	203
90. Teaching of neuroscience: computer programs	206
91. Teaching of neuroscience: curriculum development	208
Symposia—1:00 p.m.	
598. The Cell Biology of Secretion Vesicles <i>Chaired by:</i> K.J. SKINNER	1463
599. Neuropeptide Regulation of Brain Development: From Cells to Animals <i>Chaired by:</i> E.M. DICICCO-BLOOM and J.P. SCHWARTZ	1463
Special Lecture—1:00 p.m.	
600. Brain Maps for Movement R.H. WURTZ	No Abstract
Special Lecture—4:15 p.m.	
601. Muscimol, Memory, and Motivation in the Basal Ganglia O. HIKOSAKA	No Abstract
Slide Sessions—1:00 p.m.	
602. Degenerative disease: Parkinson's	1464
603. Ligand-gated ion channels II	1466
604. Calcium channels VI	1468
605. Visual system development and plasticity	1470
606. Chemical senses	1472
607. Process outgrowth II	1474
608. Visual cortex: striate V	1476
609. Ischemia: protection	1478
610. Neurotrophic factors: expression and regulation VII	1480
611. Opioid receptors	1482
612. Degenerative disease: Alzheimer's—beta amyloid X	1484
Poster Sessions—1:00 p.m.	
613. Genesis of neurons and glia III	1486
614. Cell migration and differentiation III	1489
615. Cell migration and differentiation IV	1492
616. Glia: glial response to injury, toxins, and disease	1495
617. Molecular correlates of peripheral axonal regeneration	1498
618. Neuroglia and myelin IV	1501

Session Number & Title	Page
619. Gene structure and function V	1504
620. Postsynaptic mechanisms III	1507
621. Postsynaptic mechanisms IV	1510
622. Long-term potentiation: pharmacology I	1511
623. Long-term potentiation: pharmacology II	1514
624. Pharmacology of synaptic transmission I	1517
625. Potassium channels V	1519
626. Potassium channels VI	1522
627. Ion channels: cell function II	1526
628. Excitatory amino acids: excitotoxicity and NMDA receptors	1529
629. Excitatory amino acids: excitotoxicity and non-NMDA receptors	1532
630. Excitatory amino acids: pharmacology and non-NMDA receptors	1535
631. Peptides: biosynthesis, metabolism, and biochemical characterization II	1537
632. Serotonin receptors: physiology	1539
633. Serotonin receptors: pharmacology	1542
634. Serotonin receptors: behavior	1544
635. Serotonin receptors: localization	1546
636. Neurotransmitters and other amines/purines	1548
637. Neurotransmitter interactions: serotonin	1551
638. Neurotransmitter interactions: cholinergic/GABA	1554
639. Neurotransmitter interactions	1557
640. Neurotransmitters: glutamate/nitric oxide	1560
641. Behavioral pharmacology III	1563
642. Osmotic regulation	1565
643. Somatic and visceral afferents: nociception	1568
644. Pain pathways III	1572
645. Retina and photoreceptors VII	1574
646. Visual cortex: striate VI	1577
647. Visual psychophysics and behavior II	1579
648. Motor systems and sensorimotor integration: reflex function I	1581
649. Spinal cord and brainstem: anatomy	1584
650. Spinal cord and brainstem: transmitter localization	1587
651. Spinal cord and brainstem: pharmacology	1589
652. Circuitry and pattern generation IV	1591
653. Invertebrate motor function	1594
654. Muscle: fiber types and endplates	1598
655. Suprachiasmatic nucleus: neuropeptides	1600
656. Neuropeptides and behavior: other	1601
657. Drugs of abuse: alcohol and benzodiazepines	1604
658. Drugs of abuse: alcohol and opioids	1607
659. Drugs of abuse: alcohol II	1609
660. Drugs of abuse: alcohol III	1611
661. Drugs of abuse: alcohol IV	1614
662. Drugs of abuse: alcohol V	1617
663. Drugs of abuse: CNS stimulants—cellular and molecular mechanisms	1620
664. Drugs of abuse: cocaine—dopamine	1625
665. Drugs of abuse: cocaine—dopamine receptors	1629
666. Drugs of abuse: cocaine—non-dopaminergic systems	1632
667. Psychotherapeutic drugs: atypical antipsychotics	1636
668. Epilepsy: anticonvulsant drugs—other neurotransmitter receptors	1639
669. Degenerative disease: Alzheimer's— beta amyloid XI	1641
670. Degenerative disease: Parkinson's—rodent and primate studies	1643

Session Number & Title	Page
671. Degenerative disease: other II	1646
672. Neurotoxicity: drugs	1649
673. Neurotoxicity: metals	1652
674. Neurotoxicity: striatum	1657
675. Neurotoxicity: oxidation	1659
676. Neurotoxicity: miscellaneous	1661
88. History of neuroscience	200
89. Teaching of neuroscience: laboratory courses and exercises	203
90. Teaching of neuroscience: computer programs	206
91. Teaching of neuroscience: curriculum development	208

FRIDAY, NOVEMBER 18

Symposium—8:00 a.m.

677. Neural Coding of Visual Space: Visual Mechanisms and Multimodal Integration <i>Chaired by: G. RIZZOLATTI</i>	1663
---	------

Slide Sessions—8:00 a.m.

678. Cognition: human II	1664
679. Visual psychophysics and behavior III	1665
680. Epilepsy: human studies and animal models IV	1667
681. Degenerative disease: Alzheimer's— beta amyloid XII	1669
682. Cell migration and differentiation V	1671
683. Degenerative disease: Alzheimer's—mechanisms of cellular injury II	1673
684. Drugs of abuse: addiction/tolerance	1675
685. Excitatory amino acids: excitotoxicity VI	1677
686. Ingestive behaviors VII	1678

Poster Sessions—8:00 a.m.

687. Influences on sprouting in situ	1681
688. Development of central tracts	1683
689. Neurotransmitter systems and channels: channels	1685
690. Other factors and trophic agents I	1686
691. Other factors and trophic agents II	1691
692. Nutritional and prenatal factors	1694
693. Pattern formation, compartments, and boundaries III	1697
694. Somatosensory development	1700
695. Development of retinofugal projection and targets	1703
696. Transplantation VI	1705
697. Aging process	1708

Session Number & Title	Page
698. Synaptic structure and function III	1711
699. Pharmacology of synaptic transmission II	1713
700. Chloride and other channels	1716
701. Calcium channels VII	1718
702. Excitatory amino acids: pharmacology V	1721
703. GABA receptors: function III	1723
704. Opioid receptors: tolerance and regulation	1726
705. Opioid receptors: localization	1728
706. Opioid receptors: cell biology and effector mechanisms	1730
707. Opioids: anatomy and physiology II	1733
708. Opioids: anatomy and physiology III	1736
709. Hypothalamic-pituitary-gonadal regulation: hypophysiotrophic area	1739
710. Extrastriate visual cortex: functional organization IV ...	1740
711. Cerebellum: cellular neurophysiology	1743
712. Cerebellum: behavioral neurophysiology and clinical studies	1746
713. Cerebellum: neuroanatomy	1748
714. Cerebellum: pharmacology	1750
715. Motor systems and sensorimotor integration: reflex function II	1752
716. Spinal cord and brainstem: pattern generation	1754
717. Spinal cord and brainstem: neonates	1756
718. Circuitry and pattern generation V	1758
719. Muscle: electrophysiology	1759
720. Brain metabolism and blood flow: disease mechanisms	1760
721. Learning and memory: pharmacology—others II	1762
722. Biological rhythms: light	1765
723. Biological rhythms: models	1767
724. Stress: neurochemistry and behavior II	1768
725. Hormonal control of reproductive behavior: other II ...	1770
726. Psychotherapeutic drugs: antipsychotics	1772
727. Psychotherapeutic drugs: other	1774
728. Degenerative disease: Alzheimer's—models, assessment, and treatment	1776
729. Degenerative disease: Parkinson's—human studies	1778
730. Mental illness: depression, anxiety, and schizophrenia	1781
731. Neuro-oncology: therapy II	1784
88. History of neuroscience	200
89. Teaching of neuroscience: laboratory courses and exercises	203
90. Teaching of neuroscience: computer programs	206
91. Teaching of neuroscience: curriculum development	208

THEMATIC LIST OF SESSIONS

(Includes slide and poster sessions and symposia only.)

Session Number	Session Title	Type	Mon.	Tue.	Wed.	Thu.	Fri.
THEME A: DEVELOPMENT AND REGENERATION							
697.	Aging process.....	Poster					Fri AM
28.	Aging process: cerebral cortex, hippocampus, basal ganglia, and hypothalamus	Poster	Mon AM				
368.	Aging process: genes and receptor	Poster			Wed AM		
439.	Axon guidance I.....	Slide			Wed PM		
527.	Axon guidance II.....	Slide				Thu AM	
449.	Axon guidance in the visual system.....	Poster			Wed PM		
284.	Axon guidance: regeneration	Poster		Tue PM			
280.	Cell lineage and determination I	Poster		Tue PM			
446.	Cell lineage and determination II	Poster			Wed PM		
523.	Cell lineage and determination III	Slide				Thu AM	
110.	Cell migration and differentiation I.....	Poster	Mon PM				
111.	Cell migration and differentiation II.....	Poster	Mon PM				
614.	Cell migration and differentiation III.....	Poster				Thu PM	
615.	Cell migration and differentiation IV	Poster				Thu PM	
682.	Cell migration and differentiation V	Slide					Fri AM
366.	Cerebral cortex and limbic system I	Poster			Wed AM		
543.	Cerebral cortex and limbic system II	Poster				Thu AM	
262.	Cytokines and Neural Development	SYMP		Tue PM			
688.	Development of central tracts	Poster					Fri AM
117.	Development of chemical senses	Poster	Mon PM				
695.	Development of retinofugal projection and targets	Poster					Fri AM
456.	Development of the auditory and vestibular systems	Poster			Wed PM		
98.	Development of visual cortex I.....	Slide	Mon PM				
203.	Development of visual cortex II.....	Poster		Tue AM			
457.	Development of visual cortex III.....	Poster			Wed PM		
346.	Early Development and Regionalization of the Mouse Brain	SYMP			Wed AM		
281.	External influences on neuritic outgrowth	Poster		Tue PM			
269.	Formation and specificity of synapses I	Slide		Tue PM			
363.	Formation and specificity of synapses II	Poster			Wed AM		
450.	Formation and specificity of synapses III	Poster			Wed PM		
534.	Formation and specificity of synapses IV	Poster				Thu AM	
21.	Genesis of neurons and glia I	Poster	Mon AM				
200.	Genesis of neurons and glia II	Poster		Tue AM			
613.	Genesis of neurons and glia III	Poster				Thu PM	
442.	Glia and other non-neuronal cells.....	Slide			Wed PM		
294.	Glia: differentiation and cell biology	Poster		Tue PM			
616.	Glia: glial response to injury, toxins, and disease	Poster				Thu PM	
365.	Glia: microglia and ensheathing cells.....	Poster			Wed AM		
201.	Hormones and development I	Poster		Tue AM			
202.	Hormones and development II	Poster		Tue AM			
364.	Hormones and development III	Poster			Wed AM		
545.	Influences on axonal regeneration.....	Poster				Thu AM	
687.	Influences on sprouting in situ.....	Poster					Fri AM
533.	Mechanisms of axon guidance	Poster				Thu AM	

Session Number	Session Title	Type	Day and Time				
			Mon.	Tue.	Wed.	Thu.	Fri.
542.	Molecular and pharmacological correlates of development	Poster				Thu AM	
296.	Molecular correlates of central injury	Poster		Tue PM			
617.	Molecular correlates of peripheral axonal regeneration	Poster				Thu PM	
3.	Molecular Mechanisms of Axon Guidance	SYMP	Mon AM				
27.	Motor system I	Poster	Mon AM				
116.	Motor system II	Poster	Mon PM				
112.	Neuronal death I	Poster	Mon PM				
113.	Neuronal death II	Poster	Mon PM				
114.	Neuronal death III	Poster	Mon PM				
188.	Neuronal death IV	Slide		Tue AM			
290.	Neuronal death V	Poster		Tue PM			
291.	Neuronal death VI	Poster		Tue PM			
292.	Neuronal death VII	Poster		Tue PM			
599.	Neuropeptide Regulation of Brain Development: From Cells to Animals	SYMP				Thu PM	
22.	Neurotransmitter systems and channels: amino acids	Poster	Mon AM				
689.	Neurotransmitter systems and channels: channels	Poster					Fri AM
535.	Neurotransmitter systems and channels: other transmitters	Poster				Thu AM	
193.	Neurotrophic factors: biological effects I	Slide		Tue AM			
285.	Neurotrophic factors: biological effects II	Poster		Tue PM			
286.	Neurotrophic factors: biological effects III	Poster		Tue PM			
287.	Neurotrophic factors: biological effects IV	Poster		Tue PM			
288.	Neurotrophic factors: biological effects V	Poster		Tue PM			
289.	Neurotrophic factors: biological effects VI	Poster		Tue PM			
358.	Neurotrophic factors: biological effects VII	Slide			Wed AM		
451.	Neurotrophic factors: biological effects VIII	Poster			Wed PM		
452.	Neurotrophic factors: biological effects IX	Poster			Wed PM		
453.	Neurotrophic factors: biological effects X	Poster			Wed PM		
454.	Neurotrophic factors: biological effects XI	Poster			Wed PM		
455.	Neurotrophic factors: biological effects XII	Poster			Wed PM		
23.	Neurotrophic factors: receptors and cellular mechanisms I	Poster	Mon AM				
24.	Neurotrophic factors: receptors and cellular mechanisms II	Poster	Mon AM				
25.	Neurotrophic factors: receptors and cellular mechanisms III	Poster	Mon AM				
26.	Neurotrophic factors: receptors and cellular mechanisms IV	Poster	Mon AM				
109.	Neurotrophic factors: receptors and cellular mechanisms V	Slide	Mon PM				
536.	Neurotrophic factors: expression and regulation I	Poster				Thu AM	
537.	Neurotrophic factors: expression and regulation II	Poster				Thu AM	
538.	Neurotrophic factors: expression and regulation III	Poster				Thu AM	
539.	Neurotrophic factors: expression and regulation IV	Poster				Thu AM	
540.	Neurotrophic factors: expression and regulation V	Poster				Thu AM	
541.	Neurotrophic factors: expression and regulation VI	Poster				Thu AM	
610.	Neurotrophic factors: expression and regulation VII	Slide				Thu PM	
692.	Nutritional and prenatal factors	Poster					Fri AM
690.	Other factors and trophic agents I	Poster					Fri AM
691.	Other factors and trophic agents II	Poster					Fri AM
115.	Pattern formation, compartments, and boundaries I	Poster	Mon PM				
293.	Pattern formation, compartments, and boundaries II	Poster		Tue PM			
693.	Pattern formation, compartments, and boundaries III	Poster					Fri AM

THEMATIC LIST OF SESSIONS

Session Number	Session Title	Type	Day and Time				
			Mon.	Tue.	Wed.	Thu.	Fri.
283.	Peripheral axon guidance.....	Poster		Tue PM			
97.	Process outgrowth I.....	Slide	Mon PM				
607.	Process outgrowth II.....	Slide				Thu PM	
531.	Process outgrowth and adhesion molecules	Poster				Thu AM	
532.	Process outgrowth and cytoskeleton.....	Poster				Thu AM	
282.	Process outgrowth and GAP-43.....	Poster		Tue PM			
448.	Process outgrowth and second messengers	Poster			Wed PM		
447.	Process outgrowth in retina and retinal prosection sites.....	Poster			Wed PM		
520.	Regeneration.....	Slide				Thu AM	
544.	Retinal development	Poster				Thu AM	
295.	Sequelae to central injury.....	Poster		Tue PM			
694.	Somatosensory development.....	Poster					Fri AM
204.	Successful axonal regeneration	Poster		Tue AM			
458.	Transplant- and prosthesis-assisted regeneration	Poster			Wed PM		
11.	Transplantation I	Slide	Mon AM				
118.	Transplantation II	Poster	Mon PM				
205.	Transplantation III	Poster		Tue AM			
367.	Transplantation IV	Poster			Wed AM		
546.	Transplantation V.....	Poster				Thu AM	
696.	Transplantation VI.....	Poster					Fri AM
605.	Visual system development and plasticity	Slide				Thu PM	
THEME B: CELL BIOLOGY							
548.	Blood-brain barrier.....	Poster				Thu AM	
460.	Cytoskeleton transport and membrane targeting: axon and dendrite cytoskeleton.....	Poster			Wed PM		
547.	Cytoskeleton transport and membrane targeting: axoplasmic transport and synapses.....	Poster				Thu AM	
29.	Gene structure and function I.....	Poster	Mon AM				
30.	Gene structure and function II.....	Poster	Mon AM				
100.	Gene structure and function III.....	Slide	Mon PM				
270.	Gene structure and function IV	Slide		Tue PM			
619.	Gene structure and function V	Poster				Thu PM	
300.	Membrane composition and surface macromolecules: membrane lipids and receptors	Poster		Tue PM			
206.	Membrane composition and surface macromolecules: synapses and glia	Poster		Tue AM			
299.	Neuroglia and myelin I	Poster		Tue PM			
369.	Neuroglia and myelin II	Poster			Wed AM		
459.	Neuroglia and myelin III	Poster			Wed PM		
618.	Neuroglia and myelin IV.....	Poster				Thu PM	
297.	Staining, tracing, and imaging techniques I.....	Poster		Tue PM			
298.	Staining, tracing, and imaging techniques II	Poster		Tue PM			
598.	The Cell Biology of Secretion Vesicles.....	SYMP				Thu PM	
THEME C: EXCITABLE MEMBRANES AND SYNAPTIC TRANSMISSION							
34.	Calcium channels I	Poster	Mon AM				
35.	Calcium channels II	Poster	Mon AM				
268.	Calcium channels III	Slide		Tue PM			
374.	Calcium channels IV.....	Poster			Wed AM		
375.	Calcium channels V	Poster			Wed AM		

Session Number	Session Title	Type	Day and Time				
			Mon.	Tue.	Wed.	Thu.	Fri.
604.	Calcium channels VI.....	Slide				Thu PM	
701.	Calcium channels VII.....	Poster					Fri AM
700.	Chloride and other channels.....	Poster					Fri AM
430.	Developmental Control of Electrical Excitability.....	SYMP			Wed PM		
306.	Ion channels: cell function I.....	Poster		Tue PM			
627.	Ion channels: cell function II.....	Poster				Thu PM	
463.	Ligand-gated ion channels I.....	Poster			Wed PM		
603.	Ligand-gated ion channels II.....	Slide				Thu PM	
464.	Ligand-gated ion channels: alcohol modulation.....	Poster			Wed PM		
622.	Long-term potentiation: pharmacology I.....	Poster				Thu PM	
623.	Long-term potentiation: pharmacology II.....	Poster				Thu PM	
119.	Long-term potentiation: physiology I.....	Poster	Mon PM				
195.	Long-term potentiation: physiology II.....	Slide		Tue AM			
302.	Long-term potentiation: physiology III.....	Poster		Tue PM			
354.	Long-term potentiation: physiology IV.....	Slide			Wed AM		
373.	Long-term potentiation: physiology V.....	Poster			Wed AM		
551.	Long-term potentiation: physiology VI.....	Poster				Thu AM	
93.	Molecular Mechanisms Controlling K⁺ Channel Diversity and Distribution in the Nervous System.....	SYMP	Mon PM				
347.	Molecular Plasticity in Epilepsy and Ischemia.....	SYMP			Wed AM		
183.	New Approaches to Understanding Dendrites.....	SYMP		Tue AM			
624.	Pharmacology of synaptic transmission I.....	Poster				Thu PM	
699.	Pharmacology of synaptic transmission II.....	Poster					Fri AM
279.	Postsynaptic mechanisms I.....	Slide		Tue PM			
372.	Postsynaptic mechanisms II.....	Poster			Wed AM		
620.	Postsynaptic mechanisms III.....	Poster				Thu PM	
621.	Postsynaptic mechanisms IV.....	Poster				Thu PM	
36.	Potassium channels I.....	Poster	Mon AM				
304.	Potassium channels II.....	Poster		Tue PM			
305.	Potassium channels III.....	Poster		Tue PM			
362.	Potassium channels IV.....	Slide			Wed AM		
625.	Potassium channels V.....	Poster				Thu PM	
626.	Potassium channels VI.....	Poster				Thu PM	
199.	Presynaptic mechanisms I.....	Slide		Tue AM			
371.	Presynaptic mechanisms II.....	Poster			Wed AM		
462.	Presynaptic mechanisms III.....	Poster			Wed PM		
549.	Presynaptic mechanisms IV.....	Poster				Thu AM	
550.	Presynaptic mechanisms V.....	Poster				Thu AM	
32.	Presynaptic mechanisms: calcium.....	Poster	Mon AM				
31.	Presynaptic mechanisms: vesicles.....	Poster	Mon AM				
33.	Sodium channels I.....	Poster	Mon AM				
303.	Sodium channels II.....	Poster		Tue PM			
301.	Synaptic structure and function I.....	Poster		Tue PM			
370.	Synaptic structure and function II.....	Poster			Wed AM		
461.	Synaptic structure and function III.....	Poster			Wed PM		
698.	Synaptic structure and function IV.....	Poster					Fri AM
THEME D: NEUROTRANSMITTERS, MODULATORS, TRANSPORTERS, AND RECEPTORS							
208.	Acetylcholine receptors: muscarinic molecular biology.....	Poster		Tue AM			
209.	Acetylcholine receptors: muscarinic pharmacology.....	Poster		Tue AM			
207.	Acetylcholine receptors: muscarinic signal transduction.....	Poster		Tue AM			

THEMATIC LIST OF SESSIONS

Session Number	Session Title	Type	Day and Time				
			Mon.	Tue.	Wed.	Thu.	Fri.
351.	Acetylcholine receptors: nicotinic	Slide			Wed AM		
465.	Acetylcholine receptors: nicotinic development.....	Poster			Wed PM		
468.	Acetylcholine receptors: nicotinic function	Poster			Wed PM		
466.	Acetylcholine receptors: nicotinic molecular biology	Poster			Wed PM		
467.	Acetylcholine receptors: nicotinic pharmacology	Poster			Wed PM		
37.	Acetylcholine: anatomy/imaging	Poster	Mon AM				
38.	Acetylcholine: lesions	Poster	Mon AM				
39.	Acetylcholine: molecular biology	Poster	Mon AM				
40.	Acetylcholine: regulation	Poster	Mon AM				
221.	Anatomical localization of peptides and their receptors: peptides	Poster		Tue AM			
41.	Anatomical localization of peptides and their receptors: receptors	Poster	Mon AM				
222.	Anatomical localization of peptides and their receptors: regulated expression of peptides	Poster		Tue AM			
104.	Behavioral pharmacology I	Slide	Mon PM				
557.	Behavioral pharmacology II	Poster				Thu AM	
641.	Behavioral pharmacology III	Poster				Thu PM	
558.	Behavioral pharmacology: dopamine.....	Poster				Thu AM	
16.	Catecholamine receptors I.....	Slide	Mon AM				
223.	Catecholamine receptors II.....	Poster		Tue AM			
224.	Catecholamine receptors III.....	Poster		Tue AM			
275.	Catecholamine receptors IV	Slide		Tue PM			
377.	Catecholamine receptors V	Poster			Wed AM		
555.	Catecholamine receptors VI	Poster				Thu AM	
12.	Catecholamines	Slide	Mon AM				
126.	Catecholamines: dopamine release	Poster	Mon PM				
473.	Catecholamines: measurements, spect, lesions—immediate early genes	Poster			Wed PM		
225.	Catecholamines: noradrenergic systems—neuronal circuitry	Poster		Tue AM			
125.	Catecholamines: tyrosine hydroxylase and other synthesizing enzymes.....	Poster	Mon PM				
108.	Excitatory amino acid receptors I	Slide	Mon PM				
210.	Excitatory amino acid receptors II	Poster		Tue AM			
211.	Excitatory amino acid receptors III	Poster		Tue AM			
309.	Excitatory amino acid receptors IV	Poster		Tue PM			
310.	Excitatory amino acid receptors V	Poster		Tue PM			
214.	Excitatory amino acid receptors: expression and splice variants	Poster		Tue AM			
213.	Excitatory amino acid receptors: localization	Poster		Tue AM			
212.	Excitatory amino acid receptors: metabotropic receptors	Poster		Tue AM			
312.	Excitatory amino acid receptors: posttranslational modification.....	Poster		Tue PM			
311.	Excitatory amino acid receptors: topology.....	Poster		Tue PM			
123.	Excitatory amino acids: anatomy and physiology I	Poster	Mon PM				
124.	Excitatory amino acids: anatomy and physiology II	Poster	Mon PM				
120.	Excitatory amino acids: excitotoxicity I	Poster	Mon PM				
121.	Excitatory amino acids: excitotoxicity II	Poster	Mon PM				
122.	Excitatory amino acids: excitotoxicity III	Poster	Mon PM				
198.	Excitatory amino acids: excitotoxicity IV	Slide		Tue AM			
278.	Excitatory amino acids: excitotoxicity V	Slide		Tue PM			
685.	Excitatory amino acids: excitotoxicity VI	Slide					Fri AM

Session Number	Session Title	Type	Day and Time				
			Mon.	Tue.	Wed.	Thu.	Fri.
628.	Excitatory amino acids: excitotoxicity and NMDA receptors.....	Poster				Thu PM	
629.	Excitatory amino acids: excitotoxicity and non-NMDA receptors.....	Poster				Thu PM	
96.	Excitatory amino acids: pharmacology I.....	Slide	Mon PM				
308.	Excitatory amino acids: pharmacology II.....	Poster		Tue PM			
469.	Excitatory amino acids: pharmacology III.....	Poster			Wed PM		
470.	Excitatory amino acids: pharmacology IV.....	Poster			Wed PM		
702.	Excitatory amino acids: pharmacology V.....	Poster					Fri AM
630.	Excitatory amino acids: pharmacology and non-NMDA receptors.....	Poster				Thu PM	
307.	Excitatory amino acids: pharmacology, metabotropic receptors	Poster		Tue PM			
218.	GABA receptors: development.....	Poster		Tue AM			
216.	GABA receptors: function I	Poster		Tue AM			
217.	GABA receptors: function II	Poster		Tue AM			
703.	GABA receptors: function III	Poster					Fri AM
215.	GABA receptors: function—modulation.....	Poster		Tue AM			
13.	GABA receptors: molecular biology I.....	Slide	Mon AM				
219.	GABA receptors: molecular biology II.....	Poster		Tue AM			
639.	Neurotransmitter interactions.....	Poster				Thu PM	
638.	Neurotransmitter interactions: cholinergic/GABA.....	Poster				Thu PM	
637.	Neurotransmitter interactions: serotonin.....	Poster				Thu PM	
636.	Neurotransmitters and other amines/purines	Poster				Thu PM	
42.	Neurotransmitters in invertebrates I.....	Poster	Mon AM				
226.	Neurotransmitters in invertebrates II.....	Poster		Tue AM			
378.	Neurotransmitters in invertebrates III.....	Poster			Wed AM		
526.	Neurotransmitters in invertebrates IV	Slide				Thu AM	
640.	Neurotransmitters: glutamate/nitric oxide.....	Poster				Thu PM	
524.	Neurotransmitters: neurotransmitter interactions	Slide				Thu AM	
316.	Opioids: anatomy and physiology I.....	Poster		Tue PM			
707.	Opioids: anatomy and physiology II.....	Poster					Fri AM
708.	Opioids: anatomy and physiology III.....	Poster					Fri AM
611.	Opioid receptors.....	Slide				Thu PM	
706.	Opioid receptors: cell biology and effector mechanisms.....	Poster					Fri AM
705.	Opioid receptors: localization.....	Poster					Fri AM
313.	Opioid receptors: molecular biology.....	Poster		Tue PM			
315.	Opioid receptors: physiology	Poster		Tue PM			
314.	Opioid receptors: sigma receptors.....	Poster		Tue PM			
704.	Opioid receptors: tolerance and regulation	Poster					Fri AM
20.	Peptide receptor structure and function I.....	Slide	Mon AM				
220.	Peptide receptor structure and function II.....	Poster		Tue AM			
376.	Peptide receptor structure and function III.....	Poster			Wed AM		
552.	Peptide receptor structure and function IV	Poster				Thu AM	
196.	Peptides: biosynthesis and metabolism.....	Slide		Tue AM			
472.	Peptides: biosynthesis and processing	Poster			Wed PM		
471.	Peptides: biosynthesis, metabolism, and biochemical characterization I	Poster			Wed PM		
631.	Peptides: biosynthesis, metabolism, and biochemical characterization II.....	Poster				Thu PM	
356.	Peptides: physiological effects I.....	Slide			Wed AM		
553.	Peptides: physiological effects II.....	Poster				Thu AM	
554.	Peptides: physiological effects III.....	Poster				Thu AM	
384.	Receptor modulation up- and down-regulation I.....	Poster			Wed AM		

THEMATIC LIST OF SESSIONS

Session Number	Session Title	Type	Mon.	Tue.	Wed.	Thu.	Fri.
440.	Receptor modulation up- and down-regulation II.....	Slide			Wed PM		
437.	Regional localization of receptors and transmitters I.....	Slide			Wed PM		
478.	Regional localization of receptors and transmitters II.....	Poster			Wed PM		
479.	Regional localization of receptors and transmitters III.....	Poster			Wed PM		
190.	Second messengers I.....	Slide		Tue AM			
433.	Second messengers II.....	Slide			Wed PM		
228.	Second messengers: G protein-mediated.....	Poster		Tue AM			
480.	Second messengers: kinases and phosphatases.....	Poster			Wed PM		
556.	Second messengers: NO, CO, and gene regulation.....	Poster				Thu AM	
383.	Second messengers: phospholipase C, phospholipase A2.....	Poster			Wed AM		
229.	Second messengers: protein kinase C—calcium.....	Poster		Tue AM			
128.	Serotonin.....	Poster	Mon PM				
127.	Serotonin: behavior.....	Poster	Mon PM				
519.	Serotonin receptors.....	Slide				Thu AM	
474.	Serotonin receptors: 5-HT3.....	Poster			Wed PM		
634.	Serotonin receptors: behavior.....	Poster				Thu PM	
475.	Serotonin receptors: effector mechanisms.....	Poster			Wed PM		
635.	Serotonin receptors: localization.....	Poster				Thu PM	
476.	Serotonin receptors: molecular biology.....	Poster			Wed PM		
633.	Serotonin receptors: pharmacology.....	Poster				Thu PM	
632.	Serotonin receptors: physiology.....	Poster				Thu PM	
477.	Serotonin receptors: regulation.....	Poster			Wed PM		
379.	Storage, secretion, and metabolism.....	Poster			Wed AM		
515.	Structure, Function, and Regulation of Glutamate Receptors.....	SYMP				Thu AM	
267.	Uptake and transporters.....	Slide		Tue PM			
380.	Uptake and transporters: GABA, glycine, and other amino acids.....	Poster			Wed AM		
227.	Uptake and transporters: acetylcholine.....	Poster		Tue AM			
381.	Uptake and transporters: catecholamines.....	Poster			Wed AM		
382.	Uptake and transporters: glutamate.....	Poster			Wed AM		
129.	Uptake and transporters: serotonin.....	Poster	Mon PM				
THEME E: ENDOCRINE AND AUTONOMIC REGULATION							
263.	Autonomic Integration in the Control of Food Intake.....	SYMP		Tue PM			
352.	Cardiovascular regulation.....	Slide			Wed AM		
132.	Cardiovascular regulation: dorsal vagal complex.....	Poster	Mon PM				
484.	Cardiovascular regulation: medullary reticular responses.....	Poster			Wed PM		
559.	Cardiovascular regulation: pre- and postganglionic control.....	Poster				Thu AM	
131.	Cardiovascular regulation: system organization.....	Poster	Mon PM				
51.	Cardiovascular regulation: system pharmacology.....	Poster	Mon AM				
50.	Cardiovascular regulation: system physiology.....	Poster	Mon AM				
516.	General Anesthetic Effects on Somatomotor Processing.....	SYMP				Thu AM	
276.	Hypothalamic-pituitary-adrenal axis regulation I.....	Slide		Tue PM			
386.	Hypothalamic-pituitary-adrenal axis regulation II.....	Poster			Wed AM		
436.	Hypothalamic-pituitary-gonadal regulation.....	Slide			Wed PM		
43.	Hypothalamic-pituitary-gonadal regulation: GnRH I.....	Poster	Mon AM				
272.	Hypothalamic-pituitary-gonadal regulation: GnRH II.....	Slide		Tue PM			

Session Number	Session Title	Type	Mon.	Tue.	Wed.	Thu.	Fri.
387.	Hypothalamic-pituitary-gonadal regulation: GnRH release.....	Poster			Wed AM		
709.	Hypothalamic-pituitary-gonadal regulation: hypophysiotrophic area.....	Poster					Fri AM
45.	Hypothalamic-pituitary-gonadal regulation: pituitary	Poster	Mon AM				
44.	Hypothalamic-pituitary-gonadal regulation: steroid hormones	Poster	Mon AM				
385.	Hypothalamic-pituitary-adrenal axis regulation: stress studies	Poster			Wed AM		
392.	Neural-immune interactions: cytokine effects on the nervous system.....	Poster			Wed AM		
130.	Neural-immune interactions: cytokine expression in neural tissues	Poster	Mon PM				
390.	Neural-immune interactions: hormonal regulation of immune function.....	Poster			Wed AM		
49.	Neural-immune interactions: neural regulation of immune function.....	Poster	Mon AM				
48.	Neural-immune interactions: neurotransmitter mechanisms.....	Poster	Mon AM				
391.	Neural-immune interactions: responses to immunologic challenge.....	Poster			Wed AM		
389.	Neural-immune interactions: stress and other behavioral models.....	Poster			Wed AM		
47.	Neuroendocrine regulation: estradiol	Poster	Mon AM				
388.	Neuroendocrine regulation: glucocorticoids	Poster			Wed AM		
481.	Neuroendocrine regulation: magnocellular system.....	Poster			Wed PM		
46.	Neuroendocrine regulation: neuropeptides	Poster	Mon AM				
361.	Neuroendocrine regulation: other I	Slide			Wed AM		
482.	Neuroendocrine regulation: other II	Poster			Wed PM		
106.	Osmoregulation and cardiovascular regulation	Slide	Mon PM				
642.	Osmotic regulation	Poster				Thu PM	
561.	Regulation of autonomic functions: CNS pathways and transmitters.....	Poster				Thu AM	
560.	Regulation of autonomic functions: cardiovascular	Poster				Thu AM	
562.	Regulation of autonomic functions: gastrointestinal.....	Poster				Thu AM	
52.	Regulation of autonomic functions: reproductive tract.....	Poster	Mon AM				
53.	Regulation of autonomic functions: urinary tract.....	Poster	Mon AM				
393.	Respiratory regulation: chemoreceptive mechanisms	Poster			Wed AM		
230.	Respiratory regulation: developmental mechanisms.....	Poster		Tue AM			
394.	Respiratory regulation: effects of hypoxia or hypercapnia	Poster			Wed AM		
133.	Respiratory regulation: generation and modulation of respiratory pattern	Poster	Mon PM				
563.	Respiratory regulation: human studies.....	Poster				Thu AM	
231.	Respiratory regulation: transmitter mechanisms.....	Poster		Tue AM			
483.	Thermoregulation and fever	Poster			Wed PM		
THEME F: SENSORY SYSTEMS							
400.	Auditory systems: central anatomy I	Poster			Wed AM		
401.	Auditory systems: central anatomy II	Poster			Wed AM		
62.	Auditory systems: central physiology—brainstem.....	Poster	Mon AM				
141.	Auditory systems: central physiology—cortex I	Poster	Mon PM				

THEMATIC LIST OF SESSIONS

Session Number	Session Title	Type	Day and Time				
			Mon.	Tue.	Wed.	Thu.	Fri.
142.	Auditory systems: central physiology—cortex II	Poster	Mon PM				
140.	Auditory systems: central physiology—midbrain and thalamus	Poster	Mon PM				
399.	Auditory systems: cochlea.....	Poster			Wed AM		
398.	Auditory, vestibular, and lateral line: hair cells.....	Poster			Wed AM		
606.	Chemical senses.....	Slide				Thu PM	
138.	Extrastriate visual cortex: functional organization I.....	Poster	Mon PM				
186.	Extrastriate visual cortex: functional organization II.....	Slide		Tue AM			
350.	Extrastriate visual cortex: functional organization III.....	Slide			Wed AM		
710.	Extrastriate visual cortex: functional organization IV	Poster					Fri AM
434.	Extrastriate visual cortex: inferior temporal areas.....	Slide			Wed PM		
324.	Extrastriate visual cortex: parietal areas I	Poster		Tue PM			
525.	Extrastriate visual cortex: parietal areas II	Slide				Thu AM	
402.	Gustatory and related chemical senses.....	Poster			Wed AM		
677.	Neural Coding of Visual Space: Visual Mechanisms and Multimodal Integration.....	SYMP					Fri AM
144.	Olfactory senses: central processing and behavior	Poster	Mon PM

Characterization of a novel phospholipase A₂ activity in autopsied human brain. B.M. Ross*, D.K. Kim, J.V. Bonventre and S.J. Kish. University of Toronto, Ontario and Harvard Medical School, Boston.

Phospholipases A₂ (PLA₂), the enzymes which catalyze the hydrolysis of the *sn*-2 fatty acid residue esterified to a variety of phospholipid species, were studied in preparations of autopsied human cerebral cortex. A greater amount of PLA₂ activity was found in the membrane (particulate) fractions when compared with the cytosolic fraction. The particulate and cytosolic enzymes possessed similar characteristics, including having a pH optimum of 8.5, and being maximally active in the presence of millimolar concentrations of calcium ions. The particulate enzyme could be solubilized by 1M potassium chloride, and was capable of hydrolyzing phosphatidylcholine (PC), phosphatidylethanolamine (PE) and phosphatidylinositol (PI), with a preference being displayed for PI and PE over PC. However the enzyme displayed only a small preference for arachidonic over linoleic acid residues at the *sn*-2 position of PE. When the solubilized particulate enzyme was subjected to gel filtration chromatography, PLA₂ activity eluted as a single peak of relative molecular mass greater than 67kDa. PLA₂ activity was dithiothreitol insensitive, but was inhibited by brief heat treatment, bromophenacylbromide, AACOCF₃ (the tri-fluoroketone derivative of arachidonic acid) and γ -linolenoyl amide. Thus, while the human brain enzyme displays many of the characteristics of low molecular weight platelet PLA₂, it differs in several key features, suggesting that human brain may contain a novel form(s) of PLA₂.

RECEPTOR MODULATION UP- AND DOWN-REGULATION I

DOCA-INDUCED CHANGES IN SEPTO-PREOPTIC NEURON SENSITIVITY TO ANG II AND LOSARTAN. E.P. Marital*, S.N. Thornton, F. Liénard, M.-C. Mousseau, and S. Nicolaidis. CNRS URA 1860, Neurobiologie des Régulations, Collège de France, 11 pl. M. Berthelot, 75231 Paris Cedex 05, France.

Angiotensin II (AII) and aldosterone are known to act in synergy at the central level to produce a robust sodium appetite. Our previous electrophysiological results have shown that neurons in the septo-preoptic area are influenced by these hormones. We have used iontophoresis of AII and Losartan, a non-peptide AT₁ antagonist, to investigate the effect of DOCA pretreatment on the action of AII on these neurons.

Thirty-six male Wistar rats were used in the study. A multibarrelled iontophoretic electrode attached to an extracellular recording electrode was advanced into the medial septal/median preoptic area where unit activity was recorded.

In the studied area, iontophoretic application of AII induced activation on 17 (23.3%) and inhibition on 4 (5.5%) of the spontaneous activity of the 73 neurons tested for this peptide in the control animals. In the DOCA pretreated rats, AII induced activation on 31 (35.6%) and inhibition on 7 (8%) of the spontaneous activity of the 87 neurons tested. These numbers give a ratio of excitatory/inhibitory responses to AII of 81/19 for control and of 82/18 for DOCA. Iontophoretic application of Losartan by itself in this same forebrain region induced activation on 6 (13%) and inhibition on 6 (13%) of the spontaneous activity of the 46 neurons tested in the control animals. In the DOCA group, Losartan induced activation on 14 (26.9%) and inhibition on 1 (1.9%) of the spontaneous activity of the 52 neurons tested, giving an excitatory/inhibitory ratio of 50/50 for control and of 93/7 for DOCA.

These results show that AII can be excitatory or inhibitory on neurons of the same region. The number of responses to AII is enhanced by DOCA pretreatment but the shift in excitatory/inhibitory ratio for Losartan, but not for AII suggests that several types of receptors are involved in these DOCA-induced modifications.

ADRENERGIC REGULATION OF β -ADRENERGIC RECEPTOR AND ICER (INDUCIBLE cAMP EARLY REPRESSOR) mRNA LEVELS IN C6 GLIOMA CELLS. L. Rydelek-Fitzgerald* and R.S. Duman. Laboratory of Molecular Psychiatry, Depts. of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

We have shown previously that exposure of C6 glioma cells to isoproterenol decreases the transcription rate of β 1- and β 2-adrenergic receptor (β 1AR, β 2AR) mRNA. This decrease in transcription is sensitive to inhibition of protein synthesis suggesting that isoproterenol induces a transcriptional repressor. A potential mediator of the repression is ICER, a member of the CREM (CRE modulator) family of transcription factors, which is induced by activation of the cAMP system, can bind to the CRE (cAMP responsive element), and antagonize the stimulatory effects of CREB (CRE binding protein) (Stehle et al., Nature '93). Since a CRE is present in both β 1AR and β 2AR promoters, the effects of isoproterenol on ICER regulation in C6 glioma cells were investigated. RNase protection assays reveal that exposure of C6 glioma cells to isoproterenol or forskolin for 1 hour induces levels of ICER, as well as CREM, mRNA approximately 10-fold. ICER and CREM mRNA levels return to control levels following 24 hours of exposure to agonist. The induction of ICER mRNA levels by isoproterenol is not blocked by inhibition of protein synthesis. Moreover, ICER mRNA levels are more highly induced in the presence of protein synthesis inhibitors, consistent with reports that ICER can inhibit its own production. Electrophoretic mobility shift assays show that isoproterenol and forskolin induce at least two CRE binding complexes, both of which migrate faster than the CREB containing complex. Supershift assays with a CREB antibody demonstrate that these complexes do not contain CREB and thus may contain ICER. Additional studies will be performed to fully characterize the regulation of ICER and to investigate its potential role in the repression of β 1AR and β 2AR gene transcription.

384.3

AGONIST TREATMENT DOWN-REGULATES LEVELS OF CRF-STIMULATED ADENYLYL CYCLASE, RECEPTOR BINDING AND mRNA LEVELS IN A LOCUS COERULEUS-LIKE (LC-LIKE) CELL LINE. P.A. Iredale*, H.J. Strausbaugh and R.S. Duman. Lab. of Molecular Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

Corticotropin-releasing factor (CRF) is involved in regulation of the pituitary-adrenal axis as well as the CNS response to stress. The CRF receptor is positively coupled to adenylyl cyclase, however the mechanisms which control CRF receptor expression are poorly understood. In this study we used an immortalized locus coeruleus-like (LC-like) cell line, previously shown to contain CRF receptors, as a model system to study regulation of CRF receptor coupling to adenylyl cyclase, ligand binding and mRNA levels.

CRF treatment resulted in a rapid, time-dependent down-regulation of CRF-stimulated adenylyl cyclase and CRF receptor ligand binding, which was maximal after 20 min, and was observed for up to 2-4 hrs. However, after 20 hrs of CRF treatment there was a further decrease of approximately 20-30 %. Incubation of LC cells also decreased levels of CRF receptor mRNA but with a different time-course: agonist incubation decreased levels of receptor mRNA by 30 % after 4 hrs and by 60 % after 24 hrs. The results suggest that agonist regulation of receptor expression is mediated by several processes. The rapid down-regulation is probably mediated by receptor sequestration and internalisation as described for adrenergic receptors, and decreased levels of receptor mRNA probably contributes to the more long-term decrease observed after 24 hrs of treatment.

384.4

CHRONIC MORPHINE TREATMENT DECREASES MELANOCORTIN 4-RECEPTOR mRNA EXPRESSION IN RAT FRONTAL CORTEX. J.D. Alvaro*, E.J. Nestler, and R.S. Duman. Neuroscience Program, Laboratory of Molecular Psychiatry, Depts. of Psychiatry and Pharmacology, Yale Univ. School of Med., New Haven, CT 06508.

Previously we described the cloning and characterization of a rat melanocortin 4-receptor (MC4-R) (Soc. Neurosci. Abst.19, 634.9). This receptor is 996bp in length and is 95% identical to the amino acid sequence of the published human MC4-R. In order to study the regulation of MC4-R by psychotropic drugs, we have investigated the possible effects of morphine addiction on melanocortin receptors. Rats were administered 75mg morphine pellets (s.c.) once daily for five days, and on the sixth day several brain regions from morphine- and sham-treated animals were dissected. Using an MC4-R specific riboprobe in an RNase protection assay, we found that MC4-R mRNA levels in the frontal cortex were consistently down-regulated in morphine-treated animals. To determine whether this effect was specific to MC4-R, the RNase protection assay was repeated using a riboprobe for MC3-R. Down-regulation in the frontal cortex was not seen, but rather a tendency toward up-regulation was noted. The effect of morphine treatment on melanocortin receptor RNA will be examined in the other dissected brain regions by the RNase protection assay, and *in situ* hybridization will be used to localize more discrete regions of receptor regulation. Regulation of MC4-R expression could contribute to the neurochemical adaptations underlying the long-term actions of opiates in the brain.

EFFECT OF SEROTONERGIC DRUGS ON THE UP-REGULATION OF DOPAMINE₂ RECEPTOR INDUCED BY HALOPERIDOL
T. Ishikane*, J. Kusumi, R. Matsubara, S. Matsubara and T. Koyama.
 Dept. of Psychiatry, Hokkaido Univ. Sch. of Med., Sapporo 060, Japan.

We examined the modulatory effect of serotonin(5-HT) on haloperidol-induced up-regulation of dopamine(D₂) receptor in order to elucidate the pharmacological characteristics of atypical antipsychotic drugs. Chronic treatment of rats with haloperidol (HPD, 0.1-0.5mg/kg, i.p., 3weeks) increased the number of D₂ receptors in the striatum, while no increase was observed by that with clozapine (1mg/kg) and ORG5222 (0.25mg/kg), atypical antipsychotic drug and its candidate which have high affinity at 5-HT₂ receptor sites with lower affinity at D₂ sites. Chronic treatment with MK212, a nonselective 5-HT agonist (2.5mg/kg), or with citalopram, a 5-HT reuptake inhibitor (10mg/kg), both of which had no effect on the number of D₂ receptor sites by themselves, potentiated the up-regulation of D₂ receptor sites when coadministered with HPD (0.5mg/kg). Coadministration of ritanserin(RIT), a 5-HT₂/5-HT_{1c} antagonist (1mg/kg), with HPD (0.5mg/kg), had no influence on the HPD-induced increase of D₂ receptor sites, but that with smaller dose of HPD(0.1mg/kg) attenuated the D₂ up-regulation. These results suggest that serotonergic activity may have a complex modulatory influence on the up-regulation of D₂ receptor sites induced by HPD. We are now examining the effect of 8-OH-DPAT, a selective 5-HT_{1A} agonist (0.1mg/kg), on the HPD-induced D₂ up-regulation.

ASTROGLIAL OXYTOCIN RECEPTOR DOWN-REGULATION: MODULATION BY PROTEIN(S) KINASE(S) C. D. Di Scala-Guenot, Ch. Kelche* and M. Th. Strosser. Institut de Physiologie, URA 1446, 21 rue René Descartes, 67000 Strasbourg France.

Specific oxytocin (OT) receptors have been previously characterized on hypothalamic cultured astrocytes and intracellular Ca²⁺ mobilization by the agonist has been demonstrated. The involvement of phospho-inositide hydrolysis which generates IP₃ and diacylglycerol, an activator of protein kinases C (PKC), could be hypothesized. As stimulation of PKC appears to be an important event in transduction mechanisms and receptor regulation, the role of PKC was studied on hypothalamic cultured astrocytes. Binding studies were performed on cells pretreated with a phorbol ester (phorbol-12 myristate, 13-acetate, PMA). Short-term exposure (up to 30 min) to PMA (10⁻⁷M) or OT(10⁻⁹M) alone was without effect on ligand binding whereas simultaneous addition of OT and PMA significantly decreased the binding and this effect was reversed by staurosporin. PMA long-term treatment is thought to desensitize PKC and in our system, 18 hours treatment with PMA or OT alone decreased ligand binding and simultaneous application of the drugs potentiated this effect which could not be reversed by staurosporin. In conclusion, the first step in agonist- and phorbol ester-mediated ligand binding inhibition, depends on PKC activation whereas down-regulation induced by long-term treatment is independent from PKC.

OLIGODEOXYNUCLEOTIDES TO THE CLONED DELTA OPIATE RECEPTOR, DOR-1: UPTAKE, STABILITY AND REGULATION OF RECEPTOR GENE EXPRESSION

K.M. Standifer*, C.-C. Chien², S. Jenab¹, C.E. Inturrisi¹, Y.-X. Pan and G.W. Pasternak. The Cotzias Laboratory of Neuro-Oncology, Department of Neurology, Memorial Sloan-Kettering Cancer Center, and ¹Dept. Pharmacology, Cornell University Medical College New York, NY 10021 and ²Cathay General Hospital, Taipei, Taiwan.

Previously, we reported that phosphodiester antisense oligodeoxynucleotides (ODNs) directed towards various domains of the coding region of the cloned mouse delta receptor, DOR-1, reduced delta receptor binding *in vivo* and *in vitro*. Additionally, an antisense directed toward the amino terminus of DOR-1 (Antisense A) blocked DPDPE and deltorphin II-mediated spinal analgesia with no effect on mu- or kappa-mediated spinal analgesia. Subsequently, Porrecca demonstrated that the same antisense also blocked supraspinal deltorphin II-mediated analgesia but not that of DPDPE. In this study we examined the ability of Antisense A to enter NG108-15 neuroblastoma cells and mouse spinal cord, and its stability therein. Radiolabeled Antisense A (250 nM) was taken up into cells in a time-dependent fashion, reaching a plateau after 4 hours that extended to several days. Solution hybridization assays using a riboprobe transcribed from the coding sequence of DOR-1 were used to measure levels of spinal cord mRNA after antisense A treatment. The decrease in spinal cord mRNA levels were consistent with a loss in binding levels.

384.6

EFFECT OF PRENATAL DOPAMINERGIC DRUG TREATMENTS ON THE DEVELOPMENT OF DOPAMINE D-2 RECEPTORS IN RAT BRAIN.

P. Park, J.J. Liang, R. Quirion, and L. Srivastava*. Douglas Hospital Research Centre, Departments of Psychiatry and Neurology and Neurosurgery, McGill University, Montreal (Que), Canada, H4H 1R3.

Studies on the postnatal development of dopamine receptors have shown a maturation of the receptors between the second and the third postnatal weeks. It has been suggested that the presence or absence of dopamine during prenatal or early postnatal periods may affect subsequent development of dopamine D-1 and D-2 receptors. In the present study we examined the prenatal effects of a dopamine D-2 agonist (quinpirole) and of an antagonist (raclopride) on the density and mRNA levels of dopamine D-2 receptors. Quinpirole (1 mg/kg, s.c.) and raclopride (0.5 mg/kg, s.c.) were administered daily to pregnant Sprague-Dawley rats from gestation day 10-11 till birth of the pups. Pups were sacrificed at different postnatal ages and their brains were removed and sectioned for anatomical studies. [³H]Spiperone and a D-2 selective 39-mer oligonucleotide, recognizing both alternatively spliced forms of the receptor, were used in receptor binding studies and *in situ* hybridization, respectively. In accordance with previous results, the maximum density of the D-2 receptor and its mRNA were observed at postnatal day 28. However, the striatal D-2 receptor density and mRNA levels were significantly elevated at postnatal day 28 in rats prenatally treated with quinpirole. No significant changes in D-2 mRNA levels were evident in the raclopride treated rats of the same age group. These results suggest that prenatal stimulation of dopamine D-2 (and/or D-3 and D-4 that have high affinity for quinpirole) receptors has long-term consequences for postnatal dopamine receptor development. (Supported by the Medical Research Council of Canada).

OXYTOCIN BINDING IN HIPPOCAMPUS, VMH AND AMYGDALA: EFFECTS OF STRESS AND GLUCOCORTICOID. I. Liberzon*, E. A. Young MHRI, University of Michigan, Ann Arbor, MI, 48104

Neuroanatomical studies reveal that central oxytocin receptors are concentrated in major regions of the limbic system: hippocampus, olfactory nucleus, amygdala, BNST and hypothalamus. We had previously shown that oxytocin receptor binding in hippocampus is regulated by the level of circulating glucocorticoid hormones, using adrenalectomy and corticosterone replacement model. In the current study we examined the effects of non habituating stress and high dose corticosterone implants on oxytocin binding in non adrenalectomized animals. Seventeen Sprague-Dawley male rats (250 g) were divided into 3 groups: Controls, Stressed and Corticosterone implanted (6,6 and 5 animals respectively). Animals were sacrificed 1 week after the implantation of two 100mg 100% corticosterone pellets, or 24h after the seventh day of exposure to non habituating stress (swim; cold room; restrain and ether anesthesia - two stressors/day). Oxytocin receptor binding autoradiography results suggest that non habituating stress significantly increased oxytocin receptor binding in Amygdala (p<.05) with trend to increase receptor binding in other areas examined (VMH, Dorsal hippocampus and Ventral Hippocampus). High dose corticosterone implants increased oxytocin receptor binding in Dorsal hippocampus and showed trend in Ventral hippocampus. The results of this study further support our early findings regarding the effects of glucocorticoids on oxytocin bindings. They provide first preliminary evidence for the effects of non habituating stress on central oxytocin binding and suggest that glucocorticoids play a role in mediating this effect in hippocampus.

384.10

DIFFERENTIAL EFFECT OF LONG-TERM ANTIDEPRESSANT TREATMENT ON 5-HT_{2A} VERSUS 5-HT_{2C} RECEPTOR-MEDIATED HYPERTHERMIA IN FAWN-HOODED RATS. Charanjit S. Aulakh, Pascale Mazzola-Pomietto, Anne M. Andrews*, and Dennis L. Murphy. Lab. of Clinical Science, National Institute of Mental Health, Bethesda, MD 20892.

We have recently demonstrated that hyperthermia induced by 1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane (DOI) and m-chlorophenylpiperazine (m-CPP) is mediated by selective stimulation of 5-HT_{2A} and 5-HT_{2C} receptors, respectively (Mazzola-Pomietto et al., 1993; Murphy et al., 1993). Furthermore, hyperthermia induced by either DOI (Aulakh et al., in press) or m-CPP (Mazzola-Pomietto et al., 1993) was found to be significantly less in Fawn-Hooded (FH) rats (a rat strain suggested to represent a genetic model of depression) relative to Wistar rats. In the present study, we studied the effects of long-term antidepressant treatment on DOI (2.5 mg/kg)-induced and m-CPP (2.5 mg/kg)-induced hyperthermia in male FH rats. Long-term (21 days) treatment with the tricyclic antidepressants, imipramine or clomipramine (each 5 mg/kg/day) attenuated DOI-induced hyperthermia, while m-CPP-induced hyperthermia was accentuated. On the other hand, long-term (21 days) treatment with the monoamine oxidase type-A inhibiting antidepressant, clorgyline (1 mg/kg/day) did not modify m-CPP-induced hyperthermia, but significantly attenuated DOI-induced hyperthermia. These findings demonstrate a differential effect of long-term antidepressant treatment on 5-HT_{2A} versus 5-HT_{2C} receptor-mediated hyperthermia in a genetic animal model of depression.

384.11

CHRONIC TREATMENT WITH THE 5-HT-1A RECEPTOR LIGAND LESOPITRON ALTERS LEVELS OF TYROSINE HYDROXYLASE IN THE RAT LOCUS COERULEUS. X.Guitart*, R.Sanchez-Arroyos and A.J.Farre. Dept. Pharmacology-CNS, Research Center Lab. Esteve, Barcelona, Spain.

During the last decade, several non-benzodiazepine drugs that display high affinity for the 5-HT-1A receptor subtype, including buspirone and gepirone, have been shown to be effective in the treatment of anxiety. Lesopitron is a new pyrimidinyl-piperazine that reduces behavioral responses to aversive situations in animal models of anxiety and that shows high selectivity and specificity for the 5-HT-1A receptor. On the other hand, different lines of pharmacological evidence have led to the hypothesis that the locus coeruleus (LC), the largest noradrenergic nucleus of the rat brain, is a mediator of anxiety and its behavioral manifestations. Moreover, in vivo experiments have shown that serotonin can attenuate LC activity, and serotonin-containing terminals have been described in this brain area. The current study examined the possibility that chronic lesopitron might alter levels of tyrosine hydroxylase (TH) in the LC. Rats were administered lesopitron for 14 days (15 mg/kg), and on day 15 levels of TH immunoreactivity were quantified by immunoblotting. Chronic lesopitron treatment decreased levels of TH immunoreactivity in the LC by 40%. Our results suggest a relationship between lesopitron and the noradrenergic system that could be linked to its mechanism of action.

384.13

MODULATION OF GLYCINE RECEPTOR MEDIATED CHLORIDE RESPONSES BY PROTEIN KINASE C. Y. Gu¹* and L.-Y.M. Huang^{1,2} Marine Biomedical Institute¹ and Department of Physiology and Biophysics^{1,2}, University of Texas Medical Branch, Galveston, Texas 77555-0483.

Glycine is a major inhibitory transmitter that mediates synaptic transmission in the spinal and medullary dorsal horns. We have shown previously that protein kinase A potentiates glycine-activated Cl⁻ conductance by increasing the probability of channel openings (Nature 348:242, 1990). To determine whether other second messengers also modulate the glycine responses, we studied the effects of protein kinase C (PKC) on the glycine-activated Cl⁻ in isolated trigeminal neurons. The currents were recorded using the whole cell patch-clamp recording technique. Glycine was applied to the recorded cells with a fast perfusion method. The protein kinase C and protein kinase inhibitor (PKCI) were applied intracellularly through a plastic tube inserted into the patch pipet.

PKC was found to increase the glycine-induced Cl⁻ currents up to 2 fold. This enhancing effect of PKC was blocked when PKCI(19-31), apseudosubstrate competing for the substrate recognition site of PKC, was introduced into the cells. PKC did not change the affinity of glycine to its receptors. The apparent dissociation constants for glycine were 26.4 μM in control and 25.8 μM in PKC. To determine the mechanism of PKC action on glycine-activated Cl⁻ channels, we examined the current-voltage relations of the currents in control and in PKC. PKC changed neither the kinetics nor the voltage dependence of the glycine responses. The reversal potentials of the glycine-activated Cl⁻ currents remained unchanged after PKC treatment. The effects of PKC on the channel conductance and on the probability of channel openings are currently under investigation. (The work is supported by NIH grants NS30045, NS23061 and NS11255).

REGULATION OF nAChR SUBUNIT EXPRESSION IN CHICK SYMPATHETIC NEURONS BY PRE- AND POSTGANGLIONIC PARTNERS P. Devay*, D. McGehee, S. Peng and L. Role. Dept. of Anat. and Cell Biol. & Cntr. for Neurobiol. & Behav., Columbia Univ., 722 W 168th Str., NY, NY 10032

During embryonic development in vivo ACh sensitivity of chick sympathetic neurons increases. Concomitant with these changes we find an elevated expression of α3, α5, α7 and β4 AChR subunit mRNAs (Devay et al '94). Since both pre- and postsynaptic contacts are established during this time, it is difficult to dissect which of these interactions regulates nAChR expression.

To separate the role of pre- from postsynaptic influences on nAChRs we examined sympathetic neurons in vitro alone or in the presence of either the pre- or the postsynaptic partners. The level of nAChR subunit expression was measured in individual cells with established pre- or postsynaptic contacts. Single channel recording studies of innervated neurons and neurons contacting target were performed as well, for comparison of changes in nAChR expression vs. nAChR-channel properties. To quantitatively evaluate the subunit expression levels, we developed a PCR assay. In contrast to the upregulation of α3, α5 and α7 with both input and target contact, target contact alone decreases the expression of α3 while increasing that of α5 and α7 mRNAs. Along with these changes in nAChR subunit gene expression with target contact, all three of the nAChR-channels expressed by neurons prior to innervation or target contact are suppressed and a single class of large conductance (~60-70 pS) is expressed. Since innervation by preganglionic neurons upregulates the expression of AChR subunits and the number of channels expressed by sympathetic neurons, these experiments suggest that input and target contact collaborate in the regulation of the number and properties of mature nAChRs.

384.12

COCAINE-INDUCED CHANGES IN BZD RECEPTORS: EFFECTS OF TREATMENT DURATION AND DRUG WITHDRAWAL. A.L.Gorman* and N.E.Goeders. Dept. of Pharmacology and Therapeutics, LSU-MC, Shreveport, LA 71130-3932.

Previously, we reported that chronic cocaine administration induced changes in benzodiazepine (BZD) receptor binding in brain areas associated with the mesocorticolimbic dopaminergic system, and possibly involved in the development of behavioral sensitization. Adult male Sprague Dawley rats were injected once daily with cocaine (5 or 20 mg/kg ip) or saline for 2, 4, or 8 weeks, and sacrificed 24 hrs, 14 days, or 28 days post-treatment to determine the effects of withdrawal on BZD receptor binding. BZD receptors were visualized autoradiographically using [³H]Ro 15-1788. Chronic cocaine produced minimal changes in BZD receptors 24 hrs post-cocaine, yet these rats exhibited significant increases in stereotypy after 2 weeks of cocaine, suggesting that cocaine-induced alterations in BZD receptors were not essential for the development of behavioral sensitization. BZD receptors were increased in the rostral nucleus accumbens, and in cortical areas 14 days post-cocaine, but returned to control values 28 days post-cocaine. Cocaine-induced increases in BZD receptors in these rats were related to the dose of drug, the length of exposure, and the time point of drug withdrawal. In addition, the effects of cocaine on BZD receptors may differ between Wistar and Sprague Dawley strains of rats. [supported by USPHS grant DA04293]

384.14

NON-COMPETITIVE INHIBITION BY DESIPRAMINE, PROPRANOLOL AND ALPRENOLOL OF [3H]1,3-DI-O-TOLYLGUANIDINE (DTG) DEFINED SIGMA BINDING SITES IN RAT BRAIN. Y. Shirayama, T. Nishikawa and K. Takahashi*. Div. Mental Disorder Res., Natl. Inst. Neurosci., NCNP, Tokyo, Japan.

[3H]DTG (1,3-di-o-tolylguanidine) binding to the homogenate of rat cerebral cortex was competitively inhibited by a variety of neurotropic drugs such as pentazocine, haloperidol, clomipramine and imipramine, which increased the K_d value with no changes in the B_{max} value of the [3H]DTG defined sigma binding site. In contrast, a classical antidepressant desipramine reduced B_{max} of the [3H]DTG binding in a concentration-dependent fashion without effects on its K_d. This non-competitive inhibition is unlikely to be related to the blocking action of desipramine at the N-methyl-D-aspartate receptor because selective competitive (CGS19755) and non-competitive (MK-801) antagonists of the excitatory amino acid receptor failed to mimic the effects of desipramine. Furthermore, potent antagonists of the beta-adrenergic receptors, (-)-propranolol and (-)-alprenolol also caused a non-competitive inhibition of the [3H]DTG binding. Together with the potent blocking action of desipramine at norepinephrine uptake, the present results suggest that noradrenergic systems might allosterically interact with the cerebral sigma site or that the sigma macromolecule could have certain allosteric regulation sites which would be affected by desipramine, propranolol and alprenolol.

CASTRATION CAUSES A SIGNIFICANT INCREASE IN NMDA RECEPTOR BINDING IN THE HIPPOCAMPUS OF MALE RATS. L.Kus*¹, R.I.Handa², J.M.Hautman¹, and A.L.Beitz¹. Dept. Vet. Pathobiology¹, Univ. of Minnesota, St. Paul, MN 55108 and Dept. Cell Biology, Neurobiology and Anatomy², Loyola Univ. Chgo., Maywood, IL 60153.

The hippocampus contains high levels of both NMDA and non-NMDA receptors. Previous studies have shown the CA1 region of the hippocampus to be particularly sensitive to ischemia-induced neuronal damage. Based on the observation that androgen receptor concentration is higher in CA1 than other hippocampal regions this study examined the effect of castration and castration with dihydrotestosterone propionate (DHTP) replacement on [¹²⁵I]MK801 binding in the dorsal hippocampus. Adult Sprague-Dawley male rats were castrated and implanted subcutaneously with either a 2.5 cm Silastic capsule that contained DHTP (n=3) or an empty capsule (n=5). Control rats (n=8) were left intact. Animals were sacrificed 21 days after castration. In intact control rats [¹²⁵I]MK801 binding was highest in stratum oriens and radiatum of CA1 as well as in the molecular layer of the dentate gyrus. In castrated rats, [¹²⁵I]MK801 binding was significantly increased in the pyramidal cell layer, stratum oriens and radiatum of CA1 compared to intact controls. This increase in [¹²⁵I]MK801 binding was prevented by treatment of castrated rats with DHTP. [¹²⁵I]MK801 binding in the hippocampus of castrate-DHTP treated rats did not differ from [¹²⁵I]MK801 binding in intact rats in any region of the hippocampus examined. These data suggest that androgen receptor stimulation may influence excitatory amino acid neurotransmission within the hippocampus. (NSF BNS 9109226, NIH DA06687, DE06682, DC01086, AA08696)

MODULATION OF NMDA CURRENT BY FATTY ACIDS IN MOUSE CORTICAL NEURONS. S.P. Yu*, L.L. Dugan and D.W. Choi. Dept. of Neurology and Center for the Study of Nervous System Injury, Washington Univ. School of Medicine, St. Louis, MO 63110.

We previously showed that fatty acid-induced changes in neuronal membrane fluidity were associated with alterations in NMDA-evoked $^{45}\text{Ca}^{2+}$ accumulation and death (Dugan *et al.*, Soc. Neurosci. Abs. 18:756, 1992). Modulation of NMDA current (I_{NMDA}) by fatty acids was studied in cultured mouse cortical neurons using whole-cell voltage clamp at 33°C. Each fatty acid was bath-applied at 50 μM together with 50 μM bovine serum albumin. I_{NMDA} in untreated cells was 1.19 ± 0.11 nA (SEM, $n=20$), and showed no obvious run-down (ATP was included in the recording pipette). Palmitic acid (16:0) which decreases membrane fluidity, reversibly blocked $52 \pm 11\%$ of the I_{NMDA} ($n=4$) without changing the reversal potential. Fatty acid-induced suppression of I_{NMDA} was attenuated with increasing degrees of unsaturation. Oleic acid (18:1) blocked 36% ($n=6$) of the I_{NMDA} , while linoleic acid (18:2) and docosahexaenoic acid (22:6) had little effect. In contrast, arachidonic acid (20:4) which increases membrane fluidity, enhanced I_{NMDA} ($143 \pm 9\%$ increase, $n=6$). The lipoxygenase inhibitor NDGA (10 μM), cyclooxygenase inhibitor ibuprofen (50 μM), mixed inhibitor ETYA (20 μM), or the kinase inhibitor, staurosporine (1 μM) failed to prevent arachidonic acid-induced potentiation. Diacylglycerol (50 μM ; $n=3$) which decreases membrane fluidity, blocked 31% of I_{NMDA} . We are attracted to the idea that degree of unsaturation or impact on membrane fluidity may be important determinants of the effect of fatty acids on NMDA current. Fatty acid-induced modulation of NMDA receptor current may influence the function of this receptor in physiological or disease states. Supported by NIH grants NS 30337 (DWC) and AG00599-01A1 (LLD).

N-METHYL-D-ASPARTATE RECEPTORS IN THE RAT BRAIN FOLLOWING OLFACTORY BULBECTOMY: AUTORADIOGRAPHIC AND BEHAVIORAL STUDIES. T. Dennis*, V. Beauchemin and N. Lavoie. Neurobiological Psychiatry Unit, McGill University, Montréal, Canada.

Olfactory bulbectomy (OBX) in rodents induces a variety of neurochemical and behavioral alterations unrelated to anosmia. We have demonstrated that OBX induces an antidepressant-reversible up-regulation of cortical GABA_A receptors. Recent observations have shown that increases in NMDA receptor activity may regulate GABA_A receptor subunit mRNA expression and binding levels. Such evidence suggests that the GABA_A up-regulation observed after OBX could be secondary to enhanced glutamatergic activity.

We investigated the time course of the effects of OBX on [^{125}I]D,L-2-amino-5-phosphonopentanoic acid (D,L-AP5)-MK-801 binding to NMDA receptor complex in brain tissue slices of rats 1, 2, 3 and 4 weeks after OBX using quantitative autoradiography. Persistent increases were observed in the prefrontal and piriform cortices, anterior cortical and lateral amygdaloid nuclei and anteroventral thalamic nucleus throughout the time period investigated. Significant decreases were also observed 3 weeks after OBX in frontal and parietal cortices, posteromedial cortical and dorsal endopiriform amygdaloid nuclei, lateral hypothalamus and hippocampus. Behavioral studies of open-field activity showed that the administration of MK-801 (0.2 mg/kg, i.p.) to naive rats induces hyperactivity, circling and hyperthermia. One month after surgery, OBX rats displayed a markedly decreased responsiveness to MK-801 for both behavioral activation and hyperthermia. This decreased responsiveness to MK-801 is consistent with the apparent decreases in the number of NMDA receptors disclosed in our autoradiographic studies. This could result in a reduced synaptic plasticity and may be responsible for the impaired learning displayed by OBX rats.

EFFECT OF OVARECTOMY AND ESTRADIOL REPLACEMENT THERAPY IN RATS ON SUBSTANTIA NIGRA GABA_A RECEPTOR BINDING. R. Bossé and T. Di Paolo*. School of Pharmacy, Laval University, Québec, Québec G1K 7P4 and Department of Molecular Endocrinology, Laval University Medical Center, Sainte-Foy, Québec, G1V 4G2, CANADA

Many of the basal ganglia neurons are GABAergic and are probably implicated in the development of dyskinesia. GABAergic systems, are also known to be modulated by estrogens. Furthermore, tardive dyskinesia is more important in women than men and significantly so in the age group over 50 years. To investigate the possible involvement of GABA_A receptors in the behavioral changes occurring at menopause, we investigated long-term ovariectomy (LT-OVX) as a model of decreased gonadal function associated with menopause. The effect of short-term ovariectomy (ST-OVX, 2 weeks) and long-term (LT-OVX, 3 months) and its possible antagonism with a 17- β estradiol treatment (10 μg E_2 , b.i.d., 2 weeks) on substantia nigra GABA_A receptors in rats was investigated. Female Sprague-Dawley rats were divided into 5 groups: (1) intact rats at random stages of the estrous cycle (CTRL), (2) ST-OVX, (3) ST-OVX + E_2 , (4) LT-OVX and (5) LT-OVX + E_2 . Quantitative autoradiography of 10 μm brain slices at two rostro-caudal levels was performed using [^3H]flunitrazepam (10 nM) to label the benzodiazepine site associated with GABA_A receptors. ST-OVX and LT-OVX led to an increase of respectively 20 and 50 % of GABA_A receptors compared to intact controls (330-460 fmol/mg tissue). A two week E_2 treatment before sacrifice lowered the GABA_A receptor densities toward control levels, reversing the ST-OVX as well as the LT-OVX. These results suggest supersensitivity of the substantia nigra to GABAergic inputs as a result of gonadal hormone withdrawal which may predispose to dyskinesia. Supported by the M.R.C. of Canada.

INCREASED EXPRESSION OF NMDA RECEPTOR SUBUNIT mRNA AFTER MK-801 TREATMENT IN NEONATAL RATS. M.A. Wilson*, S.L. Kinsman and M.V. Johnston. Neuroscience Laboratory, Kennedy Krieger Research Institute and Dept. of Neurology, Johns Hopkins University, Baltimore, MD 21205

Treatment with excitatory amino acid receptor antagonists has been shown to reduce neuronal damage in experimental models of brain injury. However, pretreatment of rats with the NMDA antagonist MK-801 causes a subsequent increase in vulnerability to excitotoxic injury and an increase in NMDA receptor binding (McDonald *et al.*, *Neurosci.* 38:103), suggesting an underlying alteration in receptor regulation. Kinetic analysis of this phenomenon in cultured cortical neurons indicates that a change in receptor density occurs after MK-801 exposure (Williams *et al.*, *Mol. Pharm.* 42:147). We have used *in situ* hybridization methods to determine whether mRNA for the NMDA receptor subunits is increased after MK-801 treatment. Rat pups were treated with MK-801 (1 mg/kg, s.c.) on postnatal day 6 and killed 24 hrs later or treated on P7 and killed 2 hrs later. *In situ* hybridization with oligonucleotide probes for NR1, NR2A, NR2B, NR2C, and NR2D was used to evaluate expression in cortex, hippocampus and striatum. Two hours after MK-801 treatment, NR1 increased approximately 15-20%, NR2A increased 10-40%, and NR2B increased 0-20% in the areas examined. NR2C is present in limited zones of the cerebellum at this age, and was not analyzed quantitatively. These results indicate that the alteration in binding to NMDA receptors observed after antagonist treatment is due, at least in part, to altered gene expression. Expression of NMDA receptor subunit mRNA increases within 2 hours of MK-801 treatment, and remains elevated 24 hours later. These findings should be considered in devising interventions to prevent or reduce neuronal injury in clinical settings. (Support: NICHD T32 HD07414, NINDS NS28208, NINDS K08 NS01455)

DIFFERENTIAL ALTERATIONS OF IGF-I, IGF-II AND INSULIN BINDING SITES IN THE HIPPOCAMPAL FORMATION FOLLOWING SYSTEMIC INJECTION OF KAINIC ACID TO NEWBORN RATS. N.P.V. Nair*, S. Doré, S. Kar, and R. Quirion. Douglas Hosp. Res. Ctr., McGill University, Montréal, Québec, Canada, H4H 1R3.

The insulin-like growth factors (IGF-I and IGF-II) and insulin are localized in distinct brain regions and their respective functions are mediated by specific receptors. High concentrations of binding sites for these growth factors are discretely distributed throughout the brain, including the hippocampal formation. Functionally, IGFs and insulin, in addition to their growth promoting actions, are considered to play important roles in normal cell functions as well as in response to pharmacological or surgical manipulations. Previously, we have shown that systemic injection of kainic acid (KA) to adult rats altered IGF binding sites in discrete layers of the hippocampal formation (Srivastava *et al.*, Soc. Neurosci. Abstr. 1993). Since IGFs and insulin play important roles during development, the present study was designed to evaluate the response of IGF and insulin binding sites at different times following systemic injection of KA to newborn rats. KA was injected to post-natal day 1 pups (5mg/kg; i.p.) and [^{125}I]-IGF-I, [^{125}I]-IGF-II and [^{125}I]-insulin binding sites were studied at different time periods (7, 14, 21, 28 and 35 days) using quantitative receptor autoradiography. In normal neonatal hippocampus, [^{125}I]-IGF-I binding sites are concentrated primarily in the dentate gyrus (DG) and the CA2-CA3 sub-fields whereas [^{125}I]-IGF-II binding sites are discretely localized to the pyramidal layer and the granular layer of the DG. [^{125}I]-insulin binding sites are mostly present in the molecular layer of the DG and the CA1 sub-field. Following KA injection, the level of IGF-I binding sites was increased on days 14 and 21 before returning to normal values at later times. In contrast, IGF-II and insulin binding sites decreased from day 7 to 35 in post-natally treated rats. Taken together, these results provide further evidence for the distinct existence of IGF-I, IGF-II and insulin binding sites in the rat hippocampal formation. The transient increase in IGF-I binding sites at days 14 and 21 may relate to glial cell proliferation caused by the KA treatment. (Supported by MRCC and The Alzheimer Society of Canada)

NEURAL PLASTICITY INDUCED BY EPILEPTIFORM ACTIVITY OF THE RAT MOTOR CORTEX INJECTED WITH TETANUS TOXIN: MAPPING OF CaM KINASE II, GAD, GABA_A RECEPTOR SUBUNIT mRNAs AND C-FOS IMMUNOREACTIVITY. E. Liang* and E.G. Jones. Department of Anatomy and Neurobiology, University of California, Irvine, CA 92717

To study activity-dependent plasticity in response to epileptiform activity, tetanus toxin (2-6 ng) was injected into the forelimb area of the rat motor cortex. One to 14 days later, the animals were perfused and sections of brain processed by *in situ* hybridization for Ca^{2+} /calmodulin-dependent protein kinase II α subunit (CaM kinase II α), glutamic acid decarboxylase (GAD), GABA_A receptor subunit ($\alpha 1$, $\beta 2$, & $\gamma 2$) mRNAs, and by immunocytochemistry for *c-fos* oncoprotein. CaM kinase II α mRNA was down-regulated in the injected cortex, whereas GAD mRNA was up-regulated in bilateral motor cortices, as were the $\alpha 1$ and $\gamma 2$ subunit mRNAs of the GABA_A receptor. No change in mRNA level of $\beta 2$ subunit of the receptor was detected. *C-fos* immunoreactivity was markedly up-regulated in bilateral motor cortices. Primary and secondary somatosensory cortices, rostral forelimb motor area, cingulate and insular cortices also showed intense *c-fos* labeling bilaterally, especially in layers II, III and VI. Subcortical structures exhibiting enhanced *c-fos* immunoreactivity included hippocampus, dentate gyrus, caudate-putamen, anterior olfactory nucleus, amygdala, pontine nuclei and cerebellar cortex (granular layer). No *c-fos* labeling was found in the thalamic reticular, ventrolateral and ventromedial nuclei. These results indicate that tetanus toxin induced epilepsy promotes differential plastic changes in multiple form of gene expression affecting both pre- and post-synaptic components of distributed brain structures and neural circuits. Supported by NIH grant NS21377.

DOPAMINE (DA) RECEPTOR-C-FOS COUPLING IN THE DA DEAFFERENTED AMYGDALOID COMPLEX. T.Ely*, R. Gross and C. Kilts, Emory University School of Medicine, Atlanta, GA 30322.

The autoradiographic localization of DA receptors in the rat amygdaloid complex indicated a topographic, nonoverlapping distribution of the D₁ and D₂ receptor subtypes in its component nuclei and subnuclear zones (Synapse 11:146, 1992). The functional compartmentation of amygdaloid DA receptors and their comparison to striatal DA receptors was further assessed by the effect of a unilateral 6-OHDA lesion of the MFB on the response of fos-LI in central (Ce) and basolateral (BL) amygdaloid nuclei to D₁, D₂, or D₁/D₂ receptor activation. The D₁ agonist SKF 38393 (3 mg/kg sc) produced a marked increase in fos-LI in the medial and dorsolateral caudate nucleus; the effect of SKF 38393 was enhanced greatly by the coadministration of quinpirole (0.3 mg/kg). Quinpirole did not induce fos-LI when administered alone. Though quantitatively smaller, similar effects of D₁, D₂ and D₁/D₂ receptor activation were observed in the core and shell of the nucleus accumbens and olfactory tubercle ipsilateral to the side of the MFB lesion. A strikingly different pattern of effects of activation of DA receptor subtypes was observed in the DA deafferented amygdaloid complex. Specifically, the administration of apomorphine (0.3 mg/kg), SKF 38393, or the combination of quinpirole and SKF 38393 increased fos-LI in BL, though no differences in drug effects were noted between the ipsilateral and contralateral (intact) BL. These preliminary results suggest that D₁ receptors in BL induce fos expression by an intracellular pathway that is not upregulated in response to deafferentation. The apparent lack of effect of D₂ receptor activation on the D₁ response is consistent with the negligible localization of D₂ receptors in BL. In contrast, the increase in fos-LI in Ce resulting from D₁/D₂ receptor activation was greater in the lesioned versus intact Ce.

ANALYSIS OF PHOSPHORYLATION SITES INVOLVED IN THE DEPOLARIZATION-DRIVEN INACTIVATION OF MYOGENIN. C.-T. Su, C.-F. Huang and J. Schmidt*. Dept. of Biochemistry and Cell Biology, State University of New York at Stony Brook, Stony Brook, NY 11794.

Activation of nuclear protein kinase C (PKC) is an integral element in the signaling pathway coupling the depolarization of the plasma membrane to the inactivation of genes coding for acetylcholine receptor (AChR) subunits. Since PKC activation is immediately followed by gene inhibition we assume that a transcription factor is directly targeted by the kinase. The muscle-specific expression of AChR and the presence and functional significance of E boxes in AChR subunit promoters strongly suggest that myogenic determination factors are involved. Among them myogenin is a good candidate because its activation and inactivation kinetics resemble that of the endogenous transactivator. Threonine 87 in mouse myogenin has been shown to be a target for PKC, but since it is part of the DNA binding domain it may not be accessible to the kinase in the DNA-bound factor. To determine the phosphorylation site responsible for the rapid inactivation by PKC, we have systematically replaced all eight potential PKC targets in the chicken myogenin molecule and analyzed the PKC sensitivity of the mutant factors. Results of this analysis will be presented.

Down-regulation of neurotransmitter receptors and up-regulation of neurofilament phosphorylation in the lateral geniculate nucleus of the adult cats after visual deafferentation. Y.L. Liu*, R. Douglas and M.S. Cynader. Department of Ophthalmology, University of British Columbia, 2550 Willow Street, Vancouver, B.C., Canada. V5Z,3N9

Several progressive neurodegenerative disorders such as Parkinson's disease and Alzheimer disease have been associated with abnormal neurotransmitter receptor expression and neurofilament distribution. To test the hypothesis that the redistribution and regulation of neurotransmitter receptors and cytoskeleton protein phosphorylation may trigger early neurodegenerative process induced by input deprivation, we investigated the response of several signal transduction and cytoskeletal markers to removal of retinal input in the cat lateral geniculate nucleus. Nine neurotransmitter receptors, including α and β -adrenergic receptors, muscarinic acetylcholine receptors, as well as L-type calcium channel, protein kinase C and phosphorylated neurofilaments were examined autoradiographically and immunocytochemically in the lateral geniculate nucleus (L.G.N.) of eight adult cats at various times after monocular visual deafferentation. While α and β -adrenergic receptors, and muscarinic acetylcholine receptors were down-regulated in the deafferented layers of the L.G.N. as early as 8 days after enucleation, phosphorylated neurofilaments were increased in the same layers as early as 4 days after enucleation. These results may suggest that the early changes in density of adrenergic and muscarinic acetylcholine receptors and phosphorylated neurofilament are involved in the neurodegenerative process induced by input restriction, and may be useful as markers for neurodegeneration.

HYPOTHALAMIC-PITUITARY-ADRENAL AXIS REGULATION: STRESS STUDIES

385.1

STRESS-INDUCED TRANSCRIPTIONAL ACTIVATION OF THE CORTICOTROPIN-RELEASING FACTOR GENE PRECEDES IMMEDIATE-EARLY GENES RESPONSES IN THE PARAVENTRICULAR NUCLEUS. K.J. Kovacs* and P.E. Sawchenko. Institute of Experimental Medicine, Budapest, H-1083 Hungary, and The Salk Institute, La Jolla, CA 92037

Exposure to ether vapor for 5 min results in rapid activation of the hypothalamo-pituitary-adrenal (HPA) axis in rats, with peak circulating levels of ACTH and corticosterone seen at 5-10 min and 15-30 min, respectively, after the challenge. This model was used to provide insight into the sequence of molecular events underlying the stress-induced enhancement of corticotropin-releasing factor (CRF) expression in hypophysiotropic neurons of the paraventricular nucleus of the hypothalamus (PVH). Animals were sacrificed at intervals ranging between 5 min and 4 hr after exposure to ether, or no manipulation (control). Series of sections through the hypothalamus from each animal were prepared for hybridization histochemical localization of mRNAs encoding the immediate-early genes, *c-fos* and NGFI-B, and heteronuclear RNA (hnRNA) encoding CRF, all using ³⁵[S]-labeled cRNA probes. An additional series from each animal was prepared for immunoperoxidase localization of Fos protein. Non-stressed control rats displayed no consistent expression of any of the markers of interest in the PVH. A 5 min exposure to ether resulted in robust induction of both *c-fos* and NGFI-B mRNAs whose expression was largely limited to the dorsal medial parvocellular part of the nucleus. Both immediate-early gene mRNA responses were detectable at 30 min, and maximal at 60 min, following the challenge. Induction of a Fos protein response was predictably delayed, appearing initially at 1 hr and attaining peak levels by 2 hr, following exposure to ether. By contrast, nuclear signal for CRF hnRNA was seen as early as 5 min after stress in the parvocellular PVH. The most robust response, in terms of both signal intensity and cell number, was seen at 30 min following exposure to ether, and no specific signal was detected in rats sacrificed 1 hr after the challenge. The fact that the ether-induced transcriptional activation of the CRF gene precedes the maximal immediate-early gene responses suggests that these transcription factors are not directly involved in initiating stress-induced up-regulation of CRF expression in hypophysiotropic neurons.

385.2

HIPPOCAMPAL CHOLINERGIC BLOCKADE ELEVATES STRESS-INDUCED CORTICOSTERONE (CORT) SECRETION. S. Bhatnagar*, J.W. Smythe and M.J. Meaney. Depts. of Neurology & Neurosurgery, and Psychiatry, Douglas Hosp. Res. Ctr., McGill Univ., Montreal, Quebec, Canada H4H 1R3.

The hippocampal formation (HPC) regulates stress-induced hypothalamic-pituitary-adrenal (HPA) activity. Lesions of the HPC result in hypersecretion of ACTH and CORT in response to a variety of stressors, suggesting that the HPC plays an inhibitory role in the regulation of HPA activity. Septal cholinergic projections innervate all fields and subfields of the HPC and increase HPC excitability. These cholinergic inputs are thought to regulate sensory processing of stressful environmental events, as suggested by studies on HPC electrophysiology. We investigated whether HPC cholinergic systems might underlie HPC control of HPA function. Adult rats were implanted bilaterally with cannulas aimed at the molecular layer of the dentate gyrus. Scopolamine HCl (SCOP; 10 μ g/ μ l; 3 μ l total) was administered into the HPC 20 min prior to onset of restraint stress. Plasma CORT levels were measured immediately following and up to 2 hours following termination of restraint. Rats administered SCOP (n=6) hypersecreted CORT at 0 min and showed elevated levels 2 hours following termination of restraint, relative to vehicle injected rats (n=6). These data suggest that HPC cholinergic systems actively inhibit HPA activity. Thus, compromising HPC cholinergic inputs may interfere with sensory processing and alter the ability of the HPC to exert negative-feedback control of HPA activity in response to stressful stimuli. (Supported by MRCC and FRSQ)

385.3

A CENTRAL NITRIC OXIDE SIGNALING MECHANISM MEDIATES STRESS-INDUCED CORTICOSTERONE RELEASE. M. Rackover*, D. Funk and S. Amir. CSBN, Concordia University, Montreal, Quebec, Canada.

Nitric Oxide synthase (NOS) containing neurons have been localized in the hypothalamic paraventricular nucleus (PVN), and in vitro studies suggest that nitric oxide (NO) is involved in the release of corticotrophin releasing hormone (CRH) from PVN neurons. Because CRH plays a role in the stress-induced release of pituitary adrenocorticotrophin (ACTH) and corticosterone (CORT) secretion from the adrenal cortex, we investigated the effects of blockers of NO synthesis on plasma CORT levels following immobilization stress in rats. Immobilization stress for 60 min caused a significant increase in plasma CORT levels in saline-pretreated rats (1 ml/kg i.p., 45 minutes prior to restraint), and was associated with induction of c-fos protein in a proportion of NOS-containing (NADPH diaphorase-stained) PVN cells. Pretreatment with the NOS blocker NG-nitro-L-arginine methyl ester (L-NAME, 10 mg/kg i.p.), but not with the inactive isomer NG-nitro-D-arginine (D-NAME, 10 mg/kg i.p.), significantly attenuated the stress-induced rise in plasma CORT. Similarly, pretreatment with 7-Nitroindazole (10 mg/kg i.p.), an NO synthesis blocker devoid of peripheral cardiovascular actions attenuated the stress-induced increase in plasma CORT. Finally, injection of L-NAME (100 µg) into the third cerebral ventricle attenuated the stress-induced rise in plasma CORT. The results suggest a role of a central NO signaling mechanism in the neuroendocrine response to stress.

385.5

DIFFERENTIAL REGULATION OF EGF AND TGF α mRNA IN RAT PITUITARY AND HYPOTHALAMUS INDUCED BY STRESSES. X. Fan, G. T. Nagle, T. J. Collins and G. V. Childs*. Department of Anatomy and Neurosciences, University of Texas Medical Branch at Galveston, Galveston, TX 77555

Evidence has shown that both epidermal growth factor (EGF) and transforming growth factor α (TGF α) are present in the anterior pituitary and hypothalamus, and EGF can influence the function of pituitary cells, particularly corticotropes in vivo and in vitro. However, little is known about their exact functional roles in the pituitary and hypothalamus. This study was designed to determine if EGF and TGF α mRNA are expressed in the rat pituitary and hypothalamus and how stress conditions such as cold, ether or restraint affect their expression. A sensitive mRNA detection method, ribonuclease protection assay (RPA), detected both EGF and TGF α mRNA in the rat pituitary and hypothalamus. Reverse transcriptase-polymerase chain reaction (RT-PCR) also showed the presence of EGF and TGF α mRNA in these and several other rat tissues (submandibular gland, liver, kidney, lung, cerebral cortex and testis). No TGF α mRNA was found in the kidney however. The EGF mRNA is upregulated in the pituitary after 30 min acute cold stress (CS) and rat holder-restraint stress (RS) but not after 30 min ether stress (ES), novelty stress (NS) or tape-restraint stress (TS). Longer cold exposures showed that expression of EGF mRNA was downregulated after 60 min cold stress and then upregulated after 180 min cold exposure. In contrast, EGF mRNA in the hypothalamus is not responsive to either acute stresses or longer periods of cold exposures. No significant change in TGF α mRNA expression was detected in both pituitary and hypothalamus after acute and longer cold stresses. The results suggested that the change in pituitary EGF mRNA in response to stresses varies according to the type of stress and may be under the influence of glucocorticoid feedback. Preliminary evidence suggests that the corticotrope may be one of the cells that express EGF mRNA in the pituitary. Our data further support that EGF is a stimulator of HPA axis in primates. These stress-induced changes in EGF mRNA suggest that it may play an autocrine role during some stresses. Supported by NSF # IBN-9117897.

IN VIVO QUIPAZINE INCREASES GLUCOCORTICOID RECEPTOR EXPRESSION IN THE HIPPOCAMPUS OF NEONATAL PIGS.

S. Weaver¹, D. O'Donnell², A. Schaefer¹, L. Thibault³, and M.J. Meaney². ¹Dept. Animal Sci., Univ. of Alberta, Edmonton, AB, Canada. ²Douglas Hosp. Res. Ctr., Montreal, PQ, Canada. ³Sch. Diet/Hum. Nutr., McGill Univ, Montreal, PQ, Canada.

The glucocorticoid receptor (GR) in the hippocampus is involved in the negative feedback effect of glucocorticoids in rats. Neonatal handling results in increased GR binding capacity in the hippocampus and frontal cortex and an attenuation of the stress response in rats. The postulated mechanism is via increased serotonin (5-HT) turnover in the hippocampus (Mitchell et al., 1990, J. Neurosci. 10:1745). Little is known about the presence or development of GR in porcine brain. Stress is associated with dramatic costs in the swine industry due to impaired animal growth, reproduction, and meat quality and reducing its impact represents significant savings. In the current study we examined the effect of the 5-HT agonist quipazine on GR levels in specific brain sites using Western blotting with a commercially available GR antibody (Affinity BioReagents). Pigs were injected with 1 mg/kg quipazine dissolved in saline (1 ml/kg) or saline from postnatal day 1 to 14. The animals were sacrificed on day 13, and the pituitary gland, frontal cortex, hypothalamus, and hippocampus were collected. Increased levels of immunoreactive GR were detected in the hippocampus of quipazine versus saline treated pigs. We are currently analyzing the remaining tissues to determine whether the changes in GR expression are confined to the hippocampus and frontal cortex as is the case for neonatally handled rats.

INVOLVEMENT OF C-FOS IN DEVELOPMENTAL REGULATION OF CRH GENE EXPRESSION BY COLD-STRESS. S.-J. Yi, P.S. Gott and T.Z. Baram. Neurology, Childrens Hospital Los Angeles and University of Southern California, Los Angeles, CA 90027.

C-fos expression is induced by a variety of stimuli, including stress, to regulate transcription of target genes. These genes often contain cyclic AMP-responsive elements (CREs). The corticotropin releasing hormone (CRH) gene promoter contains a CRE, and is regulated by the cAMP-dependent cascade. We postulated that cAMP-mediated induction of CRH gene promoter involved upregulation of c-fos. We previously found that cold-stress induction of CRH gene expression is developmentally regulated: CRH-mRNA abundance increased by 4 h after cold-stress on postnatal day 9 (PND9) or 16, but not on PND6. In this study we tested the hypothesis that cAMP infusion on PND6 would induce both c-fos and CRH gene expression. Rats were subjected to cold stress-anesthesia, and implanted unilaterally with a cannula directed to the paraventricular nucleus (PVN). Rats were sacrificed 4h after saline or dibutyl cAMP (db-cAMP, 1 µmole) infusion via the cannula. Fos-like immunoreactivity (Fos-IR) and CRH-mRNA abundance were determined in PVN and limbic structures involved in stress mediation. PVN-CRH-mRNA abundance was enhanced by cold stress alone or with db-cAMP on PND9. On PND6, db-cAMP infusion increased CRH-mRNA, while cold alone did not. In hippocampus, CRH-gene expression was upregulated by db-cAMP-cold, but not by cold alone in both ages. CRH-mRNA abundance in the central amygdaloid nucleus (ACE) was increased by db-cAMP infusion on PND9. Cold stress induced hippocampal Fos-IR, with a further increase by db-cAMP in both ages. Fos-IR in ACE was enhanced following db-cAMP infusion only on PND9. An additive effect of cold stress and db-cAMP on plasma corticosterone occurred on both PND6 and PND9. These data support a role for immediate early genes and cAMP-in stress-induced upregulation of CRH-gene expression in limbic structures.

MODULATION OF CELLULAR CARDIOVASCULAR COMPONENTS AND THE HPA AXIS IN CONGENITAL LEARNED HELPLESS RATS EXPOSED TO EARLY STRESS. J. A. King¹, E. Edwards², S. L. Abend³ and J.C.S. Fray¹

Depts. Psychiatry¹ and Physiology², Univ Massachusetts Med Ctr, Worcester, MA 01655, Dept. Pharmacology³, Univ. Maryland, Baltimore, MD 21201

Learned helpless behavior has been successfully bred in rats and designated as an animal model of human depression and/or anxiety. Since congenital learned helpless (cLH) animals have an altered response to stress in adulthood, we examined the effects of early stressors (at postnatal day 7, 14, & 21) on the hypothalamic pituitary adrenal (HPA) axis and the cardiovascular system. The functioning of the HPA axis was monitored through changes in adrenocorticotropin (ACTH) plasma levels in the adult animals after acute exposure to maternal deprivation (MD) stress. Cardiovascular functioning was assessed by plasma renin activity (PRA) and renin secretory competence at the intracellular level. Unstressed cLH animals had basal levels of ACTH and PRA that were similar to control animals (Sprague Dawley animals not stressed during development). However, the renin specific activity was higher in the secretion-ready vesicles of the cLH rats suggesting that even in the absence of stressors cLH rats have a system that is primed for cardiovascular responsiveness to stress, without activation of the HPA axis. cLH animals (adults) that were MD on postnatal day 14 had lower plasma levels of ACTH than control, while exhibiting a 98% increase in PRA, again pointing to a readiness potential in terms of cardiovascular functioning. The most robust effect of MD on the cLH adult animals was apparent after acute stress on postnatal day 14 as opposed to postnatal days 7 and 21. In contrast, there was a step-wise increase in ACTH plasma levels in the congenital non learned helpless (cNLH) rats with age of acute presentation of MD stress. The above results suggest that there are longterm changes in both the HPA axis and the cardiovascular system in cLH animals after acute exposure to a postnatal stressor.

PRENATAL STRESS-INDUCED CHANGES IN THE ACTIVITY OF THE HYPOTHALAMO-PITUITARY-ADRENAL AXIS OF ADULT OFFSPRING DEPEND ON MATERNAL CORTICOSTERONE. S. Maccari*, A. Barbazanges, P.V. Piazza, H. Simon, M. Le Moal. Psychobiologie des Comportements Adaptatifs, INSERM U.259, Université de Bordeaux II, 33077 Bordeaux Cedex, France.

The development of the organism is subjected to critical influences during the perinatal period. Prenatal stress can have long-term behavioral effects, such as an increased emotional reactivity and a higher vulnerability to self-administer drugs. Changes in the activity of the hypothalamo-pituitary-adrenal (HPA) axis could be one of the biological substrates of the long-term effects of prenatal stress. We have previously shown that, in adult male rats, prenatal stress prolongs stress-induced corticosterone-secretion. Such an effect is probably mediated by a decrease in the number of central corticosteroid receptors. The mechanisms by which prenatal stress could exercise its long term effects on the activity of the HPA axis are unknown. In the present experiment we tested if stress-induced increase in maternal glucocorticoids, which cross the placental and blood-brain barriers reaching the foetus, may play a role. For this purpose we investigated the effects of adrenalectomy and/or corticosterone injections to the mother on the outcome of prenatal stress on the activity of the HPA axis of adult (3 months of age) male and female offspring. Repeated restraint during the last week of pregnancy was used as prenatal stress. In adult male and female offspring of mothers with an intact HPA axis, prenatal stress prolonged stress-induced corticosterone-secretion and decreased central corticosteroid receptors. Such effects of prenatal stress depended on maternal corticosterone-secretion: 1) maternal adrenalectomy protected the offspring from the effects of prenatal stress on both corticosterone-secretion and corticosteroid receptors; 2) injections of corticosterone to the mother had the same effects of prenatal stress in adult offspring. In conclusion, stress-induced increase in maternal levels of corticosterone may be one of the mechanisms by which prenatal stress exercises its long-term effects on the activity of the HPA axis.

385.9

EFFECTS OF STRESS ON CRF AND ITS RECEPTOR GENE EXPRESSION IN THE BRAIN OF SPONTANEOUSLY HYPERTENSIVE RATS. Guy Drolet* and Serge Rivest, Laboratoires de Neurobiologie & d'Hypertension et d'Endocrinologie Moléculaire, Centre de Recherche du CHUL, Université Laval, Québec, Canada, G1V 4G2.

The present study investigated the influence of immobilization stress on corticotropin-releasing factor (CRF) system in the brain of spontaneously hypertensive (SHR) and Wistar-Kyoto (WKY) rats. Male rats (13 weeks) were rapidly anesthetized and perfused with 4% paraformaldehyde before stress, and 30, 60, and 180 minutes after the beginning of the immobilization session which lasted 60 min. Brains were cut in 30 µm sections and mounted on poly-L-lysine-coated slides. mRNAs encoding CRF and CRF-receptor (CRF-R), kindly provided by Dr. W. Vale, The Salk Institute) were assayed by *in situ* hybridization using a ³⁵S-labeled riboprobe. Strong basal levels of CRF mRNA were found consistently in both strains in the parvocellular division of the paraventricular nucleus (PVN), the central nucleus of the amygdala (CEA), the bed nucleus of the stria terminalis (BST), the Barrington/lateral dorsoventral (Bar/LDT) area, and the ventrolateral medulla (VLM). However, higher basal expression of CRF mRNA was detected in the PVN, CEA and BST of SHR rats. Immobilization stress induced notable increase of CRF transcripts in the PVN, CEA, BST of WKY, but this phenomenon was not observed in SHR rats. In this strain only, stress raised the levels of CRF mRNA in VLM and Bar/LDT. Although the PVN did not exhibit detectable levels of CRF-R mRNA before immobilization, 2 hrs after the stress session, a positive signal for CRF-R mRNA was observed in the dorsomedial parvocellular division of this nucleus in both strains. Interestingly, stress-induced CRF-R transcription in the PVN seemed lower in SHR than in WKY rats.

These results provide evidence that central CRF system may respond differently to stress in various sites, particularly in the PVN of SHR and WKY rats. These functional differences may contribute to the pathophysiology of hypertension of the SHR rats. Support: MRC, HSFQ and FRSQ.

DEVELOPMENTAL ONSET OF HYPOTHALAMO-PITUITARY-ADRENAL AXIS RESPONSIVENESS TO NGF IN RATS. G.Tagliabue* and J.R.Perez-Polo, Dept. of HBC&G, UTMB Galveston, Texas.

Nerve growth factor (NGF) is involved in the regulation of the hypothalamo-pituitary-adrenal axis (HPAA). Peripherally-injected NGF stimulates the activity of the HPAA, resulting in a long-lasting increase in plasma corticosteroid levels, whereas serum NGF levels increase in response to stressful stimuli. Autoradiographic studies after injection of ¹²⁵I-NGF indicated that a possible site for this NGF action may be the hippocampus, a limbic structure involved in the modulation of the HPAA. Since newborn rats acquire a full stress response capability after 14 days of age, consistently with completeness of hippocampal maturation, we studied the effect of injected NGF on HPAA activity in pups at different days of postnatal life. We did not observe any NGF-induced increase in plasma corticosterone levels in pups of 3, 8, and 11 days of age, while a significant response of the HPAA to NGF was attained in 15 and 22 day old pups as well as in adult rats. On the other hand, both 8 day old pups and 2.5 month old animals responded to exogenously administered CRH. These data would suggest that the onset of the HPAA responsiveness to NGF takes place concomitantly to complete maturation of the hippocampus and therefore they support the hypothesis that serum NGF participate in the stress activation of the HPAA by acting directly at the hippocampus. (This is publication 18A from USPHS grant P01 AG10514 awarded by NIA).

ADRENALECTOMY DOES NOT ALTER STRESS-INDUCED C-FOS EXPRESSION. D.L. Helmreich*, W.E. Cullinan, S.J. Watson, Mental Health Research Institute, Univ. of Michigan, Ann Arbor MI, 48109

Previously, we determined the pattern of c-fos mRNA expression throughout the brain after stress in order to gain further insight into the identification of the neural circuits mediating stress-induced activation of the hypothalamic-pituitary-adrenal axis. In the present study, to determine what portion, if any, of this widespread expression results from rapid effects of increased glucocorticoid levels after stress, stress-induced c-fos expression was characterized in adrenalectomized (ADX) animals. Male rats underwent ADX (n=4) or sham-surgery (n=4), and 5 days later were subjected to 10 min swim stress. Animals were sacrificed 30 min post-stress onset, and brains were quickly removed and frozen. *In-situ* hybridization histochemistry was used to detect c-fos mRNA throughout the brain, using a 680 nt cRNA probe. We found that the pattern of c-fos induction in the ADX animals was similar to that observed in the sham operated animals; c-fos expression was detected in multiple areas, including the ventral subdivision of the lateral septum, the medial bed nucleus of the stria terminalis, the parvocellular region of the paraventricular nucleus of the hypothalamus (PVN), the dorsomedial nucleus of the hypothalamus, the medial nucleus of the amygdala, and limbic cortices. Additionally, densitometric measurements were made to quantify the c-fos response in the PVN and the CA1-2 region of the hippocampus, areas that are believed to be targets of circulating glucocorticoids. We found that ADX did not alter the magnitude of the c-fos response to stress in these areas. In sum, these results suggest that the pattern of c-fos expression observed 30-min post stress is independent of stress-induced increases in circulating glucocorticoid concentrations. This work was supported by grant MH-42251.

IMMUNE CHALLENGE INDUCES CRF RECEPTOR GENE EXPRESSION IN THE RAT PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS. Serge Rivest*, Laboratoire d'endocrinologie moléculaire, Centre de recherche du CHUL, Québec, Canada, G1V 4G2.

The present study investigated the effect of intraperitoneal (i.p.) administration of the endotoxin lipopolysaccharide (LPS) on the genetic expression of CRF receptor (CRF-R) in the brain of conscious Sprague-Dawley rats. One, 3, 6, 9, and 12 hrs after a single i.p. injection of either the LPS (250 µg/100 g of BW) or the vehicle solution, adult male rats were anesthetized and rapidly perfused with 4% paraformaldehyde. Frozen brains were mounted on a microtome and were cut from the olfactory bulb to the medulla in 30 µm coronal sections. mRNA encoding the rat CRF-R was assayed by *in situ* hybridization histochemistry using a ³⁵S-labeled riboprobe. The rat CRF-R cDNA in Bluescript vector (prCRF-R PPI.3-BS, 4.3 kb) was kindly provided by Dr. W. Vale (The Salk Institute, La Jolla, CA). A strong basic levels of CRF-R transcripts were observed in several defined regions of the brain such as the red nucleus, the pontine gray, the cerebellum, the laterodorsal tegmental nucleus, the caudal division of the zona incerta, the endopiriform nucleus and in various layers of the cortex. A low to moderate signal was also detected in multiple sites including the medial septal nucleus, the nucleus of the diagonal band, the supraoptic nucleus, the nucleus prepositus, and the medial vestibular nucleus. While vehicle-treated rats did not exhibit detectable signal of CRF-R mRNA in the paraventricular nucleus (PVN), CRF-R gene transcription was highly stimulated by LPS administration in this hypothalamic structure. Indeed, the CRF-R mRNA signal was positive in the dorso-medial parvocellular PVN 3 hrs after LPS injection, strong and maximum at 6 hrs postinjection, and declined 9 and 12 hrs after the treatment. Systemic endotoxin did not appear to modulate the expression of CRF-R gene in other regions suggesting that this type of stress can induce a selective activation of CRF-R within the parvocellular PVN. It is thus possible that CRF plays a role in the control of the biosynthesis and/or the release of neuroendocrine CRF during immune challenge. (Supp. by the FRSQ)

Hypercaloric intake decreases both sympathetic nervous system (SNS) and hypothalamo-pituitary-adrenal (HPA) responses to acute restraint stress. S.F. Akana*, C.J. Horsley, and A.M. Strack, Dept Physiol, UCSF, San Francisco, CA 94143

SNS and HPA activity both increase in response to stress. Brown adipose tissue (BAT) activity, which promotes nonshivering thermogenesis, is an index of SNS activity. We hypothesized that a hypercaloric load would separate basal activity in the two systems and tested whether both stress responses were facilitated due to increased tone in SNS. Therefore, rats were implanted with thermister probes under BAT and were fed ad lib chow and water only (control) or chow & 30% sucrose to drink (sugar) in addition to water. On d5, subgroups of uninstrumented rats were subjected to 30m restraint before decapitation. The instrumented rats were subjected to restraint on d10 while BAT temperature was recorded every 60s. On d5 & 10, sugar rats did not differ from controls in basal activity of the HPA axis, insulin and glucose. On d5, there was no sugar effect on the responses of ACTH or B to restraint. On d10, there was no difference in ACTH response, but a smaller B response at 30m as well as lower integrated B. Both control and sugar rats increased BAT temperature with restraint but sugar rats had a smaller increase than controls. SNS (BAT) activity responds to sugar with chronic elevation of SNS tone similar to HPA responses to chronic stress. In contrast to our initial hypothesis, the chronically sugar-activated SNS hyporesponds to acute restraint in parallel with the HPA hyporesponse in ACTH and B secretion. We conclude that a hypercaloric load acts to switch SNS and HPA responses to acute restraint from high to low amplitude. (supported by DK28172 to M.F. Dallman and AHA93-42 to AMS)

IMMEDIATE EARLY GENE INDUCTION IN RAT FOREBRAIN GABAERGIC NEURONS IN RESPONSE TO AN ACUTE STRESS. W.E. Cullinan* and S.J. Watson, Mental Health Research Institute, University of Michigan, Ann Arbor MI, 48109-0720.

Previous data have suggested that the hypothalamic paraventricular nucleus (PVN) receives a prominent GABAergic input; this innervation has recently been shown to emanate in part from various hypothalamic nuclei and the bed nucleus of the stria terminalis (BST) (Roland and Sawchenko, 1993; Cullinan et al., 1993). These areas have also recently been shown to express immediate early genes in response to acute stress. In the present experiment we examined whether GABAergic neurons in these regions expressed immediate early genes (c-fos, zif/268) following acute swim stress. Rats were subjected to 10' forced swim at 37°C, and were sacrificed 30' post-stress by rapid decapitation. Brains were quickly removed, frozen, and subsequently sectioned. Tissue was processed for dual (nonradioactive-radioactive) *in situ* hybridization histochemistry. GABAergic neurons were marked using digoxigenin-labeled cRNA probes (210 and 564 nts.) for either the M_r 67,000 or M_r 65,000 isoform of glutamic acid decarboxylase (GAD), and immediate early genes were detected with ³⁵S-labeled riboprobes for c-fos (680 nt) or zif/268 (588 nt). Among areas investigated, immediate early genes were induced in GABAergic neurons in the anterior hypothalamic area, dorsomedial hypothalamic nucleus, rostromedial zona incerta, as well as additional hypothalamic loci and the BST. Experiments are underway which combine these data with retrograde neuronal tract-tracing from the PVN. Supported by grants DAO5452 and MH42251-06.

WESTERN BLOT ANALYSIS OF CYTOSOLIC AND NUCLEAR TYPE II CORTICOSTEROID RECEPTOR LEVELS IN RAT BRAIN. R.L. Spencer*, A. H. Miller, H. Moday, B.S. McEwen. Rockefeller Univ. and Mt. Sinai Sch Med, NY, NY 10021.

In vitro studies support a model in which the unoccupied corticosteroid receptor is present in the cytosolic cellular fraction, whereas the hormone activated receptor is present in the nuclear fraction. We have used the western blot procedure to measure cytosolic and nuclear levels of Type II corticosteroid receptors in rat tissues. For western blot analysis, proteins from cytosol or immunoprecipitates of cytosol and nuclear extracts were separated by PAGE and transferred to nitrocellulose. Blots were probed with Type II corticosteroid receptor reactive antibodies (GR#57 or BUGR. Affinity BioReagents), and immunoreactivity was visualized and quantitated by a chemiluminescence method (ECL, Amersham). Cytosolic Type II receptor binding level and western blot immunoreactivity were measured in cortex or hippocampus from rats that were sacrificed (in the AM) under 4 hormone conditions: 1) adrenal-intact, no stress, 2) 18 h ADX, 3) 5 d ADX, 4) adrenal-intact + 2 h CORT. Both receptor binding and western blot analysis detected parallel changes in Type II receptor levels with treatment. Relative to the no-stress group, there was no change with 18 h ADX, a 60% increase with 5 d ADX (receptor upregulation), and a 70-90% decrease with acute CORT treatment (receptor activation). In recent studies a large increase in nuclear receptor signal was detected by western blot in CORT treated animals. These studies indicate that the western blot procedure can be used to directly measure both the cytosolic and nuclear level of corticosteroid receptors in rat neural tissues, and that cytosolic changes with hormone manipulations parallel those seen with receptor binding. MODULATION OF 5-HT_{2C} RECEPTOR mRNA EXPRESSION IN THE HIPPOCAMPUS DURING THE CIRCADIAN RHYTHM AND FOLLOWING STRESS. M.C. Holmes*, K.L. French and J.R. Seckl. Dept. Med., Univ. of Edinburgh, Western Gen. Hosp., Edinburgh, UK.

Serotonin has been implicated in the generation and maintenance of circadian rhythms, as well as the modulation of HPA axis activity to certain stressors. 5-HT₂-type (2A and/or 2C) receptors in the hippocampus and hypothalamus may mediate both actions. Using *in situ* hybridization, we examined 5-HT_{2A} and 5-HT_{2C} receptor mRNA expression in the rat hippocampus at the peak and nadir of the glucocorticoid diurnal rhythm. At 08.00h (lights on 07.00-19.00h) 5-HT_{2C} receptor mRNA expression throughout the hippocampus was significantly greater than at 20.00h (CA1 oriens, 184%; CA2, 106%; ventral CA1 147%). 5-HT_{2A} receptor mRNA expression was unchanged. Receptor gene expression was also determined following acute (6h after laparotomy) and chronic (15 days adjuvant-induced arthritis) stress. 6h after acute stress (20.00h), 5-HT_{2C} receptor mRNA expression was significantly elevated in CA2 neurons (86% greater than controls). Chronic arthritis elevated plasma corticosterone, abolishing the circadian rhythm, and 5-HT_{2C} receptor mRNA expression was significantly decreased in CA1 (55%), CA2 (50%) and ventral CA1 (45%) at 08.00h, giving levels of expression similar to the normal diurnal glucocorticoid peak (20.00h). Again, 5-HT_{2A} receptor gene expression was unaltered. Our previous data showed that glucocorticoids decrease hippocampal 5-HT_{2C} receptor gene expression after adrenalectomy. However, the increase in 5-HT_{2C} receptor mRNA expression following acute stress suggests that other factors (perhaps 5-HT) are also important short-term regulators of expression of this gene.

ACUTE AND CHRONIC INTERMITTENT FOOTSHOCK DIFFERENTIALLY INDUCE FOS EXPRESSION IN THE PARAVENTRICULAR NUCLEUS AND ITS EXTRAHYPOTHALAMIC AFFERENTS. H.-Y. Li*, C.A. Arias and P.E. Sawchenko. The Salk Institute, La Jolla, Ca 92037

Immunolocalization of Fos protein was coupled with immuno- and hybridization histochemistry and/or axonal transport techniques in order to characterize the neural circuits underlying the acute and chronic effects of intermittent footshock on stress-related neuroendocrine neurons. Exposure to a single 30 min footshock session induced maximal Fos-ir in the paraventricular nucleus of the hypothalamus (PVH) at 2 hr after the challenge; at this time point, Fos induction in the parvocellular division of the PVH was localized principally to cells hybridized for corticotropin-releasing factor mRNA, while that in the magnocellular neurosecretory system was detected predominantly in oxytocinergic neurons. Relative to sham-operated controls, adrenalectomized rats replaced with low levels of corticosterone showed enhanced Fos induction in response to acute footshock in all PVH compartments. Extrahypothalamic cell groups displaying prominent Fos induction in response to acute footshock included catecholaminergic neurons in the nucleus of the solitary tract and ventrolateral medulla, the lateral parabrachial nucleus, the ventrolateral periaqueductal gray, and circumscribed aspects of the amygdala, bed nucleus of the stria terminalis, lateral septal nucleus and infra- and prelimbic cortical areas. Rats bearing retrograde tracer deposits in the PVH and sacrificed 2 hr after a single footshock session displayed Fos induction in retrogradely labeled neurons found principally in medullary catecholaminergic cell groups, and secondarily in the lateral septal and medial amygdaloid nuclei. Rats subjected to chronic intermittent stress (2 X 30 min sessions/day for 7 days), and sacrificed 2 hr after the final footshock session, displayed patterns of Fos expression that were similar to those seen acutely. Fos expression in chronically stressed animals sacrificed on the day following the final footshock session was not distinguishable from non-shocked control levels. These results suggest that the patterns of cellular activation seen in rats exposed acutely and chronically to a footshock challenge are similar. Medullary catecholaminergic cell groups are most strongly implicated as candidate afferent mediators of this stressor's effects on endocrine hypothalamic mechanisms.

ANTIDEPRESSANT DRUG TREATMENT REVERSES HPA FEEDBACK DEFICITS AND BASAL HPA HYPERACTIVITY IN THE AGED-IMPAIRED RAT. A. Steverman, M. Walker, W. Rowe, S. Sharma*, N. Barden, J.R. Seckl & M.J. Meaney, Douglas Hosp. Res. Ctr., Dept. Psychiatry, McGill Univ., Montreal H4H 1R3 Canada., Dept. Medicine, Univ. Edinburgh, Western Gen. Hosp., Edinburgh, Scotland EH4 2XU, UK and Ctr. Hosp. Univ. Laval, Québec Canada.

Aged, cognitively-impaired (AI) rats show increased basal HPA activity in comparison to both young (Y) and aged, cognitively-unimpaired (AU) rats. These findings are consistent with the idea that glucocorticoids can compromise both the function and survival of hippocampal neurons. In this study AI, AU and Y rats were treated with the antidepressant, desipramine, for 4 weeks following which time we examined basal HPA activity and delayed feedback sensitivity to elevated glucocorticoid levels.

Antidepressant drug treatment reduced PM basal levels of both ACTH and corticosterone (B) in all animals, without affecting AM hormone levels. The effect was greatest in the AI rats, such that differences in PM levels of ACTH and B observed in controls were absent following chronic desipramine treatment. In controls, a bolus injection of B 3h prior to restraint stress completely abolished ACTH responses in AU and Y rats, while in AI rats ACTH responses were only partially reduced. Following chronic desipramine treatment ACTH responses to restraint were completely abolished in AI as well as AU and Y rats. These data suggest that chronic antidepressant drug treatment enhances glucocorticoid negative feedback sensitivity and reduces PM basal HPA activity in AI rats.

These results are consistent with previous findings in young adult animals and point to potential therapeutic approaches in the treatment of HPA dysfunction in the aged. Supported by MRCC and NIA AG90488.

HYPOTHALAMIC-PITUITARY-ADRENAL AXIS REGULATION II

386.1

DECREASED HIPPOCAMPAL NORADRENALINE DOES NOT AFFECT ELECTRICALLY STIMULATED CORTICOSTERONE RELEASE. W.M.U. Daniels, A. Jaffer, V.A. Russell, S. Daya* and J.J.F. Taljaard Dept. Chem. Path., Univ. Stellenbosch, Tygerberg Hosp., P.O. Box 19113, Tygerberg, 7505, RSA.

Bipolar electrodes were implanted into the CA1 pyramidal cells of the dorsal hippocampus and the effect of electrical stimulation of these cells on corticosterone secretion was investigated in freely moving rats. Histology showed that the electrodes were positioned in close proximity to the CA1 pyramidal cells. Rats that were subjected to electrical stimulation did not only behave differently to their sham stimulated controls, but also had significantly higher plasma corticosterone levels. Prior treatment of rats with DSP₄ significantly reduced hippocampal noradrenaline content, but had no effect on electrically stimulated corticosterone release. These data suggested that excitation of CA1 pyramidal cells may lead to increased corticosterone release and that a significant decrease in hippocampal noradrenaline concentration was not able to alter this corticosterone response.

386.2

NEUROTOXIN-STIMULATED HYPOTHALAMO-PITUITARY-ADRENAL (HPA) AXIS FUNCTION IN MICE. M. Carino, B. Giovanbatista, R. Hilal and E. Spinedi* Neuroendocrine Unit, Department of Neurosciences, IMBICE, 1900 La Plata, Argentina.

The aim of the present study was to elucidate whether snake venom (SV; Sigma Chem. Co., V-7125) is able to stimulate the HPA axis activity when administered ip (25 µg/animal) in adult BALB/c mice of both sexes. Mice were killed at 0.5, 1, 2 or 4 h after SV or vehicle (sample time zero h) administration. Plasma glucose (G), ACTH and corticosterone (B) concentrations were measured. The results indicated that, SV treatment induced a significant (P<0.05 vs. 0 h) hyperglycemia at all periods studied with maximal values attained at 2 h after treatment, regardless the sex; the neurotoxin-elicited G release in plasma was significantly (P<0.05) higher in females than in males at 0.5, 1 and 2 h after administration. Neurotoxin injection significantly (P<0.05 vs. 0 h) enhanced ACTH release in plasma at 0.5 and 1 h after treatment in animals of both sexes, with 1 h-values significantly (P<0.05) higher in males than in females; then, plasma ACTH levels recovered the baseline at 2 h in both sexes. SV treatment also significantly (P<0.05 vs. 0 h) stimulated B release in plasma in a sexual dimorphic manner at 0.5, 1 and 2 h after treatment; being female values significantly (P<0.05) higher than male values. Finally, this dose of SV resulted lethal at 4 h for a 50 % of males and for a 30 % of females. These results indicate that the neurotoxic shock enhances glucose plasma levels and HPA axis activity in a sexual dimorphic fashion. It remains to be determined the mechanisms whereby SV induced such responses, as well as which steps are modulated by endogenous sex hormones. (Supported by CONICET 252 11 35 91).

386.3

HYPOTHALAMIC GALANIN-LIKE IMMUNOREACTIVITY AND ITS GENE EXPRESSION IN RELATION TO CIRCULATING CORTICOSTERONE. A. Akabayashi*, H.J. Chae and S.F. Leibowitz. The Rockefeller University, New York, N.Y. 10021

The hypothalamic peptides, neuropeptide Y (NPY) and galanin (GAL), known to stimulate feeding behavior, have differential effects on the release of the adrenal steroid, corticosterone (CORT), with NPY enhancing and GAL inhibiting its secretion. In terms of the feedback effects of CORT on endogenous peptide, other studies have shown this steroid to potentiate the production of neuropeptide Y (NPY) in specific hypothalamic areas, namely, the paraventricular (PVN) and arcuate (ARC) nuclei, as well as the locus coeruleus (LC). This investigation examined changes in GAL gene expression and peptide levels in relation to circulating CORT in male, Sprague-Dawley rats. Using radioimmunoassay (n=30, 10/group) and *in situ* hybridization (n=18, 6/group) techniques, this peptide was examined in 3 groups of rats that received either SHAM surgery, adrenalectomy (ADX), or ADX + CORT replacement. The results showed a clear, site-specific change in GAL in relation to circulating CORT. A loss of CORT after ADX caused a dramatic decline in GAL peptide (-60%, $p < 0.05$) and mRNA levels (-35%, $p < 0.05$) in the ARC and also peptide levels in the median eminence (-40%, $p < 0.05$). Other hypothalamic areas, including the PVN, showed no change. In the brainstem, a similar effect after ADX was seen in the dorsal raphe nucleus, but not the LC. The GAL peptide and mRNA levels in these brain areas of ADX rats were restored by s.c. CORT implants, which had no impact on GAL in other brain sites. These findings show GAL-synthesizing neurons to respond differently from NPY neurons in relation to circulating CORT.

386.5

CHANGES IN HIPPOCAMPAL CORTICOSTEROID RECEPTOR GENE EXPRESSION FOLLOWING 5,7-DHT LESIONS AND 8-OHDPAT ADMINISTRATION. J.R. Seckl* and J.L.W. Yau. Dept. Med. Western Gen. Hosp. Edinburgh, U.K.

Serotonergic denervation attenuates hippocampal mineralocorticoid (MR) and glucocorticoid (GR) receptor gene expression, whereas 5-HT increases hippocampal neuronal GR, at least in primary culture. The 5-HT receptor subtype(s) involved in these effects are unknown. We examined the effects of the 5-HT_{1A} receptor agonist, 8-OHDPAT, upon hippocampal MR and GR gene expression in rats bearing central 5,7-DHT lesions and controls. Rats, pretreated with desipramine, were given 5,7-DHT icv and 12 days later 8-OHDPAT (1 mg/kg/day, s.c.) or saline for 2 days. Controls (vehicle icv) were given saline or 8-OHDPAT. 5,7-DHT lesions decreased hippocampal MR (~20% fall in CA1-3) and GR (31-40% fall in the dentate gyrus, CA1 and CA2) mRNA expression. In 5,7-DHT-lesioned rats, 8-OHDPAT administration reversed the fall in hippocampal MR mRNA expression, most notably in CA1. 8-OHDPAT had no effect on MR gene expression in controls. By contrast, 8-OHDPAT led to further decreases in hippocampal GR mRNA expression in 5,7-DHT-lesioned rats (dentate gyrus, 42% fall; CA1-2, 52%). Moreover in controls, 8-OHDPAT also decreased GR mRNA expression in CA1 (31% fall) and CA2 (39%). Thus, the attenuation of hippocampal MR gene expression by 5-HT denervation can be partly reversed by 5HT_{1A} receptor agonists, whereas the attenuation of GR gene expression does not appear to be due to loss of 5HT_{1A} receptor activation. Whether the 8-OHDPAT-related decrease in GR mRNA expression is directly mediated or reflects indirect actions, such as increased corticosterone secretion, remains to be determined.

386.7

Altered Expression of GLUT1 & GLUT3 Glucose Transporters in Neurohypophyses of Dehydrated/Rehydrated Rats. Kang Li, Susan J. Vannucci, Ellen Koehler, Fran Maher and Ian A. Simpson*. Bethesda, MD 20892 and Hershey, PA 17033.

The neurohypophysis (NH) is an extension of the central nervous system which contains axon terminals of vasopressin- and oxytocin-secreting neurons of the hypothalamus and glial-like pituicytes, but lacks a blood-brain barrier. Neuronal GLUT1 and 45 kDa GLUT3 are detected in the NH. Progressive dehydration due to water deprivation increases vasopressin (VP) secretion in rats; dehydration increases NH glucose utilization. This study examined the effects of progressive dehydration and subsequent rehydration on NH GLUT1 and GLUT3. Dehydration was achieved in adult (250g) male rats by water deprivation for 1, 2 & 3d. At 3d of dehydration other rats had their water returned and were studied at 1, 2 & 3 days following rehydration. NH GLUT1 & 3 concentrations were determined in individual NH by Western blot analysis with specific anti-C-terminal antisera. With progressive dehydration, hematocrit increased and plasma VP levels, measured by RIA, increased 4-fold by 3 days with a corresponding depletion in NH VP. The concentration of GLUT1 was increased by 18% and 44% by 2 & 3 and GLUT3 was increased by 42% & 55%. With water repletion, physiological parameters, including weight gain and hematocrit returned to normal by two days. However, the levels of both GLUT1 and GLUT3 remained elevated, even at 3 days of rehydration. The results of this study suggest that NH glucose transporters are rapidly upregulated in response to the metabolic stress of dehydration but their turnover is apparently slower.

386.4

LONG-TERM FLUOXETINE, PHENELZINE AND IDAZOXAN TREATMENT INCREASES LEVELS OF POMC AND NPY mRNA LEVELS IN THE HYPOTHALAMIC ARCULATE NUCLEUS.

R.A. Baker*, M. Herkenham and L.S. Brady. Section on Functional Neuroanatomy, Clinical Neuroendocrinology Branch, NIMH, Bethesda, MD 20892.

Antidepressant drug treatments have been shown to decrease corticotrophin releasing hormone (CRH) mRNA levels in the hypothalamic paraventricular nucleus (PVN) with a delayed time course that is relevant to their clinical efficacy (Br. Res., '92, 572:117). The question of which neural inputs to the PVN may mediate this decrease remains unanswered. Inputs to the PVN from the arcuate nucleus, particularly the NPY and POMC arcuate-paraventricular projections, are candidates for mediating the effects of antidepressant drugs on CRH mRNA levels. *In situ* hybridization histochemistry was used to assess arcuate peptide mRNA levels in 4 groups of rats following daily administration of fluoxetine, phenelzine, idazoxan, or saline for 2 or 8 weeks. Long-term treatment with each of the 3 antidepressants significantly increased arcuate POMC and NPY mRNA levels, ranging from 34% to 72% above control levels. In contrast, following 2 week treatment, arcuate NPY mRNA levels were significantly increased by 31% over control levels in the phenelzine treated group, but were unchanged in the fluoxetine and idazoxan groups. Following the 2 week treatment, levels of POMC mRNA were unchanged in all 3 treatment groups. These findings suggest that NPY and POMC mRNA-containing projections from the arcuate to the PVN may contribute to the decreased levels of CRH mRNA found following long-term (8 week) but not short-term (2 week) antidepressant drug treatment.

386.6

ACUTE MDMA TREATMENT ALTERS CORTICOSTEROID RECEPTOR AND 5-HT_{2C} RECEPTOR GENE EXPRESSION IN THE RAT HIPPOCAMPUS. J.L.W. Yau* and J.R. Seckl. Dept. Med. Western Gen. Hosp. Edinburgh, U.K.

Serotonin and corticosteroids interact in the hippocampus, affecting electrophysiological, neuroendocrine and behavioural parameters. Chronic methylenedioxymethamphetamine (MDMA) administration causes selective neurodegeneration of 5-HT neurons. This decreases mineralocorticoid (MR) and glucocorticoid (GR) receptor and increases 5-HT_{2C} receptor gene expression in the hippocampus. Conversely antidepressant drugs, which potentiate monoamine action, increase hippocampal GR and MR gene expression. Acutely, MDMA releases 5-HT from nerve terminals, prior to damaging axons. In the present study, we examined the effects of acute MDMA on hippocampal MR, GR and 5-HT_{2C} receptor mRNA expression using *in situ* hybridisation. Rats were killed 16 h after MDMA (20mg/kg, s.c.). Hippocampal neuronal GR mRNA expression was decreased in the dentate gyrus (DG) (29% fall), CA2 (20%) and CA3 (24%; all $p < 0.05$). In contrast, MR mRNA expression was increased in the DG (69% rise), CA1 (41%), CA3 (35%) and CA4 (52%; all $p < 0.01$). 5-HT_{2C} receptor mRNA expression was decreased in CA3 of the dorsal (20%, $p < 0.01$) and ventral (30%, $p < 0.05$) hippocampus. Increased MR and decreased 5-HT_{2C} receptor gene expression in the hippocampus probably reflect acute MDMA-induced 5-HT release. Down-regulation of GR gene expression might be a consequence of the MR changes. These results support our previous findings suggesting 5-HT controls hippocampal corticosteroid receptor and 5HT_{2C} receptor gene expression.

386.8

MODULATION OF THE HYPOTHALAMIC-PITUITARY-ADRENAL AXIS IN BIRDS. L. Michael Romero* & John C. Wingfield. Dept. of Zoology, Univ. of Washington, Seattle, WA 98195

Recent evidence suggests that some avian species can modulate corticosterone (B) release in response to a standard stressful paradigm (capture and serial blood sampling). Stress-induced release of B varies throughout the year and appears dependent upon the animal's physiological state. In one species (white-crowned sparrow, *Zonotrichia leucophrys*), B output is inhibited during molt. We tested whether this inhibition results from adrenal or pituitary nonresponsiveness by injecting various stimulating factors into molting white-crowned sparrows and comparing B release to similarly-injected nonmolting pigeons (*Columba livia*), a species not known to modulate their glucocorticoid response.

White-crowned sparrows from eastern WA were housed in outdoor aviaries until the onset of molt. Pigeons were captured in Seattle, injected, bled, and released. Intravenous ACTH stimulated B release in the sparrows, indicating that the adrenal can still respond to an ACTH signal during molt. CRF, on the other hand, failed to stimulate B release in the sparrows, but enhanced B release 300% in the pigeon compared to vehicle-injected controls. Similarly, arginine-vasotocin and mesotocin (AVT and MT - the avian equivalents of vasopressin and oxytocin, respectively) also failed to stimulate B release in sparrows whereas AVT caused a 200% increase in the pigeon. In neither species did the combination of CRF and AVT enhance B secretion than to either hormone alone. These data suggest that the inhibition of B release seen in white-crown sparrows during molt may be mediated by pituitary insensitivity to an ACTH secretagog signal but not to adrenal insensitivity to ACTH.

PERIPHERAL NGF ADMINISTRATION INCREASES HYPOTHALAMIC C-FOS EXPRESSION. F. Passarelli*, R. Nicolai#, F.R. Buttarelli, D. Babiloni, S. Scaccianoce#, G. Cigliana#, and L. Angelucci#. Dept. of Neurosci., Univ. of Rome "La Sapienza" and #Farmacologia, 2^a, Univ. of Rome "La Sapienza".

We have recently demonstrated in the rat the hypothalamic involvement in the adrenocortical activation induced by NGF (Scaccianoce S., 1993). The *c-fos* gene, expressed at low levels in most cells types, is induced rapidly in response to a variety of extracellular stimuli in the periphery and in the CNS. We have investigated whether NGF administration is followed by an induction of hypothalamic *c-fos* mRNA expression. Freely moving male Wistar rats were injected through a permanent jugular cannula with either 1 or 5 nmol/kg of mouse β NGF (kindly donated by dr. J.R. Perez Polo, Univ. of Texas, Galvestone, Texas) or vehicle. The adrenal glands and the hypothalamus were isolated 30 min after injection and total RNA was extracted by the guanidinium thiocyanate-cesium chloride method. The levels of *c-fos* and β -actin mRNAs were measured in each sample using a RT-PCR. Compared to vehicle in the hypothalamus a 2-fold *c-fos* mRNA increment was observed after 5 nmol/kg of NGF administration but not after 1 nmol/kg. The adrenal gland mRNA *c-fos* enhancement was detected after 1 and 5 nmol/kg NGF injection. These results confirm that the hypothalamus is involved in the adrenocortical activity induced by NGF and that the *c-fos* gene is a target of intracellular second messenger pathway. (Supported by CNR grant 93.00447.PF40 to Scaccianoce S.).

GLUCOCORTICOID MODULATION OF C-TYPE NATRIURETIC PEPTIDE mRNA LEVELS IN PREOPTIC AREA AND LIMBIC STRUCTURES. M.C. Langub, Jr., D. Rucker and J.P. Herman. Dept. of Anatomy and Neurobiology, University of Kentucky Medical Center, Lexington, KY 40536-0084.

C-type natriuretic peptide (CNP) has been shown to exert inhibitory action on the HPA axis. The potential for CNP to act via central mechanisms is highlighted by recent data indicating localization to several stress relevant CNS nuclei, including the preoptic area and hippocampus. In light of the potential importance of CNP in regulation of HPA axis, we tested the hypothesis that CNP is glucocorticoid (GC) regulated by examining the effects of adrenalectomy and GC replacement on CNP mRNA. Groups of adrenalectomized (ADX) rats, ADX rats replaced with 30% corticosterone (CORT) pellets (yielding CORT levels of 40-70 ng/ml), and sham-ADX rats (CORT levels between 10-30 ng/ml) were sacrificed and brains processed for *in situ* hybridization histochemistry. Hybridization signal for CNP mRNA was present in the anteroventral periventricular area (AVPv), arcuate nucleus, hippocampal subfields CA1, CA2/3, dentate gyrus and cingulate cortex. The AVPv was the only region showing evidence of GC modulation. Semi-quantitative analysis revealed no changes between ADX and sham rats. ADX-CORT rats, which have significantly higher levels of circulating CORT than sham rats at the time of sacrifice, exhibited pronounced increases in CNP mRNA relative to ADX or sham rats. These results suggest the AVPv CNP-synthesizing neuronal population can respond directly or indirectly to high steroid levels, and therefore that these cells may modulate CNP actions on the stress axis. Supported by American Heart Association Kentucky Affiliate.

BILATERAL LESIONS OF THE CENTRAL AMYGDALOID NUCLEUS BLOCK THE EFFECTS OF CHRONIC STRESS ON THE HPA AXIS. C.M. MEYERS*, AND J.P. HERMAN. Dept. of Anatomy and Neurobiology, University of Kentucky Medical Center, Lexington, KY 40536-0084.

Chronic stress elicits long-term hypersecretion of stress-hormones by the hypothalamic-pituitary-adrenal (HPA) axis. The central nucleus of the amygdala (ACE) has been shown to potentiate HPA activation; stress-induced ACTH secretion is increased by stimulation of the ACE and decreased following ACE lesion. The present studies address the hypothesis that the ACE is involved in chronic stress-induced HPA changes. The ACE was bilaterally lesioned by injection of ibotenic acid (IBO) (3.0 μ g total in 0.3 μ l) or sham-lesioned (0.3 μ l saline/side). Groups of rats were chronically stressed using a variable stressor paradigm (bi-daily exposure to cold, warm water swim, cold water swim, crowding, vibration, isolation). Control rats were handled bi-daily. Rats were killed after 30 days of stress. Adrenal glands and thymus were removed and weighed; plasma stress hormones were determined by RIA; and CRH mRNA in the hypothalamic paraventricular nucleus (PVN) was analyzed by *in situ* hybridization histochemistry. Chronic stress decreases thymus and body weight, and increases adrenal weight and basal CORT level in sham-lesioned animals. However, in ACE lesioned rats, chronic stress did not decrease thymus or body weight and did not increase basal CORT level. Chronic stress upregulated CRH mRNA in the PVN of sham-lesioned animals, but no change was found in the IBO-lesioned rats. These results suggest that the ACE exerts an important action on maintenance of HPA axis activation following chronic stress. The ACE may therefore play a critical role in disease states associated with pathological hypersecretion of glucocorticoids. Supported by MH49698.

CATECHOLAMINERGIC AFFERENTS TO THE FETAL PARAVENTRICULAR NUCLEUS CONTAIN GLUCOCORTICOID RECEPTORS. W.W. Le, T.J. McDonald, P.W. Nathanielsz, and G.E. Hoffman. Department of Neurobiology, Univ. Pittsburgh, Pittsburgh, PA, 15261 and Laboratory for Pregnancy and Newborn Research, Cornell Univ., Ithaca NY 14853.

In fetal sheep, implants of corticosteroids adjacent to the paraventricular nucleus of the hypothalamus suppress AVP and CRH expression. These effects of glucocorticosteroids are likely mediated by actions of glucocorticoid receptors within the paraventricular (PVN) neurons. Under physiological conditions, steroids could influence the function of the hypothalamus via actions to the PVN afferent neurons as well. To assess this possibility, we determined whether the catecholaminergic afferents to the PVN in the ventrolateral medulla (A1/C1), and n. solitary tract (A2/C2) possessed immunoreactive type II glucocorticoid receptors. To accomplish this, fluorogold (FAU) was stereotactically injected into the PVN of 5 fetal sheep (120 dGA). After 3 weeks, each fetus was removed by Caesarian section, administered an overdose of anesthesia and perfused. Immunocytochemistry for GR11 (using anti BUGR11), tyrosine hydroxylase and FAU was performed in the brainstem. Staining of the hypothalamus for FAU, GR11, and CRH verified the accuracy of tracer injection and substantiated the presence of GR within the CRH neurons of the PVN. The dominant catecholamine innervation of the PVN arises from the A1/C1 and A2/C2 cell groups. In the A1/C1 cell group, 68% of the catecholamine neurons possessed GR; in the A2/C2 cell group 73% of the neurons were GR11+. Triple labeling of tyrosine hydroxylase, GR11 and FAU confirmed that approximately half of the GR11+ catecholamine neurons in both regions projected to the PVN. These data suggest that glucocorticoids can act on both the CRH neurons of the hypothalamus as well as on catecholamine afferents to the PVN. (Supported by NIH HD 21350)

BEHAVIORAL, NEUROENDOCRINE AND NEUROIMMUNE ANALYSIS OF HIPPOCAMPAL STRESS INTEGRATION. J.P. Herman*, C.M. Dolgas and S.L. Carlson. Dept. of Anatomy and Neurobiology, Univ. Kentucky Medical Center, Lexington, KY 40536-0084.

Lesion and anatomical analyses suggest that the ventral subiculum (VSUB) plays a major role in hippocampal inhibition of the hypothalamo-pituitary-adrenocortical (HPA) axis. The present study was designed to assess the nature of VSUB involvement in behavioral, neuroendocrine and neuroimmune stress responses. Groups of rats received bilateral ibotenic acid lesions of the VSUB (IBO) (n=19) or injections of saline vehicle (SAL) (n=17). All animals underwent analysis of stress-related behaviors in an open field, and were subsequently divided into three groups for analysis of endocrine and immune responsivity to acute restraint (0, 60 and 120 m). IBO rats exhibited enhanced emotional responsivity to open field exposure, manifest as increases in freezing behavior and decreased ambulation. IBO lesion increased stress-induced ACTH secretion 60 m but not 120 m after stress induction; no changes were seen in baseline release. Restraint stress caused marked decreases in splenic lymphocyte proliferation following 60m of restraint, as measured by *in vitro* mitogen assay; however, no differences were noted between groups. The results suggest that VSUB damage affects both emotional responsivity and HPA activation following exposure to a stressful situation, yet do not impair either basal ACTH release or immune reactivity in a long-term fashion. The VSUB lesion appears to bias behavioral predispositions in a direction suggesting enhanced stress responsivity. Effects of VSUB lesion on HPA activation may therefore be mediated by alterations in salience of stressful stimuli, rather than modulation of glucocorticoid negative feedback. Supported by MH49698.

THE EFFECTS OF GLUCOCORTICOIDS ON THE ELECTRICAL PROPERTIES OF IDENTIFIED HYPOTHALAMIC NEURONS. S.S. Daftary*, K. Szabo and J.G. Tasker. Molecular & Cellular Biology Program and Dept of Cell & Molecular Biology, Tulane University, New Orleans, LA 70118.

Activation of the hypothalamic-pituitary-adrenal (HPA) axis causes an increase in the circulating levels of glucocorticoids (eg. during stress). Glucocorticoids feed back onto the brain to inhibit the secretion of corticotropin releasing factor (CRF) and suppress HPA activation. To determine whether glucocorticoids feed back directly onto neurosecretory neurons of the hypothalamus, we studied the effects of the glucocorticoid analog, dexamethasone, on the membrane electrical properties of identified neurons in the rat hypothalamic paraventricular nucleus (PVN). The effects of dexamethasone on specific PVN cell populations were studied using intracellular recordings, dye injection and immunohistochemistry in the hypothalamic slice preparation. Bath application (30 min) of dexamethasone (10^{-6} M) caused a 4-14mV hyperpolarization with an increase in input resistance in low-threshold spiking (LTS) cells, or putative parvocellular neurons, and a small depolarization (2-5mV) with a decrease in input resistance in non-LTS cells, or putative magnocellular neurons. The identity of recorded cells was verified anatomically with biocytin injection and subsequent immunohistochemical processing using antisera to CRF, oxytocin, vasopressin or neurophysin. These results suggest that glucocorticoids have a direct inhibitory effect on parvocellular neurons and a weak excitatory effect on magnocellular neurons of the hypothalamic PVN.

EVIDENCE FOR GLUCOCORTICOID REGULATION OF VASOPRESSIN V1a RECEPTOR GENE EXPRESSION

J. J. Watters* and D. M. Dorsa

Departments of Pharmacology, Psychiatry and GRECC, VAMC Seattle, Univ. of WA, Seattle WA 98195

The brain vasopressinergic system is intimately involved with the hypothalamo-pituitary-adrenal axis. We have isolated a genomic clone from a rat testis library encoding a putative vasopressin V1a receptor. Analysis of the 5' flanking region of this clone revealed the presence of several putative glucocorticoid response elements suggesting that glucocorticoids might play a role in transcriptional regulation of this gene. The rat mammary tumor cell line, WRK-1, expresses a vasopressin V1a receptor similar to that expressed in rat liver. Previous studies in our laboratory have shown that treatment of these cells for 24 hours with dexamethasone (DEX), leads to an increase in PI hydrolysis, receptor number and receptor binding. These effects were blocked by the glucocorticoid receptor (GR) antagonist RU486. To determine if these increases might be due to an enhancement of V1a gene transcription, we treated cells with DEX for 1, 3, 6, 12, and 24 hours and isolated poly A+ RNA. We observed a transient increase in mRNA by Northern blot analysis, that was maximal at 12 hours. This time period, in addition to blockade of this effect by a GR antagonist, suggests a genomic mechanism of glucocorticoid modulation of the V1a receptor. *In vivo* studies are currently in progress to assess the physiologic role of glucocorticoids in expression of this receptor in rat brain. MINERALOCORTICOID RECEPTOR mRNA VARIANTS IN THE DEVELOPING HIPPOCAMPUS: DISTRIBUTION AND CORTICOID REGULATION

D.M. Vázquez*, S.P. Kwak, J.F. López, S.J. Watson and H. Akil

University of Michigan-MHRI, Ann Arbor, MI 48109-0720

Our laboratory has previously reported an MR cDNA clone from rat hippocampus (HC) which shares a high degree of homology with the kidney MR rat clone. However, these two clones differ significantly at the 5' untranslated region (5' UT) and have been named alpha (α) (kidney clone) and beta (β) (HC clone). Most recently, a third HC 5'UT cDNA clone was identified which we termed gamma (γ) (Endo 133:5-2344). Studies have shown that these 5' UT regions are located on separate exons of a single gene and give rise to three mRNAs that encode the same protein. We were interested in investigating the presence of these distinct mRNA forms and their glucocorticoid regulation in the developing rat HC. Last year we presented the α and β HC distribution in animals 10, 18, 28 and 60 (adult) days old. We have expanded the *in situ* hybridization study to younger ages and included the γ 5'UT variant in our analysis. In general, we find that α and β expression increases slowly in all HC regions during the first 2 weeks of life. Whereas α levels remain constant thereafter, β expression decreases markedly in the pubertal animal. In contrast, γ is highly expressed in all regions early during development. In the dentate gyrus this high level of expression is retained until adulthood when low levels are detected. Adrenalectomy results in up-regulation of the α 5'UT form in all ages. Our results, show that the α and β 5' UT forms achieve an adult pattern of distribution in the HC after the Stress Hypo-Responsive Period. The γ 5'UT form maybe important for proliferation and differentiation of hippocampal neurons. Supported by NIMH MH09720 and MH422251.

ADRENOCORTICAL EFFECTS ON TYPE I CALMODULIN-DEPENDENT ADENYLATE CYCLASE mRNA LEVELS IN RAT BRAIN

M.N. Gannon* and B.S. McEwen

Lab. Neuroendocrinol, Rockefeller Univ., NY, NY 10021.

Manipulation of the hypothalamic-pituitary-adrenal axis has pronounced effects on calmodulin-dependent (CaM) adenylate cyclase (AC) enzyme activity, measured in rat brain homogenates. In particular, hippocampal CaM AC activity shows diurnal variation, an effect abolished by ADX [J. Neuroendocrinol. 3:37-43, 1991]. The present study investigated whether, adrenocortical effects on AC enzyme activity were paralleled by changes in the expression of AC mRNA. Of the eight identified members of the AC gene family, only Type I ACmRNA is both present in high levels in brain and shows CaM-dependency. *In situ* hybridization analysis was conducted at the level of the dorsal hippocampus, using [35S]-oligonucleotide probes directed against rat Type I ACmRNA. Preliminary results indicate that ADX (14 days) attenuates Type I ACmRNA levels in rat dentate gyrus measured 2-4 hr into the dark cycle, but not 5-7 hr into the light cycle. Compared to ADX, corticosterone administration (40 mg/kg s.c. once daily) increased expression of Type I ACmRNA in the dentate gyrus at both time points. In a separate study, rats were housed on a 12:12 light:dark cycle, sham-operated or ADX (14 days), sacrificed at 4 hr intervals across the light:dark cycle and brain processed for *in situ* hybridization analysis. Both ADX and time of day had significant effects on Type I ACmRNA expression in the dentate gyrus. In contrast, 21 days stress, which attenuated cortical CaM AC enzyme activity [J. Neurochem. 55:276, 1990], had no significant effect on Type I ACmRNA expression in either cerebral cortex or hippocampus. These results suggest that part, but not all, of the effects of adrenocortical state on cAMP signal transduction in brain are mediated through effects on Type I ACmRNA expression. Supported by grant MH41256.

ALPHA-TOCOPHEROL SUCCINATE, BUT NOT ALPHA-TOCOPHEROL OR OTHER VITAMIN E ANALOGS STIMULATES PROLACTIN RELEASE FROM RAT ANTERIOR PITUITARY CELLS *in vitro*.

M. Badamchian*, B. Spangelo*, Y. Hagiwara*, H. Hagiwara*, H. Veyama* and A.L. Goldstein*

*Department of Biochemistry The George Washington University School of Medicine, Washington, D.C. 20037 *Department of Physiology, Medical University of South Carolina, SC 29425, **The Hagiwara Institute of Health, Hyogo, Japan

Green barley leaf extract, a dried extract of young green barley leaves, is widely used in Japan and other countries as a nutritional supplement. We have recently reported (Badamchian, et al. J. Nutr. Bioc. 5:145-150, 1994), the isolation of a vitamin E analog from green barley leaf extract that stimulates release of prolactin and growth hormone from rat anterior pituitary cells *in vitro*. This molecule was identified as α -Tocopherol succinate, an analog of α -Tocopherol, or vitamin E. In the present study we tested the commercially available forms of α -Tocopherol and also succinic acid. Treatment of normal anterior pituitary cells with different forms of tocopherol (100 μ g/ml) and succinic acid (50-100 μ g/ml) caused significant increase ($p < 0.01$) in prolactin release in only α -Tocopherol succinate-treated cells. α -Tocopherol, δ -Tocopherol, α -Tocopherol acetate, α -Tocopherol nicotinate, succinic acid disodium salt, and succinic acid butenedioic acid did not effect the prolactin release *in vitro*. Supported by a gift from Hagiwara Institute of Health, Hyogo, Japan.

HYPOTHALAMIC-PITUITARY-GONADAL REGULATION: GnRH RELEASE

387.1

GABA TURNOVER IN MICRODISSECTED BRAIN REGIONS DURING THE RAT ESTROUS CYCLE

D.R. Grattan* and M. Selmanoff

Center for Studies in Reproduction, Department of Physiology, University of Maryland, School of Medicine, Baltimore, MD 21201-1559.

GABAergic neurons terminating in the rostral and mediobasal hypothalamus are positively regulated by testosterone, an action that may play an important role in mediating the negative-feedback action of testosterone on hypothalamic GnRH release in the male rat. The present study determined whether endogenous changes in gonadal steroids during the estrous cycle were associated with changes in GABAergic neuronal activity measured in tissue punches from steroid-sensitive brain regions. Animals were decapitated at 0900 and 1700 h on diestrous day 1, and 0900, 1300 and 1700 h on proestrus, either without treatment, or 60 minutes after inhibition of the GABA degrading enzyme GABA-transaminase by aminooxyacetic acid (AOAA, 100 mg/kg, ip). The rate of accumulation of GABA in the tissue after AOAA was taken as an index of GABA turnover. In brain regions examined so far, there was no change in GABA turnover between the morning and afternoon on diestrus, or between the morning of diestrus and the morning of proestrus. In the diagonal band of Broca at the level of the OVLT, GABA turnover was significantly reduced in the afternoon of proestrus compared with activity measured in the morning. By contrast, in the central portion of the MPN, no changes were apparent at any of the timepoints examined. Analysis is continuing in the median eminence, ventromedial nucleus, septal nuclei, medial amygdala, hippocampus CA1, suprachiasmatic nucleus and cortex. The results suggest that activity of specific subpopulations of GABAergic neurons in the rostral hypothalamus changes during the estrous cycle in the female rat. It is likely that decreased GABA turnover in these regions may be important for generation of the preovulatory GnRH surge. (Supported by NIH Grant HD21351)

387.2

EFFECT OF CHRONIC MORPHINE TREATMENT ON NORADRENERGIC MODULATION OF GT1-7 NEURONS

M.A. Javors*, T.S. King, J.G. Hensler, and X. Chang

Departments of Psychiatry, Pharmacology, and CS&B, The University of Texas HSC, San Antonio, TX 78284.

Stimulation of noradrenergic, serotonergic, and opiate receptors are known to regulate release of hypothalamic GnRH, but it is not known whether the receptors exist on GnRH neurons or on other cell types that contact GnRH neurons. GT1-7 neurons, which synthesize and secrete GnRH, were immortalized in culture from transgenic mice. The purpose of this study was to examine the possible interrelationship among opiate, noradrenergic, and serotonergic input to GT1-7 neurons. We measured GnRH by RIA, $[Ca^{2+}]_{cyt}$ with the fura-2 method, and cAMP accumulation as conversion of 3H -ATP to 3H -cAMP. Our results show that norepinephrine (NE) stimulated increases in cytosolic $[Ca^{2+}]$ and GnRH release. Serotonin (5HT) had no effect on $[Ca^{2+}]_{cyt}$, basal cAMP accumulation, or forskolin-stimulated cAMP accumulation. Exposure of these cells to morphine for 5 days resulted in enhanced NE stimulation of $[Ca^{2+}]_{cyt}$ but did not change the lack of responsiveness of the cells to 5HT. These data suggest that opiate receptors may modulate noradrenergic stimulation of GnRH neurons *in vivo* and also that 5HT regulation of GnRH neurons *in vivo* is not direct. Supported by USPHS grants DA06039, AA10112, and MH52369.

387.3

GONADOTROPIN-RELEASING HORMONE (GnRH) RELEASE IN OVARECTOMIZED FEMALE MARMOSSET MONKEYS. D.H. Abbott^{1,2}, W. Saltzman¹, N.J. Schultz-Darken¹ and E. Terasawa^{1*}. ¹Wisconsin Regional Primate Research Center and ²Dept. of Ob/Gyn., University of Wisconsin, Madison, WI 53715.

Socially subordinate female marmosets, *Callithrix jacchus*, fail to ovulate because of suppressed gonadotropin secretion, presumably caused by reduced GnRH release. To investigate the causes of this pronounced reproductive suppression, we developed a push-pull perfusion technique for characterizing GnRH release in conscious female marmosets. In order to validate this technique, 5 ovariectomized females were implanted with cranial pedestals using x-ray ventriculography and a stereotaxic apparatus. After at least 6 weeks, a micromanipulator was attached to the pedestal and was used to lower a push-pull cannula (outer cannula: 20 ga, inner cannula: 28 ga) into the pituitary stalk-median eminence. The female was then placed in a jacket/sling restraint beside its social group. Two days later, we perfused modified Krebs's Ringer phosphate buffer at 23 µl/min and collected 10-min perfusate samples for 7h from fully conscious animals. GnRH in perfusate samples was measured by RIA. Following perfusion, the cannula and micromanipulator were removed and the animal was returned to its social group. We found that GnRH release in ovariectomized marmosets was pulsatile, with values ranging from 0.1-16.3 pg/ml. GnRH inter-pulse interval was 42.3±1.8 min (mean ± SEM) with a peak amplitude of 2.1±1.1 pg/ml. Perfusion sites were just ventral to the infundibular recess, within 1 mm of the midline. Repeated perfusion of individual animals indicated that multiple measurements of GnRH can be made from the same females without disturbing their social grouping. Such direct measurement of hypothalamic function now permits systematic investigation of the neuroendocrine control of female reproduction in the marmoset. [Supported by NIH grants RR00167, HD07678 and NSF grant IBN 92-21771.]

387.5

SUPPRESSION OF LUTEINIZING HORMONE SECRETION IN FOOD RESTRICTED LACTATING RATS: EFFECTS OF OVARECTOMY AND BROMOCRYPTINE TREATMENT. C.-D. Walker^{*,†}, J. B. Mitchell⁺ and B. Woodside[‡]. ^{*}Dept of Psychiatry, McGill University, [‡]CSBN, Concordia University, Montreal, Que., [†]Psychology Dept. Boston College.

It has been shown that food restricting lactating rats for the first two weeks postpartum at a level of 60% of the ad-lib daily ration increases the length of lactational diestrus by about 7 days. The aims of the present studies were 1) to examine changes in LH, PRL, and ACTH secretion in food-restricted and ad libitum fed lactating rats at various stages of lactation, and 2) to determine whether the changes in hormonal parameters induced by ovariectomy or bromocryptine treatment differed between food-restricted and ad lib fed dams. Blood samples were obtained over a 2 hour period from freely moving lactating females on Days 4, 15 and 21 of lactation. GnRH receptor number was determined by autoradiography. Our results demonstrate that food restriction during the first two weeks of lactation did not affect PRL or ACTH secretion, but decreased plasma LH levels despite comparable GnRH receptor density between food-restricted and ad lib fed females. In addition, LH reduction in food-restricted lactating females was not affected by ovariectomy or bromocryptine treatment, although the latter treatment significantly increased GnRH receptor number. These data suggest that factors other than ovarian steroids, PRL or increased adrenocortical activity modulate LH secretion and the length of lactational diestrus in food-restricted lactating females.

387.7

ACUTE INHIBITION OF LUTEINIZING HORMONE SECRETION IN RESPONSE TO ETHYL β-CARBOLINE-3-CARBOXYLATE (β-CCE) AND DIAZEPAM TREATMENTS IN CASTRATED MALE RATS. C.A. Hodson, A.T. Davenport, G.T. Price and H.W. Burden^{*}. Obstetrics and Gynecology, and Anatomy and Cell Biology, East Carolina University School of Medicine, Greenville, NC 27858

Previous studies have shown that diazepam administration can inhibit LH secretion. The present study was conducted to determine if the inverse agonist β-CCE would affect LH secretion.

Male rats castrated for 7 days weighing 350-450g were used for the study. On day 7 at time 0 a single blood sample was taken from the retro-orbital sinus under ether anesthesia. Immediately after collection of the time 0 sample the rats were injected with vehicle (2:1 propylene-glycol:ethanol), 2mg β-CCE/kg bw, 2.5mg diazepam/kg bw or β-CCE and diazepam in combination. After treatment additional blood samples were collected at 15, 30 and 60 minutes from the retro-orbital sinus.

β-CCE reduced serum LH with respect to vehicle at 15 and 30 minutes post injection. Diazepam treatment caused a reduction in LH at 30 minutes post injection. The drugs did not have an additive effect. These results suggest that diazepam and β-CCE can acutely reduce LH.

387.4

FOOD DEPRIVATION ENHANCES ESTRADIOL-INDUCED LH SURGE IN FEMALE SYRIAN HAMSTERS. R.A. Mangels, A.E. Jetton^{*}, and G.N. Wade. Neuroscience and Behavior Program, University of Massachusetts, Amherst, MA 01003.

Reproductive function is sensitive to the availability of metabolic fuels. In Syrian hamsters, two days of food deprivation prevents ovulation, inhibits lordosis, and alters brain estrogen receptor immunoreactivity (ERIR). To further assess the role of changes in neural sensitivity to estradiol (E₂) during food deprivation, we examined the effect of food deprivation on the E₂-induced LH surge. Fifty three hamsters were individually housed in a 14:10 light-dark cycle (lights on 0700h). Two weeks after ovariectomy (OVX), animals were injected at 1300h with 5 µg estradiol benzoate (EB) or oil, and food was removed from half of the animals in each group. Two days later, 4ml of blood was taken via cardiac puncture at each of three time points (1100, 1700, and 1800h). RIA revealed that EB reduced serum LH at 1100h and induced an LH surge at both 1700h and 1800h. There was no effect of food deprivation. In a second experiment, fifty nine animals were housed in identical conditions. Two weeks after OVX, food was removed at 1100h. Forty eight hours later, animals were injected with oil, 1 µg EB, or 5 µg EB, and food was returned. Two days after EB injection, animals were bled at 1100, 1600, or 1700h. Both doses of EB induced an LH surge at 1600 and 1700h, but only the 5 µg dose inhibited LH at 1100h. Food deprivation enhanced the LH surge in hamsters treated with 1 µg EB, but not in hamsters given 5 µg EB. Food deprivation inhibited LH at 1100h in oil-treated animals. Thus, two days of food deprivation preceding a low dose injection of EB increases the magnitude of the LH surge. This effect could be related to the increase in mPOA ERIR following food deprivation. Supported by NS10873, MH00321, and HD07673

387.6

BLOCKADE OF PREOVULATORY LH SURGES WITH A NEUROPEPTIDE Y RECEPTOR ANTAGONIST, PYX2. L.M. Bessecke^{*}, A.C. Bauer-Dantoin, D.K. Wong and J.E. Levine. Dept. of Neurobiology & Physiology, Northwestern University, Evanston, IL 60208.

Neuropeptide Y (NPY) plays an important role in the generation of preovulatory luteinizing hormone (LH) surges. NPY likely both stimulates LHRH release and facilitates LHRH-induced LH secretion as complementary components of an integrated LH-surge amplification process. It is not known, however, how NPY's actions are manifest at the level of the anterior pituitary, and if any such actions are requisite for the production of normal LH surges. The present experiments were undertaken to determine 1) if NPY receptor occupancy is required for the elaboration of spontaneous LH surges and 2) if pulsatile or continuous stimulation of the receptor is sufficient for expression of NPY's facilitatory effects. In experiment 1, either vehicle or the NPY receptor antagonist, PYX2 (0.5 mg/kg BW, iv), was administered at 1330, 1530, and 1730 h in proestrous rats. Blood samples obtained at 60 min intervals between 1100 and 2100 h were analyzed by LH RIA. Results revealed that the LH surges were completely blocked or significantly blunted (p<0.05) in all rats treated with the PYX2 regimen. In experiment 2, proestrous rats were anesthetized with pentobarbital (40 mg/kg BW) to block endogenous LHRH/LH surges, and then treated with pulses of LHRH (15 ng, iv) at 30 min intervals. Rats were cotreated with vehicle, continuous NPY (10 µg/h) or pulsatile NPY (1 µg/pulse/30 min). Both continuous and pulsatile NPY modes of treatment were effective in facilitating LHRH-induced LH surges. We conclude from these studies that occupation of a NPY receptor is required for the generation of LH surges in the rat. Our findings also demonstrate that the NPY stimulus pattern need not be pulsatile to affect its actions. Current work is directed at identifying the molecular characteristics of NPY receptors which may mediate these obligatory effects. (NIH HD20677, HD219121, HD00879 and HD28048)

SODIUM NITROPRUSSIDE-INDUCED RELEASE OF NITROGEN MONOXIDE (NO) FROM PROCESSES IN EWE MEDIAN EMINENCE (ME) RESULTS IN AN INCREASE OF IN VIVO ME-LHRH RELEASE. J.P. Advis^{*}, D.K. Sarkar, J. Rabii and R.O. Kuljis. Depts of Animal Sciences, Rutgers University, New Brunswick, NJ 08903; VCAPP, Washington State University, Pullman, WA 99164; Biological Sciences, Rutgers University, Piscataway, NJ 08855; and Neurology, Univ of Iowa and VAMC, Iowa City IA 52242-1053.

Physiological evidence suggests a role for hypothalamic NO, since NO synthase has been reported to be present in the hypothalamus and since NO increases the release of LHRH *in vitro*. Thus, 1) serial frozen sections of ewe hypothalamus and ME (n=5) were labeled histochemically for NADPH-diaphorase which is necessary for the synthesis of NO, and 2) ME-LHRH release was determined *in vivo* by push-pull cannula (PPC) sampling, before and after infusion of sodium nitroprusside through a ME-PPC probe (NaNP, 500 µM, n=5). The mid-hypothalamic region exhibited a collection of labeled neurons and neurites in the ventro-medial nucleus (VMN) visible even at low magnification. Additional large labeled neurons were scattered around the VMN and throughout the hypothalamus. Virtually no labeled perikarya were visible at low magnification around the fundus of the third ventricle. However, a vast network of neurites is present at that level. The interface between ME and pituitary stalk, near the palisade zone showed unequivocally labeled processes, indicating that NO-synthesizing neurites reach the ME. The precise pattern of distribution and source(s) of these neurites remain to be elucidated. Nevertheless, perfusion of NaNP increased *in vivo* pulsatile ME-LHRH release (10.8±1.3 vs 34.3±12.2 pg/100 µl PPC perfusate /2h, before vs after) predominantly by increases in pulse amplitude (2.32 ± 0.29 vs 4.79 ± 0.69). Therefore, it is possible that NO-containing processes might be involved in regulating LHRH release and other aspects of reproductive function and behavior (NJAES-Hatch 06108 and USDA 89-37240-4587 to JP Advis).

PARTIAL SURGES OF LUTEINIZING HORMONE (LH): A NEUROENDOCRINE MECHANISM FOR PROLONGED ESTROUS CYCLES. Susan E. Gans and Martha K. McClintock*. The University of Chicago, Chicago, IL 60637.

The LH surge that stimulates ovulation is triggered by a daily neural signal only when the brain has been adequately primed by ovarian steroids. This preovulatory surge is characterized by (1) a rise above diestrous LH level and (2) an accelerated rate of LH secretion. We hypothesized that these two characteristics are independent, and that rises in LH without acceleration would cause prolonged estrous cycles. We performed external jugular cannulations on 19 regularly cycling female rats. LH levels were assessed in plasma samples collected seven times a day, hourly, from each female on four proestrous days. Steroid levels were assessed in daily samples collected at lights out throughout two estrous cycles. In 57 full LH surges, the rise always preceded the acceleration in the rate of LH secretion. Nonetheless, the time of the rise did not predict the latency to the acceleration. These two independent characteristics of the LH surge correlated with different steroids. Moreover, in eight additional surges LH rose above diestrous LH levels but never achieved the acceleration typical of the rising limb of the LH surge. We termed these partial LH surges and hypothesized that they cause luteinization of the ovarian follicle without ovulation, thus initiating prolonged estrous cycles characteristic of estrous cycle distributions in our colony. The females whose full LH surges had a delayed acceleration were the ones most likely to have partial LH surges. In addition, the steroid correlates of partial LH surges were the same as those of the delayed acceleration, not the rise. Supported by MH10127 (SG) and MERIT award R37 MH41788 (MM).

DOPAMINE AND THE INHIBITION OF LUTEINIZING HORMONE PULSES IN RATS: THE SIGNIFICANCE OF HYPOTHERMIA. P. H. Strutton and C. W. Coen*. Division of Biomedical Sciences, King's College, London WC2R 2LS, U.K.

Previous work has indicated that a reduction in body temperature can be the primary factor in the suppression of luteinizing hormone (LH) in ovariectomized rats. Since it has been demonstrated in independent studies that centrally administered dopamine can induce hypothermia and inhibit LH pulses, we have examined the effects of the dopamine receptor agonist apomorphine on these two parameters concurrently; in some of the studies the agonist was administered after a dopaminergic antagonist and in others it was given at an ambient temperature (35°C) which precluded the induction of hypothermia. Ovariectomized rats were fitted with an intraperitoneal transmitter to monitor core temperature and with indwelling cannulae in the right atrium of the heart and either the lateral cerebral ventricle or the subcutaneous space. Every 5 minutes during the experiment core temperature was recorded automatically and a 25 µl blood sample was obtained using an automated system. Drugs were administered without touching the animal after a control sampling period of 2.5 hours. Subcutaneous administration of apomorphine (1.5 mg/kg) at an ambient temperature of 21°C resulted in hypothermia 30-120 minutes post-injection; during this period there was a reduction in mean LH concentration and pulse frequency but not pulse amplitude. When this experiment was carried out at 35°C there was no reduction in core temperature; nevertheless, a reduction in mean LH concentration and pulse frequency was observed. Intracerebroventricular (icv) administration of apomorphine (20 µg) at 21°C produced hypothermia 15-45 minutes post-injection; during this period there was a reduction in mean LH concentration and pulse frequency. At 35°C the icv treatment did not significantly reduce core temperature; nevertheless a reduction in mean LH concentration and pulse frequency was observed. Subcutaneous or icv administration of vehicle at 21°C or 35°C had no effect on core temperature or LH release. Subcutaneous administration of the selective D₂ receptor antagonist sulpiride (50 mg/kg) 90 minutes before subcutaneous administration of apomorphine prevented the apomorphine-induced hypothermia and suppression of the LH pulses. These results suggest that D₂ receptors are involved in the hypothermia and suppression of LH induced by apomorphine, and that this inhibitory effect on LH release is not secondary to the induced hypothermia.

NEURAL FOS-LIKE IMMUNOREACTIVITY IS NOT AUGMENTED FOR THE DURATION OF THE MATING-INDUCED LH SURGE IN THE FEMALE FERRET. S.R. Wersinger* and M.J. Baum. Department of Biology, Boston University, Boston, MA 02215.

Mating induces a prolonged (12-14 hr) preovulatory LH surge in the female ferret, most likely by stimulating the secretion of luteinizing hormone-releasing hormone (LHRH) into the pituitary portal vessels. Previous research in the ferret (Lambert et al., Endocrinol 131: 1473, 1992) demonstrated that 1 h after mating there is an increase in the percentage of LHRH neurons colabeled with FOS-like immunoreactivity (FOS-IR), suggesting that these neurons are activated at the time LHRH is being released. Mating also induces FOS-IR in non-LHRH neurons in several forebrain and midbrain sites. We sought to determine whether FOS-IR was augmented in both LHRH and non-LHRH neurons throughout the unusually long preovulatory LH surge. Estrous females received one 5-minute intromission or remained alone in a testing cage for 60 minutes. Animals were perfused 0.5, 1.5, 3.0, 6.0, or 12.0 hours after the end of the intromission. The brains were processed for LHRH and FOS immunoreactivity. The percentage of forebrain LHRH neurons colabeled with FOS-IR and the number of FOS-IR non-LHRH neurons in the medial preoptic area, bed nucleus of the stria terminalis, medial amygdala, ventromedial nucleus of the hypothalamus and midbrain central tegmental field were significantly elevated 1.5 hours after mating in comparison with unpaired controls. FOS-IR was not significantly elevated in either LHRH or non-LHRH neurons at any other timepoint. However, plasma LH was significantly elevated at 12 h. These results suggest that FOS is not essential for the maintenance of the presumed preovulatory increase in LHRH secretion and may not be a suitable marker of prolonged neural activation in response to a physiological stimulus. EFFECTS OF DIRECT INFUSION OF GLUTAMATE AND N-METHYL-D-ASPARTATE (NMDA) ON LHRH RELEASE IN FEMALE PREPUBERTAL AND PUBERTAL RHESUS MONKEYS. F. Marzban* and E. Terasawa. Wisconsin Regional Primate Research Center, University of Wisconsin, Madison, WI 53715.

It has been reported that systemic injection of both glutamate and NMDA stimulate LH and LHRH release in pubertal as well as prepubertal monkeys. In this study we examined the effects of direct infusion of glutamate and NMDA into the stalk-median eminence (S-ME) on LHRH release *in vivo* using a push-pull perfusion method. Glutamate (10⁻⁶, 10⁻⁸ & 10⁻¹⁰ M) or NMDA (10⁻⁶, 10⁻⁸ & 10⁻¹⁰ M) was infused into the S-ME of prepubertal and pubertal monkeys for 10 min at 2 h intervals, while perfusates were continuously collected in 10-min fractions for over 10 h. Vehicle was infused as a control. LHRH in perfusates was measured by RIA. Comparison was made between the values 0-20 min before infusion and the first 20 min of the infusion. **Results:** Both glutamate and NMDA induced a small, but consistent, LHRH release in all age groups. The overall effects of glutamate and NMDA were significant (for both p<0.05). However, there were no significant differences between age groups or between different concentrations. Vehicle infusion did not induce any significant effects on LHRH release. **Conclusion:** The findings support the hypothesis that glutamatergic input stimulates LHRH release in prepubertal and pubertal monkeys. However, the effects of direct infusion of glutamate and NMDA into the S-ME (where LHRH neuroterminals are concentrated) on LHRH release *in vivo* were not as robust as those observed in an experiment with i.v. injection (*Biol. Reprod.* 40 suppl: 83, 1989), indicating that input to the LHRH soma, either directly on LHRH neurons or indirectly via interneurons, rather than input to LHRH neuroterminals, may be more important for the action of glutamate and/or the activation of NMDA receptors resulting LHRH release. 387.12

PRESENCE OF FUNCTIONAL OPIOID BINDING SITES ON THE GT1-1 LHRH SECRETING CELLS. R. Maggi, F. Pimpinelli, M. Motta* and F. Piva. Dept of Endocrinology, University of Milano, 20133 Milano, Italy.

The secretion of the hypothalamic luteinizing hormone-releasing hormone (LHRH) is regulated by several neurotransmitter systems. Among these, endogenous opioids play a major role. However, it is not clear whether opioids exert a direct effect on LHRH neurons, or whether they interfere with other neuronal systems able to influence LHRH release. The neuronal LHRH-producing cell line GT1 provides a new model to evaluate which signals may directly modify LHRH release. The presence and the possible function of opioid binding sites were studied on a clone of the GT1 cells (GT1-1). A specific and saturable binding of labeled opioid antagonist diprenorphine (DIP) was detected both on crude membrane preparations and on intact GT1-1 cells. DIP apparently binds to a single high affinity site (K_d 0.2 nM), showing a B_{max} of 125 fmol/mg protein (approximately 20,000 sites/cell). Displacement of DIP binding to GT1-1 cells with the selective opioid agonists DAGO, DPDPE and U50488, which bind respectively to mu, delta and kappa opioid receptors, showed that only the delta ligand DPDPE was able to inhibit the binding of DIP (K_i 5.5 nM). As expected, the inhibitory potency of DPDPE was significantly decreased by the presence of sodium ions in the binding buffer. DPDPE addition to GT1-1 cells brought about a significant and dose-dependent inhibition of the forskolin-stimulated LHRH release. The effect was blocked by the opioid antagonist naltrrexone. These results show that functional opioid receptors of the delta type are present on GT1-1 cells. These receptors may mediate a direct opioid control of LHRH release. IN VITRO EXPRESSION OF FOS-LIKE IMMUNOREACTIVITY IN IDENTIFIED β-ENDORPHIN AND LHRH NEURONS. M. D. Loose* and M. L. Holcomb. Neuroscience Program, Oberlin College, Oberlin, OH 44074

To complement and extend *in vivo* studies we have developed an *in vitro* paradigm in which brain slices can be acutely exposed to neuromodulators and any effects on the expression of fos-like immunoreactivity (fos-l) can be determined in selected neuronal subtypes via dual label immunocytochemistry. Ovariectomized rats (60-90 days old) were injected with 10 µg estradiol benzoate 24 hrs before anesthesia and then perfused with ice cold, oxygenated Krebs buffer. Coronal brain slices (450 µm) were incubated in 100 ml buffer. Very few nuclear profiles had fos-l if slices were fixed either immediately after preparation or after incubation at 24°C. After 2-3 hrs at 34°C many cells had fos-l and 60 mM K⁺ caused no subsequent increase. However, incubation near 31°C resulted in intermediate fos-l, and 60 mM K⁺ induced additional fos-l profiles. Subsequent experiments were performed at 29-31°C. Cells containing both β-endorphin and fos-l in control media were 8 ± 2.6% of the total β-endorphin profiles (N=10 slices). Preliminary results (N=2 or 3) indicate that 30 mM K⁺ caused a 2- to 5-fold increase in the incidence of double label (DL) cells whereas a phorbol ester (0.1 µM PMA) had little effect (87% of control). Incubation with 100 pM or 10 nM LHRH resulted in an apparent decreased incidence of DL (12% and 78% of control, respectively). In contrast, a majority of LHRH containing neurons (54 ± 6.9%, N=8 slices) expressed fos-l under basal conditions. No treatment tested (30 mM K⁺, PMA, LHRH) has affected the percent of DL profiles in LHRH neurons.

CASTRATION DECREASES mRNA LEVELS ENCODING GLUTAMIC ACID DECARBOXYLASE WITHIN THAT REGION OF THE MEDIAL PREOPTIC AREA WHICH COINCIDES WITH THE SEXUALLY DIMORPHIC NUCLEUS (SDN-MPOA). C.A. Sagrillo* and M. Selmantoff. Center for Studies in Reproduction, Department of Physiology, University of Maryland, School of Medicine, Baltimore, MD 21201-1559.

We have recently reported that castration decreases single cell message levels for glutamic acid decarboxylase (GAD), the rate-limiting enzyme for γ -aminobutyric acid (GABA) biosynthesis, within regions of the brain containing GnRH cell bodies. Closer examination has revealed that the majority of GAD-labelled cells in the MPOA are coextensive with the region previously described by Gorski and colleagues as the SDN-MPOA. The objective of the present study was to determine whether castration affects GAD mRNA expression specifically within this highly steroid-sensitive area of the brain. Brain sections from two or six day orchidectomized or sham-operated male rats were hybridized with an ³⁵S-labelled 48-base oligodeoxynucleotide (cDNA) probe complementary to feline GAD mRNA. Area of grains (μm^2) within the SDN-MPOA showed a reduction at 2 days ($109,255 \pm 13,267$) and a further significant decrease at 6 days ($84,848 \pm 6,220$) postcastration compared to intact controls ($123,928 \pm 10,311$), while there was no change in the total area (μm^2) of the region. The data suggest that GABAergic neurons within the SDN-MPOA are important target sites for testosterone negative feedback in the male rat. GAD-labelled cells also are concentrated in the female SDN-MPOA, while the GABA concentration and turnover rate in microdissected tissue from this region are significantly lower in female compared with male rats. Current studies focus on whether a sex difference exists in the expression of the two isoforms of GAD, GAD₆₅ and GAD₆₇, within this sexually dimorphic nucleus. (Supported by NIH Grant HD21351).

NEUROENDOCRINE REGULATION: GLUCOCORTICOIDS

388.1

Further Inquiry into the Effects of Corticosterone on CRH mRNA and CRH Content in the Paraventricular Nucleus of the Hypothalamus, Central Nucleus of the Amygdala and Lateral Bed Nucleus. Jay Schulkin*, Shinya Makino and Philip Gold, Clinical Neuroendocrinology Branch, NIMH, Bethesda, MD., 20892. In our earlier inquiry, we observed differential effects following chronic treatment with high doses of corticosterone (CORT) on CRH mRNA in the paraventricular nucleus of the hypothalamus (PVN) in contrast with that of the central nucleus of the amygdala (CEA). In the former region CORT reduced CRH mRNA expression, in the latter region it increased it. We have now extended these results by determining the effects of high levels of CORT on CRH cells in the lateral bed nucleus or extended amygdala. Rats were treated with either daily CORT sc injections or given a silastic implant sc to deliver CORT. Rats were sacrificed and their brains removed for analysis using *in situ* hybridization to determine CRH mRNA. We found that CRH mRNA levels in the lateral bed nucleus were elevated in the CORT treated groups when compared to controls. In a separate study we also measured CRH content in rats that were given the silastic capsule of CORT. Four brain regions were micro dissected (e.g. median eminence, PVN, CEA, BNST), and a radioimmunoassay for CRH content was performed on the tissue. The largest effect was the reduction of CRH content in the median eminence, there was no reduction in the PVN. CRH content was increased in the CEA, while there was no change in content in the BNST. Taken together these results suggest that while both CEA and BNST CRH mRNA can be raised when high levels of CORT are delivered, it is only the CEA that shows both elevated CRH mRNA and CRH content to CORT. Perhaps, the local activation of CEA CRH accounts for the behavioural expression of fear associated with central infusions of CRH and systemic CORT.

CORTICOSTERONE SELECTIVELY REGULATES GABA_A RECEPTOR SUBUNIT EXPRESSION IN THE HIPPOCAMPUS. M. Orchinik*, N.G. Weiland and B.S. McEwen, Lab. of Neuroendocrinology, Rockefeller University, New York, NY 10021.

Adrenal corticosteroids (CORT) can modulate a variety of hippocampal functions. One mechanism of CORT action in the hippocampus may be via regulation of GABA_A receptor subunit expression. We examined the effects of short-term adrenalectomy and low-level CORT replacement on the expression of 5 GABA_A receptor subunits. *In situ* hybridization studies demonstrated that $\alpha 1$, $\alpha 2$, $\beta 2$, and $\gamma 2$ subunits were altered by adrenalectomy in the hippocampus of ovariectomized female rats. Two days following adrenalectomy, levels of $\alpha 1$ and $\gamma 2$ mRNA increased in CA3, $\alpha 2$ mRNA increased in the dentate gyrus, while $\beta 2$ mRNA decreased in the dentate gyrus and CA2 relative to sham-operated controls. These effects were reversed by replacement with non-stress levels of CORT (addition of 100 $\mu\text{g}/\text{ml}$ CORT to the drinking water). Adrenalectomy had no effect on $\beta 1$ mRNA levels and no effect on the expression of any subunits examined in CA1 or the cingulate cortex. These data support the conclusion that corticosteroids can modulate hippocampal excitability through the site-specific regulation of the expression of specific GABA_A receptor subunits. CORT-induced changes in subunit expression might modulate GABAergic synaptic inhibition by altering the density or pharmacological properties of GABA_A receptors. 388.2

TRANSCRIPTIONAL CONTROL OF HIPPOCAMPAL GLIAL FIBRILLARY ACIDIC PROTEIN AND GLUTAMINE SYNTHETASE IN VIVO: OPPOSITE RESPONSES TO CORTICOSTERONE. Nicholas J. Laping*, Nancy R. Nichols, Jonathan R. Day, Steven A. Johnson, and Caleb E. Finch, Andrus Gerontology Center, Department of Biological Sciences, University of Southern California, 3715 McClintock Ave., Los Angeles, CA 90089-0191

Transcriptional regulation of two astrocyte genes, glial fibrillary acidic protein (GFAP) and glutamine synthetase (GS) by glucocorticoids was determined by nuclear run-on assay. Single stranded cRNA probes to the sense and antisense strands determined that transcription on the opposite strand of the GFAP and GS genes is undetectable. GFAP transcription in the hippocampus did not change 2 hours after 10 mg CORT injection in intact male rats (2-3 months old), but was reduced by 50% at 6 and 24 hours. In contrast, CORT increased GS transcription at 2 and 6 hours. GFAP, but not GS transcription, was increased seven days after adrenalectomy. Corticosterone (CORT) replacement (200 $\mu\text{g}/\text{ml}$ in the drinking water) suppressed GFAP but did not increase GS transcription in adrenalectomized rats. Therefore, GFAP transcription is sensitive to low physiological levels of CORT whereas GS is not. Three non-overlapping probes for GFAP were used and detected the same degree of CORT-induced inhibition of transcription. This indicates that polymerase pausing is not a factor in CORT regulation of GFAP transcription. Because CORT regulation of GFAP is delayed compared with GS, we propose that additional transcription factors interact with glucocorticoid receptors to regulate GFAP transcription. (Supported by AG-07909 and J.D. and C.T. MacArthur Foundation to CEF and AG-05528 NRSA to NJL).

ALLOPREGNANOLONE: A MEDIATOR OF PROGESTERONE'S SEDATIVE AND ANTIOXYTIC EFFECTS IN HUMAN PREGNANCY? Grace Erb, Robert Morrow, Robert H. Purdy*, and Neil J. MacLusky, Division of Reproductive Science, The Toronto Hospital Research Institute, Toronto, ON, Canada, M3C 3P5.

Numerous studies over the last five years have demonstrated that the naturally occurring 3 α -hydroxy, 5 α -pregnane metabolites of corticosteroids and progestins have pronounced sedative effects on the brain, mediated through benzodiazepine-like interactions of these compounds with the GABA-chloride channel complex. These effects may be involved in physiological modulation of GABAergic brain pathways, as well as in controlling the release of a number of pituitary hormones, but definitive information on circulating and tissue concentrations of progesterone (P) and corticosteroid metabolites under physiological conditions is lacking. To test the hypothesis that allopregnanolone (3 α -OH-5 α -pregnan-20-one, AP), the principal 3 α -hydroxy, 5 α -dihydro metabolite of P, may participate in P effects on the developing central nervous system during pregnancy, we have established high-performance liquid chromatography (HPLC) and radioimmunoassay (RIA) systems to separate and measure P, AP, and other related P metabolites in biological tissue and fluid samples. Samples were extracted into diethyl ether, chromatographed on a Silica HPLC column in methylene chloride containing 0.2% ethanol. The separated P metabolite fractions were then assayed by RIA. Samples of human amniotic fluid and maternal serum were collected during cesarean section from third trimester patients in established labor, as well as from patients at the same stages of pregnancy who were not in labor at the time of surgery. For patients who were in labor and for those who were not, AP levels were approximately 10% of those of P. Levels of AP in amniotic fluid averaged 20-30% of those in the maternal circulation. These results suggest that AP is present in maternal serum and amniotic fluid at sufficiently high concentrations to potentiate GABAergic transmission, and that AP biosynthesis may contribute significantly to the actions of P on both the maternal and developing fetal central nervous systems during human pregnancy.

SYNAPTIC BURST ACTIVITY IN HYPOTHALAMIC NEURAL NETWORKS. W. Müller* and D. Swandulla. MPI biophys. Chemie, D-37077 Göttingen and Pharmakol. Institut, Universitätsstr. 22, D-91054 Erlangen, FRG.

Burst activity is important for the release of hormones from central neurons. In disinhibited (picrotoxin 20 µM) networks of hypothalamic neurons in culture, neurons exhibit 'rhythmic' burst activity that is blocked by the glutamate receptor antagonist CNQX (6-cyano-7-nitroquinoxaline-2,3-dione). Using Ca²⁺-imaging on Fura-2/AM loaded cultures and patch clamp techniques we found synchronous increases in [Ca²⁺]_i in a large majority of neurons (>85%) that corresponded to bursting activity recorded from a single neuron. In 20 µM CNQX, none of the neurons showed oscillations in [Ca²⁺]_i.

Investigation of the intervals between bursts from single cell recording revealed a random distribution over a range of 400% from the minimum interval. Poincaré maps of burst intervals, i.e. graphs of all burst intervals t_n vs. their preceding burst interval t_{n-1} , revealed that a burst interval is unpredictable from its predecessor. When synaptic coupling was attenuated by low concentrations of CNQX (50 - 500 nM), the mean burst interval was considerably increased without a change in the random character of burst activity. 4-Aminopyridine (4-AP, 1mM), known to increase synaptic efficiency, reduced the mean burst interval. CNQX (200 nM) slowed the spread of activity during a population burst in the network and reduced resting [Ca²⁺]_i. Increasing [K⁺]_o from 5 to 12.5 mM restored [Ca²⁺]_i but not mean burst frequency.

We conclude that burst activity in hypothalamic neural networks is generated primarily by a synaptically coupled network oscillator. Absence of a strong post-burst inhibition may be responsible for the wide distribution of burst intervals. Network oscillators are probably more reliable than single cell oscillators and may be controlled by synaptic modulation, a process that appears to be also important for the release of hormones and transmitters.

cFOS AND cJUN ARE EXPRESSED IN CULTURED HYPOTHALAMIC TRH NEURONS: STIMULATION BY GLUCOCORTICOIDS.

L.-G. Luo and I.M.D. Jackson*. Division of Endocrinology Brown University, Rhode Island Hospital Providence, RI 02903.

There is evidence that glucocorticoids (GC) regulate the hypothalamic-pituitary-thyroid axis. Although GC have been reported to reduce proTRH mRNA levels in the thyrotrophic area of the hypothalamus *in vivo*, it has not previously been feasible to determine the direct effect on hypothalamic TRH neurons *in vitro*. Accordingly, we have studied the effect of GC on proTRH mRNA levels in hypothalamic cultures (Jackson IMD et al, 1994) and the possible involvement of the protooncogenes *cfos* and *cjun* in this process. A non-isotopic double label *in situ* hybridization histochemistry method (ISH) was chosen to explore the possibility of colocalization of TRH with *cfos* and *cjun* mRNAs. We demonstrated that the mRNA for TRH is coexpressed with both *cjun* and *cfos* in hypothalamic cells. Treatment with dexamethasone (Dex) enhanced the cell signal for both TRH and *cfos/cjun*, and also increased the number of cells coexpressing their mRNAs. Following the use of Image Analysis, Dex 10-8M enhanced mRNA of TRH 133% ($p < 0.01$ $n=20$), *cjun* 121% ($p < 0.01$ $n=20$) and *cfos* 148% ($p < 0.01$ $n=20$). We also applied 32p-labeled RNA Blotting and Image Analysis to measure the steady state levels of *cfos/cjun* and TRH mRNA. The results show that Dex 10-8M enhanced expression of *cfos* 2.1 fold, *cjun* 4.2 fold and proTRH 3 fold ($n = 4$, $p < 0.01$). Nuclear run-on analysis of transcription was performed to measure the effect of Dex. The results showed that Dex 10-8M increased the transcription activity of *cfos* 3.4 fold, *cjun* 5 fold and proTRH 7.7 fold ($n = 3$, $p < 0.01$). Conclusions: 1. Dex enhances the expression of proTRH mRNA as well as *cfos/cjun* mRNAs in hypothalamic neurons *in vitro*. 2. Dexamethasone increases the transcription activity of *cfos/cjun* and proTRH in hypothalamic cells *in vitro*. 3. The existence of *cfos/cjun* in TRH neurons and the increase of their transcription activity by Dex suggests that these protooncogenes may mediate the effect of glucocorticoids on TRH gene transcription.

CORTICOTROPIN-RELEASING FACTOR-LIKE IMMUNOREACTIVITY IN THE BRAIN AND PITUITARY OF CHINOOK SALMON. G.T. Hofeldt, S.P. Matz, and T.T. Takahashi*. Institute of Neuroscience, University of Oregon, Eugene, OR 97403.

In mammals corticotropin-releasing factor (CRF) regulates the pituitary release of adrenocorticotropin hormone (ACTH). In teleosts CRF is also thought to stimulate the release of ACTH, but in addition, may control thyrotropin-releasing hormone release from the pituitary (Moons et al., Gen. Comp. Endocrinol. 73:270-283, 1989). This is of particular interest since thyroxine has been implicated in the imprinting of salmon to their homestream odor.

We localized CRF-like immunoreactivity in the brain and pituitary of hatchery reared juvenile, 12 to 15 months, chinook salmon (*Oncorhynchus tshawytscha*). Fish were perfused with Bouin's fixative (10% Sublimite), brains frozen and sectioned at 30 microns, and then incubated with polyclonal CRF antisera for 48 h. Incubation for less than 48 h resulted in little or no staining. Preincubation of the antibody with CRF eliminated all observed staining.

Results show CRF-positive cell bodies in the parvocellular and magnocellular nuclei of the preoptic area (POA) and in the ventral zone of periventricular hypothalamus. These hypothalamic cell bodies also extend laterally into a region that may correspond to the nucleus lateralis hypothalamus. CRF-positive fibers, presumably from the cell bodies in the POA, reside along the rostral edge of the hypothalamus, in the pituitary stalk, and in the pituitary gland. CRF-positive fibers in the pituitary were clearly distinguished only in the neurohypophysis. However, intense CRF-immunoreactive material was also present in the rostral pars distalis and pars intermedia. These findings suggest that CRF might exert control on endocrine cells of the pituitary by neuroendocrine and/or neurovascular interactions. The distribution of CRF-like immunoreactivity is consistent with the role of CRF as a pituitary releasing factor.

NEURAL-IMMUNE INTERACTIONS: STRESS AND OTHER BEHAVIORAL MODELS

389.1

PRENATAL STRESS ALTERS IMMUNE FUNCTION OF JUVENILE AND ADULT RATS. S.L. Klein* and D.R. Rager.

Dept. of Psychology, Univ. of Georgia, Athens, GA 30602. We investigated the effects of prenatal stress on cellular and humoral immune responses in juvenile and adult male and female Long-Evans rats. Pregnant rats were either exposed to restraint under bright lights for 45 minutes three times daily ($n = 7$) or were left undisturbed ($n = 8$) during days 14-21 of gestation. The offspring of these rats were tested for cellular immune responses as measured by Concanavalin A-stimulated proliferation and Natural Killer (NK) cytotoxicity of splenocytes as juveniles (30 days of age) or adults (90 days of age), or were tested for specific humoral immune responses as measured by antibody levels in serum following *in vivo* challenge with the antigen Keyhole Limpet Hemocyanin (KLH) as adults (65 days of age). Results indicated that: (1) proliferative responses did not vary as a function of sex or prenatal treatment condition in either juvenile or adult offspring; (2) in juveniles, NK cytotoxicity was marginally lower in males as compared to females, and was also marginally reduced by prenatal stress in males but not females, whereas in adults, NK cytotoxicity was marginally enhanced by prenatal stress in both sexes; and (3) prenatally stressed offspring of both sexes had higher levels of anti-KLH IgM and IgG as compared to control offspring. In summary, prenatal stress administered during the third trimester of pregnancy altered immune function, and these effects varied as a function of the sex and age of the offspring. This study provides the first experimental evidence that prenatal stress can influence nonspecific cellular and specific humoral immune responses, and provides further support for the existence of neuroendocrine-immune interactions.

CHANGES IN NK CELL FUNCTION IN FEMALE MONKEYS IN RESPONSE TO ACUTE STRESS. C.J. Rogers*, W.H. Chambers, C.S. Brissette-Storkus and J.L. Cameron. Depts. of Cell Biology & Physiology, Pathology, Pittsburgh Cancer Institute, Psychiatry, and Neuroscience. University of Pittsburgh, Pittsburgh, PA 15261.

Previous studies have shown acute stress-induced changes in both function and distribution of lymphocytes in peripheral blood in rats and humans, however the physiological mechanism underlying these stress-induced phenomena remain unclear. To begin to examine the effects of acute and chronic stress on lymphocyte function, in female cynomolgus monkeys, we measured both the number and the cytolytic activity of a specific subpopulation of lymphocytes, NK cells, at 0, 1, 2 and 3 hours after exposure to an acute stress paradigm involving the presentation of leather catch gloves (used in the colony to catch unanesthetized monkeys) twelve times at random intervals for 1 hour. Blood samples were collected before and 1, 2, and 3 hours after the stress via femoral venipuncture ($n=4$). The number of NK cells was measured using flow cytometry and the cytolytic function of NK cells assessed using a 4 hour chromium release assay against K562. NK cell activity was significantly decreased at 2 hours (37%) and 3 hours (49%) after the stress. To assess the effect of blood sampling alone as a stressor, the experiment was performed with and without glove presentation ($n=14$), and NK cell activity was quantified at two time points, 0 and 3 hours. Both blood sampling alone and glove presentation caused a significant reduction in NK cell cytolytic activity (39% and 48%, respectively) at 3 hours compared to time 0, with no significant difference between the two stress paradigms. There was no change in the percent of circulating lymphocytes identified as NK cells at any time point after stress exposure. These data indicate that the stressor resulted in reduced NK cell function on a per cell basis. We have thus chosen to use the acute stress of blood sampling as a probe to monitor changes in NK cytolytic activity in studies examining the effects of chronic stress (i.e. exercise training or chronic social stress) in adult and juvenile monkeys.

THE EFFECT OF COLD-WATER-STRESS ON MACROPHAGE FUNCTION AND SUBSTANCE P(SP) BINDING. C. CHANCELLOR-FREELAND*, G.F. Zhu, R. KAGE, D.J. BELLER, AND P.H. BLACK. Dept. of Microbiology, Boston Univ. Sch. of Med., Boston, MA 02118.

The macrophage, a critical component of the immune response, is profoundly affected by stress. We have previously reported stress-induced interleukin 1 (IL-1), prostaglandin (PGE₂), and Ia antigen alterations (Jiang, et al., 1990). We now report findings for increased interleukin 6 (IL-6) and tumor necrosis factor (TNF α) following exposure to stress ($p < 0.05$, $p < 0.01$, respectively). In addition, preliminary data show increased specific binding (B_{max}) and/or increased binding affinity (Ki) for substance P (SP) to the peritoneal macrophages from stressed mice. The stress paradigm for all work involved subjecting male C57BJ/6J mice to 5-minute swim tests in 10°C (+/-2°C) water twice daily for 4 days. Cytokine concentrations were determined by ELISA, and SP binding was assessed with fluorescein- and ¹²⁵I-labeled SP. Specificity and affinity were determined by competitive displacement with unlabeled SP. Results from this work, together with recent findings for stress-induced increases in immunoreactive SP in the peritoneal wash fluid, suggest that perhaps SP interacts with cell-surface receptors to mediate the various functional alterations in macrophages following stress.

Peripheral Benzodiazepine receptor involvement in stress-induced suppression of *in vivo* antibody response. C. Cobb¹, M. Fleschner¹, B. Shaw¹, M. L. Laudenslager², L. R. Watkins¹, S. F. Maier¹, C. D. Anderson^{3*}, R.C. Drugan³. Dept Psych, UCO-Boulder, UCO HSC², Brown Univ, Providence, RI, 02912³.

Exposure to inescapable tail shock (IS) results in decreases in anti-KLH Igs. The mechanism(s) responsible for this change are not well understood. The following studies examined the possible involvement of a putative endogenous anxiogenic benzodiazepine ligand in modulating IS-induced suppression of anti-KLH Igs. Naturally occurring compounds (e.g. diazepam binding inhibitor, DBI) have been shown to increase during stressor exposure, bind to both the central-type (CBR), & the peripheral-type (PBR) benzodiazepine binding sites, & modulate the immune system. We examined the effect of CBR & PBR blockade during IS on the IS-induced reductions in anti-KLH Igs. Rats (12/grp) were immunized with KLH (200ug IP) & injected with either RO15-1788 (RO 10 mg/kg; CBR antagonist) or PK11 195 (PK 8 mg/kg; PBR antagonist) & exposed to 100 1.6 mA inescapable tail shocks (IS) or returned to their home cages (HC). Anti-KLH IgG levels were measured using ELISA. RO did not block the IS-induced decrease in anti-KLH Igs, whereas PK did. Since prior work demonstrated that glucocorticoid (GC) type II receptor antagonist administration could also block the IS-induced reduction in anti-KLH Igs, & PK is involved in steroidogenesis, we tested whether the effect of PK was due to PK's potential alteration of IS-induced GCs. Rats were injected with PK or vehicle & exposed to IS. Blood samples were taken after 50 & 100 shocks, & 90 min & 24 hrs after IS. PK had no effect on the IS-induced changes in serum GCs. Thus, PK blockade of IS-induced decreases in anti-KLH Igs suggest an involvement of the γ BD/DBI system which is GC independent. NIH-MH45045

II. Mechanisms of Stress-induced immunomodulation: A role for the macrophage. J. L. Hermann*, M. Fleschner, K. H. Ray, L. L. Lockwood, L. Silbert, M. L. Laudenslager¹, L. R. Watkins, S. F. Maier. Dept. Psych, CU, Boulder, CO 80309, Univ. Colorado Health Sci. Cntr., Denver, CO¹.

Inescapable tail shock (IS) suppresses Ig response to KLH. Evidence suggests that alterations in early processing events such as antigen transport & processing by macrophages (M ϕ s) may be involved. Stressors can alter M ϕ function & can make M ϕ s suppressive. The following studies examined the role of M ϕ s in stress-induced decreases in anti-KLH Igs. First, stress-induced changes in M ϕ numbers were investigated immediately after IS + KLH in the peritoneal cavity, the mesenteric lymph nodes (MS), cervical lymph nodes (CN), & the spleen (SPL). Cells were labeled with ED1 (M ϕ specific), anti-TCR, & anti-CD4 antibodies and were counted using two-color flow cytometry. IS decreased ED1+ peritoneal cell number & ED1+ splenic cell number immediately after IS + KLH. In contrast, the number of ED1+ cells in both MS & CN increased following IS + KLH. If the increase in MS ED1+ cells reflects an increase in a suppressive M ϕ population, then inhibition of these cells should result in a potentiated immune response when the antigen processing involves MS. Rats (12/grp) were injected intraperitoneally (IP) with either gadolinium chloride (GdCl₃; 7.5 mg/kg, a phagocyte inhibitor), or saline. Twenty-four or 72 hrs after GdCl₃, rats were immunized with KLH (200ug) either IP, which involves the draining nodes (MS), or intravenously (IV), which bypasses the draining nodes. The Ig response to KLH, measured using ELISA, was found to be enhanced in IP immunized rats both 24 hrs & 72 hrs after GdCl₃. In contrast, GdCl₃ had no effect in IV immunized rats 24 hrs after GdCl₃ & slightly suppressed the Ig response in these rats 72 hrs after GdCl₃. It appears, therefore, that M ϕ s can have a suppressive effect on Ig production in response to IP KLH & that IS induced decreases in anti-KLH Ig production may be due to increased suppressive M ϕ s in the MS. The importance of IS-induced decreases in peritoneal and SPL M ϕ s is currently being investigated. NIH-MH45045.

CONDITIONED STRESS-INDUCED ALTERATIONS IN IMMUNE FUNCTION IN LACTATING RATS. N. Shanks*, M.A. Pezzone, G.E. Hoffmann, B.S. Rabin. Depts. of Clinical Immunopathology & Neurobiology[†], University of Pittsburgh Med. Center, Pittsburgh, PA

Stress-induced CNS and endocrine alterations are attenuated in lactating females. We determined whether lactating rats were similarly resistant to stress-induced alterations in immune function. Sprague Dawley female rats were exposed to either 2 sessions of 16 footshocks (1.6 mA, 5 sec) where shock was paired with a tone (C+), or were left undisturbed in their homecages (HC). Half of the rats were bred and on day 10 of lactation half the C+ rats were re-exposed to 16 tones, but shock was withheld (C+C-), while the other half were left undisturbed (C+HC). Diestrous rats received identical stress treatments as did lactating rats (L) and served as nonlactating controls (NL). HCNLS, HCLs and C+HCNLS and C+HCLs exhibited similar resting levels of plasma corticosterone (6.8-8.3 μ g/dl). Steroid levels were elevated in both C+C- groups immediately following re-exposure, but C+C-Ls exhibited lower levels of steroid (34.8 μ g/dl) than C+C-NLs (50.1 μ g/dl). Splenocyte aTCR stimulated proliferation was suppressed in C+C-NLs, but remained at nonstress levels in C+C-Ls. Whole blood mitogen responses (PHA, ConA) were suppressed following conditioned stress, but LPS stimulated proliferation was enhanced in both C+C-NLs and C+C-Ls. Mesenteric lymph node (MLN) lymphocyte proliferation stimulated by anti-T cell receptor antibody (aTCR) or ConA was enhanced in C+C-Ls, while this effect was less noticeable in C+C-NLs. These data suggest that lactating rats are resistant to stress-induced suppression of splenocyte proliferation, are as sensitive to alterations of blood lymphocyte immune function as are NL controls, and exhibit greater stress-related enhancement of MLN proliferation.

I. Mechanisms of stress-induced immunomodulation: T cells M. Fleschner*, J. Hermann, M. L. Laudenslager¹, L. R. Watkins, S. F. Maier. Dept. of Psychology, Univ. of Colorado, Boulder, CO 80309, Univ. Colorado Health Sci. Cntr., Denver, CO¹.

Stressors can result in changes in immune function. Exposure to inescapable tail shock (IS) results in long-term decreases in anti-KLH Igs. The mechanisms responsible for this change are not understood, but evidence suggests an involvement of altered T cell subpopulations. The following studies extended these earlier observations. Rats were immunized with KLH (200ug IP) and exposed to IS (n ~ 6) or returned in their home cages (n ~ 6). Lymphocytes from the mesenteric lymph node (MS), cervical lymph node (CN), and spleen (SPL) were removed 0, 48, 72, 96, or 168 hrs after IS termination. The percent of TCR+CD4+, TCR+CD8+, CD45RC+ CD4+ (Th1-like) and CD45RC-CD4+ (Th2-like) lymphocytes were assessed at each time point for each tissue using two color flow cytometry. The number of KLH specific splenic B cells were also measured 7 days (168 hrs) after KLH+IS using ELISPOT. IS results in a complex pattern of changes. The greatest shifts occurred immediately after IS + KLH and 96 hrs (4 days) after IS + KLH. IS resulted in an increase in CD4+ T cells and Th1-like cells per gram of wet tissue immediately after IS termination, but only in MS. Four days after IS + KLH, there was a decrease in Th1-like MS cells and an increase in Th2-like MS cells. Seven days after IS + KLH there was a reduction in the number of KLH specific splenic B cells. These changes in T cell phenotypes could be involved in causing the IS-produced reduction in the formation of KLH specific B cells and alterations in immunoglobulin levels and isotypes (IgG1 & IgG2a). NIH-MH45045

389.8

III. Mechanisms of stress-induced immunomodulation: RU 486 but not Naltrexone blocks the stress-induced decrease in anti-KLH Igs. L. R. Watkins*, M. Fleschner, F. X. Brennan, G. R. Dzung, L. L. Lockwood, M. L. Laudenslager¹, S. F. Maier. Dept. of Psychology, Univ. of Colorado, Boulder, CO 80309, Univ. Colorado Health Sci. Cntr., Denver, CO¹.

Stressors can result in changes in immune function. Exposure to inescapable tail shock (IS; 100 1.6 mA) results in decreases in anti-KLH Igs. The hormonal mechanisms responsible are not understood. Both glucocorticoids (GCs) as well as endogenous opioids are potential candidates, as both are released during stress & are capable of altering immune function. Thus, the effect of RU 486 (RU; a glucocorticoid type II receptor antagonist) & Naltrexone (NAL; an opiate receptor antagonist) on the shock-induced reduction in anti-KLH Igs was examined. Rats (12/grp) were injected with NAL (5 mg/kg or 10 mg/kg), RU (5 mg/kg or 10 mg/kg), or the appropriate drug vehicle, then immunized with KLH (200ug IP) & exposed to either IS or returned to their home cage (HC). Anti-KLH IgM & IgG levels were measured using ELISA. Exposure to IS resulted in a reduction in anti-KLH IgM & anti-KLH IgG. The high dose of RU blocked the IS-induced reduction in anti-KLH Igs, whereas the low dose was without an effect. In contrast, the high dose of NAL did not block the effect of IS on anti-KLH Igs & suppressed the Ig response in HCs. The low dose of NAL also did not block the IS-induced reduction in anti-KLH Igs & had no effect in HC controls. These data suggest a potential role for GCs but not endogenous opioids as hormonal mediators of the IS-induced reduction in anti-KLH Igs. NIH-MH45045.

389.9

IV. Mechanisms of stress-induced immunomodulation: High levels of steroids at the time of immunization are not necessary for IS-induced immunosuppression. T. L. Mayr*, M. Fleschner, M. L. Laudenslager¹, L. R. Watkins, S. F. Maier, Dept. of Psychology, Univ. of Colorado, Boulder, CO 80309, Univ. Colorado Health Sci. Ctr., Denver, CO1.

Exposure to inescapable tail shock (IS; 100 1.6 mA) results in decreases in anti-KLH Igs. The mechanism(s) responsible for this change are not well understood. Previous work demonstrated that administration of the glucocorticoid (GC) type II receptor antagonist RU 486 before IS & KLH blocked the IS-induced reduction in anti-KLH IgM & anti-KLH IgG (see companion abst. III). These data suggested that GC released during IS could mediate the effects of IS on anti-KLH Igs. The timecourse of the changes in serum GCs during & after IS are well understood. GCs increase to ~40-50 ug/dl & return to basal levels 90-120 min after IS. The following studies examined whether rats must be immunized with KLH in the presence of high GCs for a reduction in anti-KLH Igs to occur. Rats (12/grp) were immunized with KLH immediately prior to, immediately after, or 3 hrs after exposure to IS. Anti-KLH IgM, IgG, IgG1, & IgG2a levels were measured using ELISA. Data to date reveal that IS resulted in a reliable reduction in anti-KLH IgM & IgG levels at all times of immunization. Importantly, rats immunized 3 hrs after IS termination had normal GC levels. IgG1 & IgG2a are not yet available. Subcutaneous injection of 100ug/kg of dexamethasone 2 hours prior to KLH also had no effect on anti-KLH Ig levels. Thus, high levels of GCs at the time of KLH are not necessary to produce IS-induced decreases in anti-KLH Igs. Dose response experiments involving short interval timing of KLH immunization & IS exposure as well as corticosterone & dexamethasone dose response studies are currently in progress. NIH-MH45045

MONOAMINERGIC, NEUROENDOCRINE AND IMMUNE RESPONSES TO STRESS: THE INFLUENCE OF LATERALIZATION. C. Delrue, B. Deleplanque, K.-S. Li, S. Vitello, J.-I. Bouvier* and P. J. Neveu.

Stress responses including modifications of immune reactivity, neuro-endocrine functions, and brain functioning were hypothesized to depend on lateralization. To answer this question, we studied the stress responses in mice selected as left- and right-handers in a paw preference test.

First, restraint stress, known to affect immune reactivity, induced modifications in the mesolimbic dopaminergic (DA) system which are asymmetrically expressed and are related to behavioral lateralization. Indeed, the asymmetry of DA metabolism in the nucleus accumbens observed in controls and correlated to paw preference scores, disappeared after stress. Conversely, an asymmetry in DA metabolism in the frontal cortex, correlated to paw preference, appeared in stressed animals.

Second, the injection of lipopolysaccharide (LPS) is usually followed by a decrease in T-lymphocyte proliferation, an increase in ACTH and corticosterone plasma levels and an augmentation in brain monoaminergic metabolism and thus may be considered as a stress inducer. The modifications of brain monoaminergic metabolism were asymmetrically expressed and depend upon behavioral lateralization. Plasma corticosterone was enhanced in both left- and right-handers, but plasma ACTH was increased only in right-handed animals. T-lymphocyte proliferation was depressed only in right-handers.

These results show that an immune challenge, which may be considered as a stressor, induces modifications in the activity of the central nervous system, the HPA axis and the immune system, that depend on brain and behavioral lateralization. Therefore, the bidirectional pathways between the brain and the immune system appear to be subjected to lateralization.

ADVERSE EFFECTS OF CHRONIC NICOTINE ON IMMUNE ORGAN ATROPHY IN AN ANIMAL MODEL OF ANOREXIA NERVOSA. A. Chiou, D.M. Amos, H.A. Funk, T.S. Rieg*, & P.F. Aravich. Virginia Governor's School for Science & Technology, Hampton, VA 23666; Eastern Virginia Medical School, Norfolk, VA 23501; Veterans Affairs Medical Center, Hampton, VA 23667.

Anorexia nervosa (AN) is an eating disorder associated with excessive activity, weight loss and immunosuppression. Nicotine increases activity, decreases body weight and affects immune function. This investigation determined if nicotine increases activity, promotes weight loss and worsens the thymus and spleen atrophy associated with a popular animal model of AN. The model was produced by giving moderately food-deprived rats (1.5 h/day food access) free access to running wheels (22.5 h/day). Three groups of rats (9-10 rats/group) were injected with either 0, 0.4 or 0.8 mg/kg/day of nicotine bitartrate (free base; s.c.) for 11 days prior to and throughout the syndrome. Contrary to predictions, nicotine did not affect wheel running, food intake and rate of weight loss in the model. However, nicotine worsened the thymus atrophy associated with the syndrome. This effect, which was specific to the thymus and did not occur with the spleen, was related to an exacerbation of the relative adrenal hypertrophy that occurs in the syndrome. It is proposed that nicotine stimulates glucocorticoid secretion, which adversely affects the immature T lymphocytes of the thymus but spares the mature lymphocytes of the spleen. These data raise the possibility that, while nicotine may not affect weight loss in AN, it may adversely affect immune function, which is already compromised in the disorder.

389.10

FAILURE TO DETECT A DIRECT RELATIONSHIP BETWEEN STRESS-INDUCED CHANGES IN LYMPHOPROLIFERATION AND CIRCULATING CATECHOLAMINE CONCENTRATIONS. L. Pottle, S. Poucieu, C.A. Meseke, D.W. Horohov, S. Barker, M. Littlefield-Chabaud, J. Bu, S.G. Kamberling, P.A. Melrose*. School of Veterinary Medicine, Baton Rouge, LA 70803.

The present study was performed in order to determine whether stress-induced catecholamine release may be correlated with the inhibition of influenza virus (specific) and/or pokeweed mitogen (non-specific)-induced lymphoproliferation. Unconditioned Thoroughbred horses were subjected to sham, psychological or various intensities of exercise stress. Jugular blood samples were collected at 4 different time points, before and during each stress test. Triplicate cultures of 2×10^5 peripheral blood mononuclear cells were incubated at 39°C with control media, high or low dose of influenza virus or pokeweed mitogen. Proliferation was measured based on radioactive thymidine incorporated on days 5 and 7. Plasma samples obtained at the aforementioned 4 time points were also assayed for catecholamines using high performance liquid chromatography. Non-specific lymphoproliferation was significantly decreased during slow speed exercise stress. Specific lymphoproliferation declined ($P < .05$) in all but the sham stress test and it was increased ($P < .05$) at the end of psychological stress. Circulating concentrations of norepinephrine and epinephrine were increased ($P < .05$) by all stress tests. Thus, stress-induced changes in lymphoproliferation were not related to increased catecholamine concentrations that resulted from psychological and physical stressors.

389.12

ALTERATIONS IN T-CELL AND MACROPHAGE FUNCTION INDUCED BY A METABOLIC STRESS, 2-DEOXY-D-GLUCOSE (2-DG): EFFECTS AND MECHANISMS. SH Chou, LD Kojic, & JE Cunnick*. Microbiology, Immunology & Preventive Medicine, Iowa State University, Ames, IA 50011; USA.

Administration of 2-deoxy-D-glucose (2-DG, 500 mg/kg) was used to characterize the effect of metabolic stress and its mediating mechanisms on immune function. Male Lewis rats were exposed to one or five injections (one every 48 h) of 2-DG. Control rats received saline injections. In blood and spleen, T-cell function was evaluated by mitogen proliferation and production of interleukin-2 (IL-2) and interferon- γ (IFN- γ), while macrophage function was evaluated by production of nitric oxide as measured by nitrite. 2-DG induced a suppression of mitogenic responsiveness and IFN- γ production in both whole blood and spleen lymphocytes. Additionally, IL-2 production was reduced in the blood, but not the spleen. Conversely, there was a significant increase in nitrite production in cultures of Con A and PHA stimulated splenocytes from 2-DG injected animals in comparison to saline injected controls. In blood cultures stimulated with Con A and PHA, the nitrite production of the group which received five injections of 2-DG was significantly higher than the group which received one injection of 2-DG or saline.

Administration of nadolol, a β -adrenergic receptor antagonist attenuated the 2-DG induced suppression of splenic T-cell responsiveness to mitogen and IFN- γ production, as well as attenuated the increased of nitrite production in splenic cell cultures. However, nadolol did not attenuate the 2-DG induced changes of immune parameters in blood cultures. These results demonstrate that the metabolic stressor 2-DG can alter cellular immune function via neuroendocrine pathways common to physical and psychological stressors. Additionally, the use of 2-DG in rats provides an important model to study metabolic stress.

IMMUNOSUPPRESSIVE TREATMENT RESTORES EXPLORATORY BEHAVIOR IN AUTOIMMUNE MRL-lpr MICE. Boris Šakić*, Henry Szechtman and Judah A. Denburg. Depts. of Biomedical Sciences and Medicine, McMaster Univ., Hamilton, Canada L8N 3Z5.

Various behavioral deficits of unknown etiology accompany systemic autoimmune diseases in humans. Autoimmune MRL-lpr mice show a variety of behavioral deficits in comparison to undiseased age-matched MRL +/+ mice, suggesting an animal model of behavioral dysfunction in autoimmune disorder. We have recently observed impaired exploration of a novel object in the MRL-lpr group. Moreover, this behavioral deficit significantly correlated with high serum autoantibody titers (a reliable symptom of autoimmunity). In the present study we test the relationship between exploratory behavior and autoimmunity by treating young MRL-lpr and MRL +/+ mice for 6 weeks with immunosuppressive drug, cyclophosphamide (100 mg/kg/week, i.p.). It was expected that such a treatment would prevent development of autoimmune symptoms and restore normal exploratory behavior in MRL-lpr mice. Indeed, chronic immunosuppressive treatment almost completely abolished the onset of autoimmune disease and increased the duration of novel object exploration in the MRL-lpr group. Thus, in MRL-lpr mice there may be a causal relationship between autoimmune factor(s) and impaired exploration of novel objects. (BS is a OMHF Postdoctorate Fellow; supported by funds from NSERC)

INTERLEUKIN-1 INHIBITS SEXUAL BEHAVIOR OF FEMALE BUT NOT MALE RATS. R. Yirmiya*, R. Avitsur, O. Donchin, and E. Cohen. Department of Psychology, The Hebrew University of Jerusalem, Mount Scopus, Jerusalem 91905, Israel.

In response to infection and injury, a variety of cells release the cytokine interleukin-1 (IL-1), which produces immunological, neuroendocrine and behavioral effects. The present study examined the hypothesis that the previously reported suppressive effects of IL-1 on reproductive hormones and goal-directed behaviors is also associated with inhibition of sexual behavior. The effects of IL-1 on sexual motivation and sexual receptivity in female rats were examined using the partner preference (PP) paradigm and the test of lordosis quotient. The effects of peripheral (i.p.) administration of IL-1 β were examined during the estrus phase of intact cycling females. Administration of IL-1, at a dose of either 2 or 10 μ g/kg, significantly decreased proceptive (soliciting) and receptive behaviors. The suppression of sexual behavior by IL-1 was further demonstrated in ovariectomized rats, following hormonal induction of estrus: IL-1 β (2 μ g/kg) injected 2 hr before testing significantly decreased PP scores as well as proceptive and receptive behaviors. Intracerebroventricular administration of IL-1 β (10 ng/rat) suppressed PP scores and proceptive behavior in intact cycling females. The effects of IL-1 β on male sexual motivation and performance were assessed using the PP paradigm and by counting the number of mounts, intromissions and ejaculations during a 15 min testing period. IL-1 β had no effect on any component of male sexual behavior. The inhibition of female sexual behavior by IL-1 may be an adaptive mechanism, which prevents conception during an infection and therefore reduces the risk of prenatal infection. INTERFERON-ALPHA DETECTED BY *IN SITU* RT-PCR IN THE BRAINS OF AUTOIMMUNE MICE. L.S. Crnic* AND L.M. Schrott. Depts. of Pediatr. and Psychiat. and the MRRC, Univ. Colo. Sch. of Med., Denver, CO 80262

Interferons are known to be neuroactive and are up-regulated in lupus-like autoimmune diseases such as that seen in NZB x NZW F1 (B/W) hybrid mice. This study focused on the role of interferon-alpha (IFN- α) in the behavioral abnormalities seen in these mice by examining brains of female B/W mice for IFN- α mRNA. Using reverse transcription followed by polymerase chain reaction amplification (RT-PCR), IFN- α was detected in brains both before and after the onset of severe immunologic abnormalities (12 and 24 weeks). *In situ* RT-PCR was used to localize specific brain regions producing IFN- α . Following fixation and paraffin embedding, brains of 12 week old mice were sectioned in the sagittal plane. Sections were treated with trypsin to permeabilize membranes and DNAase to destroy genomic DNA. mRNA was converted to cDNA in an RT reaction and IFN- α cDNA was amplified by PCR. A digoxigenin-labelled nucleotide was incorporated into the amplified product and detected immunocytochemically. Negative and positive controls were run with each sample. Positive signal for IFN- α mRNA was found middle layers of the cerebral cortex, extending along most of the anterior-posterior axis. Signal was seen in membranes surrounding the brain and in occasional cells throughout the CNS. Dysmorphology of the cerebellum was also apparent. To determine the specificity of this pattern of signal, brains of mice injected with the IFN inducer Poly I:C were examined. These mice displayed IFN- α mRNA signal in neurons throughout the brain. Thus, it appears that the *in situ* RT-PCR technique is sensitive and specific. The production of IFN- α mRNA in the CNS may explain some of the behavioral alterations in autoimmune mice. CLASSICAL CONDITIONING OF BRAIN C-FOS EXPRESSION AND IMMUNE CELL ACTIVITY. L. Wetmore*, W. Wan, J.G. Gartner and D.M. Nance. Depts. Physiol. and Path., Univ. Manitoba, Wpg, MB, R3E 0W3.

Stress is a complex phenomenon involving a highly coordinated activation of the endocrine, immune and central nervous systems. We have reported the central pattern of c-fos expression induced by intermittent footshock and the activation of the limbic system suggests that the psychological dimension of footshock may be an important component contributing to stressor effects. We have assessed the ability of conditioned fear to induce c-fos expression in the brain and to alter immune activity in male S/D rats. Rats were given three sessions of intermittent footshock (UCS) with a tone as the conditioning stimulus (CS). One week later, animals were either re-exposed to the CS (+CS) and immediately sacrificed or were sacrificed from the home cage (-CS). We found that footshock induced c-fos expression can be classically conditioned and that the +CS animals were immunoenhanced, relative to the -CS group. The CS induced c-fos protein expression occurred in the same brain regions observed following the UCS, whereas the -CS group showed minimal brain c-fos expression. Conditioned immune effects were also found in that the +CS group had significantly enhanced splenic NK cell activity, relative to -CS animals. Spleen and blood cell lymphoproliferative responses to mitogen were also elevated in the +CS, relative to the -CS group, thus conditioned fear can induce c-fos expression in a distinct central circuit as well as produce an immunoenhancement. Presently, we are investigating the relationship between the strength of the conditioned response and the immune alterations in order to better characterize the significance of the concomitant effects of conditioned fear on central c-fos expression and immune cell activity. Supported by MRC of Canada.

EMOTIONALITY AND LEARNING IN AUTOIMMUNE MICE L.M. Schrott* and L.S. Crnic. Depts. of Psychiatry and Pediatrics and the MRRC, Univ. of Colorado School of Medicine, Denver, CO 80262

Mice with lupus-like autoimmune disorders such as NZB x NZW F1 (B/W) hybrids display specific learning deficits in shock motivated active avoidance learning. Although this deficit is not due to altered sensitivity to shock, it may be due to alterations in responsiveness to emotional stimuli such as shock. To investigate this possibility, female B/W mice were tested in an elevated plus maze, a sensitive measure of anxiety, and a simple shock-motivated black-white discrimination task. B/W mice readily learn a swim version of this task. Mice were given 10 trials a day for 6 days. In comparison to female mice from the paternal progenitor strain NZW, female B/W mice displayed an anxiety profile in the plus maze. They had fewer percent entries and spent less percent time in the open arms of the maze. In the shock discrimination learning task, B/W females were faster and had a greater number of correct responses than NZWs. Both strains of mice initially used a positional strategy and showed a high degree of response lateralization. On days 4-6 both strains stopped using a positional strategy, and the B/W mice switched to the correct strategy of associating color with escape. In the swim version of the task, B/W mice learned more quickly and did not show the initial positional strategy. These findings, in combination with the plus maze data, suggest that shock motivation does not impede learning, but that alterations in responses to aversive stimuli (such as open arms in a plus maze or footshock) may influence performance. Neuroactive cytokines that are up-regulated in the autoimmune disease may be involved in mediating these responses. Supported by MH 490423, MH10643 and HD0424.

INTERLEUKIN-2 AND UNCONTROLLABLE STRESSORS INTERACT TO ALTER NEUROENDOCRINE AND IMMUNE ACTIVITY. S. Zalcman, J.M. Green-Johnson*, A.M. Brown, D.M. Nance and A.H. Greenberg. Manitoba Institute of Cell Biology and Univ. of Manitoba, Winnipeg, Mb. R3E 0V9.

Interleukin (IL)-2 potentiates a variety of immune responses and influences central nervous system activity. We reported that IL-2 induced alterations of central monoamine activity that were similar to those provoked by uncontrollable stressors and that IL-2-induced immunological effects were mediated by non-lymphoid mechanisms. In the present study, we determined whether IL-2 would interact with a stressor to alter neuroendocrine and immune activity. BALB/c mice received either Ringer's Solution or IL-2 (200 ng, ip) and were immediately exposed to a novel environment for 0, 30 or 60 minutes. Seven fold elevations of plasma corticosterone concentrations were evident in IL-2-treated mice exposed to the stressor for 30 or 60 minutes compared with mice sacrificed immediately after IL-2 injection. These elevations were significantly greater than those observed in vehicle-treated animals exposed to the stressor for comparable periods. Corticosterone levels did not differ among vehicle- and IL-2-treated mice that were returned to their home cages for 0, 30 or 60 minutes following injection. IL-2 also potentiated corticosterone elevations following exposure to restraint stress. Mice received vehicle or IL-2 and were either not stressed or were immediately restrained for 30 minutes. Corticosterone levels were determined 0, 30 or 60 minutes after stressor termination. In vehicle-treated mice, levels were significantly increased immediately following restraint but returned to control levels within 30 minutes of stressor termination. In IL-2-treated mice, corticosterone levels were markedly elevated 0 and 30 minutes after stressor termination and returned to non-stress levels within 60 minutes of stressor termination. Additionally, the enhancing effects of IL-2 on an antigen-specific IgM PFC response were not evident in mice exposed to a mild stressor immediately after IL-2 administration. This treatment also resulted in a suppression of splenic T cell proliferation and IL-2 production that was similar in magnitude and duration to that evident in mice exposed to restraint stress. It is suggested that neuroendocrine and immune consequences of a lymphokine (i.e., IL-2) are influenced by the stressor background on which it is superimposed. Supported by NIMH, MRC of Canada.

TO THE MECHANISMS OF PRENATAL EPIGENETIC TRANSFER OF MATERNAL "ANTI-BRAIN" AUTOIMMUNITY. N.K. Vabishchevich, A.B. Poletaev*. Chernobyl-Test Ctr., Moscow, Russia.

Transfer of the specific autoimmune reactions from a mother, but not from a father to a child (described earlier) is probably connected with the genesis of some forms of inborn defects of the nervous system. It is necessary to know the mechanisms that allow the maternal immune system to play a "matrix" role in regard to the immune peculiarities of a child. It can be supposed that the modulation of the AG-specific immune status of a child is dependent on: (1) the transplacental transfer the own maternal AB; (2) the prenatal "mirror" activation of the certain clones of child lymphocytes (LC) by the maternal AB; (3) the "transplantation" of the immunocompetent LC, e.a. the maternal LC (including memory cells) transfer and their long (for years) persistence in a child. In experiments on rats and rabbits (passively or actively immunized by the S100 proteins during pregnancy) it was shown that the hypothesis (1) is groundless. In opposite real evidences for hypotheses (2) and (3) were retrieved. Thus, the transfer phenomenon is probably based on the combination of the AB-dependent modulation of the child LC repertoires and a direct transfer of the maternal AG-specific LC with their subsequent persistence in a child.

INCREASED SUSCEPTIBILITY TO BREAST CANCER METASTASIS DURING PROESTRUS/ESTRUS PHASES IN F344 RATS: IMPLICATIONS FOR PROGNOSIS FOLLOWING THE REMOVAL OF A BREAST CANCER. S. Ben-Eliyahu*, G.G. Page, J.C. Liebeskind & A.N. Taylor. Dept. of Psychology, Tel-Aviv University, Tel Aviv 69978, Israel.

Several studies report that women undergoing surgery for breast cancer during the first half of their menstrual cycle show a 3-fold increase in mortality rate over a ten-year period. We present evidence in rats in support of the hypothesis that this phenomenon is attributable to metastatic development that is induced by the surgical procedure itself and is facilitated by elevated estradiol/low progesterone levels at the time of surgery. Suppression of innate immunity is suggested to underlie this increased susceptibility to metastasis, rather than a direct effect of sex hormones on the tumor. Syngeneic mammary tumor cells (MADB106) were injected intravenously to inbred F344 rats during different phases of the estrous cycle. The metastatic efficiency of this tumor, which is confirmed here to be highly controlled by natural killer (NK) cell activity, was higher during estrous phases that are hormonally homologous to the high-risk periods in women. Estrogen treatment alone caused similar effects in ovariectomized rats and progesterone partly blocked these estradiol effects, whereas neither hormone affected the proliferation rate of the tumor *in vitro*. The tumoricidal activity per blood NK cell was diminished during the high-risk estrous phases. These findings introduce an animal model for further studying the clinical phenomenon and suggest hormonal and immunological mechanisms mediating it. Supported by NIH-HD07228, NIH/NS 07628, VA Medical Research Service, the UCLA Psychoneuroimmunology Task Force, and a research grant from Tel-Aviv University.

SEXUALLY DIMORPHIC EFFECT OF PRENATAL DHEA TREATMENT ON T-CELL FUNCTION. S. G. Shelat, I. Halasz and E. Redei* Dept. of Pharmacology, University of Pennsylvania, Philadelphia, PA 19104.

We have hypothesized that sexual differentiation of the immune function occurs prenatally and is driven by similar events as seen in the sexual differentiation of the brain. Therefore, pregnant dams were treated with different doses of dehydroepiandrosterone (DHEA), a weak androgen, in the drinking water from day 8 of gestation until parturition when DHEA treatment was discontinued. Body weights of young, prepubertal (day 35 of age) male and female pups from the DHEA groups were significantly lower than those of controls, and showed a dose response effect even at this age (control males 133.6±2.62 g; DHEA males (250 ng/ml) 87.4±5.45 g; DHEA males (25 ng/ml) 98±3.2 g; DHEA males (2.5 ng/ml) 114±3.75 g; control females 118.2±1.66; DHEA female (25 ng/ml) 82±2.26 g; DHEA female (2.5 ng/ml) 103.6±3.68 g). In contrast, both absolute thymic weights and thymic weights normalized to body weight were significantly higher in the offspring of the lowest DHEA treated dams (2.5 ng/ml) compared to those of controls (control males and females: 3.74±0.23 and 3.59±0.2 mg/g BW; DHEA males and females 4.8±0.26 and 4.46±0.17 mg/g, respectively). Splenic lymphocyte proliferative response to Concanavalin A (Con A, 2.5 µg/ml) used spleens of individual animals representing different litters. There was no significant sex difference in the proliferative response to Con A in the control animals, although control males showed a tendency toward a higher response. Prenatal treatment with DHEA (2.5 ng/ml) significantly reduced proliferation in the male offspring (controls: 210,684±35,339 cpm; DHEA: 90,897±8,594 cpm) while DHEA females were not affected significantly and showed an increased rather than a diminished response (controls: 150,682±28,818 cpm; DHEA: 220,886±21,145 cpm). This data suggest that prenatal DHEA treatment permanently alters thymic development and T-cell dependent functions, particularly in the male offspring.

PERMISSIVE ROLE OF GLUCOCORTICOIDS ON INTERLEUKIN-1 ACTIVATION OF THE SEROTONERGIC SYSTEM. L. Gemma, A. De Luigi, M.T. Tacconi* and M. G. De Simoni. Istituto di Ricerche Farmacologiche Mario Negri, Via Eritrea 62, 20157, Milan - Italy.

Glucocorticoids (GCs) are widely used in therapy for their antiinflammatory and immunosuppressive properties but their use in cytokine-mediated pathologies needs a thorough understanding of their role in modulating cytokine actions. The present study was designed to clarify the effect of GCs on the action of IL-1 β on the serotonergic system. Changes in the serotonin metabolite 5-hydroxyindolacetic acid (SHIAA) were recorded in freely moving rats by *in vivo* voltammetry using chronically implanted carbon fiber electrodes in the medial preoptic area. IL-1 β (10 ng icv) induced a dual increase in SHIAA levels: a rapid-short, term rise was followed by a lasting increase possibly due to newly synthesized IL-1. The synthetic GC dexamethasone (DEX, 3 mg/kg ip, 30 min before IL-1 β), prevented the effect of IL-1 β starting from 150 min, suggesting that it only inhibited the second increase. In adrenalectomized rats IL-1 β had no effect but when these rats were given DEX (40 µg/kg a day for 3 days) the short-term increase was restored. The GC receptor antagonist RU38486 (25 mg/kg sc, 60 min before IL-1 β) completely prevented IL-1 β activation of the serotonergic system. The results indicate that although GC are effective inhibitors of IL-1 synthesis, their presence is necessary for IL-1 β -induced activation of the serotonergic system. Thus GC may allow a number of serotonin-mediated actions triggered by IL-1 in the course of inflammation.

STRESS-INDUCED CHANGES IN LEUKOCYTE DISTRIBUTION -- HORMONE DEPENDENCY. F. S. Dhabhar*, A. H. Miller, B. S. McEwen, R. L. Spencer. Lab. of Neuroendocrinology, The Rockefeller University, New York, NY 10021.

We have previously demonstrated significant and selective changes in numbers and percentages of peripheral blood leukocyte (PBL) subpopulations in the rat. These changes were rapidly induced by mild acute stress (2 h restraint), and consisted of a decrease in numbers and percentages of lymphocytes, and an increase in numbers and percentages of neutrophils. B cells, NK cells, and monocytes showed a greater stress-induced decrease than T cells. Helper T cell number showed the lowest magnitude of decrease with stress. These stress-induced changes were rapidly reversed upon the cessation of stress.

In the present series of studies we demonstrate that adrenalectomy significantly reduced the magnitude of the stress-induced changes. Furthermore, administration of cyanoketone, a corticosterone synthesis inhibitor, eliminated the stress-induced changes in PBL. However, catecholamine receptor antagonists (phenolamine (alpha antagonist) and propranolol (beta antagonist)), failed to inhibit the stress-induced changes in PBL. Acute administration of corticosterone to adrenalectomized animals resulted in a close replication of the stress-induced changes observed in adrenal intact animals. Furthermore, acute administration of glucocorticoid receptor agonists showed that the Type II receptor agonist (RU28362) replicated all the stress-induced changes in PBL (except the decrease in NK cell percentage). The Type I receptor agonist (aldosterone) had no effect. These results suggest that corticosterone is a major mediator of the stress-induced changes in leukocyte distribution. TYPE II GLUCOCORTICOID RECEPTOR (GR) GENE EXPRESSION PARTICIPATES IN THE DEVELOPMENT OF NEUROENDOCRINE-IMMUNOLOGICAL SEXUAL DIMORPHISM: EFFECT OF ABNORMAL GR FUNCTION IN TRANSGENIC ANIMALS BEARING TYPE II GR ANTISENSE RNA. B. Marchetti*, M.C. Morale and N. Barden. Dept. of Pharmacology, University of Catania, Italy, and Molecular Psychogenetics, CHUL, Québec, Canada.

Clinical and experimental evidence indicates that gonadal steroids can modulate immunological functions and that a sexual dimorphism exists in the immune response to different noxa. The molecular mechanism(s), however, involved in sexually-dimorphic immune responses are not completely understood. We have recently (Endocrine Journal 2: 181, 1993) demonstrated that type II GR gene expression within the thymus is markedly modulated by physiological alterations of the sex steroid hormone milieu. The aim of the present study was to determine the role of type II GR gene expression in the development of neuroendocrine-immunological sexual dimorphism using a transgenic animal model created by partially knocking out gene expression with type II GR antisense RNA. In intact mice, a sexual dimorphism in the post-natal development of type II GR gene expression paralleled the development of sexually dimorphic immune responses, initiating 9 days after birth, reaching a peak of activity at 25 days of age, and declining around puberty. The development of a sex-dependent apoptotic potential after thymocyte treatment *in vitro* with corticosterone followed a similar pattern. In transgenic animals, the abolishment of a sexual dimorphism of type II GR gene expression was accompanied by a lack of sexually dimorphic immune responses and marked inhibition of the specific suicide program within the thymus, suggesting a key role for type II GR gene expression in the molecular mechanisms underlying the development of sexual dimorphism of immune responses.

CORTICOTROPIN RELEASING FACTOR (CRF) SECRETION FROM THE HYPOTHALAMUS AND THYMUS GLAND IN THE RAT. C.P. Phelps, L.T. Chen, R.A. Menzies*, J. Oliver, E. Horvath, L. Poole. Dept. of Anatomy, U. South Florida, Tampa, FL 33612

The hypothalamus (HYP) and thymus gland (THY) both contain bio- and immunoreactive CRF and CRF mRNA (Redei, 1992; 1993). Hypothalamic secretion of CRF is a well-known final common pathway for direct and indirect immunomodulation, but the role of CRF in THY function is not well understood. We have compared the *in vitro* release of CRF during a 5 hr perfusion of preoptic area-mediobasal (POA-MBH) HYP and the THY. Individual POA-MBH and THY were removed from male SD rats (350-400g) and placed in parallel perfusion chambers containing Earle's balanced salt solution (pH 7.4) at 37°C. The POA-MBH was halved longitudinally and each lobe of the THY was quartered. After a 60 min preincubation period, fractions were (300 µl/10 min) collected over 2 hr for basal release of CRF assayed by RIA (IgG Corp., Nashville) and after 56 mM KCl added to the medium during the third hr. At the end of the incubation each POA-MBH and THY was weighed and assayed for total CRF. As expected there was an approximate 10 fold higher concentration (per g wet wt) of CRF in the POA-MBH when compared to THY. However, an estimation of total secretion using a numerical integration of the release curve (trapezoidal approximation) revealed that total THY secretion of CRF was approximately 75% that of the POA-MBH. Experimental lesions of the HYP which resulted in THY involution and subsequent increased response to mitogen stimulus did not result in significant changes in CRF secretion by the thymus. Supported by NIH MH46808.

LOCALIZATION OF CRF IN THE PRIMARY AND SECONDARY LYMPHOID ORGANS OF THE RAT. S.M. Brouxhon, A.V. Prasad, S.A. Joseph, D.L. Bellinger, and D.L. Felten*. Dept. of Neurobiol. & Anat., Univ. of Rochester, NY 14642.

Numerous studies have reported the production of a variety of neuropeptides or peptide hormones in cells of the immune system, either constitutively or upon induction. Further, some cells of the immune system possess neuropeptide or hormone receptors that display ligand-receptor interactions similar to those described in the CNS. These findings suggest the capacity of some lymphoid cells to produce and respond to peptides heretofore thought to be principally neural.

Recently, the presence of CRF mRNA was detected in the rat thymus and spleen. We have performed a series of experiments to localize the CRF peptide and its mRNA in the rat spleen, thymus, and mesenteric lymph nodes employing immunocytochemistry (ICC) and *in situ* hybridization (ISH) techniques. Immunoreactive CRF was present in cells of the marginal zone and red pulp cord of the spleen, connective tissue septa and corticomedullary junction of the thymus, and the medullary cords and sinuses of the mesenteric lymph nodes. Dual ICC/ISH for CRF demonstrated CRF mRNA over CRF-immunoreactive cells suggesting CRF synthesis, not just uptake. Double-label ICC for CRF and markers for specific populations of immunocytes suggest that CRF positive cells in the spleen and the thymus are macrophages. CRF positive cells in primary and secondary lymphoid organs reside in compartments that are innervated by noradrenergic (NA) sympathetic nerves, raising the possibility that they may signal each other. The presence and production of CRF in cells in lymphoid organs suggest that CRF may play a direct or indirect role (eg induction of the POMC gene) in the immune system as part of a paracrine network that is interactive with neural fibers in these organs. SUPPRESSION OF MACROPHAGE FUNCTION BY ADRENO-CORTICOTROPIC HORMONE. M. Ichinose*, M. Sawada and T. Maeno. Dept. of Physiology, Shimane Med. Univ. Izumo 693, Japan.

Macrophages play important functional roles in the host defense against neoplasia and microbial infection. Macrophages ingest and kill microorganisms, process antigens and present them to T cells. Phagocytosis is the most representative functions of the cells. Thus, phagocytosis of latex beads by peritoneal macrophages was examined by means of flow cytometry. This assay revealed that adrenocorticotrophic hormone (ACTH) suppressed phagocytosis in a dose-dependent manner. ACTH(1-24) was more suppressive than ACTH(1-39). Control phagocytosis was partially suppressed in Ca^{2+} -free solution. Phagocytosis was suppressed by ACTH in Ca^{2+} -free solution to the same degree as in the normal solution. ACTH-induced suppression was reduced in the presence of IBMX, a phosphodiesterase inhibitor. These results suggest that ACTH suppresses extracellular Ca^{2+} -dependent and -independent phagocytosis, that the suppression is not mediated by cAMP and that the inhibition of macrophage phagocytosis by ACTH is one of mechanisms which modulate immune responses in stressful situations.

390.11

SHIFT IN CD4 AND CD8 T CELLS IN ATHYMIC MICE GRAFTED WITH THYMUS OR THYMUS & PITUITARY. G.O. Gaudio, T. Martin, R. Lin, and M.C. Diamond*. Group in Endocrinology and Department of Integrative Biology, University of California, Berkeley, CA 94720.

Research on the developmental sequence of T cell maturation has been concentrated on paracrine interactions; few investigations have focussed on the role of the endocrine system in its regulation. Cell-to-cell communication is crucial, but the internal milieu created by classical endocrine hormones during the development of the organism may also influence T cell differentiation and maturation. To investigate the role of the pituitary on T cell development, a comparison was made of CD4⁺ and CD8⁺ T cells derived from the inguinal lymph nodes of 60-day-old female mice from immune-competent strains, BALB/c/BALB/c and nude/BALB/c, and from an immune-deficient strain, nude/nude, grafted at 30 days of age with a thymus or with the combination of a thymus + pituitary underneath the kidney capsule. Fluorescence-activated cell sorter (FACS) analysis using dual color direct immunofluorescence with fluorescein isothiocyanate (FITC)-labeled anti-CD3 combined with phycoerythrin (PE)-labeled anti-CD4 (L3/T4) or PE-labeled anti-CD8 (Ly-2) monoclonal antibodies revealed a CD3⁺4⁺ to CD3⁺8⁺ T cell ratio of 3.1 ± 0.2 for both immune-competent strains; whereas, the groups reconstituted with a thymus and thymus + pituitary showed significantly ($P < 0.05$) higher ratios of 5.7 ± 0.9 and 9.1 ± 1.4 , respectively. No significant levels of CD3⁺4⁺ or CD3⁺8⁺ T cells were observed in the non-operated, sham-operated, and pituitary-grafted nude/nude mice; therefore, T cell ratios were not calculated. Addition of the pituitary to the thymus resulted in the highest CD4/CD8 T cell ratio ($P < 0.05$). The role of the pituitary seems to direct T cell development toward the CD4⁺ T cell lineage. IMMUNE AND ENDOCRINE IMPLICATIONS OF LONG-TERM INTRACEREBROVENTRICULAR CORTICOTROPIN-RELEASING HORMONE ADMINISTRATION IN THE RAT. J.M.H.M. Reul*, M.S. Labeur, G.J. Wiegers, E. Arzt and F. Holsboer. Max Planck Institute of Psychiatry, Clinical Institute, Department of Neuroendocrinology, Munich, FRG.

The brain, endocrine and immune system communicate as an integrative network, which is critical for maintaining homeostasis during disease and other stressful situations. To investigate the (patho)physiological consequences of chronic hypothalamic-pituitary-adrenocortical (HPA) axis hyperactivity, rats were intracerebroventricularly (icv) treated for 1 week with CRH via an osmotic minipump and HPA axis and immune system function were studied. As compared to the vehicle, CRH produced elevated a.m. plasma ACTH and corticosterone levels, increased anterior pituitary POMC mRNA expression, thymus involution and adrenal enlargement. Regarding immune function, CRH treatment had markedly differential effects on splenocyte proliferation and cytokine expression. Long-term CRH-treated rats displayed highly suppressed *in vitro* splenic T-cell and B-cell proliferative responses. Surprisingly, *in vitro* interleukin-2 (IL-2) production by stimulated T-cells of these rats was increased. Moreover, basal and *in vitro* LPS-stimulated IL-1 β mRNA expression in splenic macrophages of peptide-treated rats was elevated as well. Thus, chronically elevated HPA axis drive results in disparate changes in the immune system. Whether the observed changes in cytokine expression should be regarded as physiologically adaptive adjustments supporting immune function or as potentially pathological anomalies remains to be elucidated. (VW I/68 430)

390.10

MODULATION OF PHAGOCYTOSIS BY SENSORY NEUROPEPTIDE. M. Sawada*, M. Ichinose and T. Maeno. Dept. Physiology, Shimane Med. Univ. Izumo 693, Japan.

Interactions between immunocompetent cells and neuropeptides such as substance P, somatostatin and vasoactive intestinal peptide (VIP) show modulation of local immunologic responses by the peripheral nervous system. In the present study, effect of VIP on phagocytosis in peritoneal macrophages was examined by means of flow cytometry. Present experiments clarified that VIP suppressed phagocytosis at a threshold concentration of 10^{-8} M and maximum concentration of 10^{-5} M examined. Control phagocytosis was partially suppressed in Ca^{2+} -free EGTA-containing solution. Phagocytosis in Ca^{2+} -free solution was reduced further in the presence of VIP. Phagocytosis was suppressed in the solution containing IBMX, a known phosphodiesterase inhibitor. Suppressed phagocytosis by VIP was the same degree irrespective of IBMX. These results suggest that VIP suppresses extracellular Ca^{2+} -dependent and -independent phagocytosis, that the suppression is mediated by cAMP and that the inhibition of macrophage phagocytosis by VIP is one of mechanisms which modulate immune responses by the nervous system.

ALPHA-MSH ACTIVATES THE SPLENIC NERVE AND IS DEPLETED FROM THE ARCULATE NUCLEUS FOLLOWING IL-1 β INJECTIONS. C.A. Friend*, L. Janz, A. Jansen, L. Murray, A.H. Greenberg and D.M. Nance. Depts. of Psych. and Path. and Manitoba Inst. of Cell Biology University of Manitoba, Winnipeg, MB., R3E 0W3, Canada

The neuroimmune system utilizes messenger molecules such as cytokines and neuropeptides. Alpha-melanocyte-stimulating-hormone (α -MSH), is considered to be an endogenous antagonist of the central effects of interleukin-1 β (IL-1 β), a cytokine which mediates the acute phase response. Recent evidence indicates that the anti-inflammatory effects of central α -MSH are mediated by descending neural pathways which involve peripheral β adrenergic receptors. To study the direct effects of α -MSH on the neural regulation of the spleen, we examined splenic nerve activity following ICV injections of α -MSH in the rat. α -MSH (5-20 ng) significantly increased splenic nerve activity (32-115%). Previously, we showed that ICV injections of IL-1 β increased norepinephrine (NE) turnover in the spleen. To examine further the functional role of α -MSH, we tested the effects of ICV α -MSH on splenic NE turnover following synthesis inhibition. ICV α -MSH (2.5 ng) significantly increased splenic NE turnover. To investigate the relationship between IL-1 β and α -MSH in the brain, we tested the effects of ICV (5 ng) and IP (100 ng) injection of IL-1 β on the immunocytochemical staining for α -MSH neurons in the arcuate nucleus. Two hrs post injection rats were perfused and brains processed for the presence of α -MSH. In the rats which received IL-1 β IP, the number of α -MSH positive cells in the arcuate were reduced, relative to saline animals, and virtually eliminated in the animals receiving IL-1 β ICV. These results suggest that IL-1 β releases α -MSH from arcuate neurons and collectively, these data provide evidence that endogenous α -MSH may play an integral role in the sympathetically mediated downregulation of the immune response observed after IL-1 β injection. Supported by MRC and NIMH.

391.1

EFFECT OF BACTERIAL ENDOTOXIN ON HIPPOCAMPAL AND PREOPTIC NEUROTRANSMISSION, BODY TEMPERATURE, BEHAVIORAL ACTIVITY AND FREE CORTICOSTERONE LEVELS. A.C.E. Linthorst*, C. Flachskamm, F. Holsboer and J.M.H.M. Reul. Max Planck Institute of Psychiatry, Clinical Institute, Department of Neuroendocrinology, Munich, FRG.

Evidence has accumulated for a bidirectional communication between the central nervous system and the immune system. However, on the level of the brain the neural circuitry involved in the processing of signals from the immune system largely remains to be resolved. We started a study on the effects of i.p. lipopolysaccharide (LPS, bacterial endotoxin) administration on hippocampal and preoptic serotonergic and noradrenergic neurotransmission using *in vivo* microdialysis in freely moving rats. In addition, we monitored hypothalamic-pituitary-adrenocortical (HPA) axis activity by measurement of free corticosterone levels in the dialysates. Behavioral activity was scored by measuring the time during which rats were active and body temperature was assessed via biotelemetry. I.p. LPS treatment produced a dose-dependent increase in the extracellular concentrations of serotonin in the hippocampus but not in the preoptic region. In addition, the endotoxin caused a dramatic increase in preoptic levels of noradrenaline, elevations in body temperature and HPA activity, and a decrease in behavioral activity. We conclude that signals from the immune system exert differential effects on brain neurotransmission. These distinct changes in neurotransmission may be involved in the regulation of specific neuroendocrine, autonomic and behavioral responses after an immune challenge. (VW grant I/68 430)

391.3

THE EXPRESSION AND SECRETION OF INTERLEUKIN-6 FOLLOWING CENTRAL ENDOTOXIN IS DIFFERENTLY REGULATED IN THE CENTRAL NERVOUS SYSTEM AND IN THE PERIPHERY. M. G. De Simoni*, R. Dal Bo, A. De Luigi, S. Symard and G. Forloni. Istituto di Ricerche Farmacologiche Mario Negri, Via Eritrea, 62, 20157, Milano - ITALIA.

Centrally administered IL-1 results in a large increase in serum IL-6 indicating the brain's role in the acute phase response. The mechanisms of this induction and the signal conveying the information from the brain to the periphery are not known yet. To help characterize the pathway of centrally-mediated IL-6 induction, IL-6 levels, measured as hybridoma growth factor on 7TD1 cell line, were evaluated in rat serum and cerebrospinal fluid (CSF) at different times after intracerebroventricular endotoxin (LPS, 2.5 µg/rat). In the same experiments, IL-6 mRNA expression, measured by Northern blot analysis, was evaluated in periphery (in adrenals and lymphonodes) and in the brain (in hypothalamus, hippocampus and striatum). In serum, the highest IL-6 levels were reached at $t = 2$ h after which they rapidly decreased. The same time-course was shown by IL-6 mRNA in adrenals and lymphonodes. A different pattern was present in the central nervous system: in the CSF, IL-6 was detectable starting from $t = 2$ h, reached a plateau at $t = 4-8$ h and remained detectable until $t = 16$ h. IL-6 mRNA expression in the brain areas showed a similar time-course, reaching a maximum at $t = 4-8$ h. The results indicate that IL-6 synthesis is differently regulated in the brain and in the periphery.

391.5

PROHORMONE CONVERTASES PC2 AND PC3 IN RAT NEUTROPHILS AND MACROPHAGES. PARALLEL CHANGES WITH PROENKEPHALIN-DERIVED PEPTIDES INDUCED BY LPS *in vivo*. Q. Vindrola*, A. M.S. Mayer, G. Citera, J.A. Spitzer and L.R. Espinoza. Dept. of Biochem. and Mol. Biol., Dept. of Physiology* and Dept. of Med./Rheumatology*. LSU Medical Center, New Orleans, LA 70112.

Prohormone- or proneuropeptide-converting enzymes PC2 and PC3 have been observed exclusively in nervous and endocrine tissues. In this work the presence of these enzymes in cells of the immune system was demonstrated. PC2 was detected in peripheral and liver-infiltrated polymorphonuclear leukocytes (PMN) but not in alveolar macrophages (AM) or spleen mononuclear cells (SMC). PC2 proteins corresponded to 75, 71 and 56 kDa forms. PC3 appeared in AM and SMC but not in PMN, and a 66 kDa protein was the only PC3 form detected. Proenkephalin-derived peptides (PENKp) were observed in PMN and AM, showing peptides of 35, 28, 21, 18 and 14 kDa in the former cells and a doublet of 35 and 32 kDa in the latter. PC2 proteins and PENKp decreased in liver PMN and peripheral PMN 90 min after intravenous (i.v.) infusion of LPS, suggesting an increased release. However, *in vitro* assays showed that the chemotactic peptide FMLP but not LPS increased the basal secretion of PC2 proteins and PENKp in PMN. These results indicate that PC2 proteins are released from PMN, together with PENKp, and suggest that LPS *in vivo* may act through an indirect mechanism. Low levels of PC3 and PENK were detected in the AM of rats treated for 90 min with SAL or LPS. However, a significant increase of PC3 and PENKp appeared 30 h after LPS infusion. These results show for the first time that PC2 and PC3 are differentially expressed in PMN and AM, respectively, which were paralleled by the presence of different post-translational products of PENK. In addition, the *in vivo* effect of LPS on PC2, PC3 and PENKp levels in PMN and AM resembles the effect of LPS on prohormone levels in endocrine tissues, suggesting that similar mechanisms may control the turnover of PC2 in neuroendocrine and in these immune cells.

NEUROCHEMICAL SPECIFICITY OF ENDOTOXIN-INDUCED C-FOS-EXPRESSING NEURONS IN THE HYPOTHALAMUS.

A.T.K. Jackson*, A.H. Greenberg and D.M. Nance. Depts. of Pathology and Physiology and Manitoba Institute of Cell Biology, University of Manitoba, Winnipeg, MB, Canada R3E 0W3

It has been shown that injection of lipopolysaccharide (LPS), a powerful bacterial endotoxin, results in a dose- and time-dependent expression of the proto-oncogene c-fos in the brain (Wan et al, B.R.B. 32:581,1993). We have extended these studies and report here on the transmitter specificity of hypothalamic neurons that are activated following LPS injection. LPS (100 µg) was administered i.v. to male S-D rats. Two hrs later the rats were perfused and the brains processed for c-fos immunocytochemistry (rabbit anti-fos, Santa Cruz). Immunocytochemical and histochemical methods showed that many of the c-fos positive neurons were also positive for oxytocin, vasopressin or NADPH-diaphorase (NADPH-d). Double-labelled cells were predominately located in the paraventricular and supraoptic nuclei of the hypothalamus and analysis showed that NADPH-d > OXY = AVP in numbers of c-fos co-localized cells. Raw cell counts showed that LPS decreased NADPH-d staining, increased OXY, and had no effect on AVP. The LPS-induced changes in NADPH-d suggests a functional role for nitric oxide (NO). Consistent with this finding, preliminary results indicate that inhibition of NO synthase by i.c.v. infusion of L-NAME potentiates the induction of c-fos protein by LPS. Supported by MRC and NIMH.

QUINOLINIC ACID IMMUNOREACTIVE CELLS IN THE RAT BRAIN AFTER INTRACEREBRAL INJECTION OF LIPOPOLYSACCHARIDE. M.G. Espey, J.R. Moffett and M.A. Namboodin*. Georgetown University, Biology Department, Washington, DC 20057-1028.

Quinolinic acid (QUIN) is a neurotoxic tryptophan metabolite. Antibodies to quinolinic acid were used to study its cellular localization in the brain 1 to 30 days after intra-hippocampal injection of lipopolysaccharide (LPS). Quinolinic acid immunoreactive (QUIN-IR) cells were observed in hippocampus, corpus callosum, neocortex, meninges and choroid plexus 24 hr after LPS application. The immunoreactive cells were larger than lymphocytes, ranged from round to rod-shaped to complex in morphology, and were often observed around the vasculature. The overall number of QUIN-IR cells increased at 48 hours, and peaked in number at 72 hr. In saline injected control animals, only rare QUIN-IR cells were observed at 72 hr surrounding the injection site. The number of QUIN-IR cells was reduced in the periphery region by 4 days after LPS injection, but did not return to control levels until 15 to 30 days later. Tissue destruction was observed in the cortex, hippocampus and corpus callosum, and progressed in severity between days one and four. No clear correlation with QUIN-IR was found with the monoclonal antibodies ED1, ED3, F4/80, OX17 or OX41. The tissue damage observed around the injection site correlated more closely with a central mass of infiltrating leukocytes than with the relatively scattered QUIN-IR cells observed in and around the damaged region. These results suggest that QUIN, derived from a select population of leukocytes, may contribute to some of the secondary neuronal death subsequent to CNS infections. We propose that QUIN, rather than being simply a neurotoxic byproduct of tryptophan metabolism, may be a cytokine or immune modulator involved in the initial reactions to pathogens.

A MATHEMATICAL MODEL OF THE NEUROENDOCRINE-IMMUNE (NEI) AXIS. M.W. Denker*, M. Cavanagh, J.-G. Liao, L.T. Chen, R.A. Menzies, J. Oliver, L. Poole, E. Horvath and C.P. Phelps*. Depts. *Psychiatry and Behav. Med., *Elec. Eng., *Epidem. and Biostat. and *Anat., University of South Florida, Tampa, FL 33612.

Prikrylova, Jilek and Waniewski (CRC Press, 1992) described a very comprehensive mathematical model of the immune response to antigen. This model consists of 12 simultaneous first order differential equations and 6 auxiliary equations ("switches"). Eight cell types and 4 molecular messengers are represented. Here we describe an extension of the Prikrylova model which includes a provision for NEI modulation. These equations are derived from our experimental investigation of the adrenal axis response to variable in doses of endotoxin (EN, E. Coli, 10, 50 and 1000 µg per 100g b.w.) administered to male SD rats (350-400g) through jugular catheters. Rats received either saline or EN at the indicated doses and blood was withdrawn at 0, 0.5, 1 and 4 hrs later. Plasma ACTH and corticosterone (B) was assayed by RIA. Relative to 0 hr., increasing doses of EN resulted in parallel increased release of B at all intervals. However, ACTH release after 10µg EN resulted in the greatest (20X) increment from time 0 when compared to other EN treatments. After 1000µg EN there was only a 3X ACTH increase, whereas 50µg resulted in a 10X increase. Inverse changes in ACTH after EN may be explained at the H-P level, whereas the B response may be a direct cytokine effect on the adrenal. Our proposed mathematical model of the NEI axis integrates these and other findings from our experiments to stimulate NEI regulation. Supported by NIH MH46808.

EFFECTS OF VIRAL INFECTION ON ADRENAL STEROID SECRETION AND ADRENAL STEROID RECEPTOR EXPRESSION. A.H. Miller*, C.A. Biron, R.L. Spencer, P. Tanapat, J. Leung, F. Dhabhar, B.S. McEwen. Mt. Sinai Sch. Med. and Rockefeller Univ., NY, NY 10021; Brown Univ., Providence RI, 02912.

It is generally believed that during a viral infection, cytokines stimulate the release of endogenous adrenal steroids which in turn provide feedback inhibition on evolving immune responses. Although ample data demonstrates that cytokines stimulate HPA axis activity, few studies have directly examined adrenal steroid secretion during a viral infection. Accordingly, we examined corticosterone secretion at multiple time points in the am and pm of mice infected with lymphocytic choriomeningitis virus (LCMV). Since our previous studies have indicated that adrenal steroid effects on target tissue function must be established at the receptor level, we also measured cytosolic type II adrenal steroid (glucocorticoid) receptor binding in immune tissues. LCMV-infected mice exhibited modest elevations in corticosterone secretion on Days 3 through 7 post infection. Pm corticosterone values were greater than am values in all cases. Cytosolic type II receptor binding in spleen and thymus of LCMV-infected animals was significantly decreased in the pm compared to non-infected animals, indicating that infection-induced increases in corticosterone in the pm were activating receptors in these tissues. Interestingly, however, significant decreases in cytosolic type II receptors were also observed in the am in the spleen of infected mice. These receptor decreases occurred in the absence of marked elevations in corticosterone and suggest that local factors (eg cytokines) elaborated during the immune response to LCMV may directly influence adrenal steroid receptor expression. Related studies on the interferon inducer, poly I:C, indicate that interferons may mediate these adrenal steroid-immune interactions in LCMV infection by augmenting corticosterone release and decreasing cytosolic receptor expression in the presence or absence of hormone. IMPLICATION OF HYPOTHALAMIC INTERLEUKIN-6 CONCENTRATIONS AND RESPONSIVENESS OF THE HYPOTHALAMIC-PITUITARY-ADRENAL AXIS IN PRIMARY IMMUNIZATION. E. Khan Shaghaghil¹, M. Pallardy², H. Lebre², J.C. Duché³, C. Jacquot^{*1} and A.M. Gardier¹. ¹Dept. Pharmacol., ²Dept. Toxicol., ³Fac. Pharmacie, Chateau-Malabry F-92296, Dept. Pharmacol. CHIC, F-94010 Créteil, France.

Recently we demonstrated that primary immunization with sheep red blood cell (SRBC) decreases hypothalamic and cortical serotonin (5-HT) levels in F344 rats while increasing extracellular 5-HT levels (Gardier et al., *Brain Res.*, 1994). Pretreatment with an immunosuppressive drug, cyclosporine A prevented these effects suggesting that a T-lymphocyte product, but not a macrophage one, may be involved in the central serotonergic activation induced by SRBC. Thus, interleukin-6 (IL-6) might be a good candidate for being a link between the immune system and the CNS. To characterize further this hypothesis, we have now investigated the effects of keyhole limpet hemocyanin (KLH, 200 µg i.p.) on both hypothalamic IL-6 levels and the hypothalamic-pituitary-adrenal axis (HPA) response (plasma ACTH and corticosterone concentrations). The presence of specific antibodies for KLH (IgM) in the serum was also assessed by using an ELISA method at 3, 4 and 5 days following KLH injection. In the hypothalamus, 5-HT level significantly decreased by -26% (p<0.01), 5-HIAA levels increased by +43% (p<0.01) while IL-6 levels increased as compared with controls 4 days following the primary immune response to KLH. In the cortex and hippocampus, no changes were observed in the serotonergic markers studied. Antibodies directed to KLH were present since Day 3 following KLH injection. Plasma ACTH levels in KLH-treated rats were higher than responses in controls at all points, while corticosterone levels peaked at Day 4 post-immunization. These data confirm our previous results showing that long-lasting changes occur specifically in the hypothalamus as well as in the HPA axis when the production of specific antibodies is maximal following primary immunization.

THE CD4 CORECEPTOR MEDIATES EFFICACY OF T CELL ANTIGEN RECEPTOR INTERACTIONS WITH AUTOLOGOUS MYELIN BASIC PROTEIN. M.D. Mannie* and G. White. Department of Microbiology and Immunology, East Carolina University School of Medicine, Greenville NC 27858-4354.

Guinea pig (GP) myelin basic protein (MBP) is approximately 100-fold more active than rat (R) MBP as measured by induction of experimental autoimmune encephalomyelitis (EAE) in Lewis rats. A Ser for Thr substitution at position 80 comprises the distinguishing structural difference between the two 72-86 encephalitogenic regions of GPMBP and RMBP, respectively. To test whether the CD4 co-receptor has a differential role in T cell responses to these two proteins, we measured the inhibitory effects of the anti-CD4 monoclonal antibody W3/25 on in vitro proliferative responses of MBP-specific T cell lines. W3/25 only partially inhibited proliferative responses to GPMBP but fully inhibited the response to RMBP. This differential susceptibility to the inhibitory effects of W3/25 was observed across of broad concentration range of antibody and antigen as well as across a broad range of T cell densities. T cell subclones exhibiting functional uncoupling or downregulation of CD4 exhibited responses to GPMBP but did not respond to RMBP. These results suggest that the response to autologous RMBP, unlike GPMBP, is completely dependent upon CD4. In addition, T cell proliferative responses to GPMBP that were obtained in the presence of W3/25 were fully antagonized in a concentration dependent manner by RMBP. These results indicate that RMBP is a specific antagonist when CD4 is neutralized by an anti-CD4 monoclonal antibody. This work was supported by a grant from the National Multiple Sclerosis Society.

IMMUNE CELLS MEDIATE CHROMAFFIN AND SYMPATHETIC GANGLION CELL CATECHOLAMINE SECRETION. S. Jones, H. Lujan, J. Pinxteren, J. Roberts, J. Walter* and W. DePotter. Loyola Univ. Med. Center and Hines VA hospital, Maywood IL. Univ. Health Sci./The Chicago Med School (Mt. Sinai Hospital) USA and Neuropharmacology, Univ Antwerp, Belgium.

Epinephrine (E) secretion from bovine chromaffin cells in response to mononuclear cell conditioned media (Life Sci, 53:PL447-451) suggests that immune cells may mediate stress hormone secretion. In the present study, porcine chromaffin (C) and ganglion (G) cells were used to test the possibility that porcine and bovine immune cells could stimulate secretion. Blood, spleen, adrenal and superior cervical ganglion were obtained from local slaughter houses. Mononuclear cells isolated from blood or spleen were incubated (37C) overnight in RPMI media without serum; cells were removed and conditioned media (CM) frozen and kept at -20C. Porcine C and G cells were isolated using collagenase and maintained in culture at 37C. Secretion experiments were conducted after 5-7 days for C (cultured in DMEM/F12, 10% FBS) and at 4 days for G (cultured in F12, 5% Horse serum). For secretion experiments, growth media was replaced with CM or control RPMI for 90 min. at 37 C. For C, Epinephrine released into media was measured by HPLC while G secretion involved assessment of preloaded ³HNE. Secretion in response to CM is expressed as % of total cell content.

	Basal	Bovine CM	Porcine CM
C Cells	1.4 ± 3*	16.7 ± 1.8	12.1 ± 1.7
G Cells	29.3 ± 5	55.1 ± 9	41.4 ± 1.0

*Mean ± SEM with at least 3 different cell preparations. Results suggest that immune cell products can mediate secretion from the adrenal medulla and sympathetic ganglia. Thus, peripheral immune cells may be an important effector in the sympathetic-immune axis. (Supported by The Falk Research Trust)

N-(2-HYDROXYETHYL)HEXADECANAMIDE IMPROVES NEUROLOGICAL DEFICITS ACCOMPANYING EXPERIMENTAL ALLERGIC ENCEPHALOMYELITIS IN B10/PL MICE. A. Leon*, R. Canella, and S. Mazzari. Research/ife S.c.p.A., Centro di Ricerca Biomedica, Ospedale Civile, 31033 Castelfranco Veneto, Italy.

Mast cells (MCs) present in the normal CNS have been proposed to regulate interactions between the immune and nervous systems. In addition, it has been suggested that MCs are involved in the pathogenesis of experimental allergic encephalomyelitis (EAE). Recently, the endogenous N-Acylamide, N-(2-hydroxyethyl)hexadecanamide, has been proposed to behave as a local autacoid capable of negatively modulating MC activation. In agreement with this concept, termed autacoid local inflammation antagonism (ALIA) orally given N-(2-hydroxyethyl)hexadecanamide (LG 2110/1) prevents MC-dependent edema formation and substance P-induced MC activation in the mouse ear pinna (Mazzari et al., this meeting). Here we have evaluated the effect of MC modulation by LG 2110/1 in the development/progression of EAE in B10/PL mice after immunization with 1-9 Nac, the NH₂-terminal-acetylated peptide of mouse myelin basic protein (Jiang et al., *Science* 256: 1213, 1992). Oral treatment with LG 2110/1 (10 mg/kg) beginning on the day of immunization delayed the onset (6 day post-immunization) as well as the frequency of animals displaying the neurological syndrome. In addition, when treatment was begun on day 4 post-immunization (P.I.), LG 2110/1 significantly reduced the severity of EAE. The exogenous N-acylamide ameliorated the clinical scores at day 8 P.I. up to day 31 P.I. (χ² test, p < 0.05 versus vehicle, n = 19-20). These findings not only support a physiological role for N-(2-hydroxyethyl)hexadecanamide, but also suggest that this type of molecule may represent a novel therapeutic approach to the management of inflammatory conditions of the nervous system modulated by MCs, including autoimmune CNS diseases.

LOCALIZATION OF TUMOR NECROSIS FACTOR RECEPTOR mRNA IN NORMAL AND HERPES SIMPLEX VIRUS INFECTED TRIGEMINAL GANGLIA IN THE MOUSE. E.T. Cunningham, Jr.*, P.P. Sanna, F.E. Bloom, and T.P. Margolis¹. Francis I. Proctor Foundation and Dept. of Ophthalmology, UCSF, San Francisco, CA, 94143, ¹ and Dept. of Neuropharmacology, Scripps Research Foundation, La Jolla, CA, 92037.²

In situ hybridization of ³⁵S-labeled cRNA probes was used to investigate the distribution of cells expressing mRNA encoding the p60 and p80 subtypes of the tumor necrosis factor receptor (TNF-R) in normal and herpes simplex virus (HSV) infected trigeminal ganglia in the mouse. Riboprobes were derived from previously characterized murine full-length cDNA species provided by Immunex Corporation. Trigeminal ganglia were infected *via* corneal inoculation using a McKrae strain of HSV three days prior to analysis. *In situ* hybridization for both TNF-R subtypes produced a moderately intense autoradiographic signal over subgroups of neurons and neuroglial cells in both normal and HSV infected ganglia. In general, the signal intensity and the number of neurons and neuroglial cells labeled in trigeminal ganglia did not change in response to acute HSV infection. However, infection was accompanied by an intense white blood cell infiltrate, and many of these non-resident cells did display signal for both TNF-R subtypes. Signal over control sections hybridized with sense p60 and p80 TNF-R cRNA was comparable to background. The presence of TNF-R mRNA over neurons and neuroglial cells in normal and HSV infected trigeminal ganglia suggests a role for TNF in normal trigeminal functioning, and supports studies implicating TNF in the pathogenesis of immune-mediated peripheral neuropathies.

ISOLATION OF C1q PROTEIN FROM RAT BRAIN FOLLOWING INJURY. S.K. Goldsmith*, I. Rozovsky and C.E. Finch. Department of Biological Sciences, Ethel Andrus Gerontology Center Univ. South. Calif. Los Angeles, CA 90089.

There is increasing evidence for a role of complement (C) components in neurodegeneration during Alzheimer disease (AD). To date there has been immunohistochemical detection of activated C products in AD brain associated with senile plaques and neurofibrillary deposits (e.g. Eikelenboom et al., 1992). Work in this laboratory demonstrated a 2 to 3-fold increase in C mRNA in AD brain (Johnson et al., 1992; Lampert-Etchells et al., 1993). Animal studies showed an increase in C mRNA after systemic kainic acid (KA) or knife lesions (Pasinetti et al., 1993; Johnson et al., 1992). Although C1q mRNA is increased, translation of protein in brain is not certain. Present studies utilized protein chromatography and Western blots to identify C1q protein increases in brain after injury. Animals were treated in one of two paradigms. 1. Systemic injections of KA, KA + pentobarbital, pentobarbital, or saline. 2. Unilateral neocortical lesions or sham surgery. After 3 or 10 days respectively, blood was collected via cardiac puncture then rats were perfused with saline. Whole brains (excluding cerebellum) were processed for the KA group. Ipsi- and contra-lateral striata were assayed separately from cortically lesioned rats. Tissues were processed by a batch chromatography procedure modified from the methods of Tenner et al., (1981). SDS-PAGE was performed as described by Sambrook et al., (1989). Western blots were run using a goat anti-human antibody against C1q (Sigma C3900) which identified three bands of expected molecular weight (approx. 26 kDa) in both human and rat sera. C1q protein (three bands approx 26 kDa) was increased in the KA rat brains compared to controls in which the protein was not apparent. C1q was also increased in brain ipsilateral to the lesions as compared to the unlesioned side. (Supported by AG 07909 and AG 00093.)

RECRUITMENT OF MAST CELLS INTO THE CNS DURING DEVELOPMENT: IS IT TIME AND TISSUE SPECIFIC X. Zhuang¹*, A.-J. Silverman², and R. Silver^{1,3}. ¹Dept. Psychology, ²Dept. Anat. & Cell Biol., P&S, and ³Barnard College, Columbia Univ., New York, NY.

In isolated adult ring doves mast cells are relatively rare in the CNS but enter the medial habenula (MH) in large numbers at the initiation of courtship (Silver et al., J. Neuroendocrinol., 1992). During normal development mast cells are first observed in the most dorsal aspect of MH on day 21 post-hatch and gradually increase in number, until by 4 months they are distributed throughout MH. At puberty (6-7 months) mast cells reach a maximum and then decline to adult levels. At both 3 and 6.5 months, filamentous processes enclosing extracellular space are characteristic of cells in MH, suggesting migration through the tissue. Throughout this period mast cells are identified by their metachromatic properties, by their staining with alcian blue and GnRH-like immunoreactivity. Ultrastructurally, secretory granules are immature. To begin to understand what quality of MH might contribute to its being populated by this cell type, we implanted embryonic (E15) MH and, as a control, embryonic optic lobe, into the lateral ventricles of 4 months old hosts. Each host received both types of tissues and was sacrificed 2-3 months later. Both the host and transplanted MH had numerous mast cells though densities appeared to vary. The transplanted optic lobe did not contain mast cells. These data suggested that MH can 'attract' mast cells regardless of location or connectivity. Furthermore, access to the CSF is not the determining factor in mast cell recruitment into CNS tissue. Some factor(s) intrinsic to the MH may play a role in attracting, sustaining, or in the maturation of mast cells. Supported by NIMH grant 29380 (to RS).

STAPHYLOCOCCAL ENTEROTOXIN CAUSES ACUTE BLOOD-BRAIN BARRIER (BBB) PERMEABILITY IN THE RAT. W. Lo* and P. Clair, Dept. Pediatrics, Ohio State University, Columbus, OH 43205

Staphylococcal enterotoxins (SE) act as superantigens that can activate then deplete specific T-cell clones. In the rat, SE D and SE E have been reported to inhibit the clinical expression of experimental autoimmune encephalomyelitis, while SE B in the mouse can inhibit or exacerbate EAE depending upon the timing of treatment to the induction of EAE. While the effects of the SEs may be related to T-cell activation, the impact of the SEs upon BBB integrity has never been examined.

We tested the effects of SE B and SE D upon BBB permeability in Sprague-Dawley rats, 24 hours after intraperitoneal SE using 14C-aminobutyric acid autoradiography. Rats were treated with 75 ug of SE B or 50 ug of SE D, based upon pilot studies. SE D inoculated rats showed an increase in cortical BBB permeability to 7.36 ± 2.17 (mls/gm/min $\times 10^3$) (n=3) which was significantly increased compared with rats treated with SE B, 2.50 ± 1.10 (n=3), and untreated controls, 2.87 ± 1.50 (n=6). A similar increase in BBB permeability occurred in the basal ganglia, but this did not approach significance. No cellular infiltrates were detected in the CNS.

These findings show that a specific SE can alter BBB integrity acutely. This alteration can affect signaling between the CNS and the systemic immune system, and may partially explain the SE D inhibition of EAE in the rat.

391.14

NERVE GROWTH FACTOR IMMUNOREACTIVE MAST CELLS IN HUMAN PERIPHERAL NERVE. R. Dal Toso*, M. Fabris, S. Romanello, L. Petrelli, A. Buriani, A. Alexandre¹, S.D. Skaper, L. Aloe², and A. Leon. *Rescarch/life S.c.p.A.*, Centro di Ricerca Biomedica and ¹Ospedale Civile, 31033 Castelfranco Veneto, Italy; ²Institute of Neurobiology, CNR, 00137 Rome, Italy.

Mast cells purified from the rat peritoneum express NGF mRNA. In addition, these mast cells store and release biologically active NGF protein (Leon et al., PNAS, in press). Mast cell-derived NGF may thus control adaptive-reactive responses of the nervous and immune systems towards noxious tissue perturbations. The fact that mast cells are found in the peripheral nerve trunk, especially in the endoneurium, raises the possibility that mast cells could contribute a readily available source of NGF for the regenerative process. Utilizing a goat anti-mouse β NGF IgG and standard immunohistochemical techniques, specimens of adult peripheral nerve from patients undergoing reconstructive surgery for traumatic nerve injury were examined for the presence of NGF-immunoreactive mast cells. NGF immunopositive mast cells were observed not only in the epineurium, but also within the endoneurium. Particularly striking was the intensity of the staining, which was totally absent in the surrounding tissue. The anti-NGF antibodies used here block as well the activity of NGF released from peritoneal mast cells. Endoneurial mast cells may be activated by mediators liberated from the damaged nerve fiber or from mechanical stress to the nerve, possibly providing a rapid supply of NGF to counteract early neurodegenerative events. In extreme cases, release of supraphysiological quantities of NGF could, conceivably, lead to undesirable neurological consequences, including hyperalgesia, chronic pain, and formation of neuromas.

391.16

MIGRATION OF MAST CELLS INTO THE MEDIAL HABENULA (MH) OF ADULT RING DOVES. A.J. Silverman*, X. Zhuang and R. Silver. Dept. Anat. & Cell Biol., P&S, NY, NY 10032 and Dept. Psych., Barnard College, Columbia Univ. NY, NY 10027.

In adult ring doves kept in visual isolation from conspecifics mast cells can be identified using several criteria: metachromasia to aniline dyes such as acidic toluidine blue, alcian blue staining in the presence of safranin, histamine and abundant secretory granules with complex sub-granular patterns (Silverman et al., PNAS in press). In this species brain mast cells are also contain a GnRH-like peptide (Silver et al., J. Neuroendo 4:207, 92). Mast cells are present in small numbers in the MH (n=400) and increase dramatically (n=1200) when birds are allowed to court for 2 hrs (Zhuang et al., Horm&Behav 27:283, '93). The question remains whether these mature mast cells enter the CNS *de novo* or rapidly produce the GnRH-like epitope used in our initial study for identification. Independent lines of evidence support the migration hypothesis. First, the same increase in mast cell number is observed using GnRH-like ir or the cytochemical markers. Second, immature mast cells which might have been resident in the tissue have very few secretory granules compared to those seen in the MH during courtship. Finally, ultrastructural images show mast cells inserted between the ependymal cells, with numerous filamentous surface processes oriented toward the grey matter. One to two cell diameters into the MH, mast cells these processes enclose considerable extracellular space (ECS) suggesting an alteration in the local environment to create room for movement. Only deep within the MH does the ECS around the mast cell disappear, although blunt processes are still present. These two sets of observations are consistent with the transmigration of mast cells from the ventricular surface into the brain parenchyma. NIMH29380 (RS) & HD10665 (AJS).

LYMPHOCYTE AND MACROPHAGE TRAFFICKING IN THE NORMAL CHOROID PLEXUS. C.K. Petit*, A. Hanley and M.F. Falangola. Dept of Pathology, U Miami School of Medicine, Miami, FL 33136.

Activated T lymphocytes exit the blood-brain barrier and enter the normal CNS, thereby permitting immune surveillance of the brain. Because the choroid plexus (CPx) lacks a BBB, CNS exposure to circulating immune cells may be maximized in this structure. Therefore, we blindly evaluated post-mortem CPx from 22 patients for the presence of T and B lymphocytes and monocytes, using immunohistochemistry and monoclonal antibodies for cell identification (CD45Ro, CD45 and CD68 respectively, Dako Corp). The intensity of infiltrate was graded as none, mild, moderate or severe. There was one 3 m infant and 21 adults whose age averaged 47 yr. (range 22-84 yr); 15 were male. None had known infections, immunosuppression or HIV risk factors and infections were absent in the 8 with complete autopsies. T lymphocytes were present in all cases; the infiltrate was mild in 55%, moderate in 36% and severe in 9%. In contrast, lymphocyte infiltration in the brain parenchyma was rare. The CPx contained rare B lymphocytes in 9% of cases. CPx monocytes were present in 86% and the infiltration was usually mild. There was no apparent correlation between immune cell infiltration and age, sex, race or clinical disease. This prominent T cell trafficking into CPx in normal brain may be important in initiating CNS immune-related diseases or infections and may explain the periventricular localization of multiple sclerosis, certain infections, and brain lymphomas. (supported by NIH, RO1-27416)

ACTIVATION OF THE BLOOD COMPLEMENT SYSTEM IN THE HUMAN SUBARACHNOID SPACE P.J. Lindsberg*, J. Öhman, T. Lehto, M. Kaste, S. Meri. Departments of Neurology, Neurosurgery, and Bacteriology and Immunology, University of Helsinki, Helsinki FIN-00014, Finland.

The blood-brain barrier largely seals the mammalian CNS from circulating immunological factors such as complement (C), a main mediator of humoral immunity and killing of foreign cells. C activation in plasma is under stringent regulation to prevent its attack on host cells. Since a number of CNS disease states induce plasma extravasation, which may carry C proteins to escape the regulation effective in plasma, we examined whether spontaneous C activation occurs in CSF in vitro and in vivo during subarachnoid hemorrhage (SAH). CSF specimens from healthy individuals were incubated at 37°C for 30 min with varying concentrations of serum before SC5b-9 concentrations were assayed with ELISA. In CSF:serum admixtures of 1:1 and 4:1, the assembly of SC5b-9 was up to five-fold enhanced by the addition of human CSF (n=5). CSF and plasma from SAH patients were studied on day 1 and 8 after SAH (n=15) and compared to controls with no CNS disease (n=8) and patients with ischemic stroke on day 1 (n=7). The CSF SC5b-9 concentration during SAH on day 1; 210 ± 61 ng/ml, was higher than that in plasma; 63 ± 17 ng/ml ($p=0.01$), while no SC5b-9 was detected in the CSF of controls or patients with stroke ($p<0.001$). The level of CSF SC5b-9 decreased during 8 days after SAH (24 ± 10 ng/ml). We conclude that CSF lacks C regulatory capacity, thereby permitting intrathecal C activation during SAH. C activation may promote chemotaxis, vasoactive perturbations and membrane lysis, but its potential pathophysiological role in SAH needs further studies.

NEURAL-IMMUNE INTERACTIONS: CYTOKINE EFFECTS ON THE NERVOUS SYSTEM

392.1

DOSE-DEPENDENT RESPONSE OF N1E-115 NEUROBLASTOMA CELLS TO MURINE AND HUMAN TNF- α . K. Sipe, K. Kelley, R. Dantzer, A. Wonderlick, D. Srisawadi and J. Weyhenmeyer*. Department of Cell and Structural Biology, Department of Animal Sciences, University of Illinois, Urbana, IL 61801 and INRA-INSEERM, Unité 394, Bordeaux, France

Tumor necrosis factor- α (TNF) has been reported to have a variety of effects on neurons and neuroblastomas. It promotes axonal projection beyond the point of injury in severed optic nerve (Schwartz et al., *Brain Res*, 1991, 545, 334), induces differentiation of neuroblastomas in conjunction with interferon-gamma (Ponzoni et al., *Canc Res*, 1992, 52, 3194), and protects neurons against metabolic-excitotoxic insult (Cheng et al., *Neuron*, 1994, 12, 139). Using the MTT viability assay, we have observed cytotoxicity in differentiated and undifferentiated N1E-115 neuroblastoma cells (cytotoxicity indices [CI's] of $54 \pm 15\%$ and 70 ± 11 for differentiated and undifferentiated cells, respectively) treated with 250 U/ml rMuTNF- α . Treatment of undifferentiated N1E's with rHuTNF- α , an agonist specific for the murine 55 kD TNF receptor, resulted in a CI of $79 \pm 2\%$ at 400 U/ml TNF, indicating the likelihood that cytotoxicity in N1E's is mediated through the 55 kD TNF receptor. Low TNF concentrations produce little or no cytotoxicity in N1E's. The CI's for differentiated and undifferentiated cells treated with 0.025 U/ml rMuTNF- α are $-11 \pm 4\%$ and $18 \pm 17\%$, respectively. In undifferentiated N1E's treated with recombinant human TNF- α , the CI is $-10 \pm 14\%$ at 0.004 U/ml TNF. It is not clear whether the negative cytotoxicity index observed in differentiated N1E's at low TNF concentrations is due to an increase in cell proliferation or an increase in cell survival. The former seems unlikely, as the cells are treated with actinomycin D to inhibit proliferation during the course of TNF treatment. However, experiments measuring 3 H-thymidine uptake are being performed to verify that proliferation is not occurring. It has also been reported that TNF is capable of promoting cell adhesion (Mackay et al., *J Exp Med* 1993 177, 1277), so it is conceivable that TNF may promote the survival of differentiated N1E's by increasing their adhesion, either to substrate or to one another.

NEUROIMMUNOMODULATORY EFFECTS OF INTERFERON. R.A. Menzies*, C.P. Phelps*, L.T. Chen*, N.R.S. Hall*, J. Oliver*, L. Poole*, E. Horvath*, M. Wiranowska*. Depts of Anatomy*, Psychiatry and Behavioral Medicine* and Neurology*, U. South Florida, Tampa, FL, 33612.

Our laboratory has been studying the effects of interferon (IFN) on the hypothalamic pituitary adrenal axis (HPA). Last year we reported (Soc. Neuroscience Abs. 209.5, 1993) that natural rat IFN α/β (RIFN α/β) (Lee BIOMOLECULAR Research Labs) stimulated the HPA as determined by the RIA measurement of ACTH, β -endorphin and corticosterone (B) in plasma whereas human recombinant IFN α (rHuIFN α) (Hoffman LaRoche) had a minimal effect. In this report we extend those observations using the same animal preparation, e.g., 350-450 g Sprague-Dawley freely behaving male rats with indwelling jugular catheters. When either rHuIFN α or RIFN α/β is administered i.v. at doses of either 300 or 600 International units (IU) per g body weight, secretion of both ACTH and (B) is stimulated. Due to large variances, the differences at individual time points between control (either saline, serum albumen or heat inactivated RIFN α/β) and IFN injected animals were not always significant although mean differences were 2 to 4 fold. Total secretion of both ACTH and B is significantly stimulated by both IFNs although the response to RIFN α/β was greater and with less variability as compared to rHuIFN α . Total secretion was estimated by numerically integrating the release curve (trapezoidal approximation). The time course of hormone release was similar for both IFNs with the effects of RIFN α/β and rHuIFN α peaking at 30 and 60 minutes respectively and approaching baseline by 120 minutes. Both IFNs exhibit an inverse dose effect with the mean secretion of ACTH after 600 IU/g being about half that of 300 IU/g whereas there is no apparent reduction in B secretion. Supported in part by MH46808, DA 05723 and DA07976.

BRAIN INFILTRATION BY AUTOREACTIVE ANTIBODIES INDUCED BY CENTRAL INTERLEUKIN-2 (IL-2) INFUSION. U.-K. Hanisch^{1,2*}, J. Neuhaus¹, R. Quirion² and H. Kettenmann¹. Max Delbrück Center of Molecular Medicine, Cellular Neurobiology, Berlin-Buch, 13122, Germany and ²Douglas Hospital Research Centre, McGill University, Montreal, Quebec, H4H 1R3, Canada.

IL-2 regulates activities of immune and neural cells and has clinical application as an immunotherapeutic agent to treat peripheral and intracranial tumors. In this study, infusion of IL-2 (i.c.v., 5 U/hr for 14 days) in rats is shown to cause neuronal loss and myelin damage around the infusion site, along with a pronounced activation of glial cells. Within the ventricle, masses of non-neural cells intermingled with collagen and fibronectin formed a vascularized pseudotissue clot that dislodged adjacent brain regions. By means of specific antibodies, immunocytochemistry revealed not only extravasating T cells, but B cells scattered throughout the clot as well as peri-ventricular tissue. At the ultrastructural level, the B cells were identified as plasma cells endowed in protein synthesis. Accordingly, a massive inundation by genuine immunoglobulin (Ig) was detected in widespread brain areas. Fractions of the rat Ig apparently recognized populations of neuronal cells and astroglia. The results may thus be relevant both to CNS disorders involving an autoimmune component and to the adverse neurologic and neuropsychiatric symptoms induced by the application of IL-2 in the treatment of cancer. Supported by the BMFT (Germany).

LOCUS COERULEUS NEURONS RESPOND DIFFERENTLY TO INTERLEUKIN-1 β AND CORTICOTROPIN-RELEASING HORMONE. M.K. Borsody and J.M. Weiss*. Neuroscience Program and Department of Psychiatry, Emory University School of Medicine, Atlanta GA, 30322.

We administered i.c.v. recombinant human interleukin-1 β (IL-1 β ; 0.1-2.5ng) while recording extracellular activity of single LC neurons in Sprague-Dawley rats anesthetized with chloral hydrate or halothane. Our findings show that, in chloral hydrate-anesthetized rats, IL-1 β dose-dependently suppresses LC firing rates. LC sensory-evoked responses, measured as the response to 1-second paw compression, were decreased by IL-1 β proportionately with the baseline firing rate. In contrast to the effects seen in animals anesthetized with chloral hydrate, firing rates of LC units in halothane anesthetized rats did not change in response to any dose of IL-1 β . Since corticotropin-releasing hormone (CRH) is an intermediary of IL-1 in many of the cytokine's physiological actions, we compared the IL-1 β responses of LC neurons to i.c.v. CRH (1-3 μ g) under halothane and chloral hydrate anesthetics. CRH did not change LC firing rates in rats anesthetized with chloral hydrate. As reported elsewhere (Valentino et al., *Brain Res*, 270: 363, 1983), LC units in halothane anesthetized rats were excited by CRH at both 1 μ g and 3 μ g doses. The magnitude of sensory-evoked responses under halothane was not affected by CRH, but since baseline firing rates increased, the relative size of the sensory-evoked response was decreased. Supported by NIMH grant MH50420.

EFFECTS OF INTRACEREBRAL AND SYSTEMIC IL-1 α ON NE TURNOVER IN THE RAT HYPOTHALAMUS USING MICRODIALYSIS. D. Kaur, G. Chen, H. K. Manji* and W.Z. Potter* Section on Clinical Pharmacology, NIMH, Bethesda, MD 20892

IL-1 and other cytokines are known to be an integral part of the acute phase response and the hypothalamus has been postulated to be site of interaction of cytokines, particularly with respect to regulating NE release in the brain. In previous experiments we had shown that cytokines including IL-1 probably do not act directly on the hypothalamus. In our current experiments we used microdialysis in an attempt to show that IL-1 does not act centrally but does act peripherally, using NE as index of measurement. We used microdialysis for our experiments and a specially constructed CMA-12 / Cannula Combo. Animals used were Sprague Dawley rats weighing between 230-300 gms (Taconic Farms). Anesthesia used was Chloral Hydrate. Basal values of NE were established 60 min post insertion of probe. At 140 min IL-1 was then infused through the cannula at a concentration of 100 ng / ml (total delivered was 5 μ l over a 20 min period. Analysis of dialysate was done by HPLC with amperometric detection and samples were analyzed for norepinephrine. Averaged NE values in fmol/20 min collection were: Basal 358.8, Post Hypothalamic Rx: 417.2; Post i.p. Rx: 568.8. Infusion of IL-1 produced a very modest nonsignificant 11% increase in hypothalamic NE (in fact 3 of the 5 animals actually showed a decrease). By contrast, the i.p. treated animals produced a robust increase in hypothalamic NE in all 5 animals (48%). These data suggest that i.p. IL-1 induces a cascade of events which eventually result in an elevation of hypothalamic NE. Further experiments to delineate these mechanisms are underway.

Effect of cytokines on vasopressin and corticotropin releasing factor release from the hypothalamus and amygdala in vitro: possible involvement of nitric oxide mediated signalling. J. Raber*, G.F. Koob, and E.E. Bloom, Department of Neuropharmacology, The Scripps Research Institute, 10666 North Torrey Pines Rd., La Jolla, CA 92037.

Much attention has focussed on the role of selected cytokines as stimulatory factors of the HPA axis and the involvement of hypothalamic release of corticotropin-releasing factor (CRF) and arginine vasopressin (AVP) in this response. The amygdala, involved in stress related reactions and the regulation of the HPA axis, includes CRF and AVP containing neurons. An *in vitro* paradigm was used to investigate the influence of selected cytokines on the release mechanisms of CRF and AVP in the hypothalamus and amygdala, and the possible involvement of nitric oxide in this release. CRF and AVP are released, in a calcium-dependent manner from both sites, and this release is responsive to acetylcholine, norepinephrine, or high KCl (60 mM). The norepinephrine-induced AVP release is antagonized by phentolamine, but not by propranolol, while the norepinephrine-induced CRF release is antagonized by both adrenergic antagonists, suggesting an α -adrenergic receptor mediated AVP response and an α - and β -adrenergic receptor mediated CRF release. The acetylcholine-induced release is antagonized by atropine or mecamylamine, indicating that both muscarinic and nicotinic receptors can mediate the cholinergic response in the hypothalamus and amygdala. IL-2 stimulated AVP and CRF release in both regions, in a calcium- and dose dependent manner. Nitroprusside, which generates nitric oxide (NO), also induced AVP and CRF release. The IL-2 and acetylcholine-induced release is antagonized by N^G-methyl-L-arginine, a potent inhibitor of nitric oxide formation, indicating a role for NO in this release. N^G-methyl-L-arginine does not effect the norepinephrine-induced release. Finally, IFN- α stimulated CRF and AVP release from both the hypothalamus and amygdala. These data suggest that in addition to the hypothalamus, the amygdala may also play an important role in the bi-directional communication between neuroendocrine and immune systems (supported by grant MH 47680).

392.7

MODULATION OF NMDA CURRENTS BY INTERFERON- α (IFN- α) IN THE PREOPTIC ANTERIOR HYPOTHALAMUS (POA). S. Take*, T. Katafuchi, and T. Hori. Dept. Physiol., Kyushu Univ. Fac. Med., Fukuoka 812, Japan

IFN- α is produced within the brain and induces a variety of central symptoms. We have reported that microinjection of IFN- α into the POA enhances the electrical activity of the splenic sympathetic nerve and reduces the cytotoxic activity of splenic natural killer cells. We have also observed that microinjection of glutamate into the POA inhibits the activity of the splenic sympathetic nerve. NMDA type of glutamate receptors in the POA is reported to mediate the thermal information from the skin and non-NMDA type of receptors is reported to play a major role in the control of neuroendocrine neurons in the hypothalamus. Taken these things together, we have speculated that IFN- α could suppress the glutamate responses in the POA which might be involved in the regulation of the immunity as well as body temperature. In the present study, we recorded whole cell currents from the POA of male WKA rats of 10-20 days old and investigated the effects of recombinant human IFN- α on glutamate and NMDA induced inward currents with slice patch method.

Glutamate (100 μ M)-evoked inward currents was markedly attenuated by the concurrent application of D-AP5 (200 μ M). Evoked inward currents by both glutamate and NMDA (200 μ M) were suppressed by perfusion with IFN- α (100 U/ml, 2 min) for more than one hour. IFN- α -induced suppression of NMDA currents was partially abolished by simultaneous application of naloxone (10 μ M), sodium salicylate (10 μ M) and Nw-nitro-L-arginine (100 μ M). The results suggest that the POA IFN- α -induced suppression of NMDA currents is mediated by opioid receptors, prostaglandins and the nitric oxide.

INTERLEUKIN-1 AND ENDOTOXIN INCREASE RELEASE OF NOREPINEPHRINE IN HYPOTHALAMUS.

Adrian J. Dunn*, Gennady N. Smagin and Jan Lavicky. Department of Pharmacology, Louisiana State Univ. Med Ctr, Shreveport, LA 71130.

Previous studies have indicated that administration of interleukin-1 (IL-1) and endotoxin (lipopolysaccharide, LPS) increased the cerebral metabolism of norepinephrine (NE), with the greatest response in the hypothalamus. To extend these observations, we have now performed *in vivo* microdialysis to determine extracellular concentrations of NE in the hypothalamus and cortex. Intraperitoneal injection of 5 μ g LPS into freely moving rats increased microdialysate concentrations of NE and dopamine (DA) and their metabolites from the medial prefrontal cortex (PFM) and medial hypothalamus of rats. 5-HIAA was also increased. Peak responses in all cases occurred around 2 hours, and returned to baseline by about 4 hours. The response in PFM was much smaller than in the hypothalamus, but 100 μ g of LPS produced an effect in PFM comparable to that of 5 μ g in the hypothalamus. These responses were blocked by pretreatment with indomethacin.

IL-1 β (1 μ g) injected either ip or iv increased microdialysate concentrations of NE in the hypothalamus. Both injection routes elicited similar responses with dialysate concentrations increasing slowly to reach a peak after 2-3 hours. This temporal pattern differs from the elevations of plasma ACTH and corticosterone reported for IL-1; iv IL-1 elicits a rapid response with a peak around 20-30 min, whereas ip injections elicit a slower response with a peak around 2 hours after injection. This suggests that different mechanisms may be involved in the activation of cerebral NE systems and the HPA axis.

Supported by a grant from NIMH (MH 46261).

TUMOR NECROSIS FACTOR DECREASES THE LEVEL OF VASOPRESSIN BUT NOT OXYTOCIN IN RAT PITUITARY. G. V. SHURIN, D. A. PRENOVITZ, M. D. FITZSIMMONS, A. G. ROBINSON*, Dept. of Endocrinology, Univ. of Pittsburgh, PA 15261.

Cytokines derived from the immune system can modulate the activity of the hypothalamic-pituitary-adrenal (HPA) axis and thereby regulate the involvement of the neuroendocrine system in the inflammatory process. The role of major cytokines such as IL-1, IL-2, IL-6 in release of ACTH, TSH, GH has been well documented, but little is known about the effect of cytokines on arginine-vasopressin (AVP) and oxytocin (OT) secretion. In the rat many stressors stimulate OT release greater than AVP release. Yet, excess secretion of AVP is a common accompaniment of certain illness, causing excess water retention and hyponatremia. The stimulus for such elevated secretion of AVP has not been determined. We postulated that it might be mediated, at least in part, by cytokines. The present study was designed to test whether Tumor Necrosis Factor- α (TNF), derived from the immune system, can stimulate AVP and OT neuronal pathways. TNF (1 μ g) was injected (iv) into conscious, freely moving rats and the levels of pituitary AVP and OT were measured by radioimmunoassay 2 hours after cytokine injection. Pituitary AVP levels were significantly decreased after injection of TNF: baseline values (n=8) were 811 \pm 41 ng/pituitary for control animals and 671 \pm 27 ng/pituitary (p=0.012) for animals (n=8) receiving TNF. However, pituitary OT levels were not changed after administration of TNF (p>0.5). These data suggest that the immunomodulatory system (TNF) can specifically regulate AVP depletion in the posterior pituitary. The lack of effect on oxytocin indicates this is not a direct vascular (necrotic) effect on the pituitary. As "stress" stimulates OT in the rats, neither is the increased AVP a non-specific response to stress. Rather, there might be a specific neuro-immuno interaction between cytokines and vasopressin neurons.

CHRONIC EFFECTS OF IL-1: PATHOLOGIC AND ELECTROPHYSIOLOGIC CHANGES IN THE RABBIT. M. Litwak*, S. Seto, J. Martinez, J. Arezzo, C. Brosnan. Dept. of Neuroscience, Neurology and Pathology, Albert Einstein Coll. of Med., Bronx, N.Y. 10461.

Interleukin 1 (IL-1) is a protein secreted predominantly by activated macrophages that has direct acute effects on neural conduction. The present study examined the chronic effects of IL-1 using the rabbit eye model. 5 New Zealand White rabbits were treated with 300 units of IL-1 in the Rt eye, 2 controls were treated with heat inactivated IL-1 in the Rt eye and all 7 had saline in the Lt eye. Visual Evoked Potentials (VEPs) were recorded at 24 hr, 48 hr, 1wk, 2wk, 3wk, and 4wk timepoints. A parallel 5wk serial sacrifice study was conducted to determine pathological correlates of 300 units of IL-1. At 24 hrs the VEPs in the treated eye were prolonged by an average of 7.5% (1.1 msec, p=0.004) of the baseline value; at 2wks the VEPs were increased by 11.9% (1.8 msec, p=0.000) of the baseline value. The latencies for the saline control eyes were unchanged; animals injected with heat inactivated IL-1 had no delay in the VEPs. Pathology demonstrated intravascular and extravascular accumulation of inflammatory mononuclear (MN) cells and evidence of swollen and reactive astrocytes. The increase in MN cells persisted through 3wks, while altered permeability of epi-retinal vessels was detected through the 2wk timepoint. These changes were not detected in control eyes (saline and HI). These results support the conclusion that a single intraocular injection of IL-1 induces inflammatory effects that persist for up to 4wks. These alterations in function could contribute to the progressive and chronic inflammatory responses observed in diseases such as multiple sclerosis and HIV encephalopathy, where IL-1 may be released at sites of CNS lesions. SYSTEMIC INTERLEUKIN-1 β AND MILD STRESS RAPIDLY & ADDITIVELY INCREASE INTERSTITIAL LEVELS OF 5-HIAA & HVA AT THE NUCLEUS ACCUMBENS.

S. Lacosta³, Z. Merali^{1,2}, H. Anisman³, C. Belajew^{1*}. ¹Psychol & ²Pharmacol, Univ of Ottawa, ³Carleton Univ, Ottawa, Canada.

It has been proposed that the CNS interprets immunologic challenge as a stressor and that cytokines, such as IL-1, may serve as mediators between the immune system and CNS. The present investigation assessed the effect of systemic administration of hrIL-1 β and/or mild (air puff) stress on interstitial neurotransmitter and metabolite levels in the nucleus accumbens (NAcb) using microdialysis. Following steady baseline condition, male Sprague-Dawley rats were injected with IL-1 β (1 or 2 μ g/rat; i.p.) or saline (0.5 ml; i.p.) and 5 (20 min) samples collected, following which some animals were exposed to an air puff stressor (1 puff/min for 5 min) and additional 5 samples collected. Analysis of our data revealed a slight transient increase in 5-HIAA levels in control animals following saline injection stress and a second slightly larger increase following exposure to the air puff. In comparison to controls, rats injected with IL-1 β showed a significantly larger and more sustained post-injection increase in 5-HIAA. A still larger increase following air puff was seen in the IL-1 β treated animals. The HVA profile was very similar to that of 5-HIAA. However, neither DA nor DOPAC levels were affected by IL-1 β or the air puff stress. Our results support the contention that IL-1 β may be perceived by the CNS as a stressor and may cumulatively interact with other stressors to affect changes in CNS neurotransmission, particularly that of 5-HT.

392.11

INTERLEUKIN-1 α INDUCES CORTICOTROPIN-RELEASING FACTOR SECRETION AND SYNTHESIS FROM NPLC-KC CELLS THROUGH VARIOUS SECOND MESSENGER PATHWAYS J. W. Kasckow*, J. J. Mulcahey, J. Han, M. J. Owens, M. D. Stipetic, D. Breitman and C. B. Nemeroff. Dept. of Psychiat. Behav. Sci., Emory Univ. Sch. of Med., Atlanta, GA 30322

It is well documented that stress exerts effects on both endocrine and immune functions. The cytokine, interleukin-1 (IL1) is known to activate the hypothalamic-pituitary-adrenal axis by stimulating release of corticotropin-releasing factor (CRF) and to also play a preeminent role in immune function. CRF secretion and synthesis in the NPLC-KC human hepatoma clonal cell line has previously been shown to be increased by IL1. The purpose of this study was to elucidate which second messenger pathways mediate this effect. NPLC-KC cells were grown in 6 well Costar plates and treated for 12 or 24 hours with 500 pM IL1 α in the presence of the protein kinase C (PKC) inhibitor, H-7 (50 μ M), the protein kinase A inhibitor, IP20 (5 μ M), or the cyclooxygenase pathway inhibitor, indomethacin (IND, 300 nM). Both cell extracts and secretion media were assayed for CRF-like immunoreactivity in our radioimmunoassay. All 3 inhibitors reduced the IL1 effect on CRF secretion. This effect was statistically significant ($P < 0.05$) at 12 hours; although all three inhibitors reduced CRF secretion at 24 hours, only the H-7 effect was statistically significant. Only the PKC inhibitor, H-7 reduced the IL1-induced increase in CRF synthesis, an effect that was statistically significant at 12 and 24 hours ($P < 0.05$). Thus, all three signal transduction pathways are implicated in IL1-induced CRF secretion while only the PKC pathway is implicated in IL1-induced CRF synthesis. Supported by NIMH MH 42088. The work was also completed while Dr. Kasckow was a Pfizer awardee.

¹²⁵I-INTERFERON- α 2A BINDING IN RAT BRAIN. A.C. Andorn* and D. Saphier. Depts. of Psychiat. and Human Behav., St. Louis Univ. Schl. of Med., St. Louis VAMC, 63125 and Depts. of Pharmacol. and Psychiat., LSU Schl. of Med., Shreveport, LA., 71275.

The mechanism by which interferon- α 2A (IFN α 2A) contributes to neuropsychiatric sequelae in patients treated with this medication is unknown. If IFN α 2A had direct central nervous system (CNS) effects then IFN α 2A would be likely to have specific binding sites in brain. We had IFN α 2A custom radiolabeled (ICN) with ¹²⁵I. Using a centrifugation assay and nuclear and microvessel enriched particulate membrane fragment fractions of rat frontal cortex in the presence of 2 mM MgSO₄, we observed that at 4°C and 60 min incubation, and 0.1 nM ¹²⁵I-IFN α 2A, specific binding represented 40-60% of total binding when non-specific binding was determined in the presence of 10⁻⁸M unlabeled IFN α 2A. ¹²⁵I-IFN α 2A (0.1 nM) rapidly associated to the particulate membrane fragments reaching an apparent steady state within 30 min. with K_{obs} from computer assisted analyses of 3-10 and a binding maximum of .6-1 pM (N=2). ¹²⁵I-IFN α 2A binding can be dissociated by a 20-fold dilution from its putative binding sites with t_{1/2} of 20-40 min (N=2). Using these t_{1/2} and the average of the K_{obs} an approximate K_D of 1.0 pM is derived. Saturation studies (5-400 pM ¹²⁵I-IFN α 2A) had K_A of 5E10 \pm 2E10M⁻¹ (K_D = 19E-12M) and B_{max} of 0.7 \pm 0.2 pM (N=2). The computer assisted analyses of these specific binding data showed that a 1-site fit was preferred to a 2-site fit. These very preliminary findings suggest that IFN α 2A may have specific binding sites in brain, that these binding sites are of high affinity, of limited capacity, and that binding at these sites is reversible. These findings further suggest that IFN α 2A may have direct CNS effects.

RESPIRATORY REGULATION: CHEMORECEPTIVE MECHANISMS

393.1

ATP-SENSITIVE POTASSIUM CHANNELS ARE FUNCTIONAL IN NORMOXIA IN THE RESPIRATORY NETWORK OF ADULT CAT. O. Pierrefiche and D.W. Richter*. II. Physiol. Inst. Univ. Göttingen, Humboldtallee 23, 37073 Göttingen, Germany.

K⁺ channels sensitive to intracellular levels of ATP participate in the cellular response induced by oxygen deprivation. These channels are activated when intracellular levels of ATP are reduced and closed when ATP levels are normal. In some central nervous structures, a role for these channels in the hyperpolarization of cells induced by hypoxia has been described (Mourre et al. 1989; Brain Res. 496, 159). However, a functional role for such channels has not been described in respiratory neurons of adult mammals. Therefore we attempted to identify the presence and functional role of the ATP-sensitive K⁺ channels in the respiratory network of adult cats.

Experiments were performed in anesthetized, paralyzed, vagotomized and artificially ventilated cats. PO₂ and PCO₂ were monitored continuously and kept within physiological ranges to insure normoxia. Expiratory neurons were recorded intracellularly with glass micro-electrodes, filled with a solution of ATP (5mM) in K-CH₃SO₄ (1.5M) in order to study the effect of ATP injection. A specific agonist (diazoxide, 2-20mM) and 2 specific antagonists (tolbutamide, 2-20mM; glibenclamide, 5mM) were applied topically over the expiratory neuronal pool.

Fourteen cells tested for intracellular ATP injection showed a membrane depolarization of 4.1 \pm 2.4mV. Activation of the channels with diazoxide produced a hyperpolarization of 3.1 \pm 0.95mV in 12 out of the 16 cells tested with a decrease in input resistance by 18 \pm 12% (n=4). Blockade of ATP-K⁺ channels by either tolbutamide or glibenclamide evoked a depolarization of 3.4 \pm 1.02mV in 10 out of 14 cells tested with an increase in input resistance of 29.3 \pm 8.6% (n=8).

We conclude that 1) ATP-sensitive K⁺ channels are present in respiratory neurons of adult cats, 2) some of the channels are activated in normoxia and 3) opening of the remaining channels might contribute to the respiratory response during hypoxia.

BIOTINYLATED INTERLEUKIN 1 RECEPTOR ANTAGONIST (IL1RA) LABELS PARAGANGLIA IN THE RAT LIVER HILUS AND HEPATIC VAGUS. L.E. Goehler*, J. Relton, S.F. Maier, & L.R. Watkins. Dept.C&S Biology, UCHSC, Denver, CO, Synergen, Boulder, CO, & Dept. Psych., U. Colo., Boulder, CO, 80309.

Hyperalgesia resulting from immune activation by bacterial endotoxin is blocked by both IL1ra and by section of the hepatic branch of the vagus nerve (Watkins et al.,1994). Thus, some information about immune activation is conveyed to the central nervous system via peripheral nerves presumably sensitive to circulating cytokines. To determine the site of action of the IL1ra, we incubated cryostat sections of rat liver and hepatic vagus with biotinylated IL1ra. The IL1ra labeled vascular and connective tissue, tissues known to express IL1 receptors. The biotinylated IL1ra also labeled a subpopulation of cells in the paraganglia imbedded in the hepatic branch of the vagus and in the connective tissue of the liver hilus. These cells appear to be chemoreceptive, and are innervated by the vagus nerve (Prechtl & Powley, 1985). These preliminary results suggest that paraganglia are sensitive to circulating cytokines associated with immune activation, and convey this information to the brain via the vagus nerve. Supported by Synergen and NIH NS31569, MH14617.

EFFECTS OF HYPERCAPNIA ON NEURONS IN THE DORSAL MEDULLA DURING PERFORATED-PATCH RECORDINGS IN THIN SLICES. R.-Q. Huang* and J.B. Dean. Department of Physiology & Biophysics, Wright State University School of Medicine, Dayton, OH 45435.

Our previous thick slice (\approx 400 μ m) studies in adult rat have shown that CO₂-induced excitation of neurons in the solitary complex (SC), hypothesized to function in central chemoreception, is disrupted by washout during conventional whole-cell recording. The present study employed the perforated-patch technique (Amphotericin B) in thin slices (\approx 120 μ m, 1-12 day old rat) to prevent washout of the CO₂ sensing mechanisms during patch-clamp recording. Chemosensitivity was tested by increasing the percent CO₂ in the perfusion medium from 5% CO₂ (pH \approx 7.4) to 10-11% CO₂ (pH \approx 7.1) for 3-12 minutes. Stable recordings were maintained for \leq 3 hours at 25°C (R_i \leq 10 M Ω) from cell bodies ranging 10-40 μ m in diameter. Approximately 20% of the cells tested were depolarized ($\Delta V_m \leq$ 10 mV) by CO₂, often accompanied by an increased input resistance (R_{in}). Excitatory responses to high CO₂ were usually maintained during high Mg⁺⁺/low Ca⁺⁺ synaptic blockade, but were attenuated by the carbonic anhydrase II (CA II) inhibitor acetazolamide (10⁻⁴ M). Approximately 30% the neurons tested were hyperpolarized ($\Delta V_m \leq$ 7 mV) by increased CO₂, sometimes accompanied by a decreased R_{in}. In some cases, increased IPSP activity or decreased EPSP activity occurred during CO₂-induced hyperpolarization. The remainder of neurons tested (\approx 50%) were unaffected by hypercapnia. Our findings show that when whole-cell washout is prevented, SC neurons have similar types of responses to hypercapnia whether studied in thick slices (adult) or thin slices (neonate). Moreover, our results suggest that CA II plays an important role in CO₂-chemoreception in SC neurons (supported by NIH grant HL 46308).

393.3

DOES HYPOXIA-INDUCED INHIBITION OF GLOMUS CELL OUTWARD CURRENT CAUSE INCREASED CHEMORECEPTOR NERVE ACTIVITY? D.F. Donnelly*, Dept. of Pediatrics, Section of Respiratory Medicine, Yale University School of Medicine, New Haven, CT, 06510

One major theory of chemo-transduction postulates that hypoxia inhibits a glomus cell K^+ current, resulting in depolarization, calcium influx, secretion, and, thus, increased nerve activity. To test this theory, a preparation was developed which allowed for simultaneous afferent nerve recording from the intact organ and patch-clamp recording of glomus cells within the organ. Experiments were conducted using rat carotid bodies, *in vitro*, superfused with HEPES-buffered saline at 30°C. Purported glomus cell were identified based on their I/V profile: small inward currents and large, voltage-dependent outward current (760±88 pA @+40mV, n=104). Repeated measures of membrane currents and nerve activity demonstrated that hypoxia (30-60s duration, $PO_2=0$ Torr, at nadir) caused a large increase in nerve activity (15.4 x baseline, $p<0.001$), but no significant change in holding current ($p=0.1$) or R_o ($p=0.11$). Outward current significantly decreased during hypoxia ($p<0.01$), but the magnitude was small (-36±17 pA) and did not recover following reoxygenation despite the return of afferent nerve activity. Administration of the K^+ channel blocker TEA (20mM) caused a large reduction in outward current to 54% of control ($p<0.02$), but caused no significant change in afferent nerve activity ($p=0.55$). These results demonstrate an independence between changes in glomus cell outward currents and afferent nerve activity and, thus, suggests that hypoxia-transduction is not primarily mediated by modulation of glomus cell K^+ conductance.

FICTIVE VENTILATORY RESPONSE TO pH CHANGE IN AN *IN VITRO* BRAINSTEM OF RANA CATESBEIANA. W.G. Filmyer¹*, L. Kubin² and A.I. Pack³. Center for Sleep and Respiratory Neurobiology and Departments of Anesthesia¹, Animal Biology² and Medicine³, Univ. of Pennsylvania, Phila., PA 19104

We have developed an *in vitro* brainstem preparation from the bullfrog, *Rana catesbeiana* for investigation of the cellular basis of central respiratory pH/ CO_2 sensitivity and transmission of related signals within the CNS. In this study we assessed whether extracellular pH changes within a physiologic range result in an appropriate response in the multi-unit activity of the Vth cranial nerve, regarded as an index of the fictive respiratory motor output. Trials consisted of alternating two CO_2 /bicarbonate buffered mock CSF solutions with pH of 8.10 and 7.60 ±0.05 pH units, respectively, made three times for each of the six preparations studied. For fictive lung ventilation cycles, the periods and area under the bursts were measured. All of the preparations demonstrated an appropriate fictive ventilatory response, defined as an increase in the product of instantaneous respiratory rate and burst area, to the pH reduction. Changes in either the average burst area or the period alone were less consistent. Small, high frequency "buccal" oscillations, when present, demonstrated a decrease in average amplitude with pH reduction, but no change in period. Thus an *in vitro* brainstem preparation of *R. catesbeiana* has pH sensitivity and offers an attractive model for elucidation of the basic neuronal mechanisms of central chemical control of ventilation. (Supported by NIH Anesthesia Research Training Grant: GM 07612)

ANATOMY OF CO_2/H^+ -CHEMOSENSITIVE NEURONS IN THE SOLITARY COMPLEX. J.B. Dean*, R.Q. Huang, J.D. Hester and R.E.W. Fyffe². Depts. of Physiology and Biophysics, Anatomy¹, Wright State University, Dayton, OH 45435.

Neurons in the solitary complex (SC; i.e., nucleus tractus solitarius, NTS; dorsal motor nucleus vagus, DMNX) depolarized by CO_2/H^+ are hypothesized to function in central chemoreception of the cardiorespiratory systems. The present study was undertaken to determine morphological and neurochemical properties of chemosensitive SC neurons. Intracellular and perforated-patch recordings (amphotericin B) were made in transverse slices (120-400 μ m) prepared from adult or neonate rat. Neurons were stained with lucifer yellow or biocytin during intracellular recording or after rupturing the perforated patch. Chemosensitivity was tested by increasing the % CO_2 saturating the perfusion medium (pH ~7.4 → ~7.1). Chemosensitive NTS neurons had somata measuring 17-28 μ m in diameter, and 3-4 primary dendrites. Two-3 dendrites coursed dorsally or dorsomedially, producing secondary and tertiary branches, before exiting the brain slice, or terminating close to the dorsal surface of the medulla, central canal, or fourth ventricle. One dendrite usually coursed ventrally before branching and running along the dorsal border of, or extending into, the DMNX. The dendritic tree of a chemosensitive DMNX neuron extended dorsally into the NTS. The axon of chemosensitive SC neurons usually originated from the proximal part of the ventral dendrite, exited the SC ventrolaterally and projected into the medullary reticular field/nucleus before fading or exiting the slice. To date, lucifer yellow- and biocytin-labeled neurons were localized adjacent to immunopositive neurons (tyrosine hydroxylase, CGRP); however, none of the recorded neurons were immunopositive for these markers. Immunohistochemical experiments are continuing to test other neurochemicals known to be located in SC neurons. Our findings show that CO_2/H^+ -chemosensitive neurons in the SC have 1) dendritic trees that radiate towards the surfaces of the dorsal medulla, and 2) dendrites that interconnect the NTS and DMNX (supported by NIH grants HL46308 and NS25547).

IMMUNOHISTOLOGICAL DIFFERENTIATION OF CULTURED CAT CAROTID BODY CELLS. M. Shirahata*, B. Schofield and R.S. Fitzgerald. Div. of Physiology, EHS, The Johns Hopkins Medical Institutions, Baltimore, MD 21205.

Adult cats have been widely used to study the respiratory and circulatory responses to hypoxia as well as the increase in neural activity from the carotid body (CB) responsible for these reflex responses. To understand mechanisms of hypoxic chemotransduction in the CB the availability of functioning chemoreceptor cells from adult cats is extremely important. Recently we have developed methods for culturing cat CB cells which respond to hypoxia for up to one month in culture. However, a critical problem with using cats in cellular studies is identification of type I cells, because (1) the ratio of type I to type II cells is only about 2:1, and (2) both types of cells in culture are similar in size and shape. The purpose of this study was to find surface markers for identification of live type I cells. Three types of cells were clearly distinguished with three antibodies against tyrosine hydroxylase (TH), glial fibrillary acid protein (GFAP) and galactocerebroside (Gal-C). Type I cells were positive only for TH. Type II cells were positive for GFAP, but not for Gal-C or TH, suggesting that type II cells are similar to astrocytes. A third type of cell expressed only Gal-C. Both type I and type II cells were stained with tetanus toxin fragment. Since astrocytes in the central nervous system expressed immunocompetent cell markers such as CD21 and MHC-class II, we tested these markers as well. Neither type I or II cells expressed CD21, but type II cells expressed MHC-class II molecules. These results suggest that live type I cells in culture can be identified by immunohistological methods. NITRIC OXIDE MODULATES CO_2 CHEMORECEPTION IN THE PULMONATE SNAIL. J.S. Erlichman, J.C. Leiter, and F.V. McCann*. Dept. of Physiology, Dartmouth Medical School, Lebanon, NH 03756.

Winlow *et al.* (Soc. Neurosci. 19(2):A1172, 1993) have implicated the interneuronal messenger NO in the feeding and respiratory programs of the aquatic mollusc, *L. stagnalis*. We studied the role of nitric oxide (NO) in CO_2 chemoreception in the terrestrial, pulmonate snail, *H. aspersa*. Using an isolated brain-pneumostome preparation, we compared the effects of the reversible NO-synthase inhibitor, L-N^o-nitroarginine methyl ester (L-NAME) and NO donors, sodium nitroprusside (SNP), L-arginine (L-arg) and hydroxylamine (HX), on pneumostomal function during normocapnia and hypercapnia (6% CO_2). Previously, we have shown that focal exposure of a discrete area between the visceral and right parietal ganglia to 6% CO_2 causes large increases in the diameter of the pneumostome (Pn), the breathing orifice in these animals. The addition of L-NAME (10 mM) to brain perfusate decreased Pn area during normocapnia and focal hypercapnic stimulation compared to control saline, but did not affect CO_2 responsiveness *per se*. The decreased Pn area resulting from L-NAME treatment could be reversed by adding L-arg (10 mM). The inactive enantiomer, D-NAME (10 mM), had little effect on Pn area during normocapnia and hypercapnia. The NO donors, SNP (400 μ M) and HX (1 mM), added to the brain perfusate increased Pn area during normocapnia and focal hypercapnic stimulation compared to control saline, but also had no effect on the responsiveness to CO_2 . We conclude that NO modulates respiratory activity in the snail, but does not appear to be involved in the CO_2 chemotransduction process. (Supported by grants HL-01998, HL-19827 and HL-07449).

394.1

EFFECT OF HYPOXIA ON RESPIRATORY NEURONS IN THE VENTROLATERAL PONS OF ADULT RATS. S.K. Coles* and T.E. Dick. Division of Pulmonary and Critical Care Medicine, Dept. of Medicine, Case Western Reserve University, Cleveland, OH 44106-4389 USA

Bilateral chemical lesioning of the ventrolateral pons in the A5 region ablates the post-hypoxic ventilatory depression (Coles and Dick, ATS Abstract, 1994). Data from subsequent experiments using extracellular recording techniques indicate that neurons in the A5 region display highly-modulated respiratory activity (Dick et al., Neurosci. Abs., 1994). We hypothesized that if respiratory neurons in the ventrolateral pons mediate post-hypoxic ventilatory depression, these cells would be excited by hypoxia. The purpose of the present study was to characterize discharge patterns of these neurons before, during, and after exposure to acute periods of hypoxia.

Adult, male Sprague-Dawley rats (n=7) were anesthetized with Equithesin, vagotomized, paralyzed, and ventilated with 100% O₂. Glass micropipettes (R=25 MΩ) filled with a mixture of L-glutamate and 2% Fast Green were used for recording pontine neural activity extracellularly and for marking recording sites. Glutamate was iontophoresed to distinguish cell bodies from axons of passage. Respiratory activity before, during, and after hypoxia (8% O₂) was recorded from neurons located in the dorsolateral (n=3), lateral (n=13), and ventrolateral (n=10) pons.

Discharge frequency increased clearly in three expiratory cells during and following hypoxia. Surprisingly, activity was remodelled, i.e., not only did the onset and offset of neuronal discharge shift (n=5), but also cells (n=5) became active in additional phases of the cycle. Changes in activity were not evident in all cells; in 13 cells discharge frequency and activity remained stable.

These data suggest that post-hypoxic ventilatory depression is mediated potentially through respiratory neurons in the ventrolateral pons, and that the process may include "remodelling" neural activity in response to hypoxia.

CHANGES IN AUTOREGRESSIVE SPECTRA OF THE PHRENIC NEUROGRAM DURING SEVERE HYPOXIA AND SUBSEQUENT RECOVERY. M. Akay, J.E. Melton*, W. Welkowitz, N.H. Edelman and J.A. Neubauer. Department of Medicine, UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ 08903.

Progressive hypoxemia in anesthetized, peripherally chemodenervated cats results in initial depression of the phrenic neurogram (PN) culminating in phrenic silence and, eventually, gasping. These changes reverse during reoxygenation. To determine if changes in the PN power spectrum correspond to changes in temporal patterning, we examined autoregressive (AR) spectra of 100 msec bins of PN in 4 anesthetized, glomectomized, vagotomized cats during isocapnic hypoxia and reoxygenation. During normoxic eupnea, the AR spectra had peaks in the 30-60 and 60-120 Hz ranges. Hypoxia resulted in power loss at all frequencies and a shift of the 30-60 Hz peak to frequencies <30 Hz. Gasping resulted in increased power in all peaks but peaks were seen only in the 0-30 and 60-120 Hz ranges. During isocapnic recovery, the PN reverted from gasping to eupnea. Phrenic amplitude, initially 200-400% of pre-hypoxic values, returned to control values after 30 min. Power was initially increased in all peaks and returned to control levels over the same time period. The AR spectra of the PN during reoxygenation was initially gasp-like with significant power only in the 0-30 and 60-120 Hz ranges. During return to eupnea, low frequency power shifted from 0-30 to 30-60 Hz ranges. The AR spectra during intermediate recovery had characteristics of both eupnea and gasping, i.e., significant power in both the 0-30 and 30-60 Hz ranges. These results suggest that hypoxia results in a reversible reconfiguration of the central respiratory pattern generator. (Support: HL44678, HL16022, AHA/NJ)

394.3

VENTRAL MEDULLARY SURFACE RESPONSES TO TRANSIENT HYPOXIA AND HYPEROXIA IN THE CAT: EFFECT OF CAROTID SINUS DENERVATION. G. Aljadeff, D. Gozal, J.L. Carroll, D.M. Rector, O. Omidvar, R.K. Harper* and R.M. Harper. Dept. of Anatomy & Cell Biology, UCLA, Childrens Hosp., USC, Los Angeles, CA 90024; Johns Hopkins School of Medicine, Baltimore, MD 21287.

Carotid body afferents mediate components of the response to mild hypoxia within the intermediate area of the ventral medullary surface (IVMS). Changes in IVMS activity following transient peripheral chemoreceptor stimulation are unclear. IVMS neural activity in 6 spontaneously breathing, pentobarbital-anesthetized cats was measured as changes in 660 nm scattered light from the surgically-exposed IVMS, using a 3.2 mm coherent optical probe attached to a charge-coupled device. Two tidal breaths of 100% N₂ or O₂ were randomly administered before, and after carotid sinus denervation (CSD). Activity significantly increased (10.1±2.4 %) occurring within 3.1±0.7 sec following N₂ onset while decreases in activity (4.8±1.8%) were observed with O₂. CSD significantly prolonged the latency of the N₂ responses to 7.4±1.1 sec (p<0.01), and increased the magnitude of the response (14.5±1.8%; p<0.01). Similarly, CSD enhanced the effect induced by O₂ (7.2±1.3%; p<0.05) as well as prolonging the latency (8.8±1.8; p<0.01). We conclude that CSD abolishes the early IVMS responses, although deafferentation allows for development of a late IVMS activity response, possibly of central origin. 394.4

PHRENIC AND HYPOGLOSSAL NERVE RESPONSES TO SUSTAINED HYPOXIA IN DECEREBRATE CATS. M.A. Hunter, M.J. Wasicko, R.L. Joyner, J.C. Leiter, and D. Bartlett, Jr. Dept. of Physiology, Dartmouth Medical School, Lebanon, NH 03756.

A biphasic ventilatory response is observed in adults and newborns of many species during sustained hypoxia; an initial increase in ventilation is followed by a "roll off" of the response to a level greater than or equal to the control value, but less than the peak response. While the mechanism responsible for hypoxic rolloff is uncertain, previous reports suggest that it is both centrally mediated and dependent on peripheral chemoreceptor stimulation. Furthermore, the depressive effects of hypoxia differs between muscles of the upper airway and the diaphragm in piglets [Martin et al., JAP 68(2) 672-677]. In this study, we questioned 1) whether hypoxic rolloff, in the absence of changes in baroreceptor input and end tidal CO₂, is demonstrable in the adult decerebrate cat, and if so 2) whether hypoxic depression is expressed equally in hypoglossal and phrenic nerves. We measured hypoglossal and phrenic whole nerve recordings in 16 paralyzed vagotomized mechanically-ventilated decerebrate cats while arterial blood pressure and end tidal CO₂ were held constant. Following ventilation with 100% O₂, inspired O₂ was lowered to 12, 14 or 16% for 10-20 minutes. Nerve responses at all levels of inspired O₂ were biphasic. Overall, phrenic activity increased to a maximum of 17% above control before returning to the pre-hypoxic level after 7 minutes of hypoxia. Phasic hypoglossal nerve activity increased to a maximum of 40% above control and remained 25% above control after 7 minutes of hypoxia. There was no correlation between peak nerve activity and the decay constant for rolloff in either nerve. We conclude that hypoxic rolloff can be elicited in adults cats in the absence of centers rostral to the pons. Moreover, the hypoglossal nerve is more resistant to the depressive effects of hypoxia compared to the phrenic nerve in cats. (Supported by grants HL-01998, HL-19827 and HL-07449).

394.5

IMAGING OF VENTRAL MEDULLARY SURFACE CHANGES DURING HYPOXIC CHALLENGES IN WAKING GOATS. H.V. Forster, D. Gozal, D.M. Rector, P.J. Ohtake, L.G. Pan, T.F. Lowry, J. Marsh* and R.M. Harper. Dept. Physiol., Medical Coll. of Wisconsin and Zablocki VA Hospital, Milwaukee, WI 53226; Dept. of Anatomy and Cell Biology, UCLA, Childrens Hosp., USC, Los Angeles, CA 90024.

We examined activity changes on the rostral ventral medullary surface (VMS) of 5 non-anesthetized, unrestrained goats during poikilocapnic hypoxia (10% O₂ in N₂) using optical imaging procedures. Under sterile surgery, a coherent fiber probe with a charged couple device camera was placed over a rostral VMS region which elicited ventilatory and blood pressure depression during local cooling. Tracheostomy and vascular cannulation were performed for assessment of cardiorespiratory measures. Onset of 10% hypoxia was associated with a substantial increase in activation on the VMS, which was sustained for a period of time, and then gradually declined to a lower, stable level of activity as hypoxia was maintained. The temporal trends in neural activity observed are suggestive of the reported ventilatory "roll-off" phenomenon commonly associated with sustained hypoxic challenge.

394.6

INFLUENCE OF HYPERCAPNIA ON THE EXPIRATORY VOLUME-TIMING RELATIONSHIPS DURING EXPIRATORY RESISTIVE LOADING IN THE CAT. K.M. Krause*, L.-Y. Lee, and D.T. Frazier. Department of Physiology, University of Kentucky Medical Center, Lexington, Kentucky 40536-0084.

Previously, we have shown that the inspiratory volume-timing relationship during inspiratory resistive loading is linear, and that increasing levels of hypercapnia significantly increase the slope of this relationship. The specific aims of this study were to describe the expiratory volume-timing relationship during expiratory resistive loading and to determine whether this relationship is modulated by elevated CO₂ levels. Six chloralose anesthetized cats were presented with three graded levels of expiratory resistive loads (13-540 cm H₂O/l/sec) and tracheal occlusion at three levels of inspired CO₂ (room air, 7%, and 9%). The relationship between tidal volume (V_T) and expiratory duration (T_E) can be described by the following equation:

$$V_T = a + bT_E + cT_E^2$$

The influence of different CO₂ levels on this relationship is shown in the following table:

	a	b	c	r ²
Room air	-264.63	3.53	-0.0084	.94
7% CO ₂	-140.89	1.92	-0.0030	.85
9% CO ₂	-167.02	2.23	-0.0034	.89

Following vagotomy, T_E was no longer modulated in response to expiratory resistive loading. We conclude that the relationship between V_T and T_E during expiratory resistive loading can be modulated by hypercapnia and that the modulation of T_E in response to both mechanical and chemical loading is dependant upon intact vagl. (Supported by NIH #PO1 40369)

394.7

ACETAZOLAMIDE INJECTED INTO THE MEDULLARY RAPHE OF RATS INCREASES PHRENIC NERVE ACTIVITY. D.G. Bernard*, A. Li and E.E. Nattie. Dept. of Physiology, Dartmouth Medical School, Lebanon, NH 03756

The medullary raphe was examined for chemoreceptor responses (increased phrenic nerve amplitude (PNA)) to localized tissue acidosis produced by microinjection of acetazolamide (AZ). Adult male Sprague-Dawley rats were anesthetized, vagotomized, paralyzed, and artificially ventilated. The ventral medullary brainstem was exposed and 1nl injections of mock cerebrospinal fluid (mCSF), AZ (5×10^{-6} M) or an inactive AZ-analogue (5×10^{-6} M) were made in the raphe while recording integrated PNA, femoral arterial blood pressure and end-tidal CO_2 . The injection locations were demonstrated by post-mortem anatomical evaluation. PNA was expressed as percent maximum defined by 9% CO_2 stimulation. The mean change in PNA evaluated at 10, 20 and 30 min following 27 AZ injections was greater ($p < 0.001$; ANOVA) than after 16 control injections. Of the 27 AZ injections, 11 had responses greater than any control response. It appears that the traditional ventral medullary chemosensitive regions may not be the exclusive sites for sensing decreased pH by increasing PNA. Other sites, namely the locus coeruleus and the nucleus tractus solitarius have recently been described and the medullary raphe may be another such chemoreceptor site. (Supported by HL 28066 & HL 26091)

SOMATIC AND VISCERAL AFFERENTS: VISCERAL AFFERENTS

395.1

PRENATAL DEVELOPMENT OF SPINAL VISCERAL AFFERENTS IN THE RAT. Y.F. McKee*, K.I. Townley, and K.G. Ruit. Department of Anatomy and Cell Biology, University of North Dakota School of Medicine, Grand Forks, ND 58202.

We have previously described the characteristic patterns of dendritic outgrowth by sympathetic preganglionic neurons (SPNs) in the thoracic and lumbar spinal cord. In an effort to relate the temporal development of the dendritic arborizations of SPNs with the temporal development of afferent systems to SPNs, we have undertaken to describe the prenatal ingrowth of visceral afferents carried into the spinal cord via dorsal roots.

Visceral afferents were labelled by placing small crystals of DiI within celiac ganglia of aldehyde-fixed rat embryos beginning on embryonic day 15 (E15) and continuing through the day of birth (E21). Central projections of visceral afferent neurons were visualized in lower thoracic and lumbar spinal cord by fluorescence microscopy, photoconverted using diaminobenzidine, and drawn by camera lucida.

On E15, visceral afferents begin to penetrate the gray matter of the dorsal horn, entering medially. Later in prenatal development these afferents ramify primarily within ventral laminae of the dorsal horn and medial regions of the gray matter adjacent to the central canal. This medial region of the gray matter contains SPN cell bodies of the central autonomic area and also contains the medially-extending dendrites of SPNs located within the intermediolateral cell column. These neurons and their processes are clearly present in this central location before the arrival of the ingrowing visceral afferents. The appropriate development of SPNs may be important in regulating the development of spinal visceral afferents necessary for visceral reflex function.

395.3

PEROXIDE-SENSITIVE MESENTERIC AFFERENTS: AN *IN VITRO* STUDY. D.W. Adelson, J.Y. Wei, and L. Kruger*. Scripps Institution of Oceanography, UCSD 92093, the Departments of Medicine and Anatomy and the Brain Research Institute, UCLA, Los Angeles, CA 90024.

Receptive fields of single unit afferent C-fibers (conduction velocity < 2.5 m/sec) were carefully delimited and characterized on the basis of impulse activity evoked by focal mechanical and heat stimuli in an *in vitro* rat splanchnic nerve-mesenteric preparation. Units were then tested for responsiveness to $1 \mu\text{l}$ of 3% hydrogen peroxide (H_2O_2) applied to their receptive field. H_2O_2 -responsive units displayed a characteristic discharge pattern comprising windup in discharge rate, decay back to background levels, followed by bursting discharge lasting several minutes. This two-phase response and the latencies involved suggest possible participation of a second cell type. Some units initially unresponsive to H_2O_2 exhibited the characteristic response pattern upon subsequent H_2O_2 stimulation, implying that units responding to initial applications of peroxide may previously have been exposed to sensitizing factors. H_2O_2 stimulation was observed to sensitize unit discharge in response to subsequent mechanical stimulation. Since a number of immunocompetent cells (e.g. neutrophils, mast cells, macrophages) generate reactive oxygen species as a result of activation, the observed sensitivity to peroxide may mediate an interaction between the sensory nerve terminal and activated immunocompetent cells.

Supported by NIH grants NS-5685 and NS-28433.

395.2

SPINAL VAGAL AFFERENT PROJECTIONS TO THE CERVICAL SPINAL CORD. S. Kapadia, C.C. LaMotte, C. Shapiro*, K. Arsenault, and M. Wolfe. Section of Neurological Surgery, Yale University Med. New Haven, CT. 06510.

Injection of the rat cervical vagus nerve with WGA-HRP results in labeled axons and terminals at the light and EM level not only in the brainstem but also in the upper cervical spinal cord. The projection to the cervical cord consisted of a small compact bundle of nonmyelinated axons which was located in the reticular zone immediately lateral to the narrow neck of lamina V and a second, less distinctly organized, set of axons at the medial border of the dorsal horn between lamina I and the dorsal columns. Axons and terminal fields extended from each of these small bundles into lateral lamina V-VII and medial lamina I, respectively. The lamina I terminal fields were compact, lying as small "islands" in the gray matter. All axons identified at the EM level were nonmyelinated. This correlates with calculations of the diameter of vagal spinal afferents suggested by the physiological studies of the cervical respiratory neurons and dorsal horn neurons shown to be affected by vagal stimulation (Dawkins et al., '92; Fu et al., '92). Both simple and glomerular terminals were labeled, with clear vesicles and few dense core vesicles. These results extend the previous evidence (Panneton, '91; McNeill et al., '91; Robertson et al., '92; Kalia and Sullivan, '82) for the presence of afferents from branches of the vagus to the high cervical cord. (NIH grant 13335)

395.4

QUADRUPLE COLOCALIZATION OF CALRETININ, CALCITONIN GENE-RELATED PEPTIDE, VASOACTIVE INTESTINAL PEPTIDE AND SUBSTANCE P IN SENSORY FIBERS WITHIN THE VILLI OF THE RAT INTESTINE. K.R. Isaacs*, L. Winsky, K.I. Strauss and D.M. Jacobowitz. NIMH, LCS, Bethesda, MD 20892

The distribution of calretinin (CR), a calcium binding protein, was compared with several neuropeptides in fixed frozen cross-sections of rat intestine ($20 \mu\text{m}$) as well as dorsal root ganglia (DRG) using double-labelling immunofluorescence. CR was found to coexist with calcitonin gene-related peptide (CGRP), vasoactive intestinal peptide (VIP), and substance P (SP) but not calbindin D-28K and galanin in the fibers innervating the lamina propria of the rat intestinal villi. An acetylcholinesterase (AChE) histochemical stain revealed that the majority of CR cells in the myenteric ganglia were cholinergic and about one half of the submucosal CR cells contained AChE but very few fibers in the villus contained both substances. *In situ* hybridization studies confirmed the presence of CR mRNA in the DRG and enteric ganglia and a ribonuclease protection assay verified the presence of CR message in the intestine. A small proportion of the CGRP immunoreactive cells in the DRG were also immunoreactive for CR and prior studies have revealed that CGRP coexists with SP and VIP in the DRG. These findings combined with reports that the primary source of CGRP in the rat intestine is the DRG (Sternini and Anderson, Somatosensory and Motor Research, 9:45-59, 1992), suggest the source of the quadruple colocalization is the DRG. While the function of CR within these nerves is unknown, the three potent vasodilatory neuropeptides may influence the uptake of metabolized food products within the vasculature of the villi.

395.5

EFFECTS OF ANTIOXIDANTS ON CISPLATIN-INDUCED EMESIS AND RELEASE OF SEROTONIN IN *SUNCUS MURINUS*. N. Matsuki*, Y. Torii, Y. Chen and H. Saito. Department of Chemical Pharmacology, Faculty of Pharmaceutical Sciences, The University of Tokyo, Tokyo 113, Japan.

Nausea and emesis are frequent side effects during cancer chemotherapy. Antitumor drugs, such as cisplatin, are considered to release serotonin from the enterochromaffin cells that stimulates serotonergic 5-HT₃ receptors located on the vagus afferents. However, little is known how cisplatin releases serotonin from the enterochromaffin cells. We have proposed the involvement of free radicals in the process (Y. Torii et al. Eur. J. Pharmacol. 248, 131, 1993). To assess the hypothesis, effects of various antioxidants and radical scavenging drugs on cisplatin-induced emesis and the release of serotonin from the intestine were studied in *Suncus murinus*, a house musk shrew. Cisplatin (20 mg/kg) was injected intraperitoneally, and the antioxidant was injected subcutaneously either one or 24 hours before the cisplatin. Butylated hydroxyanisole, propyl gallate, ascorbic acid and acetyl-cysteine attenuated the number of vomiting animals and episodes per animal. Acetyl-cysteine also decreased cisplatin-induced release of serotonin measured *in vitro*. These results further support the hypothesis that free radical-mediated oxidation is involved in cisplatin-induced release of serotonin.

395.7

INHIBITION OF AXOPLASMIC TRANSPORT IN THE VAGUS NERVE ALTERS THE NUMBERS OF NEUROPEPTIDE AND TYROSINE HYDROXYLASE mRNA-CONTAINING AND IMMUNOREACTIVE VISCERAL SENSORY NEURONS IN THE RAT NODOSE GANGLION. H. Zhuo*, A.C. Lewin, E.T. Phillips, C. Sinclair and C.J. Helke. Department of Pharmacology, Uniformed Services University of the Health Sciences, Bethesda, MD 20814.

Previous work showed that axotomy-induced deafferentation altered the numbers of neuropeptide and tyrosine hydroxylase (TH) mRNA containing and immunoreactive neurons in the nodose ganglion. The present study was designed to selectively evaluate the loss of axonal transport on the numbers of vasoactive intestinal polypeptide (VIP), TH, and calcitonin gene-related peptide (CGRP) mRNA-containing and immunoreactive (ir) neurons of the nodose ganglion. Vinblastine (VB, 0.15mM) was administered to the cervical vagus nerve to block axonal transport. *In situ* hybridization and immunocytochemistry were used to label nodose ganglion neurons at 1, 3, 7, and 14 days after VB treatment. VB treatment of the vagus nerve markedly increased the numbers of VIP mRNA-containing and VIP-ir neurons, and slightly increased the numbers of CGRP mRNA-containing and CGRP-ir neurons in the nodose ganglion. The average labeling density of VIP mRNA-containing neurons was increased following VB treatment. VB treatment led to the appearance of low-labeling density CGRP mRNA-containing neurons which reduced the average labeling density of the CGRP mRNA-containing neurons. Application of VB to the cervical vagus nerve, decreased the number of TH mRNA-containing and TH-ir neurons in the nodose ganglion. The efficacy of VB to inhibit axonal transport and the absence of VB-induced neuronal damage were verified. These data suggest the presence of an axonally-transported influence regulating neuropeptide and neurotransmitter enzyme synthesis in mature placode-derived visceral sensory neurons of the nodose ganglion. (Supported by NIH grant R01 NS20991)

395.9

C-FOS EXPRESSION IN SPECIFIC AREAS OF THE CENTRAL NERVOUS SYSTEM INDUCED BY PROXIMAL COLON DISTENSION IN CONSCIOUS RATS. V. Martínez, L. Wang and Y. Taché. CURE, VA Med. Ctr., Brain Res. Inst. and Dept. Medicine, UCLA, Los Angeles, CA 90073.

Colorectal distension evokes *c-Fos* expression in the central nervous system (CNS) of the anesthetized rat. The aim of this study was to characterize the response of neurons in the CNS to proximal colon distension in conscious rats. A flexible balloon (5 cm) was inserted, through a medial laparotomy, into the proximal colon in ketamine anesthetized rats. 48 h later mechanical stimulation of the colon was performed for 10 min (30 s on, 30 s off), by inflating the balloon with 10 ml of air in conscious rats. In the control group the balloon was inserted into the colon but the distension was not performed. 60 min later the animals were deeply anesthetized and perfused; cryostat sections from brain and spinal cord (lumbar and sacral areas) were processed for Fos-like (Fos-Li) immunohistochemistry. After the proximal colon distension, the number of Fos-Li neurons was increased in the paraventricular nucleus of the hypothalamus (4159 ± 756 vs 393 ± 71 cells in the control group; mean ± SEM, *p* < .01), the locus coeruleus (357 ± 37 vs 116 ± 27 cells in the control group, *p* < .01) and the nucleus tractus solitarius (1947 ± 236 vs 508 ± 151 cells in the control group, *p* < .01). In the sacral part of the spinal cord, the number of Fos-Li cells was higher in the treated rats both in the laminae I-X (59 ± 2 vs 40 ± 2, *p* < .05) and the intermediolateral nuclei (12 ± 0.6 vs 4 ± 0.4, *p* < .01); while no differences were observed in the lumbar part. These data show that viscerosensitive inputs activate selective spinal cord and brain areas involved in the integration of autonomic functions, and provide anatomical substrata for the CNS pathways involved in the regulation of colonic function and pain perception. FUNCTIONAL ASSESSMENT OF CHOLECYSTOKININ (CCK) PROJECTIONS FROM THE NUCLEUS OF THE SOLITARY TRACT (NST) TO THE PARABRACHIAL NUCLEUS (PBN) IN THE RAT. R.D. HOFBAUER, P.L. FARIS*, B.K. HARTMAN. Dept. of Psychiatry, Div. of Neuroscience Research, University of Minnesota, Minneapolis, MN. 55455

Research in our laboratory has been focused on the anatomy and function of CCK-ergic neural projections from the NST to the PBN. It has been hypothesized that this is the first central nervous system component of a polysynaptic neuronal relay carrying satiety information from vagal afferents to the hypothalamus. Our laboratory began by anatomically detailing both the location of CCK-ergic neurons in the NST and localizing those CCK-ergic parakarya which project to the PBN. To accomplish this the retrograde tracer flourgold and immunohistochemical methods localizing CCK were used. Next, it was determined through the use of a computer aided data acquisition program (Bioquant), that approximately 98% of the CCK containing neurons in the medial subdivision of the NST project to the PBN. Additionally, it was determined that those CCK neurons which project to the PBN and those which do not are of disparate morphology. To assess the functionality of the circuit CCK-8 was injected intraperitoneally. C-Fos immunohistochemistry was then performed on areas of the NST receiving vagal afferents. Regions of the NST known to contain CCK-ergic neurons which project to the PBN were found to contain a high number of C-Fos containing cells when compared to controls. The results of the aforementioned experiments indicate that those CCK cells which project to the PBN may indeed be a subset of those neurons excited by IP injections of CCK-8. Future studies will be conducted to answer this question.

SPINAL AND SUPRA-SPINAL C-FOS EXPRESSION IN RESPONSE TO PERITONITIS-INDUCED DIGESTIVE ILEUS IN RATS. B. Bonaz*, P.J.M. Rivière, X. Pascaud, J.L. Junien and C. Feuerstein. Lab. of Neurophysiology, CHU Grenoble, 38043 Grenoble cedex 09 and Institut de Recherche Jouveinal, 94265 Fresnes cedex, France.

Peritonitis induced by i.p. injection of acetic acid is responsible for an inhibition of gastric emptying and intestinal transit in rats (1). **Purpose:** to map spinal and supraspinal pathways that are activated by peritonitis-induced ileus in rats. **Methods:** male fasted SD rats were injected i.p. either with vehicle (NaCl 0.9%) or with 0.6% wt/vol acetic acid (10ml/kg). Rats pretreated with systemic capsaicin (125mg/kg subcutaneously) also received acetic acid. Sixty min after injections rats were perfused with 4% PFA. Frozen sections (30 µm) of the brain and spinal cord were processed for Fos immunoreactivity (Fos-IR) (2). **Results:** no or a few Fos-IR was observed after i.p. injection of the vehicle. Acetic acid induced Fos-IR in the spinal cord, nucleus tractus solitarius (NTS) and area postrema, parabrachial nucleus, supraoptic and paraventricular nucleus (PVN) of the hypothalamus. A dramatic decrease of Fos-IR was observed in capsaicin pretreated rats. **Conclusions:** peritonitis induces *c-fos* expression in spinal cord and selective brain nuclei (NTS, PVN) involved in the control of digestive motility in rats. Such expression is vehiculated through capsaicin-sensitive afferent fibers.

WHOLE-CELL PATCH CLAMP RECORDINGS OF CULTURED DORSAL ROOT GANGLION NEURONS THAT INNERVATE THE KIDNEY OF THE ADULT RAT. M.A. Vizzard* and W.C. de Groat. University of Pittsburgh, School of Medicine, Department of Pharmacology, Pittsburgh, PA 15261.

Whole-cell patch-clamp recordings in combination with axonal tracing techniques were used to examine the electrophysiological properties of afferent neurons innervating the kidneys of the adult rat. A fluorescent axonal tracer (Fast Blue, FB or Fluorogold, FG) was injected into each kidney 7-14 days prior to the removal of the T8-L2 dorsal root ganglia (DRG) bilaterally. DRGs were dissociated with enzymatic-mechanical methods and individual FB or FG-labeled cells were identified with a fluorescent microscope. Renal afferent cells were cultured for 12 hours to 2 days prior to whole-cell recordings. Renal afferent cells were small (major axis mean; 26.5 ± 1.7 µm; range 11.9 - 44 µm) and had an average resting membrane potential of -50.5 ± 1.7 mV. Action potentials of these cells were of two types: 1) tetrodotoxin (TTX)-resistant, long duration (12.6 ± 1.2 ms) with an inflection on the repolarization phase, 2) TTX-sensitive, shorter duration (7.4 ± 0.9 ms). 64% of renal afferent neurons exhibited low threshold (-40 to -45 mV) TTX-sensitive (1 µM) action potentials and Na⁺ currents. Cells that exhibited TTX-resistant action potentials had high threshold Na⁺ currents (-20 to -30 mV). Some cells exhibited both TTX-sensitive and TTX-resistant Na⁺ currents. In contrast to bladder afferent neurons in which TTX-resistant and -sensitive Na⁺ currents were present in small and large cells, respectively, TTX-resistant and -sensitive Na⁺ currents in renal afferents were present in similar size neurons (26.8 ± 3.7 µm and 26.5 ± 2.4 µm, respectively). These results demonstrate that axonal tracing with fluorescent dyes is useful for identifying specific populations of visceral neurons for patch-clamp studies. The results provide the control data for future studies of changes in renal afferent cells following pathology in the kidney. MUSCULAR HYPERALGESIA FROM URETERAL CALCULOSIS IN RATS: RESPONSES OF SPINAL CORD NEURONS TO OBLIQUE MUSCLE STIMULATION. M.A. Giamberardino*, A. Dalal, R. Valente and L. Vecchiet, Institute of Medical Pathophysiology, University of Chieti, 66100 Chieti, Italy.

Previous studies have shown that rats implanted with an artificial stone in one ureter develop referred hyperalgesia of the ipsilateral oblique musculature which lasts many days. The present study examined input to the spinal cord dorsal horn from the hyperalgesic muscle in 15 stone-implanted rats and from the corresponding normal muscle in 15 controls, using electrophysiological techniques. Recordings were made from 113 single dorsal horn neurons in calculosis rats and 137 units in controls in the T10-T12 segments. Testing was as follows: gentle brushing of the dorso-caudal body surface, noxious skin pinch, graded pressure over muscle, noxious muscle pinch. In calculosis rats, 25.66% of the recorded neurons received input from the oblique musculature, with additional input from the skin in 21% of the cases. Of the neurons with muscular input, whether musculo-cutaneous or deep only, 79.31% displayed background activity and 17.24% were exclusively activated by noxious stimuli. In normal rats, 13.13% of the neurons received input from the oblique musculature, with additional input from the skin in 50% of the cases. Of the neurons with muscular input, 50% displayed background activity and 11.11% were exclusively driven by noxious stimuli. The statistical analysis showed that in calculosis rats with respect to controls a significantly higher number of cells with muscular input was recorded ($p < 0.001$) and, of these cells, a significantly higher number displayed background activity ($p < 0.001$). The results seem to indicate a condition of central sensitization of dorsal horn neurons in rats with referred muscle hyperalgesia from viscera.

EVIDENCE THAT THE VAGUS NERVE MEDIATES SOME EFFECTS OF VAGINOCERVICAL STIMULATION AFTER GENITAL DEAFFERENTATION IN THE RAT. R. Cueva-Rolón¹, G. Sansone¹, R. Bianca¹, L. E. Gómez¹, C. Beyer², B. Whipple¹, E. J. Muñoz-Martínez^{2*}, and B. R. Komisaruk¹. ¹Institute of Animal Behavior, Rutgers University, Newark NJ 07102 and ²CINVESTAV IPN, Apdo. Postal 14-740, México, 07000, D. F. MEXICO.

In order to ascertain whether any effects of vaginocervical stimulation (VS) are mediated by the vagus nerve, we first transected all obvious afferent nerves from the reproductive tract and then tested for residual responses to VS. After combined bilateral transection of the pelvic, hypogastric and pudendal nerves (NX), the following responses to VS were greatly reduced or abolished: lordosis to flank-perineum palpation, leg extension, immobilization and blockage of both tail withdrawal to radiant heat and leg withdrawal to foot pinch. However, after these nerve cuts, the following persisted as significant residual responses to VS: 1) Pupil Dilatation (PD): subsequent bilateral subdiaphragmatic vagotomy significantly reduced the magnitude of this residual response; 2) Analgesia: (measured as an increase in vocalization threshold to tail shock); the subsequent vagotomy abolished the analgesia; 3) Heart rate (HR): the subsequent vagotomy produced no significant effect on the HR increase to VS. The present findings provide evidence that the vagus nerve conveys vaginocervical afferent activity that produces pupil dilatation and analgesia. PUTATIVE C-FIBER SOMATIC AFFERENTS FROM THE HINDLIMB DO NOT CONVEY THERMAL SENSORY INFORMATION TO NUCLEUS TRACTUS SOLITARIUS (NTS) IN RATS. G.M. Toney* and S.W. Mifflin, Department of Pharmacology, University of Texas HSC, San Antonio, TX 78284

Activation of hindlimb somatic afferents elicits NTS neuronal discharge, but the sensory modalities mediating this excitation are unknown. Experiments were conducted in anesthetized rats to determine if hindlimb somatic afferent inputs to NTS convey thermal sensory information. The left hindlimb sciatic nerve was electrically stimulated (1 Hz frequency, 0.5 ms duration) and extracellular neuronal discharge evoked in the right NTS was recorded. Units were located medial to the tractus, near obex, at depths from 450 to 1100 μ m. To categorize unit responses as being a-fiber or c-fiber evoked, compound action potentials were recorded from the sciatic nerve and the averaged response to 30 stimuli compared at different stimulus intensities ($n=3$). Short latency excitation, presumably a-fiber mediated, was first recorded at an intensity of ~ 10 μ A and became maximal near 100 μ A. Longer latency excitation, presumably c-fiber mediated, appeared near 50 μ A and became maximal at intensities of ~ 400 μ A. NTS unit discharge was evoked at intensities averaging 217.0 ± 36.9 μ A ($n=8$), suggesting activation by c-fibers. Unit activity was further categorized as c-fiber-evoked by injecting capsaicin (10 ng) into the hindlimb arterial supply. In 7 of 8 units, discharge significantly increased from 3.1 ± 1.2 Hz to 8.9 ± 1.5 Hz ($p < 0.05$), while 1 unit failed to respond. Units were then tested for responses to thermal stimuli. Over a 10 second period, non-noxious (40 °C) and noxious (47 °C) heat was applied to the hindlimb. In no instance did heating affect NTS neuronal discharge frequency. These data indicate that NTS units activated by hindlimb somatic nerve stimulation appear to receive c-fiber inputs, but these inputs do not transmit thermal sensory information. EVIDENCE THAT THE VAGUS NERVE MEDIATES A RESPONSE TO VAGINOCERVICAL STIMULATION AFTER SPINAL CORD TRANSECTION IN THE RAT. R. Bianca*, G. Sansone, R. Cueva-Rolón, L. Gomez, M. Ganduglia-Pirovano, C. Beyer, B. Whipple, and B.R. Komisaruk, Institute of Animal Behavior, Rutgers University, Newark, NJ 07102

Vaginocervical stimulation (VS)-induced increases in pupil dilatation (PD) and analgesia [as measured by vocalization threshold (VOCT) to tailshock] are reduced, but not abolished, by combined bilateral pudendal, pelvic, and hypogastric neurectomy (NX). In the present experiment, rats underwent aspiration transection of the spinal cord at levels L5 or T7 to determine if such procedures would replicate the effects of NX, and to determine which of the residual responses, if any, are affected by vagotomy (VX). A control group received a sham operation. VS significantly increased both PD, and VOCT to front paw shock, in the SH, L5, and T7 groups. The increases in PD and VOCT in the SH group were significantly greater than those in either the L5 or T7 groups. The differences in VS-induced increases in PD and VOCT between the L5 and T7 groups were not statistically significant. VX abolished the VS-induced increase in PD in the L5 and T7 groups. The effects of VX on the VS-induced increase in VOCT could not be adequately determined after VX due to low survival rate at the time of assessment. In summary, VS-induced responses of PD and analgesia persist after spinal transection at L5 and T7, and subsequent VX abolishes VS-induced PD. These findings provide evidence that a physiological response (PD) to VS is mediated, in part, by the vagus nerve.

COMPLETE SPINAL CORD INJURY DOES NOT BLOCK PERCEPTUAL RESPONSES TO VAGINAL OR CERVICAL SELF-STIMULATION IN WOMEN. B.R. Komisaruk* and B. Whipple. IAB and College of Nursing, Rutgers - The State Univ. NJ, Newark, NJ 07102

In 8 women diagnosed as having complete spinal cord injury (SCI) [4 women @ T6-10, 4 women @ T11-L2], and a non-injured control group [5 women], vaginal or cervical self-stimulation (VCSS) significantly increased group mean pain thresholds in the SCI groups by up to 78% and in the control group by up to 67%. There were no significant differences among groups in magnitude of this effect. Seven of the 8 women with SCI reported that they experience menstrual cramps. The threshold to perceive cervical self-stimulation *per se* was significantly higher in the 4/8 women with SCI who perceived this stimulus than in the control group. The perceptual responses to VCSS in the women with SCI @ T11-L2 may utilize hypogastric nerve afferents that enter the spinal cord as far rostral as T10; however, the perceptual responses to VCSS in the T6-10 group were unexpected. Possible afferent pathways include: 1) intraspinal visceral afferent pathways that remain intact after SCI, are not tested for, and are not part of the criteria for defining "complete" SCI (i.e. absence of voluntary movement, cutaneous pain and touch below the level of SCI); 2) a vagal afferent pathway from uterine cervix and/or adjacent regions that could bypass the spinal cord and enter the medulla oblongata directly. The latter is supported by recent findings in rats. Support: NIH: R01 HD 30156.

A FLUORESCENCE-BASED METHOD FOR ASSESSING NEUROGENIC DURAL INFLAMMATION AS INDICATED BY DURAL PROTEIN EXTRAVASATION INDUCED BY TRIGEMINAL GANGLION STIMULATION. K.W. Johnson and L.A. Phebus*. Central Nervous System Research, Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285

Neurogenic dural inflammation has been proposed as a source of pain during migraine. This inflammation is produced by the release of inflammatory neuropeptides from sensory afferents in dural tissue. A method for artificially inducing dural inflammation was reported utilizing unilateral electrical stimulation of the trigeminal ganglion. This "artificial trigger" caused the unilateral release of inflammatory neuropeptides, resulting in ipsilateral dural protein extravasation from post-capillary venules and increased dural blood flow. Most groups using this animal model of migraine have quantified the amount of protein extravasation using exogenous radiolabeled albumin.

We modified the technique to measure the amount of endogenous albumin leaking into the dural tissue by exploiting the complexation reaction of albumin with the fluorescent dye, Evans Blue. The dye was injected intravenously in guinea pigs, prior to stimulation of the trigeminal ganglion to label circulating albumin. Following unilateral ganglion stimulation, samples of dura overlying both hemispheres were removed, rinsed, and mounted on a microscope slide. The amount of Evans Blue trapped in dural tissue was measured using a Zeiss fluorescence microscope equipped with a spectrophotometer. This computerized system automatically performed readings on 25 different sites on the tissue and calculated the associated statistical values. Values were expressed as the ratio of average fluorescence in ipsilateral vs. contralateral dura for each animal. This method utilized multiple measurements on each sample which resulted in very precise measurements with a small number of animals per point ($n = 3$). The ability of several compounds to prevent dural extravasation was evaluated. This model was successful in discriminating the clinically effective and ineffective compounds.

STIMULUS-STRENGTH DEPENDENT INHIBITION OR FACILITATION OF A WITHDRAWAL REFLEX BY A 5-HT_{1A}-RECEPTOR AGONIST IN THE RABBIT A.K. Houghton, S.E. Edwards & R.W. Clarke (SPON: Brain Research Association) Dept. PES, University of Nottingham, Sutton Bonington Campus, LE12 5RD, U.K.

Selective blockade of spinal 5-HT_{1A} receptors strongly potentiates spinal withdrawal reflexes in the decerebrated rabbit, a result which implicates these receptors in tonic descending inhibition (R.W. Clarke & A.K. Houghton, *J. Physiol.*, **473**, 123P, 1993). In the present study we have investigated the effects of a selective 5-HT receptor agonist, (+)-8-hydroxy-2-(di-n-propylamino)tetralin (8-OH-DPAT), on withdrawal reflexes in spinalized rabbits. Twelve animals were decerebrated and spinalized under halothane/N₂O anaesthesia. The left sural nerve was stimulated electrically to excite either A β axons only or A β + A δ fibres. Reflexes were recorded from the ipsilateral gastrocnemius medialis (GM) muscle nerve, averaged, and integrated. 8-OH-DPAT was given i.v. in doses of 1, 9 and 90 μ g/kg, followed by the selective 5-HT_{1A}-antagonist (+)-WAY-100135 (a gift of Wyeth Research (U.K.) Ltd.), also given i.v. at 1 mg/kg. When high stimulus strengths were used, 8-OH-DPAT always increased reflexes at doses up to 10 μ g/kg, after which the reflex was a median of 214% ($n=5$, range 152-362%) of pre-drug controls. Increasing the dose of 8-OH-DPAT could increase reflexes further (2 rabbits) or decrease responses (3 animals). WAY-100135 always had the opposite effect to the highest dose of the agonist. In contrast, reflexes evoked by low intensity stimuli were usually (6 of 7 animals) suppressed after 8-OH-DPAT. In these experiments, the median reflex after the 10 μ g/kg dose was 46% of controls ($n=7$, range 10-101%). The reflex increased after WAY-100135 to a median of 166% of the pre-drug values (range 44-431%). Thus, 5-HT_{1A}-receptor activation can facilitate or suppress polysynaptic reflexes, presumably through actions at multiple sites in the reflex pathway. *AKH is an SERC scholar.*

ACTIVATION OF 5-HT₂ RECEPTORS POTENTIATES PAIN PRODUCED BY INFLAMMATORY MEDIATORS. Y. Hong*, F.V. Abbott and P. Blier. Dept. Psychiatry, McGill Univ, Montreal, PQ H3A 1A1.

Serotonin (5-HT) strongly potentiates the spontaneous pain response produced by intraplantar injection of inflammatory mediators (Hong & Abbott, *Neurosci.*, in press). The present study explored the receptor subtype(s) mediating this synergistic effect of 5-HT in algogenesis, and the effects of 5-HT antagonists on formalin-induced pain.

5-HT agonists were injected, alone or with noradrenaline (NA) or prostaglandin E₂ (PGE₂), into the plantar surface of the paws of rats. The behavioral response was recorded using the rating scale developed for quantifying formalin-induced pain. 8-OH-DPAT and 2-methyl-5-HT produced only transient responses by themselves and did not interact with PGE₂ or NA. The 5-HT₂ agonists DOI, mCPP and α -methyl-5-HT produced little response alone, but induced lifting and licking lasting more than 30 min when combined with PGE₂ or NA. The algogenic effect of α -methyl-5-HT plus PGE₂ was dose-dependently blocked by intraplantar pretreatment with the 5-HT_{2A/2C} antagonists ketanserin (0.5-5 μ g) and ritanserin (5-50 μ g) and the 5-HT_{2A} antagonist spiperone (0.03-0.3 μ g), but not by α - or β -adrenergic antagonists. Similar doses of these 5-HT₂ antagonists attenuated the second phase of the pain response to intraplantar injection of 1.0% formalin. These data imply that 5-HT_{2A} antagonists may be effective peripherally acting analgesics or analgesic adjuncts in pain states associated with 5-HT release from platelets, such as acute injury and, perhaps, some chronic pain states.

396.2

EFFECTS OF CONTINUOUS, CONSTANT-RATE SPINAL INFUSION OF SNX-111 (SYNTHETIC ω -CONOPEPTIDE MVIIA) ON FORMALIN-EVOKED CUTANEOUS PAIN IN THE RAT: DOSE-RESPONSE RELATIONSHIP. S. Bowersox, T. Singh, K. Lau, K. Valentino*, and R. Luther Pharmacology Department, Neurex Corporation, Menlo Park, California, 94025.

Male, Sprague-Dawley rats were used to evaluate the analgesic properties of SNX-111 (synthetic ω -conopeptide MVIIA) administered by continuous, constant-rate spinal (intrathecal) infusion. We and others previously reported (Gohil et al. *Neurosci Abstr.* 19:235, 1993) that spinal bolus injections of SNX-111 significantly attenuate tonic nociceptive responses (ED₅₀ = 0.1 μ g) in the rat hindpaw formalin test. In the current study, animals with indwelling spinal catheters were given infusions of either sterile saline (0.9%) or SNX-111 (0.001, 0.003, 0.01, 0.03, 0.1 μ g/ μ l/hr) for 72 hours before analgesia testing. Nociceptive behavior was elicited by injecting 50 μ l of 5% buffered formalin subcutaneously into the dorsal hindpaw. Nociceptive responses were quantified by counting paw flexions at regular intervals across a 90-minute observation period beginning immediately after formalin injection. The number of paw flinches during acute (Phase 1: 0-9 minutes post-formalin) and tonic (Phase 2: 10-90 minutes post-formalin) response phases were summed for animals of each group. Group values were compared by ANOVA and *post hoc* t-tests. SNX-111 dose-dependently blocked formalin-induced nociceptive behavior in both the acute and tonic response phases. Half-maximal blockade of Phase 1 and Phase 2 responses (ED₅₀) was produced by doses of 14 ng/hr (Phase 1) and 0.82 ng/hr (Phase 2). Behavioral signs observed included stiff tails (low dose groups) and mild tremor in the 0.1 μ g/hr group. We conclude that sub-tremorgenic doses of SNX-111 administered by continuous intrathecal infusion have analgesic efficacy in both the acute and tonic phases of the rat paw formalin test.

396.4

IONTOPHORETIC APPLICATION OF SEROTONERGIC AGONISTS PRODUCES BOTH EXCITATION AND INHIBITION OF PHYSIOLOGICALLY CHARACTERIZED PUTATIVE PAIN MODULATING NEURONS IN THE ROSTRAL VENTROMEDIAL MEDULLA OF LIGHTLY ANESTHETIZED RATS. S.M. Roychowdhury and M.M. Heinricher*. Dept. Neurol., Univ. Calif., San Francisco, CA 94143.

Two classes of presumed pain modulating neurons have been identified in the rostral ventromedial medulla (RVM) of the lightly anesthetized rat: "on-cells" display a burst of activity, and "off-cells" become quiescent prior to a noxious heat-evoked tail flick reflex (TF). A third class of cells, "neutral cells," show no TF-related change in firing.

The role of serotonin within the RVM is not well understood. The aim of the present study was to examine the effect of iontophoretically applied 5HT upon the activity of on-, off- and neutral cells. Fifty-three of 59 cells (89%) responded to 5HT. The predominant effect on all cell classes was a facilitation of spontaneous (34/59) and glutamate-evoked (5/7) activity, an effect blocked by the 5-HT_{2/1C} antagonist ketanserin. 5HT also enhanced the TF-related on-cell burst. Ketanserin by itself had no effect on cell discharge.

The 5HT_{1A} agonist 8-OHDPAT and the nonselective 5HT₁ agonist 5-CT inhibited the majority of cells tested. Neurons inhibited by 8-OHDPAT were on many occasions excited by iontophoretic application of 5HT itself. Fourteen neurons were inhibited by 5HT.

These results suggest that individual neurons within the RVM can be both excited and inhibited by serotonergic agonists acting at different receptor subtypes. The results further indicate that the actions of 5HT within the RVM cannot be attributed to an influence on a particular cell class, suggesting that 5HT plays a more general role in modulating the circuitry of the region.

Supported by grants from NIDA (DA05608) and the National Headache Foundation.

396.6

EFFECTS OF MICRODIALYSIS APPLICATION OF 5-HT_{1A} AND 5-HT₂ AGONISTS ON HEAT HYPERALGESIA AND JOINT INFLAMMATION IN RATS. D.M. Rosenstein and K.N. Westlund*. Marine Biomedical Institute and Dept. of Anatomy and Neurosciences, Univ. of Texas Medical Branch, Galveston, TX 77555-0843.

It is known that systemic application of non-selective 5-HT agonists can block nociceptive transmission. We attempted to determine the antinociceptive and anti-inflammatory effects of selective 5-HT_{1A} and 5-HT₂ agonists (8-OH-DPAT and 1-phenylbiguanide (PBG), respectively) applied directly to the lumbar spinal cord in arthritic rats. It was found that treatment with both 8-OH-DPAT and PBG five hours after induction of arthritis (by intraarticular injection of the knee joint with 3% kaolin/3% carrageenan) significantly reversed the behavioral responses to noxious thermal stimuli seen in rats at four hours post-induction. However, joint circumference was not significantly reduced by post-treatment of these drugs. Application of these drugs prior to the induction of arthritis failed to significantly inhibit arthritic changes in behavior in response to noxious thermal stimuli at four hours post-induction. After eight hours, however, behavioral responses did show some return toward baseline levels. Pre-treatment with both of these drugs failed to block changes in joint circumference associated with acute arthritis. These findings suggest that while 5-HT plays a role in the processing of thermal nociception, it is not involved in the process of peripheral inflammation. (Supported by NS01445, NS28064, NS11255)

MDL 100,687A IS A 5HT-RECEPTOR AGONIST WITH UNUSUAL POTENCY VERSUS TRIGEMINO-VASCULAR COMPONENTS OF MIGRAINE. B.M. Baron¹, J. Sproune¹, M. Petty², M. Johnson¹, M. Linnik¹, J. Kehne¹, M.M. Racke¹, B.W. Siegel¹, A.L. Slone¹, R. Bernotas¹, M. Hiben², E. Hamel³, W.S. Lee⁴, and M.A. Moskowitz⁴.
¹Marion Merrell Dow Res. Institute, Cincinnati OH 45215, ²Strasbourg, France 67080; ³McGill Univ., Montreal, Canada H3A 2B4; ⁴Mass. General Hosp., Boston, MA 02114.

The clinical success of 5HT-receptor agonists has indicated a role for a 5HT₁-like receptor in migraine. Two models have been proposed which postulate either a vascular or neural location for the 5HT receptor. MDL 100,687A and sumatriptan were characterized *in vitro* and then evaluated *in vivo* for their ability, following i.v. administration, to alter blood flow in the carotid circulation (closure of arteriovenous anastomoses in cats) or transmitter release (attenuation of plasma extravasation following trigeminal nerve stimulation in guinea pigs). MDL 100,687A was similar in potency and efficacy to sumatriptan in affecting blood flow (ED₅₀ values were 438 and 726 nmol/kg, respectively). In contrast, respective ED₅₀ values vs. plasma extravasation were 2-4 orders of magnitude lower (0.035 and 5.5 nmol/kg). In addition, the minimally effective dose of MDL 100,687A was 1,000-fold lower than that of sumatriptan in the neurogenic model. Thus, in general, the 5HT₁ agonists were more potent against the neural vs. the vascular components of migraine and specifically, MDL 100,687A was exceedingly potent (compared to sumatriptan) against its neural components. These data suggest that the two responses might have differing pharmacological mechanisms.

396.9

ANTAGONISM OF NERVE GROWTH FACTOR (NGF)-INDUCED HYPERALGESIA BY THE SUBSTANCE P (SP) N-TERMINAL METABOLITE, SP(1-7). A.A. Larson* and K.E. Kitta. Department of Veterinary Pathobiology, University of Minnesota, St. Paul, MN 55108, U.S.A.

NGF has been shown to produce hyperalgesia 24 hr after injection in rats. We tested the effect of 0.1 µg of NGF injected intrathecally in mice. The withdrawal latency of the tail from a hot water bath maintained at 49°C was significantly decreased at 24 and 48 hrs after injection of NGF. In contrast, the abdominal stretch response (writhing) to an intraperitoneal injection of acetic acid was not altered by NGF pretreatment at these times. Parallel studies indicate that SP(1-7), the predominant N-terminal metabolite of SP, was antinociceptive in the abdominal stretch assay at 24 and 48 hr. However, a dose of 100 nmoles of SP(1-7), injected 24 hr before testing, elicited no change in the hot water tail-flick response. In spite of its lack of efficacy in the tail-flick assay, when 1 to 100 nmoles of SP(1-7) was administered together with 0.1 µg of NGF, this N-terminal fragment of SP inhibited the hyperalgesic effect of NGF in a dose-related fashion. D-SP(1-7), a D-amino acid substituted isomer of SP(1-7) that antagonizes SP N-terminal binding and activity, reversed the inhibitory effect of SP(1-7) on NGF-induced hyperalgesia. Together these data suggest that N-terminal metabolic fragments that are presumed to accumulate in the spinal cord during pain transmission serve as long-term modulators of pain by antagonizing the action of NGF. RPR 100893: INHIBITION OF MEMBRANE CURRENT ACTIVATED BY SUBSTANCE P IN CULTURED CELLS OF THE HUMAN ASTROCYTOMA LINE, U 373 MG. J.C.R. Randle* and M. Laville, Rhône-Poulenc Rorer S.A., Central Research, Biology Department, 94403 Vitry-sur-Seine, France

RPR 100893 is a potent and selective antagonist of human neurokinin type 1 (NK₁) receptors. We used whole-cell patch clamp techniques to evaluate the antagonist activity of RPR 100893 on the peak outward (potassium) current recorded in the human astrocytoma cell line, U 373 MG, following NK₁ receptor activation by substance P (SP; 10 nM for 5 secs once every 5 mins). At least two control responses to SP were recorded prior to a 10 minute continuous application of antagonist. RPR 100893 (10⁻¹²-10⁻⁷ M) inhibited SP-induced current in a concentration-dependent manner with an IC₅₀ value of 0.44±0.21 nM. The three enantiomers of RPR 100893 (RPR 102530, RPR 103023 and RPR 103253) were ~1000-fold less potent, with IC₅₀ values of 300-1000 nM. Under these experimental conditions, the inhibitory effect of RPR 100893 developed gradually over the 10 minute period of application but did not appear to be use-dependent. Little reversal of the inhibition was observed during washout of 10 nM and 100 nM RPR 100893. In contrast, two other NK₁ antagonists, RP 67580 (100 and 300 nM) and (±)CP 96345 (10 nM), inhibited SP responses rapidly and reversibly. These results confirm that RPR 100893 is a potent and stereoselective antagonist of human NK₁ receptors, and indicate that it may have much slower association and dissociation kinetics than previously-described NK₁ receptor antagonists.

SIMULTANEOUS ASSESSMENT OF PRE- AND POSTSYNAPTIC EFFECTS OF SEROTONIN IN THE RAT DORSAL HORN *IN VITRO*. J.A. Lopez-Garcia and A.E. King. Department of Physiology, University of Leeds, Leeds LS2 9NQ, UK. (SPON: Brain Research Association).

In an attempt to study cellular mechanisms of serotonin (5-HT) in the dorsal horn (DH), simultaneous recordings were obtained from primary afferents and DH neurons during continuous monitoring of synaptic activity in the hemisectioned spinal cord of young rats (10-14 day old). Two suction electrodes were placed in contiguous lumbar dorsal roots and used for stimulation and recording of primary afferent depolarization (PAD) respectively. Conventional sharp electrodes were lowered in the DH. After impalement of a neuron a dorsal root stimulation protocol was initiated and 5-HT superfused at different concentrations (0.01-100 µM).

Preliminary results obtained from 22 preparations show that 5-HT had effects on both pre- and postsynaptic elements. 5-HT induced a long lasting (8-15 min) PAD of small amplitude (230 µV) in all preparations tested. The dose response curve for this response was bell shaped with a peak at 5 µM. Direct effects of 5-HT on the membrane potential of the postsynaptic neuron were found in only 4 out of 16 neurons. A depolarization was observed in 3/16 neurons and hyperpolarization in 1 neuron. These responses developed slowly, were of small amplitude (3-10 mV) and displayed dose-dependency. The EPSP elicited by dorsal root stimulation was transiently depressed by 5-HT in 13/16 cases, potentiated in 2/16 and unchanged in the remaining case. 5-HT doses equal or greater than 1 µM were required to produce changes in both the EPSP and the membrane potential of the postsynaptic neuron.

These data suggest a role for 5-HT in the modulation of transmission from primary afferents to DH neurons via complex mechanisms which may include activation of low and high affinity 5-HT receptors at pre- and postsynaptic sites. Supported by The Wellcome Trust.

DELTA-OPIOID RECEPTOR MEDIATED CONTROL OF SUBSTANCE P RELEASE IN THE DORSAL HORN OF THE RAT FOLLOWING MECHANICAL OR THERMAL NOXIOUS PERIPHERAL STIMULATION. V. Zachariou* and B.D. Goldstein. Dept. of Pharmacology, Medical College of Georgia, Augusta, GA 30912.

The superficial laminae of the dorsal horn of the spinal cord (laminae I and II) are areas rich in the undecapeptide Substance P (SP). These are the areas where the small lightly myelinated and unmyelinated Aδ- and C-fibers terminate. Activation of these fibers elicits an increase in the release of SP in the dorsal horn of the spinal cord. The opioid peptide met-enkephalin, is also found in high concentrations in the dorsal horn and is a selective δ-opioid receptor agonist. The aim of this study was to determine whether δ-opioid receptors are involved in the control of the release of immunoreactive SP in the dorsal horn when noxious mechanical or thermal stimuli are applied to the ipsilateral hindpaw of the rat.

A push-pull cannula was introduced into the dorsal horn at the lumbar enlargement in decerebrate/spinal transected rats. The spinal cord was perfused with artificial CSF and immunoreactive SP (SPLI) was measured using RIA, before and after the application of a noxious mechanical or thermal stimulus. All drugs were applied to the dorsal horn through the perfusion apparatus.

ME reduced the tonic release of SPLI. It also blocked the increase in SPLI following either the mechanical or thermal stimuli. The effect of ME was blocked by naltrindole (NTD), a selective δ-opioid receptor antagonist. NTD alone, elicited an increase in the tonic release of SPLI. These results suggest that there is a δ-opioid receptor mediated control of the tonic as well as, the evoked release of SPLI.

THE SUBSTANCE P N-TERMINAL HEPTAPEPTIDE, INJECTED 24 HRS BEFORE THE FORMALIN ASSAY, POTENTIATES THE ACUTE AND INHIBITS THE TONIC PHASE. V.M. Goettl* and A.A. Larson. Graduate Program in Neuroscience, Univ. of Minnesota, St. Paul, MN 55108, U.S.A.

There is much evidence that substance P (SP) is released in the spinal cord in response to a nociceptive stimulus. Since conditions such as hyperalgesia can occur days or months after nociceptive stimulation, we investigated whether SP produces long-term effects. The SP N-terminus and SP N-terminal metabolites, such as SP(1-7), produce antinociception in the abdominal stretch assay when injected intrathecally (i.t.) 30 min before testing. However, in the formalin assay, in which mice are injected s.c. with 20 µl of 5% formalin into the dorsum of the rear foot and the amount of time spent licking or biting the foot is counted, SP(1-7) was without effect in the acute phase (0-5 min) or the tonic phase (20-30 min) of the behavioral response when SP(1-7) was injected i.t. 5 or 30 min before formalin injection. However, when administered i.t. twenty-four hrs before testing, SP(1-7) produced a U-shaped dose-response curve in both phases. The acute phase was potentiated to 127% and 135% of control at doses of 1 and 10 nmol, respectively. In contrast, the tonic phase was inhibited with decreases to 64% percent of control at 0.1 nmol, 52% at 1 nmol and 59% at 10 nmol. Ten nmol of SP(5-11), a C-terminal SP metabolite active at neurokinin receptors, was without effect. These data implicate an accumulation of SP N-terminal metabolites in the long-term and differential modulation of pain, perhaps contributing to the development of hyperalgesia or analgesia chronically, depending on the type of nociception measured. (Supported by NIDA T32 DA07234 and DA04090.)

EFFECT OF L-TYPE CALCIUM CHANNEL ANTAGONISTS ON THE RESPONSES OF DORSAL HORN NEURONS TO PERIPHERAL CUTANEOUS STIMULI AND TO SUBSTANCE P IN CATS. V. Radhakrishnan and J.L. Henry*, Departments of Physiology and Psychiatry, McGill University, Montreal, Quebec

Substance P, a mediator of nociceptive transmission at the level of the primary afferent synapse, is known to elevate intracellular levels of calcium in dorsal horn neurons. Substance P (NK-1) receptor antagonists, such as CP-96,345 and CP-99,994, have been shown to interact with L-type calcium channels, thereby raising doubts about their NK-1 receptor selectivity in blocking nociceptive responses. Therefore, in the present study we have tested the effects of L-type calcium channel blockers, verapamil and diltiazem, on the responses of spinal dorsal horn neurons to peripheral cutaneous stimulation and to iontophoretic application of substance P. Extracellular recordings were obtained using multibarrel electrodes from L₄-L₇ segments of the spinal cord in cats anesthetized with α -chloralose and spinalectomized at the L₁ level. Substance P, verapamil and diltiazem were applied to the neurons by iontophoresis. Verapamil and diltiazem depressed spontaneous activity by 20-40% in 8/10 neurons tested. The response to hair stimulation was depressed (20-50%) in 7/10 neurons. Responses to noxious mechanical and noxious thermal stimuli were depressed (40-60%) in 6/6 neurons. The response to substance P was also blocked by verapamil and diltiazem in 5/5 neurons. Thus, in contrast to NK-1 receptor antagonists which did not affect the spontaneous firing or the response to hair stimulation at doses that blocked the response to substance P, L-type calcium channel antagonists showed a suppression of all types of response, irrespective of the modality. In addition, it is likely that the antagonism of nociceptive responses by CP-96,345 and CP-99,994 is unrelated to their interaction with calcium channels. HYPERALGESIA INDUCED BY SPINALLY ADMINISTERED CELL PERMEABLE ANALOGS OF CYCLIC 3':5' GUANOSINE MONOPHOSPHATE (cGMP) Ethan Abraham[§], Mary G. Garry[†], Kenneth M. Hargreaves[†] and Lin Aanonsen^{§*}. [§]Dept. of Biology, Macalester College, St. Paul, MN 55105; [†]Depts. of Restorative Sciences and Pharmacology, University of Minnesota, Minneapolis, MN.

Recent studies have shown that spinal levels of cyclic 3':5' guanosine monophosphate (cGMP) may be involved in the development of hyperalgesia. The purpose of the present study was to investigate whether direct, spinal application of cell permeable cGMP analogs would result in a hyperalgesic response as measured in the hot-plate assay. Male, ND4 Swiss mice (10/group) were injected intrathecally (i.t.) with 8-bromoguanosine 3':5'-cyclic monophosphate (8-bromo-cGMP; 10nmol/5 μ l) or saline in order to determine 1) if there was a hyperalgesic effect (a decreased latency to lick the hind-paw) and 2) the time course of the effect. 8-bromo-cGMP produced a significant hyperalgesic response when compared to a saline control from 3 to 30 minutes post-injection. Maximal effects were observed at 10 min., thus, this time was used in subsequent studies. 8-bromo-cGMP and N², 2'-O-dibutyl-3':5'-cyclic monophosphate (db-cGMP) produced dose-related hyperalgesia with ED₅₀s of 0.69 \pm 1.59 nmol/5 μ l and 0.79 \pm 1.11 nmol/5 μ l, respectively. The selectivity of this response was determined by observing the response to i.t. injection of other, cell impermeable guanosine compounds and cAMP. The other guanosine compounds did not have an effect, while cAMP significantly increased hot-plate latency. These results suggest that spinal cGMP may be involved in the facilitation of thermal hyperalgesia in mice.

N-(2-HYDROXYETHYL)HEXADECANAMIDE GIVEN ORALLY REDUCES HYPERALGESIA BY DOWN-MODULATING MAST CELL ACTIVATION. S. Mazzari*, R. Cancella, G. Marcolongo and A. Leon. ResearchLife S.c.p.A., Centro di Ricerca Biomedica, Ospedale Civile, 31033 Castelfranco Veneto, Italy.

Inflammatory mechanical hyperalgesia induced by tissue injury (e.g. exposure to carrageenan) is due to activation/sensitization of sensory nerve terminals by mediators which are also released by mast cells. Tissue damage is also reportedly associated with increased generation of the N-acylamide N-(2-hydroxyethyl)hexadecanamide, recently proposed to behave as a local autacid capable of negatively modulating mast cell activation. To test this concept, termed autacid local inflammation antagonism (ALIA), the effectiveness of N-(2-hydroxyethyl)hexadecanamide (LG 2110/1) in decreasing functional correlates of mast cell activation in vivo was examined. Oral administration of LG 2110/1 (1-10 mg/kg) to adult rats decreased carrageenan-induced hyperalgesia and hindpaw edema. Similar anti-edema effects were observed against dextran and formalin, known to also cause mast cell activation. Locally given LG 2110/1 was likewise effective in minimizing dextran-induced hind paw edema. LG 2110/1 diminished plasma extravasation induced by injection of substance P (SP) in the mouse ear pinna but not that induced by the SP fragment (peptide 6-11), the latter known to be inactive on mast cells. The pharmacological effect after SP was associated with a reduced frequency of degranulated mast cells. Thus, orally administered N-(2-hydroxyethyl) hexadecanamide both reduces inflammatory hyperalgesia and down-modulates mast cell activation. This not only supports the proposed physiological role of the N-(2-hydroxyethyl)hexadecanamide but also suggests that this type of molecule may represent a novel therapeutic approach for the management of inflammatory conditions modulated by mast cell activity, including nerve inflammation and autoimmune diseases (Leon et al., this meeting).

396.14

EFFECTS OF THE CALCIUM CHANNEL ANTAGONISTS, SNX-111 (MVIIA) AND SNX-230 (MVIIC), ON THE RELEASE OF GLUTAMATE AND CGRP FROM SPINAL CORD SLICES. S. Gaur, J. Ramachandran and G. Miljanich*. NEUREX Corporation, Menlo Park, CA 94025

During nociception, several neuropeptides (e.g., substance P, CGRP) and excitatory amino acids (e.g., glutamate) are released at spinal cord synapses associated with the nociceptive pathway. The identities of the voltage-sensitive calcium channel (VSCC) subtypes regulating this release are not yet clear. The N-type calcium channel antagonist, SNX-111 (synthetic ω -conopeptide MVIIA), has been shown to be potentially antinociceptive in pain models, including the rat formalin test (ED₅₀=0.01 μ g intrathecally), whereas the P/Q-type antagonist, SNX-230 (synthetic ω -conopeptide MVIIC), is not antinociceptive in this model (up to 1 μ g intrathecally; Malmberg and Yaksh, *J. Neurosci.*, in press). We have studied the effects of SNX-111 and SNX-230 on K⁺-evoked, Ca²⁺-dependent release of exogenously loaded radiolabelled d-aspartate (*d-Asp, a non-metabolizable glutamate congener) and endogenous calcitonin gene related peptide (CGRP) in transverse rat spinal cord sections. The N-type VSCC blocker, SNX-111, has no detectable effect on K⁺-evoked CGRP or *d-Asp release. In contrast, the P/Q-type ligand, SNX-230, blocks approximately 100% of both *d-Asp (IC₅₀=10nM) and CGRP release. These findings indicate that the bulk of glutamate and CGRP release from spinal cord nerve terminals is not mediated by N-type VSCC, but is mediated by P/Q-type VSCC. Whether the antinociceptive effects of SNX-111 are due to inhibition of a minor but critical fraction of CGRP and/or glutamate release in the spinal cord or result from another unrelated mechanism remains to be determined.

ACTIVATION OF PROTEIN KINASE C INCREASES RELEASE OF NEUROPEPTIDES FROM RAT SENSORY NEURONS. L. A. Barber* and M. R. Vasko. Department of Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis, IN 46202.

Although activation of protein kinase C (PKC) has been shown to enhance excitability of sensory neurons, it is not known whether this activation alters the release of neurotransmitters from sensory neurons. Thus, we examined the effects of altering PKC activity on the resting and potassium-evoked release of substance P (SP) and calcitonin gene-related peptide (CGRP) from rat sensory neurons in culture.

Sensory neurons were dissociated from fetal rat dorsal root ganglia (E15-17) and grown in culture for 9-12 days. Release experiments were performed by exposing neuronal cultures for 10 min intervals to HEPES buffer containing 3.5 or 30 mM KCl, in the absence or presence of two activators of PKC, phorbol 12,13 dibutyrate (PDBu) and 1-oleoyl-2-acetyl-sn-glycerol (OAG), and a PKC inhibitor, staurosporine. SP and CGRP in the perfusate were measured by radioimmunoassay.

Exposing neurons to 10, 50, or 100 nM PDBu significantly increases SP and CGRP release at least 10-fold above resting levels in a concentration-dependent manner. One nM PDBu or 25 μ M OAG does not alter resting release, but augments K⁺-stimulated release of both peptides 2-fold. This sensitizing action of PDBu on peptide release is attenuated by 10 nM staurosporine. Peptide release is not enhanced by 100 nM 4-alpha phorbol ester, a phorbol that does not activate PKC.

These results suggest that activation of PKC is involved in the augmentation of release of SP and CGRP from sensory neurons, and also is important in sensitizing these neurons to release evoked by a depolarizing stimulus. Supported by PHS AR20582.

SUPERSENSITIVITY TO MORPHINE ANALGESIA INDUCED BY INESCAPABLE TAILSHOCK: TIMECOURSE OF EFFECT. S.E. Lea*, L. Sutton, R.E. Grahn, L.R. Watkins & S.F. Maier. Dept. Psychology, Univ. of Colorado, Boulder, CO 803092.

This lab has previously reported that inescapable tailshock produces marked enhancement of morphine analgesia, tested 24 hrs after shock. The present experiments replicate & extend this initial report by examining the timecourse of morphine supersensitivity.

Adult male albino rats were exposed either to 100 inescapable tailshocks (5 s, 1 min variable ITI, 1 mA) delivered by fixed fuse-clip electrodes or to an equivalent period of restraint (control). Rats were then tested for pain responsivity (tailflick [TF] test) in a novel environment either 1, 24, 48, or 72 hrs later. At these times, rats were first assessed for baseline pain responsivity (3 TF), followed by either 1 mg/kg s.c. morphine or equivalent volume (1 ml/kg) s.c. sterile saline. Beginning 15 min after injection, 3 TF latencies were assessed each 10 min for 60 min. Analgesia was not observed in any saline-injected groups. Likewise, morphine failed to produce analgesia in restraint controls at any time tested after shock. In contrast, profound morphine analgesia was observed in rats exposed to tailshock 24 or 48 hrs previously. This effect was strikingly time-dependent since no morphine analgesia was observed 1 hr after shock, & only modest analgesia occurred 72 hrs after shock.

These data demonstrate striking time-dependent supersensitivity to the analgesic effects of morphine following inescapable tailshock. This timecourse is in perfect agreement with other previously reported learned helplessness phenomena. NIH MH 50479

396.19

SUPERSENSITIVITY TO MORPHINE ANALGESIA INDUCED BY INESCAPABLE TAILSHOCK: NEUROPHARMACOLOGY. L. Sutton*, R.E. Grahn, M.L. Will, S.F. Maier & L.R. Watkins. Dept. of Psychology, University of Colorado, Boulder, CO 80309.

Inescapable tailshock produces supersensitivity to morphine analgesia (see companion abstract). The timecourse of supersensitivity is in agreement with other previously reported learned helplessness effects. Since several learned helplessness effects can be prevented by opiate antagonists or benzodiazepines prior to inescapable shock, these drugs were tested to determine if they would also prevent supersensitivity to morphine analgesia.

Rats were injected ip with 5 mg/kg diazepam, 10 mg/kg naltrexone, or vehicle. Rats then received either 100 tailshocks (5 s, 1 min variable ITI, 1 mA) or an equivalent period of restraint (control). Rats were then tested for pain responsiveness (tailflick (TF) test) in a novel environment 24 hrs later. Rats were first assessed for baseline pain responsiveness (3 TF), followed by either 1 mg/kg s.c. morphine or 1 ml/kg s.c. sterile saline. Beginning 15 min later, 3 TF latencies were assessed each 10 min for 60 min. Regardless of drug received prior to shock, no analgesia was observed in any group injected with s.c. saline at time of pain testing. Likewise, no analgesia was observed in any morphine-injected restraint control group. In contrast, profound morphine analgesia was observed in vehicle-injected rats exposed to tailshock 24 hrs previously. This supersensitivity to morphine analgesia was prevented in rats which received either naltrexone or diazepam at the time of inescapable tailshock.

These data replicate the striking morphine supersensitivity induced by inescapable tailshock. Prevention of these effects by opiate antagonists & benzodiazepines at time of shock is in perfect agreement with other previously reported learned helplessness phenomena. NIH MH50479

RETINA AND PHOTORECEPTORS V

GROWTH FACTOR STIMULATION OF OPSIN IMMUNOREACTIVITY IN CULTURED PHOTORECEPTORS FROM *rd* MICE. J. C. Blanks*, E. Barrón, S. Y. Schmidt, Y. Courtois and D. Hicks. Doherty Eye Institute, Los Angeles, CA 90033; INSERM, Paris, France.

Retinal cell cultures from postnatal day 1 (P1) control and *rd* mice were used to assess the effects of various growth factors on neuronal differentiation. In *rd* retinas, the photoreceptor cells degenerate during early development due to a deficiency in cGMP PDE. Our objective is to develop an *in vitro* system in order to enhance photoreceptor cell survival and/or differentiation. Retinal suspensions from P1 control and *rd* mice were grown on coverslips at 5×10^5 cells/coverslip under basal conditions or in the presence of bFGF (10 ng/ml), NGF (50 ng/ml), EGF (20 ng/ml) or bFGF and NGF combined. Photoreceptor cell viability in cultures of control and *rd* mice were evaluated by counting the numbers of opsin-positive cells (opsin⁺) throughout the entire coverslip after 4 days in culture. The numbers of opsin⁺ cells were similar in control and *rd* cultures, and in both there was a two- to three-fold increase relative to baseline in cultures with bFGF and NGF. EGF had no effect on photoreceptor numbers. There did not appear to be a synergistic effect when bFGF and NGF were combined. Cultured cells survived for a minimum of 9 days. Double-label studies are in progress with opsin and neuron-specific enolase (NSE) antibodies to determine if bFGF and NGF have a specific effect on photoreceptor cells or if their effects extend to other neuronal cell types in the retina labeled by NSE. The finding that opsin⁺ photoreceptor cell numbers were increased by growth factors in *rd* as in control retinal cultures raises the possibility that bFGF and NGF may also help the survival of *rd* photoreceptors.

IMMUNOCYTOCHEMICAL IDENTIFICATION OF COMPONENTS OF A PHOSPHOINOSITIDE PATHWAY IN ROD OUTER SEGMENTS. Y.-W. Peng¹, S.G. Rhee², T. Schoen³, G.J. Chader³ and K.-W. Yau^{1*}. ¹Dept Neurosci., Johns Hopkins Sch. Med., ²Lab. Biochem., NHLBI/NIH and ³Lab. Retinal Cell Mol. Biol., NEI/NIH.

Phototransduction in retinal rods involves a signaling cascade that leads to cGMP hydrolysis and the closure of cGMP-gated cation channels open in darkness, producing a membrane hyperpolarization as the light response. For many years there has also been some evidence for the presence of a phosphoinositide pathway in the rod outer segment, though its function and the molecular identities of its components are still unclear. We have studied this problem with immunocytochemistry using antibodies against phosphoinositide-specific phospholipase C (PLC) isozymes and also alpha subunits of the G_q family of G proteins. Among the PLC isozymes we have examined ($\beta 1-4$, $\gamma 1-2$ and $\delta 1-2$), only PLC $\beta 4$ -like immunoreactivity is found in bovine and rat rod outer segments. At the same time, we have localized $G_{\alpha 11}$, a member of the $G_{\alpha q}$ family, also in the rod outer segments of the same species. Immunoblottings of total retinal proteins with anti-PLC $\beta 4$ and anti- $G_{\alpha 11}$ antibodies also gave a single protein band of correct molecular weight in each case, suggesting specific labelings. The co-localization of PLC $\beta 4$ and $G_{\alpha 11}$ in the rod outer segment is consistent with the recent biochemical finding that PLC $\beta 4$ is activated by the G_q family of G proteins (S.G. Rhee, submitted; Jiang et al., *J. Biol. Chem.* 269, 7593, 1994). We conclude that $G_{\alpha 11}$ and PLC $\beta 4$ are likely to be part of the phosphoinositide signaling pathway in the rod outer segment. Biochemical studies are in progress.

397.2

SURVIVAL OF SPECIFIC CELL TYPES IN THE RETINA OF TRANSGENIC MICE THAT LACK ROD PHOTORECEPTORS. M.A. McCall*, K. R. Merriman & L.R. Stanford. The Waisman Center, and the Department of Comparative Biosciences, University of Wisconsin, Madison, WI 53706

We reported previously that the expression of a transgene, the rhodopsin promoter linked to an attenuated diphtheria toxin gene, eliminates rod photoreceptors in the retinae of transgenic mice, leaving what appear morphologically to be cone somata in the outer nuclear layer (ONL). In our present studies, we provide further evidence that the cells that remain in the ONL of our transgenic mouse retinae are cones, and, therefore, that the direct effect of this genetic ablation is limited to the rods. In one experiment, we used reverse transcription PCR to quantify the levels of rod and cone opsins. In our "rodless" mice, rhodopsin expression is lower at 14 days postnatally than in age-matched controls, and rhodopsin cannot be demonstrated after 21d. Blue cone opsin expression in the "rodless" retinae, while lower than in controls after 35d, can still be demonstrated in "rodless" adults. Similar experiments are now being performed to quantify the levels of red/green opsin remaining after rod ablation. We also used peanut agglutinin to selectively label cone and cone outer segments in our "rodless" mice. The proportion of labelled somata in the ONL increases with age, and only labelled somata remain at 35d. In addition, we crossed our "rodless" mice to transgenic mice in which cones express the beta-galactosidase (β -gal) gene. In the retinae of the progeny, all somata that remain in the ONL at 28d express β -gal. We are extending these observation to determine if the cones are maintained in "rodless" adults. We also examined the inner retina in the progeny of our "rodless" mice crossed to transgenic mice in which bipolar and ganglion cells express the β -gal gene. The number of bipolar cells in these retinae appears normal. Their location within the inner nuclear layer (INL) appears altered, however. Labelled bipolar cells are no longer found only near the outer margin of the INL, but are distributed throughout this layer. The selective loss of the rod photoreceptors also does not appear to affect the number of retinal ganglion cells. Supported by NIH EY10003 & EY04977.

DOCOSAHEXAENOIC ACID UPTAKE IN THE CONE-DOMINANT LIZARD RETINA. W.C. Gordon, H.E.P. Bazan* and N.G. Bazan. LSU Neuroscience Center, LSU Medical Center, New Orleans, LA 70112.

The retina effects the high-affinity uptake of docosahexaenoic acid (DHA). Photoreceptors actively accumulate DHA for synaptic and photosensitive membranes. Light- and electron microscope-level autoradiography of [3 H]DHA has shown that from 65% (primates) to 92% (amphibia) of total retinal label occurs within photoreceptors. In the frog, rod photoreceptors incorporate much more DHA than cone photoreceptors, but [3 H]DHA labeling of rods and cones is similar in monkey and rabbit retinas. To determine if some cone photoreceptors are more similar to rods, we used the American chameleon (*Anolis carolinensis*), which has a cone-dominant retina with a pronounced foveal region consisting of morphologically distinct, long, slender cone cells, and a peripheral region of shorter, wider cones. As controls, we used an all rod retina, from the Mediterranean gecko (*Hemidactylus turcicus*), and the frog (*Rana pipiens*). Retinas were incubated 4 h in 2 μ Ci/ml [3 H]DHA (SA 23 Ci/mmol). Half of each retina was prepared for lipid analysis, the other half for autoradiography. Analysis of retinas revealed typical profiles in the frog, and good, consistent labeling of the gecko rod cells. However, the density of chameleon foveal cone inner segments was only 46% that of peripheral cone inner segments. Retinal DHA mole percent content was similar in frog and gecko (32%) but only half in chameleon (18%). von Scantz et al. (Invest. Ophthalmol. Vis. Sci 32:2558-2566, 1994) recently described rod-cone similarities in the cone-dominant squirrel retina at a molecular level. Based on these differences among the cell types of the animals studied, we suggest that some cone photoreceptors may possess pathways of phospholipid metabolism that are closer to those found in rods. (Supported by NIH NEI EY05121)

IDEAL OBSERVERS OF NEURAL SIGNALS IN PHOTOTRANSDUCTION AND THE NOISE CHARACTERISTICS OF A PHOTOTRANSDUCTION MODEL. P. N. Steinmetz and R. L. Winslow*. Dept. of Biomedical Engineering, Johns Hopkins University School of Medicine, Baltimore, MD 21205

The rod phototransduction model of Forti *et al.* was linearized about operating points corresponding to various background light levels. The linearized model was used to predict low frequency quantal noise in the outer segment current. The just noticeable difference (JND) in intensity (in units of photoisomerizations/s) based on observation of outer segment current in response to 200 msec light flashes was determined at different background light levels using ideal observer theory. Performance was compared to that predicted based on optimal processing of photon counts.

Results show that the linearized Forti model of phototransduction reproduces features of low frequency outer segment current noise measured experimentally, such as: a) the magnitude of the noise is a non-monotonic function of the background light level, with the maximum occurring at a dim illumination level; and b) trapping BAPTA (a calcium chelator) in the rod increases noise level.

Ideal observer analyses indicate that intensity JNDs based on observation of outer segment current in response to light flashes are 5-10 times higher than JNDs based on photon counts. The phototransduction process therefore results in an information loss at the earliest stages of neural processing within the retina.

Rp-cAMPS: A COMPETITIVE ANTAGONIST OF CYCLIC NUCLEOTIDE-GATED CHANNELS. Richard H. Kramer*¹ and Gareth Tibbs*² ¹Dept. of Molec. & Cell. Pharmacol., Univ. of Miami School of Med, Miami, FL 33101, and ²Ctr. for Neuro. & Behav., Columbia Univ., NY, NY 10032

Cyclic nucleotide-gated (CNG) channels generate the primary electrical signal in photoreceptors and olfactory neurons during sensory responses. Cyclic nucleotides bind to a site on CNG channels that is homologous to the cyclic nucleotide-binding domain of cAMP- and cGMP-dependent protein kinases. Therefore we investigated the effect on CNG channels of thioate derivatives of cAMP and cGMP (Rp-cAMPS and Rp-cGMPS); competitive antagonists of cAMP- and cGMP-dependent kinases, respectively. In CNG channels from catfish olfactory neurons (OLF channels), Rp-cAMPS is a partial agonist. Applied alone it weakly activates OLF channels, but strongly antagonizes activation by co-applied cAMP or cGMP. The inhibition is competitive, with a large effect at low cAMP levels and no effect at saturating cAMP. Single channel analysis shows that Rp-cAMPS reduces open probability without affecting single channel conductance. In contrast, Sp-cAMPS, the diastereoisomer of Rp-cAMPS, is a full agonist of OLF channels. One might expect Rp-cGMPS to antagonize activation of rod photoreceptor CNG channels (RET channels), since these channels are selectively activated by cGMP. However, Rp-cGMPS is an agonist, activating up to 80% of the current elicited by saturating cGMP. Surprisingly, Rp-cAMPS is a pure antagonist of RET channels, exhibiting a K_i of 200-500 μ M. Rp-PCPT-cAMPS is an even higher affinity antagonist that is also membrane-permeant. Extracellular application of this analog may be useful for investigating the functional role of CNG channels in these and other cell types. Support: NIH grant NS30695.

MULTIPLE CALCIUM CHANNEL SUBTYPES IN TIGER SALAMANDER CONE PHOTORECEPTORS.

M.F. Wilkinson* and S. Barnes, Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

Numerous studies confirm that photoreceptor Ca channels, activating near -40 mV and showing little if any inactivation, are of the high-voltage-activated subtype. In this study, nystatin-permeabilized patch recordings of cone photoreceptors bathed in 5 mM Ba²⁺ revealed HVA Ca channel subtypes. The majority of Ca channel current was L-type as it was blocked in a voltage dependent manner by, for example nifedipine (0.1 - 100 μ M), but a component of Ca channel current was resistant to even the highest concentration of dihydropyridine. Kinetic properties of the current component remaining in 10 μ M nifedipine differed from the L-current in that activation occurred faster and more inactivation was seen. Most of this component was reversibly blocked by ω -conotoxin GVIA (1 μ M), indicating that these Ca channels are of the N-type. The voltage range of activation was indistinguishable for L- and N-type. Bay K 8644 enhanced the Ca channel current markedly and increased the time constant of tail current deactivation from 1 ms to 6 ms. Application of ω -conotoxin GVIA (1 μ M) to Bay K treated cells blocked a smaller proportion of current during the depolarizing test step and had no effect on the slowed tail current, suggesting that the conotoxin was not blocking L-channels. The P-channel blocker ω -agatoxin IVA (200 nM) had no statistically significant blocking effect. A small current component that could be blocked by Cd²⁺, persisted in the presence of all three channel type blockers.

D4 DOPAMINE RECEPTORS, NEGATIVELY COUPLED TO ADENYLATE CYCLASE, BLOCK THE HYPERPOLARIZATION ACTIVATED CURRENT (I_h) IN MAMMALIAN ROD PHOTORECEPTORS. B. Longoni*, G.C. Demontis, S. Bisti, P.L. Marchiafava, and L. Cervetto. Ist. Policattedra and Dipartimento Fisiologia e Biochimica, Univ. di Pisa, Ist. Neurofisiologia, CNR, Pisa, ITALY.

The voltage response of retinal rods reflects both the suppression of the dark current entering at the outer segment and the activation of voltage dependent conductances of the inner segment. We have measured the voltage dependent currents at the inner segment of mammalian rods by using the whole-cell voltage clamp technique. We found that the main component is an inward current (I_h) activated by stepping the membrane potential to voltages between -70 and -140, from an holding of -30 mV. Application of 200 μ M 8-Br-cAMP shifts the half-activation voltage from -90 to -70 mV. Dopamine 1-10 μ M reversibly shifts the half-activation voltage of I_h from -90 to -105 mV, an effect opposite to cAMP application. The results suggest that dopamine receptors, located on mammalian rod inner segments, inhibits the adenylylate cyclase. The properties of dopamine receptors were further investigated on membrane homogenates obtained from bovine rods, after isolation by mechanical dissociation and purification on Ficoll gradients. By using the [³H]-spiperone binding assay we found the specific binding to be saturable and of high affinity with a K_d of 0.05 nM. The K_i obtained from antagonist displacement curves are consistent with the known pharmacology of D₂-like receptors; moreover the K_i for clozapine (40 nM) is typical for D₄ receptors. Biphasic displacement curves for agonists suggest that dopamine receptors are coupled to an endogenous G-protein; accordingly GTP- γ -S converts the receptor from an high affinity state for agonists to a low affinity one. We conclude that dopamine affects the membrane properties of mammalian rods by activating D₄ receptors which are negatively coupled to adenylylate cyclase. Supported by the EC (SC1*-0224-C) and MPI 40% to L.C.

397.8

ROD PHOTORECEPTOR M-CURRENT (I_{KX}) IS STABILIZED BY CALCIUM-DEPENDENT PROTEIN KINASE.

D.E. Kurenniy and S. Barnes*, Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

When recorded with conventional ruptured-patch whole cell recording in bright light, kinetic parameters of the non-inactivating voltage-sensitive rod M-current (I_{KX}) change gradually ("run down") in the following manner: the maximum current amplitude and time constant of current activation decrease, while the activation curve shifts to the left. In contrast, I_{KX} was stable during ruptured-patch recording in complete darkness or when using the perforated patch technique. However, the stability of I_{KX} could be maintained in ruptured-patch recordings in bright light when the intracellular calcium concentration was increased by using either Ca-BAPTA buffer ([Ca]_i = 1 μ M), or caffeine (1 mM). IP₃, a second messenger that releases calcium from intracellular stores, stabilized I_{KX} when included in the pipette solution at 10 μ M, but not at 1 μ M. Including the phorbol ester PMA in the pipette solution (20-100 nM) also prevented rundown of I_{KX} but in only 50% of cells. The protein kinase C inhibitor, H-7, added to a pipette solution containing 1 μ M free calcium (Ca-BAPTA buffer) restored I_{KX} run-down. 1,2-dioctanoyl-rac-glycerol (50 μ M), KF/AlCl₃ (10 mM/100 μ M), cAMP or cGMP (200 μ M), ATP γ S or GTP γ S (up to 1 mM), and arachidonic acid (50-200 μ M) failed to stabilize I_{KX}. None of the drugs caused any effect on I_{KX} when applied extracellularly. We conclude that a calcium-dependent substance inhibited by H-7, probably protein kinase C, is present in photoreceptors and is necessary for I_{KX} stability.

Extra-Cellular pH and Cl⁻ Concentration modulate independently Ca²⁺ Currents in Tiger-Salamanders' Photoreceptors. R. Nitzan* and R.F. Miller, Dept. of Physiology, Univ. of Minnesota, Minneapolis, MN 55455.

Ca²⁺ currents and intracellular pH were studied in dissociated photoreceptors from tiger salamander retinas. Cells were loaded with either Fura-2 (Ca²⁺ indicator) or BCECF (pH indicator) and imaged using a dual wave length ratioing technique. The fluorescence was collected using a cooled CCD camera (Photometrics). Ca²⁺ currents were evoked by introducing high potassium concentration in the bathing solution for short durations (<30sec).

High potassium evoked Ca²⁺ currents were mainly localized in the photoreceptors soma and pedicle. Elevation of [Ca²⁺]_i was also observed in the inner segment and to a much lower extent in the outer segment. The Ca²⁺ current was slowly suppressed following introduction of Cl⁻ free medium (both SO₄²⁻ or CH₃SO₄⁻ were used as Cl⁻ replacers). At the same time no change in intracellular pH was observed. On the other hand, introducing rapid (not sufficiently long to induce intra-cellular pH changes) extra-cellular pH acidification (pH of 8.0 to 6.0) along with the high potassium stimulus was sufficient to suppress the Ca²⁺ currents, suggesting an extra-cellular mode of action of suppression of Ca²⁺ currents.

These results point to parallel mechanisms for the effects of pH and extra-cellular Cl⁻ on Ca²⁺ currents in photoreceptors.

INNER SEGMENTS OF SUNFISH SINGLE CONE PHOTORECEPTORS ARE GRADED INDEX WAVEGUIDES.

M. P. Rowe, N. Engheta, S. S. Easter, Jr., J. M. Corless and E. N. Pugh, Jr.* Inst. of Neurol. Sci., Univ. of PA, Phila., PA 19104; Dept. Electr. Eng., Univ. of PA, Phila., PA 19104; Dept. Bio., Univ. of Mich., Ann Arbor MI 48109; Depts. Cell Bio. Neurobio. & Ophth., Duke Univ. Med. Center, Durham, NC 27710, Dept. Psych., Univ. of PA, Phila., PA 19104

Cone cells isolated from the retina of the green sunfish (*Lepomis cyanellus*) were examined with a double beam scanning interferometer and also with transmission electron microscopy. With the interferometer, optical path lengths (OPLs) were measured perpendicular to the natural direction of propagation of light in the living fish eye. Measurements gave a resolution of 220 nm in diameter by 6 nm in path length for 632.8 nm (free space) incident radiation. By assuming cylindrical symmetry for the inner segment region of the cone cells, variations in refractive index can be inferred from these OPL measurements. Our analysis indicates that the average refractive index increases monotonically from around 1.39 at the base of the inner segment to 1.43 near its junction with the outer segment. This increase is consistent with general predictions based on an analysis of electron micrographs previously presented (Rowe et al, *J. Optical Soc. A*, 11:55-70).

HUMAN CONE ELECTRORETINOGRAM CAUGHT BY SECOND FLASH.

M. Saeki, P. Gouras*, W. Li, P. Lachapelle. Department Ophthalmology, Columbia University, NYC 10032 and *McGill University, Department Ophthalmology, Montreal, Canada

The b-wave of the cone electroretinogram (ERG) of monkeys and man to a flash can be caught and reduced in amplitude by a second flash if it occurs within 20 msec after the first flash. The reduction is maximum at 10-15 msec after the first flash. It occurs at different states of retinal adaptation, flash intensities and rates of double flash presentation. We suggest that this interaction between double flashes may reflect timing differences in the cone to on- and off-bipolar synapses (Ashmore & Falk, 1980; Copenhagen et al., 1983) that lead to the generation of opposing ionic currents (Sieving et al., 1994) which underly this retinal response.

SPECTRAL SENSITIVITY OF RETINAL CONES IN *Danio Malabaricus* (giant danio): A. G. Palacios, R. Srivastava & T. H. Goldsmith. Department of Biology, Yale University, New Haven, CT, USA.

The spectral sensitivity of individual cones of a fresh water fish (*Danio malabaricus*, Cyprinidae) was measured between 280 and 700 nm by recording membrane photocurrents with suction electrodes in response to brief flashes of monochromatic light of known quantum flux. These measurements extend further into the UV than have previously been obtained by this technique. We found four classes of cones with maximal sensitivity at 360 (n=5), 406 (n=7), 480 (n=10) and 561 (n=4) nm. With the exception of the UV-sensitive cone, all spectral sensitivity curves were well fit by an iodopsin template.

The identity of the retinoid chromophore was established by HPLC. Retinal oximes were recovered from eyecups by extracting with a 1:1 mixture of methanol and 1M hydroxylamine (pH 6.5). The oximes were separated on a normal-phase silica column developed with 9% dioxane in hexane. Individual eyes contained an average of 580 pmol of retinal and 10 pmol of 3-dehydroretinal.

THE VERTICAL PATHWAY IN THE RETINA IS MODULATED BY D₂ DOPAMINE RECEPTOR

D. Krizaj*, R. Gabriel*, J. Zhang* and P. Witkovsky^{1,2}. Depts Physiol¹ and Ophthalmol², NYU Med.Ctr, New York; Dep.Biology², Janus Pannonius Univ.,Pecs, Hungary

Introduction: Rod and cone signals in amphibian retina may interact at the level of the photoreceptors themselves and/or on second order cells. We have examined the role of D₂ dopamine receptors in modulation of both rod-cone coupling and transmission between *Xenopus* photoreceptors and L-horizontal/bipolar cells. **Results:** a null test, based on equal rod absorbance for red and green flicker indicated a significant presence of cone signal in mesopic and photopic rods. EM showed small gap junctions between rods and cones and injection of neurobiotin into rods labeled both adjacent rods and cones (ratio 10:1). The magnitude of cone input to rods could be manipulated with D₂ agonists/antagonists. The flicker fusion frequency ν_f of dark adapted rods (4-5Hz) was increased by the D₂-agonist, quinpirole (1-10 μ M) to 12-20 Hz. This effect was observed with red, but not green flicker, its magnitude depended on the intensity and it was not affected by SKF 38393, CNQX or kynurenic acid. Spiperone, a D₂ antagonist, reduced ν_f to 2-3Hz. In the dark adapted retina the cone signal was absent from the HC's, but was expressed strongly in bipolar cells, as evidenced by intracellular recording and ERG. Cone input to bipolar cells was blocked by the D₂ antagonist and increased by the D₂ agonist. **Conclusion:** Transmission of cone signals to rods and to bipolar cells is modulated by a D₂ dopamine mechanism. In the dark adapted state, cone signal continues to be expressed in the vertical (bipolar cells) pathway as a result of D₂-dependent modulation, but is suppressed in the horizontal pathway. **Acknowledgement:** supported by EY 03570 to P.W.

AUDITORY, VESTIBULAR, AND LATERAL LINE: HAIR CELLS

ELECTRICAL RESONANCE OF FROG SACCULAR HAIR CELLS MEASURED IN THE PERFORATED-PATCH AND WHOLE-CELL RECORDING CONFIGURATIONS. D. Lenzi*, and W.M. Roberts. Institute of Neuroscience, University of Oregon, Eugene, Oregon, 97403

Frequency discrimination in the inner ears of birds, reptiles and amphibians is accomplished in part by an electrical resonance innate to mechanoreceptive hair cells. Saccular hair cells of the frog (*Rana pipiens*) express a damped membrane potential (Vm) oscillation caused in part by the interactions of voltage-gated Ca channels with Ca-gated K channels colocalized at active zones. Since an abundant, mobile Ca buffer appears to shape the Ca landscape at active zones, we asked whether its presence (in perforated-patch recordings, PP) or absence (in whole cell recordings, WC, where the native buffer was replaced by 1 mM EGTA) influenced Vm oscillations recorded in current clamp. Oscillations during and after current steps were fitted with a damped sine wave by a least-squared-error algorithm to measure frequency (f), damping time constant, and quality factor (Q) of oscillations in 7 cells in each recording configuration. Zero-current potentials were -53 \pm 8 mV (mean \pm S.D.) in PP (series resistance, Rs: 4.8 \pm 3.3 M Ω), and -60 \pm 3 mV in WC (Rs: 3.2 \pm 1.0 M Ω) measured at least 90 s after break-in. The relationship between Q and Vm was bell shaped; peak Q (where the resonance was most robust) was 10.1 \pm 6.7 in PP, and 8.9 \pm 10.1 in WC. the potential at peak Q was 2 \pm 3 mV positive to the zero-current potential in PP, and +6 \pm 2 mV in WC. The f measured at peak Q was 198.1 \pm 21.2 Hz in PP, and 213.0 \pm 26.8 Hz in WC. Comparisons between peak Q, f at peak Q, and zero-current potentials in PP and WC were not significantly different using the Mann-Whitney test. These results suggest that the mobile Ca buffer does not greatly affect the resonant properties of frog saccular hair cells. Supported by NIH grant NS27142 and a McKnight Scholars Award to WMR.

TWO TYPES OF INWARD RECTIFIERS IN HAIR CELLS OF THE MOUSE UTRICLE. A. Rüsch* and R.A. Eatock; Dept. of Otolaryngology, Baylor College of Medicine, Houston, TX 77030

Whole-cell currents were recorded with the patch-clamp technique from hair cells in utricles excised from 2 to 17 d old mice. Recordings were obtained from both type I and II hair cells, the two morphological classes of hair cells in mammalian vestibular organs. Two kinds of inwardly rectifying conductances were found.

One type, resembling the inward rectifier I_{K1} , activated negative to -50 mV with fast monoexponential kinetics. Its mean chord conductance at -124 mV was 3.34 \pm 1 nS (mean \pm SD; n=8 cells). It was blocked by 1 mM external Ba²⁺ or Cs⁺. The second type activated more slowly and with a sigmoidal time course at potentials negative to -60 mV. Its activation curve could be fit by a first-order Boltzmann relation with a $V_{1/2}$ = -101 \pm 5 mV. The reversal potential was -43 \pm 1 mV (n=4 cells), and the chord conductance at -124 mV was 1.7 \pm 0.3 nS (n=8 cells). This current persisted in 1 mM external Ba²⁺ or 4-AP or intracellular Cs⁺, but was blocked by 1 mM external Cs⁺. This current is similar to I_h of photoreceptors and cardiac cells.

I_h was found in 24 out of 48 cells, including both type I and II. I_{K1} occurred in most type II cells, including cells with I_h . We have not yet determined whether I_{K1} occurs in type I hair cells.

(Supported by NIH grant DC02290.)

398.3

K CURRENTS IN TYPE I AND TYPE II HAIR CELLS OF THE RAT UTRICLE. M. Saeki* and R.A. Eatock, Physiology Dept., Univ. of Rochester; Otolaryngology Dept., Baylor Coll. of Med., Houston, TX 77030.

Whole-cell currents in rat utricular hair cells were studied with the ruptured- or perforated-patch technique. Cells with constricted necks were identified as type I; cylindrical cells were identified as type II. A low-voltage-activated K current ($I_{K,L}$) was correlated with type I cells: 95 and 2% of type I and type II cells, respectively, had $I_{K,L}$. $I_{K,L}$ activated above -95 mV and saturated by -30 mV. Boltzmann fits to the activation curve gave a slope (s) of 5 ± 0.2 mV (SEM, $n=6$) and a half-maximal voltage ($V_{1/2}$) that varied between -55 and -73 mV. Because $I_{K,L}$ was substantially on at the zero-current potential (V_z ; -72 ± 1 mV, $n=37$), type I cells had lower input resistances and smaller, faster responses to input currents than did type II cells (V_z : -68 ± 2 mV, $n=22$). The distributions of input resistances at -64 mV of cells with and without $I_{K,L}$ had modes of 21 M Ω ($n=24$) and 3.6 G Ω ($n=40$), respectively. $I_{K,L}$ activation was slow and sigmoidal. It was fit by an equation for a 3 state model (2 closed, 1 open), giving τ 's of ~150 and 30 ms at -64 mV. Type II cells had outwardly rectifying K currents that activated above -60 mV and had variable activation and inactivation kinetics. Monoexponential fits to inactivating currents at +40 mV produced τ 's that varied from 20 ms to 700 ms. The data are consistent with the cells having, in different proportions, two outwardly rectifying conductances with distinct kinetics. The cells with the slowest currents may have just one current; their activation curves were fit with a Boltzmann function with a $V_{1/2}$ of -17 ± 1 mV and an s value of 8 ± 1 mV ($n=14$). Ca^{2+} -dependent K currents in type II cells were negligible, even with the perforated-patch method. (Supported by NIH grant DC02290.)

CALCIUM-ACTIVATED POTASSIUM CHANNELS OF TURTLE HAIR CELLS. J.L. Art*, Y-C. Wu and R. Fettiplace. Department of Neurophysiology, University of Wisconsin, Madison, WI 53706 and Department of Pharmacological and Physiological Sciences, University of Chicago, Chicago, IL 60637.

A major factor determining the electrical resonant frequency of turtle cochlear hair cells in the range 50-500 Hz is the time course of the Ca-activated K current. We have examined the notion that this time course is dictated by the K channel kinetics by recording Ca-activated K channels in inside-out patches from isolated cells. A cell's resonant frequency was estimated from its known correlation with the dimensions of the hair bundle. All cells possess BK channels with a similar unit conductance (300 pS in symmetrical 150 mM K) but with different mean open times of 0.25-12 ms. The time constant of relaxation of the average single channel current (-50 mV, 4 μ M Ca) varied between cells from 0.4 to 13 ms and was well-correlated with the hair bundle height. The magnitude and voltage-dependence of the time constant agree with the expected behavior of the macroscopic K current, whose speed is thus limited by the K channel kinetics. All BK channels had similar Ca sensitivities with a mean half-activation at 5 μ M (0 mV); we estimate that under physiological conditions these channels may be completely activated by a local rise in Ca to 50 μ M. Membrane patches also contained 30 pS SK channels which were about ten times more Ca-sensitive than BK channels at -50 mV. Charybdotoxin (0.1 μ M) blocked both types of K channel. The SK channels may underlie the hair cell's efferent ipsp.

398.7

MOLECULAR CHARACTERIZATION OF A VOLTAGE-ACTIVATED CALCIUM CHANNEL FROM THE CHICKEN'S INNER EAR. R. Kollmar* and A. J. Hudspeth. Howard Hughes Medical Institute and Center for Basic Neuroscience Research, University of Texas Southwestern Medical Center, Dallas, TX 75235.

The influx of Ca^{2+} into hair cells of the inner ear is necessary both for frequency tuning by electrical resonance and for synaptic transmission to auditory neurons. Unlike most other voltage-activated, L-type Ca^{2+} channels, those of hair cells open at a relatively negative membrane potential and are not inactivated by Ca^{2+} influx. To understand the molecular basis of their unique characteristics, we have begun to determine the structure of Ca^{2+} channels from the chicken's inner ear.

Using RNA from the sensory epithelium of the basilar papilla and polymerase chain reactions with degenerate primer pairs, we obtained 5 kilobases of cDNA, lacking only the 5' end, for the α_1 subunit of a voltage-activated Ca^{2+} channel. The predicted protein sequence of the four homologous repeats is more than 90% identical to those of mammalian L-type channels of class D; however, several short stretches diverge markedly from any published sequence. We observed additional diversity at the 3' end: two classes of isolated cDNAs encode alternative cytoplasmic domains at the carboxy termini, neither of which resembles published sequences. We are now testing whether these divergent sequences are expressed in hair cells and whether they account for the unusual electrophysiological properties of the voltage-activated Ca^{2+} channels there.

This work was supported by NIH grant DC00317.

398.4

POTASSIUM CURRENTS IN HAIR CELLS ISOLATED FROM THE TURTLE COCHLEA. M. B. Goodman* and J. L. Art. Committee on Neurobiology, University of Chicago, Chicago, IL 60637.

The frequency of electrical resonance in turtle auditory hair cells in the range 5 to 300 Hz is correlated with the kinetics of the cell's K current. Using whole-cell voltage-clamp recordings, we have examined the extent to which these kinetics are determined by the relative contributions of distinct conductances with different pharmacology, single-channel conductance, calcium- and voltage-sensitivity. In high frequency cells (>200 Hz), superfusion with TEA and 4-AP block the K current with affinities of ~200 μ M and ~10 mM, respectively. The current is also blocked by reduction of extracellular calcium, $[Ca]_o = 1$ μ M, or internal Ca-chelation with 5 mM BAPTA. It is highly voltage-dependent, and noise analysis of the whole cell current suggests a large-amplitude unitary conductance of the calcium-activated, BK type. In low frequency cells (<50 Hz), the K current is less sensitive to TEA ($K_d = 50$ mM) and more sensitive to 4-AP ($K_d = 25$ μ M). This current is resistant to lowering $[Ca]_o$ or intracellular perfusion with 30 mM BAPTA. It activates less steeply with voltage, and the current noise is consistent with a smaller unitary conductance. A K-selective inwardly rectifying current is also present. Cells tuned to intermediate frequencies exhibit a mixture of both 4-AP- and TEA-sensitive K currents. Across the frequency spectrum, an additional, small, voltage-independent K current is present to a variable degree, and it is most easily observed under conditions that elevate $[Ca]_i$. We propose that ionic currents underlying resonant behavior vary systematically in the auditory epithelium and solitary cells that resonate at the lowest frequencies employ an ensemble of K currents distinct from those characterized previously for resonant frequencies greater than 50 Hz. Support: HHMI Predoctoral Fellowship (MBG) & NIH grant DC00454 (JJA).

398.6

CALCIUM REGULATION IN TURTLE COCHLEAR HAIR CELLS.

T. Tucker* and R. Fettiplace. Department of Neurophysiology and Neuroscience Training Program, University of Wisconsin, Madison, WI 53706.

The large size (up to 0.1 nA/pF) of the sustained Ca current in turtle hair cells imposes a considerable burden on the cell's Ca regulation about which little is known. Whole-cell recording of Ca currents from isolated hair cells using cesium-filled electrodes revealed a slow inward component of the tail current which declined over 0.2 to 2 seconds. The size of the tail current increased with the duration of the preceding voltage-step, exhibited a dependence on membrane potential that paralleled the Ca current and, like the Ca current, was blocked by 20 μ M nifedipine. The tail current was abolished by removal of external K but not by removal of Na or Cl. These properties argue that the current is carried through Ca-activated K channels, its time course reflecting the decline in Ca concentration at the membrane. Thapsigargin (0.2 μ M), a specific blocker of the endoplasmic reticulum Ca ATPase, and intracellular vanadate (1 mM) caused a progressive increase in the tail current on consecutive voltage pulses culminating in a permanent activation of an inward K current, which suggests the Ca load was no longer being cleared. We conclude that a Ca ATPase, probably located in an intracellular compartment, plays a major role in the Ca regulation in turtle hair cells and speculate that Ca may eventually be extruded by fusion of the stores with the plasma membrane.

398.8

MOLECULAR IDENTITY OF A POSSIBLE HAIR-CELL MYOSIN I. A. B. Metcalf and A. J. Hudspeth*. Howard Hughes Medical Institute and Center for Basic Neuroscience Research, University of Texas Southwestern Medical Center, Dallas, TX 75235-9117.

The hair cell's mechanosensitive organelle is the hair bundle, an organ-pipe array of stereocilia. A tip link connects each stereocilium to the tallest neighboring process; at or near this connection lie transduction channels that are gated by bundle displacements. During a hair cell's adaptation to protracted stimulation, the current flowing through transduction channels returns toward its resting level. Adaptation is thought to involve adjustment of the tension within tip links by an ATP-requiring molecular motor, possibly a myosin isoform. Consistent with this hypothesis, monoclonal antibodies raised against a bovine myosin I, MMI β , recognize a 120-kDa protein from hair bundles of the frog's sacculus. Immunofluorescence microscopy reveals that this protein is concentrated at the bundles' top edges, where the tip links and transduction channels are located.

To determine the molecular identity of the myosin isoform in hair bundles, we have investigated expression in the frog of a gene similar to that encoding MMI β . Frog brain, which contains a 120-kDa protein recognized by the same antibodies, expresses mRNA whose sequence closely resembles that of MMI β message. The saccular macula contains mRNA with a similar sequence. When expressed in bacteria, a portion of the sequence specifies a fusion protein that is recognized by the antibodies raised against MMI β . We are now attempting to determine the full-length sequence of the myosin message from frog brain.

ELECTROPHYSIOLOGICAL EVIDENCE THAT 'GLUTAMATE' IS A HAIR CELL TRANSMITTER IN THE TURTLE. S.L. Cochran* and M.J. Correia. Dept. Otolaryngology, Univ. Texas Med. Branch, Rt. J63, Galveston, TX 77555-1063.

An acidic amino acid, such as glutamate, has been implicated as the hair cell transmitter in anamniotes (e.g. frogs), which lack Type I hair cells. Since there is scant electrophysiological evidence of the nature of the hair cell transmitter(s) in amniotes, we have recorded from canal afferents of the turtle inner ear (*in vitro*), while bath-applying transmitter agonists and antagonists in order to relate their activity with the endogenous hair cell transmitter-mediated activity. During extracellular recordings from individual afferents, glutamate (5 mM) reversibly induced over a ten-fold increase in the firing rate of the afferents (N=29). Aspartate (5 mM) mimicked this effect (N=5). Kynurenic acid (1 mM) reversibly eliminated the resting firing frequency of the afferents (N=8) and reduced the excitatory action of both of these agonists (N=6). NMDA (0.5 and 5 mM) also resulted in afferent excitation (N=5). GABA (5 mM) had no consistent effect upon afferent firing (N=10), while carbachol (0.5 mM) resulted in an increase in firing, weaker than that induced by glutamate and which to some extent desensitized during application (N=6). These findings are consistent with the hypothesis that glutamate or a related compound is a hair cell transmitter in amniotes as well as anamniotes. The major difference between the turtle and the frog appears to be the sensitivity in the turtle to NMDA, not found in the frog. Otherwise the turtle afferent responses resemble those found from afferents innervated by Type II hair cells in the frog. It is as yet unclear as to whether or not axons innervated by Type I hair cells are also included in the current sample.

LOCALIZATION OF NITRIC OXIDE SYNTHASE IMMUNOREACTIVITY AND NICOTINAMIDE ADENINE DINUCLEOTIDE PHOSPHATE DIAPHORASE IN THE RAT INNER EAR. M.J. Lyon¹, D. Godin¹ and B. Mayer². 1) Dept. Otolaryngology, SUNY Health Sci. Ctr., Syracuse, NY; 2) Inst. Pharmakologie Toxikologie Univ. Graz, Graz Austria.

Nitric oxide (NO) has received considerable attention and appears to play several roles in brain function. There is evidence showing that NO can function as a neurotransmitter (Bredt et al., Nature 351:714, 1991); is involved in ischemic injury (Beckman, Nature 345:27, 1990); plays a role in regulation of cerebral blood flow (Iadecola, Proc. Natl. Acad. Sci. USA 88:4651, 1992). To determine if NO may be involved in inner ear function, a combination of histochemical and immunohistochemical techniques were used (Mayer et al., FEBS Lett 277:215, 1990) to localize nitric oxide synthase immunoreactivity (NOS) within the adult rat temporal bone. Preliminary results show similar patterns of labeling for both techniques. Spiral and Scarpa's ganglion cells are positive as are their nerve projections. Label is also observed within the neuroepithelium of all the vestibular end organs with dense label near base of some hair cells bases. The stria vascularis contained NADPH-diaphorase label but little NOS immunoreactivity. These results indicated that NO may play a role in inner ear function and that a different or previously undescribed type of NOS is located in stria vascularis.

THE PROLIFERATION OF HAIR CELL PROGENITORS IS DEPENDENT ON CELL-SUBSTRATE ADHESION. L.L. Cunningham, J.E. Finley, M.E. Warchol* and J.T. Corwin. Depts. of Otolaryngol. and Neurosci., Univ. of Virginia, Charlottesville, VA 22908.

We conducted experiments to determine whether adhesion to a substrate is required for the proliferation of supporting cells from the chick ear. Basilar papillae and utricle were dissected from young (7-14 days) White Leghorn chicks, and sensory epithelia were cultured for 5-7 days in Medium 199 supplemented by 20% fetal bovine serum. After 1-2 days in culture, hair cells extruded from the epithelium leaving sheets of supporting cells. A subset of the supporting cell sheets attached to the substrate and began proliferating. Other sheets continued to float in the culture medium during the same period. Bromodeoxyuridine (BrdU) was added to each culture for 4 hours to measure the proliferation rates of substrate-adherent supporting cell sheets and free-floating sheets. Eighteen adherent cultures had a mean of 29.2 BrdU labelled cells per 100,000 μm^2 (range: 8-59). Whereas nine free-floating cultures had a mean of 4.66 BrdU labelled cells per 100,000 μm^2 (range: 0-24), a significantly ($p > 0.005$) lower proliferation rate. The supporting cells were in the presence of the many mitogenic growth factors in serum, but only showed a significant proliferation after substrate adhesion, demonstrating that cell-substratum adherence is required for the proliferation of auditory and vestibular supporting cells. Preliminary histochemical studies reveal the presence of integrin receptors on the supporting cells which may be responsible for the adhesion-dependence of their proliferation.

EXPRESSION OF mRNA ENCODING RAT KIDNEY WATER CHANNEL IN RAT ENDOLYMPHATIC SAC. K. Doi¹, S. Iwakura¹, K. Fukazawa¹, M. Sakagami¹, M. Toyama², T. Kubo¹, K. Fushimi³, S. Sasaki³. 1. Dept. of Otolaryngology, Osaka Univ. Med. Sch.; 2. Dept. of Anatomy II, Osaka Univ. Med. Sch.; 3. 2nd Dept. of Internal Medicine, Tokyo Med. Dent. Univ., JAPAN.

The cloning of cDNAs encoding two water channels from rat kidney has been recently completed. One is CHIP28 which is responsible for the high water permeability in the proximal tubule and the descending thin limb of the loop of Henle. Another one is WCH-CD which is specifically expressed in the collecting duct where water reabsorption is regulated by the antidiuretic hormone arginine vasopressin (AVP). In the present study, the expression and cellular localization of water channel in rat endolymphatic sac was investigated, since this end-organ has been believed to be highly water permeable and play the critical role in regulation and reabsorption of endolymph in the inner ear.

Approximately 0.4 μg total RNA was extracted from each endolymphatic sac with GTC-CsTFA method. First strand cDNAs were synthesized from 3 μg total RNA with reverse transcriptase. Two degenerated oligonucleotide primers were designed from the sequence of water channel (WCH-CD) and the homologous cDNAs were amplified by using polymerase chain reaction (PCR). The amplified cDNAs were separated on 1% agarose gel and subcloned into pGEM7zf(+) vector for sequence analysis by using Sanger's dideoxy-termination method. Cryosections of dissected endolymphatic sac were immunostained with anti-WCH-CD/c, a polyclonal antibody against the peptide corresponding to the C-terminal amino acids of WCH-CD.

A cDNA band with the expected size of 369 base pairs was detected on agarose gel after PCR amplification. The sequence analysis identified the expression of mRNA encoding WCH-CD in rat endolymphatic sac. Immunofluorescence staining was detected in the cells lining the lumen of the endolymphatic sac. The results strongly suggest that water channel (WCH-CD) is the molecule responsible for the AVP-mediated reabsorption of endolymph in rat endolymphatic sac.

THE EXPRESSION OF GROWTH FACTOR RECEPTOR GENES IN MAMMALIAN HAIR CELL EPITHELIA ASSESSED BY RT-PCR.

L.D. Saffer and J.T. Corwin*. Depts. of Otolaryngol. and Neurosci., Univ. of Virginia, Charlottesville, VA 22908.

Hair cell loss in the vestibular organs of mammals has been shown to result in the proliferation of supporting cells, which are the progenitors of regenerated hair cells. In normal cell proliferation, mitogenic growth factors must bind to specific receptors before cell division can occur. Since we are interested in controlling hair cell regeneration, we need to identify the receptors that are expressed in these cells. RT-PCR provides a sensitive method to assay for the presence of low levels of messenger RNA for such receptors. Hair cell epithelia were isolated from undamaged utricle of rats, trimmed of all edges and extracellular epithelial cells, and frozen in liquid nitrogen. Total RNA was isolated from these tissues and reverse transcribed into cDNA. Specific oligonucleotide primers were selected from published sequences for growth factor receptors and these were used in hot-start PCR to amplify unique fragments of receptor cDNAs. Positive and negative controls were run with each reaction. PCR products were resolved by gel electrophoresis. These experiments have demonstrated the presence of mRNA for the insulin receptor, but as yet have not shown detectable levels of mRNA for the PDGF receptor, the IGF-1 receptor, or the EGF receptor in central regions of undamaged hair cell epithelia from mammalian utricles. Damaged utricles will be assayed for increased expression of those messages.

CYCLIC AMP IN AN INNER-EAR HAIR CELL SHEET PREPARATION. M.J. Drescher^{1,2}, D.J. Margolis^{1,2} and D.G. Drescher^{1,2,3}. ¹Lab. of Bio-otol., Depts. of ²Otolaryng. and ³Biochem., Wayne State Univ., Detroit, MI 48201.

Previously, we localized adenyl cyclase activity to specific sites within the sensory epithelium of the trout saccular macula, utilizing a modification of Mees' histochemical procedure (Kern et al., Soc. Neurosci. Abstr. 17: 29, 1991). Reaction product was concentrated in the stereocilia and apical surface of the mechanosensory hair cell. Precipitate was also found in two groups of nerve terminals in contact with hair cells, one characterized by efferent synaptic specializations and the second by efferent/afferent synaptic specializations at what appeared to be reciprocal synapses.

With an enzyme immunoassay for cAMP (Amersham, RPN 225), we have now measured cAMP levels in a hair cell sheet preparation for which the hair cell is the only intact cell type. Perchloric acid extracts of the hair cell sheet and associated saccular nerve fraction contained 5.2 ± 1.1 (5) and 15.3 ± 2.7 (5) fmol cAMP/ μg cell protein, respectively [mean \pm SEM (n)]. Depolarization of the hair cell sheet by a 10.5 mM elevation in extracellular $[\text{K}^+]$ in superfusion experiments induced an increase in efflux of cAMP of approximately 0.6 fmol/70,000 hair cells, compared to 11 pmol for glutamate, the latter presumed to be involved in receptorneural transmission. Extracellular application of ATP at 25 μM (5 min) was observed to elicit a 30% increase in intracellular levels of cAMP in the hair cell sheet relative to the paired control, significant by paired-variate analysis ($p < 0.05$, two-tailed *t* test).

The low level of cAMP in the hair cell sheet appears consistent with its limited and site-specific presence in the receptor cell by histochemical determination. The modulation of intracellular cAMP in the hair cell sheet by extracellular ATP, if not elucidated with regard to mechanism, represents preliminary evidence of the existence of a cAMP-mediated second messenger pathway in hair cells.

A MODEL FOR VESTIBULAR PRIMARY AFFERENT INTEGRATION OF HAIR CELL MORPHOLOGICAL POLARIZATION VECTORS. T.C. Chimento*, B.R. Pamas, M.D. Ross. Biocomputation Center, NASA, Ames Research Center, Moffett Field CA 94035-1000.

The functional polarization vectors derived from otolith primary afferents are commonly fit to a cosine. The morphological polarization vectors (MPV) of hair cells contribute to the afferent's response characteristics. Transmission electron microscopy of rat utricle stereocilia demonstrates that adjacent hair cells often have MPVs that vary significantly. Physiological studies of individual hair cells have demonstrated that the functional polarization vector is not described by a cosine. Instead, the differential gains for the positive and negative half cycles are not equal resulting in a clipped response waveform. We believe that this nonlinearity accounts for the deviation from the cosine relationship found by Fernández, et al. (J. Neurophys. 35, 1972) in their studies of otolith afferent responses. We have simulated the effects of hair cell MPVs on the resultant afferent polarization vectors using a simple representation for the nonlinear hair cell input/output characteristics. Early simulation results using this model exhibit the same type of nonlinearity found in otolith afferent fibers. These findings are unchanged when the contributing hair cells have widely varying MPVs. A comparison of the simulation results with otolith response characteristics suggests that the response properties of otolith afferent fibers is consistent with relatively simple integration of input from contributing hair cells. The attendant nonlinearity in the responses results from the input/output characteristics of the hair cells.

AUTORADIOGRAPHIC LOCALIZATION OF MINERALOCORTICOID (TYPE I) BINDING SITES IN THE SENSORY EPITHELIUM OF THE CRISTA AMPULLARIS. P.G. Reddy¹, R.C. Kern² and D.Z. Pitovski¹. Depts. of Otolaryngology - Head and Neck Surgery, ¹Wayne State University, Detroit, MI, 48201 and ²Northwestern University, Chicago, IL 60201.

Aldosterone, a mineralocorticoid, enhances Na retention and K excretion in various ion transporting epithelia. Previous studies have demonstrated that this mineralocorticoid regulates Na, K-ATPase in the inner ear. Na, K-ATPase has been implicated in the maintenance of high K and low Na in endolymph, ionic properties which support transduction by inner ear hair cells. Other studies have revealed a similar pattern of distribution for mineralocorticoid (type I) binding sites and Na, K-ATPase. These results indicate that mineralocorticoids may regulate endolymphatic ion content and thus modulate hair cell transduction. The purpose of our present study was to determine if mineralocorticoid binding sites are associated with sensory hair cells of the crista ampullaris.

The ampullae of the posterior, lateral and superior semicircular canals were dissected from male Hartley guinea pigs and incubated in media containing [³H]-aldosterone (60 nM) and a 1000-fold excess (60 μ M) of RU 28362, a glucocorticoid agonist, to reduce low affinity binding of tritiated ligand to glucocorticoid receptors. Competitive controls were incubated with an additional 2,000-fold molar excess (120 μ M) of unlabelled aldosterone. Specimens were then processed for autoradiographic analysis.

Examination of autoradiographs revealed silver grains in the sensory epithelium of the ampullae. Specifically, binding was localized in the nucleus, cytoplasm, and stereocilia of both type I and type II hair cells. Localization of mineralocorticoid binding sites to these cellular components suggests that aldosterone may participate in both genomic and non-genomic modulation of hair cell transduction.

MACROMECHANICAL ENDOLYMPH PRESSURE AND FLOW DESCRIBE RESPONSES TO STEP MECHANICAL INDENTATION OF THE FISH VESTIBULAR LABYRINTH. R.D. Rabbitt¹*, R. Boyle², S.M. Highstein³, and E.R. Damiano¹. Univ. Utah, Salt Lake City, UT 84112¹; Oregon Health Sci. Univ., Portland, OR 97201²; and Washington Univ., St. Louis, MO 63110³.

A piezoelectric micro-actuator was used to generate mechanical indentations of the long-and-slender region of the horizontal canal (HC) and the utricle (U) in the toadfish, *Opsanus tau*, while recording extracellular afferent responses. In the toadfish, sinusoidal $\pm 1 \mu$ m HC indentation commutes linearly with $\pm 15 \mu$ m U indentation and ± 4 deg/sec head rotation. Having established this correspondence, step mechanical indentation was applied to simulate a step increase in head velocity (Dickman and Corriera, J. Neurophysiol. 62, 1989). Afferent responses show a jump increase ($\tau < 0.02$ sec) in firing rate followed by a fast transient decay ($\tau \approx 1$ sec) and a slow exponential decay ($\tau \approx 30$ sec) approaching the resting rate. The slow exponential is relatively uniform across units and is consistent with models describing the mechanical recovery of the cupula to its original resting position. The jump increase and fast transient decay show significant inter-unit variability, from being absent in some units to exceeding the peak magnitude of the slow response in others. These fast components cannot be described by models of macromechanical cupular displacement or by established processing associated with the hair-cell-afferent complexes. The range of afferent responses to head rotation can be described by a model in which individual units exhibit varying sensitivities to macromechanical endolymph flow and pressure (Rabbitt et al., submitted J. Neurophysiol.). We apply the same model here to describe the afferent responses to the step stimuli. Results show that the fast components can be described by unit-specific sensitivity to macromechanical pressure and the slow decay by the sensitivity to macromechanical displacement of the endolymph. It is presumed that gross endolymph flow and pressure combine within the ampulla to elicit deflections of stereocilia, although the micromechanical and/or biophysical mechanisms responsible for the apparent unit-specific sensitivities to these components remain yet unknown. TOLUENE EFFECTS ON *Gallus domesticus* VESTIBULAR SENSORY EPITHELIA IN THE EMBRYOGENESIS. A. Illescas-Landgrave* and M. Lorenzana-Jimenez. Departamento de Anatomía y Departamento de Farmacología. UNAM, México, D. F. 04510.

All biologically active substances interfere, in one way or another, with the chemical system that governs the homeostatic mechanism of living organism. Many drugs create temporary or permanent alterations in auditory or vestibular function.

The purpose of this study is to show that toluene induces cellular alterations on *Gallus domesticus* internal ear vestibular sensory epithelia during its morphogenesis. To accomplish this purpose 42 fertile stage 6 (23-25 hr), eggs were used arranged on 7 groups. The applied toluene doses were 0.60, 1.12, 2.5, 5.0 and 10 μ L for the first 5 groups; 10.0 μ L of normal saline solution for the 6th group and the last one was taken as a control group. After 14 days of hatching the embryos were removed from their egg-shells. Immediately were beheaded and their internal ear were prepared to be analysed through electronic transmission microscopy. Toluene provoked loss of some hair cells in all cristae and otolithic organs, in other cells we found various stages of degeneration: loss of cilia, cytoplasmic degeneration and vacuolization of membranes. In the supporting cells the common damage observed was edema. These data suggest that toluene injured avian vestibular receptors during the embryogenesis.

RAPID DENDRITIC GROWTH IN VESTIBULAR NEURONS OF PERINATAL CHICKS. K.D. Peusner* and C. Giaume. Dept. Anatomy and Neuroscience Program, George Washington Univ., Washington, D.C. 20037.

The objective of this study was to determine whether perinatal remodeling of primary vestibular synapses in the medulla is accompanied by developmental changes in their target vestibular sensory neurons, the principal cells (PC) of the tangential nucleus. PCs are vestibuloocular collic neurons which receive large axosomatic "spoon" endings from primary vestibular fibers. Spoon synaptogenesis follows an unusual pattern: first in embryos (E7) forming chemical synapses, which then associate with gap junctions (GJs) to form mixed synapses (E15), and finally mainly GJs in hatchlings (H) (Peusner, J. Comp. Neurol. 230:386-392, 1984).

This is the first report describing PC dendritic morphology and comparing them at two ages, E15-16 and H1-2. From preliminary observations made on PCs intracellularly injected with biocytin, we observed that the characteristic oval somata do not change appreciably in size (28 ± 5 SD \times 18 ± 3 μ m; $n=12$ vs. 28 ± 4 \times 17 ± 5 μ m; $n=9$). Also, in our small sample there is no apparent change in the average number of primary dendrites (3.7 dendrites/neuron) nor in the dendritic branching pattern. However, the number of dendritic branch points per neuron increases by 32% (12.7 vs. 16.8) as well as the dendritic spread in both the mediolateral (98% ; 168 ± 87 μ m vs. 333 ± 76 μ m) and the dorsoventral axes (127% ; 103 ± 59 μ m vs. 234 ± 71 μ m). Finally, a major change of 147% was observed in total dendritic length per neuron (605 ± 426 μ m vs. 1495 ± 358 μ m).

These observations suggest that parallel to the important changes occurring at spoon ending terminals at hatching, their postsynaptic target cells rapidly and extensively generate new dendrites. (This work was supported by NIH grant RO1-DC00970).

UNIFORM RESPONSES OF RAT SEMICIRCULAR CANAL AND OTOLITH AFFERENT NEURONS TO TRAPEZOIDAL AND SINEWAVE POLARIZATION OF THE LABYRINTH. J. Kleine and Q.-J. Grüsser, Department of Physiology, Freie Universität, 14195 Berlin, Germany. (SPON: European Neuroscience Association)

Action potentials of primary afferent vestibular neurons were recorded with tungsten microelectrodes from the *Ggl. Scarpa* in pigmented anaesthetized Norwegian rats. Sinewave mechanical stimulation in yaw, pitch and roll (0.5-1 Hz) and steady inclination at different angles around different axes identified the origin of the neurons (semicircular canal or otolith afferents). Galvanic stimulation was applied through electrodes in the ear bars. Most, but not all, of the regularly discharging units (rdu) exhibited sensitivities well below the range observed in irregularly discharging units (idu). When sinewave stimulus frequency was varied between 0.1 and 100 Hz, most rdu and idu followed up to stimulus frequencies of 60-70 Hz at least; some discharged action potentials in a stimulus-dependent pattern (1:1 or 1:2) up to 100 Hz. Depending on sensitivity and spontaneous discharge rate, non-linear response components appeared at varying stimulus amplitudes and frequencies and consisted mainly of a discharge pause during the positive phase of ipsilateral labyrinth polarization. The "galvanic" frequency response properties of afferent neurons from the vertical and horizontal semicircular canals and the otoliths did not differ essentially. At low galvanic sinewave stimulus frequencies (1-2 Hz) the response threshold was about 5 μ A. No responses to galvanic stimulation were obtained in afferent auditory nerve fibers (Supported in part by a BMFT-grant).

399.1

TEMPERATURE DEPENDENCE OF TWO-TONE RATE SUPPRESSION IN THE NORTHERN LEOPARD FROG, *Rana pipiens pipiens*. P.M. Narins*, J.H. Benedix Jr., Marisa Pedemonte and Ricardo Velluti. Univ. of California, Los Angeles, CA 90024.

Stiebler and Narins (1990) reported that increasing body temperature causes low-frequency auditory nerve fibers in the frog to increase their CFs and decrease their thresholds. If two-tone rate suppression (TTRS) and excitatory tuning in the frog were to be codependent on the same processes, then excitation and suppression might be expected to exhibit similar temperature-induced shifts.

The goal of the present study was to define the TTRS existence region in the northern leopard frog and to determine its temperature dependence. Ectotherms such as anuran amphibians may experience daily temperature changes of more than 20°C in their natural habitat; thus it is of biological interest to characterize the temperature-dependence of auditory function in these animals.

Core temperature shifts were induced experimentally and the resulting changes in TTRS were quantified. The existence region of TTRS in the frog was expanded to include a suppressive region below a fiber's characteristic frequency. In response to a 3°C temperature rise, the area and the best suppressive frequency (BSF) of the low-side suppressive region increased significantly. Increasing core temperature of the frog by 6°C resulted in significant changes in the high-side suppressive region: its area decreased, and its BSF and best suppressive threshold (BST) increased. Moreover, constant-temperature control trials were run in which the probe tone was shifted within the tuning curve to partially mimic the temperature-induced changes in neural tuning properties. We found that lowering the probe tone by 0.5 oct had no effect on the low-side suppressive region, but significantly increased the area and lowered the BSF and BST of the high-side suppressive region. Temperature shifts in the frog appear to have a differential effect on the low- and high-side suppressive areas of auditory nerve fibers. Excitation and suppression also respond differentially to 6°C temperature shifts. (Supported by NIDCD grant DC-00222 to PMN and Fulbright Awards to MP and RV)

β 1 CLASS INTEGRIN IMMUNOREACTIVITY IS DEPRESSED IN THE RAT COCHLEA FOLLOWING NOISE INDUCED TTS. N.K. Woolf*, F.J. Koehn, C. Jackson-Friedman, D.V. Jaquish, V.L. Woods, and A.F. Ryan. Depts. of Otolaryngology and Medicine, UCSD and the VA Medical Center, La Jolla, CA 92093.

Previously we demonstrated that fibronectin-like immunostaining in Deiter's cells is transiently depressed following noise induced temporary threshold shift (TTS). The current study investigated temporal changes in β 1 class integrin immunolocalization in the cochlea during TTS and subsequent recovery. Under quiet control conditions, β 1 class integrins are strongly expressed within the cochlea in stria vascularis and spiral ganglion cells. Following exposure to a two-octave band of noise (5656-22,624 Hz) at 115 dB (pSPL), a 30 dB TTS was induced, which resolved within 24 hours. No changes in the intensity of β 1 class integrin immunostaining were observed in the inner ear at 1-24 hours post-exposure. At 7 days post-exposure, a significant decrease in β 1 immunostaining was observed in spiral ganglion cells, but not in stria vascularis. These long term changes following TTS may be explained by either downregulation of β 1 integrin expression or a conformational change in the protein preventing antibody binding.

EXPRESSION OF mRNA ENCODING RAT KIDNEY WATER CHANNEL IN RAT COCHLEA. S. Iwakura¹, K. Doi¹, K. Umemoto¹, M. Toyama², T. Kubo¹, K. Fushimi³, S. Sasaki³, F. Kimura⁴. 1. Dept. of Otolaryngology, Osaka Univ. Med. Sch.; 2. Dept. of Anatomy II, Osaka Univ. Med. Sch.; 3. 2nd Dept. of Internal Medicine, Tokyo Med. Dent. Univ.; 4. Dept. of Neurophysiology, Osaka Univ. Med. Sch., JAPAN.

The cloning of cDNAs encoding two water channels from rat kidney has been recently completed. One is CHIP28 which is responsible for the high water permeability in the proximal tubule and the descending thin limb of the loop of Henle. Another one is WCH-CD which is specifically expressed in the collecting duct where water reabsorption is regulated by the antidiuretic hormone arginine vasopressin (AVP). In the present study, the expression and cellular localization of water channel in rat cochlea was investigated, since the stria vascularis in the cochlea has been believed to play the critical role in regulation of production/reabsorption of endolymph in the inner ear.

Approximately 0.4 μ g total RNA was extracted from each endolymphatic sac with GTC-CsTFA method. First strand cDNAs were synthesized from 3 μ g total RNA with reverse transcriptase. Two degenerated oligonucleotide primers were designed from the sequence of water channel (WCH-CD) and the homologous cDNAs were amplified by using polymerase chain reaction (PCR). The amplified cDNAs were separated on 1% agarose gel and subcloned into pGEM7z(+) vector for sequence analysis by using Sanger's dideoxy-termination method. Cryosections of dissected cochlea were immunostained with anti-WCH-CD/C, a polyclonal antibody against the peptide corresponding to the C-terminal amino acids of WCH-CD.

A cDNA band with the expected size of 369 base pairs was detected on agarose gel after PCR amplification. The sequence analysis identified the expression of mRNA encoding WCH-CD in rat cochlea. Immunofluorescence staining was detected in the marginal cells of the stria vascularis. The results strongly suggest that water channel (WCH-CD) is the molecule responsible for the AVP-mediated reabsorption of endolymph in rat cochlea.

SIZE, DISTRIBUTION, AND THEORETICAL CONDUCTION VELOCITIES OF AUDITORY NERVE FIBERS IN THE FROG INNER EAR. B. Pesaran, D.D. Simmons, P.M. Narins, S. Parham, C. Bertolotto, and A. Newman*. Dept. of Biology and Brain Research Institute, UCLA, and the House Ear Institute, Los Angeles, CA 90024.

The leopard frog (*Rana pipiens pipiens*) has two specialized auditory organs: the amphibian papilla (AP) and the basilar papilla (BP). Nerve fibers to the AP have characteristic frequencies (CFs) from 100-1250 Hz. Nerve fibers to the BP have CFs ranging between 1200 Hz and 3000 Hz. Previous studies suggest that click latency is a function of CF i.e., low CF fibers have maximum response latencies. The purpose of this study was to estimate theoretical conduction velocities (CVs) and compare with known CFs and response latencies.

Frog inner ears were embedded in plastic and 2 μ m sections were cut through the AP and BP nerve branchlets. An automated computer algorithm was used to compute number, diameter, and area of nerve fibers. AP and BP nerves were also prepared for electron microscopy.

The AP nerve had an average of 717 fibers with areas ranging from 2-6 μ m² and diameters between 2-4 μ m. Nerve fibers terminating in caudal (high frequency) regions had smaller diameters than fibers terminating in rostral (lower frequency) regions. Virtually all of the fibers were myelinated (average myelin thickness of 0.13 \pm 0.05 μ m). The BP nerve had 200-300 myelinated fibers with areas between 2-3 μ m², and diameters between 1-2 μ m. Larger diameter fibers were more heavily myelinated and were situated centrally within the nerve bundle.

CVs were estimated for both AP and BP nerve fibers. Rostral terminating AP fibers have the highest estimated CV, while caudal terminating AP fibers and BP fibers have similar estimated CVs. Variables involved in determining response latency are discussed. (Supported by grants from the NSF and the UCLA Academic Senate)

2f1-f2 vs 2f2-f1 DISTORTION-PRODUCT OTOACOUSTIC EMISSION GENERATORS. B.L. Lonsbury-Martin*, G.K. Martin, M.L. Whitehead and B.B. Stagner. Univ. of Miami Ear Inst., Miami, FL 33101.

Early results imply that: 2f1-f2 DPOAEs are produced in frequency regions between the primaries; 2f2-f1 DPOAEs are generated basal to the f2 place; and 2 sources of DPOAE generation exist [one source is relatively invulnerable to cochlear insult and dominates at high primary levels and small f2/f1 ratios, whereas the other operates at low stimulus levels (<65 dB SPL), dominates at large f2/f1 ratios, and is vulnerable to cochlear trauma]. Other data suggest that the high-level generator located basal to f2 at high stimulus levels is the source of 2f2-f1 DPOAEs. The present study examined these notions by measuring detailed suppression areas and the latency of both DPOAEs at 3 primary levels (45,60,75 dB SPL). Suppressor tones swept in 250-Hz steps from 0.25-17.25 kHz were varied in 1-dB steps over a 40-50 dB range, and onset latencies were measured directly from DPOAE-time waveforms. Suppression contours clearly indicated that 2f1-f2 DPOAEs were generated between the primaries, with tuning-curve tips being slightly below f2, whereas 2f2-f1 DPOAEs were tuned slightly above f2. Related onset latencies revealed slightly shorter latencies for 2f2-f1s than for 2f1-f2s, consistent with evidence indicating that the 2f2-f1 is generated basal to the 2f1-f2 place. 2f1-f2 DPOAEs were measured at all primary-tone levels, whereas 2f2-f1 DPOAEs were reliably elicited by 60- or 75-dB SPL primaries, consistent with the notion that 2f2-f1 DPOAEs are generated by the high-level distortion mechanism that operates basally to the generator of low-level, physiologically vulnerable 2f1-f2 DPOAEs. INNER HAIR CELLS IN THE COCHLEA OF THE FETAL BRONX WALTZER MOUSE. D.S. Whifton¹, C. Gabel¹, and X. Zhang². Waisman Center, University of Wisconsin, Madison, WI 53706.

In the adult Bronx waltzer cochlea, more than 75% of the normal number of inner hair cells is missing or deformed. The specific loss of inner hair cells makes the mutant a potentially valuable tool to study the effects of neuron-target interactions on development and neuronal plasticity. Theories differ on whether normal inner hair cells ever form in this mutant, but all observations have been based on postnatal animals. We directly analyzed cochleas from fetal Bronx waltzer mice (E16-E18), using light and electron microscopy. Almost the complete complement of inner hair cells exists in the E17 cochlea. The youngest inner hair cells have a normal, elongated shape; stereocilia are present. Beginning in the base and progressing toward the apex, the cells protrude through the reticular lamina and eventually become rounded. The cells begin to degenerate in the basal turn at about E17-E18, and the degeneration progresses toward the apex by P2. The adhesion molecules NCAM, on nerve fiber and hair cells, and L1, on nerve fibers, show a normal distribution. However, in contrast to normal inner hair cells, inner hair cells in the mutant accumulate the extracellular matrix protein tenascin. In summary: In the Bronx waltzer cochlea, inner hair cells are formed successfully, but shortly thereafter, they express abnormal amounts of at least one protein, tenascin, and most of them degenerate. The sequence of the degeneration suggests that it coincides with the timing of base-to-apex afferent innervation. (Supported by NIDCD grant #R29DC00653).

DOPAMINE RECEPTOR SUBTYPE MESSAGES IN THE MOUSE COCHLEA. D.G. Drescher^{1,2}, J.M. Lasak¹, J. Chomchai¹, M.J. Drescher¹ and K.M. Khan². Lab. Bio-otology, Depts. ¹Otolaryng. and ²Biochem., Wayne State Univ. Sch. of Med., Detroit, MI 48201; and ³Aga Khan Univ., Karachi, Pakistan.

Published evidence indicates that dopamine is present in the auditory inner ear. Presynaptic dense-core vesicles have been observed in olivocochlear fibers by electron microscopy, and dopamine has been detected at femtomole levels in the rat cochlea by HPLC. Immunocytochemical studies of olivocochlear fibers in the cochlea and neurons in the lateral superior olivary complex have suggested the presence of tyrosine hydroxylase and absence of dopamine β -hydroxylase and phenylethanolamine N-methyltransferase.

We have utilized polymerase chain reaction (PCR) analysis to identify messages for dopamine receptor subtypes in the mouse cochlea. Specific D1A and D1B receptor primers were designed based on published rat brain sequences, and D2, D3, and D4 subtypes formulated from the corresponding mouse brain sequences. Poly A RNA was isolated from total RNA in guanidine thiocyanate extracts of cochleas of 30 CBA_J mice (16 days old) and reverse-transcribed with oligo dT primer. PCR-amplified products were separated by agarose gel electrophoresis. Results were compared to those obtained without reverse transcription (negative control) and to those using mouse brain RNA with reverse transcription (positive control).

PCR primers for all of the dopamine receptor subtypes yielded bands of expected molecular mass with cDNA from mouse brain samples, indicating that the primers were functioning. The primer designed to detect the D2 long form produced a PCR amplification product of the predicted size from mouse cochlear cDNA. D1B, D3, and D4 primers yielded faint bands after PCR amplification. The D1A amplification product was not observed. These results suggest that dopamine has a neurotransmitter role in the cochlea.

AUDITORY SYSTEMS: CENTRAL ANATOMY I

400.1

REEVALUATION OF FUNCTIONAL COMPONENTS OF THE CRANIAL NERVES. K.M. Khan^{*}. Dept. of Anatomy, The Aga Khan University, Karachi 74800, Pakistan.

The four functional components of the cranial nerves are classified as general somatic and visceral afferents and efferents. Three additional components associated with special senses are also recognized to be present in certain cranial nerves. These fibers are classified as special visceral afferents (olfactory and gustatory), special visceral efferents (striated visceral muscles), and special somatic afferents (visual, auditory, and vestibular). The sensory cells of the vertebrate inner ear are innervated by both vesiculated and nonvesiculated endings: the vesiculated endings are regarded to be efferent in nature. Anatomical studies in all classes of vertebrates have invariably demonstrated that these efferent fibers originate from specific brain stem nuclei. The vesiculated endings form axosomatic synapses with the sensory cells as well as axodendritic synapses with the peripheral processes of the bipolar sensory neurons of the 8th cranial nerve. Physiological data indicate that efferent innervation of the sensory cells of the vertebrate inner ear is either facilitatory or inhibitory in function. Establishment of efferent innervation of the vertebrate inner ear merits a reevaluation of functional components of the cranial nerves. This report is suggesting that these efferent fibers be classified as "special somatic efferent" component of the cranial nerves.

POSTNATAL IMMUNOREACTIVITY AND RETROGRADE LABELING OF OLIVOCOCHEAR NEURONS IN THE BRAINSTEM. D.D. Simmons^{*}, J. Raji-Kubba, and J.H. Kim. Dept. of Biology and Brain Research Institute, UCLA, Los Angeles, CA 90024-1606.

The olivocochlear (OC) system is the major efferent pathway to the cochlea and is responsible for modulating activity of the cochlear nerve. Acetylcholine and calcitonin gene-related peptide (CGRP) both serve as neurochemical markers for the OC system. Very little is known about the maturation of this brainstem system. Standard immunohistochemical and an *in vitro* brainstem technique were used. OC neurons were defined by injections into the crossed OC bundle (COCB) at the floor of the IV ventricle.

During the first postnatal week, all COCB injections resulted in labeled terminals under IHCs and labeled cell bodies in the VPO region of the superior olive. Both ChAT and CGRP immunoreactive cell bodies were either non-existent or weakly labeled during within the VPO and LSO. During the second and third postnatal weeks, injections resulted in labeled terminals underneath IHCs and OHCs. The majority (>70%) of retrogradely labeled cell bodies were in the VPO region. Retrogradely labeled and ChAT positive cells had similar VPO distributions. A smaller (< 15%) population of LSO capsular cells also were retrogradely labeled and double labeled with ChAT antibody. The ChAT positive VPO cells were distinct from ChAT positive LSO cells. ChAT positive LSO cells had similar distributions to CGRP positive LSO cells. The majority of double labeled ChAT and CGRP cells were found either in the medial limb of the LSO or in the capsular regions of the LSO.

Thus, the majority of COCB cell bodies are ChAT positive, CGRP negative, and found within VPO regions. Our results are consistent with the hypothesis that periolivary OC neurons initially terminate on IHCs and then on OHCs before their neurotransmitter expression is mature. THE ROLE OF MINERALOCORTICOIDS IN THE REGULATION OF COCHLEAR HOMEOSTASIS. H.H. Salem¹, W. S. Quirk¹, J. A. Kaltenbach² and D.Z. Pitovski¹. Dept. of Otolaryngology-Head and Neck Surgery¹ and Dept. of Audiology², Wayne State University, Detroit, MI 48201.

Although many studies have localized receptors postulated to control cochlear blood flow, there is still a dilemma about the exact mechanisms by which these receptors modulate inner ear function. A previous autoradiographic study conducted in our laboratory localized mineralocorticoid (type I) receptors in the walls of cochlear vasculature (Sinha et al., Soc. Neurosci. Abstr. 580.2: 1418, 1993). Furthermore, the possible physiological significance of these receptors in the regulation of cochlear blood flow (CoBF) was assessed by use of laser Doppler flowmetry (Sinha et al., Assoc. Res. Otolaryngol. Abstr. 13: 303, 1990). In both studies, we postulated that mineralocorticoids participate in regulation of CoBF.

In order to elucidate the mineralocorticoid participation in cochlear homeostasis, male Hartley guinea pigs were infused with aldosterone (10 μ g/kg) for 10 min. Continuous measurements of lateral wall capillary blood flow velocity were assessed with intravital microscopy. Blood samples, withdrawn 2 and 60 mins following completion of infusion, were analyzed for serum aldosterone and electrolytes values. Preliminary results show that serum aldosterone levels fell significantly after 60 min post-infusion (731 ng/dl) compared to its 2 min post-infusion levels (5200 ng/dl). Systemic blood pressure, serum electrolyte values (Na⁺, K⁺ and Cl⁻), and capillary blood velocity were unchanged during the experimental protocol. The stability of capillary velocity supports the presence of autoregulatory mechanism for CoBF which preserves constant capillary blood perfusion. Future studies, especially the functional effects of such steroids on arteries (and arterioles) supplying the cochlea, are needed to further delineate the association between mineralocorticoid hormones and cochlear vasculature. (Supported by NIH CIDA DC00046 and NIH T32 DC00026)

400.2

COMPARISON OF AVIAN AND MAMMALIAN COCHLEAR EFFERENT NEURONS. R.A. Code^{*}. Dept. of Zoology, Univ. of Maryland, College Park, MD 20742-4415.

Neurons of the mammalian olivocochlear (OC) system can be divided into two groups based on their location in the superior olivary complex and on their morphology. Neurons in the lateral OC group (LOC) are usually ovoid or fusiform in shape and project primarily to the ipsilateral cochlea, while those in the medial OC (MOC) group are typically stellate or radiate and project predominantly to the contralateral cochlea. The LOC and MOC can also be distinguished neurochemically: some cells of the LOC that are immunoreactive for choline acetyl transferase (ChAT), the biosynthetic enzyme for acetylcholine, are also immunoreactive for the neuropeptide, enkephalin (ENK) and calcitonin gene-related peptide (CGRP). Although cells in the MOC stain for ChAT, they do not appear to colocalize ENK or CGRP (see Eyalin, '93 for review). In order to determine whether the chick OC system can be divided into two neurochemically distinct groups similar to those in mammals, we studied cochlear efferent neurons in the brainstem of the chick (*Gallus domesticus*) using antisera to ChAT, to leu- and met-ENK, and to CGRP. Similar to mammals, ChAT-immunoreactive (ChAT-I) OC neurons in the chick brainstem are found in two groups. The morphologies of chick OC neurons, however, appear to be more varied than those of mammals and do not appear to be spatially segregated within these two groups as are those in the LOC/MOC. Some CGRP-I neurons in the chick are in locations similar to ChAT-I OC cells. Unlike mammals, chick OC neurons are not ENK-I; instead, they appear to receive ENK-I terminals. Thus, there are several striking differences in the organization of the avian and mammalian OC systems.

The ChAT antiserum was kindly provided by Dr. Miles Epstein, U. Wisconsin, Madison; the CGRP antibody was donated by Dr. Catia Sternini, UCLA. This work was supported by NIDCD grant DC01867 to RAC.

400.4

THE CYTOARCHITECTURAL ORGANIZATION OF THE MEDIAL OCTAVOLATERALIS NUCLEUS OF THE GOLDFISH. J.G. New¹, S. Coombs¹, C.A. McCormick², and P. Oshel¹. ¹Parham Hearing Institute and Biology Department, Loyola University of Chicago, IL 60626 and ²Oberlin College, Oberlin, Oh. 44074.

The cytoarchitecture of the medial octavolateralis nucleus (MON), the principal first-order nucleus of lateral line mechanoreceptors, is not well known in any fish. Using Golgi, immunocytochemical and other histological techniques, we recognize at least three layers associated with the MON. The molecular layer (cerebellar crest) consists of axons from granule cells in the eminentia granularis and axons with GABAergic terminals from cells in the metencephalic nucleus praeeminentialis. Apical dendrites from underlying crest cells extend into the molecular layer, where small, intrinsic neurons are also found. The principal cell layer is composed of large multipolar (crest) cells known to project to the torus semicircularis. Some crest cells have a single, thick basilar dendrite that extends into deeper nuclear regions, whereas others have 2 or more thin basilar dendrites that ramify near the cell body. The deep layer consists of ventral dendrites of overlying crest cells, small intrinsic neurons, terminals from primary afferent fibers and commissural GABAergic neurons. The goldfish MON shares a number of organizational features with first-order nuclei of other octavolateralis systems and thus, its function may be shaped by similar neural circuits.

EVIDENCE FOR NEUROMODULATORS IN THE COCHLEAR NUCLEI OF THE NEWLY HATCHED CHICK. E.G. Dobbins* & G. Laurent, Division of Biology, 139-74, California Institute of Technology, Pasadena, CA 91125.

Glutamate mediates rapid transmission of auditory information between the VIIIth cranial nerve afferents and the cochlear nuclei. The presence of glutamate (Raman & Trussell, *Neuron*, 9(92):173) and GABA (Code & Churchill, *Hearing Res.* 54(91): 281) receptors in chick, and of GABAergic terminals in owl (Carr, Fujita, & Konishi, *J Comp. Neurol.* 286(89):190) has been demonstrated. The potential contribution of neuromodulators to transmission across these primary synapses is unknown. The existence, and possible co-localization of neuromodulators with GABA and glutamate, in the avian cochlear nuclei has not been investigated. Immunohistochemistry was used to locate somata and terminals containing acetylcholine, catecholamines, and neuropeptides in the cochlear nuclei of the newly hatched chick. Preliminary results suggest that serotonin and acetylcholine are not present. Somatostatin is found in terminals in nucleus angularis (NA) but not magnocellularis (NM) or laminaris (NL), and in no somata. Substance P is found in terminals in NA and caudolateral NM, and in no somata. Enkephalin (5-L-methionine) is found in somata and terminals of NA. Cholecystokinin was found in somata: NM>NA>NL, and in terminals in NA. Supported by NIMH and the McKnight Foundation.

Retrograde labeling of cochlear ganglion cells with injection of biotinylated dextran (BD) into granule-cell (GC) and small-cell-cap (SCC) regions of the cat anteroventral cochlear nucleus (AVCN). D.O. Kim*, K. Parham, H. Zhao and S. Ghoshal, Div. Otolaryn., Surg. Res. Ctr., Ctr. Neurol. Sci., Univ. Conn. Health Ctr., Farmington, CT 06030-1110

The SCC (also called juxtagranular) region of the cat AVCN receives preferential input from low spontaneous rate (SR) auditory nerve fibers (Liberman, 1991). Low-SR cochlear ganglion cells are preferentially located on the scala vestibuli (SV) side (Kawase and Liberman, 1992). From these two, we hypothesize that a focal injection of a tracer restricted in the SCC region should label ganglion cells preferentially located on the SV side. The goal of this study is to evaluate this hypothesis. After a 3-10 day survival period following BD injection, the cats were perfused. The label yielded Golgi-like filling of ganglion cell somata and their axons. In cases where the injection was centered in the deep AVCN or deep DCN, the labeled cells tended to be evenly distributed on the SV and scala tympani (ST) sides in general. In cases where the injection target was the GC/SCC region, by contrast, labeled cells in certain ganglion regions were preferentially on the SV side. This supports the hypothesis. A complicating factor was that there were additional ganglion regions in the latter cases with labeled cells either on the ST side or evenly distributed. Also in these cases, label was found in type II ganglion cells and olivocochlear bundle (OCB) fibers in the intraganglionic spiral bundle. This confirms previous findings that the GC/SCC region receives input from type II cells and OCB collaterals. [Supported by NIDCD-NIH]

SYNAPTAPHYSIN IMMUNOREACTIVITY IN THE COCHLEAR NUCLEUS AFTER COCHLEAR ABLATION. C.G. Benson*, J.S. Gross, S.K. Suneja and S.J. Potashner, Department of Anatomy, University of Connecticut Health Center, Farmington, CT 06030.

A monoclonal antibody to synaptophysin, an integral membrane protein found in presynaptic vesicles, was used to immunohistochemically quantify changes in nerve terminal density in the guinea pig cochlear nucleus (CN) 2-161 days after complete unilateral cochlear ablation. In the ipsilateral ventral CN a significant reduction in the density of immunoreactive synaptic profiles was apparent 4-7 days after ablation, presumably corresponding to the loss of cochlear afferents. In the anterior division of AVCN immunoreactive density decreased to 35% of that contralaterally, and in the anterior part of PVCN to 62%. No reduction in immunoreactive density was seen in the deep layer of DCN. After 161 days there was an apparent complete restoration of immunoreactive density in the ventral CN. In PVCN this increased density could be attributed to progressive tissue shrinkage, presumably resulting from loss of cochlear nerve fibers, but in the AVCN tissue shrinkage only partially accounted for the increased density. These results suggest that the initial loss of synaptic terminal density in the AVCN after cochlear ablation may be followed by a partial resurgence at longer survival times. (Supported by DC00199 from NIDCD).

A GOLGI STUDY OF THE COCHLEAR NUCLEUS ANGULARIS IN THE BARN OWL. J.R. Carpenter and C.E. Carr*, Dept. of Zoology, Univ. of Maryland, College Park, MD 20742-4415.

Sound localization in vertebrates is achieved largely by analysis of available binaural disparities. Previous work has demonstrated that two major localization cues are interaural time differences (ITDs) and interaural intensity differences (IIDs). Moreover, such functional specialization may be reflected in structural characteristics of individual auditory cell types.

The barn owl (*Tyto alba*) is a nocturnal predator that relies on the accurate processing of binaural information to locate prey. The incoming auditory nerve fibers bifurcate upon entering the brainstem, innervating the cochlear nucleus magnocellularis, the first step in a time-coding pathway, and the cochlear nucleus angularis (NA), which encodes sound-intensity information.

Rapid-Golgi impregnated material from existing collections was used for the present study. Selected sections of NA from 3-to-30-day posthatch owls were examined by light microscopy and camera-lucida drawings were made of various cells. Observations include:

1. NA resembles an inverted U-shape oriented dorsomedial to ventrolateral on the dorsolateral edge of the brainstem, with a hilus extending ventromedially.
2. NA contains at least nine specific cell types, as defined by morphology, location and relation to afferent fibers.
3. Several cell types bear considerable morphological similarity to cell types previously defined in the mammalian posteroventral and dorsal cochlear nuclei.
4. A small cell cap containing granule and fusiform-like cells is present on the dorsolateral aspect of NA throughout its rostrocaudal extent.

The results suggest structural parallels in the cellular organization of the avian and mammalian primary auditory nuclei, possibly due to common principles of information coding.

REDUCED AUDITORY FUNCTIONAL ACTIVITY REVERSES SPONGIFORM DEGENERATION OF THE GERBIL COCHLEAR NUCLEUS. B.T. Faddis* and M.D. McGinn, Dept. Otolaryngology, Univ. of Calif. Sch. of Med., Davis, CA 95616

Spongiform degeneration of the gerbil cochlear nucleus has been shown to be dependent on auditory functional activity. The degenerative lesions primarily affect dendrites while sparing the neuronal cell body.

Ligation of the external auditory canal (EAC) in Mongolian gerbils for one week resulted in >30 dB elevation in ABR thresholds at frequencies from 1-32 kHz. This manipulation reduced the area density of a naturally occurring spongiform degeneration in the ipsilateral cochlear nucleus to 30% of that found on the contralateral (unligated) side.

Ultrastructural studies showed that some lesions "fill in" with a tubulovesicular material. Aggregations of mitochondria and filaments are also found. The tubulovesicular material is immunoreactive with antibodies to glucose regulated protein-78 (grp78), an ER-resident protein involved in the proper assembly and folding of newly synthesized proteins.

COCHLEAR ABLATION: LONG-TERM EFFECTS ON UPTAKE AND RELEASE OF D-ASPARTATE, GLYCINE AND GABA IN BRAIN STEM AUDITORY NUCLEI. S.K. Suneja, C.G. Benson and S.J. Potashner*, Department of Anatomy, University of Connecticut Health Center, Farmington, CT, 06030.

To determine if unilateral cochlear ablation leads to plastic changes in the auditory nuclei, the freshly dissected guinea pig brain stem was cut transversely into 500 µm slices and samples of the LSO, MSO, MNTB, VNLL, and ICc were microperfused to measure uptake and release activities. Five days after cochlear ablation, ³H-D-aspartate uptake and release were decreased slightly in the LSO, MSO and VNLL bilaterally, but these activities returned toward control levels at 59 and 145 days. ³H-D-Aspartate uptake and release were increased slightly at 59 and 145 days in the MNTB and ICc bilaterally. ¹⁴C-Glycine or ¹⁴C-GABA release, unchanged after 5 days except for a bilateral increase in ¹⁴C-GABA release in the ICc, increased slightly at 59 and 145 days in the MSO, MNTB, and ICc bilaterally. ¹⁴C-Glycine uptake decreased after 5 days, but increased at 59 and 145 days in the LSO and MSO bilaterally. Although modest, these changes suggest that unilateral cochlear ablation may lead to plastic compensatory responses in auditory brain stem nuclei.

400.11

EXPRESSION OF C-FOS IN THE AUDITORY BRAIN STEM FOLLOWING ELECTRICAL STIMULATION OF THE COCHLEA. S. Nagase, H.H. Lim, J.M. Miller* and R.A. Altschuler. Kresge Hearing Research Institute, University of Michigan, Ann Arbor, MI 48109-0506.

C-Fos expression (as a marker for activation of neurons) was examined in the brain stem of deafened and undeafened rats after electrical stimulation with cochlear implants. Rats were either normal hearing or deafened by inner ear injection of neomycin. After assessment of auditory brain stem response (ABR), cochleae were implanted with electrodes. Either a single ball electrode was inserted in scala tympani of the basal turn of the cochlea or bipolar electrodes were inserted into basal and apical turns. Three days later electrically evoked ABRs were taken; after five days animals were electrically stimulated at three times the EABR threshold for 90 minutes. Thirty minutes after the cessation of stimulation animals were anesthetized and perfused with 4% paraformaldehyde. Vibratome sections were cut through the auditory brain stem and sections were immunoreacted with antiserum to C-FOS (Oncogene Sciences) using ABC Vector Stain immunoperoxidase methods.

In both hearing and deafened animals, many C-Fos immunoreactive (IR) neurons were observed ipsi and contralateral to the stimulated side in the dorsal cochlear nucleus, nuclei of the lateral lemniscus and the inferior colliculus. The C-Fos IR cells were arranged in band-like patterns in the IC and the contralateral DCN. The number of IR neurons increased with bipolar stimulation. C-Fos IR neurons were occasionally seen in the superior olivary complex in periolivary nuclei and the lateral superior olive. One deafened animal demonstrated many C-Fos IR cells in the ventral cochlear nucleus but this was atypical. These results suggest that C-Fos upregulation may provide a method for assessing central auditory activation with cochlear implants and may be useful for comparing different stimulation paradigms as well as assessing their influence on deafness-related changes.

MUSCARINIC ACETYLCHOLINE RECEPTORS IN RAT COCHLEAR NUCLEUS: AUTORADIOGRAPHIC DISTRIBUTION OF [³H]SCOPOLAMINE BINDING. W. Yao* and D.A. Godfrey. Dept. of Otolaryng., Med. Coll. of Ohio, Toledo, OH 43699.

There is evidence that cholinergic effects in the cochlear nucleus (CN) may be mediated primarily by muscarinic acetylcholine receptors (mAChR). We used [³H]scopolamine to study mAChR distributions in the rat CN by receptor binding autoradiography. Rat brain sections 15 μ m thick were incubated with 10 nM [³H]scopolamine at 20 °C for 30 min, followed by two 5-min rinses with cold PBS-EDTA and a brief cold H₂O rinse. The sections were exposed to ³H sensitive film for 2 weeks, followed by exposure to NTB2 emulsion for 2 weeks. The scopolamine binding densities in various CN subregions were estimated by measurements of optical density (using NIH Image 1.44, courtesy of Dr. E. Tietz). The specificity of scopolamine binding was confirmed by blocking with 1 μ M atropine. To determine which mAChR subtypes participate in the binding, we included unlabeled subtype-preferential ligands in some preparations to block [³H]scopolamine binding. Overall CN binding was measured on isolated CN portions of sections incubated with [³H]scopolamine with and without unlabeled ligands, followed by scintillation counting. Our preliminary results suggest that scopolamine binding is highest in granular regions, followed in order by dorsal CN (DCN) deep and fusiform soma layers, DCN molecular layer, posteroventral CN, anteroventral CN, and auditory nerve root (which was similar to background). Ligands which preferentially block some mAChR subtypes competed more effectively than others with scopolamine binding. (Supported by NIH grant DC 00172)

LOCALIZATION OF GLYCINE RECEPTOR IN THE RAT COCHLEAR NUCLEUS AND SUPERIOR OLIVARY COMPLEX. K. Sato, H. Kuriyama, J. Dupont, J. Bonneau and R.A. Altschuler.* Kresge Hearing Research Institute, The University of Michigan, Ann Arbor, MI 48109-0506.

Glycine is a major inhibitory transmitter that is especially prominent in the cochlear nucleus and superior olivary complex. The glycine receptor is composed of α subunits, a β subunit and a 93 K anchoring protein (AP), also termed gephyrin. Different subunits can combine to form complexes with different physiological properties. We used radioactive and non-radioactive *in situ* hybridization methods to localize neurons expressing glycine receptor subunits in the cochlear nucleus and superior olivary complex. This expression was then compared to immunolocalization of the 93 K AP. In the lateral superior olive (LSO) and medial nucleus of the trapezoid body (MNTB) the amount of expression of different subunits was compared to number of glycine immunoreactive terminals received as well as the amount of 93 K AP. Expression of β , $\alpha 1$ and $\alpha 3$ subunits were seen over principal cells of all major CN and SOC nuclei, while the expression of the $\alpha 2$ subunit was considerably lower. All cell types that showed expression of these subunits also showed immunoreactive labeling for the 93 K AP. While there was good correlation between the number of 93K AP immunoreactivity and the amount of glycine immunoreactive innervation a cell received, there was not always a correlation between the number of silver grains over cells expressing receptor subunits and the glycinergic innervation. LSO principal neurons receive many more glycinergic terminals than MNTB principal neurons. There was a comparable increase in expression of the $\alpha 3$ subunit but not of the β subunit. We are continuing this quantitative assessment and comparison.

Supported by NIDCD Grant # DC 00383.

CHARACTERIZATION OF MOSSY FIBER PROJECTIONS FROM THE CUNEATE NUCLEUS TO THE COCHLEAR NUCLEUS. D.D. Wright*, T. Pongstaporn, and D.K. Ryugo. Center for Hearing Sciences, Depts. of Neuroscience and Otolaryngology, Johns Hopkins University Sch. of Med., Baltimore, MD 21205

The cochlear nucleus (CN) is a brainstem auditory nucleus which receives direct input from the auditory nerve. Some non-auditory inputs to the CN have also been described, including a somatosensory projection from the cuneate nucleus (Weinberg and Rustioni, 1987, *Neurosci.*, 20:209-219). We have recently shown that the cuneate projections form mossy fiber terminals in the granule cell domains of the dorsal CN (Wright and Ryugo ARO Abst., 1994). Further studies using the anterograde tracer *Phaseolus vulgaris* leucoagglutinin (PHA-L) combined with immunofluorescence have demonstrated that cuneate projections give rise to mossy fiber terminals in granule cell domains throughout the CN. The trajectory of the cuneate fibers is demonstrated in coronal sections of the brainstem where fibers are seen traversing the descending tract of V before entering the dorsal acoustic stria. Labeled fibers course along the stria for varying distances before entering the nucleus at different dorso-ventral levels, where they give rise to many *en passant* and terminal boutons in granule cell regions.

Cuneate mossy fiber terminals contain round synaptic vesicles and form asymmetric synapses with their targets, indicating that they are excitatory in nature. Using immunocytochemical techniques, we have begun to investigate which neurotransmitter is used by the cuneate mossy fibers. Preliminary experiments indicate that anterogradely labeled cuneate fibers are not double labeled with an antibody against choline acetyltransferase (Boehringer Mannheim), an enzyme used in the synthesis of acetylcholine. However, in adjacent sections, PHA-L labeled cuneate fibers coincide with glutamate immunoreactive fibers. We will test the hypothesis that the cuneate mossy fibers are glutamatergic using double labeling techniques for PHA-L and glutamate at light and electron microscopic levels.

MORPHOLOGICAL AND MORPHOFUNCTIONAL CHANGES IN THE ADULT GUINEA PIG AND RAT BRAINSTEM AUDITORY NUCLEI AFTER DESTRUCTION OF THE INNER EAR. J. Dupont, J.M. Bonneau, K. Sato, S. Bledsoe*, J.M. Aran and R. Altschuler. Kresge Hearing Research Institute, Ann Arbor, MI 48109.

In this study, changes in cell size, GABA and glycine immunoreactivities, glycine receptor subunit expression and neurotransmitter release have been analysed in auditory brainstem nuclei after unilateral and/or bilateral deafferentation. Evaluations of these changes were performed by morphometrical and image analysis of the cells, of GABA and glycine immunocytochemistry, by *in situ* hybridization of glycine receptor subunits and the implantation of microdialysis probes in brainstem auditory nuclei. Most of the neurons within the lateral superior olive (LSO) are able to shrink and then recover to their normal size after uni- or bilateral destruction. This morphological plasticity parallels the changes in the density of GABA+ cell bodies in the LSO and in the central nucleus of the inferior colliculus. The fact that this plasticity of the auditory neurons is also observed in bilateral deafferentation suggests that the central auditory system (CAS) of adult mammals has the property to recover even after total auditory deprivation. We also observe an ipsilateral decrease of glycine positive terminals in the medial nucleus of the trapezoid body (MNTB) and the dorso medial peri-olivary nucleus with a simultaneous bilateral decrease following unilateral deafferentation. Modifications of glycine immunoreactivity in LSO and MNTB appear to parallel some interesting changes in the expression of the different glycine receptor subunits. We are trying now to correlate these morphofunctional changes of the neurotransmitters with our results of microdialysis in the same experimental model. Even if the mechanisms behind these changes are still unknown, our results indicate that the CAS of mature mammals has a remarkable property of plasticity in response to partial or total auditory deprivation. SYNAPTIC ORGANIZATION WITHIN THE MEDIAL SUPERIOR OLIVE OF UNILATERALLY DEAFENED GERBILS. F.A. Russell and D.R. Moore.* University Laboratory of Physiology, Parks Road, Oxford OX1 3PT, U.K.

Neurons of the medial superior olive (MSO) are thought to contribute to sound localization by signalling the temporal correlation between excitatory input from the left and right anteroventral cochlear nuclei (AVCN). Following unilateral cochlear ablation in infancy (P0-P5), neurons in the ipsilateral AVCN die and axons from AVCN neurons on the unoperated side innervate the MSO in regions vacated by terminals from the operated side. Cochlear ablation after P10 does not produce these effects. We have used electron microscopy to examine sagittally sectioned tissue from the ipsilateral MSO of normal, P5 and P18 ablated gerbils. Synapses were classified on the basis of synaptic morphology as round (R), pleomorphic (P) or flat (F). Samples were collected at 15 μ m intervals from 60 μ m either side of the nucleus center. All types of synapses were found on both sides of the MSO in all animals. R synapses were found throughout the medio-lateral extent of the nucleus. P and F synapses were more abundant around the soma. Ablation at P5 did not reduce the density of R terminals on the operated side of the nucleus, but vesicle numbers per synapse were reduced. Ablation at P18 also resulted in reduced vesicle numbers and in a reduction in the number of dendrite profiles and synaptic active sites on the ablated side of the nucleus.

400.17

LARGE SYNAPTIC TERMINALS IN THE LATERAL NUCLEUS OF THE TRAPEZOID BODY OF THE CAT ARE PEP-19 IMMUNOREACTIVE. G.A. Spirou* and A.S. Berrebi. Dept. of Otolaryngology, West Virginia Univ. Sch. of Med. Morgantown, WV 26506-9200.

The lateral nucleus of the trapezoid body (LNTB) is a prominent periolivary cell group that contributes a large feedback projection to the cochlear nucleus. This cell group is known to receive ascending activation via collaterals of globular bushy cell axons, although existing descriptions of these terminals are sketchy. We have determined that PEP-19 antiserum labels substantial numbers of fibers and terminals in the LNTB, including globular bushy cell axons (Berrebi and Spirou, this volume). We studied the immunolabeled terminals using both light (LM) and electron microscopy (EM) to gain a clearer picture of globular bushy cell inputs to the LNTB.

Based on LM terminal labeling patterns, two zones within the LNTB can be identified. The first zone, located medially and ventrally and concentrated caudally, contains large PEP-19-IR puncta and fibers. The puncta in many cases form rings which define the perimeters of immunonegative cell bodies, and are typically on the order of 6-8µm². The second and larger zone is distinguished by having the highest density of immunolabeled puncta and fibers. This zone contains some large punctate profiles, although on average puncta are smaller than in the first zone and do not form pericellular rings. Pre-embedding EM immunocytochemistry reveals PEP-19-IR presynaptic boutons apposed to unlabeled cell bodies and dendrites. Their internal morphology is consistent with their being excitatory terminals.

These results support the notion that LNTB neurons are rapidly and securely activated by bushy cells, and may exert rapid feedback effects on cochlear nucleus neurons. Supported by NIH grant DC01387

ORIGINS AND TARGETS OF THE COMMISSURAL CONNECTIONS BETWEEN THE COCHLEAR NUCLEI IN GUINEA PIGS.

B.R. Schofield*, Dept. Neurobiology, Duke Univ., Durham, NC 27710.

Projections from the ventral cochlear nucleus (CN) to the opposite CN and to the inferior colliculi (IC) arise primarily from multipolar cells. In our first experiment, we injected different fluorescent tracers into one CN and into each IC to determine whether individual cells project to more than one of these targets. Each of the 3 tracers labeled many cells in the uninjected CN; however, no individual cell in the ventral CN contained more than one tracer. Thus, commissural projections and collicular projections arise from different populations of cells.

In a second experiment, we injected PHAL into one CN and examined the labeled axons in the other CN. In the ventral CN, labeled boutons appeared to contact primarily multipolar cell somas but were also seen apposed to spherical and globular cell somas. Many labeled terminals were also found in the granule cell regions of the CN and in the deep layer and fusiform layer of the dorsal CN.

The commissural projections arise from cells that do not project to the IC. It appears that CN cells that *do* project directly to the IC, including a subset of multipolar cells in the ventral CN as well as cells in the dorsal CN, are themselves targets of the commissural projections. Other cell types, namely globular and spherical cells, are also targets of commissural projections. These cell types project to the IC indirectly, via relays in the superior olivary complex. The commissural projections thus provide an opportunity for binaural interactions at early stages in a variety of ascending auditory pathways.

PEP-19 IMMUNOLABELING OF VCoN BUSHY CELLS AND THEIR TERMINALS IN THE SUPERIOR OLIVARY COMPLEX OF THE CAT. A.S. Berrebi* and G.A. Spirou, Dept. of Otolaryngology, West Virginia University School of Medicine, Morgantown, WV 26506-9200.

Bushy cells are specialized to preserve temporal features of auditory nerve spike patterns, and are considered to play important roles in sound localization. In general, studies of bushy cell connections within the superior olivary complex (SOC) have employed techniques that label only sub-populations of neurons. Such questions as the distribution and diversity of terminals on particular SOC cell types can only be effectively addressed by bulk labeling of all bushy cells and their axonal processes.

We demonstrate here that antiserum to PEP-19 (generously provided by Dr. J. I. Morgan), a putative calcium-binding polypeptide, is an excellent marker for the entire population of VCoN bushy cells in cats. Spherical cell axons located dorsally and thicker globular cell fibers located ventrally in the trapezoid body are well labeled. Large calyceal endings in the MNTB are distinctly immunoreactive as are small punctate profiles that outline neuronal cell bodies and dendrites in the MSO and mainly dendrites in the LSO. In the LNTB, differences in the pattern of punctate immunolabeling provides the basis for parcelling the subregions of the nucleus (Spirou and Berrebi, this volume).

Within the entire SOC, only the posterior and dorsolateral periolivary nuclei contain significant numbers of PEP-19 immunoreactive neurons, but these regions are not thought to provide significant input to principal SOC nuclei. Thus, although expression of PEP-19 is not exclusive to bushy cells, antiserum to this protein should prove useful in quantitative light and electron microscopic investigations of bushy cell synapses.

VENTRAL NUCLEUS OF THE TRAPEZOID BODY: DENDRITIC MORPHOLOGY BY INTRACELLULAR LABELING. N. Kuwabara*, Dept. of Biol. Sci. and OUCOM, Ohio University, Athens, OH 45701.

The ventral nucleus of the trapezoid body (VNTB) is a periolivary cell group at the floor of the mammalian superior olivary complex (SOC). This nucleus is strategically positioned in the trapezoid body just below the medial nucleus of the trapezoid body (MNTB) and the medial superior olive (MSO). The VNTB contains a mixed population of elongate and multipolar cells and is known to receive extensive ascending projections from the ventral cochlear nucleus (VCN; Warr, '72). Some cells of the VNTB are thought to contribute to the medial olivocochlear bundle system (Warr, '75). The VNTB also has projections to the inferior colliculus ipsilaterally (Nordeen, '83) and the cochlear nucleus bilaterally (Brown et al., '88; Winter et al., '89). However, little is known about the organization of the VNTB, its relation to the rest of the SOC, or the relationship between its afferent and efferent connections. We have begun our studies of the VNTB by examining its dendritic morphology as revealed by intracellular labeling in a gerbil brainstem tissue slice preparation.

Intracellular labeling with Neurobiotin suggests that the main dendrites of most elongate VNTB cells are oriented dorsoventrally. Dorsally oriented dendrites often invaded and arborized within the MNTB. Some small dendritic branches were traced dorsolaterally into the columnar region of the MSO. Ventral dendrites often extended across the entire width of the ventral trapezoid body. Previously, we have observed collateral axons from MNTB principal cells projecting to the VNTB (Kuwabara et al., '89). The dendritic pattern of the VNTB suggests that this nucleus may sample ascending information in the neural plexuses of both the MNTB and the MSO as well as direct projections from the VCN. AUDITORY SYSTEMS: CENTRAL ANATOMY II

401.1

SUPERIOR PARAOLIVARY NUCLEUS (SPON): CONNECTIVITY REVEALED BY TRANSPORT OF BIOTINYLATED DEXTRAN. E. Saldaña*, D.R. Lough and A.S. Berrebi. Univ. of Salamanca Med. Sch., 37007-Spain, and Dept. of Otolaryngology, West Virginia Univ., Morgantown, WV 26506.

The SPON is a prominent periolivary nucleus in rodents. In order to clarify its synaptic targets and sources of inputs, we injected biotinylated dextran (BD) into the inferior colliculus (IC) or SPON of rats. This tracer provides both retrograde and anterograde labeling of cell bodies and processes.

The projection from SPON to IC is extensive, primarily ipsilateral, and originates from large multipolar cells with flattened, parasagittally oriented dendritic trees. Medially situated SPON neurons project to ventromedial (high frequency) regions of the IC, and those situated laterally project to dorsolateral (low frequency) regions. Thus, the SPON projection to the IC appears to be tonotopically organized.

After injections restricted to the SPON, an extremely dense fiber plexus, but very few cell bodies, are labeled in the IC. Numerous retrogradely labeled neurons are found in the ipsilateral medial nucleus of the trapezoid body (MNTB) and contralateral posteroverventral cochlear nucleus (PVCn). The predominant neuronal type labeled in the PVCn corresponds to octopus cells, although occasional multipolar and scattered small stellate and bushy cells are also found.

These data suggest that SPON activity is modulated by the balance of its excitatory inputs arising from octopus cells and glycinergic synapses originating in the MNTB. Since the SPON contains primarily inhibitory neurons, it appears that complex inhibitory/disinhibitory phenomena at the level of the IC may represent an important aspect of its functional role.

EFFECTS OF STIMULUS INTENSITY ON *c-fos* mRNA EXPRESSION IN THE AUDITORY BRAINSTEM OF THE RAT. R. L. Saint-Marie*, L. Luo, and A. F. Ryan, Neuroanatomy Dept., House Ear Institute, Los Angeles, CA 90057 and *Div. Otolaryngology - Head and Neck Surgery, Univ. California, San Diego, CA 92093.

Expression of the *c-Fos* protein has been shown to be up regulated in some auditory brainstem neurons in response to tonal stimulation. In the present study we examined the expression of *c-fos* mRNA following 1 hr of free-field stimulation with a low-frequency, narrow-band noise (1.41-5.65 kHz) at intensities ranging from 80-120 dB SPL. At 80 dB elevated expression was found in subsets of neurons in the low frequency areas of the dorsal (DCN), posteroverventral, and anteroventral cochlear nuclei, the medial nucleus of the trapezoid body (MNTB), the ventral and dorsal nuclei of the lateral lemniscus, and the inferior colliculus (IC). The areas containing labeled neurons in these structures increased in size with 90 and 100 dB stimulation, but the signal began to diminish at 110 dB. In some auditory nuclei, label in low-frequency areas was nearly absent at 120 dB, which may reflect damage to the low-frequency part of the cochlea. At 90 dB additional neuronal labeling was found in the highest frequency regions of some of these structures, particularly the DCN, MNTB, and IC. These areas of label also increased in size and intensity with increasing stimulus intensity, which may reflect the greater sensitivity of the high-frequency part of the cochlea to high intensity sounds of all frequencies. Alternatively, some central auditory neurons, i.e., those in high frequency regions of DCN, MNTB, and IC, may have more sensitive stimulus/transcription coupling mechanisms than others. At the highest stimulus intensities the middle frequency regions of the auditory nuclei became heavily labeled, presumably as the tail of the tuning sensitivity for these neurons was activated. *c-fos* mRNA expression appears to be related to a biochemical response driven by, but not necessarily synonymous with, neuronal activity. Its expression may be useful as an indicator of neuronal activity in many, though perhaps not all, neurons of the auditory brainstem.

401.3

EXPRESSION OF c-fos mRNA IN THE RAT AUDITORY BRAINSTEM FOLLOWING UNILATERAL OR BILATERAL COCHLEAR ABLATION.

L. Luo¹, R. L. Saint Marie², and A. F. Ryan². ¹Neuroanat. Dept., House Ear Institute, Los Angeles, CA 90057 and ²Div. Otolaryngol., Univ. California, San Diego, CA 92093.

Transcription of the c-fos gene was examined from 30 min to 60 days after surgical ablation of one or both cochleae in adult rats using *in situ* mRNA hybridization. After unilateral ablations, basal expression in the ipsilateral ventral cochlear nucleus (VCN) and contralateral inferior colliculus (IC) began to decline 1-2 hrs post injury, was maximally depressed by 2-4 hrs, and remained suppressed at least 60 days post injury. In the cochlear nucleus contralateral to the ablation there was a rapid (30 min - 1 hr post injury) increase in neuronal expression in the deep layers of the dorsal cochlear nucleus (DCN) and some areas of VCN which remained elevated at least 60 days post injury. This suggests a release from inhibition normally driven by the contralateral ear. An intense glial expression in the acoustic and vestibular nerves of the ablated side, reflecting degeneration of the afferent axons, was first evident at 30 min and gradually involved the nerve roots, octopus cell area, and spinal tract of the trigeminal. Elsewhere there were delayed increases in neuronal expression bilaterally in periolivary nuclei, dorsal nuclei of the lateral lemniscus, paralemnisci, and commissural nuclei of the IC and in the ipsilateral ventral and intermediate nuclei of the lateral lemniscus and central nucleus of the IC. Onsets ranged from 2 hrs to 2 wks and persisted for at least 60 days after ablation. The delayed onset of these responses suggests transsynaptic effects and possibly reorganization of the central pathways in response to deafferentation in the adult. No neuronal expression was evident in any auditory nuclei 4 hrs or more after bilateral ablations, suggesting that all observed expression was acoustically driven. A single exception was in the superficial layers of the DCN, where there was an initial rapid increase in expression in medium-sized neurons that reached a maximum at 2 hrs and disappeared by 1 day. This may reflect a release from acoustically driven inhibition of high spontaneous rate neurons with subsequent adaptation or delayed depression of higher order excitatory input(s).

STRUCTURE AND INNERVATION OF NEURONS IN THE VENTRAL NUCLEUS OF THE LATERAL LEMNISCUS THAT PROJECT TO THE INFERIOR COLLICULUS. R. Batra¹, G. Beckius², D. Peruzzi², D.C. Fitzpatrick², E.M. Ostapoff² and D.L. Oliver². Dept. of Anatomy, Univ. of Conn. Health Center, Farmington, CT 06030.

A multiplicity of pathways transmit auditory information from the cochlear nucleus to the inferior colliculus. While some of these are binocular, others may convey monocular information. One potentially monocular pathway leads to the inferior colliculus via the ventral nucleus of the lateral lemniscus (VNLL). The VNLL is a major source of input to the inferior colliculus, yet neither its inputs nor the morphology of its neurons have been extensively studied.

Ascending input to the VNLL was examined by injecting biotinylated dextran in the cochlear nucleus of rats. Dextran-labeled axons that ran in the lateral margin of the lateral lemniscus periodically gave off dense arborizations that entered the VNLL. These horizontal arbors were roughly perpendicular to the lemniscus, and resembled the rungs of a ladder.

In a second experiment, neurons in the VNLL that project to the inferior colliculus were labeled with retrogradely transported fluorescent microspheres, and then intracellularly injected with a mixture of Lucifer Yellow and biotinylated Lucifer Yellow in slices of fixed tissue. The somata of stained neurons were spherical or elongate in shape. Dendrites were typically filled up to 50-150 μ m from the soma but rarely branched more than three times. Some neurons had fusiform dendritic fields oriented perpendicular to the lemniscus. Others had multipolar dendritic fields that were less oriented, but which were more parallel to the lemniscus.

Neurons with their dendrites perpendicular to the lemniscus would likely receive input from one arbor, or "rung" of fibers, from the cochlear nucleus, whereas those with dendrites parallel to the lemniscus may integrate inputs over a larger region. The relationships of dendritic orientation in the VNLL to the input from the cochlear nucleus suggests that the VNLL may play more than one role in auditory processing.

MORPHOLOGY OF COMMISSURAL AXONS IN THE INFERIOR COLLICULUS OF THE GERBIL. Nina Z. Doroshenko and Nell B. Cant¹. Department of Neurobiology, Duke University Medical Center, Durham, NC 27710.

We made small injections of biocytin into the central nucleus of the inferior colliculus and reconstructed the axons and terminals which arise from this area and project into the contralateral colliculus. All subdivisions of the inferior colliculus receive commissural connections; the patterns of branching are different in each one. Most commissural axons entering the central nucleus form planar terminal fields extending from the rostral to caudal and from the dorsomedial to ventrolateral aspects of the central nucleus; they appear to be parallel to the fibrodendritic laminae that characterize the central nucleus. Less often, labeled axons enter the central nucleus from its laterodorsal aspect almost at right angles to the fibrodendritic laminae and travel in the ventromedial direction, giving rise to simple branches.

The internal part of the external nucleus is innervated by axons which enter it by passing through the central nucleus, where some of them give rise to branches. The terminal field of each axon is confined to a limited strip along the dorsal to ventral axis of the external nucleus. The superficial part of the external nucleus receives the sparsest intercollicular connections. Most of the terminals there arise from branches of axons passing into the brachium. In the dorsal cortex, terminals of commissural axons are found most often in the middle half of the deep layer. Most of them arise from branches of axons that enter the central nucleus or the brachium of the inferior colliculus.

C-FOS EXPRESSION ELICITED BY SOUND STIMULATION IN THE AUDITORY NEURONS OF THE BIG BROWN BAT, *EPTESICUS FUSCUS* Y. Qian¹ and P. H.-S. Jen². Division of Biological Sciences, University of Missouri-Columbia, Mo 65211

Because proto-oncogene c-fos can be expressed in neurons following sensory stimulation, c-fos immunocytochemistry has been used as a rapid and sensitive marking technique to identify stimulus activated neurons. This technique has the advantage of examining c-fos expressed neurons in several brain nuclei thus providing an overall profile of the stimulus-related activity within a specific sensory system. In this study, we examined sound elicited c-fos expressed neurons in the auditory cortex, the cerebellum and subcortical nuclei of the big brown bat, *Eptesicus fuscus* under natural and monaurally plugged conditions. When stimulated with 30 and 50 kHz sounds at 79 dB SPL under natural condition, c-fos sensitive neurons were symmetrically and bilaterally observed in the ventral and dorsal cochlear nuclei (VCN, DCN), the superior olivary complex (SOC), the nucleus of lateral lemniscus (NLL), the nucleus of trapezoidal body (NTB), the inferior and superior colliculi (IC, SC), the pontine nuclei (PN), the medial geniculate body (MGB), the auditory cortex, the cerebellar fastigial and dental nuclei. However, c-fos sensitive neurons were greatly reduced and were observed in a more restricted area of all auditory nuclei when stimulated with a 20 dB SPL sound. When stimulated under monaurally plugged condition, c-fos sensitive neurons were predominantly observed in the contralateral DCN, VCN, SOC, NLL, NTB and the ipsilateral IC, SC, MGB, PN and the auditory cortex. These observations are consistent with the known neural circuits of the mammalian ascending auditory pathway. In the cerebellum, however, c-fos sensitive neurons were symmetrically observed in the rostral portion of both deep nuclei, but were predominantly observed in the caudal portion of the ipsilateral deep nuclei. (work supported by HFSP and NIH DC 247)

401.6

ORIGIN OF ASCENDING PROJECTIONS TO THE NUCLEI OF THE LATERAL LEMNISCUS IN THE BIG BROWN BAT, *EPTESICUS FUSCUS*. R.F. Huffman¹ and E. Covey².

Dept. Neurobiology, Duke University Medical Center, Durham, NC 27710.

The nuclei of the lateral lemniscus (NLL) in the echolocating bat, *Eptesicus fuscus*, are unusually large and highly differentiated. Electrophysiological studies demonstrate marked differences in the response properties of neurons in the different divisions of NLL; thus, each nucleus presumably sends a unique transformation of auditory input to the inferior colliculus. To determine whether the dissimilar response patterns of the NLL divisions are due in part to differential patterns of ascending input, we placed small deposits of HRP or WGA-HRP in the NLL of 18 bats.

The retrograde transport from these injections shows that, as in other mammals, the dorsal NLL (DNLL) of *Eptesicus* receives the bulk of its input from binocular structures. These include the lateral and medial superior olives (LSO and MSO) and contralateral DNLL. Both LSO and MSO project bilaterally; the bilateral MSO projection is unusual in that it is found in only a few mammalian species. DNLL also receives a minor projection from the anteroventral cochlear nucleus (AVCN).

The projections to the intermediate NLL (INLL) and the two divisions of the ventral NLL (VNLL) are almost exclusively monocular. Major sources of input are the AVCN, posteroventral cochlear nucleus (PVCN) and the medial nucleus of the trapezoid body (MNTB); lesser inputs originate in the lateral nucleus of the trapezoid body (LNTB) and ventral periolivary area (VPO). Although INLL and the two divisions of VNLL all receive input from AVCN, PVCN, MNTB, LNTB and VPO, they differ in the relative proportions of connectivity with these brain stem nuclei. For example, in terms of the numbers of cells labeled, the pattern of labeling for VNLL (AVCN>>PVCN>MNTB) is quite different from that for INLL (MNTB>>PVCN>AVCN). These data suggest that the diverse neural response properties in INLL and VNLL are not the result of projections from disparate sets of brain stem nuclei, but rather that they depend upon differing magnitudes of the constituent projections. 401.8

GABAergic PROJECTIONS FROM THE INFERIOR COLLICULUS TO THE MEDIAL GENICULATE BODY IN THE CAT. S. Paydar¹, R.L. Saint Marie², D.L. Oliver², D.T. Larue² and J.A. Winer². Dept. of Molecular and Cell Biology, Univ. of California, Berkeley, CA (S.P., D.T.L., J.A.W.), Dept. of Anatomy, Univ. of Connecticut Health Center, Farmington, CT (D.L.O.), and Dept. of Neuroanatomy, House Ear Institute, Los Angeles, CA (R.L.S.M.)

The mammalian auditory system is unique among sensory modalities in that many of its brain stem projections are GABAergic or glycinergic and probably inhibitory. These include ascending (feed-forward) and commissural (interaural) projections. Until recently, no such feed-forward projections had been identified in the tectothalamic system (K.A. Hutson et al., *Proc. Soc. Neurosci.*, 1993, 19:1203). We injected horseradish peroxidase (HRP), apo-HRP gold, and wheat germ apo-HRP gold in subdivisions of the auditory thalamus, and studied GABA-immunoreactivity in Vibratome tissue or in postembodied, semi-thin preparations from the inferior colliculus (IC).

We found that (1) GABAergic, retrogradely labeled neurons were present throughout the IC, including the central nucleus, dorsal cortex, and lateral nucleus; (2) such cells were diverse morphologically, ranging from the smallest to the largest GABAergic IC cells (D.L. Oliver et al., *J. Comp. Neurol.*, 1994, 340:27-42); (3) GABAergic projection cells were distributed bilaterally, though most were ipsilateral to the injection, and (4) the brachium of the IC contained many myelinated GABAergic preterminal axons.

There is an ascending, feedforward inhibitory pathway from the IC to the MGB that is parallel to the much larger, probably excitatory, midbrain input. This is one of three GABAergic inputs to the MGB, besides those from the thalamic reticular nucleus and that of Golgi type II cells with local axons. This implies a convergence of inhibitory influences arising from both auditory and non-auditory sources, and whose physiological role(s) remain obscure.

Supported by United States Public Health Services grants R01 DC00189 (D.L.O.), R01 DC00728 (R.L.S.M.), and R01 DC02319-14 (J.A.W.). We thank Dr. R.J. Wenthold for generously sharing his antiserum to GABA.

Distribution of NADPH diaphorase and cytochrome oxidase in relationship to functional organization of the inferior colliculus in guinea pig. L. Syka, R. Druga, J. Asil and J. Popelář. (SPON: European Neuroscience Association) Inst. Exp. Medicine, Czech. Acad. Sci., 142 20 Prague, Czech Republic.

The inferior colliculus (IC) in mammals consists of three subdivisions: central nucleus (CN), external cortex (EC) and dorsal cortex (DC). We analysed the distribution of NADPH - diaphorase (NADPH-d) and cytochrome oxidase (CyOx) in the IC subdivisions and compared it with functional organization of the IC. Animals anaesthetized with pentobarbital were perfused with aldehyde fixation, sections through the hemispheres and brainstem were cut on a freezing microtome and processed for NADPH-d according to Scherer-Singler *et al.* (J. Neurosci. Meth., 9: 229, 1983) and for CyOx according to Wong-Riley (Brain Res. 171:11,1979). In another group of anaesthetized guinea pigs, the IC was penetrated with a microelectrode and parameters of neuronal responses to acoustical stimuli, such as the characteristic frequency, Q_{10} , latency and binaural interaction, were evaluated. The inferior colliculus in guinea pig contains, as in the rat (Druga and Syka, Neuroreport 4:999, 1993), large amounts of NADPH-d positive neurons and neuropil. Positive neurons are present mainly in the dorsal and external cortices of the IC whereas the CN contains few positive perikarya. NADPH-d positive neurons and fibers were also found in the intercollicular commissure. CyOx in the IC was localized mainly to the neuropil. In contrast to NADPH-d, CyOx was present predominantly in the CN of the IC, mainly in its basal part. CyOx positivity was particularly weak in the DC. Isofrequency layers reconstructed from microelectrode penetrations declined in frontal sections from the dorsomedial to the ventrolateral and they mostly continued from the CN to the EC. However, the EC neurons were characterized by broader tuning curves as well as by longer latencies. Investigation of distribution of histochemical markers together with the mapping of functional properties of individual neurons enables better delineation of the subdivisions of the IC and further understanding of their role in the processing of acoustical information.

401.11

FINE STRUCTURE OF SYNAPTIC CONTACTS ON NEURONS LABELED BY RETROGRADE TRANSPORT FROM MEDIAL GENICULATE BODY IN THE RAT INFERIOR COLLICULUS. K. Ohtomo, G.E. Beckius, and D.L. Oliver*, Dept. Anatomy and Biology, College of Allied Medical Science, Akita University, Akita 010 Japan, and Dept. Anatomy, Univ. Connecticut Health Center, Farmington, CT 06030-3405.

Neurons in the inferior colliculus (IC) may project to one of several targets. The ipsilateral medial geniculate body (MGB) is the main target of the ascending pathway, but neurons also project to contralateral MGB, superior olive, and cochlear nucleus. Here, we examined the synaptic organization of IC neurons with different targets. Latex beads injected in MGB *in vivo* retrogradely labeled somata in both ipsi- and contralateral IC. Aldehyde-fixed slices, 150 μ m-thick, were prepared from the IC (Hill & Oliver, '93, J. Neurosci. Meth. 46:59-68), and bead-labeled neurons were intracellularly injected with biotinylated Lucifer Yellow. Cells were processed to visualize biotin and flat embedded. The dendritic tree was sampled at regular intervals by cutting the warmed plastic (38°C) with a glass knife into 6 μ m-thick sections. Reconstructions of neurons were made from camera lucida drawings and 6 μ m thick sections. Thin sections, 80 nm-thick, were taken at the surface each 6 μ m-thick section and examined with the electron microscope.

Seven injected neurons were studied, four with ipsilateral projections and three with contralateral projections. Most were in the central nucleus and had modest dendritic orientation ("less flat") or stellate dendritic morphology. The injected neurons could be differentiated according to their axosomatic synapses. Most neurons had relatively few axosomatic synapses, but others received many. Both types projected to ipsilateral and contralateral MGB. Neurons differed in the density of axodendritic synapses, but these differences were not easily correlated with axonal target or somatic synapses. All neurons received type 1, asymmetric, synaptic contacts from endings with round synaptic vesicles and type 2, symmetric, synaptic contacts from endings with pleomorphic vesicles. Usually type 2 synapses predominated. Neurons with projections to ipsilateral MGB tended to receive the greater proportion of type 2 synapses.

Sponsored by NIH grant DC00189 and the Japanese Ministry of Education.

401.13

CORTICOBULBAR SYNAPSES IN THE AUDITORY SYSTEM: A POSSIBLE SUBSTRATE FOR SELECTIVE ATTENTION. D.L. Weedman*, D. Vause, T. Pongstaporn, and D.K. Ryugo. Center for Hearing Sciences, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Recent studies have demonstrated the existence of direct projections from the auditory cortex to the auditory brainstem in rat (Feliciano *et al.*, 1993, Soc. Neurosci. Abs.). Specifically, descending projections were shown to distribute in the superior olivary nuclei, nuclei of the trapezoid body, and the cochlear nucleus. We hypothesize that the cortex may be able to exert direct influence on both the olivocochlear (OC) efferent system and the initial processing of afferent information. In order to test this notion, we labeled corticobulbar fibers by injecting biotinylated dextran amine (BDA), an anterograde tracer, into auditory cortex in rat. After a one-week survival time, cholera toxin subunit-B (CT-B) was injected into the cochlea to retrogradely label OC cell bodies in brainstem. We examined double-labeled tissue with electron microscopy and found synaptic contacts between the descending cortical fibers and dendrites of neurons of the medial olivocochlear system. This disynaptic pathway from cortex to cochlea provides a mechanism for cortical control over the outer hair cells, and therefore over the responses of the basilar membrane itself. In a parallel study, we have found that cortical fibers synapse in the granule cell domains of the cochlear nucleus, a region which also receives afferent input from the outer hair cells (Brown *et al.*, 1988, J. Comp. Neurol. 278: 581) and efferent collaterals from the superior olive (Brown *et al.*, 1988, J. Comp. Neurol. 278: 591). This convergence of information may represent the first central site of cortical filtering of auditory input. These findings suggest an important role for cortex in descending control of ascending information, and reveal a possible substrate for mechanisms of auditory selective attention.

CALCIUM-BINDING PROTEIN EXPRESSION DELINEATES SUBDIVISIONS OF RABBIT MEDIAL GENICULATE COMPLEX. N.T. McMullen*, R.K. de Venecia, C.B. Smelser and S.D. Lossmann. Dept. of Anatomy, Univ. of Arizona College of Medicine, Tucson, AZ 85724

Previous cytoarchitectonic studies of the medial geniculate body have recognized three major divisions: ventral, dorsal and medial. Although additional parcelling of the MGB is warranted based on Golgi and connectional studies, further subdivisions are frequently difficult to discern in routine Nissl studies. We report that immunocytochemistry for the calcium-binding proteins parvalbumin (PV) and calbindin (CB) clearly delineate subdivisions of the medial geniculate complex. Furthermore, these MGB subdivisions appear to correspond to those recently defined by AChE and NADH-diaphorase activity in the rabbit (Caballero-Bleda *et al.*, J. Chem. Neuroanat., 4, 1991). NZW rabbits were anesthetized with ketamine and nembutal and intracardially perfused with 0.1M phosphate buffered saline (PBS, pH 7.4) followed by 4% paraformaldehyde in 0.1M PBS. Serial coronal and sagittal sections through the entire MGB were cut frozen at 40 μ m. Every third section was stained with 0.1% methylene blue while the remaining sections were processed immunocytochemically with monoclonal antibodies against PV or CB (SWANT). PV and CB immunolabeling display a remarkable complementary staining pattern in the MGB: PV immunolabeling predominates in the ventral and medial division whereas CB+ cells characterize the dorsal and internal divisions. The ventral division is strongly PV immunoreactive due to dense neuropil labeling and moderately labeled PV+ somata. Sagittal sections reveal PV+ axons from the brachium of the inferior colliculus streaming into the posterior aspects of the ventral division. A CB+ marginal zone encapsulates the ventral MGB. Although CB immunoreactivity is distinctly lacking in the majority of the ventral division, the posterodorsal portion exhibits compartments of CB somata where the PV neuropil labeling is reduced or absent. PV immunocytochemistry also reveals a small medial subdivision characterized by medium and large PV+ somata, thick PV+ axons and puncta. A large wedge-shaped internal subdivision, composed of densely-labeled CB+ cells, separates the dorsal and ventral divisions. The dorsal division contains large, multipolar CB+ neurons with radiate dendrites. A deep dorsal component is characterized by PV+ axons and terminals. These cytoarchitectonic methods will be useful for guiding future connectional studies of the MGB with the brainstem and auditory cortex. (Supported by NIH/NIDCD)

MEDIAL GENICULATE BODY CHEMOARCHITECTONIC SUBDIVISIONS M. J. Campbell and D.N. Pandya ENRMVAH, Bedford, MA, USA.

Monoclonal antibodies to the nonphosphorylated KSP segment of neurofilament protein (SMI-32) and to the calcium binding proteins, parvalbumin (PV), calbindin (CB), and calretinin (CR) were used in immunohistochemical studies of the medial geniculate body (MG) in the rhesus monkey. An examination of sections from brains cut perpendicular to the rostrocaudal (RC) axis of the brainstem revealed that the three main subdivisions are present along the entire RC extent of MG. The division of MG located ventrally (MGV) with respect to the brainstem can be divided into a peripheral sector (MGVp), and a more central region (MGVc). The density of SMI-32-immunoreactive (ir) profiles is less than that of PV-ir profiles in MGV, but both have greater numbers of ir neurons and a higher density of neuropil staining in MGVp relative to MGVc. There is a striking absence of CB-ir or CR-ir profiles in MGVc, with the exception of a small subpopulation of CB-ir neurons in MGVp. The division of MG located dorsally with respect to the brainstem (MGD) is characterized by a homogeneous neuropil staining with SMI-32. There are fewer PV-ir neurons in MGD relative to MGV, and MGD is distinct in its low density of PV-ir neuropil staining. In contrast to MGV, CB-ir neurons are distributed throughout MGD and CR-ir neurons are found in a large portion of MGD. In the medial division of MG (MGmc), magnocellular neurons tend to be SMI-32-ir. PV-ir and CB-ir neurons are found in all parts of MGmc that contain smaller neurons. CR-ir cells are found only in small limited portion of MGmc. These distinct distribution patterns provide clear criteria for subdividing MG, however when the functional properties of these chemically identified neuronal populations are defined, they may also provide insights into the functional organization of the MG. 3-D MAPPING OF HUMAN AUDITORY CORTEX IN STEREOTAXIC SPACE FROM MRI DATA VB Penhune*, RJ Zatorre, D MacDonald, T Fleischer and AC Evans; Montréal Neurological Inst & McGill University, Montréal PQ H3A 2B4.

Human primary auditory cortex is located principally on the surface of the transverse gyrus of Heschl (HG). Gross morphology of this area is highly variable, both between individuals, and between hemispheres. To measure this variation, high-resolution MRI scans (64 slices, 2 mm thick) of 19 young, healthy, right-handed subjects was transformed into the standardized stereotaxic space of Talairach & Tournoux (1988). HG was identified and labelled in the horizontal, sagittal and coronal planes using an interactive voxel-painting program to produce a stereotaxic voxel map. Averaging of individual maps results in a 3-D probability map for the location of HG. The area of 100% probability for both hemispheres differs from the stereotaxic atlas in the Z dimension, extending several mms dorsally and ventrally. Significant interhemispheric differences in the average volume of HG were observed ($L=20.3 \pm 7.5$ cm³, $R=15.8 \pm 3.8$ cm³, $p < .02$). HG was larger on the left by 10% or more in 14/19 brains. Absolute location in stereotaxic space did not differ between the two hemispheres. The probability map can be used to assess the extent of damage to primary auditory areas in patients with temporal-lobe lesions, and may be useful for identifying PET activation foci within auditory cortex.

LOCAL PROJECTION PATTERNS IN THE RAT CORTEX DEMONSTRATED WITH BIOCYTIN.

D.F. Sivek* and P.B. Cipolloni E.N.R.M. VA Hospital, Bedford, MA 01730

Small iontophoretic injections of biocytin into the auditory cortices of the rat labeled the somata and processes of neurons exposed to the injected marker. In many cases well labeled processes were followed for considerable distances to targets in the ipsi- and contralateral cortices. In some cases, the injection was placed quite superficially in the auditory cortex layer (I and II/III) and in others, it was placed deeper into layer V/VI producing different projection patterns.

The laminar pattern of local circuit projections is dependent on the depth of the injection in the cortex. For example, an injection restricted to the superficial laminae in rostral auditory cortex (area 41), labeled neurons and processes around the injection site. Labeled processes were distributed most heavily in layers I, II/III and V. A prominent fascicle of labeled axons descended into the subcortical white matter before turning abruptly dorsal, and then traveling to the corpus callosum. Bundles of labeled axons also passed horizontally through the cortex (not subcortical white matter), terminating in a columnar pattern in layers I, II/III and V. The plexus of labeled processes in layer I was heaviest, followed by that in layer II/III and then layer V. In contrast, when the injection involved the full thickness of cortex, the local projection plexes terminated in a column extending through all layers. Long distance projections to ipsilateral visual cortices frequently took the most direct path to their targets, passing through the cortical laminae at oblique angles. Labeled axons were also observed in the corpus callosum. These axons entered the subcortical white matter directly beneath the injection, ran anteriorly, and passed to the opposite hemisphere in the lower half of the callosum. The results suggest that horizontal interactions among the auditory cortices have a unique laminar distribution that is dependent on the cortical lamina from which it arises. DEVELOPMENT OF AUDITORY CALLOSAL CONNECTIONS IN NORMAL AND HYPOTHYROID RATS. R. A. Lucio*, J. R. Cerazo, P. Pacheco and P. Berbel. Depto. Histología e Instituto Neurociencias, Univ. Alicante (Spain), and CIF, Univ. Auton. Tlaxcala, INE, Univ. Veracruzana and IIB-UNAM (México).

Lack of thyroid hormones produces generalized brain damage, especially in the neocortex. Recent findings show that auditory callosal connections are severely damaged in adult hypothyroid (H) rats. In normal (C) rats, retrograde labelled neurons were found in cortical layers II-III to VI with a peak in layers II-III, but in H rats, they were mostly distributed in layers IV to VI. To test for an abnormal elimination/stabilization of transitory connections in H rats, the distribution of retrograde labelled callosal neurons in the auditory neocortex during development was compared with controls. For antithyroid treatment of H rats methimazole (Sigma) was orally administered from embryonic day 14 and a thyroidectomy performed on postnatal day (P) 6. At ages between P4 and P47, C and H rats were injected in the auditory cortex with HRP or WGA-HRP, and after 2 days, brain sections were processed with TMB. Data were analyzed with the "Neurograph" computer program. Until P35, the radial distribution of retrograde labelled neurons was similar in both groups. After P35, the number of labelled neurons falls dramatically in C rats, reaching an adult-like distribution by P47. Interestingly, their number and radial distribution in H rats appears not to change from P35 levels, even during adulthood. These findings indicate that the transitory callosal connections normally eliminated, were retained in H rats. DGICYT PB90-561 (PB); Prog. Coop. Iberoamer. (PB-PP); CONACYT-PADEF 30377 (RAL)

FOREBRAIN PROJECTIONS FROM THE GUSTATORY CORTEX OF THE SYRIAN GOLDEN HAMSTER. R.G. Webby*, J. deB. Zeiger, and J.A. London. Ctr. Neurol. Sci. and Dept. BioStructure & Function, UCHC, Farmington, CT 06030.

Biotinylated dextrans (10kDa, 5%, 0.2-1.0 μ l, 6 animals) were pressure-injected into either the gustatory cortex, or into regions dorsally- or ventrally-adjacent to the gustatory cortex, of the Syrian golden hamster (*Mesocricetus auratus*). An injection into the gustatory cortex at the level of the genu of the corpus callosum demonstrated projections from this region to the ipsilateral infralimbic cortex, agranular insular cortex, piriform cortex, olfactory tubercle, amygdala, lateral hypothalamus, and contralateral homotypic gustatory cortex. An injection at a more rostral region of the gustatory cortex (approximately 500 μ rostral to the genu of the corpus callosum) revealed a similar projection pattern, but with a relatively more robust projection to the ipsilateral infralimbic cortex. Control injections in somatosensory and piriform cortices, located 1 mm dorsal or 1 mm ventral to the gustatory cortex, respectively, resulted in projection patterns consistent with those reported for these regions, and quite different from that of the gustatory cortex. This work demonstrates that projections from the gustatory cortex of the hamster communicate primarily with limbic, olfactory, autonomic, and gustatory areas of the forebrain, and that this projection pattern is different from that of adjacent cortical areas.

THE MACAQUE MONKEY AUDITORY THALAMO-CORTICAL SYSTEM DEFINED BY CALCIUM BINDING PROTEIN IMMUNOREACTIVITY. T. Hashikawa*, M. Molinari, E. Rausell, M.E. Dell'Anna, M.G. Leggio, E.G. Jones. Neural Systems Laboratory, Riken, Japan and Univ. of California, Irvine.

Immunoreactivity for calcium binding proteins is a useful marker to differentiate parallel thalamocortical projections in the monkey. The present study was aimed at analyzing the pattern of parvalbumin and calbindin immunoreactivity in the auditory cortex and thalamus of the Japanese monkey (*Macaca fuscata*) and to relate the parcellation of the cortex and thalamus thus obtained to reciprocal connectivity. The auditory areas of the supratemporal plane have been divided into 4 almost concentric zones of decreasing parvalbumin immunoreactivity (figure 1). Zone 1: intense staining corresponding to fields AI and RL; Zone 2: moderate to dense staining corresponding to anteromedial (A-m), lateral (L) and posteromedial (P-m) paraauditory fields; Zone 3: weak staining located antero laterally to zone 2; Zone 4: weakest staining; anterior pole of the supratemporal plane. These zones appear to be related to the relative density of innervation by parvalbumin immunoreactive thalamocortical fibers. Retrograde tracing studies demonstrated that zones 1-3 receive

inputs from different subnuclei of the medial geniculate (MG) complex. A direct correlation has been found between density of parvalbumin immunoreactivity in the cortex and that in MG nuclei providing thalamic afferents to an area. Zone 1 (AI + RL) receives projections from the ventral MG nucleus in which most cells are parvalbumin immunoreactive while zones 2 to 3 receive afferents from the anterodorsal and posterodorsal nuclei which show comparable differences in parvalbumin immunoreactive cell numbers. The present data demonstrate that parvalbumin immunoreactivity can differentiate parallel thalamocortical pathways of the monkey auditory system.

AUDITORY CORTICAL PROJECTIONS TO THE PONTINE NUCLEI IN THE CAT. J.J. Prieto*, R. Riquelme, M. Beneyto, and J.A. Winer. Department of Histology, University of Alicante, 03080-Alicante, Spain (JJP, RR, MB) and Department of Molecular and Cell Biology, University of California at Berkeley, Berkeley, CA 94720-3200 (JAW).

The pontine nuclei are a major source of brain stem mossy fibers to the cerebellar cortex. Little is known about how the auditory cortex influences the output of premotor nuclei in the brain stem. The sparse data available on corticopontine projections rely largely in studies which used autoradiography or silver degeneration methods. The goal of the present study was to demonstrate with more sensitive methods the pontine targets of corticofugal axons from four auditory cortical areas (AI, AII, PAF, and TE). Each was injected with WGA-HRP, and frozen sections were developed for TMB.

AI injections labeled axons in the dorsolateral, lateral, paramedian, and peduncular pontine nuclei. Injections in AII produced a lighter, but similar pattern of terminal labelling. With injections in PAF, most fibers terminated in the peduncular nucleus, while the projection to the dorsolateral and paramedian nuclei was scant. PAF was the only area that projected to the ventral pontine nucleus. TE was the origin of the heaviest projection to the pontine nuclei, and labeled fibers were located chiefly in the dorsolateral and paramedian nuclei. TE differed from the other areas since it alone projected contralaterally, to the paramedian nucleus, and also in that it sent axons to the median pontine nucleus.

These results demonstrate a convergence of auditory cortical afferents to the pontine nuclei, as well as other corticopontine projections that are specific to each auditory area. This suggests that multiple, descending corticofugal inputs to brain stem nuclei exist which may be analogous to parallel, ascending pathways to auditory cortex.

GUSTATORY AND RELATED CHEMICAL SENSES

402.2

INVOLVEMENT OF THE INSULAR CORTEX IN NAUSEA: A C-FOS IMMUNOHISTOCHEMISTRY STUDY. P.A. Bryant*, B. Boot and J.S. McGregor. Dept. Psychology, University of Sydney, NSW, 2006, Australia.

Lithium chloride (LiCl) is frequently used to examine the nature of emesis in animals. Although rats do not have an emetic reflex, the reduced food intake and conditioned taste aversions (CTA), induced by LiCl in rats suggests that this substance induces nausea in this species.

The insular cortex is a brain region containing both taste responsive and viscerosensory neurons and has been implicated in the acquisition and expression of taste-illness associations. Lesions of the insular cortex interfere with LiCl-induced CTA learning in rats while epileptic foci in the human insula are associated with nausea and vomiting. Lesions of the insular cortex in rats also cause aphagia and in body weight loss, and electrical or chemical stimulation of the insular cortex alters metabolic processes and feeding, suggesting overall involvement of this area in ingestive function (McGregor & Atrens, Behav. Neurosci., 105, 870-883).

The present study determined whether LiCl injection would activate insular neurons as indexed by c-fos immunohistochemistry. Rats were injected i.p. with either LiCl (5mg/kg of 0.6M) or an equivalent volume of 0.9% saline. Two hours later, their brains were removed and processed immunohistochemically for the protein Fos (a marker of neural activation).

Rats injected with LiCl showed greater Fos expression in the insular cortex than rats treated with saline. This result suggests possible involvement of the insular cortex in nausea. Further research in our laboratory is aimed at understanding more fully this neural substrate and its role in nausea and CTA learning.

REPRESENTATION OF STIMULUS QUALITY AND INTENSITY IN A NETWORK MODEL OF BRAIN STEM GUSTATORY NEURAL CODING. P.M. Di Lorenzo and F.W. Grasso (SUNY at Binghamton, Binghamton, NY 13902)

In the neural code for gustation, both the quality of a tastant, e.g. sweet, sour, salty or bitter, and the intensity of that tastant are conveyed by the same processing elements. Given that these elements are multisensitive across taste qualities and across concentrations within those taste qualities, it is difficult to conceptualize how a single neuron or type of neuron might convey an unambiguous signal about an unknown tastant. In this context we have devised a mathematical simulation of gustatory neural coding that demonstrates how homogeneous processing elements (analogous to neurons), differing only in the strengths of their interconnections, can collectively encode both quality and intensity of a tastant. Based on data derived from electrophysiological responses to taste recorded simultaneously in the nucleus of the solitary tract (NTS) and the parabrachial nucleus of the pons (PbN), a self-organizing neural network model, called the Gustatory Unit Stimulus Selective Topographical Organizer (GUSSTO), was constructed. The input from a "receptor" sheet was mapped with modifiable excitatory connections to processing units at the "NTS" level. Within the "NTS", processing was influenced by fixed lateral inhibitory connections. Units at the level of the "PbN" received fixed excitatory connections from the "NTS" and made plastic inhibitory connections within the layer. GUSSTO was trained with simulations of responses analogous to those in the chorda tympani nerve and permitted to self-organize. Results demonstrate that both the "NTS" and "PbN" layers acquire the ability to express different across unit patterns for different taste qualities and that these patterns are similar but distinguishable for different concentrations of the same taste quality. Individual processing elements retain the ability to respond broadly across stimuli.

RELATIONSHIPS BETWEEN THE STRUCTURE AND FUNCTION OF GUSTATORY NEURONS IN THE RAT BRAINSTEM. Z. Jin*, X. Zhang, J. Massey, L. Schweitzer and W.E. Renshan, Div. Gastroenterology, Henry Ford Health Sciences Center, Detroit, MI 48202 and Dept. Anat. Sci. and Neuro., Univ. of Louisville, Louisville, KY 40292.

Although the precise nature of the relevant neural code is still the subject of some debate, the results of recent investigations by other laboratories appear to support the hypothesis that independent taste information channels (analogous in many ways to those associated with other sensory systems) transmit data related to the gustatory environment through the central nervous system. As evidence for this theory accumulates, we have directed our attention to the potential morphologic substrates for these information channels. In the present investigation, glass microelectrodes filled with 2.0% Neurobiotin (Vector Laboratories) were used to physiologically characterize and label individual gustatory neurons in the rat nucleus of the solitary tract (NST). If we restricted our analysis to the responses elicited by NaCl, HCl, quinine and sucrose, we found a marginally significant relationship ($p = 0.06$) between best tastant and the extent in the mediolateral plane, with NaCl-best neurons more widespread than those that were most sensitive to quinine ($\alpha = 0.05$). When we further restricted our analysis to those neurons that responded to only one of these four tastants, we found that both NaCl-only and HCl-only neurons were more widespread in the mediolateral plane than quinine-only cells. Furthermore, there was an indication that the quinine-only cells were more restricted in the dorsoventral axis. The difference between these groups was clearly revealed when the area of influence was considered. Quinine-only cells were smaller in the coronal plane than the cells that responded only to NaCl, HCl or sucrose. These data support the hypothesis that the response properties of gustatory NST neurons are related to the morphology of these cells. Our results suggest that the relationship between responsivity and dendritic architecture may be especially important. Supported in part by DC01074.

402.7

IN VITRO ANALYSIS OF GLUTAMATE AGONIST EFFECTS ON NEURONS IN THE ROSTRAL NUCLEUS OF THE SOLITARY TRACT. X.Q. Shu* and R.M. Bradley, Dept. Biologic and Materials Sciences, School of Dentistry, University of Michigan, Ann Arbor, MI 48109-1078.

Glutamate receptor agonists have been shown to have excitatory effects on neurons in the caudal nucleus of the solitary tract in rats (Andresen and Yang, *Am. J. Physiol.* 259:H1307, 1990). Using whole cell recordings in brain slices of the rat medulla we have examined the effect of glutamate receptor agonists on neurons in the rostral gustatory area of the nucleus of the solitary tract (rNST). Recordings were made from 42 neurons with stable resting membrane potentials and a spike overshoot. Superfusion of the glutamate receptor agonists, α -amino-3-hydroxy-5-methyl-isoxazole-4-propionic acid (AMPA) and *N*-methyl-D-aspartate (NMDA), resulted in membrane depolarization usually accompanied by a decrease in membrane resistance. Neurons either increased their firing rate or became spontaneously active with the depolarizations. All neurons tested responded to NMDA and 83% responded to AMPA indicating that the majority of rNST neurons have both NMDA and AMPA receptors. Neurons responded to NMDA and AMPA in a dose dependent manner. NMDA was effective over a concentration range of 10 - 100 μ M and AMPA was effective over a lower concentration range (0.25 - 10 μ M). Reversal potentials for NMDA and AMPA were estimated from current-voltage relationships in control saline and in the presence of NMDA and AMPA at concentrations producing a maximal response. The NMDA reversal potential was $1.2 \text{ mV} \pm 10.2$ (mean \pm SE, $n = 5$) and the AMPA reversal potential was $-4.9 \text{ mV} \pm 7.1$ ($n = 7$). These results, together with our previous studies on synaptic potentials in rNST neurons (*Chem. Senses* 18:647, 1993), indicate that glutamate is an excitatory transmitter at the first central synapse in the taste pathway. (Supported by NIDCD grant DC00288 to R.M.B.)

402.4

MORPHOLOGY OF PROJECTION NEURONS IN THE RAT ROSTRAL NUCLEUS OF THE SOLITARY TRACT (rNST) AND EVIDENCE FOR A PROJECTION TO THE rNST FROM THE BASOMEDIAL AMYGDA. M.S. King* and D.M. Murphy, Biology Dept., Stetson University, DeLand FL 32720.

The rat rostral nucleus of the solitary tract (rNST) contains second-order gustatory neurons, some of which project to higher brain centers via an obligatory synapse in the pontine parabrachial nucleus (PbN). The morphology of the projection neurons in the rNST has been described in rat (Lasiter and Kachele, '88, Lasiter, '91) and hamster (Whitehead, '90), with some conflicting results. The first part of the current study re-examined the morphology, number and location of rNST projection neurons visualized by stereotactically injecting the fluorescent tracer DiI (Molecular Probes) unilaterally into the PbN in male Wistar rats ($n=3$) and examining the retrogradely labeled cells in the rNST. On average, each injection produced 200 retrogradely labeled cells that could be characterized morphologically. Sixty-three percent of the labeled cells were located ipsilateral to the injection. The labeled neurons were located throughout the rNST, with the highest percentage (33%) found in the rostral central subdivision. All neurons had either multipolar- or elongate-shaped somata with the majority (61%) being classified as elongate.

Evidence indicates that forebrain autonomic and limbic centers directly project to the rNST (van der Kooy et al., '84). As a preliminary step to double-labeling studies investigating the neurotransmitter within these projections, we unilaterally injected DiI into the rNST ($n=3$) and examined coronal sections through the forebrain under epifluorescence. Retrogradely labeled cell bodies were found bilaterally within the amygdala, but none were found in the hypothalamus or other limbic structures. Cells in the amygdala were most abundant in medial, and particularly, basomedial structures with few cells located in central or lateral regions. Therefore, the basomedial amygdala may have direct effects on the processing of gustatory information within the rNST.

NEUROPHYSIOLOGICAL AND MORPHOLOGICAL CHARACTERISTICS OF RAT NUCLEUS TRACTUS SOLITARI NEURONS THAT RESPOND TO STIMULATION OF UPPER AIRWAY CHEMORECEPTORS. R.D. Sweazey*, T.M. Todoran and J.A. Cook, Department of Anatomy, Indiana University School of Medicine, Fort Wayne, IN 46805.

Information from taste buds on the epiglottis and aryepiglottal folds initiates upper airway protective reflexes via a brainstem pathway that includes the nucleus tractus solitarius (NTS). Currently, little is known about the response properties and morphological characteristics of rat NTS neurons that receive upper airway chemosensory information. We recorded the responses of rat NTS neurons to stimulation of upper airway taste buds with 0.5 M KCl and NH_4Cl , 0.01 N HCl and distilled water. After determining neural response characteristics to these chemical stimuli, 1.5-2% biocytin was iontophoretically injected into the NTS to determine the morphological properties of cells near the recording site.

Chemosensitive neurons were found 0.5 mm caudal to 1.0 mm rostral to obex, 0.5-1.2 mm lateral to the midline and 200-500 μ m ventral to the brainstem surface. Most neurons were located in the medial, intermediate or interstitial NTS. The order of effectiveness for the four chemical stimuli was $\text{KCl} > \text{NH}_4\text{Cl} > \text{distilled water} > \text{HCl}$. Both KCl and NH_4Cl elicited sustained responses whereas the responses to water and HCl adapted quickly. The majority of biocytin-filled neurons had round to fusiform shaped soma and 2 primary dendrites. In general, these dendrites were oriented in the rostral-caudal or medial-lateral plane and were restricted to the NTS.

Our findings suggest that NTS neurons responsive to stimulation of upper airway taste buds exhibit different chemical sensitivities, but similar gross morphological properties when compared to more rostrally located NTS neurons that process oral cavity chemosensory inputs.

402.8

FUZZY SET ANALYSIS OF ORGANIZATION OF TASTE RESPONSES IN NTS OF RAT. R. P. Erickson*, P. M. Di Lorenzo, G. S. Doetsch and M. A. Woodbury (Department of Psychology, Duke University, Durham, N.C. 27708)

The diversity of response profiles of taste neurons in the rat NTS and PbN can be accounted for by the participation of the neurons and stimuli in grades of membership in as few as 3 general interactions; further, the temporal patterns of response are accounted for by grades of membership in as few as 4 temporal divisions of the stimulus portions of the general interactions (Erickson, R.P., Di Lorenzo, P.M. and Woodbury, M.A., *J. Neurophysiol.* June 1994). That analysis was based on 4 stimuli at the PbN level (NaCl, HCl, sucrose and QHCl) and those plus KCl at the NTS level. The question remains whether these few parameters can account for data sets with larger numbers of stimuli. The analysis was performed on NTS neurons including the above 5 stimuli plus NaNO_3 , Na_2SO_4 , LiCl , Li_2SO_4 , CaCl_2 , NH_4Cl and HNO_3 . It was found that 3 general interactions were still adequate. Further, it became clear that as few as 3 temporal courses of response were sufficient. The several known receptor processes may be considered to act in a coordinated fashion as 3 mechanisms; each stimulus may be considered to participate in each mechanism to various degrees, and each receptor cell may contain these mechanisms to various degrees. Graded membership in these mechanisms by both stimuli and receptors/neurons is a "fuzzy" classification method. Supported by Duke University and NIA/NIA.

402.9

CISPLATIN-INDUCED CONDITIONED TASTE AVERSION IN THE RABBIT IS NOT ATTENUATED BY AREA POSTREMA ABLATION. J.P. Messenger* and W.W. Blessing. Centre for Neuroscience, Flinders Medical Centre, Bedford Park, SA 5042, Australia.

Conditioned taste aversions (CTA) are food avoidance responses which develop in situations where malaise follows ingestion of a particular food, even though the food itself may not have been the actual cause of malaise. CTAs are a robust adaptive reaction of critical survival value. The neural mechanisms of CTAs in the rabbit are not known. New Zealand White rabbits were deprived of water overnight and the volume of water consumed in a 1h period was measured the next day. After 3 days the water was replaced with a 10% sucrose solution. After 1h the animals were given an i.v. injection of saline (n=2) or cisplatin (0.2 mg/kg). Three to 6 days later the sucrose solution was re-presented and the volume consumed was measured. In a further 4 animals the area postrema (AP) was ablated 10 days prior to CTA investigation. Under halothane anaesthesia (1% in O₂) the dorsal surface of the medulla was exposed by retraction of the atlanto-occipital membrane. The AP was removed by aspiration through a bevelled fine guage needle. The ablation was later verified histologically. Saline injection produced no CTA to the sucrose solution. Unoperated rabbits (n=7) consumed 99±9 ml sucrose water in 1h prior to cisplatin (0.2 mg/kg), but consumed only 28±6 ml when it was re-presented 3-6 days later. Animals which had the AP ablation consumed 63±9 ml sucrose water prior to cisplatin (0.2 mg/kg) but only 6±4 ml 3-5 days later. These results indicate that in the rabbit cisplatin-induced CTA is mediated by a neural pathway other than the chemosensory AP.

402.11

CHARACTERISTICS OF ACTION POTENTIALS AND THEIR UNDERLYING OUTWARD CURRENTS IN MAMMALIAN TASTE RECEPTOR CELLS. M. Scott Herness*, Yushe Chen, and Sun Xiao-Dong. Indiana University School of Medicine, Muncie, IND. 47306.

Many rat taste receptor cells conduct action potentials (APs). APs had a mean threshold of -35 mV (n=61 cells) and a spike height of 52mV above threshold in current clamp (hold = -80mV). APs could be classified into two significantly different (p<0.001) groups - *fast*, with short half-time durations and large outward currents (mean=1.3 ms and 2.7nA), and *slow*, with long durations and small outward currents (mean=9.2 ms and 0.29nA). AP upstrokes were conducted by TTX-sensitive sodium currents whereas the downstroke by TEA-blockable outward currents. Voltage dependent analysis of outward currents separated transient and sustained components. The transient component was specifically blocked by 4AP (1mM). A calcium-dependent outward component was also revealed by modulating voltage and external calcium concentration. The fast recovery phase of the AP appears related to the sustained outward current whereas the after hyperpolarization (AHP) was blocked by 4AP suggesting a significant contribution of the transient component. Forskolin (FSK), which elevates cAMP, reversibly blocked the majority of the sustained current without influencing the transient. FSK greatly exaggerated the AHP without changing the spike height or duration. These data suggest that several components of the outward current contribute specifically to the gustatory AP and that the AP may be modulated by cyclic nucleotides. Supported by NIH DC00401.

CHOLINERGIC RESPONSES OF TASTE CELLS IN *NECTURUS* TASTE BUDS. Douglas A. Ewald* & Stephen D. Roper. Dept. of Anatomy & Neurobiology, Colorado State U., Fort Collins CO 80523 and the Rocky Mountain Taste & Smell Center, Denver CO 80262

Focal chemical stimulation of the apical tips of intact taste buds elicits receptor potentials in receptor cells and postsynaptic responses in Merkel-like basal cells (Ewald & Roper, J. Neurophysiol. 67: 1316, 1992). There is evidence that serotonin is a neuromodulator in taste buds (Delay, Taylor and Roper, J. Comp. Neurol. 335: 606, 1993; Ewald & Roper, J. Neurosci. May 1994), but the neurotransmitter in receptor cells that produces postsynaptic responses in basal cells and afferent nerve endings is unknown. In mammalian taste buds, acetylcholine (ACh) activates muscarinic receptors (Hwang *et al.*, P.N.A.S. 87: 7395, 1990) and immunocytochemical evidence has shown the presence of choline acetyltransferase in taste buds (Kim & Roper, this volume). We have investigated the effects of focally applied ACh (10 µM to 10 mM) on cells in intact taste buds and on isolated taste cells from *Necturus*. Short pulses of ACh elicit hyperpolarizing responses in receptor cells (4.5 ± 1.3 mV; mean ± SE; N=8; ACh = 100 µM; V_m = -60 mV), accompanied by increases in input resistance (37 ± 13%). In intact taste buds these responses are enhanced by bath application of acetylcholinesterase inhibitor (10 µM neostigmine; 67 ± 6%; N=4). In isolated receptor cells, the responses are mimicked by oxotremorine (100 µM), a muscarinic agonist, blocked by atropine (30 µM), a muscarinic antagonist, and not mimicked by nicotine (100 µM). Responses are increased by hyperpolarization of the membrane potential. The zero intercept of this increase, in conjunction with an increased input resistance during the responses, suggests that ACh responses are primarily due to a transient decrease in resting Cl⁻ conductance. We speculate that cholinergic responses may be part of an efferent control circuit, or may play a role in lateral interactions between taste receptor cells. Support: NIH DC01238.

INTERACTIONS BETWEEN SENSORY PETROSAL NEURONS AND CAROTID BODY CHEMORECEPTORS IN CO-CULTURE. H. Zhong and C.A. Nurse*. Dept. of Biology, McMaster University, Hamilton, Ontario, L8S 4K1.

We are interested in chemosensory transduction and synaptic mechanisms in the mammalian carotid body, an O₂-sensing organ that regulates breathing. Several studies indicate that the O₂-sensors are glomus or type 1 cells which transduce hypoxic stimuli by the closure of K⁺ channels, followed by depolarization and neurotransmitter release at synapses formed with petrosal sensory terminals. To investigate chemosensory signaling we developed co-cultures of dissociated (rat) petrosal neurons and glomus cell clusters. Monitoring of membrane potential in isolated co-cultured petrosal neurons, before and after perfusion of hypoxic (P_{O2}=25-30 torr) solutions, revealed silent, as well as spontaneously-active neurons that showed no obvious response to hypoxia. A third, and most interesting category was juxtaposed to glomus cell clusters; 2 of 7 such neurons depolarized reversibly during hypoxia, from a typical resting potential of -55 to -70 mV, and this was accompanied by an increase in membrane conductance. These neurons are strong candidates for ones that develop *de novo* functional synapses with glomus cells, and will be useful for studying synaptic events during chemosensory signaling. INTRAGEMMAL AND PERIGEMMAL FIBERS IN TASTE BUDS: IMMUNOCYTOCHEMISTRY AND DIFFERENTIAL SENSITIVITY TO CAPSAICIN. T.E. Finger*, G.M. Nelson, B. Bryant, and P.A. Moore. Rocky Mtn. Taste & Smell Ctr., Dept. Cell. & Struct. Biol., U. Colo. Sch. Medicine, Denver CO 80262; Monell Chem. Senses Ctr., Philadelphia PA

Taste buds and the immediately adjacent epithelium are richly innervated both by specific gustatory fibers upon which taste receptor cells synapse and by free nerve endings. Classic anatomical studies have separated this rich nerve plexus into intragemmal and perigemmal classes according to whether the nerve fibers enter the taste buds. Immunocytochemical studies within the last two decades have demonstrated that many of the free nerve endings are immunoreactive (ir) for substance P (SP) and CGRP and that some of these enter the taste bud proper. Thus the designation of "intragemmal" and "perigemmal" probably does not exactly correspond to the physiological role of the particular fibers. Further, a rich synapsin- and synaptophysin-ir intragemmal nerve plexus is present and at least some of these fibers are post-synaptic to taste receptor cells. The present study on rats was undertaken to test whether the SP/CGRP-ir fibers and the synaptophysin-ir fibers represent distinct populations and whether either group is abolished following neonatal exposure of an animal to capsaicin. Co-localization experiments were carried out utilizing primary antisera raised in different species and simultaneous visualization with two different fluorescent probes. The synaptophysin-ir and SP/CGRP-ir fibers represent two largely independent and non-overlapping populations. In circumvallate papillae, a few scattered double-label fibers occur, while in the fungiform papillae, the two populations are mutually exclusive. Following perinatal treatment of rat pups with capsaicin (50 mg/kg i.p.), the SP/CGRP but not the synaptophysin-ir populations are abolished.

IN VITRO UPTAKE OF ³H-GLUTAMATE AND ³H-GABA IN *NECTURUS* TASTE BUDS. T. Nagai, R. J. Delay* and S. D. Roper. Dept. Physiol., Teikyo Univ. Sch. Med., Tokyo 173, Japan, Dept. Anat. Neurobiol., Colorado State Univ., Fort Collins, CO 80523.

Glutamate (Glu) and GABA are found in nerve fibers that innervate *Necturus* taste buds (Jain & Roper, '91; Lu & Roper, '93). To investigate whether Glu/GABA are involved in synaptic transmission in taste buds, we studied their uptake and release in taste cells. Lingual epithelium was incubated with ³H-Glu (0.5, 5.0 µM) or ³H-GABA (0.6, 6.0 µM) in amphibian physiological saline (APS) for 15 min., rinsed with fresh APS, fixed with 2% glutaraldehyde, postfixed with 2% OsO₄, embedded, and sectioned at 2.5 µm. Slides were coated with Kodak emulsion and exposed for 3-10 days. Background labeling for ³H-Glu was seen throughout lingual epithelium. However, silver grains preferentially accumulated over some taste cells. Next, epithelium was incubated with ³H-Glu and rinsed with APS containing 40 mM K⁺. K-treatment reduced the number of heavily labeled taste cells, consistent with a depolarization-induced release of Glu. Rinsing tissues with 40 mM K⁺ but in the presence of 20 mM Mg²⁺ and 0.4 mM Ca²⁺ did not reduce the number of labeled taste cells. When lingual tissues were incubated with ³H-GABA, labeling was seen over cells lying outside of taste buds, including putative glial cells in the *lamina propria*. ³H-GABA uptake was not affected by rinsing tissues with 40 mM K⁺. We conclude that *Necturus* taste buds have uptake and Ca-dependent release mechanisms for Glu that may be related to synaptic actions. We did not find evidence for depolarization-dependent release mechanisms for GABA in taste buds.

402.15

IMMUNOCYTOCHEMICAL LOCALIZATION OF CHOLINE ACETYLTRANSFERASE IN TASTE BUDS. Dae-Joong Kim and Stephen D. Roper*. Dept. of Anatomy and Neurobiology, Colorado State University, Fort Collins CO 80523 and the Rocky Mountain Taste and Smell Center, Denver CO 80262

Cholinergic synaptic mechanisms in taste buds were proposed several years ago based on the finding that injecting cholinergic agonists and antagonists into the tongue modified taste responses. Additionally, acetylcholinesterase (AChE) has been localized in taste buds from a number of species. However, AChE can be associated with noncholinergic neurons. The presence of AChE is not a reliable indicator of cholinergic neurotransmission. In contrast, the localization of choline acetyltransferase (ChAT), the biosynthetic enzyme for acetylcholine, is considered direct evidence for cholinergic mechanisms in the nervous system. We have conducted immunocytochemical studies on lingual tissues from rats and mice to determine whether ChAT is localized to taste buds. Immunocytochemistry revealed ChAT in taste receptor cells of vallate papillae. Three to eight receptor cells per taste bud showed intense ChAT immunoreactivity in their cytoplasm. ChAT-immunopositive cells were elongate and their cell processes extended from the taste pore to the base of the taste bud. Immunostained cells were mainly located at the periphery of taste buds. On the basis of these data, as well as recent findings on the physiological actions of muscarinic agonists in taste buds (Hwang *et al.*, PNAS 87: 7395, 1990; Ewald & Roper, this volume, 1994), we postulate that acetylcholine functions as a neurotransmitter in vertebrate taste buds. Supported by NIH DC00374 and DC00244.

GLUTAMATE CHEMORECEPTION IN *PARAMECIUM*. J. L. Van Houten*, W. Q. Yang, F. Hecht, C. Braun**, and H. Plattner**. Dept. of Zoology, University of Vermont, Burlington, VT 05405 and **Universität Konstanz, Konstanz, Germany

Glutamate is an attractant stimulus to *Paramecium tetraurelia*. Cells in glutamate swim smoothly and relatively fast, which is characteristic of a relatively hyperpolarized cell. Direct measurements of membrane potential confirm this. The hyperpolarization appears to be associated with an increase in intracellular cyclic AMP (cAMP). H8, an inhibitor of Protein Kinase A among others, inhibits chemoreception to glutamate but not NH₄Cl. To investigate whether the rise in cAMP were rapid enough to be part of a stimulus pathway as opposed to a desensitization pathway, we utilized a rapid mixing apparatus that allowed us to analyze whole cells that were stimulated for 30 msec to 5 sec with glutamate or low K hyperpolarizing conditions as a positive control. The 6 fold rise in cAMP was rapid, peaking at 300 msec and falling to a 3 fold elevated level of 118 pmole/mg protein. The level of cAMP approaches that of the baseline control by 5-10 min.

IMP is a repellent which depolarizes cells. The binding of and response to IMP can be inhibited by glutamate. Cyclic AMP levels decrease by 50% at 30 sec. Rapid kinetic measurements of cAMP in cells stimulated by IMP were inconclusive. However, cGMP appears to increase slightly in cells stimulated by IMP for 30 msec to 1 min, but the increases are much smaller than those caused by the high Ba depolarizing positive control.

MOTOR CORTEX: CORTICAL PHYSIOLOGY

403.1

SIMPLE AND COMPLEX RELATIONS OF MOTOR CORTICAL ACTIVITY TO GRIP FORCE IN THE ALERT MONKEY. H.-X. Qi, E.J. Huesler, J. Alio, M.-C. Hepp-Reymond*. Brain Research Institute, 8029 Zürich, Switzerland.

Neuronal correlates of force have been repeatedly shown in the primary motor cortex (M1). We wondered whether the neuronal activity in two ventral premotor regions (PMv) and M1 may code other features than just grip force.

We have analysed 242 finger-related cells, recorded from the 3 regions in 2 monkeys trained to produced isometric force in a step-tracking task. The trials varied in number of steps, in force range and direction, each alternative indicated by its own colour cue. The findings are: 1. More than half of the neurons displayed positive or negative correlation between cell activity and force. In 70% of these significant cells, similar discharge patterns were found under all test conditions. The rest, and a large proportion of non-significant cells, had more complex firing patterns. Most of these neurons (d1 cells) changed their force covariation at the highest force level, thus suggesting linearity only within a narrow force range. With high forces a few d1 cells also altered their phasic activity component during the force ramps. The minority of the neurons with complex force relation (d2 cells) clearly changed their discharge patterns during the last hold period, regardless of the type of trial. 2. The distribution of the 3 cell populations and their mean force sensitivity was comparable in the 3 explored regions. 3. Most neurons with significant correlation coefficient responded to activation of deep (muscle and joint) receptors. The proportion of cutaneously activated cells was higher in the d2 population. 4. Some PMv neurons with receptive fields on face and hand also showed significant covariation with force.

In conclusion, these findings suggest that most M1 and PMv neurons code force in simple manner, and that only a minority has activity related either to force within a narrow range or to other parameters or task features.

RELATIONSHIP OF TASTE BUD REGENERATION AND SALT DISCRIMINATION PERFORMANCE AFTER CHORDA TYMPANI TRANSECTION IN RATS. S.J. St. John, S. Markison, and A.C. Spector*. Dept. of Psychology, Univ. of Florida, Gainesville, FL 32611.

Chorda tympani (CT) transection causes anterior tongue taste bud degeneration and severely disrupts the rat's ability to discriminate NaCl from KCl. We recently demonstrated that rats trained presurgically and tested starting 49 days postsurgically (CTX/49d) could discriminate the two salts, but those tested 8 days postsurgically (CTX/8d) could not. The CTX/49d rats had ~70% of the normal complement of anterior tongue taste pores (TPs), suggesting CT regeneration. As previously, rats in the present study were trained to maintain licking to one salt and suppress licking to the other. Performance was quantified as an overlap score (0-100%) of the response distributions, where 100% indicated no difference in licking to the two salts (i.e., no discrimination). The rats tested 7 days after unilateral CTX were only slightly impaired despite that these rats (n=4) had ~50% fewer TPs than controls. The rats tested starting 28 days after bilateral CTX (n=7) displayed variability in salt discrimination performance, ranging from normal to severely impaired (overlap score range: 6.7-77.9%). A third group (n=4) tested 49 days after CTX displayed competent discrimination. When the data from the present groups were combined with the data from the control, CTX/49d, and CTX/8d groups previously reported, the overlap scores correlated (r=-0.88) with the percentage of fungiform papillae containing a TP (p<0.001, n=27). Although some rats with a small number of anterior tongue TPs were partially competent, overall it appears that there is a strong relationship between the extent of taste bud regeneration and performance in the salt discrimination task. PRIMATE MOTOR CORTEX: NEURONAL ACTIVITY CODING FOR OPERATIONS IN EXTERNAL SPACE THAT ARE INDEPENDENT OF LIMB TRAJECTORY. L. Shen* and G.E. Alexander. Dept. Neurology, Emory Univ. Sch. Med., Atlanta, GA 30322.

Two macaque monkeys were trained to perform a two-dimensional, delayed step-tracking task in which they used the right upper extremity to operate a joystick that moved a cursor on a video display screen. Single cell recordings were obtained from the shoulder and elbow regions of the primary motor cortex. The presentation of a fixation target on the center of the monitor signaled the beginning of a trial. Once the monkey moved the cursor into the fixation point, four peripheral targets were presented. One of the target subsequently dimmed briefly, signaling the target, and the monkey was to capture the target after a delay upon the dimming of the fixation point. Spatial mapping between the cursor and joystick movement was offset by either 0° or 90°. Hand trajectory was thus either parallel (0°) or perpendicular (90°) to the direction of displacement (from center) of a given target. The spacing of the targets was such that the set of movements towards all four targets was equivalent in the two conditions, allowing determination of whether neurons with directional preparatory or movement-related activity were preferentially tuned to the direction of target displacement or to the direction of hand movement. Among cells that were directionally tuned, two cell types were predominant. Tuning curves of the first type of cells were invariant with respect to hand trajectory. The second type showed directional activity that was invariant with respect to target direction. These results indicate that directional tuning of motor cortex neurons is not always representative of limb trajectory as neurons of the second type appeared to represent the intended direction of cursor movement rather than that of the limb.

403.3

CELL ACTIVITY IN MONKEY MOTOR CORTEX IS ALTERED BY CHANGES IN ARM POSTURE FOR MOVEMENTS WITH IDENTICAL HAND TRAJECTORIES. S. H. Scott* and J. F. Kalaska, Dépt. de Physiologie, Univ. de Montréal, Montréal, Québec, CANADA, H3C 3J7

The debate continues as to whether neuronal activity in the monkey motor cortex during reaching movements is better related to the extrinsic (i.e. hand trajectory) or intrinsic (i.e. muscle activity, joint moments) attributes of the motor task. We have trained a monkey to move a pendulum-like handle to visual targets using two different arm postures, but with identical hand paths. In the first posture (control), the monkey was allowed to perform the task in its preferred arm orientation (largely in the sagittal plane). In the second posture (abducted), the monkey had to abduct its arm approximately 90 degrees in order to grasp and move the handle. This perturbed arm posture changed the mechanical properties of the muscles (length and moment arm about the joints) and changed the EMG activity patterns of muscles that span the shoulder and elbow joints. We recorded the activity of a large sample of cells in the contralateral motor cortex during the motor task. In the control posture, the activity of individual cells were broadly tuned to the task. The vectorial sum of population activity was oriented approximately with the movement direction. In the abducted posture, the activity of the cells during the motor task was usually not identical to that recorded for the control posture; tonic cell activity often increased or decreased and the preferred direction often changed. The population vectors in the abducted posture varied systematically from the direction of hand movement; these vectors were skewed towards one of two possible directions in which maximal shoulder movement was required to generate the motor task. The sensitivity of cell activity in motor cortex to arm posture is inconsistent with the notion that motor cortex cells signal only hand trajectory in space. (Funded by MRC Group Grant in Neurological Sciences to JFK and MRC Post-Doctoral Fellowship to SHS).

CHRONIC NEURAL RECORDING WITH MULTICONTACT SILICON MICROPROBES: EFFECTS OF ELECTRODE BIAS. E.M. Schmidt*, W.J. Heetderks and D.M. Camesi-Cole, Lab. of Neural Control and Neural Prosthesis Program (WJH), NINDS, NIH, Bethesda, MD 20892.

Silicon microprobes with integral flexible cables (Neurosci. Abstr. 1993) have been implanted in monkey supplementary motor area for over seven months and continue to record multi-unit activity with spike amplitudes that permit unit isolation using conventional multi-unit spike sorting methods. The recording sites on our probes are sputtered iridium that have been activated to produce an oxide film that lowers the impedance of the electrodes by a factor of ten. However, this electrode impedance is voltage dependent. In this report we demonstrate that the application of a bias potential to the electrodes has a significant effect on the electrode impedance and on the recorded signal amplitude of the spikes. Signal to noise ratios are repeatedly increased by a factor of three or more by the brief application of an anodic bias to the electrode. In a typical recording session, this results in a substantial increase in the amplitude of the larger spikes and the emergence of several smaller spikes from the background hash. After several months of implantation without bias, neural activity is greatly diminished and impedances are increased. A small positive bias no longer shifts the electrode to the low impedance state. In order to return the electrode to a low impedance value, a larger bias must be applied such that currents of approximately 10 nA flow. When this occurs, the electrode impedance drops and spike amplitudes are increased. Two phenomena that appear to affect long term recordings are the impedance state of the electrode and an encapsulating sheath around the electrode that may be disrupted by the passage of currents in the nanoamp range.

403.7

CROSS CORRELATIONS BETWEEN PAIRS OF IDENTIFIED CELLS IN MONKEY MOTOR CORTEX: IMPLICATIONS FOR THE ORIGIN OF POST SPIKE FACILITATION IN RECTIFIED EMG OF HAND MUSCLES. S.N. Baker, E. Olivier, R.N. Lemon*, Sobell Department of Neurophysiology, Institute of Neurology, Queen's Square, London, WC1N 3BG, UK.

The technique of averaging rectified EMG with respect to pyramidal tract neurones (PTN's) recorded from primary motor cortex (spike triggered averaging, STA) has been claimed to allow demonstration of monosynaptic cortico-motoneuronal (CM) connections. Such connections are assumed when the average shows a short latency and duration post spike facilitation (PSF). Critics have suggested that synchrony between the firing of the recorded cell and CM cells could produce facilitation in STA without direct connections from the trigger cell to the motoneurons innervating the recorded muscle (eg Kirkwood, Behav Brain Sci 1992, 15:766-767).

Using two parallel microelectrodes separated by 2 mm, we have recorded from 16 pairs of identified PTN's in the motor cortex (7 pairs on the same electrode) of 4 *Macaca nemestrina* monkeys trained to do the precision grip task, whilst simultaneously recording EMG from 9 hand and forearm muscles. For 6 pairs (5 on the same electrode), both cells showed clear PSF in STA of at least one common muscle. In all 6 such pairs, there was a significant central peak in the cross correlograms between the two cells, mean width 15.0 ms, range 9.5-24.5 ms, mean strength as measured by fraction of total spikes synchronised 0.053 (range 0.016-0.1135), suggesting a common input to the two cells.

These data have been combined with other information in the literature to produce a realistic computational model of the effect of synchrony on the production of PSF. A previous study (Smith and Fetz, Neurosci Lett 1989, 96:76-81) addressed the same problem using a spike selection method and a convolution method. Our model takes account of non-linearities inherent in using rectified EMG, and is able to investigate the consequences of synchrony amongst different numbers of cells, allowing more comprehensive quantitative analysis of the contribution of synchrony to PSF.

Supported by the Wellcome Trust, Action Research and the MRC.

403.4

MULTI-ELECTRODE RECORDING OF NEURONAL ACTIVITY IN THE MOTOR CORTEX: EVIDENCE FOR CHANGES IN THE FUNCTIONAL CONNECTIVITY BETWEEN NEURONS DURING A REACTION-TIME TASK. J. Requin*, A. Riehle, J. Seal, B. Arnaud, M. Coulmance, R. Fayolle, and N. Vitton. Cognitive Neuroscience Laboratory, CNRS-LNC, 31 Chemin Joseph Aiguier, 13402 Marseille Cedex 20, France

We have studied the changes in the functional connectivity between neurons, within a volume comparable in size to the modular organization of cortical structures, during the construction of a motor action. Two monkeys were trained in a reaction time (RT) task in which they performed a pointing movement with the arm, after a preparatory period (PP) of variable duration. A multi-electrode microdrive was used to transdurally insert into the cortex 7 independently driven microelectrodes, spaced 160 μ m apart (Mountcastle et al., 1991). The activity of 780 neurons of the primary motor cortex was recorded during 255 sessions. In order to study the dynamic changes in interactions between sets of task-related neurons, joint peri-event time histograms (Aertsen et al., 1989) were then calculated on 265 pairs of simultaneously recorded neurons. The activity of 39 pairs of neurons (15%) was significantly synchronized during periods of time lasting 50 to 300 ms. Such periods of synchronization occurred just after the preparatory signal, at the end of the PP, during RT and/or during movement time. For 14 pairs, the neurons fired with a synchrony of less than 1 ms, whereas in the remaining 25 pairs, larger peaks of cross-correlograms were observed. Synchronized neurons were recorded with a mean horizontal distance of 377 μ m (160 to 1980 μ m) and a mean vertical distance of 464 μ m (0 to 1810 μ m). This study provides further evidence for dynamic changes in the functional connectivity within neuronal populations involved in the processing of sensorimotor information. Detailed analysis of cross-correlation data will be used in an attempt to decipher the functional organization of the basic processing unit of the cortical tissue and to investigate how cognitive functions are implemented in the microstructure of the cerebral cortex.

403.6

PRIMATE PREFRONTAL CORTEX PLAYS A SIGNIFICANT ROLE IN PERFORMING SEQUENTIAL BEHAVIOR WITH AN IMPOSED DELAY.

S. Funahashi*, M. Inoue, and K. Kubota, Dept. of Cognitive Sci., Grad. Sch. of Human and Environmental Studies, Kyoto Univ., Kyoto 606-01, and Primate Res. Inst., Kyoto Univ., Aichi 484, Japan.

To investigate the roles of the prefrontal cortex in generating sequential behavior, single neuron activity was examined in the periprincipal region while 2 monkeys performed a sequential hand-reaching task to two of three targets and a simple reaching task to one target as a control. In addition, to examine whether prefrontal neurons retain multiple target positions simultaneously, a 3-5 s delay period was imposed between the target presentation and the reaching behavior.

A total of 234 single neuron activities were analyzed. Among them, 138 exhibited task-related activity in at least one phase of either task; 85, 72, and 108 exhibited cue-, delay-, and response-related activity, respectively. A large proportion of these activities exhibited complex and context-dependent characteristics. For example, 36% of the delay-related activity was observed only when two specific targets were presented in a particular order during the cue period (pair- and sequence-dependent), and 18% of this activity was observed only when a specific target was presented in either the first or second position (position- and sequence-dependent). However, the remaining neurons exhibited task-related activity under simple conditions. For example, 8% of the delay-related activity was observed when the target was presented in a particular position, regardless of its order. A similar variety of response characteristics, from context-dependent to simple, was observed in response-related activity.

These results indicate that the prefrontal cortex plays an important role in executing sequential behavior. The prefrontal cortex may participate in complex sequential behavior by retaining target positions through a variety of activities, each of which can retain either simple information (e.g., a single position) or multiple and complex information (e.g., multiple positions and a particular order).

MOTOR CORTEX AND INTERCEPTION OF MOVING TARGETS: SINGLE CELL ANALYSIS. N. Lindman Port*, W. Kruse, P. Dassonville and A. P. Georgopoulos, Brain Sciences Center, VAMC, Minneapolis, MN.

Two monkeys were trained to use a 2D articulated manipulandum to intercept moving targets on a computer screen. In random order, 9 targets either accelerated, decelerated or traveled at a constant velocity. For each motion condition targets traveled for one of three target movement times: 0.5, 1 and 1.5 s. Targets appeared randomly in either the right or left lower corner of the screen, then traveled along a 45° path until they crossed the vertical meridian. The monkeys were required to intercept the moving target as it crossed the vertical meridian, making an upward movement (12 cm) from an initial hold position. An interception was considered successful when the movement entered, within 130 ms of the target, a 1 cm radius positional window centered on the point at which the target crossed the vertical meridian. The spike activity of 411 cells were recorded in the arm area of the motor cortex in one monkey during task performance. We found that the activity of various populations of neurons was modulated during the interception task. In most cases the change in cell activity was similar to that observed during upward movements toward a stationary target, in another task, but in other cases changes in cell activity differed between the two tasks. Moreover, cell activity during the last 200 ms of the reaction time was frequently modulated in relation to the temporal characteristics of the ensuing movement; for example, activity in 31% of cells differed significantly ($P < 0.05$, ANOVA) among trials with different target velocities, irrespective of the kind of target motion (accelerating, decelerating or constant speed), whereas in 6% of cells it differed according to the kind of motion above, irrespective of the speed itself, and in 11% of cells both speed and kind of target motion had a significant effect. These results indicate that the motor cortex is involved with processing of the temporal characteristics of the interception movement. (Supported by NIH grant PSMH48185).

403.9

MOTOR CORTEX AND 3D ISOMETRIC FORCE: STATIC RELATIONS. J. Boline*, J. Ashe, M. Taira and A.P. Georgopoulos. Brain Sciences Center, Veterans Affairs Medical Center, and Dept. of Physiology, Univ. of Minn. Med. School, Minneapolis, MN

The relations between the steady-state activity of cells in monkey motor cortex and the direction and magnitude of isometric force were determined using a 3D isometric manipulandum (Massey et al., *J. Neurosci. Methods* 26:123-127, 1988) and a visually instructed task. Five repetitions of 24 constant force levels were employed in a randomized block design where each block consisted of 3 force magnitudes (100, 150 and 200 total gm-force) exerted in each of 8 XY directions (every 45 deg); force exerted in the Z dimension was monitored but not controlled. Data from electromyographic (EMG) activity of 7 muscles and impulse activity from 91 cells were analyzed using a repeated measures analysis of variance and a multiple linear regression of EMG and cell activity versus the X, Y, Z components of force. The magnitude of force had a significant effect ($P < 0.05$) in 75% of muscles and 31% of cells studied, whereas the direction of force had a significant effect in all muscles and 70% of cells; significant magnitude x direction interactions were observed in 62.5% and 23% of muscles and cells, respectively. The multiple regression was significant in all muscles and 76% of cells. R^2 values (mean \pm SD) were 0.529 ± 0.203 and 0.239 ± 0.173 for the muscles and cells, respectively. Preferred force orientation vectors for cells and muscles were distributed throughout the XYZ directional continuum. (Supported by VA and NIH.)

403.11

MOTOR CORTEX AND ISOMETRIC FORCE: DYNAMIC VS. STATIC PROCESSES. J. Ashe*, J. Boline, M. Taira and A.P. Georgopoulos. Brain Sciences Center, Veterans Affairs Medical Center, Minneapolis, MN 55417.

The hypothesis was examined that dynamic processes, effecting change in force, and static processes, involved in the maintenance of a constant force, are reflected separately in the patterns of neural activity of cells in monkey motor cortex. For that purpose cell activity was recorded while monkeys performed 3 visually instructed tasks using a 3D isometric manipulandum (Massey et al., *J. Neurosci. Methods* 26:123-127, 1988). The tasks involved the production of (a) purely dynamic isometric force pulses (task 1, $n=430$ cells); (b) pulse-and-step forces that were maintained for 0.5 s (task 2, three step forces; $n=91$); and (c) dynamic force pulses in the presence of a constant force bias (task 3, $n=331$). Results from tasks 1 and 3 showed that cell activity associated with dynamic force pulses was similar across different force biases. Results from tasks 1 and 2 showed that the time course of cell activity in task 2 resembled initially (i.e. during the reaction time) the pattern observed in the dynamic pulse task, and then changed to the pattern appropriate for the ensuing static force step. The replacement of the dynamic by the static pattern occurred approximately 150 ms before the attainment of the static force level. Moreover, the dynamic and static patterns were frequently directionally incongruent. (Supported by NIH and VA).

403.13

CORTICOMOTONEURONAL (CM) POST-SPIKE EFFECTS ON SHOULDER, ELBOW, WRIST, DIGIT AND INTRINSIC HAND MUSCLES DURING A REACHING TASK IN THE MONKEY. B.J. McKiernan*, J.K. Marcario, J.H. Karrer and P.D. Cheney. Physiology Dept. and Smith MRRRC, Univ. of Kansas Med. Ctr., Kansas City, KS 66160.

Spike triggered averaging of rectified EMG activity has proven to be an effective means of identifying motor cortex cells with a functional linkage to motoneurons (Cheney et al., *Prog. Brain Res.*, 87: 213, 1991). Previous studies of forearm muscles have shown that many CM cells not only facilitate multiple agonist muscles of the forearm but also suppress the antagonist muscles (Kasser and Cheney, *J. Neurophysiol.* 53: 959, 1985). This reciprocal output pattern constitutes a functionally meaningful synergy raising the possibility that more complex functional synergies may also be represented in the synaptic outputs of single CM cells. The purpose of this study was to investigate 1) the possibility that during an arm reaching movement, individual CM cells may facilitate muscles at different joints; and 2) the extent to which the facilitated muscles constitute a functional synergy whose action would produce a specific phase of the movement. The spike discharges of single cells in motor cortex were used to compute spike-triggered averages of rectified EMG activity from 22 muscles of the shoulder, elbow, wrist and hand while the monkey performed an automated reaching task to retrieve a pellet from Kluver type food well. Stimulus-triggered averaging of EMG activity was used to map the location of output zones for the same 22 muscles. Of 108 motor cortex cells tested, 30 were identified as CM cells by their postspike effects in at least one of the muscles tested. Ten (33%) of these CM cells produced output effects in muscles at two or more joints. We conclude that some cells in motor cortex facilitate functional muscle synergies needed to produce specific phases of a coordinated arm reaching task. (Supported by NIH grant NS25646).

403.10

MOTOR CORTEX AND INTERCEPTION OF MOVING TARGETS: NEURONAL POPULATION ANALYSIS. W. Kruse*, N. Lindman Port and A.P. Georgopoulos. Brain Sciences Center, Veterans Affairs Medical Center, Minneapolis, MN.

A monkey was trained to intercept a moving target on a planar working surface within 130 ms and 1 cm of its arrival at the 12 o'clock position on a computer monitor. In a trial, the target moved from either of two positions, at 3 or 9 o'clock, towards 12 o'clock in a linear trajectory. The target could be accelerating, decelerating or moving at a constant velocity; each one of these conditions was presented such that the total movement time of the target was 0.5, 1 or 1.5 s. The hand movement always started from the center of the clock and ended at 12 o'clock. Moreover, trials were included in which the monkey moved in 8 directions (every 45°) towards targets on a circle. The spike activity of 212 directionally tuned cells recorded in the arm area of the motor cortex during task performance was analyzed. We calculated the population vector every 20 ms in all the conditions above; we also computed instantaneous velocity vectors of the ensuing trajectories. The population vectors pointed in the direction of the upcoming movement and did not seem to reflect the spatial motion of the stimulus. The change in the length of the population vector began -180 to -350 ms before the onset of movement, even though average reaction times (RT) varied from 345 ms (for the fastest decelerating target motion) to 1,280 ms (for the slowest accelerating motion). Assuming that information concerning stimulus motion is processed during the initial part of the RT, these results indicate that this stimulus processing may not be reflected in motor cortical activity. However, the time above by which the population vector preceded the onset of movement was systematically longer for slower speeds of target motion. This suggests that some aspects of visuomotor integration are processed in the motor cortex, most probably relating to the timing and temporal profile of the interception movement. MOTOR CORTEX AND VISUOMOTOR MEMORY SCANNING. G. Pellizzer*, P. Sargent and A.P. Georgopoulos. Brain Sciences Center, VAMC, Minneapolis, MN 55417.

We trained a monkey in a memory scanning and a control task to exert a force pulse on a 2D semi-isometric handle in 8 different directions. In the memory scanning task, (1) 3 yellow stimuli were presented sequentially and stayed on the screen; (2) one of the stimuli, except the last one, changed from yellow to blue which identified it as the test-stimulus, and gave the go signal; (3) the correct response was to the stimulus that succeeded the test-stimulus during the initial presentation. In a control task, one stimulus was presented and the response was made to that stimulus after the go signal. We recorded the activity of 247 cells in the motor cortex during the two tasks. (a) When the test-stimulus was the 1st stimulus in the sequence, cell activity during the RT did not reflect the direction of that stimulus but instead the direction of the response; similarly, the neuronal population vector, calculated every 20 ms, pointed in the direction of the response. The lack of neural representation of the 1st stimulus in this case can be explained by the fact that, by the design of the task, the 1st stimulus in the sequence was never the target of the response. (b) When the test-stimulus was the 2nd in the sequence, cell activity during the RT reflected first the direction of this stimulus, and then switched to reflect the direction of the response; similarly, the neuronal population vector pointed first in the direction of the test stimulus and then abruptly switched direction and pointed in the direction of the response. These results suggest that memory scanning involves abrupt switching of direction, a process different from a rotation discovered previously in a mental rotation task (Georgopoulos et al., *Science* 243: 234, 1989). This is in accord with the results of psychophysical experiments which suggested different constraints in directional processing between mental rotation and memory scanning tasks (Pellizzer and Georgopoulos, *Exp. Brain Res.* 93: 165, 1993). (Supported by NIH NS17413).

ACTIVITY OF MONKEY SENSORIMOTOR CORTICAL (SMC) AND NEOSTRIAL (NS) NEURONS DURING HAND MOVEMENTS MADE UNDER UNPREDICTABLE CONDITIONS. R.J. Nelson*, J.M. Denton and M.A. Lebedev. Department of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, 875 Monroe Avenue, Memphis, TN 38163.

The activity of neurons in monkey SMC and NS was studied in a paradigm where rewards for correct performance were given only 75% of the time, pseudorandomly. Monkeys made ballistic wrist flexions and extensions in response to palmar vibration (57 Hz) or visual go-cues. Animals actively held a steady position for 0.5-2.0s before the go-cue. The paradigm met NIH animal utilization guidelines. The activity during trials following rewarded trials (Regular trials) was compared to that during trials following ones in which reward for correct performance was withheld (After trials).

A total of 120/295 SMC neurons and 40/101 NS neurons were selected because their firing patterns changed before movement or with sensory cues. After trials mean reaction times (RTs) were significantly shorter regardless of cue type. Differences in RTs between visual and vibratory cued trials (Regular trials: ~45ms; After trials: ~15 ms) were significantly reduced when reward delivery became unpredictable. This resulted largely from a decrease in visual trial RTs. Activity during active hold was significantly greater in After trials for both cueing conditions. Premovement activity (PMA) occurred closer to movement onset and was greater in magnitude during After trials as compared with Regular trials. These last differences were statistically significant for SMC but not NS neurons. PMA occurred significantly earlier during After trials when the monkey moved in the direction of the stimulated hand surface (flexion) as compared to away from it (extension). Premovement activity onsets for both SMC and NS neurons preceded movement onset by about 150ms while the earliest EMG activity recorded from nine forelimb muscles was about 90ms. SMC cue related neurons were significantly more responsive to vibration during After trials.

These observations suggest that monkeys are more attentive and that SMC and NS neurons are more responsive to peripheral and central inputs during unpredictable rewarding conditions. Thus, these neurons may be gated during predictable behavioral conditions. Supported by USAF Gr AFOSR 91-0333 and NIH Gr NS 26473.

ACTIVITY OF NEURONS IN PRIMATE PRIMARY MOTOR CORTEX (MI) DURING TRAINED AND SEMI-AUTOMATIC OROFACIAL MOTOR BEHAVIORS. R.E. Martin*, Y. Masuda, P. Kemppainen, N. Narita, and B.J. Sessle. Toronto Hospital and Univ. of Toronto, Toronto, Canada.

This study aimed to determine whether tongue-MI neurons participating in trained tongue movements (Murray & Sessle, J. Neurophysiol. 92) also participate in semi-automatic movements such as those of swallowing and mastication. Extracellular single neuron recordings were obtained from tongue-MI (defined by intracortical microstimulation; $\leq 30\mu A$) while the awake monkey (M. fascicularis) (a) performed a trained tongue protrusion task, (b) swallowed a juice reward after successful tongue-protrusion trials, (c) swallowed juice from a syringe, and (d) masticated and swallowed apple. Electromyographic (EMG) activity was simultaneously recorded from various orofacial and laryngeal muscles for EMG confirmation of tongue protrusion, swallowing, and mastication. Of a total of 21 tongue-MI neurons tested to date, 12 (57%) showed alterations of firing during the trained tongue protrusion task. Of these, the activity of 92% was modulated in relation to swallowing of the juice reward and all showed modulated activity in relation to swallowing of juice from the syringe or swallowing apple. Of the neurons that showed altered activity during both trained tongue protrusion and swallowing, 89% also exhibited altered firing during mastication. Preliminary recordings more laterally in the "cortical masticatory area" of the same monkey indicate that some neurons in this area also may alter their activity in relation to both trained and semi-automatic orofacial movements. These findings suggest that neurons in tongue-MI and adjacent cortical regions may play a role in the control of semi-automatic as well as trained orofacial motor behaviors. Supported by Canadian MRC grant MT-4918.

SYNCHRONIZATION OF PRIMATE SENSORIMOTOR CORTEX NEURONS DURING 20-40 HZ FIELD POTENTIAL OSCILLATIONS. Y.N. Murthy* and E.E. Fetz. Regional Primate Research Center, Univ. of Washington, Seattle, WA 98195.

In monkeys performing exploratory and manipulatory forelimb movements, local field potentials (LFPs) in sensorimotor cortex exhibit increased levels of oscillations in the 20-40 Hz range. Previous findings that LFP oscillations occurred synchronously at diverse sites have been extended to the associated changes in single/multi unit activity. Cycle-triggered histograms (CTHs) of unit activity aligned on cycles of LFP oscillations revealed modulation in two-thirds (176/268) of recorded units. Peak spike activity occurred 2.7 ms prior to peak LFP negativity, and the average relative modulation amplitude (amplitude of oscillatory component of CTH as percent of baseline) was $45 \pm 25\%$. Cross-correlation histograms (CCHs) between pairs of ipsilaterally recorded units compiled with all spikes (during and outside oscillatory episodes) seldom revealed significant features. However, CCHs compiled selectively from spikes occurring during oscillatory episodes (OS-CCHs) revealed synchronization in 67 out of 134 pairs. The central peak in OS-CCHs had an average latency of 0.5 ± 13 ms; peak amplitude was $14 \pm 11\%$ of baseline. Simultaneous recordings in left and right motor cortex revealed significant features in OS-CCHs in 22 out of 42 pairs of bilateral units. Average peak latency (0.2 ± 8.0 ms), and average normalized peak ($10 \pm 8\%$) were similar to the values for ipsilateral pairs. These results indicate that oscillations transiently synchronize neural populations beyond the range of individual axonal projection. For pairs of ipsilateral precentral units, the probability of occurrence of significant OS-CCH features was the same whether both units of the pair were task-related (33/56), or only one unit was task-related (20/39) (χ^2 test, $p > 0.2$). Thus, oscillatory synchronization does not appear to preferentially associate task-related neurons. During oscillatory episodes the mean firing rates of single units tended to be restricted to values corresponding to the average rates just prior to or after the episodes: the coefficient of variation in firing rate during oscillations was significantly lower than that before ($p < 0.001$). This suggests that oscillatory modulation of neural activity does not involve a systematic change in the balance of excitatory and inhibitory inputs to the entrained cells. NEURONAL INPUTS TO RAT CORTICAL AREAS EVOKING CONTRACTIONS OF ANTAGONISTIC AND SYNERGISTIC MUSCLES. X. Gu, W. M. Staines, and P. A. Fortier*. Dept. Anatomy & Neurobiology, Univ. of Ottawa, Ottawa, ON, Canada, K1H 8M5.

The objectives were to determine whether primary motor cortical areas, evoking contractions in synergistic and antagonistic muscles, received inputs from common or separate sources. Intra-cortical microstimulation (ICMS) was used to map low-threshold areas capable of evoking limb movements. From this map, sites capable of evoking ankle flexion, ankle extension, hip flexion, and elbow flexion were selected for injection of fluorescent tracers. The procedures were to (1) inject fluorogold, fast blue, and propidium iodide into three separate motor output sites, (2) allow retrograde transport for 3-5 days, (3) section the brain, and (4) map distributions of differentially-labeled neurons. Computer controlled injections yielded 0.3-1 mm columns of densely filled tracer which was transported to common thalamic and cortical sites. There was limited overlap in the distribution of neurons labeled with different tracers when using small injections but this increased when using larger injections. Conversely, ventral thalamic areas did not show increased overlap with larger injections despite the presence of overlap of intralaminar thalamic areas with all injections. This study suggests that some cortical and thalamic areas provide a single command to the motor cortex for the control of coordinated muscle actions while other cortical and thalamic areas separately control individual muscle actions. [Funded by Canadian MRC]

LAMINAR DISTRIBUTION AND SYNAPTIC PATTERNS OF PARVALBUMIN- AND CALBINDIN-CONTAINING CELLS IN CAT MOTOR CORTEX. L.L. Porter* and A. Keller. Dept. Anatomy & Cell Biology and Neuroscience, USUHS, Bethesda, MD 20814.

Inhibitory interactions in the motor cortex are involved in shaping cortical output during movement. These inhibitory interactions are mediated by GABAergic neurons, that include several morphological and functional sub-classes. We examined cells in cat motor cortex that contain parvalbumin or calbindin, calcium binding proteins that occur in most GABAergic cells. Immunohistochemistry revealed that parvalbumin neurons are more numerous than calbindin cells (2.6:1) and exhibit a more heterogeneous distribution throughout the cortical laminae: 53% in II-III, 29% in V, 18% in VI for parvalbumin, and 74% in II-III, 16% in V, 10% in VI for calbindin. The synaptic relationships of these neurons with axons intrinsic to the motor cortex were examined: Intrinsic axon collaterals were labeled following local injection of fluorescein-dextran, parvalbumin and calbindin cells were labeled by immunohistochemistry. Scanning confocal microscopy was used to determine the distribution and density of appositions between labeled axon terminals and labeled neurons. Similar proportions of the parvalbumin and calbindin populations formed appositions with intrinsic axons (38% and 36%, respectively). The distribution of appositions on cells belonging to the two groups was also similar. The majority of cells formed axodendritic appositions, whereas a few cells in each group formed axosomatic appositions. The mean distance of axodendritic appositions from the soma of parvalbumin cells was 21 μm , while that for calbindin was 32 μm . Ultrastructural analysis is in progress to confirm that the appositions represent synaptic sites. Different classes of GABAergic neurons in motor cortex exhibit different densities and laminar distributions, but cells in both groups appear to receive similar patterns of input from intrinsic axons. The interactions between intrinsic axons and these interneurons may play a role in shaping the activity of functionally-defined populations of output neurons. INHIBITORY SYNAPSES WITH DIFFERENT CLASSES OF PROJECTIONS CELLS IN CAT MOTOR CORTEX. P.B. CIPOLLONI*, L. KIMERER, D. WEINTRAUB AND A. KELLER. VA Medical Center, Bedford, MA 01730; Dept. Anat. & Neurobiol. and Neurol., Boston Univ. Med. School, Boston, MA 02118; Dept. Anat. & Cell Biol., USUHS, Bethesda, MD 20814.

The mechanisms by which neurons perform spatial and temporal integration are dependent on the numbers, types, and distribution of synapses they form with their afferents. To provide data pertinent to understanding these integrative mechanisms, the distribution of synapses with identified classes of cortical projection neurons was examined ultrastructurally. Pyramidal cells in the cat motor cortex projecting to the somatosensory cortex or to the spinal cord were labeled by the retrograde transport of HRP. The somata of corticocortical and corticospinal cells were examined using serial-section electron microscopy. The profiles of these somata and the synapses formed with each of these profiles were reconstructed from each thin section with the aid of a computer-aided morphometry system. All the synapses on the somata of these pyramidal neurons were of the symmetrical, presumably inhibitory type. These synapses were not homogeneously distributed over the somatic membrane, but were clustered at several zones, particularly in the vicinity of the axon hillock. The nonhomogeneity in the distribution of axosomatic synapses indicates that analyses of synaptic innervations of neuronal somata require examination of the complete somatic surface area, and that studies in which small portions of these structures are randomly sampled may be misleading. The number, density and spatial distribution of symmetrical synapses were almost identical on the somata of different corticocortical cells. In contrast, different corticospinal cells formed varying densities of inhibitory synapses. These findings indicate that different classes of cortical neurons receive unique patterns of inhibitory inputs and support the hypothesis that the synaptic organization of the cerebral cortex is highly specific. Supported by PHS:NIH grant #NS31078 and Dept. Veterans Affairs.

INDEPENDENT ANATOMICAL CIRCUITS FOR REACHING AND GRASPING LINKING INFERIOR PARIETAL SULCUS AND INFERIOR AREA 6 IN MACAQUE MONKEY

M. Matelli[†], G. Luppino[†], A. Murata[‡] and H. Sakata[‡]

* (SPON: European Brain and Behavior Society) [†] Istituto di Fisiologia Umana Università di Parma Via Gramsci 14 I-43100 Parma Italy; [‡] Dept. of Physiology, Nihon University, Oyaguchi Itabashi, Tokyo 173, Japan.

Recent physiological evidence showed that in the intraparietal sulcus (IPS) and inferior area 6 there are areas that have similar functional properties. Anterior intraparietal area (AIP), which lies in the lateral bank of IPS, and F5, located in the rostral part of inferior area 6, are both involved in plan and control of hand grasping and manipulation movements. Ventral intraparietal area (VIP), which lies in the fundus of IPS and F4, located in the caudal part of inferior area 6, are both involved in coding the peripersonal space possibly for reaching movements.

In order to see if these functionally similar parietal and frontal areas have direct and selective anatomical connections we made restricted injections of neural tracers (WGA-HRP, FB, DY and TB) in F4, F5, AIP and LIP, an area which lies just caudally to AIP, in three macaque monkeys. After injections in F4 the labelling was found only in the middle third of the fundus (VIP) and in the rostral tip of IPS. After injections in F5 VIP was spared and the labelling was almost completely confined to AIP. The selective anatomical linkage between AIP and F5 was fully confirmed by tracers injections in AIP. The retrograde and the anterograde labelling were mostly confined to the sector of F5 located in the arcuate sulcus. A caudal injection in the lateral bank of IPS (possibly LIP) produced labelling in prearcuate cortex. Inferior area 6 was devoid of any labelling.

The present data indicate that visuomotor integration for reaching and grasping are processed along independent, parallel parieto-frontal circuits. (Supported by a Grant from Human Frontier Science Program)

TRAJECTORIES OF THE PREFRONTAL, PREMOTOR, AND PRECENTRAL CORTICOPONTINE FIBER SYSTEMS IN THE RHESUS MONKEY. J.D. Schmahmann* and D.N. Pandya, Massachusetts General Hospital and Harvard Medical School, Boston; ENRM Veterans Hospital, Bedford, MA.

We studied the course of the fiber systems from the frontal lobe to the basilar pons in 18 monkeys using the autoradiographic technique. Prefrontal fibers enter the most rostral anterior limb of the internal capsule (ICa), and progress caudally in its medial aspect with a nearly horizontal course. Fibers from lateral and dorsal prefrontal cortex (area 8B) lie within the upper third of the ICa; those from medial and ventral prefrontal cortices (areas 32 and 46v) are in the ventral third; and those from the superior frontal gyrus (area 9) occupy an intermediate location. At the genu all prefrontal fibers abruptly descend into the medial aspect of the cerebral peduncle. Premotor fibers enter the mid portion of the ICa and progress caudally. Ventral premotor and opercular fibers are situated laterally; dorsal premotor and supplementary motor fibers lie midway between the medial and lateral boundaries. All these fibers precipitously descend into the cerebral peduncle at the most rostral posterior limb of the internal capsule (ICp). Fibers from the lower part of the precentral gyrus (face area) obliquely enter the lateral sector of the caudal part of the ICa, and descend abruptly at the rostral part of the first quarter of the ICp into the middle of the cerebral peduncle. From the hand area fibers descend vertically through the white matter with an anteriorly convex course, enter the first quarter of the ICp, and descend in the first and rostral part of the second quarter, also situated laterally within the capsule. Fibers from the trunk area enter the ICp in its second quarter and descend in its second and third quarters with an intermediate mediolateral position. The dorsal precentral cortex (leg area) fibers descend with anterior bowing into the medial part of the second quarter of the ICp, and travel in the medial-intermediate compartment of the cerebral peduncle. The precise delineation of the organization of these fiber pathways provides an added dimension to the understanding of the frontal lobe and its subcortical connections. Supported by NIH 16841 and the Veterans Administration.

AN ELECTROPHYSIOLOGICAL STUDY OF THE CORTICORETICULAR PATHWAY IN THE INTACT, AWAKE CAT. K. Bouchra* and T. Drew. Dept of Physiology, University of Montréal, Canada.

As part of a study to determine the functional organization of the corticoreticular pathway in the cat, we examined the projection patterns of 459 neurones within layer V of the pericruciate cortex (areas 4 and 6) of 4 cats, each of which was implanted, bilaterally, with 6 arrays (each of 6 wires) of microwire electrodes (50µm) in the medullary reticular formation (MRF) (P2-P11; L0.5-L1.5). In addition, microwire electrodes were inserted into the pyramidal tract (PT) at a caudal level (P14.5), close to the decussation. Within the premotor cortex (Area 6), 41/129 (32%) corticofugal neurones projected only as far as the MRF (corticoreticular neurones: CRNs); 17/129 (13%) neurones were activated both from the MRF and from the PT (CRN/PTNs); and 24/129 (19%) were identified only from the PT (PTNs). In area 4, in contrast, only 62/330 (19%) cells were CRNs; 88/330 (27%) were CRN/PTNs; and 154/330 (47%) were PTNs. Furthermore, 20/58 (35%) of the neurones in Area 6 and 45/150 (30%) of the neurones in Area 4 that projected to the MRF were activated from more than three stimulating electrodes. More than 70% of the CRNs in both areas 4 and 6 had a conduction velocity (CV) of less than 20m.s⁻¹ (slow CRNs); in contrast, less than 25% of the CRN/PTNs were classified as slowly conducting. The results suggest that the major projection to the MRF from Area 6 is from slowly conducting CRNs, whereas the projection from Area 4 is both from slowly conducting CRNs and more rapidly conducting CRN/PTNs. (Funded by the FCAR and the MRC.)

NEUROANATOMICAL EVIDENCE IN SI NEOCORTEX OF RATS THAT WIDESPREAD BACKWARD PROJECTIONS IN LAYER I FROM SII AND MI CONVERGE WITH LAYER VII PROJECTIONS UPON THE DISTAL DENDRITES OF CORTICO-BULBAR NEURONS: REDUCTION OF BACKGROUND FLUORESCENCE BY SODIUM BOROHYDRIDE ENHANCES DETECTION OF AXONS IN LAYER I. Barbara Clancy* and Larry J. Cauler, GR41, Cognition and Neuroscience Program, University of Texas at Dallas, Richardson, TX 75083-0688.

In our continuing study of afferents to layer I of SI neocortex, background auto-fluorescence has greatly limited the detectability of fibers labelled with dextran tetramethylrhodamine (DTMR; 10k MW, Molecular Probes). Background fluorescence was reduced and detection of DTMR-filled axons in layer I was greatly enhanced by submerging sections in a solution of sodium borohydride (0.1% in phosphate buffer). Using this method, abundant anterogradely labeled fibers extending > 1 mm in layer I of rat SI neocortex were observed after pressure injections (< 50 nl) of DTMR in MI and SII. A similar injection of DTMR in the deep layers of the superior colliculus retrogradely labeled profuse apical dendrites in layer I of SI extending from large pyramidal neurons restricted to layer Vb. In addition, surface applications of Fast Blue (FB) and Diamidino Yellow (DY), but not HRP or DTMR retrogradely labeled neurons in layer VII throughout SI. The absence of cells labeled in layer IV indicated these surface applications were restricted to layers I/II because injections into layer II did label layer IV cells. Therefore, layer I of SI receives widespread projections from layer VII of SI as well as from SII and MI. We propose that these backward cortico-cortical projections contribute to cortico-tectal influences by means of distributed processing in layer I of the primary sensory areas.

404.6

QUANTITATIVE ANALYSIS OF THE PROJECTIONS FROM THE PERICRUCIATE MOTOR CORTEX OF THE CAT TO THE PONTO-MEDULLARY REGIONS OF THE BRAINSTEM. K. Matsuyama* and T. Drew. National Institute for Physiological Sciences, Okazaki, Japan, and Dept. of Physiology, University of Montreal, Canada.

To quantitatively examine the zones of termination of the corticofugal pathway to the lower brainstem, Phaseolus vulgaris (PHA) was injected into either the forelimb (N=4) or hindlimb (N=2) regions of motor cortex (Area 4), or into the more dorsal (N=2) or more ventral (N=1) regions of the premotor cortex (Area 6). A light microscope, equipped with potentiometers and connected to a microcomputer system, was used to measure the X and Y coordinates of PHA-labelled terminals observed in every fourth transverse section of the ponto-medullary region (section thickness=50µm). In all cases, the greatest density of terminals was found in the ipsilateral pontine grey (PG). Injections into dorsal Area 6 resulted in labelling within the ventral part of the PG, while injections in the other three regions resulted in labelling in the more dorsal regions of the PG. In addition, both dorsal and ventral Area 6 projected heavily to the ponto-medullary reticular formation (RF). The projection was mostly bilateral, although with an ipsilateral predominance in the rostral pontine region. In the medullary RF, injections in ventral Area 6 resulted in a widely distributed pattern of labelling, while the labelling from the dorsal Area 6 injections was more restricted to the medio-ventral regions. Injections in Area 4 resulted in a similar distribution of labelled terminals, but with a weaker density of labelling than those produced by Area 6 injections. (Supported by the Canadian MRC and the FRSQ).

404.8

A STUDY OF THE CORTICORETICULAR PATHWAY IN THE CAT USING RETROGRADE TRACERS. M.-J. Rho*, T. Cabana, K. Matsuyama and T. Drew. Departments of Physiology and Biology, University of Montréal, Canada, and the National Institute for Physiological Sciences, Okazaki, Japan.

To examine the organization of the corticoreticular pathway, we injected aliquots of either 2% WGA-HRP (total 0.15-0.8µl; 5 cats) or 15% Texas Red (total 0.6-1.0µl; 6 cats) unilaterally into restricted regions of the medullary reticular formation (MRF) between P5 and P12.5 and L0.3-L1.7. Both tracers heavily labelled corticoreticular neurones (CRNs) in layer V of Area 6 and rostro-medial Area 4 (corresponding to the representation of the proximal forelimb). Approximately equal numbers of neurones were labelled ipsilaterally and contralaterally by most injections, except in the banks of the presylvian sulcus where more CRNs were labelled contralaterally. Labelling in more lateral parts of Area 4 (distal forelimb representation) and in the hindlimb region of the motor cortex was less dense. In addition, CRNs labelled by injections into the rostral MRF tended to be distributed more medially than those labelled by injections into more caudal regions. In 2 of the 6 cats, 15% fluorescein (total 0.8-1.0µl) was also injected caudal to the Texas Red injection. Texas Red and fluorescein single-labelled CRNs were heavily intermingled, and between 9% and 17% of the CRNs were double-labelled. Further, double-labelled CRNs were more numerous in the contralateral cortex. These results suggest some degree of specificity in the projection from the cortex to the MRF. (Supported by the FCAR.)

MORPHOMETRIC STUDY OF PROJECTION NEURONS IN THE CORTEX OF REELER MOUSE. R. Ichikawa* and Y. Inoue, Dept. of Anatomy, Hokkaido Univ. Sch. of Med., Sapporo 060, Japan.

The projection neurons within the reeler motor cortex, the corticocortical (cc), corticospinal (cs) and cortico-thalamic (ct) neurons, were morphometrically analyzed using three parameters as follows: 1) the size of the soma, 2) the width of the main dendrite at a distance of 30 µm from the center of the soma, and 3) the direction of the main dendrite. The entire image of each neuron, labeled with biocytin, was drawn by camera lucida and was input into a personal computer through a digitizer, followed by calculation corresponding to the three parameters. The soma size and dendritic shape of normal cc-, cs- and ct-neurons, which occurred within their own proper layers of the cortex, revealed significant diversity from each other. Conversely, within the reeler cortex, where the projection neurons aligned disorderly, the three parameters calculated varied significantly among the three types of neurons, and in addition, in each layer of the cortex (divided evenly into five layers from the pial site), cc-, cs- and ct-neurons revealed different characteristics in soma size and width and direction of the main dendrite, even though the synaptic environment was common to each other. The parameters measured in this study have been said to be strongly influenced with afferent elements surrounding the neurons. In the present reeler study, the afferent elements in contact with neurons might be regulated by where their axons project. Thus, the diversity in shape of the reeler neurons within the motor cortex possibly depends upon the different projection areas.

405.1

ATTENTION TO A VISUAL STIMULUS ENHANCES NEURONAL RESPONSES IN MONKEY PREFRONTAL CORTEX. Y.Kodaka, A.Mikami* and K.Kubota, Dept. of Behavioral and Brain Sci., Primate Res. Inst., Kyoto Univ., Inuyama 484 Japan

To investigate how selective attention modulates neuronal activities in the prefrontal cortex (PFC), we recorded neuronal responses to the identical visual stimuli in non-attentive and attentive conditions in the monkey PFC. In a visual fixation task (VFT), while the monkey gazed at a fixation point, a visual stimulus, to which no behavioral meaning was attached, was presented extrafoveally in its visual receptive field. In a visual peripheral cueing task (VCT), the monkey released the lever within 800ms after an identical stimulus was dimmed. Activities of 48 neurons in the prearcuate and periprincipal areas were compared under these two conditions. In 38% of the neurons, the magnitudes of the responses in the VCT were significantly larger than those in the VFT. For each neuron, the visual response tended to be greater toward the center of the RF. In the remaining 62% of the neurons, the magnitudes of the visual responses in the VFT and VCT were similar. Neither eye movement nor lever release occurred when the visual stimulus appeared. Therefore, these enhancements were not causally related to either eye movement or lever release. These results suggest that enhanced responses due to focused attention to the visual stimulus in the PFC may facilitate the selection of a behaviorally significant stimulus within the RF.

2-DEOXY-GLUCOSE (2DG) UPTAKE IN THE MEDIAL WALL MOTOR AREAS OF BEHAVING MONKEYS. N. Picard*¹ and P.L. Strick^{1,2}, ¹VA Medical Center and ²Depts. of Neurosurgery and Physiology, SUNY Health Science Center, Syracuse, NY 13210.

The medial wall of the hemisphere contains multiple motor areas. They are the supplementary motor area (SMA), the Pre-SMA and three cingulate motor areas (CMAAd, CMAv and CMAr) (Dum and Strick, 1991). We have begun to investigate the relative involvement of these motor areas in different aspects of motor function using the 2DG method. Two monkeys were trained to perform remembered sequences of reaching movements for a juice reward (REM task). Two other monkeys were trained on a Control task to sit in the primate chair and lick juice rewards delivered at time intervals comparable to that of the reaching monkeys.

Two areas of the medial wall showed significant activation in the REM animals and not in the Controls. For the REM task, 2DG labeling was particularly prominent caudally on the dorsal bank of the cingulate sulcus (CMAAd). Focal activation was found in the region of the CMAAd that projects to cervical segments of the spinal cord and to the arm area of the primary motor cortex. Additional activation was present on the superior frontal gyrus rostrally in the territory of the Pre-SMA. Labeling in other motor areas on the medial wall was either absent or less significant.

These observations suggest that, of all the motor areas on the medial wall, the CMAAd and the Pre-SMA are preferentially involved in the internal guidance of sequential voluntary arm movements.

CINGULATE CORTEX SUBDIVISIONS IN THE HUMAN AND MONKEY REVEALED BY STAINING FOR PARVALBUMIN. A. Solodkin*¹, R.J. Morecraft² and G.W. Van Hoesen¹, ⁽¹⁾Departments of Anatomy and Neurology, University of Iowa, Iowa City, IA 52242. ⁽²⁾Department of Anatomy and Structural Biology, University of South Dakota, Vermillion, SD 57069.

The cingulate cortex has been implicated in a wide range of behaviors including motivation, attention, mechanisms relating to pain and motor control. Not unexpectedly, its structure is complex differing both in anterior-posterior and medial-lateral dimensions.

We have studied the topography of cingulate subdivisions in humans (N=15) and in the non-human primates (N=8) using immunohistochemical techniques for parvalbumin (SWant) and non-phosphorylated neurofilament protein (SMI-32, Sternberger). Krieg and Sarkisov's cytoarchitectural parcellation of 24a, b & c and 23a, b & c was used as a guide.

Our observations in the monkey revealed a clear correlation between differential cytoarchitecture and immunostaining patterns in terms of density and topography for both markers between the *indusium griseum* and areas 24a, 24b and 24c as well as for 23a, 23b and 23c. Also a clear difference was observed between areas 24 and 23, with the most prominent change between areas 24a and 23a. In the human, the subdivisions of area 24 showed a clear parallel to the cytoarchitectural and immunostaining characteristics seen in the monkey area 24.

Our observations indicate that parvalbumin immunostaining is an excellent method to delimit different subfields in the cingulate cortex in both humans and monkey. Since this calcium-binding protein coexists with a subpopulation of GABAergic neurons, its discrete distribution suggests probable functional differences between cingulate subfields.

THE HUMAN FRONTAL MESIAL CORTEX: A COMPARISON BETWEEN CYTOARCHITECTONIC, RECEPTOR AUTORADIOGRAPHIC, AND FUNCTIONAL ACTIVATION. K. Zilles*¹, G. Schlaug², S. Geyer¹, T. Schormann¹, R. Seitz², H. Steinmetz² and H.-J. Freund². Brain Research Institute¹ and Department of Neurology², University of Düsseldorf, 40001 Düsseldorf, Germany.

Four supplementary motor areas (SMA proper, pre-SMA, caudal and rostral cingulate motor areas) are described in the literature. These areas were demonstrated by PET studies in the human frontal mesial cortex. The aim of our study is the identification of cytoarchitectonic areas representing these functionally defined regions and the analysis of the regional distribution patterns of 11 transmitter receptors by quantitative in vitro receptor autoradiography in these areas.

Several architectonically and receptor autoradiographically definable areas are found in the mesial frontal lobe and in the lower bank of the cingulate sulcus. By comparison with PET studies, the caudal-mesial part of Area 6 (mesial Area 6aα) is probably identical with SMA proper, the rostral-mesial part of Area 6 (mesial Area 6aβ) with pre-SMA, and the caudal or rostral parts of the cingulate areas showing large pyramidal cells with the caudal or rostral cingulate motor areas, respectively. Our study shows for the first time that within the human mesial frontal cortex multiple, probably supplementary motor areas are definable by architectonic characteristics and by receptor autoradiography. Additionally, gross anatomical landmarks are defined, which allow the approximate location of these areas in coregistered PET/MR images.

Supported by the DFG (SFB 194, HFSP and HCMF).

NEURONAL ACTIVITY IN THE SUPPLEMENTARY AND PRE-SUPPLEMENTARY MOTOR AREA IN RELATION TO SEQUENTIAL PERFORMANCE OF MULTIPLE MOVEMENTS. K. Shima and J. Tanji*, Dept. of Physiology, Tohoku University School of Medicine, Sendai, 980, Japan

The purpose of the present study was to examine how neuronal activity in the supplementary motor area (SMA) and presupplementary motor area (pre-SMA) is involved in performance of multiple movements. We trained monkeys (*Macaca fascicularis*) to perform three different movements (push, pull or turn a manipulandum) sequentially, separated by brief waiting periods. Each movement was triggered by a tone signal. After completion of individual movements, the manipulandum was mechanically returned to a neutral position within which the animal had to hold it and wait for next movement. In one condition, a visual signal (LED of three different colors) indicated what movement to be performed. In the other condition, correct sequences of three movements had to be remembered. EMG analysis showed that magnitudes of muscle activities were equal in the two conditions. Activity changes in forelimb muscles were not detectable during the waiting periods. A majority of SMA neurons were active during the waiting periods. The activity was generally greater when the sequence of the three different movements was remembered. By contrast, a majority of pre-SMA neurons exhibited greater activity when the movement was instructed by visual signals. In both areas, there was an abundance of neuronal activity that was related to the temporal order of the three different movements, rather than related to next movement to be performed. Such neuronal activity, useful for programming the sequence of multiple movements, was not observed in the primary motor cortex. Descending Projections to the Basal Ganglia, Red Nucleus and Pontine Nuclei from the Cingulate Motor Cortex (M3 or Area 24c) in the Rhesus Monkey. R.J. Morecraft* and G.W. Van Hoesen^{2,3}, Dept. of Anatomy and Structural Biology¹, Univ. of South Dakota, Vermillion, SD 57069 and Depts. of Anatomy² and Neurology³, Univ. of Iowa, Iowa City, IA 52242

The ipsilateral corticostriate, corticorubral and corticopontine projections were studied in thirteen monkeys that received injections of tritiated amino acids into the cingulate (M3 or area 24c), supplementary (M2) and primary (M1) motor cortices. In M3 cases, light terminal labeling occurred over the head and anterior-third of the caudate nucleus. Heavy patches were observed over the anterior pole and ventrolateral part of the putamen, then posteriorly labeling shifted in the dorsolateral direction. In the red nucleus, labeling was found primarily over the ventromedial part of the parvocellular subdivision. At superior and mid-levels of the pons, labeling occurred over the ventromedial pontine gray matter. At inferior levels, patches of label formed an incomplete circle around the corticofugal axons traversing the pons.

These data were compared to the distribution of projections from M1 and M2. Some topographic differences were found, but regions of overlap occurred as well. For example, the projection from M1 favored the dorsolateral part of the putamen, M3 the ventrolateral part, and M2 an intermediate position. In the red nucleus, the densest distribution of labeled fibers terminated laterally from M1, medially from M3 and in between from M2. All three motor cortices projected heavily to the peripheral border of the medial and ventral portion of the basis pontis.

These observations show that M3 targets subcortical motor centers located at multiple levels of the neural axis. Judging from detailed comparisons, the highly interconnected cortical motor representations seem to be characterized as well, by overlap in their corticofugal projection zones. The terminal distribution of these pathways may provide opportunities of unity as well as diversity in terms of their influence on subcortical motor centers. (Support: NS 14944, USD Fac. Dev. Award)

406.1

CORTICAL STIMULATION INDUCES SELECTIVE PATTERNS OF JUN B EXPRESSION IN THE STRIATUM.

H.B. Parthasarathy*, S. Berretta, and A.M. Graybiel. M.I.T. Dept. of Brain and Cog. Sci., Cambridge, MA 02139.

It has been shown that electrical stimulation of the motor cortex in rats induces the expression of immunodetectable Fos-like protein (Fos-LI) in neostriatal neurons (L.Fu and R.M. Beckstead, Neuroscience 46(2):329-334). We have examined the effect of electrical stimulation of the motor cortex in awake and Nembutal-anesthetized rats (250 msec trains at 4 Hz of biphasic current pulses through parallel bipolar electrodes for 1 hr) on the induction of Jun B-like immunoreactivity (Jun B-LI). We show that Jun B-LI is induced in zones in the dorsolateral striatum that are in the same topographical location as Fos-LI-positive nuclei. However, with double-labeling techniques, we found that Fos-LI and Jun B-LI were only partially colocalized, i.e. some neurons expressed only Fos-LI, some only Jun B-LI, and some both. This result suggests that striatal neurons respond to cortical stimulation with heterogeneous gene expression profiles. Most Jun B-LI-positive nuclei detected were in projection neurons expressing enkephalin or DARPP-32. We found Jun B-LI-positive nuclei in a low to moderate percentage of parvalbumin-, Chat- and NADPH-diaphorase-positive interneurons. The presence of Jun B-LI in parvalbumin-positive, presumably GABAergic, interneurons contrasts with the result obtained by chemical stimulation of the motor cortex (see Berretta et al SNA 94), after which Jun B-LI was never seen in parvalbumin-positive neurons. Such specific differences in the patterns of striatal gene induction by electrical and chemical activation of the cortex may be the result of indirect antidromic effects of electrical stimulation. They might also reflect the differences in cortical activity produced by direct synchronous activation of cortical neurons by electrical stimulation, in contrast to release of endogenous cortical activity by removal of inhibition. Supported by NIH Javits Award NS25529. We thank Drs. R. Bravo, H.Hemmings, and P. Greengard for antisera.

406.3

CORTICAL FOS EXPRESSION FOLLOWING DOPAMINERGIC STIMULATION: D1/D2 SYNERGISM AND ITS BREAKDOWN. G.J. LaHoste¹*, D.N. Ruskin² and J.F. Marshall². Departments of ¹Physical Medicine & Rehabilitation and ²Psychobiology, University of California, Irvine, CA 92717-4550.

While many recent studies have examined immediate-early gene expression in the basal ganglia following dopaminergic stimulation, few have focused on the cerebral cortex, the prime target (via the thalamus) of basal ganglia output. We have examined the areal and laminar distribution of Fos immunoreactivity in the cerebral cortex of rats following systemic administration of dopaminergic agonists with particular attention to interactions between D1 and D2 receptor systems. Combined, but not separate, D1 (SKF 38393 20 mg/kg) and D2 (quinpirole 3 mg/kg) agonist stimulation induced pronounced Fos expression in frontal and parietal, but not cingulate cortex in normal rats. Similarly, following amphetamine, cortical Fos could be blocked by either a D1 (SCH 23390, 0.5 mg/kg) or a D2 (eticlopride, 0.5 mg/kg) antagonist. By contrast, following a regimen of reserpine (1 mg/kg/day for 5 days) that is known to cause a breakdown in D1/D2 synergism by behavioral and basal ganglia Fos measures, independent stimulation of D1 or D2 receptors resulted in cortical Fos expression. Irrespective of treatment condition, Fos expression occurred in a distinct laminar pattern that appeared to vary somewhat with cortical field. Dopaminergic modulation of cerebrocortical Fos may occur at the level of the striatum as part of a cortico-striato-pallido/nigro-thalamo-cortical circuit; future studies will test this hypothesis. These findings show that the principles of D1/D2 synergism and its breakdown apply to the stimulation of cerebrocortical Fos by dopaminergic agents. Furthermore, this Fos expression is correlated with motor behavior.

ELECTRONIC PUBLISHING OF A NEUROSCIENCE POSTER PRESENTATION ON THE INTERNET: THE START OF A DIGITAL NEUROSCIENCE LIBRARY AND DATABASE. D.J. Woodward, A.B. Kirillov, C.D. Myre* and A. Worthen. Dept. of Physiol./Pharmacol., Bowman Gray School of Medicine, Winston-Salem, NC 27157, and Biographics, Inc., Winston-Salem, NC 27104.

A simple method now exists to electronically publish a Neuroscience Poster Presentation on the Internet. A user of a typical desktop computer, such as PC, Mac or UNIX workstation, desiring to access published information does so by installing the Mosaic viewer software available at [ftp.ncsa.uiuc.edu](http://ncsa.uiuc.edu). This abstract and the detailed presentation can then be accessed via Mosaic by using the universal resource locator (URL) address <http://biogfx.bgsu.wfu.edu>, and the text with embedded images read through the viewer. Authors may make their documents available to the Internet community by converting computer-generated images to GIF format and scanning other images into GIF files, converting standard word processor files into HTML format and creating links to the corresponding GIF files. These files are then placed on a UNIX workstation set to operate as World Wide Web server. Instructions to perform all these operations are at the anonymous ftp site biogfx.bgsu.wfu.edu. Reprints and legacy documents after scanning and character recognition can be made available for public access using similar methods. There is a critical need for a public data base to index distributed neuroscience information. These procedures can provide, with a modest investment, immediate access to a wide range of neuroscience information. This procedure has been demonstrated as useful for dissemination of documents related to research on brain mapping and drugs of abuse. Supported by DA2338. Poster is available on WWW server <http://biogfx.bgsu.wfu.edu>

DIFFERENTIAL INDUCTION OF IMMEDIATE EARLY GENES (IEGs) BY CORTICAL ACTIVATION IN STRIATAL NEURONAL SUBPOPULATIONS. S. Berretta*, H.B. Parthasarathy, and A.M. Graybiel. M.I.T. Dept. of Brain and Cog. Sci., Cambridge, MA 02139.

Local pharmacological blockade of GABAergic transmission in the motor cortex of awake rats was induced via chronic head-mounted wells (Berretta et al. '94). This treatment evoked discrete body movements and, at 2 and 4 hours, induced the expression of IEGs in localized brain regions. We immunocytochemically characterized striatal neurons expressing IEG protein products in this paradigm. Fos-, Fos B-, Jun B- and NGFI-A-like immunoreactivity (-LI) was induced in the ipsilateral dorsolateral striatum. There was also a weak contralateral IEG induction. Large numbers of Fos- and Jun B-positive nuclei were in striatal neurons expressing enkephalin or DARPP-32, proteins characteristic of striatal projection neurons. These results parallel similar findings obtained by electrical stimulation of the rat motor cortex (see Parthasarathy et al SNA 94). Of the striatal interneurons identified within the field of IEG induction, only a few somatostatinergic (NADPH-diaphorase-positive) neurons and even fewer Chat-positive neurons were positive for either Fos-LI or Jun B-LI. By contrast, large numbers (75%; n.cells= 420; n.rats=4) of parvalbumin-positive (GABAergic) interneurons were Fos-LI-positive. This distribution implies that the signal from neocortex to striatum, whether direct or indirect, can select for subset of striatal neurons within the activated field. Moreover, although cortical stimulation induced Fos-LI in parvalbumin-positive interneurons, Jun B-LI was never found in these cells. Thus the signal from activated cortex can select for particular IEGs in individual neurons of the striatum. Selectivity in the cortically-induced patterns of IEG expression in individual striatal neurons were further suggested by the fact that while many nuclei were found to express both Fos-LI and Jun B-LI, many others expressed only one of them. We thank Drs. R. Bravo, H.Hemmings, and P. Greengard for antisera. Supported by NIH Javits Award NS25529.

Neurobiology and Anaesthesia Branch⁴, NIDR, NIH, Bethesda, MD, USA.

Using an antibody raised against the DNA binding region of Fos, we have reported that destruction of the nigrostriatal pathway by injection of 6-hydroxydopamine (6-OHDA) into the medial forebrain bundle produces a long-lasting (> 3 months) increase in striatal Fos-like immunoreactivity. In order to determine the nature of Fos immunoreactive protein(s) responsible for this increase, Western blots were performed on striatal extracts. Approximately six weeks after the 6-OHDA lesion, expression of a 38 kD Fos immunoreactive protein was dramatically enhanced. Since the molecular weight of the truncated form of FosB (Δ FosB) is 35 kD, we examined FosB and Δ FosB expression using two antibodies. One antibody recognizes both FosB and Δ FosB while the other recognizes just FosB. Western blotting revealed that dopaminergic denervation selectively increased expression of Δ FosB. This finding was confirmed by immunohistochemistry which demonstrated that the increase occurred exclusively in medium-sized neurons of the denervated striatum. These results suggest that Δ FosB may participate in those intracellular events which maintain altered neuronal gene expression in the striatum after dopaminergic denervation. EFFECTS OF METHYLAZOXY-METHANOL ACETATE ON THE FORMATION OF STRIATAL COMPARTMENTS. W.J. Rushlow*, M. Cimino, F. Cattabeni, B.A. Flumerfelt and C.C.G. Naus. Dept. of Anatomy, University of Western Ontario, London, Canada, N6A 5C1 and Institute of Pharmacological Sciences, School of Pharmacy, University of Milan, Via Balzaretti 9, Milan, Italy, 20133.

The striatum can be segregated into two compartments, the patch and matrix, based on afferent and efferent projections and certain neurochemicals (eg. calbindin, somatostatin). Lineage studies indicate that the neurons that comprise these two populations arise at two different time points from separate populations of developing neuroblasts. Neurons destined to be localized within the patch are born between E12 and 14 while matrix neurons are born between E16 and E18. In order to attempt to knockout the patch or matrix compartments, methylazoxymethanol acetate (MAM) was injected intraperitoneally (25mg/kg) into E13 or E17 pregnant rats. MAM is a potent toxin which kills dividing neuroblasts. It is effective for 24hrs. post-injection with effects peaking after 8hrs. Pups obtained from the pregnant mothers were allowed to grow to adulthood. The striatum, globus pallidus, entopeduncular nucleus and substantia nigra were then examined using immunocytochemistry for calbindin, somatostatin and parvalbumin. Preliminary data indicates that animals injected with MAM at E13 have fewer and smaller patches than control animals. There also appears to be a reduction in the size of the patch associated regions of the striatal output centres. The overall size of the striatum in animals injected at E18 is unaltered. The density of neurons in the matrix compartment, however, is reduced. These results indicate that MAM injections at the appropriate developmental time can alter the patch/matrix compartment ratio. EXCITOTOXIC LESIONS OF RAT STRIATUM: TIME COURSE OF DNA DAMAGE ASSESSED BY IN SITU NICK TRANSLATION. Y. Bordelon, L. MacKenzie, B.A. McLaughlin, and M-F Chesselet*. Department of Pharmacology, U. of Penn, Philadelphia, PA 19104.

We have used in situ nick translation to identify increases in DNA strand breaks in individual neurons of the striatum after local injections of the NMDA receptor agonist quinolinic acid (QA). Male Sprague Dawley rats (250-300 gms) received a unilateral injection of QA (60 nmol in 0.5 µl) over 5 min. in the striatum. This procedure induces a massive loss of striatal efferent neurons with relative preservation of striatal interneurons 2 weeks later (Qin et al. Exp. Neurol. 115, 1992, 200-211). Controls received saline injections. Rats were sacrificed 6, 8, 10, 12, 24, and 48 hrs after surgery by transcardial perfusion with 4% paraformaldehyde under deep anesthesia. Striatal sections (10 µm) were cut on a cryostat, incubated with 35S-dTTP in the presence of DNA polymerase I for 30 min at 37°C, and processed for emulsion autoradiography. In rats sacrificed 6 and 8 hrs post-surgery, densely labelled pycnotic cells were only detected along the needle tract and were present in both QA- and saline-injected rats. In QA-injected rats, labelled cells were observed in the striatum away from the needle tract 10 hrs after surgery. These included densely labelled pycnotic cells, and neurons with minimal morphological alteration at the light microscopic level. Labelled cells were found near unlabelled neurons with or without morphological alterations. The number of labelled cells, and the intensity of labelling, increased dramatically between 10 and 12 hrs post-lesion. Numerous labelled cells were still observed in the striatum 48 hrs after surgery. The data indicate 1) that there is a delay in the appearance of DNA strand breaks after excitotoxic lesion of the striatum but that they can precede major morphological alterations in the neurons destined to die; 2) a differential vulnerability to DNA damage among striatal neurons after QA injections; 3) in view of the presence of numerous labelled cells at both 12 and 48 hrs, that cells do not die rapidly once DNA strand breaks occur after excitotoxic injury. Supp. by PHS grant NS 23390.

PSA-NCAM IN THE DEVELOPING STRIATUM: ULTRASTRUCTURAL LOCALIZATION, EFFECTS OF EARLY POST-NATAL 6-HYDROXYDOPAMINE LESIONS, AND OF THE WEAVER MUTATION. K. Uryu*, S. Roffler-Tarlov, G. Rougon, and M-F Chesselet. Dept. of Pharmacology, Univ. of Pennsylvania Sch. of Med., Philadelphia, PA 19104. Tufts Univ. Sch. Med., Boston, MA 02111, and U. of Aix-Marseille, Luminy, France.

We have shown that loss of immunoreactivity for the immature, highly polysialylated form of the Neural Cell Adhesion Molecule (PSA-NCAM-IR) occurs at the end of the third postnatal week in rat striatum (Szele et al., Neurosci. 1994). Ultrastructural studies show that, at postnatal day 7 (P7), PSA-NCAM-IR is associated both with axonal growth cones, and with the cytoplasmic membrane of intrinsic striatal neurons. At post-natal day 18, PSA-NCAM-IR was still associated with intrinsic striatal neurons, but labelling of the cytoplasmic membrane was much more discontinuous than at P7. In addition, PSA-NCAM-IR immunoreactivity was associated with both pre and post-synaptic elements of asymmetrical synapses on dendritic spines. The results confirm that during late post-natal development, PSA-NCAM-IR is still associated with striatal neurons, as well as with striatal inputs, likely originating from the cerebral cortex and/or the thalamus. In a second set of experiments, we examined the role of dopaminergic inputs to the striatum on PSA-NCAM maturation. Lesions of the dopaminergic pathway by bilateral injections of 6-hydroxydopamine in the striatum at P2 resulted in a profound loss of tyrosine hydroxylase immunoreactivity in the striatum, but did not affect the time course of loss of PSA-NCAM-IR. In contrast, in weaver mice, which exhibit a profound loss of dopaminergic inputs to the dorsolateral striatum postnatally, the loss of PSA-NCAM-IR in striatum was delayed by approximately a week compared to wild type mice. These results suggest that dopaminergic inputs do not play a critical role in the shift from immature to mature forms of NCAM in the striatum, and that other factors than the loss of nigro-striatal neurons play a role in the delayed maturation of PSA-NCAM in weaver mice. Supp. by NS29230.

GLUTAMATE DECARBOXYLASES GENE EXPRESSION IN THE STRIATUM AND PALLIDUM OF PARKINSONIAN MONKEYS. J.-L. Soghomonian, S. Pedneault, A. Parent and R. Boucher*. Centre de recherche en Neurobiologie, Fac. de Med., Univ. Laval, Québec (Qc.), Canada, G1K 7P4

The mRNA levels encoding for the two isoforms of the enzyme glutamate decarboxylase (GAD65 and GAD67) were measured in different sectors of the caudate and putamen and in the internal (GPi) or external (GPe) segment of the pallidum in control (n=5) and parkinsonian (n=7) monkeys (*Saimiri sciureus*) after administration of the neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP). Cryostat-cut sections of the brains were processed for *in situ* hybridization histochemistry with 35S radiolabeled cRNA probes and the radioautographic labeling was quantified on X-ray films or emulsion radioautographs. The extent of dopaminergic fiber loss in MPTP-treated monkeys was measured after 3H mazindol binding and was shown to be widespread throughout the putamen and the caudate. In MPTP-treated primates, an increase in both GAD67 and GAD65 mRNA levels was measured in the striatum. At a coronal rostral level, this increase was significant only in the dorsolateral sector of the putamen. At more caudal, post-commisural level, GAD67 mRNA-levels were increased in both the dorsal and ventral putamen and the caudate. Caudally, the increase in GAD65 mRNA levels reached significance only in the ventral putamen. In MPTP-treated monkeys, individual GPe neurons exhibited an increase in GAD67 but not GAD65 mRNA levels. In individual neurons of the GPi of MPTP-treated monkeys, both GAD67 and GAD65 mRNA levels were increased. The present results demonstrate that gene expression of both GAD isoforms is significantly altered throughout the basal ganglia of parkinsonian monkeys. In the striatum, increased GAD67 and GAD65 expression appears prominent in sensorimotor territories such as defined by cortical afferents. The results also support the hypothesis of an increased activity of striatal and pallidal output GABAergic neurons in parkinsonism [Supported by FRSQ, the Parkinson Foundation of Canada and NSERC-0155607].

406.8

GLUTAMIC ACID DECARBOXYLASE (GAD 67) mRNA LEVELS IN THE GLOBUS PALLIDUS: 6-OHDA-INDUCED INCREASES ARE ABOLISHED BY LESIONS OF THE SUBTHALAMIC NUCLEUS. J.M. Dells*, V.M. Ciaramitaro, T.J. Parry, M.F. Chesselet, Inst. of Neurological Sci. and Dept. of Pharmacology, Univ. of Pennsylvania, Phila., PA 19104.

The globus pallidus (GP), one of the main output nuclei of the striatum, receives an inhibitory GABAergic projection from the striatum and an excitatory glutamatergic input from the subthalamic nucleus. Lesions of the nigrostriatal pathway result in increased expression of the mRNA encoding glutamic acid decarboxylase (GAD 67) in the GP (Soghomonian and Chesselet 1992; Kincaid et al. 1992). To determine whether this increase results from excitatory glutamatergic inputs from the subthalamic nucleus, rats received either a unilateral 6-hydroxydopamine (6-OHDA) lesion of the substantia nigra (SN), a unilateral kainic acid lesion of the subthalamic nucleus or a combination of the two lesions. Unilateral 6-OHDA lesions of the SN resulted in contralateral rotation when animals were challenged with apomorphine (0.5 mg/kg, s.c.) 7-8 days after the lesion whereas kainic acid lesions of the subthalamic nucleus resulted in ipsilateral rotation. When the two lesions were combined no rotational behavior was observed in response to systemic apomorphine. Confirming previous reports, 6-OHDA lesions increased GAD 67 mRNA levels in the GP ipsilateral to the lesion. Unilateral kainic acid lesions of the subthalamic nucleus resulted in a slight decrease in GAD 67 mRNA levels in the GP which may be related to a loss of tonic excitatory input from the subthalamic nucleus. Lesions of the subthalamic nucleus completely abolished the 6-OHDA lesion-induced increases in GAD 67 mRNA in the GP. These results suggest that increases in GAD 67 mRNA levels in the GP are triggered by excitatory inputs from the subthalamic nucleus. Supported by PHS grants MH 44896 and MH 17168.

PSA-NCAM IN THE DEVELOPING STRIATUM: EFFECTS OF EARLY POST-NATAL LESIONS OF THE CEREBRAL CORTEX. A.K. Butler*, G. Rougon, and M-F Chesselet, Inst. of Neurol. Sci., and Dept of Pharmacol., U. of Penn. Phila, PA19104 and U. Aix-Marseille, Luminy, France.

Previous studies (Szele et al. Neurosci. 1994) have shown that expression of highly polysialylated Neuronal Cell Adhesion Molecule (PSA-NCAM) remains high in the dorsolateral striatum of rat pups until the end of the third post-natal week. The loss of immunoreactivity for PSA-NCAM is one of the latest developmental events recorded so far in the striatum and follows the development of nigro-striatal dopaminergic inputs, the formation of corticostriatal synapses, and the emergence of spontaneous activity in the corticostriatal pathway (see Tepper and Trent, Prog. in Brain Res. 99, 1993, 35-50). This study examined the hypothesis that excitatory inputs from the cerebral cortex play a role in the loss of PSA-NCAM in the developing rat striatum. Unilateral cortical lesions were performed in 14 day old pups by thermocoagulation of the pial blood vessels over the frontoparietal cortex (see Salin and Chesselet, PNAS 89, 1992, 9954-9958). Animals were sacrificed at postnatal day 25, a time when PSA-NCAM is undetectable in the dorsolateral striatum of control rats, and striatal tissue processed either for immunohistochemistry or immunoblotting with an antibody recognizing specifically the alpha 2-8 linked sialic acid units associated with NCAM (Rougon et al. J. Cell Biol. 103, 1986, 2429-2437). With both techniques, the data showed a higher level of expression of PSA-NCAM in the dorsolateral striatum ipsilateral to the cortical lesion than in the contralateral striatum or in control pups. These results suggest that, in contrast to the dopaminergic input (see Uryu et al, this meeting), the corticostriatal input may play a role in NCAM maturation in the developing rat striatum. Supp. by an NSF training grant (AKB) and PHS grant NS23390 (MFC).

REGULATION OF mRNA LEVELS ENCODING FOR TWO ISOFORMS OF GLUTAMATE DECARBOXYLASE AND FOR PREPROENKEPHALIN IN THE RAT STRIATUM BY DOPAMINERGIC RECEPTORS. N. Laprade and J.-L. Soghomonian*, Centre de Recherche en Neurobiologie, Fac. Med., Univ. Laval, Quebec (QC), G1K 7P4.

The role of D1 and D2 dopamine receptor subtypes on the regulation of messengers RNAs (mRNAs) encoding for the two isoforms of glutamate decarboxylase (GAD65 and GAD67) and preproenkephalin (PPE) in rat striatum was investigated. The mRNA levels encoding for GAD65, GAD67 and PPE were detected by *in situ* hybridization histochemistry with radioactive cRNA probes and quantified by computerized densitometry. Chronic treatment (10 days) with the D1/D2 dopamine receptor agonist apomorphine or with the D1 agonist SKF 38393 significantly increased GAD65 mRNA levels but did not change GAD67 or PPE mRNA levels. Chronic treatment (10 days) with the D2 dopamine receptor agonist quinpirole decreased GAD67 and PPE mRNA levels without changing GAD65 mRNA levels. On the other hand, chronic blockade (14 days) of D1 and D2 dopamine receptors with haloperidol or D2 receptors with sulpiride increased GAD67 and PPE mRNA levels but did not change GAD65 mRNA labeling. Chronic blockade (14 days) of D1 receptors with SCH 23390 induced a slight decrease in PPE mRNA levels but did not significantly alter GAD67 or GAD65 mRNA levels. These results show that gene expression of each isoform of GAD is differentially regulated in the rat striatum. Gene expression of GAD67 or PPE appears to be under the inhibitory control of D2 dopamine receptors while GAD65 gene expression would be under the excitatory control of D1 dopamine receptors. The results also suggest that each GAD plays a distinct role in the regulation of GABA synthesis in striatal neurons (Supported by FRSQ, Parkinson Foundation of Canada and NSERC-0155607).

INTRASTRIATAL INJECTIONS OF QUINOLINIC ACID SHOW MARKED CHOLINE ACETYLTRANSFERASE AND NADPH-DIAPHORASE CELL LOSS. S.M. Walker, W.C. Perryman, and G.K. Rieke*. Department of Anatomy and Cell Biology, School of Medicine, University of North Dakota, Grand Forks, North Dakota.

The debate as to whether the striatal pathology observed in the Quinolinic Acid (QA) rat model of Huntington's Disease (HD), as it demonstrates a selective sparing of aspiny interneurons, is unresolved. QA is an endogenous, excitatory amino acid that is known to spare fibers of passage. It is the intent of this study to define cell types and the associated loss within the HD model. Alzet mini-osmotic pumps were utilized for a 14 day, 340.8 mg/ml, Ph 7-8, QA 0.5 μ l per hour injection period. Choline Acetyltransferase (ChAT) immunohistochemistry and NADPH-diaphorase (NADPH) histochemistry were used to determine cell sparing and cell loss. ChAT and NADPH cell counts were determined in adjacent sections. The results indicate marked cell loss. There is an overall 27% decrease in diaphorase-positive cells and a 36% decrease in ChAT-positive cells. Thus, preliminary results suggest a significant loss of intrastriatal ChAT and NADPH aspiny interneurons. Supported by BSRG.

OPPOSITE EFFECTS OF NIGROSTRIATAL OR SUBTHALAMIC LESIONS ON MITOCHONDRIAL ENZYME ACTIVITY IN THE BASAL GANGLIA

F. Blandini*, J.G. Greene, R.H.P. Porter, D.S. Higgins, J.T. Greenamyre. Departments of Neurology, Neurobiology & Anatomy, and Pharmacology, University of Rochester Medical Center, Rochester, NY

In Parkinson's disease (PD), the striatal dopaminergic denervation induces complex changes in the functional circuitry of the basal ganglia which result, ultimately, in an overactivity of the output nuclei, substantia nigra pars reticulata (SNr) and medial globus pallidus (MGP). Beside the loss of GABA-ergic inhibition from the striatum, the SNr and MGP hyperactivity seems to be related to an increased firing of the subthalamic nucleus (STN), a structure playing a pivotal role in the regulation of the basal ganglia output.

The aim of this study was to investigate mitochondrial enzyme activity, a reliable marker for synaptic activity, in different nuclei of the basal ganglia of rats following a selective stereotaxic lesion of the nigrostriatal pathway or the STN. For this purpose, a group of rats received a unilateral 6-hydroxydopamine lesion of the substantia nigra pars compacta and medial forebrain bundle, whereas another group had the STN selectively ablated by means of an injection of 25 nmol of N-methyl-D-aspartate. Succinate dehydrogenase and cytochrome oxidase activities were assayed histochemically on brain sections previously mounted on polylysine-coated slides. A densitometric comparison between the enzymatic staining in the lesioned and the unlesioned side was then carried out.

The rats with the nigrostriatal depletion showed, ipsilaterally to the lesion, an increased enzymatic activity in the projection nuclei of the STN: SNr, entopeduncular nucleus, and globus pallidus (the rodent homologues of MGP and lateral globus pallidus, respectively). Conversely, the enzymatic activity in these areas was reduced, ipsilaterally, by the complete ablation of the STN. These data lend further support to the more recent view of the basal ganglia circuitry organization focusing, in particular, on the modulatory activity that the STN neurons, excitatory (glutamatergic) in nature, play in the regulation of the basal ganglia output.

DECREASED NUMBER OF SOMATOSTATIN mRNA CONTAINING NEURONS IN STRIATUM OF HALOPERIDOL TREATED RATS.

¹Østergaard K*, ²Andreassen OA, ¹Finsen BR, ²West M and ³Jørgensen HA. ¹PharmaBiotec, Dept. of Anatomy, University of Odense, ²Stereological Research Laboratory, University of Aarhus, Denmark and ³Dept. of Physiology, University of Bergen, Norway.

For the first time and by stereological cell counting it has been possible to demonstrate a reduction in the number of somatostatin (SS) mRNA containing neurons in the dorsal striatum of rats with dyskinetic symptoms caused by longterm treatment with a dopamine receptor blocking drug.

Adult rat were treated with haloperidol for 6 months and the behaviour video-taped. Five rats, which developed serious dyskinetic symptoms and five rats, which did not, together with five control rats were anesthetized and perfused. One series of vibratome sections of striatum were in situ hybridized for SS mRNA using an alkaline phosphatase labeled oligonucleotide probe. The total number of neurons expressing SS mRNA in the dorsal striatum was estimated with the optical fractionator technique. The mean number of SS mRNA containing cells in the treated rats with dyskinetic symptoms was significantly less than for the rats with no symptoms and the control rats.

406.14

LOCALIZATION OF "FLIP" AND "FLOP" SPLICE VARIANTS OF AMPA-SELECTIVE GLUR2 AND GLUR3 EXCITATORY AMINO ACID RECEPTOR SUBUNITS ON STRIATAL PROJECTION NEURONS. S.J. Tallaksen-Greene* and R.L. Albin. Department of Neurology, University of Michigan, Ann Arbor, MI 48109.

We have previously shown that the majority of striatal projection neurons are immunostained using an antibody recognizing an epitope conserved on GluR2, 3 and 4c subunits and common to both "flip" and "flop" splice variants. In order to determine the relative expression of GluR2 and 3 splice variants on striatonigral and striatopallidal neurons we used *in situ* hybridization in combination with the retrograde transport of the fluorescent tract-tracer Fluoro-Gold (FG).

Unilateral injections of FG were made into either the substantia nigra or globus pallidus of adult male rats. After 12 days, the animals were killed by decapitation. Twelve μ m sections were processed for *in situ* hybridization using ³⁵S-labeled oligonucleotide probes against "flip" and "flop" splice variants of GluR2 and GluR3 mRNAs.

GluR2 flop was the splice variant expressed by the greatest percentage of both striatonigral and striatopallidal neurons: approximately 50% of labeled striatonigral neurons and 30% of striatopallidal neurons expressed GluR2 flop. The remaining splice variants were each expressed by approximately 10% of striatopallidal neurons. About 12% of striatonigral neurons expressed GluR2flip and GluR3flip and 20-25% expressed GluR3flop.

These findings indicate that splice variants of AMPA receptor subtypes are differentially expressed by striatal projection neurons.

INTERACTION OF DOPAMINERGIC AND GLUTAMATERGIC SYSTEMS IN THE REGULATION OF STRIATAL CHOLINERGIC ACTIVITY Christopher J. Schmidt* and Vicki L. Taylor. Marion Merrell Dow Research Institute 2110 E. Galbraith Road, Cincinnati, OH 45215

The balance between dopaminergic and glutamatergic activity within the corticostriothalamic pathways (CST) is an important determinant of sensory input through the thalamus.

Disturbances of this balance in favor of glutamate or dopamine are believed to produce the symptoms of Parkinson's disease or schizophrenia, respectively. The cholinergic interneurons of the striatum are regulated by long feedback loops involving dopaminergic and glutamatergic afferents from the midbrain and the thalamus, respectively. The strategic position of these neurons allows changes in tissue concentrations of acetylcholine (ACh) to be used to assess effects of dopaminergic and glutamatergic agents on striatal function and potentially the CST pathways. Consistent with a reduction in cholinergic/striatal activity, high doses of the uncompetitive NMDA antagonist MK-801 produced a modest accumulation of striatal ACh while the D₂ agonist quinpirole produced a robust increase in tissue concentrations of the transmitter. Pretreatment with quinpirole augmented the elevation of ACh produced by MK-801 in a synergistic fashion. The D₁ antagonist, SCH 23390 alone produced only a small increase in ACh yet completely prevented any further elevation of ACh by MK-801. The D₂ antagonist haloperidol produced the expected decrease in striatal ACh and also completely blocked the effect of MK-801. Thus inhibition of cholinergic/striatal activity with the D₂ agonist potentiated the effect of MK-801 whereas treatments which increase striatal/cholinergic activity prevent any further effect of MK-801. These observations suggest that glutamatergic feedback from the thalamus may be important in determining the magnitude of the MK-801 effect. To test this hypothesis, amphetamine was used to enhance thalamic activity and thereby increase thalamic feedback to the striatum. Although amphetamine alone was without effect, the combination of amphetamine plus MK-801 produced a large increase in striatal ACh concentrations. These results suggest that the effects of dopaminergic agents on the striatal cholinergic interneurons are a composite of the direct striatal effect of such drugs and of their ultimate effect on the glutamatergic thalamostriatal feedback loop.

EXPRESSION OF METABOTROPIC GLUTAMATE RECEPTOR MGLUR5 BY SPECIFIC RAT STRIATAL CELL POPULATIONS. C.M. Testa*, D.G. Standaert, G.B. Landwehrmeyer, J.B. Penney and A.B. Young. Department of Neurology, Massachusetts General Hospital, Boston, MA 02114.

Glutamate has a central role in basal ganglia regulation of motor behavior, and is the main afferent neurotransmitter to the striatum. Glutamate acts via many different striatal receptors, including metabotropic glutamate receptors (mGluRs). Striatal mGluRs are involved in motor behavior regulation, long term depression, and N-methyl-D-aspartate (NMDA) excitotoxicity. Several lines of evidence suggest that mGluR5 is particularly important in the striatum.

We used a double label *in situ* hybridization technique to determine if subpopulations of striatal neurons differentially express mGluR5. Digoxigenin labeled probes targeting enkephalin, somatostatin and acetylcholinesterase mRNAs were used in conjunction with radiolabeled probes specific for mGluR5 mRNA. We observed that mGluR5 mRNA is strongly expressed by enkephalinergic striatal neurons, but is relatively absent from at least two types of striatal interneurons: somatostatin-containing medium aspiny neurons and cholinergic neurons. Differential mGluR5 expression in striatal neuron subpopulations may underlie mGluR-mediated effects on striatal output pathways, plasticity and susceptibility of neurons to injury. Supported by USPHS grants NS19613 and NS31579. DGS is an HHMI Fellow and recipient of an AAN Research Fellowship Award in Neuropharmacology.

407.1

DOPAMINERGIC REGULATION OF THE EXPRESSION OF m1 AND m4 MUSCARINIC RECEPTOR mRNAs IN THE RAT DORSAL STRIATUM. N. Kavanian, R. Heavens, M.J. Besson, D. Tritsch* and D.J.S. Sirinathsinghji. Merck Sharp and Dohme Research Laboratories, Neuroscience Research Center, Harlow, U.K. Institut des Neurosciences, CNRS URA 1488, UPMC, 75005 Paris, France.

In the rat neostriatum, cholinergic interneurons comprise about 1-2% of the total population of neurons but play an important role in the regulation and maintenance of striatal functions e.g. in the modulation of dopamine (DA) transmission. In vitro release data indicate that DA inhibits acetylcholine (ACh) release and receptor autoradiography shows a decrease in 3H-pirenzepine (a pharmacologically M1 muscarinic receptor antagonist) binding sites after unilateral 6-hydroxydopamine (6-OHDA) lesion of the nigrostriatal DA tract. In this study, we examined the influence of striatal DA on the expression of m1 and m4 muscarinic receptor mRNAs in rats with unilateral 6-OHDA lesions of the nigrostriatal DA tract. In situ hybridization experiments of m1 and m4 mRNAs were performed using ³⁵S-labelled oligonucleotide probes, and densitometric analysis of the autoradiograms were then assessed. Three weeks following 6-OHDA lesion there was a 15% reduction in the levels of both m1 and m4 muscarinic receptor mRNAs in the dorsal striatum. These results indicate that dopamine exerts a tonic excitatory influence on the expression of the two main muscarinic receptor mRNAs (m1 and m4) expressed in the striatum. We are now investigating the role of the glutamatergic cortico-striatal pathway in the regulation of the muscarinic receptor mRNAs expression in the striatum.

ACUTE AND CHRONIC PSYCHOMOTOR STIMULANTS INDUCE DIFFERENT SETS OF IMMEDIATE-EARLY GENES IN THE STRIATUM.

R. Moratalla*, B. Eliab, A.M. Graybiel, MIT, Brain and Cognitive Sciences, Cambridge, MA 02139.

The molecular mechanisms by which psychomotor stimulants produce behavioral changes in animals and humans remain unknown. However, treatments with cocaine and amphetamine have been found to induce long-term changes of specific proteins in target neurons (a form of neural plasticity). Transcription factors, including members of the Fos and Jun families, are expressed in neurons in response to treatment with these drugs, suggesting that plasticity at the transcriptional level may underlie some of the changes in protein expression observed.

In the present study, we investigated the effects of acute and chronic treatments with cocaine and amphetamine on the induction in the rat striatum of immunohistochemically detected protein products of the immediate-early genes (IEGs) *fos*, *jun* B and *fra*. For chronic treatment, cocaine (25 mg/kg) or amphetamine (5 mg/kg) was administered twice a day for 8 days. For acute treatment, saline was administered for 7 days and cocaine or amphetamine was given on the 8th day. Brains were taken for processing 2 hours after the last treatment. The acute cocaine and amphetamine treatments resulted in the induction of Fos-, Jun B- and Fra-like immunoreactivity (LI) in the striatum in anatomical patterns specific for each drug, as reported previously. In animals treated with chronic cocaine or amphetamine, Jun B- and Fra-LI were still detectable in these specific patterns: cocaine induced broad expression, amphetamine a striosome-selective pattern. By contrast, Fos-LI was almost completely absent after chronic cocaine treatment, and was markedly down-regulated after chronic amphetamine treatment. These experiments suggest that Jun B and Fra, by having maintained responsiveness, may be involved in mediating some of the long-term effects of chronic exposure to psychostimulants. INCREASE OF DOPAMINE RELEASE BY STIMULATION OF THE CHOLINERGIC PEDUNCULOPONTINE NUCLEUS STUDIED BY INTRASTRIATAL MICRODIALYSIS.

K. Ikeguchi, K. Fujimoto*, N. Shizuma Dept. of Neurology, Jichi Medical School, Minamikawachi-machi, Tochigi, 329-04, Japan

The pedunculopontine nucleus (PPN) is large cholinergic neurons located bilaterally in the lower midbrain and pons extending from the caudal pole of the red nucleus to the parabrachial nucleus. Anatomically, the projection from the PPN to the substantia nigra (SN) is well known. Since constant ipsiversive circling behavior was observed after the chemical stimulation of the unilateral PPN of the rat, activation of the mesencephalic dopaminergic neurons by the cholinergic PPN was hypothesized.

Adult male Wistar rats were used under the anesthesia with urethane. A probe for microdialysis was inserted into the striatum and samples of each 10 min were assayed with HPLC. For the stimulation of the PPN, ibotenic acid (IBO) (7.5 µg/0.75 µl) was injected with a Hamilton syringe. In order to verify the activation of mesencephalic dopaminergic neurons to be mediated by the cholinergic transmission, scopolamine (200 µg/2 µl) was injected into the SN with a Hamilton syringe. One week after the experiment, the rats were perfused and the location of the probe and the injection syringes were histologically examined.

DOPAC in the striatum increased gradually and reached plateau about 2 or 3 hours after the operation. IBO was injected at this stage. After the injection of IBO into the PPN, DOPAC increased about 60%, while SHIAA remained in the baseline. Then, scopolamine was injected to the SN. After the injection of scopolamine, DOPAC in the striatum decreased transiently.

It is concluded that the ascending cholinergic pedunculopontine projection to the SN modulates the striatal dopaminergic release.

407.2

LOW vs. HIGH DOSE AND ACUTE vs. SUBCHRONIC HALOPERIDOL TREATMENT INDUCES DISTINCT PATTERNS OF IMMEDIATE-EARLY GENE EXPRESSION IN THE STRIATUM. B. Eliab, R. Moratalla, N. Hiroi, and A.M. Graybiel*. Dept. of Brain & Cognitive Sciences, MIT, Cambridge, MA 02139.

The extrapyramidal side effects of the typical neuroleptic haloperidol (Hal) are thought to be related, in part, to its regulation of striatal activity by antagonism of D2-like dopamine receptors. Consistent with such striatal effects, neural activity mapping with immediate-early gene protein (IEGP) immunohistochemistry has shown in rat that typical neuroleptics, more than atypical neuroleptics, induce IEGPs in the sensorimotor striatum. We have examined this acute effect and also have studied the effects of repeated Hal exposure on regulation of members of the Fos-Jun family (Fos, FosB, Fra, JunB, detected by immunostaining).

Rats received either saline or one of four doses of Hal (0.25, 0.5, 2 and 5 mg/kg, i.p., at least 2 rats per treatment group) acutely or daily for 4 or 5 days and were perfused 3 hr after the last injection. Acute administration of Hal induced striatal IEGP expression with clearly different topographies at different doses. Low-doses of Hal (0.25 and 0.5 mg/kg) induced nearly homogeneous expression of the IEGPs throughout the mediolateral axis of the striatum. Higher doses of Hal not only induced increased expression, but also produced a clear predominance of expression in the lateral (sensorimotor) caudoputamen. Medial expression was weak and often patchy. These dose-related patterns changed markedly with repeated Hal exposure. After subchronic treatment, high-dose Hal induced the IEGPs in a pattern similar to that induced by acute low-dose Hal: the IEGPs had a nearly even mediolateral expression pattern. These results imply differential up-regulation of the IEGPs medially and down-regulation of the IEGPs laterally in the striatum. Subchronic low-dose Hal diminished striatal IEGP expression throughout the caudoputamen. The induction of IEGPs in the striatum by neuroleptics may be mediated not only through modulation at the postsynaptic level, but also by presynaptic actions on dopaminergic and glutamatergic afferents. We did not distinguish among these possibilities, but our evidence does suggest that repeated exposure to neuroleptics can bring about major shifts of expression patterns in the striatum. (Supported by NIH Javits Award NS25529 and Dystonia Medical Research Foundation). We thank to Drs R. Bravo and M.J. Iadarola for their gifts of the antiserum.

DOPAMINE RECEPTORS AND CALCIUM CHANNEL ACTIVATION REGULATE PHOSPHORYLATION OF CREB IN ORGANOTYPIC CULTURES OF STRIATUM. E.-C. Liu* and A.M. Graybiel. Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139.

Phosphorylation of CREB (cAMP response element-binding protein) by activation of cAMP or voltage sensitive calcium channels (VSCC) can regulate expression of the immediate-early gene *c-fos* in PC 12 cells. In the present study, we tested whether phosphorylation of CREB was associated with Fos induction in an organotypic culture of neonatal striatum (Liu et al., 1993). Stimulation of cultured slices for 30 min with SKF-81297 (D1 agonist, 100 nM), forskolin (adenylate cyclase agonist, 10 µM) or BAY K 8644 (L-type VSCC agonist, 1 µM) resulted in phosphorylation of CREB in cultured striatum as detected by immunostaining with an antiserum recognizing Ser³³-phosphorylated CREB-like protein (PCREB) (Ginty et al., 1993). The expression of PCREB was also suggested by Western blotting, which showed induction of a 43 kD protein by forskolin. The association of PCREB and Fos-like protein (FLP) expression in cultured striatum was shown by 1) their correlated patterns of spatial expression, both being more pronounced in DARPP-32-positive developing striosomes after SKF-81297 stimulation and being striosome-matrix inclusive after forskolin and BAY K 8644 stimulation; 2) the parallel reduction of SKF-81297-induced PCREB and FLP expression by D1 antagonists (SCH-23390, 1 µM) and 3) the lack of PCREB and FLP expression in response to D2 agonists (quinpirole, 10 µM) and protein kinase C activators (phorbol ester, 80-800 µM). However, pretreating SKF-81297- or forskolin-treated slices with the kinase inhibitor H7 (50 µM) abolished FLP expression without affecting PCREB expression in the cultured striatum and with only 13% reduction in protein synthesis. Uncorrelated expression of PCREB and FLP was also observed in BAY K 8644-treated slices pretreated with the VSCC antagonist, nifedipine (1 µM), in which the decrease of PCREB expression was more pronounced than that of FLP expression. These results suggest that expression of PCREB and FLP may be subject to differential regulation in the developing striatum. We thank Drs. D.D. Ginty and M.E. Greenberg for providing PCREB antiserum. Supported by NIH 1 R01 HD28341 and grant #3244A from The Council for Tobacco Research—U.S.A., Inc.

BLOCKADE OF NMDA AND MUSCARINE RECEPTORS IN THE NUCLEUS ACCUMBENS CAUSE MICE TO ROTATE IN OPPOSITE DIRECTIONS. A. Svensson*, M.L. Carlsson and A. Carlsson. Department of Pharmacology, University of Göteborg, S-413 90 Göteborg, Sweden.

The effects on rotational behaviour of glutamate blockade and acetylcholine blockade in the nucleus accumbens were studied in male NMRI mice with different tones in the dopaminergic system.

We have previously shown that a unilateral injection into the nucleus accumbens of the competitive N-methyl-D-aspartate (NMDA) receptor antagonist AP-5 causes the animals to rotate. The rotation is predominantly ipsilateral in animals with intact dopaminergic systems. In contrast, dopamine-depleted mice, pretreated with reserpine and α-methyl-tyrosine, rotate exclusively contralaterally. We have proposed that the ipsilateral rotation is due to interference with the direct striatohalamic pathway of the basal ganglia motor circuit, whereas the contralateral rotation is due to interference with the indirect striatohalamic pathway.

In contrast to AP-5, the muscarine receptor antagonist methscopolamine induced predominantly contralateral rotation both in dopamine-depleted and intact animals, when injected unilaterally into the nucleus accumbens. Consequently, it seems as if acetylcholine in the nucleus accumbens primarily interferes with the indirect striatohalamic pathway of the basal ganglia motor circuit.

REGULATION OF Na⁺,K⁺-ATPase ACTIVITY BY PROTEIN KINASE C PHOSPHORYLATION IN RAT NEOSTRIATUM. G.L. Snyder¹, G. Fissue¹, A. Nishi^{1,2}, M. J. Caplan³, A. Aperia⁴ and P. Greengard¹. ¹Lab. of Mol. and Cell. Neurosci., The Rockefeller Univ., NY, NY 10021; ²Dept. of Pediatrics, Kurume Univ. School of Medicine, Kurume, Japan; ³Dept. of Cell. and Mol. Physiol., Yale Univ. School of Medicine, New Haven, CT 06510 and ⁴Dept. of Pediatrics, Karolinska Institute, Stockholm, Sweden.

The ion pump Na⁺,K⁺-ATPase is a ubiquitous integral membrane protein formed by a catalytic α subunit and a β subunit, which transports Na⁺ from the inside to the outside of the cell, in exchange for K⁺. This enzyme is of fundamental importance in creating and maintaining the electrochemical gradient across the plasma membrane underlying resting and action potentials in neurons. Previously, we showed that, *in vitro*, phosphorylation of purified Na⁺,K⁺-ATPase α subunit by either cAMP-dependent protein kinase or protein kinase C (PKC) significantly inhibits its activity. Three different isoforms of Na⁺,K⁺-ATPase α subunit have been identified in neurons, their distribution differing in the various brain regions. We detected both $\alpha 1$ and $\alpha 3$ isoforms in primary cell cultures from rat striatum. We found that addition of the activator of protein kinase C, phorbol 12,13-dibutyrate (PDBu) (5 μ M), to ³²P-prelabeled slices from rat striatum stimulates by several-fold the phosphorylation of the $\alpha 1$ subunit and also increases the phosphorylation of the $\alpha 3$ subunit. In agreement with the data obtained *in vitro*, treatment of striatal neurons with PDBu inhibited Na⁺,K⁺-ATPase activity by 25%. These data provide evidence for regulation of Na⁺,K⁺-ATPase activity, and hence neuronal excitability, by PKC phosphorylation in the striatum. [Supported by USPHS grant MH 40899].

407.9

ELECTROCHEMICAL EXAMINATION OF THE CONNECTIONS BETWEEN THE MESOPONTINE TEGMENTUM, VTA AND NUCLEUS ACCUMBENS IN THE RAT. C.D. Blaha, L.F. Allen, W.L. Inglis, S. Das, M.P. Latimer, S.R. Vincent and P. Winn*. Depts. Psychol. (CDB) & Psychiat. (SD, SRV), Univ. British Columbia, Vancouver B.C., V6T 1Z4, Canada and School of Psychol., Univ. St Andrews, Fife, Scotland KY16 9JU (LFA, WLI, MPL, PW)

The effects of cholinergic stimulation of ventral tegmental area (VTA) on DA efflux in the nucleus accumbens (NAcc) (measured by *in vivo* chronoamperometry: Blaha and Jung, 1991, *J. Electroanal. Chem.* 310: 317-334) were investigated in intact, pedunculopontine tegmental nucleus (PPTg) lesioned and laterodorsal tegmental nucleus (LDTg) lesioned rats under urethane anesthesia. Using steerable-modified electrodes, a dose-dependent increase in oxidation current in NAcc corresponding to DA efflux was found following microinjection into VTA of nicotine (0.2 mM, 132 \pm 4% [maximal increase as a percentage of baseline]; 2.0mM, 276 \pm 14%). Increasing extracellular concentrations of ACh in VTA by infusion of the anticholinesterase neostigmine (NEO) also increased NAcc DA efflux (0.5mM, 580 \pm 36% 1.0mM, 1044 \pm 49%). Rats with ibotenate (IBO) lesions of PPTg showed no difference to controls in their NAcc DA response to stimulation of VTA with NEO (lesion: 523 \pm 22%; control 580 \pm 36%) but rats with IBO lesions of the LDTg showed a significant ($p < 0.001$) attenuation of NAcc DA efflux in response to stimulation of VTA with NEO (lesion: 235 \pm 10%; control 580 \pm 36%). These studies show the existence of a functional cholinergic innervation of the VTA from the LDTg but not PPTg. Since lesions of the PPTg have been shown to attenuate DA efflux in the caudate-putamen after injections of NEO into the SNC (with an increase in the response to nicotine - Blaha and Winn, 1993, *J. Neurosci.* 13: 1035-1044) we can conclude that cholinergic neurons in the mesopontine tegmentum are indirectly involved in regulating DA activity in the striatum by virtue of connections in the midbrain: PPTg (Ch5) with SNC, VTA (Ch6) with VTA.

IMMUNOCYTOCHEMICAL PROPERTIES OF RAT CAUDATE-PUTAMEN NEURONS EXPRESSING DOPAMINE-MODULATED K⁺ CHANNELS. Gabriela J. Greif*, Yong-Jian Lin, June-Chih Liu, Barbara L. Waszczak and Jonathan E. Freedman. Dept. Pharmaceutical Sciences, Northeastern Univ., Boston, MA 02115.

We have previously used patch-clamp recording to describe an 85 pS K⁺ channel which is modulated by D₂-like dopamine receptors on freshly dissociated rat corpus striatum neurons. We are now using some cytochemical methods to identify the cells expressing this channel. Under phase-contrast optics, dissociated cells could be placed in two broad morphologic categories: "large" multipolar cells with diameters $\geq 10 \mu$ m, and "small" unipolar cells $< 10 \mu$ m. The 85 pS channel was observed in about 26% of cell-attached patches from "large" cells, mainly on cells with a characteristic angular shape, and never on "small" cells. Virtually all "large" cells were immunoreactive for neuron-specific enolase (NSE) and negative for glial fibrillary acidic protein (GFAP); 70% of the "small" cells expressed NSE and 30% expressed GFAP. Many of the angularly-shaped "large" cells were immunoreactive for GABA. In preliminary studies, some "large" cells of this morphology were retrogradely labeled with fluorescent microspheres injected into the substantia nigra. We conclude that the dopamine-modulated K⁺ channel is selectively expressed on a subpopulation of striatal neurons, some of which may be GABAergic medium spiny projection neurons.

INTRASTRIATAL NMDAR1 GLUTAMATE RECEPTOR SUBUNIT ANTISENSE OLIGONUCLEOTIDES INDUCE IPSILATERAL ROTATION D.G. Standaert*, C.M. Testa, Z. Hollingsworth, G. Rudolf, J.B. Penney, Jr., and A.B. Young. Dept. of Neurology, Mass. Gen. Hosp., Boston, MA 02114.

NMDA glutamate receptors, composed of subunits from a family of at least twelve structurally related proteins, have an established role in the regulation of motor behavior by the basal ganglia. Several of the NMDA receptor subunits exhibit anatomically restricted patterns of expression, so that the components of the basal ganglia have distinct NMDA receptor subunit mRNA phenotypes (*J. Comp. Neurol.* 343:1-16 (1994)).

We have used *in vivo* intrastriatal injection of synthetic antisense oligonucleotides to examine the roles of particular NMDA receptor subunits in the regulation of motor behavior. Injection of 15 nmol of a 20mer oligo targeted to the NMDAR1 subunit (a region common to all of the observed isoforms) induced ipsilateral rotation. This effect was maximal between 18 and 24 hours after a single injection. Smaller doses did not lead to spontaneous rotation, but prominent ipsilateral rotation was observed after administration of D-amphetamine. *In situ* hybridization demonstrated dose-dependent reduction in NMDAR1 mRNA in the injected striatum, while NMDAR2B and actin mRNA were not reduced. Conversely, injection of an antisense oligo targeted to the NMDAR2B subunit reduced the striatal content of mRNA for that subunit, without affecting NMDAR1 mRNA. NMDA-displaceable [³H]-glutamate ligand binding sites were not altered by injection of NMDA subunit antisense oligos in this paradigm.

DGS is a HHMI Physician Research Fellow. Supported by USPHS grants NS19613, NS1579 and an AAN Research Fellowship Award in Neuropharmacology.

NADPH DIAPHORASE EXPRESSION IN FRESHLY DISSOCIATED RAT CAUDATE-PUTAMEN NEURONS. Jonathan E. Freedman*, Gabriela J. Greif and Yong-Jian Lin. Dept. Pharmaceutical Sciences, Northeastern Univ., Boston, MA 02115.

It is known that only about 2% of the neurons in the rat caudate-putamen express NADPH diaphorase *in situ*. In the course of characterizing freshly dissociated rat striatal neurons which express a dopamine-modulated K⁺ channel in patch-clamp recordings (accompanying abstract), we have stained the dissociated cells for NADPH diaphorase using the nitro blue tetrazolium method. About 60% of "large" dissociated cells were stained for diaphorase, and about 40% were immunoreactive for GABA. In preliminary double-labeling studies, there were no obvious cases of "large" cells labeled for both markers. The diaphorase-containing cells tended to be somewhat rounded and pyramidal-like in shape, whereas the GABA-containing cells tended to be more angular, similar to the unfixed cells expressing the dopamine-modulated K⁺ channel. Among "small" cells, about 60% expressed diaphorase and about 60% expressed GABA, and we observed some doubly-labeled cells. Our results indicate either that the dissociation procedure differentially selects for diaphorase-containing cells, or induces this enzyme, or both. Interestingly, this high level of NADPH diaphorase expression in the dissociated cells resembles that seen in the brains of patients with Huntington's disease. (Supported by MH-48545.)

GAT-1 GABA TRANSPORTER mRNA IN RAT BRAIN: CELLULAR CO-EXPRESSION WITH GAD67 mRNA AND PARVALBUMIN mRNA. S.J. AUGOOD*, K. WESTMORE AND P.C. EMSON. MRC Molecular Neuroscience Group, Dept. of Neurobiology, BBSRC Babraham Institute, Cambridge CB2 4AT, U.K.

The re-uptake of GABA into pre-synaptic nerve terminals terminates GABA signalling. Several GABA transporter cDNAs have been cloned including GAT-1, which display micromolar affinity for GABA when transfected *in vitro* (1,3). It has been suggested that cells which tonically release GABA may utilise more GAD67 than GAD65; two forms of the GABA synthetic enzyme (2). Expression of the calcium-binding protein parvalbumin (PV) is associated with fast-firing cells in the rat brain. This study aimed to determine if GAT-1 mRNA was expressed by GAD67 cells, and if PV cells represented a subgroup of GAD67-GAT-1 cells.

Cellular sites of (i) GAD67 and GAT-1 mRNAs, and (ii) GAD67 and PV mRNAs were visualised using a combination of alkaline phosphatase (AP)- and 35S-labelled oligonucleotides. Strong hybridization signals for these three probes were detected in discrete cells within most brain regions including the cerebral cortex, basal ganglia, hippocampus and cerebellum. Examination of silver grain deposits overlying AP-positive cells showed that most high-GAD67 cells were enriched in GAT-1 mRNA, although the expression of GAT-1 mRNA was more widespread; a divergence of the two signals was seen in the reticular thalamus and inferior colliculus. PV mRNA was detected in some high-GAD67 cells. Detailed analysis of the striatum will be presented. These data suggest strongly that GAT-1 is a pre-synaptic marker of most high-GAD67 GABA cells *in vivo* and that tonically active striatal GABA/PV cells may utilise GAT-1 for re-uptake.

PARTIAL LESIONS OF THE NIGROSTRIATAL DOPAMINE PATHWAY ALTER SUBSTANCE P BUT NOT ENKEPHALIN mRNAs IN THE RAT STRIATUM. L.K. Nisenbaum*, S.T. Kitai, W.R. Crowley, and C.R. Gerfen, Depts. of Anatomy/Neurobiology and Pharmacology, Univ. of Tennessee, College of Medicine, Memphis, TN 38163, and Sec. of Neuroanatomy, LCB, NIMH, Bethesda, MD 20892.

The expression of striatal peptide mRNAs is regulated by the nigrostriatal dopamine (DA) pathway. For example, near total depletion of striatal DA levels results in an increase in enkephalin and a decrease in substance P mRNAs. However, it is unknown whether partial depletions of striatal DA content produce similar changes in these peptide mRNAs. To test whether compensations in DA synthesis and release following partial DA depletion prevent the lesion-induced alterations in enkephalin and substance P mRNAs, varying concentrations of 6-OHDA were injected unilaterally into the substantia nigra. Seven days after injection of 6-OHDA (2-16 µg) or vehicle, *in situ* hybridization was employed to examine tyrosine hydroxylase mRNA in the substantia nigra and enkephalin and substance P mRNAs in the striatum. The extent of the DA depletion was determined by measuring striatal DA tissue content. Subjects were divided into three groups based on the extent of striatal DA depletion: <50%; 50-90%; and >90%. The decrease in tyrosine hydroxylase mRNA closely paralleled the change in striatal tissue DA content in all groups. Although no significant change in substance P mRNA was detected in rats with <50% DA depletion, a 24% and 68% decrease was observed in the 50-90% and >90% depleted groups, respectively. In contrast, a significant increase in enkephalin mRNA was not detected until a >90% depletion of striatal DA was produced. In summary, alterations in tyrosine hydroxylase mRNA in the substantia nigra are well correlated with decreases in striatal tissue DA levels. In addition, whereas partial lesions of the nigrostriatal DA pathway produce a decrease in substance P mRNA, a near total depletion of striatal DA levels is necessary to increase enkephalin mRNA. DIFFERENTIAL INVOLVEMENT OF NMDA RECEPTORS IN STRIATUM IN D1-DOPAMINE RECEPTOR-MEDIATED BEHAVIOR AND IMMEDIATE EARLY GENE EXPRESSION. K.A. Keefe* and C.R. Gerfen, Section of Neuroanatomy, LCB, NIMH, Bethesda, MD 20892.

Dopamine's effects in striatum often are thought to result from its ability to modulate the response of striatal neurons to other afferents. For example, activation of D1-dopamine receptors increases conductance through the NMDA subtype of glutamate receptor. D1-receptor activation also increases expression of the immediate early genes *zif268* and *c-fos* in striatum. To further understand interactions between dopamine and glutamate in the regulation of striatal function, we examined the contribution of NMDA receptors to immediate early gene expression in the dopamine-depleted striatum by infusing NMDA receptor agents into the striatum of freely moving rats. Expression of *zif268* and *c-fos* was determined by *in situ* hybridization histochemistry. Infusion of NMDA (1 mM) for 20 min via a microdialysis probe induced contralateral rotation and increased expression of *zif268* uniformly throughout the striatum, as well as the cortex, on the side of the infusion. The induction in striatum and cortex, as well as the behavioral effects of NMDA, were blocked by co-infusion of the NMDA receptor antagonist CPP (1 mM). Such infusion of CPP into striatum also blocked the contralateral rotation and decreased the expression of *c-fos* induced by the D1 agonist SKF 38393 (2 mg/kg, i.p.). CPP did not, however, affect SKF 38393-mediated induction of *zif268* under the same conditions. The data indicate that D1-mediated changes in striatal output are dependent, at least in part, on ongoing excitatory input to the striatum, as evidenced by CPP blockade of D1-induced contralateral rotation and its partial reduction of D1-mediated *c-fos* induction. However, D1-mediated gene regulation in these neurons is not completely dependent on NMDA receptor activity, as evidenced by the incomplete blockade of *c-fos* induction and lack of effect on *zif268* induction.

407.14

IDENTIFICATION OF STRIATAL NEURONS SHOWING POTENTIATED ZIF268 EXPRESSION TO COMBINED D1-D2 DOPAMINE RECEPTOR STIMULATION. C.R. Gerfen* and K.A. Keefe, Section of Neuroanatomy, LCB, NIMH, Bethesda, MD 20892.

Activation of D1-dopamine receptors causes induction of immediate early genes in striatum. Numerous studies have shown that this induction occurs predominately in D1-containing striatonigral neurons. We previously have shown that stimulation of D2-dopamine receptors causes a decrease in basal expression of *zif268* in striatum (Keefe & Gerfen, *Soc. Neurosci. Abstr.*, 1993). Combined stimulation of D1 and D2 receptors, however, produces enhanced expression of immediate early genes in the dopamine-depleted striatum relative to that seen in response to D1-receptor stimulation alone. This manifestation of D1-D2 receptor synergy is a consequence of D1- and D2-receptor activation in striatum. Because D1 and D2 receptors are differentially expressed by striatonigral and striatopallidal neurons, respectively, we are interested in the identity of striatal neurons showing decreased *zif268* expression in response to D2-receptor stimulation and increased expression to combined administration of D1- and D2-receptor agonists. A double-labeling *in situ* hybridization approach is being used with ribonucleotide probes complementary to mRNAs for the D1-dopamine receptor, the D2-dopamine receptor, preproenkephalin, and *zif268* labeled with either ³⁵S or digoxigenin. Co-localization of the signal for *zif268* with selective markers for striatonigral and striatopallidal pathways should allow us to determine whether striatopallidal neurons show decreased expression of *zif268* in response to D2-receptor stimulation, and whether the enhanced expression seen in response to combined D1-D2 receptor stimulation occurs in those neurons that respond to stimulation of the D1 receptor alone or reflects induction in a novel population.

407.16

DYNORPHIN OPIOID INHIBITION OF D1 DOPAMINE RECEPTOR-MEDIATED INDUCTION OF IMMEDIATE-EARLY GENES IN THE STRIATUM. H. Steiner* and C. R. Gerfen, Section of Neuroanatomy, NIMH, Bethesda, MD 20892.

Dynorphin is an opioid peptide contained in striatonigral projection neurons. In such neurons, dopamine agonists produce rapid induction of immediate-early genes (IEGs), such as *c-fos* and *zif 268*. Recent studies showed that IEG induction by the indirect dopamine receptor agonist cocaine in striatum (1) is inversely related to striatal dynorphin expression, and (2) can be suppressed with systemic and intra-striatal administration of the dynorphin (kappa opioid receptor) agonist spiradoline. These results suggest that dynorphin is involved in the regulation of dopamine input to striatonigral neurons, directly and/or indirectly, through kappa opioid receptors located in the striatum. In the present study, we examined whether dynorphin exerts direct influence on striatonigral neurons by analyzing the effects of the dynorphin agonist spiradoline (1-10 mg/kg) on IEG induction by stimulation of D1 dopamine receptors which are expressed in these neurons. Gene expression was assessed with *in situ* hybridization histochemistry. Spiradoline partially suppressed IEG induction by the selective D1 receptor agonist SKF-38393 in the dopamine-depleted striatum, while the lesser IEG response in the intact striatum was completely blocked. Striatal regions with higher levels of dynorphin/kappa receptor expression (ventral regions) showed greater inhibition of IEG induction than regions with lower levels of these mRNAs (dorsal striatum). These results suggest that kappa opioid receptors on striatonigral neurons participate in dynorphin-mediated inhibition of dopamine input to these neurons.

CHARACTERISTICS OF THE REPRESENTATION OF HAND IN SPACE FOR 3-D TACTILE LOCALIZATION. P. Dassonville* & A. P. Georgopoulos, Minneapolis VAMC Brain Sciences Center and Physiology Dept., University of MN, Minneapolis, MN 55455.

To encode the location of a tactile stimulus in 3-D space, information of the stimulus' somatotopic location must be combined with a representation of limb position. Previously, we investigated the time course of the representation of hand in space by instructing subjects to point, in complete darkness, to the 3-D location of a tactile probe presented to the fingertip during a previous arm movement (Dassonville et al. 1993). On average, subjects perceived the probe to be at the location occupied by the hand approximately 100 ms after probe onset, indicating that the dynamic representation of hand in space does not compensate for cutaneous, kinesthetic, and/or motor delays. Moreover, this representation is seen in some subjects to change with a velocity different from that of the hand itself.

In the present study, two additional problems were investigated as follows: (1) Two subjects performed the task under normal illumination. The pattern of errors observed in each subject was similar to that observed when tested in complete darkness. Thus, the internal representation of hand in space does not have an appreciable visual component. (2) Four subjects were instructed to simply state whether the probe was presented "before", "during" or "after" the movement. Probes presented <38 ms before movement onset were perceived as occurring during the movement, whereas those presented <145 ms before movement termination were perceived as occurring after the movement. Across subjects, these temporal shifts were highly correlated with the temporal shifts measured in the original localization task. Thus, the subjects' perception of movement onset and termination appears to rely on the same internal representation of hand in space that is used for 3-D tactile localization.

REACHING ERRORS RESULTING FROM THE DEGRADATION OF AN INTERNAL MODEL. C. A. Buneo*, J. Bolino, J. F. Soechting, and R. E. Poppele, Dept. of Physiology, Univ. of Minnesota, Minneapolis, MN 55455.

We investigated, by means of simulations, possible mechanisms responsible for the systematic directional errors exhibited by deafferented patients during reaching movements (Ghez et al., 1990). Two aspects of altered feedforward control were evaluated: the inability to sense initial conditions and the degradation of an internal model. The first simulation demonstrated that the pattern of directional errors exhibited by deafferented patients could not be explained by assuming inadequate information regarding initial arm configuration. In contrast, a second simulation, which introduced random errors in torque production, produced results that corresponded more closely to the general pattern of errors exhibited by deafferented patients. We conclude that these directional errors do not result simply from a failure to compensate for inertial anisotropies, but are consistent with a degraded internal model which manifests as increased variability in the mapping between joint torques and motion.

SHORT-LASTING CONTROL SIGNALS UNDERLIE THE FASTEST SINGLE-JOINT MOVEMENTS. A.G. Feldman, S.V. Adamovich, R. Forget*, M.F. Levin. Research Ctr., Rehabilitation Inst. of Montreal, Quebec, Canada H3S 2J4

We tested two versions of the hypothesis that movements are produced by shifts in the system's equilibrium state for the fastest elbow flexions in humans: 1) that shifts end near the peak velocity of movement and 2) that shifts proceed until the end of movement. The first predicts that movement time may be significantly reduced by opposing loads without changes in the control pattern. Subjects flexed their elbows about 65° (control trials) and, in random test trials, movements were opposed by loads generated by a torque motor. Subjects had no visual feedback and were instructed not to correct arm deflections when perturbations occurred. At the end of the movement, the load was removed leading to a secondary movement to the same final position as that in control trials (equifinality). The static arm positions before unloading were related to load torques. This finding and equifinality implies that subjects could reproduce the same control patterns regardless of perturbations. Test movements opposed by a high load ended near the peak velocity of control movements. Phasic and tonic EMG patterns were load-dependent. Results indicate that the control pattern is of short duration which suggests that rather than being pre-programmed, EMG signals represent long-lasting dynamic responses of the system to the short-duration control pattern, external forces and proprioceptive feedback.

CONTROL OF INTERACTION TORQUES DURING REACHING IN NORMAL AND CEREBELLAR PATIENTS. AJ Bastian*, MJ Mueller, TA Martin, JG Keating & WT Thach. Dept of Anatomy, Program in Physical Therapy, The IWK Inst. for Rehab. Research, Wash. U. Sch. of Med., St. Louis, Mo. 63110.

Recent studies (Goodkin et al 1993, Thach et al 1992) support Gordon Holmes' observations that while cerebellar lesions affect simple movements at one joint and compound movements across several joints, the latter are affected disproportionately. From a mechanical standpoint, a multi-jointed movement is more complex than a summed combination of single-jointed movements due to interaction torques (e.g. inertial, centripetal, and Coriolis) generated by one linkage moving on the other. We have studied normal and cerebellar subjects performing two-jointed reaching movements under two conditions. For the "accurate" condition, seated subjects were asked to make a self-paced reach to touch a 1 cm target on a 4 cm ball hanging in front of them. For the "fast" condition, seated subjects were instructed to move as fast as possible and touch any part of the 4 cm ball. Subjects were videotaped with markers at the index finger, shoulder, elbow, and wrist joints. Marker positions were digitized (60 Hz) and joint angles and trajectories calculated. Inverse dynamic equations (Soechting and Lacquaniti 1981) were used to estimate 1) net torques and 2) interaction torques at the elbow and shoulder joints. Preliminary data indicate that, under the "accurate" condition, cerebellar subjects moved in a manner that reduced the complexity of torques by decomposing the reach and/or slowing it down. Slowing the reach also permitted use of peripheral feedback to help shape the ongoing movement. Under the "fast" condition, cerebellar subjects produced abnormal torque profiles and often overshoot the target. Fast reaching movements increase the magnitude of interaction torques (Soechting and Lacquaniti 1981) and normally require subjects to account for them in a predictive manner. We are currently addressing whether abnormalities in the "fast" movements made by cerebellar patients reflect the inability to account for only interaction torques or increasing magnitudes of all torques. We speculate that the cerebellum plays a role in generating appropriate commands to account for the complex nature of the torque components during fast, multi-jointed movements (NIH grant NS12777).

COORDINATION OF PLANAR TWO-JOINT ARM MOVEMENTS IN DIFFERENT DIRECTIONS. N. Virji-Babul*, J.D. Cooke. Faculty of Applied Health Science, University of Western Ontario, London, Canada N6G 1H1.

In order for coordinated movement to occur, it is generally assumed that the CNS must in some manner play an active role in counteracting the effects of interactional torques. Very few studies have directly examined the influence of such torques and identified the movement characteristics that are preserved under such compensatory conditions during two-joint movements. We examined EMG-movement relations during planar elbow and wrist movements in which the two joints moved in different directions, i.e. elbow flexion - wrist extension and elbow extension - wrist flexion. Elbow and wrist movements of different amplitude combinations were performed during a visual, step-tracking task in which subjects were specifically required to attend to the initial and final angles at each joint.

Elbow kinematics were generally unaffected by concurrent wrist movement. In contrast, wrist movement trajectories were variable and wrist movement duration increased as elbow amplitude increased. Qualitative changes were also observed in the pattern of muscle activation at the wrist joint. Specifically, wrist antagonist activity preceded wrist agonist activity in conditions where elbow reaction torques could potentially produce a larger than required wrist movement.

The variability observed in wrist trajectories suggests that the CNS may not plan movement of the distal joint in terms of kinematic variables. Rather, the observed kinematic and EMG changes at the wrist joint appear to be the direct result of a strategy used by the CNS to compensate for reaction torques resulting from elbow movements, ensuring the production of movements of designated amplitudes.

ADAPTIVE CHANGES IN TORQUE CONTROL DURING REACHING OF YOUNG INFANTS. J. Konczak*, M. Borutta, J. Dichgans. Dep. of Neurology, Univ. of Tübingen, 72076, Tübingen, Germany. (Spon: EBBS)

When newborns attempt to produce goal-directed arm movements they are faced with the problem to actively control their muscular forces with respect to external and reactive forces. We report cross-sectional data of 19 young infants between the ages of 4-15 months. They performed reaching movements to a stationary target presented at shoulder height of the infant. Time-position data of the hand, shoulder, and elbow were collected at a sampling rate of 100 Hz using an optoelectric measurement system (ELITE). We analyzed the intersegmental dynamics of 348 successful reaches to investigate how changes in torque control of the shoulder and elbow joint determined the kinematics of hand trajectory formation. Our results show: A) As expected, kinematic profiles improved over age. With increasing age the number of movement units and the curvature of the hand trajectory decreased. B) The ranges of mean peak muscular and motion-dependent torques (relative to body-weight) did not change significantly with age, while systematic changes in the relative timing of torque peaks were observed. We conclude that coordination emerges not primarily by regulating force amplitude but by modulating the correct timing of dynamic force production. INADEQUATE COMPENSATION FOR MECHANICAL COUPLING BETWEEN LIMB SEGMENTS UNDERLIES MISDIRECTIONS OF UPPER LIMB MOVEMENTS IN A SUBSET OF SUBJECTS WITH UNILATERAL BRAIN LESIONS. R.F. Beer*, J.P.A. Dewald and W.Z. Rymer. Depts. of Biomedical Engr. and Physiology, Northwestern University, Chicago, IL 60611

Previously we reported [1] that a subset of subjects with unilateral brain lesions exhibited a disturbance of reaching movements performed with the contralateral limb while the initiation phase of retractive movements was relatively undisturbed. In the aforementioned study, ballistic movements were performed in a horizontal plane from a central starting point to each of 16 targets located equidistantly around the circumference of a circle. Subsequent simulation studies indicated that the disturbances in hand paths occurred for target directions for which the initial direction of movement was most sensitive to a failure to adequately compensate for the mechanical coupling between limb segments in the motor command.

We have completed a second set of experiments in which the subjects were required to perform movements from the peripheral target locations to the central target. This "centripetal" paradigm resulted in more extended starting positions for the retractive movements and hence, substantially increased the magnitude of the inertial coupling torque at the elbow in comparison to movements made during the "radial" paradigm. Conversely, in relation to the radial paradigm, reaching movements were initiated from a more flexed elbow position which decreased the inertial coupling torque at the elbow.

Consistent with the change in coupling torques, retractive movements exhibited a significant misdirection in the centripetal paradigm while the misdirection of reaching movements was reduced. These results support the hypothesis that the observed disturbances of voluntary movement have their basis in an inadequate compensation for the mechanical coupling between limb segments rather than the use of specific muscle combinations. The origins of such inadequate compensation will be discussed.

DELAYED VISUAL INFORMATION SLOWS DOWN THE TIME COURSE OF PRISM ADAPTATION IN HUMAN. S. Kitazawa*, T. Kohno and T. Uka. Neuroscience Section, Electrotechnical Laboratory, Tsukubashi, 305, JAPAN.

Accurate pointing is initially disturbed when the visual field is displaced by prisms, but gradually recovers. To test if the improvement in the movement requires visual error signals that correlate in the time domain with the motor output, the rate of prism adaptation was studied with delayed visual information.

Nine subjects were trained to point rapidly at a target that appeared randomly in a square area (40x40 mm) on a tangent screen (400 mm away). Vision of the hand and the arm was always blocked during the movement by liquid-crystal shutters, and allowed 0, 50, 100, 500 or 5000 ms after the index finger touched the screen. One experiment consisted of 3 sets of 30 trials. In the first set, the subject wore no prisms and visual information was allowed after 0 ms delay. In the second, the visual field was displaced to the right or to the left by prisms (15 diopter), and visual information was available only after one of the 5 delay periods while the subjects maintained their final pointing position. One of the 2x5 conditions was used through the second set. Ten experiments, covering all conditions, were carried out on each subject. Initially the subject misreached the target by about 60 mm in the direction of visual displacement. Errors decreased with trials by an amount proportional to the error in the preceding trial ($r=0.76 \pm 0.17$). The rate of decrease of error was generally largest (10-40%) when the delay was 0 ms, became significantly smaller when 50 ms (median of the ratio to rates of 0 ms = 0.65) and showed little change thereafter (0.53-0.67). In the third set, the subject performed pointing without prisms and without visual delay. Initial misreaching in the direction opposite to the displacement of the second sets, reflecting the amount of adaptation in the second set, was largest with no delay: mean error was 51.2 mm with 0 ms delay and 19-43 mm with longer delays.

These results suggest that the rate of prism adaptation depends critically on visual information that closely correlates with the motor output in the time domain.

SELECTIVE PROCESSES IN THE DEVELOPMENT OF REACHING. I. SINGLE ARM TRAJECTORIES. E. Thelen*, D. Corbetta, and J. P. Spencer, Dept. of Psychology, Indiana University, Bloomington IN 47405

Developmental studies provide a window on the neural mechanisms of hand trajectory control in reaching and grasping. It is well known that during the first year, human infants' hand trajectories become straighter, smoother, and more accurate. But reaches do not develop in isolation; rather, infants learn reaching movements within a context of continuous and variable non-reaching movements of the hands and arms. Here we describe reaching development as infants' discovery of stable trajectory parameters from a wider range of movement possibilities.

We observed 4 infants (3 boys and 1 girl) weekly from 3 to 30 weeks and biweekly thereafter until 52 weeks as they reached for a toy at midline. Reaches were embedded in 14 s trials, and hand trajectories were monitored by WATSMART motion analysis at 150 Hz before, during, and after the reach. Infants first reached at 12, 15, 21 and 22 weeks and showed a dramatic improvement in trajectory straightness, smoothness and velocity modulation at 30, 32, 30, and 36 weeks, respectively. Prior to the transition, each infant had a month-long epoch of high velocity reaches, which in turn, disrupted the reach path stability. The speed increases were not unique to reaching, however, but were also characteristic of other non-reaching movements. After this active period, trajectory parameters stabilized.

Reaching improvement is not steady, linear and encapsulated. Rather, reaches are "carved out" of ongoing movements and are influenced by the ongoing movement context. Development consists of discovering consistent solutions after exploring a wide range of movement parameters.

408.11

SELECTIVE PROCESSES IN THE DEVELOPMENT OF REACHING. III. INTERLIMB COORDINATION. D. Corbetta* and E. Thelen. Department of Psychology, Indiana University, Bloomington, IN 47405.

Early patterns of interlimb coordination associated with the development of reaching follow highly unstable and rapidly fluctuating forms over time. Reaching patterns alternate between periods of one- and two-handedness, and, during one-handed periods, no clear hand preference emerges. One interpretation is that developmental fluctuations reflect steps of the maturing neuromotor system. Alternatively, we propose that developmental fluctuations emerge as "self-organized" properties of the system in interaction with the task.

We report the development of four infants that we followed weekly from 3 to 30 weeks and biweekly until 52 weeks as they were reaching for small toys at midline. Each week, we recorded the endpoint kinematics of both arms during multiple 14s trials using a WATSMART motion analysis system. Thus, we collected data including both reaching and non-reaching activity. Specific movement analyses allowed us to capture the interlimb patterns of both the reach itself and the ongoing activity from which the reach emerged.

We show that fluctuating patterns in reaching emerge from similarly fluctuating patterns in the general non-reaching activity. We show that the general non-reaching responses modulate as general movement speed changes: when speed increases interlimb patterns become more synchronous and reaches more bimanual; when speed decreases, synchronous and bimanual patterns dissolve. We finally show that decreases in movement speed coincide with the emergence of interlimb asymmetries, revealing a shift toward an increased right arm activity. We argue that the emergence of lateral, one-handed reaching is progressively carved out of the general movement activity, through dynamic and selective processes.

TEMPORAL PARCELLATION OF MOVEMENT KINEMATICS IN THE MUSCLE ACTIVITY OF MONKEYS. J. D. Coltz*, Q. G. Fu and T. J. Ebner, Graduate Program in Neuroscience and Departments of Neurosurgery and Physiology, University of Minnesota Medical School, Minneapolis, MN 55455.

Previous electrophysiological studies of the motor cortices in our laboratory (Fu et al., 1993; Fu et al., 1994, in press) revealed timing differences in the encoding of movement parameters including direction, distance, and x-y position. Specifically, these parameters are encoded separately and sequentially, with direction-related discharge occurring first, x-y position-related discharge second, and distance-related discharge last. Our paradigm required monkeys to make reaching movements in the horizontal plane, from a centrally located start position to 48 targets in 8 different directions and at 6 distances. This study extends these observations to muscle activity during the same reaching task. Intramuscular EMG's were recorded in 15 muscles and fitted to a multivariate time regression model. An ANOVA and subsequent Tukey's Test were done on a subset of 14 muscles and revealed a clear temporal ordering of parameter latency ($F=35.68$, $p<.0001$; all three means significantly different). Direction-related discharge occurred first (67 ± 68 ms following movement onset), followed by x-y position-related discharge (264 ± 151 ms), and distance-related discharge (497 ± 165 ms). Latencies for each kinematic parameter were longer, and peak R^2 values were smaller, than those for cortical cells. In addition, muscles were assigned according to their actions into upper arm, lower arm, and wrist/hand groups. Tukey's Test revealed no significant differences in discharge latency among the muscle groups for each parameter. These preliminary findings suggest that the temporal parcellation of movement parameters observed in the motor cortices is preserved at the level of muscle activation. Supported by NIH grants R01-NS18338 and R01-NS31530.

SELECTIVE PROCESSES IN THE DEVELOPMENT OF REACHING. II. PATTERNS OF MUSCLE ACTIVATION. J. P. Spencer* and E. Thelen, Dept. of Psychology, Indiana University, Bloomington, IN 47405

For decades, researchers have been searching for neuromotor constraints that limit the possible muscle activation patterns underlying multi-joint reaches. Developmental studies offer a unique window into the processes of exploration and selection through which suitable neuromotor constraints are assembled. Here we ask 1) is there selection of muscle activation patterns across the transition from pre-reaching to reaching; 2) is there a subset of activation patterns that is specific to reaching; and 3) what is the temporal organization of these "reaching" patterns.

We observed 4 infants weekly from 3-30 weeks and biweekly from 30-52 weeks as they reached for toys at midline. We collected EMG data (750Hz) from the following muscles: biceps, triceps, anterior deltoid, and upper trapezius. We computed the percentage of time spent in each muscle "state", where the state space consisted of all possible muscle combinations.

Several muscle states occurred prior to reaching onset but not after reach onset: TRI/BI, BI/TRAP, TRI/BI/TRAP. Conversely, DELT/TRAP did not occur prior to reach onset but increased dramatically after onset. This specific muscle state might serve to lift the arm (DELT) while stabilizing the head and shoulders (TRAP). In addition, the percentage of TRI/DELT, TRI/DELT/BI, TRI/DELT/TRAP increased as reaching skill improved. These states were specific to the reaching segment. DELT activity was distributed across the reaching segments, while TRI activity was specific to the final third of the reach. TRI activity likely functions to extend the arm toward the toy while counteracting DELT activity just prior to toy contact. These results suggest that 1) constraints on the patterns of muscle activation underlying reaching develop during the first year, and 2) these constraints are specific to the reaching task.

DIRECTIONAL PROPERTIES OF ARM MUSCLE ACTIVATION FOR DYNAMIC ISOMETRIC FORCES. J.J. Pellegrini* and M. Flanders, Dept. of Physiology, Univ. Minnesota, Minneapolis, MN 55455.

Recently we described how the timing and intensity of arm muscle electromyographic (EMG) activity vary with the direction of reach. After subtraction of postural activity, phasic EMG exhibited classic triphasic burst patterns. The intensity of phasic activity was a multimodal function of movement direction, rather than a unimodal cosine function.

In the current study, we examined the patterns of activity in the same muscles during dynamic isometric forces. The surface EMG of 9 elbow and shoulder muscles was recorded while human subjects rapidly exerted 10N of force at the wrist in one of 20 directions in either a sagittal or frontal plane. The onset of activity in a muscle varied with force direction: agonist bursts occurred in one range of force directions, while antagonist bursts generally occurred in the opposite range. As with reaching movements, the directional tuning of EMG intensity was multimodal. The frontal plane polar plots above illustrate that brachioradialis showed lobes of intense EMG activity (greater distance from center) for ranges of directions including and in addition to straight up. Data are from one subject; left plot from forces, right plot from 30 cm movements. Dynamic isometric forces will be useful for the study of the generation of complex motor patterns at the level of single motor units.

THE DYNAMICS OF GENERALIZATION OF LEARNING ACROSS DIFFERENT COORDINATION SYSTEMS. P.G. Zanone*, J.A.S. Kelso, and C. Brown III. Program in Complex Systems & Brain Sciences, Center for Complex Systems, Florida Atlantic University, Boca Raton, FL 33431.

Previous work [1] on perceptuomotor coordination in humans has shown that learning a new behavioral pattern can be captured as specific alterations of the underlying coordination dynamics: The to-be-learned pattern (i.e., a frequency-locked pattern between oscillating limbs with a specific relative phase) becomes an attractive state of the system's dynamics.

Here we report spontaneous generalization of learning between two different coordination systems. Subjects learned a visually-specified phase relation either between the arms or between the legs. Systematic probes of the arm and leg coordination conducted before and after practice showed that a) both initial dynamics are qualitatively comparable; and b) a phase relationship learned with one system (e.g., arms) is transferred spontaneously to the (untrained) other (e.g., legs), and vice-versa.

These results across coordination systems are in line with previous findings [2] showing automatic transfer of learning within the same coordination system. They suggest that learning of relative timing patterns is independent of the actual components performing the task and occurs at the abstract level of coordination dynamics. Such dynamics reflect the correlated spatiotemporal activity of the CNS and may be at the origin of flexibility in learning and performing behavioral patterns.

THE SUPPRESSION AND ACTIVATION OF DEGREES OF FREEDOM IN TRAJECTORY FORMATION. J.J. Buchanan*, G.C. DeGuzman, J.A.S. Kelo and P.J. Treffner. Program in Complex Systems and Brain Sciences, Center for Complex Systems, Florida Atlantic Univ., Boca Raton FL 33431.

How does the CNS spontaneously recruit/suppress biomechanical degrees of freedom (*df*) during the performance of goal directed acts? We examined the ability of subjects to trace a sequence of six arcs, each with a different curvature, displayed on a computer screen. The arcs were presented in a decreasing (most to least curved) and increasing (least to most curved) series. The task was to rhythmically trace the arcs with the hand in the sagittal plane at a fixed frequency. Kinematically monitored motions were restricted to flexion and extension of the wrist, elbow and shoulder. Only a few coordinative patterns among the three joints were observed, indicating the existence of constraints. For the most curved arc, wrist flex-ext was coordinated with elbow flex-ext with small amplitude (if any) motion of the shoulder (pattern 1). For the least curved arc, two different patterns were observed: wrist flex-ext was coordinated with elbow ext-flex with small amplitude (if any) motion of the shoulder (2a); or elbow flex-ext was coordinated with shoulder flex-ext, with a reduction or loss of wrist motion and an increase of shoulder motion (2b). On some occasions, the frequency ratio between the shoulder and elbow was 2:1, a pattern never observed between the wrist and elbow. In the decreasing series, transitions from pattern 1 to pattern 2(a or b) were observed. In the increasing series, transitions from pattern 2(a or b) to pattern 1 were observed. All coordinative patterns and their dynamics, including the suppression and activation of *df*, are accommodated by a nonlinear oscillator model that treats trajectory curvature as a control parameter and the relative phase and amplitude relations among the joints as collective variables.

EYE-ARM COORDINATION IN PATIENTS WITH PARIETAL LOBE DYSFUNCTION. S.H.Brown¹, K.R.Kessler², H.-J.Freund². Ctr for Human Motor Research, Kinesiology, Univ. Michigan, Ann Arbor, Michigan¹ & Neurologische Klinik, Heinrich-Heine-Univ., Duesseldorf, Germany².

Recent studies have shown that the performance of eye-arm tracking tasks is impaired in cerebellar patients (Brown et al., 1993). To further investigate the neural basis of oculomanual coordination, similar experiments were performed on patients with parietal lobe dysfunction. Elbow movements were studied under 4 conditions: tracking with the eyes only, eye-arm tracking with normal visual feedback of handle (arm) and target position (NVF), and tracking during either random blanking of handle (HB) or target (TB) position. The contralateral arm was tested in all cases. No signs of major visual field defects, optic ataxia or spatial neglect were clinically apparent at the time of testing. Eye movements were recorded using infrared techniques and arm movements were recorded by potentiometers mounted below the elbow.

Mean saccadic onset times were not significantly different from control values and, in contrast to cerebellar patients, were unaffected when coupled with arm movements. Onset times were, however, significantly prolonged under TB compared to NVF conditions. Arm movement onset was delayed compared to control values but was unaffected by different visual feedback conditions. However, removal of handle position information (HB) resulted in significant end point errors (undershooting), decreased peak velocities and prolonged acceleratory phases.

Preliminary findings revealed no evidence of specific disturbances in the temporal linkage of coordinated eye and arm movements. However, visual feedback-dependent changes in movement kinematics support current views of parietal cortex function in the transformation of visual and limb proprioceptive signals into spatially coded limb motor commands. PRODUCTION OF VOLUNTARY FINGER MOVEMENTS BY THE SUPPLEMENTARY MOTOR AREA WITHOUT PARTICIPATION OF THE PRIMARY MOTOR CORTEX. C.D. MacKinnon*, S. Kapur, M.C. Verrier, S. Houle, W.G. Tatton. Departments of Physiology and Physical Therapy, University of Toronto, and the PET Centre, Clarke Institute of Psychiatry, Toronto, Ontario, Canada M5T 1W5

Prominent direct projections from the supplementary motor area (SMA) to the spinal cord in monkeys have been hypothesized to drive movements independently of the primary motor cortex (M1) (Dum & Strick, 1991). We tested this hypothesis by determining the location and time course of intracerebral activity time-locked to the generation of voluntary finger movements by collecting EEG for dipole source analysis (DSA) and positron emission tomography (PET) simultaneously. Experiments were conducted to directly compare unilateral serial, repetitive finger opposition movements (SMs) performed at 2 Hz to the same movements performed intermittently (IMs) at 0.2 to 0.08 Hz. EEG epochs were obtained during the IMs by back-averaging 2.5 sec. prior to the onset of EMG activity and 0.5 after EMG onset. H₂¹⁵O PET scans were performed during the collection of the EEG epochs and foci coregistered on MRI with the DSA solutions. PET data demonstrated that the SMs involved significant activation of the contralateral M1 together with other structures in the cerebello-thalamocortical pathways and minimal activation of the SMA. DSA and PET both showed that the IMs were accompanied by activity in the SMA with minimal activation of M1. The SMA dipole orientation suggested that the IMs were generated by neuronal populations in the dorsal tier of the cingulate sulcus. We hypothesize that IMs are generated via basal ganglia-thalamocortical pathways which do not involve M1 and are separate from the pathways generating the SMs. Both the SMs and IMs are presently being investigated in patients with Parkinson's disease and neuroleptic induced Parkinsonism. UPPER LIMB FLEXOR REFLEX TORQUE RESPONSES IN HEMIPARETIC STROKE SUBJECTS. J.P.A. Dewald*, J.R. McGuire, R.E. Beer, J.D. Given and W.Z. Rymer. SMPP, R.I.C., and Dept. of PM&R, Northwestern Univ., Chicago, IL 60611.

In earlier studies of voluntary muscle activation in hemiparetic stroke subjects, we observed a significant increase in stereotypic coactivations of muscles acting at the elbow and shoulder. To determine the relation between sensory input and disturbed muscle synergic relations in hemiparetic stroke, flexion reflexes were compared in the impaired and unimpaired upper extremities of 3 hemiparetic stroke subjects. The effects of mildly noxious electrical stimuli (500 Hz; pulse duration 1 ms; train duration 20 ms) delivered to the index finger, thumb and little finger were studied using EMGs from 12 arm muscles along with elbow and shoulder torques measured at the wrist with a six degree of freedom load cell. A quantitative analysis of torque and EMG responses was performed.

Earlier torque and EMG onsets were found in the unimpaired limb relative to the impaired arm in all subjects. Muscles were also recruited proximal to distal. In the impaired limb, EMG onsets were delayed in all muscles. Furthermore, segmental muscle recruitment was lost resulting in simultaneous activation of proximal and distal muscles. Static mechanical measurements in all anatomical degrees of freedom permitted a complete characterization of the flexion withdrawal response.

The flexion withdrawal response in both normal subjects and in the unimpaired limb of stroke subjects consisted of elbow flexion combined with shoulder adduction, extension, and internal rotation torque responses. The reflex response in the impaired side was significantly altered at the shoulder. There were torque reversals in two of the three shoulder torques: a change from adduction to abduction along with shoulder flexion torque generation instead of shoulder extension. The responses were consistent regardless of stimulation location. The obligatory coupling between certain elbow and shoulder muscles in the impaired limb as observed under voluntary conditions would result in the torque reversals observed during flexor reflex activation of the limb. Since the cutaneous responses were similar to those recorded during voluntary activation, it follows that cutaneous and other sources of tonic sensory input may strongly influence muscle coactivation patterns in the impaired upper extremity of hemiparetic stroke subjects. LEFT HEMISPHERE MOVEMENT CONTROL. H. Poizner*, A. Merians, M. Clark, B. Macauley, L. Roth, K.M. Heilman. Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102; VA Medical Center and University of Florida, Gainesville.

Many investigators have explored the differential roles of the left and right hemispheres in planning and executing skilled, learned movements, although few have analyzed the kinematic properties of these movements. It has been suggested that the left hemisphere is critical for the control of skilled gestures but nonetheless, errors in movement performance have also been reported in subjects with right hemisphere damage. To further clarify the differing roles of the two hemispheres in skilled movement control, 3D motion analyses were performed on the trajectories of repetitive "slicing" gestures made to verbal command by subjects with either right or left hemisphere lesions. Four subjects with left hemisphere lesions and limb apraxia, six subjects with right hemisphere lesions and seven neurologically intact subjects participated. Left-lesioned apraxic subjects, but not right-lesioned subjects, showed marked movement deficits. The apraxic subjects exhibited decoupling of the spatial and temporal aspects of the wrist trajectories, deficits in intersegmental joint synchrony, deficits in apportioning the relative arm angles and deficits producing the appropriate phase relations among arm angles. In contrast, the right-lesioned subjects in general produced normal patterns of joint kinematics and showed the normal coupling of spatial and temporal attributes of their wrist trajectories. However, both groups of brain lesioned subjects differed from control subjects in the 3D plane of the wrist motion. Whereas control subjects produced tightly overlapping sagittally oriented planes of motion, the apraxic subjects oriented their movement in the frontal plane, while the right-lesioned subjects had a major component of the movement in the horizontal plane. The specific deficits of the right-lesioned subjects in controlling the plane of motion may reflect a deficit in the representation of external space, since the plane of the hand motion depends on the position and orientation of an object in extrinsic space. The deficits of the left-lesioned apraxic subjects in both joint and wrist kinematics instead seem to reflect a deficit in these left-lesioned subjects for the plan of the movement itself.

SCHEMA LEARNING IN MULTIJOINT PULLING. W.A. Lee*, A.M. Russo, Y.-C. Pai and D. Schena. Prog. in Physical Therapy & Inst. for Neuroscience, Northwestern Univ. Med. School, Chicago, IL, 60611 USA.

We studied whether perceptual-motor schema or exemplars are learned when subjects practice a multijoint pulling task that involves sagittal-plane movement of the whole body. Ten freely-standing subjects practiced impulse-like pulls against a load cell to three force targets (20, 40 and 80% of maximum) on four days, receiving feedback with decreasing frequency. On a fifth day, subjects pulled to both the training and novel (10, 50, 60 and 95%) targets, receiving no feedback. On half of the trials each day, subjects estimated the force produced before getting feedback. On Days 1 and 5, sagittal plane body motion (11 markers) was recorded, from which force components associated with the location (F_{grav}) and acceleration ($F_{inertial}$) of the body's center of mass were derived. Schema learning predicts similar actual and estimated force errors and similar F_{grav} and $F_{inertial}$ proportions for training and novel pulls, while exemplar learning predicts larger errors for novel pulls.

Actual and estimated force errors decreased significantly with practice. Higher correlations between actual and estimated forces on Day 5 suggest parallel improvements in force production and perception. Errors for the training and novel pulls were comparable on Day 5, except for 10% pulls which had greater errors than all other pulls. The regression equations between force components and pulling force were similar across conditions. These results support schema learning, but also suggest that much of the improvement may have been due to subjects' learning to parameterize an already familiar kinetic schema for force production.

Development of gonadotropin hormone releasing (GnRH) systems in the terminal nerve and brain of the clearnose skate, Raja eglanteria. L.S.Demski*, J.A.Beaver and J.J.Sudberry, Div. of Natural Sciences, New College of the Univ. of South Florida, Sarasota FL, 34243.

GnRH-ir (immunoreactivity) was similar in older animals (16, 32 weeks and adult). The TN has well developed ganglia of bipolar and multipolar cells that in the smaller fish span the length of olfactory bulb. The TN may enter the brain via dorsal and ventral roots. At 10 weeks TN fascicles can be traced into the ventromedial telencephalon, from here bundles of ir-fibers extend into the septo-preoptic area and continue into the basal hypothalamus. Many fibers approach the infundibulum and portal vessels. A large ir- nucleus of bipolar and multipolar cells extends most of the length of the midbrain in all stages. In older animals, ir-beaded fibers are present in the neurohypophysis and most areas of the CNS; some may extend to the ventricular surfaces. A few scattered ir-fibers are present in the olfactory epithelium. Few ir-fibers are seen anywhere in the younger fish (7-8 weeks).

SEXUAL DIMORPHISM IN THE HYPOTHALAMUS AND AMYGDALA OF THE TOKAY GECKO. L.L. Bruce* and H.A. Manley, Dept. Biomedical Sciences, Creighton Univ., Omaha, NE 68178.

Sexually specific behaviors are frequently associated with sexually dimorphic brain areas. In particular, the ventromedial hypothalamic nucleus (VMH) has been associated with the female display of receptivity in lizards. We wished to determine if the VMH and two amygdalar areas that project to the VMH, the lateral amygdala (LA) and medial amygdala, have sexually dimorphic volumes or cell sizes in a lizard, the Tokay gecko (Gekko gekko). Data was collected from 3 adult males and 3 adult females. Borders of the nuclei and somata were drawn on photographs of brain sections, then traced on a digitizing tablet linked with a computer to calculate areas and volumes. Only the values for the volume of the medial subdivision of the VMH were statistically significant, being larger in females than males. The values for the volumes of the lateral VMH and total VMH approached statistical significance with larger volumes in females. Measurements of somal areas revealed a marked sexual dimorphism, with females containing larger cells in the medial and lateral subdivisions of VMH and in the lateral amygdala. Somal areas of the other nuclei were not sexually dimorphic. Our data is consistent with previous findings in lizards and mammals that associated the VMH with sexual dimorphism and female receptivity. However, a sexually dimorphic telencephalic nucleus with larger somata in females has not previously been reported. The larger somal areas in the LA and VMH of female geckos and the strong projection from the LA to the VMH suggest that both the LA and VMH are involved in female-specific behaviors.

GLUTAMATE RECEPTOR (GluR) SUBUNIT LOCALIZATION IN PIGEON TELENCEPHALON. C.L. Veenman*, Q. Chen and A. Reiner, Dept. Anatomy & Neurobiology, Univ. Tennessee, Memphis, TN 38163.

We used specific antibodies (AB) recognizing the GluR1, GluR2/3, and GluR4 subunits of the AMPA receptor family (Chemicon) and the GluR5,6,7 subunits of the kainate receptor family (Pharmingen) to localize these ionotropic glutamate receptor subunits in pigeon telencephalon. The GluR1 AB labeled medium and large neurons throughout the densely labeled neuropil of dorsal and ventral striatum, while the neuropil and large projection neurons of dorsal and ventral pallidum remained unlabeled. Scattered neuronal perikarya were labeled for GluR1 throughout the pallidum, while the pallidum externum, archistriatum dorsale, nucleus taenia, hippocampus, prehippocampal area, and hyperstriatum dorsale and ventrale stood out by their densely labeled neuropil. The GluR2/3 AB labeled many medium and large neurons throughout the well labeled neuropil of the striatum and lightly labeled large cells in the pallidum. All pallial regions possessed very abundant populations of GluR2/3 neurons, particularly the ectostriatum and field L, while the hippocampus also possessed a densely labeled neuropil. The GluR4 AB labeled large cells throughout the striatum and the pallidum, and many neurons scattered throughout all pallial regions. The GluR5,6,7 AB labeled large and medium neurons in striatum and pallidum, including small populations of intensely labeled cells in medial striatum. GluR5,6,7 neurons were labeled throughout all pallial regions, including intensely labeled cells in the hippocampus and prehippocampal area. The distributions of these GluR subunits in the avian telencephalon share many similarities with those found in mammals, indicating similarly important roles for glutamatergic transmission in the avian pallidum, and also for pallial and diencephalic inputs to the avian basal ganglia. INCREASED LEVELS OF NEUROPEPTIDE Y (NPY) AND DOPAMINE (DA) IN THE MEDIAN EMINENCE OF CHICKS SHOWING EARLY GONADAL DEVELOPMENT. W.J. Kuenzel*, K. Macko Walsh, M.M. Abdel-Maksoud and J.P. Advis, Dept. Poultry Sci., Univ. of Maryland, College Park, MD 20742 and *Dept. Animal Sci., Rutgers Univ., New Brunswick, N.J. 08903.

Early gonadal development in chicks can be induced via: 1) parasagittal hypothalamic knife-cuts, 2) chronic intracerebroventricular injection of NPY, and, 3) feeding sulfamethazine (SMZ). An experiment was conducted to determine the neural effects of feeding 0.2% SMZ to chicks beginning at one week of age. At 3 weeks of age 4 SMZ-treated chicks and 4 controls were anesthetized, perfused with saline followed by 4% paraformaldehyde and prepared for immunocytochemistry using antibodies to gonadotropin releasing hormone (GnRH) and NPY. A second group, 6 experimental and 6 controls, was cervically dislocated, brains removed, frozen and 5 brain areas micro-dissected and prepared for radioimmunoassay (RIA) of NPY: bed nucleus (n.) of the pallial commissure (nCPa), paraventricular n. (PVN), septal area, intergeniculate n. and median eminence/infundibular n.(ME). A third group (n=5/trt) was sacrificed at 4 weeks of age. Similar to the second group, brains were frozen and 5 brain areas micro-dissected for HPLC-EC analysis of biogenic amines. Immunocytochemical results showed no significant changes in GnRH immunoreactivity (ir) in the nCPa or anterior lateral thalamic n. but significantly more NPY ir in perikarya within the ME of SMZ-treated chicks. Chicks fed SMZ also showed significantly higher NPY concentrations within the ME (1.5 ± 0.25 vs. 0.9 ± 0.09) as determined by RIA. Significantly higher concentrations dopamine and serotonin within the ME and PVN, respectively, in chicks fed SMZ. Early sexual maturation appears to be associated with elevated levels of NPY and DA within the infundibular n. and median eminence of developing chicks. UNIQUE DISTRIBUTION OF CRH-IR RELATIVE TO AVT-IR IN THE BRAIN OF THE SADDLEBACK WRASSE: A NOVEL CHARACTERISTIC OF SEX REVERSING VS. GONOCORISTIC FISH. A.A. Ghazanfar* and M.S. Grober, Department of Biological Sciences, University of Idaho, Moscow, ID 83844-3051.

The saddleback wrasse Thalassoma duperrey is a sequential hermaphrodite that begins life as a subordinate female or male and may then transform into a terminal male via sex or role change. Terminal male fish aggressively dominate subordinate fish and this social stress may function to inhibit sex/role change. In fish, corticotropin-releasing hormone (CRH) and arginine vasotocin (AVT) are the primary hypothalamic secretagogues in the stress response. CRH and AVT cells in teleosts show a robust and overlapping distribution in the magno- and parvocellular preoptic area (POA). Immunocytochemical studies on the saddleback wrasse showed that the distribution of AVT-ir cells reflects this general teleost pattern. Conversely, CRH did not conform to this pattern: in all but one individual, CRH-ir somata were entirely absent from the POA. However, there were a unique group of CRH-ir cells located in Hypothalamus ventralis (Hv). A comparative study using goldfish (Carassius auratus), a gonochoristic teleost, was conducted to assess the specificity of our results. Intense CRH and AVT immunolabeling in the magno- and parvocellular POA indicated that 1) the goldfish is representative of the general teleost pattern, and 2) our results with T. duperrey represent a novel feature of a sex reversing fish. While the paucity of CRH-ir somata in the POA may be indicative of negative feedback from stress-induced elevation in cortisol, the unique group of cells found in Hv may play a role in stress-mediated control of sex reversal. The present results underscore the importance of these fish as a model system for investigations of neuroendocrine control of vertebrate sexual plasticity. Supported by NSF (IBN-9309555 to MSG and REU to MSG/AAG) and a University of Idaho Seed Grant.

CHOLINERGIC PROJECTION FROM THE BASAL FOREBRAIN TO THE CORTICAL AREAS IN PIGEONS. L. Medina*, C.L. Veenman, C.A. McCandlish, & A. Reiner, Dept. Anat. & Neurobiol., College of Medicine, University of Tennessee, Memphis, TN 38163.

A cholinergic projection from the basal forebrain to the cortex is present in several mammalian species, and is related to basic cognitive operations such as learning and memory (1). To investigate the presence of a similar projection in birds, White Carneaux pigeons were injected with Fluorogold (FG) in either the Wulst or the external part of the dorsal ventricular ridge (DVR_e, called pallium externum in our previous works), which are avian cortical regions known to be densely innervated by cholinergic fibers (2). After FG injections in either the Wulst or the DVR_e, numerous retrogradely labeled cells were observed ipsilaterally in basal forebrain structures known to contain cholinergic neurons (2), such as the paleostriatum primitivum, the intrapeduncular nucleus, the fasciculus prosencephalicus lateralis, and less frequently in the ventral paleostriatum. Immunohistochemistry for choline acetyltransferase (ChAT) revealed that about 60-75% of the retrogradely labeled cells were also ChAT immunoreactive. Our results provide evidence for the presence of a cholinergic as well as a non-cholinergic projection from the basal forebrain to the Wulst and DVR_e in pigeons, and add proof for the similarity of the telencephalic cholinergic systems of birds and mammals. As suggested in mammals (1), the cholinergic input from the basal forebrain to the Wulst and DVR_e in birds may play a role in the involvement of these cortical structures in plasticity and learning.

IMMUNOHISTOCHEMICAL ORGANIZATION OF THE FOREBRAIN IN THE WHITE STURGEON. C. Piñuela and R. G. Northcutt*. Neurobiology Unit, Scripps Institution of Oceanography, and Dept. of Neurosciences, School of Medicine, Univ. of Calif., San Diego, La Jolla, CA 92093-0201.

To determine the pallial and subpallial divisions in ray-finned fish, the distribution of leucine-enkephalin (LENK), substance P (SP), tyrosine hydroxylase (TH), serotonin (5HT) and dopamine (DA) was determined in the forebrain of an actinopterygian, *Acipenser transmontanus* (Chondrostei). Immunoreactive TH, SP, LENK, 5HT and DA perikarya were observed in different nuclei of the area ventralis telencephali, preoptic area, periventricular nucleus of the posterior tuberculum (PPT), and inferior lobe of the hypothalamus. In the ventral thalamus, few SP+ and TH+ somata are seen, whereas in the median nucleus of the posterior tuberculum only cells positive for TH were observed. A high number of SP+, LENK+ and TH+ fibers were located in the nuclei of the area ventralis telencephali, whereas DA+ and 5HT+ fibers were confined to the dorsal nucleus (Vd) of this area. All five substances were present in fibers innervating various diencephalic areas. Earlier studies suggested that the pallial-subpallial boundary was located between the medial (Dm) and the dorsal (Dd) zones of the dorsal telencephalon, and that Dm may be homologous to the striatum of land vertebrates. The present results do not support this view, since Dm showed poor content of SP+ and LENK+ fibers compared to the nuclei of the area ventralis telencephali. In this respect, Vd appears highly similar to the striatum, with a very high concentration of SP+, LENK+, 5HT, and DA+ fibers. This is supported by the presence of DA+ cells in PPT, a presumed homolog of the substantia nigra of amniotes, which could be the source of DAergic input to Vd. Supported by NIH grant NS24869 to R.G.N. and Fulbright FU93 07857019 to C.P.

A MARINE CHAMELEON: THE SANDLANCE, LIMNICHTHYES FASCIATUS. J. D. Pettigrew and S. P. Collin*. Vision, Touch and Hearing Research Centre, University of Queensland, St Lucia 4072 and Department of Psychology, University of Western Australia, Nedlands, 6009, Australia.

The sandlance, *Limnichthyes fasciatus* (Creedidae, Teleostei), behaves like a marine chameleon, with independent movements of its turret-like eyes and rapid strikes from camouflage for swimming prey. The optical system has a fixed circular pupil, a deep pit fovea and a flattened lens unlike any other teleost lens so far described. The convex, laminated structure of the cornea is also unparalleled in a teleost and suggests that the cornea plays a refractive role. This suggestion has been supported by four independent sets of observations: i. Purkinje images formed underwater by the cornea; ii. Measurements of the magnification of intracorneal iridophores viewed through the corneal lenticle; iii. Measurements of the dissected corneal lenticle and lens when viewed over a grating; iv. Ray tracing experiments comparing the degree of refraction produced by both the lens and corneal lenticle. All four sets of observations confirm that the cornea of the sandlance has a substantial refractive power of approximately 200 D compared with a lens power of 550 D. This is the first report of a teleost cornea with a significant refractive role. The optical system of lens plus cornea, in combination with the deep pit fovea, may be more suitable for the detection and accurate depth localisation of small, moving prey than the conventional, wide-field, spherical lens system of teleosts. The evolutionary convergence of this marine optical system and lifestyle with those of the chameleon is remarkable given the constraints imposed by underwater optics.

ARE THE AMPHIBIAN "STRIATUM" AND THE REPTILIAN ANTERIOR DORSAL VENTRICULAR RIDGE HOMOLOGOUS? M.R. Braford, Jr.* Biology Department, Oberlin College, Oberlin, OH 44074

In amphibians the cell masses of the ventrolateral telencephalon are traditionally homologized to the striatum of amniotes. Comparative cytoarchitectonic studies of developing and/or adult forebrains of representatives of all three amphibian orders, together with topological, histochemical and connectional data, suggest the following new hypothesis. The "striatum" of amphibians is pallial rather than subpallial and is homologous to the anterior dorsal ventricular ridge (ADVR) of reptiles. This hypothesis is a more parsimonious interpretation of the data than the prevailing one, and it suggests that the amphibian homolog of the amniotic striatum may lie in the ventromedial telencephalic wall. It further follows that the telencephalon of all anamniotic vertebrates may be subject to a similar reinterpretation. Taken together with the idea that the reptilian ADVR is homologous to the mammalian basolateral amygdala (Neary and Bruce, 1993), the possibility is raised that a thalamo-recipient pallial amygdala is a significant and common feature of anamniotic forebrains. RAPHE NUCLEI IN THE BRAINS OF THREE CARTILAGINOUS FISHES. S. Stuesse*, D. Stuesse, Kevin Kaut, and W.L.R. Cruce. Neurobiology Department, N.E. Ohio Univ. Col. of Med., Rootstown, OH 44272.

Many nuclei that are present in other groups of vertebrates are present in cartilaginous fishes. We identified and describe raphe nuclei in three cartilaginous fishes, *Squalus*, *Heterodontus*, and *Hydrolagus*. Antibodies made in rabbit against serotonin (5HT) and enkephalin (ENK) were localized in fish brains by means of the PAP technique. Raphe cells were identified by topographic position, reaction with the antibodies, and cytoarchitectonics. The cytoarchitectonics of 5HT+ raphe cells in cartilaginous fishes are remarkably similar to that described in mammals. Raphe nuclei were clustered in inferior and superior cell groups, but within these groups, individual nuclei were identified. From caudal to rostral these nuclei are raphe (ra.) pallidus, ra. obscurus and ra. magnus in the inferior group and ra. dorsalis, ra. centralis superior, and ra. linearis in the superior group. A ra. dorsalis may not be present in *Hydrolagus*. The majority of 5HT+ cells are found in the superior group, but 5HT+ cells are present from spinal cord to caudal mesencephalon. The only sections devoid of 5HT+ cells are just caudal to cranial nerve VII. The numbers and distribution of 5HT+ and ENK+ cells are similar to each other. (Supported in part by grant NS2585 from NIH).

IDENTIFICATION OF GLOBULAR AND ASYMMETRIC FORMS OF AN INTERMEDIATE CHOLINESTERASE IN AMPHIOXUS: IMPLICATIONS FOR THE EVOLUTION OF THE CHOLINESTERASES IN THE VERTEBRATES. L. Pezzementi*, M. Sanders, M. Miller, K. Glaese and L.A. Shannon. Division of Science and Mathematics, Birmingham-Southern College, Birmingham, AL 35254.

In vertebrates, the cholinesterases, acetylcholinesterase (AChE) and butyrylcholinesterase (BuChE), are found in a variety of molecular forms. The globular forms, G₁, G₂, and G₄ are composed of one, two, or four globular subunits; the asymmetric forms A₄, A₈, and A₁₂ consist of one, two, or three globular tetramers covalently linked to a collagenous tail. Only globular forms have been described in invertebrates. As part of an investigation of the evolution of the cholinesterases, we characterized the cholinesterase activity of the invertebrate chordate, amphioxus. The kinetic and pharmacologic characteristics of the enzyme were found to be intermediate to AChE and BuChE. These biochemical findings are supported by DNA sequence data. The cholinesterase was found in two molecular forms, sedimenting at 5.5 and 17 S on sucrose gradients. The smaller form was partially purified by affinity chromatography, labeled with [³H]DFP, analyzed by polyacrylamide gel electrophoresis in the presence of sodium dodecyl sulfate, and identified as the disulfide-linked dimeric form G₂. The migration of the dimer on nonreducing gels was modified by digestion with phosphatidylinositol-specific phospholipase C, indicating that it possessed a glycolipid anchor. The larger form was found to be collagen-tailed A₁₂ asymmetric cholinesterase: collagenase digestion of the form in crude extracts or from preparative sucrose gradients increased the sedimentation rate of the enzyme. A high-salt-soluble form of G₂ was also observed. We discuss the implications of these findings for the evolution of the cholinesterases. CAVUM SEPTUM PELLUCIDUM (CSP) IN TREATMENT RESISTANT SCHIZOPHRENIA. R. Conley*, S. Daviss, C. Gounaris, C. Tamminga. Maryland Psychiatric Research Center, Univ. of MD, Baltimore, MD 21228

A number of investigations have focussed on differences in clinical characteristics between people with schizophrenia who respond well to treatment and those who do not. Schizophrenics who fail to respond to typical neuroleptics may represent a separate population, with a distinctly different etiology and/or neuropathophysiology. Compared to treatment-responsive patients, one CT study found smaller ventricles in treatment-resistant patients (Ota et al., 1987), while another found greater prefrontal sulcal prominence in these patients (Friedman et al., 1991). Examination of the neuroanatomy in these two patient populations may provide further evidence to support a biological distinction between them. We examined MRI scans from treatment-resistant and treatment-responsive schizophrenics to determine if the treatment-resistant population had a higher prevalence of CSP. A total of 28 patients with schizophrenia who had completed MRI scans were identified. As part of a larger study, they were categorized as either treatment-responsive or treatment-resistant, as defined by the Multicenter Clozapine Study criteria (Kane et al., 1988). Of the 16 treatment-responsive patients, 2 (12.5%) had a CSP rating of "probable", and 3 (18.8%) had a rating of "definite". Of the 12 treatment-resistant patients, 4 (33.3%) had a "probable" CSP, and 5 (41.7%) had a "definite" CSP. The findings in this preliminary report suggest that schizophrenics who respond poorly to neuroleptics may have evidence of neuropathology which distinguishes them from patients who respond well to these medications. In our sample, this is reflected by the presence of a CSP in 75% of treatment-resistant patients, compared to 31% of treatment-responsive.

HIGH RESOLUTION NMRI ATLAS OF AN INFANT MOUSE LEMUR (MICROCEBUS) BRAIN OBTAINED AT 12 T. Mark O'Dell*, Pratik Ghosh, Russell Jacobs, and John Allman. Department of Computation & Neural Systems* and Division of Biology, Beckman Institute, Caltech 139-74, Pasadena, CA 91125.

In preparation for doing functional brain imaging, we have constructed a 3D registered digital atlas of the head of a deceased infant Mouse Lemur (Primate M. *Mimurinus*) using a Bruker AMX500 12 Tesla Nuclear Magnetic Resonance Imaging system (^1H = 500 MHz). We obtained very high spatial resolution data (60 μm isotropic voxels) with strong intrinsic contrast (T_2 -weighted Spin Echo 3D), making it possible to see fine anatomical detail. We show 3D volume renderings of this atlas on videotape, anatomical identifications on 2D prints, and details of data acquisition and processing.

Data was acquired using TE/TR = 100ms/1.3s with the sample at 2° C.. While some MRI contrast is likely to be different from what would be obtained from a living sample, all familiar anatomical structures are clearly visible. Fine fiber tracts, the laminations of cortices, and details of the inner ears are especially striking. Mouse Lemurs were selected because they have a highly developed visual system and are small enough to fit inside our imaging system.

BRAIN METABOLISM AND BLOOD FLOW: NITRIC OXIDE

410.1

CEREBRAL BLOOD FLOW (CBF), AND NEUROLOGIC OUTCOME IN RATS SUBJECTED TO TRANSIENT FOREBRAIN ISCHEMIA (TFI) FOLLOWING CHRONIC NITRIC OXIDE SYNTHASE (NOS) INHIBITION. V.L. Baughman, D.A. Pelligrino*, and O. Wang. Dept. of Anesthesiology, Univ. of Illinois-Chicago, Chicago, IL 60612.

It is unclear if the increased presence of NO during and following cerebral ischemia is protective (e.g., via promoting vasodilation) or neurotoxic (e.g., through production of highly reactive O_2 species). These opposing actions of NO could account for some of the variability in findings present in the literature. In this study, we subjected rats to TFI, using right common carotid occlusion + hemorrhagic hypotension, and examined the effects of NOS inhibition, with nitro-L-arginine (L-NA), on: a) the CBF changes accompanying TFI, and b) neurologic outcome postschemically. In order to differentiate the potentially protective vasodilating actions of NO from other (perhaps toxic) NO actions, 2 groups of L-NA-treated rats were studied-- one (L-NA1, n=10) where the level of hypotension was matched to control (CTL, n=7) and the other (L-NA2, n=10) where blood withdrawal was altered to produce a CBF drop similar to that observed in CTL. L-NA-treated rats received daily ip injections over 3 days (300 mg/kg total) so as to achieve >95% inhibition of brain NOS (confirmed in pilot studies). On the 3rd day, under fentanyl/ N_2O anesthesia, the rats were subjected to TFI. CBF (laser-Doppler) was recorded continuously. After 30 min of ischemia, the rat's blood was reperfused, the carotid occlusion was released and CBF monitoring was continued for 15-20 min. The anesthetic was then discontinued. Rats were analyzed for neurologic function over 3 days. During ischemia, the CBF reductions measured were 65%, 95%, and 70% in the CTL, L-NA1, and L-NA2 groups, respectively. The corresponding MABP values were 31, 31, and 52 mmHg. L-NA treatment was accompanied by a greater post-ischemic hyperemic response than seen in CTL (160%, 253%, and 193% of baseline in CTL, L-NA1, and L-NA2, respectively). Neurologic outcome in the L-NA1 group was markedly worse than CTL. However, the mean score in the L-NA2 group suggested improved outcome vs CTL, although the difference was not significant. These results suggest that NO is beneficial during TFI, presumably via an intraschemic vasodilating action. That benefit may be moderately opposed, but not negated, by a neurotoxic effect of NO. The greater post-ischemic CBF in the L-NA group indicates that, in this model, post-ischemic hyperemia is not mediated by NO.

410.3

NITRIC OXIDE SYNTHESIS INHIBITION AND THE PRODUCTION OF EARLY HYPOPERFUSION DURING SPREADING DEPRESSION IN ANESTHETIZED RATS. Robert B. Duckrow* and Ariane N. Vinson. Department of Neurology, The University of Connecticut School of Medicine, Farmington, CT 06030-1845.

Inhibition of nitric oxide synthase (NOS) by N ω -nitro-L-arginine methyl ester (L-NAME) is known to be associated with the appearance of a transient hypoperfusion prior to the advancing wave of hyperperfusion which accompanies spreading cortical depression (SCD) in awake rats. It is assumed that this hypoperfusion is the result of potassium-induced vasoconstriction that would normally be balanced by NO-EDRF mediated vasodilation. Because cerebral blood flow (CBF) responses to SCD are known to be dependent on resting vascular tone, this process was reexamined in anesthetized rats. Rats were anesthetized with pentobarbital, 50 mg/kg i.p. Body temperature was maintained and arterial pressure, pH, gas tensions, and hematocrit were monitored. L-NAME, 30 mg/kg i.v., was given 20 minutes before SCD was induced by needle penetration of the frontal cortex. Local CBF was monitored by continuous laser-Doppler flowmetry using a Vasamedic BPM2 0.8 mm probe placed on a parietal bone window away from dural vessels. In separate rats, regional CBF was measured 90 and 120 s after induction of SCD using the diffusible tracer [^{14}C]isopropylodiamphetamine and quantitative autoradiography. Continuous laser-Doppler flowmetry was unable to detect the preceding hypoperfusion during SCD in L-NAME treated rats. However, 3-dimensional reconstruction of serial autoradiographic sections reliably demonstrated this hypoperfusion when L-NAME was prepared immediately prior to injection. If the L-NAME solution (30 mg/ml in normal saline) was used more than 2 days after preparation the preceding hypoperfusion was absent despite preservation of the global reduction in CBF known to accompany NOS inhibition. This disparity in the ability of L-NAME to produce resting and stimulated changes in regional CBF suggests that differential sensitivity to nitric oxide, different degrees of NOS activity, or different forms of NOS are involved in the static and dynamic regulation of blood flow in rat brain. MORPHOMETRIC VARIABILITY IN 3D HIGH RESOLUTION DIGITAL POSTMORTEM ANATOMY AND IN VIVO MRI A.W.Toga*, K.L. Ambach, M. Mega, P. Yao, and S. Schlunder. Lab of Neuro Imaging, UCLA School of Medicine, Los Angeles CA 90024

We examined morphometric variability of selected neuroanatomic structures in high resolution digital anatomy from cryosectioned whole human head and brain and in vivo MRI. Postmortem whole human head and brain were cryosectioned and high resolution color serial images were digitized from the blockface. Serial digital images were reconstructed to 3D and aligned along the bicommissural plane as described by Talairach and Tournoux (1988). Caudate, putamen, thalamus, globus pallidus, anterior commissure, cerebellum, corpus callosum, hippocampus, and ventricular system were analyzed for surface area (SA), volume (VOL), center of mass (COM), principle axes and distance from a known landmark. We were able to use the Talairach stereotactic coordinate system as a reference for alignment and analysis of 3D reconstructed data within and between subjects and modalities. Data were in general agreement with less morphometric variability demonstrated between R-L hemispheric structures than intersubject or separate modality anatomy. Sulcal anatomy demonstrated greater variability than subcortical structures. Measures for principle axes and COM were less reliable for geometrically complicated structures such as the limbic system and hippocampus. The higher resolution of cryosectioned anatomy enabled us to localize and delineate a far greater number of neuroanatomic structures than those in MR data sets. These results indicate the potential of high resolution postmortem cryosectioned anatomy of human head and brain as a standard for digital human brain atlasing.

410.2

L-ARGININE REVERSES HYPOTHALAMIC VASOCONSTRICTION INDUCED BY CHRONIC NITRIC OXIDE SYNTHASE INHIBITION IN RATS. Z. Benyó*, M. H. Velkei and P. Sándor. Experimental Research Department - 2nd Institute of Physiology, Semmelweis University of Medicine, H-1446 Budapest, POB 448, Hungary

Chronic oral administration of the nitric oxide synthase inhibitor N ω -nitro-L-arginine-methyl-ester (L-NAME) results in increased hypothalamic vascular resistance (HVR) (Benyó et al.; Society for Neuroscience Abstracts, Vol. 19, p. 1660, 1993). The aim of the present study was to investigate whether this phenomenon can be reversed by L-arginine.

Adult male Wistar rats were treated with L-NAME dissolved in the drinking water. After a week of treatment the animals were anesthetized with ip. Urethane, and hypothalamic blood flow (HBF, H_2 gas clearance method) and mean arterial blood pressure (MAP) were determined before, and 10, 20, 30 and 40 minutes after the start of iv. L-arginine administration (30mg/kg bolus followed by 10 mg/kg/min infusion).

Results	Control	10 min.	20 min.	30 min.	40 min.
HBF (ml/g/min)	0.68±0.04	0.82±0.04	0.83±0.06	0.85±0.06	0.82±0.06
MAP (mmHg)	150±10	130±11	121±11	115±10	107±10
HVR (MAP/HBF)	225±20	162±19	151±20*	141±19*	134±16**
apCO $_2$ (mmHg)	35.2±0.7	36.3±0.9	36.5±0.9	35.5±1.1	34.1±0.9
apO $_2$ (mmHg)	83.6±2.4	84.0±1.4	84.5±1.8	86.8±1.7	88.6±2.2
apH	7.35±0.02	7.33±0.02	7.32±0.02	7.31±0.02	7.31±0.02

*p<.05, **p<.01 vs. Control; ANOVA with Dunnett's test

The results indicate that the hypothalamic vasoconstrictor effect of nitric oxide synthase inhibition induced by chronic oral L-NAME treatment can be reversed by an excess amount of exogenous L-arginine.

NITRIC OXIDE PLAYS DIFFERENT ROLES IN CEREBROVASCODILATION EVOKED BY HYPERCAPNIA OR BASAL FOREBRAIN STIMULATION F. Zhang* and C. Iadecola. Dept. of Neurology, Univ. of Minnesota, Minneapolis, MN 55455.

Inhibition of nitric oxide (NO) synthase (NOS) attenuates the increases in cerebral blood flow (CBF) elicited by electrical stimulation of the basal forebrain (BF) cholinergic system or hypercapnia. We sought to determine whether the effect of NOS inhibition can be reversed by re-establishing basal levels of NO. In halothane-anesthetized and ventilated rats the NOS inhibitor nitro-L-arginine (L-NA; 1 mM) was superfused on the neocortex. CBF was monitored at the site of superfusion by a laser-Doppler probe. Inhibition of NOS activity was verified using the assay of Bredt and Snyder. With Ringer superfusion, BF stimulation (100 μA ; 50Hz) and hypercapnia (pCO $_2$ =55±1 mmHg) increased CBF by 214±6% (n=6) and 139±11% (n=6), respectively (p<0.001). Superfusion with L-NA reduced resting CBF by 33±4% (p<0.05), attenuated the increase in CBF elicited by BF stimulation (-37±2%; p<0.001) or hypercapnia (-65±4%; p<0.001) and reduced NOS catalytic activity by 95±3%. After L-NA, superfusion with the NO donor SIN 1 (0.1-0.5mM) re-established resting CBF (p>0.05 from before L-NA) and restored the CBF response to hypercapnia (p>0.05 from before L-NA). However, SIN 1 failed to counteract the L-NA-induced attenuation of the increase in CBF elicited by BF stimulation (p<0.05 from before L-NA). We conclude that both the CBF responses to hypercapnia and BF stimulation have NO-dependent components. However, the role of NO in these responses differs: In hypercapnia, unlike BF stimulation, the NO-dependent component can be fully re-established by a NO donor despite near total inhibition of NOS catalytic activity. The data suggest that the CBF response evoked by BF stimulation requires NOS activation, probably via catalytic release of acetylcholine, whereas the hypercapnic cerebrovasodilation requires a basal level of NO for its full expression. 410.5

NITRIC OXIDE SYNTHESIS IS REQUIRED FOR FUNCTIONAL HYPEREMIA IN CEREBELLAR CORTEX J. Li*, X. Xu and C. Iadecola, Dept. of Neurology, Univ. of Minnesota, Minneapolis, MN 55455.

Functional brain activation is associated with increases in cerebral blood flow (CBF) restricted to the active areas. Although the mediators of the vascular response remain to be elucidated in full, there is evidence that nitric oxide (NO), a potent vasodilator released by active neurons, may participate. We used the parallel fiber (PF) system of the cerebellar cortex as a model to investigate the role of NO in the increases in CBF elicited by neural activation. Rats were anesthetized with halothane and ventilated. The cerebellar vermis was superfused with aerated Ringer. PF were stimulated electrically (100 μ A; 30 Hz) and the associated changes in cerebellar cortex blood flow (BF_{crb}) monitored by laser-Doppler flowmetry. Field potentials evoked by PF stimulation were recorded using microelectrodes. During Ringer superfusion (n=7), PF stimulation increased BF_{crb} (+52 \pm 4%). Topical application of the nitric oxide synthase (NOS) inhibitor nitro-L-arginine (L-NA; 1 mM) attenuated the increases in BF_{crb} by 50 \pm 4% (n=9; p<0.001; analysis of variance) and inhibited NOS catalytic activity, assessed by L-arginine-to-citrulline conversion, by 95 \pm 9% (p<0.001). L-NA did not influence the increase in BF_{crb} evoked by topical application of the NO donor SIN-1 (p>0.05) or the field potentials evoked by PF stimulation. D-NA (1 mM; n=6), the inactive stereoisomer of L-NA, did not attenuate the BF_{crb} response (p>0.05). The guanylyl cyclase inhibitor and NO scavenger methylene blue (1 mM; n=7) reduced the response by 41 \pm 9% (p<0.01). Thus, the increases in BF_{crb} evoked from the PF are, in part, mediated by NO. NO could be produced either in PF terminals or in post-synaptic neurons, probably, interneurons. The data suggest that NO participates in the "coupling" of functional activity to blood flow in cerebellum and that this agent is a critical mediator of functional hyperemia in the central nervous system.

410.7

THE EFFECT OF NITRIC OXIDE SYNTHASE INHIBITION ON CARDIAC OUTPUT AND REGIONAL ORGAN BLOOD FLOW IN PIGLETS.

Lohe AS, Kuluz JW*, Gelman B, Prado RJ, Schleien CS. Department of Pediatrics, University of Miami School of Medicine, Miami, FL 33101.

We examined the effects of low dose N-nitro-L-arginine methyl ester HCl (LN) 0.1 and 1.0 mg/kg and subsequent reversal with L-Arginine (L-Arg) 11.0 mg/kg on cardiac output and regional blood flow in piglets. Under pentobarbital/fentanyl anesthesia, piglets were ventilated via tracheostomy and catheterized for measurement of cardiac output by thermodilution and regional blood flow using microspheres. Measurements were made after a 30 min stabilization, 15 min after LN 0.1 and 1.0 mg/kg, and 20 min after L-Arg. LN significantly decreased cardiac index (CI), myocardial (MBF), and renal (RBF) blood flow, without affecting jejunal (JBF) and cerebral blood flow (CBF). These changes were only minimally affected by L-Arg.

	Baseline	LN 0.1	LN 1.0	L-Arg 11.0
HR (bpm)	212	215	209	218
MAP (mm Hg)	115	121	131	129
CI (%)	100	85.9	61.1*	68.9*
PVRI (%)	100	134.2	201.3*	146.4
SVRI (%)	100	122.4*	190.9*	166.4*
CBF (%)	100	107.2	85.4	111.8
MBF (%)	100	101.6	71.3*	91.7
RBF (%)	100	62.5*	32.8*	39.9*
JBF (%)	100	107.5	75.6	82.4

Low dose LN does not affect CBF but causes deleterious effects on cardiac output and regional organ blood flow in piglets. We speculate that the reduction in cardiac output was due to a direct effect on the myocardium and not a secondary effect of increased afterload, because cardiac output decreased so rapidly after LN administration, without a significant change in MAP.

410.9

THE EFFECT OF 7-NITROINDAZOLE, AN INHIBITOR OF BRAIN NITRIC OXIDE SYNTHASE (NOS), ON BASAL CORTICAL BLOOD FLOW AND ON VASODILATION INDUCED BY WHISKER STIMULATION Y.Zagvaydin¹, G.Sancesario², M.E.C.Fitzgerald¹ and A.Reiner¹. Department of Anatomy & Neurobiology, University of Tennessee, Memphis, TN 38163¹, Università di Roma "Tor Vergata", Rome, Italy².

The brain vasculature is regulated by nitric oxide (NO) produced by endothelial and neuronal NOS isoforms. While the vasodilatory action of endothelially produced NO is well documented, the role of neurally derived NO in circulatory control is still uncertain. Recently, an apparently selective inhibitor of neuronal NOS, 7-Nitroindazole (7NI), has been described (Moore et al., 1993, Br.J.Pharmacol., 110). The goal of this study was to investigate the effects of neuronal NOS inhibition by 7NI on basal cerebral blood flow (CBF) and on the vasodilatory responses in somatosensory cortex associated with neuronal activation elicited by vibrissal stimulation. Male Sprague-Dawley rats were anesthetized with urethane and α -chloralose. Body temperature, blood gases and blood pressure were monitored. CBF was measured by a Laser Doppler flowmeter probe. Barrel cortex was activated by manual deflection of the contralateral vibrissae for 15-30 seconds. There were no significant changes in basal CBF or in dilatory responses induced by vibrissal stimulation following vehicle (i.p. oil) injection. Basal CBF decreased significantly (p<0.005) in 30 minutes after 7NI injection (i.p. in 3ml of peanut oil) with maximal reduction 71% (n=8) and 59% (n=3) of pre 7NI baseline at doses of 50 mg/kg and 75 mg/kg respectively. A slight (10-13 mm Hg) but significant increase (p<0.05) in blood pressure was observed after 7NI injection. The magnitude of the dilatory responses were decreased after 7NI injection at 50 mg/kg (88%) and 75 mg/kg (42%), but the reductions were not significant (the latter case probably due to the small number of animals yet tested). These studies revealed that 7NI reduces basal cerebral blood flow presumably via inhibition of neuronal NOS and has a slight vasopressor effect. Less NOS inhibition is required to affect basal cerebrovascular tone than to affect dilatory responses associated with neuronal activation.

INHIBITION OF NITRIC OXIDE SYNTHASE INDUCES A MARKED DECREASE OF THE CEREBROVASCULAR RESPONSIVENESS TO HYPERCAPNIA IN THE AWAKE RAT. G. Bonvento*, J. Seylaz, P. Lacombe. Laboratoire de Recherches Cérébrovasculaires, CNRS UA 641, Université Paris VII, 75010 PARIS, France

The widely accepted notion that inhibition of nitric oxide synthase (NOS) attenuates the cerebral blood flow (CBF) increase elicited by hypercapnia relies mainly on studies performed in anesthetized animals (JCBFM 14:175-192, 1994). In this study, we sought to determine whether NO mediates the CO₂ responsiveness in awake rats. Regional CBF was measured in 4 groups of 5 awake, gently restrained rats, using the quantitative [¹⁴C]iodoantipyrine technique and brain tissue sampling. CBF was determined 1h following NOS inhibition via i.v. injection of 30 mg/kg N⁰-nitro-L-arginine methyl ester (L-NAME; n=10) or saline (n=10), during normocapnic (PaCO₂: 34-46 mmHg) or hypercapnic (PaCO₂: 51-69 mmHg) conditions. L-NAME significantly decreased CBF in all 11 brain regions studied (-17 to -49%) and produced a moderate hypertension along with bradycardia. In control conditions, CO₂ responsiveness, expressed as the slope of the regression lines of the PaCO₂-CBF relationship, ranged from 1.3 \pm 0.4 in the hypophysis to 6.4 \pm 0.6 ml/100g/min/mmHg in the parietal cortex. Under L-NAME, the reactivity to hypercapnia was significantly decreased in all structures, the magnitude of the reduction ranging from 57% in the medulla (lowest density of NOS-containing neurons) to 74% in the cerebellum (highest density of NOS-containing neurons). This result suggests that neuronal NO, in addition to endothelial NO, is a mediator of the hypercapnic vasodilation in the awake rat.

410.8

NITRIC OXIDE SYNTHASE (NOS)-CONTAINING NEURONS INNERVATE HUMAN CEREBRAL MICROVESSELS. W.H.Zhang⁽¹⁾, L.Divac, M.O.Lopez-Figueroa⁽²⁾ and L.Edvinsson^{(1)*}. Dept. of Exp. Res., Malmö Gen. Hosp., The Univ. of Lund, S-214 01, Malmö, Sweden¹ and Dept. of Med. Physiol., Panum Inst., The Univ. of Copenhagen, Denmark².

Nitric Oxide(NO) is a prominent vascular and neuronal messenger molecular generated from L-argine by NOS. Although data indicate that NOS is important in the modulation of human cerebral blood vessel relaxation, there is little information about the localization of NOS in the human cerebral circulation. In the present study, we have used NADPH-diaphorase (NADPH-d) histochemistry and NOS immunocytochemistry to human tissue in order to examine the existence and distribution of cerebrovascular neurons containing NOS. Four blocks of human temporoparietal cortex were cut on a vibratome at 50 μ m. Two of five series were reserved for NADPH-diaphorase staining, two of five series were processed for immunocytochemistry for NOS reaction by a monoclonal antibody against the neuronal isoform of the enzyme and the remains was used for anatomical demonstration of neurons with Nissl staining. We found that NADPH-d and NOS positive staining is located in cells and nerve fibers surrounding cerebral vessels. Differential NADPH-d and NOS cellular and nerve fiber staining was noted at various sites of the cerebrovascular bed. In some cases, NADPH-d and NOS positive neurons in the cortex were seen close to and sending processes to the neighboring vessels; in other cases, the cell bodies were located far from the microvessels, sending processes to the blood vessels. NADPH-d/NOS positive cellular body were also situated on the wall of blood vessels and had processes that paralleled with longitudinal direction of the vessels. Part of the vessel wall with stained fibers contained varicosities. Cell bodies were oval, fusiform and triangular with one to three primary dendrites of variable length. Some of primary dendrites followed by second dendrites. The identity of neurons and fibers containing NOS in human microvessels provides morphological evidence for a role of NO in modulating human cerebral blood flow.

410.10

VASODILATORY ACTIONS OF CALCITONIN RECEPTOR-RELATED PEPTIDE AND NITRIC OXIDE IN PARENCHYMAL MICROVESSELS OF THE RAT HIPPOCAMPUS. A. Fergus, Y. Jin, Q.A. Thai, N.F. Kassell, K.S. Lee*. Dept. of Neurological Surgery and The Neuroscience Graduate Program, Univ. of Virginia, Charlottesville, VA 22908.

Calcitonin gene-related peptide (CGRP) and nitric oxide (NO) are known to exert vasodilatory actions in a variety of vascular beds. Recent evidence suggests that CGRP may mediate some aspects of the vasodilation elicited by NO. The present studies examined the responses of parenchymal microvessels in the rat hippocampus to CGRP and an inhibitor of nitric oxide synthase. Hippocampal slices were prepared from adult male Sprague-Dawley rats. Microvessels in the neuropil of submerged slices were examined using computer-assisted videomicroscopy. Drugs were administered by addition to the medium superfusing the slices.

The resting diameter of vessels analyzed in this study ranged from 12 to 25 micrometers. Treatment with the nitric oxide synthase inhibitor, N-nitro-L-arginine (NNLA; 100 μ M), constricted vessels to 51.1 \pm 7.7% of resting diameter (n=9). Application of CGRP (10 nM) in the presence of NNLA resulted in the dilation of the precontracted vessels to 97.0 \pm 9.6% of their resting diameter (n=4). These findings suggest that NO participates in the regulation of microvascular function by providing a tonic dilatory influence. The ability of CGRP to dilate vessels in the presence of NNLA suggests that CGRP-induced dilation is not mediated by increased production of NO. Ongoing experiments are investigating the possible role of CGRP in mediating NO-induced vasodilation.

410.11

NITRIC OXIDE SYNTHASE (NOS) INHIBITION DOES NOT AFFECT LEUKOCYTE-ENDOTHELIUM INTERACTION AND BLOOD BRAIN BARRIER (BBB) INTEGRITY IN THE PIAL MICROCIRCULATION OF THE RAT. U. Lindauer, J. Dreier, W. Oertel*, A. Villringer, U. Dirnagl, Dept. of Neurology, Humboldt University Berlin, FRG.

NOS inhibition causes leukocyte activation and disturbs endothelial barrier integrity in the intestinal microcirculation (Circ Res 73:164-171;1993). We investigated whether NOS inhibition activates leukocytes in the brain and disrupts the BBB. In pentobarbital anesthetized male Wistar rats under full physiological control a closed cranial window (dura removed) was implanted over the parietal cerebral cortex. For labelling of circulating leukocytes, Rhodamin 6G was injected i.v. (200µg/ml, 1ml as a bolus, followed by the same dosage per hour continuous infusion). We used a confocal laser scanning microscope (Biorad MRC 600) and studied leukocyte rolling and sticking in pial veins and arteries before and after NOS blockade. The NOS inhibitor L-NA was applied systemically (sys) (10mg/kg i.v., n=5) or topically (top) (1 mM, n=5). At the end of the experiment, Na-fluorescein was injected i.v. (2mg/100g b.w.) to test BBB integrity. The results are summarized in the table:

X ± SD	baseline (60 sec interval)			60 min (60 sec interval)		
	roller /100µm vein	stickers /100µm vein	SAP /100µm vein	roller /100µm vein	stickers /100µm vein	SAP /100µm vein
*p<0.05 to baseline						
control (n=3)	0.80 ± 0.66	0.91 ± 0.35	110 ± 17	1.86 ± 0.34	1.03 ± 0.14	102 ± 10
L-NA sys (n=5)	0.64 ± 0.94	0.76 ± 0.24	104 ± 9	1.21 ± 0.99	1.19 ± 0.23	141 ± 13*
L-NA top (n=5)	0.44 ± 0.55	0.84 ± 0.42	108 ± 3	0.67 ± 0.66	1.21 ± 0.54	100 ± 10

Systemical or brain topical L-NA application did not alter leukocyte-endothelium interaction significantly and caused only discrete Na-fluorescein leakage in one animal of each group. No rolling and sticking of leukocytes was observed in arteries. These results suggest that NO, in contrast to its action in peripheral microvascular beds, does not affect leukocyte endothelium interaction and BBB integrity in the pial microcirculation. Supported by the DFG and the Wilhelm Sander Stiftung.

NITRIC OXIDE SYNTHASE (NOS) BLOCKADE DOES NOT AFFECT CORTICAL SPREADING DEPRESSION (CSD) IN RATS: A LASER DOPPLER (LD) AND NEAR INFRARED SPECTROSCOPY (NIRS) STUDY. T. Wolf, U. Lindauer, C. A. White*, J. Dreier, H. Obrig, A. Villringer, U. Dirnagl, Dept. of Neurology, Humboldt University Berlin, Germany; and Harvard Medical School, Boston, USA

In barbiturate anesthetized, ventilated rats under full physiological control, we measured continuously: regional cerebral blood flow (rCBF) by LD; oxyhemoglobin (HbO), hemoglobin (Hb) and cytochrome a/a3 oxygenation (CytO₂) by NIRS; and cortical DC potential. CSD was induced before and 60 minutes after i.v. application of the NOS-inhibitor L-NA (10 mg/kg) 10 mm from the measurement site. The results are summarized in the table:

n=7	SAP (mmHg)	basal rCBF (%)	CSD velocity (mm/min)	CSD hyperperfusion (%)	CSD ΔCytO ₂ (arb. units)	CSD ΔHbO (arb. units)	CSD ΔHb (arb. units)
X±SD							
*p<0.05							
control	104 ± 15	100	3.4 ± 0.1	+360 ± 196	-4.6 ± 0.3	+26.1 ± 6.3	-15.4 ± 4.0
L-NA	131 ± 15*	82 ± 19*	3.4 ± 0.3	+433 ± 228	-4.8 ± 0.3	+27.9 ± 3.9	-14.7 ± 6.0

NOS inhibition did not alter significantly the quantitative changes or curve patterns in rCBF, DC potential, hemoglobin and cytochrome a/a3 oxygenation due to CSD. Particularly, there was no brief phase of hyperperfusion preceding the CSD hyperperfusion after NOS inhibition as reported by Duckrow (Brain Res, 618:190-195; 1993). We conclude that NOS inhibition in the anesthetized rat does not affect the coupling of cerebral hemodynamics and oxygen metabolism in CSD. NIRS is useful for noninvasive monitoring of hemodynamic and metabolic changes associated with CSD in rats and possibly in humans. Supported by the DFG.

MISMATCH-NEGATIVITY IN DIFFERENT BRAIN STRUCTURES - A TOPOGRAPHICAL AND DIMENSIONAL STUDY. M. Molnár*, V. Csépe, J. Winkler, J.E. Skinner* and G. Karmos

Institute for Psychology, Hungarian Academy of Sciences, Budapest, Hungary; *Totts Gap Medical Research Laboratories, Bangor, USA.

The purpose of the present investigation was twofold: 1) In animal experiments an attempt was made to record the mismatch-negativity (MMN) in other brain structures than the auditory cortex, the latter being the hypothesized generator for the MMN. In chronically implanted freely moving cats auditory evoked potentials were recorded from the auditory and association cortices, dorsal hippocampus, amygdala, dorsal raphe nucleus and vertex. Auditory stimuli were short tones of 4 kHz frequency ("standards") randomly interrupted by 2 kHz "deviant" ones (probability: 10%). 2) In human studies the mathematical tools of non-linear dynamics was used to analyze data collected in MMN-experiments from different scalp locations. The MMN, elicited by randomly appearing 1100 Hz deviant stimuli within series of 1000 Hz standards was recorded from Fz, Cz and Pz. The point-correlation dimension (PD2) of EEG epochs were calculated.

In the animal studies it was found that in the primary auditory and association cortices, hippocampus and vertex the MMN manifested itself with almost identical latencies of about 50 ms, but it started to develop with the shortest latency in the hippocampus. The MMN had a longer latency in the secondary auditory cortex. No MMN was recorded in the other structures studied. It is suggested that the hippocampus probably plays an important and early role in the stimulus comparison process the result of which is the MMN. In the human studies the occurrence of the MMN was accompanied by PD2 decreases most conspicuously in the frontal region indicating the activity of a possible frontal MMN-generator.

COMPARATIVE ANALYSIS OF CORTICAL GENERATORS OF MISMATCH-NEGATIVITY IN THE CAT AND MONKEY. G. Karmos*, I. Ulbert, D.C. Javitt*, M. Molnár, V. Csépe, Zs. Pincze and C.E. Schroeder*, Inst. for Psychology of the Hungarian Academy of Sciences, Budapest, Hungary, *Dept. of Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

Human source localization techniques indicated an auditory cortical origin of the mismatch-negativity (MMN), which is a negative component of the scalp recorded auditory evoked potential (AEP). It is elicited by infrequent, "deviant" stimuli, presented randomly within sequences of repetitive "standard" auditory stimuli.

MMN appeared also in cats and monkeys as a negative component in the epidural AEPs in the latency range of 40-120 ms. To study its intracortical generators the field potentials and multiple unit activity were recorded from the auditory areas of awake cats and macaque monkeys by intracortical multielectrodes. One dimensional current source density (CSD) analysis was used to localize intracortical sinks and sources. Surface maps in cats indicated the spread of the frequency MMN to both AI and AII auditory areas. In the middle layers of the auditory cortex of cats large amplitude local positive field was elicited by the standards in the latency range of the MMN while this positivity appeared with much smaller amplitude to the deviants. CSD analysis and the increased unit response elicited by the deviant stimuli suggested that the MMN represent a local disinhibition in the upper layers. In the AI area monkeys surface negative MMN to deviant stimuli was accompanied by an increased lamina II/III sink.

The data indicate that the MMN generators are localized in the supragranular layers of the auditory cortex.

Supported by OTKA Grant I/3/2595 and by the J.S. McDonnell Foundation.

THE GENERATOR QUESTION: A COMPARISON OF EVENT RELATED POTENTIAL (ERP) PROFILES WITH RECONSTRUCTIONS FROM CURRENT SOURCE DENSITY (CSD) ANALYSES. C.E.Tenke* and C.E.Schroeder, Dept. Biopsychology, NYS. Psychiatric Institute, NY, NY and Depts. Neurology and Neuroscience, Albert Einstein College of Medicine, Bronx, NY

One-dimensional CSD profiles of intracranial ERPs detail the temporal and spatial patterns of transmembrane current flow which underlie the local field potential, and allow inferences about the likelihood that the sampled activity is recordable at a distance. In contrast, inverse models (e.g. dipole models) simplify a scalp topography by indicating locations and waveforms for putative generators based on statistical and geometric inferences. A synthesis of these complementary approaches would provide a distinct advantage for the study of ERP generators. We recorded the Flash-ERP in the monkey within and above the lateral geniculate nucleus (LGN), and reconstructed the ERP profile from computed CSD profiles. CSD profiles were computed at low or high spatial resolution to bias the profiles toward open or closed field activity, respectively (Tenke et al., 1993). Weighting functions for these forward solutions assumed uniformly distributed cylindrical generators (Nicholson and Llinas, 1971). Reconstructed and empirical profiles were compared and residual waveforms computed from their difference. Low resolution methods produced a better overall fit to the empirical profile. High resolution methods produced an oscillatory residual, reflecting closed field activity. Factors common to empirical and reconstructed profiles were extracted using a principal components analysis, to summarize them and to provide a direct linkage between local generators and the ERP recorded within and superficial to LGN. This approach shows promise for computing waveforms of volume conducting, regional dipoles directly from measurable properties of a region.

COMBINED MEG AND ERP MEASURES OF VISUAL SPATIAL SELECTIVE ATTENTION IN HUMANS. G.R. Mangun¹, M. Sams^{2,3}, R. J. Ilmoniemi³, G.V. Simpson⁴ (1) University of California, Davis, USA; (2) University of Tampere, Finland; (3) Helsinki University of Technology, Finland; (4) Albert Einstein College of Medicine, USA

Mangun et al. (1993) investigated event-related potentials (ERPs) to attended and ignored stimuli using topographic current density analysis, and proposed that spatial selective attention first modulated visual processing in extrastriate cortex in humans. In the present study we used combined electrical (7-channel ERP) and magnetic (122-channel MEG) recording to index the processing of stimuli flashed to the four quadrants of the visual field when attended and ignored. In normal subjects (N=3) the ERPs showed significant attention-related amplitude increases of the P1 (110 ms) and N1 (190 ms) components at occipital scalp sites. No attention effects were observed for the earlier NP90 (90 ms) component thought to be generated in striate cortex. MEG recordings for the three time periods corresponding to the NP90, P1 and N1 components were analyzed and modeled as equivalent current dipoles in order to localize their brain generators. In the time period of the electrical NP90, a source was identified in the calcarine sulcus of the contralateral striate cortex that showed inversions in dipole orientation for upper versus lower field stimuli; this magnetic component was not affected by attention. Later attention-sensitive MEG components, in the time range of the electrical P1 were localized to regions of extrastriate visual cortex and were attention sensitive. Longer latency activity in the N1 range (160-190 ms) was localized to parietal and lateral temporal cortex. These findings provide further support for the idea that spatial attention first begins to affect visual processing at the level of extrastriate cortex in humans.

VISUALLY EVOKED ELECTRIC AND MAGNETIC RESPONSES: SIMULTANEOUS WHOLE-SCALP RECORDINGS. G. V. Simpson¹, R. J. Ilmoniemi², S. P. Ahlfors², M. S. Hämäläinen³, J. J. Foxe¹. ¹Depts. Neurology and Neuroscience, Albert Einstein Coll. Med., ²Low Temperature Laboratory and ³Neuromag Ltd, Helsinki University of Technology, 02150 Espoo, Finland.

The electric currents in brain areas which are active during sensorimotor and cognitive processes produce electric and magnetic fields outside the skull which can be measured in real-time as event-related electric potentials (ERPs) and magnetic fields (ERFs) respectively. The accuracy of localizing active brain sources may be improved by combining ERP and ERF data since they are complementary. Prior to recent technological advances, it has not been possible to simultaneously record both electric and magnetic field data over the whole scalp in a single experimental session. We report here, simultaneously recorded electric and magnetic responses to visual stimuli with large sensor arrays (122 magnetometers and 32 electrodes) over the whole scalp. A series of retinotopic, pattern discrimination and attention experiments were conducted. The retinotopic results are presented here. ERPs and ERFs were recorded to small checkerboard wedge stimuli delivered to each quadrant. Source configurations for the initial responses were estimated with spatiotemporal dipole analyses and minimum norm estimation. The source locations for ERP and ERF converged, and followed the expected retinotopic pattern for striate cortex, i.e., upper right, lower right, lower left and upper left quadrant stimulation activated lower left, upper left, upper right and lower right striate cortices respectively.

TOMOGRAPHIC MAPPING OF TEMPORAL LOBE P300 ACTIVITY IN THREE DIMENSIONS: ASSESSMENT OF RELIABILITY AND ACCURACY. C. C. Kessler¹ and R. L. Lloyd. Psychiatry Department, 116A, V.A. Medical Center, Sepulveda, CA 91343.

A noninvasive interpolative computer graphics algorithm for imaging the distribution of the P300 event-related potential within the temporal lobe is described. This technique takes advantage of the fact that the primate temporal lobe may be noninvasively surrounded by 4 electrodes forming a tetrahedral array consisting of three surface leads (C4, T6, and T4) and one nasopharyngeal lead (Pg2). It is then possible to calculate the potential distribution within the enclosed volume of the temporal lobe given that the field strength E_p for any point p within the tetrahedron may be represented by the sum of the field contributions to or from the surrounding vertices, weighted by the distance between point p and each of the vertices. As part of an effort to assess the reliability and accuracy of this technique, monopolar recordings were obtained from the tetrahedral array in several squirrel monkeys (*Saimiri sciureus*) using a passive oddball paradigm. Simultaneous monopolar recordings were made at indwelling electrodes from an initial depth of 10mm to a final depth of 22mm within the temporal lobe, and these measurements were used to adjust the imaging algorithm to account for variations in impedance and conductance via a linear least-squares technique. When applied to other subjects in a cross-validation procedure, the adjusted algorithm was found to yield accurate and reliable measurements at various depths which were highly and significantly correlated with simultaneous measurements obtained from indwelling electrodes at corresponding sites.

BRAIN ACTIVATION WITH A MAZE TEST: AN EEG COHERENCE ANALYSIS STUDY IN HEALTHY SUBJECTS. M. Tremblay, D. Lacroix*, V. Fraile, Y. Chaput, R. Lamar and J.-M. Albert. Département de Psychiatrie, Hôpital Notre-Dame, Université de Montréal, 1560 Sherbrooke E., Montréal, CANADA H2L 4M1.

The maze test is a complex cognitive task involving visuo-perceptual abilities and executive functions, such as planning and foresight. EEG coherence analysis is performed on the electrical signal of two electrodes and its value is analogous to a correlation coefficient between the two signals. EEGs were recorded from 20 healthy subjects (mean age \pm S.D.: 27.4 ± 5.23) during a maze test (3 mazes from the WISC and 2 from the Porteus) and during two baseline conditions: 1- rest with eyes opened; 2- mazes with dotted lines showing the way out. 19 electrodes were used according to the 10/20 system. Signals were referenced to averaged signals from both ear lobes (TC 0.3s, Filter 35 Hz). Interregional coherence (IRC) refers to coherence between each electrode paired to each of the remaining electrodes and may reflect dynamic physiological processes between brain regions during cognitive activation. Statistical probability mapping were used to show the regional distribution of changes. The results show that: 1- compared to the eyes opened condition, the maze test provoked increases of IRC mainly located between paired posterior electrodes (mostly parietal P3 and P4 sites) and decreases between all fronto-frontal sites; 2- compared to IRC of the 2nd baseline condition, the maze test provoked increases of IRC mainly between paired posterior electrodes in θ and $\beta 1$ bands and between the left prefrontal F3 site paired with frontal or posterior sites in β band and provoked decreases between centro-parietal sites paired with frontal sites in α . EEG coherence analysis detects electrical changes in regions known to be involved in visuo-analytic, visuo-practic and executive functions (posterior, central and frontal sites respectively).

VALIDATION STUDIES OF A PROBABILISTIC SOLUTION TO THE EEG INVERSE PROBLEM. D.M. Rice¹, D. Khosla², M. Singh², Andrus Gerontology Center¹ and Dept. of Biomedical Engineering², Univ. of Southern California, Los Angeles, CA 90089-0191. The EEG inverse problem is to reconstruct the distribution of currents within the brain which generate the scalp measured potential distribution. This problem has an infinite number of exact solutions, so a probabilistic solution would seem to be the most reasonable solution to this problem. The approach employed here maximizes the entropy of the source distribution subject to a system of linear equations which require that this distribution fits the scalp measured potential field and which ensure that the joint probability of sources in opposite directions at the same location is everywhere equal to zero. With this formulation, this maximum entropy solution is the probability distribution for the source(s) of the measured potential field, and it is also the most likely source distribution for the measured potential field. In addition, the current probability distribution can be easily derived from this source probability distribution. The present studies were to provide initial validation for this approach. With simulated potential fields produced by a small number of equivalent current dipoles in a homogeneous sphere model, the current probability distributions approximated the actual equivalent current dipoles which generated the potential field. With a potential field measured at the human scalp during visual checkerboard stimulation which strobed at 3 Hz., the current probability distribution computed through a four sphere model was largely concentrated in the posterior regions of the brain including a region roughly corresponding to the primary visual cortex.

THE TIME COURSE OF REGIONAL CEREBRAL ACTIVATION DURING COGNITIVE TASKS: RESULTS OF DIRECT CORTICAL RECORDING IN HUMANS. N.E. Crone, J. Hart, R.P. Lesser* and B. Gordon. Depts. of Neurology, Neurosurgery, and Cognitive Science, and The Zanvyl Krieger Mind/Brain Institute, The Johns Hopkins University, Baltimore, MD 21287

Language and related cognitive functions are considered to be the product of distinct underlying processing stages, which are often serially-connected. However, little is known about the dynamics of processing within stages, or the time relations between stages of processing. We therefore examined the onset and duration of activation in different cerebral regions during cognitive tasks, using spectral changes in human cortical EEG as indices of functional activation.

Subjects were evaluated with indwelling subdural electrode arrays placed for clinical purposes (Lesser et al., 1994). Arrays consisted of 48 or more electrodes (2.3 mm exposed surface), embedded (10 mm center-to-center) in silastic sheets. Recordings were made during the following cognitive tasks: visual object/nonobject discrimination; visual-motor decision; reading words aloud; visual object naming; and auditory word repetition. Changes in EEG spectral power (18 frequency bands; 8-100 Hz) from pre- to post-cognitive stimulus presentation, in overlapping 200 msec time segments, were used as markers for regional cerebral activation at each electrode.

In general, within a given task, cerebral activation appeared to occur in close sequence, and often overlapped considerably in time, among the different regions involved in cognitive processing. These data provide further support for cascade models (McClelland, 1979) of information flow in human cognitive processes.

411.10

EVENT-RELATED POTENTIALS DURING COMPREHENSION OF SYNTAX IN SPANISH SPEAKING SUBJECTS. F. Ostrosky*, C. Rigalt, M. Pérez, F. Cruz, J. Marcos and A. Ardila. Dep. de Psicofisiología, Facultad de Psicología, Universidad Nacional Autónoma de México, México D.F. 04510.

Event-related brain potentials (ERPs) were recorded during a syntactic decision task. Twenty-five right-handed young adults were presented with a total of 198 eight-word sentences, that were divided in three different groups: 66 Pseudo-Cleft Agent, (LO QUE UN ELEFANTE EMPUJO FUE UN OSO; "WHAT AN ELEPHANT PUSHED WAS A BEAR"); 66 Pseudocleft Passive (UN ELEFANTE FUE LO QUE EMPUJO UN OSO; "AN ELEPHANT WAS WHAT A BEAR PUSHED") and 66 sentence type without a syntactic order that were used as control (ELEFANTE UN FUE EMPUJO QUE LO UN OSO; ELEPHANT AN WAS PUSHED WHAT A BEAR). Sentences were presented randomly intermixed. Subjects had to select the agent in each sentence. Scalp electrical activity was recorded from 32 derivations of the 10/20 international system. ERPs were registered to the seventh and eighth word. Peak amplitudes were visually identified by windows of 200 msec each one (from 50 to 900 msec). ERP measures associated with each sentence type were subject to ANOVA and repeated measures. Wave differences between ERPs were obtained. A slow negative response between 300-500 msec largest over anterior regions of the left hemisphere. These data reflected an negative component around 500 msec elicited by syntactic decision.

411.11

APPEARANCE OF FRONTO-PARIETAL MIDLINE (FPM) THETA ACTIVITY IN GOOD AND POOR LEARNERS
S.J. Laukka*, J. Lindqvist, T. Järvillehto.
 Laboratory of Developmental Neuropsychology
 University of Oulu, Linnanmaa P.O. BOX 222,
 FIN-90571, Oulu, Finland.
 Fronto-parietal theta activity (FPM, 4-7 Hz) was investigated during learning process of problem solving task. In a simulated traffic situation the subject had to learn to find the right way for driving a car through a set of roads by trial-and error. Two interdependent decisions had to be made at two crossroads guided by two traffic signs. After learning the level of performance was tested in a practising situation. Feedback about quality of performance was given. EEG was recorded from Fz and Pz.
 In the learning situation the amount of appearance of theta activity did not differ either on the frontal or on the parietal area between the good learners and the poor learners. In the practising situation poor learners showed a significantly higher amount of theta than good learners in the frontal and parietal area.
 The results demonstrate a relation between the appearance of fronto-parietal midline theta activity and the quality of performance.

411.13

CORTICAL EVOKED POTENTIALS DURING A VISUAL CONTINUOUS PERFORMANCE TASK. A. Tekok-Kilic, E. Sargent, D.W. Shucard*.
 Dept. of Neurology, SUNY @ Buffalo, 100 High St. (D6), Buffalo, NY 14203.
 The Continuous Performance Task (CPT) was originally developed for the behavioral assessment of sustained attention in brain damaged patients (Rosvold et al., 1956). Different types of CPTs have been used to investigate attention in psychiatric and neurologic patient groups. It has become important to clarify the behavioral, perceptual and cognitive factors measured by the CPT in normal subjects. One of the variations of the CPT is the visual "A-X" paradigm (Halperin et al., 1988) in which subjects are asked to respond as fast as possible to the target letter "X" only if it is preceded by "A". Nontarget letters preceded by "A" and "X"s not preceded by "A" (nontarget "X"s) are also presented. In order to study the physiological aspects of sustained attention, we examined the relationship between a cortical evoked potential component (P300) and the CPT "A-X" paradigm. P300 is an endogenous component that is elicited by stimuli that are relevant to the subject. We expected that the P300 component would have the highest amplitude for both target "X"s and for other letters immediately preceded by "A". Eleven letters were visually presented as stimuli in a random sequence of 400 letters, with 40 "A-X" pairs ($p=.10$) and 68 "A-nontarget" pairs ($p=.17$). Stimulus duration was 200 msec and ISI was 1500 msec. Electroencephalographic activity was recorded at 12 scalp electrode sites of the 10-20 system, referenced to linked earlobes.
 As reported in previous studies, the P300 component was most prevalent in the midline scalp sites. As predicted, the highest amplitude responses were observed for both target "X"s and other letters that were preceded by "A"s. These results are consistent with findings showing that task relevance is an important antecedent condition of P300 amplitude. The electrophysiological data provide information not attainable through behavioral observation about possible cognitive events underlying CPT performance.

411.15

VEP ESTIMATION OF INTERHEMISPHERIC RELAY TIME.
C. Potvin, C.M.J. Braun and A. Achim*. Laboratoire de Neurosciences de la Cognition, UQAM, Montréal, Canada, H3C 3P8
 Lines, Rugg & Milner (1984) dissociated a non sensory from a sensory component of interhemispheric relay (IR) by showing that the asymmetry in N160 latency of visual evoked potentials (VEP) to contralateral and ipsilateral stimuli is affected by stimulus intensity only at occipital sites (about 11 and 18 msec for bright and dim stimuli), not at central sites (about 3 msec). It appears possible, however, that the latter 3 msec delay simply represents different shifts in the apparent peak latency of a synchronous symmetrical source, due to superimposed asymmetrical potentials of occipital origin, the central N160 peaking during the rising phase of the occipital N160. To allow more detailed topographic analysis, we obtained VEP from 21 scalp sites in 10 subjects in a simple reaction time task to yellow squares on a blue background, about 10° left or right of fixation. Preliminary N160 latency analysis shows a strong antero-posterior gradient, from 154 msec at F3/F4 to 190 msec at O1/O2. The IR estimates show a parallel gradient from 7.0 msec at F3/F4 to 15.9 msec at O1/O2, with a value of 10.3 msec at C3/C4. The latter, with a standard error of the mean of about 3.2, is a significantly larger asymmetry than those reported earlier at C3/C4. The notion of simply two levels of IR in VEP appears to be an oversimplification.

411.12

ERP CORRELATES OF ATTENTION DURING THE CUE-STIMULUS INTERVAL. A.L. Keyes & R.G. Eason*. U. of NC at Greensboro, Greensboro, NC 27412
 This study examined the effects of a cue-directing stimulus and the length of the cue-target interstimulus interval (ISI) on: (1) ERPs recorded prior to and following the occurrence of relevant (validly cued) and irrelevant (invalidly cued) target stimuli appearing in a given visual field; and (2) on rapidity (RTs) and accuracy (d-primes) of responses to cued stimuli. On a given trial a foveally-presented arrow cue directed to subject to attend (without moving the eyes) to either the right or left visual field. After a brief delay a target appeared randomly 8 degrees peripherally in either field. The subject responded as quickly as possible when the target appeared in the cued field. ERPs were recorded under one of three ISI conditions during an averaging run: 1000; 1400; or (3) a randomly presented mixture of 1000 and 1400 ms. Late ERP components occurring during the ISI interval, especially the CNV, were sensitive to the attention directing cue stimulus, length of the ISI, and degree of uncertainty as to when the target stimulus might appear (after 1000 or 1400 ms). These pretarget effects were consistent with the ERP and behavioral data obtained to the target stimulus.

411.14

THE EFFECTS OF PRECEDING INTERSTIMULUS INTERVAL ON BEHAVIORAL DISCRIMINATION AND MISMATCH NEGATIVITY. M.G. Woldorff* and M. Matzke. Univ. of Texas Health Science Center, Research Imaging Center, San Antonio, TX 78284-6240.
 The mismatch negativity (MMN) is elicited by infrequent, physically deviant sounds in a sequence of repetitive auditory stimuli. It has been asserted that this wave reflects a strongly automatic feature-analysis and mismatch-detection process, in which each stimulus is compared to the sensory template formed by the repeated standard-tone stimulus. This framework asserts that the MMN is larger at shorter interstimulus intervals (ISIs), due to the comparison template formed by the previous standard(s) being stronger. For similar reasons, this framework also predicts discriminability of the deviant stimuli should be better at shorter ISIs.
 To explore this relationship more directly, subjects were monaurally presented with tone pips at ISIs ranging randomly from 120-920 msec, with 10% of the tones either slightly fainter in intensity or slightly lower in pitch (different blocks). On half of the runs, subject tried to discriminate the deviant stimuli; on the other half, subjects read a book. Preceding ISIs were divided into 4 subranges, and target discrimination and ERPs were subdivided as a function of the ISI subrange of the preceding standard tone. The discriminability of the deviant target tones was strongly affected by preceding ISI, with subjects doing progressively worse at the shorter ISIs. Preliminary ERP results suggest that the reading-condition MMNs and the active condition MMN/DRN (deviance-related-negativity) also decreases with shorter ISIs. These data do not fit into a framework of increasing standard-tone template strengthening with decreasing ISI. Rather, as suggested by Woldorff and Hillyard (EEG, 1991), a type of neural refractoriness appears to play a major role in these phenomena at shorter ISIs.

411.16

ACTIVATION OF DURATION-SENSITIVE AUDITORY NEURONS IN HUMANS. C. Alain*, D. L. Woods, and D. Covarrubias. Department of Neurology and Center for Neuroscience, UC Davis, Northern California System of Clinics, Martinez, CA 94553.
 Auditory neurons vary in their duration tuning: some neurons fire to tones of short duration, whereas others require longer duration tones. In the current study, auditory evoked potentials (AEPs) were recorded to signals varying in duration (8, 24, or 72 ms) and frequency (250, 1000, or 4000 Hz) in an effort to characterize temporal integration functions (amplitude/latency changes with changes in tone duration) for different AEP components. High-rate sequences were used in which tones were delivered randomly to the left and right ears. Subjects attended to a designated location and frequency to detect occasional long- or short-duration targets. Subjects were more accurate and faster in detection of long- than short-duration targets. Paralleling this, AEP components increased in amplitude and decreased in latencies with increased signal duration. Since all signals had identical rise-fall times and peak-to-peak amplitudes, duration-specific difference waves could be isolated by subtracting AEPs to short-duration tones from AEPs to longer duration tones at the same location and frequency. Duration difference waves varied in amplitude and scalp distribution for tones of different frequencies. These results are compatible with different integration time for different frequencies and generators, with tonotopically organized AEP generators generally having longer temporal integration times.

411.17

EVENT-RELATED DIFFERENCES IN EEG SPECTRAL POWER (ERDISP) D. L. Woods*, C. Alain, D. Covarrubias, and M. P. Remler, Dept. of Neurology and Neurosciences Center, UC Davis, Northern California System of Clinics, Martinez, CA 94553.

Recent studies using narrow band filtering techniques have shown changes in alpha (8-13 Hz) and gamma (30-50 Hz) frequency bands of the EEG in association with the sensory and cognitive analysis of signals. A simple technique is described for analyzing Event-Related Differences in EEG Spectral Power (ERDISP) over the entire EEG frequency spectrum. Power spectra from brief EEG epochs preceding stimulus delivery are subtracted from power spectra following the stimulus. The selection of the epoch duration is based on a trade-off between temporal and frequency resolution: short EEG epochs provide good temporal resolution but poor frequency resolution, whereas long EEG epochs provide good frequency resolution but poor temporal resolution. An analysis strategy using multiple epoch durations is proposed. ERDISPs reflect both sensory and cognitive processes. ERDISPs relating specifically to higher cognitive processes can be isolated in ERDISP difference waves (Δ -ERDISPs) using multiple subtractions. For example, the effects of selective attention on ongoing EEG rhythms can be analyzed by subtracting ERDISPs to nonattended stimuli from ERDISPs to the same stimuli when attended. Δ -ERDISPs in selective attention tasks show alterations in several EEG frequency bands. The relationship between ERDISPs and event-related brain potentials (ERPs) and between ERDISPs and other techniques for analyzing event-related changes in EEG power will be discussed. Supported by NS32893 and DC01049.

SPATIO-TEMPORAL CORRELATIONS IN HUMAN GAMMA BAND ELECTROCORTICOGRAMS.

V. Menon*, W. J. Freeman and A. S. Gevins. EEG Systems Lab, San Francisco, CA 94107 and Division of Neurobiology, University of California, Berkeley, CA 94702.

Animal electrocorticogram (ECoG) studies have shown that coherent spatial patterns in the gamma band (> 20 Hz) reflect perceptual categorization. Spatio-temporal correlations were investigated in the 20–50 Hz range in search for similar phenomena in human ECoG. The ECoG was recorded in a somatosensory discrimination task from a 64-electrode subdural grid array with spacing of 1 cm between electrodes, overlying somatosensory, motor, and superior temporal cortices in two patients with intractable epilepsy.

Stimulus and response related modulations of the μ , β , and γ bands of the 1/f spectrum were observed over intervals of 500 ms in the somatosensory and motor cortices but not in the temporal cortex. No evidence was found for globally coherent activity related to behavior either in the narrow (e.g. 40 Hz) or broad bands. Instead, spatially and temporally intermittent synchronization was observed between pairs of electrodes with high variability within and across trials. The distribution of correlation coefficients differed substantially from noise levels for separations of 1 cm and 1.4 cm but not 2 cm or more. The average correlation duration for 1 cm separation was about 150 ms and the average recurrence rate of significant correlation peaks was 1/s.

The findings suggest that domains of spatial coherence in human gamma band ECoG are limited to < 2 cm, that the intermittent synchronization observed across separations of 1 cm and 1.4 cm is not solely due to volume conduction, and that the search for perceptual categorization in human gamma band ECoG needs to be at a smaller spatial scale.

411.18

OPERANTLY CONDITIONING THE P200 PEAK OF THE HUMAN SEP: EFFECTS ON PAIN SENSITIVITY AND THE R3 REFLEX. R. Dowman*, Dept. Psychology, Clarkson Univ. Potsdam N.Y., 13699-5825.

The goal of this experiment was to replicate and extend previous work suggesting that operantly conditioned changes in the amplitude of the P200 peak of the human somatosensory evoked potential (SEP) alters pain sensitivity. The SEP, R3 reflex, compound nerve action potential (CAP) and magnitude ratings were elicited by stimulation of the sural nerve. Twenty-one subjects (conditioning group) were rewarded for increasing (up-training) and decreasing (down-training) the P200 peak evoked by innocuous stimulation. Magnitude ratings and R3 reflexes elicited by innocuous and noxious stimulation were obtained immediately following each training session. An additional 12 subjects served as no-training controls.

P200 amplitude was larger during up-training than down-training in the conditioning group but not the control group. There were little or no changes in the other peaks of the SEP. There were no changes in stimulus current or CAP amplitude across the training sessions, which implies that the conditioned change in P200 amplitude was due to some change within the CNS. Magnitude ratings and the R3 reflex were the same in up-training as down-training in both the conditioning and control groups. Thus, conditioned changes in the SEP that are specific to the P200 peak do not alter pain sensitivity.

SPIKE SPACE SYNCHRONIZATION OF NEURONAL ACTIVITY AS MECHANISM OF QUICK SHORT MENTAL PROCESSES P.D. Perepelkin*, Pavlov Inst. of Physiol., St. Petersburg, Russia./ Barrow Neurological Inst. 350 W. Thomas Rd., Phoenix, AZ 85013/

Spike space synchronization (SSS) of neuronal ensemble activity of the human brain was investigated. Gold electrodes were implanted in the deep structures for therapeutic purpose. The impulse activity of 14 distant ensembles were recorded simultaneously. It has been established that there were concrete SSS for definite phases of psychological tests. This investigation was completed by chronic experiments. Monkeys (M. mulatto) were trained to differentiate colored geometric figures. The impulse activity of 6-10 neuronal ensembles was recorded simultaneously in associative, temporal and frontal cortex of the animals during their operant conditioning. It was shown the existence, the reliability and the importance of SSS. There was a nonlinear character dependency between discharge frequency charges of impulsation and spike's synchronization. The experiment showed that SSS correlated with definite phases of the monkeys behavior. The interaction of neuronal processes which have been investigated allow that such space interaction as SSS could be a special mechanism for quick short phases of integral mental processes in the primate brain and that spatial - temporal information stimulations by means of many implanted electrodes lead to modify behavior.

RECOGNITION MEMORY AND CUED RECALL IN PATIENTS WITH FRONTAL CORTEX LESIONS: ERP AND BEHAVIORAL FINDINGS. D. Swick* & R.T. Knight, Dept. of Neurology & Center for Neuroscience, UC Davis, VAMC, Martinez, CA 94553.

Frontal patients reportedly show deficits in recall but not in recognition. The first experiment examined the role of frontal cortex in verbal recognition memory and the generation of late positive potentials in this task. Words and pronounceable nonwords repeated after one of 3 delays: immediate (3 sec), 1-3 intervening items (6-12 sec), or 9-19 items (30-60 sec). Stimuli were categorized as new or old. Subjects were 11 stroke patients (10 Left, 1 Right) with lesions centered in dorsolateral prefrontal cortex and 11 age-matched controls. In controls, first presentations of words and nonwords elicited a large centro-parietal positivity (LPC) peaking at 700 msec. Immediate repetitions elicited the largest (10-14 μ V) and earliest (500 msec) LPC. LPC was still enhanced at lag 1-3 but not at lag 9-19, unlike the longer-lasting effect seen in young subjects. In frontal patients, reductions in LPC were visible at most sites and for most conditions, while the repetition effects themselves were relatively preserved. Effects were dependent on lesion size and location; focal negativities were observed in some patients. These ERP changes were primarily accounted for by patients with the most posterior lesions ($n=5$), although behavioral impairments were observed in all patients: frontals were less accurate across all conditions ($p<.05$). The ERP results in posterior frontal patients imply the loss of a neural generator and/or an input to the generators of LPC, while the performance decrement suggests that frontal cortex is important for aspects of recognition memory. An overlapping set of patients with lesions in areas 8, 9, 10, and/or 46 (5 Left, 5 Right) were run on a cued recall task. Words were presented in a semantic study condition and again at test as 3-letter stems. As a group, these patients were not significantly impaired in cued recall, although two patients (1 L, 1 R) scored more than 2 SD below controls. These results will be discussed in the context of recent PET activation studies in young subjects.

412.2

AGE-RELATED PREFRONTAL CHANGES DURING AUDITORY MEMORY

L.L. Chao* and R.T. Knight, Department of Neurology & Center for Neuroscience, U.C. Davis, VAMC, 150 Muir Road, Martinez, CA 94553-4685.

The current study examined the effects of aging and prefrontal damage on auditory memory for environmental sounds. Event-related potentials were recorded from young (mean age = 21 ± 1) and elderly (mean age = 71 ± 11) control subjects and elderly patients (mean age = 70 ± 6) with lesions due to infarcts in the dorsolateral prefrontal cortex (centered in Brodmann areas 9 and 46). Digitized environmental sounds were binaurally presented in four blocks (111-114 sounds per block, 700 msec duration, 1200 msec SOA). Twenty percent of the sounds were presented once and 80% were presented twice. Sounds that were presented twice repeated at delays of either 1.9 seconds (short delay) or 4 to 12 seconds (long delay). Subjects indicated whether they had heard the sounds before by pressing a "yes" or "no" button.

Young control subjects generated a prominent sustained frontal negativity to all stimuli. The negativity was larger for longer recognition delays. Aging was associated with decreases of the sustained frontal negativity for stimuli at all recognition lags. Prefrontal lesions resulted in further decrements of the frontal negativity. At all stimulus intervals, young, old, and frontal lesioned subjects generated comparable posterior P300 components. Changes in prefrontal activity appear to underlie age-related alterations in auditory memory processing.

412.3

THE WISCONSIN CARD SORTING TASK SHOWS LITTLE SENSITIVITY OR SPECIFICITY FOR THE FRONTAL LOBE.

Z. Caramanos* and M. Petrides. Cognitive Neuroscience Unit, Montreal Neurological Institute and McGill University, Montreal, Canada H3A 2B4.

The Wisconsin Card Sorting Task (WCST) measures an individual's ability to form, maintain, and switch categories based on external feedback. The WCST is widely used in clinical and experimental neuropsychology, and deficits on it are widely accepted as a sign of frontal-lobe disturbance. It has recently been suggested, however, that impairments on the WCST are not necessarily indicative of frontal-lobe damage. The present study examines: (a) whether or not group differences are found in the WCST performance of focal epilepsy patients with unilateral frontal- or temporal-lobe excisions, and (b) whether or not performance on this task can be used to classify such patients according to the side, the lobe, and/or the side-lobe combination of their lesion.

As part of standard clinical neuropsychological testing, patients with well-localised epileptic foci were given the WCST before, and both two weeks and at least one year after undergoing unilateral excision from the frontal- (n=23 to 34) or the temporal-lobe (n=89 to 139). The left-frontal group was statistically impaired on several WCST measures in the pre- and early post-operative period. Nevertheless, considerable between-group overlap was found on all measures at all stages of testing. Furthermore, the locus of neural disturbance in these patients could not be predicted pre-operatively based on WCST performance, either by using established cut-off scores or cross-validated linear discriminant analyses. Similarly, their site of cortical excision could not be predicted either on the basis of early post-operative or late follow-up testing. In conclusion, these findings suggest that the WCST is not effective at localising neural disturbance in frontal- and temporal-lobe epilepsy patients. Furthermore, they warn against its use as an unequivocal indicator of frontal-lobe integrity in other populations.

FRONTAL LESIONS AFFECT PURSUIT AND MIRROR DRAWING PERFORMANCES. M.J. Chouinard*, J. Rouleau. Lab. de Neurosciences de la Cognition, Université du Québec, Montréal, Qc, H3C 3P8.

As part of a larger study of the role of the frontal lobes in sensorimotor performances and learning, we examined performance of patients with frontal lesions in two tasks requiring continuous regulation of movement on the basis of sensory information. We tested 5 patients with a unilateral frontal lobe lesion (FL) and 8 patients with a unilateral temporal lobe lesion (TL) on two sensorimotor tasks: 1) Rotary Pursuit and 2) Mirror Drawing. In the Pursuit task, subjects had to keep a light detector on a target (4cm²) moving at a constant speed (15rpm, 30rpm, or 45 rpm) around a circle in three 20 sec. trials. In the Mirror Drawing task, the subjects had to trace a starlike path seen through a mirror. On the Rotary Pursuit task, FL spent less time on the target than TL at 30 and 45 rpm, suggesting a deficit in movement correction. On the Mirror Drawing task, FL showed longer total tracing time although their performance without the mirror was equivalent to that seen in TL. This slowing was mainly due to more frequent episodes of non-progressive tracing (jitter) for FL than for TL. However, line-crossing errors were not more frequent in FL. The performance of FL on both tasks suggests a difficulty in the control of movement under sensory guidance, especially under challenging conditions.

412.7

LOSS OF GLOBAL PROCESSING AFTER RIGHT HEMISPHERE ATROPHY

Alessandra Schiavetto*¹, Johannes Stauder², Laurent Mottron², Philippe Robaey² and Maryse Lassonde¹

¹ Department of Psychology, Université de Montréal, and ² Ste-Justine Hospital for Children, Montréal, Québec, CANADA

The purpose of this study was to investigate the global and local processing abilities in a patient with a right hemispheric atrophy restricted to the temporal lobe. This atrophy resulted from a viral infection, herpes encephalitis, when the patient was 9 years old. As a result of this illness, the patient became prosopagnosic, color agnosic and presented evidence of associative visual agnosia. Recent MRI (Jan. 1993) revealed discrete left temporal lesions and a right temporal atrophy, including the hippocampal region. In the present study, the patient was tested on two choice reaction time tasks in which hierarchical processing was manipulated: a global-local letter identification task and a figure parsing task. Ten age-matched controls were also tested on the same tasks. Analysis of A.R.'s response accuracy shows that she could never distinguish global patterns. Moreover, reaction times in the global-local task show that, unlike normals, she did not have interference effect from the global to the local level. Indeed, her reaction times were slowed when congruent stimuli were presented (local vs. global level). Similarly, in the parsing task, she did not show the usual advantage for Gestalt fit items. In contrast to normals, her reaction times were significantly slower for the Gestalt items. These data suggest the involvement of the right temporal lobe in global processing. Furthermore, they may offer insight into the deficits resulting from visual agnosia.

NON-CONSCIOUS AUTONOMIC SIGNALLING ADVISES THE AVOIDANCE OF RESPONSES WITH NEGATIVE FUTURE OUTCOMES. A. Bechara*, H. Damasio, A. R. Damasio, and D. Tranel. Dept. of Neurology, Univ. of Iowa, Iowa City, IA, 52242.

In a new task, subjects must choose one card at a time from one of four decks. In two decks, choosing a card is followed by a high gain of play money, but at unpredictable points, the selection of a card is followed by a high penalty. In the other two decks, the immediate gain is smaller but the future loss is also smaller. After sampling and encountering losses in each deck, normal subjects begin to avoid the decks with high immediate gain (bad decks), and generate anticipatory skin conductance responses (SCRs) prior to selecting a card from these decks. Prefrontal patients do neither. Since these patients choose disadvantageously, even when they know which decks are good or bad, the somatic signalling indexed by anticipatory SCRs must be critical for the implementation of behavior. But does this mean that somatic signalling is triggered by "knowing" which decks are good or bad, or do the SCRs arise prior to such knowledge? SCRs were recorded from 6 normal subjects while performing the card task. At various points, subjects were briefly interrupted and asked what they understood of the game. In the pre-punishment period (before any penalty cards), anticipatory SCRs averaged 0.1 μ S in all decks, and subjects made an average of 13 selections from the good versus the bad decks. In the pre-conceptual period (after penalty cards, and before knowing good from bad decks), SCRs rose to 0.45 μ S in the bad decks, and remained 0.1 μ S in the good decks. These SCRs represented an average of 10.5 cards selected from the bad decks, and 16.7 cards from the good decks. In the post-conceptual period (after realizing which decks are good or bad), SCRs and number of cards were 0.5 μ S and 11.5 cards for bad decks, and 0.15 μ S and 20.8 cards for good decks. These results go counter to the idea that only pure reason is the basis for wise decisions, and supports the notion that at least part of our advantageous behavior can be guided by covert processes.

MECHANISMS UNDERLYING ORAL AND WRITTEN PRODUCTION DIFFERENCES IN APHASIC PATIENTS. H.L. Lutsep* and N.E. Dronkers. Center for Neuroscience, UC Davis, Davis, CA 95616; and VA Medical Center, Martinez, CA 94553.

Oral and written language abilities often differ in aphasic patients. This study examined this difference in six patients with aphasia following left hemisphere infarction. All had impaired fluency, as reflected in Western Aphasia Battery (WAB) fluency scores ranging from one to six on a ten-point scale. Using 24 nouns and 24 verbs matched for length, frequency and imageability, oral and written picture naming were compared with oral and written spelling of dictated words. Oral and written naming of five different letter sounds were compared to dictation, or repetition, of the five letters themselves. Spontaneous oral and written descriptions of the WAB "picnic scene" were also obtained. The picture naming, letter dictation and spontaneous scene description tasks elicited better oral than written performances. The dictated words and letter naming, however, were more proficiently written than orally spelled. In these aphasic patients, the tasks which required involvement of letter codes appeared to be better written than spoken, whereas those tasks which bypassed letter codes were more readily orally produced.

FRONTAL LESIONS INCREASE ATTENTIONAL SUPPRESSION IN RAPID SERIAL IDENTIFICATION. F. Richer*, M. Lepage. Lab. de Neurosciences, Université du Québec, Montréal, QC, H3C-3P8.

While attentional problems have long been associated with frontal lesions in humans, the mechanisms underlying these deficits are still poorly understood. We have previously shown that frontals can have problems finding target stimuli in sequences (Richer et al., 1993) but it is not clear whether the processes of target detection or identification are different in frontal patients. To test this, we examined the effect of a first identification on a subsequent one in six patients with frontal lesions and six normals. Subjects were asked to name the two white letters embedded in rapid sequences of 15-24 black letters presented centrally on a video monitor at rates of 6 or 8/sec. After 20 practice trials, 60 sequences were presented in which the first target letter (T1) appeared randomly at positions 9 through 15 and in which the second target letter (T2) appeared randomly at positions +1, +3, +5, or +7 following T1. Both frontals and normals showed near perfect identification of T1. In the case of T2, normals showed near perfect performance at all positions while frontals showed a poorer identification of T2 at T1+1 and T1+3 (50% correct), but not at T1+5 and T1+7 at a rate of 8 letters/sec. Frontals did not show this deficit at the slower presentation rate. These results indicate that target identification produces a more pronounced or longer lasting interference on subsequent processing in frontals than normals.

412.9

SOUND LOCALIZATION PERFORMANCES BEFORE AND AFTER A THERAPEUTIC HEMISPHERECTOMY. P. Poirier*, M. Lassonde, J.G. Villemure, F. Lepore. Groupe de Rech. en Neuropsych. Exp., Univ. de Montréal, Qc, Canada, H3C-3J7.

We previously reported that localization of sound sources in hemispherectomized patients was less accurate than that of the controls in the hemifield contralateral to their removed hemisphere. Moreover, their performances obtained with fixed sources were generally more precise than those obtained with moving sources (Neuropsychologia, 1994 in press). In order to precisely evaluate the effects of the hemispherectomy on free-field sound localization performances, the present study examined response accuracy to auditory targets in one patient, shortly before and 6 months after a functional right hemidecortication was performed. We also evaluated the performances of three matched controls. Listeners reported sound positions by pointing with their dominant hand to the apparent sound location in an anechoic chamber. Two conditions were tested: (i) localization of a fixed-sound source and (ii) localization of the beginning and the end of a simulated moving stimulus. Prior to the operation, the patient was performing almost as well as the controls when fixed sources were used; however, she was completely unable to perform the task with moving sources. After the operation, the patient's responses to fixed sources were less accurate than those of the controls in all positions tested in the hemifield contralateral to the removed hemisphere. Unexpectedly, the patient was now able to perform the moving task. These results are discussed in terms of the effects attributable to the surgery per se and they suggested the existence of a differential involvement of cortical and subcortical structures in the processing of stationary and moving sounds (supported by FCAR and CRSNG).

412.11

VISUOSPATIAL ATTENTION SHIFT IN CEREBELLAR DISORDER.

S. Yamaguchi*, H. Tsuchiya and S. Kobayashi. Third Div. of Internal Medicine, Shimane Med. Univ., Izumo, 693 Japan.

Cerebellum has been suggested to be involved in attentional shift mechanism. The present study investigated contributions of cerebellum on visuospatial attentional ability in a trial-by-trial cueing task involving covert orientation of visual attention. Event-related potentials (ERPs) and reaction times (RTs) were measured in patients with cerebellar degenerative disorders and age-matched controls. The cerebellar group had slower RTs to both valid and invalid targets. The effects of cue validity on RTs were larger for the cerebellar group in both the central and peripheral cue experiments, suggesting efficiency of the attention shift process in the cerebellar group. ERP data over the cue-target interval (i.e. 800msec) in the central cue experiment demonstrated comparable effects of voluntary attention shift in both groups, the effects which were reflected in negative potential shifts at contralateral parietal and temporal sites in the early stage and at central and frontal sites in the late stage. Peripheral cues also generated comparable effects of the early automatic and late voluntary attentional shift on ERPs in the cerebellar and control groups. The only difference in ERPs was CNV amplitudes, which were significantly diminished in the cerebellar group. These results suggest a preserved ability of visuospatial attention shift in cerebellar disorder.

412.13

BRAIN VOLUME AND NERVE CONDUCTION VELOCITY: CORRELATIONS WITH IQ. J. C. Wickett¹, P. A. Vernon¹, D. H. Lee², J. D. Brown³, D. W. Snow³ and B. K. Rutt². ¹Dept. of Psychology, Univ. of Western Ontario, London, ON N6A 5C2; ²Diagnostic Radiology and Nuclear Medicine, Univ. Hospital, London, ON N6A 5A5; ³Dept. of Clinical Neurological Sciences, Univ. of Western Ontario, Univ. Hospital, London, ON N6A 5A5.

Recent research in the field of intelligence has witnessed a resurgence in the search for biological explanations. The current study examines two such explanations: brain volume and nerve conduction velocity. This study is composed of two phases. In Phase I, 40 healthy adult female subjects (ages 20 to 30 years) underwent magnetic resonance imaging (MRI) and nerve conduction velocity (NCV) procedures. It was found that brain volume was significantly correlated with IQ ($r = .395, p < .05$), but that NCV measures (taken along the median nerve of the arm) were not so correlated ($r_s = -.12$ and $.02$, both ns). A reanalysis of this and past NCV findings indicated a possible sex difference with NCV being related to IQ in males but not in females. Finally, it was found that brain volume and NCV were not correlated (r_s from $.10$ to $.19$, all ns). Phase II of this study, which is currently under way (36 subjects collected to date, with new subjects being obtained at the rate of about 3 per week), expands on these findings with a sample of healthy adult male siblings. Beyond a simple replication, Phase II uses MRI procedures that allow for advanced multi-exponential calculations of white matter relaxation times in addition to assessment of brain volume, and also incorporates central, in addition to peripheral, NCV. The use of siblings allows for assessment of within as well as between family effects, and so can illuminate the types of genetic and/or environmental factors at work in obtained correlations.

412.10

SPATIAL SELECTIVE ATTENTION IN PATIENTS WITH PARIETAL AND TEMPORAL-PARIETAL LESIONS. A.P. Iha^{1,2}, A.F. Kingstone², G.R. Mangun^{1,2}. (1) University of California at Davis Department of Psychology, Davis, CA 95616. (2) Center for Neuroscience, Davis, CA 95616.

There has been growing evidence on the role of the parietal lobes in spatial selective attention. In detection paradigms, patients with parietal damage are slower to respond to invalidly cued contralesional targets than invalidly cued ipsilesional targets. Though the relative reaction time (RT) benefits of cue validity were maintained in these patients, they were impaired in their ability to "disengage" attention from the current focus and move it to the contralesional location (Posner et al., 1984). Here we used a discrimination task, wherein d' measures were utilized to understand the role of perceptual sensitivity in the disengagement deficit. Normal and age-matched controls, and patients with parietal and temporal-parietal lesions performed a task in which central arrow cues gave predictive information about where in space (left or right of fixation) targets were likely to occur. A go/no-go response was required, with both targets and nontargets occurring with equal probability. The d' results in normal and age-matched controls indicated that perceptual sensitivity was higher for validly than invalidly cued targets. Preliminary data from temporal-parietal patients showed this pattern as well. Parietal patients, however, did not show differences in d' as a function of spatial cueing, though their overall d' scores were comparable to those of the temporal-parietal patients.

412.12

COGNITIVE DEFICITS FOLLOWING CEREBELLAR LESIONS IN HUMANS: STUDIES OF ATTENTION AND VERBAL FLUENCY. L.L. Helmuth* and R.B. Ivry. Dept. of Psych, Univ. of California at Berkeley, Berkeley, CA 94720.

The human cerebellum may participate in a number of cognitive skills. Akshoomoff & Courchesne (1992) have reported that children with cerebellar damage show deficits on attention shifting tasks. Fiez, et al. (1992) have suggested that the cerebellum plays a role in error detection. These studies have involved either case reports or children with cerebellar disorders. We have tested these hypotheses on a group of adults with cerebellar pathology. One group has bilateral cerebellar atrophy, with some showing involvement of brainstem structures. Patients in the other group have unilateral focal lesions. Subjects were tested on the Posner cueing task, a semantically cued attention shifting task, a verbal fluency task, and a verbal discrimination task. Few differences were found between age-matched controls and cerebellar subjects from either group. Performance on these cognitive tasks was relatively spared despite a wide range of differences in the patients' deficits on motor tasks. Finally, we will compare the performance of cerebellar patients on attention shifting and error detection tasks with their performance on neuropsychological measures of frontal lobe function.

412.14

CENTRAL AUDITORY PROCESSING IN A FAMILY WITH 'DYSARTHRIA'. D.M. Daly*, Box 210855, Dallas, TX 75211-0855

'Dysarthrias' include various disorders involving control of movements in speaking. Using sets of computer synthesized sounds¹ we examined auditory processing in a 6 yr. old boy referred with a diagnosis of 'functional dysarthria' and seven other members from three generations of his family. All had appropriate audiometric thresholds for age. One sibling, mother, and maternal grandmother reported similar problems: their speech is difficult for unaffected individuals to understand, yet they understand each other with less difficulty; they have difficulty drawing circles, turning a screwdriver/rolling hair curlers, or pedaling a bicycle; they are athletically challenged; they also have difficulty 'carrying a tune'. Two generations have received school based speech therapy; all three generations reported that speech improved spontaneously at 10-11 yr. All performed at or above grade level on core subjects. Unaffected individuals are free of these problems.

On sets of time varying synthesized sounds, neither proband, mother nor maternal grandmother distinguished BW. Mother and maternal grandmother reported GY as vocalic *e* and *ye* with clear transition 20-30 msec less than controls. The affected sibling also differed significantly from controls. On sets of frequency varying sounds (BDG) mother and sons were less aberrant. Paternal grandmother, father, paternal aunt, and proband's unaffected brother had clear, well-defined transitions. Concurrent testing of affected and unaffected members confirmed marked perceptual differences; LRCS measures of divergence from individual and control composites substantiated pairwise intelligibility ratings. Distribution in the pedigree is compatible with autosomal dominant expression.

A VERBAL ABSTRACTION DEFICIT IN MULTIPLE SCLEROSIS. W.W. Beatty*, K.A. Hames, C.R. Blanco, R.H. Paul and S.L. Wilbanks. Dept. Psychiatry & Behavioral Sciences, University of Oklahoma Health Sciences Center, P.O. Box 26901, Oklahoma City, OK 73190.

Impairments on nonverbal tests of abstraction by patients with multiple sclerosis (MS) have been reported frequently, but findings on the verbal Similarities test from the WAIS are equivocal. To reexamine the status of verbal reasoning in comparison to nonverbal reasoning in MS we administered the Shipley Institute of Living Scale (SILS), the Wisconsin Card Sorting Test (WCST), and a shortened version of the Free Sorting part of the California Card Sorting Test (CCST) to 100 MS patients and 32 age- and education-equated control subjects. Patients achieved fewer categories on the WCST, fewer correct sorts on the CCST, and lower scores on the Abstraction scale from the SILS than did control subjects. Patients also scored lower on the Vocabulary Scale from the SILS, but because they also attained lower Conceptual Quotients, their poorer performance on the verbal abstraction cannot be attributed solely to lower verbal ability. Perseverative responding by patients was clearly elevated on the WCST, marginally increased on the CCST, and did not occur on the SILS, suggesting that difficulties in generating and identifying concepts are the major reasons MS patients often have difficulty on tests of problem solving or abstract reasoning.

VISUOSPATIAL DYSFUNCTION AND PROBLEM SOLVING IN PARKINSON'S DISEASE. A. Cronin-Golomb*, A.E. Braun. Department of Psychology, Boston University, Boston MA 02215.

Impaired performance by subjects with Parkinson's disease (PD) on Raven's Coloured Progressive Matrices (RCPM) contrasts with their normal performance on other problem-solving tasks and suggests an underlying visuospatial deficit. We analyzed RCPM results in 59 subjects with PD (9 demented), 45 subjects with Alzheimer's disease (AD) (19 with extrapyramidal signs), and 39 healthy age-matched control subjects. The PD and AD groups all performed deficiently, especially the demented PD group. For the nondemented PD group, scores on the RCPM subtest that mainly assessed visual closure ability (RCPM-A) correlated consistently with scores on other visuospatial tests but not non-visuospatial tests. The results support the view that there is a visuospatial deficit in PD, exacerbated by dementia, and that this deficit may adversely affect problem solving. The brain basis of the visuospatial dysfunction may be the posterior parietal lobes, a major component of the basal ganglia-thalamocortical circuit that also includes the dorsolateral prefrontal cortex.

412.19

DOES IMPAIRMENT OF WORKING MEMORY PRECEDE DEVELOPMENT OF DEMENTIA IN EARLY ALZHEIMER'S DISEASE? S. Murtha, H. Chertkow*, H. Bergman, N. Phan, Bloomfield Center for Studies in Aging, Lady Davis Institute, Jewish General Hospital, Montreal, Quebec, Canada.

Working memory (the store capable of holding information in memory while another cognitive task is performed) is impaired in subjects with dementia of the Alzheimer type (DAT) compared with elderly control subjects. We wished to examine whether working memory impairment might be demonstrable in elderly subjects not yet meeting criteria for dementia but having Age Associated Cognitive Decline (AACD).

Working memory was assessed with the Brown/Peterson task on 15 DAT, 17 AACD, and 12 elderly control subjects. On this task, consonant trigrams (three letters presented visually) are recalled over periods of short duration (0, 5, 10 seconds (s)). During the time interval the subject is either allowed to rehearse the material with no distraction or is distracted with subsidiary tasks (articulation or digit reversal).

The results indicated that the average percentage of trigrams recalled by the three groups differed the most for the digit reversal distraction condition. The DAT subjects showed a moderate decline after 5s (55%) and 10s (42%) delay intervals, and the AACD subjects showed a mild decline at both the 5s (83%) and 10s (77%) interval. Elderly controls showed considerably less decline in both conditions.

The percentage of trigrams recalled with digit reversal distraction after 5s indicated that the control subjects never showed greater than a 20% decline from baseline performance. 4/17 of the AACD subjects, and 10/15 of the DAT subjects demonstrated a decline below this performance level. These results demonstrate that working memory is not only impaired in DAT, but also in AACD subjects.

It is known that up to 2/3 of AACD patients eventually progress to dementia. Since working memory impairment can be demonstrated in a percentage of the AACD subjects it is possible that this might be a cognitive marker for future development of dementia.

412.16

DISORDERS OF PROSODY IN PARKINSON'S DISEASE H. Cohen*, Laboratory of cognitive neuroscience, Université du Québec, PB 8888, Station A, Montreal, Qc, Canada H3C 3P8

Disturbances of intonational patterns of speech are some of the most common signs in Parkinson's disease (PD). If deficits in movement planning are responsible for this deterioration, we should then observe greater impairment in PD as the speech production tasks become more difficult. In this study we attempted to determine whether PD patients are more impaired, relative to controls, in the production of simple vowel syllables in increasingly more complex intonation contexts. Twenty non-demented PD patients (mean age = 68.6) and 15 controls matched for age and education (all subjects ≤ 75 yr and no other neurologic or psychiatric disorder) were asked to produce the vowels /a, e, o/ in four intonation conditions: two stable contexts (low and high intonation) and two unidirectional change contexts (ascending and descending intonation) for a period of five seconds. Subjects were recorded individually in a soundproofed room and speech was then digitized to extract indices of fundamental frequency (F_0). ANOVAS were conducted on F_0 measures, for each intonation condition, to determine the extent of group differences. Except for the low stable intonation condition, analyses revealed main effects of Group, suggesting a significantly more restricted F_0 range in PD patients when producing vowels in stable high, as well as in ascending and descending intonation conditions (all p 's $< .001$). The results suggest that the subcortical structures affected in idiopathic movement disorders are also involved in disorders of prosody. These structures are implicated in deficits in planning and sequential execution of movement and cognitive acts.

AGE-RELATED CHANGES IN THE ELECTROPHYSIOLOGICAL RESPONSE TO VISUAL STIMULUS NOVELTY: A TOPOGRAPHICAL APPROACH. K.M. Thomas*, C.A. Nelson, and S.M. Malone, Institute of Child Development, University of Minnesota, Minneapolis, MN 55455.

In this study we examined age-related changes in the scalp distribution and topography of the novelty response in a visual event-related potential (ERP) paradigm in order to examine the possible neural substrates underlying such responses. ERP data were collected from neurologically normal adults (mean age=24) and children (mean age=8). Participants completed a variation of the oddball paradigm with frequent non-target (70% probability), infrequent target (15% probability) and infrequent novel (15% probability) stimuli. Two female faces posing neutral expressions served alternately as the target or non-target stimulus. Novel stimuli consisted of non-repeating (trial-unique), easily recognizable scenes, objects and animals, as well as abstract patterns which were difficult to label verbally. Participants were required to press a button in response to the target stimuli while disregarding all other stimuli. An incidental memory task at the conclusion of the session assessed memory for the irrelevant novel stimuli. Preliminary results indicate age-related differences in the amplitude of the N200 and the latency of the P300 components to the target and novel stimuli. Topographical maps of activity to the novel stimuli show a pattern of frontal activation in children not seen in adults. Results are compared to previous work with infant subjects and are discussed in terms of differences in attentional capacity, as well as the role of hippocampal and frontal lobe development in mediating the novelty response.

IMPAIRED AUTONOMIC RESPONSES TO EMOTIONALLY SIGNIFICANT STIMULI IN ALZHEIMER'S DISEASE. C.-C. Chu*, D. Tranel, A. R. Damasio, Dept. of Neurology, Univ. Iowa, Coll. Med., Iowa City, IA 52242

Pathological changes in Alzheimer's disease (AD) selectively involve layer V neurons in Brodmann's area 25, posterior orbitofrontal cortex, and anterior insula, which project directly to subcortical autonomic centers. Disruption of these cortico-autonomic projections would be expected to compromise autonomic responses. We hypothesized that autonomic responses elicited by emotionally significant pictures would be impaired in AD patients. Color slides with high (target) or low (nontarget) emotional significance were shown for 6-s each while skin conductance and heart rate were measured. Target pictures significantly increased heart rate and skin conductance in non-demented age-matched controls (N=18). However, in mild-moderate AD patients (N=18), this effect was completely absent for heart rate responses and severely diminished for skin conductance responses. The autonomic response defect in the AD patients was specific to emotionally-charged stimuli. The initial cardiac deceleration during perception was intact, as was the ability to generate skin conductance responses to deep breathing and loud noises. Heart rate change during withheld deep breathing was also normal. The results demonstrate defective autonomic responses to emotionally charged stimuli, which may be attributed at least in part to the disruption of cortico-autonomic projections in AD patients. The findings are consistent with our proposal that activation of somatic states which play an important role in decision-making and social behavior depends on ventromedial cortices.

SIMULTANEOUSLY RECORDED NEURONS IN THE LATERAL AMYGDALA OF FREELY MOVING RATS DURING FEAR CONDITIONING. G.J. Quirk*, P. Tao, J.C. Repa, and J.E. LeDoux. Center for Neural Science, New York University, NY, NY 10003.

To understand the neural mechanisms underlying the processing of an acoustic conditioned stimulus (CS) paired with a footshock unconditioned stimulus (US) during fear conditioning, we recorded simultaneously isolated cells in the lateral nucleus of the amygdala (LA) with a movable bundle of microwires in freely moving rats. Responses to the CS (2 sec pure tone) were compared during trials involving sensitization (unpaired CS and US), conditioning (CS-US pairing), and retention (CS alone) trials. For 12/16 neurons recorded from the dorsal LA and the immediately adjacent amygdalo-striatal transition area, CS elicited responses at the end of conditioning increased an average of 5 times above sensitization. One hour post-conditioning this increase was maintained or increased for 7 cells. About one-third of the cells exhibited increases within the first 20 ms of the CS, while the increase occurred at latencies of 20-40 ms in the others. Early responses are most likely pre-cortical, while later responses may involve cortical areas. Cells in ventral part of LA or in the caudate-putamen were tone-responsive but failed to show conditioned responses. Cross-correlations between the spontaneous spike trains of cell pairs revealed examples of synchronous firing, recurrent inhibition, and monosynaptic excitation. In some cases, conditioning-induced changes in these measures were observed, suggesting plasticity in local connections. NIMH 38774, 46516, 00956.

FACILITATION OF AMPA RECEPTORS ACCELERATES CLASSICAL FEAR CONDITIONING IN RATS. M. Rogan*, U. Staubli, J.E. LeDoux. Center for Neural Science, New York University, NY, NY 10003

Ampakines are a class of drugs that facilitate AMPA receptor-mediated synaptic responses. This has the effect of increasing NMDA receptor-mediated currents in cells containing both NMDA and AMPA receptors. Ampakines have a documented memory-enhancing effect on several learning tasks, and also accelerate LTP induction *in vitro* and *in vivo*. Since fear conditioning has been found to be disrupted by interference with NMDA function, the possible enhancing effect of ampakines on fear conditioning was assessed in the present study. Rats were trained on a task that consisted of 2 pairings a day of an acoustic conditioned stimulus (CS: 10KHz, 80 dB, 20s) with a footshock unconditioned stimulus (US: 0.3mA, .5s) for 2 consecutive days. Thirty minutes prior to training on each of the 2 training days, the ampakine group (n=6) received an i.p. injection of CX-516 (50mg/kg), and the control group (n=3) received the equivalent volume of vehicle (cyclodextrin 33%). On the third day, both groups received injections of vehicle 30min prior to 2 trials of the CS alone. Learning was assessed by measuring the time accounted for by freezing during the 20s CS. The control group displayed normal acquisition of CS conditioning, freezing 6s after 1 day of training, and 11s after the second day of training. The ampakine group froze twice as much as the controls after one day of training (13s), a level that controls required 2 days of training to reach. That this effect is not reflective of a general increase of fearfulness, nor simply a hyper-reactivity to the CS, is indicated by the fact that neither group displayed any unusual behavior, nor froze to the CS or context prior to the first CS/US pairing. These findings are consistent with ampakine-induced acceleration of the formation of the aversive association between the CS and the US. That ampakine significantly accelerated, but did not significantly increase the ceiling, of learning is consistent with data on ampakine effects on LTP. Supported by MH38774, MH46516, MH00956.

POSTTRAINING LESIONS OF PERIRHINAL CORTEX DISRUPT CLASSICAL FEAR CONDITIONING: CONTRIBUTION OF CONTEXTUAL CUES. K.P. Corodimas* and J.E. LeDoux. Center for Neural Science, New York University, NY, NY 10003.

Posttraining lesions of the rostral perirhinal cortex (rPRh) disrupt conditioned fear responses to auditory and visual stimuli when presented in a novel context. We examined whether rPRh lesions have similar effects in the training context. Two days after male rats received classical fear conditioning, involving the pairing of an auditory conditioned stimulus (CS) with footshock, bilateral electrolytic lesions were produced in the rPRh. Five days later, conditioned fear (freezing) was measured to a 60 sec CS in a novel context and then in the training context. There were three major findings. First, lesioned animals froze significantly less than controls to the CS in the novel and in the training context. Second, lesioned animals also froze less to the training context itself. Third, rPRh-lesioned animals froze more to the CS in the training context than in the novel context. These findings suggest that rPRh lesions affect conditioning to contextual and discrete stimuli, and despite deficits in contextual processing, rPRh-lesioned animals were able to use contextual information to facilitate retrieval of memories about the aversive CS. We conclude that rPRh lesions affect processes related to information storage or retrieval. Supported by MH46516, MH38774, MH00956 and NSF9209646.

EFFECTS OF CORTICAL LESIONS ON GENERALIZATION OF LEARNED FEAR RESPONSES. J.L. Armony*, D. Servan-Schreiber and J.E. LeDoux. Center for Neural Science, New York Univ. and Dept. of Psychiatry, Univ. of Pittsburgh School of Medicine.

Auditory information reaches the lateral nucleus of the amygdala by way of two parallel pathways. The first one involves a direct projection from the auditory thalamus, whereas the second pathway involves transmission over thalamo-cortical routes, ultimately to the amygdala. Either pathway is sufficient for eliciting fear responses to a single auditory conditioned stimulus (CS) paired with a footshock (Romanski & LeDoux, 1992). Nevertheless, the two pathways have different physiological properties, which suggest that the cortical input to the amygdala may be necessary for an accurate representation of complex sensory stimuli. In order to further investigate the processing limitations of the direct pathway, we began a series of studies involving lesions of the auditory cortex in rats. Two weeks after aspiration of most of primary auditory cortex, animals were conditioned to a single tone paired with a 1mA footshock in a conditioned suppression of operant responding paradigm. Following conditioning, auditory stimuli of different frequencies were presented and a stimulus generalization gradient (SGG) was obtained. These lesions did not have a significant effect on the SGG. If confirmed by larger lesions, including damage to auditory association cortices, these results would suggest that the auditory cortex may not be essential for some aspects of frequency analysis. These results are consistent with predictions of a computational model of the neural circuit involved in fear conditioning (Armony et al., 1993, 1994). Supported by MH38774, MH 46516 and MH00956.

ETHANOL (ETOH) PRE-TREATMENT SELECTIVELY IMPAIRS CLASSICAL CONDITIONING OF CONTEXTUAL CUES: POSSIBLE INVOLVEMENT OF THE HIPPOCAMPUS. K. Melia*, K. Corodimas, A. Ryabinin, M. Wilson and J. LeDoux. Ctr. For Neural Science, N.Y.U., NY, NY, 10003, and Dept. Neuropharm., Scripps Res. Ins., La Jolla, CA, 92037.

ETOH pre-treatment significantly attenuates the induction of c-fos mRNA by restraint stress in hippocampus but not cortex, suggesting that ETOH intoxication impairs information processing at the level of the hippocampus (Ryabinin et al., Neurosci. Abs., 1993). This finding led us to hypothesize that ETOH exposure prior to classical conditioning would impair acquisition of hippocampal dependent associations, such as conditioning to context, but not hippocampal independent associations, such as conditioning to a tone. To test this hypothesis animals were injected with NaCl or 1.0, 1.5, or 2.0 g/kg 16% ETOH (n=6/group) 10 min prior to the presentation of 10 tone (80 dB)/foot shock (0.5 mA) pairings. Conditioned freezing to context and to the tone were measured (20s/trial) 48 hours later. Time spent freezing to context was significantly and dose dependently decreased in animals pre-treated with ETOH (NaCl = 16s; ETOH1.0 = 12s; 1.5 = 7s; 2.0 = 2s), while freezing to the tone was not affected except at the highest ETOH dose (NaCl = 18s; ETOH 1.0 = 17s; 1.5 = 17s; 2.0 = 13s).

These findings indicate that ETOH intoxication selectively impairs the acquisition of contextual conditioning. In light of our previous finding, it is possible that this impairment is due to inhibition of information processing at the level of the hippocampus. Experiments to determine whether ETOH pre-treatment alters the induction of c-fos mRNA in the hippocampus by this classical conditioning paradigm are currently underway. MEDIAL ORBITAL CORTEX LESIONS INCREASE RESISTANCE TO EXTINCTION BUT DO NOT AFFECT ACQUISITION OF FEAR CONDITIONING. M.A. Morgan*, J.E. LeDoux. Center for Neural Science, New York University, NY, NY 10003

As part of an ongoing series of experiments to examine the role of medial prefrontal cortex in fear, we examined the effects of lesions of medial orbital cortex (MO) in a fear conditioning task. Rats received lesions of MO (n=9) or sham lesions (n=12). Two weeks after surgery, they received 2 pairings a day of a tone conditioned stimulus (CS: 10KHz, 80 dB) with a footshock unconditioned stimulus (US: 0.5mA, 0.5sec.) for 2 consecutive days (acquisition). The following days were the same but no US was presented (extinction). Testing continued until extinction criterion (5 sec or fewer freezing during the CS and pre-CS on two consecutive days) was met. Conditioning to both the CS and to the context in which conditioning took place were examined. MO lesioned rats did not differ significantly from controls during acquisition to either the context or the CS. They did, however, take significantly longer to extinguish to both stimulus types. It is unlikely that this effect is due to a general increase in learned fear, given that there is no apparent increase in freezing during acquisition. Instead, the effects may reflect an emotional equivalent of the cognitive perseveration found after frontal cortex damage in humans and other primates. This conclusion is consistent with findings from single cell recordings in monkey orbitofrontal cortex indicating that these cells play a crucial role in updating the brain as to the present reward value of a stimulus. SEPTAL LESIONS POTENTIATE FREEZING BEHAVIOR TO CONTEXTUAL BUT NOT TO PHASIC CONDITIONED STIMULI. P.D. Sparks* and J.E. LeDoux. Department of Psychology and Center for Neural Science, New York University, NY, NY 10003.

Damage to the hippocampal formation interferes with the conditioning of fear responses to contextual but not phasic conditioned stimuli. Given the anatomical connections and functional relationship between the hippocampus and the septum, we examined the effects of septal lesions on the conditioning of fear reactions to phasic and contextual stimuli. In the first experiment, rats with electrolytic lesions ($n=9$) or sham operations ($n=9$) of the septum were studied. Two weeks after surgery, blocks of two conditioning trials consisting of a tone (10 kHz, 75 dB, 20 sec) paired with a foot shock (500 msec, 0.5 mA) were presented on two consecutive days. Tone alone trials were presented each day thereafter until extinction criterion was met. The amount of freezing elicited by the context but not by the tone was greater in the septal lesioned animals than in controls. The lesions involved the lateral and to a lesser degree the medial septum. In experiment two, quisqualic acid (27.7 mg/ml, 550 nl; $n=4$) or vehicle ($n=6$) was infused into the septum. The rats were treated as above. These lesions, which mainly involved the lateral septum, also potentiated the freezing elicited by the context but not the tone. Neurons in the septum thus appear to be involved in the acquisition and/or expression of defensive reactions to a dangerous context. Supported by NSF9209646, MH38774, and MH00956.

HIPPOCAMPAL LESIONS BLOCK LATENT INHIBITION BUT NOT NEGATIVE TRANSFER BY A NON-NMDA RECEPTOR MEDIATED PROCESS. S. L. Young*, S. Maren and M. S. Fanselow. Dept. of Psychol., Univ. of Cal., Los Angeles, CA 90024-1563.

Latent inhibition describes a Pavlovian learning deficit caused by preexposure to the conditional stimulus (CS). Negative transfer is also a learning deficit but is caused by prior pairing of the CS with a weak unconditional stimulus (US). The two phenomena have traditionally been considered the result of a similar CS processing deficit. Evidence that both negative transfer and latent inhibition are context specific support this speculation. Latent inhibition is reversed by hippocampal lesions but the hippocampus dependence of negative transfer has never been tested. Experiment 1 examines the possibility that negative transfer is hippocampus dependent like latent inhibition. Hippocampal lesions blocked latent inhibition but had no impact on negative transfer. These results provide evidence that latent inhibition and negative transfer are different. The second set of experiments examined the role of NMDA receptors in latent inhibition. Application of a competitive NMDA receptor antagonist (APV, 5 μ g/rat) had no impact on hippocampus and context dependent latent inhibition. These results are surprising because NMDA receptor mediated processes in the hippocampus are important for learning to recognize contextual cues. SEX DIFFERENCES IN HIPPOCAMPAL LONG-TERM POTENTIATION (LTP) AND PAVLOVIAN FEAR CONDITIONING IN RATS. M. S. Fanselow*, S. Maren and B. De Oca. Department of Psychology, University of California, Los Angeles, CA 90024-1563.

An emerging body of evidence indicates that the hippocampus is required for some forms of classical conditioning, particularly Pavlovian fear conditioning to contextual conditional stimuli (CSs). Lesions placed in either the fornix, dorsal hippocampus, or entorhinal cortex produce marked impairments in contextual fear conditioning. Additionally, recent data indicate that manipulations which affect hippocampal LTP, such as NMDA receptor antagonists or water deprivation, also affect context conditioning. Because there are sex differences in the performance of many hippocampus-dependent learning tasks in rats, we sought to determine if there are corresponding sex differences in hippocampal LTP and contextual fear conditioning. Pentobarbital-anesthetized rats of three ages (20, 35, and 60 days) were implanted with a bipolar recording electrode in the hilus of the dentate gyrus and a stimulating electrode in the perforant path. There was a robust sex difference in the magnitude of LTP induced in both 35 and 60 day old rats (20 day old rats did not show LTP) with males showing significantly greater LTP than females. This sex difference in LTP was correlated with a similar sex difference in levels of NMDA receptor activation during LTP induction. In addition to sex differences in LTP, we also observed a significant sex difference in fear conditioning to contextual cues. When tested in a chamber that was paired 24 hours earlier with footshock, male rats showed substantially greater levels of freezing, a species-specific fear response, than their female counterparts. This sex difference in freezing was specific to contextual fear conditioning because fear conditioning to a discrete tone CS was not different in male and female rats. The positive correlation between sex differences in hippocampal LTP and contextual fear conditioning provides further evidence for a linkage between the two. 413.8

C-FOS mRNA EXPRESSION FOLLOWING FOOTSHOCK STRESS AND CONTEXTUAL FEAR CONDITIONING. J. B. Rosen¹*, M. S. Fanselow², S. L. Young² and S. Maren². ¹Biological Psychiatry Br., NIMH, Bethesda, MD 20892, ²Psychol. Dept., Univ. of Cal, Los Angeles, CA 90024-1563.

Rats display conditional freezing behavior to contextual cues associated with footshock. Although the amygdala plays a prominent role in the expression of fear, and the hippocampus plays a role specific to contextual fear, little is known about other forebrain regions involved in fear. Therefore, this study examined regional expression of *c-fos* mRNA as a marker for cellular activity elicited by footshock and by context conditioning. Rats were given either a footshock immediately or 3 minutes after placement in a chamber. Other rats were placed in the chamber without receiving footshocks or handled without exposure to the chamber. Half of the rats in each group were sacrificed 15 minutes after exposure. The other half were re-placed in the chamber without shock 24 hours later for a retention test and sacrificed 15 minutes later. Only rats receiving shock 3 min after placement in the context showed significant levels of freezing. *In situ* hybridization with a cRNA probe complementary to *c-fos* mRNA was conducted. Image analysis revealed increased *c-fos* mRNA in the medial nucleus of the amygdala following both types of shock, but no increases after the retention test. No differences were found in the dorsal hippocampus. *C-fos* mRNA was increased in the pyriform cortex in both shock groups after both test situations. Cingulate and parietal cortices of all groups exposed to the context had increased *c-fos* mRNA levels relative to handled controls. The results demonstrate a complex pattern of activity of forebrain regions in response to shock and contextual fear conditioning.

413.10

SYNAPTIC PLASTICITY IN PROJECTIONS FROM THE ENTORHINAL CORTEX TO THE BASOLATERAL AMYGDALA IN ANESTHETIZED RATS: AN EXTRACELLULAR FIELD POTENTIAL ANALYSIS. S. Maren* and M. S. Fanselow. Department of Psychology, University of California, Los Angeles, CA 90024-1563.

Pavlovian fear conditioning to contextual conditional stimuli (CSs) in rats requires the hippocampus for CS representation, but not CS-unconditional stimulus (US, footshock) association. CS-US association is presumed to occur in the amygdala and may be mediated by an activity-dependent synaptic plasticity in anatomical pathways that convey context information to the amygdala. One putative context CS pathway consists of monosynaptic projections from the lateral entorhinal cortex (LEA) to the basolateral nucleus of the amygdala (BL). In the present study, we sought to determine if this pathway is capable of physiological plasticity and, if so, the nature of the plasticity. Urethane-anesthetized adult male Long-Evans rats were implanted with a bipolar stimulating electrode in the LEA and a recording electrode in the posterior BL. Single-pulse stimulation (0.1 - 2.0 mA) of LEA evoked a reliable biphasic extracellular field potential (FP) in BL, which consisted of a negative-positive-negative waveform (peak-to-peak amplitude = 1 mV). LEA-evoked unit firing in BL occurred with a short latency (5 - 8 ms) and was correlated with the initial negativity of the FP. High stimulation intensities (>500 μ A) revealed a sharp negative-going potential, possibly a population spike (PS), that was superimposed on the initial negativity of the FP. Paired-pulses (10-100 ms ISI) or short (10 ms) trains of high-frequency stimulation (HFS, 50 or 100 Hz) revealed short-term plasticity of LEA-BL field potentials, which was manifest as an increase in the amplitude of the FP peak negativity. Longer trains of HFS (10 200 ms bursts of 100 Hz delivered at 1 Hz; series repeated four times at 5 min intervals) revealed a long-term potentiation (LTP) of LEA-BL responses. In contrast, the same number of pulses delivered at low frequency (1 Hz) produced a long-term depression (LTD) of the responses. Synaptic plasticity such as that reported here may underlie CS-US association during fear conditioning. Supported by NSF grant BNS-9008820 to MSF.

DIFFERENTIAL EFFECTS OF VENTRAL AND DORSAL PERIAQUEDUCTAL GRAY (PAG) LESIONS ON DEFENSIVE RESPONSES OF RATS TO CATS, SHOCK AND TASTE AVERSION. B. De Oca, J. P. DeCola, J. C. Liebeskind* and M. S. Fanselow. Department of Psychology, University of California, Los Angeles, CA 90024-1563.

Anatomical structures within the midbrain have been implicated in fear-related and defensive behavior. The present experiments showed that lesions of the midbrain that included damage to the ventral portions of the periaqueductal gray (PAG) reduced the defensive freezing response of rats to the presence of a cat. Lesions that spared the ventral PAG did not affect freezing to a cat even if they produced extensive damage to the dorsal PAG, lateral PAG and superior colliculus. We also examined freezing conditioned by exposure to electric footshocks. Massed shocks produced less freezing than spaced shocks. This difference was eliminated by midbrain lesions because ventral PAG lesions reduced freezing under both conditions and dorsal-lateral PAG lesions selectively enhanced freezing in the massed condition. Midbrain lesions did not influence taste aversions to a saccharin solution that was associated with the gastrointestinal malaise produced by LiCl. Supported by NIMH grant MH-39786 to MSF.

413.13

LESIONS OF THE AMYGDALA BLOCK CONDITIONED EXCITATION BUT NOT CONDITIONED INHIBITION OF FEAR MEASURED WITH FEAR-POTENTIATED STARTLE. W.A. Falls* & M. Davis. Dept. of Psychiatry, Yale Univ. Med. Sch., 34 Park St., New Haven, CT 06508.

Although much is known about the neural systems responsible for the acquisition and expression of conditioned fear, little is known about the neural systems responsible for the inhibition of fear. We have recently detailed a behavioral procedure for producing conditioned inhibition of the fear-potentiated startle effect. Following training in which a light is repeatedly paired with shock (i.e., light+) and a light-noise compound is presented without shock (i.e., noise—light-), the noise acquires the ability to inhibit fear-potentiated startle to the light in a noise—light summation test (Falls & Davis, 1993; *Neurosci. Abs.* vol. 19, p.372, #155.6).

Amygdala lesions performed after either moderate or extensive training block fear-potentiated startle. However, if lesions are made after extensive training, fear-potentiated startle can be re-acquired. Because of this, it is possible to use a summation test to assess whether lesions of the amygdala would disrupt previously acquired conditioned inhibition. Rats were given 15 light+shock pairings on each of 2 days followed by conditioned inhibition training consisting of 5 light+shock trials intermixed with 15 noise—light- no shock trials on each of 5 days. Testing occurred 1 day later. All rats showed conditioned fear to the light as defined by greater startle amplitude in the presence of the light than in its absence. All rats showed conditioned inhibition of fear, defined as a reduction in fear-potentiated startle to the light when accompanied by the noise. One day later, half of the rats were given amygdala lesions and half were sham operated. All rats were tested 1 week later. As expected, lesions of the amygdala blocked fear-potentiated startle to the light. On each of the next 5 consecutive days, the rats were retrained with light+shock pairings with no further conditioned inhibition training. Testing occurred 1 day later. Amygdala lesioned rats re-acquired fear-potentiated startle to the light. Importantly, the noise conditioned inhibitor retained its ability to inhibit fear-potentiated startle to the retrained light.

These results indicate that areas of the amygdala critical for initial performance of fear-potentiated startle are not critical for the expression of conditioned inhibition.

413.15

DIFFERENTIAL EFFECTS OF AMYGDALA LESIONS ON ANTINOCICEPTIVE AND CARDIOVASCULAR RESPONSES TO CONDITIONAL AND UNCONDITIONAL AUDITORY STRESSORS. F.J. Helmstetter*, G. Gale & S.A. Tershner. Department of Psychology, University of Wisconsin, Milwaukee, WI 53201

Exposing rats to a tone that has been paired with shock or to a novel loud noise will provoke a set of fear-related defensive behaviors which includes a simultaneous increase in arterial blood pressure (ABP) and decrease in sensitivity to pain. In the present study we directly compared the expression of conditional and unconditional fear responses using these two dependent measures in animals with small lesions of the basolateral amygdala (BLA). Groups of rats were first exposed to a series of paired (or unpaired) presentations of a tone CS (60sec, 72dB) and shock and then prepared with arterial catheters and lesions. During subsequent testing all rats were exposed to both the CS and white noise (60 sec, 95dB) while recording ABP and radiant heat tail flick (TF) latencies. Both auditory stimuli produced significant inhibition of TF in sham-operated animals that had received paired training. As reported previously, amygdala lesions blocked both forms of hypoalgesia. Both stimuli also produced large time-dependent elevations in ABP with the noise-evoked response being considerably larger. However, animals with BLA damage that blocked hypoalgesia showed normal or potentiated ABP responses to both stimuli. These results suggest that neural systems responsible for the expression of learned versus unlearned fear responses may not differ although the control of ABP and TF may be dissociable within the amygdala.

413.17

A PRIMARY ACOUSTIC STARTLE REFLEX CIRCUIT: ROLE OF AUDITORY ROOT NEURONS AND THE NUCLEUS RETICULARIS PONTIS CAUDALIS. Y. Lee*, D. López, E. Meloni, & M. Davis. Dept. of Psychiatry, Yale Univ. Sch. of Med., New Haven, CT 06508.

Our laboratory proposed a primary acoustic startle circuit that consisted of the auditory nerve, posteroventral cochlear nucleus (VCP), an area ventral and medial to the ventral nucleus of the lateral lemniscus (VLL), the nucleus reticularis pontis caudalis (PnC), and motoneurons in the spinal cord (Davis et al. 1982; Cassella & Davis 1986). While lesion and stimulation data generally supported this circuitry, the relatively large lesion size and the nonselective nature of electrical stimulation made it difficult to identify the acoustic startle circuit more precisely. For example, lesions of VLL in the original study often included the paralemniscal zone (PL), ventro lateral tegmental area (VLTg), and the caudal extension of these areas. Therefore, the present studies re-evaluated the role of structures previously implicated in the primary acoustic startle circuit using discrete bilateral electrolytic and chemical lesion techniques.

Small electrolytic lesions of VLL, PL and VLTg failed to eliminate the startle reflex, whereas large electrolytic lesions including the area ventral to VLL and the caudal extension of this area (ventrolateral PnC) substantially blocked the startle reflex (88%). Furthermore, NMDA lesions restricted to the rostral part of ventrolateral PnC failed to eliminate the startle reflex, whereas NMDA lesions of the full extension of ventrolateral PnC or the lateral PnC plus the ventrolateral PnC blocked the startle reflex (88%, 90% respectively), suggesting only the ventrolateral PnC is critically involved.

In rodents, neurons have been found embedded in the cochlear nerve, named cochlear root neurons (RN), that receive input from the cochlea, and have very thick axons that give off collaterals terminating contralaterally in the ventrolateral PnC (López et al., 1993). Because it has been suggested that RN may be involved in acoustic startle (Lingenhöl & Friauf, 1994), we tested their role in the acoustic startle reflex. Kainate lesions of RN reduced the acoustic startle reflex by 90%, despite the fact that these animals still oriented to sudden noise, and had intact evoked potentials recorded from the VCN using 65-87 dB white noise pulses or 10 kHz tones.

Although the role of the VCP is yet to be fully determined, we now think that the acoustic startle pathway in the rat may be simpler than we had originally thought, consisting of only three synapses onto 1) RN; 2) neurons in the ventrolateral PnC; 3) motoneurons in the brain stem and spinal cord

413.14

CHOLINERGIC SYSTEMS AND THE CONSOLIDATION OF CONTEXTUAL AND AUDITORY FEAR CONDITIONING IN INFANT RATS. Jerry W. Rudy* and Rachael Hermance.

Department of Psychology, Univ. of Colorado, Boulder, Co 80309

Rats 23 days old that experience a pairing of an auditory cue and shock (1 mA) 24 hrs later show conditioned freezing to both the conditioning context and the auditory cue. Scopolamine hydrobromide (1.0 mg/kg) given prior to conditioning, however, blocked both forms of fear conditioning. Yet, the peripheral antagonist, methylscopolamine had no effect on either contextual or auditory cue fear conditioning. Scopolamine also retroactively influenced both forms of conditioning: Rats administered the drug either 10, 30, or 120 min after the shock also showed reduced conditioning. Yet, when the drug was administered 24 hrs after training, it had no effect. A 2-min exposure to the context 24 hrs prior to conditioning, however, protected the animals against the effects of the cholinergic blockade on contextual fear conditioning. These results suggest that central cholinergic systems play an important role in the consolidation of the memory for both contextual and auditory fear conditioning in infant rats. They also suggest that cholinergic systems contribute to contextual fear conditioning by mediating the consolidation of a memory representation of context.

MK801 ATTENUATES BOTH STARTLE PREPULSE INHIBITION AND CONDITIONED FEAR SENSITIZATION. J. Cranney*, T. Haralambous, G. Paxinos and M. Kieman. School of Psychology, The University of New South Wales, Sydney, 2052, Australia.

The non-competitive NMDA receptor antagonist dizocilpine (MK-801) is known to decrease prepulse inhibition in the auditory startle paradigm (Mansbach and Geyer, *Neuropsychopharmacology*, 1989, 2: 299-308). The present study replicates and extends these observations by measuring freezing (an index of fear sensitization) in the prepulse inhibition paradigm as well as in a startle alone paradigm. Rats were administered with either MK-801 (0.1 mg/kg s.c.) or saline and presented 20 min later with 97 startle-eliciting (122-dB) white noise stimuli. For rats in the prepulse inhibition paradigm, 48 of the 97 startle stimuli were preceded (100 msec earlier) by a low intensity (80-dB) white noise stimulus (the prepulse). For all groups the intertrial interval was varied between 10 and 20 sec (mean = 15 sec).

One hundred and five mins after the completion of the 97 trial session, all rats were subjected to another 10-trial session of startle alone (no prepulse) stimuli with the intertrial interval varied between 30 and 90 sec (mean = 60 sec). As expected, the group injected with MK-801 showed less prepulse inhibition than did the saline group. Additionally, the MK-801 group showed less freezing than did the saline group, consistent with the suggested role of NMDA receptors in the acquisition of conditioned fear. Responding to startle alone trials was similar in both the startle alone and the prepulse (excluding prepulse trials) paradigms, whereas MK-801 appeared to increase responding to startle alone trials irrespective of paradigms.

It is concluded that MK-801 produces deficits in prepulse inhibition but also in conditioned fear sensitization.

HABITUATION OF PREPULSE INHIBITION OF THE STARTLE RESPONSE WITH WEAK AUDITORY PREPULSES. J.C. Gewirtz, D.L. Walker* and M. Davis. Dept. of Psychology and Psychiatry, Yale University Sch. of Med., 34, Park St., New Haven, CT 06508.

In a variety of mammalian species, the startle response elicited by a strong stimulus (the pulse) is reduced when preceded by a weak stimulus (the prepulse) which itself does not elicit startle. The phenomenon of "prepulse inhibition" (PPI) is often viewed as the mechanism of "sensory gating", so that an impairment of PPI would result in an attentional deficit. However, PPI itself can be affected by attention. Therefore deficits in PPI may simply represent a marker for attentional deficits, rather than the mechanism which causes them.

If PPI is an early attentional filter, it should not habituate with repeated presentation of the prepulse. Consistent with this, some existing evidence indicates that the magnitude of PPI is not decremented by repeated presentation of the prepulse.

The present study re-evaluated habituation of PPI, using long intervals between startle-eliciting pulses to reduce habituation of baseline startle, because changes in baseline startle are problematic for interpreting changes in PPI. To maximize habituation of PPI and minimize dishabituation that could result from presentation of the intense (115 dB) startle-eliciting pulse, a large number (150) of auditory prepulse-alone trials were intermixed with a small number (9 pulse alone and 9 prepulse-pulse) test trials. A control group received an identical number of PPI test trials using the auditory prepulse, but received intervening presentations of a prepulse in a different modality.

When the auditory prepulse was very weak (2.5 dB above background noise), PPI showed reliable habituation. However, when the auditory prepulse was more intense (13 dB above background), PPI did not habituate, consistent with the literature.

Our findings indicate that some habituation occurs with a prepulse, only when it is close to auditory threshold. Interestingly, the disruptive effects of dopamine agonists on PPI primarily occur with weak prepulses, raising the possibility that these two sets of observations may be related.

EFFECTS OF ENTORHINAL CORTEX ASPIRATIONS ON ODOR- AND CONTEXT-GUIDED FEAR CONDITIONING. T. Otto* and K.M. Schiller. Program in Biopsychology and Behavioral Neuroscience, Dept. of Psychology, Rutgers University, New Brunswick, NJ 08903.

Previous work has demonstrated that hippocampal lesions abolish contextual fear conditioning but spare fear conditioned to a discrete tone CS (Phillips & LeDoux, 1992; Kim & Fanselow, 1992). The present study was conducted to determine the effects of damage to entorhinal cortex on contextual vs. cued fear conditioning using an odor as a CS. One group of male Sprague-Dawley rats received bilateral aspiration of the entorhinal cortex (ENT, n=12); a second group served as operated controls (SHAM, n=11). Ten days after surgery all subjects received 6 pairings of an odor (cis-3-Hexenol) and footshock (0.6mA, 2sec) in a distinctive operant chamber. On each of the 6 trials, the odor was presented for 20sec (delivered by means of a flow-dilution olfactometer and blown through the roof of the chamber) and the footshock overlapped with the final 2sec of odor delivery; the ITI was 4min. Twenty-four hours later conditioning to the context was assessed by placing subjects into the operant chamber in which training took place and measuring freezing behavior for 5min using a time-sampling method (5sec inter-sample-interval). Conditioning to the odor was assessed by placing subjects into a novel operant chamber and measuring freezing for 6min; the odor CS was presented during the second minute and remained in the chamber throughout the final 5min of sampling.

Histological verification of lesion placement has not yet been completed. However, preliminary analyses suggest that, using this paradigm, entorhinal cortex aspiration attenuates conditioning to both the context and the odor CS as indicated by significantly less freezing behavior for ENT subjects. This pattern of findings is consistent with the effects of hippocampal damage on contextual fear conditioning, but suggests that there may be a degree of sensory specificity in the role of the entorhinal cortex/hippocampal system in cued fear conditioning.

NEURAL SUBSTRATES OF APPETITIVELY CONDITIONED BRADYCARDIA. C.M. Gibbs* and K.L. Watson. WJB Dorn Veterans' Hospital & University of South Carolina, Columbia, SC 29201.

Aversive Pavlovian training procedures induce phasic, bradycardiac responses (CRs) in many mammalian species, and we have established that appetitive Pavlovian training elicits similar heart rate (HR) CRs. The present studies sought to compare the neural substrates for appetitive and aversive cardiac conditioning in rabbits. We first showed that peripheral muscarinic receptor antagonism profoundly disrupts the development of discriminative, bradycardiac CRs during differential appetitive training (CS⁺ paired with water, CS⁻ presented alone). Next, we evaluated the development of HR CRs in sham-operated animals vs. those with bilateral lesions of the medial prefrontal cortex (PFCm), the amygdaloid central nucleus (ACE) or both the PFCm and ACE during differential appetitive-aversive training (CS_{app} paired with 0.5M sucrose, CS_{av} paired with eye-shock, CS⁻ presented alone). PFCm lesions reduced the magnitude of the bradycardiac CRs to the CS_{app} and CS_{av} but did not affect their discriminative character; whereas, ACE lesions abolished bradycardiac responses to the CS_{app} and CS_{av} and significantly attenuated HR discrimination. Finally, PFCm/ACE lesions abolished the development of discriminative HR CRs. These findings indicate that (a) appetitive and aversive HR CRs involve similar peripheral and central mechanisms and (b) the PFCm and ACE are differentially involved in their development and/or expression. PREVENTION OF THE RABBIT TRACE-CONDITIONING NICTITATING MEMBRANE LEARNING BY INACTIVATION OF THE INTERPOSITUS NUCLEUS. Pezhman Eliasadeh, Georges Tocco*, Michel Baudry and Richard F. Thompson. University of Southern California, Neurosciences Program, Los Angeles, CA 90089-2520.

While the cerebellum is necessary and sufficient for the learning of the classical conditioning of the nictitating membrane in a delay paradigm, the hippocampus is required for the learning in a trace paradigm when at least 300 msec separate the end of the CS from the US onset. However the importance of the cerebellum in a trace paradigm is not well understood. While the interpositus nucleus is absolutely necessary for the performance of a previously learned trace conditioning task, its importance during the acquisition phase is not well understood. In an attempt to answer this question, we produced reversible inactivation of the cerebellum by muscimol infusion in the interpositus nucleus during the acquisition phase for a trace paradigm.

Male New Zealand white rabbits were implanted with a cannula in the interpositus ipsilateral from the stimulated eye. Rabbits were then trained on trace paradigm (500 ms trace interval) and infused with muscimol before each training session. The rabbits were trained with muscimol infusion for 12 sessions after which they were infused with saline for the following sessions. The animals did not show any CRs during the first 12 training sessions and gradually developed CRs thereafter as would naive animals.

414.3

INVOLVEMENT OF THE RED NUCLEUS IN ACCURATE TIMING OF THE RABBIT'S CLASSICALLY CONDITIONED EYEBLINK RESPONSE. D.J. Krupa*, J. Weng, & R.F. Thompson. Neurosciences Program, University of Southern California, Los Angeles, CA 90089.

Numerous studies have demonstrated that during classical conditioning of the eyeblink reflex, subjects learn to time the conditioned response (CR) so that the peak occurs at about the time the US is normally delivered. The present study was designed to investigate whether the red nucleus might play a role in accurate timing of the CR. Two groups of rabbits were implanted with cannulae aimed at the contralateral red nucleus (RN). Following recovery, all rabbits received 6 training sessions in which a tone CS (650 ms) was paired with a coterminating airpuff US (100 ms) so that the interstimulus interval was 550 ms. All rabbits were then given 7 more training sessions in which the ISI was shifted to 200 ms. Prior to the first 3 of these 200 ms ISI sessions, one group was infused with muscimol into the RN while the other group received vehicle alone infusions into the RN.

Consistent with previous studies, all rabbits learned to time the CR during the first 6 sessions so that the peak occurred about 500 ms after CS onset (as measured on CS alone test trials). When switched to the 200 ms ISI, the rabbits which were infused with saline (n=6) rapidly learned to retime the CR so that after the first session, there was a significant reduction in peak CR latency and by the end of the third session, the mean peak latency was 250 ms. In marked contrast, the rabbits infused with muscimol into the RN (n=6) performed no CRs during the 3 infusion sessions with the 200 ms ISI. On the fourth session (first session without muscimol) the mean peak CR latency did not differ from the peak latency obtained during the last session with a 550 ms ISI (session 6). During subsequent sessions, these rabbits learned to retime the CR at the same rate as the saline controls. In sum, inactivation of the RN (which previous studies have shown to have no effect on the ability to acquire the CR with a 250 ms ISI) disrupts the animal's ability to properly retime a previously learned CR. ROLE OF CEREBELLAR CORTICAL NEURONS IN CLASSICAL CONDITIONING. P.G. Shinkman*, A.J. Annala, R.A. Swain, R.E. Clark, and R.F. Thompson. Neurosciences Program, Univ. Southern California, Los Angeles, CA 90089-2520.

Classical conditioning of discrete motor responses of the facial and neck musculature has been shown in rabbits implanted with stimulating electrodes in cerebellar cortex. Following threshold measurements for the elicitation of discrete motor responses, subthreshold stimulation was used as the CS and suprathreshold stimulation through the same electrode served as the US. In this preparation, we observed conditioning following paired (but not randomly unpaired) CS-US trials, extinction following CS-alone trials, and reacquisition with savings, as well as a significant posttraining increase in local cortical excitability. These and earlier findings point to critical roles for both cerebellar cortex and deep cerebellar nuclei in classical conditioning, and suggest that such conditioning is mediated by an interaction between cortical and subcortical cerebellar circuits. The present experiment was designed to further elucidate the nature of cortical participation in the conditioning process. New Zealand white rabbits were implanted chronically with bipolar electrodes placed within the cortical layers of lobule HVI, and a cannula located 0.75 mm dorsally. Following training acute local injections of muscimol, but not saline, reversibly abolished conditioned responding. Since the muscimol selectively inactivated cell bodies at the injection site, these results strongly implicate cerebellar cortical neurons, and hence their efferent connections to the deep nuclei, in the neuronal plasticity manifested in classical conditioning. INACTIVATION OF THE SUPERIOR CEREBELLAR PEDUNCLE PREVENTS EXPRESSION BUT NOT ACQUISITION OF THE RABBIT'S CLASSICALLY CONDITIONED EYEBLINK RESPONSE. R.F. Thompson* & D.J. Krupa. Neurosciences Program, University of Southern California, Los Angeles, CA 90089.

Previous studies have shown that inactivation of a critical region of the cerebellum encompassing the dorsal anterior interpositus nucleus prevents acquisition of the classically conditioned eyeblink response (CR) while inactivation of the contralateral magnocellular red nucleus prevents expression but not acquisition of the CR. The present study was designed to extend these findings. Three groups of rabbits were implanted with cannulae in the ipsilateral superior cerebellar peduncle (SCP); one group was also implanted with stimulating electrodes in the ipsilateral lateral reticular nucleus (LRN). One group received 9 training sessions with an auditory CS (350ms) paired with a coterminating airpuff US (100ms). The second group also received 9 training sessions but with electrical microstimulation of the LRN as the CS (350ms, 200Hz, 50µA). Prior to each of the first 6 sessions, 0.9mg tetrodotoxin (TTX) was infused into the SCP. Controls were infused with TTX and placed in the behavioral recording apparatus for one hour but received no stimuli during the first 6 sessions. These rabbits then received 3 sessions of training (auditory CS) without infusion.

Rabbits trained with either the auditory CS or the LRN stimulation as CS on the first 6 sessions performed no significant number of CRs during these infusion sessions. On session 7 (first session without TTX) these rabbits performed the CR at asymptotic levels; they had fully learned the CR. The control rabbits performed the CR at significantly lower levels on session 7 and subsequently learned the CR during the following 2 sessions. Infusions of TTX on session 10 completely abolished the CR in all groups. These results indicate that cerebellar output projections (via the SCP) are not essential for acquisition of the CR. Further, this result is true for auditory CSs as well as other stimulus modalities which have previously been shown to serve as effective CSs.

FUNCTIONAL ANATOMY OF HUMAN EYEBLINK CONDITIONING DETERMINED WITH RELATIVE GLUCOSE METABOLISM AND POSITRON EMISSION TOMOGRAPHY. C.G. Logan* and S.T. Grafton. Dept. of Neurology, University of Southern California, Los Angeles, CA 90033.

Relative cerebral glucose metabolism (rCMRglu) was examined with positron emission tomography (PET) as a measure of neuronal activation during performance of the classically conditioned eyeblink response in 12 young adult subjects. Each subject received three sessions: 1) an unpaired control session with PET scan; 2) a paired training session; and 3) a paired test session with PET scan. Stimuli were tones and corneal airpuffs (ISI=500 ms, mean ITI=28 s on paired days). During the unpaired control session, subjects received the same number of tones and airpuffs in the same period of time, but with no predictive relation between the two. ^{18}F FDG was injected immediately prior to the last 6 blocks of training on sessions 1 and 3. PET scans following the training blocks measured rCMRglu.

Brain regions showing potential learning-related changes in activity were identified as those areas which showed significant differences in rCMRglu between the unpaired control condition (session 1) and well-trained state (session 3) in the 9 subjects who met learning criterion. Areas of significant activation included bilateral sites in the cerebellum; anterior cerebellar vermis*; ipsilateral hippocampal formation; ipsilateral anterior middle temporal gyrus*; and caudate nucleus bilaterally*. Among all 12 subjects, metabolic changes in the ipsilateral cerebellar deep nuclei and * sites correlated significantly with degree of learning. These results are consistent with studies in humans and other species which have demonstrated that the cerebellum plays a critical role in eyeblink conditioning, and they suggest that additional striatal and cortical sites may also be involved.

FUNCTIONAL LOCALIZATION AND NEUROANATOMICAL CONNECTIVITY OF NEURAL SUBSTRATES WITHIN THE ANTERIOR INTERPOSED NUCLEUS INVOLVED IN EXPRESSION OF THE NICITATING MEMBRANE REFLEX. S.A. Bartholomew*, M.L. Webster, J.R. Bloedel, V. Bracha. Barrow Neurological Institute, Phoenix, AZ 85013.

The purpose of the present study was to analyze the neuroanatomical connectivity of subregions within the anterior interposed nucleus (AIN) which are critical for expression of the classically conditioned nictitating membrane response (NMR) in the rabbit. Animals were chronically implanted with a matrix of three guiding cannulae in the region of the AIN and then conditioned in the standard delay paradigm. A functional map of the AIN was reconstructed from the behavioral effects of systematic muscimol nanoinjections (20 ng in 50 nL) along the three injection tracks in trained animals. In each animal, the AIN subregion in which muscimol nanoinjections most effectively blocked the conditioned response performance was electrophoretically injected with anterograde (PHA-L) and retrograde (CTB) tracers.

The neuroanatomical data indicate that besides the traditionally considered AIN connections with the red nucleus, the pontine nuclei, and the inferior olives, several other projections could also be relevant to AIN involvement in control of NMR expression: 1) a direct afferent projection from the spinal trigeminal nucleus; 2) direct efferent connections to the mesencephalic periaqueductal and reticular accessory oculomotor regions; and 3) an efferent projection to the pontine nuclei.

DESTRUCTION OF NEURONS IN THE VENTRAL POSTERIOR MEDIAL THALAMUS WITH IBOTENIC ACID PREVENTS CLASSICALLY CONDITIONED HEART RATE IN RABBITS. P.M. McCabe*, M.D. McEchron, E.J. Green, and N. Schneiderman. Behavioral Neuroscience Program, Department of Psychology, University of Miami, Coral Gables, FL 33124.

In the heart rate (HR) conditioning paradigm, an unconditioned corneal air puff stimulus (US) is paired with an acoustic conditioned stimulus (CS). Previous evidence suggests that the ventral posterior medial thalamus (VPM) receives inputs from the trigeminal nucleus, and that VPM is involved in the sensation of tactile- and nociceptive-facial information, such as a corneal air puff. Although, VPM is involved in the processing of trigeminal information, it is not clear if VPM is part of a circuit that relays US information to other critical sites of sensory convergence in the HR conditioning pathway. Therefore, the present study examined the role of VPM in the acquisition of HR-conditioned responses (CRs) and the expression of HR-unconditioned responses (UR). Rabbits were given bilateral ibotenic acid lesions in VPM and subjected to one Pavlovian HR conditioning session which consisted of 28 trials of the CS (560 Hz; 90 dB; 2 s duration) paired with the US (15 N/cm²; 0.5 s duration). Four CS-test trials were used to measure the initial (rate of first 16 beats) bradycardiac CR, and 5 US-test trials were used to measure the initial (rate of first 26 beats) tachycardiac UR. The results of the present study demonstrate that the destruction of cell bodies in VPM reduces HR-CRs to the level of a pseudoconditioning control without affecting HR baseline, or orienting responses to the CS. Lesions of VPM also significantly augment the tachycardiac UR above the level of control lesioned animals. These data suggest that VPM lesions prevent conditioning by altering the somatosensory processing of the US. These results are consistent with the notion that VPM may participate in a circuit which relays US information to other important areas of conditioning such as the medial geniculate and the amygdala. Supported by NSFIBN9222194 and NIHHL07426.

MULTIPLE UNIT RECORDINGS FROM THE TRIGEMINAL COMPLEX. EYEBLINK CONDITIONED UNIT RESPONSES DURING INTERPOSITUS OR RED NUCLEUS INACTIVATION VIA COOLING. Robert E. Clark*, Elizabeth B. Gohl, and David G. Lavond. Departments of Psychology and Biological Sciences, University of Southern California, Los Angeles, CA 90089-2520.

The trigeminal complex is of considerable interest to researchers of the conditioned eyeblink response for primarily two reasons. (i) The unconditioned response pathway involves the trigeminal system. (ii) Other research has suggested that the trigeminal complex may also participate in the generation of the behavioral conditioned response or even in the formation of the essential plasticity for the learned response.

Recordings were obtained from the trigeminal complex with the aid of a moveable electrode in rabbits classically conditioned with a tone conditioned stimulus (CS) and an airpuff unconditioned stimulus (US). Units were examined over a block of 9 trials during normal training. These unit recordings were then examined over a block of 9 trials during reversible cooling lesions of either the interpositus or red nucleus.

Unit responses to the CS and US were frequently observed as were responses that modeled the learned behavioral response. The model responses were found in various regions of the trigeminal complex, but most prominently in the principal sensory nucleus and pars oralis of the spinal trigeminal. Cooling either the interpositus or the red nucleus completely abolished the unit models but did not abolish the responses evoked by the CS or US. We conclude that the learning related activity in the trigeminal complex is driven by the interpositus via the red nucleus. CONDITIONING-SPECIFIC MODIFICATION OF THE RABBIT'S UNCONDITIONED NICITATING MEMBRANE RESPONSE

Bernard G. Schreurs*, M. Matthew Oh, Chie Hirashima, and Daniel L. Alkon. Laboratory of Adaptive Systems, NINDS, NIH, Bethesda, MD 20892, USA.

Acquisition of a classically conditioned response was shown to modify subsequent responding to the unconditioned stimulus, a phenomenon we have called conditioning-specific reflex modification. Procedurally, unconditioned responses to different values of periorbital electrical stimulation varying in intensity (.1, .25, .5, 1.0, 2.0 mA) and duration (10, 25, 50, 100 ms) were assessed within subjects before and after a between-subjects manipulation of one, three, or six days of paired, explicitly unpaired, or no presentations of tone and periorbital electrical stimulation. After three days of paired presentations (Experiment 1), conditioned responding had reached an asymptote of 94% and, on posttest, there was a significant increase in the latency to the peak of the unconditioned response ($p < .01$). The conditioning-specific increase in peak latency was replicated ($p < .05$) in a second experiment in which animals received six days of paired presentations (Experiment 2). In addition, the six days of pairings produced a significant increase in the amplitude of the unconditioned response ($p < .01$). Finally, there were no significant changes in unconditioned responses as a function of the minimal levels of conditioning produced by one day of pairings (Experiment 3). Taken together, the data show that after acquiring asymptotic levels of conditioned responding, rabbits elicited unconditioned responses that were as much as 50% larger and timed to reach a peak 20% later than before training. These results indicate that processing of the unconditioned stimulus is modified as a function of the acquisition of a conditioned response. At a neural level, the data suggest that classical conditioning induces learning-specific changes in pathways mediating the unconditioned stimulus/unconditioned response as well as those mediating the conditioned stimulus/conditioned response.

CROSS-MODALITY CORTICAL PROCESSING: SPATIO-TEMPORAL PATTERNS OF OLFACTORY, VISUAL, AUDITORY, AND SOMATIC EEGs IN PERCEPTION BY TRAINED RABBITS

J.M. Barrie, W.J. Freeman*, and M. Lenhart. Dep't of Molecular and Cell Biol., University of California at Berkeley, CA 94720

Stimulus-induced, perceptually related events are accessed in paleo- and neocortex by recording the endogenously generated spatial patterns of the EEG. They take the form of amplitude modulation in spatial coordinates of a broad spectrum, aperiodic carrier wave. This finding has been extended to characterize the evolution of such patterns across time and across sensory modalities. Arrays of 64 electrodes (8x8 at 0.79mm spacing) were fixed onto the epidural surface of either the prepyriform, visual, auditory, or somatic cortex of 18 rabbits classically conditioned to discriminate between pairs of stimuli (CS+ and CS-) not related to the cortical implant site. The 64 EEG traces were decomposed by FFT, PCA, RMS, and spectral entropy analysis for 120millisecond windows stepped at overlapping 20mSec intervals. Pattern differences were expressed as Euclidean distances in 64-space. Decomposition and successful classification of the EEG patterns shows that sensory information is shared between all primary cortical sensory processing areas during lagged time periods after stimulus arrival. Long term EEG recordings have also shown that basal state spatio-temporal patterns are inconstant and continually evolve at a constant rate corresponding to perceptual drift. A temporal frequency analysis of the EEG has demonstrated no relationship between periods where percepts are formed and an increase or decrease in the power spectral density within narrow bands of the temporal spectra. We conclude that cortical function in perception is an endogenous process in which percepts are constructed, not filtered, by chaotic nonlinear dynamics. Funded by the National Institute of Mental Health - MH06686.

THE ABSENCE OF INTERHEMISPHERIC COMMUNICATION IN THE NORMAL RABBIT. J. Steele Russell*, Anatomy, Texas A&M University, College Station, TX. 77843-1114.

The present report examines the role of the cerebral cortex to inhibit interhemispheric communication in normal rabbits.

Intact normal rabbits (N=40) were tested for visual interocular transfer (I.O.T.) using a variety of visual tasks in a two choice situation. They were first trained monocularly to criterion. Following this they were trained with the other eye. No signs of IOT were seen in any animal. All animals had to be retrained from chance and showed no savings. This suggests that the normal intact rabbit functions as a junctional "split brain" animal, i.e. the left hemisphere does not communicate with the right hemisphere.

To test this, a group of rabbits were monocularly trained on a pattern discrimination task. After reaching criterion the animals were hemidecorticated such that half of them had the hemisphere removed contralateral to the trained eye, and the others had the ipsilateral hemisphere lesioned. The results showed that following monocular learning a unilateral memory trace is established in the normal rabbit. Perfect retention of learning was found following ipsilateral hemidecortication; whereas no retention was evident when the lesion was contralateral.

These findings suggest that the contralateral optic projections play an important role in collateral inhibition of the ipsilateral projections and thus prevent the formation of a bilateral memory record. The lack of such a record would also explain the absence of I.O.T. in the rabbit. Hemidecortication prior to learning was used to disrupt this inhibitory mechanism. Such hemidecorticate rabbits when trained monocularly showed a bilateral memory record and perfect IOT. These findings argue strongly that the rabbit has a cortical inhibitory control over the extent interhemispheric communication required during monocular viewings.

ONTOGENY OF THE CONDITIONED EYEBLINK RESPONSE IN RATS: ACQUISITION OR EXPRESSION. G.D. Fox,² C.S. Carter,² & M.E. Stanton,^{1,2*} ¹Neurotoxicology Div., US EPA, RTP, NC 27711; ²Psychology Dept., UNC, Chapel Hill, NC, 27599.

Previous work in our laboratory (Stanton, Freeman, & Skelton, 1992, *Behav. Neurosci.*, 106, 657-665) has determined that the classically conditioned eyeblink response in the rat pup develops between Postnatal Day 17 (PND17) and PND24. The current study sought to explore the possibility that acquisition does occur at PND 17, but can not be expressed until a later age. Animals were trained in a Pavlovian eyeblink preparation utilizing a tonal CS and a periorbital shock US. Tones of two different frequencies, 2.8 and 9 kHz, were used because some of our recent findings have indicated that CS frequency can be an important variable in the ontogeny of conditioning in this preparation. A "savings" design was used in which acquisition on PND20 was examined as a function of prior training on PND17. Group P-P received 300 trials of paired training on PND17 and again on PND20. Performance of this group was compared with that of control groups that received no treatment (N-P) or unpaired training (U-P) on PND17, followed by paired training on PND20. A final control group (N-U) received no treatment on PND17 and unpaired stimulus presentations on PND20. Response acquisition on PND20 was found to differ reliably as a function of the animals' experience on PND17. Group P-P showed accelerated acquisition of the conditioned eyeblink response on PND20 relative to groups U-P and N-P, indicating that some unexpressed associative learning does occur during paired training on PND17. A surprise finding was that unpaired exposure with the 2.8 kHz tone had a facilitatory effect on PND20 acquisition, while unpaired exposure with the 9 kHz CS resulted in a significant retardation of day 20 acquisition. These findings suggest that maturation of fibers efferent to the cerebellum may play a role in the developmental appearance of eyeblink conditioning in the rat.

414.15

CRITICAL IMPORTANCE OF THE HIPPOCAMPUS FOR LOCAL NAVIGATION LEARNING IN YOUNG HOMING PIGEONS. V. P. Bingman*, P. Ioalé, G. Casini, P. Bagnoli and R. Strasser. Dept. Psychology, Bowling Green State Univ., Bowling Green, OH 43403.

Among the deficits in spatial cognition produced in homing pigeons following hippocampal (HF) ablation, none are as robust as those observed in young birds learning to navigate near the loft. Local navigation near the loft is based on young birds learning to use familiar landmarks to identify goal locations. Even loft identification, an ostensibly non-spatial task, is based on young birds learning about a loft's location rather than its features (e.g. color). Compared to young controls, young birds with HF lesions: (1) display less loft fidelity (e.g., they are more likely to move between lofts within a loft complex), (2) are more likely to get lost flying near the loft during training, and (3) are less likely to return home after being experimentally released the first time from short distances (20 km). Taken together, these findings emphasize the critical importance of HF for local (familiar landmark) navigational learning in homing pigeons.

414.12

DISRUPTION OF CEREBELLAR MATURATION BY AN ANTIMITOTIC AGENT IMPAIRS THE ONTOGENY OF EYEBLINK CONDITIONING IN INFANT RATS. J.H. Freeman Jr.^{1*}, S. Barone, Jr.² and M.E. Stanton^{1,3} ¹Dept. Psychology, UNC, Chapel Hill, NC, 27599-3270; ²ManTech Environmental Technology, RTP, NC 27709; ³Neurotoxicology Div., US EPA, RTP, NC 27711.

In rats, eyeblink conditioning develops dramatically between postnatal day 17 (PND17) and PND24 (Stanton, Freeman, & Skelton, 1992, *Behav. Neurosci.*, 106, 657-665). There is dramatic cerebellar growth during this period (Altman, 1969, *J. Comp. Neurol.*, 136, 269-294) and the cerebellum is critical for the acquisition of eyeblink conditioning in adult animals (Thompson, 1988, *TINS*, 11, 152-155). These observations suggest that the ontogeny of eyeblink conditioning depends upon the maturation of the cerebellum. In the present study, we experimentally manipulated cerebellar maturation by exposing neonatal rat pups to the antimitotic agent methylazoxymethanol (MAM) during cerebellar cortical neurogenesis. Pups were then trained with eyelid conditioning procedures at different ages. In Experiment 1, pups were given either saline or MAM (20 mg/kg) on PND4 and 7 and then given six 100-trial sessions of either delay conditioning or unpaired training on PND24 and 25 (3 sessions/day). A subset of the animals were then trained on T-maze delayed alternation on PND27. In Experiment 2, pups were given the same dosing treatment and trained on delay conditioning on days 17-18, 20-21, or 31-32. Staining for Nissl and glial fibrillary acidic protein immunoreactivity revealed greatly reduced volume, disrupted cellular organization, and induction of reactive gliosis within the cerebellum, respectively. There was no evidence of damage in other postnatally developing brain systems. This treatment impaired eyelid conditioning at all ages tested without affecting unconditioned responding or delayed alternation in a T-maze. This study suggests that cerebellar maturation is critical for the ontogeny of eyeblink conditioning.

AMYGDALA STIMULATION FACILITATES THE EYEBLINK RESPONSE IN RAT. T. Canli* and T.H. Brown. Depts. of Psych. and Cell. & Mol. Physiol., Yale University, New Haven, CT 06520.

The rat eyeblink reflex is an attractive model system for studying associative learning. The neural circuitry underlying its fast component (R1) involves a three-synapse arc between the (5th) sensory nerve and the orbicularis oculi (o.o.) muscle, which is responsible for the eyelid closure. In the rabbit, the nictitating membrane response can be associatively modulated by an amygdala-dependent mechanism (Weisz et al., 1992). We were interested in knowing more about the relationship between the amygdala and the eyeblink circuitry in the rat, which is more convenient for *in vitro* cellular neurophysiology.

Here we show that stimulation of the rat amygdala facilitates the R1 component of the EMG recorded in the o.o. muscle. Twelve rats were implanted with a bipolar nerve cuff placed around the 5th nerve to elicit eyeblink and a monopolar stimulating electrode targeted at the amygdala. Both nerve cuff stimulation (NCS; 0.5-2.0 mA, 0.2 ms) of the 5th nerve and electrical brain stimulation (EBS; 100-400 μ A, 0.2-0.8 ms) of the amygdala consisted of a single biphasic square wave pulse. All electrode placements were histologically verified. We found that amygdala stimulation facilitates R1 maximally when EBS and NCS were presented simultaneously, suggesting that the projection from the amygdala to the site of reflex modulation must be fairly direct.

We are presently using confocal microscopy to trace projections from the amygdala to the facial nucleus, using *in vivo* injections of anterograde fluorescent tracers into the amygdala and tetramethylrhodamine into the orbicularis oculi muscle to retrogradely identify motoneurons in the facial nucleus (Lofthus and Brown, 1993).

THE EFFECTS OF BILATERAL HIPPOCAMPAL-AREA PARAHIPPOCAMPALIS LESIONS ON VISUAL DELAYED MATCHING-TO-SAMPLE BEHAVIOR IN PIGEONS. M. Colombo*, N. Swain, D. Harper, and B. Alsop. Department of Psychology, University of Otago, Dunedin, New Zealand.

Damage to the hippocampus and area parahippocampalis (Hp-APH) in pigeons is known to impair spatial memory. Whether similar lesions impair visual memory is unclear. Although Sahgal [Behavioural Brain Research (1984), 11, 47-58] showed that Hp-APH lesions may impair visual memory in pigeons, the delayed matching-to-sample (DMS) procedure used to evaluate visual memory required the pigeons to execute responses to different spatial locations, and thus the impairments may have arisen not from impairments in visual memory but rather from impairments in processing spatial information. The purpose of the present study was to examine whether bilateral Hp-APH lesions in pigeons impairs visual memory using a visual DMS procedure which eliminated this spatial confound.

In Experiment 1, we generated retention gradients with delays of 0, 1.5, 3, 6 and 12 sec for three pigeons experimentally sophisticated with respect to visual DMS behavior. Bilateral Hp-APH lesions had no effect whatsoever on visual retention. In Experiment 2 we compared the ability of five Hp-APH lesioned pigeons and five unoperated pigeons to learn the visual DMS procedure with a variety of different delays. Again, there was no difference in the speed at which the visual DMS task was acquired by the two groups. Furthermore, there was no difference between the Hp-APH pigeons and unoperated pigeons when tested for visual retention with delays of 0, 3, 6, 12, and 24 sec. These results support the view that the hippocampus in pigeons functions mainly in the processing and retention of spatial, rather than visual, information.

414.17

THE AVIAN HIPPOCAMPUS AND MEMORY FOR CUED LOCATION. T. Fremouw*. Dept. of Psychology, University of Utah, Salt Lake City, UT 84112.

The avian hippocampus is similar to the rat hippocampus in that it processes various types of spatial information. Avian hippocampal lesions have produced deficits in place learning, cached food recovery, sun compass learning, and homing performance. All these tasks have emphasized spatial relations and the integration of spatial information (e.g., as in a cognitive map). The present study explored the role of the avian hippocampus in a task that does not involve spatial relations or a cognitive map. Pigeons (*Columba livia*) were trained to criterion on a spatial, delayed matching-to-sample task in which the pigeons saw a sample on the right or left key, experienced a delay during which they pecked the center key, and then were rewarded for pecking the key on which the sample had appeared. After the pigeons reached criterion, they were given either hippocampal lesions or sham surgery. Multiple sample durations and delays were examined. Hippocampal lesions did not appear to impair performance compared to shams. Thus, in a fairly simple and non-integrative spatial location task, pigeons with hippocampal lesions do not appear to have a memory deficit. Therefore, the avian hippocampus seems to be critical for integrating and remembering spatial information rather than processing simple features of space in isolation. Alternatively, these results can be interpreted within an allocentric versus egocentric spatial framework: previous results suggest that the avian hippocampus is critical for allocentric spatial processing and now the present results suggest that it is not critical for egocentric spatial processing.

414.19

SEX DIFFERENCES IN SPATIAL MEMORY AND HIPPOCAMPAL SIZE DO NOT OCCUR IN FOOD-STORING BLACK-CAPPED CHICKADEES. K. Petersen, D.F. Sherry and E. Hampson*. Dept. of Psychology, Univ. of Western Ontario, London, Ontario, Canada, N6A 5C2.

Several recent studies have described sex differences in the relative size of the hippocampus that are correlated with ecological differences in the use of space. Male polygynous voles and female brood-parasitic cowbirds both possess relatively large hippocampal formations compared to female polygynous voles and male cowbirds, respectively (Jacobs et al. *PNAS* 1990 87, 6349-6352; Sherry et al. *PNAS* 1993 90, 7839-7843). We wished to determine whether sex differences in the size of the hippocampus also occur in the absence of ecological differences in the use of space and whether the previously described correlations could be adventitious.

Black-capped chickadees (*Parus atricapillus*) store food and retrieve their scattered caches using spatial memory for cache sites. The present study examined sex differences in caching, cache retrieval, spatial memory, and relative hippocampal size in wild-caught chickadees. Birds were habituated to an indoor aviary for two days, followed by five days observation of caching and cache retrieval. Because black-capped chickadees are monomorphic, observations were blind with respect to sex. Sex was determined by dissection at the time of perfusion. Brains were stained with cresyl violet and volume of the hippocampus and telencephalon were determined by digital video image analysis. Behavioural results indicated no sex difference in caching, cache retrieval, or the accuracy of memory for cache sites. Neuroanatomical results indicated no sex difference in relative hippocampal size. Thus, in the absence of ecological differences between the sexes in the use of space for food caching, and in the absence of a difference in memory for spatial locations, no sex difference in the relative size of the hippocampal formation was observed.

414.21

DOPAMINE IN LEARNING RELEVANT FOREBRAIN AREAS OF THE DOMESTIC CHICK: A COMBINED IMMUNOHISTOCHEMICAL/TRACING STUDY. M. Metzger, H. J. Bischof* and K. Braun, Federal Institute for Neurobiology, Brenneckestr.6, 39118 Magdeburg & Dept. of Biology, University of Bielefeld, FRG.

As demonstrated by 2-deoxyglucose autoradiography, acoustically imprinted domestic chicks develop an increased metabolic activity of several telencephalic areas, including the medio-rostral neostriatum/hyperstriatum ventrale (MNH), the Lobus parolfactorius (LPO) and the dorsal neostriatum caudale (Nc). Since our pharmacological and biochemical assays indicate that dopamine (DA) plays a modulatory role in auditory imprinting, we wanted to know whether and to what extent these areas receive dopaminergic input. In order to elicit the sources of dopaminergic input to the imprinting relevant forebrain areas retrograde fluorescent tracing was combined with DA immunohistochemistry. 4 to 10 day old chicks received single or multiple injections of fluorescent latex microspheres (Molecular Probes) into the MNH, into the adjacent LPO and into the Nc. After an appropriate survival period chicks were perfused and immunohistochemistry was performed with an antibody against DA (Incstar), using several fluorescence detection systems. Retrogradely labelled neurons from the tracing experiments and immunolabelled fibers and somata were visualized under a confocal laser scanning microscope (Leica). The vast majority of dopaminergic fibers in the MNH emanate from neurons in the ventral tegmental area (VTA). The substantia nigra analogue Nc tegmenti pedunculo pontinus (TPc) contained a large number of DA-positive somata which were double labelled after tracer injections into the LPO and few double labelled neurons after Nc injections. Results will be discussed with regard to the possible role of DA in imprinting-like learning processes and to forebrain organisation in birds in comparison with mammalian brain circuits.

414.18

SUN COMPASS ORIENTATION IN THE FOOD-FINDING BEHAVIOUR OF THE BLACK-CAPPED CHICKADEE. S.J. Duff and D.F. Sherry*. Dept. of Psychology, Univ. of Western Ontario, London, Ontario, Canada, N6A 5C2.

Previous research indicates that food-storing birds use distal landmarks to remember the location of previously stored food (Herz et al. *Anim Behav* [in press]; Vander Wall *Anim Behav* 1982 30, 84-94). Recent evidence, however, suggests that food-storing birds that have cached food in the presence of the sun and distal landmarks, preferentially use sun compass information to relocate their stored food (Balda & Wiltschko *Condor* 1991 93, 1020-1023; Wiltschko & Balda *J Comp Physiol A* 1989 164, 717-721). The present experiment examined the role of sun compass and distal landmark information in the food-finding behaviour of the black-capped chickadee (*Parus atricapillus*). Chickadees were trained to food sites on one side of an octagonal aviary under several cue conditions: outdoors, indoors with no view of the sun, indoors with a view of the sun through floor-to-ceiling windows, and in an outdoor aviary with a view of the sun through mesh walls of the enclosure. After reaching criterion, birds were given a 6-hour counter-clockwise, or back, clockshift. Following the clockshift, birds trained and tested outdoors rotated their search patterns 90 degrees clockwise from the original trained location, as predicted if the birds were using sun compass information to locate food sites. This occurred despite conflicting landmark information. In the remaining three conditions, in which sun compass information had been eliminated or in which landmarks may have been more salient, birds did not exhibit rotated search patterns and instead maintained their pre-clockshift search patterns. The results indicate that black-capped chickadees can use both sun compass information and distal landmarks to find familiar food sites and use sun compass information preferentially under some conditions.

414.20

THE DORSOCAUDAL NEOSTRIATUM OF THE CHICK: A STRUCTURE WITH HIGHER ASSOCIATIVE FUNCTIONS ? J. Bock, S. Braun* and K. Braun, Federal Institute for Neurobiology, 39118 Magdeburg and Institute for Zoology, 64287 Darmstadt, FRG.

In the forebrain of domestic chicks several brain regions are involved in early filial imprinting. While the intermediate hyperstriatum ventrale (IMHV) seems to play a dominant role in visual imprinting, a system of interconnected forebrain areas such as the medio-rostral neostriatum/hyperstriatum ventrale (MNH), the lobus parolfactorius (LPO) and parts of the caudal neostriatum (Nc) is involved in auditory imprinting. Since a natural imprinting object combines visual and acoustic features, we postulate that forebrain regions must exist, in which the two sensory modalities are processed on a higher associative level. By using the 2-deoxyglucose (2-DG) autoradiography we compared the activation patterns of acoustically imprinted chicks with those of visually imprinted chicks. We conducted two different imprinting procedures: i) individual chicks were imprinted on rhythmic 400 Hz tone pulses without presenting visual stimuli, ii) individual chicks were imprinted on a rotating red flashing light without presenting auditory stimuli. During the 2-DG experiment imprinted chicks of both groups were exposed to either the visual or acoustic imprinting stimulus, respectively. A subregion in the dorsal part of the Nc, which we termed dorsocaudal neostriatum (Ndc), was strongly labelled in the acoustically as well as in the visually imprinted chicks. In order to rule out that the Ndc-activation is caused by emotional stress during the 2-DG experiment, we investigated the activation patterns of naive, unimprinted chicks, which were distressed. Besides other brain areas a subregion in the Nc was activated, which was localised medial from and partly overlapping with the above described Ndc.

Our results together with recent evidence for dopaminergic innervation in the Ndc (Schnabel & Braun, this meeting; Metzger et al., this meeting) strongly suggest that this area acts as a higher associative structure comparable to the mammalian prefrontal cortex.

415.1

ACCURACY OF SPATIAL NAVIGATION: THE ROLE OF PLATFORM AND TANK SIZE. C.F. Mactutus* and R.M. Booze. College of Pharmacy, Tobacco & Health Research Institute, Graduate Center for Toxicology and College of Medicine, University of Kentucky, Lexington, KY 40546.

The Morris water maze task has great popularity for assessing both the cognitive processes and neurobiological mechanisms involved in rodent spatial learning. However, little systematic attention has been given to the role of several major parameters (e.g., tank and/or platform size) which may provide very different "instructions" to the rat. Young adult Sprague-Dawley male rats were trained at 90 days of age under one of three conditions: a small (5cm²), medium (10cm²), or large (14cm²) escape platform in a standard 1.2m diameter tank. All animals (*n*=18) received 8, 8, and 4 training trials on three consecutive days followed immediately by a probe test trial on the third day. After a 10-min interval, the animals received 4 additional training trials followed by a second probe test trial (the previous extramaze cues were absent). Platform size differentially and significantly affected acquisition—the most rapid decrease in latency was associated with the largest platform. All groups demonstrated a significant spatial bias during the test trial. In marked contrast to the training data, the annulus crossing measure, the *sin qua non* index of spatial accuracy, was enhanced inversely with platform size. Additional experiments demonstrated the generality of this relationship between spatial accuracy and relative platform size (1:60–1:450) was invariant to tank size (0.6m, 1.8m) or animal age (weanling, adult). In sum, the present data indicate that relative platform size is a major determinant of spatial learning, and more importantly, spatial accuracy. Collectively these data suggest that a relatively small platform size 1) maximizes the animal's reliance on extramaze cues and 2) ought to provide a more appropriate procedure to study spatial learning than one which supports the utilization of multiple and/or nonspatial strategies. (Supported by grants from NIH (AG05114, AG10747, & ES06259) and the Commonwealth of KY).

415.3

THE ROLE OF THE HIPPOCAMPAL SYSTEM ON TWO CONTEXT EFFECTS AFTER EXTINCTION. A. Wilson*, D.C. Brooks, & M.E. Bouton. Department of Psychology, University of Vermont, Burlington, VT 05405.

Contextual cues are important in determining performance in behavioral "interference" paradigms, such as extinction, in which the CS is associated with different outcomes in successive phases of the experiment. After extinction, contexts control performance by retrieving the current relation between the stimuli. This research examined the role of the hippocampus in mediating the effects of context after extinction. In *renewal*, conditioned responding to an extinguished CS recovers in the context in which it was conditioned when extinction occurs in another context. In a CER procedure, all animals were given CS-shock pairings in Context A. Half the animals from each group were given CS alone trials in Context A (Cont A, Forn A), half in Context B (Cont B, Forn B). Testing was conducted in Context A. None of the groups differed with respect to pre-CS baseline responding, rates of conditioning, or extinction. Rats with fornix lesions (Forn A) showed increased spontaneous recovery when compared to controls, but no attenuation of renewal. Suppression ratios [means (SEM)] on the first test trial were: Control A = .54 (.04), Control B = .08 (.03), Fornix A = .41 (.04), Fornix B = .16 (.04). In *reinstatement*, conditioned responding to an extinguished CS recovers when the animal is given unsigned US presentations in the context of extinction. Animals were reassigned such that half received reinstating US presentations in the same context, half in a context different from extinction. Animals with fornix lesions (Forn Same) shocked in the extinction context did not show reinstated conditioned responding to the extinguished CS, whereas the comparable control group did (Cont Same). Suppression ratios [means (SEM)] on the first test trial were: Control Same = .16 (.06), Control Diff = .44 (.04), Fornix Same = .37 (.03), Fornix Diff = .44 (.05). Results suggest that the hippocampal system plays a role in some, but not all, effects of context after extinction.

415.5

A VISUAL CUE ENHANCED BY SOUND IMPROVES SPATIAL LEARNING AND DECREASES RESPONSES TO DISTRACTION IN ANIMALS WITH HIPPOCAMPAL DAMAGE. E. Hebda-Bauer*, T. Briones, and B. Therrien. The University of Michigan, Ann Arbor, MI 48109

Spatial disorientation is caused by damage to the hippocampal formation (HPC). We previously reported that a single visual cue improves spatial learning of animals with HPC damage but the therapeutic effects are partially reversed by a simple environmental distracter. This study used a visual cue enhanced by sound to determine the effects of a multi-modal stimulus (cue) on cue navigation in the presence and absence of an environmental distracter. Adult male (*n* = 44) and female (*n* = 42) rats received unilateral or bilateral HPC lesions or sham surgery. Upon recovery, all animals were given four days of testing on the Morris water task to determine the amount of spatial disorientation. A visual cue, enhanced by pulsatile, amplified bursts of noise was then introduced. With the enhanced cue, males with unilateral or bilateral HPC damage and females with unilateral damage were not impaired. However, females with bilateral HPC lesions remained impaired on all measures (*p* < .05). After four days of testing with the cue, a distracter was introduced. In the presence of the enhanced cue, males with unilateral HPC damage were not distracted, performing as well as controls on all test days. In contrast, all females with HPC damage and males with bilateral lesions were more distractible than controls (*p* < .05). However, all animals were less distracted in the presence of the enhanced cue as compared to animals exposed to a single visual cue. We conclude that a visual cue enhanced by sound markedly improves spatial learning of disoriented animals. Importantly it eliminates or curtails the disruptive effect of a simple environmental distracter in animals with HPC damage.

415.2

HIPPOCAMPAL LESIONS IMPAIR NEGATIVE PATTERNING, BUT NOT CONDITIONAL LEARNING, USING CONTEXTUAL CUES. D.M. Skinner* and D. van der Kooy. Dept. of Anatomy and Cell Biology, University of Toronto, Toronto, Ontario, M5S 1A8.

While performance on tasks employing spatial and contextual cues depends on the integrity of the hippocampus, we have previously shown that acquisition of conditional discriminations is not impaired by hippocampal lesions. Animals were trained on a conditional discrimination task that employed taste aversions. On some days animals were placed in a novel context (a distinct test box) prior to a flavor-LiCl pairing. On alternate days animals were exposed to a second distinct context prior to a flavor-saline pairing. Animals with aspiration lesions of the hippocampus acquired the task (learning to drink on safe context trials), but at a slightly slower rate than sham controls. We now report that these aspiration lesions of the hippocampus severely impair acquisition of a negative patterning task that employed the same cues. In a negative patterning task each of two cues is followed by an unconditioned stimulus when presented singly, but the unconditioned stimulus is withheld when the two elements are presented together. We used a novel 0.1% saccharin solution and a distinct context as cues. Each of these cues alone signaled an injection of LiCl, but when presented together signaled the absence of LiCl. Both lesioned and sham animals acquired the conditional component of the task, consuming more saccharin in the novel context than in the home cage. However, the addition of context-LiCl trials impaired the performance of both groups. With further training, only the sham lesioned animals acquired the negative patterning task.

415.4

EVALUATION OF TIME OF DAY AS A CONDITIONAL CUE FOR RATS. A. Koerner*, R. J. Sutherland, G. M. Martin, R. J. McDonald, & S. Avery. Dept. of Psychology, University of New Mexico, Albuquerque, NM 87131.

We evaluate representational theories of conditioning which ascribe an important role to when and where an event occurs. We describe 4 discrimination experiments which show that rats' sensitivity to time of day should not be given a special role in theories of learning. Our data indicate that we should distinguish between two types of where: The place of training and the contextual cues present during training.

All experiments involve conditional discrimination training based upon place or time of day. The rats are trained that cue X, not cue Y, is correct at Time 1 or Place 1, and that cue Y, not cue X, is correct at Time 2, or Place 2. Experiment 1 shows that rats can use time of day as a conditional cue after extensive training if they are required to distinguish between a black and white cue in a Y-maze and that hippocampal damage abolishes the discrimination. Experiment 2 shows that rats do not learn to use time of day as a conditional cue when they are required to distinguish between a left and right turn. Comparison with a control group reveals that the rats adopt a win-stay/lose-shift strategy. Experiment 3 shows that rats after a single reversal readily use spatial location as a conditional cue when they are required to distinguish between a left and right turn. Experiment 4 eliminates spatially differential response requirements using operant chambers. Experiment 4 shows that rats are capable of using time of day and contextual cues (presence or absence of a clear plastic floor) as conditional cues after extensive training which does not involve changes in location of responding, when they are required to discriminate between a tone and light in an operant chamber. These results question the notion that time is a generally salient dimension in discrimination learning.

415.6

RATS WITH HIPPOCAMPAL DAMAGE LEARN SPATIAL RELATIONSHIPS WHICH THEY CANNOT USE TO GUIDE NAVIGATION. R. J. Sutherland*, G. M. Martin, C. Edwards, & K. Williams. Depts. of Psychol., Univ. of New Mexico, Albuquerque, NM 87131 and Memorial Univ. of Newfoundland, St. John's, NFLD, A1B 3X9.

Many theories of hippocampal (HPC) function hold that its activity represents certain kinds of relational information. Medial temporal lobe amnesics demonstrate effects of prior learning about an episode if tested in indirect memory tasks, but not in direct tests of memory. We examined rats using two tests of spatial relational memory in the same environment; one direct (place navigation) and one indirect (dishabituation of exploration).

Twelve rats were trained in the Morris water task to locate a fixed, hidden platform. Half of the rats received multiple microinjections of a neurotoxin solution of kainate+colchicine. All rats were allowed to explore a dry pool in a new room in daily 5-min sessions for 37 days. Four objects were present in the pool in fixed locations. Two probe trials were conducted: 1. the pool and 4 objects were rotated 155° relative to the room and 2. two of the objects were transposed. Rats were tested for place navigation in the new and the old room.

The rats with HPC damage were profoundly impaired in the place navigation in the new and old rooms. In contrast, control rats and rats with damage detected the changes in spatial relationships in probe trials, as shown by reliable increases in exploration. Thus, learning the layout of an environment survives HPC damage, although this information is not used for accurate navigation.

415.7

HIPPOCAMPAL DAMAGE IN RATS CAUSES RETROGRADE AMNESIA FOR PLACE NAVIGATION BUT NOT FOR OBJECT DISCRIMINATIONS. R.S. Astur*, D.G. Mumby, M.P. Weisend, and R.J. Sutherland. Depts. of Psych. and Physiology, Univ. of New Mexico, Albuquerque, NM 87131.

In order to examine the effects of partial and complete hippocampal lesions on object and place memories, 29 rats were trained on a different object discrimination 13, 10, 7, 4, and 1 week(s) prior to surgery. To examine place memory, each rat was trained in the Morris water task in two different rooms, 14 and 2 weeks prior to surgery. Bilateral hippocampal lesions were made with multiple intrahippocampal microinjections of ibotenic acid. Ten rats received complete hippocampal lesions, 10 rats received partial hippocampal lesions, and 9 rats received sham lesions. Retrograde effects were assessed by testing all rats on the five object discriminations and the two pool problems that they had learned previously. Anterograde effects were assessed by teaching the rats two new object discriminations and one new pool problem. For the previously learned object discriminations, there were no differences between the groups in relearning the discriminations nor in their accuracy in the first five trials of testing. For the new object discriminations, there were no significant differences between the groups in learning either new object discrimination. For the previously learned pool problems, both HPC groups were impaired relative to controls in finding the platform and percent of time spent in the correct quadrant during probe trials. Only the complete HPC group did not learn the new pool problem. These data indicate that the HPC is important for navigating to places, but not for object discriminations.

415.9

OBJECT DISCRIMINATION IN NORMAL AND HIPPOCAMPUS-DAMAGED RATS. D.G. Mumby*, D. Protz, R.S. Astur, R.L. Klein, R.J. Sutherland, and G.M. Martin. Depts. of Psych, University of New Mexico, Albuquerque, NM and Memorial University of St. John's, NF.

We examined whether rats can recognize objects independently of viewing perspective. Normal rats and rats with bilateral ibotenic acid lesions of the hippocampus (HPC) were trained to discriminate between three object pairs. Initial retraining with the objects in one orientation revealed that the original discriminations were retained (Mean errors to criterion, 4.0 & 5.1 for HPC and normal rats, respectively). Changing the orientation of the objects during training disrupted performance (Mean errors to criterion, 16 & 14 for HPC and normal rats, respectively). The objects were then coated with acrylic to increase the similarity of the objects' surface properties, including odor. Retraining the rats with the objects in the original orientation revealed that the acrylic did not affect performance (Mean errors to criterion, 2.1 & 3.3 for HPC and normal rats, respectively). The final test revealed that switching the orientations of the acrylic-coated objects interfered dramatically with acquisition of the discrimination (None of the rats reached criterion; Mean errors, 78 & 65 errors for HPC and normal rats, respectively). Further tests were carried out to assess the use of spatial information when the correct choice of an object depended upon its spatial location.

Object discrimination performance in our task depends upon object orientation. Moreover, it may be that rats solve object discriminations by distinguishing between object pairs on the basis of a single visual or surface property.

415.11

THE EFFECT OF SELECTIVE FIMBRIA-FORNIX CUTS ON STEREOTYPIC BEHAVIOR AND SPATIAL MEMORY. F. Jiang, R. Racine, J. Turnbull. Depts. of Medicine and Psychology, McMaster University, Hamilton, Ontario, Canada L8N 3Z5.

Fimbria-fornix lesions cause hyperactivity and learning difficulty in rats. During the course of other studies investigating memory deficit in fornix-lesioned rats we had occasion to observe pronounced stereotypic behaviour. Specifically a cannulated knife was used to produce selective lesion to the fornix in 12 Long Evans hooded rats; 9 animals undergoing sham operation served as controls. As expected the animals with fornix lesions demonstrated impaired acquisition, reversal, and working memory in the Morris water maze ($p < 0.01$). However these animals also manifested maintained preference of swim direction, which could be clockwise or counterclockwise ($p < 0.01$). Post mortem examination revealed that the cuts were complete and it is unlikely that these observations could be explained by technical factors. The stereotypic behavior may interfere with the testing of memory in this case, and since lesions to the FF disrupt cholinergic and gabaergic input to the hippocampus these results may also have some relevance to stereotypy in human disease states with similar deficits.

415.8

RETROGRADE AMNESIA FOR PLACE AND CUE INFORMATION AFTER HIPPOCAMPAL DAMAGE IN RATS. M.P. Weisend* & R.J. Sutherland, Depts of Physiology and Psychology, University of New Mexico, Albuquerque, NM 87131.

Retrograde amnesia after hippocampal damage may not share the same task specificity as anterograde amnesia (Weisend & Sutherland, 1993). We report here a replication and extension of our previous findings. Seventy-four Long-Evans hooded rats were trained in the same pool on two versions of the Morris water task: 1) fixed, hidden platform (place task) and 2) visible platform discrimination (cue task). Rats received 80 trials with the hidden platform and 160 trials with the visible platform discrimination. Hippocampal lesions were made using microinjections of kainate + colchicine either 1, 4, 12, or 36 weeks after training. During training, normal rats chose a visible platform based on the correct place learned rapidly in hidden platform trials. Rats rapidly mastered the visible platform discrimination after concurrent training stopped. Naive rats with hippocampal lesions given concurrent training did not show this pattern. Hippocampal damage produced retrograde amnesia for both place and cue tasks. Evidence for consolidation was clear only for place information in the group with 36 weeks between training and damage. Retrograde amnesia for cue task was equal across all training-damage intervals. Rats with hippocampal damage relearned the cue task. No rats with hippocampal damage relearned the place task. Interestingly, normal rats learned the cue task in a clearly discontinuous fashion while most of the same rats relearned the same discrimination in an incremental way after damage. Most naive rats with hippocampal damage also showed incremental learning of the cue task. We conclude that: 1) the intact hippocampus is used to solve some aspect of both place and cue tasks, 2) temporally graded retrograde amnesia is clear for place but not cue tasks after hippocampal damage, 3) the rapidly acquired place task can interfere with learning the cue task, and 4) after hippocampal damage rats learn the cue task in a fundamentally different way than normals. Funded by the RAC and SRAC of the University of New Mexico.

415.10

RECOVERY OF SPATIAL NAVIGATION IN THE MORRIS WATER MAZE FOLLOWING BILATERAL TRANSECTION OF THE FIMBRIA/FORNIX IN RATS. D.K. Hannesson* & R.W. Skelton. Psychology, University of Victoria, POB 3050, Victoria, B.C., Canada, V8W 3P5.

Fimbria/fornix (FF) lesions in animals are frequently used to model neurodegenerative and traumatic neuropathologies observed in humans, and have been used to evaluate the therapeutic efficacy of a variety of interventions, such as grafting or pharmacotherapy. However, recovery in the absence of interventions (i.e., spontaneous recovery) has rarely been investigated.

The present study was designed to assess spontaneous recovery of spatial learning and navigation in the Morris water maze (MWM) following bilateral knife cuts of the FF. Subjects were 32 male Long-Evans rats. They were either pretrained (6 days) or left naive and were given either FF or sham lesions. Post-lesion assessment in the MWM consisted of 13 days of testing with the platform in one location followed by 13 days with the platform in the opposite quadrant of the maze. FF cuts produced a marked deficit in navigating to the first platform location. Pretraining attenuated the deficit. Considerable recovery was exhibited over the period of testing which probe tests indicated involved the use of a spatial strategy and not some other form of behavioral compensation. When the platform was moved, lesioned groups exhibited a marked deficit, which was not reduced in the pretrained group. Recovery was again observed which probe tests indicated entailed the use of a spatial strategy.

These results show that considerable spontaneous recovery does occur following bilateral transection of the FF but that recovery of spatial navigation may occur without recovery of spatial learning. Furthermore, these results suggest that a distinction may exist between interventions that enhance or speed spontaneous recovery and those that provide alternative recovery mechanisms. COMPLEMENTARY ROLES FOR THE HIPPOCAMPUS AND ENTORHINAL/PERIRHINAL CORTEX IN THE ACQUISITION OF SPATIAL AND NONSPATIAL TASKS IN THE RAT. L. Jarrard* and A. Hyko. Dept. of Psychol., Washington and Lee Univ., Lexington, VA 24450.

In order to study the involvement of the different components of the hippocampal formation in learning, rats with selective ibotenic acid lesions of the hippocampus, aspiration lesions of the entorhinal/perirhinal cortex (EC/PRC), and controls were trained in Exp. 1 on spatial and nonspatial versions of an 8-arm radial maze, and in Exp. 2 on concurrent visual discrimination and spatial rewarded alternation tasks. Rats with the hippocampus removed were especially impaired on the spatial tasks and did not differ from controls on the nonspatial tasks. In contrast, EC/PRC rats were like controls on the spatial tasks but were impaired on the nonspatial tasks. This pattern of results (e.g., a double dissociation) supports the view that the hippocampus and EC/PRC differ functionally. Specifically, in the rat the hippocampus seems to play an especially important role in the acquisition of spatial information, while the EC/PRC is more involved in the processing of complex, nonspatial information.

HIPPOCAMPAL AND NON-HIPPOCAMPAL BASED PLACE LEARNING IN THE RAT. Robert J. McDonald* and Norman M. White, Department of Psychology, McGill University, Montreal, Quebec, Canada, H3A 1B1.

Performance on a variety of place learning tasks is impaired by damage to the hippocampal system in the rat (Olton, Walker, & Gage, 1978; Sutherland, Kolb, & Whishaw, 1982), but understanding of the neural substrates underlying place learning tasks that are not dependent on the hippocampal system is limited. In the present experiment the participation in place learning of hypothesized memory systems that include hippocampus, lateral nucleus of the amygdala or dorsal striatum was studied by requiring rats to discriminate between 2 arms of an 8-arm radial maze. Two behavioral variables were manipulated: 1) Movement - rats were either confined to the arms of the maze or allowed to run into the maze arms during training; 2) Cue Resolution - the use of distal room cues was assured by rotating the entire radial maze one arm position to the left at the start of each training day. Rats were required to discriminate 2 widely separated arms from each of which they could see a unique cue or set of cues, or between two adjacent arms from each of which they could see largely overlapping sets of cues. In the latter case the arms could be distinguished only by computing the differences in the spatial relationship of each arm to many of the same cues. A series of single and double lesions revealed the following about the roles of the movement and cue resolution variables in each of the three hypothesized memory systems. When the animals were confined to the arms of the maze only the amygdala system could process the information required to discriminate between the arms, and the discrimination was learned faster with unique than with overlapping cues. In both cases the passive discrimination was facilitated by hippocampal system lesions. When animals ran into the maze arms during training only the hippocampal system processed the information required to discriminate overlapping sets of cues, but both the hippocampal and dorsal striatal systems processed information that discriminated between unique cues. In the latter case the two systems appeared to process different kinds of information, in parallel, that led to the same solution.

RATS WITH ANGULAR BUNDLE TRANSECTIONS SHOW NORMAL ACQUISITION BUT IMPAIRED LONG-TERM RETENTION OF OBJECT DISCRIMINATIONS. N. Vnek¹, T.C. Gleason¹, L.F. Kromer² and L.A. Rothblat¹. ¹Dept. of Psychology, George Washington University, Washington, DC 20052, and ²Dept. of Cell Biology, Georgetown University, Washington, DC 20007.

Investigations of the neurobiology of memory using experimental animals have succeeded in modeling many of the characteristic features of amnesia seen in human clinical populations. To examine long-term memory, however, animal models of amnesia often employ extended measures of acquisition, which stand in contrast to the retention measures used with humans.

To determine the role of hippocampal/parahippocampal circuitry in both information acquisition and long-term retention, rats with bilateral transections of the angular bundle were trained on three object discrimination problems and then retrained two weeks later to measure retention. Rats with discrete lesions of the angular bundle, which disrupt perforant path connections from entorhinal cortex and efferent hippocampal-cortical projections, acquired the discrimination problems normally but showed a marked deficit in retention. Thus, the role of this circuitry may be limited to maintaining some types of information (e.g., single object discriminations) for retention. Behavioral paradigms that include a measure of retention may be particularly important for characterizing mnemonic deficits in animal models of amnesia. Supported by ONR and GWU Facilitating Fund.

DISSOCIATION OF HIPPOCAMPAL AND STRIATAL CONTRIBUTIONS TO PLACE NAVIGATION IN THE WATER MAZE. B.D. Devan¹, E.H. Goad, H.L. Petri. Dept. of Psychology, Towson State University, Towson, MD 21204.

Previous studies have shown that damage to either the hippocampus or striatum of the rat results in severe spatial impairments. The purpose of the present study was to compare the effects of hippocampal (fornix/fimbria) and striatal (caudate-putamen) lesions on acquisition of the standard place version of the Morris water task and a modified cue version that attenuated simultaneous acquisition of a place response. Rats with fornix/fimbria lesions were impaired during a late stage of place task acquisition but were not impaired on the cue task. Caudate-putamen lesions resulted in a severe place task impairment and a transient cue task impairment, both of which were characterized by an early phase of thigmotactic navigation. The escape latency measure was particularly sensitive to thigmotactic behavior and may not accurately reflect allocentric spatial learning. Post-hoc analyses of start point heading angles suggested that rats with fornix/fimbria lesions used position response and guidance strategies. These rats also demonstrated a significantly weakened spatial bias for the former training quadrant on the platform removal probe and reduced flexibility in navigating to a novel platform location on the platform relocation test. In contrast, rats with caudate-putamen lesions spent a greater amount time swimming in the former training quadrant on the platform removal probe, and despite poor place acquisition latencies showed greater improvement when required to learn a new platform position on the relocation test.

The results revealed dissociable aspects of water maze performance following damage to the fornix/fimbria or caudate-putamen. It is suggested that the hippocampus mediates the allocentric spatial aspects of the water maze place task while the striatum may mediate acquisition of the non-allocentric procedural components of both place and cue versions. The results support a multiple neural-systems view of learning/memory and further suggest that in the intact mammalian brain multiple systems may acquire different forms of information simultaneously.

415.14

LESIONS TO THE HIPPOCAMPAL SYSTEM DO NOT IMPAIR SELECTIVE ASSOCIATIONS IN RATS

R.A. Murphy, R.J. McDonald, E.A. Guarraci & A.G. Baker*, Department of Psychology, McGill University, Montréal, Québec, Canada, H3A 1B1.

There is some evidence that lesions to the hippocampus impair performance on Kamin's blocking, on overshadowing and on relative validity procedures. These selective association procedures require that subjects ignore, to some extent, the relationship between a redundant CS and a US. It has been suggested that the hippocampus may be required to filter this redundant information. We trained rats with either electrolytic lesions of the fornix, or colchicine lesions of the dentate gyrus of the hippocampus, and controls on an appetitive operant version of Wagner, Logan, Haberlandt and Price's (J. Exp. Psych., 76: 171-180, 1968) relative validity procedure. We used a variable interval discrete-trial bar press procedure with two stimulus compounds containing a common element (AX, BX). Half of each group were trained with a True-discrimination (TD; AX+, BX-) in which AX trials were reinforced and BX trials were not while the other half were trained with a Pseudo-discrimination (PD; AX+/-, BX+/-) in which both AX and BX trials were reinforced 50% of the time. In spite of the fact that X is reinforced equally often in both groups, previous research has demonstrated that in comparison to PD trained animals, TD trained normals show less responding to the partially reinforced stimulus (X) because the other more valid predictors of reinforcement (A and B) overshadow conditioning to X. During our tests of X, all three groups showed overshadowing of X following true-discrimination training. Consistent with previous experiments in our lab the lesions resulted in increased rates of lever pressing during reinforced and nonreinforced trials and during the test of X. These results suggest that the hippocampus is not required for this selective association phenomenon.

MOVEMENT-PRODUCED HIPPOCAMPAL AND PASSIVE NON-HIPPOCAMPAL LEARNING IMPEDE AMYGDALA-BASED STIMULUS-REWARD LEARNING. Norman M. White* and Robert J. McDonald, Psychology, McGill University, 1205 Dr. Penfield Ave, Montreal, Quebec, H3A 1B1.

We previously reported that the conditioned cue preference (CCP) learned by rats on the 8-arm radial maze using only distal cues to distinguish between food and no-food arms is eliminated by lateral nucleus of the amygdala lesions and potentiated by fornix lesions, suggesting that this form of stimulus-reward learning is mediated by a neural system that includes the amygdala but not the hippocampus, and that the hippocampal system interferes with amygdala-based learning of the CCP. 1) We tested the hypothesis that the cause of this interference is the acquisition of a spatial map of the maze room by the hippocampal system during 10 min of free exploration pre-exposure to the maze, given to all animals before CCP training. Rats not pre-exposed to the maze, or pre-exposed to a maze in a different room exhibited potentiated CCPs, comparable to those of animals with fornix lesions, suggesting that the CCP in normal animals is inhibited due to learning about spatial cues in the maze room. 2) Rats with fornix lesions made after pre-exposure (in the same room), or after CCP training but before testing, exhibited CCPs comparable to those observed in normal animals, suggesting that acquisition of spatial information by the hippocampal system during pre-exposure requires an intact fornix; however, the fornix is not required for subsequent inhibition of stimulus-reward learning in the amygdala system. This inhibition may be mediated via entorhinal cortex. 3) When rats were pre-exposed to the maze by confining them in the arms (instead of exploring freely), the subsequently acquired CCP was comparable to that in normal animals, but was not potentiated by fornix lesions, suggesting that passive pre-exposure may produce non-hippocampal learning, possibly mediated in the amygdala system, that impedes stimulus-reward acquisition by the same system. There may be two different latent-inhibition-like effects, involving two different kinds of learning and mediated by two different memory systems.

"PLACE" VERSUS "RESPONSE" LEARNING DEBATE REVISITED IN THE BRAIN. M.G. Packard* Dept. Psychology, Univ. New Orleans, N.O., LA 70148.

The historical debate between psychologists who favored "cognitive" learning theories and those who favored "stimulus-response" learning theories can be characterized by the tendency of rats to display place or response learning in the cross-maze paradigm, respectively. Findings indicating that normal rats can employ either mechanism in learning to approach the consistently baited arm of a cross-maze (cf. Restle, 1957), raises the possibility that these two learning mechanisms are mediated by distinct neural systems. Consistent with this possibility is evidence indicating that the mammalian brain contains multiple memory systems which differ in the "type" of memory they mediate. The present study was designed to examine the hypothesis that place and response learning are mediated by independent hippocampal and caudate nucleus memory systems, respectively.

Rats were trained to approach a consistently baited arm in a cross-maze from the same start box (4 trials/day/14 days). On days 8 and 16 a single probe trial was given, in which rats were placed in the start box of the cross-maze opposite that used in training, and allowed to approach a maze arm. On the probe trials, rats which selected the baited maze arm were designated place learners, and rats which selected the unbaited maze arm were designated response learners. 3 minutes prior to the probe trials, rats received bilateral injections of either saline or a 2% lidocaine solution (in order to produce neural inactivation) into either dorsal hippocampus or dorsolateral caudate nucleus. Saline treated rats displayed place learning on the day 8 probe trial, and response learning on the day 16 probe trial, indicating that with extended training, there is a shift in learning mechanisms controlling behavior. Rats receiving lidocaine injections into hippocampus showed no preference for place or response learning on the day 8 probe trial, and displayed response learning on the day 16 probe trial, indicating a blockade of place learning following inactivation of the hippocampus. Rats receiving lidocaine injections into the caudate nucleus displayed place learning on both the day 8 probe trial and the day 16 probe trial, indicating a blockade of response learning following inactivation of the caudate nucleus. The results indicate that the hippocampus and caudate nucleus selectively mediate place and response learning tendencies, respectively, and offer a "neurobiological" solution to the place versus response learning debate.

EFFECTS OF ELECTROLYTIC AND IBOTENATE LESIONS OF THE ROSTRAL GLOBUS PALLIDUS ON WATER MAZE AND CHEESEBOARD ALLOCENTRIC SPATIAL TASKS. G.D. Coover*, M.E. Oakes, R.C. Meyer and J.V. Corwin. Psychology Dept., Northern Illinois Univ., DeKalb, IL 60115.

A very extreme deficit in performance of the Morris Milk Maze (MM) task was produced by small electrolytic lesions in rostral globus pallidus (rGP), but not by lesions in the center of GP (Meyer & Coover, *Soc. Neurosci. Abstr.*, 18:1565). The present study examined the nature of this deficit by testing performance in both negatively (MM) and positively (cheeseboard) reinforced tasks, and whether comparable deficits would be produced by ibotenate lesions of rGP.

Testing in the MM began 4 weeks following surgery with eight 4-trial sessions of escape to a platform in the center of the same quadrant of a 1.6-m diam tank. The platform was submerged after the first session, and further hidden by adding milk after the 3rd session. Two weeks later, the rats were tested during six 4-trial sessions to find half a Froot Loop in the same spatial location amongst 177 holes. Rats with electrolytic lesions of the rGP failed to escape in the MM within 120 sec in most cases (5 out of 8 rats), and showed almost no reduction in their 60+ sec latency to find the food reward. By contrast, sham surgery and vehicle injection control groups, and also a group receiving 3 µg ibotenate under ketamine anesthesia, achieved MM escape within 20 sec by the third session, and reduced their food finding latency from 60 sec the first session to less than 20 sec by the fifth session. The experimental group receiving ibotenate lesions of rGP under Nembutal anesthesia did exhibit deficient MM performance over the first four sessions, which might reflect a spatial navigation deficit. However, the more extreme deficits produced by electrolytic lesions in rGP suggest a broad disturbance of instrumental performance.

THE VENTRAL STRIATAL - VENTRAL PALLIDAL AXIS AND ASSESSMENT OF EFFORT REQUIRED FOR A REWARD. V.J. Brown*, G. Symons, P. Winn and M.P. Latimer School of Psychol., Univ. St Andrews, Fife, Scotland KY16 9JU

The ventral striatum has been implicated in reward-related processing, but its separate contributions to the perception of reward value and reward cost is not known. The present study sought to determine the involvement of the ventral striatal-ventral pallidal (VS-VP) system in assessment of reward cost. We measured progressive ratio (PR) responding, in which the cost in lever presses of a single food pellet increases incrementally with each pellet. Bilateral ibotenate (IBO) lesions were made in VS (0.06M, 0.8 µl injections/hemisphere; sham lesions 0.8 µl PBS) or VP (0.06M, 0.5 µl injections/hemisphere; sham lesions 0.5 µl PBS) of rats after 21 days training and at least 30 days before testing started. The point when normal rats and shams stopped responding (breaking point) under a PR schedule was stable over days, as were latencies to collect pellets; the post-reinforcement pause increased as a function of schedule progression. These effects are consistent with previous reports. Rats with VS IBO lesions showed significant increases in breaking point, indicating a willingness to work at greater cost for pellets. Rats with VP IBO lesions also showed increases in breaking point, and a greater range of breaking points than controls. Rats with VP lesions did not show an increase in post-reinforcement pause as a function of the PR increments. As this increase reflects a reluctance to resume work in the light of perceived greater effort required for reward this result is interpreted in terms of a deficit in perception of increasing reward cost. Overall these data demonstrate that the effect of lesions in the VS-VP axis is not simply to decrease motivation to work for food reward. Rather, these data suggest that lesioned rats may have lost the ability accurately to perceive the increasing cost of reward. Thus, rather than a change in motivation *per se* there appears to be alteration in the perception of the increasing cost of reward.

415.20

LESIONS OF THE VENTRAL PALLIDUM INTERFERE WITH REVERSAL OF ODOR DISCRIMINATION IN RATS. X.-C. M. Lu* and J. L. Price. Dept. of Anat. & Neurobiol., Washington Univ. Sch. Med., St. Louis, MO 63110.

Previous studies have shown that interruption of the projection from the globus pallidus to the ventroanterior and ventrolateral thalamic nuclei interferes with the inhibition of conflicting motor programs. Lesions of the mediodorsal thalamic nucleus, which receives input from the ventral pallidum (VP), interfere with reversal learning. A common feature of these deficits is the animals' inability to inhibit previously learned behavior in order to switch to a new behavioral or cognitive strategy.

This study examined the role of VP in inhibition of responding to a previously rewarding odor stimulus. In the first, or "inhibition", task, two odors which rats had learned as positive (rewarding) stimuli in previous separate tasks were paired together for discrimination. One odor remained positive and the other became a negative (nonrewarding) stimulus. In each of two subsequent "reversal" tasks, 2 novel odors were paired for initial discrimination learning. On the next day, the significance of these odors were reversed. Experimental rats with bilateral VP lesions, and sham controls rats were compared with these tasks. Histological

verification of the lesions was performed in experimental rats. In all three tasks the lesioned rats made substantially more errors than the control rats, and some rats failed to reach criterion in 500 trials. With the two reversal tasks these differences were significant, although with the inhibition task the difference did not reach significance. Supported by NIH grant DC00093.

LEARNING AND MEMORY: PHARMACOLOGY—EXCITATORY AMINO ACIDS

416.1

CHANGES IN GLUTAMATE RECEPTOR PROPERTIES IN THE CEREBELLAR CORTEX OF CLASSICALLY CONDITIONED RATS. Sarah Pollock, Dave Lavond*, Richard F. Thompson, Matti Mintz, & Georges Tocco. Psychobiology Unit, Psychology Department, Tel Aviv University, Israel & University of Southern California, Neurosciences Program, HEDCO Neurosciences Building, Los Angeles, CA, 90089-2520.

The cerebellar cortex is believed to be involved in the neural plasticity associated with the conditioned eyelid response. Because glutamate receptors have been shown to play a pivotal role in various forms of synaptic plasticity, we planned to determine their involvement in this learning model using quantitative ligand binding autoradiography.

Male Wistar rats were trained on a delay paradigm with paired presentations of conditioned (tone) and unconditioned (electric shock to one eye) stimuli. Naive and unpaired animals were used as controls. Quantitative ligand binding autoradiography using ligands specific for the AMPA subclass of glutamate receptors revealed an increase in tritiated AMPA and CNQX binding on the contralateral side of the trained animals (compared to the ipsilateral) with little or no side difference on the unpaired and naive animals. Conditioning did not result in any change on tritiated TCP binding (NMDA specific).

These results support molecular changes of glutamate receptors in cerebellar cortex correlated with learning.

416.2

PICROTOXIN INFUSIONS INTO A CRITICAL REGION OF CEREBELLUM PREVENT BOTH ACQUISITION AND RETENTION OF CLASSICALLY CONDITIONED EYEBLINK RESPONSE. S. Bao, L. Chen, J. J. Kim, J. K. Thompson*, and R. F. Thompson. Neurosciences Program, Univ. of Southern Calif., Los Angeles, CA 90089-2520.

Microinfusions of a GABA_A antagonist picrotoxin (PTX) in the cerebellum have been shown to block the expression of classically conditioned eyelink response. In the present study, we examined the effect of PTX on the acquisition of conditioned eyelink response. New Zealand white rabbits, implanted with cannulae aimed at the ipsilateral interpositus (IP) nucleus, underwent five days of standard delay tone-airpuff training while receiving continuous infusions (0.13 µl/min) of PTX (10 nmol/µl) into the IP. Then, they were given 3 days of training with artificial cerebrospinal fluid (ACSF) infusions. During the 5 days with PTX, animals showed no signs of CRs while exhibiting normal unconditioned responses to the airpuff. When switched to the ACSF, these animals learned eyelink CRs as if they were naive. When PTX was infused again, CRs were completely abolished. These results support earlier reversible inactivation studies that demonstrated that the cerebellum is critical for acquisition and expression of eyelink conditioning. 416.3

INVOLVEMENT OF METABOTROPIC GLUTAMATE RECEPTORS IN LONG-TERM POTENTIATION AND LEARNING AND MEMORY. G. Riedel¹, W. Wetzel, S. Vieweg and K. G. Reyman, Federal Inst. for Neurobiology, P.O. Box 1860, 39008 Magdeburg, Germany.

Metabotropic glutamate receptors (mGluRs) are known to play a crucial role in both the induction and maintenance of hippocampal long-term potentiation (LTP). It is conclusive, if LTP is of physiological relevance, that mGluRs should play an important role in learning and memory as well. We investigated this hypothesis applying electrophysiological and behavioral standard procedures.

Electrodes were implanted into the perforant path for stimulation and in the dentate gyrus for recording in the rat. (R,S)- α -methyl-4-carboxyphenylglycine (MCPG), a selective mGluR antagonist, was injected in two concentrations (A=20.8 μ g; B=104.2 μ g i.c.v.) 30 min prior to tetanus-induced LTP or learning, respectively. For comparison, a novel form of shock-reinforced Y-maze spatial alternation and a brightness discrimination task were performed. MCPG blocked different phases of LTP in a concentration dependent manner. Dosis B abolished a potentiation completely and also inhibited learning in the spatial Y-maze. Although these animals showed an acquisition deficit in the discrimination task, no difference to controls occurred during retention test 24 hours after training. Application of A resulted in a considerable 2.5 hours potentiation, which resembled the time course of short-term potentiation (STP). The same concentration had no effect in spatial alternation learning or the brightness discrimination task. These data further substantiate that mGluRs are involved in the expression of LTP in the dentate gyrus and consolidation of spatial alternation memory. The effects on both were dose-dependent, i.e. only the high concentration of MCPG induced a complete block, whereas no learning impairment occurred in the low dose group where the potentiation lasted up to 2.5 hours. We therefore assume, that STP in the hippocampus is the crucial factor for the learning of spatial tasks in the long term. Block of STP, however, results in amnesia.

416.5

THE EFFECTS OF MUSCIMOL INFUSIONS INTO THE AMYGDALA AND MEDIAL SEPTAL AREA IN MEMORY FOR MAGNITUDE OF FOOD REWARD. J.M. Williams, R.J. Nelson and D.S. Olton, Department of Psychology, The Johns Hopkins University, Baltimore, MD 21218.

Rats were trained on a go, no-go task measuring memory for magnitude of food reward. In the study phase of the task, the rats were given one of two cereals. One cereal contained 25% sugar, the other 50% sugar. One of the two cereals was designated as the positive stimulus and the other as the negative stimulus. If the rat received the positive stimulus in the study phase, in the subsequent test phase the rat received another food reward which was placed beneath an object in a foodwell. If the rat received the negative food stimulus during the study phase, no food was placed beneath the object in the foodwell. Performance was measured as latency to uncover the foodwell in the test phase. A previous study using the aforementioned procedure found that lesions to the amygdala, but not the hippocampus significantly impair performance in this memory task.

The present study seeks to further clarify the role of the amygdala in memory for magnitude of food reward. After reaching criterion level (significant difference in latency to respond to the positive vs. negative stimulus), rats received cannula implantations into both the medial septal area and amygdala. All rats received infusions of muscimol (15ng and 30ng) into the amygdala and the medial septal area. The effects of muscimol into each of these areas were compared to saline infusion trials and trials in which no infusions were given. The effects of muscimol on memory for magnitude of reinforcement will be discussed.

416.7

Microinjections of NMDA and non-NMDA receptor antagonists into the "core" and "shell" subregions of the nucleus accumbens impair acquisition and performance in a spatial learning task. C.S. Maldonado-Irizarry¹ and A.E. Kelley², ¹ Northeastern University, Dept. Psychology, Boston, MA 02115; ² University of Wisconsin-Medical School, Dept. of Psychiatry, Madison, WI 53706.

To further investigate the hypothesized functional dissociation between the core and shell subregions of the nucleus accumbens, the following experiments were conducted. The effects of microinfusions of AP-5, a NMDA antagonist, and DNQX, a non-NMDA antagonist into the core and shell subregions of rats on the acquisition and performance phases of a food search task were tested. In this spatial learning paradigm, hungry rats were required to learn a specific pattern of food-baited holes in a large open field. Parameters measured were total time spent searching for food and visits to empty and baited holes (errors). For both experiments, separate groups of rats were used for the acquisition and performance phases of this paradigm. In the acquisition phase, rats were infused with vehicle or DNQX (0.75 μ g/0.5 μ l) into either the core or shell subregions. DNQX treatment in the core group resulted in an increase in both time to complete the task and errors. DNQX in the shell group did not affect time but slightly increased errors. In the performance phase, microinjections of DNQX (0, 0.075, 0.75 μ g/0.5 μ l) were given on test days. Treatment significantly impaired both behavioral measures in the core and shell groups; however, the core group was significantly more impaired than the shell group. In Experiment 2, the effects of microinfusions of AP-5 (0, 0.2, 1.0 μ g/0.5 μ l) in the performance phase were tested. AP-5 significantly increased only the time to complete the trial in both the core and shell groups. However, AP-5 caused significantly more errors in the core than in the shell group. At this time, experiments aimed at investigating the role of NMDA receptors in the acquisition phase of this task are in progress. The present results suggest that blockade of EAA receptors in the accumbens disrupts the acquisition and performance of rats in a food search task; moreover, the accumbens core subregion is more sensitive to the effects of these antagonists on spatial learning and performance than the shell subregion.

416.4

Intra-Amygdala CNQX does not block retention of Escape Training. M.H. Mesches¹, M. Bianchin and J.L. McGaugh, Center for the Neurobio. of Learning & Memory & Dept. of Psychobiol., Univ. of Calif., Irvine, CA 92717-3800.

It is well established that manipulations of the amygdala alter memory. Recent experiments find that the memory impairment induced by lesions of the amygdala may be attenuated by increased degree of training, suggesting that the amygdala is not the critical site of memory storage. However, it can be argued that compensatory mechanisms or incomplete lesions may account for the intact memory. Moreover, if the amygdala is a site of memory storage, a possible mechanism mediating this plasticity would be long term potentiation (LTP). Several studies support the hypothesis that the activation of amygdala NMDA receptors is critical for memory storage. To test whether AMPA receptor-dependent expression of LTP within the amygdala is involved in the expression of retention, several studies have examined the effects of the AMPA-receptor blocker, CNQX on performance of aversively motivated memory tasks. In these studies CNQX blocks or impairs retention when administered prior to testing.

The present study further examined the effects of intra-amygdala infusion of CNQX on the retention of animals trained with different degrees of escape training. In addition, the effects of CNQX on locomotor activity and nociceptive thresholds were also measured. Male rats were implanted bilaterally with cannula aimed at the amygdala. One week later they were trained to escape from the dark, shock compartment of a straight alley maze, receiving either No Shock, 1 trial, or 10 trials of 0.75 mA footshock. Eight days later CNQX (0.5 μ g/0.5 μ l) was infused into the amygdala, 10 min later the rats were placed in the lighted compartment and the initial latency to enter the dark compartment was measured. Each time the rat entered the dark compartment it was shocked with a 0.3 mA footshock until it escaped to the lighted compartment. The number of trials required until the rat stayed out of the dark compartment for 100 sec was used as a measure of retention. CNQX blocked the training dependent increase in the latency to enter the dark compartment ($p < 0.05$) and increased the number of trials required to reach criterion ($p < 0.05$). However, CNQX did not block the effects of previous training. Animals under the influence of CNQX required a lower number of trials to reach criterion during training if they had previously received shock ($p < 0.05$). Rats which received CNQX 10 min before testing showed increased activity in an open field and decreased sensitivity to footshock. Taken together the data presented above suggest that the amygdala AMPA receptors are not critically involved in the retention of escape training. Furthermore, the data does suggest that other performance variables such as locomotor activity and nociceptive threshold are affected by blockade of the amygdala AMPA receptors.

INTRA-SEPTAL INFUSIONS OF MUSCIMOL IMPAIR SPONTANEOUS ALTERNATION PERFORMANCE: FAILURE TO REVERSE THE DEFICIT WITH GLUCOSE. M.B. Parent^{*} and P.E. Gold, Department of Psychology, University of Virginia, Charlottesville, Virginia 22903.

Intra-septal infusions of drugs that act at cholinergic, noradrenergic, opioid peptidergic, and glutamatergic receptors influence spontaneous alternation performance. The present experiment examined the role of the medial septal GABAergic system in spontaneous alternation performance by infusing the GABA agonist muscimol 15 min prior to training in a spontaneous alternation task. With evidence that systemic and intra-septal infusions of glucose reverse the impairing effects of intra-septal infusions of opioid agonists (Ragozzino, Parker, & Gold, *Brain Research*, 1992), the efficacy of intra-septal infusions of glucose in reversing muscimol-induced deficits was also examined. Intra-septal infusions of muscimol (1 or 3 nm/0.5 μ l/1 min) significantly impaired spontaneous alternation performance. Glucose (8.3, 16.7, or 33.3 nm/0.5 μ l/1 min) did not affect spontaneous alternation performance or reverse the deficit produced by intra-septal infusions of muscimol (1 nm). These results indicate that activation of GABAergic receptors in the medial septum impairs spontaneous alternation performance. This finding is similar to results obtained with morphine infusions. However, in contrast to the results with morphine, glucose did not reverse the muscimol-induced impairment. This pharmacological distinction suggests that glucose may interact with specific neurotransmitter systems in the medial septum to influence spontaneous alternation performance. [Supported by NIA (AG 07648), NSF (BNS-9012239), and NIH (HD07323)].

416.8

EFFECTS OF D-CYCLOSERINE, AN AGONIST AT THE GLYCINE SITE OF THE NMDA COMPLEX, ON DISCRIMINATION LEARNING IN YOUNG RATS. M.W. Lillquist^{*}, K. Nixon, and A. Amsel, Dept. Psychology and Inst. for Neuroscience, Univ. of Texas at Austin, Austin, TX 78712.

The N-methyl-D-aspartate receptor complex, a subclass of excitatory amino acid receptors, has been implicated in the processes of learning and memory. Long-term potentiation, a putative mechanism for the cellular basis of learning and memory, has been shown to be modulated by ligand activity at both the glycine and NMDA sites of the receptor complex. Previous work has shown that D-cycloserine (DCS), an anti-mycobacterial drug, binds with high affinity to the glycine site, and in separate studies has been shown to enhance performance on several types of learning and memory tasks. In the present study, young rats (16-17 d.o.) were trained on patterned single alternation (PSA), a memory-based discrimination learning task, following systemic injection with DCS (1.0, 3.0, or 10.0 mg/Kg). Additional subjects were prenatally exposed to ethanol via maternal intubation during the second half of gestation. DCS failed to facilitate PSA learning in either normal animals or in animals prenatally exposed to ethanol, even though prenatal ethanol exposure has been shown to reduce NMDA-mediated cellular response and glutamate binding. These data contribute to an emerging body of research which indicate inconsistent effects of the glycine agonist DCS on learning in both human and animal studies, and they contrast with consistent effects observed with agents which act upon other loci within the NMDA complex. DIFFERENTIAL EFFECTS OF MK-801 AND SCOPOLAMINE ON WORKING AND REFERENCE MEMORY IN RATS. P. Barnéoud*, M. Mazadier, T. Rouyer, M. Reibaud and J.-C. Blanchard. Rhône-Poulenc Rorer S.A., CRVA, 94403 Vitry sur Seine Cedex, France.

Evidence for different types of memory in rats may lead to development of animal models for human memory disorders and provides informations on neurobiological systems underlying these processes. The effects of the noncompetitive NMDA antagonist MK-801 were compared to those of the muscarinic antagonist scopolamine hydrobromide on working and reference memory in the radial maze. In order to discriminate between the working memory and the reference memory, the radial maze was partially baited with only 4 to the 8 arms baited. Moreover, we studied the consequence of angles between the baited arms ("baiting" pattern) on the memory task. The behavioral acquisition of food-deprived male Long-Evans rats was slightly delayed when the angle differed from 90° (45° or 135°), indicating that the pattern corresponding to the 90° was easier to learn. The pharmacological study was performed on the trained animals. MK-801 (0.12 mg/kg, IP, 60 min before a session) significantly increased the number of working memory errors (re-entries into baited arms) and reference memory errors (entries into never baited arms) whereas the running time was barely lengthened. In details, the working memory errors were dramatically increased in the case of "difficult" patterns (45°, 135°) but not in the "easy" one. Scopolamine (0.5 mg/kg, IP, 30 min before a session) increased the running time as much as threefold whereas it slightly increased the working memory errors and had no effect on reference memory errors, whatever the pattern may be.

These findings indicate that MK-801 interacts with memory processes more selectively than does scopolamine hydrobromide. Moreover, the use of "difficult" and "easy" baiting patterns may be a sensitive method to analyze amnesic compounds.

THE EFFECTS OF FG 7142 ON PREFRONTAL CORTICAL DOPAMINE AND SPATIAL WORKING MEMORY IN RAT AND MONKEY. BL Murphy*, RH Roth, and AFT Amsten. Yale Med.Sch, Depts. Pharmacol. & Neurobiol., New Haven, CT 06510

The benzodiazepine inverse agonist FG 7142 (20 mg/kg; i.p.) has been shown to selectively increase the DOPAC/DA ratio in the prefrontal cortex (PFC), but the consequences of this treatment on the working memory functions of the PFC have not been examined. The present study tested the effects of FG on spatial working memory in the rat (delayed alternation in a T-maze) and in the monkey (delayed response in a WGT). In rats, FG (20 mg/kg; i.p.) significantly impaired delayed alternation performance. This impairment was reversed by pretreatment with the benzodiazepine antagonist RO15-1788 (20 mg/kg; i.p.). Consistent with the hypothesis that FG impairs delayed alternation by increasing DA release, low doses of the DA antagonist, haloperidol (0.1-0.2 mg/kg; i.p.) were able to ameliorate the FG-induced delayed alternation deficit. The glycine partial agonist, (+) HA-966 can act as an antagonist at the glycine site of the NMDA receptor. Pretreatment with (+) HA (20 mg/kg; i.p.), attenuates the effect of FG on measures of DA turnover and on delayed alternation. Similar responses were observed in monkeys: FG (0.2 mg/kg; i.m.) impaired delayed response performance, and this impairment could be reversed by haloperidol (0.005mg/kg; i.m.) or the D1 antagonist SCH 23390 (0.0065 mg/kg; i.m.). Preliminary results indicate that pretreatment with (+)HA may attenuate FG-induced impairment. These results suggest that excessive DA release in the PFC impairs spatial working memory performance. (Supported by grants NSF:GER-9253954; MH 44866; and MH 14092).

ANTEROGRADE AMNESTIC AND ANTICONVULSANT EFFECTS OF TWO TYPES OF NMDA RECEPTOR ANTAGONISTS: MK-801 AND HA-966. X. Xu*, P. Klinger, and R. Davis. Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48104-1687.

The anterograde amnesic effects of noncompetitive NMDA antagonists MK-801 and HA-966 on classic fear conditioning in goldfish (*Carassius auratus*) were examined in a series of experiments. Experiments 1 and 2 contrasted the anterograde amnesic effects of MK-801, (+)HA-966, and (-)HA-966. Experiments 3 and 4 investigated whether the potency of MK-801, (+)HA-966 or (-)HA-966 in blocking NMDA induced convulsions paralleled their potency in producing amnesia. The results showed that MK-801 was more potent than (+)HA-966 in producing anterograde amnesia, while (-)HA-966 did not produce anterograde amnesia. The anticonvulsant potency of MK-801, (+)HA-966, and (-)HA-966 paralleled their amnesic potency. These findings suggested that MK-801 and (+)HA-966 produced anterograde amnesia by their antagonism of NMDA receptor complex specifically.

416.10

EFFECTS OF BACLOFEN ON LEARNING AND MEMORY IN RATS AS ASSESSED USING A WATER MAZE. R.M. Wylie*, G.J. Kant and N.G. Bowerly¹. Dept. Med. Neurosci., Walter Reed Army Inst. of Res., Washington DC 20307-5100 & ¹Dept. Pharmacol., School of Pharmacy, Univ. of London, London WC1N 1AX.

We evaluated the effects of the GABA_B agonist baclofen on learning and performance of rats in a water maze. Once the rats achieved criterion, (-)baclofen (3mg/kg) was injected i.p. in half of the rats 15 minutes prior to testing on each of 3 consecutive days. The treated rats took significantly longer to complete the maze. In two additional studies, we gave the rats daily injections of (+)baclofen (6mg/kg) prior to training them on new configurations of the maze. We found no significant difference between the treated and control rats on the number of trials required to reach criterion but did find that after reaching criterion the baclofen-treated rats required significantly longer times to complete the maze. When no drug was administered, the performance of the two groups was not significantly different. These results suggest that baclofen impairs performance but does not affect learning.

416.12

SPERMIDINE POTENTIATES DIZOCLIPINE-INDUCED LEARNING IMPAIRMENT OF RATS IN A 14-UNIT T-MAZE TO DEMONSTRATE POLYAMINE MODULATION OF NMDA RECEPTOR. A. Shimada*, E.L. Spangler, E.D. London, and D.K. Ingram. Gerontology Research Center, NIA, and Addiction Research Center, NIDA, NIH, Baltimore, MD 21224

The NMDA receptor, a ligand-gated ion channel complex has been reported to be involved in memory processes. Learning is impaired following administration of dizocilpine (DIZO), a non-competitive antagonist of the NMDA receptor. Polyamines, such as spermine and spermidine, interact with the NMDA receptor to enhance binding of DIZO, which blocks the ion channel. The present study assessed action of polyamines as modulators of learning via NMDA receptor activation. DIZO (0.05 mg/kg) was given i.p. before maze learning, at a dose that produced a slight, nonsignificant impairment of maze learning. Pretreatment with 80 mg/kg but not 15 or 40 mg/kg spermidine (SPD) (i.p.) before DIZO impaired maze learning compared to saline controls. Administration of 80 mg/kg SPD without DIZO did not impair maze learning. The results are consistent with the view that systemic injection of a polyamine can modulate learning processes involving the NMDA receptor. Studies are ongoing under the hypothesis that systemically injected SPD may ameliorate impaired maze learning in aged rats by activating the NMDA receptor.

416.14

SELECTIVE ENHANCEMENT OF AMPA RECEPTORS IMPROVES NEOCORTICAL LEARNING. R. Granger*, C. Mangione, D. Anghesom, A. Lopez, M. Davis, B. Tran, G. Rogers & G. Lynch. CNLM, Univ. of Calif., Irvine, CA 92717.

In a novel neocortically dependent auditory task, the first pharmacological agents to specifically enhance glutamatergic receptor action in the brain ("AMPAKINES") were tested for their effects on learning. AMPAKINES selectively enhance the glutamate receptor, which mediates all normal fast excitatory transmission, and is the likely site of synaptic long-term potentiation (LTP), the leading candidate substrate for learning. In the first reported tests of behavioral effects of these drugs, Staubli et al., *PNAS*, 91: 777 (1994) and Granger et al., *Synapse*, 15: 326 (1993) showed that they enhanced learning in a radial arm maze and an olfactory discrimination task, which are hippocampally and paleocortically dependent, respectively. We report here on a novel auditory discrimination task, and show that performance on this task is improved by AMPAKINES. The task consists of a maze in which each arm has a high-frequency speaker. Only two speakers are active on any given trial. Each speaker continuously plays a complex natural sound, recorded and then shifted up into the rat's hearing range (10KHz and above). On each trial, the rat receives a water reward for approaching the "correct" one of the two sounds, whose spatial location changes with each trial. Rats learn many such sounds rapidly, and exhibit weeks-long retention of learned sounds. Selective lesions of primary auditory neocortex severely impairs learning of new sounds. In an experiment counterbalanced for sound preference, learning and retention, and in which animals serve as their own controls for drug effects, rats were tested on very difficult sound discriminations, and given a small number of training trials. On days when they were not given the drug, animals were unable to learn the sounds significantly above chance approach levels. On days when they received the drug five minutes before entering the maze, they exhibited a 41% improvement over their non drug performance. This is the first demonstration of enhancement of learning in a neocortically dependent animal model. (Supported by AFOSR F49620-92-J-0307 and ONR N00014-89-J-1255).

A CRITICAL ROLE FOR THE NMDA RECEPTOR SITE IN COCAINE DRUG CONDITIONING PROCESSES. Ernest N. Damianopoulos* and Robert J. Carey. Psychiatry, SUNY Health Science Center and Research and Development Service-151, VA Medical Center, Syracuse, NY 13210

The role of the NMDA receptors in cocaine conditioning and sensitization was studied in four groups of matched Sprague-Dawley rats. A sub-motoric dose of the NMDA antagonist MK-801 (0.1 mg/kg ip) was employed using a novel dual-compartment Pavlovian drug conditioning paradigm. The animals were placed sequentially in two similar but distinct test environments. In the first compartment, the animals always received a non-drug test (20 min). Upon removal, the animals received either saline, cocaine (10 mg/kg ip), MK-801 or MK-801 plus cocaine depending on group assignment and were then placed immediately into the second compartment (20 min). Every other day over a 12-day period, the animals of each group (n = 6) received 1 non-drug test followed by 1 saline/drug test. Across all drug treatment days and subsequent tests for conditioning, there were no statistical differences between the saline and drug treatment groups in the non-drug test environment on locomotor distance. Thus, non-specific, non-associative response sensitization effects were not observed. Cocaine, however, had a consistent stimulant effect on locomotor behavior in the drug test environment either when administered alone or in combination with MK-801. Following a 1-day and again after a 21-day withdrawal, all animals were administered a non-drug test for conditioning. The results showed that the cocaine induced enhancement of locomotion was conditioned to the exteroceptive cues of the drug-associated environment but this effect was not present in the animals treated with cocaine plus MK-801. While MK-801 blocked cocaine conditioning, MK-801 had no effect on the cocaine locomotor stimulant response.

EFFECTS OF PHENYTOIN ON LEARNED APPETITIVE RESPONSES AND THE SUBSEQUENT ACQUISITION OF ESCAPE AND AVOIDANCE RESPONSES.

N.L. Mohr¹, J.E. Steinmetz^{1,2*}, and P.E. Garraghy^{1,2}. ¹Dept. of Psych. and ²Prog. in Neural Sci., Indiana Univ., Bloomington, IN 47405.

Phenytoin (Dilantin) has been used for the control of epileptic seizures for more than 55 years. This drug has proven to be an effective antileptic, but it may also be associated with deficits in behavior and cognition. Here, we have evaluated the effects of instituting chronic phenytoin maintenance in rats that had undergone initial training in an appetitive instrumental task with a subsequent switch to an aversive (escape/avoidance) task. We initially trained deprived rats to produce a bar press in the presence of a tone stimulus for a food reward. We then began treating the rats daily with phenytoin (solution, Parke-Davis). Our goals were to determine the extent to which the animals' behavior in the appetitive task was affected by the institution of phenytoin treatment, and how the acquisition of the new escape/avoidance responses were affected. Our results suggest three findings relative to control observations from drug-free rats: 1) a reduction in response latency in the appetitive phase of the experiment after the initiation of drug treatment; 2) a prolonged latency (over session days) in the acquisition of the initial escape response after the animals are switched to the aversive task; and 3) a failure to acquire the avoidance response. These results, in sum, suggest that phenytoin has substantial, and negative (at least for findings 2 and 3) consequences for learning in subjects chronically maintained on the drug, perhaps because of its antagonistic effects on NMDA receptors.

LEARNING AND MEMORY: PHARMACOLOGY—OTHERS I

417.1

ACUTE DIAZEPAM ADMINISTRATION PRODUCES MEMORY DEFICITS SIMILAR TO THOSE DUE TO CHRONIC ALCOHOL CONSUMPTION. N. Borge, R. Jaffard and D. Béracochéa*. Lab. Neurosciences Comportementales et Cognitives, CNRS URA 339, Univ. Bordeaux I, avenue des Facultés 33405 Talence Cedex France.

The effects of the benzodiazepine agonist (Diazepam) on delayed alternation in a T-maze in mice were studied. Delay intervals (DI) separating the acquisition trials from the retention trial were either 30 sec or 6 hours. The 6 hours trial was further used as an acquisition trial for a subsequent alternation trial (DI: 30 sec) aimed at measuring short-term memory as well as the eventual sedative effects of the drug. Diazepam (1.0 or 1.5 mg/kg) was administered i.p. 30 mn before the 6 hr retention trial. Results showed that the 1.5 but not the 1.0 mg/kg dose induced a memory deficit, as compared to saline treated subjects. No impairments were observed on the short-term trial. Furthermore, the Diazepam-induced memory impairment was reversed by a context-change occurring before the retention trial even though this finding requires further experiments to be firmly established. The effects of Diazepam on memory appear to be similar to those resulting from a long-term ethanol administration and which appear to result from an impairment of the retrieval phase of memory processes.

PREGNENOLONE SULFATE INFUSION ANTAGONIZES DIZOCILPINE AMNESIA: MEDIATION BY ALLOPREGNANOLONE. D.L. Cheney*, D. Uzunov, E. Costa and A. Guidotti; FGIN, Georgetown University Medical Center, 3900 Reservoir Road, N.W., Washington, D.C.

Dizocilpine, a non-competitive N-methyl-D-aspartate (NMDA) antagonist (0.1mg/kg,i.p.), disrupted the passive avoidance response in control and adrenalectomized/castrated (ADX/CX) male rats. Infusion of pregnenolone sulfate (20mg/kg,i.v., 5min) antagonized dizocilpine induced amnesia and increased the brain content of pregnenolone, progesterone and allopregnanolone as measured by gas chromatography-mass fragmentography. Similar effects were observed with CPPene, a competitive NMDA antagonist (2.5mg/kg,i.p.). Five to ten fold increases in allopregnanolone were observed in olfactory bulb, striatum, hippocampus and cortex following infusion of pregnenolone sulfate. Pretreatment with the 5 α -reductase inhibitor SKF105111 (5mg/kg,i.v.) blocked the pregnenolone sulfate antagonism of dizocilpine amnesia and prevented the increase of allopregnanolone in olfactory bulb, striatum and cortex. These results support the hypothesis that the amnesia elicited by the NMDA antagonist dizocilpine is counteracted by pregnenolone sulfate via its ability to increase the brain content of allopregnanolone.

417.2

ANATOMICAL AND TEMPORAL SPECIFICITY OF CHLORDIAZEPOXIDE- AND LIDOCAINE-INDUCED SPATIAL MEMORY IMPAIRMENTS.

R.W. Stackman* and T.J. Walsh. Dept. Psychology, Rutgers Univer., New Brunswick, NJ 08903.

The functional activity of cholinergic neurons in the medial septum (MS) that project to the hippocampus is modulated by an intrinsic GABA-benzodiazepine (BDZ) mechanism. Intraseptal injection of the BDZ, chlordiazepoxide (CDP) to rats (i) impairs working memory (WM), (ii) decreases hippocampal high-affinity choline transport, and (iii) decreases dentate gyrus extracellular responses. Further, intraseptal flumazenil, a BDZ antagonist, reverses systemic CDP-dependent amnesia (Stackman & Walsh, 1992; Walsh et al., 1993; Stackman et al., 1993). These data indicate a septal BDZ substrate capable of impairing WM and modulating cholinergic activity in the HPC, is likely the site of action of the amnesic action of CDP. Experiment 1 examined the contribution of neural regions proximal to the septohippocampal network, to the expression of CDP-induced amnesia. Infusion of 30 nmoles of CDP into the MS impaired WM in a delayed non-match-to-sample (DNMTS) radial-arm maze (RAM) task. This dose of CDP failed to alter RAM performance when infused unilaterally into the cingulate gyrus, or bilaterally into the lateral septum, or the nucleus basalis. Infusion of the local anesthetic, lidocaine (147 nmoles) into these sites produced similar behavioral effects. Experiment 2 examined the time-dependent nature of intraseptal CDP-induced amnesia. Rats were trained in the DNMTS RAM task and then injected with 30 nmoles CDP into the MS at one of the following posttraining times: 0, 15, 30, 45, or 60 mins. Rats infused with CDP immediately posttraining exhibited WM impairment. Infusion of CDP at the other posttraining times failed to significantly impair performance. These data indicate that MS is the site of action for CDP-induced amnesia, and this structure is critically involved in an early encoding or maintenance phase of spatial WM. Supported by NSF Grant BNS 922097 to TJW.

417.3

CHRONIC BENZODIAZEPINE (BZ) TREATMENT FACILITATES SPATIAL LEARNING IN THE MORRIS WATER MAZE (MWM).

M.S. Mohamed¹, W.S. Messer² and E.I. Tietz¹. ¹Dept. of Medicinal and Biological Chemistry, College of Pharmacy, University of Toledo, 43606, and ²Dept. of Pharmacology, Medical College of Ohio, Toledo, OH 43699.

Acute BZ treatment, which potentiates GABA inhibition interferes with long-term potentiation (LTP) and impairs spatial learning. Reducing GABA inhibition in hippocampal CA1 region facilitates LTP. Chronic flurazepam (FZP) treatment reduces GABA inhibition in the CA1 region *in vitro*. We hypothesized facilitation of LTP in hippocampal slices from chronic FZP-treated rats. However, in a previous study using 10 theta bursts, LTP was induced to a similar degree in FZP-treated and control slices but was not maintained in FZP-treated slices. Since LTP mediates spatial learning we evaluated the effect of 1 week FZP treatment (100 mg/kg x 3 days; 150 mg/kg x 4 days, p.o. in .02% saccharine) in the MWM. Treated rats were offered saccharine H₂O for 2 days before and after FZP treatment. Control rats received saccharine H₂O. Rats were adapted to the maze by allowing them to swim freely for 120 s over 2 days. Two days after FZP-treatment, we tested each rat's ability to find a hidden platform. Rats were trained 4 trials/day/4 days and tracked with a video camera connected to a computer. Latency to escape(s), path length (cm), and speed (cm/s) were averaged. Speed was constant for each group ($p = .77$) indicating no motor effect due to FZP treatment. The latency of FZP-treated rats to find the platform was less than controls (treatment effect, $p = .043$) suggesting that reduced GABA inhibition associated with chronic BZ treatment facilitates spatial learning, consistent with our previous hypothesis. Future studies will explore LTP in chronic FZP-treated rats using a 5 theta burst paradigm. Supported by NS01493 to W.S.M. and NIDA grants RO1-DA04075 and RSDA K02-DA00180 to E.I.T.

EFFECTS OF CONVULSANT AND ANTICONVULSANT AGENTS ON MEMORY IN SQUIRREL MONKEYS. J.M. Moerschbaecher^{*} and E.D. Pakarinen, Department of Pharmacology, LSU Medical Center, New Orleans, LA 70112

It has been reported that subconvulsive doses of convulsant agents such as strychnine and pentylenetetrazole may enhance memory in rodents studied under various behavioral procedures. The present study was designed to determine if similar results might obtain in monkeys. Responding by squirrel monkeys was maintained by food presentation under a repeated acquisition of behavioral chains procedure. Monkeys acquired a different three-response chain each session. Sequence completions were reinforced under a fixed-ratio 5 schedule (FR 5) and errors produced a brief timeout. After the monkey reached a predetermined acquisition criterion, the session was stopped and either a 90 min or 24 hr delay was interposed. Following the delay the subject was retested on the same discrimination and retention quantified as percent savings. When administered immediately after the monkey reached the acquisition criterion strychnine and pentylenetetrazole had no effect on percent savings under the 24 hr delay. Similarly, the delta opioid agonist, BW373U86[(\pm)-4-((R)- α -(2S,5R)-4-allyl-2,5-dimethyl-1-piperazinyl)-N,N-diethylbenzamididihydrochloride], had little or no effect on percent savings following either 90 min or 24 hr delays. This was true even at doses of BW373U86 which produced convulsions. In contrast, at high doses triazolam decreased percent savings following a 24 hour delay. These results suggest that at subconvulsive doses convulsant agents have little or no effect while anticonvulsant agents such as triazolam can disrupt memory processes in squirrel monkeys. (Supported by USPHS Grants DA03573 and DA04775.)

EFFECTS OF INFUSIONS OF CHLORDIAZEPOXIDE AND β -CCM INTO THE BASAL FOREBRAIN ON SUSTAINED ATTENTION. L.A. Holley^{*}, C. Apple, J. Turchi and M. Sarter. Dept. Psychology and Neuroscience Program, Ohio State Univ., Columbus, OH 43210.

Using a recently developed, valid task for the measurement of sustained attention in rats (Bushnell et al. 1994; McGaughy & Sarter 1994), the systemic administration of the benzodiazepine receptor (BZR) agonist chlordiazepoxide (CDP) was found to potently and dose-dependently decrease the relative number of hits but not of correct rejections. Furthermore, the effects of CDP interacted with signal salience. As expected in intact animals, BZR inverse agonists failed to facilitate performance. Here we show that intracranial infusions of CDP (20, 40 μ g/0.5 μ l/hemisphere) or β -CCM (1.5, 3.0 μ g/0.5 μ l/hemisphere) into the substantia innominata of the basal forebrain reproduce the effects of the systemic administration of these compounds. Moreover, the effects of intrabasalis CDP were more efficacious in decreasing the relative number of hits than following systemic administration. In contrast to the effects of systemic administration, these potent effects of intrabasalis CDP on vigilance performance were not associated with equally potent effects on the number of errors of omission. These data support the hypotheses that the basal forebrain represents a sufficient anatomical substrate mediating the attentional effects of BZR agonists. Also, these findings parallel the effects of systemic and intrabasalis administrations of BZR ligands on cortical acetylcholine efflux (Moore, Sarter & Bruno 1993, 1994).

417.4

THE BENZODIAZEPINE DIAZEPAM DISRUPTS THE REGENCY EFFECT BUT NOT THE PRIMACY EFFECT IN RHESUS MONKEYS TRAINED ON A SERIAL PROBE RECOGNITION TASK. C.A. CASTRO^{*}. Drug Assessment Division, U.S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD 21010.

The effects of diazepam (0.2, 0.8, 1.6 and 3.2 mg/kg) on the primacy and recency memory effects were evaluated in four rhesus monkeys using a serial probe recognition (SPR) task. Only the highest dose of diazepam (3.2 mg/kg) significantly disrupted the monkeys' performance on the SPR task, causing an increase in the number of errors and an increase in the response latencies on the probe trials. Analyses of the serial position curves for each monkey further revealed that the highest dose (3.2 mg/kg) of diazepam disrupted both the recency effect and the middle portion of the serial position curves in all the monkeys tested. In contrast, the primacy effect was relatively unaffected by any of the doses of diazepam tested. Previous reports have suggested that the primacy effect is mediated by the establishment of contextual or configural associations and the recency effect is mediated by the establishment of simple associations. Therefore, we have proposed that diazepam interferes with the simple associative processes involved in the recency effect to a much greater extent than it does with the contextual or configural associative processes involved in the primacy effect. This is the first demonstration showing that diazepam can produce such selective memory impairments in nonhuman primates.

417.6

LATENT INHIBITION AND PARTIAL REINFORCEMENT DO NOT RETARD THE DEVELOPMENT OF CONTINGENT TOLERANCE TO THE ANTICONVULSANT EFFECTS OF DIAZEPAM. T.E. Kippin^{*}, L.E. Kalynchuk, T.J. Komecook, & J.P.J. Pinel. Dept. of Psychology, Univ. of British Columbia, Vancouver, B.C. (Canada) V6T 1Z4.

Contingent drug tolerance is a widely reported phenomenon. However, the principles by which contingent tolerance develops are not well understood. Unlike other forms of drug tolerance, contingent tolerance does not appear to be under the influence of Pavlovian conditioning. The present study investigates the role that latent inhibition and partial reinforcement play in the development of contingent tolerance to the anticonvulsant effects of diazepam (DZ). In experiment 1, kindled rats were injected with either 5mg/kg of DZ or vehicle without convulsive stimulation, three times daily, for ten days. Forty-eight hours following the last injection, both groups were switched to a DZ before stimulation schedule to assess the development of contingent tolerance to the anticonvulsant effects of 2mg/kg of DZ. Neither group displayed significant tolerance on the first trial, however, both groups developed contingent tolerance within 15 trials. Prior DZ exposure alone, not only, failed to retard, but facilitated the development of contingent tolerance. In the second experiment, kindled rats were exposed to a schedule which alternated between DZ injection followed by convulsive stimulation and DZ or vehicle injection followed by handling. Partial pairing of DZ injections with convulsive stimulation (reinforcement) failed to retard the development of contingent tolerance to the anticonvulsant effects of 2.5 mg/kg of DZ. Further, the extinction of tolerance in the two groups did not differ significantly. The results of these two experiments suggests that contingent tolerance to the anticonvulsant effects of DZ is not under the influence of latent inhibition or partial reinforcement.

A NOVEL BENZODIAZEPINE INVERSE AGONIST, S-8510, AS A COGNITIVE ENHANCER. K.Kawasaki^{*}, T.Kihara & S.Murata, Shionogi Res.Labs., Shionogi & Co., Ltd., Toyonaka City, Osaka 561, Japan.

Benzodiazepine (BDZ) inverse agonists can be therapeutic drugs for dementia including Alzheimer's disease (TINS 11 13, 1988). We showed that some BDZ inverse agonists ameliorate amnesia produced by several procedures in animal models (Prog. Neuro-Psychopharmacol.Biol.Psychiat. 12 951, 1988). At high doses, however, the inverse agonists induce adverse actions such as proconvulsant and anxiogenic effects. Here we report that a novel BDZ inverse agonist, S-8510, promotes anti-amnesic effects without producing adverse actions. S-8510 ameliorated amnesia produced by scopolamine or BDZ in the rat water maze and passive avoidance paradigms. S-8510 did not induce any sign of anxiety and convulsion by itself even at doses 10-100 times higher than those effective for anti-amnesic tests. S-8510 increased extracellular levels of acetylcholine and noradrenaline in the hippocampus and cerebral cortex. It also augmented long-term potentiation induced by tetanic stimulation of Schaffer-collateral/commissural fiber-CA1 synapses. Dose-response relationships of these actions are finely graded, their slope being much less steep than that of a convulsant, pentylenetetrazol. Moreover, S-8510 shared some pharmacological feature with antidepressants. It is concluded that S-8510 is a nootropic drug with different mechanism of action from other previously reported nootropics.

MEMORY ENHANCEMENT WITH THE DELTA OPIOID RECEPTOR ANTAGONIST NALTRINDOLE IS DEPENDENT ON TRAINING PARAMETERS IN THE CHICK. P.J. Colombo*, S.E. Moran, J.L. Martinez, Jr., E.L. Bennett & M.R. Rosenzweig. Dept. of Psychology, Univ. of California, Berkeley, CA 94720.

Administration of enkephalins or delta opioid receptor agonists either enhance or impair memory formation and these effects are dependent on treatment and training conditions. We examined whether memory effects can be produced by administration of the delta receptor antagonist naltrindole (NTI). Two-day-old chicks were injected with saline or NTI in the medial hyperstriatum ventrale 5 min before one-trial peck-avoidance training. To give relatively weak training so that either impairment or enhancement could appear, chicks received either of 2 training conditions: (1) The Latent Inhibition (LI) condition involved 4 pretraining exposures to a dry chrome bead followed by one exposure to a bead coated with the chemical aversant methylanthranilate (MeA). (2) No-LI chicks were given one exposure to a bead coated with 1% MeA. Approximately 40-50% of saline injected chicks in each training condition avoid pecking a dry bead at 24 h test. In LI trained chicks, NTI caused a dose dependent increase in avoidance at 24 h test, the highest dose producing significant memory enhancement. In contrast, NTI had no significant effect in the No-LI trained chicks. These findings suggest that memory enhancement resulting from opioid antagonism is dependent on training conditions. Specifically, endogenous opioids may be selectively involved in memory formation for training that involves discrepant information about conditioned stimuli.

Supported by NIDA DA05492 (PJC), DA04795 (MRR) & DA04195 (JLM).

417.11

MODULATION OF MEMORY FORMATION FOR A ONE-TRIAL PECK AVOIDANCE TASK IN CHICKS GIVEN CENTRAL INJECTIONS OF MU, DELTA, AND KAPPA SELECTIVE OPIOID ANTAGONISTS. D.W. Lee*, E.L. Bennett, & M.R. Rosenzweig. Department of Psychology, University of California, Berkeley, CA, 94720.

To investigate opioid-mediated memory formation, chicks were injected with opioid antagonists or saline 5 min before training on a one-trial peck avoidance task, then tested 24 h later for retention. A weak concentration (10%) of the aversant liquid methylanthranilate (MeA) was used as the aversive stimulus; 10% MeA results in intermediate retention levels (~40%) allowing the investigation of both memory impairment and/or enhancement within identical experimental protocols. Several experiments were conducted administering i.c. bilateral injections of either mu, delta, or kappa selective antagonists (CTOP, ICI174-864, norBNI, respectively) or saline directed into the region of the intermediate medial hyperstriatum ventrale (IMHV; the avian homolog of mammalian visual association cortex) or lobus parolfactorius (LPO; homolog of basal ganglia).

Mu antagonist CTOP (.01 nmoles/hemisphere) impaired memory when injected into the LPO only. Delta antagonist ICI enhanced memory in both the IMHV (3.0 nmoles/hemisphere) and LPO (10.0 nmoles/hemisphere) but effect in LPO only approached significance ($p < .10$). Kappa antagonist norBNI impaired and enhanced memory in a dose dependent way when injected into the IMHV (.10 nmoles/hemisphere impaired; 10.0 nmoles/hemisphere enhanced). The same pattern was observed when norBNI was injected into LPO but only impairment by .30 nmoles/hemisphere was found to approach significance ($p < .10$).

Although opioids clearly modulate memory formation in the chick, the direction of their effects (impairment or enhancement) is highly dependent upon 1) dose; 2) receptor type (mu, delta, or kappa); and 3) brain location (IMHV or LPO).

NALOXONE INDUCED OPIOID WITHDRAWAL SIGNS IN RATS FOLLOWING EXPOSURE TO A CONTEXT ASSOCIATED WITH SHOCK. G.C. Abrahamsen, B.J. Caldarone, D.L. Mongeluzi, H.S. Stock, and R.A. Rosellini*. State University of New York: University at Albany.

Work in our laboratory has recently shown that acute opioid withdrawal elicited by naloxone is enhanced when morphine is administered in the presence of shock associated cues. To further explore the nature of these effects two experiments were conducted to examine whether naloxone could elicit signs of opioid withdrawal in animals exposed to a context associated with shock even in the absence of morphine. Experiment 1, utilizing a high (10 mg/kg) dose of naloxone, revealed that forepaw tremors but no other classic opioid withdrawal sign could be induced by naloxone following exposure to a context associated with shock. Experiment 2 further examined this effect across a range of naloxone doses (0, 1, 5, 10 mg/kg). This experiment revealed that the emergence of forepaw tremors following exposure to a shock associated context is dependent upon a high (10 mg/kg) dose of naloxone. Furthermore, other signs of withdrawal such as mastication and teeth chattering were most evident at lower doses of naloxone. These findings are consistent with other studies that have shown that naloxone can induce signs of opioid withdrawal following the exposure to physical stressors.

[LEU]ENKEPHALIN CAUSES MEMORY ENHANCEMENT FOR AVERSIVELY AND APPETITIVELY MOTIVATED TRAINING IN FOUR-DAY-OLD CHICKS. E.L. Bennett*, P.J. Colombo, J.L. Martinez, Jr. & M.R. Rosenzweig. Dept. of Psychology, Univ. of California, Berkeley, CA 94720.

We reported previously that administration of [Leu]enkephalin (LEU) in two-day-old chicks impairs memory formation for peck-avoidance (PA) training. The current study examined the effects of LEU administration on memory for both appetitive discrimination (AD) and PA training. Food motivation cannot be used effectively in chicks younger than three days of age, because their behavior is not influenced by ingestion of food. Therefore, the current study examined the effects of LEU on both PA and AD training in four-day-old chicks for the following reasons: (1) to determine if LEU produced similar effects at days 2 and 4 post-hatch; (2) to insure that comparison of the effects of LEU on appetitively and aversively motivated learning used chicks of the same age. Four-day-old chicks were injected with either saline, 0.03, 0.1, or 0.3 mM LEU in the medial hyperstriatum ventrale 5 min before either PA or AD training and tested 24 h later. Administration of each of the doses of LEU significantly enhanced memory for PA training when compared to saline-injected chicks at 24 h test. Similarly, chicks injected with 0.3 mM LEU showed significant memory enhancement for AD training when compared to saline-injected chicks at 24 h test. These results suggest the following: (1) LEU causes similar effects on both aversively and appetitively motivated learning in 4-day-old chicks, and (2), LEU produces different effects on memory formation in 2- and 4-day-old chicks. THE MU ANTAGONIST CTOP ENHANCES MEMORY FORMATION IN THE 2-DAY-OLD CHICK. M.A. Leissring^{1,2}, J.C. Huang¹, A.M. Anderson, M.R. Rosenzweig¹, E.L. Bennett¹ and J.S. Williston^{2*}. ¹Department of Psychology University of California, Berkeley, CA 94720. ²Department of Biology, San Francisco State University, San Francisco, CA 94132.

Leissring *et al.* (1993) reported that the mu agonist DAGO (0.01 mM) inhibits learning and/or memory formation in 2-day-old chicks. To extend these findings, we investigated the effects of the mu antagonist CTOP in two successive experiments, the first, designed to determine a dose-response function for CTOP; and the second, to evaluate if the inhibitory effect of 0.01 mM DAGO found previously could be attenuated when administered in a cocktail with various doses of CTOP. Both experiments employ the 1-trial peck-avoidance task developed by Cherkin (1969). In this task, chicks are presented for 10s with a stainless steel bead dipped in methylanthranilate, a liquid aversant. At test, animals are presented with a similar but dry bead. Chicks avoiding the test bead are recorded as having remembered the aversive stimulus, those pecking at it, as amnesic. All experimental agents were diluted in chick Ringer's solution (RING) and administered 5 min before training, via bilateral, i.e. injections (10 μ L/hemisphere) into the region of the intermediate medial hyperstriatum ventrale. Animals were tested 24h posttraining.

In the dose-response function, groups of chicks were administered either RING or various concentrations of CTOP (0.001, 0.01, or 0.1 mM). Groups injected with either 0.01 mM or 0.1 mM CTOP demonstrated significant enhancement relative to RING-injected controls ($N = 59$ -64 total chicks per group across 3 replications).

In the second experiment, groups of chicks were injected with either RING alone, DAGO (0.01mM), CTOP (0.01mM), CTOP (0.1mM), or cocktails of DAGO (0.01mM) in combination with either CTOP (0.01mM) or CTOP (0.1mM). This experiment replicated the results of the first experiment for groups given 0.1 mM CTOP, which exhibited significantly enhanced retention relative to controls; however, this experiment did not replicate those for 0.01mM CTOP. Animals administered 0.01mM DAGO exhibited significantly impaired retention relative to controls, replicating the findings obtained by Leissring *et al.* (1993). In contrast, animals administered 0.01 DAGO combined in a cocktail with 0.1 mM CTOP exhibited retention levels which did not differ significantly from RING-injected controls, i.e., co-administration of the two agents cancelled the effects of each agent administered alone. These results provide evidence that the effects of DAGO and CTOP on memory formation are mediated via their actions on the mu-opioid receptor. ($N = 57$ -64 total animals per group across three replications.) (Supported by NIDA grant DA04795)

NALOXONE AUGMENTS PAVLOVIAN CONDITIONING OF CONCOMITANT HEART RATE AND MEDIAL PREFRONTAL CORTEX NEURONAL RESPONSES. L.L. Hernandez*, K.L. Watson and C.M. Gibbs. VA Medical Center and U South Carolina, Columbia, SC 29201.

Low doses of naloxone-HCl (NX) augment Pavlovian cardiac conditioning and delay its extinction in rabbits. Since the medial prefrontal cortex (PFCm) participates in cardiac conditioning, we assessed whether NX (0.1 or 0.5 mg/kg, i.v.) has parallel influences on conditioned heart rate responses (HR CRs) and concomitant, prefrontal multi-unit activity (MUA) during differential Pavlovian training (one tone [CS+] paired with shock, another [CS-] presented alone). Prior to training, each NX dose reduced the magnitude of HR orienting responses to the tones but did not alter tone-evoked increases in PFCm MUA, compared to saline. During conditioning, 0.5 mg/kg NX increased the overall magnitude of HR CRs, while 0.1 mg/kg NX reduced HR CR magnitude; nonetheless, each dose enhanced HR discrimination during training and extinction. Unit CRs consisted of evoked activity increases that grew larger during training and, in saline-treated animals, were of greater magnitude to the CS+ vs. CS- NX augmented MUA discrimination during training and extinction, but the higher dose increased, while the lower decreased, the size of the MUA CR to the CS+. These data show that NX has similar effects on CS-evoked changes in HR and PFCm MUA during Pavlovian training and extinction, and suggest that endogenous opioid systems in or afferent to the PFCm modulate Pavlovian discrimination.

GLUCOSE INFUSIONS INTO THE SEPTUM BLOCK THE EFFECTS OF INTRASEPTAL MORPHINE INJECTIONS ON HIPPOCAMPAL ACETYLCHOLINE OUTPUT AND MEMORY. M.E. Ragozzino* & P.E. Gold. Dept. of Psychology, U. of Virginia, Charlottesville, VA 22903.

Recent findings suggest that a modest increase in circulating glucose levels directly modulates brain mechanisms involved in mnemonic processing. Glucose infusions into the septal area reverse amnesia induced by intraseptal morphine infusions. Amnesia following intraseptal morphine infusions may be due, in part, to opioid inhibition of cholinergic neurons with glucose reducing this effect. The present experiment determined whether glucose reverses the effects of intraseptal morphine injections on acetylcholine (ACh) release in the hippocampal formation and on memory. Samples of extracellular ACh were assessed at 12-min intervals using *in vivo* microdialysis with HPLC-EC. From 20-40 min after intraseptal morphine injections (4.0 nmol), ACh output was reduced by 25% compared to baseline levels. Concomitant treatment with glucose (18.3 nmol) blocked this effect, with ACh output similar to baseline rates. Glucose and CSF injections alone did not change ACh output compared to baseline. Two days after microdialysis testing, rats received septal infusions 25 min prior to spontaneous alternation testing. Intraseptal morphine infusions reduced alternation scores which were reversed by concurrent glucose infusions. The effects of intraseptal infusions on alternation performance and ACh output were significantly correlated. These findings suggest that glucose may ameliorate memory deficits produced by intraseptal morphine infusions by directly or indirectly blocking the opioid inhibition of cholinergic neurons. ENHANCEMENT OF MEMORY PROCESSING IN AN INHIBITORY AVOIDANCE AND RADIAL MAZE TASK BY POSTTRAINING INFUSION OF BOMBESIN INTO THE NTS. C.L. Williams* & J.L. McGaugh. Center for the Neurobio. of Learning & Memory and Dept. of Psychobio., U. of Calif., Irvine, CA 92717-3800.

Bombesin is a peptide known to modulate memory storage when given either systemically or intraventricularly immediately after training. Two experiments were conducted to determine whether the nucleus of the solitary tract (NTS) mediates the effects of bombesin on memory. In the first experiment male Sprague Dawley rats were trained in an inhibitory avoidance task (0.35 mA, 0.5 s footshock) and bombesin or vehicle was infused unilaterally into the NTS through implanted cannulae immediately after training. Retention was assessed either two or seven days later. Doses of 25 ng or 50 ng of bombesin significantly enhanced retention on the two day test ($p < .05$ and $.01$ compared with vehicle controls respectively). There were no differences between the drug and control groups on the seven day retention test. In the second experiment, bombesin (25, 50, or 250 ng) or vehicle was infused unilaterally into the NTS immediately after the animals were trained in a win-shift radial arm maze task. On retention tests given 18 hours later, groups that received 25 ng or 50 ng of bombesin made a significantly greater percentage of correct choices on the retention test than did the vehicle-treated controls ($p < .02$ and $p < .05$ respectively). The findings indicating that bombesin influences retention by activating the NTS is consistent with recent evidence suggesting that the NTS is involved in regulating memory storage.

NEUROTENSIN RECEPTORS DECREASE AS A FUNCTION OF AGING AND COGNITIVE PERFORMANCE IN THE RAT BRAIN. W. Rowe*, S. Kar, M.J. Meaney & R. Quirion. Depts. of Psychiatry, Neurology and Neurosurgery, Douglas Hospital, Res. Ctr. McGill Univ., Montreal, Canada, H4H 1R3

Cognitive deficits are often associated with an impairment of cholinergic function. However, functional changes in the activity of other neurotransmitter systems such as neurotensin (NT) may also underlie certain cognitive behaviors. High concentrations of NT-like immunoreactivity and receptors are often found associated with areas known to be involved in mnemonic processing as well as in cholinergic neurons. Further, alterations in NT receptor density have been reported to be associated with the amnesia produced by lesions of basal forebrain neurons (Wenk et al., 1989, *Behav. Neurosci.*, 103: 765-9). Thus, the objectives of the present study were to evaluate if NT binding sites are altered in the aged rat brain and if these alterations are related to cognitive status. Aged (24-25 month old) Long-Evans rats were behaviorally screened using the Morris Water Maze task (3 trials/day for 5 days). Animals were classified as either aged, cognitively impaired (AI) or cognitively unimpaired (AU) based on their relative performances in the task compared to young control (CTL) animals. Decreases in [¹²⁵I]NT binding were observed in the hippocampal formation (dentate gyrus), entorhinal cortex, septum and hypothalamus as a function of age. Both aged groups also showed significant ($p < 0.05$) reductions in NT binding sites compared to CTL in the hippocampal CA3 sub-field, with the AI animals exhibiting the lowest levels. Thus, the alterations in [¹²⁵I]NT binding sites in the AI animals suggest the involvement NT-ergic systems in age-related cognitive deficits.

In the nucleus accumbens and ventral tegmental area [¹²⁵I]NT binding sites were decreased as a function of age while binding in the medial forebrain bundle was decreased as a function of age and cognitive status. These decreases in [¹²⁵I]NT binding may be of particular interest given the purported relationship between NT and dopamine (DA) and considering the role of DA in cognitive processing in aged animals (see Hersi et al., 1994, this meeting).

MEMORY FACILITATION INDUCED BY SYSTEMIC AND INTRA-AMYGDALA APPLICATION OF CCK-FRAGMENTS

P. Gerhardt, J.P. Huston, M. Voits*, H. Fink*, SPON: EBBS

Inst. Physiol. Psychol., University of Düsseldorf, Universitätsstr. 1, 40225 Düsseldorf; *Inst. Pharmacol. Toxicol., Humboldt-University (Charité), 10098 Berlin; Germany.

Cholecystokinin (CCK) exists in several molecular forms in the CNS: while CCK-8S has a high affinity to A-receptors (in CNS and periphery) and central B-receptors, CCK-4 binds to the B-receptor. Involvement of CCK in memory processes has been suggested, while the critical receptor subtype has not yet been determined. We investigated memory modulating effects of CCK-8S and Boc-CCK-4 after post-trial systemic (IP) injection using habituation (rearing behavior in an open field; nose-poke in a hole-board) as a learning task. An inhibitory avoidance task was used to test the influence of both fragments after post-trial, unilateral injection into the amygdala. IP injection of both CCK-fragments immediately after training reduced exploratory activity, indicating enhanced habituation, and thus a facilitation of memory. Immediately post-trial injected CCK-8S or Boc-CCK-4 into the amygdala facilitated avoidance learning. Application with a delay of 2.5 or 5h post-trial was not effective, ruling out proactive effects of the treatments on test performance. Using a conditioned place preference task, CCK-8S and Boc-CCK-4 had neither aversive nor reinforcing properties after IP or intra-amygdala injections. The results point to an involvement of the B-receptor in memory processes and show first evidence for post-trial effects of CCK on habituation learning in rats.

COMPARISON BETWEEN TWO RAT STRAINS IN AN OBJECT EXPLORATION TEST: EFFECT OF A TRH ANALOGUE, RGH2202.

T.M. Ballard & G.W. Bennett. (SPON: Brain Research Association) Dept. of Physiology & Pharmacology, Queen's Medical Centre, Nottingham NG7 2UP, U.K.

Thyrotrophin-releasing hormone (TRH) produces a positive effect on cognition in Alzheimer's patients (Molchan et al., 1992) and a TRH analogue, RX77368, has been shown to improve performance in senescent rats in a passive avoidance task (Watson et al., 1993), which involves an aversive procedure. Object Exploration Tests (OET) for memory are based on knowledge that a rat will explore spontaneously a new environment and precludes artificial motivation of the animal.

In the present study, we used an OET protocol which has been suggested to produce delay-dependent memory disruption (Ennaceur & Delacour, 1989). Two consecutive exploration trials, T1 and T2 (t=3min) were separated by an inter-trial interval (ITI) of either 1min, 1h or 24h. During T1, two identical objects were introduced; one was replaced by a novel object in T2. There is a significant decrease in total exploration time (ET) of male Wistar (WR) rats (250-300g) from T1 to T2 following an ITI of 1min ($p < 0.01$, Mann Whitney U-test), 1h ($p < 0.05$) and 24h ($p < 0.05$). Male Lister Hooded (LH) rats (250-300g) show no difference in ET from T1 to T2. WR have a lower ET than LH during T2, which is significant following an ITI of 1min ($p < 0.01$, Mann Whitney U-test) and 24h ($p < 0.01$), and is close to significance following 1h.

LH significantly explored a novel object more than a familiar object in T2, following an ITI of 1min ($p < 0.01$, Wilcoxon Rank Sum Test) and 1h ($p < 0.01$). There was no significant difference in exploration of objects following an ITI of 24h. The effect of a TRH analogue, RGH2202 (5.0mg/kg i.p.) administered 30min prior to testing, at a dose shown to produce positive cognitive effects in other tests (Drago et al., 1991), did not produce a significant difference in time exploring objects following an ITI of 24h. There was no difference in exploration of objects following any ITI by WR, so we were unable to determine the effect of RGH2202 in this strain. Therefore, RGH2202, at this dose, does not produce cognitive-enhancing effects in LH in this test. Further work is required to determine a dose-related effect of RGH2202 to confirm these results.

DOPAMINE D1 DRUGS MODULATE LEARNING ABILITIES OF AGED MEMORY IMPAIRED RATS. A. J. Hersi*, W. Rowe*, R. Quirion and P. Gaudreau.

¹Douglas Hospital Res. Ctr. and Dept. of Neurology/Neurosurgery, McGill Univ., Verdun, Que. Canada H4H 1R3, ²Hopital Notre Dame, Dept. of Neuroend. Université de Montréal, Que. Canada H2L 4K8.

Lately, it has become apparent that besides acetylcholine, a number of other neurotransmitters contribute to learning and memory either directly or via their interaction with the central cholinergic system. For example, spatial mnemonic deficits brought on by pharmacological manipulations such as hippocampal denervation or the blockade of cholinergic receptors are reportedly attenuated by the administration of dopaminergic (DA) drugs. It is also known that DA drugs can facilitate learning in various paradigms in young animals. In the present study, we examined if DA D1 drugs can modulate learning in aged animals suffering from cognitive deficits. 24-25 mo. old Long Evans male rats that were classified as memory impaired on the basis of the Morris Swim Maze task were used. The DA D1 agonist SKF38393 (3.0 mg/kg i.p.) administered 15 min before trial significantly reduced the latency to find the platform in this task. On the other hand, the D1 antagonist SCH23390 (0.05 mg/kg i.p.) slightly, but nonsignificantly, exacerbated the mnemonic deficits in these aged animals. Interestingly, receptor autoradiography failed to reveal any differences in [³H] SCH23390 binding (D1 receptors) between young (6mo), aged-memory impaired and aged-memory unimpaired rats in any of the brain areas examined (hippocampus, cortex and striatum). In summary, D1 drugs can modulate spatial memory impairments in aged rats but these deficits do not appear to be directly related to changes in DA D1 receptor levels.

417.21

CHANGES IN BRAIN SOMATOSTATIN CONTENTS IN MEMORY DEFICIENT RATS: COMPARISON WITH CHOLINERGIC MARKER. N. Matsuoaka*, N. Maeda, M. Yamazaki and I. Yamaguchi, Basic Research Group, Tsukuba Research Laboratories, Fujisawa Pharmaceutical Co., Ltd., 5-2-3, Tokodai, Tsukuba, Ibaraki, 300-26 Japan.

To clarify the role of the brain somatostatinergic system in the cognitive function of rats, changes in the mnemonic performance of rats in passive avoidance and water maze tasks and in brain somatostatin (SST) contents were comparatively investigated in young rats subjected to brain cholinergic, somatostatinergic and serotonergic depletion and in aged rats. Lesion of the nucleus basalis magnocellularis (NBM) and treatment of cysteamine, a SST depletor, resulted in significant memory deficits in passive avoidance task, whereas neither transection of the fimbria-fornix (FF) nor raphe lesion by local injections of 5,7-dihydroxytryptamine affected the performance in the task. When their cognitive performance were assessed in the water maze, NBM-, FF-lesion and cysteamine but not raphe lesion significantly impaired the acquisition of spatial memories. Aged rats showed severe memory impairment in both tasks. Comparisons of the brain neurochemistry showed that NBM lesion produced a selective reduction in the cortical cholinergic marker, choline acetyltransferase (ChAT), and striatal SST level, while FF-lesion caused marked loss of ChAT in the hippocampus and posterior cortex and a significant reduction in hippocampal SST. On the other hand, cysteamine significantly reduced the SST contents in all the brain regions examined but minimally affected ChAT activities. Raphe lesion hardly affected either somatostatinergic or cholinergic markers in the brain areas. Significant reduction in the striatal ChAT and elevation in SST contents in the frontal cortex were found in aged rats compared with young rats. These results suggest that changes in the brain somatostatinergic and cholinergic transmission are differently involved in the cognitive deficits in experimental animal models of dementia employed.

NEUROETHOLOGY: INVERTEBRATES

418.1

NON-NOXIOUS STIMULATION ELICITS GRADED INKING IN *APLYSIA*. T.G. Nolen*, S. Robinson, P.M. Johnson and C.E. Kicklighter, Dept. of Biology, University of Miami, P.O. Box 249118, Coral Gables, FL 33124.

Ink provides *Aplysia* with a chemical defense against predators such as sea anemones (Nolen et al. submitted). In interactions with anemones, *Aplysia* release small amounts of ink following contact with a single anemone tentacle and larger amounts if they are picked up by numerous tentacles. Thus, a critical component of the RELEASER for inking may be the area of skin stimulated by the predator.

We used a mechanical stimulus array to simulate the action of anemone tentacles as they snare a snail and pull it off the substratum. An array (1 to 9 lcc syringes) was placed on the parapodium of a small adult *A. californica* (8 - 12cm) and weak suction applied as the animal was lifted off the bottom of its aquarium. The probability of inking increased as a function of the size of the array: Four of 14 animals (28.6%) inked in response to a single stimulator (12.6mm²); whereas 11 of 16 (68.8%) inked in response to a 3x3 array distributed over 4cm² of skin (p=0.0281). Ink was released in a graded fashion: Ink scores increased 2.8 times as the stimulus array was increased from 1 to 9 stimulators (p=0.025).

Substantial amounts of ink could be released on 4 successive trials from animals with full glands (using anemone tentacles or tail shocks). Animals with low ink stores had high thresholds and long latencies (latency was negatively correlated with the amount of ink released, $r = -0.9841$, $p < 0.001$). Still, these animals released only about half (or less) of their gland's stores of ink on trial one [e.g., even with a noxious head shock, only $49.7 \pm 13.8\%$ (mean \pm sem) of the gland's ink was released on the first trial; 6 to 12% was released on successive trials.]

Stereomicroscopic analysis of the gland during successive inking trials suggests that individual ink vesicles are stochastically activated and that ink secretion from vesicles is not all-or-none. The stochasticity of ink vesicle activation can be explained by branch-point conduction failures in the fine peripheral projections of ink motor neurons where they innervate vesicles in the ink gland.

NOXIOUS STIMULI INDUCE LONG-TERM CHANGES IN CARDIOVASCULAR FUNCTION IN *APLYSIA CALIFORNICA* J.K. Kroutiris-Litowitz*, Dept. of Biological Sciences, Youngstown State University, Youngstown, OH 44555.

Cardiovascular function in *Aplysia* can be altered by environmental factors. Previous studies have shown that temperature, oxygen content, and noxious stimuli can induce changes in heart rate (Dieringer et al., 1978). This study investigates whether or not environmental stimuli, particularly noxious stimuli, can induce long-term changes in cardiovascular function.

Cardiovascular function was monitored in an *in vitro* preparation via a flow-through pressure cannula implanted in the anterior aorta. Noxious, electric shocks were delivered to the lateral tail via implanted electrodes (3 trains/10 sec duration/60 Hz/15 min intervals).

Tachycardia was observed in all animals 30 min after presentation of the noxious stimulus (n=8). Heart rate was significantly increased when compared to controls that had not received noxious stimuli ($p < .05$). Tachycardia lasted for at least 90 min in 6 animals and for 6 hours in 2 animals in which observation time had been extended. These studies indicate that noxious stimuli can induce long-term changes in cardiovascular function.

418.3

COUPLED NEURONAL OSCILLATORS IN THE MEDICINAL LEECH. C.G. Hocker* and W.O. Friesen, Center for Biological Timing and Department of Biology, University of Virginia, Charlottesville, VA 22903-2477

A leech usually has five to fifty undulations during one swimming episode though longer swims can be observed. Fictive swims observed in isolated chains of midbody ganglia are typically ten to twenty cycles long in accordance with this episodic behavior. Unlike the isolated lamprey nerve cord which displays continuous fictive swimming in the presence of N-methyl-D-aspartate, no chemical has yet been found (eg. serotonin) that can remove the episodic nature of the fictive swims. However when the tail ganglion is included, spontaneous fictive swims occur with episodes an order of magnitude greater in length. The period variability of these long episodes contains a frequency modulation (FM) whose period is around ten cycles.

Since one ganglion in serotonin has a fictive swim oscillation that does not have the FM, we expect that the FM is due either to an oscillation in the excitation from the tail ganglion or to an intrinsic oscillation in the coupling between the swim oscillators. We proceeded to test this in four ways. First, recording in the anterior section from the median connective which carries much of the excitatory input from the tail ganglion does not reveal any periodic spiking of the appropriate period during fictive swimming. Second, warming or cooling the tail relative to the midbody ganglia does not cause a significant shift in the period of the FM. Third, examination of occasional long fictive swims just after removing the tail ganglion from the rest of the cord revealed that the FM still occurs without the tail. Fourth, uncoupling the anterior swim oscillators from the posterior oscillators by severing both lateral connectives between two ganglia causes long episodes to be broken apart into shorter episodes lasting around 10 cycles. We conclude that the FM is an intrinsic part of the intersegmental coupling and is not from the tail ganglion.

418.4

MECHANISMS OF INTERSEGMENTAL COORDINATION IN THE MEDICINAL LEECH. W.O. Friesen* and C.G. Hocker, Dept. of Biology, NSF Ctr. for Biol. Timing, Univ. of Virginia, Charlottesville, VA 2293-2477.

Our current understanding of the neuronal system that controls swimming in the leech includes three sets of oscillators: 1) a chain of serially homologous segmental oscillators in midbody ganglia that generates and coordinates the swimming rhythm; 2) an unidentified oscillator associated with the head ganglia, which may interfere with swimming activity via reciprocal inhibition; and 3) an unidentified oscillator in the tail ganglion that modulates the cycle period of swimming via slow, excitatory, phasic output to the swim oscillator.

We investigated the nature of the segmental oscillators to determine whether 1) midbody ganglia comprise one or two competent oscillators, 2) ascending or descending connections are strongest, and 3) termination of swimming activity might arise from destructive interference between segmental oscillators with differing cycle periods. Experiments were performed on the leech isolated nerve cord extending from midbody ganglion 2 to the tail ganglion. To separate ascending from descending inputs, we severed one lateral connective anterior to, and the contralateral lateral connective posterior to a midbody ganglion (Z-semi-isolated). We observed relative coordination in this preparation with either end of the chain exhibiting the shorter cycle period. During relative coordination, oscillations in motor neurons on the left and right sides of the Z-semi-isolated ganglion were phase-locked to impulse bursts either in the anterior or posterior chain; in no case did we see independent oscillations on the two sides of this ganglion. We conclude that midbody ganglia contain a single swim oscillator, that ascending and descending intersegmental interactions are nearly equal in strength and that swimming activity in the Z-preparation can be terminated prematurely when anterior and posterior chains have differing cycle periods.

418.5

DISHABITUATION OF ACOUSTIC STARTLE SHOWS FREQUENCY CATEGORIZATION BY CRICKETS. R.A. Wytenbach* and R.R. Hoy. Neurobiology and Behavior, Cornell University, Ithaca, NY 14853.

Flying Polynesian field crickets (*Teleogryllus oceanicus*) have an acoustic startle response to pulses of ultrasound. This consists of several movements that steer the cricket away from the sound source. One aspect of the response, metathoracic leg swing, is of short latency and duration.

Ultrasound startle decrements with repetition in a way consistent with standard criteria for habituation. It declines exponentially, recovers spontaneously, declines more rapidly with higher repetition rates or lower intensities, and dishabituates after presentation of a novel stimulus.

Dishabituation of acoustic startle can be used as a "same-different" test for crickets. A stimulus that is novel relative to the habituating stimulus will dishabituate, while a stimulus that is not considered different from the habituating stimulus will not dishabituate.

We have used this test to determine which frequencies of sound are considered different from ultrasound. Crickets were habituated with 5 pulses of 20 kHz at 10 dB over threshold (reducing the response to 35% of the initial response) and then presented with a dishabituating pulse followed by a test pulse of 20 kHz as before. All pulses were 750 ms apart. The dishabituating pulse was 10 dB greater than the habituating pulse, ranged from 5 to 25 kHz, and came either from the same side as the habituating pulses or from the opposite side.

Pulses of any frequency dishabituate when presented from the direction opposite the habituating train, but only pulses below 17 kHz dishabituate when presented from the same direction as the habituating train. Thus pulses below 17 kHz are categorized as different from 20 kHz, while those 17 kHz or greater are not distinguished from 20 kHz.

SYNCHRONIES IN THE NORTH AMERICAN FIREFLY PHOTINUS CAROLINUS. J. Copeland and A. Moiseff*. Department of Biology, Georgia Southern University, Statesboro, GA 30460 and Department of Physiology and Neurobiology, University of Connecticut, Storrs, CT 06269-3042.

Photinus carolinus shows discontinuous synchrony. Bursts of 5 - 8 flashes at 2 Hz occur concurrently every 14 - 19 sec. When the terrain is flat and forested, the synchrony is a unison synchrony. When the terrain is a steep forested hill, the synchrony is a wave synchrony. Thus, the same species of firefly is capable of showing unison or wave synchrony depending on the topographical conditions.

We studied unison synchrony by employing low light level videophotography and frame-by-frame playback analysis as well as photometric recordings. The latter was combined with computer acquisition and analysis in the field. Data obtained from groups of individually caged males revealed that group flashing began concurrently, ended concurrently, and the flashes within the burst occurred concurrently, resulting in unison synchrony. To investigate the mechanisms responsible for this synchronic behavior, simulated flashes were presented to individual fireflies at various time during their flash pattern. Stimulus flashes presented during the interburst interval enhanced or inhibited the next flash depending on when the stimulus was presented. Stimulus flashes presented during the interflash interval, however, had no noticeable effect.

We suspect that the interburst oscillator can be modulated through anticipatory (unison) or triggered (wave) mechanisms. We also suspect that the interflash oscillator, once released (in the ethological sense) is not susceptible to feedback.

TESTING FOR A POPULATION VECTOR CODE FOR WIND DIRECTION IN THE COCKROACH GIANT INTERNEURONS. R. Levi, J. M. Camhi* Dept. Cell and Animal Biology, Hebrew University, Jerusalem, Israel.

One proposed mechanism by which a neural assembly codes stimulus direction is the population vector code (PVC). Originally observed in the monkey cortex, this is tested here in the much simpler cockroach escape system. Specifically, we test 3 bilateral pairs of giant interneurons (GIs) that respond directionally to wind stimuli and evoke an evasive turn. GI 3 responds most strongly to wind from the ipsilateral front. Such wind evokes large turns away. GI 2 to responds most strongly to wind from the ipsilateral rear. Such winds evoke small turns away. GI 1 responds equally to both these directions (Kotlon and Camhi, Soc. Neurosci. Abst., 1993). By a PVC, one represents each cell's response as a vector arrow, whose direction is the cell's best excitatory direction, and whose length is the number of spikes evoked by the given wind stimulus. Vector summation of GIs 1, 2 and 3 gives good agreement ($\pm 20^\circ$) between the actual wind direction and that calculated using the PVC.

To help determine whether the cockroach actually uses a PVC, we modified the spike trains of individual GIs during wind-evoked turning behavior and determined the effects on the turn. Wind puffs from 90° right evoke, in a cockroach tethered on a slick surface, turning movements to the left. We analyzed the initial leg movements and body's turning tendency using a high speed video (250 frames/s). During another puff from the same angle, we now added spikes, by intracellular current pulses, to either right GI 3 or 2. Roughly doubling the number of spikes in GI 3 (from -6 to 12) has produced, to date, responses corresponding to larger turns to the left in 7 out of 9 cockroaches, and no change in one other. Adding spikes instead to GI 2 has produced, to date, responses corresponding to smaller turns in 4 out of five cockroaches. These results are consistent with the predictions of a PVC, since increasing the number of spikes lengthens a GI's vector arrow and thus draws the direction of the wind specified by the PVC toward that GI's best excitatory direction.

NEGATIVE THERMOKINESIS DURING FLIGHT IN THE LOCUST. R.M. Robertson* and C.T. Kuhnert. Dept. of Biology, Queen's University, Kingston, Ontario, K7L 3N6, Canada.

Locusts aggregate in regions with an optimal environmental temperature, yet there is currently no evidence for locomotor thermokinesis in locusts. We have investigated whether tethered flying locusts will steer relative to a radiant heat source.

Adult male *Locusta migratoria* were tethered and flown in front of a wind tunnel. Wing movements and postural adjustments of the abdomen and hindlegs were monitored with high-speed cinematography (250 frames s^{-1}) and with videography (60 frames s^{-1}). In separate experiments, abdominal movements were monitored using a capacitance position transducer. Brooder lamps (250 watt) on the right and left of the animal provided directional heat sources.

Within 1s of turning on a lamp, locusts made characteristic steering manoeuvres away from the direction of the source. Interposing a transparent acrylic barrier (1.2 cm thick) markedly reduced the steering responses. Neither covering the eyes and ocelli with thick nail polish, nor interposing infra-red filters (Edmund Scientific, P60 033) between the locust and the lamp, had an effect on thermokinesis.

We conclude that flying locusts steer away from heat sources by detecting infra-red radiation. We are currently investigating which structures are involved in mediating directional infra-red sensitivity.

VISUAL CUES MAY INFLUENCE THE ESCAPE RESPONSE OF COCKROACHES. S.Ye* and C.M. Comer. Neurosci. Group, Dept. Biol. Sci., Univ. of Illinois, Chicago, IL 60680

Periplaneta americana responds to abrupt touch of an antenna by turning away from the stimulus and running. This response occurs at very short latency, and the angle of initial turn is typically contraversive to the antenna touched. We have noted that vision is not essential for production of escape turns (Comer et al., 1994; J Comp Physiol 174:13). However, visual cues are usually present as touch of antennae occurs. We were therefore interested in knowing if aspects of escape are influenced by vision.

We report here behavior studies on intact animals tethered in a high-speed locomotion tracker, and electrophysiological studies of descending interneurons. When lateral eyes and ocelli were covered with opaque paint, animals turned reliably following antennal touch. But the duration of subsequent running was decreased. In another experiment, sighted animals were tested for response to a stimulus probe placed near an antenna. Animals responded by orienting an antenna toward the probe and touching it if the probe had high visual contrast with background. If the probe had low contrast, contact with the probe was at chance levels. These data indicate that cockroaches visually detect stimuli applied to the antennae, and that vision (while non-essential) may influence escape performance.

Intracellular recording and dye-injection revealed an interneuron, with soma in the brain, that responds to visual stimuli of the type used in behavior tests. In recordings from neck connective, the neuron typically responded by firing a train of spikes as a probe moved across the visual field of the contralateral eye. When antennal touch occurred, the firing of this neuron preceded that of descending mechanosensory interneurons. The cell's axon (15-20 μm in diameter) extends to the thoracic ganglia.

We suggest that while visual cues are not essential for touch-evoked escape, they may influence some elements of the escape response. The role of descending interneurons in such an influence is under investigation.

SPONTANEOUS SELF-GENERATED COUNTERTURNS DURING TETHERED FLIGHT OF MALE MOTHs, *Manduca sexta*. K. Baker¹, M.A. Willis², E.A. Arbas². ¹Center for Neurogenic Communication Disorders and ²ARL Div. of Neurobiology, Univ. of Arizona, Tucson, AZ 85721

Flight behavior of moths, *Manduca sexta*, is known to be modulated by odors and visual patterns. In plumes of female pheromones, for example, flight tracks of males assume a characteristic upwind zigzagging pattern. Our laboratory is researching the sensorimotor basis of this pattern. We have recorded spontaneous activity patterns of tethered moths in the 1st hour of their circadian activity cycle, without specific olfactory or visual stimulation. Movement patterns were logged visually and videotaped. Synchronous EMG recordings from various wing muscles revealed underlying motor patterns.

Moths typically activated wing fanning (pre-flight warmup), followed by large amplitude wing beating indicative of tethered "flight", within the first 10 min. of scotophase. Flight continued in bouts from a few sec. to 14 min. duration. During flight bouts, moths mostly maintained postures which were consistent with stable forward orientation. Often, however, they showed spontaneous changes in posture during wing beating that we interpret as attempts to turn, including: (1) turning of the head and, (2) curling the abdomen in the direction of the intended turn, as well as (3) retraction of the wings on the inside of the turn, and protraction of those outside the turn. Attempted turns were sometimes executed in rapid alternating succession, reminiscent of counterturning during unrestrained zigzagging flight. These observations suggest a capability to organize counterturning intrinsically, rather than only in response to afferent inputs. Timing of movements and motor outflow patterns underlying these spontaneous "open-loop" maneuvers are being analyzed for comparison with similar patterns activated and modulated by visual and pheromonal stimuli. [Supported by NSF IBN 9216532].

MODULATION OF MOTOR PATTERNS IN A TETHERED MOTH DURING MULTI-MODAL STIMULATION. DE Wood* and EA Arbas, ARL Div. of Neurobiology, Univ. of Az., Tucson, Az. 85721

We are studying the flight behavior of the male sphinx moth, *Manduca sexta*, as a model for the generation and control of oriented locomotion. Of interest is control of pheromone-evoked 'zig-zagging' flight of males searching for mates. This pattern of flight exhibits a consistent interturn interval as the male progresses upwind. Previous results describing flight activity in this animal used both free flying animals and reduced preparations from which EMGs of flight muscles could be monitored (Willis and Arbas, 1991; Kanzaki and Arbas, 1990). This investigation describes aspects of the control of flight under various multi-modal stimulus arrangements while recording *en passant* neurograms of particular motor nerves. Study of flight initiation shows that short bouts of stereotyped flight are evoked by short (< 1 s) exposures to light. Short bouts of flight do not include temporally regular turns as seen in zig-zagging or casting (flight after odor loss). These short bouts are useful for comparison to more complex flight patterns. Chlordimeform (CDM) induces motor outflows to flight muscles (Kanzaki and Arbas, 1990). Flight patterns evoked by this drug are less stereotyped than flight evoked by brief light stimuli and include patterns indicative of less consistent turning than in unrestrained casting or zig-zagging flight. CDM applied to flying animals accelerated bursting of indirect wing depressor muscles. Visual stimuli simulating left and right turns can initiate flight with regular turning intervals. Visual stimuli combined with pheromonal stimulation elicited frequency modulation of the flight rhythm reminiscent of that observed during free flight. We are continuing this study using more complex computer driven stimulus protocols accompanied by recordings of motor rhythms in the thoracic ganglia. (Supported by NIH NRSA 1 F32 DC 00097-01 and NSF IBN 9216532).

CAN NEUROGENESIS EXPLAIN MUSHROOM BODY REORGANIZATION IN THE BRAIN OF THE ADULT HONEY BEE? J.L. Strande, S.E. Fahrback and G.E. Robinson*, Department of Entomology and Neuroscience Program, University of Illinois, Urbana, IL 61801.

A reorganization of the mushroom bodies in the brain of the adult worker honey bee (*Apis mellifera*) is associated with behavioral development and colony division of labor (Withers et al., 1994, Nature 364, 238-240). To probe the proximate mechanisms of this neuroanatomical plasticity, we tested the hypothesis that neurogenesis occurs in the adult bee brain. Bees were exposed to the proliferation marker bromodeoxyuridine (BrdU) at 3 stages of behavioral development: one-day-old, nursing, and foraging. BrdU was administered in 3 ways: *in vivo*, either orally (in sugar syrup) or via injection into the abdomen, or *in vitro*, with brains incubated in bee culture medium containing BrdU. Immunohistochemical experiments completed to date revealed only one BrdU-labeled nucleus of a single mushroom body neuron in 2140 sections of tissue examined. Several controls were processed simultaneously with adult bee brain tissue. Nervous tissue from *Manduca sexta* larvae, in which neurogenesis is known to occur, revealed extensive BrdU labeling. Neurogenesis was also readily detected in nervous system tissue from honey bee larvae and pupae. These results indicate that neurogenesis occurs very infrequently or not at all in the adult bee brain. It does not appear that the previously observed mushroom body reorganization can be explained by neurogenesis. Supported by NSF grant IBN 9211386 and an NSF REU Award (SEF and GER) and NIMH grant MH42274-01 (GER).

DRUGS OF ABUSE: CNS STIMULANTS—TOXICITY

MDMA INCREASES THE EXTRACELLULAR CONCENTRATION OF 2,3-DIHYDROXYBENZOIC ACID IN THE STRIATUM: EVIDENCE FOR INCREASED HYDROXYL RADICAL FORMATION. G.A. Gudelsky* and B.K. Yamamoto, Dept. of Psychiatry, Case Western Reserve University, Cleveland, OH 44106

It is well recognized that the administration of 3,4-methylenedioxymethamphetamine (MDMA) results in a long-lasting depletion of brain 5-HT. Evidence is supportive of the view that MDMA-induced depletion of 5-HT is due, in part, to the acute and sustained release of dopamine (DA). The purpose of the present study was to examine whether the MDMA-induced increase in the extracellular concentration of DA in the striatum is accompanied by the formation of hydroxyl free radicals that result from DA autooxidation. Hydroxyl radical formation was assessed in dialysis samples from the striatum by quantifying the extracellular concentration of 2,3-dihydroxybenzoic acid following its conversion from salicylic acid. The dialysis probes were perfused with dialysis buffer containing 5 mM salicylate for 3 hrs at various times following drug treatment. The ip injection of MDMA (20 mg/kg) resulted in an immediate increase in the concentration of 2,3-DHBA which was 450% of that in vehicle-treated controls. An MDMA-induced increase in 2,3-DHBA formation was observed for at least 6 hrs. A 30 min application of MDMA (10 μ M) through the dialysis probe also increased 2,3-DHBA concentrations which were similar in magnitude to those produced by systemic administration. In rats in which the MDMA-induced increase in DA release was attenuated by treatment with mazindol, the MDMA-induced increase in 2,3-DHBA formation also was significantly attenuated. These findings are consistent with the view that MDMA produces a DA-dependent increase in hydroxyl radical formation.

POTENTIATION OF MDMA-INDUCED DOPAMINE RELEASE AND SEROTONIN NEUROTOXICITY BY SEROTONIN₂ AGONISTS. J.F. Nash*, B.K. Yamamoto and G.A. Gudelsky, Depts. of Psychiatry and Neuroscience, Case Western Reserve Univ., Cleveland, OH 44106

The effect of serotonin (5-HT₂) agonists, DOI and 5MeODMT (5-methoxy-N,N-dimethyltryptamine), on MDMA (3,4-methylenedioxymethamphetamine)-induced release of dopamine (DA) in the striatum was studied in rats by the use of *in vivo* microdialysis. A concentric dialysis probe was inserted into the striatum and dialysis samples were collected every 30 min for 240 min. MDMA (10 mg/kg, sc) administration increased the release of DA in the striatum. The MDMA-induced increase in the extracellular concentration of DA was enhanced significantly in rats treated with either DOI (2 mg/kg, ip) or 5MeODMT (15 mg/kg, ip). Neither DOI nor 5MeODMT alone affected the extracellular concentration of DA in the striatum. The effect of DOI on the long term depletion of striatal 5-HT produced by MDMA also was investigated. The striatal concentration of 5-HT was reduced slightly, but not significantly, 7 days following the administration of MDMA (10 mg/kg, sc). However, 7 days following the concomitant treatment with DOI and MDMA the striatal concentration of 5-HT was significantly less than that in rats treated with MDMA alone or the vehicle-treated controls. It is concluded that activation of 5-HT₂ receptors is an important determinant of the acute increase in extracellular DA and, consequently, the long-term depletion of brain 5-HT produced by high dose administration of MDMA.

THE STRIATAL NEUROTOXICITY INDUCED IN THE C57BL/6J MOUSE BY D-AMPHETAMINE IS BLOCKED BY RESTRAINT STRESS BUT NOT BY SUPPLEMENTAL CORTICOSTERONE. D.B. Miller* and J. P. O'Callaghan, U.S. EPA, RTP, NC 27711

Amphetamines (AMPs) are potent stimulants and striatal (ST) dopaminergic neurotoxicants. Stress affects AMP stimulation but its effects on AMP neurotoxicity are not well examined. Restraint stress activates the adrenal axis and elevates corticosterone (CORT) levels. Here, we determined if restraint or supplementation with CORT affected d-AMP neurotoxicity. Astroglia, quantified by immunoassay of GFA, was taken as an index of neural damage. Body temperature (BT) was also monitored as restraint can cause hypothermia and BT is a factor in AMP neurotoxicity. Female mice (6/group/cage) were given SAL or d-AMP at a dosage (s.c. as the base) of 0 or 5 mg/kg, respectively, every 2 hrs beginning at 11:30 AM for a total of 4 inj. Mice were restrained in 50 ml centrifuge tubes, beginning at 0.5 hr prior to the 1st inj and until 1 hr following the 4th inj. CORT was placed in the drinking water (20 μ g/ml; ~ 3.2 mg/kg) 1 week prior to d-AMP inj and continued until the ST was obtained at 72 hrs post the last inj. BT was recorded prior to dosing and at 2 hrs following each inj. d-AMP caused hyperthermia (1 - 2 °C) and neural damage as indicated by a large (300%) increase in ST GFA. Restraint totally blocked the d-AMP hyperthermia as well as the GFA elevation. CORT had no effects. The data suggest an elevation in BT is important in d-AMP neurotoxicity and that adrenocortical status may not play a role in AMP neurotoxicity. However, the dosage of CORT utilized was low and did not cause thymic involution. Higher dosages, as well as the elimination of circulating CORT, such as by adrenalectomy, should be investigated.

419.4

D-Amphetamine (AMPH) Levels in Caudate-Putamen (CPU) Microdialysates After Doses that Produce Either Behavioral or Neurotoxic Effects. P. Clausen*, R.R. Holson, W. Slikker Jr., B. Gough and J.F. Bowyer, NCTR/FDA, Jefferson, AR 72079-9502.

Six mo. old δ Sprague-Dawley rats (4/group) were dosed with either 1 or 2.5 mg/kg AMPH sc to produce increased motor activity and/or stereotypy. Forty to 60 min. after 1 mg/kg, when motor activity was maximum, AMPH levels in the microdialysate were maximal at (mean \pm SEM) $0.28 \pm 0.04 \mu$ M. Forty to 60 min after 2.5 mg/kg the microdialysate levels rose to a max. of $0.51 \pm 0.09 \mu$ M. Stereotypic behavior started at this time and lasted for 1-2 hrs. In a second experiment, 6 and 12 mo. old rats (5/group) were given AMPH sc either 4x5 mg/kg in a 24 °C environment (known to produce neurotoxicity) or 4x15 mg/kg in a 10 °C environment (not neurotoxic) at 2 hr intervals. It was hypothesized that in the cold environment the higher doses would produce higher CPU-extracellular AMPH levels but no long-term neurotoxicity. Peak levels were: $1.5 \pm 0.3 \mu$ M (6 mo. old, 4x5 mg/kg, 24 °C), $2.6 \pm 0.7 \mu$ M (12 mo. old, 4x5 mg/kg, 24 °C), $3.0 \pm 0.4 \mu$ M (6 mo. old, 4x15 mg/kg, 10 °C), $4.1 \pm 0.5 \mu$ M (12 mo. old, 4x15 mg/kg, 10 °C). Thus, 12 mo. old rats had significantly higher AMPH levels than 6 mo. old. Cold room rats dosed with triple the dose had 1.4-2.0 times the AMPH levels seen in rats kept at room temperature. *In vitro* recovery efficiency of the microdialysis probes was estimated to be 15-20%. Thus, approximately 2 μ M extracellular AMPH is necessary to produce behavioral effects (assuming levels in the nucleus accumbens are similar to those in the CPU) while levels after neurotoxic doses are between 10 and 30 μ M.

419.5

Using Orthophthalaldehyde (OPA) and 3-Mercaptopropionic Acid (MERA) Derivatization to Quantify D-Amphetamine (AMPH) Levels in Striatal Microdialysates by High Performance Liquid Chromatography (HPLC) J.F. Bowyer¹ and P. Clausen². NCTR/FDA, Jefferson, AR 72079-9502.

Rats implanted for microdialysis in the striatum were dosed with AMPH (1 to 15 mg/kg, sc). The microdialysis buffer consisted of 140 mM NaCl, 1.5 mM K₂HPO₄, 1.5 mM KCl, 1.5 mM MgCl₂, 1.25 mM CaCl₂ and 10 mM glucose, pH 7.4. Dialysate was collected continually at 20 min intervals (1 µl/min.) for up to 10 hrs starting at 2 hrs. prior to dosing. The samples were either stored at -70°C or analyzed immediately by HPLC. AMPH levels were determined by derivatizing 10 to 20 µl microdialysate aliquots for 2 min with 20 µl of 0.1 M borate buffer, pH 9.4, containing 5 mg OPA and 40 µl MERA per ml and 70 to 80 µl H₂O. Then 75 µl of the derivatized sample was separated on a C18 column using a 50 mM potassium phosphate buffer, pH 5.5, and a gradient of 35% to 65% methanol with 1.5 ml/min flow rate. Fluorescent detection (340 nm λ excitation, 440 nm λ emission) was used. The AMPH derivative had a retention time of 14.4 min which was 2 min more than all the amino acid derivatives and there were no peaks within ± 1.5 min of the AMPH derivative. Very little p-hydroxy-amphetamine was detected in the microdialysate after AMPH sc. Microdialysate buffer spiked with AMPH to obtain 0.1 to 10 µM AMPH concentrations was used to quantify microdialysate AMPH levels. The detection limit was 0.05 µM AMPH in 20 µl of microdialysate, equivalent to 135 picograms. From 0.27 to over 27 nanograms AMPH can be quantified in microdialysate using these methods.

419.7

PRENATAL METHAMPHETAMINE CAUSES SPECIFIC METABOLIC CHANGES IN THE BASAL GANGLIA SEEN AT MATURATION. A.D. Weissman¹ and S. Caldecott-Hazard. Department of Anesth., Seton Hall University, School of Graduate Medical Education, South Orange, NJ 07079

Methamphetamine exposure *in utero* has been shown to produce profound alterations in the adult brain monoamine system. These effects are also reflected in subtle changes in adult performance of specific behavioral tasks. Human maternal methamphetamine abuse may have a similar impact on the fetal brain that may persist into adulthood. We sought to model the drug's developmental effects by chronically exposing fetal rats to it. The ¹⁴C-deoxyglucose technique (DG) was used to measure adult brain metabolism and as a sensitive indicator of long term changes in neuronal function. *In utero* methamphetamine (10 mg/kg/bid) was administered throughout gestation. Drug related maternal anorexia, malnutrition, altered blood pressure/temperature and postnatal maternal care were controlled by using rats made tolerant to the drug's side effects and by cross fostering. At birth, the drug exposure ended and the brain metabolism of the drug-free adult offspring were behaviorally assessed and mapped with DG. An increased rate of glucose utilization was seen in the globus pallidus of the prenatally treated animals. No changes were seen in other areas of the basal ganglia, lateral habenula or medial dorsal prefrontal cortex. These results are in contrast to our previous observations in these areas following amphetamine withdrawal in adults. However, both paradigms produced a similar decrease in open field activity.

In utero drug treatment produces specific alterations in brain metabolism in the adult offspring at 30 days of age. These changes were accompanied by both neurochemical and performance deficits and point to the production of an altered adult neurochemical and behavioral state that can be attributed to the prenatal neurotoxic effects of methamphetamine on specific brain sites.

419.9

EFFECTS OF METHAMPHETAMINE-INDUCED NEUROTOXICITY ON NEUROTROPHIC FACTOR EXPRESSION IN ADULT MICE. D.S. Albers¹*, M.S. Saporito², W.J. Friedman³, P.K. Sonsalla¹. ¹Neurology Dept., UMDNJ-RWJMS, Piscataway, NJ 08854; ²Cephalon, Inc., West Chester, PA 19380; ³Dept. of Neurosci. and Cell Biol., UMDNJ-RWJMS, Piscataway, NJ 08854.

In experimental animals, methamphetamine (METH) causes pronounced neurotoxic effects to monoaminergic neurons. Studies have demonstrated that various pharmacological agents prevent METH-induced neuropathology indicating that several processes may be involved in mediating the toxicity of METH. Several neurotrophic factors, such as brain-derived neurotrophic factor (BDNF), have significant roles in development, maintenance and survival of dopaminergic neurons. Roles for neurotrophic factors in supporting the survival of dopaminergic neurons in the basal ganglia remain to be determined, especially under conditions of stress or injury. Therefore, our aim was to characterize the dynamics of BDNF expression during and after an insult to nigrostriatal dopaminergic neurons by METH in mice. Our results indicate that expression levels of BDNF increase approximately 2-4 fold in the mesencephalon and cortex 24 h after initiation of a neurotoxic regimen of METH. These results demonstrate that stress or injury to dopaminergic neurons in the basal ganglia by METH can enhance the regional expression of neurotrophic factors (i.e. BDNF) in an adult mouse brain.

419.6

Nitric Oxide May be a Prominent Factor Involved in the Release of Dopamine (DA) During Methamphetamine (METH) Exposure *In Vivo*. B. Gough, R.R. Holson, W. Slikker Jr. and J.F. Bowyer. ¹Div. of Repro. & Develop. Toxicol. and ²Div. of Neurotoxicol., NCTR/FDA, Jefferson, AR 72079-9502

We have previously shown that inclusion of the nitric oxide synthetase (NOS) inhibitor nitro-arginine (NARG) in the microdialysis buffer greatly reduced caudate/putamen (CPU) extracellular DA during exposure to neurotoxic doses of METH (Neurosci. Abs. # 686.10, 1993). We now show that, in rat, inclusion of N³-Nitro-L-Arginine Methyl (L-NAME, a NOS inhibitor) or D-NAME (less potent NOS inhibitor) in the microdialysis buffer affects CPU extracellular DA levels in a manner suggesting that NO may play a prominent role in the *in vivo* DA release from neurotoxic doses of METH. Neither D- nor L-NAME in microdialysis buffer prior to METH affected the relative CPU extracellular levels of DA, DOPAC or HVA. However, 100 µM L-NAME produced a 64% decrease in the relative extracellular CPU DA levels during METH exposure to 4 doses of METH (5 mg/kg i.p./2 hrs) while 100 µM D-NAME minimally affected (18% decrease) DA levels. At 20 µM L-NAME the relative extracellular DA levels declined 38% during METH exposure. L-NAME did not affect DOPAC and HVA levels during METH exposure. Paradoxically, 20 µM of either Na⁺ nitroprusside (SNP) or isosorbide (ISB) in the microdialysis buffer dramatically decreased the relative extracellular DA, DOPAC and HVA levels during METH exposure. It is possible that in the CPU the NO generated by SSP and/or NO₃ by ISB is much greater than NO generated by METH alone, and the excessive levels of NO₃ generated by SSP and ISB are producing neurotoxic effects or are inhibiting DA synthesis (thus the dramatic decrease in DOPAC and HVA). Alternatively, L-NAME and NARG are potent inhibitors of another enzyme/receptor other than NOS that affects DA release.

METHAMPHETAMINE NEUROTOXICITY PRODUCES ROBUST CHANGES IN OPEN FIELD BEHAVIOR IN RATS. K.A. Trujillo*, D.T. Chalmers, K. Boateng, S.J. Watson and H. Akil, Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109-0720.

Treatment with high doses of methamphetamine (METH) leads to well-described long-term decreases in serotonin and dopamine in certain regions of the brain. Despite quite dramatic reductions in these neurotransmitters, very few baseline behavioral changes have been observed in rats following neurotoxic regimens of METH. The present study was undertaken to examine behavioral and neurochemical consequences of METH neurotoxicity.

Adult, male Sprague-Dawley rats received injections of saline or METH (6.5 mg/kg s.c.) four times daily, at two hour intervals, for four days. Ten days following treatment behavior was assessed in a large (4 ft x 4 ft) plexiglass open field apparatus. Animals were placed in the center of the open field and behavior was observed for ten minutes. Four days following behavioral assessment, animals were sacrificed, and the brains examined by immunocytochemistry, receptor autoradiography and *in situ* hybridization for changes in serotonergic function.

As has been previously described, METH produced significant reductions in serotonergic indices in several brain regions, including neocortex, hippocampus and caudate-putamen. Other areas, such as substantia nigra appeared to be spared. Animals that had received METH showed a significant increases in locomotor activity and rearing, relative to saline controls. The increases in behavior were seen primarily toward the end of the ten minute session, and occurred despite the fact that animals had been drug-free for ten days. The results suggest that METH neurotoxicity produces significant changes in locomotion and exploration. These changes may be due to decreases in serotonergic and/or dopaminergic function. (Supported by NIDA DA02265 and NIMH MH42251. KAT and DTC are recipients of NARSAD Young Investigator Awards).

METHAMPHETAMINE SENSITIZATION INCREASES VULNERABILITY OF THE PREFRONTAL CORTEX TO METHAMPHETAMINE TOXICITY B.K. Yamamoto* and S.E. Stephens. Depts. of Psychiatry and Neuroscience, Case Western Reserve Univ., Cleveland, OH 44106.

Sensitization to the behavioral and neurochemical effects of stimulants occurs following a low dose intermittent pretreatment regimen. This is manifested as an increase in behavioral stereotypy and mesostriatal dopamine (DA) function subsequent to the administration of an acute low dose challenge. These effects occur without evidence of dopamine (DA) depletion. The purpose of this study was to examine if a sensitization regimen of methamphetamine (METH) enhances DA release and the subsequent depletion following neurotoxic doses of METH. Male rats were injected once daily for 7 days with METH (2mg/kg, i.p.) or saline. Following a 7 day withdrawal, the rats were challenged with 3 subcutaneous injections of METH (7.5mg/kg), each injection given 2 hours apart. Microdialysis was used to measure extracellular DA levels in striatum (str) and prefrontal cortex (pfc) of awake rats. Rats were sacrificed 4 days later and DA tissue content was assayed. In METH pretreated rats, DA release in pfc but not in str was significantly increased during the METH challenge as compared to rats pretreated with saline (p<0.02). One week later, this group of rats also exhibited a greater depletion of DA in pfc (p<0.02) compared to the saline pretreated group. Saline and METH pretreated rats given a saline challenge were not different from controls. Conversely, striatal DA was significantly less depleted by a METH challenge in METH pretreated compared to saline pretreated rats (p<0.02). These data provide evidence that pfc DA neurons are preferentially susceptible to the neurotoxic effects of METH in rats previously sensitized to METH. Augmented DA release in the pfc may be partially responsible for the dopamine depletion following a METH challenge.

DOPAMINE AND GLUTAMATE EFFLUX ARE INCREASED IN PREFRONTAL CORTEX OF RATS SENSITIZED TO METHAMPHETAMINE. S.E. Stephens and B.K. Yamamoto. Depts. of Psychiatry and Neuroscience, Case Western Reserve Univ., Cleveland, OH 44106.

Behavioral and neurochemical sensitization occurs following intermittent, low doses of psychostimulants such as methamphetamine (METH). This is manifested as behavioral stereotypy and increased mesostriatal dopaminergic function following administration of a challenge dose. No direct comparisons have been made with regard to whether the increased dopamine (DA) response *in vivo* is mediated by an impulse-dependent or independent mechanism. Furthermore, it is not known if release of other neurotransmitters is affected by this pretreatment regimen of METH. The purpose of this study was to investigate if DA and glutamate (glu) release in the prefrontal cortex (pfc) is augmented in METH sensitized rats upon a low challenge dose of METH or potassium (K⁺) stimulation. Male rats were pretreated once a day for 5 days with METH (2mg/kg, i.p.) or saline. Following a 7 day washout period the rats were challenged with either a low dose METH injection (2mg/kg, i.p.) or K⁺ (80mM) infused into pfc. Microdialysis was used to measure extracellular DA and glu in pfc. K⁺ infusion into the pfc of METH pretreated rats increased extracellular DA and glu levels significantly from baseline values ($p < .02$). These increases were greater than in saline pretreated rats ($p < .05$). The low dose METH challenge significantly increased extracellular DA but not glu concentrations to a greater extent in METH pretreated compared to saline-pretreated rats ($p < .02$). These data provide evidence that a low dose pretreatment regimen of METH enhances DA transmission in the pfc through both transporter and impulse-dependent processes. In addition, enhanced glu release in pfc may play an important role in the behavioral effects associated with METH sensitization.

METHAMPHETAMINE (METH)-INDUCED TOXICITY IN VITRO INVOLVES THE NITRIC OXIDE TOXIC PATHWAY. P. Sheng*, C. Cerruti, and J. L. Cadet. Molecular Neuropsychiatry Section, NIH/NIDA, Addiction Research Center, Baltimore, Maryland 21224.

Methamphetamine (METH) is a drug of abuse which causes deleterious effects on both the serotonin (5-HT) and dopamine (DA) in the mammalian brain. Although these effects of methamphetamine have been known for many years, the basic mechanisms involved in the manifestations of these toxic changes have remained elusive. Recent evidence suggests that the superoxide radical might play an important role in these changes (Cadet et al., 1994). In order to further evaluate the role of oxidative mechanisms in METH-induced neurotoxicity, we examined the effects of methamphetamine in a *in vitro* model of rat fetal mesencephalic cells. METH causes loss of TH-positive cells and process degeneration. In addition, the drug causes an increase in reactive gliosis as shown by the number of cells that stain for and by the intensity of staining with glial fibrillary acidic protein (GFAP) antibodies. Co-incubation of METH-treated cells with either the NOS blocker, nitroarginine, or with the ADP-ribosylation inhibitor, benzamide, attenuated METH-induced toxic effects. Both benzamide and nitroarginine also attenuated the glial response although the effects of benzamide on glial cells were somewhat more potent. These results further support a role for free radicals in METH-induced neurotoxicity and reactive gliosis.

419.15

BEHAVIORAL AND NEUROTOXIC EFFECTS OF METHCATHINONE. A. Martello*, M. Sparago, J. Yuan, G. Hatzidimitriou, J. Katz, G. Ricaurte. Department of Neurology, Johns Hopkins Medical Institutions and NIDA Addiction Research Center, Baltimore, MD 21224.

Cathinone is a naturally-occurring amphetamine analog found in the Khat plant. Like amphetamine, cathinone has been abused and, in high doses, is selectively toxic to brain dopamine (DA) neurons. Methcathinone ("Cat") is a synthetic cathinone derivative that has recently surfaced in the illicit drug market. Because it contains an asymmetric carbon, methcathinone is available in D and L forms, and it is the L form that is used recreationally. The present studies evaluated the pharmacologic and neurotoxic properties of methcathinone stereoisomers in laboratory animals. Pharmacologic studies in mice indicated that L-methcathinone was approximately five times more potent as a locomotor stimulant than D-methcathinone. By contrast, in neurotoxicity studies, the D isomer proved more toxic to DA neurons in mice. To evaluate methcathinone's serotonin (5-HT) neurotoxic potential, additional studies were performed using rats, since mice are often refractory to the 5-HT neurotoxic effects of amphetamine derivatives. In the rat, L-methcathinone produced toxic effects on brain 5-HT (as well as DA) neurons, and its effects were more pronounced than those of D-methcathinone. These results indicate that: 1) Under certain conditions, it is possible to dissociate the pharmacologic from the neurotoxic effects of amphetamine derivatives; 2) The mechanisms mediating the behavioral effects of amphetamine derivatives may be separable from those underlying their neurotoxic actions; 3) Stereochemical and species effects may influence not only the degree but also the type of neurotoxicity produced by an amphetamine derivative and 4) N-methylation confers 5-HT neurotoxic activity onto the cathinone molecule.

419.12

INFLUENCE OF PRIOR BEHAVIORAL SENSITIZATION ON THE NEUROTOXIC EFFECTS OF METHAMPHETAMINE. M. Sparago, J. Yuan and G. Ricaurte*. Department of Neurology, Johns Hopkins Medical Institutions, Baltimore, MD 21224.

Sensitization to psychomotor stimulant drugs is associated with alterations in brain dopamine (DA) neurotransmission. DA release has been implicated in the neurotoxic action of methamphetamine (METH). The purpose of the present study was to determine whether prior sensitization influenced the neurotoxic effects of METH on brain DA and serotonin (5-HT) neurons.

To produce sensitization, mice were treated with METH (15 mg/kg, i.p.) once daily for 15 consecutive days. Control animals were treated identically with saline. One week later, the development of behavioral sensitization was documented by demonstrating a leftward shift in the dose-response curve for stereotypy in METH-treated mice. After an additional one-week drug-free period, sensitized animals, along with controls, were treated with neurotoxic doses of METH. Seven days later, the animals were sacrificed and indexes of dopaminergic and serotonergic neuronal integrity were measured. Sensitization did not augment either the dopaminergic or serotonergic neurotoxic effects of METH in the striatum. To the contrary, the sensitizing regimen of METH appeared to render the animals partially tolerant to the drug's DA neurotoxic effects.

These results indicate that a chronic regimen of METH that induces behavioral sensitization does not render brain dopamine and serotonin neurons more vulnerable to METH's neurotoxic actions. Further, the partial tolerance observed suggests that the neurochemical mechanisms underlying the expression of behavioral sensitization may at least partially overlap those mediating METH's neurotoxic actions.

419.14

EFFECTS OF d-FENFLURAMINE AND m-CHLOROPHENYLPYPERAZINE ON ACUTE 5-HT RELEASE AND LONG-TERM 5-HT DEPLETION IN RAT BRAIN. M.H. Baumann*, M.A. Avestas, R.B. Rothman. Clinical Psychopharmacology Section, IRP, NIDA, NIH, Baltimore, MD 21224.

The serotonin (5-HT) agonists d-fenfluramine (FEN) and m-chlorophenylpiperazine (mCPP) are reported to release neuronal 5-HT by a Ca⁺⁺-independent, fluoxetine-reversible mechanism. In the present work, we compared the acute effects of FEN and mCPP on extracellular 5-HT and dopamine (DA) using *in vivo* microdialysis methods in rats. The long-term consequences of repeated injections of FEN or mCPP on 5-HT neurotransmission were also examined. In the acute study, FEN or mCPP (1, 10, 100 μ M) was infused into the nucleus accumbens of conscious rats via microdialysis probes, and monoamines were assayed in dialysate samples by microbore HPLC-EC. FEN and mCPP caused equivalent, dose-dependent increases in 5-HT, but not DA, at 1 and 10 μ M doses. At the 100 μ M dose, both drugs elevated dialysate DA as well as 5-HT. In the long-term study, rats were treated with FEN or mCPP (0, 3, 10 mg/kg, ip), one injection every 2 hr for 8 hr. Two weeks after the repeated dosing regimen, FEN-treated rats exhibited marked depletions in tissue levels of 5-HT (78%) and 5-HIAA (72%) in frontal cortex, whereas mCPP-treated rats showed no signs of 5-HT depletion. Thus, mCPP appears to enhance acute 5-HT release, in a manner similar to FEN, without causing damage to 5-HT nerve terminals. The present data suggest the possibility that 5-HT release per se may not be the causative factor in the serotonergic neurotoxicity associated with FEN and other substituted amphetamine derivatives.

420.1

MEDIAL SEPTAL LESIONS ENHANCE LOCOMOTOR SENSITIZATION TO AMPHETAMINE. J. E. Kelsy* and J. A. Grabarek. Dept. Psychology, Bates College, Lewiston, ME 04240.

Sensitization to the locomotor-enhancing effects of several drugs appears to critically involve the dopaminergic mesolimbic pathway from the VTA to the n. accumbens. Such locomotor sensitization appears to be modulated by projections from the hippocampus to the n. accumbens. In this experiment, we examined sensitization to the locomotor-enhancing effects of amphetamine in rats with lesions of the medial septum, which supplies the major cholinergic projection to the hippocampus. During acquisition, the rats were injected i.p. with 1.0 mg/kg amphetamine sulfate or isotonic saline and immediately placed in a 58 cm² black open field where distance travelled was measured during six 1-hr sessions spaced 2 days apart. All rats were then injected i.p. with 0.4 mg/kg amphetamine and isotonic saline 2 days apart. Although there were no differences between the sham-operated control and lesioned rats in the acute locomotor response to either 0.4 or 1.0 mg/kg amphetamine, enhanced locomotor sensitization and conditioned sensitization were observed in the rats with medial septal lesions during acquisition and testing. These data suggest that the input from the septum to the hippocampus normally serves to inhibit sensitization to the locomotor-enhancing effects of amphetamine. Perhaps this projection also acts to inhibit sensitization to the rewarding effects of amphetamine.

420.3

Effect of chronic amphetamine on the behavioral dose-response curve. P.K. Randall*, P. Hodge, J.S. Randall College of Pharmacy and Inst. for Neuroscience, Univ of Texas, Austin, Texas 78712.

The response to amphetamine (AMPH) increases with repeated administration. With drugs such as AMPH producing curvilinear dose-response curves and multiphasic time courses, sensitization-induced changes may be difficult to interpret.

The purpose of this study was to determine whether sensitization could be more simply described as a horizontal shift in the dose response curve rather than as an alteration in the magnitude of response. Sprague-Dawley rats were injected in the home cage with 5 mg/kg AMPH (IP) every 4 days for a total of 5 treatments. Four days after the last treatment the response to 0.5, 1, 2, 4, 8, and 16 mg/kg AMPH was determined. Locomotion and rearing were assessed via computer and stereotypic ratings assigned every six min for two hours prior to, and 5 hours following, injection.

Locomotion and rearing showed typical multiphasic patterns and chronic treatment elevated or diminished these depending upon the dose and time (GroupXTime interaction, $p < .05$ for both). The rating scale data were described by a family of quantal curves in which individual curves represented the probability that the rating would meet or exceed each rating from 1 to 9. The ED₅₀'s and the horizontal deviation of each were determined by non-linear regression using a maximum likelihood criterion. At 6 and 12 min post-injection there was a 3.4 fold parallel shift to the left in the overall dose-response curve. This shift systematically decreased with time until at 60-90 min there were no differences between the groups. The reciprocal of the ED₅₀'s in both groups fell exponentially following 1 hr. The sensitized animals were marked by a more rapid decrease in this measure than the control animals.

420.5

INTRAVENOUS AMPHETAMINE PRODUCES CONDITIONED PLACE PREFERENCE USING A SINGLE TRIAL IN RATS. J. M. Valone*, T. R. Gibson, R. A. Bevins and M. T. Bardo. Department of Psychology, University of Kentucky, Lexington, KY 40506.

Previous research using intravenous (IV) morphine (MORP) has shown that conditioned place preference (CPP) can be obtained after one trial. The present study assessed the rewarding effects of IV amphetamine (AMPH) using a single trial CPP procedure. Rats were surgically implanted with an IV jugular catheter for drug delivery. Conditioning consisted of injecting each rat with AMPH (0.1, 0.3, 1 or 3 mg/kg) at the beginning of a 30-min placement into one compartment of the CPP apparatus. On a separate day, animals also received a 30-min exposure to the other compartment following saline. Sham controls were exposed to both compartments without drug. On Day 3, rats received a 15-min preference test. In Experiment 1, there was a dose-dependent increase in locomotor activity on the conditioning day. Further, CPP analysis revealed that 1 and 3 mg/kg AMPH, but not 0.1 or 0.3 mg/kg AMPH, produced a significant preference for the drug-paired compartment relative to sham controls. This preference indicated that AMPH has a rewarding effect after a single injection. Experiment 2 examined whether the AMPH-induced increase in activity could be dissociated from its rewarding property. IV MORP (10 mg/kg) was used as previously described. Consistent with previous research, MORP conditioned rats preferred the drug-paired compartment compared to shams, while showing a significant decrease in activity. Combined, these data suggest that both AMPH and MORP have an acute rewarding effect that is independent of increased activity. (Supported by USPHS Grants DA-05312 and DA-07746).

420.2

LESIONS OF THE PEDUNCULOPONTINE NUCLEUS SPARE SENSITIZATION AND CONDITIONING OF AMPHETAMINE-STIMULATED LOCOMOTOR ACTIVITY. F.A. Guarraci*, N. Melanson, M.C. Olmstead and K.B.J. Franklin. Dept. Psychology, McGill University, 1205 Dr Penfield Ave, Montreal, Quebec, Canada H3A 1B1.

The locomotor stimulant effects of amphetamine and other psychostimulants have been linked to their reinforcing effects in that the phenomena seem to have a common neural substrate in the modulatory effect of dopamine on the outflow from the ventral striatum. One component of the ventral striatal outflow passes via the ventral pallidum to the region of the pedunculopontine tegmental nucleus (PPTg) which lies within the midbrain locomotor region. Recently it has been shown that excitotoxic lesions of the PPTg block the reinforcing effects of amphetamine, morphine and brain stimulation but do not appear to block the acute locomotor stimulant effects of amphetamine (Olmstead and Franklin, 1994). However it remains possible that the PPTg plays a role in the long term effects of amphetamine reflected in conditioning or sensitization of stimulant effects. We now report that NMDA-induced lesions of the PPTg do not alter the augmentation of the locomotor response with repeated injections of 1.5 mg/kg amphetamine, or the subsequent hyperactivity exhibited by animals tested drug free. The reinforcing and locomotor stimulant effects of amphetamine seem to be dissociable at the level of the PPTg.

AN INNOVATIVE TECHNIQUE FOR MEASURING AMPHETAMINE-INDUCED BEHAVIORAL SENSITIZATION: HYPER-ACTIVE RATS RANKED HIGHER THAN CONTROLS. J.G. Kohlert* and G.J. Bloch. Dep't of Psychology, Brigham Young University, Provo, UT, 84602.

General locomotor activity was used to assess the degree of "sensitization" induced by moderate doses of amphetamine. Adult male rats were given an injection of saline or amphetamine (.75, 1.0, 2.0, or 3.0 mg/kg) once per day for 4 days. The pattern of activity for each rat was scored by assigning a rank based on performance in all 4 sessions. Ranks progressed on a scale from 1 (activity seen in saline rats) to 12 (activity seen in rats spending considerable time in stereotypic behavior). Ranks differed significantly among the doses ($p < .05$, Mann-Whitney U); these increased in a dose-response fashion. Behavioral analysis revealed an inverse relationship between locomotor activity and stereotypy ($p < .0001$, Least Squares Regression). Interestingly, although total activity decreased with increased stereotypy, locomotor activity actually increased during those times when animals were not engaged in stereotypical behavior. Importantly, hyperactive rats had higher sensitization rankings than dose-matched controls ($p < .05$, Mann-Whitney U).

GENETIC ANALYSIS OF METHAMPHETAMINE'S EFFECT ON FEEDING BEHAVIOR IN BXD RECOMBINANT INBRED MICE. S. Angeli-Gade*, and J.K. Belknap. Dept. of Medical Psychology, Oregon Health Sciences University, Portland, OR 97201.

Amphetamines at low doses have been shown to produce anorexia in both humans and animals. To identify the genes mediating this effect, BXD recombinant inbred mice were tested on a five day food restriction paradigm which resulted in stable food intake. Mice from each strain were then divided into two equal groups. On Day 6, Group 1 was given 1.0 mg/kg methamphetamine (MA), s.c., whereas Group 2 was given the saline vehicle. On the next day (Day 7), both groups were given MA. Consumption was measured for the first 30 minutes. Significant drug and strain effects for the 24 strains tested were seen. Food consumption was decreased on average by 54%. In the extreme strains, food consumption was decreased by as much as 86% (BXD 1) or as little as 15% (BXD 11). Following behavioral testing, QTL analysis ($p < .01$) identified distinct candidate genes on chromosomes 4 (*Hcf-3*), 9 (*Fv-2*), 11 (*D11Mit2*), 12 (*D12Nyu1*), 13 (*Tpmt*), 15 (*D15Mit3*), 18 (*D18Mit15*) and 19 (*D19Byu1*). Verification of these loci using PCR in an independent F2 population is ongoing. Supported by NIDA DA07262 and Contract DA277-90-7405.

GENETIC RECOMBINATION OF AMPHETAMINE-INDUCED MOTOR BEHAVIORS. A. Fleischer,¹ C. Vadasz,^{1,2} ¹Laboratory of Neurobehavioral Genetics, Nathan Kline Institute, Orangeburg, NY 10962 and ²New York University Medical Center, NY 10016; USA

Quantitative Trait Loci (QTLs) responsible for high and low expression of murine mesencephalic tyrosine hydroxylase activity (TH/MES) were transferred onto C57BL/6ByJ (B6) inbred mouse strain background by successive backcrosses with concomitant selection for the extreme expressions of TH/MES (Vadasz, 1990). Subsequently, Artificially Selected Congenic Recombinant Inbred (ASCR) strains were derived from the selection lines. To investigate the effects of the gene transfer, locomotor activity (distance covered; D) and frequency of occurrence of rearing on the hind legs (R) were recorded for 30 min after i.p. injections of 0, 2.0, and 4.0 mg/kg D-amphetamine in the progenitor strains (B6 and BALB/cJ) and in two B6.C animal model lines (N=10). Analysis of the data indicates that the D/R ratio was significantly higher in the BALB/cJ strain than in the B6 strain. Similar D/R values were obtained for the B6 and the B6.C lines at 0 and 2.0 mg/kg D-amphetamine. After administration of 4.0 mg/kg D-amphetamine the four strains fell into two classes, each class consisting of a progenitor and a B6.C line. The results are consistent with the hypothesis that both TH/MES and amphetamine-induced behaviors are affected by the same QTLs.

420.9

D-AMPHETAMINE (AMPH) DECREASES SYMPATHETIC NERVE DISCHARGE (SND) IN ANESTHETIZED RATS. W. Liu, M.C. Cuntapay and K.J. Varner*. Dept. of Pharmacology and Experimental Therapeutics & Alcohol and Drug Abuse Center, LSU Medical Center, New Orleans, LA 70112.

Studies in this and other laboratories have shown that cocaine, a well known sympathomimetic, decreases rather than increases SND in anesthetized and conscious animals. The purpose of this study was to determine whether AMPH, another sympathomimetic, would also decrease SND in pentobarbital-anesthetized rats. The studies were performed in male Sprague-Dawley rats (275-325 g). Cannulae were placed in the femoral artery and vein. The trachea was cannulated and the rats mechanically ventilated. Splanchnic SND was recorded using bipolar platinum electrodes (0.30-3 KHz bandpass). Two groups of rats (n=5 each) were used. One group received 0.01 and 0.5 mg/kg AMPH, and the other 0.1 mg/kg AMPH intravenously. AMPH dose-dependently decreased SND (-4 ± 2 to $-85 \pm 5\%$). The duration of the SND responses ranged from 1.4 ± 0.6 to 66 ± 8 min. AMPH also dose-dependently increased heart rate (39 ± 19 bpm max, 1.4 ± 0.6 to 18 ± 7 min duration). Doses of 0.01 and 0.1 mg/kg, AMPH increased mean arterial pressure (MAP; 18 ± 2 mmHg max.). Doses of 0.5 mg/kg AMPH increased (32 ± 3 mmHg, 3 ± 0.5 min duration) and then decreased (-36 ± 7 mmHg, 48.5 ± 11 min duration) MAP. These data show that AMPH, like cocaine, decreases SND in anesthetized rats. These also findings suggest that an increase in sympathetic outflow is not responsible for the HR and pressor responses elicited by AMPH. (supported by NIDA DA08255).

DAILY POST-SESSION D-AMPHETAMINE OR QUINPIROLE ADMINISTRATION IMPAIRS ACQUISITION OF A POSITIVELY MOTIVATED AUTOSHAPED LEVER-TOUCH RESPONSE IN RATS. E.A. Plumley*, R.R. Rule, P.H. Janak and J.L. Martinez, Jr. Dept. of Psychology, Univ. of California, Berkeley, CA 94720.

The effects of injections of either d-amphetamine or quinpirole, the D2 dopamine receptor selective agonist, on the development of a lever-touch response in an autoshaping paradigm were investigated. Male Sprague-Dawley rats received daily, post-session, intraperitoneally administered injections after 10 pairings of the insertion of a retractable lever (CS) and the delivery of a food pellet (US). Reinforcement delivery was immediate if the subject contacted the lever, otherwise, the pellet was delivered upon lever retraction. Amphetamine, at a dose of .3 mg/kg [E (1,35) = 26.5, $p < 0.0001$] impaired the development of the lever-touch response, as compared to saline treated control rats, and quinpirole at a dose of .3 mg/kg [E (1,34) = 30.7, $p < 0.0001$] completely abolished the acquisition of the response. Neither drug affected acquisition at a lower dose (.03 mg/kg). Administration of the higher doses of amphetamine (1 mg/kg) and quinpirole (2 mg/kg) also impaired responding, although the impairment likely was due to toxic effects of the drugs. Initiation of either quinpirole or amphetamine treatment after complete acquisition of the autoshaping task did not affect responding. Taken together these results indicate that post-session administration of amphetamine impairs and quinpirole blocks the acquisition of an autoshaped lever-touch task, and that the impairment is not due to an aversive action of the drug on performance (Supported by DA 06192 to JLM and MH 15860 to EAP).

NEUROETHOPHARMACOLOGY OF AMPHETAMINE AND ANTIPSYCHOTIC DRUGS IN NUCLEUS ACCUMBENS AND AMYGDALE OF SOCIALLY INTERACTING RATS. Z. R. Wang*, M. Bonta, and G. V. Rebec. Program in Neural Science and Dept. of Psychology, Indiana University, Bloomington, IN 47405.

A neuroethological approach has been used to compare the effects of haloperidol and clozapine on motor, social, and motivational behavior of amphetamine-treated rats. Adult, male rats -- tested simultaneously in groups of three -- were exposed to a relatively enriched environment. In each tested group, one rat received amphetamine in nucleus accumbens (NAC) or amygdala (AMG) followed within 15-20 min by either haloperidol or clozapine. The other two rats were used as companions (no infusion) and controls (saline). Behavior patterns were classified into three main elements: stereotyped motor behavior, social contacts, and motivational behavior. Each element consisted of several behavioral subcategories. Behavior was recorded on video tape and rated by a trained observer. The results indicate: 1) amphetamine induces more stereotyped motor behavior in NAC rats than in AMG rats; 2) clozapine effectively reduced all amphetamine-activated stereotyped motor, social and motivational behavior in both NAC and AMG rats, while haloperidol was less effective in AMG rats; and 3) the behavioral effects of both amphetamine and the antipsychotic drugs showed marked individual differences. A neuroethological analysis can provide important new information on the mechanisms underlying the complex behavioral effects of these and other drugs known to alter dopamine transmission.

GENE EXPRESSION ASSOCIATED WITH AMPHETAMINE SELF-ADMINISTRATION BY RATS INTO THE NUCLEUS ACCUMBENS VIA MICRODIALYSIS PROBES. O.R. Javid, P.H. Janak*, S.A. Brooks, R.R. Rule, E.J. Barea-Rodriguez, W. Meilandt, J. Rigter and J.L. Martinez, Jr. Department of Psychology, University of California, Berkeley CA 94720.

We investigated whether self-administration of amphetamine could be supported by local administration of the drug into the n. accumbens via a microdialysis probe, and whether amphetamine self-administration induces alterations in gene expression. Male Sprague Dawley rats previously autoshaped to respond on a lever for food were implanted with cannulae in the n. accumbens. After surgical recovery, subjects received 60 lever presentations on a 5 min fixed-interval schedule; lever responses were reinforced by 1 min intra-accumbens infusion of either amphetamine or Ringer's solution. Lever-touch responding was maintained by delivery of $12 \mu\text{g}/2\mu\text{l}$ amphetamine, but not Ringer's solution, into the right n. accumbens via a microdialysis probe. Videotape analysis indicated that rats reinforced with amphetamine were more active than rats reinforced with Ringer's solution. Drug-induced changes in gene expression were examined by isolating mRNAs from either the drug-infused right forebrain (minus the caudate) of a single rat or the left cannula-implanted control forebrain (minus the caudate), immediately after a 5-hr self-administration session. A cDNA library generated from the right drug-infused forebrain was subtracted from cDNAs amplified *in vitro* from the contralateral control forebrain. This subtraction yielded numerous recombinant plaques that are being characterized. These results suggest that amphetamine self-administered via microdialysis probes into the n. accumbens maintains conditioned lever-touch responding, and that a single 5-hr self-administration session may induce new gene expression. (Supported by DA06192, DA04195.)

DAILY PRETRAINING ADMINISTRATION OF D-AMPHETAMINE IMPAIRS ACQUISITION OF A CLASSICALLY CONDITIONED LEVER-TOUCH RESPONSE IN RATS. R.R. Rule*, P.H. Janak and J.L. Martinez, Jr. Department of Psychology, University of California, Berkeley, CA 94720.

We previously found that posttraining administration of amphetamine does not affect performance of a classically conditioned lever-touch response. We now report that pretraining administration of d-amphetamine impairs acquisition of this same response. Sprague-Dawley rats were classically conditioned to touch a retractable lever (CS) which immediately precedes the delivery of a reward pellet. A retractable lever was presented to subjects for ten seconds. Upon retraction of this lever, rats received a pellet of food. There was no contingency between food presentation and lever-touch responding. This procedure was repeated ten times daily with an intertrial interval of 45 sec. Animals were run for ten consecutive days. Rats received a daily i.p. injection five minutes prior to each training session. Animals receiving .3 mg/kg amphetamine performed significantly fewer lever-touches than animals receiving pretrial injections of saline. The performance of the amphetamine animals increased from an average of 1.4 lever touches on Day 1 to 2.8 lever-touches on Day 10. This increase is less than that of saline-treated animals who increased from an average score of 0.9 on Day 1 to 5.9 on Day 10. The acquisition rate in the control rats is less than that seen in instrumental conditioning or combined classical and instrumental conditioning (autoshaping). This research is supported by a Ford predoctoral fellowship (RRR) and DA06192 (JLM).

420.13

DELAYED NON-MATCH TO POSITION PERFORMANCE IS IMPAIRED IN RATS GIVEN HIGH DOSES OF METHAMPHETAMINE. S.D. Friedman, A.E. Butt, B.G. Cooper, M. Hagen, M.R. Markham, and G.K. Hodge*. Dept. of Psychology, Univ. of New Mexico, Albuquerque, NM 87131. Methamphetamine (MA) administered to rats in high doses causes neurotoxic injury to dopaminergic and serotonergic neurons (De Vito & Wagner, 1989; Wagner, Woertwein, & Forman, 1990) and disrupts performance in certain behavioral paradigms (Walsh & Wagner, 1990). Previously, we have shown that MA-treated animals are impaired in operant discrimination reversal learning (Cooper et al., 1991), and in delayed alternation T-maze performance (Cooper et al., 1992; 1993). In the current study, we examine MA-induced impairments in a delayed non-match to position task using a novel, computerized, touch-screen equipped operant conditioning apparatus (Markham, Butt, & Dougher, in preparation). Rats received a total of four subcutaneous injections of either MA (12.5 mg/kg) or saline, with 2 hr intervals between injections. Upon recovery, animals were reduced to 85% of their free-feeding weight and were shaped to activate a computer touch-screen for food reinforcement. An automated version of the T-maze alternation paradigm (see Cooper et al., 1992) was then implemented in two phases. In the first phase, animals were reinforced for pressing a rectangular image located on either the left or right side (sample position) of a touch-screen equipped monitor. Following a delay of 1 s, a pair of rectangular stimuli appeared on the monitor and animals were reinforced only for selecting the stimulus located on the opposite side relative to the sample. Upon reaching a criterion of 80% correct, animals began the second phase of training where delays of 1, 10, 20, 40, and 80 s intervened between the presentation of the sample and choice stimuli. Compared to controls, acquisition performance in MA-treated animals was impaired at delay intervals of 1, 10, and 20 s (MANOVA; $p < .05$). Results suggest that high doses of MA cause lasting impairments in reinforced alternation performance and that these impairments are exacerbated by temporal delays. (GKH supported by UNM RAC #93-33).

EFFECT OF REPEATED METHAMPHETAMINE PRETREATMENT ON FREEZING BEHAVIOR INDUCED BY CONDITIONED FEAR STRESS. K. Tsuchiya, T. Inoue, and T. Koyama*. Dept. of Psychiatry, Hokkaido Univ. Sch. of Med., Sapporo 060, Japan.

We examined the effect of methamphetamine pretreatment on conditioned fear stress in male Wistar-King rats. Rats received methamphetamine or the vehicle according to the repeated escalating dose schedule (1.25, 2.5, 3.75, 5 mg/kg s.c. x2/every other day for a week). After a 5 day drug abstinent period, the rats were exposed to electric foot-shock (2.5 mA for 30 min) for two days. Twenty-four hours after the last foot-shock session, the rats were again placed in the shock chamber without shocks and observed for 5 min. Methamphetamine pretreatment significantly increased conditioned freezing behavior, suggesting that rats previously exposed to chronic methamphetamine are more sensitive to subsequent psychological stress than control rats. Repeated methamphetamine treatment did not decrease basal dopamine and serotonin concentrations in the brain. Furthermore, co-administration of MK-801 (non-competitive NMDA antagonist), amfonelic acid (dopamine reuptake inhibitor) or fluoxetine (serotonin reuptake inhibitor) with methamphetamine did not alter the enhanced freezing behavior. Taken together, it seems that methamphetamine-induced hypersensitivity to anxiety is not due to the toxic effect of methamphetamine. While co-administration of SCH23390 (D1/5 antagonist) or raclopride (D2/3 antagonist) had no effect on the methamphetamine-induced increase in freezing, co-administration of YM-09151-2 (D2/3/4 antagonist) prevented this increase. These results suggest that methamphetamine-induced enhancement of anxiety is mediated by D2-like receptors.

EFFECTS OF *d*-FENFLURAMINE ON THE STIMULUS PROPERTIES OF MDA STEREOISOMERS L.E. Baker*, C. Sullivan, and M. Taylor Department of Psychology, Western Michigan University, Kalamazoo, MI 49008.

The stereoisomers of the designer drug 3,4-methylenedioxymphetamine (MDA) have been reported to have distinct stimulus properties: (+) MDA is presumably more similar to *d*-amphetamine while (-) MDA is more closely related to hallucinogens, such as DOM. While MDA is structurally similar to amphetamine, its behavioral effects appear to be mediated by both dopamine and serotonin. We have recently demonstrated evidence which suggests serotonergic depletion (with a neurotoxic regimen of fenfluramine) may enhance the amphetamine-like effects of a related compound, MDMA.

In the present study, we examined the effects of *d*-fenfluramine administration (6.0 mg/kg b.i.d. for four days) on the discriminative stimulus properties of the stereoisomers of MDA. Male sprague-dawley rats were trained to discriminate either (+) MDA (1.5 mg/kg; $n=8$) or (-) MDA (1.5 mg/kg; $n=8$) from saline in a two-lever operant task. Several doses of *d*-amphetamine (0.25-1.0 mg/kg) and the training drugs (0.19-0.75 mg/kg) were administered during independent test sessions prior and subsequent to the *d*-fenfluramine regimen.

In contrast to previous suggestions that (+) MDA is similar to amphetamine, the present results indicated that *d*-amphetamine did not substitute for either isomer of MDA. In addition, while (+) MDA substituted completely for (-) MDA, (-) MDA only engendered partial substitution for (+) MDA. In test sessions following *d*-fenfluramine treatment, however, (-) MDA substituted completely for (+) MDA. These results suggest that *d*-fenfluramine induced neurotoxicity may influence the cue properties of the stereoisomers of MDA, making them more similar. Although there were noted increases in drug appropriate responding during amphetamine post-tests, such increases could not be attributed to the effects of *d*-fenfluramine treatment.

ENVIRONMENT MODIFIES THE PATTERN AND CHARACTER OF BEHAVIORAL SENSITIZATION PRODUCED BY METHAMPHETAMINE. T. Ohmori*, T. Abekawa, and T. Koyama. Dept. Psychiatry, Hokkaido Univ. Sapporo 060 Japan

Effects of environmental inhibition of the methamphetamine (MA)-induced behavior on the establishment and mode of expression of behavioral sensitization were examined. Rats received daily injection of MA for 10 days (1mg/kg, sc). Half of them were immediately returned to the home cage (normal cage group) and the other half were individually confined in a cylinder with a diameter of 13 cm (narrow cage group) for 3 hrs after each injection. The third group received saline in the home cage (saline group). After a 7-8 day or 17-18 day withdrawal period, they were readministered with MA (1mg/kg or 0.5 mg/kg). The normal cage group showed significant enhancement in horizontal motor activity compared with the saline group, indicating the development of behavioral sensitization. In contrast, the narrow cage group showed no or slight enhancement in the motor activity. However, they showed significantly intensified stereotyped behavior compared with the saline group. Microdialysis studies revealed no enhancement in the ability of MA to increase dopamine release from the nucleus accumbens in the normal as well as narrow cage group compared with the saline group, when examined after either a 7-8 day or 17-18 day withdrawal period. These results suggest that environmental inhibition of actual movement under the drug effect modifies the pattern and character of behavioral sensitization. The neurochemical basis of the development of behavioral sensitization and the environmental modification of its expression remains unknown.

420.16

EVIDENCE THAT HIGH AND LOW RESPONDERS TO NOVELTY SHOW DIFFERENCES IN BEHAVIORAL RESPONSES TO DEXAMPHETAMINE AND ETHANOL. M.A. Gings*, A.R. Coole, Psychoneuropharmacology University of Nijmegen, P.O. 9101, 6500HB Nijmegen, The Netherlands. ENA

The aminergic make-up of the ventral and dorsal striatum differs between high (HR) and low (LR) responders to novelty (Can.J.Phys.Pharmacol.71,335,1993). These two types of individuals normally co-occur in unselected outbred populations of Wistar rats. These rats are known to react differentially to self-administration of dexamphetamine; they also show distinct locomotor responses to dexamphetamine (Science 245, 1511, 1989). The present study had two purposes. First, it was investigated whether dexamphetamine-induced stereotyped behavior also differs between these rats; for the sake of comparison, a study of the locomotor effects of dexamphetamine was included. Second, we investigated to what extent these rats differentially react to ethanol, since this drug is also known to influence the aminergic activity in the striatum. Male HR and LR rats were selected on an open-field (Brain Res. Bull. 24, 49, 1990). Stereotyped tracking behavior (STB; dexamphetamine: 0.5-2.0 mg/kg/sc) was studied on the same open field, using an video-computer program: HR showed STB at 1.0 mg/kg, whereas LR needed a much higher dose (2.0 mg). HR showed a significant greater locomotor activity, measured in boxes (50x30 cm) than LR following administration of dexamphetamine at doses (0.5-2.0 mg/kg/ip). Second, ethanol consumption was assessed. Animals were maintained on alternate day presentation of ethanol and water; ethanol solutions were given in increasing steps of 1%. LR rats showed significantly higher ethanol intake and preference than did HR rats. Animals were maintained on 10% ethanol to determine preference stability; line differences remained stable throughout the entire period. In conclusion HR rats differ from LR rats both in stereotyped and locomotor responses to dexamphetamine and ethanol intake. It remains to be investigated to what extent these differences are causally coupled to differences in the aminergic make-up of the striatum.

420.18

DEXFENFLURAMINE LACKS AMPHETAMINE-LIKE ABUSE POTENTIAL. K.W. Locke¹, T.R. Levesque¹, K.L. Nicholson² and R.L. Balster². ¹Interneuron Pharmaceuticals Inc., Lexington, MA 02173 and ²Dept. of Pharmacol. and Toxicol., Medical College of Virginia, Richmond, VA 23298.

The amphetamine-like abuse potential of dexfenfluramine (dFEN) was evaluated using drug discrimination and self-administration procedures. Male Fischer rats were trained to discriminate either dFEN (1.0 mg/kg) or *d*-amphetamine (dAMP; 1.0 mg/kg) from saline in a two-choice discrete-trial avoidance paradigm. In dAMP-trained rats, dFEN (0.5-4.0 mg/kg) engendered almost exclusively saline-appropriate responding. In dFEN-trained rats, dAMP (1.0-4.0 mg/kg) engendered entirely saline-appropriate responding in 3 of 6 rats and intermediate levels of dFEN-appropriate responding in the remaining animals. Potential reinforcing effects of dFEN were also evaluated in 3 male rhesus monkeys trained to self-administer cocaine (iv) during daily 60 min sessions under a fixed-ratio 10 schedule. Various doses of dFEN (30-1000 ug/kg/infusion) and dAMP (10 ug/kg/infusion) were substituted for cocaine in 4 consecutive daily sessions. In all subjects, dFEN maintained rates of self-administration within the range of rates maintained by saline and considerably below those maintained by cocaine and dAMP. Furthermore, the within-session distribution of responding with dFEN resembled that produced by saline. Taken together, these results strongly suggest that dFEN will not have amphetamine-like abuse potential in man.

FACTORS AFFECTING THE DEVELOPMENT OF BEHAVIORAL SENSITIZATION TO APOMORPHINE. B.A. Mattingly*, K. Koch, F.H. Osborne, & J.E. Gotsick. Department of Psychology, Morehead State University, Morehead, KY 40351.

Research suggests that behavioral sensitization to the direct dopamine agonist, apomorphine (APO) develops through both associative and non-associative mechanisms. The present study further assessed the role of environmental factors in APO-induced behavioral sensitization. In Exp. 1, rats were treated daily with either APO (5 mg/kg) or vehicle (VEH) and tested for activity in either an open-field or a running-wheel. On Day 9, one-half the rats in each drug/apparatus group were tested in the alternate activity test apparatus. APO-treated rats displayed progressively greater activity over days in both the open-field and running-wheel (i.e., sensitization). More important, APO-treated rats displayed significant sensitization on Day 9 in both the wheel and open-field tests regardless of their prior training environment. In Exp. 2, rats were treated daily with APO (5 mg/kg) or VEH and again tested in the running wheel. For one-half the rats in each drug condition the wheel was free to move and for the remainder the wheel was immobilized. On Day 10 of testing, all rats received a challenge injection of APO (5 mg/kg) and the wheel was free to move for all rats. APO-treated rats in the free wheel displayed significant sensitization over the 10 test days. In contrast, rats pretreated with APO and placed in the immobilized wheel for 9 days were not sensitized when tested on Day 10. These results suggest that the ability to express the drug-induced locomotor response may be more important than drug-associated cues in the induction of behavioral sensitization.

EFFECTS OF WITHDRAWAL FROM NICOTINE ON INTRACRANIAL SELF-STIMULATION. M. Legault* and R. A. Wise. Center For Studies in Behavioral Neurobiology, Concordia University, Montreal, QC, CANADA H3G 1M8.

Elevated intracranial self-stimulation (ICSS) thresholds following withdrawal from repeated treatments with cocaine, amphetamine or morphine are correlates of the dysphoria and anhedonia that characterize human drug dependence. Dysphoria is also a feature of nicotine dependence and we now report the effect on ICSS of nicotine withdrawal. Animals were repeatedly injected with either 0.5 or 1.5 mg/kg of nicotine or saline. Injections were given once on the first day of treatment then twice daily for the next 13 days (equaling a dose of 1.0 or 3.0 mg/kg/day) and on the morning of the final day (day 15). Two measures of rate-frequency threshold were determined every 4 hours for 32 hours following the last injection. Nicotine withdrawal caused non-parallel rightward shifts in the rate-frequency functions. Peak effects occurred between 20 and 24 hours following the final injection. During this time period threshold determined by the lowest frequency required to reinforce responding was elevated to approximately 120% of baseline in each nicotine group, whereas the peak elevation in the frequency required to maintain half-maximal responding was only 10%. These data suggest that repeated nicotine treatment results in a dependence syndrome characterized by a phasic depression of the neural substrate underlying ICSS that is detectable at moderately reinforcing stimulation frequencies.

DEGENERATIVE DISEASE: ALZHEIMER'S—MECHANISMS OF CELLULAR INJURY I

421.1

INHIBITION OF APOLIPOPROTEIN E mRNA TRANSLATION WITH ANTISENSE OLIGONUCLEOTIDES. S. Yajima and M.M. Mouradian*. Genetic Pharmacology Unit, Experimental Therapeutics Branch, NINDS, NIH, Bethesda, MD 20892.

Alzheimer disease patients have increased frequency of apolipoprotein E (ApoE) epsilon 4, suggesting this allele is a risk factor for the disease. ApoE, which interacts strongly with amyloid beta protein in vitro, is immunohistochemically localized to the senile plaques, vascular amyloid and neurofibrillary tangles of Alzheimer disease. Thus, decreased expression of the ApoE gene might be of therapeutic value in minimizing amyloid deposition in this disease. The antisense oligodeoxynucleotide (ODN) strategy can be used as an effective tool to regulate the expression of specific genes. In this investigation, we used phosphorothioate antisense ODNs to down-regulate ApoE gene expression. An expression vector was constructed containing the 5' untranslated and part of the translated region of the human ApoE cDNA fused, in frame, with the reporter gene encoding luciferase and used to generate stably transformed CHO cells. A series of 21 mer antisense ODNs targeted to various portions of the ApoE message were used. Nonsense ODNs having the same nucleotide composition but in scrambled sequence were used as controls. Among the tested ODNs, two molecules spanning the ATG codon added to the culture medium at 5 µM four times every 12 hours decreased luciferase activity by about 20% (p<0.05). Shorter time points and a lower concentration (1 µM) were ineffective. No apparent toxicity of the ODNs to the cultured cells were noted. These findings suggest that the antisense approach could be useful to study the potential pathogenetic link between ApoE and Alzheimer disease.

421.2

HUMAN CEREBRAL CORTICAL NEURONS DISPLAY APOLIPOPROTEIN E IMMUNOREACTIVITY. R.E. Metzger, M.J. LaDu, M.T. Falduto, J.B. Pan, E.J. Mufson, G.S. Getz, and D.E. Frail*. Dept. of Neuroscience, Abbott Laboratories, Abbott Park, IL 60064, Dept. of Neurological Sciences, Rush Presbyterian-St. Lukes Medical Center, Chicago, IL 60612, and Dept. of Pathology, Univ. of Chicago, Chicago, IL 60637.

Apolipoprotein E (apoE) immunoreactivity has been identified in senile plaques (SP) of Alzheimer's disease (AD). Although apoE is synthesized in the brain in high abundance, the cellular localization of apoE in specific brain regions has not been clearly defined. We have used immunohistochemistry to determine cell types containing apoE in paraformaldehyde fixed frontal cortex sections from normal aged and AD brains. In normal brain, double-staining with apoE and microtubule associated protein-2 (MAP-2) antibodies revealed intense, specific apoE immunoreactivity in a subpopulation of projection neurons in cortical layers 3 and 5. In contrast, AD sections displayed apoE reactive SP, neurofibrillary tangles and fewer immunoreactive neurons, while MAP-2 stained neuropil threads but not neurons. Co-staining of sections with glial fibrillary acidic protein (GFAP) antibody demonstrated that apoE was not present in the GFAP positive cells found in layers 1 and 2 of control or layers 1-5 of AD sections. These results indicate that apoE may be produced or internalized by a select population of neurons in human cerebral cortex and that this process is altered in AD pathology.

421.3

APOLIPOPROTEIN E₄ ALLELE ASSOCIATION WITH ALZHEIMER'S DISEASE. S.E. Poduslo*, J.D. Schwankhaus. Dept. of Neurology, Texas Tech University Health Sciences Center and Dept. of Veterans Affairs, Lubbock, TX 79430.

The apolipoprotein E₄ allele has been strongly implicated in late onset familial and sporadic Alzheimer's Disease (Saunders, et al. *Neurol* 43:1467, 1993). The authors found the E₄ allele frequency to be 0.42 for late onset Alzheimer's patients, 0.19 for early onset patients, and 0.36 for sporadic cases, compared with 0.16 for CEPH control grandparents. In our studies we have obtained blood samples from early and late onset familial and sporadic Alzheimer's patients and spouses as well as Parkinson's patients. The patients were diagnosed as probable Alzheimer's after a CAT scan, EEG, extensive blood work, and examination by a neurologist. The diagnosis was made according to the NINCDS-ADRDA criteria (McKhann et al. *Neurol* 34:939, 1989). The apolipoprotein E₄ polymorphism was detected after PCR amplification of genomic DNA, restriction enzyme digestion with HhaI, and polyacrylamide gel electrophoresis. Ethidium bromide stained bands at 91 bp were designated as allele 3, at 83 bp as allele 2, and at 72 bp as allele 4. Of the 84 probable Alzheimer's Disease patients (all of whom were Caucasian), 45 had the 3/4 genotype, 13 had the 4/4 genotype, and 4 had the 2/4 genotype. There were 25 early onset patients and 59 late onset patients. The frequencies for the E₄ allele in the late onset familial or sporadic patients was approximately 0.4; while that for early onset sporadic patients was 0.29 and for familial was 0.64. We analyzed 77 spouses as controls, and of these, 51 had the 3/3 genotype and 15 had at least one E₄ allele for an E₄ frequency of 0.097. In a survey of 53 Parkinson's patients as another neurological control group, only 9 had the E₄ allele. Our findings support the association of the ApoE₄ allele with Alzheimer's Disease. Supported by the State of Texas DNA Bank for Genetic Studies of Alzheimer's Disease.

421.4

HIPPOCAMPAL VOLUME LOSS ON MRI SCANS IN ALZHEIMER PATIENTS AND NONDEMENTED ELDERLY SUBJECTS WITH APOLIPOPROTEIN E ε4 ALLELE. H. Soininen*, M. Lehtovirta, M. Laakso, K. Partanen, S. Helisalmi, A. Mannermaa, M. Hallikainen, T. Hänninen, A. Pitkänen, K. Koivisto, M. Ryyanen, and P.J. Riekkinen Sr. Depts. of Neurology, Radiology, Unit of Clinical Genetics, Univ. and Univ. Hospital of Kuopio, Kuopio, 70211 Finland

Several studies have indicated apolipoprotein E (apoE) ε4 as a risk factor for late-onset sporadic and familial Alzheimer's disease (AD). AD is characterized by structural damage, particularly, in the medial temporal lobe structures. Previously, apoE was implicated in regeneration of the nerve tissue and in synaptogenesis of the hippocampus in experimental animals. Here, we studied whether AD patients and nondemented elderly subjects carrying apoE ε4 allele have more severe hippocampal damage than those without ε4 allele. We measured hippocampal volumes using a 1.5 T MRI imager in 26 AD patients at the early stage of the disease and 32 healthy nondemented elderly individuals. The apoE genotype was determined using genomic DNA extraction and PCR amplification from venous EDTA-blood. We found that AD patients with apoE ε4/4 genotype had smaller hippocampal volumes (the right hippocampus, -54% of control) than AD patients with ε3/4 or ε3/3 in spite of equal clinical severity. Nondemented elderly subjects with one or two apoE ε4 alleles had a decreased volume difference between the right and left hippocampus (p<0.01) compared to those without ε4. Our data suggest that apoE ε4 allele is associated with severe hippocampal damage in AD and minor hippocampal changes can be detected in nondemented elderly, particularly, in those with ε4/4 genotype.

421.5

APOLIPOPROTEIN E3- AND E4-INDUCED DIFFERENCES IN NEURITE OUTGROWTH ARE ASSOCIATED WITH DIFFERENCES IN THE SUBCELLULAR LOCALIZATION OF APOLIPOPROTEIN E. **B. P. Nathan***, S. Bellosta, R. W. Mahley†, and R. E. Pitas†. Gladstone Institute of Cardiovascular Disease, Cardiovascular Research Institute, Departments of †Medicine and †Pathology, University of California, San Francisco, CA 94141-9100.

Apolipoprotein (apo) E4, one of the three common isoforms of apoE, has been implicated in Alzheimer's disease. Previously, we demonstrated differential effects of apoE3 and apoE4 on neurite outgrowth in cultures of dorsal root ganglion (DRG) neurons: In the presence of β -migrating very low density lipoproteins (β -VLDL), apoE3 increased neurite extension and decreased branching, whereas apoE4 decreased outgrowth (Nathan *et al.*, *Science* 1994, 264:850-852). In the present study, we examined the effects of apoE3 and apoE4 on neurite outgrowth from a murine neuroblastoma cell line (Neuro-2a). The cells were cultured in serum-free N2 medium for 48 hours in the presence of β -VLDL (40 μ g cholesterol/ml) alone or with apoE3 or apoE4 (30 μ g/ml) purified from human plasma. Consistent with the results obtained with the DRG neurons, neurite extension in Neuro-2a cells increased with apoE3 but decreased with apoE4 as compared with that seen in the cells grown in medium containing β -VLDL alone. Immunocytochemical localization of apoE in the Neuro-2a cells treated with apoE3 or apoE4 with β -VLDL revealed a differential localization of apoE. In apoE3-treated cells, intense apoE immunoreactivity was observed within the cell bodies and neurites. In contrast, apoE4-treated cells showed little, if any, immunoreactivity within the neurites. The data suggest that the localization of apoE3 (but not apoE4) in the neurites may play a role in enhancing neurite outgrowth.

421.7

MICROVASCULAR PATHOLOGIC CHANGES IN HIPPOCAMPAL FORMATION IN ALZHEIMER DISEASE. **B. Leveugle¹*, C. Yang¹, J. Eisler^{1,2}, C. Bouras³, P. R. Hof^{1,2}, and H. M. Fillit^{1,2}**. Depts of Geriatrics¹ and Neurobiology², Mount Sinai Med Ctr, New York, NY 10029; ³Dept of Psychiatry, IUPG Bel-Air, Univ of Geneva Sch Med, Switzerland.

Heparan sulfate proteoglycan (HSPG), a major component of the endothelial cell surface and extracellular matrix, plays a fundamental role in the integrity of the blood-brain barrier. Using an antibody to vascular HSPG (7E12), we recently described angio-architectural changes of cerebral capillaries in various regions of the cerebral cortex in Alzheimer's disease (AD). In addition, a decrease of the vascularization was observed in all of the cortical areas in AD cases when compared with control cases. Although the entorhinal cortex is particularly affected in AD, very little is known about pathological vascular changes in this area. Using two different antibodies to vascular HSPG (7E12, EP01), we investigated the alterations of the microvasculature in the entorhinal cortex of 12 AD cases and 13 elderly control cases. Similar staining patterns were obtained with the two antibodies. Interestingly, a weaker staining of the microvasculature was observed in the control cases in comparison with AD cases suggesting that an overexpression of vascular HSPG occurs in AD. In addition to the microvessels, some senile plaques and neurofibrillary tangles were also labeled in AD cases. The laminar distribution and relative densities of the microvessels showed a correlation between angio- and cytoarchitecture. In particular, microvascular density was higher in layer II of the entorhinal cortex and in the parvocellular layer of the presubiculum and subiculum. Numerous morphological abnormalities such as string vessels and distorted vessels were observed in AD cases. The control cases exhibited some pathological changes, however to a much lesser degree than AD cases. Preliminary data suggest that a consistent decrease of the vascular density occurs in the hippocampal formation in AD. In conclusion, the morphological and biochemical changes that were observed in the microvasculature of AD brains may profoundly affect the properties of the blood-brain barrier and cause detrimental effects to specific neuronal populations.

421.9

MHC CLASS II ANTIGEN EXPRESSION BY MICROGLIA AFTER DEAFFERENTATION IN AGED RATS. **M. N. Gordon*, L. A. Holcomb, W. A. Schreier and D. G. Morgan**. Dept. of Pharmacology, Univ. South Florida, Tampa, FL 33612-4799.

To examine microglial reactions after brain injury in the aged rat, 6-hydroxydopamine (6-OHDA; 8 μ g) was injected into the right medial forebrain bundle of male F344 rats aged 6, 15 or 24 mo. Rats were killed 2, 4, 7 or 14d after lesioning. Unlesioned rats served as controls. Microglial cell number and staining intensity were evaluated by microscopic videodensitometry. Sections stained immunocytochemically for tyrosine hydroxylase (TH) confirmed the virtually complete loss of nigrostriatal TH in all age groups. Striatal sections stained for the microglial specific markers MHC class II antigen (MHC-II; OX6) and complement receptor 3 (CR3; OX42) indicate that MHC-II is induced by the lesion, while CR3 is not. In addition, the MHC-II induction increases in magnitude and duration progressively with age.

In 6-mo-old rats, the density of microglia expressing MHC-II was 5 ± 2 cells/stratial section in control, uninjured rats. MHC-II+ microglia doubled in number 2d after 6-OHDA injection, reached a maximum 10-fold increase 4d after injury, then declined to control levels 14d after injection. In aged control rats, the density of MHC-II labeled microglia was greater than in young controls. In addition, aged rats displayed the highest number of microglia after deafferentation (207 ± 21 cells) with maximal increases observed at 14d. Importantly, middle-aged rats were intermediate in responsiveness and time course. Similar results were obtained measuring area occupied by reaction product or total reaction product (aka integrated optical density). In contrast, area occupied by CR3 and optical density of that reaction product were not affected by aging or by brain injury. These findings suggest that microglia do not increase in number during aging or after the modest deafferentation injury produced here, but that a larger fraction of existing microglia begin expressing the MHC class II antigen. Supported by AFAR. DGM is an Established Investigator of the American Heart Assn.

EFFECT OF APOLIPOPROTEIN E EXPRESSION ON SECRETION OF AMYLOID PRECURSOR PROTEIN. **M. J. LaDu*, M. T. Falduto, A. M. Manelli, C. A. Reardon, G. S. Getz, D. E. Frail**. Dept. of Neuroscience, Abbott Laboratories, Abbott Park, IL 60064 and Dept. of Pathology, University of Chicago, Chicago, IL 60637.

A recent series of observations has linked apolipoprotein E (apoE), particularly the e4 allele, to the pathogenesis of Alzheimer's disease. Amyloid precursor protein (APP) undergoes proteolytic processing to form β -amyloid (A β), a major component of Alzheimer's disease plaques. The purpose of this work was to determine whether ApoE could influence the proteolysis of APP. HEK293 cells were transiently transfected with the cDNAs encoding human apoE, human APP (751 amino acid isoform) or both cDNAs. Secreted APP relative to cellular APP was reduced by 55% (± 11.3 , n=6) in apoE3/APP co-transfected cells compared to cells transfected with APP alone. Secreted A β was also reduced in co-transfected cells. The amount of cellular and secreted apoE3 was unchanged between apoE and apoE/APP transfected cells. The effect of apoE on APP secretion appears to be independent of apoE isoform, as cotransfection of apoE3 or apoE4 with APP equally reduced APP secretion in a dose-dependent manner. These data suggest a role for apoE in APP processing. ApoE could be affecting either the proteolytic cleavage of APP or the subsequent uptake and degradation of APP and A β .

ELEVATED CSF IMMUNOGLOBULIN LEVELS AND BLOOD CEREBROSPINAL FLUID BARRIER IMPAIRMENT IN PATIENTS WITH DEMENTIA OF THE ALZHEIMER TYPE, MULTI-INFARCT DEMENTIA AND MAJOR DEPRESSION. **H. Hampel, M. Ackenheil, A. Haberl, W. Unger*, F. Müller-Spahn and C. Hock**. Department of Psychiatry and Neurochemistry, Psychiatric Hospital, University of Munich, 80336 Munich, Germany.

Other groups of dementias than the presenile onset type Alzheimer described have been included in the diagnostic concept of Alzheimer's disease (DAT). Several reports indicate possible subgroups within the DSM-III-R and NINCDS-ADRDA diagnosis. In the present study serum and CSF of 46 patients with DAT, 8 patients with Multi-infarct dementia (MID) and 17 with Major Depression (MD) were examined to investigate the intrathecal synthesis of immunoglobulins, elevated CSF levels and blood CSF barrier impairment (BCB). The DAT group was subdivided into an early onset (EO with 17 patients) and a late onset type (LO with 29 patients). Intrathecal immunoglobulin G synthesis was defined as an elevated IgG index (greater than 0.7) and/or presence of oligoclonal IgG in CSF by isoelectric focussing. The concentrations of albumin and IgG in serum and CSF have been measured to evaluate the integrity of the BCB. In total, only 1 (2.2%) of the DAT patients, subdivided in 0 EO patient and 1 (3.5%) LO patient, showed an intrathecal immunoglobulin synthesis and none among MID and MD patients. Beside these findings 8 (18%) DAT patients, 3 (18%) EO patients and 5 (17%) LO patients, 2 (25%) MID and 6 (35%) MD patients showed elevated CSF immunoglobulin levels. 5 DAT- (11%), 3 LO- (10%), 2 EO- (12%), 1 MID- (13%) and 3 MD- (18%) patients showed an impaired integrity of the BCB. Elevated CSF immunoglobulins combined with BCB impairment could be caused by a generalized immune activation. Our findings support the hypothesis that immunological mechanisms may play a role in the etiology and/or pathogenesis in at least a subgroup of patients with DAT, MID and MD.

421.10

DISTRIBUTION OF MICROGLIA IN NORMAL AND ALZHEIMER'S DISEASE (AD) BRAIN SUPPORTS MICROGLIAL INVOLVEMENT IN NEURODEGENERATION. **L. G. Sheffield* and N. E. J. Berman**. Dept. of Anatomy & Cell Biology, Univ. of Kansas Med. Ctr., 3901 Rainbow Blvd., Kansas City, KS 66160-7400.

Microglia are the macrophages of the central nervous system and are activated in response to disease and injury. While activated, they phagocytose debris and secrete factors which may be cytotoxic. In Alzheimer's disease (AD), microglia have been found in direct association with neuritic plaques (NPs), one of the hallmarks of the disease. The region-specific localization of neurofibrillary tangles (NFTs) and NPs is used to diagnose AD in postmortem brain tissue. In early stages of AD, NFTs are found in the entorhinal region of the parahippocampal gyrus. As the disease progresses, NFTs are also found in limbic structures and eventually in selected neocortical areas, but are almost entirely excluded from the primary motor cortex.

Our studies have focused on the distribution of microglia in both normal and AD brains. Microglia were visualized by lectin histochemistry using the lectin *Ricinus communis* agglutinin-1 (RCA-1). In control brains, the density of microglia was greater in the regions which are most severely affected by AD, i.e. the parahippocampal gyrus and hippocampus. The motor cortex and area 22 exhibited a much lower density. In AD brains microglial density increased in all areas of the brain with longer periods of dementia, but the pattern of distribution seen in control brains was maintained (motor cortex < area 22 < parahippocampal gyrus < hippocampus). Morphology and size of microglia also varied according to the stage of the disease and the cortical region examined. These results provide further support for microglial involvement in the degeneration caused by AD. (Supported by MH38399 and HD02528.)

QUANTIFICATION OF THE IL-18 INDUCED MESSAGES, PLASMINOGEN ACTIVATOR INHIBITOR TYPE-1 AND PROSTAGLANDIN G/H SYNTHASE-2, IN ALZHEIMER'S DISEASE. J.W. Chang¹, D.J. Selski, P.D. Coleman, and M.K. O'Banion, Departments of Neurobiology and Anatomy and Neurology, University of Rochester School of Medicine, Rochester, NY 14642.

In response to CNS injury or neurodegenerative disorders, cytokines such as interleukin-18 (IL-18) are released into the microenvironment. One role of IL-18 is to activate astrocytes and to increase the synthesis/secretion of astrocytic proteins. We have previously demonstrated that IL-18 promotes astrocytes to secrete plasminogen activator inhibitor type-1 (PAI-1), which may influence neurogenesis, and synthesize prostaglandin G/H synthase-2 (PGHS-2), an inflammatory mediator. Thus levels of PAI-1 and PGHS-2 may serve as markers for astrocyte activation by IL-18. Since IL-18 levels are elevated in Alzheimer's disease (AD) brains, we hypothesized that PAI-1 and PGHS-2 mRNA may be increased in AD brains relative to age-matched controls.

We carried out Northern hybridization of poly A⁺ RNA from the putamen and subcallosal area (neocortex area ventral to genu of corpus callosum) of AD and age-matched control brains utilizing ³²P labeled cDNA probes for human PAI-1, PGHS-2, and G3PDH. Hybridization signals, quantified using a Molecular Dynamics Phosphorimager, were normalized for RNA loading to G3PDH signals. Our preliminary data indicate little or no alteration in PAI-1 and PGHS-2 mRNA levels with disease in the putamen (N=5 AD cases, 4 controls). However, in the subcallosal area (Brodman's areas 12/32), PAI-1 and PGHS-2 mRNA levels are decreased 1.5-fold and 3-fold, respectively, between AD (N=3) and age-matched control (N=5) brains.

These observations are somewhat surprising given the detection of IL-18 in AD brain. Further studies in other affected brain regions are in progress. [Supported by LEAD award AG09016, R01 AG1121, and training grant T32 AG107]

DOUBLE IMMUNOLABELING OF COMPLEMENT PROTEINS AND NEUROFIBRILLARY TANGLE MARKER PHF-1 AT LIGHT AND ELECTRON MICROSCOPIC LEVELS IN ALZHEIMER'S DISEASE BRAIN. L.-F. Lue¹, S. Webster¹, S. Greenberg², J. Rogers¹. Sun Health Research Institute, Sun City, AZ 85372¹ and Burke Medical Research Institute, White Plains, NY 10605²

A pathogenic role of complement activation in Alzheimer's disease (AD) has been suggested by recent evidence that the complement cascade is activated at sites of amyloid β peptide (A β) deposition through A β /C1q binding. This process also appears to accelerate aggregation of soluble A β into its pathogenic fibrillar, β -pleated conformation. However, activated complement components C1q, C4d, C3d, and C5b-9 also co-localize with cells exhibiting neuronal morphology, particularly neurons containing neurofibrillary tangles (NFTs).

In this study we evaluated the percentage of complement immunoreactive, NFT containing neurons in entorhinal cortex samples from four pathologically confirmed AD patients. Light and electron microscopic assays suggest that the majority of complement immunoreactive cells in AD brain contain NFTs. Taken together with certain features of A β /C1q binding and binding sites, these data suggest that complement activation may occur at the cellular surface of degenerating neurons, with lethal consequences. An interaction with NFT formation is also possible given the mechanism of C5b-9 attack on targeted cells.

HUMAN ASTROCYTES CAN EXPRESS COMPLEMENT C4 mRNA AND SECRETE COMPLEMENT C4 PROTEIN. D.G. Walker¹*, S.U. Kim² and P.L. McGeer¹. ¹Kinsmen Lab. of Neurological Research, Department of Psychiatry, ²Division of Neurology, Department of Medicine, University of British Columbia, Vancouver, B.C. Canada, V6T1Z3.

Studies of brains from Alzheimer Disease (AD) cases have shown evidence of inflammatory changes in affected tissue, as demonstrated by complement system activation and the presence of reactive microglia. These features indicate that a chronic inflammatory response occurs in AD brains which may be contributing to the neurodegenerative process. In addition, a pronounced astrocytic gliosis occurs in affected AD tissue. There is now increasing evidence that astrocytes may be contributing to the inflammatory changes by the production of certain cytokines and complement proteins.

In this study, we showed that astrocytes isolated from human fetal brains, and cultured *in vitro*, can express the mRNA for complement C4, and can also secrete the complement C4 protein. Using the reverse transcription-polymerase chain reaction (RT-PCR) technique, the expression of C4 mRNA was shown to occur in six separate sets of cultures that were highly enriched for astrocytes (>95% of cells immunoreactive for glial acidic fibrillary protein). Expression was detected in unstimulated astrocytes and this was increased by treatment of cells with γ interferon (100 or 1000 units/ml of recombinant γ interferon). In addition, by culturing the cells in serum-free media and by using immunoblotting and ELISA techniques, we showed that human astrocytes can secrete C4 protein into the culture media. Increased secretion of C4 occurred after treatment of astrocytes with γ interferon, but not with interleukin 1 β (20 or 200 units/ml).

ALZHEIMER'S DISEASE LIKE PHOSPHORYLATION OF TAU PROTEIN IN RESPONSE TO INTERLEUKIN-1 β TREATMENT OF MIXED CELL POPULATIONS FROM RAT CORTEX. S. Wyoral and M.L. Shelanski*. Department of Pathology and Alzheimer's Disease Research Center, Columbia University College of Physicians and Surgeons, New York, NY 10032.

Immune related processes have been associated with Alzheimer's disease (AD) as have significant reductions in the prevalence of AD among patients treated with anti-inflammatory therapies. However, a physiologically relevant mechanism for the involvement of immune responses in producing AD-like pathology has not been demonstrated. Using antibodies (Abs) to phosphorylation sensitive epitopes of tau, we have now demonstrated AD-like changes in the tau protein in response to the inflammatory cytokine interleukin-1 β .

Mixed cell cultures from postnatal day one (PND-1) rat brain cortex were incubated in serum free medium augmented with the cytokine IL-1 β (500 U/ml). Whole cell homogenates were then analyzed by Western blotting with tau antibodies. IL-1 β produced an increase in high molecular weight immunoreactivity to the paired helical filament (PHF) antibody PHF-1. Antigenicity to the unphosphorylated tau specific Ab Tau-1 was lost upon prolonged incubation. These changes in antigenicity parallel the changes seen in human AD brain.

Decreased gel mobility of tau isoforms was seen upon IL-1 β treatment. Conversely, co-incubation of tissue with IL-1 β and increasing amounts of IL-1 β receptor antagonist showed a dose dependent increase in tau mobility.

These results demonstrate that IL-1 β may contribute to the abnormal phosphorylation of tau, which subsequently could decrease the stability of tau-microtubule interactions and contribute to PHF formation. Supported by NS-15076.

DEGENERATIVE DISEASE: ALZHEIMER'S—TAU PHOSPHORYLATION AND NEUROFIBRILLARY DEGENERATION

CONFOCAL LASER SPECTROMETRY FOR 3-D ANALYSIS OF ALZHEIMER PATHOLOGY Q. S. Deng¹*, M. A. DeCoster², A.W. de Feijter³, D. R. Brady¹, and Q. R. Smith¹, ¹Lab of Neurosciences, NIH, Bethesda, MD 20892; ²Dept of Med. Neurosciences, Walter Reed Army Inst. of Res, Washington, DC 20307; ³Meridian Instruments, Inc. Okemos, MI 48864.

Senile plaques (SPs), neurofibrillary tangles (NFTs) and neuropil threads (NTs) are commonly studied using light or fluorescent microscopic methods that provide 2-D images of their distribution within tissue sections. Such methods are of limited value in studies of antigen or element localization where reagent penetration or surface structure identification are important. In theory, confocal laser scanning microscopy (CLSM) provides one means to identify the 3-D location of structures within specimens, from surface to surface. To evaluate this, the morphology and distribution of SPs, NFTs and NTs were examined in the brain of one 75-yr old patient with AD. Frozen tissue sections (3-30 μ m) were cut from the hippocampus and entorhinal cortex, and stained with thioflavine S (Gunter et al., *Experientia*, 1992). Serial images (Z axis increment: 0.5-1.0 μ m) of individual SPs, NFTs and NTs (n=20) were generated with CLSM, revealing complete penetration (3-30 μ m) of the dye. SPs, NFTs and NTs on the surface were easily distinguished from those buried deeper within the section. The results demonstrate that CLSM provides a basis for determining the penetration of reagents in tissue staining and is useful as a guide for surface location of trace element distributions using SIMS.

ABNORMALITIES OF THE CALPAIN SYSTEM IN ALZHEIMER DISEASE. S. Katayama, K. Saito, A. Cataldo, T. Honda, F. Grynspan, W. Griffin, P.S. Mohan*, A.L. Schwagerl, R.A. Nixon. McLean Hospital, Harvard Medical School, Belmont, MA

Calcium-activated neutral proteinases (CANPs or calpains) are believed to be key enzymes in intracellular signaling cascades and potential mediators of calcium-induced neuronal degeneration. We have reported that the activated isoform of calpain I is significantly increased and the precursor isoform is significantly reduced in Alzheimer brain. To investigate calpain I alterations further, we raised antibodies against the four functional domains of calpain I. Using immunoblot analysis, we confirmed our previous finding (Saito et al., *PNAS* 1993;90:26-28) of a nearly 3-fold increase in the ratio of activated calpain I isoforms to the precursor isoform in prefrontal cortex from 13 Alzheimer patients and 9 normal control matched for age and postmortem interval ($p < 0.02$). In membrane fractions solubilized with Triton X-100, the ratio of activated to precursor isoforms was elevated 3.9-fold in Alzheimer brains ($p < 0.05$). The results with different calpain I antibodies, including an antibody specific for the precursor isoforms, were significantly correlated. Consistent with increased calpain I activation, levels of calpastatin activity were markedly reduced (Mohan et al., these proceedings). A significant correlation was observed between the degree of abnormal calpain I activation and reduction in levels of soluble APP. APP was not generated from membrane APP by purified calpain. By immunocytochemistry, calpain I antibodies preferentially stained neurons in human, monkey and mouse brain. Calpain I immunoreactivity was abnormally increased in some neurons displaying degenerative changes in prefrontal cortex from Alzheimer brains. These results provide further evidence that the calpain system may be activated in at-risk neurons in Alzheimer disease and play a critical role in neurodegeneration. Support: AG10916.

422.3

REDUCED CALPASTATIN ACTIVITY AND CONTENT IN ALZHEIMER BRAIN. P.S. Mohan, T.B. Shea* and R.A. Nixon, Mailman Research Ctr., Harvard Medical School, Belmont, MA 02178.

Calpains are believed to be important regulators of membrane skeleton dynamics and membrane trafficking, but mediate neurodegeneration in certain pathological states. We previously reported evidence for abnormal activation of the calpain-calpastatin system in Alzheimer brain. Also, calpastatin, the specific protein inhibitor of calpain, was shown by immunocytochemistry to be markedly depleted in Alzheimer neocortex (Nixon et al., Soc. Neurosci. 19:198, 1992). To confirm this biochemically, we measured calpastatin levels in homogenates of prefrontal cortex from 13 Alzheimer patients and 9 normal controls matched by age and postmortem interval. Calpastatin immunoreactivity and inhibitory activity were measured in soluble and membrane fractions. In normal human brain, membrane fractions solubilized by Triton X-100 contained 40% of the total calpastatin (204 ± 15.6 units/g tissue). Calpastatin was identified by immunoblotting using affinity purified antibodies to be composed of 110, 70 and 41 kDa forms. Calpastatin inhibitory activity in membrane fractions of Alzheimer prefrontal cortex was reduced to 50% of control values ($p < 0.001$). By immunoblot analysis the most abundant calpastatin form isolated from human brain ($M_r = 41$ kDa) was reduced $\geq 65\%$ in membrane fractions ($p < 0.001$). Cytosolic calpastatin activity was 25% lower ($p < 0.05$) but major immunoreactive forms were markedly reduced (75%, $p < 0.01$) reflecting proteolytic processing to smaller molecular weight inhibitory units. Calpastatin was not significantly altered in cerebellum. These results, together with the abnormal activation of μ -calpain reported earlier (Saito et al., PNAS 90:2628, 1993), implicate calpains in the disruption of membrane dynamics possibly leading to altered membrane protein processing and neurodegeneration in Alzheimer Disease. Supported by NIH (AG10916).

IN-VITRO UBIQUITINATION AND DEGRADATION OF TAU PROTEINS. RS Black* Cornell University Medical College at Burke Medical Research Institute, White Plains, NY 10605. The conjugation of ubiquitin to abnormally phosphorylated tau proteins, and the subsequent failure of their ubiquitin-mediated proteolysis is an important feature of the Alzheimer disease process. The DEAE-cellulose fraction of rabbit reticulocyte lysates containing enzymes of the ubiquitin conjugation system (Fraction II) was used to conjugate bovine ubiquitin to tau proteins prepared from twice-cycled bovine brain microtubules. In the presence of ATP, an ATP regenerating system, and hemin, which inhibits the breakdown of ubiquitin conjugates, high molecular weight ubiquitin-conjugated tau proteins accumulated. In the absence of hemin the ubiquitin conjugates did not accumulate and the tau proteins appeared to be degraded in an ATP-dependent fashion. In this system, ubiquitin-ubiquitin conjugates were detectable almost immediately in hemin-inhibited lysates, whereas tau-ubiquitin conjugates were detectable only after 1-2 hour incubations. Bovine MAP-2 was also a substrate for ubiquitin conjugation in this system. This system is being used to evaluate the effects of post-translational modifications of tau proteins on ubiquitin conjugation. Supported by the NIA (AG00504).

CONSTITUTIVE ALZHEIMER'S-TYPE TAU EPITOPES IN A NEURITIC RAT CNS CELL LINE. M.P. Lambert*, S. Sabo, C. Zhang, S.A. Enam, and W.L. Klein, Dept. of Neurobiology and Physiology, Northwestern University, Evanston, IL 60208.

Paired helical filaments (PHFs) of Alzheimer's disease (AD) largely comprise hyperphosphorylated forms of the cytoskeletal protein tau. AD-type tau phosphoepitopes are absent from normal adult neurons, but recent studies have shown that their expression may contribute to neurogenesis and axon differentiation in the developing nervous system. Therefore, we examined a brain nerve cell line that is spontaneously neurogenic for possible expression of AD-type tau epitopes. The B103 rat CNS cell line was found to produce constitutively two AD-related epitopes of tau, detected by cellular immunofluorescence with the PHF-1 and Alz-50 monoclonal antibodies. Biochemical studies showed that the antibodies bound to proteins within the molecular weight range expected for phosphorylated tau isoforms. Further verification was established by use of tau antisense oligomers, which eliminated immunofluorescence due to the AD-related monoclonals and polyclonal anti-tau, but did not eliminate fluorescence due to anti-tubulin. Cells treated with tau antisense were not neurite-free. Neurites that remained were abnormal, generally short, and wavy in appearance. Cellular distribution of the tau epitopes was particularly interesting. Alz-50 immunoreactivity was found only in the cytoplasm, while PHF-1 immunoreactivity was found in the nucleus as well as the cytoplasm. Thus the two epitopes are morphologically segregated within the cell. Because subcellular segregation of tau is compromised in Alzheimer's disease, mechanisms that segregate AD-type phosphotau epitopes in B103 cells may have relevance to this neurodegenerative disorder.

TAU IS A GLYCOPROTEIN. C.S. Arnold, R.N. Cole, G.V.W. Johnson* and G.W. Hart, Depts. of Biochemistry and *Psychiatry, Univ. of Alabama at Birmingham, Birmingham, AL 35294

Tau is a family of microtubule-associate proteins which play a crucial role in the structure and function of the neuronal cytoskeleton. Tau in hyperphosphorylated states also forms the paired helical filaments (PHFs) of Alzheimer's disease. Although the phosphorylation of tau has been extensively delineated, other modifications have not been clearly defined. Recently a protein modification has been identified at Ser and Thr residues consisting of an O-linked N-acetylglucosamine (O-GlcNAc). This modification is found on a variety of proteins, including neurofilaments. The sites of O-GlcNAc glycosylation are indistinguishable from the phosphorylation sites of Ser/Thr kinases. Purified bovine tau was analyzed using galactosyl transferase as a probe for terminal GlcNAcs, followed by peptide-N-glycosidase F treatment and β -elimination for linkage analysis. The results of these studies clearly demonstrate that tau is modified by O-GlcNAc glycosylation. This unique form of glycosylation may modulate tau function, and in specific neurodegenerative disorders could contribute to neuronal dysfunction and the formation of pathological lesions.

422.6

THE ABNORMAL PHOSPHORYLATION OF TAU PROTEIN AT SER-202 IS PREFERENTIALLY LOCATED IN NEURITES AND PRECEDES ABNORMAL PHOSPHORYLATION AT SER-396 IN ALZHEIMER'S DISEASE. Joseph H. Su*, Brian J. Cummings and Carl W. Cotman, IRU in Brain Aging, UCI, Irvine, CA 92717 USA.

Both neurofibrillary tangles (NFTs) and dystrophic neurites (DNs) contain paired helical filament (PHFs) which are composed of abnormally phosphorylated PHF-tau. During formation of NFTs and DNs in AD, the cytoskeleton undergoes a sequence of changes, including hyper-phosphorylation of tau protein (for review, see Trojanowski et al., '93). We sought to determine more specifically at what tau protein residue the earliest changes take place; and whether these alterations first occur within distal processes or within the soma. We used two monoclonal antibodies, AT8 and PHF-1, which selectively recognize phosphorylated Ser-202 and Ser-396 of PHF-tau protein respectively. Both antibodies stained NFTs and DNs, including dendrites and axons; however the quantity and distribution of immunoreactive deposits was different. AT8 immunoreactivity was usually found within intracellular NFTs as well as pretangle neurons, whereas PHF-1 fibrillar inclusions were detected within both intracellular and extracellular NFTs. Some strongly labeled AT8 DNs were continuous with "normal" neuronal soma in which AT8 immunoreactivity was absent or weak. However, PHF-1 positive DNs were only continuous with PHF-1 positive NFTs. In AD cases with mild dementia, numerous AT8 deposits were detected in the outer two-thirds of the molecular layer of the dentate gyrus, whereas no PHF-1 positive deposits could be found within the same region in adjacent sections. These results suggest that abnormal phosphorylation at Ser-202 of PHF-tau in DNs represents one of the earliest neuropathological changes within the neurites of vulnerable neurons and might play an important role in the initial pathogenesis of AD.

422.8

OKADAIC ACID INDUCES MICROTUBULE DEPOLYMERIZATION AND THE DEGENERATION OF AXONS AND DENDRITES IN THE NT2N CULTURE SYSTEM: IMPLICATION IN ALZHEIMER'S DISEASE. S.E. Merrick* and Y.M.-Y. Lee, Institute of Neurological Sciences, Department of Pathology and Laboratory Medicine, University of Pennsylvania School of Medicine, Philadelphia, PA 19104.

The building blocks of Alzheimer's disease (AD) neurofibrillary tangles (NFTs), are paired helical filaments that are comprised of hyper-phosphorylated forms of tau (i.e. PHF-tau) and the accumulation of PHF-tau may be due to an inactivation or down-regulation of brain phosphatases in NFT bearing neurons. Since excessively phosphorylated PHF-tau is unable to bind to microtubules (MTs), then conversion of normal tau into PHF-tau by the inhibition of protein phosphatases could lower the level of tau that binds MT, destabilize MTs, disrupt axonal transport, and lead to the "dying back" of axons in AD. To test this hypothesis, we developed an *in vitro* neuronal culture model that allows us to examine the consequences of the inhibition of protein phosphatases on the neuronal cytoskeleton. The model is based on neurons (NT2N) derived from a human teratocarcinoma cell line (NT2) that are treated with retinoic acid to induce differentiation and then exposed to okadaic acid (OKA), a potent phosphatase inhibitor. OKA treatment increased tau phosphorylation in NT2N neurons resulting in the inability of highly phosphorylated tau to bind MTs. Concomitant with the increase in tau phosphorylation, there was an increase in the depolymerization of MTs which was due to the increased conversion of stable Glu-tubulin in MTs to monomeric Tyr-tubulin. As a consequence of the loss of Glu-MTs, there was a "dying back" of the axons of NT2N neurons prior to the complete destruction of dendritic and cellular MTs. Our results suggest that the inhibition of protein phosphatases in neurons leads to the destabilization of the MT network in axons by: (1) Increased tau phosphorylation thus reducing MT binding; and (2) Activation of the tubulin-tyrosine ligase that converts Glu-tubulin in MTs to free Tyr-tubulin.

422.9

THE IN VITRO AND IN SITU PROTEOLYSIS OF TAU BY CALPAIN. R.P. Guttman* and G.V.W. Johnson. Dept. of Psychiatry, Univ. of Alabama at Birmingham, Birmingham, AL 35294.

Tau is a microtubule-associated protein that is found in the nucleus and associated with ribosomes, as well as bound to microtubules. In Alzheimer's disease (AD) a hyperphosphorylated form of tau forms the characteristic paired helical filaments (PHFs). Calpain is a calcium-dependent protease that is found in high concentrations in neurons, and is postulated to be involved in the limited hydrolysis of specific structural proteins. In addition, the levels of the calcium-activated form of calpain are increased in AD brain. Previously we have demonstrated that *in vitro* bovine tau and human tau recombinant tau isoforms are substrates for calpain. In addition, phosphorylation of bovine tau *in vitro* by cAMP-dependent protein kinase (cAMP-PK) increases its resistance to calpain mediated degradation. In this study we demonstrate that phosphorylation of the longest human tau isoform (441 a.a., T4L) by cAMP-PK or cyclin-dependent protein kinase 1 (p34^{cdc2}/cyclin B) significantly inhibits calpain I-mediated degradation. In contrast, phosphorylation of T4L by the proline-directed protein kinase, ERK1 (p44^{mapk}) did not alter calpain sensitivity, although alterations in electrophoretic mobility were clearly evident. Evidence is also provided to indicate that tau is a substrate for calpain *in situ*. Treatment of human neuroblastoma LA-N-5 cells, which have been differentiated into a neuronal phenotype, with the calcium ionophore, ionomycin, results in the degradation of tau. This calcium-induced proteolysis of tau was apparently inhibited by the selective calpain inhibitor, calyculin, suggesting that the loss of tau was due to calpain-mediated hydrolysis. These results indicate that tau is an *in situ* substrate for calpain and that site-selective phosphorylation modulates the susceptibility of tau to calpain-mediated hydrolysis. Supported by NIH grants #NS27538 and AG06569.

422.11

PHOSPHORYLATION STATE OF TAU IN RAT BRAIN DURING DEVELOPMENT IS REGULATED BY PHOSPHOPROTEIN PHOSPHATASES. M. Mawal-Dewan*, J. Henley, J.Q. Trojanowski, and V. M.-Y. Lee. Dept. Path. Lab. Med., Univ. of Penn. Sch. of Med., Phila, PA - 19104.

The paired helical filaments (PHFs) of Alzheimer's disease (AD) are composed of highly phosphorylated tau proteins. Several of these sites were found to be phosphorylated in PHF-tau, fetal-tau, but not in adult brain tau. To determine the regulation of phosphorylation at these sites during development, we isolated tau from fresh rat brain in the presence of the phosphatase inhibitor okadaic acid (OK) to obtain tau in its native state of phosphorylation *in situ*. Fetal tau isoform was highly phosphorylated from embryonic day 18 (E18) until post-natal day 11 (P11) after which the immature isoform diminished concomitant with the decrease in phosphorylation and the appearance of the mature isoforms. In contrast to previous studies, adult and aged rats (20 mths) were found to be phosphorylated at reduced levels suggesting that Thr¹⁸¹, Ser²⁰², Thr²³¹, Ser³⁹⁶ and Ser⁴⁰⁴ are normal sites of phosphorylation in adult rats. We also show that the inclusion of OK in the assembly buffer has a transient effect on the abilities of tau to bind MTs at any developmental stages. However, an activation of phosphatases was detected after P12 since in the absence of OK tau was shown to be partially dephosphorylated. We further demonstrate that protein phosphatase 2A (PP2A) and 2B (PP2B) from the adult rat brain could dephosphorylate tau efficiently in a site specific manner, whereas protein phosphatases from P6 had no effect indicating that OK sensitive tau after P12 may be regulated by the *de novo* induction of adult brain phosphatases. Collectively, these findings suggest that PP2A-like phosphatases are involved in regulating the adult phosphorylation state of tau *in vivo*, and they open the possibility that the generation of hyperphosphorylated tau leading to PHF formation in AD may be controlled by similar phosphatases.

422.13

THE REGULATION OF TAU PHOSPHORYLATION IN ISOLATED BOVINE BRAIN MICROTUBULES: ACTIVATION BY EXCESS ATP AND INHIBITION BY APOLIPOPROTEIN E. Q.L.U. R. Kanumury and J.G. Wood. Dept. Anatomy and Cell Biology, Emory Univ. Sch. of Med., Atlanta, GA 30322

Supply of excess ATP to isolated brain microtubules induced Alzheimer type phosphorylation of tau proteins, providing an *in vitro* model to study tau phosphorylation and its regulation. Although immunoblot analysis indicated that MAP kinase and CDK are present in microtubules obtained by purification, neither purified MAP kinase or CDK could further increase the level of tau phosphorylation induced by excess ATP. Rather, the addition of CDK 1/cyclin B to microtubules partially reverses this type of tau phosphorylation. Furthermore, ATP induced tau phosphorylation is inhibited by treatment of microtubules with apolipoprotein E. The effect of apolipoprotein E is specific and dose dependent. Inhibitors of Ca²⁺/calmodulin-dependent protein kinase and cAMP-dependent protein kinase have no profound effects on the phosphorylation of tau. Partial removal of tubulin from microtubules using taxol abolishes ATP induced tau phosphorylation, suggesting that tubulin may be involved in the regulation of tau phosphorylation by signaling proteins associated with microtubules. AG 11123, NS 27847, NS 30435.

422.10

TAU IS DEPHOSPHORYLATED IN SITU BY THE CALCIUM-DEPENDENT PHOSPHATASE, CALCINEURIN, IN RAT BRAIN CEREBRAL CORTICAL SLICES. L.M. Fleming* and G.V.W. Johnson. Dept. of Psychiatry, Univ. of Alabama at Birmingham, Birmingham, AL 35294.

Tau is a family of closely related microtubule-associated phosphoproteins which are involved in the development and maintenance of neurons. The phosphorylation state of tau modulates its ability to promote microtubule assembly, and aberrant phosphorylation has been postulated to contribute to the formation of paired helical filaments (PHFs) in Alzheimer's disease (AD). *In vitro*, tau has been shown to be phosphorylated by a variety of protein kinases. Recently, the *in vitro* dephosphorylation of tau by specific phosphatases (PP) has been studied. PP1 and 2C dephosphorylate tau which has been phosphorylated by cAMP dependent protein kinase (cAMP-PK), while PP2A and the calcium/calmodulin phosphatase, calcineurin (PP2B), dephosphorylate tau at sites phosphorylated by either Ca²⁺/calmodulin dependent protein kinase or cAMP-PK. Additionally, PP2A, PP1 and calcineurin have been shown to dephosphorylate sites on PHF-tau. However, the *in vivo* role of these phosphatases is unclear.

In this study, we examined the effect of increasing intracellular calcium concentrations on the phosphorylation state of tau in rat brain cerebral cortical slices using the glutamate analog, NMDA, and depolarizing conditions (50 mM KCl). Rat brain slices were incubated in the presence of ³²P prior to drug addition. After addition of appropriate agents, incubations were terminated and tau was immunoprecipitated from 250 µg of each sample. Tau was ³²P labeled under basal conditions. Addition of KCl and NMDA resulted in a 40 % decrease in ³²P incorporation into tau while addition of KCl or NMDA alone had no effect on tau phosphorylation. The noncompetitive NMDA receptor antagonist, MK801, completely inhibited the effect of KCl and NMDA. Cyclosporin A (CsA) has been shown *in vitro* to complex with cyclophilin and specifically bind to and inhibit calcineurin. In our study, CsA completely abolished the dephosphorylation of tau induced by KCl and NMDA treatment. Taken together, these results indicate that depolarization was required prior to activation of NMDA receptors to activate calcineurin, which in turn dephosphorylated tau. These effects were specifically blocked by MK801 and CsA. These results demonstrate that *in situ*, tau is dephosphorylated by calcineurin. Supported by NIH grants AG05643, AG066569 and NS27538.

422.12

ALZHEIMER TYPE PHOSPHORYLATIONS OF TAU PROTEIN ARE DEVELOPMENTALLY EXPRESSED IN VITRO. C.K. Combs*, P.D. Coleman, and M.K. O'Banion. Departments of Neurobiology and Anatomy and Neurology, University of Rochester, Rochester, N.Y. 14642.

It has been shown that certain Alzheimer type tau phosphorylations occur embryonically in humans and postnatally in rats. Determining the nature of the regulatory mechanisms involved in these events may provide a better understanding of the aberrant phosphorylation of tau occurring in Alzheimer's Disease.

We have utilized embryonic rat hippocampal cultures to investigate the expression of specific Alzheimer type tau phosphorylations during *in vitro* differentiation. The mouse monoclonal antibodies PHF-1 and Tau-1 recognize a phosphorylation on Ser 398 and the lack of phosphorylation on Ser 199/202, respectively. Using PHF-1 and Tau-1 we have observed a temporal expression of phosphorylation by immunocytochemical and Western blot analyses. Phosphorylation at the PHF-1 epitope is observed at the earliest time point *in vitro* (i.e. embryonic day 18). In contrast, phosphorylation at the Tau-1 epitope was detected around day 4 *in vitro* and appears to increase over the two weeks examined.

The temporal expression of these phosphorylation events suggests different regulatory mechanisms for each. Future investigations with this *in vitro* developmental system may not only define the kinases and/or phosphatases involved, but may also provide clues about the physiological roles of these phosphorylation events.

(PHF-1 and Tau-1 Abs were obtained from Peter Davies and Lester Binder, respectively)

ALZ-50 AND PHF-1 IMMUNOREACTIVITY NEAR β-AP INJECTIONS IN THE CEREBRAL CORTEX OF SHEEP. P.T. Nelson* and C.B. Saper. Beth Israel Hospital and Harvard Medical School, Boston, MA 02115.

We have recently discovered that neurons in the cerebral cortex of sheep and goats develop Alzheimer-type neurofibrillary degeneration (NFD) in the absence of beta-amyloid peptide (β-AP) deposition during aging. Hence, these domesticated animals may provide a novel model for studying the mechanism of induction of Alzheimer-type NFD.

In an effort to induce experimental neurofibrillary pathology *in vivo*, we injected β-AP (1µl) into the cerebral cortices of two five-year old sheep. Following one or two weeks' survival, brains were formalin fixed and blocks were sectioned at 50µm. Sections were stained using the immunoperoxidase technique and the monoclonal antibodies Alz-50 and PHF-1. Some sections were visualized with electron microscopy. Adjacent series were stained with thioflavine, thionin, and antiserum against β-AP.

In the animal that survived one week, the β-AP injections caused necrosis. No Alz-50 or PHF-1 immunoreactive dystrophic neurites were seen in direct apposition to the injections within deep cortical layers. However, near the cortical surface, some Alz-50 and PHF-1 immunoreactive neurites appeared that were more swollen than normal immunoreactive neurites. Alz-50 immunoreactive neurites, when viewed via electron microscopy, contained large vesicles. In the animal that lived for two weeks, similar staining was seen, except that some PHF-1 immunoreactive neurites had infiltrated the injection regions.

The current study indicates that, under the conditions we employed, injected β-AP does not induce NFD per se, but may trigger a regenerative response in which modified tau proteins are present in neurites.

DIFFERENTIAL LOCALIZATION OF APOLIPOPROTEIN E AND PHF IMMUNOREACTIVITY IN THE NEO AND LIMBIC CORTEX, AND NUCLEUS BASALIS IN ALZHEIMER'S DISEASE (AD): IMPLICATIONS FOR TANGLE PATHOGENESIS. W.C. Benzinger* and E.J. Mufson, Dept. of Neurol. Sci. Alzheimer's Disease Ctr., Rush Presb. St. Luke Med. Ctr., Chicago, IL 60612.

The localization of apolipoprotein E (ApoE) in relation to beta-amyloid (BA4) and paired helical filament (PHF) immunoreactivity was examined in the nucleus basalis (NBM), amygdala (AMY), and entorhinal (EC), temporal and insular cortices of patients with AD (n=8) and Down's syndrome (DS, n=3), age matched normals (AMC, n=8), and age matched nondemented cases with numerous senile plaques (HPND, n=5). ApoE immunostained plaques, neurons, and extracellular tangles in each group. ApoE's immunostaining of neurons differed dramatically from PHF depending upon brain region and diagnosis. In the AD and DS brain, numerous ApoE-ir neurons closely matched PHF in distribution and quantity in the NBM, AMY and EC. Although PHF-ir temporal and insular neurons were similar in density to the AMY and EC, ApoE-ir neurons were 4-fold fewer than PHF-ir neurons. In the HPND cases, many PHF-ir neurons were observed in the NBM, AMY and EC but were less than in AD. In contrast to these same regions in AD and DS, very few ApoE-ir neurons were observed relative to PHF. These findings suggest that PHF immunoreactivity precedes that of ApoE indicating ApoE may be binding to tangles only in their later stages of formation. Since in the HPND cases ApoE recognizes only a few of the PHF-ir neurons in the NBM, AMY, and EC, which are among the earliest brain regions affected in AD, it is possible that ApoE plays a secondary role in tangle formation. NEUROFIBRILLARY TANGLES (NFT) IN ALZHEIMER'S DISEASE: DOUBLE IMMUNOLABELING STUDIES OF ASSOCIATED VS. INTEGRAL PROTEINS. D.W. Dickson*, A. Ivanushkin, E. Wu, P. Davies and S.-H. Yen, Division of Neuropathology, Albert Einstein College of Medicine, Bronx, New York 10461.

Neurofibrillary tangles (NFT) composed of paired helical filaments (PHF) are the most characteristic histopathological feature of Alzheimer's disease. Recent molecular and biochemical studies have provided conclusive evidence that the major integral protein is an abnormal tau protein that is hyperphosphorylated, referred to as PHF-tau. PHF-tau antigens are present in NFT within the cytoplasm of living neurons [intracellular NFT (NFTi)] and also in NFT in the extracellular space after the neuron with NFT dies, so-called extracellular NFT (NFTe). Epitopes in the amino half of tau protein (e.g., Alz-50 epitope) are susceptible to proteolysis and are lost in NFTe. Neurons in lamina II of the entorhinal cortex (EC-II) are unusually susceptible to NFT, while those in the dentate gyrus are unusually resistant to NFT. By the time AD is advanced, most of the NFT in the entorhinal cortex are NFTe, while most of the NFT in the dentate gyrus are NFTi. Using their distribution in the hippocampus as an index to their most probable type and double-labeling immunocytochemistry of cryostat or briefly-fixed vibratome sections, we further characterized NFT in AD. Monoclonal antibodies to NFT that do not cross-react with tau proteins (Ab39 and Ab69) were used as a marker for both NFTe and NFTi, while Alz-50 served as a marker for NFTi. NFTi, but not NFTe, were labeled by monoclonal and polyclonal antibodies to p34^{cdc2}. The anti-p34^{cdc2} antibodies also labeled granular cytoplasmic and perinuclear structures consistent with so-called "pre-tangles". Monoclonal and polyclonal antibodies to apolipoprotein-E labeled primarily NFTe. NFTe were also inconsistently labeled with antibodies to C1q, A β and ubiquitin. These results suggest that in early formative stages NFT are composed of abnormal tau protein in close association with kinases, such as p34^{cdc2}, that are capable of phosphorylating tau and that only in later stages of evolution, after the neuron has died, is there substantial association with apolipoprotein-E, A β and C1q. ALZHEIMER'S DISEASE-RELATED NEUROFIBRILLARY CHANGES IN INDIVIDUALS WITH AND WITHOUT A HISTORY OF ALCOHOL ABUSE. A PREVALENCE ANALYSIS OF STAGED AUTOPSY CASES. H. Müller†, H. Braak†, E. Braak*†, J. Bohl† and T.G. Ohm†, †-Z.Morph. J.W. Goethe Universität, 60590 Frankfurt; ‡-Abt. Neuropathologie, J. Gutenberg-Universität, 55131 Mainz, Germany.

The role of alcohol abuse as a risk factor for Alzheimer's disease (AD) is still disputed. So far, there is, however, no autopsy-based study analyzing the prevalence of AD-related neuropathological changes in alcoholics.

This study is based on a sample of 67 age-matched pairs of brains staged for AD-related neurofibrillary changes and 54 age-matched pairs of brains staged for 8/A4-amyloid deposits. Cases were included in the alcohol group when there was strong evidence for alcohol-related changes at autopsy and/or an anamnestic history of relevant alcohol abuse. Controls were negative for both criteria. The non-parametric Wilcoxon-Mann-Whitney-U-test revealed no significant differences in the prevalence of the stages of AD-related neurofibrillary changes (U=2085; Z=0.7835; p \geq 0.43; Hodges-Lehmann-estimator for X1-X2=0; Mann-Whitney's-estimator for P=P(X1<X2)=0.46). The χ^2 -test equally detected no differences between age-matched controls and the alcohol group (χ^2 =8.093; p=0.62). Testing for differences in the prevalence of stages of 8/A4-amyloid deposits equally revealed no significant differences between the respective groups (U-test: U=1425.5; Z=0.2706; p \geq 0.78; Hodges-Lehmann-estimator for X1-X2=0; Mann-Whitney's-estimator for P=P(X1<X2)=0.5; χ^2 -test: χ^2 =2.214; p=0.696).

A history of alcohol abuse thus does not seem to be a risk factor for the development and/or progression of Alzheimer's disease-related changes. Supported by the DFG (TGO, HB)

NEUROFIBRILLARY TANGLE NEURONS IN ALZHEIMER'S DISEASE ARE ASSOCIATED WITH A LOSS OF SYNAPTOPHYSIN MESSAGE. L.M. Callahan*, J.E. Cheetham, W. Vauls, and P.D. Coleman, University of Rochester Medical Center, Neurobiology and Anatomy, Rochester, NY 14642). Recent evidence indicates the best correlate with the degree of dementia of AD may be the loss of synapses (e.g. DeKosky and Scheff, 1989, Terry et al., 1990). We hypothesized neurons containing tangles lose synapses due to the cytoskeletal disruption of the neuron. To investigate this possibility, we combined immunocytochemistry to identify tangle-containing neurons with *in situ* hybridization for selected messages. Message levels of synaptophysin, poly A, and cathepsin D were determined in serial hippocampal sections from 3 AD cases and 2 age-matched controls. A decrease in the level of synaptophysin, a synaptic vesicle associated protein, was detected in a majority of tangle-bearing neurons relative to levels in neighboring non-tangle neurons. Poly A (total) message levels were similar in many tangle-bearing neurons relative to non-tangle bearing neurons. An increase of message for cathepsin D, a lysosomal enzyme, was seen in many tangle neurons relative to non-tangle neurons. The demonstration of decreased message level for a protein related to synaptic function in NFT neurons would indicate that it is the NFT neurons that are correlated with synaptic loss in AD. (Supported by NIH AG00107, NIH AG01121, NIH LEAD AWARD AG09016, Alzheimer's Disease Center Grant NIH AG08665, and the American Health Assistance Foundation).

AUTODETECTION AND LARGE-AREA MAPPING OF NEUROFIBRILLARY TANGLES IN ALZHEIMER'S DISEASE. L.S. Hibbard*, D.W. McKeel, Jr., Joseph L. Price, Departments of Neurology and Neurological Surgery, Pathology, and Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.

Neurofibrillary tangles (NFT), seen in normal aged and Alzheimer's disease (AD) brains, are inhomogeneously distributed in brain. NFT anatomic distributions and densities have been shown to correlate with clinical dementia severity. To quantitate NFT deposition, we have developed computer programs which automatically locate NFT in digital micrographs of postmortem tissues stained with either the Gallyas silver stain or one of several immunostains (anti-PHF, anti-tau). Stained objects are detected by template correlation and extracted as discrete objects whose gray level and morphometric properties are used for classification and characterization. The NFT are sorted from all other detected objects using a conventional Bayesian classifier. NFT can be mapped over arbitrary, large areas of tissue, imaged as mosaics of adjacent, non-overlapping, digital microscope fields. Arbitrary regions of interest (ROI) are sketched, using computer graphics, in images of the entire mosaic at low magnification. The ROI guides subsequent processing to only those parts of fields coincident with the ROI. This method can map PHF/tau-immunoreactive cells in very mildly demented or normal aged brains. THE EFFECTS OF IN VITRO ISCHEMIA ON PROTEINS FROM THE RAT HIPPOCAMPAL SLICE. J. Murata and K.M. Raley-Susman*. Dept. of Biology Vassar College, Poughkeepsie NY 12601.

Our previous work has demonstrated that total protein synthesis is dramatically inhibited following a 5 min episode of in vitro ischemia in neurons in the rat hippocampal slice. In the present report, we explored the responses of individual proteins to this insult. We prepared 500 μ m slices from adult male Sprague-Dawley rats and incubated them in a Ringer's buffer equilibrated with 95% O₂-5% CO₂ at 37°C. Following a 2 hr preincubation period, experimental slices were exposed for 5 min to Ringer's lacking glucose and oxygen. Slices were allowed to recover for 30 min, 1 hr, 2 hr or 3 hr, then were moved into ice-cold homogenization buffer containing protease inhibitors. 15 μ g of total protein, determined with the Bradford protein assay, was loaded onto a 7.5% polyacrylamide gel and was separated in one-dimension according to Laemmli. Some gels were silver-stained and analyzed by densitometry. Proteins from some gels were transferred to immobilon membranes and exposed to antibodies against hsp-72/73, GFAP, MAP-2 or calbindin-D-28k. In some experiments, new protein synthesis was determined by exposing slices to ³⁵S-methionine and silver-stained gels were processed for autoradiography. Immunoblots and autoradiographs were also analyzed by densitometry.

In vitro ischemia inhibited new protein synthesis of most proteins analyzed. The total amount of some proteins was reduced at 2 hr postischemia, while that of others was unchanged. One notable exception was the response of hsp72/73 to in vitro ischemia. This protein showed a dramatic increase in new synthesis 30 min and 1 hr after ischemia, followed at 3 hr by a 50% decrease in new synthesis. At 2 hr following the insult, the total amount of hsp72/73 was significantly increased in postischemic slices, when compared with control slices. Thus, while total amounts of protein remains unchanged following ischemia and total new synthesis is reduced, the responses of individual proteins to ischemia varies considerably. These individual responses could play an important role in the response to ischemia.

423.3

THE RESPONSES OF ISCHEMIA-RESISTANT NEURONS AFTER TRANSIENT ISCHEMIA IS DIFFERENT FROM THOSE OF ISCHEMIA-VULNERABLE NEURONS: AN IN VIVO INTRACELLULAR RECORDING STUDY. Z. C. Xu* and W. A. Pulsinelli. Dept. of Neurology, University of Tennessee Memphis. Memphis, TN 38163.

Spiny neurons in neostriatum and CA1 pyramidal neurons in hippocampus will degenerate after transient ischemia while giant aspiny neurons, dentate granule cells and CA3 neurons in the same region survive. To reveal the neurophysiological mechanisms associated with such selective neuronal injury, we compared the responses to transient ischemia in ischemia-resistant neurons with those of previously published data on ischemia-vulnerable neurons (Soc. Neurosci. Abst. 682.18).

Intracellular recording *in vivo* was performed on halothane anesthetized Wistar rats. Severe forebrain ischemia was induced by 4-vessel occlusion in normothermic animals for 5-8 minutes. Responses of aspiny neurons, dentate granule cells and CA3 pyramidal neurons were studied following ischemia. The recorded neurons were identified by intracellular staining with neurobiotin.

The latency of ischemic depolarization (ID) induced in ischemia-resistant neurons (~3.5 min) is significantly longer than that of ischemia-vulnerable neurons (~2.5 min). The amplitude of ID in aspiny neurons (~30 mV) is smaller than that in spiny neurons (~50 mV) in neostriatum. Unlike ischemia-vulnerable neurons, the spike threshold and membrane input resistance of ischemia-resistant neurons did not increase after recirculation. No suppression of repetitive firing was observed in ischemia-resistant neurons. Such differences between ischemia-resistant and ischemia-vulnerable neurons may clarify mechanisms leading to cell death.

MAP2 IMMUNOREACTIVITY AS AN INDEX OF PATHOLOGY IN RAT HIPPOCAMPAL SLICES. Q. Zhou* and T. S. Nowak, Jr. Departments of Anatomy & Neurobiology and Neurology, University of Tennessee, Memphis, TN 38163

Loss of microtubule-associated protein 2 (MAP2) staining occurs in slices following anoxic incubation, and is a prominent feature of postischemic neuronal injury. Using various markers we have begun to systematically evaluate the pathology associated with slice preparation, with the goal of establishing a baseline for in vitro anoxia/aglycemia studies in hippocampal slices of adult rats. In this study we examined changes in MAP2 immunoreactivity during routine slice incubation.

Male Wistar rats were decapitated under halothane anesthesia and 400 μ m vibratome slices cut and incubated in artificial cerebrospinal fluid equilibrated with 95% O₂/5% CO₂ at 34°C. At t=0, 1, 2, 3, 4 and 6 h slices were fixed in 4% paraformaldehyde, and 50 μ m vibratome sections prepared for immunocytochemistry. MAP2 was visualized with a monoclonal antibody (Sigma M-4403) and peroxidase detection.

The normal *in vivo* pattern of dendritic MAP2 immunoreactivity was found in freshly cut slices (t=0). This morphology was sometimes well-preserved through 4-6 h incubation, but was lost during further incubation. In many cases, however, early changes in MAP2 staining could be detected within 1 h, with preferential loss in CA1 and the upper blade of dentate gyrus, accompanied by an increased signal in the cell body, comparable to the changes reported during anoxic incubation. Changes in MAP2 staining were well correlated with loss of Jun immunoreactivity. MAP2 therefore provides a sensitive index of slice quality that may be of general use in evaluating preparation conditions, and for comparison with other criteria of slice function.

423.2

BRIEF PRECONDITIONING HYPOXIA PROTECTS HIPPOCAMPAL NEURONS FROM SUBSEQUENT HYPOXIA-INDUCED DAMAGE VIA MECHANISMS REQUIRING ONGOING PROTEIN SYNTHESIS. A.T. Gage* and P.K. Stanton. Departments of Neuroscience & Neurology, Albert Einstein Coll. Med., Bronx, NY 10461

Pre-exposure of rat hippocampus to a short period of hypoxia increases the resistance of CA1 pyramidal neurons to a normally fatal hypoxic insult. One hypothesis for this protective effect is that a short hypoxic insult causes the synthesis of new proteins which protect neurons during subsequent, longer hypoxic insults. We tested this idea by using the reversible protein synthesis inhibitor cycloheximide (CYCLO) and determined if it prevented the priming neuroprotection during hypoxia. We used a bipolar stimulating electrode to activate Schaffer collateral axons in area CA1 of hippocampal slices every 60 s, and recorded evoked dendritic population epsps in stratum radiatum. Naïve slices subjected to a 15 min period of severe hypoxia (95% N₂/5% CO₂) showed only 1.5 \pm 1.5% recovery of epsp slope upon reoxygenation. In contrast, in slices subjected to a 5 min preconditioning hypoxic insult, followed by 2 h of recovery in normal O₂, the 15 min hypoxic episode now led to 89 \pm 8.12% recovery upon reoxygenation. When slices were bathed in 10 μ M CYCLO 1 h before the initial 5 min period of hypoxia, followed by a 2 h drug washout in normal O₂, the 15 min hypoxic challenge allowed only 20 \pm 12.54% epsp recovery. In contrast, neither the NMDA receptor antagonist D-(-)-2-amino-5-phosphonopentanoic acid (D-AP5, 20 μ M) nor the AMPA glutamate receptor antagonist 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX, 10 μ M) prevented the protective priming caused by brief hypoxia. Our data support the hypothesis that brief periods of hypoxia trigger compensatory protective events that require ongoing protein synthesis, but not activation of NMDA or AMPA glutamate receptors. Elucidation of neuroprotective protein products stimulated by hypoxia will have important therapeutic consequences to our understanding of stroke-induced brain damage.

423.4

STRESS PROTEIN INDUCTION IS NOT REQUIRED TO EXPRESS ISCHEMIC TOLERANCE IN THE GERBIL. H. Abe and T.S. Nowak, Jr.* Dept. of Neurology, Univ. of Tennessee, Memphis, TN 38163.

Brief ischemia induces tolerance to subsequent more severe insults. Preferential induction of the heat shock protein, hsp72, in vulnerable hippocampal neurons after brief ischemia suggests that the stress response could contribute to ischemic tolerance. Temperature during early recirculation can influence the severity of ischemic injury in the gerbil as well as the expression of hsp72. We have used the temperature dependence of hsp72 expression to assess its role in ischemic tolerance.

Gerbils were subjected to 2 min bilateral carotid artery occlusion followed by 90 min recirculation under halothane anesthesia, during which temperature was either maintained continuously at 37 °C (normothermic, NT) or elevated to 39.5 °C between 15 and 60 min recirculation (hyperthermic, HT). A 5 min ischemia was produced 2 d after the priming challenge, and injury to CA1 was assessed 7 d after this test insult. In other animals hsp72 induction was evaluated by *in situ* hybridization 3 h after 2 min ischemia in the NT and HT groups.

Control neuron density (295 \pm 11) was severely reduced after 5 min ischemia in naïve animals (16 \pm 4), and striking protection was observed in both NT and HT pretreatment groups (191 \pm 96 and 92 \pm 101, respectively). Reduced cell density in the HT group reflected a modest loss seen with the priming insult alone. Most importantly, 90% of 2 min NT animals showed significant protection of CA1 neurons. In contrast, only 50% of animals subjected to 2 min HT expressed hsp72 mRNA. Hsp72 induction is therefore not required for ischemic tolerance, which apparently may be achieved following insults that remain below the threshold for neuronal injury as defined by hsp72 expression.

423.6

AGING, ENERGY METABOLISM, AND THE ABILITY OF RAT HIPPOCAMPAL SLICES TO SURVIVE ANOXIA. C.-P. Chih¹ and E.L. Roberts, Jr.^{1,2*}. ¹Department of Neurology, University of Miami School of Medicine, and ²Geriatric Research, Education, and Clinical Center, Miami VA Medical Center, Miami, FL 33136

We examined whether (1) decreased ATP and PCr levels before anoxia, (2) inefficient ATP or PCr use during anoxia, (3) less recovery of ATP or PCr after anoxia, or (4) a diminished capacity for oxidative metabolism contribute to the increased vulnerability of aging brain tissue to anoxia. Hippocampal slices from 6-9, 16-19, and 26-29 month old Fischer-344 rats were exposed to physiological solutions containing 5-20 mM glucose or 20 mM sodium lactate. After an initial period of normoxia (95% O₂, 5% CO₂), slices were subjected to anoxia (95% N₂, 5% CO₂). Normoxia was returned one minute after onset of anoxic depolarization. ATP and phosphocreatine (PCr) levels, extracellular K⁺ activity (K⁺), and synaptic transmission were assessed in slices before, during, and one hour after anoxia. ATP and PCr levels in slices displayed no age- or glucose-related differences before or after anoxia, and were not correlated to postanoxic recovery of synaptic transmission. Thus, age-related vulnerability to anoxia was not due to pre- or postanoxic alterations in ATP or PCr. Slices exposed to 20 mM lactate exhibited no age-related differences in onset of anoxic depolarization during anoxia, and in recovering K⁺, homeostasis and synaptic transmission after anoxia. Thus, age-related differences in vulnerability were not due to inefficient conversion of PCr to ATP, or to a decreased capacity for oxidative metabolism. These results may mean that age-related decreases in glycolysis play a prominent role in the brain's vulnerability to anoxia. (Supported by a research grant from NIA (AG08710))

RELEASE OF (³H)-D-ASPARTATE OR ENDOGENOUS GLUTAMATE FROM RAT HIPPOCAMPAL SLICES DURING *IN VITRO* ISCHEMIA IS MEDIATED BY A HIGH AFFINITY NA-DEPENDENT CARRIER. V. Roettger* and P. Lipton. Dept. of Physiol., Univ. of Wisconsin, Madison, WI 53706.

In Vitro Ischemia (deprivation of oxygen and glucose=IVI) induces a several-fold increase in the release of endogenous glutamate (GLU) and accumulated ³H-D-Aspartate (ASP). The release mechanism is unknown although reversal of the Na-coupled high-affinity glutamate transporter has been widely suggested. We examined this hypothesis using two competitively transported inhibitors of the Na-dependent carrier, D,L-threo-B-hydroxyaspartate (THA) and L-trans-pyrrolidine-2,4-dicarboxylate (tPDC).

Slices were loaded with THA or tPDC (0.5mM) for 60' and then with ³H-D-ASP (0.25uCi/ml) for 30' after which they were exposed to IVI or veratridine (100uM) for 3 successive 5 minute periods at 37°C.

Both veratridine and IVI increased the release of ASP and GLU over basal levels. Intracellular THA or tPDC blocked these increases by 55% or greater.

This response differs from that seen with extracellular dihydrokainate (DHK, 0.5mM), a non-transported inhibitor, which blocked the increase in veratridine-induced ASP and GLU release but not the increase in release induced by IVI (Soc. for Neurosci. Abst., 18:1267, 1992).

These results suggest that glutamate release during *in vitro ischemia* is largely mediated by a high affinity Na-dependent transporter sensitive to THA or tPDC but insensitive to DHK. This pharmacology matches that of the putative neuronal carrier (EAAC1 - Kanai and Hediger, *Nature*, 360:467, 1992) and suggests that the released glutamate originates from neuronal elements. The pharmacology of inhibition of veratridine-induced release suggests that veratridine releases glutamate from both neuronal and glial elements (Pines et al., *Nature*, 360:464, 1992).

423.9

ANOXIA CAUSES CLEAVAGE AND REARRANGEMENT OF CYTOSKELETAL PROTEINS IN RAT CORTICAL NEURONS. J.E. Friedman,* J. Helenius and G.G. Haddad. Yale Univ. Sch. Med., Dept. Pediatrics, Sec. of Respiratory Medicine, New Haven, CT 06520

We have previously shown that oxygen deprivation causes an increase in intracellular Ca²⁺ and Na⁺ in central neurons. Concurrent with these events, we have observed, in both hippocampal and cortical neurons, changes in morphology, including swelling, process retraction and bleb formation (Friedman & Haddad, *J. Neurosci.* (1993) 13:63, *Brain Res.* (1994) 641:57). We hypothesized that cytoskeletal elements might be cleaved during anoxia, thus making the neuron more susceptible to osmotic stress and undergo morphologic change. Microfilaments are not only involved in maintaining a cell's structural integrity, but have also been implicated in the regulation of Na⁺ and Ca²⁺ influx through, e.g. NMDA-channels. We focused on actin, the major component of microfilaments, and the actin-cross-linking protein fodrin. We used cultured rat cortical neurons grown on poly-D-lysine coated coverslips in a chemically-defined media that does not support glial proliferation. We induced anoxia (PO₂=0) on the stage of our inverted confocal microscope, confirming its effect by observing morphological changes and increased intracellular Ca²⁺, as demonstrated by fluo-3 fluorescence. After 10 min of anoxia, the sample was rapidly removed, fixed, and, using immunocytochemistry, stained for filamentous (F-) or monomeric (G-) actin, fodrin, or the 150kD cleaved subunit of fodrin. In the normoxic (control) neuron, phalloidin staining for filamentous actin was confined to the periphery. Following anoxia, the localization of F-actin was less restricted to the periphery, and the extent of staining appeared to have increased. Staining for G-actin, (with DNase-I) demonstrated an apparent decrease following 10 min of anoxia. In the normoxic neuron, staining was observed using antibodies against native fodrin, whereas the antibody RAF-150, which is specific to the cleaved subunit of fodrin did not stain. Following 10 min of anoxia, RAF-150 staining could be observed, indicating that fodrin had been cleaved. These results demonstrate that cytoskeletal proteins are affected by acute anoxia. We suggest that early cleavage of fodrin makes the microfilaments more susceptible to mechanical disruption during swelling, resulting in an increased number of actin polymers in the cytoplasm and less well localized filamentous actin in the plasma membrane region.

423.11

ARACHIDONIC ACID PARTICIPATES IN ANOXIA-INDUCED VESICULAR GLUTAMATE RELEASE IN CA1 NEURONS OF THE RAT HIPPOCAMPUS. N. Hershkowitz* and A.N. Katchman. Georgetown Univ. Hospital, Dept. Neurol., Wash. DC 20007.

Patch clamp in the whole cell configuration was used to examine the effects of agents that influence arachidonic acid metabolism on anoxia-induced vesicular glutamate release in CA1 neurons of *in vitro* hippocampal slices. Anoxia was induced by switching perfusion and ambient gas of an interface chamber from a 95%O₂/5%CO₂ to a 95%N₂/5%CO₂ mixture. As previously demonstrated, a significant increase in the frequency (340 ± 50%, n = 18) of spontaneous glutamate-mediated miniature excitatory postsynaptic currents (mEPSCs) was observed during the first 5 mins following anoxia. This increase in frequency was almost completely abolished if slices were preincubated in artificial cerebral spinal fluid containing the phospholipase C/A₂ inhibitor bromophenacyl-bromide (20 μM, n = 8) or the cyclooxygenase inhibitors indomethacin (20 μM, n = 16) and piroxicam (10 μM, n = 4). There was no significant effect of these agents on the mean mEPSC amplitude. These data suggest that arachidonic acid (AA) and its cyclooxygenase products or by-products (oxygen free radicals) contribute to vesicular glutamate release during the early phase of anoxia. This observation may be important to our understanding of the neuroprotective action of these agents. (Supported by NINDS grant NS 14600-02)

423.8

DELAYED TREATMENT WITH APV AMELIORATES PHYSIOLOGICAL DAMAGE FOLLOWING MODERATE HYPOXIA IN RAT HIPPOCAMPAL SLICES. Chen, Z-F., Schottler, F., Kassell, N.F.*, and Lee, K.S. Department of Neurosurgery, University of Virginia, Charlottesville, VA, 22908.

Continuous application of the glutamate receptor antagonist, DL-2-amino-5-phosphonopentanoic acid (APV), improves substantially the recovery of population excitatory postsynaptic potentials (pEPSPs) after a moderate hypoxic challenge when treatment is initiated prior to hypoxia. (Chen *et al.*, 1994 *Stroke*; 1994;25:161). Since pathophysiological damage under these "penumbra-like" conditions was related to the duration of hypoxia, the aim of present experiment was to examine the time course of effectiveness of APV treatment and determine whether delayed treatment with APV is neuroprotective. Rat hippocampal slices were submerged in artificial cerebrospinal fluid at 34° C, and pEPSPs were recorded in *stratum radiatum* of CA1 in response to activation of Shaffer-Collateral/commissural fibers. Stable responses were recorded for at least 20 min under normoxic conditions (PO₂=450-600mmHg) and hypoxia was induced for 1 hour (PO₂=40-70mmHg) by substituting 95%N₂:5%CO₂ for 95%O₂:5%CO₂ in the gas supply. Slices were treated with 100μM APV for 30 minute periods initiated at various points during hypoxia and reoxygenation. Treatment with APV during the last 15 minutes of hypoxia and first 15 minutes of reoxygenation enhanced significantly the recovery of pEPSP slope and amplitude relative to that observed in non-treated controls. Other post-treatment paradigms were less effective in providing neuroprotection. In agreement with previous studies, the absence of profound negative shifts in the DC potential and persistence of the fiber volley indicate that hypoxic depolarization did not occur in these experiments. These results demonstrate that delayed treatment with APV, restricted to late hypoxia and/or early reoxygenation, ameliorates substantially physiological damage occurring during prolonged moderate hypoxia. (Supported by NS30671 to KSL).

INCREASED NEURONAL SENSITIVITY TO ACUTE HYPOXIA IN RATS AFTER LONG-TERM EXPOSURE TO A REDUCED OXYGEN ENVIRONMENT J.P.O'Reilly* and G.G.Haddad., Depts. Biology and Pediatrics, Yale University and School of Med., New Haven, CT.

Ischemia and hypoxia have both been shown to be detrimental to the central nervous system (CNS). Previous studies have been concerned with the effect of acute episodes of ischemia or hypoxia on the CNS. However, the effect of long-term (chronic) hypoxia on the CNS has not been addressed. In order to determine the effect of chronic hypoxia on the CNS, we studied baseline electrophysiologic properties and the response to acute hypoxia in brain slices from animals that had been raised (P0 to >21 days) in a chronic hypoxic environment (FiO₂ = 9 ± 1%). Age-matched rats raised in a normoxic environment served as controls. Intracellular recordings from neurons in layer 2/3 of the temporal cortex were performed. Resting membrane potential was significantly different between hypoxic rats (-77.9 ± 5.5 mV) and control rats (-83.4 mV ± 3.0 mV). Although both groups showed a biphasic response to acute hypoxia (an initial slow depolarization, followed by a large and rapid depolarization), only 40% of the control neurons showed a rapid depolarization by 7 minutes of hypoxia (latency = 13.3 ± 8.2 min), while all of the neurons from hypoxic animals showed a rapid depolarization by 7 minutes of hypoxia (latency = 5.4 ± 1.3 min). Also, during hypoxia the maximum depolarization (ΔV_m = 61.0 ± 13.2 mV) and the maximum decrease in input resistance (ΔR_i = 88.5% change from baseline) in hypoxic animals were greater than in controls (ΔV_m = 27.4 ± 27.1 mV; ΔR_i = 75.4%). These data suggest that chronic hypoxia results in an increased sensitivity to subsequent acute hypoxic stress. We speculate that long-term hypoxic exposure renders neurons in the CNS more susceptible to injury or death.

HYPOXIA/HYPOGLYCEMIA-INDUCED PHOSPHOINOSITIDE HYDROLYSIS IN HIPPOCAMPAL SLICES *IN VITRO*: A MODEL SYSTEM FOR INVESTIGATING BIOCHEMICAL MECHANISMS Masahiro Ikeda, Department of Neuroscience, Tsukuba Research Laboratories of Eisai Co. Ltd. Ibaraki 300-26 Japan

Cerebral ischemia induces degradation of phosphatidylinositol-4,5-bisphosphate (PIP₂) and phosphatidylinositol-4-phosphate (PIP), and formation of diacylglycerol (*J. Neurochem.* 47, 123-132, 1986). To investigate the biochemical mechanisms of the ischemia-induced phosphoinositide hydrolysis, an *in vitro* method has been developed. Transverse slices of rat hippocampi labelled with (³H)myo-inositol were incubated in nitrogen-saturated and glucose-free Krebs-Henseleit bicarbonate buffer in the presence of 10 mM LiCl. Inositol phosphates and inositol phospholipids were analyzed by SEP-PAKs column and TLC, respectively. The lack of glucose and oxygen induced a decrease in PIP₂ and PIP. PI did not change. The changes were very similar to those found in *in vivo* ischemia. Inositol bisphosphate(IP₂) transiently increased and then returned to control levels. Inositol monophosphate gradually increased. The increase in IP₂ was completely prevented by removing extracellular Ca²⁺ from the buffer. Addition of atropine, prazosin or ketanserin did not suppress the increase in IP₂. Antagonists of NMDA and nonNMDA receptors also had no effect. D-amino-3-phosphonopropionate (D-AP3), a putative antagonist of metabotropic glutamate receptors prevented the increase in IP₂, but the compound did not affect the decrease in PIP₂ and PIP. The effects of D-AP3 may be due to the inhibition of phosphatidylinositol synthesis as reported previously (*Neurosci. Lett.* 157, 87-90, 1993). These findings suggest that the present method is suitable for investigating the biochemical mechanism of ischemia-induced phosphoinositide hydrolysis, and finding compounds which inhibit the hydrolysis.

HYPOXIA-INDUCED CHANGES IN LIGHT TRANSMITTANCE IN HIPPOCAMPAL SLICES. N.R. Kreisman*, J.C. LaManna, S.-C. Liao, and J.R. Alcalá. Depts. of Neurology and Biomedical Engineering, Case Western Reserve U. Sch. Med., Cleveland, OH 44106 and Dept. of Physiology, Tulane U. Sch. Med., New Orleans, LA 70112.

Intrinsic optical properties of in vitro brain slices change as cells swell (Andrew & MacVicar *Soc Neurosci Abstr* 18:1125, 1992; Henn & Turner *Soc Neurosci Abstr* 19:1322, 1993; Kreisman et al *FASEB J* 8:A655, 1994). In the present study we correlated neuronal activity and light transmittance during hypoxia. Field potentials and orthodromic population spikes were recorded in CA1 stratum pyramidale of 400µm-thick rat hippocampal slices in an interface chamber. Transmitted light was detected with a silicon photodiode coupled to a dissecting microscope (optical field, 0.5 X 1.5 mm). Hypoxia (15-20 min) blocked synaptic transmission within 3 min and produced 1-3 phases of intrinsic optical changes. The three phases of light transmittance change occurred in the following sequence: 1) a small increase ($\Delta T/T = +5.4 \pm 0.7\%$; $n=16/27$) indicative of cell shrinkage, 2) a slow decrease ($\Delta T/T = -17.6 \pm 3.2\%$; $n=14/27$) indicative of cell swelling, and 3) a rapid decrease (i.e., swelling) coincident with anoxic depolarization ($\Delta T/T = -31.1 \pm 2.4\%$; $n=11/27$). Reoxygenation following 15-20 min of hypoxia only resulted in a 25% recovery of light transmittance toward baseline. Imaging showed that the largest optical changes occurred in the stratum radiatum, followed by strata pyramidale, oriens, and lacunosum-moleculare. The results suggest that cells in CA1 hippocampus swell after several minutes of hypoxia and that recovery from swelling is incomplete following 20 min of reoxygenation. (Supported by NS 22077)

SIMULTANEOUS PATCH-CLAMP RECORDINGS OF CA1 PYRAMIDAL CELLS AND INTERNEURONS IN RAT HIPPOCAMPAL SLICES: DIRECT DEMONSTRATION OF FUNCTIONAL DISCONNECTION OF INTERNEURONS BY ANOXIA. R. Khazipov, P. Congar, N. Ropert*, and Y. Ben-Ari INSERM Unite 29, 123 Bd de Port-Royal, 75014 Paris

It was proposed in our previous work (Khazipov et al., *J. Neurophysiol.* 70 : 2251-2260, 1993) that high sensitivity of polysynaptic IPSCs to anoxia is due to the functional disconnection of inhibitory interneurons from excitatory inputs. To verify this hypothesis, the effects of anoxia were studied in simultaneous whole-cell patch-clamp recordings from interneurons and pyramidal cells in CA1 region of adult rats hippocampal slices; these were both identified by their electrogenic properties and biocytin injection. Anoxia (95% N₂-5% CO₂; 5 min) generated currents in interneurons similar to pyramidal cells: the most prominent were the anoxic outward current and the postanoxic outward current. EPSCs and polysynaptic IPSCs were depressed by anoxia, and this depression was more pronounced in the interneurons. The currents evoked by pressure ejection of glutamate, AMPA and NMDA were not affected by anoxia, suggesting that the depression of EPSCs in both interneurons and pyramidal cells is due to a presynaptic mechanism. Depression of EPSCs but neither polysynaptic IPSCs nor GABA_B receptors mediated component of monosynaptic IPSCs (see Congar et al. *Soc. Neurosci. Abs.* 1994) was prevented by adenosine A₁ receptors antagonist DPCPX (200nM) indicating the involvement of presynaptic adenosine receptors in anoxic depression of EPSCs. These observations indicate that anoxia preferentially depresses excitatory inputs to anoxia leading to a functional disconnection of interneurons.

IN UTERO ISCHEMIA CAUSES HYPERSENSITIVE RESPONSES IN NMDA-STIMULATED ACCUMULATION OF GLUTAMATE AND cGMP FORMATION IN CEREBELLAR GRANULE CELL CULTURES.

P.G. Rhodes*, Z. Cai and N. Zhu. Dept. of Pediatrics, Univ. of Miss. Med. Ctr., Jackson, MS 39206.

An experimental model of in utero hypoxic-ischemia was developed to study the effects of this insult on brain development. On gestation day 17, ischemia conditions were achieved by complete clamping of the uterine vasculature for designated times followed by removal of the clamps to permit reperfusion. Sham operation (surgery without vasculature clamping) was conducted in the control groups. After surgery, the uterus was returned to the dam's abdomen to allow for natural birth. Cerebellar granule cells were cultured from the pups at 8 days of age. Cell density and protein contents of the cultures were not significantly different between intact, sham operated and ischemic groups. N-methyl-D-aspartate (NMDA, 100 µM), but not kainate, induced a significant elevation of glutamate levels in cell cultures from 20 and 35 min-ischemic groups compared to intact, sham or 5 min-ischemic groups (30.9 and 27.0 vs. 19.4, 18.5 and 18.2 nmol/mg protein, respectively). NMDA-stimulated cGMP formation in cultures from 10, 20, 25 or 35 min-ischemic groups was also significantly higher than in control cells (62.4-78.2 vs. 49 pmol/mg of protein). The hypersensitive responses in NMDA-stimulated glutamate accumulation and cGMP formation in cells from in utero ischemic groups could be blocked by addition of L-N^G-monomethyl-arginine (L-NMMA, 150 µM), a nitric oxide synthase inhibitor, before NMDA stimulation. These results indicate that in utero ischemia may result in adverse effects on later NMDA receptor-mediated neurotransmission during brain development and that nitric oxide response is possibly involved in these effects.

ALTERATIONS IN MITOCHONDRIAL FUNCTION OF PC12 CELLS FOLLOWING CHEMICAL ANOXIA/REOXYGENATION. K.M. Myers*, A.N. Murphy, and G. Fiskum. Department of Biochemistry and Molecular Biology, George Washington University Medical Center, Washington, DC 20037.

PC12 cells were used to explore the alterations in mitochondrial activity following cyanide (KCN)-induced chemical anoxia of varying durations in the absence of glucose. Recovery of mitochondrial function was also charted over periods of reoxygenation in the presence of glucose as an *in vitro* simulation of neuronal ischemia and reperfusion. Exposure of suspended PC12 cells to 3 mM KCN for 7 minutes induced an 86% decrease in ATP levels, which plummeted to 1.3% of control after 90 minutes. Glucose prevented this fall, while incubations in aglycemic media without KCN had no effect. This suggests combined oxygen and glucose deprivation are necessary to deplete ATP. Levels recovered to 56% following 30 minutes of anoxic aglycemia with 30 minutes of glycolytic reoxygenation and climbed to 87% following 24 hours of reoxygenation. Viability was >80% in most cases. The rate of mitochondrial O₂ consumption observed with cells resuspended in a KCl-based medium containing the permeabilizing agent digitonin, oxidizable substrates, and ADP (State 3) following a 30 minute incubation of intact cells plus KCN minus glucose was 83% with subsequent decreases to 76% and 67% for 60 and 90 minutes. The acceptor control ratio (ACR), which compares state 3 respiration to that of state 4, or O₂ consumption minus ADP, was 71% after 30 minutes and fell to 61% following 90 minutes of anoxic aglycemia. Although short periods of glycolytic reoxygenation allowed a virtual recovery of the ACR following 30 minutes of anoxic aglycemia (>80% after 30, 60, 120, and 240 min.), ACR declined to 52% following 24 hours of reoxygenation. This secondary impairment of function is similar to the multiphasic mitochondrial injury noted for certain animal models of cerebral ischemia/reperfusion. This system can therefore be used to test whether mechanisms of ischemic brain injury are responsible for mitochondrial injury evoked by anoxia/reoxygenation. (Supported by SigmaTau S.p.A. and Souers Stroke Fund).

SIMULTANEOUS PATCH-CLAMP RECORDINGS CA1 PYRAMIDAL CELLS AND INTERNEURONS IN RAT HIPPOCAMPAL SLICES: EFFECTS OF ANOXIA ON GABA_A AND GABA_B RECEPTORS MEDIATED SYNAPTIC CURRENTS. P. Congar, R. Khazipov, J. Hirsch*, and Y. Ben-Ari INSERM Unite 29, 123 Bd. de Port-Royal, 75014 Paris

The effects of anoxia on monosynaptic IPSCs, evoked by 'close' stimulation in the presence of glutamate receptor blockers, were studied in the CA1 region of hippocampal slices from adult rats using simultaneous whole-cell patch-clamp recording of pyramidal cells and interneurons with low-chloride pipette solution. In pyramidal cells and interneurons, anoxia (95% N₂-5% CO₂; 5 min) depressed or inverted the IPSCs, due to the shift of Cl⁻ reversal potential to more positive values, without any change of conductance. Anoxia also depressed the late postsynaptic GABA_B-receptor mediated component. Since adenosine A₁ receptors antagonist DPCPX (200µM) did not prevent the anoxic depression of IPSC_B, this depression was not due to 'occlusion' of GABA_B receptors mediated currents by adenosine which is known to accumulate during anoxia and is responsible to the presynaptic depression of glutamate release (see Khazipov et al. *Soc. Neurosci. Abs.* 1994). To study the effects of anoxia on the presynaptic GABA_B-receptor mediated mechanisms, we used a paired-pulse inhibition (PPI) protocol. In control, PPI of IPSC was observed both in pyramidal cells and interneurons. Anoxia did not affect presynaptic GABA_B-receptors mediated inhibition since there was no change in PPI during anoxia or upon reoxygenation. It is concluded that anoxia affects synaptic transmission of GABAergic inhibitory synapses on pyramidal cells and interneurons by (i) disturbance of Cl⁻ equilibrium and shift of reversal potential of IPSC_A to positive values and (ii) selective block of post- but not presynaptic GABA_B-mediated responses.

423.18

DIFFERENTIAL RESPONSES OF CA1 PYRAMIDAL CELLS AND GRANULE CELLS IN THE DENTATE GYRUS TO ISCHEMIA-LIKE CONDITIONS IN RAT HIPPOCAMPAL SLICES. H. Shimizu, Y. Fujito*, A. Mizuuchi and M. Aoki. Dept. Physiol., School of Med., Sapporo Med. Univ., Sapporo 060, Japan

We examined the regional difference of responses to oxygen-glucose deprivation (ischemia-like conditions, Hypo-G(-)) in the CA1 region and the dentate gyrus (DG) of rat hippocampal slices (350µm thick). Changes of resting membrane potentials (rest V_m) and antidromic action potentials (AAPs) were compared between CA1 pyramidal cells (PCs) and granule cells (GCs) in DG. [Ca²⁺]_i measured by Fura-2/AM loaded slices were also compared between CA1 and DG. In PCs, Hypo-G(-) produced an initial hyperpolarization and a subsequent rapid depolarization. By contrast, GCs showed a slight initial hyperpolarization and a subsequent slower depolarization than PCs. In PCs and GCs, AAPs disappeared after 7 to 9-min periods of Hypo-G(-), when rest V_m depolarized to about -50mV. Exposure to Hypo-G(-) for ≥ 10 min produced an irreversible depolarization in both neurons. However, when reoxygenation was started at the time of disappearance of AAPs, repolarization occurred in 86% (12/14) of GCs and 36% (5/14) of PCs. [Ca²⁺]_i remarkably increased at the depolarization phase both in CA1 and DG, but peak [Ca²⁺]_i were significantly higher in CA1. Under Ca²⁺-free medium, peak [Ca²⁺]_i decreased and there was no significant difference between CA1 pyramidal cell layer and granule cell layer. These results demonstrate the differential responses to Hypo-G(-) between CA1 PCs and GCs in DG, probably due to different distributions of ion channels of these neurons.

BRIEF PERIODS OF OXYGEN AND GLUCOSE DEPRIVATION IN VITRO CAUSES SWELLING AND DELAYED CELL DEATH. W.J. Goldberg*. Stroke & Trauma Lab., Dept. Veterans Affairs Medical Center, Washington, DC 20422.

An *in vitro* system was used to mimic several aspects of ischemia, including oxygen and glucose deprivation and prolonged depolarization. We replaced normal culture medium from 3-week-old spinal cord cultures with oxygen-depleted, osmotically balanced (310 mOsm) salt solution containing 55 mM Na⁺, 65 mM K⁺ and 1 μ M Ca²⁺. After incubation at 37°C for 15 minutes in an atmosphere of 7% CO₂/93% N₂, the cultures were returned to normal, oxygenated culture medium for 0, 1 or 96 hours. At the end of each recovery period, cultures were immunohistochemically stained using combined antibodies to 68kD, 150kD, and 200 kD neurofilament proteins. In non-deprived cultures, the neuronal density was 197 cells/100 mm². These cells were 96.67 \pm 6.8 μ m² (mean \pm SEM) in size. More than 88% of the original neuronal population survived the 15 minute deprivation period. Two classes of cells were observed based on cell size; one group was not different from non-ischemic neurons (109 \pm 63 μ m²) and the other was significantly swollen (255.3 \pm 25 μ m², P<0.05). The survival rate decreased to 64.7% after 1 hour of recovery. Syllons (240.1 \pm 14.3 μ m², p<0.05) and non-swollen (112.1 \pm 9.3 μ m²) neuronal populations were observed at this time. After 4 days of recovery, the survival rate decreased further to 21.6%. All surviving cells were swollen to 337 \pm 47.7 μ m² (p<0.05). No normal sized neurons were observed. Supported by the Department of Veterans Affairs.

EFFECTS OF OXYGEN- AND GLUCOSE- FREE CONDITIONS ON RAT HIPPOCAMPAL BRAIN SLICES : SIMULTANEOUS Ca²⁺ AND DC POTENTIAL MEASUREMENTS. M.L. Evans* and C.D. Benham. Biophysics Dept., SmithKline Beecham, Harlow, Essex CM19 5AD U.K.

To investigate synaptic responses, ischaemic depolarisation, and Ca²⁺ influx under oxygen and glucose free conditions, 400 micron hippocampal slices were loaded with the Ca²⁺ indicator dye INDO1-AM. Microspectrofluorimetry was used to monitor [Ca²⁺]_i within a 20 micron diameter window centred over the stratum pyramidale of either CA1 or CA3. Extracellular DC recordings were made in the stratum pyramidale adjacent to the window. Experimental temperature was 36°C. The relevant afferent pathway was stimulated every 15s to monitor synaptic responses. Synaptic responses in INDO1 loaded slices were similar to those of control slices. On switching from normal medium to N₂-saturated, glucose-free medium, synaptic responses were eliminated within 90s. After 276 \pm 45s, a large, transient, negative DC shift was observed in CA1 which was closely followed by a rapid and sustained rise in [Ca²⁺]_i. Reperfusion with normal medium shortly after the peak [Ca²⁺]_i rise resulted in a return of [Ca²⁺]_i to baseline level over 3 to 5 min. but there was no recovery of the synaptic responses. Switching to normal medium before the depolarising shift and [Ca²⁺]_i rise resulted in a slow recovery of synaptic transmission to near baseline levels. Minislices containing only CA1 gave similar responses, indicating that the CA1 events are not driven by preceding events in CA3. The depolarising wave and [Ca²⁺]_i rise in CA3 had a longer latency (395 \pm 67s) and rose more slowly to a lower peak amplitude. Reperfusion after the peak [Ca²⁺]_i rise in CA3 resulted in a sustained recovery of synaptic responses. These regional differences in response to acute oxygen and glucose free conditions may underlie the vulnerability of CA1 to injury relative to CA3 observed with *in vivo* ischaemia models.

ISCHEMIA: MECHANISMS II

424.1

SUBCELLULAR LOCALIZATION OF ISCHEMIA-INDUCED INHIBITION OF CAM KINASE II. J.T. Parsons*, S.B. Churn*, and R.J. DeLorenzo^{1,2}. Departments of Biochemistry¹ and Neurology², Medical College of Virginia, Richmond, Va. 23298.

Ischemia-induced inhibition of CaM Kinase II activity is well characterized, but ischemia-induced inhibition of CaM Kinase II activity in selected subcellular fractions has not been studied. Therefore, we examined CaM Kinase II activity in subcellular fractions isolated from control and ischemic rat forebrains. Subcellular fractions were isolated from control and ischemic animal forebrains by differential centrifugation as modified by (J. Neurosci. 5:2609-2619, 1985, J. Clin. Invest. 75:2014-2023, 1985). CaM kinase II activity was determined as the amount of autophosphorylation of the alpha (50 kDa) subunit. Autophosphorylation was quantitated by computer-assisted densitometry (Mocha®, Jandel Scientific) (J. Neurochem. 59:1221-1232, 1992). CaM kinase II activity was determined in the nuclear fraction (P₁), the plasma membrane and mitochondrial fractions (P₂), subjected to centrifugation on a discontinuous Ficoll 400 gradient), the cytosolic fraction (S₃), and the endoplasmic reticulum fraction (P₃). Both control and ischemic subcellular fractions were normalized for protein, resolved on 8.5% SDS-PAGE gels, and visualized by autoradiography. As a result of ischemia, CaM Kinase II activity was inhibited by 30% \pm 3% (n=2) in the plasma membrane fraction, 26% \pm 9% (n=2) in the mitochondrial fraction, 38% (n=1) in the nuclear fraction, 82% (n=1) in the cytosolic fraction, and 75% \pm 4% (n=2) in the endoplasmic reticulum fraction. Thus, ischemia induces a significant inhibition of CaM kinase II activity in all subcellular fractions studied. The data support the hypothesis that ischemia-induced inhibition of CaM kinase II activity may play a role in the ischemia-induced, delayed neuronal cell death.

424.2

TRANSLOCATION OF Ca²⁺/CALMODULIN PROTEIN KINASE II IN THE VULNERABLE NEURONS FOLLOWING ISCHEMIA AND HYPOGLYCEMIA IN THE RAT. Bing-Ren Hu*, Junichi Kurihara, Fredrik Kamme and Tadeusz Wieloch, Lab. for Exp. Brain Res., University Hospital, 221 85 Lund, Sweden.

Alterations of Ca²⁺/calmodulin-dependent protein kinase II (CaMKII) during and following transient cerebral ischemia (TCI) and insulin-induced hypoglycemia (HG) in the rat were studied. CaMKII is translocated to synaptic junctions after both TCI and HG as showed by immunoblots and calmodulin binding, concomitant with a decrease in enzymatic activity. The translocation is longlasting and persists for the whole period until neuronal death in vulnerable brain areas, whereas in resistant regions translocation is transient. The results suggest that a stimulation of CaMKII is ongoing in the vulnerable areas which causes translocation. The ischemia also reduces the expression of α -subunit of CaMKII mRNA in dentate gyrus as demonstrated by *in situ* hybridization at 6 to 12 hrs of reperfusion. This may be a protective mechanism of the neurons to shut off CaMKII signal after ischemia. Intraneuronal hypothermia protects ischemic neuronal damage as well as reduces the translocation and increases mRNA expression of CaM-kinase II induced by ischemia. In conclusion the persistent translocation is highly correlated to neuronal damage in both ischemia and hypoglycemia.

424.3

ALTERATIONS IN Ca²⁺/CaM-Kinase II AND OTHER PROTEINS IN POSTSYNAPTIC DENSITIES AFTER FOREBRAIN ISCHEMIA IN RATS. Jaroslav Aronowski* and James C. Grotta, Department of Neurology, University of Texas Health Science Center, Houston, Texas 77025.

Postsynaptic densities (PSDs) located beneath the postsynaptic membrane may be the organelle for organizing ion channels, receptors and enzymes that participate in signal transduction. The major PSD protein, α -subunit of Ca²⁺/Calmodulin-dependent protein kinase II (CaM-KII), account for up to 30-40% of total PSD protein. We have shown that cerebral ischemia causes inactivation and translocation of CaM-KII from cytosol to particulate fraction, and that these changes are reversible after brief but not prolonged duration of ischemia. The present study analyzes the amount and activity of CaM-KII in isolated PSDs after ischemia. Wistar rats were subjected to 20 min of ischemia using a four-vessel occlusion (4VO) model. After 0, 2 and 24 h of reperfusion, animals were decapitated and forebrains isolated in less than 15 sec and frozen in liquid nitrogen. We compared 4VO to 5 min decapitation ischemia. PSDs were isolated according to the method by Wu et al. Proteins in PSD were quantitated using immunostaining, and CaM-KII activity was measured by quantitation of its autophosphorylation and peptide substrate phosphorylation. 4VO produced a dramatic (300%) increase in amount of alpha CaM-KII in PSDs. This increase was not reversed after 2 h and only partially reversible after 24 h of reperfusion (possibly due to proteolysis of the kinase). The amount of α -tubulin, actin and neurofilaments in PSDs did not change. CaM-KII activity in PSDs was decreased to approximately 30 and 50% of control levels after 0 and 2 h of reperfusion, respectively. 5 min decapitation ischemia produced increased CaM-KII similar to the 4VO, but significantly less inactivation of the enzyme. We conclude that different severities of ischemia are associated with irreversible increases of CaM-KII in PSDs with varying degrees of enzyme inactivation. The origin of the increase of CaM-KII in PSDs will be discussed.

424.4

A reversible elevation of free calcium during simulated ischemia in neuronal tissue culture. I.I. Vornov*, M. Han, S.C. Jo and A.G. Thomas Depts. of Neurology and Neuroscience Johns Hopkins School of Medicine, Baltimore, MD 21287

Previously, we have described tissue culture models of ischemia using metabolic inhibition to cause rapid, reversible ATP depletion. Neurons can be protected by NMDA receptor blockade after simulated ischemia, allowing delayed treatment of injury. Since the accessibility of cultures is preserved, we have been able to measure free calcium changes during simulated ischemia with the calcium sensitive dyes fluo-3 or fura-2 in dissociated cortical cultures. Intracellular calcium rose reversibly during metabolic inhibition. The calcium rise was slower and the recovery faster than that caused by bath application of glutamate. Blockade of NMDA receptors with MK-801 caused no change in the calcium increase, but removal of extracellular calcium decreased the rise.

Calcium entry during recovery was investigated histochemically. Calcium permeable non-NMDA receptor channels are permeable to cobalt. Cultures were incubated in 5 mM CoCl₂ during recovery and cobalt visualized with ammonium sulfide precipitation followed by silver intensification. In both dissociated cortical cultures and organotypic hippocampal cultures, some neurons accumulated cobalt during recovery from simulated ischemia. More cells were stained during bath application of kainate or glutamate. These experiments suggest that while free calcium may rise during simulated ischemia, toxic, persistent calcium entry during recovery may not be reflected by increased free intracellular calcium.

424.5

EFFECTS OF TRANSIENT CEREBRAL ISCHEMIA ON CALCIUM CALMODULIN KINASE II mRNA LEVELS IN THE GERBIL HIPPOCAMPUS. A.M. Babcock¹, J. Nollkamper¹, C.M. Paden², P.E. Micevych³ and P. Popper³. Dept. of Psychology¹ and Biology², Montana State Univ., Bozeman MT 59717; ³Dept. of Anat. & Cell Biology, UCLA Sch. of Med., Los Angeles, CA 90024.

Previous studies have reported that hippocampal calcium calmodulin kinase II (CaM II) mRNA levels decrease at 24 hrs following transient ischemic insult in the gerbil (Hiestand & Kindy, 1992). The present study attempted to confirm this finding by evaluating regional CaM II mRNA levels using *in situ* hybridization. Gerbils (n=5/group) underwent a 5-min bilateral carotid occlusion or sham procedure. At 23 hrs post surgery, locomotor activity was assessed as a behavioral marker of ischemic cell damage. Gerbils were sacrificed at 24 hrs and sections containing the hippocampus were processed for *in situ* hybridization with cRNA probes for the α and β subunits of CaM II (separate sections). As expected, ischemic gerbils exhibited higher activity levels indicative of hippocampal damage. Contrary to previous findings however, no significant differences in hippocampal CaM II mRNA levels were observed between groups. Results are discussed in relationship to observed alterations in CaM immunoreactivity and enzyme activity following ischemia.

424.7

Na⁺ SUBSTITUTION TRIGGERS ADENOSINE EFFLUX FROM RAT HIPPOCAMPAL SLICE. J.C. Fowler^{*}. Department of Physiology, Texas Tech University Health Sciences Center, Lubbock, TX 79430.

Brain ischemia results in an increase in the extracellular levels of a number of endogenous substances. It is generally considered that an ischemic related loss of electrochemical gradient results in a reversal of Na⁺-dependent uptake mechanisms and a consequent net efflux of transported substances including glutamate and adenosine. To examine the consequences of lessened Na⁺-dependent transport we investigated the effect of substituting extracellular Na⁺ with choline on extracellular levels of adenosine.

Hippocampal slices were initially superfused at 2 ml/min with physiological medium maintained at 33 - 34°C and equilibrated with 95% O₂/5% CO₂. Extracellularly recorded DC and evoked synaptic potentials were recorded. Slices were then exposed to medium in which NaCl and NaHCO₃ were replaced with the choline salts. Aliquots of superfusate were collected at 2 min intervals and adenosine was measured using absorbance HPLC.

Choline containing medium blocked synaptic transmission within a few minutes. A transient depolarization was observed between 11 - 12 minutes. Adenosine detected in the superfusate was subsequently increased. The increased adenosine but not the depolarization was prevented with the NMDA antagonist MK-801. The depolarization was not blocked by DNQX, a non-NMDA antagonist, but was blocked by the combination of DNQX and MK-801. It is concluded that diminished extracellular Na⁺ results in an increase in extracellular adenosine via activation of NMDA receptors and a depolarization via a combined activation of NMDA and non-NMDA receptors.

424.9

THE ROLE OF INTERLEUKIN-1 IN CEREBRAL ISCHAEMIA. S. Loddick and N.J. Rothwell. (SPON: Brain Research Association). Neuroscience Division, 1.124, School of biological sciences, University of Manchester, Manchester M13 9PT, U.K.

We have previously proposed a role for the cytokine interleukin-1 (IL-1) in the pathogenesis of cerebral ischaemia, since central administration of recombinant human interleukin-1 receptor antagonist (rhIL-1ra, Syngene, USA) inhibits ischaemic damage following permanent middle cerebral artery occlusion (MCAO). Also, it has been reported that administration of interleukin-1 β (IL-1 β) exacerbates damage following global ischaemia, (Minami *et al*, Soc. Neurosci., Abstr., 18 (1992) 425.5).

We determined if the neuroprotective action of IL-1ra in cerebral ischaemia is related to changes in body temperature, and investigated the effect of IL-1 β on focal ischaemia and body temperature. Core temperature (peritoneal) was measured in conscious free-moving rats by remote radio telemetry. Temperature was recorded over the 24h preceding MCAO and for the following 24h, in animals treated with either saline or IL-1ra. These data were used to calculate the change in temperature that occurred over the 24h following MCAO. Injection of IL-1ra (2 x 10 μ g, i.c.v.) 30min before and 10min after MCAO significantly inhibited (60-70%) ischaemic damage (infarct volume) measured 24h after MCAO, but had no significant effect on body temperature at any time, indicating that the neuroprotection offered by IL-1ra is not dependent on a change in core temperature.

In a separate experiment, central administration of IL-1 β (2 x 2.5ng, specific activity 200unit/ng) 30min and 2h after MCAO significantly potentiated (80-90%) ischaemic damage when compared to saline treated animals. However preliminary experiments reveal that this dose of IL-1 β caused a large (\approx 1.5 °C) increase in core temperature, which may contribute to the exacerbation of damage.

Thus IL-1ra causes a significant inhibition of ischaemic damage which is not dependent on temperature changes, and IL-1 β causes a significant exacerbation of damage though the latter effect may be dependent on changes in core temperature.

424.6

SUSTAINED INHIBITION OF EXCITATORY SYNAPTIC TRANSMISSION BY ADENOSINE DURING PROLONGED MODERATE HYPOXIA. L. Arlinghaus^{*} and K.S. Lee. Dept. of Neurological Surgery, Univ. of Virginia, Charlottesville, VA 22908.

Adenosine is a potent inhibitor of excitatory synaptic transmission at many sites in the CNS. During ischemia and hypoxia, extracellular adenosine levels increase substantially. This elevation of adenosine appears to contribute to the initial phase of the hypoxic inhibition of synaptic responses (Fowler; Brain Res. 490, 1989). The present study examined whether adenosine contributes to later phases of intra-hypoxic inhibition of synaptic responses during 1 hour of moderate hypoxia. Hippocampal slices prepared from adult Sprague-Dawley rats were submerged in medium with an oxygen tension of approximately 470 mm Hg. Field excitatory postsynaptic potentials (fEPSPs) were recorded in the stratum radiatum of CA1 in response to stimulation at the CA1/CA2 border. Hypoxic conditions were established by changing the oxygen tension in the superfusion medium to 85 mm Hg. A complete inhibition of fEPSPs was observed within approximately 9 minutes of hypoxia. An inhibitor of adenosine A1 receptors, cyclopentyltheophylline (CPT; 10 μ M) was added to the medium at various intervals after the onset of hypoxia. The addition of CPT to the hypoxic superfusion medium after the loss of synaptic responses resulted in a substantial recovery of fEPSPs, while the loss of synaptic responses remained complete for the entire hour of hypoxia in the absence of CPT. When CPT was added 10 or 30 minutes after the loss of synaptic responses, fEPSPs recovered to 68 and 47% of their prehypoxic baseline values respectively. These results indicate that adenosine-mediated inhibition contributes significantly to the sustained loss of fEPSPs during hypoxia. The findings suggest that adenosine functions to maintain excitatory synaptic transmission at low levels during prolonged moderate hypoxia and support the concept that adenosine serves as an endogenous neuroprotectant.

ACTIVATION OF ADENOSINE RECEPTORS PROTECTS NEURONS FROM ISCHEMIA INDUCED DEATH. M.L. Sweeney^{*}. Dept. of Physiology, Univ. of Saskatchewan & Sask. Stroke Research Center, Saskatoon, SK, Canada. S7H 4T3.

The neuromodulator adenosine is released from the brain in response to ischemia, and is neuroprotective in various animal models of stroke. The aim of this study was to determine whether this protective effect is mediated via a direct effect on neurons (versus an indirect action involving other cells). Primary cultures of cerebellar granule cells containing >95% neurons were exposed *in situ* to 'simulated ischemia' (substrate deprivation plus anoxia). Adenosine release was measured by HPLC, and uptake determined using [³H]adenosine; cell death was quantitated by measuring extracellular lactate dehydrogenase (LDH) concentrations.

Exposure of cerebellar neurons to simulated ischemia induced a 10 to 25-fold increase in the release of endogenous adenosine. This was seen as early as 2.5 min after the onset of ischemia, persisted for 30 min, and then dropped from 2.2 \pm 0.35 μ M to 1.3 \pm 0.28 μ M after 30 min of reperfusion with normoxic, substrate-enriched medium. Ischemia-evoked adenosine release was reduced by 25-55% by dipyrindamole suggesting the involvement of a bi-directional nucleoside carrier. After 30 min of simulated ischemia, neurons showed a reduced ability to take up [³H]adenosine, and this may have contributed to the enhanced levels of extracellular adenosine. Ischemia (30 min) also produced a 3.4-fold increase in the extracellular concentration of LDH, an intracellular enzyme. This effect was attenuated by 45% by 1mM exogenous adenosine and by 72% with 1 μ M cyclopentyladenosine, a potent agonist at adenosine A1 receptors. The effect of both agents was inhibited by an A1 antagonist, while the effect of adenosine was only slightly reduced by a blocker of adenosine uptake. These data suggest that cerebellar granule neurons release adenosine in response to an ischemic insult. Extracellular adenosine then may have a direct neuroprotective effect via the activation of A1 receptors located on neurons, and not via uptake and subsequent metabolism to ATP.

EVALUATION OF ICBF, FORSKOLIN AND D₁ DOPAMINE RECEPTOR BINDING IN A REPERFUSION MODEL OF FOCAL CEREBRAL ISCHAEMIA. G. Gartshore, D. Dawson, J. Patterson and J.M. Macrae^{*}. Wellcome Neuroscience Group, University of Glasgow, Glasgow, G61, U.K.

Reversible focal cerebral ischaemia can be induced by the ablation application of endothelin-1 (Et-1) to the exposed middle cerebral artery (MCA). Neuroanatomical changes in local cerebral blood flow (ICBF) were examined in male Sprague Dawley rats (n=12) during ischaemia and reperfusion using i.v. administered ^{99m}Tc-HMPAO at 5 min and ¹⁴C-iodoantipyrine (IAP) at 2 h post Et-1 application. Post ischaemic changes in forskolin and D1 dopamine receptor (labelled with SCH23390) binding sites were also evaluated by receptor autoradiography at the 2 h time point. ^{99m}Tc-HMPAO uptake was significantly reduced in the frontoparietal cortex (FPC), dorsolateral (DLC) and ventromedial (VMC) caudate nucleus ipsilateral to MCA occlusion 5 min post Et-1 application (to 21%, 26% and 36% of corresponding contralateral values, respectively). Reperfusion was clearly evident 2 h post-insult (ipsilateral ICBF increased by 75%, 171% and 78% respectively). In the same animals forskolin binding in the FPC, DLC and VMC was significantly reduced ipsilateral to MCA occlusion 2 h after Et-1 application whereas D1 receptor binding was unchanged (table). This combination of double CBF measurement plus receptor binding autoradiography in the same animal provides a powerful means to study the consequences of ischaemia followed by reperfusion.

	Specific Binding		Dopamine (pmoles/gm)		Forskolin (pmoles/gm)	
	IPSI	CONTRA	IPSI	CONTRA	IPSI	CONTRA
FPC	18 \pm 2	16 \pm 2	102 \pm 8*	136 \pm 9		
DLC	195 \pm 10	198 \pm 9	343 \pm 25*	385 \pm 20		
VMC	173 \pm 10	173 \pm 9	313 \pm 22*	344 \pm 16

CHANGE OF ACETYLCHOLINE IN RAT BRAIN FOLLOWING ISCHEMIA. H. Kanemitsu¹, K. Kawai¹, T. Kirino², A. Tamura¹, K. Iwasaki³ and M. Fujiwara³. ¹Department of Neurosurgery, Teikyo University School of Medicine, Tokyo, Japan. ²University of Tokyo. ³University of Fukuoka.

We have reported that the decrement of the acetylcholine level may be related to the disturbance of spatial cognition. The purpose of the present study is to determine change of the acetylcholine levels in ischemic center and periphery in rat brain tissue following focal ischemia. Male Wistar rats weighing 280-300 g were anesthetized with 2 % halothane inhalation and the proximal portion of the left middle cerebral artery (MCA) was occluded by the microsurgical technique. The animals were treated with microwave 1, 2 and 4 weeks following MCA occlusion and the acetylcholine levels of the cerebral cortex, caudate putamen and thalamus were measured by using HPLC-ED system. The acetylcholine levels of the cerebral cortex and caudate putamen on the ischemic side in the MCA-occluded group were significantly decreased compared with those in sham-operated group. However, the levels of the opposite-side and thalamus unchanged. Those decrements of acetylcholine may be caused by interception of the neurons in the Meynert nucleus and be related to the impairment of learning behavior.

424.12

CHANGES IN TYROSINE PHOSPHORYLATION IN THE RAT BRAIN DURING AND FOLLOWING HYPOGLYCEMIC COMA. J. Kurihara, B.-R. Hu, Drake M* and T. Wieloch, Lab for Exp. Brain Res., University Hospital, S 221-85 Lund, Sweden

Hypoglycemic coma in the rat was induced by insulin and the brains were frozen in situ and the subcellular fractions of the brain regions were analyzed by immunoblot and immunoprecipitation. During 30 min hypoglycemic coma, tyrosine phosphorylation of a 43 kDa protein increased. The increase was transient in the cerebral cortex and striatum, whereas persistent in the hippocampus. During recovery period following hypoglycemic coma, a general increase in phosphotyrosine was observed in all structures studied, the increase was most obvious in the crude synaptosomal fraction. In the hippocampus, a general increase in tyrosine phosphorylation was noted even at 24 hrs of recovery, although the tyrosine phosphorylation of the 43 kDa protein normalized quickly. Immunoprecipitation study confirmed that the 43 kDa protein with increased phosphotyrosine during hypoglycemic coma was MAP kinase. The increased tyrosine phosphorylation of the brain MAP kinase during and following severe hypoglycemia may be due to increased glutamate receptor activation. This may be of significant for hypoglycemic neuronal damage.

ISCHEMIA: APOPTOSIS

425.1

APOPTOSIS OF PYRAMIDAL NEURONS IN THE CA1 ZONE OF GERBIL HIPPOCAMPUS AFTER BRIEF ISCHEMIA T. Nitatori¹*, Y. Karasawa², N. Sato¹, H. Araki², E. Kominami³ and Y. Uchiyama¹. Dept. of Cell Biol. & Neuroanat.¹, Sch. of Med. Iwate Med. Univ., Morioka, 020 Japan, Lab. of Pharmacol.², Taishou Pharmaceutical Co. Ltd., Ohmiya, 330 Japan, and Dept. of Biochem.³, Sch. of Med., Juntendo Univ., Tokyo, 113 Japan

The CA1 pyramidal neurons in the hippocampus are selectively vulnerable to transient anoxic-ischemic damage. In experimental animals the CA1 pyramidal neurons undergo cell death several days after brief forebrain ischemia. It remains, however, unknown whether this delayed neuronal death is necrosis or apoptosis. We examined the degenerating process of the CA1 pyramidal neurons in gerbil hippocampus after brief ischemia. Nuclei of the CA1 neurons were nick end labeled by biotinylated dUTP mediated by terminal deoxynucleotidyl transferase 3 and 4 days after ischemic insult, but not at the prior stages. Simultaneously, dense chromatin masses appeared in nuclei of the neurons. By electrophoretic analysis, laddering of DNA occurred only in CA1 hippocampal tissues obtained 4 days after ischemic insult. The fragmented DNA in the CA1 pyramidal layer was phagocytosed by microglial cells. The results suggest that delayed death of the CA1 pyramidal neurons after brief ischemia is not necrotic but apoptotic.

425.2

VISUALIZATION OF DNA DOUBLE STRAND BREAKS IN THE GERBIL HIPPOCAMPAL CA1 FOLLOWING TRANSIENT ISCHEMIA K. Toda, S. Kihara, T. Shiraiishi*, Y. Ju and K. Tabuchi. Dept. of Neurosurgery, Saga Medical School, Saga, JAPAN 849.

In order to clarify the relationship between delayed neuronal death and apoptosis, we made an attempt to detect DNA strand breaks in the gerbil hippocampal CA1 pyramidal neurons following transient ischemia by an in situ DNA strand breaks staining. Adult male gerbils were anesthetized with 2% halothane and transient forebrain global ischemia was produced by occluding bilateral common carotid arteries for 5 min using aneurysmal clips. Hippocampal specimens were stained using Apoptag in situ apoptosis detection kit. The condensed nuclei of neurons in CA1 were occasionally seen and positively stained 3 days after ischemia. The degenerating dark neurons with condensed nuclei in CA1 markedly increased in number and were clearly stained for DNA strand breaks 5 days after ischemia, whereas normal-looking nuclei remained unstained. No neurons were stained in other hippocampal subfields and dentate gyrus. The present study strongly indicates that the CA1 pyramidal neurons following transient ischemia die through an apoptotic process.

425.3

INDUCTION AND REPAIR OF DNA DAMAGE IN NORMAL RAT NEURONS, ASTROCYTES, AND CEREBRAL ENDOTHELIAL CELLS. G.T. Gobbel, T.Y.-Y. Chan, M. Bellinzona, J.R. Fike, P.H. Gutin and P.H. Chan*. CNS Injury & Brain Edema Res. Center, Dept. Neurol., and Brain Tumor Res. Center, Dept. Neurol. Surg., Univ. of Calif., San Francisco, CA 94143

Brain ischemia can result in oxidative stress leading to the formation of free radicals. These free radicals can potentially exacerbate tissue injury by causing chemical modifications to lipids, proteins, and DNA. Damage to critical parts of the DNA molecule could lead to cellular dysfunction and further tissue injury. In the present study, we have begun to examine the sensitivity of normal brain cells to DNA damaging agents and the ability of those cells to repair damage. Neurons, astrocytes, and cerebral endothelial cells were isolated from Sprague-Dawley rats at day 15 of gestation, postnatal day 1, and postnatal day 14, respectively, plated into plastic culture dishes, and grown to confluence. The cells were exposed to radiation doses of 0, 8, 16, and 32 Gy to induce DNA double-strand breaks (DSBs) and then incubated for 0 min to 48 hrs to allow repair of the DNA damage. The number of DSBs remaining at the various time points was determined by subjecting the DNA to pulsed-field gel electrophoresis. There was a linear increase in the number of DSBs with radiation dose. There were two components to DSB repair: a fast component with half-times of repair of 10-15 min and a slower component with half-times of repair of 3-7 hrs. While there was no difference between astrocytes and endothelial cells in either the number of DSBs induced or the rates of repair, the number of DSBs induced in neurons was reduced by 7% and the rate of repair increased by 10% relative to the other cell types. Treatment of astrocytes with 0.25 mM dibutyryl cyclic AMP decreased the number of DSBs induced and significantly increased their rate of repair. These results indicate that cyclic AMP can enhance repair of DNA damage and that neurons are better able to repair DNA damage than other brain cell types. DETECTION OF DNA STRAND BREAKS IN RAT CORTICAL NEURONS EXPOSED TO FOCAL ISCHEMIA-REPERFUSION IN VIVO. C. Du, R. Hu, S. Wong, D.W. Choi, C.Y. Hsu*. Dept. of Neurology and Center for the Study of Nervous System Injury, Washington Univ. School of Medicine, St. Louis, MO 63110.

In our rat model of focal middle cerebral artery ischemia-reperfusion, coagulation necrosis occurs confined to the distribution of the artery. In the infarcted tissue, neuronal death evolves over several days after the ischemic insult. Some recent studies have suggested that neuronal DNA fragmentation may accompany focal ischemic injury, raising the issue of apoptosis. The present study was conducted to look for evidence of DNA strand breaks in our ischemia model.

Genomic DNA isolated from the ischemic cortex was subjected to non-denaturing polyacrylamide gel electrophoresis. Twenty-four and 48 hr after ischemia, DNA fragments of various sizes were seen. 3'-OH DNA ends were immunohistochemically identified in the formalin-fixed, paraffin-embedded brain slices by in situ end labeling (using terminal transferase with dUTP-digoxigenin) followed by anti-digoxigenin-peroxidase immunohistochemistry. DNA strand breaks detectable by such immunostaining was not observed in non-ischemic cortex, or in controls stained without dUTP-digoxigenin, antidigoxigenin antibody, or terminal transferase. Strong immunoreactivity was noted in the nuclear regions of injured and near normal-appearing neurons in ischemic cortex, 6 - 48 hr after the ischemic insult. The detection of DNA strand breaks by 2 different methods supports the idea that cortical neuronal death in focal ischemia may involve endonucleolytic degradation of DNA similar to that noted in several forms of apoptosis.

DNA FRAGMENTATION IS NOT AN EARLY EVENT IN ISCHEMIC NEURONAL DEATH. P. Wu* and J.N. Davis. Dept. of Neurology, SUNY at Stony Brook, Stony Brook, NY 11794-8121.

DNA fragmentation is thought to be an early, perhaps even, initial event in programmed cell death. We have been exploring the hypothesis that ischemic cell death may be a form of programmed cell death in focal and transient global ischemia in gerbils. After 5 minutes of bilateral carotid occlusion, hippocampal CA1 neurons under go a delayed death. We studied DNA using 2% agarose gels at various times after transient carotid occlusion from whole hippocampus (3 experiments), dissected CA1 (1 experiment), and punches of CA1 pyramidal cells (3 experiments). DNA from dexamethasone-treated thymocytes served as a positive control.

We did not see DNA "laddering" either at late times (48, 54, 66, 72 hours) or at earlier times (2, 4, 6, 24 hours). While this work was in progress, Okamoto *et al* (1993) reported DNA "laddering" from gerbil whole hippocampus between 54 and 96 hours after carotid occlusion. We tried to reproduce their results (2 experiments) even using their extraction technique, but were unable to confirm their findings.

We found DNA fragmentation in focal ischemia as reported by others. After permanent ligation of one carotid artery, half the gerbils sustained an infarct (as assessed by TTC staining); some also had seizures. "Stepladders" were present at 24 hours and more obvious at 48 hours, but were not present at 3 or 6 hours after ligation. In focal ischemia DNA fragmentation was a late phenomenon appearing after necrotic cell death in the infarcted area.

We conclude that DNA fragmentation does not trigger ischemic cell death as has been shown for some other forms of apoptosis. Further it appears that DNA "stepladders" can be seen as a late event in necrotic cell death. [Supported by the NIH (NS 30559) and the VA]

425.7

DNA FRAGMENTATION FOLLOWING GLOBAL ISCHEMIA IS NOT RANDOM NECROSIS J.E. Hill, A. Buchan², E. Preston, I. Rasquinha, T. Walker, J.P. MacManus¹. ¹Institute for Biological Sciences, National Research Council Canada, Ottawa, Ontario K1A 0R6, Canada and ²Ottawa Civic Hospital, Ottawa, Ontario K1Y 4E9, Canada, from the Canada/Fisons Fight Stroke program.

Previous work provided evidence for an apoptotic component in the cell death in rat brain following global ischemia produced by two-vessel occlusion (2VO) (MacManus *et al.*, *Neurosci. Lett.* 164, 89-92 (1993)). Further studies undertaken to establish a time course for the development of this damage following 12 min 2VO showed an increase in damage with increasing reperfusion time. Cell death was quantitated by two methods. Firstly, DNA was radiolabeled with dideoxyATP at a 3' OH and the labeled DNA below 10kb following gel electrophoresis was measured. Secondly, 3' OH ends were labeled *in situ* on fixed sections taken from ischemic brains to identify those cells containing fragmented DNA. A comparison of these two parameters was undertaken for the striatum. This gave a positive correlation, thereby supporting the idea that the internucleosomally cleaved DNA seen by gel electrophoresis is derived from the cells identified by *in situ* labelling and that this provides a quantitative measurement of the cell death. It was also apparent that fragmented DNA could be detected at the same time that morphological changes in the nucleus were observed.

To further confirm an apoptotic component in the death of cells following transient ischemia a comparison was made with the necrotic cell death produced by decapitation. Degraded DNA was detected as a smear after electrophoresis, not as discrete bands. A time course study showed that selectivity in the hippocampus differed from that seen following ischemia with fragmented DNA first being detected in the dentate gyrus, followed by CA1, then CA3.

Further support for an apoptotic process being activated following ischemia is provided by these results. The time course for ischemia damage determined by conventional staining techniques correlated with that for DNA cleavage and major distinctions were observed between ischemic cell death and necrotic cell death.

425.6

BCL-2 PROTECTS NEURONAL CELLS FROM HYPOXIA/REOXYGENATION INDUCED DEATH. A.N. Murphy, K.M. Myers, C.L. Miller, D.E. Bredesen¹, and G. Fiskum². Dept. of Biochem. & Molecular Bio., The George Washington Univ. Med. Ctr., Washington, D.C. 20037, and ²Dept. of Neurology, UCLA, Los Angeles, CA 90024.

The protooncogene *bcl-2* rescues cells from a wide variety of cellular insults that may induce either apoptotic or necrotic death. Recent evidence suggests that the mechanism of action of Bcl-2 involves antioxidant activity. The involvement of free-radicals in ischemia/reperfusion injury has led us to investigate the effect of Bcl-2 in this model of cytotoxicity. We have examined the survival of control and *bcl-2* transfectants of a hypothalamic cell line, GT1-7, exposed to chemical hypoxia/aglycemia (3 mM KCN, no glucose) with or without concurrent serum deprivation. After 30 min. of treatment, no loss of viability was evident in control or *bcl-2* transfectants under any conditions. However, Bcl-2 expressing cells were protected from delayed cell death measured after 24 hours of reoxygenation (KCN washout) in growth medium (DMEM+10% fetal bovine serum). Bcl-2 expressing cells incubated for 30 min. in KCN without glucose or serum were 68 ± 11% (s.e.m.) viable after 24 hours of reoxygenation, whereas control transfectants were 40 ± 9% viable compared to cells incubated for the same period in growth media. This protective effect was also evident if dialyzed serum was included in the 30 min. treatment with KCN (Bcl-2 expressors after 24 hours were 72 ± 9% and controls were 44 ± 8% viable). Serum deprivation for 30 minutes without the addition of KCN resulted in 83 ± 11% viability at 24 hours in Bcl-2 cells, and 66 ± 9% with control cells. These results indicate that Bcl-2 can protect neuronal cells from delayed death resulting from chemical hypoxia and reoxygenation. The data also indicate that cytotoxicity of hypoxia/reoxygenation is greater than death due to serum deprivation alone, suggesting either more extensive or additional mechanisms of cell injury than those elicited in response to serum deprivation. Preliminary experiments suggest that the effect of Bcl-2 may relate to alteration in mitochondrial electron transport. [Supp. by Sigma Tau S.p.A. and Souers Stroke Fund]

425.8

APOPTOSIS AND NECROSIS CONTRIBUTE TO DELAYED CELL DEATH FOLLOWING HYPOXIC-ISCHEMIC INJURY TO THE IMMATURE RAT BRAIN. E.J. Beilharz, Chris E. Williams, M. Dragunow^{*}, E.S. Sirimanne, R. Faulk^{*}, P.D. Gluckman. Research Centre for Developmental Medicine and Biology, ^{*}Department of Pharmacology, ^{*}Department of Anatomy, University of Auckland, Auckland, New Zealand.

The mechanisms leading to delayed cell death were examined in the 21 day old Wistar rat brain following either mild (15 min) or severe (60 min) unilateral hypoxic-ischemic injury. The timecourse of DNA degradation (using gel electrophoresis and *in situ* end-labelling), microglial activation (lectin histochemistry), mitochondrial failure (TTC staining), cell death (acid fuchsin staining) and c-jun expression were examined. The mild injury led to selective neuronal loss. This was associated with the development of apoptotic morphology, DNA laddering and acidophilia from 3d post-hypoxia. Prolonged expression of c-jun occurred in these neurons before death. Cell death was accelerated by the severe injury, with DNA degradation and apoptotic morphology seen at 10hr in some regions. However, in the infarcted cortex a different pattern was seen: the DNA and mitochondria remained intact, and cells basophilic, until after 10hr post-hypoxia, then widespread necrosis developed by 24hr. In contrast to regions of selective neuronal loss, DNA degradation was initially random (at 24hr), with laddering not detected until 3d. Microglial activation coincided with the onset of DNA degradation in regions of selective neuronal loss (in both models) but not infarction. The results clearly indicate that there are two distinct pathways to cell death: cortical infarction was necrotic, and occurred independently of microglial activation and apoptosis. In contrast, selective neuronal death was apoptotic and closely coupled to the microglial reaction and c-jun expression.

NEUROTOXICITY: EAA I

426.1

EFFECTS OF NMDA ANTAGONISTS ON METHAMPHETAMINE-INDUCED STRIATAL DA OVERFLOW IN RATS.

JA Clikeman and KT Finnegan^{*}. Depts of Psychiatry and Pharmacology, Univ. of Utah Sch. Med. and the VA Med. Ctr., Salt Lake City, UT 84148.

Methamphetamine (METH) damages nigrostriatal DA nerve terminals in rodent and monkey brain. Pretreatment with alpha-methyl-p-tyrosine or DA receptor antagonists protect against the toxic effects of METH, suggesting that at least one component of the neurotoxicity involves the ability of METH to increase extracellular concentrations of DA. NMDA antagonists are also capable of blocking the neuronal-damaging effects of METH, suggesting that alterations in glutamatergic neurotransmission may be involved as well. However, several of the NMDA antagonists employed (e.g., MK801, PCP) are also reported to affect DA systems, raising the possibility that a reduction in DA neurotransmission, rather than NMDA receptor blockade, underlies their neuroprotective actions. We therefore determined the abilities of two NMDA antagonists, CGS19755 and MK801, to reduce METH-induced DA release in the rat striatum using *in vivo* microdialysis, and also determined tissue levels of striatal DA in these same animals one week after drug injection. The administration of METH by itself (10 mg/kg/inj every 2 hr x 4, s.c.) caused large increases in striatal ECF DA (> 5500 %). Pretreatment with MK801 (2 mg/kg/inj every 2 hr x 4, given 30 min before METH, i.p.) did not significantly alter METH-induced DA overflow. In a similar fashion, pretreatment with CGS19755 (35 mg/kg/inj every 2 hr x 4, given 30 min before METH, i.p.) also failed to significantly alter the DA-releasing effects of METH. Nonetheless, both CGS19755 and MK801 partially prevented the DA-depleting effects of METH in rats killed one week later. The data suggest that a reduction in METH-induced DA overflow can not explain the neuroprotective actions of CGS19755 or MK801.

426.2

METHAMPHETAMINE-INDUCED DEPLETION OF GLUTAMATE-POSITIVE NEURONS IN THE SOMATOSENSORY CORTEX OF THE RAT. C. Pu and C. V. Vorhees^{*}. Children's Hospital Research Foundation, University of Cincinnati, Cincinnati, OH 45229, USA.

The neurotoxic effects of methamphetamine on dopaminergic and serotonergic terminals have been well documented. However, the neurochemical characteristics of degenerating neurons in the somatosensory cortex seen by silver staining are unknown. By using glutamate immunohistochemistry, it was found that MA exposure in adult rats (10 mg/kg given 4 times i.p. at 2 hour intervals) causes localized depletion of glutamate-positive neurons three days following treatment. The affected region is in the somatosensory cortex, covering the middle one-third portion from the longitudinal fissure to the rhinal sulcus. The depletion of glutamate-positive neurons occurred in all layers of the cortex with layers II-III showing the most pronounced effects. This pattern of depletion is consistent with that demonstrated previously with silver staining following methamphetamine, amphetamine and methylenedioxymethamphetamine (MDMA) exposures. The results indicate that MA exposure induces degeneration of glutamate neurons in the somatosensory cortex of adult rats.

426.3

TOXICITY FOLLOWING *IN VIVO* INFUSION OF ANTISENSE OLIGONUCLEOTIDE: ROLE OF THE INTER-INFUSION INTERVAL. B.J. Chiasson* and H.A. Robertson, Dept. of Pharmacology, Dalhousie Univ. Halifax, N.S., CANADA, B3H 4H7.

Activation of *c-fos* in the amygdala is observed following a single kindling stimulus to the amygdala. We have been examining the role of *c-fos* in the development of amygdala kindling using antisense technology. In these studies, animals received an infusion into the amygdala via a chronically implanted cannula either once (Group 1) or on a daily basis (Group 2) with phosphorothioate antisense (AS) or control (C) oligonucleotides. Ten hours after the infusion rats in both groups were administered a kindling stimulus in the amygdala and an electroencephalographic afterdischarge (AD) was recorded. The AS treated animals in Group 1 showed considerable attenuation of Fos-immunoreactivity when compared to the C treated animals. However, during the course of these studies we observed that subsequent to 3-4 infusions Group 2 animals (both AS and C) no longer demonstrated ADs. Upon histological examination of these animals, lesions to the amygdala and surrounding areas were observed. Reactive gliosis was demonstrated surrounding the lesion with glial fibrillary acidic protein immunoreactivity (GFAP-IR). These detrimental effects are dose related. Further studies have now revealed that the degree of histological damage can be greatly minimized by extending the period between infusions. These results suggest that certain cautions must be taken when using antisense technology and furthermore that only certain types of experimental approaches are amenable to its use. Supported by MRC Canada and the Savoy Foundation.

426.5

MODULATION OF EXCITOTOXIC DAMAGE BY INTERLEUKIN-1 (IL-1) AND IL-1 RECEPTOR ANTAGONIST (IL-1ra).

Lawrence C.B. and Rothwell N.J.* Neuroscience Division, 1.124, School of Biological Sciences, University of Manchester M13 9PT, UK.

We have previously suggested that the cytokine IL-1 is involved in ischaemic and excitotoxic brain damage, since recombinant human IL-1ra (rhIL-1ra, Synergen, USA) inhibits neurodegeneration caused by focal ischaemia or NMDA receptor activation in the brain. Neurodegeneration has been ascribed to overactivation of AMPA as well as NMDA receptors. In the present study we have therefore compared effects of rhIL-1ra and recombinant IL-1β (rIL-1β) on damage induced by infusion of an NMDA (cis-2,4-methanoglutamate, MGLU) or AMPA (S-AMPA) receptor agonist into the striatum of the rat brain. Both agonists induced reproducible lesions assessed histologically 24-48h later. Coinfusion of rhIL-1ra (5μg) with the excitatory amino acid agonist (10nmol MGLU or 15nmol S-AMPA) significantly inhibited damage (lesion volume) by 46% or 43% when induced by NMDA or AMPA receptor activation respectively. In contrast, coinfusion of rIL-1β (14pg, 100U) did not affect either form of damage (the dose of excitotoxins used were 5nmol MGLU and 10nmol S-AMPA). Additionally IL-1β did not induce neurodegeneration when infused alone. These data indicate that endogenous, but not exogenous IL-1, mediates NMDA and AMPA receptor induced neurodegeneration.

426.7

CIS-FLUPENTHIXOL PROTECTS STRIATAL CELLS FROM MALONATE-INDUCED LESIONS P. Hantraye*, M.C. Guyot, S. Palfi and E. Brouillet. CNRS URA 1285, Service Frédéric Joliot, DRIPP-DSV, 91401 Orsay Cedex and INSERM CJF 91-02, Hôpital Henri Mondor, Créteil 94010, FRANCE.

Malonate, a succinate deshydrogenase inhibitor, has been shown to produce striatal lesions resembling Huntington's disease striatal degeneration when administered directly into the striatum of adult rats (Beal et al. 1993, J. Neurochem. 61, 1147-50). This lesion is believed to be mediated via a glutamatergic (possibly NMDA) excitotoxic-like mechanism.

Dopamine is known to modulate glutamatergic transmission in the striatum through different mechanisms (modulation of glutamate release, inhibition of NMDA-induced excitatory post-synaptic potentials). The aim of the present study was to assess the potential protective effects of various dopamine antagonists on malonate-induced lesions.

Adult rats, injected intra-peritoneously (pretreatment at 30 min and post-treatment 60 min after) with either cis-flupenthixol (a mixed D1/D2 dopamine antagonist), SCH23390 (a selective D1 antagonist) or saline (control) received a single malonate injection (2μmoles into 1μl) into the left striatum. At one week survival, the cis-flupenthixol group demonstrated a significant improvement in neuronal survival. Compared to controls, cis-flupenthixol provided more than 50% neuronal protection whereas SCH23390 had no significant protective effects.

It is concluded that manipulating the dopamine neurotransmission may confer efficient neuronal protection against excitotoxic-like striatal lesions induced by transient mitochondrial energy impairment.

426.4

TAURINE RELEASE FROM SLICES OF CEREBRAL CORTEX AND BASAL GANGLIA IN TWO RAT MODELS WITH MODERATE HYPERAMMONEMIA. W. Hilgier, J. Albrecht, J.E. Olson*, Med. Res. Ctr., Pol. Acad. Sci., Warsaw, Poland, and Wright State Univ., Dayton, OH.

Hepatic encephalopathy (HE) causes brain edema and alters the brain concentration of taurine (TAU), an amino acid implicated in brain volume regulation. We used 400 μm slices of cerebral cortex and basal ganglia to investigate the mobilization of this amino acid by hypo-osmolality in animal models of HE. Moderate hyperammonemia was produced in rats (Wistar, 130-220 g) by 3 daily i.p. injections of 250 mg/kg thioacetamide, a hepatotoxin which causes cerebral edema or 600 mg/kg ammonium acetate (simple hyperammonemia - SHA). Both treatments produce brain ammonia of ~0.6 mmoles/kg (1). Control animals were injected with normal saline. Basal release rate of loaded [³H]-taurine from cerebral cortical slices (CCS) of animals injected with TAA was 130±4% (mean±SEM) of the rate measured in control animals. Superfusion with hyposmolar (HYPO) medium (NaCl reduced from 150 mM to 40 mM) increased [³H]-taurine release from CCS of control and TAA rats by 12%. TAA injections did not alter basal or HYPO-induced [³H]-taurine release from slices of basal ganglia, a structure which does not develop edema in this animal model (1). These results are consistent with the osmoregulatory function of taurine in TAA-induced brain edema. SHA decreased both basal and HYPO-induced [³H]-taurine release in CCS. However, in this model of hyperammonemia, no edema or change in taurine content occurs in this brain region (1).

SELECTIVE VULNERABILITY OF HIPPOCAMPAL CELL FIELDS TO NEUROLOGICAL INSULTS. O.A. Ajilore, B.A. Stein-Behrens*, and R.M. Sapolsky. Dept. of BioSciences, Stanford Univ., Stanford, CA 94305

The hippocampus is a region of the brain that is particularly vulnerable to various neurological insults. Selective vulnerability occurs within the hippocampus as well. Three specific regions, CA1, CA3, and dentate gyrus, are preferentially damaged by hypoxia-ischemia, excitotoxicity and hypoglycemia, respectively. These neurological insults have an energetic component that plays an important role in neuron death. To further characterize and understand the issue of selective vulnerability in the rat hippocampus, we measured metabolic function in regions of the hippocampus during neurological insults using a device called the microphysiometer. The microphysiometer measures the acidification rate in cells in real time as an indicator of metabolic function. The acidification rate refers to the decrease in extracellular pH due to the accumulation of the acidic metabolites of ATP hydrolysis. By detecting this pH change, the microphysiometer provides a sensitive measure of cellular metabolism. Previous neurological studies have used the microphysiometer to study metabolic changes in primary fetal models, in which it was not possible to study selective vulnerability in different cell fields. In this project, we have adapted the device for use with hippocampal slices, which allows for the monitoring of the metabolic effects of specific insults on isolated cell fields with a high degree of temporal resolution. 400 μm-thick slices were generated in a standard manner and each cell field was dissected under a microscope and placed in a separate microphysiometer sensor chamber. With this method, we obtained stable metabolic rate measurements from different hippocampal cell fields using a variety of media. We also observed a dose-dependent increase in metabolic rate induced by kainic acid in CA3-derived tissue. Selective responsiveness to kainic acid was also demonstrated in that kainic acid failed to elevate metabolism in CA1-derived tissue. These studies suggest that the microphysiometer is sensitive enough for the study of selective vulnerability in the hippocampus.

DIFFERENT RESPONSES TO N-METHYL-D-ASPARTATE AND KAINIC ACID IN CEREBELLAR GRANULAR CELLS OF LEAD-EXPOSED PUPS. D.K. Lim, T. Ito¹ and I.K. Ho² ¹College of Pharmacy, Chonnam National University, Kwang-Ju, 500-757 Korea and ²Dept of Pharmacology and Toxicology, Univ. Miss. Med. Ctr., Jackson, MS 39216 USA.

To determine changes in response to N-methyl-D-aspartate (NMDA) and kainic acid (KA) in cerebellar granular cell of offspring of lead-exposed mothers, pregnant rats received 0.25% lead acetate in the drinking water 2 days after gestation. The control group was given sodium acetate (0.125%) in drinking water. The cerebellar granular cells were cultured from 7 or 8 day old pups. Changes in the levels of cytosolic Ca⁺⁺ and cGMP and the release of glutamic acid were measured using fura-2 spectrofluorometer, radioimmunoassay and HPLC, respectively. Increases in cytosolic Ca⁺⁺ were less responsive (77%) to 50 μM of NMDA and KA in the lead exposed group as compared to that of the control group. However, the maximum responses to KA were not different. The NMDA-induced elevation of cGMP was not affected in the lead exposed pups. However, the degree of KA-induced increase in cGMP level in cerebellar granular cells of lead exposed pups was significantly reduced. The increases in cGMP level in lead exposed pups were 55.5 and 51.4% of the control groups when the incubations were carried out for 3 min and one hour, respectively. The NMDA- and KA-stimulated release of glutamate from cerebellar granular cells prepared from lead exposed pups was also significantly reduced. These results indicate that lead exposure to the mother might affect the excitatory amino acid systems during the development of the offspring.

PERINATAL HYPOXIC INSULT DIMINISHES NEUROTOXICITY OF 3-NITROPROPIONIC ACID (3-NPA) IN ADULT RATS. Z. Binienda*, S.F. Ali, C.M. Fogle, W. Slikker, Jr., M.G. Paule and S.A. Ferguson. NCTR/FDA, Jefferson, AR 72079-9502.

The effects of a mitochondrial toxin 3-NPA on operant performance, dopamine (DA), serotonin and their metabolite concentrations in selected brain regions were studied in adult male Sprague-Dawley rats. Rats were delivered by cesarean section as either noninsulted (NI) or insulted (I) with hypoxia. Hypoxia was produced by submerging dissected uterine horns in saline for 15 min. NI rats were siblings of the I rats delivered from the adjacent nonsubmerged horns. Rats were cross-fostered and behaviorally assessed. At 1 year of age, NI and I rats were injected with 3-NPA at 5 mg/kg/day (Monday-Friday). The dose was increased by 5 mg weekly up to 30 mg/kg/day. After sacrifice at the end of 3-NPA treatment, brains were dissected, weighed and analyzed for neurochemistry. Operant measures significantly decreased with increasing 3-NPA doses but were not differentially affected by hypoxia. Ataxia at the highest dose of 3-NPA was observed only in NI rats (3/9 rats). A trend toward a DA concentration increase in frontal cortex was seen in both I and NI groups. While weights of brain regions in the control and 3-NPA treated I rats were similar, cerebellar weight in NI rats after 3-NPA treatment was reduced (ANOVA, $p < 0.001$). Thus, perinatal hypoxic insult may decrease subsequent sensitivity to the toxic effect of 3-NPA.

426.11

L-CHLOROPROPIONIC ACID NEUROTOXICITY INVOLVES A SUBTYPE OF N-METHYL-D-ASPARTATE RECEPTOR. E.A. Lock, I. Wyatt, M.G. Simpson, M. Lo* and P.S. Widdowson. Zeneca Central Toxicology Laboratory, Macclesfield, UK and Zeneca Inc, Wilmington, DE19897, USA.

Systemically administered L-chloropropionic acid (CPA) produces selective damage to cerebellar granule cells. We investigated whether CPA may produce the granule cell damage by acting at a subtype of the N-methyl-D-aspartate (NMDA) receptor. Groups of rats were treated with CPA (750 mg/kg/po). Some animals received the irreversible NMDA antagonist, MK-801 alone (5mg/kg/i.p.), saline or CPA plus MK-801. The neurotoxicity was assessed at days 3 and 5 of the study. Animals which received CPA alone showed marked locomotor retardation which became very severe by days 3 and 4. These animals showed marked weight loss (~22% of controls) and were terminated at days 3 and 4 of the study. In contrast, CPA and MK-801 treated animals although showing a small weight loss early on in the study did not show abnormal locomotor activity by days 2 to 5. Neuropathological examination of the brains from CPA-treated rats showed a marked (80-90%) loss in cerebellar granule cells by day 3 and 4 of the study. The co-administration of MK-801 with CPA was able to completely prevent damage to the cerebellum. MK-801 was also able to prevent the CPA-induced loss of NMDA receptors in the granular layer of the cerebellar cortex and concentrations of aspartate and glutamate in cerebellum. Finally there was a complete prevention of the CPA-induced cerebellar edema by MK-801. In conclusion we suggest that CPA is neurotoxic to rat cerebellum because this brain region contains a subtype of NMDA receptor with unique pharmacology and regulation.

ANTI-PHENYCLIDINE MONOCLONAL FAB FRAGMENTS DRAMATICALLY DECREASE PHENCYCLIDINE (PCP) NEUROTOXICITY IN SPRAGUE-DAWLEY (SD) RATS. J.L. Valentine, W.D. Wessinger and S.M. Owens*. Dept. of Pharmacology & Toxicology, Univ. of Ark. for Med. Sci., Little Rock, AR 72205.

High affinity ($K_d = 1.8$ nM) anti-PCP monoclonal Fab fragments were used to reverse *in vivo* PCP-induced behavioral toxicity. For these studies, male SD rats ($n=4$ per group) were administered four treatments in random crossover design. 1) An i.v. dose of 1.0 ml/kg saline vehicle, followed 5 min later by 1.0 ml saline (Saline-saline, negative control). All others received a behaviorally active dose of PCP (1.0 mg/kg) followed 5 min later (as toxicity began to maximize) with 2) saline (PCP-saline, positive control). 3) anti-PCP Fab (PCP-anti-PCP Fab) at 0.3, 1.0 and 3.0 times the PCP molar dose, and 4) nonspecific polyclonal human Fab (PCP-nonspecific Fab) at the same doses as the anti-PCP Fab. To assess PCP and treatment effects, locomotor activity was determined over 2-min intervals for a 60-min period on an Automex 2SD activity monitor. Baseline activity counts were monitored for 10 min prior to saline or PCP administration. Saline-saline injections resulted in relatively low background counts (0-25 counts per 2-min interval). PCP-saline injections caused extreme hyperactivity as determined by a maximum response of approximately 150 counts/2 min and a duration of 39 ± 7 min. When analyzed as a percentage of the total PCP-saline response, none of the nonspecific human Fab treatments or the 0.3 M anti-PCP Fab had a statistically significant effect on locomotor activity. However, 1.0 M and 3.0 M anti-PCP Fab significantly attenuated locomotor activity to approximately 20-30% of PCP-saline controls and the PCP-nonspecific Fab (ANOVA followed by Newman-Keuls, $p < .05$). The duration of PCP-induced effects measured from the time of Fab treatment was reduced from 34 ± 7 min to 13 ± 4 min after the 1.0 M and 3.0 M anti-PCP Fab treatments. These data show that anti-PCP Fab dramatically reverses PCP-induced toxicity. (Supported by NIDA grants DA 07610, DA 05474, and DA 00110.)

HU-211, A NON-PSYCHOTROPIC CANNABINOID AS A NOVEL NEUROPROTECTANT AGENT. N. Eshhar*, S. Striem, V. Nadler and A. Bieganski. Pharmos Corp., Kiryat Weizmann, Rehovot 76326, Israel.

Accumulation of evidence suggests that multiple processes lead to neuronal death following cerebral ischemia. These are associated with excessive activation of excitatory amino acid receptors and involve the generation of free radicals from different sources. Previous studies have demonstrated the ability of HU-211, a synthetic non-psychotropic cannabinoid, and a non competitive NMDA receptor antagonist to protect cortical neurons from damage mediated via the NMDA preferring glutamate receptors. The current study was designed to explore potential protective effects of HU-211 on neuronal degeneration following anoxia or exposure to the nitric oxide (NO) donor sodium nitroprusside (SNP) in culture. Primary cerebral cortical cell cultures were prepared from 18-20 day old fetal rats and consisted of neurons plated over a confluent glial-cell feeder layer. Toxicity experiments were performed with cells at 10 days in culture and cell viability was evaluated by morphological criteria following neuron specific enolase immunostaining and assessed quantitatively by measuring the extent of mitochondrial activity in the cells. Subjection of cultures to 1 hour deprivation of oxygen and glucose was associated with neuronal cell injury that was markedly reduced by 10 μ M HU-211 or by 30 μ M MK-801 when present during or following anoxia. By contrast, exposure of cells to SNP resulted in a massive glial and neuronal cell damage which was attenuated by the addition of 10 μ M HU-211, while not affected by the presence of 30 μ M MK-801. In conclusion, HU-211 can protect neurons from damage associated with multiple biochemical pathways, probably via more than one mechanism of action. The broad spectrum neuroprotective activity of HU-211 suggests the use of the compound for preventing ischemia-related neuronal damage in which excitatory amino acid receptors and NO have been shown to play major roles.

DODECYLGLYCEROL PROVIDES PARTIAL PROTECTION AGAINST GLUTAMATE TOXICITY IN NEURONAL CULTURES DERIVED FROM DIFFERENT REGIONS OF EMBRYONIC RAT BRAIN. J.R. Dave*, E.C. Tortella, E. Fasnacht, B.P. Doctor and H.S. Ved. Divisions of Neuropsychiatry and Biochemistry, Walter Reed Army Institute of Research, Washington, DC 20307-5100.

Earlier studies have demonstrated that similar to platelet activating factor (PAF), a structurally related glycerol ether lipid void of platelet aggregating activity, dodecylglycerol (DDG), stimulates neuronal differentiation in primary cultures via a pathway involving activation of the *c-fos* gene. The objective of the present study was to determine if DDG treatment provided protection against glutamate-mediated neurotoxicity in neuronal cells. Primary cultures enriched in neurons dissociated from embryonic rat cerebral cortex, hippocampus and cerebellum were treated in a serum-free media with either vehicle, DDG (3 μ M), glutamate (75 μ M) or DDG and glutamate together for 24 hr and their morphological and biochemical [lactate dehydrogenase (LDH) released in the culture media] assessments were made. The neuronal differentiating effects of DDG, and neurotoxic effects of glutamate, were maximum in neurons from the cerebellum and minimum in neurons from the cortex. Co-treatment of cells with DDG and glutamate failed to provide significant neuronal protection against glutamate in all the three brain regions. However, pretreatment of cells with DDG for 4 or 24 hr prior to glutamate treatment provided significant neuroprotection as judged by morphological changes and a decrease in LDH activity in the culture media. A neuroprotection of approximately 15-35% was observed following 4 hr DDG pretreatment and approximately 60-85% protection was observed after 24 hr DDG pretreatment. Although the mechanism of DDG's neuroprotective action remains to be elucidated these results demonstrate that both glutamate and DDG have differential specificity for anatomical regions of the brain.

MEASUREMENT OF NITRIC OXIDE FORMATION BY DICHLOROFLUORESCIN IN NEURONAL CELLS. P.G. Gunasekar, A.G. Kanthasamy*, J.L. Borowitz and G.E. Isom. Dept. of Pharmacology & Toxicology, Purdue Univ., W. Lafayette IN 47907-1334.

A simple and rapid spectrofluorometric assay of intracellular nitric oxide (NO) formation was developed for use in cultured neuronal cells. The technique was first studied in a cell free system using the non-fluorescent probe 2,7-dichlorofluorescein which is oxidized to a fluorescent product, dichlorofluorescein (DCF) upon addition of the strong oxidant NO. The fluorescent signal was significantly increased over 10 min period and the effect was dependent upon the concentration NO added. In DCF loaded PC12 cells, addition of NO markedly increased the fluorescence. However, pretreatment with hemoglobin (Hb) inhibited the NO mediated increase of fluorescence in both cell free and PC12 models. Similar trends were observed with the NO generator sodium nitroprusside (SNP) in the cell free system and PC12 cells. To rule out the possibility that reactive oxygen species (ROS) mediated the increased fluorescent signal, superoxide dismutase (SOD) and catalase were added. Neither enzyme blocked the fluorescent signal generated by NO in PC12 cells. To determine if NO is generated in response to glutamate, 10 μ M glutamate was added to DCF loaded cerebellar granule cells, a rapid raise of fluorescent signal was noted. However, the increase of fluorescent by glutamate was blocked 50% after addition of Hb or SOD or by following pretreatment with L-NAME (300 μ M). It was concluded that glutamate generated intracellularly both NO and ROS and at least 50% of the oxidation of DCF is attributed to NO. These results indicate that the oxidation of DCF by NO can be used to measure its intracellular generation on a real time basis and by using Hb and SOD pretreatments, the extent of oxidation of DCF attributed to NO and ROS can be determined. (Supported in part by NIH grant ES04140)

18 α -GLYCYRRHETINIC ACID (GA) BLOCKS KAINIC ACID-INDUCED SEIZURES AND NEUROTOXICITY. Diane M. Hayden-Hixson¹*, Carl Monder², and Rochelle D. Schwartz¹.
¹Dept. Pharmacology, Duke University Med. Center, Durham, NC 27710; ²Population Council, New York, NY 10021.

The overall objective of this study was to determine the effects of 18 α - and 18 β -glycyrrhetic acid (GA), potent inhibitors of adrenal and gonadal steroid metabolism, on kainic acid excitotoxicity. Nonanesthetized, adrenalectomized, male Wistar rats (N=8/group) received intracerebroventricular injections of either kainate (940 pmol) or GA (300 pmol) plus kainate (GA+KA). Rats treated with 18 α -GA had a lower incidence of seizures (0 vs 71%) and significantly reduced necrosis in the endopiriform nucleus, amygdalohippocampal area, basal, medial, central, and lateral nuclei of the amygdala, dentate gyrus, CA3/CA4 of the hippocampus, midline nuclei of the thalamus, lateral septum, and premammillary hypothalamus compared to rats treated with kainate alone. Preliminary data indicate that the 18 β -isomer is not neuroprotective. In fact 100% of the rats treated with 18 β -GA+KA had behavioral seizures and extensive damage in the amygdala, thalamus, and neocortex. Biochemical analyses indicated that neither 18 α -GA or kainate inhibited 11 β -hydroxysteroid dehydrogenase at the doses used in this study. We conclude 18 α - and 18 β -GA have differential effects on kainate excitotoxicity when administered directly into the brain. This work was supported by NIH grant ES07031.

THE ROLE OF EXCITOTOXIC GLUTATHIONE-DERIVED METABOLITE(S) IN ETHYL CHLORIDE-INDUCED HYPERACTIVITY IN MICE. R.S. Bitner, G.E. Isom and G.K.W. Yim*. Dept. of Pharmacology and Toxicology, Purdue University, West Lafayette, IN 47907.

Pottenger and co-workers (1991) demonstrated that mice displayed a glutathione (GSH)-dependent, hyperactive syndrome within 20-30 min of exposure to high concentrations of ethyl chloride (Et-Cl) (15,000 ppm). The hyperactivity resembled the wild running seizures observed in mice following i.c.v. glutamate or NMDA. To test the possibility that excitotoxic metabolites were responsible for Et-Cl-induced hyperactivity, known and potential GSH-derived metabolites of Et-Cl were examined for excitotoxic properties. S-carboxymethylcysteine (CMC) and cysteine (Cys), but not S-ethylcysteine (SEC), injected i.c.v. (3.2 μ mol) caused immediate wild running seizures in mice. 5-days later, brain sections taken from CMC- and Cys-treated mice showed selective CA1 and wide spread hippocampal damage, respectively. However, seizures caused by CMC or Cys were not blocked by MK-801 or CNQX. Systemic administration of a high dose of SEC (1 gm/kg i.p.) did not cause delayed seizures as might be expected if the cysteine conjugate were metabolized to CMC or Cys. S-ethyl-GSH (SEG) injected i.c.v. (3 μ mol) failed to cause wild running seizures, indicating that it did not share the NMDA agonist properties of GSH (Leslie et al., 1992). Mice depleted of brain GSH using buthionine sulfoximine (3 mg i.c.v.) also failed to display wild running seizures following i.c.v. administration of SEG. Thus, the results obtained with these known and potential (CMC and Cys) metabolites do not support the possibility that the neurotoxic actions of Et-Cl are due to formation of excitotoxic GSH-derived metabolites.

HISTAMINE-INDUCED NEUROTOXICITY IN THE RAT MIDBRAIN. K.K. Thoburn, H.H. Molinari and L. B. Hough*. Dept. of Pharmacology and Toxicology, Albany Medical College, Albany, NY 12208.

Several findings suggest that endogenous histamine (HA) may enhance glutamate-NMDA mediated brain excitotoxic mechanisms (Bekkers, *Science*, 47:118-120, 1993; Vorobjev, et al., *Neuron*, 11:837-844, 1993) and participate in thiamine deficiency-induced brain damage (Onodera et al., *Agents & Actions*, 27:120-122, 1989; Langlais et al., *J. Neurosci. Res.*, 1994, in press). Nevertheless, neurotoxicity produced by HA in normal animals has not been directly demonstrated. To test this hypothesis, a detailed, light-microscopic histopathological study was performed. Rats received intracerebral HA via chronically implanted guide cannulae aimed at the ventral lateral border of the periaqueductal grey. Following predetermined intervals, animals were perfusion-fixed and brain sections were stained with cresyl violet. Three days after injection of 100 μ g of HA, large areas within the midbrain showed a marked proliferation of glial cells (mean rostro-caudal extent = 1250 \pm 152 μ m). Injection of 30 and 3 μ g of HA induced proportionately smaller areas of gliosis. A dose of 0.3 μ g produced no detectable effects. Control injections of isotonic or hypertonic saline also induced little or no pathological changes. At shorter survival times (24 or 48 hr), 100 μ g of HA induced a clear loss of neurons, commensurate with a neurotoxic response. These findings show that HA can cause lesions in the central nervous system and support the hypothesis that endogenous HA may function as a mediator of neuropathological processes (Supported by DA-03816 and NS-29771).

KAINATE-ENHANCED HYPOXIC NEURONAL DAMAGE IN VITRO IS BLOCKED BY MK-801 AND GYKI-52466 BUT NOT BY APV.

A. Schurr, R.S. Payne and B.M. Rigor*. Dept. of Anesthesiology, University of Louisville, School of Medicine, Louisville, KY 40292.

We have shown recently that hypoxic neuronal damage in rat hippocampal slices can be enhanced by various excitotoxins, an enhancement that can be blocked by specific antagonists of these excitotoxins. Thus, dizocilpine (MK-801), 2-amino-5-phosphonopentanoate (APV) and 7-chlorokynurenic acid (7-Cl-KYN) antagonized the enhancement of hypoxic neuronal damage by NMDA, while 2,3-dihydroxy-quinoxaline (DHQX) and to a lesser degree, kynurenic acid (KYN), blocked such enhancement by kainate (KA) and (R,S)- α -amino-3-hydroxy-5-methyl-4-isoxazole-propionate (AMPA). APV was ineffective in blocking the enhancement of hypoxic neuronal damage by KA or AMPA, while DHQX was unable to block an NMDA-enhanced damage.

The rat hippocampal slice preparation and electrophysiological measurements were used in the present study as described elsewhere. We compared the abilities of MK-801, a noncompetitive NMDA receptor antagonist, and amino-phenyl-2,3-benzodiazepine (GYKI 52466) a specific KA receptor antagonist, to block KA-enhanced hypoxic neuronal damage. When hippocampal slices were exposed to 12-min hypoxia, 72% recovered their neuronal function following a 30-min recovery period. Inclusion of 2.5 μ M KA in the perfusion medium 30 min before and during the hypoxic period reduced the recovery rate of neuronal function to 7%. This KA-enhanced hypoxic neuronal damage was blocked in a dose dependent manner by GYKI-52466, where 200 μ M of the drug completely abolished the effect of KA. As expected, APV (100 μ M) was unable to antagonize the effect of KA (18% recovery rate). However, MK-801 (20 μ M), completely reversed the effect of KA (87% recovery rate). Preliminary results also indicate that MK-801 antagonizes the enhancement of hypoxic neuronal damage by AMPA.

The ability of MK-801 to protect neuronal tissue against both hypoxic and excitotoxic damage, cannot be explained by its NMDA receptor antagonism alone but rather by a separate and distinct mechanism, yet to be elucidated.

426.18

GLUTAMATE-INDUCED CYTOTOXICITY OF A HUMAN NEUROBLASTOMA CELL-LINE THROUGH ACTIVATION OF NMDA RECEPTORS. W. G. North*, M. J. Fay, M. Cleary, J. Gallagher, and F. McCann. Depts. of Physiology and Anesthesiology, Dartmouth Medical School, Lebanon, NH 03756.

The neutral red cytotoxicity assay was used on human LA-N-2 neuroblastoma cells to determine the effects of a 48 hour incubation with L-glutamate (0, 1, 10 mM), and with the specific NMDA agonist N-phthalyl glutamate (1 mM). The results indicate that 1 mM and 10 mM glutamate caused a 27% and 37% decrease, while N-phthalyl-glutamate exhibited a 46% decrease, in neutral red uptake. Compared to non-treated controls, the glutamate and N-phthalyl-glutamate (NPG) treated cells exhibited classic signs of toxicity, including, clumping of chromatin, the appearance of vacuoles, and cell swelling and lysis. The possible mechanism of this toxic effect was further evaluated using the whole cell configuration of the patch clamp technique, and the specific NMDA agonists NPG and (+)-1-aminocyclobutane-cis-1,3-dicarboxylic acid (ACDA). Addition of 1 mM NPG or ACDA for 5 min, resulted in an increased inward sodium current as compared to non-treated controls. These studies indicate that the toxicity of glutamate observed in the LA-N-2 human neuroblastoma cell line is due, at least in part, to the activation of NMDA receptors.

426.20

KAINATE NEUROTOXICITY IN VIVO IS GREATLY AMPLIFIED BY IMPAIRED SODIUM PUMP CAPACITY. A. O. Dare, N. C. de Lanerolle, S. Kapadia*, and M. L. Brines. Neuroendocrine Program and Section of Neurosurgery, Yale School of Medicine, New Haven, CT 06510.

Many adult neurons exhibit excitotoxicity in which death is caused by excessive transmembrane ion fluxes. Since the sodium pump (Na-pump) directly or indirectly rectifies these disturbances, we hypothesized that reduced or impaired Na-pump capacity will poorly rectify ionic disturbances and amplify the toxic potential of excitatory agents. Results of our prior work indicates that direct impairment of pump capacity in vitro markedly sensitizes neurons to glutamate. However, this model is fetal in origin and findings may not apply to adult cells. We now extend this work to adult cells in vivo, using the rat kainate-induced seizure model in which widespread excitotoxic damage occurs in the limbic system. Na-pump function of the $\alpha 2$ and $\alpha 3$ isoforms was inhibited by the cardiac glycoside ouabain given ICV to attain a final concentration of ~ 1 μ M. This dose decreased high affinity sodium pump sites by $\sim 50\%$ (assessed by quantitative autoradiography) and when given alone, produced a stereotyped pattern of extreme motor activity, followed by a brief period of hypotonia. In spite of marked motor activity, no hippocampal neuronal damage was observed, as assessed by silver staining. Although low-dose kainate (4-6mg/kg IP) was not associated with seizures or neuronal damage, when given with ouabain it produced marked epileptiform activity and neuronal death. However, unlike high dose kainate, virtually no animal mortality was observed. Delaying administration of ouabain predictably increased the latency of seizures, consistent with a primary role for ouabain in potentiating kainate. EEG recording revealed that although ouabain initially diminishes cortical activity, it later amplifies spike activity associated with lower doses of kainate. Neuronal damage under this protocol was more extensive than for kainate alone and included the CA1 subfield of the dorsal hippocampus. Treated animals subsequently suffered spontaneous seizures and also exhibited remodeling of the inner molecular layer, as assessed by Timm staining. These studies demonstrate the critical importance of the sodium pump for the survival of adult neurons after stimulation by potential excitotoxins.

427.1

EXCITOTOXIC LESIONS OF RAT STRIATUM EXACERBATE METHAMPHETAMINE-INDUCED DECREASES IN MAZINDOL-LABELED DOPAMINE UPTAKE SITES. A.J. Eisch* and J.E. Marshall. Dept. of Psychobiology, University of California, Irvine, CA 92717-4550.

Repeated systemic injections of methamphetamine (m-AMPH) produce significant damage to dopaminergic terminals in the rat striatum as shown by decreases in dopamine content and [3H]mazindol-labeled dopamine uptake sites. Previous work from this laboratory has demonstrated that a unilateral infusion of the excitotoxin quinolinic acid (QA) prior to m-AMPH treatment protects the infused striata from m-AMPH-induced decreases in dopamine content (O'Dell et al., *J. Pharm. Exp. Ther.*, in press). Here, we extend the characterization of the effect of striatal QA lesions in the m-AMPH-treated rat by utilizing quantitative autoradiography of striatal dopamine uptake sites. One week after administration of m-AMPH, and three weeks after receiving unilateral striatal QA, the density of [3H]mazindol-labeled dopamine uptake sites in the QA-infused hemisphere of m-AMPH-treated rats was less than that in the non-infused hemisphere. This finding suggests an important dissociation between measures of dopamine content and dopamine uptake sites in the QA-infused striata of m-AMPH-treated rats. Ongoing studies will address whether the uncoupling of these measures of dopamine terminal integrity may be attributed to QA-induced alterations in dopaminergic metabolism.

CHRONIC CORTICO-STRIATAL GLUTAMATERGIC ACTIVATION INDUCES A SLOWLY PROGRESSING STRIATAL LESION T. To, B. Anton, C.J. Evans, and N.T. Maidment*. Dept. of Psychiatry & Biobehavioral Sciences, University of California, Los Angeles, CA 90024.

Current excitotoxic models of Huntington's Disease involve exogenous injection of glutamate analogues to induce selective neuronal loss in the striatum. A major limitation of this approach is the very rapid progression (1-2 days) of striatal neuronal loss which impairs temporal and spatial analysis of the specific patterns of neurodegeneration. We have attempted to develop a more subtle and slowly progressing striatal lesion that reflects the anatomical and neurochemical patterns of cell death seen in HD. Our experimental approach employs a regime of repeated (three times a day) unilateral electrical stimulation (unipolar anodic square wave pulses, 1mA amplitude, 30 s trains, 60 Hz within the train, 30 s between trains for a total stimulation period of 15 min) of the cortico-striatal excitatory pathway with the aim of chronically elevating the synaptic concentration of endogenous excitatory amino acids in the striatum. Microdialysis experiments showed significant increases (two-fold) of extracellular glutamate in the striatum which remained elevated at least 2 hr after electrical stimulation. This stimulation paradigm was used for 2 weeks, 1 month, or 2 months to assess the morphological and neurochemical effects of repeatedly elevated striatal glutamate release on specific neuronal systems within the striatum. Astrocytes (labelled by GFAP staining) were increased both in size and number, this effect being evident at 2 weeks but more pronounced at 1 month and 2 months. Immunohistochemistry for the specific GABA neuronal marker GAD67 revealed significant decreases in staining at the cell body and fiber level. This model may permit future investigations into both the identification of mechanisms involved in the progression of HD and the plastic changes taking place in the striatum during this degenerative process.

PRECONDITIONING DOES NOT PROVIDE CEREBROPROTECTION FROM INTRASTRIATAL INJECTIONS OF AMPA OR NMDA. J.M. Gidday, J.C. Fitzgibbons, A.R. Shah, J.H. Thurston, T.S. Park, and J.W. McDonald. Department of Neurology and Neurological Surgery, and Center for the Study of Nervous System Injury, Washington University School of Medicine, St. Louis, MO 63110.

Recently, we were able to confer cerebroprotection from hypoxic-ischemic injury in the neonatal rat with a prior exposure to sublethal hypoxia, called preconditioning (*Neurosci. Lett.* 168:221, 1994). Using this model, we sought to determine the extent to which preconditioning would prove neuroprotective against direct injections of NMDA or AMPA. 10 litters of 6-day-old rat pups were divided; half were preconditioned with 3 h of 8% oxygen, while the rest were placed in normothermic control chambers. 24 h later, each pup was anesthetized with diethyl ether, and received a stereotaxic microinjection (0.5ul) of either AMPA (10 nM) or NMDA (10 nM) into the right striatum 2.5 mm lateral to bregma, and 3.75 mm deep. Pups recovered in an incubator for 45-60 min, then were returned to the dam. Injury analyses on day 14 revealed that preconditioned animals injected with AMPA (n=28) exhibited a 14.9±1.5% difference in hemispheric weights, which did not differ significantly from injury in non-preconditioned animals (15.3±2.1%; n=23, p>0.8, unpaired t-test). Preconditioning also failed to be protective in NMDA-injected brains (n=27), yielding a hemispheric deficit of 12.0±1.3%, compared to 12.9±1.2% in non-preconditioned animals (n=25, p>0.6). These results suggest preconditioning cerebroprotection may involve events proximal to glutamate receptor activation rather than subsequent to its release.

KAINIC ACID INDUCED DNA DAMAGE IS ASSOCIATED WITH A UNIQUE IMMEDIATE-EARLY GENE RESPONSE IN c-fos-lacZ TRANSGENIC RATS. G. M. Kasof*, A. Mandelzys, T. Curran, and J. I. Morgan. Roche Institute of Molecular Biology, Roche Research Center, Nutley, NJ 07710.

To discriminate between events that are products of seizures elicited by kainic acid (KA) and those that are specifically associated with its excitotoxic properties, we have examined the expression of cellular immediate-early genes (cIEGs) following KA or pentylenetetrazole (PTZ) treatment. While both chemoconvulsants elicit seizures, only KA leads to neuronal damage as determined by the TUNEL (terminal transferase biotinylated-UTP nick end labeling) procedure. In order to unambiguously follow the expression of one of the prototypic cIEGs, c-fos, transgenic rats were generated that produce a Fos-lacZ fusion protein. Fos-lacZ was induced by either KA or PTZ; however, its expression was more protracted following KA. In addition, within 6 hours following KA treatment, Fos-lacZ expression appeared in the cytoplasm of neurons that were destined to die 1-2 days later, a situation never observed following PTZ. Examination of other basic zipper genes, revealed a unique immediate early response following KA. These features included: the expression of *fos-1* and *fos-2* in KA treated animals; protracted and differential expression of several cIEGs; and a biphasic elevation of c-fos and *junB* in which the first peak was correlated with the initial seizure and then the second peak occurring just prior to the onset of cell death. These changes in cIEG expression were correlated with sustained increases in AP-1-like DNA binding activity in the hippocampus of KA treated rats. These features of the KA induced cIEG response suggest that there are unique AP-1 complexes that could have a critical role in leading to, or counteracting, neuronal death.

QUINOLINIC ACID IMMUNOHISTOCHEMISTRY OF NEUROBLASTOMAS AND GLIOMAS OF THE RAT BRAIN. J.R. Moffett*, M.G. Espey, T. Els*, E. Dux*, and M.A. Nambodiri. Georgetown Univ. Bio. Dept. Wash. DC 20057, *Max-Planck-Institute für Neurologische Forschung, 50866 Köln (Lindenthal).

Tumors of the central nervous system (CNS) were investigated with antibodies to quinolinic acid (QUIN), an endogenous neurotoxin produced by cells of the immune system. In advanced F98 glioblastomas and E367 neuroblastomas produced by inoculation in the striatum of rats, quinolinic acid immunoreactive (QUIN-IR) cells were observed almost exclusively within the tumors. The immunoreactive cells were round, rod-shaped or complex in morphology. No consistent differences were observed in the number, morphology or distribution of immunoreactive cells between gliomas and neuroblastomas, but more advanced tumors of both type had significantly higher numbers of stained cells. No QUIN-IR cells were observed in the contralateral hemisphere. Glial fibrillary acid protein (GFAP) immunoreactivity was strongly elevated in astrocytes in the compressed tissue surrounding the tumors, and in the contralateral corpus callosum. Immunohistochemistry with the monoclonal antibody ED1, directed against rat monocytes and macrophages, demonstrated that numerous mononuclear phagocytes had infiltrated the tumors. These results indicate that the number of infiltrating mononuclear phagocytes in CNS tumors greatly exceeds the number of QUIN-IR cells, suggesting that if quinolinic acid is produced by monocytes and their derivatives, it is a select subpopulation of these cells. The present findings are consistent with a functional role for quinolinic acid in certain infiltrating leukocytes during the immune response to CNS neoplasms.

TUMOR NECROSIS FACTOR (TNF)-α POTENTIATES GLUTAMATE NEUROTOXICITY IN HUMAN FETAL BRAIN CELL CULTURES. S. Hu* and C.C. Chao. Minneapolis Medical Research Foundation and the University of Minnesota Medical School, Minneapolis, MN 55404

Cytokines released by activated microglia have been proposed to play a pathogenic role within the brain. Since exposure of neuronal cells to the excitatory amino acid neurotransmitter glutamate induces injury to these cells, we tested the regulatory effect of cytokines on glutamate receptor-mediated toxicity in human fetal brain cell cultures. After 6 days of incubation, exogenous glutamate (5 mM) induced remarked neuronal loss (a 165% increase in release of lactate dehydrogenase and a 62% decrease in functional uptake of ³H-γ-aminobutyric acid [GABA]). Glutamate neurotoxicity was dose-dependent (ED₅₀ of 200 μM). Treatment of cell cultures with TNF-α (100 ng/ml) but not with a number of other cytokines, potentiated glutamate neurotoxicity (a 52% further decrease in ³H-GABA uptake). Exposure of brain cells to TNF-α or to cytokines tested above alone did not significantly affect neuronal cell function. TNF-α-mediated enhancement of glutamate neurotoxicity was markedly blocked (up to 80%) by the glutamate receptor antagonists DL-2-amino-5-phosphonovaleric acid (100 μM) and MK-801 (10 μM), indicating that the potentiating effect of TNF-α is mediated via glutamate receptors. Also, exposure of neuronal cell cultures to TNF-α resulted in a 27% decrease in astrocyte glutamine synthetase and in a 50% inhibition of ³H-glutamate uptake, suggesting that the effect of TNF-α indirectly involves glutamate metabolism. These findings support the hypothesis that TNF-α may impair neuronal injury by exacerbating excitotoxicity.

BCL-2 PROTECTS MN9D CELLS FROM STAUROSPORINE- BUT NOT TRIFLUOPERAZINE-INDUCED CELL DEATH. K.L. O'Malley* and Y.J. Oh. Dept. of Anatomy and Neurobiology, Washington Univ. Sch. of Med., St. Louis, MO 63110

Recently, we have shown that over-expression of the proto-oncogene Bcl-2 in a dopaminergic neuronal cell line, MN9D, can protect these cells from MPP⁺-mediated cell death. Because previous studies have demonstrated that protein kinase (PK) pathways may be involved in cell death regulation, we tested various PK inhibitors for their effects on stable transfectants expressing human Bcl-2 (MN9D/Bcl-2) or neomycin (MN9D/Neo). Cell death was monitored by measuring lactate dehydrogenase (LDH) release. In control cells, both staurosporine (0.01-1 μ M) and trifluoperazine (TFP; 1-100 μ M) led to cell death in a dose-dependent fashion. In contrast, the cyclic nucleotide-dependent PK inhibitor, KT-5720 (0.01-2 μ M), the tyrosine kinase inhibitor, herbimycin A (0.001-10 μ M), the PKC inhibitor, calphostin C (0.05-1 μ M) and long term exposure to phorbol ester failed to do so. Cell death induced by TFP could be blocked by addition of cycloheximide whereas staurosporine-induced death was not. Over-expression of Bcl-2 completely rescued staurosporine-induced but not TFP-induced cell death as measured by LDH release and internucleosomal DNA fragmentation. These results suggest that in MN9D cells at least two distinct pathways can lead to cell death. Thus these cells may serve as a useful model system for studying the mechanisms associated with CNS neuronal cell death and suppression of this process by Bcl-2.

427.8

BCL-2 PROMOTES NEURITE FORMATION AND PROTECTS FROM MPP⁺- BUT NOT 6-HYDROXYDOPAMINE-INDUCED CELL DEATH IN A DOPAMINERGIC NEURONAL CELL LINE. Y.J. Oh*, B.C. Swarzenski¹, S.C. Wong, M. Moffat, D.E. Merry², S.J. Korsmeyer² and K.L. O'Malley, Dept. of Anatomy and Neurobiology, Psychiatry¹, Medicine², Washington Univ. Sch. of Med., St. Louis, MO 63110

The protooncogene bcl-2 inhibits programmed cell death in a variety of cell types. While the mechanism for this function remains unclear, it may involve the attenuation of oxidative stress. Because oxidative stress has been hypothesized to play a role in neurodegenerative disorders such as Parkinson's disease, we sought to evaluate the potential of Bcl-2 in sparing cells from the dopaminergic neurotoxins, N-methyl-4-phenylpyridinium (MPP⁺) and 6-hydroxydopamine (6-OHDA). To test this in a dopaminergic neuronal cell line (MN9D), stable transfectants expressing either human Bcl-2 (MN9D/Bcl-2) or neomycin (MN9D/Neo) were established. Surprisingly, it was found that overexpression of Bcl-2 led to robust neurite formation. Increases in primary neurite length and total neuritic extent were highly significant in MN9D/Bcl-2 versus MN9D/Neo. Bcl-2 expressing cells also reduced cell death due to MPP⁺ treatment. In contrast, Bcl-2 overexpression did not block the cytotoxic effects of 6-OHDA. However, inclusion of antioxidant reagents or an iron chelator did substantially attenuate cell death in the 6-OHDA model. Because MPP⁺ is thought to inhibit the respiratory chain at Complex I and thus mitochondrial metabolism, rotenone was added to inhibit the activity of NADH dehydrogenase at this level. Rotenone-mediated cell death was significantly delayed in MN9D/Bcl-2. These data suggest Bcl-2 may protect cells from altered mitochondrial electron transfer processes. Thus, Bcl-2 may have dual roles in neurogenesis and in repression of cell death.

TOXIC NEURONAL EFFECTS OF THE HIV COAT PROTEIN GP120 MAY BE MEDIATED THROUGH MACROPHAGE ARACHIDONIC ACID. E. B. Dreyer* and S. A. Lipton, Harvard Medical School, Dept. of Ophthalmology, MEEI, Dept. of Neurology, Children's Hospital, Boston, MA, 02115.

Previous work in our laboratory has demonstrated a toxic effect of gp120 in mixed neuronal/glial cultures (Dreyer et al., Science 248:364). This effect is intimately associated with glutamate excitotoxicity (Lipton et al., Neuron 7:111). It is now clear that under our conditions this effect is unlikely to be a direct action of gp120 on neurons, but is instead mediated through one or more other cell types. Both HIV-infected macrophages and gp120 stimulated macrophages produce arachidonate and its metabolites. Arachidonate inhibits re-uptake of glutamate by astrocytes and synaptosomes (Barbour et al., Nature 342:918; Volterra et al., J Neurochem 59:600), and is therefore an excellent candidate for potentiating neurotoxicity in mixed culture preparations. We have found that picomolar concentrations of gp120 inhibit excitatory amino acid uptake into cultured astrocytes. These cultures contain approximately 5% monocytoid cells; when these cells are depleted by the addition of L-leucine methyl ester, then gp120 no longer inhibits excitatory amino acid uptake. This finding suggests that the effect of gp120 in our system is mediated through the monocytic cells in our cultures. Furthermore, preliminary results indicate that arachidonic acid - which inhibits phospholipase A2, and thereby decreases the production of arachidonic acid - blocks the effect of gp120 on astrocytes. These results therefore suggest that gp120's effect on astrocytes depends upon an increase in arachidonate or its metabolites, probably released by macrophages.

427.10

A COMPARISON AND APPLICATION OF BICISTRONIC HERPES SIMPLEX VIRUS VECTORS. T.J. Meier*, D.Y. Ho, R. Dash, M.S. Lawrence, R.M. Sapolsky. Department of Biological Sciences, Stanford University, Stanford, CA 94305.

Monocistronic herpes simplex virus vectors offer an effective means of delivering genes to post-mitotic neurons. They do not, however, allow ready identification of targeted cells. We have employed two different strategies to coexpress both a gene of interest and the *lacZ* marker gene: in the first approach, both cistrons are placed under a single HSV $\alpha 4$ promoter, with the translation of the second cistron made possible by employing an internal ribosomal entry site; in the second approach, the two genes placed under the control of the opposite reading HSV $\alpha 4$ and $\alpha 22$ promoters, respectively. Both bicistronic systems show consistent coexpression of the two genes as assessed by double immunofluorescence, indicating that recombination deletions do not occur and that such vectors can be reliably used to identify targeted cells. We have employed such vectors to investigate the neuroprotective effects of various gene products. a) Cultured hippocampal neurons receiving a bicistronic vector bearing the bcl-2 gene show enhanced survivorship when challenged by an oxidative insult as compared to those receiving a control vector. b) Delivery of a bicistronic vector bearing the glucose transporter gene protects hippocampal neurons against glutamate excitotoxicity in vitro and kainate-induced seizure in vivo. c) Delivery of a vector expressing the gene for calbindin D28K causes a significant diminution and delay in excitotoxin-induced mobilization of free cytosolic calcium in cultured hippocampal neurons.

427.11

EXACERBATION OF GP120 EFFECTS ON RAT PRIMARY NEURONAL CULTURES BY CORTICOSTERONE. S.M. Brooke, J.D. Miller*, and E. B. Sapolsky. Dept. of Biological Sciences, Stanford University, Stanford, CA, 94305.

The section of the protein coat of the HIV virus known as gp120 may be the causal agent in AIDS dementia. It has been shown to cause neuronal death and increase in cytosolic calcium levels in neuronal cultures. The injury to neurons is thought to be mediated by release of a toxin from macrophages or glia that acts through the excitatory amino acid pathway. Corticosterone (CORT), the rat specific glucocorticoid (GC) secreted from the adrenals, is involved in the mediation of the stress response. CORT increases the effects of excitotoxins such as kainic acid, glutamate, and quinolinic acid. CORT also augments the mobilization of calcium in cytosol after an excitotoxic insult. We have investigated whether CORT exacerbates the effects of gp120 on neuronal death and cytosolic calcium levels in cultured neurons. As assessed immunocytochemically with Map2 staining, 200 pM gp120 killed about 20% of hippocampal neurons. The addition of 1 μ M cort resulted in a further significant decrease in survival of approximately 25%. Using standard imaging techniques and the dye fura-2, we were able to confirm reports that gp120 can cause, in some cortical neurons, a rise in cytosolic calcium. The time required to reach this peak (300% of baseline) was approximately 600 seconds. Twenty-four hour pretreatment with 1 μ M CORT resulted in doubling the magnitude of the peak and accelerating of the onset. Some hippocampal cells in the presence of gp120 peaked at 600% of baseline after 900 sec exposure. Pretreatment with CORT did not affect the peak or onset, but did significantly impair recovery from the peak. It would appear that the stress hormone CORT may exacerbate the effects of gp120 on neuronal tissue. This fact could be relevant to the use of megadoses of GC's to control the *Pneumocystis carinii* pneumonia in AIDS.

INFLUENCE OF TH2-DOMINATED CNS IMMUNITY ON TUMOR GROWTH IN THE BRAIN L. B. Gordon, H. F. Cserri, P. M. Knop^{*}, Dept. of Physiology, Brown University, Providence, RI, 02912.

We have developed a model to study CNS immune privilege in Balb/c mice to mastocytoma cell line P511. When introduced into the putamen of syngeneic DBA/2 or minor histoincompatible Balb/c mice without blood-brain barrier disruption, 10^4 P511 cells form a progressively growing tumor, exhibiting angiogenesis, central necrosis, and brain tissue infiltration. Average time to death of mice is 25.7 ± 2.6 days postinfection (dpi) in DBA/2 and 34.7 ± 1.1 dpi in Balb/c ($p < 0.05$). We suspect that an ineffective anti-tumor response is prolonging survival of Balb/c mice. In contrast, injection of 2×10^6 P511 cells subcutaneously (SC) results in tumor formation in syngeneic DBA/2 mice, but cytotoxic T cell (CTL)-mediated rejection in Balb/c mice. Thus, we have established a model to study immune privilege to MHC compatible, minor histoincompatible tumor cells in the brain, a subset of natural brain tumor situations. This allows us to examine the following hypothesis: tumor cells in the brain are detected by the immune system, but the response is directed along the Th2/humoral immunity pathway, whereas responses to tumors in a nonCNS setting favor a Th1/cellular immunity pathway.

In support, immunohistochemistry on brain sections showed scattered CD3+, CD4+, and CD8+ T cells present in and around Balb/c, but absent from DBA/2 tumors. A more dense distribution of F4/80+ and of Ig+ cells are present in brain tumors and surrounding neural tissue exclusively in the tumor-laden hemisphere of Balb/c and DBA/2 mice 14 dpi. Anti-P511 serum antibody responses have been detected in Balb/c mice with brain tumors and flank tumors 14 dpi. Precursor CTL activity, but no active CTL are detected in spleens of brain-infused or SC-injected Balb/c mice 14 dpi. Tumor-infiltrating lymphocytes (TIL) from SC tumors display active CTL activity. We are assaying TIL in brain tumors, and anticipate a lack of CTL activity due to an immunosuppressive environment towards Th1 responses.

428.3

THE CLONING OF MULTIPLE PROTEIN TYROSINE KINASE GENES EXPRESSED IN HUMAN PEDIATRIC BRAIN TUMORS AND DEVELOPING BRAIN. Edward B. Ziff, Marc Rothman, Howard L. Weiner^{*}, and Maria McCarthy. Howard Hughes Medical Institute, Department of Biochemistry, New York University Medical Center, New York, NY, 10016

Emerging evidence indicates that growth factor receptor tyrosine kinases (RTKs) play a central role in regulating normal cell growth and differentiation in the central nervous system (CNS). Aberrant expression of members of this family of proteins has been associated with tumorigenesis. However, little is known about the role of RTKs in early neural development or in human CNS tumors which arise from primitive neural precursors. Using degenerate oligonucleotide primers complementary to conserved sequences within the tyrosine kinase catalytic domain, we have cloned thirteen distinct tyrosine kinases from two surgically resected human malignant pediatric brain tumors, a malignant ependymoma and a glioblastoma multiforme. These two tumor types are presumed to derive from embryonic stem cells of the CNS. We hypothesized that the molecular phenotype, including receptor expression, of specific tumor cells is informative of early glial or neuronal precursors. Expression of nine of these kinase genes in human brain tumors has not been reported previously. Kinase clones analyzed thus far are identical or bear significant homology to: MET, FER, TIE, HEK2, FLK1, FLT4, PDGFR, IGF-R, and EGF-R. Cytoplasmic PTKs, including TYK2, SLK, the human JAK2 homologue and a novel protein kinase C isoenzyme have also been identified. In order to compare the pattern of RTK expression in tumors of the developing CNS to that of normal brain, we have applied this technique to the isolated brains of E17 rats. From these studies several kinases have been identified, including rat homologues of the FAK and JAK1 kinases.

EFFECT OF CELL ADHESION MOLECULES (CAMs) AND LAMININ ON THE DIFFERENTIATION OF NEURO-2A CELLS. W.-W. Chung^{*}, Laboratory of Molecular Pathology, Department of Pathology, Veterans General Hospital-Taipei, Taipei 112, Taiwan, Republic of China

Development of the polarity, extension of processes, and further formation of axon and dendrites are crucial steps in the differentiation of a neuron. The effects of laminin and CAMs on neurite differentiation have been demonstrated in various normal neurons. The effects of laminin and antibodies recognizing N-CAM (12F8, against polysialic acid) and L1 (gifts from Dr. C.F. Lagenaur) on the differentiation of a mouse neuroblastoma cell line, Neuro-2A, were tested. RT97, antibody against phosphorylated neurofilament, was used to label the differentiation of axons. Many multipolar cells were identified in the 80-hour culture plated on polylysine. Some cells extended short RT97(+) neurites, most were of less than 5 times the diameter of cell body. Only 5-10 % cells had RT97(+) neurites of total length more than 5 times the cell diameter. Many cells plated on laminin extended long and branching RT97(+) neurites. Up to 30 % had RT97(+) neurites of total length more than 5 times the cell diameter. N-CAM and L1 antibodies were tested either by adding into the medium as free form or coating (bound form) on the coverslips for culture. Although there was no L1 expression detected by ABC-peroxidase method, the effect of free form L1 antibody was observed as numerous (up to 15%) cells extended fine and long RT97(+) neurites. No significant effect is noted for the bound form L1 antibody. In contrast, both the free and bound forms of 12F8 antibody do not produce significant effect, even though the expression of N-CAM is confirmed. Evidently, laminin and L1 antibody, similar to the effects on some neurons in primary culture, also promote the *in vitro* differentiation of Neuro-2A cells. (Supported by NSC-83-0412-B-075-055, TAIWAN, ROC)

ORIGIN OF PC12 PHEOCHROMOCYTOMA CELLS: EVIDENCE THAT LOSS OF THE MYC DIMERIZATION PARTNER MAX WAS A TRANSFORMING EVENT. B. Hopewell and E. B. Ziff^{*}, Howard Hughes Medical Institute, Kaplan Cancer Center and Department of Biochemistry, New York University Medical Center, New York NY 10016.

Max formation of heterodimers with the nuclear oncoprotein Myc and the differentiation-associated proteins Mad and Mxi1 enables these factors to bind DNA and control genes implicated in cell proliferation and differentiation. We show that the PC12 tumor cell line, derived from a rat pheochromocytoma, fails to express Max protein, due to aberrant splicing of max mRNA. RNAse protection and Northern analysis show that only exons encoding N-terminal sequences of Max up to the loop region of the helix-loop-helix dimerization motif are expressed, whereas max exons 3' of this are not expressed. We have cloned a cDNA from PC12 by hybridization to a max probe. The cDNA encodes a truncated Max protein which we call MaxPC12, containing a novel C-terminal sequence. MaxPC12 is incapable of homo- or heterodimerization *in vitro*, indicating that the protein cannot functionally substitute for wild-type Max.

Reintroduction of wild-type Max into PC12 cells is strongly growth inhibitory, suggesting that mutational loss of Max expression may have provided a growth advantage for these cells, contributing to the transformed phenotype, and that Max may therefore be a tumor suppressor in a restricted class of tumors. We have reintroduced Max into PC12 cells under the inducible metallothionein promoter. Experiments examining the effect of Myc and Max expression in these cells will be presented.

IMMUNOCYTOCHEMICAL ANALYSIS OF MEDULLOBLASTOMA

López-Robles EE, Feria-Velasco A^{*} and Ortiz GG^{*} Centro de Biología Experimental, Universidad Autónoma de Zacatecas. Apartado Postal 12. 98600 Guadalupe, Zac^{*} Centro Médico Nacional Siglo XXI IMSS, México, D.F. +Lab. de Neuropatología Experimental. CIBO CMNO. Guadalajara, Jal.

The histogenesis of the medulloblastoma has been controversial since the original description of the tumor in 1925 by Bailey and Cushing, recent debates have focused towards cellular lines glial or neuronal.

We studied retrospectively the histological and immunocytochemical features with stained routinely for H/E, Klüber-Barrera, Gomori's reticulin method, and with ABC technique, of 20 cases of classical medulloblastoma with a mean of 14.2 years and 5 cases of desmoplastic medulloblastoma with a mean of 25.8 years, using a panel of antibodies neuronal and neuroglial (GFAP, Neuron-Specific Enolase, Neurofilament 160 kD, S-100 and Synaptophysin) in tissues fixed in formalin and embedded paraffin. In the classical group high population of cells were observed with Homer-Wright rosettes, degeneration, necrosis and mitosis were observed and showed glial and neuroblastic differentiation. In the desmoplastic variety bands of connective tissue separating neoplastic cells into rows and surrounding reticulin-free islands of tumor cells, cytoplasmic processes and presence of perivascular pseudorosettes that showed ependymal differentiation were observed.

In the immunocytochemical study there was a reaction observed to all the antibodies in the classical group, and there was a reaction to all them except S-100 in the desmoplastic group.

This study shows that medulloblastoma is a neuroepithelial neoplasm that can differentiate into ependymal, neuronal and neuroglial lines.

428.6

Increases in Cyclic AMP Induce Morphologic Differentiation of MCD-1 Cells in Vitro. K. Moore, O. Dillon-Carter, M. Poltorak, M. Chedid¹, and W. Freed². NIMH Neuroscience Center at St. Elizabeths, 2700 Martin Luther King Ave, Washington, D.C. 20032, and (¹Medical College of Georgia, Augusta, GA)

Medulloblastomas are undifferentiated CNS tumors, cells from which may undergo morphologic differentiation following addition of exogenous agents such as retinoic acid and dibutyryl cAMP (dBcAMP). The potential of cultured medulloblastoma cells to differentiate following the addition of NGF alone or in combination with agents which influence the cAMP second messenger system was studied. MCD-1 cells were exposed to NGF, dBcAMP, IBMX, forskolin, retinoic acid, arginine-L-carnitine (ALCAR), and mixtures of NGF+IBMX, NGF+IBMX+dBcAMP, and NGF+Forskolin+dBcAMP, and process outgrowth was measured after 48 hr. There were statistically significant increases in process outgrowth in cells treated with IBMX, dBcAMP, as well as NGF+IBMX, NGF+IBMX+dBcAMP, and NGF+Forskolin+dBcAMP. Cells treated with forskolin, NGF, ALCAR or retinoic acid did not show increased growth of processes. NGF alone had little effect on process outgrowth and did not augment the effects of IBMX or dBcAMP. Immunohistochemically the cells were positive for neuron-specific enolase (NSE), synaptophysin, and vimentin, but negative for GFAP. There were no changes in expression of NSE or synaptophysin following addition of differentiating agents. Thus morphologic differentiation of MCD-1 cells was induced by agents that increase cellular cAMP.

428.7

Biochemical and immunocytochemical characterization of the human medulloblastoma cell line MCD-1. O. Dillon-Carter*, K. Moore, M. Poltorak, M. Chedid¹, and W.J. Freed. NIMH Neuroscience Center at St. Elizabeths, Washington, D.C. 20032, and (¹Medical College of Georgia, Augusta, GA).

The MCD-1 medulloblastoma cell line was isolated from a human cerebellar tumor. MCD-1 cells express several cytoskeletal markers, including vimentin, alpha- and beta-tubulin, and microtubule-associated protein-2. The cells are also positive for Thy-1 and fibronectin, but negative for N-CAM and L1 antigen. The cells are negative for markers of glia and differentiated neurons, including GalC, MBP, GFAP, neurofilaments, synapsin, TH, GAD, DBH, and PNMT. The cells express glutamate, choline, and serotonin uptake, but are negative for uptake of GABA and dopamine. Glutamate uptake is sodium-dependent and blocked at 0°C and by DL-threo-β-hydroxyaspartate. Serotonin uptake is inhibited by clomipramine, and choline uptake by hemicholinium-3. In addition, MCD-1 cells secrete the tumor-growth regulatory molecule TGFβ2, and grow in serum-free medium. The presence of serotonin, glutamate, and choline uptake suggests that medulloblastoma cells may use these substances as biochemical mediators. The MCD-1 cell line may be useful for studies of medulloblastoma growth and differentiation.

SYMPOSIA

429

SYMPOSIUM: TOWARDS A NEUROBIOLOGY OF VISUAL CONSCIOUSNESS. C. Koch, Caltech (Chairperson); S. Kosslyn, Harvard University; P. Stoerig, Ludwig-Maximilian's University, München, Germany; R. Desimone, Lab. Neuropsychology, NIMH; E. Crick, Salk Institute.

The aim of the symposium is to demonstrate that the neurological and neurophysiological substrate underlying conscious visual perception in humans can be approached in a rigorous experimental and reductionist manner. We have the tools in hand to explore this most central of our subjective "states" and its disruption in pathology in terms of particular types of (bio)-electrical activity in particular neurons, areas or pathways in the brain.

Kosslyn will discuss how the phenomenological qualities of visual mental imagery relate to activity in specific brain regions in human subjects, using PET and functional MRI studies. Stoerig will consider "blindsight", in which patients have a loss of conscious visual perception in the presence of demonstrable residual functions. A similar phenomenon exists in monkeys with striate cortical ablations. Desimone will discuss single-unit electrophysiological studies carried out in cortex of the awake and behaving monkey, suggesting ways in which prefrontal mechanisms prepare the visual system for expected stimuli, possibly providing the substrate for imagery. Crick will outline a general framework within which the problem of the Neural Correlate of Consciousness (NCC) can be approached using theoretical, neuroanatomical and electrophysiological studies.

428.8

NEURON-GLIAL REGULATION OF PROLIFERATION BY ACTIVATION OF TGFβ2 IS ALTERED IN MALIGNANT ASTROCYTOMAS. D.L. Cooper*, C.N. Metz, D.B. Rifkin, C.J. Hodge, Jr., and M.E. Hatten. The Rockefeller University, New York, N.Y. New York University School of Medicine, New York, N.Y., SUNY Health Science Center, Syracuse, N.Y.

Understanding the control of cell proliferation during the development of the brain is crucial to our understanding of proliferation in malignant astrocytomas. Previous analyses, in which cerebellar astroglia and granule neurons were purified from early postnatal cerebellum and recombined *in vitro*, demonstrated that neuron-glial interactions inhibit astroglial proliferation and induce differentiation of normal astrocytes and some astrocytoma cell lines. In the present study, we have compared the effects of transforming growth factor-beta (TGFβ) on the proliferation of postnatal cerebellar astroglia and astrocytomas. We also examined the role of neuron-glial and neuron-glioma interactions in TGFβ activation.

TGFβ1 or TGFβ2 reduced DNA synthesis by postnatal cerebellar astroglia and by low grade G26-24 rodent glioma cells by 30-60%. In contrast, TGFβs increased DNA synthesis by two human malignant glioma lines (U87, U118), and had little effect on two other human glioma lines (U138, U373). All four human glioma lines produce latent TGFβ alone, and in co-culture with neurons. Studies on activation of TGFβ *in vitro* demonstrated that gliomas activate TGFβ, even in the absence of neurons. By contrast, normal astrocytes require neuronal contact to activate TGFβ.

These experiments demonstrate that control of TGFβ activation is lost in malignant gliomas, where gliomas activate TGFβ without neuronal contact. In the context of gliomas, where control of activation is lost, TGFβ may interact with other cytokines to stimulate rather than inhibit proliferation.

SYMPOSIUM. DEVELOPMENTAL CONTROL OF ELECTRICAL EXCITABILITY. A. B. Ribera, University of Colorado Health Sciences Center(Chairperson); M.E. Barish, Beckman Research Institute, City of Hope; W.L. Moody, University of Washington; G. Mandel, SUNY Stony Brook.

Although it is firmly established that electrical excitability is developmentally regulated, its role in the emerging nervous system is less well understood. The functions of electrical excitability in developing neurons and associated regulatory mechanisms will be discussed. Barish will present data that indicate that environmental influences, provided by cells such as glia, affect development of ion channels and membrane currents. Moody will present studies that test the role of electrical activity in development by embryonic misexpression of ion channels. Ribera's work examines the specific functions of identified potassium channel genes in embryonic neurons. Mandel will discuss the genetic elements that are involved in activation of expression of a sodium channel gene during differentiation of peripheral neurons.

SECOND MESSENGERS II

433.1

MODULATION OF PLASMA MEMBRANE CALCIUM ATPASE (PMCA) ALTERS CALCIUM EFFLUX IN CULTURED SENSORY NEURONS. J.L. Werth* and S.A. Thayer. Department of Pharmacology, University of Minnesota Medical School, Minneapolis, MN 55455.

Intracellular calcium concentration ($[Ca^{2+}]_i$) and whole cell Ca^{2+} current (I_{Ca}) were measured simultaneously in single rat dorsal root ganglion (DRG) neurons grown in primary culture. Following a modest rise in $[Ca^{2+}]_i$ (100-600 nM), recovery to basal $[Ca^{2+}]_i$ was fit well by a single exponential. The decay time constant (τ) was similar for action potential-evoked (no cell dialysis) and depolarization-induced (whole-cell configuration) Ca^{2+} loads ($5.85 \pm .61$ s vs. $5.94 \pm .56$ s, respectively). Omitting ATP from the patch pipette led to large increases in $[Ca^{2+}]_i$ and blocked recovery to basal $[Ca^{2+}]_i$. Thapsigargin (100 nM), a selective inhibitor of sarco- and endoplasmic reticulum Ca^{2+} ATPases (SERCA), did not slow buffering kinetics. Inclusion of 1 μM calmodulin in the pipette caused a slight decrease in τ compared to control ($4.52 \pm .51$ vs. $5.94 \pm .56$, respectively). Inclusion in the patch pipette of a 28-amino acid peptide (C28R2, 10 μM) corresponding to the autoinhibitory domain of the PMCA slowed recovery and led to a use-dependent increase in $[Ca^{2+}]_i$. The increase in τ could be prevented by 100 nM phorbol dibutyrate, an activator of protein kinase C. These data indicate that small Ca^{2+} loads are buffered predominantly by PMCA's. Furthermore, the data suggest that Ca^{2+} /calmodulin and protein kinase C play a role in regulating PMCA's in intact neurons.

MICROPIPETTE LOADING OF FLUO-3 CAN ELEVATE BASELINE NUCLEAR CALCIUM SIGNALS. Mark N. Rand*, Trese Leinders-Zufall, Samuel Agulian, and Jeffery D. Kocsis. Yale University School of Medicine, Dept. Neurology, New Haven, CT 06510 and V.A. Medical Center, West Haven, CT 06516.

Several recent imaging studies of neurons have reported that nuclear Ca^{2+} signals can exceed those of the cytoplasm upon stimulation, and it has been speculated that elevated nuclear Ca^{2+} transients might play a role in gene expression. Most of these studies used the acetoxymethyl ester (AM) form of the Ca^{2+} indicator dye fluo-3, which crosses the cell membrane and becomes metabolically trapped, loading the cells in a non-disruptive manner. A recent report using micropipette loading of fluo-3 has been interpreted as suggesting that depolarization-induced Ca^{2+} signals are not higher in the nucleus (Al-Mohanna et al, Nature 367:745). However, we have found that mechanical methods of dye-loading can elevate baseline nuclear Ca^{2+} signals, confounding measurements of $[Ca^{2+}]_i$ relative to baseline. When cultured adult rat DRG neurons were impaled and filled with fluo-3 using sharp electrodes, slow stabilization of the resting potential was associated with baseline nuclear Ca^{2+} signals which were greater than those in the cytoplasm. In contrast, when resting potentials stabilized rapidly after impalement, nuclear Ca^{2+} signals were about equal to those in the cytoplasm at baseline and increased 1.5 times more than those in the cytoplasm upon depolarization. Whole-cell patching of retinal ganglion cells loaded with fluo-3AM indicated the same problem. Despite buffering the intracellular pipette solution to 10 nM Ca^{2+} and presetting the amplifier to the average resting potential, imaging the neurons at the moment of membrane disruption showed a large increase in intracellular Ca^{2+} , and resulted in elevated nuclear Ca^{2+} signals which lasted for many minutes. In contrast, when DRG neurons were non-disruptively loaded with fluo-3AM and depolarized with 60 mM KCl, Ca^{2+} signals were ~25% lower in the nucleus than in the cytoplasm at rest, and increased 2.5 times more than those in the cytoplasm. These data indicate that baseline nuclear Ca^{2+} signals can increase with micropipette disruption of the neuronal membrane, confounding the estimation of nuclear $[Ca^{2+}]_i$ after stimulation.

CHIMERIC RECOMBINANT AEQUORINS: NEW TOOLS FOR THE STUDY OF Ca^{2+} HOMEOSTASIS IN NEURONS AND MYOCYTES. R. Rizzuto, M. Brini, C. Bastianutto, L. Pasti, R. Marsault, M. Montero, P. Gambetti⁸ and T. Pozzan. Department of Biomedical Sciences, University of Padova, 35121 Padova Italy; ⁸ Division of Neuropathology, CWRU, 2085 Adelbert Rd, Cleveland, OH 44106.

In recent years, much interest has been devoted to the study of cytosolic Ca^{2+} homeostasis, not only because changes of Ca^{2+} concentration in this phenomena, but also because, until recently, the cytosol was the only cell compartment in which this cation could be measured quantitatively in intact cells. We here describe a new methodology, recently developed in our laboratory, for the measurement of Ca^{2+} concentration within specific subcellular regions, and its application to the study of Ca^{2+} homeostasis in cultured neurons and myocytes. The methodology is based on the modification of the cDNA encoding the Ca^{2+} -sensitive photoprotein aequorin, modified in order to include organelle specific targeting sequences, and on the recombinant expression of the chimeric photoprotein in cultured cells. Three chimeras are now available in the laboratory, which allow the monitoring of Ca^{2+} concentrations in the mitochondria ($[\text{Ca}^{2+}]_m$), nucleus ($[\text{Ca}^{2+}]_n$) and endoplasmic reticulum of living cells ($[\text{Ca}^{2+}]_{er}$). Cell stimulation coupled to increases in cytosolic Ca^{2+} concentration invariably results in increases of $[\text{Ca}^{2+}]_m$ and $[\text{Ca}^{2+}]_n$, but the kinetics and amplitudes of these changes are very different. In neurons, large changes of $[\text{Ca}^{2+}]_m$ are evoked by the activation of plasma membrane channels, while in skeletal muscle myotubes changes in $[\text{Ca}^{2+}]_m$ appear closely linked to Ca^{2+} release from sarcoplasmic reticulum. $[\text{Ca}^{2+}]_n$, on the other hand, seems to closely follow cytosolic Ca^{2+} both in kinetics and amplitude. Finally, a large drop in $[\text{Ca}^{2+}]_{er}$ occurs upon depletion of intracellular Ca^{2+} stores, though the kinetics of this decrease are complex.

433.5

INTERLEUKIN 1 ENHANCES RECEPTOR-DEPENDENT AND INDEPENDENT INDUCED RELEASE OF ARACHIDONIC ACID FROM MOUSE STRIATAL ASTROCYTES N. Stella, J. Siciliano, D. Pionelli, M. El-Etr, J. Glowinski and J. Prémont. Collège de France, 75231 Paris, France.

The present study was undertaken to determine the interference of this cytokine in receptor-dependent and independent induced release of arachidonic acid from cultured striatal astrocytes. As previously shown, both 100 μM ATP or the combination of 0.1 μM PMA and 2 μM ionomycin stimulated the release of ^3H -AA from striatal astrocytes ($136 \pm 7\%$ and $54 \pm 3\%$ above basal level, respectively) (N. Stella et al. (1994) J. Neurosci. 14:568-575). When 100 pM IL-1 β was added simultaneously with ATP, the nucleotide-induced release of ^3H -AA was not changed ($165 \pm 8\%$). However, when astrocytes were pretreated for 24 hrs with IL-1 β , both the ATP- and PMA-ionomycin-evoked release of ^3H -AA were potentiated ($350 \pm 20\%$ and $252 \pm 22\%$, respectively). The half maximal potentiating response was observed with 10 pM IL-1 β . IL-1 β -effect was mimicked by IL-1 α , not by IL-6.

IL-1 β did not alter the concentration-dependent ATP-evoked accumulation of ^3H -inositol phosphates. Moreover, the amount of G_α_i or G_α_o protein, as estimated by pertussis toxin induced-ADP-ribosylation, were not affected by IL-1 β . Finally, although IL-1 β treatment did not modify the Ca^{2+} -independent membrane-bound phospholipase A2 (mPLA2) activity, it increased by two fold the amount of the Ca^{2+} -dependent cytosolic PLA2 (cPLA2) as estimated by immunoblotting technique.

These results indicate that IL-1 β treatment has a potentiating effect on the receptor-dependent and independent induced release of AA by enhancing specifically the amount of cPLA2. Considering the role of AA in the regulation of glutamate uptake into astrocytes, IL-1 β could be involved in the glutamate-evoked neurotoxicity observed in brain inflammatory processes.

A DIFFUSIBLE MESSENGER MEDIATES SUBSTANCE P-INDUCED INHIBITION OF THE INWARD RECTIFIER K^+ CHANNEL IN NUCLEUS BASALIS NEURONS. K. Takano, P.R. Stanfield, S. Nakajima and Y. Nakajima*. Dept. of Anat. and Cell Biol., and Dept. of Pharmacol., Univ. of Illinois at Chicago, Chicago, IL 60612.

Our previous studies showed that substance P (SP) excites nucleus basalis neurons cultured from the rat forebrain by suppressing an inward rectifier K^+ current, and this effect is mediated by a pertussis toxin-insensitive G protein. We have further studied the signal transduction mechanism of this effect. Single channel activity (on-cell mode) of the inward rectifier was inhibited by SP applied outside the patch. With the whole-cell patch clamp, intracellular application of 20 μM of the PKC inhibitor PKC(9-36) almost abolished the SP-induced suppression of the inward rectifier, while 20 μM of the PKA inhibitor PKI(5-24) had no effect. Extracellular application of 10 μM 1,2-sn-dioctanoylglycerol (a PKC activator) mimicked the SP effect. The SP effect was suppressed by pretreatment with 5 μM Ro 31-8220 (a selective PKC inhibitor, a gift from Roche Products Ltd.) in both single channel and whole-cell experiments. These results indicate that the SP effect on the inward rectifier is mediated by a diffusible messenger, and the signal transduction involves PKC activation. Treatment with okadaic acid prolonged the SP-induced K^+ channel inhibition, suggesting that a serine/threonine protein phosphatase is involved in the recovery from the SP effect. SP also excites locus coeruleus neurons. However, it is still unknown whether the same signal transduction mechanism is involved. Supported by NIH grant AG06093 and NATO grant CRG 920143.

ACTIVATION OF PHOSPHOINOSITIDES HYDROLYSIS BY ENDOTHELIN-1, ENDOTHELIN-3 AND BIG ENDOTHELIN IN THE RAT SPINAL CORD. P. Poulat*, J. de Champlain and R. Couture. Department of Physiology, Université de Montréal, Montréal, Qué., Canada H3C 3J7.

The activation of endothelins receptors results in the activation of phosphoinositides hydrolysis in peripheral and central tissues of the rat. However, this has not yet been shown in the rat spinal cord where endothelins receptors have been shown. The present study was undertaken to examine the inositol phosphates formation induced by endothelin-1 (ET-1), endothelin-3 (ET-3), big endothelin-1 (big ET-1) with or without presence of a selective ET $_A$ receptor antagonist (BQ-123) in the rat spinal cord. The entire spinal cord of male Wistar rat, was cross-chopped sliced at 350 μm . Slices (50 μl) were incubated with 0.13 μM of myo-[2- ^3H] inositol (specific activity 23.4 Ci/mmol) and 7 mM LiCl for 60 min in a final volume of 500 μl of Krebs buffer and stimulated with the proper agonist for an additional 60 min. The radioactivity in the total inositol fraction (IP1, IP2 and IP3) was determined as described by Berridge et al. (Biochem. J., (1982), 212, 437-82) and blank value (before stimulation) was subtracted from all values. ET-1 (1 nM - 10 μM), induced dose-dependent increases of labelled inositol phosphates. At equimolar doses (1 μM), the rank order of potency in stimulating production of inositol phosphates was ET-1 > ET-3 > big ET-1 in slices. BQ-123 (100 μM) reduced by about 50% the response to ET-1 and ET-3. These results suggest that activation of endothelin receptors in the spinal cord triggers inositol phospholipid hydrolysis which is partly mediated by an ET $_A$ receptor. Furthermore, the stimulation obtained with big ET-1 suggests the presence of an endothelin-converting enzyme in the spinal cord. [Supported by the MRC of Canada].

CYTOSOLIC PHOSPHOLIPASE A2 (cPLA2) mRNA DISTRIBUTION AND TRANSFECTION STUDIES QUESTION THE ROLE OF cPLA2 IN NEUROTRANSMISSION. L.L. Lautens, W.S. Young*, J.D. Sharp*, D.L. White*, X.G. Chiou* and C.C. Felder. Lab. of Cell Biology, NIMH, Bethesda, MD 20892 and *The Lilly Research Laboratories, Lilly Corporate Center, Indianapolis, IN 46285.

The identification of an 85 kD cPLA2 raised hopes that the effector enzyme mediating receptor-evoked release of arachidonic acid (AA) had been isolated. cPLA2 mRNA distribution was evaluated in adult mouse brain by *in situ* hybridization. cPLA2 mRNA was found in white matter of cerebellum, brain stem and fiber tracts; scattered cells in gray matter (adjacent to pia mater) of olfactory bulb and occipital cortex; pia mater and choroid plexus. cPLA2 brain distribution did not correlate with previous reports of neurotransmitter-evoked AA release via PLA2 in neurons cultured from specific brain regions. cPLA2 mRNA expression was also detected in peripheral tissue of newborn mouse: pigment layer and ciliary body of the choroid and anterior lens capsule in eye; kidney; stomach; intestine; bronchi; ducts of salivary glands; oral and pharyngeal epithelium; hair follicle sheathes; mesenchyme about and pulp within molars; and ossifying cartilage primordium of nasal septum. To further evaluate the potential role for cPLA2 as a signal transducing effector, muscarinic m1 receptors were stably transfected into U373 astrocytoma cells which lack cPLA2. Carbachol, a muscarinic agonist, stimulated the release of AA in U373 cells suggesting that cPLA2 was not necessary for AA release and that other PLA2(s) may serve this function. Furthermore, carbachol-stimulated AA release was blocked in CHOm5 cells expressing the forward but not the backward orientation of cPLA2. These results suggest that cPLA2 is unlikely to be the primary effector of AA release in neurotransmission. The role of cPLA2 in transporting epithelium has yet to be determined. THE ACETYLCHOLINE RECEPTOR LINKED TO A CHLORIDE CHANNEL IN *APLYSIA* ALSO ACTIVATES A NOVEL NEURAL LIPOXYGENASE PATHWAY. S.J. Feinmark*, D.J. Steel, and J.H. Schwartz. Depts. of Pathology, Pharmacology, and the Center for Neurobiology & Behavior, Columbia University, NY 10032.

Homogenates of *Aplysia* nervous tissue contain an 8-lipoxygenase (8-LO). Although this pathway has not been previously described in nervous tissue, products of the 12-LO pathway have been shown to act as neuromodulators in *Aplysia* identified neurons (see Schwartz, *Biochem Soc Trans*, 19:387, 1991). 8-LO converts arachidonic acid to 8(R)-hydroperoxyeicosatetraenoic acid (8-HPETE) from which 8-keto-eicosatetraenoic acid (8-KETE) is enzymatically derived. In ganglia prelabeled with [^3H]arachidonic acid, this pathway is activated in a dose-dependent manner by the application of acetylcholine (ACh; 0.1-1000 μM). ACh is as effective in normal sea water as it is in a high Mg^{2+} /low Ca^{2+} , suggesting that the effect is direct and does not require activation of other neurons. Of 10 neurotransmitters tested, ACh is the only one to activate this pathway. Likewise, histamine specifically activates the 12-LO in this nervous system. Cholinergic agonists activate the *Aplysia* 8-LO, but several ACh antagonists including, tubocurarine, hexamethonium, triethylammonium and atropine are ineffective. Activation of the 8-LO pathway is blocked by α -bungarotoxin, which selectively blocks the ACh-gated chloride current in *Aplysia* (Kehoe et al., *Brain Res*, 107:527, 1976), raising the possibility that products of the 8-LO pathway may modulate neural function through the ACh-activated chloride channel. In support of this idea, suberyldicholine, a selective agonist, activates the 8-LO in *Aplysia* nervous tissue. Thus, 8- and 12-LO are selectively and independently activated by distinct neurotransmitters in *Aplysia*. Preliminary experiments suggest that the 8- and 12-LO pathways interact to generate lipid messengers that cannot be produced by either pathway alone.

433.9

A PAF ANTAGONIST OR DEXAMETHASONE INHIBITS THE SEIZURE-TRIGGERED SUSTAINED UPREGULATION OF THE INDUCIBLE PROSTAGLANDIN SYNTHASE IN THE HIPPOCAMPUS. V. L. Marcheselli* and N. G. Bazan, Louisiana State University Medical Center, LSU Neuroscience Center, New Orleans, LA, U.S.A.

Electroconvulsive shock (ECS) activates phospholipase A₂ that leads to accumulation of free arachidonic acid and platelet-activating factor (PAF). PAF is a messenger in the ECS induced transcriptional activation of c-fos and zif-268 in hippocampus (J. Neuroscience Res. 37:54-61, 1994). Here we report that ECS effects sustained upregulation of the inducible prostaglandin synthase (PGS-2, or TIS-10) expression in rat hippocampus. The increase of PGS-2 mRNA, peaking at two hours after ECS, still have elevated levels detected after 24 hours. The zif-268 mRNA in hippocampus peak at 1 hour after ECS, but return to normal after two hours. Pretreatment with dexamethasone (6.7 mg/kg body weight) produces a 34% inhibition of ECS induced PGS-2 mRNA expression. The PAF antagonist BN-50730 when injected intracerebroventricularly (icv) 15 min before ECS (30 µg/animal) produces a 70% inhibition of PGS-2 mRNA expression. It is concluded that in the hippocampus PAF is a mediator of inducible prostaglandin synthase expression and may in turn modulate synaptic function and seizure activity through prostaglandin synthesis. Supported by NIH NINDS NS23002.

CELLULAR COMPARTMENTALIZATION AND DEVELOPMENTAL PROFILE OF COX-2, AN ENZYME INDUCED AS AN EARLY GENE, IN RAT FOREBRAIN. W.E. Kaufmann* and P.F. Worley, Depts. of Neurology and Neuroscience, Johns Hopkins University, Baltimore, MD 21205.

COX-2 is the inducible form of prostaglandin-synthase, the enzyme that catalyzes the first step in prostaglandin synthesis. Previously, we demonstrated that this enzyme is regulated as an immediate early gene in rat brain (Yamagata et al, Neuron 11: 371-386, 1993). Here, we describe our further studies to characterize the cellular compartmentalization and developmental pattern of COX-2 expression.

A COX-2 selective mouse monoclonal antibody was generously provided by Monsanto/Searle, and used for single and double-labeling immunocytochemical studies of rat forebrain (P0-adult), with markers of glia, and GABAergic and excitatory neurons. In adults, COX-2 immunoreactivity is present exclusively in neurons, restricted primarily to cerebral cortex layers II-III and hippocampus, and co-localizes with both GABA and non-GABA markers including NADPH diaphorase. Most of the COX-2 cells are excitatory given their co-expression of Cal/Cam kinase II. In the hippocampus, COX-2 is discretely compartmentalized to granule cells and excitatory and GABAergic neurons of CA3-4. The developmental profile of COX-2 immunoreactivity parallels its mRNA expression, beginning at P10 and subsequently increasing to peak between P15 and P21. Overall, laminar distribution and cytological features are similar to adult animals although qualitative analysis demonstrates a higher density of COX-2 stained cells in the developing cortex (P21).

Our study indicates that COX-2 has a developmental profile that parallels the cerebrocortical "critical period". Since COX-2 immunoreactivity is present in all neuronal types of cortical layers II-III, COX-2 expression seems to be laminar-specific rather than cell type-specific. Supported by EY09374 and HD01046.

EXTRASTRIATE VISUAL CORTEX: INFERIOR TEMPORAL AREAS

434.1

MULTIPLE SUBDIVISIONS OF THE ANTERIOR INFEROTEMPORAL CORTEX OF MACAQUE MONKEYS. E. McClendon* and D.J. Felleman, Dept. of Neurobiology and Anatomy, Univ. of Texas Med. School, Houston, TX 77030.

Anterior inferotemporal cortex (AIT) is a large portion of the temporal lobe that extends approximately 10-12 mm from just posterior to the anterior middle temporal sulcus (AMTS) to the temporal pole. Previous architectonic (Seltzer and Pandya, '78) and connective studies (McClendon and Felleman, '93) have suggested that this region is heterogeneous and may contain several distinct cortical areas. To investigate further the organization of AIT, we examined the distribution and laminar patterns of labeled cells and/or terminals following 12 injections of neuroanatomical tracers into area CITv, PITv, or PITd in 7 hemispheres of 6 monkeys. The distribution of callosal projecting neurons and/or myeloarchitecture served as an independent reference for various areal borders. Injections of retrograde tracers into area PITv (n=6) produced 2 dorsoventrally-separated projection zones in AIT that were clearly anterior to the large projection zones in areas CITv and CITd. Characterized by infragranular labeling, these 2 zones were located near the posterior end of the AMTS: one on the IT gyrus and the other within the superior temporal sulcus (areas AITpv and AITpd, respectively). Injections of retrograde tracers into CITv (n=4) labeled 4 projection zones in AIT: labeled cells were found bilaterally in areas AITpv and AITpd (layer 5 > layer 3). Labeled cells were found in layers 5/6 in the anteroverentral zone (area AITav), while the anterodorsal zone (area AITad) was only weakly labeled. A complementary injection of ³H-proline into CITv yielded robust feedforward projections (layer 4) to areas AITpv, AITpd, and AITav, with only scattered labeling in AITad. In contrast to PITv, a single injection of retrograde tracer in PITd labeled AITpv, and AITav. These data indicate that AIT consists of 4 distinct areas and extend current views of hierarchical processing within the inferotemporal cortex. Supported by NEI EY-08372, the Sloan Foundation, and the Whitehall Foundation.

434.2

CAT VISUAL CORTICAL CELLS ARE SENSITIVE TO THE ORIENTATION AND DIRECTION OF 'ILLUSORY' CONTOURS Audie G. Leventhal* and Yifeng Zhou, Dept. of Neurobiology and Anatomy, Univ. of Utah School of Medicine, Salt Lake City, Utah 84132.

The visual responses of cells in the lateral geniculate nucleus (LGNd) and cortical areas 17, 18 and LS [lateral suprasylvian visual area (PMLS)] were studied. Visual stimuli consisted of spots, bars, sinusoidal gratings, and illusory contours (ICs). Stimuli producing ICs consisted either of two sinusoidal gratings differing only in spatial phase or a sinusoidal grating abutting a blank field of the same mean luminance (Grosfof et al. *Nature*, 365: 550-552, 1993).

LGNd cells responded poorly to ICs. Most cells in areas 17 and 18 also responded poorly to ICs. Simple cells and complex cells with relatively small receptive fields were especially insensitive to ICs.

Some complex cells in areas 17 and 18 (Redies et al. *Exp. Brain Res.*, 61: 469-481, 1986) and many cells in LS responded well to ICs. Their responses were tuned to the direction and/or orientation of the ICs. Thus, cells responding best to vertical bars and gratings responded best to vertical ICs produced by moving horizontal gratings. Some cells responded more strongly to moving ICs than to moving bars and were more sensitive to the orientation and direction of ICs than of bars.

Cats can discriminate IC orientation. This ability is reduced by lesions of LS as well as of areas 17 and 18 (De Weerd et al. *Eur. J. Neurosci.*, 5: 1695-1710, 1993). Since more cells in LS than in areas 17 and 18 signal IC orientation, inputs from IC sensitive cells in areas 17 and 18 may produce LS cells that are sensitive to IC orientation. (EY08523)

434.3

ELEMENTS OF FORM PROCESSING FROM MOTION IN MONKEY PRESTRIATE CORTEX. E. Peterhans* and R. Baumann, Department of Neurology, University Hospital, CH-8091 Zurich, Switzerland.

We have studied early stages of form processing from motion in the visual cortex of the alert rhesus monkey. During periods of active visual fixation we recorded the responses of single neurons to rows of dots (size 1 min arc, spacing 12-36 min arc) moving relative to a background of dots of similar size and density (area 4-6 deg²) which either was kept stationary or moved in antiphase. These stimuli induced percepts of moving bar-like objects, segregated from a dotted background. For control, all dots were either kept stationary or moved in phase, conditions in which no such object was perceived.

In prestriate cortex many neurons were selective for the orientation of such motion defined bars as they were for bars defined by luminance contrast. The control stimuli either failed to produce a response, or evoked weak activity at all orientations. Rows of dots moving on a uniform background also produced a response as long as the dots moved coherently; motion out of phase reduced or abolished this response. The critical stimulus parameter was coherence of motion and not collinearity. Dot misalignments were tolerated, sometimes up to ±30 min arc. In area V2 34% (38/111), and in the area V3/V3A complex 75% (24/32) of the neurons studied showed these properties, but so far none in area V1 (0/22). We conclude that motion and luminance contrast as cues of form perception are first integrated in prestriate cortex, and that areas V3/V3A play a special role in this process.

NEURONAL MECHANISMS FOR PERCEPTUAL FILLING-IN. P. De Weerd*, R. Gattass, R. Desimone & L.G. Ungerleider, Laboratory of Neuropsychology, NIMH, NIH, Bethesda, MD 20892.

When a patch of dynamic texture with a hole in the middle is viewed eccentrically, the hole eventually disappears as it fills in with the surrounding texture. We trained a rhesus monkey to maintain fixation for 14 secs while recording the activity from cells with their receptive field (7-8 deg of eccentricity) positioned in the hole. Neurons in area V3 showed a gradual increase in firing rate (climbing activity) which reached an asymptote at the moment humans report filling-in (De Weerd et al., *Soc. Neurosci. Abstr.* 19:27, 1993). Changes in the size of the hole, or in the extent to which the hole was surrounded by the texture, caused changes in the time course of the climbing activity corresponding to the time required by humans to experience filling-in.

We now report that after offset of the stimulus many V3-neurons show an after-discharge which may be related to the after-image experienced by humans after stimulus offset. In addition, we confirm that in contrast with V3, there was little evidence of climbing activity in the averaged population of V1 and V2 cells. Some cells in these areas, however, did show climbing activity. In V2, the proportion of cells showing climbing activity increased at greater receptive field eccentricities, in line with psychophysical observations that filling-in is more effective the farther out the hole is in the periphery (Ramachandran et al., *Vision Res* 33:717-721, 1993). The color, direction, and orientation selectivity of V2-cells showing climbing activity was not different from the rest of the V2 population. Therefore, even with the dynamic texture used, climbing activity is not exclusively a magnocellular phenomenon. This is supported by preliminary data in V4, where we found strongly color-selective cells with clear climbing activity.

434.5

SENSORY INTERACTIONS AND EFFECTS OF SELECTIVE SPATIAL ATTENTION IN MACAQUE AREA V2. J. Reynolds, L. Chelazzi, S. Luck, R. Desimone*. Lab. of Neuropsych., NIMH, Bethesda, MD and Dept. of Neurosciences, UCSD, La Jolla, CA.

It was previously found that when two stimuli fall within a cell's receptive field, attention directed to one of them seems to filter out the influence of the other. To test this directly, we recorded the responses of V2 neurons in a macaque monkey to an optimal, or preferred, stimulus in the presence of a second, nonpreferred stimulus. We measured changes in response caused both by the sensory interaction between the two stimuli in a passive viewing condition as well as by the effects of attention directed to the first or second stimulus.

During passive viewing, a nonpreferred stimulus in the receptive field typically caused a partial suppression of response to the preferred stimulus. The suppressive effects of a nonpreferred stimulus diminished with distance from the receptive field but were still present in some cases beyond the field border. Attention directed to the preferred stimulus appeared, on average, to diminish the suppressive effects of the nonpreferred stimulus whereas attention directed to the nonpreferred stimulus seemed to magnify its suppressive effects. The time course of both the attentional and sensory effects on the response was similar. As in earlier studies (Neurosci. Abs., 19:19.6), an increase in baseline activity typically occurred when attention was directed to a location within the receptive field.

We hypothesize that the baseline shift is due to a spatially selective attentional signal which increases the average firing rate of those cells whose receptive fields are at the attended location. We further suggest that the sensory interaction, which could serve preattentive visual processes such as separation of figure from ground, may also be the mechanism by which the attentional signal biases sensory processing in favor of attended stimuli.

434.7

REPRESENTATION OF STIMULUS POSITION RELATIVE TO ATTENDED OBJECTS IN MACAQUE AREA V4. C.E. Connor*, J.L. Gallant and D.C. VanEssen. Dept. of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.

We have previously shown that changes in the position of an attended object affect the spatial response profile and overall response level of cells in macaque visual area V4 (Connor et al., *Soc. Neurosci. Abstr.* 19: 974 (1993)). In particular, many V4 cells respond differentially to an oriented bar stimulus depending on which side of the bar the attended object appears on (a laterality preference). We have explored this phenomenon further by varying the location of the attended object across multiple positions in 1 and 2 dimensions. The attended object was a ring, flashed briefly near the receptive field as part of a serial size comparison task. The probe stimulus was a behaviorally irrelevant bar of optimal orientation, color, and size flashed at various locations inside the receptive field. A single bar stimulus appeared 200 msec following each ring onset. In one paradigm, ring position was varied across 7 locations along an axis perpendicular to the optimal bar orientation. Responses to the bar were often tuned for distance relative to the attended ring, as well as showing a laterality preference. In a second paradigm, the position of the ring was varied across multiple locations in 2 dimensions, all equidistant from the receptive field. Bar response strength often depended on 2-dimensional position relative to the attended ring. These findings suggest that area V4 processes information about stimulus position relative to nearby attended objects.

SHAPE SELECTIVITY OF INFERIOR TEMPORAL NEURONS UNDER CONDITIONS OF BACKWARD MASKING. Gy. Kovács, R. Vogels, G.A. Orban*. Lab. Neuro- en Psychofysiologie, KUL, B-3000 Leuven, Belgium.

In humans, the visibility of a briefly presented shape is impaired when it is followed by another stimulus (backward masking). We observed the same phenomenon in 2 rhesus monkeys: discrimination performance for geometrical shapes presented at 20 msec exposure time (ET) was strongly impaired when the shape was immediately followed by a patterned mask. To determine the neuronal correlate of this phenomenon, we measured the responses of inferior temporal neurons in the same 2 monkeys, performing a fixation task, to these briefly presented shapes which were either followed by the mask (M) or not (NM). Although the response magnitude strongly declined with decreasing ET (tested range: 20-100 msec), shape selectivity remained present even at 20 msec ET (n = 54 units) in the NM condition. The surprising finding was that a majority of the units showed significant shape selectivity in the 20 msec M condition too. When using the initial 60 msec of the response, the difference between the response to the preferred and non-preferred shape was on average 0.6 and 1.0 spikes in M and NM conditions, respectively. This small but significant difference between the selectivity in M and NM conditions, increased notably when considering the first 200 msec of the response: average response differences of 0.6 and 2.6 spikes in M and NM conditions, respectively. Thus, longer temporal integration of the response results in a marked increase in discrimination capacity in the NM condition, but not when the briefly presented shape is followed by another stimulus. This suggests that the behaviorally observed backward masking is the result of temporal integration of the neuronal responses. (Supported by IUAP-22 & FGWO)

RESPONSES OF V4 NEURONS DURING VISUAL SEARCH. L. Chelazzi* and R. Desimone. Lab. of Neuropsychology, NIMH, Bethesda MD, 20892 and Dept. of Neurol. and Vis. Sci., Univ. of Verona, Verona, Italy.

In a previous study of the mechanisms underlying visual search (Chelazzi et al., *Nature* 1993, 363:345-347) we reported that cells in inferotemporal (IT) cortex of the macaque may participate in storing a representation of a searched-for (target) stimulus and in selecting the target from distractors. In the present study we investigated whether area V4 also contributes to such operations. A total of 140 neurons with extrafoveal receptive fields (RFs) were recorded in one macaque monkey. Each trial began with a brief presentation of a cue stimulus at fixation. Following a delay of 1.5 s, during which fixation had to be maintained, a pair of test stimuli was presented in the periphery, at random locations, and the animal was required to saccade to the target stimulus that matched the earlier cue, ignoring the other (distractor) stimulus. Contrary to what was previously found in IT, V4 neurons did not display cue-selective sustained activation during the delay interval. However, similar to IT cortex, V4 responses to the distractor stimulus were suppressed well before the eye movement to the target. This effect was maximum when target and distractor both lay within the RF borders, diminished substantially when the target stimulus was moved outside the RF, and diminished further with increasing distance of the target from the RF borders. Thus, in addition to IT cortex, V4 contains mechanisms for selecting a relevant target based on its features and discarding distractors. The fact that these mechanisms are most evident when target and distractor are located within a cell's receptive field suggests that they are based on local competitive interactions within area V4. The competition between target and distractor in V4 may be biased by top-down, or feedback, signals directed at cells coding the expected target's features.

NEURONAL RESPONSES IN MONKEY INFERIOR TEMPORAL CORTEX DURING LEARNING OF THE BEHAVIORAL RELEVANCE OF A VISUAL STIMULUS. B. Jagadeesh*, L. Chelazzi, R. Desimone, M. Mishkin. Lab. of Neuropsychology, NIMH, Bethesda, MD and Dept. of Neurol. and Vis. Sciences, Univ. of Verona, Italy.

With repeated stimulus-response-reward pairings, stimuli become behaviorally relevant and typically elicit orienting responses. To examine the neuronal mechanisms underlying the learning of stimulus relevance, we recorded from neurons in anterior inferior temporal cortex of a macaque monkey while the monkey acquired a stimulus-response-reward association. Pairs of stimuli were presented at random locations extrafoveally, and the monkey was rewarded for making a saccadic eye movement to one stimulus of each pair (the positive stimulus). During the recording session for a single cell, the animal learned "on-line" which stimulus was associated with the reward through trial and error.

Each pair was chosen on the basis of pre-testing to include one stimulus that activated the cell well on its own (good stimulus) and one that was ineffective (bad stimulus). Two pairs of stimuli were used for each cell, and good and bad stimuli were randomly assigned to be either positive or negative. The animal learned to find and saccade to the positive stimulus with a very short (150 ms) latency. Responses to the good-bad stimulus pair were averaged across the population of cells. During the 150 ms presaccadic period, responses were larger when the good stimulus of the pair was positive than when the bad stimulus was positive. The difference in the responses was present even though both good and bad stimuli were always present within the receptive field during that time. This result suggests that the competitiveness of representations of visual stimuli in anterior inferior temporal cortex can change with learning and influence the selection of targets from a scene.

Area TE connections with inferior prefrontal regions responsive to complex objects and faces. J.F. Bates*, F.A.W. Wilson, S.P. O'Scalaidhe and P.S. Goldman-Rakic. Yale Univ. Sch. Med., New Haven, CT 06510

Neurons in the inferior convexity of the prefrontal cortex have recently been found to respond selectively to complex stimuli such as pictures of objects and faces. These responses resemble those of feature-selective neurons in area TE of inferotemporal cortex. In order to investigate the connections between area TE and prefrontal cortex, we combined physiological mapping with WGA-HRP histochemistry to identify afferents of the prefrontal cortex involved in object vision. Injections were made in the inferior prefrontal cortex in three cases. Two cases received injections in area 45, one of which was first characterized electrophysiologically at the time of injection. The third animal received an injection in area 12. Following injections of area 45, we found retrogradely labeled cells and anterogradely labeled terminals in caudal TE, and in subdivisions TEa and TEm in the ventral bank of the STS. Labeling of area TE was also found in the case with an area 12 injection; in this case, the labeling was restricted to areas TEa and TEm in the ventral bank of the STS, and was located slightly rostral to that seen following injection of area 45. These findings indicate that area TE in the inferior temporal cortex, including the ventral bank of the STS, is a selective channel of object and feature information which links specific regions of the prefrontal cortex with the visual system. Learning a Visual Task as Reflected in Activity Dynamics of Macaque Inferotemporal Neurons Shaul Hochstein* and Volodya Yakovlev
Neurobiology Dept & Neural Computation Ctr, Hebrew Univ, Jerusalem, Israel

It is well-known that inferotemporal (IT) cortex of monkeys plays a crucial role in learning visual discrimination tasks. We now ask if the activity of IT neurons changes from session to session while the monkey's performance improves.

Multiple single-unit recordings were taken from IT cortex of macaque monkey performing a standard match-to-sample task. The stimuli were a bright solid circle and rectangle, of equal area and energy. We studied the responses of IT cells at all stages of learning: from the level of chance performance to 90% correct responses. For analysis the learning period was divided into 3 stages: I. chance performance; II. ~ 60% correct responses; and III. > 60% correct responses.

We found that the most dramatic changes in activity of IT cells occurred as the monkey progressed from stage I to stage II of the learning. For the SAME condition, in stage I the activity of IT cells was greater during the first, SAMPLE, stimulus than during the second, MATCH, stimulus while at later stages the response to the MATCH stimulus grew in size. The activity of cells during the inter-stimulus-interval (ISI) in stage I was suppressed compared to background activity, while in stages II and III for most cells ISI activity was stronger than background activity. Many cells were activated in the ISI as strongly as during stimulus presentation, implying that they may be involved in remembering the SAMPLE stimulus. Finally, in stage I, responses of IT cells to the second (MATCH) stimulus were suppressed for the SAME condition compared to the DIFFERENT condition. In later stages, the SAME response grew in size and presumably in importance. Thus, specifically the memory aspect of IT develops during learning.

A β -PROTEOGLYCAN INTERACTIONS ARE MEDIATED VIA CARBOHYDRATE MOIETIES. Rekha Gupta-Bansal, Robert C. A. Frederickson*, and Kurt R. Brunden. GliaTech, Inc., Cleveland, OH 44122

It is now well accepted that a variety of proteoglycans, including HSPG, CSPG and DSPG, are localized within amyloid plaques of Alzheimer's Disease. We have now fully characterized the binding of A β to these classes of proteoglycans, utilizing a solid-phase binding assay. In a typical assay, proteoglycan is immobilized on a microtiter dish and the bound A β is detected with an A β antibody (4G8). The data suggest that A β binding to proteoglycans (under physiological conditions) is dependent upon the physical state of the amyloid; proteoglycans bind fibrillar A β while no specific interaction is observed with non-fibrillar peptide. At pH values below neutrality, both non-fibrillar and fibrillar A β peptide bind proteoglycans. Complete inhibition of fibrillar A β binding to immobilized proteoglycan was observed with free glycosaminoglycans at physiological pH. These data suggest that the binding of proteoglycans to A β fibrils is mediated via carbohydrate moieties.

The demonstration of high affinity interactions between A β and proteoglycan classes localized to senile plaques, and our previous demonstration that A β -proteoglycan complexes are resistant to degradation, suggest a mechanism for amyloid accumulation and persistence. The development of specific compounds to disrupt A β -proteoglycan binding may result in improved A β clearance by naturally occurring proteases.

IDENTIFICATION OF PROTEINS THAT INTERACT WITH MEMBERS OF THE APP/APLP SUPERFAMILY. S. Guénette*, W. Wasco and B.E. Tanzi. Laboratory of Genetics and Aging and Molecular Neurogenetics Unit, Mass. General Hospital, Boston, MA 02129

The normal physiological role of members of the amyloid β -protein precursor (APP)/APP-like protein (APLP) superfamily is not clearly understood. However, the identification and characterization of proteins that specifically interact with select regions of APP and/or the APLPs may provide critical clues towards the elucidation of their normal cellular function(s). To identify proteins that interact with APP/APLP family members, we employed the transcription-based screening assay for interacting proteins known as the "interaction trap" (Gyuris *et al.* Cell 75:791, 1993). To this end, we have screened a human frontal cortex acid fusion cDNA library (a gift from Roger Brent's laboratory) for the purpose of identifying proteins that specifically associate with the following domains of the APP protein: 1) the extracellular Cys-rich region of APP751 (a.a. 38-187) and 2) the cytoplasmic domain of APP751 (a.a. 705-751). The cysteine-rich domain was chosen for the initial screen since its predicted secondary structure may allow for binding to brain-derived proteins acting as specific ligands for APP. Several cDNAs have been obtained which encode potentially interacting proteins for this region of APP. We will discuss the putative function of the proteins encoded by these cDNAs, the possible significance of their interaction with APP and/or the APLPs and their potential role in the neuropathogenesis of Alzheimer's disease.

435.2

INFLUENCE OF APO E PROTEIN ON APP METABOLITES IN INTACT LIVING CELLS. Anja L. Bieri, Douglas C. Anthony*, and Dennis J. Selkoe. Center for Neurologic Diseases, Brigham & Women's Hospital, Harvard Medical School, Boston, MA.

Both late onset familial and sporadic Alzheimer's disease (AD) show segregation with the ϵ 4 allele of the ApoE gene, which is located on chromosome 19. The biological mechanism by which the ApoE4 protein confers a greater risk of developing AD remains unclear. Although a direct amyloid- β -peptide (A β)-ApoE interaction was suggested based on *in vitro* data by Strittmatter *et al.* (PNAS, 1993), no corroborating *in vivo* data have been reported to date. We sought to investigate under *in vivo* conditions the influence(s) of ApoE on APP and its metabolites, with special focus on differences between the two ApoE alleles, E3 and E4. As a first step, we have constructed expression plasmids with ApoE transcription under control of an RSV LTR promoter. An ApoE3 cDNA was converted to ApoE4 by mutagenesis, resulting in a substitution of arg for cys at amino acid 112. ApoE expression of both plasmids was tested by Western blotting and immunoprecipitation of transient and stable transfectants. These APP/ApoE double transfected lines are highly useful for detailed investigations of ApoE influence on APP processing and/or A β aggregation and stability. In preliminary experiments, we detected no effect of either ApoE allele on APP proteolytic processing in both CHO and 293 cells stably transfected with APP695. In addition, both cell types showed no major differences between ApoE3 and 4 in A β secretion. Additional experiments with the doubly transfected cells and with incubations of recombinant ApoE3 and 4 with intact cells are underway.

435.4

BEYOND β -PROTEIN—THE ROLE OF AMYLOID-PROMOTING FACTORS, LYMPHOKINES, AND NON-NEURONAL CELLS AND TRISOMY 21 IN THE PATHOGENESIS OF ALZHEIMER'S DISEASE. H. Potter*, S. Das, L. Geller, J. Ma, M. Niethammer, *L. Scinto, *K. Daffner, and D. Dressler. Department of Neurobiology, Harvard Medical School and *Beth Israel Hospital, Boston MA 02115

Two puzzling features of the filamentous amyloid of Alzheimer's disease and Down syndrome are the regional specificity of the deposition and the presence of other structural components, such as the protease inhibitor ACT and the lipid carrier apoE. We believe, on the basis of recent data from our own and other labs, that the solution to these puzzles lies in the brain-region-specific expression by astrocytes of amyloid-promoting agents (pathological chaperones) that catalyze the polymerization of A β into amyloid filaments. Specifically, we have found that the two amyloid-associated proteins, ACT and apoE, stimulate amyloid filament formation 10 to 20-fold (see Ma *et al.*). Furthermore, preliminary evidence indicates that ACT and apoE increase A β neurotoxicity. The expression of the amyloid catalyst ACT is induced in cultured human astrocytes by IL-1, which, in turn, is expressed by cortical microglial cells both *in vivo* and *in vitro*. Trisomy 21 causes AD in Down syndrome individuals. We have found that non-Down syndrome AD patients also show an increase in trisomy 21. Furthermore, we have found that AD patients, like Down syndrome persons, show a marked hypersensitivity to the pupil dilating effect of cholinergic receptor antagonists (see Scinto *et al.*). These two results are consistent with the hypothesis that AD is a mosaic form of trisomy 21 Down syndrome.

SEQUESTRATION OF AMYLOID β -PROTEIN BY TRANSTHYRETIN: STRUCTURAL STUDIES OF TTR- $\text{A}\beta$ INTERACTION. A.L. Schwarzman, M. Tsiper, M.P. Vitek, M. Eisenberg, and D. Goldgaber*. Dept. of Psychiatry and Pharmacology, SUNY, Stony Brook, NY 11794 and The Picower Institute, Manhasset, NY, 11030.

Recently, we proposed that sequestration of $\text{A}\beta$ in biological fluids and extracellular space is the key step in the homeostatic mechanism which prevents $\text{A}\beta$ amyloidosis, and that failure to sequester $\text{A}\beta$ may lead to amyloid formation. We then found that in cerebral spinal fluid, TTR sequesters $\text{A}\beta$ into stable complexes. We also showed that TTR prevented amyloid formation *in vitro*. In order to investigate the interaction of the two proteins, a computer graphic model of the TTR- $\text{A}\beta$ complex was built and the $\text{A}\beta$ binding domain with several negatively charged amino acid was predicted. To verify this model, forty different mutations were introduced into the putative binding domain of recombinant TTR and the mutants were tested for binding of radioiodinated $\text{A}\beta$. The mutants of TTR that failed to bind $\text{A}\beta$ and to prevent amyloid formation were identified and the key amino acids of TTR that interact with $\text{A}\beta$ were determined. These results enabled us to refine the model and predict possible variants of TTR that may be associated with $\text{A}\beta$ amyloidosis. The correct model of TTR- $\text{A}\beta$ complex will identify structural requirements for compounds that prevent amyloid formation.

DISTRIBUTION OF APOLIPOPROTEIN E AND β -AMYLOID PROTEIN IN CULTURES OF NEURONS, MICROGLIA AND ASTROCYTES. M.D. Ard*, G.M. Cole, and A.P. Mehrle. Dept. of Anatomy, U. of Miss. Med. Ctr., Jackson, MS 39216, & Dept. of Medicine, UCLA and GRECC, VAMC, Sepulveda, CA 91343.

Understanding the mechanistic basis for apolipoprotein E (ApoE) genotype as a major risk factor for β -amyloidosis and Alzheimer's disease requires an exploration of ApoE and β -amyloid protein ($\text{A}\beta$) interactions with CNS cells.

Cells were cultured from embryonic (neurons) or neonatal (astrocytes) rat cerebral cortex or from adult rat spinal cord (microglia), in serum-free medium. After incubation with ApoE (Organon Teknica or Calbiochem), only microglia showed substantial cellular immunostaining with anti-ApoE, indicating a high density of receptors consistent with existing data on macrophages. Neuronal cell bodies and astrocytes were rarely immunopositive. $\text{A}\beta$ (42 amino acids) added to culture medium was cleared from the medium and accumulated intracellularly by microglia (immunoblots and immuno-EM) and accumulated by neurons and astrocytes. Incubation with both ApoE and $\text{A}\beta$ together resulted in increased anti-ApoE immunostaining in all three cell types, colocalized with $\text{A}\beta$ immunoreactivity; however, by Western analysis, ApoE dramatically reduced the amount of $\text{A}\beta$ monomer and aggregates accumulated by microglia. These results, suggesting that ApoE may be an important determinant of microglial $\text{A}\beta$ clearance rates, provide both a mechanism for $\text{A}\beta$ clearance and a rationale for ApoE as a risk factor for Alzheimer's. Supported by the Alzheimer's Association (MDA) and NIH AG9009-04 and the Cal. State Dept. of Health (GMC).

Alzheimer's disease (AD) is characterized by formation in brain of neurofibrillary tangles and of amyloid deposits. Brain amyloid burden is highest in AD patients homozygous for the apolipoprotein E $\epsilon 4$ (*apoE* $\epsilon 4$) allele, inheritance of which is a major risk factor for the development of AD. To investigate the relationship of *apoE* genotype with brain metabolism of the amyloid β -protein precursor (APP), we measured cerebrospinal fluid (CSF) levels of amyloid β -protein ($\text{A}\beta$) and of secretory N-terminal APP derivatives in 19 AD patients with varying degrees of dementia and with the most common combinations of *apoE* alleles, that is, $\epsilon 3/\epsilon 3$, $\epsilon 3/\epsilon 4$, and $\epsilon 4/\epsilon 4$. Mean CSF levels of $\text{A}\beta$, of the 106 and the 25 kDa N-terminal APP derivatives were similar among the *apoE* genotype groups. In contrast, CSF levels of $\text{A}\beta$ were inversely and significantly correlated both to cognitive and to functional measures of dementia severity. We conclude that measurements of CSF $\text{A}\beta$ provide a useful biochemical marker which parallels dementia severity in AD but is independent of *apoE* genotype.

435.6

ISOFORM-SPECIFIC BINDING OF APOLIPOPROTEIN E TO β -AMYLOID PEPTIDES. M.T. Falduto*, M.J. LaDu, A.M. Manelli, C.A. Reardon, G.S. Getz, D.E. Frail. Dept. of Neuroscience, Abbott Laboratories, Abbott Park, IL 60064 and Dept. of Pathology, University of Chicago, Chicago, IL 60637.

Apolipoprotein E (apoE), particularly the $\epsilon 4$ allele, is genetically linked to Alzheimer's disease (AD). ApoE has previously been shown to bind to β -amyloid ($\text{A}\beta$), an amyloidogenic, proteolytic product of amyloid precursor protein. To analyze the interaction of $\text{A}\beta$ and apoE, we used Western immunoblotting of $\text{A}\beta$ peptides incubated with concentrated, conditioned media from HEK293 cells stably transfected with either apoE3 or apoE4 human cDNA. Non-reducing SDS-PAGE revealed the presence of a ~45kd multi-protein complex with both $\text{A}\beta$ and apoE immunoreactivity. Using either $\text{A}\beta$ 1-40 or $\text{A}\beta$ 1-28 peptides, the level of apoE3/ $\text{A}\beta$ complex was ~20-fold greater than apoE4/ $\text{A}\beta$ complex. This apoE isoform-specific binding pattern was maintained at concentrations of $\text{A}\beta$ from 10uM to 1mM, from pH 5 to pH 9, and from 2 minutes to 24 hours of peptide incubation. The higher level of apoE3 binding to $\text{A}\beta$ are in contrast to previously published data using purified apoE that had been delipidated and denatured (Proc. Natl. Acad. Sci. 90:8098, 1993). These data suggest that apoE3 may play a role in protecting against AD by binding $\text{A}\beta$ and preventing aggregation or facilitating uptake/removal of this amyloidogenic fragment.

435.8

APOLIPOPROTEIN E (APOE) GENOTYPE AND IMMUNOHISTOCHEMICAL FINDINGS IN ALZHEIMER'S DISEASE (AD) WITH AND WITHOUT PARKINSON'S DISEASE (PD) CHANGES. M. Gearing*, J.A. Schneider and S.S. Mirra. Department of Pathology and Laboratory Medicine, VA Medical Center and Emory University School of Medicine, Atlanta, GA 30322.

The $\epsilon 4$ allele of ApoE has recently been identified as a risk factor for the development of AD, and colocalization of ApoE and $\text{A}\beta$ has been observed in senile plaques. Genetic dysequilibrium of the $\epsilon 4$ allele and the ApoE-amyloid association in senile plaques were investigated in 100 dementia patients with neuropathologically confirmed AD with and without coexistent PD pathology (nigral degeneration and Lewy bodies at any site). AD+PD (n=50) and "pure AD" (n=50) cases were matched for age, sex, and duration of dementia. DNA was extracted from frozen or formalin fixed paraffin-embedded tissues, and ApoE genotype was determined using a PCR/restriction enzyme method. We found that 72% of the patients in each group had at least one ApoE $\epsilon 4$ allele compared with reported estimates of 20-25% in the general population. The AD vs. AD+PD groups also showed similar immunohistochemical findings. Although cortical plaques generally demonstrated $\text{A}\beta$ ApoE colocalization, $\text{A}\beta$ ApoE-positive plaques in focal neocortical regions were ApoE-immunonegative. In all cases, $\text{A}\beta$ ApoE-positive diffuse plaques in the striatum failed to label with antibody to ApoE, whereas cerebellar diffuse plaques showed consistent colocalization of $\text{A}\beta$ and ApoE. These discrepancies may be explained in several ways: (1) amyloid processing differs regionally, and the association between $\text{A}\beta$ and ApoE is not universal; (2) ApoE-immunonegative plaques may represent an earlier stage in plaque evolution than ApoE-positive plaques, and the ApoE- $\text{A}\beta$ colocalization is a later phenomenon; (3) ApoE is present in all plaques, but in some plaques the levels are too low to be detected with our methods; or (4) ApoE is more sensitive to technical vagaries than $\text{A}\beta$. Supported by VA Merit Award and NIH grant AG10130.

INCREASED APOLIPOPROTEIN E $\epsilon 4$ ALLELE FREQUENCY IN ALZHEIMER'S DISEASE (AD) AND IN VASCULAR DEMENTIAS (VD). S. Govoni, G. Frisoni[#], A. Bianchetti[#], G. Franceschini[#], L. Calabresi[#], Y. Olgiati^{*A} and M. Trabucchi^S. Inst. Pharm. Sci. and ^EE. Grossi Paoletti Ctr., Univ. of Milano, [#]Alzheimer's Disease Unit, FBF-S.Heart Hospital, Brescia, ^AR&D Poli, Milano; ^SDept Exptl. Med. Biochem. Sci., Univ. of Roma T.Vergata, ITALY

ApoE is the only apolipoprotein expressed in the nervous system where it may participate in the transport of cholesterol and lipids via binding to LDL and LRP receptors. In AD apolipoprotein E has been found in senile plaques and ApoE4 (Apo E is encoded by a single gene, a common polymorphism is determined by alleles $\epsilon 2$, $\epsilon 3$ and $\epsilon 4$) binds *in vitro* to β -amyloid. These observations stimulated the search of ApoE genes in AD leading to the discovery that ApoE $\epsilon 4$ frequency is raised in AD (Corder et al., Science 261, 921, 1993). The increased prevalence of $\epsilon 4$ allele is confirmed in our series of AD patients. The ApoE $\epsilon 4$ frequency determined in 120 clinically diagnosed AD patients was 0.43 (P<0.0001) compared to 0.09 in 64 age and sex matched controls. The presence of two copies of ApoE $\epsilon 4$ alleles was associated with an earlier onset of the illness. The age adjusted risk for AD increased with the allele dose. Notably a gender effect was observed, since the presence of one $\epsilon 4$ allele was sufficient to significantly increase the odds ratio for AD in females (5.6, P<0.009), but not in males (2.8, n.s.) suggesting an interaction between Apo E $\epsilon 4$ and sex hormones. This view is supported by the observation that estrogen replacement therapy may decrease the risk for AD in women (Paganini et al. Soc.Neurosci. Abs., 1993). Moreover an increased $\epsilon 4$ frequency (0.41, 32 patients; P<0.001) was observed in VD. This last observation indicates that the ApoE $\epsilon 4$ allele specificity for AD is doubtful and that the modified allele frequency may have some more fundamental role in altering the sensitivity of neurons to damage, perhaps through an impairment of repair processes in the brain.

435.11

SECRETION OF β -APP INTO THE RAT CSF: AGED RATS SECRETE SIGNIFICANTLY HIGHER LEVELS OF β -APP FOLLOWING FOREBRAIN CHOLINERGIC LESIONS THAN YOUNG RATS. V. Haroutunian*, K.L. Davis, R. Gluck, E. Fiber & W.C. Wallace. Department of Psychiatry, Mount Sinai School of Medicine, NY, NY, and Laboratory of Biochem. Genetics, NIMH, Washington, D.C.

Experimental lesions of various subcortical neurotransmitter systems (cholinergic, noradrenergic, serotonergic) induce β -APP expression in the cortex of the rat. This induction results in the persistent secretion of β -APP into the cerebrospinal fluid (CSF). In the current series of experiments young (2 month old) and old (24 month old) Fischer 344 rats received unilateral N-methyl-D-aspartic acid lesions of the cholinergic basal forebrain. One week after lesioning, cisternal CSF was collected and the rats were sacrificed. Analysis of cortical choline acetyltransferase activity (ChAT) showed that cortical cholinergic marker activity was significantly ($p < 0.001$) reduced by approximately 50-56% in both groups. Immunoblots of the CSF using an antibody ($\alpha 5$) to the secreted β -APP showed that significantly higher levels of β -APP were present in the CSF collected from lesioned rats relative to sham operated controls ($p < 0.0001$). In addition, a significantly ($p < 0.0002$) greater amount of β -APP was present in the CSF of lesioned aged rats relative to lesioned young rats (118% increase vs 66% increase). Basal levels of β -APP in the CSF of young and old sham lesioned rats did not differ ($p > 0.2$). The levels of β -APP in the CSF were highly, and inversely, correlated with the degree of cortical ChAT depletion ($r = -0.55$, $p < 0.001$). Since secreted β -APP contains the potentially amyloidogenic $A\beta_{1-28}$ amino acid sequence, these results suggest that the consequences of cholinergic system dysfunction may be more deleterious in the old than in the young.

IMAGING STUDIES OF A TC-99M ANTI-A β FAB MONOCLONAL ANTIBODY (MAB) IN ALZHEIMER'S DISEASE (AD) USING SPECT. R.P. Friedland, J.M. Reno, R.E. Majoie, M.S. Berridge, F. Miraldi, P. Hedera*, L.R. Lyle, C.A. Marotta. Alzheimer Center, University Hospitals, CWRU, Cleveland, OH 44106; NeoRx Corp., Seattle, WA; Mallinckrodt Medical, St. Louis, MO; Brown University, Providence RI.

A Mab (10H3) targeting the AD A β protein has been developed as a tool for the in vivo assessment of amyloid angiopathy using SPECT. Results from immunocytochemical studies using the 10H3 antibody suggest that microvascular A β is accessible to an imaging agent delivered via the IV route. The 10H3 antibody is stably radiolabeled by conjugation of a preformed Tc 99m diamine dithiolate chelate active ester with the protein amino groups, and fractionated to Fab fragments. In vitro and animal studies in vivo have demonstrated the safety, sensitivity, specificity and satisfactory biodistribution of the labeled 10H3 Fab (*J. Nuc. Med.* 33:2184, 1992; *Mol. Neurosci.*, in press). SPECT and gamma camera imaging in 4 patients with AD demonstrate rapid appearance of activity in the blood pool in the thorax and brain, with rapid uptake in liver and kidney. Clearance of the label from serum is slower than expected, with an initial half life of 3 to 4 hours. No binding to rbc's could be shown, and free Tc-99m was minimal. Tomographic brain images obtained up to 15 hours after injection show retained activity in the venous sinuses with patchy activity in the brain parenchyma. Studies are currently underway to compare the brain distribution of the label to known blood volume markers, and compare patients in the early and later stages of the disease. A label with a longer physical half life may be needed to allow for imaging at later times following clearance of the radiopharmaceutical from the blood.

HYPOTHALAMIC-PITUITARY-GONADAL REGULATION

436.1

DO THYROID HORMONES REGULATE THE ONSET OF THE BREEDING SEASON IN THE EWE? L. T. Thrun, G. E. Dahl*, E. J. Karsch. Repro. Sci. Prog., Dept. of Biology, and Dept. of Physiol., Univ. of Michigan, Ann Arbor, MI 48109.

Thyroid hormones are required for the transition from the breeding to non-breeding state in a variety of species ranging from starlings to sheep. The onset of the breeding season appears to be thyroid hormone-dependent as well in the starling because premature testicular recrudescence occurs in birds thyroidectomized (THX) as they enter the non-breeding state (*J. Exp. Zool.*, 179: 331-338). In the present study, we tested the hypothesis that thyroid hormones are involved in the transition from the non-breeding season (anestrus) to the breeding season in the ewe, a species in which both onset and end of the breeding season are generated by an endogenous rhythm. We determined the influence of thyroidectomy on the onset of the breeding season in ewes maintained outdoors and ewes held in a fixed short-day photoperiod in which the endogenous reproductive rhythm would be unmasked. All animals were ovariectomized (OVX) and received s.c. Silastic implants of estradiol. As an index of reproductive neuroendocrine activity, luteinizing hormone (LH) was measured in twice weekly blood samples. A sustained increase in circulating LH above 1 ng/ml denoted the onset of the breeding season. Ewes maintained outdoors were either THX in late anestrus (Aug., n=8), THX in early anestrus (Mar., n=4), or remained thyroid intact (n=7). There was no group difference in the mean date of increase in LH (20 Sept \pm 10, 16 Sept \pm 6, and 14 Sept \pm 3, respectively). Ewes held in constant photoperiod were either THX early in anestrus (a month after LH decreased; n=3) or remained thyroid intact (n=3). Again, there was no difference in the onset of the subsequent breeding season, with LH rising 6 mo. after the previous decline. We conclude that thyroid hormones do not influence the transition into the breeding season in the ewe. Rather, thyroid hormone action on the reproductive neuroendocrine axis appears to be limited to the processes involved in the development of anestrus. CHOLINE ACETYLTRANSFERASE ACTIVITY IS DECREASED IN FRONTAL CORTEX BIOPSY SAMPLES OF DEMENTED PATIENTS WITH ELEVATED EXTRACELLULAR β -AMYLOID.

O.S. Jørgensen, G. Waldemar*, M. Juhler* (SPON: European Neuroscience Association). Laboratory of Neuropsychiatry, Department of Pharmacology, University of Copenhagen, Rigshospitalet-6102, DK-2100 Copenhagen, Denmark, and *Departments of Neurology and Neurosurgery, University Hospital, Rigshospitalet, Copenhagen, Denmark.

Demented patients suspected to suffer from normal-pressure hydrocephalus were evaluated for shunt surgery and a small biopsy was taken from the right frontal cortex of fourteen patients. One patient with tumour cerebri was excluded. Slight-to-moderate Alzheimer disease (AD) was demonstrated in three of the patients (β -amyloid peptide containing plaques, a few tangles) and diffuse β -amyloid peptide staining was shown in one patient. The specific activity of choline acetyltransferase (ChAT) in the frontal cortex of these four patients (mean age 68 years, range 63-70) was decreased 33 percent in comparison with the other nine patients ($p < 0.05$; mean age 64 years, range 53-75) which apparently had a normal level of ChAT (68 ± 5 pmol/min/mg protein, 37°C). The decrease in ChAT was only half the decrease previously observed in autopsy frontal cortex samples of AD patients. Glial fibrillary acidic protein and glutamine synthetase were not significantly changed. Blood flow in the right frontal cortex was decreased in eight of the patients, including the patients with positive β -amyloid peptide staining. In the low-flow patients ChAT was decreased 26 percent ($p = 0.08$, two-tailed t-test). The results cannot exclude that precipitation of β -amyloid peptide and down-regulation of the cholinergic function are associated early in the pathogenesis of AD and might be a consequence of a decreased regional blood flow (Supported by The Danish Medical Research Council).

A PHYSIOLOGICAL ROLE FOR EXCITATORY AMINO ACIDS IN THE CONTROL OF PULSATILE LH SECRETION. V.B. Mahesh*, L. Ping and D.W. Brann. Department of Physiology & Endocrinology, Medical College of Georgia, Augusta, GA 30912.

The purpose of the present study was to determine the role of excitatory amino acids (EAAs) such as glutamate and aspartate in the regulation of pulsatile luteinizing hormone (LH) secretion in adult male and female rats. To achieve this aim, specific EAA receptor antagonists were injected into the third ventricle of castrated adult rats and the effect on pulsatile LH secretion was determined. The specific N-methyl-D-aspartate (NMDA) receptor antagonist AP5 (2-amino-5-phosphono-pentanoic acid, 10 μ g/rat) and the specific non-NMDA receptor antagonist DNQX (6,7-dinitroquinoxaline-2,3-dione, 30nM) were utilized in these studies. In female rats, administration of either AP5 or DNQX resulted in a significant suppression of mean LH levels which was due to a suppression of both LH pulse frequency and amplitude. In male rats, AP5 suppressed mean LH levels and amplitude with no effect on frequency, while DNQX had no effect on any parameter of LH secretion. Increasing the duration of exposure to the antagonists by administering three injections (instead of one) at 20 minute intervals yielded similar results to a single injection for AP5, while three injections of DNQX (20 nM each injection) now caused a significant suppression of mean LH levels and pulse amplitude with no effect on frequency. These studies provide evidence that EAAs acting through both NMDA and non-NMDA receptors play a significant role in regulating pulsatile LH secretion and that female animals have a higher sensitivity than male animals to this regulation.

436.3

EFFECT OF MACRONUTRIENT COMPOSITION ON FEEDING-INDUCED LUTEINIZING HORMONE SECRETION IN RHESUS MONKEYS. D.A. Schreihofer*, E. Renda, and J.L. Cameron. Departments of Neuroscience, Psychiatry, and Cell Biology and Physiology, University of Pittsburgh, Pittsburgh, PA 15260.

One day of fasting significantly suppresses pulsatile LH secretion in adult male rhesus monkeys. Feeding on the day following a fast (refeeding) leads to a rapid resumption of pulsatile LH release that is dependent on the amount eaten. The current study examined the role of macronutrient content of the refeed meal on LH secretion. Seven adult male rhesus monkeys were fitted with indwelling venous and intragastric catheters and maintained on standard jacket-tether-swivel systems. Monkeys were fasted on the day before the study. On the following day monkeys were either fasted for a second day or fed a liquid diet through the indwelling gastric catheter. Three diets of equal volume (600 ml) and caloric content (600 Cal) were used. One was equal in macronutrient content to their normal monkey chow (mixed meal); one consisted of a pure carbohydrate source (dextrose); and one consisted of a mixture of protein (casein) and fat (Liposyn) in the same ratio as the mixed meal. Blood samples were collected every 20 min from 1100-2400 h, and LH was measured by RIA. On a day of fasting LH secretion was low, however, administration of all three liquid diets significantly stimulated pulsatile LH secretion in a similar manner (see example). These results suggest that the feeding-induced stimulation of LH secretion is more dependent on caloric content than macronutrient composition.

EFFECTS OF ETHANOL (ETOH) ON NMA-INDUCED SECRETION OF LH AT THE TIME OF FEMALE PUBERTY. C.L. Nyberg, J.K. Hiney, V. Srivastava, W.L. Dees*, Department of Vet. Anatomy, Texas A&M Univ., College Station, TX. 77843

We have shown that EtOH can delay puberty and block LHRH secretion *in vitro*. Additionally, we have shown that EtOH blocks LHRH secretion induced by NMA *in vitro* and delays NMA-induced precocious puberty. The present study determined if EtOH could block NMA's ability to elicit LH release *in vivo*. Prepubertal female rats were implanted with jugular cannulae and blood samples were drawn at 10 min intervals on the following day. Four samples were taken to establish basal release before a 3g/kg dose of EtOH (or an equal volume of saline) was administered by gastric gavage. After 90 min to allow for EtOH absorption, the animals received NMA (2.5 mg/kg IV) then four more blood samples were taken. Rats were killed and confirmed to be in first proestrus. In the EtOH-treated animals, the peak LH pulse after NMA was blunted to a $24.0 \pm 12.1\%$ increase over basal. In the saline control animals, the peak LH pulse was increased by $167.8 \pm 58.1\%$, significantly ($p < 0.01$) greater than the EtOH-treated animals. These results suggest that EtOH is capable of altering the excitatory amino acid-induced LH secretion at the time of first proestrus. (Supported by NIH-AA07216)

APPROXIMATE ENTROPY STATISTICS REVEAL NON-GNRH-DEPENDENT SUBORDINATE ACTIVITY IN FSH CONCENTRATIONS IN THE PERIPHERAL AND HYPOPHYSAL PORTAL CIRCULATIONS OF OVARECTOMIZED SHEEP. A.R. Midgley*, S.M. Pincus and V. Padmanabhan. Reproductive Sciences Program, National Center for Infertility Research, Univ. of Michigan, Ann Arbor, MI 48109 and 990 Moose Hill Rd., Guilford, CT 06437 (SMP)

Continuous sampling of hypophyseal portal blood (HPB) from unrestrained sheep is not only providing an unprecedented means for defining the secretory profiles of GnRH, this method can also be used to reveal the dynamics of pituitary hormone secretion without deconvolution (Midgley et al., Program, Endocrine Soc., 1992). These studies have shown that, while GnRH pulses are followed by secretion of LH and FSH, non-GnRH-driven pulses of FSH can also be observed in HPB. In contrast, discrete pulses of FSH cannot be discerned reliably in peripheral blood. Recently, a novel algorithmic method was developed that provides an estimation of the regularity in a data set by means of calculating the approximate entropy or ApEn statistic (Pincus, PNAS 88:2297, 1991). The objective of this study was to determine if the ApEn statistic would be able to discern in peripheral blood the dissociations in LH and FSH secretory bursts revealed in the HPB. We calculated the ApEn statistic for concentrations of LH and FSH in 7 sets of 72 samples of peripheral and portal blood obtained every 5 min from ovariectomized ewes. Group comparisons of ApEn for secreted HPB FSH (1.415 ± 0.097 SD) and HPB LH (0.822 ± 0.213 SD) differed with $P = 0.00077$ by paired t-test. Of greater interest was the persistence of these differences in the periphery, $FSH = 1.431 \pm 0.101$ and $LH = 1.252 \pm 0.086$ with $P = 0.024$. These highly significant differences in ApEn suggest that FSH has considerably more irregularity than LH, a result that confirms our measurements at the site of secretion. This approach may help delineate differences in LH and FSH secretory patterns in the peripheral blood of humans, in whom HPB cannot be obtained readily. (Supported by NIH U54 HD29184)

436.4

INFLUENCE OF ETHANOL (ETOH) ON INSULIN-LIKE GROWTH FACTOR-1 (IGF-1) AND IGF-1 RECEPTOR (IGF-1R) SYNTHESIS DURING FEMALE PUBERTY. V. Srivastava, J.K. Hiney, C.L. Nyberg, N.H. McArthur*, and W.L. Dees. Dept. of Vet. Anatomy, Texas A&M University, College Station, TX 77843-4458.

Recently, we showed that most IGF-1 available to the hypothalamus at puberty is derived from peripheral sources and that IGF-1 activates the LHRH/LH releasing system of prepubertal female rats; thus, indicating IGF-1 may participate in the control of LH secretion at the time of puberty. Since EtOH delays puberty and is associated with depressions in GH and LH, we investigated in this study whether EtOH can affect a) IGF-1 gene expression in liver, b) IGF-1R gene expression in the median eminence (ME) and c) serum levels of IGF-1 and LH. Prepubertal female rats were implanted with gastric cannulae on day 24 and began receiving control or EtOH liquid diets on day 29. On day 34, rats were killed, determined to be anestrus, and tissues and blood collected. Results indicate that the EtOH-fed rats showed a decrease ($p < .001$) in liver IGF-1 mRNA levels compared with the controls, and this paralleled depressions in both serum IGF-1 ($p < .01$) and LH ($p < .05$). No changes were detected in IGF-1R mRNA within the ME. These results suggest that EtOH may alter the pubertal process, at least in part, by blocking the peripubertal increase in the synthesis of IGF-1, a peptide suggested as a metabolic signal involved in the onset of puberty. (Supported by NIH-AA07216)

PULSATILE FSH SECRETION IN THE OVARECTOMIZED EWE IS CONTROLLED BY BOTH GnRH-DEPENDENT AND GnRH-INDEPENDENT MECHANISMS. V. Padmanabhan*, K.L. McFadden, N.P. Evans, G.E. Dahl, D.T. Mauger, F.J. Karsch. Department of Pediatrics and Physiology, Reproductive Sciences Program and the National Center for Infertility Research at Michigan, University of Michigan, Ann Arbor, MI.

The objectives of this study were to determine: i) if FSH secretion is episodic and ii) if a GnRH-independent control of episodic FSH secretion exists. Hypophyseal portal blood and peripheral blood were collected from five short-term ovariectomized ewes at 5-min intervals for 6 h before and 6 h after a single i.v. injection of Nal-Glu, a GnRH antagonist (10 µg/kg body weight). GnRH in portal blood, and LH and FSH in both jugular and portal blood were determined by radioimmunoassays. Pulsatile GnRH secretion was evident both before and after Nal-Glu administration. Pulses of LH in the portal circulation coincided with those seen in the peripheral circulation but were larger and more discrete in nature. The pattern of FSH in peripheral blood was not episodic. In marked contrast, FSH in portal blood was unambiguously pulsatile. Prior to Nal-Glu treatment, each pulse of GnRH correlated with a pulse not only of LH but also of FSH in portal blood. However, 49% of the total FSH pulses occurred in the absence of corresponding GnRH pulses. Following Nal-Glu administration, LH pulsatility was completely eliminated, demonstrating its dependence on GnRH. In contrast, Nal-Glu administration blocked only GnRH associated pulses of FSH; it did not block other episodes of FSH release. We conclude that in the ovariectomized ewe: i) FSH secretion is episodic; ii) all GnRH pulses induce an FSH pulse; iii) there exists a GnRH-independent episodic component of FSH release. Our results are consistent with the hypothesis of a dual regulation of FSH release. Supported by NIH grants U54 HD 29184, P30 HD 18258.

INHIBITION OF ENDOGENOUS NEUROPEPTIDE Y (NPY) SYNTHESIS BY ANTISENSE OLIGODEOXYNUCLEOTIDE ADMINISTRATION SUPPRESSES THE PROGESTERONE-INDUCED LH SURGE. Kalra, P.S.*, Bonavera, J.J., Dube, M.G., Crowley, W.R. and Kalra, S.P., Departments of Physiology and Neuroscience, Univ. Fla., Gainesville, FL 32610 and Department of Pharmacology, Univ. Tenn, Memphis, TN 38163

Evidence shows that NPY is involved in stimulation of the LHRH and LH surges induced by progesterone (P) in estradiol benzoate (EB)-primed ovariectomized (ovx) rats. We have also reported that P stimulates NPY peptide content and preproNPY mRNA levels in the hypothalamus of these rats, thereby suggesting P-induced activation of NPY synthesis. To evaluate whether newly synthesized NPY is critical in induction of the P-induced LH surge, ovx rats fitted with permanent cannulae in the lateral cerebroventricle (icv) were primed with EB (30 µg/rat s.c.). Two days later, these rats received P at 1000 h (2 mg/rat s.c.). Additionally, they were injected icv at 1000, 1200 and 1400 h with either NPY antisense or scrambled oligodeoxynucleotides (OLIGO); controls were injected with saline. Blood samples were withdrawn via pre-implanted intra-atrial cannulae at 1000 h and at hourly intervals between 1400-1800 h for LH analysis. Results show that robust LH surges occurred in controls and in rats injected with scrambled OLIGO. However, in rats injected with NPY antisense OLIGO to block NPY synthesis, the P-induced LH surge was completely suppressed. These results support the hypothesis that P activates *de novo* synthesis of NPY, which is necessary to evoke LHRH and LH surges. (Supported by NIH HD 08634).

FOOD RESTRICTION INCREASES NPY GENE EXPRESSION IN A SUBPOPULATION OF NPY NEURONS IN THE ARCULATE NUCLEUS OF PREPUBERTAL RATS. J.L. Cameron*, D.J. Hollingshead and M.S. Smith. Departments of Psychiatry, Neuroscience and Neurobiology, University of Pittsburgh, Pittsburgh, PA 15261.

Food restriction has been shown to delay the onset of puberty in female rats. Others have reported that food restriction increases hypothalamic NPY activity. These studies examined whether changes in NPY gene expression were associated with the delayed onset of puberty induced by food restriction. Three groups of prepubertal rats (n=6 each) began treatment on day 28 of age and were sacrificed on day 42: 1) controls (C), ad lib feeding; 2) food restriction (FR); 3) food restriction + 24 hrs of ad lib feeding before sacrifice (FR + 24 hr refeed). Average body weights on day 42 were C, 136.6 ± 3.3 gm; FR, 74.2 ± 0.7 gm; and FR + 24 hr refeed, 99.6 ± 1.3 gm. At the time of sacrifice, C animals were in various stages of the estrous cycle, whereas none of the FR groups had exhibited first estrus. *In situ* hybridization was performed on 20 µm brain sections using a ³⁵S riboprobe for rat NPY mRNA. The data were analyzed by measuring the area occupied by silver grains over the arcuate nucleus. NPY mRNA levels did not differ among the three groups in the rostral portions of the arcuate nucleus. However, in the caudal portions of the arcuate nucleus, NPY mRNA levels were increased by 76% in response to food restriction: C = 59,108 ± 5,774 (area occupied by silver grains); FR = 104,042 ± 6715. FR + 24 hr refeed resulted in NPY mRNA levels that were in-between C and FR values (FR + 24 hr refeed = 84,302 ± 8769). These data demonstrate that the delay in the onset of puberty induced by food restriction is associated with an increase in NPY mRNA levels in a specific population of NPY neurons in the caudal portion of the arcuate nucleus. Further studies will be necessary to determine whether these NPY neurons play a role in causing the suppression of GnRH secretion that underlies the delay of puberty induced by food restriction.

AXONAL TRANSCRIPTS IN THE RAT HYPOTHALAMO-NEUROHYPOPHYSIAL TRACT: G.F. Jirikowski*. Dept. of Neuroendocrinology, Max Planck Inst. for Psychiatry, Klin. Inst., Munich, Germany.

With light- and electron microscopical *in situ* hybridization and non radioactive detection methods, we could obtain evidence that oxytocin- and vasopressin- encoding mRNA is present in the axonal pathway of magnocellular hypothalamic perikarya, probably associated with a fraction of the large secretory vesicles. mRNA is likely to be subject to rapid axonal transport, since osmotic challenge changes axonal concentrations of transcripts, while colchicine treatment blocks such effects. In recent studies we could demonstrate that several other transcripts occur in magnocellular hypothalamic axons in the median eminence and the posterior lobe: mRNA coding for cfos and cjun as well as tyrosine hydroxylase mRNA could be found in the median eminence and the posterior lobe. Salt loading resulted in a shift of hybridization signal to the magnocellular perikarya within 15min, which could be prevented by pretreatment with colchicine. Pretreatment with a polymerase II inhibitor did not affect increase of hybridization signals in the paraventricular and supraoptic nuclei upon osmotic stimulation. It is likely that neuroendocrine systems with high secretory capabilities, like the hypothalamo neurohypophyseal system, utilize their large axonal volume for storage of transcripts, which are perhaps compartmentalized in vesicles, to circumvent degradation. Retrograde transport upon specific stimulation may allow for immediate de novo translation, to replenish depleted peptide pools in terminal sites, prior to the onset de novo gene expression.

GAP JUNCTION PROTEINS ARE DIFFERENTIALLY EXPRESSED IN NEURONS OF THE MATURING MONKEY HYPOTHALAMUS. P.C. Goldsmith* and K.K. Thind. Reproductive Endocrinology Center, Univ. California Sch. of Med., San Francisco, CA 94143-0556.

Gap junctions (GJ) establish cytoplasmic continuity and synchronize activity between adjacent cells. In the brain, the GJ proteins, connexins (Cx), exhibit developmentally regulated expression and restricted distribution. Although Cx26 and Cx43 were thought to occur predominantly in astrocytes, a recent report demonstrated functional GJs and Cx26 expression in GnRH GT1-7 neurons *in vitro* [Neuroendocrinology (1993) 58:485-492]. To reevaluate which cell types express Cx isoforms in the intact brain, we analyzed the distribution and expression of Cx26 and Cx43 in the primate hypothalamus during development. Vibratome sections were immunostained with optimal dilutions of affinity-purified polyclonal antibodies against Cx26, residues 108-117 (from J.A. Germak) or 112-125 (from N.B. Guilula), and a mouse monoclonal IgG₁ against 19 residues of Cx43 (Zymed). Two fetal males (142-150 dga) had few Cx immunoreactive (-ir) fibers. However, in 4 infant females (4.5-7.5 mo), faint or speckled Cx26-ir and Cx43-ir perikarya also were seen, especially in animals pre-treated with colchicine. In 3 juvenile females (14.7-19.2 mo), Cx26-ir and Cx43-ir somata had light to intense, uniform or speckled staining. In 3 adults, Cx43-ir perikarya were absent, but speckled Cx26-ir somata remained. In addition, Cx-ir periventricular and Cx26-ir fibers in the ventral hypothalamic tract continued into the infundibulum (INF) and median eminence. Considering that Cx-ir was found in perikarya retrogradely labeled from the INF, and staining mimicked that for neuronal but not astrocytic markers, we conclude that Cx26 and Cx43 are present in neurons. Since GJs create electrotonic connections and allow small molecular diffusion between coupled cells, developmental changes in Cx expression may help coordinate maturation and synchronize specialized functions of hypothalamic neurons. Supported by HD10907 and HD11979.

IDENTIFICATION, ANALYSIS AND CLONING OF NEUROPEPTIDE Y1 RECEPTOR (NPY1r) TRANSCRIPTS IN THE PITUITARY. J.H. Urban*, J.E. Levine. Dept. Neurobiol. & Physiol, Northwestern Univ., Evanston, IL 60208.

Neuropeptide Y (NPY) regulates preovulatory luteinizing hormone secretion in female rats. The receptor which mediates NPY's pituitary actions remain uncharacterized. The present studies were designed to determine whether the pituitary expresses NPY1r. RT-PCR, with primers derived from extracellular loops 3 & 4, identified the presence of NPY1r by producing an appropriately sized PCR product within the hippocampus as well as in whole and anterior pituitary. To determine whether full length NPY1r transcripts are present within the pituitary, Northern analysis was performed on mRNA obtained from pituitary with hippocampal tissues as a control. Using a cDNA probe complementary to the 3' end of the coding region (TM7 and intracellular tail) of NPY1r, Northern analysis revealed the presence of a full length transcript (approx. 3.7 kb) for NPY1r in both pituitary and hippocampus. In addition, a smaller size transcript (approx. 1.6 kb) was also seen in pituitary but not hippocampus. RNA mapping was used to identify sequence homology of the coding region of the smaller pituitary transcript with the known NPY1r sequence. Restriction fragments along the coding region of NPY1r (5' and 3' of the 80 bp intron splice site) hybridized with the full length transcript in both pituitary and hippocampus; but only the probe encoding the 3' end of NPY1r hybridized to the small transcript. Screening and partial sequence analysis of clones from a rat pituitary cDNA library to identify NPY1r transcripts have verified the presence of a full length NPY1r. These studies suggest that mRNA for NPY1r is expressed within the pituitary and that an additional transcript within the pituitary may also encode a region, or splice variant, of the NPY receptor. The functional significance and complete identity of this transcript is unknown, and studies are in progress to identify this gene product. (NIH HD20677, HD219121, HD28048)

SEX DIFFERENCE IN COEXPRESSION BY GALANIN NEURONS ACCOUNTS FOR SEXUAL DIMORPHISM OF VASOPRESSIN IN THE BED NUCLEUS OF THE STRIA TERMINALIS. B. Planas*, P.E. Kolb, M.A. Raskind and M.A. Miller. Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA 98195.

Vasopressin (VP) neurons in the bed nucleus of the stria terminalis (BNST) are steroid sensitive and the number of VP mRNA expressing neurons is larger in males compared to female rats. This difference in VP cell number has been attributed to proliferation and/or survival of VP neurons following exposure to gonadal steroids during the critical period. We have shown that galanin (GAL) and VP mRNAs are coexpressed in the BNST of the adult male rat and recently, that GAL mRNA gene expression in the BNST is not sexually dimorphic. These results suggest that the index of coexpression of these neuropeptides differs in male and female rats.

Here, we hypothesized that VP neurons represent a subset of GAL cells in the BNST and that the incidence of coexpression of VP mRNA by GAL mRNA expressing neurons in the BNST would be reduced in female rats compared to male rats. We performed double *in situ* hybridization histochemistry on sections through the BNST from male and female Wistar rats (90 d). Brain sections were hybridized with ³⁵S-labeled and digoxigenin-labeled cRNA probes complementary to GAL and VP mRNAs, respectively. Radioactive grains were detected over VP cells indicating the presence of GAL gene expression. We divided the BNST into two anatomical regions which are part of separate functional pathways: medial (BSTM) and lateral (BRTL) divisions. We found a significant sex difference in the number of GAL cells which coexpressed VP in the BSTM (Mean±SEM; male: 124±8, female: 56±6; p<0.0001). However, no difference was found in the BRTL (male: 80±9, female: 83±15). Likewise, the number of cells expressing GAL mRNA only was significantly higher (p<0.002) in the BSTM of female (85±9) compared to male rats (43±5). We provide evidence that VP is coexpressed by a subset of GAL neurons and that the reduced incidence of coexpression of VP by GAL neurons in the medial BNST accounts for the sex differences in VP cell number in this limbic region.

REGIONAL DISTRIBUTION OF AGMATINE AND ARGININE DECARBOXYLASE IN RAT BRAIN. H. Wang*, K. Otake, D.A. Ruggiero, T.A. Milner, G. Li, W. Raasch, C. Youngson, S. Regunathan and D.J. Reis. Div. of Neurobiol., Dept. of Neurol. and Neurosci., Cornell Univ. Med. Coll., New York, NY 10021.

Agmatine, an amine, is an endogenous ligand for imidazoline and α_2 -adrenergic receptors recently detected in bovine brain (Li et al., *Science* 263:966, 1994). We investigated if agmatine is present in rat brain and if it, and its biosynthetic enzyme, arginine decarboxylase (ADC), are regionally distributed. Agmatine, measured by HPLC, is present in rat brain (2.4 ± 0.6 ng/gm wet wt). A polyclonal antibody (Ab) was produced in rabbits by injection of an agmatine-KLH complex. Specificity of the agmatine Ab was established by: (a) dot blots; (b) immunoprecipitation; (c) demonstration that cultured bovine chromaffin cells (which contain agmatine) exhibited positive immunostaining with immune but not pre-immune serum; (d) loss of immunostaining after preabsorption with agmatine. Immunoreactive agmatine was localized to neurons preponderantly in cerebral cortex in laminae VI>V>III and the subiculum. The greatest staining was in retrosplenial, cingulate and primary somatosensory cortices. A few neurons were detectable in posterior hypothalamus. ADC activity, measured in regions by conversion of 14 C-arginine to 14 CO₂ (nmol CO₂/h/mg protein) (see Li et al., *Soc. Neurosci. Abstr.*, 1994), ranked: cortex (16) > hippocampal formation (subiculum, hippocampus and entorhinal cortex) (8.5) > hypothalamus (6.3) > brainstem = cerebellum (3.5) in agreement with the immunocytochemical distribution of agmatine. We conclude: agmatine is synthesized in rat brain, is neuronal, unevenly distributed and most concentrated in cerebral cortex. The findings are consistent with the hypothesis that agmatine may be a novel neurotransmitter.

437.3

MOLECULAR CLONING OF A NEW MEMBER OF G PROTEIN-COUPLED RECEPTOR FAMILY EXPRESSED IN MOUSE CENTRAL NERVOUS SYSTEM. Y. Saeki, S. Ueno, R. Mizuno, H. Fujimura and T. Yanagihara. Dept. of Neurology, Osaka Univ. Med. Sch., Osaka 565, Japan.

A novel cDNA clone encoding a putative G protein-coupled receptor (named GPCR21) was isolated from mouse brain cDNA library along with its homologue, GPCR01 (the mouse counterpart of previously reported rat receptor R334 [(1991) FEBS Lett. 292, 243-248.]) by the polymerase chain reaction using degenerate oligonucleotide primers. Both polypeptides encoded by these clones had seven hydrophobic transmembrane domains which are characteristic for G protein-coupled receptor superfamily. Northern blotting and reverse transcription-polymerase chain reaction analyses showed predominant expression of these two receptors in the central nervous system. *In situ* hybridization analysis revealed their prominent expression in the limbic system and further demonstrated the differential distribution of their mRNAs in mouse brain. Although the ligands for these receptors are yet to be identified, the significant sequence homology between these receptors suggests that they constitute a new receptor subfamily and they possibly represent different receptor subtypes for an unknown neurotransmitter. The prominent expression of GPCR21 in medial habenular nucleus, shown by *in situ* hybridization analysis, suggested that further characterization of GPCR21 may facilitate our understanding of the function of the habenular nuclei.

RECEPTOR AUTORADIOGRAPHIC ANALYSIS OF α_2 -ADRENOCEPTOR DISTRIBUTION IN RAT HYPOTHALAMUS. M. Savola*, M. Kulatunga, P. Panula and M. Scheinin. Dept. of Pharmacology, Univ. of Turku, and Dept. of Biology, Åbo Akademi University, FIN-20520 Turku, Finland.

Hypothalamic α_2 -adrenoceptors (AR) participate in endocrine and cardiovascular regulation, and have also been implicated in complex integrative behaviors and adaptive functions. Receptor autoradiography with [3 H]para-aminoclonidine has revealed relatively dense binding in most hypothalamic nuclei, some of which may have been to non-adrenergic imidazole sites, e.g. in the arcuate nucleus⁽¹⁾. Intense immunohistochemical α_{2A} -AR labeling has been seen in some hypothalamic nuclei⁽²⁾. *In situ* hybridization also indicates that the main α_2 -AR subtype in the rat hypothalamus would be α_{2A} ⁽³⁾. We have performed receptor autoradiography with brain sections of adult male Sprague-Dawley rats using the subtype-nonspecific α_2 -AR radioligand [3 H]RX821002⁽⁴⁾ (in K⁺-phosphate buffer). Specificity of binding was determined with 100 μ M adrenaline. Regional receptor binding was quantitated with the MCID image analysis system. B_{max} and K_d values were derived from saturation assays with 7 concentrations of [3 H]RX821002 (0.1-15 nM). Specific α_2 -AR binding (B_{max} 50-185 fmol/mg tissue) was detected in all hypothalamic regions analyzed (35 regions). The paraventricular and dorsomedial hypothalamic nuclei had the highest receptor densities. Similar K_d values (0.5-0.6 nM) were found in all regions. Co-incubation with 100 nM oxymetazoline indicated that α_{2A} is the predominant α_2 -AR subtype in rat hypothalamus. ENZYMATIC SYNTHESIS OF ANANDAMIDE, AN ENDOGENOUS LIGAND FOR THE CANNABINOID RECEPTOR; PROPERTIES AND DISTRIBUTION IN THE BRAIN. W.A. Devane* and J. Axelrod. Lab. of Cell Biology, National Institute of Mental Health, Bethesda, MD 20892.

Anandamide (arachidonyl ethanolamide) was the first endogenous cannabimimetic compound to be identified in brain (Devane et al., *Science* 1992). The purpose of this study was to characterize the enzymatic synthesis of anandamide using brain membranes.

Bovine membranes (P₂ fraction) were incubated with [14 C]ethanolamine and varying concentrations of ethanolamine and arachidonic acid for 20-40 min at 37°C. This resulted in the formation of a radioactive product which had the same R_f value as authentic anandamide using both normal and reverse phase thin layer chromatography. Incubation of [3 H]arachidonic acid and ethanolamine also resulted in the synthesis of a radioactive product having the same R_f value as anandamide in both chromatographic systems. The synthesis of anandamide had a pH optimum of 9 to 10, and the amount of product formed was linear up to 50 min, using 70 μ g of membrane protein/200 μ l.

When varying the concentration of arachidonic acid, the enzymatic activity exhibited a biphasic curve, suggesting substrate inhibition. When compared to a number of related fatty acids, arachidonic acid proved to be the best substrate with the lowest EC₅₀ and the highest V_{max}. A distribution study in bovine brain indicated that anandamide synthase levels are high in the hippocampus, followed by cortex, striatum, and thalamus. Lower levels of enzymatic activity were observed in the pons, cerebellum, and medulla. These findings suggest the presence of anandergic neurons.

INVESTIGATION OF VASOPRESSIN RECEPTORS IN CELLS FROM CIRCUMVENTRICULAR ORGANS USING CALCIUM MEASUREMENTS. M. Jurzak, A. R. Müller and R. Gerstberger. MPI for Physiol. & Clin. Res., W.G. Kerckhoff-Inst., Parkstr. 1, 61231 Bad Nauheim, Germany.

Circumventricular organs (CVO) of the rat brain lamina terminalis lacking a blood-brain-barrier, the subfornical organ (SFO) and the organum vasculosum laminae terminalis (OVLT), are involved in body fluid and cardiovascular control by sensing blood-borne substances. *In vitro* autoradiography on brain tissue sections showed binding sites for vasopressin (AVP) and its AVP(4-9)-fragment within the SFO and OVLT. For characterization of AVP and AVP(4-9) receptors in cells cultured from the SFO and OVLT, rises in [Ca²⁺]_i were measured in fura-2 loaded single neurons and glial cells. The investigated cell type was verified by immunofluorescence using NSE- and GFAP-specific antibodies. SFO- (n=19) and OVLT- (n=25) neurons were found to increase their [Ca²⁺]_i after exposure to AVP in a dose-dependent manner (0.1-100 nM). Glial cells from SFO (n=21) and OVLT (n=10) were found to respond to AVP with similar sensitivity. The pharmacological characterization revealed the presence of a V1 receptor subtype, since specific antagonists inhibited the AVP evoked responses in neurons (SFO n=4, OVLT n=9) and in glial cells (SFO n=9, OVLT n=3). Ca²⁺-transients measured in the absence of extracellular Ca²⁺ suggest intracellular stores to be the Ca²⁺-source. An additional AVP receptor subtype in OVLT-neurons is implicated by the finding of Ca²⁺-signals induced by the V2 receptor agonist dDAVP (n=7). Furthermore, Ca²⁺-transients were evoked with AVP(4-9) (1-100 nM) in SFO- (n=6) and OVLT- (n=7) neurons as well as in SFO- (n=2) and OVLT- (n=6) astrocytes. A significant number of cells (n=9) responded exclusively to the fragment peptide, indicating the existence of yet another member of the AVP receptor family.

ALTERED α_2 -ADRENOCEPTOR GENE EXPRESSION IN BRAINS OF TRANSGENIC MICE. M. Scheinin*, R. Link, M. Kulatunga, J. Marttila, M. Savola, G. Barsh and B.K. Kobilka. Dept. of Pharmacology, Univ. of Turku, FIN-20520 Turku, Finland, and Howard Hughes Medical Institute and Stanford University, Stanford, CA 94305.

Three α_2 -adrenoceptor (AR) genes are expressed in brains of rodents and are evolutionarily conserved in humans. One of the subtypes, α_{2A} , mediates both presynaptic regulatory functions and postsynaptic effects. To probe the neurophysiologic roles of α_2 , mice were genetically altered to express increased or decreased levels of α_2 . Mice that overexpress α_2 were generated by pronuclear injection of the α_2 gene flanked by 10 kb of genomic DNA, and α_2 knockout mice were generated by homologous recombination in embryonic stem cells using a gene targeting vector that introduced stop codons into all three frames of the gene. Total α_2 -AR density was determined with the subtype-nonspecific ligand [3 H]RX821002. The proportion of α_{2A} -binding was determined by co-incubation with 100 nM oxymetazoline, an α_{2A} -selective ligand. α_2 -ARs were selectively labeled by low concentrations of the α_2 -preferring ligand [3 H]rauwolscine + 100 nM oxymetazoline. Homozygotes for the α_2 knockout had no detectable α_2 binding in brain, and overexpressing transgenic mice had several-fold increased α_2 binding in the brain regions normally expressing α_2 , i.e. the caudate-putamen, olfactory tubercle, cerebral cortex, and parts of the hippocampal formation. Levels of α_{2A} -binding were not altered in either strain. Thus, 10 kb of flanking genomic DNA is sufficient to confer regional tissue specificity for expression of the α_2 gene. The α_{2A} gene does not compensate for altered levels of α_2 expression. These mouse strains may provide useful models for studies on the physiological and pharmacological functions of the α_2 -AR.

LOCALIZATION OF CALCIUM RECEPTOR mRNA IN RAT BRAIN USING *IN SITU* HYBRIDIZATION HISTOCHEMISTRY.K.V. Rogers¹, E.M. Brown² and S.C. Hebert², 1) NPS

Pharmaceuticals, Salt Lake City, UT 84108, and 2) Endocrine-Hypertension and Renal Divisions, Dept. Of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA 02115.

The capacity to sense changes in the level of extracellular Ca^{2+} is an important function in several cell types. For example, hormone secretion by parathyroid cells and thyroid C cells is primarily regulated by extracellular Ca^{2+} . The protein that enables these cells to detect and respond to extracellular calcium has recently been cloned and shown to be a 7-transmembrane, G-protein-coupled receptor linked to the mobilization of intracellular Ca^{2+} in response to increases in extracellular Ca^{2+} . Northern blot hybridization and PCR analysis have indicated that transcripts for this Ca^{2+} receptor (CaR) are present in several tissues including thyroid, kidney and brain. We have used *in situ* hybridization histochemistry to localize CaR mRNA in the adult rat CNS. *In situ* hybridization was performed on 20 μ m brain slices using ³³P-labeled riboprobes complementary either to the entire rat CaR coding region or to the 5' most 1.2 kb portion of the cDNA. The results with both probes were identical. Cells expressing CaR mRNA were scattered throughout the CNS including the cortex, midbrain, hindbrain, and spinal cord; however, the density of CaR expressing cells within these regions varied considerably. Particularly high numbers of cells were present in the hippocampus, corpus callosum, piriform cortex, caudate-putamen, amygdala, and several hypothalamic nuclei. These data indicate that a subset of cells within the CNS express parathyroid CaR mRNA and that this expression may have important functional consequences in the brain.

STIMULATION OF C-FOS EXPRESSION IN SELECTIVE BRAIN NUCLEI BY EXOGENOUS ARGININE-8-VASOPRESSIN: QUANTITATIVE IMMUNOCYTOCHEMICAL STUDY. P.H. Wu, A.J. Lanca, B. Jung, J-F. Liu, L. Grupp^{*} and H. Kalant, Dept. Pharmacology, Univ. of Toronto, and Addiction Research Foundation, Toronto, Ont., Canada M5S 1A8

Peripheral administration of arginine-8-vasopressin (AVP) has been shown to retard the decay of learned behaviors and to maintain tolerance to ethanol by the action on AVP-V1 receptors. Others found that i.c.v. injection of AVP increased c-fos mRNA in the septum and hippocampus. However, the precise site(s) of action of peripherally injected AVP remain unknown. Adult male Sprague Dawley rats were injected with saline (S, 0.3 ml, s.c., n=6), AVP (10 μ g/0.3 ml, s.c., n=6), saline (2 ml, i.p., n=1) or pentyleneetetrazole (PTZ, 50 mg/kg, 2.0 ml, i.p., n=2) and were sacrificed 2 h later. Serial coronal brain sections were processed with antibodies against Fos and Fos-like proteins and AVP. Brain areas containing nuclei of similar size and shape were quantified by counting the number of neuronal cell bodies showing Fos immunoreactivity (Fos-IR) in each nucleus in left or right side under a Nikon Optiphot microscope with 20 X objective and CFPL ocular (2.5 X). The average Fos-IR cell counts/side/section (Fos-IRCSS) for the suprachiasmatic nucleus (Sch) were 9.2 ± 5.9 (S, s.c.) and 96.8 ± 16.9 (AVP, s.c.) [$p < 0.001$, t-test]. In Sch, the i.p. injection of S and PTZ yielded Fos-IRCSS of 43.5 and 33.3 respectively. The supraoptic nucleus (SON) had 0.72 ± 0.3 (S) and 60.6 ± 11 (AVP) [$p < 0.019$, t-test], but PTZ did not stimulate Fos expression. AVP significantly increased Fos-IRCSS in the paraventricular nucleus (PVN) [19.4 ± 5.9 (S) vs 164.3 ± 44.7 (AVP), $p < 0.023$, t-test] and so did PTZ. The lateral septum showed no Fos-IR either in the S- or AVP-treated rats. Fluorescent labelling of AVP cell bodies revealed that Fos-IR cells were also AVP-IR cells. Results indicate that AVP cells in the Sch, SON and PVN are potential sites of action for the exogenous AVP. Supported by NIAAA grant #1 R01-AA08212-05.

IMMUNOHISTOCHEMICAL STUDIES OF SITES IN THE VENTROLATERAL MEDULLA THAT EXERT CONTROL OVER CARDIOVASCULAR FUNCTION

Erin L. Meyer*, L.W. Dickerson, W.P. Norman, R.A. Gillis, Department of Pharmacology, Georgetown University, Washington D.C., 20007

Physiological studies using microinjections of L-glutamate into specific sites in the rostral ventrolateral medulla and monitoring of cardiac function and vascular blood flow (Doppler flow probes) of pentobarbital-vagotomized dogs revealed two sites where consistent responses were obtained. The first is an area located 3.5 to 5.8 mm rostral to obex, 4.2 to 5.1 mm lateral to midline, 0.5 to 1.5 mm below the ventral surface [referred to as the subretrofacial area (SRfN)] and the second is an area located 6.2 to 7.1 mm rostral to obex, 2.9 to 5.4 mm lateral to midline, 0.5 to 2.0 mm below the ventral surface (referred to as rostroventromedial area). L-glutamate microinjected into the subretrofacial area produces increases in arterial blood pressure associated with decreases in femoral and renal vascular bed conductances. L-glutamate microinjected into the rostroventromedial area produces only a slight pressor response associated with a decrease in renal arterial bed conductances but an increase in femoral arterial bed conductance. Using immunohistochemical methods and specifically tyrosine hydroxylase (TH) and phenylethanolamine-N-methyltransferase (PNMT) colometric immunohistochemistry, we determined whether TH and/or PNMT immunoreactive neurons were present at the two microinjection sites. Results indicate that neurons in the canine subretrofacial nucleus are immunoreactive to antibodies against PNMT and therefore contain epinephrine. Further analysis show that neurons in the rostroventromedial area are mainly composed of neurons exclusively immunoreactive to antibodies against tyrosine hydroxylase (TH) although some neurons also contain PNMT. Previous investigators have included this region anatomically as part of the SRfN (Dampney et al. 1992). However, physiologic responses to L-glutamate microinjection in this area are characterized primarily by a significant increase in femoral conductance consistent with vasodilation.

437.10

ESTROGEN-SPECIFIC TARGET SITE IDENTIFIED BY PROGESTERONE-11 α -HEMISUCCINATE-(2-[¹²⁵I]-) IODOHISTAMINE IN MOUSE BRAIN MEMBRANES. C. Bukusoglu and N.R. Krieger*, Dept. of Anesthesia, Harvard Medical School, Brigham & Women's Hospital, Boston, MA 02115

Using photoaffinity labeling with the progesterone analogue, progesterone-11 α -hemisuccinate-(2-[¹²⁵I]-)iodohistamine ([¹²⁵I]-his-PG), we have recently identified a protein band of MW 29 kDa (band 4) in mouse cerebellar membranes. Inhibition of the labeling was specific with respect to steroid structure and was most effectively inhibited by preincubation with estradiol. Among estrogens, the labeling was strongly inhibited by estradiol 17 β , estradiol 17 α . The antiestrogen tamoxifen and the synthetic estrogen diethylstilbestrol were also effective. Other estrogens (estrone, estrone) were less effective and the steroids, dihydroandrosterone, androsterone and aldosterone were inactive. Preincubation with estradiol 17 α or estradiol 17 β inhibited the labeling in a dose-dependent manner with IC₅₀ values of 0.3 and 2.0 μ M; respectively. The extent of labeling was three times as high in male as in female cerebellar membranes. In males labeling of cerebellar membranes was greater than that of cortex or limbic region. In contrast to the well described steroid receptors which are in the cytosolic fraction; the newly identified estrogen target site (band 4) has a membrane localization.

ISCHEMIA: MECHANISMS III

438.1

EFFECT OF MK-801 IN FOCAL CEREBRAL ISCHEMIA IN THE MONKEY. R.N. Auer*, G.W. Jason, B.I. Tranmer, and S. Coupland, Department of Neuroscience, University of Calgary, Canada, T2N 4N1

To determine the effectiveness of MK-801 in primate focal ischemia, transorbital occlusion of the middle cerebral artery (MCA) was done in female squirrel monkeys (*Saimiri sciureus*). Clip occlusion was verified under the operating microscope, while blood pressure was controlled to 60 mm Hg using halothane. No other drugs were administered. Ambient temperature was controlled under the operating drapes to roughly 33°C, and temporalis temperature was controlled to 37.5°C. MK-801 (1 mg/kg) was administered 20 minutes after occlusion. Following 110 minutes of occlusion, the clip was released and restoration of flow was verified visually. Quantitative histopathology at 52 coronal planes was performed after 2 weeks. There was no statistically significant difference in the infarct volumes between treated and untreated animals. Neuropsychologic testing also revealed no difference between the groups.

The cingulate cortex was carefully examined in the oldest animals, and no evidence of acidophilic neuronal necrosis, microglial nodules, or other evidence of MK-801 induced cell death was seen.

We conclude firstly that MK-801 is ineffective in reducing cerebral infarct volume in this model of transient focal ischemia. Secondly, although 1 mg/kg is a relatively high dose of MK-801 in the primate, we conclude that the neuronal necrotizing effect of this NMDA antagonist, which has been well-described in the cingulate cortex of the rodent, does not occur in this primate.

IMMUNOCYTOCHEMICAL DETECTION OF GLUT1 IN BRAIN MICROVESSELS AND PARENCHYMA: EFFECTS OF FOREBRAIN ISCHEMIA. A. McCall, A. Van Bueren, N. Lessov, D. Lattemann* and C. Meshul, Depts. of Cell Biology & Anatomy, Med. Psych. and Pathology, Oregon Health Sci. Univ., and VA Medical Ctr., Portland, OR 97201.

Transport across the blood-brain barrier and into some brain parenchymal cells is believed to be mediated by two differently glycosylated forms of GLUT1. The effects of cerebral ischemia for GLUT1 mRNA have been described but not for the protein. Using a high affinity, isoform-specific, polyclonal antiserum (ALM1-K) generated by a special intravenous secondary immunization protocol, we have examined immunocytochemical distribution of GLUT1 in rat brain 1 and 4 days after global forebrain ischemia using a 2-vessel occlusion/hypotension model. In non-ischemic rats, GLUT1 immunoreactivity was intensely concentrated in cerebral microvessels as previously noted. In addition, diffuse parenchymal staining was also detectable and was completely inhibited by preincubation of antisera with 10 μ g/mL of peptide. Preliminary electron micrographic localization (ALM1-K; 1:5000) confirmed the asymmetric distribution of GLUT1 with abluminal > cytoplasmic > luminal concentrations. After ischemia, both microvascular and non-microvascular GLUT1 concentrations increased markedly by as soon as 1 day and persisted through 4 days after ischemia. Conclusions: GLUT1 may be detected in both cerebral microvessels and parenchyma using a high affinity, isoform-specific antiserum. Global forebrain ischemia rapidly and persistently increases GLUT1 expression of both forms. Supported by NS22213 and NS17493.

438.3

INDUCTION OF BASIC FIBROBLAST GROWTH FACTOR EXPRESSION FOLLOWING FOCAL CEREBRAL ISCHEMIA-REPERFUSION INJURY. T.N. Lin*, J. Te, M. Lee, C.Y. Hsu. Neuroscience Research Division, Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan, ROC.

Basic fibroblast growth factor (bFGF) is a biologically active polypeptide with mitogenic, angiogenic, and neurotrophic properties. Significant increase in the level of bFGF immuno-reactivity were found after neuronal injury. In the present study, we examined the temporal and spatial expression of bFGF mRNA during ischemia-reperfusion, using a three-vessel occlusion focal cerebral ischemia model. Northern blot analysis showed that severe ischemia induced a two- to three-fold increase in a single species of 6.0 kb bFGF mRNA transcript in the ischemic cortex, which peaked at 12 h during reperfusion. There was no obvious increase in the contralateral cortex. Similar two- to three-fold enhanced expression of bFGF mRNA also found in the ipsilateral hippocampus, however, unlike the ipsilateral cortex, this higher expression were maintained up to 2 weeks of reperfusion. *In situ* hybridization studies further revealed a constitutive expression of bFGF mRNA in discrete areas within the central nervous system (CNS). Ischemia-reperfusion increase the expression of bFGF mRNA in three distinct areas: (1) rostral area of the infarct, close to the outer layer of cerebral cortex, (2) area surrounding the infarction, penumbral area, and (3) dentate gyrus of hippocampus. The mechanisms leading to this discrete enhancement is not clear, however, it is likely that the effect of bFGF is regulated in the transcriptional level not the post-translational modification level. These results suggest that during ischemia-reperfusion, bFGF may be released from different pools of cells and synergistically performed their beneficial effect through different mechanisms.

438.5

INTERCELLULAR ADHESION MOLECULE-1 IS UPREGULATED ON BRAIN MICROVASCULAR ENDOTHELIAL CELLS IN FOCAL ISCHEMIA. F.C. Barone*, A.L. Siren, T. Liu, T.L. Yue, G.Z. Feuerstein and X.K. Wang. SmithKline Beecham Pharmaceuticals, King of Prussia, PA 19406 and Uniformed Services University of the Health Sciences, Bethesda, MD 20814

The adhesion of leukocytes to endothelium is the first step for cellular infiltration in the inflammatory response to ischemic tissue injury. Therefore, the expression of intercellular adhesion molecule-1 (ICAM-1) was studied in rat focal ischemic cortex and compared to the known inflammatory response in this model. A significant increase in ICAM-1 mRNA expression in the ischemic cortex over levels in contralateral (control) cortex was observed by means of Northern blot analysis following either permanent or temporary (160 min) occlusion with reperfusion of the middle cerebral artery (PMCAO or MCAO with reperfusion) in spontaneously hypertensive rats. In the ischemic cortex, levels of ICAM-1 mRNA increased significantly at 3 hours (2.6-fold, $N=3$, $p<0.05$), was peaked at 6 and 12 hrs (6.0-fold, $p<0.01$) and remained elevated up to 5 days (2.5-fold, $p<0.05$) after PMCAO. A similar profile of ICAM-1 mRNA expression in the ischemic cortex following MCAO with reperfusion was observed, except that ICAM-1 mRNA increased significantly as early as 1 hr (6.3-fold, $N=3$, $p<0.05$) and then more gradually reached a peak at 12 hrs (12-fold, $p<0.01$) after reperfusion. ICAM-1 mRNA expression in ischemic cortex following PMCAO was significantly greater in hypertensive rats, that are more sensitive to focal ischemia, than in two normotensive rat strains. Immunohistochemical staining using anti-ICAM-1 antibodies indicated that ICAM-1 was localized to endothelial cells of intraparenchymal blood vessels in the ischemic but not control cortex. The increased expression of ICAM-1 message and protein significantly precedes the influx of leukocytes into ischemic tissue which occurs at 12 hr post-PMCAO and 6 hr post-MCAO with reperfusion. These data suggest that an upregulation of ICAM-1 mRNA and protein in brain capillary endothelium plays an important role in leukocyte migration into the ischemic brain.

438.7

Suppression of Hippocampus Fos Expression and Activator Protein-1 (AP-1) Activity during Focal Cerebral Ischemia using Antisense Strategy. P.K. Liu, A. Salminen, Y.Y. He, I.M. Tarkka* and C.Y. Hsu. Div. of Restorative Neurology and Human Neurobiology, Baylor College of Medicine, Houston, TX 77030.

An activation of *c-fos* and the subsequent expression of the Fos protein were noted following focal cerebral ischemia. Fos and Jun form a heterodimer as AP-1 which modulates the expressions of several genes. To study the post-ischemic events related to *c-fos* expression, we sought to suppress the post-ischemic expression of *c-fos* by intraventricular infusion of an antisense phosphothioated DNA of *c-fos* mRNA. The antisense DNA blocked *in vitro* *c-fos* mRNA translation into Fos. In the uptake study, we noted that the ^{32}P -labelled antisense DNA was internalized within 6 h and detectable in the RNA fraction up to 41 h after intraventricular delivery. The antisense DNA formed DNA:RNA hybrid after uptake. When focal cerebral ischemia was induced 6-16 h after the infusion of the antisense DNA, the post-ischemic increase in Fos expression and AP-1 binding activity were suppressed. The binding activity of a cyclic AMP response element was not blocked by the antisense DNA. The results support that Fos expression is at least partially responsible for an increase in AP-1 binding activity after focal cerebral ischemia.

438.4

High +G_z exposure followed by expression of heat shock protein 70 (HSP70) in rat brain: A RT-PCR study. A. R. Shahed*, S. Galindo Jr., R. Echon, J. A. Barber and P. M. Werchan. Operational Tech. Corp., Krug Life Sci. and Armstrong Laboratory, Brooks AFB, TX. 78235.

We have previously reported that a 30 s, high +G_z (head-to-foot inertial load) exposure of > +20 G_z causes global cerebral ischemia in rats (Werchan and Shahed, *The Physiologist*, 35: S143-146, 1992). Also six +25 G_z exposures have been shown to cause transient brain edema (Shahed et al. *Aviat. Space Environ. Med.* 63:5, 1992). In the present study HSP70 expression was investigated as an early marker of cellular stress.

Methods: Protocol 1: Rats were exposed to +22.5 G_z for either 15, 30 or 60 s in a small animal centrifuge, and brains were collected immediately and 0.5 to 24 hr after the run. Control rats were exposed to +0.5 G_z.

Protocol 2: rats were subjected to six 30 s exposures of +22.5G_z and brains were collected as in Protocol 1. Total RNA was extracted by RNeasy B method. RT-PCR was performed using 1 µg of RNA for cDNA synthesis and specific HSP 70 primers were used for subsequent amplification. The PCR products (235 bp) were visualized on agarose gels.

Results: Expression of HSP 70 did not increase above the control level after 15 or 30 s exposure. Following the 60 s exposure, HSP 70 expression increased at 60 and 180 min after the centrifuge run. In protocol 2, expression of HSP 70 increased at 60 and 180 s min after the run. **Discussion:** High +G_z exposure of at least 60 s duration or six exposures of +22.5G_z were required to increase expression of HSP70. The time points of increased HSP70 expression were similar to those previously reported for brain edema. This suggests that HSP70 expression could be a suitable marker for monitoring post +G_z exposure effects.

438.6

Time Course of Basic Fibroblast Growth Factor (bFGF) Expression Following Focal Cerebral Ischemia in the Rat. E.K. Speliotis*, C.G. Caday, J. Weise, T. Do, P. Ge, N.W. Kowall, and S.P. Finklestein. Massachusetts General Hospital and Harvard Medical School, Boston, MA 02129; Veteran's Administration Medical Center, Bedford, MA 01730 and Boston University Medical School, Boston, MA 02118.

Basic fibroblast growth factor (bFGF) is a polypeptide found in brain that has potent trophic effects on neurons. In this study, we examined changes in bFGF expression in tissue surrounding focal infarcts of the right cerebral hemisphere of rats sacrificed at 4hr, 1,3,7, and 14 days following permanent occlusion of the middle cerebral artery. Northern blot analysis of the right cerebral cortex revealed a three fold increase in bFGF mRNA levels at 24 hours after ischemia that declined somewhat by 3 days and returned to control levels at 7 and 14 days after ischemia. *In situ* hybridization corroborated the Northern blot findings and revealed that the upregulation of bFGF mRNA occurred throughout the entire right cerebral cortex, and in the contralateral cingulate cortex. At 1 and 3 days following ischemia increased numbers of bFGF immunoreactive astrocytes were detected in the right cerebral cortex concomitant with a shift from nuclear to nuclear plus cytoplasmic localization of bFGF immunoreactivity. The time course and distribution of bFGF expression suggests that this factor may play a role in cytoprotective and/or reparative processes following ischemia.

438.8

DIFFERENTIAL EXPRESSION OF mRNA ENCODING PROSTAGLANDIN ENDOPEROXIDASE SYNTHASE AND c-fos IN REVERSIBLE CEREBRAL ISCHEMIA. M.H. Ruppert (1,3), M.S. Kindy (1), H.H. Tai (2), and L.C. Pettigrew (1,3)*. (1) Stroke Program, Sanders-Brown Center on Aging and (2) College of Pharmacy, University of Kentucky, (3) Department of Veterans Affairs Medical Center, Lexington, Kentucky.

Postischemic reperfusion of brain activates PGH Synthase (PGHS), known previously as cyclooxygenase, to generate vasoactive eicosanoids from arachidonic acid. Recent studies have identified two isoforms of PGHS, denoted PGHS-1 and PGHS-2. Knowing that inducible PGHS-2 is transcriptionally regulated at its AP-1 gene sequence by *c-fos* translational products, we hypothesized that the constitutive isoform, PGHS-1, is under separate transcriptional control in ischemic brain. We examined levels of PGHS-1 and *c-fos* mRNA immediately after reversible cerebral ischemia by the 4-vessel occlusion (4VO) technique or after 60 or 180 min of postischemic reperfusion. Levels of PGHS-1 mRNA peaked immediately after ischemia (263±85; mean±SD, expressed as %sham; $p=0.01$), which was significantly different from levels at 60 (80±22) and 180 (77±40) min. In contrast, *c-fos* mRNA levels peaked after 60 min of reperfusion (743±317; $p=0.01$) compared to levels immediately after ischemia and after 180 min of reperfusion. We conclude that prior induction of the *c-fos* gene (with probable translation into Fos protein) does not precede transcription of PGHS-1 mRNA in ischemic brain.

438.9

DNA FRAGMENTATION INDICATIVE OF APOPTOSIS OCCURS IN A NEONATAL MODEL OF CEREBRAL HYPOXIA-ISCHEMIA. U.I. Tuor^{*}, J.E. Hill, I. Rasquinha and J.P. MacManus. Institutes for Biological Sciences and Biodiagnostics, NRC, Ottawa and 435 Ellice Ave., Winnipeg, Manitoba, R3B 1Y6

A well established model of neonatal cerebral hypoxia-ischemia involves subjecting 7 day old rats to unilateral carotid artery occlusion and exposure to 3 hr. of hypoxia which results in damage ipsilateral to the carotid occlusion. In several adult animal models of cerebral ischemia, DNA fragmentation indicative of apoptosis has been observed. Whether programmed cell death contributes to the damage which occurs following hypoxia-ischemia in neonates is not known.

The pattern and incidence of DNA fragmentation was investigated by *in situ* end-labelling with terminal transferase. Brains of 7 d rats which had been subjected to either 0, 2 or 3 hrs of hypoxia-ischemia (unilateral carotid occlusion + hypoxia) were perfused fixed either 0 or 18 hr post hypoxia. Paraffin embedded sections were stained with hematoxylin-eosin or processed for *in situ* labelling. In additional animals, the brains were dissected and frozen 0 or 18 hr after the hypoxia. The tissue was homogenized and DNA extracted and processed for detection of DNA laddering by gel electrophoresis.

Breaks in DNA were observed in brain sections ipsilateral to the carotid artery occlusion in rats exposed to 3 hrs of hypoxia-ischemia corresponding to extensive damage observed in the H&E sections. In some animals subjected to 2 hr of hypoxia-ischemia, the damage was less severe and selective areas of positive DNA fragmentation were observed in the hippocampus, thalamus, caudate nucleus and cerebral cortex. Tissue analysis of these regions confirmed the presence of laddered DNA fragmentation. Thus, in this model of neonatal hypoxia-ischemia there is evidence that DNA fragmentation indicative of apoptosis can occur suggesting that programmed cell death contributes to the damage observed.

(Supported in part by Heart and Stroke Fdn. and Canada/Fisons Fight Stroke Program).

THE EFFECT OF TRANSIENT GLOBAL ISCHEMIA ON ACTION POTENTIAL AND SYNAPTIC INDUCED CALCIUM TRANSIENTS IN CA1 PYRAMIDAL NEURONS. Y. Schiller¹, C. Sommer² and M. Kiessling² Abt. Zellphysiologie, MPI Med. Forschung¹ and Dept. Neuropath., Univ. of Heidelberg², Heidelberg, Germany.

Elevation of the $[Ca]_i$ were implicated to play an important role in the ischemic induced delayed cell death. We were interested in characterising the effect ischemia on calcium transients evoked by electrical and synaptic activity in CA1 pyramidal neurons. Brain slices were prepared from normal and ischemic gerbils (5 minute transient global forebrain ischemia). Simultaneous recordings of $[Ca]_i$ and the electrical activity were performed in CA1 neurons using patch clamp and fluorometric fura-2 techniques. Calcium transients were measured at the soma and at different location along the apical dendrite (10-300 μm)

The major findings of this study are: 1) The resting $[Ca]_i$ was not significantly different in control and ischemic gerbils up to 24 hours after the ischemic event. 48-72 hours after ischemia a small increase of the resting $[Ca]_i$ was observed. 2) The $[Ca]_i$ transients evoked by a train of 5 action potentials (synaptic or electrically evoked) were not significantly altered up to 24 hours after the ischemic event. 48-72 hours after the ischemic event a 30% prolongation of these $[Ca]_i$ transients was observed. 3) Following a 0.5 second 100Hz synaptic stimulation the peak and decay of the $[Ca]_i$ transient did not differ significantly in normal and ischemic gerbils 24 hours after the ischemic event. In both groups about 85% of this $[Ca]_i$ transient was blocked by APV. From these findings we concluded that during the first and potentially reversible period after the ischemic event (24h) no significant abnormalities were detected in the amplitude of synaptic and action potential induced $[Ca]_i$ transients and in the ability of CA1 pyramidal neurons to eliminate this calcium load.

PHOTOCHEMICAL UNILATERAL CORTICAL STROKE IN RATS CAUSES DNA FRAGMENTATION AND INCREASES p53 IMMUNOREACTIVITY IN THE AREA PENUMBRA. A. Kharlamov^{*}, D.M. Armstrong, D.B. Grayson, C.M. Cagnoli and H. Maney. Allegheny-Singer Res. Inst., Med. Coll. of Pennsylvania, Pittsburgh, PA 15212

Apoptosis, or programmed cell death (PCD), is the process by which certain stimuli can force a cell to commit suicide. PCD is usually associated with intranucleosomal DNA fragmentation, which may lead to an upregulation of certain proteins such as p53, a member of the heat-shock protein family. We have shown that following unilateral focal stroke, induced in rats by photochemical thrombosis (rose bengal is injected intravenously and the skull is irradiated with a beam of focussed light; *Neuroscience* 1993, 55: 473; *J Neurosci* 1993, 13: 2483) there is in the cortex a primary thrombotic/necrotic core and an area penumbra where the cells are injured and may eventually die, but which also can be pharmacologically protected. In the present study we investigated whether PCD may contribute to cell death in the area penumbra. We collected brain samples at different times post-stroke and determined immunohistochemically: a) *in situ* DNA fragmentation by staining the brain slices with anti-digoxigenin antibody to detect the digoxigenin-dUTP-extended DNA complexes (ApotTag, Oncor); b) the presence of p53 (antibody PAb240, Oncogene Science Inc.); and c) the presence of 72 kD heat-shock protein (72 kD antineuronal monoclonal antibody, Amersham). Following stroke, we observed increases in DNA fragmentation, p53, and 72 kD protein in the cortex ipsilateral to the thrombotic core. These increases occurred in different brain regions: DNA fragmentation and p53 increased only in the area penumbra, while 72 kD heat-shock protein increased throughout the ipsilateral cortex, except in the area penumbra. DNA fragmentation was evident as early as 6 hrs post-stroke, peaking at 8-12 hrs, and leveling off at 24 hrs. In contrast, p53 and 72 kD immunoreactivity was not increased until 8 hrs and peaked at 12-24 hrs post-stroke. These results suggest that stroke-triggered p53 upregulation might be responsible for the PCD in the area penumbra.

ROLE OF THE Na^+Ca^{2+} EXCHANGER DURING ANOXIC AND GLUCOPENIC CONDITIONS IN C6 GLIOMA CELLS. S. Amoroso, E. Iannotti, N. Caso, G. Russo, A. Bassi, G.F. Di Renzo and L. Annunziato^{*} Unit of Pharmacology, Dept. of Neuroscience, School of Medicine, University "Federico II" of Naples, Via S. Pansini 5, 80131 Naples, Italy.

Under anoxic and glucopenic conditions the homeostasis of intracellular Ca^{2+} and Na^+ ions is altered. The Na^+Ca^{2+} exchanger is a bidirectional pathway which couples the extrusion of Ca^{2+} to the entrance of Na^+ ions or viceversa Na^+ ion efflux to Ca^{2+} ion influx. The aim of the present study was to characterize the mode of operation of the Na^+Ca^{2+} exchanger, under anoxic and glucopenic conditions, and the role played by this exchanger in anoxia-glucopenia induced neurotoxicity.

In C6 glioma cells, a cell line that has been extensively used as a model for cerebral glioma, anoxic-glucopenic conditions, mimicked by adding a mixture of oligomycin plus 2-deoxyglucose to the incubation medium, induced a massive release of intracellular LDH, used as an index of neurotoxicity. The activation of the Na^+Ca^{2+} exchanger as a Na^+ extrusion pathway coupled to Ca^{2+} ion entry, obtained by the removal of Na^+ ions from the extracellular medium, reduced the release of LDH, induced by anoxic-glucopenic treatment. CB-DMB, a rather specific inhibitor of the Na^+Ca^{2+} exchanger, in a dose-dependent way, completely reverted the reduction of LDH release, induced by the removal of Na^+ ions from the extracellular medium, under anoxic-glucopenic conditions. These results suggest that the Na^+Ca^{2+} exchanger during anoxic-glucopenic conditions operates as a Na^+ efflux mechanism coupled to Ca^{2+} ion entry and that this mode of operation, although intracellular Ca^{2+} ion concentrations increase, may be protective against anoxia-glucopenia-induced brain cell death. (Supported by C.N.R. and 40-60% MURST Grant to L. Annunziato and G.F. Di Renzo)

GENETIC MANIPULATION OF ORGANOTYPIC COCULTURES WITH RECOMBINANT ADENOVIRUS DOES NOT ALTER THALAMOCORTICAL PROJECTIONS. M. Wilkemeyer^{*} and K. Angelides. Dept. of Cell Biology, Baylor College of Medicine, Houston, TX 77030.

The structure and organization of thalamocortical (TC) axons in the developing mammalian neocortex is the focus of continued investigation. Organotypic cocultures of fetal thalamic and neonatal cortical explants permit the *in vitro* dissection of the signals and mechanisms underlying the development of TC projections. Genetic manipulation of various receptor and signal transduction molecules is a potentially powerful tool for examining the development of this circuitry. Recently, several labs have demonstrated the utility of using viral vectors (herpes simplex virus 1 and adenovirus) to transfect neurons *in vivo* and *in vitro*. Replication-defective, recombinant (RDR)-adenoviruses have several advantages over herpes virus vectors, including: i) high titre, ii) safety and iii) relative long-term expression of the recombinant gene. To explore the possibility for genetic manipulation of organotypic cocultures, rat cortical explants, cocultured with thalamic explants, were infected with Ad.RSVBgal. Infection of cortical explants, via both bulk and focal application, resulted in relatively long-term expression (2 weeks) of the reporter gene (β -galactosidase) with little gross, structural alterations in the explant. Dil-labeled thalamic ingrowth was also assayed 1-2 weeks post infection. In 22 cocultures where the thalamic explants were sandwiched between infected and control cortical explants, no gross differences in the extent of thalamic ingrowth or axonal arborization were detected. These data suggest that adenoviruses are suitable gene transfer vectors for genetic manipulation of target tissue. Future experiments will concentrate on designing recombinant adenovirus for studying target selection and circuitry formation in thalamocortical cocultures. Supported by NIH grant NS 26733. M. W. is an NIH postdoctoral fellow (NS 09306).

439.2

DISRUPTION OF ONE CELL ADHESION SIGNAL IS SUFFICIENT TO HINDER AXONAL NAVIGATION IN DEVELOPING VISUAL CORTEX. Fidelma A. Nazif^{*} and Kimon J. Angelides. Dept. of Cell Biology, Baylor College of Medicine, Houston, TX 77030.

Synaptic patterning in the developing visual cortex requires precise spatial and temporal pathfinding by afferent axons. The initial stages of axonal targeting are directed by activity-independent signals, such as cell adhesion molecules (CAM). In cultured neurons the presence or absence of a single CAM can drastically affect axonal growth and targeting. In the more complex environment of the visual cortex, it is not known whether a single molecule can have such a strong effect.

In organotypic co-cultures of fetal mouse thalamic lateral geniculate nucleus (LGN) and neonatal visual cortex (VC) thalamic afferents grow into the VC and terminate in layer IV, as *in vivo*. This preparation allows direct manipulation of the cortical environment. NCAM is expressed throughout the cortex during development. The anionic polysialic acid (PSA) extracellular moiety of NCAM is thought to attenuate cell interactions, allowing neurite elongation during development. In this study, co-cultures were treated with the enzyme neuraminidase, which cleaves the PSA moiety off NCAM, and axonal growth and targeting were examined.

Co-cultures were treated daily, beginning either 20 hr or 48 hr after plating. Controls were treated with vehicle alone. After one week thalamocortical afferents were labelled with Dil. In those co-cultures treated after 20 hr, bridges of tissue formed between the LGN and VC. In 66% of co-cultures very short axons reached the proximal cortex but did not grow into the cortex. In 50% of co-cultures outgrowth from LGN over the collagen coated membrane was extensive. In 66% of control experiments ingrowth into the cortex was observed. In co-cultures treated with neuraminidase after 2 days in culture 83% showed growth into the proximal cortex and 17% showed axons extending deeper into the cortex, but not as deep as layer IV. 100% of control co-cultures showed thalamocortical afferents growing deep into the cortex, mostly terminating in layer IV, some extending almost to the pial surface. We conclude that disruption of one signal which regulates axonal navigation may be sufficient to disrupt axonal targeting in the visual cortex. Supported by NS 26733.

LAMINAR SPECIFIC ATTACHMENT AND NEURITE OUTGROWTH OF THALAMIC NEURONS ON CULTURED SLICES OF DEVELOPING CEREBRAL NEOCORTEX. D.E. Emerling and A.D. Lander*. Dept. of Brain and Cognitive Sciences, Massachusetts Institute of Technology, Cambridge, MA 02139.

In nervous system development, the growth cones of advancing axons are thought to navigate to their targets by recognizing cell-surface and extracellular matrix molecules that act as specific guidance cues. To identify and map cues that guide the growth of a particular axonal system, the thalamocortical afferents, an assay was devised to examine short-term interactions of dissociated embryonic thalamic cells with living, ~150 μ m slices of developing mouse forebrain. Thalamic cells rapidly (<3 hours) and efficiently attached to and extended neurites on pre- and postnatal slices, but a broad zone throughout the neocortex was generally non-permissive for both thalamic cell attachment and the ingrowth of neurites. This zone coincided with the cortical plate at early stages (embryonic day 15), but later became restricted, in rostral-to-caudal fashion, to cortical laminae 2/3. Thus, at each stage, thalamic cells *in vitro* avoided just that area that thalamic axons confront, but generally do not enter, *in vivo*. In addition, neurites that extended on some layers were found to be significantly oriented in directions that coincide with the pathways that thalamic axons follow *in vivo*. Furthermore, these laminar specific behaviors of thalamic cells on cortical tissue were not observed when fresh frozen cryostat sections were substituted for living brain slices. The results imply that local adhesive cues and signals that affect process outgrowth are distributed among developing cortical laminae in a manner that could underlie much of the temporal and spatial patterning of thalamocortical innervation. By investigating what cell-surface and extracellular matrix molecules account for the behavior of thalamic cells in this rapid *in vitro* assay, we hope to elucidate some of the molecules that control the *in vivo* development of the thalamocortical pathway.

NETRINS: A FAMILY OF AXON OUTGROWTH-PROMOTING PROTEINS HOMOLOGOUS TO *C. ELEGANS* UNC-6. T. Serafini*, T.E. Kennedy, M.J. Galko, C.M. Mirzayan, T. Jessell† and M. Tessier-Lavigne. Dept. of Anatomy, University of California, San Francisco, CA 94143-0452; †Howard Hughes Medical Inst., Columbia University, New York, NY 10032.

In the embryonic spinal cord, commissural axons pioneer a circumferential pathway from dorsal regions to the floor plate at the ventral midline. Floor plate cells secrete a factor that attracts these axons *in vitro*, suggesting that the ventral growth of these axons may be directed partly by chemotropism. Floor plate cells have also been shown to secrete a (possibly distinct) diffusible factor that promotes the outgrowth of commissural axons into collagen gels *in vitro*. Using outgrowth of commissural axons into collagen as an assay, we have purified from embryonic brain two proteins, netrin-1 and netrin-2 (78 kD and 75 kD, respectively, by SDS-PAGE), that each mimic the outgrowth-promoting activity of the floor plate. We have also identified a distinct activity in embryonic brain that potentiates their effects. Cloning of cDNAs encoding the two netrins show that they are homologous proteins (72% identical), which are structurally related (50% identical) to UNC-6, a laminin-related protein required for the circumferential migration of cells and axons in the nematode *C. elegans*. This homology suggests that the guidance of growth cones in the vertebrate spinal cord and the nematode are directed by similar molecular cues.

GENETIC ANALYSIS OF GROWTH CONE GUIDANCE AT THE MIDLINE IN DROSOPHILA: EXPRESSION AND FUNCTION OF D-NETRIN. K.J. Mitchell*, J. Doyle*, G. Tear*, T. Serafini*, T.E. Kennedy*, C. Mirzayan*, M. Tessier-Lavigne*, and C.S. Goodman*, *HHMI, Neuro. Div., Dept. of Mol. and Cell Biol., U. C. Berkeley, CA 94720; # Dept. of Anatomy, U. C.S.F., CA 94143

We have been characterizing the expression and function of several genes involved in growth cone guidance at the midline of the *Drosophila* central nervous system (CNS). In mutations in the *commissureless* (*comm*) gene, growth cones that would normally cross the midline instead stay on their own side (Seeger et al., 1993). In mutations in the *roundabout* (*robo*) gene, growth cones that would normally stay on their own side instead now cross the midline. The *comm* gene encodes a novel transmembrane protein expressed by a subset of midline cells (Tear, Seeger, and Goodman, unpublished results). Cloning of the *robo* gene is underway.

Here we describe the characterization of a third gene -- *D-netrin* -- that was cloned on the basis of homology to the two vertebrate netrin genes and the nematode *unc-6* gene. In the nematode, UNC-6 appears to control circumferential guidance. In vertebrates, netrin-1 and netrin-2 are expressed by the floor plate and ventral neural tube, respectively, and can function *in vitro* to attract commissural growth cones. The *D-netrin* gene is located on the X chromosome. It is strongly expressed by a subset of midline cells during the period of axon outgrowth, and by visceral mesoderm. Based on its homology to the netrins/UNC-6 and its expression along the *Drosophila* CNS midline, we propose that D-Netrin plays an important role in midline guidance. To test this model, we are using genetic approaches, including the analysis of specific growth cones in loss-of-function mutations and in embryos carrying transgenic constructs which produce specific patterns of ectopic D-netrin expression.

CNS-ASSOCIATED CUES ARE REQUIRED FOR CENTRALLY-DIRECTED NAVIGATION BY PERIPHERAL SENSORY NEURONS IN THE EMBRYONIC MEDICINAL LEECH. J. Jellies*, K. Johansen† & J. Johansen†. Neurobiol. Res. Center and Dept. of Physiol. and Biophysics, Univ. of Alabama, Birmingham, AL 35294 & †Dept. of Zool. and Genetics, Iowa State Univ., Ames, IA 50011.

The axons of peripheral sensory neurons in *Hirudo medicinalis* navigate through several potential choice points toward the CNS where they then segregate into discrete axon tracts which can be distinguished by differential expression of surface antigens. The earliest population of sensory cells arise in discrete clusters called sensilla and pathway selection by individually dye-filled sensillar growth cones is highly specific. We have shown earlier that one potential source of guidance information proximal to the CNS was the outgrowing axons of central pioneer neurons. To examine the potential influence of CNS-associated cues, we performed CNS ablations early on embryonic day 10. Ganglionic primordia were removed from anesthetized embryos which were allowed to survive for 6-8 days before labeling them with the monoclonal antibody Lan3-2 to stain all sensillar axons. Control preparations involved surgically opening the body wall but not removing the ganglionic primordia. Pathfinding and selective fasciculation in control preparations were indistinguishable from normal. In contrast, in each of 110 hemisegments deprived of CNS (15 animals), the sensillar axons appeared undirected. In all cases the majority of sensillar axons fasciculated extensively upon one another following a tight circular pathway around the nephridiopore. Normally these axons project some distance from this pore. There were also a few instances where normally separate peripheral fascicles became tightly fasciculated along abnormal pathways. These results demonstrate that the CNS normally provides cues necessary for correct navigation, and in their absence the peripheral neurons default to fasciculate with each other. Further evidence in support of this is that later-developing extrasensillar neurons do differentiate and project axons in the absence of the CNS, but appear unable to identify an appropriate direction for growth. Instead they form short bundles of axons that do not join their normal pathways. Thus, the peripheral sensory neurons of leeches require CNS-derived guidance information. We are currently further examining the nature of the cues provided by CNS neurons necessary to direct afferent ingrowth. Supported by NSF 9209237 and a Sloan Foundation Fellowship (JJe) and NIH 28857 (JJo).

439.6

NETRINS ARE CHEMOTROPIC FACTORS THAT MAY GUIDE COMMISSURAL AXONS IN THE DEVELOPING SPINAL CORD.

T.E. Kennedy*, T. Serafini, J.R. de la Torre, C. Mirzayan, M. J. Galko, and M. Tessier-Lavigne. Dept. of Anatomy, University of California, San Francisco, CA 94143-0452

The guidance of axons to their targets in the developing nervous system is believed to involve diffusible chemotropic factors secreted by target cells. Floor plate cells at the ventral midline of the spinal cord secrete a diffusible factor (or factors) that promotes the outgrowth of spinal commissural axons and attracts these axons *in vitro*. Two proteins from embryonic brain, netrin-1 and netrin-2, possess the outgrowth-promoting activity of floor plate cells. Here we report that during the period of commissural axon growth to the ventral midline, *netrin-1* is expressed at high levels in the floor plate region, whereas *netrin-2* is expressed more widely and at lower levels in the ventral spinal cord. Moreover, heterologous cells secreting either netrin can mimic both the outgrowth promoting and the long-range chemotropic activities of floor plate cells. Thus, netrin-1 and netrin-2 are chemotropic factors that may guide commissural axons in the developing spinal cord.

GENETIC ANALYSIS OF SEMAPHORIN II FUNCTION DURING GROWTH CONE GUIDANCE AND TARGET RECOGNITION IN DROSOPHILA.

D.J. Matthes, A.L. Kolodkin*, and C.S. Goodman, HHMI, Neuro. Div., Dept. of Mol. and Cell Biol., U. C. Berkeley, CA 94720

The Semaphorin genes encode a family of highly related secreted and transmembrane proteins which appear to function during growth cone guidance. Antibody blocking experiments have shown that grasshopper Semaphorin I (formerly Fasciclin IV) is required for the proper guidance and fasciculation of the T1 growth cones in the limb bud of the grasshopper embryo (Kolodkin et al., 1992). Chick collapsin, a secreted member of the Semaphorin family, is capable of causing growth cone collapse in an *in vitro* assay (Luo, et al., 1993).

We previously identified two members of the Semaphorin gene family in *Drosophila* (Kolodkin et al., 1993). Semaphorin II (Sema II) is a secreted protein that is structurally similar to chick collapsin; both are comprised of a signal sequence, a 500 amino acid Semaphorin domain, a single immunoglobulin domain, and a short C-terminal region. In the embryo, Sema II is expressed by a small subset of cells in the CNS and by muscle 31 in the body wall of the T3 segment, suggesting a role in the generation of neuromuscular connectivity.

We have taken a genetic approach to characterize the function of Sema II. Adult flies homozygous for loss-of-function mutations in *semaII* have a variety of behavioral phenotypes including partially penetrant flightlessness, visual orienting defects, and abnormal drinking behavior. To gain insight into the origins of these behavioral defects, we have examined the effect of the *semaII* loss-of-function mutations on the innervation of muscle 31 in the embryo and larva. To complement these studies, we have used transgenic constructs to ectopically express Sema II by novel sets of muscles. In this way, we hope to determine the function of this secreted Semaphorin during growth cone guidance and target recognition.

439.9

EXPRESSION OF THE SEMAPHORIN III GENE DURING DEVELOPMENT OF THE MOUSE NERVOUS SYSTEM. E. Messersmith*, A. L. Kolodkin, C. S. Goodman, and C. J. Shatz. Division of Neurobiology, Dept. of Molecular and Cell Biology, University of California, Berkeley, CA 94720

The Semaphorin genes encode a family of highly related secreted and transmembrane proteins that appear to function during growth cone guidance. Semaphorin I (Sema I; formerly Fas IV) in the grasshopper is a transmembrane protein that functions in vivo in growth cone guidance (Kolodkin et al., Neuron, 1992). Sema II in *Drosophila* is a secreted protein that is essential for adult behavior and survival (Kolodkin et al., Cell, 1993). Chick collapsin, a secreted protein that is closely related to D-Sema II, can function in vitro to cause DRG growth cone collapse (Luo et al., Cell, 1993).

Based on the sequence of human Sema III (Kolodkin et al., Cell, 1993), we used PCR to clone mouse Sema III which is likely to be the homologue of chick collapsin. Here we conduct in situ hybridization using a mouse Sema III cDNA to analyze Sema III expression during mammalian development. Whole-mount embryos (E9.5) and tissue sections (E13.5, E15.5, P0, P7, and P21) were hybridized with antisense and sense riboprobes. Some of the structures showing the most prominent labeling with the M-Sema III probe include posterior dermomyotome and branchial arches at E9.5, ventral neural tube motoneurons, cells surrounding dorsal root ganglia, pons, and cortical plate at E13.5, retina and olfactory tract at E15.5, and olfactory tract, cerebellar Purkinje cells, and cortical layers 6b and 5 at P0. The spatial and temporal patterns of M-Sema III expression correlate with periods of axon outgrowth and are thus consistent with its proposed role as a growth cone guidance molecule. Supported by Fight for Sight (EM), NIH NS 18366 (ALK), Howard Hughes Medical Institute (CSG), and March of Dimes and NIH EY02858 (CJS).

AXONIN-1- AND Ng-CAM-LIKE IMMUNOREACTIVITY DURING THE DEVELOPMENT OF THE RETINOTECTAL SYSTEM IN THE CHICK. G. Rager*, P. Morino and P. Sonderegger¹. Institute of Anatomy, University of Fribourg, CH-1700 Fribourg, and ¹Institute of Biochemistry, University of Zürich, CH-8057 Zürich, Switzerland.

The development of the retinotectal system seems to follow the rule of chronotopy (Rager et al., Anat. Embryol. 179, 135-148, 1988; Rager et al., J. Comp. Neurol. 334, 529-544, 1993). To produce this type of order, the expression of cell adhesion molecules could play an important role. Recently, two axonal cell adhesion molecules, axonin-1 and Ng-CAM, have been found to interact during the process of outgrowth (for review see Sonderegger and Rathjen, J. Cell Biol. 119, 1387-1394, 1992). We have analyzed the expression of axonin-1 and compared it with the distribution of Ng-CAM in the retina and in the retinotectal system of the chick throughout the period of development. At stage 18 both axonin-like (A-LI) and Ng-CAM-like immunoreactivity (Ng-CAM-LI) are clearly present in the area where first retinal ganglion cells (RGC) are generated. The immunoreactivity spreads synchronously with the formation of RGCs over the developing retina. From stage 32 on the inner plexiform layer was also stained according to its temporospatial gradient of maturation. In later stages the outer plexiform layer and the inner segments of photoreceptors show immunoreactivity, too. The development of A-LI and Ng-CAM-LI along the optic nerve, chiasm, optic tract, and in the superficial layers of the optic tectum seem to follow the chronotopic distribution of axons as it was found by earlier morphological investigations. Older axons seem to lose their A-LI which allows us to localize the position of newly formed axons. The fact that A-LI and Ng-CAM-LI go in parallel with the formation and maturation of axons allows us to suggest that axonin-1 and Ng-CAM may play an important role in the organization of the retinotectal system. Supported by Swiss N.S.F. grant 31-36468.92.

ISOLATION OF DROSOPHILA VISUAL SYSTEM CONNECTIVITY MUTATIONS. K. A. Martin, H. Roth, A. Ebens S. L. Zipursky*. Dept. of Biological Chemistry, UCLA Sch. of Med., Los Angeles, CA 90024.

Orderly neuronal maps of visual space are created in the fly brain by precise retinal cell (R cell) contacts to the optic lobe. To identify genes that regulate R cell connectivity we screened *Drosophila* larvae for mutations affecting the R cell projection pattern. We analyzed over 5000 EMS mutagenized lines for aberrant R cell projections and isolated 44 mutations. Each mutation was characterized to determine if the gene underlying the defect 1) is required in the R cells, 2) affects R cell fate determination, 3) affects cell fate determination in the optic lobe. A genetic mosaic analysis was used to determine if the gene is required in the eye. In this procedure a patch of mutant eye tissue is generated in an otherwise normal fly. Those mutations that produce a defect within the optic lobe region innervated by a mutant patch are required in the eye. This class of mutations is particularly interesting because it is likely to include genes that function in the R cell growth cones. Neuronal fate determination was assessed in both the eye and the optic lobe. In particular we wanted to eliminate from further analysis those mutations that disrupt R cell fate determination because connectivity defects may be a secondary consequence of changes in neuronal identity. Three mutants were isolated that are required in the eye but do not affect the determination of R cell fate. These mutants represent candidate genes which function in the R cells to generate precise connections with their targets.

RETINAL AXONS SUDDENLY STOP ELONGATING AFTER SIGNIFICANT EXTENSION ONTO GRADIENTS OF POSTERIOR TECTAL MATERIAL. R. W. Davenport*, J. Löscher, J. Huff, J. Jung, E. Bonhoeffer. Max-Planck-Institut für Entwicklungsbiologie, Spemannstr. 35/1, D72076 Tübingen, Germany.

Fundamental questions remain concerning the cellular phenomena responsible for development of topographic retinal projections. By a matching of coordinate molecular gradients across retinal and tectal surfaces, growth cones could uniquely identify their target location (Sperry, 1963)¹. Recently, Baier and Bonhoeffer (1992)² developed an assay to present exponentially increasing gradients of tectal material to retinal ganglion axons extending *in vitro*. Cultures fixed at a given interval after retinal explantation clearly demonstrated that retinal axons can respond to graded molecular cues; temporal axons were shorter than their nasal counterparts when faced with increasing amounts of posterior tectal material. To begin to understand cellular mechanisms that underpin guidance in this system, technical modifications of the methods of Baier and Bonhoeffer (1992) were made in the present investigation. Retinal axons were forced to extend in lanes with relatively linearly increasing amounts of repulsive guidance activities which were bounded by non-substrate lanes. Temporal axons extended considerable distances onto the repulsive material, yet not to lengths as great as their nasal counterparts. To investigate what characteristics of continuous, long-range guidance cues were responsible for such changes in axon behavior, systematic modifications were made of gradient amplitude, slope and the growth supportive material encountered prior to the gradient. The modifications led to the following results: temporal growth cones stop at approximately the same point in a given gradient, the stop position is slope-dependent and independent of the repulsive materials' absolute amount. High concentrations of repulsive material at the site of axon initiation seem to shift the stop position higher into the gradient. Time-lapse movies reveal that upon entering the gradient axonal extension rates do not gradually diminish. These results suggest that growth cones may sense a particular difference between amounts of guidance material measured at positions near the site of axonal initiation and termination.

A GENETIC MODEL FOR RETINOTOPIC MAP DEVELOPMENT: THE DROSOPHILA R7/R8 VISUAL PROJECTIONS. E. N. Katz* and J. A. Ashley. Dept. of Biochemistry, University of Texas Southwestern Medical Center, Dallas, TX 75235-9038.

The *Drosophila* compound eye is composed of 800 simple eyes which each contain eight photoreceptor neurons. Two of these neurons, R7 and R8, project axons to the medulla of the optic lobe, where they establish a retinotopic map. In a search for mutations that disturb map formation, the *gap1^{mc}* mutation was recovered (Buckles et al., 1992: Neuron 8, 1015-1029). Loss of function for this gene results in stable hyperinnervation of the optic lobe, caused by the differentiation of extra R7 neurons. Using somatic mosaic constructions, wild-type or hyperinnervated terminal sites were juxtaposed with areas lacking innervation. Collateral sprouts were observed to invade unoccupied sites only in the hyperinnervated configuration, suggesting a balance between intrasite and intersite competition may be involved. During the third instar, the growth cones of wild-type R7/R8 axons send out promiscuous filopodia that overlap surrounding terminal sites and provide a means of assessing neighboring site occupancy. This is followed by a period of terminal refinement, which does not require visually evoked electrical activity for maintenance. R7/R8 axon behavior in the absence of neighbors suggests that photoreceptor neurons have positional labels that influence their connectivity in the brain, and a set of genes that have regional expression in the eye consistent with such positional subdivisions have been recovered. We propose that the position and morphology of each axon terminal is determined by the positional specification of its soma, the synaptic sufficiency of its termination site, and the availability of adjacent sites.

439.14

DROSOPHILA RECEPTOR TYROSINE PHOSPHATASES ARE EXPRESSED IN THE DEVELOPING VISUAL SYSTEM

C. Desai, E. Popova, B. Hamilton and K. Zinn*. Dept. of Biol., Caltech, Pasadena, CA 91125.

Several receptor-linked protein tyrosine phosphatases (R-PTPs) appear to be expressed on most or all CNS axons in *Drosophila*. We purified one such R-PTP, DPTP69D, using antiserum against horseradish peroxidase (HRP) as immunaffinity reagent. Anti-HRP antibodies recognize a carbohydrate epitope selectively expressed in insect nervous systems. Many neuronal glycoproteins (denoted 'HRP proteins') apparently bear the HRP carbohydrate epitope. Protein sequence data also defines neurotactin and fasciclin I as HRP proteins. Western blotting data suggest that fasciclin II, neuroglian, DPTP10D, and DPTP99A are also HRP proteins.

Like previously characterized R-PTPs, DPTP69D is localized to CNS axons in the embryo. In third instar larvae, DPTP69D expression is restricted to subsets of neuronal processes in the brain, ventral nerve cord, and eye disc. In particular, DPTP69D is expressed on photoreceptor axons and on the neuropils of the developing lamina, medulla and lobula complex. Interestingly, DPTP99A is also expressed in the optic lobes in a similar pattern, but at lower levels. We have made DPTP99A mutants; these are viable with normal embryonic CNSs. We are examining the visual system in larvae and adults lacking DPTP99A for possible defects. We are also trying to disrupt DPTP69D by mobilizing a P element located 8 kb downstream from DPTP69D.

UP-REGULATION OF [¹²⁵I]-NCQ 298 BINDING SITES IN RAT BRAIN FOLLOWING CHRONIC TREATMENT WITH REMOXIPRIDE OR HALOPERIDOL. H. Eriksson*, G. Ericsson and A. Westlind-Danielsson, Department of Neuropharmacology, CNS Preclinical R & D, ASTRA ARBUS AB, S-151 85 Södertälje, Sweden.

As the antipsychotic effect of neuroleptic drugs is believed to be a result of dopamine D2 receptor blockade it can be assumed that chronic treatment with such drugs leads to an up-regulation of D2 receptors. We tested this hypothesis for remoxipride, with haloperidol as a positive control.

Rats were administered remoxipride (10 mg/24 hrs/rat) or haloperidol (0.1 mg/24 hrs/rat) for 14 days with osmotic pumps implanted s.c. After this period dopamine D2 receptor concentrations were determined in six different brain regions using the specific high affinity D2 antagonist [¹²⁵I]-NCQ 298.

[¹²⁵I]-NCQ 298 binding sites increased in striatum by 40 % after remoxipride treatment while a 50 % increase was apparent after the haloperidol treatment. In addition, a clear increase in [¹²⁵I]-NCQ 298 binding sites were also measurable in the olfactory tubercle and nucleus accumbens with remoxipride treatment by 35-41 % over control values. A slight increase in [¹²⁵I]-NCQ 298 binding sites was also notable in both the medial prefrontal cortex and hippocampus. However, the entorhinal cortex displayed about a 40 % decline in [¹²⁵I]-NCQ 298 binding sites with either treatment. The control levels of [¹²⁵I]-NCQ 298 binding was found in the range 6.4-254 fmol/mg protein. The lowest level in the hippocampus and the highest in the striatum. This report is the first account of dopamine D2 receptor up-regulation in several different brain regions of the rat after chronic remoxipride administration. The results strengthen the notion that postsynaptic D2 receptor blockade is involved in antipsychotic action.

PRODUCTION OF MICE WITH A CONSTITUTIVE DEFICIENCY OF THE β ADRENERGIC RECEPTOR KINASE BY HOMOLOGOUS RECOMBINATION. B. Giros, R. J. Lefkowitz and M.G. Caron*. HHMI, Duke University Medical Center, Box 3287, Durham, NC 27710, USA.

Protein phosphorylation represents one of the most prominent molecular mechanisms responsible for cellular plasticity and adaptability. Within the large family of G-protein-coupled receptors, phosphorylation of the agonist-activated state of the receptor underlies rapid desensitization, a condition which leads to a blunted efficiency of coupling and signal transduction. G protein-coupled Receptor Kinases (GRKs), specifically recognize the activated form of the receptor as the preferred substrate for phosphorylation, and are therefore responsible for homologous desensitization. In order to study the physiological role of this homologous desensitization, we decided to produce a mouse line in which a targeted disruption of the β -adrenergic receptor kinase (β ARK-1, GRK-2) would be engineered. First, the entire genomic organization of the gene encoding the murine β ARK-1 was established. It is composed of 21 exons in the coding part, interspersed with introns ranging from 68 bp to more than 12 kb. A plasmid was constructed in which four exons covering part of the catalytic domain of β ARK-1 were substituted with the neomycin resistance gene. This plasmid was used to transfect embryonic stem cells from 129/Sv mice, and clones with one event of homologous recombination were selected to inject into blastocysts. Chimeric males obtained from these manipulations were mated with wild-type females, and successfully produced animals with a genotype β ARK-1 (+/-). Heterozygote animals are being bred to produce homozygotes β ARK-1 (-/-). The detailed study of these animals should provide a much better understanding of the biological functions which are dependent on the β ARK-1 phosphorylation processes.

MODULATION OF THE SUBCELLULAR DISTRIBUTION OF THE BETA-ADRENERGIC RECEPTOR KINASE IN CELLS OVEREXPRESSING THE BETA2-ADRENERGIC RECEPTOR. A. Ruiz-Gómez*, C. Murgo*, J.A. De Carlos* and F. Mayor, Jr.*. ¹Instituto Cajal, 28002 Madrid and ²Centro de Biología Molecular, "Severo Ochoa" (CSIC-UAM) Universidad Autónoma de Madrid, 28049 Madrid, Spain.

β -adrenergic receptor kinase (β ARK) is a regulatory enzyme involved in the modulation of the β -adrenergic and other G protein-coupled receptors in the brain and many other tissues. β ARK has been described as a soluble, cytosolic protein that transiently translocates to the plasma membrane in order to specifically phosphorylate agonist-occupied receptors. In addition, we have recently shown that a significant amount of β ARK is associated to microsomal membranes (García-Higuera et al (1994) J.Biol.Chem. **269**, 1348-1355). The existence of different β ARK pools (i.e., soluble, microsome-bound and plasma membrane-bound) has been investigated further in HEK-293 cells overexpressing β ARK either alone or in combination with β 2-adrenergic receptors (β 2AR), by using both immunofluorescence assays with specific β ARK antibodies and subcellular fractionation followed by Western blot and β ARK activity determination. These studies confirm the complex subcellular distribution of β ARK both in wild type and stably β ARK-transfected cells. To examine the role of the β -adrenergic receptor in modulating the subcellular localization of β ARK, cells were cotransfected with plasmids encoding for β ARK and β 2AR. All stable clones expressing both β ARK and β 2AR display a different distribution of the kinase. In these cells, the ratio between the pools of β ARK protein changed from microsome-bound > plasma membrane-bound > soluble, in cells expressing β ARK alone, to plasma membrane-bound > microsome-bound > soluble in cells expressing both β ARK and β 2AR. This experimental system may prove useful in identifying the role of the β -adrenergic receptor presence and activation in regulating β ARK subcellular distribution. Supported by DGICYT PB92-0135, EC Biotech CT930083, Boehringer Ingelheim and Fundación Ramón Areces.

REGULATION OF DOPAMINE D3 RECEPTORS EXPRESSED IN HEK-293 CELLS. M. A. Pacheco*, K. D. Burris and P. B. Molinoff, Department of Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, PA 19104-6084.

We have previously reported a drug-induced increase in the density of D2 receptors expressed in transfected HEK-293 cells (Mol. Pharmacol. **44**:371-379). D2 and D3 dopamine receptors have similar structural and pharmacological properties. It was of interest to determine whether the D3 receptor regulates in a fashion similar to the D2 receptor. A stable cell line was created by transfecting cDNA encoding the D3 receptor, under the control of a cytomegalovirus promoter, into human embryonic kidney cells (HEK-293). Changes in the density of receptors after treatment with compounds known to be agonists or antagonists at D2 receptors were measured in homogenates using radioligand binding assays with the D2 agonist [¹²⁵I](R)trans-7-hydroxy-PIPAT or the D2 antagonist [¹²⁵I]NCQ-298. HEK-293-D3 cells express a density of receptors of 551 ± 45 fmole receptor per mg of protein. Exposure of HEK-293-D3 cells to quinpirole (5.0 μ M) for 18 hr resulted in a 77% increase in the density of binding sites for both [¹²⁵I](R)trans-7-hydroxy-PIPAT and [¹²⁵I]NCQ-298. This increase in density was both time- and concentration-dependent. Exposure of cells to 7-hydroxy-DPAT (5.0 μ M) for 18 hr, resulted in a 57% increase in the density of D3 binding sites. Treatment with the dopamine antagonist haloperidol (5.0 μ M) for 18 hr resulted in a 145% increase in the density of D3 receptors. The increase in the number of D3 binding sites induced by haloperidol was also concentration-dependent. The data suggest that both D2 agonists and antagonists induce an increase in the density of D3 receptors expressed in transfected HEK-293 cells. (Supported by MH14654, and NS18591.)

ENDOCYTOSIS, DESENSITIZATION AND RESENSITIZATION OF NK₁ AND NK₂ RECEPTORS. A.M. Garland, E.F. Grady, M. Lovett, J.E. Krause, and N.W. Bunnett*. Depts. of Surg. and Physiol., UCSF, San Francisco, CA 94143-0660 and Depts. of Anat. and Neurobiol., Washington University, Saint Louis, MO, 63110.

Endocytosis of NK₁ and NK₂ receptors, stably expressed in CHO cells, was studied by confocal microscopy using substance P (SP) or neurokinin A (NKA) labeled with the fluorophore cyanine 3 (cy3). When cells expressing the NK₁ receptor or the NK₂ receptor were incubated with cy3-SP or cy3-NKA, respectively, for 2 h at 4°C, fluorescence was confined to the plasma membrane. By 5 min of warming to 37°C, a marked reduction in cell surface labeling occurred and fluorescence was observed in endosomes beneath the plasma membrane. At 30 min, the signal was located in larger, more central vesicles. Endocytosis was quantified by binding with ¹²⁵I-SP or ¹²⁵I-NKA, using an acid wash to separate cell surface from internalized label. At 4°C, label was mostly found in the cell-surface fraction. After 10 min at 37°C, 90±1% of specifically bound ¹²⁵I-SP and 85±2% of specifically bound ¹²⁵I-NKA were internalized by cells expressing the NK₁ and NK₂ receptors, respectively. Truncated mutant receptors, lacking portions of the C-terminal tails (NK₁-Δ325, NK₂-Δ367, NK₂-Δ347), internalized normally, as assessed by microscopy and ligand binding. Desensitization and resensitization of wild type NK₁ and NK₂ receptors to SP and NKA, respectively, were examined by measuring IP3 generation. When cells were exposed to a test dose of agonist 10 min after a desensitizing dose, the IP3 response diminished to 28.8±7.9% for the NK₁ receptor and 48.6±17.8% for the NK₂ receptor of the control response (no desensitizing dose). The response recovered to control levels after 30 min. Treatment of cells with phenylarsine oxide, to block endocytosis, had no effect on desensitization but prevented resensitization. In summary, fluorescently labeled peptides can be used to localize receptors. Wild type NK₁ and NK₂ receptors internalize within minutes of binding ligand, and mutant receptors lacking portions of the C-terminal tail internalize normally. Endocytosis of NK₁ and NK₂ receptors is not required for desensitization of the IP3 response but is necessary for resensitization.

440.6

CATECHOLAMINE DENERVATION BY 6-OHDA INCREASES THE mRNA EXPRESSION OF BARK AND β -ARRESTIN IN DIFFERENT RAT BRAIN AREAS. A. De Biasi, M. Salles, P. Liquori, R. Marinacci and E. Esposito*. Istituto di Ricerche Farmacologiche "Mario Negri", Consorzio "Mario Negri" Sud, S. Maria Imbaro (Chieti), Italy.

Two types of proteins play a major role in determining homologous desensitization of G-coupled receptors: β -adrenergic receptor kinase (β ARK), which phosphorylates the agonist-occupied receptor and its functional cofactor, β -arrestin. β ARK is a member of a multigene family, consisting of six known subtypes, which have also been named G-protein coupled receptor kinase (GRK1 to 6) due to the apparently unique functional association of such kinases with this receptor family. The four members of the arrestin/ β -arrestin gene family identified so far are: arrestin, X-arrestin, β -arrestin1 and β -arrestin2. Both β ARK and β -arrestin are highly expressed in the central nervous system (CNS), suggesting a relevant role of these proteins in synaptic receptor-mediated responses. However, informations regarding the role played by β ARK/ β -arrestin in the modulation of CNS receptors are still lacking. To investigate this point we treated intracerebroventricularly male Sprague-Dawley rats with 6-hydroxydopamine (6-OHDA), a neurotoxin which destroys catecholaminergic neurons. Ten days after 6-OHDA (200 μ g/20 μ l of a saline solution containing 0.05% ascorbate) or vehicle administration, animals were killed and several brain areas were rapidly removed. In lesioned rats, the mRNA expression of β -arrestin was significantly increased in corpus striatum, nucleus accumbens, hippocampus and brainstem. The mRNA expression of β ARK was increased in the hippocampus, while it was only slightly, if at all, affected in different other areas. These preliminary data suggest that β ARK and β -arrestin are selectively modulated in response to reduced catecholaminergic tone.

NUCLEAR PROTEINS FROM YOUNG AND OLD RAT TISSUES INTERACT DIFFERENTLY WITH THE D2 DOPAMINE RECEPTOR GENE PROMOTER. J. M. Chernak*, G. S. Roth, T. Minowa and M. M. Mouradian. Molecular Physiology and Genetics Section, Laboratory of Cellular and Molecular Biology, NIA, NIH, Baltimore, MD 21224; Genetic Pharmacology Unit, Experimental Therapeutics Branch, NINDS, NIH, Bethesda, MD 20892.

Loss of D2 dopamine receptors and/or changes in their activity may lead to compromised neuronal functioning in aging and certain neurodegenerative diseases. To study the mechanisms of regulation of the D2 dopamine receptor gene in different tissues with aging, we carried out gel mobility shift experiments using nuclear extracts from young and old rats and DNA fragments or oligonucleotides containing different parts of the rat D2 promoter. A 415 bp DNA fragment containing sequences from -490 to -76 relative to the major transcriptional start point and a 378 bp fragment containing sequences from -75 to +302 bound to protein(s) present in nuclear extracts prepared from rat cortex, cerebellum, hippocampus, striatum, kidney and liver. In addition, the 378 bp probe bound to purified AP2 protein as well as protein(s) present in AP2-enriched extracts. We have also shown that an oligonucleotide containing sequences from -75 to -30 binds protein(s) present in extracts from rat cortex, hippocampus, striatum and liver. In several cases, nuclear factor(s) present in extracts from cortex, cerebellum, hippocampus, or striatum formed DNA-protein complexes with different gel mobilities than those formed with liver extracts, suggesting that the identity of some of the nuclear factors binding to the D2 promoter may differ between brain and peripheral tissues. Furthermore, with equal amounts of total nuclear protein, greater binding was observed using cerebellar and liver extracts from young rats than from old rats. These results suggest that the concentration and/or binding activity of nuclear factors interacting with the D2 dopamine promoter may change with age. Further characterization of putative DNA regulatory sites and regulatory proteins in different tissues of young and old animals is in progress.

DOWNREGULATION OF THE HISTAMINE H₂ RECEPTOR EXPRESSED IN CHINESE HAMSTER OVARY CELLS M.J. Smit*, R. Leurs, Y. van de Vrede and H. Timmerman. Leiden/Amsterdam Center for Drug Research, Department of Pharmacochimistry, De Boelelaan 1083, 1081 HV Amsterdam, The Netherlands.

Under several pathophysiological conditions, where histamine is released in large quantities, or during treatment with histaminergic drugs in various disorders regulatory processes such as desensitization and downregulation may become apparent.

Long-term exposure (24 hrs) of CHO cells, overexpressing the rat histamine H₂ receptor (CHORH₂), to histamine resulted in a dose dependent decrease in the number of H₂ receptors (max. reduction 50 %). The receptor affinity remained unaltered. This process appeared to be a H₂ receptor mediated process as dimaprit induced downregulation and its structural analogues, homo- and nordimaprit, which are devoid of H₂ activity, did not. All compounds generating cAMP upon stimulation, such as H₂ agonists, forskolin and cholera toxin, induced histamine H₂ receptor downregulation, suggesting the possible involvement of protein kinase A in the process of receptor downregulation. In contrast, treatment of CHORH₂ cells with various H₂ antagonists resulted in an upregulation of H₂ receptors (200 %). This effect could probably explain therapeutic observations of reduced efficacy after some period of time.

Currently, we examine the possible role of different kinases in this process and determine which structural elements of the receptor are essential for H₂ receptor downregulation.

STEROID RECEPTOR MEDIATED EFFECTS OF NEUROSTEROIDS. R. Rupprecht, J. M. H. M. Reul, T. Trapp, B. van Steensel, C. Wetzel, W. Ziegängsberger and F. Holsboer*. Max-Planck-Institute of Psychiatry, Clinical Institute, Department of Neuroendocrinology, Kraepelinstr. 2-10, 80804 Munich, FRG.

Several 3 α -hydroxy steroids accumulate in the brain after local synthesis or after metabolism of steroids that are provided from the adrenals. As this may occur independently from peripheral sources these steroids are called neurosteroids. The 3 α -hydroxy ring A-reduced pregnane steroids allopregnanolone and tetrahydrodeoxycorticosterone are believed not to interact with intracellular receptors but enhance γ -aminobutyric acid (GABA)-mediated chloride currents.

The present study shows that these neurosteroids can regulate gene expression via the progesterone receptor (PR). Although they do not bind to the PR of either species, they confer an exclusively nuclear localization of the PR. However, the induction of DNA-binding and transcriptional activation of the PR requires intracellular oxidation of the neurosteroids into PR-active 5 α -pregnane steroids. Thus, in physiological concentrations, these neurosteroids regulate neuronal function through their concurrent influence on transmitter-gated ion channels and gene expression. These findings extend the concept of a "cross-talk" between membrane and nuclear hormone effects and provide a new lead for the therapeutic application of these steroids in neurology and psychiatry.

440.8

PINEAL α -1B ADRENERGIC RECEPTOR mRNA: HIGH ABUNDANCE, DEVELOPMENT AND ADRENERGIC REGULATION. S.K. McCune*, S. L. Coon, D. E. Brenneman and D. C. Klein. Section on Developmental and Molecular Pharmacology and Section on Neuroendocrinology, Lab. of Developmental Neurobiology, NICHD, NIH, Bethesda, MD 20892.

Adrenergic receptors mediate tissue responses to catecholamines. Binding studies have documented the presence of α -1 adrenergic receptors in the pineal gland and pharmacological studies have demonstrated a role of these receptors in the adrenergic regulation of many aspects of pineal function, including melatonin production. In an effort to better define α -adrenergic receptors in the pineal gland, α -1B adrenergic receptor expression was examined using *in situ* hybridization and Northern blot analysis.

Developmental expression of the α -1B adrenergic receptor subtype was determined by Northern blot and densitometric analysis of *in situ* hybridization of brain sections through the pineal as well as sections of individual pineal glands. Alpha-1B receptor mRNA was highest in the early perinatal time periods and decreased with maturation. The abundance of mRNA encoding this receptor subtype in the pineal gland was extremely high as compared to brain and other tissues; a strong hybridization signal was detected on Northern blot with 2 μ g of total RNA.

Northern blots of pineal mRNA from day and night animals showed a 2.5-3 fold increase in the α -1B adrenergic receptor mRNA at night without a similar increase in the mRNA encoding G3-PDH. This change is probably due to nocturnal adrenergic stimulation of the pineal gland, because *in vitro* stimulation of the pineal gland for 4 hours with norepinephrine (1 μ M) induced a selective 2-fold increase in the abundance of α -1B adrenergic receptor mRNA.

The presence of high levels of α -1B adrenergic receptor mRNA in the pineal gland and evidence of neural regulation of expression make this tissue an excellent model for further analysis of this receptor subtype.

440.10

GSH RECEPTOR REGULATION IN RAT CORTICAL ASTROCYTES. C.A. Shaw*, H. Bining, B.A. Lanius, and B.A. Pasqualotto. Depts. of Ophthalmology and Physiology and Neuroscience Program, c/o Dept. of Anatomy, Univ. British Columbia, Vancouver, B.C., Canada, V6T 1Z3.

Recent studies have suggested that glutathione (GSH) may act as a neurotransmitter at specific receptors in the mammalian CNS. One of the highest concentrations of GSH receptors (GSHR) are on cortical astrocytes (Guo & Shaw, 1992, *Mol. Brain Res.*, 15, 207) and activation by GSH stimulates an increase in IP₃ activity. In other studies, the regulation of GSHR in spinal cord appears to depend on protein kinase C (PKC) (Lanius et al., 1994, *J. Neurochem.*, in press). We have now examined the actions of GSH, a PKC activator (phorbol ester (PB)), and cellular depolarization (veratridine) in the presence or absence of kinase or phosphatase blockers on GSHR in cultured rat cortical astrocytes. Exposure of astrocytes to GSH (10-5M) produced a significant decrease in [35S]-GSH binding (-17.9% \pm 2.4%, n=21, p<0.05) compared to untreated cells. This effect was time and concentration dependent and could be blocked by co-incubation with the ser/thr phosphatase inhibitor N-B-D-glycerophosphate but not the tyrosine-selective inhibitor sodium orthovanadate. The effects of PKC activation by PB produced a significant increase in [35S]-GSH of 21.4% \pm 3.7% (n=17, p<0.05) which could be blocked by co-incubation with PKC inhibitors. Veratridine was without significant effect. These data suggest that GSHR may be regulated by opposing actions of kinase/phosphatase activity in a manner similar to that reported for several neurotransmitter receptors in brain.

441.1

IMMUNOHISTOCHEMICAL CHARACTERIZATION OF CULTURED, COLCHICINE-TREATED CRF-CONTAINING NEURONS OF THE RAT AMYGDALA. R. W. Gabr*, A. K. Salm¹, and D. L. Birkle. Departments of Pharmacology and Toxicology and ¹Anatomy, West Virginia University School of Medicine, Morgantown, WV, 26506.

CRF is a 41 amino acid peptide first isolated and characterized in 1981 (Vale et al). CRF is part of a dynamic system which regulates central and peripheral components of the stress response (Owens and Nemeroff, 1991). Depolarization-induced, calcium-dependent release of CRF from fetal neuronal cultures of the amygdala has been previously demonstrated (Cratty and Birkle, 1994). Fetal cell culture (E17-E18) of the rat amygdala on glass coverslips (2 x 10⁶ cells/slip) yielded a 5:1 mixture of neurons and glia after 15-18 DIC. Immunostaining with anti-neurofilament marker, anti-glia acidic protein and DAPI allowed quantification of total cell types in the culture system. The proportion of CRF-containing neurons was determined using indirect immunofluorescence with rabbit anti-rat/human CRF (rC70) followed by anti-rabbit IgG conjugated to FITC. Total cells per 330 μ m² field were 32 ± 4 (n=122), with 6 ± 1 (n=53) cells staining positive for GFAP. NFM immunostaining revealed long bundles of fibers coursing from neuron cluster to cluster, as well as the distinct bead-like processes of peptidergic neurons in culture. 0.65 ± 0.25 cells (n=40) stained positive for CRF (2%). 24 hr incubation with colchicine (0.01mM) dramatically increased staining intensity, resulting in positive anti-CRF staining in 19% of cultured cells. Preliminary studies further indicate that a majority of fetal neuronal cells cultured from the amygdala contain glutamate. These results indicate that a high proportion of amygdala neurons (24%) may contain CRF, as revealed by colchicine treatment. Furthermore, immunohistochemical characterization of these cells in culture demonstrates compartmentalization of neurons into clusters connected by networks of fiber bundles, providing evidence that the heterogeneity of the amygdala is maintained in the *in vitro* culture system. Supported in part by NSF (IBN-9222263)

LEARNING DEFICITS IN TRANSGENIC MICE WITH CENTRAL OVEREXPRESSION OF CORTICOTROPIN-RELEASING FACTOR. S.C. Heinrichs^{1*}, M.P. Stenzel-Poore², L.H. Gold, E. Battenberg, F.E. Bloom, G.F. Koob, W.W. Vale³ and E. Merlo Pich. The Scripps Research Institute, Dept. of Neuropsychopharmacology, 10666 N. Torrey Pines Rd., La Jolla CA 92037, ¹Neurocrine Biosciences, Inc., 3050 Science Park Rd., San Diego CA 92121, ²Oregon Health Sciences University, Dept. of Microbiology and Immunology, P.O. Box L220, 3181 Sam Jackson Park Rd., Portland OR 97201 and ³The Salk Institute, Clayton Foundation Laboratories for Peptide Biology, 10100 North Torrey Pines Rd., La Jolla CA, 92037.

Transgenic (Tg) mice with central overexpression of corticotropin-releasing factor (CRF) exhibit a Cushing's Disease-like picture, elevated plasma levels of ACTH and corticosterone, increased behavioral reactivity to stressors and an anxiogenic-like state which is reversed by central administration of a CRF antagonist. Moreover, centrally administered CRF alters learning/memory processes in animal behavioral models and CRF substrates are altered in post-mortem tissue taken from Alzheimer's patients exhibiting learning/memory pathology. The present studies were designed to test the cognitive capacity of CRF Tg mice in a forced alternation water T-maze task and in the Morris water maze. In T-maze testing, littermate control mice reached criterion after five days of trials while the performance of CRF Tg subjects was random after the same training. In Morris maze testing, control subjects reached the submerged platform significantly faster after three days of trials while the performance of CRF Tg mice was unimproved over the same period. The deficit in Morris maze performance in CRF Tg mice was reversed when the platform was visible above the surface of the water and by pre-test administration of chlordiazepoxide (10 mg/kg IP) prior to acquisition training. Finally, the was no evidence of hippocampal cell loss in CRF Tg animals. Taken together, these results suggest that dysregulation of brain CRF may produce hyperemotionality that interferes with cognitive performance.

PRENATAL STRESS CAUSES HYPERSECRETION OF CORTICOTROPIN-RELEASING FACTOR (CRF) FROM AMYGDALA. MS Cratty*, HE Ward, EA Johnson, AJ Azzaro, DL Birkle. Depts. of Pharmacology/Toxicology, Behavioral Medicine/Psychiatry, and Neurology, West Virginia University School of Medicine, Morgantown, WV 26506.

The neuropeptide, corticotropin-releasing factor (CRF), has been found distributed throughout the central nervous system. CRF has a proposed role in emotional and behavioral states including stress and anxiety. The amygdala, a limbic structure important in the delicate control of emotions and autonomic responses to stress, contains CRF nerve terminals and CRF receptors. We examined CRF release from the amygdala of adult, male offspring of dams exposed to daily saline injection (0.1 ml, s.c.) from G14 to G21. This prenatal stress model produces offspring that are hyper-responsive to stress (Ward et al, this volume). In light of the role of amygdala CRF release in anxiogenic responses, we hypothesized that exposure to prenatal stress would increase CRF release from the amygdala. CRF release from amygdala slices (1 mm³) was time-dependent, depolarization-induced and calcium-dependent. There was a 32% increase in depolarization-induced CRF release from the amygdala of prenatally stressed rats. Prenatally stressed offspring also had elevated CRF concentrations in the amygdala. The data suggest that CRFergic neurotransmission in amygdala is upregulated after prenatal stress, an effect that may contribute to the hyperemotional state observed in these animals. Supported in part by NIH (2S07RR05433-31 and GM07039) and UHA.

SUPPRESSION OF CORTICOTROPIN-RELEASING FACTOR IN THE AMYGDALA ATTENUATES AVERSIVE CONSEQUENCES OF MORPHINE WITHDRAWAL. F. Menzaghi*, G. Schulteis, G.F. Koob, L. Stinus¹ and S.C. Heinrichs². The Scripps Research Institute, Dept. of Neuropharmacology, CVN7, 10666 N. Torrey Pines Rd., La Jolla CA, 92037, ¹Psychobiologie des Comportements Adaptatifs, INSERM Unité 259, Bordeaux, France and ²Neurocrine Biosciences, Inc., 3050 Science Park Rd., San Diego CA, 92121.

The central nucleus of the amygdala is a CRF-containing limbic brain site which mediates both fear-like and avoidance behaviors, and intra-amygdala administration of a CRF antagonist blocks the increase in anxiogenic-like behavior characteristic of ethanol withdrawal. In order to evaluate the role of brain CRF in negative motivational states associated with other classes of abused drugs, the present studies examined the effects of suppression of amygdala CRF systems on the characteristic aversive state of precipitated withdrawal in morphine-dependent subjects. In a place conditioning paradigm, administration of a CRF antagonist, α -helical CRF (9-41) [250 ng], bilaterally into the central nucleus of amygdala reversed the withdrawal-induced conditioned place aversion produced by injection of the opiate antagonist, methylnaloxonium [500 ng], into the same site. Impairment of CRF neurons by immunotargeted toxins administered into the central nucleus of amygdala one month prior to testing attenuated conditioned morphine withdrawal as measured by a decrease in response rate produced by exposure to distinctive sensory cues associated previously with systemic administration of naloxone [25 μ g/kg SC] in morphine-dependent subjects. These results indicate that suppression of intra-amygdala CRF systems weakens the aversive stimulus properties of conditioned opiate withdrawal and suggest a general role for CRF in coordinating behavioral responses to negative motivational effects of drug withdrawal.

CENTRAL AMYGDALOID CORTICOTROPIN-RELEASING HORMONE MODULATION OF THE STRESS RESPONSE IN ROMAN HIGH- AND ROMAN LOW AVOIDANCE RATS.

A. Wiersma, J.P. Koonman, S. Knollerna^{*}, J. Korf^{*}, S.F. DeBoer^{*}, B. Bohus and J.M. Koolhaas.

University of Groningen, Dept. of Animal Physiology, P.O.BOX 14, 9750 AA Haren, ^{*}Biological Psychiatry, P.O.BOX 30001, 9713 EZ Groningen, The Netherlands.

The central nucleus of the amygdala (CeA) is known to be involved in the regulation of the parasympathetic and passive coping response to conditioned and acute stressors. Neuroanatomical studies revealed that the majority of the corticotropin-releasing hormone (CRH) containing neurons in the CeA have direct connections with autonomic regulatory nuclei in the brainstem.

In this study we used the Roman High Avoidance (RHA/verh) and the Roman Low Avoidance (RLA/verh) rats (kindly provided by P. Driscoll, Zürich) to examine the effects of locally applied CRH into the CeA in both a stress-free and a conditioned stress situation. The RHA/verh and RLA/verh rats are considered to use an active and a passive coping style respectively.

A 7-min infusion of 30 ng CRH (in 0.5 μ l aCSF) into the CeA of freely moving male RHA/RLA rats under stress-free conditions, led to an increase in heart rate and behavioural activation only in the RHA treated animals, leaving the RLA rats unaffected. This is in contrast with the conditioned situation in which only the RLA/verh males responded. These results suggest a differential CRH central amygdaloid control of the behavioural and physiological stress response in the two selected strains of rats.

Subsequently experiments using CRH mRNA and Fos immunocytochemistry are in progress to obtain further experimental evidence for a differential central amygdala CRH modulation in the RHA/RLA rats.

CORTICOTROPIN-RELEASING FACTOR INFUSED INTO THE LOCUS COERULEUS INCREASES NOREPINEPHRINE RELEASE IN MEDIAL PREFRONTAL CORTEX. Gennady N. Smagin, Artur H. Swiergiel, Glenn Guerin* and Adrian J. Dunn. Dept Pharmacology, Louisiana State University Medical Center, Shreveport, LA 71130.

Previous studies have indicated that intracerebroventricular administration of corticotropin-releasing factor (CRF) increases the firing rate of noradrenergic neurons in the brain stem locus coeruleus (LC) and metabolites of norepinephrine (NE) metabolism in terminal regions in the forebrain, as well as extracellular concentrations of NE. To assess the possibility of direct effects of CRF in the LC, 100 ng of CRF was infused into the LC and concentrations of NE and metabolites were measured in microdialysates collected from ipsilateral or contralateral medial prefrontal cortex (PFM) with a 22 min sampling interval. Infusion of CRF significantly increased concentrations of NE in dialysates from the ipsilateral PFM in the first three postinfusion samples (26, 82 and 54% of baseline, respectively). No changes were observed with infusions of aCSF, or when CRF infusions occurred outside the LC - in the parabrachial nucleus, the tegmental area, the fourth ventricle or the cerebellum. Although dialysate concentrations of NE were slightly increased in the contralateral PFM, this effect was not statistically significant. The effect of CRF on NE release was prevented by a simultaneous infusion into the LC of 1 μ g of the CRF antagonist, α -helical CRF₉₋₄₁. These results are consistent with anatomical and electrophysiological evidence suggesting that CRF may directly activate noradrenergic neurons in or close to the LC, affecting cortical NE secretion and behavior.

SENSITIZATION OF THE EXCITATORY EFFECTS OF VASOPRESSIN OR CORTICOTROPIN RELEASING FACTOR ON THE ACOUSTIC STARTLE REFLEX BY VASOPRESSIN. G.H. Pelton, Y. Lee, M. Bowers*, M. Davis. Dept of Psychiatry, Yale Univ. School of Med. 34 Park St., New Haven, CT 06508

In the rat, evidence now suggests a neurotransmitter function for arginine vasopressin (AVP), implicating it in various autonomic, behavioral, and neuroendocrine responses. One characteristic of AVP's central effect is a sensitization phenomenon, in which repeated intracerebroventricular (ICV) injections of AVP lead to an increase of its initial effect on behavior. This has begun to be characterized by other investigators via a profoundly abnormal motor response called "barrel rolling", which occurs with repeated ICV AVP administration.

We used a simpler, neuroanatomically-defined behavior, the acoustic startle reflex in the rat, to evaluate whether repeated ICV AVP would cause sensitization. Different groups of rats were infused with various doses of AVP (30, 300, 3000 pg) or vehicle on Day 1. On Day 2, 48 hours later, all animals were infused with a single test dose of AVP (300 pg) or vehicle. The 300 pg dose of AVP was subthreshold for increasing baseline startle on Day 1. The results showed that 30 pg of AVP on Day 1 did not sensitize the effect of AVP on Day 2, but 3000 pg did ($p < 0.05$).

Because stress is known to activate release of both AVP and corticotropin releasing factor (CRF) and ICV CRF is known to increase baseline startle, we wondered if AVP would also sensitize the excitatory effect of CRF on the acoustic startle reflex. To test this, various doses of AVP (3, 30, 300, 3000 pg) were infused ICV on Day 1. On Day 2, 48 hours later, all rats were infused with a dose of CRF (0.25 µg) that usually has no effect on baseline startle. The results showed a non-monotonic excitatory effect of CRF on startle, with the combination of 30 pg AVP/0.25 µg CRF showing a significant increase ($p < 0.05$) over vehicle/vehicle or vehicle/0.25 µg CRF. The time course of the effect was similar to that usually seen when 1 µg of CRF is given ICV.

Taken together, these results show that a single infusion of AVP sensitized the excitatory effect of either AVP or CRF on the acoustic startle reflex, when given 48 hours later. This may provide a model system for analyzing how prior stress leads to enhanced reactions to subsequent stressors and dysregulation of the stress response.

PROXIMAL SEPARATION FROM PUPS REESTABLISHES OXYTOCIN CONTROL OF MATERNAL BEHAVIOR IN EXPERIENCED RAT MOTHERS. C.A. Pedersen*, J.M. Johns, B.M. Faggin, G. Ayers and J.D. Caldwell. BDRC, Dept. of Psychiatry and The Neurobiology Curriculum, School of Medicine, the University of North Carolina at Chapel Hill, Chapel Hill, N.C. 27599.

We previously reported that subjecting primiparous rat dams to proximal separation (PS), a condition in which pups were isolated in a small metal mesh cage within each dam's cage so that the dam could smell, hear and see pups but could not touch them, for 6 days beginning on Day 5 of lactation markedly depleted immunostaining of oxytocin (OT) neural cell bodies in many forebrain sites compared to rat dams subjected to total separation (TS) or no separation (NS) from pups. In recent studies, we found that all rats subjected to 4-6 days of PS (10/10) or NS (10/10), but only 4/11 rats subjected to TS, retrieved in the first 3 hrs after being given free access to pups (Fisher's exact probability, $p < .01$). Infusion of OTA, an OT antagonist, but not normal saline, into the VTA (a site that receives projections from OT neurons located in the forebrain) significantly inhibited the rapid reemergence of retrieval and crouching behavior in dams subjected to PS for 4-6 days. In contrast, infusion of OTA into the VTA had no inhibitory effect on the reemergence of maternal behavior (MB) in rats that were separated from pups for only 1 hr. Additional experiments have established that 4 or more days of PS are necessary to reinstate OT control of MB. Our behavioral pharmacological findings indicate that the depletion of OT immunostaining by PS probably results from an increased rate of OT release. These observations also suggest that, shortly after parturition and the OT dependent onset of MB, either OT control of MB is inhibited and a nonOT control mechanism is activated by some aspect(s) of physical contact with pups (suckling?), or a nonOT mechanism that depends upon physical contact with pups emerges and maintains MB in parallel with the OT mechanism. Supported by HD25255 and MH31327.

POLYMORPHISM AND GENETIC MAPPING OF THE HUMAN OXYTOCIN RECEPTOR GENE ON CHROMOSOME 3.

S. Michelini*, M. Urbanek, M. Dean and D. Goldman.

Laboratory of Neurogenetics, National Institute of Health-National Institute on Alcohol Abuse and Alcoholism, Rockville, Maryland.

Centrally administered oxytocin has been reported to facilitate affiliative and social behaviours. In functional harmony with its well known peripheral effects on uterine contraction and milk ejection. The biological effects of oxytocin could be perturbed by mutations occurring in the sequence of the oxytocin receptor gene, and it would be of interest to establish the position of this gene on the human linkage map. Therefore we identified a polymorphism at the human oxytocin receptor gene. A portion of the 3' untranslated region containing a 30 bp CA repeat was amplified by polymerase chain reaction (PCR) and evaluated by electrophoresis, revealing a polymorphism with two alleles occurring with frequencies of 0.77 and 0.23 in a sample of Caucasian CEPH parents (n=70). The CA repeat polymorphism was detected was used to map the human oxytocin receptor to chromosome 3p25-3p26, in a region which contains several important genes, including loci for Von Hippel-Lindau disease (VHL) and renal cell carcinoma.

THE DISTRIBUTION OF OXYTOCIN RECEPTOR BINDING IN THE BRAIN OF COMMON MARMOSETS. K.K. Moody*, J.D. Newman and T.R. Insel. Lab of Comparative Ethology, NICHD and Lab of Clinical Science, NIMH, NIH, Poolesville, MD 20837.

The neurohypophyseal peptide oxytocin has been implicated in the mediation of several forms of affiliative behavior. Marked species and gender differences have been found in monogamous and polygamous rodents, suggesting that oxytocin may play a role in species-typical patterns of social behavior. Using *in vitro* receptor autoradiography with a selective oxytocin receptor ligand [125 I]d(CH₂)₅[Tyr(Me)₂Tyr-NH⁹]OVT ([125 I]OTA) we examined the brains of a monogamous nonhuman primate, the common marmoset. [125 I]OTA binding sites were apparent in several brain areas including the diagonal band, lateral septum, nucleus accumbens and brain stem. In addition, neonates showed a marked pattern of [125 I]OTA binding in cortical regions which was not apparent in adults. The distribution of [125 I]OTA binding is consistent with those found in several highly affiliative species of rodents and represents the first evidence of oxytocin receptor binding in a monogamous nonhuman primate.

COLOCALIZATION OF OXYTOCIN (OXT) AND C-FOS IMMUNOREACTIVITY IN FEMALE HAMSTER BRAIN. D.C. Whitman* and H.E. Albers. Lab. of Neuroendocrinol. & Behav., Dept. of Biol., Georgia State Univ., Atlanta, Ga. 30303.

Central administration of OXT facilitates the expression of lordosis in rodents. In addition, central administration of an OXT antagonist reduces or eliminates gonadal hormone-stimulated lordosis. Since OXT appears to mimic the effects of progesterone (P) on lordosis, the present study tested the hypothesis that OXT influences lordosis by mediating the effects of P on lordosis. Double immunocytochemical techniques were used to examine whether OXT neurons also exhibit c-fos immunoreactivity (a marker of cellular activity) in the brains of OVX hamsters treated with estradiol benzoate (EB) (unmated), EB+P (unmated) and EB+P (mated). Preliminary analysis indicates that OXT- and c-fos-immunoreactivity were colocalized in the paraventricular and supraoptic nuclei of mated hamsters. C-fos immunoreactivity was not observed in either of the unmated groups. This study was supported by NSF IBN-9222099.

AN ANXIOLYTIC ACTION OF OXYTOCIN IS ENHANCED BY ESTROGEN IN THE MOUSE. M.M. McCarthy* & D. Goldman. Department of Physiology, University of Maryland, Baltimore, MD and Laboratory of Neurogenetics, NIAAA, Rockville, MD.

The neuropeptide oxytocin exerts broad effects on social and affiliative behaviors and has been speculated to exert an anxiolytic action but this hypothesis has not been rigorously tested. In Experiment 1, NIH-Swiss ovariectomized mice were pretreated with 10µg estradiol (E2) in oil or oil alone 48 & 24 hr prior to i.p. injection of either 3mg/kg oxytocin (Sigma) or saline. Forty min later animals were tested for 5 min each on a hole-board apparatus followed by an elevated plus maze using a computerized activity monitor. Data were analysed by 2-way ANOVA and post-hoc Tukey's. A combination of E2+oxytocin significantly increased percent and total time spent on the open arms and the number of entries onto the open arms. The amount of time spent on closed arms was decreased by oxytocin in both E2 and oil-treated females. There was no effect on motor activity or head dips in the hole board apparatus in this experiment. I.P. injection of oxytocin in NIH Swiss males did not significantly alter behavior but baseline levels of activity were comparable to E2-treated females. In Experiment 2, NIH-swiss ovx'd females bearing in-dwelling cannula aimed at the lateral ventricle were pretreated with E2 or oil as before and infused ICV with either oxytocin or vasopressin (8µg in 4µl saline) and behaviorally tested 20 min post-inj. The percent and total time spent on open arms was significantly increased by oxytocin regardless of steroid treatment and the percent and number of entries onto the open arms was increased by the combination of E2+oxytocin over all other groups. The combination of E2+vasopressin significantly decreased the percent time spent on the open arms compared to other groups. This combination in general exerted opposite effects to that of E2+oxytocin. There was an increase in time spent head-dipping in the hole board apparatus in E2-treated females but this was not affected by oxytocin or vasopressin. These findings indicate that oxytocin can act as an anxiolytic and that E2 enhances that effect. Furthermore, E2 may be exerting opposite effects on vasopressin, causing it to act as an anxiogenic. Brains are prepared for receptor autoradiography and results will be reported.

ASTROCYTES IN THE DEVELOPING MACAQUE MONKEY RETINA C. Distler* and M.A. Kirby, Zoology & Neurobiology, Ruhr-University Bochum, 44780 Bochum, FRG and Dept. of Pediatrics & Div. Perinatal Biology, Loma Linda University, Loma Linda CA 92350

In mammals, two types of macroglia are known to exist in the retina, Müller cells and astrocytes. While Müller cells are ubiquitous throughout the retina, astrocytes are only found in vascularized retinae or vascularized retinal regions. It has recently been shown that there is an exception to this rule: in the parafoveal region of the adult macaque monkey retina no astrocytes are found even though this retinal region is heavily vascularized. To test if the parafoveal region is astrocyte-free at all stages of development or if it is secondarily deserted by astrocytes, we investigated the spatial distribution of astrocytes in fetal macaque monkey retinae using GFAP immunocytochemistry. Fetuses were obtained by Caesarian section under aseptic conditions, deeply anesthetized with pentobarbital and perfused through the heart with 3-4% paraformaldehyde. The retinae were dissected free and processed for GFAP immunocytochemistry as whole mounts.

At embryonic day 120 (term gestation is 165 days), i.e. shortly after formation of the foveal pit, a distributional pattern of astrocytes similar to that found in adults is evident. Astrocytes are found at all retinal eccentricities with the exception of the parafoveal region. Fetal astrocytes are small with delicate processes, but already adultlike in their association with axon bundles and blood vessels and their segregation into two subpopulations, one to be found in the ganglion cell layer, the other in the nerve fiber layer. These data together with preliminary observations in even younger fetuses (E90) suggest that the parafoveal region of the monkey retina is avoided by astrocytes prior to the time of foveal pit formation.

Supported by grant Di 391/2-1 of the Deutsche Forschungsgemeinschaft to C. Distler.

SCHWANN CELL EXPRESSION OF CD9 IS REGULATED BY NERVE CRUSH AND SUBSEQUENT REGENERATION. S. A. Banerjee* and P. H. Patterson, Division of Biology, Caltech, Pasadena, CA 91125.

CD9 is a 26 kD cell surface glycoprotein with four transmembrane domains that has been implicated in signaling in platelet activation, and is present in both the peripheral and central nervous systems (PNS and CNS). In the PNS, CD9 is expressed in several neuronal populations and in Schwann cells of the sciatic nerve. CD9 expression follows a developmental time-course in the nerve that closely parallels that of the myelin genes P_0 and myelin basic protein. Here we report the response of CD9 following injury to the nerve.

CD9 and P_0 mRNA levels were analyzed following nerve crush in 30-day old rats. CD9 mRNA drops approximately 10-fold in the nerve distal to the crush, similar to the change in P_0 mRNA. By two weeks following injury, when axons are known to be rapidly regenerating, CD9 and P_0 mRNAs recover to levels slightly higher than those found in the normal adult. By 30 days, levels reach those found in the normal adult. A smaller, but significant response is also observed in the part of the nerve proximal to the crush.

These results suggest that Schwann cell expression of CD9, like P_0 expression, requires the presence of axons. This would also be consistent with our observation that when primary Schwann cells are placed in culture, CD9 immunoreactivity is lost. We are currently investigating the role of axons on CD9 expression in cultured Schwann cells.

REGULATION OF TRANSFORMING GROWTH FACTOR ALPHA ($TGF\alpha$) GENE EXPRESSION IN HYPOTHALAMIC ASTROCYTES BY METABOTROPIC GLUTAMATE RECEPTORS. Y.J. Ma*, F. Rage and S.R. Ojeda, Division of Neuroscience, Oregon Regional Primate Res. Ctr., Beaverton, OR 97006.

Excitatory amino acid (EAA) neurotransmitters influence the initiation of mammalian puberty by stimulating the secretory activity of neurons producing luteinizing hormone releasing hormone (LHRH). Evidence also exists that $TGF\alpha$, a trophic factor of glial origin, contributes to this activation via a paracrine mechanism involving glial production of eicosanoids. The functional relationships that may exist between these two regulatory systems are not known. Since glial cells are endowed with both ionotropic and metabotropic glutamate receptors, we have initiated experiments to determine if glial expression of the $TGF\alpha$ gene is subjected to EAA-mediated regulatory inputs. Purified astrocytes from neonatal rat hypothalamus were exposed to glutamate receptor agonists including glutamate itself, N-methyl-D-aspartate (NMDA) and the metabotropic receptor agonists quisqualate and ACPD (aminocyclopentane-1S,3R-dicarboxylic acid) (100 μ M each). Changes in $TGF\alpha$ mRNA levels were measured by quantitative reverse transcription-polymerase chain reaction at different intervals after initiation of the treatment (15 min-24h). The results showed that both glutamate and metabotropic receptor agonists, but not NMDA, rapidly upregulated $TGF\alpha$ gene expression (within 15 min exposure), with maximal mRNA values being reached between 8-16h. These initial findings suggest that hypothalamic astrocytes are targets for EAA acting via metabotropic receptors, and that EAA may represent one of the neuronal signals involved in the control of glial expression of the $TGF\alpha$ gene during development. Supported by NIH Grants HD25123, HD18185 and RR00163.

CHANGES IN RPTP- β EXPRESSION DURING GLIAL CELL DIFFERENTIATION. P.D. Canoll, S. Petanceska, G. Barnea, J. Schlessinger, J.M. Musacchio* Dept. of Pharmacology, N.Y.U. Medical Center, New York, NY 10016.

RPTP- β is a receptor type tyrosine phosphatase that is expressed in glia and glial progenitors (Canoll et al., Dev Brain Res 75:293, 1993). Nucleotide probes to RPTP- β hybridize to three major transcripts on northern blot analysis. Two of the transcripts (9.5 kb and 6.4 kb) encode transmembrane glycoproteins which contain a carbonic anhydrase related domain in the extracellular portion and tandem phosphatase domains in the intracellular portion. The third transcript (8.4 kb) encodes a secreted chondroitin sulfate proteoglycan which contains the extracellular portion of RPTP- β , but does not contain the intracellular phosphatase domains (Maurel et al. PNAS 91:2512, 1994). In situ hybridization and northern analysis show that the relative abundance of the 3 transcripts changes during brain development. During postnatal development, the 9.5 and 6.4 kb transcripts (transmembrane forms) are predominantly expressed in glial progenitors located in the proliferative subventricular zone, whereas high levels of the 8.4 transcript (secreted form) are seen in differentiated glia that have migrated out of the subventricular zone. A similar transition in expression can be induced by treating cultured glial cells with the differentiating agent dibutyryl cAMP. The different forms of RPTP- β have very different structure, and most likely perform different functions. The shift in the relative abundance seen during glial cell differentiation may relate to important changes in the role glial cells play during brain development and regeneration.

Human Fetal Spinal Cord Slice Cultures: A Model for the Study of Neurodevelopment and Neuropathology.

W.E. Grever*, K.M. Weidenheim and W.D. Lyman, Department of Pathology, Albert Einstein College of Medicine, Bronx, New York, 10461.

Human fetal spinal cords are obtained from abortions that range in age from 20 to 24 weeks of gestation. Spinal cords are stripped of meninges and cut into 800 μ m transverse sections. The slices are cultured on collagen-coated tissue culture inserts in chemically-defined media. Slice cultures have been grown for up to 28 days under these conditions. Histological and immunocytochemical examination of the cultures reveal the presence of neurons, oligodendrocytes, microglia, astrocytes, ependyma and endothelial cells. Indirect immunofluorescent confocal microscopy shows intact myelin basic protein-positive sheaths around neurofilament-positive axons. These myelinated axons can be observed by summation of optical sections and span over 60 μ m. Additional evidence of active myelination during the culture period is observed by light and electron microscopy. Some axons contain mitochondria with distinct cristae and are surrounded by large inner loops of a myelinating oligodendrocyte process. Inner loops are found inside layers of compacted myelin. After one week in culture, the slices are surrounded by an outgrowth of cells. The outgrowth area contains microglia, astrocytes, and oligodendrocytes as determined by morphology and immunocytochemical labeling. This culture system provides a unique model to study the development of the human central nervous system and neuropathologic changes that result from exposure to inflammatory cytokines, infectious agents such as HIV, drugs of abuse, or physical damage.

442.6

IMMUNOGENICITY OF SCHWANN CELL POPULATED ACCELLULAR BASAL LAMINA NERVE GRAFTS. D.R. Rai, D.W. Slickes* and A.K. Gulati, Department of Cellular Biology and Anatomy, Medical College of Georgia, Augusta, GA 30912.

Accellular basal lamina (BL) allografts are known to exhibit reduced immunogenicity. It is also known, that the extent of host axonal regeneration through accellular BL grafts is reduced in comparison to cellular grafts. In the present study, isogenic (genetically identical) and allogeneic (genetically different) Schwann cell populated accellular BL grafts were transplanted into host rats to define their immunogenicity. Inbred strains of Fischer (FR) and Buffalo (BF) rats were used. Accellular BL grafts were prepared, by freeze-thawing (5x), 6-week predegenerated FR rat nerve. Accellular BL nerves were placed in dishes with cultured Schwann cells established from FR or BF rat nerves. After 7 days, 2 cm long Schwann cell cocultured nerves were transplanted in a surgically created gap in the FR host peroneal nerve. Transplanted nerves were analyzed at 1, 2, 4 and 8 weeks later to determine their immunological fate and axonal regeneration through them with light microscopy. Accellular BL grafts populated with isogenic FR Schwann cells survived and were supportive of host axonal regeneration through them. On the other hand, accellular BL grafts with allogeneic BF Schwann cells underwent rejection and were unsuccessful. The results indicate that cultured Schwann cells continue to exhibit immunogenicity. Thus, it is important to employ host matched (isogenic) Schwann cells to populate accellular BL grafts in attempts to enhance their axonal growth supporting function. (Supported by NIH Grant NS-24834).

DEVELOPMENTAL AND GROWTH FACTOR-INDUCED REGULATION OF THE NEURAL STEM CELL MARKER NESTIN IN OLIGODENDROCYTE LINEAGE CELLS. V. Gallo and R. C. Armstrong* Lab. of Cell. Mol. Neurophysiol., NICHD, NIH, Bethesda, MD 20892 and Dept. Anat. Cell Biol., USUHS, Bethesda, MD 20814.

The expression and regulation of the neural stem cell marker nestin was studied in cells of the oligodendrocyte lineage. Glial cells from late embryonic rat cerebral cortex, tissue prints from neonatal brains and the oligodendrocyte cell line CG4 were used. In both culture systems, nestin mRNA was highly expressed in proliferating O-2A progenitors, but down-regulated in differentiated oligodendrocytes. Immunocytochemistry of cultured cells and tissue prints, demonstrated that O-2A progenitors express high levels of the nestin protein. In addition, rapidly dividing pre-O-2A cells, which were not labeled with anti-GD3 antibody, expressed nestin. In contrast, the majority of O4⁺-pro-oligodendroblasts and O1⁺-oligodendrocytes were not labeled with anti-nestin antibodies. In cortical astrocyte cultures, type-1 astrocytes, but not type-2, expressed nestin mRNA and protein. Culture conditions which prevented O-2A progenitors from differentiating (PDGF+bFGF or B104-conditioned medium), upregulated nestin at the mRNA and protein levels. These results demonstrate PDGF, bFGF and B104-secreted mitogens up-regulate expression of nestin in O-2A progenitors, which is indicative of a proliferative state.

442.9

MICROGLIAL REACTIONS TO FOCAL RETINAL INJURY IN THE RABBIT. M.F. Humphrey* and S. Moore. WA Retinitis Pigmentosa Research Centre, Lions Eye Institute, Perth, Western Australia 6009.

As preliminary experiments to examine the role of microglia in retinal injury reactions, the microglia were labelled using nucleoside diphosphatase (NDP-ase) histochemistry following argon laser photocoagulation lesions in the peripheral rabbit retina. At 2, 6, 24 and 48hrs, and 7, 14 and 21 days after moderate photocoagulation lesions (argon green laser at 300-400mW for 0.2sec, 200µm diameter) in pigmented rabbits, animals were anaesthetised, perfused and the retinas immersion fixed in 4% paraformaldehyde containing 8% sucrose and 5% DMSO. The next day the retinas were processed for NDP-ase activity, using cytidine diphosphate as a substrate, wholemounts and analysed. Normal retinas had microglia in the nerve fiber layer (NFL) the inner plexiform layer (IPL) and outer plexiform layer (OPL). The distributions were similar to those previously reported (Schnitzer, J. Comp. Neurol., 282, 1990, p779). Following lesioning the IPL microglia had processes pointing into the lesion by 2hrs and had migrated to leave a vacant zone around the lesion by 6hrs, this vacant zone was gradually filled by 7 days. The NFL microglia did not react until 7 days when they became aligned with degenerating axons between the lesion and optic disc. By 14 days these cells were no longer reactive but reactive cells were now found extending from the lesion to the periphery and by 21 days the reaction was largely over. The OPL contained increased numbers of microglia from 6hrs after lesion until 14 days but by 21 days the levels were reduced again. Thus, the microglia in each layer of the retina reacted in different ways reflecting the injury response of the other cells in each layer.

I_{HA} IN CULTURED RAT ASTROCYTES. D. Janigro^{††}, D.L. Tinklepaugh[†], L.G. Costa[†] and H.R. Winn^{††}. Depts. of Neurosurgery[†] and Environmental Health^{††}, University of Washington, Seattle, WA 98104

Hyperpolarization-activated, cesium-sensitive Na⁺/K⁺ currents play an important role in the regulation of neuronal excitability. However, these ionic currents (named I_h or I_q) are not expressed only in excitable cells. We have recently described a similar ionic current (I_{HA}) in non-excitable brain microvascular endothelial cells (*Neurosci. Abstr.* 19, 692, 1993). We here describe a hyperpolarization-activated current recorded under voltage clamp from cultured rat astrocytes after wash out of inward potassium currents with 0.2 mM GTP-γ-S. Astrocytes were obtained from purified glial cultures obtained from E21 rats and were visually identified as non-OX 42 positive cells. In astrocytes, I_{HA} was activated at around -55 mV and had a reversal potential of -25 mV under physiological ionic conditions. I_{HA} conductance was greatly increased by increases of [K⁺]_o from 5 to 15-30 mM. In addition, the current was blocked by extracellular (5 mM) but not intracellularly applied (140 mM) Cs⁺. The whole cell current was decreased by acetyl-β-methyl choline or carbachol (0.1-1 mM) and these effects were prevented by atropine. Our results suggest that non-excitable CNS cells express a hyperpolarization-activated current previously associated with the regulation of neuronal firing and resting potential. Due to its ionic nature, sensitivity to [K⁺]_o and strategically important expression in both endothelial and glial cells, I_{HA} may play a role in the regulation of Na/K homeostasis in the brain. Supported by NS 51614, NS30305, NS21076, NS07144 and AA08154.

INTRACELLULAR CALCIUM REGULATION IN ASTROCYTES IN ADULT RAT SPINAL CORD PREPARATIONS. E. Theriault^{*,1,2}, M.G. Fehlings², S. Agrawal² and L.R. Mills². The Toronto Hospital Arthritis Centre¹ and Playfair Neuroscience Unit², University of Toronto, Toronto, Ontario CANADA, M5T 2S8.

We have previously described the presence of a metabotropic glutamate receptor subtype (mGluR1) on a subpopulation of astrocytes in the rat spinal cord (Theriault et al., '93a,b). The subcellular location of these astrocytes is correlated with the characteristic region of tissue survival following traumatic spinal cord injuries (Theriault, '93), and our electrophysiological studies demonstrate a neuroprotective effect of mGluR activation following *in vivo* and *in vitro* clip compression injuries (Theriault et al., in prep.). To determine the mechanism(s) underlying the neuroprotection, we have developed an *in vitro* preparation of the spinal cord. Adult female Wistar rats (n=5, 280-300 gms) were anaesthetized, a thoracic laminectomy performed and a 20mm by 400 µm strip of the dorsal columns was removed. The isolated strip was secured in a chamber and incubated in 95-5% oxygenated Ringers with Fluoro-3/AM. Using confocal microscopy we have examined changes in intracellular calcium [Ca²⁺]_i levels of spinal cord astrocytes in response to K⁺, bromo-A23187, and trans-ACPD. Rest levels of fluorescence in spinal cord astrocytes were increased two-fold following application of 100 mM K⁺, and five-fold after ionophore. Interestingly, preliminary experiments with 100 µM trans-ACPD in *uninjured cords* revealed no detectable changes in [Ca²⁺]_i levels. Ongoing studies are examining [Ca²⁺]_i regulation in clip compression-injured spinal cord preparations.

INVERTEBRATE LEARNING AND BEHAVIOR IV

443.1

EFFECTS OF apNPY ON BEHAVIOR IN *APLYSIA*.

Valerie L. Begnoche, Samuel K. Moore and Earl Mayeri* Dept. of Physiology, University of California, San Francisco, CA 94143-0444 USA.

Aplysia neuropeptide Y (apNPY) is a 40 amino acid peptide that is homologous to NPY in vertebrates. Immunoreactivity for apNPY is widespread in the neuropile of all central ganglia, suggesting that the peptide may have many roles. In the eye, stained neurons may correspond to circadian pacemaker neurons.

To explore a possible role for the peptide in control of circadian rhythms, we did a behavioral study in which animals were kept in constant darkness for 21 days, and then injected with the peptide 3 times a day for 11 days. We found that apNPY was capable of phase-shifting the endogenous rhythm of locomotor activity. In another experiment, eyes were removed from animals that had been kept in a 24 hr light-dark cycle for 4 days. In the days following eye removal, the animals were kept in constant darkness and apNPY was injected each day at projected dawn. We found that injection of the peptide each day was followed by increased locomotion for several hours, but that this effect wore off after several days. These initial behavioral results are consistent with a role for apNPY in imposing a circadian rhythm of behavior, but more work will be needed before a firm relationship is established. Lastly, injection of apNPY causes an increase in the rate of spontaneous respiratory pumping that lasts for one hour. This suggests that apNPY may have a role in other behavioral processes as well.

443.2

HOMOSYNAPTIC LTP AND PTP OF SENSORIMOTOR SYNAPSES MEDIATING THE TAIL WITHDRAWAL REFLEX IN *APLYSIA* ARE REDUCED BY POSTSYNAPTIC HYPERPOLARIZATION. M. Cui* and E.T. Walters. Dept. of Physiology & Cell Biology, University of Texas Medical School at Houston, TX. 77225.

Tetanization of nociceptive tail sensory neurons (TSNs) causes LTP of monosynaptic connections to tail motor neurons (TMNs) lasting > 90 min in isolated ganglia (Walters & Byrne, *JNeurosci* 5:662, 1985). It was not known if this potentiation was produced homo- or heterosynaptically, but Lin & Glanzman (*ProcRSocLondB*, 255:113, 1994) recently showed clear homosynaptic LTP of sensorimotor synapses in dissociated cell culture. The LTP in culture was blocked by postsynaptic hyperpolarization during tetanization. As a first step in determining mechanisms and functions of homosynaptic LTP in defensive circuits, we have examined the dependence of TSN-TMN potentiation upon TMN membrane potential in whole ganglia. After 2 baseline tests, half the TSNs were tetanized (10 x 0.4 ms trains, 25 Hz each) with the TMN at normal resting potential. The other TSNs received identical tetanization, except that the TMN was hyperpolarized to -120 mV during the tetanus. EPSPs were then tested at 5 min intervals for at least 25 min afterwards. As predicted, LTP in the ganglia was significantly reduced by TMN hyperpolarization during the tetanus (120% of baseline vs 70% of baseline at 25 min; t_g=3.77, p<0.05). Interestingly, PTP observed 1 min after tetanization was also reduced by TMN hyperpolarization (387% vs 242%; t_g=3.04 p<0.05). Observations of homosynaptic LTP in nociceptive synapses of *Aplysia* and rat (Randic et al., *JNeurosci* 13:5228, 1993) suggest that LTP (perhaps NMDA receptor-mediated) might be a primitive mechanism for storing memory of injury.

443.3

TEMPORAL SPECIFICITY OF HEBBIAN LONG-TERM POTENTIATION OF *APLYSIA* SENSORIMOTOR SYNAPSES IN CELL CULTURE. X.-Y. Lin and D. L. Glanzman*. Dept. of Physiological Sci., UCLA, Los Angeles, CA 90024.

Long-term potentiation (LTP) of in vitro *Aplysia* sensorimotor synapses can be induced by pairing brief stimulation of the presynaptic sensory neuron with strong depolarization of the postsynaptic motor neuron (Lin & Glanzman, *Proc. R. Soc. Lond. B* 255:215-221, 1994). This pattern of neuronal activity resembles that which occurs during classical conditioning of the *Aplysia* withdrawal reflex (Carew et al., 1981, 1983). Specifically, presentation of the CS (weak stimulation of the siphon) and US (tail shock) yields brief sensory neuron activation together with strong motor neuron depolarization (Frost et al., 1988). Classical conditioning of the withdrawal reflex might therefore be mediated in part by Hebbian potentiation of sensorimotor synapses. However, Lin and Glanzman (1994) used simultaneous pre- and postsynaptic stimulation to induce Hebbian LTP, whereas during behavioral conditioning the onset of the CS occurred 0.5 sec before the onset of the US.

We have systematically varied the interval between sensory neuron stimulation and motor neuron depolarization to investigate whether the induction of Hebbian LTP of in vitro sensorimotor synapses exhibits temporal specificity. The interval between pre- and postsynaptic stimulation was varied from -5.0 sec (the onset of motor neuron depolarization preceded the onset of sensory neuron stimulation by 5.0 sec) to +5.0 sec (the onset of sensory neuron stimulation preceded the onset of motor neuron depolarization by 5.0 sec). We find that an interstimulus interval of +0.5 sec produces significant LTP of sensorimotor synapses. But the temporal specificity of Hebbian LTP for these synapses does not match that reported for the CS-US interval in conditioning of the reflex (Hawkins et al., 1986). Therefore, although Hebbian modulation of sensorimotor synapses may contribute to classical conditioning (see Murphy & Glanzman, 1994), other cellular mechanisms must also be involved.

443.5

REGULATION OF UBIQUITIN-MEDIATED PROTEIN DEGRADATION DURING DEVELOPMENT OF LONG-TERM FACILITATION IN *APLYSIA* SENSORY NEURONS. A.N. Hegde*, K. Inokuchi, N. Yamamoto, D.G. Chain, E.R. Kandel and J.H. Schwartz. Center for Neurobiology & Behavior and Howard Hughes Medical Institute, Columbia University College of Physicians & Surgeons, New York, NY, 10032.

Persistent activation of the cAMP-dependent protein kinase (PKA), which occurs during the development of long-term presynaptic facilitation of the sensory-to-motor neuron synapses underlying the defensive reflexes, results from proteolysis of dissociated regulatory (R) subunits. Persistence of kinase activity, which requires new protein synthesis, lasts for at least 24 h. Hegde et al. (*PNAS* 90:7436) presented evidence that this proteolysis is mediated by the ATP-ubiquitin-proteasome pathway. Using a variety of subcellular fractionation and immunohistochemical techniques, we find that both ubiquitin and the proteasome complex are abundant in all parts of the neuron: cell body, axons and terminals. We presume that the degradation of R subunits is regulated by induction of some new proteins. Consistent with this idea, we find that one of the immediate early genes induced by 5-HT encodes a 29,000-molecular-weight protein with similarity to L1-type vertebrate ubiquitin C-terminal hydrolases (UCH). Peptide antibodies against the predicted sequence encoded by the *Aplysia* mRNA recognize an Mr 29,000 protein, which, like vertebrate L1, is expressed only in nervous tissue. Low molecular-weight UCHs are believed to process polyubiquitin precursors to monoubiquitin. Nonetheless, we find this *Aplysia* UCH-immunoreactivity to be associated with proteasomes. Eytan et al. (*JBC* 268:4668) showed that high molecular-weight UCHs are associated with proteasomes and postulated that the multiubiquitin chains cleaved from degraded proteins clog the complex, thereby slowing degradation. It is attractive to think that the low molecular-weight UCH (which we also find to be associated with proteasomes in rat brain) also can enhance degradation. We are also looking for the induction of other proteins that might regulate R subunit degradation during the development of long-term memory.

443.7

EARLY STEPS IN LEARNING-RELATED SYNAPTIC GROWTH: 5-HT INDUCES INTERNALIZATION OF THE TRANSMEMBRANE BUT NOT THE GPI-LINKED ISOFORM OF apCAM IN *APLYSIA* SENSORY NEURONS. C.H. Bailey*, B.-K. Kaang, M. Chen, and E.R. Kandel. Ctr. Neurobiol. & Behav., Columbia Univ., HHMI, NY, NY 10032, & Inst. Mol. Biol. & Genetics, Seoul Natl. Univ., Korea.

The synaptic growth that accompanies 5-HT-induced long-term facilitation of the sensory-to-motor connection in dissociated cell culture is associated with a down-regulation of cell adhesion molecules (apCAMs) on the surface membrane of the sensory neuron (Mayford et al., 1992). Down-regulation is achieved by activation of the endosomal pathway leading to internalization and apparent degradation of apCAM (Bailey et al., 1992). Which of the two types of isoforms is internalized, the transmembrane (TM) or the phosphoinositol-linked? To address this question, we selectively expressed epitope-tagged constructs of the two isoforms in cultured sensory neurons. By combining thin section EM with gold-conjugated Ab we have found 5-HT leads to a 68% decrease in the density of gold-labeled complexes bound to the TM form at the surface membrane ($8.7/\mu\text{m} \pm 0.5$, $n = 8$, vs. Control $27.7/\mu\text{m} \pm 2.9$, $n = 7$, $p < 0.001$) and to a 24-fold increase in their internalization (53 ± 4.4 vs. 2.2 ± 0.7 , $p < 0.001$). By contrast, 5-HT has no effect on either the surface distribution ($26.8/\mu\text{m} \pm 1.8$, $n = 7$ vs. 25.6 ± 2.4 , $n = 6$) or internalization (1.7 ± 0.5 vs. 2.2 ± 0.9) of the GPI-linked isoform. The selective internalization of the TM form highlights the potential regulatory significance of its intracellular domain, which contains a PEST sequence (thought to target degradation) and has two consensus sites for MAP kinase phosphorylation (Michael and Kandel, 1994). The availability of TM constructs with deletions of, or mutations in, the cytoplasmic tail should now allow us to determine which part of this molecule triggers internalization and which part targets degradation.

443.4

INFUSION OF BAPTA INTO POSTSYNAPTIC SIPHON MOTOR NEURONS BLOCKS THE CELLULAR ANALOGUE OF CLASSICAL CONDITIONING IN *APLYSIA*. G.G. Murphy* and D.L. Glanzman. Interdepartmental Program for Neurosci. and Dept. of Physiological Sci., UCLA, Los Angeles, CA 90024.

Classical conditioning of the *Aplysia* siphon withdrawal reflex (Carew et al., 1981, 1983) is thought to be due to a presynaptic mechanism—activity-dependent presynaptic facilitation of sensorimotor connections (Hawkins et al., 1983; Walters & Byrne, 1983). Recent work on sensorimotor synapses in cell culture (Lin & Glanzman, *Proc. R. Soc. Lond. B* 255:215-221, 1994), however, provides another cellular mechanism for classical conditioning—Hebbian potentiation of sensorimotor connections. Lin and Glanzman's data indicate that Hebbian LTP of these connections is mediated by activation of NMDA-related receptors and requires the postsynaptic elevation of intracellular Ca^{2+} because it can be blocked by APV or by infusing the motor neuron with BAPTA, a specific chelator of intracellular Ca^{2+} .

To determine whether the cellular mechanism of classical conditioning in *Aplysia* also involves elevation of intracellular Ca^{2+} in the motor neurons, we carried out experiments on preparations consisting of the CNS of *Aplysia* together with the posterior pedal nerves, which innervate the animal's tail. We examined changes in the strength of siphon sensorimotor connections following an analogue of classical conditioning training like that used by Hawkins et al. (1983). Preparations which received paired sensory neuron activation (CS) and pedal nerve shock (US) exhibited significant enhancement of monosynaptic sensorimotor EPSPs 60 min after the last US compared to preparations which received only the test stimuli alone (Test Alone) ($p < 0.03$, Mann-Whitney *U* test). By contrast, the size of the monosynaptic EPSPs in preparations which also received CS+ training, but which had BAPTA (50 mM) infused into the motor neuron, were not significantly different from those of EPSPs in Test Alone preparations at the 60-min posttest ($p > 0.9$). These results implicate a postsynaptic, possibly Hebbian, mechanism in classical conditioning in *Aplysia*.

443.6

POSTSYNAPTIC MODIFICATIONS IN LONG-TERM FACILITATION IN *APLYSIA*: UP-REGULATION OF EXCITATORY AMINO ACID RESPONSES. L.-E. Trudeau* and V.F. Castellucci. Lab. of Neurobiology and Behavior, IRCM, Univ. de Montréal, Montréal, Québec, H2W 1R7.

Long-term sensitization of the gill and siphon withdrawal in *Aplysia* is accompanied by facilitation of sensory-motor synaptic connections in the abdominal ganglion which depends on new protein synthesis. This phenomenon has been previously shown to involve presynaptic growth and an increase in transmitter release without any change in the size of miniature EPSPs. At the postsynaptic level, a reorganization should occur to parallel the formation of new synaptic contacts. We show here that 24h following an application of 5-HT which produces long-term synaptic facilitation (LTF), the response of the motoneuron to an excitatory amino acid agonist of the synaptic receptors is increased (day2/day1 = $+60.4 \pm 11.9\%$, $n=9$). Inhibition of protein synthesis in the whole ganglion using anisomycin or limited to the postsynaptic neuron by injection of gelonin, a ribosome-inactivating toxin, blocks this enhancement ($-12.5 \pm 19.2\%$, $n=5$, and $-21.5 \pm 4.4\%$, $n=6$). The postsynaptic inhibition of protein synthesis however fails to block 24h LTF. Although these results show that 24h LTF is independent of postsynaptic protein synthesis, the data are still compatible with a model of LTF that involves coordinate pre- and postsynaptic changes. The latter alterations may be initially independent of protein synthesis, but may gradually become dependent on transcription for stages of LTF lasting more than 24h. An increase in the number of functional postsynaptic receptors in a reserve pool may also prime the postsynaptic neuron for subsequent learning-associated plasticity. TAIL SHOCK DIFFERENTIALLY MODULATES TWO FORMS OF SYNAPTIC PLASTICITY IN INHIBITORY INTERNEURON L30 OF *APLYSIA*. T.M. Fischer*¹ and T.J. Carew^{1,2}. Yale University, Departments of Psychology¹ and Biology², New Haven, CT 06520.

In the siphon withdrawal network of *Aplysia*, activation of the L30 inhibitory interneurons, either directly or by mild tail stimulation, produces significant inhibition which is mediated through post-tetanic potentiation (PTP) of the L30 IPSP (Fischer and Carew 1993a,b). In the present study we describe the suppression of PTP in L30 by a modulatory stimulus, tail shock.

Synaptic transmission from L30 was measured as inhibitory post-synaptic currents (IPSCs) in L29 excitatory interneurons (voltage clamped at -85 mV). Following a baseline measurement, L30 was directly activated for 5 sec (8 to 12 Hz) to potentiate the synapse. Two forms of L30 activity-induced plasticity were examined: (1) frequency facilitation (FF), the enhancement of the L30 IPSC during intracellular activation (measured as the mean of the last 5 evoked IPSCs in the train); and (2) post-tetanic potentiation (PTP), the additional enhancement of the IPSC following activation (measured 20 sec after the train). Prior to tail shock, the largest increase in the L30 IPSC occurred 20 sec following activation: PTP was three times greater than FF ($p < 0.05$, $N = 6$). 90 sec following tail shock, the baseline IPSC was significantly reduced ($p < 0.05$, $N = 5$; also see Frost et al., 1988), yet the IPSC still exhibited significant FF ($p < 0.05$; compared to baseline) that was not significantly different from pre-shock FF values ($p = 0.22$). However, no significant enhancement of the IPSC was observed following activation: there was no difference between FF and PTP ($p = 0.41$). Tail shock thus appears to selectively suppress one form of plasticity, potentiation of the L30 IPSC following activation (PTP), while sparing another form (FF). Additional data indicate that tail-shock suppression of PTP may last at least 40 min. We are currently examining the cellular mechanisms of this suppression, as well as its functional consequences (see Blazis et al., this volume).

443.9

HOMOSYNAPTIC DEPRESSION IN TAIL SENSORY NEURONS IS NOT THE MECHANISM OF HABITUATION OF TAIL-INDUCED TAIL OR SIPHON WITHDRAWAL IN APLYSIA. M. Stopfer* and T.J. Carew. Departments of Psychology and Biology, Yale University, New Haven, CT. 06520

Homosynaptic depression of sensory neuron (SN) output is considered a primary cellular mechanism of habituation in several systems. We have examined the contribution of homosynaptic depression in tail SNs to habituation of two tail-induced reflexes in *Aplysia*: (1) tail withdrawal, which has both direct and indirect SN input to tail motor neurons (MNs); and (2) siphon withdrawal, which has only indirect SN input to siphon MNs. In behavioral experiments, repetitive, mild tail stimulation (30s ISI) significantly habituated both tail and siphon reflexes ($p < 0.001$ in each case). In parallel cellular experiments, the same repetitive stimuli induced progressively fewer action potentials in both tail and siphon MNs ($p < 0.001$ in each case).

When tail SNs were repeatedly activated (30s ISI) with intracellular pulses, significant homosynaptic depression of the monosynaptic EPSP onto tail MNs was exhibited ($p < 0.001$); depression did not generalize to other, non-activated SNs connected to the same MN. However, when the same SN EPSP was examined during behavioral training that caused significant reflex habituation ($p < 0.001$), SNs activated by tail stimulation showed significant facilitation of their output to tail MNs (\bar{x} EPSP increase = 463%, $p < 0.02$). SNs not activated by tail stimulation also showed significantly facilitated EPSPs (\bar{x} EPSP increase = 385%, $p < 0.05$), indicating that SN facilitation was heterosynaptic.

In summary, by using behaviorally relevant stimuli and simultaneously measuring reflex behavior, MN output, and SN output we found that, while the behavioral responses and MN output significantly decreased during habituation, SN output significantly increased. We are currently exploring whether: (1) increased SN output onto inhibitory interneurons; and (2) increased inhibition and/or homosynaptic depression at interneuronal sites contribute to habituation in these reflex systems.

443.11

ARE LEARNED BIASES IN APLYSIA HEAD-WAVING BEHAVIOR DUE TO ASSOCIATIVE OR NONASSOCIATIVE MECHANISMS? J. Chey, P. Cisek, P. Gaudiano*, R. Wood. Boston University, Dept. of Cognitive and Neural Systems, Boston, MA 02215.

A long term bias in the exploratory head-waving behavior of *Aplysia* can be induced using flashed lights as an aversive stimulus (Cook and Carew, 1986, 1989). Coupling onset of the lights with a particular direction of head movement results in a bias away from that direction. This bias has been interpreted as a form of operant conditioning, and has been simulated with a neural network model based on associative synaptic facilitation (Raymond *et al.*, 1992). We simulate the head-waving behavior using a recurrent gated dipole, a nonlinear dynamical neural model previously used to explain various data including oscillatory behavior in biological pacemakers. In our model two recurrent neural circuits inhibit each other to generate oscillations, which drive the side-to-side head-waving. Within each channel the frequency and amplitude of oscillations depend on transmitter mobilization dynamics, which exhibit both short- and long-term adaptation. We assume that light onset results in an increase in nonspecific arousal to both sides of the dipole. Repeated pairing of arousal increments with activation of one side (the "paired" side) of the dipole leads to a bias in transmitter dynamics, which causes the oscillation to last a shorter time on the paired side than on the unpaired side. This model provides a parsimonious explanation of the observed behavior, and it avoids some of the unexpected results obtained with the Raymond *et al.* model. In addition, our model makes predictions concerning the rate of onset and extinction of the biases, and suggests new lines of experimentation to test the nature of the head-waving behavior.

DISTINCT COMPONENT OF PRESYNAPTIC CALCIUM CURRENT IS INCREASED BY CYCLIC AMP AT APLYSIA SENSORIMOTOR SYNAPSES IN CULTURE. M. Klein*, Lab. of Neurobiology & Behavior, Clinical Research Inst. of Montreal & Univ. of Montreal, Montreal, Quebec H2W 1R7, Canada.

Synaptic augmentation of transmitter release by serotonin (5HT) at *Aplysia* sensorimotor synapses can be mimicked by activation of adenylyl cyclase and is blocked by inhibiting cyclic AMP-dependent protein kinase. Two components of calcium current have previously been identified in *Aplysia* sensory neurons, a slowly-inactivating current that is enhanced by 5HT and blocked by dihydropyridines and a rapidly-inactivating current that is reduced by FMRFamide; of the two, only the rapidly-inactivating component appears to participate in transmitter release caused by single action potentials under most conditions. Chlorophenylthio-cyclic AMP augments synaptic currents at sensorimotor synapses in culture and also causes an increase in a slowly-inactivating calcium current in the sensory neurons. However, this latter current differs from the major current modulated by 5HT in that it is not affected by dihydropyridine antagonists, and, unlike the current described earlier, is not blocked by H7, an inhibitor of protein kinase C in these neurons. The current modulated by the cyclic AMP analog is also not affected by FMRFamide. These findings thus raise the question of whether an increase in a cyclic-AMP-sensitive calcium current may contribute to the enhancement of transmitter release that occurs during synaptic augmentation by 5HT.

PLASTICITY OF LE AND NON-LE SIPHON SENSORY NEURONS DURING HABITUATION AND DISHABITUATION OF THE APLYSIA GILL-WITHDRAWAL REFLEX. S.W. Kaplan*, E.R. Kandel, and R.D. Hawkins. Ctr. Neurobiol. & Behav., Columbia Univ., HHMI, NY, NY 10032

We have developed a simplified preparation, consisting of the isolated mantle organs of *Aplysia*, that undergoes habituation, dishabituation, sensitization, and classical conditioning of the gill-withdrawal reflex. We previously found that the LE siphon sensory neurons contribute to the reflex elicited by controlled force stimulation of the siphon. However, a weak water movement stimulus that can produce PSPs in motor neurons and withdrawal of the gill does not cause the LE cells to fire, suggesting that other, unidentified sensory neurons can also contribute to the reflex (Cohen *et al.*, 1991). To compare plasticity of PSPs from the LE and non-LE sensory neurons we stimulated the siphon with either a controlled force tap or weak water movement and measured the complex PSP in a gill motor neuron. The ganglion was perfused with $hi\ Ca^{2+}$, $hi\ Mg^{2+}$ ASW, which blocks most of the polysynaptic component of the PSP. With the controlled force tap there was a decrease in the remaining monosynaptic component during habituation, and an increase 2.5 min after shock during dishabituation. With the weak water movement stimulus, the results were very similar. Furthermore, like the PSP from LE sensory cells, the PSP produced by the weak water movement stimulus was facilitated when the ganglion was perfused with serotonin, which mediates some of the effects of the shock during dishabituation. These results suggest that PSPs from the LE sensory neurons and the unidentified sensory neurons have basically similar plasticity during habituation and dishabituation of the reflex.

LEARNING AND MEMORY: SYSTEMS AND FUNCTIONS VIII

444.1

NEURONS IN RHESUS MONKEY VENTRAL STRIATUM SHOW RESPONSE CHANGES RELATED TO ASSOCIATIVE LEARNING. M. Shidara*, T.G. Aigner & B.J. Richmond. Lab. of Neuropsychology, NIMH, Bethesda, MD 20892.

The ventral striatum is considered to have a role in motivation. Neurons in the ventral striatum respond during a task in which monkeys earn water reward by releasing their grip on a bar when a visual target changes color. The number of correct trials required to get a reward was randomly varied from 1 to 3. A cue located above the target signaled progress toward obtaining a reward, with the brightest cue indicating that a reward was forthcoming if the current trial were completed successfully (brightening paradigm). The mean reaction time to bar release decreased as the cue brightness approached the level that signaled reward, suggesting that the monkey was more motivated. When we randomized the sequence so that cue brightness lost its meaning (random paradigm), the mean reaction time was always near the shortest value.

Some ventral striatal neurons responded when the cue brightness changed, some when target changed color, and others when the reward was delivered in the brightening paradigm. About one-third of the neurons showed significantly different firing frequencies after the cue brightness lost its meaning. Some neurons responded most vigorously to the cue brightness for the rewarded trial in the brightening paradigm and decreased their firing in the random paradigm. Others responded most vigorously for the non-rewarded trial in the brightening paradigm and also decreased their firing in the random paradigm. These changes in firing frequency paralleled the changes in reaction times, suggesting that the firing frequencies of these neurons are closely related to the current meaning of the cue, i.e., they show effects related to associative learning.

EVIDENCE FOR DIFFERENT FORMS OF MEMORY RETENTION IN MACAQUES FOR TASKS REQUIRING JUDGEMENT FOR RECENCY COMPARED WITH FAMILIARITY. J.L. Ringo* and Mark D. Diltz. Department of Physiology, University of Rochester School of Medicine.

When a single pair of images is repeatedly re-used in a delayed matching to sample task, the subject must choose on the basis of recency. When trial-unique images are used, the subject may use simple familiarity. The mechanisms mediating these kinds of memory were investigated by disruption confined to the retention period.

Disruption was provided by 1-sec of electrical stimulation to the medial temporal lobe in the middle of the delay period. Sessions with repeated images and sessions with trial-unique images were interleaved. Delays of 4, 8, 16 and 32 sec were used. The duration of the sample image presentation was varied in order to approximately equalize performances (shorter sample durations for trial-unique than for repeated images, and shorter sample durations for shorter delays). Control performances, without stimulation, were roughly 80-85% correct.

The same levels of electrical stimulation delivered to the same electrodes in the same monkeys produced significantly ($P < 0.01$) more disruption when delivered during testing with repeated images than testing with trial-unique images. Compared to interleaved trial without stimulation, electrical stimulation caused a 15% reduction of performance with repeated images. A smaller but still significant 7% reduction of performance was found with trial-unique images. These effects were seen at all delays. Built in controls indicate that the effects of the stimulation occurred at the time of stimulation, i.e., were not due to lingering aftereffects.

These data suggest that active memory, (e.g., the persistent neuronal firing often seen in memory tasks) may be an important mediator of memory in these monkeys when repeated images were used.

444.3

CRUCIAL ROLE OF GLUTAMATE-MEDIATED TRANSMISSION IN MONKEY PERIRHINAL CORTEX FOR VISUAL RECOGNITION MEMORY. K. Gale¹, M. Frank-Molina¹, D. Olson, D. Dybdal¹, F. Fornai¹, M. Dubach* and V. Gunderson. Regional Primate Ctr., Univ. of Washington, Seattle, WA 98195 and ¹Dept. of Pharmacology, Georgetown Univ. Med. Ctr., Washington, DC 20007.

In an attempt to identify brain regions in which glutamate receptors may mediate memory processes, we examined the effect of focal intracerebral application of a glutamate antagonist on the performance of pigtailed macaques in a delayed nonmatch-to-sample (DNMS) task. Kynurenate, an antagonist at NMDA and non-NMDA glutamate receptors, was microinjected into various sites within the inferotemporal cortex and hippocampus of awake, behaving juvenile Macaca nemestrina (n=5). All subjects were trained to a stable performance (>90%) at 10, 30 and 60 sec delays prior to the experiments. Kynurenate infusions into the perirhinal cortex, but not into the neighboring hippocampus or parahippocampal cortex, produced reversible, delay-dependent impairment of performance (90% correct at 10 sec delays and 65% correct at 60 sec delays). This impairment required bilateral infusions of kynurenate and was not obtained with control infusions of saline. Spontaneous behavior and motor function were not altered by the focal infusions of kynurenate. These findings indicate that glutamate transmission in a relatively selective region of perirhinal cortex is a crucial component of the neural substrate for visual recognition memory. Moreover, these results demonstrate the utility of focal drug application for exploring neural networks subserving cognitive function in the primate brain.

MONKEYS WITH RHINAL CORTEX LESIONS ARE IMPAIRED ON MATCHING-TO-SAMPLE WITH LARGE STIMULUS SETS, EVEN AT 0-SEC DELAYS, BUT ARE NOT IMPAIRED ON MATCHING-TO-SAMPLE WITH SMALL STIMULUS SETS. E.A. Murray*, M.J. Eacott, and D. Gaffan, Lab. of Neuropsychology, NIMH, NIH, Bethesda, MD 20892, U.S.A. and Dept. of Experimental Psychology, Oxford OX1 3UD, U.K.

Seven cynomolgus monkeys were trained to perform simultaneous and delayed matching-to-sample (DMS) both with a large stimulus set and with a small one. Preoperatively, the monkeys were given performance tests in which 4 delays (0, 5, 15, and 30 sec) and the simultaneous condition were mixed within sessions. After training, monkeys either received bilateral ablations of the rhinal cortex (Group Rh, N=3) or were retained as unoperated controls (Group Con, N=4), and were then retrained on DMS with 0-sec delay. After relearning, the monkeys were again given the performance tests, which were presented in the same way that they had been preoperatively. Group Rh scored significantly more poorly than Group Con on the performance test with the large stimulus set (Group Con, mean = 93% correct; Group Rh, mean = 77% correct). Further, there was a significant interaction of Group and delay, which was still the case even if the data from the delay used for relearning (0-sec delay) were omitted from the analysis. However, Group Rh was also impaired relative to Group Con in the 0-sec delay and simultaneous matching conditions. When data from two versions of DMS with trial-unique stimuli (regular task plus "difficult" version in which physical discriminability of stimuli was reduced) were considered together, Group Con scored 93% correct on simultaneous and 0-sec delay conditions combined whereas Group Rh scored 86% correct. Surprisingly, when the stimulus set was restricted to a single pair, the DMS performance test scores of Group Rh and Group Con did not differ. The results indicate that the rhinal cortex is not specialized for performance on DMS or DNMS, but instead plays a broader role in the processing of visual stimuli. The rhinal cortex appears to be critical both for storing information about novel visual stimuli, and for identification of those stimuli.

EFFECTS OF LESIONS OF PERIRHINAL CORTEX OR PARAHIPPOCAMPAL CORTEX ON MEMORY IN MONKEYS. S.J. Ramus*, S. Zola-Morgan, and L.R. Squire. UCSD Depts. of Neurosciences and Psychiatry, La Jolla, CA 92093, and V.A. Medical Center, San Diego, CA 92161.

The perirhinal cortex (PR) and the parahippocampal cortex (PH) are part of the medial temporal lobe memory system and are themselves important for memory. For example, previous studies have shown that conjoint lesions of PR and PH impaired memory performance in both the visual and the tactual modalities. Recent anatomical studies raise the possibility that PR and PH may contribute to memory in different ways. Specifically, PR receives strong inputs from unimodal visual areas in the inferotemporal cortex and the ventral bank of the superior temporal sulcus. By contrast, PH receives relatively little input from these areas and instead receives major inputs from polymodal association areas. Accordingly, one possibility is that damage to PR could produce more impaired performance than damage to PH on tasks of visual memory. In order to assess the separate contributions to memory of PR and PH, we prepared two groups of monkeys, one with lesions limited to the PR (n=5), and one with lesions limited to PH (n=5). Findings with the delayed nonmatching to sample task, a test of visual object recognition memory, showed that monkeys with lesions limited to PR were impaired relative to 7 normal control monkeys (p<.001) and relative to monkeys with PH lesions (p<.05). Monkeys with lesions of PH were unimpaired (p>.10). These findings, together with preliminary data from other visual memory tasks, suggest that lesions of PR produce a memory impairment in the visual modality while lesions of PH do not.

444.4

COLOUR BLINDNESS IN MACAQUES AFTER ANTERIOR TEMPORAL CORTEX ABLATIONS: FEATURE PERCEPTION AND OBJECT PERCEPTION. D. Gaffan*, C. A. Heywood, M. Buckley, A. Cowey and S. A. Gutnikov. Exp Psychology, Oxford University, Oxford OX1 3UD, U.K.

Colour blindness resulting from cortical lesions occurs clinically in man but has not until now been demonstrated in the monkey. Previous experiments have shown, for example, that monkeys with ablations of area V4 have only mild impairments in colour vision. In three preoperatively trained macaques (M. fascicularis) we made ablations of temporal neocortex anterior to V4. These ablations extended from the upper bank of the superior temporal sulcus to the parahippocampal gyrus, including the entire cortical area TE and also some cortex adjacent to area TE, but sparing V4. All three monkeys were unable postoperatively to discriminate hue (red from green) or saturation (red from grey). They were only mildly impaired in brightness discrimination. One further monkey (M. mulatta) with total ablation of area TE, and with the remaining temporal cortex intact, also showed colour blindness. Three monkeys with cortical ablations restricted to the inferior temporal gyrus (perirhinal cortex) had no impairment in colour vision, but demonstrated impairments in object discrimination in a concurrent learning task with 24-h intertrial intervals. These results show that the role of perirhinal cortex in object perception is not limited to short-term recognition memory (matching or nonmatching to sample), and is not based on the detection of simple features such as colour, while the cortex between V4 and perirhinal cortex is essential for colour vision. Thus, the temporal cortex contains both a mechanism for perception of object features such as colour and also a mechanism for the individual identification of complex objects. These mechanisms may not necessarily be hierarchically arranged, but may represent parallel specializations for aspects of visual perception and memory.

ABNORMAL PERFORMANCE DURING THE FIRST 10 TRIALS OF LEARNING THE TRIAL UNIQUE DELAYED NONMATCHING TO SAMPLE TASK BY MONKEYS WITH LESIONS LIMITED TO THE HIPPOCAMPAL REGION. S. Zola-Morgan*, L.R. Squire and P. Alvarez. V.A. Medical Center, San Diego, and Depts. of Psychiatry and Neurosciences, U.C.S.D. School of Medicine, La Jolla, CA 92093.

Work with humans, monkeys, and rodents has shown that damage limited to the hippocampal region (i.e., the hippocampus proper, dentate gyrus and the subicular complex; referred to as the H lesion), is sufficient to impair memory. On the delayed nonmatching to sample task (DNMS), monkeys with H lesions were impaired at each of the two longest delay intervals (10 min and 40 min). By contrast, the monkeys with H lesions learned the task at a normal rate with a delay interval of 8 sec. In addition, the H monkeys performed as well as normal monkeys at the shorter delays of 15 sec and 60 sec. The DNMS task takes advantage of the normal tendency of monkeys to prefer the novel object in a 2-choice test. Tasks that depend on spontaneous tendencies have proven especially sensitive to hippocampal lesions. Accordingly, we examined the 20 trials that comprise the first day of training on DNMS. During this very early stage of training, performance primarily reflects the spontaneous tendency to select the novel object rather than acquisition of the nonmatching rule. Monkeys with H lesions were impaired during the first 10 trials of training on the first day. Normal monkeys scored 81% correct. Monkeys with H lesions scored 60% correct (P<.05). These findings show that damage to the hippocampal region can impair memory when the delay interval between sample and choice is only 8 sec.

444.8

INFEROTEMPORAL CORTEX AREA TE AS REDEFINED BY RECENT ANATOMICAL STUDIES. E.A. Buffalo, S. Zola-Morgan and L.R. Squire*. Departments of Philosophy, Psychiatry, and Neurosciences, University of California at San Diego, La Jolla, California, 92093 and Veterans Affairs Medical Center, San Diego, California, 92161.

Work with monkeys has helped identify the structures in the medial temporal lobe that are important for memory: the hippocampal region, and anatomically related areas, i.e., the entorhinal, perirhinal, and parahippocampal cortices. Inferotemporal cortex area TE lies adjacent to these cortical areas and has significant projections to one component of this system, the perirhinal cortex (PR). Previous studies of the effects of lesions of area TE have reported impaired pattern discrimination learning and impaired visual recognition memory. Typically, these TE lesions involved the temporal polar region anteriorly, extended posteriorly to 10 mm in front of the ascending inferior occipital sulcus, were bound dorsally by the superior temporal sulcus, and extended ventrally to the rhinal and occipito-temporal sulci. However, recent neuroanatomical studies show that PR occupies some of the temporal polar region and the ventral region previously considered part of area TE. Moreover, our laboratory and others have shown that PR plays an important role in memory function. Thus, it is possible that in previous studies of the effects of TE lesions, the inclusion of PR contributed to the reported memory impairment. We have prepared a group of monkeys (n=5) with bilateral lesions limited to area TE that did not include PR. Preliminary behavioral findings indicate that the monkeys with TE lesions are impaired on the visual nonmatching to sample task. With additional tests, it should be possible to dissociate impairments in visual perception from impairments in memory.

444.9

DAMAGE TO THE HIPPOCAMPAL REGION IN HUMAN AMNESIA: NEUROPSYCHOLOGICAL AND NEUROANATOMICAL FINDINGS FROM TWO NEW CASES N.L. Rempel-Clower*, S. Zola-Morgan, and L.R. Squire. Depts. of Neurosciences and Psychiatry, UCSD, La Jolla, CA 92093, and V.A. Medical Center, San Diego, CA 92161

Patient RB had a moderately severe and long-lasting anterograde memory deficit following an ischemic episode that resulted in a circumscribed, bilateral lesion of the entire CA1 field of the hippocampus (Zola-Morgan, et al., 1986). Two new cases of human amnesia resulting from an anoxic or ischemic event have now undergone extensive postmortem neuropathological analyses. These amnesic patients, LM and GD, were studied for 6 and 8.5 years, respectively, together with other amnesic patients using tests of anterograde memory, retrograde memory, and other cognitive functions. Both patients had exhibited significant anterograde and retrograde amnesia, and normal intellectual and cognitive abilities. Both LM and GD had complete bilateral lesions of the CA1 field of the hippocampus. In addition, LM had damage to other areas of the hippocampal region including the anterior part of the CA3 field and slight damage to the subiculum and dentate gyrus. GD did not sustain damage to any area of the hippocampal region other than the CA1 field. In both patients, damage in the medial temporal lobe was limited to the hippocampal region, with no degeneration apparent in the amygdala or entorhinal, perirhinal, and parahippocampal cortices. In neither case was damage evident in the mammillary nuclei or the medial thalamic nuclei, other areas associated with memory function. Although minor pathology was present outside the hippocampal region in both cases (e.g., in LM there was cell loss in the right medial occipitotemporal gyrus; in GD there was a small infarct in the right globus pallidus), the primary damage in LM and GD was limited to the hippocampal region. Complete bilateral loss of CA1 pyramidal cells is a consistent finding in all three amnesic cases (RB, LM, and GD) and the pathology in the hippocampal region is the only damage that can be reasonably associated with their memory deficits.

444.11

MEMORY CONSOLIDATION AND THE MEDIAL TEMPORAL LOBE: A SIMPLE NETWORK MODEL. P. Alvarez* and L.R. Squire. V.A. Medical Center, San Diego, CA 92161, Dpts. of Psychiatry and Neuroscience, UCSD, La Jolla, CA 92093, and Computational Neurobiology Laboratory, The Salk Institute, La Jolla, CA 92037.

Declarative memory has been shown to depend on a system of medial temporal lobe structures that includes the hippocampus and the adjacent cortical areas (entorhinal, perirhinal and parahippocampal cortex). The role of this system is only temporary, however, as shown by the fact that after damage to the medial temporal lobe, recent memories are impaired but remote memories are intact. This suggests that the medial temporal lobe memory system is involved in a process of consolidation: memories that are initially dependent on this system gradually become established elsewhere, presumably in neocortex. Several proposals for how interactions between the medial temporal lobe and neocortex may mediate consolidation have been presented, but they are often not explicit on many key points. We have attempted to synthesize a number of the existing ideas into a concrete proposal that can be implemented as a neural network model. We propose that a key role of the medial temporal lobe in memory is to bind together the different portions of a memory representation that are distributed over separate areas of neocortex. This binding is mediated by fast changes in the connections between medial temporal lobe and neocortex, and within the medial temporal lobe. The medial temporal lobe then directs the slower changes in the connections between neocortical areas that underlie consolidation. We show that a simple neural network model based on this proposal behaves in a way consistent with experimental observation. This model addresses several current questions about consolidation, and provides a reference point for further experimental investigation and a starting point for improved models.

INTACT ARTIFICIAL GRAMMAR LEARNING IN PATIENTS WITH HUNTINGTON'S DISEASE. B.J. Knowlton, L.R. Squire, & N. Butters, VA Med. Ctr., San Diego, and Depts. of Psychiatry and Neuroscience, UCSD, La Jolla, CA 92093.

Artificial grammar learning appears to be an example of implicit learning. It is normal in amnesic patients and occurs independently of the medial temporal lobe memory system. Patients with Huntington's disease (HD), who have striatal damage, are impaired in learning certain motor and perceptuomotor skills which are also examples of implicit learning. We tested whether artificial grammar learning depends on the same kind of skill learning by testing 11 patients with HD and 12 control subjects. During the study phase, subjects were shown 23 letter strings generated by a finite-state rule system. Each letter string was presented for 9 sec, and the subjects attempted to reproduce the item. The set of training items was repeated once. Five min later, subjects were told that the training items were generated by a set of rules, and that their task would be to decide for a new set of items whether or not each adhered to these rules. This classification test consisted of 23 new grammatical items and 23 nongrammatical items. Performance by the patients on the classification test was not significantly different from the performance of the control subjects (60.3±3.4% vs. 64.3±3.6% correct). The patients were marginally impaired when asked to recognize letter strings that had been presented during the study phase (65.4±3.1% vs. 73.3±2.9% correct $p < .1$). Artificial grammar learning appears to be unaffected by the striatal pathology and dementia associated with HD.

SHORT TERM MEMORY FOR DURATION IN HYPOXIC SUBJECTS. R.O. Hopkins* and R.P. Kesner, Department of Psychology, University of Utah, Salt Lake City, Utah 84112.

Previous research has demonstrated that an hypoxic episode can cause damage to the hippocampus as determined by volumetric MRI analysis. There are several ways in which temporal information can be represented in the brain, including temporal order and duration. Previous research has shown that hypoxic subjects are impaired for memory for novel linguistic and spatial temporal order information. Subjects who experienced an hypoxic episode and matched control subjects (N=9) were tested for short term memory for duration (STMD). The STMD task assessed memory for duration across a variety of delays. Subjects were presented with a single object (square, circle, etc.) on a computer screen, for a duration of 1 or 3 seconds. Subjects were instructed to remember the duration of presentation of the object. After a delay of 1, 4, 8, 12, 16 or 20 seconds, the same object reappeared for 1 or 3 seconds and the subject determined if the object appeared for the same or a different duration. There were 48 trials which allowed for 8 observations for each interval. Hypoxic subjects were impaired relative to control subjects in short term memory for duration. In order to determine if the deficits were due to impaired memory for the items, instead of duration, a control task was developed. The same subjects were presented with a single object for a duration of 1 to 3 seconds and were asked to remember the object. After a delay of 1, 4, 8, 12, 16 or 20 seconds, either the identical object or a different object appeared on the screen. The subjects were asked to determine if it was the same object or a different object. No significant differences between hypoxic and control subjects were found on this task. These results suggest that hypoxic subjects are impaired for memory for duration information, but not for memory for single objects. Hypoxic subjects, with damage to the hippocampus, appear to be impaired in the temporal coding of information.

DEGENERATIVE DISEASE: OTHER I

TRINUCLEOTIDE REPEAT EXPANSION AND DRPLA (SMITH'S DISEASE): MOLECULAR CHARACTERIZATION OF ATROPHIN-1. R.L. Margolis*, S.H. Li, C.A. Ross. Laboratory of Molecular Neurobiology, Johns Hopkins University, School of Medicine, 720 Rutland Ave., Ross 615, Baltimore, MD 21205.

Smith's disease (also known as dentatorubral pallidoluysian atrophy or DRPLA) is a rare, progressive, fatal neuropsychiatric disorder similar to Huntington's disease. Smith's disease is characterized by ataxia, choreoathetosis, myoclonic epilepsy, dementia, and the genetic phenomenon of anticipation. A few cases have been misidentified as schizophrenia. Neuropathological findings include prominent cell loss in the dentate nucleus of the cerebellum, the globus pallidus, the red nucleus, and the subthalamic nucleus. An expansion of a CAG trinucleotide repeat encoding polyglutamine in a gene originally identified in our laboratory (CTG-B37, Li et al, Genomics, 1993) has now been identified as the cause of this disorder (Nagafuchi et al and Koide et al, Nature Genetics, 1994). Northern analysis indicates that the gene, which we have termed atrophin-1, is widely expressed as a 5 kb mRNA in human tissue. Cloning and sequencing of the open reading frame from inserts contained in brain cDNA libraries is in progress. In addition to the CAG repeat, the ORF contains an unusual region of alternating acidic and basic amino acids and a region just 5' to the CAG repeat remarkably prone to chimerism during cDNA library construction. Further characterization of atrophin-1 cDNA should lead to a better understanding of the normal and mutant forms of this gene.

THE PRION PROTEIN 178^{Asn} MUTATION ALTERS PROCESSING IN A TRANSFECTED HUMAN CELL LINE. R.B. Petersen*, S.L. Richardson, S. G. Chen, P. Parchi, C.B. Uriq, and P. Gambetti. Institute of Pathology, Case Western Reserve University, Cleveland, Ohio 44106

The prion protein, PrP, has been implicated in a number of neurodegenerative diseases which can occur sporadically, by transmission, or through inheritance of a mutated allele. A unifying feature of all these diseases is the presence of protease resistant PrP in the brain of affected individuals. The protease resistance is a result of the altered conformation of the PrP; as is the case in Alzheimer disease the change seems to involve a transition of alpha helix to beta pleated sheet. The mechanism by which this transition occurs and is subsequently propagated is unknown. We previously described two subtypes of prion diseases that share a single mutation, Asp to Asn, at codon 178 of the PrP, but are differentiated by a common Met/Val polymorphism at codon 129. We created transfected cell lines expressing either normal PrP or PrP with the 178^{Asn} mutation to determine if the processing of the resulting protein was altered. We used a homologous system, the human PrP coding sequence and the human neuroblastoma cell line M17, to simplify analysis. Our findings show that the 178^{Asn} mutation results in an alteration of the metabolism of the prion protein. This work was supported by NIH grant AG-08992 and AG-08155.

SCRAPIE PRION PROPAGATION ALTERS THE HEAT SHOCK RESPONSE IN NEUROBLASTOMA CELLS. J. Tatzelt*, W. J. Welch*, J. Zuo*, R. Voellmy*, S. B. Prusiner**. *University of California, San Francisco, ^University of Miami.

The fundamental event underlying scrapie infection seems to be a conformational change in the prion protein (PrP). Because changes in the conformation of PrP might require the participation of molecular chaperones, we examined the expression of heat shock proteins (Hsp) that are known to function as molecular chaperones in scrapie infected cells. Neither heat shock nor exposure to sodium arsenite induced Hsp synthesis in scrapie infected neuroblastoma (ScN2a) cells in contrast to uninfected, control neuroblastoma (N2a) cells. Constitutively expressed Hsp 73 was observed primarily within distinct, localized areas in the cytoplasm of ScN2a cells; upon heat shock it was dispersed throughout the cytoplasm and failed to be redistributed into the nucleus/nucleolus. Hsp 73 was widely dispersed throughout the cytoplasm and was translocated into the nucleus/nucleolus after heat shock in the N2a cells as observed for other cell types. While most of Hsp 73 could be removed following nonionic detergent extraction of the N2a cells, significant amounts of Hsp 73 remained within a detergent insoluble fraction of the ScN2a cells. These alterations in the stress response observed for the ScN2a cells may feature not only in the pathogenesis of the prion diseases but also in the formation of PrP^{Sc}.

IS THE APOLOPOPROTEIN E (APOE) $\epsilon 4$ ALLELE OVERREPRESENTED IN DIVERSE NEURODEGENERATIVE DISORDERS (ND)? J.A. Schneider, M. Gearing, and S. S. Mirra. Dept. of Pathology and Laboratory Medicine, VA Med. Center & Emory University School of Medicine, Atlanta, GA 30322.

The apoE $\epsilon 4$ allele is overrepresented in late onset familial and sporadic Alzheimer's disease (AD). While other amyloid-associated disorders, e.g. Creutzfeldt-Jakob disease and amyloid polyneuropathy, have failed to demonstrate this disequilibrium (Saunders et al. Lancet 1993;342:710), we sought evidence of increased representation of the $\epsilon 4$ allele in ND that, like AD, are associated with increased age, neuronal loss, and cytoskeletal pathology. DNA was extracted from paraffin blocks or frozen tissue, and ApoE genotype was determined using a polymerase chain reaction/restriction enzyme method in 48 cases of ND: progressive supranuclear palsy (PSP; n=17), Pick's disease (n=6), corticobasal ganglionic degeneration (CBGD; n=7), Parkinson's disease (PD; n=7), diffuse Lewy body disease (DLBD; n=1), multisystem degenerations (MSD; n=7), lobar atrophy without Pick bodies (n=2), and entorhinal sclerosis (n=1). Coexistent AD pathology of varying severity was present in 16 of the 48 ND cases. We found at least one ApoE $\epsilon 4$ allele in 27 of 48 cases of ND (56%) as compared with estimates of 20-25% in the general population and 60-80% in AD (72% in our own series). When the 16 cases with coexisting AD were excluded, 15 of the remaining 32 ND cases (47%) had at least one ApoE $\epsilon 4$ allele. The proportion of cases with the $\epsilon 4$ allele increased to 56%, when only those ND with neuronal cytoskeletal abnormalities or inclusions (PSP, Pick's disease, PD, DLBD, and CBGD; n=25) but without AD were analyzed. In the seven ND cases without concomitant AD or neuronal inclusions, however, an $\epsilon 4$ allele was found in only one case (14%). These findings suggest that the ApoE $\epsilon 4$ allele is overrepresented in ND other than AD, particularly those with neuronal cytoskeletal abnormalities. Further genetic analysis of additional cases is needed to clarify the role of ApoE in these diverse disorders. Supported by AG10130 and VA Merit Award.

APOLOPOPROTEIN E, LRP, AND ALZHEIMER DISEASE: NEW OBSERVATIONS OF SHED RECEPTORS AND ISOFORM SPECIFIC COMPLEX FORMATION IN CSF. G. W. Rebeck*, S. Harr, H.L. West, A. J. Mendez, J. H. Growdon, M. Kounnas, W. S. Argraves, D. Strickland and B.T. Hyman. Mass. General Hospital, Boston, MA 02214 and the Holland Laboratories, American Red Cross, Bethesda, MD.20855

Increased risk of Alzheimer disease (AD) is associated with inheritance of different alleles of the apolipoprotein E (apoE) gene (apo $\epsilon 4$ > apo $\epsilon 3$ > apo $\epsilon 2$). The apoE isoforms differ by single amino acid changes in the receptor binding domain: apoE2 has two Cys, apoE3 one Cys, and apoE4 none. ApoE binds A β in vitro and immunostains senile plaques (SP). We previously found that an apoE receptor, the low density lipoprotein receptor-related protein (LRP) also stains SP, and proposed that apoE acts as a transport mechanism for A β . We have now studied apoE and LRP in CSF. Two new results are evident: Surprisingly, LRP is present in CSF, as a novel shed form of the receptor. This form appears to contain the extracellular ligand binding domain but not the intracellular internalization domain of LRP. Second, in addition to being present as monomers, apoE2 > apoE3 exist as large complexes due to disulfide bonds forming homodimers and apoA-II heterodimers; ApoE4 does not form these complexes. Because dimers may bind receptors less well than monomers, this difference may be of biological importance.

445.4

TRUNCATED FORMS OF PRION PROTEIN IN NORMAL AND PATHOLOGICAL HUMAN BRAINS. S.G. Chen*, P. Parchi, R. Petersen, L. Monari, W. Wang, P. Gambetti, L. Gambetti. Case Western Reserve University, Cleveland, Ohio 44106.

The prion protein (PrP) is a glycosyl-phosphatidylinositol (GPI) anchored membrane protein of unknown function. An abnormal PrP isoform, partially resistant to proteases, is a hallmark of prion diseases in humans and animals. Immunoblot analysis of normal human brains using antibodies specific to various regions of PrP, has revealed the presence of truncated PrP forms. These fragments are not the product of autolysis, since they were also present in neuroblastoma cells in culture. The most abundant of these fragments is N-terminal truncated and is found in amounts comparable to that of full length PrP. This truncated form is also attached to the cell membrane through a GPI anchor, since it can be released from neuroblastoma cells in culture as well as from brain microsomal fractions by treatment with PIPLC. Our ongoing studies indicate that the relative amount and type of these truncated forms vary according to severity and type of pathology in brains from subjects with human prion diseases, such as Creutzfeldt-Jakob disease and Fatal Familial Insomnia. Studies of these fragments may help understand the role of PrP processing in normal and pathological conditions. Supported by NIH grants AG-08155 and AG-08992.

445.6

QUANTITATIVE ANALYSIS OF SENILE PLAQUES: EFFECT OF APOLOPOPROTEIN E GENOTYPE. B.T. Hyman*, H.L. West, G. W. Rebeck, S. Buldyrev, R.N. Mantegna, S. Haylin and H.E. Stanley. Mass General Hospital, Boston, MA 02214 & Center for Polymer Studies, Boston Univ, Boston, MA 02215

Quantitative analysis of senile plaque (SP) number, size, and amyloid burden (percent of cortex covered by A β) in Alzheimer disease (AD) show that the amount of A β deposited correlates with apoE genotype, with apoE $\epsilon 4/4$ > apoE $\epsilon 3/4$ > apoE $\epsilon 3/3$. To test the hypotheses that this genotype effect is due either to differences in nucleation events or to alterations in the kinetics of SP growth and dissolution, we used computerized image analysis techniques to analyze the size distribution of about 400 SP/case in the superior temporal sulcus of 42 AD cases. We discovered a remarkable homogeneity of size distribution that fits a log-normal curve. This size distribution profile suggests that SP growth is not dependent on time or simple surface area, but instead that the interior of SP may be available for A β deposition and resolution. Comparing the A β measures among AD patients with different genotypes, we find increased total A β deposition with apoE $\epsilon 4$ but no difference in the size distribution curves among genotypes. This suggests that the major difference accounting for the larger amount of A β in apoE $\epsilon 4$ is formation and stabilization of SP nucleation rather than alterations in ongoing deposition of A β . Supported by NIH AG08487.

SUPEROXIDE DISMUTASE, AMYOTROPHIC LATERAL SCLEROSIS (ALS) AND ASTROCYTES. S.A. O'Reilly, J. Roedica, D. Nagy, R. Hallowell, K. Alderson, S. Marklund, J. Kuby and P.D. Kushner. Dept of Biol, San Francisco State Univ, San Francisco, CA, Dept of Mol Biol, Imperial Col, London, England, Dept of Neurol, Univ of Utah Sch of Med, Salt Lake City UT, and Dept of Clin Chem, Umea Univ, Umea, Sweden.

Copper, zinc superoxide dismutase (SOD1) is involved in neutralizing free radicals within cells and has recently been shown to be defective in some familial ALS cases. In this study, we have analyzed SOD1 in sporadic ALS with activity assays and immunocytochemistry. We found no difference in erythrocyte SOD1 activity between 13 ALS cases and 4 controls. Spinal cord sections from 6 ALS cases, 1 primary lateral sclerosis (PLS) case and 1 control case were stained using 3 different antibodies to SOD1; since astrocytes are involved in neutralizing free radical damage, antibodies to glial fibrillary acidic protein (GFAP) and vimentin were used as independent monitors of astrocytes. Our three principal findings from localizations are 1) ALS spinal cord displayed a reduction or absence of SOD1-reactive astrocytes, compared to the control and PLS cases, and 2) examination of GFAP-stained sections showed that, besides the reactive gliosis in the lateral tracts and ventral white and gray matters in ALS and PLS cases, there was a close relationship between astrocytic processes and motor neuron somata in the control case, which was decreased in the ALS and PLS cases and confirmed with morphometry. 3) Vimentin-positive astrocytes were found either in the lateral tracts or in the ventral white matter or in both, in all ALS cases; the case of PLS had none. We conclude that an absence of detectable SOD1 in subpopulations of spinal cord astrocytes and alterations of the motor neuron-glia relationship may play an important role in ALS.

ERYTHROCYTE SUPEROXIDE DISMUTASE ACTIVITY IN SPORADIC AND FAMILIAL AMYOTROPHIC LATERAL SCLEROSIS. S. Przedborski, D. Donaldson, O. Hirsch, D.J. Lange, N. Latov, P.L. Murphy and L.P. Rowland. Department of Neurology, Columbia University, New York, NY 10032

Free radicals have been implicated in several neurodegenerative disorders, such as Parkinson's disease, Alzheimer's disease, and more recently amyotrophic lateral sclerosis (ALS). Reduced activity of superoxide dismutase (SOD), an enzyme that protects the cell against free radical oxidative damage, has been detected in some patients with the familial form of ALS (FALS) as a result of gene mutations. Thus far, whether SOD activity is changed in patients with the sporadic form of ALS (SALS) is unknown. We have therefore measured the levels of erythrocyte SOD activity in 29 SALS patients, 4 FALS patients and 19 normal controls by a spectrophotometric assay. We found that erythrocyte SOD activity was significantly reduced ($F=7.55$, $p=0.014$) in both SALS (mean \pm SEM, 934.88 ± 61.54 U/mg protein; -19%) and FALS (529.88 ± 60.90 U/mg protein; -54%) patients compared to controls (1161.57 ± 71.02 U/mg protein). Values of SOD activity measured in both controls and FALS are closely clustered around their respective means. In contrast, in SALS the distribution of SOD activity seemed to be in two clusters: one in the range of normal activities ($n=18$, 1139.66 ± 55.33 U/mg protein) and a second ($n=11$, 599.80 ± 55.33 U/mg protein) close to FALS values. Although, additional investigation is required to clarify the underlying mechanism responsible for the bimodal distribution of SOD activity in SALS as well as for the reduction in SOD activity in some of these patients, our data support the hypothesis that free radicals may play a role in the sporadic form of the disease. IN VIVO NEUROCHEMICAL ABNORMALITIES IN HUNTINGTON'S DISEASE: EVIDENCE FOR A METABOLIC DEFECT? WJ KOROSHETZ, BG JENKINS, BR ROSEN, MF BEAL. NEUROLOGY AND RADIOLOGY, MASSACHUSETTS GENERAL HOSPITAL, HARVARD MEDICAL SCHOOL, BOSTON MA. 02114

Huntington's disease (HD) is a genetic neurodegeneration that preferentially affects the striatum. Patients with Huntington's disease appear hypermetabolic with large caloric requirements, atrophy of body fat and muscle. We have searched for a neurochemical evidence consistent with a generalized metabolic defect.

1 H magnetic resonance spectroscopy demonstrated that persons with clinical Huntington's disease have elevated lactate levels in striatum and occipital cortex. Persons who are asymptomatic but gene positive have normal lactate levels in the occipital cortex; but lactate may be elevated in striatum. Photoc stimulation caused a 3 fold increase in occipital lactate in controls but a decrease of occipital lactate (50% decrease) in HD. 12/14 HD pts treated with ubiquinone demonstrated a lowering of occipital lactate (29% decrease). In some, treatment with riboflavin/nicotinamide also lowered brain lactate levels. Blood lactate or pyruvate levels were normal. CSF lactate/pyruvate ratios were mildly elevated (12.67 ± 0.38 HD vs 15.82 ± 1.03 controls). Ratios of resting organic/inorganic phosphate measured by MRS in calf muscle are decreased in HD affected (6.5 ± 1.4 HD vs 9.8 ± 1.4 control).

Many of these abnormalities occur in patients with known mitochondrial disorders. We hypothesize that elevated lactate may be a measure of a pathologic metabolic strain leading to neuronal death and pharmacologic strategies which lower lactate might slow the neurodegeneration.

CELL LINEAGE AND DETERMINATION II

MOLECULAR CLONING OF PROTEIN TYROSINE KINASES FROM AN IMMORTALIZED, DIENTEPHALIC CELL LINE AND DIFFERENTIATION BY TROPIC FACTORS. K. Shimoda¹, T. Kitagawa¹, H. Takahashi² and J.W. Commissiong³. ¹Div. Neurol., Natl. Nishitottori Hospital, Tottori 68902, Japan, ²Dept. Path. and Microbiol., Tokyo Metropol. Inst. Geront., Tokyo 163, Japan. ³NTU, LMCN, NINDS, NIH; Bldg 10/5N214, Bethesda, MD 20892.

Diencephalic cells from the brain of the E13 rat fetus were immortalized by transfection with the SV40 LT antigen temperature sensitive mutant, carried by a retroviral vector. Degenerate, oligoprimers were proliferated by the PCR method, and used to clone protein tyrosine kinases (PTK). We sequenced the clones from one cell line that we designated S1, that was cultured at the permissive temperature ($39-40^\circ\text{C}$) and identified the following PTKs: Jak1, Jak2, bFGFR, hck/bmk and Tyro10. At the non-permissive temperature ($33-35^\circ\text{C}$), when the cells were cultured with bFGF or IL-3 (both are coupled to Jak2), the cell extended processes and differentiated to a neuron-like morphology. These results strongly suggest that PTKs may be involved in controlling cell growth and differentiation in this S1 cell line. They may also have a similar function during normal development of the CNS. This S1 cell line may become a useful model for studies involving the molecular aspects of neuronal differentiation and signal transduction.

446.3

CHARACTERIZATION OF THE RT4 NEURONAL CELL LINES. M.A. Turnbow^{*} and L.M. Donahue. Dept. of Cell Biology and Anatomy, Texas Tech Univ. H.S.C. Lubbock, TX 79430.

We are interested in the molecular mechanisms whereby multipotential stem cells in the mammalian nervous system give rise to differentiated daughter cell types. To study differentiation we are using an *in vitro* system called RT4: a family of four cell lines isolated from an ethylnitrosourea-induced rat peripheral neurotumor. The stem cell spontaneously converts in culture to three derivative cell types: two are neuronal and one is glial. Although the RT4 glial cell line has been well characterized, much less is known about the neuronal lines which were originally classified as neuronal based on (1) the ability to fire action potentials and (2) the morphology of the long neurite-like processes they extend upon treatment with cAMP and steroids. Recently we discovered that the neuronal derivatives express an unusual voltage-sensitive sodium channel, the cardiac or SkM2 channel. The SkM2 channel gives rise to a sodium current that is relatively resistant to tetrodotoxin (TTX). Based on the fact that the RT4 neuronal derivatives express SkM2 but do not express neurofilament proteins, we hypothesized that they might be related to small cell neurons from dorsal root ganglia (DRG). Small cell DRG neurons do not express neurofilament proteins and have TTX-insensitive sodium currents. Therefore, we analyzed the following sensory neuron markers in the RT4 cell lines: peripherin, CGRP, KH10, LA4 and Brn-3. All were negative. We have since extended our analysis to include markers for adrenergic, cholinergic and serotonergic neurons. In addition, we are examining the cells for the expression of markers of very immature neural cells such as the intermediate filament protein nestin.

446.2

REGULATION OF NEURONAL DETERMINATION GENES IN PC12 AND P19 CELLS. P.S. Issack^{*} and E.B. Ziff. Dept. of Biochemistry, New York Univ. Sch. of Med., NY, NY 10016.

The role of neuronal determination genes in maintaining the neuronal phenotype was assayed by northern analysis. cDNAs of several genes important in neurogenesis were used to probe RNA from PC12 rat pheochromocytoma cells, P19 murine embryonal carcinoma cells, and Ela- or Wnt-1 transformed PC12 cells. The above cell lines are considered model systems of neuronal determination, differentiation and tumorigenesis respectively. We have observed a complete down regulation of the mRNA of the neuronal determination basic-helix-loop-helix factor MASH-1 in Ela-transformed PC12 and Wnt-1-transformed PC12 cells; expression of MASH-2, another bHLH factor, is unaffected. This is consistent with the hypothesis that oncogenic factors may disrupt the neuronal phenotype by repressing neuronal determination genes which may function to maintain the neuronal phenotype. We are currently analyzing (1) the possible cell-state specific ability of the MASH proteins to transactivate from a reporter construct containing a multimerized E box, a sequence which specifically binds bHLH proteins (2) the effects of abolishing MASH-1 expression in PC12 cells by antisense and (3) the effects of overexpressing MASH-1 in Ela- and Wnt-1 PC12.

MULTIPLE TROPIC SIGNALS ARE REQUIRED FOR DIFFERENTIATION OF OLIGODENDROCYTE PRECURSORS DERIVED FROM AN IMMORTALIZED NEURAL STEM CELL LINE. R. Marmur, M. F. Mehler, S. M. Crain^{*} and J. A. Kessler. Depts. of Neurology & Neuroscience, Albert Einstein Coll. of Med., Bronx, NY 10461

The trophic signals and intracellular transduction pathways that mediate oligodendroglial development are still largely unknown. To establish an *in vitro* model system to investigate these issues, we utilized a clonal, conditionally-immortalized cell line (MK-31), derived from embryonic day 17 mouse hippocampus, that exhibits neural stem cell characteristics. MK-31 has previously been shown to acquire a neuronal phenotype following application of specific subsets of cytokines (Mehler et al., *Nature*, 1993). In the current study, we test the hypothesis that the differentiation and survival of oligodendrocyte (OL) precursors derived from MK-31 stem cells is dependent on signaling from a specific subset of growth factors (GF), as suggested by Barres et al. (1993). Cells grown in the absence of GF, at non-permissive conditions (39°C), gave rise to small subpopulations of rounded cells that extend radial processes and exhibit 04 immunoreactivity, typical of pro-OLs (Pleiffer et al., 1993). These pro-OLs normally die after several days in culture. Application of a limited subset of GFs from several subclasses: bFGF, PDGF-AA, IGF-1, NT-3 and the IL6/LIF family significantly increased survival and also promoted the differentiation from stem cells of a distinct OL precursor population with bipolar morphology, that initially exhibits GD3 and A2B5 immunoreactivity, characteristic of oligodendroblasts (OBs). These OB cells gradually extend radial processes typical of pro-OL cells and subsequently acquire immunoreactivity for the Ranscht monoclonal antibody, indicative of pre-OLs. Some of these pre-OLs progress to the immature OL stage and exhibit galactocerebroside immunoreactivity. These observations establish an *in vitro* model system for molecular analysis of graded stages of early oligodendroglial differentiation.

PREFERENTIAL EXPRESSION OF MEF2C IN INHIBITORY INTERNEURONS IN HUMAN CEREBRAL CORTEX. D. Leifer* and K. Wehr. Dept. of Neurology, Yale University School of Medicine, New Haven, CT.

MEF2C (myocyte-specific enhancer binding factor 2C) belongs to the MADS family of transcription factors, is expressed in muscle and brain, and activates transcription by binding to the MEF2 element, a DNA regulatory element found in certain genes expressed in muscle and brain (Leifer et al., PNAS 1993; 90:1546-50). MEF2C is present at high levels in the cerebral cortex where it is found in post-mitotic neurons that have migrated to the cortical plate. We have now studied MEF2C in human brain samples resected during surgery for intractable epilepsy. Strongly MEF2C-immunoreactive (IR) nuclei occur predominantly in layers II, IV, and VI, and are also scattered in layers III and V, where more numerous weakly reactive nuclei are found. Some MEF2C-IR nuclei are present in layer I. Many of the strongly MEF2C-IR cells that predominate in layers II, IV and VI and the rarer strongly MEF2C-IR cells in layers III and V are also labeled with antibodies against parvalbumin or calbindin, calcium-binding proteins found in GABAergic inhibitory interneurons. These cells have a variety of non-pyramidal morphologies. Many of the weakly MEF2C-IR nuclei in layers III and V are in pyramidal cells, as determined by double labeling with SMI-32, a monoclonal antibody against nonphosphorylated neurofilaments found in pyramidal cells.

These results indicate that the level of MEF2C immunoreactivity correlates with neuronal phenotype and that strong immunoreactivity is present in inhibitory interneurons. The level of MEF2C expression may therefore have a role in regulating genes that control neuronal phenotype.

CLONING AND CHARACTERIZATION OF RAT PBX1, A HOMEODOMAIN GENE DEVELOPMENTALLY REGULATED IN THE CNS. M.A. Morabito*, S. Hockfield and J. Redmond. Section of Neurobiology and Dept. of Pharmacology, Yale Univ. Sch. of Med., New Haven, CT 06510

In CNS development a homogeneous neuroepithelium gives rise to a multitude of cell types as the result of cell proliferation, differentiation and migration. The regulation of these processes is controlled by many genes whose expression is both temporally and spatially restricted during development. This specificity of expression is presumably the result of expression and activation of transcription factors. Recently a novel group of human homeobox genes, PBX1, 2 and 3, have been identified. They show a high level of divergence from previously reported homeodomains, and only 36% identity to yeast MATa1. Expression of PBX genes was observed in a variety of adult and fetal tissues and PBX1 is expressed abundantly in human fetal (18-22wk) brain (Monica, et al., 1991, Mol. Cell. Biol. 11, 6149-6157).

To characterize the expression of PBX1 in the mammalian CNS and to investigate its putative role in nervous system development, the rat homologue of PBX1 was cloned by PCR amplification from an adult rat brain library using synthetic oligonucleotides. The clone obtained was used in Northern and *in situ* hybridization analysis of embryonic and postnatal rat brains. Both studies revealed expression of rat PBX1 in the CNS over the course of embryonic and postnatal development. Rat PBX1 expression is observed in the CNS at embryonic day 15 (E15), peaks in expression postnatally, and is subsequently down regulated in the adult. Rat PBX1 is detected in the cortex at all ages and in the olfactory bulb postnatally. Several structures in the midbrain, diencephalon and cortex show transient expression during development.

The temporal and spatial pattern of expression of rat PBX1 mRNA suggests a role for this homeodomain protein in mammalian brain development. (Supported by NS22807 to SH)

THE REGULATION OF NESTIN EXPRESSION R. McKay*, T. Hayes, R. Lin*, K. Johe, O. Brustle, T. Hazel, C. Vicario, R. Josephson, LMB/NINDS, Bldg36, Rm3D02, NIH, Bethesda, MD 20892; *Physiology & Biophys., Hahnemann U., Philadelphia.

Expression of the intermediate filament protein nestin is characteristic of stem cells in the mammalian CNS. This conclusion is based on extensive *in vivo* analysis of the expression of both the endogenous protein and the identification of a tissue specific enhancer in the nestin gene. Nestin is down-regulated in primary cultures of hippocampal cells that differentiate to express neuronal markers. Nestin is also expressed in glial precursor cells. In the adult brain, re-expression of nestin has been observed in reactive astrocytes and in neuroepithelial tumors. We are currently focussing on the identification of regulatory sequences controlling nestin expression. Both gel shift analysis and the generation of transgenic mice are being used to determine whether the same DNA elements are regulating transitions in nestin expression in different cell types. The identification of these regulatory elements in the nestin gene will establish whether the expression of nestin in different cell types reflects the action of common mechanisms.

446.6

HIGHLY RESTRICTED EXPRESSION PATTERN OF A NOVEL ZINC FINGER PROTEIN, ZIC, IN CEREBELLAR GRANULE CELL LINEAGE. J. Aruga¹, N. Yokota¹, and K. Mikoshiba^{1,2*} 1) Lab. of Mol. Neurobiol., Tsukuba Life Science Center, RIKEN, Tsukuba Ibaraki Japan 2) Institute of Medical Science, Univ. of Tokyo

Cerebellar granule cells are generated from the unique neuroblast-proliferative zone, the external germinal layer (EGL). To clarify the mechanism underlying the generation of the EGL and the subsequent differentiation process to cerebellar granule cells, we have cloned a gene, named *zic* as a molecular marker for EGL-granule cell lineage. *zic* encodes 48kDa protein with a tandem repeat of five zinc finger motifs. It showed a significant homology to *Caenorhabditis elegans* sex determining gene *tra-1*, *Drosophila* segment polarity gene *cubitus interruptus* *Dominant* and human *GLI* oncogene.

In situ hybridization and immunohistochemical study revealed that *zic* was expressed abundantly in the EGL-granule cell lineage throughout the development of cerebellum. Before the formation of EGL, *zic* was expressed in the neuroblast proliferative zone which faces the fourth ventricle and the area of cerebellar anlage adjacent to the primordium of choroid plexus. It is expressed at an early embryonic stage in the dorsal half of the neural tube. Furthermore, the bacterially expressed fusion protein of *zic* containing the zinc finger domain showed a sequence specific DNA binding activity. The cotransfection assay using the *zic* expression vector and *zic* promoter-driven luciferase gene indicated that *zic* acts on its own promoter.

These findings suggest that *zic* is a member of transcription factors involved in both differentiation and maintenance of properties of the cerebellar granule cells.

MOLECULAR CLONING OF CHICK BRAIN-3.0 AND THE DISTRIBUTION OF ITS mRNA DURING DEVELOPMENT OF THE CHICK NERVOUS SYSTEM. Jonas Lindeberg, Reg Williams, Anders Bäckström*, Finn Hallböök and Ted Ebendal. Department of Developmental Biology, Box 587, Uppsala University, S-751 23 Uppsala, Sweden.

Brn-3.0, a member of the POU transcription factor family, is mainly expressed at high levels in sensory neurons and retina. We wanted to isolate the chicken homologue to rat Brn-3, investigate its mRNA expression pattern development and to examine possible correlation between Brn-3 mRNA and the expression of the neurotrophin high-affinity Trk receptors. Using degenerate oligonucleotide primers and PCR we isolated the chicken Brn-3.0 from spinal ganglia cDNA. This fragment was then used to screen cDNA libraries and a chicken genomic library in order to get the full length sequence promoter and gene structure. *In situ* hybridization histochemistry was performed on consecutive sections using probes specific for the detection of mRNA for Brn-3.0 and for the neurotrophin high-affinity receptors. Brn-3.0 was expressed within neurons of many of the cranial ganglia, specifically localized to neurons derived from the epibranchial placodes, and generally absent from neurons derived from the neural crest. TrkC mRNA and Brn-3.0 mRNA were expressed in the same populations of neurons at all stages of chicken development. Whereas the expression of trkC mRNA appeared to decrease with age, no decrease in the expression of Brn-3.0 was observed. At the earliest stage examined (stage 13) Brn-3.0 mRNA expression was quite strong in the presumptive neuroblasts migrating from the trigeminal placode, while the expression of trkC mRNA was just beginning. This indicates a possible influence of Brn-3.0 on trkC expression in trigeminal placode derived neuroblasts.

446.10

RESTRICTED CLONAL ALLOCATION IN THE CHIMERIC MOUSE BRAIN C. Kuan*, E. Elliott#, R. Levenson*, R. Flavell#, and P. Rakic Sect. Neurobiol., *Sect. Immunobiol., #Dept. Cell Biol., Yale School of Medicine, New Haven, CT 06511

Lineage analysis in *Drosophila* wing development revealed restricted clonal allocation and led to the concept of compartmentalization. Whether similar principles apply for embryogenesis of the vertebrate nervous system remains an issue under debate. Here we address this issue by examining distribution of clonally related cells in chimeric mouse brains. Stable transfected embryonic stem (ES) cell clones were generated to express *lacZ* gene driven by chick beta-actin promoter as lineage marker. Mouse blastocyst embryos were injected with such *lacZ*(+) ES cells, transferred to foster mother mice, bred to term and sacrificed at postnatal day 10 for examination by X-gal histochemical staining. Although X-gal positive and therefore clonally related cells were intermingled with X-gal negative cells in the chimeric brain, the overall distribution was not random but highly regionalized. Each animal exhibited a distinct subset of brain regions colonized with X-gal(+) cells, and within each colonized structure the density of marked cells could be highly enriched compared to surrounding tissues. Furthermore, a bilateral symmetry in distribution and density of X-gal(+) cells was a prevailing feature in all examined animals. Thus, for example, when a group of X-gal(+) cells were localized in CA2 region of hippocampus or in a subcortical nucleus, a mirror image of distribution was also observed in the opposite side of brain. Taken together, the regionalized and bilaterally symmetric distribution of clonally related cells in chimeric mice suggests a restricted and precise clonal allocation exists in the vertebrate nervous system.

IN VIVO CHARACTERIZATION OF PROLIFERATING CELLS IN ADULT RAT WHITE MATTER. J. M. Gensert and J. E. Goldman*. Dept. of Pathology, Columbia University, New York, NY 10032.

Dividing cells persist in the adult mammalian CNS. Although these cells have been presumed to be immature glia, their nature has not been fully characterized. Furthermore, their developmental fates and migratory potential are not understood.

Proliferating cells in adult rat brain subcortical white matter were examined *in vivo* using stereotactic injections of a replication-deficient retrovirus that expresses β -galactosidase. Cells were visualized by X-gal histochemistry or by immunocytochemistry with anti- β gal antibodies. These cells exhibit an immature morphology and are unipolar or contain very few or no detectable processes. There are no clear astrocyte forms in the population of cells labeled, and these cells do not express the astrocyte markers glial fibrillary acidic protein (GFA), glutathione-S-transferase Yb, or S100 β as determined with immunohistochemical techniques. A very small subset of these cells, however, does express vimentin, and a significant subpopulation expresses an isoform of glutathione-S-transferase that is oligodendrocyte-specific, Yp. However, neither of two other antibodies used to identify oligodendrocytes (carbonic anhydrase and RIP) gave a positive signal, nor had the cells produced any apparent myelin sheaths. Since the initial population of labeled cells resides only in a small area, migration of these cells can be followed. The cells, however, do not appear to migrate from the initial area of labeling, and furthermore, they continue to exhibit a simple morphology when followed *in vivo* for 30 days. Our results suggest that we are labeling a heterogeneous population of immature cells, some of which have begun to develop through an oligodendrocyte lineage pathway. It remains to be determined if these cells have the potential to differentiate into myelinating oligodendrocytes *in vivo* when provided the appropriate signals. Supported by NS17125.

EMX2 IS SELECTIVELY EXPRESSED IN GERMINAL NEUROEPITHELIUM OF DEVELOPING DORSAL TELEENCEPHALON OF THE MOUSE. M. Gulisano^{1,2}, V. Broccoli¹ and E. Boncinelli¹ Dibt, Scientific Institute H San Raffaele, Via Olgettina 60, 20132 Milano and ²Istituto di Biologia Generale, Università di Catania, 95124 Catania, ITALY

We recently cloned two vertebrate homeobox genes, Emx1 and Emx2, related to *empty spiracles*, a gene controlling very anterior body regions during early *Drosophila* embryogenesis.

Both vertebrate genes are expressed in the brain of mouse embryos. They are expressed in the embryonic cerebral cortex in a developmental period, between day 10 and day 16 post coitum, corresponding to major events in cortical neurogenesis. In its full extension, days E12.5 to E13.5, their expression domain comprises cortical regions including promordia of neopallium, hippocampal and parahippocampal archipallium. In particular, Emx1 expression seems restricted to cortical regions, mainly if not exclusively hexalaminar in nature. At day E17, cortical expression of the two genes is almost exclusively confined to hippocampal germinal layers. It seems reasonable to speculate about a role of Emx1 and Emx2 in establishing the limits and identity of the embryonic cerebral cortex. In addition to presumptive cortex, Emx2 is also expressed in some embryonic neuroectodermal areas including olfactory placodes and olfactory epithelia.

We have now studied in detail their expression pattern in relation to cortical neurogenesis in E12-16 mouse embryos. Preliminary data show that Emx2 is expressed in germinal neuroepithelium but neither in the cortical plate nor in the so-called transition field. Conversely, Emx1 is expressed in both the neuroepithelium and the transition field.

PROCESS OUTGROWTH IN RETINA AND RETINAL PROJECTION SITES

447.1

DETECTION OF HIGH MOLECULAR WEIGHT MATERIAL IMMUNOREACTIVE WITH ANTIBODIES TO THE 72 Kd GELATINASE IN EMBRYONIC CHICK RETINA. H. Peng, P. Alexander*, and J.B. Sheffield*. Department of Biology, Temple University, Philadelphia, PA 19122 and *Department of Ophthalmology, University of Oregon, Portland, OR 97201.

In previous studies, we have detected extracellular proteases in embryonic chick retinal cell culture supernatants and pellets by zymograms and substrate digestion. We have now used western blotting techniques to further characterize the enzymes in retinal tissue extracts. Embryonic chick retinal tissue ranging from E8 to E18 days were dissected and transferred to a Tris buffer pH 7.6 containing 0.5 M NaCl, 0.05% Brij-35, 20 mM PMSF, and 10 mM CaCl₂. The tissue was homogenized in 0.15 M NaCl Tris-buffer and centrifuged at 1,000 rpm for 10 minutes, and then at 50,000 rpm for 10 minutes. Western blotting was performed using an avidin-biotin-peroxidase-luminol technique. Specific antibodies made against peptides of human stromelysin and 72 Kd gelatinase and purified by affinity chromatography, as well as commercial antibodies against α -1-antitrypsin and α -2-macroglobulin were used. The extract from all ages stained intensely with antibodies to 72 Kd gelatinase. The primary band of reactivity was at an apparent molecular weight of about 230 KD. Analysis of a possible 72kd band was obscured by reaction of the extracts with avidin. Densitometry indicated that the staining intensity for the 230 Kd band increased from E8 to E10, by a factor of two, and then decreased gradually from E12 to E18. No reaction was found with antibodies to human stromelysin, α -1-antitrypsin, α -2-macroglobulin. The high molecular weight of the band that we detected may be due to a complex between the enzyme and an endogenous inhibitor.

446.12

HAIR CELLS AND SUPPORTING CELLS SHARE A COMMON PROGENITOR IN THE DEVELOPING CHICKEN INNER EAR. S. Muthukumar and D.M. Fekete*. Dept. of Biology, Boston College, Chestnut Hill, MA 02167.

The basilar papilla, the avian counterpart to the mammalian organ of Corti, consists of a contiguous mosaic of hair cells and supporting cells. The present study sought to establish the lineage relationship between these two cell types. Individual progenitor cells were labeled by targeting replication-incompetent retroviruses encoding a marker gene (alkaline phosphatase) into the otocyst on embryonic day 3 (E3) or E4. In most cases, a library of avian retroviruses with >10⁵ complexity was used so that clonal assignments could be verified later by PCR amplification and DNA sequencing (Cepko, Fields-Berry and Golden, unpublished). Tentative clonal assignments were made on the basis of close grouping of labeled cells in E18-20 whole mounts of the basilar papilla. These were sectioned to determine cell types. The average clone size was 4.8 ± 2.6 cells (range 1-10; n=24). The ratio of hair cells to supporting cells was 1:3.5, which is close to the overall ratio of these two cell types. 20% of the clones consisted of supporting cells only. The remainder had a mixture of hair cells and supporting cells. Since there was only a single 2-cell clone (both supporting cells) in the data set, it was not possible to determine whether a progenitor can give rise to both a hair cell and a supporting cell at the final mitotic division. In no case did a clone contain more hair cells than supporting cells. Thus it is not yet possible to distinguish between a stochastic mode of cell type determination versus an obligatory mechanism in which a hair cell is always generated in concert with a supporting cell. Supported by the March of Dimes and a Clare Boothe Luce Professorship (to DMF).

EFFECTS OF ADDED GLYCOSAMINOGLYCANS ON NEURITE OUTGROWTH FROM REGENERATING GOLDFISH RETINAL EXPLANTS. J. S. Elam* and J. F. Challacombe. Program in Neuroscience and Department of Biological Science, Florida State University, Tallahassee, FL 32306.

Proteoglycans (PGs) and their glycosaminoglycan (GAG) chains have been shown to modulate neurite outgrowth during development of the nervous system. That PGs are multifunctional growth-regulatory molecules is becoming increasingly apparent, but few studies have focused on the functions of PGs during regeneration. Our laboratory has demonstrated that inhibition of PG synthesis by addition of 4-methylumbelliferyl- β -D-xyloside to the culture medium of goldfish retinal explants reduces regenerative axonal outgrowth on poly-L-lysine (PLYS), but not on poly-L-lysine+laminin (PLYS+LN) (Challacombe and Elam, Soc. Neurosci. Abs. 19, 877, 1993).

To extend this study, explants growing on both PLYS and PLYS+LN substrates were exposed to soluble chondroitin 4-sulfate (CS), while heparan sulfate (HS) was added to explants on PLYS. The data show that CS dose-dependently stimulates regenerative axon growth on both substrates, while the effects of HS depend on the concentration added to the culture medium. Low doses of soluble HS stimulated outgrowth, while at a high concentration, inhibition was observed. These findings suggest that PGs containing CS and HS GAG chains participate in events underlying the regeneration of goldfish optic axons following injury.

DYNAMICS OF RETINAL GROWTH CONES ENCOUNTERING THEIR TARGET IN CO-CULTURE: A TIME-LAPSE STUDY. A. El-Bohy*, D. F. Chen, G. E. Schneider & S. Jhaveri. Dept. Brain & Cognitive Sciences, Massachusetts Institute of Technology, Cambridge, MA 02139

Our previous studies showed that in explant co-cultures, retinal axons from embryonic hamster grow readily into tectal slices prepared from animals of all ages, including adult; however, retinal axons reveal different patterns of growth when challenged with tectal slices from animals of different ages. In embryonic tectum, embryonic retinal fibers elongate with very little branching; whereas in postnatal and adult tectum, significantly more ramifications are observed. In order to further characterize the growth of embryonic retinal axons in targets of different ages, we have used time-lapse video microscopy to examine the morphology of retinal growth cones as they encounter and begin to invade target tissue. Explants of retina and tectum were maintained in serum free medium for 15 - 72 hr. Crystals of DiI were placed in the retina 10 hr prior to the beginning of observations. Images of labeled retinal axons were recorded on a low-light SIT camera every 2-4 min for a period of 5-8 hr. In general, fibers from E14 retina growing into E14 tectum have simple growth cones which form swellings at the tip of the axons and have few filopodia. Significantly more growth cones were seen extending along other labeled axons than in the older tissue. When retinal explants were co-cultured with postnatal or adult tectum, the growth cones were typically larger (2-5 times those in embryonic tectum), more lamellate, and had longer, more numerous filopodia. Over the 8-hr observation period, some filopodia were observed to stabilize and become collaterals on trunk axons once the growth cone moved ahead. Our results suggest that the shape of growth cones on afferent fibers and the number of filopodia decorating them reflect the patterns of axonal growth, which are dependent on the maturational state of the target substrate. (Support: NIH grants T32-MH15761, EY05504, EY00126, EY02621).

GROWTH PATTERNS OF CHICK RETINAL AXONS IN RETINA-TECTUM COCULTURES. Stefan Meyer* & Friedrich Bonhoeffer. Max-Planck-Institut für Entwicklungsbiologie, Spemannstrasse 35/I, 72076 Tübingen, Germany.

During retinotectal map formation in the chick, growth of temporal axons is restricted to the anterior half of the tectum, whereas nasal axons invade the posterior tectum (Nakamura and O'Leary, 1989). Innervation of a terminal zone is achieved by sidebranch formation and subsequent elimination of overshooting parts of the axon. It is assumed that a repulsive guidance molecule (RGM) expressed predominantly in the posterior tectum prevents growth of temporal axons into this region (Walter et al., 1987).

In order to investigate axonal growth and branching in vitro, we developed a co-culture assay of retina with tectum. DiI-labeled pieces of retina were cultured together with a piece of anterior and posterior tectum on opposite sides in a collagen matrix. Growth patterns of labeled axons were investigated after 48 hours or continually by using time lapse video microscopy. As in vivo, temporal axons did not invade posterior tissue, but grew and branched in anterior tissue. Nasal axons grew into and branched in both tissues. These results indicate that failure of temporal axons to invade the posterior tectum is linked to repulsive molecules and not due to attraction by the anterior tectum. When cocultures were treated with the enzyme PI-PLC, temporal axons could invade posterior tissue. This is consistent with the earlier findings that RGM is GPI-linked.

In a different paradigm, both tectal pieces were placed on one side of the explant. Thus, axons first grew through anterior tissue before they reached posterior tissue. We found that temporal axons were restricted to the anterior tectal piece, whereas nasal axons continued to grow into posterior tissue. Time lapse analysis revealed that temporal growth cones collapsed after they reached the A-P border. We are presently investigating whether such encounters with repulsive tissue can also lead to the formation of new sidebranches at a distance from the growth cone.

RETINAL GANGLION CELL GROWTH CONE COLLAPSE CAUSED BY NITRIC OXIDE DONORS. R. C. Renteria, C. J. Barnstable, and M. Constantine-Paton.* Yale University, Interdepartmental Neuroscience Program, New Haven, CT 06511.

The amphibian retinotectal projection is a useful system in which to study mechanisms of activity-dependent synaptic development. Chronic application of NMDA-receptor agonists and antagonists to tectal cells *in vivo* is known to cause modification of retinal afferent arbors (Cline and Constantine-Paton, *J. Neurosci.* 10(4):1197, 1990). Nitric oxide (NO), a multifunctional molecule, is a proposed retrograde messenger in the CNS for the activity-dependent modification of synaptic efficacy. A subpopulation of rat retinal ganglion cells contains a putative cGMP-gated cation conductance which is blocked by Cd²⁺ and activated by the NO donors sodium nitroprusside (SNP) and S-nitrosocysteine (SNOC), most likely through NO activation of soluble guanylyl cyclase (Ahmad et al., *Neuron* 12:155, 1994). We have developed a culture system in which *Xenopus laevis* retinal ganglion cells extend neurites from explanted retina on polylysine- and laminin-coated glass coverslips. We show that bath application for several minutes of these nitroso-compounds (100 µM) in normal saline solution causes rapid growth cone collapse. Potassium ferricyanide, cysteine, sodium nitrite (each at 200 µM), and "exhausted" SNOC and SNP had no effect with similar application times. Cd²⁺ and nifedipine both caused collapse of these growth cones in a dose-dependent manner. However, this effect was not seen with 1mM 8-Br-cGMP application, similar to results with DRG neurites (Hess et al., *Nature* 366:562, 1993). Peroxynitrite, a species formed by the reaction of NO with superoxide anion, is known to be cytotoxic to cortical cells in dissociated culture (Lipton et al., *Nature* 364:626, 1993). However, application of SNOC with superoxide dismutase (50 U/mL) to scavenge free radicals and prevent peroxynitrite formation did not prevent the effect. Further investigations will study the mechanism of this nitroso-compound-induced effect on RGC growth cones and the effects of NO on these same axons after they contact cocultured tectal neurons. (R.C.R. is supported by a Howard Hughes Medical Institute Predoctoral Fellowship.)

CELL LINES GENERATED FROM AVIAN EMBRYONIC RETINA BY ONCOGENE-TRANSFECTION EXHIBIT MATURE GANGLION CELL CHARACTERISTICS AND RESPOND TO POSITIONAL CUES OF TECTAL MEMBRANES IN VITRO. G. E. Pollerberg*, C. Kuschel, B. Eickholt, M. Zenke, H. Beug & U. Schwarz. Dept. of Biochemistry, Max-Planck-Institute for Developmental Biology, D-72076 Tübingen, Germany

We generated cell lines by transfecting quail embryo retina with a retroviral construct containing v-myc fused to the hormone-binding domain of the estrogen receptor, allowing for the activation of the chimeric protein by estradiol. The oncogene myc was chosen because of its proliferation-inducing capacity and differentiation compatibility. The infection was performed by cocultivation of virus-producing, proliferation-incompetent fibroblasts with embryonic day 3.5 quail eyes. In these organ-cultured retinæ, cells proliferate and differentiate within a time span of less than 20 hours, a prerequisite for both the generation of stable as well as neuronally differentiated cell lines. The transfected neuroretinæ were separated into nasal and temporal parts, dissociated, and kept as single-cell cultures. Individual cell colonies were isolated and expanded; these cell lines have been maintained in culture over 6 months with a doubling time of approximately 20 hours and can therefore be considered immortal.

Spontaneously differentiating cells were observed within the cell line cultures, exhibiting morphological features of mature retinal neurons in vitro. Some of these differentiated cells displayed the morphological characteristics and marker expression of mature retina ganglion cells. The differentiation rate could be substantially increased by the administration of retinoic acid or basic fibroblast growth factor. The differentiated cells maintained functional properties of ganglion cells as revealed by a substrate choice assay. When confronted with substrate stripes of membrane vesicles prepared from target and non-target parts of the tectum, the axonal processes of temporal lines preferred to grow on target stripes, indicating that the cell lines will be useful for the investigation of mechanisms underlying axon-target interactions.

447.6

MOLECULAR CHARACTERIZATION OF REGGIE-ANTIGEN: A GROWTH ASSOCIATED CELL SURFACE PROTEIN IN THE RETINOTECTAL SYSTEM OF GOLDFISH T. Schulte, F. Lottspeich* and C.A.O. Stuermer* Faculty of Biology, University of Konstanz, and *MPI for Biochemistry, Munich, Germany

Reggie-Antigen, which is recognised by the monoclonal antibody M802, was identified as a cell surface protein appearing on goldfish retinal ganglion cells (RGCs) and regenerating RGC axons after optic nerve transection (ONS) (Paschke and Stuermer, *Soc. Neurosci. Abstr.* 1991). In addition to its expression on RGCs and regenerating RGC axons, Reggie antigen is also found on cells lining blood vessels in the CNS and on microglial cells in the injured optic nerve.

Reggie-Antigen was purified by immunoaffinity chromatography with M802 from total membrane fractions of adult goldfish brains and from total larval goldfish (age: 30-60 d). In SDS PAGE the immunopurified protein has an apparent molecular weight of 48 kD under reducing conditions. We here report cloning of a 300 bp cDNA fragment coding for part of the Reggie-Antigen. It was obtained by PCR using degenerate oligonucleotide primers derived from internal peptide sequences of the immunopurified protein. So far the cDNA clone and the peptide sequences show no homology to known proteins.

Anchored PCR strategy as well as cDNA library screening is now being performed to obtain a full length clone.

RETINOGENICULATE PATHWAY IN THE NORMAL AND DEAFFERENTED MOUSE: A DiI STUDY. R. De Guevara¹, P. Clairambault¹, M. Diagne¹, M.T. Droy-Lefaix², G. Pinganaud¹, and L. Bueno*. ¹ Neuroembryology Lab., University Paris 7, Paris; ² IPSEN Institute, Paris, * INRA, Toulouse, France.

We studied, after placing a crystal of DiI (fluorescent marker) in an experimental eye, the retinogeniculate pathway at 0, 3, 7 and 15 days of postnatal development in the C57BL/6J mouse. We used controls and animals which were monocularly deafferented at birth. Results show that, in the controls, the map of visual projections in the dorsolateral geniculate nucleus is present at D7. Deafferentation causes the loss of this map and an increase in ipsilateral visual projections. Until D7, the retinofugal fibres present many varicosities which thereafter start to regress and at D15 become sparse both in control and deafferented animals. Collateral fibres lead off perpendicularly from the superficial optic tract in the direction of the visual neuropil. They are numerous at D3 and D7 and scarce at D15. We do not observe any difference between controls and deafferented animals. We used the same methods on animals treated with a free radical scavenger (EGb 761, IPSEN). It seems that at D7, the varicosities on the fibres are slightly more numerous; the same for the perpendicular collateral fibres of the superficial optic tract.

TYROSINE PHOSPHORYLATION AT FILOPODIAL TIPS OF VERTEBRATE GROWTH CONESD.-Y. Wu*, L.-C. Wang, D.J. Goldberg and C.A. Mason, Depts. of Pharmacology & Pathology, Ctr. for Neurobiology & Behavior, College Physicians & Surgeons, Columbia Univ., NY, NY 10032.

We have previously reported that phosphotyrosine is concentrated at filopodial tips of *Aplysia* growth cones, suggesting a role in regulating filopodial function. We have now used immunocytochemistry to show concentrations of phosphotyrosine at filopodial tips of the growth cones of several types of cultured vertebrate neurons: neonatal rat hippocampal neurons, embryonic chick retinal and sympathetic neurons and embryonic mouse retinal ganglion cells. Accumulation of phosphotyrosine at filopodial tips was sensitive to the culture substrate. Increasing the density of laminin on the substrate increased neurite outgrowth from mouse retinal ganglion cells, but decreased the percentage of filopodia displaying strong tip phosphorylation. Concentration of phosphotyrosine at filopodial tips and its sensitivity to the substrate suggest the potential importance of tyrosine phosphorylation in pathfinding decisions.

To identify proteins associated with phosphotyrosine in filopodial tips, we double-stained growth cones with antibodies to phosphotyrosine and each of several proteins known both to associate with actin filaments and to be substrates for tyrosine phosphorylation. Cortactin, integrin and ezrin (or a congener) frequently co-localized with phosphotyrosine. Tensin, vinculin and paxillin, actin-associated proteins found at focal contacts, were observed in lamellipodia around cell bodies, but not in growth cones.

FACTORS CONTROLLING DENDRITIC ARBORIZATION OF RETINAL GANGLION CELLS. D. Troilo, M. Xiong, J. Crowley, and B.L. Finlay* Psychology, Cornell University, Ithaca, NY 14853.

The establishment of precise retinal connectivity during development is essential for the retina to transmit visual information. The factors that regulate convergence and divergence during development between bipolar, amacrine, and retinal ganglion cells (RGCs) are poorly understood. We manipulated RGC density and availability of pre-synaptic sites to examine their effects on the development of RGC dendritic arbor.

Visual form deprivation induces ocular enlargement, producing a larger than normal retinal area and a reduction in RGC density of 20-30%. Partial optic nerve section produces areas of RGC depletion with a mean reduction in density of 64%. In the former case, the ratio of pre-synaptic cells to RGCs remains constant, while in the latter the ratio is increased. This contrast allows us to separate the effects of RGC density from pre-synaptic input on RGC dendritic field area and arbor complexity.

In experimentally enlarged retinas, RGC dendritic arbors expand with increased area in a compensatory manner that is consistent with simple stretching; arbor area was about 30% larger than normal, branch density was decreased, and arbor length was about 14% longer than normal. In RGC-depleted retinas, dendritic fields of RGCs are larger than controls but do not fill the space available. Branch density of RGC dendrites in RGC-depleted areas is greater than in controls.

We conclude that both local RGC density and the availability of pre-synaptic terminals control RGC dendritic size and complexity. The limited growth of the RGC dendritic fields in areas with large space availability, together with the increase in arbor branches per unit area, suggest that pre-synaptic input is important in the shaping of RGC arbors postnatally.

RETINAL GROWTH CONE RESPONSES TO CELLULAR CUES FROM THE OPTIC CHIASM MIDLINE L.-C. Wang*, D.-Y. Wu, J. Dani, D.J. Goldberg and C.A. Mason, Depts. Path. and Pharm., Cntr. Neurobiol. Behav., Columbia Univ., NY, NY 10032.

During divergence of retinal axons to both sides of the brain, both crossed and uncrossed fibers initially travel toward the midline, pause for several hours, and either cross the midline or turn back to ipsilateral optic tract, respectively (Godement et al., J. Neurosci., in press). To investigate how growth cones detect cues and which cells in the midline provide those cues, we analyzed the behavior of retinal growth cones from dorsal or ventral temporal retina (source of crossed and uncrossed fibers) as they interact with chiasm cells *in vitro* by video microscopy and DIC optics. When axons grew on a polylysine/laminin substrate, they advanced rapidly and had long lamellopodial forms. Within 50 microns of a chiasm cell, growth cones slowed and became more filopodial. After filopodial contact, all growth cones paused in advance, with a single filopodium attached to the cell. Subsequently, the behavior of the two sets of growth cones differed. Uncrossed growth cones displayed a greater degree of collapse, did not grow onto the cells, and took longer to turn away from the cells. Retrospective immunocytochemistry will indicate the extent to which neural and non-neural chiasm cells inhibit uncrossed growth cones.

To further characterize the intracellular machinery in detection of cues, we are investigating filopodia-specific phosphotyrosines by using retrospective immunocytochemistry of identified growth cones and antibodies to phosphotyrosine. These studies should elucidate the detection and sources of cues leading to retinal axon divergence.

447.12

DYNAMICS OF DENDRITE DEVELOPMENT IN THE OPTIC TECTUM OF LIVE ZEBRAFISH EMBRYOS. R.J. Kaethner* and C.A.O. Stuermer, University of Konstanz, D-78464 Konstanz, Germany.

To visualize the development of dendrites in the zebrafish optic tectum, 0.5 - 30pl of the fluorescent dye DiO (in solution) were pressure-injected into the cell rich layer of tecta in 50 - 78hr old embryos. These cells reside deep to the tectal neuropil into which retinal axons enter and where they form their terminal arbors (Stuermer, J. Neurosci 8, 1988). Labeled cells and dendrites were viewed from above through the unopened skull of live embryos with low intensity light and a SIT camera (Hamamatsu), and monitored through a time lapse video recording system.

The tectal neurons were observed to send out efferent axons to subtectal regions. Simultaneously they begin to develop their dendrites which grow in a radial orientation towards the developing neuropil. While elongating, the dendrites form branches with growth cone like structures and up to 15µm long filopodia which radiate into all directions. As has previously been described for retinal axons (Kaethner & Stuermer, J. Neurosci 12, 1992), dendrites develop through the emission and retraction of filopodia and primary branches over periods up to 17hr. With time some branches stabilize while others are entirely reabsorbed. Gradually, the dendritic arbors increase in diameter up to 30µm in 90hr old embryos.

Thus, developing dendrites of tectal neurons exhibit an exploratory growth behavior similar to that of retinal axon arbors in the developing tectal neuropil. Retraction and extension of processes of dendrites coincides with the dynamic modeling of retinal axon arbors, suggesting that processes of both may contact each other and influence each other's growth and shaping. Supported by DFG, SFB 156, TPC6.

PROCESS OUTGROWTH AND SECOND MESSENGERS

DEVELOPMENTAL EXPRESSION OF G PROTEINS IN THE EMBRYONIC NERVOUS SYSTEM OF MANDUCA SEXTA. P.F. Copenhagen*, Michelle Rasmussen, and A.M. Horgan, Cell Biol. & Anat. L215, Oregon Health Sciences University, Portland, OR 97201.

We are investigating the developmental role of G proteins (heterotrimeric guanyl nucleotide binding proteins) during the formation of the CNS in *Manduca*. This highly conserved family of intracellular signalling molecules is widely distributed in the nervous systems of all organisms, but the potential role of G proteins in development remains poorly defined. Using affinity-purified antisera against different G_{α} subunits, we characterized the developmental expression of the major classes of G proteins (including proteins related to G_{α} , G_i , G_s , & G_t) during the formation of the embryonic CNS. Whole-mount immunohistochemical staining and protein immunoblots of embryonic tissue revealed that the different G protein classes appeared in precise spatiotemporal patterns within the developing ganglia. Several G proteins were initially seen in subsets of undifferentiated precursors but underwent a subsequent phase of regulation as development progressed, suggesting that individual G proteins may serve a progression of functions during the formation of the nervous system. In particular, while several G proteins could be detected in the mature nerves of the CNS, only G_{α_q} -related proteins could be detected in regions of axonal outgrowth. Preliminary experiments using aluminum fluoride to stimulate G protein activity caused a substantial inhibition of process outgrowth, suggesting that one function of G_{α} may be to regulate the extent or duration of neuronal motility. These results can now be used to examine more specific effects of individual G proteins in the context of identified neurons within the embryonic nervous system. Supported by NSF BNS9010538.

SECOND MESSENGERS AND GROWTH CONE MORPHOLOGY. Jane H. Viti, Cynthia Lance-Jones*, and Carl Lagenaur, Dept. Neurobiol., Univ. Pittsburgh, Pittsburgh, PA 15261.

Multiple extracellular signals have been shown to contribute to neurite outgrowth and growth cone guidance. Such cues activate intracellular signal transduction pathways which in turn lead to changes in growth cone morphology. Additionally, second messenger systems are likely to influence the ability of the growth cone to interact with specific cell adhesion molecules. Protein kinases and phosphatases might play a crucial role as second messengers which regulate neurite growth and migration. For these studies, mouse cerebellar cells were cultured on three different substrates; L-1, NCAM, and P84. Various kinase and phosphatase inhibitors were then administered to the cells and the effect on growth cone morphology was assessed. Cells grown on L-1 or NCAM which were exposed to genistein, a tyrosine kinase inhibitor, had more filopodia, both at the growth cone and along the neurite. Treated cells also exhibited more side branching of the neurite. When the cells were grown on P84, the effect of genistein was less obvious and the cells resembled those in the control. Interestingly, growth cones on P84 normally have extensive filopodia. The lack of effect of genistein on cells grown on P84 may reflect a difference in the role played by tyrosine kinases in cells growing on different substrates. When cells growing on L-1 were treated with okadaic acid, a serine/threonine phosphatase inhibitor, the growth cones became more lamellopodial or sheetlike in appearance. Okadaic acid-treated cells grown on NCAM seemed to have larger growth cones than the control cells. Okadaic acid did not seem to have an effect on cells grown on P84. Each of the inhibitors affect the cells differently and the effect each drug was substrate dependent. These results support the idea that protein kinases and phosphatases are involved in the regulation of growth cone morphology.

DISTRIBUTION OF PROTEIN KINASE C (α , β , γ SUBTYPES) IN REGENERATING GROWTH CONES OF RAT SCIATIC NERVE. S. Okajima, Y. Hirasawa, A. Mizoguchi and C. Ide. Dept. Orthopedic Surg., Kyoto Pref. Univ. Med., Kyoto 602 and Dept. Anatomy, Kobe Univ. Sch. Med., Kobe 650.

Protein kinase C (PKC) is an enzyme activated by diacylglycerol resulting from the receptor-mediated hydrolysis of inositol phospholipids and is involved in a variety of functions, including signal transduction, regulation of ion channels and neurotransmitter release, control of cell growth and differentiation, changes in cell morphology, and gene expression. In the present study, distribution of PKC (α , β , γ subtypes) was studied immunocytochemically in the normal nerve fibers and in the regenerating sprouts (growth cones) from nodes of Ranvier following crush injury in rat peripheral nervous system. Sciatic nerves of Sprague-Dawley male rats weighing 200-250 gms were ligated for 24 h and unligated 24 h prior to sacrifice. The animals were anesthetized with ether and perfused with 2% paraformaldehyde in PBS. The injured nerve segment was removed, embedded in OCT compound, quick-frozen, and cut on a cryostat. The sections were immunostained with anti-PKC α , β , γ subtype polyclonal antibodies (GIBCO/BRL) and after incubation in DAB solution containing 0.01% H_2O_2 , the sections were observed by light microscopy. For electron microscopy, some selected sections were dehydrated in a graded series of ethanol, followed by QY-1, and embedded in Epon 812. Ultrathin sections were made and viewed on an electron microscope. In the normal nerve, PKC (α , β , γ) immunoreactivity (IR) was present in all myelinated and unmyelinated axons. Electron microscopy showed that IR was localized on the axolemma and in a part of axoplasm. In the injured nerves, growth cones extending through the crushed area exhibited intense and diffuse PKC (α , β , γ)-IR in the axoplasm. Thus, PKC-IR is strong in growth cones and demonstrates a pattern of distribution that differs from that of the parent axon, suggesting that PKC may have important functional roles in axonal sprouting and in the regulation of growth cone activity in the peripheral nervous system.

448.5

LOCALIZATION OF RYANODINE RECEPTORS AT GROWTH CONES OF CULTURED NEURONS. Y. Ouyang*¹, J. Airey*², L.L. Sutko*² and M.H. Ellisman*¹. ¹San Diego Microscopy & Imaging Resource, Dept. Neurosciences, Univ. Calif. San Diego, La Jolla; ²Dept. Pharmacology, Univ. Nevada, Reno

In a previous investigation in chicken cerebellum, a developmental change in the distribution pattern of the beta or cardiac form of the ryanodine receptor (RyR) was observed (Ouyang et al., 1992, Soc. Nsci.). Immunolabeling for the beta or cardiac form of the RyR showed an increase in a staining pattern associated with parallel fibers in the cerebellar molecular layer between one to seven days posthatch. The change might be related to neurite extension in the molecular layer, where the increase may be required to regulate the intracellular calcium storage sites for the growth process. Also, since calcium release from caffeine-sensitive intracellular storage sites was reported to be crucial in NI-35-evoked growth cone collapse (Bandtlow et al., 1993, Science 259:80-3) and the RyR is a calcium release channel sensitive to caffeine, we decided to examine the RyR distribution within growth cones. Using a monoclonal antibody 34C, which recognizes all RyR isoforms in chicken, RyR-like immunoreactivity was observed within growth cones of chicken ciliary ganglion neurons and dorsal root ganglion neurons in primary cultures. Labeling was mainly concentrated in the lamellipodia of the growth cones, but not in the fine filopodia. The pattern of labeling was similar to that observed with alpha-tubulin in double-labeling experiments. This result suggests that the RyR gated calcium storage sites may be associated with the microtubule based cytoskeleton and/or transported into growth cones along microtubules. The IP3 receptor and cardiac SR Ca^{2+} -ATPase, two other proteins involved in intracellular calcium regulation, also exhibited a similar distribution to the RyR. The presence of RyR and other calcium regulatory proteins in growth cones suggests that calcium released from intracellular storage sites may play an important role in the regulation of growth cone dynamics.

INHIBITION OF PI 3-KINASE BLOCKS NERVE GROWTH FACTOR STIMULATED NEURITE OUTGROWTH AND MAINTENANCE IN PC12 CELLS. I. Blader*, T. Jackson*, C. Burga, A. Wolf, L. Fraser, L. Hammonds-Odie, and A. Theibert. Neurobiology Research Center/Department of Cell Biology, University of Alabama at Birmingham, Birmingham, Alabama 35294 and [†]Babraham Institute, Cambridge UK CB2 4AT.

In response to NGF, PC12 cells undergo morphological and biochemical changes, extending processes, called neurites, and differentiating into sympathetic neuron-like cells. NGF activates tyrosine kinases, phospholipase Cs and arachidonic acid release, leading to activated PKC, ras and MAP kinases. NGF also stimulates phosphoinositide 3-kinase (PI3K), which phosphorylates PIP₂, resulting in rapid, sustained increases in phosphatidylinositol 3,4,5-trisphosphate (PIP₃). We have used an inhibitor of PI3K, wortmannin, to investigate the role of PI3K in NGF signalling. Wortmannin (WM) inhibited *in vivo* NGF-stimulated increases in PIP₃ by direct inhibition of the catalytic activity without affecting recruitment to tyrosine phosphorylated complexes. At concentrations used (100nM), WM appeared to specifically inhibit PI3K since calcium responses to NGF or ATP were unaffected. In morphological studies, treatment of cells with WM resulted in inhibition (>80%) in the number of cells extending neurites in response to NGF. Application of WM to cells with existing neurites resulted in a rapid loss of neurites. Our results indicate that activation of PI3K may be required for neurite extension and maintenance in PC12 cells. Investigations are underway to identify targets for PIP₃, specifically cytoskeletal elements, and determine roles for PI3K in axonal or dendritic growth in cultured neurons.

Ca^{2+} SIGNALS AND NEURITE GROWTH INDUCED BY N-CADHERIN AND LAMININ IN CHICK NEURONS. J.L. Bixby*, G.B. Grunwald*, and R.J. Bookman. Dept. Pharmacology, University of Miami, Miami, FL 33101, & [†]Dept. Neurobiology, Thomas Jefferson Med. Coll., Philadelphia, PA.

We are interested in the intracellular signals underlying the induction of axon growth by substrate-bound growth-promoting factors. Previous studies indicate that cell adhesion molecules like N-cadherin promote neurite growth through the action of a PTX-sensitive G protein leading to the opening of voltage-sensitive Ca^{2+} channels, while integrin-dependent growth does not involve these pathways (Williams et al., J. Cell Biol. 124:1029, 1994). We have examined this hypothesis using chick ciliary ganglion (CG) neurons responding to purified N-cadherin and laminin (LN). When these proteins were used as substrates, neurite growth was insensitive to PTX. However, fura-2 imaging of single cells revealed that soluble forms of N-cadherin were able to induce increases in $[Ca^{2+}]_i$, when pressure-applied to neurons growing *in vitro*. Ca^{2+} increases could be seen both in cell bodies and in growth cones. N-cadherin-induced $[Ca^{2+}]_i$ increases were relatively insensitive to diltiazem and ω -conotoxin, but were very sensitive to $NiCl_2$. In addition, $NiCl_2$ but not diltiazem and ω -conotoxin, was able to inhibit neurite growth from CG neurons on N-cadherin or on LN. Although we have not yet obtained direct evidence for Ca^{2+} increases induced by LN, $NiCl_2$ decreases "resting" intracellular Ca^{2+} when added to neurons growing on LN, and we have seen spontaneous transient Ca^{2+} elevations in the growth cones of these neurons. Our results are consistent with a role for Ca^{2+} signals in neurite growth induced by N-cadherin and by LN, but suggest a revision of currently accepted models of signal transduction involving these proteins.

448.6

INTERCELLULAR ASSOCIATIONS STABILIZE MORPHOLOGICAL PLASTICITY AND CALCIUM RESPONSIVENESS IN HIPPOCAMPAL NEURONS. C.V. Williams*, P.J. Meberg, S.B. Kater. Dept. Anatomy & Neurobiology, Colorado State University, Fort Collins, CO 80523.

We have previously found that local changes in calcium can result in local morphological changes (i.e. filopodia induction) in isolated *Helisoma* neurons. The present study asked if: 1) local calcium rises can modify dendritic morphology of isolated hippocampal pyramidal neurons in culture and, 2) intercellular associations alter the magnitude of calcium rise and modify dendritic plasticity. Using a focal electric field, both local rises in intracellular calcium and filopodial extensions were induced from dendritic shafts of isolated hippocampal neurons. Since previous studies suggest that contact with glial cells alters calcium homeostasis, we asked if such intercellular associations would indeed alter calcium responsiveness and morphological plasticity in dendritic shafts. The average rise in intracellular calcium levels obtained in dendrites was nearly 2-fold lower in neurons contacting other cells than in isolated neurons. Irrespective of the type of contact (i.e., via axons or dendrites), neurons contacting other cells also had a significantly reduced frequency of filopodia induction in comparison with isolated neurons. These results indicate that factors which regulate calcium responsiveness may also regulate morphological plasticity. Local rises in calcium, such as induced in the present study could occur *in vivo* via presynaptic inputs or via the release of neurotransmitter from approaching axons during development. Subsequent morphological changes could lead to altered neuronal connectivity; in several cases, induced dendritic filopodia became new arbors in the dendritic tree. Thus tight regulation of intracellular calcium may be crucial for the establishment, maintenance and modification of neuronal architecture and the resultant neuronal circuitry.

448.8

DIFFERENTIAL CONTROL OF NEURONAL GROWTH CONE FILOPODIA: NERVE CELL TYPE-SPECIFIC REGULATORY MECHANISMS. V. Rehder* and S.B. Kater*, [†]Dept. of Biology, Georgia State University, Atlanta, GA 30302, and [†]Dept. of Anatomy and Neurobiology, Colorado State University, Ft. Collins, CO 80523

Neuronal filopodia serve as sensory extensions of neuronal growth cones as they navigate through a three-dimensional terrain towards their target. Given their function, their number and length critically determine the area a growth cone can actively survey. Changes in filopodial disposition were recently shown to be under physiological control, involving the concentration of the intracellular second messenger calcium in the snail *Helisoma* (Rehder 1992, J. Neurosci. 12:3175-3186) and the degree of protein tyrosine phosphorylation in *Aplysia* (Wu and Goldberg (1993) J. Cell Biol 123:654-664).

The present study tests treatments previously demonstrated to cause rapid filopodial elongation in several cell types *in vitro* to investigate whether the underlying mechanisms for filopodial elongation are general or neuron-type specific. With this comparative approach, including *Helisoma* neurons B5, chick DRGs, and chick ciliary ganglion neurons (CGN), we demonstrate that a defined stimulation such as raising the free intracellular calcium concentration, or inhibiting tyrosine kinase activity affects filopodial disposition (i.e. filopodial length and number) differently in different neuronal types. For example, KCl depolarization causes a decrease in filopodial number in *Helisoma*, an increase in chick ciliary ganglion neurons, and has no effect on chick DRGs. Tyrosine kinase inhibition leads to a dose-dependent increase in filopodial length in *Helisoma* neurons, while identical concentrations applied to CGN cause a spectrum of responses ranging from an increase to a decrease in filopodial length. Thus the filopodial parameters length and number which provide the growth cone with an optimal flow of information about its environment may be controlled in a neuron-type specific fashion. Such findings suggest that the implementation of a specific second messenger system for the control of a given growth cone function may depend upon the full spectrum of second messenger functions that must be served by a given neuronal cell type.

448.9

SECOND MESSENGER INVOLVEMENT IN PREGANGLIONIC GROWTH CONE COLLAPSE *IN VITRO*. James J. Walker* and Richard I. Hume. Department of Biology, University of Michigan, Ann Arbor, MI 48109.

Sympathetic preganglionic growth cones collapse and retract when they contact the processes of dorsal root ganglion neurons (DRG) *in vitro* (Moorman and Hume, 1990). The signals that trigger this behavior and the signal transduction mechanisms are unknown. In the present study we used time lapse video microscopy to determine whether inhibitors of specific second messenger systems prevent the collapse of preganglionic growth cones when they contact DRG neurites.

Preganglionic neurons were retrogradely labeled by Dil injections into the sympathetic chain of stage 30 chick embryos. Sixteen to 20 hours later the medial spinal cord containing the labeled preganglionic neurons was cut into small pieces and plated as explants on a laminin-coated substrate. After allowing several hours for these cells to extend neurites, DiO labeled DRG's were added to the dish and time lapse images were acquired. We examined preganglionic growth cone-DRG neurite interactions in the presence of pertussis toxin (100 ng/ml) or omega conotoxin GVIA (5 μ M). Cultures were pre-incubated in pertussis toxin for at least 2 hours prior to observation. For each growth cone studied, both surface area and length measurements were made at regular time intervals.

Our results show that pertussis toxin, a blocker of G protein activation, and omega conotoxin, a blocker of N-type calcium channels, inhibit the collapse of preganglionic growth cones when contacting DRG neurites. These findings suggest that calcium and a G protein may both play a role in mediating growth cone collapse in preganglionic growth cones.

448.11

INTRACELLULAR Ca^{2+} OF SENSORY AXONS DURING GROWTH IN CA-FREE MEDIA. Jun Fukuda, Kazuko Keino-Masu and Keiichi Torimitsu*, Laboratory of Molecular and Cellular Physiology, Department of Physiology, National Defense Medical College, Tokorozawa, Saitama 359, and NTT Basic Research Laboratories, Atsugi, Kanagawa 243-01, Japan.

Ca influx is essential for neurite growth and elongation in nerve cells. To examine the localization of Ca influx mediating axonal growth, we cultured newborn rat DRGs with their peripheral nerves in a specially designed 2-chamber dish, which allowed culture of the cell bodies and peripheral nerves in media of different Ca^{2+} concentrations. When the cut nerve ends were cultured in Ca-free medium, neurites whose length was 70-80 % of that in control cultures grew from the cut ends, as long as the cell bodies were in normal Ca medium. In contrast, neurites failed to grow from the cut ends that were bathed in normal Ca medium, when the cell bodies were cultured in Ca-free medium. We thus conclude that Ca influx at the cell body is crucial for regeneration of new axons, while Ca influx in the growing axon itself makes only a limited contribution. Measurement of intracellular Ca^{2+} level using fluo3 under a confocal laser microscope revealed that $[Ca^{2+}]_i$ was reduced from 150 nM (control culture) to 50-70 nM during growth in the Ca-free medium. No centro-distal gradient of $[Ca^{2+}]_i$ was observed in axons growing in Ca-free medium. As Ca influx is absent in the axon during growth in Ca-free medium, Ca^{2+} that enters at the cell body is apparently transported to the regenerating axon.

448.13

NEURONS AND GLIA USE PHOSPHOTYROSINE IN DIFFERENT ADHESIVE STRATEGIES *in vitro*. J.S. Deitch*, Cell Biol., UMDNJ-SOM, Stratford, NJ 08084

During development, neuronal processes are in constant contact with a substrate, other neurons, or glia. This study investigated the possibility that tyrosine kinases may transduce signals concerning adhesion in neurons and glia. Hippocampal neurons from E18 rat embryos or glia from P3 rats were plated on poly-L-lysine (1 mg/ml) -treated coverslips. A monoclonal anti-phosphotyrosine (PY) antibody (4G10, UBI), and α -mouse-Texas Red, labeled short (2-3 μ m) dashes located mostly at the periphery of glia cells, which coincided with the ends of actin cables, as determined by double-labeling with phalloidin-FITC (Sigma). Conversely, 4G10 labeling of hippocampal neurons (1-14 days *in vitro*) was very dim and diffuse (no dashes). Phalloidin intensely labeled the growth cones and filopodia of neurons at all ages examined, but glial-like actin cables were absent. Cultures were treated with 1 mM sodium vanadate (VO_4), a phosphotyrosine phosphatase inhibitor, to enhance a possible weak tyrosine kinase activity in neurons. Labeling remained dim up to 6 hrs in VO_4 . By 9 hrs, 20% of the neurons were labeled more intensely, especially in patches on the surface contacting the substratum. Furthermore, axons and dendrites were flattened considerably and covered with filopodia. After 18 hrs in VO_4 , labeled neurons possessed beaded axons: brightly labeled enlargements connected by thin strands of axon. Some neurons began to disintegrate. Neurons allowed to recover for 6 hr in VO_4 -free media regained normal cylindrical processes, and 4G10 labeling returned to near control levels. Conversely, VO_4 treatment of glia resulted in a progressive loss of 4G10 staining, and some glia became more angular. With recovery the dashes reappeared. In both neurons and glia, actin labeling disappeared with time in VO_4 and returned with recovery. These observations suggest that glia utilize a tyrosine kinase in relation to actin filaments in their adhesion strategy, similar to fibroblasts. Neurons may also require PY for adhesion, but keep PY levels low in their processes, perhaps to enhance growth by limiting adhesion.

448.10

THE EFFECT OF cAMP/PROTEIN KINASE A AND TPA/PROTEIN KINASE C ON THE NEURITE OUTGROWTH OF MOUSE NEUROBLASTOMA N1E115 CELLS

H.Li, W.-H.Tsai*, and F.L.Huang, NICHD, NIH, Bethesda, MD

The neurite outgrowth (NOG) of N1E115, mouse neuroblastoma cell line derived from C1300 clones, can be induced by 1mM 8-Br-cAMP or cAMP-raising agents. The mechanism of 8-Br-cAMP induced NOG is not clear. Here the mode of N1E115 cell differentiation induced by 8-Br-cAMP and the crosstalk between cAMP/PKA and TPA/PKC signal pathways were investigated. Treatment of N1E115 with TPA, either simultaneously or briefly before the addition of cAMP, resulted in the inhibition of NOG induced by 8-Br-cAMP. However, such inhibition was released after prolonged TPA treatment. Most importantly, these phenomenon were not affected by the presence of 10 μ M cycloheximide. By immunoblot analysis, PKC β 1 and PKC ζ were found to be present in N1E115 cells. While brief treatment of cells with TPA effectively translocated PKC β 1 from cytosol to membrane, long-term treatment nearly completely down regulated this PKC isoform. Similar treatments, however, had no effect on PKC ζ . Furthermore, TPA enhanced the phosphorylation of several proteins especially that of a Mr=90K protein on SDS/PAGE. In comparison, cAMP greatly reduced the phosphorylation of this 90kDa protein. These results indicate that NOG is likely associated with the dephosphorylation of the 90kDa protein which is directly or indirectly promoted by the cAMP/PKA reaction(s). On the contrary, TPA/PKC (likely PKC β 1) may block the NOG through promoting its phosphorylation.

448.12

EXPOSURE TO VOLATILE ANESTHETICS AFFECTS PROTEIN PHOSPHORYLATION IN DEVELOPING NEURONAL TIPS. S. Saito, T. Fujita, M. Igarashi*, *Department of Molecular and Cellular Neurobiology, and *Department of Anesthesiology and Reanimatology, Gunma University School of Medicine, Maebashi, Gunma 371, Japan.

The biochemical characteristics of developing neural tips (growth cones) was examined after exposure to anesthetics to elucidate molecular mechanisms of neuroteratogenicity by general anesthetics. Neonatal rats were exposed to an atmosphere containing inhalational anesthetics, 1% halothane or 75% nitrous oxide, or a control atmosphere for 6 hours at postnatal day 1. After this exposure, growth cone particles were isolated from forbrains using a subcellular fractionation method at postnatal day 2,3,4 and 5. Protein composition, phosphoprotein patterns and protein kinase C (PKC) activities of the isolated growth cones were compared between each group exposed to the anesthetics and the control group. Calcium-dependent protein phosphorylation of a 46 kDa protein and of an 80 kDa protein, which is reported to be mediated by PKC, were significantly reduced after exposure to the anesthetics. Direct assays of PKC activity in growth cone particles have indicated that PKC activity in the growth cone is decreased at 24 hours after exposure to 1% halothane, and after exposure to 75% nitrous oxide. Considering crucial roles of growth cones in the establishment of the neuronal network, interruption of signal transduction in growth cones at a critical time for axonal pathfinding, is possible to provoke long lasting alteration of neural network.

PROTEIN PHOSPHORYLATION REGULATES DENDRITE BRANCHING IN CULTURED RAT HIPPOCAMPAL NEURONS. G. Audesirk*, M. Kern, and L. Cabell. Biology Department, Univ. of Colorado at Denver, Denver, CO 80217-3364.

The microtubule-associated protein MAP2 is preferentially localized in dendrites. Friedrich and Aszodi (1991) have hypothesized that increased phosphorylation of MAP2 stimulates dendrite branching. We tested this hypothesis by culturing rat hippocampal neurons with selective inhibitors of protein kinases (calphostin C: inhibits PKC; KT5720: inhibits PKA; KN62: inhibits Ca^{2+} -calmodulin-dependent protein kinase) or phosphatases (okadaic acid). We found that dendrite branching was significantly inhibited by KN62, but not by calphostin C or KT5720 at comparable concentrations. Dendrite branching was enhanced by okadaic acid. Western blots immunostained for MAP2 show that culturing neurons with okadaic acid shifts the apparent molecular weight for MAP2c (the low molecular weight, juvenile form of MAP2) to higher values, consistent with increased phosphorylation. Culturing neurons with KN62 shifts the apparent molecular weight of MAP2c to lower values, consistent with decreased phosphorylation. These results suggest that increased protein phosphorylation enhances dendrite branching, whereas decreased phosphorylation, at least by CAM kinase, inhibits dendrite branching. Although there are undoubtedly many proteins whose phosphorylation is altered by inhibitors of protein kinases and phosphatases, our data are consistent with a specific role for phosphorylation of MAP2 in regulating dendrite branching.

MONOCLONAL ANTIBODY PHAGE DISPLAY LIBRARIES FROM MICE IMMUNIZED WITH THE INTRACELLULAR DOMAIN OF A LEECH RECEPTOR PROTEIN TYROSINE PHOSPHATASE. M.N. Nitabach* & E.R. Macagno Dept of Biological Sciences, Columbia University, New York, NY 10027.

We have previously identified a leukocyte antigen-related (LAR) receptor protein tyrosine phosphatase (rPTase), *HmLAR2*, which is localized to a set of identified growth cones in the embryonic medicinal leech, *Hirudo medicinalis*. We are interested in the role played by *HmLAR2* in the regulation of the motility and pathfinding ability of these growth cones. Like all rPTases, those of the LAR subfamily possess an intracellular catalytic domain and an extracellular domain resembling a cell-adhesion molecule. Affinity-purified polyclonal antibodies were raised in rabbits against the intracellular domain of *HmLAR2*, and used to detect *HmLAR2* protein both *in situ* in fixed embryos, and on Western blots of total embryonic protein. However, for use as function blocking reagents for intracellular injection, we desired monoclonal antibodies reactive to various *HmLAR2* intracellular epitopes.

In order to obtain such reagents, we have generated a monoclonal antibody phage display library from the spleen of a mouse hyperimmunized with the bacterially-expressed *HmLAR2* intracellular domain. PCRs were performed using spleen cDNA as template, and primers designed based on IgG heavy and light chain sequences. Fab fragments are expressed as a fusion with the filamentous phage gIII coat protein. Thus, upon superinfection with helper phage, the antibody is expressed on the surface of a phage particle which contains the genetic material which encodes that particular Fab fragment. This system allows for the affinity purification of phages on immobilized *HmLAR2*, followed by amplification of the recovered phages in a suitable bacterial host. The affinity purification-amplification can then be iterated until the desired enrichment of *HmLAR2*-binding phage clones has been achieved. Individual clones can then be isolated and assayed individually for *HmLAR2* reactivity. We are now in the process of analyzing clones from this library.

AXON GUIDANCE IN THE VISUAL SYSTEM

449.1

THE FUNCTION OF THE OPTIC DISC AND THE RETINAL PERIPHERY IN THE ONTOGENY OF THE CENTRIPETAL PATTERN OF OPTIC AXONS IN THE RETINA

W. Halfter* Dept. of Neurobiology; University of Pittsburgh

In the early embryonic retina optic axons grow toward the optic disc and form a centripetal axon pattern. To address the question whether the directed growth of axons results from an attraction by the optic disc or from repulsion by the retinal periphery pieces of donor retina were grafted to ectopic sites of E3 organ-cultured eyes. After 24-48 hrs the eyes were studied for alteration in the axonal pattern as a result from the transplants. 1. Peripheral donor retina grafted into the central position of the host are non-permissive for growing axons. 2. The grafting of an optic disc to an ectopic site of the host and the removal of the original optic disc caused a major rerouting of axons to the grafted optic disc. 2. Axons encountering the grafted optic disc left the optic fiber layer to exit the eye. The experiments demonstrate that the centripetal pattern of axons in the retina is caused by a repulsion of axons by the retinal periphery and by a local attraction by the optic disc. The optic disc operates as an exit for the axons from the eye into the optic nerve.

bFGF DISRUPTS TECTAL RECOGNITION IN THE DEVELOPING VISUAL SYSTEM OF XENOPUS. S. McFarlane* and C.E. Holt Dept. Biology, Univ. of California San Diego, La Jolla, CA 92093.

We are investigating the molecular cues that developing retinal ganglion cell (RGC) axons of *Xenopus laevis* use to recognize and synapse with their tectal target. Since growth factors are known to affect neuronal differentiation, are spatially and temporally regulated in the developing brain, and are expressed in the target cells of some neurons, it is possible that they may be involved in these recognition events. The fibroblast growth factor (FGF) family and its receptors have been found in the visual system; therefore, we have investigated the role of one member, basic FGF (bFGF), in target recognition.

A recombinant form of *Xenopus* bFGF (XbFGF) was applied to exposed embryonic brain preparations during the period when RGC axons grow from the optic chiasm to the tectum (stage 33/34 to 40). Axons were visualized with HRP at stage 40. XbFGF (0.5-5nM) severely affected retinotectal targeting. In the majority of cases (94%, n=19), axons failed to enter the tectum, instead, they skirted around the diencephalon/tecal border, growing rostrally towards and occasionally over the dorsal midline, and ventrally towards the medulla. We performed timing experiments in an attempt to elucidate XbFGF's action. First, XbFGF was applied at stage 33/34 for 2 hours. This early pulse was sufficient to disrupt target recognition (90%, n=19). Concordantly, if XbFGF application was delayed until stage 37/38, when the first RGC axons usually reach the tectum, target recognition was essentially normal. These results indicate that XbFGF needs to be present early on, for a short period of time, to exert its effects. Immunostaining shows that exogenous XbFGF binds to nerve fibers in the developing brain, including RGC axons, raising the possibility that bFGF acts on the RGCs themselves. These findings suggest that bFGF may play a role in target recognition. (Supported by NIH #NS23780, PEW Scholars Award and MRC of Canada)

CHONDROITIN SULFATE INTERFERES WITH RETINAL GANGLION CELL AXON PATHFINDING IN THE VISUAL SYSTEM OF XENOPUS A. Walz* and C.E. Holt Dept. of Biology, UCSD, La Jolla, CA 92093-0357.

The axons of developing retinal ganglion cells (RGC) navigate along a defined route to reach their target, the optic tectum. Pathfinding is mediated by specific interactions between the growth cones and the substrate presented by the local environment. We investigated the putative involvement of chondroitin sulfate (CS) in the development of the retinotectal projection.

Exposed brain preparations were used to investigate the influence of free CS on the developing optic projection during the period when RGC axons grow from the base of the optic tract to the tectum (stages 33/34 to 40), and axons were visualized with anterograde HRP at stage 40. In contrast to other bath applied glycosaminoglycans, CS (200µM) showed a dramatic effect on pathfinding. The tract was highly broadened with axons growing virtually over every area of the telen- and diencephalon. These widened tracts were not shorter and growth cone morphology did not appear to be different compared to controls. Immunolabeling revealed that normal CS expression in the neuropil overlapped with RGC axon staining showing that RGC axons grow on a CS rich substrate.

Explanted intact eyes grown in culture on a laminin (LN) substrate with CS (1mg/ml) added to the medium did not show any change in either neurite outgrowth or elongation. However, when explanted eyes were grown on a CS/LN substrate, a dose dependent inhibitory effect on neurite outgrowth was observed, suggesting that even though CS does not inhibit growth per se, it may direct growth toward lower CS concentrations in the embryo during pathfinding. Chondroitinase ABC and xylosides were used to create CS free embryos and the pathfinding behavior of RGC axons was examined. (Supported by NIH #NS23780 and PEW Scholars Award)

PERTURBATION OF G-PROTEIN FUNCTION AND RETINAL GROWTH CONE BEHAVIOR. C.-B. Chien*, A.T. Benedict and W.A. Harris Dept. of Biology, UC San Diego, La Jolla, CA 92093-0357.

Heterotrimeric G-proteins are ubiquitous intermediates in signal transduction which are enriched in growth cone membranes. We are studying their possible function in the guidance of *Xenopus* retinal growth cones both *in vitro* and *in vivo*.

In culture, the wasp venom peptide mastoparan (MP), which directly activates G proteins, has been shown to cause growth cone collapse [Igarashi *et al.*, (1993) *Science* 259:77]. Furthermore, this collapse was prevented by pretreatment with pertussis toxin (PTX), which inactivates G proteins by covalent modification. We have obtained similar effects with *Xenopus* retinal growth cones in culture. 10 µM MP applied for 30 min increased the fraction of collapsed growth cones (lacking either filopodia or lamellipodia when viewed with Nomarski optics) from 27±2% (control, *±s.e.m.*) to 69±3%. Preincubation for 2 h with 200 ng/ml PTX before MP treatment reduced the fraction of collapsed growth cones to 51±2%, while treatment with PTX alone gave 41±2% collapse. Viewed in time-lapse, the effect of MP was quick and dramatic: within a few minutes of MP addition, growth cones first retracted their lamellipodia, then their filopodia, and eventually collapsed altogether.

Applying 10 µM MP for 2 h to retinal growth cones *in vivo* using an exposed-brain preparation, we find similar effects: 53% of growth cones were collapsed, compared with 12% in control brains. We are currently investigating whether PTX can protect against collapse *in vivo*, and whether MP or PTX perturb retinal axon pathfinding or arborization, which would indicate a role for G-proteins in the signal transduction pathways used for normal growth cone guidance and target recognition.

CHICK RETINAL AXONS BRANCH PREFERENTIALLY ON MEMBRANE STRIPES DERIVED FROM TOPOGRAPHICALLY APPROPRIATE TECTUM. A.L. Roskies* and D.D.M. O'Leary. Molecular Neurobiology Lab, Salk Institute, La Jolla CA 92037.

Membrane-bound molecules with position-dependent distributions are hypothesized to guide or restrict growing retinal axons to topographically appropriate sites in their central targets. In vivo studies in developing chicks and rats indicate that retinal axons form topographically ordered arbors by the extension of collateral branches along their length. We have recently reported that E18 rat temporal retinal axons grown perpendicular to membrane lanes derived from rostral and caudal E18 superior colliculus (SC) branch preferentially on rostral SC membranes due to an inhibitory molecule PI-anchored to caudal SC membranes.

To determine whether chick retinal axons exhibit a branching specificity similar to that found for rat, we have grown E6 chick retinal explants on carpets of alternating lanes of membrane fragments from rostral and caudal E9 chick tecta. Temporal chick retinal axons show a consistent branching preference for their topographically appropriate rostral membrane lanes. Nasal axons show no consistent preference. Time-lapse videomicroscopy of the stripe assay cultures reveals that branches form interstitially along the axon shaft, as they seem to in vivo, as well as by growth cone bifurcation. Thus, in chick, as in rat, the topographic bias in retinal axon branching observed in vivo may be controlled by membrane bound molecules. Further time-lapse microscopy of branch formation will allow us to determine whether the observed branching preference is a result of substrate-influenced branch initiation or branch stabilization.

TOPOLOGICAL SPECIFICITY IN REINNERVATION OF THE SUPERIOR COLICULUS BY REGENERATED RETINAL GANGLION CELL AXONS IN ADULT HAMSTERS. Yves Sauvé, Hajime Sawai, Michael Rasminsky. McGill University Centre for Research in Neuroscience, Montreal General Hospital Research Institute, 1650 Cedar Ave., Montréal, QC, Canada, H3G 1A4.

In rodents, nasal and temporal retinal ganglion cells (RGCs) project their axons to caudal and rostral contralateral superior colliculus (SC) respectively. We have examined the projections of RGC axons regenerated through unbranched peripheral nerve grafts led from the eye to the contralateral SC in adult hamsters. Responses to visual stimulation were recorded from terminal arbors of individual regenerated RGC axons and the postsynaptic neurons with which they make synapses in the reinnervated SC. RGC positions in the retina corresponding to these terminal arbors were inferred from the location of their visual receptive fields on a tangent screen. 6 to 63 RGCs with projections to the SC were identified in 11 animals 30 to 60 weeks after grafting.

At a given site in the SC, recordings could be made from axon terminal arbors emanating from widely separated RGCs. Conversely, nearby RGCs could project to widely separated sites in the SC. The relative position of each possible pair ($n=2695$) of RGCs was determined with respect to the nasotemporal axis of the retina; relative positions of the axonal projections of these RGCs were inferred from the caudorostral displacement of corresponding sites of responses in the SC. Pairs were excluded as ambiguously oriented if the direction of displacement fell beyond $\pm 45^\circ$ from the nasotemporal axis in the retina or $\pm 45^\circ$ from the caudorostral axis in the SC. Of the 1016 evaluable pairs of RGC projections, 622 had appropriate and 394 inappropriate caudorostral displacements in the SC. Although normal retinotectal topography is not reproduced, this 3:2 preference for appropriate projection suggests that RGC axons may recognize caudorostral positional cues as they reinnervate the SC.

THE ORIGIN AND COURSE OF RETINO-FUGAL AXONS DURING NORMAL DEVELOPMENT OF THE FERRET. G.E. Baker and R.J. Colello (SPON: Brain Research Association). Department of Human Anatomy, University of Oxford, South Parks Road, Oxford OX1 3QX, U.K.

Developing retinal ganglion cell axons grow into either the contralateral or ipsilateral optic tract. We have studied the course of these axons in fetal ferrets to examine their development and to determine if their preciasmatic organization at any age might predispose them to a crossed or uncrossed course at the optic chiasm.

Pregnant jills were deeply anesthetized and fetuses were fixed with 4% paraformaldehyde. Retinal implants of the tracer Dil were made to label axons from one eye, and unilateral optic tract implants were made to label the uncrossed axons and ganglion cells of one eye, and the crossed population of the other.

Retinofugal axons were first observed in the optic tracts at E25. Between this age and E27 the distributions of ganglion cells giving rise to the first uncrossed and crossed axons overlap in the dorso-central retina, as previously found in mice and rats (Godement et al, Development 101, 515; Chan et al, JCN 336, 362). The ipsilaterally-projecting cells have no apparent preferred location within that region. Behind the eye, the uncrossed axons are widely dispersed but become increasingly concentrated laterally closer to the optic chiasm where few are found in medial locations. A narrow ventrotemporal (VT) crescent of ipsilaterally-projecting cells is first observed at E28 and broadens at later stages. The distribution of axons in the optic nerve at this and later ages contrasts with the earlier stages and resembles that of the adult; postoptically the majority of uncrossed axons are concentrated ventrolaterally, becoming more dispersed along the course of the nerve. At the chiasm many are found in a medial location. At no age are the uncrossed and crossed axons segregated preciasmatically.

We conclude that spatial location in the preciasmatic nerve may determine the uncrossed path of the earliest fibres but is not relevant for the later VT component.

DEVELOPMENT OF CROSSED AND UNCROSSED VISUAL PATHWAYS IN PIGMENTED AND ALBINO MICE. R.C. Marcus* and C.A. Mason. Dept of Path, Coll Phys Surg, Columbia Univ, NY, NY 10032.

In the mammalian visual system optic axons project to both sides of the brain. Compared to pigmented mice, in albino mice, a smaller number of retinal ganglion cells project ipsilaterally. To determine the site of action of the albino mutation, we studied the projection pattern of retinal ganglion cells and the environment they traverse in albino mice between E12.5 and E15.5. Dil was used to label either the entire eye or ventro-temporal retina which gives rise to the ipsilateral pathway. In pigmented mice, the retinal origin and pattern of growth of the earliest optic axons differs from the later, permanent optic projection (Marcus and Mason, Soc Neurosci Abstr, 1993). In albino mice, although decreased in size, the ipsilateral projection followed the normal pattern of growth at all ages. Thus, the reduction in the ipsilateral projection is not due to a defect in either the early or late pattern of growth. In addition, immunocytochemical labeling of the albino chiasm with MAb RC2 which recognizes radial glia, MAb F4/80 which recognizes microglia, and MAb 480-1.1 against the stage specific embryonic antigen was normal, suggesting that the albino mutation exerts its effects in the retina.

To further test this hypothesis we are studying "chimeric" cultures in which explants of pigmented retina are co-cultured with chiasm cells dissociated from albino animals at E14 - E15. In pigmented mice, crossed and uncrossed axons respond differentially to dissociated chiasm cells (Wang et al, Soc Neurosci Abstr, 1992). Preliminary results reveal that uncrossed axons from pigmented animals grown on chiasm cells from pigmented or albino animals behave similarly, i.e., neurites from uncrossed axons are shorter and more fasciculated compared to neurites from crossed axons. These results are consistent with the hypothesis that cells in the developing optic chiasm are unaffected by the albino mutation and that the mutation acts at the retinal level.

449.8

AN ANTIGEN IN THE OPTIC PATHWAY IS EXPRESSED IN EYELESS ANIMALS. Nielsen Fernandez and Sally Hoskins. Department of Biology, City College of the City University of New York, New York, NY 10031.

To analyze the molecular basis of axon guidance in the developing optic nerve of the frog *Xenopus laevis*, we made monoclonal antibodies to optic tract membrane fragments and produced gro1, which stains the optic nerve projection to the optic tectum beginning at embryonic stages. As reported previously, the pathway to the thalamus and the thalamic target zones are not stained by gro1, raising the possibility that the gro1 antigen plays a role in optic axon target selection.

To examine whether all of the staining seen in the optic pathway was associated with the optic nerve, we deleted optic cups from early embryos, and assessed gro1 immunoreactivity in cryostat sections of eyeless brains at tadpole stages. Eyeless tadpoles showed gro1 immunoreactivity in the position normally occupied by the optic chiasm, as well as in a line of cells marking the position of the optic tract along the wall of the diencephalon, and in the optic tectum. We conclude that the gro1 antigen is associated both with the developing optic nerve and with its pathway, raising the possibility that early gro1 expression in the optic pathway marks the route taken by the subset of retinal ganglion cell axons that projects to the optic tectum. Experiments in progress will establish how early the pathway-associated gro1 appears.

A STUDY OF THE MICROENVIRONMENT IN THE EMBRYONIC MOUSE OPTIC CHIASM. S.J. Tavendale and L.A. Coleman*. Dept. of Human Anatomy, Oxford University, South Parks Rd, Oxford, UK, OX1 3QX.

In the developing visual system, retinal ganglion cell axons navigate through a range of environments to reach their final destination. We have studied the microenvironment in the developing mouse optic chiasm (OC) electron microscopically. Mouse embryos (at E16) were perfused and processed for EM analysis. In a 100µm deep ventro-dorsal strip of the lateral OC, 150-200µm from the midline, axon and growth cone (GC) densities and GC shapes were plotted. Using serial sections, the relationships of GCs to glial cells at the ventral surface and in a region 50µm dorsally were studied and the relative frequencies of specialized membrane junctions were also compared. Axon density increased with distance from the pial surface, peaking at 60µm and remaining constant (at around 300-350 axons/100µm²). GCs were found throughout the depth of the OC. Those close to the pial surface represented a much higher proportion of axon profiles and were larger and more bulbous compared with the thin, elongate and branched GCs seen dorsally. Serial section reconstructions confirmed these impressions. At the ventral surface, glial endfeet separated GCs from the basement membrane but not all GCs grew along endfeet and this area was not as rich with glial cell processes as the dorsal region, where portions of all GCs were in apposition to glial processes. Specialized membrane junctions occurred most frequently between axons and glial processes or GCs and glial processes and were characterized by an invagination where the glial cell membrane was darker, thicker and slightly fuzzy in appearance. Portions of axons or GCs often occupied this concavity and across the cleft between the two membranes fine filaments were seen. Dorsally these junctions were twice as frequent between axons and glial cell processes as between GCs and glial processes but were seen with equal frequency ventrally. We have shown that although GCs are present throughout the ventro-dorsal extent of the OC, both the environment and GC morphology varies. The nature of these environments may constrain or determine the range of GC morphologies in different regions of the OC.

SUBTRACTIVE cDNA LIBRARY SCREEN FOR GENES UPREGULATED OR DOWNREGULATED AFTER DEAFFERENTATION OF THE RAT SUPERIOR COLLICULUS. A. D. Crawford¹, F. Bonhoeffer¹, and M. Bähr^{1,2}. Max-Planck-Institut für Entwicklungsbiologie¹, and Neurologische Universitätsklinik², 72076 Tübingen, Germany.

During development of the vertebrate visual system an orderly projection of retinal ganglion cells onto the superior colliculus is established. The molecular mechanisms that might govern this process are still unknown, but probably include the coordinated interaction of target-specific axon guidance molecules and their corresponding growth cone receptors. Until recently, it was believed that in higher vertebrates, these molecules are only expressed during the actual formation of the retinocollicular projection. However, it was recently shown that cell-surface guidance activities that are not normally detectable in the superior colliculus (SC) of the adult rat reappear following deafferentation of the SC through axotomy of the optic nerve (Wizenmann *et al.*, 1993). We have initiated a subtractive cDNA library screen to clone the genes encoding these guidance molecules, or possibly those molecules that are responsible for masking them in the normal adult. The subtraction protocol involved multiple rounds of hybridization of cDNA from deafferented SC with an excess of biotinylated cDNA from normal SC, and vice versa, each round followed by extraction with streptavidin and PCR amplification of the remaining cDNA (Wang and Brown, 1991). The resulting subtracted cDNA libraries, one highly enriched for genes that are upregulated after deafferentation, the other for downregulated genes, were then differentially screened to identify these upregulated and downregulated clones. In an initial pilot screen of about 250 clones from each library, 16 upregulated and 7 downregulated clones were identified. These clones are currently being subjected to sequence, Northern, and *in situ* analysis. In addition, full-scale screens of about 5000 clones from each library are currently in progress. The differences in expression in normal versus deafferented SC of those clones isolated to date varied from 2-fold to at least 10-fold, with 2 upregulated clones showing no detectable expression in normal SC.

PRECOCIOUS INVASION OF THE OPTIC STALK BY TRANSIENT CENTRIFUGAL AXONS IN THE FERRET. B.E. Reese* and S.F. Geller. Neuroscience Research Institute and Departments of Psychology and Biology, University of California at Santa Barbara, CA 93106-5060

The present study demonstrates 1) that the fetal optic nerve contains a conspicuous population of centrifugal axons; 2) that the cells of origin are situated in both the ventrolateral diencephalon and in the chiasmatic region; 3) that the projection is transient, and never invades the retina itself; and 4) that these centrifugal axons invade the optic stalk prior to the arrival of the retinofugal axons. Fetal ferrets (E-22 through E-36) were fixed with 4% paraformaldehyde and examined using Dil to trace the retinofugal and centrifugal pathways. In addition, we used β -tubulin immunohistochemistry to detect the differentiation of the first axons within the retina and optic stalk.

Dye implants into the optic nerve head, but not the retinal periphery, retrogradely label somata in the ventrolateral diencephalon, provided the implants are made in fetuses before E-30. Likewise, dye implants into this region of the diencephalon, rostral to the optic tracts, anterogradely label centrifugal axons that course through the optic nerve but never enter the retina. The centrifugal axons course ventrally from their cells of origin as 2-5 fascicles and turn laterally to enter the optic nerve where it emerges from the hypothalamus. Some of the fascicles course extra-cerebrally for a short segment at this junction, as described by Guillery and Walsh (*J. Comp. Neurol.* 1987a, 265, 203; 1987b, 265, 218).

The optic nerve head and retinal fiber layer are immunoreactive for β -tubulin on E-24 and thereafter, whereas on E-22, they are immunonegative. Yet immunopositive fascicles of axons course from the ventral diencephalon into the optic stalk on E-22, confirming the precocious nature of the centrifugal projection. These fascicles are identical in trajectory to the centrifugal axons which are still readily labelled by dye implants into the future optic nerve head on E-22. These same implants on E-22, and only on E-22, also label cells in the future chiasmatic region, situated immediately ipsilateral to the midline.

These centrifugal axons may serve a transient, guidance, function for later developing optic axons. The cells situated at the midline may additionally play a signalling function for optic axons as they invade the optic chiasm. The existence of these centrifugal axons complicates the identification of early-developing optic axons in otherwise unlabelled tissue.

FORMATION AND SPECIFICITY OF SYNAPSES III

450.1

FASCICLIN III AS A SYNAPTIC TARGET RECOGNITION MOLECULE IN DROSOPHILA. A. Chiba¹, P. Snow² & Y. Hotta¹. ¹Dept. Physics, Univ. Tokyo, Tokyo, Japan, & ²Dept. Biol., SUNY, Albany, NY.

Motoneuron RP3 consistently innervates muscles 6 and 7 in *Drosophila* embryos. During RP3 synaptogenesis, the cell surface glycoprotein fasciclin III appears in both the RP3 growth cone and muscles 6 and 7. As fasciclin III has been shown to be a homophilic adhesion molecule, such expression raises the possibility that it may function as a specific "target recognition molecule" for RP3. We have tested whether fasciclin III is necessary and/or sufficient for RP3 target selection *in vivo* by examining the effects of deletion or misexpression of this molecule as assessed by intracellular dye injection and immunocytochemistry. First we have found that in the existing *fasciclin III* null mutant RP3 reliably forms synapse with its normal targets. Next, we have generated transgenic flies which misexpresses fasciclin III ectopically on all skeletal muscles during neuromuscular synaptogenesis. This was accomplished by creating a construct which placed the *fasciclin III* gene under the control of the *Myosin heavy chain* promoter, and transforming this construct into flies by P element-mediated genomic transformation. In these transformant flies, we have observed that RP3 often innervates non-target muscle cells while other motoneurons (e.g. RP1) innervate their targets normally. Therefore, this provides single cell-level evidence supporting that fasciclin III functions as a specific "synaptic target recognition molecule" for a small set of neuronal growth cones. Furthermore, taken together with the analysis on the null mutation, the results also suggest that fasciclin III is one member of a set of functionally redundant recognition molecules which are involved in an "either/or" manner during target recognition by RP3. Controlled misexpression of such recognition molecules is an effective approach to determining the functional roles of these proteins *in vivo*, which may be difficult to confirm by analysis of null mutations alone.

A MONOCLONAL ANTIBODY RECOGNIZING A PUTATIVE GUIDANCE MOLECULE REVEALS AN ANTERIOR-POSTERIOR GRADIENT IN THE EMBRYONIC TECTUM OF CHICK AND RAT. B.K. Müller * and F. Bonhoeffer. Max-Planck-Institut für Entwicklungsbiologie, Spemannstrasse 35, D-72076 Tübingen, Germany.

Gradients of directional cues have been proposed to be important for the guidance of retinal ganglion cell axons to their tectal target cells. *In vitro* temporal retinal axons can detect concentration differences of glycosylphosphatidylinositol (GPI) anchored guidance molecules (33/35 kD; Stahl *et al.*, Neuron 5, 1990) expressed predominantly on membranes from the posterior part of the optic tectum. We have isolated a monoclonal antibody (F3D4) recognizing these molecules. The antigens of the F3D4 antibody are also found in fish and rat. On cryostat sections from embryonic chick tectum, antibody staining revealed a gradient in the outermost tectal layer, decreasing from the posterior to the anterior pole of the optic tectum. Strongest immunoreactivity is observed in the stratum opticum (SO) and some immunoreactivity is also found in the stratum griseum et fibrosum superficiale (SGFS). In a preparation free of neuronal elements, F3D4 stained glial endfeet. F3D4 antigens are expressed in embryonic chick and rat tectum, before and during the time of retinal axon ingrowth and not thereafter. These observations suggest that the F3D4 antigens might be important for the construction of the retinotectal map.

MOTONEURONS DISCRIMINATE APPROPRIATE FROM NOVEL TARGETS DURING SYNAPSE FORMATION IN CULTURE. J. C. Poyer and M. J. Zoran*. Department of Biology, Texas A&M University, College Station, TX 77843.

Neuron B19 innervates the supralateral radular tensor (SLrT) muscle of the *Helisoma* buccal musculature. This neuromuscular synapse reforms in culture and its regeneration requires target-dependent induction of secretion capabilities. The presynaptic mechanism underlying this induction involves modifications in secretory function such that action potentials, uncoupled from secretion prior to contact, evoke neurotransmitter release following SLrT muscle contact.

Previous studies have shown that novel muscle targets, not typically innervated by B19, vary in their ability to induce secretory changes. For example, contact with supramedial radular tensor (SMrT) muscle causes an enhancement of secretory capabilities while contact with foot (POD) muscle fibers does not. Based on these results, we hypothesize that B19 has the capacity to recognize specific muscle fibers and that muscle contacts trigger different presynaptic secretory responses. Our hypothesis maintains that mechanisms responsible for these differential changes govern discriminate synapse formation. To further test the ability of B19 to discriminate between muscle targets, dual target-contact experiments were performed where single B19's were contacted in culture by two muscle partners. After 3 days of contact, rates of spontaneous synaptic potentials (SSPs) and the presence of evoked synaptic potentials were assayed. In B19-SLrT/SMrT preparations (n=24), SSP rates detected from SLrT- and SMrT-contacted neurites were 9.6 and 1.6 SSPs/min, respectively. Evoked release was detected from 20% of SLrT- and 13% of SMrT-contacted neurites. In B19-SLrT/POD preparations (n=15), SSP rates detected from SLrT- and POD-contacted neurites were 3.0 and 1.1 SSPs/min, respectively. Evoked release was detected from 50% of SLrT-contacted neurites and never in POD-contacted neurites. These data, taken together with mechanistic studies, suggest that specific neuron-muscle contacts can regulate secretory properties of motoneuron B19 in a cell-specific manner.

450.3

ACTIVITY REGULATES THE SEGREGATION OF PRESYNAPTIC INPUTS ON A COMMON POSTSYNAPTIC TARGET IN VITRO. Z. Sun* and S. Schacher. Ctr. Neurobiol. & Behav., Columbia Univ. College of P & S, NYSP1, New York, NY 10032.

Previous studies indicate that *Aplysia* sensory neurons may 'compete' with one another in establishing chemical connections with a single motor target *in vitro*. Although the sensory cells display no spontaneous action potential activity, they segregate their varicosities to different portions of the motor axons over time. The functional consequence is a cell number-dependent decrease in the average EPSP evoked by each sensory cell. We examined whether adding activity known to evoke a facilitatory response in mature connections--increase in cAMP levels via iontophoretic injection or tetanic stimulation (10 Hz for 4-5 sec)--during the early stages of synapse formation would modulate the intrinsic segregatory process. Two sensory cells were cocultured with one motor cell and examined on day 2 and day 4 for changes in synaptic efficacy and structure. There were no significant differences in the functional and structural changes for each sensory cell over time with control treatments or following tetanic stimulation of the motor cell. Injection of cAMP or tetanic stimulation of one sensory cell significantly increased the amplitude of the evoked EPSP and varicosities of the treated cells compared to their respective control sensory cells in the same cultures. Increasing cAMP levels appeared to increase the rate of new varicosity formation by the injected cell while tetanus also evoked an increase in turnover of pre-existing varicosities of the control unstimulated cell. The transynaptic effect may be mediated by coincident depolarization in the motor cell. Paring tetanic stimulation in both the motor and one sensory cell resulted in a larger difference in the functional and structural development by the two sensory cells. These results suggest that different forms of activity may regulate specific aspects of the segregatory process--formation or elimination of synapses--associated with the fine tuning of connections formed by converging presynaptic inputs on a common target.

DIFFERENTIAL EXPRESSION OF G-PROTEINS IN IDENTIFIED *LYMNAEA* NEURONS MAY DETERMINE TARGET CELL SELECTION AND SPECIFICITY OF SYNAPTIC CONNECTIONS Gaynor Spencer, N.I. Syed* and Lukowiak, K. Departments of Anatomy and Medical Physiology, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

We have recently developed an *in vitro* model system to study mechanisms underlying target cell selection and specificity of synaptic contacts in the snail *Lymnaea stagnalis*. An identified dopaminergic interneuron termed Right Pedal Dorsal 1 (RPeD1) makes monosynaptic connections with a number of target cells (Right Parietal A) *in vivo* and these connections are reestablished *in vitro*. RPeD1 does not however, synapse with non target cells (Left Pedal A) either *in vivo* or *in vitro*, despite the presence of functional dopamine receptors on these cells. In the present study, we therefore hypothesized that differential G-protein couplings to the dopamine receptor may determine target selection by RPeD1 *in vitro*. We first determined whether the effects of exogenous dopamine on both target and non target cells were mediated through different G-proteins. We used the bacterial toxin, Pertussis toxin (PTX), which is known to inhibit Gi and Go. Both target and non target cells were incubated in PTX (1 µg/ml) for 18-24 hours. The inhibitory responses of the non target cells to dopamine were found to persist in PTX (n=7), whereas the similar inhibitory responses of the target cells were abolished (n=5). These data lend support to the hypothesis that G-proteins may play an important role in determining the specificity of target cell selection by *Lymnaea* neurons.

RESTORATION OF MOSSY FIBER PROJECTION IN CO-CULTURED SLICES OF DISLOCATED DENTATE GYRUS AND γ -IRRADIATED HIPPOCAMPUS. B. Heinrich* and J.L. Gaiarsa. Inst. Anat., Univ. Freiburg, P.O.B. 111, D-79001 Freiburg; INSERM U29, 75014 Paris, France

In rodent brains the excitatory input from the dentate gyrus to the hippocampus, the mossy fiber projection, shows a strong region and layer specific distribution. The granule cells of the fascia dentata which give rise to this projection are mainly generated postnatally. Thus, the major part of this pathway develops after birth, and neonatal irradiation of the hippocampus can prevent the formation of this pathway. In an *in vitro* system we have investigated if mossy fiber axons of ectopically positioned dentate granule cells can reach their target area in the irradiated hippocampus, form the characteristic type of synapse and may therefore compensate for the loss of intrinsic mossy fiber input. We co-cultivated a slice of dentate gyrus and irradiated hippocampus up to 16 days on Millipore membranes. The dentato-hippocampal pathway developed *in vitro* was analyzed using the anterograde tracer biocytin. Thin and varicose fibers originating from labeled hilar neurons invaded all parts of the co-cultured hippocampus and established symmetric as well as asymmetric synapses. Biocytin labeled giant mossy fiber boutons were only found in the CA3 region of the co-cultured hippocampal slice. They often showed invaginations of spines and formed the characteristic multiple synaptic contacts on target cells.

From our data we conclude that the mossy fibers emerging from dislocated dentate gyrus explant form the correct termination pattern, develop specific connections, and even partially restore this excitatory pathway. (Supported by INSERM and the DFG: SFB 325)

PRESYNAPTIC CALCIUM LEVELS AT THE CHEMICAL CONNECTION BETWEEN MOLLUSCAN NEURONES IN VITRO. A. Casadio, R. Levi*, L. Morando, G. Naretto and P.G. Montarolo*. Dept. of Hum. Anat. and Physiol., c.so Raffaello 30; #Dept. of Anim. Biol., via S. Croce 8, Univ. of Turin, Turin, Italy.

The studies on neuromuscular junction suggest that during synaptogenesis the muscle provide a retrograde signal which induced a twofold general increase of resting calcium level and a local action potential-evoked Ca^{2+} influx, dependent on cAMP, in the motoneurone (Funte and Haydon, Neuron 10:1069, 1993). The aim of our experiments was to study the Ca^{2+} homeostasis in functionally different neurones and in the presynaptic cell at the axon-axonal synapse. We have measured the resting level and action potential-evoked accumulation of Ca^{2+} in the motoneuron C3 of *Helix pomatia*, plated in culture alone, and in the multitarget metacerebral giant cell (MGC) either cultured alone or cocultured with the neurone B2, one of its target in the buccal ganglion, placed near the stump of the cerebro-buccal connective (CBC). The resting Ca^{2+} level in the C3 neurite terminals was found to be 126 ± 27 nM with a negligible increase to 156 ± 22 nM after a train of action potentials. Instead, in the terminals of the CBC branch of MGC plated alone the Ca^{2+} level increased to 243 ± 136 nM from a resting value of 129 ± 11 after stimulation. This difference was not observed at the posterior lip nerve (PLN) branch (127.5 ± 71 nM and 147 ± 2.25 respectively). After the functional synaptic contact was well established between CBC and neurone B2, the action potential evoked Ca^{2+} accumulation at the putative synaptic sites increased to 481 ± 197 nM from a resting level of 123 ± 24 . This increase was significantly more robust than that measured at PLN (267 ± 18 nM vs. a resting level of 129 ± 29 nM). Our preliminary experiments suggest that in motoneuron C3, as previously reported, no significant Ca^{2+} increase can be observed in the absence of the target, while in the multifunctional MGC neurone a more complex pattern is present, depending both on the presence of a target and on which principal branch of the neurone is considered.

TIMING OF AFFERENT INGROWTH AND TARGET-DERIVED STOP SIGNALS IN DEVELOPING CEREBELLUM Q. Zhang, R. Blazeski, and C.A. Mason*. Dept. Pathology, Coll. Phys. Surg., Columbia Univ., NY, NY 10032.

Our previous work has demonstrated a "stop-growing signal" derived from target cells, based on the behavior of pontine mossy fibers and granule cells from mouse cerebellum *in vitro* (Baird et al., 1992, J. Neurosci. 12:619). To further investigate the nature of the stop signal and its specificity (Baird et al., 1992, J. Neurobiol. 23:579), we examined afferent-target interactions in two situations: when afferents arrive before target cell availability, and when the available target cells are more mature than usual.

First, vestibular mossy fiber ingrowth, position and contacts were studied by DiI labeling, immunocytochemistry with calbindin antisera to label Purkinje cells, and electron microscopy of photoconverted DiI-labeled terminals. At E17, vestibular fibers extend well into the emerging cortical layers in lobule X. Vestibular fibers with small growing tips terminate amongst the Purkinje cell zone and on the underside of the external granule cell layer. Immature contacts are made primarily on Purkinje cells, an inappropriate target, but switch to granule cells after the first few postnatal days.

Second, explants of pontine nuclei were cocultured with purified granule cells, which were aged *in vitro*, or taken from different aged animals. After P11 (or the equivalent days *in vitro*), less than half of the explants exhibited short neurites, compared to about 90% at earlier ages, indicating lack of or waning of a stop signal. These results point to temporal and spatial orchestration of stop signals on target cells. (Supported by NS 15961 to C.A.M.)

SYNAPSIN-LIKE IMMUNOREACTIVITY IN INVERTEBRATE NEURONS *IN VITRO*: REDISTRIBUTION FOLLOWING THE ESTABLISHMENT OF SYNAPTIC CONTACTS. G. Cibelli¹, F. Benfenati²*, M. Ghirardi³, F. Vitello¹ and P.G. Montarolo². ¹Inst. of Human Physiology, University of Bari; ²Dept. of Experimental Medicine, University of Rome "Tor Vergata"; ³Dept. of Human Anatomy and Physiology, University of Turin, Italy.

The characterization of proteins involved in the storage and release of neurotransmitters has been a major step in understanding the synaptic function. Among them, the synapsins, a family of evolutionary conserved, neuron-specific phosphoproteins associated with mammalian small synaptic vesicles, appear to play a pivotal role in both mature and developing nerve terminals. Neuronal cultures from invertebrate nervous system represent a model particularly suitable to analyze the synaptic functions; in fact, in these cultures presynaptic and target neurons form active contacts which can undergo synaptic plasticity. We studied the redistribution of the synapsin-like immunoreactivity in identified *Aplysia* and *Helix* cultured neurons following the establishment of synaptic contacts. To this aim we cocultured a large serotonergic cell (GCN) from the cerebral ganglion and its target neuron (B2) from the buccal ganglion; these cells form *in vitro* reliable synaptic contacts that can be electrophysiologically tested. After different periods in culture we localized the synapsin-like immunoreactivity by means of a battery of anti-synapsin polyclonal antibodies. In the presence of the target neuron the synapsin-like immunoreactivity in the presynaptic cell substantially overlapped the serotonin immunostaining (used as a marker of active synapses). On the contrary, in the absence of the physiological target a diffuse labelling pattern along the outgrowing neurites was observed. This is in good agreement with the data showing that in cultures of hippocampal neurons of mammal synaptic vesicle proteins cluster in presynaptic terminals following contacts with dendrites of other neurons. Our results suggest that in invertebrate cultured neurons the sorting of synaptic vesicle proteins to the presynaptic ending is strongly affected by the presence of the target cell.

TARGETING OF FUNCTIONAL SUBSETS OF NEURONS MEDIATED VIA THEIR AXONAL CARBOHYDRATE MARKERS. B. Zipser* and J. Song. Dept. Physiol., Michigan State University, East Lansing, MI, 48824.

Sensory information is commonly channeled into multiple target regions in the CNS. Some of these target regions are exclusively innervated by just one sensory modality while other target regions are multimodal, receiving input from several sensory modalities. There is increasing evidence throughout phylogeny that neurons conveying different sensory modalities are chemically encoded with surface glycoconjugates. We investigated to what extent two such carbohydrate markers mediate the targeting of their respective axonal subsets in the CNS by molecularly perturbing cultured leech embryos. We found that the targeting of each axonal subset in the synaptic neuropil was perturbed only by Fab fragments binding to the subset's own carbohydrate marker. Characterizing the nature of the interactions mediated by these two carbohydrate markers with glycosidases and neoglycoproteins indicated that the targeting of putative mechanodetectors is mediated by a galactose-specific recognition; in contrast, the targeting of putative chemodetectors is mediated mostly by a glucose-specific recognition with some galactose component. The different interactions of the two neuronal subsets, one mediated exclusively by galactose and the other one mostly by glucose with a minor galactose component, are consistent with the observation that their projections show partial overlap in the synaptic neuropil. Thus, the intact-cultured leech embryo is a suitable model system to study the normal function of neuronal carbohydrate markers in synaptic connectivity.

450.11

MORPHOLOGICAL AND NEUROCHEMICAL TARGET PREFERENCES OF ADULT PHOTORECEPTORS REGENERATING *IN VITRO*. D.M. Sherry* and E. Townes-Anderson. Cornell U. Med. Coll., Dept. Physiology and Dyson Vision Research Institute, 1300 York Ave., NY, NY, 10021.

The specificity of regenerative synaptogenesis by adult vertebrate neurons is poorly understood. Contact formation between photoreceptors and second- and third-order retinal neurons with identified amino acid content was examined by culturing differentiated neurons isolated from salamander retina in a defined medium. In this system, neurons retain characteristic morphological features and regenerate synapses. Regenerating photoreceptors form presynaptic varicosities that contain synaptic vesicles and the transmitter glutamate. 134 varicosity contacts have been analyzed. Varicosities usually contacted cell bodies (82.3%) rather than processes. Photoreceptors had the opportunity to interact with all retinal cell types, but contacted more improper targets: multipolar cells (32.8%; includes amacrine, ganglion and interplexiform cells); than proper targets: bipolar (0.7%), horizontal (0.7%) or photoreceptor cells (5.2%). However, most contacts (60.4%) were onto cells that had lost processes during isolation and could not be identified unequivocally, but their morphology and growth were inconsistent with photoreceptor or horizontal cells. Single-label immunocytochemistry showed that less than 34% of target cells contained aspartate or glycine, but over 50% contained GABA or glutamate, consistent with a high proportion of amacrine cell targets. These data suggest that regenerating photoreceptors *in vitro* prefer inappropriate target cell types, however, the transmitter content of most target cells (GABA, glutamate) is similar to that of cells postsynaptic to photoreceptors in the intact retina.

450.13

SYNAPTIC COMPETITION BETWEEN SUPERNUMERARY AND NORMAL SENSORY NEURONS IN THE COCKROACH IS MEDIATED THROUGH A CHANGE IN QUANTAL CONTENT AND NOT QUANTAL SIZE. M.A. Sosa* and J.M. Blagburn. Institute of Neurobiology, University of Puerto Rico School of Medicine, San Juan, Puerto Rico 00901.

The cerci of the first instar cockroach (*Periplaneta americana*) bear two filiform hairs each, one lateral (L) and one medial (M), which are innervated by individual sensory neurons. These sensory neurons project to the CNS, where they synapse with giant interneurons (GIs) in the terminal ganglion. Mutant nymphs had been previously discovered which have an extra L hair on one or both cerci. The sensory neuron that innervates the extra L hair, known as Space Invader Neuron (SIN), projects to the same GIs as the normal L hair, in effect competing for these synaptic targets. The size of the L EPSP in GI3 is reduced in the presence of SIN. We wanted to determine whether this reduction in EPSP amplitude was the result of pre- or post-synaptic changes.

Intracellular recordings of ipsilateral GI3 EPSPs, in response to movement of the L hair, were made in normal cockroach saline and [a] 1 mM Ca^{2+} /10 mM Mg^{2+} (low Ca /high Mg) saline, or [b] normal saline + 1 μ M tetrodotoxin (TTX). Quantal content was determined by the direct method (EPSP/quantal size). Measures of quantal size were obtained from the first peak of histograms of EPSPs recorded in low Ca /high Mg saline and/or from amplitudes of miniature EPSPs recorded following addition of 1 μ M TTX. EPSP amplitude was significantly reduced from 2.42 ± 0.16 mV (mean \pm s.e.; $n=7$) in wild-type nymphs to 1.74 ± 0.26 mV ($n=6$) in the SI mutants ($p<0.045$). Mean quantal size in wild-type and mutant nymphs was not significantly different (0.23 ± 0.02 mV ($n=7$) and 0.27 ± 0.04 mV ($n=6$), respectively). Quantal content, however, was significantly reduced from 10.99 ± 1.03 ($n=6$) in wild-type nymphs to 6.70 ± 0.79 ($n=6$) in the SI mutants ($p<0.008$). These results indicate that the reduction in synaptic efficacy observed in the presence of SIN is presynaptic in nature.

DEVISING A MODEL SYSTEM TO STUDY THE ROLE OF LECTINS IN NEURAL CONNECTIVITY IN LEECH. M.-T. Tai, M. B. Rheuben* and B. Zipser. Dept. of Physiology, Michigan State University, E. Lansing, MI 48824.

We are investigating the role of carbohydrate-lectin interactions in neuronal connectivity. Previous work demonstrated the critical importance of carbohydrate markers for axonal targeting in the synaptic neuropil. We are now devising a system to study the role of leech galectins, LL35 and LL16, in the formation of an identified synapse. Several lines of evidence indicate that galectins are expressed by photodetectors in midbody sensilla and eyes. One to two cell bodies in midbody sensilla and their central projection into a distinct neuropil target region, the sensory midline tract, express galectins (Cole and Zipser, J. Neurochem. 64, 1994). We now showed that DiO-labeling photodetectors led to prominent axonal staining of the sensory midline tract with more lateral neuropil regions receiving only sparse projections. Immunostaining all sensory neurons and DiO-labeling photodetectors demonstrated that the sparse projections of photodetectors away from the sensory midline tract are into the more lateral target regions of mechano/chemo/heat detectors. To search for postsynaptic partners of photodetectors, we injected central neurons with Lucifer yellow after immunostaining sensory neurons. The axonemeric projections of the AP cell demonstrated the strongest colocalization with the sensory midline tract, the target region of the photodetector. In preliminary experiments, illuminating leech eyes led to an increase in AP cell excitability. Thus, photodetectors appear to form a synapse with the AP cell that could serve as a model system for studying the role of lectin in target recognition.

SYNAPTOGENESIS AND SYNAPTIC PLASTICITY IN DISSOCIATED CHICK CEREBRAL NEURONS. T. Taguchi*, K. Kiyosue, S. Kudo, M. Kasai, Lab of Biomol. Eng., Osaka Nat'l. Res. Inst. AIST, Ikeda 563, Japan, and Lab. of Mol. Biol., Fac. of Eng. Sci., Osaka Univ., Toyonaka 560, Japan.

To elucidate mechanisms of formation, maturation and plasticity of central nervous system at single cell level, it is essential to analyze the synaptic transmission at cellular and molecular level. We developed a dissociated neuron culture system, in which it is possible to analyze the synapse between two particular neurons. The neurons from cerebral hemispheres of chick embryos were dissociated by trypsinization and cultured on polylysine-coated dish containing 50% of modified Earle's minimum essential medium, 10% of fetal calf serum and 40% artificial medium (GIT, Nihon seiyaku, Japan). Using whole cell patch clamp technique, we confirmed synapse formation *in vitro*. The synaptogenesis seemed to proceed in proportion to the embryonic equivalent days (E.E.days) which are the sum of the days in incubation and culture. The synapses were found to begin to form at E.E.days 15 and mature at 17. We also demonstrated the long-term increase of synaptic efficiency in the same culture. After the neurons were exposed in the recording solution without Mg^{2+} , the long-lasting (more than 40 min) increase was observed from two neurons showing synchronous excitatory postsynaptic current. This phenomenon was abolished by the addition of tetrodotoxin and glutamate receptor antagonists in the Mg^{2+} -free solution.

INTERACTIONS BETWEEN PHOTODAMAGED AND INTACT TERMINALS AT POLYNEURONALLY INNERVATED FROG NEUROMUSCULAR JUNCTIONS. V. Pitaevski* and A.A. Herrera. Dept. of Biological Sciences, University of Southern California, L.A., CA 90089-2520.

Our goal is to study how changes induced in one motor nerve terminal can affect another in polynuronally innervated neuromuscular junctions in frog. This approach can give important information about the role and nature of competition during synapse elimination in neuromuscular junctions.

Reinnervated sartorius muscle of *Rana pipiens* has a substantial percentage of polynuronally innervated junctions 8 weeks after nerve crush. Our previous *in vivo* observations indicated that under normal conditions such junctions are morphologically stable over a period of several weeks which makes artificially induced changes easily detectable in this system. To induce changes in a small portion of a terminal *in vivo* we used the fluorescent dye 4-Di-2-Asp combined with local illumination by blue light at an intensity level shown to cause terminal damage *in vitro*. The vital fluorescent dye RH414 and low-light video microscopy was used for repeated *in vivo* observations of exposed and intact terminals. In cases where photodamage caused retraction of exposed branches, no changes were detected in intact branches in the same neuromuscular junction a week after photodamage.

We are continuing to make repeated observations of identified neuromuscular junctions over longer periods of time after selective photodamage. Our study also includes an electrophysiological investigation of how stimulation of one input in a doubly innervated junction affects the other input.

A HIGH NUMBER OF GABA SYNAPSES TARGETING DISTAL PORTIONS OF CORTICAL NEURONS IS LOST AFTER PERIPHERAL DEPRIVATION. C. Beaulieu*, K. Micheva and C. Crevier, Dept Pathology and Centre de Recherche en Sciences Neurologiques, Université de Montréal, Montréal, (Qué) CANADA.

The numerical density (N_V) and proportion (%) of GABA synapses on dendritic spines, shafts, somata, and initial segments of the axon was estimated in the somatosensory barrelfield areas of 5 rats having their vibrissae from the right face continuously removed from birth.

For the entire cortical depth, no significant differences in the N_V and % of GABA synapses on these postsynaptic elements were found in the barrelfield cortex contralateral and ipsilateral to the deprivation. About 19.7 million GABA synapses per mm^3 of tissue were devoted to spines (representing 3.8% of all contacts on spines), 55.7 million were on dendritic shafts (38.1%), 5.6 million on somata (71.0%) and less than 0.01 million on the initial segments of the axon (100%).

In layer IV however, sensory deprivation induced a drop from 55.6 in the ipsi cortex to only 11.9 million/ mm^3 of GABA synapses on spines in the contra cortex (a 4.7 times loss; $p < 0.0001$) and from 82.2 to 33.8 million/ mm^3 on shafts ($p < 0.05$). Only 2.2% and 29.1% of all contacts on spines and on shafts respectively, were GABA in the contra compared to as many as 9.3% and 49.1% in the ipsi layer IV.

We conclude that the population of GABA synapses located on distal portions of layer IV neurons is the most plastic of all populations of cortical synapses. (Supported by MRC, FRSQ, and FCAR).

Development of iterated structures in the NMDA receptor deficient mice Yueqing Li*, Reha S. Erzurumlu*, Chong Chen, Sonal Jhaveri* & Susumu Tonegawa HHMI at the Ctr. for Cancer Res., *Dept. of Brain and Cognitive Sci., MIT, Cambridge, MA 02139.

Sensory pathways of the brain generally develop from crudely wired networks to precisely organized system and in some cases to iterated structures such as ocular dominance columns and barrels in the cerebral cortex. Several studies have implicated neural activity-dependent mechanisms including NMDA receptors, in this refinement process. We applied the gene targeting in mouse embryonic stem cells to the NMDAR1 gene and created a mutant mouse which lacks functional NMDA receptors. We analyzed the formation of iterated structures in the mutant mice. The development of glomeruli in the olfactory bulb of mutant mice is compared to that of wild type animals. The number of glomeruli in the mutant mice is the same as their normal littermates, suggesting that the development of glomeruli is not dependent on NMDA receptor activation. In contrast, whisker-related patterns in the trigeminal nuclei (barrellettes) failed to develop as judged by both cytochrome oxidase staining and immunohistochemistry, although pathfinding, initial targeting and crude topographic projection of trigeminal axons in the brainstem are unaffected. In addition, in the absence of functional NMDA receptors, the synaptic transmission from trigeminal ganglion to the second order neurons in the brainstem trigeminal complex is functional in mutant mice. These results suggest that NMDA receptor and/or activity is essential for the development of somatosensory maps in the mammalian brain. Funded by HHMI and the Shionogi Inst. for Medical Science (ST) and NS27678 (SJ).

HOMONYMOUS NEUROMUSCULAR PREPARATION USING THE CAMPENOT CHAMBER. A. Parfitt, E.A. Neale*, S.C. Fitzgerald and P.G. Nelson: Laboratory of Developmental Neurobiology, NICHD, NIH, Bethesda, MD 20892.

We have shown that mouse ventral horn motor neurons grown on mouse cortical astrocytes, in the side wells of Campenot chambers that have been sealed onto laminin-coated plastic culture dishes, will extend axons underneath the chamber barrier into the center compartment, there to make functional contact with mouse striated muscle fibers. These fibers will contract in response to electrical field stimulation across one or both of the Campenot barriers. Most field-induced contractions could be blocked by rhodamine- α -bungarotoxin, which was used to label post synaptic cholinergic receptors, suggesting that they were neurally mediated and not the result of direct electrical stimulation of muscle fibers which had grown into or under the Campenot barrier. Neurites that were immunoreactive for ChAT could also be found in association with muscle fibers that had contracted in response to electric field stimulation. Cells and their processes in the side wells of the Campenot chamber could be stained with Fast DiI/DiO. Intramembrane diffusion of these dyes along the neurites that passed under the chamber barrier permits visualization, and will facilitate the differential characterisation, of the neurite fields in the center compartment. Preliminary experimental data include evidence for activity-dependent synapse elimination.

450.16

SELECTIVE DECREASE IN THE NUMBER OF GABA SYNAPSES IN LAYER IV AFTER SENSORY DEPRIVATION. K. Micheva*, C. Crevier and C. Beaulieu, Dept Pathology and C.R.S.N., Université de Montréal, (Qué) CANADA.

The effects of modified peripheral activity at cortical level were estimated by quantifying the overall and GABA synaptic populations in the somatosensory barrelfield cortex of 5 rats whose whiskers on the right face were continuously removed after birth.

The numerical density of GABA synapses was found to decrease more than twice ($p < 0.01$) in layer IV contralateral to the deprivation (63 million/ mm^3) compared to the ipsilateral layer IV (145 million/ mm^3). Accordingly, GABA synapses represented only 9.4% of the overall synaptic population in the contralateral versus 18.7% in the ipsilateral layer IV. At the same time, GABA synapses in the deprived layer IV were bigger (0.48 μm in the contralateral layer IV vs 0.32 μm in the ipsilateral layer IV; $p < 0.05$). No significant changes in the numerical density, proportion or size of GABA synapses were detected in any other cortical layer. No differences in these parameters were found for the total synaptic population either.

As the firing activity and receptive field properties of cortical neurons are under the control of GABA, such a selective reduction in the number of GABA synapses in layer IV, the major recipient of thalamocortical inputs, would undoubtedly lead to profound functional alterations in the entire circuitry of the deprived somatosensory cortex.

NITRIC OXIDE SYNTHESIZED IN DEVELOPING CHICK TECTUM IS INVOLVED IN ELIMINATION OF THE IPSILATERAL RETINOTECTAL PROJECTION. H.H. Wu* and S.C. McLoon, Univ. Minnesota, Minneapolis, MN 55455.

The adult pattern of axonal connections from the eye to the brain arises during development by refinement of a roughly ordered pattern of connections in chick. One characteristic of the early pattern of connections is a transient ipsilateral retinotectal projection. Previous studies showed that administration of arginine analogs prevented the loss of this transient ipsilateral projection. The most likely interpretation of this result is that the drug inhibited nitric oxide (NO) synthesis in the visual system, and that NO is somehow involved in the refinement process. The present study examined whether administration of an arginine analog actually reduces NO synthesis and identified the most likely site of this action. L-NOARG was applied to the chorioallantoic membrane of embryos. Controls received saline. On E13, the middle of the period of refinement, nitric oxide synthase (NOS) activity was assayed by measuring the conversion of arginine to citrulline in homogenates of retina and tectum. In normal embryos, NOS activity was detected in the tectum but not in the retina. This was consistent with the histochemical detection of NOS in these tissues during the period of refinement. NOS activity in the tectum was inhibited in the L-NOARG treated group but not in the saline treated group. The effect of L-NOARG was dose-related. There was a correlation between the level of NO synthesis inhibition and the degree of preservation of the ipsilateral projection in the tectum. These results suggest that NO serves as a messenger from the tectal cells back to the retinal axons and that it is involved in the developmental refinement of the visual projection. (Supported by EY05371.)

ACTIVATION OF MOUSE SKELETAL MUSCLE IN VITRO PRODUCES INCREASED SECRETION OF THROMBIN. P. G. Nelson*, K. Yadav, S. Fitzgerald and D. E. Brenneman, Lab. Dev. Neurobiol., NICHD, NIH, Bethesda, MD 20892.

Thrombin, at nM concentrations, has been implicated in the process of activity-dependent synapse reduction (ADSR) in a mouse neuromuscular junction preparation *in vitro* (Liu et al., Soc. Neurosci. Abs, this volume). This is based on the block of ADSR by nM concentrations of hirudin, a highly specific thrombin inhibitor. Also exogenous thrombin (~10 nM) causes synapse loss which is blocked by hirudin. We have, therefore, investigated the regulation of thrombin release from muscle cells. We compared the levels of thrombin in media conditioned by muscle cells treated with tetrodotoxin (TTX, 1 μM , to block activity) or acetylcholine (ACh, 10 μM , to activate the cells). Significantly more thrombin was released by the ACh treated cells (0.056 nM \pm 0.03 nM; S.D., n=18 with ACh vs 0.027 \pm 0.02 nM, n=15 with TTX). (The medium with 5% horse serum contained 0.006 nM thrombin). We hypothesize that increased thrombin secretion produced by muscle activation could contribute to ADSR.

OVEREXPRESSION OF NGF IN TRANSGENIC MICE INDUCES NOVEL SYMPATHETIC PROJECTIONS TO PRIMARY SENSORY NEURONS. B.M. Davis*, D.M. Katz*, K.B. Seroogy and K.M. Albers*. Dept. of Anatomy & Neurobiology, and *Pathology, Univ. of Kentucky College of Medicine, Lexington, KY 40536; *Dept. of Neuroscience, Case Western Reserve Univ. School of Medicine, University Hospital of Cleveland, Cleveland, OH 44106.

Peripheral nerve crush induces novel projections from sympathetic neurons to sensory ganglia, and it has been suggested that these projections are the anatomical substrate for chronic pain syndromes. Our study demonstrates that novel sympathetic projections to sensory neurons are also induced in transgenic mice that overexpress NGF in the skin. Specifically, a large proportion of primary sensory neurons in NGF transgenic mice were innervated by tyrosine hydroxylase (TH)-positive pericellular arborizations that were seen only rarely in controls. Removal of the superior cervical ganglion abolished TH immunoreactive arborizations in the ipsilateral trigeminal ganglion confirming that these fibers were sympathetic axons. A two-site ELISA revealed that transgenic ganglia contained a ten fold increase in NGF peptide. Reverse transcriptase PCR analysis showed no apparent expression of transgene mRNA in sensory ganglia suggesting that the additional NGF was derived from increased NGF expression in the skin. These results indicate that NGF induces novel sympathetic projections to sensory neurons, and supports the hypothesis that increased NGF expression is a critical link in the development of sympathetic hyperalgesia. Supported by AR-40873 (KMA), NS-31826 (BMD), HL-42131 (DMK) and IBN-9221136 (KBS).

451.3

CHARACTERIZATION OF MICE OVEREXPRESSING BDNF IN THE EPIDERMIS. A.M. LeMaster*, B.M. Davis, T.N. Perrone, F. Davis, Z. Pang and K.M. Albers. Depts. of Anatomy and Neurobiology and Pathology, Univ. of Kentucky Sch. of Med., Lexington, KY 40536.

Neurotrophins, nerve growth factor (NGF), brain derived neurotrophic factor, (BDNF), neurotrophin-3 (NT-3), and neurotrophin-4/5 (NT-4/5), are a family of homologous proteins that affect neuronal cell survival and support neuronal growth and differentiation. During development neurotrophins are made by neuronal target tissues such as skin and the decline in their expression levels correlates with the onset of naturally occurring neuronal cell death. To examine the role of neurotrophins in the development of the peripheral nervous system, we isolated transgenic mice that express fusion gene constructs containing a human keratin (K14) gene promoter ligated to the various mouse neurotrophin cDNAs. Transgene expression begins in the basal cell layer of epidermis around embryonic day 14 (E14), coinciding with the normal decline in neurotrophin levels. Previously we have isolated and characterized mice containing a K14-NGF transgene. In the present study, mice expressing a K14-BDNF transgene have been isolated. BDNF is normally expressed in neuronal tissues of both the central and peripheral nervous system and in nonneuronal tissues such as heart, lung and skin. By overexpressing BDNF in the epidermis, its role in development and in the adult may be elucidated. Three lines of mice have been isolated that express the K14-BDNF transgene as shown by Southern and Northern hybridization. Mice appear normal in size and health. Initial histological examination of the skin and sensory ganglia show no major alterations in these structures. Supported by NS 31826 (BMD) and AR40873 (KMA).

ANALYSIS OF MICE CARRYING TARGETED MUTATIONS OF THE BDNF GENE. P. Carroll, G.R. Lewin, M. Koltzenburg, K.V. Toyka, E. Wolff, G. Brem, E. Castrén* and H. Thoenen. Dept. Neurobiochemistry, Max-Planck Institute for Psychiatry D-82152, Martinsried. §Dept. Neurology, University of Würzburg, D-97080 Würzburg, #Dept. Molecular Animal Breeding, Veterinary School, Veterinärstr. 13, D-80539 Munich, Germany.

Brain derived neurotrophic factor is a member of the family of related molecules, which includes NGF, NT3, and NT 4/5. Neurotrophins effects on neuron survival and differentiation *in vitro* and *in vivo* suggest important roles for these molecules on essential developmental processes such as programmed cell death and determination of neuronal phenotype. As part of our efforts to clarify the *in vivo* role(s) of the neurotrophins we have generated, using gene targeting methodology, mice in which most of the sequence coding for BDNF was deleted and replaced with a neomycin resistance gene. Homozygous mutant mice (-/-) are reduced in size compared to their litter mates and most die within the first three postnatal weeks. Analysis of DRG cell numbers and size indicates that many neurons die in the (-/-) animals. Heterozygous animals (+/-) were viable but consistently intermediate in size. This prompted us to examine the functional properties of primary afferents innervating skin in adult (+/-) mice using an *in vitro* recording technique (Koltzenburg et al. Soc Neurosci., this meeting). Briefly, single primary afferents were recorded in the saphenous nerve using standard teased fiber techniques. All cutaneous primary afferent types were encountered and characterized in wild type and (+/-) animals (A β , A δ and C-fibers), however, only one type was severely affected in the (+/-) animals. These fibers, slowly adapting mechanoreceptors conducting in the A β fiber range, had very elevated mechanical thresholds. These initial results suggest that BDNF is critically important for the regulation of this afferent type. It will be important to see if total absence of BDNF in (-/-) animals has more widespread effects on the functional properties of sensory neurons.

451.2

CHARACTERIZATION OF TRANSGENIC MICE THAT OVEREXPRESS NT-3 IN THE EPIDERMIS. K.M. Albers*, T. N. Perrone and B.M. Davis*. Depts. of Pathology and Anatomy & Neurobiology*, Univ. of Kentucky Sch. of Med., Lexington, KY, 40536.

During development of the mammalian skin neurotrophic molecules are expressed at times overlapping with sensory neuron outgrowth to the periphery. The production of neurotrophic compounds by the skin is thought to promote neuronal survival and differentiation and thus serve as a means to tailor the innervation pattern of the skin. To examine the role of neurotrophins in an *in vivo* system, we have isolated transgenic mouse lines that overexpress either NGF, NT-3 or BDNF in basal cell keratinocytes of the epidermis. NGF overexpression appears to block the naturally occurring program of neuronal cell death and leads to the formation of a dramatically hypertrophied peripheral nervous system. To isolate NT-3 expressing mice, the NT-3 gene sequence encoding the precursor and active peptide sequence was cloned from mouse genomic DNA using the polymerase chain reaction. The sequence was confirmed by DNA sequencing and then cloned into an expression cassette containing the human keratin K14 gene promoter and enhancer elements. Lines of NT-3 overexpressing mice have been characterized by Southern, northern, and *in situ* hybridization assays and show high levels of transgene expression. Mice appear normal in size and health. Gross and histological examination of the skin show it to contain a greater number of larger touch dome units, suggesting that NT-3 plays a role in the survival of the SA1 type neurons that innervate these structures. To begin to chemically characterize the sensory neurons of the dorsal root ganglion, the percentage of trk A, trk B, and trk C expressing neurons are being determined. Supported by AR40873 (KMA) and NS 31826 (BMD).

NGF OVEREXPRESSION IN EPIDERMIS DISRUPTS SYMPATHETIC INNERVATION OF SWEAT GLANDS AND DIFFERENTIALLY ALTERS TRANSMITTER PROPERTIES. G. Guidry¹, B.M. Davis², S.C. Landis^{1*} and K.M. Albers³.

¹Dept. of Neurosci., Case Western Reserve Univ., Cleveland OH 44106, ²Dept. of Anatomy and Neurobio. and ³Dept. of Path., Univ. of Kentucky College of Medicine, Lexington KY 40536

We examined sympathetic innervation in transgenic mice carrying multiple copies of the NGF gene driven by an epidermal keratin promoter. In adult wild-type mice, cholinergic and noradrenergic sympathetic fibers and peptidergic sensory fibers innervated distinct targets in the footpad. Acetylcholinesterase (AChE) and vasoactive intestinal peptide (VIP) sympathetic axons were associated with sweat glands while catecholaminergic fibers innervated blood vessels. All sympathetic innervation was restricted to tissues in the pad interior. Calcitonin gene-related peptide (CGRP) and substance P (SP) sensory fibers traversed the pad and terminated at the interface between the epidermis and dermis. While the timing of innervation in footpads did not appear to be affected in transgenic mice, segregation of sympathetic and sensory innervation was altered. A dense plexus of AChE and catecholaminergic fibers was found beneath the epidermis and VIP fibers extended into the epidermis. The plexus was absent from footpads of mice treated as neonates with the adrenergic neurotoxin 6-OHDA, indicating its sympathetic origin. This same region was hyperinnervated by CGRP and SP sensory fibers. In addition, sweat gland innervation was disrupted. While some glands were innervated by AChE and VIP fibers, most lacked innervation. Despite the sparse gland innervation, secretory responsiveness appeared normal. Our findings suggest that over-expression of NGF in skin interfered with the normal segregation of sensory and sympathetic fibers. Further, the ectopic sympathetic fibers displayed an abnormal neurotransmitter phenotype, expressing both catecholamines and cholinergic properties.

TRANSGENIC MICE OVEREXPRESSING BDNF IN NEURAL STEM CELLS. Torkel Falkenberg^{1,4}, Thomas Ringstedt^{1,2}, Erik Nilsson³, Urban Lendahl³, Ron McKay⁵, Håkan Persson¹ and Carlos F. Ibáñez¹. ¹Molecular Neurobiology, Medical Biochemistry and Biophysics, ²Department of Women and Child health, ³Developmental Biology, Cell and Molecular Biology, ⁴Department of Pharmacology and Physiology, Karolinska Institute, Stockholm, Sweden, ⁵Molecular Biology, NIH, Bethesda, MD, USA.

Neural stem cells in the neuroepithelium of the neural tube are transiently present during embryonic life and later differentiate to form neurons and glial cells. The neural stem cell state is accompanied by expression of the intermediate filament nestin. Regulatory regions controlling the nestin expression in the stem cell have previously been characterized in transgenic mice using lacZ as a reporter gene. To address the effects of overexpression of the neurotrophic factor BDNF (brain derived neurotrophic factor) in neural stem cells we have linked the regulatory regions of the nestin gene to the coding portion of the BDNF gene. This DNA construct was injected into fertilized mouse eggs with the attempt to generate stable transgenic mouse lines. With this particular construct we have observed a very low frequency of postnatal transgenic mice (6% of all offspring, compared to 20-40% for other constructs). Moreover, one of the founders did not express BDNF from the exogenous gene, while another one did not pass the gene further to its offspring. These data suggest that transient expression of BDNF in neural stem cells may be detrimental for the transgenic embryos. Ongoing experiments are aimed at analyzing phenotypes in transgenic embryos at different developmental stages.

CHARACTERIZATION OF DOPAMINE- β -HYDROXYLASE: BDNF TRANSGENIC MICE. C.G. Causing*, S. Bamji, A. Gloster, A. Speelman, R. Yama, E. Chang, and F.D. Miller. Centre For Neuronal Survival, Montreal Neurological Institute, Montreal, Quebec, H3A 2B4

Neurons secrete neurotrophins that may play a role in neuron:neuron interactions. Brain-derived neurotrophic factor (BDNF), is widely distributed in the mammalian CNS. In the PNS, sympathetic neurons of the superior cervical ganglia (SCG) express the mRNA encoding BDNF. Since sympathetic neurons do not respond to BDNF in culture, and since they do not express the BDNF receptor, trkB, we have hypothesized that sympathetic neuron-derived BDNF may provide neurotrophic support for their input neurons, the preganglionic sympathetic neurons. To examine this possibility, we have generated transgenic mice expressing BDNF from a 1.6 kb fragment of the dopamine- β -hydroxylase (DBH) promoter, which is sufficient to target gene expression to adrenergic and noradrenergic neurons (including sympathetic neurons) of transgenic mice. Based on Northern blot analyses, we have found that three of the lines generated express the BDNF transgene in the SCG, adrenals, and brainstem with varying levels of expression. There was a dramatic increase in ChAT staining within both the SCG and the thoracic spinal cord regions which contain the preganglionic neurons projecting to the SCGs (intermediolateral nucleus, the central autonomic area, and the intercalated region). The overexpression of BDNF also resulted in a hyperinnervation of the sympathetic neurons by the cholinergic preganglionic neurons. In addition, there was a 25% increase in SCG neuronal cross-sectional area, and possibly an increase in sympathetic innervation density within an SCG target tissue, the pineal gland. Thus, the BDNF induced hyperinnervation of the SCGs may produce an increase in SCG neuronal size and hyperinnervation of sympathetic target tissues. These studies provide support for the concept that sympathetic neuron-derived BDNF is a neuron-derived neurotrophic factor for their preganglionic input, and suggest that the density of afferent input may regulate the biology of the target neuron.

451.9

NEURON-SPECIFIC OVEREXPRESSION OF NEUROTROPHIN-3 IN TRANSGENIC MICE. C. Helbig, M. Meyer*, E. Wolf*, G. Brem* and H. Thoenen. Max-Planck Institute for Psychiatry, D-82152 Martinsried, Germany; *Ludwig-Maximilians University, D-80539 Munich, Germany

Neurotrophin-3 (NT3) is widely expressed in the central and peripheral nervous system as well as in various peripheral tissues. Although the expression pattern of NT3 is well known and *in vitro* effects on sensory, sympathetic and motoneurons have been described, little is known about the *in vivo* function of NT3.

To investigate the function of NT3, transgenic mice were generated. In these mice NT3 expression was driven by a 1.5 kb fragment of the PDGF-B chain promoter, previously shown to drive expression mainly to neurons.

Four founder animals were obtained by pronucleus injection. Two lines showed the same transgene expression pattern. By Northern blot analysis a 2-5 fold higher NT3 expression in cerebellum, cerebrum, lung, kidney, uterus and ovary was detected comparing F2 adult homozygous transgenic to wildtype littermates. Ectopic expression was detected in olfactory bulb, spinal cord, testes and vas deferens.

In situ hybridization was performed to examine the cellular localization of transgene expression. High expression was observed in mitral and periglomerular cells of the olfactory bulb, in granular neurons and Purkinje cells of the cerebellum. In addition to the endogenous hippocampal NT3 expression in dentate gyrus, CA2 and medial CA1, NT3 mRNA was detected in CA3 and CA4 neurons. Neurons of the neocortex also showed strong labelling, which was not seen in wildtype controls. Finally motoneurons in the spinal cord and more than 50% of DRG neurons were strongly labelled.

The transgenic animals showed no obvious phenotype with respect to weight, behaviour or gross morphology. Effects due to the overexpression or ectopic expression of NT3 on the sensory, sympathetic and motor nervous system are under investigation.

451.11

Effects of Transgenic Over-expression of CNTF in the CNS. J.T. Henderson*, N.A. Seniuk, P.M. Richardson, J.C. Roder. Mount Sinai Hospital, Toronto, ONT M5G-1X5.

CNTF has been shown *in vitro* to mediate a wide variety of effects on neural cell. In order to more clearly delineate the developmental and regenerative effects of proteins using the CNTFR α /gp 130/LIFR β receptor system, transgenic mice were created which over-express CNTF in the CNS. Both the endogenous (CNTF-ns) and secreted (CNTF-s) forms of rat CNTF were placed under the control of either the glial fibrillary acidic protein (GFAP) or the neuron specific enolase (NSE) promoters. Examination of the facial nucleus of transgenic mice which over-express GFAP/CNTF-ns show a developmental increase in the number of motoneuron (150% of non-transgenic siblings). In contrast, transgenic lines derived from the GFAP/CNTF-s transgene exhibit relatively normal numbers of facial motoneuron, however demonstrate a marked increase in motoneuron survival compared to non-transgenic siblings following axotomy of the facial nerve at postnatal day 3 (70% vs. 25%), concomitant with reactive gliosis at this site. Murine lines expressing NSE/CNTF-s exhibit alterations in oligodendrocyte gene expression, in proportion to the level of CNTF transgene expression. These results indicate CNTF can exert a variety of neural effects which are context dependent.

451.8

VISCERAL SENSORY NEURONS ARE SEVERELY DEPLETED IN MICE LACKING FUNCTIONAL trkB PROTEIN TYROSINE KINASE RECEPTORS.

J.T. Erickson*, R.J. Smeyne*, M. Barbacid* and D.M. Katz*. ¹Departments of Neurosciences and Medicine, Case Western Reserve University School of Medicine, Cleveland, OH 44106 and ²Department of Molecular Biology, Bristol-Myers Squibb, Princeton, NJ 08543.

Gene disruption targeting the catalytic domain of the trkB neurotrophin receptor results in deficits of somatosensory and somatomotor neuronal pools, and neonatal mortality, in mice homozygous for this mutation (Klein et al. Cell 75:113.1993). Recent findings from one of our laboratories (DMK) indicate that trkB ligands may also mediate peripheral target support of visceral afferent survival. In particular, BDNF mRNA is expressed in visceral receptor tissues *in situ*, and local application of BDNF can rescue visceral afferents following peripheral target removal *in vivo* (Hertzberg et al., this volume and submitted for publication). To further define the role of trkB ligands in visceral sensory development, the present study examined visceral afferent survival in the nodose and petrosal cranial sensory ganglia of trkB knockout mice. Ganglion volume, as well as cell number, were severely depleted in mice homozygous for the targeted allele. Furthermore, immunohistochemical detection of tyrosine hydroxylase, a marker of dopaminergic cardiorespiratory afferents in the rat petrosal ganglion (Katz and Black, 1986), revealed a striking reduction in catecholaminergic nodose-petrosal neurons. These results indicate that a large proportion of cranial visceral afferents, including many, but not all, of the catecholaminergic neurons in the nodose-petrosal complex, require trkB ligand(s) for survival during perinatal development. Nodose and petrosal neurons relay visceral sensory information from the cardiovascular, respiratory and gastrointestinal systems to the central nervous system, and thereby play a key role in regulating autonomic homeostasis. We hypothesize that deficits in these neuronal populations, and cardiorespiratory afferents in particular, may contribute to the lethality of the trkB mutant phenotype. Supported by HL-42131 (DMK) and training support from HL-07288 (JTE).

451.10

STRUCTURE AND TRANSGENIC EXPRESSION OF RAT NEUROTROPHIN-4 GENE. M. Metsis, T. Salin, Y. Hurd** and T. Timmusk. Lab. of Molecular Neurobiology, Karolinska Institute and *Dept. of Clinical Neuroscience, Karolinska Hospital, 17177 Stockholm, Sweden.

Neurotrophin-4 (NT-4) expression is very low in the adult organism, while higher levels are present during embryogenesis. Developmentally regulated expression of NT-4 in whisker pad has led to the hypothesis of its target derived action on the trigeminal ganglion. To study the regulation of the NT-4 gene and to evaluate the possible roles of this neurotrophin in developing and in adult nervous system we have characterized rat NT-4 gene. A cDNA library was made from P1 testis, where a high expression level was previously detected. Screening of this library resulted in 10 cDNA clones that were used to screen a rat genomic library. 10 overlapping genomic clones were isolated that covered 45 kb of the NT-4 locus. Mapping of the intron-exon structure revealed two upstream noncoding exons separated by an 800 bp intron. Transient expression analyses with bacterial chloramphenicol acetyl transferase reporter gene suggests an important role of intronic sequences in supporting the promoter activity. Rat NT-4 gene fragment containing upstream exons, promoter region and coding exon was introduced into transgenic mice. The expression pattern of the transgene recapitulates the endogenous gene expression pattern and regulation. Transgenic mice with high level of NT-4 expression have altered levels of other members of neurotrophin family in distinct brain regions.

451.12

SYNAPSE WITHDRAWAL FROM DEVELOPING NEUROMUSCULAR JUNCTIONS OCCURS EARLIER IN LIF DEFICIENT TRANSGENIC MICE. Young W. Kwon*, Susan J. Abbondanzo*, Colin L. Stewart*, and Mark E. Gurney*. ¹Dept. of Cell, Molecular and Structural Biology, Northwestern Univ., Chicago, IL, 60611 and ²Dept. of Cell and Developmental Biology, Roche Institute of Molecular Biology, Nutley, NJ, 07110.

We previously showed that leukemia inhibitory factor (LIF) mRNA expression occurs in both embryonic and neonatal muscle and that it is developmentally regulated. Furthermore, administration of exogenous LIF delays the timing of programmed synapse withdrawal without affecting its rate. Hence, endogenous LIF is a likely candidate for a cytokine that regulates this process during normal development. To provide additional evidence for this hypothesis, we examined the course of synapse withdrawal in mice whose LIF gene was disrupted by homologous recombination. Muscles from animals of various genotypes were stained by a combined silver and cholinesterase method and then were examined microscopically for the presence of multiply innervated fibers. The percentages of multiply innervated fibers in various animals are as follows (+/+; wild-type; +/-; heterozygote; -/-; homozygote):

Age (days)	+/+	+/-	-/-
5	75±3%	74±3%	75±2%
7	53±3%	52±3%	38±2% *
9	26±3%	19±2%	12±2% *

a) p<0.001, unpaired T-test.

Thus, synapse withdrawal occurs earlier in LIF deficient transgenic mice. This study, together with the previously mentioned results, provide evidence that endogenous LIF regulates the timing of programmed synapse withdrawal from the developing neuromuscular junction.

451.13

EVALUATION OF GROWTH FACTOR EFFECTS ON MESENCEPHALIC DOPAMINERGIC NEURONS USING A *FOS-LACZ* TRANSGENIC MOUSE LINE

J. Engele* and K. Schilling, Dept. Anatomy and Cell Biology, University of Ulm, 89069 Ulm, FRG.

One of the initial effects of many growth factors is the rapid and transient induction of immediate early genes such as *c-fos* in their target cells. In the present study, we have exploited this feature to probe the cellular target(s) of growth factors previously observed to support survival of cultured dopaminergic neurons. Specifically, we used low density cultures established from the dissociated mesencephalon of E14 *fos-lacZ* transgenic mice (generously provided by J.I. Morgan, Roche Institute, Nutley, N.J.) to monitor *c-fos* expression in immunocytochemically identified cellular phenotypes. NT-3 (10 ng/ml; 3 hrs), bFGF (25 ng/ml) or a combination of aFGF (50 ng/ml) and heparin (2.5 U/ml) induced transgene expression in subpopulations of tyrosine hydroxylase-immunoreactive dopaminergic neurons as well as in non-dopaminergic neurons and glial cells. The effects of these growth factors on dopaminergic neurons were not affected by cellular plating density or by eliminating synaptic communication. In contrast, TGF α (50 ng/ml) and PDGF-BB (30 ng/ml) induced transgene expression exclusively in glial cells but not in dopaminergic neurons.

These studies identify mesencephalic dopaminergic neurons as the primary target of NT-3 and FGF and further demonstrate that sensitivity for these growth factors is restricted to distinct subsets of dopaminergic neurons. Finally, our results suggest that the known survival-promoting effects of TGF α and PDGF-BB on dopaminergic neurons are mediated through mesencephalic glia.

451.15

ROLE OF ESTROGEN IN AFFECTING INCREASED ALCOHOL INTAKE IN TRANSGENIC TGF α MICE. Leena Hilakivi-Clarke*, Lombardi Cancer Research Center, Georgetown University, Washington, DC 20007

Results with transgenic CD1 mice that overexpress transforming growth factor α (TGF α) suggest that this growth factor alters non-reproductive sex-related differences in behavior. Specifically, male TGF α mice exhibit a feminization of locomotor activity, immobility in the swim test, and sodium preference. These effects may be mediated through an interaction between TGF α and estrogen. The TGF α mice exhibit elevated plasma 17 β -estradiol (E2) levels. Castration reverses the feminized behavioral patterns in the male TGF α mice. The present study investigated the effect of orchietomy, E2 and the antiestrogen tamoxifen on voluntary alcohol consumption in transgenic TGF α mice. Both the male and female transgenics consumed more 5% alcohol (expressed as a percentage of total fluid intake) than the non-transgenic mice ($F(1,39)=8.8$, $p<.005$). Orchietomy did not have a significant effect on alcohol intake. In non-transgenic CD1 male mice, treatment with pellets releasing E2 increased and treatment with tamoxifen reduced alcohol intake, when compared with placebo-treated mice ($H(5)=25.2$, $p<.001$). In ovariectomized females, E2 reduced alcohol intake ($H(4)=12.6$, $p<.006$). These data suggest that overexpression of TGF α increases alcohol consumption in both sexes. Estrogen also increases alcohol intake in non-transgenic male mice, and this is reduced by the antiestrogen tamoxifen. However, since orchietomy at adulthood did not reverse the increased alcohol intake patterns in the transgenic mice, the effects of TGF α on alcohol consumption may be mediated through other pathways than elevated E2. Alternatively, the effects of E2 occurred during the critical period of sexual differentiation.

NEUROTROPHIC FACTORS FAIL TO PREVENT CASTRATION-INDUCED REGRESSIVE CHANGES IN AN ANDROGEN-SENSITIVE RAT SPINAL NUCLEUS. M.C. Clark-Phelps¹, N.T. Neff², and D.R. Sengelaub¹.

¹Program in Neural Science, Indiana University, Bloomington, IN 47405; ²Cephalon, Inc., West Chester, PA 19380.

Motoneurons in the rat spinal nucleus of the bulbocavernosus (SNB) are sensitive to androgens. Castration of adults significantly reduces SNB dendritic length, soma size, and target muscle weight, and these changes can be prevented or reversed with androgen treatment. Using compounds demonstrated to have trophic effects on motoneurons in several models, we assessed maintenance of muscle weight and motoneuron morphology of the androgen-sensitive SNB system following castration in adulthood.

Adult male rats (Sprague-Dawley) at approximately 90 days of age were either castrated or left intact. Castrated rats received daily subcutaneous injections over the SNB target muscles of either IGF-I (1 mg/kg), CNTF (1 μ g), or vehicle alone for six weeks. Following treatment, SNB target muscles (bulbocavernosus and levator ani; BC/LA) were weighed and motoneuron morphology was visualized histochemically after retrograde labeling with a cholera toxin-HRP conjugate. Castration significantly reduced SNB soma size and BC/LA muscle weight relative to intact males, and treatment with either IGF-I or CNTF had no effect. Thus, unlike androgen, IGF-I and CNTF failed to prevent castration-induced regressive changes in these aspects of SNB morphology, suggesting that the androgen-dependent trophic effects observed in this system are not mediated by these compounds in adulthood. (Supported by Cephalon)

EFFECTS OF GROWTH FACTORS AND CYTOKINES ON HIPPOCAMPAL CELLS DERIVED FROM THE H-2Kb-tsA58 TRANSGENIC MOUSE.

F. Rashid-Doubell, Spon: Brain Research Association, Dept of Psychology, Institute of Psychiatry, De Crespigny Park, London SE5 8AF, UK.

A number of workers have made use of transfection and retroviral-mediated gene insertion using a variety of oncogenes in order to immortalise neural precursor cells. This study used a conditionally immortalised hippocampal cell population derived from the H-2Kb-tsA58 transgenic mouse. The mouse possesses an established integrated copy of the early region of the large tumour antigen from the temperature sensitive gene allowing immortality to be controlled at the permissive temperature of 33°C, the non-permissive temperature being 39.5°C.

We examined the effects of several growth factors including basic fibroblast growth factor (bFGF), nerve growth factor (NGF), brain-derived neurotrophic factor (BDNF) and neurotrophin-3 (NT-3). The cytokines used were γ -interferon and ciliary neurotrophic factor (CNTF) on E15 transgenic mouse hippocampus progenitor cells.

Initial results showed that bFGF produced an elevation in both survival and proliferation in the hippocampal cells with maximal effects produced at a concentration of 10ng/ml. NGF produced minimal increase in cell number, but did however induce differentiation when kept at 39.5°C. The other 2 neurotrophins (BDNF and NT-3) as well as CNTF produced interesting results which will be shown in the poster. Cells treated with γ -interferon (γ -IFN) were lower in number and longevity at the higher concentrations.

Nerve growth factor (NGF) regulation of estrogen receptors in the developing nervous system. R.C. Miranda*, F. Sohrabji, C.D. Toran-Allerand, Columbia University, Dept. Anatomy and Cell Biology, 630 West 168th St., New York, NY 10032

We are interested in examining mechanisms regulating estrogen actions during neuronal differentiation in the central nervous system. Our research has focused on one possible mechanism, the developmental interactions of nerve growth factor (NGF) and estrogen receptors. Using a combination of steroid autoradiography, immunohistochemistry and *in situ* hybridization methodologies, we have shown that estrogen target neurons of the developing forebrain express the NGF receptors, p75^{NGFR} (the pan-neurotrophin receptor) and *trkA* (the specific tyrosine kinase receptor). Moreover, NGF and estrogen reciprocally regulate their receptors in PC12 cells, a neurotrophin-responsive cell line. In this study, we examined the regulation of estrogen binding by NGF in the developing forebrain using organotypic explant cultures maintained in roller tube assemblies. Explant cultures of the postnatal day 2 rat cerebral cortex and basal forebrain were maintained 8 days *in vitro*, in the presence or absence of NGF (100 ng/ml). Our data indicate that estrogen receptors and receptor mRNA are expressed in these cultures, in patterns similar to those observed *in vivo*. Using a modified nuclear exchange assay to measure specific, intra-nuclear estrogen (³H-moxestrol) binding, we found that NGF alters nuclear estrogen binding in a regionally specific manner. We are currently examining mechanisms underlying regionally-specific NGF regulation of estrogen binding. (Supported by grants from the NIH, NIMH, NSF, AHA and an ADAMHA-RSA to C.D.T.A.)

NERVE GROWTH FACTOR-INDUCED PLASTICITY OF CEREBROVASCULAR INNERVATION. D. Ondris, C. Billieu, K. Schwenk, S. Page, and L.G. Isaacson*. Dept of Zoology, Miami University, Oxford, OH 45056.

We have shown that a two week intracerebroventricular infusion of nerve growth factor (NGF) into a female adult rat results in a sprouting response by mature sympathetic perivascular axons associated with the intradural internal carotid artery (ICA). The purpose of the present study was to 1) use electron microscopy to examine the role of afferent input to the superior cervical ganglion (SCG) in the sprouting response, 2) carry out calcitonin gene related peptide (CGRP) immunohistochemistry with and without sympathectomy to examine whether sensory perivascular axons respond to NGF infusion 3) use High Performance Liquid Chromatography (HPLC) to determine whether increased catecholamines accompany the morphological response. The number of axons observed following deafferentation and subsequent NGF infusion was similar to that observed following NGF infusion only (1832 vs. 1829 axons). NGF infusion resulted in increased perivascular density of CGRP-positive axons compared to VEH infused animals but the most significant increase in CGRP-positive axons was observed following bilateral ganglionectomy and NGF infusion. In HPLC studies, ICA norepinephrine concentrations were significantly increased following NGF infusion (52 µg/g vs. 22 µg/g). These findings suggest that afferent input to the SCG is not a prerequisite to the NGF-induced sprouting response, that mature sensory perivascular axons respond to NGF infusion, and that increased catecholamines accompany the sprouting response.

452.3

INTRAVENTRICULAR INJECTIONS OF NGF FAIL TO INCREASE THE HEMICHOLINIUM-3 BINDING IN THE HIPPOCAMPUS OF NEONATAL RATS. X. Tian, N. A. Bourjeily, J. Weingartner, K. A. Crutcher, and J. B. Suzski. Depts. of Physiology & Biophysics, and Neurosurgery, University of Cincinnati, Cincinnati, OH 45267-0576.

The effect of NGF on the development of cholinergic phenotypic markers in the septo-hippocampal pathway (SHP) was investigated in the rat at postnatal days 7 (PN7) and 14 (PN14). Relative to adult levels, the septa of PN7 and PN14 animals contained respectively, 31.3% and 84.1% NGF, and 24.6% and 92.9% cholineacetyltransferase (ChAT) activity. The densities of [³H]hemicholinium-3 (HC-3) binding sites in the hippocampi of PN7 and PN14 animals were 7.1% and 11.8% of adult, respectively. Intraventricular administration of NGF three days prior to assays, increased septal ChAT to 70.8% at PN7 and 120% at PN14, but had no significant effect on the [³H]HC-3 binding in the hippocampus. These results indicate that in contrast to ChAT activity, the developmental expression of the high affinity choline transport (HACU) in the terminals of septo-hippocampal neurons is not regulated by NGF. Furthermore, assuming that density of HACU sites provides an index of cholinergic innervation in the hippocampus, these data suggest that NGF probably has no effect on the extent of innervation of the hippocampal targets by the septal cholinergic neurons during development of SHP in the rat. Supported by NIH grants ES06365 (JBS) and NS17131 (KAC).

REGULATION OF SURVIVAL IN DEVELOPING NON-DOPAMINERGIC NEURONS BY GLIAL CELL LINE-DERIVED NEUROTROPHIC FACTOR (GDNF). A. Newsome, D. Prevette, J. Johnson, S. Wang and R. Oppenheim. Dept of Neurobiology & Anatomy, Bowman Gray Sch of Med, Winston Salem, NC 27157.

GDNF is a potent neurotrophic factor that enhances the survival of cultured midbrain dopaminergic neurons. Although the highest levels of expression of GDNF are in developing brain cells and CNS regions that receive dopaminergic innervation (e.g., the striatum), it is also expressed in other areas including spinal cord. To examine the possible role of GDNF in the survival of non-dopaminergic neurons in brain and spinal cord, avian embryos were treated *in ovo* with GDNF during periods of naturally occurring (programmed) cell death. Treatment during a period of "early" cell death [embryonic day (E)6-9] greatly enhanced the number of surviving spinal motoneurons (MNs) and sympathetic ganglion (SG) cells but was without effect on sensory neurons in the dorsal root (DRG) and nodose ganglia (NG). GDNF also promoted survival in cultures enriched (60-80%) for MNs suggesting that it may promote survival *in vivo* by a direct action on neurons. Treatment at a later period of cell death (E9-E14) also rescued MNs and SG cells but was ineffective on cell death in the DRG, NG and ciliary ganglion. Several populations of neurons in the brain (sensory, motor, interneurons) that undergo late cell death between E9 and E15 were also examined following GDNF treatment from E9-E14. These included the III, IV, V, VI and VII cranial motor nuclei, the sensory mesencephalic nucleus of V, the auditory nuclei magnocellularis and laminaris, the accessory oculomotor nucleus (AON) and the isthmus-optic nucleus (ION). Preliminary cell counts indicate that only the AON, ION and n.III exhibit small, but statistically significant, increases in survival. Although additional studies are in progress, these data suggest that GDNF may be a trophic agent for non-dopaminergic populations of neurons.

452.2

THE ADULT RAT HIPPOCAMPUS CONTAINS NGF IN SOLUBLE AND BOUND FORMS. J. Costello, J. Conner, P. Burnham* and S. Varon. Dept of Biology 0601, Univ. of Calif., San Diego, San Diego, CA 92093.

The hippocampus is a primary site of neurotrophin mRNA expression in both developing and adult rats. Neonatal sympathetic ganglia transplanted into adult rat hippocampus grow neurites selectively into dentate gyrus and CA3 regions, which display NGF-like staining. The discrete boundaries of this staining suggest the occurrence of NGF, or a related neurotrophin, firmly bound to hippocampal structures. To test this possibility, supernatant and resuspended pellet fractions from centrifuged hippocampal sonicates were assayed on E8 DRG neurons, with one trophic unit (TU)/ml of NGF defined as the concentration required for half maximal survival.

Activity was found in both soluble (15 TU per hippocampus) and pellet (68 TU per hippocampus) fractions. The number of neurons supported by optimal pellet and soluble concentrations was the same as that supported by NGF, although the soluble fraction contained a toxic material which in some cases reduced maximal survival. No additional neuronal survival was achieved by combining optimal concentrations of soluble and pellet fractions or by combining either one with NGF. An amount of anti-NGF antibody that completely blocks the activity of 50 ng/ml of NGF blocked greater than 60% of the soluble fraction activity and fully blocked optimal concentrations of the pellet fraction. BDNF and NT-3 supported 70% and 55%, respectively, of the number of neurons as did NGF, but did not add further support when combined with NGF, and their activity was not blockable by the NGF antibody.

These data indicate that the adult rat hippocampus contains a bioactive neurotrophin—probably NGF—in both soluble and bound forms. The bound factor could be the material that displays NGF-immunoreactivity in the hippocampal sections and might be the signal that is responsible for the selective hippocampal innervation by NGF-sensitive fibers.

452.4

STAGE-SPECIFIC EFFECTS OF NEUROTROPHIN-4/5 AND BRAIN DERIVED NEUROTROPHIC FACTOR DURING CEREBELLAR GRANULE CELL NEUROGENESIS. J.L. Zheng, M. Karihaloo and W.-Q. Gao*. Department of Neuroscience, Genentech, Inc., South San Francisco, CA 94080

We have used purified, well-characterized granule cell cultures (Gao et al., 1991, Neuron 6:705-715) to examine possible effects of the neurotrophins on four different stages of cerebellar granule cell neurogenesis. The four stages included neuronal proliferation, initiation of neuronal differentiation, neuronal maturation and neuronal maintenance. None of the neurotrophins stimulated proliferation of the granule cell precursors or rescued any phenotypic defects of the mutant *weaver* granule cells in the initiation of neuronal differentiation. However, neurotrophin-4/5 (NT-4/5) and BDNF, but not neurotrophin-3 (NT-3) or nerve growth factor (NGF), promoted neurite extension and survival of differentiated cerebellar granule cells. Moreover, NT-4/5 and BDNF enhanced neurite extension by *weaver* granule cells which were rescued by wild-type granule cells during differentiation. These findings suggest that NT-4/5 and BDNF promote the maturation and maintenance of differentiated granule cells, which are downstream to the *weaver* gene. In addition, no additive effects were seen with the combination of NT-4/5 and BDNF. The neurite-promoting and survival effects of NT-4/5 and BDNF could be completely blocked by the specific tyrosine kinase inhibitor K-252a. Thus, the two neurotrophins activate the same receptor trkB for signal transduction.

TRKB LIGANDS REGULATE CARDIORESPIRATORY AFFERENT DEVELOPMENT T. Hertzberg^{1,3}, J.T. Erickson¹, G. Fan¹, J.C.W. Finley^{1,2*} and D.M. Katz¹

¹Depts. of Neurosciences and ²Medicine, CWRU School of Medicine, Cleveland, OH 44106-4975 and ³Dept. of Woman and Child Health, Div. of Neonatology, Karolinska Hospital, S-171 76 Stockholm, Sweden.

Carotid body afferent (CBA) neurons in the rat petrosal ganglion (PG) were used as a model system to define trophic requirements of cardiorespiratory sensory neurons *in vivo* and *in vitro*. CBA neurons are distinguished from other visceral afferents by expression of dopaminergic traits, including the catecholamine-synthesizing enzyme, tyrosine hydroxylase (TH; Finley, et al., 1993). *In vitro*, coculture of the PG and carotid body led to a 4-fold increase in TH neuron survival that was not seen in the presence of other tissues. The trophic effect of the carotid body was mimicked by treatment of PG explants with the trkB ligands brain-derived neurotrophin factor (BDNF) and neurotrophin-4 (NT-4), whereas nerve growth factor (NGF) and NT-3 had no effect. To determine whether similar mechanisms regulated development *in vivo*, we examined the effect of carotid body removal (glomectomy) on CBA survival in newborn rats. The majority (73%) of TH⁺ CBA neurons died following glomectomy, indicating a predominant role of peripheral targets in regulating survival *in vivo*. However, at least half these cells could be rescued by replacing the carotid body with BDNF implants, indicating that BDNF could substitute for target-derived trophic support *in vivo*. Moreover, BDNF mRNA was detected in the newborn carotid body by RT-PCR, raising the possibility that BDNF normally plays a role in mediating carotid body influences on CBA development. CBA survival was unaffected, however, by glomectomy at three weeks of age, indicating that peripheral target dependence is limited to the immediate postnatal period. Our findings demonstrate that survival of this subset of cardiorespiratory afferents is critically dependent on peripheral target-derived support during a restricted period of perinatal development and suggest that trophic influences are mediated by trkB ligands, such as BDNF or NT-4. Supported by HL-42131 (DMK) and Wenner-Gren Foundation, Swedish Society of Medicine and Swedish MRC (TH).

INVOLVEMENT OF NEUROTROPHINS IN THE PHENOTYPIC SPECIFICATION OF CHICK CUTANEOUS AFFERENTS: G.R. Lewin*, M. Koltzenburg[§], K.V. Toyka[§], and Y.-A. Barde. Dept. Neurobiochemistry, Max-Planck Institute for Psychiatry D-82152, Martinsried. [§]Dept. Neurology, University of Würzburg, D-97080 Würzburg, Germany.

Neurotrophins may influence the phenotypic fate of sensory neurons during development. Here we have used an electrophysiological recording technique to study the functional properties of sensory neurons in the chick whose access to neurotrophins was manipulated *in ovo*. Monoclonal antibodies (anti-NGF and anti-NT3) were delivered by hybridoma cells placed on the chorioallantoic membrane at E3, whilst NT3 was secreted by A-293 cells. Between E17 and hatching recordings were made from cutaneous sensory neurons as described (Koltzenburg et al. Soc. Neurosci. this meeting). After anti-NGF treatment fibers conducting in the C-Fiber range (<1 m/s) were still observed (n=11), however, none of these fibers responded to noxious heat, although all had mechanical thresholds similar to those in normal chicks (ie. they were C-M). This is in contrast to untreated control animals where nearly 50% of the fibers respond to noxious heat (C-MH). The functional properties of presumptive A-fibers appeared normal (conduction velocity >2 m/s). This is consistent with the idea that only C-MH fibers in the chick depend on NGF for survival. After NT3 treatment the conduction velocity range of recorded afferents was indistinguishable from controls. A-fibers also appeared unaffected by the treatment in terms of mechanical threshold. However, amongst the C-fiber population all the fibers studied (n=12) had unusually low mechanical thresholds, and none responded to noxious heat. Comparison of the NT3 treated C-fibers to control A-fibers revealed that their mechanical thresholds were very similar. Anti-NT3 treatment did not appear to affect the physiology of C-fiber afferents. The results indicate that the availability of neurotrophins can selectively effect the functional properties of developing sensory neurons *in vivo*.

452.9

INFLUENCE OF NEUROTROPHINS ON THE DEVELOPMENT OF PRIMARY AFFERENT PROJECTIONS IN THE CHICK SPINAL CORD. A.L. Eide*, G.R. Lewin and Y.-A. Barde. Inst. Basic Medical Sciences, University of Oslo, N-0317 Oslo, Norway. Dept. Neurobiochemistry, Max Planck Institute for Psychiatry, D-82152 Martinsried, Germany.

Primary afferent projections in the chick can be studied using the lipophilic tracer Dil in fixed embryos. In the present experiments we have examined the influence of neurotrophin treatment or deprivation with monoclonal antibodies to NT3 and NGF. NT-3 was delivered by NT-3 secreting A-293 cells placed on the chorioallantoic membrane at E3, whilst antibodies were delivered by hybridoma cells. At E12 or E14 treated and control embryos were fixed and Dil was injected into the LS6 DRG, the LS6 spinal nerve or into an identified muscle or skin nerve. In normal embryos primary afferents have long ranging projections outside their segment of entry and have collaterals at least 6 segments beyond their segment of entry (Eide & Glover J. Comp Neurol in press). In contrast LS6 afferents in anti-NT3 treated embryos projected primarily to their segment of entry. Furthermore, axons projecting ventrally to the motoneuron pools were largely absent although labelled collaterals were seen innervating all dorsal horn laminae. Interestingly, sensory neurons and their collaterals in the dorsal horn were labelled from muscle nerves, but few collaterals were seen in the ventral horn. After NT-3 application intersegmental projections appeared normal, although there appeared to be fewer collaterals in Lamina II within the segment of entry. This may be related to a change in the phenotype of sensory neurons treated with NT-3 (Lewin et al. Soc. Neurosci. Abstr. this volume). Finally, animals treated with anti-NGF showed little projection to laminae II which is consistent with the idea that C-MH fibers are killed by this treatment. The results suggest that primary afferent projections may be molded by the availability of neurotrophins.

452.11

HIGH-AFFINITY NEUROTROPHIN RECEPTOR EXPRESSION IN THE CAT RETINA DURING NORMAL DEVELOPMENT AND FOLLOWING NEONATAL VISUAL CORTEX DAMAGE. V.R. King, J.-T. Xue, and P.D. Spear*. Dept. of Psychology and Ctr. for Neuroscience, Univ. Wisconsin, Madison WI 53706.

We recently reported that normal 1-day to 4-week-old kittens show pericellular labeling of the low-affinity nerve growth factor receptor (LNGFR) in the retinal ganglion cell layer (GCL). In addition, kittens that receive a visual cortex (VC) lesion from 1 day to 18 weeks of age show an upregulation of this labeling in the hemiretinae that project to the damaged hemisphere. We examined retinal sections from these same cats to determine if similar changes are seen for the high-affinity tyrosine kinase (trk) receptors.

Sections were taken through the areas centralis and processed with rabbit polyclonal antibodies to the trkA, full length trkB, truncated trkB, and trkC receptors. Cats of all ages showed patterns of trkA and full length trkB labeling consistent with expression on Müller cells. Pericellular trkB labeling also was seen in the GCL of normal 1-day to 4-week-old kittens. Soma and dendrite labeling indicated that many of these cells are ganglion cells. Kittens that received VC damage on the day of birth had greater pericellular trkB labeling in the hemiretinae projecting to the damaged hemisphere than in the hemiretinae projecting to the intact hemisphere. This difference was seen in kittens that survived from 3 days to 8 weeks, but not for ≥ 12 weeks. It also was seen in cats that received a VC lesion at ≤ 18 weeks of age, but not ≥ 26 weeks of age. TrkC labeling was seen only on blood vessels. Truncated trkB labeling was light and limited to the nerve fiber layer.

The present study suggests that brain-derived neurotrophic factor (BDNF), which binds preferentially to trkB, is involved in retinal development and plasticity. In addition, both nerve growth factor, which binds preferentially to trkA, and BDNF may affect the retina via Müller cells.

452.8

SINGLE UNIT RECORDINGS OF CHICK CUTANEOUS SENSORY NEURONS IN VITRO M. Koltzenburg*, G.R. Lewin, Y.-A. Barde, K.V. Toyka. Dept. Neurology, University of Würzburg, D-97080 Würzburg, Dept. Neurobiochemistry, Max-Planck Institute for Psychiatry, D-81512 Martinsried, Germany.

Chick sensory neurons have been commonly used as a model system to study the effects of neurotrophins on neuronal survival *in vitro*. As these DRG neurons are physiologically heterogeneous, we have developed a technique to characterize functionally the different types during late embryonic development and early post-hatching period (E17-P21) *in vitro*. The cutaneous femoralis medialis nerve innervating medial thigh was dissected out together with the skin of its innervation territory and placed in an organ bath. Single unit recordings were obtained using standard teased fiber techniques and units were analyzed with controlled mechanical, thermal and chemical stimuli. A total of 91 neurons conducting between 0.31-6.6 m/s were studied. Units displayed no ongoing activity and mechanical thresholds (von Frey hairs) ranged from 1-64 mN. Of 44 units conducting ≤ 1 m/s many had probably nociceptive function, as 16/34 were excited by noxious heat (thresholds 39.5-47°C) and 4/33 by noxious cold. Application of algescic chemicals (mixture of 10µM bradykinin, 5-HT, histamine, PGE₂) activated 14/27 units all of which were also thermosensitive. Following chemical stimulation 10/14 units displayed lowered heat thresholds and stronger suprathreshold responses indicating sensitization. Heat-insensitive fibers did not respond to chemical stimulation. During the observed developmental interval mechanical thresholds tended to increase. At all ages units conducting > 2 m/s (presumptive A-fibers) could be classified on the basis of a slowly or rapidly responses to innocuous skin indentation, none responded to noxious heat or chemical stimuli. We conclude that the chick skin-nerve *in vitro* preparation is suitable for the study of functional properties of diverse cutaneous sensory neurons both during embryogenesis and the early post-hatching period.

POSTNATAL AUDITORY NEURONS DEPEND UPON BRAIN DERIVED NEUROTROPHIC FACTOR FOR SURVIVAL AND BOTH NERVE GROWTH FACTOR AND NEUROTROPHIN-3 FOR THE MAINTENANCE OF PERIPHERAL NEURITES IN VITRO. H. Staecker^{1,3}, V. Galinovic-Schwartz¹, W. Liu¹, P.P. Lefebvre^{1,2}, B. Malgrange³, G. Moonen¹, and T.R. Van De Water^{1,2,3}. Depts. of ¹Otolaryngology & ²Neuroscience, Albert Einstein College of Medicine, Bronx, New York 10461; Dept. of ³Human Physiology & Pathophysiology University of Liege, Liege, B4020 Belgium.

Both *trkB* and *trkC* immunolocalized over neurons while *trkA* staining associated with the supporting cells of the postnatal spiral ganglion. Using *in situ* RT-PCR of postnatal cochlea tissue sections, we identified products for NGF, BDNF and NT-3 mRNAs in this tissue. Organotypic explants of postnatal organ of Corti were cultured in the presence of either antisense or sense oligonucleotides (5µM) for NGF, BDNF or NT-3. ELISA testing showed a 90% reduction in NGF protein levels in response to NGF-AS oligo. Evaluation of the effects of neurotrophin antisense treatment in explants was accomplished by confocal microscopy of *α*NF66 immunostained whole mounts. BDNF-AS treatment resulted in neuronal cell death, NT-3-AS treatment affected synaptic contacts, and downregulation of NGF destabilized peripheral axons. These findings demonstrate that the neurotrophins studied play separate, unique but interrelated roles in postnatal organ of Corti explants. NORADRENERGIC NEURONS IN THE LOCUS COERULEUS OF BIRDS EXPRESS TRKA AND P75 AND RESPOND TO NGF. C.S. von Bartheld¹, A. Schober¹, Y. Kinoshita¹, R. Williams², and M. Bothwell¹.

¹Dept. of Physiology and Biophysics, University of Washington, Seattle, WA 98195 & ²Dept. of Developmental Biology, Biomedical Center, Uppsala Universitet, Uppsala, Sweden.

The noradrenergic neurons in the chicken locus coeruleus express the neurotrophin receptor p75 (von Bartheld & Bothwell 1992, J. Comp. Neurol. 320:479-500). To determine which neurotrophin may regulate these neurons, expression of trk receptors was examined by *in situ* hybridization. A sub-population of neurons in the locus coeruleus expresses trkA receptors at 9 and 18 days of incubation (E9 & E18). To test if these neurons can bind and internalize NGF, retrograde transport of radio-iodinated (I-125) NGF was examined. Neurons in the locus coeruleus of E15 chick embryos accumulate I-125 NGF after injections into the basal forebrain. The retrograde transport of radio-iodinated NGF is restricted to the noradrenergic neuronal population as evidenced by double-labeling with an antibody against dopamine-beta-hydroxylase (DBH). To test if noradrenergic coeruleus neurons respond to NGF, explant cultures and dissociated neurons were treated with or without NGF. NGF did not significantly improve neurite outgrowth from E15 explants or the survival and morphology of DBH-labeled coeruleus neurons that were dissociated at E12 and labeled with DBH antibody two days later. *In vivo*, the size of DBH-labeled coeruleus neurons was significantly increased after injections of NGF into the telencephalon of E19-20 embryos, but NGF did not rescue these neurons from toxin-induced cell death after injections of 6-hydroxydopamine into the telencephalon. These results indicate that NGF may play a role in the development and physiology of the avian locus coeruleus. The data confirm major species differences between birds and mammals with regard to trophic regulation of presumptive homologous neuronal populations.

452.13

GLIAL CELL LINE-DERIVED NEUROTROPHIC FACTOR (GDNF), A POTENT SURVIVAL FACTOR FOR SPINAL MOTONEURONS, IS PRESENT IN DEVELOPING LIMB. C.E. Henderson*, R.A. Pollock, M. Armanini#, H.S. Phillips# and A. Rosenthal#. INSERM U.382, 34033 Montpellier, France; and #Dept. Neuroscience, Genentech, Inc., So. San Francisco, CA 94080.

Several neurotrophic factors enhance motoneuron survival *in vitro* and *in vivo*. The most potent of those reported to date, the neurotrophins BDNF, NT-3 and NT-4/5, act at picomolar concentrations. In mice in which the genes for trkB or trkC are inactivated, there is significant but not complete motoneuron loss, suggesting that the neurotrophins may not be the only factors required for physiological motoneuron survival.

GDNF was originally purified on the basis of its trophic actions on midbrain dopaminergic neurons. We tested recombinant rat GDNF on purified motoneurons from E14 rat spinal cord. After 3 days in culture, GDNF maintained nearly all (>90%) motoneurons that initially developed; similar efficacy was obtained for BDNF. However, dose response curves revealed that GDNF was 20- to 50-fold more potent than the neurotrophins; half-maximal survival was achieved at 10^{-14} M.

Using RT-PCR, GDNF mRNA was detected in E15 rat limb bud, cultured neonatal Schwann cells and embryonic myotubes; levels in skin were considerably lower. *In situ* hybridization on sections of E14.5 rat embryos showed signal over some muscle masses and some developing nerve tracts; labeling was essentially absent from the spinal cord and skin.

Taken together, these findings suggest that GDNF plays an important role in early motoneuron development. Its actions may be complementary to those of the neurotrophins (and perhaps other factors) both during development and in therapeutic approaches to human motoneuron diseases.

FETAL NGF AUGMENTATION AFFECTS WHISKERPAD INNERVATION DENSITY AND PATTERNS AT BIRTH. F.L. Rice*, T.A. Henderson, P.A. Osborne, E.M. Johnson & M.F. Jacquin. Pharmacology, Albany Med. Coll., Albany NY 12208; Anatomy & Neurobiology, St. Louis Univ. Sch. Med., St. Louis MO 63104; Molecular Biology & Pharmacology, Neurology, Washington Univ. Sch. Med., St. Louis MO 63110.

Systemic NGF injections in fetal rats preserve excess trigeminal ganglion cells and interrupt whisker-related pattern formation in the brainstem (Henderson et al., *J. Neurosci.* 14, '94); primary afferents in the brainstem also lack somatotopic patterns and collaterals do not have exuberant arbors. Because these findings suggest mechanisms by which the periphery makes CNS patterns, it is important to understand how NGF alters pattern formation. One idea is that high levels of NGF preserve (or induce) a transient exuberant projection to inter-whisker surfaces that lessens disparity in the innervation densities of the whisker follicles and intervening skin, therein lessening the "digitized" nature of the receptor sheet and its resultant CNS map. A related idea is that NGF accelerates development of a late-arriving innervation of inter-whisker skin, leading to the same CNS effect. These hypotheses were tested by injecting rats systemically with NGF on embryonic days 15 and 18, sacrificing at birth, confirming that CNS patterns were absent, and examining the mystacial pad innervation with PGP 9.5 and RT97 immunofluorescence. Comparable infraorbital nerve fascicles in NGF-treated neonates were larger and contained more labeled axons than in normal neonates, although the innervation of whisker follicles seemed comparable in both distribution and maturation. However, preliminary observations indicate that the innervation of the intervibrissal epidermis is more mature in the NGF-treated cases. These data support both of the above hypotheses and suggest that neurotrophins control pattern formation by orchestrating innervation density patterns in the whiskerpad during a critical period in development. IDENTIFICATION OF DIFFERENT ARIA SPLICE VARIANTS EXPRESSED BY CHICK CNS AND PNS NEURONS DURING DEVELOPMENT

X. Yang*, Y. Kuo & L. Role. Dept. of Anat. & Cell Biol. in the Ctr for Neurobiol. & Behav. Columbia Univ. P&S, 722 W. 168th. St. New York, NY 10032

Many studies have shown that innervating motor neurons regulate the accumulation and enhanced synthesis of acetylcholine receptors at early nerve-muscle contacts. Two factors important to the clustering and enhanced synthesis of muscle AChRs have been identified (Agrin and ARIA respectively; work of Scheller, McMahan, Fischbach and their colleagues).

Presynaptic input to CNS and PNS neurons can also regulate nAChR expression. For example, preganglionic input increases the ACh sensitivity, as well as the number, clustering and biophysical properties of surface nAChRs on sympathetic neurons from embryonic chicken. Conditioned medium (CM) from both preganglionic neurons (dorsal spinal cord) and motor neurons (ventral spinal cord) mimic the effects of innervation. These observations suggest that Agrin, ARIA and/or related molecule(s) might be expressed by preganglionic neurons and regulate the expression of neuronal nAChRs with the innervation of sympathetic neurons. To identify ARIA like molecule(s), an embryonic day 5-11 spinal cord cDNA library was constructed and screened with a PCR derived ARIA probe (~1.1kb). More than 10 distinct splice variants were cloned, including multiple "nARIA" like splice forms (Kuo et al., Abstract, this volume). *In situ* hybridization reveals that ARIA, nARIA and Agrin are expressed in several regions of brain and spinal cord. In spinal cord, clear positive signals were detected with each probe in ventral motor neurons, with a full length nARIA probe yielding the strongest signal seen in the preganglionic (visceral) motor neurons at embryonic day 8. (supported by NS29071).

EXPRESSION AND FUNCTION OF TGF- β 2 AND - β 3 IN THE EMBRYONIC CHICK SPINAL CORD, HINDBRAIN, AND SPINAL GANGLIA. K. Unsicker, C. Meier, and K.C. Flanders (SPONS: JEN*). Dept. of Anat. & Cell Biol., Univ. Heidelberg, D-69120 Heidelberg, Germany.

TGF- β s are multifunctional cytokines playing prominent roles in the control of cell proliferation, extracellular matrix composition, and inflammatory events. Established functions on neural cells include regulation of neuron survival as well as glial cell proliferation and gene expression. We have studied the distribution of TGF- β 3 mRNA by *in situ* hybridization and the localization of TGF- β 2 and - β 3 immunoreactivities (ir) with isoform-specific probes in the embryonic chick spinal cord, hindbrain, and dorsal root ganglia (DRG). At E3, TGF- β 3 mRNA as well as TGF- β 2 and - β 3-ir were prominent in the notochord, wall of the aorta, and dermomyotome, but absent to low in the neural tube and at sites, where DRG coalesce. At E5 and E7, strong TGF- β 2 and - β 3 ir was seen in radial glia of spinal cord and hindbrain as well as in fiber strands transversing the DRG and extending into spinal nerves, but not in neuronal cell bodies. Neuronal perikarya in DRG did not become ir for TGF- β 2 and - β 3 until E11, but even then the signals for TGF- β 3 mRNA could not specifically localized to the neuronal cell bodies. In the spinal cord, glial/glia progenitor cells were most strongly labeled by *in situ* hybridization for TGF- β 3 mRNA at this age. DRG explants from E8 embryos were used to investigate whether TGF- β interfered with neurite growth. All TGF- β isoforms augmented the number of neurites emerging from the explant rim, and increased average neurite length over a period of 24 hours, as compared to untreated cultures. At the concentration applied (20 ng/ml) TGF- β s were, however clearly less potent than NGF. Although the site(s) of action of TGF- β in the complex culture system employed remain to be explored, our data are consistent with the notion that TGF- β s are present at sites where they can affect neuron migration, differentiation and axon outgrowth.

bFGF INDUCES ASTROGLIOSIS IN ADULT MOUSE BRAIN.

X.F. Zhang, E.J. Elliott*, D.A. Parks and P.S. Fishman. Neurology and Research Svc., Baltimore VAMC, and the Univ. of Md. Sch. of Med., Baltimore, MD 21201.

Basic fibroblast growth factor (bFGF) is a multipotential stimulant of many cell types including astrocytes. In culture bFGF stimulates both proliferation and protein synthesis in astrocytes. The effects of bFGF on astrocytes *in situ* are less clear. Some studies have found that bFGF increases the number of GFAP positive astrocytes while other investigations showed no increase in gliosis over controls. To resolve this question we evaluated mice treated with bFGF with both immunocytochemical and quantitative immunohistochemical techniques. Adult C57BL/6 mice were injected in the striatum with either saline, human recombinant bFGF (2 μ l) or an equal amount of human recombinant albumin. Immunocytochemical studies showed pronounced gliosis in the entire injected striatum of bFGF injected mice. This response consisted not only of an increase in number and density of GFAP positive astrocytes, but also in a dramatic increase in astrocyte size. Increased gliosis was also seen after injection of human albumin compared to saline injected animals, but this increase was not as pronounced as with bFGF. This effect was maximal at 4 to 7 days. Immunoblot analysis for GFAP of injected hemispheres confirmed the observation of bFGF > albumin > saline > normal brain in stimulating GFAP accumulation.

ISOLATION AND CHARACTERIZATION OF CHICK AND HUMAN nARIA, A NOVEL MEMBER OF THE ERBB2/HER LIGAND FAMILY WHICH LACKS THE IMMUNOGLOBULIN DOMAIN.

Y. Kuo*, X. Yang, and L. Role. Dept. Anat. & Cell Biol. in the Ctr. Neurobiol. & Behav. Columbia Univ., P&S, 722 W. 168th St. NY, NY 10032.

ARIA is believed to mediate the increased transcription of muscle type nicotinic AChR subunits during innervation of the muscle by motor neurons (Falls et al. *Cell* 72, 801-815, 1993). The ARIA message is a splice variant of a gene that also encodes the glial growth factors, heregulins, and NDFs. Media conditioned by somatic or visceral motor neurons increase the number of new surface AChRs in sympathetic neurons (Gardette et al. *Dev. Biol.* 147, 83-95, 1991). We have begun to test the hypothesis that homologs of ARIA might be the active component released by visceral motoneurons by first identifying candidate regulators of neuronal nAChR expression.

Screening of an E13 chick brain cDNA and a human cerebellar cDNA library resulted in the isolation of a novel ARIA splice variant (nARIA). Unlike previously reported splice forms, the nARIA clone does not contain an extracellular Ig domain. An N-terminal domain unique to nARIA is spliced to the EGF-like domain of ARIA. The nucleotide sequence of the chick nARIA clone 3' to the splice junction is identical to the published ARIA sequence. Northern blotting shows that nARIA expression is nervous system specific, with particularly high levels detected in the cerebellum. *In situ* studies are underway to further localize expression of this splice form (See abstract by Yang et al). Members of the ARIA/NDF/GGF family have been shown to bind to erbB2/neu/her2 and her4, which are of 185kd and 180kd respectively. To test the role of the domain N-terminal to the EGF-like domain in receptor binding, mammary tumor cell lines which overexpress erbB2 were treated with conditioned media from nARIA transfected COS cells. Treatment results in a time- and dose-dependent tyrosine phosphorylation of an approximately 180kd protein. We hypothesize that the region N-terminal to the EGF-like domain is not necessary for receptor binding, but may restrict interaction between family members or modulate affinity for the receptor. (Supported by NS29071)

MICROCEPHALY AND DELAY OF DEVELOPMENTAL BEHAVIORS INDUCED BY PRENATAL BLOCKADE OF VIP.

J. M. Hill*, P. Gressens, B. Paindaveine, J. Y. Wu, I. Gozes, M. Fridkin and D. E. Brenneman. Lab. of Dev. Neurobiol., NICHD, NIH, Bethesda, MD 20892; Ped. Neurol., Univ. Louvain Med. Sch., Brussels, Belgium; Dept. Chem. Pathol., Tel Aviv, Israel; Weizmann Inst. Sci., Rehovot, Israel.

VIP has neurotrophic properties in CNS cultures (*PNAS* 83:1159, 1986), influences neurobehavioral development (*Peptides* 12:87, 1991) and stimulates *in vitro* embryonic growth during mid gestation through VIP receptors localized to the CNS (*Nature* 362:155, 1993). In the present study, embryonic growth and neonatal behaviors were examined in the offspring of pregnant mice treated with a VIP antagonist during mid gestation. Treatment with a VIP antagonist resulted in a dose-dependent decrease in DNA (52% of controls), protein (43% of controls) in the heads of embryos which was prevented with cotreatment with VIP. In contrast, the DNA and protein content of the body was less affected (89% and 72% of the controls). Cortical wall thickness was reduced and BRDU incorporation demonstrated that the reduction was due to an inhibition of the G1-S transition of mitosis. Treatment later in development did not have growth-inhibiting effects. VIP antagonist treatment delayed both developmental milestones and the performance of neonatal behaviors in a dose-dependent manner. Co-treatment with VIP prevented antagonist-induced deficits. Milestones, including eye opening, ear twitch, and auditory startle, were delayed by about one day in treated rats. Motor behaviors such as surface righting, air righting, negative geotaxis, cliff aversion and rooting were slower developing in treated animals, with a delay of as much as 4 days in achieving normal performance. This *in vivo* evidence supports the importance of VIP in the growth and development of the nervous system.

452.20

Evidence for the role of DARP (Dopamine-Releasing Protein) during the development of rat dopaminergic neurons and the adrenal gland.

D.A. Llano* and V.D. Ramirez. Department of Molecular and Integrative Physiology, University of Illinois at Urbana Champaign 61801. Recent work from this laboratory suggests a role for DARP during development. DARP is a glycoprotein that stimulates dopamine release from the corpus striatum *in vitro* (Brain Res. 463: 335) and has been immunocytochemically located in the adrenal gland (Neuroendocrinology 58: 444) and in close association with catecholaminergic neurons in the rat CNS (Neuroendocrinology, in press). In addition, intrafetal administration of an anti-DARP monoclonal antibody (DARP mAb) at embryonic day 17 (E17) induces fetal resorption in a dose-dependent manner (Mol. Cell. Neurosci. 2: 410). In this study, ELISA analysis of crude E17 brain homogenates demonstrates the presence of a DARP-like protein. Purification of these crude homogenates with concanavalin A and immunoaffinity chromatography yielded a single 60 kDa protein that displayed dopamine-releasing activity in an *in vitro* superfusion assay. In addition, intrafetal administration of DARP mAb at E17 significantly elevated DA levels in the mesencephalon 24 and 48 hours post-injection, while decreasing these levels 72 hours post-injection. No changes in DA levels were detected in the diencephalon or in the telencephalon. We have shown that neonatal DARP mAb injections delay the development of hypothalamic and striatal dopamine levels and increases adrenal weight (Mol. Cell. Neurosci. 2: 410). Herein, we report that daily administration (Postnatal days 1-10) of a synthetic 36 amino acid peptide from the N-terminus of DARP causes adrenal atrophy in a dose-dependent manner at day P11. In addition, ELISA analysis indicates that DARP concentrations in whole brain extracts from E17 brains are two to three times higher than similar extracts from P5 rats. These findings demonstrate that DARP is present in the embryonic and early postnatal rat brain and may play a role in the prenatal development of dopaminergic neurons of the mesencephalon and the postnatal development of the adrenal gland.

NEUROTROPHIC FACTORS: BIOLOGICAL EFFECTS X

453.1

RECOMBINANT HUMAN INSULIN-LIKE GROWTH FACTOR-I (rhIGF-I) PREVENTS CISPLATIN-INDUCED NEUROPATHY P. C. Contreras, C. Steffler, J. A. Gruner, A. Yee, J. Roberts-Lewis* and J.L. Vaught. Cephalon, Inc., West Chester, PA 19380.

rhIGF-I *in vitro* supports the survival of motor and sensory neurons and *in vivo* prevents development of the motor and sensory neuropathy induced by vincristine and paclitaxel, respectively. Cisplatin is an antitumor agent that produces a dose-limiting peripheral neuropathy. The purpose of this study was to evaluate whether rhIGF-I could also prevent the neuropathy induced by cisplatin. Male CD-1 mice were dosed once a week with cisplatin (10 mg/kg, ip) and daily with rhIGF-I (1 mg/kg, sc) for 16 weeks. Cisplatin treatment reduced body weight, decreased conduction velocity and amplitude of the compound action potential of caudal and tibial nerves, increased tail-flick and hot-plate latencies, altered parameters of gait and decreased ganglionic content of CGRP. The changes in neuronal conduction and tail-flick and hot-plate latencies were not due to changes in body, paw or tail temperatures. Co-treating cisplatin-treated mice with rhIGF-I prevented all of the effects of cisplatin except for the change in body weight. Since, rhIGF-I had no effect on the loss in body weight induced by cisplatin, rhIGF-I was not just simply a cisplatin antagonist. These results suggest the therapeutic utility of rhIGF-I in preventing the cisplatin-induced neuropathy.

NEUROTROPHIN-3 REDUCES DEPLETION OF STRIATAL CHAT AND GAD ACTIVITIES FOLLOWING QUINOLINIC ACID LESION. T. M. Engber*, S. A. Dennis, S. L. Meyer and P. C. Contreras. Cephalon, Inc., West Chester, PA 19380.

Injection of the endogenous excitotoxin quinolinic acid into the rat striatum produces a lesion which is neurochemically similar to that seen in Huntington's disease. We examined whether neurotrophin-3 (NT-3), a member of the neurotrophin family of growth factors, is capable of reducing the damage caused by quinolinic acid in the rat striatum. NT-3 (0.15 or 0.5 µg/day in PBS) was infused via osmotic pump into the left striatum for 12 days, beginning immediately after injection of quinolinic acid (225 nmol in 1 µl PBS); controls received PBS infusion following quinolinic acid injection. Rats were sacrificed on day 12 and both the lesioned and intact striatum dissected for measurement of choline acetyltransferase (ChAT) and glutamic acid decarboxylase (GAD) activities, neurochemical markers for cholinergic and GABAergic neurons, respectively. Quinolinic acid injection depleted ChAT activity by 35% relative to that on the intact, uninjected side; NT-3 infusion at a dose of 0.15 µg/day attenuated the effect of quinolinic acid, with ChAT activity on the lesioned side reduced by only 12% (p<0.05), while NT-3 at a dose of 0.5 µg/day did not have a significant effect. In the quinolinic acid-lesioned striatum, GAD activity was decreased by 62% relative to that on the intact side; following infusion of NT-3 at a dose of 0.15 µg/day, GAD activity was reduced by only 29% (p<0.05), while NT-3 at 0.5 µg/day did not have a significant effect on the depletion of GAD activity. These findings suggest a possible therapeutic role for neurotrophic factors in reducing or reversing neuronal damage in Huntington's disease.

453.3

NEUROTROPHIN-4/5 AND TRANSFORMING GROWTH FACTOR-α PARTIALLY PROTECT STRIATAL CALBINDIN-CONTAINING NEURONS AFTER QUINOLINIC ACID LESION. T. Alexi*, J.L. Venero and E. Hefti. Andrus Gerontology Center and Department of Biological Sciences, University of Southern California, Los Angeles, CA 90089.

Lesioning of the mammalian striatum by the excitotoxin quinolinic acid (QA) results in the degeneration of medium spiny neurons which contain γ-aminobutyric acid (GABA). Neurotrophic factors have been shown to rescue degenerating cells in a variety of lesion types, including chemical lesions. Several neurotrophic factors have either survival-promoting actions on striatal GABAergic neurons or are localized within the striatum. Of these factors, transforming growth factor α (TGFα) and neurotrophin-4/5 (NT4/5) were chosen for administration to rats lesioned acutely with QA.

Cannulated rats received a single unilateral intrastriatal injection of QA (150 nM). Trophic factors (1 µg TGFα, 0.8 µg NT4/5, or control protein cytochrome C) were administered for 7 days. The pattern of neuropathology was assessed by both *in situ* hybridization and immunolabeling. As expected, QA resulted in a preferential degeneration of medium spiny GABAergic neurons with a relative sparing of NADPH-diaphorase neurons, as well as neuronal fibers. GABA-expressing neurons were not rescued by either NT4/5 or TGFα. However, the degeneration of a subpopulation of cells which express calbindin was partially reversed by both factors, in an area limited to the medial aspect of the caudal striatum. The striatal patch-matrix pattern was disrupted by QA, such that the staining intensity of the matrix by both cholinesterase histochemistry and calbindin terminal staining was considerably decreased, except in the medial and ventral aspects of the striatum, where staining intensity approached control levels. Neither factor affected these staining patterns. These findings indicate that neurotrophic factors may provide protection for subpopulations of striatal cells.

FAILURE OF CONTINUOUS INTRATHECAL NGF INFUSION TO PREVENT TOXIC CHEMICAL-INDUCED DISTAL AXONOPATHY DESPITE REDUCING THE INJURY-INDUCED UPREGULATION OF C-JUN EXPRESSION IN DRG NEURONS. B.G. Gold*†, T. Storm-Dickerson† and D.R. Austin†. †Center for Research on Occupational & Environmental Toxicology (CROET) and ‡Department of Cell Biology & Anatomy, Oregon Health Sciences Univ., Portland, OR 97201.

Clinical trials of NGF for the treatment of peripheral neuropathies have begun. However, direct (morphological) evidence that NGF prevents axonal degeneration is lacking. In the present study, we asked whether supplementing the cell body's supply of retrogradely transported NGF prevents the development of distal axonal degeneration in a prototypic model of dying-back neuropathy: 3,4-dimethyl-2,5-hexanedione (DMHD), a potent derivative of the gamma-diketones. Rats were given daily intraperitoneal injections of DMHD (0.25 mM/kg/day) and NGF (125 ng/hr) was continuously infused into the subarachnoid space of the lumbar spinal cord via an osmotic minipump (Alzet); controls received cytochrome C. At 9 days, rats were perfused with 5% glutaraldehyde. Quantitation of the numbers of degenerating profiles and the total numbers of myelinated fibers was performed in the sciatic, tibial and sural nerves. To date, no significant differences have been found; in the soleus nerve, the percentage of degenerating fibers was $3.0 \pm 0.22\%$ (SEM) and $2.7 \pm 0.31\%$ in cytochrome C-infused (n=3) and NGF-infused (n=3) DMHD-treated rats, respectively. NGF also failed to prevent degeneration of fibers in the dorsal columns of the spinal cord (C1). In a separate immunocytochemical study, animals were perfused with 4% paraformaldehyde at 7 days. We previously reported (*Neurosci. Lett.* 154:129, 1993) that axotomy-induced induction of the protooncogene c-jun in DRG neurons is reduced by NGF infusion. Similarly, NGF markedly reduced (by 70%) the numbers of DRG neuronal nuclei demonstrating intense c-JUN-like protein immunoreactivity in DMHD-treated rats. Thus, NGF infusion to the cell body does not appear to prevent the development of DMHD axonopathy, but does decrease the injury-induced upregulation of c-jun expression. It remains possible, however, that delivery of NGF to the nerve itself could prevent axonal degeneration. Supported by NS19611 and the Paralyzed Veterans of America Spinal Cord Research Foundation.

BDNF PROTECTS CULTURED DENTATE GRANULE CELLS AGAINST HYPOGLYCEMIC DAMAGE

Zaal Kokaia*, Agneta Othberg, Merab Kokaia, and Olle Lindvall

Restorative Neurology Unit, Department of Neurology, University Hospital, S-221 85 Lund, Sweden

We have previously shown (Lindvall et al., PNAS, 1992, 89, 648-652) that 1 and 30 min of insulin-induced hypoglycemic coma leads to a marked increase of BDNF and NGF mRNA levels in dentate granule cells. The aim of this study was to explore whether brain-derived neurotrophic factor (BDNF) can improve neuronal survival in cell cultures of rat dentate gyrus subjected to a hypoglycemic insult. Dentate gyrus was dissected from rat pups (P5-6), dissociated and cells were plated on chamber slides at 37°C in 5% CO₂ and with 95% humidity. After 24 h the serum-containing medium was switched to serum-free N2 medium. The hypoglycemic insult was induced after 7 days *in vitro* by glucose deprivation. The duration of hypoglycemia was 15 h and cultures were fixed and processed for MAP-2 immuno-cytochemistry immediately thereafter. In control cultures 40 mM glucose was added. Glucose deprivation for 15 h caused severe neuronal loss (about 70%). BDNF added either 24 h before or 4 h after onset of hypoglycemia completely protected granule cells against the insult-induced damage. Nerve growth factor (NGF) had similar effects. These findings support the hypothesis that the rapid upregulation of BDNF and NGF mRNAs in dentate granule cells after brief periods of hypoglycemic coma and other insults is a local protective mechanism.

453.7

A QUANTITATIVE ANALYSIS OF ASTROGLIAL AND MICROGLIAL CELL REACTIONS IN PRIMARY SENSORY PROJECTION AREAS FOLLOWING SCIATIC NERVE INJURY AND TREATMENT WITH NERVE GROWTH FACTOR IN THE ADULT RAT.

N.P. Eriksson, J. K. E. Persson, M. Svensson, and H. Aldskogius*

Dept. of Neuroscience, Karolinska Institutet, S-171 77, Stockholm, Sweden.

Previous quantitative immunohistochemical studies have shown that the microglial cell reaction in primary sensory projection areas after peripheral nerve injury follows a very rapid exponential growth phase which is succeeded by a considerably slower decline phase; the peak being approximately 7-10 days after injury (Eriksson et al., Exp. Brain Res., 1993; 96:19-27). Further, it has been shown that following peripheral nerve injury, astrocytes are activated via reactive microglial cells (Svensson et al., J. Neurosci., 1993; 35: 373-381).

Using image analysis we have examined quantitatively the temporal appearance of the astroglial reaction to sciatic nerve injury as revealed by the area of glial fibrillary acidic protein (GFAP) immunoreactivity in the lumbar dorsal horn and the gracile nucleus. Concomitantly, the temporal appearance of GFAP-mRNA profiles were observed by *in situ* hybridization. Astroglial cells in the dorsal horn and the gracile nucleus were shown to follow similar growth and decline curves with an increase two days and a maximum two-three weeks following sciatic nerve transection. However, treatment with nerve growth factor (NGF) during four weeks following sciatic nerve transection did not result in any different glial expression, as investigated with our quantitative methods.

These results indicate that, even though promoting dorsal root ganglion (DRG) cell survival, NGF does not seem to have any influence on the glial cell reaction neither directly nor indirectly through the rescued DRG-neurons. The microglial cell reaction therefore does not seem to be triggered by the target loss of the sensory neurons.

453.9

CHRONIC NGF TREATMENT RESTORES HIPPOCAMPAL MUSCARINIC, BUT NOT NICOTINIC RECEPTOR FUNCTION FOLLOWING FIMBRIAL TRANSECTIONS. P.A. Lapchak*, D.M. Araujo and F. Hefti. Andrus Gerontology Center, University of Southern California, Los Angeles, CA 90089-0191.

The effects of chronic NGF administration (icv, 1 µg qod for 21 days) on hippocampal muscarinic and nicotinic receptor densities and functions were determined in adult rats with partial fimbrial transections. First, the distribution of cholinergic receptors in the hippocampus was determined using autoradiography. Neither fimbrial transections nor NGF treatment altered the density of muscarinic M1 [³H-pirenzepine] or M2 [³H-AF-DX 384] binding sites in the hippocampus. In addition, neither the lesion nor NGF treatment altered the distribution or density of nicotinic [³H-cytisine] sites in the hippocampus. Second, we determined the effect of NGF treatment on muscarinic receptor-mediated second messenger production in rats with fimbrial transections. In lesioned rats, oxotremorine increased IP₃ synthesis by 81% ipsilaterally to the lesion compared to the contralateral unlesioned side. This lesion-induced supersensitivity of M1 muscarinic receptor function was prevented by chronic NGF treatment. Third, we determined whether nicotinic receptor function was altered by fimbrial transections using nicotine-induced uptake of [³H]-tetraphenylphosphonium (TPP⁺) into hippocampal synaptosomes as a marker. In the unlesioned control hippocampus, nicotine produced a characteristic 35% reduction of [³H]-TPP⁺ uptake into synaptosomes. However, in rats with partial fimbrial transections there was a loss of nicotine-induced alterations of [³H]-TPP⁺ uptake into synaptosomes. Chronic NGF treatment did not affect nicotine-induced [³H]-TPP⁺ uptake. The present results indicate that NGF-induced increases of presynaptic hippocampal cholinergic functions involved in ACh turnover (Lapchak, Exp. Neurol. 124, 16-20, 1993) translate into an enhanced function of postsynaptic muscarinic M1 receptor function. However, chronic NGF treatment does not attenuate the lesion-induced loss of presynaptic nicotinic autoreceptor function.

453.6

IMPORTANCE OF COLONY STIMULATING FACTOR-1(CSF-1) FOR NEURONAL SURVIVAL IN ISCHEMIC CORTICAL LESIONS. Q. Berezovskaya, D. Maysinger and S. Fedoroff*. NCE Neuroscience Network at Department of Pharmacology and Therapeutics, McGill University, Montreal, Que., and Department of Anatomy, University of Saskatchewan, Saskatoon, Sask., CANADA S7N 0W0.

In osteopetrotic op/op mice, deficient in CSF-1 (microglial survival and proliferation factor), microglia form in approximately normal numbers. However, their response to injured neurons is abnormal: initially there is some degree of microglial proliferation but the recruitment of microglia is only meager. The microglia initiate phenotypic transformation but do not transform to the extent seen in normal animals. The expression of CR3 and MHC-1 receptors in microglia seems to be unaffected as does astroglial hypertrophy. In ischemic cerebral cortical lesions in op/op mice, neuronal survival is significantly reduced as compared to that in normal CSF-1 producing animals. When CSF-1 producing astroglia are grafted in the vicinity of the ischemic lesion, or when encapsulated CSF-1 producing LM cells are implanted intraperitoneally into op/op mice, the microglial response to injured neurons is partially restored and neuronal survival in the ischemic lesion is significantly potentiated. We found a significantly greater number of surviving neurons in the area of ischemic cerebral lesions made in osteopetrotic op/op mice previously grafted with CSF-1 producing cells, as compared to the number of surviving neurons in similar lesions made in op/op mice or even in normal CSF-1 producing C3H/HeJ mice. We conclude that CSF-1 secretion by astroglia is essential for normal function of microglia and for potentiation of survival of injured neurons.

Supported by a grant from Canadian NCE Neuroscience Network.

THE MICROGLIA/MACROPHAGE RESPONSE FOLLOWING NGF INJECTION INTO THE RAT SPINAL CORD

M. Klotz*, D. Ellegala, K. Andrus, M. Gross, & A.M. Avelino. Department of Neurological Surgery, University of Washington School of Medicine & Seattle VAMC, Seattle, WA. 98104.

The response of macrophages and microglia during wallerian degeneration of axons is remarkably different in the peripheral [PNS] and central [CNS] nervous systems of adult mammals (Griffin et al., 1993; Perry et al., 1987). In the PNS, blood monocytes rapidly infiltrate degenerating nerve to clear axonal as well as myelin debris. In striking contrast, the infiltration of monocytes and response of microglia with clearance of cellular debris is much slower in the CNS. The mechanisms underlying this differential response of macrophages and microglia are unknown. Nerve Growth Factor (NGF) has been shown to be a possible chemotactic factor for leukocyte recruitment (Boyle et al., 1985). The low affinity (NGF) and high affinity (Trk A) NGF receptor have been detected in certain types of monocytes and microglia (Ehrhard et al., 1993; Yan and Johnson, 1990; Morgan et al., 1989). In addition, a linear arrangement of macrophages was found immediately apposed to NGF-treated but not untreated nitrocellulose implants inserted into rat spinal cords (Houle, 1992). NGF may therefore play a role in modulating the response of macrophages and microglia.

To test this hypothesis, we performed local needle injections of NGF, vehicle (2% bovine serum albumin), or needle injections alone into rat spinal cords either with or without transection of an adjacent dorsal root (n=28). We employed the ED1 monoclonal antibody which normally stains peripheral rat macrophages and monocytes but not CNS microglia. Immunohistochemistry was performed upon paraffin embedded parasagittal sections of spinal cords. Following simple transection of a dorsal root, we found ED1 labeled cells infiltrating the PNS portion of the cut dorsal root after a delay of 3 days that stopped abruptly at the PNS/CNS interface and did not extend into the spinal cord for up to 3 weeks. Needle injections into the spinal cord induced the local appearance of ED1 staining cells. The number of cells and volume of tissue staining with ED1 was greatest following injections of NGF, significantly less with injections of vehicle alone, and smallest following needle injection alone. Spinal cord injections of NGF combined with transection of an adjacent dorsal root resulted in ED1 labeled cells extending across the PNS/CNS interface of the cut dorsal root towards the injection site. These results suggest that NGF may activate microglia to express ED1 and/or induce the migration of peripheral ED1 monocytes/macrophages into the CNS. Supported by NIH and VA funds.

THE EFFECT OF DOSE AND TIME ON THE EFFICACY OF NGF IN THE FIMBRIA FORNIX LESION MODEL

E. Robbins*, M.S. Saporito, K.C. Hartpence, J. Battle, L.F. Kromer¹, J.L. Vaught, and S. Carswell. Cephalon, Inc., 145 Brandywine Parkway, West Chester, PA 19380. ¹Georgetown University Medical Center, Washington, D.C. 20007.

We are interested in determining whether small brain-permeable molecules that upregulate endogenous NGF in the CNS can promote the survival of degenerating cholinergic neurons in a manner comparable to that demonstrated using exogenous NGF. Previous work has shown that treatment with various agents results in modest (1.5 to 2-fold) increases in NGF in the adult rat brain. The purpose of this study was to determine: (1) whether ICV administration of amounts of NGF approximating those obtained after NGF induction can prevent the cholinergic losses of fimbria fornix lesioning and (2) whether dose of NGF alters the time required to obtain neurotrophic effects. ICV injection of 1 µg NGF resulted in an approximate 4-fold transient increase in NGF levels in the septum, hippocampus and basal forebrain, as measured by a two-site immunoassay. In contrast, changes in NGF could not be detected in these brain regions when doses of 0.25 µg or less were used. Nonetheless, analysis of hippocampal ChAT activity in fimbria fornix lesioned rats 14 days after lesioning revealed that daily doses as low as 0.1 µg had maximal efficacy, suggesting that small increases in NGF can be therapeutically significant. The increase in ChAT activity using 1 µg/day occurred after 10, but not 7, days of treatment. The effects of dose on the time required to achieve efficacy will be discussed.

NT-3 ENHANCES GROWTH AND UPREGULATES GAP43 IN A SUBSET OF RETINAL GANGLION CELLS AFTER AXOTOMY. P. Kittlerova, D.E. Playford*, G.M. Bray and A.J. Aguayo, Centre for Research in Neuroscience, McGill University and Montreal General Hospital Research Institute, 1650 Cedar Ave., Montréal, Québec H3G 1A4.

Retinal ganglion cell (RGC) survival can be enhanced by the intraocular administration of BDNF or NT-4 (Mansour-Robaay et al., PNAS 91: 1632-1636, 1994; Clarke et al., Soc. Neurosci. Abstr. 19: 1104, 1993). We have now investigated the role of NT-3 on RGC survival and regrowth.

Intraocular injections of NT-3 (provided by Regeneron Pharmaceuticals Inc.) had only a minor effect on the overall survival of axotomized RGCs, consistent with the observation that immunocytochemistry for *TRKC*, the high affinity receptor for NT-3, revealed staining in only 5% of RGCs. However, in comparison with other neurotrophins, NT-3 increased intraretinal axonal growth, as revealed by staining with RT97, a monoclonal antibody to the heavy neurofilament subunit.

The effect of NT-3 on the expression of GAP43 mRNA was then investigated by *in situ* hybridization. Two weeks after axotomy, approximately 10% of the surviving RGCs expressed high levels of GAP43 mRNA. After NT-3 treatment, the incidence of these GAP43-expressing cells increased to 30% of surviving RGCs. Furthermore, GAP43 mRNA levels within these cells doubled, compared to operated controls. These findings suggest that NT-3 has a significant effect on GAP43 expression and on axonal growth of a discrete population of RGCs.

453.13

EFFECT OF NT-4/5 ON AXOTOMIZED RAT FACIAL MOTONEURONS. Karl Fernandes, Annie Bedard and Wolfram Tetzlaff*, Dept. of Physiology, University of Ottawa, Ottawa, Canada.

We have previously shown that axotomy of facial motoneurons induces the expression of GAP-43 and α -tubulin mRNAs while the expression of neurofilament mRNA is decreased. In addition, we report here that the mRNA expression for AChE is reduced by about 35% consistent with a general downregulation of neurotransmitter related mRNAs after axotomy. In the present study we have tested the role of a presumed target derived neurotrophin, NT-4/5, in the regulation of these changes in gene expression. The facial nerve of male adult Sprague Dawley rats was transected at the stylomastoid foramen and the proximal nerve stump attached to the lumen of a silastic tubing. The latter was connected to an osmotic minipump which delivered 1 μ l with 125 ng (low dose) or 500 ng (high dose) NT-4 per hour over a period of 7 days. The contralateral proximal nerve stump received vehicle only. *In situ* hybridization revealed that application of NT-4 sustained the expression of AChE mRNA at normal levels (202 % of vehicle, n=4) and further stimulated the expression of GAP-43 (211 % of vehicle, n=4) and α -tubulin (170 % of vehicle, n=4) mRNA. The expression of neurofilament-M (NFM) mRNA was increased to 150% of vehicle (n=4), but was only significantly different from vehicle in 1 of 4 animals. NFM expression was still far below a normal level of expression, thus, not normalized by NT-4 application.

These data show that NT-4/5 enhances regeneration associated gene (GAP-43, α -tubulin) expression and might be useful to stimulate peripheral nerve regeneration.

Supported by MRC of Canada.

EFFECT OF CNTF DELIVERY METHODS TO RESCUE FACIAL MOTONEURONS FROM INJURY INDUCED CELL DEATH. S.A. Tan*, V. Padrun, A. Menoud, J. Hammang, E. Baetge, A.D. Zurn, P. Aebischer, Lausanne University Medical School, Switzerland; CytoTherapeutics, Providence, RI.

Ciliary Neurotrophic Factor (CNTF) has been shown to increase the survival of motoneurons *in vitro* and *in vivo*. For potential human application, the mode of delivery needs to be investigated. In the present study, local application of CNTF on the transected facial nerve of neonatal rats was compared to systemic delivery through subcutaneous injections of human recombinant (rhCNTF) and to transplantation of genetically engineered cells. Baby hamster kidney cells (BHK) were transfected with a pNUT vector containing either the gene for mouse CNTF (mCNTF) or human CNTF (hCNTF) and were encapsulated in polypropylene fibers to prevent tumor formation and immune rejection. Facial nerves of neonatal rats (P2) were transected and CNTF was delivered i) by direct application of CNTF on the nerve stump using gelfoam impregnated with rhCNTF (0.25mg/ml); ii) by repeated subcutaneous injections of rhCNTF (1mg/kg) 3 times a week; or iii) by subcutaneous implantation of 1×10^4 encapsulated BHK cells releasing either mCNTF or hCNTF. Control animals received either bovine serum albumin or the parent BHK cell line. One week post-lesioning, the number of surviving motoneurons on the lesioned side was compared to the non-lesioned side. All three methods of CNTF application significantly improved motoneuron survival with the encapsulated method appearing to be the most efficient.

Mode of delivery	Control	CNTF treated	p values
hCNTF capsule	11%	40%	p<0.001
mCNTF capsule	11%	38%	p<0.001
repeated injection	18%	33%	p<0.02
gelfoam application	18%	31%	p<0.005

Encapsulated transfected cells offer a mean for the continuous slow release of trophic factors, as well as the potential for intrathecal delivery.

453.12

ROLE OF NT-3 IN INTACT & INJURED PRIMARY SENSORY NEURONS. K.A. Gratto¹, B. Friedman², L. Liu², R.M. Lindsay² & V.M.K. Verge^{*1}, ¹Dept of Anatomy, Univ of Saskatchewan, Canada S7N 0W0, ²Regeneron Pharmaceuticals Inc., Tarrytown NY 10591

The hypothesis that NT-3 plays a role in maintaining the differentiated state of responsive *trkC*-expressing neurons and may be responsible for reversing changes observed after injury, *in vivo* was tested. Adult rat right sciatic nerves were proximally cut. 14d after injury NT-3 was intrathecally infused for an additional 7d in half of the rats. Cryostat sections of intact and injured DRG with and without NT-3 infusion were processed for *in situ* hybridization to detect mRNAs encoding *trkC* and peptides α -CGRP and NPY. Preliminary results indicate that in intact neurons, α -CGRP and *trkC* are abundantly and heterogeneously expressed, whereas few if any neurons express detectable NPY mRNA. Two weeks after injury levels of α -CGRP and *trkC* mRNA are dramatically reduced, while, many neurons now express abundant NPY mRNA. Infusion of NT-3 counteracted injury-induced decreases in *trkC* mRNA and was also effective in upregulating expression of α -CGRP in many neurons, but the percentage of neurons appeared smaller when compared to injured ganglia infused with NGF. Finally, NT-3 infusion resulted in reduced expression of NPY mRNA in injured neurons, suggesting a role for NT-3 in gene suppression in intact neurons. The ability of exogenous NT-3 to regulate expression of its receptor *trkC* and differentially regulate peptide expression supports a role for it in maintaining aspects of the differentiated state of adult primary sensory neurons. Canadian MRC supported.

NT-3 AND BDNF PREVENT AXOTOMY INDUCED DEATH OF CORTICOSPINAL NEURONS

Klaus M.G. Giehl* and Wolfram Tetzlaff

Dept. of Physiology, University of Ottawa, Ottawa, Canada,

A major problem of regeneration in the CNS is atrophy and cell death of injured neurons. We have quantified the death of corticospinal neurons (CSN) induced by axotomy at the level of the internal capsule and tested the effect of survival promoting factors in this system. *In situ* hybridization combined with retrograde tracing revealed that CSN express mRNA for both *trkB* and *trkC* but not *trkA* receptors. This provided the rationale to test the survival effect of Neurotrophins in this model. Again, the CSN were positively identified by spinal cord injection of Fast Blue and a second spinal cord injection of Rhodamine Dextran was applied after internal capsule lesion to confirm the axotomy. The area of axotomized CSN extended in anterior posterior direction over 5-6mm. A mean of 49.6% (n=4) of the axotomized CSN died within 7 days after injury. Continuous application of saline and 0.5% rat serum albumin (vehicle) via an osmotic minipump over 7 days reduced this cell death to 30.4% (n=8), application of NGF (500ng/ μ l/h) resulted in a further reduction to 24.2% (n=4), however this was not significantly different from the vehicle. The application of NT-3 (500ng/ μ l/h) or BDNF (500ng/ μ l/h) prevented the axotomy induced death and only 3.7% (NT-3, n=7) and 10.2% (BDNF, n=4) of the CSN died within the first week after axotomy. These findings are the first demonstration for survival factors for CSN *in vivo* and may be important for traumatic brain injury and in neurodegenerative disorders which involve death of CSN like amyotrophic lateral sclerosis.

DOSE-DEPENDENT REVERSAL OF BDNF RESCUE EFFECTS ON MOTONEURONS.

B. Vejsada, Y. Sagot and A.C. Kato*, Div. Clinical Neurophysiol. & Dept Pharmacol., CMU, University of Geneva, Geneva, Switzerland.

Brain-derived neurotrophic factor (BDNF) promotes the survival, differentiation and maintenance of motoneurons. We compared the effects of different BDNF doses on the rescue of axotomized sciatic and facial motoneurons in neonatal rats. Application of BDNF directly to the central nerve stump significantly enhanced motoneuron survival. Additional BDNF supplied with intermittent subcutaneous injections (1 mg/kg, at 3-day intervals) yielded a further small survival increase; however, injecting BDNF daily markedly reduced the motoneuron rescue at both 1 week and 2 weeks post-lesion. These results, corroborated by findings in motoneuron primary cultures, show that a dose-dependent reversal of BDNF-mediated motoneuron rescue may occur both *in vitro* and *in vivo*.

453.17

NERVE GROWTH FACTOR GENE TRANSFER TO THE ADULT AND AGED RAT BRAIN USING CNS DERIVED NEURAL PROGENITOR CELLS: CELLULAR EFFECTS AND BEHAVIORAL RECOVERY. A. Martínez-Serrano, W. Fischer, G. Nikkha, C. Lundberg and A. Björklund, Dept. of Medical Cell Research, University of Lund, S-223 62-Lund, Sweden.

Conditionally immortalized neural progenitors were infected with a retrovirus coding for mNGF, and clones were isolated and analysed for NGF production. Among them, one clone produced 20 ng of NGF/hour/10⁶ cells. The cells were characterised *in vitro* for their ability to produce NGF and for the expression of the retroviral vector, finding no differences between the proliferative and growth arrested cultures (permissive and non-permissive temperature). After grafting to the septum, striatum or nucleus basalis in young animal, the cells survive well and migrate away from the implantation site. Expression of the transgene *in vivo* and NGF production were studied in dissected pieces of nc basalis tissue 4 and 10 weeks after grafting. RT-PCR revealed moderate but stable expression of the transgene, and a bioassay for NGF demonstrated the presence of the neurotrophic activity (the NGF-grafted nc basalis showed as high neurotrophic activity on PC12 cells as the hippocampus tissue). Cells grafted to the nc basalis induced a consistent 40% hypertrophy of the cholinergic cell bodies (1, 4 and 10 weeks post-grafting). When grafted to the septum in rats with fimbria-fornix lesion, over 90% of the cholinergic cells on the lesion side was rescued from axotomy-induced death. Thus, there seems to be a good correlation between cell survival, expression of the transgene, NGF production and cellular effects observed.

We next looked for behavioural effects of the NGF cells *in vivo* by grafting into the medial septum and/or nc. basalis of memory impaired aged animals. In the Morris water maze test, there was a progressive improvement of their performance (2 and 4 weeks after grafting) up to the point when they were not different from the control, non-impaired animals. Histological analyses revealed surviving grafted cells, as well as a clear hypertrophic effect in the host cholinergic neurons, that showed the same size as in young rats. Data on expression and recovery of NGF-like neurotrophic activity from grafted brains will also be presented.

453.19

EFFECTS OF ACIDIC FIBROBLAST GROWTH FACTOR ON DETERIORATED LEARNING AND MEMORY IN SENESCENCE ACCELERATED MICE. K. Sasaki, Y. Oomura, A. Li, H. Kimura, I. Tooyama, K. Hanai, Y. Nomura, Y. Kitamura, N. Yanaiharu and H. Yago, ¹Fac. Eng., Toyama Univ., Toyama 930, ²Inst. Bio-Active Sci., Nippon Zoki Pharm. Co., Hyogo 673-14, ³Fac. Med., Kyushu Univ., Fukuoka 812, ⁴Inst. Molec. Neurobiol., Shiga Univ. Med. Sci., Shiga 520-01, ⁵Fac. Pharm. Sci., Hokkaido Univ., Sapporo 060, ⁶Fac. of Pharm. Sci., Univ. Shizuoka, Shizuoka 422, Japan

Subcutaneous injection of acidic fibroblast growth factor (aFGF) into senescence accelerated mice (SAM-P/8) at one per week was started at 3 weeks after birth and continued for 9 months. When tested by passive avoidance and Morris' water maze tasks, learning and memory performances deteriorated in the control group, while those of the aFGF-treated group did not. At the end of the 9 month, brain tissues of sacrificed animals were stained immunohistochemically using anti-choline acetyltransferase (CAT) antibody. The number of cholinergic neurons in the medial septum (MS) decreased by 15% in the control group and was no change in the aFGF-treated group, as compared to SAM-R/1, a reference strain of SAM-P/8. The activity of CAT in individual cholinergic neurons in the MS also decreased significantly in the control group. Results suggest that aFGF has neurotrophic effects on cholinergic neurons in the MS of SAM-P/8 and ameliorate learning and memory disorder in both tasks tested.

THE EFFECTS OF NGF AND BDNF ON THE MORRIS WATER MAZE IN AGED RATS. M.A. Pelley, M.J. Cullen and M.B. Baker, Dept. of Neurobiology, Amgen, Inc., Thousand Oaks, CA 91320.

Infusion of NGF into the lateral ventricle has been shown to improve water maze performance in aged rats, along with increasing septal cholinergic cell size and number. We have compared the effects of NGF with BDNF in acquisition and retention of the Morris maze in aged Long-Evans male rats. Prior to infusion of NGF or BDNF into the dorsal third ventricle, aged rats were separated into impaired or unimpaired subpopulations, based upon spatial bias demonstrated during the 12th training trial. Impaired rats were then equally distributed between PBS, NGF and BDNF groups. Infusions were conducted for a 4 week period, using Alzet mini-pumps (6 µg/day; 0.5 µl/hour). On the seventh day of infusion, rats continued their training on the Morris maze, where they were given three trials/day, with a probe trial inserted every 6 trials to assess spatial bias. Young and unimpaired rats showed significantly lower latencies and distances than their impaired PBS, NGF and BDNF-treated counterparts. Young, unimpaired and NGF-treated impaired rats performed significantly better than the PBS or BDNF-treated impaired rats on the spatial bias trials, however ($p < .05$). Seven weeks after all rats had reached a learning criterion based upon spatial bias, half were tested for retention of the task, and half were sacrificed for assessment of brain cholinergic activity and hypothalamic biogenic amine levels. Interestingly, once aged rats had met a spatial bias criterion, their retention of the task was similar to young rats, except that young rats made more annulus crossings in the retention probe trial ($p < .05$). Choline uptake was generally reduced in impaired old rats; NGF increased hippocampal choline uptake, whereas BDNF increased cortical choline uptake ($p < .05$). Further, hypothalamic NE, 5-HIAA and 5-HT were all increased in old rats; BDNF, however, significantly reduced both 5-HIAA and 5-HT to the levels of young rats ($p < .01$). In conclusion, NGF improved the acquisition of the Morris maze in aged impaired rats, along with increasing hippocampal choline uptake. BDNF, however, did not improve any aspect of Morris maze learning, despite altering cortical cholinergic and hypothalamic serotonergic activity.

AIT-082 MODULATES NEURITOGENESIS THROUGH A CARBON MONOXIDE/GUANYLATE CYCLASE MECHANISM AND RESTORES AGE-INDUCED MEMORY DEFICITS. A.J. Glasky^{1,2}, R.F. Ritzmann^{1,2}, C.L. Melchior², S. Hindley³, J.W. Gysbers³, P. Middlemiss and M.P. Rathbone³ ¹Adv. ImmunoThera-peutics, Tustin, CA 92680, ²Olive View/UCLA MC, Sylmar, CA 91342 and ³Depts. Biomed. Sci. and Medicine, McMaster U., Hamilton, Ontario L8N 3Z5

Age-related memory loss is associated with loss of NGF-dependent basal forebrain neurons. Since guanosine and inosine (3-300 µM) enhanced the neuritogenic effects of NGF on PC12 cells *in vitro*, we tested whether AIT-082, a purine analogue could promote neurite outgrowth from PC-12 cells *in vitro* and determine the mechanism of this effect. AIT-082, when added to cultures of PC12 cells at concentrations of 0.1 to 10 µM, promoted neuritogenesis and enhanced the effects of NGF. The neuritogenic effect of AIT-082 was reduced (a) by hemoglobin, which binds extracellular nitric oxide and carbon monoxide (CO), (b) by methylene blue, which inhibits soluble guanylate cyclase and (c) by Zn protoporphyrin IX, an inhibitor of heme oxygenase, which produces CO. AIT-082 (30 mg/kg) was able to increase the duration of the working memory trace utilizing the win-shift paradigm in mice (Pharmac. Biochem. Behav. 47:325,1994), in one year old Swiss Webster or C57BL/6 mice with mild or moderate memory deficits. AIT-082 may be the first agent that restores working memory deficits through a mechanism that involves CO and soluble guanylate cyclase. Since AIT-082 is orally active and rapidly passes the blood-brain barrier, it may have therapeutic potential as a NGF-mimetic agent. (Supported by NIA AG09911 and Hospital for Sick Children Foundation)

NEUROTROPHIC FACTORS: BIOLOGICAL EFFECTS XI

454.1

EFFECTS OF BDNF IN ANIMAL MODELS OF PARKINSON'S DISEASE. C.W. Shults¹, C. Shin², and C.A. Altar¹, ¹VA Med. Ctr., San Diego, CA 92161; ²Dept. of Neurosciences, Univ. Cal., San Diego; ³Regeneron Pharm., Tarrytown, NY.

Groups of 8 naive rats received 3 unilateral, intrastriatal injections of either BDNF or cytochrome c (22.5 µg/injection) on consecutive days. Following the injection of BDNF or cytochrome c on the second day, the animals received an intrastriatal injection of 25 µg of 6-hydroxydopamine hydrobromide (6-OHDA). The animals were then tested weekly for amphetamine and apomorphine-induced rotation for 4 weeks. The BDNF treated animals had fewer apomorphine-induced contraversive and amphetamine-induced ipsiversive rotations than did the cytochrome c treated group. At the fourth testing session, the BDNF treated group had 0.8 ± 0.4 (mean \pm SEM) apomorphine-induced and 0.7 ± 0.8 amphetamine-induced rotations/min, and the cytochrome c treated group had 3.1 ± 1.0 apomorphine-induced and 2.7 ± 0.6 amphetamine-induced rotations/min.

Two groups of rats with partial unilateral lesions of the mesostriatal dopaminergic system, which had been matched for apomorphine-induced rotation, received six injections of either BDNF or cytochrome c (22.5 µg/injection) into the partially denervated striatum over 2 weeks. After the sixth injection the BDNF-treated group had significantly fewer apomorphine-induced rotations (2.6 ± 0.4 , $n=10$) than the cytochrome c treated group (5.4 ± 1.0 , $n=11$).

454.2

EFFECTS OF BDNF-PRODUCING FIBROBLASTS ON SUBSTANTIA NIGRA DOPAMINERGIC NEURONS *IN VIVO*. W. R. Galpern^{1,3}, S. B. Tatter^{1,2}, M. F. Real², D. M. Frim^{1,2}, X. O. Breakefield² and O. Isacson^{1,2} ¹Neuroregeneration Laboratory, McLean Hospital, Belmont, MA 02178; ²Molecular Neurogenetics Unit, Neurosurgery and Neurology Services, Massachusetts General Hospital, Boston, MA 02114; ³University of Massachusetts Medical Center, Worcester, MA 01655.

We have previously demonstrated that brain-derived neurotrophic factor (BDNF) is able to protect against dopaminergic (DA) cell loss in the substantia nigra pars compacta (SNc) following striatal infusion of the mitochondrial complex I inhibitor MPP+ in rats. To investigate the effects of BDNF on SNc neuronal function *in vivo*, DA metabolism in the SN was assessed by HPLC. Groups of animals received either genetically engineered BDNF-secreting or control fibroblast implants dorsal to the SNc. Half of the implanted rats received unilateral striatal infusion of MPP+ one week after grafting. For the non-lesioned animals, tissue was processed for tyrosine hydroxylase (TH) immunocytochemistry or for neurochemical analysis 1-2 weeks following implantation. Lesioned animals were sacrificed two weeks after implantation, and the effect of BDNF on the generation of free radicals using salicylate spin-trapping as well as thiobarbituric acid histological assays was evaluated. Initial neurochemical observations reveal an increase in DA content in SN neurons associated with BDNF administration. Preliminary assessment of the effects of BDNF on cellular morphology indicate there is no generalized effect on TH+ cell size in the SN. Further experiments aimed at determining the effect of BDNF on the metabolic and oxidative states of DA neurons in intact and MPP+ lesioned rats are in progress.

454.3

BDNF SECRETING ASTROCYTES GRAFTED INTO THE STRIATUM OF A PARTIALLY LESIONED RAT MODEL OF PARKINSON'S DISEASE AMELIORATE AMPHETAMINE-INDUCED ROTATIONAL BEHAVIOR. Q. Lin, Y. Yoshimoto, T.J. Collier*, D.M. Frim, X.O. Breakefield and M.C. Bohn, Dept. Neurobio. & Anat., Univ. of Rochester Med. Ctr., Roch., NY 14642 and Molec. Neurogenetics Unit, Mass. Gen. Hosp., Harvard Med. Sch., Boston, MA 02129.

Brain-derived neurotrophic factor (BDNF) is a neurotrophic factor for dopaminergic (DA) neurons, the cell type that degenerates in Parkinson's disease (PD). To examine the potential BDNF gene therapy for PD, astrocytes transduced with a BDNF cDNA or alkaline phosphatase (AP) cDNA (control) and prelabeled with Dil were grafted into the right rat striatum 15 days after partial lesioning of the right substantia nigra with 6-hydroxydopamine. Prior to grafting, BDNF mRNA was expressed by BDNF but not AP astrocytes. At 32 days, BDNF astrocytes, but not AP astrocytes, attenuated amphetamine-induced rotation by 45% ($p \leq 0.05$). Apomorphine-induced rotation was not significantly changed in either group. At 42 days, Dil labeled astrocytes were present in the graft site, however, BDNF mRNA positive cells were not detected with *in situ* hybridization. Analysis of the density of tyrosine hydroxylase (TH) immunoreactive fibers showed no effect of BDNF astrocytes on the area occupied by TH-positive fibers in the lesioned striatum. These findings suggest that BDNF gene therapy ameliorates Parkinsonian symptoms through a mechanism that does not involve regeneration or sprouting from DA neurons. Furthermore, expression of BDNF from this retroviral construct appears to be down-regulated in grafted astrocytes, a characteristic that needs to be addressed before this method can be utilized for long-term delivery of biologically produced BDNF. (Supported by Markey Charitable Trust & AG09016)

454.5

INHIBITION OF BDNF EXPRESSION BY ANTISENSE OLIGONUCLEOTIDE AFFECTS DOPAMINERGIC NEURONAL FUNCTION IN ADULT RATS. Y.-S. Lau*, T. M. Anderson, Y.-K. Fung, J. F. Bishop, M. M. Mouradian. Dept. of Pharmacol., Creighton Univ., Omaha, NE 68178; Dept. of Oral Biol., Univ. of Nebraska, Lincoln, NE 68583; Exp. Ther. Branch, NINDS, Bethesda, MD 20892.

Brain-derived neurotrophic factor (BDNF) has trophic actions on developing dopaminergic neurons and alters the function of the nigrostriatal system in adult rats. In this investigation, we studied the effects of stereotaxic injections of a BDNF antisense oligodeoxynucleotide (ODN) on nigrostriatal dopaminergic transmission. The antisense molecule was an 18-mer phosphodiester ODN targeted to the translation start site of the rat BDNF mRNA. A nonsense ODN having the same base composition but in scrambled sequence was used as control. Two days following the injection of antisense ODN (0.5 $\mu\text{g}/\mu\text{l}$) into the right striatum, dopamine content in the substantia nigra increased by more than three fold bilaterally compared with nonsense or saline injected rats, while dopamine levels in the striatum were unaffected. Injections of antisense, nonsense or saline into the right substantia nigra did not produce significant changes in dopamine content in either side of the nigra or striatum. Seven days after striatal injection of the antisense ODN, nigral dopamine levels had returned to normal, while striatal levels had increased by two fold. These data add further support that BDNF has a critical function in modulating the function of the nigrostriatal dopamine system in adult rats. The neuronal and intracellular mechanisms responsible for such regulation remain to be determined.

454.7

REGULATION OF PLATELET-DERIVED GROWTH FACTOR (PDGF) AFTER NEURONAL LESIONS AND EFFECTS OF PDGF ON DOPAMINERGIC AND STRIATAL NEURONS IN VITRO. K. Pietz¹, K. Funa², N. Nakao¹, A.E. Ballagi², A. Tingsröm¹, A. Öthberg¹, A. Åhgren², P. Brundin¹, O. Lindvall¹, and P. Odin^{1*}. ¹Restorative Neurology Unit, University Hospital, S-221 85 Lund, Sweden. ²Ludwig Institute for Cancer Research, Biomedical Centre, University of Uppsala, S-751 24 Uppsala, Sweden.

We have previously demonstrated an increased expression of platelet-derived growth factor (PDGF) around intrastriatal implants of fetal dopamine (DA)-rich mesencephalic tissue in a rat model of Parkinson's disease. PDGF-BB but not PDGF-AA promotes survival and neurite outgrowth from rat and human DA neurons *in vitro* and influences expression of c-fos and tyrosine hydroxylase mRNA in mesencephalic cell cultures. These effects could be directly mediated via PDGF beta receptors expressed on the mesencephalic DA neurons. The objective of the present study was to further characterize the changes of PDGF expression following insults to the brain and to analyze the effects of PDGF-AA and -BB on striatal DARPP-32-positive neurons *in vitro*. Immunohistochemical, PCR and primary cell culture techniques were used. Following an ibotenic acid lesion to the rat striatum (model for Huntington's disease), a strong increase in the expression of PDGF was observed in astrocytes in the striatal tissue. Also increased PDGF receptor expression was induced in the lesioned area. In cell cultures of fetal striatum PDGF-BB but not PDGF-AA promoted the survival of DARPP-32-positive neurons. Also neurite outgrowth from these striatal cells was significantly more pronounced in the presence of PDGF-BB. These findings indicate that PDGF could be of importance for the survival and function of CNS neurons after lesions and in neurodegenerative processes.

454.4

BDNF-TRANSFECTED OLIGODENDROCYTES INCREASE DOPAMINERGIC FETAL NIGRAL NEURON SURVIVAL AND ENHANCE NEURITIC EXTENSION IN VITRO. S.B. Schueler*, D.E. Bredesen¹, R. Anton¹, P.M. Carvey², and J.H. Kordower². Dept. of Anatomy and Cell Biology, Univ. Illinois Sch. Med., Chicago, IL 60612; 1 U.C.L.A., Los Angeles, CA 90024; 2 Dept. Neurological Sciences, Rush Presbyterian Med. Ctr. Chicago, IL 60612.

Clonal lines of mouse oligodendroglia which have been genetically modified to secrete brain derived neurotrophic factor (BDNF) were examined for their ability to enhance the neuronal survival and neurite extension of embryonic rat dopaminergic neurons *in vitro*. Rostral mesencephalic tegmentum (RMT) of E15 rat embryos were harvested, dissociated, and cultured in a serum-containing medium. Shortly thereafter, three BDNF oligodendrocyte clones (A1, B6, and B12) and the non-BDNF secreting parental line (N20.1) were individually cocultured with RMT and placed in a 37°C incubator. The coculture medium was changed to a serum-free medium after 24 hours and placed back into the incubator for 4 days. The number of dopaminergic neurons as well as the number of neuritic extensions per neuron were then quantified in 7-8 replicates using tyrosine hydroxylase (TH) immunocytochemistry. An mean increase in TH-positive neurons of 3.5%, 41.0%, and 10.5% was observed in cocultures with clones A1, B6, and B12, respectively when compared to RMT alone or RMT cocultured with N20.1 oligodendrocytes. Thirty-40% of TH-immunoreactive neurons exhibited 3 or more processes when cultured alone or with N20.1 oligodendrocytes. In contrast, 60%, 80% and 84% of TH-immunoreactive neurons exhibited 3 or more processes when cocultured with the A1, B6, and B12 clones, respectively. BDNF-secreting oligodendrocytes enhance the viability and neuronal differentiation of embryonic dopaminergic ventral mesencephalic neurons suggesting that BDNF oligodendrocytes might enhance the structural and functional consequences of fetal nigral grafts in animal models of Parkinson's Disease.

454.6

PHYSICAL PROPERTIES AND BIOLOGICAL ACTIVITIES OF MICROENCAPSULATED BDNF AND BDNF-PRODUCING CELLS. D. Maysinger*, A. Cohen, K. Kriegelstein and K. Unsicker. Dept. Pharmacology & Therapeutics, McGill University & MGH, Montreal H3G1Y6, Canada, and Dept. Anat. & Cell Biology, University of Heidelberg, D-69120 Heidelberg, Germany.

The delivery of neurotrophic factors to the CNS poses a major obstacle to the treatment of neurodegenerative disorders such as Parkinson's disease. We have developed a polymer encapsulation technology that provides a means for the delivery of BDNF (generously provided by Regeneron) for a prolonged period of time. Several different types of chitosans, alginates and co-polymers with various proportions of poly-L-lactic acid were used. Size distribution profiles were determined by an image analysis system and surface characteristics were assessed by electron microscopy. The mean diameter of microspheres with BDNF was 1.2 \pm 0.05 μm whereas spheres with genetically transformed cells secreting BDNF (provided by X.O. Breakefield and M.P. Short) were much larger (300-500 μm). The total content of BDNF as well as the amounts released per day were determined by dot blot assays. The results from the release kinetics demonstrate that longterm secretion (30-60 days) of BDNF is achieved by chitosan microspheres. Alginate spheres provided only relatively short term release (2-7 days) and the type of macromolecules co-encapsulated with BDNF significantly influenced the rate of BDNF delivery. Neuron survival and neurite growth in cultures of rat retinal ganglion cells, DRG, and midbrain floor were supported by microencapsulated BDNF indicating biological stability of BDNF. BDNF-secreting cells survived for different periods of times depending on cell density within spheres, sphere sizes, and properties of the semipermeable membranes. These model systems can also be used for delivery of other trophic factors such as CNTF and GDNF. These studies provide a basis for future comparisons of microencapsulated genetically engineered cells and agents used in the treatments of neurodegenerative disorders.

454.8

NEUROTROPHIC FACTORS AND CELL DEATH OF A CELL LINE DERIVED FROM RAT VENTRAL MESENCEPHALON.

H. Takashima* Department of Neurology, Kawatana National Hospital, Kawatana, Nagasaki 859-36, Japan

Basic fibroblast growth factor (bFGF) has neurotrophic effects on dopaminergic neurons. Recently, reduced concentration of bFGF in substantia nigra in the Parkinson's disease brain has been reported. Reduction of this factor might be related to the cell death of dopamine neuron in Parkinson's disease. In this study, the effects of neurotrophic factors on the differentiation and cell death of a neural cell line derived from rat ventral mesencephalon were investigated.

A cell line was established from rat ventral mesencephalon using a retroviral vector containing the temperature-sensitive allele of the SV40T antigen. When cultured with serum-free medium at the permissive temperature, this cell line showed cell death accompanied with DNA laddering in gel electrophoresis and positive *in situ* staining for DNA 3'-OH ends. An addition of bFGF (10 ng/ml) prevented cell death, supported cell proliferation and increased the expression of neurofilament in serum-free medium.

NGF (10 ng/ml) and NT3 (10 ng/ml) did not support the survival of the cells in serum-free medium at the permissive temperature.

454.9

GLIAL CELL LINE-DERIVED NEUROTROPHIC FACTOR (GDNF) PROMOTES SURVIVAL AND REGROWTH OF MESENCEPHALIC DOPAMINE NEURON CULTURES DAMAGED BY MPP⁺. J.G. Hou* and C. Mytilineou, Dept. of Neurology, Mount Sinai Sch. of Medicine, New York, NY 10029

Astrocytic glia promotes neuronal growth and survival, but the mechanisms of the trophic effect are still not clear. It has been suggested that trophic substances secreted by astrocytes can modify the sensitivity of neurons to neurotoxins. GDNF, a selective dopaminergic neurotrophic factor secreted by a glial cell line, was purified and cloned (Lin et al., *Science* 260:1130-1132, 1993). We used human recombinant GDNF to determine whether it could protect dopamine (DA) neurons from the neurotoxins MPP⁺ and 6-OHDA. Mesencephalic cultures prepared from E14.5 rats were maintained in serum-free medium. GDNF increased [³H]DA uptake at concentration as low as 0.01 ng/ml, reached plateau at 1 ng/ml and reduced activity at 10 ng/ml. To test for neuroprotection, 100 μM MPP⁺ (60 min) or 30 μM 6-OHDA (45 min) were applied at day 6 *in vitro* and the extent of neurotoxicity was assessed 24 hours later by [³H]DA uptake. In the presence of 1 ng/ml GDNF, MPP⁺ treatment caused a 44% decrease in uptake, compared with a 66% decrease in the controls. When the uptake was measured 5 days after MPP⁺ treatment, control cultures showed a further reduction in uptake, which was prevented by treatment with GDNF. Furthermore, GDNF added only after the end of MPP⁺ treatment also prevented the continuing decline in [³H]DA uptake. GDNF, however, did not protect from 6-OHDA toxicity (63% reduction compared to 53% in controls). In contrast, bFGF, which increased the growth of glial cells in cultures, had a strong protective effect against 6-OHDA toxicity. These results indicate that the presence of glial cells is necessary for protection from oxidative damage by 6-OHDA; while GDNF, secreted by glial cells, supports DA neuron maintenance and regrowth. (Supported by NIH, NS-23017 and NS-30898)

454.11

GLIAL CELL LINE-DERIVED NEUROTROPHIC FACTOR (GDNF): EFFECTS ON NIGROSTRIATAL DOPAMINE NEURONS AND BEHAVIOR IN MPTP-TREATED MICE. A. Tomac¹, E. Lindqvist¹, B. Hoffer¹, SO Ögren¹, L.-F. H. Lin² & L. Olson¹. ¹Department of Neuroscience, Karolinska Institute, S-171 77 Stockholm, Sweden. ²Synergen, Inc., Boulder, CO 80301.

We examined the effects of a single intracranial injection of human recombinant GDNF 24 hours prior to or 7 days after MPTP exposure in C57/BL mice, monitoring neurochemical and behavioral changes. C57/BL mice, 11-12 weeks old, were exposed to the neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP), 2x40mg per kg body weight s.c., given 24 hr apart. Mice were unilaterally injected with 10 μg GDNF or vehicle in a volume of 2 μl, into striatum or over substantia nigra. Animals were monitored for either 5 or 18-20 days postoperatively, and were then sacrificed for HPLC analysis. Behavioral data indicated a significant increase in spontaneous motor activity (rearing, locomotion and motility) in GDNF-treated compared to vehicle-treated animals. HPLC data showed significant increases in dopamine levels in striatum (192%, p=0.010) and substantia nigra (187%, p<0.003) compared to vehicle-treated animals, when GDNF was given in striatum 24 hours prior to MPTP exposure. When GDNF was given into the striatum 7 days after MPTP exposure and mice sacrificed 18-20 days later, increases in dopamine levels were found in striatum (70%, p=0.003) and in substantia nigra (94%, p<0.0001) compared to vehicle-treated mice. Injection over substantia nigra also led to increases in dopamine levels, but only in substantia nigra (64%, p=0.004) compared to vehicle-treated animals. The findings reported here suggest that GDNF may play a crucial role for dopaminergic neurons, reversing effects of MPTP toxicity in this rodent model of Parkinson's disease.

454.13

DISTRIBUTION OF GLIAL CELL LINE-DERIVED NEUROTROPHIC FACTOR (GDNF) DURING PRE- AND POSTNATAL DEVELOPMENT IN RAT CENTRAL AND PERIPHERAL TISSUES. E. Lindqvist¹, A. Tomac¹, J. Luthman², B. Hoffer¹, S. Bektesh², L. Olson¹. ¹Dept. of Neuroscience, Karolinska Institute, S-171 77 Stockholm, Sweden, and ²Synergen, Inc., Boulder, CO 80301.

Glial cell line-derived neurotrophic factor (GDNF), a recently described protein related to the transforming growth factor beta-superfamily, has dopaminergic activity. We have previously demonstrated by *in situ* hybridization that GDNF mRNA is expressed in the developing striatum but is not confined exclusively to brain areas with a rich dopamine innervation. We have now carried out a more detailed *in situ* hybridization mapping study of GDNF mRNA using two non-overlapping oligonucleotide probes. The striatal anlage signal is present from E17, maximal during the first week of life, and declines to low levels by postnatal week 4. The message is present in patches and with a stronger signal in dorsal striatum. Several other areas of the developing CNS express GDNF mRNA, such as sensory and motor trigeminal nuclei, the cerebellar anlage, hippocampus, pons, and the spinal cord where neurons of Clark's column are positive. In the olfactory tubercle, another dopamine-innervated area, GDNF mRNA persists into adulthood. Certain thalamic nuclei are strongly positive in P7 animals. The pineal gland and the subcommissural organ are both strongly positive in the neonate. Expression was also found in cingulate and piriform cortex postnatally, declining in 4-week-old animals. Interestingly, GDNF mRNA was also found in the periphery in sensory systems such as vibrissae, the developing tooth buds, as well as developing taste bud areas in the tongue. Furthermore, message was found in skeletal muscle tissue during development. We conclude that GDNF is expressed during development in dopamine-innervated areas of the brain as well as along neuronal systems associated with sensory information processing and proprioception.

THE NEUROPROTECTIVE EFFECTS OF GDNF ON SUBSTANTIA NIGRAL DOPAMINE NEURONS IN 6-OHDA LESIONED RATS C. Kearns* and DM Gash, Dept. of Anatomy and Neurobiology, University of Kentucky, Lexington, KY 40536

Glial-cell-derived neurotrophic factor (GDNF), a novel member of the TGF-β superfamily, has been shown to promote the survival and morphological differentiation of dopaminergic neurons *in vitro* (Lin et al, *Science*, Vol 260, 1130, 1993). Recent interest has focused on the use of neurotrophic factors in preventing the degeneration of nigrostriatal dopaminergic neurons observed in Parkinson's disease. Since GDNF may specifically prevent this degeneration and enhance the functional activity of the remaining dopamine neurons, the present study was designed to investigate a possible neuroprotective role for GDNF in rats receiving 6-OHDA administered either into the ipsilateral substantia nigra or striatum. Prior to surgery, 32 young adult male Fischer 344 rats were divided into the following groups: 1) intranigral saline + intranigral 6-OHDA, 2) intranigral saline + intrastriatal 6-OHDA, 3) intranigral GDNF + intranigral 6-OHDA and 4) intranigral GDNF + intrastriatal 6-OHDA. The saline treated groups received a single 2ul intranigral injection of phosphate buffered saline (PBS) while the GDNF treated rats received 10ug/2ul GDNF in PBS. Twenty four hours later, the animals received a unilateral 2.5ug/ul 6-OHDA infusion either in the substantia nigra or striatum. The rats were sacrificed by intracardiac perfusion two weeks postsurgery and the brains processed for GFAP and TH immunocytochemistry. Cell counts of remaining dopamine neurons in the substantia nigra were evaluated in all groups. In the nigral lesioned groups, there was only a 50% loss of dopamine neurons within the substantia nigra of the GDNF treated rats as compared to the 90% loss of dopamine neurons in those treated with saline. In the striatal lesioned groups, there was a 75% loss of dopamine neurons in the substantia nigra of the GDNF treated rats, while a 90% loss of dopamine neurons was observed in those treated with saline. These results demonstrate a significant protective role of GDNF in the nigral lesioned animals and a moderate sparing of dopamine neurons in striatal lesioned rats.

BEHAVIORAL, NEUROCHEMICAL, AND HISTOLOGICAL CHANGES IN THE DOPAMINERGIC SYSTEM OF UNILATERALLY 6-OHDA LESIONED RATS FOLLOWING INTRANIGRAL ADMINISTRATION OF GLIAL CELL-DERIVED NEUROTROPHIC FACTOR (GDNF). K. E. Bowenkamp*, A. F. Hoffman*, A.-C. Granholm*, M. A. Henry*, P. Biddle*, P. Huetti*, L.-F. H. Lin*, D. Martin*, J. L. Hudson*, G. A. Gerhardt*, and B. J. Hoffer*, Depts. of Pharmacology*, Psychiatry*, and Dentistry*, University of Colorado Health Sciences Center, Denver, CO 80262 and Synergen, Inc., Boulder, CO 80301.

Young adult male Fischer 344 rats were unilaterally injected into the medial forebrain bundle with 6-hydroxydopamine (6-OHDA, Sigma, 9 μg/4 μl in 0.02% ascorbate and 0.9% NaCl over 4 minutes). Apomorphine-induced rotational behavior (Sigma, 0.05 mg/kg in 0.02% ascorbate and 0.9% NaCl injected SC) was used to select animals whose average rotation exceeded 300 turns/hour, corresponding to greater than 99% dopamine (DA) depletion in the ipsilateral striatum. Six weeks later, 0.1 to 100 μg of GDNF (Synergen, Inc.) or vehicle was injected intranigral ipsilaterally to the lesion. Apomorphine-induced rotational behavior was quantified weekly for up to five weeks post-GDNF injection. Rats were sacrificed at 1, 3, and 5 weeks post-GDNF, for tyrosine hydroxylase (TH) immunohistochemistry and HPLC-EC analysis for the presence of NE, DA, DOPAC, HVA, 5-HT, and 5-HIAA in the right and left substantia nigra (SN), ventral tegmentum, and striatum. The highest dose of GDNF tested (100 μg) produced a greater than 65% decrease in rotational behavior which persisted for 5 weeks. This dose also produced levels of DA and DOPAC in the ipsilateral SN which were not statistically different from the contralateral, unlesioned side. Vehicle-treated animals showed a marked DA depletion in the ipsilateral SN. In contrast, there was no change from the lesioned state in the ipsilateral striatum. Immunohistochemistry of nigral sections from the 100 μg GDNF dose groups showed vacuoles associated with increased TH-immunoreactivity. These results demonstrate neurochemical and behavioral improvements in unilaterally-lesioned rats following intranigral administration of GDNF, suggesting that GDNF may be a useful therapy for Parkinson's Disease.

GLIAL CELL LINE-DERIVED NEUROTROPHIC FACTOR (GDNF) AS A NIGRO-STRIATAL DOPAMINOTROPHIC FACTOR LINKED TO CORTICO-STRIATAL EXCITATION. R. Schmidt-Kastner*, A. Tomac, B. Hoffer, S. Bektesh¹, B. Rosenzweig¹ and L. Olson. Dept. of Neuroscience, Karolinska Institute, S-171 77 Stockholm, Sweden; ¹Synergen Inc., Boulder, CO, USA.

Glial cell line-derived neurotrophic factor (GDNF) has recently been cloned and shown to have trophic effects on dopaminergic nigral neurons. GDNF mRNA was detected in the striatum of newborn rats, but not in adults. Enhanced neuronal excitation and depolarization in epileptic seizures has been shown to elevate the expression of several neurotrophins. Pilocarpine induces limbic motor status epilepticus, activating the limbic system and also basal ganglia circuits. Using this model, we have investigated GDNF mRNA production in forebrain of adult rats employing *in situ* hybridization with two independent oligonucleotide probes. GDNF mRNA was undetectable in striatum, cortex or hippocampus of controls. After 6 h of seizures, hybridization for GDNF mRNA was detected in cells in the caudal striatum. Signals were positive in granule cells of the dentate gyrus at 3, 6 and 24 h, and in lateral CA3 and medial CA1 area of hippocampus at 24 h. Cellular labelling was also found in neocortex at 24 h. The positive findings in the striatum support the hypothesis that GDNF may be a target-derived, trophic factor in the nigro-striatal system. Excitatory cortical input onto striatal neurons might be responsible for the regulation of GDNF expression. This initial demonstration of GDNF mRNA expression in the adult brain is critical for postulates on the trophic interplay between substantia nigra and striatum in Parkinson's disease. Increases in GDNF mRNA after status epilepticus in hippocampus and neocortex may indicate additional roles for GDNF.

POSTNATAL SPINAL CORD GRAFTS IN OCULO: EFFECTS OF TREATMENT WITH GLIAL CELL LINE-DERIVED NEUROTROPHIC FACTOR. K. Trok, B. Hoffer,* D. Russell,¹ L. Olson. Dept. of Neuroscience, Karolinska Institute, Stockholm, Sweden, and ¹Synergen Inc., Boulder, CO.

Glial cell line-derived neurotrophic factor (GDNF) is postulated to be a trophic factor for developing dopaminergic neurons. However, the distribution of mRNA for GDNF in the prenatal rat, including the spinal cord and skeletal muscle, suggests that GDNF has additional roles. Thus, we sought to determine if GDNF would also have a trophic effect on spinal cord tissue. The intraocular transplantation of neural tissue provides a unique approach to study the actions of trophic factors in vivo. In the case of spinal cord, although prenatal tissue matures well in the anterior chamber, grafts from newborn animals show limited survival and reduce their size. Grafts from two-week old animals usually do not survive at all. In our studies spinal cord tissue from newborn (P1) rats was transplanted to the anterior eye chamber of host rats after incubation in 100 µg/ml, 20 µg/ml, 10 µg/ml GDNF or vehicle. GDNF in doses of 0.5 µg, 0.1 µg, 0.05 µg or vehicle was then injected into the anterior eye chamber at days 5, 10, 15 and 20. There was a dose-dependent increase in growth of the transplants induced by GDNF. Indeed, grafts treated with 0.5 µg actually grew to larger than their initial size at grafting. We also transplanted P14 spinal cord to the anterior eye chamber and injected 0.5 µg GDNF or vehicle at days 5, 10, 15, 20, 25, 30 and 35. Grafts treated with GDNF also responded with increased growth compared with controls, but did not exceed their initial size at transplantation. We are currently investigating the immunohistochemical properties of these grafts.

EFFECT OF GLIAL CELL LINE-DERIVED NEUROTROPHIC FACTOR (GDNF) ON THE SURVIVAL OF CULTURED PERIPHERAL NERVOUS SYSTEM (PNS) NEURONS. T.J. Neuberger, D.J. Smith and L.F. H. Lin* Synergen Inc., Boulder, CO 80301

GDNF was known to enhance the survival and development of midbrain dopaminergic neurons with an EC₅₀ of ~40 pg/ml (Lin et al., Science, 260:1130, 1993). To further define the specificity of the neurotrophic activity of GDNF, we determined the EC₅₀ for promoting the survival of several distinct classes of embryonic chick PNS neurons including sympathetic lumbar chain (SC) neurons, parasympathetic ciliary ganglion (CG) neurons and sensory dorsal root ganglion (DRG) neurons. In addition, we also examined GDNF as a neurotrophic factor for neonatal rat superior cervical ganglion (SCG) neurons. GDNF promoted the survival of SC, CG and DRG neurons with an EC₅₀ of 9, 13 and 325 ng/ml, respectively. However, these values are several orders of magnitude greater than that required for GDNF to function as dopaminergic neurotrophic factor in midbrain cultures. GDNF at all concentrations tested (100 pg/ml to 10 µg/ml) could not support the survival of rat SCG neurons in serum-free defined culture medium whereas NGF at 50 ng/ml promoted neuronal survival and neurite extension. Hence, although GDNF can promote the survival of some PNS neurons, GDNF appears to be most potent with cultured midbrain dopaminergic neurons.

MODULATION OF NEUROTROPHIN RECEPTOR TYROSINE KINASE (RTK) PATHWAYS IN THE MESOLIMBIC DOPAMINE SYSTEM BY DRUGS OF ABUSE. D.S. Russell*, M.T. Berhow, K.L. Widnell, D.W. Self, and E.J. Nestler. Laboratory of Molecular Psychiatry, Depts of Neurology and Psychiatry, Yale Univ Sch of Med, New Haven, CT 06508

The cAMP system is an important mediator of neuronal changes due to drugs of abuse in the mesolimbic dopamine system (Neuron, 11:995, 1993). Neurotrophins can modify or mitigate these changes (see accompanying abstract, Berhow, et al.). Various methods are being employed to investigate the role of the neurotrophin RTK pathways, and their regulation by the cAMP system, in the changes induced by morphine and cocaine. Chronic morphine treatment in rats increases PLC-γ immunoreactivity in the VTA by 20-30% as determined by western blotting. Morphine also appears to regulate ERK1 and 2 differentially, while significant changes in the levels of raf1, PI-3-kinase, and ras were not observed. Chronic cocaine, however, decreased PLC-γ by 10-20%. Several proteins that are immunogenically like insulin receptor substrate-1 (IRS-1) are detected in rat brain and some appear to be associated with trk receptor complexes. Levels of a 200 kDa IRS-1-like protein decrease in the VTA with morphine treatment, while levels of a 130 kDa form increase in the hippocampus. Studies of regulation of the phosphorylation states and activities of these proteins are ongoing. Several recent studies demonstrate interactions between the cAMP system and RTK pathways. Some proteins likely to mediate this include raf, ERK and CREB. Single injections of CREB antisense S-oligonucleotides into the nucleus accumbens lead to a 50% decrease in CREB levels, and attenuate Fos-like protein expression and result in rotation behavior in response to an acute amphetamine challenge. This approach should enable the study of CREB, and the various other proteins mentioned above, in mediating the converging actions of neurotrophins and drugs of abuse in specific brain regions.

Effects of Glial Derived Neurotrophic Factor (GDNF) on the Nigrostriatal Dopamine System in Non-human Primates. G.A. Gerhardt*, W.A. Cass*, Z. Zhang¹, A. Ovidia², M. Cheesman³, B.J. Hoffer, P. Huettl, D. Russell², D. Martin² and D.M. Gash¹. Department of Psychiatry, Univ. of Colo. Health Sci. Ctr., Denver, CO, ²Department of Anatomy and Neurobiology, Univ. of Kentucky, Lexington, KY, and ³Synergen, Inc., Boulder, CO.

In the present study, the effects of single injections of GDNF into the substantia nigra or striatum of normal female Macaque monkeys were investigated using immunohistochemical, neurochemical, and behavioral methods. GDNF was injected using MRI-guided sterile stereotaxic surgery in isoflurane anesthetized monkeys; 150 µg/18 µl was injected into the right substantia nigra or 450 µg/18 µl into the right caudate nucleus. A separate group of animals served as controls receiving equal volume injections of phosphate buffered saline. Monkeys were monitored behaviorally each day both pre- and post-GDNF infusions. GDNF was seen to produce some behavioral changes in the animals for up to three weeks following the injections. Some decrease in body weight, increase in activity and occasional sleep disturbances were seen in the GDNF injected group as compared to controls. *In vivo* electrochemical studies involving local application of potassium using Nafion-coated carbon fiber electrodes showed increased DA release in areas of the caudate nucleus and putamen, ipsilateral to the GDNF injections. HPLC-EC studies of tissue punches of caudate nucleus and putamen of GDNF injected animals showed an increase in DA content bilaterally in animals which had received GDNF as compared to controls. Immunohistochemical studies showed a proliferation of TH-positive neurites in the substantia nigra of the animals receiving intranigral GDNF injections. These studies demonstrate increases in the functional properties of DA neurons upon exposure to GDNF in monkeys and support the hypothesis that GDNF may be a useful therapy in Parkinson's disease.

INFLUENCE OF NEUROTROPHIC FACTORS ON BIOCHEMICAL CHANGES IN THE MESOLIMBIC DOPAMINE SYSTEM ASSOCIATED WITH DRUGS OF ABUSE. M.T. Berhow*, D.S. Russell, D.W. Self, R.M. Lindsay*, and E.J. Nestler. Laboratory of Molecular Psychiatry, Yale Univ Sch of Med, New Haven, CT; *Regeneron Pharmaceutical Inc., Tarrytown, NY

Chronic morphine and cocaine treatments have been shown to regulate levels of tyrosine hydroxylase (TH) and glial fibrillary acidic protein (GFAP) in the ventral tegmental area (VTA) of the adult rat brain. Previous research demonstrated that the morphine-induced changes could be prevented by direct infusion of BDNF or NT4 (2.5 µg/day) midline into the VTA. In contrast, CNTF (1.5 µg/day) infusions mimicked these biochemical changes that are characteristic of chronic morphine treatment (Beitner-Johnson et al, Neurosci Abs 1993). In the present study, two alternative experimental paradigms were utilized. The first tested the ability of neurotrophins to reverse the biochemical changes in rats already pretreated with chronic morphine pellets. NT-4 infusion reversed the characteristic increases in TH and GFAP without any effect on these proteins when given alone. CNTF mimicked the morphine induced increase, but was not additive with morphine. The second paradigm tested the effect of concurrent cocaine (15mg/kg twice daily for 10 days) and growth factor treatment. As with morphine, BDNF abolished the cocaine-induced increases in TH levels.

A possible site of convergence for the intracellular actions of neurotrophins and drugs of abuse are the ERK's (extracellular-signal regulated kinases). We are infusing ERK1 and ERK2 antisense oligonucleotides into the VTA by osmotic minipumps. Initial studies suggest that these infusions can reduce ERK protein levels detected via immunoblotting. These studies, and related studies of other intracellular targets (Russell et al. Neurosci Abs, this volume), will help elucidate the molecular actions that may be common to the neurotrophins and drugs of abuse.

CONDITIONED MEDIUM DERIVED FROM MESENCEPHALIC TYPE-1 ASTROCYTES EXERTS DIFFERENT EFFECTS ON DOPAMINERGIC NEURONS AND PC12 PHEOCHROMOCYTOMA CELLS.

J.M. Johnston,* T. Takeshima,* H. Balling & J. W. Commissiong NTU-LMCN-NINDS-NIH, Park Bldg/415, Bethesda, MD 20892. *Div. Neurol., Tottori Univ. Sch. Med., 86 Nishimachi, Yonago 683, Japan.

Previously, we have developed a primary neuronal culture of the ventral mesencephalic region of the E14 rat in which 20% of the neurons are dopaminergic (Shimoda et al., Brain Res. 586: 319-331 1992). In the absence of serum, glial proliferation is suppressed and the percentage of dopaminergic neurons is reduced to <2% at five days in vitro (DIV 5). These cultures are thus good model systems for the bioassay of specific dopaminergic neurotrophic factors. In this study we use our model culture and a PC12 differentiation bioassay to demonstrate specific effects of conditioned medium derived from type-1 astrocytes (A-CM) on dopaminergic neuron survival.

When cultured in defined medium, 3.8±1.6 x 100/cm² dopaminergic neurons were present at DIV 5. The addition of 10% serum, A-CM or conditioned medium derived from B49 glial cells (B49-CM) increased the number of dopaminergic neurons present to 42.4±15.9 x 100/cm², 30.6±26.7 x 100/cm² and 8.3±1.9 x 100/cm² respectively. Few PC12 cells express neurites in culture medium, however, 80% expressed neurites when cultured with 100ng/ml of NGF and 48% expressed neurites when cultured with B49-CM. A-CM had no significant effects on PC12 cells. In addition, two partially purified A-CM glycoproteins with molecular weights of 30 000 and 15 000 increased dopaminergic neuron survival but did not effect neurite expression in PC12 cells.

B49-CM increases the survival of dopaminergic neurons and promotes the differentiation of PC12 cells, however, the effects of A-CM are specific to the survival of dopaminergic neurons. We are presently further characterizing the active glycoproteins that we have identified. The *in vivo* significance of these factors remains to be elucidated.

A BIOASSAY METHOD FOR DOPAMINERGIC NEUROTROPHIC FACTORS BASED ON THE USE OF MICROCULTURES AND IMAGING METHOD:

T. Takeshima¹, G. Ishida, K. Takahashi, J.M. Johnston¹, J.W. Commissiong¹
Div. Neurol., Tottori Univ. Sch. Med., 86 Nishimachi, Yonago 683, Japan. ¹NTU, LMCN, NINDS, NIH, Bldg. 10/Rm5N214, Bethesda, MD 20892.

BDNF, GDNF, IL-6, bFGF, PDGF- β , EGF, TGF- α , type-1 astrocytes, type-2 astrocytes, O-2A progenitors, microglia, and injured striatum all promote the survival of dopaminergic neurons in culture directly or indirectly. Experimental conditions used to assess the survival of dopaminergic neurons differ widely among investigators: 1) cell density, 2) fetal age, 3) dissection technique, 4) the use of serum, 5) the age of the cultures when stained and 6) the methods selecting fields for analysis are among the most important variables. We have developed a method that, if used widely, could bring a degree of objectivity to the field, and allow for a comparison of data from different laboratories. In this method, the E14 fetus is used. Only 1.0 mm³ of ventral mesencephalic tissue, which contain 90% of dopaminergic neurons, is dissected. The growth medium contains 0% of serum throughout. The cells are suspended at a density of 5.0×10^5 /ml. Only 25 μ l of the cell suspension is plated per chamber (area covered=6.2mm²) as a microisland (MI), on a substrate of poly-D-lysine. The equivalent plating density is $\sim 2.0 \times 10^5$ cells/cm². Cell attachment is completed in 4hr, and 375 μ l of growth medium is added. The untreated culture contains approximately 20%, 5%, 1% and 0% of tyrosine hydroxylase positive (TH⁺) neurons at 12 hr, DIV3, DIV5 and DIV7, respectively. The center of the MI is selected for analysis, using an imaging system with software capable of preparing a graphical montage. Four (2x2), or nine (3x3), or sixteen (4x4) adjacent fields are recorded (using a x20 objective), depending on the type of experiment, and especially the age of culture. Total neuronal counting is obtained by staining with anti-NSE or Neurotag. Double-staining is done for each neuronal phenotype of interest. The recorded image is displayed as a montage, saved as a .TIF file, and printed graphically. We have used this method successfully to compare the relative potency of most of putative dopaminergic neurotrophic factors listed above.

455.3

LONG-TERM SURVIVAL AND DEVELOPMENT OF DOPAMINERGIC NEURONS IN ORGANOTYPIC CULTURES OF POSTNATAL RAT VENTRAL MESENCEPHALON: DEPENDENCE ON BDNF FOR EXPRESSION OF NEUROTRANSMITTER SPECIFIC PHENOTYPE. **C. Hyman¹, M. Juhasz, R.M. Lindsay** Regeneron Pharmaceuticals Inc. Tarrytown, New York 10591.

Dissociated cultures of embryonic ventral mesencephalon have been successfully used to establish survival and early differentiation effects of specific neurotrophins on nigral dopaminergic neurons (Hyman et al., 1994, Knisel et al., 1991, Beck et al., 1993). It was of interest to determine whether the same neurotrophins are required for sustained survival and differentiation of postnatal dopaminergic neurons.

We have developed a method for the long-term maintenance of organotypic cultures of postnatal rat ventral mesencephalon under defined conditions. Viability and function of dopaminergic neurons were assessed by measurement of high affinity dopamine uptake activity, ³H-mazindol binding, and immunocytochemical staining of tyrosine hydroxylase. Culture conditions were selected which resulted in stable neuronal survival over 2 to 7 weeks in vitro, as determined by measurement of neurofilament content. High affinity dopamine uptake activity increased to reach a maximum level at 4 weeks in vitro. At 3-5 weeks in vitro ³H-mazindol binding was high but declined after 8 weeks. Exogenously added BDNF, included in culture medium at 50ng/ml, did not influence the survival or function of dopaminergic neurons as assessed by dopamine uptake activity or ³H-mazindol binding. In contrast, treatment of cultures with a neutralizing anti-BDNF antibody resulted in a 90% decrement in dopamine uptake activity after 3 weeks in vitro. This effect was reversible, indicating that postnatal dopaminergic neurons can survive in the absence of exogenous BDNF, but fail to express their appropriate transmitter-specific phenotype. Furthermore this suggests that locally synthesized BDNF may be required to maintain the phenotype of mature dopaminergic neurons.
