A consistent analysis of a visual scene requires the recognition of different separated objects. In vertebrate brains it has been suggested that this is achieved by synchronization of the activity of disjunct nerve cell assemblies. During such a process cross-talk between spatially adjacent image parts occurs, preventing efficient synchronization. Temporal differences, naturally introduced by stimulus latencies in every sensory system, are utilized in this study to counteract this effect and strongly improve network performance. In our nine-layer network we use the first three layers ("Retina+LGN") for the generation of contrast dependent visual latencies. In the remaining six layers ("Cortex") cell activities are synchronized by a commonly used algorithm relying on spatial neighborhood relationships to achieve feature binding. The contrast dependent visual latencies result in a large temporal separation of objects with different contrast. This leads to a much faster and much better synchronization of neurons representing corresponding image parts. The network model requires a direct link between visual latencies and the onset of synchronous oscillations in cortical cells. We recorded visually evoked local field potentials in area 17 of the anesthetized cat using flashing squares or bars of different contrast as stimuli. We observed a latency range of 33 to 113 ms for contrasts between 1.0 and 0.04. Generically the initial biphasic response was immediately followed by synchronous oscillations. Thus, the oscillation onset seems to be reset by the stimulus and the latency of the oscillations is therefore directly related to the actual stimulus induced visual latency.

## 592.10

**TRANSFORMATIONS OF PHYSIOLOGICAL PROPERTIES BETWEEN THE LGN AND V1 OF THE BEHAVING MONKEY.**

M. Gur<sup>1,2</sup> and D. M. Snodderly<sup>2,3</sup> <sup>1</sup>Dept. of Biomedical Engineering, Technion, Haifa, Israel; <sup>2</sup>Schepens Eye Research Institute, Boston; <sup>3</sup>Dept. of Ophthalmology and Program in Neuroscience, Harvard Medical School, Boston.

It is usually thought that the main difference between the parvo layers of the LGN and the input layer of V1, 4C $\beta$ , is manifested in the rearrangement of the layered input from the two eyes into one layer and not in the physiological properties of single cells. We investigated whether important transformations in physiological properties can be seen in the awake monkey.

Single cells were recorded from in the parvo layers of the LGN and in 4C $\beta$  using dye marks and/or physiological criteria to verify recording sites.

Width of activating regions (ARs) were measured in 15 LGN and 9 4C $\beta$  cells. Binocularity was tested in 25 LGN and 12 4C $\beta$  cells. In the LGN cells, visual field locations ranged from 17 to 65 deg ( $\mu = 37$  deg) with AR widths ranging from 9' to 42' ( $\mu = 16.8'$ ); visual field locations for the 4C $\beta$  cells ranged from 2.25 to 5.7 deg ( $\mu = 4$  deg) with AR widths ranging from 26' to 100' ( $\mu = 61.4'$ ). All LGN cells were influenced by one eye only while 11/12 4C $\beta$  cells showed overt binocular interactions.

We conclude that in the awake monkey, profound transformations, not seen in the anesthetized preparation, take place between the parvo layers of the LGN and layer 4C $\beta$  of V1. We assume that these transformations result from cortico-cortical and cortico-LGN interactions.

## 592.11

HOW COMPLEX CELLS USE THEIR LATENCIES TO TELL US ABOUT SHAPES DEFINED BY TEXTURE DIFFERENCES. T.J.Gawne\* and B.J.Richmond, Lab of Neuropsychology, National Institute of Mental Health, Bethesda, MD 20892.

Complex cells respond to boundaries that are defined by many different cues, including texture and local motion in addition to luminance. Previously we showed that the response strength of complex cells is affected by stimulus orientation and the response latency is affected by the cue that defined the stimulus. The relationship between response strength and response latency is separable with respect to orientation and cue (Gawne et al., 1994). Existing models of complex cells have concentrated on explaining the relationship between stimulus orientation and response strength.

Here we present a model that combines previously observed properties of LGN cells to duplicate the complex cell properties that we saw in our experiments. We start by making use of our previous model of LGN neurons (Gawne et al., 1991), where the sustained component was driven by a linear center-surround spatial filter, and the transient component was driven more nonspecifically by the difference in luminance of adjacent regions of a stimulus, i.e. the contrast. We use correlation between the activities of spatially shifted populations of LGN afferents to generate orientation specificity to boundaries defined by many cues. Direct connections between LGN afferents and the complex cell allows the transient to 'prime' the complex cell, affecting the time for the sustained component to move the membrane potential to threshold. The model does not have any elements in it with the properties of simple cells. Nonetheless, this model reproduces the effects we saw in complex cells: (1) The response strength shows similar orientation tuning to stimuli defined by a variety of cues, and (2) the response latencies are instead primarily a function of the cue.

## 592.13

PHYSIOLOGICAL COMPUTATION OF BINOCULAR DISPARITY  
N. Qian\* and Y.-D. Zhu, Center for Neurobiology and Behavior, Columbia University, 722 W. 168th St., New York, NY 10032

We previously proposed a physiologically realistic model for stereo vision (Qian, 1994, *Neural Computation*, 6:390-404) based on quantitative receptive field (RF) profiles mapped by Ohzawa et al. (1990, *Science*, 249:1037-41). Here we present several new results. First, we show that our model can be significantly improved by considering the fact that complex cell RFs are on average larger than those of simple cells. This fact is incorporated into the model by averaging many quadrature pairs of simple cells with nearby and overlapping RFs to construct a model complex cell. The disparity tuning curve of the resulting complex cell is much more reliable than that constructed from a single quadrature pair of simple cells used previously, and the computed disparity maps for random dot stereograms with a population of complex cells are very similar to human perception, with flat surfaces and sharp transitions at disparity boundaries (see figure). Second, we demonstrate through analyses that complex cells as described by Ohzawa et al. compute disparity by effectively summing up two related cross correlations between band-pass filtered left and right image patches. Third, we show that our model can be extended to a more general class of RF profiles than the commonly used Gabor functions. Finally, we demonstrate that as few as two complex cells at each spatial location are sufficient for a reasonable estimation of binocular disparity.

Computed disparity map for a 100-pixel by 100-pixel random dot stereogram with  $\pm 2$  pixels of disparities on a central square and the surround respectively. Eight model complex cells were used at each location for disparity computation. Each small square of the grid represents an area of  $2 \times 2$  pixels. Transitions at disparity boundaries occur over a distance of only 2-6 pixels.

## 592.12

GAP JUNCTIONS MAY PROVIDE AN IMPORTANT MEANS OF COMMUNICATION BETWEEN CELLS IN THE CEREBRAL CORTEX  
I.G. Parnavelas\* and B. Nadarajah, Dept. of Anatomy, University College London, London WC1E 6BT, U.K.

Ample evidence is now available to indicate that neurons and glia in many parts of the mammalian CNS are electrically and metabolically coupled through gap junctions. Dye coupling studies have demonstrated that gap junctions between cortical neurons are particularly prominent during development but less so in the adult cerebral cortex. In the present study, we examined the frequency and distribution of gap junctions (patch-like membrane appositions with a gap of 2nm) and the differential expression of gap junction proteins (connexins; cx) in the adult rat visual cortex. Brains of rats (3 to 6 months of age) were fixed with a mixture of aldehydes and processed for conventional and freeze-fracture electron microscopy. Connexins were visualized using immunohistochemical techniques in cryostat-cut sections with antisera directed against cx26, 32 and 43. Examination of coronally-cut ultrathin sections revealed the presence of a large number of gap junctions throughout the cortical thickness. Detailed analysis in layer V showed on average 33 gap junctions/grid square in a 200 mesh grid (100 x 100  $\mu$ m area). The majority of these junctions involved glial cells (63% between astrocytes and 6% between astrocytes and oligodendrocytes) but about 10% involved neurons. In approximately 20% of the cases, we were unable to identify unequivocally the cell types involved in the formation of the gap junctions. This high incidence of gap junctions were confirmed by freeze-fracture analysis. Immunoreactivity for cx32 and 43, purported to be expressed by neurons and astrocytes respectively, appeared as discrete puncta throughout the cortical thickness; cx26 labelling was confined to meninges. These results suggest that gap junctions are present in very significant numbers in the adult visual cortex and may be involved in electrical and metabolic coupling between cortical cells.

## 593.1

IN VITRO PROLIFERATION OF PRIMATE CORTICAL PRECURSORS AND SPECIFICATION OF CORTICAL AREAS. H. Kennedy\*, C. Dehay, M. Berland, P. Savatier\* and V. Cortay, INSERM U371, 18 Av. Doyen Lépine, 69675 Bron Cedex (France), \*Laboratoire de Biologie Moléculaire et Cellulaire, Ecole Normale Supérieure, 46 Allée d'Italie, 69364 LYON, (France).

Modulation of cell cycle kinetics underlies the histogenesis of areas 17 and 18 in the monkey (Dehay et al., 1993). Here we have investigated whether these regional differences in cell cycle parameters are determined by environmental factors. We have compared the proliferative characteristics of precursors cells of areas 17 and 18 in vitro. Dissociated cell cultures were prepared from the telencephalic wall of the occipital cortex of E80 and E74 monkeys and cells were grown in BHK21 culture medium. Presumptive area 17 was dissected out from the most posterior part of the occipital lobe and presumptive area 18 from the posterior bank of the lunule sulcus. Proliferation was studied by means of BrdU incorporation by cells in S phase. The total cycling population (ie the growth fraction) was revealed by PCNA (proliferating cell nuclear antigen) immunostaining. We estimated the labelling index (LI) by computing the proportion of BrdU positive cells with respect to the total cycling population. Our results show a significantly higher (LI) in area 17 precursors compared to area 18 precursors after 1, 2, 3 and 5 days in vitro. These results show that the higher rate of proliferation that characterises A17 precursors cells in vivo, is maintained in vitro. This suggests that the proliferative characteristics of cortical precursors cells are autonomous. When ventricular zone cells from A17 are cultured alone, the LI shows similar values to those obtained when they are cultured with the immature neuroblasts of the cortical plate and intermediate zone. This suggests that the higher rate of proliferation characteristics of A17 precursors is not solely mediated by an autocrine effect.

## 593.2

MODULATION IN VITRO OF THE PROLIFERATION OF RODENT CORTICAL PRECURSORS BY A THALAMIC CYTOKINE. C. Dehay\*, A. Guibert, P. Savatier\*, V. Cortay and H. Kennedy, INSERM U371, 18 Av. Doyen Lépine, 69675 Bron Cedex (France), \*Laboratoire de Biologie Moléculaire et Cellulaire, ENS, 46 Allée d'Italie, 69364 Lyon Cedex 07, (France).

In vivo results suggested that thalamic afferences may regulate cell proliferation in the ventricular zone of the monkey cortex (Dehay et al., 1991; Kennedy and Dehay, 1993). We have tested this hypothesis by studying the proliferative activity in dissociated cultures of E14 mouse cortex. The results show a significant increase of Tritiated-Thymidine incorporation in cortical precursors cultured during 48 hours in the presence of E14 dorsal thalamic explants placed in a transwell. This shows that the thalamic cells exert a mitogenic effect on cortical precursors that is mediated by a diffusible factor. By using BrdU incorporation which labels cells in S phase in combination with PCNA immunostaining which labels cycling cells, we have studied the effect of E14 thalamus conditioned medium (TCM) on the proliferation of E14 cortical precursors. Under these conditions, there is a 20% increase of the total cell number in the presence of the TCM. Further, in the presence of the TCM, there is an increase in the labelling index (LI = BrdU positive cells/ cycling cells) which reflects changes in the kinetics of the cell cycle. Higher values of LI are likely to reflect a shortening of the total duration of the cell cycle rather than a change in the absolute duration of S phase. Moreover, in the presence of TCM, there is a significant increase in the proportion of PCNA positive cells. This means that TCM induces more cell precursors to remain in the cell cycle. Therefore, the embryonic thalamus secretes a cytokine that (1) inhibits differentiation and (2) stimulates the proliferation of cortical precursors.

**RADIAL AND HORIZONTAL DEPLOYMENT OF CLONALLY RELATED CELLS IN THE RHESUS MONKEY NEOCORTX: RELATIONSHIP TO DISTINCT MITOTIC LINEAGES.** D.R. KORNACK\* AND P. RAKIC. Section of Neurobiology, Yale University School of Medicine, New Haven, CT 06510.

Cells of the neocortex are organized into functionally distinct columnar and laminar domains. To examine whether cell lineage may contribute to the formation of these domains in the primate, we used recombinant retroviruses to label individual progenitor cells in the ventricular zone (VZ) of the fetal rhesus monkey *in vivo*, then determined histochemically the distribution of their progeny during and after the period of cortical neurogenesis. Distribution patterns of labeled cells in the VZ suggested the coexistence of asymmetrically and symmetrically dividing progenitor cells, indicating that both postmitotic and mitotic progeny are produced during cortical neurogenesis. In the cortex, several distinct patterns of clone distribution were observed and interpreted as follows: clones aligned radially suggested that asymmetrically dividing progenitors generate sequential "siblings" that migrate, in tandem, along a common radial path to the cortex. In contrast, clones oriented horizontally within a single lamina suggested that symmetric divisions produce multiple, laterally displaced progenitors which, in turn, simultaneously generate "cousin" cells that migrate, in concert, to the same cortical layer. Such simultaneous generation and migration of cousin cells may be particularly relevant in the primate cortex, in which cells generated at a particular time during neurogenesis eventually distribute as a sharp horizontal band within a lamina, as revealed in previous 3H-thymidine neuronal 'birthdating' studies in this species. Thus, we propose that different mitotic lineages, which coexist in the monkey VZ, produce distinct radial or laminar patterns of clone deployment that foreshadow the cytological organization of the adult neocortex. **CORPUS CALLOSUM CELLS OF ORIGIN INCLUDE CAJAL-RETIUS LAYER 1 CELLS IN VISUAL CORTEX: DI/DIA AND CONFOCAL LASER SCANNING MICROSCOPE (CLSM) ANALYSIS.** A.J. Elberger\*. Dept. of Anatomy and Neurobiology, The University of Tennessee, Memphis TN 38163.

Crystals of Dil or DiA placed in rat corpus callosum (CC) *in vitro* retrogradely label many cells throughout visual cortex via transitory CC axons which gradually disappear by postnatal day (PND) 26 (Elberger 1994). In rats with such labeling at PND 0 (day of birth) through 20, the CC cells of origin in layer 1 were examined in detail using a CLSM. The layer 1 CC cells were most abundant at PND 0-1, and absent by PND 9.

Many layer 1 CC cells were classified as Cajal-Retzius (C-R) cells because they met 2 criteria: axons and dendrites parallel to the pia for long distances, and dendrites with projections orthogonal to the pial surface. Axons of C-R cells could be followed for long distances through layer 1 and into layer 2. No cells in layers 2-6 met the C-R criteria. By PND 3 there were far fewer C-R CC cells; those present had shorter dendrites with fewer orthogonal projections. At PND 3 there were still many other layer 1 CC cells with axons and dendrites parallel to the pial surface, but they did not have dendritic projections orthogonal to the pial surface. By PND 7 there were almost no layer 1 CC cells, and by PND 9 none could be detected.

These results are almost certainly not due to transcellular DiI/DiA diffusion because: 1) many C-R CC cells were far from CC cells/processes in layers 1 and 2, 2) all C-R CC cells were as intensely labeled as other CC cells in layers 1-6, and 3) in tissue with DiI labeling cortical afferents and efferents at PND 0-20, no C-R cells were observed even when layer 1 connections were labeled. This new finding of C-R CC cells supports hypotheses about the functions of transitory CC connections, and indicates that the function of C-R cells may need to be reevaluated. **Neurosteroid modulation of GABA currents and  $[Ca^{++}]_i$  in embryonic neocortical cells.** D.F. Owens, M.B.E. Davis, M.J.S. Heath and A.R. Kriegstein\* Depts. of Neurology and Anesthesiology, Columbia Univ. Med. Center, N.Y., N.Y. 10032

Progesterone metabolites have been found to modulate GABA<sub>A</sub> receptor-mediated currents. GABA produces membrane depolarization in ventricular zone (VZ) cells of the embryonic rat cortex via activation of GABA<sub>A</sub> receptors. Since progesterone metabolites are present in the fetal circulation they could modulate GABA<sub>A</sub> currents in embryonic cells. We investigated the effects of progesterone metabolites on GABA induced currents in embryonic rat neocortex using *in situ* patch clamp recording techniques. At embryonic day 16 (E16), 5 $\alpha$ -pregnan-3 $\alpha$ -ol-20-one (3 $\alpha$ -OH-DHP) at concentrations ranging from 1 nM to 1  $\mu$ M was found to produce an enhancement of GABA-induced current in VZ cells. On average, 100 nM 3 $\alpha$ -OH-DHP produced a 48% increase in the GABA current. In contrast, steroid potentiation of GABA current was not observed in embryonic cortical plate (CP) cells. In addition, using Fura-2 imaging techniques GABA was found to increase  $[Ca^{++}]_i$  in both VZ and CP cells. 3 $\alpha$ -OH-DHP (200 nM) was found to potentiate the GABA mediated  $Ca^{++}$  increase in VZ cells, but not CP cells. These differences in steroid sensitivities could reflect different subunit compositions of GABA<sub>A</sub> receptors in these two distinct regions, and could implicate a differential role for neurosteroid/GABA interactions during development.

## 593.4

**DEVELOPEMENT OF CORTICAL PATHWAYS IN PRIMATES SHOW LIMITED EXUBERANT CONNECTIVITY.** A. Batardière\*, C. Dehay, M. Berland\*, P. Barone and H. Kennedy. INSERM U371, 18 Av. Doyen Lepine, 69675 Bron Cedex, France, \*Centre Hospitalier Lyon Sud, 165 Chemin du Grand Revoyet, 69495 Pierre Benite Cedex, France

A characteristic feature of the development of cortical projections to area 17 in the monkey is the prolonged reorganization of the laminar distribution of afferent neurons<sup>1</sup> and the absence of labeled neurons in inappropriate cortical regions (Dehay and Kennedy unpublished). To investigate whether these developmental features are unique to projections to area 17, we have injected tracers into presumptive area V4 in fetal and postnatal monkeys and analysed qualitatively the areal and laminar distribution of labeled neurons. In the fetus, injections restricted to the gray matter labeled neurons limited to cortical regions which project to area V4 in the adult. However injections which involved the white matter revealed a transient projection from the auditory cortex. Feedforward projections from visual areas V2 and V3 showed no laminar distribution changes during development. This contrasted with feedback projections from anterior cortical regions which showed massive developmental reductions of the proportion of labeled supragranular layer neurons during fetal development.

These results suggest (1) that the laminar remodeling of connectivity is a characteristic feature of feedback connections and (2) that although transient cortical connections are rare in the developing monkey they do interconnect the auditory cortex with a visual cortical area which is implicated in color vision.

## 593.6

**SHIFTS IN GABA<sub>A</sub> REVERSAL POTENTIAL DURING NEOCORTICAL DEVELOPMENT.** L.H. Boyce, D.F. Owens, M.B.E. Davis, D.C. DeVivo\*, A.R. Kriegstein Dept. of Neurology, Columbia University College of Physicians and Surgeons, NYC, NY 10032

In the adult CNS, GABA mediates fast inhibitory neurotransmission through activation of GABA<sub>A</sub> receptors. However, in immature neurons, activation of GABA<sub>A</sub> receptors can produce membrane depolarization presumably due to high  $[Cl^-]_i$ . Using *in situ* patch-clamp techniques with gramicidin perforated patches, which leave  $[Cl^-]_i$  undisturbed, we were able to study the change in the GABA reversal potential ( $E_{GABA}$ ) in embryonic and postnatal neocortical cells. GABA<sub>A</sub> currents are inward at resting membrane potential in ventricular zone cells throughout the embryonic period. By inhibiting  $Cl^-$  exchange with furosemide, the reversal potential can be shifted to a more negative value, consistent with  $Cl^-$  mediation of GABA<sub>A</sub> current and a high  $[Cl^-]_i$ . In embryonic (E19) cortical plate neurons,  $E_{GABA}$  is approximately -36 mV while resting membrane potential is approximately -65 mV.  $E_{GABA}$  becomes progressively more negative postnatally; at postnatal day 2 (P2)  $E_{GABA}$  is approximately -43 mV, and by P16  $E_{GABA}$  is -59 mV. These data confirm a progressive shift in the GABA<sub>A</sub> reversal potential, and may reflect a changing role for GABA during early neocortical development.

## 593.8

**NMDA-INDUCED  $[Ca^{++}]_i$  INCREASE IN VENTRICULAR ZONE CELLS OF EMBRYONIC NEOCORTX.** A.C. Flint, M.B.E. Davis, M.J.S. Heath, J.J. LoTurco\*, A.R. Kriegstein Depts. Neurology and Anesth., Columbia Physicians and Surgeons, NYC, NY 10032 and Dept. of Physiology, U of Conn., Storrs, CT 06269

Ventricular zone cells of embryonic neocortex have been previously thought to lack NMDA receptors. We found evidence of functional NMDA receptors in embryonic rat neocortical cells in the ventricular zone (VZ) and cortical plate (CP) at E16 using  $Ca^{++}$ -sensitive dyes. NMDA (10-100  $\mu$ M) induced increases in  $[Ca^{++}]_i$  in cells in the VZ and CP in brain slices loaded with fluo-3 and imaged using laser confocal microscopy. NMDA-responsive VZ cells included rounded cells at the ventricular surface as well as bipolar cells within the VZ. In the CP, responsive cells included more mature process-bearing cells resembling young neurons. NMDA responses were sensitive to the specific receptor antagonist AP-5 and were abolished in 0 mM  $[Ca^{++}]_o$ . VZ cells often responded in advance of CP cells and in the presence of TTX, bicuculline, and CNQX, arguing against indirect activation of VZ cells by NMDA-responsive CP neurons. In addition, a tissue printing technique was developed to obtain acutely isolated cells from the ventricular surface. These cells were loaded with fura 2-AM and NMDA application demonstrated a subset of responsive cells. The presence of NMDA-responsive cells in the VZ of rat embryonic cortex suggests a possible role for NMDA receptors during proliferative stages of cortical development.

## 593.9

ONTOGENESIS OF NADPH-DIAPHORASE EXPRESSION IN THE VISUAL CORTEX OF THE MONKEY. P. Barone\*, C. Debay, M. Berland and H. Kennedy. INSERM U371 Cerveau et Vision. BRON (France)

The free radical neurotransmitter nitric oxide (NO) is implicated in a number of developmental processes including the establishment of the adult pattern of connectivity. The presence of NO in the central nervous system can be detected by mean of histochemical visualization of the enzyme NADPH-diaphorase (NADPH-d) activity, a NO synthase. We have investigated the distribution of NADPH-d expression during fetal and postnatal development in monkeys. During development, changes of NADPH-d expression are observed in the neopile as well as in a sub-population of cortical and white matter cells.

**Neopile.** In area V1, NADPH-d activity in the neopile of the cortical plate is first detected at E84, where it is largely restricted to infragranular layers. Activity increases with age and adult-like levels are observed at birth where a high level of activity is located in the upper part of layer 4. Sections cut parallel to the surface reveal the presence of NADPH-d blobs in supragranular layers of the adult monkey that are co-extensive with CO blobs.

**Cells.** A small population of cells express NADPH-d in area V1. They are characterized by a large cell body (15-20  $\mu$ m diameter), predominantly of non-pyramidal shape, and by an extensive dendritic arborization covering distances up to 1 mm or so. The size, the shape and the laminar distribution of NADPH-d positive cells changes during maturation. No labelled cells are present in the E75 fetus, and only a few labelled cells are observed in the intermediate zone and subplate of the E84 fetus. NADPH-d expression in cortical plate cells begins at E94 (i.e. at the end of neurons migration) in infragranular layers. Quantification of labelled cells in area V1 shows a continuous increase in the number of cells from E115 reaching peak values 4 months postnatally. There is a decrease in cell number between 4 months and adulthood. While this increase is moderate between birth and 4 months in infragranular layers, it is significantly higher in the supragranular layers, leading to the high proportion of NADPH-d positive cells in this compartment in the adult. White matter cells follow this developmental time course. In fetuses, NADPH-d expressing cells have a deeper distribution compared to postnatal animals where they are located just below layer 6. Our results show that NADPH-d activity maturation is reached late in postnatal life and parallels synaptogenesis. NADPH-d is found to selectively label an important sub-population of subplate neurons. These early generated neurons are known to play a crucial role in determining the precision of thalamo-cortical connections during development.

## 593.11

EXPRESSION OF  $\alpha$ -4-1 NICOTINIC ACETYLCHOLINE RECEPTOR mRNA IN THE RAT TELENCEPHALON DURING FETAL AND EARLY POSTNATAL DEVELOPMENT. H. Schröder\*, N. Moser\*, J. Grünwald\*, C.-H. Ostermann\*, A. Wevers\*, D.E. Lorke\*, U. Schütz\* and A. Maelicke\*. 'Inst. II für Anatomie, Univ. Köln, Köln, F.R.G., 'Abt. Neuroanatomie, Univ. Hamburg, Hamburg, F.R.G., 'Inst. für Physiologische Chemie und Pathobiochemie, Univ. Mainz, Mainz, F.R.G..

So far, neuronal nicotinic acetylcholine receptor (nAChR) expression has mainly been studied in adult human and rat telencephalon. In contrast, only few studies address nAChR expression in the course of embryonic and perinatal development, or under conditions of neuronal degeneration.

Gene expression of the  $\alpha$ -4-1 nAChR subunit was studied by in situ hybridization from embryonic day 14 to postnatal day 120 (E14-P120), in rat neocortex, hippocampus and olfactory bulb, using a digoxigenin-labeled  $\alpha$ -4-1 riboprobe, an alkaline phosphatase-coupled digoxigenin antibody and a color substrate reaction (Wevers et al., *Mol. Brain Res.*, 25:122, 1994). In all regions,  $\alpha$ -4-1 mRNA expression showed a transient upregulation in distinct neuronal subpopulations and preceded cholinergic fiber ingrowth (Nyakas et al., *Neuroscience*, 59:541, 1994). Neocortical  $\alpha$ -4-1 mRNA expression was increased in layer VIB between E20 and P7. In dentate gyrus granule cells  $\alpha$ -4-1 mRNA expression was prominent about birth, still present at P25 and subsequently decreased to adult levels (P120). The olfactory bulb showed strongest expression in the mitral cell layer (MCL) at P0. During further development the number of  $\alpha$ -4-1 expressing MCL neurons decreased. Prenatally, some neurons of the external plexiform layer showed strong  $\alpha$ -4-1 expression which decreased in adult stages.

Transient mRNA expression preceding cholinergic innervation has been reported to occur at the developing neuromuscular endplate. It needs to be elucidated whether an innervation-associated switch in non- $\alpha$  nAChR isoform expression as observed for the developing skeletal muscle may also occur in the central nervous system.

## AXON GUIDANCE MECHANISMS AND PATHWAYS VII

## 594.1

TRANSIENT INTERMEDIATE ZONE NEURONS PROJECT TO THE SPINAL CORD, THE SUPERIOR COLLICULUS, AND THE CONTRALATERAL HEMISPHERE IN RATS.

N. Tamamaki\*Dept. of Anatomy, Fukui Medical School, Matsuoka, Fukui 910-11 Japan

The developing mammalian telencephalon contains many transient neurons. Transient subplate neurons have been proposed to lay down the first axonal pathways as a scaffold for the establishment of permanent cortical projections to the thalamus, the superior colliculus, and the contralateral hemisphere in cats. The questions whether there are pioneer fibers to the spinal cord and whether these pioneer neurons are prevailed in other mammalian are important issues in neocortical development. Here, I have searched for neurons giving rise pioneer fibers to the subcortical structures in rats. Tracers (Dil or BDA) were injected into the spinal cord, the superior colliculus, or the contralateral hemisphere in vivo, and a population of labeled cells were found in the lower intermediate zone (IZ) of the dorsomedial cortex. Cresyl violet staining showed an accumulation, which also corresponded to a population of GABA-immunoreactive cells in the lower intermediate zone, in a similar location. These retrogradely labeled cells were MAP2-positive (microtubule associated protein 2; neuron-specific protein), and some of them also expressed somatostatin. The IZ neurons in the dorsomedial cortex underwent their final round of cell division before embryonic day 14 (E14) and sent out fibers to the internal capsule before E16, disappearing from the IZ as the brain matured. These characteristics imply that the IZ neurons in rats pioneer the major corticofugal pathway.

## 593.10

MODULATORY NEUROTRANSMITTERS REDUCE DYE-COUPPLING BETWEEN DEVELOPING LAMINA II/III PYRAMIDAL NEURONS IN RAT NEOCORTX. B. Roerig\*, G. Klaus and B. Sutor. Institute of Physiology, University of Munich, Pettenkoferstrasse 12, D-80336 Munich, Germany.

During the early postnatal period neurons in rat neocortex are extensively coupled via gap junctions (Connors et al., *J Neurosci* 3:773, 1983; Peinado et al., *Neuron* 10:103, 1993). To investigate whether modulatory transmitters regulate gap junction coupling layer II/III pyramidal cells in slices from rat prefrontal and frontal cortex (P7-P19) were impaled with sharp microelectrodes and injected with the tracer neurobiotin.

On P7-P10 the average number of cells coupled to the injected neuron was 30.36 (SEM 5.72, n=14) under control conditions. Preincubation with dopamine (100  $\mu$ M) or the D1 dopamine receptor agonist SKF 38393 (100  $\mu$ M) significantly ( $P < 0.005$ , Mann-Whitney U-test) reduced the average cluster size by approximately 70%. A 50% reduction in the number of coupled cells per injection was produced by the D2 dopamine receptor agonist quinpirole. The transmitters serotonin (100  $\mu$ M) and norepinephrine (30  $\mu$ M) as well as the  $\beta$ 1 adrenergic agonist isoproterenol (30  $\mu$ M) also induced a statistically significant reduction in tracer coupling by 60-70%. Dye-coupling was furthermore markedly suppressed by preincubation of slices with the adenylate cyclase activator forskolin (20  $\mu$ M) or with the direct protein kinase A activator Sp-cAMPS (100  $\mu$ M). Application of forskolin to neurons recorded in the whole cell configuration of the patch clamp technique induced a reversible increase in input resistance which was not observed in uncoupled neurons during the third postnatal week.

We conclude that modulatory afferents to the developing neocortex affect metabolic and electrical signal transfer as well as electrotonic cell properties by regulating the extent of gap junction coupling between immature neurons. Activation of adenylate cyclase and protein kinase A by G-protein coupled receptors presumably represents one major second messenger pathway involved.

Supported by DFG (SFB 220 / A9).

## 594.2

DEVELOPMENT OF CHICK MOTONEURON AFFERENT AND EFFERENT CONNECTIONS. P. Ouehada, M. J. Ignatius\*. Div. of Neuroscience, MCB, U.C. Berkeley, Berkeley CA 94720-3200.

Motoneuron outgrowth from the vertebrate neural tube occurs at discrete ventral sites through an extracellular matrix. Sensory cells must also cross this matrix barrier from outside the neural tube, through a dorsal root entry point, then synapse on targets in both the dorsal and ventral horns. Development of these connections do not require activity or experience in the chick, suggesting pre-formed pathways rather than synaptic remodeling drive the development. We have followed the development of these motoneuron projections using several early markers of differentiation in combination with Dil tracing. By stage 15, chick motoneurons begin to project out of the ventral aspect of the neural tube. 12 to 24 hours later, subpopulations of motoneurons project dorsally and exit out the dorsal aspect of the neural tube. Their projections appear to stop in the region eventually occupied by the sensory ganglia. Sensory cell axons next enter the neural tube in close proximity to the tracts established by these motoneurons and the gamma Ia afferents send branches ventrally. During this period both population of cells express the homophillic cell adhesion molecule, DM-GRASP.

The dorsal motoneuron projection appears to be transient, but while present, may serve as a pathway used by sensory afferents to first cross this matrix barrier, then to find targets in the ventral horn of the neural tube. In addition, the breaching of the matrix may occur in concert with a population of non-neuronal cells that occupy at least the ventral site prior to axon outgrowth. Immunologically identical non-neuronal cells remain associated with the motor projections as they depart the neuronal tube, suggesting a persistent and necessary interaction. Supported by ALS Assoc. and a NIH RO1 to MJL.

## 594.3

**DUAL FUNCTION OF CALCIUM IN LAMININ-MEDIATED GROWTH CONE GUIDANCE: I. EARLY CA<sup>2+</sup> SIGNAL IN FILOPODIA UNDERLIES GROWTH CONE TURNING.** C.V. Williams\*, T.B. Kuhn, P. Dou, S.B. Kater. Anatomy & Neurobiology, Colorado State University, Fort Collins, CO 80523.

Chick drg growth cones respond to laminin (LN) model guideposts with characteristic behaviors (Kuhn et al., 1995). We assessed the role of Ca<sup>2+</sup> in the initial response to LN guideposts; namely filopodial contact and subsequent growth cone reorientation toward the bead. In control experiments, filopodial contact with LN-coated beads resulted in 79±1% growth cones turning toward the bead (n=21). In contrast, only 19±1% of growth cones loaded with 2μM Bapta-AM (K<sub>d</sub>=340) turned (n=21) (p<0.01). Similarly, neurons bathed in 2mM EGTA made filopodial contact with beads and adhered, but did not turn. Growth cones bathed in the inorganic Ca<sup>2+</sup> channel blockers cobalt (2mM) or nickel (2mM) also failed to turn. These data suggest that an influx of Ca<sup>2+</sup> underlies filopodial responses to LN-coated beads.

To test this, neurons were loaded with the Ca<sup>2+</sup> indicator Fura2-AM and LN-coated beads or soluble LN were presented to growth cones. No significant changes in intracellular Ca<sup>2+</sup> in filopodia or growth cones were observed during initial contact. It seemed likely that a rapid Ca<sup>2+</sup>-dependent exchange of information between filopodia and growth cones may exist, as supported by the pharmacological data above. We reasoned that isolation of filopodia would therefore interrupt this exchange and possibly result in a detectable Ca<sup>2+</sup> signal. Thus we applied soluble LN to isolated filopodia and observed a rapid, sustained rise in intrafilopodial Ca<sup>2+</sup>: 80nM±12nM (n=9). These data demonstrate that growth cone turning requires an early transient Ca<sup>2+</sup> signal restricted to filopodia contacting LN-coated beads.

## 594.5

**REQUIREMENT OF CALCIUM IONS AND FILOPODIA ASYMMETRY IN CHEMOTROPIC TURNING OF NERVE GROWTH CONES.** J.-J. Wan, J.Q. Zheng, and M.-M. Poo\*. Dept. Biol. Sci., Columbia Univ., New York, NY 10027

Microscopic gradients of glutamate were established near the growth cone of cultured *Xenopus* spinal neurons by repetitive pulsatile ejection of picoliters of glutamate solution from a micropipette at a distance of 100 μm from the center of the growth cone. Over a restricted range of glutamate concentration (0.05 to 0.5 mM in the pipette), the growth cones exhibited positive chemotropic turning toward the source of glutamate. The filopodia appeared to be essential for the growth cone to sense and/or to respond to the glutamate gradient, since disruption of filopodia by bath-application of cytochalasin B (0.17 μg/ml) abolished the chemotropic turning response. Furthermore, time-lapse microscopy showed that a filopodia asymmetry, with more filopodia facing the glutamate source, is induced soon after the onset of the glutamate gradient, prior to the turning response. When the glutamate gradient was applied in Ca<sup>2+</sup>-free medium, the turning response was abolished, and no filopodia asymmetry was induced. Although Ca<sup>2+</sup> appears to be an essential second messenger for the glutamate-induced turning, robust turning response was observed over a wide range of extracellular Ca<sup>2+</sup> concentration (100 nM - 2 mM). The turning response was completely blocked by AP-5, suggesting that influx of Ca<sup>2+</sup> through NMDA receptors is required. Taken together, these results suggest that asymmetric influx of Ca<sup>2+</sup> at the growth cone, preferential filopodia formation, and the turning of the nerve growth cone are causally-linked sequence of events.

## 594.7

**PURIFICATION AND SEQUENCE ANALYSIS OF THE AXON FASCICLE SPECIFIC LAN3-2 ANTIGEN AND OF A PROTEIN WITH WHICH IT MAY INTERACT** Y. Huang\*, A. Dietz, J. Jellies\*, K.M. Johansen, and J. Johansen. Department of Zoology & Genetics, Iowa State University, Ames, IA 50011 and \*Department of Biological Sciences, Western Michigan University, Kalamazoo, MI 49008.

In leech, the mAb lan3-2 defines a small population of tightly fasciculated axon tracts in the nerve roots and interganglionic connectives which are formed by peripheral neurons. The lan3-2 antigen is a 130 kD surface glycoprotein which may be directly involved in the assembly of these axon tracts since lan3-2 antibody perturbation disrupts normal fascicle formation in embryos (Zipser et al., *Neuron* 3:621). To further characterize its function in specific tract formation we are molecularly identifying and cloning the lan3-2 antigen. Since the lan3-2 epitope is partly made up of sugar moieties we purified the antigen from leech CNS extracts by immunoaffinity chromatography. The purified protein was fractionated by SDS-PAGE, blotted onto PVDF membrane, and the 130 kD band cut out and trypsin digested. The sequence of seven of the resulting peptides were determined by gas-phase microsequencing. Searches of the data banks show that all seven peptides represent novel sequences; however, four (pep1-4) have limited homology to Ig- or FNIII-domains, two (pep5-6) are unique, and one (pep7) has homology to the C-terminal sequence of vertebrate thrombospondins. To test whether these peptides are indeed derived from the lan3-2 antigen we have made new antibodies to pep1 and pep7 both of which specifically recognize a 130 kD band on Western blots of leech CNS proteins. Pep1-antibody does not stain immunocytochemically so we do not yet know whether it corresponds to the lan3-2 antigen. Interestingly, while the pep7-antibody does not recognize the lan3-2 positive peripheral neurons it does label all central neurons and their peripheral axons. This suggests that we may have obtained microsequence from a copurifying protein which may interact with the lan3-2 antigen. We are screening leech cDNA expression vector libraries with the antibodies in order to obtain full length sequence of these proteins for further analysis. Supported by NIH NS28857 (JJo) and NSF 9209337 and a Sloan Fellowship (JJe).

## 594.4

**DUAL FUNCTION OF CALCIUM IN LAMININ-MEDIATED GROWTH CONE GUIDANCE: II. LATE SUSTAINED CA<sup>2+</sup>-SIGNAL IN GROWTH CONES LONG AFTER TRANSIENT CONTACT IS ASSOCIATED WITH ENHANCED OUTGROWTH.** T.B. Kuhn\*, C.V. Williams, P. Dou, S.B. Kater. Dep. of Anatomy and Neurobiology, Colorado State University, Ft Collins, CO 80523

Laminin (LN)-coated beads provide unique guidance instructions to advancing chick DRG growth cones. Upon transient interactions, growth cones display a series of stereotypic changes in their behavior and morphology, some lasting considerably beyond the time of actual contact (Kuhn et al., 1995). Among the most striking growth cone response are early turning and late, enhanced outgrowth after transient LN-contact. Growth cone turning is mediated by an influx of extracellular calcium into filopodia (Williams et al. preceding abstract).

We investigated possible targets of the early Ca<sup>2+</sup>-signal: Calmodulin (CaM), CaM-dependent kinase II (CaMK-II) and further Ca<sup>2+</sup>-signals. Inhibition of CaM completely blocked the turning response of growth cones towards LN-coated beads suggesting CaM as a primary target of the early Ca<sup>2+</sup>-signal in filopodia. In contrast, the specific CaMK-II-inhibitor, 10μM KN-62, prevented only late, enhanced outgrowth without altering growth cone turning. A late, sustained rise in intracellular Ca<sup>2+</sup> (93±5nM, n=30) was associated with late, enhanced outgrowth as revealed by Ca<sup>2+</sup>-imaging. Importantly, this late, sustained Ca<sup>2+</sup>-signal was restricted to growth cone bodies as opposed to the early Ca<sup>2+</sup>-signal in filopodia. Inhibition of CaMK-II abolished the late, sustained Ca<sup>2+</sup>-signal and late, enhanced outgrowth.

Together with the data above this suggests the following intracellular signaling for the regulation of multiple components of growth cone behavior:

Ca<sup>2+</sup>↑(filopodia) → CaM → CaMK-II → Ca<sup>2+</sup>↑(growth cones)

## 594.6

**SIGNAL TRANSDUCTION OF RECEPTOR-LINKED PROTEIN TYROSINE PHOSPHATASES.** S.J. Fashenag\*, M. Tiemeyer\*, and K. Zinn\*. +Biology 216-76, Caltech, Pasadena, CA 91125 and \*Cell Biology Dept. C244 SHM, Yale University School of Medicine, New Haven, CT 06510.

We are interested in the signal transduction pathways through which receptor-linked protein tyrosine phosphatases (R-PTPs) transmit extracellular cues into intracellular responses. We are investigating two R-PTPs, DPTP99A and DPTP10D, that are expressed in the CNS during *Drosophila* embryo development. To elucidate the signaling pathways utilized by these R-PTPs, we are searching for their ligands and downstream signaling molecules.

To this end, we have made receptor globulins (Rgs) containing the extracellular domains (ECD) of either DPTP99A or DPTP10D linked to an IgG Fc domain. We are using these Rgs to screen a *Drosophila* embryo cDNA library for R-PTP ligands by expression cloning in Cos cells. We are now performing secondary screens on library pools that bind Rg99A, which includes the full-length ECD of DPTP99A. We hope to identify the ligands for both R-PTPs, delineate the essential recognition domains of the R-PTPs and their ligands, and elucidate the effect of ligand binding on R-PTP activity.

We are also investigating the downstream signaling pathways of these R-PTPs. Members of the Zinn lab have identified gp150, a putative substrate and downstream signaling molecule of DPTP10D (Tian and Zinn, JBC 269: 28478). Gp150 is a transmembrane glycoprotein which includes an ECD of leucine-rich repeats and a cytoplasmic domain in which 4 tyrosine residues are present within motifs that could be recognized by SH2-domains of downstream effector molecules. In vitro, DPTP10D binds specifically to gp150 and dephosphorylates phosphorylated gp150. We have recently shown that gp150 and DPTP10D, but not DPTP99A, coimmunoprecipitate in lysates from transfected fly S2 cells. Furthermore, transfected gp150 is phosphorylated on tyrosine residues in response to a variety of treatments of whole cells. Based on these results, we can now ask whether DPTP10D dephosphorylates gp150 "in vivo" in transfected S2 cells.

## 594.8

**PERTURBATION OF A GRASSHOPPER SEROTONERGIC INTERNEURON.** B.G. Condron\* and K. Zinn. Division of Biology, 216-76 Caltech, Pasadena, CA 91125. (condron@caltech.edu)

We are interested in how the CNS is patterned in the developing grasshopper embryo. To date, we have developed microinjection techniques to perturb specific cells. Using this approach, we have shown that the transcription factor engrailed and the signal transduction molecule protein kinase A are required to regulate the identity of cells produced by the median neuroblast. We are now examining the patterning of the lineage which produces a serotonergic interneuron. This interneuron makes very extensive connections throughout the neuropil and is thought to regulate many aspects of adult synaptic transmission. We aim to dissect the molecular and cellular cues that specify the identity of this neuron relative to its neighbors as well as those that regulate the neurite branch patterns in the CNS. We have found that neurite extension in the developing neuropil is inhibited by the neuron's own neurotransmitter serotonin as well as dopamine. Each transmitter affects outgrowth via different second messenger pathways. We have identified antagonists to both putative receptors. These specifically relieve the inhibition of neurite extension due to exogenously added neurotransmitter. When added alone antagonists increase the amount of neurite outgrowth substantially.

## 594.9

NEURAL RECEPTOR TYROSINE PHOSPHATASES (R-PTPs) ARE ESSENTIAL FOR MOTOR AXON GUIDANCE IN THE *DROSOPHILA* EMBRYO. Chand Desai<sup>1</sup>, Joseph Gindhar<sup>2</sup>, Lawrence S.B. Goldstein<sup>2</sup>, and Kai Zinn<sup>1\*</sup>.

1) Division of Biology 216-76, California Institute of Technology, Pasadena, CA 91125; 2) Dept. of Pharmacology, School of Medicine, University of California, San Diego, La Jolla, CA 92093.

Four R-PTPs are selectively expressed on central nervous system axons in the *Drosophila* embryo (Desai *et al.* (1994), *J. Neurosci.* **14**, 7272). We used local P-element transposition to generate mutations in the *DPTP69D* gene. Null mutations are homozygous lethal, and cause defects in the pattern of motor axon projections to body wall muscles. The SNb branch, which contains the axons of the RP neurons and projects to ventrolateral muscles, is most strongly affected. A variety of SNb phenotypes are observed, including bypass of the entire muscle field and stalling of growth cones prior to their arrival at their appropriate muscle targets. The SNa branch also displays errors in *DPTP69D* mutants. Our previous studies had shown that null mutations in another R-PTP gene, *DPTP99A*, produce no detectable phenotypes (Hamilton *et al.* (1995), *Roux's Arch. Dev. Biol.* **204**, 187). However, double mutant embryos (*DPTP69D; DPTP99A*) show a greatly increased frequency of SNb targeting errors. Similarly, the frequency of SNa branch errors also increases in double mutants. In summary, our data show that: 1) neural R-PTPs are involved in signaling events that are essential for several of the pathway choices made by SNb and SNa growth cones during outgrowth to their muscle targets; 2) the R-PTPs have partially redundant functions, so that double mutants have stronger phenotypes than single mutants.

## 594.11

IDENTIFICATION OF 12 GENES INVOLVED IN AXON GROWTH, DIRECTION, AND FASCICULATION, INCLUDING A FLY HOMOLOG OF THE HUMAN "DELETED IN COLON CANCER" GENE. Peter A. Kolodziej, Les Timpe, Sharon Fried, Lily Yeh Jan, and Yuh Nung Jan.\* Howard Hughes Medical Institute and Depts. of Physiology and Biochemistry, Univ. of California, San Francisco, Third and Parnassus Aves., San Francisco, CA 94143.

In wild-type *Drosophila* embryos, five lateral chordotonal (lch) axons in each abdominal hemisegment originate from a midlaterally positioned cluster of neurons and grow, fasciculate, and orient ventrally as they connect with targets in the central nervous system (CNS). We have identified twenty-two recessive lethal mutations in 12 complementation groups, 8 of which are novel, that differentially affect lch axon growth, fasciculation, and ventral orientation. Mutations in 3 loci result in shorter, but fasciculated and ventrally directed axon bundles. Mutations in 5 genes cause lch axon defasciculation. Mutations in 7 genes cause some lch axon bundles to grow dorsally along a trajectory 180° from normal.

One of the genes, *frazzled*, that is required for lch axon fasciculation is generally required for axon routing and fasciculation in the embryo. *frazzled* is related to the human "deleted in colon cancer" (DCC) gene. The DCC and *frazzled* proteins are part of a novel subfamily of transmembrane proteins within the immunoglobulin superfamily. DCC is expressed in the vertebrate nervous system on axons, and figures prominently in colon cancer tumor progression.

## 594.13

ZEBRAFISH MUTATIONS AFFECTING RETINOTECTAL AXON PATHFINDING. B. Karlstrom\*, T. Trowe, H. Baier, S. Klostermann, and F. Bonhoeffer. Max-Planck-Institut für Entwicklungsbiologie, 72076 Tübingen, Germany.

A fundamental issue in neurobiology is how proper neuronal connectivity is established during development. We have taken a genetic approach to this question using the zebrafish *Danio rerio*. In collaboration with the lab of Dr. Nüsslein-Volhard, we have identified mutant zebrafish that have defects in axonal connectivity between the retina and tectum. 3000 mutant families were screened by labeling retinal ganglion cells (RGCs) of 5 day fixed embryos with Dil and DiO and observing their axonal projections to and on the tectum. 154 mutants (comprising 16 complementation groups to date) were identified with defects in either the axon trajectory between eye and tectum (pathfinding mutants), or with altered trajectories on the tectum (topographic mutants).

This abstract focuses on the pathfinding mutants. The pathfinding mutants fall into four classes based on the location of pathfinding errors between eye and tectum. In class I, axons grow immediately toward the ipsilateral tectum upon leaving the eye (*belladonna*). In class II (*detour*, *you-too*, *lizard*) axons grow toward the midline before turning back to the ipsilateral tectum; in wildtype zebrafish all RGCs project to the contralateral tectum. Class III mutants (*boxer*, *dackel*) show defects in proper dorso-ventral axon sorting at the midline. Finally, class IV mutants (*bashful*, *A172*) show rostro-caudal trajectory defects at or after the midline. In *bashful*, axons grow rostrally around the telencephalon instead of turning caudo-dorsally to the tectum. In *A172*, axons either grow rostrally or turn caudally to grow under the tectum.

Taken together, these mutants support a model in which sequential guidance cues guide retinal axons to the contralateral tectum. Since the observed pathfinding errors are made at a limited number of distinct points along the retino-tectal pathway, the mutants may reveal the important choice points encountered by growth cones as they navigate between eye and tectum.

## 594.10

A SUPPRESSOR SCREEN FOR ELUCIDATING THE UNC-5/UNC-6 AXON GUIDANCE SIGNALING PATHWAY IN *C. elegans*. S. Chan, J. Culotti\*, A. Colavita, M. Hamelin, Y. Zhou, M.-W. Su, R. Steven, & I. Scott. Mt. Sinai Hospit. Res. Inst., Toronto, Canada M5G 1X5.

In *C. elegans*, 3 genes have been identified that are required to guide pioneer growth cone and cell migrations on the basal surface of the epidermis. *unc-6* encodes a laminin-related path cue molecule that guides both dorsally-oriented and ventrally-oriented migrations. Homologues of UNC-6 have now been identified in vertebrates and in fruit flies, where they carry out similar guidance functions. *unc-5* encodes a transmembrane receptor that is activated by the UNC-6 path cue molecule and responds to it by orienting the migration towards the dorsal side. The intracellular signaling mechanisms by which UNC-5 activation is able to reorient the actin-based cytoskeleton at the leading edge of migration are unknown. We have shown that ectopic expression of UNC-5 in neurons that normally grow longitudinally on the epidermis is sufficient to steer their axons dorsally. The UNC-5-induced steering requires UNC-6, since in *unc-6* mutants ectopically expressing UNC-5, these axons have a longitudinal trajectory. This suggests a genetic paradigm for identifying additional genes that encode components of the UNC-5/UNC-6 molecular pathway for guidance, including possible accessory factors to UNC-5 or UNC-6 or components of the intracellular signaling cascade stimulated by UNC-5 activation. By looking for mutations that, like *unc-6* mutations, suppress the UNC-5-induced reorientation of these axons, we have identified several candidate genes, including *unc-40*, which has major effects on ventrally-oriented and minor effects on dorsally-oriented migrations, respectively. *unc-40* encodes a transmembrane protein related to human DCC (Deleted in Colorectal Cancer) protein.

MOTONEURONAL MUTANTS IN EMBRYONIC ZEBRAFISH. C.E. Beattie\*, K.L. Stoesser and J.S. Eisen.

Institute of Neuroscience, University of Oregon, Eugene OR 97403.

Pathfinding is a complex process that is dependent upon both the neuron and its pathway expressing the right molecular components at the appropriate times. To identify the molecular mechanisms involved in pathfinding, we have undertaken a mutagenesis screen in zebrafish. Progeny of fish containing germline mutations induced by exposure to N-ethyl-N-nitrosourea were screened with antibodies that recognize motoneurons. Several mutations have been recovered that affect pathfinding by a small set of individually identified motoneurons. Here we focus on a dominant mutation which affects at least one primary motoneuron, CaP. Normally the axons of CaP and the other primary motoneurons leave the spinal cord, extend along a common pathway and then diverge along separate cell-specific pathways on the myotome. In this mutation, CaP is present in normal numbers and extends its axon along the common pathway but fails to extend an axon on its cell-specific pathway. We performed transplantation experiments to learn if this mutation is acting in the neuron or the myotome. Myotomes were removed from mutant embryos before axogenesis and replaced with wildtype myotomes. Preliminary results reveal that wildtype myotomes do not rescue mutant CaP axons, suggesting that the mutation is acting cell-autonomously. CaP pathfinding, therefore, appears to depend on cell intrinsic factors that differentially regulate axon outgrowth along distinct pathway regions.

## 595.1

CHARACTERIZATION OF NEURONAL PROGENITOR CELLS ISOLATED FROM THE NEONATAL FOREBRAIN. M.B. Lusk\*, R. Stewart, T. Zigova and B.J. Soteres. Dept. of Anatomy & Cell Biology, Emory Univ. Sch. of Med., Atlanta, GA 30322.

Recent studies have shown that the postnatal subventricular zone of several mammalian species is a source of neurons as well as glia. We have shown that in vivo the anterior portion of the neonatal subventricular zone (SVZa) generates an immense number of cells which migrate to the olfactory bulb and differentiate into interneurons (Luskin, *Neuron*, 11:173, 1993). To investigate the properties of neonatal SVZa cells we devised a procedure to isolate and culture these cells. Ham's F10 medium, DMEM, or a 1:1 mixture of Ham's F10:DMEM supplemented with 10 % fetal calf serum was used with several different substrates. The phenotype of the cultured cells was determined 1 - 10 days later using a number of cell type-specific markers including TuJ1, an antibody recognizing neuron-specific class III  $\beta$ -tubulin and an antibody against GFAP to distinguish astrocytes. We demonstrated that after 1 day in culture the SVZa cells proliferated and that virtually all cells were TuJ1(+). In addition, there were substrate specific effects on neurite outgrowth. After several days in culture the vast majority of cells were TuJ1(+), while < 5% were GFAP(+). This indicates that in vitro, as in vivo, the SVZa cells and their progeny have a neuronal identity. Thus, the SVZa appears to constitute virtually a pure population of neuronal progenitor cells. Supported by the March of Dimes, NIH and the Pew Charitable Trusts.

## 595.3

THE PRODUCTION OF NEURONS THROUGH ASYMMETRIC CELL DIVISIONS IN THE DEVELOPING FOREBRAIN. Anjen Chenn\* and Susan K. McConnell. Dept. of Biological Sciences, Stanford University, Stanford, CA 94305

We have established a system in which to observe directly the behaviors of cycling precursor cells in the mammalian central nervous system, processes which previously could be studied only indirectly. With the cellular techniques developed here, we provide evidence for the production of neurons by asymmetric division of progenitor cells. Slices through the developing cerebral wall support the normal cell movements and nuclear migrations that accompany the division of neuroepithelial progenitors. By imaging individual fluorescently-labeled progenitor cells over time, we have observed two distinct behaviors of cells following division. The first type of division is symmetric in nature, with cleavages perpendicular to the ventricular surface. These divisions are both morphologically and behaviorally symmetric: both daughter cells derived from these vertical cleavages appear to retain contact with the ventricular surface, and their subsequent movement away from the lumen is generally slow and paired. We propose that early in cortical development, these symmetric divisions are proliferative in nature and serve to maintain or expand the precursor pool. The second type of division is asymmetric, with cleavage planes parallel to ventricular surface. This type of division, observed only rarely prior to the onset of neurogenesis, becomes common as neurons are generated. Following cleavage in nearly all of these cases, the two daughters separate from one another and the basal or outer daughter moves away at rates that can be extremely rapid, approximating the rates of outward migration of young postmitotic neurons. We therefore propose that these asymmetric divisions are differentiative in nature, possibly representing a stem cell mode of division in which one daughter becomes a neuron and the other reenters the cell cycle. Supported by NIH MH51864 and GM07365.

BONE MORPHOGENETIC PROTEINS INDUCE ASTROGLIAL DIFFERENTIATION OF NEURAL STEM CELLS. RE Gross<sup>1</sup>, MF Mehler<sup>2</sup>, T Ngo<sup>1</sup>, L. Santhi<sup>1</sup> and JA Kessler<sup>2,3</sup>. Depts. of Neurosurgery<sup>1</sup>, Neurology<sup>2</sup> and Neuroscience<sup>3</sup>, Albert Einstein College of Medicine, Bronx, NY.

Bone morphogenetic proteins (BMPs) are a class of proteins within the TGF $\beta$  superfamily that were originally characterized for their osteoinductive properties. The BMPs and their relatives, including *decapentaplegic*, activin, and TGF $\beta$ 1,2 & 3, have a broad range of early morphogenetic (such as dorsal/ventral determination) and differentiative activities. We therefore evaluated the effects of BMPs on lineage commitment, survival and differentiation of neural stem cells. EGF-dependent neural stem cells were dissociated and cultured in serum-free medium in the presence of various BMPs, of which we will concentrate on BMP2 here. Immunocytochemistry with cell specific markers was used to define the effects on development of mature cells from stem cells. BMP2 led to a marked proliferation of GFAP+ astrocytes from stem cells. The effect was dose-dependent; all BMPs tested had similar effects, but had different dose-response curves, whereas TGF $\beta$  had no effect. Astrocytes generated in the presence of BMP2 were morphologically more highly differentiated than in its absence, and produced more GFAP/cell, based on Western blots. Dual immunofluorescence indicated that both type I (GFAP+, A2B5-) and type II (GFAP+, A2B5+) astrocytes accumulated in the presence of BMP2, whereas only type I astrocytes were present in its absence. Under conditions that lead to increased numbers of oligodendrocytes, BMP2 preferentially produced type II astrocytes over oligodendrocytes (O4+, A2B5+), presumably derived from O2A progenitors. BMP2 had similar effects on astrocytes generated from embryonic cortical cells. We conclude that BMPs are growth factors for both type I and type II astrocytes.

## 595.2

THE EFFECT OF BULBECTOMY ON NEUROGENESIS IN THE NEONATAL FOREBRAIN. R. Betarbet\*<sup>1,2</sup>, T. Zigova<sup>1</sup>, R.A.E. Bakay<sup>2</sup> and M.B. Lusk<sup>1</sup>. <sup>1</sup>Depts. of Anatomy and Cell Biol. & <sup>2</sup>Neurosurgery, Emory University School of Medicine, Atlanta, GA 30322.

In the rat, the anterior part of the subventricular zone (SVZa) is known to generate an immense number of neurons during the first week of postnatal life which are destined to become the interneurons of the olfactory bulb (*Neuron*, 11:173,1993). In this experiment we wanted to study the effect of neonatal bulbectomy on SVZa neurogenesis. Unilateral bulbectomy was performed on hypothermically anesthetized Sprague Dawley rats at postnatal day 0 (P0) or P1. One to five days after bulb ablation the pups received two intraperitoneal injections of the cell proliferation marker, BrdU (5 mg/ml; 0.3 ml/pup), which were given 6 hours apart. The pups were perfused at various times, their brains were sectioned on a cryostat in the horizontal or sagittal plane and processed for immunohistochemistry to reveal BrdU-positive cells. We compared the density and the distribution of the BrdU-positive cells on the experimental side to the control side of the forebrain. Unilateral bulbectomy resulted in an increase in the size of the subventricular zone, including the SVZa, on the experimental side. In addition, there was at least a two-fold increase in the density of BrdU-labeled cells. The increased size of the SVZa, in conjunction with the increased density of BrdU-labeled cells, indicates that the ablation leads to an increase in cell proliferation. Collectively, the results demonstrate that the proliferation of SVZa cells can be experimentally manipulated. Supported by Pew Charitable Trusts, NIH and March of Dimes.

## 595.4

THE ROLE OF NEUREGULINS IN OLFACTORY NEUROGENESIS. N. Mahanthappa\* and G. A. Schwarting. Cambridge Neuro-Science Inc., Cambridge, MA 02139; and E. K. Shriver Center, Waltham, MA 02254.

The neuregulins are peptide growth factors of the EGF superfamily (reviewed by Peles and Yarden, *BioEssays* 15: 815 [1993]). They are differential splice products of a single gene and were independently cloned as neu differentiation factor, heregulin, glial growth factor, and acetylcholine receptor inducing activity. Neuregulins are known to signal via receptor tyrosine kinases of the EGF receptor family including erbB2 (c-neu), erbB3, and erbB4. Heparan sulfate proteoglycans are likely to play roles as co-receptors (Sudhalter, *et al.* Soc. Neurosci. Abs. 20: 1691 [1994]).

By *in situ* hybridization, Meyer and Birchmeier (PNAS 91: 1064 [1994]) have demonstrated that neuregulin message is highly expressed in the neuronal layer of embryonic murine olfactory epithelium (OE). In OE cultures, we have demonstrated immunocytochemically that neuregulins are expressed by olfactory receptor neurons (ORNs). In addition, erbB3 and erbB4 are expressed both by neurons and a subset of OE basal cells. These patterns of expression suggest that neuregulins may play a role in mediating ORN survival and regulating basal cell behavior. In ongoing studies, we are determining the expression of these proteins *in vivo*, and analyzing neuregulin actions on OE cells in culture.

DYNAMICS OF MASH1 EXPRESSION IN MOUSE OLFACTORY EPITHELIUM SUGGESTS A NON-STEM CELL SITE OF MASH1 ACTION. A.L. Calof\*, J.S. Mumm, R.A. Davis, J.D. Holcomb, and M.K. Gordon. Dept. of Anatomy & Neurobiology, Univ. California Col. Med., Irvine, CA 92717.

Olfactory receptor neurons (ORNs) of the mouse olfactory epithelium (OE) are produced by the terminal division of a cell called the INP (for Immediate Neuronal Precursor or ORNs). Studies indicate that INPs behave like neuronal transit amplifying cells, undergoing a limited number of amplification divisions regulated by FGFs while remaining committed to a neuronal fate (e.g. DeHamer *et al.*, 1994, *Neuron* 13:1083). The cell that precedes the INP in the ORN lineage is unknown: this cell could be the stem cell thought to underlie the OE's capacity for continual neuron renewal, or it could be an earlier, distinct stage of amplifying precursor cell. Deletion by homologous recombination of the gene encoding the transcription factor MASH1 results in a profound loss of ORNs, indicating a crucial role for MASH1 action in ORN neurogenesis (Guillemot *et al.*, 1993, *Cell* 75:463). To determine whether MASH1 is acting in cells of the ORN lineage, and at what stage, we investigated expression of MASH1 during OE neurogenesis, both in vitro during embryonic development, and in vivo during neurogenesis induced by ablation of one olfactory bulb (OBX) in adult mice. MASH1+ cells are present in embryonic OE and form a small subset of proliferating ORN precursors in OE explant cultures. Both INPs and MASH1+ cells divide rapidly and then disappear from OE cultures as neurogenesis proceeds, but disappearance of MASH1+ cells precedes that of INPs, suggesting that MASH1+ cells give rise to INPs. Following OBX, MASH1+ cells undergo a transient increase in number in OE on the OBX side, suggesting that MASH1+ cells are not stem cells, since stem cells typically generate one copy of themselves and one other cell with each division. <sup>3</sup>H-TdR incorporation studies in OBX mice indicate that the peak of MASH1+ cell proliferation precedes that of INPs, suggesting that MASH1+ cells precede INPs in the ORN lineage in adult OE in vivo, as well as embryonic OE in vitro. Thus, MASH1+ cells appear to be progenitors of INPs, and like them, function as neuronal transit amplifying cells in the ORN lineage. Supported by NIH grant DC02180 to ALC.

SPINAL CORD SUBPENDYMAL PROGENITOR CELLS DIFFERENTIATE TO ASTROCYTES AND CONTRIBUTE TO SCAR FORMATION AFTER INJURY. Clas B. Johansson<sup>1,2</sup>, Urban Lendahl<sup>3</sup> and Jonas Frisén<sup>1</sup>, Dept. of Neuroscience<sup>1</sup>, Dept. of Prosthetic Dentistry<sup>2</sup> and Dept. of Cell and Molecular Biology<sup>3</sup>, Karolinska institute, S-171 77 Stockholm, Sweden.

After injuries in the central nervous system astrocytes form a dense scar which may impede axonal regeneration. Reactive astrocytes synthesize high levels of the intermediate filament GFAP. We have studied the expression of nestin, an intermediate filament protein which is highly expressed by progenitor cells for neurons and glial cells, after dorsal funiculus incision in adult rats. Nestin induction was seen within 2 days after injury in subependymal cells close to the central canal, while nestin expressing cells at later time points were found progressively further out from the central canal. From one week on nestin-immunoreactive cells were abundant in the scar tissue which formed at the injury. The nestin expressing cells in the scar tissue coexpressed GFAP. In nestin promoter/lacZ transgenic mice, lacZ expression mimicked the nestin expression pattern. These data suggested that there may exist a population of subependymal progenitor cells close to the central canal which migrate and differentiate to astrocytes in response to injury. In order to test this cells lining the central canal were selectively labeled by injecting the fluorescent tracer Dil in the fourth ventricle in adult rats. Six days after the injection, cells lining the central canal at least 50 mm caudal to the fourth ventricle were Dil-labeled. Two days after an incision in the dorsal funiculus Dil-labeled cells could be seen dorsal to the central canal, and at later time points fluorescent cells were scattered in the scar tissue which had formed at the lesion. The Dil-labeled cells in the scar tissue showed GFAP- and nestin-immunoreactivity.

These data suggest the existence of undifferentiated progenitor cells in the subependymal zone lining the central canal which may differentiate to astrocytes and contribute to scar formation in the injured spinal cord.

## 595.9

STUDY OF EARLY REGIONALISATION OF THE VENTRICULAR ZONE AND ITS ROLE IN THE PRODUCTION OF DISTINCT NEOCORTICAL AREAS.

E. Poileux<sup>\*</sup>, C. Dehay and H. Kennedy, INSERM Unité 371-18 Av Doyen Lépine 69675 BRON (FRANCE).

Recently Dehay et al. [Nature 366: 464] showed that in primate the difference in the number of neurons per unit of surface area in area 17 and 18 is due to differences in rates of proliferation in the prospective ventricular zones. Can this principle be generalised to other cortical areas and to other species? We have taken advantage of the fact that in mouse the frontal agranular cortex contains about 27% less neurons than the adjacent parietal granular field and that this difference can be largely attributed to the absence of layer IV in the frontal cortex [Beaulieu, Brain Research 609: 284]. We determined the percentage of neurons heavily labelled (LI labelling index) by 11 single pulsed injections of [<sup>3</sup>H] thymidine made at regular intervals throughout neurogenesis of the mouse (E11.0 to E18.5 with E1 as day of vaginal plug). This estimation has been made in adult frontal agranular area 6, frontoparietal (intermediately granular) area 4 and parietal granular area 3 as defined by Caviness. When estimated within a single layer the LI is independent of regressive events such as naturally occurring cell death and is thought to reflect neuronal production in the ventricular zone that give rise to these cortical areas. We found that the rate and tempo of neurogenesis is characteristic for each area. Rate of production of infragranular layers of area 3 was higher than those for area 4 and 6. The switch to the production of layer IV occurs earlier in granular areas than it does in agranular ones but the rate of production of neurons destined to reside in layer IV is lower in agranular area 6 than it is in areas 4 and 3. The duration and rate of production of supragranular layers are the same in all three areas examined. Using Dil we were able to show that thalamic afferents arrive after the areal differences in neurogenesis are established.

In conclusion, we show that in mouse, the generation of cortical areas is ensured by differences in the rate of neuron production, implying an important degree of heterogeneity of the ventricular zone which is independent of thalamic innervation.

## 595.11

A retinoic acid driven switch-like mechanism is involved in the choice between neural and mesodermal fates. D. Gottlieb, G. Bain, M. Yao Dept. of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO 63110

Recently we showed that genetically normal, totipotent mouse embryonic stem (ES) cells can be efficiently induced to differentiate into neuron-like cells (NLCs) in culture (Bain et al., Developmental Biology 168:342-357, 1995). Here we show that the pathway from ES cells to NLCs has two distinct steps. Efficient neural differentiation is obtained by culturing undifferentiated ES cells as aggregates for four days in standard medium (4-) and for an additional four days in medium with retinoic acid (4+). Treatment of undifferentiated ES cells with RA for four days does not induce overt neural differentiation or the expression of MASH-1 or wnt-1, 2 early neural genes. In contrast, treatment of ES cells after 4- culture induces overt neural differentiation and expression of both genes. The transition to competence is blocked if LIF is present during 4- culture. After six days in culture in standard medium, aggregates contain cells undergoing mesodermal differentiation as evidenced by expression of the brachyury, cardiac actin and  $\xi$ -globin genes. Addition of RA to 4-aggregates completely suppresses expression of these genes. In summary, ES cells cultured as aggregates in the absence of added regulatory factors make a transition to a cell type that is responsive to RA. This cell type expresses an RA-sensitive genetic pathway which simultaneously up-regulates neural gene expression and down-regulates mesodermal gene expression. Supported by NSF (IBN-08787) and NIH (NS12867).

## 595.8

DISTINCT ROLES FOR bFGF AND NT3 IN THE CONTROL OF CORTICAL NEUROGENESIS. A. Ghosh<sup>\*</sup> and M. E. Greenberg, Div. of Neuroscience, Childrens Hospital and Dept. of Neurobiology, Harvard Medical School, Boston, MA 02115

While it is generally accepted that extracellular signals can influence the development of various neural populations, the molecules that regulate the transition of dividing neuroblasts to terminally differentiated neurons have not been fully defined. Based on the effects of exogenous growth factors and neutralizing antibodies, we show here that bFGF and NT3 have striking and distinct effects on the development of cortical neurons. The proliferation of both neuronal and glial precursor cells in vitro is controlled by bFGF. The proliferative effects of bFGF do not preclude the action of endogenous differentiation promoting factors as differentiated neurons and glia are generated in these cultures in appropriate developmental sequence. Since NT3 is expressed in the cortex during embryonic development, the role of NT3 in regulating neurogenesis in these cultures was examined by direct addition to cultures or by inhibiting endogenous NT3 action using neutralizing antibodies. Whereas addition of NT3 antagonized the proliferative effects of bFGF and enhanced neuronal differentiation, blocking NT3 function led to a marked decrease in the number of differentiated neurons without affecting the proliferation of cortical precursors or the survival of postmitotic cortical neurons. These observations suggest that bFGF and NT3, by their distinct effects on cell proliferation and differentiation, are key regulators of neurogenesis in the central nervous system.

MOLECULAR GENETICS OF A DEVELOPMENTAL DISORDER OF THE CEREBRAL CORTEX ASSOCIATED WITH EPILEPSY. Y. Z. Eksicoglu<sup>1</sup>, P. Cardenas<sup>1</sup>, K. Kamuro<sup>2</sup>, F. J. DiMario<sup>3</sup>, P. R. Huttenlocher<sup>4</sup>, G. M. Duyk<sup>5</sup> and C. A. Walsh<sup>\*1</sup>, <sup>1</sup>Lab. of Neurogenetics, Dept. of Neurology, Beth Israel Hospital/Harvard Medical School, Boston, MA 02115, <sup>2</sup>Dept. of Pediatrics, Kokubu Seikyo Hospital, Kagoshima 899-48, Japan, <sup>3</sup>Dept. of Pediatrics, Univ. of Connecticut, Farmington, CT 06030, <sup>4</sup>Dept. of Pediatrics, University of Chicago, Chicago, IL 60615, <sup>5</sup>Millenium Pharmaceuticals, Cambridge, MA 02139

Widespread use of magnetic resonance imaging in humans has revealed genetic transmission of some developmental malformations of the human cerebral cortex. Periventricular heterotopias (PH) are non cancerous nodules of neural cells in the ventricular zone beneath the cerebral cortex. Recently, a distinctive, inherited form of PH was identified that is associated with seizures, but normal intelligence and no other peripheral stigmata. Therefore, the PH gene plays a role in cerebral cortical development, as well as representing a novel epilepsy susceptibility gene.

In three multiplex pedigrees, PH was restricted exclusively to females. Males were normal and there was an excess of miscarriages suggesting that PH may be lethal to males. We tested linkage of PH to markers on the p and q arms of the X chromosome. Genetic analysis of the families revealed positive linkage to markers in distal Xq, with a maximal two-point LOD score of 3.44 for F8C ( $\Theta=0$ ), and a maximal multipoint LOD score of >3.7, suggesting X-linked, dominant inheritance with embryonic lethality in affected males. Thus, affected females are likely to be mosaics, since random inactivation of one X chromosome occurs early in cortical neurogenesis, and is inherited in clonal fashion.

ASCORBATE IN NEURONS AND GSH IN GLIA: EVIDENCE FROM DEVELOPING CORTEX, HIPPOCAMPUS, AND CEREBELLUM. M. E. Rice<sup>\*</sup> and I. Russo-Menna, Depts. of Physiology & Neuroscience and Neurosurgery, N.Y.U. Medical Center, New York, NY 10016.

Ascorbic acid (ascorbate) and glutathione (GSH) are the most abundant low molecular weight antioxidants in the CNS, yet little is known about their cellular localization. We have proposed that ascorbate predominates in neurons and others have suggested that GSH predominates in glia. Because ascorbate and GSH are readily washed out of mammalian tissue *in vitro*, cell-specific contents have proved difficult to confirm. We addressed this question by monitoring ascorbate and GSH levels (by HPLC) during postnatal development of rat brain, when regionally distinct changes in neuron:glial ratio occur. In cortex and hippocampus, the ascorbate content and ascorbate:GSH ratio were highest shortly after birth when neuron:glial ratio was also highest. Over the next three weeks, as gliogenesis progressed, GSH rose steadily while ascorbate fell, resulting in a linear decrease in ascorbate:GSH ratio. At P3 in cortex, for example, ascorbate levels were 5  $\mu\text{mol g}^{-1}$ , with an ascorbate:GSH ratio of 4. By P23, GSH had risen to adult levels (2  $\mu\text{mol g}^{-1}$ ), while ascorbate fell to 3.5  $\mu\text{mol g}^{-1}$ , giving an ascorbate:GSH ratio less than 2. In cerebellum, by contrast, ascorbate and GSH levels were constant from P3-P9, with lower ascorbate and higher GSH than cortex or hippocampus. From P9, coincident with the birth of granule cells, ascorbate levels increased, rising to 7  $\mu\text{mol g}^{-1}$  by P17, then falling again toward adult levels (3  $\mu\text{mol g}^{-1}$ ). Taken together, these data are consistent with preferential localization of ascorbate in neurons and GSH in glia. High levels of ascorbate in neurons (5-9 mM estimated from tissue contents and cell volume fractions) suggest that this antioxidant may provide specialized neuroprotection in developing and in adult brain.

**COMMISSURAL PROJECTIONS OF THE RAT PREFRONTAL CORTEX: SYNAPTIC ASSOCIATIONS WITH INTRINSIC NEURONS AND DOPAMINE AFFERENTS.** D.B. Carr\* and S.R. Sesack. Departments of Neuroscience and Psychiatry, University of Pittsburgh, PA 15260.

Commissural connections play an important role in the integration of complex behaviors governed by the prefrontal cortex (PFC). We sought to examine the synaptic targets of commissural terminals within the rat PFC, as well as their relation to other PFC afferents. Commissural terminals, labeled by either anterograde transport of *Phaseolus vulgaris* leucoagglutinin or anterograde degeneration following electrolytic lesion of the contralateral PFC, formed primarily asymmetric synaptic junctions on dendritic spines. Some of these spines received a second input from unlabeled terminals forming symmetric synapses. Commissural terminals were less frequently observed to form asymmetric axodendritic synapses. However, several dendrites that received such input exhibited a morphology consistent with GABAergic interneurons. These findings suggest that commissural PFC afferents utilize an excitatory neurotransmitter and the majority target spiny pyramidal neurons. A small subset of commissural projections may provide excitatory input to interneurons. Since both dopamine and GABA terminals have been reported to form symmetric synapses on dendritic spines of pyramidal cells, double-labeling studies are in progress to determine whether commissural PFC afferents converge with dopamine and/or GABA terminals onto common spines. Such a finding would suggest a role for these transmitters in modulating excitatory commissural afferents. This work is supported by USPHS grant MH50314

**IN VIVO MAPPING OF DOPAMINE-(DA)- D4 RECEPTORS IN PRIMATE BRAIN.** C. Boy<sup>3</sup>, A. Klimke<sup>4</sup>, M. Holschbach<sup>2</sup>, H. Herzog<sup>1</sup>, E. Rota-Kops<sup>1</sup>, G. Wunderlich<sup>1</sup>, P. Seeman<sup>5</sup>, H. Van Tol<sup>6</sup>, R. Markstein<sup>1</sup>, W. Gaebele<sup>1</sup>, G. Stöcklin<sup>2</sup>, H.W. Müller-Gärtner<sup>1,3</sup>, <sup>1</sup>Inst. Med., <sup>2</sup>Inst. Nucl. Chem., Res. Center Jülich, 52407 Jülich; <sup>3</sup>Dept. Nucl. Med., <sup>4</sup>Dept. Psychiatry, 40225 Düsseldorf, Germany; <sup>5</sup>Sandoz Pharm., Preclin. Res., 4002 Basel, Switzerland; <sup>6</sup>Depts. Pharm. & Psychiatry, Toronto, M5S 1A8, Canada

A significant increase of DA-D4 receptors has been reported in postmortem striatal tissue of patients with schizophrenia. This study describes the first attempt to quantify D4-like binding sites in the normal primate brain *in vivo*. Dynamic positron emission tomography (PET)-scans were performed in baboons (n=3) using [<sup>11</sup>C] SDZ GLC 756 (GLC; K<sub>d</sub>-values at human DA receptors *in vitro*: 1.1 nM at D1; 0.4 nM at D2; 25 nM at D3; 0.3 nM at D4.2). In PET the striatum/cerebellum-ratio (SCR) and the neocortical gray matter/cerebellum-ratio (NCR), measured 20 minutes after the injection of GLC, were used as indicators of specific DA receptor binding. The SCR and NCR were 3.4±0.4 (mean±SD) and 1.6±0.3, respectively, and increased linearly as a function of time. Blockage of D1 and D5 receptors by SCH 23390 (SCH; 0.5 mg/kg) reduced SCR and NCR by up to 40%. Following the blockage of D1, D5, D2 and D3 receptors by SCH + raclopride (RAC; 2.0 mg/kg), SCR and NCR were 1.7±0.5 and 1.5±0.3, respectively. Again, the ratios increased as function of time. Finally, blocking all known DA receptor subtypes by SCH + RAC + spiperone (1.0 mg/kg) further reduced striatal binding to an unspecific level. The data suggest a low homogeneous concentration of D4-like binding sites in striatum and neocortex. In conclusion, this differential DA receptor mapping approach indicates that D4-like binding sites, as measured *in vivo* by PET, are present at similar concentrations in striatum and neocortex of healthy primates. This new approach should therefore be useful to test the hypothesis of an increased D4 receptor density in striatum of schizophrenic patients *in vivo*.

## 596.5

**AMISULPRIDE, AN ATYPICAL ANTIPSYCHOTIC, PREFERENTIALLY BLOCKS DOPAMINE D<sub>2</sub>/D<sub>3</sub> AUTORECEPTORS.** H. Schoemaker<sup>1</sup>, Y. Claustre, A. Oblin, L. Rouquier, R. Depoortere, D. Fage, G. Perrault, C. Carter, J. Benavides and B. Scatton. Synthelabo Recherche, 31, av. P.V. Couturier, 92220 Bagneux, France

Amisulpride, a new benzamide derivative with high affinity for both dopamine (DA) D<sub>2</sub> (K<sub>d</sub> = 2.6 nM) and D<sub>3</sub> receptors (K<sub>d</sub> = 3.6 nM) and a degree of limbic selectivity, shows a unique therapeutic profile against both negative, at low doses, and positive, at high doses, symptoms of schizophrenia. We sought to further define its interaction with pre- and postsynaptic dopamine receptors.

*In vitro*, amisulpride opposes the inhibitory effects of the D<sub>2</sub>/D<sub>3</sub> agonist 7-OH-DPAT on electrically stimulated [<sup>3</sup>H]DA and [<sup>14</sup>C]acetylcholine release from rat striatal slices at similar concentrations.

However, *in vivo* and at low doses (<10 mg/kg ip) amisulpride preferentially blocks DA autoreceptors as shown by its antagonism of the inhibitory effect of 7-OH-DPAT on DA synthesis in the presence of γ-OH-butyric acid, the increase in extracellular DA levels as measured by microdialysis, and the inhibition of the hypomotility induced by low doses of apomorphine or 7-OH-DPAT. Only at higher doses (40-80 mg/kg) postsynaptic DA receptor occupancy and antagonism is apparent, as shown by a decrease in striatal acetylcholine levels and the inhibition of striatal [<sup>3</sup>H]raclopride binding and apomorphine-induced hypermotility and stereotypies. In contrast, haloperidol is approximately equipotent in all of these paradigms.

The present data suggest that amisulpride is a specific DA antagonist with a preferential effect at low doses on D<sub>2</sub>/D<sub>3</sub> autoreceptors *in vivo* and that the mechanisms governing *in vitro* and *in vivo* DA release may not be identical. These studies further demonstrate that an atypical preclinical antipsychotic profile can be obtained through selective DA (auto)receptor blockade.

## 596.2

**THE ROLE OF DOPAMINE (DA), GLUTAMATE RECEPTORS, AND OXIDATIVE STRESS IN INFLUENCING THE LONG-TERM EFFECTS OF REPEATED COCAINE ON THE DYNAMICS OF DA METABOLISM IN RAT CORTEX.** F. Karoum\*, J.M. Masserano and R.J. Wyatt. Neuropsychiatry Branch, NIMH Neuroscience center at St. Elizabeths, Washington, DC 20032

Repeated administration of cocaine selectively down-regulates the rate of formation of 3,4-dihydroxyphenylacetic acid (DOPAC, DOPAC T/O) in the rat frontal and cingulate cortices but not in the entorhinal cortex, the nucleus accumbens or the striatum, one week after cocaine discontinuation. To better understand how these changes occur, we have carried out several pharmacological manipulations. Cocaine was administered for one week, twice daily (10 mg/kg I.P.) alone and 30 minutes after pre-treatment with one of the following: vitamin E (15 mg/kg), haloperidol (HAL) (0.5 mg/kg); clozapine (CLZ) (20 mg/kg); or MK801 (0.3 mg/kg). Rats were sacrificed one week after termination of treatment. DOPAC T/O was assessed from the exponential decline in DOPAC concentrations 0, 20 and 40 minutes after the administration of pargyline (100 mg/kg).

Pretreatment with HAL or CLZ completely abolished the reduction in DOPAC T/O in frontal and cingulate cortex produced by cocaine. Vitamin E also protected the cingulate cortex from the long-term effects of cocaine. MK801 had no protective effect on either the frontal or cingulate cortex.

These results suggest that DA receptor activation and oxidative mechanisms may be involved in the reduction of cortical DA metabolism during repeated exposure to cocaine. NMDA receptors do not appear to be involved.

## 596.4

**QUANTIFICATION OF STRIATAL DOPAMINE RELEASE BY AMPHETAMINE IN LIVING HUMAN BRAIN** DF Wong\*, F Yokoi, C Hong, G Grunder, A Imperial, H Ravert, R Dannals, V Cunningham\*, A Gjedde\*. Johns Hopkins Medical Inst., Baltimore, MD; \*Hammersmith, London; Aarhus Univ Hosp, Denmark

Neuroleptics and dopamine (DA) transporter antagonists increase DA in the synaptic space. The increase affects the quantification of DA receptors using labeled neuroleptics. This hypothesis was tested with amphetamine (AMP) in five normal volunteers undergoing measurements of D<sub>2</sub>-like DA receptor density.

To measure the density of D<sub>2</sub>-like DA receptors, high (1.7 μCi pmol<sup>-1</sup>) and low (0.019 μCi pmol<sup>-1</sup>) specific activity (SA) [<sup>11</sup>C]raclopride (rac) were injected i.v. on two days each before and after the i.v. administration of 0.3 mg kg<sup>-1</sup> AMP, respectively. PET images of the labeled tracer in putamen (PU) and cerebellum (CB) were obtained over 90 min. Steady-state partition volumes (V<sub>s</sub>) of [<sup>11</sup>C]rac in CB were determined by spectral analysis (Cunningham 1993). The initial unidirectional clearances of rac into PU were used with the distribution volumes to determine free and receptor-bound contents of the tracer in PU (Blomquist et al). B<sub>max</sub> and K<sub>d</sub>/V<sub>d</sub> were determined from bound tracer content (M<sub>b</sub>) and binding potential (M<sub>b</sub>/M<sub>f</sub>) at equilibrium, where V<sub>d</sub> is volume of distribution, M<sub>f</sub> is free tracer content and K<sub>d</sub> is dissociation constant.

The partition volume was unaffected by the SA but declined significantly after injection of AMP. The rac B<sub>max</sub> declined significantly after AMP administration (34 ± 5 vs. 21 ± 2 pmol cm<sup>-3</sup>, p<.05, 1-tailed t). The K<sub>d</sub>/V<sub>d</sub> was 8.5 ± 1.4 and 6.8 ± 0.7 pmol cm<sup>-3</sup>, resp (NS). When the results were interpreted as a reflection of receptor blockade by DA induced by the IV AMP, the bound quantity of DA averaged 9 pmol cm<sup>-3</sup> at high SA and 10 pmol cm<sup>-3</sup> at low SA. Low SA rac alone reduced the bound quantity of DA (6 pmol cm<sup>-3</sup>), suggesting a brief blockade of the receptors by unlabeled rac, the latter significant (p=0.031; 1-tailed paired t-test). The results support the hypothesis that AMP releases DA that blocks D<sub>2</sub>-like DA receptors and lowers B<sub>max</sub> estimates. Supported by MH42821, NARSAD, HD24061, DA09482.

## 596.6

**DOPAMINE (D<sub>2</sub>) RECEPTOR ACTIVATION BLOCKS SENSORY EVOKED EXCITATION OF RAT MITRAL CELLS IN VITRO.** L.A. Zimmer\*, S. Phillips, M. Ennis, & M.T. Shipley. Dept. Anat., Univ. Maryland, Baltimore, MD 21201

A large population of juxtaglomerular interneurons in the rat main olfactory bulb (MOB) contain dopamine (DA). DA-D<sub>2</sub> receptors are localized in the glomerular (GL) and olfactory nerve (ONL) layers of MOB. Destruction of the olfactory epithelium eliminates D<sub>2</sub> receptors in both the ONL and the GL, suggesting that D<sub>2</sub> receptors are present on olfactory nerve terminals. Consistent with this, olfactory receptor neurons contain abundant D<sub>2</sub> receptor mRNA transcripts. Together, these findings suggest that DA, released from juxtaglomerular neurons presynaptically regulates ON terminals. Mitral cells of the OB receive direct excitatory input from ON terminals. Glutamate released from ON terminals excites mitral cells via non-NMDA and NMDA receptors in the rat (Ennis, et al., this meeting). Activation of non-NMDA (AMPA/kainate) receptors evokes rapid, brief (10-40 msec) excitation of mitral cells; NMDA receptors mediate a delayed, long-lasting (100-500 msec) excitatory response. The goal of this study was to determine if glutamate transmission at ON->MC synapses is modulated by activation of D<sub>2</sub> receptors on ON terminals.

Olfactory bulbs were rapidly removed from anesthetized rats (50-125 g), 500 μm-thick horizontal slices were submerged in a recording chamber perfused with oxygenated Krebs' solution. Single (0.4 Hz), low intensity (4-40 μA) shocks were applied to the ONL while recording action potentials from mitral cells. ONL shocks evoked the short latency non-NMDA response, and the delayed, long lasting NMDA response. Bath application of DA (100 μM) decreased the response magnitude of both non-NMDA and NMDA responses by 70%. Bath application of the selective D<sub>2</sub> agonist, quinpirole (100 μM) also decreased the magnitude of both responses by a comparable amount. ONL-evoked excitation of mitral cells recovered 5-15 min after termination of DA or quinpirole. Bath application of the D<sub>2</sub> antagonist, eticlopride (200 μM) prevented DA-induced inhibition of mitral cell responses to ONL shocks. These results indicate that activation of D<sub>2</sub> receptors on ON terminals presynaptically inhibits glutamate release onto mitral cells. We conclude that DA release from juxtaglomerular neurons inhibits ON->MC transmission through activation of presynaptic D<sub>2</sub> receptors. Support: NIH DC00347, DC02588 and NS29635.

REGULATION OF [<sup>3</sup>H]DOPAMINE ([<sup>3</sup>H]DA) RELEASE FROM MESOLIMBIC AND MESOCORTICAL AREAS OF GUINEA PIG BRAIN BY SIGMA ( $\sigma$ ) RECEPTORS. J.K. Weatherspoon\*, Grace M. Gonzalez-Alvarez and L.L. Werling. Dept. of Pharmacology, The George Washington University Medical Center, Washington, DC 20037.

Sigma receptors are present in nucleus accumbens (NAC) and prefrontal cortex (PFC). We have previously shown that  $\sigma$  receptors regulate NMDA-stimulated [<sup>3</sup>H]DA release in caudate putamen (Gonzalez-Alvarez and Werling, J. Pharm. Exp. Ther. 271:212-219, 1994). We sought to determine whether  $\sigma$  receptors might similarly regulate [<sup>3</sup>H]DA release in NAC and PFC. Using a superfusion system, we tested the  $\sigma$  agonists (+)pentazocine ((+pent) (1nM-10 $\mu$ M) and BD737 (1 nM -1  $\mu$ M) alone and in the presence of the  $\sigma_1/\sigma_2$  antagonist BD1008 (10 nM) or the  $\sigma_1$ -selective antagonist Dup734 (100 nM). In both areas, inhibition of [<sup>3</sup>H]DA release was produced at nM concentrations consistent with a  $\sigma$  receptor-mediated process. BD1008 significantly reversed the inhibition in NAC mediated by 1  $\mu$ M (+)Pent and 100 nM BD737. Most of the inhibition produced by 1  $\mu$ M (+)Pent (40% of control-stimulated release) and all the inhibition produced by 100 nM BD737 (30% of control-stimulated release) was reversible by Dup734. Thus, in NAC, regulation of [<sup>3</sup>H]DA release by (+)pent was predominantly through the  $\sigma_1$  receptor. In PFC, both Dup734 and BD1008 significantly reversed the inhibition mediated by 100 nM BD737. However, the lesser ability of Dup734 to reverse (+)pent-mediated inhibition indicates a potential  $\sigma_2$  receptor-mediated component of inhibition in PFC. Furthermore, in control experiments, we determined that this inhibition of release in NAC and PFC was not likely to be mediated via opioid receptors or the PCP receptor. Supported by NARSAD.

PARAQUAT-INDUCED ACTIVATION OF CENTRAL CATECHOLAMINE SYSTEMS. B.K. Edmonds\* and G.L. Edwards. Dept. of Physiol. & Pharm., College of Vet. Med., Univ. of Georgia, Athens, GA 30602.

Paraquat (PQ) is a toxin capable of activating neuronal and neuroendocrine systems including the hypothalamic-pituitary-adrenal (HPA) axis. The neural substrates for PQ-induced activation of the HPA axis may involve central catecholamine systems. Activation of central catecholamine systems by PQ was investigated in this study. Sprague-Dawley rats received injections (s.c.) of either PQ (25  $\mu$ mol/kg) at a dose shown previously to activate the HPA axis or saline (1 ml/kg). Two hours following treatment the animals were decapitated, the brains removed, and tissue punches made through discrete brain regions, including the AV3V, the paraventricular nuclei (PVN), the ventral medial hypothalamus (VMH), and the cortex. Tissue catecholamine levels were measured using HPLC. Norepinephrine levels were significantly lower in the region of the PVN in PQ-treated as compared to saline-treated animals; however, no difference was seen in the AV3V, the VMH and the cortex. Determination of neuronal activation using proto-oncogene *c-Fos* immunoreactivity (FLI) revealed increased FLI in the PVN, VMH, and AV3V of animals treated with PQ as compared to saline. Collectively, these results suggest that PQ activates central catecholamine pathways resulting in an increased release of neurotransmitter at terminal regions in the hypothalamus. This increase in catecholamine activity may be involved in PQ-induced activation the HPA axis. (Supported by UGA Physiol. & Pharm.)

MUSCARINE AND CAFFEINE USE DIFFERENT INTERNAL  $\text{Ca}^{2+}$  POOLS TO EVOKE EXOCYTOSIS IN RAT CHROMAFFIN CELLS.

X. Guo\*, DA. Przywara, TD. Wakade, and AR. Wakade. Dept. of Pharmacology, Wayne State University, Detroit, MI 48201.

The effects of muscarine (Mus) and caffeine (Caf) on [ $\text{Ca}^{2+}$ ], and exocytosis were studied in cultured rat chromaffin cells. Two protocols were used to identify the contribution of internal and external  $\text{Ca}^{2+}$ . First, in a  $\text{Ca}^{2+}$  containing medium, the environment surrounding single cells was controlled by ejecting agonist with or without  $\text{Ca}^{2+}$  from an ejection pipette. Second, intracellular stores of  $\text{Ca}^{2+}$  were depleted by soaking cells in  $\text{Ca}^{2+}$ -free plus EGTA solution before transient exposure to agonist plus  $\text{Ca}^{2+}$ . Exocytosis from individual cells was measured electrochemically using a carbon fiber electrode, and [ $\text{Ca}^{2+}$ ], measured using indo-1. Caf (10 mM) and Mus (30  $\mu$ M) evoked exocytosis whether or not  $\text{Ca}^{2+}$  was included in the pipette, but neither produced elevated [ $\text{Ca}^{2+}$ ], or exocytosis in cells depleted of internal  $\text{Ca}^{2+}$ . Both elevated [ $\text{Ca}^{2+}$ ], and exocytosis exhibited long latency to onset after stimulation by Caf (2.9  $\pm$  0.38 sec) or Mus (2.2  $\pm$  0.25 sec). However, the duration of Caf-evoked exocytosis was significantly different from that evoked by Mus (7.1  $\pm$  0.8 and 33.1  $\pm$  3.5 sec, respectively, 5 sec application). Even after changing Caf application between 0.5 and 30 sec, duration of exocytosis was unaffected (7.6  $\pm$  1.1 and 7.3  $\pm$  0.9 sec, respectively). Repeat application of Caf after the burst of exocytosis revealed an approximate 20 sec refractory period for exocytosis but not elevated [ $\text{Ca}^{2+}$ ]. There was no refractory period for Mus. The refractoriness of Caf-evoked exocytosis was not due to vesicle depletion because Mus or nicotine could evoke a second round of exocytosis immediately after Caf-evoked exocytosis. Pretreatment of cells with ryanodine (0.1 to 10  $\mu$ M) inhibited Caf- but not Mus-stimulated exocytosis and elevated [ $\text{Ca}^{2+}$ ]. We conclude that kinetics of exocytosis by Mus and Caf are different and different pools of internal  $\text{Ca}^{2+}$  are used by these agents in rat chromaffin cells.

## 596.8

THE REGULATION OF DOPA DECARBOXYLASE IN BRAIN OF LIVING RAT BY DOPAMINE RECEPTORS. P. Cumming\*, A. Ase, H. Kuwabara, and A. Gjedde. Montreal Neurological Institute, McGill University, Montreal, Que. Canada H3A 2B4

Male Wistar rats received [<sup>3</sup>H]DOPA (300  $\mu$ Ci/kg, i.v.) 45 minutes after apomorphine (0.1 mg/kg, s.c.), or flupenthixol (1 mg/kg, i.p.) in addition to carbidopa (5 mg/kg, i.p.). After tracer circulation lasting 3-120 min, extracts of plasma and striatum were fractionated by HPLC to measure the contents of [<sup>3</sup>H]DOPA, [<sup>3</sup>H]DA and other metabolites. These concentrations were used to estimate the relative activity of DOPA decarboxylase (DDC) with respect to [<sup>3</sup>H]DOPA and the activity of monoamine oxidase (MAO) with respect to [<sup>3</sup>H]DA formed in striatum.

	DDC (min <sup>-1</sup> )	MAO (min <sup>-1</sup> )
Saline	0.26	0.013
Apomorphine	0.20	0.000
Flupenthixol	0.40	0.10

Thus, apomorphine, a D1/D2 agonist, reduced the turnover of [<sup>3</sup>H]DA without altering DDC activity, while flupenthixol, a D1/D2 antagonist increased the activity of DDC by 50% with a concomitant large increase in [<sup>3</sup>H]DA catabolism.

## 596.10

IDENTIFICATION OF OOCYTES AS ONE OF THE INTRAGONADAL SITES OF NOREPINEPHRINE SYNTHESIS IN THE PRIMATE OVARY. A. Mayerhofer\*, G. D. Smith\*, M. Danilchik\*, J.E. Levine\*, D. Wolf\*, M. Costa\*, and S.R. Ojeda\*. Div. Neurosci., Div. Reprod. Sci., OR Reg. Primate Res. Ctr, Beaverton, OR 97006, \*SD, OHSU, Portland OR 97201, \*Northwestern Uni., Evanston, IL 60201.

Catecholamines, which participate in gonadal development and function, are thought to derive mainly from the extrinsic innervation of the ovary. However, the primate ovary contains tyrosine-hydroxylase (TH) immunoreactive neuron-like cells (Dees et al., 74th Ann. Mtg. Endo. Soc., p. 59, 1992), and expresses the TH gene (Mayerhofer et al., Soc. Neurosci. Abstr. 20:11, 1994), suggesting an intragonadal source of catecholamines. Reverse transcription-PCR of ovarian RNA, using oligodeoxynucleotides complementary to highly conserved sequences of the human and rat dopamine-beta-hydroxylase (DBH) genes, yielded a cDNA encoding a mRNA species identical to adrenal DBH mRNA. An antisense RNA transcribed from this cDNA template was fully protected by ovarian RNA in a ribonuclease protection assay. Surprisingly, *in situ* hybridization identified oocytes as a major site of DBH mRNA expression, a localization verified by RT-PCR cloning and sequencing of a DBH cDNA from cumulus-free oocytes. Immunohistochemical localization of DBH protein by conventional and confocal laser microscopy showed that oocyte DBH mRNA is translated into its protein product. Oocytes do not contain TH mRNA and protein, but were found to express a dopamine (DA) transporter gene, similar to the one found in human brain (99% homology at the amino acid level). The biological relevance of this transporter system was suggested by the ability of isolated oocytes to metabolize DA into norepinephrine (NE), as determined by HPLC-electrochemical detection. Thus, follicular development in the primate ovary may be affected by a novel cell-cell regulatory loop involving a) DA released by nerve terminals and TH-positive neuron-like cells, b) uptake of DA by oocytes, and c) conversion of DA to NE, which may then feed back on cumulus/granulosa cells to affect their function, presumably via  $\beta$ -adrenergic receptors. Supported by grants from DFG (Ma 1080/4-1 to AM) and NIH (HD-24870, HD-18185 and RR-00163).

## 597.1

PENICILLIN MICROINJECTIONS IN MESENCEPHALIC RETICULAR FORMATION INDUCED CLINICAL AND EEG GENERALIZED SEIZURES. Francisco Velasco\*, Marcos Velasco, Fiacro Jiménez and Francisco Estrada. Div. Neurophysiology, Nat. Med. Center, IMSS, México, D.F., MEXICO.

Fifteen adult cats had implanted electrodes to record EEG from precruciate and suprasylvian cortices and EMG from neck muscles in both sides. With the animals fully awake, the head was fixed through a implanted head holder device in the stereotactic frame and the body in a transparent plastic cage to observe them during the experiments, while EEG and EMG were recorded. A solution containing 5000 µl of sodium penicillin (osmolality and pH adjusted), were stereotactically injected through a Hamilton syringes along the brain stem. Three different places were injected per animal in different days. Upon completion of the experiment the places of injection were marked by the same volume of a dye (fucina). Animals were then sacrificed and frozen sections of the brain stem obtained to determine the places of injection. 0.25 to 0.5 µl of penicillin solution along mesencephalic reticular formation invariably induced EEG and clinical generalized seizures. In contrast injections on pontine reticular formation induced slow wave sleep, injections in the raphe induced paradoxical sleep, while injection in cranial nerve nucleus induced signs of focal hyperactivity (VII= hemifacial spasm, VIII= nystagmus, X= salivation, etc) but no clinical or EEG seizures.

## 597.3

EPILEPTIC SEIZURES CAUSED BY INACTIVATION OF A NOVEL GENE IN TRANSGENIC MICE. M. Toth\*, J. Grimsby, G. Buzsáki, and G.P. Donovan. <sup>1</sup>Department of Pharmacology, Cornell University Medical College, New York, NY 10021, <sup>2</sup>Department of Molecular Pharmacology and Toxicology, University of Southern California, Los Angeles, CA 90033, <sup>3</sup>Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102

Epidemiological data and genetic studies indicate that certain forms of epilepsy are inherited. Based on the similarity between the human and mouse genomes, mouse models of epilepsy could facilitate the discovery of genes associated with epilepsy syndromes. We have identified a line of transgenic mice that shows handling-induced behavioral seizures characterized by whole body jerks, generalized clonic seizures, and epileptic brain activity, resembling human partial epilepsy with secondary generalization. Similar to human epilepsies, the onset of seizures is age dependent, the seizure threshold is remarkably lowered, and the phenotype shows variable penetrance in the transgenic animals. Molecular and genetic studies demonstrated that the phenotype was caused by the disruption of a novel brain specific gene. Based on the characteristic phenotype, we have named the locus and the putative gene defined by the transgene insertion "jerky". The chromosomal localization of the *jerky* gene was mapped between D15Mit3 and the retrovirus integration site Pmv17/Tef loci on chromosome 15 by screening an interspecies cross panel. The *jerky* gene encodes a putative 41.7 kD protein displaying homology to a number of nuclear regulatory proteins.

## 597.5

NEUROSTEROID MODULATION OF BENZODIAZEPINE BINDING TO NEOCORTICAL GABA<sub>A</sub> RECEPTORS IN HUMAN FOCAL EPILEPSY VARIES WITH PATHOLOGY. P.C. Van Ness, J.A. Awad, M. Estes, Cleveland Clinic, Cleveland, OH 44195; Q. Nguyen, R.W. Olsen, UCLA School of Medicine, Los Angeles, CA 90024

Different pathologies cause similar epilepsies. Epilepsy pathology and localization may alter neurotransmitter receptor subunits. GABA<sub>A</sub> receptors have multiple possible subunit combinations which may play a role in some human epilepsies. Excessive subcortical heterotopias (which are associated with mesial temporal sclerosis (MTS)) and cortical dysplasia are both developmental disorders that could have altered receptors

Oriented neocortical tissue obtained at time of surgery in 34 intractable partial epilepsy patients was sliced into 5 mm slabs. Assayed tissue was frozen in isopentane cooled with liquid nitrogen; alternate sections had routine histopathology. Temporal and frontal neocortex with tumor, heterotopias and cortical dysplasia were studied, cases with multiple pathologies were excluded. Tumoral epilepsy tissue was intentionally from uninvolved regions. GABA<sub>A</sub> receptor binding was assayed autoradiographically on frozen, unfixed specimens using [<sup>3</sup>H]flunitrazepam (FLU) for the benzodiazepine (BZ) site (Nguyen et al., 1995), with and without 10 µM alfaxalone. An investigator, blind to pathology, quantitated FLU binding to cortical laminae I-III, IV, and V-VI.

Regional FLU binding without alfaxalone was similar for all pathologies. Temporal neocortex with subcortical heterotopia (N=17) had increased laminar FLU binding of 10.4-12.8% with alfaxalone compared to decreases of 6.4-8.8% in tumor (N=8) and 1.9-5.6% in cortical dysplasia (N=4). In frontal neocortex, alfaxalone enhanced FLU binding by 12.9-18.2% in heterotopias (N=2) compared to 5.8-9.8% for cortical dysplasia (N=3).

The pathology-specific neurosteroid modulation of BZ binding suggests possible GABA<sub>A</sub> receptor subunit alterations such as increased numbers of steroid-sensitive subunits or decreased steroid-insensitive subunits. Temporal lobe receptor changes possibly cause or result from MTS. Other non-mesial temporal lesions have been associated with hippocampal cell loss. Understanding pathology specific receptor differences could lead to more specific pharmacologic and preventive interventions for epilepsies. Supported by NS22071

## 597.2

DECREASED SEIZURE THRESHOLD IN ADULT HIPPOCAMPAL SLICES AFTER PERINATAL HYPOXIA IN VIVO. F.E. Jensen\*, C.D. Wang, and C. Geary. Div. Neurosci., Children's Hosp., Harvard Med. Sch., Boston, MA 02115

We have shown that perinatal hypoxia in the rat (postnatal (P) days 10-12) acutely induces seizures and permanently decreases seizure threshold to the convulsants flurothyl and pentylenetetrazol. Depth electrode recordings during hypoxia show seizures induced in neocortex, pyriform cortex, and hippocampus. To determine whether there are long lasting changes in the hippocampus, hippocampal slices were prepared from P70-80 rats with previous exposure to a single episode of hypoxia (3% O<sub>2</sub>) at P10. Following incubation in ACSF, extracellular recordings were made in area CA1 during 60 min incubation in Mg<sup>2+</sup>-free ACSF. Slices from previously hypoxic rats were compared to litter mate controls (one slice per rat). Incubation in Mg<sup>2+</sup>-free medium induced ictal discharges in 6/10 slices from rats with previous perinatal hypoxia (n=10 rats), while no ictal discharges were seen in control rats (0/10, n=10 rats) (p<0.02). Slices from control adults showed only interictal bursting. These data are consistent with our in vivo results suggesting that even a single episode of hypoxia can permanently decrease seizure threshold. In addition, these data suggest that hypoxic exposure during development induced hyperexcitability intrinsic to the hippocampus which is not dependent on coactivation of other structures. Supported by NS31718, NS32570 (FEJ).

## 597.4

INHIBITORY POSTSYNAPTIC CURRENTS IN DENTATE GRANULE CELLS OF HUMAN AND RAT EPILEPTIC HIPPOCAMPUS. Masako Isokawa\* and Izhak Fried. Brain Research Institute and Dept. of Neurosurgery, Sch. of Medicine, UCLA, Los Angeles, CA 90024-1761.

Previous studies indicated that 80-90% of GABA inhibition was preserved in human epileptic hippocampus (Masukawa et al., 1989; Babb et al., 1989). We have recorded IPSPs from morphologically-identified human epileptic dentate granule cells (DGCs) (Isokawa et al., 1991). The present study was initiated to further characterize GABA<sub>A</sub> receptor-mediated synaptic transmission in epileptic DGCs using whole-cell patch clamp recording. Hippocampal slices were prepared from surgically resected temporal lobe specimens of epileptic patients and from pilocarpine-treated chronically epileptic rats. Inhibitory postsynaptic currents (IPSCs) were isolated as outward currents at 0 mV, near the reversal potential of glutamate-mediated excitatory postsynaptic currents (EPSCs). IPSCs were pharmacologically confirmed as GABA<sub>A</sub> IPSCs by 10 µM bicuculline methiodide. With single orthodromic activation of DGCs, IPSC amplitude was similar in human and rat epileptic DGCs and in normal rat DGCs. However, tetanic stimulation at -30 mV, at which NMDA receptors were activated, reduced IPSC amplitude at 0 mV in all epileptic cells. In some cases, IPSCs were completely abolished. IPSC amplitude recovered in several tens of seconds to several minutes. Although the magnitude of the effect of tetanic stimulation on IPSCs varied, the effect was stronger on epileptic DGCs compared to control DGCs. An excitatory neurotransmitter glutamate may interact with inhibitory GABA<sub>A</sub> neurotransmission in epileptic hippocampus in a perverted way to give rise to epileptogenic excitation. Supported by NINDS grants NS02808 and NS31180.

## 597.6

METHYLATION OF NUCLEIC ACID DURING NEUROBLASTIC DIVISION INDUCES EXPERIMENTAL NEURONAL MIGRATION DISORDERS.

I.M. Germano\*, MD and E.F. Sperber, PhD, Department of Neurosurgery, Mount Sinai School of Medicine and Department of Neurology and Neuroscience, Albert Einstein College of Medicine, New York, NY

Neuronal migration disorders (NMD) are often found in patients undergoing evaluation for epilepsy. Although recent data suggest that some types of NMD may be genetically inherited, the mechanisms leading to NMD have not been fully investigated yet. The aim of the present study is to assess the effects of alteration to nucleic acids during the neuroblastic division on NMD. We exposed pregnant rats to the alkylating neurotoxin methylazoxymethanol (MAM; 25 mg/kg in saline i.p.) at pregnancy day (PG) 13, 14, 15, and 16. In the rat, neuroblastic division occurs at PG 15.

Histological examination of 150 14 day-old rat pup belonging to X litters showed that all rats (100%) exposed to MAM at PG 15 had NMD. The incidence of NMD in the other groups was as following: 63% in PG 13, 70% in PG 14, 85% in PG 16. Histological features of experimentally-induced NMD included neuronal dysplasia of the cortex and hippocampus. In the neocortex, we found cortical laminar disorganization, ectopic neurons in the subcortical white matter, ectopic neurons in cortical layer I, persistent granular layer and marginal glial neuronal heterotopia. Hippocampal features included discrete areas of neuronal ectopia in the CA1 subfield. Based on histological criteria, NMD were divided into 3 groups: mild, moderate, severe. Moderate and severe NMD were found only in PG 15 rats.

These data shows that methylation of the nucleic acid at the time of neuroblastic division induces NMD. In our study the methylation was "environmentally" acquired, however, a similar mechanism may be genetically inherited. MAM-induced experimental NMD have histological characteristics similar to those observed in patients with NMD and epilepsy. Ongoing studies in our laboratory are using this model to bring insights on the link between NMD and epilepsy.

## 597.7

OPPOSITE CHANGES OF "CENTRAL" AND "PERIPHERAL" BENZODIAZEPINE RECEPTORS IN HIPPOCAMPUS OF ELECTRICALLY KINDLED RATS.

C.Ferrarese\*, G.Bianchi, M.Bugiani, T.Cogliati, M.Frigo, D.Passoni, N.Pecora, R.Tortorella, L.Fratola and A.Vezzani. Dept. of Neurology, Univ. of Milan, 20052 Monza, and \*Inst. M.Negri, 20157 Milan, Italy.

Modifications of glutamate and GABA-A receptor subunits have been described in animal models of kindling epileptogenesis.

To investigate possible mechanisms of GABA-A receptor modifications, central (CBR) and peripheral (PBR) benzodiazepine binding sites and the levels of their endogenous ligand diazepam binding inhibitor (DBI) were studied in ventral and dorsal hippocampus of rats electrically kindled in amygdala or dorsal hippocampus. CBR density and affinity were studied by the specific binding of  $^3\text{H}$ -Flumazenil, PBR by the specific binding of  $^3\text{H}$ -PK-11195 and DBI levels were assayed by RIA using polyclonal rabbit antibodies raised against rat DBI.

CBR density (Bmax) was decreased ( $p < 0.05$ ) in ventral hippocampus of rats fully kindled in amygdala and hippocampus, whereas PBR density was significantly increased in the same areas. Binding affinity did not change in any investigated area. DBI levels were increased, although not significantly, in ventral and dorsal hippocampus of rats kindled in amygdala and hippocampus.

These data support a possible role of DBI and its receptors in kindling epileptogenesis; PBR might induce CBR-GABA-A receptor modifications through neurosteroids active at this receptor complex.

## 597.9

EPILEPTIFORM DISCHARGES AND THEIR RELATION TO FOCAL CEREBRAL HEMODYNAMIC ABNORMALITIES: AN EEG TRIGGERED FUNCTIONAL MRI STUDY. G. Schlaug\*, J.R. Ives, M. Patel, V. Thangaraj, R.R. Edelman, D.L. Schomer and S. Warach. Depts. of Neurology and Radiology, Beth Israel Hospital, Boston, MA 02215.

Localization of the epileptogenic zone in patients with medically intractable epilepsy depends on the detection of structurally and functionally abnormal brain areas. However, their relationships to the patient's regional epileptiform discharges are difficult to assess using current imaging techniques such as PET and SPECT and often require invasive procedures. We have implemented a system that allows us to monitor the patient's electroencephalogram (EEG) in the bore of a 1.5 Tesla magnet using cable telemetry techniques and fiber-optical isolation. Echo planar fMRI scans using blood oxygen level dependent (BOLD) contrast as well as MR-perfusion techniques (EPISTAR) can be manually triggered using various time delays after epileptiform discharges are detected on EEG recordings. Images during the patient's subclinical electrographic epileptic events are compared to baseline scans without discharges. Functional MR images are coregistered with high resolution anatomical images allowing direct structural-functional comparisons.

Thresholded and spatially filtered percentage change maps and cross-correlational analysis of MR signal changes comparing fMRI images with and without epileptiform discharges revealed focal MR signal increases in patients with subclinical epileptiform discharges of presumably temporal and extra-temporal origin.

Time-locking epileptiform discharges obtained from EEG recordings while the patient is in the MRI scanner offers a new approach to the study of hemodynamic/metabolic changes during focal and even generalized epileptic discharges, and may be sensitive for non-invasive localization of epileptic foci in human epilepsy.

## 597.11

EQUIVALENT PROTECTION AGAINST NMDA SEIZURES BY MK801, PHENYTOIN AND A DC ELECTROMAGNETIC FIELD. J.Eric Piña-Garza, Robert R. Holcomb, Michael J. McLean. Department of Neurology, Vanderbilt University, Nashville TN 37212.

We evaluated a DC electromagnetic (DCEM) device against seizures induced by intracerebroventricular (i.c.v.) injection of N-methyl-D-aspartate (NMDA) in mice, a model used to evaluate novel antiepileptic drugs (AEDs). The DCEM device consists of four coils of alternating polarities connected to a DC power supply. Soft iron cores in the centers of the coils were located at the corners of a 14 cm. square. This array produced a time invariant electromagnetic field of  $\pm 60$  mT. Seizures produced by i.c.v. injection of 1 nmol of NMDA consisted of wild running, loss of righting reflex, myoclonus, clonus, tonus and rarely death within 2 min. Seizure stages were characterized electrographically. MK-801 (2 mg/Kg intraperitoneally, 30 min. before NMDA) and phenytoin (40 mg/Kg intraperitoneally, 2 h before NMDA) pretreatment blocked all but the wild running phase. For up to 2.5 h before NMDA injection, a single 15 min. treatment with DCEM in positions of steep gradients had similar efficacy. No protection was afforded by (1) an AC electromagnetic device; (2) interposing a flux return ring between the DCEM device and the mice; or, (3) positioning the mice over a single pole of the DCEM (no gradient).

DCEM fields with steep gradients merit further evaluation as a non-pharmacological adjunct for the treatment of seizures.

[Supported by the Holcomb Medical Research Institute]

## 597.8

METABOLIC MARKERS OF SEIZURES AND SEIZURE-INDUCED NEURONAL DAMAGE AS ASSESSED BY MAGNETIC RESONANCE SPECTROSCOPY. Imad Najm\*, Youssef Comair, Yang Wang, Thuan Ng, and Hans Lüders, Depts of Neurology, Neurosurgery and Radiology, Cleveland Clinic, Cleveland, OH 44195

Kainic acid (KA)-induced seizures lead to a cascade of molecular and metabolic changes associated with neuronal loss in the hippocampus. Pretreatment with cycloheximide, a protein synthesis inhibitor, protects against KA-induced cell damage. This model represents a unique way to dissociate status epilepticus from seizure-induced neuronal damage. We used  $^1\text{H}$ -MR Spectroscopy to identify specific metabolic markers of seizure activity without cell damage as compared to markers of seizure-induced neuronal loss. Rats were pretreated with normal saline or cycloheximide (s.c. injection, 2mg/Kg) one hour before KA injection (10 mg/Kg). Rat brains (n=10) were scanned at the hippocampal level before and 24 hours after the seizures. Spectra were recorded and the relative ratios of N-acetylaspartate (NAA), choline, and lactate (Lac) over creatine (Cr) were calculated and compared between the 2 groups. Cresyl violet staining of 30  $\mu\text{m}$  sections showed a lack of significant neuronal loss in CA3 and CA1 areas of the hippocampus in cycloheximide pretreated rats. A significant increase in lactate ratios was observed in KA-treated rats 24 hrs after the seizure onset but no significant lactate increase was found in cyclo-pretreated rats. NAA ratios were significantly lower in KA-treated rats as compared to control rats. Cyclo-pretreatment prevented any change in NAA ratios 24 hrs after the seizures. No change in choline ratios was found in any of the 2 treatment groups as compared to control values.

Our results show that a prolonged increase in lactate after status epilepticus is associated with neuronal damage and confirm the hypothesis that NAA is a neuronal density marker.

Temporal Alteration of Sodium Content and Apparent Diffusion Coefficient in Epileptic Rat Brain Induced by Kainic Acid

Y. Wang, A. Majors, T. Ng, J. Najm, M. Xue, H. Lüders, M. Modic, Y. Comair\*, The Cleveland Clinic Foundation, Cleveland, OH 44195

*In situ* 3-dimensional sodium magnetic resonance imaging (MRI) technique was used to study temporal changes in cellular sodium in various regions (hippocampal formation, pyriform cortex and amygdala) of seizing rat brains induced by kainic acid (KA) in the ictal phase and many time points postictally. We concomitantly measured the ADC changes. Adult Sprague Dawley rats (n=12), weighing 230-280g, were used. MRI of their brains were scanned 5 hrs, 24 hrs and 7 days post KA. The apparent sodium concentration calculated from the known capillary reference was about 50 mM in control rat brain. During the early postictal phase, no significant changes of sodium concentration in hippocampus, pyriform cortex and amygdala were observed while ADC were decreased in pyriform cortex and amygdala. At 24 hours postictally, sodium increased to  $62.1 \pm 12.0$  mM in hippocampus, and  $89.5 \pm 11.3$  mM in pyriform cortex and  $88.3 \pm 12.5$  mM in amygdala, while ADC were decreased in pyriform cortex, amygdala, and hippocampus. High sodium level persisted till 7 days later as ADC were back to normal. Our *in situ* sodium measurements showed a pronounced elevation of sodium signal intensity in areas (90%,  $p < 0.01$  in pyriform cortex) susceptible to neuronal damage, e.g. the hippocampus and pyriform cortex, which signifies the ionic steady states being perturbed by KA induced seizure. The ADC decreased at 24 hr postictally changes could be due to increase of intracellular space due to edema and increased permeability of cell to the water. The ADC increased in these area 7 days later implies that the dead neurons were replaced by water and glial cells.

## 597.12

ALTERED GABA-A RECEPTOR SUBTYPE-SPECIFIC AND ALLOSTERIC BINDING PROPERTIES IN NEOCORTEX RESECTED FROM HUMAN FOCAL EPILEPSY TISSUE ASSOCIATED WITH SEVERE HIPPOCAMPAL PATHOLOGY AND SPROUTING. R.W. Olsen, C.R. Houser<sup>1,2</sup>, R. Makela, and A.V. Delgado-Escueta<sup>2</sup>. Depts. of Pharmacology, Neurobiology<sup>1</sup>, UCLA, and Neurology<sup>2</sup>, West LA VAMC, and Cal. Comprehensive Epilepsy Program, Los Angeles, CA 90024.

GABA<sub>A</sub> receptor (GABAR) binding was altered in temporal neocortex of surgically resected tissue from human focal epilepsy patients with severe hippocampal pathology. Frozen unfixed temporal cortex sections were assayed for a battery of GABAR ligands and allosteric modulators using semi-quantitative autoradiography. The density and distribution of three sites on the GABAR complex (GABA, benzodiazepine [BZ], and picrotoxin/TBPS) were measured, as well as allosteric interactions between sites. Two parameters differed from normal autopsy tissue: modulation of TBPS binding by the anesthetic neuroactive steroid alphaxalone (increased), and the levels of diazepam-insensitive binding of the BZ ligand Ro15-4513, indicative of the  $\alpha 4$  subunit (also increased). Alterations were significant only in patients with severe hippocampal sclerosis, neuronal cell loss, and sprouting, compared to epilepsy patients with less severe hippocampal involvement. Further, changes were more marked in the anterior or posterior regions presenting 'more spiking' activity in intraoperative corticography recordings relative to nearby tissue. These GABAR changes in neocortex of patients with severe hippocampal involvement are likely to be representative of several altered neurochemical anatomy markers, suggestive of incorrect cell positioning, synaptic organization, and/or circuitry in cortex, presumably related to comparable pathophysiology in the hippocampus. Supported by NS21908 and NS22071.

## 598.1

## NERVE GROWTH FACTOR NEUROPROTECTION IS DEPENDENT UPON INDUCTION OF CATALASE.

A. J. Windebank<sup>1</sup> and J. L. Podratz<sup>2</sup>. Molecular Neuroscience Program, Mayo Clinic and Mayo Foundation, Rochester, MN.

Understanding the potential neuroprotective role of neuronal growth factors requires development of relevant cellular and molecular models. When tissue culture medium is exposed to hemodialyzers it causes beading and degeneration of dorsal root ganglion (DRG) axons *in vitro*. Toxic activity was dependent upon ethylene oxide (EO) sterilization of the dialyzer. In the present study, we found that increasing the concentration of NGF prevented this toxicity. Cells were exposed to dialyzer treated medium with either 3.5, 5, or 10 ng/ml NGF. Beading of neurites was seen at 3.5 and 5 ng/ml, but was completely inhibited at 10 ng/ml NGF. DRG neurons were exposed to dialyzer treated medium with various combinations of catalase (100 u/ml), glutathione peroxidase (GSH-PX 1u/ml) or superoxide dismutase (SOD 35 u/ml) together with the minimum level of NGF needed to give sustainable neurite outgrowth (3.5 ng/ml). The toxic beading was completely inhibited by catalase and GSH-PX but not by SOD. The protective effect of both NGF and catalase were abolished by combination with the specific catalase inhibitor 3-amino 1,2,4-triazole. Excess peroxides could be eluted from dialyzers and NGF was shown to increase catalase activity by 55-80% in DRG neurons.

**Conclusion.** EO used for sterilization of hemodialyzers reacts with a plasticizer in the dialyzer or a component of serum in the medium to form peroxides that causes oxidative stress in DRG neurons. NGF protects the DRG specifically by upregulating catalase or GSH-PX activity. This provides a new cellular model of NGF neuroprotection, the components of which are testable in animals and humans (supported by NS14304).

## 598.3

## NEUROTOXIC AND NEUROPROTECTIVE EFFECTS OF POLYCHLORINATED BIPHENYLS AND ADENOSINE LIGANDS IN RAT BRAIN

NY Choksi, CL Waller, RG Booth\*. Division of Medicinal Chemistry, School of Pharmacy, University of North Carolina at Chapel Hill, NC, 27599; US-Environmental Protection Agency, Research Triangle Park, NC, 27711.

Loss of dopaminergic cells in the substantia nigra decreases dopamine (DA) concentration in the striatum and produces the main symptoms of Parkinson's disease. Although the etiology of Parkinson's disease is unknown, environmental factors are proposed to play a role in development of the disease. Polychlorinated biphenyls (PCBs) are widespread in the environment and have been shown to cause central and peripheral toxic effects in humans and animals. We report that several PCBs inhibit tyrosine hydroxylase (TH) activity and DA synthesis in rat striatum *in vitro* (IC<sub>50</sub> ~ 150-200 µM). In contrast to the inhibition of TH activity by PCBs, we have observed that TH activity and DA synthesis in striatal tissue is stimulated by activation of adenosine A<sub>2</sub> receptors. We report that 2-phenylamino-adenosine (2-PAD) stimulates TH activity and DA synthesis in rat striatum *in vitro* (EC<sub>50</sub> = 10 µM) through an A<sub>2</sub> receptor mechanism. 2-PAD also stimulates DA synthesis in rat striatum *in vivo* (ED<sub>50</sub> ~ 0.6 µmoles/kg) after intracerebroventricular injection. These results suggest that A<sub>2</sub> ligands may attenuate PCB induced inhibition of TH activity and DA synthesis. We propose that PCBs, present as contaminants in the environment, may be dopaminergic neurotoxins and may play a role in the etiology of Parkinson's disease. Furthermore, we propose that adenosine receptor mechanisms may play a neuroprotective role to modulate PCB-induced dopaminergic neurotoxicity. [Support: US-EPA and UNC-CH #544786]

## 598.5

## WALLERIAN DEGENERATION AND ACRYLAMIDE NEUROPATHY ARE INHIBITED BY CALCIUM ANTAGONISTS IN CULTURED MOUSE SENSORY AXONS.

AXONS. E. B. George\*, J. D. Glass, and J. W. Griffin, Neurology Dept., Johns Hopkins University; Baltimore, MD 21287-6953

The axonal neuropathies produce an axonal degeneration which is similar in appearance to Wallerian degeneration. The distal axonal degeneration produced by axonopathies is often called "Wallerian-like degeneration" because of the morphologic similarities, but the degree to which these two forms of axonal degeneration share a similar underlying mechanism remains uncertain. Using a cultured murine dorsal root ganglion model, we have previously demonstrated that axonal degeneration after axotomy can be inhibited by calcium channel and calpain inhibitors, and is delayed in cultures prepared from C57BL/6 mice. We now extend these results to the toxic axonopathy produced in established axons by acrylamide.

We have developed a tissue culture model of axonal neuropathy using low dose acrylamide to produce distal axonal degeneration in cultured murine dorsal root ganglia. The axonal degeneration produced in this tissue culture model is comparable to *in vivo* axonopathy in several key respects. These cultured axons show initial changes in the distal portions of the axons, with subsequent involvement of the proximal axon and progression to axonal loss. The morphologic appearance of the acrylamide-injured axons is similar to the morphology of axotomy-induced axonal degeneration in these cultures. The neurons are able to regenerate axons once acrylamide is withdrawn.

The progression of the acrylamide-induced changes is delayed in cultures exposed to calcium antagonists at doses which inhibit axotomy-induced axonal degeneration. Cultures can also be prepared with ganglia from C57BL/6 mice, which show delayed Wallerian degeneration after axon transection *in vivo*. Cultures prepared using ganglia taken from C57BL/6 mice are less susceptible to acrylamide-induced axonal toxicity than cultures prepared from normal (C57BL/6) mice. These observations are consistent with a common mechanism for axonal degeneration induced by either axotomy or acrylamide toxicity.

## 598.2

## IMMUNOSUPPRESSANT, FK506, PROTECTS AGAINST METHAMPHETAMINE NEUROTOXICITY

T. Shibata<sup>1</sup>, L.M. Ensz<sup>2</sup>, H.-Y. Yun<sup>1</sup>, V.L. Dawson<sup>1</sup>, T.M. Dawson<sup>2</sup>. Departments of Neurology<sup>1</sup>, Neuroscience<sup>2</sup> and Physiology<sup>3</sup>, Johns Hopkins University School of Medicine, Baltimore, MD 21287

Besides their roles in the immune system, the immunophilins cyclophilin and FK506 binding protein (FKBP) are highly concentrated in the brain in discrete neuronal structures where they are colocalized with the Ca<sup>2+</sup>-activated phosphatase, calcineurin. We recently showed that cyclosporin A and FK506 block the neurotoxicity elicited by glutamate acting at N-methyl-D-aspartate (NMDA) receptors in cerebral cortical cultures. The mechanism for the neuroprotective effects of these drugs appears to be inhibition of calcineurin. Methamphetamine is neurotoxic to dopamine containing neurons as indicated by permanent depletions in striatal dopamine (DA) after methamphetamine administration. Depletions in striatal DA following methamphetamine is blocked by antagonists of the NMDA receptor, thus suggesting that NMDA receptor activation is some how involved in methamphetamine neurotoxicity. Based on these findings we examined the effects of FK506 and cyclosporin A on methamphetamine neurotoxicity. Methamphetamine (10 mg/kg sc) was given every 2 hrs X 4 doses to 8 week and 24 week old C57B6J mice who were pretreated with varying doses of either FK506, cyclosporin A or vehicle. Mice were killed 4 days later and DA and its metabolites were measured by HPLC. FK506 and cyclosporin A prevented the depletions in DA due to methamphetamine toxicity. These data suggest that immunophilins and calcineurin play a role in methamphetamine neurotoxicity.

## 598.4

## BCL-2 INHIBITS APOPTOSIS INDUCED BY THAPSIGARGIN OR CAFFEINE IN GT1-7 NEURONAL CELLS.

D.C. Perry<sup>1</sup>, H. Wei, W. Wei and D.E. Bredesen\*. Dept. of Pharmacology, George Washington University Medical Center, Washington, D.C. 20037, and \*La Jolla Cancer Research Foundation, La Jolla, CA 92037.

Cell death induced by thapsigargin (TG) or caffeine was investigated in GT1-7 cells, an immortalized mouse hypothalamic neurosecretory line. Cells overexpressing the protooncogene *bcl-2* were compared with control cells; trypan blue exclusion was used to determine cell viability. Apoptosis was determined by nuclear condensation and margination seen after acridine orange staining, and by regular DNA fragmentation ("laddering") seen with agarose gel electrophoresis. After 24 hr treatment, TG (50 nM) caused 45% death in control cells, but only 2% death in *bcl-2* cells (P<0.01), while caffeine (10 mM) caused 41% death in control cells, but only 2% in *bcl-2* cells (P<0.01).

After 48 hours treatment, TG caused 95% death in control cells, but only 16% death in *bcl-2* cells (P<0.01), while caffeine caused 76% death in control cells, but only 4% in *bcl-2* cells (P<0.01). After 24 hr or 48 hr treatment with 50 nM TG or 10 mM caffeine, control cells showed a significantly higher percentage of nuclear condensation and margination compared to *bcl-2* cells with same treatment. DNA laddering was also detected in drug-treated control cells. TG and caffeine cause release of intracellular Ca<sup>2+</sup> stores, so we tested whether drugs that inhibit such release would protect against TG- or caffeine-induced death. Dantrolene (120 µM) and TMB-8 (100 µM) gave significant protection against both drugs at 24 hr. These results indicate that TG or caffeine cause death in GT1-7 cells at least in part through an apoptotic mechanism, and that this death is likely precipitated by release of intracellular Ca<sup>2+</sup> stores. Overexpression of *bcl-2* protects against cell death initiated by intracellular calcium release in these neuronal cells. Supported by the Souer Stroke Fund and NIH AG12282.

## 598.6

## IN VITRO AND IN VIVO NEUROPROTECTION WITH MELATONIN AGAINST THE TOXICITY OF SINGLET OXYGEN.

H. Maney\*, C.M. Cagnoli, A. Kharlamov, C. Atabay and E. Kharlamov, ASRI, Medical College of Pennsylvania and Hahnemann University, Allegheny Campus, Pittsburgh, PA, 15212.

Singlet oxygen [O<sub>2</sub>(<sup>1</sup>Δg)] is a very reactive molecule that can be produced by living cells and may contribute to cytotoxicity. The pineal hormone melatonin has been reported to possess potent antioxidant activity (Exp. Neurol. 1995, 131:39), and to be capable of scavenging free radicals and O<sub>2</sub>(<sup>1</sup>Δg). We investigated whether melatonin might reduce the neurotoxic action of O<sub>2</sub>(<sup>1</sup>Δg) that was generated by exposing a photosensitive dye, rose bengal, to light. In a cell-free system, melatonin protected the enzyme creatine kinase (EC 2.7.3.2) from the rose bengal-induced injury. The cytotoxic effect of singlet oxygen was studied *in vitro* in primary cultures of rat cerebellar granule neurons pretreated with a photosensitive dye, rose bengal, and exposed to light. We found that this procedure triggers neuronal death which is preceded by mitochondrial impairment (assayed by the rate of the reduction of MTT into formazan), and by DNA fragmentation - a marker of apoptosis (determined *in situ* by terminal deoxynucleotidyl transferase assay). Cell death was assayed with trypan blue. In this model of apoptotic neuronal death protection was obtained with melatonin. *In vivo*, unilateral cortical thrombosis was induced by illuminating the skull of rose bengal-treated rats for 10 min with a focused beam of light (A. Kharlamov *et al.*, this meeting). The core of the thrombotic lesion was associated with a rapid cell degeneration. The extent of the lesion was assayed 24 h after injury. Brain slices were incubated with 2% triphenyltetrazolium chloride for 15 min at 37°C and the size of the infarcted area was measured. Melatonin (3 × 2.5 mg/kg; intraperitoneally) significantly reduced the lesion size. The results suggest that melatonin counteracts the cytotoxic action of singlet oxygen *in vitro* and *in vivo*. Further studies should define the role singlet oxygen and melatonin play in neurodegenerative pathologies.

## 598.7

**DIRECT CYTOTOXICITY OF HIV COAT PROTEIN GP120 ON HUMAN NT NEURONS.** P. Wu, B. Du, W. Hatch\* and E.F. Terwilliger. Divisions of Infectious Disease and Hematology/Oncology, New England Deaconess Hospital, Harvard Medical School, Boston, MA 02215

HIV-1-induced neurotoxicity is currently believed to be mediated through an indirect mechanism involving activation of macrophages/microglia by its coat protein gp120. Neurotoxins released from these cells then trigger neuronal death through a final common pathway containing the NMDA receptor and its  $Ca^{++}$  channel. We report here, for the first time, a moderate yet direct toxic effect of gp120 on human NT neurons. NT neurons were obtained, as a pure population (>95%) of cells with neuronal phenotype, from retinoic acid-induced terminal differentiation of NT2/D1 precursor cells, a subline of human teratocarcinoma cells. These cells were treated with recombinant gp120 in the presence or absence of  $Ca^{++}$  or MK801. The viability of the neurons was monitored by both morphological appearance and the quantitative MTT assay. Treatment of mature NT neurons at 6 weeks of age with 1 nM gp120 for 24 h caused a 25% loss in cell number. However, no toxic effect was detectable on cultures at only 4 weeks of age, at which time neuronal maturation has not been completed. Furthermore, the gp120-mediated neurotoxicity was abolished either by a NMDA receptor open-channel blocker, MK801, or by culturing in a  $Ca^{++}$ -free environment. Together these data indicate that the HIV-1 gp120 protein can cause a direct neurotoxicity on mature human NT neurons by acting through the NMDA-receptor pathway. NT neurons may be a useful model for future studies to understand mechanisms underlying the gp120-mediated neurotoxicity.

## 598.9

**NO<sup>+</sup> INDUCES CYTOSKELETAL CHANGES DURING APOPTOSIS IN CEREBELLAR GRANULE CELLS.** E. Bonfoco\*, B. Zhivotovsky, S.A. Lipton<sup>1</sup> and P. Nicotera<sup>2</sup>. Inst. of Environmental Med., Box 210, Karolinska Institutet, 17177 Stockholm, Sweden, <sup>1</sup>Laboratory of Cellular and Molec. Neurosci., Children's Hosp., Harvard Med. School, Boston 02115 USA and <sup>2</sup>Faculty of Biology, Univ. of Konstanz, Box 5560, Konstanz, Germany.

We have recently reported that NO<sup>+</sup> and O<sub>2</sub><sup>-</sup>, which react to form peroxynitrite, can induce either necrosis or apoptosis in cortical cultures depending on the intensity of the insult. Here, we further investigate the mechanisms by which treatment with NO<sup>+</sup> donors elicits apoptosis in a virtually pure neuronal population, cerebellar granule cells. We found that the NO<sup>+</sup>-donor, SNOC (S-nitrosocysteine), causes early cytoskeletal alterations which precede formation of high molecular weight DNA fragments and apoptotic body formation. Actin fragmentation occurred 1h after exposure to 300  $\mu$ M SNOC. At 6 h,  $\alpha$  and  $\beta$ -tubulins were also fragmented. Concomitantly, formation of 200 kbp-sized DNA fragments and initial chromatin condensation became appreciable. Later, at 12 h, formation of 50 Kbp DNA fragments and DNA laddering appeared on agarose gels. Pretreatment with agents that stabilize the cytoskeleton partially prevented the formation of high molecular weight DNA fragments and apoptotic bodies. This suggests that the early cytoskeletal changes induced by NO<sup>+</sup> treatment, are a critical step in the progression of neuronal apoptosis.

## 598.11

**INHIBITION OF NITRIC OXIDE SYNTHASE IN RAT BRAIN BY AROCLOR 1242.** K. L. Chandna, P. J. S. Vig\*, M. Pande, V. R. Janapala and D. Desaiiah. Dept. Neurol., Univ. Miss. Med. Ctr., Jackson, MS 39216.

Polychlorinated biphenyls (PCBs), called Aroclors, are industrial chemicals, and cause persistent environmental contamination. PCBs exist as 209 different congeners depending on the chlorine substitution patterns on the biphenyl rings. Exposure to high concentrations of PCBs results in adverse health effects involving many organ toxicity. Nitric Oxide (NO) is a known messenger molecule and is synthesized from L-arginine by Nitric Oxide Synthase (NOS). The aim of this study was to investigate the effect of Aroclor 1242 on brain NOS. The crude NOS was prepared from normal rat brain and its activity was determined by enzymatic conversion of [<sup>3</sup>H] arginine to [<sup>3</sup>H] citrulline. NOS activity was quantified by measuring the radioactivity of the flow through fraction containing [<sup>3</sup>H] citrulline. Nitric Oxide Synthase activity was significantly inhibited *in vitro* by Aroclor 1242 in a concentration (100-250  $\mu$ g/ml) dependent manner. A 50% inhibition of the enzyme was obtained at 150  $\mu$ g/ml concentration of Aroclor 1242. These results indicate that Aroclor 1242 is a potent inhibitor of neuronal NOS which may be related to the neurotoxic action of PCBs.

## 598.8

**LEAD (Pb<sup>2+</sup>) FACILITATES THE ONSET OF APOPTOSIS IN NEURONS.**

A. Oberio, N. Marks\*, H. Evans\* and A. Guidotti

\*Center for Neuropharmacology and Neurochemistry, N. S. Kline Institute for Psychiatric Research, Orangeburg, NY 10962, and \*Dept. of Environmental Medicine, NYU Medical Center, N.Y.

Pb<sup>2+</sup> exposure has devastating neurotoxic effects on the developing nervous system. In the present study, we examined in primary cultures of cerebellar granule cells prepared from 6 day old rats whether Pb<sup>2+</sup> neurotoxicity is mediated by necrosis or apoptosis (programmed cell death).

Pb<sup>2+</sup> (10 to 100  $\mu$ M) failed to potentiate neuronal necrosis induced by 10 to 100  $\mu$ M glutamate in presence of 1  $\mu$ M glycine, 25 mM K<sup>+</sup> and nominal absence of Mg<sup>2+</sup> in 8 DIV cerebellar cultures. Moreover, 100  $\mu$ M Pb<sup>2+</sup> added to 8 DIV cultures induced death in 20% of neurons even when Pb<sup>2+</sup> was applied to the cultures together with 5  $\mu$ M MK 801 (to block NMDA receptors) or 10  $\mu$ M NBQX (to block AMPA/kainate receptors).

Since this effect of Pb<sup>2+</sup> was abolished by treating the cultures with actinomycin D, we studied whether Pb<sup>2+</sup> potentiates neuronal apoptosis in 8 DIV cerebellar neurons deprived of serum in presence of 5 mM K<sup>+</sup>, 5  $\mu$ M MK 801 and 10  $\mu$ M NBQX. In this model of apoptosis Pb<sup>2+</sup> treatment facilitated apoptosis in a dose dependent manner. A two fold increase of apoptotic neuronal death was induced by 100  $\mu$ M Pb<sup>2+</sup> whereas, a 50% increase in neuronal death was observed with 25  $\mu$ M Pb<sup>2+</sup>. Apoptotic cell death was revealed morphologically by cell shrinking and chromatin condensation, and biochemically by the typical DNA fragmentation pattern. Lead potentiated apoptosis was completely blocked by 1  $\mu$ g/ml of cycloheximide and 1  $\mu$ g/ml of actinomycin D. Supported by Grant NS28130-04.

## 598.10

**MARINE BIOMOLECULES INHIBIT RAT BRAIN NITRIC OXIDE SYNTHASE.**

V. R. Janapala, D. Desaiiah\*, P. J. S. Vig, Y. Venkateswarlu and A. V. Rama Rao. Dept. Neurology, Univ. Miss. Med. Ctr., Jackson MS 39216; Org. Chem., Indian Inst. Chem. Technol., Hyderabad, India.

A large number of substances of medical importance have been isolated from marine flora and fauna and their chemical structures were elucidated. Among the many compounds isolated in our laboratories only two compounds were identified as neurotoxins. The pure (100%) compounds Xestospongins D and Araguspongins C isolated from sponge *Haliclona exigua* were tested for their effects on rat brain nitric oxide synthase (NOS) activity *in vitro*. The results showed that NOS was inhibited in a dose and time dependent manner with an estimated I<sub>50</sub> of 31.5  $\mu$ M, Xestospongins D and 46.5  $\mu$ M, Araguspongins C and the maximum-inhibition occurred within 3 minutes. To explore the mechanism of action of these compounds on NOS, we have conducted kinetic studies with L-arginine, NADPH and Ca<sup>2+</sup> in the presence of I<sub>50</sub> concentration of the two compounds. The V<sub>max</sub> and K<sub>m</sub> values were calculated using the Michaelis-Menten equation. The results show that both the compounds are competitive inhibitors of NOS with the substrate, L-arginine and uncompetitive with NADPH and free Ca<sup>2+</sup>. The NOS inhibition by these two compounds was similar to L-NAME a known inhibitor of NOS. These results suggest that the marine biomolecules are modulators of neuronal NOS.

## 598.12

**INHIBITION OF NEURONAL NITRIC OXIDE SYNTHASE BY 3,3'-IMINODIPROPIONITRILE *IN VIVO*.**

P.J.S. Vig, V. V. Vedanarayanan, D. Desaiiah, V.R. Janapala, M. Pande and S. H. Subramony\* Depts of Neurology and Pediatrics, Univ. of Miss. Med. Ctr. Jackson, MS. 39216.

3,3'-Iminodipropionitrile (IDPN) is a well known neurotoxin and affects peripheral and central nervous system. Nitric oxide has been described as a novel neurotransmitter and a retrograde modulator of synaptic transmission. Therefore, the present study was initiated to determine the *in vivo* effects of IDPN on neuronal nitric oxide synthase (nNOS) in rats treated with a single IP injection of 0.5, 1.0, 1.5 and 2.0g IDPN/kg body weight. The animals were sacrificed after 72 hrs. post-treatment. A dose-dependent and significant inhibition of nNOS was observed in the spinal cord and frontal cortex of IDPN treated rats. Whereas, in temporal cortex and brain stem the decrease of nNOS was not significant as compared to the control group. These data suggest that IDPN neurotoxicity is associated with the decrease in nNOS activity in discrete brain regions.

## 598.13

INDUCTION OF IMMUNOLOGIC NITRIC OXIDE SYNTHASE IN AIDS DEMENTIA. B. Wildemann<sup>1</sup>, M. Sasaski<sup>1</sup>, J.D. Glass<sup>1</sup>, J.C. McArthur<sup>1</sup>, V.I. Christov<sup>1</sup>, T.M. Dawson<sup>1,2</sup>, V.L. Dawson<sup>1,2</sup>. Departments of Neurology<sup>1</sup>, Neuroscience<sup>2</sup> and Physiology<sup>1</sup>, Johns Hopkins University School of Medicine, Baltimore, MD 21287

AIDS is often associated with multiple neurological abnormalities including deficits in cognitive and motor functions. Progressive dementia develops in 15-20% of adults with AIDS, and less severe cognitive impairment is even more frequent. Although evidence of productive HIV replication is nearly universal in the brain at autopsy, the pathogenesis of HIV dementia remains elusive. The principal targets for HIV replication within the CNS are macrophages and microglia, and infection is rarely identified within glial cells or neurons. The clinical severity of dementia correlates strongly with macrophage activation in autopsy tissue (J.D. Glass, unpublished). Thus, neuronal cell injury and death may occur through indirect mechanisms from the release of toxic substances from adjacent HIV-infected cells. HIV-1 and its associated coat proteins can induce immunologic nitric oxide synthase (iNOS) in *in vitro* culture systems and we have shown that activation of iNOS can cause neuronal injury. We therefore speculate that activation of iNOS may be linked to the development or progression of HIV dementia. Using semi-quantitative reverse transcriptase polymerase chain reaction (RT-PCR) for human iNOS mRNA expression we analyzed cortical brain tissue from HIV positive (AIDS) demented and non-demented patients, and seronegative controls and compared it to the expression for human  $\beta$ -actin. Human iNOS is markedly elevated in AIDS with severe dementia and modestly elevated in AIDS with mild dementia and in AIDS without dementia compared to seronegative controls. These data indicate that induction of iNOS may play a role in severe AIDS dementia.

## PRESYNAPTIC MECHANISMS IX

## 599.1

SYNAPTIC DEPRESSION INDUCED BY POST-SYNAPTIC ELEVATION OF CALCIUM AT DEVELOPING NEUROMUSCULAR JUNCTIONS. S. Cash<sup>1</sup>, M-m. Poo<sup>1</sup>, and R.S. Zucker<sup>2</sup>. <sup>1</sup>Dept. Biol. Sci., Columbia Univ., N.Y., N.Y. 10027, <sup>2</sup>Neurobiology Div., Univ. of Calif., Berkeley, CA. 94720

Previous studies have shown that persistent synaptic depression can be induced by brief repetitive activation of postsynaptic acetylcholine receptors in *Xenopus* nerve-muscle co-cultures. Increased postsynaptic  $Ca^{2+}$  may be required. Using photolysis of caged  $Ca^{2+}$  compounds loaded into the postsynaptic muscle cell we examined whether  $Ca^{2+}$  elevation is sufficient to induce synaptic depression. Postsynaptic myocytes were loaded with DM-Nitrophen (NP) or NITR-5 (N5) through a whole-cell patch pipette. Brief illumination of the myocyte resulted in a significant reduction ( $69 \pm 17\%$ , and  $55 \pm 13\%$ , for NP and N5 respectively, 5 min post-illumination) in the amplitude of evoked postsynaptic currents (EPCs). Similar illumination of unloaded myocytes was without significant effect. We also examined whether postsynaptic elevation of  $Ca^{2+}$  may result in depression of synapses made by the presynaptic neuron on another muscle cell. Myocytes loaded with N5 were manipulated close to or in direct contact with a neurite innervating another myocyte. Illumination of the loaded myocyte resulted in a significant reduction of EPC amplitudes in the innervated myocyte. The effect appeared to be larger if the loaded myocyte was in contact with the neurite ( $59 \pm 5\%$  in contact, vs.  $36 \pm 9\%$  not in contact). These results suggest that postsynaptic elevation of  $Ca^{2+}$  may induce depression mediated by a retrograde signal that propagates to adjacent presynaptic sites.

## 599.3

PRE- VS. POSTSYNAPTIC MODULATION OF CORTICAL SYNAPTIC ACTIVITY BY PHOSPHATASE 2B VS. PHOSPHATASES 1 AND 2A. G.D. Thomas\*, R.G. Victor, E. Marban, and B. O'Rourke. UT Southwestern Medical Center, Dallas, TX 75235 and Johns Hopkins University, Baltimore, MD 21205.

Reversible protein phosphorylation is thought to play an important regulatory role in synaptic neurotransmission. We recently have shown in cultured rat cortical neurons that inhibition of phosphatase (PP) 2B increases the frequency, but not the amplitude, of postsynaptic glutamatergic currents, implicating a presynaptic site of action for PP2B. To determine the role of other phosphatases in synaptic neurotransmission, we used whole-cell voltage clamp to record spontaneous glutamatergic currents in the presence of calyculin A ( $1 \mu M$  in bath solution), a membrane permeant inhibitor of PP1 and 2A which has no effect on PP2B. In 9 neurons, calyculin increased postsynaptic current amplitude ( $-155 \pm 16$  pA before vs.  $-211 \pm 32$  pA after,  $p < 0.05$ ) without changing current frequency. In these same neurons, subsequent inhibition of PP2B with cyclosporine A or FK506 had no further effect on current amplitude, but increased current frequency ( $0.80 \pm 0.06$  Hz before vs.  $1.03 \pm 0.07$  Hz after,  $p < 0.05$ ). The increased current amplitude seen with calyculin involved a postsynaptic mechanism, since the effect was reproduced by microcystin ( $10 \mu M$  in pipette solution,  $n=5$ ), which is a membrane impermeant inhibitor of PP1 and 2A. Thus, in rat cortical neurons, glutamatergic neurotransmission appears to be frequency-modulated through a presynaptic mechanism by PP2B, and amplitude-modulated through a postsynaptic mechanism by PP1 and 2A.

## 599.2

CAPACITANCE CHANGES CAN BE ELICITED BY ACTIVATION OF VOLTAGE-DEPENDENT  $Ca^{2+}$  CHANNELS OR NICOTINIC ACH RECEPTORS. A.B. Harkins\* and A.P. Fox. Dept. of Pharmacological and Physiological Sciences, Univ. of Chicago, Chicago, IL 60637.

$Ca^{2+}$ -dependent secretion may be regulated by multiple  $Ca^{2+}$  influx pathways. Differentiated PC-12 cells were voltage-clamped at  $-80$  mV in the whole-cell recording configuration. Membrane capacitance and conductance changes were measured simultaneously with solutions that optimized both  $Ca^{2+}$  currents and secretion. Activation of voltage-dependent  $Ca^{2+}$  channels with a depolarizing train of twenty voltage steps to  $20$  mV (each step,  $200$  ms duration and  $200$  ms interpulse) evoked an increase in membrane capacitance that corresponds to the secretion of  $\sim 220$  vesicles (Fig. A). Similarly, while the cell was voltage-clamped at  $-80$  mV, activation of nicotinic ACh receptors with a solution that contained  $100 \mu M$  ACh and  $1 \mu M$  atropine evoked an increase in membrane capacitance that corresponds to the secretion of  $\sim 140$  vesicles (Fig. B). These results suggest that  $Ca^{2+}$  influx through multiple pathways may each be important for secretion.

\*Mollard, P., et al. (1995) Biophysical J. Abstracts. 68:A395.

## 599.4

A PRESYNAPTIC MECHANISM FOR SHORT-TERM DEPRESSION B.A. Armitage\* and S.A. Siegelbaum. Columbia University, New York, New York, 10032.

Homosynaptic depression (HSD) is a steady decrease in the amplitude of the excitatory postsynaptic potential (EPSP) in response to successive stimuli. Previous work showed that HSD is due to a decrease in transmitter release (Castellucci & Kandel, 1974). We have used the glutaminergic synapse between an *Aplysia* pleural sensory neuron and the L7 motor neuron to study the mechanisms of induction and expression of HSD.

We first asked whether this induction occurs as a result of activity in the presynaptic cell, in the postsynaptic cell, or of simultaneous activity in both cells. Pressure applications of glutamate to the synapse ( $100$  msec,  $5X$ ,  $ISI=1$  min.) activated the postsynaptic cell but did not cause HSD ( $n=5$ ). Stimulation of the sensory cell in the presence of DNQX ( $8X$ ,  $ISI=1$  min.), which blocked the EPSP, produced HSD ( $n=5$ ). These two results show that presynaptic activity alone is necessary and sufficient to induce depression.

We next asked whether induction of HSD is due to calcium influx during the action potential or to vesicle fusion/transmitter release. In order to differentiate these two events, we used high osmotic solution to trigger release in the absence of calcium influx. Although this massive release transiently depleted vesicles, the synapse recovered from depletion within 5 minutes at which point the evoked release had not changed, indicating that vesicle fusion/transmitter release did not induce HSD. It is therefore likely that calcium influx during an action potential is necessary for induction of HSD.

We also investigated the mechanism of expression of HSD. We tested the hypothesis that the decrease in release was due to a decrease in calcium influx using fluorescence imaging and video microscopy. The calcium transient during a single action potential at presynaptic release sites was quantified. This transient showed no significant change ( $<5\%$ ) during HSD, (6 stim.,  $ISI=20$  sec,  $n=18$ ). The mechanism of expression of HSD must therefore involve a change in the release apparatus itself. An intriguing possibility is that this change is mediated by a calcium dependent enzyme, such as calcineurin.

## 599.5

**DEPOLARIZATION-EVOKED CALCIUM-DEPENDENT SECRETION OF TRANSMITTER FROM FIBROBLASTS.** H.-j. Song\* and M.-m. Poo, Dept. Biol. Sci., Columbia Univ., New York, NY 10027

Within minutes following loading of acetylcholine (ACh) into Swiss 3T3 fibroblasts with a whole-cell recording pipette, a brief (5 msec) step-depolarization of the fibroblast frequently evoked a pulse of ACh secretion, as revealed by the appearance of endplate current (EPC)-like events in a *Xenopus* myocyte manipulated into contact with the fibroblast. The failure rate of evoked ACh secretion decreased and the mean amplitude of EPC-like events increased with time, with a characteristic time of about 10 min. The evoked secretion appears to result from  $\text{Ca}^{2+}$ -dependent exocytosis of vesicles that had accumulated cytosolic ACh, since (1) it was blocked by extracellular application of either  $\text{Co}^{2+}$  (10 mM) or  $\text{Cd}^{2+}$  (1 mM), or by cytosolic loading of BAPTA (5 mM), a  $\text{Ca}^{2+}$  buffer with fast binding kinetics, (2) it was significantly reduced by the treatment of FCCP, an ionophore that dissipates the proton gradient across the vesicular membrane, and (3) it exhibited paired pulse facilitation in a  $\text{Ca}^{2+}$ -dependent manner. Spontaneous quantal ACh secretion also occurred in the absence of depolarization, resulting in miniature endplate current-like events in the myocyte of similar time course as that induced by the evoked release. These results suggest that the basic machinery for packaging and  $\text{Ca}^{2+}$ -dependent secretion of neurotransmitter exists in the fibroblast, and the exocytotic machinery at the nerve terminal differs from that in non-neuronal cells only in a quantitative manner.

## 599.7

**LACK OF SATURATION OF POSTSYNAPTIC RECEPTORS BY SINGLE TRANSMITTER PACKETS AT EXCITATORY HIPPOCAMPAL SYNAPSES.** G. Liu\* and R.W. Tsien, Dept. of Mol. Cell. Physiol., Stanford Univ., CA 94305.

It has often been suggested that a single packet of neurotransmitter is sufficient to saturate postsynaptic receptors at excitatory glutamatergic synapses between CNS neurons. To test this saturation hypothesis, we used the styryl dye FM1-43 to visualize individual synapses between cultured hippocampal neurons, and focally stimulated them with a puffer pipette while recording EPSCs under whole-cell voltage clamp (*Nature* in press). The amplitude distribution of single bouton EPSCs was broad and skewed, with a coefficient of variation (C.V.) averaging ~0.45. The wide variability of EPSC size at individual synapses would be inconsistent with the saturation hypothesis, unless one invokes some mechanism of trial-to-trial variation of postsynaptic responsiveness due to desensitization or concerted regulation (e.g. by phosphorylation). Such a scenario was not supported by analysis of single bouton EPSC amplitude as a function of latency from the immediately preceding synaptic event. Over a range of 20-140 ms, there was no significant correlation between EPSC amplitude and preceding interval. As a direct measure of postsynaptic variability, we recorded responses to focal iontophoretic application of glutamate at single synapses. The response to direct glutamate application (1 ms pulse) was very fast, with rise and decay characteristics approaching the kinetics of EPSCs themselves. The maximal peak inward current produced by a saturating glutamate application was about twice as big as the median size of spontaneous minis in the same neurons, suggesting that the concentration of endogenous release transmitter generally falls short of that needed to saturate all postsynaptic receptors. Furthermore, with submaximal glutamate application, responses averaging ~30 or ~70% of maximal showed little variability (CV ~ 0.1). This provides strong evidence that the large variation in the amplitude of single bouton EPSCs must originate from presynaptic factors.

**RETROGRADE SIGNALLING AND POSSIBLE AXONAL CONDUCTION BLOCK IN DEPOLARIZATION-INDUCED SUPPRESSION OF INHIBITION IN RAT HIPPOCAMPAL CELLS.** T.A. Pitler\*, B.E. Alger, J.J. Wagner, and R.A. Lenz, Dept. Physiol., Univ. Maryland Sch. Med., Baltimore, MD 21201.

Transient depolarization of pyramidal cells, via action potentials or brief voltage steps, suppresses spontaneous  $\text{GABA}_A$ ergic inhibitory postsynaptic currents (sIPSCs) for 1-2 min. Depolarization-induced suppression of inhibition (DSI) is induced by events in the postsynaptic cell (e.g., postsynaptic BAPTA inhibits DSI) but does not involve decreases in  $\text{GABA}_A$  receptor sensitivity assessed with iontophoretic GABA or mIPSC analysis. DSI could therefore involve depression of GABA via a retrograde mechanism.

We investigated DSI expression following 1-s, 60-mV voltage steps ( $V_H = -60$  mV) with whole-cell voltage clamp of pyramidal cells in the rat hippocampal slice. Normal mIPSC frequency is low, and an effect on mIPSCs could have been missed, so we increased mIPSC frequency by bath applying 15 mM KCl. Although numerous  $\text{Ca}^{2+}$ -sensitive mIPSCs appeared in high  $[\text{K}^+]_o$ , DSI was not seen, further arguing against a reduction of postsynaptic  $\text{GABA}_A$  receptor sensitivity in DSI. On the other hand, 50-100  $\mu\text{M}$  4-aminopyridine or 250 nM veratridine blocked DSI presynaptically. We observed an increase in failures of evoked monosynaptic IPSCs during DSI, which also supports a presynaptic locus of expression. Interestingly, paired-pulse depression of IPSCs, which is mediated by presynaptic processes, did not change during DSI, indicating that DSI expression may involve presynaptic axonal conduction block rather than alteration of the GABA release mechanism per se. Supported by NS30219 and NS22010 to B.E.A.

**IMAGING ZINC RELEASE FROM MOSSY FIBER TERMINALS.**

A.R. Kay\*, T. Budde, A. Minta†, J.A. White†, C.J. Frederickson\*. Biol. Sci., Univ. of Iowa, Iowa City, IA 52242, †Texas Fluorescence Laboratories, Austin, TX 78747, †Biomed. Engin., Boston Univ., Boston, MA 02215. \*Lab. for Neurobiol. Univ. of Texas at Dallas, Richardson, TX 75080.

Zinc is released synaptically by the stimulation of some excitatory pathways in the mammalian cortex. In spite of zinc's action upon a number of ion channels *in vitro*, the precise role of the zinc release remains uncertain. In addition, little is known about the conditions for zinc release. We have used a zinc specific probe TFLZn (TeFLabs) to image zinc release from mossy fiber terminals of live rat hippocampal slices.

Slices (350  $\mu\text{m}$ ) were loaded with TFLZn ( $\text{K}^+$  Salt, 0.25 mM, 1 hr.). The slices were imaged with an intensified CCD camera, the illumination being provided by a pulsed laser (337 nm, 3 ns). Mossy fibers terminals with high levels of TFLZn fluorescence could be clearly discerned in live slices and on mossy fiber boutons on acutely isolated CA3 neurons.

Electrical stimulation of the mossy fiber pathway led to a rapid decline in the mossy fiber fluorescence, that was blocked by TTX and low extracellular  $\text{Ca}^{2+}$ , consistent with the synaptic release of zinc. Zinc release could only be elicited by stimulating the mossy fiber pathway at a rate greater than 5 Hz. We present evidence that electrical stimulation triggers the replenishment of synaptic vesicles with zinc from an intracellular source.

## 599.8

**PRESYNAPTIC INHIBITION AT HIPPOCAMPAL SYNAPSES: DEVELOPMENT AND ROLE OF PRESYNAPTIC  $\text{Ca}^{2+}$  CHANNELS.** K.P. Scholz\* and Richard J. Miller, Dept. of Pharm. and Physiol. Sci. Univ. of Chicago, 60637.

Previous results revealed a developmental change in the presynaptic  $\text{Ca}^{2+}$  channels coupled to glutamate release in cultured rat hippocampal pyramidal neurons (J. Neurosci. in press). This preparation has now been used to examine whether such a switch in presynaptic  $\text{Ca}^{2+}$  channels is manifest as a change in the ability of the synapse to undergo presynaptic inhibition. Experiments entailed whole-cell voltage clamp recordings of monosynaptic or autaptic excitatory postsynaptic currents (EPSCs) in cultured pyramidal neurons. Application of a maximal concentration of the A1 adenosine receptor agonist  $\text{N}^6$ -cyclopentyladenosine (CPA) inhibited EPSCs by  $74 \pm 2\%$  in immature cells (<15 days in culture). The inhibition induced by CPA was significantly less in mature cells (>20 days in culture;  $47 \pm 3\%$ ). Thus, presynaptic inhibition became weaker during synapse maturation. This change correlates with the developmental reduction in the role of N-type  $\text{Ca}^{2+}$  channels in transmitter release reported earlier. A second series of experiments examined the role of N-type  $\text{Ca}^{2+}$  channels more directly. In mature cells, the application of the N-type  $\text{Ca}^{2+}$  channel blocker  $\omega$ -conotoxin GVIA ( $\omega$ -CTx GVIA; 2.5  $\mu\text{M}$ ) between two successive applications of CPA caused a reduction in the percentage inhibition induced by CPA. In contrast, application of the P/Q-type  $\text{Ca}^{2+}$  channel blocker  $\omega$ -Aga IVA (1  $\mu\text{M}$ ) led to an enhancement of the percentage inhibition induced by CPA (confirming results of Wu and Saggau, Neuron 12:1139). A third series of experiments examined the stoichiometry of N-type versus P/Q-type channels for triggering transmitter release under control conditions and during presynaptic inhibition. Under control conditions,  $\omega$ -CTx GVIA blocked EPSCs by  $41 \pm 4\%$ . During maximal inhibition by CPA, subsequent application of  $\omega$ -CTx GVIA blocked only  $19 \pm 8\%$  of the remaining EPSC. In contrast, the percentage block by  $\omega$ -Aga IVA was increased from  $47 \pm 5\%$  under control conditions to  $76 \pm 4\%$  in the presence of CPA. Together, the results indicate that CPA inhibited N-type but not P/Q-type  $\text{Ca}^{2+}$  channels at the presynaptic terminal.

**NOREPINEPHRINE HYPERPOLARIZES A SUBSET OF HIPPOCAMPAL INTERNEURONS LOCATED IN STRATUM LACUNOSUM-MOLECULARE.** D. E. Bergles\*, V. A. Doze, D. V. Madison, and S. J. Smith, Dept. of Molecular and Cellular Physiology, Beckman Center, Stanford University School of Medicine, Stanford, CA 94305-5426.

Norepinephrine (NE) has potent inhibitory effects in the *in vivo* hippocampus, a structure which contains a high density of noradrenergic terminals. We previously demonstrated that NE caused an increase in tonic inhibition in rat hippocampal slices, visible as an increase in the frequency of spontaneous IPSCs recorded from CA1 pyramidal cells. Whole-cell recordings from visualized interneurons in different strata of area CA1 confirmed that NE has a direct depolarizing action on most interneurons, which is primarily mediated by an  $\alpha_1$  adrenoceptor-dependent reduction in a resting  $\text{K}^+$  conductance.

We have now identified a subset of interneurons located in distal stratum radiatum and stratum lacunosum-moleculare (L-M) which are hyperpolarized (~8 mV) by NE (10  $\mu\text{M}$ ). This response appears to be mediated by an  $\alpha_2$  adrenoceptor, as it was mimicked by  $\alpha$ -methylnorepinephrine, and blocked by RX-821002. The hyperpolarization was associated with a large decrease (> 25%) in input resistance, and an outward current (~25 pA) at the resting potential. This current reversed at  $-E_K$  and was unaffected by changes in  $[\text{Cl}^-]_o$ , suggesting that the NE-induced hyperpolarization is mediated by an increase in  $\text{K}^+$  conductance. These interneurons had electrophysiological and morphological properties distinct from those which were depolarized by NE, with axonal ramifications found primarily in stratum L-M. The amplitude of isolated late-IPSPs evoked through distal L-M stimulation was reduced in CA1 pyramidal cells by  $\alpha$  adrenoceptor agonists, suggesting that these interneurons may contribute to the activation of  $\text{GABA}_B$  receptors on pyramidal cells. These results suggest an important role for NE in modulating inhibitory circuits in the hippocampus through its divergent actions on inhibitory interneurons.

**PRESYNAPTIC INHIBITION OF EVOKED NEUROTRANSMISSION BY REDOX CONGENERS OF NITRIC OXIDE.** Zhuo-Hua Pan\*, Michael M. Segal, and Stuart A. Lipton. Dept. of Neurology, Children's Hospital and Program in Neuroscience, Harvard Medical School, Boston, MA 02115.

Nitric oxide (NO<sup>•</sup>) reacts only very slowly with thiol (-SH) groups under physiological conditions, while other endogenous redox-related species of the NO group, such as nitrosonium ion (NO<sup>+</sup>, with one less electron than NO<sup>•</sup>), react rapidly with thiol and thus can regulate protein function (Lipton et al., *Nature* 1993). Here, we found that nitroso-compounds, such as nitroglycerin (NTG) and S-nitrosocysteine (75-1000 μM each), acting as nitrosonium donors, decreased the efficacy of evoked neurotransmission 20-80% in a dose-dependent manner by a presynaptic, thiol-related mechanism (n = 26). Nitrosonium donors inhibited both excitatory and inhibitory synaptic activity in cortical neuronal cultures recorded with patch electrodes in the absence of TTX. In contrast, NO<sup>•</sup> donors, such as DEA/NO (≤1000 μM), did not inhibit synaptic activity. The NO moiety may exert its effects by stimulating guanylate cyclase; however, the addition of 1 mM 8-bromo-cGMP to the extracellular solution did not decrease synaptic activity in this preparation. Recording evoked autaptic excitatory postsynaptic currents from isolated hippocampal neurons in the presence of TTX (Segal, *J. Neurophysiol.* 1991), we found similar inhibitory effects of nitrosonium donors (n = 6). In contrast, spontaneous miniature excitatory postsynaptic currents under these conditions were enhanced 42% by NTG in perforated patch recordings (P < 0.001, n = 4). These findings may help explain otherwise puzzling observations that the NO moiety can either increase, decrease, or have no net effect on synaptic activity.

**FUNCTIONAL DIFFERENTIATION OF PRESYNAPTIC COMPARTMENT DURING SYNAPTOGENESIS IN CULTURED HIPPOCAMPAL NEURONS** S. Coco, C. Verderio, M. Parenti, G. Fumagalli and M. Matteoli. CNR Center of Cytoparmacology and \*Dept. of Med. Pharmacol. Univ. of Milano, via Vanvitelli 32, 20129 Milano, Italy; and \*Dept. of Pharmacol. Univ. of Verona, Italy.

Hippocampal neurons maintained in primary culture recycle synaptic vesicles (Matteoli et al., 1992) and express functional glutamate receptors (Verderio et al., 1994) since very early stages of neuronal development. The establishment of neuronal polarity and the formation of synaptic contacts is accompanied by a regional redistribution of presynaptic and postsynaptic components. It has been found recently that mechanisms for calcium-dependent recycling of synaptic vesicles (Kraszewski et al., 1995) and glutamate release (Verderio et al., 1995) are activated already before synaptogenesis. However, formation of synaptic contacts coincides with a change in the subtype of calcium channels primarily involved in mediating neurotransmitter release, ω-CTx-GVIA sensitive channels being primarily involved in mediating glutamate release at early developmental stages and ω-Aga-IVA sensitive channels playing a prominent role in controlling neurotransmitter secretion at mature synaptic contacts. Moreover, formation of synaptic contacts coincides with the activation of a low-affinity calcium sensor for exocytosis. These results indicate that the secretory and transducing neuronal machinery is already functional before synaptogenesis. On the other hand, specific components of the exocytotic machinery appear to be selectively activated only after the maturation of synaptic contacts.

## GENESIS OF NEURONS AND GLIA V

600.1

**IDENTIFICATION OF CIS-ELEMENTS IN THE Tal PROMOTER RESPONSIBLE FOR NEURON-SPECIFIC GENE EXPRESSION IN TRANSGENIC MICE** D. Rogers\*, A. Gloster, N. Laferriere\*, D. Brown\*, A. Peterson\*, F.D. Miller\*, + Dept. of Biology, University of Ottawa; # Dept. of Molecular Oncology, Royal Victoria Hospital, Montreal; Centre For Neuronal Survival, Montreal Neurological Institute, Montreal, Canada, H3A 2B4

The rat Tal gene belongs to the α-tubulin gene family. Expression of the Tal gene is restricted to neurons. In the developing embryo, Tal is initially expressed in populations of cells undergoing neuronal commitment and differentiation, and is maintained during the period of elaboration of neuronal processes. A 1.1kb stretch of the Tal 5' upstream promoter sequence is sufficient to confer this pattern of expression to a lacZ reporter gene in transgenic mice (Gloster et al 1994.) In vitro, we have used the P19 embryonal carcinoma (EC) cell line to assay promoter activity. This same 1.1kb promoter construct is turned on in stably transfected P19 EC cells coincident with neuronal differentiation and neurite extension. Deletion of a specific 66bp region from this 1.1kb fragment altered the activity of the promoter both in vivo and in vitro. In differentiated P19 EC cells, the activity of the mutant construct preceded the activity of the wild type construct, and the activity of the mutant construct was not restricted to neurons. In transgenic mice, expression in both the developing embryo and the adult was perturbed in a manner consistent with the P19 EC cell data. Thus, the deleted 66bp sequence contains one or more functional cis elements, which are involved in specification of gene expression in early developing neurons.

**REGULATORY ELEMENTS IN THE MURINE NEUROFILAMENT LIGHT CHAIN GENE THAT ARE ACTIVE DURING DEVELOPMENT IN A BINARY TRANSGENIC MOUSE SYSTEM.** P. J. Yaworsky\* and C. Kappen, S.C. Johnson Med. Res. Center, Mayo Clinic, 13400 E. Shea Blvd., Scottsdale, AZ 85259.

We report here on the developmental activity of regulatory elements that direct transgene expression specifically to neurons in our binary transgenic mouse system. In this system, the transgene of interest (transresponder) is transcriptionally active only in the presence of the viral transactivator VP16. The transactivator is supplied by a second strain of transgenic mice (transactivator) harboring the VP16 gene under control of specific regulatory elements. Using a LacZ transresponder gene, we here show transactivation of LacZ specifically in developing neurons.

To direct VP16 expression to differentiating neurons, we have initially used 1.7 kb upstream sequence of the murine neurofilament light chain (NF-L) gene promoter. Here we report that this fragment reflects the activity of the endogenous NF-L promoter only at certain stages of development. Thus, additional elements appear to control NF-L gene expression. Based on the evolutionary conservation to the intermediate filament gene nestin and on published reports implicating intragenic sequences in tissue-specific expression, we have isolated intron sequences from the murine NF-L gene. These putative regulatory elements were linked to the VP16 gene and injected into transgenic eggs harboring a LacZ transresponder gene. At different stages of development, embryos were isolated, screened for the presence of the transgene, and stained for β-galactosidase activity. We will present the results of our characterization of the activity of the NF-gene promoter as well as our progress in identifying additional neuron-specific regulatory elements in the NF-L gene.

Our transactivators with neurons-specific VP16 expression will allow us to target transresponder gene expression specifically to the developing nervous system. These transgenic mice will be useful to study the function of various transgenes in neuronal development.

600.3

**EXPRESSION OF mRNA FOR GDNF AND THE NEUROTROPHINS, NGF, BDNF AND NT-3, BY ADULT HUMAN ASTROCYTES IN CULTURE** G. Moretto<sup>1</sup>, B. Kirschenbaum<sup>2</sup> and S. A. Goldman<sup>2</sup> Depts. of <sup>1</sup>Neurol. Science, Univ. of Verona, Italy, and <sup>2</sup>Neurology, Cornell Univ. Medical Col., NYC, 10021.

The adult mammalian forebrain harbors neuronal precursor cells throughout an extensive area of the subependymal zone (SZ). However, in vivo neurogenesis is limited to a few sites in the adult brain, such as the olfactory bulb. The limited occurrence of neurogenesis in vivo contrasts to the wide distribution of SZ neuronal precursor cells found in vitro, in human as well as rat brain (*Cereb. Cortex* 6:576-89, 1994). Neurons arising from these cells express *trkB*, and their survival is specifically promoted by BDNF (*PNAS* 92:210-4, 1995). This suggests that the permissiveness of adult brain to neurogenesis might depend in part upon the local availability of post-mitotic trophic support in vivo. In fetal rats and humans, the production of BDNF has been noted by astrocytes as well as by neurons (*J. Neurop. Exp. Neurol.* 53:78-85, 1994). We thus asked whether adult human astrocytes could also express BDNF. We further asked if adult glia could express the neurotrophin (NT) family members NGF and NT-3, and 2 other neurotrophic agents, CNTF and GDNF. We used RT-PCR to detect their mRNAs in highly enriched, multipassaged and neuron-free cultures of astrocytes, derived from fresh resections of adult human temporal cortex. We found that mRNA for NGF, BDNF and NT-3 were each expressed in these cultures, appearing as PCR products of 189, 296 and 176 base pairs, respectively. Stimulation for 3 d with 1 mM dibutyryl-cAMP, with resultant astrocytic stellation, generally up-regulated the mRNA of each NT. GDNF mRNA was also detected, as possible splice variants of 197 and 272 bp, but at lower levels than the NTs; GDNF was also up-regulated by dbcAMP. The astrocytes never expressed CNTF mRNA, despite high levels of G6PDH mRNA, a positive control, under the conditions. Thus, adult human cortical astrocytes can express mRNAs for members of the NT family, including NGF, BDNF and NT-3, as well as for GDNF.

**SPATIO-TEMPORALLY DIFFERENTIAL EXPRESSION AND KINASE-INDUCIBILITY OF GENE FOR THREE SPECIES OF FATTY ACID BINDING PROTEINS IN DEVELOPING AND MATURE RAT BRAIN.** X. Oyada\*, and H. Kondo. Dept. of Anatomy, Tohoku Univ. Sch. of Med., Sendai 980, Japan.

By in situ hybridization, the expression signals for heart type (H-) FABP mRNA in the brain were under the detection levels at embryonic stages and they gradually increased after birth and localized in neuronal cells in the gray matters including the cerebral cortex, thalamus and cerebellar granule cell layer at postnatal stages. In contrast, brain type (B-) and cutaneous type (C-) FABP mRNA levels were very high at embryonic stages and decreased dramatically as the postnatal development proceeded. B- and C-FABP mRNA were expressed intensely in the ventricular germinal zones, whereas the cerebellar external granule cells expressed C-FABP mRNA intensely but not B-FABP mRNA. B-FABP mRNAs was expressed in glial cells, such as cells in the olfactory nerve fiber layer and cerebellar medulla and radial glial cells in the Purkinje cell layer at embryonic and early postnatal stages, while C-FABP mRNA was detected in both glial and neuronal cells. In addition, while the expression of B- and C-FABP mRNAs was markedly elevated in the hippocampus, corpus callosum and cerebral cortex 48 hr after KA treatment, no such expressional change was observed for H-FABP mRNA. These differential expression patterns suggest that H-, B- and C-FABP may play different roles in neuronal and glial cells during their proliferation, differentiation and reaction to pathological lesions.

## DEVELOPMENTAL MECHANISMS RESPONSIBLE FOR STRAIN DIFFERENCES IN THE RETINAL GANGLION CELL POPULATION

R.C. Strom\*, R.W. Williams, and D. Goldowitz. Department of Anatomy and Neurobiology, Univ. Tennessee, Memphis, TN 38126

We have found substantial strain variation in the retinal ganglion cell population among inbred strains of mice. These differences may be caused by variation in the magnitude of cell production or the severity of cell death. To assess mechanisms producing these differences we estimated the number of ganglion cells in several strains of mice at birth (P0), before the onset of naturally occurring ganglion cell loss in this species (Williams et al., 1990, Exp Brain Res 82:393). Therefore, the population of cells at P0 provides a good estimate of total ganglion cell production. The cell population was estimated from electron microscopic analysis of axons in optic nerve cross-sections. Four strains of mice have been examined: two with high populations at maturity (BALB/c:  $64,400 \pm 2,200$ ; DBA/2:  $62,400 \pm 1,100$ ) and two with low populations (LP:  $52,200 \pm 1,900$ ; C57BL/6:  $53,900 \pm 1,400$ ) at maturity. At birth, one low strain, C57BL/6, has a population of  $175,000 \pm 12,000$  cells ( $n=10$ ). A high strain, BALB/c, has  $237,000 \pm 17,000$  cells ( $n=4$ ). The increased cell production in BALB/c relative to C57BL/6 can account for the adult differences. The decrease in the population from P0 to maturity in both strains amounts to 70%. However, LP neonates have an average of  $210,000 \pm 22,000$  cells ( $n=4$ ), well above the neonatal average of the other low strain. In the LP strain, 75% of the neonatal population dies. Preliminary analysis of the DBA/2 strain suggests that only 60% of the neonatal population is eliminated. These results indicate that strain differences in the ganglion cell population at maturity are due both to variation in ganglion cell production and death.

## 600.7

THE SEQUENCE OF EXPRESSION OF THE  $\alpha 7$  NICOTINIC ACETYLCHOLINE RECEPTOR SUBUNIT IN THE EMBRYONIC CHICK BRAIN. W.M. Kaneko\* and H.J. Karten University of California, San Diego, La Jolla, CA 92093.

The neuronal nicotinic acetylcholine receptor (nAChR) is composed of two  $\alpha$  (ligand binding) and three  $\beta$  (structural) subunits that assemble to form an ion channel. Nine  $\alpha$  and three  $\beta$  subunits have been identified. Therefore, depending on how the different  $\alpha$ s and  $\beta$ s are combined, there is potentially a large number of nAChR subtypes that may differ in their ligand affinity and physiological characteristics. Initial attempts to identify cholinergic cells in the brain used  $\alpha$ -bungarotoxin ( $\alpha$ Bgt), a protein from snake toxin, which binds with high affinity to muscle nAChRs. It was first believed that the high affinity  $\alpha$ Bgt binding in the brain represented all functional nAChRs. However, more recently, it has been demonstrated that there are neuronal nAChRs that do not bind  $\alpha$ Bgt and that  $\alpha$ Bgt binds selectively to nAChRs consisting of  $\alpha 7$  and/or  $\alpha 8$  subunits. The  $\alpha 7$  subunit is the major  $\alpha$ Bgt binding protein in the chick brain and has been found to form functional nAChRs. In the present study, the mouse monoclonal antibody 306 (kindly provided by Jon Lindstrom) was used to detect  $\alpha 7$  subunits in the developing brain of chick embryos from embryonic day 4 (E4) to hatching (E21). The purpose of this study was to determine the timing of the first appearance of  $\alpha 7$  subunits in various brain areas. A high density of cells containing  $\alpha 7$  subunits were detected in the nucleus isthmi, pars magnocellularis as early as E12. Alpha-7 immunoreactive cells in other structures did not appear until later during development: in the nucleus spiriformis lateralis at E13; in the nucleus isthmi, pars parvocellularis at E14; in the central nucleus of the inferior colliculus and stratum griseum centrale at E16. The present study demonstrates that  $\alpha 7$  subunits are expressed in various brain regions at different times during embryogenesis. These studies will characterize the normal developmental pattern of nAChRs and aid in determining the effects of early exposure to nicotine and various cholinergic ligands. Supported by NIH EY 06890 (HJK) and NIH AG 00216 (FHGage).

## 600.9

## ONTOGENY OF MITOCHONDRIAL BENZODIAZEPINE RECEPTOR AND ITS PUTATIVE ENDOGENOUS LIGAND DIAZEPAM BINDING INHIBITOR IN RAT BRAIN AND PERIPHERAL TISSUES. M. Kolmer, M. Pelto-Huikko and H. Alho\* Laboratory of Neurobiology, Tampere Univ. Medical School, Finland.

A recognition site for benzodiazepines (BD) structurally different from that linked to the "central type" BD-receptor has been designated as mitochondrial BD-receptor (MBR), on the basis of its localization. One putative endogenous ligand for MBR is the diazepam binding inhibitor (DBI) peptide. It has been suggested that this peptide is involved in the regulation of steroidogenesis, metabolism of acyl-CoA, modulation of GABA-A receptor and several other biological processes.

The expression of MBR and DBI was studied during rat embryonic development by immunohistochemistry and *in situ* hybridization. Both methods demonstrated that the expression of DBI in brain, dorsal root and trigeminal ganglion was detectable as early as E13-14. In brain DBI expression was most abundant in ependymal cells. The staining intensity of DBI increased during gestation. In the peripheral tissues, such as kidney, pancreas, heart, skin, thymus, intestine, adrenal gland, lung, salivary gland and thyroid gland, the expression of DBI occurred at later embryonic stages, being detectable after E16-19; DBI was present at E14 only in liver. Simultaneous expression of DBI and MBR occurred e.g. in brown adipose tissue and liver. In nervous system DBI is expressed in early embryonic life, suggesting that it may play an important role during ontogenesis.

## 600.6

MESENCEPHALIC PROGENITOR CELLS: ENDOGENOUS AMINO ACID PROFILE DURING *IN VITRO* DIFFERENTIATION. C.J. Paño\*, E. Bazán, M.A. López-Toledano, M.A. Mena, R. Martín del Río and A.S. Herranz. Depto. de Investigación, Hospital Ramón y Cajal, INSALUD, Madrid, SPAIN.

Multipotential progenitor cells obtained from embryonic or adult CNS can be grown as spheric aggregates (neurospheres) in medium containing EGF. Plating these cells on an adhesive substrate induces phenotypic differentiation, thus allowing us to characterize this process. Endogenous amino acids (AAs) can play a role as neurotransmitters, metabolic precursors or even as differentiating agents. Here we correlate the presence of the different cell types with their content of free AAs. Neurospheres, obtained from dissociated E15 rat embryo ventral mesencephalon, were grown in DMEM:F-12 (1:1) supplemented with glucose, N2 components and 20 ng/ml EGF for a minimum of 5 passages, and then plated on poly-L-ornithine coated dishes or coverslips. Immunocytochemical and biochemical analyses were performed at 2 hours, 1, 3, 6, 10 or 20 days post plating (dpp). AA contents were analyzed by HPLC (OPA-precolum, fluorimetric detection). During the initial 6 dpp, the cultures contained mostly undifferentiated cells (nestin<sup>+</sup>), and a minority of oligodendrocytes (O1<sup>+</sup>); neurons (8-tubulin III<sup>+</sup>) peaked at 10 dpp, and astrocytes (GFAP<sup>+</sup>) were majority at 20 dpp. The levels of all AA underwent a sharp decrease after cell plating. Most of them increased gradually during the following 10 or 20 days. Gln was the majority AA at 20 dpp (more than 300  $\mu$ mol/mg cell protein). Taurine also accumulated in cells, peaking (125  $\mu$ mol/mg protein) at 10 dpp; taurine is probably synthesized *de novo*, since it was not included in the feeding medium. GABA is present in small quantities in neurospheres and disappears after plating, but its synthesis is active between 10 and 20 dpp. The serotonine precursor Trp is only detectable at 10 dpp. Putative neurotransmitters Glu and Asp reach high levels by 10 dpp. The time course of appearance of some AAs agree with their role as neurotransmitters or suggest their implication in CNS differentiation processes.

## 600.8

## CHANGES IN THE EXPRESSION OF GAP JUNCTIONS DURING NEURONAL DIFFERENTIATION OF NTERA-2 CLONAL HUMAN EMBRYONAL CARCINOMA CELLS. Bani-Yaghoob, M., J.F. Bechberger, R.R. Shivers\* and C.C.G. Naus. Department of Anatomy, The University of Western Ontario, London, Ontario, Canada N6A 5C1

Gap junctions are intercellular membrane channels which provide for the transfer of low molecular weight molecules and ions between the cytoplasm of adjacent cells. In the central nervous system, gap junctions have been detected in a variety of cell types including neurons, astrocytes and oligodendrocytes. During development, there is extensive regulation of the spatial and temporal expression of gap junctions which controls differentiation and growth. The function of gap junctions in neurons and other neural cell types can be investigated by using a human teratocarcinoma cell line, NTERA-2/clone D1 (NT2), which exhibits properties characteristic of a committed neuronal precursor at an early stage of development. NT2 cells can differentiate into postmitotic CNS neurons (NT2-N) upon addition of retinoic acid (RA). For differentiation studies, cells were treated with  $1 \times 10^{-5}$  M RA for 4 weeks and then incubated in mitotic inhibitors for 3 weeks. NT2 cells expressed connexin 43 when they were not treated with RA and within their first 3 weeks of RA-treatment. The level of connexin 43 immunoreactivity decreased during RA-treatment. There was no connexin 43 immunoreactivity in NT2-N cells. The microtubule associated proteins (MAP2 and MAP5) immunoreactivity started at the end of first week of RA-treatment and became much stronger in the following stages. The differentiated NT2-N cells showed a strong immunoreactivity for MAP2 and MAP5 but they were negative for glial fibrillary acidic proteins (GFAP). The dye-coupling techniques showed that the gap junctional communication in NT2 cells decreased when the cells were treated with RA for 10 days. (Supported by MFC of Canada, CO3N)

## 600.10

## EXPRESSION OF TRYPTAMINE IN RAT BRAIN EMBRYOS

Tagliaferro P., Canessa O., López E.M., Ramos A.J., Pecci Saavedra J. and Brusco A.\* Instituto de Biología Celular y Neurociencias "Prof. Eduardo De Robertis" Facultad de Medicina. UBA. Paraguay 2155. (1121) Buenos Aires. Argentina.

Tryptamine (T) is present in the rat central nervous system in very low concentration. The maximum of its brain concentration is in the first postnatal day. In a previous work we have demonstrated the localization of tryptamine in the adult rat brain (Brusco et al., 1994, NeuroReport 5).

In this work we have studied the immunocytochemical expression of T in brains of rat embryos at different developmental stages. Rat embryos from E12 to E20 obtained by caesarea operation (Ei. day i of embryo development) and newborns (within the first day of life) were fixed in 5% glutaraldehyde by intracardiac perfusion or by immersion of the brains in the fixative solution. After 2 hs of fixation the brains were immersed in 5% saccharose and then embedded in 30% saccharose previous freezing at -60 °C. Serial cryostat sections of 15-20  $\mu$ m thick were mounted in gelatinated slides. The immunocytochemical peroxidase anti-peroxidase reaction was carried out using anti-T as the primary antibody.

The results showed that T is present in the rat brain starting the 14 th day of embryonic development. The localization of T is restricted to neurons and fibers. A network of thin tryptaminergic fibers in the ependymal epithelium of the aqueduct was found in the ventral zone.

This work was supported by grants of CONICET and UBACYT, Argentina.

## 600.11

PRODUCTION AND DIAGNOSTIC VALIDATION OF TIMED PREGNANCIES IN THE BRAZILIAN OPOSSUM. J. Songa\*, S. Di J. Iqbal, K. Miles, E. Riedesel and C. D. Jacobson. Departments of Veterinary Anatomy and Veterinary Clinical Sciences and the Neuroscience Program, Iowa State University, Ames, Iowa 50011

The Brazilian Opossum, *Monodelphis domestica*, is a small marsupial whose young are born in an extremely immature state with a protracted period of development. Studies utilizing postnatal administration of tritiated thymidine and Bromodeoxyuridine immunohistochemistry have indicated that morphogenesis and neurogenesis of the forebrain continue during the early postnatal life of the opossum. However, these studies also indicate that the hindbrain is significantly more developed at birth than that of the forebrain. In order to determine the patterns of neuronal differentiation, neurogenesis and patterns of connectivity during early development it is necessary to look at hindbrain development during the prenatal period. Thus, we have devised a technique to produce timed pregnancies. This procedure will be described. Further, in order to verify the time of conception, we have devised a scheme to accurately characterize the sexual behaviors of adult male and female opossums. These data will also be presented. Once a timed pregnancy has occurred, utilizing diagnostic ultrasound evaluation on day 12 of gestation, we have successfully demonstrated the presence of multiple amniotic sacs in the gravid uterus. This procedure has allowed the creation of a protocol to administer bromodeoxyuridine to the pregnant female and thereby determine the neurogenesis of hindbrain structures. Preliminary results of this technique will be demonstrated. In summary, we have successfully created a technique to accurately determine the time of conception in *Monodelphis*. This technique will allow studies to determine the complete developmental history of hindbrain structures. In combination, with the ability to study development of forebrain structures postnatally, studies can now be conducted to relate the neurogenesis, morphogenesis and connectivity patterns of structures in the forebrain and hindbrain.

## 600.12

POSTLARVAL NEUROGENESIS IN THE OLFACTORY MIDBRAIN OF A DECAPOD CRUSTACEAN. M. Schmidt<sup>1</sup>. Institut für Biologie, TU Berlin, 10587 Berlin, Germany.

After a short larval development decapod crustaceans obtain adult morphology and by successive molts grow in size continuously up to 1000 times throughout their entire, often very long life-span. This poses the question by which adaptive mechanisms the CNS copes with such a dramatic growth of body size, specifically whether neurogenesis may be involved. To address this question, the number of olfactory projection neurons was quantified by two independent measures in the brains of shore crabs, *Carcinus maenas*, ranging from 100 mg to 50 g in weight. Firstly, the number of somata, which form a compact and isolated cluster (lateral cluster), was determined by dividing the total cluster volume obtained from serial sections by the average soma volume ( $n \geq 100$ ) measured with an image analysis system (SIS). Secondly, the number of axons arising from the olfactory projection neurons was counted on TEM-micrographs of cross-sections through the easily identifiable olfactory globular tract which is constituted by these extremely thin axons (diameter  $\leq 0.1 \mu\text{m}$ ). Both measures yielded very similar results. From the smallest to the largest animal the number of olfactory projection neurons doubled (from 15,000 to 30,000 in one hemibrain) and the increase in neuron number was continuous over the entire size range. In brains of small crabs, several somata in the lateral cluster showed nuclei in different stages of mitosis (metaphase, anaphase), providing direct evidence for ongoing cell divisions. Together these data demonstrate that among olfactory projection neurons of the shore crab neurogenesis prevails throughout the entire life-span. Future investigations will show whether neurogenesis in the decapod brain is a common feature or a specialization of the central olfactory system. Supported by DFG grant Schm 738/4-1.

## CELL DIFFERENTIATION AND MIGRATION VI

## 601.1

HUMAN LIGANDS OF THE NOTCH RECEPTOR G. E. Gray\*, R. Mann\*, D. Henrique\*, D. Ish-Horowitz\*, and S. Artavanis-Tsakonas# Dept. of Cell Biology and HHMI, Yale University Medical School, New Haven, CT#, Oxford University, Oxford, UK\*.

Intercellular signaling through the Notch pathway affects cell-fate decisions in several *Drosophila* tissues, including the CNS. In vertebrates, a set of studies by a number of different groups has established the importance of Notch signaling in normal development and in cell-fate decisions, in the nervous system and elsewhere. To study the intercellular interactions that regulate vertebrate Notch activity, we have cloned and sequenced two candidate human Notch ligands. These genes code for putative transmembrane proteins bearing extracellular EGF repeats, including the cryptic EGF repeat (the "DSL domain") that has been found in all identified ligands of Notch and its homologues. The number and organization of EGF repeats in these ligands suggests they are homologues of the *Drosophila* Notch ligand *Serrate*, which functions in wing development. Both ligands have substantial similarity to Jagged, the rat Notch ligand recently identified by Lindsell et al. (1995, Cell, 909-917). We are currently investigating the expression patterns of these ligands in normal developing tissues and in human cancers.

Supported in part by American Cancer Society grant #PF-4036 to GEG.

## 601.2

A POU TRANSCRIPTION FACTOR, BRN-2, IS REQUIRED FOR THE EARLY DEVELOPMENT OF HYPOTHALAMIC NEUROSECRETORY NEURONS. H. Kawano<sup>1</sup>, K. Kawamura<sup>1\*</sup>, S. Nakai<sup>2</sup>, T. Noda<sup>2</sup> <sup>1</sup>Dept of Anatomy, Sch. of Med., Keio Univ., Tokyo 160 and <sup>2</sup>Dept. of Cell Biology, Cancer Institute, Tokyo 170, Japan

The POU gene family is a large group of transcription factors sharing a conserved bipartite DNA-binding domain. They have been shown to serve as developmental transactivators of genes that define and maintain specific cell phenotypes. Brn-2 is a member of POU transcription factors and is expressed in the nervous system in a region-specific manner. In the present study, we created a null mutation in mouse Brn-2 gene by homologous recombination and analyzed the phenotypes of Brn-2-deficient mice. All homozygous mice died in a few days after birth and histological examination of the central nervous system of neonatal homozygotes revealed severe defects in the hypothalamo-hypophysial neuroendocrine system. By immunohistochemistry, vasopressin neurons in the paraventricular and supraoptic nuclei, as well as TRH and CRF neurons in the paraventricular nucleus, and somatostatin neurons in the periventricular area were not found in the homozygotes. Hypothalamic magnocellular neurosecretory neurons immunoreactive for spot 35, a calcium-binding protein, were detected from embryonic day 11 (E11) in the wild-type. In homozygotes, these neurons were gradually eliminated between E12 and E14 during the migration.

Since the paraventricular and supraoptic nuclei specifically express Brn-2 mRNA signals in normal animals, Brn-2 is likely to transactivate the genes prerequisite to survival of certain hypothalamic neurosecretory neurons in the early developmental stage.

## 601.3

DEVELOPMENTAL EXPRESSION OF SCIP AND KROX-20 IN RODENT SCIATIC NERVE: IMPLICATIONS FOR THE TRANSCRIPTIONAL CONTROL OF MYELIN GENE EXPRESSION.

Todd S. Zorick and Greg Lemke\*. Molecular Neurobiology Laboratory, The Salk Institute for Biological Studies, 10010 N. Torrey Pines Rd., La Jolla, CA 92037.

Preliminary data have indicated that non-myelinating Schwann cells are differentiated from myelinating Schwann cells by only a few transcription factors that may differ between the two states; in particular, myelinating Schwann cells seem to express SCIP and Krox-20, while non-myelinating Schwann cells express Pax-3. We report here a study of the developmental expression of SCIP and Krox-20 in Schwann cells of Rat sciatic nerves from the time of birth to adulthood. SCIP and Krox-20 both are detectable by immunohistochemistry at postnatal day 2, and are expressed at a high level in virtually every myelinating Schwann cell nucleus by day 4. Krox-20 expression is then maintained in myelinating Schwann cell nuclei, whereas the number of nuclei expressing SCIP declines exponentially, with less than 1% of myelinating Schwann cell nuclei being SCIP+ by postnatal day 13. SCIP and Krox-20 expression is inversely related to the expression of the p75 low-affinity NGF receptor, a marker of immature and nonmyelinating Schwann cells, and coincident with myelination and the high level of expression of myelin gene products, such as P<sub>0</sub>. The results of the present study lead to further questions about the possible interaction between SCIP and Krox-20 in the elaboration of myelin in peripheral nerve, and serve to precisely define the spatial and temporal expression of these transcription factors.

## 601.4

CHARACTERIZATION OF THE PAX 2 AND EN-1 EXPRESSING CELLS IN THE EMBRYONIC CHICK SPINAL CORD. J. D. Burrill\*, S. E. Koester, and M. Goulding, MNL-G, Salk Institute, La Jolla, CA. 92037

To identify the cells that express the transcription factors Pax 2 and En-1 wholemounts or vibratome sections of st 15-21 chick neural tubes were labeled with antibodies against Pax 2 and En-1. Pax 2 and En-1 are both expressed in a band of cells in the intermediate third of the spinal cord. Pax 2+ cells were located between the dorsal root entry and the ventral root exit zones. En-1+ cells were located immediately dorsal to the ventral root exit zone, corresponding to the ventral third of the Pax 2+ band.

We have used two approaches to morphologically identify the Pax 2+ and En-1+ cells. First, we have double labeled neural tubes with either the antibody against Pax 2 or En-1 and an antibody against neuron specific  $\beta$ -tubulin (TUJ1). Second, we have used a replication competent retroviral vector, RCAS(A), to express a fusion of the microtubule associated protein tau and the myc epitope in a random subset of cells. The fusion protein is transported in the processes of infected cells enabling their morphological characterization by staining with an antibody against myc. These embryos were then labeled with an antibody against either Pax 2 or En-1.

Both Pax 2+ and En-1+ cells extend a process ventrally toward the floor plate. In most cases, the process of Pax 2+ cells continues ventrally past the lateral longitudinal fasciculus (LLF) toward the midline, but occasionally it entered the ipsilateral LLF and turned rostrally. Dorsal commissural neurons and association interneurons were never Pax 2+ or En-1+. Examination of caudal portions of neural tube revealed that some neuroepithelial shaped cells were Pax 2+ or En-1+, suggesting that Pax 2 and En-1 are expressed in cells before differentiation, and therefore may play a role in controlling cell fate.

## 601.5

EXPRESSION OF ETS1 GENE IN THE HYPOTHALAMUS AND PITUITARY DURING RAT DEVELOPMENT. F.M. Laurent-Huck\*, C. Egles, P. Kienlen, C. Nelson, M.E. Stoeckel and J.M. Félix. IPCB, Univ. Louis Pasteur, 67084 Strasbourg, France.

The family of "ets" genes is coding for transcription factors; these proteins contain a conserved DNA binding domain: the Ets binding domain. Ets-1 is a member of this family, essentially expressed in the thymus, but also in endothelial cells during vessel formation (angiogenesis).

We study Ets-1 gene expression in the developing rat hypothalamo-hypophyseal system, using *in situ* hybridization on paraformaldehyde-fixed coronal and sagittal brain sections.

At Embryonic day 12 (E12) and E13, Ets-1 mRNA is already synthesized in the neural tube. Cells synthesizing Ets-1 mRNA form small and heavily labeled cord-like or round structures. Mesenchymatous cells surrounding the brain and hypophysis are also heavily labeled. In the hypophysis, cells synthesize Ets-1 mRNA in the neural lobe from E15, and in the anterior lobe from E16, slightly preceding the establishment of vascularization; no Ets-1 mRNA is detected in the avascular intermediate lobe of the hypophysis, at any stage. From E14, cord-like Ets-1 mRNA labeling is very intense in the whole diencephalon. During perinatal stages, it is detected in several hypothalamic nuclei, especially in the supraoptic and paraventricular nuclei. In both hypothalamus and hypophysis, Ets-1 gene expression is maximal during fetal and perinatal stages, and progressively decreases thereafter until adulthood.

A spatiotemporal correlation is observed between Ets-1 gene expression and blood vessel formation in the hypothalamus and pituitary of the Rat, suggesting a role for Ets-1 in angiogenesis, in this system.

## 601.7

ECTOPIC EXPRESSION OF A FOREBRAIN-SPECIFIC TRANSCRIPTION FACTOR INTO THE MID/HIND-BRAIN OF TRANSGENIC MICE: THE ROLE OF BF-1 IN MOUSE BRAIN DEVELOPMENT. S.O. Huh\* and E. Lai. Laboratory of Molecular Developmental Biology, Cell Biology and Genetics Program, Division of Endocrinology, Memorial Sloan-Kettering Cancer Center, New York, NY 10021.

Mouse Brain Factor-1 (BF-1) gene is a member of winged-helix (or fork-head) transcription factor gene family with an important function in the development of forebrain. In developing rodent brain, BF-1 gene is specifically expressed in telencephalon, neural retina, and olfactory neuroepithelium.

From the study of microcephalic-phenotype of the BF-1 knock-out mice generated in our laboratory (Xuan et al., *Neuron*, 1995 in press), we have learned that BF-1 might play an important role in determination of the forebrain structure. To study more about the function of the BF-1 gene in brain development, we produced transgenic mice expressing BF-1 in the mid/hind brain region. About 400 fertilized eggs were microinjected with En2-BF-1 transgene. So far, 28 offspring have been analyzed and two of them carried the En-2-BF-1 transgene in the genome, as shown by genomic southern blot analyses. Preliminary observation of the hematoxylin/eosin-stained brain sections from transgenic E15.5 embryo reveals some phenotypic abnormalities when compared to the wild-type embryo. The periaqueductal gray and future colliculi, where the endogenous En-2 gene is expressed, is enlarged to about two-fold thicker layer compared to that of the control mouse brain. In addition, the cerebral aqueduct expanded to a round tube-like structure with its diameter about 5 fold larger than that of wild-type aqueduct. To identify potential targets of BF-1 that are ectopically induced in the mid/hind brain region of the En-2-BF-1 transgenic mice, we are carrying out *in-situ* hybridization analyses using probes from candidate regulatory genes, such as *dlx* and *emx*.

## 601.9

REGIONAL INTEGRATION OF NEURAL PRECURSORS DERIVED FROM SELECTED REGIONS OF THE FETAL MOUSE BRAIN AFTER GRAFTING INTO THE DEVELOPING RAT FOREBRAIN. M. Olsson\*, K. Campbell, K. Bierregaard, C. Winkler and A. Björklund. Dept. of Medical Cell Research, Univ. of Lund, S-223 62 Lund, Sweden

We have previously reported (Soc. Neurosci. Abstr. 205.10, 1994) that embryonic neural precursors derived from the E14 mouse lateral ganglionic eminence (LGE) injected isochronically into the developing E15 rat forebrain ventricle are capable of incorporating into the host striatum (in contrast to precursors derived from the medial ganglionic eminence (MGE)) and to differentiate like their host counterparts with respect to phenotypical expression and axonal projections. The same *in utero* cross-species transplantation model was used here in order to examine the influence of donor and host age as well as the origin of the progenitor pool on the ability of the progenitors to integrate regionally and develop in a site-specific manner in the developing brain. Precursors derived from the mouse embryonic day (E) 11.5-12 or 13.5-14 LGE, MGE and cortical ventricular zone (CVZ) were injected into the E15, E17 or E19 rat cerebral ventricle. At 0 to 42 days postnatal age, brains were fixed and processed for M6 (a mouse-specific neuronal marker) immunoreactivity and regional brain markers. M6-positive cellular profiles were observed in numerous forebrain nuclei after grafts of either LGE, MGE or CVZ tissue. Isochronically grafted CVZ precursors were distributed in a distinct pattern different from that previously observed for the LGE derived progenitors. Thus the CVZ cells integrated less frequently into the striatum and they were more frequently observed to integrate into the frontal and parietal cortex extending appropriate cortical projections. The degree of parenchymal integration appeared to be less extensive in older recipients (E17 and E19), with a larger proportion of M6-positive clusters remaining attached to the ventricular walls. Nevertheless, the specificity of the integration and projection patterns was maintained in the older recipients. Furthermore, progenitors derived from E11.5-12 appear to follow similar patterns as those from the E13.5-14 brains. Preliminary results indicate that mouse progenitors derived from mid- and hindbrain regions such as the ventral mesencephalon and rhombencephalic lip also display distinct and different patterns of integration and axonal projections after grafting into the forebrain ventricle. These results suggest that intraventricularly injected neural progenitors obtained from diverse brain regions possess the ability to integrate homotypically and undergo site-specific differentiation into the host brain during an extended period (E15-19) of fetal rat brain development.

## 601.6

ISOLATION AND CHARACTERIZATION OF 118 C2H2-TYPE ZINC FINGER cDNAs FROM HUMAN BRAIN. K. G. Becker<sup>1</sup>, J. W. Nagle<sup>2</sup>, M. E. Franko<sup>1</sup>, J. Joy<sup>1</sup>, A. Gado<sup>1</sup>, K. Ozato<sup>2</sup>, W. E. Biddison<sup>1</sup>, and P. D. Drew<sup>1</sup>. <sup>1</sup>Molecular Immunology Section, Neuroimmunology Branch, <sup>2</sup>Neurogenetics Section, NINDS, <sup>3</sup>Lab. of Molecular Growth Regulation, NICHD, NIH, Bethesda, MD 20892.

Transcription factors have been shown to exist in gene families, with similar structural and functional characteristics. We have recently isolated 118 novel cDNAs from the C2H2-type zinc finger family of DNA binding proteins<sup>1</sup>. These clones may represent a large percentage of the zinc finger genes expressed in the human brain. This was done using family specific degenerate oligonucleotide hybridization followed by rapid domain specific partial sequence tagging. We are also in the process of isolating members of the steroid-thyroid hormone receptor and forkhead families, as well as cDNAs positive for CAG trinucleotide repeats.

We are currently involved in the biological characterization of many of the novel clones found to date. We have developed a large scale quantitative differential screening assay using over 600 known purified phage isolates corresponding to each novel clone. These phage are gridded onto phage plates, transferred to filters, and hybridized with differential cDNA probes from different neural cell types and regions of the brain. Using this approach, we have screened for relative RNA expression patterns of a large number of C2H2-type zinc finger genes in human neuroblastomas, astrocytomas, glioblastomas, as well as in the human hippocampus, cerebral cortex, and cerebellum.

We have also obtained northern blot data, full length cDNA sequence, and chromosomal localization on a subset of novel clones. The novel zinc finger clone, C2H2-150, maps to 7q35-36.1 and is currently a candidate for a developmental disorder.

The zinc finger cDNA clone, C2H2-34.10, is the human equivalent of the *Xenopus* Pol III basal transcription factor TFIIB<sup>2</sup>. We show that this gene has nine fingers corresponding to the frog cDNA organization, is expressed in neuronal cells, and has at least one splice variant with specific excision of the fifth finger unit.

## 601.8

PRECURSOR CELL MIGRATION AND DIFFERENTIATION IN EMBRYONIC MOUSE-RAT BRAIN CHIMAEAS. O. Brüstle, U. Maskos, and R.D.G. McKay\*. Lab. of Molecular Biology, NINDS, NIH, Bethesda, MD 20892

To test whether the developmental potential of a neuronal progenitor in a given part of the neuroepithelium is restricted to a local fate, precursor cells derived from distinct aspects of the developing mouse brain were distributed over a large area of the embryonic rat neuroepithelium, using intrauterine transplantation. The transplanted cells were traced with two independent genetic marking methods, i.e., *in situ* hybridization with a probe to mouse satellite DNA, and X-Gal histochemistry following implantation of *lacZ*-expressing donor cells. Single cell suspensions prepared from E14 mouse cortex or ganglionic eminences were deposited in the telencephalic vesicles of E16 - E18 rat fetuses. The implanted cells entered the host neuroepithelium, and neurons generated by both donor cell populations migrated with high efficiency and along legitimate pathways into the developing cerebral cortex and the hippocampal formation. The young neurons acquired region-specific morphologies and expressed antigens appropriate for their final location. For example, cortical interneurons and cells integrated into the dentate granule cell layer displayed immunoreactivity for calbindin, a calcium-binding protein typically expressed in these neuronal subpopulations. The limbic system-associated membrane protein (LAMP; Levitt P, *Science* 223:299-301, 1984) was detected in donor-derived neurons in hippocampus and cingulate cortex but not in those which had settled in the sensorimotor cortex. Transplanted precursors were found to migrate into various other areas undergoing neurogenesis at or after the timepoint of implantation, i.e., septum, striatum, and late developing nuclei of thalamus, hypothalamus, midbrain, and pons. These observations show that heterotopically positioned E14 mouse neuroepithelial precursors adopt the migration behavior of neighboring host cells and can be recruited to a variety of local fates.

## 601.10

ADULT RAT HIPPOCAMPAL PROGENITOR CELLS GRAFTED INTO THE OLFACTORY BULB SURVIVE AND EXPRESS A NEURONAL PHENOTYPE. J.O. Suhonen\*, D.A. Peterson, J. Ray and F.H. Gage. Laboratory of Genetics, The Salk Institute, La Jolla, CA 92037-1099 U.S.A.

Although most neurons in adult CNS are postmitotic and terminally differentiated, neurogenesis does occur in certain regions of the adult CNS such as ventricular zone, hippocampus and olfactory bulb (OLB). Recently, we have shown that adult hippocampal cells can be cultured for over one year in the presence of basic fibroblast growth factor (FGF-2). When grafted back to adult rat hippocampus, these progenitor cells differentiate into neurons or glial cells.

To determine whether these cultured adult neuronal progenitor cells would survive and differentiate into neurons after grafting into olfactory bulb, bromodeoxyuridine (BrdU) labeled cells were grafted into the intact olfactory bulb of adult rats at the base of the olfactory tubercle. Eight weeks post-grafting, transplanted cells migrated up to 6 mm rostral into the OLB, but only 1.0 - 1.5 mm caudal to the site of injection. After migration, grafted cells integrated into the cytoarchitecture of the OLB. Most of the cells were observed in the granule (GR) and glomerular (GLM) cell layers or in the subependymal zone of OLB. Some BrdU-positive cells in the GR and GLM cell layers showed co-localization with NeuN, a marker for differentiated neurons.

These findings indicate that adult neuronal progenitor cells survive, migrate several millimeters, integrate, differentiate and express neuronal marker after grafting in the olfactory bulb. Although the cells are derived from hippocampus, they survive engraftment in a different target zone, the OLB, where they respond to local environmental cues resulting in integration into the target cytoarchitecture and differentiation.

Supported by the NIA PO1 AG10435 and the Medical Research Council of the Academy of Finland #8471.

## 601.11

GENETICALLY MARKED CLONES OF ADULT RAT PROGENITORS RESPOND TO CHANGES IN EXOGENOUS CUES BY DIFFERENTIATING INTO NEURONS OR GLIA. T.D. Palmer\*, H.K. Raymon, J. Takahashi, J. Ray and F. H. Gage. Laboratory of Genetics, The Salk Institute, La Jolla, CA 92037

Basic fibroblast growth factor-responsive progenitors from the adult rat hippocampus were retrovirally marked and clonal populations were evaluated for their ability to differentiate into glia or neurons *in vitro*. Each clone gave rise to cells expressing markers characteristic of astrocytes (GFAP), oligodendrocytes (galactocerebroside, myelin basic protein) or neurons (Map5, NeuN, Tau, and high molecular weight neurofilament). Differentiation was strongly influenced by the culture environment with oligodendrocyte differentiation favored in the presence of FGF-2 and astrocyte and neuronal differentiation favored by withdrawal of FGF-2. Serum stimulation yielded monolayers of protoplasmic astrocytes upon which neurons were observed. Further treatment of the serum stimulated cultures with retinoic acid induced immature NeuN, Map5-positive neurons to differentiate into mature NF200 and Tau-positive neurons. Populations enriched for oligodendrocytes (<80%) or mixtures of astrocytes (40%) and immature neurons (30%) were evaluated by southern blot. The integrated retroviral genome in all clones confirmed that each population was derived from a single marked cell. Two of these multipotent clones were grafted into the adult rat hippocampus where cells expressing the retrovirally transferred alkaline phosphatase gene were readily detected after one week. Comparison of progenitor differentiation *in vitro* and *in vivo* will provide insights into the local cues which regulate neurogenesis and gliogenesis in the adult mammalian brain.

## 601.13

ORIGIN OF RHOMBOMERE DETERMINES AUTONOMOUS VERSUS ENVIRONMENTALLY REGULATED EXPRESSION OF *Hoxa3* IN THE AVIAN EMBRYO. J. R. Saldivar<sup>1</sup>, C. E. Krull<sup>1</sup>, R. Krumlauf<sup>2</sup>, and M. Bronner-Fraser<sup>1</sup>. <sup>1</sup>Dev. Biol. Ctr., UC-Irvine, Irvine, CA 92717. <sup>2</sup>Lab. of Dev. Neurobiol., Natl. Inst. for Med. Res., The Ridgeway, Mill Hill, London NW7 1AA.

The spatiotemporal patterns of *Hoxa3* expression in the neuroepithelium and associated neural crest cells of the chick hindbrain was examined using *in situ* hybridization in conjunction with Dtl labeling. Initial expression of *Hoxa3* is diffuse in the neural plate; later expression becomes restricted rostrally to the r4/r5 border. Neural crest cells from r5 contribute to both the r4 and r6 streams that eventually populate branchial arches 2 and 3 respectively. Neural crest from r5 that migrate rostrally into the r4 stream down-regulate expression of *Hoxa3* while neural crest cells that migrate caudally into the r6 stream maintain gene expression. Transposition of r4 plus r5 by grafting results in *Hoxa3* expression in the neural tube according to the rhombomere's original location. While neural crest cells migrate laterally from r5 into branchial arch 2, *Hoxa3* expression is down-regulated as they emigrate from the neural tube. Rotations of r4 to r6 performed prior to rhombomere formation also show autonomous expression of *Hoxa3* in the neural tube, while migrating neural crest cells from r6 into branchial arch 2 also down-regulate *Hoxa3* expression. Conversely, rotations of r4 to r6 after rhombomere formation reveals autonomous expression of *Hoxa3* both in the neural tube and neural crest from r6 migrating into branchial arch 2. Our results suggest that neural crest cells expressing the same Hox gene may respond differently to environmental signals depending on their rhombomeric origin. Supported by DE 10066.

## 601.12

IN VITRO AND IN VIVO CHARACTERIZATION OF A NEURAL PROGENITOR POPULATION GENETICALLY MODIFIED TO EXPRESS HUMAN TYROSINE HYDROXYLASE. H.K. Raymon\*, S. Thode, J. Winkler, J. Ray, D.E. Michalik, L.J. Thal, L.J. Fisher, and F.H. Gage. Laboratory of Genetics, Salk Institute, La Jolla, CA 92037-1099 and Dept. of Neurosciences, UCSD, La Jolla, CA 92093.

The adult rodent hippocampus harbors progenitor cells which have the ability to proliferate and differentiate into neurons. Using the mitogen, basic fibroblast growth factor (FGF-2), we have been able to isolate neural progenitors *in vitro* from the hippocampus of adult rats. These cells retain the capacity to differentiate into both neurons and glia in culture and when implanted into the adult brain. The purpose of the present study was to assess the potential of neural progenitors for gene delivery to the CNS. In addition, the effect of foreign transgene expression on the fate determination of hippocampal neural progenitors is currently being determined.

Cells from the adult hippocampus were cultured in the presence of 20 ng/ml FGF-2 for several months through 18 passages. Neural progenitors were infected via retroviral-mediated gene transfer to express human tyrosine hydroxylase (hTH). Immunohistochemical and Western blot analysis of infected cell cultures revealed TH immunoreactivity (TH-IR) while uninfected parent cultures did not exhibit any staining. Infected cells were assayed for the production and release of L-DOPA in the presence of the co-factor, tetrahydrobiopterin (BH<sub>4</sub>). Following a 16 hr incubation with 100  $\mu$ M BH<sub>4</sub>, detectable levels of L-DOPA were noted in the medium and in the cell pellet, indicating that not only is the transgene expressed *in vitro* but that it is functional. In order to determine whether the transgene functions *in vivo*, infected cells have been grafted into the dopamine-depleted striatum of adult rats. The rotational behavior of the animals is currently being analyzed. At one week, infected hippocampal neural progenitors still expressed the transgene as evidenced by TH-IR providing preliminary support for using this cell type for gene delivery to the brain. Supported by NS09627-01 and the Alliance for Research on Aging.

## 601.14

ORIGIN AND SPECIFICATION OF SPINAL CORD OLIGODENDROCYTES. Pringle, N.P., Guthrie, S., Yu, W.-P., Lumsden, A., Harper, S. & Richardson, W.D. MRC Laboratory for Molecular Cell Biology and Department of Biology, University College London, Gower Street, London WC1E 6BT. <sup>2</sup>Department of Anatomy, Guy's Hospital Medical School, UMDS, London Bridge, London SE1 9RT. <sup>3</sup>Merck Sharp & Dohme, Neuroscience Research Centre, Terlings Park, Harlow, Essex CM20 2QR.

We generated chick-quail chimeras in which dorsal or ventral segments of the developing chick spinal cord were replaced by homotypic segments of quail spinal cord. When quail ventral spinal cord was grafted into a ventral position, quail oligodendrocytes and their precursors were found throughout the operated side of the cord including the most dorsal white matter. They were also found up to 1mm away from the grafts in both rostral and caudal directions. Thus, oligodendrocyte precursors migrate both radially and longitudinally from their site of origin during normal development. These *in vivo* results confirm that oligodendrocyte precursors originate in the ventral part of the cord, in accord with previous circumstantial evidence<sup>1,4</sup>. Preliminary results from experiments in which dorsal quail tissue was grafted into a dorsal position in the chicken recipient indicate that no oligodendrocytes arise from the dorsal half of the cord.

In the absence of a notochord (in ultraviolet-irradiated *Xenopus* embryos or in caudal regions of the Danforth's Short Tail mouse mutant), cells of the ventrally-derived oligodendrocyte lineage fail to develop. When a second notochord was grafted into a dorsolateral position relative to the spinal cord of a chick embryo, a second floor plate was induced along with a new source of PDGFR $\alpha$  oligodendrocyte precursors, displaced dorsally with respect to the original source. Thus, development of ventrally-derived glia, like ventral neurons, relies on signals from the notochord/floor plate complex. These signals appear to act early, by influencing the specification of neuroepithelial precursor cells in the ventricular zone. 1. Warf, B.C., Fok-Seang, J., Miller, R.H. (1991) J. ## CELL DIFFERENTIATION AND MIGRATION VII

## 602.1

IDENTIFICATION OF NEURONAL PRECURSORS IN THE DEVELOPING OLFACTORY SYSTEM BY HU ANTIGEN EXPRESSION

M. I. Shipley<sup>1</sup>, W.-L. Liu<sup>1</sup> and H. Furneaux<sup>2</sup>. <sup>1</sup>Dept. of Anat., Univ of Maryland, Baltimore, MD 21201 & <sup>2</sup>Sloan-Kettering, New York, NY.

Recent evidence suggests that pioneer olfactory axons modulate the proliferation and differentiation of telencephalic precursor cells to induce the morphogenesis of the olfactory bulb. If true, the region of the telencephalon targeted by pioneer axons should have more cells differentiating into neurons than the rest of the telencephalon. Hu proteins (Hu D, Hu C and Hel N-1) are the earliest known proteins expressed exclusively by mammalian neurons and are the human homologues of Elav, which is required for neurogenesis in *Drosophila*. Mab 16A11 which binds specifically to an epitope present in all known Hu proteins was used to investigate neuronal development in the olfactory system of E12-20 rats.

At E12-13, Hu+ neurons were located in the basal half of the olfactory epithelium. From E14 to E20 Hu+ cells increased dramatically and were present throughout the basal two-thirds of the epithelium. Numerous globular-shaped cells expressed Hu in the deepest part of the epithelium. From E12-15, numerous Hu+ cells were intimately associated with growing olfactory axons. These cells may be migrating from the olfactory epithelium. At E12, Hu+ cells comprised a single layer located just below the surface of the entire telencephalic vesicle. At E13-14 Hu+ cells were still limited to the superficial layer of the telencephalon except in a small ventral region corresponding to the site containing pioneer olfactory axons. Double labeling with GAP43 showed that Hu+ cells were closely associated with pioneer olfactory axons in the olfactory bulb primordium. At E15-16 the olfactory bulb appeared and pioneer axons were no longer present in the ventricular zone. A thick layer of Hu+ cells was present throughout the olfactory bulb but none were present in ventricular zone.

These findings indicate that: (1) Hu is expressed by very immature ORNs and possibly ORN precursors; (2) neurons are present along the olfactory pathway from its earliest stages of development (3) the arrival of pioneer olfactory axons is associated with the differentiation of neuronal precursors in the telencephalon. ## 602.2

IN VIVO FATES OF THE CONSTITUTIVELY PROLIFERATING SUBEPENDYMAL POPULATION IN ADULT MAMMALIAN FOREBRAIN. D. van der Kooy\*, C.G. Craig, R. D'Sa, C. Murhead, A. Roach. <sup>1</sup>Depts of Anatomy and <sup>2</sup>Molecular and Medical Genetics, Univ. of Toronto and <sup>3</sup>Samuel Lunenfeld Research Institute, Toronto, Ontario M5S 1A8.

In adult mouse brain, the subependymal region lining the forebrain lateral ventricles contains at least two kinetically distinct cell populations—a relatively quiescent neural stem cell population and a constitutively proliferating neural progenitor population. Experiments utilizing retroviral (RV) labeling of the constitutively proliferating adult mouse population *in vivo*, determined there to be a progressive loss of  $\beta$ -gal<sup>+</sup> cells with increasing survival times. Relative to 1 day survival animals, 6, 12 and 28 days following RV injection there were 61, 95 and 100% loss of  $\beta$ -gal<sup>+</sup> cells in the lateral ventricle subependyma, respectively. This temporal loss of  $\beta$ -gal<sup>+</sup> cells could be due to a progressive loss of RV reporter gene expression, the migration of  $\beta$ -gal<sup>+</sup> cells away from the lateral ventricle, or cell death. If the loss of  $\beta$ -gal<sup>+</sup> cells is due to a loss of RV gene expression, then a progressive increase in  $\beta$ -gal/RV-DNA<sup>+</sup> cells would correlate with increased survival time. Regions of RV infected brain sections containing  $\beta$ -gal<sup>+</sup> cells and nearby negative regions were assayed for RV-DNA by nested-PCR. Of the  $\beta$ -gal<sup>+</sup> regions tested, 22% from day 1 sections resulted in positive PCR signals (probably due to non-integrated transient RV-DNA), whereas 6 and 28 days following infection this percentage decreased to 1.2 and 0.8%, respectively. Thus, loss of RV gene expression does not contribute to the temporal loss of lateral ventricle  $\beta$ -gal<sup>+</sup> cells. To determine if  $\beta$ -gal<sup>+</sup> cells migrate away from the lateral ventricle, larger brain regions were sectioned and assayed for  $\beta$ -gal<sup>+</sup> cells. Correlating with increased survival times was a progressive rostral migration of  $\beta$ -gal<sup>+</sup> cells to the olfactory bulb (OB). The total number of  $\beta$ -gal<sup>+</sup> cells (including the OB) increased approximately 2.5-fold over 28 days. These results were reproduced with BrdU-labeling of constitutively proliferating cells, and suggest that rostrally migrating cells continue to proliferate en route to the OB. Thus, a major *in vivo* fate of some of the progeny of constitutively proliferating adult lateral ventricle subependymal cells is rostral migration to the OB. However, the lack of a larger temporal increase (it was only 2.5-fold) in the  $\beta$ -gal<sup>+</sup> cell population, even though migrating cells continue to proliferate on the way to the OB, suggests that a major fate of other progeny of the  $\beta$ -gal<sup>+</sup> lateral ventricle cells is cell death.

## 602.3

KALLMANN PROTEIN EXPRESSION IN THE DEVELOPING CHICK BRAIN. R.B. Norgren, Dept. Cell Biol. & Anat., Univ. Nebraska Med. Ctr. Omaha, NE. 68198.

LHRH neurons originate in the olfactory placode and migrate to the brain during embryonic development. Some of the symptoms associated with X-linked Kallmann's disease are due to a failure of the olfactory nerve to enter the telencephalon and LHRH neurons to migrate into the brain. The gene involved in this disease, *KAL*, has been identified in humans and chick. Based on the predicted protein sequence of chick *KAL*, we chose three peptides for production of polyclonal antibodies. Using immunocytochemistry, we examined the distribution of *KAL*-like immunostaining in the E16 chick nervous system. In the telencephalon, there was strong staining in what appear to be mitral cells of the olfactory bulb. The lamina medullaris dorsalis demarcated a region of strong staining (including the ectostriatum, neostriatum, hyperstriatum ventralis and hyperstriatum accessorium) from a region of weak staining (including the lobus parolfactorius). In the diencephalon, dorsal structures (thalamic nuclei) were more intensely stained than ventral structures (preoptic area, ventral hypothalamus). Several nuclei in the mesencephalon were labeled. A distinct band of immunostaining was observed in the stratum griseum centrale of the optic tectum. Strong immunostaining was also observed in purkinje cells of the cerebellum. Immunostaining in alternate sections was blocked when the antibody was preabsorbed with the synthetic peptide used to make the antibody. It will be necessary to perform a western blot in order to confirm that the staining we observed represents only *KAL* immunostaining. In general, our immunocytochemistry results are in agreement with previous reports of *KAL* message in the chick brain. The pattern of *KAL* protein expression may help explain some of the symptoms of Kallmann's syndrome. This work was funded by NIH grant R01 NS30047 (RBN).

## 602.5

SUBPOPULATIONS OF MIGRATING NEURONS EXPRESS DIFFERENT LEVELS OF LHRH IN QUAIL AND CHICK EMBRYOS. C. Gao, R. Abou-Nasr and R.B. Norgren, Dept. of Cell Biol. and Anat., Univ. of Nebraska Med. Ctr., Omaha, NE 68198.

LHRH neurons of the septal-preoptic area originate in the olfactory placode and migrate in the olfactory nerve into the brain during embryonic development. In adult birds, LHRH neurons have been found in the septal-preoptic area, mesencephalon and more recently in the lateral anterior nucleus of thalamus (LA) (Kuenzel & Blahser, '91). LHRH neurons of the LA do not originate in the olfactory placode (Norgren & Gao, '94). Using immunocytochemistry, we examined the distribution of LHRH neurons in the embryonic and adult quail nervous system. The pattern of LHRH immunostaining in quail embryos was similar to chick. However, there were many fewer neurons immunostained for LHRH from the olfactory placode to the septal-preoptic area in quail than in chick embryos. In contrast, there were more labeled neurons and more intense LHRH immunostaining in the thalamus of the quail than in the thalamus of chick embryos. Several results suggest that our immunostaining reflects differences in LHRH expression in quail and chick embryos rather than differences in antibody binding or in the number of migrating LHRH neurons. 1. The antibodies we used worked well on all LHRH neurons in adult quail. 2. Species differences in LHRH expression during development have also been found in rats and mice. 3. *In situ* hybridization experiments indicate LHRH message is not expressed in the developing olfactory system of amphibian embryos although ablation studies show LHRH neurons must be migrating in the olfactory system. Therefore, it is likely that there are species differences in LHRH expression in migrating neurons. The current results should also be considered for quail-chick chimeras involving the olfactory placode. This work was funded by NIH grants R01 NS30047 (RBN) and DE06632 (D. Noden).

## 602.7

MIGRATION OF GnRH AND NEUROPEPTIDE Y (NPY) NEURONS FROM THE OLFACTORY PLACODE TO THE CNS. E.M. Hilal, P. Gandhi and A.J. Silverman, Dept. Anat. & Cell Biol., Columbia Univ., NY NY.

The olfactory epithelium (OE) of the vertebrate embryo gives rise to sensory neurons and several populations of migratory cells. Prominent among the latter are GnRH neurons which differentiate within the OE and migrate along the olfactory nerve (ON) to the CNS. Evidence from several laboratories has suggested that there are non-GnRH neurons which follow this pathway. We have initiated studies to characterize the phenotype of these migratory cells. NPY neurons are functionally related to the reproductive axis, modulating the release of GnRH and directly enhancing GnRH-induced LH secretion from gonadotropes. NPY terminals innervate the hypothalamic and basal forebrain regions and are closely associated with the cell bodies and fibers of GnRH neurons. Based on the functional and anatomical relationship of GnRH and NPY, we asked if a population of NPY neurons originates within the OE. Embryonic chicks were prepared for immunocytochemical detection of either peptide. At stages 28-30, NPY-positive neurons and processes were present in the OE, ON and at the junction of the ON and forebrain. There was also a "stream" of NPY cells within the telencephalon that appeared to be an extension of those in the ON. The number of NPY positive cells in the OE/ON increased between stages 28 (39-81) and 30 (110-227). At the earlier stage NPY cells were relatively more numerous in the OE than at the later stage. The NPY cells in OE/ON are 1/10th as numerous as those containing GnRH. By stage 42, there were neither NPY-positive neurons nor neurites remaining in the periphery. This suggests that all NPY immunoreactivity in the OE and ON is due to the migratory population. These data further suggest that, similar to GnRH neurons, a NPY population originates in the OE and migrates into the CNS during embryogenesis. Experiments are now in progress to determine the earliest appearance of NPY immunoreactivity. The possibility that some GnRH neurons express NPY will be tested. HD 10665.

CARNOSINE-LIKE IMMUNOREACTIVITY IN THE SUBEPENDYMAL LAYER AND IN THE ROSTRAL MIGRATORY STREAM OF THE ADULT RAT. L. Bonfanti, P. Peretto, A. Merighi and A. Fasolo, Dip. di Morfologia Veterinaria and Dip. di Biologia Animale, University of Turin, Turin, Italy.

The mammalian subependymal layer (SEL) of the lateral ventricles and its rostral extension in the olfactory bulb are a site of continued cell proliferation and migration during adulthood (Lois & Alvarez-Buylla, *Science* 264 : 1145, 1994). Cells migrate to the superficial layers of the olfactory bulb following a characteristic pattern commonly referred to as the "rostral migratory stream". The whole system is specifically marked by antibodies against the highly sialylated, weakly adhesive isoform of the neural cell adhesion molecule NCAM (PSA-NCAM, Bonfanti & Theodosis, *Neuroscience* 62 : 291, 1994), a molecule related to structural plasticity. Carnosine and other related aminoacylhistidine dipeptides are considered to play a role in the plasticity of some peripheral sensory cells, i.e. the primary olfactory neurons and the hair cells of the inner ear (in frogs), whereas in the brain the molecule is present in glial elements. In this study, a strong immunoreactivity (IR) for carnosine was found in the SEL of the adult rat brain. At the ventricular level, carnosine-IR structures included the ependyma and the SEL; more anteriorly they were associated with the rostral extension of the SEL occupied by the migratory stream. Double labellings in combination with GFAP and vimentin revealed a high density of glial cells and processes throughout the SEL, although there was no co-localization with carnosine. The latter filled the spaces between glial processes, which also contained PSA-NCAM-positive structures. In the olfactory bulb, the staining for carnosine was limited to the SEL. After systemic injections of 5-bromo-2'-deoxyuridine (BrdU), at different survival times, the BrdU-positive nuclei appeared broadly distributed with carnosine-IR in the SEL. Our observations show that carnosine is present in the SEL and in the rostral migratory stream of the adult rat, but does not appear to be associated with glial structures.

## 602.6

NEURAL CELL ADHESION MOLECULE (N-CAM), L1 AND S100-IMMUNOREACTIVITY ON THE MIGRATION ROUTE OF LUTEINIZING HORMONE-RELEASING HORMONE (LHRH) NEURONS ORIGINATING FROM THE OLFACTORY PLACODE OF THE EARLY HUMAN EMBRYO. M. Schwanzel-Fukuda and D.W. Pfaff, The Rockefeller University, New York, NY; J.J. Hemperly, Becton Dickinson and Co., Research Triangle Park, NC; K.L. Crossin, Scripps Research Institute, La Jolla, CA; P.M.G. Bouloux, Royal Free Hospital, London, UK; J.-P. Hardelin and C. Petit, Institut Pasteur, Paris, France.

LHRH-immunoreactive (ir) neurons are present in the epithelium of the medial olfactory pit on day 42 of embryogenesis (E) and migrate into the brain along branches of the terminal and vomeronasal nerves. By 28 E neural cell adhesion molecule (N-CAM)-ir cells are seen only in the epithelium of the medial olfactory pit. These "pioneer" N-CAM-ir cells migrate out of the epithelium of the medial olfactory pit, form an aggregate in the nasal mesenchyme between the olfactory pit and the developing forebrain and receive the ingrowing N-CAM-ir central processes of the olfactory, vomeronasal and terminal nerves. The N-CAM-ir cellular aggregate contacts the rostral forebrain and N-CAM-ir central processes now form a scaffold along which the LHRH neurons migrate into the brain. Numerous blood vessels develop in this part of the nasal mesenchyme at this time and may assist in formation of the migration route into the brain. In a search for guiding principles in addition to N-CAM adjacent sections were treated with antibodies to L1 and S100. L1-ir was seen on cell bodies and axons of the migration route (similar to N-CAM) and in the olfactory bulb itself (in contrast to N-CAM). Antibody to S100 shows a later-appearing (by 42 E) population of glial cells which also originate in the epithelium of the olfactory pit and closely follow the axons of the migration route. These cells form the sheath cells of the olfactory, vomeronasal and terminal nerves, and do not appear to lead the migration of LHRH cells into the brain. Supported by NIH grant DC 00880 (M.S.-F.)

## 602.8

DISRUPTION OF N-GLYCOSYLATION IN OLFACTORY EXPLANTS: EFFECTS ON PERIPHERIN FIBER OUTGROWTH AND LHRH NEURONAL MIGRATION. S. Fueshko and S. Wray, Lab of Neurochemistry, NINDS, NIH, Bethesda, MD 20892.

During development, luteinizing hormone releasing hormone (LHRH) neurons arise from progenitor cells in the olfactory placode, and migrate into the CNS along a subset of peripherin positive axons. Utilizing an *in vitro* explant system we are examining the mechanisms involved in directing the outgrowth of the peripherin fibers, and the subsequent neurophilic migration of LHRH neurons. We have previously shown that these processes do not appear to be dependent on spontaneous electrical activity and/or depolarization. We have therefore begun to examine the role of glycosylation in the movement of LHRH neurons. Inhibition of N-glycosylation was accomplished by treatment of cultures with tunicamycin. A time course experiment using 1.25 µg/ml tunicamycin indicated a critical period between 24 and 36 hrs *in vitro*, roughly equivalent to E12-E12.5 *in vivo*. Surprisingly, during this period, an exposure to tunicamycin for as few as 12 hrs abolished the olfactory epithelium, including LHRH neurons and peripherin fibers. This phenomenon was not observed at later timepoints. These data suggest that N-glycosylation may be involved in the early stages of peripherin fiber outgrowth, but is not involved in the association of LHRH neurons with the peripherin fibers. This does not rule out a role for other forms of glycosylation in these processes. Studies utilizing lectins are currently underway to determine what specific carbohydrate moieties are involved in LHRH neuronal migration and/or the outgrowth of olfactory axons.

## 602.9

MECHANISMS OF MIGRATION OF OLFACTORY INTERNEURON PRECURSORS IN THE SUBVENTRICULAR ZONE. H. HU, H. TOMASIEWICZ, T. MAGNUSON AND U. RUTISHAUSER\*. Department of Genetics, Case Western Reserve University School of Medicine, Cleveland, OH 44106.

Olfactory interneuron precursors migrate to the olfactory bulb through a specific tangential pathway within the subventricular zone (SVZ). This migration process is retarded in NCAM-mutant mice, a defect reflecting their loss of NCAM polysialic acid (PSA). To study the mechanism of this migration, we have carried out transplantations of SVZ cells of NCAM mutant and wild type newborn mice. Surprisingly, mutant cells were found to migrate normally when transplanted to the SVZ of a wild type host, whereas wild type cells did not migrate in a mutant host. These findings suggest that the host SVZ environment, and not the individual transplanted cells, is the determining factor in generation of the mutant phenotype. However, migration of cells from SVZ explants into a collagen matrix was also found to be PSA-dependent, suggesting that a specific SVZ environment is not required. A resolution of this apparent paradox was suggested by observations of the behavior of cells during migration. That is, the migration *in vitro* occurred as streams or chains of closely-apposed cells, suggesting that SVZ cells may serve as their own migration environment. Such chains of migrating SVZ cells have also been observed in the adult animal (Rousselot et al., J. Comp. Neurol. 351:51-61, 1995). Additional transplantation studies indicate a strong rostral attraction of these cells toward but not within the bulb, and that PSA is not required for radial migration of cells within the bulb.

## 602.11

IMMATURE NEURONS PROLIFERATE AND MIGRATE ALONG AN ASTROCYTE/TENASCIN-RICH PATHWAY FROM THE ADULT SUBPENDYMAL ZONE TO THE OLFACTORY BULB. J.B. Thomas\*, M.A. Gates, and D.A. Steindler. Dept. of Anat. & Neurobiol. and Neurosurg., Univ. of Tenn., Memphis, TN 38163

The rodent subependymal zone (SEZ) has recently received much attention as it has been demonstrated that stem cells persist in this area in adult mammals which can be manipulated to produce neurons *in vitro* in the presence of selected growth factors. Furthermore, it has been demonstrated that some of the progeny of these stem cells migrate to the olfactory bulb *in vivo* and differentiate into mature neurons. A recent study has examined the developmental expression of certain astrocyte-derived, extracellular matrix (ECM) molecules such as tenascin (TN) and chondroitin sulfate containing proteoglycans (CSPG) in the SEZ (Gates et al., J. Comp. Neurol., in press). These molecules form boundaries around developing functional units in the brain. They are, for the most part, expressed in very low levels in the adult brain. Interestingly, the expression of these molecules remains high in the SEZ throughout adulthood. Using the neuronal marker TuJ1 (which stains class III  $\beta$ -tubulin expressed only in immature and mature neurons), we demonstrate that the path along which these neurons migrate is distinctly rich in TN and CSPG. Furthermore, this path contains a high number of glial fibrillary acidic protein (GFAP) + astrocytes in the normal adult brain. Using immunohistochemistry for bromodeoxyuridine (BrdU), a thymidine analog incorporated into the DNA of dividing cells during the S phase, we demonstrate that cell proliferation occurs along the entire course of this pathway from the SEZ to the olfactory bulb. This study has important implications concerning the migration of neurons in the mature CNS. It appears that these neuronal stem cells are born and migrate preferentially along this ECM-rich pathway. Preliminary studies suggest that these ECM molecules may also be expressed in the human SEZ. These findings may explain why young neurons migrate only towards the olfactory bulb and not into other CNS regions such as the overlying cortex or striatum that are normally ECM- and growth factor-poor. Supported by NIH/NINDS grant 29225.

## 602.13

MIGRATION OF LHRH NEURONS IN EXPLANT CULTURES OF EMBRYONIC CHICK OLFACTORY PLACODE. M. R. L. Maas\*, P. F. Gadson, Jr. and R. B. Norgren. Dept. of Cell Biol. and Anat., Univ. of Nebraska Med. Ctr., Omaha, NE 68198

During embryonic development LHRH neurons originate in olfactory epithelium (OE) and migrate to the telencephalon within the olfactory nerve. Apparent migration of LHRH neurons has been observed in mammalian explant systems but has not been previously reported in the chick. In this study, we examined the effect of age of OE on LHRH neuron organization, the possible role of soluble factors in LHRH neuron differentiation, and the early migratory behavior of LHRH neurons. Explants from early (HH Stages 14-19) and later embryos (HH Stage 20 and older) contained intensely immunostained LHRH neurons. LHRH neurons were closely associated with each other and organized in cell streams in explants from the later but not the earlier stage embryos. Large numbers of LHRH neurons were observed in 30.9% of OE explants which received either conditioned media or were co-cultures but in only 14.8% of untreated OE explants indicating a soluble factor from brain explants may enhance LHRH production either directly or by blocking an inhibitor to LHRH differentiation. Untreated OE explants which were disturbed contained large numbers of LHRH neurons in 28.6% of the cultures, compared to only 11.7% in undisturbed untreated OE cultures. Although most LHRH neurons *in vivo* originate from rostral-medial OE, LHRH neurons were found in explant cultures of dissected medial, lateral, rostral, and caudal halves. Thus, disruption of the organization of the OE appeared to stimulate LHRH proliferation or expression, indicating a possible role of the local environment in the regulation of LHRH expression. This work was funded by NIH grant R01 NS30047 (RBN).

## 602.10

LHRH NEURONAL MIGRATION IS DISRUPTED BY ENZYMATIC REMOVAL OF POLYSIALIC ACID IN EMBRYONIC MICE. K. Yoshida<sup>1</sup>, G.A. Schwarting<sup>1</sup>, U. Rutishauser<sup>2</sup>, and J.E. Crandall<sup>1</sup>. <sup>1</sup>The Shriver Center, Waltham, MA 02254 & Program in Neuroscience, Harvard Med. Sch., Boston, MA 02115 and <sup>2</sup>Dept. Neuroscience, Case Western Res. Med. Sch. Cleveland, OH 44106.

The unique migrational pathway of LHRH neurons begins in the olfactory placode, crosses the cribriform plate, continues into the basal forebrain and reaches the hypothalamus. Experiments in chick suggest that the polysialated form of N-CAM (PSA-NCAM) is involved in the selective movement of these cells. In embryonic mice and rats PSA-NCAM is associated with the caudal branch of the vomeronasal nerve which may act as a selective guidance pathway. To directly test the notion that PSA-NCAM is involved in LHRH cell migration, we micro-injected the enzyme, endoneuraminidase N, into embryonic day 12 (E12) and E13 mice. Three days later, the heads were processed for immuno-cytochemistry for PSA-NCAM, NCAM and LHRH. PSA-NCAM was not detectable in the nasal cavity, olfactory bulb or forebrain of endo N-treated embryos whereas NCAM immunoreactivity was similar to controls. The distribution of LHRH cells was clearly altered in animals where there was no detectable PSA-NCAM. More LHRH cells remained in groups along branches of the vomeronasal nerve in the nose compared to the controls. Conversely, significantly fewer LHRH cells were present in the basal forebrain. Thus, PSA may be required to aid the movement of LHRH cells in their migration from the nasal cavity to the forebrain. Supported by HD05515.

## 602.12

A NOVEL METHOD TO CULTURE THE SUBPENDYMAL ZONE OF THE ADULT RODENT REVEALS IMMATURE NEURONS THAT PREFER AN ENVIRONMENT RICH IN EXTRACELLULAR MATRIX MOLECULES. H. Fillmore, M.A. Gates, J.B. Thomas, J.B. Schweitzer\* and D.A. Steindler. Dept. of Anat. & Neurobiology and Neurosurgery, Univ. of Tenn., Memphis, TN 38163

The adult rodent subependymal zone (SEZ) has been an area of intense study since several laboratories have recently reported that SEZ stem cells can generate neurons *in vitro* in the presence of certain growth factors. Studies of the SEZ to date have predominantly utilized dissociated cell suspensions to produce these neuronal cells. We report a novel method in which the SEZ is cultured as an explant on a filter. Using this technique, spheres of cells immunoreactive for neuronal markers are detected similar to those seen in dissociated culture paradigms. We demonstrate that cells in the SEZ explants are immunoreactive for the neuronal markers neuron specific enolase and TuJ1 (which recognizes class III  $\beta$ -tubulin found only in immature or mature neurons), as well as for the cell proliferation marker BrdU. Using this culture system allows detailed studies which more accurately reflect the *in vivo* environment. We have recently demonstrated that the extracellular matrix (ECM) molecules tenascin and chondroitin sulfate containing proteoglycans (CSPG) persists in the SEZ throughout adulthood. Furthermore, it has been demonstrated that cells born in the SEZ migrate to the olfactory bulb where they differentiate into neurons. This migratory path is rich in ECM molecules. We therefore hypothesize that the stem cells migrate freely to the olfactory bulb along this path, but they do not migrate into the overlying cortex and striatum because of a lack of ECM and perhaps certain growth factors in these adult regions. This explant culture method has allowed us to examine the role of ECM molecules in and around the SEZ as well as the effect of such ECM molecules on SEZ stem cells. Preliminary studies suggest that different dissociated cells selectively adhere to the ECM-rich SEZ, and perturbing these cultures with, for example, tenascin and CSPG antibodies, affects cell attachment and subsequent neurite growth. Supported by NIH/NINDS grant 29225.

## 602.14

IN VITRO IMMUNOCYTOCHEMICAL STUDIES OF NEURONAL MIGRATION IN EMBRYONIC RODENT FOREBRAIN. S.A. Tobet\*, I.K. Hanna, T.W. Chickering, & G.A. Schwarting. Prog. Neuroscience, The Shriver Center, Waltham, MA 02254 & Harvard Medical School, Boston, MA 02115.

During development neurons migrate across diverse terrains that range from crossing the cribriform plate into the brain, to moving through a maze of radial glial or axonal fibers, to traversing fiber bundles such as the anterior commissure (AC). To study the migration of neurons in development we are utilizing an approach wherein cell migration is visualized *in vitro*, in tissue slices that maintain the structure of the forebrain. On days 15 or 18 of gestation rat embryos were dissected, and the heads embedded in agarose and cut by Vibratome into 300-350 micron slices. In some slices individual cells were randomly labelled by brief immersion in the carbocyanine dye, DiI and followed by fluorescence video microscopy (e.g., Tobet et al., Horm Behav (1994) 28:320-327). Alternatively, similarly cut sections were fixed by acrolein or formaldehyde on days 0 to 3 after preparation. Sections taken from rats at E15 were sagittal and processed for gonadotropin releasing hormone (GnRH) immunocytochemistry (ICC). Sections taken from rats at E18 were coronal and processed for tyrosine hydroxylase (TH) ICC. In each case, immunoreactive cells occupied stereotyped positions on the day of preparation - GnRH cells close to the cribriform plate and TH cells under and within the AC. By examining slices by ICC after varying days *in vitro*, cell migration can be assessed from the changes in cell orientations and positions. The data reveal patterns and rates of cell movements that are complementary to studies utilizing fluorescence video microscopy.

## 603.1

LONGITUDINAL AXON TRAJECTORIES CORRELATE WITH HOMEOBOX GENE EXPRESSION DOMAINS IN MOUSE EMBRYOS. G.S. Mastick\* and S.S. Easter, Jr. Dept. Biology, U. Michigan, Ann Arbor, MI 48109

We previously described the formation of a continuous longitudinal tract through the early brain: axons of the tract of the postoptic commissure (tpoc) project caudally from the most anterior neuromere of the prosencephalon, prosomere 6 (p6), to merge with the pre-existing descending tract of the mesencephalic nucleus of the trigeminal nerve (dtnesV) in p1 and mesencephalon (mes), into the rhombencephalon. The tracts thus appear to course along the dorsal side of the alar-basal boundary, projecting through several neuromeres and intervening transverse boundaries.

We demonstrate that dtnesV and tpoc axon trajectories, and subsequent shapes of the tracts, vary in a neuromere-specific manner that correlates with gene expression domains. Axons were labelled with diI on embryonic days 9.5 and 10.5, then photoconverted; subsequent whole mount in situ hybridization revealed expression of the homeobox genes *Nkx-2.2*, *Pax-6*, and *Pax-3*. The dtnesV axons initially project ventrally, then turn caudally into a narrow path, passing ventral to a dorsal *Pax-3* domain, and dorsal to a longitudinal *Nkx-2.2* stripe. The tract widens, as its axons make loops and errors at a gap in the *Pax-3* domain and *Nkx-2.2* stripe coinciding with the mes/rhombomere 1 border. The tpoc is initially narrow, just dorsal to the *Nkx-2.2* stripe in p6 and p5, widens upon entering *Pax-6* and *Nkx-2.2* zones in dorsal p4 and p3, narrows again upon diving through a dorsal-ward deflection of the *Nkx-2.2* stripe, and widens in a *Pax-6* zone in p2. Our results imply that the navigation of these longitudinal axons is regulated by gene-specific cellular domains, corresponding to neuromeres, interneuromeric boundaries, and the longitudinal alar/basal boundary. In the basal plate, axons of the medial longitudinal fasciculus (mlf) have relatively uniform caudal trajectories, suggesting that these domain-specific effects on axon growth are limited to the alar plate.

THE MURINE *ENGRAILED* GENES ARE REQUIRED FOR THE FORMATION OF DEEP MESENCEPHALIC NUCLEI. H.H. Simon\*, W. Wurst† and D.D.M. O'Leary. The Salk Institute, La Jolla, CA #GSF-Research Center, Oberschleissheim, Germany.

The embryonic expression domains of *En-1* and *En-2* in the murine brain overlap to a large extent. They are expressed in the dorsal aspect of the most rostral hindbrain and throughout the neuroepithelium in caudal midbrain. These expression domains coincide with the embryonic regions which give rise to the cerebellum, the inferior and superior colliculi, and more ventrally located mesencephalic nuclei. Homozygous mice for the *En-2* mutation show only a small change in the organization of the cerebellum. The *En-1* mutant mice, which die at P0, are more severely affected; dorsally, the entire cerebellum, inferior colliculus and the caudal superior colliculus are absent; ventrally, only the mesencephalic cranial nerves are affected.

Here we describe the phenotype of the *En-1/En-2* double mutant. The double mutant phenotype reflects the actual expression patterns of *En-1* and *En-2* to a greater extent than either of the single mutants. In addition to the already described deficiencies in the cerebellum and colliculi, these mice are deprived of deeper located mesencephalic neuronal cell types. The largest source of noradrenergic neurons in the central nervous system, the locus coeruleus, cannot be detected immunohistochemically using antibodies to tyrosine hydroxylase. The mesencephalic dopaminergic cell groups A8, A9 and A10 are reduced to a few TH positive neurons. Furthermore, the midbrain serotonergic cell groups, B7 and B8, the dorsal and median raphe nuclei, respectively, are not detectable using antibodies to serotonin. Although these populations of TH and serotonin positive cells can be detected as early as E11.12 in normal mice, they were not detected in the double mutant mice. Our results suggest that the normal induction of these chemically-defined neuronal cell types does not occur. Furthermore, the phenotype of the double mutant strongly supports the hypothesis of functional redundancy of *En-1* and *En-2* during embryogenesis.

## 603.5

EVIDENCE FOR PRENATAL DETERMINATION OF CONE OPSIN PHENOTYPES AND POSITION IN THE MOUSE RETINA. K. C. Wikler\*, A. Szel and A. L. Jacobsen. Sect. of Neurobiol., Yale U. Sch. Medicine, New Haven, CT; Dept. Anatomy, Semmelweis U. Med. Sch. Budapest, Hungary.

We proposed that cone: cone interactions may underlie the specification of the wavelength-sensitive cone subtypes in the fetal monkey retina. To explore this issue we developed an organotypic culture system to exploit the topographic separation of red/green (R/G) and blue (B) cones into respective dorsal and ventral fields in the mouse retina. Dorsal (D) and ventral (V) hemi-retinae from postnatal (P) day 3 mice, prior to opsin expression, were flatmounted onto collagen-coated porous membranes, incubated for 8 to 10 days, fixed, and processed for immunocytochemical identification of the R/G and B opsins.

The distribution of cone subtypes *in vitro* paralleled that seen *in vivo*: R/G cones were found exclusively in dorsal retina and B cones were abundant in ventral retina, decreasing in density dorsal to the optic disc. The emergence of the asymmetric D-V distribution of B cones was also evident in explants taken from P0 retinae; however, dorsal cones failed to express the red/green opsin in these cultures.

To test whether immature cones can be induced to express an ectopic opsin, we exposed prospective R/G or B cones to putative locally restricted diffusible factors. Separate D and V retinal pieces from P0 or P3 retinae were co-cultured with D or V hemi-retinae from either same age or P14 tissue. The emergence of the D-V gradient of B cones was unperturbed in all co-culture conditions and the expression of the R/G opsin remained restricted to incubated P3 explants. These results suggest that the regional segregation of cone subtypes is intrinsically determined prior to birth, however, the completion of R/G cone differentiation appears to be dependent on events occurring during the first two postnatal days.

Supported by EY09917 (KCW).

## 603.2

cDNA SUBTRACTION AND ANALYSIS OF THE GENES EXPRESSED IN MES-METENCEPHALIC BOUNDARY OF CHICK EMBRYO. J. Funahashi\*, and H. Nakamura. Inst. Development, Aging and Cancer, Tohoku Univ., Sendai 980-77, Japan.

The optic tectum is a primary visual center of avian brain that differentiates from mesencephalon and receives retinal fibers. The projection is organized in a topographically ordered fashion such that nasal retinal fibers project to caudal part of the tectum, and temporal fibers to the rostral. We are interested in the molecular basis for positional specification in the tectum along the rostrocaudal axis. Recently we have shown that the ectopic expression of *En*, the chick homologue of the *Drosophila engrailed*, induced branching of the nasal fiber in rostral part of mesencephalon. This suggests that *En* play an important role in determination of positional specificity in mesencephalon. On attempt to clone genes which expression is regulated by *En*, or which regulate the expression pattern of *En*, we constructed subtracted cDNA libraries; rostral minus caudal and caudal minus rostral. Some of the isolated clones exhibit spatially and temporally restricted expression pattern in mesencephalon. Functional analysis of these clones using retrovirus infection technique and embryonic manipulation is under way.

## 603.4

CELLULAR PROCESSES DURING THE ONTOGENY OF A TRANSIENT DRG IN THE CHICK EMBRYO. R.S. Goldstein\*, O. Rosen, R. Gefen, C. Avivi and R. Freidman. Dept. Life Science, Bar-Ilan Univ. 52900 Ramat-Gan, ISRAEL.

A striking example of axial variation or patterning in nervous system development is the disappearance of the DRG that develop adjacent to the occipital and the first cervical segments of the CNS of the amniote embryo. It was recently shown that the overexpression of a single *Hox* gene can "rescue" one of these "transient" DRG. We have now characterized the cellular processes taking place during the ontogeny and demise of the 2nd cervical DRG (C2) in the chick embryo, to serve as a basis for examining the roles of *Hox* genes in pattern formation of the nervous system of the trunk. At St. 18 (E2.5), the C2 DRG is indistinguishable from permanent DRG C5 and C6 in whole-mount and in cross-sections stained with the HNK-1 antibody. A few hours later at E3 (H&H St. 20), it first appears different from conventional neighboring DRG. At this stage, C2 has half the volume and number of cells as ganglia C5 and C6, has a distinctive shape and location, and its peripheral nerve root begins to degenerate. The early difference in size/cell number appears to be caused by both differential rates of proliferation and apoptosis. At St. 20 50% fewer cells in C2 are in S-phase than in neighboring ganglia, and apoptotic cells are more abundant in C2 than in conventional DRG. C2 grows at a slower pace than do neighboring ganglia, from St 18 through St. 32. At the height of normal DRG apoptosis in cervical ganglia at St. 28, 3-4 times more pycnotic nuclei are present in C2, resulting in the elimination of this ganglion in 80% of St. 36 embryos. In spite of the programmed removal of C2, neurons differentiate successfully there, and are present at least from St 20 to St. 32. Our results suggest that *Hox* genes may produce the difference in fate between C2 and other cervical DRG by modifying the expression of trophic factor(s) and/or their receptors involved in DRG cell survival and proliferation, starting at St. 18-20.

## 603.6

RETINOIDS AS CANDIDATE MOLECULES FOR THE EMERGENCE OF SEGREGATED COMPARTMENTS OF CONE SUBTYPES IN THE MOUSE RETINA. D. L. Stull\* and K. C. Wikler. Section of Neurobiology, Yale Sch. Medicine, New Haven, CT, 06510.

We are interested in the cellular and molecular mechanisms underlying the emergence of separate fields of red/green and blue cone subtypes in the mouse retina. In this study, we selected the retinoids as candidate molecules since they appear to regulate pattern formation in the developing central nervous system. To determine if neuroblasts in the retinal neuroepithelium are responsive to endogenous retinoids, we examined embryonic mice possessing a retinoid-dependent LacZ reporter transgene (Balkan et al, 1992).

Transgenic mice at embryonic (E) day E10, E11, E12, or E14 were sectioned, immunoreacted for  $\beta$ -galactosidase ( $\beta$ -gal), and counterstained with Bis-benzidine. A dynamic pattern in the cellular response to retinoids during this embryonic period was revealed by reconstruction of the distribution of  $\beta$ -gal positive cells from immunoreacted serial sections. Retinoid-responsive neuroblasts were found throughout the optic vesicle at E10. However, we observed the emergence of a striking dorsal-ventral asymmetry in the distribution of immunoreactive dividing cells in the neuroepithelium by E11 and E12, coincident with the formation of the retinal pigment epithelium and neural retina. Neuroblasts located dorsal to the optic disc demonstrated a functional response to endogenous retinoids, while the majority of dividing cells in ventral retina remained quiescent. By E14, neuroblasts located in ventral and peripheral retina showed an increased response to these molecules.

These results indicate retinal neuroblasts respond to endogenous retinoids prior to (E10 and E11) and coincident with (E12 and E14) cone genesis. In addition, the asymmetric response of the neuroepithelium reveals an early parcellation of the retina into dorsal and ventral compartments. Together these results suggest that the retinoids regulate the specification of early-generated retinal cell types and contribute to the emergence of the dorsal-ventral separation of red/green and blue cone subtypes. Supported by EY09917 (KCW).

## 603.7

PCR-CLONING AND EXPRESSION PATTERN OF COLLAPSPIN IN THE EMBRYONIC RAT. R.J. Giger, G. de Wit, J. Verhaagen\*. Netherlands Institute for Brain Research, Amsterdam, NL.

The establishment of specific connections in the developing nervous system depends on the capability of axons to reach distant target areas. In addition to neurite outgrowth promoting molecules, repulsive factors, which induce growth cone collapse and paralysis, have been shown to be important cues for axon guidance. Recently a chicken growth cone-collapsing protein, named collapsin, has been cloned and shown to induce the collapse of chicken DRG growth cones (Luo et al., 1993; Cell 75, 217-227). To investigate the expression pattern of collapsin in mammals, the rat homologue was cloned from adult rat brain material by RT-PCR using primers based on the human semaphorin sequence. The PCR product covers the entire translated part of the collapsin mRNA and shows a sequence identity of ~82% to chicken collapsin and ~93% to human semaphorin. Cryostat sections of embryonic rat were analyzed for expression of collapsin by *in situ* hybridization, using an antisense cRNA probe labeled with digoxigenin-11-UTP. In sagittal sections of embryonic day 15 rats, collapsin was found to be expressed in the basal telencephalon; the vestibular ganglion; in close contact with the olfactory epithelium; in the pons; the medulla; and the spinal cord. In transversal sections the ventral horn of the spinal cord and cells surrounding the central canal were stained. Collapsin shows a dynamic expression pattern in the nervous system, but is also expressed in non-neuronal tissue like intestine and muscle.

## 603.9

SYNAPTIC COMPETITION OBSERVED DURING THE REFORMATION OF A NEUROMUSCULAR TOPOGRAPHIC MAP. M.B. Laskowski\*, H. Colman and J.W. Lichtman. WAMI Medical Program, University of Idaho, Moscow, ID 83844 and Dept. of Anatomy and Neurobiology, Washington University, St. Louis, MO 63110.

We have been studying the mechanisms whereby regenerating motoneurons reestablish a rostrocaudal bias on the surface of some skeletal muscles. The serratus anterior (SA) muscle of the rat displays a topographic map prior to birth, and the map is reestablished after denervation of the long thoracic nerve (LTN) (J. Neurosci. 8:3094, 1988). Here we explored the progress of the formation of this map under conditions of potentially enhanced synaptic competition. The SA muscles of 3-day old neonatal rat pups were denervated by crushing the LTN. Two days later the rostral (C6) branch to the LTN was crushed, and the caudal half of the muscle removed. This experimental approach allowed unopposed access of caudal (C7) motoneurons to vacated synaptic sites on the remaining rostral half of the SA. Intracellular recording revealed that 2 days after the second denervation, 62% of the reinnervated end-plates contained only axons from the C7 branch; 18% from C6; and 18% from both C6 and C7 branches. Four days after the second denervation only 14% of the reinnervated end-plates retained input solely by C7 axons; 52% by C6 only; and 33% by both C6 and C7. This progressive loss of input by C7 continued, so that after 6 days, axons from C6 were the sole input to reinnervated end-plates. During the transition from C7-dominated to C6-dominated input, we recorded from selected end-plates with inputs from both C6 and C7 axons. At end-plates co-innervated by C6 and C7 axons, the average quantal content from C6 was greater than C7. In some of these cases, we also noted a difference in quantal size. We have thus developed an experimental situation where axons are forced to compete with each other, and where the outcome is predictable: inputs from C6 axons will suppress inputs from C7 axons. Further, we have observed evidence of synaptic competition during this process, with significant differences in synaptic efficacy between the two inputs to an end-plate. Supported by NIH.

## 603.11

NEURON-SPECIFIC GENE EXPRESSION DURING DEVELOPMENT IN A BINARY TRANSGENIC MOUSE SYSTEM. C. Kappen\*, D. P. Gardner, M. P. Macias and P. J. Yaworsky. S. C. Johnson Medical Research Center, Mayo Clinic Scottsdale, Scottsdale, AZ, 85259.

Transgenic mouse technology has been widely used to study gene expression and function in the developing embryo and in adult tissues. Many transgene products, however, interfere with embryonic development precluding the establishment of permanent transgenic mouse lines. To overcome these limitations, we utilize a binary system of gene regulation in transgenic mice. This system consists of two components in independently transgenic mouse lines. One transgenic mouse strain carries a silent transgene (transresponder) that is activated only when a transcriptional activator is supplied by a second transgenic mouse line (transactivator). This transgenic mouse line harbors the gene for the potent viral transcriptional activator VP16, under the control of a neuron-specific promoter. The parental strains can be maintained independently without phenotypic effects, and double transgenic embryos and offspring can be generated reproducibly simply by breeding. This system affords the ability to study genes that could disrupt normal embryonic development.

We here report transactivation of transgenes in this system specifically in the developing nervous system. We have created transgenic mice in which VP16 expression is controlled by the promoter of the murine neurofilament light subunit (NF-L) gene that directs transgene expression in differentiating neurons. Additional transactivator mice have been generated that express VP16 under control of the rat nestin gene enhancer. This regulatory element directs transgene expression to proliferating neuroepithelial precursor cells. We have crossed these transactivator strains to transresponder mice carrying a LacZ reporter gene and examined embryos at various stages for  $\beta$ -galactosidase activity. The patterns of LacZ activity indicate that transactivation is specific to precursors and early differentiation stages of neurons in the developing brain and spinal cord. Our goal is to apply the VP16-based binary transgenic system to investigate the role of homeobox genes for regional and cell-type specification in the developing nervous system.

## 603.8

ROBUST OUTGROWTH AND PATTERNING OF AXONS FROM EMBRYONIC MOUSE XENOGRAFTS INTO NEONATAL RAT CORTEX. S. Jhaveri\*<sup>1</sup> & M.H. Hankin<sup>2</sup>. <sup>1</sup>Department of Brain & Cognitive Sciences, Mass. Institute of Technology, Cambridge, MA 02139; <sup>2</sup>Departments of Anatomy & Neurobiology, Medical College of Ohio, Toledo, OH 43614.

The capacity of homotopic and heterotopic cortical grafts to form patterned connections in the host brain was explored using a xenografting paradigm. Cortical tissue from embryonic (E15-18) mouse donors was transplanted to parietal or occipital cortex of neonatal rats. After 1-8 weeks, graft outgrowth into the recipient brain was visualized immunohistochemically, using the mouse-specific antibody M6 (Neurosci.Letts. 61:221, 1985).

Despite considerable variability in the extent of M6 immunoreactivity, some general observations can be made regarding donor tissue outgrowth. Invasion of neonatal rat cortex by transplant-derived fibers was extensive and frequently showed growth into the white matter; in some brains M6-positive axons could be traced rostrally from donor tissue in occipital cortex. Axons preferred to travel in supra- and infra-granular layers, avoiding layer IV. In fortuitous cases with grafts placed in the barrelfield cortex, M6-positive axons surrounded large clusters of host cells, reminiscent of the callosal projection to the barrel septae. Widespread migration of donor glia (assessed using the mouse glia-specific antibody M2) into the host tissue was evident. Fiber outgrowth was usually more widespread than that seen for glia; the fiber and glial outgrowth did not show a tight spatial relationship.

Based on results obtained so far, our working hypothesis is that projections from cortical xenografts grow out in a manner similar to that seen for cortical callosal afferents in normal animals.

Support: NIH Grants EY05504 (SJ) and NS26777 (MH).

## 603.10

EARLY BORN CHOLINERGIC NEURONS HAVE A PREFERENCE FOR THE STRIATAL PATCH COMPARTMENT, WHILE LATE BORN CHOLINERGIC NEURONS ARE MORE LIKELY TO BE LOCATED IN THE MATRIX COMPARTMENT. E.H.S. van Vulpes\* and D. van der Kooy. Neurobiology Research Group, Dept Anatomy, University of Toronto, Toronto, Ontario, M5S 1A8.

The striatal patch and matrix compartment neurons are born at different times during rat development. The majority of the early born neurons (embryonic (E) days 13-17) preferentially end up in the patch compartment, while the majority of the later born neurons (E18-postnatal (P) day 2) end up in the matrix compartment. Although the cholinergic interneurons are born early in neurogenesis (between E12 and E17), and we would therefore expect them to be located mainly in the patches, they are relatively homogeneously distributed in the adult, with a preference for the matrix area just outside the patches (intermediate zone-IZ). To ask if birthdate can predict the localization of cholinergic neurons in the striatum, we marked new postmitotic neurons in the embryo with a maternal injection of bromodeoxyuridine (BRDU) on E13, E15 or E17. The pups were sacrificed at P40 and the tissue was processed for BRDU and choline acetyltransferase double labelling. Cholinergic neurons that became postmitotic at E13, had a significantly higher chance of ending up in the patch compartment compared to either IZ or matrix. On the other hand cholinergic neurons that became postmitotic at E17 had a higher chance of ending up in either the IZ or the rest of the matrix compartment. We conclude that birthdate can predict compartmental localization, with cholinergic neurons in the intermediate zone following the same pattern as the cholinergic neurons in the rest of the matrix compartment. Thus, cholinergic neurons show the same relative birthdate/compartment relationship as to other striatal neurons, although the absolute birthdates of cholinergic neurons are shifted earlier in neurogenesis. Because selective adhesiveness of the early born patch neurons is thought to be important in the formation of patches, we predict that only the earliest born cholinergic neurons in the patches will show adhesive properties.

## 603.12

Regulation of ventral polarity in the vertebrate CNS by a 19 kiloDalton form of Sonic hedgehog.

Elisa Martí, David A. Bumcrot, Ritsuko Takada, Paola Bovolenta\* and Andrew P. McMahon. Department of Molecular and Cellular Biology, Harvard University, 16 Divinity Avenue, Cambridge, MA 02138

Patterning of the vertebrate central nervous system (CNS) depends on cell interactions. For example, induction of a specialized population of ventral midline cells, the floor plate require signaling from the underlying notochord, whereas signals from the notochord and floor plate induce motor neuron differentiation. Experiments in a variety of vertebrate embryos and in neural explants *in vitro* indicate that Sonic hedgehog (Shh) can mediate floor plate induction. Shh encodes a signal which is implicated in both short and long range interactions that pattern the CNS, somite and limb. Shh is processed to generate two peptides (19 kiloDalton and 26/27 kiloDalton) both of which are secreted. However, the *in vivo* distribution of Shh peptides in relation with these patterning events, has not been reported. To investigate Shh distribution *in vivo* we have generated peptide specific antibodies. Immunostaining of chick and mouse embryos indicates that Shh peptides are expressed in the notochord and floor plate at the appropriate time for their postulated patterning functions. To further investigate Shh inductive abilities we have applied recombinant Shh peptides to neural explant in serum free medium.

High concentrations of Shh bound to a matrix induce floor plate and motor neurons, whilst addition of Shh to the medium leads to a dose dependent induction of motor neurons. All inducing activity resides in a highly conserved 19 kiloDalton amino terminal peptide. Moreover, antibodies which specifically recognize this peptide block induction of motor neurons by the notochord. We propose that Shh acts as a morphogen to induce distinct ventral cell types in the vertebrate central nervous system.

## TROPOMYOSIN EXPRESSION MARKS SEGMENT BOUNDARIES AND EARLY SEGREGATION OF NEUROEPITHELIUM IN THE DEVELOPING RAT BRAIN.

K.L. Nicholson, S.E. Hitchcock-DeGregori and P. Levitt\* Department of Neuroscience and Cell Biology, UMDNJ-RWJMS, Piscataway, NJ 08854.

Segmentation is important in the patterning of the vertebrate hindbrain. These segments, rhombomeres, are morphologically similar units which eventually develop characteristic, segment-specific structures. It has been proposed recently that similar segmentation exists in the developing prosencephalon, dividing it into prosomeres. While numerous genes have been identified that specify individual segments, the cellular and molecular nature of the boundaries between adjacent segments is not clear. Immunocytochemical mapping in early embryos was performed with TM311, a monoclonal antibody recognizing an epitope encoded by exon 1a of the rat  $\alpha$ -tropomyosin (TM) gene, found in all 284 residue (long) TMs. At embryonic day (E)11/12, TM specifically marks boundaries between rhombomeres in the hindbrain. At E12, TM is expressed in neuroepithelial cells at the: 1) caudal boundary of P1, between the pretectum and tectum; 2) P2-P3 boundary including the zona limitans intrathalamica; 3) P3-P4 boundary between the ventral thalamus and hypothalamus; and 4) P5-P6 boundary between the preoptic areas and presumptive basal ganglia. Interestingly, TM immunoreactivity at boundaries is usually accompanied by morphological distinctions, suggesting a structural role for TM in shaping the neuroepithelium. Furthermore, TM is expressed at E11 in cells that appear to serve as forerunners of the choroid plexus (CP), almost 3 days prior to CP expansion into the lateral ventricle. At E14, TM marks the ventro-medial wall of the dorsal telencephalon, an area thought to be presumptive hippocampus. These cells are not immunoreactive for a neuron-specific marker, microtubule associated protein 1B (MAP1B), indicating that the neuroepithelium that forms the choroid plexus is functionally segregated early from neuronal precursors. The specific TM expression patterns may reflect a role for the protein in dynamic regulation of cell shape in specific brain regions during embryogenesis. Supported by NIMH45507 (PL) and HL35726 (SEHD).

A NOVEL PREPARATION FOR INVESTIGATING TRIGEMINAL CONNECTIONS IN FETAL RATS. P.M.E. Waite\*, S. Ho and T. A. Henderson, Anatomy, UNSW, Sydney; Devel. Neurobiol., ANU, Canberra, Australia; Neurology, Washington Univ., St. Louis, MO 63110.

Sensory connections from trigeminal ganglion cells innervating rat facial skin and whiskers grow into the brainstem from embryonic day (E) 13 and are topographically organised (Erzurumlu & Jhaveri '92, J. Neurosci. 12:3946). However, it is not known whether individual arbourts are initially circumscribed and precisely localised or are initially exuberant and later pruned back. We utilised a novel method to investigate this early arbour development. The preparation consists of a horizontal 'slice' through the head, containing the base of the skull, the maxillary and mandibular processes and the brainstem, maintained in oxygenated Krebs solution at 27°C. The trigeminal ganglion and its peripheral and central connections are preserved intact and are accessible for recording and labelling. Injections of 6% neurobiotin have been made into the trigeminal ganglion of rat pups from E14-E21. At E14 axons are present throughout the trigeminal tract from the pons to upper medulla but no collaterals are seen in the trigeminal nuclei. By E15, simple collaterals are present in the trigeminal nuclei at all levels. Two days later individual collaterals are relatively widespread and overlapping, with arbourts covering, on average, 2.1% of the cross-sectional area of the principal nucleus. By E19, single collaterals are more densely branched and restricted in size, with the cross-sectional area reduced to 1.2% of the total nuclear area. This compares with the value of 0.75% for the cross-sectional areas of individual arbourts, relative to the total area of the principal nucleus, in adult rats (Shang et al. '93, Soc. Neurosci. Abs. 19: 326). These results indicate that the central arbourts of trigeminal afferents are relatively more widespread during an early stage of development than in mature animals. ## 603.17

FORMATION OF THE TAIL SPINAL CORD *IN VITRO*. R.D. Heathcote\*, N. Vali and A. Chen, Department of Biological Sciences, University of Wisconsin-Milwaukee, Box 413, Milwaukee, WI 53201.

In the frog *Xenopus laevis*, new spinal cord forms as the tail elongates. Recent work in other laboratories suggests that the "tail organizer" derives from the dorsal lip of the blastopore, or Spemann's organizer. Studies in our laboratory showed that neural plate explants containing the tail organizer differentiated tail-like structures, including notochord and neural tube. To determine whether these tail structures resulted from the differentiation of new tissue, we surgically removed the notochord from neural plate explants and tested for notochord differentiation in the resulting tails. At the time of surgery (stage 14/15), notochord is immunoreactive for the notochord marker keratan sulphate (monoclonal antibody MZ-15; courtesy of Dr. F. Watt). Removal of the notochord eliminated staining; however, after two to three days in culture, neural plates had tails that contained differentiated notochord immunoreactive for MZ-15. Thus notochord and presumably other tissue in the growing tail must come from new differentiation.

Neural tissue resembling spinal cord associated with notochord in the tail structures formed *in vitro*. We used the organization of catecholaminergic neurons to test whether normal spinal cord morphogenesis occurred *in vitro*. In the spinal cord, catecholaminergic neurons form two longitudinal columns of dispersed cells. In neural plate explants without tail organizer, catecholaminergic neurons differentiated in a dispersed pattern, but lacked longitudinal columns. In explants with tail organizer, catecholaminergic neurons associated with new notochord and formed longitudinal columns of dispersed cells. These results indicate that differentiation and morphogenesis of some populations of tail spinal cord neurons occur *in vitro*.

RE-CONSTRUCTION OF THE MOUSE *Hox-b3* GENE EXPRESSION PATTERN IN TRANSGENIC MICE. C.T. Kwan, P.M. Chiu, R. Krumlauf and M.H. Sham (SPON: The Hong Kong Society of Neurosciences). Department of Biochemistry, University of Hong Kong, Sassoon Road, Hong Kong. \*National Institute for Medical Research, Mill Hill, London, NW7 1AA, U.K.

Developing hindbrain are subdivided into repeated morphological units, known as rhombomere in which each of them can establish a distinct phenotype. *Hox-b3* gene belongs to a class of gene, which is involved in pattern formation, expresses in the developing hindbrain with an anterior boundary in rhombomere 5 (r5). To identify the regulatory elements in the large genomic region of nearly 30 kb of the *Hox-b* cluster, we generated *lacZ* reporter gene constructs with a series of genomic sequences flanking the *Hox-b3* gene. Studies of the whole mount *lacZ* expression patterns revealed that different genomic sequences can specifically direct expression in wide range of tissues including hindbrain, spinal cord and mesodermal derivatives in transgenic embryos. Each of these elements can impose a subset of *Hox-b3* expression patterns in transgenic mice. Of these, two neural specific elements can direct *lacZ* expression in (r5) while another one in r6, r7 and the spinal cord. Recombinant reporter gene construct containing both of these two elements direct *lacZ* expression from the spinal cord, extending to the hindbrain with a limit of expression at r5. Interestingly the expression level in both r5 and r6 were higher than the remaining CNS regions. We have also isolated mesodermal specific element which direct *lacZ* expression in the somites of the 9.5 dpc embryo. Histological studies of the 12.5 dpc transgenic embryo revealed that expression were also found in the fore- and hindlimb buds, stomach, heart, pancreas and muscle surrounding the vertebrae. When genomic regions containing the tissue specific regulatory elements were introduced into transgenic mice, the expression of the reporter gene was detected in all the endogenous expression domains. Moreover, higher level of *lacZ* expression was detected in r5. Our results suggest that the cis-acting elements identified by transgenic mice analyses are able to direct spatially-specific expression of *Hox-b3*, and when recombined, could re-construct the endogenous pattern.

## 603.16

REGULATION OF COLLAGEN TYPE XIV EXPRESSION IN THE EARLY CHICK EMBRYO AND ITS FUNCTION. S. Tono-oka<sup>1,3</sup>, M. Fukushima<sup>1</sup>, S. Tanase<sup>2</sup>, K. Ohta<sup>1</sup>, T. Mijke<sup>3</sup>, and H. Tanaka<sup>1</sup>\*. <sup>1</sup>Div. Dev. Neurobiol., Kumamoto Univ. Graduate Sch. Med. Sciences, Kurohiji 4, Kumamoto 862, <sup>2</sup>Dept. of Biochemistry, <sup>3</sup>Dept. of Child Development, Kumamoto Univ. Sch. Med., Honjo 2, Kumamoto 860, Japan

We isolated a monoclonal antibody, called DBM, that uniquely stained dorsal aspect of the spinal cord basement membrane. Asymmetric antibody staining on the spinal cord basement membrane was detected just after neural tube closure. DBM antigen was restricted to only on the ectoderm, but not on the endoderm nor notochord basement membrane at early developmental stages and distributed with the dorsoventral gradient at the entire body. DBM staining in the main muscle connective tissue was developmentally transient and reappeared after denervation. Furthermore, since notochord basement membrane became to express DBM antigen after neural tube removal or transplantation under the skin ectoderm, DBM expression on the neural tube basement membrane was appeared to be regulated by skin ectoderm.

DBM antigenic molecule was purified from E 10-12 whole chick embryos and found to be FACIT (fibril associated collagens with interrupted triple helices) collagen type XIV. It seems to control the temporal and spatial arrangement of collagen fibrils that are specific to the tissues. These unique expression and regulation of collagen type XIV in the basement membrane suggest its importance of body development. We are now examining the roles of collagen type XIV on cell adhesion and neurite outgrowth of neural tube cells in cell culture.

## 603.18

## SECONDARY NEURULATION IN TELEOSTS OCCURS BY APOPTOSIS.

E.K. Findeis and C.E. Milligan\*

Department of Biology, University of Massachusetts, Amherst, MA

In most vertebrates, primary neurulation occurs by elevation and medial folding of the neural plate resulting in the neural plate. In teleost fishes however, the neural tube forms as a solid mass of cells, the medullary cord, that opens by a process referred to as secondary neurulation or cavitation. The mechanism of cavitation has been in question, but one hypothesis is that programmed cell death ablates cells centrally to open the medullary cord. Apoptosis, a type of programmed cell death involves the cleavage of genomic DNA. Cells undergoing apoptosis can be identified in tissue sections by performing an *in situ* nick translation reaction. In this study, catfish embryos (*Ictalurus punctatus*) were collected and fixed during the time of cavitation. Apoptotic cells were detected in the developing neural tube, particularly within the center region prior to apparent cavitation. These results suggest that programmed cell death is partly responsible for the establishment of early CNS of teleosts.

**DISTRIBUTION OF INJECTED  $^{59}\text{Fe}$  AND  $^{54}\text{Mn}$  IN THE HYPOTRANSFERRINEMIC (Hp) MOUSE.** T.K. Dickinson, A.G. Devenyi, & J.R. Connor\*, Penn State University, Hershey Medical Center, Hershey, PA 17033.

The hypotransferrinemic (Hp) mouse has a mutation in the transferrin (Tf) gene causing defective splicing of a Tf precursor mRNA. This results in production of <1% of the normal circulating level of Tf. Homozygous mutant animals require supplemental injections of mouse serum of purified Tf. Heterozygote (Hh) Hp animals have approximately 50% of normal circulating Tf levels require no supplemental Tf and live a normal life span. Hh animals are, however, subject to abnormal iron (Fe) deposition with age. For this study, adult wild type (WT), Hh and mutant Hp mice were injected with  $^{59}\text{Fe}$  or manganese ( $^{54}\text{Mn}$ ) to determine their distribution in Tf-deficient animals. Our goal is to utilize the mutant and Hh Hp mice to further our understanding of Tf's role in normal Fe and Mn mobilization and diseases in which brain Fe (Parkinson's, Alzheimer's) or brain Mn (chronic liver disease) are altered. Animals received a single injection and were sacrificed at 24 hours, 7 days and 4 weeks. Analysis included brain, liver, spleen, heart, plasma and blood formed elements. Over the 4 week period, plasma, brain and heart levels of Fe and Mn remained constant whereas liver and spleen levels fell. WT and Hh animals had similar Fe and Mn arguing that 50% Tf levels are sufficient for normal Fe and Mn delivery to tissue. Alterations in both Fe and Mn delivery to liver and spleen in mutant animals is evidence for Tf's role in proper tissue targeting. Similarity in brain levels of Fe and Mn in all three animals argues for the existence of a significant, non-Tf mediated, Fe and Mn delivery to brain.

## 604.3

**IMMUNOHISTOCHEMICAL LOCALIZATION OF GLIAL CELL-LINE DERIVED NEUROTROPHIC FACTOR IN THE HUMAN BRAINS OF NORMAL AND PARKINSONIAN CASES.** A. Matsuo, D.G. Walker, P.L. McGeer and E.G. McGeer\*, Kinsmen Lab. of Neurol. Res., Univ. of British Columbia, Vancouver, B.C., Canada, V6T 1Z3.

Glial cell-line derived neurotrophic factor (GDNF) is a recently identified protein, known to be produced by astrocytes, and known to have protective effects on dopamine neurons. We employed immunohistochemistry to study the cellular localization of GDNF in normal and Parkinson's disease (PD) cases. In normal brains, GDNF was found as granular deposits on woolly fibers in the substantia nigra (SN) and globus pallidus, especially in the internal segment. It had a more distributed granular localization in the neuropil of the caudate and putamen. Double immunostaining established that the woolly fibers were substance-P positive. Some neuronal nuclei in the SN, caudate, putamen and thalamus were more smoothly stained, suggesting a translocation to nuclei. In PD SN, GDNF staining was less intense than in controls. We detected GDNF mRNA expression in the SN of normal and PD cases using the reverse transcriptase-polymerase chain reaction technique, establishing local production. This may be from astrocytes, since occasional astrocytes in the area were GDNF positive.

The present study supports a role for GDNF in basal ganglia function. Changes of GDNF expression in Parkinsonian brains could be related to the pathology of the disease. (Supported by a grant from the Parkinson Foundation of Canada.)

## 604.5

**NEUROTROPHIC FACTOR EXPRESSION IN CULTURED ASTROCYTES FROM NEONATAL, ADULT AND INJURED RAT BRAIN.** Vivian W. Wu and Joan P. Schwartz\*. Clinical Neuroscience Branch, NINDS, NIH, Bethesda, MD 20892

Much interest has focused on the role of cytokines as modulators of neurotrophic factor production by astrocytes in brain, particularly after injury when cytokine levels are increased. Astrocytes cultured from 6-hydroxydopamine (6-OHDA) lesioned brain can be distinguished from normal adult astrocytes on the basis of enhanced staining with either of two monoclonal antibodies (13A11 and 01E4; gift of Dennis Landis) which bind to an epitope present only in reactive astrocytes in vivo. Cultured astrocytes from neonatal animals show an intermediate degree of staining. Comparable differences are seen in GFAP staining. Levels of NGF mRNA were compared in astrocytes cultured from postnatal day 2 rats with those from adult rats with or without 6-OHDA lesion. Interleukin-1 $\beta$  (IL-1 $\beta$ ), tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) and interferon- $\gamma$  (IFN- $\gamma$ ) increase NGF mRNA expression in neonatal striatal and cortical astrocytes, but had only minimal effect in quiescent adult striatal and cortical astrocytes. IL-1 $\beta$  treatment also caused a significant increase in NGF mRNA in reactive striatal astrocytes prepared 7 days after 6-OHDA injection relative to those prepared from saline-injected brain. The effects of TNF- $\alpha$  and IFN- $\gamma$  are now being tested. These cultures will allow us to study the processes by which quiescent astrocytes in adult brain convert to reactive astrocytes following injury.

## 604.2

**S100 AND CALMODULIN EXPRESSION IN DIABETES.** J. Chessher, N. Gardner, S. Schaffer, G. Wilson, W. E. Zimmer, and D. B. Zimmer\*, Departments of Pharmacology and Structural and Cellular Biology, University of South Alabama, Mobile, AL 36688.

The calcium-modulated proteins S100A1, S100B, and calmodulin are expressed at high levels in the nervous system. Altered expression of these proteins has been documented in many disease states in which intracellular calcium levels are altered, including some neurodegenerative disorders and diabetes. In order to better understand the mechanisms which regulate calcium-modulated protein expression in diabetes, we have examined the steady-state mRNA levels for S100A1, S100B, and calmodulin in Type I and Type II diabetic rats and age-matched controls. Total RNA from aorta, fast and slow-twitch muscle fibers, liver, heart, brain, large intestine, kidney, white and brown fat, and spleen was blotted onto nylon membranes. The resulting filters were hybridized with probes specific for the single rat S100A1 or S100B mRNAs or the multiple rat calmodulin mRNAs produced by each of the three rat calmodulin genes. In the brain, S100A1 and S100B mRNA levels were lower in animals with Type I diabetes when compared to control animals. However, S100A1 levels were decreased and S100B levels unaltered in animals with Type II diabetes. The levels of the three calmodulin mRNAs were unaltered in Type I diabetes while the level of two calmodulin mRNAs decreased in Type II diabetes. The mRNA levels for these proteins also changed in the other tissues examined, but these changes did not always parallel those observed in brain. These results demonstrate that the diabetic state does not coordinately regulate the expression of these calcium-binding proteins. Thus, the contribution of these gene products to the expression of the diabetic phenotype will be specific for the diabetic state and will vary from tissue to tissue. Supported by grants from the NIH (30660 to DBZ and ES-03456 to GW)

## 604.4

**THYROID HORMONE DEFICIENCY DISRUPTS THE DEVELOPMENTAL PATTERN OF EXPRESSION OF NEUROTROPHINS AND THEIR RECEPTORS IN THE CEREBELLUM.**

Isabelle Neveu\*, Hiroshi Funakoshi and Ernest Arenas. Lab of Molecular Neurobiology, Karolinska Institute, S-17177 Stockholm, Sweden.

Neurotrophic factors play important roles in neuronal development and are likely to participate in the development of the cerebellum. Alteration in the expression of neurotrophins and/or their receptors may contribute to the impairment observed in the development of the cerebellum in case of thyroid hormone (T3) deficiency. Therefore, we have compared the developmental expression of neurotrophins and their receptors in the cerebellum of normal and hypothyroid rats. RNase protection assay did not show any significant changes in the levels of the high-affinity receptors such as full length trk B and trk C mRNAs. However, we have observed a retardation in the downregulation of the low-affinity receptor, P75<sup>NTR</sup>, which resulted in 2-3 times higher levels of P75<sup>NTR</sup> mRNA at postnatal day 10. T3 deficiency also disrupted the developmental pattern of neurotrophins expression. In normal rats, the levels of BDNF, which were relatively low during the first two postnatal weeks, dramatically increased from P15. This upregulation appeared to be strongly impaired in hypothyroid rats since the BDNF mRNA levels was 4-fold lower in treated rats compared to controls. T3 deficiency also disrupted the transient increase of NT-3 mRNA levels which occurs in normal rats during the second postnatal week. These results suggest that alterations in BDNF and NT-3 expression may contribute to the impairments observed in the development of the cerebellum in hypothyroid rats. To test this hypothesis, we have grafted in the cerebellum of newborn rats, genetically-modified cell lines producing NT-3 or BDNF and we are currently studying if supplying neurotrophins would prevent some impairments occurring during the development of the cerebellum in hypothyroid rats.

## 604.6

**REGULATION OF BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF) PROTEIN LEVELS IN RAT BRAIN FOLLOWING GLOBAL FOREBRAIN ISCHEMIA** Zaal Kokaia<sup>1</sup>, Hiroyuki Nawa<sup>2</sup>, Hiroyuki Uchino<sup>3</sup>, Eskil Elmér<sup>1</sup>, Merab Kokaia<sup>4</sup>, Maj-Lis Smith<sup>3</sup>, Josette Carnahan<sup>4</sup>, Bo K. Siesjö<sup>3</sup> and Olle Lindvall<sup>1</sup>

<sup>1</sup> Restorative Neurology Unit, Department of Neurology, University Hospital, S-221 85 Lund, Sweden; <sup>2</sup> Beckman Neuroscience Center, Cold Spring Harbor Laboratory, Cold Spring Harbor, New York, 11724, USA; <sup>3</sup> Laboratory of Experimental Brain Research, University Hospital, S-221 85 Lund, Sweden; <sup>4</sup> Amgen Center, Thousand Oaks, California 91320, USA.

In previous studies, we have demonstrated differential and insult-specific changes of BDNF mRNA in different structures of the brain after kindling-evoked seizures, global forebrain ischemia, cortical spreading depression and hypoglycemic coma. Whether these changes of mRNA levels lead to the presumed alterations of BDNF protein levels has been unclear. Here we show differential changes of BDNF protein levels in the hippocampus and cortex of animals subjected to forebrain ischemia.

Male Wistar rats (n=24) were anesthetized with halothane and global forebrain ischemia was then induced for 10 min by bilateral occlusion of the common carotid arteries combined with hypotension. The animals were sacrificed after 6 h, 12 h, 24 h and 1 week of recovery. After decapitation the brains were immediately removed and dentate gyrus, hippocampal CA1 and CA3 regions and parietal cortex were dissected bilaterally. BDNF protein levels were measured using a two-site enzymatic immuno-assay which detects trace amounts of BDNF protein (>1 pg/assay) (Nawa et al., 1995).

Following global forebrain ischemia there was an increase of BDNF protein levels in the dentate gyrus and the CA3 region (6 h and 1 week after the ischemic insult, respectively). In contrast, in the CA1 region and the parietal cortex, which show selective neuronal damage after the forebrain ischemia, reduced levels of BDNF protein were detected 24 h after the insult. These data show that insult-induced changes of BDNF gene expression are followed by alterations of BDNF protein levels. Our findings are in good agreement with the hypothesis that BDNF has a neuroprotective role after brain insults.

## 604.7

**INCREASED EXPRESSION OF CNTF mRNA IN RAT HIPPOCAMPUS FOLLOWING ENTORHINAL CORTEX ABLATION** A. G. Woods\*, K. M. Guthrie and C. M. Gall, Departments of Anatomy and Neurobiology, and Psychobiology, University of California, Irvine, CA 92717.

Ciliary neurotrophic factor (CNTF) has been demonstrated to promote neuronal survival both *in vivo* and *in vitro*, and to induce the differentiation of both neurons and astrocytes. In the peripheral nervous system, CNTF mRNA is primarily localized to Schwann cells. In the normal adult central nervous system, the highest levels CNTF mRNA are found in the olfactory bulb and in areas of white matter, such as the optic nerve and spinal cord. Application of CNTF induces axonal sprouting and reinnervation of muscle in the periphery, raising the possibility that it may also facilitate sprouting in brain. We have recently shown that the mRNA for insulin-like growth factor-1 (IGF-1) increases with a temporal and spatial correspondence to reactive hippocampal sprouting which occurs following entorhinal cortex lesion. Using *in situ* hybridization we examined levels of CNTF mRNA in the brains of rats sacrificed at 3, 5, 7, 10 and 14 days following unilateral lesion of entorhinal cortex. CNTF mRNA was increased with a similar time course and distribution to IGF-1 mRNA, although CNTF mRNA appeared to be expressed slightly earlier and was primarily concentrated in areas of white matter. At 3 days postlesion, substantial increases in CNTF mRNA hybridization occurred in the dentate gyrus outer molecular layer and hilus, stratum lacunosum moleculare, fimbria and alveus. This effect occurred bilaterally, although hybridization density was greater in the hippocampus ipsilateral to the lesion. By 10 days postlesion, hybridization in most areas had returned to control levels, although labeling was still evident in corpus callosum at 14 days. Dense hybridization was also observed at the site of the lesion beginning at three days, and remained elevated through 14 days. These data indicate that CNTF mRNA expression by oligodendroglia is increased in regions containing degenerating axons and that this factor may play a role in reactive axonal growth in brain. Supported by NIA grant AG 00538.

## 604.9

**NEUROTROPHIC FACTOR EXPRESSION IN THE RAT BRAIN FOLLOWING CYTOTOXIC LESIONS TO THE HIPPOCAMPAL DENTATE GYRUS GRANULAR CELLS** C.R. Breese\*, J. Logel, C. Drebing, C.E. Adams, Y. Rollins, S. Leonard, Department of Pharmacology, University of Colorado Health Sciences Center, and Veterans Administration Medical Center, Denver, CO 80262.

Previous studies from our laboratory have shown that intradentate cytotoxic colchicine injections induces a substantial increase in IGF-1 gene expression in lesioned dentate gyrus and the damaged cortex (Neuroscience Abstracts 541.1, 1994). In the present study, the temporal and cellular expression of neurotrophic factors from several different families were examined in normal and lesioned rat brains, including, BDNF, CNTF, aFGF, bFGF, FGF-5, GDNF, NGF, NT-3, and TGF $\beta$ 1. In comparison, IGF-1 demonstrated the highest levels of expression in the lesioned hippocampus and damaged cortex. A large, temporally dependent increase was observed for BDNF in both ipsilateral and contralateral hippocampal CA3 neurons and dentate gyrus granular cells. There was only a negligible increase in bFGF, NGF, and TGF $\beta$ 1 gene expression in the lesioned hippocampus; with expression changes primarily restricted to later post-lesion time points (3-10 days). The other neurotrophic factors examined were either not expressed at detectable levels in the hippocampus (CNTF, aFGF, and GDNF), or demonstrated little or no change as a result of the lesion (FGF-5 and NT-3). While the present results demonstrate potential role for different neurotrophic factors in coordinating the post-injury response in the brain, particularly that of IGF-1. Compared to IGF-1, the lesion induced expression changes in the neurotrophic factors examined were temporally correlated, and therefore, probably not directly involved with the temporal coordination of IGF-1 expression, but may provide for other important aspects of the post-traumatic injury response in the CNS.

## 604.11

**EXPRESSION OF P75 (LOW AFFINITY NGF RECEPTOR) IN SCHWANN CELLS (SC) FOLLOWING LONG TERM DENERVATION** S. You, Th. Petrov, P.H. Chung, R.S. Smith\* and T. Gordon, Dept. of Pharmacology and Div. of Neuroscience, Univ. of Alberta, Edmonton, Alberta, Canada T6G 2S2.

p75 is synthesized in SC in the distal stump of injured peripheral nerves. We have used short term (1 week) and long term (1-12 months) transected distal sciatic nerves of the rat to determine the variations in the expression of p75 by using immunocytochemistry and *in situ* hybridization.

Semi-quantitative analysis of the intensity of the immunocytochemical reaction revealed that the synthesis of the p75 protein is rapidly enhanced to reach a peak at 1 month after denervation. Subsequently it decreased and was almost undetectable 6 months following denervation. Double immunocytochemistry for p75 and the S-100 protein (an excellent marker for SC) confirmed that the p75 immunoreactivity is confined to the SC. In our *in situ* hybridization experiments the mRNA was detected by autoradiography. Quantitative analysis revealed that the upregulation of the p75 mRNA coincides in time with the enhanced synthesis of the p75 protein and reaches a peak at 1 month after denervation. However, the downregulation at later stages is more rapid and after the 4 months p75 mRNA was undetectable.

The presence of p75 in the SC is necessary for regeneration, and our results suggest that, the SC's will ensure support for regeneration primarily in the 1st month after the denervation. The lack of p75 in long-term denervated distal nerve stumps may be one of the factors that contribute for unsatisfactory functional recovery after prolonged denervation.

## 604.8

**NEUROTROPHIN EXPRESSION IN RAT BRAIN AFTER IMMUNELESION** J.Yu\* and R. Perez-Polo, Dept. Of Human Biological Chemistry and Genetics, Univ. of Texas Medical Branch, Galveston, Texas 77555-0652.

Neurotrophin is expressed at high levels in adult hippocampus, and to a lesser extent, in cerebral cortex, two principal targets of the ascending basal forebrain cholinergic projection systems. Since neuronal activity imposes a regulatory influence over the expression of NGF and BDNF genes in adult hippocampus, the topographical correlation of neurotrophin expression with cholinergic terminal distribution from septal cholinergic neurons raises the question as to whether the cholinergic system regulates the synthesis of neurotrophins. Studies using fimbria-fornix transection or pharmacological manipulations have been controversial, since they cause confounding changes to the cholinergic and other neurotransmitter systems. Our aim was to examine the importance of cholinergic regulation of neurotrophin synthesis by intraventricular injections of 192 IgG-saporin, a cytotoxin to septal cholinergic neurons that extensively and selectively kills p75<sup>NTR</sup>-bearing neurons in basal forebrain. We showed that 192 IgG-saporin resulted in profound decreases in p75<sup>NTR</sup> and *trkA* mRNA levels in the basal forebrain at 1 week and up to 5 months after injection, but there were no significant decreases of p75<sup>NTR</sup> and/or *trkA* expressions in striatum and cerebellum. Ribonuclease protection assays showed that the cholinergic deafferentation of the hippocampus, cortex, and olfactory bulb-the three main targets of basal forebrain cholinergic neurons-failed to produce any significant changes in NGF, BDNF and/or NT-3 mRNA levels there. Thus, the cholinergic system in the adult rat brain does not influence neurotrophin expression in a significant way and the reported effects of fimbria-fornix transection and pharmacological manipulations on neurotrophin expression in adult hippocampus may be mediated via other neurotransmitter or signalling mechanisms. Supported in part by NINDS NS18708. This is publication #28A and supported by USPHS grant P01AG10514 awarded by NIA.

## 604.10

**EXPRESSION OF NEUROTROPHIC FACTORS IN A DEMYELINATING NEUROPATHY** H. Hyman, Friedman, T.N. Jelsma\*, Y.-C. Wang, G.M. Bray, and A.J. Aguayo, The Montreal General Hospital Research Institute, 1650 Cedar Ave., Montreal, P.Q., H3G 1A4.

Peripheral nerve transection is known to result in a strong upregulation of NGF and BDNF mRNA expression in the degenerating distal stump. Concomitantly, CNTF expression is reduced more than ten fold. On the other hand, the patterns of neurotrophin expression in demyelinating diseases of the peripheral nervous system have not been investigated. Trembler (Tr) mice have a dominantly inherited demyelinating neuropathy due to a point mutation in the *pmp22* gene. In this neuropathy, there is incomplete ensheathment of axons by myelin-forming Schwann cells, myelin breakdown, and Schwann cell proliferation throughout the life of the animal. To determine if the abnormal Schwann cell phenotype affects the expression of neurotrophic factors, we compared mRNA levels of BDNF, NGF, and CNTF in Tr and control peripheral nerves. Using a sensitive RT-PCR quantitation technique, the levels of BDNF mRNA and of NGF mRNA were similar in intact and Tr nerves. In contrast, the level of CNTF mRNA was dramatically reduced in the Tr nerve. The levels of expression of neurotrophic factors in sciatic nerves following transection were also tested to determine if Tr myelin-forming Schwann cells maintain the ability to upregulate BDNF and NGF.

Two weeks after transection, the levels of BDNF and NGF mRNAs were increased in the distal stumps of both intact and Tr nerves. These results indicate that demyelination and Schwann cell proliferation in the Trembler mouse are not accompanied by an increase in neurotrophin expression as seen after axonal breakdown; however, both cause a downregulation of CNTF mRNA. The effects of such changes on neuronal function have not been clarified.

## 604.12

**BDNF GENE EXPRESSION IN CULTURED RAT ASTROCYTE IS ENHANCED UPON GLIA DAMAGE** M.J.Tsai\*, W.Y.Lee, H.C.Hung, A.M.Huang and E.H.Y.Lee, Institute of Biomedical Sci., Academia Sinica, Taipei 115, Taiwan, R.O.C.

Brain-derived neurotrophic factor (BDNF) has been shown to be a neurotrophic factor for several types of neurons. Recent study indicates the presence of BDNF gene also in astrocytes. The present work examined the possible role of BDNF also as a trophic factor for glial cells. Cultured rat and mouse astrocytes were used. 1-Methyl-4-phenylpyridinium (MPP<sup>+</sup>) and  $\alpha$ -amino-adipate ( $\alpha$ -AA) were adopted as pharmacological tools to destroy glial cells and the quantitative RT-PCR method was used to assess BDNF gene expression. Results indicated that MPP<sup>+</sup> (10-75  $\mu$ M) produced a dose-dependent loss of cell viability as judged by the amount of lactate dehydrogenase (LDH) released into the incubation medium in rat astrocyte, while it also markedly elevated BDNF gene expression in a dose-response fashion. However, MPP<sup>+</sup> (5-40  $\mu$ M) also produced a dose-dependent cell damage in mouse astrocyte, while BDNF gene expression was not increased accordingly. The gliotoxin  $\alpha$ -AA yielded similar results. These results together partially explain the differential vulnerability of mouse and rat to MPP<sup>+</sup> toxicity and suggest that BDNF may serve as a trophic factor for rat astrocyte cells.

## 604.13

**EXPERIMENTALLY INDUCED DIABETES ALTERS TRK A GENE EXPRESSION IN PRIMARY SENSORY NEURONS OF RATS** *Alison S. Depto, Francis J. Liuzzi\* and Aaron J. Vinik*. The Diabetic Neuropathy Study Group. The Diabetes Institutes and Departments of Internal Medicine, and Anatomy and Neurobiology, Eastern Virginia Med. Sch. Norfolk, VA 23501

Diabetic neuropathy has significant sensory and autonomic components as well as impaired nerve regenerative capacity. Abnormalities in expression of nerve growth factor (NGF) or its receptors may be involved. NGF regulates expression of the preprotachykinin gene products which are decreased in diabetes. Tyrosine receptor kinase (trk) A, the high affinity receptor for NGF, is necessary for survival, maintenance, and growth of a subset of sensory neurons. In this study, we used in situ hybridization and Northern blot analyses to examine expression of trk A in L4 and L5 dorsal root ganglion (DRG) neurons from normal and streptozotocin-induced diabetic rats. Overall levels of trk A was approximately two fold higher in DRG neurons from diabetic animals. TrkA mRNA were expressed by 33% of neurons in both groups. To examine expression of trk A during nerve regeneration, normal and diabetic animals were subjected to sciatic nerve transection, and silicon tube implantation, followed by 4 weeks of nerve regeneration. Axotomy decreased expression of trk A in both regenerative groups by approximately half compared to DRGs from non-axotomized counterparts. In normal regenerative animals, trk A was expressed by 15 % of neurons. DRGs from diabetic regenerative animals demonstrated 24% trk A positive neurons. These data demonstrate that trk A mRNA expression increases in diabetes. It is unimpaired in diabetic sensory neurons undergoing regeneration. The cause for sensory neuropathy in diabetes may not reside in defective Trk A gene expression. It may yet be related to abnormalities in neurotrophins and their receptors.

## 604.15

**INFLAMMATION PRODUCES UP-REGULATION OF NEUROTROPHIN MESSENGER RNA LEVELS IN BLADDER**

*Daniela Oddi\*, Steve B McMahon\* and Marcus Rattray\** \*Division of Biochemistry and Molecular Biology and \*Division of Physiology, UMDS, University of London, Guy's Hospital, London SE1 9RT, U.K.

There is increasing evidence that neurotrophins can influence the activity of sensory neurones after acute inflammation. Using reverse-transcriptase PCR and in situ hybridisation, we have measured changes in levels of NGF, BDNF and NT3 mRNAs in bladder after inflammation. Inflammation was induced by administration of 0.5 ml 25% turpentine oil into the bladder for one hour. RNA was extracted from bladder and used for RT-PCR using primers 5'-end labelled with <sup>32</sup>P. Quantification of gel autoradiograms showed that inflammation produced a marked up-regulation of BDNF mRNA with a smaller increase in the levels of NGF and NT3 mRNA (see figure). The maximum effect occurred two hours after inflammation, and had disappeared 6 h and 24 h after inflammation. In situ hybridisation analysis suggested that NGF mRNA was expressed by epithelial cells of the bladder, whereas BDNF mRNA was mostly expressed in the muscular layer. Our results support the hypothesis that production of neurotrophins in target tissues is a component of the pronociceptive response to inflammation. Research supported by MRC

## NEUROTROPHIC FACTORS: BIOLOGIC EFFECTS X

## 605.1

**THE ROLE OF SECONDARY MUSCLE FIBER AND MUSCLE-DERIVED NT-4/5 FOR MOTONEURON SURVIVAL IN TRANSGENIC MICE** *T.J. Brennan, E.N. Olson, W.H. Klein, H.S. Phillips\*, J.W. Winslow*. Genentech, Inc., S. San Francisco, CA 94080 and M.D. Anderson Cancer Center, Houston, TX 77030.

We have generated transgenic mouse models to determine aspects of the muscle target which may regulate motoneuron number during programmed cell death. The role of target size and stage of muscle development on motor neuron survival was studied in mice in which the muscle regulatory gene myogenin was mutated, resulting in the loss of secondary myofiber formation. Over 60% of lumbar spinal motoneurons, and 100% of facial motoneurons survive at E18 relative to wild-type controls despite the loss of approximately 90% of hindlimb and facial muscle mass, respectively. DiI-retrograde labelling, cholinesterase and bungarotoxin staining of motor endplates and clustered nicotinic acetylcholine receptors, respectively, demonstrate that the surviving motoneurons have normal projection characteristics into the hindlimb, and establish synaptic contact into the remaining rudimentary fibers. These findings indicate that primary muscle fibers, representing only a fraction of normal muscle mass, contribute significantly to the control of motoneuron survival during development. To determine whether an increased level of a muscle-derived, motoneuron trophic factor is sufficient to promote survival during programmed cell death, 2 lines of transgenic mice were generated overexpressing NT4/5 mRNA in skeletal muscle. Normal numbers of facial motoneurons in postnatal NT4/5 transgenic mice were observed, suggesting limited availability of NT4/5 protein, or the limited responsiveness of motoneurons to ectopic trophic factor expression in vivo.

## 604.14

**NEUROTROPHIC ACTIVITY FOR BRAINSTEM CHOLINERGIC NEURONS IN CYTOKINE-ACTIVATED ASTROCYTES** *M. Sagoh\*, K. Yoshida, H. Kamiguchi, M. Inaba, H. Sasaki, M. Otani, S. Toya*. Dept. of Neurosurg., Sch. of Med., Keio Univ., Shinjuku-ku, Tokyo 160, Japan

Astrocytes has various types of neurotrophic activity. We have previously demonstrated that some cytokines, including fibroblast growth factor (FGF), interleukin-1 $\beta$  (IL-1 $\beta$ ), tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) increase choline acetyltransferase (ChAT) activity of the septal cholinergic neurons via nerve growth factor produced by astrocytes. In the present study, neurotrophic activity for NGF-insensitive brainstem cholinergic neurons in astrocytes was investigated. The effect of astrocyte-conditioned medium (ACM) on selective neuronal cultures obtained from E-16 rat brainstem was examined. ChAT activity of the brainstem neurons was enhanced by the addition of ACM. The effect of ACM obtained from astrocytes stimulated by acidic FGF, IL-1 $\beta$  and TNF- $\alpha$  was more potent than that of unstimulated ACM. Subsequently, partial purification of the neurotrophic molecules for brainstem cholinergic neurons in cytokine-stimulated ACM was performed by using a heparin-affinity column and a gel-filtration column. Neurotrophic factor for brainstem cholinergic neurons was identified as a heparin binding protein, which molecular weight was 40 - 60 kD.

## 605.2

**EFFECT OF NEUROTROPHINS ON mRNA LEVELS IN AXOTOMIZED ADULT RAT FACIAL MOTONEURONS** *K.Fernandes, B.J.Jasmin, W.Tetzlaff\**. Department of Physiology, Faculty of Medicine, University of Ottawa, Ottawa, Canada.

We have previously reported that direct osmotic minipump application of NT-4 to the proximal stump of axotomized adult rat facial motoneurons increases the axotomy-induced expression of GAP-43 and  $\alpha$ 1-tubulin mRNA over contralateral vehicle-treated axotomized facial motoneurons, while preventing the axotomy-induced decline in AChE mRNA. In the present study we further describe the ability of the other neurotrophin family members, BDNF, NT-3 and NGF, to regulate these genes associated with regeneration or neurotransmission. *In-situ* hybridization reveals that, in comparison to contralateral vehicle treated axotomized facial motoneurons, AChE mRNA expression after axotomy is significantly elevated by BDNF (195%, n=8), NT-4 (202%, n=4), and NT-3 (146%, n=6), while NGF had no effect. The axotomy-induced increase in GAP-43 mRNA (33X) is further increased with NT-4 (211%, n=4), and to a lesser extent by BDNF (120%, n=9), but not by NT-3 (99%, n=6). Similarly, the axotomy-induced stimulation of  $\alpha$ 1-tubulin (17X) is increased by BDNF (166%, n=4), NT-4 (170%, n=4), and NT-3 (124%, n=6).

These results support the hypothesis that the axotomy-induced decrease in neurotransmission associated gene expression, but not the accompanying increase in regeneration associated genes (GAP-43,  $\alpha$ 1-tubulin), may be triggered by the loss of target-derived neurotrophins.

## 605.3

**Expression of neurotrophic molecules under control of muscle specific promoters** M. Willem, A. Kawata, P. Carroll, M. Meyer\* and H. Thoenen. Department of Neurochemistry, Max-Planck-Institut für Psychiatrie, Am Klopferspitz 18a, D-82152 Martinsried, Germany. Several molecules exhibit trophic effects on motoneurons either in vivo or in vitro or both. CNTF (Ciliary Neurotrophic Factor) and BDNF (Brain Derived Neurotrophic Factor) represent two of these factors and it is the goal of our investigations to elucidate, in a mouse model system, their suitability for the treatment of degenerative diseases of motoneurons. Muscle fibres have the special ability to take up and express intramuscularly injected DNA. Our studies evaluate muscle as a delivery system to introduce neurotrophin molecules postnatally into mice. CNTF and BDNF genes under the control of various viral and muscle specific promoters were introduced into muscles by direct plasmid injection. Muscle tissues from such mice are being analysed to examine the extent and length of time of the expression of the transfected genes. We are analysing the effect of an unilateral injection of these plasmids into the gastrocnemius- and soleus-muscle of pmm/pmm mice, an autosomal recessive mutant leading to caudo-cranial motor neuron degeneration. In parallel we are establishing transgenic mice overexpressing BDNF or a secretable form of CNTF driven by a muscle creatine kinase promoter in skeletal muscle. Five founder animals expressing BDNF were obtained by pro nucleus injection. 3 lines showed specific expression of the transgene in skeletal muscle. The consequences of the muscle specific BDNF-overexpression especially on the motor nervous system are under investigation. The mice carrying the transgene have been crossed with a BDNF mutant mouse line to achieve a rescue effect on the PNS in the BDNF -/- mice, which die within the first three postnatal weeks.

**CNTF POTENTIATES THE EFFECTS OF BDNF, GDNF, OR HGF IN CULTURED MOTOR NEURONS.** V. Wong\*, Y. Song, R. Arriaga, and R.M. Lindsay. Regeneron Pharmaceuticals, Tarrytown, NY 10591.

CNTF, BDNF, GDNF, and hepatocyte growth factor (HGF) have been shown to promote survival and/or differentiation of motor neurons in vitro and in vivo. In this study, we show that CNTF synergizes with BDNF, GDNF, or HGF, but not NT-3, to enhance motor neuron survival and/or differentiation in vitro. When added alone to motor neuron cultures, CNTF, BDNF, GDNF, or HGF all stimulated choline acetyltransferase (ChAT) activity. However, when CNTF was added in combination with BDNF, GDNF, or HGF, ChAT activity was elevated to levels above the sum of each of the two factors alone. For example, when saturating concentrations of HGF (50ng/ml) and CNTF (1ng/ml) were added simultaneously to motor neuron cultures, ChAT activity was elevated 14-fold after 48 hr, almost doubling the sum of the 2 factors alone. Matrix studies showed that much lower concentrations of these factors can be used in combination to achieve effects equivalent to that of high doses of a single factor. In the presence of 1ng/ml GDNF, <0.1ng/ml of CNTF was required to achieve its maximal stimulation of ChAT activity, as compared to 1ng/ml when administered alone. The cellular mechanisms that mediate these synergies are currently being investigated. Thus, we show that the combination of neurotrophic factors at low doses results in equivalent or better effects on motor neuron survival and/or differentiation compared to the individual factors alone. These findings may be relevant to the treatment of human motor neuron diseases where previous studies have shown that high doses of neurotrophic factors can result in deleterious effects.

**LOCAL ADDITION OF NEUROTROPHINS NGF, BDNF AND NT-3 ENHANCES PERIPHERAL NERVE REGENERATION IN ADULT ANIMALS.** R.D. Lainetti<sup>1</sup>, R.L. Sidman<sup>2</sup>, R.M. Lindsay<sup>3</sup> and C.F. Da-Silva<sup>1</sup>.

<sup>1</sup>Dept. of Histology, University of Sao Paulo, SP 05508-900, Brazil, <sup>2</sup>New England Reg. Primate Res. Ctr., Harvard Med. Sch., Southborough, MA 01772-9102, <sup>3</sup>Regeneron Pharm., Tarrytown, NY 10591.

Neurotrophins were tested for their effects on regenerating peripheral neurons in adult animals. In 12 male adult C57BL/6J mice the left sciatic nerve was cut and both proximal and distal stumps were sutured into a polyethylene tube (PT) (0.76 mm ID) leaving a 4 mm gap. The animals were divided into 4 groups of 3 animals each and implanted with PTs filled with one of the following solutions: (1) purified preparation of collagen (Vitrogen, 2.4 mg/ml) plus cytochrome C (a protein used as a control for neurotrophins); (2) Vitrogen +  $\beta$ -NGF; (3) Vitrogen + BDNF and (4) Vitrogen + NT-3. All solutions (2  $\mu$ l/tube) were made up in 1:1 volume ratio, with 100  $\mu$ g/ml of neurotrophin in the tubes. After a survival time of 4 weeks, the PTs with the regenerated nerve cables were processed for Epon embedding. Myelinated axons were counted from the mid-portion of the cables with a computer-controlled system (Biographics). The results showed a significant difference ( $p < 0.05$ ) in the number of axons between the control cyt. C group (1338 $\pm$ 200, mean $\pm$ SEM) and the NGF (1982 $\pm$ 115), BDNF (2282 $\pm$ 114) and NT-3 (2671 $\pm$ 245) groups. These data demonstrate that local administration of neurotrophins increases peripheral axon regeneration in adult animals. Sensory DRG and spinal motor neuron counts as well as axon counts in the L<sub>5</sub> spinal roots are in progress and should determine whether this stimulatory effect of neurotrophins is due to a neurite-promoting activity or a survival action on axotomized neurons or both.

## 605.4

**TrkB Neurotrophic Factor Receptor Agonists Prevent Loss of the Cholinergic Motor Neuronal Phenotype after Injury in the Adult Rat.** A. Blesch<sup>1</sup>, D. O'Keefe<sup>2</sup>, E. Mafong<sup>2</sup>, M.H. Tuszynski<sup>1,2</sup>. <sup>1</sup>Dept Neurosciences, University of California-San Diego, La Jolla, CA. 92093; <sup>2</sup>VA Medical Center, San Diego, CA.

CNS neurons demonstrate differential responses to neurotrophic factors depending upon phenotype, age, and presence of appropriate neurotrophin receptors. Injured neonatal motor neurons respond to BDNF, NT-3, CNTF and GDNF, but injured adult motor neuron responses to neurotrophic factors have not been fully characterized. In the present study, the ability of various neurotrophins to prevent injury-induced downregulation of the cholinergic neuronal phenotype in injured adult motor neurons was assessed.

Adult Fischer 344 rats underwent unilateral hypoglossal nerve transections, followed by intracerebroventricular infusions of either human NGF, BDNF, NT-3, NT-4/5, CNTF, GDNF or artificial CSF continuously for two weeks (1.4  $\mu$ g/d). 2 weeks later, ChAT immunoreactivity could be detected in only 26.5 $\pm$ 4.1% of hypoglossal neurons in control animals that received artificial CSF infusions. In contrast, the trkB agonists BDNF and NT-4/5 prevented the loss of ChAT labelling in 97 $\pm$ 11% and 99 $\pm$ 5% of neurons, respectively. NGF and NT-3 exerted no protective effect; CNTF and GDNF effects are under assessment. In all cases, injured hypoglossal neurons upregulated expression of the p75 low affinity neurotrophin receptor.

Thus, injured adult motor neurons remain responsive to trkB but not to trkA or trkC agonists. ICV delivery of neurotrophins is an effective means of eliciting responses from motor neurons.

## 605.6

**COMPARISON OF THE EFFECTS OF CNTF, BDNF AND GDNF ON CULTURED MOTOR NEURONS.** R. Y. Xu\*, S. Kahn and J. Lile. Dept. of Neuroscience, Amgen Inc. Thousand Oaks, CA 91320

CNTF, BDNF, and GDNF have been shown in vitro and in vivo to support the survival and differentiation of developing and adult chick or rat motoneurons. Two of these factors currently in clinical trial for potential treatment of ALS. Using partial purified rat and chick motor neurons, we examined the effects of these factors or the combinations of these factors in cultures grown for 3 days. The level of choline acetyltransferase (ChAT) and 3-<4,5-Dimethylthiazol-2-yl>-2,5-diphenyltetrazolium bromide (MTT) uptake was determined in the presence of CNTF, BDNF, or GDNF or with the combination of these factors at concentration from 0.01 ng/ml to 10 ng/ml. Each of these factor alone increased ChAT activity by 30% to 200% over the control, and MTT by 30% to 150% over the control. The combination of CNTF and GDNF, CNTF and BDNF, or GDNF and BDNF were greater than either alone measured by ChAT and MTT. Combinations with GDNF achieved greater ChAT activity than other combinations. The findings indicate some overlapping effects of these factors and some intriguing functions of each factor, which may be useful when the combinations are tested in animal models of motoneuron diseases.

## 605.8

**EFFECTS OF BDNF OR CNTF TREATMENT ON GALACTOSE NEUROPATHY.** A.P. Mizisin\*, M. Bache, P. DiStefano, R.M. Lindsay, N.A. Calcutt. University of California, San Diego, La Jolla, CA and Regeneron Inc., Tarrytown, NY.

Amelioration of Schwann cell injury and axonal dwindling in galactose intoxication by aldose reductase inhibitors prompted speculation that exaggerated sugar metabolism in Schwann cells and skeletal muscle disrupts synthesis and release of neurotrophic factors that influence maintenance of axonal structure and function. The present study investigated the effects of BDNF or CNTF, neurotrophic factors normally localized to skeletal muscle and Schwann cells respectively, on myelinated fiber disorders of galactose-fed rats. Adult, female Sprague-Dawley rats were fed diets containing complete micronutrient supplements and either 0% D-galactose (control) or 40% D-galactose. Groups of control or galactose-fed rats received either BDNF (15 mg/kg) or CNTF (1 mg/kg) by three weekly subcutaneous injections. The aldose reductase inhibitor (ARI), Ponalrestat (50 mg/kg/d), was administered to another group by oral gavage. After two months, motor and sensory nerve conduction velocity (MNCV and SNCV) were measured and the sciatic nerves processed for light microscopy. The distal sciatic nerve and soleus and extensor digitorum longus muscles were analyzed for polyol content. In galactose-fed animals, Ponalrestat reduced dulcitol accumulation by 80% in nerve and by >50% in muscle while BDNF and CNTF were without effect. Galactose significantly reduced MNCV by 13% and SNCV by 17% compared to untreated or BDNF-, CNTF- and ARI-treated controls. ARI-treatment of galactose-fed animals resulted in MNCV and SNCV that were 93% and 99% of control values. Treatment with neurotrophic factors resulted in differential effects on CV. MNCV in the BDNF-treated galactose-fed group was increased to 92% of control values while SNCV was not affected. In contrast, SNCV in the CNTF-treated galactose animals was increased to 96% of control values while MNCV was not affected. Ponalrestat, but not BDNF or CNTF, prevented the observed 19% decrease in mean axonal diameter and a shift in axonal size-frequency histograms towards smaller fibers apparent in the sciatic nerve of galactose-fed rats. These observations indicate that BDNF and CNTF have differential effects on motor and sensory nerve function by mechanisms not obviously dependent on restoration of axonal caliber.

PERIPHERAL NERVE REGENERATION AND BDNF. D.M.Shirley, S.A.Williams, P.M.Santos\*, Southern IL Sch. of Med., Div. of Otolaryngology, Springfield, IL 62794

Brain derived neurotrophic factor (BDNF) has demonstrated trophic activities in the developing and adult rat and a rescue effect following axotomy-induced cell death in the rat embryo. No previous studies have evaluated functional nerve regeneration following supraphysiologic concentration of BDNF exposure. We studied the potential effects of BDNF on motor nerve regeneration following transection injury in adult rats. Gait analysis and the tension transduction device (TTD) for neuromuscular evaluation allowed for sensitive and functional evaluation of peroneal nerve regeneration. Twenty four rats underwent entubulation repair. BDNF, (100mg/uL) or control (phosphate buffered solution) was injected into a Silastic channel holding the transected nerve ends. Gait analysis, measuring the ankle angle, was performed preinjury and 2, 4, 6, 10, and 12 weeks postinjury and demonstrated a significant difference between uninjured and injured legs, 19 degrees and 64 degrees, respectively ( $p < 0.001$ , ANOVA). The TTD measured elicited force development of dorsiflexion at 13 weeks postinjury and demonstrated a significant difference in force development between injured and uninjured legs, 148 grams and 58 grams, respectively ( $p < 0.001$ ). No difference was demonstrated between BDNF versus control solution with either gait analysis or the TTD.

## 605.11

INVOLVEMENT OF THE MUSCLE-DERIVED NEUROTROPHIC FACTOR IN THE MATURATION OF NERVE TERMINAL AT THE DEVELOPING NEUROMUSCULAR SYNAPSES. J. C. Liou, W. M. Fu\*, Pharmacological Institute, College of Medicine, National Taiwan University, Taipei, Taiwan.

Although the effects of neurotrophins on neuronal survival and differentiation have been extensively studied, little is known about their effects in synaptic development and function. Here we reported the chronic effects of neurotrophin-3 (NT-3) in the maturation of neuromuscular synapse in *Xenopus* nerve-muscle co-cultures. Compared with the myocyte-contacted neuron, nerve terminals which were not contacted by the myocyte released ACh with a smaller quantal size detection by manipulated myoball in 3-day-old culture implicating an indispensable role of muscle in the maturation and/or survival of neuromuscular synapses. Chronic treatment with d-tubocurarine (d-Tc) or tyrosine kinase inhibitor k252a for 2 days then washout before the measurement of synaptic currents, spontaneous synaptic currents (SSCs) and impulse-evoked synaptic currents (ESCs) occurred with much smaller amplitude at natural synapses. However, postsynaptic iontophoretic ACh-induced currents were not greatly affected by these treatments. Simultaneous chronic treatment with NT-3 and d-Tc partially reversed the suppression effect of d-Tc and such reversal effect could be further abolished when k252a was applied concomitantly. In addition, treatment non-myocyte-contacted neurons with NT-3 for 2 days increased the size of SSCs which was detected by manipulated myoball. Taken together, these results suggest that muscle-derived NT-3 may participate in the functional maturation of synapses and the secretion of NT-3 is activity-dependent.

THE EFFECTS OF NEUROTROPHINS ON MUSCLE AFFERENTS AND EFFERENTS IN ADULT RATS. John B. Munson\*, David L. Shelton+ and Stephen B. McMahon. Dept Physiol, St Thomas Hospital Medical School, London, UK, and Dept Neurosci+, Genentech, San Francisco, USA.

Axotomy of muscle afferents and efferents alters many functional properties, including slowing of axonal conduction velocity (CV: Titmus & Faber, Prog in Neurobiol 35). These alterations might result from deprivation of specific neurotrophins (NTs) normally obtained from target tissue. We tested this in adult Wistar rats by providing to intact or axotomized gastrocnemius muscle nerves NTs or molecules capable of sequestering particular NTs (trk-IgG fusion molecules, Shelton et al, J Neurosci 15) chronically via osmotic pumps. We also studied unoperated rats and rats with axotomized muscle nerves only. We determined the CV distribution of myelinated afferent and efferent fibres by single unit recording from dorsal and ventral root filaments. Results are based on experimental times of 2 weeks.

We first confirmed that CV of muscle afferents and efferents slows progressively for at least 4 weeks following chronic axotomy. Infusion of trkB-IgG (at 0.5 µg/hr) into the popliteal fossa significantly slowed CV of intact gastrocnemius efferents but not afferents, explainable if either BDNF or NT4/5 were essential to efferent (but not afferent) function. Infusion of trkA-IgG at 0.5 µg/hr was without effect on CV of intact myelinated afferents or efferents, suggesting these neurones are unresponsive to NGF and providing also a control for non-specific effects of the procedures. NT5 provided to axotomised nerves at 125 ng/hour, partially restored CV for efferents but not afferents.

These experiments suggest that endogenous NTs have a physiological role in the maintenance of muscle nerve properties in adult mammals, and that exogenous NTs may rescue neurones from some of the effects of nerve injury. Supported by the MRC (SBM) and USPHS (JBM).

## 605.10

ADDITIVE RESCUE EFFECTS OF GDNF AND BDNF ON AXOTOMIZED SCIATIC MOTONEURONS IN NEWBORN RATS. R.Vejsada<sup>1</sup>, R.M.Lindsay<sup>2</sup> and A.C.Kato<sup>1\*</sup> <sup>1</sup>Dept. Pharmacology and Div. Clinical Neuromuscular Research, CMU, University of Geneva, Switzerland; <sup>2</sup>Regeneron Pharmaceuticals Inc., Tarrytown, N.Y., USA

Both GDNF and BDNF, members of distant families of trophic factors, promote survival of motoneurons *in vitro* and *in vivo*. We have compared the effects of GDNF and BDNF, and of co-treatment with these factors, on axotomized sciatic motoneurons in neonatal rats. Motoneurons were quantified using the fluorescent retrograde tracer Fluoro-Gold to specifically label the sciatic pool. Application of GDNF directly to the transected nerve significantly enhanced motoneuron survival, as determined 7 days later, in comparison to controls treated with BSA. Dose-response studies showed that the effects of GDNF were superior or equal to BDNF within the concentration range tested (0.01-1.6 mg/ml). However, the number of surviving cells dramatically decreased at 2 weeks post-lesion; the rescue effects of a single dose of GDNF were thus transient, as we have previously shown for several other neurotrophic factors (Eur. J. Neurosci. 7, 108-115, 1995). When both GDNF and BDNF were applied simultaneously, motoneuron survival was better than with each of these factors alone, suggesting that their effects may be additive. Furthermore, when a single dose of GDNF to the nerve stump was combined with BDNF injections (5 mg/kg, s.c.) at 3-day intervals for 2 weeks, motoneuron loss during the later post-lesion period could be partially arrested. These results show that combinations of neurotrophic factors from different families may be more effective than administration of single factors for rescuing lesioned motoneurons.

## 605.12

BDNF AND GDNF BUT NOT CNTF INHIBIT AXOTOMY-INDUCED NITRIC OXIDE SYNTHASE (NOS) EXPRESSION IN MOTOR NEURONS OF CRANIAL NERVES. W.H.A. Yu\*. Department of Cell Biology & Anatomical Sciences, City University of New York Medical School, NY, NY 10031.

We have shown previously that following unilateral transection of the hypoglossal, vagus, and facial nerves of adult rats, a number of neurons in the ipsilateral hypoglossal nucleus, dorsal motor nucleus of the vagus (DMV), and facial motor nucleus exhibited NADPH-diaphorase activity coincident with neuronal NOS immunoreactivity. Target reinnervation down-regulated axotomy-induced NOS expression. When the nerves failed to regenerate or were prevented from target contact, increasing numbers of axotomized neurons became intensely NADPH-diaphorase positive with time, suggesting that targets may contain "signals" which normally suppress NOS expression. Soluble factors synthesized in targets and taken up by neurons via retrograde axonal transport are likely candidates for such "signals". The present study tested the possibility of BDNF, CNTF, and GDNF acting as such "signals". Following unilateral transection of the adult rat hypoglossal and vagus nerves, gelfoams (5 mm<sup>2</sup>) containing either BDNF, CNTF, GDNF (30 µg each), or vehicle (0.1 M PBS, 20 µl) were applied to the proximal nerve stumps. BDNF partially and GDNF nearly completely suppressed NOS expression 4 days after axotomy in hypoglossal and DMV neurons. CNTF by itself was ineffective but potentiated the BDNF effect in hypoglossal neurons. The inhibitory effects of BDNF and GDNF on NOS expression were, however, diminished 7 days after axotomy. Infusion of GDNF (1 µg/h) or BDNF combined with CNTF (0.5 µg each/h) to the hypoglossal nerve stump over a period of 7 days by a catheter connected to an osmotic pump (Alzet, model 2001) was effective in keeping NOS expression near zero for 7 days after axotomy. These results are consistent with the hypothesis that axotomy interrupts and target reinnervation restores target-derived "signals" to motor neurons for inhibiting NOS expression.

## 605.14

EFFECTS OF EXCESS BDNF ON THE DEVELOPMENT OF MOTONEURONS AND THE Ia AFFERENT-MOTONEURON SYNAPSE IN THE NEONATAL RAT SPINAL CORD. B.S. Seebach\* & L.M. Mendell. Dept. of Neurobiology & Behavior, SUNY, Stony Brook, NY 11794.

The "neurotrophic hypothesis" predicts that the level of available neurotrophin during periods of rapid development should influence cell and synaptic properties of neurons expressing the appropriate *trk* receptor. Because motoneurons express *trkB* receptors, the amount of available BDNF, a neurotrophin that binds to and activates *trkB* receptors, may be important during their development. The present study examined the effect of excess BDNF on the postnatal development of motoneuron and synaptic properties by comparison with results from previous observations of normal development (Seebach & Mendell, Neurosci. Abst. 1994). Rats (n=7) unselected as to sex received daily injections of BDNF from birth through 7 d. At postnatal day 8, the excised spinal cord was hemisected, L5 dorsal and ventral roots were stimulated via suction electrodes, and evoked responses were recorded intracellularly from motoneurons. Rheobase and input resistance of motoneurons and amplitude of monosynaptic epsps evoked by dorsal root stimulation were examined in animals receiving 2, 5, or 10 µg/g doses of BDNF and were compared with normals. BDNF injections did not affect the average weight of animals. However, average motoneuron rheobase increased steadily with larger doses of BDNF (from 2.5 nA in normals to 4.0 nA at 10 µg/g BDNF,  $p < 0.05$ ), while input resistance decreased (from 21.0 MΩ in normals to 12.9 MΩ at 10 µg/g BDNF,  $p < 0.05$ ), indicating that excess BDNF may increase motoneuron size. NT-3 injections were without effect on these measures. Although epsp amplitude bears an irregular relationship to cell resistance for individual motoneurons in the immature spinal cord, the average amplitude of monosynaptic epsps was inversely correlated with BDNF dose, consistent with the idea that motoneuron size increases with larger doses of BDNF. We conclude that the postnatal development of motoneurons in the rat is influenced by the level of available BDNF. Supported by NIH. BDNF courtesy of Regeneron Pharmaceuticals.

## 605.15

**NEUROTROPHIC REGULATION OF EXCITABILITY IN ADULT RAT MOTONEURONS.** M. Gonzalez\* and W.E. Collins, III. Dept. of Neurobiology and Behavior, SUNY, Stony Brook, NY 11794.

While neurotrophins have profound effects on developing neurons, little is known about possible effects on adult neurons. The observations of BDNF and trkB receptor m-RNAs in hindlimb muscle and motoneurons, respectively, suggest that muscle-derived BDNF is important in the maintenance of motoneuron properties.

To investigate this possibility, male Sprague-Dawley rats (300-450 g) were anesthetized with a mixture of ketamine and xylazine and a 3x3x5 mm piece of gel foam, saturated with BDNF (16 mg/ml in phosphate buffered saline, pH 7.4), or saline was inserted into the left popliteal fossa (6 rats per treatment group). After 5 days survival, the animals were prepared for *in vivo* intracellular recording and the electrical properties of medial gastrocnemius (MG) motoneurons in the BDNF (n=49) and saline treated (n=45) rats were measured. Data were analyzed using ANOVAS.

BDNF produced significant decreases in mean MG motoneuron rheobase and total cell capacitance that were associated with a tendency towards increased mean input resistance. The significant increase in excitability along with the other observed changes are indicative of a decrease in motoneuron size. No significant treatment effect was observed in conduction velocity, membrane and equalizing time constants, afterhyperpolarization amplitude and duration, membrane potential sag, action potential height, and electrotonic length.

One functional implication of these results is that motoneurons innervating BDNF-producing muscle fibers would be expected to exhibit increased excitability and be recruited earlier. Furthermore, differential expression of BDNF by different muscle units could underlie motor unit type-specific differences in motoneuron excitability and recruitment order.

Supported by grants from NIH and NSF. BDNF was generously provided by Regeneron Pharmaceuticals, Inc.

## 605.17

**IMMUNOGLOBULIN LOCALIZATION IN RAT SKIN, DRG, AND SPINAL CORD AFTER RABBIT SERA INJECTIONS.** J.R. Tonra<sup>1</sup>, L.M. Mendell<sup>2</sup>.

<sup>1</sup>Dept. Physiol. & Biophys. and <sup>2</sup>Dept. Neurobiol. & Behav., SUNY Stony Brook, Stony Brook, NY 11794.

Rabbit sera raised against antigens (e.g. NGF) are injected into rats to elucidate antigenic function *in vivo*. In order to localize structures to which antibodies have access, we examined rabbit IgG IR in rat tissues after normal rabbit serum (NRS) injections. NRS was administered daily to female Sprague Dawley rats at embryonic days (E) 20-22, postnatal days (PND) 2-4, and PND 15-17 (3 rats/group). For the embryonic treatment the mother was injected with 2 ml NRS s.c. Postnatal treatments were 5 µl/gram s.c. Negative controls included staining of tissue from treated rats with primary antibody against rabbit IgG preabsorbed with rabbit IgG, and staining of untreated rat tissue. Rats were anesthetized one day after the last treatment and perfused transcardially with 2 ml saline followed by 20-30 ml fixative. Lumbo-sacral spinal cord, L5 DRGs and glabrous skin from the foot pad were analyzed. In skin, rabbit IgG IR is intense in dermis but barely detectable in epidermis, suggesting a dermal-epidermal barrier to rabbit IgG in this region of skin. The spinal cord exhibited little rabbit IgG IR and IgG permeability appeared to decrease with age (Hulsebosch & Fabian, Neurosci. Lett. 98). DRG cells from the two older groups displayed very few IgG IR cells but large clusters of IR cells were found in rats treated from E20-22, often in the same section as large clusters of negative cells. Preliminary results with longer treatments starting on PND 2 suggest strong IR develops in a subset of DRG cells after extended treatments with NRS or rabbit serum raised against NGF. Supported by NIH.

## 605.19

**THE EFFECTS OF CILIARY NEUROTROPHIC FACTOR ON GAP-43 mRNA EXPRESSION IN THE PERIPHERAL NERVOUS SYSTEM.** S.G. Siegel\*, A.W. English, and G.K. Pavlath. Depts. of Anatomy & Cell Biology and Pharmacology, Emory University, Atlanta, GA 30322.

The growth associated protein GAP-43 has been localized to neurons and glial cells of the peripheral and central nervous systems. Motoneurons express GAP-43 during development, after which GAP-43 levels decline substantially. However, significant upregulation of GAP-43 is observed following peripheral nerve injury and has been associated with regeneration. In partially denervated muscle, GAP-43 immunoreactivity is found in Schwann cells as well as in axons near the denervated zone, suggesting a role in neuronal sprouting. Neuronal sprouting from axons following partial denervation is known to be accompanied by extension of processes from axon sheath (Schwann) cells. Ciliary neurotrophic factor (CNTF) induces sprouting in intact motor axons, but it is not known whether CNTF acts directly on neurons or indirectly via Schwann cells. Since GAP-43 mRNA from sciatic nerve and muscle is exclusively of Schwann cell origin, any upregulation of GAP-43 mRNA in these tissues indicates that Schwann cells are responding to CNTF. Adult rats were injected with CNTF either intramuscularly or into the sciatic nerves. Control animals received similar injections of saline. The triceps surae muscles, sciatic nerves, and lumbo-sacral spinal cords were removed from the animals and analyzed for GAP-43 mRNA by Northern analysis. Intramuscular injections of CNTF resulted in an increase in muscle GAP-43 mRNA, suggesting a local response by the Schwann cells within the muscle. These data are consistent with the hypothesis that Schwann cells, which produce CNTF, are also responsive to CNTF.

CNTF was a gift from Regeneron Pharmaceuticals, Inc.

**NGF-INDUCED INCREASE IN THERMAL SENSITIVITY OF NOCICEPTIVE FIBERS IN VITRO.** A. Rueff\* & L. M. Mendell. Dept. Neurobiol. & Behavior, SUNY, Stony Brook, NY 11794.

Injection of NGF into adult rats induces a prolonged hyperalgesia with hypersensitivity to thermal and mechanical stimulation (Lewin *et al.*, 1993, J. Neurosci. 13, 2136-2148). Previous studies have suggested a peripheral component in the mechanism responsible for NGF-induced thermal hyperalgesia whereas mechanical hyperalgesia appeared to be centrally mediated (Lewin *et al.*, 1994, Eur. J. Neurosci. 6, 1903-1912; Rueff & Mendell, 1994, Soc. Neurosci. Abstr. 20, 287.2).

Here we used a previously described *in vitro* skin-saphenous nerve preparation that allowed us to study isolated cutaneous receptive fields (Reeh, 1986, Neurosci. Lett. 66, 141-146). After having established the conduction velocity of clearly identified single units with unmyelinated (C-fibers) or myelinated (Aδ- and Aβ-fibers) axons, we studied the sensitivity to noxious heat and mechanical thresholds of each unit under control conditions. Subsequently, we superfused the receptive field, that had been isolated with a metal cylinder, for 15 min. with up to 400ng/ml NGF. No spontaneous activity was observed in any fiber class while applying NGF. Following exposure to NGF mechanical thresholds as well as receptive field sizes of either nociceptive (C- and Aδ-fibers) or non-nociceptive (Aβ-fibers) units remained unchanged. However, we observed a clear increase in noxious heat evoked discharge in about 50% of all heat sensitive units following NGF. This result confirms a possible peripheral site for NGF-induced thermal sensitization. Possible mechanisms will be discussed. **FUNCTIONAL ROLES OF NEUROTROPHIC FACTORS DURING SYNAPTOGENESIS IN A NEURON-MUSCLE CO-CULTURE SYSTEM.**

A. K. Y. Fu\*, K. M. Chan, K. W. K. Tsim and N. Y. Ip. Department of Biology, Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong.

The formation of the neuromuscular junction involves the co-ordination and expression of pre- and post-synaptic proteins. Although a number of such proteins have been identified, their precise functional roles remain to be elucidated. One approach to study this problem is to manipulate the level of pre- and/or post-synaptic proteins, and examine the functional consequence on synapse formation. Previous studies suggest that neurotrophic factors may enhance the activity and efficacy of developing neuromuscular synapse. Consistent with this finding, transcripts encoding for specific neurotrophic factors in muscle were found to be developmentally regulated during the critical period for the formation of neuromuscular junctions. We have set up a co-culture system of neurons and muscles, i.e. neuroblastoma NG108-15 and C2C12 myoblasts, to examine the functional consequence of overexpressing neurotrophic factors in muscle cells. The C2C12 cells were stably transfected with expression constructs of neurotrophic factors tagged with the green fluorescent protein. These transfected C2C12 cells were co-cultured with NG108-15 cells, and their ability in inducing the formation of acetylcholine receptor (AChR) aggregates was compared with the untransfected C2C12 cells. In addition, the transfected C2C12 cells were fused with untransfected C2C12 cells, and co-cultured with NG108-15 cells. The extent and localization of AChR aggregates were analyzed in the vicinity of neurotrophic factors (as indicated by the green fluorescent signal) expressed in the C2C12 myotubes.

## 605.20

**IN VIVO EFFECTS OF PUTATIVE NEUROTROPHIC FACTORS CEP 1347, CNTF, AND IGF-I IN RESCUING MAMMALIAN MOTONEURONS FROM NATURALLY OCCURRING DEATH.** M.W. Harty<sup>1</sup>\*, M.A. Glicksman<sup>2</sup>, N.T. Neff<sup>2</sup>, C. Murakata<sup>3</sup> and D.R. Sengelaub<sup>1</sup>. <sup>1</sup>Program in Neural Science, Indiana University, Bloomington, IN 47405; <sup>2</sup>Cephalon, Inc., West Chester, PA 19380; <sup>3</sup>Kyowa-Hakko Kogyo, Tokyo, Japan.

The spinal nucleus of the bulbocavernosus (SNB) of male rats contains about three times as many motoneurons as the SNB of female rats, the result of an androgen-induced rescue of motoneurons during development. Several trophic factors have been identified which influence neuronal survival, and it is likely that androgen's trophic effects on the SNB are mediated through the action of such factors. To assess the efficacy of compounds demonstrated to have trophic effects on motoneuron survival *in vivo*, developing females were treated with either insulin-like growth factor (IGF-I), ciliary neurotrophic factor (CNTF), or CEP 1347 (a K-252a analogue).

Female rats were injected (s.c., over the SNB target muscles) from postnatal (P) day 1 (day of birth) through P5 with either IGF-I, CNTF, CEP 1347, or vehicle. During this period, SNB motoneurons normally die in females, but can be rescued with androgen treatment. Counts of SNB motoneurons at P10 in pups treated with IGF-I (1 mg/kg) did not differ from those of normal or vehicle-treated pups. However, CEP 1347 (0.1 or 1 mg/kg) significantly reduced motoneuron death; SNB motoneuron numbers were equivalent to those of androgen-treated females. As previously reported (Forger *et al.*, '93), CNTF (0.5 µg) also significantly masculinized SNB motoneuron number. Thus, like CNTF, CEP 1347 can rescue SNB motoneurons from naturally occurring death. (Supported by Cephalon)

## 605.21

TrkB RECEPTORS MEDIATE SURVIVAL OF FACIAL MOTONEURONS AFTER AXOTOMY. J. Frisén\*, M. Barbacid and I. Silos-Santiago. Department of Molecular Oncology, Bristol-Myers Squibb Pharmaceutical Research Institute, Princeton, NJ 08540.

Brain-derived neurotrophic factor (BDNF) and neurotrophin-4 (NT-4) are known to support motoneuron survival in vitro. BDNF has also been shown to prevent the death of motoneurons after neonatal axotomy. Expression of BDNF and NT-4 increase after peripheral nerve lesion in Schwann cells distal to the injury and BDNF expression increases in denervated muscle. Furthermore, the expression of TrkB, the signaling receptor for BDNF and NT-4, also increases in motoneurons after axotomy. These data, taken together, suggest that TrkB receptors may mediate signals that support regeneration and/or survival of motoneurons after axotomy. We have studied the role of TrkB in motoneuron survival after axotomy in postnatal mice that lack the TrkB tyrosine kinase receptor. The facial nerve was cut unilaterally at postnatal day 6 (P6) in wild type and trkB (-/-) knock out mice. Animals were allowed to survive until P10 and their motoneurons were counted in the injured and uninjured facial motor nucleus. In wild type mice the number of facial motoneurons decreased by about 40% in the axotomized side when compared with the unoperated control side. In the trkB (-/-) mutant mice, the reduction of neurons in the injured facial motor nucleus was 65% compared with the uninjured side. These results suggest that neurotrophin signaling through TrkB receptors has an important role in the survival of at least certain injured neurons.

## 605.23

EVALUATION OF PEG-BDNF IN AXOTOMIZED FACIAL MOTOR NEURONS OF ADULT RATS. O. T. Lopez, O. Kinsler, E. Cheung, A. A. Welcher\*, Q. Yan Amgen, Inc., Amgen center, Thousand Oaks, CA 91320

Brain derived neurotrophic factor (BDNF), a member of the NGF family of neurotrophins, is involved in survival and maintenance of function of motor neurons. Systemically administered BDNF has been shown to attenuate the decrease of choline acetyltransferase (ChAT) immunoreactivity in axotomized facial motor neurons of adult rats. We have compared the effects of BDNF with a polyethylene glycol conjugated BDNF analog (PEG-BDNF) in this model by reducing the dose and administration frequency of the analog while still producing the attenuating effects on ChAT following motor neuron axotomy. Our results show that due to its short half-life and rapid clearance, it requires a BDNF dose of 10mg/kg (s.c., q.d.) to attenuate (by 66±1%) the decrease of ChAT immunoreactivity, while the PEG-BDNF at a dose of 0.3mg/kg (s.c., q.d.) produced superior effects (attenuated decrease by 83±3%). Furthermore, when injected every other day, the PEG-BDNF (0.3mg/kg) produced similar effects to those seen with daily treatments of 10mg/kg BDNF (68±2% vs 66±1%). The pharmacokinetics study indicates that there is a 2x increase in bioavailability, a 15x decrease in absorption, a 10x decrease in protein clearance, and a 10x increase in the terminal half-life with PEG-BDNF compared to the native form. The results of this study suggest that PEG-BDNF may provide an alternative for in vivo applications without compromising the overall effectiveness of the BDNF protein as a therapeutic agent for adult motor neuron disease.

## 605.25

MOTOR ENDPLATE PHOSPHOTYROSINE LOSS FOLLOWING DENERVATION. S.R. Songer\*, E.A. Lassiter, and A.W. English. Dept. of Anatomy and Cell Biology, Emory Univ., Atlanta, GA 30322.

Several muscle proteins are phosphorylated on tyrosine residues. Tyrosine phosphorylation of muscle acetylcholine receptors (AChRs), which are densely aggregated at motor endplates, is innervation-dependent. Longitudinal sections of adult rat gastrocnemius muscle were stained to separately label AChRs and tyrosine-phosphate residues. The only detectable phosphotyrosine (PY) was localized to the motor endplate and corresponded to labeling for AChRs. Endplates viewed at high magnification were scored as either PY-positive or -negative based on visible PY labeling. In intact control muscle and in reinnervated muscle, 100% of the endplates were PY-positive. The medial gastrocnemius muscle was permanently denervated by nerve transection in different subjects for varying periods of time. The percentage of PY-positive endplates underwent a sharp decline during the first 1-2 days after denervation, but returned to a normal level by days 7-8. From this point, PY underwent a long-term decline. An examination of time intervals immediately following denervation revealed that at 6 and 12 hours most endplates were PY-positive. However, by 18 and 24 hours the percentage of PY-positive endplates was markedly decreased. This post-denervation pattern of PY loss, return, and decline may be a consequence of the absence of neuromuscular and/or neurotrophic activity. In support of the role of neurotrophic action, the length of the distal nerve stump following denervation may influence the time course of endplate PY loss. Longer stump-lengths promote the retention of PY at times when it would be expected to be reduced. In conclusion, these results are consistent with the innervation-dependence of endplate PY; however, it is possible that some aspect of innervation other than activity is involved.

## 605.22

BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF) SPARES CHOLINE ACETYLTRANSFERASE mRNA FOLLOWING AXOTOMY OF MOTOR NEURONS *IN VIVO*. W. Wang, P. Salvaterra\*, S. Loera, A. Rosenthal, M. Glicksman\*, and A.Y. Chiu. Beckman Res. Inst., City of Hope, Duarte, CA, <sup>1</sup> Genentech, S. San Francisco, CA, <sup>2</sup> Cephalon, West Chester, PA.

Choline acetyltransferase (ChAT, EC2.3.1.6) is a specific marker gene for neurons that use acetylcholine as a neurotransmitter. Using a quantitative RNase protection assay, we have investigated the dynamic changes in ChAT mRNA levels following axotomy and with application of trophic molecules to the proximal nerve stump. A week after unilateral transection of the hypoglossal nerve in adult rats, the levels of ChAT mRNA in the axotomized neurons decreased dramatically to around 15% of the uninjured, control half of the motor nucleus. When the cut end of the nerve was chronically exposed to BDNF for a week, ChAT mRNA levels were 60% of control. BDNF thus prevented the injury-induced loss of ChAT mRNA. NT4/5 also partially prevented this decrease, although not as effectively as BDNF. NT4/5-treated neurons expressed 30% of normal levels of ChAT mRNA. However, if the nerve stump was exposed to PBS-BSA, ChAT mRNA levels fell to 15% of normal, indicating that the trophic molecules acted with some specificity. These effects of BDNF and NT4/5 on ChAT mRNA levels following motor neuron injury suggest the existence of regulatory pathways responsive to these neurotrophic factors that can "rescue" cholinergic gene expression. The effect of neurotrophins, and BDNF in particular, on motor neurons after lesion raises the possibility that they may be useful in treating patients with motor neuron and neuromuscular disorders, such as motor neuropathies and amyotrophic lateral sclerosis. Supported by the Council for Tobacco Research (PMS) and NICHD (AYC).

## 605.24

CILIARY NEUROTROPHIC FACTOR REGULATES MULTIPLE INNERVATION ONLY DURING NEUROMUSCULAR SYNAPSE ELIMINATION. C. L. Jordan\* Dept. Psych., UC Berkeley, CA 94720.

Recent demonstrations suggest that exogenous ciliary neurotrophic factor (CNTF) can prevent the normal loss of synapses during developmental synapse elimination. However, because CNTF can also induce motor axons in adult muscle to sprout, which might lead to the formation of multiple innervation, the present study sought to determine whether the effects of CNTF on multiple innervation in development are restricted to the period of synapse elimination. Human recombinant CNTF (1 µg/g body weight) or vehicle was delivered daily to the hind limbs of male rat pups. Animals received bilateral s.c. injections of vehicle only or CNTF on one side and vehicle on the other. Treatment occurred from postnatal day 7 (P7) to P14 or from P14 to P21. The earlier treatment period (P7-P14) overlaps with synapse elimination in the extensor digitorum longus (EDL). Based on the number of stained motor axons innervating individual EDL muscle fibers, I found that CNTF influenced the level of multiple innervation during only the first treatment period and only in EDL muscles from the CNTF-treated limb. Thus, CNTF probably regulates the level of multiple innervation in the EDL by controlling synapse elimination and not by an effect on axonal sprouting. Because CNTF had only unilateral effects on synapse elimination in the EDL, skeletal muscles are probably an important site for the direct action of CNTF on synapse elimination or for the directed transport of CNTF to motoneuronal cell bodies. Supported by IBN-9210229, IBN-9309856 and Regeneron Pharmaceuticals.

## 606.1

LUMBAR DRGs OF *trkA*(-/-) MICE EXHIBIT MASSIVE APOPTOSIS PRIOR TO INNervation OF DISTAL HINDLIMB TARGETS. F.A. White<sup>1</sup>, J. Silos-Santiago<sup>2</sup>, D.C. Molliver<sup>1</sup>, J.C. Harding<sup>1</sup>, M.T. Saxena<sup>1</sup>, M. Barbacid<sup>2</sup>, and W.D. Snider<sup>1</sup>. <sup>1</sup>Dept. of Neurology, CSNSI, Washington University, St. Louis, Mo, 63110, <sup>2</sup>Dept. of Molecular Biology, Bristol-Myers Squibb, Princeton, NJ 08543. Recently reported differences in the magnitude of DRG neuron loss in *trkC*(-/-) and *NT-3*(-/-) mutant mice have led to the idea that NT-3 may transiently support sensory neurons by acting on the NGF signaling receptor TrkA. However, temporal relationships between the onset of TrkA expression by sensory neurons, the arrival of TrkA(+) sensory axons in the proximity to sources of NGF and NT-3, and the onset of neuronal dependence on TrkA-signaling for survival have not been determined. We show here that *trkA* is expressed in DRGs at E10.0, the earliest day at which a collection of ganglion cells is apparent. Neuronal apoptosis is detected in DRGs as early as E11.5 in wild type mice. Analysis of DRGs in *trkA*(-/-) mice shows no increase in this early death suggesting that survival of neurons at E11.5 is independent of *trkA* signaling. However by E13.5, we find that most lumbar DRG neurons are dependent on TrkA-signaling as evidenced by massive apoptosis in lumbar DRGs in *trkA*(-/-) animals. In order to examine relationships between onset of TrkA signalling and access to sources of neurotrophin support, we stained sensory axons with an antibody to TrkA and studied neurotrophin expression in the hindlimb bud at these same ages. NT-3 mRNA is present in hindlimb as early as E11.5. In contrast, NGF mRNA does not appear until 24-48 hours later. These neurotrophin mRNA distributions are different in that NT-3 is expressed in muscle precursors in the interior of the limb bud, whereas NGF expression is superficial and restricted to surface ectoderm. TrkA+ sensory axons innervate surface ectoderm between E11-13 in proximal hindlimb regions, but do not reach the surface of the distal hindlimb until after E15. Our results demonstrate that many DRG axons are in proximity to sources of both NT-3 and NGF at the onset of TrkA dependence. However, many DRG neurons in lower lumbar ganglia are TrkA-dependent before their axons are in proximity to a source of NGF in the surface ectoderm.

## 606.3

IMPAIRED REGENERATION OF NOCICEPTIVE FIBRES IN STEEL/C-KIT MUTANT MICE. S. Lourenssen<sup>1</sup>, M. Kluppel<sup>2</sup>, A. Bernstein<sup>2</sup> and J. Diamond<sup>1\*</sup>. <sup>1</sup>Dept. of Biomedical Sciences, McMaster University, Hamilton, Ontario, Canada, L8N 3Z5 <sup>2</sup>Program in Molecular Biology and Cancer, Samuel Lunenfeld Research Institute, Toronto, Ontario, Canada, M5G 1X5

The *steel* locus in the mouse encodes steel factor, the ligand for the c-kit tyrosine kinase receptor encoded by the *W* locus. Mice with mutations in the *Sl* or *W* loci are characterized by defects in melanogenesis, gametogenesis, and hematopoiesis. Interestingly, steel and c-kit are expressed in cell lineages that appear not to be affected by mutations in *Sl* or *W* loci, including peripheral and central nervous systems; one of the highest levels of expression occurs in dorsal root ganglia (DRG). Steel factor, which is expressed in Schwann cells, has been shown to induce neurite outgrowth from a sub-population of NGF-responsive embryonic DRG neurons *in vitro*, and also to act as a survival factor for these neurons.

We have now examined cutaneous mechano-nociceptive (Aδ) and heat-nociceptive (C) fibres in adult mice with mutations in *Sl* or *W* loci. The regeneration of these axons after nerve crush occurs entirely independently of NGF, while the collateral sprouting of the undamaged fibres into adjacent denervated skin is totally dependent on the availability of NGF. In the mutant animals collateral sprouting was perfectly normal. Unexpectedly, however, the regeneration of the same sensory axons was significantly impaired. The growth processes underlying regenerative neurite extension are likely to be similar, perhaps identical, to those underlying collateral sprouting. If so, then the activation of c-kit signalling pathways is probably an important event in the triggering of the regenerative program by nerve damage, while the initiation and maintenance of collateral sprouting by NGF must utilize other signalling pathways. We hope also to present results on changes in c-kit and steel expression in the nerves and dorsal root ganglia of normal animals during these two growth processes.

## 606.5

DEVELOPMENTAL DISTRIBUTION OF ECTOPIC SUBSTANCE P FIBERS IN THE CNS OF TRANSGENIC MICE OVER-EXPRESSING NERVE GROWTH FACTOR IN MYELINATING OLIGODENDROCYTES. Weiya Ma, A. Ribeiro-da-Silva<sup>\*</sup>, J.-P. Julien and A. C. Cuello. Dept. of Pharmacology & Therapeutics and Centre for Research in Neurosciences, McGill University, Montréal, Québec, Canada. We have generated transgenic mice which over-express NGF driven by myelin basic protein promoter. In an early study (Ma et al., Eur.J.Neurosci., in press), we showed NGF immunoreactive (IR) oligodendrocytes and substance P (SP)-IR ectopic fibers of sensory origin in the white matter of the spinal cord of adult transgenic mice. In the present study, we investigated the postnatal distributions of NGF-IR oligodendrocytes and ectopic SP-IR fibers in the CNS of transgenic mice. NGF-IR oligodendrocytes were found in the white matter of CNS from postnatal day (PD) 0 to 2 months. Unexpectedly, SP-IR fibers were found in the white matter of the spinal cord, medulla, pons and cerebellum of both transgenic mice and controls from PD 0 to 2. By PD 5, these SP-IR fibers had decreased dramatically in controls, but increased markedly in transgenic mice. From PD 5 on, the ectopic SP-IR fibers in transgenic mice increased in numbers to reach the adult level by PD 20 and remained throughout adulthood. The percentages of SP-IR cells in sensory ganglia were significantly higher than in controls. We conclude that the myelinating oligodendrocytes in the CNS of this transgenic mice creates an environment in which the over-expression of NGF induce SP-IR fibers normally occurring in the white matter of CNS during early postnatal period to sprout in an abnormal territory. In adulthood, the maintenance of the ectopic fibers is likely independent of NGF expression. (Supported by Neuroscience Network of Canadian Centres of Excellence)

## 606.2

LACK OF COLLATERAL SPROUTING OF NOCICEPTIVE NERVES IN ADULT p75 KNOCK-OUT MICE. J. Diamond, S. Lourenssen, E. Pertens, and B. Urschel<sup>\*</sup>. Dept. of Biomedical Sciences, McMaster University, Hamilton, Ontario, Canada. L8N 3Z5

While the high-affinity *trkA* receptor seems essential for survival and neurogenesis in NGF-responsive neurons during development and *in vitro*, the function of the low-affinity p75 receptor is less clear. We have now studied sensory neurons in adult mice with a targeted mutation in the p75 receptor; the results provide new insight into the function of this transmembrane molecule.

Undamaged mechano-nociceptive (Aδ) and heat-nociceptive (C) fibers (but not the mechanosensory Aα fibers) normally undergo vigorous collateral sprouting into adjacent denervated skin; this is a totally NGF-dependent nerve growth. In contrast, after nerve crush all three classes of sensory axons regenerate independently of NGF. Nevertheless, both regenerating and collaterally sprouting fibers use the same dermal perineurial pathways to reinnervate denervated skin. Interestingly, both p75 and *trk* expression increase in DRG neurons prior to and during the collateral sprouting of their axons, but not during their regeneration.

In adult p75 knock-out mice the collateral sprouting of both classes of nociceptive fibres appears to be totally absent. Thus the utilisation of NGF for this type of growth appears to be entirely dependent on the presence of the p75 receptor. In contrast, regeneration of all sensory nerves appears perfectly normal, and is clearly independent of the p75 receptor. Preliminary nerve counts show reductions of almost 40% in both large and small myelinated sensory axons, and about 60% in the unmyelinated population. Thus during development of these mice a significant fraction of differing DRG sensory neuron subgroups survives the absence of the p75 receptor, including a subpopulation of the NGF-sensitive neurons whose collateral sprouting in the adult continues to be totally dependent on this neurotrophin, and on the presence of the p75 receptor.

## 606.4

NGF DEPRIVATION DURING EARLY LIFE PERMANENTLY IMPAIRS COLLATERAL SPROUTING BUT NOT AXONAL REGENERATION. Y. Kri<sup>\*</sup>, J. Fawcett, K.M. Mearow, E. Pertens, J. Diamond. Dept. of Biomedical Sciences, McMaster University, Hamilton, Ontario, Canada. L8N 3Z5.

A chance observation prompted us to examine the possibility that a brief interference in the availability of endogenous NGF during early postnatal life might permanently compromise the reparative capacity of mature NGF-sensitive sensory and sympathetic neurons. We have focused our attention on the ability of these neurons to functionally reinnervate denervated skin by (1) collateral sprouting of undamaged neurons, and (2) by the regeneration of damaged axons. Neonatal rats were treated with antibodies to NGF (anti-NGF) during various critical periods of neuronal development; non-immune serum-treated littermates served as controls. Aside from a slight ptosis in the earliest treated groups, the adults in the anti-NGF treated rats showed no obvious behavioral differences from their control littermates. After nerve crush, all classes of sensory axons regenerated normally in all animals (such growth, we have shown, is NGF-independent). However, in the adults that had received daily anti-NGF injections during the first two weeks of life, the collateral sprouting of nociceptive Aδ and C fibres into adjacent denervated skin was markedly reduced, and in some instances was absent altogether. Such sprouting is entirely NGF-dependent. This result could not be explained by the reported phenotypic switching of nociceptive neurons.

Thus trophic deprivation in early life can permanently impair reconstructive mechanisms in the peripheral sensory system. Since regeneration was unaffected, the impairment probably centres on the regulation of neuritic outgrowth, rather than the growth process itself. We are now examining whether the normal upregulation of p75 and *trkA* receptor mRNA that precedes, and accompanies, collateral sprouting (but is unchanged during regeneration) is affected in these sprouting-compromised rats, and are also extending the study to sympathetic neurons.

## 606.6

OVEREXPRESSION OF NGF IN SKIN OF TRANSGENIC MICE INCREASES TRKA AND P75 EXPRESSION AND SIZE AND NUMBER OF SYMPATHETIC NEURONS. Isaac B. Caton<sup>\*</sup>, David M. McKinnon<sup>1</sup>, Hong-Seng Wang<sup>1</sup>, Thomas P. Goodness, Frankie E. Davis, Kathryn M. Albers, and Brian M. Davis. Depts. of Anatomy & Neurobiology and Pathology, Univ. of Kentucky College of Med., Lexington, KY; <sup>1</sup>Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook, NY.

Recently, our laboratories isolated transgenic mice (K14-NGF mice) that express elevated levels of NGF mRNA in stratified epithelium including skin (J. Neurosci. 14:1422). Morphometric analysis shows that NGF increases the number (ca. 2.5 fold) and size of neurons in sympathetic ganglia. The neuron size difference between control and transgenic mice is greatest at PN6 but is still significant in adults. In addition, electrophysiological analysis revealed that male mouse superior cervical ganglia has two physiological distinct types of sympathetic neurons and that these are differentially affected by the increased level of NGF. The distribution of sympathetic fibers in several tissues was also examined by tyrosine hydroxylase immunocytochemistry. Despite the dramatic hypertrophy of sympathetic ganglia, hyperinnervation was confined to structures known to either express the NGF transgene (e.g. skin) or contain supernormal levels of NGF peptide (e.g. lymph nodes, dorsal root ganglia) as demonstrated by ELISA. RT-PCR analysis also showed an increase in both *trkA* and p75 NGF receptor mRNA expression in sympathetic ganglia but no change for either NGF receptor in sensory ganglia from the same animals. Funded by NS 31825 (BMD) and NS-29755 (DMM).

## 606.7

EFFECTS OF NGF AND NT-3 OVEREXPRESSION IN SKIN OF TRANSGENIC MICE ON INNERVATION AND CGRP AND OPIATE RECEPTOR IMMUNOLABELING OF DORSAL HORN. Brian M. Davis<sup>\*</sup>, Kathryn M. Albers, Bruce E. Maley, Robert P. Elde<sup>\*</sup>, Thomas P. Goodness and Bruce Mendelson<sup>\*</sup>. Depts. of Anatomy & Neurobiology and Pathology, Univ. of Kentucky College of Med., Lexington, KY; <sup>\*</sup>Anatomy, Univ. of Arkansas Medical Sch., Little Rock, AR; <sup>2</sup>Cell Biology & Neuroanatomy, Univ. of Minnesota, Minneapolis, MN.

To determine if the somatotopic organization of cutaneous nerve projections was altered in transgenic animals overexpressing NGF in epithelial structures (J. Neurosci. 14:1422), dorsal primary rami were labeled with DiI at the level of thoracic segment 10 in neonatal mice. In control and transgenic animals, the central processes of the labeled primary afferents projected to the lateral portions of the ipsilateral and contralateral dorsal horns. There were no apparent differences in the spatial patterns of cutaneous nerve projections between transgenic and control mice. However, the density of the labeled fibers and boutons was significantly greater in transgenic mice. Characterization of primary sensory fiber projections using CGRP immunocytochemistry revealed similar hyperinnervation that was apparent as early as postnatal day 7, and maintained in adults (but decreased compared to earlier time points). Adult transgenic mice were also examined for distribution of  $\mu$  and  $\delta$  opiate receptors using immunocytochemistry. Preliminary results indicate a significant increase in  $\mu$  opiate receptor immunoreactivity in both NGF and NT-3 transgenic mice particularly in ventral horn and in ependymal cells. Funded by NS 31825 (BMD) and AA 09205 (BM).

## 606.9

DIFFERENTIAL EFFECTS OF VARIOUS NEUROTROPHIN AND *TRK* RECEPTOR DELETIONS ON THE UNMYELINATED INNERVATION OF THE EPIDERMIS IN THE MOUSE WHISKER PAD. G.A. Wilkinson, F.L. Rice, B.T. Fundin, I. Silos-Santiago, A.M. Fagan, R.J. Smeyne, S.D. Glick<sup>\*</sup>, P.J. Ernfors, L.F. Reichardt, M. Barbacid, Program in Neurosci., Howard Hughes Med. Center, Univ. of California, San Francisco, CA 94143; Dept. of Pharmacol. & Neurosci., Albany Medical College, Albany, NY 12208; Dept. of Molecular Biol., Bristol-Myers Squibb, Princeton, NJ 08543; Dept. of Neurosci. and Lab. of Molecular Neurobiology, Karolinska Institute, Stockholm, Sweden S0104 01.

Fine caliber unmyelinated innervation of the epidermis in the whisker pad was analyzed by immunofluorescence in mice, ranging in age from P0 (i.e. day of birth) to P25, that had selective homozygous deletions of either a neurotrophin gene (BDNF, NT3) or a receptor gene (*trkA*, *trkB*, *trkC*). This innervation was revealed by using antibodies against PGP 9.5 (a neuronal cytoplasmic protein) and CGRP as well as antibody RT97 against a phosphorylated component of neurofilament protein. *TrkA* deletions resulted in the permanent absence of all the innervation which normally consists of numerous fine profiles labeled only with anti-PGP 9.5 and a smaller contingent that also labels with anti-CGRP. *TrkB* deletions resulted in a surprisingly massive increase in both components during the first postnatal week that was partially maintained at enhanced levels during subsequent maturation. *TrkC* deletions resulted in a transient increase only of anti-PGP 9.5 profiles but actually reduced the presence of profiles colabeled with anti-CGRP. The epidermal innervation was slightly increased at birth in BDNF and NT3 knockouts but the loss of BDNF eventually resulted in normal appearing innervation whereas the loss of NT3 resulted in a drastic reduction of the CGRP component. These results indicate that the development or maintenance of the unmyelinated epidermal innervation is regulated by positive and negative interactions of several neurotrophins and *trk* receptors.

## 606.11

COMPOSITION OF THE DEEP NERVES INNERVATING THE POSTERIOR ORBITAL SINUS HAIR IN TRANSGENIC MICE THAT OVEREXPRESS NERVE GROWTH FACTOR IN THE EPIDERMIS. Thomas P. Goodness<sup>\*</sup>, Bruce E. Maley, Mary Gail Engle, Kathryn M. Albers, Brian M. Davis, Depts. of Anatomy & Neurobiology and Pathology, University of Kentucky College of Medicine, Lexington, KY.

Electron microscopy was used to compare the fiber composition in the deep vibrissal nerves (DVN) innervating the posterior orbital sinus hair (POSH) of control mice and transgenic mice (NGF-mice) that overexpress nerve growth factor (NGF) in the epidermis. The POSH is an isolated vibrissa located approximately midway between the eye and the ear. The DVN, which is composed of myelinated and unmyelinated axons, pierces the outer capsule of the POSH, and then courses superficially, running parallel to the vibrissa. Cross sections were taken of the POSH where the DVN enters the outer capsule. Counts of axonal profiles revealed that NGF-mice had significantly more unmyelinated axons within the DVN than control mice, whereas there was no difference in the number of myelinated axons. In addition, large fascicles of unmyelinated axons were found outside the DVN of NGF-mice, in the dermal capsule surrounding the root sheath. These fascicles, which contained unmyelinated axons of a wide range of sizes, were not observed in control mice. The origin of the fascicles is not yet known. We are currently performing immunocytochemistry to further characterize these axons. These results indicate that increased levels of NGF selectively increase the number of unmyelinated axons in the vibrissae of mice. Funded by NS 31825 (BMD).

## 606.8

DIFFERENTIAL EFFECTS OF VARIOUS NEUROTROPHIN AND *TRK* RECEPTOR DELETIONS ON MECHANORECEPTORS IN THE MESENCHYMAL SHEATH AFFILIATED WITH MOUSE WHISKER FOLLICLES. B.T. Fundin<sup>\*</sup>, F.L. Rice, I. Silos-Santiago, A.M. Fagan, H. Altskogius, M. Barbacid, P.J. Ernfors, Dept. of Neuroscience and Lab. of Molecular Neurobiology, Karolinska Institute, Stockholm, Sweden S0104 01; Dept. of Pharmacology and Neuroscience, Albany Medical College, Albany, NY 12208; Dept. of Molecular Biology, Bristol-Myers Squibb, Princeton, NJ 08543.

Three types of mechanoreceptors arising from large myelinated axons are in the mesenchymal sheath that encases each whisker follicle in the mouse: straight lanceolate endings at the level of the ring sinus as well as irregular lanceolate endings and reticular endings at the level of the cavernous sinus. Anti-PGP 9.5 and the antibody RT97 were used to examine these endings by immunofluorescence in mice, ranging in age from P0 (i.e. day of birth) to P25, that had selective homozygous deletions of either a neurotrophin gene (BDNF or NT3) or a receptor gene (*trkA*, *trkB* or *trkC*). The amount of straight lanceolate endings was reduced although not eliminated by the absence of *trkA*, *trkB* and BDNF. Deletions of *trkC* resulted in a slight but distinct increase, while the loss of NT3 had no obvious effect. In contrast, reticular endings were totally lacking after *trkA* deletions, and substantially increased by the absence of *trkC*. No obvious effect was obtained by the loss of *trkB*, BDNF and NT3. Finally, deletions of *trkB* and BDNF resulted in a complete loss of irregular lanceolate endings, and only NT3 deletions resulted in a noticeable increase. Unlike with the two other sets of endings, *trkA* and *trkC* deletions had no obvious effects on the irregular lanceolate endings. These results indicate that the development or maintenance of each of these three presumptive mechanoreceptors is regulated by positive and negative interactions of different sets of neurotrophins and receptors. Moreover, each of these neurotrophins and *trk* receptors, including *trkA*, has an effect on at least two types of mechanoreceptors.

## 606.10

EFFECTS OF NT3 AND *TRKC* MANIPULATIONS ON DEVELOPING MERKEL INNERVATION IN THE MYSTACIAL PAD OF THE MOUSE. J. Arvidsson, F.L. Rice<sup>\*</sup>, B.T. Fundin, K.M. Albers, I. Silos-Santiago, A.M. Fagan, M. Barbacid, P.J. Ernfors, B.M. Davis, Dept. of Neuroscience and Lab. of Molecular Neurobiology, Karolinska Institute, Stockholm, Sweden S0104 01; Dept. of Pharmacology and Neuroscience, Albany Medical College, Albany, NY 12208; Dept. of Pathology and Dept. of Anatomy and Neurobiology, Univ. of Kentucky, Lexington, KY 40536; Dept. of Molecular Biology, Bristol-Myers Squibb, Princeton, NJ 08543.

The Merkel innervation in the whisker pad was analyzed by immunocytochemistry in mice, ranging in age from P0 to P25, that had selective homozygous deletions of either a neurotrophin gene (BDNF or NT3) or a receptor gene (*trkA*, *trkB*, *trkC*). In other mice, NGF or NT3 was hyperexpressed through a transgene construct containing an epidermal-specific promoter gene. This innervation was revealed by antibodies against PGP 9.5 (which label all innervation and Merkel cells) and the antibody RT97 which labels myelinated axons and their endings. Normally, all Merkel innervation in the whisker pad is well developed at birth and is located at the mouth of guard hair and whisker follicles and in the outer root sheath of whisker follicles. In contrast to other vibrissa related mechanoreceptors, the Merkel innervation was only affected by manipulations of NT3 and *trkC*. In newborn mice lacking NT3 or *trkC*, many Merkel cells were present, however, few if any were obviously innervated. By two weeks, virtually all of the Merkel cells had disappeared and no Merkel endings were evident. Consistent with this observation, the hyperexpression of NT3 resulted in a dramatic increase in the presence of Merkel cells and endings at least at the mouth of guard hair and whisker follicles. Consistent with preferential high affinity binding found in previous studies, these results indicate that the development or maintenance of Merkel endings is dependent on NT3 acting through the *trkC* receptor.

## 606.12

DIFFERENT EFFECTS OF FETAL NGF INJECTIONS AND TRANSGENIC NGF ENHANCEMENT ON THE INNERVATION OF THE WHISKER PAD IN NEONATAL RATS AND MICE. F.L. Rice, T.A. Henderson, K.M. Albers, B.M. Davis, J.N. Carlson<sup>\*</sup>, M.F. Jacquin, Dept. of Pharmacology and Neuroscience, Albany Medical College, Albany, NY 12208; Dept. of Neurology, Washington Univ., St. Louis, MO 63110; Dept. of Pathology and Dept. of Anatomy and Neurobiology, Univ. of Kentucky, Lexington, KY 40536.

Substantial neuron death occurs in the trigeminal ganglion (Vg) of rats and mice during the last week of gestation following a precipitous decline in the production of NGF in the mystacial pad. Previously we have found as much as a 36% increase in Vg neurons in neonatal rats after systemic injections of NGF on embryonic days 15 and 18 but whisker related projection patterns, normally present in the brainstem nuclei, were lost. In contrast, virtually no neuron loss occurred and whisker patterns were present in mice that had continuously enhanced NGF levels provided by an epidermal specific transgene construct. In this study, the innervation of the whisker pad was examined by immunofluorescence in such neonatal rats and mice. After NGF injections, the innervation of the skin between the whiskers as revealed by anti-PGP 9.5 was selectively increased and relatively more mature compared to controls. Also a far greater proportion of the innervation labeled with anti-CGRP. After transgenic enhancements, the interwhisker skin had even greater and more mature innervation but a relatively normal proportion labeled with anti-CGRP. Moreover, a component of whisker follicle innervation that is normally sparse and labels with anti-CGRP was enormously increased only in the transgenic paradigm. These results suggest that the NGF injections had a more selective effect among NGF responsive populations perhaps enhancing only a CGRP component of epidermal innervation. The relative imbalance between the impact on the interwhisker and whisker innervation after NGF injections might be related to the loss of the whisker related projection patterns in the brainstem. NIH DE 07734.

**NERVE GROWTH FACTOR AND HYPERINNERVATION IN NEONATAL SKIN WOUNDS.** M.L. Reynolds and M. Fitzgerald (SPON: Brain Research Association). Dept. Anatomy & Developmental Biology, University College London, U.K.

Skin wounds made during the newborn period result in sensory hyperinnervation of the wounded area which lasts for over 12 weeks (Reynolds & Fitzgerald, J. Comp. Neurol., in press). NGF levels (measured by ELISA) increased from 30-149 pg mg<sup>-1</sup> tissue in surrounding skin during the 3 days following wounding, returning to control levels by P10 (Constantinou et al., NeuroReport 5: 2281, 1994). We have used a tissue culture model to examine the relationship between NGF upregulation, developmental stage and the production of hyperinnervation during wound healing in perinatal skin. Pieces of skin taken from around the scar area of wounds made 3 days before on the dorsal surface of the hindpaw of neonatal rat pups were cocultured in collagen gels with dorsal root ganglia (DRG) from E7 chick. The area surrounding the DRG explant was divided into 4 equal quadrants and the number of PGP9.5 immunostained neurites growing in each counted. With skin wounded 3 days previously the number of neurites in the quadrant adjacent to the skin was 15.1 ± 0.28 and on the segment away from the skin 4.9 ± 0.13. In age matched normal skin the comparable figures were 2.4 ± 0.18 and 3.2 ± 0.18. The addition of anti-NGF antiserum used in the ELISA estimations and shown to reduce neurite outgrowth in control ganglia by 75-94% resulted in an insignificant change in neurite outgrowth in these cultures; 13.7 ± 0.34 and 3.9 ± 0.12 neurites in adjacent and opposite quadrants respectively. Conditioned medium made by culturing 3 day post wound skin in serum free medium was shown by ELISA to have 3-5 times the NGF concentration of age matched P3 skin cultured in the same way. The results suggest that although NGF levels rise dramatically in neonatal skin after wounding other cytokines or growth factors may be involved in establishing the resulting hyperinnervation.

**NERVE GROWTH FACTOR ADMINISTRATION REVERSES DEFICITS IN SUBSTANCE P GENE EXPRESSION, BUT NOT TRKA AND NEUROFILAMENT L, IN SENSORY NEURONS OF DIABETIC RATS.** L.T. Diemel<sup>1</sup>, P. Fernyhough and D.R. Tomlinson. Dept. of Pharmacology, Basic Medical Sciences, Queen Mary and Westfield College, University of London, U.K..

Effects of nerve growth factor (NGF) treatment on sensory neuron gene expression for substance P, neurofilament L (NFL) and trkA were studied in control and diabetic rats. Control rats were treated s.c. 3x weekly for 4 weeks with 0.2 and 1.0mg/kg hrNGF. Diabetic rats (65mg/kg streptozotocin i.p.) were treated for 1, 2 and 4 weeks with low dose hrNGF (total duration of diabetes was 8 weeks). Total RNA was isolated from the L4 and L5 dorsal root ganglia (DRG) and subjected to Northern blotting. Sciatic nerve samples were analysed for substance P and NGF protein. In control rats NGF treatment, at low dose, elevated  $\gamma$ -PPT mRNA (substance P precursor) greater than 2-fold ( $p < 0.05$ ) and trkA mRNA 1.33-fold in DRG. High dose NGF treatment had no greater effect even though NGF protein levels in sciatic nerve were raised 2-fold above those measured at low dose NGF. The levels of mRNA for  $\gamma$ -PPT, NFL and trkA were reduced by 25-40% in DRG of diabetic rats. NGF treatment for 4 weeks only reversed the deficit in  $\gamma$ -PPT mRNA. NGF treatment also reversed substance P protein levels, with an effect by 2 weeks of treatment of diabetic rats. At all time periods the levels of NGF protein in sciatic nerve of diabetic rats were significantly lower than control ( $p < 0.05$ ). The results show that diabetic sensory neurons have a reduced capacity to bind and/or retrogradely transport NGF. Furthermore, sensory neurons of diabetic rats mimic regenerating neurons in the ability of NGF treatment to reverse substance P gene expression but not that of NFL and trkA.

## 606.17

**CEREBROVASCULAR AXONS OF THE AGED RAT RESPOND TO INTRACEREBROVENTRICULAR INFUSION OF NERVE GROWTH FACTOR.** K.L. Schwenk<sup>1</sup>, G.N. Greenlees<sup>1</sup>, R.G. Sherman<sup>1\*</sup>, K.A. Crutcher<sup>2</sup>, and L.G. Isaacson<sup>1</sup>. <sup>1</sup>Center for Neurosci Res, Dept Zoology, Miami Univ, Oxford, OH 45056; <sup>2</sup>Dept Neurosurg, Univ of Cincinnati Coll of Med, Cincinnati, OH 45267.

Although there is evidence for loss of neuronal plasticity with age, very few models permit assessment of the extent to which this loss of plasticity is due to changes in the neuronal environment or to a loss of growth potential of the aged neurons. A 2 week intracranial infusion of nerve growth factor (15  $\mu$ g; NGF) into young rats (10 wks) results in sprouting of perivascular axons associated with the intradural internal carotid artery (ICA). This sprouting response results in a 2-fold increase in the total number of perivascular axons, the majority of which are sympathetic in origin. The robust response by young, intact sympathetic neurons provides the opportunity to determine whether aging affects such neuronal plasticity. Aged (24 mo.) Fischer female rats received a 2 week intracranial infusion of NGF (15  $\mu$ g; n=4) or VEH (n=4) and were perfused for electron microscopy. The mean number of axons associated with the ICA was increased by 120% following NGF infusion when compared with VEH controls (383 vs. 841 axons). These results suggest that aged cerebrovascular neurons retain their responsiveness to exogenous trophic factors. The data are also consistent with previous findings suggesting that the decline in plasticity in the aged sympathetic nervous system is not due to the loss of growth potential of the aged neurons. ## 606.14

**INFLUENCE OF STIMULATION AND NGF ON GENE EXPRESSION IN COLLATERALLY SPROUTING DRG NEURONS.** K.M. Mearow\*, Div. Basic Medical Sciences, Memorial University of Newfoundland, St. John's, NFLD, Canada, A1B 3V6.

Collateral sprouting of mature cutaneous nociceptive fibres is regulated by the availability of NGF. Furthermore, the onset of this sprouting is accelerated by electrical stimulation of the intact nerve. To investigate this influence of stimulation on the sprouting of DRG neurons the following experimental paradigms were used: adult rats were administered NGF (60  $\mu$ g/100 g, ip) daily for 1-12 days; cytochrome c was injected in control animals. The dorsal cutaneous nerves were exposed, and those on the left side were electrically stimulated, while the ones on the right were not. At 12 days post-stimulation, the extent of nociceptive fibre sprouting was examined by an established behavioural mapping technique, and found to have occurred only in the NGF-treated animals. DRGs were removed at 6 hrs, 1, 2, 6 and 12 days post-stimulation, cryosectioned and processed for in situ hybridization to examine mRNA expression of the NGF receptors (p75 and trkA), GAP-43 and  $\alpha$ -tubulin; as well, the neurotrophins NGF, BDNF and NT-3 were examined. Expression of p75, trkA,  $\alpha$ -tubulin and GAP-43 mRNAs was upregulated in the NGF-treated (2d and longer), but not in the control DRGs. Stimulation resulted in these increases being observed 1-3 days in advance of that in the absence of stimulation; nerve stimulation alone had no effect on expression of these mRNAs. Examination of neurotrophin mRNAs confirmed the absence of neuronal NGF and NT-3 expression, and the presence of BDNF expression. However, preliminary results suggest that stimulation significantly increased BDNF expression in these DRG neurons. These results demonstrate that stimulation influences the expression of mRNAs involved in the sprouting response, and suggest the possibility of the involvement of BDNF in the stimulation-induced acceleration of the sprouting response. **THE EFFECT OF NERVE GROWTH FACTOR ON AXOTOMIZED DORSAL ROOT GANGLION CELLS AND THEIR CENTRAL TERMINALS.**

N.P. Eriksson, C. Rivero-Melán\* and H. Aldskogius  
Department of Neuroscience, Karolinska Institutet, Stockholm, Sweden

Nerve Growth Factor (NGF) is known to have a function as a neuron-survival factor in dorsal root ganglion- (DRG) neurons as well as a differentiating factor for neuroepithelial cells in their central terminals. However, NGF is unlikely to be of importance for the majority of the carbonic anhydrase- (CA) expressing DRG neurons, which lack the high-affinity NGF binding sites. This is also the case for the fluoride resistant acidic phosphatase- (FRAP) neurons in the spinal cord dorsal horn. It is not clear, however, whether the neuroepithelial cells are really needed for neuronal survival. In our experiments we therefore wanted to study the effects of NGF on the differentiation of the neuroepithelial cells, CA and FRAP as well as the neuron survival. The sciatic nerve was either transected or its transected proximal nerve stump was put in a capsule containing NGF or control substance. The animals were allowed to survive for two or four weeks thereafter they were sacrificed and the DRGs L4-L6 as well as the spinal cord were dissected out and processed for SP, CGRP, CA and FRAP using either immunohistochemical-, radioimmunoassay- or ELISA-techniques. DRGs were also cresyl stained for quantification. Ratios operated/unoperated sides were used as an index of depletion. Altogether, the neuroepithelial cells results from DRG and spinal cord show no significant difference between the NGF- and the control substance groups. However, regardless treatment protocol, there is a larger side-to-side difference in the spinal cord than in the DRGs. Further, following nerve transection only there is no significant decrease in the amount of CGRP in the DRG. On the other hand, the immunohistochemical material reveal a difference between the NGF-treated and untreated material, which is also the case for the DRG-counts. The CA- and the FRAP-results reveal no significant difference between the NGF- and the control substance groups. Thus, despite rescuing the neurons, NGF in the concentration and durations used does not completely reverse the axotomy induced depletion of neuroepithelial cells in the dorsal horn.

## 606.18

**IN VIVO RESPONSIVENESS OF SENSORY AND SYMPATHETIC NERVES TO NGF IN MATURITY AND OLD AGE.** J. Gavazzi\*, K.L. Railton, T. Cowen, Dept. of Anatomy and Developmental Biology, Royal Free Hospital School of Medicine, London NW3 2PF, UK

Reduced responsiveness of ageing neurons to trophic factors could lead to decreased neuronal plasticity in old age. We have investigated this issue in the peripheral nervous system, evaluating the responsiveness to NGF of mature and aged sympathetic and sensory neurons supplying the innervation to the rat iris. Sprague-Dawley rats, aged 6 weeks or 24 months, received 4 weekly transcleral injections into the anterior eye chamber of 5  $\mu$ l (young rats) or 10  $\mu$ l (old rats) of: a) 100  $\mu$ g/ml Cytochrome C (CytC); b) 25  $\mu$ g/ml NGF; c) 100  $\mu$ g/ml NGF, or d) 200  $\mu$ g/ml NGF. CytC and NGF were dissolved in 1mg/ml rat albumin in PBS. One week after the final injection the irides were dissected and processed as whole mounts by conventional immunofluorescence techniques, using antibodies against TH (tyrosine hydroxylase, a sympathetic marker) or CGRP (calcitonin gene-related peptide, a marker for a subpopulation of sensory neurons). The density of innervation on the irides was measured by computerized image analysis. The density of CGRP-immunoreactive nerves was decreased on control irides from old animals as compared to young ( $p < 0.05$ ), whilst TH-positive nerve density was unaltered. CytC treatment had no effect on nerve density. The density of TH- and CGRP-positive nerves was increased by NGF treatment in both young and old rats. There appeared to be no loss of responsiveness in old age. However, CGRP-positive nerves were more sensitive to NGF treatment, showing significant growth responses to 25  $\mu$ g/ml NGF ( $p < 0.05$ ). In contrast TH-positive nerves responded only to NGF concentrations of 200  $\mu$ g/ml. We conclude that aged sympathetic and sensory nerves retain unaltered ability to respond to NGF as measured by changes in density of TH and CGRP immunoreactivity. Both in young and in old animals, sensory nerves are more sensitive than sympathetic nerves to variations in NGF availability.

## 606.19

INCREASED VULNERABILITY OF SYMPATHETIC, BUT NOT SENSORY, NEURONS TO NGF DEPRIVATION IN AGEING RATS: THE ROLE OF LOW-AFFINITY NGF RECEPTORS. T. Cowen\*, R.E.M. Canavan and I. Gavazzi, Dept. of Anatomy and Developmental Biology, Royal Free Hospital School of Medicine, London NW3 2PF, UK.

In order to study the causes of selective neuronal vulnerability during normal ageing, sympathetic and sensory nerves to the irises of young (6wk) and old (24m) rats were treated daily for 7 days with anti-NGF antibody ( $\alpha$ NGF; 0.5mg/ml) raised in sheep (Cedar Lane Ltd, Canada) or sheep IgG alone by transcleral injection into the anterior eye chamber under halothane anaesthesia. 0.5  $\mu$ l were injected into young rats and 10  $\mu$ l into old using sterile Hamilton syringes. Irises from untreated young and old rats were also studied. Animals were killed under terminal anaesthesia, irises were dissected and processed as whole mounts for CGRP immunohistochemistry to demonstrate sensory nerves or treated with glyoxylic acid for the demonstration of noradrenergic nerve fibres. Some untreated irises were double-immunolabelled for tyrosine hydroxylase (TH) and low-affinity NGF receptor (p75NGFr) or CGRP and p75NGFr. Nerve densities and co-localized double labels were assessed using computerized image analysis. Sympathetic nerve fibre density was reduced by about 40% ( $p < 0.05$ ) in old rat irises following treatment with  $\alpha$ NGF whilst in young rats little change was observed. In contrast, sensory nerve fibres to the iris were relatively unresponsive to  $\alpha$ NGF treatment showing few changes in either young or old rats. p75NGFr showed substantial reductions in sympathetic nerve fibres from untreated old rat irises compared to young, whilst p75NGFr on sensory nerves showed less obvious changes with age. We conclude that sympathetic nerves become more vulnerable to deprivation of target-derived NGF with age and are more vulnerable than sensory nerves innervating the same target. We hypothesize that reduced p75NGFr expression contributes to the increased vulnerability of ageing sympathetic nerves.

## 606.21

AUTOCRINE OR PARACRINE ROLE OF NGF IN DORSAL ROOT GANGLIA DURING DEVELOPMENT. J.S. Gill<sup>1</sup> and A.J. Windebank. Molecular Neuroscience Program, Mayo Foundation, Rochester, MN 55905.

NGF is a target derived growth factor. In the peripheral nervous system, it is produced by tissues innervated by the sympathetic nervous system and small sensory neurons. In the present study, we tested the hypothesis that an alternate source of NGF must be available to support dorsal root ganglion (DRG) neurons before they make connection with the target. Expression of NGF in rat DRG during development (E12 to adult) was examined. Using reverse transcriptase-polymerase chain reaction (RT-PCR), we were able to demonstrate NGF mRNA from E12-E17 (maximal at E13), while transcripts were not detected in adult DRG. Parallel studies using RT-PCR revealed mRNA for the high affinity NGF receptor/TrkA at all time periods studied. Functional assays were carried out to determine the level of receptor activation during development. Western blot analysis of DRG cell lysates (E12 to adult) revealed tyrosine phosphorylation of TrkA from E13-E17 only. Digoxigenin labelled riboprobes were constructed and used for *in situ* hybridization studies over the same time period to localize the site of NGF mRNA synthesis at the cellular level.

**Conclusion:** NGF mRNA is expressed in DRG after neuronal birth and before axons make contact with their targets. This demonstrates a potential paracrine or autocrine role for NGF during development of primary sensory neurons (supported by NS 29769).

## 606.20

AXONAL REGENERATION OF SENSORY NERVES IS REDUCED BY CONTINUOUS INTRATHECAL INFUSION OF NERVE GROWTH FACTOR (NGF). B.G. Gold<sup>1,2</sup>, M. Lacerange<sup>1</sup> and M. Zelan-Pooly. <sup>1</sup>Center for Research on Occupational & Environmental Toxicology (CROET) and <sup>2</sup>Department of Cell Biology & Anatomy, Oregon Health Sciences University, Portland, OR 97201.

While it is well established that NGF is growth promoting for sensory neurons in culture, it is unclear whether it serves such a function *in vivo*. In fact, recent evidence indicates that NGF does not support regeneration of adult rat peripheral nerve (Diamond et al. *J Neurosci* 12:1467, 1992). Furthermore, the ability of NGF to prevent the induction of many axonal injury-induced changes in the neuronal cell body, such as increased *c-jun* expression (Gold et al., *Neurosci Letters* 154:129, 1993), suggests that NGF may actually impair axonal regeneration by reducing the cell body response to injury. To test this hypothesis, rats given a bilateral sciatic nerve crush received NGF (125 ng/hr) as a continuous infusion into the subarachnoid space of the lumbar spinal cord via an osmotic minipump (Alzet); controls received cytochrome C. At 7 or 10 days, the pump was removed and L4 or L5 dorsal root ganglion (DRG) exposed and injected with 50  $\mu$ Ci of [<sup>3</sup>H]-leucine. Animals were killed 24 hours later, the sciatic nerves removed, cut into 3-mm segments and the radioactivity in each segment determined by liquid scintillation spectrophotometry. Maximal regeneration distances were determined from the front of the resultant transport curves. At 8 days, the apparent rate of regeneration (distance divided by the number of days following nerve crush) was significantly ( $p < 0.001$ ) reduced (by 19%) in nerves from NGF-infused rats to 3.4  $\pm$  0.04 mm/day (n=6) (mean  $\pm$  SEM) from 4.2  $\pm$  0.11 mm/day (n=7) in cytochrome C-infused rats. However, actual regeneration rates (between 8 and 11 days) were unaltered (regeneration distances were similarly reduced by NGF at 8 and 11 days) suggesting that NGF delays the onset of regeneration (ca. 3 days). The data support a role for two signals in the regenerative response: an early, induction signal (e.g. loss of NGF; present study) and a later, maintenance signal (see Gold et al., *Neurosci Letters* 176:123, 1994). Supported by the Paralyzed Veterans of America Spinal Cord Research Foundation and NS19611.

## 606.22

AN EFFICIENT, UNBIASED METHOD TO ESTIMATE CELL NUMBER AND VOLUME IN MULTIPLE DORSAL ROOT GANGLIA. C. Avendano<sup>1</sup> and A. Lagares. Dept. Morphology, Aut6noma Univ., Sch. of Medicine, 28029 Madrid, Spain.

Few neuronal ensembles would seem better suited for being counted and measured than the primary sensory neurons in the dorsal root ganglia (DRG). Cell counts are useful to investigate developmental or degenerative processes in DRG, and cell body size is used, among other purposes, to recognize anatomical and functional subpopulations of neurons. However, despite a wealth of quantitative studies on DRG, progress is still hampered by conflicting results largely arising from methodological disagreements on sampling, counting or measuring procedures. Recent stereological developments have introduced unbiased methods which allow to efficiently obtain precise estimates of numbers and sizes of cell populations. We have applied the optical disector, rotator and fractionator principles (Gundersen et al., *APMIS* 96:857, 1988; Jensen and Gundersen, *J. Microsc.* 170:35, 1993) to estimate the total number of neurons, as well as the cell body size in groups of DRG. All left DRG of a rat, and sets of C<sub>4</sub> through T<sub>2</sub> DRG from both sides of 5 macaques (*M. nemestrina*) were orderly arranged and embedded in single blocks of celloidin. Sections cut at 50  $\mu$ m were Nissl-stained. Cell counts and volume measurements were performed using an interactive computer system running the GRID<sup>®</sup> Stereological Software Package (Olympus Denmark). In the rat the total number of left DRG neurons was 155000. In monkeys, cell counts averaged 252000 per side (range: 203000 to 277000), with 45% belonging to the A type. Coefficients of error for these estimates were below 8%. Mean somatic volume (uncorrected for shrinkage) was 32400  $\mu$ m<sup>3</sup> for A-cells and 4960  $\mu$ m<sup>3</sup> for B-cells. Soma size distribution was skewed to the right in all cases and there was moderate overlap between the distributions of the two cell types. Cell counts performed on individual ganglia showed significant side differences in C7 and C8. It is expected that methodological developments like this one will encourage the use of quantitative approaches to the study of developmental, pathological and plasticity processes in the sensory systems.

## NEUROTROPHIC FACTORS: BIOLOGIC EFFECTS XII

## 607.1

DISTINCT CELLULAR TARGETS OF THE BONE MORPHOGENETIC PROTEINS IN NEURAL DEVELOPMENT. P.C. Mabie, M. Mehler, A. Papavasiliou, R. Marmur, S. Qingbin, K. Shen\*, J. Kessler. Depts. of Neurology and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

Bone morphogenetic protein (BMP) members of the transforming growth factor beta superfamily have complex effects on developing neural cells *in vitro*, including region-specific induction of apoptosis, enhanced neuronal outgrowth and survival, promotion of astrocyte differentiation and proliferation, and modulation of neuropeptide gene expression. Regulated BMP transcript expression during neural development *in vivo* suggests that the BMPs may function as inductive signals for multiple lineages at different developmental stages. To define the direct target(s) of the BMPs and to elucidate their mechanism(s) of action, purified cultures of murine neurons, epidermal growth factor-generated multipotent progenitors, astroblasts, oligodendroblasts, and microglia were analyzed for transcript expression of activin receptor-like kinases (ALK) 3 and 6, putative BMP type I receptors, and for effects of BMP treatment. Neurons, multipotent progenitors, and protoplasmic astroblasts express both ALK 3 and 6, whereas oligodendroblasts and microglia express only ALK3. BMP treatment of primary embryonic serum-free cultures results in increased neuronal outgrowth and survival, as well as astroblast differentiation and proliferation. BMP treatment of multipotent progenitors favors differentiation and proliferation of astrocytes, while also enhancing outgrowth in surviving neurons. BMP-treated astroblasts and microglia do not significantly differentiate or proliferate. Preliminary experiments utilizing BMP-conditioned media from purified cell preparations suggest that the BMPs exert their trophic effects in part by actions on distinct cellular targets. These results suggest that the BMPs have distinct effects on neural cells of different lineages and stages of maturation and participate in complex signaling events between early diverging neural lineages.

## 607.2

OSTEOGENIC PROTEIN-1 (OP-1) INDUCES DENDRITIC GROWTH AND BRANCHING IN CULTURED HIPPOCAMPAL NEURONS. G. Withers<sup>1</sup>, D. Higgins<sup>2</sup>, D. Rueger<sup>3</sup>, and G. Banker<sup>1</sup>. <sup>1</sup>Dept. of Neurosci., Univ. Virginia Sch. of Medicine, Charlottesville, VA 22908, <sup>2</sup>Dept. of Pharmacology, State Univ. of New York, Buffalo, NY 14214, <sup>3</sup>Creative Biomolecules, Hopkinton, MA 01748

Osteogenic Protein-1 (OP-1), a member of the TGF $\beta$  superfamily, was originally isolated from bone but is expressed in both developing and mature brain. Previous studies have demonstrated that OP-1 stimulates dendritic growth in cultured sympathetic neurons. We examined the effects of OP-1 on process development in cultured hippocampal neurons.

Under our standard culture conditions (co-culture with astroglial in serum-free medium), dendritic development begins after several days in culture and by two weeks in culture, the cells have highly elaborate dendritic arbors. In cultures maintained in serum-free medium (without glia), treatment with OP-1 markedly enhanced the rate and extent of dendritic development. By 1 day *in vitro* (DIV) most neurons had generated tapered and highly branched processes, several days before dendrites develop in our standard cultures. Dendritic length and branching was quantified after 3DIV using the Sholl concentric ring analysis. Neurons exposed to OP-1 were significantly increased on most branching and length measures compared with neurons from our standard coculture, e.g. number of Sholl ring intersections (39.6 vs. 16.02), number of terminal branches (13.05 vs. 6.64). There were no significant differences in the number of primary dendrites.

These observations provide further support for the view that neuronal morphology can be regulated by polypeptide growth factors. Supported by NS23094 (GB) and NS09652 (GW).

## 607.3

SOURCES OF TRANSFORMING GROWTH FACTORS AND THEIR ACTIONS ON DOPAMINERGIC NEURONS IN CULTURE. **J.W. Commissiong\*, P. Tsoulfas, T. Takeshima, and R.D. McKay**, LMB-NINDS-NIH, Bldg 36/3D02, Bethesda, MD 20892. \*Div. Neurol., Tottori Univ. Sch. Med., 86 Nishimachi, Yonago 683, Japan.

The transforming growth factors (TGF) are a family of multifunctional compounds that promote the growth, differentiation and morphogenesis of cells. Glial cell line-derived neurotrophic factor (GDNF), (Lin et al., 1993), and TGF- $\beta$ 1, TGF- $\beta$ 2 and TGF- $\beta$ 3 (Kriegstein and Unsicker, 1994; Poulsen et al., 1994) were reported to enhance the survival of dopaminergic (TH-pos) neurons in culture. We tested each compound at 0.1, 1.0 and 10 ng/ml, under optimal conditions of culture of cells from the ventral mesencephalon of the E14 rat, and stained on the seventh day to identify TH-pos and total (MAP2-pos) neurons. GDNF, but not TGF- $\beta$ 1, caused an increase in TH-pos neurons per field ( $320 \mu\text{m}^2$ ), without a corresponding increase in MAP2-pos cells. TGF- $\beta$ 2 and TGF- $\beta$ 3 at 1.0 and 10 ng/ml, caused a decrease in TH-pos and MAP2-pos cells. Type-1 astrocytes (T1-As) and oligodendrocyte, type-2 astrocyte progenitor (O-2A) cells, expanded from the striatum of the E16 rat, and the B49 glial cell line, produce factors that promote the survival of TH-pos neurons in culture. We used the RT-PCR method to test for the expression of mRNA for the above mentioned compounds in all three glia. mRNA for TGF- $\beta$ 1, TGF- $\beta$ 2, TGF- $\beta$ 3 and GDNF was identified in T1-As and B49 cells. mRNA for TGF- $\beta$ 1, and TGF- $\beta$ 3 was identified in O-2A progenitor cells. Experiments are in progress to determine the corresponding degree of protein synthesis. The results indicate that GDNF is unlikely to be the dopaminergic neurotrophic factor that is produced by O-2A progenitor cells (Takeshima et al., 1994), and that the effects exerted by the TGF family of compounds on neurons may be critically dependent on the conditions of the assay. The results also indicate that caution must be exercised in any suggested use of these factors to treat neurodegenerative diseases. Kriegstein, K. and Unsicker, K. (1994) *Neuroscience* 63:1189-1196. ## 607.5

BONE MORPHOGENETIC PROTEINS BMP-2 AND -4 STIMULATE THE EARLY DEVELOPMENT OF AVIAN SYMPATHOADRENERGIC CELLS.

**E. Reißmann, U. Ernsberger, P. H. Francis-West\*, P. M. Brickell\* and H. Rohrer\***, Max-Planck-Institut für Hirnforschung, D-60528 Frankfurt/M. 71, F.R.G. and UCL, London\*.

Adrenergic differentiation of sympathoadrenergic precursor cells is elicited early during development in the vicinity of notochord and dorsal aorta by interactions with the environment. Quail neural crest cell cultures were used to identify signals that affect development of sympathoadrenergic cells. BMP-2 and -4 strongly increase the number of tyrosine hydroxylase-immunoreactive cells. When other members of the TGF- $\beta$  superfamily were tested, BMP-7 was found to be active at high concentrations, whereas TGF- $\beta$ 1, TGF- $\beta$ 3 and GDNF displayed no effect. BMPs, as well as TGF- $\beta$ 1 and TGF- $\beta$ 3 reduce the number of melanocytes developing in these cultures. Preliminary in situ hybridization experiments indicate expression of BMP-4 in dorsal aorta and the developing heart. We propose that BMP-2 and/or BMP-4 may play an important role for the induction of adrenergic differentiation of sympathetic neurons.

## 607.7

EXPRESSION OF ACTIVIN A AND FOLLISTATIN mRNA IN TARGETS OF THE CILIARY GANGLION. **D.C. Darland\* and R. Nishi**, Dept. of Cell Biology and Anatomy, Oregon Health Sciences University, Portland, OR 97201

We are interested in examining target-derived factors that affect the neurotransmitter phenotype of neurons in the avian ciliary ganglion (CG). The CG consists of two populations of neurons: the ciliary neurons which innervate the ciliary body and iris, and the choroid neurons which innervate the arterial smooth muscle of the choroid layer. Both neuron types are cholinergic, but only the choroid neurons express the neuropeptide transmitter, somatostatin. Previous studies implicated a role in somatostatin induction for activin A, a member of the TGF $\beta$  superfamily of molecules. Activin A and follistatin, a protein which binds activin A and inhibits its action, have been proposed to act in concert to affect a number of critical processes in development. To assess whether both factors play a role in somatostatin induction in CG neurons, we established a multi-probe ribonuclease protection assay in which we could examine both activin A and follistatin mRNA in the same sample. Levels for mRNA were normalized to an internal loading control, chick ribosomal protein S17. Choroid cells in culture express high levels of activin mRNA and low levels of follistatin mRNA. In the choroid tissue in vivo from E9-E16, activin A levels remain fairly stable and follistatin is low. Iris cells in culture express similar levels of activin and follistatin mRNA. This is also seen in vivo, in iris tissue from E9-E16. These data lead to the hypothesis that differential expression of somatostatin in the CG neurons is due to the expression of follistatin in the iris, which may prohibit the ability of activin A to signal the somatostatin induction in the ciliary neurons. Further examination of these factors which affect neurotransmitter phenotype should help to clarify the role of neuron/target interactions during development of the CG. Supported by NS25767 (RN) and NIH5T32EY07123 (DD).

## 607.4

6-OHDA LESION AND TGF $\alpha$  INFUSION-INDUCED PLASTICITY IN THE NIGROSTRIATAL DOPAMINE SYSTEM -- TRACING CHANGES WITH MARKERS FOR NEURODEGENERATION. **S. Reid\*, S. Patel, S. Mungania, S.E. Loughlin, R. Giolli and J.H. Fallon**, Department of Anatomy and Neurobiology, University of California, Irvine, CA 92717.

The nigrostriatal dopamine system displays considerable plasticity in response to injury or administration of exogenous dopaminergic factors. In a previous series of experiments, we examined the changes in nigrostriatal expression of transforming growth factor alpha precursor (TGF $\alpha$ -P) and epidermal growth factor receptor (EGFR) mRNAs and peptides in lesioned and TGF $\alpha$ -infused adult rats (Loughlin et al., 1992, 1994; Fallon et al., 1994). In related studies, we determined that TGF $\alpha$  infusions can reduce apomorphine-induced rotation behavior in unilaterally 6-OHDA lesioned rats (Loughlin et al., 1992) and may spare tyrosine hydroxylase-immunoreactive (TH-IR) afferents to the striatum (Loughlin et al., 1993). In the present study, we traced the 6-OHDA-induced degeneration of both striatal afferent fibers and mesencephalic dopaminergic cell bodies with markers selective for degeneration of each cellular structure and assessed the time course of protective effects of infused TGF $\alpha$ . Lesioned animals received either artificial cerebrospinal fluid (aCSF) alone or TGF $\alpha$  in aCSF (50  $\mu\text{g}/\text{ml}$ , 0.5  $\mu\text{l}/\text{hr}$ ). A modified Nauta silver impregnation technique was used to label degenerating axonal processes at selected timepoints after lesion and infusion. The fluorescent stain, Fluoro-Ruby (courtesy L. Schmued), was used to identify degenerating cell bodies within the substantia nigra. The combined degenerative profiles from these stains are presented and compared with data from TH immunostaining during the progressive loss of nigrostriatal dopaminergic innervation. Nairobi.

## 607.6

THE EFFECTS OF BMP-2, -4 AND -6 ON THE DEVELOPMENT OF THE ADRENERGIC PHENOTYPE IN QUAIL TRUNK NEURAL CREST CULTURES. **J.E. Varley and G.D. Maxwell\***, Dept. of Anatomy, Univ. of Connecticut Health Center, Farmington, CT 06030-3405

Members of the TGF- $\beta$  superfamily of growth factors have a wide range of actions in developing and mature systems. Within this superfamily are the dpp and 60A subfamilies which contain several of the bone morphogenetic proteins (BMPs). The BMPs were originally identified based on their ability to stimulate new bone formation, but more recent investigations have revealed that they can act in nervous tissue as well. We have investigated the effects of BMP-2 and BMP-4, members of the dpp subfamily, and BMP-6, a member of the 60A subfamily, on the development of quail trunk neural crest cells in tissue culture. Cultures were grown in medium containing 15% horse serum and 10% chick embryo extract. When human recombinant BMP-2 or BMP-4 was present in the medium at 10 ng/ml the number of tyrosine hydroxylase (TH)-positive cells which developed after 7 days in vitro was increased 100-fold relative to control values. Total cell number was not altered by BMP-2, while melanocyte cell number was reduced to about two-thirds of the control value. In contrast to BMP-2 and BMP-4, BMP-6 at 10 ng/ml resulted in a less than two-fold increase in TH-positive cell number and 100 ng/ml of BMP-6 resulted in a six-fold increase. These results show that BMP-2 and -4 are potent stimulators of adrenergic development in avian trunk neural crest cultures, while BMP-6 is much less effective at promoting adrenergic development.

This work was supported by grant NS16115 from the NIH. Human recombinant BMPs were the generous gift of the Genetics Institute, Inc.

## 607.8

CHARACTERIZATION OF FOLLISTATIN PROTEIN IN TARGETS OF THE CILIARY GANGLION. **B.A. Link\* and R. Nishi**, Dept. of Cell Biology and Anatomy, Oregon Health Sciences University, Portland, OR 97201.

Our goal is to understand the regulation of somatostatin expression in avian ciliary ganglion (CG) neurons. The CG is composed of ciliary neurons which innervate the ciliary body and iris muscles and the choroid neurons which innervate the choroid vasculature. Both ciliary and choroid neurons are embryonically derived from the mesencephalic neural crest, receive pre-synaptic input from cholinergic neurons of the accessory ocular nucleus, and are themselves cholinergic. However, the two populations of neurons differ not only by the targets that they innervate, but also by the selective expression of the neuropeptide somatostatin in choroid neurons. Results from our lab suggest a model where activin A, which induces somatostatin in choroid neurons, is expressed in all targets of CG neurons; however, activin A is prevented from acting on ciliary neurons by follistatin, an inhibitor of activin, which is expressed in the iris and ciliary body (see Darland and Nishi, Soc. Neurosci. Abstr., 1995). In support of this model, we show that iris conditioned medium can inhibit the ability of activin A to induce somatostatin immunoreactivity in CG neuron cultures. In the same experiment iris conditioned medium did not affect neuronal survival or choline acetyltransferase activity, a marker of the cholinergic phenotype. In vivo, follistatin immunoreactivity can be detected in and around the muscle cells of the iris and ciliary body, but not in cells of the choroid coat. We are currently examining the developmental expression of follistatin in the eye.

Supported by NIH5T32EY07123 (BAL) and NS2567 (RN).

## 607.9

TGF- $\beta$ 1 EFFECTS ON GLIAL CELLS: A DIFFERENTIAL DISPLAY STUDY.

K.K. Krohn\* and C.E. Finch#. University of Heidelberg, Dept. of Anatomy and Cell Biology, 69120 Heidelberg, Germany, #Andrus Gerontology Center, University of Southern California, Los Angeles, CA 90089-0191

Transforming Growth Factor- $\beta$ 1 (TGF- $\beta$ 1) has been recently established as a potent factor during glial reactions after brain lesion and as a modulator of cytoskeletal protein expression in neurons and glia. This contribution reports ongoing studies that address TGF- $\beta$ 1 effects on gene expression in glial cells. C6-glioma cells were treated with 0.2 to 5 ng/ml TGF- $\beta$ 1. Total RNA was extracted and reverse transcribed using 4 different d(T)<sub>12</sub>VN primers. In a Differential Display PCR (DDRT-PCR) approach cDNA from each experimental group was amplified using the 4 reverse transcription primers in combination with 9 different arbitrary primers. Nine fragments which suggest a differential expression were reamplified and cloned. For each fragment, 5 clones were sequenced. So far, 2 fragments were confirmed to be differentially expressed using northern blot hybridization. TGF- $\beta$ 1 reduces the mRNA level corresponding to one cDNA identified as glycerol-3-phosphate dehydrogenase by 85%. Another fragment which does not show any homology to known sequences showed a 3-fold induction. This study further demonstrates that TGF- $\beta$ 1 affects glial gene expression and that DDRT-PCR is useful in identifying novel changes in gene expression. (Supported by AG-07909 to CEF and a grant by DAAD to KK)

## 607.11

## THE SWEAT GLAND-DERIVED CHOLINERGIC DIFFERENTIATION FACTOR IS DISTINCT FROM LIF, CNTF AND CT-1. N. Francis, B. Habegger, D. Pennica\* &amp; S. Landis\* Dept. of Neurosci. Case Western Res. Univ., Cleveland, OH 44106 &amp; Genentech, San Francisco, CA 94080\*

During development, rodent sweat glands release differentiation factors which induce their noradrenergic sympathetic innervation to decrease catecholamines and instead produce acetylcholine and vasoactive intestinal peptide (VIP). Two cytokines, leukemia inhibitory factor (LIF) and ciliary neurotrophic factor (CNTF), promote similar changes in cultured sympathetic neurons. There is biochemical and immunological evidence for a CNTF-like activity in footpad extracts. While neither LIF nor CNTF have been localized in sweat glands, LIF mRNA is detected in footpads and CNTF is present in footpad extracts. Sweat gland neurons, however, in LIF-deficient mice change their phenotype appropriately. To determine whether CNTF or CNTF and LIF, alternatively or together, direct the phenotypic switch in sweat gland neurons, we analyzed the function of sweat glands and the phenotype of sweat gland innervation in mice in which the genes for CNTF or both CNTF and LIF were disrupted. Since development of secretory responsiveness requires cholinergic innervation, we assayed agonist-induced sweating and found that mutant and control mice showed equally robust sweat secretion. The activity of choline acetyltransferase (ChAT), which catalyzes acetylcholine production, was also similar in footpads from mutant and control mice. Further, the sweat gland innervation in mutant and control animals lacked catecholamines, but contained VIP and acetylcholinesterase. Taken together, these data indicate that CNTF and LIF are not required for acquisition of the mature phenotype of sweat gland neurons. The newly identified cytokine, Cardiotrophin-1 (CT-1), shares about 20% homology with LIF and CNTF and induces ChAT in cultured sympathetic neurons. However, ChAT induction by footpad extracts or co-culture with sweat gland cells is not altered by function-blocking antiserum to CT-1. In addition, CT-1 protein was not detected in footpad extracts by Western blot. Thus, the factor released by sweat glands that prompts development of cholinergic and peptidergic properties in sweat gland neurons is not LIF, CNTF, or CT-1. This work was supported by NS23678 and the McKnight Foundation.

ASTROCYTES AND PARALBUMIN-POSITIVE NEURONS IN MICE LACKING THE GENE FOR LEUKEMIA INHIBITORY FACTOR S.S. Cheema<sup>1</sup>, E.C. Lopes<sup>1</sup>, F. Koentgen<sup>2</sup>, M. Murphy<sup>2</sup> and P. F. Bartlett<sup>1</sup>. <sup>1</sup>Anatomy Dept., Monash University, Clayton and <sup>2</sup>The Walter & Eliza Hall Institute of Medical Research, Parkville, Victoria Australia.

Our previous studies have shown that leukemia inhibitory factor (LIF): i) promotes the in vitro survival and differentiation of sensory dorsal root ganglion neurons and fetal spinal cord cells, ii) is expressed in the target tissues of sensory neurones during neurogenesis, iii) can be retrogradely transported in situ, and iv) prevents the in vivo loss of axotomised sensory neurons in the dorsal root ganglia and axotomised motor neurons in the spinal cord of neonatal rats. We have now extended our studies to mice where the LIF gene is deleted by homologous recombination.

Adult mice were anaesthetised with chloral hydrate (400 mg/kg, ip) and killed by intracardiac perfusion with 4% buffered paraformaldehyde. Brains were dissected out, frozen on a CO<sub>2</sub> freezing microtome and serial parasagittal sections cut at 40  $\mu$ m. Sections were immunostained using polyclonal antibodies against GFAP and paralbumin. The number of astrocytes within a reference grid in CA3 of the wild-type (WT) and null-mutant (NM) was 54 $\pm$ 2 and 40 $\pm$ 3 (mean  $\pm$  sem) respectively which represents a significant reduction ( $p < 0.001$ ). The number of astrocytes within a reference area in the dentate gyrus in the WT was 30 $\pm$ 3 and in the NM 21 $\pm$ 2 which also represented a significant ( $p < 0.001$ ) reduction. The numbers of paralbumin-positive neurones within reference areas of the hippocampus (WT 76 $\pm$ 7 versus NM 67 $\pm$ 6) and visual cortex (WT 31 $\pm$ 3 versus NM 35 $\pm$ 2) were not significantly reduced.

These studies indicate that LIF plays an important role in the development of astrocytes during the maturation of the hippocampus and dentate gyrus.

## 607.10

TGF- $\beta$ 1 PROTECTS SKELETAL MUSCLE FROM APOPTOTIC AND NECROTIC INJURY. S. Abu-Shakra\*, M.S. Alhalabi, Dept. of Neurology, Wayne State Univ., Sch. of Med., Detroit, MI 48201.

Skeletal muscle is normally capable of mounting successful regenerative responses to injury. However, in certain muscle diseases, this regenerative capacity fails to compensate for cell death. Our aim is to enhance muscle recovery after an injury. We have established two models of acute muscle injury in the C2 differentiating skeletal muscle line. In one model, anabolic steroids (stanozolol) induce apoptosis of muscle cells (LD50 100  $\mu$ M, at 3 hrs). In a second model, the calcium ionophore A23187, induces necrosis (LD50: 1  $\mu$ M, at 3 hrs.). We asked whether the growth factors bFGF and PDGF-BB, and cytokines LIF and TGF- $\beta$ 1 protect skeletal muscle cells from these two acute injuries. Mature skeletal muscle expresses receptors to these factors. As an index of injury, cellular creatine kinase (CK) levels were assayed. Cultures were treated with growth factor/cytokine for 5 hrs. followed by injury (stanozolol at 100  $\mu$ M or A23187 at 1  $\mu$ M). Cellular CK levels were measured 3 hrs. later. We found that TGF- $\beta$ 1, at 0.5 ng/cc, protected skeletal muscle cells from necrosis (-42%), and apoptosis (-40%). In contrast, bFGF, PDGF-BB, and LIF afforded muscle < 10% protection each. We conclude that TGF- $\beta$ 1 rescues skeletal muscle from both apoptosis and necrosis, and may be of use in treating certain myopathies.

## 607.12

CARDIOTROPHIN-1 INDUCES THE SAME NEUROPEPTIDES IN SYMPATHETIC NEURONS AS THE NEUROPOIETIC CYTOKINES. J.-Gang Cheng\*, Diane Pennica<sup>1</sup> and Paul H. Patterson, Division of Biology, California Institute of Technology, Pasadena CA 91125 and <sup>2</sup>Department of Molecular Biology, Genentech, South San Francisco, CA 94080.

Cardiotrophin-1 (CT-1) was cloned from a mouse embryoid body cDNA library by its ability to induce hypertrophic growth of neonatal rat cardiac myocytes (PNAS 92: 1142, '94). Predictions of its secondary structure suggest that CT-1 belongs to a family of cytokines with four amphipathic helices. Sequence comparison revealed a weak homology to leukemia inhibitory factor (LIF) and ciliary neurotrophic factor (CNTF) (24% and 19%, respectively). Using a RT-PCR assay system with rat sympathetic neuron cultures, we find that CT-1 induces and suppresses the expression of the same set of neuropeptides and neurotransmitter synthesizing enzymes as do LIF and CNTF. This functional data confirms that CT-1 is a member of the neuropoietic cytokine family, and suggests that the CT-1 receptor complex contains the gp130 signal transducing component.

## 607.14

LEUKEMIA INHIBITORY FACTOR ENHANCES THE REINNERVATION OF MUSCLE. D.I. Finkelstein<sup>1</sup>, M.K. Horne, P.F. Bartlett<sup>2</sup>, S.S. Cheema, Department of Anatomy, Monash University, Australia, 3168. <sup>1</sup>Walter & Eliza Hall Institute for Medical Research Institute<sup>2</sup>, Vic, 3052, Australia.

Transaction of a peripheral nerve in the adult, results in atrophy of muscle. Subsequent regeneration of axons, results in regrowth of axons of reduced diameter. Leukemia Inhibitory Factor (LIF), is released by damaged muscle and has been shown to be important for motor and sensory neurones. The aim of these experiments was to determine the effect of intramuscular injections of LIF into denervated muscles and reinnervating muscles. Under sodium pentobarbitone anaesthesia, the nerve to medial gastrocnemius (MG) muscle was cut in both legs and sutured into the popliteal fat pad to prevent reinnervation, (Denervation Group n=12). In a second group the nerve to (MG) was crushed 10 mm from the muscle (Reinnervation Group n=7). LIF was injected into the left MG and vehicle on the right. After 6-8 weeks, LIF was found to provide a limited protection against denervation-induced changes and improves the reinnervation of muscle following a nerve crush and reinnervation. Muscle cross-sectional area was greater in LIF treated denervated (46 %) and reinnervating groups (60 %) compared to those of the control. Nerve fibre diameters below the crush were larger in LIF treated reinnervating group. The LIF treated nerves had 24% of the axons larger than 6  $\mu$ m in diameter compared to 4% in the control.

## 607.15

LEUKEMIA INHIBITORY FACTOR-MEDIATED ACTIVATION OF STAT PROTEINS AFTER NEURONAL INJURY *IN VIVO*. P. Rajan\*, C. L. Stewart† and J. S. Fink. Molecular Neurobiology Laboratory, Massachusetts General Hospital and Department of Neurology, Harvard Medical School, Boston, MA 02114, USA.†Department of Cell and Developmental Biology, Roche Institute of Molecular Biology, Nutley, NJ 07110, USA.

Leukemia inhibitory factor (LIF) is a member of a family of neurotrophic cytokines which influence neuronal survival, differentiation and response to injury. LIF synthesis is increased by neuronal injury, but the intracellular mechanisms of action of LIF in neurons have not been characterized *in vivo*. In cell lines LIF activates the Jak/Tyrosine kinases and the STAT family of transcription factors. In this report we have investigated the intracellular signaling pathways activated by LIF after neuronal injury *in vivo*. Axotomy of postganglionic sympathetic nerves resulted in sustained activation of members of the STAT transcription factor family. This activation is dependent on LIF as axotomy failed to activate STAT proteins in LIF-deficient mice. These data indicate that LIF-dependent activation of STAT proteins is an essential molecular mechanism underlying the response of sympathetic neurons to injury. A similar activation of STAT proteins is seen in organ cultures of the superior cervical ganglion.

## 607.17

CILIARY NEUROTROPHIC FACTOR (CNTF) AND NEUROTROPHIN-3 (NT-3) POTENTIATE ONE ANOTHER IN PROMOTING ENTERIC NEURONAL DEVELOPMENT. A. Chalazoni\*, T.P. Rothman and M.D. Gershon. Dept. Anat. & Cell Biol., Columbia Univ. P&S. New York, NY 10032

Pluripotent neural crest-derived precursors interact with microenvironmental signals in forming the enteric nervous system (ENS). To identify signaling molecules, we have studied the development of neurons *in vitro* from crest-derived cells isolated from the fetal rat gut by immunoselection. Immunoselected crest-derived cells express TRKC and NT-3 specifically promotes the development of enteric neurons. Both CNTF and the  $\alpha$  subunit of the CNTF receptor are expressed in the fetal mouse gut. The present study thus determined the effect of CNTF, alone, and in combination with NT-3 on the *in vitro* development of enteric neurons. Crest-derived cells, which virtually all express p75<sup>LNGFR</sup>, were immunoselected with IgG192. The isolated crest-derived cells were grown for 8 days in defined medium; neural markers included process formation and neurofilament or peripherin immunoreactivities. By itself, CNTF (0.01-100 ng/ml) promoted neuronal development. This effect was concentration-dependent and maximal at 0.1 ng/ml (178  $\pm$  15 % of control). CNTF (0.01-100 ng/ml) was then applied together with NT-3 (40 ng/ml), which, by itself, promoted neuronal development to 207% of control. The effect of this combination of factors was greater than that of either factor alone; the number of neurons was 390% of control at 1 ng/ml CNTF and 529% of control at 100 ng/ml. At least some neurons became dependent on NT-3; thus, survival of neurons was reduced by 57  $\pm$  6.1% when NT-3 was withdrawn for the final 3 of 8 days of incubation. When cells were co-treated with NT-3 and CNTF, survival was reduced from 222.7  $\pm$  26.5% to 151  $\pm$  20.5% if NT-3 was withdrawn for the final 3 of 8 days of incubation; thus CNTF may not fully compensate for the withdrawal of NT-3. These data are compatible with the idea that cytokines that react with CNTF receptors may combine with NT-3 in promoting the development of enteric neurons. Supported by NIH grants NS15547 and HD20470

## 607.19

CILIARY NEUROTROPHIC FACTOR REGULATES INJURY-INDUCED GROWTH FACTORS. T.L. Wood\*, S. O'Donnell and S.W. Levison. Dept. Neuroscience and Anatomy, PSU College of Medicine, Hershey, PA 17033.

Growth factor induction is a major component of the response to central nervous system trauma. The insulin-like growth factors (IGFs) and IGF binding proteins (IGFBPs) are among the molecules induced by injury that have demonstrated neuroprotective actions. Ciliary neurotrophic factor (CNTF) recently has been described as a major injury signal and can induce several aspects of reactive gliosis. To establish whether this cytokine is responsible for inducing specific growth factors following CNS injury, we injected CNTF intracerebrally into the neocortex of adult rats and measured changes in mRNA expression for bFGF, IGF-I, IGF-II, IGFBPs, and the type I IGF receptor. By *in situ* hybridization analysis, bFGF mRNA increased by 10 hours following CNTF injection when compared to a control hemisphere injected with heat-inactivated CNTF. IGFBP-2 mRNA showed a dramatic increase following CNTF injection, peaking between 24-48 hours and then rapidly declining. The majority of the cells in which BP2 mRNA was induced also were immunopositive for GFAP, indicating that astrocytes are the source of the increased BP2. The type I IGF receptor mRNA also was up-regulated by CNTF. Interestingly, IGF-I and IGF-II were unchanged up to 72 hours following CNTF injection. Similarly, CNTF had no effect on either BP3 or BP5. These results suggest that CNTF is a major regulator of specific growth factor systems following CNS injury. Supported in part by NSF/IBN94-08860 to T.L. Wood and by NMSS #PP0407 to S. Levison.

## 607.16

CDF/LIF mRNA INCREASES FOLLOWING ADJUVANT-INDUCED INFLAMMATION. L. R. Banner\*, C. J. Woolf† and P.H. Patterson†. \*Biology Division, California Institute of Technology, Pasadena, CA 91125 and †Department of Anatomy, University College London, London WC1E 6BT.

Intraplantar injection of complete Freund's adjuvant (CFA) produces an inflammatory response characterized by local swelling, sensory hypersensitivity and a rapid up-regulation of IL-1 $\beta$  and NGF. In addition, there is an increase in the neuropeptides substance P and CGRP in the neurons of the dorsal root ganglia. The neurotrophic cytokine, cholinergic differentiation factor/leukemia inhibitory factor (CDF/LIF), plays a role in the response of adult sympathetic neurons to injury, mediating neuropeptide induction. To test whether CDF/LIF regulates a neurogenic response to inflammation, CDF/LIF mRNA levels were determined following CFA injection. We find that LIF mRNA increases in both plantar skin and sciatic nerve following inflammation. This response occurs within 6 hrs on the ipsilateral side and also occurs to a lesser extent on the contralateral side. Although intraplantar injections of 50 or 100 ng of CDF/LIF produced no direct change in mechanical or thermal behavioral sensitivity, or in IL-1 or NGF levels in skin, increased levels in inflamed tissue may modify neuropeptide expression in primary sensory and sympathetic neurons.

## 607.18

MULTIPLE APPROACHES TO ALTERING LEVELS OF CILIARY NEUROTROPHIC ACTIVITY IN OVO. T.P. Finn and B. Nishi\*. Dept. of Cell Biology and Anatomy, Oregon Health Sci. Univ., Portland, Oregon 97201.

Growth promoting activity (GPA), is a potent neurotrophic factor for chicken ciliary ganglion neurons *in vitro* which can be purified from both embryonic eye and adult sciatic nerve. We have previously shown by immunocytochemistry the presence of GPA within both targets of CG neurons: the choroid layer and iris of the eye. GPA message can first be detected at E6 and increases significantly through the critical time window of development when the CG neuronal population is being restricted. As part of an effort to determine whether or not GPA meets the requirements of a true target-derived trophic factor *in vivo*, we are attempting to alter the level of CG neuronal survival by adjusting the amount of GPA made available to the neurons. Four approaches have been taken: 1) direct injection of either recombinant GPA or blocking antibodies to GPA; 2) Immunization of adult hens with GPA in order to produce blocking GPA antibodies in the fertile eggs; 3) infection of chick embryos with replication competent retrovirus (RCAS) that either over-expresses GPA or produces GPA antisense; and 4) injection of chick embryos with antisense oligonucleotides against GPA. In order to facilitate injections *in ovo*, we have optimized methods for maintenance of chick embryos in shellless cultures from E2 through E18. Embryos injected with either GPA or GPA blocking antibodies survive and have a normal appearance. One adult hen injected with GPA antigen produced a high titer to GPA and the antibodies have partial blocking ability *in vitro*. We have expressed a marker gene within structures in the eye using the RCAS system and have GPA sense and antisense constructs prepared. Results from GPA over-expression and blocking experiments will be presented at the meeting. Funded by NS25767 to R.N.

VASOACTIVE INTESTINAL PEPTIDE STIMULATION OF EMBRYONIC GROWTH IN CULTURED E9 MICE IS PARTIALLY MEDIATED THROUGH ACTIVITY-DEPENDENT NEUROTROPHIC FACTOR. G. W. Glazner\*, J. Y. Wu, P. Gressens, I. Gozes, D. E. Brenneman and J. M. Hill. Lab. Dev. Neurobiol., NICHD, NIH, Bethesda, MD, 20892; Univ. of Louvain Med. Sch., Brussels, Belgium; Dept. of Clin. Biochem., Tel Aviv Univ., Tel Aviv, Israel.

Vasoactive intestinal peptide (VIP) increases growth in mouse embryos *in vitro*. VIP (10<sup>-7</sup> M) increased somite number, DNA and protein content, embryo size, and BRDU incorporation. Recent work has shown that VIP is a secretagogue for a novel neurotrophic factor in cultured astrocytes: activity-dependent neurotrophic factor (ADNF). We tested the hypothesis that stimulation of embryonic growth by VIP was mediated through ADNF. Embryonic day 9.5 embryos (15 to 18 somites) were cultured in serum alone or with 10<sup>-7</sup> M VIP, 10<sup>-15</sup> M ADNF, anti-ADNF antiserum (AAA), or a combination of AAA and either VIP or ADNF. After four hours, embryos were measured for somite growth, protein and DNA content, and BRDU incorporation. VIP-stimulated growth was prevented by AAA. Both VIP and ADNF equally increased somite number relative to control animals (4.6 v. 2.3). ADNF treatment also significantly increased protein (15%) and DNA (22%) content, and number of BRDU-positive cells relative to control animals, indicating increased mitotic activity. As with VIP, ADNF-stimulated growth was blocked by AAA. Embryos treated with AAA alone had significantly decreased somite growth (0.8 v. 2.3) and reduced BRDU incorporation compared with controls. In an additional test of mediators of VIP action as a mitotic stimulator, cyclin A gene expression was measured in embryos grown for two hours in the presence or absence of VIP. Using both semi-quantitative RT-PCR and competitive PCR, cyclin A mRNA levels were significantly greater (2-3 fold) in VIP-treated embryos compared to control animals. These data indicate that VIP-stimulated growth in the embryo is mediated in part by ADNF, and is correlated with increased cyclin A mRNA.

## 607.21

## VASOACTIVE INTESTINAL PEPTIDE-INDUCED SHORTENING OF S PHASE IN WHOLE CULTURED MOUSE EMBRYOS.

P. Gressens\*, B. Paindaveine, J.M. Hill, P. Evrard & D.E. Brenneman. Lab. Dev. Neurol., Univ. of Louvain Medical Sch., Brussels, Belgium; Lab. Exp. Neuropathol. & Lab. Dev. Neurobiol., NIH, Bethesda, MD.

Vasoactive intestinal peptide (VIP), a neurotrophic and mitogenic factor, has been shown to stimulate embryonic and neural growth in a model of whole embryo culture (Nature 362: 155, 1993). *In vivo* inhibition of this growth function between embryonic day (E) 9 and E11 by the administration of a specific VIP antagonist induces severe microcephaly in mouse embryos (J. Clin. Invest. 94: 2020, 1994). In these models, VIP regulated cell multiplication (or survival) in the germinative neuroepithelium. To address the potential effects of VIP on the different phases of the cell cycle of neural cells, we used whole E9 embryo cultures combined with cumulative labelling of S phase cells by incorporation of BRDU. When embryos were cultured in the presence of  $10^{-7}$  M VIP, S phase and G1 phase of neuroepithelial cells were shortened by 46% (295 to 160 minutes) and 57% (110 to 47 minutes), respectively. Consequently, the length of the mitotic cycle was reduced by 40% (500 to 302 minutes). G2 and M phases were not affected in this model. By *ex vivo* autoradiography, VIP binding sites were detected in the germinative neuroepithelium between E9 and E11 but not beyond E12, during neuronal migration. Together, these data support the hypothesis that VIP shortened S and G1 phases during premigratory stages of *in vivo* brain development. A critical component of VIP-induced embryonic growth probably resides in this reduction in S phase kinetics, the first demonstrated in response to a physiological peptide.

## NEUROTROPHIC FACTORS: BIOLOGIC EFFECTS XIII

## 608.1

## FIBROBLAST GROWTH FACTORS REGULATE CGRP mRNA EXPRESSION IN RAT MOTONEURONS AFTER LESION AND IN CULTURE. S. Cullheim\*(1), F. Pichl (1), J. Ru-Rong (1), T. Hökfelt (1), D. Lindholm (2) and R.A. Hughes (2). Dept. of Neuroscience, Karolinska Institute, S-171 77 Stockholm, Sweden (1) and Dept. of Neurochemistry, Max-Planck-Institute for Psychiatry, 82152 Martinsried, Germany (2).

Adult motoneurons respond to axotomy with a rapid up-regulation of calcitonin gene-related peptide (CGRP) mRNA expression. This may reflect a direct response to injury or may be a consequence of a loss of target-derived factors. In this study, we have analyzed one *in vivo* and one *in vitro* system in an attempt to identify target-derived factors with a potential effect on CGRP levels in motoneurons. In *in vivo* experiments, young adult Sprague-Dawley rats were subjected to a unilateral transection of the sciatic nerve. The proximal nerve stump was inserted into a capsule filled with either brain derived neurotrophic factor (BDNF; 15 µg), basic fibroblast growth factor (bFGF; 0.2 or 1 µg) or saline. After 3 days survival, the animals were sacrificed and sciatic motoneurons were studied with *in situ* hybridization histochemistry for detection of alpha- and beta-CGRP mRNAs. In cell cultures, embryonic rat motoneurons were treated with BDNF (10 ng/ml) or fibroblast growth factor-5 (FGF-5; 50 ng/ml). After 24h incubation, RT-PCR was used to estimate the levels of alpha- and beta-CGRP mRNAs, with GAPDH mRNA as an external control. *In vivo*, the local administration of bFGF at a dose of 1 µg abolished the upregulation of alpha-CGRP following axotomy, while BDNF did not significantly alter the expression of CGRP mRNAs. The motoneuron cultures treated with FGF-5 had a lower ratio of alpha- and beta-CGRP mRNAs to GAPDH mRNA, than did control or BDNF treated cultures. The results suggest that members of the FGF family of growth factors influence the expression of CGRP in rat motoneurons, and that the increase of this neuropeptide induced by axotomy may, at least in part, be due to deprivation of these target-derived factors.

## 608.3

## IMMUNOHISTOCHEMICAL LOCALIZATION OF ALL 4 HIGH AFFINITY FGF-RECEPTORS IN ADULT RAT SENSORY GANGLIA, PERIPHERAL NERVES AND ADRENAL GLAND. R. Westermann\* &amp; P. Hartmann, Dept. Anat. &amp; Cell Biol. Philipps-Univ., D-35033 Marburg, Germany

FGF-2 is known to be expressed by and to act on cells of the peripheral nervous and endocrine systems. Action occurs via 4 families of high affinity receptors [FGFR-1 to 4]. We have used antibodies against the different receptors to identify possible target cells for FGF-2 in sensory ganglia, peripheral nerves and the adrenal gland. Results, summarized in the table below, show that i) a given cell may express simultaneously more than one receptor type, ii) nearly all cells analyzed express FGF-receptors, iii) nearly all cells may therefore be addressed by FGFs and iv) FGF seems to serve multiple auto- and paracrine functions in the peripheral nervous system and the adrenal gland.

	FGFR-1	FGFR-2	FGFR-3	FGFR-4
DRG neurons	+/f	+/A	+++A	+/f
satellite cells	-	-	+++A	-
nerve fibers/Schwann cells	+++A	+/S	+/S	+/s

## 608.2

## TISSUE SPECIFIC EXPRESSION OF bFGF BY A TYROSINE HYDROXYLASE PROMOTER IN TRANSGENIC MICE. K. Neary, P. Yaworsky\*, J. Moffett, E. Mordechai, I.H. Perline\*, C. Kappen\*, M.K. Stachowiak, Barrow Neurol. Inst. Phoenix Az 85020, \*Mayo Clinic Scottsdale Az 85250, \*Mesa Comm. Col. Mesa Az 85202.

Development, survival and plasticity of catecholaminergic (CA) systems may be controlled by number of sequentially expressed growth factors. One such protein is bFGF expressed in developing and adult NS in areas containing CA cells. *In vitro* bFGF stimulates mitosis, growth, synaptogenesis, and supports survival of CA cells and neurons. The role of bFGF *in vivo* is suggested by the observations that in Parkinson's Disease degeneration of dopaminergic neurons is preceded by depletion of bFGF, and that bFGF stimulates recovery of function in mice rendered Parkinsonian by MPTP. To investigate the roles of bFGF in development and plasticity of CA systems we have generated transgenic mice that carry human bFGF gene under the control of the rat tyrosine hydroxylase (TH) gene promoter. The construct contained a 940 bp human bFGF cDNA coding for all the known bFGF isoforms, the SV<sub>40</sub> small T antigen splice and polyadenylation sites, and the 4.8 kb of the rat TH promoter fragment (previously shown to restrict expression of a reporter gene to CA cells-containing tissues; Banerjee et al., 1992). FVB embryos were injected with linearized DNA fragment purified on a sucrose gradient. Out of 107 live-born offspring, PCR screening of the tail DNA identified 8 potential founders. Offspring from one of these founders (#73) was also examined by Western blot analysis for tissue specific expression of human bFGF. A marked increase in bFGF expression was observed in adrenals, striatum, and olfactory bulbs in agreement with high expression of the TH gene in those tissues. Tissues devoid of CA cells (cerebellum, hippocampus, heart, lungs, liver or kidneys) expressed basal levels of bFGF in the transgenic progeny. (APDA and NPF).

## 608.4

## THE IN VIVO EFFECTS OF BASIC FIBROBLAST GROWTH FACTOR ON ASTROCYTES. D. H. Segal, MD\* and I. M. Germano, MD, Department of Neurosurgery, Mount Sinai Medical Center, New York, N. Y. 10029

Basic Fibroblast Growth Factor (bFGF) is a polypeptide with *in vitro* mitogenic effects on a variety of cells. The aim of this study is to investigate the *in vivo* effects of bFGF on astrocyte proliferation. Adult rats underwent intraventricular or intraparenchymal stereotactic implant of gelfoam (3mm<sup>3</sup>) with 4µg (N=10) or 60µg (N=10) of recombinant human bFGF (Synergen, Boulder,CO) or saline (controls). To assess acute and delayed effects of bFGF, rats were sacrificed by intracardiac perfusion with carbon black and paraformaldehyde 4 (N=20) or 30 (N=20) days after the implant. Histological evaluation was done on paraffin embedded 10-µm-thick coronal sections stained with Nissl stain and immunohistochemically for glial fibrillary acidic protein (GFAP). Four days after bFGF treatment there was a mild increase in GFAP expression in 4µg-bFGF-rats and a moderate increase in 60µg -bFGF-rats around the site of implant. Thirty days after the implant 60µg-bFGF-rats had a robust increase in GFAP expression. These changes were not seen in controls. These data corroborate that bFGF plays a significant role on astrocytic proliferation.

## 608.5

**ADULT HYPOTHALAMIC CELLS PROLIFERATE IN LONG-TERM CULTURE WITH FGF-2.** P.W. Coates<sup>1</sup>, J. Miller<sup>2</sup>, H. Parikh<sup>1</sup>, L.-X. Liu<sup>1</sup>, L. A. Chiodo<sup>1</sup> and S. Thode<sup>1</sup>. Depts. Cell Bio/Biochem. & Pharm., TTUHSC, Lubbock, TX 79430, and Dept. Neurosci., UCSD, La Jolla, CA 92093.

A culture system patterned after that used to promote proliferation of adult hippocampal, nigral, septal and cortical neurons (Gage et al., SN Abs. 20: 670, 1994; Raymon et al., *ibid.*; Palmer et al., *ibid.*) has been developed for adult hypothalamus. Cells from normal rat hypothalamus were grown in defined medium supplemented with N2 and recombinant human basic fibroblast growth factor (FGF-2, 20 ng/ml, courtesy Syngene) without antibiotics. Proliferation was assessed by quantitative analysis of cell numbers over time, incorporation of BrdU and microscopy. Phenotypic identification of cells was determined by immunostaining with neuronal or glial markers. Ultrastructure was evaluated with scanning and transmission E.M. Cultures have been maintained for over a year, can be passaged, cryopreserved and reestablished. Cell proliferation, organizational complexity and expression of immature and more differentiated features developed over time *in vitro*. Subsets of cells displaying morphological properties of neurons were positive for neuron-specific enolase or neurofilament protein. Large, flat stellate cells stained for glial fibrillary acidic protein. Results suggest that neural precursor or even stem cells may be present in normal adult hypothalamus and can be cultured long-term. Cells appear to progress along neuronal or glial lineage pathways, remain uncommitted or die. We are continuing to characterize the cultures with other markers. Preliminary RT-PCR data indicate a weak signal corresponding to tyrosine hydroxylase mRNA. We are also beginning to pharmacologically characterize the cells by calcium imaging and patch clamp recording. Supported by TTUHSC-RSG & MH41557.

## 608.7

**BASIC FIBROBLAST GROWTH FACTOR SELECTIVELY INCREASES DESENSITIZATION OF NMDA RECEPTOR CURRENTS IN CULTURED RAT HIPPOCAMPAL NEURONS.** A.L. Boxer\* and E. B. Ziff. Howard Hughes Medical Institute and Department of Biochemistry, New York University Medical Center, New York, NY 10016. Basic Fibroblast Growth Factor (FGF-2) has been shown to ameliorate excitotoxicity *in vitro*, possibly by inhibiting calcium entry through the NMDA receptor. Previously, we reported that when 40  $\mu$ M glutamate was applied alone, then in the presence of CNQX (without washout of the first test pulse), to embryonic hippocampal neurons cultured in the absence or presence of FGF-2 (10 ng/ml,  $\geq$  5 days), NMDA receptor peak currents were 18.1% of controls ( $p < .005$ ,  $n = 13$ ) in the FGF-2 treated cells. To further characterize this effect, E17/18 hippocampal neurons were grown in the presence of FGF-2 (10 ng/ml) for 24 or 120 hours, and peak current densities after superfusion of 500 msec. test pulses of 100  $\mu$ M kainate, 1, 5, 10, 50, or 100  $\mu$ M NMDA were assayed by whole cell patch clamp techniques after 7-10 days in culture. Cells exposed to FGF-2 for 24 hours had significantly smaller peak voltage-activated sodium channel and 100  $\mu$ M kainate-evoked current densities than controls, which returned to control levels after 120 hours of treatment. Surprisingly, initial NMDA-evoked current densities were significantly larger in response to 10 and 50  $\mu$ M NMDA in cells treated with FGF-2 for 120 hours than in control cells (cells treated for 24 hours had intermediate values between the two). To test whether increased desensitization of NMDA receptor currents could explain our original observation, we applied 10  $\mu$ M glutamate (in 1 mM external  $Ca^{2+}$ ) for 3 sec. out of every 30 sec. for 25 min. and then measured kainate- or NMDA-evoked currents. Under these conditions, NMDA receptor currents did not appreciably desensitize, however cells treated with FGF-2 for 24 or 120 hours both displayed significantly ( $p < .05$  for both, pooled student's *t* test) increased desensitization (mean  $\pm$  SEM ratio of currents after/before desensitization for 5, 10, 50, and 100  $\mu$ M NMDA is  $1.17 \pm 0.23$ ,  $n = 29$  in controls;  $0.70 \pm 0.08$ ,  $n = 11$  after 24 hours;  $0.70 \pm 0.11$ ,  $n = 18$  after 120 hours). There was no difference in kainate-evoked current desensitization. Analysis of kainate-induced current rectification suggested that a change in cultures' cellular composition did not explain the effect.

## 608.9

**TEMPORAL ROLES OF BASIC FIBROBLAST GROWTH FACTOR (FGF-2) AND BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF) IN THE DEVELOPMENT OF CHICKEN COCHLEO-VESTIBULAR GANGLION (CVG) IN VITRO.** W. Amin Hossain\*, A. Rutledge and D. Kent Morest, Dept. Anat., Univ. CT Health Ctr., Farmington, CT 06030.

Previous studies showed that FGF-2 can stimulate migration and differentiation of CVG cells by activating their receptors *in vitro* (Hossain et al., Assoc. Res. Otolaryngol. Abstr. 18: 109, '95). Adding FGF-2 increased CVG growth for the first 2 days *in vitro*, but after 5 days led to degeneration, implicating other factors in its later development. To see if BDNF could be such a factor otocysts were explanted from white leghorn embryos at Hamburger-Hamilton Stages 14-16, when CVG precursors normally start to migrate from the otic epithelium. Careful dissection and treatment with cold collagenase were effective in removing the adjacent mesenchyme and neural crest precursors of Schwann cells. Measurements of neuroblast migration and neurite outgrowth were made by time-lapse imaging techniques in living cultures. Cultures were grown in a defined medium [Ham's F12 base, L-glutamine, and other defined additives (ITS, Collaborative)] with or without human recombinant FGF-2 (UBI), 1 ng/ml daily for 2 days. On day 3, FGF-2 was replaced completely either with BDNF (2 ng/ml in defined medium) or with defined medium. With BDNF, cell migration and neurite outgrowth from the explant increased and continued for more than 3 weeks, but cultures receiving defined medium from day 3 gradually died after 10-12 days. However, control cultures (receiving only defined medium from day 1) did not survive more than 3-4 days. These findings suggest a temporal sequence in which FGF-2 acts early in development, while BDNF affects a later stage. Supported by NIH grant NS29613.

## 608.6

**ACIDIC FIBROBLAST GROWTH FACTOR AND/OR ITS FRAGMENTS AMELIORATE LEARNING AND IMMUNOLOGICAL DYSFUNCTIONS IN SENESCENCE ACCELERATED MICE.** K. Sasaki, Y. Oomura, A. Li, N. Hori, H. Yoshii, Y. Fukata, H. Yago, H. Kimura, I. Tooyama, K. Hanai, and N. Yanaihara. Fac. Eng., Toyama Univ., Toyama 930, Inst. Bio-Active Sci., Nippon Zoki Pharm. Co., Hyogo 673-14, Fac. Med., Kyushu Univ., Fukuoka 812, Inst. Molec. Neurobiol., Shiga Univ. Med. Sci., Shiga 520-01, Fac. of Pharm. Sci., Univ. Shizuoka, Shizuoka 422, Japan.

Subcutaneous (SC) injection of acidic fibroblast growth factor (aFGF) or its fragments such as [Ala<sup>10</sup>]-aFGF(1-29) into senescence accelerated mice (SAM-P/8) at one per week was continued for 7-9 months. Learning dysfunction appeared in controls was ameliorated in animals treated by fragments as well as aFGF, when tested in some learning paradigms. After 9 months, an induction of long-term potentiation was examined in hippocampal slices of those animals. As stimulation was given to the stratum radiatum, the magnitude of population spikes recorded in CA1 pyramidal cell layer increased in aFGF- and [Ala<sup>10</sup>]-aFGF(1-29)-treated groups. During the period of SC injection, a delayed type hypersensitivity reaction (DTHR) in footpad caused by trinitrophenyl was also measured. The DTHR in controls became lower, but that in the aFGF-treated group did not. Results suggest aFGF and/or its fragments improve learning and immunological dysfunctions which are accompanied with senescence.

## 608.8

**BASIC FIBROBLAST GROWTH FACTOR INDUCES THE PRODUCTION OF A GLIA-DERIVED NEURON SURVIVAL FACTOR(S) FOR BASAL FOREBRAIN NEURONS.** L.D. Cain\* and L.A. Perkins. Dept. of Anatomy & Neurosciences, UTMB, Galveston TX 77555-1043.

Previous work in our laboratory has shown that in culture in the presence of basic fibroblast growth factor (bFGF), the number of embryonic and postnatal cholinergic basal forebrain neurons surviving after five days increases significantly over control cultures receiving no bFGF. These results occurred only in the presence of serum and glia. To determine the importance of serum in neuron survival, serum-containing cultures were treated with bFGF in the presence of Ara-C. We observed that serum and bFGF alone could not elicit survival. We now report that conditioned media (CM) removed from cultures stimulated with bFGF increases cholinergic neuron survival significantly over control cultures receiving no CM. This effect is seen in the absence of glia, in serum-free cultures containing Ara-C and anti-bFGF. Our data further indicates that the CM is not a mitogen for type I astrocytes as defined by glial fibrillary acidic protein staining. These results indicate that bFGF induces the survival of basal forebrain neurons by stimulating glia to produce a neuron-survival factor(s). The observation that this CM is not a mitogen for glia is significant for possible therapeutic purposes. (Supported UTMB Small Grant Program)

## 608.10

**TROPHIC EFFECTS OF FGF-2 ON DEVELOPMENT OF COCHLEO-VESTIBULAR NEURONS IN VITRO DO NOT DEPEND ON MITOGENIC ACTIVITY IN THE CHICK EMBRYO.** A. Hossain, W. Amin Hossain, A. Rutledge, and D. Kent Morest\*, Dept. of Anatomy, Univ. CT Health Ctr., Farmington, CT 06030.

FGF-2 is well known as a mitogen for many cell types. It also has strong trophic effects on the early development of neurons of the cochleo-vestibular ganglion (CVG) and of the acoustico-vestibular nuclei (AVN) *in vitro* (Hossain et al., Molec Biol Cell Suppl 4: 18a, '93; Morest et al., Soc Neurosci Abstr, 19, 1101, '93). Do these effects depend on cell proliferation *in vitro*? The otocyst, anlage of the CVG, was explanted from white leghorn embryos at Hamburger-Hamilton Stages 14-16, when CVG precursors normally start to migrate from the otic epithelium and continue to proliferate *in vivo*. The part of the rhombic lip that forms the AVN was explanted at Stage 28 (E5.5), when many precursors are still dividing in the matrix zone but the first postmitotic neuroblasts normally are starting to migrate *in vivo*. *In vitro* some neuroblasts continue to proliferate, while others migrate onto a substrate of purified collagen and differentiate. In both types of cultures, half were supplemented with fetal bovine serum, and half with human recombinant FGF-2 (UBI). The optimum FGF concentration for each type of explant was determined by dose response curves. FGF-2 increased migration and neurite outgrowth of CVG neuroblasts and early differentiation of AVN processes during the first 3 days *in vitro*. Cell proliferation in these cultures was measured on days 2 and 3 by using 5-bromo-2'-deoxyuridine (BrdU) pulse-labeling for 4 hrs or 24 hrs and fluorescence immunocytochemistry. In each condition about 20% of the neuroblasts in both control and treated groups in CVG and AVN cultures were immunolabeled. Hence there were no significant differences in the numbers of cells dividing in control and FGF-treated cultures. Thus the trophic effects of FGF-2 on the migration and early differentiation of cochleo-vestibular neurons do not depend on a mitogenic effect. Supported by NIH grant NS29613.

## 608.11

## LONG TERM SURVIVAL OF NEURONS ISOLATED FROM THE ADULT GUINEA PIG CNS

Jacopo Magistretti, Angela Griati, Marco de Curtis, Eugenio Parati and Angelo Vescovi. Istituto Nazionale Neurologico, via Celoria 11, 20133 Milan, Italy. Sponsored by Roberto Spreafico.\*

Cultures of central nervous system (CNS) neurons isolated from embryos and from young postnatal animals are a popular tool in neurobiology research. However, since several neuronal properties are differentially expressed during development, the use of mature neurons is preferable to that of embryonic or neonatal cultures, unless specific developmental studies are undertaken. Unfortunately, *in vitro* survival of mature CNS neurons is poor under culture conditions. The second postnatal week is the usual age limit to establish viable cultures of neocortical, hippocampal and diencephalic neurons.

Here we describe a method for long-term culturing of neurons isolated from adult (60 to 90-day-old) guinea pig CNS. Piriform cortex slices (500- $\mu$ m thick) were incubated with papain (Worthington, type 3126, 14 U/ml) or trypsin (Sigma, type XI, 1 mg/ml) for 40-60 minutes at 37°C under continuous oxygenation and stirring. After a light mechanical trituration, cells were collected by centrifugation and were plated onto matrigel-coated glass coverslips or plastic Petri dishes (15,000/cm<sup>2</sup>) in a chemically-defined DMEM/F12 medium containing 2 mM glutamine, 6 mg/ml glucose, 9.6  $\mu$ g/ml putrescine, 6.3 mg/ml progesterone, 5.2 ng/ml sodium selenite, 25  $\mu$ g/ml insulin, 0.1 mg/ml transferrin, 20 ng/ml basic fibroblast growth factor, 2  $\mu$ g/ml heparin. After 5-6 days in culture cytosine arabinoside (1  $\mu$ M final concentration) was added to prevent overgrowth of glial cells. At this time different neuron-like cell types were found, with multipolar, pyramidal or small globular shape, which gave off dendrite- or axon-like processes. In these culture conditions cell viability was maintained for up to 1 month. Indirect immunocytochemistry showed that the neuron-like cells expressed the neuronal antigens MAP-2 and Tau1. Electrophysiological current-clamp recordings, performed by means of the patch-clamp technique, demonstrated that these cells retain the membrane properties necessary to generate action-potential firing.

## 608.13

## DECREASED SKIN INNERVATION IN TRANSGENIC MICE OVEREXPRESSING INSULIN-LIKE GROWTH FACTOR II (IGFII) IN THE EPIDERMIS. M. Fitzgerald\*, M.L. Reynolds\*, L.J. Bindman\*, A. Ward\* and C.F. Graham\*. \*Dept. Anatomy &amp; Developmental Biology, \*Dept. Physiology, University College London, \*Dept. Zoology, Oxford University, U.K.

There is increasing evidence that insulin-like growth factors have important stimulatory effects in the developing nervous system. We have examined the effects of IGFII on developing cutaneous sensory neurons in transgenic mice carrying multiple copies of the *Igf-2* gene driven by the epidermal keratin promoter. These animals have wrinkled skin due to hyperplasia of the epidermis corresponding to the expression of transgene transcripts in the skin from embryonic day 16 (E16) (Ward et al., 1994, PNAS 91:10365). Innervation of hindlimb skin in P1 and P22 transgenic mouse pups and their normal littermates was examined using PGP9.5 immunostaining. At both ages innervation was markedly reduced, particularly in distal regions. The fine terminal plexus of the epidermis was affected rather than the coarser subepidermal axonal branches. Innervation pad was reduced by 44% at birth and 68% at P21, ankle hairy skin by 40% at birth and 55% at P21. Cell numbers of L4 dorsal root ganglion (DRG) at P21 were the same in transgenics (9494 $\pm$ 112) and controls (9307 $\pm$ 637). The effects of IGFII on neurite outgrowth was tested in embryonic mouse L4 DRG explants in culture. In the absence of NGF, IGFII (20-100ng/ml<sup>-1</sup>) stimulates neurite outgrowth at E18 but does not at E14. However, in the presence of NGF, the same doses of IGFII did not have an additive effect on neurite outgrowth and under some conditions (E18, 5ng/ml NGF) actually inhibits it. Overexpression of IGFII in the epidermis reduces cutaneous innervation density, while leaving DRG cell number intact. Tissue culture studies support the conclusion that under some conditions IGFII can inhibit sensory terminal growth.

## INSULIN-LIKE GROWTH FACTOR II REGULATION OF CELL NUMBER. Robin L. Mozell\* and Lydia Villa-Komaroff. Dept. of Neurology, Children's Hospital, Harvard Medical School, Boston, MA 02115.

Growth factors are critical signals in the regulation of cell growth, proliferation and differentiation. We have used a mouse line bearing an inactivated IGF-II gene (IGF-II nulls; Gift from A Efstratiadis, Columbia Med. Sch.) to investigate the function of IGF-II during development of the CNS. At birth, these mice are 60% the size of their wild type (WT) littermates, and remain so throughout their lifespan. However, the sizes of neural and non-neural cells in the IGF-II null mice are no different than cells in WT controls. This suggests that IGF-II regulates the number of cells produced and not the size of individual cells. The interplay between cell cycle length and programmed cell death is likely to determine the ultimate number of cells. As a first step in elucidating the mechanisms underlying the decreased cell number, we compared the cell cycle lengths of IGF-II null mice to WT controls. By BrdU/IrdU incorporation and double immunohistochemistry, we show that cerebellar granule cells in the IGF-II null mice have an altered cell cycle in that the S-phase is substantially elongated.

## 608.12

## EPIDERMAL GROWTH FACTOR PREVENTS OXIDATIVE STRESS-INDUCED NEURONAL APOPTOSIS IN CULTURED CEREBRAL CORTICAL NEURONS. M. Yamada\*, Y. Enokido, T. Ikeuchi, and H. Hatanaka. Institute for Protein Research, Osaka University, 3-2 Yamadaoka, Suita, Osaka 565, Japan.

Epidermal growth factor (EGF) is a polypeptide growth factor which promotes cell proliferation of various types of cells including epithelial and fibroblast cells. In the central nervous system, EGF acts as a neurotrophic factor on cultured cerebral cortical, subneocortical telencephalic, and cerebellar neurons, enhancing neurite outgrowth and cell survival. In the present communication, we reported that EGF prevented the death of rat cerebral cortical neurons cultured in a 50% oxygen atmosphere. EGF protected the oxygen-induced neuronal cell death in a concentration-dependent manner. The maximal effect was exerted at an EGF concentration of 10 ng/ml, and the half maximal effect occurred at 0.3 ng/ml. Basic fibroblast growth factor (bFGF) also prevented this cell death, although there was no apparent additive effect of EGF and bFGF. This high oxygen-induced death showed a nuclear condensation and was blocked by RNA or protein synthesis inhibitor and antioxidants, vitamin E and N-acetylcysteine. These results indicated that EGF prevented the oxidative stress-induced apoptosis of the cortical neurons. We confirmed that the cultured cortical neurons possessed the EGF receptor and expressed c-Fos protein in response to EGF. The viable astroglial cells were below 0.5% of that of the corresponding MAP2-positive neurons under the culture condition using a serum-free medium with cytosine arabinoside. Therefore, the effect of EGF on the cultured cortical neurons is thought to be due to a direct action. In addition, we examined EGF-induced signaling in the cultured cortical neurons. We found that EGF induced the sustained tyrosine phosphorylation of the EGF receptor and sustained the activation of mitogen-activated protein kinase in the cultured cortical neurons. We suggest that the sustained activation of the EGF signal is the mechanism by which it acts as a neurotrophic factor, preventing neuronal apoptosis.

## 608.14

INSULIN ATTENUATES THE SURVIVAL EFFECTS OF IGF-1 ON CHICK MOTONEURONS *IN VITRO*. A.P.D'Costa\*, S. Wang, D.M. Prevette and R.W. Oppenheim. Dept. of Neurobiology and Anatomy, Bowman Gray School of Medicine, Winston-Salem, NC 27157.

Insulin-like Growth Factors (IGFs) have been shown to be involved in the regeneration, sprouting and survival of motoneurons (MNs) both *in vivo* and *in vitro*. However, in previous experiments, the administration of IGF-1 to purified avian MN cultures resulted in only a slight rescue effect (15%). We hypothesized that this may be due to a confounding effect of insulin present in the media used to culture MNs. Accordingly, we examined the survival effects of various concentrations of IGF-1 (0.1 to 100ng/ml) on MN cultures from the lumbar spinal cords of E5 chicken embryos, with or without insulin in the media. In the presence of insulin (5ug/ml), MN survival was modest (maximal effect=13%) and did not exhibit dose dependence, whereas in the absence of insulin, survival was dose dependent and reached 40% following IGF-1 treatment. Additionally, when IGF-1 was co-administered with CNTF (ciliary neurotrophic factor) and chicken muscle extract the synergistic effects on MN survival were more pronounced when insulin was absent in the media. These data suggest that supraphysiological amounts of insulin present in the media act to inhibit IGF-1 action, probably, by displacing IGF-1 from its receptor.

## 608.16

## RETINAL GANGLION CELL SURVIVAL AND AXON GROWTH INTO ACCELLULAR PNS GRAFTS WITH GROWTH FACTOR REPLACEMENT. J. J. Norden\* and B. Wouters. Dept. of Cell Biology, Vanderbilt University Medical School, Nashville, TN 37232.

The survival and axon growth of retinal ganglion cells (RGCs) were assessed in adult male Sprague-Dawley rats with cellular or acellular grafts into the optic nerve. A peroneal nerve segment was excised and transplanted into the transected optic nerve within 3 mm of the eye. This procedure results in growth of RGC axons into the grafts and in the sustained upregulation of GAP-43 (Doster et al. Soc. Neurosci., 14: 802, 1988; Wouters and Norden, Soc. Neurosci., 16: 338, 1990). To examine the effects of specific growth factors on axon growth and RGC survival, some grafts were rendered acellular by repeated freeze-thawing (which kills Schwann cells but leaves basal lamina intact) and an Elvax implant inserted which released BSA, basic fibroblast growth factor/BSA, or insulin-like growth factor-I/BSA. Animals survived for 4 wks. Axon growth was present in all cellular grafts and in acellular grafts in which growth factors were released. There was no RGC axon growth past the site of anastomosis in acellular grafts, or in acellular grafts with implants releasing BSA alone. Cresyl-violet stained retinal whole mounts were used to estimate the number of surviving RGCs. The results from this quantitative analysis indicated that the release of IGF-I in acellular grafts rescued the greatest number of RGCs. Supported by NIH Grant EY01117.

DEVELOPMENTAL ROLE OF INSULIN-LIKE GROWTH FACTOR SYSTEM GENES DURING INTEGRATION OF TRANSPLANTED PURKINJE CELLS INTO THE CEREBELLUM OF GENETICALLY ATAXIC MICE. W. Zhang, W.-H. Lee\* and L. C. Triarhou. Dept. of Anatomy, Pediatrics, Pathology and Laboratory Medicine, Indiana Univ. Sch. of Med. Indianapolis, IN 46202.

Insulin-like growth factor I (IGF-I) plays a functional role in postnatal cerebellar development, as suggested by its spatially-temporally coordinated expression with the type I IGF receptor (IGFR-I) and with IGF binding proteins (IGFBP) 2 and 5. To understand the interaction between the IGF system and the developing cerebellum, we analyzed the distribution of IGF-I, IGFR-I, IGFBP2 and IGFBP5 mRNAs in normal embryonic cerebellar cells transplanted into the cerebellum of adult "Purkinje cell degeneration" (*pcd*) mutant mice. The *pcd* mutation leads to a degeneration of mature Purkinje cells, the only neurons that express IGF-I in the cerebellar cortex. Cell suspension (80,000 viable cells/2  $\mu$ l) derived from normal cerebellum at embryonic day (E) 11-13 was implanted in adult *pcd* cerebellum. At 21 and 31 days after transplantation, IGF system gene expression was examined in cerebellar grafts by *in situ* hybridization histochemistry and by immunocytochemistry. Purkinje cells from the grafts migrated to form a distinct layer replacing the missing host Purkinje cells. Compared with the normal developing cerebellum, IGF-I mRNA in the cerebellar grafts was expressed at a similar level and showed a similar pattern of cellular distribution, as were IGFR-I, IGFBP2 and IGFBP5 mRNAs. These observations suggest that normal IGF system gene expression may be indispensable for cerebellar development, and that IGF-I may be important in the maturation and integration of the implanted Purkinje cells into the host cerebellum.

## 608.19

REGULATION OF NEURITE OUTGROWTH AND CELL DIVISION IN GT1 GnRH CELL LINES BY GROWTH FACTORS. A. Ochoa, G. Naya, C. Domenzain, C. Clapp and G. Martínez de la Escalera\*. Neurobiology Center, National University of México, México City 04510, México.

Studying the mechanisms responsible for the development and function of GnRH neuronal networks is fundamental to understand the regulation of reproduction. However, GnRH neurons are sparse and scattered, impeding their experimental access. The availability of homogeneous populations of GnRH neurons such as the GT1 cell lines, facilitates the analysis of factors that may affect aspects such as cell division and differentiation. We tested the effects of various growth factors, including NGF, EGF, TGF- $\alpha$ , IGF-1 and bFGF on neurite outgrowth and mitotic rate in GT1-1 cells. Preliminary findings suggested that the number of neurites per cell was stimulated by protein kinase C activation (TPA 2.5 nM), while the length of the neurites was stimulated by cAMP (forskolin 10  $\mu$ M). In 24 h, both treatments decreased <sup>3</sup>H-thymidine incorporation over 50%. While bFGF (10 ng/ml) by itself stimulated 50% the number of neurites per cell, TGF- $\alpha$  (10 ng/ml) and EGF (10 ng/ml) decreased over 50% and IGF-1 stimulated 30% the number of neurites induced by TPA. bFGF also increased (35%) <sup>3</sup>H-thymidine incorporation, while TGF- $\alpha$ , EGF and IGF-1 decreased the mitotic rate between 30 and 50%. NGF showed no effect on any parameter. These findings revealed that GnRH neuronal differentiation and reproduction may be affected in parallel or in opposed fashion by a single influence, and highlights the existence of various putative factors involved in this regulation. (Work supported by grants from the National University of Mexico (IN200393) and the Mexican Council of Science and Technology (1775N).

## 608.21

IDENTIFICATION OF A BIOCHEMICAL SURROGATE MARKER FOR THE IN VIVO EFFECTS OF INSULIN-LIKE GROWTH FACTOR-I. R.V. Bhat\*, Y. Zhu, M. Miller and P.C. Contreras. Dept. of Pharmacology, Cephalon Inc., West Chester, PA 19380.

Insulin-like growth factor-I (IGF-I) plays an essential role during development of a variety of tissues, including brain. Recently, daily s.c. injections of rhIGF-I (1-3 mg/kg, 17 days) has been shown to be efficacious in enhancing the regeneration of the injured sciatic nerve in mice. In an attempt to identify a biochemical marker that is altered in association with the administration of an efficacious dose of IGF-I, we have determined the acute and chronic effects of rhIGF-I on serum levels of glucose and IGF binding proteins (IGFBPs). Serum glucose levels decreased in a dose-related fashion, following either acute (single) or chronic injections (1 mg/kg, s.c., once daily for 17 days) of rhIGF-I. Neither tolerance nor potentiation was observed to the peak hypoglycemic effects of rhIGF-I. However, the rate of recovery of serum glucose to normal levels in chronic rhIGF-I treated mice was prolonged compared to that after an acute injection. Acute injections of 0.1, 1 and 10 mg/kg of rhIGF-I resulted in a dose-dependent increase in serum IGFBP2 while IGFBP3 levels increased only after administration of 10 mg/kg of rhIGF-I. Although chronic administration of rhIGF-I also resulted in a similar effect, it was observed that IGFBP2, but not IGFBP3 levels were significantly higher in the chronic treatment group, compared to the acute injection group. There were no significant changes in IGFBP4 observed. Since IGFBP2 levels are increased at doses of rhIGF-I that are efficacious at enhancing regeneration of injured sciatic nerve, IGFBP2 may be useful as a surrogate marker for the *in vivo* neuroprotective effects of rhIGF-I.

## 608.18

IGF AND IGF BINDING PROTEIN EXPRESSION IN SENSORY NEURONS. A. Randolph\* and E.L. Feldman. Department of Neurology, University of Michigan, Ann Arbor, 48109.

The insulin-like growth factors (IGF-I and IGF-II) are polypeptides with both growth-promoting and insulin-like metabolic activity whose actions are modulated, in part, by a family of six proteins, the insulin-like growth factor binding proteins (IGFBPs). Diabetic neuropathy is primarily a disturbance of sensory nerves. IGF-I has been proposed as a treatment for diabetic neuropathy, however its effects on sensory dorsal root ganglion neurons (DRG) have not been well-characterized. In the current study, we examined the role of exogenous IGFs on growth and expression of IGFs and IGFBPs in ND26 cells, a cloned line derived from neonatal DRG neurons fused with a mouse neuroblastoma. ND26 cells were plated in either serum-free media (SFM) or with the addition of increasing concentrations of serum  $\pm$  IGF-I. After 1, 2 and 3 days cell growth was measured using a colorimetric assay that detects reduction of the tetrazolium salt MTT. Cells remained viable in 0.3% serum, and at serum concentrations  $\geq$  0.6%, cell number increased in a dose-dependent fashion. IGF-I alone in SFM did not stimulate cell growth, however IGF-I + 0.3% serum resulted in a dose-dependent increase in cell number.  $\alpha$ -IR3, an antibody that inhibits the type I IGF receptor, blocked IGF-I coupled growth. Northern analysis of ND26 cells revealed IGF-I receptor and IGF-II gene expression. Western ligand blotting demonstrated ND26 cells highly express IGFBP-4 with lesser amounts of IGFBP-3 and IGFBP-5. In summary, ND26 cells express IGF-II, functional IGF-I receptors and 3 of 6 IGFBPs, capable of sequestering and targeting bioavailable IGF-I. Coupled with IGF-I's growth promoting effects on ND26 cells, these data suggest IGF-I may have a therapeutic role in the treatment of disorders of sensory nerves, such as diabetic neuropathy. Sponsored by R29 NS32843 and a grant from the Juvenile Diabetes Foundation #194130.

## 608.20

EFFECTS OF IGF-1 INFUSION ON SERUM IGF BINDING PROTEINS AND FUNCTIONAL RECOVERY FOLLOWING SCIATIC NERVE CRUSH. T. M. Engber\*, R. V. Bhat, S. A. Dennis, Y. Zhu, M. Miller and P. C. Contreras. Cephalon, Inc., West Chester, PA 19380.

Insulin-like growth factor 1 (IGF-1) promotes the survival of neurons in a number of *in vivo* models of nerve injury and toxic damage. However, it is not clear whether it is advantageous to deliver IGF-1 by repeated injections or by continuous infusion, in particular since the pharmacokinetics of IGF-1 administration are complicated by the presence of specific binding proteins (IGFBPs) which may transport IGF-1 to target tissues and modulate its effects. We have used the mouse sciatic nerve crush model to compare the effects of s.c. infusion of rhIGF-1 at a variety of doses (0.003-8 mg/kg/day via osmotic minipump) with those of the optimal dose by repeated s.c. injection (1 mg/kg/day) on functional recovery and serum levels of rhIGF-1, glucose and IGFBPs. Continuous infusion of rhIGF-1 improved functional recovery of male CD-1 mice following bilateral sciatic nerve crush injury in a manner similar to repeated rhIGF-1 injections, but only at the highest dose tested (8 mg/kg/day). Serum levels of rhIGF-1 achieved after infusion at this dose in sham-operated animals did not differ from peak levels seen after s.c. injection at 1 mg/kg, but were 34% lower in mice with sciatic nerve crushes. Blood glucose levels decreased by 40% following injection of rhIGF and only 20% following infusion at 8 mg/kg/day. Infusion of rhIGF-1 increased serum IGFBP2 in a dose-dependent manner, but had no effect on serum IGFBP4. Serum IGFBP3 was also elevated following infusion of rhIGF-1 in sciatic nerve-crushed mice, but showed a bell-shaped dose response, with the peak increase seen at a dose of 3 mg/kg/day and levels close to control values following infusion of 8 mg/kg/day. These results indicate that the efficacy of IGF-1 in the sciatic crush model is related to serum IGF-1 levels and that IGF-1 infusion does not offer any obvious therapeutic advantage over IGF-1 injections.

## 608.22

IMMUNOCYTOCHEMICAL LOCALIZATION OF INSULIN-LIKE GROWTH FACTOR BINDING PROTEIN-2 IN PITUITARY CELLS DURING POSTNATAL DEVELOPMENT IN THE RAT. X. Zhou and C.M. Paden\*. Dept. of Biology, Montana State Univ., Bozeman, MT 59717.

The insulin-like growth factors (IGF-I and IGF-II) are a family of peptides with both growth-promoting and insulin-like activity. The action of the IGFs are modulated by insulin-like growth factor binding proteins (IGFBPs), and IGFBP-2 mRNA is known to be expressed at high levels in fetal and adult posterior pituitary. We have performed an immunocytochemical study to characterize the cellular localization of IGFBP-2 in the neural lobe (NL) of the rat at postnatal days (PD) 1, 11, 24, 37 and 53 using a polyclonal rabbit anti-human IGFBP-2 antisera (UBI). Cells immunoreactive for IGFBP-2 were identified as pituitary cells by immunofluorescent co-localization of S-100 protein. In contrast, microglia labeled with antibody OX-42 were not IGFBP-2 positive. While IGFBP-2 staining was present at all ages, the pattern of immunoreactivity changed during maturation. At PD1 and PD11, IGFBP-2 immunoreactivity was primarily localized in the perinuclear cytoplasm of pituitary cells, while at later ages staining appeared to be concentrated near the pituitary cell membrane. Scattered cells immunoreactive for IGFBP-2 were also present in the intermediate lobe at each age. These results are consistent with a potential role for IGFs in development and/or function of the magnocellular neurosecretory system, and suggest that pituitary cells may modulate any such effects through expression of IGFBP-2. Supported by NINDS NS32507 to CMP.

## 609.1

**TRKc EXPRESSION IN INTACT AND INJURED ADULT RAT RETINAS.** P. Kittlerová, G. M. Bray and A. J. Aguayo\*. Centre for Research in Neuroscience, McGill University and Montreal General Hospital Research Institute, 1650 Cedar Ave., Montreal, Quebec, H3G 1A4.

After axotomy, NT-3 transiently increases retinal ganglion cell (RGC) survival by about 20% and dramatically enhances GAP-43 expression in 50% of the axotomized RGCs 2 weeks after injury. In contrast, BDNF induces an early up-regulation of GAP-43 in most RGCs (Fournier et al., unpublished observations) and markedly increases the survival of these neurons (Mansour-Robaei et al., PNAS 91: 1632, 1994). These effects of BDNF are presumably mediated by TrkB, the high-affinity receptor expressed by most RGCs (Jelsma et al., J. Neurobiol. 24: 23, 1993). We have now investigated TrkC expression in adult rat retinas using immunocytochemistry and *in situ* hybridization. Antibodies (provided by D. Kaplan) and oligonucleotide probes show similar distributions of the *trkC* mRNA and protein in the retina. Using cell size criteria, populations of both RGCs and amacrine cells expressed TrkC. Approximately 30% of RGCs were immunostained with the TrkC antibody. Labelled amacrine cells were found in the inner nuclear layer and in the ganglion cell layer.

Two weeks after axotomy, more than one-half of the surviving RGCs were TrkC positive. However, quantitative *in situ* hybridization revealed a 50% decrease of *trkC* mRNA levels in the axotomized RGCs. In surviving RGCs, neither the incidence of the TrkC expression, nor their mRNA levels were affected by the intravitreal injection of a single dose of NT-3 (5µg).

These results indicate that a sizable number of RGCs and amacrine cells express TrkC. Because TrkB is found on most RGCs, the demonstration that approximately one-third of RGCs is TrkC positive suggests that some of these neurons express both these receptors.

## 609.3

**CONTRASTING CHANGES IN NEUROTROPHIN RECEPTOR AND TYROSINE HYDROXYLASE GENE EXPRESSION IN THE AGING SYMPATHETIC NERVOUS SYSTEM.** G. A. Kuchel\* and C. Richard. Geriatric Medicine, Montreal General Hospital Res. Inst., 1650 Cedar, Montreal, Quebec, Canada H3G 1A4

Quantitative *in-situ* hybridization with a riboprobe complementary to gp75 (low-affinity neurotrophin receptor) mRNA showed a 25% decrease in the mean neuronal Labeling Index (LI) in aged (24 m), as compared to mature (10 m) male rat SCG (superior cervical ganglia), while LI for cyclophilin mRNA did not change. A ribonuclease protection assay demonstrated a 25-30% decrease in levels of gp75 mRNA per cyclophilin mRNA. Although generalized, the decrease in the gp75 Labeling Index was greatest in <10% neurons (small & intermediate-sized), a population which resembles those neurons innervating the pineal and midline cerebral vessels. It is known that the innervation to these two SCG targets declines ~50% with aging, while that to other targets does not change.

Mean LI for *trkA* mRNA was decreased 13%, while the LI for tyrosine hydroxylase mRNA was 74% higher in aged SCG. The latter change was mostly due to very large increases in <10% neurons (small & intermediate-sized). Further studies will be needed to characterize the subset(s) of neurons in which these large changes take place and to determine whether they correspond to the neurons innervating the two targets whose innervation declines in old age. Our results demonstrate that when examining gene expression in neuronal aging, considerable specificity exists in terms of the genes and neuronal populations affected and that neuronal aging may also be associated with increased expression of some genes. Finally, decreased gp75 mRNA expression may be a marker of neuronal vulnerability and axonal degeneration in aging.

## 609.5

**MOLECULAR CHANGES ASSOCIATED WITH PERIPHERAL NERVE REGENERATION** E.J. Livesey and S.P. Hunt (SPON: Brain Research Association), MRC Laboratory of Molecular Biology, Hills Road, Cambridge, CB2 2QH, U.K.

We have investigated the potential role in regeneration of candidate factors found in the peripheral nerve, in this case the neurotrophins, by studying the neuronal expression of receptors for those factors by *in situ* hybridisation under normal conditions, following injury and during regeneration. We found that the proportions of regenerating sensory neurons expressing the low-affinity neurotrophin receptor (LNGFR) and two of the high affinity receptors, *trkA* and *trkB*, decreased seven days after nerve crush to 89%, 68% and 81% respectively of control values. Similar changes were observed in a non-regenerating lesion of the nerve (LNGFR, 72%; *trkA*, 76%; *trkB*, 80%), while the number of neurons expressing *trkB* remained constant in both lesion models. Given the decrease in neuronal expression of neurotrophin receptors described here, we suggest that signalling through *trk* receptors may not be essential for neuronal regeneration.

Secondly, we are searching for genes which are differentially expressed in the peripheral nerve and in denervated peripheral targets during regeneration, assuming that some of the changes observed will be necessary for successful regeneration. We have used the mRNA differential display technique to compare more than 3,000 mRNAs from normal and injured sciatic nerve and innervated and denervated muscle and have found a small number of cDNAs which are reproducibly found in one tissue state but not the other. The true differential expression of each of these is presently being confirmed by northern blot analysis. The sequences of 10 of the mouse clones show no direct homologies to the non-redundant databases (GenBank BLAST search), although one of the clones contains the rat BCl1 or ID motif, and some show partial homologies to human ESTs of unknown identity.

## 609.2

**CHANGES IN VGF mRNA EXPRESSION IN THE RAT BRAIN AFTER KAINIC ACID INDUCED SEIZURE AND CORTICAL LESION.** S. E. Snyder<sup>1</sup>\*, H.-W. Cheng<sup>2</sup>, K. D. Murray<sup>3</sup>, P. J. Isackson<sup>3</sup>, T. H. McNeill<sup>2</sup>, and S. R. J. Salton<sup>1</sup>. <sup>1</sup>Fishberg Research Center for Neurobiology, Mount Sinai School of Medicine, New York, NY 10029; <sup>2</sup>Division of Neurogerontology, Andrus Gerontology Center, University of Southern California, Los Angeles, CA 90089; <sup>3</sup>Department of Biochemistry and Molecular Biology, The Mayo Clinic Jacksonville, Jacksonville, FL 32224.

VGF was cloned on the basis of its rapid, selective induction by NGF in PC12 cells. Its expression is restricted to neurons and neurosecretory cells, is regulated during development, and is found in many neurons in the adult. The VGF protein is secreted and is likely cleaved into peptides.

In this study, recurrent seizures were induced in adult rats by i.p. injection of kainic acid. *In situ* hybridization to sections of rat brain perfused at various times after injection shows rapid induction of VGF mRNA in dentate granule cells, evident by 1 hr, which disappears by 48 hrs. VGF mRNA also increases in the hippocampal CA fields and the piriform cortex, following a more protracted time course.

In another paradigm, brains were taken at various intervals following unilateral cortical lesions. By 3 hrs, we observe a substantial induction of VGF mRNA throughout the ipsilateral cortex. By 6 hrs, we also see down-regulation of VGF in the ipsilateral striatum. By 3 days, cortical VGF levels have returned to normal, while the striatal levels remain depressed. Then, at 10 days, there is robust induction of VGF in a restricted area of the rostromedial ipsilateral striatum, coinciding closely in both timing and location with sprouting of contralateral cortical projections into this region.

Thus, kainate-induced seizure, either via depolarization or as a result of excitotoxicity, rapidly induces VGF mRNA in selected neurons. Also, direct lesion of the brain can both induce and repress VGF. Further studies will be needed to elucidate the cellular mechanisms by which such regulation occurs, and the function of VGF in response to such injury.

## 609.4

**Tooth Injury Induces Expression of Nerve Growth Factor Receptors in the Trigeminal Ganglia.**

E. F. Wheeler, Ph.D.\* and M. Byers, Ph.D. The University of Texas at San Antonio, University of Washington, Seattle, WA  
Six hours post injury, NGF mRNA and protein biosynthesis increase in the pulp of injured teeth to levels five to eight times those in normal teeth (Byers et al., Growth factors 6: 41-52, 1992). Profuse sprouting of sensory nerve fibers occurs in tooth pulp by 1 to 4 days following dentin injury. These events suggest that the trigeminal neurons that innervate the teeth may be responding to the increased levels of NGF post injury. To further characterize the effects of NGF on the trigeminal neurons after tooth injury, we tested the trigeminal ganglion for expression of the NGF receptors (*trkA* and *p75*) at 4, 12, 28 and 52 hours after injury. For tooth injuries, the occlusal surface of rat molar cusps was drilled partway to the pulp and then etched, air dried and sealed with resin. At different times after injury, the trigeminal ganglia were harvested from perfusion-fixed rats and subjected to *in situ* hybridization analysis with riboprobes encoding sense and antisense sequences for *trkA* or *p75*. Trigeminal neurons that innervate the teeth showed increased levels of *p75* and *trkA* 28 and 52 hours after injury that were 2-3 times higher than in uninjured controls. These results indicate that increased levels of NGF receptors in the trigeminal neurons are a part of the dental injury response. The timing of receptor upregulation suggests that retrograde transport of NGF may be necessary for the increases in the *trkA* and *p75* receptors in the neurons that innervate injured teeth. Supported by NIH Grant DE 05159.

## 609.6

**DIFFERENTIAL CHANGES IN TRK A AND TRK B NEUROTROPHIN RECEPTORS IN THE RAT HIPPOCAMPUS FOLLOWING TRIMETHYLTIN INTOXICATION.** M. Skup, D. Koczyk, M. Zaremba and B. Oderfeld-Nowak. (SPON: European Brain and Behaviour Society). Department of Neurophysiology, Nencki Institute of Experimental Biology, 3 Pasteur Street, 02 - 093 Warsaw, Poland.

Trimethyltin (TMT) intoxication produces neuronal damage in the limbic system and in the hippocampal formation in particular. In the hippocampus TMT-evoked injury was reported to induce reactive sprouting of dendrites (D. Koczyk, Acta Neurobiol. Exp. 54, 1994) and nerve terminals. We have recently found that these responses are accompanied by an enhanced hippocampal neurotrophic activity. The aim of the present study was to examine the distribution of the high-affinity neurotrophin Trk A and Trk B receptors in the TMT-injured hippocampus to evaluate the presumably changed pattern of neurotrophin-responsive nerve terminals and to detect the putative targets of altered trophic activity. The immunocytochemical study with anti-Trk A and anti-Trk B (full-length) polyclonal antibodies (Santa-Cruz, CA) was carried out on the adult male Wistar rats at 4, 7, 14, and 21 days after TMT administration (8mg/kg, i.p.). Trk A labeling of punctate appearance suggesting nerve-terminal localization detected in the control PBS-treated rats, in the hilus, along the mossy fibres pathway, in CA3 and in CA2 pyramidal cell layers was not changed in TMT-treated animals. An intense Trk B immunoreactivity (IR) in neurons of CA1 and CA2/CA3 pyramidal cell layer with dense dendritic labeling in CA1 as well as Trk B-IR in hilar interneurons were found in control rats. A loss of Trk B-IR in TMT-treated rats occurred. A decrease of labeling was observed predominantly in CA1 damaged neurons. The pattern of loss of dendritic Trk B-IR detected in CA1 and CA2 layers paralleled that of dendritic marker (MAP 2) found by us previously. No induction of Trk B-IR was found in non-neuronal elements. On the other hand multiple cells of astroglial appearance became Trk A-IR. Low number of Trk A-IR astrocytes detected at 4 and 7 days after TMT-intoxication increased significantly at 14 and 21 posttreatment days. Trk A expression in astrocytes may indicate responsiveness of reactive astrocytes to NGF and further supports the postulated (Oderfeld-Nowak et al., IX Int. Symp. on Cholinergic Mechanisms, Mainz, 1995) involvement of glial neurotrophic activity in neuronal survival and/or plastic postinjury rearrangements.

## 609.7

**NEUROTROPHIN-4/5 UPREGULATES PROTEIN LEVELS OF NITRIC OXIDE SYNTHASE IN CULTURED STRIATAL NEURONS.** H.R. Widmer\*, H. Heider, H. Hoppeler, B. Knüsel and F. Hefti. Andrus Gerontology Center, University of Southern California, Los Angeles, CA 90089 and Institute of Anatomy, University of Bern, CH-3012 Bern, Switzerland.

We have recently shown that chronic treatment of the neurotrophin NT-4/5 promotes the survival and differentiation of striatal GABAergic neurons prepared from fetal rat brain. Furthermore, this treatment elevates levels of the calcium-binding protein calretinin, suggesting that NT-4/5 may exert neuroprotective actions in striatal cells. Nitric oxide (NO) mediates a variety of physiological functions in the central nervous system and has been proposed to protect neurons from cytotoxic events. We now found that chronic treatment of primary cultures from embryonic rat striatum with NT-4/5 increased the amount of nitric oxide synthase (NOS) as measured by Western blot analysis. The treatment elevated cell number and protein content of the cultures. No significant increase in thymidine incorporation was observed during any culture period investigated, indicating that NT-4/5 treatment reflects increased survival rather than cell proliferation. In support of this conclusion we found levels of cdc2 p34, a cyclin-dependent protein kinase involved in cell cycle regulation, were not altered after NT-4/5 treatment. Furthermore, no alterations were detected for c-jun, erk-1 and ras-GAP protein levels. The findings suggest that NT-4/5 improves survival of striatal neurons by a mechanism involving NOS.

## 609.9

**EXTRACELLULAR MUTANTS OF THE RAT TRKA RECEPTOR** S.O. Meakin<sup>1,2</sup>, H. Schneider<sup>1</sup> and J.L.S. MacDonald<sup>1</sup>. <sup>1</sup>Neurodegeneration Research Group, The John P. Roberts Research Institute, <sup>2</sup>Department of Biochemistry, University of Western Ontario, London, Ontario, N6A 5K8, Canada]

TrkA is a ligand-activated tyrosine kinase receptor which binds to the closely related neurotrophic molecules, nerve growth factor (NGF) and neurotrophin-3 (NT-3). The extracellular domains of rat and human trkA contain 3 highly conserved regions, namely, the second and third leucine rich motifs (96% and 91% identity respectively) and the second IgC<sub>2</sub> domain (91% identity). Despite the conservation of these sequences, the functional roles of these domains have not yet been determined. Using standard genetic approaches we have introduced uni-directional 5' and 3' deletions into the extracellular domain of rat trkA and assayed the effects of these mutations on ligand binding, activated tyrosine kinase activity and neurite outgrowth. All mutants were engineered to contain a wild type signal sequence to facilitate similar levels of cell surface receptor expression. A third trkA mutant was also generated which lacks 20 amino acids in the hinge region just 5' to the transmembrane domain. Interestingly, the leucine rich motifs were found to be dispensable for ligand binding, ligand-activated tyrosine kinase activity and ligand-induced neurite outgrowth. In contrast, both the hinge region and the IgC<sub>2</sub> domains were found to be indispensable for ligand binding. These data indicate that sequences in the IgC<sub>2</sub> domains form the NGF binding site(s) in trkA and suggest an alternative role of the leucine rich motifs in trk-mediated protein-protein interactions.

## 609.11

**trkA-MEDIATED REGULATION OF ACETYLCHOLINESTERASE IN ADRENAL MEDULLA AND SPINAL CORD: EVIDENCE FROM THE trkA KNOCKOUT.** A. Schober<sup>1</sup>, L. Minichiello<sup>2</sup>, R. Klein<sup>2</sup>, M. Keller<sup>3</sup>, P.G. Layer<sup>1</sup>,\* and K. Unsicker<sup>1</sup>

<sup>1</sup>Dept. Anatomy & Cell Biology III, Univ. Heidelberg, <sup>2</sup>EMBL, Heidelberg, <sup>3</sup>Dept. Zoology, Technical Univ. Darmstadt, Germany.

NGF induces neuritic growth of adrenal medullary chromaffin cells. To determine whether NGF has physiologically relevant functions for the adrenal medulla and its innervation, we have studied the distribution and activity of acetylcholinesterase (AChE) in adrenal medullae and spinal cords of *trkA*<sup>-/-</sup> mice. Histologically, adrenal medullae and spinal cords of mutants appear grossly normal. Shortly after birth (P0 and P3), patterns and intensities of staining for AChE enzyme activities do not differ between wildtypes and mutants. At P6/7 and P12, however, AChE staining is strongly decreased in spinal cords and in adrenal medullary nerve fibers of *trkA*<sup>-/-</sup> as compared to wildtype animals. Quantitative measurements of AChE activities reflect this decrease in staining intensities (adrenal: -64%; spinal cord: -25% relative to wildtypes). Interestingly, immunocytochemical staining with an antibody to AChE does not detect differences in the adrenal medullae of wildtype and mutant animals. Our results suggest a role of NGF in the regulation of AChE activity of nerves innervating chromaffin cells, possibly also chromaffin cells themselves. The molecular basis of this regulation will now be explored. Supported by DFG (SFB 317/C8, 269/A2).

## 609.8

**PRODUCTION AND BIOLOGICAL ACTIVITY OF NGF:NT-4/5 HETERODIMERS** B. Knusel\*, F. Hefti, L.E. Burton and J.J.S. Treanor. University of Southern California, Los Angeles, CA 90089 and Genentech, Inc., South San Francisco, CA 94080.

Neurotrophins (NGF, BDNF, NT-3, NT-4/5) exist in solution as non-covalently linked dimers. The interface residues of neurotrophins are highly conserved and heterodimeric neurotrophins can be formed. We generated recombinant human (rh) NGF:NT4/5 by acid-driven rearrangement and purification by HPIEC. rhNGF:NT4/5 was assayed for heterodimeric stability and analyzed by radioligand binding and ligand induced tyrosine phosphorylation in cell lines expressing individual neurotrophin receptors. Functional activity was tested in PC12 cells and primary cultures of rat brain cells. Compared with respective homodimers, NGF:NT4/5 was as potent at binding and signaling through rat trkA but 10-20 fold less potent through rat trkB receptors. In cultures containing cholinergic neurons of the basal forebrain, the order of potency for stimulating choline acetyltransferase activity was NGF > NGF:NT-4/5 > NT-4/5. The shape of the dose-response curve for NGF:NT-4/5 suggested involvement of more than one receptor. In cultures of the striatum, NT4/5 was approximately 3-10-fold more potent than the heterodimer in increasing GABA uptake activity. A similar difference was found in neurotrophin induced Trk tyrosine phosphorylation in cultured neurons. Our results indicate that NGF:NT-4/5 heterodimers are biologically active under physiological conditions. Such heterodimers might exist *in vivo* and present a control mechanism of neurotrophin action. Heterodimers and other pan-neurotrophins should become useful in the treatment of neurodegenerative diseases with more than one afflicted cell population.

**CHOLINERGIC NEURONS IN TRANSGENIC MICE WITH AN ALTERED LOW-AFFINITY NGF<sub>r</sub> GENE** T.T. Yeo\*, J.H. Kunimitsu, D.H. Bredesen#, and L.L. Butcher. Departments of Psychology and Neurology#, UCLA, Los Angeles, CA 90095-1563.

The functions of the low-affinity NGF receptor (p75NGFr) in the nervous system are poorly understood. Although *in vitro* cell culture studies have indicated that it may facilitate high-affinity binding of NGF to Trk and mediate apoptosis in NGF-dependent neurons upon trophic factor withdrawal, virtually nothing is known about its function *in vivo*. The recent production of a "p75-knockout" mouse (transgenic mouse with an altered p75NGFr gene; Lee et al., Cell, 1992) offers new opportunities in further elucidating the role(s) of the p75NGFr in neuron physiology and biochemistry. This mouse can also serve as an *in vivo* model for studying the role of the p75NGFr in mediating NGF actions in the development and survival of basal forebrain cholinergic neurons, which undergo degeneration in Alzheimer's disease.

We found that in the normal (wildtype) mouse, as in the rat, the p75NGFr is colocalized with cholinergic neurons in the basal forebrain (i.e. medial septal nucleus, diagonal band, magnocellular preoptic area, ventral pallidum, nucleus basalis, and nucleus of the ansa lenticularis) but not the local-circuit cholinergic neurons of the dorsal and ventral striata and mesopontine complex. In "p75-knockout" mice, basal forebrain cholinergic neurons are devoid of p75NGFr immunoreactivity, but the number and distribution of neurons displaying immunopositivity for choline acetyltransferase (ChAT) remain unchanged. Levels of ChAT-like immunoreactivity also appear normal. These data suggest that the p75NGFr may not be crucial for proper development of the cholinergic phenotype in the basal forebrain. ## 609.12

**SOME NOCICEPTIVE NEURONS INNERVATING THE CORNEA SURVIVE IN trkA KNOCKOUT MICE.** M. López de Armentia<sup>1</sup>, F. de Castro<sup>1</sup>, I. Silos-Santiago<sup>2</sup>, M.A. Garber<sup>2</sup>, M. Barbacid<sup>2</sup> and C. Belmonte<sup>1</sup>. Instituto de Neurociencias Universidad de Alicante, Spain<sup>1</sup>; Dept. Molecular Biology, Bristol-Myers Squibb, Princeton NJ<sup>2</sup>.

Mutant mice in which NGF/*trkA* signaling has been abolished by inactivation of the *trkA* gene, have depleted populations of nociceptive neurons in sensory ganglia and do not respond to painful stimuli. Whether or not all subtypes of nociceptive neurons are absent is unknown. The cornea is innervated by trigeminal nociceptive neurons, that respond to different noxious stimuli. Only sensation of pain can be elicited by corneal stimulation. We have compared corneal innervation and responsiveness to noxious stimulation in *trkA* knockout (-/-), wild type (+/+) and heterozygous (+/-) mice. Corneal nerves were stained using gold chloride impregnation. Blinking movements evoked by von Frey hairs (7-144 mN/mm<sup>2</sup>) and topical application of 0.1-10 mM acetic acid, saline at 0-90°C and 33 mM capsaicin were counted. A dramatic reduction of nerve trunks in the corneal stroma and of thin nerve terminals was observed in (-/-) animals. Blinking in response to various modalities of noxious stimuli was either absent or significantly reduced. We concluded that most corneal trigeminal nociceptive neurons depend on NGF for survival. However a small population of corneal sensory neurons appears to be NGF-independent and may belong to all functional types. (CITYT SAF93-0267, Spain; F.C. & M.L.A. are MEC fellows).

## 609.13

**p75 INHIBITION AND KNOCK-OUT EFFECTS ON ADULT CHOLINERGIC FOREBRAIN NEURONS** C.E.E.M. Van der Zee\*, G.M. Ross\*, R.J. Riopelle\*, T. Hagg Dept. Anatomy & Neurobiology, Dalhousie Univ., Halifax, B3H 4H7. Canada; # Dept. Medicine, Queen's University, Kingston, K7L 2V7 Canada.

NGF (nerve growth factor) can activate its transducing TrkA receptor and can bind to the low-affinity NGF p75 receptor. The role of p75 is unclear but it can enhance the transduction efficiency of TrkA. p75 also may have a TrkA-independent signaling capacity by activation of the sphingomyelin pathway and has been implicated in developmental apoptosis. We have used a conformationally constrained synthetic peptide designed from putative p75-interacting NGF residues 28-36. This cyclic peptide (c28-36) blocked neurite outgrowth in cultured chick DRG neurons and inhibited crosslinking of <sup>125</sup>I-NGF to p75 receptor but not to TrkA. We are investigating potential p75-specific signaling functions in the basal forebrain cholinergic system. After a 14 day infusion of c28-36 (6 nmol/d; ~7 µg/d) into the lateral septum or hippocampal formation of normal adult female Sprague-Dawley rats, the diameter of medial septal cholinergic (ChAT-positive) neurons was reduced by 35%, similar to the atrophy seen after axotomy or in aging. In animals with an entorhinal lesion, non-lesioned septal cholinergic axons undergo collateral sprouting in the outer molecular layer of the dentate gyrus. An 8-day infusion of c28-36 into the hippocampal formation caused neuronal atrophy but did not diminish the extent of sprouting. Transgenic mice (4-6 weeks old) with a p75 null mutation had almost twice as many medial septum ChAT-positive neurons compared to F2 control mice and these neurons were 30% larger in diameter. Thus, in the cholinergic basal forebrain, p75 receptor appears to be involved in regulation of developmental neuronal death and cell body size.

## 609.15

**TrkB/TrkC DOUBLE KNOCKOUT MICE COMPLETELY LACK SEVERAL PERIPHERAL SENSORY GANGLIA BUT EXHIBIT ONLY MINOR ABNORMALITIES IN THE CENTRAL NERVOUS SYSTEM.** J. Silos-Santiago\*, A.M. Fagan\*, D.R. Fuschini\*, S. Ozaki\*, W.D. Snider\* and M. Barbacid\*. Dept. of Molecular Oncology, Bristol-Myers Squibb Pharmaceutical Research Institute, Princeton, NJ 08543; \*CSNSI, Washington University, St. Louis, MO 63110.

The paucity of deficits found in the CNS of "knockout" mice lacking either TrkB or TrkC tyrosine kinase receptors suggests that the survival of most CNS neurons depends on multiple growth factors. Indeed, many CNS neurons, such as hippocampal and motor neurons, express both TrkB and TrkC receptors *in vivo* and respond to their cognate neurotrophins (BDNF/NT-4 and NT-3, respectively) *in vitro*. Therefore, the absence of dramatic CNS phenotypes in single *trk*(s) knockout mice may reflect compensatory survival-promoting effects of the unaffected neurotrophin signalling pathway. To address this possibility, we have generated double knockout mice in which both *trkB* and *trkC* genes have been inactivated. These *trkB(-/-)trkC(-/-)* mice develop until birth, the latest time point evaluated. Gross histological evaluation indicates that CNS structures, including the hippocampal formation and motor pools, appear to be formed normally in these double *trkB/trkC* mutants. Preliminary quantitation analysis demonstrates only a slight decrease in motor neuron number as compared to wildtype controls. Expression of parvalbumin, calbindin, and tyrosine hydroxylase appears to be normal in CNS regions. In contrast, several peripheral sensory ganglia, including the vestibular, cochlear and geniculate ganglia, are completely missing in the double *trkB/trkC* null animals. Other sensory ganglia, although present, have more neuronal cell loss than in single *trkB* or *trkC* knockout mice. These results indicate that neurotrophin signalling may not be required for survival of CNS neurons, at least during embryonic development. However, in the PNS, neurotrophin signalling is absolutely required and may cooperate in promoting neuronal survival.

## 609.17

**NEURONAL DEFICITS IN THE TRIGEMINAL SYSTEM OF KNOCK OUT MICE LACKING THE TrkA NGF RECEPTOR** D.R. Fuschini\*, D.P. Crockett\*, M.D. Egger\*, M. Barbacid\*, and J. Silos-Santiago\*. Dept. of Molecular Oncology, Bristol-Myers Squibb, Princeton, NJ 08543 and \*Dept. Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Med. Sch., Piscataway, NJ 08854.

Mice carrying germ line mutations in the genes encoding the TrkA, TrkB, and TrkC neurotrophin receptors display an array of distinct neurological deficits, mainly limited to the PNS. Whether or not these neurons die before or after reaching their peripheral and central targets remains to be determined. In the trigeminal (TRG) ganglia, the period of naturally occurring programmed cell death is simultaneous with TRG neuron target innervation and precedes the emergence of the vibrissae-related cytochrome oxidase (CO) patterns in the trigeminal brainstem complex. We have studied the development of this system in the absence of neurotrophin signalling. We have observed that in the *trkA* null mice TRG sensory neurons are born. Some neurons are likely to be NGF-dependent since transcripts for the extracellular domain of the TrkA receptor have been detected in these mutant mice by *in situ* hybridization at early embryonic stages. However, by E11.5 there is an increase in the rate of cell death in these mutant mice, and by E13.5, 50% of the TRG neurons are lost and levels of TrkA transcripts are lower than in wild-type mice. By E15.5 the TRG ganglion of the *trkA* null mice only had 16% of the neurons found in their wild-type littermates. At this time expression of TrkA mRNA is completely absent. In addition, the whisker-related CO pattern appears to be less prominent in the *trkA* null mice. These results suggest that the death of NGF-dependent trigeminal neurons may occur before they reach their targets and have an effect on central pattern formation.

## 609.14

**EXPRESSION OF p75 IN THE TRIGEMINAL GANGLION OF TRANSGENIC MICE THAT OVEREXPRESS NGF IN THE SKIN.** P.H. Kitzman\*, K.M. Albers and B.M. Davis. Depts. of Pathology and Anatomy and Neurobiology, University of Kentucky, Lexington, KY.

During development a subset of neural crest -derived sensory neurons and sympathetic neurons are dependent on NGF for survival and differentiation. NGF has been shown to bind to both the Trk A tyrosine kinase receptor and the low affinity NGF receptor (or p75). However, at present, whether binding to both the Trk A and p75 receptors is required for NGF-induced activity remains controversial. Recently it has been shown that exogenously increased target-derived NGF increases p75 expression (Miller et al., 1994). Our lab has previously described a transgenic mouse line that overexpresses NGF in the skin (Albers et al., 1994). These mice demonstrated a two-fold increase in the number of neuronal cell bodies in the trigeminal ganglia as compared with control mice. In addition, the number of Trk A expressing neurons increased 5-fold and the number of Trk C expressing neurons increased 2-fold. To determine whether expression of p75 is similarly effected, *in situ* hybridization using a riboprobe for the p75 receptor was performed. Results of this study suggest a trend for an increase in the number of neurons expressing p75 in trigeminal ganglia of the NGF transgenic mice. RT-PCR was performed to determine the change in p75 mRNA expression in the trigeminal ganglion as well as in other tissues. Preliminary results indicate an increase in p75 mRNA expression in the skin and tongue of the NGF transgenic mice as compared with control mice. Finally, immunohistochemistry utilizing an antibody to the p75 receptor was performed to determine whether there is a change in the number of neurons expressing the p75 protein.

## 609.16

**OVEREXPRESSION OF Bcl-2 DOES NOT PREVENT THE DEATH OF NEUROTROPHIN-DEPENDENT PNS NEURONS IN THE TrkA KNOCKOUT MOUSE.** A.M. Fagan\*, M.A. Garber\*, O. Bernard\*, M. Barbacid\*, and J. Silos-Santiago\*. Dept. of Molecular Oncology, Bristol-Myers Squibb Pharmaceutical Research Institute, Princeton, NJ 08543; \*The Walter and Eliza Hall Institute of Medical Research, Royal Melbourne Hospital, Victoria, Australia.

Neurotrophin signalling is absolutely required for the survival of specific populations of developing neurons in the PNS. We have recently shown that ablation of *trkA*, the gene encoding the NGF signalling receptor, results in the developmental death of sympathetic and nociceptive sensory neurons. However, the intracellular mechanisms involved in neurotrophin-dependent cell survival are unknown. Bcl-2 is a candidate molecule for mediating the survival effects of neurotrophic factors since it has been shown to enhance the survival of PNS neurons following neurotrophin withdrawal *in vitro*. *In vivo*, Bcl-2 has been reported to protect PNS neurons from programmed cell death during development, as well as prevent the axotomy-induced death of neonatal motor neurons. In an effort to explore the role of Bcl-2 in neurotrophin-dependent cell survival, we have generated *trkA(-/-)* mice which constitutively overexpress *bcl-2* under the direction of the neuron-specific enolase promoter. Developmental expression of the Bcl-2 protein in these animals was confirmed by Western blot analysis. However, Bcl-2 expression was unable to rescue sympathetic or sensory neurons from cell death in the neonatal *trkA(-/-)* mouse. These data indicate that whereas Bcl-2 may confer a survival advantage for neurons at earlier stages of neurotrophin-dependence, its overexpression is not sufficient to compensate for the absence of NGF signalling in these *trkA* null animals.

## 610.1

AGE-RELATED DNA REPAIR ACTIVITY IN NEURONAL CORTICAL CULTURES. P. Corsi\*, G. Brescia and G. Assenato. \*Istituto di Fisiologia Umana, Istituto di Medicina del Lavoro, Facoltà di Medicina e Chirurgia, Bari, Italy.

Possible age-related deterioration in the efficacy of DNA repair was investigated in neuronal cortical cultures as a function of degree of cellular differentiation and ageing. DNA repair capacity was measured as spontaneous and UV induced unscheduled DNA synthesis (UDS). While not necessarily related to the induction of accelerated ageing in neurons, ultraviolet (254 nm) light (UV) may represent an excellent model agent for studying the role of DNA damage in ageing. At 7, 14, 21 days in vitro, the neuronal cultures were incubated with hydroxyurea (HU), a DNA replicative synthesis inhibitor and irradiated with a UV light at 24 J/m<sup>2</sup>. The DNA content was determined and UDS measured by the DNA incorporation of [<sup>3</sup>H]thymidine and expressed in cpm/μg of DNA; the amount of DNA damage has been evaluated as sensitivity to S1 nuclease representing the proportion of single stranded DNA. In UV irradiated cultures, parameters referring to total cell survival, neuronal cytotoxicity and morphology were also considered. Our experimental evidence suggest that a lowered performance of age-related repair activity has been observed indicating that a DNA damage potentially accelerates the ageing processes altering the primary information of the DNA macromolecule.

ANTI-OXIDANTS AND NMDA RECEPTOR ANTAGONISTS PROTECT AGAINST AGE-INDUCED APOPTOSIS IN CEREBELLAR GRANULE CELLS. D.-M. Chuang<sup>1</sup>, P. Leeds<sup>1</sup>, K.-G. Zhang<sup>1</sup>, X.-M. Gao<sup>1</sup> and R. Ishitani<sup>2</sup>. <sup>1</sup>Section on Molecular Neurobiology, Biological Psychiatry Branch, NIMH, NIH, Bethesda, MD 20892 and <sup>2</sup>Group on Cellular Neurobiology, Josai Univ., Saitama 350-02, Japan.

Cerebellar granule cells (CGC) prepared from neonatal rats undergo apoptosis within 3 weeks in culture under typical growth conditions, i.e. in the presence of 25 mM KCl without medium change and glucose supplement. This age-induced apoptosis involves over-expression of glyceraldehyde-3-phosphate dehydrogenase (Ishitani et al., this volume). Here, we found that NMDA antagonists, MK-801 (0.1-10 μM) and AP-5 (1-100 μM), dose- and time-dependently protected against age-induced death of CGC as evidenced by microscopic inspection and MTT assays after 20 days *in vitro* (DIV). The anti-oxidants, vitamin E and melatonin, also dose-dependently protected against age-induced apoptosis with an EC<sub>50</sub> of about 3 μM and 30 μM respectively. Maximal protection occurred when vitamin E (10<sup>-5</sup> M) or melatonin (10<sup>-4</sup> M) was added after 10 DIV. Confirming previous observations, periodic supplements with glucose markedly prolonged the life span of CGC. These results suggest that age-induced death of CGC involves over-stimulation of NMDA receptors by the release of endogenous glutamate. This NMDA receptor activation may trigger the production of reactive oxygen intermediates which contribute to age-induced CGC apoptosis.

## 610.5

APOPTOSIS INDUCTION IN A CNS NERVE CELL LINE BY MICROTUBULE DEPOLYMERIZATION: SELECTIVE CHANGES IN PROTEIN PHOSPHORYLATION. M.P. Lambert\*, B. Chromy, G. Stevens, and W.L. Klein. Dept. of Neurobiology and Physiology, Northwestern University, Evanston, IL, 60208.

The B103 cell line is a spontaneously neurotogenic CNS nerve cell model recently used in studies of cell death evoked by the Aβ peptide (Zhang et al., 1994 J.Biol.Chem.269:25247). It also can be used, as shown here, for studies of an apoptotic cascade evoked by colchicine. Colchicine is a microtubule depolymerizing agent that recently has been reported to cause programmed cell death in several non-neuronal cell lines. Viewed by VEC-DIC microscopy, B103 cells exposed to chronic colchicine round up, undergo neuritic atrophy and retraction, begin extensive membrane blebbing and lose adhesion to the culture substratum -- morphological changes similar to those seen in apoptosis and in mitosis. During the response to colchicine, significant decreases occur in levels of phosphorylated nuclear tau (detected by PHF-1 immunofluorescence; Lambert et al., Neuro.Aging, in press). Cytoplasmic PHF-1 immunofluorescence increases, most likely due to the concomitant increase of a novel PHF-1 immunoreactive protein seen in immunoblots at 120 kDa. Nocodazole also induces the 120 kDa band, as well as several PHF-1 immunoreactive bands not seen with colchicine. Cells that have detached from the culture substratum comprise two populations. Some remain viable, shown by replating sans colchicine. The others have apoptosed, as evidence by the diagnostic 180-200 kb DNA ladder. The disadherent cells show a striking increase in a tyrosine phosphorylated protein at ~90 kDa. We hypothesize that kinase activities associated with mitotic control of adhesion and the cytoskeleton lead to apoptosis when aberrantly activated.

## 610.2

CROSSLINKING OF MEMBRANE GLYCOPROTEINS BY CONCAVALIN A INDUCES APOPTOSIS IN CORTICAL NEURONS. V.M. Kreng, D.H. Cribbs, A.J. Anderson, A. Russo-Neustadt\* and C.W. Cotman. Irvine Research Unit in Brain Aging, University of California, Irvine, CA 92717.

Recently apoptosis has been implicated in the loss of neurons during normal aging and in neurodegenerative diseases. This has led to an increased interest in the type of stimuli that initiate neuronal apoptosis *in vivo*. Unfortunately, many agents capable of activating apoptosis do not mimic *in vivo* events and also hit multiple targets (i.e., radiation, hydrogen peroxide, and staurosporine). However, activation-induced cell death (AICD), which occurs when the oligomerization of membrane receptors by multivalent ligands leads to signal transduction that triggers apoptosis is one well defined activating event. We have used the lectin concanavalin A (Con A), to study whether crosslinking of membrane glycoproteins on neurons will activate apoptosis. Cortical neurons treated with Con A exhibit the morphological and biochemical characteristics of apoptosis, including membrane blebbing, condensation of nuclear chromatin and internucleosomal DNA fragmentation. In addition, Con A produced a rapid, robust and prolonged increase in the immediate early gene c-jun which precedes the onset of other markers for apoptosis in neurons. Interestingly, succinyl Con A, the dimeric form of the lectin which is much less effective at crosslinking, was not neurotoxic although it did bind to the neurons and Con A specific monosaccharides were able to block Con A-induced apoptosis. Thus, Con A provides a clearly defined activating signal to study apoptosis in cultured neurons.

## 610.4

COMPARISON OF CARBAMAZEPINE, PHENYTOIN, AND AGE-INDUCED CELL DEATH IN CEREBELLAR GRANULE CELLS. P.A. Saunders\*, R. Ishitani\*, P. Leeds, and D.-M. Chuang. Sect. Molecular Neurobiol., Biol. Psychiatry Branch, NIMH, NIH, Bethesda, MD 20892, @ Josai U., Sakado, Saitama 350-02, Japan.

We have used primary cerebellar granule cells to study the mechanisms involved in neuronal apoptosis. The properties of the apoptosis caused by the anticonvulsants carbamazepine (CBZ) and phenytoin (PHE) are different from that found with aging. Age-induced apoptosis was inhibited by the anti-oxidants, vitamin E and melatonin (Chuang et al., this volume). In addition, chronic exposure to the glutamate receptor agonist, NMDA, hastened the onset of apoptosis. In contrast to aging, short pretreatment of the cells with NMDA protected the cells against CBZ- and PHE-induced apoptosis and the antioxidants were not protective. Increased levels of a 38 kDa protein identified as glyceraldehyde-3-phosphate dehydrogenase (GAPDH) and its mRNA were seen during age-induced apoptosis. An antisense oligonucleotide against its mRNA delayed age-induced apoptosis (Ishitani et al., this volume), suggesting the protein plays a role in programmed cell death. In contrast to aging, CBZ and PHE caused a rapid and persistent decrease in GAPDH mRNA levels. Pretreatment with NMDA caused an increase of GAPDH mRNA and prevented the CBZ- and PHE-induced GAPDH mRNA loss. These observations suggest that age-induced apoptosis which is due, at least in part due, to oxidative or free radical damage to the cell, while the anticonvulsant induced apoptosis is due to another mechanism which may not require induction of GAPDH.

## 610.6

GLIAL AND OXIDATIVE STRESS MARKERS IN TWO MODELS OF GLIAL ACTIVATION IN RATS. K. Sugaya\*, S.J. Xu, T. Pauly and M. McKinney. Dept. of Neuropharmacology, Mayo Clinic Jacksonville, Jacksonville, FL 32224.

Nitric oxide synthase (NOS) containing cells are relatively preserved in certain neurodegenerative diseases and in some lesion animal models. NOS-positive cells may have more robust protection systems for oxidative stress that may be generated by nitric oxide (NO). The inducible type of NOS (i-NOS) is one source of NO. We have found indications of gliosis in aged memory-impaired rats; such activated glia might express i-NOS. In the present study of glial activation, we injected ibotenic acid into the nucleus basalis magnocellularis (NBM), or endotoxin (LPS) into the lateral ventricle. Glial fibrillary acidic protein (GFA), amyloid beta precursor protein (APP), i-NOS and Mn-superoxide dismutase (Mn-SOD) mRNAs were assessed with *in situ* hybridization histochemistry (ISH) combined with GFA or OX-42 immunohistochemistry. The production of NO (as nitrate) after LPS injection was measured by *in vivo* microdialysis and ion exchange chromatography.

By 6 hr post-treatment, GFA mRNA had increased in the LPS-injected rat, but delayed to a later period in the NBM-lesioned rat. In the NBM lesion model, APP mRNA was increased early and was followed by an increase in i-NOS mRNA. In the LPS-injected rat, APP mRNA was elevated within the same time frame as GFA mRNA. LPS also elicited an increase in i-NOS mRNA at the injection site by 6 hr after the injection, and this was accompanied by an increase in nitrate levels in the ventricle. Mn-SOD mRNA was elevated in parallel with i-NOS mRNA in both animal models. The number of GFAP and OX-42 immunostained cells were increased and their processes were heavily stained in both models, following peak of GFA and i-NOS mRNA elevation.

These results indicate that the involvement of astrocyte and microglial activation differs in these two animal models and that APP may be involved in the glial activation cascade. The increase in levels of Mn-SOD mRNA that paralleled the increase in i-NOS mRNA may indicate the induction of cellular oxidative stress protection systems.

## 610.7

DOUBLE *IN SITU* HYBRIDIZATION FOR NITRIC OXIDE SYNTHASE AND SUPEROXIDE DISMUTASE mRNA COMBINED WITH CHAT IMMUNOCYTOCHEMISTRY IN THE RAT BRAIN. S.-J. Xu\*, K. Sugaya, C. Kent and M. McKinney. Dept. of Neuropharmacology, Mayo Clinic Jacksonville, Jacksonville, FL 32224.

Neurons expressing the constitutive nitric oxide synthase (c-NOS) are relatively resistant to degeneration in several diseases including Alzheimer's disease (AD). This may indicate the existence of neuroprotective mechanisms against diffusible free radicals like nitric oxide in these cells. One candidate for this protection mechanism is superoxide dismutase (SOD), since Cu/Zn-SOD is elevated in AD hippocampus and SOD protects cells from free radicals. Differential expression of these protection mechanisms could explain the differential vulnerability in neuronal systems in AD.

In this study, we focused mainly on cholinergic systems and we examined whether SOD mRNA was co-localized with c-NOS mRNA in ChAT-positive cells. For this purpose, we developed a method of "double", *in situ* hybridization histochemistry (ISHH), in which one probe is labeled by [<sup>35</sup>S] and another probe is labeled by digoxigenin (DIG), and ISHH is combined with ChAT immunocytochemistry.

SD rats were perfused with 4% buffered paraformaldehyde and brain sections were immunostained for ChAT. The sections were hybridized with a [<sup>35</sup>S]-labeled Cu/Zn-SOD or Mn-SOD riboprobe and a DIG-labeled c-NOS riboprobe. After hybridization, sections were incubated with alkaline phosphatase (AP) conjugated anti-DIG-IgG and c-NOS positive cells were visualized with a substrate for AP. The sections were then emulsion-coated and developed to visualize the radioactive probe. Brown ChAT-immunostained cells expressing c-NOS had a purple deposit. These cells were overlaid with silver grains if Cu/Zn- or Mn- SOD mRNA was also present. The c-NOS message level varied in ChAT-positive neurons in different division of the basal forebrain system, while all the upper brainstem cholinergic cells contained c-NOS mRNA. High level of mRNA for the SODs were not frequently found in cNOS-positive cells. These data suggest that c-NOS has a variable relationship to the cholinergic phenotype, perhaps in a way related to differential vulnerability in disease, and that SOD may not be the protection mechanism against NO in these c-NOS positive cells.

## 610.9

GLYCERALDEHYDE-3-PHOSPHATE DEHYDROGENASE (GAPDH) ANTISENSE OLIGODEOXYNUCLEOTIDE PROTECTS AGAINST LOW K<sup>+</sup>-INDUCED APOPTOSIS OF CULTURED CEREBELLAR NEURONS. K. Sunaga<sup>1</sup>, M. Tanaka<sup>2</sup>, H. Aishita<sup>2</sup>, D.-M. Chuang<sup>\*3</sup> and R. Ishitani<sup>1</sup>. 1)Group on Cellular Neurobiology, Josai Univ., Saitama 350-02, Japan. 2)Fukui Research Institute, Ono Pharmaceutical Co., Ltd., Fukui 913, Japan. 3)Section on Molecular Neurobiology, BPB, NIMH, Bethesda, MD 20892, U.S.A.

D'Mello et al. have reported the induction of apoptosis in cerebellar granule cells (CGC) by lowering K<sup>+</sup> to 5 mM in culture medium. We have shown that GAPDH is involved in age-induced apoptosis of CGC. Therefore, we examined the role of GAPDH in low K<sup>+</sup>-induced apoptosis of CGC. Within 24 hrs after exposure of mature CGC to low K<sup>+</sup>, a fraction of neurons undergo apoptosis, as revealed by ultrastructural changes and DNA fragmentation. Preceding cell death, the levels of mRNA and protein of GAPDH are markedly increased. Antisense, but not sense, oligodeoxyribonucleotide to GAPDH effectively protects against low K<sup>+</sup>-induced apoptosis. Cycloheximide and actinomycin-D block the low K<sup>+</sup>-induced increase of GAPDH mRNA and cell death. These results suggest that over-expression of GAPDH mRNA and protein is intimately coupled to low K<sup>+</sup>-induced apoptosis in CGC.

## 610.11

TETRAHYDROAMINOACRIDINE AND ONO-1603, A POTENTIAL ANTIDEMENTIA DRUG, ATTENUATE AGE-INDUCED APOPTOSIS OF CULTURED CEREBELLAR NEURONS. N. Katsube<sup>1,2</sup>, K. Sunaga<sup>1</sup>, M. Kimura<sup>1</sup>, M. Yamamoto<sup>\*2</sup>, H. Aishita<sup>2</sup> and R. Ishitani<sup>1</sup>. 1)Group on cellular Neurobiology, Josai Univ., Sakado, Saitama 350-02, Japan. 2)Minase Research Institute, Ono Pharmaceutical Co., Ltd., Mishima-Gun, Osaka 618, Japan.

Tetrahydroaminoacridine (THA) is effective in the treatment of some Alzheimer's patients. It seems unlikely that THA's therapeutic effect is simply due to its anticholinesterase activity, since other cholinesterase inhibitors show little clinical efficacy. Our present report demonstrates that a lower dose of THA (3-10 µM) added to mature cerebellar granule cells (CGC) significantly attenuates apoptotic cell death and this neuroprotection is correlated with the ability of THA to suppress the expression of the particulate 38-kDa protein, i.e., glyceraldehyde-3-phosphate dehydrogenase. These novel effects of THA provide a new avenue to investigate the mechanisms of action of this drug. This paradigm may also be used to screen for more effective drugs in the treatment of Alzheimer's disease. ONO-1603, a novel prolyl endopeptidase inhibitor and possessing an anti-amnesic effect, significantly delays the age-induced apoptosis of CGC at a dose of 0.03-0.1 µM, as similar to THA.

## 610.8

EVIDENCE THAT GLYCERALDEHYDE-3-PHOSPHATE DEHYDROGENASE MEDIATES AGE-INDUCED APOPTOSIS IN MATURE CEREBELLAR NEURONS IN CULTURE. R. Ishitani<sup>1</sup>, K. Sunaga<sup>1</sup>, A. Hirano<sup>2</sup>, N. Katsube<sup>\*2</sup>, P. Saunders<sup>3</sup> and D.-M. Chuang<sup>3</sup>. 1)Group on Cellular Neurobiology, Josai Univ., Saitama 350-02, Japan. 2)Minase Research Institute, Ono Pharmaceutical Co., Ltd., Osaka 618, Japan. 3)Section on Molecular Neurobiology, BPB, NIMH, MD 20892, U.S.A.

Under typical culture conditions, cerebellar granule cells die abruptly after 17 days *in vitro*. This burst of neuronal death involves ultrastructural changes and internucleosomal DNA fragmentations characteristic of apoptosis and is effectively arrested by pretreatment with actinomycin-D, cycloheximide, or aurointricarboxylic acid. The level of a 38-kDa protein in the particulate fraction is markedly increased during age-induced cell death. This increment is suppressed by all above-mentioned agents. N-terminal microsequencing of the 38-kDa protein revealed sequence identity with glyceraldehyde-3-phosphate dehydrogenase (GAPDH). A GAPDH antisense oligodeoxyribonucleotide blocks age-induced expression of this 38-kDa protein and effectively prevents neuronal apoptosis, while the corresponding sense oligonucleotide was completely ineffective. Thus, over-expression of GAPDH in the particulate fraction has a direct role in age-induced apoptosis of cerebellar neurons.

## 610.10

ANTISENSE OLIGODEOXYNUCLEOTIDE TO GLYCERALDEHYDE-3-PHOSPHATE DEHYDROGENASE (GAPDH) BLOCKS AGE-INDUCED APOPTOSIS IN CEREBRO-CORTICAL NEURONS IN CULTURE. M. Kimura<sup>1</sup>, D.-M. Chuang<sup>2</sup> and R. Ishitani<sup>\*1</sup>. 1)Group on Cellular Neurobiology, Josai Univ., Sakado, Saitama 350-02, Japan. 2)Section on Molecular Neurobiology, BPB, NIMH, Bethesda, MD 20892, U.S.A.

We have shown that GAPDH is involved in age and low K<sup>+</sup>-induced apoptosis of cerebellar granule cells. To further examine the role of GAPDH in the apoptosis of other cell types, we have extended the study using cerebro-cortical neurons. Similar to cerebellar granule cells, cortical neurons undergo age-induced apoptosis after 15 days in culture which is characterized by DNA fragmentation and chromatin condensation. Cycloheximide, actinomycin-D and aurointricarboxylic acid markedly protect against this apoptosis of cortical neurons. Preceding the apoptosis, we found a marked increase in the GAPDH mRNA level. A GAPDH antisense oligodeoxyribonucleotide markedly delays this cell death by 3 to 4 days, an effect which is as robust as that of cycloheximide. In contrast, the corresponding sense oligonucleotide is totally ineffective in the protection. These results suggest that GAPDH is involved in the apoptosis of not only granule cells but also cortical neurons.

## 610.12

EXPRESSION OF p53 IN THE PONTINE PRINCIPAL SENSORY NUCLEUS (PSN) FOLLOWING TRANSECTION OF THE INFRAORBITAL NERVE. P.E. Kuhn<sup>\*</sup> and M.W. Miller. Prog. Cell & Devel. Biol., Rutgers Univ., Piscataway NJ 08854, Depts. Psychiatry & Pharmacology, Univ. Iowa Coll. Med., Iowa City IA 52242 and Res. Serv., V.A.M.C., Iowa City IA 52246.

We tested the hypothesis that increased expression of p53 heralds neuronal death by examining the expression of p53 in the PSN (second order neurons) after transecting a primary afferent, the infraorbital nerve (IO) on the right side. In addition, we examined the temporal expression of ALZ-50 immunoreactivity, for it has been shown that the ALZ-50-positive 56 kDa antigen is a marker for dying neurons. Fresh tissue was harvested 1 hr, 2 d, 12 d, and 21 d post-lesion for immunoblots and fixed tissue was prepared immunohistochemically. The analysis of the blots showed that p53 was significantly higher in the right pons (i.e., the side ipsilateral to the lesion) using the left side as a control. This increase was lost 2 d post-lesion. The expression of p53-immunoreactivity was increased in the ventral, ipsilateral PSN (the target of the transected IO) and the adjacent trigeminal sensory tract of the neonate. In contrast, an increase in ALZ-50 immunoreactivity (in blots and sections) achieved significance only 2 d post-lesion. Thus, it appears that as neurons degenerate, p53 is upregulated early, even before the ALZ-50-positive antigen. Funded by the Department of Veterans Affairs and NIH grants DE 07734, AA 06916, and AA 07568.

## 610.13

**RADIATION-INDUCED APOPTOSIS IN RAT DRG NEURONS.** J.X. Tong, R. Drzymala, J.R. Simpson, V.S. Tantuwaya, and K. M. Rich\*. Department of Neurological Surgery, Washington University School of Medicine, St. Louis, MO 63110.

Embryonic dorsal root ganglion (DRG) neurons are susceptible to trophic factor deprivation-induced apoptotic cell death *in vitro*. Radiation is known to induce apoptosis in several cell lines. We examined radiation-induced cell death in DRG neurons *in vitro*.

Primary dissociated culture of DRG neurons were prepared from embryonic-day-15 (E-15) Sprague-Dawley rats. Cells cultured for 6, 11, and 21 days were exposed to varying doses of radiation, and death was assessed by cell counts after crystal violet staining. Maximal cell death occurred in 6 and 11 day old neurons at 24 Gy radiation (24% death for 6-day-old neurons, 18% death for 11-day-old neurons). Twenty one-day-old neurons underwent significant cell death only at higher doses (10% death at 32 Gy; 13% death at 40 Gy).

Five, 10, and 21-day-old DRG neurons were stained with the fluorescent DNA-binding dye Hoechst 33258 at various time points after 24 Gy irradiation. The percentage of cells displaying DNA condensation were compared with non-irradiated controls. DNA condensation increased 4.5% in 5-day-old DRG neurons 12 hours after irradiation. In 10-day-old DRG neurons, the percentage of cells displaying DNA condensation increased 2.5% at 12 hours after irradiation. Twenty one-day-old DRG neurons demonstrated no significant increase in DNA condensation after 24 Gy radiation at any of the time points tested.

DRG neurons are sensitive to radiation-induced death. This death is dose-dependent and is less effective in older neurons. The DNA condensation seen after radiation is consistent with apoptotic cell death. These changes are age dependent, similar to trophic factor deprivation-induced apoptosis in DRG neurons.

## 610.15

**NEURONAL DEATH DOES NOT PLAY SIGNIFICANT ROLE IN THE RODENT SUBPLATE.** L. López-Mascaraque\*, J.A. De Carlos, M. Santacana and F. Valverde. Laboratorio de Neuroanatomía Comparada. Instituto Cajal (CSIC), Madrid, Spain.

In the rat, the lower neocortical layer forms a conspicuous cell band known as subplate (layer VIb). Subplate cells are among the first to differentiate during cortical development. Cell death in this layer has been shown in carnivora and primates and it is considered as universal feature for subplate cells. In order to assess the validity of this assert, we examined the sequence of generation and the extent of cell death in the rodent subplate layer. We used injections of <sup>3</sup>H-thymidine and two methods for direct visualization of apoptotic figures (Nissl staining and *in situ* apoptosis detection kit). Single injections of <sup>3</sup>H-thymidine were performed between E12 and E15 (E0 is the day of insemination) and the brains were examined at different postnatal ages between P1 and P63. The number of heavily labeled cells were counted through the subplate layer in six standard equally spaced coronal sections for each brain. Single injections at E12 labels about 3% of the entire population of layer VIb cells, 17% at E13, 30% at E14 and <1% at E15. Our results indicate that the absolute number of heavily labeled cells in subplate layer remains constant. The analysis of variance (one-way ANOVA) showed that the difference among the group means was not significant from P1 to P63 after injections at either age of E12, E13 or E14. In order to confirm these results we evaluated the distribution of pyknotic (apoptotic) cell bodies in neocortex. The visualization of apoptotic cells was performed using Nissl stained preparations and by immuno staining using an *in situ* apoptosis detection kit (ApopTag, Oncor). The analysis was done in rats from E18 to P15. Both methods gave comparable results. We found that the amount of cell death in subplate layer is neither particularly prominent nor significantly different than that occurring in the remaining neocortical layers, except in layer II and in the white matter of the corpus callosum. We conclude that neuronal death does not play any significant role in the rodent subplate. (Supported by MEC Research Project PB 91-0066).

## 610.17

**TRK ONCOGENE EXPRESSION PROTECTS AXOTOMY-INDUCED APOPTOSIS IN ADULT RAT RETINAL GANGLION CELLS.** S.C. Sharma\*, E. Garcia-Valenzuela. Dept. of Cell Biology, New York Medical College, Valhalla, NY 10595.

Reporter plasmid application to terminal areas of retinal ganglion cell (RGC) axons results in retrograde transport to their somas and consequently to its specific expression. Here we utilize similar gene transfer approach to study transfection of RGCs with TRK-T1 oncogene under the promoter control of CMV. TRK-T1 contains the cytoplasmic domain of the high affinity NGF receptor and has been shown to initiate signal transduction common to all members of the TRK family.

pCMV/TRK-T1 was injected in rat superior colliculi. Controls were rats with either uninjected tectum or injected with pRSV-lacZ. Three days following plasmid injections, optic nerves were transected and fast blue (FB) applied to the cut ends. Rats were sacrificed 7-30 days post optic nerve section. Retrograde transport of the plasmids and their expression were confirmed through biotinylation of plasmid DNA and immunocytochemical staining. Counts of FB-labeled RGCs and terminal transferase labeled apoptotic profiles were made on flatmounted retinae. Expression of TRK-T1 correlated with survival of RGCs, and was over 50% higher than control animals. In addition, there were less apoptotic profiles. These *in-vivo* results support the dependence of RGCs on neurotrophins for survival. The present approach provides an avenue for rescuing and promoting regeneration of retinal ganglion cells.

## 610.14

**CORTICAL EFFECTS OF SELECTIVE IMMUNOLESIONS IN THE BASAL FOREBRAIN CHOLINERGIC SYSTEM.** S. de Lacalle\* and R.G. Wiley. Dept. of Neurology, Beth Israel Hospital/Harvard Medical School, Boston, MA 02115 and Neurology Service, VAMC, Nashville, TN 37212.

Excitotoxic lesions of the basal forebrain cholinergic neurons induce a decrease in ChAT activity in the neocortex, which recovers over time. The compensatory mechanisms responsible for this restoration are not known, although some authors have postulated a compensatory increase of the functional activity of intrinsic cholinergic neurons in the cortex. We set out to investigate the effect that lesions of the basal forebrain cholinergic system exert on cholinergic cortical interneurons. Unilateral infusion of 20 ng of 192 IgG-saporin in the nucleus of the horizontal diagonal band (HDB) induced a significant 30% decrease in the number of ChAT immunoreactive (-ir) neurons in the lesioned side, compared with the contralateral side. Qualitative and quantitative estimation of the effects of these lesions in the entorhinal cortex showed a moderate loss of ChAT-ir fibers and a significant 11% decrease in the number of ChAT-ir interneurons ipsilateral to the lesion. In order to assess whether this effect was indeed specific to the target area for HDB neurons, similar counts were performed in the anterior cingulate cortex, where no significant difference was found in the number of ChAT-ir neurons between the two sides. In contrast to what has been previously reported, we conclude that the loss of cholinergic neurons in the HDB induces transsynaptic changes in the population of ChAT interneurons in the cortex. It remains to be seen whether these changes are reversible, and the implications in the understanding of cholinergic deficits in the cortex.

## 610.16

**INCREASED APOPTOSIS IN THE ZEBRAFISH OPTIC TECTUM FOLLOWING ENUCLEATION.** M.E. Murray\* and L.S. Ross. Neurobiology Program, Dept. of Biological Sciences and College of Osteopathic Medicine, Ohio University, Athens, OH 45701.

Programmed cell death is a common process during development of the nervous system. Apoptosis is genetically programmed cell death, mediated by an endonuclease's fragmentation of genomic DNA. During neural development, ingrowing afferents to a brain region may secrete a trophic factor that maintains the target cells. In the absence of this innervation and the associated trophic factor, the target cells may die by apoptosis. We investigated the hypothesis that removing the eye may increase apoptosis in the eye's target, the developing optic tectum. Using the ApopTag™ kit (Oncor, Gaithersburg, MD), we examined the distribution of labeled apoptotic nuclei in the optic tectum following unilateral enucleation. Since the zebrafish retina innervates only the contralateral tectum, the ipsilateral tectum serves as a convenient control. Enucleation increases apoptotic nuclei numbers in the two day old experimental tectum. Labeled apoptotic nuclei are located dorsally throughout the rostrocaudal extent of the experimental tectum. After two days, apoptotic nuclei numbers decreased dramatically, and by three days, there was no difference in the number of apoptotic nuclei on the experimental and control sides. These results suggest that retinal innervation has a trophic effect on optic tectal cells by maintaining the target cells and thereby preventing apoptosis.

## 610.18

**VISUAL RESPONSES OF AXOTOMIZED RETINAL GANGLION CELLS ARE PRESERVED IN TRANSGENIC MICE OVEREXPRESSING BCL-2.** Porciatti V.†, Pizzorusso T.‡, Martinou J.§, Maffei L.††\* ‡ Scuola Normale Superiore, Pisa, Italy; † Institute of Neurophysiology, CNR, Pisa Italy; § Glaxo Institute for Molecular Biology, Geneva Switzerland.

Bcl-2 is a membrane protein which it has been shown to protect neurones from apoptosis. Recently, transgenic mice have been generated which contain the gene coding the human Bcl-2 protein. In these mice (bcl-2 mice), neurones have a larger than normal amount of Bcl-2, and most of them are preserved from natural and pathological cell death. We asked the question of whether the function of axotomized retinal ganglion cells is preserved in mice overexpressing bcl-2.

The ganglion cell visually driven activity has been recorded by means of the electroretinogram in response to alternating gratings (P-ERG). It is known that the P-ERG depends on ganglion cell activity, since it disappears progressively after optic nerve cut, with a time course comparable to that of ganglion cell degeneration. The experiments have been performed on bcl-2 (n=5) and wild type mice (n=2) before and at different times after unilateral optic nerve cut.

In wild type mice, the P-ERG is abolished already one month after axotomy, when ganglion cells have undergone massive degeneration. In bcl-2 mice, by contrast, the P-ERG is in the normal range three and half months after axotomy.

Results indicate that overexpression of bcl-2 in transgenic mice allows the survival of axotomized retinal ganglion cell and preserves their function after optic nerve cut. Experiments are in progress to establish whether bcl-2 overexpression preserves indefinitely ganglion cells from death or simply delays their death destiny.

## 610.19

LONG-TERM SURVIVAL OF RETINAL GANGLION CELLS AFTER OPTIC NERVE TRANSECTION IN *bcl-2* TRANSGENIC MICE: ANATOMY.

M.C. Cenni<sup>1</sup>, E. Strettoi<sup>1\*</sup>, L. Bonfanti<sup>1</sup>, G.M. Ratto<sup>1</sup>, S. Rabacchi<sup>2</sup>, J.-C. Martinou<sup>3</sup> and L. Maffei<sup>1,2</sup>. <sup>1</sup>Istituto di Neurofisiologia CNR, Pisa, <sup>2</sup>Scuola Normale Superiore, Pisa Italy, and <sup>3</sup>Glaxo Institute for Molecular Biology, Geneva, Switzerland.

*Bcl-2* is one member of a family of related genes encoding proteins that regulate apoptotic cell death. Recent studies on transgenic mice overexpressing the human *bcl-2* gene in neurons show that the BCL-2 protein protects adult nerve cells from death following ischemia (Martinou *et al.*, Neuron 1994). Transection of the optic nerve in adult mice induces massive degeneration in retinal ganglion cells (RGCs). To investigate whether in the adult *bcl-2* transgenic mice RGCs are protected from axotomy, we performed intracranial optic nerve transection on both wild type and *bcl-2* adult mice. We tested survival of RGCs 3.5 months following axotomy. We counted the cell bodies of all the nerve cells in retinal ganglion cell layer of whole-mounted retinas stained with cresyl violet. In addition, we examined the morphology and fine structure of the proximal stump of the sectioned optic nerves at the light and electron microscope. It has been reported that, in mice, two months after axotomy 50/60 % of all the cells in the retinal ganglion cell layer have degenerated (Grafein and Ingolia, Exp. Neurol. 1982). We confirmed this report in wild type animals at 3.5 months. In *bcl-2* transgenic mice, however, up to 75% of all neurons in retinal ganglion cell layer survived. The difference between wild type and *bcl-2* was even more evident comparing the proximal stumps of sectioned optic nerves. These showed a very large number of surviving axons with normal ultrastructure in *bcl-2* transgenic animals, but only few axons within a general degenerating picture in wild type animals. We conclude that the overexpression of BCL-2 protein in nerve cells is a very effective strategy to ensure long-term survival in axotomized neurons.

## 610.20

Survival Of Retinal Ganglion Cells Over-Expressing *Bcl-2* Protein In Neonatal Transgenic Mice Following Optic Nerve Section.

L. Bonfanti, S. Chierzi, M.C. Cenni, E. Strettoi, X.-H. Liu, J.-C. Martinou, L. Maffei and S.A. Rabacchi\*. Institute of Neurophysiology (CNR) and Scuola Normale Superiore, 56100 Pisa, Italy; <sup>†</sup>Glaxo Institute for Molecular Biology, 1211 Geneva, Switzerland.

*bcl-2* protein overexpressed in neurons of transgenic mice reduces natural cell death (Martinou *et al.*, 1994, Neuron). We have previously found that optic nerve section induces massive apoptosis in retinal ganglion cells of neonatal rats, with a peak of degeneration at 24 hours post-lesion (Rabacchi *et al.*, 1994, J. Neurosci.).

Here, we compare the effects of section to the optic nerve between neonatal *bcl-2* transgenic mice and their wild-type littermates. Whole-mounted retinas were stained with cresyl violet 24 h post-lesion and the apoptotic and surviving cells were counted. While optic nerve transection in neonatal wild-type mice causes a great increase in apoptotic ganglion cells ( $61,387 \pm 9,793$  SE  $n=5$ ), the number of degenerating cells in *bcl-2* transgenic mice was found to be remarkably reduced ( $7,761 \pm 1,198$  SE  $n=5$ ,  $p<0.05$ ).

We have also found that in the *bcl-2* transgenic animals the number of surviving cells ( $138,332 \pm 9,990$  SE  $n=3$ ) was much greater with respect to that found in the axotomized retinas of wild-type mice ( $65,514 \pm 11,839$  SE  $n=3$ ,  $p<0.05$ ).

These results demonstrate that the *bcl-2* protein protects ganglion cells from axotomy and that most of the cellular degeneration induced by axotomy follows a *bcl-2* dependent pathway.

## RETINAL DEVELOPMENT

## 611.1

## INVOLVEMENT OF E-BOX ELEMENTS IN THE DEVELOPMENTAL REGULATION OF THE PHOTORECEPTOR-SPECIFIC GENES. I. Ahmad\*. Dept. of Cell Biology and Anatomy, University of Nebraska Medical Center, Omaha, NE 68198.

The homologues of *Drosophila achaete-scute* complex genes play an important role in vertebrate neurogenesis. These genes encode bHLH transcription factors that are thought to regulate downstream genes by interacting with the cis-acting element, E-box. We have shown that Mash-1, a mammalian achaete-scute homologue, may regulate opsin gene expression by binding to the E-box element, *E<sub>opsin</sub>* during photoreceptor differentiation (ARVO Abst. 1995). To evaluate whether Mash-1 participates in the developmental regulation of other photoreceptor-specific genes we have begun identifying and analyzing E-box elements in their promoters. We have identified an E-box element, *E<sub>α-transducin</sub>* in mouse  $\alpha$ -transducin gene which is situated upstream of  $\alpha$ -1, a RET-1/PCE1 cis-acting element that binds a developmentally regulated retina-specific factor (Ahmad *et al.* J. Neurochem. 1994 62:396-399). DNase I footprint and mobility shift assay showed that *E<sub>α-transducin</sub>* binds factors present in the retinal nuclear extract. We have also identified an E-box element, *E<sub>β-PDE</sub>* in the human  $\beta$ -PDE gene which, like *E<sub>opsin</sub>* and *E<sub>α-transducin</sub>* is situated upstream of RET-1/PCE1 like element and forms complexes with retinal nuclear extracts. Experiments are underway to determine whether the complex formation at *E<sub>α-transducin</sub>* and *E<sub>β-PDE</sub>* is due to Mash-1 or other bHLH transcription factors. The location of the E-box and RET1/PCE1 elements suggests the involvement of bHLH transcription factors in the multifactorial regulation of the photoreceptor specific genes. Supported by NIH EY10313-03.

## 611.3

IN VITRO DEVELOPMENT AND DIFFERENTIATION OF THE POSTNATAL RETINA OF THE BRAZILIAN OPOSSUM, *MONDELPHIS DOMESTICA*.

M.H. West<sup>1,2,3</sup>, C.D. Jacobson<sup>1,2,4</sup> and D.S. Sakaguchi<sup>1,2,3</sup>. <sup>1</sup>Department of Zoology and Genetics, <sup>2</sup>Neuroscience Program, <sup>3</sup>Signal Transduction Training Group, and <sup>4</sup>Department of Veterinary Anatomy, Iowa State University, Ames, Iowa 50011.

In the present analysis we have used an *in vitro* system to examine the postnatal differentiation of the retina of the Brazilian opossum, *Monodelphis domestica*. *Monodelphis* is a small, pouchless marsupial whose young have a protracted period of postnatal neurogenesis and differentiation. In this study, retinas from postnatal day (PN) 1, 2.5 and 12 opossum pups were cultured on laminin containing substrates. Within three days, most explants have attached to the substrate and elaborated an extensive carpet of non-neuronal cells. These cellular carpets provided a substrate that supports extensive neurite outgrowth. Many of the neurites growing on the cellular carpets were immunoreactive for neurofilament protein, providing evidence that they may be axons of retinal ganglion cells (RGCs).

Antibodies directed against presynaptic terminal-associated proteins were used to examine retinal differentiation after seven days *in vitro*. *In vivo*, immunoreactivity (IR) for Synaptosomal Associated Protein-25 (SNAP-25), which is not present at birth, appears by PN5 in RGCs, their axons, and in the outer portion of the retina. PN1 retinas after 7 days in culture, exhibit IR for SNAP-25 in occasional cell bodies and processes. In PN5 retinas Rab3A IR is observed along the inner half of the retina. However, by PN10 the retina exhibits more lamination with Rab3A IR in the RGC axons and inner plexiform layer. PN5 retinas after 7 days in culture, also exhibited a laminar pattern of Rab3A reactivity. Taken together these results show that development and differentiation of the *Monodelphis* retina continues *in vitro* and may parallel *in vivo* development. Supported by grants from the ISU Biotechnology Council, the Carver Trust and the NSF.

## 611.2

EFFECTS OF ANTI- $\beta_1$  INTEGRIN ANTIBODIES ON THE HISTOGENESIS AND DIFFERENTIATION OF THE *XENOPUS* RETINA *IN VIVO*. J. Leonard and D.S. Sakaguchi\*. the Department of Zoology and Genetics, the Signal Transduction Training Group and the Neuroscience Program, Iowa State University, Ames, IA 50011

In the present study we have examined the role of  $\beta_1$  integrins during the normal histogenesis and differentiation of the *Xenopus* retina. Immunohistochemical analysis has revealed that  $\beta_1$  integrins are expressed in the developing neural and pigmented retina, as well as in the neural tube. *In vitro* assays have demonstrated that function blocking antibodies directed against the  $\beta_1$  integrin subunit inhibit axon and glial cell outgrowth from embryonic retina growing on extracellular matrix substrates in a dose-dependent fashion. To examine the possible role of  $\beta_1$  integrins during *in vivo* retinal differentiation the function blocking antibodies were injected into the optic vesicle of stage 23 embryos. After injections, embryos were allowed to develop for 36 hours. The retinas were then examined immunohistologically using antibodies directed against neurons (XAN-5) or photoreceptors (XAP-1 and 2). In control eyes XAN-5 immunoreactivity (IR) displayed a laminar pattern with the outer nuclear layer and the outer and inner plexiform layers exhibiting the strongest IR. XAP-1 and 2 IR was restricted to the outer neural retina, labeling the photoreceptor outer segments (XAP-1: rods and cones or XAP-2: rods). Compared to controls, those eyes injected with the anti- $\beta_1$  antibodies often displayed abnormal lamination patterns. In some cases XAP-1/2 IR was observed in ectopic locations within the inner retina. Taken together, these results provide evidence that  $\beta_1$  integrins play an important role during the normal development of the vertebrate retina. Supported by grants from the NSF, the ISU Biotechnology Council and the Carver Trust.

## 611.4

EMBRYONIC RETINAL ANATOMY AND PAX2 IMMUNOSTAINING IN THE NORMAL AND *Krd* MUTANT MOUSE. P.F. Hitchcock\*, J.T. VanDeRyt\*, J.M. Jones\* and M.H. Meisler\*. Depts. of \*Ophthalmology, \*Anatomy and Cell Biology and \*Human Genetics. The University of Michigan, Ann Arbor.

*Krd* mice contain a transgene-induced mutation of chromosome 19 that includes the developmental regulatory gene, *Pax2*. *Krd/+* adults have anatomical defects in both kidney and retina that range from mild to severe (Keller *et al.*, (1994) Genomics, 23:309; see also Sanyanusin *et al.*, (1995) Nature Gen., 9:358). Defects in the retinas of severely affected mice include spherical aggregates of photoreceptors and laminar malformations in central retina and hypocellularity of all nuclear layers. We have now examined heterozygous embryos (E15.5-E18.5) and newborns, and our observations indicate that the defects seen in the adult are of embryonic origin. In the central retina of transgenic embryos, ectopic cells and folds in the outer neuroblastic layer are present, and with the formation of the IPL (E18.5 to P1), in some retinas there are markedly fewer cells in the ganglion cell layer. Further, in affected retinas the anatomical organization of the optic disc, the site of *pax2* expression (Nornes *et al.*, (1990) Development, 109:797), is abnormal. Based upon this latter observation, we also examined the expression of *Pax2* in the retinas of normal and *Krd* embryos (E14.5-E17.5) using polyclonal antibodies against a recombinant *Pax2* protein (a gift from G. Dressler). This immunostaining confirmed the original observations (see above), and revealed an additional population of *Pax2*-containing cells that reside within the neural retina and encircle the optic nerve. Together our observations suggest that the genetic defect in the *Krd* mouse affects the cellular organization of the neuroepithelium, cell proliferation and the normal formation of the optic disc.

## 611.5

INSULIN-RELATED FACTORS STIMULATE *IN VITRO* PROLIFERATION OF PLURIPOTENT NEUROEPITHELIAL CELLS BUT NOT ROD PRECURSORS OR INJURY-INDUCED NEURAL PROGENITORS IN ADULT GOLDFISH RETINA. S. E. M. Boucher\* and P. F. Hitchcock. The University of Michigan, Depts. of Ophthalmology and Anatomy and Cell Biology and The Neuroscience Program, Ann Arbor, MI.

The retina of the adult goldfish continually generates new neurons and regenerates when injured. Two populations of progenitors are normally present in the goldfish retina: pluripotent neuroepithelial cells at the margin and rod precursors in the outer nuclear layer. Rod precursors are presumed to be the origin of injury-induced neural progenitors. Little is known about molecules that modulate the normal or injury-induced neurogenesis. We assayed the ability of individual peptide growth factors to modulate proliferation of neural progenitors using an organ culture system. Retinas were surgically injured, and eyecups (1 week post-lesion) were incubated in defined media for three days with or without a growth factor. On day 2, the eyecups were pulsed overnight with bromodeoxyuridine (BrdU) to label dividing cells. The eyecups were fixed, frozen, sectioned and processed for BrdU immunocytochemistry. BrdU-labeled cells in retinal sections were counted and averaged. Confirming earlier results (S.E.M. Boucher and P. Hitchcock, (1994) Soc. Neurosci. Abstr. 20: 1322), treatment with 25 nM insulin, insulin-like growth factor-I, or insulin-like growth factor-II increased the number of BrdU-labeled cells in the margin by 461, 845, and 702 %, respectively, over media alone. In contrast, these insulin-like factors did not significantly increase the number of BrdU-labeled rod precursors or injury-induced neural progenitors. These data suggest that one of these insulin-related factors may regulate normal proliferation of pluripotent neuroepithelial cells, but may not regulate the proliferation of rod precursors and injury-induced neural progenitors. Supported by NIH (NEI) grants EY07060 and EY07003 (CORE).

## 611.7

ORGANIZATION OF THE RETINA FOLLOWING CEREBRAL HEMISPHERECTOMY IN THE VERVET MONKEY. <sup>1,2</sup>M. Herbin\*, <sup>1,3</sup>D. Boire, <sup>1,2,3</sup>M. Pito, and <sup>3</sup>A. Pito. <sup>1</sup>Neuropsychol. Unit and <sup>2</sup>CRSN, Université de Montréal and <sup>3</sup>McGill University, Montreal, CAN.

Vervet monkeys underwent the surgical removal of a whole cerebral hemisphere at various post-natal ages. After 48 months of survival, their retinas were removed, flat mounted and Nissl stained. Retinal ganglion cell (RGC) distribution and morphometry were studied using a computer controlled image analysis system. Our results on RGC counts were verified by studying Nissl-stained horizontal sections of the retinae and with electron microscopy of the optic nerves, thus eliminating the possible overestimation of RGC due to displaced amacrine cells. Moreover, the results obtained on the young-lesioned monkeys (YLM) were compared to adult-lesioned (ALM) ones and to normal controls (NC). The axial length of the eyeball was identical for all groups of animals (ca 21.3mm). RGC were dispersed throughout the retina in YLM whereas in ALM they were mainly restricted to the intact hemiretinae. The highest density of RGC was found in the fovea of all groups but was significantly lower in ALM and YLM compared to NC. In the "blind" hemiretinae of ALM there was very few RGC; for YLM, the "blind" hemiretinae comprised numerous RGC whose distribution in regards to eccentricity followed the one observed in NC. The only difference between YLM and NC concerned the relative density of RGC. As far as soma size is concerned, we found in the "blind" hemiretinae mainly small (W-like) and large (Y-like) cells. Results are discussed in terms of plasticity of the retinofugal pathway.

## 611.9

EXPRESSION OF CONE OPSIN mRNA IN THE ADULT AND FETAL PRIMATE RETINA. K.M. Bumsted\*, C.L. Jasoni and A.E. Hendrickson. Departments of Biological Structure and Ophthalmology, University of Washington, Seattle, WA 98195.

Adult Macaca monkey retina contains an average of 3.1 million cones which are divided into long (L), medium (M), and short (S) wavelength-specific subtypes. During development, primate cones are generated in a foveal to peripheral sequence between Fetal day (Fd) 38 and Fd100. The aim of this study was to determine a) the distribution of opsin mRNA in adult cones and b) the temporal and spatial pattern of M/L and S opsin expression during retinal development. We used *in situ* hybridization on retinal whole mounts and sections with digoxigenin-labeled RNA probes to human M/L and S opsin.

The majority of message was localized to the inner segment below the ellipsoid in adult and fetal cones. In adult cones, 8-12% expressed S and 88-90% expressed M/L mRNA. At Fd88 in the nasal retina no cones contained M/L mRNA. At the most central point, 7% expressed S mRNA, but none were present in the periphery. By Fd97, cones expressing either S or M/L mRNA were present centrally with 85-90% containing M/L mRNA. This percentage of M/L mRNA expressing cones decreased to 10-20% at 2mm and to 0% at 3mm eccentricity. In a matched retinal sample, 10-13% of central and 4-8% of cones at 2.7mm eccentricity expressed S mRNA. At 6mm eccentricity, the most peripheral extent of S mRNA expression, 1% of cones are recognized.

These results confirm the adult percentages of S and M/L cones determined with opsin antibodies. In fetal retina, our results indicate that S mRNA expression precedes that of M/L mRNA at any given eccentricity. These data support our previously-identified sequence of S before M/L opsin expression which was based on immunocytochemical labeling in the developing primate retina. ## 611.6

THE VERVET (*CERCOPITHECUS AETHIOPS SABEUS*) RETINA. <sup>1,2,3</sup>M. Pito\*, <sup>1,2,3</sup>M. Herbin, <sup>1,3</sup>D. Boire, <sup>1</sup>S. Montfort. <sup>1</sup>Neuropsychol. Unit and <sup>2</sup>CRSN, Université de Montréal and <sup>3</sup>McGill University, Montreal, CAN.

This study is to establish normative data on the organization of the retina of the Vervet monkey, a species increasingly used in visual neuroscience. The axial length of the eyeball is 21.3 mm. Ganglion cells (RGC) distribution and morphometry were studied in Nissl-stained whole-mounts retinae using a computer controlled image analysis system developed in our laboratory. RGC isodensity maps showed that the fovea is located temporally and at about 3.4 mm from the optic disk. This region has the highest density (ca 38 000) of RGC that are densely packed forming four to five layers of cells. From the fovea, cell density falls rapidly until 3-4 mm (d= 5000) and the decrease is slower thereafter (d=<1000). The RGC counts were confirmed by the electron microscopy of the optic nerves thus eliminating the possible overestimation of RGC due to displaced amacrine cells. The soma size of RGC range from 5.73 µm to 22.87 µm and appear to form three distinct groups: small (x= 7.84 µm), medium (x= 12.32 µm) and large (x= 16.50 µm). The foveal region comprises exclusively small RGC; in the periphery medium and large cells are added and the frequency distribution of cell size appears to become trimodal. These results are comparable to those reported for several species of Old World monkeys such as *Macaca mulatta* and *Macaca fascicularis* and indicate that the Vervet monkey has similar visual capabilities.

## 611.8

TIME BETWEEN CELL BIRTH AND OPSIN EXPRESSION IS GREATER FOR GOLDFISH RETINAL CONES THAN FOR RODS. D.L. Stenkamp\* & P.A. Raymond. Dept. Anat. & Cell Biology, Univ. of Mich., Ann Arbor, MI 48109.

Cone photoreceptors in teleost retinas are arranged in a precise mosaic in which the 4 spectral subtypes (red, green, blue, ultraviolet [uv]) have consistent relative positions. By using *in situ* hybridization with opsin cDNA probes to identify specific photoreceptor types, we showed that rod opsin was the first retinal opsin to be expressed in goldfish embryos (*Invest Ophthalmol Vis Sci* 36:S1055, 1995). Red cone opsin expression began 10 hours later, followed by green, then blue, then uv; this temporal order predicts the spatial positions of cone types in the mosaic. We proposed a model in which precocious rods establish the spacing of the mosaic unit, and a cascade of lateral signals from sequentially differentiating photoreceptor subtypes induces neighboring presumptive photoreceptors to become committed to specific spectral subtypes.

Since birthdating studies have shown that teleost cones are born before rods, one prediction of the model is that onset of opsin expression is delayed in cones relative to rods. To test this prediction, we injected juvenile goldfish eyes with BrdU to label proliferating cells in the marginal germinal zone and later examined the newly generated cells with *in situ* hybridization and BrdU immunocytochemistry. By 3 days, photoreceptor cells were double-labeled for BrdU and rod opsin mRNA; however, cells double-labeled for cone opsins were not found until 9 days. At 9 days, the number of double-labeled cells was greatest when retinas were hybridized with the red cone opsin probe, followed in descending order by green, then blue, then uv, suggesting that the order of opsin expression in adults may mimic the order observed in embryos. These results verify the prediction that opsin expression in cones is de-layed as compared to rods, and are consistent with the hypothesis that rods may play a role in commitment of cones to specific phenotypes. ## 611.10

RETINOIC ACID INDUCES THE EXPANSION OF ROD PHOTORECEPTORS IN THE DEVELOPING ZEBRAFISH RETINA. G.A. Hyatt, E. A. Schmitt, and J. E. Dowling\* Dept. Molecular and Cellular Biology, Harvard University, Cambridge, MA 02138.

Retinoic acid (RA) alters the expression of cellular and molecular markers of dorso-ventral polarity in the early zebrafish retina (Schmitt et al., this meeting). These observations suggest that RA is instrumental in establishing ventral retinal characteristics. To determine if RA is involved in cellular patterning at later stages of retinal development, zebrafish embryos were exposed to RA or to inhibitors of endogenous RA synthesis during the onset of photoreceptor histogenesis (approx. 2 days pf). An increase in the number of rod photoreceptors was observed at 3 days pf within the ventral retina, 24 hours following the application of RA. The continued exposure of embryos to RA increased the number of rods within both the ventral and dorsal segments of the eye by 4 days of development. By treating zebrafish embryos with citral, a competitive inhibitor of a dehydrogenase that converts endogenous retinaldehyde to retinoic acid within the ventral segment of the retina, a dose dependent decrease of rod photoreceptor differentiation was observed. These treatments generated only slight effects upon the histogenesis of the uv-light sensitive photoreceptor cells.

## 611.11

POSTNATAL EXPRESSION OF DEVELOPMENTALLY REGULATED MOLECULES IN CULTURED MOUSE RETINA. Zhi-Ping Mi\*, and C. Lagenaur Dept. Neurobio., Univ. Pittsburgh, Pittsburgh, PA 15261.

Our earlier studies identified retinal cell surface molecules that defined important developmental events in vivo. To determine if these molecules are similarly expressed in vitro, we stained postnatal retina cultures with M6, L1, M4(Thy-1) and NGP-1 antibodies. In culture, over 90% of the cells were M6 positive. One population of M6 positive cells had relatively flat cell bodies with a dandelion-like morphology and may be glial cells or progenitors. The second group of M6 positive cells were cluster of small spherical cells with few processes. Occasionally, M6 immunoreactivity was also seen on isolated round cells without processes. In contrast, L1 staining was found on relatively few cells. These L1-positive cells had two or three long processes. In addition, both L1 and M4 were found on large dying cells with the immunoreactive remnants surrounding the cell bodies, indicating that the cells had been undergoing degeneration. NGP-1 is a newly identified antibody that recognizes a subset of neural glycoproteins and stains apical region of rod photoreceptors in vivo. It stained a type of small cells in vitro with one or rarely two processes. Most of these cells had an apical cilium known to be one of the characteristics of cultured photoreceptor cells. To further define the staining by NGP-1, we used Ret P1, a marker for photoreceptors to compare the staining pattern to that of NGP-1. We found that almost all the NGP-1 positive cells were Ret P1 positive, although about two-thirds of the Ret P1 positive cells were NGP-1 negative. NGP-1 may recognize subpopulation or maturational state of photoreceptors.

## 611.13

EXPRESSION OF GAP-43 IN THE RETINA OF RATS FOLLOWING PROTRACTED ILLUMINATION. J. J. López Costa\*, J. Goldstein and J. Pecci Saavedra. Instituto de Biología Celular y Neurociencias "Prof. E. De Robertis". Fac. de Med., Univ. de Buenos Aires, Argentina.

Neuronal expression of the Growth Associated Protein-43 (GAP-43) has been reported in developmental and regenerative stages of the CNS, including the normal retina. Continuous illumination produces degeneration of photoreceptors, which is reversible after an adequate period of darkness.

Distribution of GAP-43 in the retinas of rats during the regenerative period after continuous illumination (12000 LUX during 8 days) was studied in 30/35-days Wistar rats, followed by different darkness periods. Retinas were fixed by perfusion with a 4% paraformaldehyde solution, in phosphate buffer, immediately after the period of illumination or after 2, 10 or 20 days of total darkness. Criostat sections were immunocytochemically stained with antibodies to GAP-43 (generously provided by G. Wilkin) (dil. 1:5000), sheep anti-rabbit IgG (Sigma) and rabbit peroxidase anti-peroxidase IgG complex (Sigma).

GAP-43 Immunoreactivity was detected in the outer segment of photoreceptor membranes and in the plexiform layers in all observed retinas. It was maximum in the outer segments of rats kept in total darkness for 10 days and decreased thereafter, while in the plexiform layers a delicate plexus of fibers with a minimum of immunolabelling was found at 10 days and recovered the original parameters at 20 days. In both cases staining stabilized at 20 days.

We conclude that the described changes in GAP-43 expression could indicate the participation of the protein in plastic changes occurring in photoreceptor outer segments and across plexiform layers.

## 611.15

BDNF ENHANCES DIFFERENTIATION OF NEURONS OF THE ROD PATHWAY IN ORGANOTYPIC CULTURES OF NEONATAL RAT RETINA. Dennis W. Rickman\*. Department of Ophthalmology, Anheuser-Busch Eye Institute, St. Louis University, St. Louis, MO 63104.

We have previously shown that the high-affinity neurotrophin receptors, *trkA* and *trkB*, are expressed in ganglion cells and in some cells of the inner nuclear layer (INL) of the developing rat retina. We have also shown that intraocular treatment with an antisense oligonucleotide targeted to *trkB* mRNA in the developing retina alters the expression of parvalbumin (PV)-immunoreactivity (IR), a morphological marker for the narrow-field, AII, amacrine cell in the rod pathway. The present studies examined the effects of nerve growth factor (NGF) and brain-derived neurotrophic factor (BDNF), the primary ligands for *trkA* and *trkB*, respectively, on neuronal differentiation in explant cultures of neonatal rat retina. Neonatal retinas were explanted onto laminin-coated inserts and cultured in media supplemented with NGF (Boehringer Mannheim) or BDNF (Regeneron, Inc.). After 15 days in culture (a time that represents eye opening *in vivo*), cultures were fixed and either embedded in Epon or cryosectioned and processed for immunohistochemistry using antibodies to parvalbumin (PV) and protein kinase C (PKC), a marker for the rod bipolar cell. Analyses showed that explants treated with either NGF or BDNF displayed well-defined nuclear and plexiform layers, as well as inner and outer limiting membranes. Ganglion cells, however, were sparse. PV-IR in NGF-treated cultures revealed the presence of well-stained horizontal cells and occasional lightly-stained cells in the proximal INL; weak PKC-IR was present in a few cells in the outer INL. In BDNF-treated cultures, PV-IR showed well-stained horizontal cells and also numerous robustly-labeled cells in the proximal INL and their processes in the inner plexiform layer (presumed AII amacrine cells). Furthermore, PKC-IR was strong, labeling numerous bipolar cell somata in the outer INL, as well as their radially-oriented processes. These results suggest that BDNF enhances the expression of specific neurochemical phenotypes in a well-defined retinal circuit during the postnatal period.

## 611.12

NUMBERS AND DISTRIBUTIONS OF LARGE RETINAL GANGLION CELLS IN THE FROG: CORRELATION WITH MYELINATION OF OPTIC AXONS: <sup>1</sup>S.A. Dunlop\* and <sup>2</sup>D.E. Playford <sup>1</sup>Dept. Zoology, University of Western Australia and <sup>2</sup>Current address: Dept. Neuroscience, McGill University, Canada.

In the optic nerve of the adult frog *Litoria moorei*, 3% of axons are myelinated. These axons acquire myelin in a biphasic pattern (1). The first phase is complete at metamorphic climax and the second in fully mature adults. Both phases result in optic axons being myelinated along their length, but for most of tadpole and post-metamorphic life, many axons are myelinated only partway. Cresyl-violet stained retinal whole-mounts were used to determine whether, as in cat (2), numbers of large retinal ganglion cells correlated with myelinated axon counts. We studied 2 and 6 month tadpoles, animals at metamorphic climax, 5 and 7cm (body length) frogs and 9cm adults, thus encompassing both phases of myelination. Tadpoles were anaesthetised in MS222 (immersion, 2%) and post-metamorphic animals with Saffan (0.4-0.6 ml; 1.8mg/g Alphaxalone, 0.6mg/g Alphadolone acetate, ip). At all stages, there was a distinct population of pale staining large cells (range  $x \pm$  sd:  $11.6 \pm 2.1$ - $12.5 \pm 1.7 \mu m$ ); the remaining cells were darker and smaller (range  $x \pm$  sd:  $5.7 \pm 1.2$ - $7.9 \pm 1.5 \mu m$ ). The correlation ( $r^2 = 0.99$ ) of large cell totals with peak values of myelinated axons (1) suggests that large cells give rise to myelinated axons and that these cells assume a large size even if their axons are only myelinated partway along their length. Analysis of cell densities revealed a regular mosaic of large cells at all stages but a changing distribution of the total cell population as the area centralis and visual streak emerged. The pan-retinal increase in densities of large cells at metamorphic climax indicated the late maturation of a large cell class with myelinated axons, a phenomenon which also occurs in *Rana pipiens* (3).

Development of Tyrosine Hydroxylase Immunoreactive (TH-I)

Amacrine Cells in Primate Retina. AE Hendrickson\*<sup>1</sup>, A Erickson<sup>1</sup> and JM Provis<sup>1,2</sup>, Dept Biological Structure<sup>1</sup>, Univ. Washington, Seattle, WA 98195 and Depts Anatomy and Histology and Clinical Ophthalmology<sup>2</sup>, Univ. Sydney, N.S.W. 2006, Australia.

The appearance of TH-I was correlated with birthdates of amacrine cells in primate retina. Pregnant *M. fascicularis* monkeys were injected twice with 5mCi/kg tritiated thymidine 1 hour apart on embryonic day (E)42, E43, E47, E55, E57 or E72. Fetuses or infants were sacrificed between E112 and P11mo. Frozen sections including the entire horizontal meridian were stained for TH-I which was visualized with diaminobenzidine and then coated for autoradiography. Frozen sections from twenty-four other fetal monkey retinas between E45 and P6weeks were also stained for TH-I.

Large TH-I+ somas first appeared at E60 in the inner nuclear layer (INL) of the developing fovea. By E70 numerous intensely TH-I somas were present in foveal retina and pale TH-I+ somas extended to the optic disk with a TH-I plexus in s1 of the central IPL at E74. By E97 heavily TH-I large cells and the s1 plexus extended throughout much of peripheral retina with smaller pale TH-I cells in far periphery. At E115 both cells and plexus reached the retinal edge. TH-I double-labeled cells born at E57 are located in mid-peripheral retina at E105. The preliminary data suggest that TH-I amacrine cells are some of the first amacrine generated, but TH-I does not appear until 2-3weeks later. Supported by EY04536 and Research to Prevent Blindness, Inc.

## 611.16

SUPPRESSION OF *trkB* EXPRESSION BY ANTISENSE OLIGONUCLEOTIDES ALTERS NEUROCHEMICAL PHENOTYPES IN THE DEVELOPING RAT RETINA. C. Bowes Rickman\* and D.W. Rickman. Department of Ophthalmology and Anheuser-Busch Eye Institute, St. Louis University, St. Louis, MO 63104.

Brain-derived neurotrophic factor (BDNF) has a purported role in retinal neuronal development. Since considerable neuronal differentiation in the rodent retina occurs postnatally, transgenic mice in which BDNF or its high-affinity receptor, *trkB*, have been "knocked out" are of limited use because they die shortly after birth. Therefore we have designed a strategy to selectively block expression of *trkB* in the postnatal retina in order to assess the role of BDNF in its neurochemical differentiation. Phosphorothioated oligonucleotides were generated in sense and antisense orientations and injected intraocularly into neonatal Sprague-Dawley rats following a defined regimen. On postnatal days 10-15, animals were sacrificed and retinas were processed for immunohistochemistry using antibodies to *trkA* and *trkB*. Alternatively, retinal RNA was extracted for Northern blot analysis using <sup>32</sup>P-labeled probes for *trkB*. Retinas were also analyzed for expression of specific neurochemical phenotypes using antibodies to parvalbumin (PV) and protein kinase C (PKC), markers for the narrow-field, AII, amacrine and the rod bipolar cell, respectively. In retinas treated with sense oligonucleotides, both *trkA*- and *trkB*-immunoreactivities (IR) were present in numerous cells in the ganglion cell and inner nuclear layers (INL) and in fibers in the inner plexiform layer (IPL) and nerve fiber layer. In *trkB* antisense-treated retinas, *trkB*-IR was unchanged, while *trkA*-IR was greatly reduced. Northern blot analysis showed that *trkB* mRNA transcription was not affected in antisense-treated retinas. In controls, PV-IR labeled numerous cells in the proximal INL and their fibers in the IPL (presumed AII amacrine cells); PKC-IR labeled numerous cells in the distal INL and their radially-oriented fibers (rod bipolars). In *trkB* antisense-treated retinas, PV-IR and PKC-IR were decreased in both the numbers of cells stained and in staining intensities. These data suggest that the ligands for *trkB* influence the neurochemical differentiation of specific neurons of the rod pathway.

## 611.17

REORGANIZATION OF RETINAL AXONS IN THE OPTIC FISSURE OF THE CHICK. U. Rager and G. Rager\*. Institute of Anatomy, University of Fribourg, CH-1700 Fribourg, Switzerland.

From the data of our earlier tracer study (Rager et al., Anat. Embryol. 179, 135-148, 1988) we postulated that the organization of retinal fibers is transformed in the optic fissure. In order to analyze the rules according to which the reorganization of fibers takes place in the optic fissure, we injected Dil and DiA into various sites of the retina in chick embryos and in adult chicks. The position of the injection sites was determined by measuring their polar coordinates with respect to the coordinate system defined by the longitudinal axis of the optic fissure and a line which was set perpendicular to this axis at the apex of the optic fissure.

The results show that axons originating in an early formed ganglion cell field (Rager et al., J. Comp. Neurol. 334, 529-544, 1993) enter the optic fissure near its apex, axons originating from later formed ganglion cell fields enter it further ventrally. Thus, the time of origin of retinal axons is represented along a dorsoventral gradient in the optic fissure, i.e. axons are organized chronotopically in the optic nerve head. They form bands which are slightly curved ventrally and resemble crescents as we have observed them earlier in the embryonic period. Axons originating in the peripheral temporal retina stay on the same side in the nerve. Axons originating in the peripheral nasal retina cross to the other side. They are represented in the temporal periphery of the nerve and overlap with peripheral temporal axons. Although axons are organized chronotopically in the optic fissure, an additional process may be required to sort out temporal and nasal fibers. Supported by Swiss N.S.F. grant 31-36468.92.

## 611.19

DEVELOPMENTAL CHANGES IN THE PATTERN OF CORRELATED SPONTANEOUS BURSTING ACTIVITY IN THE FERRET RETINA. K.R. Fischer, D.M. Oakley and R.O.L. Wong\*. Dept. of Anatomy and Neurobiology, Washington Univ. Sch. Med., St. Louis, MO 63110.

Ganglion cells (GCs) of the neonatal ferret retina undergo periodic spontaneous increases in intracellular calcium levels prior to eye-opening (postnatal day, P30). Calcium waves, composed of correlated bursts of neighboring cells, propagate across the retina. With increasing age, cells participate in the waves to varying degrees. We are examining whether the degree of participation of GCs in the waves reflect their class or subclass ('on' or 'off'), and which physiological changes account for these variations. Using calcium imaging techniques, the activity of GCs was recorded between P1 and P24, and bursting cells were classified after intracellular dye filling.

Between P1 and P24, every wave involved  $\alpha$ ,  $\beta$ , and  $\gamma$  classes of GCs, but the bursting patterns of each cell class changed with age. Neighboring presumed 'on' and 'off'  $\beta$  GCs, classified by their dendritic stratification, participated in every wave between P9 and P16. However, presumed 'on' and 'off'  $\beta$  GCs differed in the degree to which they participated in the waves at P21 and P24. The age-related changes among cell types was also reflected in the effects of bicuculline, a GABA<sub>A</sub> receptor antagonist, and adenosine on the waves. Between P1 and P14, bicuculline (100  $\mu$ M) blocked the bursting of most GCs, while it was less effective at P21. Likewise, most cells at P1-P14 responded to adenosine (50-100  $\mu$ M) with a 2-5 fold decrease in their interburst intervals, but only a subpopulation of cells responded to adenosine in this manner at P21.

Maturation of the physiological properties and connectivity of retinal cells is likely to underlie the age-related changes in the waves.

## 611.18

FORM DEPRIVATION MYOPIA (FDM) IN THE CHICK RETINA - A PHARMACOLOGICAL INVESTIGATION OF THE OPIATE AND NMDA SYSTEMS. R.L.P. Seltner and W.K. Stell\*. Lions Sight Centre/Dept. of Anatomy, Faculty of Medicine, University of Calgary, Calgary, Alberta, CANADA T2N 4N1

Form-deprivation myopia (FDM) is characterized by increased axial and equatorial eye length, increased eye weight and large negative refractive error. It can be induced in hatching chicks by monocular application of a goggle which blurs the image to the retina. Induction of FDM leads to changes in the enkephalin containing retinal amacrine cells. Pharmacological studies were therefore undertaken to investigate the role of the opiate system in the genesis of FDM. The opiate antagonist naloxone blocked development of FDM in a dose-dependent manner when injected daily into the vitreous chamber, while the opiate agonist morphine had no effect on FDM at any dose tested. Opiate antagonists specific for  $\mu$  and  $\delta$  receptors had no effect on development of FDM. A  $\kappa$  specific antagonist reduced development of FDM by only a maximum of 50 %, while  $\kappa$  specific agonists completely eliminated development of FDM in a dose dependent manner. Naloxone was developed as a non-specific opiate antagonist. However, it has also been shown to be an ion channel blocker at the NMDA receptor (NMDA-R). The inconsistency between actions of naloxone and those of other opiate antagonists and agonists suggests that the naloxone induced prevention of FDM may occur as a result of antagonism at the NMDA receptor rather than opiate receptors. Two NMDA specific receptor antagonists were therefore tested: MK-801 and AP5 which act at the NMDA-R channel and at the glutamate site respectively. Both NMDA-receptor antagonists completely blocked development of FDM. **Conclusions:** The results of these studies suggest independent roles for both opiate and NMDA systems in the genesis of FDM. The opiate receptor agonists appear to prevent FDM via  $\kappa$  receptors. NMDA receptor antagonists also prevent FDM, suggesting that glutamatergic retinal pathways utilizing NMDA-receptors are instrumental in controlling ocular growth.

## 611.20

SELECTIVE LOSS OF ALPHA GANGLION CELLS IN THE POSTNATAL CAT RETINA CONTRIBUTES TO THE FORMATION OF MATURE DISTRIBUTION PATTERNS. G. Jeyarasasingam, G. M. Ratto\* and L. M. Chalupa, Section of Neurobiology, Physiology & Behavior, UC Davis, CA 95616.

We assessed the possibility that retinal ganglion cell loss during postnatal development contributes to the formation of orderly distribution patterns characterizing these neurons at maturity. The distribution and density of retrogradely labeled alpha cells in central regions of postnatal retinas (beginning at P12) were compared with those found in equivalent regions of mature retinas. This showed that the density of alpha cells was significantly greater in neonatal retinas (at P12: 27-34%) than at maturity. This density decrease reflects cell loss since the central region of the postnatal retina does not undergo significant expansion (Mastrorade et al., 1984). Nearest neighbor analyses revealed that alpha cells in the neonatal retina are distributed in a significantly different pattern than at maturity. Subtraction of adult nearest neighbor distributions from neonatal patterns indicated that the "excess" cells were differentially distributed within bins corresponding to the shortest distances from their neighbors. These observations indicate that selective alpha cell loss contributes to the formation of mature distribution patterns. (Supported by NSF IBN 94-12593)

## AXONAL REGENERATION II

## 612.1

DISRUPTION OF THE MYELIN-ASSOCIATED GLYCOPROTEIN (MAG) GENE IMPROVES AXONAL REGENERATION IN C57BL/WLD<sup>S</sup> MICE. M. Schäfer\*, M. Fruttiger, D. Montag, M. Schachner, and R. Martini. Department of Neurobiology, Swiss Federal Institute of Technology, Hönggerberg, 8093 Zürich, Switzerland.

It has recently been shown that the cell recognition molecule MAG is inhibitory for neurite outgrowth *in vitro*. These findings have been used to explain in part the poor regenerative capacity of injured myelinated tracts in CNS. Moreover, the unusually poor axonal regrowth into lesioned peripheral nerves of mouse mutants with abnormally slow Wallerian degeneration (C57BL/Wld<sup>S</sup> mice) has been attributed to the prolonged presence of MAG-positive structures in denervated nerve stumps. To test this hypothesis, we generated MAG-deficient C57BL/Wld<sup>S</sup> mice by cross-breeding C57BL/Wld<sup>S</sup> mice with mice deficient in the MAG gene. Axonal regeneration in crushed femoral nerves was assessed at the light- and electron microscopic levels by counting anterogradely labeled axons having regenerated into the first 2 mm of the distal nerve stumps at postlesion day 7. The number of regenerating axons in association with persisting, apparently intact myelin sheaths was increased in MAG-deficient C57BL/Wld<sup>S</sup> mice versus C57BL/Wld<sup>S</sup> mice expressing MAG. Thus, MAG could contribute to the poor substrate properties of intact myelin in peripheral nerves. Alternatively, N-CAM which is upregulated in MAG-deficient mice and/or other disregulated molecules could influence the axonal regeneration along myelinated fibers.

## 612.2

LACK OF EVIDENCE THAT THE MYELIN-ASSOCIATED GLYCOPROTEIN (MAG) IS A MAJOR INHIBITOR OF AXONAL REGENERATION. U. Bartsch, L. Schnell\*, S. Bartsch, D. Montag, M. Schwab<sup>1</sup> and M. Schachner\*. Dept. of Neurobiology, Federal Institute of Technology, Zürich, Switzerland and <sup>1</sup>Brain Research Institute, Univ. of Zürich, Switzerland

It has recently been suggested that the myelin-associated glycoprotein (MAG) inhibits axonal regeneration *in vivo*, since MAG interferes with neurite elongation from distinct nerve cell types at certain developmental ages (McKerracher et al., 1994; Mukhopadhyay et al., 1994). To test this hypothesis, we have analyzed regeneration in lesioned optic nerve and corticospinal tract of adult wild-type and MAG-deficient (Montag et al., 1994) mice. Length of regrowing axons in both fiber tracts distal to the lesion site was not significantly different between wild-type and mutant mice. In both fiber tracts, however, length of regrowing axons increased considerably after application of IN-1 antibodies (Schwab et al., 1993). Again, length of regrown axons in each fiber tract was similar for both genotypes. Strongest inhibitory activity of MAG *in vitro* has been demonstrated for small cerebellar neurons. Axons of these nerve cells are normally not myelinated. Therefore, small cerebellar neurons were cultured on optic nerve cryosections from adult wild-type and MAG-deficient mice. On both substrates, cerebellar neurons extended neurites of similar length. Together, our observations do not support the view that MAG is a significant inhibitor of axonal regeneration.

## 612.3

MAG INTERACTS WITH A NEURONAL SIALO-GLYCOPROTEIN TO AFFECT NEURITE OUTGROWTH. M.T. Filbin\*, M.E. de Bellard and S. Tang. Biology Dept., Hunter College, CUNY, New York, NY 10021

Depending on the age and the type of neuron, myelin-associated glycoprotein (MAG) can either inhibit or promote axonal regeneration. Neurite outgrowth from all post-natal cerebellar and from adult dorsal root ganglion (DRG) neurons is inhibited by 40-70% on MAG-expressing transfected Chinese hamster ovary (CHO) cells, while neurites from newborn DRG neurons are twice as long on MAG-expressing cells compared to on control cells. Furthermore, MAG binds specifically to a sialic acid residue attached to a neuronal glycoprotein in a 2,3 O-linkage, regardless of whether neurite outgrowth is promoted or inhibited. To determine if, like the binding, the effect of MAG on neurite outgrowth is dependent on its interaction with a sialo-glycoprotein on the neuronal plasma membrane, first, neurons were desialylated prior to comparing the neurite outgrowth on MAG-expressing and control cells, and, second, small sialic acid sugars were included in the co-cultures. The removal of sialic acid from the neuronal cell surface abolished completely the ability of MAG to promote neurite outgrowth from newborn DRG neurons. Similarly, the ability of MAG to inhibit neurite outgrowth from cerebellar neurons was reversed by about 50% if the neurons were desialylated prior to the neurite outgrowth assay. Two sialo-sugars were tested, 2,3 dehydro-2-deoxy-N-acetylneuraminic acid (DD NANA) and sialo-lactose. At 20 mM DD NANA completely blocked the promotion of neurite outgrowth from newborn DRG neurons by MAG and reversed the inhibition of neurite outgrowth from cerebellar neurons by 65%. Sialo-lactose, at 9 mM, blocked promotion by 80% and reversed inhibition by 40%. Lactose, as a control, had no effect. These results suggest that the effect of MAG on both promotion and inhibition of neurite outgrowth from neurons is mediated through a neuronal sialo-glycoprotein and that the specific binding we measure is, most likely, to the physiological receptor for MAG. Supported by the RCMI and NS 26242.

## 612.5

NEURITE GROWTH INHIBITORY SCARS ARE INDUCED IN NEWBORN SPINAL CORD BY LESION BUT NOT BY CYTOKINES AND GROWTH FACTORS.

M.E. Schwab\*, R. Schneider, L. Schnell. Brain Research Institute, University of Zurich, CH-8029 Zurich, Switzerland.

After partial transection of spinal cords of adult rats followed by injections of NT-3 or E14 spinal cord transplants, many regrowing corticospinal tract (CST) fibers end at glial scars (Schnell and Schwab 1993, Schnell et al. 1994). When we lesioned the growing CST in the thoracic spinal cord (postnatal day, P5) or the future CST area before the tract has reached the lesion site (P2) most of the CST fibers were again arrested at the small scar areas. In spite of an intact ventral gray and white matter, most of the growing or regenerating CST fibers were unable to circumvent the lesion. Microglia and astrocytes were activated at these lesion sites. In order to induce the expression of putative growth inhibitory scar constituents, various factors involved in inflammation and scarring reactions were injected into 2-day old rat spinal cords. Although they often produced microglia activation, neither LPS, IL-1, IFN $\gamma$ , TNF $\alpha$  and MIP1 $\alpha$ , nor CNTF, LIF, PDGF or FGF alone or in combinations arrested the growing CST fibers.

PURIFICATION OF A NEURITE GROWTH INHIBITOR FROM BOVINE CNS MYELIN. A.A. Spillmann, C.E. Bandtlow, F. Keller\* and M.E. Schwab. Brain Research Institute, University of Zurich, August-Forel-Strasse 1, CH-8029 Zurich, Switzerland.

Inhibitors of neurite growth play a substantial role in the development and regeneration of the nervous system. Two of them, NI-35 and NI-250, cause collapse of neuronal growth cones and strongly inhibit neurite growth *in vitro*. These low abundant proteins are associated with oligodendrocyte membranes and are present in the myelin sheath of the CNS in higher vertebrates. Previous studies have demonstrated both *in vivo* and *in vitro* that the monoclonal antibody (IN-1), which has been raised against NI-250, neutralizes the neurite growth inhibiting properties of differentiated oligodendrocytes and of CNS myelin, and allows regeneration of lesioned nerve fibers in the adult rat spinal cord and brain.

We report here the protein purification of an inhibitory protein of 250 kd starting with crude bovine spinal cord myelin and using various chromatography techniques in combination with three bioassays. The first two bioassays are screening assays which test the effect of different column fractions on the spreading of 3T3 fibroblasts and on neurite outgrowth of PC12 cells. The third bioassay tests for the collapsing activity on growth cones of primary rat dorsal root ganglion neurons. Using a five step purification protocol, which includes discontinuous flotation sucrose density centrifugation, strong anion exchange chromatography and size exclusion chromatography, a highly active protein fraction was obtained. The biological activity of this fraction is enriched 15000 fold, is fully neutralized by the monoclonal antibody IN-1 and shows one detectable band at 250 kd in the SDS-PAGE (silver stain). Microsequencing the gel eluted protein band reveals an amino acid sequence which could not be found in SwissProt and GenEMBL data bases.

Present Address: Laboratory of Neuroscience, Libero Istituto Universitario Campus Bio-Medico, 00155 Roma, Italy.

## 612.4

DISCOVERY OF A BRAIN-DERIVED PEPTIDE, WHICH PROVIDES A BIOCHEMICAL BASIS FOR IMMUNE PRIVILEGE AND THE EVOLUTIONARY LOSS OF CNS REGENERATION. P. Beserman, D.L. Hirschberg and M. Schwartz\*. Dept. of Neurobiology, Weizmann Institute of Science, Rehovot, Israel.

The evolutionary basis for the loss of the ability of mammalian CNS to regenerate is not known. One of the features of regeneration failure is an inadequate posttraumatic macrophage response. We have recently shown that this impairment of macrophage response is due, at least in part, to a CNS-resident inhibitor of macrophage migration. We here identify the inhibitor as a CNS endogenous peptide and demonstrate its presence in the CNS, but not in the PNS of mammals. It is possible that this peptide provides the mammalian CNS with an immune brain barrier (IBB), in addition to the evolutionarily early barrier, the blood brain barrier (BBB). The presence of this inhibitor in the CNS may underlie the poor ability of macrophages to invade the CNS, thus providing a molecular link between the well-known phenomenon of immune privilege and poor regeneration in the CNS. Since communication of an injured nerve with the immune system is probably an early event, possibly governing all subsequent steps in regeneration, it may be possible to enhance the regenerative capacity of the mammalian CNS by creating a temporary breach in this immune barrier.

## 612.6

INDUCTION OF MITOSIS BY TRANSECTION INJURY MAKES SCHWANN CELLS SUSCEPTIBLE TO CHEMOTHERAPEUTIC CYTOTOXICITY. D.A. Wittrock, X. Sun\* and A.J. Windebank. Molecular Neuroscience Program, Mayo Foundation, Rochester, MN.

Chemotherapeutic neurotoxins produce axonal injury and do not damage myelin nor stable adult Schwann cells (SC). Axonal injury results in Wallerian degeneration which induces a wave of Schwann cell division. The mitotic Schwann cell is then potentially susceptible to cytotoxic effects. SC may be a source of trophic or guidance factors for regenerating axons. Loss of SC may retard recovery from neurotoxic injury. To test this hypothesis, we treated 250 g rats with fluorodeoxyuridine (FUDR, 1 mg/kg daily i.p.) or saline control for one week and then crushed the left sciatic nerve at the notch. Treatment was continued for 4 weeks. Two weeks and 4 weeks later, near nerve conduction velocities and amplitudes were measured. After 4 weeks, animals were euthanized, nerves removed, fixed, and embedded. 0.75  $\mu$ m sections prepared for morphometric analysis.

Nerve action potential amplitudes and conduction velocities ( $8.2 \pm 3.2$  vs.  $0.01 \pm 0.01$  msec $^{-1}$ ;  $p=0.13$ ) were significantly reduced in FUDR treated animals at six weeks. Morphometric analysis of peroneal nerve at the knee showed a small reduction of mean of myelinated fiber (MF) number per nerve (controls,  $3789 \pm 125$  vs. FUDR,  $3509 \pm 267$   $p=0.23$ ). Means of median MF fiber diameter ( $3.89 \pm .24$  vs.  $3.37 \pm .15$   $\mu$ m;  $p=0.37$ ) mean of median axon diameter ( $2.26 \pm .09$  vs.  $2.01 \pm .07$   $\mu$ m;  $p=0.27$ ) and mean of median myelin thickness ( $1.76 \pm .07$  vs.  $.63 \pm .04$   $\mu$ m;  $p=0.49$ ) were all significantly reduced in FUDR treated animals. There was no significant difference between the corresponding uncrushed nerves. FUDR ( $10^{-6}$  to  $10^{-3}$  M) has no effect on axonal growth rate from DRG neurons *in vitro*.

**Conclusions.** FUDR is not toxic to the normal PNS and has no direct effect on axonal growth. Regeneration after crush injury is significantly retarded by FUDR treatment because of loss of trophic support from SC (supported by NS14304).

## 612.8

REGULATION OF ANDROGEN RECEPTOR mRNA EXPRESSION IN ADULT HAMSTER FACIAL MOTOR NEURONS (FMN). S.M. Drenth\*, R.J. Handa, K.J. Jones. Dept. of Cell Biology, Neurobiology and Anatomy, Loyola University Chicago, Maywood, IL 60153.

We have previously shown that exogenous testosterone propionate (TP) differentially regulates both the rate of facial nerve regeneration after injury and androgen receptor (AR) mRNA levels in FMN of both intact and gdx male/female hamsters. Since TP can be converted to estrogen by endogenous aromatization, it is possible that a component of the steroid regulation of AR mRNA in FMN could be due to estrogen. In this study, we examined regulation of AR mRNA in FMN by the non-aromatizable androgen, dihydrotestosterone (DHT). Four groups of hamsters, intact and gonadectomized (gdx), males/females, were implanted with DHT capsules for 0, 1, 2, or 7 d. *In situ* hybridization was performed using an  $^{35}$ S-labeled antisense AR cRNA probe (encoding 350 NTs of the ligand binding domain). Unlike our previous studies using TP, DHT was effective in rapidly upregulating AR mRNA only in intact female rats. These data demonstrate a sex difference in the regulation of AR mRNA which is dependent on the presence of the gonad, and support the hypothesis that there is a synergism between androgen and estrogen in regulating AR mRNA in FMN. Studies are in progress to evaluate the interactive effects of hormonal/injury states on AR mRNA expression in HFMN. Supported by NIH grant NS28238.

## 612.9

REGENERATION OF SEPTO-HIPPOCAMPAL CHOLINERGIC FIBERS AND EXPRESSION OF CELL ADHESION MOLECULES IN THE ADULT RAT BRAIN. I. Aubert\*, J.-L. Ridet and F.H. Gage. Salk Institute, Laboratory of Genetics, La Jolla, California 92037-1099.

Cell adhesion molecules (CAMs), such as polysialylated NCAM (PSA-NCAM) and nerve growth factor inducible large external glycoprotein (NILE), are thought to play an important role in cell migration, axonal growth and guidance, as well as maintenance of stable contact between cells. In the present study, we investigated the immunoreactivity of PSA-NCAM and NILE in relation to choline acetyltransferase (ChAT) and glial fibrillary acidic protein (GFAP) in adult rats which received unilateral aspirative lesions of the fimbria-fornix and implantation of bridging grafts containing either  $\beta$ -galactosidase ( $\beta$ -gal) or nerve growth factor (NGF)-producing fibroblasts. The relationship between CAMs and neuronal or glial cells is investigated by confocal and electron microscopy. After two weeks survival, PSA-NCAM, NILE and GFAP immunoreactivities are observed in the host tissue surrounding the  $\beta$ -gal or NGF grafts. One month post-operation, PSA-NCAM, NILE and GFAP positive fibers start to invade the NGF, but not the  $\beta$ -gal, producing grafts. After two months survival, most of the surface of NGF grafts is filled with PSA-NCAM and ChAT positive fibers. The  $\beta$ -gal grafts do not contained significant amount of PSA-NCAM and ChAT immunoreactivity. In contrast to PSA-NCAM and ChAT, NILE and GFAP positive fibers are limited to the periphery of the NGF grafts. Simultaneous labeling of PSA-NCAM, NILE, ChAT and GFAP suggest that in the NGF grafts, at all time points, PSA-NCAM, NILE, ChAT, and GFAP positive fibers are in close association in the host tissue and in the periphery of the graft. However, at two months post-operation, only PSA-NCAM and ChAT positive fibers are present in significant amounts in the center of NGF grafts. The results suggest that PSA-NCAM and NILE, along with reactive astrocytes, are permissive substrates for regeneration of cholinergic fibers in presence of NGF. NERVE DERIVED SCHWANN CELLS PRODUCE ACETYLCHOLINESTERASE. B. Haesaert, S. Rotshenker, R. Cohen and L. Anglister\*. Dept. of Anatomy, The Hebrew University Medical School, Jerusalem, Israel.

Acetylcholinesterase (AChE) is highly concentrated at the neuromuscular junctions (NMJs) and appears in several molecular forms: A12, G1, G2 and G4. It is not clearly understood which cell type(s) (nerve, muscle or Schwann) produce and deposit AChE at NMJs. All forms of AChE can be extracted from intact peripheral nerves that innervate muscle. The A12 isoform is carried by fast anterograde axonal transport, thus suggesting its neural origin. The major AChE isoform detected in peripheral nerves undergoing Wallerian degeneration (WD), thus lacking axons, is G4. The G1 and G2 are detected to a much lesser extent and A12 is nondetectable. To examine whether the Schwann cells that reside in the WD nerves produce G4 we studied AChE production in nerve-derived Schwann cell cultures. Fourteen days WD-frog sciatic nerves were dissociated and highly enriched Schwann cell cultures (>95%) obtained (modified after Reichert et al., J. Neurosci. 14:3231-3245, 1994). Schwann cell cultures contained AChE activity, extracted primarily as globular forms G4, and to a lesser extent as G1 and G2. These AChE isoforms could have been synthesized by Schwann cells or acquired by them by phagocytosis of degenerating axons. To determine which is the case, Schwann cells were first exposed to DFP to inhibit irreversibly all AChE present in them. Then, after 4-10 days in culture Schwann cells were analyzed for AChE activity and immunostaining. Newly synthesized AChE, mainly the G4 species, was extracted. Thus, nerve derived Schwann cells produce G4 isoforms. (Supported by Israel Acad. Sci.- Revson Found. 675/94).

SPATIAL CONTROL OF NEURONAL CELL ATTACHMENT AND NEURITE OUTGROWTH BY LIGHT-INDUCED IMMOBILIZATION OF A LAMININ-DERIVED PEPTIDE. J.-F. Clémence<sup>1</sup>, J.P. Ranieri<sup>2</sup>, P. Aebischer<sup>2</sup>, H.R. Lüscher<sup>3\*</sup> and H. Sigrist<sup>1</sup>. <sup>1</sup>Institute of Biochemistry, University of Berne, Berne, Switzerland. <sup>2</sup>Division of Surgical Research, Lausanne University Medical School, Lausanne, Switzerland. <sup>3</sup>Institute of Physiology, University of Berne, Berne, Switzerland.

Tissue engineering in the nervous system requires topical organization of cells in three dimensions (3-D). Photolabel-derivatized, bioactive laminin fragments were synthesized, characterized, and photoimmobilized onto biocompatible materials. Laminin-derived CDPGYIGSR was thermochemically coupled to either diazirine or benzophenone photo crosslinker. Covalent high-resolution (20 and 300  $\mu$ m) patterning of CDPGYIGSR to hydroxylated fluorinated ethylene propylene (FEP-OH), poly(vinyl alcohol), and glycophasic glass was achieved. Radiolabeled, photolabel-derivatized peptide patterns were visualized by autoradiography. The cellular interaction of photoimmobilized CDPGYIGSR was demonstrated by the selective, receptor-mediated attachment of NG 108-15 neuroblastoma-glioma cells. On peptide-patterned FEP-OH membranes, NG 108-15 cells differentiated within one day. Specific cell attachment to immobilized CDPGYIGSR was assessed through competitive binding studies. Further, an extracellular matrix analogue was developed on agarose as 3-D scaffold. Agarose provided the chemical basis for functionalization, and the physical support for neurite extension from primary cells. Typically selective peptide immobilization of agarose gels in 3-D was explored with benzophenone-modified CDPGYIGSR using an argon laser light source. The 3-D functionalization of agarose hydrogels sets the basis for spatially addressable directed neurite outgrowth *in vitro* and *in vivo*.

## TRANSPLANTATION: GROWTH FACTORS

MODULATION OF O-2A PROGENITOR CELLS IN THE RAT CERVICAL SPINAL CORD BY EX VIVO GENE DELIVERY OF PLATELET DERIVED GROWTH FACTOR. E. Noel\*, A. Ichiji, S. Sakuma, M. Weil and P.J. Tofilon. Dept. of Experimental Radiotherapy, MD Anderson Cancer Center, Houston, TX 77030.

A target cell population for radiation-induced spinal cord myelopathy is considered to be the oligodendrocyte-type 2 astrocyte (O-2A) progenitor. The loss of the reproductive potential of these cells after irradiation leads to a depletion of functional oligodendrocytes and ultimately demyelination. Platelet derived growth factor (PDGF) enhances the proliferation and migration of O-2A cells. To increase or replenish the O-2A cells in the cervical spinal cord, we have begun to develop an ex vivo gene therapy approach for delivering PDGF. Initial studies using recombinant Rat-1 fibroblasts expressing  $\beta$ -galactosidase indicated that cells injected into the cisterna magna of adult rats localized in the subarachnoid space of the brain stem and cervical spinal cord. The effects of cisterna magna injection of recombinant fibroblasts expressing PDGF A chain on O-2A progenitors were evaluated using an excision/clonogenic assay. In this procedure the cervical spinal cord is disaggregated, seeded onto a monolayer of astrocytes and the number of O-2A colonies (A2B5+) determined 3 weeks later. The number of O-2A colonies was increased by 4 days after injection of the PDGF expressing cells reaching a maximum (approximately 2-fold over sham injected rats) by 8 days. These data indicate that the implantation of PDGF expressing cells into the cisterna magna can increase the number of O-2A progenitors in the rat cervical spinal cord and suggest that the cell-mediated delivery of growth factors may be used in the treatment of demyelinating disorders.

## 613.2

AN ALTERNATIVE TO THE REPLACEMENT THERAPY IN THE TREATMENT OF THE EFFECTS OF BRAIN NEURONS DEGENERATION. A. Ennaceur\*, S.M. Ennaceur, P. Monmaur, Univ. Durham, Dept Psychol., South Road, England & Univ. Paris 7, Lab. Psychopharmacol. & Cognit. Process, Place Jussieu, Paris 5, France.

It has been reported that lesions of the basal forebrain cholinergic neurons prevent the hippocampus and the frontal cortex from their main input of Acetylcholine (ACh) and produce memory dysfunction. Neuropharmacological studies of memory have generally focused on the properties of the damaged neurons and tried to replace them either by increasing the release of ACh from the remaining neurons or by implanting a graft that provide new inputs to the target of the lesioned neurons. Nobody have paid attention to the fact that there are many adaptive changes that follow a brain damage, among which the target of the degenerated neurons may increase in number, size or change their affinity. Furthermore, there are other neurons that were acting presynaptically and deprived from their main target by the lesion. It is not clear how to increase the release of ACh from mostly lacking pre synaptic neurons and stimulate their post synaptic target. Furthermore, the acetyl cholinesterase inhibitors and the muscarinic agonists are often applied too late after the damage and for a short lasting duration. The projections sent by a graft also reach their targets too late. We suggest here a new alternative to the replacement strategy: the post synaptic targets of the lesioned neurons should be maintained "normal" by an immediate and continuous stimulation (osmotic minipump) that prevent their adaptation to the new environment induced by the lesions. Therefore, if a graft is implanted and succeed in sending new projections, these will find a "normal" target to bind to.

## 613.3

THE CHRONICALLY INJURED SPINAL CORD EXHIBITS RESPONSIVENESS TO NGF DELIVERED LOCALLY BY GENE THERAPY. M.H. Tuszynski<sup>1,2</sup>, R. Gorsline<sup>1</sup>, Y. Nakahara<sup>1</sup>, F. Gage<sup>3</sup>, A. Rosetti<sup>1</sup>, K. Murai<sup>1</sup>. <sup>1</sup>Dept Neurosciences, Univ Calif-San Diego, La Jolla, CA, 92093; <sup>2</sup>VA Med Ctr, San Diego, CA. <sup>3</sup>Salk Institute, La Jolla, CA.

Previously we reported that grafts of NGF-secreting genetically modified fibroblasts into the acutely injured spinal cord elicited outgrowth from local spinal sensory and motor neurites. In the present experiment, we determined whether these neuritic populations retained NGF responsiveness after chronic injury.

Primary Fischer 344 rat fibroblasts were transduced with MLV retroviral vectors to produce human B-NGF. *In vitro*, transduced cells secreted 2 ng NGF/hr/10<sup>6</sup> cells.

Adult Fischer 344 rats underwent spinal dorsal hemisection lesions at the T7 level. 6 weeks later, the spinal injury site was re-exposed and NGF-secreting fibroblasts (n=7) or control, uninfected fibroblasts (n=3) were grafted in collagen gels into the lesion cavity. 4 weeks later, NGF-secreting grafts were extensively penetrated by neurofilament-, p75-, and CGRP-immunolabeled fibers. Control grafts contained significantly fewer neurites. ChAT-labeled fibers did not penetrate either NGF- or control grafts. Thus, sensory neurites continue to exhibit NGF responsiveness after chronic injury, whereas local motor neurites do not. Temporal changes in neurotrophin receptor expression after injury in relation to neuritic responses to NGF are being examined. Some neuritic populations maintain neurotrophin responsiveness in the chronically injured spinal cord, providing a potential means of promoting axon regeneration.

## 613.5

SPECIFIC HEPARAN SULFATES CAN POTENTIATE THE EFFECTS OF FGF-1 ON NEURONAL DEATH AFTER EMBRYONIC TRANSPLANTION

S.D. Portbury, S.J. Royal, M.D. Ford and V. Nurcombe\*, Dept. of Anatomy and Cell Biology, University of Melbourne, Parkville Vic., Australia 3052.

Embryonic transplants have been extensively used over the last few years in order to ameliorate the death of neurons in many neurological disease models. Generally these models have indicated that very early embryonic cells transplant much better than neurons of differentiated phenotype. Recently it was found that fetal dopaminergic neurons grafted in conjunction with cells engineered to express high levels of FGF-2 survived in up to 10 times greater numbers than dopaminergic neurons alone, indicating that FGF-2 may be an important co-factor for the successful integration of transplanted cells [1]. We have successfully isolated FGF-specific heparan sulfates [2] from neural precursor cells and shown them to be an absolute requirement for the binding of FGFs to their high affinity receptors. The aim of this work was to transplant an FGF-1 producing cell line, created by inserting full length FGF-1 coding region cDNA into the murine neuroepithelial cell line 2.3D [2], into the ventricular space within the optic tectum of the embryonic chick, with or without increasing concentrations of specific heparan sulfate, and monitor the effects on developing neuronal populations. Much greater levels of FGF-1 were able to reach susceptible neuronal compartments when presented to the embryo in conjunction with heparan sulfate, confirming a protective role for the sugar. Significantly greater numbers of motor neurons within the lumbar spinal cord of the embryo were able to survive the period of normal histogenetic death when the FGF-1 was presented to the neurons in conjunction with their appropriate heparan sulfate co-factor. The heparan sulfates may therefore have important uses in controlling the survival of neuronal cells responsive to FGF-1 in a transplantation paradigm.

## 613.7

EFFECTS OF BDNF INFUSION ON LOCOMOTOR BEHAVIOR AND DOPAMINE NEURITE OUTGROWTH FROM FETAL MESENCEPHALIC TRANSPLANTS. S.J. Wiegand\*, C.A. Altar, K.D. Anderson, C. Alexander, M. Fritzsche, M. Juhasz, R.M. Lindsay and D.M. Yurek†. Regeneron Pharmaceuticals, Inc., Tarrytown, NY 10591 and †Dept. of Surgery/Neurosurgery, Univ. of Kentucky, Lexington, KY 40536.

Infusion of BDNF adjacent to grafts of fetal ventral mesencephalon (VM) enhances dopamine neurite outgrowth and augments the effects of the transplants on amphetamine-induced turning in hemiparkinsonian rats (Yurek et al, *Exp. Neurol.* 129:14, 1994). To determine if similar results obtain when BDNF is infused at a distance from the transplant, fetal VM (E14) were grafted into the medial or rostral striatum and BDNF (36 µg/d) or PBS was infused into the striatum 1-2 mm from the transplant site. Pumps were removed 4 weeks post-transplantation, and the animals allowed to survive for an additional 4-8 weeks. Grafted animals that received BDNF showed a complete amelioration of amphetamine-induced ipsiversive rotation, whereas grafted animals infused with PBS showed a modest improvement. Non-grafted animals that received BDNF or PBS showed no improvement, or a worsening of behavior. Grafts contained numerous tyrosine hydroxylase-positive (TH+) neurons in both PBS and BDNF-infused animals, and a plexus of TH+ fibers was apparent within the host striatum in the immediate vicinity of the transplants. When the BDNF infusion cannula was located within ~1 mm of the transplanted VM, a markedly enhanced outgrowth of TH+ neurites was seen, directed towards the cannula. No selective outgrowth of fibers in the direction of the cannula was noted in PBS-infused animals, or in BDNF-infused rats when the cannula was located >1.5 mm from the graft. Thus, transient infusion of BDNF produces a long-lasting change in the functional integration of fetal VM grafts, and can exert a tropic effect on dopamine neurite outgrowth.

## 613.4

TRANSPLANTATION OF POLYMER-ENCAPSULATED HUMAN NGF-SECRETING CELLS PROMOTES CHROMAFFIN CELL SURVIVAL AND BEHAVIORAL RECOVERY IN HEMIPARKINSONIAN RATS.

I. Date<sup>1</sup>, D.F. Emerich<sup>2</sup>, T. Ohmoto<sup>1</sup> and J.P. Hammang<sup>2</sup>. 1) Dept. of Neurological Surgery, Okayama University Medical School., Okayama 700, JAPAN and 2) CytoTherapeutics, Inc., Providence, RI 02906, U.S.A.

Encapsulated cell grafting is one approach for the delivery of neurotransmitters and/or neurotrophic factors into the brain. Baby hamster kidney (BHK) cells were genetically modified to secrete high levels of human nerve growth factor (BHK-hNGF). Following polymer encapsulation, the NGF-secreting devices were implanted into the left lateral ventricle or into the left striatum 1.5 mm (in both cases) from co-grafted rat adrenal medullary chromaffin cells in hemiparkinsonian rats. Although the animals receiving chromaffin cells alone or chromaffin cells with intraventricular hNGF-secreting devices did not show recovery from apomorphine-induced rotational behavior, the animals receiving chromaffin cells with intrastriatal hNGF-secreting cell implants showed a significant reduction in rotational behavior 2 and 4 weeks after transplantation. Histological analysis revealed that in animals receiving chromaffin cells and an intraventricular hNGF-secreting device, there was an approximately 5-6 fold increase in chromaffin cell survival (TH-IR) when compared to animals receiving chromaffin cells alone. In contrast, in those animals receiving chromaffin cell grafts together with intrastriatal hNGF-secreting devices, the number of surviving chromaffin cells that were TH-IR was more than 20 times higher than in animals receiving adrenal medullary cells alone. Analysis of retrieved capsules revealed that hNGF continued to be released by encapsulated BHK-hNGF cells after 4 weeks *in vivo*. These results indicate the potential use of intrastriatal implantation of encapsulated hNGF-secreting cells for augmenting the survival of co-grafted chromaffin cells.

## 613.6

OPTIMAL EFFECTS OF EXOGENOUS BDNF ON GRAFTS OF FETAL DOPAMINE NEURONS COINCIDES WITH THE ONTOGENIC PERIOD WHEN DOPAMINE CONTENT AND BDNF EXPRESSION INCREASE WITHIN THE STRIATUM.

D.M. Yurek\*, C.A. Altar\*, R. Ventimiglia\*, R.M. Lindsay\* and S.J. Wiegand†. Dept. of Surgery/Neurosurgery, Univ. of Kentucky, Lexington, KY 40536 and †Regeneron Pharmaceuticals, Inc., Tarrytown, NY 10591.

The expression of brain-derived neurotrophic factor (BDNF) within the developing striatum was measured using Northern blot analysis of BDNF mRNA and an enzyme-linked immunosorbent assay (ELISA) for BDNF protein. BDNF mRNA within the striatum is not detectable before P7, increases transiently between P10-P28, and then decreases in adult. Similarly, BDNF protein levels in the striatum show a sharp increase between P10-P30, which is closely paralleled by increases in striatal dopamine content. These data suggest that BDNF may act as a target-derived trophic factor for dopaminergic neurons destined to innervate the striatum.

The hypothesis that developing dopamine neurons might be most responsive to BDNF during this discrete developmental period was tested in grafts of fetal dopamine neurons implanted into the denervated striatum. Rats received unilateral 6-OHDA lesions and four weeks later were transplanted with E14 ventral mesencephalic tissue, then infused with BDNF at different time points. Animals receiving grafts and immediately infused with BDNF for two weeks showed slight enhancement in rotational behavior compared to that observed in grafted animals receiving PBS infusions. Grafts infused with BDNF 3-4 weeks after transplant surgery, which is equivalent to neuronal age P7-P21, showed a profound effect on rotational behavior and extensive TH+ outgrowth when compared to grafts infused with PBS or BDNF 1-2 weeks after surgery. These data suggest that transplanted immature dopamine neurons may be more responsive to the neurotrophic action of BDNF during a critical period of neuronal development which ordinarily occurs postnatally.

## 613.8

Effects of NGF-Secreting Genetically Modified Cell Grafts on Cholinergic Neuronal Morphology and Cognition in Aged Primates. J. Roberts<sup>1</sup>, P. Rapp<sup>2</sup>, F.H. Gage<sup>3</sup>, M.H. Tuszynski<sup>4,5</sup>. <sup>1</sup>UC-Davis; <sup>2</sup>SUNY-Stony Brook, Stony Brook, NY; <sup>3</sup>Salk Institute, La Jolla, CA; <sup>4</sup>Dept Neurosciences, Univ Calif-San Diego, La Jolla, CA; <sup>5</sup>VA Med Ctr, San Diego, CA.

Basal forebrain cholinergic neuronal atrophy occurs in Alzheimer's disease and in aged rats and monkeys. Age-related deficits on selected cognitive tasks also occur in rats and primates. Nerve growth factor (NGF) can ameliorate age-related cognitive dysfunction in rats and can reduce injury-induced cholinergic neuronal degeneration in primates. In the present study, we examined the effects of genetically modified NGF-secreting fibroblast grafts in aged rhesus monkeys.

18 aged subjects were pre-operatively assessed on a delayed response (DR) task. 9 of these subjects showed DR deficits relative to young control animals, whereas 9 subjects showed no impairment.

The 9 unimpaired subjects then received grafts of either NGF-secreting fibroblasts (n=6; NGF production *in vitro* 15 ng/10<sup>6</sup> cells/h) or control, unmodified fibroblasts (n=3) into 10 intraparenchymal sites spanning the Nucleus Basalis of Meynert (NBM) bilaterally. On post-operative testing, NGF-graft recipients showed a decline in performance on the DR task compared to control subjects, indicating that modulation of cholinergic systems by NGF influences cognition in primates.

The 9 aged-impaired subjects have also received grafts of NGF-secreting cells (n=5) or control cells (n=4) into the NBM. Effects of NGF on age-related declines in cholinergic neuronal morphology and function will be presented.

## 613.9

**ASTROCYTE-INDUCED NEUROTOXICITY OF DOPAMINERGIC GRAFTS IN A RAT MODEL OF PARKINSON'S DISEASE: EFFECTS OF ASTROCYTE AGE AND EXPRESSION OF RECOMBINANT BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF).** L. Lopez-Colberg, K.A. Krobot, P.A. Castillo, G. Laks and L.A. Cunningham\*, Dept. Pharmacology, Univ. New Mexico School of Medicine, Albuquerque, NM 87131.

These studies were performed to determine whether primary astrocytes genetically engineered to express recombinant BDNF could enhance the survival or function of co-grafted embryonic dopaminergic (DA) neurons in the unilateral 6-OHDA-lesioned rat model of Parkinson's disease. Using a MoMLV-based retroviral vector, primary type I astrocytes derived from newborn (P0) rat striatum and maintained in culture for at least two weeks were genetically transduced *in vitro* to express recombinant BDNF and tested for their survival effects on embryonic day 15 midbrain DA neurons in culture and following intracerebral transplantation. In culture, both control non-transduced astrocytes and BDNF-producing astrocytes supported the survival of DA neurons, however, only BDNF-producing astrocytes were neuroprotective for DA neurons following a 24 hour exposure to 100  $\mu$ M 6-OHDA. Following intrastriatal transplantation, control astrocytes reduced the survival of DA neurons within embryonic ventral midbrain (VM) grafts by ~2-fold compared to grafts of VM alone. This astrocyte-induced toxicity was attenuated when VM was co-grafted with BDNF-producing astrocytes. In addition, the neurotoxic effect of the astrocytes was age-dependent; astrocytes derived from embryonic day 18 striatum and maintained in short-term culture were not neurotoxic for dopaminergic neurons. These studies suggest that a) astrocyte age and maturation are important considerations when using astrocytes as gene delivery vehicles and b) co-delivery of recombinant BDNF may provide protective effects to DA neurons following intrastriatal transplantation. Supported by NIH-NINDS R29-NS32562 and The National Parkinson Foundation.

## 613.10

**A GENE THERAPY APPROACH FOR THE TREATMENT OF AMYOTROPHIC LATERAL SCLEROSIS.** P. Aebischer\*, N. Dégion<sup>1</sup>, B. Heydt<sup>1</sup>, A.D. Zurn<sup>1</sup>, A.C. Kato<sup>2</sup>, J.P. Hamman<sup>3</sup>, E.E. Baerje<sup>3</sup>. <sup>1</sup>Gene Therapy Center and Surgical Res. Div., Lausanne University Medical School, Switzerland; <sup>2</sup>Div. of Clinical Neurophysiology, Geneva University Medical School; <sup>3</sup>CytoTherapeutics Inc., Providence, RI.

Amyotrophic lateral sclerosis (ALS) is a disease characterized by the progressive degeneration of motoneurons leading to paralysis and death in 2-3 years. Even though the cause of the disease remains unknown, gene therapy strategies using neurotrophic factors have been developed, since recent experiments demonstrated increased survival of motoneurons *in vitro* and in animal models of neurodegeneration. Exposure to ciliary neurotrophic factor (CNTF), for instance, has been shown to reduce motoneuron cell death associated with peripheral nerve axotomy. The present study used an encapsulation technology to deliver CNTF directly into the CNS. Baby hamster kidney cells (BHK) were transfected with an expression vector containing the human CNTF gene. About  $1 \times 10^4$  parent BHK cells or hCNTF-producing cells were loaded in polyethersulfone fibers. BHK-hCNTF cells were shown to release approximately  $5 \mu\text{g}/10^6$  cells/day as measured by Elisa assay. The *in vivo* bioactivity of the BHK-hCNTF cells was tested using the pmn/pmn mutant mouse model of motoneuron degeneration. Animals implanted with BHK-hCNTF capsules showed a significantly longer survival time and improved motor functional activity as compared to control mice. In order to proceed with a clinical trial, tumorigenicity and toxicity studies were performed. Unencapsulated BHK-hCNTF cells were injected into the lateral ventricle of rats ( $2 \times 10^6$  cells), sheep and primates ( $1 \times 10^7$  cells). Histological analysis showed no tumor formation in any of the animals during the 3 month trial. No side effects, such as fever or weight loss, were noticed in rats implanted with capsules containing up to 100x the human dosage. Finally, the BHK-hCNTF cells, which express the suicide gene thymidine kinase (HSV-tk), were sensitive to ganciclovir treatment *in vitro* and *in vivo*. A clinical program aimed at the treatment of ALS through the transplantation of encapsulated cells genetically engineered to release hCNTF has just been initiated.

## AGING PROCESSES: ANATOMY

## 614.1

**AGE-RELATED REGRESSIVE CHANGES IN MOTONEURON ULTRASTRUCTURE IN AN ANDROGEN-SENSITIVE RAT SPINAL NUCLEUS.** M.C. Clark-Phelps\* and D.R. Sengelaub, Program in Neural Science, Indiana University, Bloomington, IN 47405.

Motoneurons in the spinal nucleus of the bulbocavernosus (SNB) in rats are sensitive to androgens during development, at adulthood, and in old age. Castration of young adults significantly reduces SNB soma size and dendritic length (Kurz, *et al.*, 1986). Ultrastructurally, synapse number and size are also reduced following castration (Matsumoto, *et al.*, 1988). Androgen titers decline with normal aging in male rats, and we have previously reported androgen-dependent declines in SNB target muscle weight, soma size, dendritic length, and steroid receptor density through 22 months of age. In this study, we have extended our analysis of age-related changes in the SNB to the ultrastructural level, examining whether synapse number and size also decline with advancing age.

SNB synapse number was assessed in male rats at 4 and 22 months of age (4-5 motoneurons per animal, n=6). SNB motoneurons were retrogradely labeled with cholera toxin-HRP, reacted with TMB/DAB, and processed for electron microscopy. Somatic and proximal dendritic membranes of HRP-labeled SNB motoneurons were examined for synaptic contacts. Preliminary results reveal a significant decrease (33%) in the number of synapses per micron of somatic membrane in aged rats. Like the other morphological regressive changes we have observed, it is likely that the age-related decline in SNB synapse number results from the normal decline in circulating androgen and can be reversed with androgen treatment. (Supported by NIH AG09309)

## 614.3

**PURKINJE CELL DENDRITIC SPINE ALTERATIONS IN AGING.** S. Chen\*, R. Bing, R. Llinas and D.E. Hillman, Depts. of Otolaryngol. and Phys./Neurosci., NYU Medical Center, New York, NY 10016.

The inability to demonstrate major decreases in neuronal number during normal aging has directed our attention to dendritic synapses. Spines of Purkinje cells are major indicators for synaptic inputs from granule cells. Using immunoreactions for the cytosolic protein-calbindin, computer assisted light and electron microscopy were used to analyze the shape and number of synapses between young (3 month) and aged (24 month) Fisher 344 rats. The animals were perfused, under pentobarbital anesthesia, through the aorta with 4% paraformaldehyde, 0.5% glutaraldehyde and 1% sodium bisulfate for 10 minutes. The cerebellar vermis was sectioned sagittally with a vibratome into 6x50  $\mu$ m and 300  $\mu$ m thick serial sections. Immunohistochemical reactions for calbindin were processed by either HRP-DAB or postembedding nanogold reactions on one micron plastic sections. Calbindin clearly labeled somata, dendrites and spines of Purkinje cells in both methods. The thin plastic sections provided excellent resolution for accurate sampling of spine density. The spine density in aged animals was substantial less than in young. Osmicated thin sections examined in electron microscopy revealed changes in spine and synaptic sizes.

The reduced number of synapse on Purkinje cells in the absence of cerebellar cell losses raises the question of selective dendritic spine death or pruning granule cell axons. These findings suggest that aged rats have some compensatory capability by increasing the size of synapses with synapse loss. Grant NIA AG-09480

## 614.2

**QUANTITATIVE ANALYSIS OF THE CEREBELLAR PURKINJE CELLS DURING AGING OF THE HETEROZYGOUS STAGGERER MOUSE.** N. Hadj Saharaoui\*, H. Zanjani\*, F. Frédéric\*, N. Delhaye-Bouchaud\*, K. Herrup\* and J. Mariani\*\*. \*Université P & M. Curie, CNRS, URA 1488, 75005 Paris. \* Alzheimer Research Laboratory, Cleveland, OH 44106.

The staggerer (sg) mutation causes a severe ataxia correlated with digenesis of the cerebellar cortex in the sg/sg mouse. The Purkinje cells (PC) are reduced in number by about 75 % and the remaining ones are ectopic and reduced in size with a profound dendritic atrophy. The mutation is described as recessive because the heterozygote, +/sg, is behaviorally normal. However when the +/sg mouse advances in age, 25-30 % of the PC are gone as early as 12 months postnatal. In the present study we aimed to see whether morphological abnormalities accompany the PC loss. We used a semiquantitative method to characterize several morphological parameters of a large number of Golgi-impregnated PC in 4, 12 and 22 month old +/sg and +/+ mice. In 4-month old +/sg mice, most cells are indistinguishable from +/+. The dendrites are profusely branched and extend to the pial surface but they frequently deviate from the ideal, perpendicular orientation. By 12 months, +/sg PCs are slightly but significantly atrophic compared to +/+. In 22-month-old the PC branching complexity is reduced in both genotypes: many cells appear atrophic and dendritic trees often fail to reach the pial surface but the +/sg cells deteriorate far more and completely than +/+ ones. From these results it appears that the heterozygous staggerer is a model of early aging of the cerebellum.

## 614.4

**AGING OF THE CEREBELLAR HEMISPHERES AND VERMIS OBSERVED *IN VIVO*.** I.H. Dupuis\*, C.A. McGavran, N. Raz, S.D. Briggs, and J.D. Acker\*, Department of Psychology, The University of Memphis, and Baptist Memorial Hospital, Memphis, TN 38152.

We investigated patterns of cerebellar aging using MRI based morphometry in a sample of 93 healthy volunteers (19 to 77 years old). Cerebellar volume was computed for each hemisphere from series of consecutive 1.5 mm coronal sections. On midsagittal sections, we measured the area of five vermal regions: (1) lingula and centralis, (2) culmen, (3) declive, folium and tuber, (4) pyramis, and (5) uvula and nodulus. We also measured the cross sectional area of the ventral pons. The volume of the cerebellar hemispheres decreased significantly with age. The rate of decline was consistent for both hemispheres, and for men and women. The vermis as a whole was also affected by age, but not as strongly as the hemispheres. The degree of shrinkage associated with age varied among the vermal regions. Only the posterior vermis showed an age related shrinkage. More specifically, the cross sectional area of the declive, folium, and tuber was most strongly affected. In contrast, the anterior vermis and the ventral pons appear resistant to the effects of age. The pattern of age effects found here with the cerebellar hemispheres, the vermis, and the pons is consistent with the notion that phylogenetically older structures tend to be more resistant to the effects of age, whereas relatively newer structures tend to significantly decrease in size over the life span. Supported by the NIA grant AG11230 to N.R.

## 614.5

**AGE, GENDER, AND HEMISPHERIC DIFFERENCES IN THE HUMAN STRIATUM.** F. Gunning\*, D. Head, N. Raz, J. McQuain, & J.D. Acker\*. Department of Psychology, The University of Memphis, and \*Baptist Memorial Hospital, Memphis, TN 38152.

Age and gender differences as well as lateral asymmetries have been noted in motor behavior. These differences may be related to the morphology of the basal ganglia. In this study we attempted to replicate and extend previously reported findings of the variability in the basal ganglia volume by gender, hemisphere, and age. We examined the neostriatum of 66 healthy right-handed adults (19 - 77 years old). MRI-based morphometry was used to quantify the volume of the head of the caudate nucleus (Cd) and the putamen (Pt). Our analysis revealed bilateral age-related shrinkage in both the Cd ( $r = -.34$ ,  $p < .006$ ) and the Pt ( $r = -.41$ ,  $p < .001$ ). In this sample age-related differences in neostriatal nuclei were associated neither with gender nor with hemisphere. However, both Cd and Pt were larger in males than in females, even after adjustment for body size (height) differences. There was a significant rightward asymmetry in the Pt, whereas no hemispheric differences were observed in the Cd. Supported by the NIA grant AG11230 to N.R.

## 614.7

**AGE-RELATED CHANGES IN THE RHESUS MONKEY: MRI CHANGES IN FOREBRAIN WHITE MATTER BUT NOT GRAY MATTER.** ZC Lai\*, DL Rosene, RJ Killiany, D Pugliese, MS Albert and MB Moss, Dept. of Anatomy & Neurobiology, Boston University School of Medicine, Boston MA 02118, Dept. of Psychiatry & Neurology, Massachusetts General Hospital, Boston MA 02114 and Yerkes Regional Primate Research Center, Emory University, Atlanta, GA 30322.

To study the neurobiological bases of age-related decline in cognitive function in vivo, 8 young (5 - 14) and 8 elderly (20 - 32 years of age) monkeys that were behaviorally tested were given MRI scans in a GE Signa scanner (3D SPGR T1-weighted, TR56, TE12, 1.3 mm thickness, 512 x 512). The total forebrain volume was measured using in-house software on a Sun Sparcstation. To determine relative volumes of forebrain gray matter (cortex, basal ganglia and diencephalon), white matter (subcortical white and cerebral peduncles) and ventricles, the scans were analyzed by point counting using either a plastic overlay on the Sun or a grid macro for NIH Image on a Macintosh Quadra. There was a significant ( $r = .55$ ,  $p < .05$ ) age-related decline in the overall forebrain volume (gray and white matter and ventricles combined) but no significant change in the gray matter volume. Additionally, there was a significant decline in the white matter volume ( $r = .63$ ,  $p < .05$ ) while ventricular volume appeared to decrease ( $r = .36$ ,  $p < .10$ ). Comparison of these results with our studies of age-related cognitive dysfunction revealed a significant correlation between the white matter loss and performance on the acquisition component of the delayed non-matching to sample test ( $r = .52$ ,  $p < .05$ ). This suggests that there may be an impairment in connectivity resulting from white matter loss that underlies age-related cognitive changes. (Supported by a grant from the Dana foundation and by NIH grants AG00001 and RR00165)

## 614.9

**AGE-RELATED CHANGES IN THE RHESUS MONKEY: CHOLINERGIC RECEPTOR BINDING IN THE HIPPOCAMPUS AND TEMPORAL LOBE.** TJ Nicholson, EC Johnson, A Doolittle, MB Moss, and DL Rosene\*, Dept. of Anatomy and Neurobiology, Boston University School of Medicine, Boston MA 02118 and Yerkes Regional Primate Research Center, Emory University, Atlanta, GA 30322.

Previous research has demonstrated that the cholinergic neurotransmitter system may contribute to changes in memory that occur in normal aging. To characterize the neurobiological changes underlying these cognitive deficits, three cholinergic receptors (M1, M2, and the high affinity choline uptake site [HACU]) were examined using in vitro, on the slide, autoradiography of 15 micron thick coronal sections from the brains of old (>20) and young (<14) monkeys. The binding of tritiated ligands (5nM  $H^3$ -hemicholinium to HACU, 10nM  $H^3$ -pirenzepine to M1, 1nM  $H^3$ -oxotremorine to M2) in different regions of the hippocampus and temporal lobe was measured. A significant overall decrease in binding was found for the M1 ( $p < .0001$ ) and M2 ( $p < .0001$ ) receptors in all areas. In contrast the HACU receptors showed a significant ( $p < .0094$ ) increase in binding with age but only within the hippocampus and not in the remainder of the temporal lobe. Until saturation binding experiments can be completed it is not clear if these changes are due to a change in affinity or the number of receptors but the increase in HACU sites suggests a compensatory response to cholinergic deafferentation. These results compared with our studies of age-related cognitive dysfunction revealed a significant correlation ( $p < .05$ ) between the decreased M2 binding and impairments of memory on the delayed non-matching to sample basic task. (Supported by NIH grants PO1 AG00001 and RR 00165)

## 614.6

**AGE-RELATED CHANGES IN THE RHESUS MONKEY: MEMORY, EXECUTIVE FUNCTION AND "IQ" IN A NON-HUMAN PRIMATE MODEL OF NORMAL HUMAN AGING.** RJ Killiany, MB Moss, DL Rosene, J Herndon\* & ZC Lai, Dept. of Anatomy and Neurobiology, Boston University School of Medicine, Boston, MA 02118 and Yerkes Regional Primate Research Center, Emory University, Atlanta, GA. 30322.

As part of an ongoing project aimed at identifying the neurobiological bases of cognitive decline with normal aging, a group of 8 young (5 - 14) and 16 elderly (20 - 32 yrs of age) rhesus monkeys were behaviorally tested on tasks designed to assess specific cognitive functions that have been previously shown to undergo age-related declines in human subjects. The monkeys were administered two tasks of recognition memory; the Delayed Non-Matching to Sample and Delayed Recognition Span Task as well as two tasks of executive function; Spatial & Object Reversal Learning. A standardized composite score, weighted equally on measures of initial learning, recognition memory, and reversal performance, was derived for each monkey. The composite score served as a global index of each monkey's level of cognitive ability. Overall, the findings of this study revealed that monkeys, like healthy adult humans, evidence significant age-related declines in both memory and executive system function. The onset of the memory impairments preceded those of executive function. Secondly, aged monkeys, like healthy aged humans, evidence marked individual differences in the extent of memory impairment. Thirdly, the data suggest that spatial abilities may be more vulnerable to age than non-spatial abilities. Finally, our data suggest that in monkeys, as in healthy adult humans, select individuals age more "successfully" than others. (Supported by a grant from the Dana foundation and by NIH grants PO1 AG00001 and RR 00165)

## 614.8

**AGE-RELATED CHANGES IN THE RHESUS MONKEY: PET IMAGING AND REDUCTIONS IN CYTOCHROME OXIDASE MARKERS.** DL Rosene, ZC Lai, AA Bonab, N Alpert, R Rizkalla, KJ Page, BT Hyman, R Killiany\*, MS Albert & MB Moss, Dept. of Anatomy and Neurobiology, Boston University School of Medicine, Boston MA 02118 and Depts. of Psychiatry and Neurology and of Radiology, Massachusetts General Hospital, Harvard Medical School, Boston MA 02114 and the Yerkes Regional Primate Research Center, Emory University, Atlanta, GA 30322.

To identify the neurobiological bases of observed age-related declines in cognitive function, young (5 - 14) and elderly (20 - 32) behaviorally tested monkeys were examined with a GE4096 PET camera using 15-O-water to assess cerebral blood flow and cortical metabolism. Results demonstrated an apparent decline in global cerebral blood flow with age. Regional analyses revealed that the greatest reductions occurred in posterior slices of the brain. To further examine the basis of this apparent decline in metabolism, fresh frozen cryostat sections through the forebrain were processed with oligonucleotide probes to the RNA message for nuclear subunit IV and mitochondrial subunit II of cytochrome oxidase (COX). Adjacent sections were processed with COX histochemistry to assess functional activity. All three measures demonstrated a significant decline in COX with age. Since other studies from this laboratory indicate that there is an age-related loss of white matter without a significant loss of gray, these results suggest that age-related declines in cognition may result from an anatomical and/or functional deafferentation of the cortex that is reflected in reduced cerebral blood flow, cytochrome oxidase activity and overall cortical metabolism. (Supported by a grant from the Dana foundation and by NIH grants AG00001 and RR00165)

## 614.10

**AGE-RELATED CHANGES IN THE RHESUS MONKEY: EXCITATORY AND INHIBITORY AMINO ACID RECEPTOR BINDING IN THE HIPPOCAMPUS AND TEMPORAL LOBE.** MB Moss\*, TJ Nicholson, R Rizkalla, C Fitzgerald, and DL Rosene, Dept. of Anatomy and Neurobiology, Boston University School of Medicine, Boston MA 02118 and the Yerkes Regional Primate Research Center, Emory University, Atlanta, GA 30322.

Previous research has demonstrated that the excitatory amino acid and inhibitory GABAergic systems are potential contributors to changes in memory that occur in normal aging. To characterize the changes in these two systems, the N-methyl-D-aspartate (NMDA), kainate (KAI), gamma-aminobutyric acid type A ( $GABA_A$ ), and benzodiazepine (BZD) receptors were examined using in vitro, on the slide, autoradiography of 15 micron thick coronal sections from the brains of old (>20) and young (<10) monkeys. The binding of tritiated ligands (7nM  $H^3$ -MK-801 to NMDA, 15nM  $H^3$ -KAI to KAI, 5nM  $H^3$ -muscimol to  $GABA_A$ , 2nM  $H^3$ -flunitrazepam to BZD) in the temporal lobe was determined. The NMDA ( $p < .0001$ ), KAI ( $p < .0001$ ), and  $GABA_A$  ( $p < .0001$ ) receptors all decreased binding significantly whereas the BZD ( $p < .0001$ ) receptors increased binding with age. Saturation binding experiments must be completed to determine whether changes in binding are due to a change in affinity or the number of receptors. The decrease in NMDA and KAI binding may reflect degenerative changes in dendrites. The increase in BZD binding suggests alteration in the subunit composition of the  $GABA_A$  receptor. These results compared with our studies of age-related cognitive dysfunction revealed a significant correlation ( $p < .05$ ) between the increase in BZD binding and impairments of spatial short term memory. (Supported by NIH grants PO1 AG00001 and RR 00165)

## 614.11

AGE RELATED CHANGES IN THE RHESUS MONKEY: NEURONAL LOSS IN SUBSTANTIA NIGRA-PARS COMPACTA AND VENTRAL TEGMENTAL AREA. Z. A. Siddiqui, T. L. Kemper, D. L. Rosene and M. Feldman\*, Dept. of Anat. and Neurobiology, Boston Univ. Sch. of Med., Boston, MA & The Yerkes Regional Primate Center, Amory Univ., GA

Advancing age in rhesus monkeys is associated with a reduction in the dopamine concentration in the prefrontal association cortex (Goldman-Rakic and Brown, Neurosci. 6:177-187, 1981). The cells of origin of this prefrontal dopaminergic projections are mainly in the anterior part of ventral tegmental area (VTA) and medial one third of the substantia nigra, pars compacta (PC). We report initial morphometric findings in PC and the cortically projecting subnuclei of VTA, Pars nigralis (PN) and Pars brachialis pigmentosus (PBP) in rhesus monkeys ages 5, 15, 22 and 32 years. The analysis was made using every 10th section in a series of 30µ thick Nissl stained frozen sections. The extent of these dopaminergic nuclei was determined with an immunohistochemical stain for tyrosine hydroxylase. Location of soma, somal size, cell packing density and melanin were used in defining PN and PBP. We used the three dimensional cell counting system of Williams & Rakic (J. Comp. Neur. 278:344-352) and systematic sampling was done with an X-Y stage encoder. All three regions showed a progressive decrease in neuronal packing density with age. This ranged up to 25%, 24% and 12% in the PC, PBP and PN respectively in the oldest monkey as compared to the youngest monkey. The most severe reduction was observed in the monkey aged 22 years, 37%, 36% and 35% in PC, PBP and PN respectively. This animal had shown severe age-related behavior deficits on a variety of cognitive tests. These preliminary results support the earlier neurochemical findings that the dopaminergic system is effected by age and may play a pivotal role in age-related cognitive decline. (Supported by NIH Grants P01 AG00001 & RR 00165).

## PHARMACOLOGY OF SYNAPTIC TRANSMISSION II

## 615.1

A NOVEL SUBTYPE OF THE CNS PROSTACYCLIN RECEPTOR: ITS INVOLVEMENT IN SYNAPTIC TRANSMISSION IN THE HIPPOCAMPUS H. Takechi\*, K. Matsumura, Yu. Watanabe, and Y. Watanabe, Subfemtomole Biorecognition Project, Research Development Corporation of Japan, and Department of Neuroscience, Osaka Bioscience Institute, Osaka 565, Japan.

We found a new presumable subtype of the prostacyclin receptor abundantly expressed in the central nervous system. Several prostacyclin analogues showed the different binding properties of the subtype compared with the known prostacyclin receptor, which was tested by *in vitro* autoradiography in male adult rats. Isocarbacyclin (TEI7165), which is a potent agonist for the known prostacyclin receptor, had high affinity for this novel subtype (the dissociation constant,  $K_d$ , was 7.8 nM). However, iloprost, which had been usually used as a stable prostacyclin agonist and had a high affinity site in the mastocytoma cell line or CHO cells transfected with a cloned prostacyclin receptor cDNA, showed a low affinity binding (the  $K_d$  was 159.3 nM) for this subtype. Other prostaglandins had no or little affinity for the subtype. The density of the subtype was high in the thalamus, lateral septal nuclei, hippocampus, cerebral cortex, striatum and dorsal cochlear nucleus. Although the nucleus of the solitary tract (NTS) and spinal trigeminal nucleus showed a high density binding of [ $^3H$ ] isocarbacyclin, [ $^3H$ ] iloprost had also high affinity in these regions and the binding specificity was similar to that found in the peripheral organ. Hemilection studies of striatal neurons or afferents revealed that the binding sites of the novel subtype existed on neuronal cells in the striatum, not on presynaptic terminal of dopaminergic afferents nor glial cells. Since the expression of the receptor in the hippocampus was observed along with the pyramidal cell layer, we tested whether prostacyclin analogues had some effects in synaptic transmission in the CA1 region using rat hippocampal slices. We found that prostacyclin analogues caused a transient increase of field epp. Surgical removal of the CA3 region did not affect the enhancement. These results suggest that prostacyclin had some physiological roles in synaptic transmission.

## 615.3

PHARMACOLOGICAL CHANGES IN PAIRED PULSE DEPRESSION OF DENTATE GRANULE CELL FIELD POTENTIALS. L. J. Burdette\*, S. M. Lasley & M. E. Gilbert, Dept. Neurology, Graduate Hospital, Philadelphia, PA, 19146, Dept. Basic Sciences, U. of Illinois, Peoria, IL, 61656, and Curriculum in Toxicology, U. of North Carolina, Chapel Hill, NC 27599

We previously have shown that moderate to high stimulation reduces late paired pulse depression and the 1 Hz depression of the population spike (PS) in field potential recordings. Antagonists to GABA<sub>B</sub> (CGP-35348, 50 mg/kg ip) receptors and NMDA (MK-801, 0.25 mg/kg ip) or Ca<sup>2+</sup> channels (flunarazine, 80 mg/kg po) were given to evaluate cellular processes that modulate paired pulse depression of dentate granule cell field potentials in the unanesthetized rat. Following drug or vehicle administration, paired pulses (0.1 ms, 20 or 200 ms interpulse interval) were delivered to the perforant path at 0.05 Hz and 1 Hz (30 sec) for a range of stimulus intensities. MK-801 increased the strength of late paired pulse depression and the 1 Hz depression of the PS at all but the highest stimulus intensity. CGP-35348 had no effect on any measure of paired pulse depression. Flunarazine exerted a marginal decrease in both early and late paired pulse depression that was not significant. The results suggest that NMDA-mediated currents reduce the strength of late paired pulse depression at all stimulus intensities but do not account for the loss of late paired pulse depression with maximal stimulation. Consistent patterns exhibited by late paired pulse depression and the 1 Hz depression of the PS provide confirmation that the same currents participate in both events. As a loss of late paired pulse depression precedes a failure of early paired pulse depression and seizure initiation in naive rats, additional study is needed to identify mechanisms responsible for the disinhibition observed with moderate to high stimulation. (Supported by MH45961(LJB), ES06253(SML,MEG) & U.S. EPA (MEG)).

## 614.12

THE HUMAN NUCLEUS COERULEUS IN AGING - A STEREOLOGICAL ANALYSIS OF FEMALES AND MALES

Ch. Busch (1), H. Braak\* (1), J. Bohl (2), and T. G. Ohm (1,3)

(1) Zentrum der Morphologie, J.W. Goethe-Universität, 60590 Frankfurt,

(2) Neuropathologie, J. Gutenberg-Universität, 55131 Mainz,

(3) Institut für Anatomie, Charité, Humboldt-Universität, 10098 Berlin, Germany

The few recent studies on the effect of aging on the total cell number of noradrenergic (i.e. neuromelanized) neurons of the nucleus coeruleus are detracted either from the lack of detailed neuropathological characterization of the used cases or because no unbiased modern stereological tools were applied. Moreover, no gender-related analysis was performed so far. In the present approach we used a newly developed unbiased sampling scheme and examined the total number of neuromelanized neurons in 31 individuals between 49 and 98 years of age. All were clinically without signs for neurological or psychiatric disorders, however, at histopathological inspection four met the criteria for stage II (Braak and Braak, 1991) of Alzheimer's disease-related neurofibrillary changes, and 12 for stage III. We did not uncover a significant decrease in total neuron numbers, neither when analyzing females (n=14) and males (n=17) together or separately: There was no correlation between the stage and the total cell numbers. In line with previous findings, we did not detect side differences. However, a gender difference in total cell numbers is suggested. Females showed a mean ( $\pm$  SD) of 18913 ( $\pm$  3023) with a range from 13501-26031 whereas males showed 14844 ( $\pm$  2494) with a range of 11737-20707. Taken together our data show (i) no age-related cell loss between 50 and 100 years of age, (ii) a sexual dimorphism with males having 20% fewer neuromelanin-containing neurons, and (iii) Alzheimer's disease-related cell loss in the nucleus coeruleus is not an early event.

## 615.2

THE MEMBRANE PERMEABLE CALCIUM CHELATOR, BAPTA-AM, ATTENUATES SYNAPTIC TRANSMISSION *IN VITRO* IN THE HIPPOCAMPUS CA1 REGION. A. Ouanounou, L. Zhang, M. Tymianski, M.P. Charlton, C.M. Wallace and P.L. Carlen\*, Playfair Neuroscience Unit, Toronto Hospital Research Institute, Depts of Medicine (Neurology), Physiology and Surgery (Neurosurgery), Bloorview Epilepsy program, University of Toronto, Toronto, Ont, Canada.

To assess a possible neuroprotective mechanism of the membrane-permeable calcium chelator, BAPTA-AM, we examined its effects on synaptically evoked field potentials in the stratum radiatum of the hippocampal CA1 region in rat brain slices. Perfusing with 50-0.5 µM BAPTA-AM caused a reversible, concentration-dependent reduction of the synaptically evoked field potential by 45-23%, without affecting the presynaptic volley or antidromically evoked responses. Similar application of 5'5'-dinitro BAPTA-AM, which is a low-affinity BAPTA analogue, did not decrease synaptic field potentials. Repetitive stimulation (1 Hz) in the presence of BAPTA-AM caused an increase in the orthodromically evoked field potentials. These results demonstrate that extracellular BAPTA-AM, at a concentration as low as 0.5 µM, can depress synaptic transmission in mammalian CNS, likely by decreasing evoked neurotransmitter release.

## 615.4

THE QUANTITATIVE SENSITIVITY OF SYMPATHETIC GANGLION TRANSMISSION TO VOLATILE ANESTHETICS. J.B. McCallum, O. Hogan, J.L. Seagani\*, and Z.J. Bosnjak, Dept. of Anesthesia, Med. College of Wisconsin, Milwaukee, WI 53226.

Inhalational anesthetics depress peripheral ganglionic transmission, but the quantification of this effect remains unknown. The purpose of this study was to compare the effects of halothane (H), isoflurane (I) and enflurane (E) on ganglionic transmission at equimolar anesthetic concentrations using isolated *in vitro* canine stellate ganglia. Eleven ganglia were isolated from adult mongrel dogs after halothane anesthesia, desheathed, and superfused with Krebs' solution equilibrated with a mixture of 97% O<sub>2</sub> and 3% CO<sub>2</sub> maintained in a specially designed tissue chamber at a pH of 7.4±0.5 and a temperature of 37±0.5°C. Compound action potentials (CAP) were generated by supramaximal stimulation of the preganglionic T3-ramus at a frequency of 0.4 Hz. The percent CAP depression from control was measured 10 min. after exposure to increasing anesthetic concentrations delivered to the ganglia through a vaporizer attached to the gas flow. The following superfusate concentrations (in mM) were measured in the superfusate by gas chromatography: H: 0.099, 0.16, 0.3, and 0.72. I: 0.09, 0.17, 0.32, and 0.72. E: 0.1, 0.19, 0.31, and 0.74. The EC<sub>50</sub> value (with its 95% confidence limits) for each anesthetic are as follows: H: 0.3(0.27-0.33). I: 0.32(0.29-0.35). E: 0.34(0.31-0.37). Equivalent MAC values for these concentrations are 1.25, 1.03 and 0.5, respectively. While the percent suppression achieved at equimolar anesthetic concentrations was essentially the same, inhibition of ganglionic transmission was significantly different in terms of equivalent MAC values. These results indicate that the mechanisms underlying anesthesia in the peripheral ganglia are more sensitive to plasma concentrations than partial pressures.

## 615.5

A SLOW EXCITATORY SYNAPTIC CURRENT RECORDED FROM DOPAMINERGIC NEURONS IN RAT MIDBRAIN SLICE. K.-Z. Shen\* and S. W. Johnson. Department of Pharmacology, Oregon Health Sciences University, Portland, OR 97201.

Synaptic currents were evoked with bipolar electrodes while recording whole-cell currents with patch pipettes from ventral tegmental neurons in rat midbrain slices. A late-onset slow inward current (50 - 300 pA at -70 mV) was evoked by a train of stimuli in most of dopaminergic neurons superfused with solution containing APV, CNQX, bicuculline and CGP 35348. These slow EPSC were voltage-dependent, and was abolished in low calcium/high magnesium solution. Antagonists of muscarinic, serotonergic (5-HT<sub>2</sub>), and noradrenergic receptors failed to block the slow EPSC, as well as by antagonists of neurotensin and NK1 receptors. Senktide (0.1 - 5  $\mu$ M), an agonist of NK3 receptors, and substance P (3 - 5  $\mu$ M) evoked inward current and occluded the slow EPSC in some neurons. In contrast, NMDA (10  $\mu$ M) failed to occlude the slow EPSC although it also evoked an inward current. In neurons recorded with cesium gluconate in the pipette, baclofen (3 - 10  $\mu$ M) reduced the amplitude of the slow EPSC by 80%, this effect was blocked by CGP 35348 (300  $\mu$ M). These results suggest that the slow EPSC is mediated by substance P acting at NK3 receptors. Furthermore, GABA acting at GABA<sub>B</sub> receptors mediate presynaptic inhibition of the slow EPSC.

## 615.7

RECURRENT EXCITATION IN THE DENTATE GYRUS REVEALED BY OPTICAL AND MICROELECTRODE RECORDING. Meyer B. Jackson\* and Helen E. Scharfman\*, \*Dept. of Physiology, University of Wisconsin, Madison, WI 53706. #NRC, Helen Hayes Hospital, NY State Dept of Health, W. Haverstraw NY 10993 and Depts. of Pharmacology and Neurology Columbia University, NY, NY 10032.

A voltage-sensitive dye (RH414) was used to image electrical activity in the dentate gyrus in rat hippocampal slices. Electrical stimulation of the molecular layer (ML) evoked large responses throughout the ML and hilus. Bath application of the excitatory amino acid receptor antagonists DNQX and APV blocked ML responses distal to the stimulating electrode, indicating a dependence on excitatory synaptic transmission. In slices with a lesion through the outer two thirds of the ML, made by cutting radially through the crest, ML stimulation on one side of the lesion evoked nearly equal responses on both sides. EPSPs that triggered action potentials could be recorded in granule cells on the side of the lesion opposite from the stimulating electrode located in the ML. When field potentials were recorded on the side of the lesion opposite from the stimulating electrode, the largest negative potentials were seen in the inner ML. Focal application of excitatory amino acids to the hilus evoked negative field potentials in the ML. In slices with a lesion in the hilus, parallel and subjacent to the granule cell layer, responses to distal ML stimulation were much reduced in the ML above the lesion. Intracellular recording from granule cells above the lesion demonstrated that they had normal membrane properties (i.e. they were not damaged by the lesion). These results confirm that hilar neurons form excitatory synapses on granule cell dendrites, and indicate that the strength of this pathway has been underestimated by previous studies. Supported by NINDS grants NS30016 to MBJ and NS30831 to HES.

## 615.9

SYNAPTIC INTERACTIONS IN COCULTURES OF POSTNATAL RAT SENSORY AND SPINAL CORD NEURONS. E. Sermasi, P. Feltz\* and R. Schlichter. Lab. Physiologie générale, Univ. Louis Pasteur, URA 1446 / CNRS, 21 r. Descartes, 67084 Strasbourg, France.

The aim of this study was to characterize the synaptic interactions between postnatal (1-3 days old) rat dorsal root ganglion (DRG) and spinal cord neurons in a coculture preparation. It was possible to distinguish between both cell populations on the basis of morphological and electrophysiological criteria. DRG neurons have large (25 to 40  $\mu$ m diameter), spheric, phase-bright cell bodies with a prominent nucleolus and one or two neurites whereas spinal cord neurons are small in size (5 to 15  $\mu$ m diameter), irregularly shaped phase-dark cells with multiple processes. Whole-cell patch-clamp recordings were made from visually identified spinal neurons from 1 to 3 weeks old cocultures. Care was taken to record only from neurons having a projecting DRG neuron nearby. At a holding potential of -60 mV, spontaneously occurring synaptic events were characterized as transient inward currents of variable amplitude (10-500 pA) and short duration (10-50 ms). Occasionally, it was also possible to observe synaptic events having a slower time course (>50 ms). The majority of the synaptic activity is reversibly abolished by application of CNQX (5  $\mu$ M) but not by a similar concentration of APV (5  $\mu$ M) or bicuculline (5  $\mu$ M). However a small subpopulation of fast (< 15 ms) and small-sized (<25 pA) synaptic events was resistant to the blocking action of CNQX. Application of capsaicin (0.5  $\mu$ M) appeared to enhance and/or to evoke these fast synaptic currents. Our results suggest that at least part of the synaptic activity in spinal cord neurons is due to an input from A $\delta$  and C fibers acting on non NMDA glutamate receptors. Thus our model is useful to study in detail the synaptic interactions of A $\delta$  and C nociceptive neurons with postnatal spinal cord neurons under experimental conditions of ideal electrophysiological and pharmacological access.

E.S. is funded by an ULP-CNRS-LILLY postdoctoral fellowship

## 615.6

GLUTAMATE AND GABA IN ANESTHETIC-INDUCED NEOCORTICAL BURST SUPPRESSION ACTIVITY *IN VITRO*. H. S. Lukatch\* and M. B. MacIver. Dept. of Anesthesia, Stanford University School of Medicine, Stanford, CA 94305.

The present study used an *in vitro* neocortical EEG brain slice preparation to determine the neuronal loci for propofol, thiopental and isoflurane-induced burst suppression activity. Control EEG responses within the theta frequency range (4-8 Hz) were electrically evoked (0.5 ms, 5 V, 0.033 Hz) in the presence of carbachol (100  $\mu$ M) and bicuculline (10  $\mu$ M) in layers 2/3 of Oc2MM neocortex. Clinically relevant concentrations of propofol (10  $\mu$ M, n=3), thiopental (50  $\mu$ M, n=12) and isoflurane (0.9 vol %; ~ 140  $\mu$ M, n=4) produced burst suppression EEG patterns in neocortical brain slices. Bursts ranged in amplitude from 150-500  $\mu$ V, and occurred with a frequency of 0.3 - 2.0 Hz similar to anesthetic-induced burst activity seen *in vivo*. The GABA<sub>A</sub> agonist muscimol (1 mM, n=5) produced burst suppression activity in the absence of anesthetics. Glutamate receptor antagonists CNQX (8  $\mu$ M, 5 of 5 slices) or APV (42  $\mu$ M, 3 of 3 slices) forced anesthetic-induced burst suppression activity to isoelectric activity. These results indicate that enhanced tonic GABAergic transmission and intact glutamatergic transmission are required for burst suppression activity.

## 615.8

#### FUNCTIONAL CHARACTERIZATION AND PLASTICITY OF FEEDBACK INHIBITORY CIRCUITS IN AREA CA3 OF HIPPOCAMPAL SLICE CULTURES.

C. Fortunato, M. Scanziani, B.H. Gähwiler and S.M. Thompson\*

Brain Research Institute, University of Zurich, CH-8029 Zurich, Switzerland

Pyramidal neurons of the hippocampus, especially in the CA3 region, are interconnected by recurrent excitatory axon collaterals. The spread of excitation is controlled by feedback and feedforward inhibitory circuits. Intracellular recordings in current clamp mode were used to study feedback inhibition. Single action potentials (APs) were evoked by brief depolarizing current pulses in CA3 pyramidal cells. In 40% of pyramidal cells, the AP was followed by an inhibitory postsynaptic potential (IPSP) within 3-5 ms, which was blocked by bicuculline, hence mediated by GABA<sub>A</sub> receptors. The probability of activation of the inhibitory cell was decreased by reducing the probability of its excitation with adenosine (0.1-0.2  $\mu$ M). Adenosine increased the number of failures of transmission from <10% to >50% of APs, indicating that the EPSPs in the interneurons were indeed reduced, and decreased the amplitude of non-failure IPSPs. The comparison of the IPSP amplitude distribution before and after adenosine application suggests that the simultaneous activation of multiple interneurons was decreased by adenosine. In some experiments, adenosine increased the failure rate, but did not change the IPSP amplitude, suggesting that feedback inhibition was mediated by only one interneuron. When the frequency of APs was increased from 1/6 to 2 Hz for 20-40 seconds, the IPSP amplitude decreased by ~35%. CGP 35-348 (0.5-1 mM), a GABA<sub>B</sub> receptor antagonist, did not affect the amount of depression. We conclude that more than one inhibitory interneuron is usually involved in feedback inhibition in area CA3 of hippocampal cultures. When the interneurons fire at a frequency of 2 Hz, IPSPs are depressed in a GABA<sub>B</sub> autoreceptor-independent manner.

#### ESTABLISHMENT OF LONG TERM PRIMARY NEOSTRIATAL NEURONAL MICROCULTURES OF POSTNATAL RAT.

P. B. Senatus\*. Department of Neurobiology, Harvard Medical School, Boston, MA 02115.

The rat neostriatum is known to consist of various morphological and cytochemical neuronal types including GABAergic medium spiny projection neurons (~95%) [Wilson and Groves (1980) J Comp. Neurol. 194: 599-615] and several classes of nonspiny interneurons (~5%) [Kawaguchi (1993) J Neuroscience 13: 4908-23; Kubota (1993) Neuro-Report 5: 205-8]. A major concern of this study is the investigation of synaptic interactions among rat neostriatal neurons.

Neuronal microcultures and mass cultures from the postnatal rat neostriatum were prepared by methods similar to those described by Segal and Furchspan (1990) [J Neurophysiology 64: 1390-99] and Furchspan and Potter (1989) [Neuron 3: 199-207], and could be maintained up to four weeks in culture. The microculture format was chosen in order to reduce the number of interacting neurons and to permit electrophysiological, cytochemical, and electron microscopic examination of the same neuron. By two days in culture, the neurons increased in size and extended neuritic processes. After one week, dendritic arbors became elaborate and axonal varicosities, including terminal boutons, could be visualized by light microscopy. On the basis of prevalence and somatic diameter, distinct sets of neurons could be identified. After 2 weeks in culture, about 90% of the neurons were GABA-immunoreactive, and just under 2% of the neurons expressed NADPH diaphorase activity. These results are consistent with proportions observed *in vivo* in the adult rat neostriatum. Supported by 5 F31 GM 14736 to P. B. Senatus and NS02253 to D. D. Potter, Ph. D..

## 615.11

EFFECTS OF MELATONIN ON SYNAPTIC TRANSMISSION AND LONG-TERM POTENTIATION IN THE DENTATE GYRUS OF THE HIPPOCAMPUS. R.G. Gonzales\* and D.L. Armstrong. Div. of Life Sciences, University of Texas at San Antonio, San Antonio, TX 78249.

The indoleamine, melatonin, was investigated as a possible modulator of synaptic transmission in the dentate gyrus of rat hippocampal slices. Reports demonstrating specific binding of melatonin to both calmodulin and CNS receptors coupled to regulatory G-proteins suggest that this hormone could mediate profound effects on neuronal function, including the induction and maintenance of long-term potentiation (LTP). Mature male rats housed under a 12:12 LD cycle were used, with hippocampal slices prepared midway through the dark period. Evoked field excitatory postsynaptic potentials (fEPSP) were recorded in the dentate molecular layer following perforant path stimulation at 0.1 Hz. Bath application of 0.1 to 0.5 mM melatonin for thirty min. reduced fEPSPs as compared to basal levels. The average percent decrease in the slope and amplitude was 9% and 13%, respectively. To test the effect of melatonin on LTP induction, the hormone was present during the application of three 100 Hz trains with an intertrain interval of 10 sec, and then washout was begun. Increases of greater than 20% in fEPSP slope and greater than 14% in amplitude were observed 30 min. after tetanization. This potentiation was within the range of that observed under control conditions. By contrast, in slices where melatonin was applied prior to, during and following tetanization (n=3), no LTP was induced in two cases, but rather a slow decrease in fEPSP response was produced. These findings suggest that melatonin not only depresses normal synaptic transmission, but might also modulate the processes involved in the induction and maintenance of LTP.

## 615.13

CHRONIC CYCLOSPORIN A TREATMENT DECREASES ELECTRICALLY STIMULATED RELEASE OF [3H]-D-ASPARTATE FROM RAT HIPPOCAMPAL SLICES. S.A. Queen\*, J. Stepanek, and W.C. Buss. Dept of Pharmacology, Univ. New Mexico Sch. Med., Albuquerque, NM 87131.

The immunosuppressant cyclosporin A (CsA) forms a binary complex with cyclophilin, interrupting the immune response by inhibiting protein phosphatase 2B (PP2B) in T-cells. Although highly effective as an immunosuppressant, CsA is neurotoxic in some patients. We hypothesized that some of the neurotoxic symptoms of CsA, such as cortical epileptiform activity and seizure, result from altered release of excitatory amino acid neurotransmitter in the hippocampal formation.

Sprague-Dawley rats were injected daily with control vehicle or 20 mg/kg CsA for 14 days. This dose of CsA has been shown to generate cortical epileptiform activity (Famiglio et al., 1989). Hippocampal tissue slices (350 µm) were prepared and preloaded with 300 nM [3H]-D-aspartate (D-Asp). Following a 1 hour equilibration in a superfusion apparatus at a flow rate of 0.4 mL/min, tissue slices were superfused at 0.8 mL/min and 3 minute aliquots were collected for 1 hour. Tissue slices were equilibrated and superfused in continuously oxygenated Krebs-Henseleit buffer, pH 7.4. L-Cysteine sulfinic acid (500 mM) was included during the last 20 minutes of equilibration and throughout superfusion to inhibit neurotransmitter reuptake. Release of D-Asp was stimulated electrically by two 5 Hz, 3 minute stimulations, separated by a 21 min interval. Release of D-Asp from CsA exposed tissue was equivalent to controls in response to the first electrical stimulus, but significantly decreased by 27% in response to the second stimulus. We propose that the reduced release of [3H]-D-aspartate is due to changes in phosphorylation of presynaptic proteins resulting from inhibition of PP2B by a CsA-cyclophilin complex. (Supported by NIH R01-AI25555)

## 615.15

FUNCTIONAL UNMASKING OF L-TYPE VOLTAGE-SENSITIVE CALCIUM CHANNEL INVOLVEMENT IN K<sup>+</sup>-EVOKED [3H]-NORADRENALINE RELEASE FROM RAT AND HUMAN NEOCORTICAL SLICES. D.J. Dooley\*, T. Ginap\*, R. Scheremet\*, and T.J. Feuerstein\*. \*Klinische Neuropharmakologie, Neurozentrum, 79106 Freiburg, Germany; \*Neurochirurgische Universitätsklinik, 79106 Freiburg, Germany; and \*Dept. of Neuroscience, Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Co., Ann Arbor, MI 48106.

Central noradrenaline (NA) release is predominantly subserved by N- and P/Q-type voltage-sensitive calcium channels (VSCCs). The role of L-VSCCs in this release has been demonstrated to be minimal or nonexistent. There are, however, two conditions known which permit an increase in *in vitro* neurotransmitter release by the L-VSCC activators Bay K 8644 and FPL 64176: a reduction of the K<sup>+</sup> stimulus concentration and the block of N-VSCCs by ω-conotoxin GVIA. In the present study, L-VSCC-mediated [3H]-NA release from rat or human neocortical slices, induced by Bay K 8644 (1 µM) or the endogenous indirect L-VSCC activator endothelin-3<sup>2</sup> (10 nM), was assessed as a function of K<sup>+</sup> stimulus concentration, N-VSCC antagonism (ω-conotoxin GVIA (1 µM)), and P/Q-VSCC antagonism (ω-agatoxin IVA (1 µM)). Bay K 8644 or endothelin-3 markedly increased [3H]-NA release in the presence of 25 mM K<sup>+</sup> and N- and/or P/Q-VSCC blockade, at 15 mM K<sup>+</sup>. These results suggest that a decrease of NA release effected by several mechanisms, including N- and P/Q-VSCC antagonism or a lower stimulus intensity, permits functional consequences of either direct or indirect L-VSCC activation.

NITRIC OXIDE INCREASES CALCIUM/CALMODULIN-DEPENDENT PHOSPHORYLATION OF PROTEINS IN POSTSYNAPTIC DENSITY FRACTIONS FROM ADULT RAT CEREBRAL CORTEX. K. Wu\*, H.T.J. Mount, J.L. Xu and I.B. Black. Dept. Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854.

Nitric oxide (NO) plays important roles in diverse processes, including neurotransmission within the peripheral and central nervous systems. Nitric oxide synthase (NOS), the enzyme that catalyzes formation of NO from L-arginine, is an intrinsic component of the postsynaptic density (PSD), an electron-dense proteinaceous specialization of the postsynaptic membrane. This raises the possibility that NO may have actions on enzyme functions within this structure.

To begin defining local actions of NO, we examined effects of NO on calcium/calmodulin-dependent phosphorylation (C/C-DP) of proteins in cortical PSD from adult rat brain. Treatment of PSD with sodium nitroprusside (1 mM, 5 min), a NO donor, caused a dramatic 10-fold increase in C/C-DP, relative to C/C treatment alone. S,S'-Dinitrosodithiol (0.1 mM), another NO donor, elicited a 2-fold increase in C/C-DP. Treating PSD fractions with L-arginine (1 mM, 10 min), to produce endogenous NO, also doubled C/C-DP activity. The effect of L-arginine was blocked by a competitive NOS inhibitor, N<sup>G</sup>-Nitro-L-arginine methyl ester (N-LAME). Pretreatment of cortical tissue with N-LAME (0.5 mg/ml, 5 min), before isolation of PSD fractions, decreased basal C/C-DP of PSD proteins by 50%. The inhibitor had no effect on cAMP-dependent phosphorylation of the proteins, suggesting specificity of NO action on C/C-DP.

Our observations indicate that NO enhances C/C-DP of PSD proteins. It has been shown previously that C/C-DP inactivates NOS. These findings raise the possibility that NO effects on C/C-DP may constitute a mechanism for feedback regulation of NOS activity. (Supp: NICHD 23315 and MRCC.)

## 615.14

INHIBITION OF ELECTRICALLY-STIMULATED [3H]GLUTAMATE RELEASE BY THE SUBSTITUTED BENZIMIDAZOLONE NS-004. H.L. Wiener\* and J.R. Torrente.

CNS Drug Discovery, Bristol-Myers Squibb Co., Wallingford, CT 06492.

During ischemic brain damage, excess release of the excitatory amino acid glutamate may damage brain tissue by a multi-faceted process.

Since stroke-related damage can potentially be reduced by limiting glutamate release, we developed an assay that measures the amount of preloaded [3H]glutamate released from rat hippocampal slices in response to electrical stimulation. NS-004 (5-trifluoromethyl-1-(5-chloro-2-hydroxyphenyl)-1,3-dihydro-2H-benzimidazole-2-one) opens neuronal and vascular smooth muscle large-conductance calcium-activated potassium (maxiK) channels. In addition, NS-004 blocks delayed rectifier and ATP-sensitive potassium channels in smooth muscle and is both cardio- and neuroprotective. The present studies investigated the ability of NS-004 to modulate electrically-stimulated [3H]glutamate release in rat hippocampal slices *in vitro*. NS-004 inhibited [3H]glutamate release in a concentration-dependent and saturable manner. To test the hypothesis that maxiK channel opening by NS-004 contributed to its ability to attenuate [3H]glutamate release, NS-004 was assayed in the presence of iberiotoxin (IbTX), a highly specific blocker of the maxiK channel.

Although 100 nM IbTX did not itself affect [3H]glutamate release, it prevented NS-004-induced inhibition of [3H]glutamate release. That the response to NS-004 was IbTX-sensitive suggests that NS-004 inhibits electrically-stimulated [3H]glutamate release in hippocampal slices *in vitro* by opening the maxiK channel and that this may contribute to its neuroprotective action.

## 615.16

ARG-VASOPRESSIN REDUCES FAST EXCITATORY SYNAPTIC TRANSMISSION IN THE SUPRAOPTIC NUCLEUS *IN VITRO*. Samuel B. Kombian\*, Jeffrey A. Zidichouski & Quentin J. Pittman. Neuroscience Research Group, University of Calgary, Calgary, AB Canada T2N 4N1.

The supraoptic nucleus (SON) is a hypothalamic structure that contains vasopressin and oxytocin releasing cells. There is evidence that these peptides are released locally and may influence SON cells. These cells receive glutamatergic and GABAergic afferents which may regulate them. We examined the action of vasopressin on glutamate-mediated fast synaptic transmission in an *in vitro* slice preparation of the SON using the whole cell nystatin patch recording technique. 400 µm thick coronal hypothalamic slices containing the SON were made from 25-40 days old Sprague-Dawley rats. Nystatin patch recordings were made with K-acetate filled electrodes (5-10 MΩ). Access (resistance 20-30 MΩ) was attained in 1-30 min using an Axopatch 1D amplifier. Synaptic responses were evoked (5-50V, 100-500 µs) through a bipolar electrode placed dorso-medial to the SON. Stable recordings (lasting 45-150 min) were made from SON cells with RMP of -84.6 ± 2.1 mV, SEM, n=35 cells. All cells were voltage clamped at -80 mV (V<sub>h</sub>) and intensity dependent inward currents (I<sub>in</sub>) could be evoked in >80% of cells at this V<sub>h</sub>. The evoked I<sub>in</sub> were mediated by both non-NMDA and GABA<sub>A</sub> receptors as CNQX (10 µM) decreased the response by 46.7 ± 14.2% (p<0.05, n=3) while picrotoxin (25 µM) reduced it by 25.4 ± 7.3% (p<0.05, n=3). A combination of these antagonists reduced the I<sub>in</sub> by 94.1 ± 3% (p<0.001, n=3). To examine the pure glutamate-mediated I<sub>in</sub>, picrotoxin (25 µM) was present throughout the remaining experiments. Arginine-vasopressin (AVP; 1 or 3 µM) caused no change in holding current (I<sub>h</sub>, 6/8 cells). However the synaptically evoked I<sub>in</sub> was reduced by 33.7 ± 5.8%, p<0.005, n=6 in these cells. AMPA-induced inward currents were not altered 4 of 6 of these SON cells (0.1 ± 1.2%, p>0.5, n=4). AVP therefore reduces fast excitatory synaptic transmission in the SON mainly by a presynaptic mechanism. Supported by MRC; SBK is supported by H&SF, AHFMR and MRC.

**cAMP-BINDING PROTEINS AFTER PAROXETINE AND FLUVOXAMINE ADMINISTRATION** S. Mori<sup>1</sup>, M. Caivano<sup>1</sup>, S. Garbini<sup>1</sup>, A. Dorigo<sup>1</sup>, M. Motta<sup>3</sup>, G. Racagni<sup>1</sup>, J. Perez<sup>1,2</sup>. 1- Center of Neuropharmacology, Inst. Pharmacological Sciences. 2- Department of Neuropsychiatry HSR, University of Milan. 3- Inst. of Endocrinology, University of Milan, Via Balzaretti 9, 20133 Milan, Italy.

cAMP-dependent protein kinase (PKA) is a serine-threonine kinase, which plays a crucial role in the cAMP signaling. The activation of this enzyme proceeds by a reaction where cAMP binds to the regulatory (R) subunits enabling free catalytic (C) moieties to phosphorylate specific substrate proteins, which in turn are involved in a wide variety of cellular functions. Recent data obtained in our and other laboratories have suggested that the cAMP binding to R subunit, as well as the activity of the enzyme, can be markedly modified following administration of different antidepressants. We have now extended these studies to determine whether cAMP binding activity could be affected in cerebrocortical soluble (S1 or S2) and microtubule fractions after short and long term administration of paroxetine (5 mg/kg) and fluvoxamine (15 mg/kg), two selective serotonin reuptake inhibitors (SSRIs). The results show that either paroxetine and fluvoxamine after 12 days, but not after 5 days of treatment, significantly enhanced the covalent binding to 52 kDa R subunit in the S1 as well as in the microtubule fractions. Following 21 days of treatment these compounds markedly increased the cAMP binding to R subunits only in the S2 fraction, which is devoid of cytosolic microtubules, suggesting that long-term administration of SSRIs could induce a translocation of cAMP receptors from the cytoskeletal to the cytosolic compartment of the cell. In conclusion, our results seem to demonstrate that cAMP binding proteins could be involved in the biochemical action of SSRIs.

## PHARMACOLOGY OF SYNAPTIC TRANSMISSION III

## 616.1

**VERY SLOW CURRENTS RECORDED FROM DEEP DORSAL HORN NEURONS IN ADULT MOUSE SPINAL CORD *IN VITRO*** B. A. Miller and C. J. Woolf. (SPON: Brain Research Association) Dept. of Anatomy & Developmental Biology, University College London, Gower Street, WC1E 6BT.

Slow excitatory synaptic events, lasting up to 60 seconds, have been recorded from neonatal rat spinal cord neurons *in vitro* in response to stimulation of high-threshold afferents (Aδ- and C-fibers). However, it is uncertain whether such slow events reflect the immaturity of the preparation or whether they also occur in the adult. To investigate this, we recorded postsynaptic currents from deep dorsal horn neurons in adult mouse spinal cord *in vitro*.

Thick (700 μm) horizontal spinal cord slices with intact dorsal roots were prepared from adult male mice (MF1 strain, 21-27 g). Neurons at the lamina IV/V border were whole-cell voltage-clamped at -70 mV. Currents were evoked by stimulation (500 μA/500-μs) of high-threshold afferents in dorsal roots L4 or L5, via a suction electrode.

Single-shock stimulation evoked very slow inward currents (peak amplitude, 612.0 ± 63.3 pA; duration, 4.1 ± 0.8 mins; mean ± S.E.M., n = 10), such currents were not observed with stimulation of the low-threshold Aβ-fibers. The currents were voltage-dependent, becoming larger at depolarized potentials and reversing around 0 mV.

Stimulation of primary sensory afferents, therefore, evokes very slow postsynaptic currents in the deep dorsal horn of the adult mouse spinal cord. These currents are considerably longer than any recorded from neonatal *in vitro* preparations. Understanding the transmitter and cellular mechanisms involved may contribute to an understanding of activity-dependent synaptic plasticity in the spinal cord.

This work was supported by the Wellcome Trust.

## 616.3

**EFFECTS OF TRH ON GABAERGIC SYNAPTIC TRANSMISSION OF THE RAT HIPPOCAMPUS** M. Atzori, A. Nistri, M. Sciancalepore\* and G. Stocca. Biophys. Lab., Int. Sch. Adv. Studies (SISSA), 34013 Trieste, Italy.

The effects of Thyrotropin Releasing Hormone (TRH), a neuropeptide present in the mammalian hippocampus, on inhibitory synaptic transmission of the rat hippocampal slice were studied with intracellular or patch clamp recording. After block of glutamate receptors 10 μM TRH increased the frequency of spontaneous GABA<sub>A</sub> receptor mediated currents of CA1 pyramidal neurons (from 1.07±0.68 Hz to 3.16±0.73 Hz) and of Stratum Lacunosum Moleculare (SL-M) interneurons (from 1.6±0.5 to 3.4±0.9). In TTX solution TRH did not change miniature currents. Simultaneous patch recordings from one pyramidal cell and one SL-M interneuron displayed synchronous events suggesting that they shared a common input. Conversely, TRH depressed by 39±6 % average GABAergic responses evoked by stimulation of SL-M whereas it enhanced (by 43±13 %) those induced by Stratum Pyramidale (SP) stimulation. TRH decreased (by 35%) intracellularly recorded GABA<sub>A</sub> receptor mediated potentials evoked from SL-M in half of the cells tested, while leaving unchanged those evoked by SP stimulation. Responses to 10 μM isoguvacine or 10 μM baclofen remained the same in the presence of TRH (104±1% or 105±4%, respectively). The simplest interpretation of these data is that pyramidal neurons and SL-M interneurons received a common GABAergic inhibitory input by a distinct class of SP interneurons selectively modulated by TRH. In this way, spontaneous GABAergic activity and SP-evoked responses of CA1 cells were enhanced while SL-M induced inhibition was depressed by upregulated SP interneurons. The limited sensitivity of GABA<sub>A</sub> receptor mediated responses to TRH might reflect their relatively small contribution to the overall process of GABAergic synaptic inhibition. Supported by a HCMP grant from the EU.

## 616.2

**MODULATION OF EXCITATORY SYNAPTIC TRANSMISSION IN THE NUCLEUS ACCUMBENS BY DOPAMINE D<sub>1</sub> RECEPTORS** J. Harvey & M.G. Lacey. (SPON: Brain Research Association), Dept. of Pharmacology, The Medical School, University of Birmingham, Birmingham, B15 2TT, UK.

In the nucleus accumbens (NAc), dopamine (DA) is known to be involved in locomotion and behavioural reward, but the cellular mechanisms underlying these actions of DA remain unclear. In this study, whole-cell patch clamp recording has been used to investigate the actions of DA and psychostimulants on excitatory synaptic transmission in the NAc. Experiments were performed on 350 μm horizontal rat forebrain slices, maintained at 32-33 °C and perfused with a standard superfusate. Fast glutamate receptor-mediated synaptic currents (EPSCs) were evoked by cortical stimulation, in the presence of picrotoxin (50 μM). In 9 of 11 cells, DA (10-60 μM) produced a reversible and dose-dependent depression of the peak EPSC amplitude, in the absence of any discernable postsynaptic effect. DA (30 μM) produced a depression of 56 ± 11% (mean ± SEM; n=6), which was completely reversed by the selective D<sub>1</sub> receptor antagonist, SCH23390 (1 μM) (n=3). The depressant actions of DA were mimicked by the D<sub>1</sub> receptor agonists, SKF 38393 (10 μM; 42 ± 6%; n=4) and SKF 81297A (1 μM; 39 ± 4%; n=2). In contrast, the selective D<sub>2</sub> receptor agonist, quinpirole (10 μM), failed to affect the peak EPSC amplitude or the holding current (n=4). These data suggest that D<sub>1</sub> receptors, possibly located presynaptically, modulate excitatory synaptic transmission in the cortico-accumbens pathway. In a further 11 of 23 cells, cocaine (10 μM), the DA uptake inhibitor, depressed the peak amplitude (40 ± 6%) of EPSCs in a reversible manner. The D<sub>1</sub> receptor antagonist, SCH23390 (1 μM), completely reversed the depression evoked by 10 μM cocaine (n=3). Amphetamine (10-30 μM), also induced a reversible depression of the peak EPSC amplitude (62 ± 9%; n=6/11), which was antagonised by 1 μM SCH23390 (n=2). Together these data suggest that endogenous DA depresses glutamate receptor mediated synaptic transmission in the NAc, via an action at D<sub>1</sub> receptors.

**LOW CONCENTRATIONS OF ADENOSINE AND THE A<sub>2</sub> AGONIST CGS 21680 FAIL TO ELICIT EXCITATORY EFFECTS IN HIPPOCAMPAL BRAIN SLICES** L.H. Diao\*, C.R. Lupica and T.V. Dunwiddie, University of Colorado Health Sci. Cntr., Dept of Pharmacology, and VA Medical Center, Denver, CO 80262.

The inhibitory effects of adenosine and related compounds on evoked field excitatory postsynaptic potentials (fEPSP) and population spikes (PS), have been consistently observed in a number of laboratories, and are likely due to both pre- and postsynaptic actions at adenosine A<sub>1</sub> receptors. In contrast, the excitatory effects of adenosine, which have been hypothesized to reflect the activation of A<sub>2</sub> receptors, have not been consistently observed. We have attempted to characterize the excitatory effects of adenosine using protocols shown to generate this phenomenon in other laboratories. Thus, low concentrations of adenosine and the selective A<sub>2a</sub> receptor agonist CGS 21680 were tested on fEPSPs and PSs in the CA1 area of hippocampal slices obtained from male Sprague-Dawley and Wistar rats, and Guinea pigs. Neither adenosine (10 nM-1 μM) nor CGS 21680 (1 nM-100 nM) consistently altered the amplitudes of these responses. Also, pretreatment with the selective A<sub>1</sub> adenosine receptor antagonist 8-cyclopentyltheophylline (CPT, 0.1 μM) did not reveal excitatory effects of adenosine (30 μM-100 μM) on fEPSPs and PSs. Higher adenosine concentrations (250-500 μM) significantly decreased both fEPSPs and PSs in the presence of CPT. The reason(s) why low concentrations of adenosine and CGS 21680 were unable to consistently produce excitatory effects are unclear at this time. One possibility is that A<sub>2a</sub> receptors exist only in specific strains of animals that were not tested in the present experiments. Alternatively, these receptors may be present, but are not coupled to the modulation of transmitter release under the present experimental conditions. However, these findings, together with the observation that antagonists such as theophylline, CPT and DPCPX produce only increases in synaptic responses, suggest that the predominant effect of both exogenous and endogenous adenosine in this preparation is inhibitory. **DIRECT AND DISINHIBITORY EFFECTS OF NICOTINE IN THE HIPPOCAMPAL SLICE.** C.J. Frazier\*, G.M. Rose, and T.V. Dunwiddie. Neuroscience Training Program, UCHSC, and Medical Research, VAMC, Denver, CO 80220

We have used extracellular recording techniques, in conjunction with an antidromic-orthodromic paired pulse paradigm, to examine the effects of nicotine on GABAergic inhibition in area CA1 of rat hippocampal brain slices. In this system we are able to measure the effects of nicotine on the amplitude of control population spikes generated by direct orthodromic activation of Schaffer and commissural afferents, and on orthodromic population spikes that were inhibited by prior antidromic (alvear) activation of CA1 interneurons. Our results indicate that 300  $\mu$ M nicotine exerts a small excitatory effect on the control population spike, which is likely to be mediated either by direct depolarization of pyramidal neurons, or by antagonism of feedforward inhibition. However, the most pronounced effect of nicotine is a dose dependent reduction of the inhibition produced by antidromic stimulation. This disinhibitory effect is likely due to nicotinic inhibition of interneuron function. Further efforts towards characterizing this system have indicated that acetylcholine (50-200  $\mu$ M), and 1,1-dimethyl-4-phenylpiperazinium iodide (DMPP; 200  $\mu$ M) are also effective agonists, while cytosine (30-200  $\mu$ M), methyl-carbachol (5-50  $\mu$ M), and 2,4-dimethoxybenzylidene anabaseine (DMXB; 5-50  $\mu$ M) are not. We have also demonstrated that hexamethonium (5 mM), and methyllycaconitine (1-5  $\mu$ M) partially antagonize the effects of 300  $\mu$ M nicotine, while  $\alpha$ -bungarotoxin (300 nM - 1  $\mu$ M), mecamylamine (100-500  $\mu$ M), Dihydro- $\beta$ -erythroidine (10-40  $\mu$ M), and the serotonergic antagonist MDL 72222 (50  $\mu$ M) do not. These results suggest the existence of an  $\alpha 7$  mediated component in hippocampal nicotinic function, however they do not rule out the possibility of a significant  $\alpha 4$  component. The emerging pharmacological profile, and the lack of complete antagonism, may indicate a more complex system, involving multiple receptor types.

## 616.7

**CANNABINOID RECEPTOR AGONISTS INHIBIT GLUTAMATERGIC SYNAPTIC TRANSMISSION IN RAT HIPPOCAMPAL CULTURES.** M. Shen, T. M. Piser and S. A. Thayer\*. Dept. of Pharmacology, Univ. of Minnesota, Minneapolis, MN 55455.

Reduced extracellular  $Mg^{2+}$  (0.1 mM) elicited repetitive intracellular  $Ca^{2+}$  concentration ( $[Ca^{2+}]_i$ ) spikes in cultured rat hippocampal neurons as detected by indo-1-based microfluorimetry. Combined whole-cell current clamp and microfluorimetry showed that a burst of action potentials underlies each  $[Ca^{2+}]_i$  spike.  $[Ca^{2+}]_i$  spiking activity was inhibited by the NMDA receptor antagonist CGS19755 (10  $\mu$ M) and abolished by either the non-NMDA receptor antagonist CNQX (10  $\mu$ M), or TTX (1  $\mu$ M), indicating that the spiking results from glutamatergic synaptic transmission. Anandamide, an endogenous cannabinoid receptor ligand, inhibited the frequency of  $[Ca^{2+}]_i$  spiking with an  $EC_{50}$  of 71 nM. Inhibition of  $[Ca^{2+}]_i$  spiking by cannabinoid receptor agonists was prevented by pretreatment of the cultures with pertussis toxin. Activation of cannabinoid receptors did not affect kainate or AMPA-induced  $[Ca^{2+}]_i$  transients, but did inhibit CNQX-sensitive excitatory postsynaptic currents elicited by stimulation of the presynaptic neuron with an extracellular electrode. Thus, activation of cannabinoid receptors inhibits the presynaptic release of glutamate via an inhibitory G protein. Modulation of excitatory neurotransmission may account for many of the CNS effects of the cannabinoids and suggests that cannabinoid receptor agonists may reduce synaptically mediated excitotoxicity.

## 616.9

**MU OPIOID AND METABOTROPIC GLUTAMATE RECEPTOR AGONISTS MODULATE NMDA SYNAPTIC POTENTIALS IN NUCLEUS ACCUMBENS.** G. Martin, T. Krucker\* and G.R. Siggins. Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

Opiates decrease glutamatergic EPSPs in the nucleus accumbens (NAcc; Yuan et al., Neurosci. Lett. 134: 223, 1992). Therefore, we investigated the effects of a specific  $\mu$  opioid receptor agonist DAMGO ([D-Ala<sup>1</sup>-N-Me-Phe<sup>4</sup>-Gly<sup>5</sup>]-enkephalin) and the metabotropic glutamate agonist trans-ACPD (trans-( $\pm$ )-1-amino-1,3-cyclopentanedicarboxylic acid) on events mediated by N-Methyl-D-Aspartate (NMDA) receptor activation, using intracellular recording in rat NAcc slices. The mean resting membrane potential of NAcc core neurons was -85 mV; mean input resistance was 78 M $\Omega$  and spike size, 124 mV. Superfusion of DAMGO (1  $\mu$ M) or trans-ACPD (10-50  $\mu$ M) did not alter membrane potential or input resistance in any cell. In the presence of 10  $\mu$ M CNQX (6-cyano-7-nitroquinoxaline-2,3-dione) to block non-NMDA glutamate receptors and 15  $\mu$ M bicuculline to block GABA<sub>A</sub> receptors, EPSPs evoked by focal stimulation displayed the characteristics of NMDA components, including voltage-dependence and blockade by the NMDA receptor antagonist D-APV (60  $\mu$ M). DAMGO (1  $\mu$ M) significantly decreased NMDA-EPSP amplitudes by up to 50% of control, with reversal of this effect by naloxone and the  $\mu$ -selective opiate antagonist CTOP (0.5  $\mu$ M). To examine possible postsynaptic actions of DAMGO, we superfused slices with TTX (1  $\mu$ M) under voltage-clamp and evoked inward currents by pressure application of NMDA from pipettes. Here, 1  $\mu$ M DAMGO markedly enhanced (by 75%) NMDA currents ( $n = 8$ ), with naloxone reversal. In 18 cells, trans-ACPD (10 to 50  $\mu$ M), like DAMGO, decreased NMDA-EPSC amplitudes dose-dependently. Surprisingly, this effect was not mimicked by quisqualate (1  $\mu$ M,  $n = 6$ ). Neither L-AP5 (50  $\mu$ M,  $n = 5$ ), MCPG (0.5 mM,  $n = 3$ ), nor naloxone (1  $\mu$ M,  $n = 3$ ) antagonized the trans-ACPD-induced decrease of NMDA-EPSCs. Unlike DAMGO, trans-ACPD (5  $\mu$ M) markedly decreased the current evoked by pipette application of NMDA. These results suggest a complex modulation of the NMDA glutamatergic neurotransmission by  $\mu$  opioid and metabotropic receptors: both agonists decrease the amplitude of NMDA-EPSCs but have opposite effects on currents evoked by exogenous NMDA.

## 616.6

**SEROTONERGIC MODULATION OF SYNAPTIC TRANSMISSION IN THE BASOLATERAL AMYGDALA.** D.G. Rainnie\*. Harvard Medical School & Brockton VAMC, Department of Psychiatry, Brockton, MA 02401, USA

Altered neuronal activity within the amygdala has been regarded as a substrate for several pathophysiological states such as epilepsy, depression and schizophrenia. Although the response of basolateral neurones to extrinsic fibre stimulation has been reported in several studies, little information is available concerning the regulation of synaptic transmission by catecholamines.

Whole cell patch-clamp records were obtained from neurones of the basolateral amygdala in an *in vitro* slice preparation using standard techniques. Patch electrodes (6-10 M $\Omega$ ) were filled with recording solution containing, in mM: KMeSO<sub>4</sub>, 140, MgCl<sub>2</sub>, 3; EGTA, 3; HEPES, 4; CaCl<sub>2</sub>, 1; MgATP, 2; NaGTP, 2; and biocytin 0.25%. Stable records were obtained from 64 neurones, approximately 6% of which were considered to be putative interneurons. Passive membrane properties reveal no significant difference in the resting membrane potential or input resistance of these neurones (-60  $\pm$  6 mV compared to -62  $\pm$  3 mV, and 195  $\pm$  90 M $\Omega$  compared to 135  $\pm$  58 M $\Omega$  respectively). Application of serotonin (5HT, 5-100  $\mu$ M) had no effect on membrane properties of the majority of projection neurones examined ( $n=20$ ). In contrast, 5HT caused a membrane depolarization (5.0  $\pm$  1.8 mV,  $n=5$ ) and concomitant increase in the input resistance of putative interneurons. This action was not mimicked by 1-(*m*-chlorophenyl)-biguanide (1  $\mu$ M) or 8-OH-DPAT (1  $\mu$ M) suggesting that 5HT<sub>1</sub> and 5HT<sub>2</sub> receptors are not involved in this response. Serotonin application also caused a reduction in the amplitude of evoked synaptic potentials and had a biphasic effect on spontaneous potentials. In control ACSF, spontaneous IPSPs occur at ~ 0.7Hz in projection neurones. Superfusion of 5HT (30  $\mu$ M) increased IPSC frequency to 1.4Hz but then caused a progressive decrease in IPSC amplitude until they were abolished. Experiments are in progress to determine the subtype/s of serotonin receptor mediating these responses.

**COCAINE, AMPHETAMINE, AND DOPAMINE DEPRESS SYNAPTIC TRANSMISSION IN THE NUCLEUS ACCUMBENS VIA A PRESYNAPTIC MECHANISM.** S.M. Nicola\*, S.B. Kombian, and R.C. Malenka. Dept. of Psychiatry and Program in Neuroscience, University of California, San Francisco, CA 94143.

We have continued to investigate the actions of psychostimulants on excitatory synaptic transmission in rat nucleus accumbens slices. Previously (Soc. Neurosci. Abstr. 20: 1517, 1994) we reported that cocaine and amphetamine depressed EPSPs at cortico-accumbens synapses, and that dopamine (DA) mimicked these effects. The DA-induced depression of synaptic transmission was accompanied by an increase in paired-pulse facilitation, suggesting a presynaptic site of action. We have now extended this analysis by examining miniature EPSCs. DA (100  $\mu$ M,  $n=15$ ) and amphetamine (10  $\mu$ M,  $n=6$ ) decreased the frequency of mEPSCs by 33% and 44%, respectively, while leaving their amplitude unchanged. These findings confirm that the mechanism of psychostimulant-induced depression is presynaptic at this synapse.

We found previously that the actions of cocaine, amphetamine, and DA were antagonized by the D1 receptor antagonist SCH23390 (2 to 10  $\mu$ M), while the D2 antagonist sulpiride (10  $\mu$ M) had no effect. However, upon re-examination, the effects of agonists are less clear. Neither the D2 agonist quinpirole (20  $\mu$ M,  $n=6$ ) nor the D1 agonists (+)-SKF38393 (10 to 30  $\mu$ M,  $n=6$ ) and (-)-SKF81927 (30  $\mu$ M,  $n=11$ ) appreciably depressed synaptic transmission. However, (+)-SKF38393 at 100  $\mu$ M depressed EPSPs by 23% ( $n=4$ ). To determine whether a different catecholamine or receptor contributed to the psychostimulant-induced synaptic depression, we applied 2  $\mu$ M serotonin ( $n=7$ ) which decreased the EPSP by 20%; however, this effect was not antagonized by SCH23390 (10  $\mu$ M,  $n=9$ ). Norepinephrine (100  $\mu$ M,  $n=11$ ) depressed synaptic transmission by 30%; this depression was blocked by the  $\alpha$ -adrenergic antagonist phentolamine (10  $\mu$ M,  $n=7$ ) whereas 10  $\mu$ M phentolamine had no effect on the depression induced by 10  $\mu$ M amphetamine ( $n=6$ ). These results are consistent with the hypothesis that psychostimulant-induced synaptic depression is mediated primarily by DA.

## 616.10

**METABOTROPIC GLUTAMATE RECEPTORS AT THE MOSSY FIBER SYNAPSES OF THE GUINEA PIG HIPPOCAMPUS.** P.E. Castillo\*, O.J. Manzoni and R.A. Nicoll. Depts. Cellular and Molecular Pharmacol. and Physiol., UCSF, San Francisco, CA 94143-0450.

We have tested the ability of several specific agonists of metabotropic glutamate receptors (mGluRs) to depress synaptic transmission at mossy fiber (MF) synapses in the CA3 region of the guinea pig hippocampus. 1S,3R-1-amino-cyclopentyl-1,3-dicarboxylate (ACPD) reversibly inhibited monosynaptic MF field potentials, presumably by a presynaptic mechanism, with an  $EC_{50}$  of 2.0  $\pm$  0.4  $\mu$ M. This finding suggests that mGluRs of the group 1 or 2 category are on MF synaptic terminals. L-2-amino-4-phosphono butanoate (L-AP4) also inhibited responses with an  $EC_{50}$  of 1.1  $\pm$  0.2  $\mu$ M, suggesting that mGluRs of the group 3 (mGluR4, 6, 7 and 8) category of receptors are also present on MF terminals. Both (2S,1'S,2'S)-2-(2'-carboxycyclopropyl)glycine (L-CCG1) and (S)-4-carboxy-3-hydroxyphenyl-glycine (4C3HPG) were also efficacious at blocking MF transmission, with  $EC_{50}$ s of 1.1  $\pm$  0.1  $\mu$ M and 4.8  $\pm$  0.6  $\mu$ M, respectively. The latter finding suggests the involvement of mGluRs belonging to the group 2 (mGluR2,3) category of receptors. The effects of L-AP4 and L-CCG1 were both antagonized by (+)- $\alpha$ -methyl-4-carboxyphenylglycine ([+]-MCPG). MAP4, an antagonist of group 3 mGluRs in other systems, blocked the effect of L-AP4, but not the effect of L-CCG1. These pharmacological findings provide strong evidence for the coexistence of group 2 and 3 mGluRs on the terminals of MFs in the guinea pig.

## 616.11

PROPERTIES OF ACPD-INDUCED LTD OF SYNAPTIC TRANSMISSION IN IMMATURE CA1 L.S. Overstreet\*, J.F. Pasternak, N.T. Slater, J.W. Cozzens, B.L. Trommer, Pediatric Neurology Research Laboratory, Northwestern Univ. Medical School, Evanston Hospital, Evanston, IL, 60201

Bath application of the metabotropic glutamate receptor (mGluR) agonist (S,3R)-ACPD (10  $\mu$ M, 20 min) induces an acute partially reversible decrease (~60% baseline) followed by long-term depression (LTD, ~75% baseline at 30 min) of the field EPSP slope at the Schaffer collateral-CA1 synapse of 8-12 day rats. We examined several pharmacologic properties of this phenomenon. ACPD-induced LTD was blocked by the NMDA receptor antagonists AP5 (20  $\mu$ M, n=7) and MK-801 (20  $\mu$ M, n=4), although the acute reversible depression was observed in 9/11 slices. The enzyme glutamic pyruvic transaminase (5u/ml) in pyruvic acid (2mM) also blocked ACPD-induced LTD (acute depression of EPSP slope to 79  $\pm$  14%, recovery to 94  $\pm$  12% of baseline, n=4; interleaved controls=77  $\pm$  10% of baseline). The protein kinase inhibitor staurosporine (0.4  $\mu$ M) blocked ACPD-induced LTD (99  $\pm$  21% baseline; control=62  $\pm$  6% baseline, n=5). ACPD-induced LTD was not blocked by the L-type  $Ca^{2+}$  channel blocker nifedipine (5  $\mu$ M, 77  $\pm$  26% baseline, n=6) or the A-1 adenosine receptor blocker CPT (5  $\mu$ M, 68  $\pm$  10% baseline, n=5). These data suggest that 1) ACPD-induced LTD is independent of both L-type voltage-gated  $Ca^{2+}$  channels and A-1 adenosine receptors; 2) ACPD-induced LTD is NMDA receptor dependent and the requisite NMDA-mediated current results from background activity generated by extracellular glutamate rather than glutamate released by axon terminals; and 3) ACPD-induced LTD depends on the activation of protein kinase C.

## 616.13

ACTIVATION OF GROUP I MGLURS REVERSIBLY DEPRESSES GABAERGIC INHIBITION IN THE HIPPOCAMPUS. V.R.J. Clarke<sup>1</sup>, C.H. Davies<sup>2</sup>, G. Henderson<sup>2\*</sup> & G.L. Collingridge<sup>1</sup>. <sup>1</sup>Depts. of Anatomy & Pharmacology<sup>2</sup>, University of Bristol, Bristol, U.K. BS8 1TD & Dept. of Pharmacology<sup>3</sup>, University of Edinburgh, Edinburgh, U.K. EH8 9JZ.

Activation of metabotropic glutamate receptors (mGluRs) by ACPD has been shown to depress GABAergic inhibition in CA1 hippocampal neurones (Desai, M.A. & Conn, P.J., 1991, J. Neurophysiol., 66, 40-52; Liu, Y-B. *et al.*, 1993, J. Neurophysiol., 69, 1000-1004). We have examined the effects of (1S,3R)-ACPD and the more selective agonists DHPG (group I), DCG-IV (group II), and L-AP4 (group III) on monosynaptically-evoked inhibitory postsynaptic potentials (IPSPs) and currents (IPSCs).

Standard intracellular recordings were obtained from 400  $\mu$ m thick transverse rat hippocampal slices. Monosynaptic inhibitory responses were evoked by low frequency stimulation (0.033 Hz) of the Schaffer collateral-commissural pathway close to the recording site in the presence of 20  $\mu$ M CNQX and 50  $\mu$ M D-AP5. CA1 neurones were manually current clamped at -62  $\pm$  1 mV (mean  $\pm$  S.E.M.; n=19) or voltage clamped at -60  $\pm$  3 mV (n=3). (1S,3R)-ACPD (50  $\mu$ M; 10 mins) induced an inward current, increased input resistance (by 11  $\pm$  1%), blocked action potential accommodation and depressed the peak amplitude of the IPSP (by 17  $\pm$  3%) or IPSC (by 24  $\pm$  5%). On washout, all the effects were fully reversible. The IPSPs and IPSCs recovered to 97  $\pm$  2% (n=19) and 97  $\pm$  5% (n=3) of control, respectively. Similar results were obtained under current clamp conditions for DHPG (50-100  $\mu$ M; n=8). In contrast, no effect of DCG-IV (5  $\mu$ M; n=3) or L-AP4 (50-500  $\mu$ M; n=5) was observed. These data suggest that activation of a group I mGluR produces a reversible depression of inhibitory synaptic transmission.

PHARMACOLOGY OF METABOTROPIC GLUTAMATE RECEPTORS INHIBITING HIPPOCAMPAL CA3-CA1 SYNAPSES.

O. Manzoni-Etxepare and J. Bockaert<sup>\*</sup>.

CNRS-UPR 9023, Rue la Cardonille 34094 Montpellier Cedex 5 France  
In the CA1 region of rat hippocampal slices, we have studied the ability of several specific agonists of metabotropic glutamate receptors (mGluRs) to depress transmission at the CA3-CA1 pyramidal cells synapses. We found that the broad-spectrum agonist (1S,3R)-ACPD and the group 1 specific agonist (R,S)-dihydroxyphenyl-glycine both reversibly inhibited evoked field excitatory post-synaptic potentials (with EC50s of 13  $\pm$  1  $\mu$ M (n=6) and 18  $\pm$  3  $\mu$ M (n=5) respectively), indicating the presence of group 1 mGluRs. (R,S)-dihydroxyphenyl-glycine inhibited transmission via a presynaptic mechanism, as whole-cell voltage-clamp recordings revealed that inhibition of the synaptic transmission was always accompanied with an increase of paired-pulse facilitation (176  $\pm$  30 % of control, n = 5). Treatment with a specific blocker of mGluR1 receptors, (+)-4-carboxyphenylglycine, was without effect on the (1S,3R)-ACPD-induced depression of the field excitatory post synaptic potentials, strongly suggesting that mGluR5 receptors are responsible for the (1S,3R)-ACPD effect. Two selective agonists of group 2 mGluRs, L-CCG1 and (S)-4C3HPG, were totally ineffective at blocking CA3-CA1 evoked synaptic transmission excluding the involvement of mGluR2/3 subtypes. Finally, we confirmed that the specific group 3 agonist L-AP4 was also capable of reducing transmission with an EC50 of 112  $\pm$  22  $\mu$ M (n=4) and we propose that mGluR7 mediate this inhibition. We are currently investigating the transduction mechanisms responsible for these effects.

## 616.12

PHARMACOLOGICAL CHARACTERISATION AND NOVEL ANTAGONISM OF METABOTROPIC GLUTAMATE RECEPTORS IN THE LATERAL PERFORANT PATH OF THE NEONATAL RAT HIPPOCAMPUS. T.J. Bushell<sup>1</sup>, D.E. Jane<sup>2</sup>, J.C. Watkins<sup>2</sup>, E.J. Coan<sup>1\*</sup> and G.L. Collingridge<sup>1</sup>.

<sup>1</sup>Depts. of Anatomy & Pharmacology<sup>2</sup>, University of Bristol, Bristol, U.K. BS8 1TD.

Standard extracellular recording techniques were used to investigate the actions of various mGluR agonists and antagonists on synaptic transmission in the lateral perforant path of hippocampal slices prepared from neonatal (12-16 day old) rats.

The lateral perforant path is highly sensitive to low concentrations of the group III mGluR agonist, L-AP4 (i.e. > 50% depression using 10  $\mu$ M L-AP4). In this study we confirmed this observation and also showed that this pathway is depressed by group II mGluR agonists, (1S,3S)-ACPD (46  $\pm$  4 %, n=12; 10  $\mu$ M) and DCG-IV (63  $\pm$  3 %, n=3; 500 nM). In contrast, the group I selective mGluR agonist DHPG (50-100  $\mu$ M; n=5) had no effect. These data suggest that group II and group III mGluRs mediate the depressions of synaptic transmission in the lateral perforant path of rat hippocampus.

Novel mGluR antagonists, (R,S)- $\alpha$ -methyl-4-phosphonophenylglycine (MPPG), (R,S)- $\alpha$ -methyl-4-sulphonophenylglycine (MSPG) and (R,S)- $\alpha$ -methyl-4-tetrazolylphenylglycine (MTPG) have been shown to antagonise L-AP4 and (1S,3S)-ACPD-induced depressions in the neonatal rat spinal cord (Jane *et al.* Neuropharmacology, in press). The actions of these new antagonists were tested against the synaptic depressions induced by L-AP4 and (1S,3S)-ACPD in the lateral perforant path. MPPG most potently antagonised L-AP4-induced depressions with a K<sub>1/2</sub> of 8  $\mu$ M. The potency for the antagonism of (1S,3S)-ACPD-induced depressions was MTPG > MSPG = MPPG > MCPG. The advent of these new mGluR antagonists may help determine the physiological roles of class II and III mGluRs.

ELECTROPHYSIOLOGICAL EFFECTS OF KAINATE RECEPTOR ACTIVATION IN THE HIPPOCAMPUS. M. Vignes, Z. I. Bashir\* and G. L. Collingridge. Dept. of Anatomy, University of Bristol, BS8 1TD, UK.

By the use of the selective AMPA receptor antagonist GYKI 52466 and whole-cell patch-clamp technique we have investigated the effects of the activation of kainate (KA) receptors in CA1 hippocampal neurones. Experiments were performed on hippocampal slices, obtained from 12-16 day old rats, perfused with a standard Mg<sup>2+</sup>-containing medium at room temperature. NMDA receptor-mediated synaptic currents, isolated by using GYKI 52466 (100  $\mu$ M) picrotoxin (50  $\mu$ M) and intracellular Cs<sup>+</sup>, were evoked by stimulation of Schaffer collateral-commissural pathway. Neurones were voltage-clamped at -45 mV.

Three effects were observed. KA (1  $\mu$ M; 5 min) evoked, firstly, an increase in the NMDA receptor-mediated synaptic noise, secondly, an NMDA receptor-independent inward current and, thirdly, a reversible depression of the NMDA receptor-mediated synaptic current (by on average 60%). The depression of the synaptically-evoked current outlasted the inward current. All three effects of KA were mimicked by domoate (100 nM) but not by AMPA (10  $\mu$ M). The effects of kainate were antagonised reversibly by CNQX (10-20  $\mu$ M).

It is suggested that activation of kainate receptors can have both postsynaptic excitatory and presynaptic inhibitory effects within the hippocampus.

METABOTROPIC GLUTAMATE RECEPTOR TYPE 1/5 MEDIATES BOTH DIRECT AND INDIRECT EXCITATION OF CA1 PYRAMIDAL CELLS. P.J. Conn\* and R.W. Gereau IV. Department of Pharmacology and Program in Neuroscience, Emory Univ. School of Medicine Atlanta, GA 30322.

Previous studies have shown that the excitatory effects of metabotropic glutamate receptor (mGluR) activation on CA1 pyramidal cells are mediated by direct excitatory effects and a reduction of synaptic inhibition in area CA1. Studies that have examined the physiological roles of mGluRs have generally used agonists that do not differentiate between the various subtypes. We have performed a detailed pharmacological analysis, including examination of the effects of agonists which are selective for Group I (DHPG), Group II (DCG-IV), and Group III (L-AP4) mGluRs as well as rank orders of agonist potencies, to determine the specific mGluR subtypes involved in the direct and indirect excitatory effects of mGluR activation in area CA1. All direct excitatory effects on CA1 pyramidal cells tested including depolarization, increased input resistance, blockage of the slow afterhyperpolarization (AHP), and spike frequency adaptation have pharmacological profiles that are consistent with mediation by a Group I mGluR (mGluR1/5), but not consistent with mediation by Group II (mGluR2/3) or III (mGluR4/6/7/8) mGluRs. The mGluR that reduces transmission at inhibitory synapses in area CA1 also has a Group I-like pharmacological profile. Analysis of miniature IPSCs suggests that this mGluR is localized presynaptically on GABAergic nerve terminals in area CA1. Supported by grants from the NIH (PJC) and a predoctoral fellowship from the Howard Hughes Medical Institute (RWG).

## 616.17

**MULTIPLE METABOTROPIC GLUTAMATE RECEPTORS REDUCE EXCITATORY SYNAPTIC TRANSMISSION IN AREA CA1 BY DISTINCT PRESYNAPTIC MECHANISMS.** R.W. Gereau IV\* and P.J. Conn. Department of Pharmacology and Program in Neuroscience, Emory Univ. School of Medicine Atlanta, GA 30322.

Many studies have shown that metabotropic glutamate receptors (mGluRs) reduce excitatory synaptic transmission in the hippocampus. The conventional view is that this effect is mediated by an L-AP4-sensitive mGluR (mGluR4, 6, 7, or 8). However, some studies suggest that other mGluR subtypes may also be involved. We have found that two pharmacologically distinct presynaptic receptors are involved in the depression of excitatory postsynaptic currents (EPSCs) at the Schaffer collateral-CA1 synapse. Consistent with previous studies, one receptor subtype is an L-AP4-sensitive receptor that is pharmacologically similar to mGluR4 or mGluR7. However, we have found that a second mGluR subtype, which is pharmacologically similar to mGluR1 or mGluR5, can also reduce EPSCs in area CA1. While the mGluR1/5-like receptor is sensitive to inhibition by the mGluR 1/2 antagonist, MCPG, the mGluR4/7-like receptor is insensitive to MCPG. Analysis of miniature EPSCs suggests that both receptors are localized presynaptically, but act to reduce glutamate release via different mechanisms. Supported by grants from the NIH (PJC) and a predoctoral fellowship from the Howard Hughes Medical Institute (RWG).

## CALCIUM CHANNEL STRUCTURE, FUNCTION AND EXPRESSION II

## 617.1

**L-TYPE CALCIUM CHANNELS MODULATE EVOKED TRANSMITTER RELEASE AT NEWLY FORMED NEUROMUSCULAR JUNCTIONS.** Y. Sugiura\* and C.-P. Ko Dept. Biol. Sci., University of Southern California, Los Angeles, CA 90089.

Evoked-transmitter release at adult mammalian neuromuscular junctions (NMJs) is blocked by P/Q-type voltage-sensitive calcium channel (VSCC) blockers but not by N- or L-type VSCC blockers. To study the ontogenic change of VSCC subtypes, we examined the effects of several  $Ca^{2+}$  channel ligands on synaptic transmission at developing rat NMJs. Similar to adult NMJs, omega-conotoxin MVIIIC blocked evoked transmitter release at developing NMJs. Nifedipine, a dihydropyridine (DHP) that blocks L-type VSCCs, increased evoked transmitter release at developing NMJs in dose- and age-dependent manners. At embryonic day 17, one, five, and 10  $\mu$ M nifedipine increased endplate potentials (epps) amplitude 1.8-, 2.5- and 5.4-fold, respectively. This potentiation effect of nifedipine was dramatically weakened after birth. 10  $\mu$ M nifedipine increased epp amplitude by only 30% at two weeks, and had little effect at one-month. Nimodipine, another L-type blocker, showed a similar effect. The potentiation effect of nifedipine was also observed during the initial stage of reinnervation at the adult mouse and frog NMJs. Nifedipine had little effect on the amplitude and frequency of miniature epps. Charybdotoxin (ChTX), a  $Ca^{2+}$ -activated  $K^{+}$  channel ( $gK_{Ca}$ ) blocker, increased epp amplitude at regenerating NMJs similar to normal NMJs. However, nifedipine following ChTX showed no additive effect on epp amplitude at regenerating NMJs. The results indicate that L-type VSCCs modulate evoked transmitter release at newly formed, but not mature, NMJs. Blocking L-type VSCCs may prevent the activation of nearby  $gK_{Ca}$  and result in a lengthening of presynaptic action potential duration and thus an increase in transmitter release. (Supported by NIH grant NS 30051).

## 617.3

**STRUCTURE OF CALCIUM CHANNEL  $\alpha_1$  SUBUNITS FROM CNIDARIANS AND PLATYHELMINTHS.** R.M. Greenberg, K.S. Clark, M.C. Jeziorski, G.B. White, and P.A.V. Anderson. Whitney Lab, University of Florida, St. Augustine, FL 32086.

The phylum Cnidaria is the lowest extant phylum to possess a recognizable nervous system. The platyhelminths, which include the flatworms and flukes, are the earliest animals with a distinct rostral brain and nervous system plasticity, and are thought to have emerged close to the divergence of the deuterostome and protostome branches. We are characterizing the molecular structure of components underlying nervous system function in these animals to provide clues to nervous system evolution as well as insights into structure/function relationships in these molecules. We have recently used degenerate primers and RT-PCR to clone cDNA fragments from neuron-enriched perirhopalial tissue from the jellyfish *Cyanea capillata*, and from the ectoparasitic flatworm *Bdelloura candida*, that are homologous to vertebrate  $Ca^{2+}$  channel  $\alpha_1$  subunits. In *Cyanea*, the single  $Ca^{2+}$  channel sequence we have obtained is encoded by a  $\approx 8.5$  kb mRNA and is most similar to vertebrate L-type  $\alpha_1$  subunits. In *Bdelloura*, fragments of two separate  $\alpha_1$  subunit cDNAs were cloned, each encoded by a distinct mRNA of either 7.2 kb or 7.6 kb. Preliminary evidence suggests that they are most similar to vertebrate L- and N-type  $\alpha_1$  subunits, respectively. All three of the sequences show extensive similarity to the vertebrate  $Ca^{2+}$  channels, particularly in the transmembrane domains. For example, the *Cyanea* fragment shows as much as 72% amino acid sequence identity to the  $Ca^{2+}$  channel from rabbit cardiac muscle, suggesting that rather rigorous constraints are operating on the structure of these channels. (Supported by NSF grant #BIR9200417).

## 616.18

**METABOTROPIC GLUTAMATE RECEPTOR AGONISTS MODULATE PAIRED-PULSE DEPRESSION IN THE DENTATE GYRUS OF THE RAT IN VITRO.** R.E. Brown\* and K.G. Reymann, Dept. of Neurophysiology, Federal Inst. for Neurobiology, Brenneckestr. 6, POB 1860, D-39008, Magdeburg, Germany.

The medial perforant path input to the dentate gyrus exhibits paired-pulse depression (PPD), a presynaptically-mediated, short-term form of synaptic plasticity, whereby the synaptic response elicited by the second of a pair of pulses delivered with inter-pulse intervals (ISIs) of up to 2 seconds is depressed relative to the first. We have analyzed the effects of agonists acting at different classes of metabotropic glutamate receptors (mGluRs) on PPD to reveal which classes regulate this process and therefore, which are located presynaptically at this synapse. Hippocampal slices were maintained according to standard procedures; picrotoxin (50  $\mu$ M) was present in all experiments. A monopolar stimulating electrode was placed in stratum moleculare of the dentate to stimulate the medial perforant path input and field excitatory postsynaptic potentials were recorded. Paired pulses were given at 3 minute intervals during drug application. Interpulse interval was 40 or 500ms.

None of the drugs tested affected PPD with an ISI of 500 ms. In contrast, both 1S, 3R-1-aminocyclopentane-1,3-dicarboxylic acid (100  $\mu$ M, n = 5), which acts at class I (mGluR1, 5) and class II (mGluR2, 3) mGluRs and L-2-amino-4-phosphobutyric acid (100  $\mu$ M, n = 4) which is specific for class III (mGluR 4, 6-8) mGluRs, strongly reduced PPD with an ISI of 40 ms ( $p < 0.01$ ). The class I specific agonists trans-azetidine-2,4-dicarboxylic acid (100  $\mu$ M, n=7) and 3,5-dihydroxyphenylglycine (100  $\mu$ M, n = 4) did not affect PPD. The relatively specific class II agonists S-3-carboxy-4-hydroxyphenylglycine (n = 5) and 2S,3S,4S- $\alpha$ -carboxycyclopropyl-glycine (n = 4) did reduce PPD but only at very high concentrations (500 and 40  $\mu$ M respectively). These results suggest that 2 types of mGluRs control PPD at this synapse - a class III mGluR and a class II-like mGluR which may not correspond to one of the currently cloned receptors.

## 617.2

**A CALCIUM CHANNEL FROM THE PRESYNAPTIC NERVE TERMINAL OF THE NARKE JAPONICA ELECTRIC ORGAN CONTAINS AN L-TYPE  $\alpha_2\delta$  SUBUNIT.** Y. Kirino<sup>a,b\*</sup>, H. Tokumaru<sup>a</sup>, S. Shojaku<sup>a</sup>, H. Takehara<sup>b</sup>, N. Hirashima<sup>a,b</sup>, T. Abe<sup>c</sup>, H. Saisu<sup>c</sup>. <sup>a</sup>Faculty of Pharmaceutical Sciences, The University of Tokyo, Bunkyo-ku, Tokyo 113, JAPAN, <sup>b</sup>Faculty of Pharmaceutical Sciences, Kyushu University, Higashi-ku, Fukuoka 812, Japan, <sup>c</sup>Department of Neurochemistry, Brain Research Institute, Niigata University, Niigata 951, Japan

A monoclonal antibody (MCC-1) that recognizes the  $\alpha_2\delta$  subunit complex of L-type Ca channels from rabbit skeletal muscle membranes partially inhibited the evoked release of acetylcholine from synaptosomes isolated from the electric organ of the marine electric ray, *Narke japonica*. A potent L-type Ca channel blocker, calciseptine, inhibited the evoked release of acetylcholine to the same extent. Digitonin extracts of synaptosomal plasma membranes were subjected to immunoadfinity column chromatography on MCC-1-Sepharose. The purified fraction contained a 170 kDa protein, which reacts with MCC-1 and dissociates into smaller polypeptides under reducing conditions. In addition, immunoblotting analysis revealed the existence of syntaxin in the purified fraction, suggesting that the Ca channel forms a complex with syntaxin. However, MCC-1 did not immunoprecipitate an  $\omega$ -conotoxin GVIA-binding protein. These findings indicate that the 170 kDa protein may be the  $\alpha_2\delta$  subunit of an L-type Ca channel that is distinct from the  $\omega$ -conotoxin GVIA-sensitive N-type Ca channel and partially responsible for the Ca influx that triggers the evoked release of acetylcholine.

## 617.4

**DISTRIBUTION OF ALPHA 1A, ALPHA 1B AND ALPHA 1E VOLTAGE-DEPENDENT CALCIUM CHANNEL SUBUNITS IN THE HUMAN MOTOR SYSTEM.** N.C. Day<sup>1\*</sup>, P.G. Ince<sup>1</sup>, P.J. Shaw<sup>2</sup>, S.G. Volsen<sup>3</sup>, A.L. McCormack<sup>3</sup>, P.J. Craig<sup>3</sup>, W. Smith<sup>3</sup>, A. Gillespie<sup>4</sup>, S.B. Ellis<sup>4</sup> and M.M. Harbold<sup>4</sup>. MRC Neurochemical Pathology Unit<sup>1</sup> and Division of Clinical Neurosciences<sup>2</sup>, University of Newcastle upon Tyne, England; Lilly Research Centre<sup>3</sup>, Surrey, England; SIBIA Inc.<sup>4</sup>, La Jolla, CA 92037, USA.

Voltage-dependent calcium channels (VDCCs) play an important role in neuronal excitability and neurotransmitter release. Six classes of VDCC, termed T, L, N, P, Q and R, have been identified. Expression data for cloned alpha 1 ( $\alpha_1$ ) calcium channel subunits suggest that  $\alpha_1B$  is a major component of the N channel, while  $\alpha_1A$  and  $\alpha_1E$  may correspond to P/Q and R channels respectively. We have investigated the distribution of  $\alpha_1A$ , B and E in the normal human motor system by *in situ* hybridization and immunocytochemistry. The *in situ* hybridization studies were performed using riboprobes directed towards the intracellular loop between transmembrane domains II/III of  $\alpha_1A$ , B and E. Fusion proteins of this region were used to generate subunit-specific rabbit polyclonal antisera which were used for immunocytochemistry.

In this study there was good correlation between the distribution of subunit mRNA and protein.  $\alpha_1A$  subunits were expressed in spinal cord, XII nucleus and III nucleus motor neurones, as well as in Betz cells in the motor cortex. Preliminary studies suggest that the  $\alpha_1B$  subunit exhibits a similar pattern of distribution to  $\alpha_1A$ , while the  $\alpha_1E$  subunit is only weakly expressed in motor system neurones. In general,  $\alpha_1A$  and  $\alpha_1E$  antisera stained somatodendritic compartments while  $\alpha_1B$  antisera labelled cell bodies but exhibited diffuse neuropil staining. Thus  $\alpha_1A$ , B and E exhibit a differential distribution pattern in the human motor system which may reflect their different functions.

## 617.5

**LOCATION OF L-TYPE  $\text{Ca}^{2+}$  CHANNELS AT PERISYNAPTIC GLIAL CELLS OF THE FROG NEUROMUSCULAR JUNCTION.** R. Robitaille, M.J. Bourque and S. Vandaele. Département de Physiologie et Pathologie and CRSN, Université de Montréal, Montréal, Canada, H3C 3J7.

Glial cells may modulate synaptic activity because of their close proximity of synapses. To understand the roles of glial cells at synapses, it is important to know the subcellular distribution of glial receptors and channels in relation with transmitter release sites. This work aims at characterizing the type and subcellular distribution of  $\text{Ca}^{2+}$  channels at perisynaptic Schwann cells (PSC) of the frog neuromuscular junction. The activity of  $\text{Ca}^{2+}$  channels was tested by monitoring changes in intracellular  $\text{Ca}^{2+}$ . Depolarisation of PSCs with KCl (25 mM) produced  $\text{Ca}^{2+}$  entry which was not blocked by  $\omega$ -conotoxin GVIA (2  $\mu\text{M}$ ) but prevented by L-type  $\text{Ca}^{2+}$  channel blockers (+)R-BayK 8644, 2  $\mu\text{M}$ ; nimodipine, 5  $\mu\text{M}$ ). In addition, L-type  $\text{Ca}^{2+}$  channels are functionally modulated by an ATP receptor of the  $\text{P}_{2\text{U}}$  subtype. The distribution of L-type  $\text{Ca}^{2+}$  channels was studied using a monoclonal antibody directed against the  $\alpha_1\beta$  subunit of these channels and observed using confocal microscopy. L-type  $\text{Ca}^{2+}$  channel immunoreactivity was distributed as irregular clusters along the frog endplate, mainly absent from the PSC cell bodies. A similar pattern was observed using a fluorescent phenylalkylamine. Clusters of L-type  $\text{Ca}^{2+}$  channels were preferentially located in between bands of cholinergic receptors stained with  $\alpha$ -bungarotoxin-TRITC.  $\text{Ca}^{2+}$  channel labeling was absent after mechanical removal of nerve terminal and PSCs but remained after denervation. Cross sections of motor endplate showed that  $\text{Ca}^{2+}$  channels are strictly located at the processes of the PSCs. Thus, perisynaptic Schwann cells present a highly organized distribution of L-type  $\text{Ca}^{2+}$  channels around the presynaptic nerve terminal. (Supported by MRC, FRSC, FCAR and the Sloan Foundation).

## 617.7

**IMMUNOCHEMICAL IDENTIFICATION AND DIFFERENTIAL DISTRIBUTION OF ALTERNATIVELY SPLICED FORMS OF THE  $\alpha_1$  SUBUNIT OF NEURONAL CLASS A CALCIUM CHANNELS.** T. Sakurai, R. E. Westenbroek, J. Rettig, and W. A. Catterall\* Dept. of Pharmacology, SJ-30, Univ. of Washington, Seattle, WA 98195.

Biochemical properties and subcellular distribution of the  $\alpha_1\text{A}$  subunits were examined in rat brain using anti-peptide antibodies (anti-CNA3 and anti-NBI-2) against unique sequences in the rat rBa and rabbit BI  $\alpha_1\text{A}$  cDNAs, respectively. In immunoblotting, anti-CNA3 recognized two  $\alpha_1\text{A}$  polypeptides, a major 190 kDa form and a minor 220 kDa form. The 220 kDa and 190 kDa forms were also recognized by antibodies against the predicted NH<sub>2</sub>- and COOH-termini of  $\alpha_1\text{A}$ , indicating that these isoforms of  $\alpha_1\text{A}$  arise from alternative RNA splicing rather than post-translational proteolytic processing. Anti-NBI-2 specifically recognized a 190 kDa form of  $\alpha_1\text{A}$  in rat brain membrane. Both anti-CNA3 and anti-NBI-2 specifically immunoprecipitated high affinity receptor sites for  $\omega$ -conotoxin MVIIC ( $K_d \sim 100$  pM). Immunofluorescence studies reveal that calcium channels recognized by anti-NBI-2 are localized predominantly in dendrites and nerve terminals forming synapses on them while calcium channels recognized by anti-CNA3 are localized more prominently in neuronal cell bodies and to a lesser extent in punctate structures in dendritic fields. These results indicate that an  $\alpha_1\text{A}$  subunit with a sequence related to the rabbit BI cDNA is present in the rat brain, and that the rBa and BI cDNAs encode  $\alpha_1\text{A}$  subunits with distinct biochemical properties and subcellular distribution.

## 617.9

**LOW THRESHOLD (T TYPE)  $\text{Ca}^{2+}$  CHANNELS CONTROL MINIATURE EPSC FREQUENCY IN THE SPINAL SUBSTANTIA GELATINOSA.** J. Bao, J. Li, B. Wall and E. R. Perl\*. Dept. of Physiology, CB #7545, Univ. of North Carolina, Chapel Hill, NC 27599

The relationship of presynaptic  $\text{Ca}^{2+}$  influx to release of transmitter evoking miniature EPSCs (mEPSCs) is not clearly established. We explored the effects of  $\text{Ca}^{2+}$  channel manipulation on synaptic events in 500-700  $\mu\text{m}$  transverse spinal cord slices prepared from deeply-anesthetized 45-65 gm Syrian Golden Hamsters. The slices were maintained *in vitro* by superfusion with oxygenated artificial cerebrospinal fluid (ACSF).  $\text{Cs}^+$  internal solution electrodes were used to make tight-seal whole-cell recordings from neurons of the substantia gelatinosa (SG). Inward currents representing mEPSCs or EPSCs evoked by stimulation of dorsal rootlets (DR) or adjacent regions of superficial dorsal horn were used to evaluate synaptic events.

Substances modifying  $\text{Ca}^{2+}$  channel function proved to have differential effects on evoked EPSCs and mEPSCs.  $\text{Cd}^{2+}$  <50  $\mu\text{M}$  blocked evoked responses without appreciable effect upon mEPSC frequency. A putative selective T-type  $\text{Ca}^{2+}$  channel blocker, Ro 40-5967, decreased mEPSC frequency 45% (n=16), while reducing average DR-evoked EPSC amplitudes only 16% (n=12); in 6 neurons Ro 40-5967 reduced mEPSC frequency 43% without any significant effect on DR evoked EPSCs.  $\text{La}^{3+}$ , another reported T-type channel blocker, decreased mEPSC frequency 35% (n=10) while reducing DR-evoked EPSCs amplitude only 5.5% (n=10). Increasing  $[\text{K}^+]_o$  from 2.5 to 5 or 10 mM, causing relatively small membrane depolarizations, sharply increased (>70%) EPSC frequency (N=7). These results suggest that transmitter release contributing to mEPSCs is governed by  $\text{Ca}^{2+}$  channels of the low threshold (T) type, opening near background transmembrane potentials. Low threshold  $\text{Ca}^{2+}$  channel kinetics in the SG thereby may be a factor in modulating the background excitability of neurons concerned with pain and temperature functions. Supported by NINDS Research Grant NS-10321.

## 617.6

**LOCALIZATION OF CALCIUM CHANNEL AND PLASMALEMMA CALCIUM PUMP PROTEINS ON COCHLEAR STEREOCILIA.** D.E. Hillman\*, S. Apicella, I. Arital, S. Chen, R. Bing, J.T.B. Penniston, R. Llinas. Depts. of Otolaryngol., Phys./Neurosci., NYU Medical Center, New York, NY 10016 and Biochem. Mayo Clinic & Foundation, Rochester, MN 55905

This study determined the location of specific protein epitopes belonging to calcium voltage activated channels and the plasmalemmal calcium pump. Cochlear hair cells transform mechanical energy into neurochemical signals via ion-fluxes with subsequent neurotransmitter release. Electrophysiological evidence supports the existence of voltage activated calcium and potassium channels in cochlear hair cells. Five types of calcium channels have been described but none explain the mechanism of mechanical transduction. We tested the location of proteins of voltage activated channels and the plasmalemmal calcium pump in the organ of Corti using immunohistochemical assays. The antibody reaction product to P-type voltage activated calcium channels was observed on the tips of stereocilia of both outer and inner hair cells.

The plasmalemmal calcium pump protein localized by the 5F10 antibody revealed reaction product all along the stereocilia. The presence of labeling for P-type voltage activated calcium channels on stereocilia may indicate association with mechanical activation or the usual voltage activation via membrane depolarization. Although preliminary analyses show promising evidence that voltage activated calcium channels and a related calcium pump protein are located on cochlear stereocilia, ultrastructural localization and functional testing are needed to clarify the precise location and role of these channel proteins. NIH Grant NS-13742

## 617.8

**CLUSTERING OF  $\text{Ca}^{2+}$  CHANNELS IN RAT CEREBELLAR PURKINJE CELLS.** J.R.B. Dupure and M.M. Usowicz\*. Dept. Pharmacology, University of Bristol, UK

The spatial localisation of high voltage activated  $\text{Ca}^{2+}$  channels determines the electrical properties and influences local changes of  $[\text{Ca}^{2+}]_i$  in cerebellar Purkinje neurons. However, the elucidation of the sub-cellular distribution of these channels is incomplete. Therefore, to examine this distribution, we made cell-attached patch clamp recordings from Purkinje cells in slices of mature rat (5-7 week) cerebellum. Currents were evoked in somatic patches by voltage ramps (160mV, 100ms) from a holding potential 30-40mV negative to the resting potential. Patch pipettes (5-12M $\Omega$ ) contained  $\text{BaCl}_2$  (5mM), TTX (1 $\mu\text{M}$ ), TEA-Cl (134mM), HEPES (10mM), EGTA (0.1mM), pH 7.4 (TEA-OH).

Current amplitudes varied considerably between patches. Peak currents (at -10mV) ranged from -0.1 to -67.7pA, with a non-normal distribution and a marked skew towards more negative values. The average size was  $-7.9 \pm 10.4$  pA ( $\pm$  s.d., 93 patches). There was no correlation between peak current and pipette resistance.

The  $\text{Ca}^{2+}$  channels in cerebellar Purkinje cells were examined further pharmacologically. A blocker of N-type  $\text{Ca}^{2+}$  channels,  $\omega$ -conotoxin-GVIA (3 $\mu\text{M}$ ), reduced the mean current to  $-3.2 \pm 4.0$  pA ( $\pm$  s.d., 31 patches). The distribution of currents was less skewed in the presence than in the absence of  $\omega$ -conotoxin-GVIA. The proportion of currents more negative than -10pA was 6% (2/31 patches) with  $\omega$ -conotoxin-GVIA and 27% (25/93 patches) without. The effect of  $\omega$ -conotoxin-GVIA is consistent with immunohistochemical studies which identified N-type  $\text{Ca}^{2+}$  channels in cerebellar Purkinje cells (Westenbroek et al., Neuron 9: 1992, 1999). In contrast, electrophysiological studies revealed few  $\omega$ -conotoxin-GVIA-sensitive  $\text{Ca}^{2+}$  channels in these cells (Llinas et al., PNAS 86: 1689, 1989; Mintz et al., Neuron 9: 85, 1992).

In summary, cerebellar Purkinje somata possess N-type channels in addition to P-type  $\text{Ca}^{2+}$  channels. The relatively large size of  $\omega$ -conotoxin-GVIA-sensitive currents indicates clustering of N-type channels.

## 617.10

**UP-REGULATION OF L-TYPE CALCIUM CHANNELS IN REACTIVE ASTROCYTES FOLLOWING BRAIN INJURY AND HYPOMYELINATION.** R.E. Westenbroek\*, S.B. Bausch<sup>1</sup>, J.E. Franck<sup>2</sup>, J.L. Noebels<sup>3</sup>, and W.A. Catterall<sup>1</sup>.

Depts of Pharmacology<sup>1</sup> and Neurosurgery<sup>2</sup>, Univ. of Washington, Seattle, WA 98195 and Developmental Neurogenetics Lab, Dept. of Neurology<sup>3</sup>, Baylor College of Medicine, Houston, Texas 77030.

Affinity-purified anti-peptide antibodies which distinguish the alpha 1 subunits of class C L-type (anti-CNC1, Hell et al., JCB 123: 949-962, 1993) and class B N-type calcium channels (anti-CNB2; Westenbroek et al., Neuron 9: 1099-1115, 1992) in rat brain along with a monoclonal antibody to the alpha 2 subunit of L-type calcium channels (MANC1; Ahljian et al., Neuron 4: 819-832, 1990) have been well characterized and shown to have distinct patterns of staining in the CNS. These antibodies have been used in combination with the indirect peroxidase-anti-peroxidase technique to investigate if the expression pattern of various voltage-gated calcium channels is affected by brain injury. Light microscopic studies reveal that reactive astrocytes within the CA3 region of the hippocampus following intraventricular injection of kainic acid (KA) become immunoreactive for anti-CNC1 and MANC1, but not for anti-CNB2. In KA animals the normal pattern of neuronal staining remains unaltered in regions of the hippocampus outside of the CA3 region. Normal patterns of staining were observed in sham operated control animals. In the *shiverer* mouse, a deletion at the *shiverer* locus (chr 18) results in the absence of myelin basic protein gene expression and development of hyperexcitability. In these animals reactive gliosis was observed in hypomyelinated fiber tracts including the corpus callosum, internal capsule, fimbria, fornix, and cerebellum, which was not observed in normal mice. The reactive astrocytes stained positive with the anti-CNC1 and MANC1, but not with the anti-CNB2 antibodies. These findings demonstrate that L-, but not N-type calcium channels are expressed *in vivo* in reactive astrocytes in response to brain injury and hypomyelination and suggest that L-type calcium channels may play an important role in the ability of reactive astrocytes to promote neuronal survival.

## 617.11

DOPAMINE  $D_2$  RECEPTORS REGULATE MELANOTROPE P-TYPE VOLTAGE OPERATED  $Ca^{2+}$  CHANNELS. D.M. Beatty, P. Sharma, K.E. Hagler, S.A. Sands, B.M. Chronwall, S.J. Morris, School of Biological Sciences, University of Missouri-Kansas City, MO 64110.

Chronic dopamine  $D_2$  receptor stimulation of primary intermediate lobe cultures depresses melanotrope P-type voltage operated  $Ca^{2+}$  channel activity as well as P-type  $\alpha_1$  subunit mRNA. This was measured by real time image analysis fluorescence microscopy and *in situ* hybridization histochemistry.

In untreated melanotropes,  $K^+$  depolarization induced an increase in  $[Ca^{2+}]_i$ , which was partially sensitive to  $\omega$ -agatoxin, a P-type channel blocker. The P-type  $Ca^{2+}$  channel activity increased during maturation of the rat. When melanotropes were treated for 4 days with bromocriptine, a dopamine agonist, the  $K^+$  depolarization-induced  $Ca^{2+}$  influx via P-type  $Ca^{2+}$  channel was decreased.

Melanotropes chronically treated with bromocriptine showed a decrease in the relative levels of the  $\alpha_1$  subunit mRNA of the P-type channel, while haloperidol, a dopamine antagonist, increased the relative mRNA levels as compared to controls. These results confirm the presence of P-type  $Ca^{2+}$  channel in melanotropes and that channel activity and mRNA are regulated by dopamine receptor stimulation.

This work was supported by NIH Grant NS-28019, NSF Grant IBN-9211912, grants from the Kansas Affiliate of the American Heart Association, and the Loeb Charitable Foundation. P.S. is a Marion Merrell Dow-Scientific Education Partnership Fellow.

## CALCIUM CHANNEL STRUCTURE, FUNCTION AND EXPRESSION III

## 618.1

A CELL LINE EXPRESSING ONLY A T-LIKE CALCIUM CHANNEL. W. GOTTSCHALK\*, D.S. KIM\*, H. CHIN\*, E.F. STANLEY\* SMS\*, LNC\*, NINDS, NIH, Bethesda, MD 20892.

We have examined calcium current components in a series of neuroblastoma cell lines (from Busis *et al.* Brain Res., 324: 201-210, 1984). One line, 140-3, is deficient in high-voltage activated calcium channels, and only expresses a T-like current. This current is recruited at about -40 mV from a holding potential of -90 mV and is inactivated at a holding potential of -50 mV. The calcium channel is insensitive to agents reported to block T-type current, including nickel, ethosuximide and RO 40-5967, but is blocked by 250  $\mu$ M cadmium and 10  $\mu$ M nifedipine. Both low- and high-voltage activated currents were recorded in a control cell line, NG108-15. We have examined the expression of the  $\alpha_1$  subunit transcripts by the RT-PCR method. The NG108-15 cells express  $\alpha_1$  subunits, but we have not as yet detected any  $\alpha_1$  subunits in the 140-3 cells.

## 618.3

Genomic Analysis of a Human N-Type Calcium Channel  $\alpha_1$  Subunit. J. Francis\*, J.H. Eubanks, and O.T. Jones, Playfair Neuroscience Unit, The Toronto Hospital (Western Division), Toronto, Ontario, Canada.

We are interested in studying the targeting and maintenance mechanisms governing N-type voltage-dependent calcium channel (N-VDCC) distribution in neurons, where these multimeric channels display a marked degree of polarization. To this end, an understanding of the genomic regulation of these channels is necessary. Since little is presently known about the genomic characteristics of the N-VDCC subunits, we have attempted to identify the human gene for the N-VDCC pore-forming ( $\alpha_1$ ) subunit.

A human pWE2 placental cosmid library was screened with a random-primed probe derived from a 1243 bp PCR fragment from the C-terminal of the rat rB1  $\alpha_1$  subunit. A single, positively hybridizing colony was identified which was confirmed to be homogeneous on a secondary screen. The cosmid has an insert of approximately 38 kb. Rare-site mapping indicates the presence of two *Clal* and five *SacII* sites in the insert. A 4.4 kb *EcoRI* fragment containing a dinucleotide repeat ( $CA_n$ ), identified in the insert, has been subcloned and is being investigated for possible polymorphisms. Details of PCR, sequencing and genomic structural analysis will be presented and discussed. These studies attempt to provide a first look at the genomic organization of this important class of human calcium channel subunit gene.

## 618.2

STRUCTURAL IMPLICATION OF THE ABSENCE OF  $\beta$  SUBUNIT-INDUCED FACILITATION OF L-TYPE  $Ca$  CHANNEL WITH  $\beta_2$ . T. Cens, Mangoni, M., J. Nargeot and P. Charnet\*, CRBM-CNRS UPR9008, Route de Mende, 34033 Montpellier France

We have recently characterized a facilitation of the class C L-type  $Ca$  channel expressed in *Xenopus* oocyte. This facilitation was recorded when positive prepolarizations were applied before the test potential and required the coexpression of the  $\beta_{1b}$  subunit with the class C  $\alpha_1$  subunit (Bourinet *et al.*, 1994, EMBO J., 13: 5032-5039). It could also be recorded when  $\beta_{1a}$  or  $\beta_3$  subunits were coexpressed with  $\alpha_{1C}$  in oocytes, but was specific of the class C channel.

Here we show, by using a similar approach, that this facilitation is also observed in oocytes injected with the  $\beta_4$ , but not the  $\beta_2$  subunit, and the  $\alpha_{1C}$   $Ca$  channel subunits. Specific structural determinants on the  $\alpha_1$  and  $\beta$  subunits are thus necessary for the induction of facilitation. The four  $\beta$  subunit genes have a similar structure composed of two conserved regions flanked by variables, alternatively spliced, NH2 and COOH termini. A third variable region resides between the two conserved segments. These three variable regions are potential candidates to account for the modulation of the facilitation recorded when different  $\beta$  subunits are expressed. Deletions experiments and single point mutations on these segments are under way to identify the molecular determinants of the induction of facilitation.

## 618.4

STRUCTURE/FUNCTION STUDIES OF THE RAT N-TYPE CALCIUM CHANNEL EXPRESSED IN *XENOPUS* OOCYTES. D. Shuey, R. Numann, Rod Parsons and R. Franco\* CNS Disorders, Wyeth-Ayerst Research, Princeton, NJ 08543-8000

Modulation of the N-type  $Ca^{++}$  channel appears to play an important role in both neurotransmission and ischemic cell death (Dunlap *et al.*, 1995). In this study, we analyze the  $Ca^{++}$  currents that result from the introduction of cloned rat calcium channel cDNA's into *Xenopus* oocytes. Control experiments demonstrate that the elicited  $Ca^{++}$  currents are almost entirely dependent on nuclear microinjection of the rat  $\alpha_1B$  cDNA ( $\alpha_2$ ,  $\beta_3$  mean = 0.128  $\mu$ A;  $\alpha_1$ ,  $\beta_3$ ,  $\alpha_2$  mean = 6.6  $\mu$ A).

We wished to study how cyclic AMP dependent protein phosphorylation (kinase A) might alter the function of this channel. Application of forskolin (50  $\mu$ M) produced an immediate decrease in N-type  $Ca^{++}$  current amplitude (41.5%  $n=2$ ). This decrease continued for 10-15 min. at which time a steady-state level of 74% was reached. In parallel studies we activated protein kinase A by perfusing the selective lipid soluble SP isoform of cAMP (100mM). This produced a similar decrease in the inward current (41.2% at 3 min. and 60% at 15 min., mean of two). This down-regulation was reversible.

To further explore the effects of phosphorylation and allosteric modulation, we utilized site-specific mutagenesis to create three point mutations in the  $\alpha_1B$  subunit. Consensus sequences for cAMP dependent protein kinase phosphorylation (aa 898 S-A) and nucleotide binding (aa 458 K-A) were altered. Preliminary studies of these mutants have failed to detect any measurable current. Injection of a mutated putative tyrosine kinase site (aa 789 Y-F) cDNA, however, expressed as robustly as wild type and showed a consistent 12.4mV negative shift in steady-state activation ( $n=3$ ). Observed changes in the inactivation of this current are also being investigated.

**PCR AMPLIFICATION AND CLONING OF HUMAN GENOMIC AND cDNA SEQUENCES SIMILAR TO A P-TYPE  $\text{Ca}^{2+}$  CHANNEL SEGMENT FROM SCLC CELL LINES.** R.K. Haelela\* and W.D. Atchison, Department of Pharmacology & Toxicology and Program in Neuroscience, Michigan State University, E. Lansing, MI 48824-1317.

We are interested in studying the biology of the  $\text{Ca}^{2+}$  channels responsible for transmitter release at the motor neuron terminals using molecular clones of genes coding these channels by expression in the *Xenopus* oocyte. This information may help us gain a better understanding of presynaptic neuromuscular disorders like Lambert-Eaton Myasthenic Syndrome (LEMS). Since the soma of the motor neurons resides in the spinal cord, we decided to isolate genes from a cDNA library of human spinal cord. P-type  $\text{Ca}^{2+}$  channels, believed to be the main types responsible for  $\text{Ca}^{2+}$  influx resulting in transmitter release and muscle contraction at the neuromuscular junctions, were targeted first for these studies. PCR primers were synthesized based on the published sequence of a P-type  $\text{Ca}^{2+}$  channel segment spanning regions IV5 and IV6 (Barry et al., 1995, *J. Neurosci.* 15:274-283). Template DNA prepared from human spinal cord cDNA libraries or cultured HPBL cells was used to amplify a corresponding fragment using these primers. The amplified DNA was cloned in pAMP1 cloning vector (Gibco-BRL Life Technologies), sequenced to ascertain the identity of cloned inserts and used as probe to isolate cDNA clones from the human spinal cord cDNA libraries. Isolated clones are being sequenced and used to assemble the entire coding sequence for expression experiments. This work was supported by grant #1-R01 NS33006 from the NIH.

## 618.7

**FUNCTIONAL AND PHENOTYPIC ANALYSIS OF THE EXPRESSION OF  $\alpha_{1A}$  AND  $\alpha_{1E}$  VOLTAGE DEPENDENT CALCIUM CHANNEL (VDCC) SUBUNITS IN RAT CEREBELLAR PURKINJE CELLS.** S. Volsen, P. Craig, A. McCormack, D. Bell, C. Bath, W. Smith, D. Tupper\* and D. Bleakman, Lilly Research Centre, Erl Wood Manor, Windlesham, Surrey, GU20 6PH, UK.

We have examined the relationship between whole cell VDCC current characteristics and the expression of  $\alpha_{1A}$  and  $\alpha_{1E}$  subunits in cerebellar tissues derived from 6-9 day old rats. These analyses were performed on Purkinje cells in parallel patch clamp-single cell reverse transcription PCR, in situ mRNA hybridisation and immunohistochemical experiments.

Whole cell voltage clamp recordings were made in acutely isolated cerebellar Purkinje cell bodies and inward calcium currents evoked by depolarisation from a holding potential of -90mV to various test potentials. Analysis of current-voltage relationships showed no evidence for the presence of T-type VDCCs. The majority of the whole cell current was inhibited by 50nM  $\omega$ -Aga-IVA (89  $\pm$  2%, n=6) and the remainder blocked by 1 $\mu$ M  $\omega$ -CgTx GVIA (9  $\pm$  2%, n=4) and 5 $\mu$ M nimodipine (2  $\pm$  1%, n=4). Whole cell currents were also blocked by  $\text{Cd}^{2+}$  (IC<sub>50</sub> value ~ 5 $\mu$ M) and  $\text{Ni}^{2+}$  (IC<sub>50</sub> value > 300 $\mu$ M).

Single cell RTPCR experiments demonstrated the presence of  $\alpha_{1A}$  and  $\alpha_{1E}$  transcripts in Purkinje cells which was supported by the results from in situ mRNA hybridisation analysis of cerebellar sections using  $\alpha_{1A}$  and  $\alpha_{1E}$  specific riboprobes. The protein products of both  $\alpha_1$  subunits were demonstrated in Purkinje cells by immunohistochemical analysis.

The combined results demonstrate that both  $\alpha_{1A}$  and  $\alpha_{1E}$  subunits are present in Purkinje neuron cell bodies. Since we have no evidence for the presence of either the T or R-type VDCC in Purkinje soma, the precise role of the  $\alpha_{1E}$  subunit in these cells remains to be elucidated.

## 618.9

**SPLICE VARIANTS OF THE *DROSOPHILA* CALCIUM CHANNEL  $\beta$  SUBUNIT DIFFERENTIALLY STIMULATE  $\alpha_1$ -MEDIATED CALCIUM CURRENTS IN *XENOPUS* OOCYTES.** Maninder Chopra\*, Dejian Ren and Linda M. Hall, Dept. of Biochemical Pharmacology, SUNY at Buffalo, Buffalo, NY 14260.

The mammalian calcium channel  $\beta$  subunit enhances expression and modifies the kinetics and voltage-dependence of activation of  $\alpha_1$  subunits expressed in *Xenopus* oocytes. It has two conserved domains: Domain I (toward the amino end) and Domain II (toward the carboxyl end). Structure-function analysis has shown that a conserved proximal region of Domain II is necessary for its interaction with  $\alpha_1$  subunits (De Waard et al., *Neuron* 13:495, 1994). A recently cloned *Drosophila* calcium channel  $\beta$  subunit resembles mammalian  $\beta$  subunits, since it has both the conserved domains. Analysis of *Drosophila* cDNA clones shows that they fall into three categories. One class ( $\beta$ -DN1C1) encodes both domains. The second class ( $\beta$ -DN1 $\Delta$ C,  $\beta$ -DN2 $\Delta$ C) encodes only Domain I. The third class ( $\beta$ -DN1C1) encodes only Domain II. In addition, alternative splicing at the N-terminus generates at least two different N-terminal regions preceding Domain I. The presence of two highly conserved domains in the  $\beta$  subunit in species ranging from *Drosophila* to human suggests that both domains must play important roles in the organism. Expression of spliced forms with Domain II ( $\beta$ -DN1C1) with a cardiac  $\alpha_1$  subunit in *Xenopus* oocytes alone was sufficient to stimulate calcium channel currents, while coexpression with Domain I alone ( $\beta$ -DN1 $\Delta$ C) was without an effect. *Drosophila* genetic tools will be useful to determine the functional significance of conserved Domain I.

## 618.6

**THE EXPRESSION OF THE  $\alpha_{1E}$  VDCC SUBUNIT IN HUMAN CNS.**

N. Moore<sup>1</sup>, S. Volsen<sup>1</sup>, A. McCormack<sup>1</sup>, P. Craig<sup>1</sup>, W. Smith<sup>1</sup>, N. Day<sup>2</sup>, P. Ince<sup>2</sup>, P. Shaw<sup>3</sup>, N. Smith<sup>4</sup>, S. Ellis<sup>5</sup>, A. Gillespie<sup>5</sup> and M. Harpold<sup>5</sup>. Lilly Research Centre<sup>1</sup>, Windlesham, Surrey, UK; MRC Neurochemical Pathology Unit<sup>2</sup> and Division of Clinical Neuroscience<sup>3</sup>, University of Newcastle Upon Tyne, UK; Department of Paediatric Pathology<sup>4</sup>, Royal Hospital for Sick Children, Edinburgh, UK; SIBIA Inc<sup>5</sup>, La Jolla, CA 92037.

Little is known about the regional distribution of the  $\alpha_{1E}$  VDCC subunit in human CNS. We have studied the expression of  $\alpha_{1E}$  by in situ mRNA hybridisation and immunohistochemistry in a range of neuroanatomical sites. Areas of particular interest, for example the cerebellum and hippocampus, were examined for age related changes in  $\alpha_{1E}$  expression by studying tissues obtained from individuals 3 weeks to 74 years of age.

Both  $\alpha_{1E}$  mRNA and subunit protein had discrete yet widespread localisation in the adult human brain. Expression was observed, though at different apparent levels, in areas including the hippocampus, para hippocampal gyrus, inferior temporal cortex, basal ganglia, midbrain and spinal cord. The most intense signal was however noted in the cerebellum.

Within the cerebellar cortex,  $\alpha_{1E}$  transcripts were at highest density in the Purkinje cell layer and antibody staining showed that these cells labelled intensely both in their soma, dendritic tree and axons. There was however little evidence of staining in the neuropil of the dentate nucleus. In cerebellar sections from infant brains,  $\alpha_{1E}$  expression was less extensive than that seen in the adult and immunohistochemical analysis revealed that only a population of Purkinje cells appeared to express  $\alpha_{1E}$ . These data show that  $\alpha_{1E}$  is differentially distributed in the adult CNS and that its pattern of expression alters during development.

## 618.8

**MOLECULAR CLONING OF A CLASS D L-TYPE CALCIUM CHANNEL WITH AN ELONGATED CARBOXYL TERMINUS.** E. Mathews and T.P. Snutch\*, Biotechnology Laboratory, University of British Columbia, Vancouver, B.C., Canada V6T 1Z3.

Molecular cloning and transient expression studies have identified five major types of calcium channel  $\alpha_1$  subunits expressed in the mammalian nervous system ( $\alpha_{1A}$ ,  $\alpha_{1B}$ ,  $\alpha_{1C}$ ,  $\alpha_{1D}$  and  $\alpha_{1E}$ ). Both the  $\alpha_{1C}$  and  $\alpha_{1D}$  subunits encode L-type calcium channels and are colocalized to the cell bodies and proximal dendrites of many central neurons (Hell et al., *J. Cell Biol.* 123:949-962). In contrast to other classes of rat brain  $\alpha_1$  subunits, a previously reported  $\alpha_{1D}$  subunit (RB $\alpha$ 1; Hui et al., *Neuron* 7:35-44) terminated approx. 170 residues past domain IV S6 resulting in a 1634 amino acid protein with a predicted molecular mass of 187 kDa. Utilizing the screening of a rat brain cDNA library and the PCR amplification of rat cerebellar RNA we have isolated an  $\alpha_{1D}$  isoform similar in size to other calcium channels. Compared to RB $\alpha$ 1, the  $\alpha_{1D-a}$  protein is extended by greater than 500 amino acids in the carboxyl terminus and has a predicted molecular mass of ~ 244 kDa. The extended carboxyl terminus of  $\alpha_{1D-a}$  contains several consensus sites for phosphorylation by PKA and PKC and may be involved in modulation of  $\alpha_{1D}$  channels. Northern blot analysis indicates that the  $\alpha_{1D-a}$  isoform is encoded by an ~ 9.5 kb mRNA and is expressed throughout the rat CNS. Examination of several cDNAs indicates that additional  $\alpha_{1D}$  isoforms are generated by alternative splicing of at least two regions: the domain I-II cytoplasmic linker and the domain IV S3 transmembrane segment. While the  $\alpha_{1C}$  and  $\alpha_{1D-a}$  calcium channels share ~ 75% amino acid identity in domains I - IV, they are significantly different in the carboxyl tail (<50% identity). Current experiments are aimed at comparing the biophysical and modulatory properties of the  $\alpha_{1C}$  and  $\alpha_{1D}$  L-type calcium channels.

## 618.10

**PREPULSE FACILITATION OF CARDIAC ALPHA ONE AND ENDOGENOUS CALCIUM CHANNELS IN *XENOPUS LAEVIS* OOCYTES.** M. Chahine\*, A. Figourov\*, and A. Sculptoreanu\*, Laval Hospital Research Center, Laval University, Ste-Foy, Qc, Canada, Roche Inst. for Mol. Biol., Nutley, NJ, Lady Davis Institute of Jewish General Hospital\*, McGill University, Montreal, Qc, Canada.

We reported previously that cardiac L-type calcium channels are facilitated by depolarizing prepulses and this type of facilitation requires phosphorylation by cAMP dependent protein kinase (PKA). *Xenopus laevis* oocytes can be selected to express relatively high levels of endogenous Ca-currents. These currents are facilitated by prepulses. Facilitated endogenous Ca-currents are unaffected by okadaic acid, Rp-cAMP or the dihydropyridine (DHP) antagonist (+)PN200-110. The endogenous current and facilitation of endogenous current are fully blocked by 1 mM  $\text{Cd}^{2+}$ . In contrast, oocytes injected with mRNA encoding for the rabbit cardiac  $\alpha_1$ -subunit, express prepulse facilitated Ca-channel currents which are highly enhanced by phosphoprotein phosphatase inhibitor okadaic acid (3 fold), blocked by Rp-cAMP and the DHP antagonist (+)PN200-110. While okadaic acid selectively stimulates prepulse facilitated cardiac Ca-currents, L-type Ca-channel agonist (+)SDZ202-791 largely increases (5 fold) both the control (before prepulse) and prepulse facilitated currents. (+)SDZ 202-791 did not prevent the effect of Rp-cAMP or okadaic acid on facilitation of cardiac  $\alpha_1$  suggesting that stimulation by Ca-agonist is independent of phosphorylation leading to channel facilitation. In conclusion, oocytes express a Cd-sensitive-DHP-insensitive endogenous Ca-current which is facilitated by depolarizing prepulses. However, unlike facilitation of cardiac  $\alpha_1$  expressed in oocytes which is mediated by PKA phosphorylation, prepulse facilitation of endogenous Ca-channels may be mediated by a yet a unrecognized protein kinase. (Supported by grants from MRC to AS and MC and Heart Foundation to MC and AS. PN200-110 & SDZ 202-791 were gifts from Sandoz Canada.)

## 618.11

HUMAN CALCIUM CHANNEL  $\alpha_{1C}$  SUBUNIT SPLICE VARIANTS SHOW DIFFERENT VOLTAGE-DEPENDENT INHIBITION BY DIHYDROPYRIDINES. Nikolai M. Soldatov, Alexandre Bouron, Harald Reuter and Erwin Sigel\*. Dept. of Pharmacology, Univ. of Bern, Friedbuehlstrasse 49, CH-3010 Bern, Switzerland.

Voltage-dependent inhibition by 1,4-dihydropyridines is a characteristic property of L-type calcium channels. Eight out of 50 exons of the channel  $\alpha_{1C}$  subunit gene are subjected to alternative splicing, thus generating channel isoform diversity. Using *Xenopus* oocytes as an expression system, we have found that transmembrane segments IIIS2 and IVS3 of human  $\alpha_{1C}$  subunit, genetically regulated through alternative splicing of exons 21/22 and 31/32, respectively, are involved in the control of voltage-dependence of dihydropyridine action. When elicited from the holding potential  $V_h = -40$  mV,  $Ba^{2+}$  current through both  $\alpha_{1C,21,32}$  and  $\alpha_{1C,22,32}$  channels was inhibited by (+)-isradipine with  $IC_{50} = 7$  nM. However, at  $V_h = -90$  mV the inhibitory potency of the drug towards  $\alpha_{1C,21,32}$  was 8.6-fold lower than for  $\alpha_{1C,22,32}$ . Site-directed mutagenesis points to two amino acids (Gly/Phe-954 and Tyr/Ile-958), which determine the difference of the splice variants  $\alpha_{1C,21,32}$  and  $\alpha_{1C,22,32}$  in their sensitivities to dihydropyridines. This difference was sharply diminished by incorporation of exon 31 instead of exon 32. Our finding provides new insight into molecular mechanisms of calcium channel inhibition by this important class of drugs.

This work was supported by grants from the Swiss National Science Foundation (31-29862.90) and from the Sandoz Foundation.

## CALCIUM CHANNELS: MODULATION BY PEPTIDES AND HORMONES

## 619.1

SELECTIVE VOLTAGE-DEPENDENT AND VOLTAGE-INDEPENDENT INHIBITION OF CALCIUM CHANNEL SUBTYPES BY OPIOIDS IN BOVINE CHROMAFFIN CELLS. A. Albillos, E. Carbone<sup>§</sup>, L. Gandia, A.G. Garcia and A. Pollo<sup>§</sup>. Dept. of Pharmacology, Univ. of Madrid, Spain. <sup>§</sup>Dept. of Anatomy and Human Physiology, Univ. of Turin, Italy.

The opioid agonists methionine-enkephalin and DAGO (0.1-10  $\mu$ M), markedly and reversibly inhibited the high-voltage-activated  $Ba^{2+}$  currents of bovine chromaffin cells. Inhibition depended on the day of cell culture (50-60% in 1-2 days old cells, 20% in cells 7 days old) and caused a pronounced slow-down of current activation together with a marked amplitude depression. The slow phase of activation was relevant around 0 mV but decreased at more positive potentials ( $>+30$  mV). Strong facilitating pre-pulses (50 ms, +90 mV) induced only a partial recovery of the inhibition (60%, voltage-dependent) suggesting the presence of a significant voltage-independent component (40%). In most cells, both inhibitions were effectively removed by intracellular perfusion with GDP- $\beta$ -S (0.2-1 mM) or by cell preincubation with pertussis toxin (100 ng/ml, 24 h). The opioid-induced inhibition was not selective for any  $Ca^{2+}$  channel subtype, being not prevented after the addition of specific  $Ca^{2+}$  channel antagonists (nifedipine,  $\omega$ -CTx-GVIA,  $\omega$ -Aga-IVA,  $\omega$ -CTx-MVIIIC). However, when separately analyzing the contribution of each channel subtype to the voltage-dependent and voltage-independent modulation, a sharp distinction could be achieved. The voltage-dependent process was abolished by acute application of 3  $\mu$ M  $\omega$ -CTx-MVIIIC and unaffected by 3  $\mu$ M nifedipine, suggesting a selective action on non-L-type channels (N-, P-, and Q-types). On the contrary, the voltage-independent opioid inhibition was sensitive to all  $Ca^{2+}$  channel antagonists, particularly to nifedipine (3  $\mu$ M), suggesting that the voltage-insensitive modulation is common to all  $Ca^{2+}$  channel subtypes but predominant on L-type channels. Our data suggest that  $Ca^{2+}$  channels which are crucial for the control of catecholamine and opioid secretion from chromaffin cells (L- and Q-type) may be differently modulated by the secreted material itself.

## 619.3

ENKEPHALINS MODULATE DEPOLARIZATION-ACTIVATED CALCIUM CONDUCTANCES IN RAT INTRACARDIAC NEURONS. D.J. Adams\*, and C. Treguadrini. Dept. of Physiology & Pharmacology, Univ. of Queensland, Brisbane, QLD 4072, Australia and Dept. of Pharmacology Univ. of Miami, FL 33101, USA.

Modulation of depolarization-activated  $Ca^{2+}$  channels by enkephalins was investigated in isolated parasympathetic neurons of rat intracardiac ganglia using the amphotericin B perforated-patch technique. Focal application of met-enkephalin (10  $\mu$ M) to the soma membrane did not alter the resting membrane potential but reduced the maximum amplitude and slowed the rate of rise and repolarization of the action potential reversibly. Under voltage-clamp, Met-enkephalin reversibly inhibited the peak amplitude of  $Ba^{2+}$  currents evoked at 0 mV by 53% and increased 3-4-fold the time to peak. Met-enkephalin had no effect on either voltage-dependent  $Na^+$  or  $K^+$  currents in rat intracardiac neurons. Half-maximal inhibition of  $I_{Ba}$  was obtained with ~300 nM met-enkephalin or leu-enkephalin. The enkephalin derivatives, DAMGO (1  $\mu$ M) and DADLE (5  $\mu$ M) but not DPDE (10  $\mu$ M) inhibited  $Ca^{2+}$  channel currents and were antagonized by the opioid receptor antagonists, naloxone and naltrindole with  $IC_{50}$ 's of ~100 nM and 1  $\mu$ M, respectively. Taken together, these data suggest that enkephalin-induced inhibition of  $Ca^{2+}$  channels in rat intracardiac neurons is mediated by the  $\mu$ - and  $\delta$ -opioid receptor types. Inhibition of  $I_{Ba}$  amplitude by enkephalins was abolished using the conventional (dialyzed) whole cell recording configuration but was observed when 100  $\mu$ M GTP was added to the pipette internal solution. Internal perfusion of the cell with GDP- $\beta$ -S or incubation of the neurons in Pertussis toxin (PTX) also abolished the modulation of  $I_{Ba}$  by enkephalins, suggesting the involvement of a PTX-sensitive G-protein in the signal transduction pathway. Given that enkephalin peptides have been shown to be synthesized and secreted from cardiac muscle (Springhorn & Claycomb, 1992, *Am. J. Physiol.*, 263, H1560-H1566), the activation of opioid receptors in postganglionic intracardiac neurons suggests that it may serve for negative feedback regulation of vagal transmission to the heart.

## 619.2

MODULATION OF CALCIUM CHANNELS BY OPIOIDS, BACLOFEN AND SOMATOSTATIN IN ACUTELY DISSOCIATED NEURONS FROM THE RAT NUCLEUS TRACTUS SOLITARIUS (NTS). Hyewhon Rhim\*, Peter T. Toth and Richard J. Miller. Department of Pharmacological and Physiological Sciences, The University of Chicago, Chicago IL 60637.

We previously reported that activation of opioid receptors inhibit N- and P/Q-type  $Ca^{2+}$  channels but not L-channels in neurons acutely isolated from the rat NTS (*J Neurosci.* 14:7608, 1994). In the present studies, we further investigated the coupling mechanism between opioid receptors and  $Ca^{2+}$  channels and compared this with the effects of baclofen and somatostatin in these cells. 30  $\mu$ M baclofen and 300 nM somatostatin suppressed 40% (n=9) and 28% (n=6) of peak  $Ca^{2+}$  whole cell currents respectively and targeted the same types of  $Ca^{2+}$  channels (N & P/Q) which were inhibited by opioids. The inhibition of  $Ca^{2+}$  currents by the  $\mu$ -selective opioid agonist, DAMGO, baclofen and somatostatin was reduced by overnight treatment of 200 ng/ml PTX. It is known that G-protein-mediated inhibition of  $Ca^{2+}$  currents can be relieved by strong depolarization. We examined neurotransmitter-mediated inhibition of  $Ca^{2+}$  currents using 50 ms prepulse to +80 mV prior to the test pulse. The mean inhibition of peak current produced by DAMGO, baclofen and somatostatin was 42(n=4), 41(6), and 36(6)% for a constant voltage step (HP = -80 mV, TP = 0 mV). This inhibition was decreased to 23, 25, and 18% by a strongly depolarizing prepulse. In order to investigate which PTX-sensitive G-protein transduces the inhibitory signal to  $Ca^{2+}$  channels, we examined cells dialyzed with the specific G-protein antibody, GC/2, raised against the N-terminal of  $G_{\alpha c}$ . A 30 min perfusion of cells with non-immune serum did not alter the inhibitory response to the three neurotransmitters. Intracellular loading with GC/2 markedly attenuated the somatostatin-induced inhibition (n=11), but did not block the DAMGO- (n=5) and baclofen- (n=14) induced inhibition. These findings suggest at least two different PTX-sensitive G-protein-mediated pathways are involved in receptor-induced inhibition of  $Ca^{2+}$  currents in the NTS.

## 619.4

ACETYLCHOLINE AND ENKEPHALIN INHIBIT HIGH AND LOW VOLTAGE-ACTIVATED CALCIUM CHANNELS IN THALAMIC RELAY NEURONS.

A. Formenti\*, E. Arrigoni, A. Bejan, G. Avanzini\*, M. Mancina. Inst. of Human Physiol. II, Univ. of Milan and \*Dip. of Neurophysiol., Nat. Inst. of Neurol. C. Besta, Milan I-20133 Italy.

Thalamic relay neurons present two different functional states. During wakefulness they send sensory information to the cortex from the periphery. During synchronized sleep and epileptic seizures they show an oscillatory burst discharge.  $Ca^{2+}$  currents are crucial in determining the characteristic firing patterns. LVA  $Ca^{2+}$  channels can give rise to low threshold  $Ca^{2+}$  spikes. On top of these, a high-frequency burst discharge can occur. HVA  $Ca^{2+}$  channels contribute to the intracellular  $Ca^{2+}$  rising phase. Calcium entry into the cell is responsible for a  $Ca^{2+}$ -dependent  $K^+$ -current activation and burst termination. The modulatory effects induced by acetylcholine (ACh) and D-al<sup>2</sup>-D-leu<sup>5</sup>-enkephalin (DADLE) on voltage-dependent  $Ca^{2+}$  channels have been investigated. The experiments were carried out on acutely dissociated neurons from the ventrobasal thalamus, of 2-14 day-old Wistar rats. The currents were recorded by means of whole-cell patch-clamp technique. ACh (20  $\mu$ M) extracellularly perfused inhibited the peak amplitude of HVA  $Ca^{2+}$  currents of an average -54% in 26 out of the 36 cells tested (+10 mV). DADLE (400 nM) reduced HVA  $Ca^{2+}$  currents -58% in 31 out of 38 cells (+10 mV). The two neurotransmitters induced a voltage-dependent inhibition, relieved at more positive potentials and/or a voltage-independent effect persistent at all the potentials tested [Formenti et al. 1993 *Biophys J.* 64:1029-1037]. LVA  $Ca^{2+}$  currents were less sensitive to the two neurotransmitters (DADLE -40% in 4 out of 11 cells ACh -40% in 2 out of 33). In conclusion, the modulation of the voltage-dependent  $Ca^{2+}$  channels may play a role in the production and control of the rhythmic discharge during slow-wave sleep and pathological seizures. The action of DADLE suggests a postsynaptic inhibitory mechanism on nociceptive pathways.

## 619.5

DYNORPHIN MODULATES DISTINCT CALCIUM CHANNEL SUBTYPES IN THE SOMATA AND AXON TERMINALS OF A MAMMALIAN CENTRAL NEURON. T.E. Fisher\* and C.W. Bourque. Centre for Research in Neuroscience, Montreal General Hospital and McGill University, Montreal, Canada, H3G 1A4.

Although much is known about the modulation of calcium channels in neuronal somata, less is known about effects in nerve terminals. This is of particular importance since effects there are likely to influence transmitter release. The magnocellular neurosecretory cells (MNCs) of the rat supraoptic nucleus offer an opportunity to compare effects in the somata and axon terminals since both can be isolated and subjected to whole cell patch clamp. Dynorphin A (1-13), a  $\kappa$ -opioid selective agonist, may modulate influx through voltage-gated calcium channels in both locations since it has been shown to decrease the calcium component of action potentials in MNC somata as well as oxytocin release from MNC terminals. Addition of 1  $\mu$ M dynorphin A to terminals selectively and reversibly decreased an inactivating ( $\tau = 132 \pm 31$  ms at -10 mV;  $n = 7$ ),  $\omega$ -CTX-sensitive component of the calcium current. In the somata, dynorphin A inhibited two  $\omega$ -CTX-insensitive currents: a low-threshold, rapidly-inactivating current ( $\tau = 62 \pm 6$  ms at -10 mV;  $n = 8$ ), likely a T-type, and a high-threshold, non- or slowly-inactivating current. These data demonstrate that dynorphin A modulates multiple calcium channel subtypes and that these actions are segregated in different cellular locations. Supported by the Heart & Stroke Foundation and the Medical Research Council of Canada.

## 619.7

RECEPTOR REGULATION OF  $\text{Ca}^{2+}$ -CHANNELS IN HEK 293 CELLS. Lee R. Shekter\*, Arthur A. Simen, Peter T. Toth & Richard J. Miller. Dept. of Pharmacology and Physiology, University of Chicago, Chicago, IL 60637

Receptors have been shown to regulate voltage sensitive  $\text{Ca}^{2+}$ -channels through G-proteins and second messengers. We compared receptor regulation of N ( $\alpha 1B$ ) and R ( $\alpha 1E$ ) currents in HEK 293 cells. N-type and R-type  $\text{Ca}^{2+}$ -channels consisted of  $\alpha_{1B-1}\alpha_{2\beta 1-3}$  and  $\alpha_{1E-3}\alpha_{2\beta 1-3}$  subunits respectively. Perfusion of both types of cells with GTP- $\gamma$ -S produced inhibition of the  $\text{Ca}^{2+}$ -currents which was relieved by prepulse depolarization. N-channel activity in on cell and excised patches could be inhibited by F and GTP- $\gamma$ -S respectively. The somatostatin analogue ([D-Trp<sup>7</sup>]-Somatostatin, 300nM) inhibited the whole cell N-current by 17.6% ( $n=23$ ). Prepulse depolarization also relieved the inhibitory effect of somatostatin. The somatostatin analogue (300nM) inhibited the R-current to a lesser extent. The somatostatin effect was also tested in HEK 293 cells expressing N-type  $\text{Ca}^{2+}$ -channels with different subunit compositions. Somatostatin was still effective when the  $\beta$ -subunit was replaced with a different splice variant ( $\beta_{1-2}$ ). HEK 293 cells also express muscarinic receptors. Muscarinic receptor activation released  $\text{Ca}^{2+}$  from intracellular stores. However it did not inhibit the whole-cell  $\text{Ca}^{2+}$ -current. The above experiments suggest the heterogeneity of the signalling pathways for different  $\text{Ca}^{2+}$ -currents.

## 619.9

VARIOUS NEUROTRANSMITTERS INHIBITED N- AND Q-TYPE  $\text{Ca}^{2+}$  CHANNELS VIA DIFFERENT G-PROTEINS IN RAT SYMPATHETIC NEURONS. M. Miyake<sup>1</sup>, R. Shibata<sup>1</sup> and A. Urano\*. <sup>1</sup>Faculty of Pharmacology, Sci. and <sup>2</sup>Grad. School of Sci., Hokkaido Univ., Sapporo 060, Japan.

Recent progress in pharmacological studies reveals that at least six classes (T-, L-, N-, P-, Q- and R-types) of functional  $\text{Ca}^{2+}$  channels were present in the central and peripheral nervous system. Furthermore, various neurotransmitters modulate some  $\text{Ca}^{2+}$  channels through intracellular signaling pathways coupled to separate G-proteins.

In this study, we measured  $\text{Ba}^{2+}$  currents through  $\text{Ca}^{2+}$  channels in cultured neurons (up to 5 weeks) dissociated from superior cervical ganglia of a new born rat. Whole-cell recordings showed that these  $\text{Ba}^{2+}$  currents were approximately composed of 60% of the  $\omega$ -CTX-GVIA sensitive- (N-type), 20% of the nifedipine sensitive- (L-type), less than 2% of the  $\omega$ -Aga-IVA (30 nM) sensitive- (P-type), 10% of the  $\omega$ -CTX-MV1C sensitive- (Q-type) and the residual components. Norepinephrine (NE) and somatostatin (SST) caused modulating effects (inhibition) on the N- and Q-type current components through pertussis-toxin sensitive intracellular pathway(s). Vasoactive intestinal peptide (VIP) and bradykinin (BK) brought about a similar inhibition of the two components through a cholera-toxin sensitive pathway and through that resistant to both toxins, respectively. The inhibition of the N-type currents was voltage-dependent, whereas the inhibition of the Q-type currents was voltage-independent.

## 619.6

SOMATOSTATIN TARGETS BOTH N- AND L-TYPE CALCIUM CHANNELS IN CHICK PARASYMPATHETIC NEURONS. Mark A. Crumling\* & Stephen D. Meriney\*. Department of Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.

Somatostatin (SOM) is endogenous to choroid neurons in the chick ciliary ganglion and is a potent inhibitor of transmitter release at choroid nerve terminals. At nerve terminals *in vivo*, the calcium channel types that regulate transmitter release switch during development from L-type before hatching to N-type after hatching (Gray et al., 1992 *Neuron* 8:1-20). Both ciliary and choroid neuron cell bodies express SOM receptors that can mediate a ~50% reduction in calcium current and an ~80% reduction in potassium-evoked somal ACh release. Here, we report the use of perforated patch recordings ( $R_{\text{access}} = 11 \text{ M}\Omega$ ) from acutely dissociated ST 40 ciliary ganglion neurons to test the hypothesis that SOM targets both N- and L-type calcium channels. Ciliary ganglion neurons expressed calcium current that was comprised of 60% N (sensitive to 1  $\mu$ M  $\omega$ -CGTX GVIA), 31% L (sensitive to 5  $\mu$ M nitrendipine) and 9% non-N or L (as yet unidentified). SOM (100 nM) inhibited 25 pA/pF (49%) of current from control cells, 15 pA/pF (37% of control current) from cells pretreated with 5  $\mu$ M nitrendipine, 5 pA/pF (9%) from cells pretreated with 1  $\mu$ M  $\omega$ -CGTX GVIA, and 2 pA/pF (4%) from cells pretreated with both nitrendipine and  $\omega$ -CGTX GVIA. SOM affected Bay K 8644-induced tail currents in a complex manner suggesting either multiple L- channel subtypes or voltage-dependent effects at hyperpolarized potentials. These data indicate that SOM targets both N- and L-type calcium channels. Supported by Univ. of Pitt. Small Grants Program, a Winters Foundation Award, and NIH NS 32345.

SOMATOSTATIN (SS) MODULATION OF HVA CALCIUM CURRENTS IN ACUTELY ISOLATED NEURONS OF RAT AMYGDALA. E.Viana\* and B. Hill. University of Washington, Dept. of Physiology & Biophysics, Seattle, WA 98195.

Immunohistochemical and autoradiographic studies have revealed the presence of the neuropeptide SS and SS receptors (SSR) in the amygdala. We used the whole-cell configuration of the patch-clamp technique to investigate the effects of SS and SS-analogs on calcium currents in acutely dissociated, pyramidal-shaped, rat amygdala neurons (P7-P21). Depolarizing voltage steps from -90 mV revealed a robust,  $\text{Cd}^{2+}$ -sensitive, inward current ( $1821 \pm 659$  pA,  $n=23$ ) that peaked at -10 mV and inactivated partially within 100 ms. Application of SS reduced peak inward currents (5-30%) in a reversible and dose-dependent manner. During prolonged applications (3 min) the inhibition showed little desensitization (<20%). The inhibition was voltage-dependent and accompanied by a marked slowing in activation kinetics. Brief prepulses to +70 mV produced a partial relief of the inhibition and slowing. Application of BIM-23060 (2-200 nM), a SSR2 agonist, but not BIM-23058, a SSR3 agonist, mimicked all the effects of SS. Cell dialysis with GTP $\gamma$ S also mimicked and occluded the actions of subsequent SS application. A 2 min pre-incubation with the alkylating agent N-ethylmaleimide (50  $\mu$ M) prevented the modulatory effects of SS. A double pulse protocol isolated a transient LVA calcium current that was not inhibited by SS.

In the presence of  $\omega$ -CGTX GVIA (2-4  $\mu$ M) or  $\omega$ -AgTx IVA (100 nM), the % inhibition was reduced, while the combined application of these toxins nearly blocked the modulation, suggesting the involvement of N- and P-type calcium channels. The L-type channel blocker nifedipine (10  $\mu$ M) reduced the peak inward about 20% without affecting the modulation by SS. The slow tail currents induced by +202-791 were slightly reduced by SS, but also by  $\omega$ -CGTX GVIA.

Supported by USPHS grant # NS 08174 and the W.M. Keck Foundation.

## 619.10

CALCIUM CURRENTS AND CORTICOTROPIN-RELEASING FACTOR (CRF) IN PYRAMIDAL AND NON-PYRAMIDAL NEURONS OF THE BASOLATERAL AMYGDALA (BLA). P. Shinnick-Gallagher\*, F.-C. Chang, P.W. Gean and B. Yu. Dept. of Pharmacology, University of Texas Medical Branch, Galveston, TX 77555-1031.

We have previously shown that in the central amygdala (CeA), CRF enhances calcium currents ( $I_{\text{Ca}}$ ) and that the  $I_{\text{Ca}}$  is composed of L-(22%), N-(30%), and Q-(12%) type currents and dihydropyridine (DHP) and neurotoxin-resistant (37-53%) currents. In the present study we analyzed  $I_{\text{Ca}}$  and CRF actions in the BLA using whole cell patch recording in young rats. DHP-sensitive (L-type) currents comprised ~34%, while  $\omega$ -conotoxin GVIA (N-type) account for 15% of  $I_{\text{Ca}}$  in pyramidal cells ( $n=17$ ). Q-type,  $\omega$ -conotoxin MV1C- or P-type,  $\omega$ -agatoxin IVA-sensitive, currents contributed to 3% and 5% of  $I_{\text{Ca}}$  respectively.  $I_{\text{Ca}}$  in non-pyramidal neurons was composed of L-(33%), N-(13%), Q-(3%) and P-(8%) type currents. A resistant current comprised ~43% and 43% of the total  $I_{\text{Ca}}$  in the respective neurons. CRF (50 mM) inhibited  $I_{\text{Ca}}$  ~17% in 10/15 pyramidal and ~12% in 6/7 non-pyramidal neurons while it enhanced  $I_{\text{Ca}}$  ~23% in 5/15 pyramidal neurons. These data suggest that the composition of  $I_{\text{Ca}}$  in the CeA and BLA are different and that the excitatory and inhibitory actions of CRF in the amygdaloid nuclei may underlie the differential function of these structures in the stress response (supported by NS29265).

**CORTICOSTEROID ACTIONS ON IONIC CONDUCTANCES IN ACUTELY DISSOCIATED RAT HIPPOCAMPAL NEURONS.** I. B. Werkman\*, S. van der Linden, M. Struik and M. Joëls, Dept. Exp. Zoology, University of Amsterdam, Kruislaan 320, 1098 SM Amsterdam, The Netherlands.

Previous *in situ* whole-cell voltage clamp studies have shown that steroid hormones are involved in the regulation of the excitability of hippocampal neurons by acting at mineralocorticoid (MR) and glucocorticoid (GR) receptors. In the present study whole-cell voltage clamp recordings of acutely dissociated CA1 neurons were made. As in the *in situ* experiments it was found that in neurons of adrenalectomized Wistar rats (weight 100-200 gram) the amplitude of voltage-dependent calcium currents was increased as compared with currents in neurons treated with 30 nM corticosterone (occupying both MR and GR) or neurons of sham-operated rats (peak current amplitudes at 0 mV:  $1.12 \pm 0.09$  nA (n=56),  $0.66 \pm 0.03$  nA (n=50),  $0.72 \pm 0.06$  nA (n=33), respectively). However, selective activation of the MR after treatment with 30 nM corticosterone and 500 nM of the GR antagonist RU38486, did not decrease calcium current amplitudes (peak current amplitude:  $0.72 \pm 0.06$  nA (n=25)), as was observed in the *in situ* experiments. Similar observations were made in acutely dissociated neurons of adrenalectomized rats injected with steroid and antagonist. Since in the acutely dissociated cell preparation the neurons have lost most of their dendritic processes, this indicates that the current involved in the MR effect in the slice preparation has a dendritic origin. Other electrophysiological characteristics of the calcium currents like threshold of activation, activation time, time-course of inactivation and steady-state inactivation were not affected by steroid treatments. In old animals (weight  $\geq 400$  gram) the difference in calcium current amplitudes between adrenalectomized and sham-operated was not observed anymore. To know whether the calcium currents are the only voltage-dependent ionic conductance affected by corticosteroid receptor activation, we are currently investigating the effects of steroid treatments on sodium currents in acutely dissociated neurons.

**DUAL PATCH PIPETTE RECORDINGS IN HIPPOCAMPAL NEURONS: EVIDENCE THAT LONG  $\text{Ca}^{2+}$  TAIL CURRENTS REFLECT  $\text{Ca}^{2+}$  CHANNEL ACTIVITY AT RESTING POTENTIAL.** O. Thibault\*, N.M. Porter, M.L. Mazzanti-Rose, L.W. Campbell, E.M. Blalock and P.W. Landfield, Dept. Pharmacology, Univ. Kentucky Med. Center, Lexington, KY 40536.

We have previously reported the presence of a long-lasting  $\text{Ca}^{2+}$  or  $\text{Ba}^{2+}$  tail current which outlasts a depolarization pulse by several hundred to thousand milliseconds in cultured and adult hippocampal neurons. This tail current could arise from  $\text{Ca}^{2+}$  channel activity at resting potential or, alternatively, from inadequate space clamp of the large apical dendrite or from non- $\text{Ca}^{2+}$  currents.

To resolve this issue, we conducted experiments in cultured neurons using dual patch pipette recordings. Simultaneous recordings from the soma and from mid-way along the dendrite were performed on the same cells. Current clamp recordings at the dendritic pipette showed that the dendritic voltage response mirrored the depolarization command step given at the somal pipette, including a rapid return to -70 mV. Further, simultaneous voltage clamp of the dendrite and soma did not selectively reduce the somal tail current, indicating that the  $\text{Ca}^{2+}$  tail is not of dendritic origin. In addition, severing or applying  $\text{Cd}^{2+}$  to the dendrite did not selectively reduce the tail at the soma. A series of pharmacologic/ionic manipulations ruled out non- $\text{Ca}^{2+}$  currents as the basis for the tail.

Thus, the long  $\text{Ca}^{2+}$  tail currents reflect true  $\text{Ca}^{2+}$  channel activity at resting potential levels, apparently due to a reversible voltage-shifted mode of the channel, and may mediate a major unrecognized pathway of  $\text{Ca}^{2+}$  entry. **CHRONIC GLUCOCORTICOID TREATMENT ENHANCES HIGH VOLTAGE-ACTIVATED CALCIUM CURRENTS IN RAT HIPPOCAMPAL NEURONS IN CULTURE.** N.M. Porter\*, V. Thibault and P.W. Landfield, Dept. Pharmacology, Univ. of Kentucky, Lexington, KY 40536.

Corticosterone has been shown to enhance the slow  $\text{Ca}^{2+}$ -dependent afterhyperpolarization in rat hippocampal slice neurons. In addition, specific glucocorticoid receptor agonists increase  $\text{Ca}^{2+}$  spikes and currents through a cycloheximide-sensitive process in the same preparation. However, prior studies have used relatively high concentrations of glucocorticoids and the hippocampal slice is a preparation generally not well suited for long-term pharmacological manipulation or concentration-response analyses. In the present studies, therefore, we chose to study the actions of a glucocorticoid receptor type II agonist, dexamethasone (DEX), on  $\text{Ca}^{2+}$  currents in hippocampal neurons in culture using more physiologically relevant concentrations.

Primary hippocampal neurons were isolated from fetuses of pregnant (E18) Fischer 344 rats. Cells were subsequently treated with either ethanol vehicle (0.05%) or DEX (0.1 to 1000 nM) on days 3 and 6 in culture. High voltage-activated  $\text{Ca}^{2+}$  currents were recorded on day 7 using the whole cell patch clamp technique.

The peak current amplitude was similar for pyramidal neurons chronically treated with either ethanol vehicle or concentrations of DEX (0.1 and 1 nM) below the  $K_d$  for the receptor. However, peak currents were increased by 40-60% in cells which had been treated with higher concentrations of DEX. The present results indicate that chronic treatment with physiologically relevant concentrations of glucocorticoids increases  $\text{Ca}^{2+}$  currents. Thus, adrenal steroid hormones may modulate  $\text{Ca}^{2+}$  channel function in mammalian neurons. (Supported by AG10836)

## CALCIUM CHANNELS: CHARACTERIZATION AND ELECTROPHYSIOLOGY

## 620.1

**CALCIUM CURRENTS IN HUMAN POLYMORPHONUCLEAR NEUTROPHIL LEUKOCYTES.** M.A. SCHUMANN\*, Y. OKA, M. NAKAYAMA, N. HASEGAWA, and T. A. RAFFIN, Division of Pulmonary and Critical Care Medicine, Stanford University School of Medicine, Stanford, California 94305-5236.

Calcium involvement in neutrophil activation is underscored by its mediation of a variety of cytoplasmic processes and changes in membrane potential. Our laboratory has investigated  $\text{Ca}^{2+}$  oscillations and activation of membrane ion channels in human neutrophils. Although nonselective cation, potassium, and chloride channels in these cells have been found to be  $\text{Ca}^{2+}$ -activated, the presence of  $\text{Ca}^{2+}$ -selective channels linking transient changes in membrane conductance to neutrophil signaling have not been characterized. In the present study, we recorded  $\text{Ca}^{2+}$  currents in human neutrophils using barium, as the major charge carrier, and the electrophysiological whole-cell patch-clamp technique. The sodium-free bath solution contained  $\text{Ba}(\text{CH}_3\text{CO}_2)_2$  100 mM,  $\text{MgCl}_2$  2 mM, HEPES 10 mM, and glucose 15 mM (pH 7.4). The pipette solution included  $\text{CsCH}_3\text{CO}_2$  140 mM, EGTA 0.5 mM,  $\text{MgCl}_2$  2 mM, ATP (Mg salt) 2 mM, and HEPES 10 mM (pH 7.3). Transient inward currents were elicited at room temperature by depolarizing 25-mV steps (between -75 and +75 mV) delivered from holding potentials ranging from -60 to -100 mV. Currents reached a peak value between -40 and -10 mV (n = 15). As the depolarization was raised the current eventually became outward with a reversal potential of  $\approx +40$  mV. Currents were activated at holding potentials  $< -60$  mV, and fully inactivated at holding potentials  $> -60$  mV. In addition, currents decreased when  $\text{Ba}^{2+}$  decreased, and were significantly blocked by 1 mM  $\text{Cd}^{2+}$ . These electrophysiological observations suggest that these currents are contributed by  $\text{Ca}^{2+}$  channels of low-voltage-activated "T"-type. This work was supported by National Institutes of Health Grant HL455330.

## 620.2

**Differential Ontogeny of Calcium Currents in the Rat Nigro-Striatal System.** T. DeFazio\* and J.P. Walsh, Andrus Gerontology Center, University of Southern California, Los Angeles, CA 90089-0191

Thick slice patch clamp techniques were used to examine changes in morphology and calcium channel physiology during rat postnatal development. Biocytin-filled dopaminergic Substantia Nigra pars Compacta (SNc) neurons at 1 day postnatal (1d) displayed extensive dendritic arbors comparable to those observed in adult tissue. At birth, striatal medium spiny (MS) neurons were aspiny and bipolar with tufts of dendrites at each end and a tip-to-tip diameter of  $\sim 100\mu\text{m}$ . During the first two postnatal weeks these tufts extended, the two primary dendrites began to split, and a few spines were present. By adulthood these neurons exhibited many spiny dendrites extending hundreds of microns.

Whole cell calcium currents recorded from 0-30d rats revealed both different types and developmental time courses of calcium currents. 0-2d SNc neurons exhibited typical  $\sim 100\text{pA}$  LVA and sustained HVA inward currents. Unclamped 100-500pA HVA currents appeared after 2d. After 7d LVA currents were no longer observed and the runaway HVA currents increased to adult levels ( $> 500\text{pA}$ ).  $\sim 20\%$  of the HVA current was blocked by  $5\mu\text{M}$  SNX-124 ( $\omega$ -conotoxin GVIA, N-type calcium channel antagonist).

0-2d MS neurons also exhibited  $\text{Ni}^{2+}$ -sensitive  $\sim 60\text{pA}$  LVA currents (although with a more depolarized activation profile); but, very little HVA current was observed ( $< 50\text{pA}$ ). After 3d, LVA currents disappeared and runaway 100-300pA HVA currents appeared.  $\sim 30\%$  of the HVA current was blocked by  $5\mu\text{M}$  SNX-124.

## 620.3

AN ANALYSIS OF THE LOW THRESHOLD CALCIUM CONDUCTANCE IN THE SUBSTANTIA NIGRA. L. R. Johnson and S.A. Greenfield\* University Department of Pharmacology, Oxford, UK. OX1 3QT

The low threshold calcium conductance (LTS, T type channel) has been well documented in the thalamus, the hippocampus CA3 and the anterior SNpc (Nedergaard and Greenfield, 1992) where in all cases its activation leads to a burst of action potentials. However, more recently an apparent LTS has been described in some dopaminergic neurons of the rat SNpc (Kang and Kitai, 1993) which does not lead to a burst of action potentials *in vitro*.

Using the *in vitro* intracellular current clamp technique we have explored this apparent difference in the LTS in two populations of guinea-pig SNpc neurons with similar morphology. We identified the LTS in 10% of posterior SNpc neurons and all of the anterior SNpc neurons. Activating the LTS with a depolarising current pulse or rebound hyperpolarisation led to bursts of action potentials in the anterior SNpc neurons; however a burst was never activated in the posterior SNpc. The presence of the LTS was later confirmed by blocking action potentials with TTX.

A further difference between the LTS in anterior and posterior SNpc populations was found in sensitivity to pharmacological blockade. For example in the presence of TTX equimolar concentrations of cadmium was applied: It was found that the LTS in anterior SNpc cells was abolished while the LTS in the posterior SNpc cells was not.

These results suggest that two distinct T channels may operate in different populations of substantia nigra neurons. Although the function of that seen in the anterior SNpc appears to be to favour generation of burst firing, that in the posterior SNpc is still unknown; perhaps it could play a role in dendritic dopamine release.

CALCIUM CHANNELS OF EMBRYONIC RAT SPINAL MOTONEURONS

B. Hivert and D. Pietrobon Dept. of Biomedical Sciences, Univ. of Padova, 35121 Padova, Italy.

Single channel patch-clamp recordings (with 90 mM  $\text{Ba}^{2+}$  as charge carrier) were used to characterize the calcium channels expressed by E15 rat spinal motoneurons purified by immunopanning and maintained in culture for 1-2 days. The  $\text{Ca}^{2+}$  channels most frequently observed (in 20 out of 40 patches with 1-3 channels) were dihydropyridine (DHP)-sensitive L-type channels, as judged from the prolongation of openings in the presence of the DHP agonist (+)-S-202-791. Three different DHP-sensitive gating patterns were distinguished. The most frequent L-type activity was characterized (in the presence of (+)-S-202-791) by long closings and relatively short openings (average open time,  $t_o = 2.5$  ms at +20 mV), and by a rather peculiar fast inactivation (time constant of decay of the average single channel current: 100 ms at +20 mV). Single channel currents and conductance (24 pS) were indistinguishable from those of a different DHP-sensitive gating pattern with  $t_o = 10$  ms and negligible inactivation during 700 ms (in the presence of DHP agonist at +10 mV). Two patches contained L-type channels with smaller conductance (20 pS) and anomalous gating similar to those recently characterized in cerebellar granule cells (Forti and Pietrobon, 1993, Neuron 10, 437). The DHP-insensitive  $\text{Ca}^{2+}$  channels observed most frequently (in 40% of patches) had functional properties similar to those of T-type channels (conductance: 7 pS, activation threshold: -40 mV, time constant of decay of average current: 28 ms at +10 mV). 20% of the patches showed DHP-insensitive  $\text{Ca}^{2+}$  channels (most likely N-type) with 20 pS conductance, 0 mV activation threshold, almost complete steady-state inactivation at -40 mV and biexponential time course of inactivation (with time constants of 27 and 253 ms at +20 mV). Several other DHP-insensitive  $\text{Ca}^{2+}$  channels were observed less frequently and remain to be characterized.

## 620.7

IN THE PRESENCE OF BAY K 8644, LONG DEPOLARIZATIONS SLOW DEACTIVATION OF L-TYPE  $\text{Ca}^{2+}$  CHANNELS IN GH<sub>3</sub> CLONAL PITUITARY CELLS BY PROMOTING ACCESS TO A THIRD OPEN STATE. D. M. Fass\* & E. S. Levitan. Departments of Neuroscience and Pharmacology, Univ. of Pittsburgh, Pittsburgh, PA 15260.

Application of BAY K 8644 (1  $\mu\text{M}$ ) produces a dramatic slowing of deactivation of L-type  $\text{Ca}^{2+}$  channel currents in GH<sub>3</sub> cells. Specifically, whole-cell tail current decay after brief (10 ms) depolarizations is fit by a single exponential with a  $\tau$  of  $\sim 150$   $\mu\text{sec}$  in drug-free conditions and two exponentials with  $\tau_{\text{fast}} = \sim 2$  ms and  $\tau_{\text{slow}} = \sim 8$  ms in the presence of the drug. On the single channel level, we have found that these two exponentials arise from two open states visited by each L-channel. In the presence of 1  $\mu\text{M}$  BAY K 8644, deactivation is further slowed when recorded upon repolarization after long (200 ms) depolarizing pulses. Analysis of whole-cell tail currents recorded in the presence of BAY K 8644 from 5 cells indicates that both  $\tau$ s are increased in magnitude ( $\tau_{\text{fast}}$  increases from  $2.0 \pm 0.7$  to  $3.7 \pm 0.5$  and  $\tau_{\text{slow}}$  increases from  $7.7 \pm 1.4$  to  $9.9 \pm 1.2$ ,  $p < 0.05$ , data are mean  $\pm$  SD), and also that the relative amount of current deactivating with the slow  $\tau$  increases (from  $64 \pm 19\%$  to  $80 \pm 20\%$ ,  $p < 0.05$ ). In cell-attached patch recordings performed in the presence of BAY K 8644 on patches containing single L-channels, ensemble average tail currents from patches subjected to long (100 ms) depolarizations showed slower deactivation than those recorded from separate patches subjected to brief (10 ms) depolarizations. In 4 of 5 patches subject to the long depolarizations, this effect appeared to be due in part to a time-dependent increase in access to a third, slower open state (open time  $\tau = 14.4 \pm 1.3$ ).

## 620.4

MULTIPLE COMPONENTS OF THE LOW-THRESHOLD CALCIUM CURRENT IN HIPPOCAMPAL CA3 PYRAMIDAL NEURONS. R.B. Avery\* and D. Johnston, Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030

In recent years there has been compounding evidence that low-threshold  $\text{Ca}^{2+}$  currents contribute to sub-threshold signalling in central neurons. Because they may be particularly crucial to the physiological functions of hippocampal CA3 pyramidal neurons, we have studied the low-threshold  $\text{Ca}^{2+}$  current in these cells.

We used 2 mM  $\text{Ca}^{2+}$  to record whole-cell  $\text{Ca}^{2+}$  currents from acutely isolated CA3 pyramidal cells from rats age 7-14 days. We elicited low-threshold currents by giving test pulses to -50 mV from a holding potential  $\leq -80$  mV. High-threshold currents were isolated by holding at -50 mV and stepping to 0 mV. Long (600 ms) pulses to -50 mV revealed two kinetically distinct components to the low-threshold  $\text{Ca}^{2+}$  current: one inactivating (mean amplitude  $38 \pm 3$  pA) and one non-inactivating ( $23 \pm 7$  pA). The inactivating component decayed with a time constant of  $55 \pm 6$  ms. Half-maximal steady-state inactivation of the component occurred at -86 mV. The inactivating current was preferentially blocked by nickel and amiloride.

The non-inactivating component persisted throughout the step, even for depolarizations lasting several seconds. As measured at the end of a 600 ms pulse, the sustained component was enhanced by switching to equimolar  $\text{Ba}^{2+}$  (2 mM,  $113 \pm 9\%$ ), a manipulation that reduced the amplitude of the inactivating component ( $66 \pm 6\%$ ). The sustained component was inhibited by nimodipine (10  $\mu\text{M}$ ,  $75 \pm 4\%$ ) and potentiated by BayK8644 (1  $\mu\text{M}$ ,  $126 \pm 6\%$ ). It was also inhibited by the L-channel toxin calciseptine (5  $\mu\text{M}$ ,  $75 \pm 2\%$ ). The inactivating component was not affected by these agents.

These data suggest that at least two-types of  $\text{Ca}^{2+}$  channels can be operative at potentials near rest; the inactivating T-type channel and a non-inactivating, dihydropyridine-sensitive channel (MH10473, MH44754, MH48432, NS11535).

## 620.6

EXPRESSION AND SUBCELLULAR DISTRIBUTION OF L-TYPE CALCIUM CHANNELS IN GLIA *IN VITRO*.

Sylvie VANDAELE\* and Philippe PIERRET, Unité de neurocytologie moléculaire, Département de pathologie, Université de Montréal, Montréal, Québec, Canada.

Glial L-type calcium channels are involved in a variety of cellular functions, such as the astrocytic response to variations of extracellular  $\text{K}^+$ , or in oligodendrocytic myelination process. The aim of this work is to examine the expression and the sub-cellular distribution of L-type channel subunits on primary culture of glial cells from new-born rats.

Primary cultures of astrocytes (> 98%) from cerebral cortex were characterized by their phenotype, which is vimentin+/GFAP- at one week, vimentin-/GFAP+ at 2-3 weeks, and A2B5- at all stages. In certain cell culture conditions, oligodendrocytes are present either at a progenitor stage (GD3+), either at preoligodendrocyte stage (Rmab+, O4+).

On all these cells, antibodies directed against  $\alpha_1$  or  $\alpha_2$  subunits reveal a punctiform immunoreactivity. The similarity of this immunoreactivity with that of clathrin and caveolin suggests that these channels could be concentrated in invaginated regions of the membrane.

Calcium channel subunit expression varies depending on the batch of horse serum used in the culture. It is significantly increased following dbcAMP treatments. This suggests that seric factors and/or cell processes modulating cAMP may be involved in the regulation of the synthesis of L-type calcium channel subunits. Supported by the Savoy Foundation and the CAFIR.

SINGLE CALCIUM CHANNEL CURRENTS RECORDED AT PHYSIOLOGICAL CALCIUM LEVELS. P.J. Church\* and E.F. Stanley SMS, NINDS, NIH, Bethesda, MD 20892.

The influx of calcium ions through voltage sensitive ion channels is critical for the gating of several cellular processes. However, little is known about the conductance of these channels at physiological  $\text{Ca}^{2+}$  levels. We used quartz glass electrodes to record single neuronal  $\text{Ca}^{2+}$  currents in external  $\text{Ca}^{2+}$  down to 0.5mM.

Ciliary ganglia from 15-day-old chick embryos were enzymatically dissociated, triturated to single neurons and plated onto coverslips. 140 KAsp was used to collapse the membrane potential. Single channel current at -40mV was approximately 1pA with 80mM  $\text{CaCl}_2$  in the pipette and approached 0.1pA with 0.5mM  $\text{CaCl}_2$ . Even at these low concentrations, channel conductance was not linearly related to external divalent cation concentration.

Shown below is an on-cell patch recording exhibiting a single open level of 0.203pA (dashed line) in response to a 300ms step to -40mV in physiological (2mM)  $\text{Ca}^{2+}$ .

## 620.9

ASYMMETRIC INTRAMEMBRANE CHARGE MOVEMENT IN MICE HIPPOCAMPAL NEURONS. R. Boumaud, P. Chameau and T. Shimahara\*. Lab. Neurobiol. Cell. & Mol., CNRS, 91198 Gif sur Yvette Cedex, France.

Intramembrane charge movement elicited by membrane depolarization is believed to be electrical manifestation of the conformational change in the channel protein. The highly conserved S4 region of voltage gated channels is assumed: 1-to be a voltage sensor because of the presence of repeated motifs of positively charged amino acid residues (arginine and lysine) followed by non polar residues. 2-to carry a part of intramembrane charge movement. So far, asymmetric currents related to charge movement in the central nervous system were recorded in molluscan neurons and recently in Purkinje neurons from mouse cerebellum. In the present work, we studied intramembrane charge movement in hippocampal pyramidal neurons using the whole cell clamp technique. The hippocampal cells were enzymatically dissociated from 14 to 18 day-old mice. The relationship between the amount of charge movement and pulse potential is described by a two state Boltzmann equation ( $Q_{max}=10.87 \pm 0.62 \text{ nC/pF}$ ,  $V_{1/2}=72.2 \pm 9.1 \text{ mV}$ ,  $k=18.84 \pm 1.20 \text{ mV}$ ,  $n=16$ ). The arginine modifying reagent phenylglyoxal (10mM) decreases  $Q_{max}$  to about 14% of control. The charge movement was partially immobilized by nifedipine in a dose dependant manner with a  $IC_{50}$  of 350nM. Nifedipine (5μM) reduces  $Q_{max}$  to about 46% of the control value. Our results show that asymmetric currents can be elicited in pyramidal cells; these current are related to the conformational changes involved in the gating mechanism of the voltage sensitive channels. A nifedipine sensitive component of charge movement can be isolated. The nifedipine sensitive charge movement presumably originates the gating current of the L type calcium channels expressed in pyramidal neurons. Supported by AFM and DRED.

## 620.11

Pb<sup>2+</sup> ACTIVATES THE RELEASE OF Ca<sup>2+</sup> FROM ISOLATED ENDOPLASMIC RETICULUM (ER) VESICLES FROM RAT CEREBELLUM. D.K. Bartschat, T.E. Rhodes, and D.C. Meyer\*. Dept. of Physiology, Eastern Virginia Medical School, Norfolk, VA 23501.

Pb<sup>2+</sup> influx activates the release of Ca<sup>2+</sup> from an intracellular thapsigargin-sensitive, ryanodine- and caffeine-insensitive store in hippocampal synaptosomes (see accompanying abstract). We isolated microsomes from rat cerebellum, a preparation rich in ER vesicles containing Type I IP<sub>3</sub> receptors, in order to determine if Pb<sup>2+</sup> activates IP<sub>3</sub>-sensitive Ca<sup>2+</sup> channels. Ca<sup>2+</sup> flux was monitored spectrophotometrically using fluo-3 or chlortetracycline (CTC) as extravascular (fluo-3) or intravascular (CTC) Ca<sup>2+</sup> indicators.

Incubation of the ER vesicles with Ca<sup>2+</sup> (1 - 50 μM) resulted in accumulation of Ca<sup>2+</sup> that was dependent on ATP, was largely blocked by thapsigargin, and was reversed by ionomycin. Addition of IP<sub>3</sub> ( $IC_{50} \approx 0.1 - 0.5 \mu\text{M}$ ) resulted in the prompt discharge of 1/4 - 1/2 of the accumulated Ca<sup>2+</sup>, an effect blocked by preincubation with heparin. Addition of heparin after IP<sub>3</sub> resulted in re-accumulation of Ca<sup>2+</sup>, which could subsequently be discharged again by further IP<sub>3</sub> addition. In stopped-flow experiments, mixing of the vesicles with 1 μM IP<sub>3</sub> resulted in two kinetically resolvable phases of release, with  $k_1 \approx 15 \text{ sec}^{-1}$  and  $k_2 \approx 1 \text{ sec}^{-1}$ . Elevated (> 10 μM) extravesicular Ca<sup>2+</sup> reduced the IP<sub>3</sub> effect.

Addition of Pb<sup>2+</sup> (1 - 100 μM) induced a rapid release of Ca<sup>2+</sup> from ER vesicles in the absence of IP<sub>3</sub>. Pb<sup>2+</sup> addition after Ca<sup>2+</sup> release by 1 μM IP<sub>3</sub> resulted in no further release, and IP<sub>3</sub> addition after Pb<sup>2+</sup>-induced release resulted in no further Ca<sup>2+</sup> release. The effect of Pb<sup>2+</sup> was reduced in solutions containing > 10 μM Ca<sup>2+</sup>. The apparent  $IC_{50}$  for Pb<sup>2+</sup>  $\approx 5 \mu\text{M}$  (added Pb<sup>2+</sup>), is probably orders of magnitude too high owing to the substantial complexation of Pb<sup>2+</sup> with components of our solutions (e.g. ATP, PO<sub>4</sub><sup>3-</sup>). These results indicate that Pb<sup>2+</sup> directly activates IP<sub>3</sub>-activated Ca<sup>2+</sup> channels, possibly through interaction with a Ca<sup>2+</sup> binding/modulatory site, and suggest inappropriate activation of IP<sub>3</sub>-activated Ca<sup>2+</sup> channels may underlie some aspects of Pb<sup>2+</sup> neurotoxicity.

## 620.13

EXTERNAL AND INTERNAL pH SHIFTS MODULATE VOLTAGE-GATED CALCIUM CURRENTS IN ISOLATED RAT CA1 NEURONS. G.C. Tombaugh\* and G.G. Somjen. Dept. of Cell Biology, Duke Univ. Med. Ctr., Durham, NC 27710.

The effects of extracellular and intracellular H<sup>+</sup> (pH<sub>o</sub>, pH<sub>i</sub>) on voltage-gated Ca<sup>2+</sup> currents were examined in acutely dissociated rat hippocampal CA1 neurons using the whole-cell patch clamp technique (21-24°C). Ca currents could be carried by Ba<sup>2+</sup>, blocked by Cd<sup>2+</sup>, and were found to be primarily of the high-voltage activated (HVA) type. Moderate external acidosis (pH 6.9-6.0) reversibly depressed HVA Ca current amplitude and caused a depolarizing (+8mV) I-V shift compared to control (pH 7.4); alkaline treatment (pH 8.0) had the opposite effect. The depression of HVA Ca currents by low pH<sub>o</sub> was unaffected when the internal H<sup>+</sup> buffering was raised from 10 to 50mM HEPES. A Hill plot of the effect of pH<sub>o</sub> on HVA current amplitude revealed a pK of 7.1 and a slope of 0.625. Neither HVA current decay kinetics nor steady-state inactivation ( $I_{\infty}$ ) were significantly affected by external H<sup>+</sup> within the pH range tested (6-8). Internal alkalization by exposure to the weak acid NH<sub>4</sub>Cl (20mM) caused a rapid increase in HVA current amplitude and a positive I-V shift, followed by a more modest depression and a slight negative I-V shift upon washout. Internal acidification by exposure to Na-acetate (20mM) depressed the HVA current by 50% while causing a 10-20mV hyperpolarizing I-V shift. In the presence of acetate HVA currents could be further depressed by external acidosis, indicating that physically separate and independent H<sup>+</sup>-sensitive sites exist on each face of the cell membrane. Low threshold Ca currents, though observed less frequently, were also depressed by external H<sup>+</sup> but appeared insensitive to internal acidosis (acetate). These results demonstrate that pH shifts within the pathophysiological range are capable of modulating voltage-gated Ca channels in CA1 neurons and strengthen the idea that endogenous pH shifts may modulate both neuronal activity and vulnerability in situ. Supported by the National Stroke Association and NS18670 (NINDS).

## 620.10

LEAD MEDIATED RELEASE OF CALCIUM FROM INTRACELLULAR STORES IN ISOLATED HIPPOCAMPAL NERVE TERMINALS. T.E. Rhodes\* and D.K. Bartschat. Dept. of Physiology, Eastern Virginia Medical School, Norfolk, VA 23501.

Isolated presynaptic nerve terminals were prepared from rat hippocampus and loaded with the intracellular calcium indicator Fura-2. The changes in cytoplasmic free calcium ( $[Ca^{2+}]_i$ ) were measured by stopped-flow fluorescence spectroscopy following depolarization with elevated  $[K^+]_o$  on a millisecond time scale (Lentzner et al., J. Physiol. 450:613-628, 1992). Depolarization promoted a rapid increase in intracellular  $[Ca^{2+}]_i$  which occurred in two phases: a fast component, representing the activity of rapidly inactivating Ca<sup>2+</sup> channels ( $\tau \approx 30 - 60 \text{ msec}$ ), and a slow component, which is comprised of slowly inactivating Ca<sup>2+</sup> channels ( $\tau \approx 1 - 2 \text{ sec}$ ) and Na<sup>+</sup>/Ca<sup>2+</sup> exchange operating in reverse. Low Pb<sup>2+</sup> (<1 μM) competitively blocked both the fast and slow channels ( $K_i \approx 0.1 \mu\text{M}$ ,  $0.2 \mu\text{M}$ , respectively). At  $\geq 1 \mu\text{M}$ , Pb<sup>2+</sup> permeated the fast channels. Pb<sup>2+</sup> did not permeate the slow channels and Na<sup>+</sup>/Ca<sup>2+</sup> exchange did not promote Pb<sup>2+</sup> transport. Lead permeation led to a subsequent rise in intracellular Ca<sup>2+</sup> even in the absence of extracellular calcium. The rise in Ca<sup>2+</sup> was reduced by thapsigargin, which depletes non-mitochondrial Ca<sup>2+</sup> stores, suggesting Pb<sup>2+</sup> activates Ca<sup>2+</sup> release from Ca<sup>2+</sup> storing organelles. The Pb<sup>2+</sup> mediated rise in Ca<sup>2+</sup> occurred in terminals treated with ryanodine and caffeine suggesting Pb<sup>2+</sup> does not act upon these stores. Furthermore, it appears that Pb<sup>2+</sup> mediates release from 2 distinct pools, a thapsigargin sensitive pool, and a Ca<sup>2+</sup> sensitive or labile pool which fills when the nerve terminals are incubated with Ca<sup>2+</sup> (100 μM). The release of Ca<sup>2+</sup> by Pb<sup>2+</sup> was greater in younger animals (35g) than in older (350g) rats for both pools, and the ability to load the labile store also diminishes during development. These results suggest age dependent changes in intracellular Ca<sup>2+</sup> storage and Pb<sup>2+</sup> sensitivity and that the neurotoxic effects of Pb<sup>2+</sup> may be due in part to interference with Ca<sup>2+</sup> metabolism in the presynaptic terminal.

## 620.12

EXTRACELLULAR IONIZED Mg ( $[Mg^{2+}]_o$ ) REGULATES INTRACELLULAR Ca<sup>2+</sup> CONCENTRATION ( $[Ca^{2+}]_i$ ), NOT INTRACELLULAR Mg<sup>2+</sup> CONCENTRATION ( $[Mg^{2+}]_i$ ), IN ACUTELY ISOLATED HIPPOCAMPAL CA1 PYRAMIDAL CELLS OF THE GUINEA-PIG. A. Zhang, S. Fan, T.P.O. Cheng, B.T. Altura, R.K.S. Wong, and B.M. Altura\*. SUNY Health Science Center at Brooklyn, NY 11203

Hypo- or hypermagnesemia are associated with manifestations of central nervous system dysfunction. The mechanism(s) by which  $[Mg^{2+}]_o$  affects neuronal excitability is not fully understood. The present studies, using digital imaging microscopy and ion selective electrodes, determined whether  $[Mg^{2+}]_o$  could affect  $[Ca^{2+}]_i$  and  $[Mg^{2+}]_i$  in single, acutely isolated pyramidal cells from the hippocampal CA1 region of the guinea-pig. After loading with fura-2 or mag-fura-2, the cells were perfused 15 min with HEPES buffer solutions containing 0.3, 0.6, 1.2 or 4.8 mM  $[Mg^{2+}]_o$ , respectively, and then  $[Ca^{2+}]_i$  and  $[Mg^{2+}]_i$  in these CA1 neurons were measured. Lowering  $[Mg^{2+}]_o$  increases

$[Mg^{2+}]_o$ (mM)	N	$[Ca^{2+}]_i$ (nM)	N	$[Mg^{2+}]_i$ (mM)	Effects on $[Mg^{2+}]_i$
0.3	32	$304 \pm 23^*$	62	$549 \pm 32$	Ca <sup>2+</sup> , but exerts no significant effects on $[Mg^{2+}]_i$ . However, 1 μM MK-801 and 5 mM Ni <sup>2+</sup> inhibited 0.3 mM $[Mg^{2+}]_o$ -induced Ca <sup>2+</sup> increase by 39.7% and 99.5%, respectively. The subcellular distributions of Ca <sup>2+</sup> , but exerts no significant effects on $[Mg^{2+}]_i$ . However, 1 μM MK-801 and 5 mM Ni <sup>2+</sup> inhibited 0.3 mM $[Mg^{2+}]_o$ -induced Ca <sup>2+</sup> increase by 39.7% and 99.5%, respectively. The subcellular distributions of
0.6	37	$158 \pm 27$	68	$618 \pm 11^*$	
1.2	34	$118 \pm 10$	72	$529 \pm 15$	
4.8	21	$100 \pm 7$	80	$506 \pm 20$	

\*  $P < 0.05$  compared to all other  $[Mg^{2+}]_o$ ; both  $[Ca^{2+}]_i$  and  $[Mg^{2+}]_i$  appeared to be heterogeneous. These data suggest that: 1)  $[Mg^{2+}]_o$  regulates  $[Ca^{2+}]_i$  in hippocampal pyramidal cells, probably by modulating Ca<sup>2+</sup> entry via voltage-sensitive Ca<sup>2+</sup> channels and N-methyl D-aspartate channels; 2)  $[Mg^{2+}]_i$  is not acutely sensitive to  $[Mg^{2+}]_o$  in these cells; and 3) the neurons seem to have active Mg<sup>2+</sup> transport system(s) which maintains steep concentration gradients of Mg<sup>2+</sup> across membranes.

## 620.14

EFFECTS OF pH ON CALCIUM CURRENTS AND SURFACE CHARGE IN BULLFROG SYMPATHETIC NEURONS. W. Zhou and S. W. Jones\*. Department of Physiology and Biophysics, Case Western Reserve University, Cleveland, OH 44106.

H<sup>+</sup> can affect gating and permeation in ion channels, in part by binding to negative "surface charges" on or near the channel. Whole-cell currents through calcium channels (2 mM Ba<sup>2+</sup>) are increased at high extracellular pH (8-9), and reduced at low pH (buffered with 5-10 mM HEPES and TAPS or MES extracellularly and 60 mM HEPES intracellularly). There are corresponding shifts in the activation curve, as expected for titration of a surface charge associated with gating. The shift of activation is best described with 2 classes of surface charge (1 e<sup>-</sup> per 100 Å<sup>2</sup> with pK=4.9, and 1 e<sup>-</sup> per 300 Å<sup>2</sup> with pK=6.7). The estimated net surface charge at pH 7.2 is 1 e<sup>-</sup> per 112 Å<sup>2</sup>. In contrast, there is no detectable effect of increased pH on the instantaneous I-V relation for fully activated channels, implying that no surface charge associated with permeation can be titrated in that region. The increased currents at high pH can be explained by the shifted activation curve. The instantaneous I-V is reduced at low pH, possibly reflecting channel block. Effects of low pH are complex, as both fast (< 1 s) and slow (seconds) effects are observed. The conclusion that the surface charge associated with permeation is much lower than that associated with gating, and the estimate of the surface charge for gating, are in good agreement with our previous work, based on effects of Ba<sup>2+</sup> and ionic strength (J. Gen. Physiol. 105:441-462, 1995).

## 620.15

**VOLTAGE-DEPENDENT FACILITATION OF CALCIUM CONDUCTANCES IN RAT NEOSTRIATAL NEURONS.** *W.-J. Song\* and D.J. Surmeier.* Dept. of Anatomy and Neurobiology, College of Medicine, U. of Tennessee, Memphis, TN 38163.

In a variety of cell types, a large depolarizing prepulse enhances calcium currents evoked by weaker stimuli. While this voltage-dependent facilitation has been intensively studied in non-neuronal cells and peripheral neurons, few studies have focused on central neurons. This type of facilitation is potentially important in the understanding of repetitive activity and neuromodulatory processes. We sought to determine whether similar facilitation currents were present in neostriatal neurons and, if so, what were their characteristics.

To this end, calcium currents were recorded in acutely-isolated and cultured neostriatal neurons with the whole-cell form of patch clamp recording with  $Ba^{2+}$  as the charge carrier. In some neurons, amphotericin perforated patch recording was used to determine the impact of cellular dialysis on the facilitation process.

In acutely isolated neostriatal neurons, a 30 msec prepulse to 100 mV typically increased the currents evoked by a -20 mV test pulse by 40-60%. Similar results were obtained in cultured neurons and in acutely isolated neurons recorded with perforated patch. This facilitation was voltage- and time-dependent. Pharmacological experiments suggested that N-, P-, Q- and L-type currents contributed to the facilitation currents. Although dialysis with GTP analogs (GTP- $\beta$ -S, GTP- $\gamma$ -S) failed to alter their magnitude, inhibition of protein kinase A/protein kinase G with H-89 eliminated the resting facilitation currents.

Supported by NIH grant NS26473 to D.J.S. and S.T. Kitai.

## 620.17

**EXPRESSION AND REGULATION OF VOLTAGE-GATED SODIUM AND CALCIUM CHANNELS IN RAT RETINAL GANGLION CELLS DURING DEVELOPMENT.** *Susanne Schmid and Elke Gunther.* Dept. Exp. Ophthalmology, Univ. Eye Hospital Tübingen, Germany. **SPON: European Neuroscience Association**

**Purpose:** The aim of this study was to characterize the expression of voltage-gated sodium channels and of different subtypes of voltage-gated calcium channels in retinal ganglion cells (RGCs) during the development of the retina.

**Methods:** Patch-clamp recordings of RGCs were performed in the perforated patch mode. Retinas were obtained from pigmented rats (*Brown Norway*) of different ages and cut into slices of 200  $\mu$ m. Extracellular solution contained (in mM): NaCl (130), KCl (5),  $BaCl_2$  (2),  $MgCl_2$  (1), Hepes (10) and Glucose (20), continuously bubbled with oxygen. Calcium currents were isolated replacing sodium by choline chloride and adding (in mM) TEA-Cl (20) and 4-AP (0.1) to block potassium currents. The pipette solution contained CsCl (130),  $MgCl_2$  (2), EGTA (10), Hepes (10) and ATP (2). Nystatin (100  $\mu$ M) was added to perforate the patch.

**Results:** Amplitude and activation threshold of sodium currents increase during development. RGCs of fully differentiated retinas show an action potential always larger than 1 nA. Additionally they show a large voltage-activated calcium inward current, of which one fraction (30%) can be blocked by the N-type channel blocker  $\omega$ -conotoxin GVIA and another fraction (17%) can be blocked by the L-type channel blocker Nifedipine, Diltiazem and Verapamil ( $n=50$ ). There is no detectable T-type calcium current. More than 50% of the voltage-gated calcium current is resistant against any known selective calcium channel antagonist.

Whereas N- and L-type currents are present in most RGCs of neonatal rats, the resistant fraction of the calcium current is expressed only after the second postnatal week, resulting in a strong increase of total  $I_{Ca}$  at that time.

**Conclusion:** RGCs express N- and L-type calcium channels and at least one more type of calcium channel which is resistant to all known calcium channel antagonists. Expression of N- and L-type channels and the "unknown" channel is differentially regulated during development.

## 620.16

**RUN-UP OF P-TYPE CALCIUM CHANNEL CURRENT IN ACUTELY DISSOCIATED PURKINJE NEURONS DURING WHOLE CELL RECORDINGS.** *B. Lükensmeier and A.J. Hansen\*.* Novo Nordisk A/S, 2760 Måløv, Denmark.

The function of many ion channels is dependent upon soluble factors in the cytoplasm. Usually ion currents are diminished with time after establishment of the whole cell configuration – the so-called run down phenomenon. Run up has also been described, but less frequently.

We used acutely dissociated Purkinje cells from cerebellar vermis of 5–10 day-old rats. Whole cell calcium currents were recorded with 1–3 M $\Omega$  electrodes and filled with, in mM: 100 CsCl, 40 HEPES, 10 EGTA, 2.9  $CaCl_2$ , 2.5  $MgCl_2$ , 1 ATP and 0.3 GTP (pH = 7.2). The external medium was: 10  $BaCl_2$ , 130 TEACl, 10 glucose, 10 HEPES, 1  $MgCl_2$  (pH = 7.3). In whole cell mode most of the cells had the P-type current (90% inhibitable by Ag $^{+}$  IVa). When the current was evoked from a holding potential of -80 mV to 0 mV, the amplitude increased 5–10 fold during the following 3–5 min after going whole cell. The phenomenon was observed whether or not the currents were elicited. The voltage-activation of the current was unchanged during this period. The prolonged time course of the run up suggests that rather small molecules like GTP are not involved, but points to a large intracellular factor (eg phosphatase) that is being washed out.

## 620.18

**SLOW CURRENT-DEPENDENT INACTIVATION EXPLAINS CHANGES IN BASAL FOREBRAIN HVA  $Ca^{2+}$  CURRENTS DURING AGING.** *D.A. Murchison and W.H. Griffith\*.* Dept. Medical Pharmacol. & Toxicol., Texas A&M University Health Science Center, College Station, TX 77843-1114.

Age-related increases in high voltage-activated (HVA) calcium ( $Ca^{2+}$ ) currents have been proposed to explain possible changes in  $Ca^{2+}$  homeostasis during aging. We now provide evidence that changes in the inactivation properties of this current rather than the absolute current magnitude may explain the age-related changes. Conventional whole-cell and nystatin perforated-patch clamp recordings were made from acutely dissociated neurons from male Fischer 344 rats of 1–2 months (young) and 20–26 months (aged). Barium ( $Ba^{2+}$ , 2 mM) was used as the charge carrier across the calcium channel and interfering conductances were blocked. Current-voltage relationships following ramp step changes showed no difference in peak current-density or voltage-dependence in young ( $n=94$ ) and aged ( $n=76$ ) cells. Conversely, voltage-steps delivered at 6 sec intervals, revealed a larger current-density in aged cells. This difference between age groups was explained by a greater current-dependent inactivation in young cells. When currents were generated at varying frequencies (0.5–0.05 Hz), current-dependent inactivation was statistically greater in young cells ( $p < 0.05$ ). Using the perforated-patch recording techniques inactivation was always reversible with appropriate recovery periods (3–4 min). Little current-dependent inactivation was generated if slow stimulation rates ( $\geq 0.033$  Hz, or every 30 s) were used. These results suggest that subtle rather than global changes in HVA  $Ca^{2+}$  currents may control changes in  $Ca^{2+}$  homeostasis during aging.

(Supported by NIH grant AG07805)

## ACETYLCHOLINE RECEPTOR: NICOTINIC II

## 621.1

**PRONOUNCED CELLULAR DIVERSITY AND EXTRASYNAPTIC LOCATION OF NICOTINIC ACETYLCHOLINE RECEPTOR SUBUNIT IMMUNOREACTIVITIES IN THE CHICKEN DIENCEPHALON.** *E.M. Ullian\* and P.B. Sargent.* Neuroscience Graduate Program and Depts. of Stomatology and Physiology, UCSF, San Francisco, California 94143

The diversity of nicotinic acetylcholine receptor (AChR) expression in the chick lateral spiriform nucleus (SpL) was assessed using subunit-specific monoclonal antibodies (mAbs) and laser scanning confocal microscopy. The late embryonic SpL was immunoreactive for mAbs against the  $\alpha 2$ ,  $\alpha 5$ ,  $\alpha 7$ ,  $\alpha 8$ , and  $\beta 2$  AChR subunits. Distinct neuronal cell classes were identified using pair-wise staining of mAbs. Approximately 90% of the neurons in the SpL contained both  $\alpha 5$ -like immunoreactivity (LI) and  $\beta 2$ -LI, with no neurons having only one of these subunit-LIs. Approximately 70% of the neurons contained  $\alpha 2$ -LI. All  $\alpha 2$ -LI neurons contained  $\alpha 5/\beta 2$ -LI; thus, neurons having  $\alpha 2$ -LI are a subset of those having  $\alpha 5$ - and  $\beta 2$ -LI. Fewer neurons, approximately 20%, contained  $\alpha 7$ -LI. A subset of  $\alpha 7$ -positive neurons were immunoreactive for other subunits; for example, some  $\alpha 7$ -positive neurons also contained  $\alpha 2$ -LI. Fewer than 15% of the neurons contained  $\alpha 8$ -LI. Some of the  $\alpha 8$ -LI-containing neurons contained  $\alpha 7$ -LI. The 14 week post-hatch SpL resembles the late embryonic nucleus in the percentage of neurons immunoreactive for  $\alpha 2$ ,  $\alpha 5$ ,  $\alpha 7$ ,  $\alpha 8$ , and  $\beta 2$  AChR subunits, and in the presence of multiple classes based on AChR subunit immunoreactivity. In addition,  $\alpha 4$ -LI was found in about 20% of the 14 week SpL neurons. Double-label immunofluorescence experiments with mAbs to AChRs and to synaptic vesicle antigens showed that most clusters of  $\alpha 5$ -LI and  $\beta 2$ -LI are extrasynaptic. The pronounced diversity of AChR subunit expression and the extrasynaptic location of AChR-LI suggest that AChR-like molecules in the SpL do not function solely to respond to transmitter focally released from presynaptic terminals.

Supported by NIH grants GM07449, NS 24207, and RR 07131.

## 621.2

**PERISYNAPTIC SURFACE DISTRIBUTION OF MULTIPLE CLASSES OF NICOTINIC ACETYLCHOLINE RECEPTORS ON NEURONS IN THE CHICKEN CILIARY GANGLION.** *H.L. Wilson Horch and P.B. Sargent\*.* Depts. of Stomatology and Physiology and the Neuroscience Graduate Program, UCSF, San Francisco, CA 94143

Most nicotinic acetylcholine receptors (AChRs) studied to date in the embryonic chicken ciliary ganglion are recognized either by monoclonal antibody (mAb) 35 or by  $\alpha$ -bungarotoxin ( $\alpha$ -Bgt). Previous studies found that mAb 35-AChRs are found at both synaptic and extrasynaptic sites, while  $\alpha$ -Bgt-AChRs are exclusively extrasynaptic [Loring et al., Neurosci. 14(1983)645-660; Jacob and Berg, J. Neurosci. 3(1983)260-271; Jacob et al., Proc. Natl. Acad. Sci. USA, 81(1984)3223-3227; Loring and Zigmond, J. Neurosci., 7(1987) 2153-2162]. To gain a three-dimensional understanding of the spatial relationship of these two AChR classes to one another and to synaptic sites, we visualized clusters of mAb 35-AChRs and  $\alpha$ -Bgt-AChRs immunofluorescently using laser scanning confocal microscopy and compared their distribution with that of the synaptic vesicle antigen SV2. Both mAb 35-AChR and  $\alpha$ -Bgt-AChR clusters are widely distributed over the neuronal surface. Some mAb 35-AChR clusters are located at synaptic sites, but the bulk of them are located extrasynaptically in well-defined patches measuring 1–4  $\mu$ m in diameter.  $\alpha$ -Bgt-AChRs are found almost exclusively in these extrasynaptic sites, which thus contain both AChR types. These sites are often surrounded by elements of the synaptic calyx but are themselves largely free of synaptic antigen. In 14 week chickens the relationship between mAb 35-AChRs,  $\alpha$ -Bgt-AChRs, and synaptic sites is similar to that in embryos except that in this instance, individual synaptic boutons are often partly surrounded by AChR-containing patches. These results suggest that most surface AChRs on chicken ciliary neurons are perisynaptic, and they raise questions about the function of these AChRs.

Supported by NIH grants NS24207 and RR07131.

## 621.3

MAPPING THE LOCATION OF FUNCTIONAL NICOTINIC ACETYLCHOLINE RECEPTORS (nAChRs) ON HIPPOCAMPAL NEURONS OF THE RAT. M. Alkondon<sup>1</sup>\*, E.F.R. Pereira<sup>1,2</sup> and E.X. Albuquerque<sup>1,2</sup>. <sup>1</sup>Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. of Med., Baltimore, MD 21201, USA; <sup>2</sup>Lab. Mol. Pharmacol., IBCCF, UFRJ, RJ 21944, Brazil.

Hippocampal neurons of the rat express multiple subtypes of functional nAChRs (*J. Pharmacol. Exp. Ther.* 265:1455, 1993). In the present study, we investigated the distribution and location of the nAChRs along the somatic and dendritic membranes of hippocampal neurons. To this end, either neurons obtained from the hippocampi of fetal rats and grown in culture or 200- $\mu$ m slices obtained from the hippocampi of postnatal rats (P8-P18) were used. The presence of nAChRs was assessed from the whole-cell currents elicited by either focal or U-tube application of ACh. Infrared video microscopy was used to view the neurons in hippocampal slices and a 'nanorobot' micromanipulator was used to position the ACh-containing pipette at locations near the soma or the dendrites. Exposure of cultured hippocampal neurons to the microtubule-destabilizing agent colchicine (100 nM for 3 days) caused a marked decrease in the dendritic branching pattern and a significant decrease in the peak amplitude of  $\alpha$ -bungarotoxin-sensitive nicotinic currents. Nicotinic currents could be recorded from the whole-cell pipet positioned at the cell soma when ACh (1 mM) was applied to the soma itself or to various regions of the apical dendrites (even up to 100  $\mu$ m from the soma). NMDA-evoked currents were also detected at the soma when NMDA (20  $\mu$ M) and glycine (10  $\mu$ M) were coapplied focally either at the soma or at different parts of the dendrites. Similar results were obtained when the pyramidal cells of the CA1 region of hippocampal slices were used. The present results indicate that the  $\alpha$ -bungarotoxin-sensitive nAChR is located both on the soma and along the dendritic membranes, suggesting a synaptic role for this nAChR subtype. (USPHS Grants NS25296, ES05730 & T32-ES07263).

CHARACTERIZATION OF  $\alpha$ -BUNGAROTOXIN SENSITIVE NICOTINIC RECEPTORS IN AN IMMORTALIZED HIPPOCAMPAL CELL LINE. J. Komourian\* and M. Quik, Dept. of Pharmacology, McGill University, Montreal, Canada, H3G 1Y6.

The functional significance of neuronal nicotinic  $\alpha$ -bungarotoxin ( $\alpha$ -BGT) receptors is not fully understood. As a model for studying this receptor in the CNS, we have selected an immortalized rat hippocampal cell line H19-7 (courtesy Dr. B. Wainer). Our previous work demonstrated that when differentiated, these cells express saturable high affinity  $\alpha$ -BGT receptors with characteristics similar to rat brain  $\alpha$ -BGT sites. In the present study, we show that these receptors are located extracellularly; exposure of the cells to  $\alpha$ -BGT to block receptors show that  $92.4 \pm 2.6\%$  ( $n=3$ ) of the sites are located on the cell surface. The neuronal nicotinic receptor subunit  $\alpha 7$  has been linked to  $\alpha$ -BGT binding sites and here we show using the RNase protection assay that the  $\alpha 7$  mRNA transcript is present in differentiated H19-7 cells, as well as  $\alpha 4$  and  $\beta 2$  mRNAs. These receptor subunit mRNAs are not present in undifferentiated cells. No RNA transcripts were identified encoding the nicotinic receptor subunits  $\alpha 2$ ,  $\alpha 3$ ,  $\alpha 5$  and  $\beta 3$  in either differentiated or undifferentiated H19-7 cells. Initial results indicate that nicotinic receptor activation increases the intracellular calcium concentration in these cells. The present results suggest that H19-7 cells may represent a useful model system to study the identity and role of CNS  $\alpha$ -BGT receptors.

## 621.7

IN VITRO SYNCHRONIZATION OF AChR DEGRADATION RATES BY EXOGENOUS ATP OR ADENOSINE. J.P.O'Malley\* & M.M. Salpeter, Section of Neurobiology and Behavior, Cornell University, Ithaca NY 14857.

Acetylcholine receptors (AChRs) can be classified as two distinct physiological entities based on their metabolic degradation rates. The two forms have been called Rr and Rs to designate rapidly degrading and slowly degrading AChRs respectively. The Rr degrades with a half-life ( $t_{1/2}$ ) of 1 d while the Rs degrades with a  $t_{1/2}$  of 10 d in innervated muscle and 3 days in denervated or cultured muscle. Furthermore the 3-day-Rs of denervated or cultured muscle can be converted to a 10-day-Rs by elevating intracellular cAMP. To date, we have not been able to alter the  $t_{1/2}$  of the Rr from that of 1 day.

However evidence exist which suggests that the Rr and the Rs may share a common  $t_{1/2}$  of 3 days during reinnervation (see Liu, Szabo and Salpeter abstract this meeting). To determine if such Rr stabilization can be achieved, and may be due to the motor nerve, we tested the effect of putative neurotrophic factors on Rr degradation. We report that Rr of cultured rat myotubes are stabilized from their default  $t_{1/2}$  of 1 d to a  $t_{1/2}$  of 3 days within a 24 h period by exogenously applied ATP. Furthermore after this 24 h period the newly inserted and existing AChRs (both the Rr and Rs) all decayed with the same  $t_{1/2}$  of  $\approx 3$  in the presence of ATP. This degradation profile is very similar to that of the AChRs inserted into the membrane of reinnervating muscle (Liu et al abstract this meeting). The same results were also obtained with Adenosine but not with Inosine.

We also report that treatment of AChRs with dibutyryl cAMP converted the 3-day-Rs, but not the ATP stabilized 3-day-Rr, to a 10-day Rs. Thus the Rr can exist with a  $t_{1/2}$  of 1 or 3 days and the Rs with a  $t_{1/2}$  of 3 or 10 days. We suggest that this ability to share a common  $t_{1/2}$  of 3 days may be important during periods in which the Rr and Rs content of the muscle is changing such as during normal development or reinnervation. If both Rr and Rs share a common  $t_{1/2}$  during these periods it would allow for a smooth transition of receptor type without altering the postsynaptic AChR content and thus ensuring the integrity of neuromuscular communication. ## 621.4

EFFECTS OF PRENATAL NICOTINE EXPOSURE ON LOCOMOTOR ACTIVITY, SENSORY GATING, AND CENTRAL NICOTINIC RECEPTORS. Y. Tizabi\*, E. J. Popke, M. A. Rahman, S. M. Nespor and N. E. Grunberg, Dept. of Pharmacology, Coll. of Med. Howard Univ., Washington, DC 20059, and Uniformed Services Univ. of the Health Sciences, Bethesda, MD 20814.

Prenatal exposure to nicotine may be a contributing factor in the manifestation of attention-deficit hyperactivity disorder. To evaluate possible involvement of neuronal nicotinic receptors in a model of this disorder, pregnant rats were implanted with osmotic minipumps to receive nicotine (6 mg/kg/day) or saline throughout gestation. The offspring were tested for locomotor activity on postnatal days 19-24, and prepulse inhibition (PPI) on days 31-36. Hyperactive and non-hyperactive offspring as well as high and low (impaired) PPI responders of both sexes were analyzed for nicotinic receptor densities utilizing <sup>3</sup>H cytosine binding to homogenates of cerebral cortex (left hemisphere, LCN), striatum, hippocampus, thalamus, colliculi, substantia nigra region and cerebellum. Prenatal nicotine exposure resulted in approximately 50% more hyperactive offspring for both sexes. Prenatal nicotine also impaired PPI response in the offspring and the effect was more dramatic in females. Male offspring with low PPI, regardless of prenatal nicotine exposure, exhibited an upregulation of nicotinic receptors in LCN compared to high PPI responders. The LCN nicotinic receptors were also significantly elevated in the male hyperactive (vs non-hyperactive) offspring that were prenatally exposed to nicotine. Additionally, there was an upregulation of nicotinic receptors in the striatum of PPI impaired male offspring that were exposed to nicotine prenatally. It is concluded that hyperactivity and impaired PPI in male offspring that were exposed to nicotine prenatally are associated with upregulation of nicotinic receptors in specific brain regions. Since nicotine upregulation is associated with a functional impairment of these receptors, it is postulated that such offspring could experience a reversal or reduction of their symptoms with administration of nicotine.

## 621.6

POSTNATAL EXPRESSION OF NICOTINIC ACETYLCHOLINE RECEPTOR SUBUNIT mRNAs IN RAT VISUAL CORTEX. B.S. Stoveken\*, U.H. Winer-Serhan, F.M. Leslie, Dept. Pharmacology, Univ. of California, Irvine, CA 92717.

A transient increased binding of [<sup>3</sup>H]nicotine and [<sup>125</sup>I] $\alpha$ -bungarotoxin has been reported in primary visual cortex (V-1) during postnatal development. These two ligands bind to nicotinic acetylcholine receptors (nAChR) of different subunit compositions in rat brain. In order to elucidate possible subunit contributing to this binding, we studied the mRNA expression of  $\alpha 3$ ,  $\alpha 4$ ,  $\alpha 5$ ,  $\alpha 7$ ,  $\beta 2$ , and  $\beta 4$  nAChR subunits in V-1. Transverse sections of rat brains collected from postnatal (P0) to P30 were processed for *in situ* hybridization with [<sup>32</sup>S]labeled riboprobes. All nAChR subunit mRNAs were found to be expressed in V-1 at P0 and throughout postnatal development. However, expression intensity and distribution varied greatly among subunits. The highest levels of mRNA expression throughout development were seen for  $\alpha 4$  and  $\beta 2$  which were both expressed in layers II-VI. The  $\alpha 7$  nAChR subunit was moderately expressed in all layers, and showed transient increased mRNA expression in layer IV and VI during the first two postnatal weeks.  $\alpha 3$  nAChR mRNA was expressed at low levels of intensity in several cortical layers during development. By P3 an increase in  $\alpha 3$  mRNA expression was detected in layer IV of V-1 which remained at moderate levels into adulthood. The expression of  $\beta 4$  exhibited a similar distribution pattern to that of  $\alpha 3$  during the first and second postnatal week, but then declined at P15 to very low levels of expression. The  $\alpha 5$  subunit showed the most discrete expression pattern, and was almost exclusively found in the subplate or layer VIIb during development and into adulthood. This study confirms that a number of nAChR subunit mRNAs are expressed in V-1 during development. The transiently increased expression of  $\alpha 3$  and  $\beta 4$  mRNAs in layer IV suggest that these subunits may be responsible for the increased nicotine binding in this layer. The lack of increased expression of other nAChR subunits in layer VI besides  $\alpha 7$  supports previous findings that  $\alpha 7$  forms functional homomeric receptors and is not associated with other known nAChR subunits. Supported by PHS grant # NS30109.

## 621.8

ACETYLCHOLINE RECEPTOR DEGRADATION AND mRNA LEVELS DURING REINNERVATION OF DENERVATED MOUSE MUSCLE

Enchi Liu\*, Maria Szabo, Miriam M. Salpeter, Section of Neurobiology & Behavior, Cornell University, Ithaca, NY.

At innervated neuromuscular junctions, (nmjs) acetylcholine receptors (Rs AChRs) have a stable degradation half-life ( $t_{1/2}$ ) of  $\approx 8$ -10 days (10-day Rs). After denervation the Rs degrade with a  $t_{1/2}$  of  $\approx 3$  days (3-day Rs) and, as they degrade are replaced by embryonic-like AChRs (Rr) with a rapid degradation  $t_{1/2}$  of  $\approx 1$  day (1-day Rr). To understand the molecular structure of the Rs and Rr, we examined events during reinnervation. When mouse sternomastoid muscles are denervated by multiple nerve crushes, regeneration begins within 3 to 4 days after the last crush and is complete by day 7. EM autoradiography established that AChRs inserted at the nmj during and after reinnervation degraded with 3 and 8 day half-lives, respectively. In addition, the AChR site density decreased only slightly during this reinnervation period. *In situ* hybridization was used to quantify g and e subunit mRNAs. We report that at the nmj the g subunit mRNA is increased over non-specific levels by about 6 fold after denervation, by 4.5 to 3.5 fold during reinnervation and is back to innervated levels within four days after full reinnervation. The junctional e subunit is increased only about 1.5 fold after denervation, remaining so throughout the reinnervation period and decreasing to innervated values by one day after full reinnervation. Assuming that mRNA levels reflect AChR content (Witzemann et al FEBS 223:104, 1987), our data suggest that in denervated muscle the 1-day Rr are predominantly g containing which are replaced by e-containing Rs as the g mRNA drops after reinnervation. Finally, our data on AChR degradation rate, site density and g mRNA levels fit a model suggesting that the 1-day Rr may stabilize to a 3-day Rr during reinnervation (see abstract by O'Malley & Salpeter) before being replaced by e-containing 3- or 10-day Rs. Such a mechanism would have the advantage of preventing a major decrease in AChR site density expected if replacement of 1-day Rr by 10-day Rs would occur without a 3 day intermediate. Supported by NIH NS 09315

## 621.9

ANALYSIS OF BRAIN NICOTINIC ACETYLCHOLINE RECEPTORS WITH SUBUNIT-SPECIFIC ANTIBODIES AND [<sup>3</sup>H]EPIBATIDINE. W.G. Conroy\* and D.K. Berg. Dept. of Biology, UC San Diego, La Jolla, CA. 92093.

Although eleven neuronal nicotinic acetylcholine receptor (AChR) genes have been identified, the combinations of subunits forming native AChRs in the CNS remain uncertain. Previous work distinguished two classes of AChRs in chick brain based on high affinity nicotine binding (AChRs with  $\alpha 4$  and  $\beta 2$  subunits) or  $\alpha$ -bungarotoxin binding (AChRs with  $\alpha 7$  and/or  $\alpha 8$  subunits). We report that additional AChRs can be identified using the nicotinic ligand [<sup>3</sup>H]epibatidine and subunit-specific monoclonal antibodies (mAbs). A filter assay for [<sup>3</sup>H]epibatidine binding yields values of about 140 fmol/mg protein in brain extracts prepared from 18 day chick embryos. About 90% of the sites can be immunoprecipitated with either  $\alpha 4$ - or  $\beta 2$ -specific mAbs. [<sup>3</sup>H]epibatidine does not bind detectably to  $\alpha$ Bgt-AChRs. A solid-phase immunotethering assay demonstrates that mAbs to  $\alpha 3$ ,  $\alpha 5$ , and  $\beta 4$  also are able to retain brain AChRs labeled with [<sup>3</sup>H]epibatidine. Performing sequential immunodepletions indicate that some AChRs containing  $\alpha 3$ ,  $\beta 4$ , or  $\alpha 5$  subunits also have  $\alpha 4$  and/or  $\beta 2$  subunits. These results confirm the abundance of  $\alpha 4\beta 2$  AChRs in brain and go on to identify novel AChRs that may possess distinctive properties. (NS 12601 & 25916)

## 621.11

TYROSINE KINASE INHIBITORS SELECTIVELY DOWN-REGULATE A SUBPOPULATION OF NEURONAL ACH RECEPTORS. R.C. Haselbeck, E.M. Blumenthal, and D.K. Berg\*. Dept. of Biology, UCSD, La Jolla, CA 92093.

Protein tyrosine kinases (PTKs) play key roles in signal transduction pathways for a wide range of cellular processes and are highly expressed in the nervous system. We used PTK inhibitors to examine the possible involvement of PTKs in regulating ACh receptors in chick ciliary ganglion neurons. The neurons express several classes of ACh receptors including a class (mAb 35-AChRs) that binds mAb 35 and is responsible for synaptic transmission through the ganglion. They have a second class ( $\alpha$ Bgt-AChRs) that binds  $\alpha$ -bungarotoxin and lies predominantly in non-synaptic membrane. Treatment of cultured neurons with the membrane-permeant PTK inhibitor herbimycin (0.5  $\mu$ g/ml) reduces surface expression of mAb 35-AChRs by two-fold but does not affect  $\alpha$ Bgt-AChRs. Little change is seen in the large intracellular pool of mAb 35-AChRs. Lavendustin, a second PTK inhibitor, also reduces surface expression of mAb 35-AChRs. The herbimycin-induced decrease in mAb 35-AChRs requires protein synthesis, and therefore is unlikely to represent increased receptor turnover. The findings implicate a PTK in the regulation of AChR surface number. It may increase synthesis of certain AChR gene products, though one cannot yet exclude a posttranslational effect that depends indirectly on protein synthesis. (NS12601 & 25916; AHA93-72)

## 621.13

RESIDUES FROM NON-ALPHA SUBUNITS OF NICOTINIC ACETYLCHOLINE RECEPTOR PARTICIPATE IN AGONIST BINDING - EVIDENCE FROM SINGLE CHANNEL STUDIES. Y. Zhang, J. Chen, G. Akk, M. Slaughter\*, S. Sine and A. Auerbach. Dept. of Biophysics, SUNY Buffalo NY 14214, and Dept. Physiology, Mayo Foundation, Rochester, MN 55905.

Macroscopic recording and photolabelling studies revealed that residues from  $\delta$  and  $\gamma$  subunits of nAChR contribute to agonist binding. In  $\delta$ -subunit these residues include W57, D180, and E189 (<sup>1,2</sup>). We have mutated the  $\delta$ W57 into aromatic (Y, F) and non-aromatic (T, E) residues. We have also changed the negatively charged D175 and E184 in the  $\epsilon$ -subunit to their uncharged counterparts, N and Q. Receptors were expressed in oocytes and HEK 293 cells. Single channel data indicate that the aromatic nature of W57 is important to ACh binding and channel gating. The EC<sub>50</sub> values are (in  $\mu$ M): 11 (wt  $\alpha 5\beta 6$ ), 19 (Y), 9 (F), 543 (T) measured as intracellular P<sub>open</sub> vs. ACh concentration. Kinetic analysis indicates that both ligand binding and channel gating steps are affected by the mutations. The mutant receptors open at a rate that is about 10 times slower than the wild type. The channel closing rate is unchanged. Our data indicate that channel block by ACh and QX-222 is enhanced by the mutation suggesting that structural changes in agonist binding site caused by mutation may have propagated to the pore region.

Mutants D175N and E184Q have their dose response curves shifted towards higher agonist concentrations. The EC<sub>50</sub> values are (in  $\mu$ M): 29 (wt  $\alpha 5\beta 6$ ), 246 (D175N), and 81 (E184Q). Single-channel analysis shows that i) D175N has slower opening rate (2000s<sup>-1</sup>) which accounts for most of the effect on the dose-response curve, ii) E184Q has similar gating rates as wt receptor but drastically increased dissociation rate suggesting its participation in the ACh binding.

## 621.10

$\alpha$ BGT-SENSITIVE ACH-INDUCED CURRENTS IN PC12 CELLS. E.M. Blumenthal\*, W.G. Conroy, S.J. Romano, and D.K. Berg. Dept. of Biol., UCSD, La Jolla, CA. 92093.

PC12 cells have been widely used to study neuronal nicotinic ACh receptors (AChRs). Despite having  $\alpha 7$  transcripts and  $\alpha$ -bungarotoxin ( $\alpha$ Bgt)-binding sites, the cells have not been found to express  $\alpha$ Bgt-sensitive ACh-induced currents. Using whole-cell patch-clamp and rapid application of agonist (500  $\mu$ M ACh), we examined three PC12 variants. One (vI) expressed small, rapidly desensitizing currents that were completely blocked by 60 nM  $\alpha$ Bgt; the cells also displayed high-affinity  $\alpha$ Bgt-binding sites on the cell surface. The second (vII) expressed slow,  $\alpha$ Bgt-insensitive currents and had no  $\alpha$ Bgt surface binding. The third (vIII) expressed both the rapid, toxin-sensitive current and a slow, insensitive current; vIII cells had  $\alpha$ Bgt-binding sites on the cell surface. While levels of  $\alpha$ Bgt-binding among the three variants correlated approximately with the  $\alpha$ Bgt-sensitive currents, they did not correlate with  $\alpha 7$  transcript levels. RNase protection showed, surprisingly, that  $\alpha 7$  transcript levels are close to 10-fold higher in vII than in either vI or vIII. Discrepancies were also found between levels of other AChR subunit mRNAs and the amplitude of the slow current. The results demonstrate that transcript levels are not a reliable indicator of functional receptor abundance, and suggest that important regulatory controls may exist at posttranscriptional steps. In addition, the results are the first to demonstrate functional  $\alpha$ Bgt-AChRs on PC12 cells. (NS 12601 & 25916)

## 621.12

REGULATION OF THE NEURONAL ACETYLCHOLINE RECEPTOR GENE  $\alpha 7$  IN VERTEBRATE SKELETAL MUSCLE. S.J. Romano\* and D.K. Berg. Dept. of Biology, UC San Diego, La Jolla, CA 92093.

Several of the neuronal nicotinic ACh receptor (AChR) genes are expressed in embryonic chick skeletal muscle. One of the most abundant,  $\alpha 7$ , produces a component having the size expected for a fully assembled AChR. Because  $\alpha 7$  and  $\alpha 1$  gene expression rise and fall roughly in parallel during muscle development, experiments were designed to determine if the two are co-regulated. Hatching chicks were unilaterally denervated by transecting the sciatic nerve, and total RNA extracted from leg muscles 2-14 days later. RNase protections revealed the expected large increase in  $\alpha 1$  mRNA; in contrast,  $\alpha 7$  message levels increased only modestly and with a slower time course. The regulatory role of electrical activity was examined by treating cultured myotubes with TTX to block spontaneous contractions. Consistent with the denervation results, TTX increased the  $\alpha 1$ -containing AChRs and  $\alpha 1$  transcripts in cultured muscle without appreciably increasing  $\alpha 7$  protein or mRNA levels. To investigate potential regulation by neuronal factors, muscle cultures were treated with ARIA.  $\alpha 1$  message levels were increased by ARIA as expected, but  $\alpha 7$  mRNA expression was not enhanced. Though both  $\alpha 1$  and  $\alpha 7$  mRNA levels decline markedly in vivo around embryonic days 15-17, the results suggest that different regulatory mechanisms may be responsible. (NS12601 & NS25916)

## 621.14

BIOTINYLATED ARSENICALS: PROBES FOR THE AGONIST BINDING SITE OF TORPEDO NICOTINIC RECEPTORS. R.H. Loring\*, X.G. Zhang, A. Sharma, A. Baaj, R. Moaddel, and G.S. Jones, Jr. Dept. Pharmacol. Sci., Northeastern University, Boston, MA 02115.

Unwin (Nature 373:6509, 1995) proposes that the agonist binding site on Torpedo nicotinic receptors is located within a pit visualized on the  $\alpha$  subunit. Adjacent cysteine residues Cys<sup>192</sup>-Cys<sup>193</sup> on the  $\alpha$  subunit are part of the agonist binding site, and we previously demonstrated (Loring et al., Mol. Brain Res. 15:113, 1992) that aromatic trivalent arsenicals, which recognize paired but not single thiols, will covalently bond to reduced Torpedo receptors and block  $\alpha$ -bungarotoxin (ABT) binding. We therefore investigated the properties of N-biotinyl-p-aminophenyl arsonous acid (Bio-APA) as a labeling agent for nicotinic receptors. Bio-APA blocks ABT binding to Torpedo receptors treated with dithiothreitol with an IC<sub>50</sub> of 30 nM, but has no effect on untreated receptors. The effect of Bio-APA is long-lasting (> 9 d), but can be reversed at any time with the anti-arsenical agent dimercaptopropionate sulfonate (DMPS). However, [<sup>125</sup>I]-streptavidin, which binds to biotin, does not bind to intact Torpedo receptors in which ABT binding is blocked by Bio-APA. Streptavidin does bind to Bio-APA when covalently bonded to an 18mer peptide corresponding to the portion of Torpedo  $\alpha$  subunit containing Cys<sup>192</sup>-Cys<sup>193</sup>. The labeling of peptide blotted onto PVDF membranes is prevented if the peptide is alkylated with N-ethylmaleimide prior to Bio-APA treatment, or if DMPS is used after labeling. Taken together, these data suggest that the 3D protein structure of intact Torpedo receptors prevents streptavidin binding to covalently attached Bio-APA. We are examining analogs of Bio-APA with varying spacer groups between the arsenical and biotin moieties to map the agonist binding site. Supported by NS22472 and Smokeless Tobacco Research Council.

## 621.15

EFFECTS OF A BIOTINYLATED ARSENICAL ON NEURONAL NICOTINIC RECEPTORS. X.G. Zhang\*, T. McHugh, R. Moaddel, G.S. Jones, Jr. and R.H. Loring. Dept. Pharmacol. Sci., Northeastern U., Boston, MA 02115.

Since N-biotinyl-p-aminophenyl arsonous acid (Bio-APA) covalently bonds near the agonist binding site of reduced *Torpedo* nicotinic receptors (Loring et al., Soc. Neurosci. Abstr., 1995), we investigated whether Bio-APA has similar effects on neuronal nicotinic receptors. Nicotinic responses in intact chick retina are blocked by treatment with dithiothreitol (DTT), but this effect is readily reversed by reoxidation by dithiois-nitrobenzoate (DTNB). Bio-APA (20  $\mu$ M) completely blocks the ability of DTNB to restore function to DTT-treated retina, but subsequent treatment with the anti-arsenical reagent dimercaptopropionate sulfonate (DMPS) restores nicotinic function to arsenylated receptors. Similarly, Bio-APA treatment (20  $\mu$ M) protects DTT-treated ciliary ganglia receptors against irreversible alkylation by bromoacetylcholine. Bio-APA blocks [<sup>125</sup>I]- $\alpha$ -bungarotoxin binding to DTT-treated immunoprecipitated  $\alpha 7$ -containing receptors from chick brain with an IC<sub>50</sub> of 100 nM, but had no effect on untreated receptors or receptors reoxidized with DTNB. The effect of Bio-APA was long lasting (> 1 d), but could be reversed at any time by DMPS. Arsenylation with Bio-APA also blocks the binding of [<sup>3</sup>H]-cytisine to immunoprecipitated  $\alpha 4$ -containing receptors from chick brain. The ability of [<sup>125</sup>I]-streptavidin to bind to arsenylated receptors (immunoprecipitated  $\alpha 3$ ,  $\alpha 4$ ,  $\alpha 7$ , or  $\alpha 8$  receptors, antibodies from Dr. J. Lindstrom) was also determined. In no case did [<sup>125</sup>I]-streptavidin bind to neuronal receptors arsenylated with Bio-APA. These data suggest that neuronal nicotinic receptors are similar to *Torpedo*  $\alpha 1$  receptors in that the thiols arsenylated by Bio-APA are not located at sites on the receptor surfaces easily accessible to streptavidin. Supported by NS22472 and STRC.

## 621.17

EXPRESSION OF A SOLUBLE 62 AMINO ACID PEPTIDE FRAGMENT FROM THE EXTRACELLULAR DOMAIN OF THE  $\alpha$ -SUBUNIT OF THE NICOTINIC ACETYLCHOLINE RECEPTOR. E. Hawrot, M.A. Grant, Q.-L. Shi, R. Patrick\*, L.N. Gentile. Department of Molecular Pharmacology and Biotechnology and Department of Neuroscience, Brown University, Providence, RI 02912.

We have constructed a synthetic gene for a 62 amino acid fragment ( $\alpha 143$ -204) of the N-terminal portion of the nicotinic acetylcholine receptor (nAChR) using the protein sequence of the  $\alpha$ -subunit from *Torpedo californica*. This gene was attached to the C-terminus of thioredoxin and expressed in plasmid pTrxFus as a soluble fusion protein. The polylinker region separating thioredoxin and the receptor fragment was re-designed to include a thrombin cleavage site. The fusion protein was over-expressed in *E. coli* G1724 cells, purified by 35% ammonium sulfate precipitation, and treated with thrombin to liberate the desired 62mer. Following purification by ion exchange and gel filtration chromatography a calculated yield of 6.86 mg of the 62mer protein was obtained from a 2 L prep in M-9 media.

Both the fusion protein and the cleaved 62mer were shown to have excellent binding affinity for a variety of nAChR ligands by [<sup>125</sup>I]-bungarotoxin (BGTX) competition binding assays. The apparent affinity of both the fusion protein and of the isolated 62mer for BGTX was within a factor of five of the affinity obtained with native AChR receptor (*Torpedo* electric organ membranes). Furthermore, competition binding experiments with the 62mer indicate an apparent IC<sub>50</sub> of 35  $\mu$ M for curare. The CD spectrum of the isolated 62mer is suggestive of a protein with  $\beta$ -structure. Metabolic labelling to incorporate the [<sup>15</sup>N] and/or [<sup>13</sup>C] labels needed for high resolution NMR analysis of the receptor fragment as well as of its stoichiometric complex with BGTX is currently underway. (Supported by NIH GM32629.)

## 621.19

CHARACTERIZATION OF HUMAN NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR SUBUNITS  $\alpha 3$ ,  $\beta 2$ ,  $\beta 4$ , and  $\alpha 5$  EXPRESSED IN *XENOPUS* OOCYTES

F. Wang, V. Gerzanich, R. Anand\*, X. Peng, and J. Lindstrom. Dept. of Neuroscience, Univ. of Pennsylvania Medical School, Philadelphia, PA 19104-6074.

We have isolated cDNAs for the human neuronal nicotinic acetylcholine receptor (AChR) subunits  $\alpha 3$ ,  $\beta 2$ ,  $\beta 4$  and  $\alpha 5$  from a library prepared from the human neuroblastoma cell line SH-SY5Y. The subunit compositions of functional human AChRs assembled in *Xenopus* oocytes have been studied by using subunit-specific mAbs and tagging of subunits with reporter epitopes. By using voltage clamp functional assays and radioimmunoassays, both electrophysiological and pharmacological properties of human  $\alpha 3$  AChRs expressed *in vitro* have been characterized.

When expressed in *Xenopus* oocytes, both human AChR subunit combinations  $\alpha 3\beta 2$  and  $\alpha 3\beta 4$  form functional ligand-gated ion channels with strong inward rectification.  $\alpha 3\beta 2$  and  $\alpha 3\beta 4$  AChRs show different ligand binding and ion channel properties. For example,  $\alpha 3\beta 2$  AChRs exhibit significantly faster desensitization than do  $\alpha 3\beta 4$  AChRs; radioimmunoassay shows  $\alpha 3\beta 2$  AChRs have higher affinity by at least 10 fold than  $\alpha 3\beta 4$  AChRs do for epibatidine (a potent agonist for neuronal AChRs).  $\alpha 5$  efficiently co-assembles with both  $\alpha 3\beta 2$  and  $\alpha 3\beta 4$  in oocytes; but in both cases, no substantial change in either ligand binding or channel properties of the resulting AChRs was detected. According to results with subunit specific mAbs and comparisons of their binding affinities for epibatidine, the subunit compositions and pharmacological properties of the heterologously expressed  $\alpha 3$ -type AChRs from *Xenopus* oocytes resemble those of native  $\alpha 3$ -type AChRs from the human neuroblastoma cell line SH-SY5Y. (Supported by grants from NINDS, STRC, CTR, and MDA).

ACETYLCHOLINE RECEPTOR  $\gamma$  SUBUNIT ASP<sup>174</sup> CONTRIBUTES TO THE BINDING OF ACETYLCHOLINE AND CURARE. M. Martin, C. Czajkowski and A. Karlin\*. Center for Molecular Recognition, Columbia University, New York, NY 10032.

Muscle-type nicotinic acetylcholine receptors have the composition  $\alpha 2\beta \gamma \delta$ . One of the two acetylcholine binding sites is formed between an  $\alpha$  subunit and the  $\delta$  subunit, and the other binding site between the second  $\alpha$  subunit and the  $\gamma$  subunit.  $\delta$ Asp<sup>180</sup> is within 1 nm of the disulfide-linked cysteines,  $\alpha$ Cys<sup>192</sup> and  $\alpha$ Cys<sup>193</sup>, and the mutation of  $\delta$ Asp<sup>180</sup> to Asn decreased the affinity for ACh by two orders of magnitude (Czajkowski and Karlin, J. Biol. Chem. 270: 3160-64, 1995). The residue that aligns with  $\delta$ Asp<sup>180</sup> in mouse-muscle  $\gamma$  subunit is  $\gamma$ Asp<sup>174</sup>. We mutated this residue and each of the other nine negatively charged residues contained in the extracellular segment from Glu163 to Glu203. The mutants were co-expressed in *Xenopus* oocytes with wild-type  $\alpha$ ,  $\beta$ , and  $\delta$  subunits, or with just  $\alpha$  and  $\beta$ . In the latter case, the mutation of  $\gamma$ Asp<sup>174</sup> to Asn ( $\gamma$ D174N) decreased the affinity for ACh 170 times and for d-tubocurarine 10 times, as measured by their competition with  $\alpha$ -bungarotoxin. Mutation of the other nine negatively charged residues to Asn or Gln did not significantly change the affinity for ACh. No detectable ACh-induced current was obtained with oocytes co-expressing  $\gamma$ D174N and wild-type  $\alpha$  and  $\beta$ , but with the additional co-expression of wild-type  $\delta$ , ACh-induced currents were obtained and were characterized by an apparent affinity for acetylcholine one-seventh that of wild-type receptor. Mutation of  $\gamma$ Asp<sup>174</sup> to Glu had no effect on the affinity for ACh, or on ACh-induced currents.  $\gamma$ Asp<sup>174</sup>, which aligns with  $\delta$ Asp<sup>180</sup>, is likely to interact electrostatically with ACh at the binding site formed between  $\alpha$  and  $\gamma$ . Supported by T32-NS07258, RO1-NS07065, and MDA Research Grant.

## 621.18

SUBUNIT COUPLING IN THE ACETYLCHOLINE RECEPTOR IS AFFECTED BY MUTATIONS THAT DESTROY POST-TRANSLATIONAL MODIFICATION SITES. E.C. Walcott\* and K. Sumikawa. Dept. of Psychobiology, University of California, Irvine, CA 92717.

We have further investigated the role of two post-translational modifications, disulfide bond formation and N-glycosylation, in the biosynthesis of the nicotinic acetylcholine receptor (AChR). These modifications are thought to occur on each of the four types of AChR subunits ( $\alpha, \beta, \gamma, \delta$ ) after translation in the endoplasmic reticulum. Site-directed mutant subunits were generated lacking one of the conserved cysteines (Cys  $\rightarrow$  Ser) or one residue in the conserved N-glycosylation site (Ser  $\rightarrow$  Ala), and tested in *Xenopus* oocytes. Oocytes were injected with three wildtype mRNAs ( $\alpha\beta\gamma$ ,  $\alpha\beta\delta$ ) with or without a mutant subunit mRNA lacking a conserved post-translational modification site (myC128S, m $\delta$ C130S, myS143A, m $\delta$ 145A). Dose-response curves generated from whole cell ACh responses revealed that the maximal currents ( $I_{max}$ ) from these groups were generally less than 5% of wildtype responses. Other physiological activation parameters (EC<sub>50</sub> and Hill coefficients) were also changed. When either mutant  $\gamma$  subunit (myC128S or myS143A) was co-expressed with  $\alpha\beta\delta$  compared to  $\alpha\beta\delta$  alone, EC<sub>50</sub> values and  $I_{max}$  values shifted indicating that mutant  $\gamma$  subunits are capable of assembling into functional receptors. In contrast, few differences were observed between mutant  $\delta$  subunits co-expressed with  $\alpha\beta\gamma$  and  $\alpha\beta\delta$  alone, indicating that mutant  $\delta$  subunits may not be incorporated into the correctly assembling receptor. Biochemical evidence suggests that subunits containing each of these mutations associate with other subunits, but the efficiency of correct subunit coupling is decreased and may at least partly account for the reduction in physiological responses. (Supported by NIMH-NRSA 14599-19 and MDA).

## 621.20

THE NICOTINIC ACETYLCHOLINE RECEPTOR IN CEREBELLUM IS COMPOSED OF FOUR DIFFERENT SUBUNITS. J.R. Forsythe\*, E. Kobrin, B.D. Winegar and D.J. Fitzgerald. Dept. Anesthesia, University of California San Francisco, CA 94143-0542

Nicotine has well described effects on motor coordination exerted in part through receptors in the cerebellum. We investigated the distribution of nicotinic receptor subunits in rat cerebellum and brain-stem with immunohistochemistry on free-floating sections. Two rabbit polyclonal antibodies were generated with bacterially synthesized cytoplasmic loop fragments encoded by the  $\beta 3$  and  $\beta 4$  subunits. In order to ensure maximum specificity, antisera were further purified with immobilized unique peptides. Immunoprecipitation of subunits from extracts of transfected COS cells showed that the antibodies were specific. Immunoperoxidase staining with sections of fixed rat brain showed strong staining with both antibodies in the granular layer and in Purkinje cells with both antibodies. Staining was also seen in cell bodies in Trigeminal nuclei and Vestibular nuclei in the medulla. Staining in Pons by the  $\beta 3$  antibody and the  $\beta 4$  subunit antibody was strong. Receptor composition was assayed by making detergent extracts from rat cerebellum and precipitating receptors with the anti- $\beta 2$  antibody, mAb270. The immunoprecipitate contained the  $\alpha 4$ ,  $\beta 3$  and  $\beta 4$  subunits (Western). All four antibodies could precipitate acetylcholine binding activity in the detergent extracts of COS cells transfected with a combination of the four subunit cDNAs. We conclude, therefore, that the nicotinic receptor in the cerebellum is composed largely of a receptor with the stoichiometry  $\alpha 4\beta 2\beta 3\beta 4$ . This study was supported by a grant to J.R.F. from the NIH.

**HYPOXIA-INDUCED NEURONAL INJURY IN CORTICAL-PIAL COCULTURES.** S.-I. Chi\*, T.-L. Bai, T.-I. Wong and T.-N. Lin. Department of Physiology, Tzu-Chi College of Medicine, Hualien and Institute of Biomedical Sciences Academia Sinica, Taipei, Taiwan.

The role of cerebral vessels and extracellular acidity in hypoxic-ischemic neuronal injury have been controversial. We studied the interaction between cultured cortical neurons and pial vessels under oxygen-glucose deprivation conditions typical of hypoxia-ischemia in vivo. A progressive neuronal loss in neuronal-pial cocultures induced by oxygen-glucose deprivation was in a time-dependent manner, assessed by phase-contrast microscopy and release of lactate dehydrogenase into medium. No significant injury was found in cultured pial vessel cells after deprivation for 6 hours. In neuronal-astrocyte cocultures, neuronal injury was induced by deprivation for 60 minutes. While to produce significant neuronal injury in neuronal-pial cocultures required longer deprivation for 100 minutes even with higher neuronal density. The neuronal death was partially attenuated by both NMDA antagonist MK-801 (10  $\mu$ M) and extracellular acidity (pH 6.4).

These observations suggest that hypoxic neuronal injury in the neuronal-vessel mix cultures may be mediated partly by NMDA receptors and cerebral vessels and extracellular acidity may have neuroprotective effects during hypoxia-ischemia.

## 622.3

**FIMBRIA-FORNIX (FF) LESIONS AND EXCITOTOXIC INJURY PRODUCE SIMILAR DAMAGE TO SEPTAL NEURONS.** S.D. Ginsberg<sup>1,2</sup>, C. Portera-Cailliau<sup>1,2,4</sup>, D.L. Price<sup>1,4</sup>, and L.J. Martin<sup>1,2,4</sup>. <sup>1</sup>Neuropathology Lab., Dept. of Pathology, <sup>2</sup>Neurology, and <sup>3</sup>Neuroscience, The Johns Hopkins Univ. Sch. Med., Balt., MD 21205.

The FF transection paradigm has been used primarily as a model of retrograde degeneration within the medial septal nucleus (MSN). We tested the hypothesis that anterograde and transynaptic degeneration, as well as retrograde degeneration, occurs following unilateral FF transections in adult rats. The MSN, dorsolateral septal nucleus (LSNd), and medial mammillary nucleus (MMN) were analyzed ultrastructurally at 3, 7, 14, and 30 days postlesion. Terminal degeneration was observed predominantly at 3 and 7 days postlesion within the MMN and at 7 and 14 days postlesion within the MSN and LSNd. Somatodendritic changes, including membrane-bound vacuoles and loss of cytoplasmic matrix, occurred mainly at 7 and 14 days postlesion within the ipsilateral MSN, LSNd, and MMN, suggesting both retrograde and transynaptic degeneration. The somatodendritic pathology resembled some of the morphological changes following excitotoxic damage to forebrain neurons. We tested whether excitotoxic injections of quinolinolate (60 nmol) or kainate (25 nmol) into the septal complex of adult rats would mimic the transynaptic ultrastructural damage observed following FF transections. Similar patterns of somatodendritic injury were observed between the axotomy and excitotoxicity models, suggesting that an excitotoxic-like event occurs transynaptically as a result of FF transections. Because glutamate is the principal transmitter of hippocampal/subicular efferents within the FF, axotomy of these fibers may cause a traumatic release of glutamate and resultant excitotoxic damage to postsynaptic targets expressing functional glutamate receptors.

## 622.5

**GLUTAMATE MEDIATED EXCITOTOXICITY IS MACROMOLECULAR SYNTHESIS DEPENDENT IN CULTURED CEREBELLAR GRANULE NEURONS.** J. Rollins and J. Holliday\*. Department of Neurobiology and Anatomy, University of Rochester Medical Center, Rochester, NY 14642.

There is evidence that several types of cellular mechanisms can be involved in neuronal glutamate toxicity depending upon the cell type, age, and glutamate challenge paradigm. However, toxicity usually depends upon activation of the NMDA-subtype of glutamate receptor with a subsequent increase in intracellular calcium. We have tested the hypothesis that excitotoxicity is a result of a glutamate-activated apoptosis, or "programmed" cell death, in a cellularly defined culture system of purified cerebellar granule neurons.

Exposure of neuron cultures (11 days *in vitro*) to glutamate under conditions that permit the activation of the NMDA receptor (low magnesium) for 15 minutes causes approximately 15% of the cells to undergo glutamate-induced death after 12 hours. Control neurons were treated with the low magnesium solution without added glutamate. Application of transcription or translation inhibitors significantly reduces the death due to glutamate exposure by nearly 50%. In addition, glutamate challenge specifically increases the expression of key proteins, despite the decline in neuronal viability. These data support the notion that glutamate-mediated cell death utilizes mechanisms common to other types of apoptotic neuron death, such as nerve growth factor deprivation (Martin et al. 1988).

## 622.2

**ISCHEMIA-INDUCED CHANGES IN EXCITATORY AMINO ACID CONCENTRATIONS AFTER TRAUMATIC BRAIN INJURY.** L.W. Jenkins, M.H. Zomow\*, D.S. Prough, D.J. McAdoo, D.S. DeWitt. Department of Anesthesiology and Marine Biomedical Institute, The University of Texas Medical Branch, Galveston, TX 77555-0591.

**Introduction:** Both laboratory and clinical evidence suggest that traumatic brain injury (TBI) sensitizes the brain to secondary insults (1). Laboratory studies suggest that excitotoxicity may play a role in this sensitization; one possible mechanism for this hypersensitivity is an enhanced release or failure of reuptake of excitatory amino acids (EAA) (2). To study this possibility, the technique of *in vivo* microdialysis was used to measure glutamate and aspartate levels in the perischemic period after fluid-percussion TBI.

**Methods:** Fasted male Wistar rats (N=6) were anesthetized with isoflurane. A femoral arterial catheter was inserted and snares were placed around the carotid arteries before the production of TBI (0.8 atm). Sixty minutes after TBI, a microdialysis catheter was stereotactically inserted into the dorsal hippocampus and perfused at 2  $\mu$ l/min for an additional 30 minutes before the collection of a preischemic sample. Six minutes of forebrain ischemia was then produced by carotid occlusion and hypotension to 40 mmHg. Dialysis samples were collected throughout the ischemic period and for 30 minutes of reperfusion. Body temperature was maintained at 38°C. Ischemia-only rats (n=6) were treated in an identical fashion, but were not subjected to TBI.

**Results and Conclusions:** Forebrain ischemia resulted in a 50-100% increase in EAA concentrations in both groups. Although EAA levels were higher in the TBI group throughout the duration of the study, this finding reached statistical significance only for aspartate concentrations. These results suggest that EAA levels may be tonically elevated after TBI thereby increasing the brain's duration of exposure to these potential excitotoxins.

## 622.4

**CHARACTERIZATION OF DELAYED NEURODEGENERATION INDUCED BY OXYGEN/GLUCOSE DEPRIVATION IN ISOLATED RETINA.**

C. Romano<sup>1</sup>, M.T. Price<sup>2</sup>, T. Almi<sup>2</sup>, and J.W. Olney<sup>2</sup>. Depts. of Ophthalmology<sup>1</sup> and Psychiatry<sup>2</sup>, Washington University Medical School, St. Louis, MO 63110.

The isolated embryonic chick retina is an excellent preparation for studying the acute pathomorphological changes resulting from excitotoxic stimulation. We have recently adapted this preparation for studying delayed excitotoxicity by maintaining isolated chick embryo retinas in isolation for 24 hours and assessing the health of the tissue by both histological and biochemical means (LDH release). Studies of neurotoxicity induced by brief exposure to excitatory amino acid agonists in this system have indicated that non-NMDA receptor activation, as well as NMDA receptor activation, leads to delayed neurodegeneration (*J. Neurochem.* 65:59-67). This is in marked distinction to other *in vitro* systems, such as cultures of cortical or hippocampal neurons from embryonic rodent brain, in which prolonged stimulation of non-NMDA receptors with high concentrations of agonists is necessary to cause neuronal death.

Neurodegeneration was induced by simulated ischemia (SI, i.e. combined oxygen/glucose deprivation) in this preparation. The retinas were subjected to varying periods of SI, then placed into glucose-containing, oxygenated media and the incubation continued until 24 h from the start of the experiment. Two hours of SI led to substantial but submaximal retinal LDH release by the next day, and was chosen as a standard lesion. LDH release occurred gradually after two hours of SI, requiring about 12 hours for half of the amount eventually released to appear in the medium. Providing low concentrations of glucose during SI could prevent LDH release: 100  $\mu$ M glucose prevented half that caused by oxygen/glucose deprivation.

Glutamate receptor antagonists were effective neuroprotectants. Maximally effective concentrations of the NMDA receptor antagonist MK-801 (10  $\mu$ M) and the non-NMDA receptor antagonist GYKI 52446 (100  $\mu$ M) lowered LDH release to 23±3 and 42±2%, respectively, of that observed in their absence. Combining the antagonists resulted in near complete protection (2±0.2%). These results indicate that neurodegeneration induced by SI in this preparation is an excitotoxic process mediated by both classes of ionotropic glutamate receptors.

## 622.6

**THREE TYPES OF EXCITOTOXICITY EVALUATED FOR "APOPTOSIS" SIGNALS.** M. Ishimaru, T. C. Der, T. I. Tenkova, M.A. Sesma, J. H. Thurston\*, and J. W. Olney. Dept. of Psychiatry, Washington Univ Med School, St. Louis MO.

Using available tools for diagnosing apoptosis, several authors have recently reported that excitotoxicity can trigger an apoptotic cell death process. This prompted us to use Apop Tag, a commercially available *In Situ* Apoptosis Detection Kit @ (Oncor) to see if apoptotic signals occur in the following types of excitotoxic neurodegeneration: 1. Seizure-mediated brain damage induced by sc administration of kainic acid (KA). 2. Subacute degeneration of posterior cingulate cerebrocortical neurons induced by the NMDA antagonist, phencyclidine (PCP). 3. Acute degeneration of arcuate hypothalamic (AH) neurons induced by sc administration of glutamate (Glu) to infant rats. Following KA treatment, Apop Tag signals started to appear at 12 h post-treatment (pt) and were detectable for up to 7 days pt in various brain regions subject to seizure-mediated damage. Following PCP treatment, there were no Apop Tag signals detected in the posterior cingulate cortex over a 4 day period during which abundant cell death was occurring in this brain region. Following Glu treatment, robust Apop Tag signals began to appear in AH at 4 hr pt and became increasingly more abundant at 8 and 16 hr. Interestingly, Apop Tag positivity in AH was not only associated with individual dying neurons but with macrophages that were engorged with degeneration products. It is also of interest that individual "necrobiotic" neurons scattered over other parts of the infant CNS were Apop Tag positive.

Many years ago, when excitotoxic neuronal necrosis was first described (Olney, 1969), it was contrasted with "necrobiosis", a type of necrosis occurring as a programmed biological event during development. Today, "necrobiosis" has been supplanted with "apoptosis", and "necrosis" is an abused word that no longer connotes cell death but only non-apoptotic cell death. This is confusing: would it not be better to let necrosis mean cell death and recognize two categories of cell necrosis: apoptotic and non-apoptotic? But, if cell necrosis is to be subdivided into apoptotic and non-apoptotic categories, we need valid tools for defining apoptosis. Apop Tag may not be a valid tool since it marks both excitotoxic "necrosis" and "necrobiosis" as if both were "apoptosis". Supported by DA 05072, AG 11355 & RSA MH 38894 (JWO).

## 622.7

CALCIUM IONOPHORES CAN INDUCE EITHER APOPTOSIS OR NECROSIS DEATH OF CULTURED CORTICAL NEURONS. B.J. Gwag\*, S.L. Sensi, L.M.T. Canzoniero, J.A. DeMaro, J. Koh, M.P. Goldberg, M.F. Jacquin, and D.W. Choi. Dept. of Neurology and the Center for the Study of Nervous System Injury, Washington Univ. Sch. of Med., St. Louis, MO 63110.

Cultured murine cortical neurons exposed to low concentrations of the  $\text{Ca}^{2+}$  ionophores, ionomycin (250 nM) or A23187 (100 nM), for 24 hours underwent apoptosis, characterized by early degeneration of neurites, cell body shrinkage, chromatin condensation, and internucleosomal DNA fragmentation (laddering). This apoptosis death could be attenuated by inhibitors of protein or RNA synthesis, or certain growth factors - BDNF or IGF-I, but not bFGF. If the ionomycin concentration was increased to 1 - 3  $\mu\text{M}$ , then neurons underwent necrosis, characterized by early cell body swelling without DNA laddering, and lacking sensitivity to cycloheximide or growth factors. Calcium imaging with fura-2 suggested a possible basis for this differential effect of low and high concentrations of ionomycin. At low concentrations, ionomycin induced greater increases of  $[\text{Ca}^{2+}]_i$  in neurites than in neuronal cell bodies, whereas at high concentrations, ionomycin induced high levels of  $[\text{Ca}^{2+}]_i$  simultaneously in both neurites and cell bodies. In addition, high concentrations of ionomycin also produced a marked increase in  $[\text{Na}^+]_i$  detected with SBFI. The ability of low concentrations of  $\text{Ca}^{2+}$  ionophores to raise  $[\text{Ca}^{2+}]_i$  preferentially in neurites may be responsible for early neurite degeneration, leading to loss of growth factor availability to the cell body and consequent apoptosis. High concentrations of ionomycin may induce overwhelming  $\text{Ca}^{2+}$  overload resembling that induced by NMDA receptor overactivation, and consequent necrosis.

## 622.9

Stimulation of NMDA but not AMPA/KA Receptors Induces Internucleosomal DNA Fragmentation in Rat Striatum. Zheng-Hong Qin, Yumei Wang and Thomas N. Chase\*, Experimental Therapeutics Branch, National Institute of Neurological Disorders and Stroke, NIH, Bethesda, MD 20892

Previous studies have indicated that the intrastriatal administration of the excitotoxin quinolinic acid induced apoptosis in rat striatum. To evaluate whether glutamate receptor agonists generally act by apoptotic mechanism to induce cell death, and to characterize the subtypes of glutamate receptors which are involved in inducing apoptosis, we examined the biochemical and morphological effects of intrastriatal administered various doses of N-methyl-D-aspartate (NMDA) receptor agonist NMDA and quinolinic acid (QA); AMPA receptor agonist quisqualate (QUIS); and kainate receptor agonist kainic acid (KA). All these agonists induced profound striatal cell death as indicated by the significant loss of D1 and NMDA receptors. Agarose gel electrophoresis revealed that only NMDA (75-300 nmol) and QA (60-240 nmol) but not QUIS (75-300 nmol) and KA (1.25-5 nmol) induced internucleosomal DNA fragmentation. TUNEL labeled nuclei were observed in all four agonists treated striatum. Many fragmented nuclei were seen in NMDA or QA-treated striatum but are rarely detected in QUIS or KA-treated striatum. The NMDA or QA-induced internucleosomal DNA fragmentation and positive TUNEL labeling were abolished by the NMDA receptor antagonist MK-801 but not by the AMPA/KA receptor antagonist NBQX. Treatment with MK-801 but not NBQX also prevented NMDA or QA-induced cell death in striatum.

These results demonstrate that excessive stimulation of NMDA receptors leads to apoptotic cell death but stimulation of AMPA/KA receptors may lead to necrosis, suggesting that different cellular mechanisms are involved in neurodegeneration induced by different glutamate receptor agonists.

## 622.11

ANTI-EXCITOTOXIC EFFECT OF MILD HEAT STRESS ON CULTURED CORTICAL NEURONS IS NOT DEPENDENT ON HSP70 EXPRESSION. B.J. Snider\* and D.W. Choi. Dept. of Neurology and Center for the Study of Nervous System Injury, Washington Univ. School of Medicine, St. Louis, MO 63110.

The cytoprotective effects of heat stress in many systems are correlated with expression of the 70 kDa heat shock protein (hsp70). Heat stress leading to hsp70 expression protects cerebellar or cortical neurons from excitotoxic insults (Lowenstein et al., *Neuron* 7: 1053, 1991; Rordorf et al., *Neuron* 7: 1043, 1991). Last year we reported that high level heat stress (44 °C for 25 min), a paradigm that produces hsp70 expression in astrocytes but not neurons, protected neurons in our murine cortical cell cultures from oxygen-glucose deprivation-induced injury, but not excitotoxic injury (*Soc. Neurosci. Abstr.* 20: 1479, 1994). Here, we examined the possibility that more gentle heat stress would have an anti-excitotoxic effect.

Mixed neuronal-glial or neuronally-enriched (>95% neurons) murine cortical cultures were heat stressed at 42.5 °C for 1 hr or at 44 °C for 25 min. Immunocytochemistry and Western blotting showed that both treatments induced hsp70 in the glia but not neurons. Mixed cortical cultures that were heat stressed at 42.5 °C exhibited 20-50% less neuronal death after 24 hr exposure to 17.5  $\mu\text{M}$  NMDA, or 10 min. exposure to 10-1000  $\mu\text{M}$  glutamate in low chloride medium, than control cultures or cultures heat stressed at 44 °C. Neuronally-enriched cultures that were heat stressed at 42.5 °C exhibited less  $^{45}\text{Ca}^{2+}$  influx and neuronal death after a subsequent 10 min exposure to glutamate (10-1000  $\mu\text{M}$ ) in low chloride media, than control cultures. These data confirm earlier work suggesting that heat stress can reduce neuronal vulnerability to excitotoxicity, but raise the possibility that this neuroprotection need not be due to hsp70 induction.

Supported by NIH grant NS 30337 (DWC).

## 622.8

EVEN SLOWLY-TRIGGERED EXCITOTOXIC NEURONAL DEATH OF CULTURED CORTICAL NEURONS OCCURS BY NECROSIS, NOT APOPTOSIS. D.W. Choi\*, J. Koh, J.A. DeMaro, H.S. Ying, M.F. Jacquin and B.J. Gwag. Dept. of Neurology and Center for the Study of Nervous System Injury, Washington Univ. School of Medicine, St. Louis, MO 63110.

We have previously reported that the rapidly-triggered death of cultured murine cortical neurons induced by brief intense exposure to NMDA or glutamate occurs by necrosis. Here we examined graded levels of slowly-triggered excitotoxic neuronal death induced by NMDA, AMPA, or kainate to determine whether it occurred by necrosis or apoptosis. As previously reported, exposure of murine cortical cell for 24 hours to 10-50  $\mu\text{M}$  concentrations of NMDA, AMPA, or kainate produced degeneration of neurons without glial death. Neuronal cell body swelling was evident after 2 hr of agonist exposure, associated at the electron microscope level with disruption of cytoplasmic membrane integrity and organelles, and nuclear chromatin condensation in a dispersed pattern. Death was not attenuated by cycloheximide, or the neurotrophic factors BDNF or IGF-I, agents that are effective in blocking several types of apoptosis neuronal death in the same cultures. However, agarose gel electrophoresis revealed some internucleosomal DNA fragmentation (ladders) appearing transiently 8 hr following excitotoxin exposure. Despite these transient DNA ladders (and acknowledging the somewhat vague boundaries of the necrosis and apoptosis categories), we view the above data in sum as most supportive of necrosis death.

Supported by NIH NINDS grant NS 30337 (DWC) and NIH DE0 7734 (MFJ).

## 622.10

TYROSINE KINASE INHIBITORS INDUCE NEURONAL APOPTOSIS, BUT ATTENUATE NMDA-MEDIATED NEUROTOXICITY IN CORTICAL CELL CULTURES. M.M. Behrens\*, B.J. Gwag, J. Koh and D.W. Choi. Dept. of Neurology and Center for the Study of Nervous System Injury, Washington Univ. School of Medicine, St. Louis, MO 63110.

Protein tyrosine kinase (PTK) inhibitors, genistein or lavendustin A, produced a concentration-dependent, slowly evolving neuronal death in cortical cell cultures containing both neurons and glia. This neuronal death was associated with cell body shrinkage and attenuated by cycloheximide, consistent with apoptosis. Cotreatment with 100  $\mu\text{M}$  vanadate, a phosphotyrosine phosphatase inhibitor, substantially reversed the neuronal death induced by genistein or lavendustin A. In contrast, vanadate did not attenuate apoptosis induced by staurosporine (a nonspecific protein kinase inhibitor; 100 nM) or GF 109203X (a selective PKC inhibitor; 15  $\mu\text{M}$ ).

Since several studies have implicated protein kinases as downstream mediators of excitotoxicity, we performed additional experiments to see if inhibitors of PTK or PKC would block excitotoxicity in the same cultures. Indeed, the  $^{45}\text{Ca}^{2+}$  accumulation or the excitotoxic neuronal necrosis induced by exposure to 10 - 30  $\mu\text{M}$  NMDA for 24 hr was attenuated by cotreatment with 10  $\mu\text{M}$  lavendustin A or 100  $\mu\text{M}$  genistein; slowly-triggered AMPA or kainate toxicity was not reduced. Although cycloheximide itself did not reduce neuronal death following NMDA exposures, the combination of cycloheximide together with a tyrosine kinase inhibitor almost completely blocked NMDA induced neuronal death. Vanadate reversed the protective effect of PTK inhibitors against NMDA neurotoxicity. These data suggest that tyrosine kinase activity may be a two-edged sword relative to neuronal cell death: needed to suppress apoptosis, but capable of promoting NMDA receptor-mediated excitotoxic necrosis. Supported by NIH grant NS 30337 (DWC); MMB was a recipient of a fellowship from the Spanish Ministry of Science and Education

## 622.12

IN SITU NICK TRANSLATION DEMONSTRATES WIDESPREAD DNA FRAGMENTATION IN RAT BRAIN AFTER KAINIC ACID-INDUCED STATUS EPILEPTICUS. L.S. Dure IV\*, M.G. Kautzman, and A.J. Newman. Neurobiology Research Center, University of Alabama at Birmingham, Birmingham, AL 35294-0021.

Kainic acid (KA), a rigid analog of glutamate, is a potent neurotoxin which produces a syndrome of limbic status epilepticus after systemic administration in the rat. Previous studies have revealed significant losses of CA3 and CA1 pyramidal neurons after KA exposure, with concomitant neuropathology in the amygdala, midline thalamus, and septal regions. To elucidate the anatomical distribution of KA-induced neuronal loss, we utilized the method of *in situ* nick translation to incorporate biotinylated dUTP into fragmented DNA in rat brain after limbic status epilepticus. A time course of labeling was also performed to examine the temporal distribution of DNA fragmentation. Our results indicate that DNA fragmentation does not appear before 12 hours post-KA, and the earliest regions to demonstrate DNA fragmentation were the amygdala and midline thalamic nuclei. By 24 hours, CA1 pyramidal neurons were strongly labeled, and labeling persisted for some days after KA administration. Anatomic distribution of DNA fragmentation was compared to regions of neuronal loss as determined by silver impregnation and found to be correspondent. *In situ* nick translation is an extremely sensitive marker for DNA fragmentation, and is a powerful tool for assessing the extent of neuronal loss after excitotoxic lesions.

## 622.13

GLUTAMATE AND DOMOATE EXCITOTOXICITY IN CULTURED RAT CEREBELLAR GRANULE NEURONS IS COMPOSED OF ACUTE OSMOTICALLY MEDIATED AND DELAYED NEURODEGENERATIVE COMPONENTS. F.W. Berman, P.H. Franklin\* and T.F. Murray, College of Pharmacy and Toxicology Program, Oregon State University, Corvallis, OR 97331

The effect of osmotically mediated neuronal swelling on the acute and delayed neurotoxicity induced by excitatory amino acids *in vitro* was assessed in cerebellar granule neurons. Neurons were exposed to glutamate (300  $\mu$ M) or domoate (10  $\mu$ M) for two hours in physiologic buffer at 22°C followed by a 22hr incubation in conditioned growth media at 37°C. Excitotoxicity was monitored at several timepoints by analysis of lactate dehydrogenase (LDH) activity in the exposure buffer and conditioned media. Under these conditions, 50% and 65% of the 24hr LDH efflux was produced after 2hrs by glutamate and domoate, respectively. This acute toxicity was completely prevented by the presence of 100mM sucrose, indicating that osmotic swelling contributed significantly to neuronal injury induced by these neurotoxins. Subsequent delayed neurodegeneration however, was not affected by the hyperosmolar medium. The competitive NMDA receptor antagonist D-AP5 reduced total LDH efflux by 75% and 70%, whereas the non-NMDA receptor antagonist NBQX reduced total LDH efflux by 25% and 100% for glutamate and domoate, respectively. The acute osmotically mediated LDH efflux appeared to be due primarily to NMDA receptor activation. These results suggest that glutamate toxicity is mediated primarily by activation of NMDA receptors, however stimulation of non-NMDA receptors by glutamate produces significant toxicity in the presence of an NMDA receptor antagonist. Although domoate toxicity is mediated by activation of non-NMDA receptors, domoate-induced release of glutamate and subsequent activation of NMDA receptors underlies the majority of domoate-induced LDH efflux.

A COMPARISON OF THE NEUROTOXIC EFFECTS OF DIFFERENT EXCITOTOXINS IN THE RAT LATERODORSAL TEGMENTAL NUCLEUS. W.L. Inglis\* and K. Semba, Department of Anatomy and Neurobiology, Faculty of Medicine, Dalhousie University, Halifax, Nova Scotia, Canada B3H 4H7.

Excitotoxins are valuable tools in neuroscience research as they can help us to discover the extent to which certain neurons are necessary for different types of behavior. They have distinctive neurotoxic effects depending on where they are infused: for instance, AMPA is able to make relatively selective lesions of basal forebrain cholinergic neurons (Robbins *et al.*, Neuroscience 28: 337), but has indiscriminate effects in the pedunculopontine tegmental nucleus (PPTg) where quinolinate is fairly selective under certain anaesthetic conditions (Rugg *et al.*, Brain Res. 589: 181; Inglis *et al.*, Neurosci. Lett. 156: 78). This study was conducted to determine whether the neurotoxic profile of excitotoxins in the laterodorsal tegmental nucleus (LDTg) is similar to that which has been described in the PPTg. Two 0.1  $\mu$ l infusions of 0.1 M ibotenate, 0.1 M quinolinate, 0.04-0.1 M NMDA, or 0.05-0.015 M AMPA, were made unilaterally into the LDTg in 48 rats (300-320 g) under either pentobarbitone or Avertin anaesthesia. Co-ordinates were AP +0.1 IAL, ML  $\pm$ 3.2, DV -5.8 SkS and AP -0.4 IAL, ML  $\pm$ 3.6, DV -6.4 SkS with the injection needle oriented at an angle of 24° in the ML plane. After 23-27 days, sections through the mesopontine tegmentum were processed using standard histochemical procedures for ChAT, NADPH diaphorase, TH and Nissl substance. Lesions were assessed by the size of the damaged area (identified by reactive gliosis) and degree of cholinergic and other cell loss. Ibotenate induced compact lesions in the LDTg (80-90% cholinergic loss) but did not affect locus coeruleus. Quinolinate and low doses of AMPA and NMDA made very small lesions (<20% cholinergic loss), while at higher doses AMPA and NMDA had destructive effects over very large areas but killed only some of the neurons within this. These data are consistent with neurotoxic effects of the same excitotoxins which have been previously documented for the PPTg. Supported by The Wellcome Trust (038117/93) and the MRC of Canada (MT-11312).

## 622.17

HIGH CONCENTRATIONS OF GLYCINE CAUSE NEUROTOXICITY IN RAT HIPPOCAMPAL SLICE CULTURES BY ACTIVATION OF NMDA RECEPTORS. A. Barth, D.W. Newell\*, T.N. Ricciardi, A.T. Malouf, Dept. of Neurological Surgery, Sch. of Med., Univ. of Washington, Seattle, WA 98195

Glycine can act both as an inhibitory neurotransmitter and as a modulator of the NMDA receptor. Glycine (3-4 mM) induced neurotoxicity in hippocampal slice cultures. CA1 pyramidal neurons were significantly more susceptible to glycine toxicity than CA3 pyramidal neurons and dentate granule cells. All subregions of the hippocampus were equally damaged by 10 mM glycine. Glycine neurotoxicity developed within minutes after administration and was complete after 5-6 hours. Intracellular recordings from CA1 pyramidal neurons showed that 10 mM glycine initially produced an 11 mV hyperpolarization followed by repolarization and tonic spiking (n=6). Large depolarizations and sustained bursts of action potentials were observed in 2/6 cultures. Glycine abolished all synaptic transmission after 5 to 20 min. Neuronal damage and increased excitability caused by 10 mM glycine were completely blocked by 10  $\mu$ M MK-801 or 100  $\mu$ M D-APV. DNQX (100  $\mu$ M) provided significantly less protection than the NMDA antagonists. These results demonstrate that high concentrations of glycine are neurotoxic and that glycine-induced neurotoxicity is mediated by activation of NMDA receptors. Supported by: NIH Grants 1P50NS30305-1 (DWN,ATM), NS28650 (ATM), Ciba-Geigy-Jubilee-Foundation (AB), CIDA IK08NS01596901 (DWN), and T32NS-07144-15 (TNR).

## 622.14

Differential Effects of Kainic Acid at The Caudal and Rostral Ventrolateral Medulla. R.M. Douglas\*, C.O. Trouth, L.M. Sexcius, E.T. Anderson, T. Cofield, and P. Khansari, Dept. of Physiol. and Biophysics, Coll. Med., Howard University, Washington, D. C. 20059.

The caudal (CVLM)- and rostral (RVLM)-ventrolateral medulla are involved in cardio-respiratory regulation. In this investigation, kainic acid (KA) (1%; 47 mM) was applied to the CVLM and RVLM in spontaneously breathing, chloralose-urethane anesthetized rats. Extracellular medullary neuronal activity (MNA) and diaphragmatic electromyographic activity (DEA) were recorded. Unilateral KA application to the RVLM, near the retro-trapezoid nucleus, produces a transient decrease in MNA and DEA and a loss of CO<sub>2</sub> responsiveness- recovery occurring within 60 min. Bilateral application abolishes MNA and DEA. KA applied uni-laterally to CVLM evokes a dramatic transient increase in MNA and DEA followed by a decrease to extinction and irreversible apnea. The CVLM appears to exert a greater influence on the respiratory motor output within a hierarchy of brainstem chemosensory elements. Support: NIMH 5T32M19547 and ONR N00014-94-1-0523.

## 622.16

IMAGING CELL SWELLING & TOXICITY IN THE HIPPOCAMPAL SLICE PRODUCED BY DOMOIC ACID AND ANTAGONIZED BY GYKI 52466.

Trevor M. Polischuk\* and R. David Andrew, Department of Anatomy & Cell Biology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

Excitotoxic processes are implicated in many neurodegenerative disorders. Early excitotoxic events are characterized by an acute phase of cell swelling. Cell swelling alters intrinsic optical signals of brain slices such that changes in light transmittance ( $\Delta T/T$ ) correlate with changes in cell volume. We imaged the effects of domoic acid (DOM), a seafood contaminant and potent glutamate agonist, on light transmittance through the rat hippocampal slice. At 22°C, 1 min exposure to 10  $\mu$ M DOM elicited reversible changes in transmittance in CA1 dendritic regions. DOM maximally elevated  $\Delta T/T$  by 56 $\pm$ 2% in CA1 stratum radiatum (RAD), returning to baseline levels by 30 min (n=10). At 37°C, DOM elevated  $\Delta T/T$  by 58 $\pm$ 2% and rapidly reversed within 13 min (n=5). Prolonged exposure to 10  $\mu$ M DOM (10 min) at 37°C resulted in an irreversible transmittance change in CA1 RAD. A peak response of 57 $\pm$ 2% in CA1 RAD was followed by a latent and pronounced decrease in light transmittance (-34 $\pm$ 4%) which did not return to baseline levels (n=10). This irreversible "swell/shrink" phenomenon was regarded as an indicator of neuronal death. GYKI 52466 (100  $\mu$ M), a highly selective antagonist of AMPA/kainate receptor responses, reduced the peak response of 10  $\mu$ M DOM (1 min/22°C and 10 min/37°C) to 61% and 21 $\pm$ 3% respectively. Interestingly, GYKI blocked the irreversible "swell/shrink" event of the prolonged DOM exposure. Transmittance changes evoked by 10  $\mu$ M AMPA (1 min/22°C) were reduced from 53 $\pm$ 2% to 2 $\pm$ 1%. Reduction of [Cl<sup>-</sup>], completely blocked DOM-evoked changes in light transmittance from 56 $\pm$ 2% to 0 $\pm$ 2%. We conclude that exposure to DOM evokes Cl<sup>-</sup>-dependent dendritic swelling in the CA1 region mediated by AMPA receptors. Prolonged exposure at body temperature leads to irreversible damage to CA1 neurons. This response can be inhibited by hypothermia or specific glutamate antagonists and can be imaged in real time. Supported by the Canadian MRC

PERSISTENT DEPRESSION OF SYNAPTIC RESPONSES IN QUISQUALATE-SENSITIZED HIPPOCAMPAL SLICES AFTER EXPOSURE TO L-ASPARTATE- $\beta$ -HYDROXAMATE. J.F. Koerner and R.J. Roon\*, Department of Biochemistry, Medical School, University of Minnesota, Minneapolis, MN 55455.

Neurons of the rat hippocampal CA1 pathway are sensitized at least 100-fold to depolarization by certain phosphonate compounds after brief exposure to L-quisqualic acid (QUIS). Three classes of compounds with distinct modes of action interact with this system: the prototypic agonist for sensitization, QUIS; phosphonate compounds such as L-AP4, L-AP5 and L-AP6, to which neurons become sensitized; and compounds such as L- $\alpha$ -aminoadipic acid ( $\alpha$ AA) which pre-block or reverse sensitization. The phosphonates appear to act at extracellular receptors to induce neuronal depolarization, and their effects are rapidly reversed by washout. We now report a novel class of compounds which behave in a similar manner to the phosphonates except that their effects persist after washout. Exposure of QUIS-sensitized slices to 400  $\mu$ M L-aspartate- $\beta$ -hydroxamate for eight minutes results in complete depression of extracellular synaptic field potentials. This depression persists for at least one hour after washout. Complete restoration of the field potentials can be achieved by a 10 minute application of the reverser  $\alpha$ AA, suggesting that there is some mechanistic commonality between the effect of phosphonates and L-aspartate- $\beta$ -hydroxamate. L-Glutamate- $\gamma$ -hydroxamate, D-aspartate- $\beta$ -hydroxamate, and L-AP3 exhibit similar but weaker depressive activity. (Supported by NIH NS 17944).

## 622.19

QUISQUALATE SENSITIZATION AS A PUTATIVE EARLY STEP FOR QUISQUALATE NEUROTOXICITY OF HIPPOCAMPAL CA1 PYRAMIDAL NEURONS. L.A. Chase\*, B. Rupert, R.J. Roon and J.F. Koerner. Department of Biochemistry, Medical School, University of Minnesota, Minneapolis, MN 55455.

L-Quisqualic acid (QUIS) sensitizes hippocampal pyramidal cells to depolarization by phosphonates.<sup>1</sup> Sensitization involves uptake of QUIS into a subset of hippocampal interneurons<sup>2,3</sup> and subsequent release of QUIS or an endogenous excitatory amino acid which acts postsynaptically as both an NMDA and a non-NMDA receptor agonist.<sup>4</sup> Pharmacological similarities of QUIS sensitization in hippocampal slices and of QUIS toxicity on cultured pyramidal cells<sup>5,6</sup> suggest that the mechanism which mediates QUIS sensitization also initiates QUIS neurotoxicity. As is true for QUIS-mediated neurotoxicity,<sup>5</sup> we observed sensitization to occur in low Ca<sup>2+</sup> (0.5 mM) medium and in medium in which Na<sup>+</sup> was replaced by choline. Sensitization also occurred in the presence of L-trans-pyrrolidine-2,4-dicarboxylic acid (1 mM). This suggests that synaptic function and concentrative Na<sup>+</sup>-dependent uptake of QUIS may not be required for sensitization. Addition of 0.5 mM Cd<sup>2+</sup> blocks L- and N-type Ca<sup>2+</sup> channels and inhibits orthodromic field potentials, but QUIS sensitization is observed antidromically. CNQX prevents QUIS toxicity when maintained in the culture medium after QUIS exposure.<sup>6</sup> Antidromic recording demonstrated that CNQX prevents depolarization by phosphonates in QUIS-sensitized slices. This supports previous intracellular observations with organotypic slice cultures. (Support: NIH NS 17944).

## EXCITATORY AMINO ACID RECEPTORS XII

## 623.1

ATTENUATION OF MK-801-INDUCED LEARNING IMPAIRMENT BY THE NEUROSTEROID DHEAS: IMPLICATION OF  $\sigma_1$  RECEPTORS.

T. Maurice<sup>1</sup>, J.-L. Junien<sup>2</sup> and A. Privat<sup>1</sup>.

<sup>1</sup>INSERM U. 336, E.N.S.C.M., 34053 Montpellier Cedex 1, France; <sup>2</sup>Neuroscience Division, Douglas Hospital Research Centre, Verdun H4H 1R3, Québec, Canada.

We previously reported that high affinity  $\sigma_1$  ligands attenuate the learning impairment induced in mice by MK-801, a non-competitive N-methyl-D-aspartate (NMDA) antagonist, in a similar manner as they modulate several NMDA-evoked responses in vitro and in vivo in rats. Neurosteroids, such as pregnenolone sulfate, progesterone and dehydroepiandrosterone sulfate (DHEAS), modulate some NMDA-evoked responses. Furthermore, some of them were reported to interact with  $\sigma$  receptors. We thus investigated whether DHEAS, a neurosteroid with memory enhancing effects, attenuates the MK-801-induced learning impairment in mice and, if so, by a mechanism involving  $\sigma_1$  receptors. Behavioural tests included spontaneous alternation behaviour in the Y-maze, for spatial working memory, and step-down passive avoidance, for long-term memory. DHEAS (5-20 mg/kg sc) dose-dependently and significantly attenuated the impairment of alternation and decrease in step-down latency induced by MK-801 (0.15 mg/kg ip). These effects were suppressed by the simultaneous administration of the  $\sigma_1$  antagonist BMY-14802 (5 mg/kg ip), and significantly reduced in mice sub-chronically treated with haloperidol (4 mg/kg/day sc for 7 days), a treatment down-regulating the  $\sigma_1$  receptors. Furthermore, at the same dose range, DHEAS significantly decreased the in vivo [<sup>3</sup>H]SKF-10,047 binding to  $\sigma$  receptors in the mouse cortex and hippocampus. These results confirm that neurosteroids, such as DHEAS, are positive modulator of the NMDA receptor activation, and modulate the NMDA dependent learning processes. This effect appears to be mediated through an interaction with  $\sigma_1$  receptors.

## 623.3

BIOCHEMICAL AND BEHAVIORAL ACTIONS OF INHIBITORS OF KYNURENINE-HYDROXYLASE AND/OR KYNURENINASE. A. Chiarugi, R. Carpenedo and F. Moroni\*. Department of Preclinical and Clinical Pharmacology, University of Florence, Viale Morgagni 65, 50134 Florence, Italy.

Kynurenic acid (KYNA), an endogenous antagonist of the glutamate receptors, is synthesized from kynurenine (KYN) by the enzyme kynurenine-aminotransferase. KYN is also a substrate of the enzymes kynurenine hydroxylase, which catalyzes the formation of 3-OH-KYN, and kynureninase, which metabolizes both KYN and 3OH-KYN into anthranilic acid (ANA) and 3-OH-ANA, respectively. Further metabolism of these molecules may lead to quinolinic acid, an endogenous NMDA agonist and an excitotoxin. In order to switch KYN metabolism toward KYNA formation, we previously studied several inhibitors of kynurenine hydroxylase and kynureninase (*Neuroscience* 61: 237, 1994; *J. Neurochem.*, in press). We report now the effects of systemic administration of *m*-nitrobenzoylalanine (*m*NBA, an inhibitor of kynurenine hydroxylase) and of *o*-methoxybenzoylalanine (*o*MBA, an inhibitor of kynureninase) on the content of KYNA, 3-OH-KYN, ANA, 3-OH-ANA in brain and blood of mice treated with KYN (0.3 mmol/kg i.p.). Both *m*NBA (200-400 mg/kg i.p.) and *o*MBA (400-800 mg/kg i.p.) increased the concentration of KYNA in brain and blood, but *m*NBA was more potent than *o*MBA, thus confirming that the hydroxylation is the main pathway of KYN metabolism in mice. As expected, *m*NBA decreased the content of 3-OH-KYN in the brain and periphery, while *o*MBA increased the content of this potentially toxic metabolite. Interestingly, while *m*NBA decreased brain content of 3-OH-ANA, *o*MBA did not change the brain content of this metabolite, thus suggesting that *o*MBA inhibits kynureninase when the substrate is KYN but does not affect the metabolism of 3OH-KYN. This observation was confirmed in *in vitro* experiments. Finally, the increased synthesis of KYNA obtained by inhibiting KYN metabolism was associated with behavioral effects such as sedation and antagonism of amphetamine actions, compatible with the expected functional antagonism of excitatory amino acid receptors.

## 623.2

CO-ADMINISTRATION OF MONOSODIUM GLUTAMATE (MSG) AND MONOSODIUM ASPARTATE (MSA) FOLLOWING PRETREATMENT WITH MK-801 HYDROGEN MALEATE IN PRE-WEANLING RATS. T. Bambrick and M. Saari\*. Neuroscience Research Unit, Nipissing University, 100 College Dr., North Bay, Ontario, Canada, P1B 8L7.

Neonatal male rat pups were randomly allocated to eight treatment groups in a 2 X 2 X 2 factorial design. Half of the rats were injected with either MK-801 or saline (SAL) on postnatal day (PND) 4. Two hours following the initial injection the rats in each group were injected with either MSG (4g/kg; sc.) or SAL and MSA (2g/kg; sc.) or SAL. Following weaning at PND 25 the rats were housed in standard individual Nalgene cages in reversed light, controlled humidity and temperature until PND 62. Behavioral testing in the water maze commenced on PND 63. The rats were sacrificed on PND 72, carcasses dissected and organ weights taken. The experiment was replicated in a smaller study without MK-801 pretreatment. Analysis of the water maze data revealed the expected main effects as well as an unexpected MSG X MSA interaction. A similar pattern of results was found in both the body weight and organ weight data. Maximal MK-801 "protective" effects were observed in the groups receiving both MSG and MSA.

## 623.4

EFFECTS OF SYSTEMIC MK-801 ADMINISTRATION ON THE EXPRESSION OF GLUTAMINE SYNTHETASE mRNA. T. Kakigi\*, R. Kamidate, M. Hatakoshi, Y. Yamamoto, M. Yasuda, K. Maeda and C. Tanaka. Neuropharmacology Lab., Dept. of Neuroscience, Hyogo Institute for Aging Brain and Cognitive Disorders, 520 Saisho-ko, Himeji 670, Japan.

Glutamine synthetase (GS), which is specifically located in astrocytes, but not in neurons, convert synaptic glutamate to glutamine. Glutamine is then sent back to the pre-synaptic neuron for conversion to glutamate. This is one of the protective mechanisms to remove highly excitatory glutamate from the synapse. MK-801 is one of the dissociative anesthetics and acts by interacting with a so-called PCP receptor in the ion channel as potent non-competitive antagonist of the NMDA receptor. In this study, to investigate the effect of MK-801 on the elimination mechanism of glutamate, we measured the levels of GS mRNA in rat brain after subcutaneous injection of MK-801 (1.0mg/kg) at 4 time points (0 hour before injection and 1, 4 and 10 hour after injection). *In situ* hybridization technique using <sup>35</sup>S-dATP labeled oligodeoxynucleotide probe was used to determine the GS mRNA levels. Densities of the interested regions were measured by BAS2000 image analyzing system. Results were shown as % of value of 0 time point and statistically analyzed by ANOVA. Results were as follows: density of dorsolateral frontal cortex was significantly reduced (13.8% reduction compared to the value of 0 time point) after 1 hour, significantly elevated in hippocampus (21.4% increase), amygdala (20.4% increase), piriform cortex (18.6% increase) after 10 hour and had no changes after 4 hour of injection. Results showed that non-competitive NMDA receptor antagonist, MK-801, altered the expression of GS mRNA and suggests the alteration of the elimination system of the transmitter glutamate.

## 623.5

UNCOMPETITIVE NMDA RECEPTOR ANTAGONISTS (MK-801 AND MEMANTINE) IMPAIR OR ENHANCE LEARNING DEPENDING ON DOSE AND EXPERIMENTAL DESIGN - COMPARISON WITH EFFECTS ON LTP *IN VITRO*. C.G. Parsons<sup>1</sup>, G.L. Collingridge<sup>2</sup>, B. Potier<sup>2</sup>, T. Frankiewicz<sup>1</sup>, W. Zajackowski<sup>1</sup>, M. Misztal<sup>1</sup> and W. Danysz<sup>2\*</sup>. Dept. Pharmacol., Merz + Co, 60318 Frankfurt / Main, Germany<sup>1</sup>, Dept. Anatomy, The Medical School, Bristol BS8 1TD, England<sup>2</sup>.

It is accepted that NMDA receptor antagonists inhibit learning and LTP. In a dark avoidance task uncompetitive NMDA receptor antagonists (+)-MK-801 and memantine impaired learning but starting at relatively high doses (0.2 and 20 mg/kg respectively) leading to serum (and predicted CSF) concentrations far above the respective IC<sub>50</sub>s for NMDA receptor antagonism (patch clamp studies). Similarly, relatively high concentrations of (+)-MK-801 and memantine were required to inhibit LTP in CA1 of hippocampal slices (threshold 0.1 and 10 μM respectively). To maintain *in vivo* steady-state concentrations close to the IC<sub>50</sub>s assessed in patch clamp studies, these antagonists were infused s.c. for two weeks by osmotic minipumps. Infusion of memantine (20 mg/kg/day) failed to change LTP *ex vivo* or radial maze learning (4/8 design) but in the same test improved reference memory in rats with lesions of the entorhinal cortex (EC). In contrast, (+)-MK-801 (0.31 mg/kg/day) impaired reference memory in naive rats and failed to improve it in rats with EC lesions. It has been suggested (Jones et al. *Pharmacol. Biochem. Behav.* (1989) 34:181) that direct tonic, i.e. non-temporal, activation of NMDA receptors - in contrast to learning - may lead to an increase in synaptic "noise" and in turn to a loss of association detection. In fact, we also observed disruption of dark avoidance learning by NMDA (25 mg/kg) that was not related to toxic effects. NMDA-induced amnesia was antagonised by (+)-MK-801 and memantine at low doses of 0.05 and 2.5 mg/kg respectively. Thus, under some conditions NMDA receptor antagonists can paradoxically enhance learning, and this effect may be related to a restoration of signal to noise ratio following tonic activation of NMDA receptors.

## 623.7

NEUROPROTECTION FROM NMDA WITHIN THE NUCLEUS BASALIS MAGNOCELLULARIS. G.L. Wenk\*, W. Danysz, M.K. Chawla, N.E. Rance. Division of Neural Systems, Memory & Aging and Dept. of Pathology, Univ. of Arizona, Tucson, AZ 85724, and Dept. of Pharmacol., Merz + Co. GmbH & Co., Frankfurt, Germany.

The activation of glutamate receptors has been implicated in the processes that underlie the development of some neurodegenerative diseases. The antagonism of N-methyl-D-aspartate (NMDA)-sensitive glutamate receptors may therefore have therapeutic applications. The present study compared the neuroprotective potency of MK-801, memantine, amantadine, and the tachykinin Neurokinin B (NKB), against NMDA injected directly into the nucleus basalis magnocellularis of rats. Each drug significantly attenuated the loss of nucleus basalis magnocellularis cholinergic cells. The ED<sub>50</sub>s were respectively 0.077, 2.81 and 43.5 mg/kg for (+)-MK-801, memantine and amantadine, giving a relative potency ratio of 1:36:565. The results indicate a potential neuroprotective action of these noncompetitive NMDA receptor antagonists. In the case of memantine and amantadine, ED<sub>50</sub>s are expected to lead to serum levels close to a therapeutic range. When NKB was co-injected with NMDA, it attenuated cholinergic cell loss by 67%, as compared to rats that were co-injected with saline. The neuroprotective actions of the NKB are potentially important inasmuch as a significant proportion of basal forebrain cholinergic cells in humans also contain this tachykinin. NIA R01 AG10546 & Merz+Co.

## 623.9

IRREVERSIBLE INHIBITION OF <sup>3</sup>H-KAINATE BINDING BY A PHOTOACTIVATED KAINATE ANALOGUE. R.D. Bartlett\*, D. Wacker, C. Willis, A.R. Chamberlain, R.J. Bridges. Dept. of Pharm. Sci. Univ. of Montana, Missoula, MT 59812 and Dept. of Chem. Univ. of California, Irvine CA 92717

In the present study we examine the binding properties of trifluoromethyl-diazokainate (DKA), a putative photoaffinity label for the high-affinity kainate class of EAA receptors. Synaptic plasma membranes (SPMs) were prepared from the forebrains of male Sprague-Dawley rats and assayed for <sup>3</sup>H-kainate (KA), <sup>3</sup>H-AMPA, and NMDA sensitive <sup>3</sup>H-L-glutamate binding. As a competitive inhibitor (in the absence of UV irradiation) DKA preferentially blocked high-affinity <sup>3</sup>H-KA binding (IC<sub>50</sub> = 1 μM). At higher concentrations of DKA, some cross reactivity was observed with the AMPA and NMDA sites. For example, inclusion of 100 μM DKA reduced control levels of binding to the kainate, AMPA, and NMDA sites by 98%, 46%, and 38%, respectively. Irreversible inactivation of the binding sites was examined by exposing SPMs to UV irradiation in the presence of DKA, reisolating the SPMs to remove unbound DKA, and then assaying for radioligand binding. Incubation of the SPMs with 50 μM DKA in the presence of UV resulted in the irreversible loss of about 40% of the high-affinity KA sites. Control experiments demonstrated that neither UV nor DKA alone significantly reduced <sup>3</sup>H-kainate binding. The irreversible loss of the binding sites was considerably more selective for the kainate sites than would have been predicted from the initial binding studies. Thus, 250 μM DKA in the presence of UV led to an irreversible loss of only 25% of the NMDA sensitive glutamate sites and an insignificant amount of AMPA sites. Consistent with the action of DKA at the kainate ligand binding site, the irreversible loss of the KA sites could be prevented by including an excessive level of L-glutamate (250 μM). These results identify DKA as a useful tool in studying-structure function relationships of KA receptors. This work was supported in part by NIH NS27600.

## 623.6

Ethanol effects on GLU/GLY stimulated changes in the intracellular concentration of magnesium. W. R. Wilson\*, K. S. Phillips and S. W. Leslie. College of Pharmacy, University of Texas, Austin, TX 78712.

It is well established that NMDA-stimulated increases in intracellular calcium are sensitive to inhibition by physiologically relevant concentrations of ethanol; however, the mechanism of ethanol inhibition is still unknown. NMDA-like (GLU/GLY) stimulated increases in intracellular magnesium have also been reported. The effects of ethanol on this response have not yet been examined.

Acutely dissociated neurons isolated from day old rat pups and loaded with the magnesium sensitive fluorescent probe, fura-2, demonstrated GLU/GLY-stimulated increases in intracellular magnesium that were independent of the presence of magnesium in the extracellular buffer. In the presence of 50mM ethanol the GLU/GLY-stimulated response was not significantly affected. Interestingly, ethanol alone caused an apparent dose-dependent increase in the intracellular concentration of magnesium.

These findings demonstrate that intracellular magnesium can be imaged in acutely dissociated neurons and NMDA-stimulated responses can be monitored. This GLU/GLY-stimulated response does not appear to display the expected inhibition by ethanol, but the effect of ethanol on the homeostasis of intracellular magnesium merits further attention. ## 623.8

Intrathecal NMDA evokes pain behavior and structural alteration of neurons that express the substance P receptor (SPR) via an action on SP-containing primary afferent terminals in the spinal cord dorsal horn. H. Liu\*, P.W. Mantyh and A.L. Basbaum. Depts. Anat. and Physiol. and W.M. Keck Fdn. Ctr. for Integrative Neurosci., UCSF, CA and Molec. Neurobiol. Lab., VA Med. Ctr. Minn, MN.

Intrathecal (i.t.) injection of SP or NMDA evokes a short-lived pain behavior. Since i.t. injection of SP, or noxious stimulation, also evokes profound internalization of the SPR and a structural reorganization of neurons that express the SPR and since the NMDA receptor is expressed on small diameter primary afferents we hypothesized that SP contributes to the NMDA-evoked effects. Our first study demonstrated that the duration of pain behavior produced by i.t. NMDA (6.8nM) was significantly reduced by prior injection of selective SPR antagonists (CP-99,994 and RP-67,580) or by neonatal injection of capsaicin, to destroy C-fibers. NMDA injection also resulted in extensive internalization of the SPR in neurons of lamina I. EM immunogold analysis revealed that in uninjected rats, approximately 73% of the SPR is associated with plasma membrane of neurons; within 5 minutes of NMDA injection, 85% of the SPR was internalized into cytoplasmic endosomes. NMDA also evoked dramatic structural reorganization of the dendrites that express the SPR. Within 5 minutes, 68% of SPR-immunoreactive dendrites in lamina I and in dorsally-directed dendrites of labelled neurons in lamina III became highly varicose. EM established that the varicosities (2.3-15 μm in diameter) were packed with SPR-immunoreactive endosomes; the intervacular segments (0.4-1.6 μm in diameter) contained little label. Within one hour of injection most of the SPR was recycled to the plasma membrane and the morphology of these neurons returned to normal. 24 hours later i.t. NMDA again evoked pain behavior and structural changes, indicating that its effects are reversible. I.t. injection of SPR antagonists, or neonatal capsaicin treatment, also significantly reduced these structural changes. We suggest that the effects of NMDA are in part mediated via an action on a presynaptic receptor located on SP-containing small diameter primary afferents. Supported by: NS 21445, 14627 and DA 08377.

THE TREATMENT OF CHRONIC NERVE INJURY PAIN WITH EXCITATORY AMINO ACID ANTAGONISTS AND A NITRIC OXIDE SYNTHASE INHIBITOR IN YOUNG, MATURE AND AGED MALE RATS. M.A. King\*, T. Gordon and T. Crisp. Departments of Pharmacology and Neurobiology, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272.

Unilateral ligation of the rat sciatic nerve is used as an animal model of neuropathic pain. Recent studies have shown that excitatory amino acid antagonists (EAA) and nitric oxide synthase (NOS) inhibitors reverse the behavioral hyperalgesic response to sciatic nerve ligation. These studies were designed to investigate: (1) the effects of aging on the thermal hyperalgesic response to sciatic nerve ligation; and (2) age-related differences in the spinal antinociceptive properties of EAA antagonists, (e.g., D-APV or MK-801) or a NOS inhibitor (L-NAME) administered intrathecally (i.t.). Male Fischer 344 rats (5-6 mos., 15-16 mos. and 25-26 mos.) were used in all experiments, and thermal hyperalgesia was measured using a Plantar Analgesic Meter. No age-related differences were observed in the ability of the sciatic nerve ligation surgery to induce hyperalgesia to a thermal stimulus in young, mature and aged rats. Additionally, D-APV, L-NAME and MK-801 reversed the thermal hyperalgesic response to sciatic nerve ligation in a dose-dependent manner.

## 623.11

## DIFFERENTIAL CHANGES IN GLUTAMATE RECEPTOR SUBUNITS WITHIN SPINAL MOTONEURONS AFTER PERIPHERAL NERVE INJURY.

J.C. Holstege\* and J.H.H. Kennis, Dept. of Anatomy, Erasmus University Medical School, P.O. Box 1738, 3000 DR Rotterdam, The Netherlands.

Immunoreactivity for the AMPA-type glutamate receptor subunits GluR1, GluR2/3 and GluR4 and the NMDA-type receptor subunit NMDAR1 was studied after sciatic nerve lesion or crush using 2, 6, 10, 14 and 20 days survival. For each survival time, 2 rats were operated: in one rat the sciatic nerve was cut on one side, with the other side as control, while in the other rat the sciatic nerve was cut on one side and crushed on the other side. The rats were perfused (4% paraformaldehyde), and the spinal cords processed for immunocytochemistry using antibodies against the GluR1, GluR2/3, GluR4 (Chemicon) and NMDAR1 (Pharmagen) receptor subunits.

In the L3-S1 spinal segments, immunoreactivity in the motoneurons of the sciatic nerve was assessed. In all animals GluR1 labeling was weak and variable without differences between axotomized, crushed and control motoneurons. GluR2/3 labeling was strong and consistent on the control side. However, axotomized motoneurons showed a strong decrease in immunoreactivity, starting at 2 days. After 6, 10, 14 and 20 days GluR2/3 labeling was very low, while femoral nerve motoneurons in the same ventral horn, showed strong immunoreactivity like the control side. Motoneurons with crushed axons also showed a decrease in immunoreactivity, which was most apparent after 6 days, increasing again after 10 days survival. In all animals GluR4 labeling of motoneurons was strong and consistent without differences between axotomized, crushed and control motoneurons. NMDAR1 labeling was weak but consistent in the sciatic motoneurons, without significant differences between axotomized, crushed and control motoneurons.

It is concluded that after peripheral axotomy, motoneurons show a strong decrease in the expression of GluR2 and 3 subunits, while GluR1, GluR4 and NMDAR1 remain unchanged. After nerve crush, GluR2 and 3 subunit expression also decreased but may return to normal. Thus after axotomy AMPA receptors may be assembled without the GluR2 subunit. As a result, these AMPA receptors may be calcium permeable.

## GABA RECEPTORS IV

## 624.1

GENOMIC REGULATION OF A PROMOTER FOR THE HUMAN GABA<sub>A</sub> RECEPTOR  $\alpha 1$  SUBUNIT GENE. M. D. Leach\* and D. H. Farb, Laboratory of Molecular Neurobiology, Department of Pharmacology, Boston University School of Medicine, Boston MA 02118.

The regulation of GABA<sub>A</sub> R subunit gene expression is of great interest as there are 17 distinct subunit genes that have distinct patterns of expression within the CNS as determined by *in situ* hybridization. The mechanisms that lead to the precise expression of the GABA<sub>A</sub> R subunit genes are unknown. We have reported previously that the immediate 5'-flanking region of the human GABA<sub>A</sub> R  $\alpha 1$  subunit gene contains an active promoter as measured by transiently transfecting luciferase reporter constructs into primary embryonic cell cultures. Here, we report that the 5'-flanking region of the human  $\alpha 1$  subunit gene confers tissue-specific gene expression. The transcriptional start sites have been identified by primer extension analysis. To map the minimal core promoter, we made a series of 5'-deletion constructs. Results show that the minimal core promoter is located within the immediate 5'-flanking region. A similar deletion strategy was used to identify the region involved in transcriptional initiation, demonstrating that a 76 bp region is important for transcriptional activation. Interestingly, comparison of our results with those of Bateson *et al.* (Gene (1995) 153:243-47) show that the 5'-flanking region for the human and chick  $\alpha 1$  subunit genes exhibit a high degree of sequence similarity. Finally, we have examined regulation of the  $\alpha 1$  promoter by GABA, demonstrating the existence of autologous regulation of the  $\alpha 1$  promoter by GABA<sub>A</sub> R activation.

## 624.2

REGULATORY ELEMENTS IN THE  $\beta 2$  GABA<sub>A</sub> RECEPTOR GENE. H.Y. Kim and A.J. Tobin\*.

Departments of Physiological Science and Neurology, Brain Research Institute and Molecular Biology Institute, University of California, Los Angeles, CA 90095. The predominant form of GABA<sub>A</sub> receptors in the adult rat brain contains  $\alpha 1$ ,  $\beta 2$ , and  $\gamma 2$  subunits. We have isolated and characterized the rat  $\beta 2$  gene promoter. Sequence analysis revealed several regulatory sequence elements, which include: (1) multiple TATA elements; (2) a CAAT box element; (3) a Neuron-Restrictive Sequence Element; (4) Zif268 protein binding site; (5) multiple AP-1 and SP-1 sites; (6) and a cAMP responsive element. Functional analysis from transient transfection assays of  $\beta 2$  promoter reporter constructs revealed at least three separate functional promoter domains: (A) a region containing the "minimal"  $\beta 2$  promoter; (B) an activation domain; (C) and a silencer domain. Within domain B, a stretch of alternating G and T residues is important for maximal expression of the  $\beta 2$  subunit gene. Gel mobility shift assays suggest that the (GT)<sub>n</sub> sequence enhances transcription by interacting with sequence-specific DNA-binding proteins. A (GT)<sub>n</sub>-binding factor is present in extracts from several different cell lines, as well as in an extract from neonatal rat cerebella. Together, our data suggest that expression of the  $\beta 2$  GABA<sub>A</sub> receptor gene depends upon the concerted efforts of multiple regulatory elements.

## 624.3

REGIONAL CHANGES IN GABA<sub>A</sub> RECEPTOR (GABA<sub>A</sub>)  $\alpha_1$  SUBUNIT PROTEIN IN FLURAZEPAM (FZP) TOLERANT RATS: IMMUNOCYTOCHEMICAL DETECTION USING COMPUTER-ASSISTED IMAGE ANALYSIS. X.G. Huang\*, S. Chen, W. Sieghart\* and E.L. Tietz, Dept. of Pharmacology, Med. Coll. of Ohio, Toledo, OH 43699 and Dept. of Biochem. Psychiatry, Univ. Clinic of Psychiatry, A-1090 Vienna, Austria.

Changes in GABA<sub>A</sub>  $\alpha_1$  subunit protein were examined in FZP-treated rats using immunocytochemical methods on thin brain sections. Several approaches were first used to assess the reliability and sensitivity of computer-assisted densitometry as a quantitative method to detect regional changes in antigen concentration as a function of immunohistochemical staining intensity. First, a model system was designed to mimic variations in antigen concentration in post-fixed, slide-mounted sections by varying the ratios of conjugated (biotinylated) to unconjugated 2° antibody (Ab). Antigen concentration was also varied in tissue discs made from rat brain homogenates with increasing amounts of tissue embedding compound. The monoclonal Ab to the GABA<sub>A</sub>  $\beta_{2/3}$  subunit was used as the 1° Ab in these studies. Immunostaining was visualized with diaminobenzidine and staining density was measured over images acquired with NIH Image software. A significant, positive linear relationship ( $r = .97-.99$ ) was found between immunostaining intensity and antigen concentration. Using this approach changes in antigen of  $< 20\%$  were detectable. Since  $\alpha_1$  subunit mRNA is decreased in the CA1 region of hippocampus and cortex after chronic benzodiazepine treatment, this method was then used to analyze changes in GABA<sub>A</sub>  $\alpha_1$  subunit protein in 10  $\mu$ M sections from 1 week FZP-treated and control rats using a polyclonal Ab to the  $\alpha_1$  subunit (Sieghart *et al.*). A significant decrease in  $\alpha_1$  staining was detected between groups ( $p = .004$ ). Individual comparisons showed reductions ( $p < .01-.03$ ) in stratum oriens (26%), radiatum (21%) and lacunosum (35%) of CA1, as well as layer IV (28%) and V (30%) of cortex. The regional changes in  $\alpha_1$  subunit staining in chronic FZP-treated rat brain are consistent with the changes in mRNA detected previously and confirm the reliability and sensitivity of computer-assisted image analysis immunostaining as a quantitative technique for detecting changes in antigen content changes in brain tissue. R01-DA-04075 and RSDA K02-DA00180 to EIT.

## 624.4

## DECREASED AMPLITUDE AND FREQUENCY OF SPONTANEOUS IPSCS RECORDED IN HIPPOCAMPAL CA1 PYRAMIDAL NEURONS AFTER CHRONIC FLURAZEPAM (FZP) TREATMENT. Xu Zeng\* and E.L. Tietz, Department of Pharmacology, Medical College of Ohio, Toledo, OH 43699

Intracellular recording from CA1 neurons in *in vitro* hippocampal slices from chronic FZP-treated rats showed a reduction in the amplitude of GABA<sub>A</sub> and GABA<sub>B</sub>-mediated IPSPs evoked by direct stimulation of GABAergic interneurons. These findings implied that changes in both pre- and postsynaptic GABA function may contribute to reduced GABA inhibition benzodiazepine tolerant rats. The present experiment was designed to examine this possibility by recording spontaneous IPSCs in hippocampal slices (500  $\mu$ M) from rats sacrificed 2 days after FZP treatment (100 mg/kg X 3 days; 150 mg/kg X 4 days, p.o. in .02% saccharin H<sub>2</sub>O). Control rats received saccharin H<sub>2</sub>O. The experimenter was blind to rat's treatment histories. Spontaneous IPSCs were recorded in CA1 neurons using whole-cell patch clamp techniques ( $V_h = -70$  mV). Patch pipettes (6-10 M $\Omega$ ) filled with 135 mM CsCl (mM: 130 CsCl, 1.0 EGTA, 0.5 CaCl<sub>2</sub>, 2.0 MgCl<sub>2</sub>, 2.0 ATP, 10.0 HEPES, pH 7.2). Inward currents, recorded at -70 mV, were reversed at positive potentials ( $E_{Cl} = 0$  mV) and could be inhibited by 5  $\mu$ M bicuculline in a reversible manner. The amplitude and frequency of spontaneous events was analyzed from 2 min segments using Strathclyde software. Detection threshold was 10 pA. There was a significant difference between the FZP-treated and control groups in the cumulative relative frequency of sIPSC inter-event intervals ( $p = .02$ ) and amplitudes ( $p = .005$ ). A decrease in the frequency (1/inter-event interval) and amplitude of events suggests a decrease in pre- and postsynaptic GABA function, respectively, in the CA1 region of FZP tolerant rats. Support: R01-DA04075 and RSDA K02-DA00180.

## 624.5

TEMPORAL REGULATION OF GABA<sub>A</sub> RECEPTOR (GABAR) BINDING AND COUPLING IN FLURAZEPAM (FZP) TOLERANT RATS. S. Chen, A. Cox, and E. L. Tietz\*

Dept. of Pharmacology, Med. Coll. of Ohio, Toledo OH 43699. GABA-mediated IPSCs are decreased in the CA1 region of hippocampus (HIP). Our recent *in situ* hybridization studies in FZP tolerant rats revealed discrete changes in the regulation of GABAR subunit mRNAs. The  $\alpha_1$  and  $\beta_1$ , but not the  $\alpha_2$ ,  $\alpha_3$  or  $\gamma_2$  subunits were decreased in CA1 region and cortex (CTX) immediately (0 days) and 2, but not 7 days after FZP treatment, coinciding with recovery of anticonvulsant tolerance *in vivo*. These findings prompted the systematic re-examination of BZ and GABA binding and coupling, using autoradiographic techniques, at several time points after 1 week FZP treatment. Rats were treated with FZP (100 mg/3 days; 150 mg/kg X 4 days) in 0.02% saccharin H<sub>2</sub>O and sacrificed 0, 2 or 7 days after treatment. Sagittal brain sections (10  $\mu$ M) were cut from FZP-treated rats and their matched controls (n=8/group). As previously reported, [<sup>3</sup>H]flunitrazepam (1 nM FNP) binding was significantly decreased in all areas of HIP and CTX 0 days after FZP treatment. BZ/GABA coupling, measured by the ability of 1  $\mu$ M GABA to potentiate [<sup>3</sup>H]FNP binding, was decreased in FZP-treated rats in stratum oriens (SO), laminae (SL) and moleculare (SM), but not stratum pyramidale (SP) of CA1, as well as CER molecular layer. There were significant differences in coupling at 0 days with 8  $\mu$ M GABA in CA3 SO, SM and CER. BZ receptor downregulation was reversed in all brain regions 2 days after ending FZP treatment, as previously reported, and 7 days after treatment. The impaired coupling persisted in SO, but not SR of CA1, 2 days after treatment. In the absence of changes in BZ binding 2 days after FZP treatment, coupling was decreased with 8  $\mu$ M GABA in SO, SR and SP of CA1; SO of CA3 and SM and granule layer of dentate gyrus. Uncoupling of BZ and GABA sites did not persist 7 days after treatment when rats are no longer tolerant. [<sup>3</sup>H]GABA binding (50 nM) in the presence of 100  $\mu$ M baclofen was not altered between groups 2 days after treatment. Since EPSP amplitude is also increased in FZP-treated rats, binding at NMDA receptors was studied with [<sup>3</sup>H]glutamate and [<sup>3</sup>H]MK-801 2 days after treatment. There were no differences in NMDA receptor binding between groups. Changes in GABA/BZ coupling, which may relate to specific changes in GABAR subunit composition following chronic BZ treatment, may contribute to decreased BZ and GABA potency in the HIP CA1 region and to BZ tolerance. Support: R01-DA04075 and KO2-DA00180.

## 624.7

GABA<sub>A</sub> RECEPTOR SUBUNIT mRNA LEVELS ARE DIFFERENTIALLY AFFECTED BY CHRONIC DIAZEPAM AND ABECARNIL EXPOSURE. R.A. Holt\*, A.N. Bateson and J.L. Martin. Department of Pharmacology, University of Alberta, Edmonton, AB, T6G 2H7, Canada.

Diazepam and abecarnil produce their anxiolytic and anticonvulsant effects by interaction with the GABA<sub>A</sub> receptor (1,2). Chronic treatment with abecarnil, however, does not induce diazepam-like withdrawal effects in experimental animals (3). This study investigates the effects of chronic diazepam and abecarnil treatment on expression of the GABA<sub>A</sub> receptor  $\alpha_1$ -,  $\beta_2$ - and  $\gamma_2$ -subunit isoforms in rat cortex and cerebellum. It is possible that changes in receptor expression underlie the development of withdrawal.

Male Sprague-Dawley rats, 250 to 300g, were injected sub-cutaneously once daily for 14 days with 15mg/kg diazepam or 6mg/kg abecarnil in a "slow release" sesame oil vehicle. These doses have previously been reported to be equivalent in terms of kinetics and receptor occupancy in mice (3). The animals were killed 24 hours following their final injection and CNS drug levels were assessed by competition radioligand binding. Steady-state levels of GABA<sub>A</sub> receptor  $\alpha_1$ -,  $\beta_2$ - and  $\gamma_2$ -subunit mRNA were quantitated by solution hybridisation using oligonucleotide probes specific for these subunits and the results were normalized to the levels of  $\beta$ -actin mRNA (4). A significant decrease in  $\gamma_2$ -subunit mRNA was found in the cortex but not in the cerebellum of both diazepam (73.7% of control) and abecarnil (58.5% of control) treated rats. The levels of  $\alpha_1$ -subunit mRNA were increased significantly in the cerebellum of diazepam treated rats (121.4% of control) while  $\beta_2$ -subunit mRNA levels were decreased significantly in the cortex of abecarnil treated animals (72.9% of control). No other significant changes were found. The changes observed in GABA<sub>A</sub> receptor subunit mRNA levels are, therefore, both drug and region specific.

## 624.9

EFFECTS OF CHRONIC ETHANOL ADMINISTRATION ON GABA<sub>A</sub> RECEPTOR SUBUNIT mRNAs: A COMPETITIVE, QUANTITATIVE RT-PCR ANALYSIS. F.D. Smith<sup>1</sup>, L.L. Devaud<sup>1</sup>, D.R. Grayson<sup>2</sup>, and A.L. Morrow<sup>1</sup>, <sup>1</sup>Bowles Center for Alcohol Studies, UNC School of Medicine, Chapel Hill, NC, and <sup>2</sup>Allegheny Singer Research Institute, Pittsburgh, PA.

GABA<sub>A</sub> receptors are thought to play a major role in the development of ethanol tolerance and dependence. Chronic ethanol exposure significantly alters GABA<sub>A</sub> receptor function through an undetermined mechanism, possibly through alterations in subunit assembly. Absolute messenger RNA levels of several GABA<sub>A</sub> receptor subunits in rat cerebral cortex were determined after chronic ethanol consumption using a competitive, quantitative RT-PCR assay. Ethanol was administered for two weeks by liquid diet to adult male rats in a pair fed design. An increase of 89% in  $\alpha_4$  subunit mRNA levels (77.5  $\pm$  15.9 vs. 146.2  $\pm$  41.3 pg/ $\mu$ g total RNA) was detected, while  $\alpha_1$  subunit mRNA levels decreased by 43% (86.5  $\pm$  17.8 vs. 49.1  $\pm$  7.8 pg/ $\mu$ g total RNA). The increase in  $\alpha_4$  subunit mRNA was equal to the decrease in  $\alpha_1$  subunit mRNA. The  $\gamma_2$ s splice variant increased 32%, from 23.5  $\pm$  3.1 to 31.1  $\pm$  4.2 pg/ $\mu$ g total RNA, while the  $\gamma_2$ l splice variant showed no change in absolute mRNA levels. The  $\gamma_1$  subunit message levels increased 70%, from 3.5  $\pm$  0.6 to 6.0  $\pm$  1.3 pg/ $\mu$ g total RNA. No changes were found in  $\alpha_5$ ,  $\beta_1$ ,  $\beta_2$ ,  $\beta_3$ ,  $\gamma_3$ , and  $\delta$  subunits. These data provide evidence for the hypothesis that chronic ethanol exposure alters the subunit composition of GABA<sub>A</sub> receptors, which may account for alterations in GABA<sub>A</sub> receptor function. (Supported by AA09013 and AA00191).

## 624.6

CHRONIC DIAZEPAM TREATMENT DECREASES BZ<sub>1</sub>( $\omega_1$ )-SITE MEDIATED POTENTIATION OF GABA-INDUCED CURRENTS IN ACUTELY DISSOCIATED HIPPOCAMPAL NEURONS. P. Avenet\*, V. Lhuier, P. Granger, H. Depoortere and B. Scatton. CNS Research Department, Synthelabo Recherche, 31 Ave. P. Vaillant-Couturier, 92220 Bagneux, France.

We compared, using the whole-cell patch-clamp technique, the functional and pharmacological properties of GABA<sub>A</sub> receptors in hippocampal pyramidal neurons (HPN) acutely dissociated from adult rats in control conditions and after repeated p.o administration of diazepam (15 mg/kg twice a day for 10 days). A significant decrease in the potency of diazepam to prevent pentylenetetrazole-induced convulsions was observed 48 hours after withdrawal indicating occurrence of tolerance. HPN were acutely dissociated 24 hours (HPN-24) and 48 hours (HPN-48) after diazepam withdrawal using an enzymatic/low Ca<sup>2+</sup> protocol and were patch-clamped. In control HPN, HPN-24 and HPN-48, no significant difference was observed in the EC<sub>50</sub> values for GABA-induced responses (6.32, 6.95 and 7.14  $\mu$ M, respectively), in the density (at -20 mV) of 1  $\mu$ M GABA-induced currents (8.75, 8.38 and 10.55  $\mu$ A/cm<sup>2</sup>, respectively) or in the EC<sub>50</sub> values of diazepam at potentiating 1  $\mu$ M GABA-induced currents (32.3, 52.8 and 37.5 nM, respectively). However, the EC<sub>50</sub> value of zolpidem at potentiating GABA-induced currents in HPN-48 (276 nM) was significantly higher than in control HPN (130 nM). These results show that GABA<sub>A</sub> receptor sensitivity and density do not change following chronic diazepam treatment but that the BZ<sub>1</sub>-site mediated allosteric modulation of this receptor is decreased, suggesting a modification in the GABA<sub>A</sub> receptor subunit assembly.

## 624.8

CHRONIC BENZODIAZEPINE EFFECTS ON THE GABA<sub>A</sub> RECEPTOR COMPLEX OBSERVED *IN VIVO* IS REPLICATED IN AN *IN VITRO* RECOMBINANT EXPRESSION SYSTEM. D.W. Gallager\*, J. Yu, J. Xu, T.V. Ramabhadran, C. Hartnett, M. Brown, M. Meyyappan, C. Kostas, J. Tallman and R.J. Primus, Neurogen Corporation, 35 NE Industrial Road, Branford, CT 06405.

Recent advances in our knowledge of the molecular biology of the GABA<sub>A</sub> receptor system have yielded insight into the heterogeneity of receptor subtypes. The development of efficient recombinant expression systems has permitted the physiological and pharmacological characterization of the multiple subunits and various combinations of those subunits which are believed to make up the native GABA<sub>A</sub> receptor complex. In our earlier studies, different human GABA subunit constructs expressed in baculovirus infected insect cells were characterized by their ligand binding properties.

The present studies have compared the effects of chronic exposure to nonselective agonists (diazepam, bretazenil) and subtype selective agonists (e.g. zolpidem) on the binding characteristics of various recombinant human constructs of the GABA<sub>A</sub> receptor complex expressed in insect (Sf9) cells. These experiments demonstrate that phenomena observed following chronic exposure to diazepam *in vivo* in rats (including 'uncoupling' or a decrease in the allosteric GABA potentiation of benzodiazepine binding without a change in benzodiazepine density or affinity) can be replicated in the Sf9 expression system *in vitro*. As reported for the *in vivo* system, changes observed in *in vitro* reconstitution experiments are ligand specific and appear to be subtype selective as well. Reversal of the chronic agonist induced uncoupling process in the Sf9 expression system is produced by brief exposure to the antagonist, Ro15-1788 (flumazenil), in further analogy to effects observed *in vivo*. These data suggest a utility for recombinant expression systems in studies examining pharmacodynamic changes at the receptor complex in addition to subtype characterizations.

## 624.10

GABA<sub>A</sub> SITE ISOFORM GENE mRNA EXPRESSION IN PATHOLOGICALLY ALTERED CORTICAL REGIONS OF HUMAN CHRONIC ALCOHOLICS. P.R. Dodd\* and G.J. Thomas. Clinical Research Laboratory, Royal Brisbane Hospital Research Foundation, Brisbane Q4029, AUSTRALIA.

Although pathological changes such as loss of dendritic arborization are widespread in the brains of long-term chronic alcoholics, neuronal loss and reactive gliosis are marked in superior frontal cortex (SFC) but generally not apparent in most areas (e.g., primary motor cortex: PMC). Cirrhosis of the liver associated with the alcoholism may exacerbate the pathological changes. Our binding studies have shown that GABA<sub>A</sub> receptor sites are selectively altered in SFC synaptic membranes, on indices of both the form and quantity of the receptor. Since variations in GABA<sub>A</sub> isoform gene expression may provide a mechanism to explain changes in its receptor subtype, we assayed the mRNA expression of the seven isoform genes for which human sequence data were available, using S<sub>1</sub> protection assays and phosphorimager quantitation. Combined GAPDH and 18S mRNA expression values were used to normalize the data; SFC values were then adjusted to those in PMC, to control for the effects of age, post mortem delay, etc. Tissue samples were obtained at autopsy from 9 non-cirrhotic and 7 cirrhotic alcoholics (ethanol intake > 80 g/day), 10 controls, and 5 non-alcoholic cirrhotic cases (< 20 g/day).  $\alpha_1$  expression was reduced *cf* controls, slightly in both alcoholic groups but markedly (to 74%;  $P = 0.05$ , *t* test) in non-alcoholic cirrhotics.  $\beta_3$  expression was reduced *cf* controls in uncomplicated alcoholics (81%) but raised in both alcoholic (134%) and non-alcoholic (180%) cirrhotics ( $P = 0.05$ , ANOVA).  $\beta_1$  expression was slightly lower in both alcoholic groups, but unchanged in non-alcoholic cirrhotics. Recombinant studies suggest these changes have implications for GABA<sub>A</sub> receptor functionality. The variations were further defined by using *in situ* hybridization histochemistry in the two cortical regions.

## 624.11

PENTOBARBITAL TREATMENT ALTERS THE GABA<sub>A</sub> RECEPTOR SUBUNIT GAMMA 2 L/S RATIO. R.F. Tyndale\*, S.V. Bhavé, P.L. Hoffman, B. Tabakoff, A.J. Tobin and R.W. Olsen. Addiction Research Foundation and Department of Pharmacology, University of Toronto, Toronto, Canada; Department of Pharmacology, University of Colorado, Denver; and Departments of Biology and Pharmacology, UCLA, Los Angeles.

Cerebellar granule cells in primary culture were treated with pentobarbital (PB) which caused a change in the  $\gamma$ -aminobutyric acid (GABA)<sub>A</sub> receptor subunit mRNA  $\gamma 2L/\gamma 2S$  ratio. The long form of the  $\gamma 2$  subunit mRNA contains a 24 base-pair exon which codes for an 8 amino acid insertion in the cytoplasmic domain between the putative third and fourth transmembrane regions. This 8 amino acid insertion contains a protein kinase C consensus phosphorylation site which is phosphorylated *in vitro*. In the present study cerebellar granule neurons were cultured from postnatal day 7 rats for 4 days before treatment with PB (500  $\mu$ M) or ethanol (100 mM) in the medium for 3 days. RT-PCR and Southern blotting were used to detect the GABA<sub>A</sub> receptor subunit mRNAs in a blind study, with non-neuronal enolase as an internal standard.  $\gamma 2L/\gamma 2S$  Ratios were consistent from 22 to 30 cycles of amplification and over serial dilutions of PCR product. PB decreased the  $\gamma 2L/\gamma 2S$  ratio up to 65 percent, while ethanol did not. The change in the  $\gamma 2L/\gamma 2S$  ratio was dependent on dose and on duration of the treatment. The PB did not affect the total amount of  $\gamma 2$  subunit mRNA suggesting that the mechanism of action involves a change in alternate splicing of a common pre-messenger  $\gamma 2$  mRNA. We are currently investigating whether PB is acting via GABA<sub>A</sub> receptor activation or through alternate mechanisms. It is interesting that while barbiturates do not require a  $\gamma 2$  subunit for binding to the GABA<sub>A</sub> receptor, pentobarbital alters this subunit in a very specific manner, which may modify the phosphorylation of the  $\gamma 2$  subunit. Supported by NIAAA and MRC of Canada and the Addiction Research Foundation of Ontario.

## 624.13

CHRONIC NEUROSTEROID TREATMENT DECREASES THE EFFICACY OF GABA AND NEUROSTEROIDS AT THE GABA<sub>A</sub> RECEPTOR COMPLEX IN CORTICAL NEURONS. R. Yu\* and M.K. Ticku. Department of Pharmacology, University of Texas Health Science Center, San Antonio, TX 78284-7764

In previous studies we have observed that chronic neurosteroid 5 $\alpha$ -pregnan-3 $\alpha$ -ol-20-one (5 $\alpha$ 3 $\alpha$ ) (1 or 2  $\mu$ M) treatment produced downregulation of GABA<sub>A</sub> receptors and heterologous uncoupling at the GABA<sub>A</sub> receptor complex in cultured mammalian cortical neurons (Yu and Ticku, Mol. Brain Res. 47:603-610, 1995). In the present study, we examined if chronic neurosteroid treatment decreased the efficacy of GABA and 5 $\alpha$ 3 $\alpha$  to potentiate GABA responses, utilizing [<sup>36</sup>Cl<sup>-</sup>] influx and patch clamp assays. Chronic 5 $\alpha$ 3 $\alpha$  (1  $\mu$ M; 5 days) treatment decreased the efficacy of GABA and 5 $\alpha$ 3 $\alpha$  to potentiate GABA responses in these neurons. In [<sup>36</sup>Cl<sup>-</sup>] influx assay, the chronic 5 $\alpha$ 3 $\alpha$ , while not altering the EC<sub>50</sub> values of GABA, decreased its E<sub>max</sub> values from 84  $\pm$  2% to 26  $\pm$  2% (-69%). Furthermore, chronic 5 $\alpha$ 3 $\alpha$  treatment decreased the E<sub>max</sub> value of 5 $\alpha$ 3 $\alpha$  to potentiate GABA-induced [<sup>36</sup>Cl<sup>-</sup>] influx, without altering its EC<sub>50</sub> value. Since the cortical neurons used for [<sup>36</sup>Cl<sup>-</sup>] influx represent a heterogeneous population of neurons, we examined the effect of GABA and 5 $\alpha$ 3 $\alpha$  on GABA potentiation of single cell responses in control and chronically treated neurons, using patch clamp technique. We found that following chronic 5 $\alpha$ 3 $\alpha$  treatment, GABA (3  $\mu$ M) induced current was decreased from 513 pA  $\pm$  144 to 112 pA  $\pm$  33 (-78%). We also observed a decrease in 5 $\alpha$ 3 $\alpha$  (150nM) potentiation of GABA current from 62  $\pm$  9% in control to 30  $\pm$  10% in chronically treated neurons (-52%). These findings support the notion that both GABA response and its potentiation by neurosteroid 5 $\alpha$ 3 $\alpha$  are attenuated after chronic 5 $\alpha$ 3 $\alpha$  treatment.

## 624.15

TESTOSTERONE REGULATES GABA<sub>A</sub>  $\alpha 2$  SUBUNIT mRNA EXPRESSION IN NEWBORN FEMALE CNS

L. Zhang\*, W. Ma, A.N. Feldman, F. Lahjouji, J.L. Barker, D.R. Rubinow. Biological Psychiatry Branch, NIMH and Lab. Neurophysiology, NINDS, NIH, Bethesda, MD 20892

In the CNS testosterone is aromatized to estrogen, which binds to intracellular receptors and organizes male brain function during a critical in postnatal CNS development. A single injection of testosterone given to a female rat within the first few days after birth induces in male behavior in the mature animal. Thus, the sex hormones may play a very important role in the developing CNS. Here we have examined whether circulating testosterone regulates GABA<sub>A</sub> and 5-HT<sub>1A</sub> and 5-HT<sub>2A</sub> receptor mRNA expression in the newborn female CNS. *In situ* hybridization using <sup>35</sup>S-labeled oligonucleotides against  $\alpha 1$  and  $\alpha 2$  subunit mRNAs of GABA<sub>A</sub>, 5-HT<sub>1A</sub> and 5-HT<sub>2A</sub> receptors followed by densitometry was used to demonstrate that  $\alpha 2$  mRNA levels were increased 30-60% in olfactory bulbs, cortex, hippocampus, septum and hypothalamus, but decreased in preoptic areas by 60% 4 hrs after single injection of testosterone (150  $\mu$ g, ip). Testosterone exposure did not effect GABA  $\alpha 1$ , 5-HT<sub>1A</sub> and 5-HT<sub>2A</sub> receptor mRNA expression anywhere. The results indicate that specific receptor mRNAs are regulated differently by testosterone in the new born female. These data suggest that acute effects on GABA receptor expression may contribute to the organizing effects of testosterone on capacity for masculine behavior.

## 624.12

THE EFFECT OF CHRONIC PENTOBARBITAL TREATMENT ON GABA<sub>A</sub> RECEPTOR  $\delta$  SUBUNIT mRNA LEVEL IN MOUSE BRAIN. L.-H. Lin\* and L.-H. Wang. Department of Pharmacology, Chang Gung College of Medicine and Technology, Tao-Yuan 333, Taiwan, R.O.C.

Previous studies have suggested that chronic pentobarbital exposure decreases the high affinity GABA binding. It has also been shown that the  $\delta$  subunit may constitute the high affinity GABA<sub>A</sub> receptor. The present study was set out to address the issue whether chronic pentobarbital treatment results in a change in  $\delta$  subunit expression. The male ICR mice were injected with pentobarbital (75 mg/kg i.p.) three times per day, 7 days in a row. We found that in comparison with the first day, duration of pentobarbital-induced loss of righting reflex was significantly reduced by the end of the 7th day of injection (paired t test,  $p < .0001$ ). This suggests that tolerance has been developed by the treatment. To assess the change of mRNA level, we isolated cerebellar RNA from pentobarbital- and saline-injected mice. RNase protection assay was used to quantify  $\delta$  subunit mRNA level. To minimize experimental variation, the amount of  $\delta$  subunit mRNA was normalized to the internal standard of house keeping genes ( $\beta$ -actin or glyceraldehyde-3-phosphate dehydrogenase) within each RNA sample. We found that pentobarbital-treated mice showed significantly higher  $\delta$  subunit mRNA level than that of saline-treated mice (unpaired t test,  $p < .05$ ). The result suggests that increase of  $\delta$  subunit expression may contribute to or be resulted from the development of tolerance to pentobarbital.

## 624.14

CHRONIC NEUROSTEROID TREATMENT DECREASES THE EFFICACY OF BENZODIAZEPINE LIGANDS AND NEUROSTEROIDS AT THE GABA<sub>A</sub> RECEPTOR COMPLEX IN MAMMALIAN CORTICAL NEURONS. M.K. Ticku\* and R. Yu. Department of Pharmacology, University of Texas Health Science Center, San Antonio, TX 78284-7764

The effect of chronic 5 $\alpha$ -pregnane-3 $\alpha$ -ol-20-one (5 $\alpha$ 3 $\alpha$ ; neurosteroid) treatment was investigated on the GABA, 5 $\alpha$ 3 $\alpha$ , and ligands that bind to the benzodiazepine (BZ) site on GABA-induced [<sup>36</sup>Cl<sup>-</sup>] influx in intact cultured mammalian cortical neurons. Chronic 5 $\alpha$ 3 $\alpha$  treatment (1  $\mu$ M; 5 days) decreased the efficacy of GABA, because its E<sub>max</sub> (maximal response) value was decreased, whereas the EC<sub>50</sub> (potency) value was not altered. Chronic 5 $\alpha$ 3 $\alpha$  treatment also decreased the E<sub>max</sub> value of BZ agonists like diazepam to potentiate GABA-induced [<sup>36</sup>Cl<sup>-</sup>] influx, and decreased the -E<sub>max</sub> (maximal inhibitory response) value of inverse agonists like DMCM (methyl-6,7-dimethoxy-4-ethyl-8-carboline-3'-carboxylate) to inhibit GABA-induced [<sup>36</sup>Cl<sup>-</sup>] influx, while not altering their EC<sub>50</sub>/IC<sub>50</sub> values. Furthermore, chronic 5 $\alpha$ 3 $\alpha$  treatment decreased the E<sub>max</sub> value of 5 $\alpha$ 3 $\alpha$  to potentiate GABA-induced [<sup>36</sup>Cl<sup>-</sup>] influx, without altering its EC<sub>50</sub> value. The decreased efficacy of GABA and 5 $\alpha$ 3 $\alpha$  were reversed by concomitant exposure of the neurons to R 5135 (a competitive GABA antagonist). Taken together, these findings suggest that chronic 5 $\alpha$ 3 $\alpha$  treatment produces decreased efficacy of GABA, ligands that bind to the BZ site, and neurosteroids at the GABA<sub>A</sub>BZ receptor complex. The decreased efficacy is heterologous in nature and involves mediation via the GABA<sub>A</sub> receptor site.

## 624.16

GABAA/BENZODIAZEPINE RECEPTOR CHANGES IN GLOBUS PALLIDUS AFTER STRIATAL LESIONS.

L.C. Yang, Z. Hollingsworth\*, A.B. Young and J.B. Penney. Neurology Service, Massachusetts General Hospital, Boston, MA 02114.

Globus pallidus (GP)  $\gamma$ -aminobutyric acid A/ benzodiazepine (GABA<sub>A</sub>/BZ) receptors have predominantly high BZ affinity (BZ1) and are composed of  $\alpha 1$ , B2 and  $\gamma 2$  subtypes. We examined the time course of GP GABA<sub>A</sub>/BZ receptor ligand binding (using quantitative [<sup>3</sup>H]muscimol and [<sup>3</sup>H]flumazenil autoradiography) and gene expression (using *in situ* hybridization of [<sup>35</sup>S]-labelled oligonucleotide probes) changes in rat brain after unilateral striatal ibotenic acid lesions. Ligand binding was lower on the lesioned than on the unlesioned side at 3 days but returned to normal at 7 days. Muscimol binding remained normal thereafter while flumazenil binding kept rising through 90 days. The IC<sub>50</sub> of alpidem displacement was unchanged indicating no shift in BZ receptor subtype. The binding changes dramatically corresponded to  $\alpha 1$  and B2 gene expression changes. Film optical density and grain counting results indicated that both  $\alpha 1$  and B2 expression were decreased at 3 days and increased at 7 days. At 30 and 90 days, B2 expression returned to normal, a pattern similar to that of muscimol which predominantly binds B2 peptides.  $\alpha 1$  expression continued to rise at 30 and 90 days, identical with the changes in flumazenil binding to receptor  $\alpha$  peptides. Our study implies that, after striatal lesions, GABA<sub>A</sub>/BZ receptor peptides in the ipsilateral GP increase in different patterns but these increases correspond well to changes in the expression of their respective mRNAs.

Supported by USPHS NS31579 and the PRC education committee.

## 624.17

EXPRESSION OF GABA<sub>A</sub> RECEPTOR  $\delta$  SUBUNIT mRNA IN CULTURED CEREBELLAR GRANULE NEURONS IS REGULATED BY DEPOLARIZATION. L.M. Gault and R.E. Siegel\*. Dept. of Pharmacology, Case Western Reserve University, Cleveland, OH 44106-4965

The GABA<sub>A</sub> receptor is a multisubunit, ligand-gated ion channel that mediates the inhibitory actions of GABA. The regional and temporal expression of GABA<sub>A</sub> receptor subunit mRNAs has been well-characterized, but little is known about the factors that regulate their expression. To address this issue, we focused on the expression of the  $\delta$  subunit mRNA in cultured cerebellar granule neurons. In cultures maintained in complete medium containing fetal bovine serum and 25 mM KCl (CM), the  $\delta$  subunit transcript level increases several-fold between 4 and 8 days in culture. In contrast, the transcript is undetectable in neurons cultured in a chemically defined, serum-free medium containing only 5 mM KCl (DM). The lack of  $\delta$  subunit mRNA expression in DM is not due to a permanent change in neuronal properties; expression returns within 2 days after switching cultures from DM to CM. Furthermore, supplementing DM with 25 mM KCl results in an increase in  $\delta$  subunit mRNA expression comparable to that observed in CM. This effect of KCl is dose-dependent, is maintained in the presence of 1  $\mu$ M TTX and is not mimicked by the addition of glutamate to DM. Thus, KCl-induced depolarization alone is sufficient to induce  $\delta$  subunit mRNA expression; additional serum factors are not required. The signalling pathways involved in this cascade are currently under investigation.

## 624.19

RAPID DOWN-REGULATION OF GABA<sub>A</sub> RECEPTORS IN THE GERBIL HIPPOCAMPUS FOLLOWING TRANSIENT CEREBRAL ISCHEMIA. Bruno Alick\* and Rochelle D. Schwartz-Bloom. Department of Pharmacology, Duke University Medical Center, Durham, NC 27710.

During transient cerebral ischemia, there is a temporary, but robust, accumulation of extracellular GABA in the hippocampus. Within an hour following ischemia, GABA levels return to baseline. We examined whether the acute exposure of GABA<sub>A</sub> receptors to high concentrations of GABA results in down-regulation in vivo, as observed in vitro. Gerbils were subjected to 5 min bilateral carotid occlusion and sacrificed 30 or 60 min later. Brain sections were prepared for receptor autoradiography using the hydrophilic GABA<sub>A</sub> receptor antagonist, [<sup>3</sup>H]SR95531 and the hydrophobic benzodiazepine agonist, [<sup>3</sup>H]flunitrazepam, to distinguish between cell surface and internalized receptors. The oil:water partition coefficients were determined for [<sup>3</sup>H]SR95531 and [<sup>3</sup>H]flunitrazepam to be 0.037 and 21.0, respectively. Ischemia significantly decreased [<sup>3</sup>H]SR95531 binding to GABA<sub>A</sub> receptors in the dendritic fields of hippocampal areas CA1, CA3 and dentate gyrus 30 and 60 min after the onset of reperfusion ( $p=0.001$ ). Scatchard analysis of [<sup>3</sup>H]SR95531 binding revealed that ischemia caused a 51% decrease in the B<sub>max</sub>. The affinity of the remaining sites was increased substantially (69% decrease in K<sub>d</sub>). In contrast, no changes were observed in the binding of [<sup>3</sup>H]flunitrazepam at 30 and 60 min following ischemia. This is expected since the benzodiazepine has access to the cell interior where it can bind to internalized receptors as well as those on the cell surface. We hypothesize that prolonged exposure (~30-45 min) of GABA<sub>A</sub> receptors to high concentrations of synaptic GABA in vivo causes receptor down-regulation, via receptor internalization. ## 624.21

ANTISENSE KNOCKOUT OF  $\alpha 6$  SUBUNIT ALTERS PHARMACOLOGICAL PROPERTIES OF GABA<sub>A</sub> RECEPTORS IN CEREBELLAR GRANULE NEURONS. W.J. Zhu\*, J.F. Wang, S. Vicini, & D.R. Grayson<sup>1</sup> Georgetown University, Washington D.C.; <sup>2</sup>Med. College of Pennsylvania, Pittsburgh, PA.

Analysis of the profile of GABA<sub>A</sub> receptor subunit gene expression in cerebellar granule neurons have indicated that several forms of  $\alpha$  subunit, including  $\alpha 1$ ,  $\alpha 6$ , together with  $\beta 2$ ,  $\gamma 2$  and  $\delta$  subunit, are expressed to form unique subtypes of GABA<sub>A</sub> receptor channels. To characterize the role of the  $\alpha 6$  subunit in the native GABA<sub>A</sub> receptor, which are exclusively expressed in the granule cells, primary cerebellar cultures from 7 days old rats were treated with antisense oligodeoxynucleotides (aODNs) spanning the initial ATG codon of the  $\alpha 6$  subunit mRNA. ODNs were applied for 48 hours in culture medium at the concentration of 5  $\mu$ M. Sister cultures were treated with mismatch (scrambled) mODNs. Inhibition of GABA-gated currents by furosemide, a selective inhibitor of GABA<sub>A</sub> receptors containing  $\alpha 6$  subunit, was attenuated following aODNs treatment. Furthermore, aODNs specifically reduced immunocytochemical staining for  $\alpha 6$  subunits. We observed a concomitant alteration of the  $\alpha 6$  subunit expression and pharmacological properties of GABA<sub>A</sub> receptors in granule cells. Treatment with  $\alpha 6$  aODNs increased EC<sub>50</sub> and caused an inhibition of GABA-induced maximal currents when compared with control or mODNs treated cultures. Furthermore, the depletion of  $\alpha 6$  subunits from cerebellar granule cells enhanced flunitrazepam-induced potentiation of GABA-activated currents. These results show that  $\alpha 6$  subunit expression can be blocked by means of synthetic aODNs complementary to the initial coding exon, and that  $\alpha 6$  subunits in the GABA<sub>A</sub> receptor form a part of native neuronal Cl<sup>-</sup> channels and modify their pharmacology, suggesting that  $\alpha 6$  subunit expression during in vivo development contributes the plasticity of GABA<sub>A</sub> receptors in the cerebellar development. ## 624.18

$\gamma$ -HYDROXYBUTYRATE (GHB)-INDUCED ABSENCE-LIKE SEIZURES DECREASES THE EXPRESSION OF GABA<sub>A</sub> RECEPTOR  $\alpha 4$  mRNA IN THALAMUS. P.K. Banerjee\*, N.J.K. Tillakaratne\*, S. Brailowsky<sup>1,3,4</sup>, R.W. Olsen<sup>3,5,6</sup>, O.C. Snead<sup>1</sup>, and A.J. Tobin<sup>1,3,4,5,6</sup>. <sup>1</sup>Department of Neurology, University of Southern California, Los Angeles, CA 90027; <sup>2</sup>Departments of <sup>3</sup>Neurology, <sup>4</sup>Pharmacology, and <sup>5</sup>Physiological Science, <sup>6</sup>Molecular Biology Institute, and <sup>7</sup>Brain Research Institute, University of California, Los Angeles, CA 90095.

During the course of absence-like seizures induced by  $\gamma$ -hydroxybutyrate (GHB), neurosteroids continue to modulate ligand binding to thalamic GABA<sub>A</sub> receptors, except in mediodorsal, intralaminar, and ventrobasal thalamic relay nuclei, where GHB-induced spike and wave discharges originate. (Snead and Banerjee, SFN Abstract, 1994.) Since  $\alpha 4$  mRNA is present at higher levels in these nuclei than other GABA<sub>A</sub> receptor mRNAs, we hypothesized that the altered expression of this subunit might account for the suppression of neurosteroid modulation. To look for such alterations, we used *in situ* hybridization with digoxigenin-labeled cRNAs to determine the levels of the mRNAs for the  $\alpha 4$  subunit of GABA<sub>A</sub> receptors and for the GAD<sub>67</sub> form of glutamate decarboxylase in the thalamus of rats with GHB-induced seizures. In GHB-naïve animals, both darkly and lightly labeled cells were most abundant in the thalamic relay nuclei, while  $\alpha 4$  mRNA expression was low in the reticular nucleus (RT). In contrast, GAD<sub>67</sub> cRNA hybridized strongly to the RT, but not to the relay nuclei. In GHB-treated animals,  $\alpha 4$  mRNA levels decreased with time of GHB treatment, while GAD<sub>67</sub> mRNA levels were unaffected. The observed decrease in  $\alpha 4$  mRNA may underlie the observed suppression of neurosteroid modulation in the relay nuclei during GHB seizures.

## 624.20

ANTISENSE OLIGONUCLEOTIDE MODULATION OF GAD ALTERS COCAINE-INDUCED SEIZURES IN MICE. M.S. Abel\* and T. J. Kirages. Dept. of Cell Biology & Anatomy, FUHS/The Chicago Medical School, North Chicago, IL 60064.

The administration of synthetic antisense oligonucleotides (oligo) is an elegant method of regulating gene expression. In this study, we undertook to decrease cerebral GABA levels by inhibiting translation of glutamic acid decarboxylase (GAD), the rate-limiting enzyme for GABA synthesis, and determine susceptibility to seizures by the acute administration of the ED<sub>20</sub> dose of cocaine. The lateral ventricles of BALB mice (20-25g) were unilaterally infused with 2  $\mu$ l [0.5 ng] of either 1) antisense oligonucleotide in artificial CSF, 2) artificial CSF alone, or 3) random oligonucleotide in artificial CSF. After surgery, animals were allowed to recover for 15 hours before analysis of GABA levels and/or behavioral testing. Mice were injected i.p. with the ED<sub>20</sub> dose (55 mg/kg) of cocaine, and seizure behavior was evaluated. Antisense oligonucleotide to GAD significantly increased the number of cocaine-induced seizures. 33.3% of mice in the CSF group exhibited cocaine-induced seizures. 0% of mice in the random-oligo group exhibited cocaine-induced seizures. 75% of mice in the antisense-oligo group exhibited cocaine-induced seizures. The seizures consisted of severe tremors initially, followed by tonic-clonic extensions and contractions. Seizure latency and duration were not significantly different between groups. These data suggest that 15 hours after ICV injection, GABA levels are decreased sufficiently to reduce either a) widespread tonic inhibition by GABA, or b) specific inhibitory GABAergic pathways.

## 624.22

ALTERED GABAERGIC FUNCTIONS IN MICE LACKING THE  $\gamma 2$  SUBUNIT OF GABA<sub>A</sub> RECEPTORS. B. Lüscher\*, J.-M. Fritschy, U. Günther, J. Benson, D. Benke, F. Crestani, F. Knoflach, A. Aguzzi, M. Arigoni, Y. Lang, H. Bluethmann, H. Möhler. Institute of Pharmacology, University of Zürich, Winterthurerstrasse 190, 8057 Zürich, Switzerland.

Vigilance, anxiety, epileptic activity, and muscle tone can be modulated by drugs acting at the benzodiazepine (BZ) site of  $\gamma$ -aminobutyric acid type A (GABA<sub>A</sub>) receptors. *In vivo*, BZ sites are potential targets for endogenous ligands regulating the corresponding CNS states. To assess the functional properties of GABA<sub>A</sub> receptors devoid of BZ sites, mutant mice lacking the  $\gamma 2$  subunit were generated by gene targeting. Newborn mutant mice were morphologically indistinguishable from wildtype littermates. The size and cytoarchitecture of their brain were conserved, and, except for the  $\gamma 2$  subunit, the level of expression and the regional and cellular distribution of the major subunits were unchanged. Biochemical analysis revealed a loss of 94% of BZ sites while the number of GABA sites was only slightly changed, suggesting that the  $\gamma 2$  subunit was dispensable for proper expression and assembly of GABA<sub>A</sub> receptors during embryogenesis. Patch clamp analysis revealed that the single channel main conductance level and the Hill coefficient were reduced to values consistent with recombinant GABA<sub>A</sub> receptors composed of  $\alpha$  and  $\beta$  subunits. The GABA response was potentiated by pentobarbital but not by flunitrazepam. Diazepam was inactive behaviorally. Thus, in newborn mice, the  $\gamma 2$  subunit is dispensable for the assembly of functional GABA<sub>A</sub> receptors, but is required for normal channel conductance and the formation of BZ sites *in vivo*. Postnatally, however, the reduced GABA<sub>A</sub> receptor function was associated with retarded growth, sensorimotor dysfunction, and drastically reduced life span. In addition, abnormal dendritic targeting of GABA<sub>A</sub> receptor subunits was observed immunohistochemically in postnatal brain, which might exacerbate the impairment of inhibitory neurotransmission and contribute to the mutant phenotype.

## 624.23

TREATMENT WITH AN ANTISENSE OLIGODEOXYNUCLEOTIDE TO THE GABA-A RECEPTOR  $\gamma 2$  SUBUNIT INCREASES CONVULSIVE THRESHOLD FOR  $\beta$ CCM, A BENZODIAZEPINE "INVERSE AGONIST", IN RATS. T.-J. Zhao, T.H. Chiu\* and H.C. Rosenberg. Dept. of Pharmacology, Medical College of Ohio, Toledo, OH 43699.

Modulation of GABA actions by benzodiazepines and related drugs is associated with the presence of a  $\gamma 2$  subunit in the GABA-A receptor. Male Sprague-Dawley rats were surgically implanted with guide cannulae to allow unilateral intracerebroventricular (ICV) injections of phosphorothioate-modified antisense oligo (ASO; 18  $\mu$ g in 2  $\mu$ l saline) every 12 hr for 3 days. Other rats received the corresponding sense oligo. 6 hr after the last ICV treatment, rats were given a slow IV infusion of  $\beta$ CCM, a benzodiazepine "inverse agonist". The time to onset of myoclonic jerking was recorded, and the threshold convulsant dose determined. Compared to naive rats (n=5), the rats that had received sense oligo (n=4) had no significant change in  $\beta$ CCM threshold. Rats that had been treated with ASO (n=5) required an 87% larger dose of  $\beta$ CCM to induce convulsions. These results suggest that ASO treatment can alter GABA-A receptor composition *in vivo* and may provide a tool to study regulation of receptor structure and function. Supported by DA02194.

## 624.24

SMALL REDUCTION OF BENZODIAZEPINE RECEPTOR RADIOLIGAND BINDING IN RAT BRAIN FOLLOWING INTRACEREBROVENTRICULAR ADMINISTRATION OF ANTISENSE OLIGODEOXYNUCLEOTIDE TO GABA<sub>A</sub> RECEPTOR  $\gamma 2$  SUBUNIT SUBTYPE. J. Karle, S.E.W. Hansen, M.R. Witt\* and M. Nielsen. The Research Institute of Biological Psychiatry, St. Hans Psychiatric Hospital, DK-4000 Roskilde, Denmark.

Brain GABA<sub>A</sub> receptor chloride channel complexes are probably pentamers of different polypeptide subunits. Five different subunit families with several subunit subtypes ( $\alpha 1-6$ ;  $\beta 1-4$ ;  $\gamma 1-3$ ;  $\delta$  and  $\rho 1-2$ ) have been characterized. There is evidence indicating that the  $\gamma 2$  subunit subtype is a functionally integral part of the benzodiazepine binding site of the GABA<sub>A</sub> receptor complex, important for optimal binding of benzodiazepines. By means of benzodiazepine receptor radioligand binding assays we have evaluated the possibility of specifically reducing benzodiazepine receptor binding properties *in vivo* using phosphorothioate antisense oligodeoxynucleotides to GABA<sub>A</sub> receptor  $\gamma 2$  subunit subtype. Infusions of an 18-mer antisense oligonucleotide into the right lateral cerebral ventricle once daily (2  $\mu$ g/ $\mu$ l; 5  $\mu$ l infusion volume) for two days induced a significant and reproducible reduction of [<sup>3</sup>H]flunitrazepam (11%;  $p < 0.005$ , Mann-Whitney U test, n=8) and [<sup>3</sup>H]Ro 15-1788 (15%;  $p < 0.05$ , n=4) binding in preparations of right cortex compared to preparations from animals treated with saline. In preliminary experiments the corresponding sense oligonucleotide did not reduce radioligand binding compared to saline. There were no differences in [<sup>3</sup>H]QNB binding between antisense oligonucleotide and saline treated animals. These results illustrate that an antisense oligonucleotide to GABA<sub>A</sub> receptor  $\gamma 2$  subunit can selectively reduce benzodiazepine receptor radioligand binding *in vivo*.

## PEPTIDE RECEPTOR STRUCTURE AND FUNCTION III

## 625.1

Characterization of tachykinin NK1/NK3 chimeric receptors constructed by exon shuffling. Fu-Zon Chung\*, Lan-Hsin Wu, and Ye Tian. Department of Biotechnology, Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Company, Ann Arbor, MI 48105

All three tachykinin receptor genes contain five exons which are separated by introns of variable length. Interestingly, the location of all exon/intron junctions are completely conserved among these receptor genes. To explore the possibility that these evolutionary conserved exons may serve as functional units, three chimeric receptors were constructed by shuffling exons between tachykinin NK1 and NK3 receptors. In NKC-1, NKC-2, and NKC-3 chimeric receptors, various portions of the N-terminal sequences of the human NK3 receptor encoded by exon 1 (transmembrane domains 1-3), exon 1-2 (transmembrane domains 1-4), and exon 1-3 (transmembrane domains 1-5), respectively, were systematically replaced by their counterparts of the human NK1 receptor. All three chimeric receptors retained relatively high affinity binding for the natural ligand substance P, indicating that sequences located at the N-terminal end of the NK1 receptor are important for substance P binding. On the contrary, in the NKC1 receptor, in which the first exon (transmembrane domains 1-3) of the human NK3 receptor was replaced by its counterpart of the human NK1 receptor, the binding affinity of the natural ligand neurokinin B is almost the same as that in the wild type human NK3 receptor. It is concluded that sequences located at the N-terminal end of the human NK3 receptor are not important for binding to neurokinin B. These data indicate that chimeric receptors constructed by exon shuffling may be useful tools for accessing the functional importance of individual exons of these tachykinin receptors.

## 625.2

Asp<sup>131</sup> of the Neurokinin-3 receptor is important for G-protein coupling but not for ligand binding: a mutagenesis study. Ye Tian\*, Lan-Hsin Wu and Fu-Zon Chung. Department of Biotechnology, Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Company, Ann Arbor, MI 48105

Neurokinin receptors belong to the G-protein coupled receptor superfamily. One of the common features of this receptor superfamily is the conservation of an aspartate residue in the TM II domain which has been hypothesized to be important for receptor G-protein coupling. The NK3 receptor is highly expressed in neuronal cells but its biological function has not yet been elucidated. Similar to other G-protein coupled receptors, human NK3 receptor contains an Asp<sup>131</sup> in the TM II. In the present study, the involvement of the Asp<sup>131</sup> of the human NK3 receptor in receptor-ligand interaction was examined. Two mutant receptors were constructed from the human NK3 receptor with Asp<sup>131</sup> being mutated to either Glu or Asn. Receptor binding and agonist-induced receptor activation were measured to evaluate the interactions between mutant NK3 receptors and their ligands. Here we report that mutation of Asp<sup>131</sup> to either Glu or Asn residue conserves high affinity binding to selective NK3 ligands such as [MePhe<sup>7</sup>]NKB. The conversion of Asp<sup>131</sup> to Glu fully conserved the ability for the receptor to conduct agonist-induced phosphatidylinositol turnover. In contrast, the conversion of Asp<sup>131</sup> to Asn which lost side chain charge but preserved the size of the residue resulted in a total loss of receptor activation as evaluated by agonist-induced phosphatidylinositol turnover. These results suggest that the Asp<sup>131</sup> is crucially involved in the receptor-G-protein coupling, but not in ligand binding.

## 625.3

NOVEL HIGH-AFFINITY NPY ANTAGONIST IDENTIFIES DIFFERENT SUBCLASSES OF Y2 TYPE OF NPY RECEPTORS. J.E. Matthews, M. Jansen, R.J. Slepetis, V.A. Rash and A.J. Daniels\*. Burroughs Wellcome Company, Research Triangle Park, North Carolina 27709.

Identification of NPY receptor subtypes has relied on the differential binding and activity of C-terminal fragments (NPY 13-16) and C-terminally modified analogs of NPY (Lcu<sup>31</sup>, Pro<sup>34</sup> NPY). At least two NPY receptor subtypes have been described based on the relative affinity of different NPY agonists: NPY-Y1 receptors require essentially the full NPY sequence of amino acids for activation and have high affinity for the analog [Lcu<sup>31</sup>, Pro<sup>34</sup>]NPY, whereas NPY-Y2 receptors can be activated by both NPY and NPY 13-36 but have low affinity for [Lcu<sup>31</sup>, Pro<sup>34</sup>]NPY. We have found a high-affinity, apparently non-selective, NPY receptor antagonist (1229U91). 1229U91 is a very potent Y1 antagonist when tested in three models used for the characterization of Y1 receptors: SK-N-MC cell binding (IC<sub>50</sub> 0.2 nM), HEL cell intracellular calcium release (IC<sub>50</sub> 0.25 nM), and perfused isolated rat kidney (IC<sub>50</sub> 3 nM). 1229U91 displays an even higher affinity for the Y2 rat brain receptor (IC<sub>50</sub> 21 pM), being 700 fold more potent than NPY 13-16 (IC<sub>50</sub> 15 nM). However, 1229U91 displays lower potency than NPY 13-36 on other Y2 binding and functional assays: In the human neuroblastoma cell line, KAN-TS, the affinity of 1229U91 is 300 fold lower than for NPY 13-36 (IC<sub>50</sub> 2.7  $\mu$ M and 8 nM respectively). Likewise, while NPY 13-36 antagonized the Y2 mediated inhibition of the electrically stimulated twitch in the rat vas deferens (ED<sub>50</sub> 60 nM), 1229U91 at 1  $\mu$ M does not show agonistic or antagonistic activity. The different relative affinities for NPY 13-36 and 1229U91 for NPY receptors previously characterized as being of the Y2 class, leads us to propose the existence of subclasses of Y2 receptors.

## 625.4

BINDING OF [<sup>125</sup>I]-[LEU<sup>31</sup>, PRO<sup>34</sup>]-PEPTIDE YY (LP-PYY) TO RECEPTORS FOR NEUROPEPTIDE Y (Y-1) AND PANCREATIC POLYPEPTIDE (PPI). S.L. Gackenheim\*, J. Lundell<sup>1</sup>, R. Schmidt, L. Beavers, R.A. Gadsby, M. Berglund<sup>1</sup>, D.A. Schober, N.L. Mayne, J.P. Burnett, D. Larhammar<sup>1</sup> and D.R. Gehlert. Lilly Research Laboratories, Indianapolis, IN and <sup>1</sup>Dept. Pharmacol., Uppsala University, Uppsala, Sweden.

Neuropeptide Y (NPY) is the predominant brain peptide of the PP-fold peptide family. The other members, peptide YY (PYY) and pancreatic polypeptide (PP) are primarily circulating endocrine peptides though receptor sites for these peptides have been found in brain. Receptor populations for NPY were subdivided into Y1 (postsynaptic) and Y2 (presynaptic). NPY and PYY have similar affinity for Y1 and Y2 but may have their own distinct receptor subtypes as well. PP was believed to have its own distinct receptor population. The exchange of the Pro<sup>34</sup> found in PP for the Gln<sup>34</sup> in NPY and PYY produces NPY and PYY analogs with selectivity for Y-1 over Y-2 receptors. In the present study, we have characterized the binding of [<sup>125</sup>I]-LP-PYY to Y1 and the newly identified PPI receptors. In addition we have examined the distribution of binding sites for this radioligand in the rat brain.

The DNA encoding for the Y1 receptor and the PPI receptor were subcloned into the pHD vector and expressed in AV-12 cells. [<sup>125</sup>I]-LP-PYY bound to the Y1 receptor with a K<sub>d</sub> of 320 pM and a B<sub>max</sub> of 2700 fmol/mg protein. This ligand also bound to the PPI receptor with a K<sub>d</sub> of 120 pM and a B<sub>max</sub> of 2050 fmol/mg protein. The pharmacology of the binding was consistent with the pharmacology of Y1 and PPI binding in the respective cell lines. The localization of [<sup>125</sup>I]-LP-PYY binding sites was compared with the localization of Y-2 and PP receptors in rat and guinea pig brain using receptor autoradiography. In general, [<sup>125</sup>I]-LP-PYY bound to Y1 receptors in most brain regions. However, in areas that contained high densities of PP receptors such as the nucleus of the solitary tract and interpeduncular nucleus, binding of [<sup>125</sup>I]-LP-PYY was also observed.

Therefore, [<sup>125</sup>I]-LP-PYY binds to both Y1 and PP receptors. Caution needs to be exercised when using this peptide analog in *in vitro* and *in vivo* assays.

## 625.5

DIFFERENTIAL DISTRIBUTION OF NEUROPEPTIDE Y1 AND Y2 RECEPTORS IN HUMAN AND RAT BRAIN. M.A. Stancik\*, D.A. Schober, J.P. Burnett, N.G. Mayne, R. Sharp, Y. Snyder, and D.R. Gehlert, Central Nervous System Research, Lilly Research Labs, Eli Lilly and Company, Indianapolis, IN 46285.

Neuropeptide Y (NPY) is a 36 amino acid amidated peptide present in both peripheral and central nervous system (CNS) neurons. Receptor subtypes for NPY have been elucidated by the differing affinity of [Leu<sup>31</sup>, Pro<sup>34</sup>]NPY and NPY<sub>13-36</sub> to displace [125I]-NPY or [125I]-Peptide YY ([125I]-PYY) binding from Y1 and Y2 receptors, respectively. The CNS distribution of these receptor subtypes has been extensively studied in the rodent. In general, Y1 receptors are found in the cerebral cortex, while Y2 receptors are found in the hippocampus and hypothalamus (Gehlert et al., *Neurochem Int* 21: 45-67, 1992). Recently, species differences in the distribution of Y1 and Y2 receptors have been described in human and rat brain (Widdowson, *Brain Res* 631: 27-38, 1993). To further characterize these findings, we examined the pharmacology of NPY receptors in the human and rat cerebral cortex and hypothalamus by radioligand binding. Moreover, the pharmacology of a cell line stably expressing a cloned human Y1 receptor gene (hNPY1/AV12) and of a Y2 receptor expressing cell line (SMS-KAN) were examined for comparative purposes. In hNPY1/AV12 cells, analysis of saturation curves with [125I]-PYY showed a single binding site with a K<sub>d</sub> = 172 pM and a B<sub>max</sub> = 3.2 pmol/mg protein. Displacement of 100 pM [125I]-PYY binding and inhibition of forskolin stimulated adenylate cyclase displayed a Y1 profile in hNPY1/AV12 cells, while in SMS-KAN cells displacement of [125I]-PYY binding was Y2. In human cortex homogenates, displacement of [125I]-PYY binding with various peptides displayed a distinct Y2 receptor profile (PYY > NPY > NPY<sub>2-36</sub> > PYY<sub>13-36</sub> > NPY<sub>3-36</sub> > NPY<sub>13-36</sub> >>> h[Pro<sup>34</sup>]NPY = h[Leu<sup>31</sup>, Pro<sup>34</sup>]PYY). Conversely, displacement of [125I]-PYY binding from rat cortical membranes was Y1 in nature (h[Pro<sup>34</sup>]NPY > NPY > h[Leu<sup>31</sup>, Pro<sup>34</sup>]PYY > NPY<sub>2-36</sub> >> NPY<sub>13-36</sub> > NPY<sub>3-36</sub> > PYY<sub>13-36</sub>). NPY receptor binding in the hypothalamus was Y2 for both species (PYY > NPY = NPY<sub>2-36</sub> > NPY<sub>13-36</sub> >>> [Leu<sup>31</sup>, Pro<sup>34</sup>]NPY = hPP = [dTrp<sup>32</sup>]NPY). Therefore, it appears that species differences exist in the distribution of NPY receptor subtypes expressed in the cerebral cortex, while in the hypothalamus the receptor subtype appears to be similar between species. The functional consequences of these differences await further study.

## 625.7

CLONING OF A HUMAN RECEPTOR OF THE NPY RECEPTOR FAMILY WITH HIGH AFFINITY FOR PANCREATIC POLYPEPTIDE AND PEPTIDE YY. I. Lundell\*, A. G. Blomqvist, M. Berglund, D. A. Schober<sup>1</sup>, D. Johnson<sup>1</sup>, R. A. Gadske<sup>1</sup>, D. R. Gehlert<sup>1</sup>, and D. Larhammar. Dept. of Medical Pharmacology, Uppsala University, Box 593, S-751 24 Uppsala, Sweden, <sup>1</sup> Lilly Research Laboratories, Eli Lilly and Company, Indianapolis.

Neuropeptide Y (NPY), peptide YY (PYY) and pancreatic polypeptide (PP) form a family of structurally related peptides. NPY is expressed exclusively in neurons whereas PYY is produced in endocrine cells of colon and pancreas as well as in some brainstem neurons. PP is exclusively expressed in pancreas. Several receptor subtypes have been identified pharmacologically, but only the NPY/PYY receptor of subtype Y1 has been cloned. We have isolated the gene for a novel human receptor, called PP1, with 43% overall amino acid sequence identity to Y1 and 53% identity in the transmembrane regions. The PP1 gene lacks the intron present in the Y1 gene. When transiently expressed in COS cells, the PP1 receptor displays a pharmacological profile that distinguishes it from all previously described NPY-family receptors. It binds PP with an affinity (K<sub>i</sub>) of 16 pM, PYY with 100 pM and NPY with 36 nM. The Y1-selective NPY analogue [Leu<sup>31</sup>, Pro<sup>34</sup>]NPY has a K<sub>i</sub> of 10 nM. Northern hybridization to human organ and brain-region mRNA panels detected mRNA in colon and pancreas. Because all three endogenous peptides may be present in these organs through either endocrine release or innervation, all three peptides may be physiological ligands. Thus, PP1 represents a novel peripheral subtype of the PP-fold receptor family. This sequence provides not only a novel pharmacological entity, but should facilitate identification of other family members.

## 625.9

PANCREATIC POLYPEPTIDE POTENTIATES CA<sup>2+</sup> CHANNEL CURRENTS IN CULTURED RAT HIPPOCAMPAL NEURONS. D.L. Czilli\*, W.Y. Li and L.K. Simmons. CNS Research, Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285.

Pancreatic polypeptide (PP) belongs to a family of structurally related peptides which includes neuropeptide Y (NPY) and peptide YY (PYY). Although cells containing PP are localized primarily in the gut and pancreas, there is evidence suggesting that PP receptors depress Ca<sup>2+</sup> channel activity in rat superior cervical ganglia. Here we describe a PP-mediated potentiation of voltage-sensitive Ca<sup>2+</sup> channel currents in embryonic day 18 rat hippocampal neurons. Using whole-cell voltage clamp protocols with 10 mM Ba<sup>2+</sup> in the bath as the charge carrier, PP (3 - 100 nM) enhanced the peak Ba<sup>2+</sup> currents (I<sub>Ba</sub>) elicited with voltage steps to +10 mV from a membrane holding potential of -70 mV. In response to 100 nM PP, I<sub>Ba</sub> was enhanced (relative to control values) by a mean of 56±3 %. Therefore, unlike NPY, which depresses excitatory transmission presynaptically in hippocampal neurons via a Y2 receptor subtype, PP enhances the activity of post-synaptic Ca<sup>2+</sup> channels. Future studies will investigate whether PP is acting at a distinct receptor in this neuronal population.

## 625.6

PHARMACOLOGICAL AND BIOCHEMICAL CHARACTERIZATION OF A NOVEL MEMBER OF THE NEUROPEPTIDE Y (NPY) RECEPTOR FAMILY. P.P. D.A. Schober\*, J. Lundell<sup>1</sup>, R. Schmidt, L. Beavers, R.A. Gadske, M.A. Stancik, M. Berglund<sup>1</sup>, J.A. Hoffmann, R. Chance, D. Larhammar<sup>1</sup>, and D.R. Gehlert. CNS Research, Lilly Research Laboratories, Indianapolis, IN and <sup>1</sup>Dept. Pharmacology, Uppsala University, Uppsala, Sweden.

Receptors for NPY have been traditionally divided into Y1 and Y2 subtypes based on peptide pharmacology and synaptic localization. Other receptors have been proposed based on preferences for NPY, peptide YY (PYY) or pancreatic polypeptide (PP). Until recently, only the Y1 receptor has been cloned and pharmacologically evaluated. At this meeting (see Lundell et al.) we have disclosed a novel member of this receptor family that exhibits high affinity for PP and PYY. In the present study, we have stable expression of the PP1 receptor in CHO cells and evaluate its pharmacological properties with an array of peptides.

When expressed in CHO cells, the PP1 receptor bound both [125I]-pPYY and [125I]-bPP with K<sub>d</sub>'s in the 30-50 pM range. Human, rat and bovine PP inhibited binding with similar affinities while chicken PP was less potent with a K<sub>i</sub> of 1 nM. PYY inhibited binding with a K<sub>i</sub> of 300 pM while NPY was much less potent with a K<sub>i</sub> of 10 nM. Examination of a variety of PP fragments indicated the importance of the N- and C-terminus of PP in the binding to the receptor. Deletion of the first 4 amino acids reduced affinity of bPP to 1 nM. Deletion of Tyr<sup>36</sup> produced a substantial reduction in affinity. Leu<sup>31</sup>-Pro<sup>34</sup> substituted NPY and PYY had increased affinity when compared to the native peptides. In biochemical assays, PP and PYY were able to produce a concentration dependent reduction in forskolin stimulated adenylate cyclase activity while NPY did not affect activity at concentrations of up to 1 μM. Thus, PP1 is a novel member of the PP-fold receptor family and has a distinctive pharmacology. Like Y1 and Y2 it is coupled negatively to adenylate cyclase.

## 625.8

MUTAGENESIS OF CONSERVED AMINO ACID RESIDUES IN THE RAT Y1 RECEPTOR. Magnus Berglund\*, Anders G. Blomqvist & Dan Larhammar. Dept. of Medical Pharmacol., Uppsala Univ., Sweden, <sup>1</sup>Lab. for Mol. Endocrinol., Rigshosp., Copenhagen, Denmark

Neuropeptide Y (NPY) and peptide YY (PYY) are structurally related peptides that function as a neurotransmitter and gastrointestinal hormone, respectively. At least four distinct NPY and/or PYY receptors, called Y1, Y2, Y3, and "feeding receptor" have been described. The cloning of the Y1 receptor in several species (rat, mouse, human and *Xenopus laevis*) as well as the cloning of a Y1-like receptor (Lundell et al, submitted) allows the identification of well conserved amino acid residues in the Y1-family of receptors. We have mutated conserved positions in the rat Y1 receptor to study the effects on ligand interactions.

Amino acids that have been chosen for site-directed mutagenesis are polar and charged residues located in the transmembrane regions and in the extracellular loops. Mutations have been introduced by using a two step PCR method with mutant primers. Upon sequence confirmation the mutated receptors have been cloned into the expression vector pTEJ8 (kindly provided by T.W. Schwartz, Denmark) and CHO-K1 cells have been stably transfected. Ten mutant receptor clones are being studied with regard to their ability to bind iodinated NPY and PYY. A number of different peptide analogs are used to displace these radioligands.

Mutant receptors that bind neither NPY nor PYY will be checked with an antibody to the carboxy terminus of the receptor to investigate cell-surface expression.

## 625.10

CYSTEINE 199 IN TM V OF THE SUBSTANCE P RECEPTOR IS THE SITE FOR MODULATION OF PEPTIDE BINDING BY SULFHYDRYL SPECIFIC REAGENTS. H. Li<sup>1</sup>, B. S. Sachia<sup>2</sup>, J. E. Krause<sup>2</sup>, S. E. Leeman<sup>1</sup>, N. D. Boyd<sup>1</sup>. <sup>1</sup>Dept. of Pharmacology, Boston Univ. Sch. of Med, Boston, MA 02118 and <sup>2</sup>Dept. of Anat. & Neurobiol., Washington Univ. Sch. of Med., St. Louis, MO 63110.

Substance P (SP) is a peptide neurotransmitter that produces multiple responses in both the central and the peripheral nervous system through a G-protein coupled receptor. The primary structure of the rat SP receptor contains a number of cysteine residues. To study the role of these cysteines in the structure-function of the SP receptor, we have examined the effect of sulfhydryl specific reagents on radiolabeled SP ([125I]-BH-SP) binding to the rat SP receptor stably expressed in CHO cells. The membrane-permeable reagent N-ethyl-maleimide (NEM) inhibits [125I]-BH-SP binding in a concentration-dependent manner, while charged and thus membrane-impermeable reagents had no effect on binding. These results indicate that the site of NEM modulation is located within the transmembrane (TM) domain of the receptor. To locate the reactive sulfhydryl group, we used amphipathic maleimide analogues which penetrate to different depths within the plane of membrane. The results obtained suggest that the maleimide-sensitive sulfhydryl group is about 11 Å from the extracellular membrane boundary. The residue cys199 is predicted to be close to the extracellular end of the fifth TM helix of the SP receptor. The receptor mutant C199S, in which cys199 has been replaced by a serine, is no longer sensitive to modulation by NEM treatment, indicating that cys199 of the receptor is the target of NEM modulation. In addition, the occupation of the receptor by SP protects cysteine 199 from modification by NEM. Thus, this residue is either located at or conformationally linked to the SP binding site.

## 625.11

**EXPRESSION OF THE RAT B<sub>2</sub> BRADYKININ RECEPTOR IN STABLY TRANSFORMED CHINESE HAMSTER OVARY CELLS.** S. Yokoyama\*, Y. Kimura, M. Taketo, K. Iki and H. Higashida. Dept. of Biophysics, Neuroinformation Research Institute, Kanazawa University School of Medicine, Kanazawa 920, Japan

In the previous study we demonstrated that both the rat and mouse B<sub>2</sub> bradykinin receptors (BKR) of the smooth muscle type are expressed in NG108-15 mouse neuroblastoma x rat glioma hybrid cells (BBRC 200: 634-641, 1994). For further analysis, we have established transformed Chinese hamster ovary (CHO) cells which stably express the rat B<sub>2</sub> BKR and developed a polyclonal antibody. Rat B<sub>2</sub> BKR cDNA was amplified from brain mRNA by reverse transcription polymerase chain reaction (RT-PCR) and cloned into pRC/CMV. The expression plasmid was transfected into CHO cells and two cell lines, designated as CHO-RBKR8 and CHO-RBKR11, were isolated. RNA blot hybridization analysis identified a proper transcript in these transformed cells. Upon application of bradykinin, a transient increase of intracellular calcium was observed in both cells, but not in parental CHO cells. Next, cDNA corresponding to the C-terminal region of the rat B<sub>2</sub> BKR was subcloned into pGEX2T, a bacterial expression vector, and the fusion protein expressed in *E. coli* was used to generate rabbit antisera. The transformed cells exhibited intense immunoreactivity with the antibody. In contrast, the occasional faint staining was observed in parental CHO cells. These transformed cells may provide a useful system to study the properties of the B<sub>2</sub> BKR.

## 625.12

**CONSERVED CYSTEINE RESIDUES IN THE CYTOPLASMIC TAIL OF THE HUMAN NEUROKININ A RECEPTOR ARE INVOLVED IN RECEPTOR DESENSITIZATION.** C.R. Cyr, S. Josiah, B. Rudyk, L. Devi\* and R.M. Kris. Department of Pharmacology and Physiology, New York University Medical Center, 550 First Avenue, New York, New York 10016

Neurokinin A receptor, a member of the tachykinin family of G protein coupled receptors, produces vasoconstriction of smooth muscle and a number of other effects. When neurokinin A receptors were expressed in *Xenopus laevis* oocytes, stimulation by neurokinin A produced a calcium dependent chloride response that desensitized for 25-35 minutes. In an effort to characterize the role of two cysteine residues within the cytoplasmic tail of the neurokinin A receptor on desensitization, three palmitoylation mutants and two chimeric receptors were expressed and analyzed in the *Xenopus* oocyte system. Two single point mutations and a double mutation of adjacent cysteines within the cytoplasmic tail were constructed. Both of the single mutations desensitized for only 5 minutes while the double mutation was not functional. Substitution of 61 amino acids of the neurokinin A receptor by an equivalent region of the endothelin A receptor produced a chimeric receptor that desensitized for a period equal to that of wild type neurokinin A receptor, while substitution of 81 amino acids resulted in a chimeric receptor that does not undergo desensitization. This data demonstrates that alteration of the two cysteine residues within the cytoplasmic tail affects normal desensitization of the neurokinin A receptor and supports a role for palmitoylation in receptor desensitization. C.R. Cyr is supported by Postdoctoral Training Grant DA 7254 and NIH NS30989.

## 625.15

**CLONED RECEPTORS FOR NPY, PYY AND PP. RAT Y2 AND Y4 SUBTYPES.** K.E. Smith\*, M.W. Walker, C. Gerald, J.A. Bard, S. Daouti, P.J.-J. Vaysse, T.A. Branchek and R.L. Weinshank. Synaptic Pharmaceutical Corporation, Paramus, NJ 07652.

Multiple receptor subtypes are proposed to mediate the diverse physiological effects of the related peptides neuropeptide Y (NPY), peptide YY (PYY) and pancreatic polypeptide (PP). Using expression cloning and homology approaches, we recently isolated DNAs encoding two novel human Y-type receptors, designated Y2 and Y4 based on their pharmacological properties (Gerald et al., Bard et al., and Walker et al., Soc. Neurosci. Abst., 1995). We report here the cloning of the rat Y2 and Y4 receptors using the nucleotide sequences of the corresponding human receptors.

The predicted protein sequence of the rat Y2 receptor exhibits 95% identity with the human Y2 receptor. The pharmacological properties of the rat Y2 receptor transiently expressed in COS-7 cells parallel those of the human Y2 receptor and are characterized by high-affinity binding of NPY, PYY and PYY 13-36 (K<sub>d</sub> values 0.28-1.5 nM). Human [Leu<sup>3</sup>,Pro<sup>34</sup>]-NPY and rat PP were inactive at concentrations up to 1 μM. Thus, the rat Y2 receptor, like the human Y2, is relatively tolerant of N-terminal ligand deletions and intolerant of Pro<sup>34</sup> or C-terminal substitutions. We recently isolated DNA encoding a second isoform of the rat Y2 receptor that differs by two amino acids and may represent an allelic variant of the Y2 receptor gene.

The amino acid sequence of the rat Y4 receptor displays 75% identity with the human Y4 receptor (84% in TM domains); the third intracellular loop is particularly divergent (56%). The pharmacological profile of the rat Y4 receptor transiently expressed in COS-7 cells, when tested with human peptides, is similar to that of the human Y4 receptor: PP>[Leu<sup>3</sup>,Pro<sup>34</sup>]-NPY>NPY. However, certain nonmammalian PP homologs (avian, frog PP) bind selectively to rat or human Y4 receptors. The relatively low degree of sequence identity between rat and human Y4 receptors, combined with their contrasting affinities for PP-related peptides, may reflect the fact that PP itself is not highly conserved across species.

Comparison of rat Y2 and Y4 receptors with their human homologs will help to elucidate the roles of NPY, PYY and PP in rat and human physiology.

## 625.12

**CLONING AND EXPRESSION OF THE HUMAN NEURONAL B<sub>2</sub> BRADYKININ RECEPTOR.** J. Baumgold\* and J. S. Handen. Receptor Biology Inc., Baltimore, MD 21227 and Neuroscience Program, The George Washington University, Washington, DC 20007.

Two B<sub>2</sub> bradykinin receptor subtypes have been described in the literature: a "smooth-muscle" B<sub>2</sub> receptor, and a "neuronal" B<sub>2</sub> receptor which differ pharmacologically. The "smooth-muscle" B<sub>2</sub> receptor has been cloned from several species, whereas this is the first report of cloning the "neuronal" B<sub>2</sub> receptor.

We used the published sequence of the smooth muscle B<sub>2</sub> receptor to design PCR primers which were used for RT-PCR. The resulting DNA fragment was then used to screen a cDNA library from a human cell line. One of the resulting positive clones contained a sequence that has 83% homology to the human "smooth muscle" B<sub>2</sub> receptor. We transfected this cDNA into COS-7 cells, and found that transfected cells exhibit bradykinin-mediated PI turnover (K<sub>act</sub> = 4 nM), whereas untransfected cells do not. Furthermore, NPC431 which has been previously described as a full agonist at "neuronal" B<sub>2</sub> receptors and as an antagonist at "smooth muscle B<sub>2</sub> receptors", acted as a full agonist in the transfected cells. Stably-transfected cell lines expressing this novel bradykinin receptor are currently being established, and will be used to characterize this receptor further. Taken together, our data indicate that we cloned the human "neuronal" B<sub>2</sub> receptor.

## 625.14

**ELUCIDATION OF STRUCTURAL REQUIREMENTS OF NEUROPEPTIDE Y FOR RECOGNITION BY Y<sub>2</sub> RECEPTOR USING ACYLATED AND CROSS-LINKED ANALOGS.**

N. Yumoto\*, S. Murase, Y. Shigeri and S. Yoshikawa. Osaka National Research Institute, AIST, Ikeda, Osaka 563, Japan.

Neuropeptide Y (NPY) is an amidated peptide of 36 amino acids which has an α-helical part between residues 13 and 32. Among the subtypes of receptor for NPY, the Y<sub>2</sub> receptor is thought to mediate several important central activities such as memory retention. The Y<sub>2</sub> receptor can effectively bind long C-terminal fragments, in which the critical region for receptor recognition is the C-terminal hexapeptide. By comparing IC<sub>50</sub> values of a series of analogs ([Xaa<sup>11</sup>]NPY(11-36), [Xaa<sup>12</sup>]NPY(12-36) and [Xaa<sup>13</sup>]NPY(13-36)) in binding assays, we found, in the present study, that removal of residue 11 caused a significant decrease in the binding affinity for the Y<sub>2</sub> receptor. Acetylation or succinylation of the α-amino group of [Xaa<sup>12</sup>]NPY(12-36) largely increased the binding affinity without any exceptions. Upon such modification, the binding affinity returned to a level similar to that of [Xaa<sup>11</sup>]NPY(11-36), an indication that the region around the peptide bond between residues 11 and 12 interacts directly with the receptor. Next, we investigated whether or not the affinity of the NPY analogs for binding to the Y<sub>2</sub> receptor is affected by cross-linking of a dimer. By oxidation of an analog of NPY(12-36), in which Ala-12 and Ile-31 were substituted with Cys residues, we prepared parallel and antiparallel dimers. The IC<sub>50</sub> value of the antiparallel dimer was of the same order as that of the reduced molecule, whereas the binding affinity was greatly decreased by the formation of parallel dimer.

## 625.16

**IDENTIFICATION OF RESIDUES INVOLVED IN THE BINDING OF THE ANTAGONIST BIBP3226 TO THE HUMAN Y1 RECEPTOR.** J.A. Salon\*, J.A. Tamm, C. Hou, P. Du, P.J.-J. Vaysse, B. Dowling, Y. Shifman, M.W. Walker, N. Adham, N. Boyle, D. Dhanoa, W. Cui, T.A. Branchek, R.L. Weinshank and C. Gluchowski. Synaptic Pharmaceutical Corporation, Paramus, NJ 07652.

The recently reported compound BIBP3226 is a non-peptide antagonist of neuropeptide Y (NPY) with high affinity and selectivity for Y1 over Y2 receptors. The compound was designed to mimic the C-terminus of the agonist NPY. To investigate antagonist/receptor interactions we performed site-directed mutagenesis on the human Y1 receptor and compared the binding affinity of BIBP3226 with that of NPY by measuring displacement of [<sup>125</sup>I]-NPY. Mutation of residues Y47, F173, Y196, Y211, Q219, F282, F286 and H306 in the human Y1 receptor was found to decrease the binding affinity for BIBP3226 by 5 to 25-fold. Computer modeling and docking studies suggest that these residues may interact with the ligand through hydrophobic or polar contacts. Mutation of five of these residues (F173, Y196, Y211, F286 and H306) had little or no effect on NPY binding affinity indicating that these amino acids were selectively interacting with the antagonist. Conversely, mutation of several residues important for NPY binding (Y100, D190 and Y192) had little effect on antagonist binding affinity. Taken together, the data suggest that certain residues are common to the NPY and BIBP3226 binding sites, while other residues are used exclusively by the antagonist. These findings support the premise that this antagonist acts, in part, by competing for specific residues important for agonist attachment. (Note: BIBP3226 was synthesized and supplied by Ciba-Geigy Limited, Basel, Switzerland.)

## 625.17

NPY, PYY, OR PP ALTER cAMP AND  $Ca^{2+}$  IN CELLS EXPRESSING CLONED HUMAN Y2 OR Y4 RECEPTORS. P.J. Vaysses\*, M.W. Walker, C. Gerald, J.A. Bard, R.L. Weinshank and T.A. Branchek. Synaptic Pharmaceutical Corporation, Paramus, NJ 07652.

Pancreatic polypeptide family members neuropeptide Y (NPY), peptide YY (PYY) and pancreatic polypeptide (PP) function as neurotransmitters or hormones through activation of membrane bound receptors. At least 5 receptor subtypes are proposed: Y1 (previously cloned from vertebrates), Y2, Y3, PP, and Y4-like "feeding" receptors. We recently isolated human cDNA for two novel Y-type receptors and classified them as Y2 and Y4 subtypes based on peptide binding profiles of transiently transfected COS-7 preparations (Gerald et al., Bard et al., Walker et al., Soc. Neurosci. Abst. 1995). Y2 receptor function was tested using 293 cells stably transfected with Y2 cDNA (293-Y2). Forskolin-stimulated [cAMP] detected by RIA decreased  $\geq 70\%$  when 293-Y2 cells were incubated with human PYY (EC<sub>50</sub> = 0.31 nM) or NPY (EC<sub>50</sub> = 0.25 nM), but not [Pro34]-PYY (up to 100 nM). Y2-selective analogs were potent, including the cyclic disulfide analog C2-NPY (EC<sub>50</sub> = 0.14 nM) plus C-terminal fragments PYY 13-36 (EC<sub>50</sub> = 0.13 nM) and NPY20-36 (EC<sub>50</sub> = 3.2 nM). Intracellular free [ $Ca^{2+}$ ] detected by Fura-2 fluorescence increased in 293-Y2 cells incubated with human PYY: Emax = 41 nM, EC<sub>50</sub> = 39 nM. [cAMP] reduction is consistent with reports for pharmacologically defined Y2 receptors;  $Ca^{2+}$  mobilization is less often noted. Y4 receptor function was tested using LMtk- cells stably transfected with Y4 cDNA (LM-Y4). Forskolin-stimulated [cAMP] decreased  $\geq 65\%$  when LM-Y4 cells were incubated with human PP (EC<sub>50</sub> = 0.09 nM) or PYY analogs (EC<sub>50</sub> = 47 nM for PYY, 1.1 nM for [Pro34]-PYY) or NPY (EC<sub>50</sub> = 20 nM). Intracellular free [ $Ca^{2+}$ ] increased when LM-Y4 cells were incubated with human PP: Emax = 334 nM, EC<sub>50</sub> = 35 nM. Y4 preference for PP > PYY, NPY resembles that for pharmacologically defined PP receptors and supports a role for cAMP and  $Ca^{2+}$  in PP-mediated cell signaling. We propose the name "Y4" to account for activity of all PP family members and to extend the Y-type nomenclature.

## 625.19

EXPRESSION OF VIP-R mRNA IN MURINE LYMPHOCYTES. M.C. Johnson, B. Wortham, R.J. McCormack, D. Ganca\*, Dept. of Biological Sciences, Rutgers University, Newark, NJ 07102.

Our laboratory has previously reported that the neuropeptide vasoactive intestinal peptide (VIP) inhibits IL-2 and IL-4 production in activated murine T lymphocytes. This response appears to be mediated through specific receptors since structurally-related peptides such as secretin and glucagon have little or no activity. To determine whether the inhibitory effect of VIP on cytokine production by T cells is indeed mediated through specific receptors, we investigated the expression of VIP-R mRNA in murine lymphocytes by RT-PCR. Specific primers were designed based upon the published rat lung and human intestine VIP-R cDNA sequences. RT-PCR was performed on both unstimulated and stimulated murine Balb/c spleen cell cultures and the predicted 453 bp fragment was amplified. The 453 bp fragment has also been amplified from murine brain, lung, highly purified CD4<sup>+</sup> T cells, and thymocytes. The specificity of these fragments has been confirmed by Southern blots. The amplified fragment from unstimulated and stimulated spleen cells was cloned and sequenced. The murine VIP-R cDNA sequence, which spans the IV, V, VI, and VII transmembrane domains of the receptor, shares greater homology with the rat lung than with the human intestine VIP-R cDNA sequence. Quantitative PCR needs to be performed to investigate the possible upregulation of VIP-R expression in murine lymphocytes. These preliminary results indicate that VIP-R mRNA is expressed in murine lymphoid organs, as well as brain and lung tissues.

## 625.18

CLONING OF RECEPTOR GENES THAT SHARE IDENTITY WITH PEPTIDE BINDING GPCR GENES. A. Marchese, T. Nguyen, B. P. Jung, Y. Shen, V. R. Saldivia, P. Seeman\*, S. R. George, B. F. O'Dowd, Addiction Research Foundation, Dept. of Pharmacology, Univ. of Toronto, Toronto, ON, M5S 1A8.

G protein-coupled receptors (GPCR) are involved in a variety of brain mechanisms, including reward, pain, mood and learning. We have cloned 11 human genes for which the endogenous ligands are unknown (GPR1 to 10 and APJ). These genes share identity to known peptide binding GPCRs (Genomics 23: 609; DNA and Cell Biol. 14: 25; Gene 136: 355). Gene GPR1 is abundantly expressed in hippocampus in human but not in rat, and is expressed in rat heart, kidney and spleen. Primers designed based on sequences of GPR1 were used to search for related genes, and from PCR amplification of human DNA we isolated 4 novel genes (including GPR14) and each shares identity with genes encoding peptide binding GPCRs. GPR14 shares significant identity to opioid and somatostatin receptors (41% in TM domains). Also, in our search for novel opioid receptors we used primers based on the sequences encoding the opioid receptor genes and the related genes, GPR7 and 8, to amplify human DNA. This resulted in the isolation of 2 genes encoding novel receptors and each shares greatest identity with the ATP receptor. We also designed primers based on the sequences of  $\mu$ ,  $\delta$  and  $\kappa$  opioid receptors, contained on a single exon (encoding TM2 to TM3), to amplify human genomic DNA. This PCR resulted in the isolation of 2 other novel genes. One of these genes contained sequence identical to an EST fragment (GenBank Accession Number: F03704) isolated from human brain and which showed high identity to the ATP receptor. Ultimately, it is hoped that the discovery of novel GPCR genes and their categorization into distinct families of receptors will advance our understanding of the complex actions of peptide binding receptors.

PHARMACOLOGICAL PROFILES OF NEWLY SYNTHESIZED NEUROTENSIN(8-13) ANALOGS. B.M. Cusack, D. McCormick, C-T Phung, R. Perry, Y-P Pang, A. Fauq, and E. Richelson\*, Neuropsychopharmacology Research, Mayo Foundation for Medical Education and Research, Mayo Clinic, Jacksonville, FL 32224.

We recently reported results with 33 newly synthesized NT(8-13) analogs at both the human and rat neurotensin receptors expressed in CHO cells. We derived equilibrium dissociation constants ( $K_d$ 's) and EC<sub>50</sub>'s for phosphatidylinositol turnover. We found that side chain length at position 9 and steric bulk/pi electron density at position 11 were important for binding and functional NT parameters. We have synthesized 11 additional compounds, which explore further permutations of these variables. Specifically, by increasing side chain length at position 8 and 9 (with homoarginine), we obtained a  $K_d$  of  $0.27 \pm 0.05$  nM (geo. mean  $\pm$  SEM). For another compound, we shortened the position 9 side chain by substituting diaminopropionic acid for this residue. The  $K_d$  derived for this analog was  $8.6 \pm 0.8$  nM, which was a decrease in binding affinity over our previously synthesized compound with diaminobutyric acid at position 9 ( $K_d = 0.27$ ). For position 11 substitutions, we further explored steric bulk effects by substitution with both D- and L-forms of 3,1- $\beta$  naphthylalanine and also the conformationally constrained analog of phenylalanine, 1,2,3,4-tetrahydroisoquinoline-3-carboxylic acid. The results with these 11 compounds present further evidence of the importance of side chain length at position 8 and 9 as well as steric bulk effects at position 11. [Support: Mayo Foundation & USPHS Grant MH27692 to E.R.]

## NEUROTRANSMITTER RELEASE

## 626.1

EFFECT OF HALOPERIDOL ON NEUROTENSIN RELEASE IN THE RAT BASAL GANGLIA: A MICRODIALYSIS STUDY

J.M. Radke, M.D. Stipetic\*, M.J. Owens and C.B. Nemeroff, Dept. Psychiat. & Behav. Sci., Emory Univ. Sch. of Med., Atlanta GA.

Neurotensin (NT) is an endogenous CNS tridecapeptide which has been implicated in the mechanism of action of antipsychotic drugs. Administration of haloperidol has repeatedly been shown to increase both NT concentrations and NT mRNA expression in the rat striatum and nucleus accumbens. The purpose of these experiments was to ascertain the effect of haloperidol on NT release using *in vivo* microdialysis. This method has been used extensively to measure neurotransmitter release, however few have examined NT release due to the low concentrations found in the brain. Using a 'loop' designed probe, coupled with a solid phase radioimmunoassay, we have successfully measured both striatal (4-5 pgrams/25 min sample) and nucleus accumbens (1-2 pgrams/sample) NT release. Both regions showed 2-3 fold increases in NT release following depolarizing concentrations of potassium and these increases were shown to be calcium dependent. Following these studies, we examined whether the acute administration of haloperidol alters NT release. No differences in NT release were observed over a 30 hour period in control animals nor were changes in NT release observed following the acute administration of haloperidol (2.0 mg/kg). These results indicate that acute haloperidol administration has no effect on the basal release of neurotensin in the rat striatum. Future work analyzing the effects of chronic administration of haloperidol and other antipsychotics on NT release in both the nucleus accumbens and the striatum are in progress.

## 626.2

STRUCTURE SPECIFIC DETECTION OF NEUROTENSIN IN THE RAT BRAIN BY UTILIZING MICRODIALYSIS AND MICRO-ELECTROSPRAY MASS SPECTROMETRY. P.E. Andrén\* and R.M. Caprioli, Analytical Chemistry Ctr., Dept. of Biochemistry & Molecular Biology, Univ. of Texas Medical School, 6431 Fannin, Houston TX 77030

The structure specific molecular detection of the endogenous neuropeptide neurotensin has been accomplished in *in vivo* microdialysates and brain tissue homogenates by using capillary liquid chromatography (LC) and mass spectrometry. Microdialysis probes implanted in specific brain regions of unanesthetized freely moving rats were used to collect samples from brain extracellular fluids. Micro-electrospray/tandem mass spectrometry (micro-ES MS/MS) was used to achieve the molecular weight/specific identification of the neurotensin with a sensitivity in the attomole/ $\mu$ L range. Basal levels of neurotensin in microdialysates were approximately similar in hypothalamus ( $73 \pm 12$  attomoles/ $10 \mu$ L) and the globus pallidus/ventral pallidum region ( $84 \pm 27$  attomoles/ $10 \mu$ L). A 7-8 fold increase in neurotensin in microdialysates from these regions of the brain was observed after KCl-stimulation.

In other experiments, rat brain tissue was homogenized and purified using Sep-Pak columns and HPLC, and neurotensin was detected from striatum, globus pallidus and substantia nigra by subsequent analysis by capillary LC/micro-ES MS/MS.

The present study shows that the mass and molecular structure specific detection of neurotensin by mass spectrometry can be used to measure baseline and stimulated release in *in vivo* microdialysates in different brain regions.

## 626.3

**CO-INDUCTION OF c-JUN AND NEUROTENSIN mRNAs IN THE DORSOLATERAL STRIATUM FOLLOWING HALOPERIDOL TREATMENT** R. J. Harrison<sup>1,2</sup>, P. R. Dobner<sup>2</sup> and R. H. Melloni Jr<sup>1</sup> <sup>1</sup>Behav. Neurosci. Prog., Dept. Psych., and <sup>2</sup>Dept. of Mol. Genetics and Micro. and Prog. in Neurosci. Univ. of Mass. Med. Ctr., Worcester, MA 01655. The dopamine (DA), D2 receptor antagonist, haloperidol causes a transient induction of neurotensin/neuromedin N (NT/N) mRNA in the dorsolateral striatum (DLS). We have previously detailed the AP-1 dependent activation of the NT/N gene in neuroendocrine PC12 cells and the potent ability of c-Jun to drive NT/N gene expression. Neuroleptic blockade of DA receptors causes induction of c-Jun, c-Fos and Jun B in the DLS. c-Fos mRNA expression has been co-localized to striatal neurons expressing NT/N mRNA following haloperidol, and antisense c-Fos oligonucleotides decrease NT/N mRNA induction by haloperidol in this region suggesting a functional correlation. c-Fos, however is unable to bind to the AP-1 elements within the NT/N gene *cis*-regulatory region in the absence of a dimerization partner. We report here on the induction of c-Jun in the DLS following DA D2 receptor blockade by haloperidol. The c-Jun hybridization signal was restricted to the DLS and paralleled the induction of NT/N mRNA in this region. c-Jun hybridization signals were also prominent in other regions of the CNS where NT/N mRNA expression is observed. Taken together with our previous functional studies in PC12 cells and additional antisense data presented here, the temporal and spatial localization c-Jun mRNA in the DLS following haloperidol blockade of DA receptors suggests that c-Jun serves as a key regulator of NT/N gene expression in the CNS.

## 626.5

**THE DISCOVERY AND STRUCTURE ACTIVITY RELATIONSHIP OF A NOVEL SERIES OF SMALL MOLECULE NEUROTENSIN ANTAGONISTS.** S. Johnson, S. Kesten, H. Akunne, D. Wustrow, T. Pugsley, T. Heffner, L. Wise\* Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Company; Ann Arbor MI, 48105

Neurotensin (NT) is a tridecapeptide thought to modulate dopamine neurotransmission in the CNS. As part of a program to identify novel nonpeptide ligand for the NT receptor we carried out a high volume screen against the Parke-Davis compound library. Structure activity relationship (SAR) studies on an initial lead will be presented. These studies led to the discovery of PD 156425 which has affinity for the NT receptor in an immature mouse brain preparation (K<sub>i</sub> = 42 nM). It has also been shown to be an antagonist *in vitro*, inhibiting the effects of NT on the mobilization of calcium in HT-29 cells. SAR studies indicate that the carboxylic acid and the appropriately substituted phenone residues are required for compounds of this type to exhibit good binding to the NT receptor

PD 156425

## 626.7

**KINDLING INDUCED CHANGES IN mRNA EXPRESSION OF PRO-TRH AND PROHORMONE CONVERTASES IN DENTATE GYRUS** L. P. Pu<sup>1</sup> and I.B. Rosen<sup>2</sup>, <sup>1</sup>LDN, NICHD, <sup>2</sup>Biol. Psychiatry Br., NIMH, NIH, Bethesda, MD 20892.

The mRNA encoding several pro-neuropeptides and the neuropeptides themselves are dramatically increased in the granule cells of the dentate gyrus following an amygdala kindled seizure. It is not known whether the enzymes related to the maturation of these neuropeptides are also altered after kindling. The prohormone convertases PC1 and PC2 have been shown to be able to process several pro-neuropeptides including pro-TRH at paired-basic residue cleavage sites, a key step involved in neuropeptide maturation. In this study, we have examined the co-regulation of expression of PC1 and PC2 mRNAs with pro-TRH mRNA in the dentate gyrus after amygdala kindling. Rats were kindled daily until a fully generalized (stage 5) seizure was elicited. The rats were sacrificed either 4 or 24 hrs following the last seizure. *In situ* hybridization using cRNA probes for PC1, PC2 and pro-TRH mRNAs was performed on brain sections containing the dentate gyrus. High levels of pro-TRH mRNA were expressed in the dentate gyrus 4 hrs after the seizure, while at 24 hrs they were diminished but still elevated compared to non-kindled sham controls. PC1 mRNA expression was also increased 4 hrs after the seizure in the dentate gyrus, although it was below control levels at 24 hrs. Similarly, an increase in PC2 mRNA expression levels was observed at 4 hrs, but was significantly decreased at 24 hrs following the seizure. These data demonstrate that in the dentate gyrus, there was co-ordinate expression of prohormone convertase mRNAs with pro-neuropeptide mRNA expression, suggesting that these enzymes play a role in pro-TRH processing *in vivo*.

## 626.4

**FUNCTIONAL ACTIVITY OF C-TERMINAL CYCLIC NEUROTENSIN FRAGMENT ANALOGS.** Hyacinth C. Akunne\*, Kim T. Zoski, Selina Darling, Andrea M. Sefler, Wayne L. Cody, Thomas A. Pugsley, <sup>1</sup>Psychiatric Disorders Therapeutics and Department of Chemistry, Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Company, 2800 Plymouth Road, Ann Arbor, MI 48105.

Neurotensin (NT, -pGlu-Leu-Tyr-Glu-Asn-Lys-Pro-Arg-Arg-Pro-Tyr-Ileu-Leu) is a tridecapeptide that displays a wide spectrum of biological actions both in the central and peripheral nervous systems of different mammalian species. Identification of functionally active and metabolically stable small molecule peptides or non-peptides has been difficult. Cyclic derivatives of a hexapeptide NT(8-13) (N<sup>α</sup>MeArg-Lys-Pro-Trp-Leu-Leu) which is active upon systemic administration and was metabolically stable were synthesized by a combination of solution and solid-phase peptide synthetic methodologies. As reported previously, several analogs had nanomolar binding affinities both in newborn (10-day-old) mouse brain and HT-29 (human colonic adenocarcinoma) cell membrane preparations. The major signal transduction pathway for NT receptors is the G-protein dependent stimulation of phospholipase C, leading to the mobilization of intracellular free calcium, [Ca<sup>2+</sup>]<sub>i</sub>. We tested agonist or antagonist effects of these analogs in this *in vitro* assay using the Ca<sup>2+</sup>-sensitive dye fura-2/AM for quantitative measurement of the cytosolic free Ca<sup>2+</sup> concentration in HT-29 cells. Of most interest were PD 149966, PD 151482, PD 151149 which had respective K<sub>i</sub> values of 16, 28 and 83 nM in mouse brain membranes and 194, 3499 and 4175 nM in the HT-29 cell membranes, respectively. In the functional assay, PD 149966 and PD 151482 exhibited agonist effects with EC<sub>50</sub> values of 130 nM and 20 μM, respectively. PD 151149 exhibited an antagonist profile in blocking the NT-induced increase in intracellular Ca<sup>2+</sup> mobilized, with an IC<sub>50</sub> of 1700 nM. The present findings indicate that small molecule cyclic analogs with functional activities can be designed which might be of potential use in the treatment of schizophrenia and possibly other disorders.

## 626.6

**NEURAL REGULATION OF TRH BIOSYNTHESIS.**

R.M.Urbe, L.Pérez-Martínez, M.L.Covarrubias, B.O.Gómez, J.L.Charli and P. Joseph-Bravo, Instituto de Biotecnología, UNAM (A.P. 510-3, Cuernavaca Mor., Mexico 62271)

Thyrotropin releasing hormone (TRH) controls the biosynthesis and release of thyrotropin and prolactin from the hypophysis. TRH mRNA levels are negatively controlled by thyroid hormones in the paraventricular hypothalamic nucleus and increased, in a fast and transient manner (30-60min), in conditions where TRH release is stimulated, such as cold exposure or suckling (Neuroendocrinology 58,140,1993). In order to get insight if TRH mRNA increase is due to transsynaptic stimulation we studied the effect of second messenger pathways' stimulation on primary cell culture of rat hypothalamus. Embryonic hypothalami (17 day gestation) were dispersed with trypsin-DNase and incubated in complete DMEM-FBS for 18 days. Culture conditions have been optimized to express TRH mRNA and TRH utilizing autologous conditioning medium. Cultures were treated with phorbol ester (TPA, 100 nM) or dibutyl cAMP (1 mM) for various times. TRH mRNA quantified by Northern blot. Levels of TRH-mRNA raised from the 1st hr of dBcAMP or 2h of TPA treatment. An increase was still observed at 24h with both drugs. These results provide evidence for a neural regulation of TRH biosynthesis. *Financed by DGAPA (IN206094) and CONACYT (0776 N9110).*

## 626.8

**NEUROPEPTIDE Y BIOSYNTHESIS AND METABOLISM IN THE HIPPOCAMPAL MOSSY FIBER SYSTEM** J.B. McCarthy\* and J.D. White<sup>1</sup> Dept. Neurobiology & Behavior, SUNY Stony Brook, Stony Brook, NY 11974; <sup>1</sup>Trophix Pharmaceuticals, Inc., S. Plainfield, NJ 07080

As a first step in understanding the physiological role(s) for neuropeptide Y in specific projection systems in the CNS, neuropeptide Y biosynthesis was investigated in the hippocampal granule cell mossy fiber projection. Previous studies demonstrated increased hippocampal NPY gene expression in response to both recurrent and single seizure episodes. To study NPY biosynthesis and transport in the mossy fiber system, male Sprague Dawley rats were subjected to a single seizure with pentylenetetrazole (57 mg/kg ip). To radiolabel newly synthesized NPY, <sup>35</sup>S-methionine was delivered unilaterally to the dentate gyrus at a rate of 1 μl/hr with osmotic mini-pumps via an indwelling cannula. *In vivo* radiolabeling was performed at a post-seizure time point coincident with maximal preproNPY mRNA expression. Following labeling, the ipsilateral hippocampus was dissected and sliced (500 μm) with a McIlwain tissue chopper. CA3 subfields were then collected from each slice and the resulting tissue pool was homogenized in acid extraction buffer. This homogenate was then subjected to immuno-affinity purification followed by sequential reverse phase HPLC purification. The resulting radio-chemical purification of bona fide NPY from the CA3 subfield supports the hypothesis that there is a novel post-seizure expression of NPY in granule cells, and that this peptide is transported to mossy fiber boutons. Current experiments are examining the *in vitro* metabolism of NPY by synaptosome peptidases to assess the possibility that bioactive fragments of NPY can be generated extracellularly following release from the mossy fibers.

## 626.9

HUMAN FETAL BRAIN CELLS IN AGGREGATE CULTURE: A MODEL SYSTEM TO STUDY REGULATORY PROCESSES OF NEUROPEPTIDE Y (NPY) PRODUCING NEURONS. N. Aguila-Mansilla, G. Kozłowski\* and A. Barnea, Dept. of OB/GYN, UT Southwestern, Dallas, TX 75235-9032.

NPY, a 36 amino acid peptide, is one of the most abundant neuropeptides in the brain and it has been implicated in a wide range of brain functions including mentation. The aim of this study was to establish a culture system of human fetal brain cells expressing NPY in a regulated manner. NPY production in response to forskolin (For) and phorbol 12-myristate 13-acetate (PMA) was taken as a criterion for regulated expression of NPY. Aggregates were formed from dissociated cells derived from the cerebral hemispheres of human fetuses (12-19 wks gestation) by constant rotation and were maintained in serum-free medium. A 24 h exposure to 10  $\mu$ M For + 20 nM PMA led to a 3-5-fold increase in NPY content of the cultures, most (80-90 %) of which was secreted into the medium. The latter consisted of two substances differing in size: one corresponding to proNPY and the other to NPY. Thus, For+PMA led to an increased production of NPY. Exposure to PMA alone led to an increase in NPY production comparable to that seen after For+PMA; this effect of PMA was dose-dependent. In contrast, For alone did not induce NPY production. Eliminating the dividing cells from the aggregates totally abolished For+PMA induction of NPY production. Thus, expression of the NPY neurons in this culture system is a regulated process: activation of the protein kinase C pathway enhances NPY production and input from glial cells is involved. These results support the proposition that this culture system is an excellent model to study regulatory processes of the human fetal NPY neuron.

## 626.10

NEUROPEPTIDE Y (NPY) GENE EXPRESSION AND INTRACELLULAR TRANSDUCTION MECHANISMS IN PHEOCHROMOCYTOMA (PC12) CELLS. X.L. Chen\*, S.P. Han, M. Weidman, Y.M. Wu, L. Naes and T.C. Westfall, Dept. of Pharmacol. and Physiol. Sci., Saint Louis Univ. Health Sciences Center, St. Louis, MO 63104.

NPY is a vasoconstrictor peptide primarily co-synthesized and co-released with catecholamine from sympathetic nerve terminals and the adrenal medulla. NPY is thought to play an important role in blood pressure regulation and may participate in development and/or maintenance of hypertension. We have previously used rat pheochromocytoma (PC12) cells differentiated with NGF or dexamethasone as model systems of peripheral sympathetic neurons or the adrenal medulla cells, respectively. In the present study, we examined the mechanisms mediating NPY gene expression in PC12 cells using Northern hybridization techniques. Depolarization of NGF-differentiated PC12 cells with nicotine produced a concentration-dependent (10-300  $\mu$ M) and time dependent (4-48 hours) increase in NPY mRNA abundance. In contrast, the increase in NPY mRNA abundance in undifferentiated PC12 cells was much smaller. Nifedipine, attenuated nicotine-induced NPY gene expression in NGF-differentiated PC12 cells, suggesting that the response is mediated by L-type calcium channel. Additional experiments have examined the intracellular transduction mechanisms mediating NPY gene expression in PC12 cells. Calmidazolium attenuated NPY gene expression response to nicotine suggesting that calcium/calmodulin-dependent protein kinases may be involved in mediating NPY gene expression. Both forskolin and PMA produced an increase in NPY mRNA abundance and had a synergistic effect on NPY gene expression. The results suggest that multiple protein kinase pathways are involved in regulating NPY gene expression in PC12 cells. (Supported by NIH HL-26319 and HL-35202).

## 626.11

EXPRESSION, SECRETION AND PLASTICITY OF ENDOGENOUS PITUITARY ADENYLATE CYCLASE ACTIVATING POLYPEPTIDES (PACAP) IN RAT SUPERIOR CERVICAL GANGLION NEURONS. C. A. Brandenburg\*, K. M. Braas and V. May, Department of Anatomy and Neurobiology, University of Vermont College of Medicine, Burlington, VT 05405.

Neurons of the superior cervical ganglion (SCG) express a wide variety of neuropeptides as well as classical neurotransmitters, and the specific complement of signaling molecules present in individual cells depends on developmental and environmental cues. This phenomenon contributes to the neurophenotypic plasticity and functional diversity of the nervous system. Many SCG target tissues respond to PACAP27 and PACAP38, members of the VIP/secretin/glucagon family of bioactive peptides. The current studies examined whether PACAP peptides are expressed by rat SCG. Endogenous PACAP38 and PACAP27 were identified in adult, neonatal and cultured SCG neurons. PACAP38 levels were approximately 5 fmol/adult SCG, 2 fmol/neonatal SCG and 2 fmol/10<sup>4</sup> cultured neurons; comparable PACAP27 levels were identified. Authentic peptide immunoreactivity was verified by coelution with synthetic PACAP in reversed phase HPLC. Reverse transcription PCR and sequence-specific hybridization revealed PACAP mRNA in adult, neonatal and cultured SCG neurons. Endogenous neuronal PACAP peptides must be released to function as important signaling molecules and influence target tissues. Assay of conditioned medium established basal PACAP38 secretion from cultured SCG neurons. Furthermore, depolarization with 40 mM potassium stimulated the secretory rate approximately 10-fold; cellular peptide content and PACAP mRNA expression were also increased. Axotomized and decentralized adult SCG exhibited a dramatic over 40-fold increase in PACAP38 content. These studies identify PACAPs as important peptides contributing to the functional diversity and phenotypic plasticity of sympathetic neurons. Supported by HD27468 and NS01636 (VM) and AHA94015540 (KMB).

DELAYED HIGH POTASSIUM-EVOKED RELEASE OF GLUTATHIONE AND  $\gamma$ -GLUTAMYL-GLUTAMATE FROM RAT HIPPOCAMPAL SLICES Sandberg, M., Li, X., Orwar, O. and Revesjö, C. Institute of Anatomy and Cellbiology, Univ. of Gothenburg, S-413 90 Göteborg, SWEDEN

The potassium-evoked release of amino acids and  $\gamma$ -glutamyl di- and tripeptides was studied from rat hippocampal slices. The concentrations of amino acids and peptides in the incubation media were determined by precolumn derivatization with OPA followed by reversed phase HPLC and fluorescence detection. The release of glutathione (analyzed as GSH) and  $\gamma$ -glutamyl-glutamate was delayed in comparison to glutamate release. Preincubation with acivicin, an enzyme blocker of  $\gamma$ -glutamyl transpeptidase, inhibited the release of  $\gamma$ -glutamyl-glutamate and increased the release of GSH while the release of glutamate was unaffected. Our results imply: i) delayed release of GSH from slices may be coupled to prior reuptake of released glutamate. ii)  $\gamma$ -glutamyl transpeptidase may utilize a fraction of released glutamate as an acceptor amino acid during situations with high extracellular glutamate concentrations. iii)  $\gamma$ -glutamyl transpeptidase does not appear to contribute to uptake of glutamate even when glutamate-carriers are reversed by high potassium.

## 626.14

LIPOLYSACCHARIDE (LPS) FACILITATES RELEASE OF CGRP FROM THE RAT TRACHEA X.-Y. HUA\*, P. CHEN & T.L. YAKSH Dept. of Anesthesiology, Univ. of California, San Diego, CA 92093-0818, USA.

LPS, an endotoxin, produces pain behavior, inflammation and changes of immune function. Many of these effects of LPS are secondary to the production of cytokines. LPS and cytokines upregulate expression of neuropeptide such as substance P and its receptor. In the present study, we investigate the effect of LPS treatment on tracheal calcitonin gene-related peptide (CGRP)/neurokinin A (NKA) release as well as changes of the peptide content in the trachea and vagus nerve. Application of capsaicin 0.1  $\mu$ M to an intralumenally perfused *in vitro* rat trachea induced an increase in CGRP outflow ( $\Delta$ CGRP 131 $\pm$ 24 fmol/fraction, n=10), which was significantly enhanced in the tracheas from the LPS-treated rats (0.3 mg/kg iv or 0.75 mg/kg ip, -5hrs) ( $\Delta$ CGRP 295 $\pm$ 59 fmol/fraction, n=8, P<0.05). This enhancement was blocked by IL-1 $\beta$  antagonist, Lys-D-Pro-Thr, at concentration of 10  $\mu$ M ( $\Delta$ CGRP 137 $\pm$ 12 fmol/fraction, n=4). LPS 10  $\mu$ g/ml added directly to tracheal perfusates did not induce any release of CGRP or NKA. CGRP level in the vagus nerve, but not in the trachea, was significantly increased by LPS treatment (LPS vs Saline: 623 $\pm$ 94 vs 407 $\pm$ 4 CGRP fmol/mg protein, n=5, P<0.05). In contrast, neither NKA release caused by capsaicin nor NKA level in trachea or vagus nerve was altered by LPS treatment at 5 hrs, although LPS treatment at 2 hrs caused a moderate but significant reduction of NKA content in the rat trachea (LPS vs Saline: 4.1 $\pm$ 0.2 vs 6.1 $\pm$ 0.5 NKA fmol/mg tissue, n=5, P<0.05). These data suggest that LPS may not have direct stimulatory effect on sensory neurons, but sensitize CGRP-containing sensory nerves via a mechanism requiring production of cytokines such as IL-1 $\beta$ . LPS may have a different interaction with NKA processing system as compared with CGRP. (This work was supported by NIH R29 HL 50403, X.-Y. H.)

## 626.15

CHARACTERIZATION OF SUBSTANCE P RELEASE FROM THE INTERMEDIATE AREA OF RAT THORACIC SPINAL CORD. L.Yano<sup>1</sup>, N.D.Thomas<sup>2</sup> and C.J.Helke<sup>1,3</sup>. <sup>1</sup>Dept. of Pharmacol. & <sup>3</sup>Neurosci. Program, Uniformed Services Univ. of the Health Sci., Bethesda, MD 20814; <sup>2</sup> NIMH, Bethesda, MD 20892.

Substance P (SP) coexists with serotonin (5-HT), neurokinin A (NKA) and thyrotropin-releasing hormone (TRH) in nerve terminals of the intermediolateral cell column (IML), site of sympathetic preganglionic neurons. Neither the depolarization-induced release of SP nor the regulation of SP release has been studied in this system. Basal and K<sup>+</sup>-evoked release of SP from the microdissected intermediate area (includes the IML) of the rat thoracic spinal cord and the regulation of SP release by 5-HT, NKA and TRH were studied using an *in vitro* superfusion system. Elevated K<sup>+</sup> evoked a concentration- and extracellular Ca<sup>2+</sup>-dependent release of SP. In rats pretreated with serotonergic neurotoxin, 5,7-dihydroxytryptamine (5,7-DHT), both SP content and the absolute amount of SP released from the intermediate area were decreased. However, the fraction of the remaining tissue content of SP released by K<sup>+</sup>-depolarization was not changed subsequent to 5,7-DHT treatment. Moreover, 5-HT, 5-HT<sub>1B</sub> agonists (CGS-12066B and RU 24969) and a 5-HT<sub>2</sub> agonist (2-methyl-5-HT) did not alter the K<sup>+</sup>-evoked release of SP. A neurokinin-1 (NK<sub>1</sub>) antagonist (GR 82334) dose-dependently (10<sup>-9</sup>-10<sup>-7</sup> M) increased the K<sup>+</sup>-stimulated release of SP suggesting the presence of presynaptic inhibitory NK<sub>1</sub> autoreceptors. However, NK<sub>1</sub> agonist GR 73632 (10<sup>-9</sup>-10<sup>-6</sup> M) increased both the basal and K<sup>+</sup>-stimulated release of SP and the excitatory effects were not blocked by the NK<sub>1</sub> antagonist. Neither NKA, a NK<sub>2</sub> agonist (GR 64349) nor a TRH analog (MK-771) changed the K<sup>+</sup>-evoked release of SP. These data demonstrate the depolarization-induced release of SP and the release (at least in part) comes from serotonergic nerve terminals in the intermediate area of the rat thoracic spinal cord. Although 5-HT, NKA and TRH coexist with SP in the IML, they are devoid of activity in the regulation of SP release (NIH NS24876).

## 626.17

LOCALIZATION OF PROOPOMELANOCORTIN (POMC) mRNA AND PEPTIDES IN DEVELOPING AND ADULT RAT HEART. C. Nyquist-Battie\*, C. B. Unal, S. A. Sands, B. M. Chronwall, W. R. Millington. School of Biol. Sciences, Univ. of Missouri, Kansas City, MO 64108.

$\beta$ -Endorphin,  $\alpha$ -MSH and other POMC peptides have been identified in mammalian heart. In the present study, the regional distribution of POMC mRNA and peptides, and the physiological regulation of POMC peptides were examined in adult and developing rat heart. POMC mRNA was demonstrated in atria by *in situ* hybridization. Polymerase chain reaction amplification confirmed that full-length POMC mRNA transcripts are present in atrial extracts. The distribution of POMC peptides was examined immunohistochemically using antisera against  $\alpha$ -MSH and N-acetyl- $\beta$ -endorphin, which we showed previously to be the major end-products of POMC processing in heart. Atrial myocytes, especially in the atrial appendages, contained  $\alpha$ -MSH immunoreactivity (IR) and N-acetyl- $\beta$ -endorphin-IR. Ventricular myocytes and cardiac nerves were not stained. Atrial natriuretic factor (ANF)-IR was similarly distributed. During renovascular hypertension produced by constriction of the abdominal aorta,  $\alpha$ -MSH- and ANF-IR were again detectable in ventricular myocytes. Neonatal atrial and ventricular myocytes exhibited  $\alpha$ -MSH- and ANF-IR, but by postnatal day 21, ventricular staining was reduced. In correlative studies,  $\alpha$ -MSH was detectable by RIA in neonatal ventricular myocyte cultures (37  $\pm$  3.3 fmol/10<sup>5</sup>, n = 6 cultures). These results demonstrate that POMC peptides are synthesized by cardiac myocytes, and further indicate that POMC peptides and ANF are co-regulated in heart during development and pathophysiological states. (Supported by a grant-in-aid from American Heart Association-Kansas Affiliate).

## 626.16

NOVEL POTENT INHIBITORS OF N-ACETYLATED- $\alpha$ -LINKED ACIDIC DIPEPTIDASE ACTIVITY FAIL TO REDUCE EXTRACELLULAR GLUTAMATE EFFLUX OR STIMULATED RELEASE. B.A. Donzanti\*, L.E. Ross, S.L. Stetz, B.S. Slusher, R.A. Keith, D.C. Cole, P.F. Jackson. Departments of Pharmacology and Medicinal Chemistry, Zeneca Pharmaceuticals, 1800 Concord Pike, Wilmington, DE 19850-5437.

N-Acetyl-aspartyl-glutamate (NAAG) is an acidic dipeptide which has been proposed to be a storage form of synaptically available glutamate due to its neuronal metabolism by N-acetylated- $\alpha$ -linked acidic dipeptidase (NAALADase) to N-acetyl-aspartate and glutamate. To test this hypothesis *in vivo*, we developed two novel NAALADase inhibitors with low nanomolar potency and evaluated their ability, along with  $\beta$ -NAAG (a competitive but weak NAALADase inhibitor), to alter extracellular basal glutamate efflux and K<sup>+</sup>-evoked glutamate release using microdialysis. Male Sprague-Dawley rats were anesthetized with urethane (1.5 g/kg, i.p.) and stereotactically implanted with microdialysis probes into the ventroposterior thalamus or striatum. Artificial CSF was perfused at a flow rate of 2.5  $\mu$ l/min and samples were collected at 10 minute intervals. Following the collection of 3 consecutive basal samples, an inhibitor was perfused directly into the brain through the probe for 30 minutes during which 3 additional dialysate samples were obtained. Finally, at the 30-40 minute collection period, high K<sup>+</sup> (100 mM) CSF containing an inhibitor was perfused to observe local effects on evoked glutamate release. Samples were analyzed using LC-EC methods. All three NAALADase inhibitors failed to reduce basal or evoked glutamate release as predicted by the working hypothesis. In fact, all of the compounds had a tendency to elevate both basal and stimulated glutamate release for reasons which are not completely understood. Since NAALADase inhibitors do not reduce extracellular glutamate *in vivo*, it is concluded the NAAG does not serve as a major depot of synaptic glutamate under normal physiological conditions.

## 626.18

LOCALIZATION OF VASOPRESSIN mRNA AND IMMUNOREACTIVITY IN PITUITARY STALK-TRANSECTED RATS AFTER OSMOTIC STIMULATION Y.P. Loh\*, L. P. Pu, H.L. Tracer, M.A.F. Sonnemans, and F.W. Van Leeuwen. LDN, NICHD/NIH, Bethesda, MD 20892. Netherlands Institute for Brain Res, Amsterdam, The Netherlands.

The presence of vasopressin (AVP) mRNA and AVP immunoreactivity (AVPi) in pituitary cells of the neural lobe (NL) of intact and pituitary stalk-transected rats, with and without osmotic stimulation was examined. AVP mRNA was analyzed by Northern blot and *in situ* hybridization in combination with immunocytochemistry using anti-GFAP as a marker for pituitary cells. In intact rats, a 0.62 kb AVP mRNA with a truncated poly A tail was detected in the NL and increased 10-fold with 7 days of continuous salt-loading. Morphological analysis of these 7 day salt-loaded rats revealed the presence of AVP mRNA in a significant number of GFAP positive pituitary cells in the NL. Eight days after stalk-transection the NL AVP mRNA disappeared in animals given water to drink, whereas in those given 2% saline for 18 h followed by 6 h of water, a treatment repeated on 6 successive days beginning 2 days post-surgery, the 0.62 kb AVP mRNA was present. The AVP mRNA in the stalk-transected, salt-loaded rats showed an exclusive cellular distribution in the NL, indicative of localization in pituitary cells. Furthermore, immunoelectron microscopic examination showed the presence of AVPi in a subpopulation of pituitary cells 7 and 10 days after pituitary stalk transection in salt-loaded animals. In these animals, almost all AVP fibers had disappeared from the NL. These data indicate that the expression of AVP mRNA and AVP is upregulated in pituitary cells in response to osmotic stimulation.

## 627.1

PHARMACOLOGY OF VIP-MEDIATED RELEASE OF CYTOKINES FROM ASTROGLIAL CULTURES. D.E. Brenneman\*, J.M. Hill, J. Gozes, M. Fridkin and T.M. Phillips. Lab. Dev. Neurobiol., NICHD, NIH, Bethesda, MD; Dept. Clinical Biochem., Tel Aviv Univ., Israel; Weizmann Inst. Science, Rehovot, Israel; Immunochem. Lab. George Washington Univ. Med. Ctr., Washington, D.C.

The neuroprotective action of vasoactive intestinal peptide (VIP) is mediated through the release of astroglial factors. VIP treatment produces an increase in the secretion of 8 cytokines from astroglial cultures derived from rat cerebral cortex. To investigate the pharmacology of the VIP receptor(s) mediating this secretion, the actions of VIP-related substances and VIP analogues were compared. Stearyl norleucine<sub>17</sub> VIP (SNV), an analogue shown to be 100 times more effective than VIP in neuroprotection, produced secretion equivalent to that of VIP. Peptide T also increased secretion, but was 3-5 fold less efficacious than equimolar VIP. Neither SNV or peptide T had a detectable increase on cAMP. An antagonist to VIP inhibited VIP-stimulated secretion of cytokines. Reduced extracellular calcium attenuated the release of 3 of the 8 cytokines. Pituitary adenylate cyclase activating peptide (PACAP-38), a homologue peptide to VIP, produced an increase in the same cytokines as VIP; however, equimolar PACAP released 60-80% less than VIP. Except for TNF  $\alpha$ , 10 nM PACAP released the same amount of the 8 cytokines as 1 mM 8-bromo cAMP. Stimulation of microglial cultures with 0.1 nM VIP produced no detectable release of the 8 cytokines observed with astrocytes. Although cAMP-associated mechanisms can result in the release of cytokines, these data suggest VIP-stimulated secretion of cytokines from astrocytes was mediated by a receptor that was not linked to adenylate cyclase and by a process that was relatively insensitive to extracellular calcium.

## 627.2

EFFECT OF PROCTOLIN ON CONTRACTILE PROPERTIES OF CRUSTACEAN SKELETAL MUSCLE. A. Romero-Vázquez, G. Maynard-Salgado, S. Soto-Morales and C. Zúñiga\*. Institute of Neurobiology, University of Puerto Rico, Medical Sciences Campus, San Juan, PR 00901.

Mechanical activation of tonic flexor muscle fibers of the crustacean *Atya lanipes* is strictly dependent on extracellular Ca<sup>2+</sup>, even though the fibers do not generate Ca<sup>2+</sup> action potentials. Proctolin's action on this muscle results on an increase of the isometric tension in a dose- and [Ca<sup>2+</sup>]<sub>o</sub>-dependent manner, although action potentials are not induced (Romero et al., Biophys. J. 64:A24, 1993). We have been investigating the mechanisms by which proctolin enhances tension without changing the electrical properties of the muscle fiber. Using immunocytochemistry we found that proctolin-like immunoreactivity is present at the neuromuscular system in two neurons in each abdominal ganglia of the central nerve cord and in axons localized in the motor root that innervates the muscle. K<sup>+</sup>-contractures shows two phases of tension development. A phasic component that contributes mostly to the maximal tension is partially blocked by Cd<sup>2+</sup> ions (2 mM, 15 min), and is strongly dependent on [Ca<sup>2+</sup>]<sub>o</sub>. The subsequent tonic component is highly reduced in presence of the Na-Ca exchanger inhibitor 3',4'-dichlorobenzamil (DCB, 10  $\mu$ M). When exposed to DCB, the resting tension increases slowly and spontaneous contractile activity was also observed; K<sup>+</sup>-contractures were reduced and prolonged in a reversible manner. The effect of proctolin on the activity of the Na-Ca exchanger was also studied by examining Na<sup>+</sup>-withdrawal contractures ([Na<sup>+</sup>]<sub>o</sub> substituted with NMG or Li<sup>+</sup>) and K<sup>+</sup>-contractures. In both cases, the tension generated was potentiated in the presence of proctolin (1  $\mu$ M). We conclude that proctolin alters [Ca<sup>2+</sup>]<sub>o</sub> homeostatic regulatory systems in this muscle. Supported by NIH NS07464, RR 03051.

## 627.3

ACCUMBAL MODULATION OF VENTRAL PALLIDAL RESPONSES TO ACTIVATION OF THE AMYGDALA. I. Mitrovic\* and T.C. Napier. Dept. of Pharmacol., Loyola Univ. Chicago, Sch. of Med., Maywood, IL 60153.

The nucleus accumbens (NA) is a primary source of opioid and substance P (SP) input to the ventral pallidum (VP). We have previously demonstrated that VP neurons decrease firing during microiontophoresis of DAMGO (a  $\mu$  opioid receptor-selective agonist) and increase firing with SP iontophoresis. We also have shown that VP neurons respond to electrical stimulation of the basal lateral amygdala (BLA) which provides glutamatergic innervation of the VP. This study investigated the ability of DAMGO and SP to modulate BLA-evoked neuronal responses in chloral hydrate-anesthetized rats. BLA stimulation (1 Hz, 0.4-1.2mA, 0.1ms) altered firing by more than 20% of baseline in 25 of 28 VP neurons tested. Nine neurons exhibited an early-onset excitation (latency  $\leq 12$ ms, putative monosynaptic input) with a magnitude of  $651 \pm 170\%$ . Four neurons exhibited an early-onset inhibition. Late-onset (latency  $> 12$ ms, putative polysynaptic input) excitation and inhibition were observed in 10 and 7 VP neurons, respectively. Five neurons demonstrated more than one type of evoked response. Of 22 neurons evoked by the BLA stimulation and tested with iontophoresis of DAMGO, 14 (63%) were sensitive to the opioid. Of 14 BLA-evoked neurons tested with SP, 8 (57%) were sensitive to the tachykinin. Iontophoretic ejection current levels that did not alter spontaneous firing were used to study peptide effects on BLA-evoked responses. DAMGO and SP altered at least one evoked component in 93% and 88% of the neurons tested, respectively. Both peptides exhibited the most prominent effects on early-onset excitation. DAMGO potentiated this evoked component in 5 of 6 neurons tested, to  $232 \pm 86\%$  of the pre-DAMGO excitation level. SP decreased the magnitude of this component in 2 of 3 neurons, to  $62 \pm 18\%$  of pre-SP excitation. These data suggest that peptide projections from the NA may be able to alter the "gain" of the excitatory input from the BLA to the VP. Work supported by DA05255 to TCN.

## 627.5

GLUTATHIONE AS A NEUROACTIVE PEPTIDE. B. A. Pasqualotto\*<sup>1</sup>

and C. A. Shaw<sup>2,3,1</sup>. Depts. of Physiology<sup>1</sup>, Ophthalmology<sup>2</sup>, and Neuroscience Program<sup>3</sup>, University of British Columbia, Vancouver, B.C., Canada.

Glutathione is a tripeptide comprised of glutamate, cysteine, and glycine which is abundantly distributed in the CNS. In its reduced form, glutathione (GSH) plays an important role in antioxidant defense mechanisms and free radical scavenging. However, evidence is accumulating which suggests a role for GSH in signal transduction as well. Specific, high affinity [<sup>35</sup>S]GSH binding sites have been characterized previously in cultures of rat cortical astrocytes (Guo & Shaw, Mol. Brain Res. 15, 207, 1992) and in thin sections of human spinal cord (Lanius et al., Neurosci. Lett. 163, 89, 1993). GSH binding to synaptic membranes from rat cortex was assayed using [<sup>35</sup>S]GSH. Homologous competition experiments reveal the presence of two binding sites for [<sup>35</sup>S]GSH ( $K_{d1} = 693$ nM,  $K_{d2} = 10.8$  $\mu$ M). These results are in good agreement with previous experiments characterizing the binding of [<sup>3</sup>H]GSH to rat cortical synaptic membranes (Ogita & Yoneda, Neurosci. Res. 4, 486, 1987).

Cortical slices perfused with 100 $\mu$ M GSH responded with rapid depolarizing potential shifts as assayed by the cortical wedge recording preparation. Binding interactions between GSH and certain glutamate receptors have been reported previously. GSH may compete for binding at some glutamate receptor types (Ogita et al. Life Sciences, 39, 2411, 1986) and some glutamate receptor ligands may compete for GSH binding sites (Ogita & Yoneda, Neurosci. Res. 4, 486, 1987). Experiments to determine whether GSH depolarizes cortical slices through interaction with its own binding sites or through interaction with glutamate receptors are currently underway.

## 627.7

CHARACTERIZATION OF CP-212,454: A SELECTIVE, CCK-B RECEPTOR ANTAGONIST. S.H. Zorn\*, J.M. Morrone, S. McLean, D.K. Bryce, R.T. Crawford, A.A. Fossa, M.J. DePasquale and J.A. Lowe, III. Department of Neuroscience and General Pharmacology, Pfizer Inc., Central Research Division, Groton, CT 06340.

The CCK-B receptor has been implicated as a molecular target involved in the etiology of panic. CCK-B receptor antagonists have been shown to be active in anxiety models in rodents and may have anxiolytic activity in man. We have identified CP-212,454 as a selective ligand with high affinity for the CCK-B receptor (IC<sub>50</sub> = 0.45 nM). The present study was undertaken to characterize CP-212,454 by examining its effects in various assays reflective of CCK receptor function. In AR 4-2J cells where pentagastrin (PG) stimulates phosphatidylinositol (PI) turnover via CCK-B receptors, CP-212,454 was a more potent antagonist of the PG-induced response than the CCK-B receptor antagonists CI-988 and L-365,260 (IC<sub>50</sub>'s = 0.65 nM, 2.03 nM, and 4.14 nM, respectively). In this system, CP-212,454 was found to be a competitive antagonist with a pA<sub>2</sub> = 9.7 (K<sub>b</sub> = 0.18). When evaluated for functional activity at CCK-A receptors in rat pancreas, CP-212,454 only weakly antagonized CCK-stimulated PI turnover (IC<sub>50</sub> > 200 nM). CP-212,454 was also found to be an antagonist *in vivo* in three animal models of CCK-B receptor action. Thus, in the rat, CP-212,454 was a potent antagonist of PG-induced acid secretion after s.c. administration. In the conscious guinea pig, CP-212,454 administered orally blocked the CCK-4 (i.v. bolus)-induced decrease in heart rate and increase in blood pressure. And finally, in the conscious dog, orally administered CP-212,454 antagonized CCK-4 (i.v. bolus)-induced increases in both heart rate and blood pressure. Thus, CP-212,454 is a potent, selective and orally active CCK-B receptor antagonist which may prove useful in studying the pharmacology of this receptor.

## 627.4

NEUROMODULATION BY ACHE IN IDENTIFIED CHOLINERGIC AND NON-CHOLINERGIC NEURONS. B. Peretz\*, D. R. Brown and M. Srivatsan. Dept. of Physiology, Univ. of Kentucky Col. of Medicine, Lexington, KY 40536-0084.

AChE (acetylcholinesterase) is released by neurons and is found circulating within nervous tissue, yet the function of this unbound AChE is poorly understood. When superfused over neurons, AChE appears to have direct neuromodulatory actions on both vertebrate and invertebrate neurons (Webb & Greenfield, 1992; Peretz, 1994); no function has been found for this action. We report here that in *Aplysia*, AChE modulates the activity of both cholinergic (R2 and LDG1) and non-cholinergic neurons (L7, L9 and R15); three sources of AChE were used: from human (from T. Rosenberry), *Aplysia* hemolymph and eel (Sigma). In the isolated and partially desheathed abdominal ganglion, each neuron under study (impaled with two electrodes) had a distinct spike signature; all five neurons exhibited inward rectification (IR) when their membrane potentials were hyperpolarized ca 30mV below resting levels of 50-60 mV. After a latency of 15 min., AChE (ca 30 U/ml in *Aplysia* saline) elicited changes of the following in the non-cholinergic neurons, compared to control values: spike rate increased 50 to 90%, spike width increased 10-15% and IR decreased 30-40%. In cholinergic neurons, AChE elicited decreased IR, with no detectable changes in spike rate and spike broadening. After washout of AChE, the spike rate returned to control levels as did spike width. The decrease of IR persisted for at least 1 hour after washout in all five neurons. These actions of AChE were tested when the catalytic activity of AChE in the superfusate was inhibited with BW284c51, blocking the catalytic sites and a peripheral site, and edrophonium, blocking just the catalytic sites. BW284c51 blocks AChE's actions in both types of neurons, yet inhibition with edrophonium fails to block the actions. The three actions are not dependent on the enzymatic sites. Our findings show that AChE's modulatory actions are non-cholinergic and have a differential effect on cholinergic vs non-cholinergic neurons. By modulating spike width and IR, unbound AChE may be regulating synaptic input and output of non-cholinergic neurons.

## 627.6

A COMPARISON OF THE EFFECTS OF A GnRH AGONIST AND ANTAGONIST, WITH AND WITHOUT SUPPLEMENTAL ANDROGEN, ON PITUITARY GnRH RECEPTOR mRNA LEVELS. A. Robbins\*, A. Moo-Young, I. Huhtaniemi\*, C.W. Bardin and M.M. McCarthy\*. The Center for Biomedical Research, The Population Council, New York, NY 10021; \*Dept. Physiology, University of Turku, Turku, Finland; \*Dept. Physiology, University of Maryland, Baltimore MD 21201.

Gonadotrophin Releasing Hormone receptors (GnRH-R) are regulated by endogenous GnRH and androgen levels in male rats. In the present study, the effects of continuous administration of 100  $\mu$ g/day of the GnRH agonist, Histrelin, or the GnRH antagonist, Azaline B on pituitary GnRH-R mRNA and serum FSH, LH and testosterone (T) levels in intact male rats were compared to untreated control rats at 1, 2, 3, 4 or 8 weeks. During weeks 5 through 8, half of the rats in the 8 week group received the synthetic androgen, 7 $\alpha$ -methyl 19-nortestosterone (MENT; 30  $\mu$ g/day). A castrated control group at week 8 was also included (n=7 rats for all groups). A GnRH-R riboprobe was used in a lysate version of the RNase protection assay to measure pituitary GnRH receptor mRNA levels. Data were quantified by densitometry and expressed as the ratio of signal for GnRH-R to GAPDH mRNA. LH was measured by an immunofluorometric assay (Delfia) and FSH and testosterone by standard RIA.

At one week, Histrelin and Azaline B significantly suppressed T compared to intact rats. Serum LH was completely suppressed by Azaline B, whereas FSH levels were lower in the Histrelin group compared to intact rats. There were no significant differences in GnRH-R mRNA levels. At 8 weeks, in rats without supplemental androgen, serum LH, FSH and T were significantly suppressed in both the agonist- and antagonist-treated rats compared to intact levels. Histrelin, but not Azaline B, suppressed pituitary GnRH-R mRNA levels compared to intact rats. Castration significantly increased LH and FSH, and decreased GnRH mRNA, compared to intact rats. In the rats receiving Histrelin or Azaline B with supplemental MENT, levels of T, FSH and LH remained low, and GnRH-R mRNA levels in both groups were significantly suppressed compared to Intact+MENT. MENT given to intact or castrated rats decreased serum LH, FSH and T compared to non-MENT treated rats, but increased GnRH-R mRNA.

## 627.8

DIURETIC AND NATRIURETIC ACTIONS OF MELANIN CONCENTRATING HORMONE (MCH) IN CONSCIOUS SHEEP. D.G. Parkes\*. Howard Florey Institute of Experimental Physiology and Medicine, Parkville 3052, Australia.

MCH is a 19 amino-acid peptide expressed in high concentrations within the dorso-lateral hypothalamus of rats, sheep and man. MCH regulates skin color and ACTH release in teleost fish, however its physiological relevance in mammals is unclear. The present study examined the cardiovascular and metabolic actions of intracerebroventricular (icv) infusion of MCH in conscious, chronically instrumented sheep. Human MCH (1-19) was infused icv for 24 hours at 10 $\mu$ g/h into 6 sheep, and measurements were made every 10min of arterial pressure, heart rate, cardiac output, stroke volume and peripheral conductance. Recordings of water intake (H<sub>2</sub>Oin), urine volume (Uv), urinary Na (UNaV) and K excretion (UKV) were made, as well as hematocrit, plasma Na, K, osmolality, protein, glucose, ACTH, vasopressin, renin, endothelin, ANF, cortisol and aldosterone.

After 24 hours of infusion, MCH produced a significant increase in Uv from  $0.8 \pm 0.2$  to  $1.4 \pm 0.3$  l/day ( $P < 0.05$ ), together with an increase in UNaV from  $56 \pm 8$  to  $107 \pm 14$  mmol/day ( $P < 0.01$ ), and in UKV from  $202 \pm 18$  to  $369 \pm 38$  mmol/day ( $P < 0.001$ ). H<sub>2</sub>Oin was unchanged. There was no change in any cardiovascular parameter, although hematocrit exhibited a large decrease from  $26 \pm 1$  to  $22 \pm 1\%$  ( $P < 0.01$ ) after 24h infusion. Plasma osmolality increased from  $291 \pm 1$  to  $295 \pm 1$  mosm/kg ( $P < 0.05$ ), whereas total protein and plasma Na and K were unchanged. Plasma glucose increased from  $3.4 \pm 0.2$  to  $3.8 \pm 0.2$  mmol/l ( $P < 0.05$ ). All other plasma concentrations did not change. This study has shown that icv infusion of MCH can produce diuretic, natriuretic and kaliuretic changes in conscious sheep, triggered by a possible increase in plasma volume as indicated by the changes in hematocrit. These results, together with anatomical data reporting the presence of MCH in fluid regulatory areas of the brain, indicate that MCH may be an important peptide involved in the central control of fluid homeostasis in mammals.

## 627.9

VASODILATOR RESPONSE TO BRADYKININ (BK) AND [desArg<sup>2</sup>]BK IN CYTOKINE TREATED RABBIT KNEE JOINT SYNOVIUM. H. Cambridge, M.P. Cautfield<sup>1</sup> & S.D. Brain Dept. Pharmacology, Kings College, London SW36LX & <sup>1</sup>Dept. Pharmacology, University College, London WC16BT.

[DesArg<sup>2</sup>]BK is a selective BK B<sub>1</sub> receptor agonist which produces hyperalgesia and oedema formation in inflamed but not normal joints, implying induction of B<sub>1</sub> receptors. We hypothesised that B<sub>1</sub> receptor activation would result in vasodilation of the synovial microcirculation in cytokine treated joints. Rabbits (NZW, 2.5-3.5kg, both sexes, n=18) were anaesthetised (thiopentone iv; 1.5-2.5% halothane in O<sub>2</sub>) and the femoral artery retrogradely cannulated, allowing close intra-arterial infusion into the synovial circulation. Blood flow (arbitrary flux units) was continuously monitored by laser-Doppler flowmetry using a needle probe positioned in the joint adjacent to the medial synovium. Results are expressed as AUC (x10<sup>3</sup>) of the change from baseline. Infusion of BK (10µmol) produced vasodilation in all joints co-injected (-5-7 h) with IL-1β plus TNFα (both 100ng) or vehicle (means±s.e.mean, 306.6±40.0, n=8, 404.5±81.1, n=10). Infusion of the B<sub>2</sub> antagonist HOE140 (0.1nmol) abolished the response to BK in the 5 joints tested from each group. [DesArg<sup>2</sup>]BK (up to 10nmol) had no effect in 7 vehicle treated joints but in 3 animals 10-100nmol produced small responses (89.2, 131.5, 150.1). In cytokine treated joints [desArg<sup>2</sup>]BK (10 and 100nmol) produced vasodilation (258.5±44.2, n=4; 553.0±131.9, n=3) with no response obtained in 1 animal. HOE140 (0.1nmol) abolished the response in 1 animal whereas in the others the response after HOE140 was 51-73% (n=4) of control. The finding that cytokine treatment increased the number of animals in which a response to [desArg<sup>2</sup>]BK could be measured provides some evidence for the induction of B<sub>1</sub> receptors, and the failure of HOE 140 to totally inhibit this response points to B<sub>1</sub> receptor mediated vasodilation, however the potency difference between BK and [desArg<sup>2</sup>]BK suggests that B<sub>2</sub> receptors remain of major physiological or pathological importance in this site.

## 627.11

HALOPERIDOL-RESISTANT REDUCTION OF SUBSTANCE P CONTENT IN THE PREFRONTAL CORTEX OF THE RAT BY AN ACUTE INJECTION OF PHENCYCLIDINE. Y. Shirayama<sup>1</sup>, T. Nishikawa, H. Mitsushio and K. Takahashi, Div. Mental Disorder Res., National Institute of Neuroscience, NCNP and Dep. Psychiatry, Kanto Teishin Hospital, Tokyo, Japan.

The effects of a schizophrenomimetic drug, phencyclidine (PCP), on substance P (SP) contents have been investigated in the discrete brain areas of the rat. To this end, a simple and sensitive enzyme-immunoassay for SP has been developed. An acute administration of PCP (10 mg/kg, intraperitoneally (i.p.)), which is a non-competitive antagonist of N-methyl-D-aspartate (NMDA) type excitatory amino acid receptor, reduced the concentration of SP in the prefrontal cortex, limbic forebrain (nucleus accumbens, septum, olfactory tubercle, etc.), striatum and substantia nigra at 60 min post-injection. A selective non-competitive NMDA antagonist, (+)-MK801 (1 mg/kg, i.p.) also caused a decrease in SP in the prefrontal cortex and limbic forebrain, but failed to alter the content in the other areas, 30 min thereafter. In contrast, dopamine (DA) agonists, methamphetamine (4.8 mg/kg, i.p.) and apomorphine (4.4 mg/kg, i.p.) reduced the content in the striatum and substantia nigra, but not in the other regions at 60 min after the injection. Furthermore, the pre-injection of DA antagonist, haloperidol (1 mg/kg, i.p.) blocked the ability of PCP to decrease SP content in the substantia nigra but not in the prefrontal cortex. The present results suggest that PCP may reduce SP content by blockade of the NMDA receptor in the prefrontal cortex and limbic forebrain and by activation of DA neurotransmission in the striatum and substantia nigra.

## 627.10

INTRADERMAL INJECTION OF SUBSTANCE P INDUCES HIND-PAW SCRATCHING MEDIATED BY SENSORY STIMULATION OF TREATED SKIN. Y. Kuraishi<sup>1</sup>, T. Nagasawa<sup>1</sup>, T. Andoh<sup>1</sup>, K. Hayashi<sup>1</sup>, M. Satoh<sup>2</sup>. <sup>1</sup>Dept. of Applied Pharmacol., Res. Inst. for Traditional Medicines, Toyama Med. & Pharm. Univ., Toyama 930-01, and <sup>2</sup>Dept. of Mol. Pharmacol., Fac. of Pharm. Sci., Kyoto Univ., Kyoto 606-01, Japan.

Substance P (SP), a pruritogenic peptide, elicits hind-paw scratching when applied to the mouse skin. The present experiments were conducted to determine whether scratching behaviors induced by intradermal SP would be due to a sensation, especially an itch sensation, of the treated skin. Male ICR mice were used unless otherwise mentioned, and SP was intradermally injected (50 µl) into the back. When injected into the rostral back, SP (10-135 µg) dose-dependently elicited scratching of the injected skin by the hind paws. The effects were not apparently different between doses of 135 µg (= 100 nmol) and 300 µg. When injected into the caudal back, a site that the mouse cannot scratch by the hind paws, SP (100 nmol) elicited few or no scratches of the rostral back. Pretreatment with capsaicin (50, 50, 100, 150 and 200 mg kg<sup>-1</sup> day<sup>-1</sup>, s.c. for 5 days) significantly inhibited SP (100 nmol)-induced scratching. SP (300 µg) elicited scratching either in the mast cell-deficient mice (WBB6F1 W/W<sup>-</sup>) or in the wild-type mice (WBB6F1 +/+). Pretreatment with compound 48/80 (100 µg, s.c. for 2 or 3 h), an agent that inhibits SP-induced itching in humans, significantly suppressed scratching induced by SP (100 nmol) in the mast cell-deficient mice as well as in the wild-type and ICR mice. These results suggest that at least in the mouse, hind-paw scratching, an itch-related behavior, induced by intradermal SP is due to the sensory stimulation of the injected skin and that the cutaneous mast cells are not exclusively responsible for the SP-induced scratching.

## PEPTIDES: PHYSIOLOGICAL EFFECTS III

## 628.1

ANORECTIC AND NEUROCHEMICAL EFFECTS OF PITUITARY ADENYLATE CYCLASE ACTIVATING POLYPEPTIDE (PACAP) IN RATS. W.T. CHANCE<sup>1</sup>, H.L. THOMPSON and I. THOMAS, Dept. Surgery, Univ. Cincinnati Med. Ctr. and VA Med Ctr., Cincinnati, OH 45267.

Although PACAP reduces food intake in mice following intraventricular injection, no tests of this peptide have been reported for intra-hypothalamic (i.h.t.) administration in rats. Therefore we tested the anorectic and neurochemical effects of PACAP (1.25 & 2.5 µg) following perifornical i.h.t. injection. Pretreatment of rats with PACAP 10 minutes prior to the injection of 1 µg neuropeptide Y (NPY), significantly reduced food and water intake during the 1 to 4 hr measurement periods. PACAP treatment of schedule-fed rats also reduced food and water intake for 2 hrs. A smaller 1 hr reduction of water intake was observed in water-deprived rats, suggesting that the anticonsummatory effects of PACAP were primarily against food intake. PACAP treatment did not alter hypothalamic level of NPY, nor were neurotransmitters, precursors or metabolites altered in corpus striatum or nucleus accumbens regions. These results indicate primary anorectic effects of PACAP, and may suggest a role of cAMP activation and inhibition in the control of food intake.

## 628.2

PITUITARY ADENYLATE CYCLASE ACTIVATING POLYPEPTIDE MODULATES INTRACELLULAR CALCIUM IN RAT PINEAL CELLS. N. Darvish, H. Jiang<sup>1</sup> and J. T. Russell LCMN and OSD NICHD, NIH, Bethesda, MD, 20892 USA.

In this study we have examined the effect of pituitary adenylate cyclase activating polypeptide (PACAP) on [Ca<sup>2+</sup>]<sub>i</sub> in adult rat pineal cells. Pinealocytes in primary culture were loaded with Fura-2 and then exposed to 100nM PACAP. This treatment resulted in an increase in [Ca<sup>2+</sup>]<sub>i</sub> in 51% of the cells examined. Similar treatment with norepinephrine (1µM), however, resulted in [Ca<sup>2+</sup>]<sub>i</sub> responses in 95% of the pinealocytes. The PACAP-induced [Ca<sup>2+</sup>]<sub>i</sub> signals were heterogeneous, ranging from rapid transients to a slow sustained elevation in Ca<sup>2+</sup> (1.5mM) containing medium. This response persisted when extracellular Ca<sup>2+</sup> was removed. Under this condition, the [Ca<sup>2+</sup>]<sub>i</sub> changes were rapid and transient followed by a sustained decrease to levels lower than before PACAP was applied. These findings suggest that the PACAP-induced [Ca<sup>2+</sup>]<sub>i</sub> signals in pineal cells are, at least in part, due to release of Ca<sup>2+</sup> from intracellular stores. The sustained decrease in [Ca<sup>2+</sup>]<sub>i</sub> in the absence of extracellular Ca<sup>2+</sup> remains to be explored.

## 628.3

A NOVEL PACAP ANTAGONIST, NEUROTENSIN<sup>6-11</sup>PACAP<sup>7-28</sup>: EFFECTS ON NEURONAL SURVIVAL AND SPERM MOTILITY: A. Davidson\*, A. Reshef, O. Ashur-Fabian, R. Zamostiano, I. Schochat, L.M. Lewin, S. Rubinrout, M. Fridkin, D.E. Brenneman and I. Gozes. Dept. Clin. Biochem. Sackler Med. Sch. Tel Aviv Univ. Israel, 69978; Dept. Organic Chem. Weizmann Inst. Rehovot, Israel 76100; Section Develop. & Molec. Pharmacol. LDN, NIH, Bethesda, MD 20892, USA.

Pituitary stimulating adenylate cyclase (PACAP) is a major regulatory peptide with two active molecular forms: PACAP-27 and PACAP-38 (Regul. Pept. 37: 287, 1992). Both molecular forms promote neuronal survival and protect against neurotoxicity (N.Y. Acad. Sci. 739,228, 1994). By Northern blot hybridization utilizing synthetic oligodeoxynucleotides we have identified a 1464 base PACAP receptor mRNA in rat cerebral cortical cultures. Based on our previous hybrid peptide strategy in designing VIP antagonists (J. Pharmacol. Exp. Therap. 273:161, 1995), a novel PACAP analogue was synthesized (neurotensin<sup>17</sup>PACAP<sup>7-27</sup>). In addition to the hybrid modification, the methionine in position 17 was replaced by norleucine (Nle). Treatment of cerebral cortical cultures for five days with the putative PACAP antagonist (1 nM) resulted in a 47% reduction in neuronal cell counts as compared to controls and the EC50 of this effect was about 100 pM. Co-administration of the PACAP hybrid analog with picomolar amounts of PACAP-38 or PACAP-27 with the Met in position 17 replaced by Nle attenuated the reduction in neuronal cell counts. The putative PACAP antagonist also inhibited sperm motility in a dose dependent manner (Golden Hamster) as assessed *in vitro*. Complete inhibition was observed at 10  $\mu$ M, suggesting a role for PACAP in sperm motility and sexual function. The availability of a novel PACAP antagonist should help to further delineate role of this neuropeptide in neurodevelopment and sexual activity.

## 628.5

THE ROLE OF CA<sup>2+</sup> IN CHANGES OF MEMBRANE FUNCTION AND THE PROTECTION OF CGRP IN HIPPOCAMPAL SLICE DURING HYPOXIA. Fu-Zhuang Wang\*, Zhen-Wei Liu and Ai-Shi Ding. Dep of Neurobiology, Institute of Basic Medical Sciences, Beijing 100850, China

Recent findings suggest that elevation of free intracellular calcium ([Ca<sup>2+</sup>]<sub>i</sub>) is the important factor triggering cell injury in hypoxia. The role of Ca<sup>2+</sup> in the mechanisms of acute hypoxia involved in neurons and synaptic transmission in CA1 area of rat hippocampal slice were studied by using extra- and intracellular recording techniques and biochemical methods. From extracellular recordings it was found that phasic changes showing initial disappearance, reappearance and re-disappearance of evoked population spike (PS) in CA1 pyramidal neurons were caused by hypoxia. After reoxygenation the recovery rate of PS was obviously higher in slices perfused with calcitonin gene-related peptide (CGRP, 4nM) or Ca<sup>2+</sup>-free artificial cerebrospinal fluid (ACSF) than in controls. Intracellular recordings showed that hypoxia also caused phasic changes of membrane potential in CA1 pyramidal neurons, which included an initial hyperpolarization, a slow depolarization and a final rapid depolarization. Ca<sup>2+</sup>-free ACSF reduced the amplitude of depolarization and delayed the occurrence of depolarization in hypoxia. By measuring of [Ca<sup>2+</sup>]<sub>i</sub> with fura-2 it was found that hypoxia induced a marked phasic elevation of [Ca<sup>2+</sup>]<sub>i</sub> in hippocampal neurons. The phasic changes disappeared when removing Ca<sup>2+</sup> from extracellular fluid and CGRP can inhibit the hypoxic elevation of [Ca<sup>2+</sup>]<sub>i</sub>. These results indicate that the phasic elevation of [Ca<sup>2+</sup>]<sub>i</sub> induced by influx of Ca<sup>2+</sup> play an important role in phasic changes of membrane function in hippocampal neurons and its synaptic transmission during hypoxia. CGRP may have a neuronal protective action against hypoxia.

This work was supported by NSF of China.

EFFECTS OF CORTICOTROPIN-RELEASING FACTOR (CRF) ON SLEEP CYCLES IN THE RAT MEDIAL Diencephalic STRUCTURES. Y. Slijsli, P. Denise and R. de Beaurepaire\*. Lab. de Pharmacologie, Lab. de Physiologie, & INSERM U.320, CHRU, 14032 Caen, FRANCE.

We have previously shown that injections of salmon calcitonin into the rat hypothalamic paraventricular nucleus and perifornical area produce dramatic changes in sleep cycles, with suppression of slow wave sleep and predominant insomnia during approximately 18 hours (Soc Neurosci Abstr. Vol 20, Part 1, p 160, 1994). In the present work, we studied the effects of another peptide, CRF, on sleep. Sprague-Dawley female rats were implanted with electrodes for chronic EEG recordings, and with a cannula directed into several hypothalamic and thalamic sites. All animals were injected twice, once with CRF (0.5  $\mu$ g in 0.3  $\mu$ l) and once with the vehicle (0.3  $\mu$ l) and recordings made over 3 hours post injection. An insomnia during the 3 hours period was observed after injections into the hypothalamic ventro- and dorso-medial nuclei, an area internal to the mamillo thalamic tract, the bed nucleus of the stria terminalis, the internal part of the zona incerta, the nucleus reuniens, and the nucleus paracentralis of the thalamus. CRF had no effects in the tuber cinereum, the lateral and posterior hypothalamus, and the centro-medial, ventro-medial and ventro-lateral nuclei of the thalamus. The effects into the paraventricular nucleus and perifornical area were not interpretable because of constant diffusion of the CRF to the above nucleus reuniens and zona incerta. Some rats were tested after 3 hours in the paraventricular nucleus/nucleus reuniens, and the insomnia never lasted more than 5 hours. In conclusion, CRF produces an insomnia when injected into several hypothalamic and thalamic sites, but the sleep abnormalities observed with CRF are always less dramatic than those observed with salmon calcitonin injected into the hypothalamic paraventricular nucleus and perifornical area.

## 628.4

BIOLOGICAL ACTIVITY OF THE CALCITONIN SOME FRAGMENTS. N. Balashov\*, V. Akopian, S. Burov, G. Vlasov. Sechenov Institute of Evolutionary Physiology and Biochemistry, 194223, St. Petersburg, Russia.

Calcitonin, gene-related peptide, is a neuropeptide. It has been shown that calcitonin to be a potent vasodilator. However not only does the whole molecule of calcitonin exhibit the biological activity but also its some fragments do. We studied the following fragments of calcitonin gene related neuropeptide (1-9), -(10-20), -(15-24), -(20-29), -(30-37). The fragment (20-29) was the single one to decrease arterial blood pressure. Effects of this fragment on the arterial, venous and lymphatic microvessels of the rat mesentery by method of the vital television microscopy has been investigated. It was found that this fragment can exhibit a vasodilator activity during experiments on the arterial and venous microvessels but to exert also some stimulating effect on the lymphatic ones, raising there tones and increasing spontaneous contractions. This fragment was applied on the microvessels surface. Thus these findings suggest that fragment -(20-29) in polyfunctional molecule is responsible for the effects on the microcirculation bed.

## 628.6

CALCITONIN GENE-RELATED PEPTIDE DOES NOT INHIBIT UTERINE CONTRACTION THROUGH ATP-SENSITIVE K<sup>+</sup> CHANNELS IN THE RAT UTERUS. R.L. Shew\*, C. Gatto, J.S. Shenberger and D.E. Johnson. Departments of Cell Biology & Neuroanatomy and Pediatrics/Neonatology, University of Minnesota and Children's Health Care-St. Paul, Minneapolis, MN 55455 and St. Paul, MN 55102.

Calcitonin gene-related peptide (CGRP) is localized in nerves in the uterus and relaxes uterine contraction in a dose-related manner. While the mechanism of CGRP on uterine relaxation is unclear, K<sup>+</sup> channels have been suggested to play a role in the regulation of myometrial activity. In addition, the vasodilatory effect of CGRP on uterine arteries has been inhibited by ATP-sensitive K<sup>+</sup> channel blockers. Thus, we investigated the role of ATP-sensitive K<sup>+</sup> channels and CGRP relaxation in rat uterine tissue. Mature Sprague-Dawley rats (200-225 g) were treated with diethylstilbestrol and uterine horns removed 24 hours later and examined using an *in vitro* uterine assay. Both CGRP (10<sup>-7</sup> M) and cromakalim (10<sup>-7</sup> and 10<sup>-6</sup> M), an ATP-sensitive K<sup>+</sup> channel activator, inhibited acetylcholine (ACh)-stimulated (10<sup>-6</sup> M) uterine contraction by 73% and 41-38% respectively. Glybutride (10<sup>-10</sup>-10<sup>-3</sup> M), an ATP-sensitive K<sup>+</sup> channel blocker, blocked the ability of cromakalim to inhibit ACh-stimulated uterine contraction (38% versus 0%). However, glybutride at effective doses failed to block CGRP inhibition of ACh-stimulated uterine contraction. These data suggest that in our assay ATP-sensitive K<sup>+</sup> channels do not play a role in CGRP relaxation of ACh-stimulated uterine contraction.

## 628.8

EXPRESSION PATTERN OF CORTICOTROPIN-RELEASING FACTOR (CRF) BINDING SITES IN RAT BRAIN AND PITUITARY DURING THE 24-HOUR CYCLE. E. FUCHS\*, J.-C. Wasmuth, G. Flügge, G. Huether. German Primate Center and Department of Psychiatry, 37077 Göttingen.

CRF is thought to be involved in the regulation of the diurnal activity of the HPA-axis and to act as a neurotransmitter in the brain. To date it is unknown whether the cellular effectors of the central CRF system are subject to diurnal variations. We therefore measured the number of binding sites for iodinated ovine CRF over a complete 24-hr light-dark cycle in the pituitary, amygdala, bed nucleus of the stria terminalis (BNST), paraventricular nucleus of the hypothalamus, hippocampus, and locus coeruleus of rats by *in vitro* receptor autoradiography. A 24-hr time course was also established for plasma corticosterone. Within the brain, CRF binding in the basolateral nucleus of the amygdala showed a U-shaped curve with maximum levels in the morning and a wide hollow between 15:00 h and 19:00 h. A biphasic profile with a small depression in the afternoon and more pronounced depression in the second half of the activity period is characteristic for the other brain areas and for the pituitary. The profile for the pituitary correlates with those for the BNST and the area of the locus coeruleus. The diurnal pattern of CRF binding sites in the BNST correlates with that of the hippocampus. Since the CRF-binding profiles in the brain and the pituitary clearly differ from the profile of plasma corticosterone we conclude that the diurnal pattern of the central CRF binding sites is not directly coupled to the activity of the HPA-axis.

## 628.9

## SLEEP DEPRIVATION INCREASES CRF LEVELS AND CRF mRNA EXPRESSION IN RAT BRAIN.

P.Fadda\*, A.Porcella, L.Pani\*, M.L.Pani and W.Fratta\*. B.B.Brodie  
Department of Neuroscience and \*Center for Neuropharmacology  
C.N.R., University of Cagliari, Cagliari, Italy.

Evidence has been accumulated suggesting that corticotropin-releasing factor (CRF) might play a physiological role in the regulation of sleep-wake cycle. EEG studies have shown that CRF administration induces EEG activation and decreased sleep time both in rat and humans. We have previously shown that i.c.v. administration of CRF increases paradoxical sleep rebound in sleep deprived rats (Marrosu et al., Brain Research 515, 315; 1990). In the present study we have investigated on the possible effect of sleep deprivation on CRF levels and CRF mRNA expression in different brain areas and pituitary. Sleep deprivation was induced by the water tank method in male Sprague-Dawley rats (175-200 gr.) for 72 hours. CRF levels were detected by radioimmunoassay; CRF mRNA was measured by RT-PCR method. The results obtained indicate that sleep deprivation induces a significant increase both in CRF levels and CRF mRNA in striatum (+225% and +30%), limbic system (+144% and +28%) while in hypothalamus an increase in CRF mRNA (+30%) was concomitant to a decrease (-58%) of CRF levels. Such a decrease could reflect a CRF over-release from the hypothalamus to the pituitary, where CRF levels were found increased without any significant changes in CRF mRNA. These data indicate that CRF neuronal activity is enhanced by sleep deprivation and might strengthen the hypothesis of a functional role of CRF in the regulation of sleep-wake cycle.

## 628.11

GLYCYL-L-GLUTAMINE ANTAGONISM OF IL-1 $\beta$ . G.E. Resch\* and W.R. Millington. Division of Molecular Biology & Biochemistry, Univ. Missouri, Kansas City MO 64108-2792.

Glycyl-L-glutamine (Gly-Gln;  $\beta$ -endorphin-30-31) was previously shown to antagonize  $\alpha$ -MSH and PGE<sub>2</sub>. Since PGE<sub>2</sub> mediates some thermogenic responses to IL-1 $\beta$  in the medial preoptic area (mPOA), the hypothesis was tested that Gly-Gln would also antagonize the thermogenic response to IL-1 $\beta$ . Groups of 3 to 5 Sprague Dawley rats were stereotactically implanted with guide tubes 0.5 mm lateral of the midline at bregma with tips 7 mm below the surface of the skull. Sites sensitive to PGE<sub>2</sub> (1 pg/ $\mu$ l) in the mPOA were selected for a rise in colonic temperature (T<sub>c</sub>) vs saline vehicle. Injection of IL-1 $\beta$  (1 U in 1  $\mu$ l) into these sites elicited a T<sub>c</sub> rise of 1.02  $\pm$  0.06  $^{\circ}$ C (Mean  $\pm$  SEM). Injection of IL-1 $\beta$  mixed with Gly-Gln (3 nmol) abolished the response (-0.18  $\pm$  0.22  $^{\circ}$ C) vs saline controls (-0.03  $\pm$  0.18  $^{\circ}$ C) in the same mPOA sites. The antagonism did not occur to equimolar Gly and Gln nor did T<sub>c</sub> change to Gly-Gln injected alone (0.20  $\pm$  0.20  $^{\circ}$ C). Gly-Gln also antagonized the PGE<sub>2</sub>-elicited rise in T<sub>c</sub> (0.86  $\pm$  0.10  $^{\circ}$ C vs 0.1  $\pm$  0.03  $^{\circ}$ C). These data are consistent with PGE<sub>2</sub> mediation of the IL-1 $\beta$ -elicited fever. The data show Gly-Gln antagonizes the febrile responses to IL-1 $\beta$  and PGE<sub>2</sub>. Since Gly-Gln is co-released with  $\beta$ -endorphin, the data suggests a possible link between effects of  $\beta$ -endorphin and IL-1 $\beta$ .

## ROLE OF CORTICOTROPIN-RELEASING HORMONE (CRH) AND EXCITATORY AMINO ACIDS (EAA) IN LOCUS COERULEUS (LC) ACTIVATION BY COLONIC DISTENTION. S.M. Florin\*, A.L. Curtis and R.J. Valentino, Dept. Psychiatry, Hahnemann University, Philadelphia, PA 19102.

The LC-noradrenergic system is activated by a variety of visceral stimuli including bladder and colon distention. The present study was designed to determine the neurochemical mediators of LC activation by colon distention. Extracellular LC spontaneous discharge was recorded from halothane-anesthetized rats during 2 min of sustained colon distention produced by injection of 0.5, 1.0 or 3.0 ml of water into a balloon catheter inserted in the distal colon. Consistent with previous reports (Elam, et al., Brain Res 375:117-125, 1986), colon distention increased LC spontaneous discharge rate in a volume dependent manner, with distention produced by 0.5, 1.0 and 3.0 ml injections resulting in a 16 $\pm$ 3%, 35 $\pm$ 5% and 52 $\pm$ 3% increase in discharge rate, respectively (n $\geq$ 6). I.C.V. administration of the CRH antagonist, D-PheCRH<sub>12-41</sub> (3.0  $\mu$ g) completely prevented LC activation produced by 0.5 ml colon distention (n=5), and decreased LC activation produced by 1.0 ml colon distention by 64% (n=5; p<0.005). A higher dose of D-PheCRH<sub>12-41</sub> (10  $\mu$ g) was no more effective than the 3.0  $\mu$ g dose. Interestingly, D-PheCRH<sub>12-41</sub> did not attenuate LC activation associated with a 3 ml distention. EAA neurotransmission in the LC has been demonstrated to mediate LC activation by a variety of stimuli. In this study, the EAA antagonist, kynurenic acid (5.0  $\mu$ mol, i.c.v.), significantly decreased LC activation associated with both a 1.0 ml and a 3.0 ml colon distention (n=5). These findings suggest that EAA neurotransmission is integral to LC activation by colonic distention and that CRH may be selectively involved in LC activation by low levels of colonic distention. Supported by PHS grants MH40008 and MH00840.

## 628.12

## MODULATION OF THE SPREAD OF EXCITATION IN RAT NEOCORTICAL SLICES BY INTERLEUKIN-1 BETA, VISUALIZED WITH INFRARED-DARKFIELD VIDEO MICROSCOPY. G. D'Arcangelo\*, H.U. Dodt and W. Zieglgänsberger, Univ. of Rome Tor Vergata, Rome, Italy; Max-Planck-Institute of Psychiatry, Clinical Institute, Clinical Neuropharmacology, Kraepelinstr. 2, 80804 München, FRG.

The combination of infrared videomicroscopy with darkfield techniques allows the visualization of the spread of excitation in neocortical slices without the use of voltage sensitive dyes. With this technique optical recordings were performed in neocortical slices of adult rats. Tetanic stimulation of white matter or Layer VI of the neocortex with trains of 50 Hz for 2 sec induced a column-like pattern of increased brightness, the "intrinsic optical signal" (i.o.s.). This signal is considered an indicator of the spread of neuronal excitation. To visualize the i.o.s. an averaged darkfield image was stored in computer memory and subsequently subtracted in real time from the incoming image during tetanic stimulation of the slice. The contrast of the resulting image was digitally enhanced and displayed in false colours.

The cytokine interleukin-1 beta (IL-1 $\beta$ ) added to the bath at a concentration of 1 ng/ml for 60 min (n=8) induced a reduction of the i.o.s. to 88  $\pm$  6% of control value. Application of IL-1 $\beta$  at a concentration of 10 ng/ml for 30 min (n=8) reduced the i.o.s. to 67  $\pm$  10% with a recovery of the signal after 90 min of washout. No change of the i.o.s. was observed during control experiments (n=5) when heat-inactivated (100  $^{\circ}$ C for 30 min) IL-1 $\beta$  was applied. The action of IL-1 $\beta$  resembles the effect of GABAergic agonists like muscimol or the neuroactive steroid THDOC. These findings support the notion that IL-1 $\beta$  enhances GABAergic inhibition. Such enhancement of GABAergic inhibition may underlie behavioural effects mediated by IL-1 $\beta$ , such as fever associated "sickness behaviour".

## OPIOID RECEPTORS: MOLECULAR BIOLOGY

## 629.1

## KOR-3: STRUCTURE AND CHARACTERIZATION OF A KAPPA3-RELATED OPIOID RECEPTOR GENE Y. X. Pan\*, J. Xu, and G.W. Pasternak. The Cotzias Laboratory of Neuro-Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY 10021

We have cloned and sequenced a kappa<sub>3</sub>-related opioid receptor (KOR-3) gene from a mouse genomic library. The mouse KOR-3 gene is 8.3 kb in length containing five exons of 0.26, 0.25, 0.3, 0.91 and 1.14 kb. The first and fifth ones are noncoding while the second, third and fourth contain the complete coding region, with intron junctions at the position 522 and 878 of cDNA nucleotide sequence. The intron between second and third exons is 2.4 kb, and the intron between third and fourth is 81 bp. The transcription initiation site was determined by primer extension and 5'RACE. Several putative regulatory elements were found in the 5' flanking sequence, such as AP1 and GRE. A polyadenylation signal (AATAAA) was identified in the 3' flanking region. (YXP is supported by an Aaron Diamond Postdoctoral Fellowship.)

## 629.2

## CHARACTERIZATION OF A HUMAN MU-OPIOID RECEPTOR GENE PROMOTER Matthew L. Andria, George K. Ehrlich\*, and Eric J. Simon, New York University Medical Center, New York, NY 10016, USA

The human mu-opioid receptor gene, cloned in this laboratory, was studied to evaluate DNA sequences which may influence transcription. Portions of the gene which are upstream of the translation start codon were isolated and placed upstream of a reporter gene to assess transcription rate by assaying reporter protein level. These reporter constructs were transfected into a mu-opioid receptor expressing cell line and into non mu-opioid receptor expressing cell lines. A construct containing 61 basepairs (from -337 to -397 bases upstream of the translation start codon) significantly promoted transcription of the reporter gene in both mu-opioid receptor expressing and non-expressing cell lines. This minimal promoter lacks a TATA box sequence but does contain a sequence that matches the consensus for an initiator. Other upstream portions of the mu-opioid receptor gene were shown to influence the level of transcription of the reporter gene. (Supported by NIDA grant DA-00017 to E.J.S. and by an Aaron Diamond Foundation Fellowship to M.L.A.)

## 629.3

DIFFERENTIAL EXPRESSION OF RAT KAPPA OPIOID RECEPTOR GENE. A.G. Yakovlev\* and A.I. Faden. Departments of Neurology and Pharmacology Georgetown University Medical Center, Washington, DC 20007

Kappa opioid receptors mediate a number of physiological functions, including feeding behavior, fluid balance, cardiorespiratory activity and antinociception among others. They may also be involved in pathophysiological responses, such as in CNS injury. The existence of multiple kappa isoreceptors has been suggested by pharmacological studies. However, a number of cDNA cloning experiments from various laboratories have resulted in isolation of only a single sequence, one encoding for the kappa-1 isoreceptor, as demonstrated by transfection of COS-1, COS-7 and PC12 cells. Recently, we isolated a gene encoding the rat kappa opioid receptor (Yakovlev et al., 1995). Results of genomic library screening and southern blot analysis showed that the kappa receptor gene represented at one copy per haploid genome. RT-PCR analysis indicated that alternative splicing of KOR RNA did not occur. However, we demonstrated that two species of transcripts are differentially produced by a single KOR gene in tissue-specific manner. The first transcript (KOR1) is equivalent to the cDNA sequence characterized elsewhere for kappa-1 opioid receptor. The second transcript (KORx) begins in intron 1 and thereby retains the intronic sequence in the mature mRNA. Within this sequence there is a potential translation initiation codon that is in frame with the first ATG codon for KOR1. The results of comparative *in vitro* translation of KOR1 and KORx mRNA demonstrated that the extension of an open reading frame upstream in KORx mRNA leads to the translation of a larger variant of KOR protein having an additional peptide sequence at its amino terminus. Immunoprecipitation analysis showed that monoclonal antibodies KA8 directed against the kappa-2 opioid receptor enriched fraction of frog brain (Maderspach et al., 1991) recognized rat KOR1 but not KORx protein synthesized by the *in vitro* translation. Taken together the data suggest that the existence of multiple KOR isoreceptors might result from different posttranslational modifications of a single KOR protein and/or its interaction with different membrane proteins. Studies of a functional role of KORx protein in the modulation of kappa opioid receptor signaling system are in progress.

## 629.5

TRP<sup>284</sup> IS IMPORTANT FOR THE BINDING OF THE NONPEPTIDE SNC121 TO THE HUMAN DELTA OPIOID RECEPTOR. X. Li, R.J. Knapp, D. Stropova, Y. Wang, E. Varga, E. Malatynska, S. Calderon, K. Rice, R. Rothman, F. Porreca, V. Hruby, W.R. Roeske and H.I. Yamamura. U. of Arizona, Tucson, AZ 85724, <sup>1</sup>NIH and <sup>2</sup>NIDA, MD.

Based on the comparison of the structure of the three ( $\delta$ ,  $\mu$  and  $\kappa$ ) opioid receptor proteins, three single amino acid mutations of hDOR were constructed to elucidate the ligand selectivity and binding domain of human delta opioid receptor. Here we report the Trp<sup>284</sup> in extracellular loop III of the human  $\delta$ -receptor, corresponding to Lys<sup>305</sup> in hMOR and Glu<sup>297</sup> in hKOR, is involved in binding of nonpeptide SNC121. Saturation binding studies revealed that (1) no difference was observed between W284L and wild-type receptors in the ligand binding affinity of the  $\delta$ -selective antagonist [<sup>3</sup>H]Naltrindole (K<sub>d</sub> = 140 vs. 53 pM, respectively) and the  $\delta$ -selective peptide agonist [<sup>3</sup>H]pCI-DPDPE (K<sub>d</sub> = 320 vs. 260 pM), (2) no specific binding was observed for 1.0 nM [<sup>3</sup>H]SNC121 to the W284L mutation receptor. Inhibition binding studies of [<sup>3</sup>H]Naltrindole to both W284L and wild-type receptors was inhibited by pCI-DPDPE (K<sub>i</sub> = 1.1 vs. 3.6 nM and Deltorphin II (K<sub>i</sub> = 11 vs. 14 nM) with high affinity. But SNC121 inhibited [<sup>3</sup>H]pCI-DPDPE binding to the W284L mutant with a K<sub>i</sub> of 144 nM in contrast to the K<sub>i</sub> of 3.7 nM at the wild-type. These results indicate that Trp<sup>284</sup> of hDOR plays an important role in the binding of SNC121, but not pCI-DPDPE, Deltorphin II and Naltrindole. Furthermore it suggests that nonpeptide and peptide agonists and antagonists have different binding domains. Supported by NIDA grants.

## 629.7

THE DELTA OPIOID RECEPTOR BINDING SITE. Katia Befort, Lina Tabbara, Dominique Kling, Bernard Maigret and Brigitte Kieffer\*. UPR 9050, ESBS, Université Louis Pasteur, 67400 Illkirch, France.

Opiates act through three classes of membrane receptors known as mu, delta and kappa. We have recently cloned a mouse opioid receptor of delta subtype. Analysis of the primary sequence of the cloned receptor indicates that it belongs to the G protein-coupled receptors superfamily. Using 3D computer modeling, we have constructed a model for the delta receptor based on the resolved structure of bacteriorhodopsin. In this model, a hydrophilic site together with a strongly hydrophobic pocket are postulated to form the active site of the receptor. To test this model, we are using site-directed mutagenesis and examine the binding properties of single-amino-acid substituted mutant receptors expressed in Cos cells. Preliminary experiments partly support our model. We have also examined in details the possibility that aspartate 128 (Tm III), which is classically found also in catecholamine receptors, might provide a counterion for the positively charged opioids. We have found that this residue is differently involved in ligand binding as previously demonstrated for the beta-adrenergic receptor. Taken together our results should allow to establish a putative topology of the delta opioid receptor binding site.

## 629.4

IDENTIFICATION OF REGIONS OF THE HUMAN DELTA OPIOID RECEPTOR INVOLVED IN THE SELECTIVE BINDING OF AGONISTS AND ANTAGONISTS: A CHIMERIC RECEPTOR STUDY. E.V. VARGA, X.P. LI, D. STROPOVA, S. CALDERON, K. RICE, R. ROTHMAN, F. PORRECA, V. HRUBY, W. R. ROESKE\* and H.I. YAMAMURA. U of Arizona, Tucson, AZ.

Three major types of the human opioid receptors have been cloned: the mu, delta and kappa receptors. They show unusually high homology in the putative transmembrane and intracellular domains. The hypothesis we tested in this study is that the signal transducing "message" part of the opioid peptides binds in the transmembrane domains, while the specificity determining "address" part interacts with the extracellular domains. To study the role of the extracellular loops in the ligand recognition we replaced the 2nd and 3rd extracellular loops of the human delta opioid receptor with those of the human mu opioid receptor. The chimeras were spliced together using a modified PCR overlap extension method. The chimeric PCR fragments were digested with the appropriate restriction enzymes and ligated into the digested human delta receptor fragment. The chimeras were transferred into the mammalian expression vector pcDNA3. COS-7 cells were transiently transfected with the constructs using the DEAE-dextran method. The binding experiments were performed using cell membranes two days after the transfection. The specific binding of [<sup>3</sup>H]-pCI-DPDPE and [<sup>3</sup>H]-SNC 121 decreased dramatically to both chimeras, while the binding of [<sup>3</sup>H]-DAMGO remained similar to that of the wild type (wt) delta receptor. Unexpectedly, the replacement of the 3rd extracellular loop conferred a wt mu affinity to the chimera against [<sup>3</sup>H]-Naltrindole (low) and [<sup>3</sup>H]-Naloxone (high). The chimeric receptors were labeled with [<sup>3</sup>H]-Naloxone and the inhibition constants of opioid ligands of different classes were measured. The affinity of NTI decreased more than 100-fold. The decrease in the affinity of the linear deltorphin was more robust than that of the cyclic peptide pCI-DPDPE. Supported by NIDA grants.

## 629.6

A CHANGE IN A SINGLE AMINO ACID RESIDUE ENABLES THE DELTA OPIOID RECEPTOR TO BIND DAMGO, A MU OPIOID RECEPTOR SELECTIVE LIGAND, WITH HIGH AFFINITY.

M. Minami\*, T. Nakagawa, Y. Jenaga, S. Katsumata and M. Satoh. Dept. Molecular Pharmacology, Fac. Pharmaceutical Sciences, Kyoto Univ., Kyoto 606-01, Japan.

We have previously reported that DAMGO, a  $\mu$ -opioid selective ligand, distinguishes between  $\mu$ - and  $\delta$ -opioid receptors (OPRs) in the region around the first extracellular loop, in which only seven amino acid residues are different between these receptors (*FEBS Lett.* 357 (1995) 93-97). In this study, we examined which amino acid residue(s) is involved in the distinction between the two OPRs by DAMGO. Each amino acid residue of the seven residues in the region around the first extracellular loop of the  $\delta$ -OPR was changed to the corresponding residue found in the  $\mu$ -OPR by site-directed mutagenesis. The mutated cDNAs were transfected to COS cells and binding assay was carried out with [<sup>3</sup>H]DADLE and non-radioactive DAMGO. Among the seven mutated  $\delta$ -OPRs, only the  $\delta$ K108N bound DAMGO with a high affinity. A replacement of lysine 108 of the  $\delta$ -OPR with alanine ( $\delta$ K108A) also gave a high affinity for DAMGO to the mutated receptor, suggesting that lysine 108 of the  $\delta$ -OPR is obstructive to the binding of DAMGO rather than that asparagine at the corresponding position of the  $\mu$ -OPR is necessary to that. Furthermore, the mutated receptors  $\delta$ K108N and  $\delta$ K108A mediated the signals of agonist binding to the inhibitory system of adenylate cyclase in CHO cells. These results indicate that the difference in a single amino acid residue of the first extracellular loop between the  $\mu$ - and  $\delta$ -OPRs is critical for the subtype-specificity in the binding to DAMGO.

## 629.8

THREE DIMENSIONAL MODEL OF THE  $\delta$  OPIOID RECEPTOR: INTERACTION OF AGONISTS AND ANTAGONISTS IN THE PUTATIVE BINDING SITE. P.A. Maguire\*, J. Alcorta, P. Du and G.H. Loew. Molecular Research Institute, Palo Alto, CA 94304.

A 3D model of the transmembrane domain of the  $\delta$  opioid receptor was constructed using Sequence Divergence Analysis of 42 homologous sequences of G-protein coupled receptors belonging to the opioid, somatostatin and angiotensin receptor families. No template was used in the prediction steps, which included multiple sequence alignment, identification of the boundaries of the transmembrane regions by calculation of a variability profile of the aligned sequences and optimization of the packing shape in the helix bundle. A candidate ligand binding site was identified using the  $\delta$ -selective antagonist, naltrindole, as a probe. The interaction of the protonated amine nitrogen of naltrindole with the highly conserved Asp-127 in TM 3 was used as an anchoring point. This binding site was also used to dock other ligands, including the  $\delta$ -selective peptide antagonist Tyr-Tic-Phe-Phe-NH<sub>2</sub> (TIPP-NH<sub>2</sub>) and two agonists from different structural families, lofentanil and BW373U86. The resulting ligand-receptor complexes were then energy optimized. Common interaction points for recognition of these ligands were identified, involving at least two of three lipophilic moieties and two polar substituents of the ligands. In addition, comparisons of agonist and antagonist binding allowed preliminary identification of polar interactions that could be involved in activation. Specific amino acid residues interacting with these ligands were identified that could direct the design of mutation studies that would be invaluable in the efforts to validate and refine the model. This work was supported by NIDA Grant (DA02622)

## 629.9

SINGLE AMINO ACID MUTATION IN TRANSMEMBRANE REGION CONFERS AGONIST ACTIVITY TO ANTAGONISTS. P. Claude, L. Erickson, P. Prather\*, H. Loh and P. Law. Dept. of Pharmacology, University of Minnesota, Minneapolis, Minnesota, 55455.

A chimeric receptor was created from the N-terminus of the C-terminus of the second transmembrane regions of the  $\mu$  opioid receptor and the N-terminus of the first extracellular loop to the C-terminus of the  $\delta$ 2 opioid receptor ( $\mu\delta$ 2). In order to analyze ligand/receptor binding and subsequent signal transduction, the  $\mu\delta$ 2 chimeric receptor was stably expressed in CHO cells then screened for binding properties and the ability to inhibit adenylyl cyclase with a number of  $\mu$  and  $\delta$  selective agonists and antagonists. Binding and adenylyl cyclase assays determined that the  $\mu\delta$ 2 chimeric receptor was exhibiting  $\delta$ -like characteristics. However, opioid antagonists (NTB, naloxone, naltrexone) did not reverse DPDPE inhibition of adenylyl cyclase nor did they produce a compensatory increase in cAMP production when assayed in  $\mu\delta$ 2 stably transfected CHO cells that had been chronically treated with DPDPE. Antagonist assayed on their own, though, did produce an inhibition of adenylyl cyclase activity. Sequencing of the  $\mu\delta$ 2 chimera uncovered a single amino acid mutation in a single transmembrane region. Mutation of this amino acid back to the wildtype sequence abolished the agonistic effects that the antagonists exhibited. Analogous mutations in wildtype  $\delta$ 2 and  $\mu$  opioid receptors again conferred full-agonist properties to antagonists. None of the mutant receptors demonstrated significant differences in binding affinity as compared to wildtype for any of the ligands assayed. This implies that the mutated amino acid is not involved in ligand recognition but rather with signal transduction. (supported in part by NIDA grant #DA07339, 0564, 01583, 07234, 05695)

## 629.11

THE  $\mu$  OPIATE RECEPTOR TM 6 HISTIDINE RESIDUE IS CRITICAL FOR HIGH AFFINITY AGONIST BINDING. C.K. Surra†\*, P.S. Johnson#, C.E. Spivak#, B.K. Seidleck#, L.D. Hirschbein#, C.J. Blaschak#, A. Moriawaki#, G.R. Uhl†#

#Molecular Neurobiology Branch#, Office of the Director#, Intramural Research Program/NIDA; Dept. of Neurology and Neuroscience@, Johns Hopkins School of Medicine.

A transmembrane (TM) 6 histidine residue is conserved among several G-coupled receptors including the rat and human  $\mu$ ,  $\delta$  and  $\kappa$  opiate receptors, and represents the lone positive charge predicted to lie in the TM region of the  $\mu$  receptor. To characterize the role of His-297 in  $\mu$  receptor function, substitution mutants were tested using radioligand binding, adenylyl cyclase inhibition and agonist-catalyzed opening of co-expressed  $K^+$  channels. His-297 was replaced with amino acids of like or opposite charge or structure, and cell surface expression was verified immunocytochemically. Ligand binding  $B_{max}$  values quantitated expression levels for several mutants. Substitution with asparagine and glutamine retained high affinity binding of radiolabeled DAMGO and naloxone, while substitutions with alanine, aspartic acid, glutamic acid, arginine, lysine or phenylalanine resulted in dramatically reduced affinities for both peptide and alkaloid ligands. Application of high agonist concentrations mediated inhibition of adenylyl cyclase and opening of inwardly-rectifying  $K^+$  channels co-expressed in *Xenopus* oocytes for all mutant receptors. These results suggest that His-297 contributes prominently to both agonist and antagonist binding sites, and support a role of the His-297 sidechain in  $\mu$  receptor function that cannot be duplicated by sidechains which merely donate  $\pi$  electrons or a full positive charge.

## 629.13

BINDING DOMAIN OF FENTANYL AND SUFENTANIL IN THE CLONED  $\mu$  OPIOID RECEPTOR. J.Zhu\*, J.Yin, P.-Y.Law<sup>1</sup>, P.A.Claude<sup>1</sup>, C.Chen, C.Evans<sup>2</sup>, L. Yu<sup>3</sup> and L.-Y.Liu-Chen. Dept. Pharmacol., Temple Univ. Sch. Med., Philadel., PA 19140; <sup>1</sup>Dept. Pharmacol., Univ. Minnesota Sch. Med., Minneapolis, MN 55455; <sup>2</sup>Neuropsychiat. Inst., UCLA, Los Angeles, CA 90024; <sup>3</sup>Dept. Med. & Mol. Genetics, Indiana Univ. Sch. Med. Indianapolis, IN 46202.

Fentanyl and its analog sufentanil are narcotic analgesics with high potency and short duration of action. Both are highly selective  $\mu$  opioid agonists and displayed morphine-like side effects clinically. Recently  $\mu$ ,  $\delta$  and  $\kappa$  opioid receptors have been cloned, which permits identification of structural basis of binding selectivity of these receptors at the molecular level. In this study, we determined the binding domain of fentanyl and sufentanil in the  $\mu$  receptor by examining their binding to  $\mu$  and  $\delta$  receptors and  $\mu\delta$  chimeric receptors. Four chimeras constructed from the mouse  $\delta$  and the rat  $\mu$  receptors were used. For  $\mu\delta$ 1 and  $\delta\mu$ 1, the segments from the N-terminus to the beginning of the first intracellular loop were exchanged. For  $\mu\delta$ 4 and  $\delta\mu$ 4, the fragments from the N-terminus to the beginning of second extracellular loop were swapped. All four  $\mu\delta$  chimeric receptors bound [<sup>3</sup>H] diprenorphine with high affinity, similar to  $\mu$  and  $\delta$  receptors. Fentanyl and sufentanil inhibited [<sup>3</sup>H] diprenorphine binding to  $\mu$ ,  $\delta\mu$ 1 and  $\delta\mu$ 4 with high affinity, but to  $\delta$ ,  $\mu\delta$ 1 and  $\mu\delta$ 4 with low affinity. Thus, the segment from the beginning of the second extracellular loop to the C-terminus of the  $\mu$  receptor appears to confer the binding selectivity for fentanyl and sufentanil. (Supported by NIDA grants 04745 and 06650)

## 629.10

DETERMINING THE SPECIFIC INTERACTIONS BETWEEN OPIOID LIGANDS AND THEIR RECEPTORS: A COMPLEMENTARY STUDY F. Meng\*, M.T. Hoversten, R.C. Thompson, L. Taylor, S.I. Watson and H. Akil MHR, Univ. of Michigan, Ann Arbor, MI48109

To fully understand the working mechanism of a receptor, one need to learn how a ligand interact with its receptor. The combination of both receptor mutagenesis and ligand "mutagenesis" (comparing the binding properties of structurally similar compounds) may help us to empirically determine some of the specific interactions between a ligand and its receptor. The richness of opioid ligands creates a very good opportunity to implement such a complementary study. There are many well characterized ligands that only differ slightly in structure but differ greatly in binding properties. An interesting example is U63,639 and U63,640. While being mirror images to each other, U63,639 prefers the  $\mu$  receptor whereas U63,640 binds the  $\kappa$  receptor with high affinity. Furthermore, a pair of structurally similar ligands, (+)U50,488 and (-)U50,488, show a different binding profile. Although (-)U50,488 is still  $\kappa$ -selective, (+)U50,488 exhibits similar affinities toward both the  $\kappa$  and the  $\mu$  receptors. By analyzing their binding profiles on a series of  $\kappa/\mu$  chimeric receptors as well as on the wild type  $\kappa$  and  $\mu$  receptors, we are able to determine that (1) a single functional group on U63,639 is solely responsible for its  $\mu$  selectivity (2) this particular functional group most likely interacts with a region in the  $\mu$  receptor containing the sixth transmembrane domain(TM6) and the third extracellular loop (3) U63,640 and (-)U50,488 achieve  $\kappa$ -selectivity mainly through their interactions with a  $\kappa$  receptor region spanning from TM1 to the beginning of TM3. Site-directed mutagenesis studies are underway to pinpoint the individual residues that may directly interact with specific functional groups in these ligands.

## 629.12

DETERMINATION OF THE REGION INVOLVED IN [<sup>3</sup>H]8-FUNALTREXAMINE COVALENT BINDING IN THE CLONED RAT  $\mu$  OPIOID RECEPTOR BY PEPTIDE-MAPPING. C. Chen<sup>1</sup>, L. Yu<sup>2</sup>, Y.-W. Chen<sup>1</sup>, J. Zhu<sup>1</sup> and L. Liu-Chen<sup>1\*</sup>. <sup>1</sup>Dept. of Pharmacology, Temple Univ. Sch. of Med., Philadelphia, PA 19140. <sup>2</sup>Dept. of Med. & Mol. Genetics, Indiana Univ. Sch. Med., Indianapolis, IN 46202.

We previously demonstrated that [<sup>3</sup>H]8-funaltrexamine ([<sup>3</sup>H]8-FNA) specifically and irreversibly labeled rat brain  $\mu$ -opioid receptors as well as the cloned rat  $\mu$  opioid receptor expressed in COS or CHO cells. SDS-PAGE and fluorography showed that [<sup>3</sup>H]8-FNA-labeled receptors migrated as one broad band with Mr of 80 kDa in CHO or COS cells and as one band with Mr of 67 kDa in the rat brain. Upon removal of N-linked carbohydrates, labeled receptors became a sharp band with Mr of ~40kDa. In order to locate the covalent binding site of [<sup>3</sup>H]8-FNA within the  $\mu$  receptor, we carried out peptide-mapping studies on the labeled cloned rat  $\mu$  receptor.  $\mu$  receptors expressed in CHO cells were labeled with [<sup>3</sup>H]8-FNA and then purified by wheat germ lectin affinity chromatography followed by immunoaffinity chromatography with antibodies against a C-terminal domain peptide. The partially purified receptor was treated with endoproteinase Glu-C or CNBr. Glu-C digestion of [<sup>3</sup>H]8-FNA labeled  $\mu$  receptor generated a diffuse labeled band with Mr 53-69 kDa, which after deglycosylation with N-Glycanase, became a sharp band with Mr of ~25kDa. CNBr treatment yielded a labeled fragment with Mr of 4.5 kDa. The glycosylation nature of the labeled fragment generated by Glu-C and the size of the deglycosylated fragment suggest that this peptide corresponds to the one from Met1 to Glu229 (calc.mw 25016). In addition, the size of CNBr-generated labeled fragment suggests that the site is within Ser162-Met203 (calc.mw 4668) or Ala206 - Met243 (calc.mw 4546). We will determine more precisely the region and eventually the amino acid residue of 8-FNA covalent incorporation. Since [<sup>3</sup>H]8-FNA is a rigid molecule, the information will be very useful for computerized modeling of the  $\mu$  receptor. (supported by NIDA grant 04745).

## 630.1

OPIATE BINDING AFTER TREATMENT WITH THE NONEQUILIBRIUM  $\kappa$ -ANTAGONIST DIPPA. W.E. Polgar,<sup>1</sup> I. Berzetei-Gurske,<sup>1</sup> A.-C. Chang,<sup>2</sup> P.S. Portoghese,<sup>2</sup> and L. Toll.<sup>\*</sup> <sup>1</sup>SRI International, Menlo Park, CA 94025; <sup>2</sup>University of Minnesota, Minneapolis, MN 55455.

The benzeneacetamide DIPPA has been shown to cause long-lasting inhibition of antinociception induced by the selective  $\kappa$ -agonist U50,488 but was ineffective in inhibiting the actions of  $\mu$  and  $\delta$  agonists. This compound also caused wash-resistant inhibition of binding when tested *in vitro*, and so we examined binding parameters after intraperitoneal injection into guinea pigs. Guinea pigs were injected with 0.25, 0.5, or 1.0 mg/kg DIPPA. Brains were removed and binding was conducted 24, 48, or 72 hr after injection. DIPPA caused a dose- and time-dependent inhibition of binding of the  $\kappa$ -selective ligand [<sup>3</sup>H]U69,593 without affecting the binding parameters of the  $\mu$ -selective ligand [<sup>3</sup>H]DAMGO or the  $\delta$ -selective ligand [<sup>3</sup>H]CI-DPDPE. DIPPA caused maximal inhibition of binding at 0.5 mg/kg, inhibiting 35% of specific [<sup>3</sup>H]U69,593 binding. DIPPA was most effective 48 hr after injection, but [<sup>3</sup>H]U69,593 binding was significantly lower than control at both 24 and 72 hr after DIPPA injection. As expected for an irreversible inhibitor, DIPPA induced a decrease in  $B_{max}$  without significantly affecting the  $K_d$  of [<sup>3</sup>H]U69,593. These results complement our studies showing a DIPPA-induced inhibition of  $\kappa$ -activity in the guinea pig ileum after intraperitoneal administration.

## 630.3

N-CBM-TAMO: A SHORT-TERM OPIOID AGONIST AND A LONG-TERM OPIOID ANTAGONIST. I. Y. Xu,<sup>\*</sup> S. Archer,<sup>\*</sup> and J. M. Bidlack. University of Rochester, Rochester, NY 14642 and <sup>\*</sup>Rensselaer Polytechnic Institute, Troy, NY 14181.

The antinociceptive and opioid binding properties of the N-cyclobutylmethyl analogue of normorphine, 14 $\alpha$ ,14' $\beta$ -[dithiobis(2-oxo-2,1-ethanediyl)imino]bis[7,8-dihydro-N-(cyclobutylmethyl)-normorphine] (N-CBM-TAMO) were investigated. In the mouse 55°C warm-water tail-flick test, N-CBM-TAMO given supraspinally acted as a short-term partial agonist, because only submaximal antinociception was observed at doses up to 100 nmol. Pretreatment of mice with i.c.v. N-CBM-TAMO at 10 nmol which exhibited moderate short-term antinociception produced a time- and dose-dependent long-term antagonism of morphine-induced antinociception. In the mouse writhing test, N-CBM-TAMO acted as a full agonist with a  $D_{50}$  value of 0.08 (0.044-0.147) nmol and the antinociception was blocked by co-administration of the  $\kappa$ -selective antagonist, nor-BNI. These *in vivo* data are consistent with the *in vitro* binding study which demonstrated: 1) incubation of membranes with N-CBM-TAMO resulted in wash-resistant inhibition of  $\mu$  and  $\kappa$  opioid binding; 2) the wash-resistant inhibition of  $\mu$ , but not  $\kappa$  opioid binding was partially reversed by the addition of the disulfide reducing reagent dithiothreitol; 3) Scatchard analysis of saturation binding data showed that N-CBM-TAMO decreased the  $B_{max}$  value without affecting the  $K_d$  value for the  $\mu$ -selective peptide [<sup>3</sup>H]DAMGO. Whereas, N-CBM-TAMO increased the  $K_d$  value without altering the  $B_{max}$  value for the  $\kappa$ -selective ligand [<sup>3</sup>H]U69,593. This study demonstrates that N-CBM-TAMO is a very potent  $\kappa$  agonist and at higher concentrations produces long-term antagonism of antinociception mediated by  $\mu$  opioid receptors. (Supported by USPHS grant DA03742, DA07232 and DA01674)

## 630.5

IRREVERSIBLE BLOCKADE OF THE  $\kappa$  OPIOID RECEPTORS IN GUINEA PIG ILEUM. R.W. Schwartz, A.-C. Chang, P.S. Portoghese, and I. Berzetei-Gurske.<sup>\*</sup> SRI International, Menlo Park, CA 94025

In studies by Chang et al. (J. Med. Chem. 37:4490, 1994) on a new  $\kappa$ -selective affinity label for opioid receptors, 2-(3,4-dichlorophenyl)-N-methyl-[(1S)-1-(3-isothiocyanatophenyl)-2-(1-pyrrolidinyl) ethyl] acetamide (DIPPA), the compound was shown to be a selective  $\kappa$ -opioid receptor antagonist with a long duration of action *in vivo*, but no antagonist activity was found in the *in vitro* bioassay on guinea pig ileum (GPI). However, our studies showed that DIPPA is a very powerful irreversible  $\kappa$  receptor blocker 24-72 hr after i.p. injection into guinea pigs.

Effects on GPI were evaluated 24-72 hr after male Hartley guinea pigs were injected i.p. with single doses of DIPPA ranging from 0.1 to 10 mg/kg. By 24-48 hr, doses as low as 0.5 mg/kg caused complete blockade of the  $\kappa$ -opioid receptors, with only a minimal shift (1.45-3.41) in the  $IC_{50}$  value for the  $\mu$  receptor agonist [D-Ala<sup>2</sup>,MePhe<sup>4</sup>, Gly-ol] enkephalin (DAMGO). U69,593 (5 $\alpha$ ,7 $\alpha$ ,8 $\beta$ -(+)-N-methyl-N-[7-(1-pyrrolidinyl)-1-oxaspiro-(4,5)-dec-8-yl]), which has an  $IC_{50}$  of 1.9 nM for untreated GPI, turned out to be a partial agonist, with less than 30% agonist activity at  $10^{-6}$  M; higher concentrations ( $5 \times 10^{-5}$  and  $10^{-4}$  M) caused enhancement, which could not be blocked by naloxone or the other selective opiate antagonists tested.

This new assay will be very useful for studying compounds with  $\kappa$  agonist/ $\mu$  antagonist activity where determination of  $\mu$  antagonism was hindered by the presence of a strong  $\kappa$  agonist activity.

## 630.2

N-TERMINAL ALKYLATED DERIVATIVES OF [D-Pro<sup>10</sup>]DYNORPHIN A-(1-11) ARE HIGH AFFINITY PARTIAL  $\kappa$ -OPIOID RECEPTOR AGONISTS. K. Soderstrom, H. Choi, J.V. Aldrich, and T.F. Murray.<sup>\*</sup> College of Pharmacy, Oregon State University, Corvallis OR 97331.

As part of an effort to develop peptides with selective  $\kappa$ -opioid antagonist activity, a series of N-alkylated [D-Pro<sup>10</sup>]Dyn A(1-11) derivatives were made through solid-phase peptide synthesis: R-Tyr-Gly-Gly-Phe-Leu-Arg-Arg-Ile-Arg-D-Pro-LysOH, where R = monobenzyl (MB), monocyclopropyl (MCP), dicyclopropylmethyl (DCPM), or diallyl (Diallyl). These derivatives and dynorphin A(1-13)NH<sub>2</sub> (DynA) were evaluated for  $\kappa$ -opioid receptor binding affinity and potency as inhibitors of adenylyl cyclase (AC). Equilibrium competition binding experiments using [<sup>3</sup>H]diprenorphine (0.5 nM) were performed on membranes prepared from CHO cells stably expressing the rat  $\kappa$ -opioid receptor. Cultures of these  $\kappa$ -receptor-expressing cells were used to evaluate opioid peptide inhibition of forskolin-stimulated (50  $\mu$ M) AC. Displacement of [<sup>3</sup>H]diprenorphine specific binding by these peptides was observed with a rank order of affinity ( $K_i$ , nM) = DynA (0.84) > MCP (1.3) > DCPM (12.7) > MB (19.1) > Diallyl (25.7). A similar rank order was observed for potency of AC inhibition ( $EC_{50}$ , nM): DynA (0.19) > MCP (2.9) > DCPM (10.2) > Diallyl (11.2) > MB (51.6). The peptides differed in their maximal inhibition of AC: DynA (89%)  $\approx$  MCP (84%) > MB (63%) > Diallyl (25%)  $\approx$  DCPM (24%). As the DCPM and Diallyl derivatives were found to have only weak partial agonist activity with respect to AC inhibition, they were evaluated for their ability to reverse DynA (10 nM) inhibition of AC activity. DCPM and Diallyl reversed DynA inhibition to levels equal to the maximal inhibition produced by DCPM and Diallyl alone. This weak partial agonism combined with nanomolar potency render the DCPM and Diallyl compounds promising leads for further attempts to synthesize peptide  $\kappa$ -opioid receptor antagonists. (Supported by PHS grant DA05195 to J.V.A.)

## 630.4

LIGAND BINDING PROFILES OF U-69,593-SENSITIVE AND -INSENSITIVE KAPPA OPIOID RECEPTORS IN HUMAN CEREBRAL CORTEX MEMBRANES. K. W. Kim,<sup>1</sup> H. I. Kim,<sup>2</sup> H. W. Rho,<sup>3</sup> D. G. Kim,<sup>4</sup>, and K. P. Cho.<sup>1</sup> Dept. of Pharmacol.,<sup>1</sup> and Neurosurg<sup>2</sup> and Biochem<sup>3</sup>, Chonbuk Univ. Med. Sch., Chonju 560-182, Chonbuk, Dept. of Pharmacol.,<sup>4</sup> Yonsei Univ. Med. Sch., Seoul 120-752, Republic of Korea

*In vitro* competition studies were performed to characterize the properties of subtypes of  $\kappa$  opioid receptors in membrane preparations of epileptic human cortex.  $\kappa_1$  and  $\kappa_2$  sites are labeled by [<sup>3</sup>H]U-69,593 ([<sup>3</sup>H]U-69), a selective  $\kappa_1$ -agonist, and [<sup>3</sup>H]diprenorphine ([<sup>3</sup>H]DIP), a non-selective opioid antagonist, in the presence of 1  $\mu$ M each of DAMGO, DPDPE and U-69 to block  $\mu$ -,  $\delta$ -, and  $\kappa_1$  sites, respectively. [<sup>3</sup>H]U-69 binding site is of single-population and low density ( $K_d$  = 3.1 nM,  $B_{max}$  = 8 fmol/mg protein) and have a binding profile that corresponds to  $\kappa_1$  opioid receptor. That is, dynorphine-A(1-13)(Dyn-A), bremazocine (BZC), U50,488H (U50), (-)-ethylketocyclazocine (EKC) and nor-binaltorphimine (nor-BNI) bind to this site with high affinities, whereas  $\mu$ - and  $\delta$ -ligands do not. [<sup>3</sup>H]DIP binding site is of single-population and high density ( $K_d$  = 9 nM,  $B_{max}$  = 352 fmol/mg protein). [<sup>3</sup>H]DIP binding was not influenced by U-50,488H, confirming it is not  $\kappa_1$ -site, but inhibited by BZC, EKC and nor-BNI ligands that possess affinities to  $\kappa_2$  opioid receptors. The rank order of affinities of these ligands are correlated with that of  $\kappa_2$  receptor originally reported in rat brain. These results show existence of both  $\kappa_1$  and  $\kappa_2$  opioid receptors in human cortex. (This work is supported by 1994 KOSEF Grant.)

## 630.6

RESOLUTION OF TWO SUBTYPES OF DELTA<sub>ANCX</sub> BINDING SITES IN RAT BRAIN USING [3H]DADL: SELECTIVE EFFECTS OF DELTA ANTISENSE DNA. Q. Ni,<sup>\*</sup> X.Y. Cha,<sup>\*</sup> H. Xu,<sup>\*</sup> F. Porreca,<sup>†</sup> J. Lai,<sup>†</sup> J.S. Partilla,<sup>†</sup> K.C. Rice,<sup>†</sup> D. Matecka,<sup>†</sup> and R. B. Rothman.<sup>\*</sup> <sup>\*</sup>CPS, DIR, NIDA and <sup>†</sup>LNC, NIDDK, NIH, Baltimore and Bethesda, MD. <sup>†</sup>Department of Pharmacology, University of Arizona, Tucson, AZ 85724.

Quantitative binding studies resolved two high affinity [3H]DADL binding sites in rat brain membranes depleted of  $\mu$  binding sites by pretreatment with BIT. Assays were conducted in 50 mM Tris-HCl, pH 7.4, containing 100 mM NaCl, 2  $\mu$ M GTP, 3 mM MgCl<sub>2</sub> and 5 mM 2-mercaptoethanol for 4-6 hr at 25°C. The two binding sites had lower (DELTA<sub>ANCX1</sub>,  $K_i$  = 96.6 nM) and higher (DELTA<sub>ANCX2</sub>,  $K_i$  = 1.55 nM) affinity for DPDPE. The ligand-selectivity profile of the DELTA<sub>ANCX2</sub> site was that of a classic delta binding site. The ligand-selectivity profile of the DELTA<sub>ANCX1</sub> site was neither  $\mu$ - or delta-like. The  $K_i$  values of selected agents were: ([pCl]DPDPE, 3.91 nM), (DPLPE, 142 nM), (DAMGO, 2.65 nM). Under these assay conditions, [3H]DADL binding to the cells expressing the cloned  $\mu$  receptor is very low and pretreatment of cell membranes with BIT almost completely inhibits [3H]DAMGO and [3H]DADL binding. Chronic administration of morphine pellets up-regulated [3H]DAMGO binding to  $\mu$  receptors, but decreased DELTA<sub>ANCX2</sub> binding. I.c.v. administration of antisense DNA to the cloned delta receptor selectively decreased [3H]DADL binding to the DELTA<sub>ANCX1</sub> site. Viewed collectively, these studies have identified a novel non- $\mu$ , delta-like binding site in rat brain.

## 630.7

ONE OF THE MOUSE BRAIN DELTAN<sub>1</sub> BINDING SITES IS SIMILAR TO THE CLONED OPIOID DELTA RECEPTOR: FURTHER EVIDENCE FOR HETEROGENEITY OF DELTA RECEPTORS. H. Xu\*, X.Y. Cha, J.S. Partilla, F. Porreca†, J. Lait†, J. Pinto\*, S.N. Calderon\*, D. Matecka\*, K.C. Rice\*, S. Ananthan† and R.B. Rothman\*. \*CPS, DIR, NIDA, NIH, Baltimore, MD 21224. †Department of Pharmacology, College of Medicine, University of Arizona, Tucson, AZ 85724. \*LMC, NIDDK, NIH, Bethesda, MD 20892. #Organic Chemistry Department, SORI, Birmingham Alabama 35255.

We recently presented evidence for subtypes of the deltan<sub>1</sub> binding site in rat and mouse brain which we termed deltan<sub>1</sub> and deltan<sub>2</sub>. Cha et al. (this meeting) report that i.c.v. administration of antisense DNA complementary to the cloned delta opioid receptor (CDOR) to rats decreased [3H]DADL binding to one of the binding sites. Here we compare the binding parameters, ligand selectivity profile and pharmacological properties of the mouse CDOR stably expressed in a cell line to the deltan<sub>1</sub> binding sites of mouse brain. [3H]DADL labeled a single binding site in membranes prepared from these cells. BIT-pretreatment had no significant effect on [3H]DADL binding parameters. The DOR had high affinity for delta agonists and antagonists. [3H]DADL labeled two binding sites in mouse brain membranes depleted of mu receptors by pretreatment with BIT: the deltan<sub>1</sub>-1 site (high affinity for DPDPE and deltorphin) and the deltan<sub>2</sub> site (low affinity for DPDPE and deltorphin). Some agents were moderately selective for the deltan<sub>2</sub> site: [pCl]DPDPE (10.9-fold), JP41 (5.9-fold) and JP45 (3.8-fold). The K<sub>i</sub> values of 12 opioids at the mouse CDOR were determined. These values were highly correlated (r=0.996) with their values at the deltan<sub>1</sub> site but not the deltan<sub>2</sub> site (r=0.05). These data suggest that the deltan<sub>2</sub> site may be distinct from the cloned delta opioid receptor.

## 630.9

INHIBITION OF FORSKOLIN-STIMULATED cAMP FORMATION BY PEPTIDE AND NON-PEPTIDE AGONISTS ACTING AT THE HUMAN  $\delta$  OPIOID RECEPTOR. E. Malatynska\*, Y.J. Wang, R.J. Knapp, G. Santoro, X. Li, S. Waite, H. Nagase, S. Calderon, K. Rice, W.R. Roeske and H.I. Yamamura. University of Arizona, Tucson, AZ 85724, Toray Industries, Japan and NIH, MD.

Stable expression of a human  $\delta$  opioid receptor (hDOR) was established in Chinese hamster ovary (CHO) cells. This cell line has a high density of hDORs (137,000  $\pm$  21,000 receptors per cell) that bind the  $\delta$  receptor selective antagonist naltrindole (NTI) with a K<sub>d</sub> of 139  $\pm$  36 pM. The recombinant cells were used to characterize the potency of opioid agonists for the inhibition of cAMP accumulation. Ligands selective for  $\mu$  (DAMGO) and  $\kappa$  (U50488) opioid receptors inhibit forskolin-stimulated cAMP formation with low potency (EC<sub>50</sub>, 2.0  $\mu$ M and 85  $\mu$ M, respectively). DOR selective agonists inhibit forskolin-stimulated cAMP formation with high potency (EC<sub>50</sub> for the peptides DPDPE, 1.0 nM and pCl-DPDPE, 0.4 nM and for non-peptides, SNC80, 8.3 nM and TAN67, 1.8 nM). This inhibition was antagonized by NTI in a dose dependent manner. Schild analysis showed that NTI competitively antagonized (slope 0.9) pCl-DPDPE induced cAMP inhibition with a pA<sub>2</sub> value of 9.4 that is consistent with the high affinity of this antagonist.

Receptor desensitization is thought to be one of the reasons for the development of tolerance and/or dependence observed after prolonged opioid administration. However, DOR selective agonists are less effective at producing these effects than  $\mu$  receptor selective agonists when tested in animals. We pretreated CHO cells expressing hDOR with non-peptide DOR agonist, SNC80 for 24 hr. After such treatment the B<sub>max</sub> value obtained for [<sup>3</sup>H]NTI binding was reduced by 41% relative to untreated control cells. Cells exposed to SNC80 for 24 hr show a 10 fold reduction in the potency of SNC80 to inhibit forskolin-stimulated cAMP formation and decreased the E<sub>max</sub> value to 50% inhibition compare to 85% for control. We conclude that the hDOR undergoes down-regulation after exposure to delta agonist. Supported by NIDA grants.

## 630.11

Isolation and pharmacological characterization of a novel neuropeptide specific to an opioid-like receptor

Rainer K. Reinscheid\*, Hans-Peter Nothacker, Robert Henningsen, Frederick J. Monsma Jr. & Olivier Civelli. Hoffmann-La Roche, PRPN, CH-4002 Basel, Switzerland.

A cDNA encoding a G protein-coupled receptor which shows high homology to  $\mu$ ,  $\delta$  and  $\kappa$ -opioid receptors has recently been cloned by several groups. However, none of the classical opioid ligands was able to bind to this receptor. We have now purified and characterized an endogenous ligand for this opioid-like G protein-coupled receptor. The ligand was isolated from porcine brain extracts and identified as a 17 amino acid peptide which bears structural similarity to the opioid peptides. The corresponding synthetic peptide was shown to potentially inhibit forskolin-stimulated cAMP accumulation in CHO and HEK 293 cells stably transfected with the opioid-like receptor. Interestingly, this novel peptide was unable to activate opioid receptors. In addition, we found that opioid ligands were unable to antagonize binding of this novel peptide at its receptor. Preliminary studies indeed suggest that the mode of interaction of the peptide with its receptor may be different from that proposed for the opioid peptides. To further the characterization of this novel neuropeptide, we have developed a radioligand binding assay and began to correlate the tissue distribution of this peptide with that of its corresponding receptor and that of the opioid peptides. Taken together these results suggest that this peptide belongs to a peptidergic transmitter class reminiscent of but different from that of the opioid peptide family.

## 630.8

EFFECT OF NONPEPTIDIC AGONISTS AT THE CLONED HUMAN DELTA OPIOID RECEPTOR. G. Santoro, R.J. Knapp, K.B. Lee, S. Edsall, J. De Leon, S. Waite, S.N. Calderon\*, K.C. Rice\*, F. Porreca, L. Stern\*, W.R. Roeske and H.I. Yamamura. Dept. of Pharmacology and Medicine, College of Medicine, Univ. of Arizona, Tucson, AZ 85724 and \*Laboratory of Medicinal Chemistry, NIDDK, NIH, Bethesda, Maryland.

Cloning of the three receptor types from different species including human, and the availability of recombinant cell lines expressing a homogeneous opioid receptor population present new research opportunities for the characterization of opioid ligands. Drugs acting at the delta opioid receptor may have therapeutic advantage over opiate narcotic acting primarily at the  $\mu$  receptor. Nonpeptidic agonists are recently being developed given their capability to cross the blood-brain-barrier. BW 373U86 was the first nonpeptidic agonist selective for the delta opioid receptor. Due to the capability of this compound to induce convulsions in mice, a series of compounds were developed from the original structure of BW 373U86. We report here the characterization of SNC 67, SNC 79, SNC 80, SNC 83, SNC 85, SNC 86, SNC 88, SNC 89, SNC 121 and SNC 162. All compounds were tested for their capability to inhibit specific [<sup>3</sup>H]-Cl-DPDPE binding measured on membrane homogenate obtained from CHO cells stably expressing the human delta opioid receptor (hDOR) and specific [<sup>3</sup>H]DAMGO binding measured on membrane homogenates from B 82 cells stably expressing the human  $\mu$  opioid receptor (hMOR). These compounds, with the exception of SNC 67, showed high selectivity for the delta receptor with K<sub>i</sub> values for [<sup>3</sup>H]-Cl-DPDPE ranging from 0.4 nM to 15 nM and K<sub>i</sub> values for [<sup>3</sup>H]DAMGO ranging from 50 nM to 12,000 nM. The high selectivity of these agonists for the hDOR makes these compounds potential therapeutic agents for the management of pain.

Supported by NIDA grants.

## 630.10

A NEW DIHYDROCODEINONE DERIVATIVE DISPLAYS OPIOID AGONISTIC AND ANTAGONISTIC PROPERTIES. J.P. McLaughlin\*, J.P. Egaminio, W. El-Hamouly\*, S. Archer\* and J.M. Bidlack. Univ. of Rochester, Rochester, NY 14642 and \*Rensselaer Polytechnic Institute, Troy, NY 12181.

N-Cyclobutylmethylnor-14 $\beta$ -(p-nitrocinnamoylamino)-7,8-dihydrocodeinone (N-CBM-CACO) was characterized for opioid affinity, selectivity and activity with receptor binding and analgesic studies. In competition binding assays with bovine striatal membranes, nanomolar concentrations of N-CBM-CACO inhibited  $\mu$ ,  $\delta$  and  $\kappa$  opioid binding. Like previously characterized cinnamoylamino opioid derivatives, N-CBM-CACO inhibited binding of the  $\mu$ -selective peptide [<sup>3</sup>H][D-Ala<sup>2</sup>,(Me)Phe<sup>4</sup>,Gly(ol)<sup>5</sup>]enkephalin (DAMGO) in a wash-resistant manner, but produced no significant inhibition of  $\delta$ - or  $\kappa$ -opioid binding. A concentration of 16 nM N-CBM-CACO produced a 50% wash-resistant inhibition of the binding of 0.25 nM [<sup>3</sup>H]DAMGO, with complete inhibition occurring at 100 nM. Scatchard analysis of [<sup>3</sup>H]DAMGO saturation binding revealed a two-fold reduction of the B<sub>max</sub> value, suggesting N-CBM-CACO may bind covalently to the  $\mu$  opioid receptor. In the mouse 55°C warm-water tail-flick test, N-CBM-CACO produced antinociception that lasted up to 80 min, and displayed a D<sub>50</sub> value of 8 nmol after i.c.v. administration. However, 24-hr N-CBM-CACO pretreatment of mice inhibited the antinociceptive effect of 3-nmol morphine. These results suggest this compound possesses both short-term agonistic and long-term antagonistic effects at the opioid receptor. The receptor selectivity of N-CBM-CACO is currently being characterized in the mouse tail-flick and acetic-acid writhing tests. (Supported by USPHS grants DA03742 and DA06786).

## 630.12

PHOLCODINE, AN ANTITUSSIVE OPIOID DRUG, SHOWS VERY LOW AFFINITY FOR  $\mu$ ,  $\delta$  OR  $\kappa$  OPIOID RECEPTORS. M. Attila\*, J. Waldén, T. Heikkinen and J. Aaltonen\*. Div. of Pharmacology and Toxicology, Dept. of Pharmacy, Univ. of Helsinki and \*Leiras Oy, Helsinki, Finland.

Pholcodine is used as an antitussive agent which does not possess analgesic properties although it is structurally related to morphine. Pholcodine is classified into narcotic drugs which restricts its marketing. Binding of pholcodine to opioid receptors has been only sporadically studied. Chen et al. (Life Sci. 48: 2165-2171, 1991) reported negligible binding of pholcodine to  $\mu$  opioid receptors (about 4700 times lower affinity than morphine). In this study we have confirmed the low affinity of pholcodine to  $\mu$  opioid receptors and report its even lower affinity to  $\delta$  and  $\kappa$  opioid receptors. Synaptosomal (P<sub>2</sub> fraction) preparations from whole brain (minus cerebellum) of adult male Wistar rats (Lazarus et al., J. Med. Chem. 35: 1222-1227, 1992) were used for the binding assays. Competition studies with pholcodine, morphine, DPDPE, DAMGO, or U-69593 were conducted using 6 nM [<sup>3</sup>H]DPDPE, 3.5 nM [<sup>3</sup>H]DAMGO or 6 nM [<sup>3</sup>H]U-69593 to label  $\delta$ ,  $\mu$  or  $\kappa$  sites, respectively. The non-specific binding was defined by displacing the label with cold DPDPE, DAMGO or U-69593 (15.5, 19.5 or 28.0  $\mu$ M, respectively). Competition curves were calculated by using non-linear regression analysis each combined from 3 to 5 assays using different synaptosomal preparations. Pholcodine showed K<sub>i</sub> values at  $\mu$ M or mM level - thus being 900 to 2000 times less potent than morphine. We conclude that due to the low affinity of pholcodine on  $\mu$ ,  $\delta$  or  $\kappa$  opioid receptors this antitussive drug should not any more be classified into narcotic drugs.

## 630.13

NALTREXONE ANTAGONISM OF MORPHINE AND U50,488 IN A THREE-KEY DISCRIMINATION IN PIGEONS. M. Makhay\* and A. Poling. Department of Psychology, Western Michigan University, Kalamazoo, MI 49008.

It has been demonstrated that morphine and U50,488 are discriminable in a three-key assay in pigeons (Makhay, 1994). To determine if the discriminative and rate-decreasing effects of U50,488 and morphine were differentially sensitive to opioid antagonists, naltrexone was administered in combination with morphine and U50,488. Five pigeons were tested with various doses of naltrexone (0.01 to 3.2 mg/kg) in combination with morphine and U50,488 in doses ranging from 3.2 to 32 mg/kg. Low doses of naltrexone administered in combination with the training doses of U50,488 and morphine (5.6 mg/kg) occasioned about 50% drug-appropriate responding, whereas higher doses of naltrexone completely blocked the drug cues. Naltrexone did not substantially affect rates when compared to control values. High doses of naltrexone completely antagonized high doses of morphine, but only reduced U50,488-appropriate responding by about 50%. These results are in contrast with those of Picker & Dykstra (1987) in that naltrexone did not differentially antagonize the stimulus and rate-reducing effects of the training doses of morphine and U50,488.

## OPIOID RECEPTORS: SIGMA RECEPTORS

## 631.1

SIGMA2-MEDIATED INHIBITION OF ELECTRICALLY-EVOKED GUINEA-PIG ILEUM LONGITUDINAL MUSCLE/MYENTERIC PLEXUS (GPLMMP) CONTRACTIONS. G.G. Kinney\*, E.W. Harris, R. Ray and T.J. Hudzik, Astra Pharm., Dept. of Biol., Box 1071, Rochester, NY 14603.

At least two subtypes of the sigma binding site are known to exist in the brain and periphery. Little is known, however, about any biological function these sites may subserve. Thus, the potency of a number of sigma ligands to inhibit electrically-stimulated contraction of the GPLMMP was compared to their relative affinities for sigma<sub>1</sub> and sigma<sub>2</sub> binding sites. The rank potencies (IC<sub>50</sub>) of compounds to suppress contraction of the GPLMMP perfectly matched the rank affinities (IC<sub>50</sub>) of these compounds for the sigma<sub>2</sub> site (r=1.0), while no significant correlation with sigma<sub>1</sub> (r=0.28, P>.46) binding was found. In addition, no significant correlation between GPLMMP efficacy and previously reported muscarinic cholinergic (r=0.04, P>.94), dopamine D<sub>2</sub> (r=-0.18, P>.67), and PCP (r=-0.58, P>.18) binding affinities were found. Thus, the GPLMMP appears to represent a functional biological assay linked to the sigma<sub>2</sub> binding site which has important implications for future research into the etiology of disorders in which sigma receptors have been implicated.

## 631.3

DUAL MODULATION OF CELLULAR CALCIUM BY SIGMA RECEPTOR LIGANDS: RELEASE FROM INTRACELLULAR STORES AND BLOCKADE OF VOLTAGE-DEPENDENT INFLUX. B.J. Vilner\* and W.D. Bowen. Unit on Receptor Biochemistry and Pharmacology, Laboratory of Medicinal Chemistry, NIDDK, NIH, Bethesda, MD 20892.

Changes in intracellular Ca<sup>2+</sup> [Ca<sup>2+</sup>]<sub>i</sub> were measured in single human SK-N-SH neuroblastoma cells and rat cerebellar granule cells by the indo fluorescence ratio method in PBS. Data taken from several cells were averaged and reported as maximal % increase over existing baseline. In SK-N-SH cells, 100 μM BD737, reduced haloperidol (RHAL), and CB64D produced small but significant increases in [Ca<sup>2+</sup>]<sub>i</sub> (23.2±1.4%, 38.0±3.5%, and 71.6±3.7%, respectively). The changes in [Ca<sup>2+</sup>]<sub>i</sub> occurred over a 5 min period, first increasing, followed by a decrease. Depolarization by addition of 55 mM KCl, produced a sharp "spike" of [Ca<sup>2+</sup>]<sub>i</sub> (~600%). Removal of extracellular Ca<sup>2+</sup> reduced the effect of added KCl on [Ca<sup>2+</sup>]<sub>i</sub> to 0%, but did not change the effect of sigma ligands. Thus, sigma ligands appear to release Ca<sup>2+</sup> from intracellular stores. This was confirmed by pretreatment of cells with thapsigargin for 10 min to deplete stores, which eliminated the rise in [Ca<sup>2+</sup>]<sub>i</sub> produced by 100 μM BD737. In cerebellar granule cells, the effect of sigma ligands on depolarization-induced Ca<sup>2+</sup> entry was examined. KCl (55 mM) produced a large "spike" of [Ca<sup>2+</sup>]<sub>i</sub> (2,302% increase). Sigma ligands (0.5 - 100 μM) were added to cells prior to addition of KCl. BD737, RHAL, CB64D, BD1008, and (+)-pentazocine, dose-dependently blocked the KCl-induced rise in [Ca<sup>2+</sup>]<sub>i</sub>, with most ligands having strong effects at 1 μM. Ligands lacking sigma affinity (BD1006, CB53D, (-)-sulpiride) had little effect at 30 - 100 μM. Nitrendipine completely blocked the Ca<sup>2+</sup> entry. However, the effect of sigma ligands did not appear to coincide with binding to channels since most exhibited IC<sub>50</sub> values > 100 μM vs. 1 nM [<sup>3</sup>H]nitrendipine. Sigma receptors may thus be capable of signalling intracellular Ca<sup>2+</sup> release and of modulating L-type Ca<sup>2+</sup> channels. (We thank Dr. Yael Eilam for helpful discussions.)

## 631.2

SIGMA LIGANDS DIMINISH THE ABILITY OF RIMCAZOLE TO INHIBIT PCP *hsp70* INDUCTION.

J.W. Sharp\* and D.S. Williams, Dept Anatomy & Physiology, College of Veterinary Medicine, Kansas State University, Manhattan, KS 66506-5602.

PCP(phencyclidine) binds at the NMDA receptor calcium channel PCP site and at the sigma receptor. PCP also induces the heat shock gene, *hsp70*, in cingulate and retrosplenial cortex neurons (Sharp *et al.*, 1991). PCP has also been implicated in drug induced schizophrenia-like behavior. Rimcazole, an antipsychotic drug, inhibits PCP *hsp70* induction (Sharp *et al.*, 1992). Rimcazole binds predominately to sigma-2 sites. It is hypothesized that sigma ligands without antipsychotic properties and with some sigma-2 affinity should partially reverse the effects of rimcazole.

(+)-3-PPP, (+)-cyclazocine, and (+)-pentazocine bind predominately to sigma-1 sites. (+)-3-PPP, and (+)-cyclazocine are modest sigma-2 ligands. Female Sprague Dawley rats(200-250g) were injected(ip) with (+)-3-PPP (50mg/kg), rimcazole (60mg/kg), and after 5 minutes with PCP (40mg/kg). Rats were anesthetized after 24hrs with halothane and perfused. Brains were sectioned (100μm) and reacted immunocytochemically for the protein product of the *hsp70* gene, *HSP70*, with the monoclonal anti-72kd heat shock protein antibody. Appropriate controls were conducted. Analogous experiments and controls employed either (+)-cyclazocine (15mg/kg ip) or (+)-pentazocine (50mg/kg ip) in the place of (+)-3-PPP.

(+)-3-PPP and (+)-cyclazocine diminished the ability of rimcazole to inhibit PCP *hsp70* induction in the cingulate and retrosplenial cortex. The number of *hsp70* induced neurons in rats given (+)-3-PPP (50mg/kg), rimcazole (60mg/kg), and PCP (40mg/kg) was significantly greater (p<.05) than rats given rimcazole (60mg/kg) and PCP (40mg/kg). (+)-Cyclazocine showed similar findings. (+)-Pentazocine did not diminish the ability of rimcazole to inhibit PCP *hsp70* induction.

## 631.4

SIGMA-1 RECEPTOR-MEDIATED INHIBITION OF THE MUSCARINIC PHOSPHOINOSITIDE RESPONSE IS ASSOCIATED WITH M1 RECEPTOR-G PROTEIN UNCOUPLING. D.B. Joseph\* and W.D. Bowen. Unit on Receptor Biochemistry and Pharmacology, Laboratory of Medicinal Chemistry, NIDDK, NIH, Bethesda, MD 20892.

Previous studies from this laboratory have shown that activation of σ<sub>1</sub> receptors in rat synaptoneurosomes (SN) reduced the maximal stimulation of phosphoinositide (PPI) turnover by muscarinic agonists. This was associated with a reduction in the number of surface muscarinic receptors. Here we have examined the possible role of muscarinic receptor/G-protein uncoupling. SN were treated with 50 μM (+)-pentazocine (a σ<sub>1</sub>-selective agonist) for 30 min followed by centrifugal washing and challenge with the muscarinic agonist, oxotremorine-M. Maximal stimulation of PPI turnover was reduced by 50% in (+)-pentazocine-treated SN compared to control tissue. Binding studies were carried out in treated SN after lysis to allow access to the total receptor pool. Competition of oxotremorine-M against the M1-selective antagonist [<sup>3</sup>H]pirenzepine in untreated lysed SN revealed the presence of a guanine-nucleotide sensitive high affinity state (IC<sub>50</sub> = 8 ± 3 nM, 24%) and a low affinity state (IC<sub>50</sub> = 5,590 ± 360 nM, 76%) (n<sub>1</sub> of one-site fit = 0.49 ± 0.01). In the presence of the guanine-nucleotide GppNHP, only the low affinity state was observed (n<sub>1</sub> = 0.72 ± 0.02), indicative of G-protein uncoupling. (+)-Pentazocine pretreatment caused a reduction in the population of high affinity sites to undetectable levels and a significant increase in n<sub>1</sub> (n<sub>1</sub> = 0.64 ± 0.02), thus mimicking the action of GppNHP. However, the n<sub>1</sub> was further increased by GppNHP in the (+)-pentazocine-treated tissue (n<sub>1</sub> = 0.76 ± 0.03). The results suggest that σ<sub>1</sub> receptor activation produces at least partial uncoupling of muscarinic M1 receptors from G-proteins, which may contribute to the heterologous desensitization of the muscarinic PPI response. Studies are in progress to determine if the effects of (+)-pentazocine on muscarinic receptor-effector coupling are mediated by protein kinases.

## 631.5

**EFFECTS OF SIGMA LIGANDS ON THE NEURONAL ACTIVITY IN THE RAT MESOLIMBIC AND NIGROSTRIATAL DOPAMINERGIC SYSTEMS.** B. Gronier\* and G. Debonnel. Neurobiological Psychiatry Unit, Department of Psychiatry, McGill University, Montréal, Québec, Canada H3A 1A1.

The present studies were undertaken to investigate, *in vivo*, the effects of selective sigma ( $\sigma$ ) ligands on the neuronal firing activity of dopaminergic (DA) neurons of the  $A_9$  and  $A_{10}$  areas, as well as of neurons of the caudate and accumbens nuclei. Using extracellular unitary recording and microiontophoresis, we assessed the effects of  $\sigma$  ligands on the spontaneous firing activity, the NMDA-induced neuronal activation and the DA-induced suppression of firing activity. The selective  $\sigma_1$  ligand S 21378, microiontophoretically applied, increased the spontaneous activity of both  $A_9$  and  $A_{10}$  DA neurons as well as the NMDA-induced neuronal activity, whereas JO-1784, another  $\sigma_1$  ligand, had no or little effect. DTG (20  $\mu$ g/kg, i.v.), a non selective  $\sigma_1/\sigma_2$  ligand, decreased the spontaneous activity of 30 % of  $A_{10}$  neurons. Microiontophoretic application and systemic administration (20  $\mu$ g/kg, i.v.) of JO-1784 produced a marked increase of the NMDA-induced activation in the accumbens but not in the caudate. The  $\sigma_1$  ligand (+)-pentazocine (30  $\mu$ g/kg, i.v.) did not modify significantly the NMDA-induced activation of accumbens neurons, but potentiated slightly the NMDA response in the caudate. Microiontophoretic applications of JO-1784 increased significantly the suppressant effect of DA on NMDA-induced activation of accumbens neurons, but did not modify the suppressant effect of DA on  $A_9$  and  $A_{10}$  neurons. These findings suggest that  $\sigma$  ligands differentially affect the glutamatergic activity in these two DA systems. The fact that the  $\sigma_1$  ligands JO-1784, S 21378 and (+)-pentazocine had different modulatory effects further supports the existence of subtypes of  $\sigma$  receptors, heterogeneously distributed. In addition, the fact that JO-1784 modulates the effect of DA in the accumbens suggests the existence of a functional interaction between  $\sigma$  and DA receptors in this area.

## 631.7

**MODULATION OF NMDA NEURONAL RESPONSE BY SIGMA<sub>1</sub> AND SIGMA<sub>2</sub> LIGANDS.** G. Debonnel\*, R. Bergeron, B. Gronier, N. Lavoie, M.C. Retton\* and B. Guardiola\*. Depart. Psychiatry, McGill University, Montréal, Qc, Canada and \*Institut de Recherche International Servier, Paris, France.

Using *in vivo* extracellular recording and microiontophoresis, we have shown that low doses of various  $\sigma$  ligands potentiate selectively the NMDA response of CA<sub>3</sub> pyramidal neurons in the rat dorsal hippocampus. The present experiments were undertaken to assess in our electrophysiological paradigm and in radioligand binding studies the selective  $\sigma_1$  and  $\sigma_2$  ligands S 21377, S 21378, S 20955, S 21272, NE-100, FH-510, BD-1008, JO-5220 and SR-31742A. The affinity of these ligands was assessed for the  $\sigma_1$  ( $^3$ H]-(+)-pentazocine) and the  $\sigma_2$  ( $^3$ H]-DTG 1-150 nM in the presence of 500 nM cold (+)-pentazocine) subtypes. The order of potency for  $\sigma_1$  binding sites was: BD-1008 > NE-100 > FH-510 > S 20955 > S 21272 > SR-31742A > JO-5220. The order of potency for  $\sigma_2$  binding sites was: BD-1008 > S 21272 > NE-100 > SR-31742A > S 20955 > FH-510 > JO-5220. S 21377 and S 21378 (1 to 2000  $\mu$ g/kg) induced a selective dose-dependent potentiation of the NMDA response. S 21272 (5-25  $\mu$ g/kg) also increased the NMDA response and, similarly to DTG, at higher doses, induced an epileptoid activity upon application of NMDA. All other  $\sigma$  ligands acted as antagonists, i.e. reversed the potentiating effects of  $\sigma$  agonists. S 20955 reversed the potentiating effects of S 21377 or (+)-pentazocine, but not those of S 21378 and of JO-1784. NE-100 suppressed the potentiation of the NMDA response induced by DTG but not those induced by S 21378 or JO-1784. The epileptoid activity induced by either S 21272 or DTG was prevented by haloperidol, and BD-1008 suppressed S 21272-induced potentiation of the NMDA response.

Our results constitute another argument in favor of the existence of several subtypes of  $\sigma_1$  receptors they also suggest that the epileptoid activity induced by some  $\sigma$  ligands could be mediated via  $\sigma_2$  receptors.

## 631.9

**A NEARLY 2,000-FOLD AFFINITY-PURIFICATION OF SIGMA RECEPTORS SOLUBILIZED FROM RAT LIVER MEMBRANES: BIOCHEMICAL AND PHARMACOLOGICAL CHARACTERIZATION.** Li-J. Tsao\* and T.-P. Su. Molecular Pharmacology Section, DIR, NIDA/NIH, Baltimore, MD 21224.

$\sigma$  receptors have been implicated in many physiological functions including learning and memory (Maurice *et al.*, *Pharmacol. Behav.* 42: 859-869, 1994). However,  $\sigma$  receptors have not been sequenced or cloned. In this study, we continue to purify  $\sigma$  receptors from rat liver membranes. The liver was chosen since the  $\sigma$  receptor density is ten times higher in the liver than in the brain.  $\sigma$  receptors were solubilized from rat liver membranes by 3-[(3-cholamidopropyl)dimethylamino]-1-propanesulfonate (CHAPS) and subjected to an affinity chromatography utilizing a newly developed ligand DAFE (*N*-(2-[3,4-dichlorophenyl]ethyl)-*N*-(6-aminohexyl)-2-(1-pyrrolidinyl)ethylamine). Solubilized  $\sigma$  receptors were adsorbed to the DAFE-coupled Sephadex G-25 resin and eluted with 10 mM haloperidol. This chromatography resulted in nearly 2,000-fold purification of  $\sigma$  receptors. The affinity-purified  $\sigma$  receptors were  $\sigma_1$  receptors as they exhibited about 100-fold higher affinity for (+)-SKF-10047 than for (-)-SKF-10047. Silver staining of the sodium dodecyl sulfate/polyacrylamide gel electrophoresis (SDS/PAGE) of the affinity-purified  $\sigma$  receptors revealed a major diffuse band with a molecular mass of 31 kDa and minute amounts of a polypeptide near 65 kDa and a polypeptide larger than 97 kDa. CHAPS-solubilized  $\sigma$  receptors could be adsorbed to a wheat germ lectin Sepharose column and were eluted by *N*-acetyl-D-glucosamine. These results demonstrate a near-purity purification of  $\sigma$  receptors and show that highly-purified  $\sigma$  receptors retain appropriate pharmacological activity. The results also suggest that  $\sigma$  receptors in rat liver membranes are glycoproteins and that the main constituent of  $\sigma$  receptors in the rat liver membranes is a 31 kDa polypeptide.

## 631.6

**PHARMACOLOGICAL EVIDENCE FOR AN HALOPERIDOL-INSENSITIVE SIGMA RECEPTOR THAT MODULATES THE NMDA RESPONSE IN THE RAT CNS.** F.P. Monnet\* & E.E. Baulieu, DRC-DPIM Assistance Publique-Hôpitaux de Paris, CNRS-UPR2212 & INSERM-U33, F-94276 Kremlin Bicêtre, France.

The prototypic and high affinity sigma ( $\sigma$ ), [(+)-pentazocine, (+)PTZ] and  $\sigma_2$  [1,3-di(2-tolylguanidine), DTG] agonists are known to modulate selectively the neuronal response to *N*-methyl-D-aspartate (NMDA) in the rat CNS. Conversely, we have reported that the high affinity  $\sigma$  agonist (+)-cis-*N*-methyl-*N*-(2-(3,4-dichlorophenyl)ethyl)-2-(1-pyrrolidinyl) cyclohexylamine [BD-737] enhanced both NMDA and non-NMDA glutamatergic responses, suggesting that it may interact with an atypical  $\sigma$  site. The present study was thus undertaken to investigate the receptor by which BD-737 acts, using an *in vitro* model of release of [ $^3$ H]norepinephrine (NE) evoked by NMDA. Hippocampal slices (400  $\mu$ m thick) from Sprague-Dawley rats were incubated with 0.1  $\mu$ M [ $^3$ H]NE for 30 min and superfused continuously with Mg<sup>++</sup>-free Krebs' solution containing one of the selective and high affinity  $\sigma$  ligands DTG, (+)PTZ, BD-737 or its negative isomer BD-738 in the presence or absence of haloperidol, reduced haloperidol, BD-1063 [1-[2-(3,4-dichlorophenyl)ethyl]-4-methyl piperazine] or *N*-(2-(3,4-dichlorophenyl)ethyl)-*N*-methyl-2-(1-pyrrolidinyl)ethylamine (BD-1008). Forty min later, the [ $^3$ H]NE overflow was evoked by NMDA (200  $\mu$ M). BD-737 and (+)PTZ, from 10 nM to 1  $\mu$ M, potentiated, while DTG (> 30 nM) decreased NMDA-evoked [ $^3$ H]NE overflow, BD-738 being less active than BD-737. Haloperidol and BD-1063 (> 30 nM) antagonized both effects of (+)PTZ and DTG but failed to reverse BD-737-induced potentiation. Conversely, reduced haloperidol and BD-1008 (> 10 nM) reversed the effect of BD-737, being much less active on both (+)PTZ- and DTG-related modulations. The present data constitute the first functional characterization supporting the notion that  $\sigma$  ligands, such as BD-737, reduced haloperidol and BD-1008, may act on an atypical  $\sigma$  receptor insensitive to haloperidol.

## 631.8

**THE POTENTIATION OF THE NMDA RESPONSE INDUCED BY SIGMA LIGANDS IS MARKEDLY REDUCED DURING PREGNANCY.**

R. Bergeron\*, C. de Montigny and G. Debonnel. Neurobiological Psychiatry Unit, McGill University, Montréal, Québec, Canada H3A 1A1.

Some gonadal and adrenal steroids such as progesterone have high affinity for  $\sigma$  receptors. Low doses of  $\sigma$  ligands such as DTG and of DHEA act as agonists, i.e. potentiate the neuronal response to NMDA of pyramidal neurons in the CA<sub>3</sub> region of the rat dorsal hippocampus, whereas other  $\sigma$  ligands such as haloperidol act as antagonists, i.e. reverse this potentiation. We have shown that low doses of progesterone also reverse the potentiating effect of DHEA as well as those of several  $\sigma$  ligands. In late pregnancy, the levels of progesterone increase markedly. Thus, the present experiments were undertaken to determine if the potentiation induced by  $\sigma$  agonists is modified during pregnancy using an *in vivo* electrophysiological paradigm.

Glass micropipettes were used for extracellular recording of CA<sub>3</sub> pyramidal neurons in Sprague-Dawley rats. At day 18 of pregnancy, DTG (1  $\mu$ g/kg, i.v.) did not modify the neuronal response to NMDA, whereas in control females this dose induced a three-fold increase of NMDA-induced activation. The potentiating effects of DHEA and of the  $\sigma$  agonist (+)-pentazocine were also markedly attenuated in pregnant rats. At a dose of 10  $\mu$ g/kg, DTG induced a two-fold increase of the neuronal response to NMDA in pregnant rats whereas, in control females, such a dose induced epileptoid responses to subsequent applications of NMDA. In contrast, a significantly greater potentiation of the NMDA response by DTG was observed at post-partum day 5. At the post-partum days 10 and 15, the effect of DTG was back to normal.

These results suggest that the high levels of progesterone in late pregnancy dampen of the effect of  $\sigma$  receptor activation.

## 631.10

**CHARACTERIZATION OF NOVEL SIGMA LIGANDS FOR USE IN SYNTHESIS OF AFFINITY CHROMATOGRAPHY MATRICES AND BIOCONJUGATES.** Q. Torrence-Campbell\*, Y. Zhang, W. Williams, B.R. de Costa and W.D. Bowen. Unit on Receptor Biochemistry and Pharmacology, Laboratory of Medicinal Chemistry, NIDDK, NIH, Bethesda, MD 20892.

Several primary amine derivatives, for example compounds 1 and 2 below, of the potent sigma ligands BD1008 (an aryl ethylene diamine) and BD1063 (an aryl piperazine) were synthesized and evaluated for sigma-1 and sigma-2 receptor affinity. The primary amine enables immobilization on column matrices or synthesis of bioconjugates. Since the ligands will be coupled via an amide linkage resulting from reaction of the primary amine with an appropriately activated carboxyl group in the acceptor molecule, the corresponding acetamide or N-Boc derivatives were synthesized and tested as well. The affinity of the primary amine for sigma-1 and sigma-2 receptors generally increased upon derivatization of the amine group, suggesting that there may be minimal loss of affinity in the conjugates. These compounds should be useful for the development of tools such as affinity chromatography matrices, biotinylated conjugates, and fluorescent probes for the further study of sigma receptors. Several compounds were coupled to CH-Sepharose-4B for affinity chromatography. Preliminary data also indicates successful coupling to imino-biotin. Results regarding these conjugates will be discussed.

**631.12**

The 1-phenyl-3-amino-1,2,3,4-tetrahydronaphthalines (1-phenyl-3-aminotetralins, PATs) have previously been shown to stimulate tyrosine hydroxylase activity as well as dopamine synthesis in rat brain through interaction with the neuromodulatory  $\sigma_1$  receptor. Experiments with resolved ( $\pm$ )-H<sub>2</sub>-PAT indicate that the activity resides in the *trans*-(1R,3S)-(-) isomer of H<sub>2</sub>-PAT. Structural requirements for binding were examined by altering the position and substitution pattern of the amino group and other functional groups on the tetralin moiety. A ligand based receptor model has been established using several PAT and non-PAT compounds. Two non-PAT compounds that exhibit high binding affinities are GBR-12909 and Ketanserin. These compounds have large N-alkyl substituents, that are well accommodated within the receptor model. Glennon has also reported that large N-phenylalkyl substituents on aminotetralins provide high affinity binding to the  $\sigma_1$  receptor. To test how the  $\sigma_1$  receptor might accommodate these large N-phenylalkyl substituents, we synthesized a series H<sub>2</sub> PAT analogs that include this moiety. Results indicate that this modification not only reduces affinity for the  $\sigma_1$  receptor, but also increases affinity for  $\sigma_1 / \sigma_2$  receptors negating the previous selectivity for  $\sigma_1$ . This data has been used to refine our receptor binding model. To further enhance the model, we have also undertaken the resolution of *cis*-( $\pm$ )-H<sub>2</sub>-PAT, an antagonist, which also has high affinity and selectivity for the receptor site, and to determine if these enantiomers follow the above noted stereoselective trend. This was accomplished by recrystallization techniques and the absolute configuration of *cis*-(+) H<sub>2</sub> -PAT was found to be (1R,3R) as determined by x-ray crystallography. [Support: URC Grant 5-44786, Pharmacy Foundation of NC #6-68379 1]

**631.14**

We have used *in vitro* receptor autoradiography to determine the distribution in rat spleen of binding sites for sigma receptor ligands.  $\sigma_1$  sites were labeled with 5nM [ $^3$ H]pentazocine in the presence of 100 $\mu$ M naltrexone, and nonspecific binding was defined using 1 $\mu$ M haloperidol.  $\sigma_2$  sites were labeled with 10nM [ $^3$ H]DTG in the presence of 1 $\mu$ M dextralorphan and 100 $\mu$ M naltrexone, and nonspecific binding was defined using 2 $\mu$ M haloperidol. Novel binding sites for sigma ligands that we have recently described (see accompanying abstract) were labeled with 8nM-1 $\mu$ M [ $^3$ H]-(+)-3-PPP in the presence of 10-50 $\mu$ M haloperidol, and nonspecific binding was defined using 100 $\mu$ M naltrexone.  $\sigma_1$  sites localized evenly through the outer (T cell-rich) regions of the periarterial lymphatic sheath of the white pulp.  $\sigma_2$  sites were distributed in a smooth pattern including the red pulp and the marginal zones of the white pulp. Very little  $\sigma_2$  labeling was seen in the lymphocyte-rich regions of white pulp. The novel sites localized with a coarse, punctate pattern to the marginal zones and red pulp. While the distribution of  $\sigma_2$  sites is difficult to interpret, these results suggest that  $\sigma_1$  receptors may be present primarily on T cells, while the novel sites may be quite dense on macrophages or dendritic cells.

**631.16**

We have previously demonstrated sigma receptors ( $\sigma_1$  and  $\sigma_2$ ) in immune tissues and have shown that proliferation of T cells is suppressed by sigma agonists through interaction with  $\sigma_1$  receptors. The objective of the current study was to determine whether this effect was due to suppression of the proliferation-supporting cytokine, IL-2. We measured  $\sigma_1$  receptors in saturation binding assays using [ $^3$ H]-(-)-pentazocine, which bound mouse spleen and the IL-2 producing LBRM33 T cell line with  $K_d$  values of  $10.1 \pm 1.0$  and  $10.7 \pm 0.3$  nM, respectively. LBRM33 cells displayed approximately 40,000 binding sites/cell. We confirmed the  $\sigma_1$  identity of the labeled sites by determining that they bound haloperidol and DTG, and were selective for the (+) over the (-) enantiomer of N-allylnormetazocine (SKF $_{10,047}$ ). We then determined that sigma agonists could suppress PHA-induced IL-2 production by LBRM33 cells. The ability of sigma agonists to suppress IL-2 (EC $_{50}$ ) correlated well ( $r = 0.84$ ) with their affinity at  $\sigma_1$  receptors ( $K_i$ ). A good correlation ( $r = 0.91$ ) also existed between suppression of T cell proliferation and suppression of IL-2 production. Our conclusions are: (1) suppression of IL-2 production by sigma agonists is due to drug interactions with  $\sigma_1$  receptors on T cells; (2) inhibition of T cell proliferation by sigma agonists in prior studies was due to this suppression of IL-2 production.

631.17

**B lymphocyte proliferation is not regulated by sigma receptors.** Y. Liu, C.C. Whitacre\* and S.A. Wolfe, Jr. Department of Medical Microbiology and Immunology, Ohio State University, Columbus, OH 43210.

In contrast to their inhibitory actions on T cells, sigma agonists have been reported to potentiate B cell activities. In the present study, we tested the ability of sigma agonists to modulate proliferation of purified mouse B cells stimulated with antibody (anti- $\mu$ ) directed against cell surface immunoglobulin. The sigma agonists DTG and (+)- and (-)-pentazocine had no effect, but haloperidol enhanced the proliferation of B cells and lowered the threshold of anti- $\mu$  antibody needed to trigger cell proliferation. Since haloperidol can also act as an antagonist at D<sub>2</sub> and 5-HT<sub>2</sub> receptors, several D<sub>2</sub> and 5-HT<sub>2</sub> antagonists were also tested. Spiperone, but not other D<sub>2</sub> and 5-HT<sub>2</sub> antagonists, potentiated B cell proliferation. Our conclusions are: (1) since the classical sigma agonists DTG and (+)- and (-)-pentazocine failed to show any effect, sigma receptors or our newly described, novel sites probably do not modulate B cell proliferation; (2) the enhancement of proliferation by haloperidol and spiperone is probably not mediated through D<sub>2</sub> or 5-HT<sub>2</sub> receptors; (3) at this time, the mechanism of haloperidol's and spiperone's actions on B cells is unknown.

### CATECHOLAMINE RECEPTORS: ALPHA ADRENERGIC

632.1

**ALPHA-2A- AND 2C-ADRENOCEPTOR-LIKE IMMUNOREACTIVITIES (-LIs) IN THE RAT CNS.** C. Broberger, L. Stone†, A. Szallasi\*, R. Elde† and T. Hökfelt. Department of Neuroscience, Karolinska Institutet, 17177 Stockholm, Sweden and †Department of Cell Biology and Neuroanatomy, Univ. of Minnesota, MN 55455, USA.

Adrenoceptors are grouped into  $\alpha_1$ ,  $\alpha_2$ ,  $\beta_1$  and  $\beta_2$  types.  $\alpha_2$ -adrenoceptors can be further divided into A-, B- and C-types. mRNAs for these  $\alpha_2$ -receptor subtypes have been detected and found to be differentially localized in the CNS by in situ hybridization and Northern blot. Immunohistochemistry and binding studies also confirm the heterogeneity of  $\alpha_2$ -receptor subtypes in the CNS. In this study, antibodies were developed by immunizing rabbits with thyroglobulin-conjugated peptides corresponding to the C-terminal portion of the  $\alpha_{2A}$ - and  $\alpha_{2C}$ -adrenoceptors. Antibodies were utilized for immunohistochemistry on formalin-fixed sections of rat brain using the indirect immunofluorescence method.  $\alpha_{2A}$ -adrenoceptor-LI was found in perikarya in many regions of the brain, e.g. the hypothalamus, amygdala and pons, and in fibers e.g. in the forebrain and amygdala.  $\alpha_{2C}$ -adrenoceptor-LI was detectable in cell bodies e.g. in the cerebral cortex, hypothalamus and pons, with fibers innervating large parts of the brain. Immunoreactivity for both receptors was seen in the dorsal horn of the spinal cord. Specificity of staining was controlled for by pre-absorbing the antibodies with their corresponding antigen. Also, antibodies raised in different rabbits against the same antigen showed the same staining patterns.

632.3

**ACTIVATION OF THE HUMAN  $\alpha_2A$ ,  $\alpha_2B$ , AND  $\alpha_2C$  ADRENERGIC RECEPTOR SUBTYPES STIMULATES MAP KINASE ACTIVITY IN COS CELLS.** W.D. Stamer, R.P. Gruener\*, T.H. Burkey, and J.W. Regan. Depts of Pharm/Tox and Physiology, The University of Arizona, Tucson, AZ 85721.

Activation of  $\alpha_2$ -adrenergic receptors (AR) modulates various cellular second messenger systems including adenylyl cyclase and mitogen-activated protein (MAP) kinase. In stably transfected CHO cells, it has been previously shown that the rat  $\alpha_2A$  and  $\alpha_2B$  subtypes couple to MAP kinase whereas the rat  $\alpha_2C$  does not. The purpose of this study was to determine the subtype-specific coupling of the human  $\alpha_2$ -ARs to MAP kinase in transiently transfected COS cells. COS cells were transfected with 50  $\mu$ g of plasmid DNA encoding either the  $\alpha_2A$ ,  $\alpha_2B$  or  $\alpha_2C$  using DEAE-dextran/DMSO shock. Cells were incubated in the presence of serum for 48 hours and then were serum starved for 24 hours. Cells were stimulated with either phorbol myristate acetate (100 nM), epinephrine (10  $\mu$ M), dexmedetomidine (100 nM), or dexmedetomidine (100 nM) plus yohimbine (10  $\mu$ M) and lysates were prepared. MAP kinase activity was measured by the incorporation of  $\gamma^{32}$ P-ATP into myelin basic protein. Activation of all three human  $\alpha_2$ -ARs by agonists resulted in a significant increase in the activity of MAP kinase over controls (unstimulated); e.g. dexmedetomidine yielded a 1.8 fold increase for the  $\alpha_2A$ , a 1.7 fold increase for the  $\alpha_2B$  and a 1.6 fold increase for the  $\alpha_2C$ . Preincubation of cells for 30 minutes with yohimbine significantly reduced activation of MAP kinase by agonists. Western blot analysis further showed that the amount of immunoreactive protein was the same in both control and agonist treated cells which is consistent with an increase in the activity, rather than, the amount of MAP kinase. In conclusion, all three human  $\alpha_2$ -AR subtypes are capable of stimulating MAP kinase in transiently transfected COS cells.

632.2

**PARTIAL PURIFICATION OF RECOMBINANT HUMAN  $\alpha_2C2$ -ADRENOCEPTORS FROM YEAST CELLS.** S. Ala-Uotila, U. Petäjä-Repo, K. Keinänen, A. Marjamäki\*, M. Scheinin and M. Jalkanen. Dept. of Pharmacology and Centre for Biotechnology, Univ. of Turku, PO Box 123, FIN-20521 Turku, Finland, VTT Biotechnical Laboratory, PO Box 202, FIN-02151 Espoo, Finland.

Recombinant human  $\alpha_2C2$ -adrenoceptors were solubilized and partially purified from *Saccharomyces cerevisiae* cells. The  $\alpha_2C2$ -construct expressed in yeast cells was modified in its N-terminus where the first nine amino acids of the human  $\alpha_2C2$ -adrenoceptor were replaced by the peptide MDYKHHHHH. The B<sub>max</sub> of the resulting clone FH-11 was 40 pmol/mg total cellular protein. Recombinant  $\alpha_2C2$ -receptors were solubilized with the non-ionic detergent sucrose monolaurate. The solubilization yield was approximately 50%. The expressed histidine-tagged protein was partially purified by metal-affinity chromatography. The presence of  $\alpha_2C2$ -adrenoceptors in the soluble fraction, in the pellet and in metal affinity chromatography fractions was visualized by immunoblotting with a rabbit polyclonal antibody. The yield of this step was 80-90% as determined by computer densitometer of SDS-PAGE immunoblots.

632.4

**COTRANSFECTION OF  $\alpha_2C10$  ADRENERGIC RECEPTOR WITH G-PROTEIN ALPHA SUBUNITS DRAMATICALLY INCREASES AGONIST POTENCY IN PI AND R-SAT ASSAYS.** D.W. Gil\*, T. Messier, D. Eubanks, L.A. Wheeler and M.R. Brann. Biological Sciences, Allergan, Inc., Irvine, CA 92713-9534 and Receptor Technologies, Inc. Winooski, VT 05404.

The fact that G protein coupled receptors can activate multiple signaling pathways, often with substantially different EC<sub>50</sub>s, has led to the suggestion that different receptor conformations are necessary for activating various G proteins. We investigated this possibility by studying the activation of several signaling pathways by the  $\alpha_2C10$  receptor coexpressed with G protein alpha subunits. The  $\alpha_2C10$  receptor transiently transfected into COS-7 cells mediated a weak phosphoinositide (PI) response. UK14304, for instance, elicited a 2-fold stimulation (EC<sub>50</sub>=155 nM) while the oxymetazoline (EC<sub>50</sub>=33 nM) response was only 25% over basal levels. Since  $\alpha_2$  receptors couple primarily to G<sub>i</sub>, the receptor was coexpressed with  $\alpha q_{i5}$ , a G protein alpha subunit chimera in which the five C-terminal amino acids of  $\alpha q$  are replaced with the corresponding residues of  $\alpha_2$  so that it mimics the receptor coupling of  $\alpha_1$  (Conklin et al., Nature 363, 274-6). The PI signal was enhanced 3-6 fold and compounds were 10-fold more potent, approximating their potency at inhibiting adenylyl cyclase. The results were even more dramatic in the Receptor Selection and Amplification Technology (R-SAT) assay, a high-throughput reporter gene assay that measures the G<sub>q</sub>-dependent amplification of NIH-3T3 cells. The coexpression of  $\alpha q_{i5}$  enhanced the oxymetazoline response more than six-fold and shifted the EC<sub>50</sub> from 2800 nM to 2.3 nM. In order to determine whether the potency shifts were due to more efficient coupling of  $\alpha q_{i5}$  or alpha subunit overexpression, the receptor was coexpressed with  $\alpha q$  resulting in a three-fold enhancement of the R-SAT signal and a similar increase in agonist potencies (oxymet. EC<sub>50</sub>=4.6 nM). Thus, large differences in an agonist's potencies for activating multiple signal pathways via a single receptor can be attributed to differences in G protein reserve and receptor/G protein coupling efficiency.

## 632.5

$\alpha_2$ C10 ADRENERGIC RECEPTOR WITH MINIMAL  $\alpha_1$ A THIRD INTRACELLULAR LOOP ELICITS  $\alpha_1$ A SIGNAL IN RESPONSE TO  $\alpha_2$  AGONISTS. K.M. Kozlcz, D. Eubanks, E.P. Monaghan\*, M.R. Brann and D.W. Cull, Allergan, Inc., Irvine, CA 92713-9534, University of Vermont, Burlington, VT 05405 and Receptor Technologies, Inc., Winooski, VT 05404.

The  $\alpha_2$  receptors are primarily coupled to inhibition of adenylate cyclase, which is a difficult response to measure in high throughput drug screening. We determined whether the signaling repertoire of the  $\alpha_2$ C10 receptor could be rewired by replacing its third intracellular (i3) loop with portions of the  $\alpha_1$ A receptor i3 loop that have been implicated in G-protein coupling. A chimeric receptor was constructed by replacing the i3 loop of the  $\alpha_2$ C10 receptor with 22 and 20 amino acids of the amino and carboxyl ends, respectively, of the  $\alpha_1$ A i3 loop. In phosphoinositide hydrolysis (PI) assays and the high-throughput R-SAT assays (patent pending), the  $\alpha_2$  agonist, UK14304, but not the  $\alpha_1$  agonist, phenylephrine, elicited responses that were blocked by the  $\alpha_2$  antagonist rauwolfscine. Using both assays, the rank order of potency for a series of compounds was the same for activation of the  $\alpha_2$ C10 and the  $\alpha_2/\alpha_1$  receptors. Unlike the parent  $\alpha_2$ C10 receptor, but like an  $\alpha_1$  receptor, the  $\alpha_2/\alpha_1$  PI response was not sensitive to pretreatment with pertussis toxin. In an assay of cyclic AMP accumulation, using a cyclic AMP-responsive CAT reporter gene, the chimeric receptor no longer inhibited cyclic AMP levels. Interestingly, it retained the ability to stimulate cyclic AMP accumulation. Thus, replacement of the i3 loop of the  $\alpha_2$ C10 receptor with two fragments from the  $\alpha_1$ A i3 loop alters its signaling repertoire without changing its pharmacology.

## 632.7

DISSOCIATION OF ANESTHETIC ACTIONS OF  $\alpha_2$  AGONISTS FROM A DECREASE IN CYCLIC AMP IN THE RAT. B.C. Rabin, T.Z. Guo, L.R. Poree\*, and M. Maze, Stanford Univ. Sch. of Med., Stanford, CA 94305.

$\alpha_2$  adrenergic agonists ( $\alpha_2$  AA) are used clinically for their anesthetic, analgesic and sympatholytic actions in surgical patients. All  $\alpha_2$  adrenergic receptors ( $\alpha_2$  AR), when activated by  $\alpha_2$  AA's, are able to inhibit adenylate cyclase. Correspondingly, elucidation of the role of adenylate cyclase in  $\alpha_2$  AR-elicited biologic responses is of principal importance to understanding the transduction mechanisms of these receptors.

In this study we have examined the  $\alpha_2$  AR-mediated anesthetic actions of dexmedetomidine, a highly selective  $\alpha_2$  AA, after pretreatment of the animals with rolipram, a cAMP-specific phosphodiesterase inhibitor. Cyclic AMP (cAMP) accumulation and monoamine turnover were measured in the locus coeruleus (LC) and hippocampus (Hc) following administration of rolipram (275  $\mu$ g·kg<sup>-1</sup>·i.p.) and dexmedetomidine (100  $\mu$ g·kg<sup>-1</sup>·i.p.). The hypnotic response to dexmedetomidine was also measured in these animals. In other experiments, rats were stereotactically cannulated in the LC with an indwelling catheter, and after the second day, the tail flick analgesic response to dexmedetomidine (7  $\mu$ g·0.2ul<sup>-1</sup> LC), following rolipram (275  $\mu$ g·kg<sup>-1</sup>·i.p.) pretreatment, was assessed.

In the presence of elevated cAMP levels, the hypnotic, analgesic, and sympatholytic effects of dexmedetomidine persisted. These data suggest that adenylate cyclase activity does not mediate the cellular responses to  $\alpha_2$  AAs but instead may act in concert with other  $\alpha_2$  AR-coupled effector mechanisms to transduce the anesthetic actions of these agents.

## 632.9

$\alpha_2$ -ADRENERGIC RECEPTOR AGONIST ACTIVITY OF DESIPRAMINE IN GT1 CELLS. P.G. Guyenet\*, D. Huangfu, Y. Zhu, and R.L. Stornetta, Dept. of Pharmacology and Neuroclinical Trials Center, Univ. of Virginia, Charlottesville, VA 22908.

Experiments were designed to test whether the tricyclic antidepressant desipramine (DMI) has agonist activity at  $\alpha_{2A}$ -adrenergic receptors ( $\alpha_{2A}$ -ARs), a receptor subtype involved in CNS sympathetic control. In the presence of blockers of dopamine and  $\beta$ -adrenergic receptors,  $\alpha$ -methyl noradrenaline (MNE), clonidine and UK14304 dose-dependently inhibited the forskolin-stimulated (2  $\mu$ M) accumulation of cAMP by GT1 cells (log<sub>10</sub>ED<sub>50</sub>: -5.3, -6.8, -6.2; max inhibition: 38%, 25% and 32%, respectively). These inhibitions disappeared after pertussis toxin treatment and were blocked by either yohimbine or methoxyidazoxan (MOI 10  $\mu$ M). Yohimbine and MOI had no effect on cAMP accumulation by themselves. DMI (10<sup>-8</sup> to 10<sup>-5</sup> M) dose-dependently inhibited forskolin-stimulated cAMP production (50±3% at 10<sup>-5</sup> M). The effect of DMI was abolished in pertussis toxin treated cells and was attenuated 70% by yohimbine or MOI. No evidence was found that DMI might have partial agonist activity at the  $\alpha_{2A}$ -ARs of GT1 cells. Amitriptyline (AMI), another tricyclic antidepressant, also reduced cAMP accumulation (56±4% at 10<sup>-5</sup> M) but this effect was reduced only 15% by MOI. The effect of 1  $\mu$ M AMI was eliminated by pertussis toxin treatment, while that of 10  $\mu$ M AMI was reduced by 40%. In conclusion, DMI is a full agonist at  $\alpha_{2A}$ -ARs in GT1 cells. CNS  $\alpha_{2A}$ -AR stimulation probably contributes to DMI's sympatholytic effect. AMI has little  $\alpha_{2A}$ -AR agonist activity but it and DMI may also activate other G-protein coupled receptors negatively linked to adenylate cyclase in GT1 cells (Grant HL-28785 to PGG).

## 632.6

ANTISENSE KNOCK-DOWN OF  $\alpha_{2C}$ -ADRENOCEPTORS IN RAT STRIATUM. Lingen Lu\* and Gregory A. Ordway, Departments of Psychiatry & Human Behavior and Pharmacology & Toxicology, University of Mississippi Medical Center, Jackson, MS 39216.

The predominate subtypes of  $\alpha_2$ -adrenoceptors in the brain are  $\alpha_{2A}$  and  $\alpha_{2C}$ . The shortage of selective ligands for each of the  $\alpha_2$ -adrenoceptor subtypes hampers the functional characterization of these receptors. We exploited an antisense strategy as an alternative pharmacological tool to study  $\alpha_{2C}$ -adrenoceptors. In rat corpus striatal membranes,  $\alpha_2$ -adrenoceptors were characterized using the subtype-nonspecific antagonist [<sup>3</sup>H]2-(2-methoxy-1,4-benzodioxan-2-yl)-2-imidazoline ([<sup>3</sup>H]RX821002). Specific [<sup>3</sup>H]RX821002 binding was saturable and to a single class of high affinity sites (K<sub>d</sub> = 0.45 ± 0.04 nM; B<sub>max</sub> = 159 ± 3 fmol/mg protein). Curves for the inhibition of [<sup>3</sup>H]RX821002 binding by the  $\alpha_{2C}$ -selective compound, prazosin, were fit best by a model assuming binding to two sites, (%R<sub>1</sub> = 41%; %R<sub>2</sub> = 59%; p < 0.005), presumably reflecting binding to  $\alpha_{2C}$ - and  $\alpha_{2A}$ -adrenoceptors, respectively. A 15-mer phosphorothiate oligodeoxynucleotide ( $\alpha_{2C}$ AS) complementary to  $\alpha_{2C}$ -adrenoceptor mRNA, or a random sequence (RS), was administered to rats continuously for 4-5 days directly into the striatum.  $\alpha_{2C}$ AS treatment significantly reduced the B<sub>max</sub> of [<sup>3</sup>H]RX821002 in striatal homogenates (in fmol/mg protein, RS = 151 ± 10;  $\alpha_{2C}$ AS = 98 ± 8; p < 0.01). Curves for the inhibition of [<sup>3</sup>H]RX821002 binding by prazosin were fit best to a model assuming a single site interaction in  $\alpha_{2C}$ AS-treated rats and to a model assuming two sites of binding in RS-treated rats. These results confirm the existence of  $\alpha_{2A}$ - and  $\alpha_{2C}$ -adrenoceptors in the rat corpus striatum and also demonstrate the feasibility of an antisense approach to studies of  $\alpha_2$ -adrenoceptor pharmacology.

## 632.8

A POSSIBLE EXPLANATION FOR THE LACK OF A PALMITOYLATION SITE IN THE CARBOXY TERMINUS OF THE  $\alpha_2$ C ADRENERGIC RECEPTOR. A.C. Porter, H.E. Laird, II\* and J.W. Regan, Dept. of Pharmacology and Toxicology, University of Arizona, Tucson, AZ 85721

Most adrenergic receptors (AR), including the  $\alpha_2$ A and  $\alpha_2$ B subtypes, have a carboxy terminal cysteine which is a potential site for post-translational modification by palmitoylation. Palmitoylation of this cysteine has been hypothesized to form a fourth intracellular loop which may be involved in receptor/G-protein coupling. The  $\alpha_2$ C subtype, on the other hand, has phenylalanine instead of cysteine at this position. In these experiments, phenylalanine 452 in the  $\alpha_2$ C was mutated to cysteine (F452→C) and was then evaluated in terms of its ability to be expressed, its second messenger coupling and its ability to bind [<sup>3</sup>H]rauwolscine, an  $\alpha_2$  selective antagonist. Immunohistochemical analysis using an  $\alpha_2$ C specific antibody directed against the third intracellular loop, indicates that the mutant receptor is expressed in COS-7 cells at levels which are comparable to the wild type receptor. In contrast, when transiently expressed in JEG-3 cells, the F452→C mutant was unable to inhibit the activity of a forskolin-stimulated cyclic AMP responsive reporter gene. This indicates that the mutant receptor is non-functional. The F452→C mutant also did not show any specific binding of [<sup>3</sup>H]rauwolscine. However, prior treatment of the membranes with hydroxylamine, followed by washout, restored some specific binding of [<sup>3</sup>H]rauwolscine. Since hydroxylamine can selectively hydrolyze thioester linkages between palmitic acid and cysteine, these results suggest that palmitoylation is not tolerated in the carboxy terminus of the  $\alpha_2$ C AR.

## 632.10

MEDIAN PREOPTIC NUCLEUS (MnPO) NEURONS POSSESS FUNCTIONAL  $\alpha_1$  AND  $\alpha_2$  ADRENERGIC RECEPTORS. D. Bai\* and L.P. Renaud, Neuroscience, Loeb Research Institute, Ottawa Civic Hospital and University of Ottawa, Ottawa, Ontario, CANADA K1Y 4E9

The MnPO is an important CNS site for hydromineral and cardiovascular homeostasis. In addition to local amino acid and peptidergic inputs, MnPO receives a prominent innervation from medullary catecholaminergic neurons. To define the nature of this adrenergic innervation, we utilized whole cell patch clamp recordings obtained in vitro from MnPO neurons in coronal and sagittal slices of rat forebrain. Some 20% of cells responded to brief (10-30 sec) applications of noradrenaline (NA, 50  $\mu$ M) or phenylephrine with a TTX-resistant, prazosin-sensitive membrane depolarization; in some cells a reduction in membrane conductance was observed. Another 20% of cells responded to NA or the  $\alpha_2$  agonist UK14,304 with a TTX-resistant yohimbine-sensitive membrane hyperpolarization accompanied by an increase in a membrane K<sup>+</sup> conductance. This diversity in catecholamine receptor neuropharmacology among MnPO cells supports functional heterogeneity in their responsiveness to diverse cardiovascular stimuli. Supported by MRC and the Heart & Stroke Foundation of Canada.

**COMPARATIVE EXAMINATIONS ON SOME EFFECTS OF ALPHA<sub>2</sub>-ADRENOCEPTOR AGONISTS WITH DIFFERENT LIPOPHILICITY (DEXMEDETOMIDINE AND ST-91)** M. Szikszay, G. Horváth, G. Szabó, G. Benedek. Dept. Physiol., A. Szent-Györgyi Med. Univ., Szeged, Hungary

Alpha<sub>2</sub>-adrenoceptor agonists have sedative and mydriatic effects that originate supraspinally. There analgesic effect is mediated predominantly at the level of the spinal cord. Because intrathecal (IT) administration of a lipophilic compound can cause supraspinal effects, it is necessary to compare a hydrophilic (ST-91) and a lipophilic (dexmedetomidine, DEX) alpha<sub>2</sub>-adrenoceptor agonists given IT to evaluate whether the effects result from actions at spinal vs supraspinal sites. Additionally, we examined whether the enhanced urine flow induced by these drugs might be modulated by centrally and/or peripherally.

The IT administration of DEX led to dose-dependent analgesia (tail-flick, TF and hot-plate HP tests) and mydriasis, although the mydriasis appeared at subanalgesic dose (1 µg). The effective analgesic dose (9 µg), however, caused a visible sedation and motor impairment. The ST-91 (20 µg IT) caused dose-dependent analgesia only at HP test, without any mydriasis, sedation or motor impairment. Systemic administration of both agents caused an increased urine output volume, the intrathecally applied ST-91, however, failed to influence it, suggesting a peripheral site of action. Our results clearly proved the effects of the IT applied highly-lipophilic alpha<sub>2</sub>-adrenoceptor agonist, DEX, may result from a rapid diffusion into the general circulation and than into the brain. These observed discrepancies suggest that consideration should be paid not only the route of administration, but also to the physico-chemical properties of a given compound.

Supported by the National Science Foundation of Hungary (OTKA-06379)

## 632.13

**HIGH AFFINITY AGONIST BINDING IN TRANSFECTED CLONED HUMAN α<sub>2</sub>-ADRENOCEPTORS.** A. L. KIRIFIDES\* and E. E. CODD. Drug Discovery Research, The R.W. Johnson Pharmaceutical Research Institute, Welsh and McKean Roads, Spring House, PA 19477-0776.

Human α<sub>2A</sub>-, α<sub>2B</sub>- and α<sub>2C</sub>-adrenoceptors belong to the family of membrane bound G-protein coupled receptors regulated by mono and divalent cations and guanine nucleotides. Whereas many previously published radioligand binding assays used conditions conducive to formation of the agonist low affinity state of the receptor (Uhlen, JPET, 1994), the present study was performed using 50 mM Tris buffer in the presence of 5 mM MgCl<sub>2</sub> to promote formation of the agonist high affinity state. The cloned receptors were expressed in insect cells with a baculovirus expression vector (Biosignal). The α<sub>2</sub>-antagonist [<sup>3</sup>H]-MK-912 was used as the ligand due to its high affinity for α<sub>2</sub>-adrenoceptors and low non-specific binding. Saturation studies fit a single site model with K<sub>d</sub> values of 0.405 for α<sub>2A</sub>- and 0.114 nM for α<sub>2C</sub>-, similar to the results of Uhlen. The inhibition curve of the α<sub>2</sub>-antagonist yohimbine fit a single site model with K<sub>i</sub> values of 5.0 nM at the α<sub>2A</sub>- and 5.69 nM at the α<sub>2C</sub>-adrenoceptor. However, the inhibition curve of the α<sub>2</sub>-agonist clonidine was best fit by a two site model with K<sub>i</sub> values of 22.9 and 328 nM (p = 0.023) for α<sub>2A</sub>- and 160 and 1395 nM (p < 0.0005) for α<sub>2C</sub>-receptors. These and related data suggest that the present assay conditions distinguish agonist from antagonist binding to cloned α<sub>2</sub>-adrenoceptors, greatly enhancing the usefulness of this assay as a pharmacological tool.

## 632.15

**ESTROGEN DECREASES THE LEVEL OF α<sub>2D</sub>-ADRENERGIC RECEPTOR mRNA IN FEMALE RAT CORTEX.** George B. Karkianis\* and Anne M. Eigen. Department of Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461

We previously demonstrated that estrogen increases the density of α<sub>2D</sub>-adrenoceptor binding sites in female rat hypothalamus by ~30% while causing a concomitant ~16% decrease in cortical α<sub>2D</sub>-adrenoceptors. The present experiments test the hypothesis that estrogen also regulates the level of α<sub>2D</sub>-adrenoceptor (RG20) mRNA in the hypothalamus and cortex of female rats. To test this hypothesis we developed a quantitative RNase protection assay for the measurement of RG20 mRNA. We found that ovariectomized female rats injected twice with 2 µg of estradiol benzoate 24 and 48 hrs prior to sacrifice demonstrated a 50% reduction in the level of cortical RG20 mRNA when compared to ovariectomized, oil-treated control animals. Estrogen treatment for 48 hrs did not alter the level of RG20 mRNA in female rat hypothalamus. These findings suggest that the estrogen-mediated decrease in cortical α<sub>2D</sub>-adrenoceptor levels may result from hormone-dependent reductions in the mRNA encoding this receptor. Supported by HD29856, MH41414, RSDA MH00636 and T32 NS07183.

## 632.12

**MODULATION OF RECOMBINANT HUMAN α<sub>2</sub>-ADRENOCEPTORS BY SODIUM: EFFECTS ON AGONIST BINDING.** M. Halmé, B. Sjöholm and M. Scheinin\*. Department of Pharmacology and Centre for Biotechnology, University of Turku, FIN-20520 Turku, Finland.

Sodium ions modulate agonist binding to several G-protein coupled receptors, presumably by interfering with a charge interaction of a conserved aspartate residue that participates in the maintenance of the active conformation of the receptor proteins. This study utilized recombinant human α<sub>2</sub>-adrenoceptor subtypes (α<sub>2A</sub>, α<sub>2B</sub>, α<sub>2C</sub>) expressed in S115 mouse mammary tumour cells. The osmolality of the binding medium was held constant using 35 or 75 mM N-methyl-D-glucamine·Cl<sup>-</sup> buffer (pH 7.4). The affinities of all three α<sub>2</sub>-adrenoceptor subtypes for the α<sub>2</sub>-antagonist radioligand [<sup>3</sup>H]RX821002 were increased in the presence of 40 mM NaCl. The increase in affinity was 1.5-fold for α<sub>2A</sub>, 3-fold for α<sub>2C</sub> and 4-fold for α<sub>2B</sub>. NaCl potentially decreased the affinity of catecholamine agonists at α<sub>2A</sub>-adrenoceptors, whereas the affinities of clonidine and dexmedetomidine were increased 3.5-fold. The potency order of monovalent cations was Na<sup>+</sup> > Li<sup>+</sup> >> K<sup>+</sup> for (-)-noradrenaline binding to α<sub>2A</sub>-receptors. At α<sub>2C</sub>-receptors, the affinities of (-)-noradrenaline and dexmedetomidine were clearly reduced by Na<sup>+</sup>, whereas the affinity of clonidine was not influenced. At α<sub>2B</sub>-receptors, the affinity of dexmedetomidine was reduced by Na<sup>+</sup>, but the affinity of noradrenaline was only slightly decreased and clonidine binding was not affected. The results indicate that the effects of Na<sup>+</sup> on agonist affinity to α<sub>2</sub>-adrenoceptors are complex and may depend on ligand structure. The concentration of Na<sup>+</sup> in the binding assay may critically affect the apparent receptor subtype selectivity of drugs.

## 632.14

**AGONIST SPECIFIC COUPLING OF A CLONED HUMAN α<sub>2A</sub>-ADRENERGIC RECEPTOR TO MULTIPLE SECOND MESSENGERS.** P.D. Evans<sup>1</sup>, C.N. Aitriess<sup>1</sup>, L.S. Swales<sup>1</sup>, T.R. Cheek<sup>1</sup> and J.M. Midgley<sup>2</sup>. <sup>1</sup>The Babraham Institute Laboratory of Molecular Signalling, Dept. Zoology, Univ. Cambridge, Cambridge, CB2 3EJ, U.K. and <sup>2</sup>Dept. Pharmaceutical Sciences, Univ. Strathclyde, Glasgow, G1 1XW, U.K.

Agonist-specific coupling of a cloned *Drosophila* octopamine/tyramine receptor, expressed in a Chinese hamster ovary (CHO) cell line, has been demonstrated by us (Robb *et al.*, 1994, EMBO J. 13:1325). Thus, octopamine and tyramine, which differ structurally by only a single side-chain hydroxyl group, differentially couple the receptor to cyclic AMP and Ca<sup>2+</sup>-based second messenger systems. Here we report on the ability of octopamine, which is a naturally occurring ligand of sympathetic α-adrenergic receptors, to couple a cloned human α<sub>2A</sub>-adrenoceptor (α<sub>2A</sub>-2AR) to multiple second messenger systems when expressed in a CHO cell line. The ability of agonists to inhibit or stimulate forskolin-stimulated cyclic AMP levels in this cell line was assessed in the presence or absence of pertussis toxin and their ability to change cytosolic Ca<sup>2+</sup> levels was assessed using ratio imaging techniques with the dye fura 2. (-)-Octopamine was more potent than either (+)-octopamine or (-)-p-octopamine in inhibiting adenylate cyclase activity in CHO cells expressing the α<sub>2A</sub>-2AR and both enantiomers of the positional isomers of octopamine were less potent than either (-)-epinephrine or (-)-norepinephrine. However, in contrast to the catecholamines, both positional isomers of (-)-octopamine did not stimulate adenylate cyclase activity in cells incubated with pertussis toxin, indicating that the α<sub>2A</sub>-2AR is coupled to G<sub>i</sub> but not G<sub>q</sub> when activated by octopamine. Another difference between *m*-octopamine and the catecholamines was the ability of very low concentrations (10<sup>-12</sup> to 10<sup>-9</sup>M) of the former, but not the latter, to initiate cytosolic Ca<sup>2+</sup> signals. These studies suggest a functional role for the octopamine co-released with norepinephrine from sympathetic neurons in the down-regulation of adenylate cyclase activity. Further, they raise the potential for a specific functional role for octopamine mediated by changes in cytosolic Ca<sup>2+</sup> levels through the activation of an α-adrenergic receptor.

## 632.16

**EFFECT OF SELECTIVE α<sub>2</sub>-ADRENERGIC AND IMIDAZOLINE I<sub>2</sub> RECEPTOR DRUGS ON EARLY RESPONSE GENE AND GFAP mRNA IN RAT BRAIN.** A.L. Gundlach\* and T.C.D. Burazin. Dept. of Medicine, University of Melbourne, Austin and Repatriation Medical Centre, Heidelberg, Vic. 3084, Australia.

In brain, imidazoline drugs such as idazoxan are known to interact with both neuronal α<sub>2</sub>-adrenoceptors and imidazoline I<sub>2</sub> receptors, thought to be predominantly located on glial cells. Previous studies have shown that chronic treatment with idazoxan, but not other α<sub>2</sub>-adrenoceptor antagonists, increases the level of glial fibrillary acidic protein (GFAP) immunoreactivity in cerebral cortex and GFAP mRNA in cultured astrocytes. The imidazolines methoxyidazoxan (MeIDAZ) and 2-(4,5-dihydroimidaz-2-yl)-quinoline (BU224) are ≥ 5000-fold selective for α<sub>2</sub>-adrenoceptors and I<sub>2</sub>-receptors, respectively. This study examined the acute effects of these drugs on the level of mRNAs encoding the early response genes, *c-fos* and *NGFI-A*, and GFAP in rat forebrain. Male Sprague-Dawley rats (4 per group) were injected intraperitoneally with either MeIDAZ, BU224 (1 or 10 mg/kg) or vehicle and killed after 1 h. Brains were processed for *in situ* hybridization histochemistry with specific [<sup>35</sup>S]-labeled oligonucleotides and x-ray film autoradiograms were generated and analyzed by computer-assisted densitometry (MCID). High basal levels of *NGFI-A* mRNA were present in regions such as cerebral cortex (especially layers IV & VI), hippocampal pyramidal cells, amygdala and caudate putamen. Basal levels of *c-fos* mRNA were low throughout the forebrain. After 1 h, both doses of MeIDAZ produced a marked induction of *NGFI-A* and *c-fos* mRNA in cortex (25-110%) and the dorsal caudate putamen (45-120%). BU224 also increased mRNA levels in these areas, but to a lesser extent (25-40%). These results confirm the constitutive, inhibitory effect of α<sub>2</sub>-adrenoceptors on forebrain *NGFI-A* and *c-fos* expression and the weak α<sub>2</sub>-adrenoceptor activity of BU224. In vehicle-treated rats, high levels of GFAP mRNA were present in the major white matter tracts such as the corpus callosum, fimbria, stria terminalis and optic tract, in the molecular layer of the hippocampus, and in the arcuate and interpeduncular nuclei. After 1 h, neither MeIDAZ or BU224 had any apparent effect on GFAP mRNA levels, suggesting that any specific glial effects of these drugs may occur over a longer time-course (≥ 3 h) and this possibility is currently under investigation.

## 632.17

EFFECT OF ACUTE DEXAMETHASONE INJECTION ON ADRENERGIC RECEPTOR SUBTYPE mRNA EXPRESSION IN THE THALAMUS OF ADULT RATS. S. K. McCune\* and J. M. Hill. Dept. of Pediatrics, Johns Hopkins University School of Medicine, Baltimore, MD 21287 and Lab. of Dev. Neurobiol., NICHD, NIH, Bethesda, MD 20892.

Adrenergic receptors mediate tissue responses to catecholamines. However, the physiologic and functional roles of multiple receptor subtypes in the CNS has yet to be well defined. It is thought that the multiplicity of homologous subtypes may allow for differential tissue responses to treatment with various ligands. In order to investigate this hypothesis, we treated animals with dexamethasone and studied the regional CNS effect on  $\alpha$ -1A,  $\alpha$ -1B and  $\beta$ -1 adrenergic receptor subtype mRNA expression. Dexamethasone, a glucocorticoid, has been shown to promote catecholaminergic activity in the CNS of the neonatal animal.

Adult male rats were injected with either dexamethasone 0.8 mg/kg or an equal volume of saline. The animals were sacrificed 2 hours after injection and the brains frozen at -80°C until use. *In situ* hybridization using oligonucleotide probes for each of the subtypes was performed followed by densitometric analysis.

The  $\alpha$ -1A and  $\beta$ -1 subtypes were localized in the reticular nucleus of the thalamus while the  $\alpha$ -1B subtype had a more widespread thalamic expression. Preliminary results showed that acute treatment with dexamethasone did not alter  $\alpha$ -1A expression but caused a significant up-regulation of  $\alpha$ -1B and  $\beta$ -1 subtype mRNAs in their respective areas of the thalamus.

These data suggest that multiple adrenergic receptor subtypes localized in the thalamus have differing responses to identical ligands. These unique responses may influence subtle alterations in thalamic integration.

## 632.19

COLOCALIZATION OF  $\alpha$ 1AD ADRENORECEPTOR mRNA WITH TYPE I AND TYPE II GLUCOCORTICOID RECEPTOR mRNA IN RAT HIPPOCAMPUS USING DOUBLE IN SITU HYBRIDIZATION. R.L. Petit\*, A. M. Williams, and D. A. Morilak. Dept. Pharmacology, Univ. Texas Health Science Center, 7703 Floyd Curl Drive, San Antonio, TX, 78284-7764.

Noradrenergic transmission plays an important role in the hormonal response to stress, and also in the mechanisms of antidepressant drug action. An important component of adaptation to chronic stress, and perhaps also in antidepressant effects, is regulation of glucocorticoid receptors (GRs) in the hippocampus. We postulate a regulatory influence of  $\alpha$ 1 adrenoceptors on hippocampal GRs that may provide a link between stress, noradrenergic transmission, and antidepressant activity. In this study, we have identified hippocampal neurons that coexpress  $\alpha$ 1A/D adrenoceptor mRNA with either mineralocorticoid (Type I GR) or glucocorticoid (Type II GR) receptor mRNA using double in situ hybridization.

Fresh frozen 20  $\mu$ m rat brain sections were mounted on poly-lysine coated slides and processed for combined in situ hybridization. Hippocampal sections were co-incubated with a digoxigenin-UTP-labeled riboprobe for the  $\alpha$ 1A/D receptor mRNA, and  $^{35}$ S-labeled riboprobes for either the glucocorticoid or mineralocorticoid receptor mRNA. Following visualization of the digoxigenin label via an alkaline-phosphatase reaction (Boehringer-Mannheim), the slides were dipped in nuclear track emulsion, exposed at 4°C and developed. We observed extensive colocalization of  $\alpha$ 1A/D receptor mRNA with both glucocorticoid and mineralocorticoid receptor mRNA in the dentate gyrus and CA fields of the hippocampus. This colocalization, which was not observed in  $\alpha$ 1A/D expressing cells in other brain regions, provides an anatomical substrate for potential regulatory interactions between noradrenergic transmission and GR regulation in stress and depression.

## 632.18

STRUCTURE ACTIVITY RELATIONSHIPS OF A SERIES OF BUSPIRONE ANALOGS AT  $\alpha$ 1-ADRENOCEPTORS. D.L. Saussy, Jr., A.S. Goetz, H.K. King\* & R.J. Unwalla. Departments of Cellular Biochemistry and Structural Chemistry, Glaxo Res. Inst., Res. Tri. Park, NC 27709.

The activities of a series of buspirone analogs at human  $\alpha$ 1B,  $\alpha$ 1C, and  $\alpha$ 1D adrenoceptors were determined by radioligand binding assays using membranes prepared from Rat-1 fibroblasts expressing recombinant receptors with [ $^{125}$ I]-HEAT as the radioligand. BMY 7378 (pK<sub>i</sub>  $\alpha$ 1B, 7.25;  $\alpha$ 1C, 6.80;  $\alpha$ 1D, 9.39) and MDL 73005EF (pK<sub>i</sub>  $\alpha$ 1B, 6.88;  $\alpha$ 1C, 6.10;  $\alpha$ 1D, 8.16) were found to have significant selectivity for the  $\alpha$ 1D subtype. The corresponding butyl-linker compounds, 8-(2-[4-(2-methoxyphenyl)-1-piperazinyl]butyl)-8-azaspiro[4.5]decane-7,9-dione dihydrochloride (pK<sub>i</sub>  $\alpha$ 1B, 8.04;  $\alpha$ 1C, 9.08;  $\alpha$ 1D, 8.76) and MDL 72832 (pK<sub>i</sub>  $\alpha$ 1B, 7.94;  $\alpha$ 1C, 8.41;  $\alpha$ 1D, 8.11) had substantially increased affinity for  $\alpha$ 1C and  $\alpha$ 1B and a slight decrease in the affinity for  $\alpha$ 1D. Similarly, replacement of the bulky 8-azaspiro[4.5]decane-7,9-dione moiety with a planar phthalimido-group yielded compounds that had roughly equivalent affinities for all three subtypes for both the ethyl-linker compound, 1-(2-methoxyphenyl)-4-[4-(2-phthalimido)ethyl] piperazine (pK<sub>i</sub>  $\alpha$ 1B, 6.87;  $\alpha$ 1C, 7.55;  $\alpha$ 1D, 7.52) and butyl-linker compound, NAN-190 (pK<sub>i</sub>  $\alpha$ 1B, 9.02;  $\alpha$ 1C, 9.66;  $\alpha$ 1D, 9.47) compounds. Molecular modeling studies were performed to map the important pharmacophores for the different subtypes and generate a hypothesis which offers the most plausible explanation for differences in their activity. This series of compounds should be useful for characterizing the structure, pharmacology, and tissue distribution of  $\alpha$ 1 adrenoceptor subtypes.

## 632.20

A POLYCLONAL ANTISERUM AGAINST THE RAT  $\alpha$ 1B ADRENERGIC RECEPTOR PROTEIN: INITIAL CHARACTERIZATION AND IMMUNOREACTIVITY IN THE RAT HYPOTHALAMUS. A.M. Williams and D.A. Morilak\*. Dept. of Pharmacology, University of Texas Health Science Center at San Antonio, 7703 Floyd Curl Dr., San Antonio, TX, 78284-7764

$\alpha$ 1 adrenergic receptors are now classified into several related subtypes. To address the specific functions of the different subtypes in such contexts as stress, arousal or depression, it would be useful to identify the specific subpopulations of neurons that express  $\alpha$ 1 receptor subtypes in the brain. Toward this end, we have raised a polyclonal antiserum against the rat  $\alpha$ 1B receptor protein, and demonstrated its utility in immunohistochemical applications. A bacterial TrpE- $\alpha$ 1B fusion protein was generated by subcloning a fragment of  $\alpha$ 1B cDNA coding for a unique portion of the C-terminal into the inducible pATH-10 expression vector. After PAGE separation, excision and electroelution, the fusion protein was used to inoculate rabbits (HTI BioProducts). Serum from one rabbit produced a consistently high titer ( $>10^4$ ) by ELISA. Dilutions of antiserum at  $>10^{-4}$  were able to detect 20 ng of antigen in dot-blots. Specificity of the antiserum is currently being characterized in COS7 cells transiently transfected with an expression plasmid containing the entire coding region of the rat  $\alpha$ 1B receptor (pcDV $\alpha$ 1B, J. Lomasney, Duke University). Controls include omission of primary antiserum, preadsorption with the fusion protein antigen, untransfected COS7 cells, and incubation with pre-immune serum in place of primary antiserum. In preliminary immunocytochemical experiments in rat hypothalamus, antibody dilutions from 1/500 to 1/2000 label a distinct population of cell bodies in the ventral-medial and the dorsal parvocellular paraventricular nucleus. A more extensive, punctate labelling, some of which was localized to cell processes, was seen throughout the PVNpc and other hypothalamic subnuclei, as well as in specific extrahypothalamic sites, including the dorsal thalamus.

## CATECHOLAMINE RECEPTORS: BETA ADRENERGIC

## 633.1

MECHANISM OF ACTION OF CISSUS SICYOIDES WATERY EXTRACT ON MALE GUINEA PIG INTESTINAL MUSCLE. X. García\*, L. Cartas, M. Lorenzana-Jimenez, and E. Gijón. Dept. of Physiology and Dept. of Pharmacology, School of Medicine, UNAM. México D.F. 04510. México.

Cissus sicyoides extract 1:10 w/v from dry leaves applied to the organ bath (10 ml) induces relaxation, biphasic or contraction responses dose dependent (0.01-1.6 ml). As relaxation or inhibitions from intestinal smooth muscle are induced by stimulation of adrenergic receptors we tested a beta adrenergic blocker, propranolol on Cissus sicyoides biphasic responses from intestine. Propranolol increased relaxation response without affecting contraction, did not change biphasic responses, or blockade relaxation without changing contraction responses, in a dose dependent form. This suggest that relaxation responses are mediated by beta adrenergic receptors.

## 633.2

PARTICIPATION OF VITAMIN B12 IN  $\beta$ -RECEPTOR MEDIATED REGULATION OF ADENYL CYCLASE SYSTEM. M. Watanabe\*, S. Hattai, H. Ikeda, S. Toki, H. Ozawa, T. Saito, and N. Takahata. Department of Neuropsychiatry and Pharmacology<sup>1</sup>, School of Medicine, Sapporo Medical University, Sapporo, 060 Japan

It has been suggested that psychiatric and behavioral symptoms such as depression, schizophrenia, and dementia can be attributed to a deficiency of vitamin B12. Low levels of vitamin B12 has also been reported in dementia of Alzheimer type and vitamin B12 deficiency is thought to be related to cognitive impairment in Alzheimer patients. Furthermore, several studies have indicated that methyl-vitamin B12 (mecobalamin) has clinical effects for non-24-hour sleep-wake syndrome and delayed sleep phase syndrome. On the other hand, vitamin B12 is known to be involved in the synthesis of S-adenosyl-L-methionine, which has been demonstrated to possess the anti depressive effect. Thus, there are several lines of evidence to suggest that vitamin B12 participates in the regulation of cellular responsiveness, especially in neuronal systems. The  $\beta$ -adrenergic receptor adenyl cyclase (AC) system is one of the best-characterized hormonal signal transduction systems which mediate intracellular effects through the Gs protein. In this study, rats were fed with and without mecobalamin. Basal, GppNHP-, forskolin-, and MnCl<sub>2</sub>-stimulated AC activities were significantly lower in mecobalamin-deficient rats than in controls. Activation of AC with isoproterenol in the presence of GppNHP was also significantly reduced in mecobalamin-deficient rats compared with that in controls. However, there was no difference in quantitative and qualitative estimation of G proteins between control and mecobalamin-deficient rats.

Furthermore, mecobalamin restored the lowered level of AC activities in mecobalamin-deficient rats to control levels. These findings indicate that vitamin B12 play a dynamic role in the neuronal signal transduction cascade.

## 633.3

BETA ADRENERGIC RECEPTORS AS A TOOL FOR EVOLUTION STUDIES? A. Fernández-López<sup>1</sup>, V. Revilla<sup>1</sup>, M.A. Candelas<sup>1</sup>, R. Revilla<sup>1</sup> and A. Pazos<sup>2</sup>. <sup>1</sup>Dpt. Biología Celular, Facultad de Biología, Universidad de León, León Spain. <sup>2</sup>Dpt. Fisiología y Farmacología, Facultad de Medicina, Universidad de Cantabria, Santander, Spain.

An autoradiographic study of  $\beta$ -adrenoceptors with [<sup>125</sup>I] cyanopindolol was performed in avian brain from a number of representative orders. Several structures from different functional systems have been measured. Since some of the species studied are scarce, only injured animals discarded from a recuperation center were used in that case.

The following density's profiles were obtained in some of the different structures studied. Cerebellum: Passeriformes(100%) > Psittaciformes(75%) > Columbiformes(68%) > Falconiformes(54%) > Caprimulgiformes(53%) > Galliformes(48%) > Strigiformes(41%). Tectum opticum (layer 3) Passeriformes (100%) > Psittaciformes(82%) > Caprimulgiformes(68%) > Columbiformes(52%) > Falconiformes(47%) > Strigiformes(35%) > Galliformes(26%). The results described here roughly correlate with the postulated cladistic relationships of avian from a number of synapomorphies. The similarity of the density's profile throughout these orders strongly supports the idea that  $\beta$ -adrenoceptors could be an important tool to study the evolution in birds in order to establish phylogenetic relationships. However it must be taken into account that a higher number of taxa, species and samples have still to be studied for further corroboration. This work has been supported by a the grant LE 10/94 from Junta Castilla-León, Spain.

## 633.5

MODULATION OF  $\beta$ -ADRENERGIC RECEPTOR SUBTYPE DENSITY USING INDUCIBLE VECTORS: EFFECTS ON CATECHOLAMINE RESPONSIVENESS IN RAT C<sub>6</sub> GLIOMA CELLS. Shelly D. Wood\*, Hongying Zhong and Kenneth P. Minneman. Dept. of Pharm., Emory Univ. Sch. of Med., Atlanta, GA 30322.

Receptor density increases during the phenomenon of supersensitivity. To better understand the impact of such changes, we studied the relationship of  $\beta$ -adrenergic receptor (AR) density and subtype ratio on catecholamine signaling. C<sub>6</sub> cells, which natively express  $\beta_1$ - and  $\beta_2$ -ARs, were stably transfected with an inducible vector containing the cDNA for the  $\beta_1$ - or  $\beta_2$ -AR, and receptor expression was modulated in a time and concentration-dependent manner by exposure to the nonhydrolyzable galactose analog, IPTG. Receptor number increased ~20- and ~7-fold for  $\beta_1$ - and  $\beta_2$ -ARs, respectively.

We studied catecholamine signaling by measuring: (1) whole cell cAMP accumulation and (2) membrane adenylyl cyclase (AC) activity. In whole cells, increases in  $\beta_1$ - AR expression resulted in parallel increases in agonist potency with no change in the maximum cAMP response whereas, increases in  $\beta_2$ -AR density enhanced agonist potency, but decreased the maximum by ~30%. Neither cell type showed a change in basal cAMP levels following receptor induction. In contrast, induction of  $\beta_1$ -ARs increased membrane AC basal activity ~2-fold relative to that of noninduced cells, and surprisingly, the maximum agonist stimulated response increased ~2-fold relative to the induced basal activity and therefore ~4-fold relative to the noninduced basal activity. In addition, induction of  $\beta_1$ -ARs increased agonist potency at least 5-fold. (Supported by NS 21325 and DA05677)

## 633.7

DELINEATION OF LIGAND-SPECIFIC CONFORMATIONAL CHANGES IN THE  $\beta_2$  ADRENERGIC RECEPTOR BY FLUORESCENT LABELING WITH AN ENVIRONMENTALLY SENSITIVE CYSTEINE REAGENT. U. Gether\*, Sansan Lin and B.K.Kobilka, Howard Hughes Medical Institute, Stanford University, Stanford, CA 94305.

Purified  $\beta_2$ -adrenergic receptor was fluorescently labeled with an environmentally sensitive cysteine reagent (IANBD) to directly monitor structural changes in the receptor in response to ligand binding. These studies represent the first attempt to correlate the conformational state of a purified G protein coupled receptor with the functional properties of different classes of receptor ligands. All tested compounds including 'neutral' antagonists surprisingly caused an apparent conformational change in the receptor as reflected in a change in the fluorescent emission from the covalently bound IANBD. The conformational change induced by full agonists was clearly distinguishable from that induced by inverse agonists (negative antagonists) and from the unoccupied receptor. Thus, full agonists induced a stereo-selective, dose-dependent, reversible decrease in fluorescence, whereas inverse agonists caused a relative increase in baseline fluorescence, which correlated with their negative intrinsic activity in biological assays. However, weak partial agonists induced a change in fluorescence that was more similar to the change induced by antagonists than by full agonists. These results cannot be simply explained by the current and most widely accepted two-state model for G protein coupled in which the receptors are assumed to exist in a dynamic equilibrium between two states; an inactive (R) and active conformation (R\*). Rather our fluorescent data suggest that the two-state model may have to be extended to a model involving multiple conformational states induced or stabilized by different classes of ligands.

## 633.4

EFFECTS OF PRENALTEROL ON BETA ADRENERGIC RECEPTORS EXPRESSED IN CHINESE HAMSTER OVARY CELLS. K. Zhang, Y. Li, F. Karim, R. Maloney\* and J. M. O'Donnell, Dept. of Pharmacology, LSUMC, Shreveport, LA 71130

Prenalterol, although shown to be a  $\beta_1$ -selective adrenergic receptor (AR) agonist in functional studies, has been suggested not to stimulate  $\beta_1$ -AR-linked adenylyl cyclase activity in rat cerebral cortex. In order to assess its activity at human  $\beta_1$  ARs, the binding of prenalterol and its effects on adenylyl cyclase activity were studied in Chinese Hamster Ovary (CHO) cells that were permanently transfected either with human  $\beta_1$ -AR cDNA or human  $\beta_2$ -AR cDNA cloned into a plasmid pcDNA1. The binding of prenalterol to  $\beta_1$  ARs were studied using a competition assay in membrane preparations. The ability of prenalterol to stimulate adenylyl cyclase activity through these receptors was studied using a cyclic AMP accumulation assay in intact cells. Prenalterol inhibited the binding of [<sup>125</sup>I]-pindolol to  $\beta_1$ - and  $\beta_2$ -ARs with IC<sub>50</sub> values of 1.2 and 4.0  $\mu$ M, respectively. The nonhydrolyzable GTP analog GppNHP (250  $\mu$ M) shifted the competition curve for  $\beta_1$ -ARs to the right about 1.5 fold, but had no effect on prenalterol binding to  $\beta_2$ -ARs. Prenalterol stimulated cyclic AMP production dose-dependently in CHO cells transfected with human  $\beta_1$ -ARs; this effect was antagonized by propranolol, a  $\beta_1$ -AR antagonist. By contrast, prenalterol did not increase cyclic production at all in CHO cells transfected with human  $\beta_2$ -ARs at concentrations up to 100  $\mu$ M. These results are in agreement with the cardioselectivity of prenalterol observed clinically, and suggest that lack of effect of prenalterol on  $\beta_1$ -AR-linked adenylyl cyclase activity in rat brain may either be due to its low intrinsic activity or to a species difference.

## 633.6

BINDING OF FLUORINATED CATECHOLAMINES TO ADRENERGIC RECEPTOR SUBTYPES M. Singh<sup>1</sup>, J. Wess, B.K. Kobilka<sup>1</sup>, K.L. Kirk. Lab. of Biochemistry, NIDDK, NIH, Bethesda, MD 20892, <sup>1</sup>Dept. Of Cardiology and Molecular and Cellular Physiology, Howard Hughes Medical Institute, Stanford CA 94305.

Introduction of fluorine into biologically active molecules often produces analogues with markedly altered behavior. The lack of steric interactions accompanying fluorine substitution coupled with the high electronegativity of this element are important factors that influence biological behavior. Our previous studies with ring-fluorinated catecholamines have revealed that fluorine substitution can dramatically affect interactions of adrenergic agonists with  $\alpha$ - and  $\beta$ -adrenergic receptors. We have found that  $\alpha$ -adrenergic receptors have a higher affinity for 6-fluoro-epinephrine (6FE) and 6-fluoro-norepinephrine (6FNE) than for the 2-fluorinated analogues (2FE and 2FNE). On the other hand,  $\beta$ -adrenergic receptors have a higher affinity for 2FE and 2FNE than for 6FE and 6FNE. Binding studies with cloned receptors confirmed these results originally obtained by the use of tissue preparations. To identify the receptor sites determining the selectivity of these compounds, their ability to bind to chimeric  $\alpha_2/\beta_2$ -receptors transiently expressed in COS-7 cells was examined. Preliminary studies showed that more than one receptor domain is responsible for the observed selectivity profiles of the various fluorinated analogues.

## 634.1

**B-CARBOLINES STIMULATE BENZODIAZEPINE-INDEPENDENT RECEPTOR MECHANISMS.** H. Rommelspacher\*, S. Sällström Baum, J.F. Klinker. Dept. Neuropsychopharmacology, Free University, D-14050 Berlin, Germany.

The function of the two  $\beta$ -carbolines harman (H) and norharman (NH) has been investigated in various *in vitro* and *in vivo* systems. [ $^3$ H]norharman binds with high affinity to a specific membrane site in rat brain membranes (Pawlik and Rommelspacher, Eur. J. Pharmacol. 147, 163, 1988). We will present evidence that a high affinity site is coupled to G-proteins and causes an increase of inositol 1,4,5-triphosphate production in a neuronal cell line. The effect does not involve benzodiazepine-activated and  $\mu$ -opioid receptor mechanisms. A second binding site was detected with an affinity of about one magnitude less. Pharmacological characterization of the binding sites revealed that several  $\beta$ -carbolines bind to both sites in contrast to benzodiazepines and those  $\beta$ -carbolines, which are inverse agonists at the benzodiazepine receptor. The function of the new receptor sites was investigated *in vivo* using *in vivo* microdialysis techniques. The extraneuronal concentrations of dopamine, DOPAC, HVA, serotonin and 5-HIAA were determined in the nucleus accumbens following intraperitoneal injection of various doses of H and NH in the freely-moving rat. Low doses of NH (e.g. 0.5 mg/kg) caused an increased concentration of dopamine whereas somewhat higher doses of NH reduced the level of DA. 9 mg/kg caused again an increase, which was prevented by flumazenil (Sällström Baum et al. Life Sci 56, 1715, 1995). The injection of H caused U-shape changes of dopamine concentrations in the nucleus accumbens as well. In conclusion, the findings demonstrate the existence of a new class of receptors, which are expressed in neuronal cell lines and in limbic structures of rat brain. - Supported by the DFG (AZ: He 916/7-2).

## 634.3

**DEFECTIVE HERPES SIMPLEX VIRUS VECTORS FOR THE STUDY OF GLUTAMATE DECARBOXYLASE EXPRESSION IN CELLS OF THE CNS** K. C. New\*, M. R. Proctor, R. L. Martuza, K. Gale, S. D. Rabkin. Departments of Microbiology, Neurosurgery and Pharmacology, Georgetown Univ. Med. Cen., Washington, DC 20007.

Glutamate decarboxylase (GAD) exists in the brain as two isoforms, 65 or 67 kD, which are responsible for the synthesis of  $\gamma$ -aminobutyric acid (GABA). We have constructed defective herpes simplex virus vectors containing GAD65, GAD67 or  $\beta$ -galactosidase (lacZ, control). These vectors were used to infect primary cultures of: a) cerebellar granule cell neurons; and b) cortical astrocytes. In both cultures, GAD vector infection resulted in a greater number of GAD and GABA-like immunoreactive cells compared to lacZ infected cultures. Further, infected granule cell cultures contained neurons expressing GAD65 or GAD67 in both their cell bodies and processes. Amino acid levels from infected cells (moi 1.0) were determined after OPA derivatization by HPLC and fluorescent detection. Intracellular GABA was (pmole/ $\mu$ g protein):

	GAD65	GAD67	lacZ
Neurons	10.8 $\pm$ 2.0 *	14.9 $\pm$ 2.2 *	0.5 $\pm$ 0.5
Astrocytes	25.0 $\pm$ 4.3 *	60.8 $\pm$ 12.6 *	1.0 $\pm$ 1.0

\* p<0.01 compared to lacZ

Increased levels of extracellular GABA were detected after GAD65 infection of granule cell cultures. Intracellular glutamate levels in GAD infected cultures did not vary significantly compared to controls. We conclude that vector derived GAD65 and GAD67 proteins are able to synthesize GABA in neurons and astrocytes. Neurologic disorders that result from decreased GABA levels are potential targets for gene therapy using these vectors.

## 634.5

**ACTION OF THE VOLATILE ANESTHETIC ISOFLURANE ON NEURONAL & CLONED GLYCINE RECEPTORS.** A.C. Hall\*, D.L. Downie, R. Dickinson, S.L. Tomlin, N.P. Franks & W.R. Lieb. Biophysics Section, Imperial College, London SW7 2BZ, UK.

The effect of the volatile general anesthetic isoflurane was investigated on glycine-evoked  $Cl^-$  currents recorded from neonatal rat medullary neurons (whole-cell patch clamp) and from *Xenopus* oocytes co-injected with cDNAs encoding the human  $\alpha_1$  and rat  $\beta$  subunits of the glycine receptor (two-electrode voltage clamp).

In the acutely dissociated neurons held at -40 mV, strychnine-sensitive  $Cl^-$  currents (demonstrated by appropriate reversibility) were evoked by exposure to glycine (3-300  $\mu$ M) via a local perfusion system. Co-application of isoflurane (0.31 mM, a concentration corresponding to anesthesia in humans) with a low concentration of glycine (10  $\mu$ M) resulted in a reversible, voltage-independent potentiation (by  $82 \pm 20\%$ , mean  $\pm$  sem,  $n = 10$  cells) of the non-desensitising control response. Maximal potentiation ( $405 \pm 94\%$ ,  $n = 6$  cells) of the 10  $\mu$ M glycine response was achieved with 1.52 mM isoflurane, while higher concentrations resulted in reduced potentiations. Isoflurane (0.61 mM) was always observed to potentiate responses to 3 and 30  $\mu$ M glycine, while a maximal response (to 300  $\mu$ M glycine) was either unaffected or slightly inhibited, indicating that isoflurane causes a leftward shift in the concentration-response relationship for glycine.

In experiments with oocytes, held at -50 mV, bath application of glycine (300 nM - 10 mM) evoked a concentration-dependent inward current response ( $EC_{50} = 216 \pm 6 \mu$ M, Hill coefficient =  $1.7 \pm 0.1$ ,  $n = 4$ ). The response to glycine (300  $\mu$ M) was virtually abolished by co-application of strychnine (100 nM), but was insensitive to picrotoxin (100  $\mu$ M). Co-application of isoflurane (0.15 - 1.2 mM) with glycine (10  $\mu$ M, 1% of maximum response) produced a concentration-dependent enhancement of the glycine current (up to 50 fold = 45% of max.). Examination of the effect of isoflurane (0.15 - 0.6 mM) on the glycine concentration-response relationship reveals a parallel leftward shift of the glycine curve, with no significant increase in the amplitude of the maximal response to glycine ( $EC_{50} = 84 \pm 7 \mu$ M, Hill coefficient =  $1.6 \pm 0.2$ ,  $n = 4$ , at 0.6 mM), mirroring the effect on the native receptors.

## 634.2

**ENDOGENOUS GABA MODULATES HISTAMINE RELEASE FROM THE ANTERIOR HYPOTHALAMUS OF RAT.** K. Okakura, Mochizuki, T. Mochizuki, Y. Yamamoto, A. Uno, Y. Kondo, M. Suzuki and A. Yamatodani\*. Dept. of Medical Physics and Otolaryngol., Faculty of Med., Osaka Univ., Suita, Osaka 565 Japan.

Using a microdialysis method, we investigated the effects of GABA on *in vivo* release of histamine from the anterior hypothalamic area (AHy) of urethane anesthetized rats. Infusion of nipecotic acid (0.5mM), an uptake inhibitor of GABA, decreased histamine release to about 60% of the basal level. This effect was partly antagonized by both picrotoxin (0.1mM), an antagonist of GABA $_A$  receptors, and phaclofen (0.1mM), an antagonist of GABA $_B$  receptors. These results show that endogenous GABA modulate histamine release through GABA $_A$  and GABA $_B$  receptors.

When the tuberomammillary nucleus, where the cell bodies of the histaminergic neurons are localized, was electrically stimulated, the evoked release of histamine from the nerve terminals was enhanced by phaclofen, suggesting that GABA $_B$  receptors may be located on the histaminergic nerve terminals and presynaptically modulate histamine release. On the other hand, picrotoxin caused an increase of histamine release to about 170% of the basal level, and this increase was diminished by co-infusion of AP5 (0.1mM), an antagonist of NMDA receptors. Previously, we indicated that glutamate makes a tonic control of histamine release through NMDA receptors which are located on the histaminergic terminals in the AHy. These results suggest that GABA $_A$  receptors are located on glutamatergic nerve terminals and indirectly regulate basal release of histamine.

## 634.4

**NULL MUTATIONS OF THE GLYCINE RECEPTOR ALPHA 1 SUBUNIT GENE IN MOUSE AND HUMAN.** C.-M. Becker, W. Brune, C. Kling, R. Weber, B. Saul, H.-M. Meink, K. Kellermann\* (SPON: ENA). Neurologische Klinik, Zentrum für Molekulare Biologie, and Institut für Humangenetik, Universität Heidelberg, 69120 Heidelberg; \*Städtisches Kinderkrankenhaus, 50335 Köln, Germany.

The adult isoform of the strychnine-sensitive glycine receptor, GlyR $\alpha_1$ , comprises ligand-binding  $\alpha_1$  and structural  $\beta$  subunits. The *oscillator* (*spd<sup>0</sup>*) mouse carries a microdeletion within the  $\alpha_1$  gene (*Glra1*) that produces a frameshift affecting a C-terminal segment of the subunit. Although neonates appear normal, homozygous mutants develop a motor disorder leading to death at the age of  $\approx 3$  weeks. Western blots and immunoassays employing subunit-selective antibodies showed that the  $\alpha_1$  polypeptide is completely absent from mutant CNS. Residual [ $^3$ H]strychnine binding can be attributed to the minor receptor isoforms. Thus, *oscillator* represents a functional null mutation of *Glra1* which becomes apparent in adult mice.

The human disorder hyperekplexia, which is characterized by neonatal hypertonia and exaggerated startle responses persisting into adulthood, has been associated with point mutations of the  $\alpha_1$  gene (*GLRA1*). In a sporadic, recessive case of hyperekplexia, we identified an extensive deletion affecting *GLRA1*. Southern blots and PCR amplification of genomic DNA revealed the absence of exons 1 to 6. By FISH, the corresponding null allele was detectable in the child's genome as well as on parental chromosomes. In the human, the homozygous null mutation is phenotypically indistinguishable from dominant variants of the disease. These observations suggest a disparate regulation of glycine receptors in mice and humans.

## 634.6

**EXPRESSION OF GLYCINE RECEPTOR SUBUNITS IN GLIAL CELLS OF THE RAT SPINAL CORD.** Frank Kirchhoff\*, Cornelia Mühlhardt\*, Andrea Pastor\*, Cord-Michael Becker\* and Helmut Kettenmann\*

\* Center of Molecular Biology Heidelberg, University of Heidelberg, Im Neuenheimer Feld 280, 69120 Heidelberg; \* Max-Delbrück-Center for Molecular Medicine, Berlin-Buch, Robert-Rössle-Str. 10, 13122 Berlin, Germany.

By electrophysiological methods it was shown that different glial cells, namely astrocytes, oligodendrocytes and precursor cells of the rat spinal cord respond to the inhibitory neurotransmitters glycine.

In this study the reverse transcription mediated polymerase chain reaction (RT-PCR) in combination with the patch-clamp technique was applied to individual glial cells to investigate subunit expression of the receptor. After electrophysiological recording in the whole-cell configuration the cytoplasm of those glial cells was harvested which displayed a response to glycine. After reverse transcription of cellular mRNA glycine receptor subunit specific DNA fragments were amplified by PCR and analyzed by agarose gel electrophoresis, Southern blotting and cDNA sequencing. The  $\alpha_1$  subunit of the glycine receptor but not  $\alpha_2$ ,  $\alpha_3$  or  $\alpha_4$  could be detected in all glial cell types investigated in rats of postnatal day 3 to 18. In addition, about half of the glial cells investigated expressed  $\beta$  subunit transcripts.

The detection of glycine receptor subunit mRNAs in glial cells confirms the electrophysiological studies showing glycine evoked inward currents and substantiates that glial cells themselves express the receptors. The physiological role of them may be controlling the microenvironment in the vicinity of neurons during synaptic transmission. The contribution of other neurotransmitter receptors known to be expressed in glial cells is conceivable.

634.7

CLONING OF A HUMAN P<sub>2</sub>Y PURINERGIC RECEPTOR.

J. B. Schachter\*, Q. Li, J. L. Boyer, R. A. Nicholas, and T. K. Harden. Dept. of Pharmacol., Univ. of North Carolina, Chapel Hill, NC 27599. Extracellular adenosine and uridine nucleotides interact with P<sub>2</sub> purinergic receptors to produce a broad range of physiological effects. One impediment to the development of selective drugs for these receptors is the lack of tissue sources known to possess single subtypes of nucleotide receptors. To facilitate the pharmacological analysis of one of these receptor subtypes, we have undertaken the cloning and expression of a human P<sub>2</sub>Y purinergic receptor (P<sub>2</sub>Y-R). A 702 base DNA probe was generated by PCR from rat genomic DNA using primers based upon the sequence of a P<sub>2</sub>Y-R from turkey. This probe was used to screen a cDNA library prepared from human brain RNA. One positive clone was obtained from 4x10<sup>6</sup> clones screened. Although incomplete at the 5' end, sequence analysis indicated that this clone contained an open reading frame of 972 bases that was 79 % homologous with a P<sub>2</sub>Y-R cloned from turkey. A 300 base fragment of this clone was used to probe a human genomic library. Two genomic clones containing the cDNA sequence were obtained, both of which contained an ATG start site and an open reading frame of 1119 bases. The overall homology between the human sequence and that of the turkey was 74% at the nucleotide level and 82% at the amino acid level. The human receptor is being expressed in 1321N1 cells to compare its pharmacological profile with that of the P<sub>2</sub>Y-R from turkey, which has also been expressed in these cells.

634.8

CHARACTERIZATION OF P<sub>3</sub> PURINOCEPTOR-LIKE PROTEIN PURIFIED FROM RAT BRAIN MEMBRANES. Y. Saitoh<sup>1</sup>, Y. Sekino<sup>2\*</sup>, and H. Nakata<sup>1</sup>. <sup>1</sup>Dept. of Mol. & Cell. Neurobiol., Tokyo Metropolitan Inst. for Neurosci., Fuchu-shi, Tokyo 183, Japan, <sup>2</sup>PRESTO, JRDC, c/o Mitsubishi-kasei Inst. of Life Sci., Machida-shi, Tokyo 194, Japan.

Purinoceptors are traditionally classified into P<sub>1</sub> and P<sub>2</sub> on the basis of their pharmacological properties. We found a novel adenosine-binding protein in the rat brain which is not classified into the traditional purinoceptors. The protein showed the highest affinity to 5'-N-ethylcarboxamidoadenosine (NECA) among various adenosine agonists. The NECA binding activity was not inhibited by xanthines, antagonists of P<sub>1</sub> purinoceptor. We developed the binding assay system of this protein, and determined tissue and subcellular distributions. It prominently distributed in the brain, and most of the binding activity was located to synaptosomal membranes. Detailed studies on the ligand binding specificity revealed that this adenosine-binding protein can bind to adenosine nucleotides and adenosine with the same affinity. It was classified into neither the traditional purinoceptors, nor adenosine-like proteins. We purified it >10,000-fold from rat brain membranes using six chromatography steps. Recently, a new purinoceptor site (P<sub>3</sub> purinoceptor) which is activated by both adenosine and ATP was proposed in the rat caudal artery (Shinozuka et al, 1988). These results suggest that this adenosine-binding protein is a new purinoceptor in the brain, probably P<sub>3</sub> purinoceptor.

## REGIONAL LOCALIZATION OF RECEPTORS AND TRANSMITTERS I

635.1

DEVELOPMENTAL LOCALIZATION OF D-SERINE IN RAT BRAIN ASTROCYTES. M.J. Schell\*, O.B. Zand, and S.H. Snyder. Department of Neuroscience, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Recent studies indicate that free D-serine is present in brain regions enriched in NMDA receptors. Because D-serine is a potent agonist at the NMDA receptor glycine site, it may act as an endogenous ligand for these sites in brain—instead of or in concert with glycine. In a previous study, using an antibody highly specific to D-serine coupled to glutaraldehyde, we localized D-serine to astrocytes of the gray and white matter of the adult rat telencephalon. We have now localized D-serine during the first three postnatal weeks, a period when NMDA receptor expression varies both regionally and temporally. D-Serine immunopositive glial cells were present at birth in the thalamus and brainstem. During the first postnatal week, large pools of small, round cells proliferated near the lateral ventricles and appeared to cluster over thalamic nuclei and migrate on top of white matter tracts. By day 7, most subcortical regions contained large numbers of these cells. During the second postnatal week, D-serine positive cells appeared in the cerebral cortex and hippocampus and elaborated immunopositive processes; staining in the cerebellar molecular layer also increased rapidly. By day 14, immunoreactivity began to diminish in the midbrain, brainstem and spinal cord, presumably reflecting the expression of D-amino acid oxidase in astrocytes of these regions. During week three, D-serine positive astrocytes became increasingly prominent and elaborate in the gray matter of the telencephalon and assumed an adult-like pattern by day 21. We conclude that, throughout the postnatal period, astrocyte-derived D-serine is well-positioned to be an endogenous modulator of NMDA receptors.

635.2

CHARACTERIZATION OF NEUROTROPHIN RECEPTOR CONTAINING-ENTERIC NEURONS OF THE RAT SMALL INTESTINE. J. Arakawa, R. De Giorgio\*, D. Su, N.C. Brecha and C. Sternini. CURE:VA/UCLA Gastroent. Biol. Ctr., & Depts. Neurobiol. & Med., UCLA & VAMC-WLA, LA, CA 90073.

Neurotrophins (NT) and their high-affinity receptors (*trk-A*, *-B* and *-C*) are widely distributed in the developing and mature nervous system, suggesting that NT may have other effects in addition to support differentiation and survival. We have demonstrated that *trk-C*, the high-affinity receptor for NT-3, is expressed in a large population of neurons of the enteric nervous system (ENS). The aim of this study was to characterize *trk*-expressing enteric neurons using double labeling with *trk* antibody and markers for distinct types of enteric neurons. Many *trk*-immunoreactive (IR) enteric neurons, in both ganglionated plexuses, contained tachykinin-IR. A subpopulation of *trk*-IR submucosal neurons was positive for vasoactive intestinal polypeptide (VIP)-IR. In contrast, no apparent *trk* and VIP colocalization was observed in the myenteric plexus. Enteric neurons stained for NADPH-diaphorase, which was used to identify neurons synthesizing NO, appear to be distinct from those expressing *trk*. The presence of *trk*-IR in distinct subpopulations of enteric neurons supports the hypothesis that NT-3 is involved in the maintenance and function of different neuronal circuits in the mature ENS.

635.3

AUTORADIOGRAPHIC VISUALIZATION OF RECEPTOR-ACTIVATED G-PROTEINS USING [<sup>35</sup>S]GTPγS BINDING. Laura J. Sim\*, Dana E. Selley, Ruoyu Xiao and Steven R. Childers. Dept. of Physiology & Pharmacology, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27157.

We have developed an autoradiographic technique to identify receptor-activated G-proteins in brain sections using agonist-stimulated binding of [<sup>35</sup>S]GTPγS in the presence of excess GDP. In this study, [<sup>35</sup>S]GTPγS binding was examined in response to specific opioid (mu, delta and kappa), cannabinoid and GABA<sub>B</sub> agonists in rat and guinea pig brain sections. Agonist-stimulated [<sup>35</sup>S]GTPγS binding was shown to be receptor-mediated, since the effect was concentration-dependent and blocked by appropriate antagonists. The anatomical distribution of agonist-stimulated [<sup>35</sup>S]GTPγS binding corresponded to known receptor distributions characteristic of each receptor system. For example, [<sup>35</sup>S]GTPγS labeling in the cerebellum was stimulated by cannabinoid, kappa opioid and GABA<sub>B</sub> agonists, whereas [<sup>35</sup>S]GTPγS binding in the striatum was stimulated by mu, delta and kappa opioid, and cannabinoid agonists. However, quantitative analysis of agonist-stimulated [<sup>35</sup>S]GTPγS binding among these receptor systems revealed that the maximal stimulation of [<sup>35</sup>S]GTPγS binding by agonists was not always correlated with the number of receptor binding sites: although the number of cannabinoid binding sites exceeded that of mu sites by tenfold, mu opioid-stimulated [<sup>35</sup>S]GTPγS binding was higher than that of cannabinoid agonists. These data reveal potential differences in receptor coupling efficiency.

635.4

GABAergic AND OTHER NON-CHOLINERGIC BASAL FOREBRAIN NEURONS PROJECT TO MESO- AND ISO-CORTICAL REGIONS IN THE RAT BRAIN. B.E. Jones\*, L. Mainville\*, M. Mancina\* and I. Gritti\*. <sup>1</sup>Montreal Neurological Institute, McGill University, Montreal, Quebec, Canada H3A 2B4 and <sup>2</sup>Institute of Human Physiology II, University of Milano, Milano, Italy 20133.

In the present study in the rat, we investigated whether GABAergic basal forebrain neurons project to the cerebral cortex by employing retrograde transport of cholera toxin subunit (CT) from the prefrontal cortex, a meso-cortical region, and from the parietal cortex, an iso-cortical region, presumed to receive input predominantly from cholinergic magnocellular basal forebrain neurons. Brains were processed by dual immunohistochemical staining for CT and glutamic acid decarboxylase (GAD) or choline acetyltransferase (ChAT) in adjacent series. Of a large number of cells that projected to the prefrontal cortex (~6800, mean, n=3) and the parietal cortex (~5100, mean, n=3), the proportion which were GAD-positive (~31% and ~35%, respectively) was found to be approximately equivalent to that which were ChAT+ (~19% and ~27%). Another equivalent or larger proportion (~50% and ~38%) would be neither GABAergic nor cholinergic. As evident in 3-dimensional reconstructions, the cortically projecting GABAergic, cholinergic and other non-cholinergic neurons were co-distributed through the basal forebrain and were commonly medium to large in size, thus collectively comprising neurons of the magnocellular basal cell complex. These results demonstrate that a significant number of GABAergic and other non-cholinergic magnocellular basal forebrain neurons project to the cerebral cortex and could thus serve in parallel with the cholinergic magnocellular neurons to modulate cortical activity. (Supported by MRC and ASSORN.)

## 635.5

SEMIQUANTITATIVE IMMUNOCYTOCHEMICAL ANALYSIS OF GABA<sub>A</sub> RECEPTOR SUBUNITS EXPRESSION IN THE RAT NEOSTRIATUM. H.J. Caruncho<sup>1</sup>\*, I. Liste<sup>1</sup>, C. Pesold<sup>2</sup>, F. Impagnatiello<sup>2</sup>, A. Guidotti<sup>2</sup> and J.L. Labandeira-Garcia<sup>1</sup>. 1. Department of Morphological Sciences, University of Santiago de Compostela School of Medicine, Spain. 2. Center for Neuropsychopharmacology, N.S. Kline Institute for Psychiatric Research, Orangeburg, NY 10962.

Different striatal regions receive afferents from different neocortical structures. In addition, striatal interneurons expressing a variety of neurotransmitters are unevenly distributed in different striatal areas. To assess the possible existence of specific GABA<sub>A</sub> receptor subtypes in the dorso-lateral, dorso-medial and ventro-medial striatum, we used an immunogold silver enhancement technique with GABA<sub>A</sub> receptor subunit specific antibodies. The results document a different abundance in the striatum of three groups of GABA<sub>A</sub> subunits:  $\alpha 1$  and  $\alpha 3$  (labeling density of less than 100 gold particles per 1000  $\mu^2$ ),  $\gamma 2$  and  $\delta$  (labeling density between 100 and 200 gold particles per 1000  $\mu^2$ ),  $\alpha 2$  and  $\beta 2/3$  (labeling density of more than 300 gold particles per 1000  $\mu^2$ ). Analysis of the labeling density in different striatal regions shows that  $\alpha 1$  and  $\alpha 3$  subunits are more abundant in the dorsal than in the ventral striatum where the labeling density is 35% lower;  $\beta 2/3$  and  $\gamma 2$  subunits are more abundant in the medial than in the lateral striatum where the labeling density is 40% lower, while the  $\alpha 2$  and  $\delta$  subunits fail to show differences in regional expression. The present data is consistent with a probable existence of differences in GABA<sub>A</sub> receptor subtype expression in the three striatal regions mentioned above. Supported in part by DGICYT grant PB92-0378 (Spain) and NIH grant RO1-MH49486-01A3.

## 635.7

DISTRIBUTION OF AMPA AND KAINATE RECEPTOR SUBUNIT MESSENGER RNA IN PRIMATE AND HUMAN BRAIN. J.H. Meador-Woodruff<sup>1</sup>, R.E. King, S.P. Damask. Mental Health Research Institute and Department of Psychiatry, University of Michigan, Ann Arbor MI

Four major families of glutamate receptors have been defined: three families of ionotropic receptors (the NMDA, kainate, and AMPA families), and one family of metabotropic receptors. Each of these glutamate receptor subfamilies contains multiple specific receptor members. The ionotropic receptor families are characterized by genes that encode receptor subunits with three or four putative transmembrane domains. These expressed subunits are assembled to form ligand-gated ion channels. On the other hand, the metabotropic glutamate receptors are members of the superfamily of the seven transmembrane domain, G-protein coupled receptors. We have initiated studies examining the anatomy and regulation of the mRNAs encoding these receptors and receptor subunits, and have primarily focused on the AMPA and kainate receptor subunits to date. The kainate family of receptors consists of two high (KA1, KA2) and three low (gluR5-gluR7) affinity kainate receptor subunits. The AMPA receptors are derived from four distinct subunits (gluR1-gluR4). These subunits can be expressed in a number of forms, due both to alternative splicing and to RNA editing. The AMPA receptors are widespread in the rat brain, especially in cortex and hippocampus; the kainate receptors may have a more limited distribution. Less is known, however, about the distributions of these mRNAs in primate and human brain. In this study, we have determined the distributions of the AMPA and kainate subunit mRNAs in old-world monkey and human brain by *in situ* hybridization using [<sup>35</sup>S]-labeled riboprobes. These subunit mRNAs were found to be differentially distributed in monkey and human brain, and in many cases different from what has been reported in the rat brain. These data reflect the complexity of the mammalian glutamate systems, and prepare the way for our ongoing studies on the expression of glutamate receptors in postmortem brains of schizophrenics.

## 635.9

N-METHYL-D-ASPARTATE RECEPTOR LOCALIZATION, IDENTIFIED USING ANTIBODY IMMUNOCYTOCHEMISTRY, IS PRIMARILY POSTSYNAPTIC IN THE CAT SUPERIOR COLLICULUS. R.R. Mize\* and G.D. Butler. Dept. of Anatomy and Neuroscience Center, Louisiana State University Medical Center, New Orleans, LA 70112

The n-methyl-d-aspartate receptor (NMDAR), an ionotropic glutamate receptor, is known to play an important role in long term potentiation and synapse plasticity. However, little is known about the subcellular distribution of this receptor in brain. We have used antibody immunocytochemistry to localize receptor sites for the NMDAR1 subunit of this receptor in the cat superior colliculus (SC). Lesions of areas 17-18 were made in 2 adult cats in order to identify cortical terminals within SC.

At the light microscope level, NMDAR1 receptor labeling was distributed throughout all layers of SC. The densest labeling was seen in the superficial gray layer (SGL). The antibody labeled both dendritic processes and selected cell bodies. At the electron microscope level, the NMDAR1 receptor subunit had a highly specific distribution. Label was identified at many synaptic sites, primarily at the postsynaptic densification. Internalized label was also seen occasionally along the membranes of mitochondria and on microtubules and neurofilaments within labeled dendrites. Presynaptic profiles opposite labeled dendrites were frequently retinal terminals with pale mitochondria (RTs) or cortical terminals (CTs), both of which contain round synaptic vesicles and are known to be glutamatergic. Labeled profiles receiving input from synaptic terminals with flattened vesicles were also seen occasionally. The types of profiles labeled by NMDAR1 included both large caliber conventional dendrites, and frequently, presynaptic dendrites containing loose accumulations of pleomorphic synaptic vesicles which are known to be GABAergic. By contrast, label was rarely if ever found in association with presynaptic axon terminals.

These results show that the NMDAR1 receptor subunit is selectively associated with the postsynaptic densities of synapses known to use glutamate. It also frequently labels the postsynaptic densities found on the membranes of GABAergic presynaptic dendrites. Supported by NIH EY-02973.

AMPA RECEPTOR SUBUNIT AND GAD-65/67 EXPRESSION PROFILE IN NOS POSITIVE NEURONS: A DOUBLE-LABELING STUDY. M.V. Catania<sup>1</sup>, T. Tölle<sup>2</sup>, P.H. Seeburg<sup>1</sup>, R. Bernardini<sup>2,3</sup> and H. Monyer<sup>1</sup>. <sup>1</sup>Center for Molecular Biology (ZMBH), INF 282, 69120 Heidelberg, FRG, <sup>2</sup>Max Planck Institute for Psychiatry, Kraepelin Straße 10, 80804 München, FRG and <sup>3</sup>Institute of Pharmacology, University of Catania, 95100 Catania, Italy.

NOS (nitric oxide synthase) positive neurons in the cortex, striatum and hippocampus represent a small population of scattered aspiny interneurons which contain a Ca<sup>2+</sup>/calmodulin dependent constitutive NOS. The functional role of these neurons is not completely established. We studied the expression profile of AMPA receptor subunits in NOS-positive neurons of the adult rat cortex, striatum and hippocampus by a double-labeling approach, combining non-radioactive *in situ* hybridization and immunohistochemistry. We also examined the expression of GAD-65 and -67 isoforms in order to establish which of these is present in NOS positive neurons.

The majority of cortical and hippocampal NOS-positive neurons were characterized by a predominant expression of GluR-A and -D mRNAs and low or undetectable expression of GluR-B and -C mRNAs. In the striatum all AMPA receptor subunit mRNAs were expressed at low levels. A marked regional diversity of NOS-positive neurons emerged from our studies analyzing the expression of GAD-65 and -67 mRNAs: NOS positive neurons expressed high levels of GAD-65, but not -67 in the cortex, high levels of both GAD-65 and -67 in the hippocampus and low or undetectable levels of both mRNAs in the striatum.

Our results indicate that NOS positive neurons in the three regions examined share the common feature of low GluR-B expression, suggesting the presence of AMPA receptor channels with high Ca<sup>2+</sup> permeability, regardless of the regional location. The region dependent variability found in the expression of the GluR-A and -D as well as in the expression of the GAD isoforms suggests a different functional role of this special type of interneurons within a distinct circuit.

## 635.8

SUBCELLULAR LOCALIZATION OF CAM II KINASE- $\alpha$  AND GLUTAMATE RECEPTORS IN VB NUCLEUS OF RAT THALAMUS.

X.-B. Liu\*, R.M. Mansour and E.G. Jones. Department of Anatomy and Neurobiology, University of California, Irvine, CA 92717.

Low threshold somatosensory input to the ventrobasal thalamus (VB) is mediated by NMDA and non-NMDA receptors. Both NMDA and non-NMDA receptors are substrates for CAM II kinase which is specifically expressed by thalamic relay neurons. The precise location of immunoreactivity for the receptor proteins in relation to identified afferent axon terminals has not been established. Preembedding immunostaining (for receptor proteins) and postembedding immunogold labelling (for glutamate and GABA) revealed the relationship of CAM II kinase- $\alpha$ , glutamate receptor proteins and glutamatergic or GABAergic axon terminals in rat VB nucleus. Immunostaining for CAM II kinase- $\alpha$ , NMDAR1 and GluR2/3 labeled many neurons in VB. NMDAR1, GluR2/3 and CAM II kinase- $\alpha$  immunoreactivity was found within somata and dendrites of glutamatergic relay cells. Glutamatergic RL type terminals were associated with postsynaptic density immunoreactivity for all three in large dendrites. CAM II kinase- $\alpha$ , NMDAR1 and GluR2/3 immunoreactivity in distal dendrites was confined to postsynaptic densities and especially associated with glutamatergic RS terminals. GABAergic terminals were not associated with CAM II kinase- $\alpha$ , NMDAR1 or GluR2/3 immunoreactive synaptic densities. These results indicate: (1) CAM II kinase- $\alpha$ , NMDAR1 and GluR2/3 have similar distribution patterns in VB, and are colocalized within excitatory relay cells. (2) CAM II kinase- $\alpha$  and glutamate receptor proteins are localized postsynaptically and associated specifically with glutamatergic terminals.

Supported by NIH grant NS 21377.

## 635.10

THE LOCALIZATION OF GLUTAMATE RECEPTOR SUBTYPE-1 (GluR1) mRNA EXPRESSION IN HUMAN POSTMORTEM BRAIN TISSUE.

J. Logel\*, C.B. Breese, C.E. Adams, and S. Leonard. Department of Pharmacology, University of Colorado Health Sciences Center, and Veterans Administration Medical Center, Denver, CO 80262.

Glutamatergic receptors have been localized throughout the mammalian central nervous system (CNS). Since glutamatergic neurotransmission plays a crucial role in normal CNS function, changes in glutamate receptor function may be important in the pathogenesis of a number of neurological disorders. A human cRNA probe to GluR1, was used for *in situ* hybridization to examine the anatomical and cellular localization of the GluR1 receptor subunit in various regions of human post-mortem brain tissue. Our results indicate that the highest levels of hybridization were to the hippocampal pyramidal cells of the CA1-CA3 region, and the granular cells of the dentate gyrus. Hybridization was also observed in medium to large neurons of the cingulate cortex, temporal lobe, septum, and amygdala, as well as in scattered neurons in the thalamus, cerebral cortex, and medulla. Light hybridization was also observed along the granular/molecular layer border of the cerebellum. These results closely correspond with relative GluR1 receptor levels observed in several of these brain regions examined using a western blotting protocol (Breese and Leonard, J Mol Neurosci 4:263-275, 1994), as well as for the observed and reported mRNA localization in the rat brain (Keinanen et al., Science 249:556-560, 1992). Studies are currently underway to map and compare the localization of other members of the AMPA family of glutamatergic receptors in the human brain. Examination of the glutamatergic receptor protein and mRNA expression in human postmortem brain tissue may provide information on the molecular basis of a variety of neurological disorders of the CNS.

## 635.11

EXPRESSION OF NADPH-DIAPHORASE IN THE CROTALINE SNAKE NERVOUS SYSTEM. S. Terashima\* and P.-J. Jiang. Dept. of Physiol., Univ. of Ryukyus Sch. of Med., Nishihara-cho, Okinawa 903-01 Japan.

As a specific method for detecting nitric oxide-producing neurons we used NADPH-diaphorase histochemistry. We found some discrete populations for NADPH-d in the brain, spinal cord, and ganglia of the crotaline snake *Trimeresurus flavoviridis*.

Nine snakes were anesthetized with halothane gas and with ketamine (n=7) or pentobarbital sodium (n=2) (no difference was observed between the results of the two groups), and paralyzed with pancuronium with artificial respiration. The snakes were perfused with freshly prepared fixative solution consisting of 2.5% paraformaldehyde and 1.5% glutaraldehyde in 0.1 M phosphate buffer (PB, pH 7.4). The brain was postfixed in the same fixative for 1 hour. Serial frozen sections were cut at 30-50  $\mu$ m coronally or sagittally and collected into 0.1 M PB. The free-floating sections were reacted for 1-3 hrs using conventional NADPH-d histochemical procedures. The reaction solution contained 100 mg  $\beta$ -NADPH (Kohjin Co., Japan), 20 mg nitroblue tetrazolium (Sigma), and 0.3% Triton-X 100 in 100 ml 0.1 M PB. Histochemical control experiments were reacted without NADPH.

Some populations were positive in NADPH-d labeling: 1) periglomerular cells of the accessory olfactory bulb, 2) supraoptic nucleus, 3) tall ependymal cells of the subcommissure organ, 4) neurons and their fibers in the descending nucleus of the trigeminal nerve, 5) large and small cells of the nucleus mesencephalicus n. trigemini, 6) nucleus loci coerulei, 7) columnar visceromotorius, 8) neurons in the trigeminal ganglion, 9) neurons in the nodose ganglion, and 10) fibers of the dorsal root. We could not find NADPH-d positivity in the cortex or the cerebellum.

In conclusion, NADPH-d positivity is very specific for some cells in the nervous system of the crotaline snake.

## 635.13

HISTAMINE H3 RECEPTORS AND DENERVATION SUPERSENSITIVITY. T. Watanabe\*, J. H. Ryu, Y. Nakagawa, X. L. Zhao, H. W. M. Steinbusch\* and K. Yanai. Depts. Pharmacology I and Ophthalmology<sup>1</sup>, Tohoku Univ. Sch. of Med., Sendai 980, Japan, and <sup>2</sup>Dept. Psychiatry and Neurophysiology, Univ. of Maastricht, the Netherlands.

Histamine H3 receptors are not only presynaptic autoreceptors of histaminergic neurons but also heteroreceptors located at their postsynaptic neurons. We examined changes of the density of H3 receptors using 3 different types of neurotoxic and mechanical denervation by quantitative autoradiography with tritium sensitive phosphor imaging plates and [<sup>3</sup>H](R)- $\alpha$ -methylhistamine as ligand. Changes in NADPH diaphorase histochemistry and NO synthase (NOS) immunostaining were examined in parallel. H3 receptor binding in the visually deprived superior colliculus, contralateral to the enucleated eye, was markedly increased 5-50 days after unilateral orbital enucleation of PVG rats, but NOS was not induced in the superior colliculus. H3 receptors were also highly up-regulated in the denervated striatum and substantia nigra of rats after unilateral intranigral injection of 6-hydroxydopamine. The distribution of H3 receptors was not changed in the dorsal motor nucleus of the vagus and the ambiguous nucleus of rats after unilateral vagotomy, although NADPH/NOS were highly increased in the vagal complex. These data showed that H3 receptors are markedly up-regulated at the postsynaptic sites of denervated neurons, whereas NOS is highly increased at the damaged neurons by neuronal injuries probably due to the increased cytosolic free calcium concentrations.

## 635.15

EXPRESSION OF THE INOSITOL 1,4,5-TRISPHOSPHATE RECEPTOR TYPE 1 (IP3R1) PROMOTER-*lacZ* FUSION GENE IN TRANSGENIC MOUSE BRAIN. D. Furutani<sup>1,2</sup>, K. Shimoda<sup>3</sup>, S. Yoshikawa<sup>1</sup>, A. Miyawaki<sup>1</sup>, T. Furuchi<sup>1</sup>, and K. Mikoshiba<sup>1</sup>

1: Dept. of Mol. Neurobiol., Institute of Med. Sci., Univ. of Tokyo, 2: First Dept. of Internal Medicine, Osaka Med. College, 3: Lab. of Animal Center, Sch. of Med., Keio Univ., Japan

To analyze the spatial and temporal pattern of IP3R1 expression in detail, we generated lines of transgenic mice carrying sequences upstream of mouse IP3R1 gene (5'-promoter regions; 1N region from -528 to +169 or 4N region from -4187 to +169) fused to *E. coli*  $\beta$ -galactosidase ( $\beta$ -gal) gene (*lacZ*). The cell type specificity of transgene expression was examined by tissue histochemistry for  $\beta$ -gal activity using a chromogenic substrate, X-gal. Two of ten lines obtained, both 1N lines and 4N lines, showed characteristic patterns of  $\beta$ -gal activity in brain as well as in non-neuronal tissues, almost consistent with the expression of the endogenous IP3R1 expression known thus far. The transgene expression in a 1N line showed segment-like pattern in the developing cerebellar Purkinje cells, but not in the 4N lines. These findings suggest that the short region from -528 to +169 is involved in the cell type-specific expression of IP3R1, and might confer the segment-like gene expression in the cerebellar Purkinje cells.

## 635.12

NADPH DIAPHORASE IN THE INSULAR CORTEX OF THE SYRIAN GOLDEN HAMSTER. R.G. Wehby\*<sup>1</sup> and J.A. London<sup>1,2</sup>. Center for Neurological Sciences<sup>1</sup> and Department of BioStructure and Function<sup>2</sup>, University of Connecticut Health Center, Farmington, CT 06030.

NADPH diaphorase (NADPHd) activity in the insular cortex of the Syrian golden hamster was examined. Staining was found in both cell bodies and fibers (n = 7 animals). The cell body staining is of two types: (a) cells that are filled solidly with reaction product, or (b) cells that display granules of reaction product in the cytoplasm. The solid cells are: (1) found scattered singly, (2) mostly large, aspiny and multipolar, (3) mostly (>85% of cells, two animals, n = 622 cells) located in layers V and VI, and (4) mostly (>54% of cells, two animals, n = 622 cells) located rostral to and including the genu of the corpus callosum. In contrast, the cells with the granular cytoplasmic reaction product are: (1) very numerous and are grouped together, so that they appear to form a band or ribbon of labeled cells, (2) medium-sized, (3) found almost exclusively in layers II and III of the dysgranular and agranular insular cortex, and (4) found throughout the rostrocaudal extent of the insular cortex. Stained fibers are found largely in layers II, III, V, VI, and have a strong radial orientation in layers V and VI. The NADPHd procedure used in this study indicates nitric oxide synthase is present (Matsumoto et al., 1993). These data thus suggest that nitric oxide plays a role in the function of the insular cortex of the hamster.

## 635.14

IMMUNOCYTOCHEMISTRY FOR ARGININE IN THE RAT CENTRAL NERVOUS SYSTEM. Petrusz P.\*, Kharazia V.N., Grossman G., Weinberg R.J., Salt T.E.<sup>†</sup> Dept. of Cell Biology & Anatomy, U. of North Carolina, Chapel Hill, NC 27599, U.S.A.; <sup>†</sup>Institute of Ophthalmology, U. of London, U.K.

Activity in the thalamus may be modulated via multiple mechanisms. Stimulation of afferents to the ventrobasal thalamic complex triggers release of arginine (Do et al., 1994), suggesting a modulatory role for nitric oxide in thalamic mechanisms of somatosensation. We performed immunocytochemistry to study the regional and cellular distribution of arginine. Antibodies were prepared in rabbits against arginine, conjugated to keyhole limpet hemocyanin according to Aoki et al. (1991). As shown by ELISA these antibodies are highly sensitive and specific for L-arginine. Anesthetized Sprague-Dawley rats were perfused with aldehydes; brains were removed and postfixed in the same fixatives for 2-8 hours. Sections of paraffin-embedded material on slides, or free-floating Vibratome-cut material, were processed for immunocytochemistry. Staining in the thalamus was predominantly in endothelium and in cells recognizable for their appearance and distribution as neuroglia. Nuclei of many neurons were immunopositive and staining was in the cytoplasm of neurons in some extrathalamic structures, e.g. raphe and septum. Post-embedding electron microscopic immunocytochemistry confirmed that staining is predominantly in endothelial cells and glia. These results extend and support previous information about the location of arginine in the central nervous system (Aoki et al., 1991). Arginine in the thalamus may be stored in glia whence it is supplied to terminals as substrate for the activity of nitric oxide synthase.

## 635.16

CORTICOTOPIC ORGANIZATION OF THE CHOLINERGIC PROJECTIONS FROM THE BASAL FOREBRAIN IN RATS: PARALLEL ELECTROPHYSIOLOGY AND MICRODIALYSIS-HPLC DATA. R.W. Dykes, M.E. Capdeville and A.A. Myasnikov\* Dept. de physiol., Faculté de med., Univ. de Montreal, C.P. 6128, Succ. centre-ville, Montreal (Que.) H3C 3J7.

The acetylcholine (ACh) released from the somatosensory and either the visual or motor areas of cortex was measured simultaneously in acute experiments using microdialysis and high performance liquid chromatography (HPLC) in 23 adult male rats anesthetized with urethane or sodium pentobarbital. Electrical stimulation of different basal forebrain (BF) sites released different amount of ACh from different cortical sites suggesting some degree of corticotopic organization of the cholinergic projections from BF. The BF sites provoking the highest rates of release from the somatosensory and visual cortex were found at greater distances from one another than the sites in the BF capable of most effectively releasing ACh from the somatosensory and motor regions.

Stimulation of the BF also changed cortical neuronal activity recorded with a tungsten-in-glass electrodes. The magnitude, duration and delay of the multiunit responses in somatosensory cortex varied with the BF site stimulated. The nature of the response served as a predictor of the amount of ACh that would be released by stimulation of that BF site. Some BF sites provoked a long inhibition of spontaneous cortical neuronal activity and did not increase the ACh released while others provoked a marked enhancement of cortical activity and significant increases in ACh release. The changing relationship among the excitatory sites and the inhibitory sites suggests an elaborate control of sensory cortex by a BF mechanism involving an interaction of the gabaergic and cholinergic neurons found there.

## 635.17

## INVESTIGATION OF IL-1 RECEPTORS EXPRESSION IN THE RAT BRAIN

G. N. Luheshi<sup>1</sup>, C. Davies, N. J. Rodwell and S. Toulmond.

School of Biological Sciences, Neuroscience Division, 1.124 Stoford Building, University of Manchester, Manchester M13 9PT, UK.

Interleukin-1 (IL-1) is a potent endogenous pyrogen which acts directly on the central nervous system to induce fever. Our studies in rats show that intracerebroventricular injections of IL-1 $\beta$  induce marked increases in body temperature, which is inhibited by the central injection of ALVA-42, an antibody raised against the human 68kDa Type-II IL-1 receptor, suggesting the involvement of this receptor in fever. Other groups have suggested that the type II receptor is not functional, but acts as a decoy receptor, and that although ALVA-42 binds to IL-1 type II receptor expressing cells (human B lymphocytes), it does not bind to the type-II receptor but instead to MHC class II antigen expressed on the same cells. While distribution of type II receptors in rat brain is unknown, MHC class II antigens are known not to be expressed by normal brain cells, but to be induced by inflammatory challenges or after brain lesion. We have therefore investigated and compared ALVA-42 binding and MHC class II antigen expression in both normal and injured (lateral fluid percussion trauma) rat brain. Immunocytochemical analysis (avidin-biotin method) was carried out on vibratome sections (80  $\mu$ m) of perfused-fixed rat brain, with monoclonal mouse anti-human IL-1 type II receptor (ALVA-42; Genzyme) and monoclonal mouse anti-rat MHC class II antigen (OX6; Serotec) as primary antibodies. Results from these studies revealed positive ALVA-42 binding to astrocytes in identical areas of normal and injured brain (hypothalamus, hippocampus, corpus callosum). In contrast, MHC class II antigens were not detected in normal brain, while their expression by microglia-like cells was evident at the lesion site in the injured brain. MHC class II antigens were not detectable in any of the brain regions positive for ALVA-42 binding. These observations indicate that, in rat brain, ALVA-42 is binding to sites other than MHC class II antigens. Further experiments are required to confirm ALVA-42 binding to IL-1 type II receptors.

## 635.18

DISTRIBUTION OF PROGESTERONE RECEPTOR mRNA IN THE MOUSE BRAIN AS DETERMINED BY *IN SITU* HYBRIDIZATION.C. M. Isbister<sup>1</sup>, A. El-Husseini, S. R. Vincent and P. B. Reiner. Kinsmen Laboratory of Neurological Research, Dept. of Psychiatry, University of British Columbia, Vancouver, B.C. Canada, V6T 1Z3.

Hormones exert profound effects upon behaviour. Many of these effects are mediated by classic intracellular hormone receptors, acting as ligand-dependent transcription factors. As part of an ongoing research program aimed at understanding the role of hormones in altering gene transcription in the brain, we have mapped the distribution of progesterone receptors in the mouse brain. To determine the distribution of progesterone receptor (PR) in the mouse brain, RT-PCR and *in situ* hybridization techniques were applied. A PCR product the size predicted from the cDNA for mouse PR was obtained from mouse uterine total RNA. The amplified product of this cDNA was subcloned, sequenced and consequently confirmed to be PR. *In situ* hybridization with riboprobes derived from the cloned PR PCR product indicate that this steroid receptor is highly expressed in the hypothalamus, cortex, amygdala, substantia nigra and the bed nucleus of the stria terminalis, and moderately expressed in the hippocampus and habenula. Similar expression patterns have been observed in previous mRNA localization studies performed on rats. These data demonstrate that the distribution of progesterone receptors is well conserved in rodent brains, and lays the foundation for studying progesterone receptor function in the mouse brain.

## 635.18

ESTROGEN RECEPTOR IMMUNOREACTIVE CELLS IN THE FOREBRAIN OF FEMALE RABBITS: EFFECT OF ESTRADIOL. M. Caba<sup>1,2</sup>, C. Beyer<sup>1</sup>, G. González-Mariscal<sup>1\*</sup>, and J.I. Morrell<sup>3</sup>. <sup>1</sup>CIRA: CINVESTAV-Universidad Autónoma de Tlaxcala and <sup>2</sup>Universidad Veracruzana(México); <sup>3</sup>Center for Molecular and Behavioral Neuroscience, Rutgers University (Newark NJ, USA).

Little is known about the distribution of estrogen receptors (ERs) in the female rabbit brain. Yet, as in many mammals, estradiol in female rabbits regulates many reproductive events (e.g., ovulation, scent-marking, sexual behavior, maternal behavior). Therefore, information on the distribution and regulation of ERs in the brain of female rabbits is crucial for understanding many aspects of the female rabbit's reproductive physiology. Rabbits from three different conditions were used: estrous (E), ovariectomized-non treated (OVX), and OVX-estrogen treated (OVX-E<sub>2</sub>: 5  $\mu$ g estradiol benzoate/day for five days). Subjects (Ss) were perfused with paraformaldehyde and sections through the forebrain were incubated with the H222 antibody (Abbot labs.) and reacted with nickel-intensified diaminobenzidine. Nuclear staining was observed in OVX does in: preoptic area (POA), ventromedial hypothalamus (VMH), arcuate nucleus (ARC), and lateral hypothalamus (LH). Neurons in the LH also showed immunoreactivity in the cytoplasm. The presence of estradiol, in both E and OVX-E<sub>2</sub> Ss, down-regulated ER-immunoreactivity in the POA and LH but only slightly decreased staining in the VMH and ARC. Thus, the effects of estrogen on ER-immunoreactivity in the female rabbit brain are apparently not uniform: while this steroid may selectively down-regulate ER-immunoreactivity in some brain regions, it seems to have little or no effect in other areas.

## REGIONAL LOCALIZATION OF RECEPTORS AND TRANSMITTERS II

## 636.1

DIFFERENTIAL LOCALIZATION OF D<sub>2</sub> VERSUS D<sub>3</sub> mRNA IN MIDGESTATIONAL HUMAN FOREBRAIN BY *IN SITU* HYBRIDIZATION. A.S. Unis<sup>\*</sup>, M.D. Roberson, K. Hill, M.W. Hamblin and D.M. Dorsa. Dept. of Psychiatry & Beh. Sci., and the Seattle VAMC, Univ. of Washington, Seattle, WA 98195-6560.

Dopamine receptors are expressed in human forebrain in the first trimester and increase approximately 10-fold in concentration by the second trimester. Because dopamine appears to induce neuronal differentiation when D<sub>2</sub> and D<sub>3</sub> receptors are transfected into mouse neuroblastoma cells, Todd et al. (1992) have suggested that dopamine may play a "morphogenic" role in brain development. Using *in situ* hybridization with <sup>32</sup>P-UTP-labeled antisense and sense riboprobes for D<sub>2</sub> and D<sub>3</sub> receptor mRNA's, we characterized the similarities and differences in dopamine D<sub>2</sub> and D<sub>3</sub> receptor gene expression in first and second trimester human forebrain.

Antisense D<sub>3</sub> receptor riboprobe hybridization could be clearly identified in the first trimester forebrain within the cerebral vesicles. At midgestation, intense hybridization signal localized to the periventricular germinal matrix and the cortical plate. Hybridization signal in the germinal matrix appeared to intensify from frontal to parietal coronal sections and attenuated in occipital regions until it was undetectable in sections containing striatal cortex. Some antisense hybridization signal could be seen in the caudate but was dorsomedial in its localization and weak in comparison to that seen in the germinal matrix. As expected, D<sub>3</sub> sense riboprobe controls failed to hybridize to any anatomic areas in corresponding sections. In marked contrast to the D<sub>3</sub> findings, D<sub>2</sub> antisense riboprobe hybridized at midgestation to caudate and midbrain, with no detectable hybridization signal in adjacent differentiating neuronal populations. Hybridization signal intensity appeared to follow a ventrolateral-to-medial gradient within brain sections and was higher when comparing brains from gestational week 24 to 20.

If dopamine plays a role in neuronal differentiation in the human brain, the prominent expression of D<sub>3</sub> receptors in extra-striatal, rapidly developing brain regions make this receptor a likely candidate to mediate dopamine's effects.

## 636.2

## FLUORESCENCE COLOCALIZATION OF D1 AND D2 DOPAMINE RECEPTORS ON LIVING NUCLEUS ACCUMBENS MEDIUM SPINY NEURONS IN VITRO. M. Shetreat and S. Rayport\*. Depts. Psychiatry, Anatomy &amp; Cell Biology, and Ctr. Neurobiology &amp; Behavior, Columbia Univ.; Dept. Neuroscience, New York State Psychiatric Institute, NY 10032.

In the striatal complex, it has been controversial as to whether D1-D2 interactions occur at the level of individual postsynaptic neurons. To address this issue, we visualized D1 and D2-like receptors on living postnatal rat nucleus accumbens (nAcc) neurons in culture. Previously, we have shown that rhodamine-NAPS (10 nM), a fluorophore derivative of the D2 antagonist spiperone, labels D2 receptors on living nAcc neurons (Rayport and Sulzer, *J. Neurochem.*, 1995). We now show that rhodamine-SCH23390 (Molecular Probes; 30 nM), a derivative of the D1 antagonist, labels D1-like receptors. Putative specific membrane labeling reached a plateau after about 20 min. Labeling was stereospecific, as it was unaffected by competition with 100 nM (-)-butaclamol, while it was completely blocked by 100 nM (+)-butaclamol (the butaclamol enantiomers show a ~10,000-fold differential affinity for cloned D1 receptors). In 14 cultures (n = 178 cells), we found that 52  $\pm$  7% of nAcc medium spiny neurons showed D1 labeling. D1 labeling was also seen on larger putative cholinergic neurons as well as on presynaptic terminals abutting D1-labeled and unlabeled cell bodies. By sequential labeling of the cultures first with the rhodamine-SCH23390 and then rhodamine-NAPS, we found that 38  $\pm$  6% of medium spiny neurons express both D1 and D2-like receptors. This indicates that D1-D2 interactions in the nAcc are likely to occur at the level of individual postsynaptic cells.

## 636.3

**ENRICHMENT OF DOPAMINE TRANSPORTER, AND D<sub>1A</sub> AND D<sub>2A</sub> RECEPTORS IN STRIATAL PATCHES DURING ONTOGENY.** B.J. Ciliax\*, N.F. Ciliax, A.L. Levey. Department of Neurology, Emory University School of Medicine, Atlanta, GA 30322

Striatal patch and matrix compartments receive dopaminergic nigrostriatal afferents and send out striatonigral efferents at different times during ontogeny. Relative expression, however, of dopamine receptor molecular subtypes and dopamine transporter (DAT) in these striatal compartments and in substantia nigra has not been determined during pre- and postnatal development. We used characterized anti-fusion protein antibodies specific for dopamine D<sub>1A</sub> and D<sub>2A</sub> receptors, and DAT for light microscopic immunocytochemistry in developing rat brain. Each of these dopaminergic proteins were enriched in the striatal patch compartment by postnatal day 0. In rostral striatum, patches were located more ventrolaterally early and dorsomedial patches appeared later. Expression of these proteins in matrix occurred in a similar ventrolateral to dorsomedial sequence. In substantia nigra, D<sub>1A</sub> was localized to puncta in pars reticulata, while D<sub>2A</sub> and DAT were localized to neurons in pars compacta, similar to respective adult distribution patterns. These data indicate that dopaminergic connections in patch compartment mature more quickly than those of matrix. Moreover, since proteins responsible for dopaminergic signal transduction and termination are present early in development, dopamine neurotransmission is probably functional in perinatal basal ganglia. Supported by the APDA and the Stanley Foundation.

## 636.5

**IN VIVO RECEPTOR BINDING BY A UNIQUE PET D-2 RADIOLIGAND: N-METHYL-[F-18]BENPERIDOL.** S.M. Moerlein\*, J.S. Perlmutter and M.J. Welch. Mallinckrodt Institute of Radiology, Washington University School of Medicine, St. Louis, MO 63110.

Previous PET studies have shown that N-methyl-[F-18]benperidol ([F-18]NMB) is a high-affinity D-2 ligand that binds specifically to D-2 receptors *in vivo* (JCBFM 13: S235 [1993]). In this work we have further evaluated the D-2 receptor binding characteristics of this PET radioligand. In particular, the reversibility of binding, inertness to elevated dopamine levels, and internalization of the radioligand were studied in primates with use of PET. [F-18]NMB selectively localizes in control studies within D-2 receptor-rich tissues, resulting in striatum/cerebellum radioactivity concentration ratios as high as 15 after 3 h. Unlabeled D-2 antagonist eticlopride (4 mg/kg, i.v.) given 45 min after [F-18]NMB caused a rapid decrease in striatal activity to cerebellar levels, indicating that D-2 receptor binding was reversible. *In vivo* localization of [F-18]NMB in the striatum was unaffected by dextroamphetamine (1 mg/kg, i.v.) or levodopa/carbidopa (20 and 10 mg/kg, p.o.), showing that receptor binding by the radioligand was resistant to competitive displacement by synaptic dopamine. [F-18]NMB does not undergo agonist-mediated internalization, as demonstrated by studies involving sequential i.v. administration of [F-18]NMB, dextroamphetamine (1 mg/kg 30 min after [F-18]NMB), and eticlopride (4 mg/kg 68 min after [F-18]NMB). In this experiment, dextroamphetamine had no effect on striatal binding, yet subsequent administration of eticlopride completely displaced [F-18]NMB from D-2 receptors. The special combination of reversible D-2 binding by [F-18]NMB that is fully displaceable by D-2 antagonists yet resistant to physiologically-meaningful levels of dopamine makes this radioligand unique among all other PET radiopharmaceuticals.

## 636.7

**DOPAMINE, NOREPINEPHRINE, AND SEROTONIN AXONS IN THE HUMAN AND MONKEY NUCLEUS BASALIS, AND IN ALZHEIMER'S DISEASE.** J.F. Smiley\* and M.-M. Mesulam. Northwestern University, Chicago, IL.

Physiology studies in the rat have shown that monoaminergic modulation of the nucleus basalis can affect cortical acetylcholine release. While anatomical studies in the rat have shown monoamine input to the nucleus basalis, similar evidence is lacking in primates. We used single- and double-labeling immunocytochemistry to visualize monoamine axons and their proximity to cholinergic Ch4 cells in the nucleus basalis. Norepinephrine axons, labeled with anti-dopamine- $\beta$ -hydroxylase (DBH), formed a bed of fine varicose axons that co-distributed with Ch4 neurons. Double labeling showed frequent contacts with the soma and dendrites of cholinergic cells. Tyrosine hydroxylase (TH)-immunoreactive axons, presumed to be mainly dopaminergic, were 10 to 20 times more abundant than DBH axons. While many TH axons were thick and non-varicose, there were also small varicose axons, which appeared in double labeled sections to make contacts with Ch4 neurons. Reliable serotonin-immunoreactivity was obtained only in the monkey. Fine serotonin-immunoreactive axons were abundant throughout the basal forebrain, and double labeling showed many axons in contact with Ch4 neurons. In summary, all three monoamine systems appear to innervate the cholinergic (and probably also non-cholinergic) neurons of the nucleus basalis. Preliminary measurements of DBH and TH axon density in Alzheimer's and non-Alzheimer nucleus basalis suggest that the density of these monoamine axons in diseased brains is within the range of density seen in controls. Supported by NS20285-11.

**DISTRIBUTION OF DOPAMINE D<sub>2</sub>-FAMILY RECEPTORS IN HUMAN POSTMORTEM BRAIN SECTIONS: COMPARISON OF RECEPTOR DENSITIES BETWEEN NORMALS AND SCHIZOPHRENICS OFF AND ON NEUROLEPTICS.** R.A. Lahti\*, R.C. Roberts, R. Conley and C.A. Tamminga. Maryland Psychiatric Research Center, Univ. of Maryland School of Medicine, Baltimore, MD 21228.

The D<sub>2</sub>, D<sub>3</sub> and D<sub>4</sub> receptors comprise the D<sub>2</sub>-family of receptors (Bunzow, 1988; Sokoloff, 1990; Van Tol 1991). Most neuroleptics are D<sub>2</sub> selective yet have high affinity for the D<sub>4</sub> receptor; clozapine is selective for the D<sub>4</sub> receptor. Studies have found increases in the D<sub>4</sub> density in striata of schizophrenic vs normal postmortem tissue (Seeman, 1992; Sumiyoshi, 1994; Murray, 1995). We have determined receptor distributions autoradiographically in sections from normal human postmortem tissue (Maryland Brain Collection). The ligands were [<sup>3</sup>H]-raclopride for D<sub>2</sub>/D<sub>3</sub>; [<sup>3</sup>H]-YM-09151-2 for D<sub>2</sub>/D<sub>3</sub>/D<sub>4</sub>; and [<sup>3</sup>H]-(+)-7-OH-DPAT for the D<sub>3</sub>. The difference between [<sup>3</sup>H]-raclopride and [<sup>3</sup>H]-(+)-7-OH-DPAT is taken as D<sub>2</sub> distribution, between [<sup>3</sup>H]-YM-09151-2 and [<sup>3</sup>H]-raclopride as the D<sub>4</sub> distribution. D<sub>2</sub> receptors are most dense in putamen, caudate and nuc. accumbens; D<sub>3</sub> in nuc. accumbens; D<sub>4</sub> in cortical areas, hippocampus, with little evident in the caudate-putamen. These receptor distribution patterns are similar to those found for their mRNAs (Meador-Woodruff, 1994, 1995; Landwehrmeyer, 1993). Numerous brain structures were analyzed for receptor densities in normal controls (n=9), and schizophrenic subjects off (n=5) and on (n=3) drug at the time of death. No statistically significant differences were found between normals and either group of schizophrenics using [<sup>3</sup>H]-YM-09151-2, [<sup>3</sup>H]-raclopride or the difference between the two ligands, the "presumed D<sub>4</sub>" receptor. Thus no evidence was found for an increase in any D<sub>2</sub>-family receptor in schizophrenics off neuroleptics, including the D<sub>4</sub> receptor, as reported by others.

## 636.6

**WHOLE-BODY BIODISTRIBUTION OF THE PET D2 RADIOLIGAND N-METHYL-[F-18]BENPERIDOL IN PRIMATES.** I. Giovanni, J.S. Perlmutter\*, S.M. Moerlein, P.D. Cutler, M.M. Anderson and M.J. Welch. Mallinckrodt Institute of Radiology, Washington University School of Medicine, St. Louis, MO 63110.

PET imaging studies of nonhuman primates have shown that N-methyl-[F-18]benperidol ([F-18]NMB) is a unique radioligand for noninvasive investigation of cerebral D2 receptors. Preceding application of this tracer in humans, we have estimated its absorbed radiation dosimetry via PET imaging of baboons injected with [F-18]NMB. Four scanning positions corresponding to different regions of the animals' bodies were imaged sequentially. Position 1 included the brain and eyes, position 2 the heart and lungs, position 3 the liver, gall bladder, upper intestines and kidneys, and position 4 the bladder, lower intestines and gonads. Accumulation of radioactivity accumulation in tissues other than these organs was uniform and minimal. Tissue attenuation was measured for each position via a transmission scan using rotating rod sources of [Ge-68]/[Ga-68]. After injection of [F-18]NMB, 5-min long scans were acquired for each position sequentially over a 4 h interval; for each position, 4-5 scans were obtained. For smaller organs, regions of interest (ROI) were defined that completely encompassed the target organ. For larger organs, multiple large representative ROIs were identified that included all local peaks of radioactivity. The average activity concentration then was calculated for the target organ and multiplied by the organ weights to give the radioactivity accumulation per organ as a function of time. The residence time of radioactivity in each organ and S-values were used to derive absorbed dose per unit cumulated activity. For reference man, the critical organ was the gall bladder (0.6-1.1 rad/mCi), with relatively high dose delivered to the heart wall (0.3 rad/mCi) as well. Gonadal dose was minimal (0.05 rad/mCi). The results suggest that ca. 5 mCi of [F-18]NMB can be safely administered to human subjects for PET study of cerebral D2 receptor binding *in vivo*.

## 636.8

**LOCALIZATION OF MULTIPLE DOPAMINE D1 RECEPTOR SUBTYPES IN AVIAN BRAIN USING IN SITU HYBRIDIZATION AND RECEPTOR AUTORADIOGRAPHY.** L.L. Demchyshyn\*, L.M. Dixon, J.N. Nobrega and H.B. Niznik. Depts. of Psychiatry & Pharmacology, Univ. of Toronto and Lab. Mol. Neurobiology, Clarke Institute of Psychiatry, Toronto, Canada, M5T 1R8.

To date, the avian dopamine D1 receptor subfamily is encoded by three distinct genes termed D1A, D1B, and D1D, which are distinguished on the basis of their pharmacological and structural profiles. Northern blot analysis has demonstrated the expression of all three receptors in brain. We assess here the distribution of these receptors by *in situ* hybridization of messenger RNA's encoding D1A, D1B and D1D receptors and by *in vitro* receptor autoradiography in chicken brain. At 1-2nM, [<sup>3</sup>H]SCH23390 bound receptors primarily in 'striatal' regions, specifically the paleostriatum complex, as well as nucleus accumbens and olfactory tubercle. Non-specific binding was determined in the presence of 2 $\mu$ M (+)-butaclamol. The D1A receptor mRNA visualized by non-overlapping [<sup>35</sup>S]-dATP labelled oligonucleotide probes from unconserved 3' regions were strongly expressed within striatal regions. Preliminary observations indicate that the D1B and D1D receptors were also expressed to a lesser extent within these regions. Control slices were either RNase pre-treated or incubated in the presence of excess unlabelled oligonucleotides. The distribution of dopamine D1-like receptor mRNA's corresponded to receptor binding. Localization of D1 receptor subtypes in the paleostriatum coincide well with observations reported on the effects of dopaminergic agonists and antagonists on stereotypical and motor behaviour in birds. The analysis of these receptor subtypes may help to better understand the anatomical organization and how they further relate to the pharmacological and biochemical multiplicity of D1-mediated events.

## 636.9

INTERNALIZATION OF SIGMA( $\sigma$ )-1 RECEPTORS INTO THE PRIMARY CULTURED NEURONAL CELLS. H. Yamamoto<sup>1</sup>, T. Yamamoto<sup>1,2</sup>, A. Baba<sup>1</sup>, E. Takamori<sup>1</sup>, Y. L. Murashima<sup>3\*</sup> and S. Okuyama<sup>4</sup>. <sup>1</sup>Dept. of Psychopharmacol., <sup>2</sup>Dept. of Neurophysiol., Tokyo Inst. Psychiatry, Tokyo 156, <sup>3</sup>Mol. Recog., Yokohama City Univ., Yokohama 236, <sup>4</sup>Taisho Pharmaceutical Co., Ltd., Saitama 330, Japan.

Bindings to the primary cultured neuronal cells were performed using [<sup>3</sup>H]NE-100 or [<sup>3</sup>H](+)-pentazocine as selective  $\sigma$ -1 ligands. To assess the properties of  $\sigma$ -1 receptor, first, living cells in DMEM were incubated with [<sup>3</sup>H]NE-100, [<sup>3</sup>H](+)-pentazocine or [<sup>3</sup>H]TCP for 60 min at 4° and then 37°. Bounds of [<sup>3</sup>H]NE-100 or [<sup>3</sup>H](+)-pentazocine at equilibrium were markedly higher at 37° than 4° and not dissociated by the addition of excess  $\sigma$  ligand. By contrast, bound of [<sup>3</sup>H]TCP at 37° was not potently increased. When cells incubated at 37° were washed with acidic high sodium solution (pH 2.5) to wash out surface-bound radioactivity, a significant radioactivity was remained as a non-washable fraction. Second, incubating of cells with [<sup>3</sup>H]NE-100 at 37°, but, in the presence of an endocytosis inhibitor, the binding was similar to that seen at 4°. Third, when cells were subjected to  $\sigma$  ligands at 37° for 30 min prior to binding, the non-washable bound was decreased in proportion to its affinity for  $\sigma$ -1 receptor. Although the results described here do not completely elucidate the question that the internalization process of  $\sigma$ -1 ligand is due to ligand alone or ligand-receptor complex, the result which pre-exposure of cells to  $\sigma$  ligands induced reduced bound suggests that a time- and temperature-dependent increase of the selective  $\sigma$ -1 ligand binding to living cells is a consequence of receptor internalization.

## 636.11

Immunohistochemical localization of  $\alpha_2$ -adrenergic receptors in rat forebrain: light (LM) and electron microscopy (EM). D.L. Rosin<sup>1</sup>, E.M. Talley<sup>1</sup>, T.A. Milner<sup>2</sup>, P.G. Guyenet<sup>1</sup> & K.R. Lynch<sup>1</sup>. Dept. of Pharmacol., Univ. of Virginia, Charlottesville, VA 22928<sup>1</sup> and Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., NY, NY 10021<sup>2</sup>

We have described previously the immunohistochemical localization of  $\alpha_2$ -adrenergic receptors ( $\alpha_2$ -ARs) in rat brainstem using a subtype-specific polyclonal antibody (Rosin et al., 1993; Guyenet et al., 1994) and now report the distribution of  $\alpha_2$ -ARs in di- and telencephalic nuclei. Light microscopic examination revealed discrete intracellular (dotted in appearance) and diffuse perikaryal  $\alpha_2$ -immunoreactivity ( $\alpha_2$ -LI) as well as neuropil labeling. Intense labeling was observed in the anterior olfactory nucleus, lateral septum, diagonal band, bed nucleus of the stria terminalis, fundus striatum and substriatal area, and various nuclei of the amygdala and hypothalamus. Labeling in the cortex and hippocampal formation displayed a clearly laminar distribution. Particularly striking was the intense neuropil labeling in the lacunosum molecular layer of CA1. The distribution of  $\alpha_2$ -LI in rat brain resembles closely the pattern of [<sup>3</sup>H]-aminoclonidine binding autoradiography reported by others. The dotted perikaryal  $\alpha_2$ -LI in the medial septum and in the CA1 region of hippocampus appeared by EM to correspond to peroxidase product associated with the Golgi apparatus and rough endoplasmic reticulum. In CA1 pyramidal cells,  $\alpha_2$ -LI was also found in large (0.5-1.0  $\mu$ m in diameter) intracellular structures close to the nucleus that may be endosomal in nature but are clearly not lysosomal. Dendrites exhibited immunoreactivity associated with plasmalemmal surfaces both in terminals and at postsynaptic densities. Immunoreactivity (either by LM or EM) was eliminated by preadsorption of the antibody with excess antigen. In summary,  $\alpha_2$ -LI shows a wide pattern of distribution in rat forebrain consistent with other measures of receptor localization. Further ultrastructural analyses will help to define the cellular substrates of  $\alpha_2$ -AR function. Supported by DA07216, DA08259, MH42834 and the Virginia Amer. Heart Assoc.

## 636.13

DISTRIBUTION OF THE VESICULAR TRANSPORTER FOR ACETYLCHOLINE IN THE RAT CNS. R.H. Edwards<sup>1</sup>, A. Shirzadi<sup>1</sup>, L.L. Butcher<sup>1</sup> and A. Roghani<sup>2</sup>. Depts of Neurology and Psychology, UCLA, Los Angeles, CA 90024. Abundant evidence has implicated acetylcholine (ACh) in the pathogenesis of neurodegenerative disorders. ACh and other transmitters are stored into synaptic vesicles from which their release can be regulated in response to neural activity. This storage requires active transport from the cytoplasm. We recently found that vesicular monoamine transporters can protect against the neurotoxin MPP<sup>+</sup> and we used this phenomenon to clone two rat transporters (Cell 70, 539). Genetic studies in the nematode *C. elegans* recently identified a putative vesicular ACh transporter (*Unc-17*). This protein shows sequence homology to the vesicular amine transporters and its distribution supports a role in cholinergic transmission. Using RT-PCR, we have recently isolated homologous transporters, first from *Torpedo californica*, and then from rat spinal cord (rVACHT) (PNAS 91, 10620). We also have demonstrated expression of high affinity vesamicol binding with this clone. In situ hybridization using labeled rVACHT RNA showed expression in all of known cholinergic nuclei in the central nervous system, including the basal forebrain, dorsal and ventral striata, mesopontine complex, motor and autonomic cranial nerve nuclei, and ventral and intermediolateral horns of the spinal cord. Hybridization with probes for choline acetyltransferase (ChAT) showed an identical pattern. We have also raised high titer antipeptide antibodies against the cloned transporter in rabbits. All the antisera recognize the VACHT protein on western blots of membrane preparations from VACHT-transfected cells. One of the antibodies stains apparent cholinergic neuronal cell bodies in all of known cholinergic nuclei identical to those we observed in our in situ hybridization studies. We also detect staining of cholinergic fibers and terminals in the cortex, basolateral amygdala, hippocampus, medial habenula, laterodorsal tegmental nuclei, thalamus, basal forebrain, superior colliculus, interpeduncular nucleus and dorsal and ventral striatum. The VACHT-positive cells often extend processes radiating in multiple directions with occasional branching, where many of these fibers are fine caliber and possess numerous puncta. Thus, the pattern of staining with antibodies to rVACHT strongly resembles that reported for the ChAT distribution in the rat CNS.

## 636.10

THE EFFECTS OF AGING ON SPINAL NEUROCHEMISTRY IN THE RAT. M.L. Ko, J.L. Stafinsky and T. Crisp\*. Departments of Pharmacology and Neurobiology, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272.

The purpose of this study is to assess the effects of aging on basal levels of norepinephrine (NE), dopamine (DA), serotonin (5-HT) and their respective metabolites in the spinal cord using high performance liquid chromatography (HPLC) and electrochemical detection. Young, mature and aged (5-6, 15-16 and 25-27 months old respectively) male Fischer 344 rats were used in all experiments. Dorsal and ventral halves of each vertebral section (cervical, thoracic, lumbar and sacral) were analyzed. In general, the results indicate that aged rats have less neurotransmitter/ug tissue than their younger cohorts with the main differences being in the levels of NE and 5-HT. An age-related increase in monoamine oxidase (MAO) activity may account for the observed decreases in biogenic amine levels with advanced age. Moreover, since NE and 5-HT are believed to play a role in the inhibition of primary nociceptive neurons in the spinal cord, a decrease in these neurotransmitters may diminish pain tolerance in aged animals.

## 636.12

DIFFERENTIAL DISTRIBUTION OF  $\alpha_2$ -ADRENOCEPTORS AND NORADRENERGIC NEURONS IN THE HUMAN LOCUS COERULEUS.

V. Klimek\*, G.W. Cason, S.N. Luker, C.A. Stockmeier, G. Dilley, H.Y. Meltzer, J. Overholser, G.A. Ordway. Dept. Psychiatry & Human Behavior, University of Mississippi Med. Ctr., Jackson, MS 39216; Depts. Psychiatry & Psychology, Case Western Reserve University, Cleveland, OH 44106.

Morphometric changes in the human locus coeruleus (LC) have been described for normal aging, neurodegenerative diseases, and most recently, in major depression and in victims of suicide. Independently, changes in concentrations of  $\alpha_2$ -adrenoceptors ( $\alpha_2$ AR, noradrenergic autoreceptors) in the LC have been reported for normal aging and in victims of suicide. The relationship between neurochemical and cellular alterations in the LC has not been addressed. In this study, the quantitative autoradiography of p-[<sup>125</sup>I]iodoclonidine ([<sup>125</sup>I]PIC) binding to  $\alpha_2$ AR was assessed coordinately with a morphometric analysis of neuromelanin-containing cells (noradrenergic neurons) in tissue sections cut at 10-14 levels along the rostral-caudal axis of the LC in normal subjects (n = 7; ages 44-78). Both [<sup>125</sup>I]PIC binding and the number of LC neurons were differentially distributed (p < 0.01) along the LC axis with almost identical topographic patterns. The highest concentrations of binding and the greatest number of noradrenergic cells per section occurred near the middle portion of the nucleus. There was a significant correlation between the number of noradrenergic cells per section vs. specific [<sup>125</sup>I]PIC binding at any particular level of the LC (r<sup>2</sup> = 0.59, p < 0.0001). These data suggest that noradrenergic cell number determines the density of [<sup>125</sup>I]-PIC binding to  $\alpha_2$ AR throughout the LC. Studies using the same measurements in suicide victims with retrospective diagnoses of major depression will also be presented. (Supported by MH46692 and MH45488).

## 636.14

DISTRIBUTION OF MONOAMINES IN THE CORPUS CALLOSUM OF THE CAT. B. Jardon<sup>1</sup>, F. Lepore<sup>1</sup>, T.A. Reader<sup>2</sup>, A.R. Asse<sup>2</sup>, and C.E.P. Casanova<sup>1\*</sup>. *CRSN, Département de Psychologie et Physiologie<sup>1</sup>, Université de Montréal, et Département d'Ophtalmologie<sup>2</sup>, Université de Sherbrooke, (Québec) Canada.*

The aim of this work was to determine the presence of chemically-identified neurotransmitters in the corpus callosum (CC) of the cat. Brains from adult cats were rapidly frozen, sliced in coronal 3-4 mm thick sections, and the CC dissected over a cold plate under a binocular microscope. Three different portions of the CC were removed along a rostro-caudal axis, namely the anterior or genu (CCA), the middle or body (CCM) and the posterior or splenium (CCP). Samples from the visual cortex (VIS), or areas 17-18, as well as of the suprasylvian gyrus (SS) were also removed for comparison purposes. After extraction in 0.1 N monochloroacetic acid (pH 3.3) the samples were centrifuged (40,000 x g for 45 min at 4°C), and the supernatants assayed by HPLC with electrochemical detection (650 mV). The pellets were dissolved overnight in 1 N NaOH for protein assay. The catecholamines noradrenaline (NA), adrenaline (AD) and dopamine (DA) were present in all divisions of the CC; the greatest amounts were found in the CCA. There were also trace amounts of the NA metabolite 4-hydroxy-3-methoxyphenylglycol (MHGP), and of the DA metabolites 3,4-dihydroxyphenylglycol (DOPAC) and homovanillic acid (HVA). The indoleamine serotonin (5-HT) was measured in all the divisions of the CC, and was especially abundant in the CCP. Its main metabolite 5-hydroxyindole-3-acetic acid (5-HIAA) followed the same pattern of distribution. To confirm the identification of the monoamines, cats were treated with p-chlorophenylalanine (PCPA) or with  $\alpha$ -methyl-p-tyrosine ( $\alpha$ MPT) to block 5-HT or catecholamine synthesis, respectively. After PCPA, the indoleamine peaks (5-HT and 5-HIAA) were greatly reduced, while the DA and NA peaks decreased after  $\alpha$ MPT. The results demonstrate the presence of monoamines in the cat CC. The data will be compared to anatomical studies of the CC using tracing methods, and to measurements obtained from animals that were callosotomized 6 months earlier. [Supported by the MRC(C) and NSERC(C)]

## 636.15

DISTRIBUTION OF THE  $\alpha_{1A}$  ADRENOCEPTOR IN RAT CNS - COMPARISON OF *IN SITU* HYBRIDIZATION AND RECEPTOR AUTORADIOGRAPHY STUDIES. M.M. Durkin\*, E.L. Gustafson, C. Forray, K.E. Smith, J.M. Wetzel, C. Gluchowski, T.A. Branchek. Synaptic Pharmaceutical Corporation, Paramus, NJ 07652.

In the present study we have employed two localization techniques to compare the anatomical distribution of the  $\alpha_{1A}$  adrenoceptor (formerly  $\alpha_{1C}$ ) mRNA and binding sites in rat brain. *In situ* hybridization was performed to localize those cells which express the  $\alpha_{1A}$  receptor RNA utilizing two sets of antisense/sense [<sup>35</sup>S]dATP labeled oligoprobes designed to the coding region of the  $\alpha_{1A}$  gene. *In vitro* receptor autoradiography using 1 nM [<sup>3</sup>H]prazosin in the presence of 10  $\mu$ M norepinephrine and 100 nM SNAP 5272, to selectively block the  $\alpha_{1B}$  (formerly  $\alpha_{1A}$ ) and  $\alpha_{1A}$  adrenoceptors, respectively, enabled us to evaluate the displacement of the ligand from its binding sites thereby indicating the presence of the  $\alpha_{1A}$  receptor in the CNS. Nonspecific binding was determined using 10  $\mu$ M phentolamine. The areas of highest gene expression were observed in the hippocampus and motor trigeminal nucleus, however, receptor binding in these areas was very low. Moderate levels of mRNA expression and binding sites were detected in the olfactory bulb, bed nucleus of the stria terminalis, hypothalamus, medial amygdala and horizontal diagonal band. Lower expression of message and number of binding sites were observed in all the layers of the cerebral cortex, caudate-putamen, nucleus solitarius, thalamus, central gray and in the brainstem. There is a high degree of correlation between the localization of the mRNA and the presence of binding sites for the  $\alpha_{1A}$  adrenoceptor. The presence of  $\alpha_{1A}$  receptor message, as well as the localization of binding sites to the same regions might imply a postsynaptic somatodendritic location for the receptor in these areas. These regions are all areas of known adrenergic innervation. However, a presynaptic localization cannot be excluded as suggested by the localization of mRNA in the hippocampus.

## 636.17

THE EXPRESSION OF KAPPA OPIOID RECEPTOR MESSENGER RNA IN THE HIPPOCAMPUS AND THE ENTORHINAL CORTEX OF ALZHEIMER'S DISEASE PATIENT. M. Yamada\*, N. Nakachi, K. Groshan, Mi. Yamada and E. Richelson. Mayo Foundation and Mayo Clinic Jacksonville, Jacksonville, FL 32224

We recently cloned the kappa opioid receptor from a human brain cDNA library. A northern blot analysis showed the presence of a single transcript of about 6 kB in size for mRNA prepared from several human brain regions, which hybridized to the human kappa opioid receptor cDNA. These regions included the amygdala, caudate nucleus, corpus callosum, hippocampus, hypothalamus, substantia nigra, subthalamic nucleus, and thalamus. Using *in situ* hybridization histochemistry techniques, with a <sup>33</sup>P-labeled antisense RNA probe complementary to this receptor cDNA, we studied the expression of this receptor in the hippocampus and the entorhinal cortex of post-mortem human brain from control and from Alzheimer's disease subjects. Kappa opioid receptor mRNA was present in high levels in the stratum granulosum of the dentate gyrus, the stratum pyramidale of region CA1-CA4, the subiculum and the entorhinal cortex. On the other hand, Alzheimer's disease brain had lower levels of mRNA for the kappa opioid receptor in these regions. It is proposed that the kappa opioid receptor expressed in the hippocampus and the entorhinal cortex may play an important role in the normal function of the limbic system and possibly in the pathophysiology of Alzheimer's disease. (Supported by USPHS Grant MH27692 and Mayo Foundation).

## 636.16

LOCALIZATION OF VASOPRESSIN RECEPTORS, BUT NOT OF OF OXYTOCIN RECEPTORS, IN PUTENDAL MOTOR NUCLEI IN BOTH MALE AND FEMALE RATS. E. Tribollet<sup>1</sup>, G. Kato\* and Y. Arsenijevic<sup>1</sup>. <sup>1</sup>Dept. of Physiol., Univ. Med. Center, 1211 Geneva 4 and Neurotech., 1228 Plan-les-Ouates, Switzerland.

Central administration of oxytocin (OT) facilitates lordosis in female rat and penile erection in male rat. This suggests that endogenous OT present in the spinal cord may participate to the regulation of sexual behavior in the rat, possibly by acting on motor nuclei innervating pelvic muscles. In the present work, we have labelled OT and vasopressin (AVP) receptors throughout the spinal cord of adult male and female rats by using selective radiolabelled antagonists and *in vitro* autoradiography. In both sexes, AVP binding sites were detected in the segment L6, localized in the four pelvic motor nuclei, i.e. the dorso-medial, ventral, dorso-lateral and retrodorsolateral groups of motoneurons. The density of binding was high in the ventral, dorso-lateral and retrodorsolateral groups in both males and females, while in the sexually dimorphic dorso-medial group, binding was dense in males, but just detectable in females. In addition to L6 motor nuclei, AVP receptor binding sites were only found in the most lateral motor nucleus in segment C8; motor nuclei in other spinal segments were not labelled with the radiolabelled AVP antagonist. With the radiolabelled OT antagonist, low amounts of binding was found in laminae I and II at all spinal levels, as previously described; specific binding was never detected in motor nuclei, neither in L6, nor in other segments. These observations indicate that AVP rather than OT may be involved in the control of motor sexual behavior in the rat, at least at the spinal cord level.

## 636.18

DEVELOPMENTAL PROFILE OF THE NEUROPEPTIDE Y Y<sub>1</sub> RECEPTOR SUBTYPE IN THE RAT BRAIN: A COMBINED *IN SITU* HYBRIDIZATION AND RECEPTOR AUTORADIOGRAPHIC STUDY. Y. Tong<sup>1,2\*</sup>, Y. Dumont<sup>1</sup>, J.G. Chabot<sup>1</sup>, S.H. Shen<sup>2</sup> and R. Quirion<sup>1</sup>. <sup>1</sup>Douglas Hospital Research Center, Dept. Psychiatry, McGill University, 6875 LaSalle Blvd. Montréal, Québec, Canada. H4H 1R3. <sup>2</sup>Biotechnology Research Institute NRCC, 6100 Royalmount Ave., Montréal, Québec, Canada H4P 2R2

The developmental profile of the neuropeptide Y (NPY) Y<sub>1</sub> receptor in the rat brain was assessed by *in situ* hybridization (ISH) and receptor autoradiography using a rat <sup>35</sup>S-cRNA probe (Eva et al., FEBS Lett. 271: 81-84, 1990) and a selective Y<sub>1</sub> radioligand ([<sup>125</sup>I]Leu<sup>31</sup>,Pro<sup>34</sup>)PYY: Dumont et al., J. Pharmacol. Expt. Ther. 272: 673-680, 1995). As early as by gestational day 12 (E12), low amounts of specific Y<sub>1</sub> receptor mRNA are detectable in few neuronal cells while Y<sub>1</sub>/[<sup>125</sup>I]Leu<sup>31</sup>,Pro<sup>34</sup>)PYY binding sites failed to be detected at this early developmental stage. Specific Y<sub>1</sub> mRNA ISH signals increased rapidly during the last week of gestation. At E15, a strong ISH signal is observed in the spinal cord and the striatum. By E18, the Y<sub>1</sub> receptor mRNA is widely distributed in the fetal brain including in the olfactory tubercle, neocortex, nucleus accumbens, thalamus, brainstem and spinal cord. Specific Y<sub>1</sub> mRNA ISH signals remained elevated early neonatally and up to post-natal day 12 to decline thereafter to reach adult levels by post-natal day 30. Overall, specific Y<sub>1</sub>/[<sup>125</sup>I]Leu<sup>31</sup>,Pro<sup>34</sup>)PYY binding sites are distributed in a manner similar to that of the Y<sub>1</sub> receptor mRNA except that significant labelling was generally seen few days (2-3) after the detection of the specific mRNA suggesting the occurrence of a lag phase to allow for the accumulation of the translated receptor protein. Moreover, the very early embryonic expression of the NPY Y<sub>1</sub> receptor mRNA and its translated protein suggest that the Y<sub>1</sub> receptor subtype likely plays a regulatory role in normal brain development. ## BEHAVIORAL PHARMACOLOGY II

## 637.1

THE SEPTOHIPPOCAMPAL SYSTEM IS INVOLVED IN PREPULSE INHIBITION OF THE ACOUSTIC STARTLE RESPONSE IN RATS. M. Koch (SPON: European Neuroscience Association). Tierphysiologie, Universität Tübingen, Auf der Morgenstelle 28, D-72076 Tübingen, Germany.

The magnitude of the acoustic startle response (ASR) is reduced if a weak prepulse is presented 30 - 500 ms prior to the startle stimulus. This phenomenon is termed prepulse inhibition (PPI), and can be used as an operational measure for brain mechanisms that protect early stimulus processing routines from disruption by other stimuli. Deficient PPI has been observed in schizophrenic patients, a fact that has kindled much interest in understanding the neural basis of PPI. The present study investigated the role of the septohippocampal system in PPI. Lesions of the medial septal nucleus, made by local infusion of the glutamate receptor agonist AMPA (0.3  $\mu$ l of a 0.015 M solution), did not affect PPI. Chemical stimulation of the medial septal nucleus by micro-injections of the glutamate receptor agonist kainate (0.8 - 1.2 nmol) led to a profound disturbance of PPI and also reduced the ASR amplitude in the absence of prepulses. The PPI deficit induced by intraseptal kainate was attenuated by systemic or intrahippocampal administration of the acetylcholine antagonist scopolamine. The present data suggest that stimulation of the septohippocampal system reduces PPI of the ASR, and that this deficit of response suppression is based upon activation of cholinergic receptors in the hippocampus.

## 637.2

LOCOMOTION INDUCED BY SCOPOLAMINE: ROLE OF LATERODORSAL TEGMENTAL NUCLEUS (Ch6) CELLS. S. LaViolette and J.S. Yeomans\*. Dept. of Psychology, Univ. of Toronto, Toronto, Canada M5S 1A1.

Cholinergic cells of the pedunculopontine (Ch5) and laterodorsal (Ch6) tegmental nuclei monosynaptically activate dopamine cells of the ventral tegmental area and substantia nigra. Microinjections of the antimuscarinic scopolamine (10-200  $\mu$ g) in either cell group induces locomotion that resembles the locomotion induced by i.p. scopolamine (1-10 mg/kg). Either scopolamine-induced or spontaneous locomotion is blocked by carbachol (1-4  $\mu$ g) in the dorsal tegmentum. In this study, ibotenate lesions of Ch6 cells attenuated locomotion induced by scopolamine (3 mg/kg) 7 days after the lesion as compared with pre-lesion scopolamine, without altering locomotion induced by the saline control. The difference between saline and scopolamine conditions was reduced by 70%. These lesions had no effect on scopolamine-induced stereotypy, however. When tested 28 days after the lesions, however, scopolamine-induced locomotion completely recovered. This recovery is consistent with the recovery of ChAT-labelled terminals in the ventral tegmental area and substantia nigra after ibotenate lesions of the Ch5 cell group. Therefore, Ch6 cholinergic cells appear to be important for scopolamine-induced locomotion, but other systems contribute and can take over following ibotenate lesions.

GLUTAMATERGIC-CHOLINERGIC INTERACTION ON MEMORY CONSOLIDATION IN MICE. C. Castellano<sup>1</sup>, A. Mele<sup>1</sup>, V. Cestari<sup>1</sup> and A. Oliverio<sup>2</sup>. <sup>1</sup>Università degli Studi di Roma "La Sapienza", Dipartimento di Genetica e Biologia Molecolare, P.le A. Moro, 5 - 00185 Roma, Italy. <sup>2</sup>Istituto di Psicobiologia e Psicofarmacologia del C.N.R., Via Reno, 1 - 00198 Roma, Italy.

Post-training administration of the muscarinic agonist oxotremorine (0.02, 0.04, 0.06 mg/kg) dose-dependently improves retention of an inhibitory avoidance response in NMRI mice. In contrast, post-training administration of the muscarinic antagonist atropine (2, 3, 4 mg/kg) dose-dependently impairs retention in the same test. Moreover, the N-methyl-D-aspartate (NMDA) non-competitive antagonist MK-801 (0.1, 0.25, 0.5 mg/kg) dose-dependently impairs the performance in the retention test. In addition, oxotremorine (at per se ineffective dose of 0.02 mg/kg) antagonizes the impairing effects of MK 801 (0.25, 0.5 mg/kg) in the retention test, while atropine (at per se ineffective dose of 2 mg/kg) enhances the effects of two doses (0.1, 0.25 mg/kg) of MK 801.

The present results confirm previous data showing that cholinergic enhancing drugs improve learning and memory in a number of tasks, while memory impairments can be induced by drugs blocking cholinergic neurotransmission. Moreover, our results confirm previous ones showing the impairing effects of MK 801 in the same experimental conditions. Lastly, our results show a clear interaction between the cholinergic and glutamatergic systems in the modulation of memory consolidation, as it can be seen by the effects of the pretreatment with oxotremorine (antagonism) or atropine (enhancement) on the impairing effects of the treatment with MK 801.

GAMMA-HYDROXY-BUTYRATE PREVENTS THE STRESS-INDUCED ESCAPE DEFICIT IN RATS

Gambiarra C.<sup>1</sup>, Ghisleni O., De Montis M.G., Tagliamonte A.  
<sup>1</sup>Institute of Pharmacology, University of Siena, Italy

Gamma-hydroxy-butyrate ( $\gamma$ -OH-B) is a general anaesthetic used as a substitute of ethanol in the treatment of alcoholics. Given acutely to rats at doses of 50-100 mg/kg i.p.,  $\gamma$ -OH-B increases the firing of dopaminergic neurons in the VTA, while decreasing it at anaesthetic doses (750 mg/kg). At high doses it also induces dopamine accumulation in the caudate-putamen and the limbic areas. Moreover, in animals made dependent on ethanol  $\gamma$ -OH-B completely substitutes for it. Its possible antidepressant effect was tested on a model of escape deficit, induced by exposing restrained rats to 80 electric shocks (1mA x 5 s, every 30 s) delivered through an electrode placed on the distal third of the tail (pre-test). Twenty-four hr after the pre-test, control animals, if exposed to escapable shocks, show an average of  $2 \pm 1$  escapes out of 30 trials (escape deficit: ED); whereas, rats never exposed to previous shocks (naïve) have  $27 \pm 2$  successes.  $\gamma$ -OH-B injected acutely (50-100 mg/kg) 30 min before the pre-test did not prevent ED development. However, administered daily (75 mg/kg i.p. twice a day) during the 12 days preceding the pre-test, it completely prevented the occurrence of ED ( $20 \pm 2$  escapes). Moreover, the long-term  $\gamma$ -OH-B effect was significantly antagonized by SCH 23390 (0.03 mg/kg s.c.), a selective  $D_1$  dopamine receptor antagonist, given 20 min before the pre-test ( $6 \pm 2$  escapes), while pindolol (5 mg/kg i.p.), a rather specific 5-HT<sub>1A</sub> receptor inhibitor, failed to modify it. It was concluded that  $\gamma$ -OH-B has a potential antidepressant activity, with an efficacy and a mechanism of action similar to those of imipramine.

Previous research has demonstrated that several effects of Neuropeptide Y (NPY) are naloxone reversible. The present study sought to further characterize interactions between NPY and the opioid system. Male Long-Evans hooded rats (n=8) were trained to discriminate 5.6 mg/kg morphine from saline using a standard two-lever, food-reinforced, drug discrimination procedure. Following training, cannulae were implanted in the right lateral ventricle of each animal. Across a range of doses (3, 5, & 10  $\mu$ g), NPY failed to substitute for or antagonize the stimulus effects of the training dose of morphine. In addition, NPY (10  $\mu$ g) failed to significantly alter the morphine dose-effect curve. The antinociceptive efficacy of NPY alone and in combination with morphine was examined using a warm water tail-withdrawal procedure. NPY (10  $\mu$ g) failed to alter tail-withdrawal latencies when examined in 52° and 56° C water, whereas morphine produced a dose-related increase in latencies. This same dose of NPY also failed to alter morphine's antinociceptive efficacy. These results do not support a role for intraventricular administration of NPY in the discriminative stimulus and antinociceptive effects of morphine. (Supported by DA07327 and VA Merit Award).

ROLE OF GABA<sub>A</sub> RECEPTORS IN MEDIAL AMYGDALOID SUPPRESSION OF PREDATORY ATTACK BEHAVIOR FROM THE LATERAL HYPOTHALAMUS IN THE CAT. Y. C. Han<sup>\*</sup>, M. B. Shaikh, K. L. Schubert and A. Siegel. Lab. of Limbic System & Behavior, Dept. of Neurosciences, N.J. Medical School, and Graduate School of Biomedical Sciences, UMDNJ, Newark, N.J. 07103.

The medial amygdala (ME) suppresses quiet biting "predatory" attack behavior (QBA) via a disynaptic pathway involving an initial projection to the medial hypothalamus (MH) from ME and a second limb linking MH and the lateral hypothalamus (LH). This study tested the hypothesis that a GABAergic pathway from MH to LH provided the substrate for ME-induced suppression of QBA. Monopolar and cannula electrodes were implanted into ME and LH, respectively, for stimulation or drug infusion. Microinfusion of the GABA<sub>A</sub> antagonist, bicuculline (.015, .075, .15 nmole/.25 $\mu$ l) into LH significantly reduced ME-induced suppression of QBA ( $p < .01$ ). Microinfusion of the GABA agonist, muscimol (10, 25, 50 pmole/.25 $\mu$ l) into LH resulted in a significant increase in response latencies for QBA in a time- and dose- dependent manner. The results suggest the presence of an inhibitory GABAergic pathway between MH and LH that is activated following stimulation of ME, thus providing the basis for ME-induced suppression of QBA.

AN ANALYSIS OF THREE SEDATIVE HYPNOTIC DRUGS IN RAT BEHAVIORAL MODELS OF SEDATION, SLEEP, ETOH INTERACTION, AND LEARNING AND MEMORY. T. Efferen, M. Grace, L. Rajachandran, A. Johnson, A. Enders, and J. V. Cassella<sup>\*</sup>. Neurogen Corporation, Branford, CT 06405.

The ability to predict side effects as well as efficacy from animal models is an important part of drug discovery. For benzodiazepine-type sedative/hypnotic agents, interaction with ethanol and memory impairments are sometimes noted as side effects. Spontaneous Locomotor Activity, a rat model sensitive to sedative drug effects, was significantly reduced by temazepam (0.25 mg/kg, IV), lorazepam (0.03 mg/kg, IV), and zolpidem (0.25 mg/kg, IV). The latency to assume a sleep posture was significantly reduced by temazepam (2.5 mg/kg, PO), lorazepam (0.94 mg/kg, PO), and zolpidem (24 mg/kg, PO). All three drugs significantly potentiated the ETOH-induced loss of righting reflex (LRR): temazepam = 2.5mg/kg, PO; lorazepam = 0.16 mg/kg, PO; zolpidem = 16 mg/kg, PO. These compounds also produced significant retention deficits in the step-down passive avoidance (temazepam : 1.0 mg/kg, IV, lorazepam : 0.06 mg/kg, IV; zolpidem : 0.5 mg/kg, IV) as well as in the spatial water maze (temazepam: 5 mg/kg, PO; lorazepam 0.6 mg/kg, PO; zolpidem: 16 mg/kg, PO) models of learning and memory. (Note: all doses above represent the MED). These animal models may be useful in predicting amnesic and ETOH interaction effects, as well as efficacy, of potential sedative/hypnotic compounds. For between drug comparisons, various Therapeutic Indexes can be calculated.

EVIDENCE FOR INVOLVEMENT OF NMDA RECEPTORS IN MEDIAL HYPOTHALAMIC FACILITATION OF DEFENSIVE RAGE BEHAVIOR. K.L. Schubert<sup>\*</sup>, M.B. Shaikh, Y. C. Han, K. Goldstein and A. Siegel. Lab. of Limbic System & Behavior, Dept. of Neurosciences, N.J. Medical School and Graduate School of Biomedical Sciences, UMDNJ, Newark, N.J. 07103.

Projections from the medial hypothalamus (MH) to the periaqueductal gray (PAG) serve as a substrate for defensive rage behavior (DR) in the cat. We have proposed that this pathway utilizes excitatory amino acids as a neurotransmitter that act upon NMDA receptors within the PAG. This study demonstrated that glutamate positive cells, present in MH, project to the PAG and that NMDA receptors are also present in the PAG. A retrograde axonal tracer, Fluoro-Gold, (4-8%/0.5  $\mu$ l) was microinjected into DR sites within the PAG and the tissue was processed for labelling of glutamate positive cells. Double labeled cells for both glutamate and Fluoro-Gold were identified in the MH, indicating the presence of a glutamatergic pathway to the PAG from MH. Immunohistochemical and autoradiographic analyses of the tissue revealed the presence of NMDA<sub>R1</sub> receptors on dorsal PAG neurons. These data support the hypothesis that MH-induced DR is subserved by a descending pathway to the PAG whose functions are mediated by NMDA receptors.
