The mechanisms by which antidepressants and electroconvulsive seizures (ECS) relieve clinical depression are not well understood. However, potential candidates might include neurotrophic factors which regulate the development, plasticity and survival of neurons. To explore this hypothesis we examined the effects of antidepressants and ECS on neurotrophin expression in the rat brain. Using *in situ* hybridization we found that chronic treatment with tricyclic antidepressants decreased basal levels of neurotrophin-3 (NT-3) mRNA in the locus coeruleus (LC) and brain-derived neurotrophic factor (BDNF) in the hypothalamic paraventricular nucleus (PVN). Desipramine for 21 days partially attenuated the increases in LC NT-3 and PVN BDNF mRNA levels that occur in response to repeated immobilization stress. However, desipramine did not block the effects of immobilization stress on NGF, BDNF or NT-3 expression in the hippocampus and cortex. ECS also decreased NT-3 in the LC, but in addition, dramatically decreased NT-3 and increased NGF and BDNF mRNA expression in the hippocampus and cortex. Thus antidepressants and ECS affect neurotrophic factor expression in an opposite manner compared to stress which exacerbates depression. These results raise the possibility that some of the effects of antidepressants and ECS could be mediated through alterations in neurotrophic factor expression in areas such as the hippocampus, PVN and locus coeruleus that are important for regulating mood.

## 386.20

PHARMACOLOGICAL PROFILE OF HT-90B, A PUTATIVE ANXIOLYTIC WITH POTENT ANTIDEPRESSIVE ACTIVITY (II).

K. Inagawa<sup>\*</sup>, H. Uchida, C. Tameda, and T. Miyauchi, Fuji-Gotemba Research Labs., Chugai Pharmaceutical Co., Ltd., 412, Japan.

HT-90B, (-)-N-([2-(8-methyl 1,4-benzodioxane-2-ylmethyl) amino]ethyl)tricyclo[3.3.1.1.3.7]decanol-carboxamide, has been shown to be a putative anxiolytic with potent antidepressive action with minimal side effects (Miyauchi et al. (1993) Soc Neurosci Abstr. 10:1867). The present study evaluated the effects of HT-90B on 1) the light-dark exploration in mice and 2) the increased motor activity in the olfactory bulbectomized rats. Receptor binding profile using autoradiography (*in vitro* and *ex vivo*) was also studied. In the light-dark exploration in mice, HT-90B (1 and 10 mg/kg, po) shortened duration time spent in the dark compartment without inhibiting the motor activity. Although buspirone (30 mg/kg, po) showed the effect on the duration time spent in the dark compartment, it inhibited the motor activity. Single oral dose of HT-90B (10 mg/kg) reduced the increased motor activity in the olfactory bulbectomized rats, as multiple i.p. injection of desipramine did (10 mg/kg X 4). Both HT-90B and desipramine did not change the motor activity. In *in vitro* labeling autoradiography, HT-90B displaced [3H]-8-OH-DPAT (pIC<sub>50</sub>=9.6) and [3H]-ketanserin specific binding in concentration dependent manner. Results from *ex vivo* labeling autoradiography will also be presented.

## GENETIC MODELS OF HUMAN NEUROPSYCHIATRIC DISORDERS III

## 387.1

NEURONAL LOSSES IN THE BRAIN OF MICE TRANSGENIC FOR THE HUMAN NF-L NEUROFILAMENT PROTEIN. D. Ma<sup>1</sup>, K. Micheva<sup>1</sup>, L. Descarries<sup>1</sup>, J.-P. Julien<sup>2</sup> and G. Doucet<sup>1</sup>. <sup>1</sup>Département de pathologie et CRSN, Université de Montréal; <sup>2</sup>Center for Research in Neuroscience, Montreal General Hospital and McGill University, Montréal, Québec, Canada.

Mice transgenic for the human form of the neurofilament protein NF-L display abnormal perikaryal immunoreactivity for NF-L in layers II/III of the parietal cortex (Par) and in the ventrobasal complex of the thalamus (VB). This aberrant immunoreactivity is associated with an accumulation of disarrayed filaments in the perikarya as well as dendritic and axonal processes of the affected neurons. It is transient in the cortex (maximal on postnatal day 10), but persistent in the thalamus. To determine its consequences on neuronal survival, cell counts were obtained from Par and the VB of transgenic and normal mice 10 days to 18 months of age. The disector method was used on methylene blue-stained semi-thin sections after fixation of the brain by perfusion with aldehydes and post-fixation with osmium tetroxide. A loss of neurons was apparent in the parietal cortex of transgenic mice as soon as 20 days postnatal (-10% by comparison to controls). In older transgenic mice (14 to 18 months), this loss of neurons had slightly increased in magnitude (-18%) and could be attributed mainly to layers II/III. In the VB, considerable reductions in the number of neurons were detected in the transgenic mice, but only after 3 months (21%) and later (14 to 18 months: -39%). The volume of the VB was then significantly reduced and the lateral ventricles were enlarged. These results indicate that the abnormal accumulation of NF-L leads to premature neuronal death in these transgenic mice. The time course of these neuronal losses depends on the anatomical region examined, presumably reflecting different mechanisms, which remain to be defined. [Supported by FCAR (GRSNC) and MRC grants MT-10982 and MT-3544].

## 387.2

ACCELERATED AND WIDESPREAD NEURONAL LOSS OCCURS IN MOTOR NEURON DEGENERATION (*mnd*) MICE EXPRESSING A NEUROFILAMENT-DISRUPTING TRANSGENE. J. Plummer, A. Peterson and A. Messer<sup>\*</sup>. Wadsworth Ctr. for Labs and Research, N.Y. State Dept. of Health and Dept. of Biomed. Sci., SUNY, P.O. Box 509, Albany, NY 12201-0509; and Dept. of Neurology and Neurosurgery, McGill Univ., Montreal, Canada H3A1A1.

To examine the effects of multiple stressors on the rate and specificity of a neurodegenerative disease, we derived *mnd/mnd* mice expressing a neurofilament-H/lac Z transgene. The *mnd* mutation produces abnormal ubiquitous accumulation of autofluorescent lipopigment, with retinal degeneration and late-onset motor neuron degeneration. The neurofilament H-β-galactosidase fusion protein causes endogenous neurofilament subunits to precipitate in perikarya, without significant neuronal degeneration until advanced age. In *mnd/mnd*-transgenic animals, lipopigment accumulation and motor neuron loss were substantially accelerated. Also, newly vulnerable populations of neurons degenerated, including cerebellar Purkinje cells and dorsal roots. This study helps define factors underlying the specificity of neuronal degeneration in a system displaying a ubiquitous defect. It further indicates that cytoskeletal abnormalities similar to those observed in late-onset human neurodegenerative disorders can interact with other cellular defects and contribute to pathogenesis. Transgenic *mnd/mnd* mice expressing wild type and mutant forms of human Cu,Zn superoxide dismutase are currently being bred, to study the effects of SOD mutations (which themselves produce motor neuron loss in transgenic mice) on the neurodegenerative process triggered by the *mnd* mutation.

## 387.3

A POSSIBLE IN VITRO MODEL FOR ALZHEIMER'S DISEASE BASED ON IMMORTALIZED CELL LINES FROM THE TRISOMY 16 MOUSE. O.F. Olesen<sup>1</sup>, A. Thorpe<sup>2</sup>, K. Frederiksen<sup>1</sup>, L. Larkfors<sup>1</sup> and S.J. Richards<sup>2</sup>. 1) Pharmacological Research, H.Lundbeck A/S, Ottilievej 9, DK-2500 Copenhagen-Valby, Denmark and 2) Dept. of Medicine, University of Cambridge, Addenbrooke's Hospital, Cambridge CB2 2QQ, UK.

An additional copy of chromosome 21 in humans (trisomy 21) results invariably in Down syndrome and early development of neuropathological lesions indistinguishable from those of Alzheimer's disease (AD). Mouse chromosome 16 is partly syntenic to human chromosome 21 and the trisomy 16 (Ts16) mouse has therefore been suggested as an animal model for Down syndrome and AD. However, the utility of this model is severely hampered by the fact that Ts16 embryos die *in utero*. To overcome this obstacle, we have immortalized precursor cells from embryonic Ts16 mouse brain using a retroviral construct based on the temperature sensitive mutant of SV40 large T antigen. This procedure yielded a number of stable cell lines that could either be maintained at the permissive temperature of 33°C or alternatively be induced to halt proliferation and begin differentiation at the nonpermissive temperature of 39°C. Southern blotting confirmed that the cell lines were indeed clonal and the trisomic karyotype was confirmed by fluorescent *in situ* hybridisation with mouse chromosome 16 paints. Initial immunocytochemical analysis revealed that most cell lines expressed GFAP, MBP, nestin and APP at 33°C. After 2 weeks of cultivation at 39°C, most cell lines had lost T antigen and nestin immunoreactivity, whereas two cell lines (TH173 and TH176) demonstrated an upregulated expression of GFAP and exhibited classical astrocytic morphology. Following receptor studies and further immunochemical characterization, these cells can be useful in studying the expression of APP and other molecules involved in the pathogenesis of AD.

## 387.4

AGED MICE TRANSGENIC FOR THE HUMAN β-AMYLOID GENE: BEHAVIOURAL CHARACTERIZATION. E.G. Momtaz<sup>1</sup>, J. Nalbantoglu, S.A. Weiner, Douglas Hospital Research Centre, Departments of Psychiatry and Neurology & Neurosurgery, McGill University, Montreal, Canada, H4H 1R3.

Alzheimer's Disease (AD) is characterized by a progressive deterioration of cognitive function as well as certain alterations in affective behaviours. Since excessive deposition of β-amyloid in areas of hippocampus and neocortex is also characteristic of AD, aged mice (18-24 mo), transgenic for human β-amyloid, compared to aged and young (2-8 mo) controls, were tested in several behavioural paradigms designed to assess cognitive and affective performance. A cDNA fragment of amino acids 591-695, spanning the amyloid and C-terminus portion of the β-amyloid precursor protein, was inserted into the human neurofilament NF-L gene, under transcriptional control of the NF-L promoter. Mice with the same transgenic construct were previously found to be deficient in spatial memory performance in the Morris Water Maze (Tirado-Santiago et al. Soc. Neurosci. Abstr. 18: 1437, 1992). In the present experiments, using the Forced Alternation T-Maze with a zero delay, a task which involves working and reference memory, the transgenic mice demonstrated poor acquisition, failing to attain criterion performance of 70% correct. In the Porsolt Forced Swim Test, comparing the first minute of immobility-time on the training day and the retention day, the transgenic mice were found to be less immobile than controls on the second day of testing, suggesting poor retention. Although there were no deficits in performance on Step-Down Passive Avoidance, this was likely due to the ease of the learned task and the salience of the electric shock reinforcement. In comparison to the young controls, the aged transgenics, but not aged controls, displayed longer latencies to begin eating in the Thatcher-Britton Novelty Conflict paradigm, suggesting a higher degree of anxiety. These test differences were not due to a confound of motor-performance since no apparent group differences in locomotor activity were observed. Therefore, aged transgenic mice appear to have cognitive and affective impairments, and thus may provide an advantageous model in which to assess AD-related pathological and behavioural symptoms.

## 387.5

ACCUMULATION OF  $\beta$ AMYLOID FIBRILS IN PANCREAS OF TRANSGENIC MICE. T. Kawarabayashi<sup>1</sup>, M. Shoji<sup>1</sup>, M. Sato<sup>2</sup>, A. Sasaki<sup>3</sup>, L. Ho<sup>4</sup>, C. B. Eckman<sup>4</sup>, C-M. Prada<sup>4</sup>, S. G. Younkin<sup>4</sup>, T. Kobayashi<sup>2</sup>, N. Tada<sup>2</sup>, E. Malsubara<sup>1</sup>, K. Kasai<sup>2</sup> and S. Hirai<sup>1</sup>. <sup>1</sup>Department of Neurology, and <sup>2</sup>Department of Pathology, Gunma University School of Medicine, Maebashi, Gunma 371, Japan; <sup>3</sup>Laboratory for Animal Center, Pharma Research and Development Division, Hoechst Japan Limited, Kawagoe, Saitama, 350-11, Japan; <sup>4</sup>Departments of Pathology and Neuroscience, Case Western Reserve University, Cleveland, Ohio 44106.

Overproduction of amyloid  $\beta$  protein (A $\beta$ ) derived from amyloid  $\beta$  protein precursor ( $\beta$ APP) is one of the causes of Alzheimer's disease. In an effort to produce substantial A $\beta$  *in vivo*, we generated mice expressing the transgene of signal peptide and ninety-nine residues of carboxyl-terminal fragment (CTF) of  $\beta$ APP under control of the cytomegalovirus enhancer / chicken  $\beta$ -actin promoter. The transgenic mRNA was detected in many tissues of these mice, but the levels of transgenic mRNA, CTF, and A $\beta$  did not correlate well. A $\beta$  was detected biochemically in brain, kidney, pancreas, and plasma with the largest amount present in pancreas. Thus these mice produce and secrete considerable A $\beta$ . Despite the elevated A $\beta$  in brain, immunocytochemistry revealed no consistent cerebral A $\beta$  deposition. In pancreas, however, intracellular A $\beta$  deposits were detected immunocytochemically in acinar cells and interstitial macrophages, some of which showed severe degeneration. Examination of these cells by electron microscopy revealed many putative amyloid fibrils (7-12 nm) that were stained by anti-A $\beta$  antibodies. Our findings indicate that cell-specific posttranslational processing may play a pivotal role in A $\beta$  production and amyloid fibril formation *in vivo*. These mice could be a useful model to investigate the factors that determine the location and amount of A $\beta$  that accumulates as amyloid.

## 387.7

PRODUCTION OF REACTIVE OXYGEN SPECIES CORRELATES WITH DECREASED CYTOCHROME OXIDASE ACTIVITY IN ALZHEIMER'S DISEASE CYBRIDS. J. Lakis<sup>1</sup>\*, S. Glasco<sup>1</sup>, S.W. Miller<sup>1</sup>, and L.J. Thal<sup>1</sup>, R. E. Davis<sup>1</sup>. <sup>1</sup>Applied Genetics, Inc., San Diego, CA 92121; <sup>2</sup>Department of Neurology, VA Medical Center, San Diego, CA 92161.

Defects in cytochrome oxidase (Complex IV) activity have been associated with Alzheimer's disease but the cause of these defects are unknown. Complex IV is the product of two genomes, with protein constituents being encoded by both mitochondrial (mtDNA) and nuclear DNA (nDNA). Decreases in Complex IV activity could arise from genetic lesions in one or both of these genomes. To evaluate the contributions of the mitochondrial genome to AD associated Complex IV defects, we created mtDNA deficient SH-SY5Y neuroblastoma cell lines, p<sup>9118/5</sup> cells (Applied Genetics, San Diego, CA). These cells lack mtDNA encoded electron transport chain activities and normal respiration. Respiratory function can be recovered by repopulation of p<sup>9118/5</sup> cells with the exogenous human platelet mitochondria (cybrid). We have created disease specific cybrids by fusion of p<sup>9118/5</sup> cells with the platelets from AD and age-matched control platelets. These cybrids have nDNA with origins in the parental SH-SY5Y cells and mtDNA with origins in the human donor platelets. Alzheimer's disease cybrids show decreased cytochrome oxidase activity when compared to age-matched control cybrids. However, Complex I activity, another mitochondrial encoded ETC enzyme, was equivalent in both AD and age-matched control cybrids, demonstrating the specificity of the mtDNA defect. The decrease in COX activity in AD cybrids was directly correlated with a 75% increase in reactive oxygen species (ROS) as measured by oxidation of dichloro-fluorescein-diacetate in cultured cybrids. We have modeled AD mtDNA defects in cybrids and measured biochemical defects in COX activity and ROS production. These cybrids will be useful as models for dissecting the role of the mitochondrial genome in AD.

## 387.9

BDNF, BUT NOT NGF, RESCUES TRISOMY 16 CORTICAL NEURONS IN VITRO. M.T. Caserta\*, J. Muller and A. Guillozet. Dept. of Psychiatry, Northwestern University Medical School, Northwestern University Institute of Neuroscience and Evanston Hospital, Chicago, IL 60611. Murine trisomy 16 (ts 16) is a well-accepted model of human trisomy 21 or Down Syndrome. Since all individuals with Down Syndrome develop the neuropathological findings of Alzheimer's Disease (AD) by their third or fourth decade, the ts 16 mouse has been used as a susceptibility model for AD. Our laboratory has previously shown that ts 16 cortical neurons *in vitro* are morphologically undifferentiated and over-express somatostatin and neuropeptide Y and are more susceptible to the toxic effects of the beta A4 peptide fragment 25-35 when compared to euploid cortical neurons. It is not known whether ts 16 cortical neurons are responsive to nerve growth factor (NGF) or other known neurotrophic factors, such as BDNF. In this study, we investigated the effects of varying concentrations of NGF and BDNF (0-100 ng/ul) on trisomic and euploid cortical neurons *in vitro* when applied to the growth media for 2-5 days. Cultures were fixed and stained with an antibody to neuron-specific enolase (NSE) and NSE positive neurons were counted and photographed. The results indicate that BDNF rescued trisomy 16 cortical neurons in a dose-dependent manner while NGF had no effect. The addition of BDNF was found to have a deleterious effect on the survival of euploid cortical neurons. These results suggest a possible role for BDNF in the treatment of AD.

## 387.6

ALZHEIMER'S DISEASE CYBRIDS MANIFEST A CYTOCHROME OXIDASE DEFECT. S. Glasco<sup>1</sup>\*, S.W. Miller<sup>1</sup>, and L.J. Thal<sup>1</sup>, R. E. Davis<sup>1</sup>. <sup>1</sup>Applied Genetics, Inc., San Diego, CA 92121; <sup>2</sup>Department of Neurology, VA Medical Center, San Diego, CA 92161.

Defects in cytochrome oxidase (Complex IV) activity have been found in the blood and brain of patients with Alzheimer's disease. The cause of these defects remain unknown. Because Complex IV is encoded by both nuclear and mitochondrial genes, decreases in Complex IV activity could arise from genetic lesions in one or both of these genomes. We have created mtDNA deficient SH-SY5Y neuroblastoma cell lines, p<sup>9118/5</sup> cells (Applied Genetics, San Diego, CA). These cells lack mtDNA encoded electron transport chain activities and normal respiration but are still able to differentiate in response to various differentiation factors. We have created disease specific cybrids by fusion of p<sup>9118/5</sup> cells with the platelets from AD and age-matched control platelets. These cybrids have nDNA with origins in the parental SH-SY5Y cells and mtDNA with origins in the human donor platelets.

Alzheimer's disease cybrids show a 30% reduction in cytochrome oxidase activity when compared to age-matched control cybrids. However, Complex I activity, another mitochondrial encoded ETC enzyme, was equivalent in both AD and age-matched control cybrids, demonstrating the specificity of the mtDNA defect. Upon differentiation for three weeks with retinoic acid the AD cybrids maintain the cytochrome oxidase defect.

We have modeled cytochrome oxidase defects in AD cybrids. The defect probably reflects mutations in cytochrome oxidase subunits encoded by mtDNA. These cybrids will be useful as a model for elucidating the role of the mitochondrial genome in AD and other neurodegenerative diseases.

## 387.8

EXTRACELLULAR APP DEPOSITS IN NEURAL TRANSPLANTS HARBORING A MUTANT HUMAN APP. T.A. Bayer<sup>a</sup>, A. Fölggreen<sup>b</sup>, C. Czech<sup>b</sup>, K. Beyreuther<sup>b</sup> and O.D. Wiestler<sup>a</sup>. <sup>a</sup>Department of Neuropathology, University of Bonn Medical Center, Sigmund-Freud-Strasse 25, D-53105 Bonn, FRG; <sup>b</sup>ZMBH, Im Neuenheimer Feld 282, D-69120 Heidelberg, FRG.

Using retrovirus-mediated gene-transfer, we have introduced a mutant cDNA of human APP 695 into rat brain transplants. This mutant APP (with point mutations at positions 670/671) has been associated with Alzheimer's disease in a Swedish kindred and was shown to induce the formation of  $\beta$ -A4 peptide in human cell lines. A minor population of recombinant neural cells with expression of APP was identified immunohistochemically in the grafts. The expression was maintained for a period of six months, i.e. the longest post-transplantation interval studied so far. Neurons with strong immunoreactivity for human APP exhibited a markedly swollen cell body and showed evidence for cellular degeneration. After a six months period, extracellular APP positive deposits were observed. These precipitates had a plaque like appearance. Studies to characterize the morphology and molecular composition of affected neurons and extracellular deposits are in progress. The data indicate that a disease-related mutant form of human APP has the potential to induce morphological features of Alzheimer's disease in the rodent CNS.

Supported by the Fritz-Thyssen-Stiftung.

## 387.10

INCREASED LEVELS OF KYNURENIC ACID IN BRAINS OF GENETICALLY DYSTONIC HAMSTERS. A. Richter, W. Löscher, M. Gramer and H. Baran (SPON: European Neuroscience Association). Dept. of Pharmacology, Toxicology and Pharmacy, School of Veterinary Medicine, 30559 Hannover, Germany; \* Childrens Hospital, Vienna

Recent pharmacological studies have shown antidystonic effects of NMDA and non-NMDA receptor antagonists in an inbred line of Syrian hamsters (dt<sup>m</sup>) with primary generalized dystonia, i.e. a neurological syndrome of sustained muscle contractions which occurs in the absence of any pathomorphological alterations. This prompted us to examine the levels of kynurenic acid, an endogenous non-selective antagonist of the excitatory amino acid receptors. The concentrations of kynurenic acid were determined by HPLC in forebrain, cerebellum, brain stem and plasma in dystonic hamsters and age-matched non-dystonic controls. Dystonia in mutant hamsters is transient and disappears completely at the age of 70 days. In order to prove if neurochemical changes are related to dystonia, kynurenic acid was determined at the age of maximum severity (30 days) and after remission (70 days). The levels of kynurenic acid were significantly increased in forebrain, cerebellum and brain stem (37-130%) in dystonic hamsters at the age of maximum severity of dystonia (30 days of life) compared to both a genetically related non-dystonic inbred line and a non-related outbred line. The increase of kynurenic acid in brain regions was accompanied by enhanced plasma levels. However, there was no correlation between brain and plasma levels. Since the changes disappeared in parallel with dystonia (70 days), the present data provide further evidence that abnormal activity of excitatory amino acids may be pathogenetically involved in dystonia in mutant hamsters. The recent finding of antidystonic effects of glutamate receptor antagonists can not be explained by a loss of the endogenous inhibitor kynurenic acid. The increased levels of kynurenic acid could be related to an overactivity of NMDA receptors.

## 387.11

KAINIC ACID-INDUCED SEIZURES IN INBRED MICE: QUANTITATIVE TRAIT LOCI (QTL) MAPPING. T.N. Ferraro\*, G.T. Golden, C. Ballas, G.G. Smith, N.J. Schork, W.H. Berrettini, Thomas Jefferson University, Philadelphia, PA, DVAMC, Coatesville, PA and Case Western Reserve Univ., Cleveland, OH.

Mature DBA/2J (D2) mice are very sensitive to seizures induced by various chemical and physical stimuli whereas C57BL/6J (B6) mice are relatively seizure-resistant. We have studied the sensitivity of an F2 intercross population of D2 and B6 mice ( $n = 257$ ) to the seizure-inducing effect of the glutamate agonist kainic acid (KA) and have begun to map quantitative trait loci (QTL) which influence this phenomenon. Subsequent to dose-response and pharmacokinetic studies in parental mice, F1 and F2 mice (8-10 weeks of age) were injected (sc) with a KA dose of 25 mg/kg and observed for 2 hours. Latencies to clonus, tonic/clonic seizure and *status epilepticus* were recorded and an overall seizure score calculated. Mean ( $\pm$  SD) seizure scores are as follows: D2:  $1.17 \pm 1.00$  ( $n = 10$ ); B6:  $0$  ( $n = 10$ ); B6D2F1/J (F1):  $0.93 \pm 0.58$  ( $n = 10$ ); and F2:  $1.06 \pm 0.99$  ( $n = 257$ ). Distribution of maximum seizure responses among F2 mice (*status epilepticus*:  $n = 77$ ; tonic/clonic:  $n = 70$ ; clonus:  $n = 40$ ; no seizure:  $n = 70$ ) suggests that the difference in KA seizure susceptibility between the D2 and B6 mice is a polygenic phenomenon with about 65% of the variance in seizure score between parental strains due to genetic factors and 35% due to environmental factors. First-pass screening of the murine genome (10 cM marker intervals) using F2 mice with the highest ( $n = 77$ ) and lowest ( $n = 70$ ) seizure scores has documented a QTL of moderate effect on chromosome 1 between D1Mit30 and D1Mit16 (LOD score = 5.46 with Mapmaker/QTL; 11% of variance explained) indicating the presence of a gene in this region which has a significant influence upon KA seizure susceptibility in D2 and B6 mice. Putative QTL of small effect have been detected on chromosomes 11, 15, and 18; however, these loci require further evaluation. Supported by NINDS grant RO1-NS3243-01 and VA funds.

## 387.13

ESTABLISHMENT AND CHARACTERIZATION OF MICE LACKING Cu/Zn SUPEROXIDE DISMUTASE. E.K. Hoffman, A.G. Reaume, H. Wilcox, D.G. Flood\*, Y.G. Lin, and R.W. Scott, Cephalon Inc., 145 Brandywine Parkway, West Chester, PA 19380.

Oxidative damage has been implicated as a contributing factor in several neurodegenerative conditions including normal aging, stroke, Parkinson's disease, Alzheimer's disease and Huntington's disease. To establish an animal model predisposed to oxidative injury, the SOD-1 gene encoding Cu/Zn superoxide dismutase has been deleted in mice. A gene replacement strategy was utilized to remove all SOD-1 coding sequences in ES cells that were in turn used to generate Cu/Zn SOD-deficient mice lacking one or both copies of the SOD-1 gene. The homozygous SOD-1 null animals contain no detectable Cu/Zn SOD on immunoblots and have approximately 5% residual superoxide scavenging activity in a spectrophotometric assay. These animals survive to at least six months of age and show no apparent behavioral or gross neuroanatomical abnormalities. Initial biochemical surveys have revealed no significant differences in markers of oxidative damage (protein carbonyl content, lipid peroxidation) and oxidative stress (reduced glutathione and Mn-SOD) in brain and select peripheral tissues. The lack of any neuromuscular functional deficits to date supports the gain-of-function hypothesis for the SOD-1 mutations linked to familial ALS. The absence of an overt phenotype in the SOD-1 deficient mice is in marked contrast to results with other Cu/Zn SOD-deficient organisms including yeast and *Drosophila*. Several possibilities for this difference are that the presence of redundant or compensatory mechanisms protect the SOD-deficient mouse from oxidative injury, or Cu/Zn SOD plays a more crucial protective role in mammals under conditions of pathological stress. To address this issue, the animals are currently being aged and subjected to a variety of lesion and stress conditions to identify potentially vulnerable neuronal populations.

## 387.15

THE MITOCHONDRIAL GENOME ENCODES THE COMPLEX I DEFECT IN PARKINSON'S DISEASE. R. Swerdlow, J.K. Parks, S.W. Miller, R.E. Davis\*, and W.D. Parker, Department of Neurology, University of Virginia, Charlottesville, VA 22908 and Applied Genetics, San Diego, CA 92121.

Proposed etiologies of Parkinson's Disease (PD) include toxic and inherited causes. Environmental toxins have been associated with higher disease incidence, but such findings have been questioned. Epidemiologic studies to define genetic contributions also have been confusing. This confusion may arise from previously unsuspected heterogeneity in PD. Mitochondrial inheritance may contribute to PD, accounting for its sporadic, non-Mendelian occurrence. To test this hypothesis, we created cybrid cell lines (PD-p0) using mitochondria donated by PD patients. Cybrids are unique cells created by introducing exogenous mitochondrial DNA (mtDNA) into host cells depleted of mtDNA. In this case, human SH-SY5Y neuroblastoma cells were depleted of endogenous mtDNA by prolonged exposure to ethidium bromide (p0118/5, Applied Genetics, San Diego, CA) and were repopulated with platelet mtDNA from PD patients or age-matched controls. This resulted in cell lines whose only genetic differences were in the origin of their mtDNA and therefore any differences between cell lines must arise from differences in the exogenous mtDNA.

In previous work we showed that the mitochondrial enzyme NADH:ubiquinone oxidoreductase (Complex I) is deficient in PD. Since complex I is the target of the PD-inducing toxin MPP+, this complex I lesions may be pathologically important. PD-p0 cells were complex I deficient compared to age-matched controls. Activities of other mitochondrial enzymes (cytochrome oxidase, citrate synthase) were similar in PD-p0 and control-p0 cells. This demonstrates that the focal defects in complex I activity are brought into the cells along with the transferred mtDNA from donor mitochondria.

## 387.12

STRAIN DIFFERENCES IN COCAINE-INDUCED STEREOTYPY IN DBA/2J AND C57BL/6J MICE: DOSE RESPONSE. G.T. Golden\*, T.N. Ferraro, G.G. Smith, W.H. Berrettini, DVAMC, Coatesville, PA 19320 and Jefferson Medical College of Thomas Jefferson University, Philadelphia, PA 19107

Cocaine-induced stereotypy (CIS) and cocaine-induced locomotor activity may be mediated by separate neural pathways. The C57BL/6J (B6) inbred mouse prefers cocaine more than other inbred strains, such as the DBA/2J (D2). D2 mice develop a high degree of CIS after chronic injections of cocaine (32mg/kg, ip) whereas B6 mice show no CIS (Tolliver & Carney, 1994). As a step toward characterization of genetic elements which may be involved in differential CIS in these mice, CIS was compared in 8 wk old D2 and B6 mice ( $n = 6$ -8/strain/dose) injected ip once daily with cocaine (30 or 40mg/kg) or saline for 10 days. CIS was rated for 50 min after injection on days 3, 7 and 10 by two blinded observers using a five point stereotypy scale. StrainXdose ANOVA with CIS scores as the dependent variable showed highly significant strain and dose main effects and significant strainXdose interaction effects for day 7 and day 10 CIS scores.

STRAIN	3/INJ	7/INJ	10/INJ	DOSE
DBA/2J	4.3 (3.2)	4.3 (2.3)	8.3 (1.1)	saline
C57BL/6J	7.7 (1.1)	7.0 (1.0)	6.7 (2.1)	saline
DBA/2J	15.8 (9.8)	26.4 (5.8)	33.1 (4.0)	30mg/kg
C57BL/6J	10.4 (2.4)	10.4 (3.6)	11.0 (2.3)	30mg/kg
DBA/2J	24.2 (8.1)	33.0 (3.7)	36.0 (2.1)	40mg/kg
C57BL/6J	9.5 (1.1)	11.8 (3.4)	12.5 (5.3)	40mg/kg

Results confirm the previously reported large strain differences in CIS between D2 and B6 mice and suggest that quantitative trait loci mapping strategies would be a feasible approach for identifying the gene(s) which influence this complex trait. This may lead to new avenues of research, improved treatment and identification of individuals at high risk for cocaine addiction. Supported by the Department of Veterans Affairs.

IMMUNOHISTOCHEMICAL CHARACTERIZATION OF DEGENERATING NEURONS IN THE SPINAL CORD OF MUTANT SUPEROXIDE DISMUTASE TRANSGENIC MICE. B.M. Morrison\*, J.W. Gordon\*, P.R. Hui\*, M.E. Ripps\*, and J.H. Morrison\*, <sup>1</sup>Fishberg Res. Ctr. for Neurobiol., <sup>2</sup>Brookdale Ctr. for Mol. Biol., and <sup>3</sup>Dept. of Obs/Gyn and Reproductive Sci., Mount Sinai School of Medicine, New York, NY 10029.

Transgenic mice with a point mutation in the mouse superoxide dismutase (SOD) gene that results in a Gly86→Arg substitution, corresponding to a mutation observed in familial amyotrophic lateral sclerosis (ALS), display progressive loss of motor function and provide a valuable model of ALS. Parallel series of spinal cord sections from control and mutant SOD transgenic animals were stained with Nissl, Campbell-Switzer silver method, and immunohistochemical markers for phosphorylated neurofilament (NFP), non-phosphorylated NFP, and calcium-binding proteins (CaBP). Qualitatively, there were argyrophilic dystrophic neurites, ghost cells, a few cells exhibiting pyknosis and karyorrhexis, and a pronounced loss of motoneurons within the ventral horn of the spinal cord. Unlike other SOD transgenic mice and ALS patients, we have not observed vacuolization or disruption of the NFP cytoskeleton within motoneurons. To quantify the neuronal degeneration in these mice, neurons were counted, using the optical fractionator, in the ventral horn of both the cervical and lumbar enlargements of SOD transgenic and control spinal cords. By comparing the number of neurons in transgenic versus control animals, we estimated the loss of Nissl-stained neurons (used as a measure of total neuron number) in the SOD transgenic mice to be 25%, and the loss of NFP-immunoreactive neurons to be 50%. This finding suggests that NFP-containing neurons are particularly vulnerable to the cellular insult resulting from mutations in the SOD gene, consistent with several studies demonstrating that these neurons are particularly vulnerable in neurodegenerative diseases. Interestingly, preliminary results indicate that CaBP-containing neurons are lost in significant numbers, although they are not as vulnerable as NFP-enriched neurons. This contrasts with several studies that have reported these neurons to be resistant in neurodegenerative diseases. Supported by NIH grants AG10520 and AG06647.

IMMUNOLOGIC AND BEHAVIORAL ABNORMALITIES IN A MOUSE MODEL OF DOWN SYNDROME. M.E. Coussons-Read\* and L.S. Cmic, Depts. of Psychiatry and Pediatrics, Univ. of Colo. Sch. of Med., Denver, CO 80262.

The Ts65Dn mouse is trisomic for a region of mouse chromosome 16 which has high homology to the Down syndrome (DS) region of human chromosome 21, and is thus a potential animal model of DS. Among the characteristics of DS are mental retardation, behavioral disturbances, impaired immune function, and increased disease susceptibility. The behavior of Ts65Dn and littermate control mice was assessed in the elevated plus maze, lighted and dark open field, and in a step-down passive avoidance task. In the elevated plus maze, Ts65Dn had more total arm visits than controls, entered the open arms more frequently than control mice, and showed no preference for the closed arms. Ts65Dn mice were more active in both open field situations, regardless of light condition, and entered the center of the arena more than controls. No significant differences were observed in acquisition and retention of the step-down passive avoidance task, indicating that this simple form of associative learning is intact in these mice. Overall, the data show that Ts65Dn mice are more active than control mice in two testing situations. Most striking, Ts65Dn mice did not respond to variations in environmental cues which induce wariness in normal mice. At the conclusion of behavioral testing, spleens were collected for immunological analysis. The level of Con-A induced lymphocyte proliferation was depressed in cultures of splenocytes from the Ts65Dn mice compared to their non-trisomic littermates. Lymphocytes from Ts65Dn mice were also much more sensitive than controls to the antiproliferative effects of interferon  $\alpha$  (IFN $\alpha$ ), results consistent with the immunologic anomalies reported in DS, and with the presence of the IFN $\alpha$  receptor gene in the trisomic region. These data begin to characterize the Ts65Dn phenotype, and support its use as a model of aspects of DS, since similar behavioral and immunologic traits appear to exist in the Ts65Dn mouse and DS. Supported by HD04024, HD17449, MH49043, and MH15440.

THE NEUROHISTOLOGY OF THE SCID MOUSE BRAIN, F. J. Denaro\*, TTUHS, Lubbock, TX 79430 and R. Jones, Portland VAMC.

Human lymphocytes and hematopoietic stem cells can be transplanted into SCID mice without rejection. This has enabled the development of the SCID mouse as a model system for studying important human diseases, viral infections, transplantation and immune system development. In the present study, a neurohistological examination was conducted in SCID mice following transplantation of human PBLs or bone marrow. Histological examination two months following transplantation revealed a normal brain. Neurons, astrocytes, oligodendrocytes, microglia and the vascular system appeared normal. Stains, such as Bielschowsky, PAS, and LFB demonstrated an unremarkable brain at the cytologic and gross levels. EM has not revealed any abnormalities two months after transplantation. Longer term animals will be studied. Reactive gliosis, however, was found in animals which were reconstituted by intercerebral injections. In these cases reactive glial cells and possibly microglia were found around injection sites. NS31857, Veterans Affairs

## EPILEPSY: BASIC MECHANISMS II

## 388.1

FIELD-POTENTIAL ACTIVITY INDUCED BY 4-AMINOPYRIDINE IN THE RAT HIPPOCAMPAL/ENTORHINAL SLICE PREPARATION, R. Köhling\*, T. Nagao, A. Lücke and M. Avoli, Montreal Neurological Inst., Dept Neurology & Neurosurgery, McGill Univ., MONTREAL, Canada H3A 3B4

An in vitro slice preparation of combined hippocampus and entorhinal cortex from adult rat was used to study the modalities of generation and propagation, and the pharmacological properties of the synchronous activity induced by 4-aminopyridine (4AP, 50  $\mu$ M). Simultaneous field-potential recordings were made in the entorhinal cortex, dentate gyrus, and CA3 and CA1 sectors. 4AP made three types of spontaneous activity appear. The first occurred synchronously in both entorhinal cortex and hippocampal areas and consisted of a long-lasting (0.3-1s) field potential that was reminiscent of the GABA-mediated event described in isolated hippocampal slices (*J Neurosci*, 12 (1992) 104-105). The second type was only observed in CA3 and CA1 sectors and consisted of brief (<15ms) interictal epileptiform discharges (rate = 1-2.5Hz). The third type of activity resembled ictal epileptiform discharges (duration up to 180 s) and originated in the entorhinal cortex from where it propagated to the dentate, CA3 and CA1 via the hippocampal trisynaptic loop as revealed by latency analysis and lesion experiments. Both types of epileptiform activity were blocked by the non-NMDA receptor antagonist CNQX (10  $\mu$ M), while the NMDA receptor antagonist CPP (10  $\mu$ M) only abolished entorhinal ictal discharges. Concomitant application of CNQX and CPP did not influence the occurrence of the presumably GABA-mediated potentials that were abolished by bicuculline methiodide. This study confirms that the combined hippocampal/entorhinal slice represents a suitable model for analyzing the pathogenesis of limbic seizures and points to the entorhinal cortex as the site of origin of an NMDA-mediated ictal discharge.

## 388.3

[K<sup>+</sup>]<sub>o</sub> MEASUREMENTS DURING SYNCHRONOUS ACTIVITY INDUCED BY 4-AMINOPYRIDINE IN THE RAT ENTORHINAL CORTEX, M. Barbarosie, R. Köhling, A. Lücke, T. Nagao, and M. Avoli\*, Montreal Neurological Institute and Department of Neurology and Neurosurgery, McGill University, MONTREAL, QC, Canada H3A 2B4

The synchronous activity induced by 4-aminopyridine (4AP, 50  $\mu$ M) in the entorhinal cortex was analyzed with extracellular field-potential and K<sup>+</sup>-selective recordings in an in vitro slice preparation. [K<sup>+</sup>]<sub>o</sub> rose to 3.4-7.6 mM during a negative-going field potential that lasted 0.5-3.5 s and occurred at rates of 0.013-0.13 Hz. This event could be followed within a few hundred ms by an ictal epileptiform discharge that was associated with [K<sup>+</sup>]<sub>o</sub> elevations of 14-17 mM. The termination of the ictal discharges was accompanied by [K<sup>+</sup>]<sub>o</sub> undershoots. Depth-profile analysis of the field-potential and [K<sup>+</sup>]<sub>o</sub> activity indicated that during ictal discharge the largest values were recorded in the deep layers of the entorhinal cortex. During blockade of ionotropic excitatory amino acid receptors, the negative-going potentials continued to occur and they were accompanied by [K<sup>+</sup>]<sub>o</sub> increases of 3.6-5.8 mM. They were blocked by the GABA<sub>A</sub> receptor antagonist bicuculline methiodide or the  $\mu$ -opioid receptor (D-Ala<sup>2</sup>, N-Me-Phe<sup>4</sup>, Gly<sup>5</sup>-ol)-enkephalin. These findings demonstrate that the occurrence of ictal discharge in the entorhinal cortex is preceded by a GABA-mediated increase in [K<sup>+</sup>]<sub>o</sub>. As reported in the immature hippocampus (*J Neurophysiol* 70 (1993) 1018-1029), such a potential appears to be instrumental in initiating ictal activity in the entorhinal cortex of adult rat brain. Supported by MRC of Canada and Savoy Foundation.

## 388.2

POST-ANOXIC CHANGES IN SYNAPTIC EXCITABILITY IN THE CA1 SUBFIELD OF THE RAT HIPPOCAMPUS, V. Tancredi\* and M. Avoli, Dip. Med. Sper., Univ. di Roma "Tor Vergata", 00173 Rome, Italy and Montreal Neurological Institute and Department of Neurology and Neurosurgery, McGill University, MONTREAL, QC, Canada H3A 2B4

We used field-potential recording techniques to study the long-lasting changes in synaptic excitability induced by brief (<7min) episodes of anoxia in the CA1 subfield of rat hippocampal slices. Disappearance of the population spike and/or substantial reduction of the field excitatory postsynaptic potential (EPSP) induced by stratum radiatum (SR) stimuli occurred with anoxia. The amplitude of the population spike increased during re-oxygenation by 87  $\pm$  68% (n = 35 slices) as compared to control. This post-anoxic potentiation was detected for several tens of minutes after re-oxygenation. Further anoxic episodes could induce the appearance of SR-induced epileptiform bursts, that were reduced by NMDA receptor antagonists and completely blocked by the non-NMDA antagonist CNQX. Paired-pulse stimulation protocols demonstrated that inhibitory mechanisms decreased by as much as 75% after a single episode of anoxia (n = 5 slices). Such reduction of inhibition persisted over time and became more evident as more anoxic episodes were delivered until the final appearance of epileptiform bursts. Our findings demonstrate that anoxia can induce enhancement of synaptic excitability of CA1 pyramidal cells leading to the appearance of epileptiform activity. The long-lasting changes are associated with a reduction of polysynaptic inhibitory mechanisms. Moreover, anoxia makes an NMDA-mediated component of excitatory synaptic transmission appear, which might contribute to the appearance of SR-induced epileptiform bursts. Supported by Quebec Heart and Stroke Foundation, CNR of Italy and MRC of Canada.

## 388.4

INTRACELLULAR ACTIVITY OF RAT ENTORHINAL NEURONS DURING ICTAL-LIKE EPILEPTIFORM DISCHARGES INDUCED BY 4-AMINOPYRIDINE, V. Lopantsev\* and M. Avoli, Montreal Neurological Inst., Dept Neurology & Neurosurgery, McGill University, MONTREAL, QC, Canada H3A 3B4

Spontaneously occurring ictal-like epileptiform discharges, were induced by 4-aminopyridine (4AP, 50  $\mu$ M) in slices of entorhinal cortex from adult rats. Conventional intracellular recordings were made from 29 neurons of the entorhinal cortex (0.2-1.3 mm from glial surface). The intracellular counterpart of the ictal epileptiform discharge consisted of a long-lasting (29-110s), large-amplitude (20-52mV) depolarization of the membrane associated with discharge of fast action potentials. At resting membrane potential (RMP = -72  $\pm$  7.1 mV) such ictal activity was often initiated by a depolarization (duration = up to 2.7 s) that corresponded to a negative-going, presumably GABA-mediated field potential and was not associated with action-potential discharge. When the RMP was depolarized with intracellular injection of current, this depolarization inverted to a hyperpolarizing potential (reversal potential = approx. -63 mV). Blockade of ionotropic excitatory amino acid receptors abolished the epileptiform discharges, while the presumably GABA-mediated potentials continued to occur. At control RMP, it consisted of a long-lasting depolarization associated with a large increase in membrane conductance. These potentials were abolished by the GABA<sub>A</sub> receptor antagonist bicuculline methiodide or the  $\mu$ -opioid receptor agonist DAGO. Our findings show that entorhinal neurons generate a GABA-mediated depolarization that is due to postsynaptic activation of GABA<sub>A</sub> receptors, is resistant to antagonists of ionotropic excitatory amino acid receptors and might be instrumental in initiating ictal discharge.

## 388.5

**SYNCHRONOUS ACTIVITY IN THE ABSENCE OF EXCITATORY AMINO ACID-MEDIATED TRANSMISSION IN THE RAT HIPPOCAMPUS IN VITRO.** T. Nagao\*, R. Köhling, A. Lücke, D. Mattia and M. Avoli, Montreal Neurological Institute, Dept Neurology & Neurosurgery, McGill University, MONTREAL, QC, Canada H3A 3B4

Field-potential recordings were performed in the CA3 stratum radiatum of rat hippocampal slices during concomitant application of 4-aminopyridine, tetraethylammonium, and ionotropic excitatory amino acid (EAA) receptor antagonists. Prolonged synchronous field potentials (duration =  $40.2 \pm 4.5$  s,  $n = 18$  slices) occurred spontaneously and were made up of positive-negative components associated with population-spike discharges. In 80% of the slices spreading depression-like episodes also occurred (duration =  $120 \pm 19$  s). The field-potential discharges were associated with  $[K^+]_o$  elevations of  $6.1 \pm 0.7$  mM ( $n = 5$ ), while during spreading depression  $[K^+]_o$  increased up to 27 mM. Both types of activity were blocked by the GABA<sub>A</sub> antagonist bicuculline or application of  $Ca^{2+}$ -free, high- $Mg^{2+}$  medium. Simultaneous field potential recordings in different hippocampal areas demonstrated that the prolonged field-potential discharges occurred in a synchronous fashion. By contrast, spreading depression episodes were more frequently recorded in the CA1 than in the CA3 subfields and were never seen in the subiculum or the dentate area. Our findings indicate the presence of a novel type of prolonged field-potential discharge and spreading depression-like episodes in the rat hippocampal slice when ionotropic EAA receptors are blocked. The occurrence of this synchronous activity is presumably dependent upon the postsynaptic activation of the GABA<sub>A</sub> receptor located on neuronal and glial elements, while rises in  $[K^+]_o$  and consequent redistribution processes are sufficient to make all types of synchronous activity propagate. Supported by MRC of Canada.

## 388.7

**BRIEF PERIODS OF EPILEPTIFORM ACTIVITY INDUCE LONG-TERM POTENTIATION IN RAT HIPPOCAMPAL SLICE CULTURES.** S.M. THOMPSON, D. DEBANNE\* and B.H. GÄHWILER.

Brain Research Institute, University of Zurich, 8029 Zurich Switzerland

CA1 pyramidal cells were recorded intracellularly in rat hippocampal slice cultures, and EPSPs were evoked at low frequency (0.3 Hz), with an extracellular stimulating electrode located in area CA3. A brief period of epileptiform activity was induced by bath application of the GABA<sub>A</sub> receptor antagonist bicuculline. An increase in the evoked EPSP amplitude, lasting for more than 30 minutes, was observed after complete washout of bicuculline. A similar long-lasting potentiation could be observed when epileptiform activity was produced by bath-application of magnesium-free extracellular saline, indicating that epileptiform activity itself elicits the potentiation. In addition to the bicuculline-induced potentiation of the monosynaptic EPSP, a polysynaptic excitatory component triggered by stimulation in area CA3 was unmasked. As excitatory connections are four times more probable between CA3 pyramidal cells than between CA1 cells in slice cultures, the recruitment of polysynaptic excitation could be due to potentiation of excitatory connections within area CA3. In order to test this hypothesis, pairs of monosynaptically connected pyramidal CA3 cells were recorded intracellularly. Long-lasting potentiation of EPSPs at CA3-CA3 unitary synapses was also found to result from epileptiform activity. Bicuculline-induced potentiation required NMDA-receptor activation, occluded further LTP induction, and could be reversed by 3 Hz presynaptic tetani. We conclude that short periods of epileptiform activity induce an LTP-like long-lasting potentiation of excitatory connections at CA3-CA1 and at CA3-CA3 cell synapses. The long-term modification of the balance between synaptic excitation and inhibition in favour of excitation could represent a substrate underlying the persistence of epilepsy after an initial insult.

## 388.9

**MINIMAL DISINHIBITION CAN ALTER SYNCHRONIZATION IN COMPUTER MODELS OF OLFACTORY CORTEX SLICE.**

S. N. Deyo\* and W. W. Lytton. Neurosimulation Laboratory, Dept. of Neurology, University of Wisconsin School of Medicine and Middleton VAMC, Madison, WI 53706.

We studied the role of GABA<sub>A</sub>-mediated inhibition in switching between synchronized and desynchronized activity in a computer simulation of an endopyriform nucleus slice. In our simulations inhibitory current induced by activation of GABA<sub>A</sub> synapses produced desynchronization by delaying the AMPA/NMDA-mediated depolarization. Thus, inhibited neurons took longer to initiate bursting after glutamatergic activation. The variability of the lag to burst onset produced phase shifting and desynchronization in the population. Desynchronization occurred at GABA<sub>A</sub> strengths that did not shorten burst duration and would therefore be difficult to observe physiologically. This effect was particularly pronounced in networks whose activity was maintained by spontaneously bursting cells or by tonic excitation whether intrinsic to the network or due to afferents. By contrast, intrinsic afterhyperpolarizing currents, which limited both burst length and duration of network oscillation, did not desynchronize the network. The pronounced effects of relatively subtle disinhibition on synchronization suggests a way that seemingly minor inhibition/excitation imbalances might lead to focal epilepsy.

Supported by both NINDS and VA grants.

## 388.6

**IMAGING SPREADING DEPRESSION IN THE RAT HIPPOCAMPAL SLICE USING INTRINSIC OPTICAL SIGNALS**

R.D. Andrew<sup>1</sup>, S. Duffy<sup>2</sup> and B.A. MacVicar<sup>2\*</sup> <sup>1</sup>Dept. of Anatomy and Cell Biology, Queen's University, Kingston, Ontario <sup>2</sup>Neuroscience Research Group, University of Calgary, Calgary, Alberta

Spreading depression (SD), a pre-migraine event characterized by propagating waves of membrane depolarization and extracellular DC potential shifts across grey matter, was induced in rat hippocampal slices by superfusion of 100  $\mu$ M ouabain (35°C). Increases in tissue light transmittance (T), which correlate with cell swelling, occur during SD onset and were used to map the propagation of SD. Following ouabain exposure, T increased by 30-50% in CA1 stratum oriens (OR) and spread along OR and into CA1 stratum radiatum (RAD) (6/6 slices). This wave front traversed CA1 OR with an average peak velocity of  $6.7 \pm 3.2$  mm/min. As the optical wave passed a recording electrode in CA1 RAD, the DC potential shifted by -20 to -30 mV, consistent with a spatiotemporal correlation of optical signals and electrophysiological SD. Propagation stopped at CA3, but with a delay crossed the hippocampal fissure into dentate gyrus ( $n = 5/6$ ). Increased T in CA1 RAD reversed over 0.5-1.5 min. Subsequently, T decreased below baseline in CA1 RAD/OR and increased in CA1 stratum pyramidale, indicating dendritic shrinkage and somatic swelling. Imaging of SD in real time using intrinsic optical signals will allow for a systematic study of the cellular mechanisms of SD propagation.

## 388.8

**DISINHIBITION IN RAT VENTRAL HIPPOCAMPAL SLICES CAUSES PROLONGED EPILEPTIC DISCHARGES WITH THREE DISTINCT PHASES**

C. Borch, R. D. Traub\*, J. G. R. Jefferys\*, Department of Physiology & Biophysics, St. Mary's Hospital Medical School, Imperial College, Norfolk Place, London, W 2 1 PG, UK; \* IBM Research Division, T.J. Watson Center, Yorktown Heights, NY 10598, USA.

Blocking inhibitory transmission in hippocampal slices causes epileptic discharges. In standard transverse slices taken from dorsal hippocampus, pharmacological blockade of GABA<sub>A</sub>-mediated inhibition with bicuculline (BIC; 10 - 30  $\mu$ M) leads to brief synchronized population bursts, often followed by a series of shorter secondary bursts, and lasting a few hundred ms overall. Here we show that disinhibition and relatively high extracellular potassium (5mM) causes much longer bursting activity in ventral hippocampal slices prepared from normal male Sprague Dawley rats. BIC (10-30  $\mu$ M) induced spontaneous synchronized bursts in the CA3 region. Stimulation of the perforant path evoked bursts lasting up to 40 s (Fig.) and spreading synchronously through the entire hippocampus proper. Bursts in the ventral hippocampus started with a primary burst and a short series of secondary bursts similar to those in dorsal slices. Subsequently, a long train of short tertiary bursts separated by brief intervals was generated in the CA3 region. These tertiary bursts differed from the primary and secondary bursts in shape and duration. They also were more resistant to NMDA receptor antagonists, indicating different means of discharge generation and synchronization for primary, secondary and tertiary components.

## 388.10

**NMDA-DEPENDENT INDUCTION OF EPILEPTIFORM ACTIVITY IN PIRIFORM CORTEX IN VITRO DOES NOT INVOLVE KINASES THAT ARE REQUIRED FOR LTP.** M.E. Domroese\* and L.B. Haberly, Neurosci. Training Prog., Dept. of Anatomy, and MD-PhD Prog., Univ. of Wisc., Madison, WI 53706.

Interictal-like epileptiform activity can be induced in piriform cortex in vitro by a brief period of bursting activity resulting from removal of  $Mg^{2+}$  or  $Cl^-$  from the bathing medium (WH Hoffman and LB Haberly, J Neurosci 9:206). This epileptiform activity usually persists for the duration of experiments after return to normal bathing medium. Because the mechanism of generation of this abnormal activity resembles that observed in slices taken from previously kindled animals (WH Hoffman and LB Haberly, Soc Neurosci Abs 17:511), the process of induction is being investigated to gain possible insights into temporal lobe epileptogenesis.

The present study tested the hypothesis that an LTP/LTD-like change in efficacy of excitatory or inhibitory synapses contributes to the burst-induction of epileptic activity. This hypothesis is suggested by the finding that, like NMDA-dependent LTP in piriform cortex (ED Kanter and LB Haberly, Br Res 525:175) and elsewhere, the induction of epileptic activity by bursting is dependent on the activation of NMDA receptors, but once induced, this dependence is lost. The hypothesis was tested by comparing the effects of KN-62, a relatively specific inhibitor of  $Ca^{2+}$ -CaM-KII, on the induction of LTP and epileptiform activity. LTP was assayed at synapses of the intrinsic associational fiber system in piriform cortex using extracellular recording methods as described previously (ED Kanter and LB Haberly, J Neurosci 13:2477). As reported for hippocampus (Ito et al, Neurosci Lett 121:119), synaptic potentiation induced by shock trains returned to near baseline within 1 hour in the presence of KN-62 (3  $\mu$ M), whereas it remained elevated in control slices. By contrast, the induction of epileptiform activity was unaffected by KN-62. Other relatively non-specific kinase inhibitors including W-7 (10-100  $\mu$ M) and H-7 (10-50  $\mu$ M), also failed to block the induction of epileptiform activity, although the effects of H-7 were complicated by its blockade of GABA<sub>A</sub>-mediated inhibition as previously documented in hippocampus (Arai et al, Soc Neurosci Abs 15:84).

It is concluded that the changes that underlie the bursting-induction of epileptiform activity in piriform cortex in vitro do not include an NMDA-dependent LTP or other process that depends on the activation of  $Ca^{2+}$ -CaM-KII, PKC, or PKA. Supported by NS19865 from NINDS.

INTRINSIC AND SYNAPTIC RESPONSES OF NEURONS IN THE RAT PERIRHINAL CORTEX. H.J. Lennox\* and D.C. McIntyre, Psychology Dept., Carleton Univ., Ottawa, Ont., Canada K1S 5B6.

The perirhinal cortex (PRh) has recently been linked to both memory and rapidly-kindled short-latency seizures. Oscillatory activity is arguably a factor in the induction and expression of both of these behaviours. Previously, we demonstrated that both the perirhinal and piriform (Pir) cortices of the rat develop and sustain prolonged oscillatory activity when a coronal slice of these structures and the adjacent amygdala nuclei is exposed to 0-Mg perfusate. The same slice preparation was used in the present study to assess the intrinsic and synaptic excitability of PRh cells. Activity in over 40 cells was recorded intracellularly in response to both briefly injected depolarizing current and to field stimulation of up to 19 slice locations. Field potentials were also recorded in the neighbourhood of the PRh cell and in dorsal Pir. Injected current evoked bursts (2-5 spikes, 4-16 ms apart) from about 1/3 of the cells. The bursts were followed by single spikes whose number increased with current intensity. Although the remaining 2/3 cells fired only single spikes during current injection, bursts were later induced in some of these cells by stimulations of the PRh, Pir, and of the lateral and basolateral (BL) nuclei. BL stimulation also elicited many of the synaptically-evoked bursts and single spikes in burst cells, and several of the larger eppsp responses in both cell types. Recurrent synaptic activity was evident both intracellularly and extracellularly from the increase in interstimuli "spontaneous" events during stimulations of either type, and from recurrent responses associated with virtually all stimulation sites. While some recurrent activity was oscillatory in nature, other events occurred at less predictable and sometimes very long intervals (sec). Although recurrent activity was not generally more than pairwise-synchronous across recording sites, stimulation of the dorsal endopiriform nucleus was notably effective in eliciting large and/or recurrent activity coincident at all three recording sites. Thus, intrinsic, local and larger network activation all support the recurrent excitation of perirhinal cells.

RHYTHMIC EXCITATORY SYNAPTIC EVENTS IN CA3 INTERNEURONS. G.J. Klapstein\* and W.F. Colmers, Dept. of Pharmacology, University of Alberta, Edmonton, Alberta, Canada T6G 2H7

Neuropeptide Y potentially inhibits epileptiform activity induced by several different methods in the *in vitro* rat hippocampal slice preparation. In the stimulus train induced bursting (STIB) model, trains of stimuli are delivered every 4 to 5 minutes to stratum radiatum of area CA3. CA3 pyramidal neurons exhibit clonic or tonic-clonic afterdischarges and delayed, spontaneous, interictal bursts. Following several trains, spontaneous, rhythmic, synchronous events (SRSEs) become evident in whole-cell pyramidal cell recordings. SRSEs are inhibited by the GABA<sub>A</sub> antagonist picrotoxin (100µM), but also require glutamate, as they can also be inhibited by the AMPA receptor antagonist NBQX (1µM), but are insensitive to NPY.

Recordings from interneurons in stratum oriens or radiatum of CA3 revealed excitatory events of similar frequency to the SRSEs recorded in pyramidal neurons. These are also inhibited by 1µM NBQX, and reverse near -9mV, indicating a glutamatergic origin, although they are not affected by the NMDA or metabotropic receptor antagonists, APV (50µM) or MCPG (100µM). They are not inhibited by 1µM NPY, differentiating their glutamatergic afferents from those innervating CA3 or CA1 pyramidal neurons. Their frequency is independent of membrane potential, suggesting that they are not caused by intrinsic oscillations. Their frequency is also unaffected during paroxysmal depolarization shifts, suggesting that the afferent drive may have distant origins.

HIGH-FREQUENCY SYNCHRONOUS FIRING OF INTERNEURONS INCREASES THE EFFECTIVENESS OF GABAERGIC TRANSMISSION. M.F. Jackson, B. Esplin and R. Čapek\*, Dept. of Pharmacol. & Therap., McGill Univ., Montreal, Que. H3G 1Y6.

Whole-cell recordings of monosynaptic IPSPs were made from rat CA1 pyramidal cells in order to determine the mechanism responsible for the increase in the effectiveness of GABA-mediated inhibition following high-frequency stimulation of inhibitory pathways, which we recently reported (Epilepsy Res. 16 (1993) 123-130). With excitatory amino acid receptors blocked by CNQX (10 µM) and CPP (5 µM) direct stimulation of interneurons by a single stimulus produced both fast- (f-) and slow-IPSPs (s-IPSPs). Stimulation by a train of 2 to 100 pulses at 100 Hz caused (1) an increase in both the amplitude and duration of the f- and s-IPSPs (by as much as 200% following a train of 5 pulses), as well as (2) the appearance of a depolarizing response (DR) which occurred between, and overlapped with, the two components of the IPSP. The amplitude of each component of the triphasic response increased with the number of pulses over the range of 2 to 5. Further increases in the amplitude of the f- and s-IPSP, over the range of 10 to 100 pulses, could not be observed due to the prominent increase in the DR. In fact, the DR increased to the point that it was able to cause the firing of a burst of action potentials. Both the f-IPSP and the DR were completely blocked by bicuculline methiodide (40 µM) suggesting that they were GABA<sub>A</sub> receptor-mediated. Under these conditions, the train-induced s-IPSP was isolated and showed a nearly fourfold increase in amplitude as well as a pronounced increase in duration. In separate experiments, the s-IPSP was blocked by the GABA<sub>A</sub> receptor antagonist, 2-hydroxysaclofen (200 µM). Such block resulted in a substantial increase of the DR indicating that the DR and s-IPSP occluded each other. The frequency-dependent changes in GABA-mediated transmission described here may play a role in synaptic plasticity (LTP and kindling) as well as in the propagation of seizures. (Supported by the MRC of Canada and FCAR)

DYE COUPLING BETWEEN RAT HIPPOCAMPAL CA1 PYRAMIDAL CELLS IN THE TETANUS TOXIN MODEL OF EPILEPSY.

S.B. Colling, W.D.C. Man, A. Draguhn\* and J.G.R. Jefferys, SPON. Brain Research Association

Department of Physiology & Biophysics, St Mary's Hospital Medical School, Imperial College, London, W2 1PG, UK. § Institut für Physiologie, Abteilung Neurophysiologie, Humboldt-Universität zu Berlin, Tucholskystr. 2, 10117 Berlin, Germany.

Electronic coupling via gap junctions represents a mechanism for intercellular communication, with the possibility for synchronization of neuronal discharge. The tetanus toxin chronic model of epilepsy produces epileptiform activity in the hippocampus, initially involving disinhibition (Whittington and Jefferys, *J. Physiol.* 481: 593-604, 1994). We have used intracellular injections of biocytin to examine whether there are morphological changes which could also be associated with this model of epilepsy.

Tetanus toxin (6ng protein; 12 MLD's), or its buffer, was stereotactically and unilaterally injected under general anaesthesia into the hippocampus of male Sprague Dawley rats (250-300g). Hippocampal slices (400µm thick) were prepared after 8 weeks. Biocytin was injected into individual CA1 pyramidal cells and then visualized using the diaminobenzidine method for peroxidase.

Only 7% of biocytin injections into single cells from the buffer injected group resulted in "dye-coupled" cells. In contrast, a significantly higher number of cell impalements in the tetanus toxin treated group resulted in dye-coupled cells (63%,  $P < 0.007$ ). Half of these coupled cells were joined at the soma, and the other half appeared to be linked by dendrodendritic contacts. In the latter case, the separation of the soma was  $84 \pm 24 \mu\text{m}$ .

Increased electrotonic connectivity in the tetanus toxin treated group may play a role in the synchronization and maintenance of epileptiform activity. Further work is required to determine whether these dendrodendritic contacts are gap junctions.

NEURONAL BURSTING ACTIVITY INDUCED BY RISING TEMPERATURE IN THE HIPPOCAMPAL SLICE. V.Y. Vasilenko, T.A. Petrushuk, R. Sankar\* and R.A. Wallis, Inst. Physiol. Acad. Sci., 220072 Minsk, Belarus; and Depts. of Neur. & Ped., UCLA and Sepulveda VAMC, Sepulveda, CA 91343.

The occurrence of febrile seizures has been demonstrated to correlate with the rate of temperature rise developing during fever. The hippocampus is known to be involved in the development of seizures from a variety of etiologies. Therefore, we evaluated the effect of temperature rise upon the firing rate of CA3 pyramidal neurons in the hippocampal slice.

Single-unit activity of CA1 and CA3 neurons in the pyramidal layer of guinea pig slices was recorded extracellularly at temperatures ranging from 32 to 40°C. At a constant temperature of 38°C,  $4.2 \pm 0.6$  S.E. spontaneous bursts/min, and  $5 \pm 1$  impulses per burst were observed. No significant difference was seen at 32 or 40°C.

In contrast, slices given gentle warming (0.5°C/min) between 36 and 40°C displayed significant increases in firing. Spontaneous bursts/min increased to  $9.6 \pm 1.2$  ( $P < 0.01$ ), while the number of impulses per min increased to  $10 \pm 2$  ( $P < 0.05$ ). Cessation of warming or cooling at any temperature within 32-40°C was followed by a return of neuronal activity to original levels.

These data demonstrate the existence of hippocampal, which respond to temperature rise, but not constant temperature elevation, with increased burst activity. This increased neuronal firing with temperature rise, is similar to the occurrence of febrile seizures seen with rapid temperature elevation, and suggests that neuronal bursting in response to temperature rise may play a role in the generation of febrile seizures.

## 388.16

Waves of synchronous neuronal activity in neonatal rat cortical slices. A. Peinado\* Dept. of Neuroscience, Albert Einstein College of Medicine, Bronx, NY, 10461.

We have previously demonstrated that injections of the gap junction tracer Neurobiotin into single neurons in developing neocortical slices results in labeling of up to 80 neurons in the immediate vicinity of the injected cell (Peinado et al., 1993). The pattern of labeling suggested that neurons are coupled in a syncytium that spans large areas of cortex. To test this I have analyzed spatiotemporal patterns of neuronal activity under conditions that favor spread of electrical activity via gap junctions.

Transverse slices of neocortex were made from neonatal and early postnatal rat pups (P0-P7) and stained with Fura-2 AM (Yuste and Katz, 1991). Neuronal activity, as reflected by changes in Fura-2 fluorescence, was monitored at a single excitation wavelength (380 nm) with a fast cooled integrating CCD camera. Imaged area was 350µm x 350 µm.

As early as P0, addition of K<sup>+</sup> channel blockers (TEA or barium) to the aCSF to enhance the flow of currents through gap junctions induced the appearance of synchronized neuronal activity occurring as waves that travel along the horizontal axis of the cortex at 500-1000 µm/sec. Waves were abolished by TTX (1µM) but not by the broad spectrum glutamate antagonist kynurenic acid (2mM) or by combined application of NMDA and non-NMDA antagonists (APV, 100µM and CNQX, 50µM). Wave duration and frequency are 5-10 sec. and 0.02-0.1 Hz, respectively. Not all cortical areas support wave-like synchronous activity.

These results are consistent with the idea that gap junctions between neurons in developing neocortex link neurons into a syncytium capable of synchronizing large numbers of neurons under conditions that reduce potassium channel activity. Enhanced gap junctional communication may be important in synchronizing activity during seizures in early development.

INTRINSIC FIRING PATTERNS OF RAT HIPPOCAMPAL PYRAMIDAL CELLS MODULATED BY EXTRACELLULAR OSMOLALITY. R. Azouz, G. Alrov & Y. Yaari\*. Dept. of Physiology, The Hebrew University Medical School, Jerusalem, Israel.

Pyramidal cells (PCs) in the hippocampus display a gradient of burst characteristics, which ranges from regular firing to spontaneous bursting (Jensen et al., *J. Neurophysiol.* 71, 831-839, 1994). Intracellular recordings in rat hippocampal slices were used to examine the modulation of these firing patterns in CA1 PCs by extracellular osmolality.

Exposing PCs to hyposmolar saline (260 mOsmol/Kg) had no effect on passive membrane properties, but the spike afterdepolarization was increased. Most regular spiking cells were converted to bursters by hyposmolar saline. Conversely, subjecting PCs to hyperosmolar saline (340 mOsmol) decreased fast spike afterhyperpolarization and afterdepolarization. Most burst-firing PCs were converted into regular spiking cells.

Burst firing persisted in normosmolar saline in which  $\text{Ca}^{2+}$  currents were suppressed by equimolar replacement of  $\text{Ca}^{2+}$  with  $\text{Mn}^{2+}$ . Hyperosmolar saline converted burst firing cells into regular spiking cells also in this condition, indicating that modulation of  $\text{Ca}^{2+}$  currents and  $\text{Ca}^{2+}$ -gated  $\text{K}^{+}$  currents is not involved in this action.

Blocking most  $\text{K}^{+}$  currents with TEA and  $\text{Ca}^{2+}$ -free  $\text{Mn}^{2+}$  saline induced  $\text{Na}^{+}$ -dependent plateau afterdepolarizing potentials. Hyposmolality prolonged the duration of the plateau potential, whereas hyperosmolality reduced it.

We conclude that the firing pattern of CA1 PCs are strongly modulated by extracellular osmolality. The osmotic effects may be mediated by alterations of the ratio of persistent  $\text{Na}^{+}$  to  $\text{K}^{+}$  currents.

ROLE OF NONSYNAPTIC MECHANISMS IN THE SPREAD OF EPILEPTIFORM ACTIVITY IN AREA CA1 OF THE HIPPOCAMPUS. S.R. Sinha\* and P. Saggau. Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

*In vitro* studies have shown that epileptiform activity can occur even when synaptic transmission is blocked. Thus, in addition to synaptic spread, several nonsynaptic mechanisms, including electrotonic coupling, changes in ionic concentrations and ephaptic coupling, have been postulated. We are investigating if such nonsynaptic mechanisms play a role in the spread of epileptiform activity in an *in vitro* epilepsy model where synaptic transmission remains intact: application of the  $\text{K}^{+}$ -channel blocker 4-aminopyridine to guinea pig transverse hippocampal slices.

We employed a technique using two optical indicators for simultaneously recording transients of membrane potential ( $V_m$ ) and calcium ( $[\text{Ca}^{2+}]_i$ ) with high spatio-temporal resolution (Sinha, et al., *J. Neurosci. Methods*, in press). The optical indicators were bath applied; therefore, both signals recorded at each location are the weighted average of pre- and postsynaptic structures. We observed that the delay between the voltage and  $\text{Ca}^{2+}$  transients increased in the direction of propagation. The  $\text{Ca}^{2+}$  transient consists of two temporally distinct components, presynaptic followed by the postsynaptic transient. We hypothesized that the increase in delay reflected a decreased contribution from the presynaptic component, and the occurrence of a postsynaptic  $\text{Ca}^{2+}$  transient without a presynaptic transient is indicative of nonsynaptic spread. To test this hypothesis we investigated the effect of changing the osmolality of the bathing medium on this delay during evoked epileptiform activity. A hypo-osmolar solution (-40 mOsm) increased the delay compared to control conditions in the same slice; hypo-osmolality shrinks the extracellular space and thus enhances the effects of changes in extracellular concentrations and of ephaptic coupling. Accordingly, a hyper-osmolar solution (+40 mOsm) should reduce these effects and indeed caused a slight decrease in the delay. Thus, even when synaptic transmission is intact, nonsynaptic mechanisms play a role in the spread of epileptiform activity in area CA1 of the guinea pig hippocampus.

## 388.18

EFFECTS OF REDOX MANIPULATIONS ON LOW MAGNESIUM-INDUCED EPILEPTIFORM ACTIVITY IN IMMATURE RAT HIPPOCAMPAL SLICES. C. Wang\* and E. E. Jensen, Dept. Neurol. Children's Hosp. Boston, MA 02115.

Recent studies have demonstrated that sulfhydryl residues in NMDA receptor may function as redox modulatory sites and redox manipulations of these sites can regulate NMDA-induced currents. In this study, we tested the effects of 5,5'-dithiobis-2-nitrobenzoic acid (DTNB) and sodium nitroprusside (SNP), which are shown to oxidize NMDA receptor redox sites, on low magnesium-induced ictal activity in hippocampal slices from immature Long Evans rat pups (10-15 day old). Extracellular field potentials were recorded in area CA1. Bath application of the oxidizing agent DTNB (1 mM) completely blocked spontaneous ictal discharges in 9/14 slices ( $p = 0.0003$ ) within one hr perfusion period. The effect of DTNB persisted after 30 min washout. Application of the reducing agent dithiothreitol (DTT, 1 mM) or tris-(2-carboxyethyl)phosphine (TCEP, 1 mM) reversed the effect of DTNB in 5/5 and 3/4 slices respectively. Bath application of SNP, (50  $\mu\text{M}$ ) inhibited ictal activity in all tested slices ( $n = 8$ ,  $p < 0.0001$ ) within 30 min. The effect of SNP persisted after 30 min washout. DTT (1 mM) reversed the effect of SNP in 7/8 slices. Interictal activity was seen when ictal activity was inhibited by DTNB or SNP. These results indicate that redox agents can modify epileptiform activity, possibly via an action on the NMDA receptor redox site. Redox agents may have potential in the treatment of epilepsy. ## EPILEPSY: BASIC MECHANISMS III

## 389.1

ABSENCE OF GRANULE CELLS DOES NOT PREVENT KAINIC ACID INDUCED PYRAMIDAL CELL DEATH IN THE CA3 AREA OF THE ADULT RAT HIPPOCAMPUS. Zs. Horváth\*, G. Czéh, B. Czéh and L. Seress. Department of Physiology, University Medical School Pécs, 7643-Pécs, Hungary.

Newborn Wistar rats were X-ray irradiated. Two and three month after irradiation kainic acid were injected into the cerebral ventricles or directly into the Ammon's horn, using stereotaxic conditions. Other animals received colchicine injection into the remaining dentate gyrus and two weeks later they were also injected with kainic acid. The effect of kainic acid was also examined in slice preparations.

X-ray irradiation destroyed 85% of granule cells of the dentate gyrus. A consecutive colchicine injection resulted in a complete loss of granule cells. Under both experimental conditions a single injection of kainic acid resulted in behavioral signs of seizures and loss of CA3 pyramidal cells both in Nissl and Timm stained sections. In the slice preparations from X-ray irradiated animals, perfusion of 500 nM kainic acid induced epileptiform discharges of the CA3 pyramidal cells.

**In conclusion:** Loss of presynaptic kainic acid receptors does not prevent kainic acid induced epileptic activity, and the consequent pyramidal cell loss in the adult rat hippocampus. This suggests that matured kainic acid receptors at the postsynaptic site are sufficient to mediate the typical overexcitation of pyramidal cells. Therefore, not the lack of mossy fibers, but immaturity of kainic acid receptors may explain the lack of kainic acid effect in the young (1-15 day old) rats.

## 389.2

NPY RECEPTORS IN THE RAT HIPPOCAMPUS AFTER KAINIC ACID-INDUCED LIMBIC SEIZURES. C. Schwarzer, C. Röder, G. Sperk\*, M. Gobbi\*, T. Mennini\* and A. Vezzani\*. Dept. of Pharmacology, Univ. Innsbruck, A-6020 Innsbruck, Austria. \*Istituto di Ricerche Farmacologiche "Mario Negri", I-20157 Milan, Italy.

Changes in peptide YY (PYY) receptor binding were investigated at various intervals after kainic acid (KA, i.p., 10-12 mg/kg) induced limbic seizures. Brain slices were incubated with  $^{125}\text{I}$ -PYY (75 pM) in the presence and absence of  $[\text{Leu}^{31}][\text{Pro}^{34}]\text{NPY}$  (100 nM), representing global and  $\text{Y}_2$  specific binding, respectively. PYY binding consisted mainly of  $\text{Y}_2$  sites in the hilus of the dentate gyrus and in the hippocampus proper and of  $\text{Y}_1$  sites in the molecular layer of the dentate gyrus. Six to 24 h after KA, global PYY binding and  $\text{Y}_2$  specific binding were markedly enhanced in the strata radiatum and oriens CA3 (maximal increase of 185% and 175% of control respectively). Seven and 30 days after KA, a reduction of these sites by up to 63% was found. In the hilus of the dentate gyrus an increase of global PYY binding by up to 400% was observed after 24 h which became attenuated to 125% above controls after 30 days. In the molecular layer of the dentate gyrus global PYY binding increased by up to 90% between 6 and 24 h after KA injection and was reduced by 37% after 30 days. These late reductions in receptor binding were prevented by injecting phenobarbital (60 mg/kg) 3 h after KA.

The early general increase in NPY receptors suggests a facilitation of NPY-mediated neurotransmission. The subsequent decrease in NPY binding may be related to seizure-induced neuronal damage and/or to increased NPY release previously demonstrated. The lasting increase in  $\text{Y}_2$  specific receptors in the dentate hilus is consistent with their proposed localization on mossy fibers. Augmented transmission through these receptors may suppress glutamate release from mossy fibers and thus may ameliorate seizure activity.

## 389.3

**NEUROPROTECTIVE EFFECT OF BASIC FIBROBLAST GROWTH FACTOR ON SEIZURE-INDUCED BRAIN DAMAGE** Z. Liu<sup>1</sup>, J.C. Neill, C.E. Stafstrom and G.L. Holmes Dept. of Neurology, Children's Hospital and Harvard Medical School, Boston, MA 02115

We have previously reported that chronic infusion of basic fibroblast growth factor (bFGF) during seizures reduced seizure-induced cell loss in the hippocampus. In this study, we further examined the effect of such treatment on seizure-induced long-term behavioral deficits.

Prolonged seizures were induced by i.p. injection of kainic acid (KA) in 35 day-old rats. bFGF or phosphate buffered saline (PBS) was chronically infused into the lateral ventricle 2 days before and 5 days after the induction of seizures. Treatment with bFGF or PBS did not modify the latency and duration of the acute seizures. However, rats pretreated with bFGF had significantly less behavioral deficits than rats pretreated with PBS. These results suggest that bFGF is neuroprotective against seizure-induced brain damage.

**NGF REDUCES DNA FRAGMENTATION IN CA1 NEURONS BUT NOT ELSEWHERE AFTER SYSTEMIC KAINATE-INDUCED SEIZURES IN THE RAT.** S. W. Weiss, O. Cataltepe and A.J. Cole\*. Epilepsy Research Lab, Neurology Service, Massachusetts General Hospital, and Harvard Medical School, Boston, MA, 02114.

In previous studies we have used in situ nick translation histochemistry to characterize the magnitude and distribution of DNA fragmentation in rat brain after limbic seizures induced by systemic kainate. This assay offers single cell resolution and results may be easily quantified, especially in anatomically compact structures such as hippocampus. NGF is neuroprotective in models of cerebral ischemia which may induce excitotoxic cell death. We therefore examined the effect of intraventricular infusions of NGF on the occurrence of DNA fragmentation after systemic kainate. Male SD rats (200 gm) were implanted with osmotic pumps containing NGF or 1% BSA in ACSF. NGF was infused into the lateral ventricle at a rate of 1 µg/day for 6 days. On day 3, all animals were treated with systemic kainate (15 mg/kg) and severity of resultant seizures was graded. 72 hours later animals were sacrificed and brains were processed for in situ nick translation histochemistry. Cryostat sections (11 µm) were incubated with DNA polymerase I in the presence of biotinylated dUTP, and incorporation was visualized with avidin-biotin-peroxidase histochemistry. Sections were examined by an observer blinded to treatment and staining severity was assessed. Cell counts in hippocampus were performed. Animals were stratified according to seizure severity grade. At every grade, we found significant reductions in nick translation positive cells in NGF treated animals in CA1 (paired t-test  $p < .0001$  in preliminary analysis) but not in other structures. We conclude that NGF protects CA1 neurons from kainate induced DNA fragmentation. While NGF may prevent apoptosis during neuronal development, the mechanism of NGF's neuroprotective action in this model remains uncertain.

## 389.7

**MUSCIMOL INJECTIONS IN THE ZONA INCERTA EXACERBATE PILOCARPINE-INDUCED SEIZURES.** S. Sakabe, C. Hamani, L. E. A. M. Mello Departamento de Fisiologia, Escola Paulista de Medicina-UNIFESP, 04023-900 São Paulo, Brazil.

The Zona Incerta (ZI), a subthalamic structure, has been proposed to play an important role in motor control mechanisms in animals and humans. Connections of the ZI to the substantia nigra (SN), entopeduncular nucleus have been demonstrated in rats. Furthermore manipulation of excitatory neurotransmission within the SN pars reticulata or entopeduncular nucleus modulates the threshold for pilocarpine-induced seizures. The ZI appears to give rise to a major cortical projecting system and to receive inputs from the cortex, dorsal column nuclei, trigeminal nuclear complex and some portions of the superior colliculus. The ZI neurons may collateralize to provide GABAergic inputs to both neocortex and brain stem structures. Due to all the above mentioned structural connections it is supposed to provide an important link between ascending sensory and motor systems. Male Wistar rats were stereotactically implanted with guide cannulae into ZI bilaterally under chloral hydrate anesthesia. After a three to five days postoperative period, rats were injected with (0.5 µL/side, over a period of 2 min) saline or muscimol (100 nmol/side) into the ZI. After another 30 min period animals were injected with Pilocarpine (PIL), either 350 mg/kg or 250 mg/kg, i.p.. At the end of the experiments animals were deeply anesthetized, injected with 0.2 µL of a 2% Evans Blue solution via the guide cannulae, perfused with 10% formalin, and had their brains processed for histological analysis. Injection of Muscimol in the ZI reduced in 60% the latency for status epilepticus after 350 mg/kg of Pilo. Under 250 mg/kg of Pilo every muscimol injected rat developed SE, compared to only 40% of the control animals. Our results suggest an important role for the ZI in modulating the limbic seizures induced by PIL. Research supported by CNPq, CAPES, FAPESP and FINEP (Brazil).

## 389.4

**IBOTENIC ACID-INDUCED LESIONS OF THE PONTINE RETICULAR FORMATION ATTENUATE MAXIMAL ELECTROSHOCK SEIZURES IN RATS.** M.L. Maring-Smith\*, R.W. Clough<sup>1</sup> and R.A. Browning. Depts. of Physiology and Anatomy<sup>1</sup>, So. Ill. Univ. Sch. of Med., Carbondale, IL 62901.

Large bilateral mechanical lesions of the pontine tegmentum involving the superior cerebellar peduncles (PCS) and the nucleus reticularis pontis oralis (RPO nucleus) are more effective in attenuating the tonic components of maximal electroshock (MES) seizures than discrete electrolytic lesions, which damage only the PCS or the RPO. Further, reversible inactivation of the RPO, via microinfusion of lidocaine HCl, attenuates MES seizures in a dose- and volume-dependent manner. As electrolytic lesions and mechanical lesions do affect, and lidocaine microinfusion may affect cell bodies and fibers of passage, the effect of ibotenic acid (IBO)-induced lesions of the RPO on MES seizures was examined. IBO, an excitatory amino acid agonist, has been reported to damage cell bodies, while sparing fibers of passage. Additionally, in order to investigate whether the total volume of pontine tegmentum damaged influences the degree of seizure attenuation, the effects of bilateral lesions produced by 0.25 or 0.5 µl of IBO were examined. Sprague-Dawley rats received MES seizure pretreat (150 mA, 0.2 sec, 60 Hz, via corneal electrodes). Under anesthesia, bilateral injections into the RPO (AP 6.5 mm posterior to bregma, ± 1.5 mm lateral from the midline, 7.5 mm ventral to dura) of 0.25 or 0.5 µl of IBO (10 µg/µl) or saline, were made at a rate of 0.25 µl/min. MES testing was carried out 4, 7, 14, 21, and 28 days later. Seizure attenuation was found to correlate with the extent of damage produced. The largest lesions reduced tonic seizure severity in up to 100% of animals. However, histological examination suggested that fibers of passage within the lesions may have sustained damage. In summary, IBO-induced lesions of the RPO attenuated the tonic components of MES seizures. Whether the effect is due to intrinsic neuron death or damage to fibers of passage remains to be determined.

## 389.6

**EFFECTS OF PENTOBARBITAL, SCOPOLAMINE AND MK-801 ON PILOCARPINE-INDUCED SEIZURE AND BRAIN DAMAGE.** M. G. Lee\*, B. J. Choi, K. H. Lee, J. Y. Chou, and C. Y. Kim. Dep't of Pharmacology, Sch. of Med., and <sup>1</sup>Dep't of Dental Pharmacology, Sch. of Dent., Kyungpook Nat'l Univ., Dong-In-Dong 2-101, Taegu 700-422, Korea

Intraperitoneal pilocarpine (500 mg/kg) injection induced tonic and clonic seizures for 10-20 min and electrical seizure activities persisted after the behavioral seizures in rats. Pilocarpine-induced behavioral seizure was monitored by recording the vibration and electrical activity was measured from hippocampal electrodes. The behavioral seizure was significantly suppressed by the order of pentobarbital (5 mg/kg i.p.), scopolamine (10 mg/kg i.p.) and MK-801 (0.5 mg/kg i.p.). The electrical seizure was suppressed by pentobarbital, but was enhanced by MK-801. In scopolamine-treated group the electrical seizure was suppressed but there were regular bursts. We observed pyramidal layer of CA1 and CA3 area and granule cell layer to examine the degree of the hippocampal damage. Pentobarbital, scopolamine and MK-801 protected the pilocarpine-induced hippocampal damage. These results suggest that the pilocarpine-induced brain damage may be a consequence of NMDA receptor activation which may not be related to electrical seizure and behavioral seizure.

## 389.8

**ULTRASTRUCTURAL ANALYSIS OF THE HIPPOCAMPUS FOLLOWING KAINIC ACID ADMINISTRATION IN THE RAT: EFFECTS OF AGE.** K.K. Weireter, E.F. Sperber<sup>1</sup> and M.T. Romero\*. Psychology Department, SUNY Binghamton, NY 13902 and <sup>1</sup>Dept. of Neurology, Albert Einstein College of Medicine, Bronx, NY 10461

The immature brain appears to be resistant to the neurotoxic effects of kainic acid (KA) administration and subsequent seizure activity. Light microscopic analysis of the adult brain demonstrates neural degeneration, cell loss and mossy fiber sprouting in the CA3/CA4 areas of the hippocampus following systemic KA administration. In the young animal however, these effects have not been observed.

In order to determine whether previously undetected ultrastructural changes occur in the hippocampus of the young animal, we injected 14-day rat pups with a single dose of KA (5mg/kg) or vehicle. Four days later the animals were sacrificed and their brains processed for electron microscopy. The CA3/4 regions were dissected and analyzed at the ultrastructural level. Preliminary data indicate that there are alterations in CA3/4 pyramidal cells in the KA treated animal. Small cytoplasmic vacuoles are found and irregular cell limits. The neuropil surrounding the cells is also changed, with slight enlargement of neuronal processes. The number and characteristics of synapses appear not to be affected. Subsequent studies will determine whether these changes are the acute response to tissue insult.

## 389.9

ULTRASTRUCTURAL CHANGES IN THE PILOCARPINE MODEL OF CHRONIC EPILEPTIC SEIZURES. R.V.R. Duran\*, R.L. Smith, E.F. Haapalainen and L.E.A.M. Mello. Depto. de Fisiologia e Depto. de Morfologia, Escola Paulista de Medicina, UNIFESP, São Paulo, 04023-900 Brazil.

Assessment of the morphological changes in the epileptic condition has helped in the understanding of brain circuitry and its plasticity. Chronic spontaneous recurrent seizures were obtained by inducing status epilepticus (SE) in adult male, EPM-1 Wistar rats with pilocarpine (320 mg/kg, i.p.). More than 9 (nine) months after SE, the animals were perfused and fixed with paraformaldehyde 2% and glutaraldehyde 2.5% under anesthesia. The hippocampal subfields were dissected under light microscopy and processed for electron microscopy. Qualitative analysis of the different hippocampal layers (e.g. oriens, radiatum, etc.) revealed that changes in the neuropil were specific for each different layer. Findings included: enlarged and discontinuous (perforated) synapses; normal mitochondria (not swollen) but with asymmetrical aspects of the inner membrane; aberrant extracellular collagen deposited in the neuropil, next to pericytes; regions of the neuropil, surrounded by glial cell membranes, without necrotic features but with apoptotic motifs. Evidence of apoptosis, plastic changes of membranes (synapses and mitochondria) and collagen synthesis 9 months after the induction of SE, suggest that these events may be related to the spontaneous seizure episodes occurring in these animals. Furthermore, it suggests that epilepsy is an ongoing plastic process.

Supported by FAPESP, CNPq and FINEP (Brazil). R.V.R. Duran is a FAPESP fellow (93/0666-3).

## 389.11

DIFFERENTIAL ALTERATIONS OF HIPPOCAMPAL LEVELS OF [MET5]-ENKEPHALIN AND SOMATOSTATIN AFTER KAINIC ACID TREATMENT. K. H. Zhang, X. P. Wu, J. Wang, W. O. Zhang\* and J. S. Hong.\* Dalian Medical University, Dalian, China. +NIEHS/NIH, Research Triangle Park, NC 27709.

Several studies have shown that intrahippocampal injection of enkephalins enhance hippocampal excitability and may produce both EEG and behavioral seizures. In contrast, somatostatin has been reported to have an inhibitory action on the pyramidal neurons of the hippocampus. To further study the roles of enkephalins and somatostatin in the excitability of the hippocampus, we determined the changes of these two neuropeptides after kainic acid (KA) treatment. A single injection of KA (10 mg/kg, s.c.) produced limbic seizures lasting 4-6 hours in rats. Two days after KA injection, hippocampal level of somatostatin were significantly reduced. Immunocytochemistry revealed a large loss of somatostatin-positive neurons in the hilar region. Similar to previous reports, KA treatment greatly enhanced the immunoreactivity of [Met5]-enkephalin in both the mossy fiber and perforant path terminals of the hippocampus. In addition, [Met5]-enkephalin-immunoreactive neurons were observed in the ventral hippocampus. *In situ* hybridization revealed an elevation of pre-enkephalin mRNA in both the hippocampus and entorhinal cortex of the convulsed rats. The differential changes of somatostatin and enkephalins after KA treatment may be responsible for the enhanced seizure susceptibility which is often observed in animals with a prior history of seizures.

## 389.13

DECREASED MAGNESIUM AFFINITY OF NMDA RECEPTOR-CHANNELS UNDERLIES EPILEPTIFORM ACTIVITY IN THE KAINIC ACID-LESIONED RAT HIPPOCAMPUS. Y. Chen, J.E. Chad & H.V. Wheal\*. Dept. of Physiology & Pharmacology, University of Southampton, Southampton, SO16 7PX, U.K.

An enhanced NMDA component in synaptic transmission has been shown in various animal models of epilepsy, such as the kainic acid-lesioned model and the kindling model, as well as in human epileptic tissue. The reduced sensitivity of the NMDA-mediated response to  $Mg^{2+}$  has also been demonstrated (Turner & Wheal, 1991, *J. Neurosci.* 11: 2786-2794). We therefore set out to investigate the role of NMDA receptor-channels and their voltage-dependent block by  $Mg^{2+}$  in the kainic acid model of epilepsy (Chen et al., 1994, *Soc. Neurosci. Abstr.* 20:407).

Unilateral kainic acid-lesion was carried out on adult Wistar rats (180g) by injecting kainic acid (0.5 µg in 0.5 µl, phosphate buffer, pH 7.4) into the left ventricle. The rats were left to recover for one or four weeks. In our recent experiments, using whole-cell patch clamp recordings from CA1 cells in both lesioned and control slices (400 µm), we have demonstrated that the voltage-dependence of the NMDA receptor-channel has been altered. The calculated apparent dissociation constant of the  $Mg^{2+}$  block ( $K_{Mg}$ ) was 7.52 mM for the lesioned ones ( $n=4$ ), which was 4.3 times that of the control (1.76 mM,  $n=6$ ). The reduced voltage dependence was brought back towards the control level in the presence of higher  $[Mg^{2+}]_i$  (2.6 mM instead of the normal 1 mM). The same concentration of  $Mg^{2+}$  was also shown to diminish the bursting activity recorded as population spikes in the CA1 area. The effect of 2.6 mM  $[Mg^{2+}]_i$  for 10 min was equivalent to that of 10 µM DL-APV for the same time period, suggesting (1) that a large portion of the bursting activity is NMDA-mediated, and (2) the sensitivity of the NMDA component to  $Mg^{2+}$  ions.

Our results support the essential role of NMDA receptors in maintaining the epileptiform activity. The long-term (one to four weeks) reduction of the  $Mg^{2+}$  block of NMDA receptor-channels induced by the lesion process is instrumental in this role of NMDA receptors.

(Supported by the Wellcome Trust.)

## 389.10

SUPPRESSION OF PILOCARPINE-INDUCED EPILEPTIFORM ACTIVITY IN THE CA3 REGION OF RAT HIPPOCAMPUS. E.J. Hader, Y. Yang and P.A. Rutecki\*. Depts. of Neurosurgery and Neurology, Univ. of Wisconsin Medical School, Wm. S. Middleton Memorial V.A. Hospital, Madison, WI 53792

The CA3 subfield of rat hippocampal slices bathed in 7.5 mM  $[K^+]_o$  & 10 µM pilocarpine (pilo) displays ictal-like epileptiform activity (bursting at >2 Hz. for periods >3 sec.). Modeling studies suggest that dendritic  $Ca^{2+}$  oscillations and NMDA receptor activation lead to afterdischarges (Traub *et al.* *J. Physiol.* 461:525, 1993). We tested if blockade of NMDA receptors or calcium channels altered pilo-induced ictal-like activity.

Rat hippocampal slices were incubated in 7.5 mM  $[K^+]_o$  & 10 µM pilo to induce ictal-like activity. Extracellular recordings were made and the duration of ictal-like discharges and the period between them were compared before and after the addition of specific pharmacologic agents.

The NMDA antagonist DL-APV (100 µM) had no effect on ictal-like discharges. Dantrolene (100 µM), which blocks release of  $Ca^{2+}$  from intracellular stores, stopped ictal-like activity in 55% of slices. Nifedipine (1 µM), a L-type  $Ca^{2+}$  channel blocker, eliminated the ictal-like pattern in 80% of slices.  $N^6$ -Cyclopentyladenosine (CPA, 100 nM), a specific agonist of the  $A_1$  adenosine receptor, blocked ictal-like activity in 75% of slices. Baclofen (1 µM), a GABA<sub>B</sub> receptor agonist also stopped ictal discharges in >80% of slices.

We conclude that NMDA activation is not required for generation of the ictal-like activity produced by pilocarpine. This pattern appears to be mediated in part by activation of L-type  $Ca^{2+}$  channels and can be blocked by adenosine  $A_1$  and GABA<sub>B</sub> receptor activation. Supported by the NIH and VA research.

PILOCARPINE-INDUCED SEIZURES CAUSE CHANGES IN MU AND DELTA OPIOID RECEPTOR CIRCUITRY IN THE RAT DENTATE GYRUS. S.B. Bausch\*, T.M. Esteban and C. Chavkin. Department of Pharmacology, University of Washington, Seattle, WA 98195-7280

The pilocarpine model of temporal lobe epilepsy described by Turski *et al.* (1983) was used to study changes in dentate gyrus circuitry induced by recurrent seizures. As previously reported by other investigators, pilocarpine-treated rats developed recurrent seizures and showed a loss of hilar neurons and mossy fiber sprouting. Mu opioid receptor immunoreactivity (-IR) was not significantly changed in the granule cell layer but was decreased by approximately 60% in the hilus. In contrast, delta opioid receptor-IR was decreased by 30-40% in both the granule cell layer and hilus. By 14 days an increase in diffuse mu opioid receptor-IR and GABA-IR was evident in the inner molecular layer of animals that had pilocarpine-induced seizures. No change in delta opioid receptor-IR was observed in the molecular layer. These data suggest sprouting of mu opioid receptor-positive GABAergic fibers.

The sensitivity to opioids was also affected by pilocarpine-induced seizures. Application of the mu opioid receptor agonist, DAMGO, caused a 40% increase in primary population spike excitability in control animals. In animals that exhibited seizures, this response to DAMGO was decreased to approximately 6% at 5-13 days post-injection of pilocarpine then recovered to control levels by 2-6 weeks post-injection. A secondary spike was generated in response to DAMGO at all time points. Application of the delta agonist, DPDPE, caused an increase in primary population spike excitability in control animals but decreased excitability in rats that had pilocarpine-induced seizures. Preliminary data showed that in the presence of bicuculline, DPDPE caused a decrease in population spike excitability in both control and pilocarpine-treated animals. These data suggest that there is a loss of a subpopulation of mu and delta opioid receptors followed by compensatory changes for mu but not delta opioid receptor circuitry. Supported by DA04123 and DA07278.

## 389.14

LOSS OF NADPH DIAPHORASE-POSITIVE NEURONS IN THE DORSAL HIPPOCAMPAL FORMATION OF PILOCARPINE CHRONIC EPILEPTIC RATS. C. Hamani<sup>1</sup>, L. E. A. M. Mello<sup>1</sup>, F. T. A. Costa<sup>2</sup>, R. Mendez-Otero<sup>2</sup>. Depto. de Fisiologia, Escola Paulista de Medicina UNIFESP, 04023-900 São Paulo, Brazil<sup>1</sup>; Instituto de Biofísica, UFRJ, 21949-900 Rio de Janeiro, Brazil<sup>2</sup>

Nitric oxide (NO) is a novel neuronal retrograde messenger proposed to play important roles in various CNS functions and neuronal plasticity. In the kainic acid model of epilepsy, N-nitro-L-arginine, a nitric oxide synthase inhibitor, was suggested to enhance the severity of the seizures through suppression of the NO synthase activity in the vascular endothelium. In our study, adult male Wistar were injected with pilocarpine (PIL) (350 mg/kg i.p.) developing status epilepticus (SE), and following a period of approximately two weeks spontaneous recurrent seizures could be behaviorally observed. Six to nine months after induction of SE, they were sacrificed, perfused with a mixture of paraformaldehyde 0.5% and glutaraldehyde 2%, and their brains were processed for direct NADPH histochemistry. Quantitative counts of NADPH-positive neurons were made with a reticulate grid under optical microscopy for each of the subfields of the dorsal hippocampus. Compared to an age-matched control group, the PIL injected rats showed a significant decrease in NADPH-stained neurons in the hilus, superior blade of the polymorphic layer of the dentate gyrus, stratum pyramidale and radiatum in the CA3, and stratum oriens, pyramidale and radiatum in CA2 and CA1 of the dorsal hippocampal formation. Overall the reduction in NADPH-stained neurons in the epileptic animals was of 50%. No change between the two groups was seen for stratum granulosum and moleculare of the dentate gyrus, the inferior blade of the polymorphic layer of the dentate gyrus, nor for the CA3 oriens. Considering the fact that NADPH-positive neurons in the hippocampal formation are mostly GABAergic, the loss of these neurons may be associated to the epileptic condition of these animals.

REGIONAL DISTRIBUTION AND TIME-COURSE OF CALPAIN ACTIVATION FOLLOWING KAINATE-INDUCED SEIZURE ACTIVITY IN RAT BRAIN. X. Bi\*, V. Chang, G. Tocco and M. Baudry, Neurosci. Prog., USC, Los Angeles, CA 90089

Systemic injection of kainic acid (KA) in adult rat elicits epileptic seizure activity and a pattern of neuronal pathology which exhibits several features of human temporal lobe epilepsy. KA-induced seizure activity is accompanied by the activation of calpain in limbic structures. In the present study, we evaluated the spatio-temporal activation of calpain after the onset of seizure activity by immunohistochemistry using an antibody for the selective breakdown product of spectrin (sbdp) generated by calpain-mediated proteolysis of spectrin. In addition, we compared the spatio-temporal pattern of changes in SBDP immunoreactivity with that of changes in immunoreactivity to some subunits of AMPA receptors. One hour after seizure onset, sbdp accumulation was observed in selected interneurons in stratum oriens and in the hilus of dentate gyrus. By 4 hrs after seizure onset, sbdp immunoreactivity was prominent in dendritic fields of the hippocampus as well as in neurons in thalamus and piriform cortex. By 8 hrs, sbdp immunoreactivity had disappeared from interneurons but was localized in pyramidal cell bodies in hippocampus. Intense labeling of cell bodies and dendritic fields persisted until 5 days following KA treatment. Changes in GluR subunit immunoreactivity were mirror images of those seen for sbdp. In general, increased sbdp immunoreactivity in dendritic fields was associated with decreased GluR1 immunoreactivity. However, increased sbdp immunoreactivity in neuronal perikarya was also associated with increased GluR1 immunoreactivity. These results indicate that calpain activation following seizure onset exhibits a very specific spatio-temporal pattern, with activation in restricted interneurons preceding widespread activation in pyramidal neurons. Calpain activation also precedes clear signs of neuronal pathology and could thus represent an initial trigger for neuronal pathology. Finally, the results clearly demonstrate that calpain activation results in rapid alterations in GluR subunit properties which could be involved in the development of hyperexcitability observed following seizure activity.

## 389.17

ELEVATION OF  $[K^+]_o$  REVEALS ABNORMAL ACTIVITY IN THE DENTATE GYRUS OF SLICES FROM EPILEPTIC KAINATE-TREATED RATS. P.R. Patrylo\* and F.E. Dudek, Department of Anatomy and Neurobiology, Colorado State University, Fort Collins, CO 80523

The kainate-treated rat is an animal model of temporal-lobe epilepsy. Rats were given either multiple kainate (IP; 5 mg/kg per hr) or saline (150 mM NaCl) injections for 5-8 hr. Approximately 1-4 months post-treatment, most kainate-treated rats started having spontaneous convulsive seizures. In normal ACSF (i.e., 1.3 mM  $Ca^{2+}$ ; 3 mM  $K^+$ ) most slices prepared from kainate-treated rats displayed multiple population spikes to perforant path stimulation. Hilar stimulation resulted in abnormal responses, ranging from multiple population spikes to prolonged negative field-potential shifts, in approximately 15% of slices. When  $[K^+]_o$  was elevated to 6 mM, however, most slices showed prolonged negative field-potential shifts with a corresponding increase in multiple-unit activity to hilar stimulation. In control slices, hilar stimulation did not elicit prolonged negative field-potential shifts. Raising  $[K^+]_o$  to 9 mM resulted in spontaneous bursts, ranging in duration from 200 ms to 20s, in some slices from the kainate-treated rats. Timm's staining revealed mossy fiber sprouting in all slices from kainate-treated rats. These results suggest that physiological changes (i.e., elevated  $[K^+]_o$ ) can unmask new recurrent excitatory circuits in the dentate gyrus from epileptic kainate-treated rats.

Supported by NIH grant NS16683

## 389.19

EVIDENCE FROM GLUTAMATE MICROSTIMULATION FOR NEW LOCAL EXCITATORY CIRCUITS IN THE DENTATE GYRUS OF KAINATE-TREATED RATS

J.-P. Wuarin\* and F.E. Dudek, Dept. of Anatomy and Neurobiology, Colorado State Univ., Fort Collins, CO 80523.

Hippocampal mossy fiber reorganization occurs in patients with temporal lobe epilepsy and in animal models of epilepsy. Mossy fiber sprouting has been proposed to form excitatory connections between dentate granule cells, which could lead to hyperexcitability and contribute to the generation of seizures. To test this hypothesis, we used intracellular recordings, combined with microapplication of glutamate in the granule cell layer, to determine if local excitation of granule cells could evoke an increase in the size and/or frequency of excitatory postsynaptic potentials (EPSPs) in neighboring granule cells. Slices were prepared from kainate-treated animals ( $n = 5$ ) that displayed spontaneous recurrent seizures. Timm's stain revealed mossy fiber sprouting in all the slices from all the animals. In the presence of bicuculline (10  $\mu$ M) and high  $K^+$  (6 mM), electrical stimulation of the hilar region (which antidromically activated mossy fibers), evoked bursts of population spikes, negative field-potential shifts and delayed bursts in the dentate gyrus in all slices tested ( $n = 24$ ). In these conditions, glutamate microdrops (20 mM, 50-100  $\mu$ m in diameter) applied in the granule cell layer near the recorded cells (50-700  $\mu$ m) evoked bursts of EPSPs in 20 out of 27 cells tested. Glutamate microdrops, tested in 16 cells from 5 control rats, had no effect on the size and frequency of EPSPs. These results support the hypothesis that the reorganization of mossy fibers in rats treated with kainate forms excitatory connections between granule cells and leads to seizure-like activity.

Supported by NIH grant NS16683.

## 389.16

INTRACELLULAR CORRELATES OF SYNCHRONOUS EXCITATORY AND INHIBITORY ACTIVITY INDUCED BY CARBACHOL IN ENTORHINAL CORTEX LAYER II. R. Klink\*, C. T. Dickson and A. Alonso, Dept. Neurology & Neurosurgery, M.N.I. and McGill University, Montreal, PQ, Canada, H3A-2B4

As shown in an accompanying communication (Dickson and Alonso, *Soc. Neurosci.* 1995), synchronized field oscillations resembling ictal and/or inter-ictal events can be generated by bath application of the cholinomimetic carbachol (CCh; 10-30  $\mu$ M) independently in layer II and layer IV of the entorhinal cortex (EC). In the present study we examined the cellular and synaptic mechanisms underlying CCh-induced population oscillations in neurons from EC layer II by means of intracellular recordings in slices. We focused on layer II since it is the main origin of the perforant path and it does not contain intrinsically bursting cells; it is comprised instead of two electrophysiologically and morphologically distinct types of projection neurons: stellate cells and pyramidal-like cells (Alonso and Klink, *J. Neurophysiol.* 70, 128 1993). CCh induced a sustained depolarization in both types of neurons which led to tonic firing in the pyramids and to the manifestation of the typical intrinsic subthreshold oscillations and "cluster" discharge of the stellates. Following the depolarizing responses, field oscillations (ictal-like events) developed. These were correlated with synchronous *epsp*-driven oscillatory bursting discharge in pyramids, stellates, and interneurons. Block of glutamergic transmission with CNQX and AP-5 abolished the population oscillations and the intracellular *epsp*s. However, in these conditions, "giant" *ipsp*s, comprised of a fast and a slow component, were observed in the projection cells. These events were often, but not necessarily, correlated with small amplitude field events and could show periodicities of ~ 0.2 Hz. Both the *ipsp*s, and the field potentials were blocked by bicuculline or picrotoxin. These data suggest that CCh can induce the synchronization of GABAergic EC interneurons in the absence of excitatory amino acid transmission.

## 389.18

HYPEREXCITABILITY IN THE BASOLATERAL AMYGDALA OF KAINATE-TREATED RATS. B.N. Smith\* and F.E. Dudek, Dept. of Anat. and Neurobiol., Colorado State Univ., Fort Collins, CO 80523.

The kainate-treated rat has been used as a model of temporal lobe epilepsy. We used a modified kainate injection protocol (see Patrylo and Dudek, this meeting) that induced spontaneously recurring seizures for over one year post-injection. The hypothesis of the present study is that neuronal excitability in the basolateral amygdala (BLA) is altered after kainate treatment. Using extracellular field potential and intracellular recordings in horizontal slices, the excitability of the BLA of kainate-treated rats was compared with that of age-matched saline-treated animals.

Resting membrane potential, input resistance, and spike amplitude were not different between cells from control and kainate-treated rats. Maximal orthodromic stimulation resulted in a single population spike in the BLA of control slices and 3 to 10 spikes ( $5 \pm 2$ ; mean  $\pm$  SD;  $p < 0.001$ ) in slices from kainate-treated rats. In the presence of 10-30  $\mu$ M bicuculline, spike number was increased to  $6 \pm 1$  in control and  $8 \pm 2$  in kainate-treated animals ( $p > 0.05$ ). In nominally  $Mg^{2+}$ -free perfusion medium, control responses were only slightly modified, but population spike number was increased by more than 200% in slices from kainate-treated animals. In  $Mg^{2+}$ -free solutions containing bicuculline, spontaneous ictal-like bursts and negative DC shifts were seen in most slices tested from control and treated animals. The frequency of these events, as well as spike frequency within the bursts, was greater in the BLA of kainate-treated animals.

Therefore, kainate treatment leads to increased excitability in the BLA, which may involve both decreased inhibition and increased excitation of neurons in the BLA. Supported by postdoctoral fellowship NS09289 (BNS) and NIH grant NS16683 (FED).

## 390.1

PSYCHOTROPIC DRUG TREATMENT AND CONCENTRATIONS OF AMYLOID PRECURSOR-LIKE PROTEIN IN VENTRICULAR CSF OF DEPRESSED PATIENTS. P.T. Francis, N.A. Clarke, L.M. Brown, M.T. Webster, A.W. Procter and D.M. Bowen (SPON: Brain Research Association) Institute of Neurology, Queen Square, London, WC1N 1PJ, U.K.

We have previously shown that intractably depressed patients' psychotropic drug treatment affects the concentration of amyloid precursor protein (APP)-like immunoreactivity (APPLIR) in ventricular CSF (VCSF, Clarke et al. 1993, *Neurodegeneration* 2, p243-248). Thus, those patients receiving treatment with lithium and antidepressants had significantly lower VCSF concentrations of APPLIR than those receiving neither. The antibody used for quantitation, 22C11, does not distinguish between APP and amyloid precursor-like protein 2 (APLP2). Using a recently developed monoclonal antibody to APLP2 (Webster et al. 1995, *Biochemical Journal*, in press) we have re-examined these samples using the same paradigm. There was no significant effect of antidepressants with anticholinergic side effects or lithium on the VCSF concentrations of any of the three major high molecular weight bands identified by western blotting with the APLP2 specific antibody (Kruskal-Wallis ANOVA,  $P > 0.05$ ). This is consistent with the previous study where an APP specific antibody, 10D5, showed a greater effect of treatment conditions than the 2-fold difference demonstrated with 22C11 labelling of N-termini of APP and APLP2. This data suggests that there may be some difference in the factors controlling secretion of APP and APLP2 in humans.

## 390.3

THE EFFECTS OF HEAVY METAL IONS ON METABOLISM OF  $\beta$ -AMYLOID PRECURSOR PROTEIN AND  $\beta$ -AMYLOID IN CULTURED SMOOTH MUSCLE CELLS. J. Frackowiak\*, B. Mazur-Kolecka, R.T. Carroll\*, D.O. Espinoza, H.M. Wisniewski. NYS Institute for Basic Research in Developmental Disabilities, Staten Island, NY 10314, \*Parke Davis, Ann Arbor MI 48105.

Formation of  $\beta$ -amyloid is suggested to be the crucial pathological event in Alzheimer's disease (AD) dementia, however the cellular mechanisms of this process remain to be elucidated. Exposure to metal ions (e.g. aluminum) has been considered as one of the environmental risk factors in AD. Recently we have developed a cell culture model to study accumulation of  $\beta$ -protein and formation of  $\beta$ -amyloid using isolated canine vascular smooth muscle cells [*Neurosci Lett* 183 (1995) 120-123; *Brain Res* 676 (1995) 225-230]. We applied this culture model to study the influence of heavy metals,  $Al^{3+}$ ,  $Co^{2+}$ ,  $Cu^{2+}$ ,  $Mn^{2+}$ ,  $Zn^{2+}$ ,  $Fe^{2+}$ , and  $Fe^{3+}$  on secretion and accumulation of  $\beta$ -peptide and on the metabolism of  $\beta$ -amyloid precursor protein ( $\beta$ APP) in human and canine smooth muscle cells. Exposure to iron cations altered maturation of  $\beta$ APP and induced accumulation of  $\beta$ -protein, but not its secretion. The effect on accumulation of  $\beta$ -protein was time- and dose-dependent. The treatment with ferric and ferrous ions also stimulated cell metabolic activity (in MTT reduction test), increased cell protein content and slightly stimulated cell proliferation. These data indicate that both ferric and ferrous ions may play a role in the induction and acceleration of the pathological mechanisms leading to  $\beta$ -amyloidogenesis in AD. Supported in part by funds from the NYSOMRDD and the Fund for the Center for Trace Element Studies and Environmental Neurotoxicology.

## 390.5

AMYLOIDGENIC PROCESSING OF ALZHEIMER'S AMYLOID RECURSOR PROTEIN BY THE PROTEOLYTIC ACTIVITY ASSOCIATED WITH ACETYLCHOLINESTERASE: ITS MODULATION BY METAL IONS AND TACRINE. Young Hae Chong<sup>1,2</sup> and Yoo-Hun Suh<sup>1</sup>. <sup>1</sup>Institute of Genetic Engineering Center, Inje University, Pusan 614-735, Korea, <sup>2</sup>Department of Pharmacology, College of Medicine, <sup>3</sup>Department of Molecular Biology, Neuroscience Center, Seoul National University, Seoul 151-749, Korea.

We evaluated the possible role of AChE-AP in amyloidogenic processing of APP by the Western blot analysis using  $A\beta$  specific monoclonal antibodies. Prolonged incubation of a recombinant APP770 substrate with different AChE preparations produced several amyloidogenic fragments on the immunoblots. Protease inhibitory profiles on this processing confirmed the trypsin-like serine protease activity present in AChE preparation. This observed APP processing was significantly enhanced by  $Ca^{2+}$ ,  $Mg^{2+}$ , or  $Mn^{2+}$  at 2 mM concentration, accumulating a relatively stable 18 kDa carboxy terminal fragment, which could be further degraded with higher AChE concentration. Furthermore, APP processing was shown to be modulated in concentration dependent manners by physiologically available metal ions such as  $Ca^{2+}$ ,  $Zn^{2+}$ , or  $Fe^{2+}/Fe^{3+}$ ,  $Al^{3+}$  or a tacrine, centrally active cholinesterase inhibitor, with higher concentrations increasing accumulation of APP. These observations imply that AChE and its associated proteolytic activity may be involved in the generation of potential sources of amyloidogenic peptides under certain physiological conditions. Furthermore, our data provide the direct evidence supporting that locally disturbed homeostasis of essential metal ions or imbalance of protease and protease inhibitors may result in abnormal accumulation of APP and subsequent deregulated metabolism of APP, eventually leading to amyloid deposition in AD brain. In addition, this study raises the possibility that zinc or tacrine treatment of AD patients with high dosage or in the long term may have effects on the process of amyloidogenesis.

## 390.2

THROMBIN PROMOTES SECRETION OF AMYLOID PRECURSOR PROTEIN (APP) FROM HUMAN ENDOTHELIAL CELLS. J.R. Ciallella\* and J.P. McGillis. Dept. Microbiology and Immunology, and Sanders Brown Center on Aging, University of Kentucky College of Medicine, Lexington, KY 40536

Alzheimer's disease (AD) is a neurodegenerative brain disorder presenting hallmark pathological lesions called neuritic and cerebrovascular plaques. The core of these plaques is comprised of a 42-43 amino acid peptide known as  $A\beta$ . This peptide is cleaved from amyloid precursor protein (APP), which is ubiquitously expressed throughout the body. The normal or pathological function for APP is not known. In this study, human umbilical vein endothelial cells (HUVEC) were used to examine the effects of thrombin, a major coagulant, on APP expression. Thrombin has been localized to senile plaques and can process purified APP. Since thrombin induces secretion of growth and coagulant factors in HUVEC, it was examined whether APP is also secreted under these conditions. HUVEC were treated with thrombin for various time periods. Cell supernatants were collected, concentrated, and immunoblotted to measure secreted APP. Thrombin specifically induced secretion of APP which peaked at approximately thirty minutes post-treatment. The secretion was protein kinase C (PKC) dependent since it was diminished by an inhibitor of PKC. Moreover, thrombin induced a marked increase in intracellular calcium levels, which was partially inhibited by a secreted form of APP. These data suggest that thrombin may be involved in secretion and accumulation of APP leading to a protective effect and/or increased amyloidogenic species.

## 390.4

CHOLINESTERASE INHIBITORS ALTER APP SECRETION AND APP mRNA IN RAT CEREBRAL CORTEX. E. Giacobini, F. Mori, A. Buznikov and R. Becker<sup>1,2</sup>. Depts. of Pharmacology and <sup>1</sup>Psychiatry, Southern Illinois Univ. Sch. Med., P.O. Box 19230, Springfield, IL 62794-9230 USA.

Three cholinesterase inhibitors (ChEI), both reversible and irreversible, were tested for their ability to enhance the release of nonamyloidogenic APP soluble derivatives (APPs): physostigmine (PHY), heptylphysostigmine (HEP) and 2,2-dichlorovinyl dimethyl phosphate (DDVP), at concentrations producing cholinesterase (ChE) inhibition ranging from 5% to 95%. All three ChEI elevated APPs release significantly above control levels. Similar increase was observed after muscarinic receptor stimulation with bethanechol (BETHA). Level of total APP RNAs in rat cortical slices did not change after incubation with BETHA, DDVP and PHY. Activation of protein kinase C with phorbol 12-myristate 13-acetate (100 nM) increased the level of total APP mRNA by 50%. Physostigmine and metrifonate administration (0.3 and 80 mg/kg s.c., 3-48 hrs) did not significantly change the levels of APP 695 mRNA and APP-KPI mRNA. On the other hand, HEP administration (5 mg/kg s.c., 3-48 hrs) decreased the level of APP-KPI mRNA 35% in rat cerebral cortex. These findings suggest that administration of ChEI to Alzheimer disease patients may have a neuroprotective effect by activating normal APP processing.

## 390.6

THA: A NOVEL TOOL TO STUDY THE PROCESSING OF THE AMYLOID PRECURSOR PROTEIN. C.M. Reeve\*, M.P. Vitek and D.D. Flynn. Dept. of Pharmacology, Univ. of Miami School of Medicine, Miami, FL 33101 and The Picower Institute for Medical Research, Manhasset, NY 11030.

Tacrine (THA) is one of very few drugs approved for the treatment of mild to moderate Alzheimer's disease (AD). The therapeutic efficacy of THA has been attributed to its action as a potent, centrally-active acetylcholinesterase (AChE) inhibitor elevating cortical levels of acetylcholine. While THA's purported improved clinical effects over other cholinesterase inhibitors have been attributed to its improved pharmacokinetics, THA's complex pharmacological profile may also contribute to its antedementia activity. Recent studies (Lahiri et al. *J. Neurosci. Res.* 37:777, 1994), have suggested that THA plays a role in the proteolytic processing of the amyloid precursor protein (APP) by inhibiting a cholinesterase-like protease. These findings have implications for the use of THA as a therapeutic treatment for AD, since the processing of APP leading to the progressive cerebral deposition of  $\beta$ -amyloid is believed to be a pathogenic event in the disease. We have further evaluated the role of THA and other cholinergic agents in the regulation of APP proteolysis. THA produced a time- (4-16 hrs) and concentration- (10-400  $\mu$ M) dependent decrease in APPs secretion from IMR-32 neuroblastoma cells and Chinese Hamster Ovary (CHO) cells. The effects of THA were not mediated by esterase inhibition or via actions at the muscarinic receptor since: 1) CHO cells do not express AChE, 2) physostigmine did not show similar effects, 3) THA effects were observed both on ml receptor-transfected and non-transfected CHO cells, and 4) THA effects were not mimicked by muscarinic antagonists or allosteric modulators. THA-mediated decreases in APPs secretion were mimicked by the lysosomotropic agents, NH<sub>4</sub>Cl and chloroquine. These findings are consistent with THA's action as a weak base and possible inhibitor of lysosomal function, and with the proposed endocytic processing within the endosomal/lysosomal compartment as a major metabolic pathway for APP.

## 390.7

AMYLOID PROTEIN PRECURSOR SECRETION FROM CONTROL, ALZHEIMER'S AND DOWN'S FIBROBLASTS IN BASAL CONDITION AND FOLLOWING PROTEIN KINASE C ACTIVATION. S. Bergamaschi, L. Gasparini, C. Quaglia, M. Racchi, G. Bincetti, S. Govoni, F. Battaini, A. Bianchetti, F. Giovetto, and M. Trabucchi<sup>1</sup>. Inst. Pharmacol. Sci., Univ. Milano, <sup>1</sup>Alzheimer's Dept., Sacred Heart, Hospital of Brescia, <sup>2</sup>Inst. Pharmacol. Univ. Pavia, <sup>3</sup>Hospital Inst. of Sospiro, Italy.

Literature data show that Down patients overexpress amyloid precursor protein (APP) in various brain areas and in fibroblasts. We previously demonstrated that PKC activity and PKC $\alpha$  immunoreactivity are reduced in Alzheimer disease (AD) fibroblasts. Moreover, we observed in the medium of AD fibroblasts, a reduced soluble APP release both in basal conditions and following PKC activation using low phorbol-12,13-dibutyrate (PdBu) concentrations (9 and 18 nM). The present study compares PKC $\alpha$  immunoreactivity and APP secretion in fibroblasts cultured from ten Down, several AD and respective age-matched controls. PdBu treatment of the cells (for 2 hrs) was carried out with concentrations ranging from 4.5 to 150 nM. PKC $\alpha$  immunoreactivity, in soluble and particulate fractions, was not statistically different in control and Down fibroblasts (while it was lower in the soluble fraction of AD cells). The basal secretion of soluble APP was higher (+101%,  $P < 0.001$ ) in Down cells respect to controls (while it was lower in AD cells). In Down's fibroblasts PdBu was able to stimulate maximally APP secretion (+37%) already at low concentrations (9nM), while in control and AD fibroblasts APP release showed a dose-dependent response reaching the maximum (+79%) at 150 nM PdBu. The results indicate that in Down fibroblasts the mechanisms controlling APP release differ both in comparison with control and AD cells. (Partially supported by grants from the Regione Lombardia and the Ministry of Health)

## 390.9

REGULATION OF AMYLOID PRECURSOR PROTEIN METABOLISM IN NEURONS AND ASTROCYTES BY SECOND MESSENGERS COUPLED TO METABOTROPIC GLUTAMATE RECEPTORS. R. K. Lee\*, R. J. Wurtman, A. J. Cox, K. Brown and B. Tan. Dept. Brain Cog. Sci., M.I.T., Cambridge 02139.

Metabolism of amyloid precursor protein (APP) is regulated by second messengers coupled to cell-surface receptors. We showed that in both hippocampal neurons and cortical astrocytes of fetal rats, aminocyclopentane dicarboxylic acid (ACPD; 10 $\mu$ M) activates metabotropic glutamate receptors (mGluR) coupled to phosphatidylinositol (PI) hydrolysis, and increases secretion of soluble APP (APPs) peptides by 3- to 4-fold.

Diacylglycerol and IP<sub>3</sub>/calcium mobilization generated during PI hydrolysis activate protein kinase C (PKC). We now demonstrate that direct activation of PKC by the phorbol ester phorbol myristate acetate (PMA; 5 $\mu$ M) also increases APPs secretion by 2-3 fold relative to unstimulated controls ( $p < 0.05$ ). However, a PKC-independent pathway for regulating APP processing exists in both neurons and astrocytes since ACPD increased APPs release by ~1-fold above unstimulated controls after down-regulation of PKC by chronic (24h) PMA incubation ( $p < 0.05$ ). Consistent with the presence of redundant signalling pathways, the mGluR antagonist (+)- $\alpha$ -methyl-4-carboxyphenylglycine (MCPG; 500 $\mu$ M), which suppresses mGluR-mediated PI hydrolysis ( $p < 0.05$ ), had no inhibitory effect on mGluR-mediated APPs secretion ( $p > 0.05$ ). The addition of 5 $\mu$ M EGTA to the incubation medium did not suppress the stimulatory effects of ACPD. Although APP proteolysis appears to be insensitive to extracellular calcium, BAPTA (5 $\mu$ M), which chelates intra- and extracellular calcium, was an effective inhibitor of ACPD-mediated APPs secretion ( $p < 0.05$ ).

Various mGluR subtypes can affect both intracellular cAMP and PI hydrolysis. Elevating intracellular cAMP levels by addition of either forskolin (10 $\mu$ M) or membrane-permeant dibutyryl cAMP (10 $\mu$ M) potentially inhibited APPs secretion during ACPD or PMA (both 10 $\mu$ M) treatment. These studies suggest that aberrant neurotransmission created by either a loss of PI-coupled mGluR or an increase in receptors activating cAMP may exacerbate amyloid formation.

## 390.11

CELL CYCLE REGULATED APP SECRETION IN ST14A AND HIB5 CONDITIONALLY IMMORTALIZED CNS PROGENITOR CELL LINES.

N. Salvietti, M. Racchi, S. Govoni, M. Trabucchi, L. Vicentini, and E. Cattaneo<sup>2</sup>. Lab. of Mol. and Cell. Neurobiol. Sacred Heart Hospital-FBF, Brescia,

<sup>1</sup>Institute of Pharmacological Sciences, Università di Milano, Italy; <sup>2</sup>Institute of Pharmacology, University of Pavia, Italy; <sup>3</sup>Dept. Pharm. Chem. Tox. Univ. Milan

Cell cycle dependent APP phosphorylation linked to a modulation of APP metabolism (Suzuki, EMBO J., 1994) has been shown. Specifically, a reduced secretion of APP is detected in G2/M phase cells paralleled by maximal phosphorylation of APP. To ascertain whether such phenomenon occurs also in CNS derived cells, ST14A and HIB5 cell lines, immortalized using the temperature sensitive allele of the Large T antigen from SV40, were used. Both cell lines secrete substantial amounts of APP readily detectable in the culture medium at two hours of incubation. Time course experiments demonstrated that the secretion of APP from serum deprived cells at 33°C follows a cyclic pattern. Indeed 48h after serum deprivation, the APP secretion doubled in ST14A cells compared to the 24h time point. At 72h the level of secretion sharply dropped, however it increased steadily at the following time points reaching again the maximum at 168h. Secretion from HIB5 cells followed a similar pattern. It has also been demonstrated that PKC activation stimulates APP secretion. To further characterize our cellular system, we have investigated the activation of the secretory pathway of APP metabolism through pharmacological modulation. Direct activation of PKC with 12,13 phorbol dibutyrate (PdBu) in either cell lines stimulated APP secretion in a concentration dependent manner at 33°C. Cells incubated at 39°C are blocked in their proliferative activity as the immortalizing oncoprotein is inactivated. In these conditions the cells still respond to the phorbol ester. However the secretory effect observed was less pronounced. These findings suggest the possibility that the physiological regulation of APP metabolism may be dependent on proteins associated with the cell cycle. Alteration in these proteins may play a role in the pathogenesis of Alzheimer disease (partially supported by Alzheimer's Association PRG-94-057 to E.C.).

DEHYDROEPIANDROSTERONE (DHEA) AUGMENTS AMYLOID PRECURSOR PROTEIN SECRETION IN DESENSITIZED M1-TRANSFECTED PC12 CELLS. R. Haring, D. Gurwitz\*, E. Heldman, Z. Pittel, A. Fisher and H.D. Danenberg<sup>1</sup>. Israel Institute for Biological Research, P.O.B. 19, Ness-Ziona 74100, and <sup>2</sup>Div. of Medicine, Hadassah University Hospital, Jerusalem, ISRAEL.

Secretion of amyloid precursor protein (APP) by cultured cells is coupled to several receptors including m1 muscarinic acetylcholine receptors (mAChR), and is associated with decreased production of amyloid  $\beta$ -protein ( $\beta$ A4). Amyloid  $\beta$  A4 is the major component of senile plaques, a distinct neuropathological lesion in the brains of Alzheimer disease (AD) patients. Dehydroepiandrosterone (DHEA) is an abundantly secreted adrenal steroid with weak androgenic activity. Plasma levels of DHEA progressively decline with advancing age, reaching 10-20% of adulthood levels. Epidemiological studies suggest that the age-associated decline in DHEA levels is correlated with AD. We have investigated the effect of DHEA on APP processing in mAChR-transfected PC12 cells. DHEA (0.1  $\mu$ M, 24 h) did not significantly alter basal or mAChR-stimulated (100  $\mu$ M carbachol; 1 h) APP secretion. However, DHEA significantly diminished the desensitization of APP secretion in cells exposed to carbachol for 24 h. In similar experiments, basal, mAChR-stimulated and desensitization of APP secretion were not affected by the potent glucocorticoid dexamethasone (0.1  $\mu$ M, 24 h). The effect of DHEA on APP processing is probably not related to up-regulation of mAChR or increased mAChR-activated phosphoinositide hydrolysis since these occurred with dexamethasone but not with DHEA treatment. The elucidation of a mechanism by which DHEA affects mAChR-stimulated APP metabolism may help in identifying events involved in the formation of amyloid deposits and the cholinergic deficiency in AD.

## 390.10

INTRACELLULAR DETECTION OF  $\beta$ A4-AMYLOID;  $\beta$ A4 SECRETION CAN BE MODULATED BY PHOSPHORAMIDON BUT IS NOT COUPLED TO SECRETION OF APP IN SYSY CELLS.

Fuller, S.J., Li, O.X.\*, Storey, E., Boyreuther, K. and Masters, C.L. Pathology Department, Melbourne University, Parville, Vic 3052, and Mental Health Research Institute, Parkville, Vic 3052, Australia. <sup>2</sup>Centre for Molecular Biology, Heidelberg University, Heidelberg 6900, Germany.

The metabolism of the amyloid precursor protein (APP) of Alzheimer's disease involves at least two pathways: one pathway includes cleavage at the  $\alpha$ -secretase site within the  $\beta$ A4 sequence, releasing a secreted form (sAPP); another pathway involves cleavage at the  $\beta$ - and  $\gamma$ -secretase sites releasing full-length  $\beta$ A4. Studies of protein kinase C (PKC) activation have suggested a reciprocal relationship between sAPP secretion and  $\beta$ A4 release. Our studies show that phorbol ester activation of PKC in SYSY human neuroblastoma cells increases sAPP secretion but has no effect on  $\beta$ A4 release.  $\beta$ A4 is produced intracellularly and subsequently secreted from these cells. Treatment with the metalloprotease inhibitor phosphoramidon (but not thiorphan) results in a 2-fold increase in  $\beta$ A4 recovered from the medium and an increase in  $\beta$ A4 recovered from cell lysates, yet does not affect sAPP secretion. Phosphoramidon appears to inhibit breakdown of  $\beta$ A4 after its production but prior to release as no extracellular breakdown of  $\beta$ A4 was detected in our system.

## 390.12

AB SECRETION AND CLEARANCE IN MIXED FETAL GUINEA PIG BRAIN CULTURES. Y. Ohya, S. Gillespie, and S. G. Younkin<sup>1,2</sup>. Case

Western Reserve Univ., Cleveland, Ohio; <sup>2</sup>Mayo Clinic Jacksonville, Jacksonville, FL.

Amyloid  $\beta$  protein (AB), which deposits as insoluble amyloid fibrils in Alzheimer's disease (AD) brain, is secreted by normal cellular metabolism. To better understand AB metabolism in brain, we studied AB secretion and clearance in primary cultures from the fetal guinea pig brain. Mixed glial/neuronal cells prepared from embryonic day 30 guinea pig brain were cultured in Opti-MEM containing 5% calf serum. Since guinea pig and human AB have the same sequence, we were able to analyze guinea pig AB using the same ELISAs that we previously employed to study human AB. After plating, medium was changed every three days, with cultures maintained for as long as 18 days. The accumulation of AB1-40, AB1-42, and total AB was followed by analyzing aliquots taken at 4, 8, 24, 48, and 72 hours after each medium change. AB clearance was evaluated by removing conditioned medium from the cells, adding synthetic AB1-40 or AB1-42, and following it by analyzing aliquots drawn at 4, 8, 24, 48, and 72 hours after AB addition. As cultures were maintained, the amount of AB accumulating in 3 days gradually increased with ~3 pmol/ml of AB accumulating from day 15-18. Consistent with our previous analysis of human cell lines, CSF, and plasma, most of the AB secreted by these cultures was AB1-40 and ~10% was AB1-42. Synthetic AB1-40 and AB1-42 were cleared from conditioned medium, although the rate of removal was much less than that observed in many human cell lines. As cultures were maintained over several weeks, the conditioned medium removed every three days showed a progressive decrease in the rate at which exogenously added AB1-40 or AB1-42 was cleared. These results show (i) that mixed fetal guinea pig brain cultures release large amounts of AB1-40 and AB1-42 and (ii) that AB is cleared from medium conditioned by these cultures. Further study of these cultures may provide insight into the secretory and clearance mechanisms that regulate AB concentration in brain.

## 390.13

**$\beta$ -AMYLOID<sub>1-40</sub> INCREASES EXPRESSION OF  $\beta$ -AMYLOID PRECURSOR PROTEIN IN NEURONAL HYBRID CELLS.** W.-D. Le\*, W.J. Xie, O. Nyormoi, B.K. Ho, R.G. Smith and S.H. Appel. Department of Neurology, Baylor College of Medicine, Houston, TX 77030.

Studies of cell injury and death in Alzheimer's disease (AD) have suggested a prominent role for  $\beta$ -amyloid peptide ( $\beta$ -AP), a 40-43 amino acid peptide derived from a larger membrane glycoprotein,  $\beta$ -amyloid precursor protein ( $\beta$ -APP). Previous experiments have demonstrated that  $\beta$ -AP induces cytotoxicity in a neuronal hybrid cell line (MES 23.5) *in vitro*. Here, we demonstrate that accompanying  $\beta$ -AP induced cell injury, cell-associated  $\beta$ -APP can be increased up to 14 fold; while secreted forms of  $\beta$ -APP including c-terminal fragments and  $\beta$ -AP can also be significantly elevated.  $\beta$ -APP mRNA is increased up to 3.5 fold in 24 hours after treatment with  $\beta$ -AP<sub>1-40</sub>. Application of  $\beta$ -APP antisense oligodeoxynucleotide reduces both cytotoxicity and  $\beta$ -APP expression. While 6-hydroxydopamine application or glucose deprivation cause extensive cell damage, they do not increase  $\beta$ -APP expression. These results suggest a selective positive feed back mechanism whereby  $\beta$ -AP may induce cytotoxicity and increase levels of  $\beta$ -APP as well as its amyloidogenic fragments which, in turn, could lead to further neuronal damage.

## 390.15

**CHOLESTEROL MODULATES STABILITY AND  $\alpha$ -SECRETASE CLEAVAGE OF AMYLOID PRECURSOR PROTEIN.** Steven Bodovitz\* and William L. Klein. Neurobiology and Physiology, Northwestern University, Evanston, IL 60208.

We have examined the hypothesis that cellular levels of cholesterol modulate the processing of amyloid precursor protein (APP). Both APP and cholesterol metabolism are genetically linked to Alzheimer's disease (AD), the latter through apolipoprotein E, a lipid and cholesterol transport protein. The ApoE4 allele is associated with an increased risk of AD as well as higher plasma cholesterol levels. In the current study, methyl- $\beta$ -cyclodextrin solubilized cholesterol was added to the culture media of APP 751 stably transfected HEK 293 cells. Radiolabeled APP and APP<sub>sol</sub>, the soluble N-terminal derivative following  $\alpha$ -secretase cleavage, were precipitated from lysates and conditioned media; the relative levels were determined by quantitative densitometry following separation by SDS-PAGE. The data show that increasing cellular cholesterol augments levels of both mature and immature APP holoprotein in a dose-dependent fashion, while dramatically reducing levels of APP<sub>sol</sub>. The effects were specific for APP processing because similar changes did not occur in general cellular or secreted proteins. Cholesterol may act by impeding membrane fluidity, which could account for the increased levels of the membrane-spanning APP holoprotein by impeding turnover and degradation. The decreased fluidity may also account for the reduction of APP<sub>sol</sub> by impeding the interaction of the substrate with its protease(s). If APP<sub>sol</sub> were to function trophically, as suggested by other studies, the current conclusion suggests that changes in cellular cholesterol levels in Alzheimer's disease could contribute to neuronal degeneration by decreasing the production of APP<sub>sol</sub>.

## 390.17

**ARACHIDONIC ACID ACTIVATES  $\alpha$ -SECRETASE PROCESSING OF THE AMYLOID PRECURSOR PROTEIN.** R.J. Wurtman\*, R. K. Lee, B. Tan and K. Brown. Dept. Brain & Cognitive Sciences, MIT, Cambridge 02139.

Metabotropic glutamate receptors (mGluR) can generate second messengers which regulate APP processing. In rat hippocampus and transfected cells expressing mGluR, the selective mGluR agonist aminocyclopentane dicarboxylic acid (ACPD) stimulates phosphatidylinositol (PI) hydrolysis and arachidonic acid formation. We showed that mGluR-mediated secretion of soluble APP (APPs) peptides in hippocampal neurons is dependent on the phospholipase C/protein kinase C signal transduction cascade. Quinacrine (5 $\mu$ M), an inhibitor of phospholipase A<sub>2</sub>, did not suppress APPs secretion in ACPD-treated neurons, suggesting that phospholipase A<sub>2</sub> does not regulate APP processing during mGluR activation.

Arachidonic acid (AA), which is liberated during ischemia and neuronal injury, mediates glutamatergic signalling in neurons. AA, in conjunction with phorbol esters, can also potentiate glutamate release from synaptic terminals. We now report that incubation of primary hippocampal neurons (derived from fetal rats) with AA (100 $\mu$ M; 1h) increases APPs secretion into the extracellular medium by 2-3 fold compared to unstimulated controls (p<0.05). This stimulatory effect is attenuated and reduced to baseline levels (p>0.05) by the putative mGluR antagonist, L-AP3 (250 $\mu$ M) or by inhibiting glutamatergic transmission at the glutamate autoreceptor with 2-amino-4-phosphonobutyrate (AP4; 100 $\mu$ M).

Depolarizing with KCl (30 $\mu$ M), or directly activating PKC with phorbol esters, promotes glutamate exocytosis and synaptic transmission and also mimics the action of AA by increasing APPs secretion ~2-fold relative to controls (p<0.05). Consistent with a role for arachidonic acid in modulating glutamatergic transmission, we further demonstrate that AA enhances ACPD-induced release of APPs and that this effect is blocked when glutamate is inhibited with AP4. These data show that arachidonic acid can enhance glutamatergic transmission at metabotropic receptors to increase APPs secretion.

**STUDY ON THE PROTEOLYTIC ACTIVITY OF APP  $\alpha$ -SECRETASE: A MODEL FOR AN ENZYME ASSAY *IN VITRO***

M. Raccchi<sup>1,5</sup>, M. O. Livicy<sup>2</sup>, M. Trabucchi<sup>3</sup> and S. Govoni<sup>4</sup>

<sup>1</sup>Lab. of Mol. and Cell. Neurobiol. Sacro Heart Hospital-FBF, Brescia; <sup>2</sup>Bowman Gray Sch. Med. Winston Salem, NC, USA; <sup>3</sup>Dept. Exptl. Med. Biochem. Sci., Univ. of Roma Tor Vergata; <sup>4</sup>Institute of Pharmacology, University of Pavia; <sup>5</sup>Inst. Pharm. Sci., Univ. of Milan

Several studies have demonstrated that " $\alpha$  secretase" cleavage is not sequence specific and requires a substrate associated with the membrane. In light of these data it is evident that screening for the "secretase" using synthetic peptide substrates might not be useful. We have approached the problem by constructing synthetic substrates for " $\alpha$  secretase" that can be integrated *in vitro* in membranes as the physiologic precursor. A construct encoding APP751 in pGEM3ZII(+) vector that allows *in vitro* transcription of the cDNA was used for the construction of two substrates. The first, referred to as  $\beta$ AXB, was obtained by deleting the region included between the XhoI and BglII sites of the APP 751 cDNA. This construct transcribed and translated *in vitro* yielded a protein of 50 kDa that was integrated during translation in dog pancreas microsomal membranes in the same orientation as authentic cellular APP. A second substrate referred to as HPLAPP, was obtained by recombinant PCR technique and is a fusion construct between the entire coding region of human placental lactogen (HPL) and a C terminal region of the APP cDNA beginning 6 aminoacids N terminal to the  $\beta$ A4 peptide. Transcription and translation of this construct yielded a protein of 38 kDa immunoprecipitable by antibodies directed against HPL or the C terminus of APP. These substrates integrated in microsomal membranes have been used to characterize *in vitro* the " $\alpha$  secretase" processing activity of membrane fractions of COS cells and human fibroblasts, in a wide variety of conditions including detergents and protease inhibitors. Current experiments are aimed at the assessment of the specificity of the assay. (Supported by Alzheimer's Association PRG-94-135 to M.R.)

**$\alpha$ -SECRETASE DOES NOT APPEAR TO BE GELATINASE A.**

D. Allsop<sup>1</sup>, D.M. Walsh<sup>2</sup>, C.H. Williams<sup>2</sup>, H.E. Kennedy<sup>2</sup>, G. Murphy<sup>3</sup>, R. Markwell<sup>1</sup>, H. Wadsworth<sup>1</sup>, G. Christie<sup>1</sup>, C. Gray<sup>1</sup> & G.W. Roberts<sup>1\*</sup>

<sup>1</sup>Discovery Research, SmithKline Beecham Pharmaceuticals, Harlow, Essex CM19 5AW, UK; <sup>2</sup>School of Biology & Biochemistry, The Queen's University of Belfast, Belfast BT9 7BL, UK; and <sup>3</sup>Cell & Molecular Biology Dept., Strangeways Research Laboratory, Cambridge CB1 4RN, UK.

It was suggested recently that the matrix metalloproteinase (MMP) gelatinase A (EC 3.4.24.24) may be responsible for the  $\alpha$ -secretase-mediated cleavage of the amyloid precursor protein (APP) associated with Alzheimer's disease. We have examined the effects of two MMP inhibitors on the release of soluble APP by PC-12 cells. These inhibitors were tissue inhibitor of MMP-1 (TIMP-1) and [4-(N-Hydroxyamino)-2R-isobutyl-3S-(2-thiophenylthiomethyl) succinyl]-L-phenylalanine-N-methylamide (SBI). The latter is a small, potent hydroxamate-based inhibitor of MMP that was shown to penetrate cells. Neither TIMP-1 nor SBI prevented the secretion of APP. Furthermore, purified gelatinase A was shown to cleave the  $\beta$ A4 peptide (residues 1-40) at more than one site and PC-12 cells were found to possess only small amounts of gelatinase A activity, whereas BU-17 cells (which secrete very little APP into the culture medium) were found to have much higher gelatinase activity. These results strongly suggest that  $\alpha$ -secretase is not gelatinase A, but do not preclude a role for gelatinase A in  $\beta$ A4 degradation.

**Inhibition of  $\beta$ A4 production by specific modulation of  $\beta$ -secretase activity** Thomas Dyrks, Jonathan Turner, Heidrun Fink<sup>1,2</sup>, K. Beyreuther<sup>2</sup> and Britta Urmoneit

Research Laboratories of Schering AG, Dep. of Neuropsychopharmacology, 13342 Berlin, Germany

<sup>1</sup>Inst. Pharmacology, Humboldt University, Berlin, Germany

<sup>2</sup>Center for Molecular Biology, University of Heidelberg, Im Neuenheimer Feld 282, 69120 Heidelberg, Germany

To study APP processing we expressed different APP isoforms with and without the Swedish mutation and the membrane inserted C-terminal 100 residues of APP (SPA4CT) in the human neuroblastoma cell line SY5Y. We show that expression of the Swedish mutation results in a significant production of the amyloidogenic intermediate A4CT which is further processed by  $\gamma$ -secretase leading to an overproduction of  $\beta$ A4. Treatment with methylamine and ammonium chloride, inhibitors interfering with intracellular transport mechanisms, inhibits  $\beta$ -secretase activity without influencing the physiological APP cleavage by  $\alpha$ -secretase activity.

By expressing SPA4CT we demonstrate that secretion, but not generation, of  $\beta$ A4 from SPA4CT is inhibited by methylamine resulting in intracellular  $\beta$ A4. This is the first experimental evidence for the intracellular localisation of  $\gamma$ -secretase activity and  $\beta$ A4 generation.

## 391.1

BROMODEOXYURIDINE (BrdU) INCORPORATION OF CELLS IN GERBIL HIPPOCAMPUS FOLLOWING TRANSIENT GLOBAL ISCHEMIA. J. Liu\*, M. Hill and E. R. Sharp. Dept. of Neurology, Univ. of California at San Francisco and SFVAMC, San Francisco, CA 94121.

Neuronal cell loss is a common event after brain injury, however, the mechanisms of which are poorly understood. The CA1 pyramidal neurons in the hippocampus have been shown to undergo selective cell death both in experimental animals and in humans after ischemic insult. Recent developments have suggested the delayed death of the CA1 pyramidal neurons after transient ischemia is apoptotic. Some apoptotic cell death may involve abortive activation of cell cycle, as shown in developing CNS and axotomized neonatal rat facial motoneurons. The current study was designed to look for proliferating cells after transient global ischemia and to determine the cell types involved. BrdU (50 mg/kg) was given i.p. daily to control gerbils and animals received an ischemic insult via bilateral occlusion of common carotid arteries for 5 and 10 minutes. The animals were sacrificed 3 days after ischemia and the brains were prepared for immunostaining. Elevated BrdU staining was seen in the hippocampus of 5 minute-ischemic gerbils, and in the cortex, striatum in addition to hippocampus of 10 minute-ischemic animals. The control gerbils showed positive staining in the of medial striatum near ventricles, and in the pyramidal layers of dentate gyrus. In situ nick-end labeling of biotinylated dUTP mediated by terminal deoxynucleotidyl transferase (TUNEL) confirmed the apoptotic cell death in CA1 regions in all ischemic animals tested. The origin and nature of the proliferating cells in hippocampus have yet to be determined by using cell specific markers. If neurons are incorporating BrdU in the CA1 dying neurons, this might suggest they are re-entering the cell cycle prior to an apoptotic-like cell death. The role of BrdU uptake into glia surrounding the same neurons remains to be answered.

## 391.3

TRANSIENT RETINAL ISCHEMIA LEADS TO APOPTOTIC CELL DEATH AND MAY BE AMELIORATED BY AURINTRICARBOXYLIC ACID. D.M. Rosenbaum\*, P.S. Rosenbaum, D.M. Michaelson, D. H. Hall, and J.A. Kessler. Albert Einstein College of Medicine, Bronx, NY 10461.

The purpose of this study was to determine if the delayed cell loss seen after transient retinal ischemia is apoptotic and whether drugs which have been shown to inhibit neuronal apoptosis *in vitro* prevent ischemic retinal neuronal death *in vivo*. Transient retinal ischemia was produced in rats by raising IOP to greater than systemic pressure for 60 minutes. Morphologic and biochemical evidence for apoptosis was determined by electron microscopy (EM) and Southern blot analysis. Both ultrastructural and Southern blot analysis were consistent with apoptosis after 12 hours of reperfusion. We, therefore, administered aurintricarboxylic acid (an agent that has been shown to inhibit neuronal apoptosis *in vitro*) intravitreally either 24 hours prior to ischemia or in a separate set of experiments, 6 hours after ischemia, and the retinas analyzed 7 days later. The animals treated with ATA either before (100%;  $p < .001$ ) or after (54%;  $p < .01$ ) ischemia demonstrated significantly less ischemic damage in the inner retinal layers. There was also preservation of the retinal histoarchitecture. These data support the hypothesis that delayed cell death after transient retinal ischemia may, in part, result from apoptosis and opens new strategies aimed at preventing retinal damage from this process.

## 391.5

DELAYED INDUCTION OF IMMEDIATE EARLY GENES (IEGs) FOLLOWING TRANSIENT FOCAL CEREBRAL ISCHEMIA. J. Pykäläinen\*, R. Keinänen\* and J. Koistinaho. A.I. Virtanen Institute, University of Kuopio, FIN-70211 Kuopio, Finland.

Middle cerebral artery (MCA) occlusion transiently induces IEGs in the cortex adjacent to the ischemic core as well as in subcortical structures remote from the infarction. Even though this IEG induction is thought to be mediated by spreading depression, the regulation of IEG induction in focal brain ischemia is not well understood. In this study we compared the temporal and regional patterns of *c-fos* induction following 30 and 90 minutes of MCA occlusion. MCA occlusion in halothane-anesthetized rats was produced using an intraluminal suture without craniotomy. The rats were anesthetized and decapitated 0 h, 1 h, 4 h, 12 h, 24 h, 3 or 7 days following 30 min or 90 min of ischemia. The brains were removed and processed for *in situ* hybridization. In MCA territories adjacent to the ischemic core and in the hippocampus and substantia nigra the expression of *c-fos*, *jun-B* and *NGFI-A* peaked within one hour following the ischemia. The expression of IEG mRNAs was back to control levels 12-24 h following 30-min ischemia and 3 days following 90-min ischemia. There was no or only minor IEG induction in the infarct core within 24 h following the insult. However, a delayed IEG expression occurred in the infarct core 3-7 days following 30-min ischemia but not following 90-min ischemia. Emulsion-coated sections hybridized with IEG probes showed grains throughout the core, but more distinctly over a few neuronal cell bodies. The early IEG expression is likely to be induced in neurons by spreading depression and is therefore stronger following a long-lasting ischemia when more glutamate is released to stimulate NMDA receptors. A delayed IEG expression in the infarct core following 30-min of ischemia may be required for regeneration of the surviving neurons.

## 391.2

DIFFERENTIAL DISPLAY PCR AND TRANSIENT FOREBRAIN ISCHEMIA IN THE RAT. E. Kamme\*, J. Babity, H. Robertson and T. Wieloch. Lab. for Exp. Brain Research, 221 85 Lund, Sweden and Dept. of Pharmacology, Dalhousie Univ., Halifax, Canada.

We have previously shown that there is a late induction of Immediate Early Genes and Tumor suppressor genes after transient forebrain ischemia prior to delayed neuronal death, predominant in vulnerable areas of the hippocampus. This is shifted temporally to an earlier timepoint by intraischemic hypothermia, which also prevents cell death. Thus, many of the genes seen to be induced late after ischemia are not unique to dying cells and may be part of adaptive responses such as a stress response or repair mechanism. In an attempt to identify genes involved in the death mechanism of CA1 neurons after 15 min. of transient forebrain ischemia in the rat, we have employed the Differential Display PCR technique. Total RNA was extracted from normothermic ischemic brains after 48 h of reperfusion and compared to RNA from hypothermic ischemic brains after 12 and 18 h of reperfusion.

On average, 1-2 bands per primer combination were found to be differentially expressed, i.e. expressed at 48 h in normothermic animals but neither in 12 or 18 h hypothermic ones. These were reamplified and sequenced directly and subcloned into a TA vector. In a number of cases direct sequencing was not possible due to the presence of several sequences contained within the same band.

## 391.4

EFFECT OF TTC-909 ON DELAYED NEURONAL DEATH OF CA1 PYRAMIDAL NEURONS FOLLOWING BRIEF ISCHEMIA; AN IMMUNOCYTOCHEMICAL STUDY.

Y. Kasawa<sup>1</sup>, T. Nitoriji<sup>2</sup>, H. Araki<sup>3</sup>, S. Higuchi<sup>4</sup>, F. Mizobe<sup>1,2</sup>, E. Kominami<sup>3</sup>, and Y. Uchiyama<sup>4</sup>. Dept. of Pharmacol., Taisho Pharmaceutical Co. Ltd., Saitama 330, Japan<sup>1</sup>, Dept. of Cell Biol. & Neuroanat., Sch. of Med., Iwate Med. Univ., Iwate 020, Japan<sup>2</sup>, Dept. of Biochem., Sch. of Med., Juntendo Univ., Tokyo 113, Japan<sup>3</sup>, Dept. of Anat., Osaka Univ. Med. Sch., Osaka 565, Japan<sup>4</sup>.

We have previously shown that delayed neuronal death occurring in the CA1 pyramidal layer of gerbil hippocampus after brief ischemia is not necrosis but apoptosis (J. Neurosci. 15: 1001-1011, 1995). In the dying processes of the CA1 pyramidal cells, cytoplasmic alterations are largely mediated by the formation of autophagolysosomes immunopositive for lysosomal cysteine proteinases, cathepsins B, H and L, 3 days after ischemic insult, while nuclear DNA fragmentation into oligonucleosomes is demonstrated by *in situ* nick end labeling of dUTP (TUNEL staining) and Southern blot analysis 3 and/or 4 days later. Moreover, heterophagocytosis by microglial cells immunopositive for cystatin  $\beta$  (C $\beta$ ), an endogenous cysteine proteinase inhibitor, and cathepsin H is also seen 4 to 7 days after ischemic insult. Using this neuronal death model, we examined effects of TTC-909, isocarboxycillin methyl ester incorporated in lipid microsphere, administered (i.v.) soon after ischemic insult. In some cases of gerbil brains treated with TTC-909 (500 ng/kg), invasion of C $\beta$ -immunopositive microglial cells into the CA1 region was largely inhibited even on day 7, whereas GFAP-immunopositive astrocytes extended their cytoplasmic processes into the CA1 region as greatly as seen in those of the control brains without TTC-909 treatment. Moreover, in these brains, the CA1 neurons showing negative staining of TUNEL appeared abundantly even on day 7. The results suggest that TTC-909 may be potent in suppression of delayed neuronal death in the CA1 pyramidal layer after brief ischemia.

## 391.6

DNA-FRAGMENTATION, INDUCTION OF IEGs, p53 AND WAF1 IN HYPOGLYCEMIC COMA IN RAT. M. Ferrand-Drake\*, P. Stubberöd, G. Tomasevic, E. Kamme, M. Shamloo, T. Wieloch. Lab. for Experimental Brain Research, University Hospital, Lund, 221 85 Sweden.

Using *in situ* hybridisation we studied the expression of the Immediate Early Genes (IEGs) (*c-fos*, *fosB*, *c-jun*, *junD* and *fra-2*) and *p53* and *WAF1* following hypoglycemic coma in the rat. All of the IEGs studied were induced after hypoglycemia. A peculiarity is seen with the induction of *c-fos*; it is induced already at the end of the hypoglycemic period in the tip of Dentate Gyrus (DG), which exhibits necrosis already at this timepoint. *c-jun*, *junD* and *fra-2* are maintained at a high level until 6 h of recovery and then progressively decline. In the vulnerable CA1 region, however, expression is elevated until 48 h of recovery. *c-fos* declines by 3 h but is reinduced later on in areas that are susceptible to damage, i.e. the tip of DG, subiculum and parts of CA1. We propose that *c-fos* is reinduced in vulnerable areas, perhaps due to activation of microglia, and that *c-jun*, *junD* and *fra-2* are expressed persistently in neurons as a reaction to stress. We also found induction of these genes in the synovial membrane overlying CA1 and the distribution of labelling corresponded to the distribution of damage seen in the CA1 underneath.

Additionally we studied *p53* and *WAF1* which are induced in CA1 at 24 h and not at all in the DG. We therefore suggest that in some vulnerable areas after a hypoglycemic insult, *p53* and *WAF1* are induced as an indication of DNA damage.

As a measure of cell death, DNA-fragmentation was detected by the TUNEL-method and electrophoresis and appeared at the end of the hypoglycemic period in the tip of DG, at 24 h. in CA1 and in cortex.

## 391.7

CONSECUTIVE EXPRESSION OF AP1 COMPLEX IN THE RAT HIPPOCAMPUS AFTER TRANSIENT CEREBRAL ISCHEMIA. Bing-Ren Hu\* and Tadeusz Wieloch, Lab. for Exp. Brain Res., University Hospital, 221 85 Lund, Sweden.

The AP-1 DNA binding activity and the alterations in its Fos and Jun protein components, were studied in the rat hippocampus after transient forebrain ischemia. The AP-1 complex in the nuclear extract was markedly induced at 4 hrs and was still elevated at 24 hrs of reperfusion. Expression was observed both in CA1 region and in CA3/dentate gyrus (DG) area, albeit with different intensities. Nearly all of members of the Fos and Jun families were expressed in the AP-1 complex at 4 hours of reperfusion. By 24 hrs of reperfusion, c-Fos/Jun B disappeared while Fras/Fos-B and c-Jun/Jun-D were still present. On brain sections, immunoreactivity of Fras first appeared at 1 hour, was strong at 4-6 hrs and was still elevated at 24 hrs of reperfusion in DG neurons. Induction of Fras was delayed 2 hrs in pyramidal neurons. Expression of c-Jun was temporally dissociated between CA1 and DG neurons, i.e. stronger in the DG neurons than in CA1 neurons before 24 hrs and then strong in CA1 but not present in DG neurons after 24 hrs of reperfusion. Immunoblots confirmed that c-Fos was transiently induced at 4 hrs of reperfusion. The dissociated c-Jun expression between CA1 and CA3/DG neurons was also observed on Western blots. The data demonstrate a dynamic change in AP1 complex formation presumably reflecting activation of different intracellular signalling pathways, which may alter gene programs causing long lasting effects or/and neuronal damage.

## 391.9

EXPRESSION OF PROLIFERATING CELL NUCLEAR ANTIGEN IN THE POSTISCHEMIC RAT HIPPOCAMPUS. G. Tomasevic, P. Stubberud, T. Wieloch, F. Boris-Möller\*, Lab. Exp. Brain Res., Lund University Hospital, Lund, Sweden.

Proliferating cell nuclear antigen (PCNA) is an important auxiliary factor in DNA replication, and is also required for DNA excision repair. PCNA's replicative - but not its reparative - function is inhibited by p21/WAF1. We used *in situ* hybridization to study the expression of PCNA mRNA following transient (15 min) global normo- (37° C) and hypothermic (33° C) cerebral ischemia in the rat. PCNA protein expression was studied by means of immunocytochemistry. In the normothermic situation, PCNA mRNA and protein were induced after 2 hrs of recirculation in the resistant dentate gyrus subfield only. We have previously shown that these neurons express p21/WAF1 mRNA at this timepoint, which indicates that DNA-reparative processes might be activated early during recirculation in resistant neurons. No PCNA induction was detected in the sensitive CA1 neurons following normothermic ischemia. Intra-ischemic hypothermia is known to confer protection against neuronal damage. Following hypothermic ischemia, PCNA mRNA was also induced in the CA1 and CA3 regions after 24 hrs of recirculation. We have previously shown that the hypothermic CA1 neurons express p21/WAF1 mRNA after 18-24 hrs of recirculation. The induction of PCNA in the hypothermic CA1 subfield indicates that DNA-reparative functions play an important role in the neuronal defense against hypoxic damage.

## 391.11

EXPRESSION OF p53 AND CYCLIN G IN NUCLEI OF CELLS UNDERGOING ISCHAEMIA-INDUCED APOPTOSIS IN THE RAT BRAIN. M. van Lookeren Campagne, Ch. Köhler\* and B. Gill, F. Hoffmann-La Roche, PRPN Bau69/402, Grenzacherstrasse 124, 4002 Basel, Switzerland.

Recent evidence suggests that some forms of ischaemia induced cell death may occur through apoptosis. We have investigated the gene-products which may be involved in a cell death program, using a rat model of focal cerebral ischaemia.

Ischaemia was induced by permanent occlusion of the left middle cerebral artery. Internucleosomal DNA fragmentation was studied 24 h after ischaemia using a method of terminal d-UTP nick end labelling (TUNEL) on paraffin sections. Adjacent sections were immunocytochemically stained for the tumor suppressor protein p-53 and one of its transcriptional targets, cyclin G. Nuclear morphology was revealed by counterstaining with methyl green.

In the ischaemic core area, involving part of the striatum and cerebral cortex, a high density of TUNEL-positive cells were found 24 h post-ischaemia. Less than 20% of the TUNEL-stained nuclei had an apoptotic morphology and these were mainly located in the ventrolateral part of the affected striatum and cerebral cortex. P-53 and Cyclin G immunoreactivities were present in all nuclei with an apoptotic morphology. In addition, immunoreactivity for cyclin G was found in small-sized nuclei, presumably non-neuronal, with the highest density in the corpus callosum followed by the striatum and cerebral cortex in both the ipsi- and contralateral hemispheres.

The present study demonstrates that focal ischaemia induces internucleosomal DNA fragmentation associated with both apoptotic and necrotic cell death. The presence of cyclin G in all apoptotic cells indicates a possible relationship between the expression of genes involved in the regulation of the cell cycle and apoptotic cell death. Further studies will identify the cell types expressing cyclin G and characterise the temporal expression of related genes involved in ischaemia-induced programmed cell death.

## 391.8

HYPOXIA-INDUCIBLE FACTOR 1 (HIF-1) AS A MEDIATOR OF ADAPTIVE RESPONSES TO HYPOXIA IN NG108 CELLS.

Robert A. Forbes, Joseph A. Haney, Anna-Leena Siren\* and Ajay Verma, Depts. of Neurology and Anesthesiology, Uniformed Services Univ. of the Health Sciences, Bethesda, Maryland 20814

The central nervous system displays high vulnerability to hypoxic insult. Little is known about the way neuronal cells respond to hypoxic stress. Recently a hypoxia-inducible DNA binding activity was identified in erythropoietin (EPO) producing cells. The transcription factor responsible for this activity has been named hypoxia-inducible factor 1 (HIF-1) and binds to a region upstream from the EPO gene. Using a double-stranded radiolabelled DNA probe corresponding to the specific HIF binding element in the EPO gene, we monitored the induction of HIF-1 in the EPO producing cell line Hep3B and non-EPO producing cell line NG108 with the gel-shift assay. Exposure of both cell lines to 1% O<sub>2</sub> induced HIF-1 activity within 4 hours as compared to normoxic conditions (20% O<sub>2</sub>). In both cell lines hypoxic induction of HIF-1 activity was inhibited by a 2 hour prior exposure to the general protein kinase inhibitor 2-aminopurine (2-AP). These results suggest a role of HIF-1 as a mediator of adaptive responses to hypoxia in neuronal cells and implicate protein phosphorylation in the transduction of hypoxic signals.

## 391.10

EXPRESSION OF Myc AND p53 FOLLOWING TRANSIENT GLOBAL ISCHEMIA

L. McGahan<sup>1,11</sup>, G.S. Robertson<sup>1</sup> and A.M. Hakim<sup>1†</sup>, Dept. of Pharmacology<sup>1</sup>, and Neuroscience Research Institute<sup>†</sup>, University of Ottawa, Ottawa, ONT, CANADA, K1H 8M5.

The proto-oncogene *c-myc* and the tumor suppressor gene p53 encode proteins that function as transcriptional regulating factors which govern cell proliferation, differentiation, and apoptosis. The objective of this study was to determine whether the protein products of these genes are expressed in neurons that undergo delayed neuronal death following transient global ischemia. Four vessel occlusion was produced in male Wistar rats by cautery of the vertebral arteries and clamping of the common carotid arteries for 20 min. Animals were perfused transcardially 2, 12, 24, and 48 h following recirculation. Immunohistochemical staining revealed a dramatic increase in both mutant and wild type p53-like immunoreactivity exclusively in vulnerable CA1 neurons of the hippocampus 48 h after the ischemic insult. Myc-like immunoreactivity was also elevated in the majority of CA1 neurons at this time. The close temporal correlation between these changes in gene expression, and the loss of CA1 neurons suggest that alterations in Myc and p53 expression may contribute to the delayed neuronal death of CA1 neurons following transient forebrain ischemia. (Supported by a grant from the Heart and Stroke Foundation of Canada.)

## 391.12

GADD45 MRNA IS PERSISTENTLY EXPRESSED IN VULNERABLE NEURONS FOLLOWING GLOBAL CEREBRAL ISCHEMIA IN THE RAT. K.L. Jin, M. Nakayama, M. Botscheller\*, S. H. Graham, R.P. Simon, J. Chen, Dept. of Neurology, Univ. of Pittsburgh, Sch. of Medicine, PA 15261

Growth arrest and DNA damage-inducible (GADD) genes are novel genes that encode at least five acidic proteins that are induced by growth arrest signals, DNA-damage and other genotoxic stresses. Although the precise function of GADD gene products is unclear, they have been suggested to be important regulatory factors for growth control and apoptosis in proliferating cells. Recently one of this gene family, GADD45, has been found to be induced in the rat brain by UV radiation, suggesting that this gene may also be inducible in postmitotic cells by DNA damage. Therefore, we studied the mRNA expression of GADD45 in the brain following global ischemia.

Adult rats were subjected to 15 min of incomplete global ischemia by means of four-vessel occlusion. The brains were taken at a variety of time points during the reperfusion period and processed for *in situ* hybridization using 35S-labeled GADD45 antisense oligonucleotide probe, for TUNEL staining (24h and 48h) and for cresyl violet staining (72h). The specificity of the oligonucleotide probe was verified with northern analysis.

Elevation of GADD45 mRNA was detectable in CA1 neurons and DG granule cells at 2h. By 4-8h, intensive GADD45 mRNA induction was shown throughout the hippocampal formation, the caudate putamen, cortex, and the thalamus. By 24-48h, elevation of GADD45 mRNA was detected only in CA1 neurons, coinciding with the distribution of positive TUNEL staining. By 72h, GADD45 mRNA signal was lost in CA1 neurons, coinciding with histological cell death.

These data show that transcriptional expression of GADD45 can be induced in rat brain neurons following transient global ischemia. This gene was transiently expressed in non-vulnerable neuron populations but was persistently expressed in vulnerable CA1 neurons. These data also suggest that GADD45 may have a role in regulating neuronal responses to DNA damage and subsequent apoptotic cell death. Whether GADD45 is induced alone or concurrently induced with other GADD members is currently under investigation.

## 391.13

THE EXPRESSION OF CYSTATIN C, A CYSTEINE PROTEASE INHIBITOR, IN THE RAT HIPPOCAMPUS FOLLOWING TRANSIENT FOREBRAIN ISCHEMIA. D. Palm\*, N. Knukey, M. Primiano, S. Cascio, C. Johanson, Dept. Clin. Neurosci., Program in Neurosurg., Brown Univ. & RI Hospital, Providence, RI 02902

Recent immunohistochemical studies have demonstrated a temporal profile of the cysteine protease inhibitor, cystatin C, in degenerating rat hippocampal neurons following 10 min of transient forebrain ischemia (TFI). We have also demonstrated that cystatin C immunoreactivity (CC-IR) coincides with the density of neuronal damage following a mild to severe ischemic insult. However, the origin of cystatin C in the degenerating hippocampus following TFI is unknown. To address this issue, northern blot hybridization analysis was performed to examine cystatin C mRNA concentrations in rat hippocampus at 3, 7 and 14 days following TFI. The two-vessel occlusion model with hypotension for 10 min was used to induce TFI. Total hippocampal RNA was isolated from frozen tissue using the standard guanidinium thiocyanate method and 10 µg aliquots of RNA were separated by gel electrophoresis and transferred to Nytran. Cystatin C cDNA provided by Dr. Gerhard Schreiber, was used to probe the filters under stringent hybridization and washing conditions. Our results demonstrate that hippocampal cystatin C mRNA concentrations are identical in normal and sham animals and in 3, 7 and 14 days following TFI. These results indicate that cystatin C is produced in the hippocampus following TFI. Also, the elevated levels of cystatin C visualized after TFI by immunohistochemical analysis may therefore require post-transcriptional regulation.

## 391.15

EXPRESSION OF CYTOSKELETAL PROTEINS IN HYPOTHERMIC FOREBRAIN ISCHEMIA. K. Kumar\*, A.T. Evans and X. Wu, Department of Pathology, Michigan State Univ., E. Lansing, MI 48824.

The expression of  $\beta$ -actin mRNA was examined in hypothermic ischemic animals and compared to that in normothermic ischemic animals. Mongolian gerbils were subjected to forebrain ischemia by bilateral carotid occlusion of 10 min at 30°C followed by normothermic reperfusion for 1 h, 6 h, 1 d, 3 d, 2 weeks, and 1 month. The expression of  $\beta$ -actin mRNA was determined in hypothermic control and posts ischemic (PI) animals subjected to intraischemic hypothermia ( $n = 3$  in each gp.) by using *in situ* hybridization. In the case of normothermic ischemic brains, there was decrease in the expression of  $\beta$ -actin in the CA1 region beginning by 6 h PI, clearly diminished by 3 d, only faintly visible by 7 d, and completely absent by 1 month PI (shown by us previously). In contrast, the hypothermic ischemic brains showed no significant decline in its expression in the CA1 region. The expression was preserved in the CA1 region in all except one hypothermic ischemic animal in the 2 week PI period. These results indicate that hypothermia leads to preservation of the expression of a cytoskeletal protein,  $\beta$ -actin, in a selectively vulnerable region of the brain following ischemia.

## 391.17

REDUCED EXPRESSION OF  $\text{Na}^+$ -DEPENDENT PHOSPHATE COTRANSPORTER mRNA PRECEDES LOSS OF HIPPOCAMPAL CA1 PYRAMIDAL NEURONS FOLLOWING TRANSIENT GLOBAL ISCHEMIA IN THE RAT. B. Ni\*, D. Stephenson, X. Wu, J. A. Clemens and S. M. Paul, Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285.

The brain concentration of high-energy organic phosphates is frequently used as a measure of tissue viability and, more specifically, as an index of mitochondrial function after transient ischemia. We have recently cloned a brain-specific  $\text{Na}^+$ -dependent phosphate (Pi) cotransporter (rBNP1) which is specifically expressed in pyramidal and granule neurons of the cerebral cortex and hippocampus (Ni et al., Proc. Natl. Acad. Sci. 91:5607-5611, 1994) and have found that  $\text{Na}^+$ -dependent  $^{32}\text{P}$  uptake in cultured rat fetal cortical neurons correlates positively with intracellular energy charge (Glenn et al., J. Neurochem, in press). Using *in situ* hybridization histochemistry, we now report that expression of rBNP1 mRNA is markedly reduced in hippocampal CA1 pyramidal neurons by 22 hrs and completely abolished by 72 hrs after 4-V occlusion. No decrease in rBNP1 mRNA was observed in other regions of the brain. Cell staining with H/E, immunostaining with a MAP2 antibody as well as cellular morphology analysis with DIC microscopy reveal that CA1 pyramidal neurons are morphologically intact at 22 hrs postischemia but begin to degenerate by 72 hrs; consistent with the delayed neuronal death of CA1 neurons in the transient ischemia model. Our findings indicate that a decrease in Pi import may precede cell death of CA1 hippocampal neurons induced by transient global ischemia and may, in part, account for the reduction in high energy organic phosphates which occur in delayed neuronal death.

## 391.14

*IN SITU* HYBRIDIZATION STUDIES OF  $\beta$ -ACTIN GENE EXPRESSION IN RAT BRAIN TISSUE FOLLOWING ISCHEMIC INJURY AND REPERFUSION. J. P. Ray\*, P. Britton, X.-C. M. Lu, E. C. Tortella and J.R. Dave, Division of Medical Neurosciences, Walter Reed Army Institute of Research, Washington, DC 20307.

In an effort to identify the ischemic "penumbra", the viable (and potentially salvageable) but compromised area of neuronal tissue circumscribing the core infarct, we have examined the distribution of several markers (including *c-fos* and *hsp-70* gene) of cellular viability in infarcted rat brains using the *in situ* hybridization technique. Here we describe the patterns of  $\beta$ -actin mRNA in brains which have received 2 hr of intraluminal middle cerebral artery occlusion (MCAO) and 24 hr of reperfusion. MCAO was achieved by advancing a 3-0 monofilament nylon suture into the internal carotid artery of male Sprague-Dawley rats (270-330 g). After 2 hr of complete MCAO the filament was retracted to allow for reperfusion. Large infarcts (volume approximately 20% of the contralateral hemisphere) were routinely obtained with this technique. In comparison to the contralateral hemisphere, infarcted brain regions exhibited only very low levels of  $\beta$ -actin mRNA. However, regions adjacent to the primary lesion exhibited consistently elevated  $\beta$ -actin mRNA. This elevated expression of  $\beta$ -actin gene in brain regions adjacent to the lesioned tissue may be due to a precompensatory state of neuronal function following MCAO insult. Thus, the region over-expressing the  $\beta$ -actin gene may represent a true penumbra sensitive to neuroprotective therapies.

## 391.16

ALTERATIONS OF  $\beta$ -TUBULIN AND MICROTUBULE-ASSOCIATED PROTEIN IMMUNOSTAINING INDICATE AXONAL PATHOLOGY IN RESPONSE TO FOCAL CEREBRAL ISCHEMIA IN VIVO. D. Dewar\*, M. Fitzpatrick & D. Dawson, Wellcome Surgical Institute, University of Glasgow, Glasgow, G61 1QH, U.K.

Despite the clinical importance of white matter damage resulting from cerebral ischemia, axonal pathophysiology has been relatively neglected in comparison with that of neuronal perikarya. This study examined the axonal cytoskeleton following focal cerebral ischemia *in vivo* by means of immunohistochemical staining of  $\beta$ -tubulin and microtubule-associated proteins (MAPs).

All experiments were performed in physiologically monitored, mechanically ventilated, halothane anesthetized rats. Permanent focal ischemia was induced by occlusion of one middle cerebral artery (MCA). Sham controls had the artery exposed but not occluded. Two or 6 hours later the brains were perfused fixed and processed for MAP1A, MAP5 and  $\beta$ -tubulin immunohistochemistry. In white matter tracts within MCA territory (corpus callosum and fiber bundles within the caudate nucleus) there was increased  $\beta$ -tubulin, MAP1A and MAP5 immunoreactivity compared to shams. The white matter staining in MCA-occluded rats had a more granular appearance than the shams. The changes in immunostaining of all antibodies were more pronounced at 6 compared to 2h of MCA occlusion. Axons with an irregular, beaded profile were detected with all three antibodies. This morphological appearance has been suggested to represent the early stages of axonal pathology which precede axotomy. Alterations in microtubule proteins indicate the development of axonal pathology relatively early in response to focal cerebral ischemia *in vivo*.

## 391.18

STRIATAL DOPAMINE RECEPTOR GENE EXPRESSION FOLLOWING TRANSIENT GLOBAL ISCHEMIA. M.Y.-T. Globus\*, J. Singer, J. Rabe, D. Mash, R. Busto, I. Valdes, and M.D. Ginsberg, Cerebral Vascular Disease Research Center, Department of Neurology, University of Miami, School of Medicine, Miami, FL, 33101.

We have previously demonstrated that ischemia leads to a selective loss of D1 receptors, linking the detrimental role of dopamine (DA) to a D1-mediated process. To determine whether the changes in DA receptors are due to alteration in mRNA synthesis, we evaluated the effects of ischemia on striatal DA D-1 and D-2 receptor gene expression by *in situ* hybridization. Animals were subjected to 20 min of 2-vessel occlusion combined with hypotension, followed by 24h ( $n=6$ ) or 7 days ( $n=6$ ) of reperfusion. Adjacent sections were probed for D-1 and D-2 receptor mRNA using  $^{35}\text{S}$ -riboprobes. Negative and positive controls were included using sense and antisense probes, and regional hybridization signals were analyzed autoradiographically. In the dorsolateral striatum, reductions in D1 (% reduction from controls  $\pm$  SD;  $62\% \pm 39$ ,  $p < 0.01$  by ANOVA) and D2 ( $63\% \pm 20$ ,  $p < 0.01$ ) mRNA were detected following 24h of reperfusion. After 7 days of recirculation, D1 mRNA remained low ( $73\% \pm 24$ ,  $p < 0.01$ ) while D2 mRNA normalized. In the medioventral striatum, a  $29\% \pm 18$  and  $37\% \pm 8$  ( $p < 0.01$ ) reduction in D1 mRNA were observed at 24h and 7 days of reperfusion, respectively. D2 mRNA demonstrated a  $43\% \pm 13$  ( $p < 0.01$ ) reduction at 24h, while no significant changes were observed 7 days following ischemia. These results indicate that ischemia leads to a sustained inhibition of striatal D1 gene expression, while only a transient decrease in D2 mRNA was observed. These results could provide an explanation for the selective loss of D1 receptor observed following ischemia.

## 391.19

**WORSENING OF FOCAL CEREBRAL ISCHEMIC DAMAGE IN TRANSGENIC MICE OVEREXPRESSING AMYLOID PRECURSOR PROTEIN** F. Zhang<sup>1</sup>\*, K.K. Hsiao<sup>1</sup>, L. Mucke<sup>2</sup> and C. Iadecola<sup>1</sup>, <sup>1</sup>Department of Neurology, Univ. of Minnesota, Minneapolis, MN 55455; <sup>2</sup>Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037

Cerebral ischemia may activate the amyloidogenic pathway for processing of amyloid precursor protein (APP), resulting in accumulation of the neurotoxic A $\beta$  peptide (J. Biol. Chem. 269, 15253, 1994). In this study we used transgenic (Tg) mice expressing APP to determine whether excess APP, and presumably A $\beta$ , can influence the outcome of cerebral ischemia. The middle cerebral artery was occluded in Tg C57B16xSJL (B6xSJL) mice expressing human APP<sub>751</sub> (HuAPP<sub>751</sub>) and in Tg FVB/N mice overexpressing HuAPP<sub>695</sub>. Both APP transgenes contained a mutation (V717I) associated with familial Alzheimer's disease. One day after ischemia, infarct volume was determined in thionin-stained sections by computer-assisted planimetry. In non-Tg FVB/N (n=16) and B6xSJL (n=9) mice neocortical infarct volume was 27.6 $\pm$ 2.0 and 24.7 $\pm$ 1.5mm<sup>3</sup>, respectively. Cortical infarct volume increased by 43% in HuAPP<sub>751</sub> (35.2 $\pm$ 2.5mm<sup>3</sup>; n=9; p<0.05) and by 30% in HuAPP<sub>695</sub> (36.0 $\pm$ 3.0mm<sup>3</sup>; n=7; p<0.05). The larger infarct volume in APP transgenics was not due to an increase in ischemic edema because tissue swelling, measured by the method of Lin et al. (Stroke 24, 117, 1993), did not differ between Tg and non-Tg mice. Thus APP Tg mice have larger infarcts than non-Tg controls. Although we did not rule out the possibility that the greater damage is due to transgene-dependent vascular factors resulting in more severe ischemia, the data provide evidence that expression of APP worsens the outcome of focal cerebral ischemia. These findings suggest the possibility that cerebral ischemia induces alternative processing of APP resulting in increased levels of A $\beta$ , a peptide that may worsen brain damage by impairing calcium homeostasis in the ischemic penumbra.

(Supported by AHA and NIH)

## ISCHEMIA: GLUTAMATE

## 392.1

**NMDA CHANNEL ACTIVITIES IN RAT CA1 HIPPOCAMPAL NEURONS FOLLOWING A BRIEF HYPOXIC-HYPOGLYCAEMIC CHALLENGE IN BRAIN SLICES.** L. Zhang\*, P. Miu & J.H. Eubanks, Playfair Neuroscience Unit, Toronto Hospital, Departments of Medicine (Neurology) and Surgery (Neurosurgery), Bloorview Epilepsy Program, University of Toronto, 399 Bathurst Street, Toronto, Canada M5T 2S8.

We have demonstrated that a brief hypoxic-hypoglycaemic (H-H) challenge in brain slices causes an up-regulation of NMDA NR2C gene expression in hippocampus and cerebral cortex. In the present study, we examined the possible functional correlation of NR2C gene induction in H-H challenged CA1 neurons. Slices were exposed for 3 min to an external medium which contained 10 mM sucrose rather than glucose and was aerated with 95% N<sub>2</sub>-5% CO<sub>2</sub> rather than 95% O<sub>2</sub>-5% CO<sub>2</sub>. In control slices, which were maintained at 34°C for more than 12 hours, CA1 neurons showed synaptic field potentials and basic membrane properties comparable to those previously reported, with the exception of a decreased sAHP. Recorded in the cell-attached mode, NMDA channel activities in these neurons were dominated by a main conductance level of 60-70 pS. In slices examined at 9-12 hours following the H-H challenge, CA1 neurons exhibited decreased synaptic field potentials, but no apparent change in their membrane properties in comparison with those in control slices. Interestingly, in these challenged neurons, we consistently observed a population of subconductance opening in the range of 35-40 pS. The appearance of this subconductance level could be abolished by removing Ca<sup>2+</sup> from the recording pipette, thereby implicating dependency on external Ca<sup>2+</sup>.

We hypothesize that the subconductance level may reflect the functional expression of newly induced NMDA channels following the H-H. Supported by the MRC and Heart and Stroke Foundation of Canada.

## 392.3

**MODULATION OF NMDA-MEDIATED EXCITOTOXICITY BY GABA UPTAKE INHIBITORS OR BENZODIAZEPINES IN CORTICAL CELL CULTURE.** J.K. Muir\* and D.W. Choi, Dept. of Neurology and the Center for the Study of Nervous System Injury, Washington Univ. Sch. of Med., St. Louis, MO 63110.

We have previously reported that the GABA<sub>A</sub> agonist, muscimol, attenuated excitotoxic neuronal death, but exacerbated the neuronal death induced by oxygen-glucose deprivation (Soc. Neurosci. Abstr. 20:182, 1994). Here we examined whether these observations would extend logically to GABA uptake inhibitor and benzodiazepine drugs.

Murine cortical cell cultures containing both neurons and glia were exposed for 24 hr to NMDA (15  $\mu$ M), AMPA (10  $\mu$ M) or kainate (40  $\mu$ M) with or without drugs of interest. The GABA uptake inhibitors, guvacine or nipecotic acid (10-1000  $\mu$ M), both attenuated the neuronal death induced by 24 hr exposure to NMDA, but not AMPA or kainate. These drugs are not acting as NMDA receptor antagonists since they do not alter <sup>45</sup>calcium uptake stimulated by a 5 min exposure to 200  $\mu$ M NMDA. The benzodiazepine chlordiazepoxide (1-100  $\mu$ M) alone had no effect on neuronal injury induced by 5 min exposure to 100-300  $\mu$ M NMDA, but potentiated the protective effect of 10  $\mu$ M muscimol in the same paradigm. Both GABA uptake inhibitors and chlordiazepoxide potentiated the neuronal death induced by a 40-55 min period of oxygen-glucose deprivation. These observations add further support to the idea that activation of GABA<sub>A</sub> receptors may be paradoxically harmful to hypoxic cortical neurons, despite anti-excitotoxic effects on normoxic neurons.

Supported by NIH NINDS grant NS 32636 (DWC).

## 392.2

**BOTH APOPTOSIS AND EXCITOTOXIC NECROSIS CONTRIBUTE TO INFARCTION INDUCED BY FOCAL CEREBRAL ISCHEMIA.** C. Du\*, R. Hu, C.A. Csernansky, X.Z. Liu, C.Y. Hsu and D.W. Choi, Dept. of Neurology and Center for the Study of Nervous System Injury, Washington Univ. School of Medicine, St. Louis, MO 63110.

The temporal evolution of cerebral infarction was examined in rats subjected to transient occlusion of both common carotid arteries and the right middle cerebral artery. Consistent with other studies, the extent of tissue infarction after severe (90 min) ischemia was predictable after 6 hr and fully developed after 1 day (compared with 14 d). After mild (30 min) ischemia, no cortical infarction or histological evidence of injury was present by 1 d. However, modest infarction was evident after 3 d, and by 14 d infarction volume was comparable to that induced by the 90 min insult. 3 d after such mild ischemia, TUNEL staining and DNA gel electrophoresis revealed prominent evidence of internucleosomal DNA fragmentation in neurons destined to die; furthermore, progression to infarction at 14 d could be attenuated by pretreatment with 1 mg/kg i.p. cycloheximide.

In addition, combination treatment with the NMDA antagonist, dextrorphan, and cycloheximide produced an additive protective effects against infarction induced by severe transient ischemia. Administration of either 30 mg/kg dextrorphan or 0.5 mg/kg cycloheximide, i.p. 15 min before 90 min ischemia, reduced acute infarct volume by about 65%. When effective concentrations of both drugs were given, infarct volume was reduced by 87% as measured 14 d later. Taken together, present observations support the idea that infarction induced by transient focal ischemia occurs both by excitotoxicity, and by apoptosis dependent on new protein synthesis. Combined therapies directed at both mechanisms may be more effective than therapies directed at either mechanism alone. Supported by NIH NINDS grant NS 32636 (DWC).

## 392.4

**EFFECTS OF MK 801, 7-CHLOROKYNURENIC ACID AND GYKI 52466 ON STRIATAL DOPAMINE RELEASE DURING ISCHAEMIA.** C.C. Toner & J.A. Stamford\*, Anaesthetics Unit (Neurotransmission Laboratory), London Hospital Medical College, London E11BB, UK.

Massive release of neurotransmitters, including dopamine (DA), is thought to play a central role in neuronal death during acute cerebral ischaemia. Since DA is under presynaptic glutamatergic control, we investigated the effects of MK 801, 7-chlorokynurenine acid (7-CK) and GYKI 52466, antagonists at the NMDA phencyclidine binding site, glycine site and AMPA receptor respectively. Rat striatal slices were superfused (400ml/h) with artificial cerebrospinal fluid (ACSF) at 34°C. "Ischaemia" was mimicked by removal of O<sub>2</sub> and reduction in glucose concentration from 4 to 2mM. The latency (T<sub>on</sub>), rate ( $\Delta$ [DA]) and maximum level of DA release (DA<sub>max</sub>) were monitored by fast cyclic voltammetry. Control (means  $\pm$  s.e.m, n=8) values were 156 $\pm$ 5s (T<sub>on</sub>), 8.3 $\pm$ 2.2 $\mu$ M/s ( $\Delta$ [DA]) and 84 $\pm$ 12 $\mu$ M (DA<sub>max</sub>). MK 801 (10 $\mu$ M) significantly prolonged T<sub>on</sub> (to 197 $\pm$ 10s, P<0.01), reduced  $\Delta$ [DA] (to 1.6 $\pm$ 0.4 $\mu$ M/s, P<0.05) and decreased DA<sub>max</sub> (to 60 $\pm$ 7 $\mu$ M, P<0.05), (n=8). 7-CK (50 $\mu$ M) and GYKI 52466 (25 $\mu$ M) had no effect on any parameter. These data suggest that NMDA but not AMPA receptors are involved in ischaemia-induced DA release and, surprisingly, that the glycine site does not appear to modulate NMDA receptor function in this model.

## 392.5

KETAMINE ANTAGONIZES HYPOXIA-INDUCED DOPAMINE RELEASE IN RAT STRIATUM. Y. Wang\*, A.L. Chiu, J.C. Lin. Dept. of Pharmacology, Nat'l Defense Med. Ctr., Taipei, Taiwan 100.

The purpose of this study is to investigate the hypothesis that ketamine, a non-competitive antagonist of the NMDA receptor, attenuates hypoxia-induced striatal dopamine release *in vivo*. High-speed chronoamperometric recording techniques, using Nafion-coated carbon fiber electrodes, were used to evaluate extracellular dopamine (DA) concentration in the striatum. KCl and DA were locally applied directly to the striatum of urethane-anesthetized Sprague-Dawley rats. These anesthetized animals were paralyzed with d-tubocurarine and connected to a respirator to allow controlled respiration. Systemic concentrations of oxygen and carbon dioxide were altered by changing the partial pressure of O<sub>2</sub>, CO<sub>2</sub>, N<sub>2</sub> of inspired air and the rate of the respirator. Our data indicates that lowering the respiratory rate from 90 to 20 times/min for 5 minutes, in room air, caused a decrease in blood O<sub>2</sub> while increasing the CO<sub>2</sub> concentration. We also found that lowering the respiratory rates potentiated K<sup>+</sup>-induced DA release but not DA clearance in the striatum. In an attempt to induce hypercapnia, the room air was replaced with high CO<sub>2</sub>-containing air, and this change resulted in increased blood CO<sub>2</sub> levels without lowering O<sub>2</sub> concentration. The hypercapnia did not alter K<sup>+</sup>-induced DA release in the striatum. Next, we attempted to simulate anoxic hypoxia in the absence of hypercapnia. Respiration with pure N<sub>2</sub> for 30 sec resulted in lowering blood O<sub>2</sub> without increasing CO<sub>2</sub> levels. Both basal and K<sup>+</sup>-evoked DA release were increased during N<sub>2</sub>-induced anoxic hypoxia, suggesting that transient hypoxia facilitates DA release in the striatum. We also found that systemic application of ketamine antagonized hypoxia-induced electrochemical responses. These data suggest that the increase in DA release *in vivo* during short term hypoxia may probably be mediated through NMDA receptors.

## 392.7

CHARACTERIZATION OF MORPHINANS HIGHLY PROTECTIVE IN PERMANENT MIDDLE CEREBRAL ARTERY OCCLUSION (MCAO) IN RATS. G. Fischer, A. Bourson, J.A. Kemp\*, H.P. Lorez, V. Mutel and G. Trube. Preclinical Research, F. Hoffmann La-Roche, 4002 Basel, Switzerland

A series of dextrorotary morphinans was tested in 3H-MK 801 binding with rat brain membranes. They showed different affinities for the NMDA receptor open-channel blocker binding site and were further characterized *in vitro* with protection of cultured rat cortical neurons against glutamate toxicity and electrophysiology on recombinant NMDA receptors expressed in *Xenopus* oocytes. *In vivo* tests included seizures in mice (audiogenic seizures, i.c.v. NMDA-induced convulsions) as well as permanent focal ischemia (MCAO) in rats. A high correlation was found between affinity in binding experiments and protection against glutamate toxicity as well as blockade of NMDA-induced currents. However, although anticonvulsant effects were seen at comparable doses for all compounds, only the most potent ones were found to be neuroprotective in MCAO given post-occlusion. Ro 24-6173 was neuroprotective at a dose that had only slight effects on motor behaviour and was without cardiovascular or vacuole-inducing effects in cingulate-retrosplenial cortex.

## 392.9

CNS 1102 PROTECTS AGAINST BRAIN DAMAGE DUE TO HYPOXIC ISCHEMIA (HI) IN THE NEONATAL RAT. S. Wang, D. Zhou\*, J.B. Fischer, A.G. Knapp and W. F. Holt. Pharmacology Department, Cambridge NeuroScience, Inc., Cambridge, MA 02139.

Perinatal asphyxia/ischemia is a frequent cause of neurological disorders in human neonates. Such deficits incurred during birth may produce permanent brain damage. Presently, there is no effective treatment for perinatal ischemia. The excitatory amino acid glutamate has been postulated to be an important mediator of focal ischemic brain damage in adult mammals. This suggested a possible role for glutamate in promoting ischemic damage in neonatal mammals, particularly since NMDA receptor density is at its zenith in neonates. Thus we evaluated a neuroprotective role for the noncompetitive NMDA antagonist, CNS 1102 (currently in Phase II clinical trials for traumatic brain injury and stroke) in a neonatal rat model of hypoxic ischemia (HI)-induced brain damage. The left common carotid artery of 7-8 day old rats was ligated, and the animals were then exposed to 7.8% O<sub>2</sub> for 1.5 hours in an incubator at 37°C. Two days later the animals were sacrificed, and their brain removed and cut into four 2 mm thick slices prior to staining with TTC (triphenyltetrazolium chloride). Image analysis of brain slices indicated that HI caused measurable infarction (Mean±SEM=18.4±3.3 mm<sup>3</sup>) in approximately 85% of the 22 control animal brains evaluated. Treatment of rat pups with CNS 1102 by intraperitoneal injection immediately before and after HI resulted in about 40% reduction in the incidence of infarction (p<0.05) at a 2 X 3 µmol/kg drug dose (i.e. 2 X -1 mg/kg; n=21) and approximately 90% reduction (p<0.001) at 2 X 10 µmol/kg drug dose (n=21). Infarcts were observed in only 52% and 10% of the HI rat pups treated with CNS 1102 at 3 and 10 µmol/kg, respectively. The results suggest that glutamate mediates HI-induced brain damage in neonatal rats and that the NMDA ion-channel blocker CNS 1102 can protect against such lesions.

## 392.6

NEUROPROTECTIVE EFFECT OF DEXTROMETHORPHAN FOLLOWING TRANSIENT, BUT NOT PERMANENT, FOCAL CEREBRAL ISCHEMIA IN THE RAT. P. Britton, X.-C.M. Lu, D. Lloyd, S. Gribben, J.I. Loats, and F. Tortella\*. Walter Reed Army Inst. Res., Washington, DC 20307, Loats Associates, Westminster, MD 21158.

Dextromethorphan (DM) has been observed to afford neuroprotection in a variety of *in vitro* and *in vivo* experimental models of CNS injury. In the present study we have evaluated the neuroprotective activity of DM following both transient and permanent focal cerebral ischemia in the rat. Middle cerebral artery occlusion (MCAO) was achieved by advancing a 3-0 monofilament nylon suture up the internal carotid artery of male Sprague-Dawley rats (270-330 g, n=4-7/group). In rats subjected to transient focal ischemia, the endovascular suture was retracted to allow reperfusion 2 hours after MCAO. Body temperature was maintained normothermic throughout stroke surgery and reperfusion procedures. Animals were dosed s.c. with 20 mg/kg DM at 0.5, 1, 2, 4, and 6 hours post occlusion. Following 24 hours of permanent occlusion or reperfusion, animals were sacrificed and their brains removed for analysis of infarct volume using TTC staining and computer-assisted image analysis. As a result of transient MCAO, vehicle treated rats exhibited a total infarct volume of 203.3 ± 32.6 mm<sup>3</sup>. DM treatment produced a 61% reduction in infarct volume to 78.7 ± 12.8 mm<sup>3</sup>. In contrast, permanent MCAO not only produced a larger infarct volume (406.3 ± 43.5 mm<sup>3</sup>) when compared to corresponding transient MCAO values, but also one which was not significantly reduced in size by treatment with DM (313.8 ± 58 mm<sup>3</sup>). Infarcted hemispheric edema was not different in vehicle treated rats following transient or permanent MCAO and was not significantly reduced by DM in either group. In summary, the reduction in infarcted tissue volume produced by treatment with DM in our model of transient focal cerebral ischemia provides further support for the *in vivo* neuroprotective activity of this compound. Importantly, the severity of injury resulting from permanent MCAO may ultimately underlie the lack of protective effect of DM, thereby questioning the ability of this model to effectively evaluate the activity of putative neuroprotectants.

## 392.8

EFFECT OF IFENOPRODIL ON INFARCT SIZE, BLOOD-BRAIN BARRIER BREAKDOWN, AND EDEMA FORMATION AFTER FOCAL CEREBRAL ISCHEMIA IN THE CAT. M. K. Baskaya, A. M. Rao, D. Donaldson, M. R. Prasad, R. J. Dempsey\*. Division of Neurosurgery, Department of Surgery, University of Kentucky Medical Center, Lexington, Kentucky, 40536-0084.

The effect of the glutamate N-methyl-D-aspartate (NMDA) receptor antagonist ifenoprodil in reducing infarct area has been examined in anesthetized cats, with drug (n=7) or saline (n=7) treatment being initiated 5 min after the induction of cerebral ischemia. Focal ischemia was produced by permanent occlusion of right middle cerebral artery, and animals were sacrificed 6 h later. Local cerebral blood flows in ischemic, penumbra, and contralateral brain regions were measured during the experimental procedure. Ifenoprodil reduced the total area of infarct (51.7±3.9 vs 29.6±7.3). Infarct area was expressed as a percentage of right hemisphere area (mean±SE). Although ifenoprodil decreased the brain edema (1.028±0.02 vs 1.035±0.02), it attenuated the Evans blue extravasation, an indicator of blood-brain barrier breakdown, in only one brain section, but not in all brain sections. There was no significant difference in cerebral blood flow measurements between control and drug treated groups. Results from this study suggest that ifenoprodil has a tissue sparing effects and this is not related to its vasodilatory or vasoconstrictor effects. It is likely that its neuroprotective effect may be related to its ability to antagonize NMDA receptors.

## 392.10

PROTECTION OF RODENTS AGAINST GLOBAL ISCHEMIA BY FPL 15896AR. E.E. Cregan, A.S. Howell, M.L. Stagnitto, R.J. Murray, J.A. Miller\* and G.C. Palmer. Fisons Pharmaceuticals, Box 1710, Rochester, NY 14603.

FPL 15896AR(+) exhibits moderate uncompetitive antagonism of the NMDA receptor (IC<sub>50</sub> to displace MK801 binding - 1.3 µM), as well as sigma-1 receptor affinity (IC<sub>50</sub> to displace [3H]pentazocine binding = 4.5 µM). Moreover, FPL 15896AR possesses antiepileptic activity (Knowles et al., FASEB J. 9:A394, 1995) and reduces infarct damage in rodent models of focal ischemia (Murray et al., Med. Chem. Soc. 209: MEDI 074, 1995). In the present study FPL 15896AR treatment prolonged survival of rodents exposed to hypoxia: The ED<sub>50</sub>s (mg/kg) to extend survival in mice were: i.v. = 21; p.o. = 36.7. FPL 15896AR (24 mg/kg) likewise extended the time to loss of righting reflex and survival in rats. When rats were subjected to a period of 20 min of global ischemia (4-vessel occlusion technique) followed by dosing of FPL 15896AR (24 mg/kg, po at reflow and b.i.d. for 7 days), CA1 neuronal damage along the septotemporal hippocampus axis was significantly reduced. Experiments are in progress to evaluate efficacy of the compound in other global models as well as the MCA suture occlusion model of focal ischemia.

## 392.11

## HU-211, A NOVEL NON-COMPETITIVE NMDA ANTAGONIST, REDUCES FOCAL ISCHEMIC BRAIN DAMAGE IN THE RATS.

L. Belayev\*, O. Alonso, R. Busto, S. Kraydich, W. Zhao, and M. Ginsberg. Cerebral Vascular Disease Research Center, Department of Neurology (D4-5), University of Miami School of Medicine, P.O. Box 016960, Miami, FL 33101.

HU-211 is a non-psychotropic cannabinoid analog which has been shown to act as a functional N-methyl-D-aspartate (NMDA) receptor blocker. We have investigated the neuroprotective efficacy of HU-211 following transient middle cerebral artery occlusion (MCAo) in rats. We modified the method of Zea Longa et al., 1989 to study focal cerebral ischemia.

Male Wistar rats were anesthetized with halothane and subjected to 90 min of temporary MCAo by retrograde insertion of an intraluminal nylon suture coated by polylysine (polycationic polymer) through the external carotid artery into the internal carotid artery and MCA. The drug (HU-211 in cosolvent, 4 mg/kg, i.v.) or vehicle was administered in a blinded fashion 70 min after onset of MCAo. The neurological status was evaluated during occlusion (60 min) and 3 days after MCAo. Three days after MCAo, the rats were perfusion-fixed and infarct volumes were determined.

HU-211 significantly improved the neurological score compared to vehicle 3 days after MCAo (1.71±0.28 and 4.07±0.47 respectively). Treatment with HU-211 significantly reduced infarct size (55.52±10.01 vs. 121.58±28.9 mm<sup>3</sup>) and brain edema (2.61±1.33 vs. 6.66±1.24%) compared to vehicle rats.

These results demonstrate the neuroprotective ability of HU-211 against focal cerebral ischemia as judged by neurological score, infarct size and brain edema. We have found also that the modified technique of MCAo is reliable, effective and produced consistent results.

## 392.13

## A MECHANISM FOR ISCHEMIC DELAYED NEURONAL DEATH BASED ON ALTERED METABOTROPIC GLUTAMATE RECEPTOR (mGluR) TRANSDUCTION PATHWAYS AND APOPTOSIS. L.J. Martin\*, F.E. Sieber and R.J. Traystman. Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205.

Cerebral ischemia causes selective delayed neuronal death (DND). We propose a cascade for DND in which posts ischemic alterations in signal transduction pathways that modulate intracellular Ca<sup>2+</sup> predispose neurons to apoptosis. Using a global incomplete cerebral ischemia model, we tested the hypothesis that DND has characteristics of apoptosis and that ischemia promotes in neurons that undergo DND an aberrant expression of mGluRs and their molecular effectors. Compression ischemia was induced (20 min) in dogs (n=11), decreasing cerebral blood flow by 80%. Nonischemic dogs (n=4) served as controls. After 7 days recovery, brains were prepared for neuropathology, TUNEL, immunocytochemistry (ICC) and histochemistry (ischemia, n=9; control, n=2) or for immunoblotting (ischemia, n=3; control, n=2). Cerebellum was used as a regional model for DND. Purkinje cells (70 ± 7% [M ± SE]) showed evidence for DND. By TUNEL, Purkinje and granule cells undergo nuclear DNA fragmentation postischemia, and ICC showed that expression of the apoptotic protein Bax is upregulated postischemia in these neurons. By ICC, mGluR1α and phospholipase Cβ (PLCβ) expression is increased relative to controls. Granule cells which do not express mGluR1 in controls are enriched in mGluR1 postischemia. Areas with increased mGluR/PLC expression showed elevated Ca<sup>2+</sup>-ATPase activity. Brain regions nonvulnerable to DND did not show increased mGluR1α/PLCβ expression. Immunoblots confirmed that expression of Bax and membrane fraction mGluR and PLCβ was elevated relative to controls. We conclude that selective DND is associated with posts ischemic changes in mGluR-coupled transduction mechanisms that regulate intracellular Ca<sup>2+</sup> and that abnormalities in these pathways may precondition neurons for apoptosis. (Supported by NIH NS20020).

## 392.15

## AMPA PARTIALLY PROTECTS THE CEREBRAL CORTEX FROM BRIEF LOCAL ISCHEMIA. J. Addae\*, L. Morav, S. Evans, University of the West Indies, St. Augustine, Trinidad &amp; Tobago.

Topically applied NMDA has been shown to abolish cortical neuronal electrical activity. This effect of NMDA is prevented by a preceding application of AMPA. Since activation of NMDA receptors plays an important role in ischemia-induced neuronal damage, we set out to establish whether AMPA could reduce this damage. Male Sprague Dawley rats were anesthetized with urethane. Cerebral ischemia was induced by ligation of one common carotid artery followed by clipping of the ipsilateral middle cerebral artery (MCA) for 5-10 mins. The forepaw was stimulated and the somatosensory evoked potentials (SEPs) recorded. MCA occlusion caused a gradual decrease in the amplitude of the SEPs. The time taken (T) for the eventual abolition of the SEPs was used as an estimate of the effects of compounds applied to the cortex. Topical application of AMPA (25-100 μM) for 10 mins prior to and during MCA occlusion caused a slight increase in the amplitude of the SEPs, and increased the time taken for the response to be abolished. This effect occurred in a dose dependent manner. AMPA at 25μM, 50μM and 100μM produced T values of 129±14s (n=7), 154±12s (n=13) and 217±32s (n=9) [mean±sem]; compared with control values of 99±12s, 116±10s and 121±15s respectively. A Wilcoxon test showed the effects of AMPA at 50μM and 100μM to be significant (p<0.01). The effects of 50μM AMPA were prevented by a preceding application of CNQX (10μM). Higher concentrations of AMPA abolished the SEPs. In comparison, MK801 (4mg/Kg i.p.) totally prevented the abolition of SEPs by the ischemia (n=5). The protective effect of AMPA may be due to desensitization of the receptors.

## 392.12

## NEUROPROTECTIVE EFFECTS OF A NOVEL NMDA GLYCINE SITE ANTAGONIST, SM-18400, IN THE RAT MODEL OF CEREBRAL ISCHEMIA. H. Yasuda, H. Tanaka, K. Ohtani, T. Kato, Y. Maruoka, A. Kawabe, C. Kawashima, H. Sakamoto, S. Tojo\* and M. Nakamura. Research Center, Sumitomo Pharmaceuticals Co., Ltd., Osaka 554, Japan.

SM-18400((S)-9-chloro-5-[p-aminomethyl-o-(carboxy-methoxy)phenyl-carbamoylmethyl]-6,7-dihydro-1H,5H-pyrido[1,2,3-de]quinoxaline-2,3-dione hydrochloride trihydrate) has high affinity and selectivity for NMDA receptor associated glycine sites in vitro. In the current study, we investigated the neuroprotective effects of SM-18400 in both a global and focal ischemia model in rats. In the global ischemic model, SHR rats were subjected to a permanent occlusion of the bilateral common carotid artery. SM-18400 was injected i.v. immediately and 2 hrs after the occlusion. The results showed that the ischemic insult produced severe brain edema and death. SM-18400 inhibited edema as measured by the reduction of water content in the forebrain when measured 3 hrs after the occlusion. SM-18400 also improved the survival rate at 24 hrs after the occlusion. In the focal ischemic model, SD rats received a transient left middle cerebral artery occlusion by the insertion of a nylon suture in the proximal anterior cerebral artery simultaneously with a permanent occlusion of the left common carotid artery. Starting 1 hr after the occlusion, SM-18400 was administered i.v. (bolus + infusion) for 25 hrs. SM-18400 dose-dependently reduced the infarction volume in the cerebral hemisphere. These findings show that the novel glycine antagonist, SM-18400, has protective effects against both global and focal ischemic brain injury. The present study strongly suggests a high therapeutic potential of SM-18400 in the treatment of stroke.

## 392.14

## NEONATAL ASPHYXIC BRAIN DAMAGE IS SYSTEM PREFERENTIAL. R.J. Traystman\*, A. Brambrink, R.C. Koehler and L.J. Martin. Johns Hopkins Univ. Sch. Med., Baltimore, MD 21287.

We used a piglet model of asphyxial cardiac arrest to test the hypothesis that neonatal brain shows system selective vulnerability to hypoxia-ischemia that is related to regional metabolism and ameliorated by AMPA receptor blockade with NBQX. Piglets (1-week-old) were exposed to 30 min hypoxia (arterial O<sub>2</sub> saturation 30%), 5 min room air (O<sub>2</sub> saturation 65%), and 7 min airway occlusion (O<sub>2</sub> saturation 5%). NBQX (n=10) or vehicle (n=10) was given (30 mg/kg, i.v.) before airway occlusion and during early recovery (15 mg/kg). Shams received (n=2) or did not receive (n=5) NBQX. Most asphyxial piglets seized after 24 h and received diazepam. After 4 days, brains were prepared for neuropathology, morphometry, and histochemical assays for cytochrome oxidase (CO) and Na<sup>+</sup>,K<sup>+</sup> ATPase activities to evaluate regional damage and metabolic abnormalities. Asphyxial-vehicle and -NBQX piglets had 30% and 70% reductions in viable parietal cortical neurons, respectively. Neuron loss in hippocampus, not differing among asphyxial cohorts, was 10% (CA1) and 50% (CA3). Injury distribution was selective in asphyxial-vehicle piglets, with damage to somatosensory cortex and thalamus, putamen, and nigra reticulata. In asphyxial-NBQX piglets, damage was augmented and expanded into additional regions. In shams, CO and ATPase were higher (ca. 30%) in vulnerable regions relative to less vulnerable regions. Postasphyxial changes in CO and ATPase were regional, with reductions (40-50%) in vulnerable regions but increases (30-40%) in less vulnerable areas. NBQX worsened postasphyxial metabolic deficits. This neonatal asphyxial encephalopathy is consistent with combined hypoxic-ischemic and seizure-related insults that preferentially damage somatosensory systems in which regional metabolism and connectivity are possible determinants. Asphyxial injury is potentiated by AMPA receptor blockade which may alter adaptive synaptic and metabolic plasticity. (Supported by NS20020)

## 392.16

## METABOTROPIC-GLUTAMATE RECEPTOR ACTIVATION DOES NOT CAUSE ANOXIC HYPERPOLARIZATION OF HIPPOCAMPAL NEURONS. A.T. Tan\*, G. Erdemli and K. Krnjević. Anaesthesia Research Dept., McGill Univ., H3G 1Y6, Montréal, P.Q. Canada.

Brief anoxia (2-3 min) induces a characteristic G<sub>K</sub>-mediated hyperpolarization and conductance increase in CA1 neurons. The depression of the anoxic response by internal EGTA (Erdemli and Krnjević (1994) Proc. Can. Fed. Biol. Soc. p123) and by some blockers of internal Ca<sup>2+</sup> release (Belousov et al J.Physiol. 1995 in press) indicated that internal Ca<sup>2+</sup> release is a major element in the anoxic response. In this study, we tested an agonist (t-ACPD) and antagonists (MCPG and L-AP3) of metabotropic glutamate receptors (mGluR) on anoxic responses of CA1 neurons recorded with patch electrodes filled with KMeSO<sub>4</sub> in slices kept at 33°. In 6 cells clamped at -45 mV, t-ACPD (50 μM) caused a decrease in input conductance (G<sub>N</sub> by 31.4±6.9 %) and an inward shift in holding current (ΔI<sub>H</sub>= -72±20 pA). In these cells, 8 anoxic trials (2 min) raised G<sub>N</sub> by 8.4±1.5 nS and shifted I<sub>H</sub> outward by 281±32 pA; and t-ACPD had no significant effect on anoxic ΔG<sub>N</sub> (6.2±1.4 nS) and ΔI<sub>H</sub> (254±57 pA). In another 4 cells, MCPG (0.5 mM) was also ineffective: the anoxic changes were 105±65.2 % for ΔG<sub>N</sub> and 273±27 pA for ΔI<sub>H</sub> in control runs and 130±102 % and 155±117 pA in the presence of MCPG. L-AP3 (1 mM) also had no effect on anoxic responses: in control runs, anoxic G<sub>N</sub> increased by 106±65.2 % and ΔI<sub>H</sub> was 273±27 pA; in the presence of L-AP3, the corresponding ΔG<sub>N</sub> was 130.5±10.1 % and ΔI<sub>H</sub>=155±116.9 pA.

These preliminary results suggest that Ca<sup>2+</sup> release from mGluR-activated internal stores is not responsible for the hyperpolarization of CA1 neurons induced by brief anoxia.

ONSET AND DURATION OF OCCLUSION EVOKED GLU AND DA RELEASE IN THE RAT BRAIN USING THE REAL-TIME MONITORING METHOD. Y. Watanabe<sup>1)</sup>, H. Uchino<sup>2)</sup>, A. Ishiki<sup>3)</sup>, T. Nishimura<sup>4)</sup>, T. Nishimori<sup>4)</sup> and T. Shibuya<sup>3,4)</sup>. 1) Dept of Pharmacology, Tokyo Medical College, Tokyo 160, Japan. 2) Dept of Anesthesiology, Tokyo Medical College, Tokyo 160, Japan. 3) Environmental Biological Life Science Research Center Inc., Shiga 528, Japan. 4) Dept of Biomed Sci. Sch of Med, Univ of IL at Rockford, U.S.A.

It has been documented that the tolerance of neuronal change induced by repeated occlusion is seen in the post-synaptic neuron. The changes in the pre-synaptic neuron, however, are still unknown. In this experiment, we measured the onset and duration of the increases of glutamic acid (Glu) and dopamine (DA) levels in the rat caudate putamen after ischemia, using the microdialysis biosensor (for Glu) and fast cyclic voltammetry (for DA). Two types of ischemic animal models were used. One was the two vessel occlusion plus exsanguination treated normoglycemic model, and the other was the streptozotocin induced hyperglycemic ischemia model. In the normoglycemic ischemia model, the levels of Glu and DA were raised within one minute of the first occlusion, and these levels increased during ischemia. In addition, unlike the previous reports, the increases of Glu and DA levels evoked by ischemia were not transient. The ischemia evoked Glu release was much faster than DA release. The magnitude of these increases seen in normoglycemia was much less than those seen in hyperglycemia. After re-perfusion, the inflated levels of both transmitters were gradually decreased. Moreover, repeated occlusion delayed the onset of transmitter release, although the total quantity of neurotransmitters remained unchanged. These results suggest that neuronal activities in pre-synaptic neurons are influenced by repeated occlusion, and that serum glucose levels are related to the resultant quantity of Glu and DA release.

## ISCHEMIA: NITRIC OXIDE AND OTHER TRANSMITTERS

## 393.1

SPONTANEOUSLY HYPERTENSIVE RATS HAVE DECREASED CEREBRAL NITRIC OXIDE ASSAYED BY ELECTRON SPIN RESONANCE. Neal J. Sondheimer, Mark E. Mullins, Yanming F. Wang\*, and Stuart A. Lipton. Dept. of Neurology, Children's Hospital, Prog. in Neurosci., Harvard Med. Schl., Boston, MA 02115; Dept. of Chemistry, Harvard Univ., Cambridge, MA 02138.

Electron spin resonance (ESR) spectroscopy was used to monitor nitric oxide (NO<sup>•</sup>) levels in rodent cerebral cortex under various conditions. Male spontaneously hypertensive rats (SHR, *n* = 4) weighing 300-320 g or control rats (Wistar-Kyoto (WKY) or Sprague-Dawley (SD), *n* = 16), were injected parenterally with the NO<sup>•</sup>-specific spin trap, iron/diethyldithiocarbamate [Fe(II)/DETC] under chloral hydrate sedation. Within 30 min, a filament was threaded into the lumen of the middle cerebral artery to produce transient occlusion (Longa et al., *Stroke* 1989), and the animals were sacrificed 10 min later. Cortical tissue was then harvested and analyzed by ESR for NO<sup>•</sup>; basal levels of NO<sup>•</sup> were determined on unoperated rats 40 min after Fe(II)/DETC injection. We found that basal NO<sup>•</sup> production in SHR was dramatically lower than in the cortex of WKY or SD rats (*P* < 0.05 by ANOVA). We also observed that the induction of focal ischemia in SHR (*n* = 6) did not significantly elevate NO<sup>•</sup>, whereas SD rats displayed >100% increase in NO<sup>•</sup> compared with basal levels (*n* = 12). Brain nitric oxide synthase activity is reportedly normal in SHR (Clavier et al., *Stroke* 1994). However, it has been hypothesized that there is increased activity of superoxide anion (O<sub>2</sub><sup>•-</sup>) in SHR (Nakazono et al., *PNAS* 1991). In theory, this could account for the decrement in NO<sup>•</sup> since O<sub>2</sub><sup>•-</sup> and NO<sup>•</sup> react to form peroxynitrite (ONOO<sup>-</sup>). This reaction would decrease NO<sup>•</sup> and potentially contribute to neuronal damage in these animals.

## 393.3

THE ROLE OF ATP AND NITRIC OXIDE IN HYPOXIA-INDUCED POTENTIATION IN THE RAT HIPPOCAMPUS. M. Lyubkin, D. M. Durand, M. A. Haxhiu, K. E. Ward, T. S. Whittingham\*. Departments of Biomedical Engineering, Medicine, Neuroscience, Neurosurgery, Case Western Reserve University, Cleveland, OH 44106.

Recently, it was demonstrated that the pharmacologically isolated N-methyl-D-aspartate (NMDA)-mediated responses in the CA1 region of the rat hippocampus were significantly potentiated for at least one hour by a (1-3 min) hypoxic-aglycemic episode. Little is known about the mechanisms responsible for the induction and maintenance of this novel form of potentiation. In the present study, we investigated the role of ATP and nitric oxide (NO) in hypoxia-induced potentiation using extracellular recordings in the CA1 region of the rat hippocampus. Hippocampal slices were taken from Sprague Dawley rats and placed in an interface chamber containing normal ACSF solution. 0%O<sub>2</sub>-hypoxia was induced by replacing the 5%CO<sub>2</sub>, 95% O<sub>2</sub> gas mixture with 5%CO<sub>2</sub>-95%N<sub>2</sub> for 2 min. Significant potentiation of the slope of the dendritic EPSP was found in normal ACSF fluid (69% ± 23 SEM, *P* < 0.01, *n* = 10). One hour pre-incubation in creatine (25mM) rich ACSF inhibited hypoxia-induced potentiation even in the presence of picrotoxin (10μM). L-arginine, a substrate of NO, also blocked hypoxia-induced potentiation at 50μM but not at 25μM. These data indicate that 1) low levels of ATP are in part responsible for the induction of hypoxia-induced potentiation; 2) creatine blockade of hypoxia-induced potentiation is not mediated by GABA-ergic inhibition and; 3) that nitric oxide may play a concentration-dependent role in the induction and maintenance of hypoxia-induced potentiation. Supported by NIH grant #HL25830.

## 393.2

INDUCTION OF NEURONAL NITRIC OXIDE FOLLOWING HYPOTHERMIC CIRCULATORY ARREST IN A CANINE SURVIVAL MODEL. M.V. Brock, C.J. Lowenstein, M.A. Lange, M.V. Johnston\*, W.A. Baumgartner, M.E. Blue. The Johns Hopkins Medical Institutions, Baltimore, MD 21287

Permanent neurological injuries after hypothermic circulatory arrest (HCA) are problems in cardiac surgery occurring in approximately 12% of children and 15% of adults. The cause of this neurotoxicity is unknown and there is no treatment.

We have developed a canine survival model of HCA that closely simulates clinical practice. We have previously shown that this model produces a consistent neurologic deficit and histopathological pattern of selective neuronal death involving neurotransmitter excitotoxicity and changes in glutamate specific receptors. Adult male hound dogs (*n* = 12) were exsanguinated using cardiopulmonary bypass (CPB) and subjected to 2 hours of HCA at a brain temperature of 18°C. The animals were then slowly reperfused to normothermia, separated from CPB, survived for 6, 18 and 72 hours, and compared with controls (*n* = 6) who did not undergo HCA.

In canine striatal homogenates, the expression of neuronal nitric oxide synthase (nNOS) increases significantly at 6 and 18 hours after reperfusion (340% and 500% respectively; *p* < 0.05), but returns to baseline by 72 hours. Concomitant with this increased enzymatic activity is a 7-fold accumulation of nitric oxide (NO) metabolites in the serum (*p* < 0.05) 4 hours after reperfusion which also returns to baseline by 3 days. Furthermore, immunocytochemical staining with nNOS specific monoclonal antibody (Transduction Labs) reveals marked augmentation of nNOS expression 6-18 hours after HCA that is attenuated by 72 hours. Dark field analysis demonstrates localization of nNOS to neuronal processes with the development of a widespread, dense plexus of these NOS fibers throughout the neocortex 6-18 hours after HCA.

We conclude that excitatory neurotransmitter mediated neuronal death during HCA involves a significant increase in nNOS expression in neuronal processes in the brain and that this leads to widespread augmented NO production. Supported by NIH-ROINS 21238

## 393.4

NEITHER L-ARGININE NOR L-NAME ALTER NEUROLOGIC OUTCOME FOLLOWING GLOBAL ISCHEMIA IN CAT. J.R. Kirsch, A. Bhardwaj, L.J. Martin, D. Hanley\*, R.J. Traystman. Dept. of Anesth. Crit. Care Med. Johns Hopkins Med. Inst. Balt. MD 21287

We tested the hypothesis that inhibition of nitric oxide (NO) synthase with N<sup>•</sup>-nitro-L-arginine methyl ester (L-NAME) would improve neurologic outcome and L-arginine (L-ARG) would worsen neurologic outcome following transient global ischemia. During halothane anesthesia cats were mechanically ventilated. A heat lamp was used to maintain esophageal temperature at 38.0 ± 0.5°C in all groups at baseline, during ischemia and the immediate period (30 min) of reperfusion. Cats (*n* = 6 each group) were treated with IV saline, L-NAME (5 mg/kg or 10 mg/kg) or L-ARG (300 mg/kg) 30 min prior to onset of ischemia. Ischemia was produced for 10 min by tightening ligatures around the left subclavian and brachiocephalic arteries with hemorrhagic hypotension to a mean arterial pressure of 50. Time to isoelectric EEG was similar between groups (saline 26 ± 11; L-NAME-5 15 ± 4; L-NAME-10 36 ± 27; L-ARG 22 ± 7 sec). At 30 min of reperfusion cats in the L-ARG group were administered an additional 300 mg/kg IV. After wound closure all cats emerged from anesthesia and were extubated. At 72 hrs reperfusion neurologic deficit score was similar between groups (saline 38 ± 25; L-NAME-5 52 ± 15; L-NAME-10 47 ± 18; L-ARG 40 ± 30). Likewise, severity of neurodegeneration in CA1 hippocampus and cerebellum was similar in all groups. Because L-NAME and L-ARG do not affect neurologic, and possibly neuropathologic, outcomes we conclude that NO does not appear to be important in the mechanism of brain injury following global ischemia. Supported by NS 20020.

**NOS INHIBITION INDUCES BILATERAL NEUROBEHAVIORAL DEFICITS AFTER NON-OCCLUSIVE COMMON CAROTID ARTERY THROMBOSIS IN RATS.** N.E. Alexis\*, W.D. Dietrich, R. Prado, E. Green, and B.D. Watson. Departments of Neurology and Psychology, University of Miami School of Medicine, Miami, FL

Photochemically induced common carotid artery thrombosis (CCAT) leads to transient neurobehavioral deficits. Because the role of nitric oxide in the pathophysiology of thromboembolic stroke has not been investigated, we determined the neurobehavioral consequences of NOS inhibition following CCAT. Rats were assigned into 4 groups. Group 1 (n=12) underwent right CCAT. Group 2 (n=12) served as sham-operated controls. Group 3 (n=8) underwent right CCAT and were immediately given 15 mg/kg L-NAME i.v. Group 4 (n=8) served as CCAT controls but were administered 15 mg/kg L-NAME. Beginning 24 hr after injury, rats were tested daily for 3 days using a battery of 3 standard sensorimotor tasks. Statistical analysis was performed using the Kruskal-Wallis nonparametric test. Although no differences across groups in postural reflex scores were observed, differences existed in beam balance scores among both CCAT groups and shams ( $p < 0.05$ ). Elicited forelimb placing data indicated that the CCAT/L-NAME group exhibited consistent bilateral deficits which were significantly greater and more reproducible than in the non-treated CCAT group. In addition to the anticipated contralateral placing deficits, ipsilateral placing scores were  $0.2 \pm 0.2$ ,  $1.0 \pm 0.5$  and  $3.2 \pm 0.6$  in the sham, CCAT, and CCAT/L-NAME groups, respectively ( $p < 0.01$ ). In this thromboembolic model, acute NOS inhibition may aggravate neurobehavioral outcome by increasing platelet capture and thus intensifying brain ischemia.

## 393.7

**NITRIC OXIDE INHIBITORS ATTENUATE CA1 DEGENERATION INDUCED BY ISCHEMIC CONDITIONS IN RAT HIPPOCAMPAL SLICES** A.M. Benz, Y. Izumi, D.B. Clifford\* and C.F. Zorumski. Depts. of Psychiatry and Neurology, Washington Univ., School of Med., St. Louis, MO 63110.

In rat hippocampal slices, we previously observed that nitric oxide synthase (NOS) inhibitors attenuate neuronal damage produced by N-methyl-D-aspartate (NMDA), suggesting a role for NO in excitotoxic injury (Izumi et al. *Neurosci Lett*, 135:227,1992). Despite evidence implicating excitotoxic processes in stroke, the role of NO in ischemic brain damage remains unclear. We examined the involvement of NO in ischemic damage using hippocampal slices prepared from 30 day old albino rats and exposure to 20 min of oxygen/glucose deprivation (ischemia) followed by 90 min postincubation in oxygen and glucose containing media. Damage in the CA1 region was rated on a 0 (intact) to 4 (severe neuronal damage) scale by a rater blind to the experimental condition. Control slices exposed to ischemia were rated as  $2.8 \pm 0.5$  (N=9). L-N<sup>G</sup>-monomethylarginine (L-NMMA), a non-selective NOS inhibitor, partially attenuated ischemic damage in CA1 at concentrations of 30-300  $\mu$ M. At 300  $\mu$ M L-NMMA, slices were rated as  $1.3 \pm 0.5$  (N=8). A specific inhibitor of brain NOS, 7-nitroindazole (30  $\mu$ M), was also effective against ischemic degeneration ( $0.7 \pm 0.3$ , N=5). These results suggest that activation of brain NOS is involved in ischemic degeneration in the CA1 region.

**NITRIC OXIDE SYNTHASE INHIBITION, ADENOSINE RECEPTOR BLOCKADE, AND BLOOD FLOW AFTER RETINAL ISCHEMIA.** S. Roth\*, P. Ostwald, I. Goldstein, A. Pachnanda, S. Park, A. Moshfeghi. Dept of Anesthesia and Critical Care, Univ of Chicago, Chicago, IL 60637

We found previously that hyperemia follows a 60 min period of retinal ischemia in cats. To determine the mechanisms responsible, we examined the effects of nitric oxide synthase (NOS) inhibition and adenosine (ADO) receptor blockade in our ischemia model using measurements of retinal blood flow and the electroretinogram (ERG). Cats were anesthetized with chloralose and divided into four groups. In all groups, one eye was subjected to 60 min of ischemia by raising intraocular pressure above systolic arterial pressure. Group 1 received 30 mg/kg L-NG-nitro-arginine-methylester (L-NAME), group 2 intravitreal 8-SPT (ADO receptor antagonist), group 3 combined L-NAME and 8-SPT, and group 4 was a saline control. Five minutes after the end of ischemia, blood flow in the retina, choroid, and iris/ciliary body was measured using injections of radioactively labeled microspheres. ERG studies were carried out before, during, and 1, 2, 3 and 4 hours after ischemia ended. Basal retinal blood flow was decreased by L-NAME, but not by 8-SPT. Posts ischemic retinal hyperemia was eliminated by 8-SPT, but not by L-NAME, and slightly decreased by combined L-NAME/8SPT. ERG a- and b-wave recoveries were not altered by L-NAME or by 8-SPT; L-NAME infusion significantly decreased b-wave amplitude. Adenosine appears to be the primary regulator of increased blood flow after retinal ischemia. The interaction of ADO and NO after ischemia deserves further study. Study supported by NIH grant RO1EY10343

## 393.6

**NO-NITRO L-ARGININE METHYLESTER (L-NAME) REDUCES CORTICAL INFARCT AND NECROTIC DAMAGE BUT NOT APOPTOTIC CELL LOSS.** C. Chariat-Marguier\*, J. Margail\*, R.J. Walsh\*, M. Plotkin\* and Y. Ben-Ari, Université René Descartes, Paris V - INSERM U29, 123 bd de Port-royal, 75014 Paris. 24 avenue de l'observatoire, 75006 Paris. France.

Activation of apoptosis has been suggested to play a role in pathological situation in the adult central nervous system, namely after global ischemia as demonstrated by oligonucleosomal degradation of genomic DNA and protection with protein synthesis inhibitors (J. Neurochem, 1993, 61, 1973). Since nitric oxide (NO) plays a role in neuronal cell death, we have examined the effects of L-NAME on the DNA fragmentation damages in the striatum and cortex produced by a transient MCA occlusion in the rat brain. One hour MCA and CCAs occlusion induced oligonucleosomal fragments that are recognized as the characteristic DNA ladder at 18 h recirculation associated with a slight random DNA fragmentation. The random DNA cleavage was predominant at 48 h. Using PFGE, we have detected initial stages of DNA fragmentation (300 and 50 kbp) which occurred already at 6 h reperfusion whereas they were not detectable on conventional gel. A significant number of cells in the striatum, cortex, and islands of Calleja die with the characteristics of apoptosis (chromatin condensation, nucleus segmentation and apoptotic bodies) as detected by DNA nick-end labeling (TUNEL staining) preferentially in the penumbra, i.e. in cells mainly located to the inner borders of the necrotic volume. In rats treated with L-NAME (3 mg/kg, i.p., 5 min and 3 hours following MCA occlusion), a 24 % ( $P < 0.01$ ) reduction of cortical infarct volume was found at 24 h. However, DNA fragmentation at 18 h recirculation, in the cortex and striatum, was also observed but laddering was more conspicuous. In addition, scattered apoptotic nuclei were always present in these regions as well as in islands of Calleja. In contrast, the number of necrotic cells decreased in the ischemic core as shown with the TUNEL staining. L-NAME, which significantly decreased the cortical infarct, decreases the necrotic component but not the apoptotic component of cell death.

## 393.8

**NOS INHIBITION ATTENUATES KCN-INDUCED "EXCITOTOXIC" LESIONS AND EXCITATORY AMINO ACID RELEASE** G.S. Neal, W.J. Nicklas\* and G.D. Zeevalk. Dept. of Neurology, UMDNJ-Robert Wood Johnson Med. Sch., Piscataway, N.J. 08854.

Pathological production of nitric oxide (NO) during hypoxia has been linked to activation of nitric oxide synthase (NOS) upon prolonged activation of glutamate receptors (excitotoxicity). This association led to the hypothesis that ischemia-induced CNS damage, in part, is mediated by pathophysiological effects of NO. In these studies, 450  $\mu$ m transverse hippocampal slices from male rats were used to investigate the ability of N<sup>G</sup>-methyl-L-arginine (100  $\mu$ M NMA), a NOS inhibitor, to attenuate efflux of EAAs and associated neuronal damage induced by chemical hypoxia (2.5mM KCN). Histology and amino acid release were used as indices of excitotoxicity. To investigate the temporal effects of NOS inhibition on EAA release and glutamatergic receptor activation, we treated slices with KCN in the presence or absence of NMA for 5, 10, 20 or 30 min. At 5 min there was rounding of CA1 neurons that did not coincide with increased EAA efflux, but was substantially attenuated by NMA or a NMDA antagonist. At 10 min there was increased EAA efflux, moderate CA1 and CA4 damage, and mild CA3 damage. At 20 to 30 min, in addition to increased EAA efflux, all hippocampal regions appeared severely damaged. NMA substantially decreased EAA efflux. NMA or a combination of NMDA and non-NMDA antagonists afforded neuronal protection during 10, 20 or 30 min KCN exposure. These data support our previous studies which suggest that when energy stores are compromised, changes in the physiological state of the NMDA receptor, rather than increases in extracellular EAAs may be responsible for early receptor activation. At later times, increased EAA efflux may correlate with non-NMDA receptor activation. Moreover, these data suggest that NO augments the formation of "excitotoxic" lesions and concomitant EAA efflux.

**EFFECTS OF ADENOSINE ON NEURONAL DAMAGE PRODUCED BY INTRASPINAL OR INTRATHECAL INJECTION OF THE NITRIC OXIDE SYNTHASE (NOS) INHIBITOR L-NAME** R.P. Yezierski\*, R. Buchanan, S. Koch, H. Belmont, and A. Sanchez, The Miami Project and Depts. of Neurology and Neurological Surgery, University of Miami, Miami, FL 33136.

Intraspinal or intrathecal injections of L-NAME produce dose-dependent damage of spinal neurons. This damage is thought to result from a reduction in basal levels of nitric oxide (NO) producing an ischemic reaction secondary to vasoconstriction and reduced spinal cord blood flow (SCBF). The putative cellular mechanism of L-NAME induced neuronal damage may involve the release of glutamate, a substance known to have a role in excitotoxicity. Adenosine, a vasoactive agent, has been reported to have neuroprotective properties due to its actions as a vasodilator and inhibitory effects on glutamate release. Together these results led to the hypothesis that adenosine should exhibit neuroprotective effects against neuronal injury induced by inhibitors of NO synthesis. Intraspinal (0.3-0.6  $\mu$ l) or intrathecal (5-10  $\mu$ l) injections of L-NAME (50-250mM), adenosine (10-50mM) or L-NAME+adenosine were made at spinal levels T10-L5 in adult rats. After 48 hour survival periods spinal segments containing injection sites or those at the tip of intrathecal cannula were cut on a freezing microtome and stained with cresyl violet. The rostrocaudal extent of neuronal loss and the area of gray matter damage were evaluated with light microscopy and/or image analysis. The present results confirm previous observations of dose-dependent L-NAME damage of spinal neurons. Additionally, control injections of adenosine showed no effects, while there was a significant reduction in neuronal damage with injections of L-NAME+adenosine. These data suggest that adenosine may have neuroprotective effects against injury induced vasoconstriction and reduced SCBF resulting from reduced tissue levels of NO. ADENOSINE RECEPTOR ANTAGONISTS REDUCE  $[K^+]_e$  INCREASE AS A RESULT OF OXYGEN AND GLUCOSE DEPRIVATION IN THE RAT HIPPOCAMPUS *IN VITRO*. M.D.R. Croning, T.S.C. Zetterström, T.W. Stone\* and N.R. Newberry, Oxford University-SmithKline Beecham Centre for Applied Neuropsychobiology, University Department of Clinical Pharmacology, Radcliffe Infirmary, Oxford, OX2 6HE, England, U.K. and \*Department of Pharmacology, University of Glasgow, G12 8QQ, Scotland, U.K.

In the CA1 region of the hippocampal slice preparation, oxygen or oxygen+glucose deprivation is known to cause an increase in the extracellular  $K^+$  concentration ( $[K^+]_e$ ). We have investigated whether adenosine receptors might have a modulatory role in this increase by studying the effects of adenosine receptor antagonists.

Submerged rat hippocampal slices were superfused with aCSF (3 mM  $K^+$ , 5 mM glucose) at 30 °C.  $[K^+]_e$  was measured in the CA1 stratum pyramidale using valinomycin-based  $K^+$ -selective microelectrodes. Slices were subjected to a single insult: either oxygen or oxygen+glucose deprivation with or without antagonist pretreatment (30 min).

Oxygen deprivation (5 min) resulted in small changes in  $[K^+]_e$ , reaching 4-5 mM from the basal level of 3 mM. Pretreatment with theophylline (100  $\mu$ M) or 8-cyclopentyl-1,3-dipropylxanthine (100 nM) reduced this increase by ca. 50%.

Oxygen+glucose deprivation (10-25 min) resulted in a biphasic increase in  $[K^+]_e$ ; the initial increase was gradual (phase 1) reaching 7-12 mM in 6-8 min then the rate of rise increased sharply (phase 2) reaching 20-30 mM over the next 1-3 min. Both antagonists reduced the phase 1 increase in  $[K^+]_e$  by ca. 40% and delayed the onset of the phase 2 increase without affecting its magnitude.

In conclusion, these experiments suggest that adenosine  $A_1$  receptors may contribute to the increase in  $[K^+]_e$  in the CA1 pyramidal cell layer as a result of oxygen or oxygen-glucose deprivation.

## 393.15

DIAZEPAM PRODUCES SUSTAINED NEUROPROTECTION IN GERBIL HIPPOCAMPUS & PREVENTS ISCHEMIA-INDUCED WORKING MEMORY DEFICITS. Rochelle D. Schwartz-Bloom\*, Peter D. Chase, Janet Ko and Edward D. Levin. Depts. Pharmacology & Psychiatry, Duke University Medical Center, Durham, NC 27710.

Previously we showed that acute injection of diazepam following transient cerebral ischemia in both gerbils and rats produces substantial neuroprotection of the hippocampus 4-7 days later (Brain Res. 647:153-160, 1994; J. Neurosci. 15:529-539, 1995). In the present study we determined if neuroprotection by diazepam is long-lasting and if diazepam also prevents ischemia-induced working memory deficits. Gerbils were trained on an 8 arm radial maze for 20 sessions, when they reached asymptotic performance for choice accuracy. They were subjected to 5 min bilateral carotid occlusion and then injected 30 and 90 min later with diazepam (10 mg/kg). Four weeks later, they were retrained on the radial arm maze for 5 days; the following week they were sacrificed for histological analysis. Transient cerebral ischemia produced significant deficits in working memory tasks measured 4 weeks later ( $p < 0.0001$  in 3 different measures of choice accuracy). Diazepam completely prevented the ischemia-induced working memory deficits ( $p < 0.0001$ ). In the same gerbils, diazepam produced complete neuroprotection of area CA1 pyramidal neurons in 3/8 gerbils, partial protection in 3/8 gerbils and little protection in 2/8 gerbils. The degree of neuroprotection was the same at 5 weeks post-ischemia compared to 7 days post-ischemia. We conclude that enhancement of GABA neurotransmission with a benzodiazepine provides long-lasting neuroprotection in the hippocampus and, more importantly, it prevents memory deficits associated with cerebral ischemia.

## 393.12

ADENOSINE RE-UP TAKE INHIBITORS ARE NEUROPROTECTIVE. S.L. Moon\*, L. Signor, R.A. Myers, F. Matos, L. Lombardo, J. Hibbard, A. Ortiz, S. Reid, and N. Balasubramanian<sup>1</sup>. CNS Biology and <sup>1</sup>Central Chemistry, Bristol-Myers Squibb, Wallingford CT, 06492. Adenosine, acting as an endogenous neuroprotectant, inhibits the release of neurotransmitters including glutamate, and this effect is mediated by adenosine ( $A_1$ ) receptors. Presynaptically,  $A_1$  receptor activation hyperpolarizes the membrane, and postsynaptically adenosine stabilizes the membrane. However, in the brain, adenosine is rapidly removed from the extracellular space by a re-uptake mechanism. The therapeutic potential of adenosine receptor activation has been investigated previously, mainly through the use of  $A_1$  agonists. We have investigated adenosine re-uptake inhibitors (ARIs) as neuroprotective agents; unlike  $A_1$  agonists, their functional effect could be greater at the site of injury, i.e., where the adenosine level has been greatly elevated. Through the use of ARIs, a high concentration of extracellular adenosine could be sustained, and thereby potentiate adenosine's neuroprotective action.

When administered 1 hr. after bilateral carotid occlusion in the gerbil, our novel ARIs significantly decreased hippocampal damage. A single dose given at 2 hr. post-insult reduced infarct size after permanent middle cerebral artery occlusion in the spontaneously hypertensive rat by as much as 29% and improved neurologic outcome. In the mouse, pretreatment with ARIs completely blocked seizures induced by electroshock. Through the use of *in vivo* micro-dialysis, we have shown that a systemically delivered ARI increased extracellular striatal adenosine for > 12 hr. in the rat after anoxic insult. ARIs induced hypotension in the dog. We have blocked this hypotension by co-administering 8-(*p*-sulfonyl)theophylline, a polar  $A_1$  antagonist that poorly penetrates brain.

## 393.14

POST-ISCHEMIC CHANGES IN GABAA RECEPTOR  $\alpha 1$  SUBUNIT EXPRESSION IN CA1 HIPPOCAMPUS: REVERSAL BY DIAZEPAM. L.R. Ingelfield\*, C.A. Wilson, A.E. Barrier, P.J. Chase, K.S. Jones and R.D. Schwartz-Bloom. Dept. Pharmacology, Duke Univ. Med. Ctr., Durham, NC 27710

Following cerebral ischemia, hippocampal area CA1 pyramidal cells degenerate over 2-4 days, while the interneurons are spared. At the same time, GABAA receptor binding decreases within area CA1 dendritic fields. Here we examined the expression of GABAA receptor  $\alpha 1$  subunits on vulnerable CA1 pyramidal cells and on interneurons up to 35 days after 5 min bilateral carotid occlusion in the Mongolian gerbil. Beginning at 3-4 days and continuing up to 35 days after ischemia, there were degenerative changes in  $\alpha 1$ -immunoreactive (IR) CA1 pyramidal cell dendrites (beading, followed by loss). At the same time, the number of  $\alpha 1$ -positive CA1 interneuron soma increased progressively over the 35 day survival period. Many area CA1  $\alpha 1$ -IR interneurons also developed beaded dendrites by day 3, and had reduced dendritic extensions later. The  $\alpha 1$ -subunit expression was neuron-specific, and no changes were observed in area CA2-3 or dentate gyrus at any time. Subsequently, we compared  $\alpha 1$  subunit expression with the degree of protection of CA1 pyramidal cells 3-5 weeks after treatment with diazepam (DZ) (10 mg/kg, 30 + 90 min post-ischemia) or the GABA uptake inhibitor, tiagabine (TG; 45 mg/kg, 10 min post-ischemia). These drugs protect CA1 pyramidal cells when assessed 4-7 days after ischemia (Schwartz *et al.*, Brain Res. 647:153, 1994; Ingelfield *et al.*, submitted). Three weeks after ischemia, TG protected only 23±9% of these cells, while DZ protected 71±11% 5 weeks after ischemia (see poster by Schwartz-Bloom *et al.*). Similarly, DZ markedly attenuated the ischemia-induced increase in  $\alpha 1$ -IR interneurons and the pyramidal cell dendritic beading 35 days later. However, while such changes in  $\alpha 1$ -IR were prevented in TG-treated gerbils at 4 days, TG failed to prevent this pathology 3 weeks post-ischemia. We conclude that 1) there are pathologic changes in GABAA receptor phenotype in both ischemia-sensitive and -resistant hippocampal neurons, and 2) that DZ is superior to TG in preventing these changes in both pyramidal cells and interneurons long-term. Supported by NS28791, NS07274, and American Heart Assoc.

## 393.16

SUPPRESSION OF GABA<sub>A</sub>-MEDIATED CURRENTS BY METABOLIC INHIBITION IN RAT HIPPOCAMPAL NEURONS CORRELATES WITH ELEVATED  $[Ca^{2+}]_i$ .

Alex V. Nowicky\* and Michael R. Duchen. Physiology Dept. University College London, Gower St, London, U.K. WC1E 6BT.

Ischemia or hypoglycemia are associated with the development of seizures. Hypoxia also causes: i) failure of GABA-mediated IPSPs before failure of glutamate-mediated EPSPs in brain slices and ii) a rise in  $[Ca^{2+}]_i$  in isolated hippocampal cells (Nowicky & Duchen, (1994) J. Physiol., 475P, 148). As GABA<sub>A</sub>-mediated  $Cl^-$  currents may be depressed by a rise in  $[Ca^{2+}]_i$  (Inoue *et al.* (1986) Nature, 324:156-58, and Stelzer *et al.* (1988) Science, 241:339-41), we have examined the relationship between metabolic inhibition,  $[Ca^{2+}]_i$ , and GABA<sub>A</sub>-mediated currents in isolated hippocampal neurons.

Perforated patch clamp recordings using amphotericin B were obtained from CA1 neurons freshly dissociated from hippocampal slices of 15-25 day old rats. GABA (10  $\mu$ M) was applied repeatedly near the soma by pressure ejection, and elicited an inward current at a holding potential of -50mV. The current reversed at  $E_{Cl}$  and was blocked by the GABA<sub>A</sub> antagonist, bicuculline (100  $\mu$ M). No run-down of the current was seen for periods of up to 1 hour. Both uncoupling mitochondrial oxidative phosphorylation with 1  $\mu$ M FCCP or inhibition of the respiratory chain with 2mM NaCN for 2-5 min reversibly reduced the mean peak current by 66% ± 6.7% (mean ± sem, n=6). In a further series of experiments, changes in  $[Ca^{2+}]_i$  and GABA current were measured simultaneously in cells loaded with fura-2 (AM). The reduction in the GABA current showed a clear temporal correlation with the rise in  $[Ca^{2+}]_i$ . These data suggest that impaired mitochondrial function may lead to a reduction of GABA<sub>A</sub>-mediated  $Cl^-$  conductance triggered by a  $[Ca^{2+}]_i$ -dependent postsynaptic regulatory mechanism.

DIFFERENT DISTRIBUTION OF GABAERGIC COMPONENTS BETWEEN CA1 AND CA3 REGION IN RAT HIPPOCAMPUS Yao, Z.B.\*, Li, Z.C. and Xu, Z.C. Dept. of Neurology, University of Tennessee, Memphis, Memphis TN 38163

CA1 pyramidal cells in hippocampus degenerate while cells in CA3 region survive following transient forebrain ischemia. Excitotoxic effect has been hypothesized as the cause of this selective neuronal loss. Disturbance in the balance between excitation and inhibition may contribute to the hyperactivity of the vulnerable neurons. To examine the morphological basis of the above hypothesis, we compare the GABAergic components between CA1 and CA3 region in rat hippocampus using quantitative light (LM) and electron microscopy (EM).

Male Wistar rats (230-350 gm) were perfused transcardially with 2% paraformaldehyde and 1% glutaraldehyde in 0.1 M phosphate buffer. Vibratome sections (50µm) were processed for GABA immunocytochemistry using monoclonal antibodies (Chemicon). Sections for EM were postfixed in 0.5% osmium tetroxide for 1 hr and then embedded in Araldite. Ultrathin sections were cut and observed with a JEOL 1200 electron microscope.

Under LM, GABA positive somata and puncta scattered in all layers of hippocampus. GABA positive neurons exhibited a variety of sizes and shapes. Quantitative analysis showed that the ratio of GABA positive neurons to pyramidal neurons was 1:12 in CA1/subiculum area and 1:9 in CA2/CA3 area (n=7, P<0.01). In stratum pyramidale, GABA positive puncta appeared as pericellular baskets around cell bodies. The number of GABA positive puncta around each soma in CA1 was 7.05±2.06 (n=204) and 10.01±3.02 in CA3 (n=199, P<0.01). The number of puncta per 10 µm pericellular membrane was compared. It was 1.71±0.05 in CA1 and 2.03±0.05 in CA3 region respectively (P<0.01). EM observation revealed that these GABA positive puncta were axon terminals. They formed symmetrical synapses on pyramidal cell bodies and their dendrites. The present study suggested that CA1 pyramidal neurons may receive less inhibition than CA3 neurons, which may partially contribute to the selective neuronal damage following transient ischemia.

## 393.19

EFFECT OF DEXMETETOMIDINE ON HIPPOCAMPAL STRUCTURES FOLLOWING TRANSIENT ISCHEMIA IN GERBIL J. Sivenius\*, J. Kihmonen, R. Miettinen, P.J. Riekkinen Sr, J. Pokorny, A. Haapalinnu. Dept. of Neurology and A.I. Virtanen Institute, University of Kuopio, Kuopio, Finland.

Dexmedetomidine is an agonist of presynaptic  $\alpha_2$ -adrenergic receptors that is shown to inhibit the synaptic release of norepinephrine in a variety of noradrenergic neurons. There is biochemical evidence that norepinephrine potentiates the actions of excitatory amino acids in the hippocampus. Neuroprotective effects of an  $\alpha_2$  agonist dexmedetomidine were investigated in a gerbil transient cerebral ischemia model, involving bilateral carotid occlusion of 5 min in ether inhaled normothermic animals. Dexmedetomidine was administered subcutaneously in four different dose regimens (8 animals in each group): 3 µg/kg or 30 µg/kg 30 min before the induction of ischemia, and the same dosages given 3 hours after the ischemia induction. In addition, animals of each group received a corresponding dose 3, 12, 24 and 48 hours after ischemia. One group of ischemic animals received saline only. After one week the animals were killed and the brains fixed by transcardiac perfusion. Delayed neuronal damage of cells of sectors CA1, CA3 and hilus was evaluated after silver staining, with counting damaged cells in an area of 1 mm<sup>2</sup>, and the data were analyzed by Mann-Whitney U-test. Most effective dose regimen was 3µg/kg given before the induction of ischemia. Mean number of damaged cells in comparison with saline treated animals was 9.1% in CA3 (p<0.01), 10% in hilus (p<0.01) and 51% in CA1 (p<0.05), respectively. These data demonstrate that dexmedetomidine effectively prevents ischemic damage when given before the induction of ischemia in the model of transient forebrain ischemia. The reason for more potent effect on CA3 and hilar neurons than on CA1 neurons may be due to different density of  $\alpha_2$  receptors in these structures.

## 393.18

HALOTHANE EFFECT ON ISCHEMIC OUTCOME AND TEMPERATURE PATTERN FOLLOWING TRANSIENT FOREBRAIN ISCHEMIA IN RATS Ren, Y.B.\* and Xu, Z.C. Dept. of Neurology, University of Tennessee, Memphis, Memphis TN 38163

Anesthetics and brain temperature have great effects on neuronal injury following transient forebrain ischemia. Using ischemic depolarization (ID) as an indication of complete ischemia, the present study investigated the temporal threshold of severe CA1 cell damage under halothane anesthesia and the pattern of brain and body temperature change 6 days after ischemia.

Male adult Wistar rats were fasted overnight and anesthetized with 1-2% halothane. Severe forebrain ischemia was induced using 4-vessel occlusion method. ID was recorded using electrodes filled with 3 M KCl. Brain temperature were maintained at 37°C during and shortly after ischemia. Brain and body temperature were monitored continuously for 6 days. The extent of CA1 cell damage was evaluated on Hematoxylin-Eosin staining sections 6 days after reperfusion.

Under halothane anesthesia, 13 min ID (~15 min ischemia) was required to produce complete CA1 cell damage. The brain temperature dropped to approximately 36°C within 2 h after recirculation then rose to about 38.3°C within 30 h. The brain temperature gradually returned to around 37.5°C 40 h after reperfusion and fluctuated between 37° and 38°C with a diurnal rhythm. Same pattern was observed in sham-operated animals but the temperature was about 0.5°C lower than that in ischemic animals during the first 21 h of reperfusion (P<0.05). The brain temperature was 0.5-1.0°C lower than body temperature at the first 58 h of reperfusion in ischemic animals (P<0.05), at the first 20 h of reperfusion in sham-operated animals (P<0.05). No significant difference was found in control animals. Our data suggests that halothane anesthesia attenuates neuronal damage in rat hippocampus following ischemia. Ischemic insult delays brain temperature recovery following ischemia. Halothane anesthesia also contributes to the delay of postischemic brain temperature recovery.

## ISCHEMIA: OXIDATIVE INJURY

## 394.1

FREE RADICAL PRODUCTION AFTER FOREBRAIN ISCHEMIA IN THE RAT, AS MEASURED WITH THE SALICYLATE-HYDROXYLATION METHOD: INFLUENCE OF BODY TEMPERATURE. K. Pahlmark\*, B. K. Siesjö. Lab for Exp Brain Research, University of Lund, Sweden.

Salicylate hydroxylation rates, assumed to reflect hydroxyl radical (\*OH) formation, were measured in control rats, as well as in those subjected to 15 min of forebrain ischemia, and allowed recirculation periods of 5 and 15 min at body and brain temperatures of 33°C, 37°C and 39°C. HPLC was used to measure the formation of 2,5-dihydroxybenzoic acid (DHBA) in samples from neocortex, hippocampus, and caudoputamen. Hydroxylation of salicylic acid in control animals was similar in neocortex and hippocampus, and lower in caudoputamen. Results obtained at body temperatures of 37°C and 39°C showed similar hydroxylation rates after 5 and 15 min of recirculation, but at 33°C an increased hydroxylation was seen only after 5 min in the examined regions.

The results demonstrated that, in contrast to gerbils, rats do not show a higher rate of postischemic \*OH production in the hippocampus than in the neocortex. Furthermore, although temperature affects the basal rate of benzoic acid hydroxylation, it does not influence the production of \*OH during the first 5 min of recirculation. However, since an increased hydroxylation was not observed after 15 min in the 33°C group, hypothermia seems to shorten the period of postischemic hydroxyl radical production.

## 394.2

BRAIN LIPID OXIDATION FOLLOWING CARDIAC ARREST AND RESUSCITATION. G. Fiskum\*, Y. Liu and R.E. Rosenthal. Depts. of Biochemistry and Molec. Bio. and Emergency Medicine, George Washington Univ. School of Medicine, Washington, D.C. 20037

This study tested the hypothesis that high ventilatory [O<sub>2</sub>]s during and following resuscitation (RE) after 10 min canine cardiac arrest (CA) worsen neurological outcome and result in high levels of brain lipid oxidation. The mean neurological deficit scores (0=normal, 100=brain dead) measured at 23 hr after RE were 45.1±3.6 s.e. for animals given 21% O<sub>2</sub> during RE and 58.3±3.8 for animals given 100% O<sub>2</sub> during and for 1 hr after RE (p<0.05). HPLC and mass spectrometry measurements of oxidized lipids in frontal cortex samples taken 24 hr post-RE showed increased levels of 13-hydroxyoctadecadienoic acid (HODE) for hyperoxic animals (5.0±0.8 µg wet wt.) compared to normoxic dogs (2.3±0.2, p<0.05) and compared to non-ischemic control samples (1.6±0.2, p<0.05). Total oxidized lipids in hyperoxic animals was twice as high in the striatum than in the cortex and hippocampus with the striatum also displaying the largest increase (300%) compared to non-ischemic controls. These results support the results of Zwemer *et al.* (Resusc 27:159-170, 1994) indicating that 100% inspired O<sub>2</sub> during and following RE exacerbates delayed neurological injury and provide new evidence that high [O<sub>2</sub>] may be neurotoxic following global cerebral ischemia through its potentiation of free-radical dependent lipid oxidation. (Supp. by the Emergency Med. Foundation and NS 34152)

## 394.3

PARABANIC ACID FOR MONITORING OF OXYGEN RADICAL REACTIONS IN THE ACUTELY INJURED HUMAN BRAIN. L. Hillered\*, L. Persson, Departments of Clinical Chemistry and Neurosurgery, Uppsala University Hospital, Uppsala, Sweden.

Oxygen radicals are currently thought to play an important role in the pathophysiology of acute brain injuries, including stroke and trauma. There is a great need for methods by which oxygen radical activity can be measured *in vivo*. The endogenous scavenger uric acid, the end product of purine metabolism in man, is oxidized to mainly allantoin and parabanic acid when exposed to highly reactive radical species *in vitro*<sup>1,2</sup>.

We used microdialysis<sup>3</sup> to harvest allantoin and parabanic acid in the frontal cortex of neurointensive care patients after aneurysmal subarachnoid hemorrhage. Dialysate samples were collected 24h/d during 7-8 days and analyzed for lactate, pyruvate, allantoin and parabanic acid by HPLC.

Clinical events involving secondary ischemia (as evidenced by increased lactate/pyruvate ratios), eventually leading to structural damage, were associated with a dramatic elevation of the dialysate level of parabanic acid, whereas allantoin showed less robust changes. In one patient with an uneventful clinical course without signs of secondary ischemia parabanic acid levels remained low.

In conclusion, the results support the involvement of highly reactive oxygen radical species in human cerebral ischemia. Parabanic acid appears to be an important marker of free radical reactions *in vivo* and may be used to monitor increased free radical activity and to evaluate pharmacological therapy with radical scavengers in acute brain injuries.

## 394.5

CALCIUM-INDUCED INCREASE IN THE OXIDATIVE METABOLISM OF CEREBELLAR NEURONS DISSOCIATED FROM THE RATS. Y. Oyama\*, T. Ueha and L. Chikahisa, Lab. of Cell Signaling, Fac. of Integrated Arts and Sciences, The University of Tokushima, Tokushima 770, Japan.

Excessive Ca influx into neurons plays a key role in neuronal death during brain ischemia although the cellular events resulting from excessive Ca influx are not fully elucidated. We examined the effect of ionomycin on the oxidative metabolism (the formation of reactive oxygen species) of rat cerebellar neurons using a flow cytometer and 2',7'-dichlorofluorescein (DCF) diacetate, an indicator for intracellular H<sub>2</sub>O<sub>2</sub>. Ionomycin increased the intensity of DCF fluorescence, but not under the external Ca-free condition. Time-course for ionomycin in increasing the intracellular Ca concentration ([Ca]<sub>i</sub>) was more rapid than that in augmenting DCF fluorescence. Furthermore, there was a good correlation between the augmented DCF fluorescence and the increased [Ca]<sub>i</sub>. Therefore, the excessive Ca influx may lead to a great increase in oxidative metabolism.

## 394.7

MUTAGENESIS and NEURODEGENERATION AFTER CEREBRAL ISCHEMIA. JK Cui, YY He, CY Hsu\* and PK Liu, Div. Restorative Neurology and Human Neurobiology, Baylor College of Medicine, Houston, TX 77030 and Dept. of Neurology, Washington University St. Louis, MO 63110

Hydroxyl radicals that are increased in the brain due to cardiac arrest, stroke or head injury are known to be toxic and mutagenic in a variety of testing systems. To determine DNA damaging effects caused by cerebral ischemia in mice, we measured mutation frequency of the reporter *lac I* gene in the  $\lambda$  phage from the Big Blue transgenic mice. Cerebral ischemia was induced for 30 min, followed by variable periods of reperfusion (expression time). The  $\lambda$  phage was rescued from brain genomic DNA using *in vitro* packaging extract and *E. coli* SCS-8. After plating in the presence of X-gal (70 mg/plate), mutants in this reporter gene were selected on the basis of exhibiting blue plaques from the non-mutant clear plaques. The background frequency was  $2 \times 10^{-5}$  (n=3), and the frequency after ischemia was increased from  $2 \times 10^{-5}$  (at 1/4 h, n=3) to  $8 \times 10^{-5}$  (at 8 h, n=7) and  $6 \times 10^{-5}$  (at 24 h, n=3). Base substitutions (4/4) were found in the *lac I* mutants from the sham-operated mice, but deletions (10/26), base substitutions (13/26) and insertions (3/26) were found in ischemia-induced *lac I* mutants. DNA fragmentation as detected using the Apop Tag (TUNEL) kit did not occur on 1 day (n=4), but occurred in samples on 2-3 days (n=4) after ischemia. The results supported the hypothesis that the genome instability can be initiated by cerebral ischemia, and may be linked to neuronal degeneration. (Sponsored by the Vivian L. Smith Foundation for Restorative Neurology, Baylor College of Medicine, Houston, Texas)

## 394.4

DIFFERENTIATION OF NEUROBLASTOMA 104 CELLS INCREASES SUSCEPTIBILITY TO PEROXIDATIVE INSULT. J.A. Rafols\*, B.J. O'Neil, S. Alousi, and B.C. White, Departments of Anatomy/Cell Biology and Emergency Medicine, Wayne State Univ., School of Medicine, Detroit, MI 48201.

Undifferentiated (UNDIFF) and differentiated (DIFF: 1mM each dibutyl cAMP and theophylline) NB104 cell cultures were exposed to 50 nM cumene hydroperoxide added to the media containing  $3 \mu\text{M FeSO}_4$  for 2.4 and 6 hours. Reactions were stopped along the time course with 1 mM DETAPAC. To examine the extent and progression of subcellular organelle damage, controls (unexposed) and exposed cultures were fixed with a mixture of aldehydes, embedded in 1.5% agarose, post fixed with OsO<sub>4</sub>, and processed for electron microscopy. Control DIFF cells developed a lobulated nucleus with patches of heterochromatin, and unlike that of UNDIFF cells, the cytoplasm contained many RER and Golgi cisternae, as well as a dense feltwork of intermediate filaments. Following 2 hrs of peroxidative insult many DIFF and UNDIFF cells showed vesiculation of Golgi cisternae and increased numbers of lysosomes and membranous whorls. Large vacuole containing filaments and microvesicles or RER and polysomal debris were observed, many in close proximity to the plasmalemma. By 6 hrs most DIFF cells observed had shrunken nuclei with dense heterochromatin, electron dense cytoplasm, and extruded cytoplasmic debris between adjacent cells; all signs of apoptosis. In contrast UNDIFF cells had electron lucent cytoplasm with intact organelles, although a few showed advanced stages of degeneration. The results indicate that the membranes of the Golgi and RER are early targets of peroxidative insult. They also suggest that DIFF cells undergo earlier and more severe subcellular damage than UNDIFF cells. Further characterization of this model may advance our knowledge of selective vulnerability in neurons. (Supported by NIH grant NS01585 and the Detroit Neurotrauma Institute at Wayne State University).

## 394.6

EFFECT OF GINKGO BILOBA EXTRACT ON CALCIUM-INDUCED INCREASE IN THE OXIDATIVE METABOLISM OF RAT CEREBELLAR NEURON. L. Chikahisa\*, E. Okazaki and Y. Oyama, Lab. of Cell Signaling, Faculty of Integrated Arts and Sciences, The University of Tokushima, Tokushima 770, Japan.

Excessive Ca influx into neurons results in an increased formation of reactive oxygen species which are involved in ischemic brain damage. We examined the effect of Ginkgo biloba extract (EGb) on the oxidative metabolism of rat cerebellar neurons using 2',7'-dichlorofluorescein (DCF) diacetate, a fluorescent indicator for intracellular H<sub>2</sub>O<sub>2</sub>. Incubation with EGb at concentrations of 0.3  $\mu\text{g/ml}$  or higher (up to 3  $\mu\text{g/ml}$ ) decreased the DCF fluorescence of resting neurons in a dose-dependent manner. EGb also reduced the ionomycin-induced increase in DCF fluorescence without affecting the intracellular Ca concentration. Quercetin, a constituent of EGb, at concentrations of 30 nM or more resembled the EGb. Therefore, the flavonoid constituents in EGb may be partly responsible for the protective actions of EGb in the brain neurons subjected to ischemia or hypoxia.

## 394.8

POSTISCHEMIC, SYSTEMIC ADMINISTRATION OF MODIFIED SUPEROXIDE DISMUTASE PREVENTS HIPPOCAMPAL CA1 NEURODEGENERATION IN RAT GLOBAL CEREBRAL ISCHEMIA. T.M. Wengenack\*, G.L. Curran, and J.E. Poduslo, Molec. Neurobiol. Lab., Mayo Clinic and Foundation, Rochester, MN 55905.

Free radicals are believed to play an important role in cerebral ischemia. Free radical scavenging enzymes such as superoxide dismutase (SOD) have shown neuroprotective effects in animal models of cerebral ischemia. Due to the low blood-brain barrier (BBB) permeability and short plasma half-life (~4 min) of SOD, experiments using native enzyme have had limited success, only with very high doses. Thus far, various modifications to increase the half-life or permeability of SOD have resulted in limited neuroprotective effects. Furthermore, none of these studies have demonstrated neuroprotection with postischemic administration. Permeability of native (nSOD) and modified SOD (mSOD) across the BBB was determined using an I.V. bolus injection technique. Transient, global cerebral ischemia was produced in male Wistar rats for 12 min using the four-vessel occlusion method. Animals were dosed (I.V.) 1.5 min after reperfusion with either saline, nSOD (5,000 or 10,000 U/kg), or mSOD (5,000 U/kg) twice daily for 3 days. Neuroprotective effects on hippocampal CA1 pyramidal cells were then assessed using a standard neuropathological rating scale (0 = 0%, 1 = 25%, 2 = 50%, 3 = 75-100% damage). The permeability coefficient-surface area product (PS) at the hippocampal BBB was  $1.68 \pm 0.10 \times 10^{-6} \text{ ml/g/s}$  ( $\bar{x} \pm \text{SEM}$ ) for nSOD. The PS increased fivefold to  $8.93 \pm 0.74 \times 10^{-6} \text{ ml/g/s}$  for mSOD. Histologically, saline-treated animals had total CA1 damage ( $2.99 \pm 0.01$ ). Native SOD did not show any neuroprotective effects at the doses tested (5,000 U/kg:  $2.86 \pm 0.15$ , 10,000 U/kg:  $2.57 \pm 0.43$ ). Modified SOD, however, resulted in significantly less CA1 damage ( $1.48 \pm 0.36$ ; Mann-Whitney U-test:  $p < 0.02$ ). Modification of SOD and other antioxidant enzymes, as well as growth factors, resulting in increased permeability across the BBB may provide a useful tool for the systemic delivery of therapeutic proteins in neurodegenerative disorders.

## 394.9

ANTIOXIDANT NEUROPROTECTION FOLLOWING ANOXIA IN HIPPOCAMPAL SLICES. T.J. Sick\*, P.L. Mumford, M. Rosenthal and M. A. Pérez-Pinzón. Dept. of Neurology, U. of Miami Sch. of Medicine, Miami, FL 33101

Evidence indicates that damage may occur not only during brain ischemia but also during reperfusion afterward. Our studies in rat cerebral cortex showed that reperfusion after global ischemia (10-60 min duration) was characterized by hyperoxidation of the electron carriers of the mitochondrial respiratory chain. Recovery of evoked potentials was improved by respiring these animals with a slightly 'hypoxic' gas mixture which also ameliorated post-ischemic mitochondrial hyperoxidation (PIMHo). When rats were respired with 'hyperoxic' gas mixtures during reperfusion after global ischemia, PIMHo was increased and electrical recovery was lessened. Mitochondrial hyperoxidation (particularly hyperoxidation of NAD) also characterized reoxygenation following anoxia in hippocampal slices. Present goals were to determine if antioxidants could suppress PIMHo and improve electrical recovery after anoxia in hippocampal slices which were reoxygenated for 60 min after 2 min of anoxia-induced 'anoxic depolarization' (AD). Ascorbate did not influence the reduction/oxidation (redox) status of NAD which became approx 30% hyperoxidized after anoxia. However, ascorbate significantly improved evoked potential recovery. We conclude that at least one antioxidant (ascorbate) improved electrical recovery after anoxia in slices but through mechanisms not apparent in the redox state of NAD.

• EFFECTIVENESS OF ANTIOXIDANTS AGAINST OXIDATION OF CIS-PARINARIC ACID ENRICHED LIPOSOMES. • M.R. Emerson, F.E. Samson\*, T.L. Pazdernik. Smith Research Bldg., Dept. of Pharm., Tox., & Ther., Univ. of Kansas Med. Center, Kansas City, KS 66160.

• Free radical damage by reactive oxygen species, is implicated in several neuropathologies. Transition metals (Fe,Cu) may be dislocated into the extracellular fluid during brain trauma, ischemia, etc. and then may catalyze the formation of oxygen radicals by the Fenton reaction. This leads to a lipid peroxidation cascade, membrane damage and loss of cellular integrity. A membrane model of a liposome preparation enriched with cis-parinaric acid was used to study protection against lipid peroxidation from an aqueous metal catalyzed radical generating system of ascorbate (330 µM), copper (1.0 µM) and H<sub>2</sub>O<sub>2</sub> (10 mM). Oxidative decay of cis-parinaric acid was measured fluorimetrically. Antioxidant effectiveness of alpha-tocopherol (0.1-10 µM), lactate (1.0-10 mM) and U-74389F (1.0-10 µM) was studied. Alpha-tocopherol as low as 0.1 µM gave a 50% reduction in oxidized cis-parinaric acid, but increases up to 10 µM did not go above 65% protection. U-74389F was less potent than alpha-tocopherol. Lactate, an aqueous oxidizable substrate, provided a maximum of 20-40% protection even at a concentration of 10 mM. This data suggests that formation of hydroxyl radicals in solution is not as important as site specific oxidation within the lipid membrane. Thus, the effectiveness of antioxidants against lipid peroxidation depends critically on their location and insertion into lipid bilayers.

LEVELS OF IRON DURING INCOMPLETE GLOBAL ISCHEMIA. P.D. Hurn\*, D.C. Lipscomb, L.K. Gorman, R.J. Traystman. Dept. of Anesthesiology and Critical Care Medicine, Johns Hopkins Medical Institutions, Baltimore, MD 21287

We hypothesized that during global cerebral ischemia with high density tissue acidosis, levels of low molecular weight (LMW) Fe<sup>2+</sup> are increased and potentially catalyze free radical-mediated oxidant injury via Fenton-Haber chemistry. Pentobarbital-fentanyl anesthetized dogs received intravenous dextrose (plasma glucose ≈ 500 mg/dl) followed by an infusion of artificial cerebrospinal fluid into the lateral ventricle to reduce cerebral perfusion pressure (10 mm Hg for 30 minutes). Cerebral energy metabolites and intracellular pH were monitored by magnetic resonance spectroscopy. After ischemia, the brain was perfused with ice-cold phosphate buffered saline solution, and many different brain areas were sampled. Iron levels (total and LMW Fe<sup>2+</sup>) were determined by the rapid colorimetric micromethod (W. Fish, 1988). With hyperglycemic ischemia, intracellular pH decreased from 7.1-7.2 to 5.9-6.1, and phosphocreatine and ATP decreased to 0% and <50% of control values, respectively. In cortical regions, hippocampus, caudate, and thalamus, LMW Fe<sup>2+</sup> was increased in ischemic animals as compared to sham-operated controls. There were no differences in the cerebellum and other brain stem structures. These regional differences may reflect the basal localization of iron which is to a large extent in the cortex and hippocampus. These results suggest that global incomplete ischemia when accompanied by exaggerated tissue acidosis results in a regionally specific pattern of increased LMW Fe<sup>2+</sup> that may play a role in oxidative injury in these areas. (Supported by NR03521, NS20020)

## 394.10

IN VITRO AND IN VIVO NEUROPROTECTIVE EFFECTS OF CYCLIC NITRONE ANTIOXIDANTS. C.E. Thomas, D.E. Ohlweiler, D.R. McCarty, J.V. Ficorilli, H.C. Cheng, P.A. Chmielewski and M.P. Johnson\*. Marion Merrell Dow Research Institute, Cerebrovascular Biology, Cincinnati, OH, 45215.

The nitron spin trap  $\alpha$ -phenyl-tert-butyl nitron (PBN) has been shown to provide neuroprotection in models of acute and chronic neurodegeneration, presumably via trapping of reactive oxygen-derived free radicals. We have synthesized a series of novel cyclic nitron spin traps and examined them for radical trapping activity *in vitro* and for neuroprotective effects in animal models of stroke. The cyclic nitrones were all found to be active inhibitors of iron-dependent lipid peroxidation with the most potent compound, MDL 104,342, being 550-fold more active than PBN. Likewise, the compounds prevented both lipid peroxidation and the loss of viability resulting from treatment of cerebellar granule cells in culture with ferrous iron. Using electron spin resonance (ESR) spectroscopy, we determined that MDL 101,002 was a more efficient hydroxyl ( $\cdot\text{OH}$ ) and superoxide anion radical trap than was PBN. The  $\alpha$ -hydroxy nitroxide adduct derived from trapping of  $\cdot\text{OH}$  was more stable than that of PBN ( $t_{1/2}$  of 5 min vs < 1 min) suggesting it to be a superior ESR reagent. In the 3-vessel occlusion model of stroke in the Wistar rat, treatment with a bolus plus infusion dose of MDL 101,002 (75 mg/kg + 270 mg/kg/6 hr) provided substantial protection (~95% reduction in infarct size). Similarly, in a permanent model of ischemia in the spontaneously hypertensive rat, MDL 101,002 provided greater than 50% protection vs. control animals when administered as a single bolus dose (100 mg/kg). These data indicate that cyclic nitron spin traps such as MDL 101,002 have improved radical trapping efficacy relative to PBN and may be useful agents for treatment of neurodegenerative diseases.

## 394.12

DEHYDROEPIANDROSTERONE (DHEA) AND HYDROXYL FREE RADICAL ( $\cdot\text{OH}$ ) IN ISCHEMIC GERBIL BRAIN. B. Delbarre\*, G. Delbarre and F. Calinon. Faculté de Médecine, 37032 Tours, France.

DHEA, a first neurosteroid, was introduced by Beaulieu to study aging. Some compounds, analogs to neurosteroids, were investigated in cerebral ischemia. Delbarre et al. show that  $\cdot\text{OH}$  increased with age during brain injury. A study was undertaken to show the relation between DHEA and  $\cdot\text{OH}$ . Four groups of 7 adult gerbils were used: One sham operated (SO), and three (1 control and 2 DHEA, 3 or 10 mg/kg, i.p., 30 min. before occlusion) were subjected to unilateral left carotid occlusion (60 min. followed by 30 min. reperfusion).  $\cdot\text{OH}$  was determined in left hemisphere by HPLC/Electrochemical (salicylate as scavenger) according to Floyd method (Floyd, R. A., et al. *Free Rad. Biol. Med.* 2:13-18, 1986).

		SO	Control	10mg/kg	3mg/kg
$\cdot\text{OH}$	Mean	0.170	2.910	0.492	0.248
	$\pm$ sem	0.025	0.303	0.081	0.059
		-	***	NS	NS

Results were given in ng/mg of proteins. Student Newman-Keuls test versus Control group. n = 7.  $p \geq 0.05$  NS -  $p < 0.001$  \*\*\*

Results show that  $\cdot\text{OH}$  is significantly increased in ischemic group. DHEA (3 and 10 mg/kg) reverses this increase. The low dose is more effective. Our study shows the importance of the doses of DHEA for maintaining the normal activity of the brain.

The currently pharmacological action of DHEA may be reconsidered.

## 394.14

SEVERE HYPOXIA IN PC12 CELLS INCREASES MITOCHONDRIAL MEMBRANE POTENTIALS WHILE MARKEDLY ELEVATING [Ca<sup>2+</sup>]. H. Zhang, R.C. Carson, H.M. Thomas III and G.E. Gibson\*. Cornell University Medical School at Burke Medical Research Inst. White Plains, NY 10605.

Studies with isolated mitochondria and synaptosomes suggest that reduced oxygen or high calcium diminishes the mitochondrial membrane potential, indicating an abnormal oxidative state. To study the effect of anoxia on mitochondrial oxidative state in intact cells, the relation of [Ca<sup>2+</sup>], (measured with fura-2) to mitochondrial membrane potentials (measured with TMRE) was tested in NGF-differentiated PC12 cells during anoxia with or without glucose. By the use of pre-tonometered buffers, the pO<sub>2</sub> on the microscope stage was changed from 140  $\pm$  2 to 2.5  $\pm$  0.7 mm Hg (mean  $\pm$  SE). In the presence of glucose, 30 min of anoxia increased [Ca<sup>2+</sup>], in the growth cones (from 102  $\pm$  2 to 424  $\pm$  196 nM) and cell bodies (from 78  $\pm$  7 to 502  $\pm$  171 nM). The [Ca<sup>2+</sup>], then gradually returned toward the basal value. K<sup>+</sup> depolarization after 5 min of anoxia greatly increased [Ca<sup>2+</sup>], in growth cones (1126  $\pm$  171 nM) and cell bodies (>5000 nM). In similarly treated cells, anoxia increased the mitochondrial membrane potentials in the growth cones (from -108  $\pm$  2 to -152 mV) and cell bodies (from -125  $\pm$  1 to -158  $\pm$  2 mV). The absence of glucose reduced the mitochondrial membrane potentials but the pattern of response to anoxia was similar; the mitochondrial membrane potential increased in the growth cones (from -65  $\pm$  7 to -82  $\pm$  1 mV) and cell bodies (from -103  $\pm$  1 to -118  $\pm$  1 mV). Thus, in intact cells anoxia raised [Ca<sup>2+</sup>], as expected, and, in contrast to results with fractionated cells, increased the mitochondrial membrane potentials. The elevated potentials indicate an abnormal oxidative state in response to anoxia, which does not resemble the effect of cyanide, but parallels that of oligomycin, an inhibitor of both ATP synthesis and uncoupler-stimulated ATP hydrolysis.

**VOLTAGE-SENSITIVE CALCIUM CHANNELS MEDIATE CALCIUM ENTRY INTO MAMMALIAN SYMPATHETIC NEURONS FOLLOWING AXOTOMY.** R. Sattler, J. Favaz, C.H. Tator, M. Hafner, M.C. Wallace\*, and M. Tymianski, *U. of Toronto, Canada & Tech. University of Mannheim, Germany.*

Some mechanisms linking axonal injury and neurological dysfunction are thought to be associated with a rise in free intracellular  $\text{Ca}^{2+}$  concentration ( $[\text{Ca}^{2+}]_i$ ). We studied the effects of axotomy on  $[\text{Ca}^{2+}]_i$  in axons and cell bodies of cultured superior cervical ganglion (SCG) neurons using the fluorescent  $\text{Ca}^{2+}$  indicator fluo-3 and a laser-scanning confocal microscope. Axotomy produced a rapid  $[\text{Ca}^{2+}]_i$  rise in the cell soma which preceded any  $[\text{Ca}^{2+}]_i$  rise in the axon ( $n=30$ ), suggesting a role for membrane depolarization, and voltage sensitive  $\text{Ca}^{2+}$  channels (VSCCs). Inhibiting membrane depolarization by bath-applying 140mM potassium prior to axotomy prevented any significant calcium rise from occurring ( $n=9$ , Mann-Whitney rank-sum test,  $p<0.001$ ). However, axotomy-induced depolarization did not require the activation of conventional sodium channels sensitive to tetrodotoxin (TTX), a  $\text{Na}^+$  channel blocker, as there was no difference between the calcium rise observed following axotomy in control solution or in the presence of TTX ( $n=15$ ;  $p=0.265$ ). To test whether axotomy-induced  $\text{Ca}^{2+}$  influx also occurred via  $\text{Ca}^{2+}$  conductances other than conventional VSCCs, we blocked  $\text{Ca}^{2+}$  channels during the axotomy using nimodipine and  $\omega$ -conotoxin GVIA, blockers of L-type and N-type  $\text{Ca}^{2+}$  channels, respectively.  $\text{Ca}^{2+}$  channel blockade significantly attenuated axotomy induced  $[\text{Ca}^{2+}]_i$  increases both in the cell soma and in axons ( $n=21$ ,  $p<0.001$ ). These data contradict the intuitive hypothesis that  $\text{Ca}^{2+}$  entry following mechanical axotomy occurs via non-specific influx pathways produced by cell-membrane disruption. The results provide the first evidence in mammalian neurons that immediate, traumatically-induced, increases in neuronal  $[\text{Ca}^{2+}]_i$  occur through well-defined pathways which are amenable to pharmacological manipulation.

## 395.3

**4-AMINOPYRIDINE AFFECTS CONDUCTION IN INJURED SPINAL CORD AXONS IN VITRO AT CLINICALLY RELEVANT CONCENTRATIONS.**

Riyi Shi\*, W. H. Ferrell III, J. E. Gadjia and A. R. Blight, Division of Neurosurgery, Univ. of North Carolina, Chapel Hill, NC 27599.

Previous studies have shown restoration of action potential conduction in chronically injured spinal cord axons *in vitro* in the presence of 0.1 - 1 mM concentrations of the potassium channel blocking drug 4-aminopyridine (4-AP). Clinical studies have shown improvements in function in human subjects with chronic spinal cord injury using systemic doses that give rise to peak serum concentrations of 1-2  $\mu\text{M}$  4-AP. The question arises whether the clinical effects of the drug seen in spinal cord injury and multiple sclerosis are due to improved safety factor for conduction in myelinated axons, to enhanced synaptic transmission or a combination of the two. Data from rat central axons demyelinated with ethidium bromide indicate that the effective dose for restoration of conduction is too high (>100  $\mu\text{M}$ ) to be achieved clinically, and this has been interpreted as suggesting the clinical effects of the drug are principally or exclusively on synaptic transmission (Felts & Smith, *Ann. Neurol.* 36:454, 1994). We examined the dose-response characteristics of 4-AP in isolated normal and traumatically injured guinea pig spinal cord, using a sucrose-gap technique for recording conduction in strips of white matter superfused with oxygenated Krebs solution. In contrast to data from chemical demyelination in rats, this preparation showed evidence of enhanced conduction through both acutely (<6 hr) and chronically (>4 month) injured axons with a threshold around 1  $\mu\text{M}$  and a peak effect at 10  $\mu\text{M}$  4-AP. These low concentrations had no effect on normal spinal cord tissue. These data, together with parallel histopathology, are interpreted as support for the concept that clinical response to 4-AP, at least in trauma, may involve significant enhancement of safety factor for action potential conduction in partially demyelinated or poorly remyelinated nerve fibers. (Supported by a grant from the Canadian Spinal Research Organization and by grant NS21122 from NIH, NINDS)

**PATTERN OF AXONAL DEGENERATION IN THE BRAIN AFTER TRAUMATIC BRAIN INJURY (TBI) OF RAT SENSORIMOTOR CORTEX.** J.S. Soblosky\*, Murray A. Matthews<sup>1</sup>, D.A. Chorney, June F. Davidson, L.L. Colgin and M.E. Carey, Neurotrauma Res. Lab., Dept. Neurosurgery, and <sup>1</sup>Dept. of Anatomy, LSU Medical Ctr, New Orleans, LA 70112

Isoflurane-anesthetized rats were injured on the right side fore- and hindlimb sensorimotor cortex by a piston impact depressing the dura 1mm @ 5 M/sec. We have previously shown that this TBI results in unilateral long lasting fore- and hindlimb deficits. We determined the pattern of subsequent axonal degeneration in the brain using a silver staining method. Eight weeks after TBI there was extensive axonal degeneration 1) around the injury site with many degenerating fibers crossing the corpus callosum and entering the contralateral sensorimotor cortex; 2) in the ipsilateral dorsolateral and medial striatal areas; 3) in the ventrobasal, ventromedial, ventroposterolateral, ventroposteromedial, ventrolateral, and posterior nuclei of the ipsilateral thalamus; 4) in the cerebellum occurring bilaterally around the lateral, medial and interpositus nuclei. Degenerating fibers extended well into the folia terminating predominantly in the granule cell layer. These results: 1. suggest that significant transsynaptic axonal degeneration occurs after TBI; 2. may aid in determining brain areas involved in neuronal reorganization leading to functional recovery after TBI.

## 395.2

**POST-TRANSECTION CHANGES IN AXOPASMIC SODIUM ION CONCENTRATION IN VERTEBRATE PERIPHERAL MYELINATED AXONS.** G. David\*, J.N. Barrett and E.F. Barrett, Dept. of Physiology & Biophysics, Univ. of Miami Med. Sch., P.O. Box 016430, Miami, FL 33101.

To investigate the effects of axonal transection on the axoplasmic concentration of  $\text{Na}^+$  ( $[\text{Na}^+]_i$ ), we obtained ratiometric estimates of  $[\text{Na}^+]_i$  from SBFI-injected motor axons innervating the ceratohmandibularis muscle of lizards (*Anolis sagrei*).

Two phases were observed following transection in normal lizard saline ( $[\text{Na}^+]_{\text{out}} 160 \text{ mM}$ ): 1. Increase in  $[\text{Na}^+]_i$  spreading from the transection site along the axon and usually reaching  $[\text{Na}^+]_i$  within 1-10 min at distances of up to ~800  $\mu\text{m}$  from the cut end (Fig. a-d). This phase could not be mimicked by depolarizing the axons with high bath  $[\text{K}^+]$ , was resistant to TTX, but was abolished if axons were transected in both solutions in which  $[\text{Na}^+]$  was replaced with  $[\text{K}^+]$ , indicating that  $\text{Na}^+$  entry through the cut end (but not through voltage sensitive  $\text{Na}^+$  channels) is the major contributor to the increased  $[\text{Na}^+]_i$ . The time course of this phase could be accounted for by  $\text{Na}^+$  diffusing in the axoplasm with a diffusion coefficient of  $\sim 1 \cdot 10^{-5} \text{ cm}^2/\text{sec}$ .

2. Recovery of  $[\text{Na}^+]_i$  starting 5-50 min after the transection, during which  $[\text{Na}^+]_i$  decreases to resting levels in all imaged regions of the axon (Fig. c, d) except a 5-200  $\mu\text{m}$  segment adjacent to the transection site (Fig. a, b). This re-establishment of normal  $[\text{Na}^+]_i$  may be initiated by resealing of the axon membrane (e.g., between sites b and c in Fig.).  $[\text{Na}^+]_i$  recovery along the axon is faster than expected by diffusional redistribution of  $\text{Na}^+$  along the axon, suggesting a contribution of active  $\text{Na}^+$ -removal mechanisms, such as  $\text{Na}^+/\text{K}^+$  pumps.

## 395.4

**AXONAL INJURY AND NEURONAL STRESS AFTER UNILATERAL SOMATOSENSORY CORTEX CONTUSION INJURY.** A.A. Dunn-Meynell\*, & B.E. Levin, Neurology Svc., VA Med. Ctr., E. Orange, NJ 07018 and Dept. Neurosciences, New Jersey Medical Sch., Newark NJ 07103.

To characterize the effects of unilateral traumatic injury of the somatosensory cortex, c-fos immunoreactivity (IR) was used to identify neuronal stress and 68kd neurofilament revealed axonal injury. A pneumatically powered cylinder (5mm diameter tip) was driven 3 mm deep into the exposed somatosensory cortex of anesthetized adult male SD rats to produce a unilateral contusion. Immunocytochemistry was examined after 3hr (c-fos) or 24 hr (68kd) survival.

The injury produced severe disruption of the impact site, without gross damage to subcortical structures. Both c-fos IR and axonal injury was seen in structures close to and underlying the injury including ipsilateral cortex, lateral thalamus (ventroposterior, ventrolateral, and reticular nuclei), dorsal striatum, hippocampus and internal capsule. Axonal injury was sometimes present but always sparse in more remote structures (including ipsilateral cerebellum, superior colliculus, and deep mesencephalic nuclei), and was rarely seen in the intact hemisphere. However, c-fos was induced in discrete structures remote from the injury including, the entire cortex and the subthalamic nucleus ipsilaterally, and bilaterally in some medial thalamic nuclei (e.g. centrolateral, paraventricular, centromedial), cerebellar white (but not grey) matter, and brainstem. c-fos IR seemed mainly confined to neurons as addition of GFAP IR showed few double labelled cells.

Therefore, axonal injury was largely a function of distance from injury site, whilst neuronal stress tended to be seen in discrete brain nuclei adjacent to and remote from the injury site.

## 395.6

**CALCIUM DEPENDENCE OF MEMBRANE RESEALING IN TRANSECTED MYELINATED RAT AXONS.** M.J. Howard, G. David, and J.N. Barrett\*, Dept. of Physiology and Biophysics, Univ. of Miami School of Medicine, Miami, FL 33136.

Calcium has been implicated in promoting the resealing of damaged cell membranes in a number of different cell types, both *in vivo* and *in vitro*. We examined the  $\text{Ca}^{2+}$ -dependence of the resealing process in transected rat dorsal root and sciatic nerve axons *in vivo*, using a dye-exclusion assay to estimate resealing. When spinal roots where transected in physiological saline containing no added  $\text{Ca}^{2+}$  (free  $[\text{Ca}^{2+}]$  estimated to be  $<5 \mu\text{M}$ ), the percentage of axons that resealed increased with time from 13% when dye was added 15 minutes following the lesion, to 16% at 30 minutes, 27% at 60 minutes and 41% at 120 minutes. In physiological saline containing 2 mM  $\text{Ca}^{2+}$ , resealing was 45% at 15 minutes, 47% at 30 minutes, 70% at 60 minutes and 86% at 120 minutes. At each time point, resealing was significantly higher in the 2 mM  $\text{Ca}^{2+}$  saline ( $P>0.001$ , SNK, Tukey-Kramer test, Dunn's test). Similar experiments done on the sciatic nerve showed resealing to be 60% at 30 minutes and 62% at 60 minutes in the low  $[\text{Ca}^{2+}]$  solution. In 2 mM  $\text{Ca}^{2+}$ , resealing was 72% at 30 minutes and 86% at 60 minutes. Again, resealing was enhanced by 2 mM  $\text{Ca}^{2+}$  ( $P>0.01$ , SNK, Dunn's test).

Based on these findings, we hypothesize that there are  $\text{Ca}^{2+}$ -dependent processes that contribute to the overall resealing mechanism in myelinated rat axons. Additionally, the data suggest that the resealing process in the spinal roots may be slower and have a different  $\text{Ca}^{2+}$  dependence than peripheral nerve.

## 395.7

**EARLY CYTOKINE INDUCTION FOLLOWING CNS TRAUMA.** J.A. Olschowa<sup>1</sup>, B. Harvey, J. Merola, K. Sakai<sup>1</sup>, and J.T. Hansen, Dept. of Neurobiology & Anatomy, Univ. of Rochester Sch. of Med., Rochester, NY 14642 and <sup>1</sup>Dept. of Neurol. Surgery, Okayama Univ. Med. Sch., Okayama, Japan.

A hallmark of CNS injury is the rapid appearance of inflammatory cells, phagocytosis of damaged or dead cells, and the hypertrophy and proliferation of astrocytes. These events are mediated by proinflammatory cytokines and include molecules such as IL-1 $\beta$ , IL-6, and TNF $\alpha$ . Repair of the CNS injury site depends principally on the important interplay between these inflammatory cytokines, glial derived neurotrophic factors, and endogenous CNS cells responsible for removing cellular debris and facilitating tissue homeostasis. To experimentally address the roles of these molecules, rats received a unilateral stab injury to their parietal cortex. Two, 6, 12 and 24 hours postlesion, tissue was collected for determination of cytokine mRNA levels using quantitative RT-PCR. IL-1 $\beta$  mRNA levels were seen to be increased by 2 hrs and to remain elevated at 24 hrs in the lesioned cortex. Immunocytochemical staining for IL-1 $\beta$  at 6 hrs postlesion demonstrated a few faint cortical microglial (?) cells. More marked staining was observed in cells within the underlying corpus callosum, presumably astrocytes. At 12 hrs, the staining intensity was increased. Additional staining was also observed in the contralateral corpus callosum and in areas surrounding the lateral ventricles. Double labeling techniques to determine the cell types expressing IL-1 $\beta$  are currently underway, as well as studies of other cytokines. In conclusion, there appears to be a rapid induction of cytokines following CNS trauma that may play a role in its remodeling. Supported by PHS NS25778 (JH) and NS29400 (JO).

## 395.9

**FOCAL OPTIC NEUROPATHY PRODUCED BY ELEVATED INTRAOCULAR PRESSURE IN A RAT MODEL OF GLAUCOMA.** E.C. Johnson<sup>1</sup>, B.G. Gold<sup>2</sup>, C.G. Moore<sup>1</sup>, and J.C. Morrison<sup>1</sup>, Casey Eye Institute<sup>1</sup>, Center for Research on Occupational and Environmental Toxicology and Dept. of Cell Biology and Anatomy<sup>2</sup>, Oregon Health Sciences University, Portland, OR 97201.

Glaucoma, a major cause of blindness, is characterized by regional optic nerve fiber susceptibility to elevated intraocular pressure ( $\uparrow$ IOP). The mechanism whereby  $\uparrow$ IOP leads to axonal degeneration is unknown. A rat model of glaucoma has been created by unilateral sclerosis of the aqueous humor outflow pathways to produce sustained  $\uparrow$ IOP. This study examines, by light and transmission electron microscopy, the characteristics of optic neuropathy in this model.

After 1 to 65 days of mean  $\uparrow$ IOP of 4-30 mmHg (relative to fellow untreated eyes), rats were perfused with 5% glutaraldehyde, optic nerve samples embedded in plastic, 1  $\mu$ m sections cut and stained with toluidine blue. Mean  $\uparrow$ IOP of  $<10$  mmHg for 3-34 days produced focal optic nerve lesions characterized by axonal swellings, axonal degeneration and myelin debris. Similar lesions were observed in nerves with  $\uparrow$ IOP of 10-20 mmHg for  $<3$  weeks. Digitization (on micrographs at 620 $\times$ ) of damaged areas revealed lesions comprising 0.5% to 10.4% of the total neural area, with 70% of the lesions located in the superior temporal quadrant.  $\uparrow$ IOP of 10-20 mmHg for  $>3$  weeks or  $>20$  mmHg for  $>1$  week resulted in total involvement of the optic nerve, with occasional morphologically normal axons. Ultrastructurally, axonal swellings demonstrated a central neurofilamentous core with peripherally segregated accumulations of membranous vesicles and microtubules.

This rat model reproduces the variability in optic nerve axon susceptibility to  $\uparrow$ IOP observed in human glaucoma. Although the mechanism leading to development of these structural alterations is unknown, the presence of neurofilamentous and membranous axonal swellings suggests underlying axonal transport deficits in the pathogenesis of  $\uparrow$ IOP neuropathy.

## NEUROMUSCULAR DISEASES: MOTONEURONS

## 396.1

**DISTRIBUTION AND LEVELS OF INSULIN-LIKE GROWTH FACTOR (IGF-I AND IGF-II) AND INSULIN RECEPTOR BINDING SITES IN THE SPINAL CORDS OF AMYOTROPHIC LATERAL SCLEROSIS (ALS) PATIENTS.** C. Krieger<sup>1</sup>, S. Dore<sup>2</sup>, S. Kar<sup>3</sup>, and R. Quirion<sup>4</sup>, Univ. British Columbia, Vancouver, B.C. V6T 1Z3<sup>1</sup>, Douglas Hosp. Res. Ctr., McGill University, Montreal, Qc. Canada, H4H 1R3<sup>2</sup>.

IGF-I, IGF-II and insulin are structurally related peptides with a wide spectrum of functions. These trophic factors are important for neuronal survival and the maintenance of the integrity of the organism. ALS is characterized by the progressive degeneration of motoneurons. Recently, reports have been provided to suggest a role for various neurotrophic factors, including IGFs, in the maintenance and survival of motoneurons, potentially opening new therapeutic approaches toward the treatment of ALS. Additionally, it was shown that the apparent density of IGF type I receptor is increased in ALS cords (Adem et al. Mol. Neurobiol. 9:225, 1994). However, the status of other related receptor populations such as the IGF-II and insulin receptors remains to be established in ALS. The main objective of the present study was to compare the anatomical distribution of <sup>125</sup>I-IGF-I, <sup>125</sup>I-IGF-II and <sup>125</sup>I-insulin binding sites in the human spinal cord, and their possible alterations in ALS. Twenty  $\mu$ m lumbar spinal cord sections were obtained from three controls and three ALS cases and processed for quantitative receptor autoradiography as described earlier (Kar et al. J. Comp. Neurol. 333:375, 1993) using 25pM of each radioligand. Specific <sup>125</sup>I-IGF-II binding sites were most abundant in the normal human spinal cord followed by <sup>125</sup>I-IGF-I and <sup>125</sup>I-insulin sites. For all these ligands, the highest amounts of binding were located around the central canal/lamina X area  $>$  dorsal horn  $>$  intermediate zones  $>$  ventral horn  $>$  white matter. Unlabelled insulin (10 $\mu$ M) was found to compete for <sup>125</sup>I-IGF-I and <sup>125</sup>I-IGF-II binding sites suggesting that these sites represent genuine receptors and not IGF binding proteins (IGFBPs) which are generally believed to be devoid of affinity for insulin. As reported earlier, highly significant increases in the levels of <sup>125</sup>I-IGF-I binding sites were apparent in the ALS lumbar cord being particularly evident around the central canal as well as the dorsal and ventral horns, the latter showing extensive neuronal degeneration in ALS. In contrast, no significant difference in <sup>125</sup>I-insulin binding was observed while <sup>125</sup>I-IGF-II labeling was significantly increased only in the dorsal horn and white matter areas of the ALS lumbar cord. Hence, the apparent levels of <sup>125</sup>I-IGF-I, <sup>125</sup>I-IGF-II and <sup>125</sup>I-insulin binding sites are differently altered in ALS cords. The distribution of IGF receptors in the normal spinal cord and changes in ALS cords may be of relevance for future therapeutic strategies.

## 395.8

**INCREASES OF CALPAIN I SPECIFIC CYTOSKELETON BREAK DOWN PRODUCTS FURTHER IMPLICATE CALPAIN PROTEOLYSIS FOLLOWING TRAUMATIC BRAIN INJURY (TBI).** R.M. Posmantur<sup>1</sup>, A. Kampfl<sup>2</sup>, S.J. Liu<sup>3</sup>, G. Clifton<sup>4</sup>, R.L. Hayes<sup>5</sup>, Department of Neurosurgery, UT Health Science Center-Houston, Texas, USA.

Previous quantitative Western blot analyses have demonstrated the loss of neurofilament 68 (NF68) and neurofilament 200 (NF200) protein subunits following lateral cortical impact injury. Loss of NF68 in cortical homogenates was associated with the concomitant increase of low molecular weight immunopositive break down products (BDP's) suggesting calpain mediated proteolysis of the neuronal cytoskeleton persisting for at least 24 hrs after injury (Posmantur et al., J. Neurotrauma 11: 533-545, 1994). Recent immunohistochemistry studies examining corresponding morphopathology have found diffuse process injury (DPI) preferentially occurring in dendrites rather than axons at early time points following injury (Posmantur et al; J. Neur. Exp. Neurol., submitted). To further examine the role of calpain mediated proteolysis 24 hrs after TBI, we used Western blots to examine BDP's both for NF68 and alpha spectrin using a polyclonal antibody (Robert-Lewis et al., J. Neurosci 14: 3934-3944, 1994) specifically recognizing calpain I mediated spectrin BDP's. Spectrin BDP's increased 374% in cortex ipsilateral to injury ( $p \leq 0.004$ ) and increased 178% in the contralateral cortex ( $p \leq 0.042$ ) compared to sham injured levels. Other comparisons indicated that spectrin was more vulnerable than NF68 to calpain mediated proteolysis. BDP's for spectrin but not NF68 were detected in the contralateral cortex. In addition, BDP's for spectrin but not NF 68 were detected bilaterally in the cortices of animals surgically prepared for injury (bilateral craniotomies) but not injured. Our ongoing examinations of cytoskeleton proteolysis employing *in vivo* and *in vitro* models of TBI have also provided evidence that specific anti-proteolytic compounds may provide a therapeutic approach to treating these protein losses (e.g. Kampfl et al., this meeting). (Supported by NIH grants PO1 NS 31998 and RO1 NS 21458)

## 396.2

**DIFFERENTIAL ACTIONS OF BCL-2 AND CILIARY NEUROTROPHIC FACTOR ON A GENETIC MOUSE MODEL WITH NEUROMUSCULAR DYSFUNCTION**

A. Kato<sup>1</sup>, M. Dubois-Dauphin<sup>2</sup>, S.A. Tan<sup>3</sup>, F. de Bilbao<sup>4</sup>, J.Y. Fischer-Lougheed<sup>5</sup>, P. Aebischer<sup>6</sup>, J.C. Martinou<sup>7</sup> and Y. Sagot<sup>8</sup>, <sup>1</sup>Dept. Pharmacology, <sup>2</sup>Division of Clinical Neuromuscular Research, <sup>3</sup>Dept. Physiology, Geneva University, Switzerland; <sup>4</sup>Gene Therapy Center & Division of Surgical Research, Lausanne University, Switzerland; <sup>5</sup>Glaxo Institute for Molecular Biology, Geneva, Switzerland.

Cell death is a major event in the developing nervous system and in certain pathological states such as neurodegenerative diseases. In vertebrates it has been shown that the proto-oncogene, bcl-2, can act as a natural repressor of apoptosis in the nervous system.

To determine whether the protein Bcl-2 could prevent the disease progression in an animal model which mimics a human motor neuron disease, we have used a genetic mouse model with neuromuscular dysfunction called *pnn* because of its progressive motor neuropathy. The *pnn* mice show degeneration in motor nerves and motoneuron cell bodies associated with a severe muscle wasting leading to death. After crossing them with Bcl-2 overexpressing mice, we observed a rescue of the facial motoneurons with a preservation of the soma size. However, Bcl-2 did not prevent degeneration of motor nerve fibers nor increases the life-span of the *pnn* mice. In contrast, treatment of *pnn* mice with polymer-encapsulated cells releasing ciliary neurotrophic factor (CNTF) improved their life-span. Therefore, we suggest that divergent pathways exist for neuronal survival versus fiber outgrowth and that CNTF can act on both pathways whereas Bcl-2 acts more specifically on neuronal survival.

## 396.3

**EFFECT OF GDNF ADMINISTRATION IN AN ANIMAL MODEL OF MOTONEURON DISEASE.** Y. Sagot<sup>1</sup>, S.A. Tan<sup>2</sup>, J. Hamming<sup>3</sup>, D. Muller<sup>4</sup>, A.C. Kato<sup>5</sup> and P. Aebischer<sup>1</sup>. <sup>1</sup>Dept of Pharmacology and <sup>2</sup>Div. of Clinical Neuromuscular Research, Geneva University, Switzerland; <sup>3</sup>Gene Therapy Center & Division of Surgical Research, Lausanne University, Switzerland; <sup>4</sup>CytoTherapeutics Inc., Providence, RI, USA.

Glial cell line-derived neurotrophic factor (GDNF), a member of the TGF- $\beta$  superfamily, has been shown to be a very potent neurotrophic factor that enhances survival of various neuronal cell types including motoneurons. In order to assess its therapeutic potential in treating neurodegenerative diseases such as amyotrophic lateral sclerosis (ALS), we treated *pnn* mice (a mutant mouse model displaying motoneuron degeneration) with encapsulated GDNF-secreting cells. Effects of GDNF treatment on *pnn/pnn* mice were compared with previous results obtained with CNTF.

In contrast to CNTF, GDNF could not significantly improve the motor function or increase the life-span of *pnn* mice. However, counts of facial motoneurons revealed that in GDNF-treated mice, the motoneuron loss was significantly reduced as compared to untreated *pnn* mice. Surprisingly, axonal counts revealed that the GDNF action on nerve degeneration was negligible as compared to CNTF. Therefore GDNF and CNTF are equally potent in rescuing motoneuron cell bodies whereas GDNF is less efficient in preventing or compensating for nerve degeneration in *pnn* mice. This difference between CNTF and GDNF in their biological action may be relevant for clinical trials in neurodegenerative diseases.

## 396.5

**CLINICAL AND HISTOLOGICAL FEATURES OF THE NZB-ELICITED WOBBLER ("NEW") MOUSE HYBRID.** T. Ishiyama, B. Klinkosz, E.P. Pioro<sup>2</sup> and H. Mitsumoto. Depts of Neurology & Neuroscience, Cleveland Clinic Fdn, Cleveland OH 44195.

The wobbler (wr) mouse is an extensively studied animal model of motor neuron disease (MND) but its molecular basis is still unknown. However, the wr gene is closely linked to the pseudogene glutamine synthetase (*glns*) on mouse chromosome 11 allowing linkage analysis. Recently, Junier et al., (J. Neurosci., 1994) used PCR to genetically identify homozygous wr mice from a new cross-bred strain (C57BL/6J wr x New Zealand Black) which carries 2 different sized *glns* microsatellites. The purpose of our study was to characterize this NZB-elicited wobbler ("new") mouse and compare it with the original wr that we have extensively used. Weekly assessments of various parameters were made in new and original wr mice beginning at 2 weeks of age. Body weight was slightly greater in new mice. Paw position and walking abnormalities (both grade 1) developed by 4 weeks and worsened with age, particularly in new mice. Grip strength in new mice (n=11) was significantly less (p<0.001) than in wr mice from the onset of disease at 4 weeks. Running speed showed a similar trend. Most wr and new mice survived beyond 6 months. Histological study of both groups at 8 weeks of age showed vacuolar degeneration in cervical cord anterior horn cells and no difference in numbers of axons in C5 and C6 ventral roots. Thus histological features were similar in the new and wr mice although new mice were more affected clinically. Genetically identifiable new mice will be useful for further studies in this MND. (We thank F. Rieger & A. Ait-Ikhlef, INSERM, France for *glns* primers and helpful discussion.)

## 396.7

**ACTIVATION OF PROTEIN KINASE C HAS MULTIPLE EFFECTS ON NEUROFILAMENTS OF MOTOR NEURONS.** M. M. Doroudchi<sup>1</sup> and H. D. Durham. Montreal Neurological Institute, McGill University, Montreal, Quebec, Canada, H3A 2B4.

Characteristic responses of motor neurons to injury include accumulation of neurofilaments in perikarya and proximal axons and apparent increase in the phosphorylation of C-terminal domains of neurofilament proteins. Experiments were conducted in dissociated cultures of murine embryonic spinal cord to determine if activation of Protein Kinase C (PKC) would induce such changes in mammalian motor neurons. PKC was activated by: (1) exposure of cultures to 10 nM 12-O-tetradecanoyl phorbol 13-acetate (TPA); (2) microinjection of 1 mM dioctanoylglycerol (DiC<sub>8</sub>, DAG) directly into perikarya of motor neurons; (3) addition of 10  $\mu$ M DiC<sub>8</sub> to the culture medium. Within 1 to 4 hrs, fragmentation and disassembly of the neurofilament network was observed in neuronal perikarya by indirect immunocytochemistry. 1-7 days following treatment, motor neurons were observed with extensions of perikaryal cytoplasm or massive enlargements of proximal processes, both containing intact neurofilament networks. Over 3-12 days, there was a gradual increase in the number of motor neuronal perikarya immunoreactive with antibodies specific for neurofilaments phosphorylated at C-terminal domains. These results demonstrate that activation of PKC leads to different immediate and long term effects on neurofilaments of motor neurons. These changes resemble alterations in shape and in neurofilament phosphorylation occurring in motor neurons following injury.

## 396.4

**THE EFFECTS OF PROLONGED CO-ADMINISTRATION OF CNTF AND BDNF IN WOBBLER MICE.** B. Klinkosz, H. Mitsumoto. Neurology & Neuroscience, Cleveland Clinic, Cleveland, Ohio 44195, J.M. Cedarbaum, V. Wong, R.M. Lindsay Regeneron Pharmaceuticals, Tarrytown, NY.

Systemic co-administration of CNTF/BDNF for 4 weeks arrests the progression of wobbler mouse motor neuron disease (MND) (Science 265, 1107-94). To investigate the effects of an extended CNTF/BDNF treatment, we administered subcutaneously, recombinant human CNTF (1mg/kg, 3/week) and BDNF (5mg/kg, 3/week) alternately in a randomized, blinded, placebo (vehicle)-controlled fashion. Eleven wobbler mice received CNTF/BDNF for the entire 8 weeks -Grp A; 10 mice received CNTF/BDNF for the first 4 weeks and vehicle for the second 4 weeks-Grp B; Grp C (8 mice) received vehicle alone for 8 weeks. 6 animals died in Grp A (between week 2 and 7) and 2 animals in Grp B (in week 2), and none in Grp C. Body weight decreased more in Grp A and Grp B (both P<.01) than in Grp C early on. Mice that died in Grp A weighed less than those which survived (P<.02 at week 3). The average grip strength did not decline in Grp A but rather increased from baseline in 60% of animals. Grp B started losing strength after week 4, but was still stronger (P<.0001) than Grp C, which lost nearly 100% strength by week 6. Running speed was faster in Grp A (P<.001) than in Grp C; in Grp B it was similar to Grp A but slowed after week 4. Semiquantitative paw abnormality and walking patterns (grade 1, minimum; grade 4, maximum deficits) deteriorated slightly in Grp A (60% remained in grade 1 by week 8), whereas Grp B only deteriorated after week 4 (40% in grades 3-4 by week 8). 100% of Grp C were in grade 4 by week 8. This study not only confirms our previous observation that 4-week administration of CNTF/BDNF clinically arrests wobbler mouse MND, but also shows that combination treatment sustains the synergistic effect of these neurotrophic factors as long as treatment was continued.

## 396.6

**ABNORMAL DNA REPAIR IN PATIENTS WITH ALS.** Z.L. Oikowski<sup>1</sup> and J. Rosenfeld<sup>2</sup>. Depts of Radiation Oncology<sup>1</sup> and Neurology<sup>2</sup>, Emory University School of Medicine, Atlanta, GA 30322

DNA injury and compensatory repair mechanisms are frequent processes found in all eukaryotic cells. Among the most common DNA injury, the formation of abasic sites (AP), results from the removal of a purine base. This common injury is normally repaired by an endogenous repair enzyme, AP-endonuclease which is among the most abundant DNA repair enzymes. DNA injury is accelerated in the presence of reactive oxygen species (ROS), implicated in many neurodegenerative conditions; if DNA injury is unopposed by DNA repair, cell injury or death will result.

ROS have been implicated in the pathogenesis of many neurodegenerative diseases. In a search for etiologic factors contributing to neurodegenerative disease, we have examined the quantity and activity of AP-endonuclease in patients with familial and sporadic ALS compared to unaffected control patients.

AP-endonuclease activity is significantly decreased in lymphocytes from patients with sporadic ALS (decr. 53%, n=3) and familial ALS (decr. 31%, n=2) when compared to healthy controls (n=3). Furthermore, initial sequencing revealed an abnormal 5' c-DNA insertion. Complete gene sequencing as well as analysis of other neurodegenerative disorders will be presented.

This abnormality in AP-endonuclease, a major DNA repair enzyme, results in an increased number of unrepaired AP sites and may be reflected in dystrophic cell changes and/or cell death. Such abnormalities may have primary importance in the pathophysiology of ALS as well as other neurodegenerative diseases.

## 396.8

**TRANSGENIC ANIMAL MODEL OF AMYOTROPHIC LATERAL SCLEROSIS: ENHANCED RELEASE OF ACETYLCHOLINE FROM THE MOTOR NERVE TERMINALS.** Yong J. Kim\* and Mark E. Gurney. Departments of Biomedical Engineering and Neurology, University of Virginia, Charlottesville, VA 22908 and Department of Cell and Molecular Biology, Northwestern University, Chicago, IL 60611.

The transgenic mice that express a human Cu,Zn superoxide dismutase (SOD) mutation are a plausible animal model of amyotrophic lateral sclerosis (ALS) in familial form (Science 264: 1772-1775, 1994). To explore the effects of the SOD mutation on the motor nerve terminal (MNT) function, we studied neuromuscular transmission in three different groups of animals: (i) mice with the mutated human SOD gene (herein called "G1H"); (ii) mice with the wild-type human SOD gene (N29) for use as a control; and (iii) normal untreated (wild-type, wt) animals. Phrenic nerve-diaphragm muscles were exposed to 1.2 mM [Ca<sup>2+</sup>]<sub>i</sub> and 10 mM [Mg<sup>2+</sup>]<sub>i</sub> solution and the number of ACh quanta released per motor nerve impulse was measured using the direct method. In 75 to 113 days old G1H animals, quantal content (m) of the neurally-evoked end-plate potentials (EPPs) was 1.86  $\pm$  0.14 (mean  $\pm$  SEM, n = 16 animals), significantly increased (P<0.001) from the values found in the corresponding control N29 mice (1.14  $\pm$  0.09, n = 11) or wt animals. The EPP quantal content in 54 to 65 days old G1H mice, however, did not differ significantly from either N29 or wt animals. The frequency and amplitude of the spontaneously occurring miniature end-plate potentials (MEPPs) were not significantly different between the three groups of animals.

We suggest two possible explanations for this finding. (1) calcium entry into the MNT, presumably mediated by the voltage-dependent calcium channels, is significantly increased in G1H mice; and/or (2) increase in m may represent the effect secondary to the motor nerve sprouting, a known morphological feature in G1H mice (Supported by NINDS and the Muscular Dystrophy Association).

## 396.9

IRON IN SPINAL MOTOR NEURONS IN AMYOTROPHIC LATERAL SCLEROSIS (ALS). E.J. Kasarskis\*, M. Lovell, X. Bi. Dept. Neurology, VA and Univ. Kentucky Medical Centers, Lexington KY 40511.

Free radicals have been implicated in the death of spinal motor neurons in ALS. Iron (Fe) participates in the generation of the hydroxyl free radicals from hydrogen peroxide. In a previous study, we found that total Fe was increased nearly two-fold in cervical motor neurons from ALS patients compared to matched controls using Laser Microprobe Mass Spectrometry (In press, J. Neurol. Sci., 1995).

In the present work, we have examined Fe distribution within motor neurons in paraffin embedded spinal cord from 10 ALS and 10 matched controls. Non-heme Fe was visualized using Perl's reaction enhanced with DAB and silver. The distribution of total Fe was mapped using an Fe-specific chelating agent coupled to rhodamine.

Iron was distributed heterogeneously in control motor neurons with the highest apparent concentration in the perinuclear cytoplasm. Iron was also visualized in the pia, endothelial cells, and glia. Although Fe distribution was similar in ALS, degenerating and some large motor neurons were intensely stained for Fe which had a homogeneous cytoplasmic distribution.

These studies indicate that Fe is present in spinal motor neurons and may be available to catalyze the generation of hydroxyl free radicals within the cells subject to ALS-type degeneration. (Supported by the VA Research Service).

PHARMACOLOGICAL ACTION OF RILUZOLE ON CHOLINERGIC TRANSMITTER RELEASE. Michael P. Viglione\*, J. Mark Longacher, Tanja M. Pieters and Yong I. Kim. Departments of Biomedical Engineering and Neurology, University of Virginia School of Medicine, Charlottesville, VA 22908.

Recent studies have shown that riluzole (2-amino-6-trifluoromethoxy benzothiazole) increased survival rate of amyotrophic lateral sclerosis (ALS) patients. To explore the possible therapeutic mechanism of this drug, we determined the pre- and post-junctional effects of riluzole on cholinergic neuromuscular transmission.

Experiments were conducted to establish a comprehensive dose-response relationship from 1 to 400  $\mu$ M. When riluzole up to 100  $\mu$ M was applied to mouse phrenic nerve-diaphragm muscle preparations in normal Ringer's solution, the miniature end-plate potential (MEPP) frequency was relatively unchanged. At 100 to 400  $\mu$ M, however, MEPP frequency was significantly increased ( $p < 0.05$ ) by 82 to 226% ( $n = 21-38$  fibers) compared to control fibers. Pretreatment with  $\omega$ -agatoxin IVA (40 nM), a specific P-type calcium channel blocker, did not compromise the riluzole-induced enhancement of MEPP discharge. Using muscles bathed in 1.6 mM  $\text{Ca}^{2+}$ /10 mM  $\text{Mg}^{2+}$  Ringer, spontaneous MEPPs and nerve-evoked end-plate potentials (EPPs) were recorded and quantal content (m) was estimated. Riluzole produced no consistent change in m; however, at higher concentrations ( $> 100 \mu$ M), some motor end-plates exhibited a complete failure of EPPs. Similarly, in more than 35% of fibers exposed to 140  $\mu$ M riluzole, indirectly and directly elicited muscle fiber action potentials (APs) failed to occur.

These findings suggest that (1) riluzole does not interfere with the function of P-type calcium channels at the neuromuscular junction; and (2) the blockade of evoked EPPs occurs at high concentrations of riluzole as a result of the failure in the production and propagation of APs. (Supported by a research grant from the Muscular Dystrophy Association).

## 396.13

SERUM AUTO-ANTIBODIES OTHER THAN ANTI-GM-1 IN THE PATHOGENESIS OF PROGRESSIVE MUSCULAR ATROPHY. R. Atkinson, C. Williams, W.K. Engel and C.A. Miller\*. Univ. So. Cal. Sch. of Med., Dept. of Pathology, Los Angeles, CA 90033.

Some patients with progressive muscular atrophy (PMA), a lower motor neuron disease, have circulating immunoglobulins that bind to surfaces of alpha-motor neuron somas and proximal dendrites. In most of those cases, circulating antibodies to GM-1 ganglioside were demonstrated. We previously found that sera from three PMA patients also identified a 400kDa chondroitin sulfate proteoglycan (CSP-400) on Western blots. To determine the localization of this antigen, serum from one PMA patient with circulating anti-GM-1 antibody was absorbed by GM-1 bound to octyl-sepharose. The eluate (GM-1 fraction) and the non-bound fraction were tested for immunoreactivity on cryostat sections of normal human lumbar spinal cord. The eluate showed diffuse spinal cord grey matter localization. The non-bound serum fraction showed only motor neuron immunoreactivity, with distinct perineuronal and proximal dendritic staining, including circular profiles. Anti-cholera toxin, which binds specifically to GM-1 ganglioside only diffusely stained the neuropil. Thus, this patient's perineuronal immunoreactivity: a) seems to be the result of an autoantibody other than that one specific for GM-1 ganglioside, and b) may be involved in the pathogenesis of lower motor neuron disease.

## 396.10

PHARMACOLOGICAL ACTION OF RILUZOLE ON ION CHANNELS OF EXCITABLE MEMBRANES. Hyung C. Kim, Taick S. Nam, Anna M. Preta, Joseph J. Pancrazio\* and Yong I. Kim. Departments of Biomedical Engineering, Neurology and Anesthesiology, University of Virginia School of Medicine, Charlottesville, VA 22908.

In a recent investigation by Bensimon *et al.* (*N. Eng. J. Med.* 330: 585-591, 1994), riluzole (2-amino-6-trifluoromethoxy benzothiazole), a newly synthesized antitumor drug, significantly increased survival time of amyotrophic lateral sclerosis (ALS) patients. However, the pharmacological mechanism underlying the therapeutic action of riluzole is not clearly understood. The present study is aimed at determining the pharmacological action of riluzole in modifying the function of voltage-dependent  $\text{Ca}^{2+}$  and  $\text{Na}^{+}$  channels.

Riluzole was applied to bovine adrenal chromaffin cells at concentrations of 1, 3, 10, 30, 55, 100, 200, and 400  $\mu$ M and whole-cell patch-clamp measurements of voltage-dependent calcium ( $I_{\text{Ca}}$ ) and sodium ( $I_{\text{Na}}$ ) currents were performed. The drug caused a dose-dependent blockage of the function of these ion channels. In the range of concentrations from 1 to 30  $\mu$ M, riluzole produced a slight to moderate effect on  $I_{\text{Ca}}$ ; at 30  $\mu$ M, peak  $I_{\text{Ca}}$  was reduced by 12% ( $n = 77$  cells) and the steady-state  $I_{\text{Ca}}$  by 27% ( $n = 81$ ) compared to the control. The steady-state component of the current was consistently more inhibited than the peak at all concentrations studied. With a 200  $\mu$ M concentration, nearly complete inhibition of  $I_{\text{Ca}}$  and  $I_{\text{Na}}$  was observed, which fell by 93 and 72% ( $n = 27$ ), respectively, from the control.

These findings suggest that riluzole blocks the function of L- or N-type  $\text{Ca}^{2+}$  channels and  $\text{Na}^{+}$  channels. (Supported by a research grant from the Muscular Dystrophy Association).

## 396.12

NEW GENE TRANSFER FOR MOTOR NEURON DISEASES AND TRAUMA. F.F. Finiels\*, M. Gimenez, Y. Ribotta, M. Barkats, M.L. Samolyk, J.J. Robert, A. Privat, F. Revah and J. Mallet, UMR C9923 CNRS-Rhône-Poulenc Rorer-Gencell F-91198 Gif-sur-Yvette and U 336 INSERM, F-34095 Montpellier, France.

Several neurotrophic factors are candidates for the therapy of motor neuron degenerative diseases such as Amyotrophic Lateral Sclerosis (ALS), Kennedy's disease and Spinal Muscular Atrophy (SMA). However, there is no efficient, safe, and practicable administration route which hampers the clinical use of these potentially therapeutic agents. We show that specific and high yield gene transfer into motor neurons can be obtained by peripheral intramuscular injections of recombinant adenoviruses. These vectors are retrogradely transported from muscular motor units to motor neuron cell bodies. Gene transfer can thus be specifically targeted to particular regions of the spinal cord by appropriate choice of the injected muscle. The efficiency of gene transfer is high, with more than 50 % of the motor neurons afferent to the injected muscle taking up the transgene. This new therapeutic protocol allows specific targeting of motor neurons without lesioning the spinal cord, and should avoid undesirable side effects associated with systemic administration of therapeutic factors.

## 396.14

UPTAKE OF IMMUNOGLOBULIN G FROM AMYOTROPHIC LATERAL SCLEROSIS(ALS) PATIENTS BY MOTOR NERVE TERMINALS IN THE MICE. S.A. Frattoloni\*, S.E. Starkstein and O.D. Uchitel. FLENI e \*Inst. de Biología Celular y Neurociencias Dr. E.D.P. De Robertis, Fac. de Medicina, Univ. de Buenos Aires, 1211, Buenos Aires, Argentina.

Animal studies have established that there is a normal motor nerve terminal uptake, retrograde axonal transport, and soma accumulation of immunoglobulin G (IgG). This process could be implicated in neuromuscular diseases. The passive transfer of dysfunction in the neuromuscular transmission treated with ALS-IgG supports an autoimmune etiopathogenesis for ALS (*PNAS* vol 88: 647-651; *Neurology* 42: 2175-2180). In the present study, we investigated in mice motoneuron somas, the presence of human ALS and control IgGs applied on the motor nerve terminals. We applied the IgGs from 6 ALS patients and 6 controls by subcutaneous injections on the facial nerve terminals of the Levator auris longus muscle. After repetitive injections (10 per week, 1mg of IgG each) the brainstem containing the facial nucleus was serially cut into slices and immunoprocessed to detect human IgG. The immunoreactive neuronal somata were quantitatively evaluated with a computerized image analyzer. In all cases the number of motoneurons remained constant and they were immunoreactive in different degrees for human IgG. Motoneuron labeling was more intense in the ipsilateral facial nucleus compared with the contralateral side for all IgG tested. The difference between ipsi and contralateral side was more pronounced in all the ALS-IgG treated animals. Furthermore, in the ALS IgG treated mice the ipsilateral labeling was significantly higher than the ipsilateral control IgG treated mice ( $P < 0.001$ ). Therefore, our results are compatible with the concept that motoneurons differentially take up, transport or accumulate ALS-IgG with respect to control IgG. Uptake of pathogenic antibodies by motoneuron terminals may play a role in the pathogenesis of motoneuron disease. Supported by Muscular Dystrophy Association.

## 396.15

BRAIN FREE RADICAL SCAVENGING ENZYME ACTIVITIES IN AMYOTROPHIC LATERAL SCLEROSIS. D. Donaldson<sup>1</sup>, M.W. Jakowec<sup>1</sup>, A.B. Naini<sup>2</sup>, S. Kish<sup>2</sup> and S. Przedborski<sup>1</sup>. Dept. Neurol., Columbia University, New York, NY, 10032 and <sup>2</sup>Clarke Instit. of Psychiatry, Toronto, Ontario, Canada.

Amyotrophic lateral sclerosis (ALS) is a fatal paralytic disorders of unknown cause. Recent evidence has implicated the role of free radicals in the death of motor neurons in this disease. To further investigate this hypothesis, we have measured the activity of the main free radical scavenging enzymes copper/zinc-superoxide dismutase (SOD-1), manganese-superoxide dismutase (SOD-2), catalase, and glutathione peroxidase (GPx) in post-mortem samples from nine patients with ALS and from nine controls. We examined samples from the motor area of the cerebral cortex, a regions affected in ALS, and from the cerebellar cortex, a region not affected in ALS. The two groups did not differ in age or post-mortem delay. In the cerebral cortex motor area from ALS patients, GPx activity measured by an indirect spectrophotometric assay ( $0.46 \pm 0.08$   $\mu\text{mol/min/mg}$  protein; [mean  $\pm$  SEM]) was reduced significantly as compared to controls ( $0.76 \pm 0.08$   $\mu\text{mol/min/mg}$  protein). The homosppecific activity of GPx determined by ELISA was significantly reduced in ALS by 44% of the control values. In contrast, neither GPx activity or its homosppecific activity was significantly altered in the cerebellar cortex from ALS as compared to controls. SOD-1, SOD-2 (corrected for citrate synthase or not corrected), and catalase were not significantly altered in the cerebral cortex motor area or cerebellar cortex in ALS samples. This study indicates that in ALS GPx enzymatic activity is reduced in brain regions affected in this disease and thus suggests that this finding may be relevant to the physiopathology of ALS.

## 396.17

INHIBITION OF ANTAGONIST MUSCLES DURING AUTOMATIC POSTURAL PERTURBATIONS FOLLOWING UPPER MOTOR NEURON (UMN) DAMAGE IN HUMANS. P.M.Diedrich, T. Matsumoto, J.A. McMillan\*, and C.T. Leonard. Motor Control Research Laboratory, The University of Montana, Missoula, MT, 59812 USA.

Individuals with UMN damage are unable to sufficiently inhibit the soleus muscle alpha motoneuron pool, as measured by H-reflex testing, during attempts at voluntary ankle dorsiflexion. Automatic reactions are typically not controlled directly by cortical projections. Rather, they are triggered by proprioceptive and vestibular input. The present study compared soleus muscle alpha motoneuron inhibition during activations of the tibialis anterior (TA) muscle initiated voluntarily or elicited by automatic postural perturbations. Although there were exceptions, individuals with UMN damage did not inhibit antagonist alpha motoneuron pools during automatic perturbations. Although tonic effects of descending cortical projections cannot be ruled out, it appears unlikely that the abnormal cocontraction associated with UMN damage can be explained solely by simultaneous activation of agonists and antagonists by descending cortical projections.

SUPEROXIDE DISMUTASE AND AXOTOMY J. Rosenfeld and M. Crutcher\* Department of Neurology, Emory University School of Medicine, Atlanta, Georgia 30322

Endogenous antioxidant proteins, such as superoxide dismutase (SOD), are present in all cells in response to volatile free radical molecules. Many disparate complex neurodegenerative conditions have been related to intracellular oxidative stress. The purpose of this study is to investigate a simple model of neuronal injury on the expression of SOD. Using reversible and nonreversible axotomy, Mn-SOD and Cu/Zn-SOD are studied by immunocytochemistry and quantitative western blot analysis at multiple time points during neuronal recovery or degeneration.

After crush (reversible) or transection (non-reversible) lesion of the sciatic nerve both dorsal root ganglia and ventral horn motor neurons are evaluated. By 12 days following lesion, Mn-SOD reveals a marked increase in immunoreactivity in the dorsal root ganglia (DRG) along with a detectible increase on immunoblot compared to unoperated controls. Increased immunoreactivity appears greater in the transected nerve. By 60 days, the increased immunoreactivity subsided in the DRG following both lesions. Motor neurons did not display the same enhanced immunoreactivity, however, preliminary results from quantitative immuno blots suggest an increase of at least 25% in Mn-SOD by 24 days after reversible lesion. Data correlating quantitative western blots, immunocytochemistry and cellular morphology will be presented.

These data suggest that after axotomy, the simplest of neuronal injuries, Mn-SOD increases its expression presumably in response to intracellular reactive oxygen species. This increase may be greatest in the DRG and following complete nerve transection. This model lends itself to subsequent study of therapeutic agents with potential antioxidant effects.

## ALZHEIMER'S DISEASE: ApoE AND GENETICS

## 400.1

POSITRON EMISSION TOMOGRAPHY, APOLIPOPROTEIN E EPSILON 4 HOMOZYGOSITY, AND THE GENETIC RISK FOR ALZHEIMER'S DISEASE. E.M. Reiman\*, R.J. Caselli, S. Minoshima, S.N. Thibodeau, D. Bandt, J. Lawrence, and K. Chen. Univ. Arizona, Mayo Clinic Scottsdale, Mayo Clinic Rochester, Univ. Michigan, and the Samaritan PET Center, Good Samaritan Regional Medical Center, Phoenix, AZ 85006.

Positron emission tomographic (PET) measurements of the cerebral metabolic rate for glucose (CMRgl) were used to compare individuals with two copies of the apolipoprotein E epsilon 4 (APOE- $\epsilon$ 4) allele to those with no copies of this allele prior to the age of risk for late-onset Alzheimer's disease (AD).

Advertisements were used to recruit 235 50-65 year-old volunteers with a family history of probable AD. Two had the  $\epsilon$ 2/2, 19 had the  $\epsilon$ 2/3, 5 had the  $\epsilon$ 2/4, 124 had the  $\epsilon$ 3/3, 73 had the  $\epsilon$ 3/4, and 12 had the  $\epsilon$ 4/4 genotype.

Eleven subjects with the  $\epsilon$ 4/4 genotype (mean age 55) and 22 age- and gender-matched control subjects (mean age 56) had neurological and psychiatric evaluations, a neuropsychological test battery, a T1-weighted volumetric magnetic resonance image (MRI), and PET measurements of CMRgl as they rested quietly with their eyes closed. An automated algorithm previously used to characterize posterior parietal and posterior cingulate abnormalities in patients with probable AD was used to investigate group differences in regional measurements and asymmetries.

In comparison to the control group, the APOE- $\epsilon$ 4/4 group had significant, bilateral reductions in posterior cingulate and prefrontal CMRgl, nonsignificant reductions in parietal CMRgl, no differences in whole brain CMRgl, and no significant memory or naming impairments.

This study provides preclinical evidence that the APOE- $\epsilon$ 4 allele is a risk factor for the development of AD. It demonstrates brain regions that are altered prior to the onset of illness, illustrates the value of studying APOE- $\epsilon$ 4 homozygotes prior to the age of risk, and suggests PET's potential to rapidly test future AD prevention drugs.

## 400.2

APOLIPOPROTEIN E4 AND AMYLOID ANGIOPATHY-ASSOCIATED INTRACEREBRAL HEMORRHAGE. S.M. Greenberg\*, G.W. Rebeck, J.P.G. Vonsattel, T. Gomez-Isla, B.T. Hyman. Dept. of Neurology, Mass. General Hosp. and Brain Tissue Res. Center, McLean Hosp., Harvard Med. School, Boston, MA 02114

Cerebral amyloid angiopathy (CAA) is characterized by deposition of the amyloid  $\beta$ -peptide in cerebral arterioles and, in severe cases, intracerebral hemorrhage. We tested whether the apolipoprotein E4 (apoE4) allele was associated with 1) pathologic severity of CAA and 2) the presence and age of onset of intracerebral hemorrhage. ApoE genotype was determined without knowledge of pathology for 93 postmortem cases systematically graded for severity of CAA and for 20 patients with CAA-associated intracerebral hemorrhage. We found a significant and independent effect of apoE genotype in both cohorts. In the pathologic cases, the presence of apoE4 increased the odds ratio for moderate or severe CAA by 2.9-fold relative to cases without E4; two copies of apoE4 increased the odds ratio 13.1-fold. This effect was independent of senile plaque density. In the cohort of CAA-associated cerebral hemorrhages, apoE4 allele frequency was 0.38, significantly greater than the control frequency of 0.14 ( $p < 0.0005$ ). Among cases in which full clinical history was available ( $n=11$ ), average age at the time of first hemorrhage was significantly less in the presence of apoE4 (70.0 yrs) than in its absence (81.1 yrs;  $p < 0.05$ ). Our results suggest that apoE4 is a risk factor for both CAA and CAA-associated intracerebral hemorrhage.

## 400.3

DISTRIBUTION OF APOE-IMMUNOREACTIVE NEURONS IN CONTROL AND AD BRAINS. G. Einstein\*, P. Bautista, V. Patel, M. Kenna, L. Melone, R. Fader, K. Karson, A. Saunders, C. Hultice, A. Roses, and D. Schmechel. Depts. of Neurobiology and Neurology, Duke U. Med. Cent., Durham, NC 27710.

The genotype of apolipoprotein E is a susceptibility factor in familial and sporadic late-onset Alzheimer's disease (AD). However, the relationship of the protein (apoE) to the primary pathology of AD, neuronal degeneration and death, is unknown. Since apoE is present in cortical neurons in both control and AD brains we reasoned that if apoE in neurons was related to pathogenic processes in AD its distribution would match the distribution of neuronal death in AD established by Braak and Braak (1991) and be coincident with other markers of AD pathology. To test this hypothesis we examined in detail, across neocortical areas 17, 18, and posterior inferior temporal cortex (IT), the relationship of apoE-immunoreactive neurons (apoE-IRn) to tau, GFAP, and A4 in both AD and control brains of known APOE genotype and cognitive status. Tissue was collected at autopsies performed no longer than 8 hours postmortem, placed in 4% paraformaldehyde in 0.1M phosphate buffer, fixed for 24 hours, vibratome sectioned at 40  $\mu$ m, and stained consecutively for Tau, GFAP, A4, and Nissl. We found that apoE-IRn were (1) present in both control and AD brains but were more intensely stained in AD than controls; (2) present rarely in area 17, occasionally in area 18, and regularly in IT; (3) correlated in AD with dense gliosis and tau-IR but not with plaque formation. Finding that the distribution of apoE-IRn follows the staging of the progression of AD and is correlated with markers of AD pathology suggests that apoE plays a role in the pathological process of AD. The presence of apoE in aged control brains as well as in AD suggests that its presence marks a general response to stress. Whether its presence is harmful or protective is as yet to be determined and may depend on genotype. Supported by AG-05128 and the John A. Hartford Foundation.

## 400.5

INFLUENCE OF APOE GENOTYPE ON DEVELOPING COGNITIVE IMPAIRMENT IN THE GENERAL POPULATION. B.T. Hyman\*, T. Gomez-Isla, M. Briggs, H. Chung, S. Nichols, F. Kohout and R. Wallace. Neurology, Mass. Gen. Hosp, Boston, MA 02114 & Depts. Prevent Med and Periodontics, Univ. Iowa, Iowa City, IA 52242.

ApoE  $\epsilon 4$  (E4) is over-represented, and E2 under-represented, in clinic populations of Alzheimer disease (AD) patients and in late onset familial AD (fAD). It has been suggested that E4/4 genotype leads to nearly inevitable development of dementia by age 80 in fAD (Corder et al, 1994). To evaluate the degree of E2 or E4 associated increased risk for cognitive impairment in the general population, we studied participants in the Iowa 65+ Rural Health Study. This 10 year, population based epidemiological study screened multiple social and medical factors, including cognitive function screening tests, in essentially all individuals over the age of 65 in 2 rural counties. At year 7 (FU-6), 1899 blood samples were obtained. ApoE allele frequencies were: E2 0.09; E3 0.76; E4 0.14. Longitudinal analysis showed that after controlling for demographic variables, participants with any E4 were more likely to have lower FU-10 delayed recall scores ( $p=0.002$ ) and those with any E2 were likely to have better delayed recall scores ( $p=0.017$ ) than those with other genotypes. Cross-sectional analysis at FU-6 showed that E4 was 1.8X more common in the lowest 25% of verbal delayed recall scores ( $p<0.01$ ), and 0.5X as common in the top 25% ( $p<0.01$ ). Nonetheless, 11 of 34 E4/4's (age  $77.2 \pm 3.8$  yrs) scored above the mean in verbal recall, including 2 in the top 10th percentile. Thus E4 and E2 have opposing influences on risk of developing cognitive impairment with increasing age. However, the magnitude of this influence is not as large in the general population as predicted from fAD or clinic-based samples.

## 400.7

IN VITRO INTERACTIONS OF APOLOPOPROTEIN E ISOFORMS WITH TAU. W.J. Strittmatter\* and V. deSerrano Bryan Alzheimer's Disease Research Center, Duke University Medical Center, Durham, NC, 2771

The apolipoprotein E4 (apoE4) allele is a susceptibility gene for late-onset Alzheimer's disease. ApoE is found in neurofibrillary tangle bearing neurons. Neurofibrillary tangles are formed from the hyperphosphorylated microtubule associated protein tau. Previous studies showed that apoE3, and not apoE4, irreversibly bound tau, and synthetic peptides representing each of the four microtubule-binding domains of tau. Reversible interactions of the apoE isoforms with tau are being studied with plasmon resonance technology. Both apoE3 and apoE4 reversibly bind tau with similar time and concentration dependence. Binding is inhibited by peptides of each of the microtubule binding domains of tau. These observations support a two-step interaction of apoE with tau: reversible and non-isoform specific, followed by irreversible, isoform-specific binding. Interactions of apoE with tau may regulate intraneuronal tau metabolism in Alzheimer's disease and alter the rate of formation of neurofibrillary tangles.

## 400.4

NEURONAL APOLOPOPROTEIN E RECEPTOR, LRP, IN THE HUMAN CENTRAL NERVOUS SYSTEM SYNAPTIC NERVE TERMINAL. T.W. Kim\*, M. Di Figlia, W. Wasco, G.W. Rebeck, B.T. Hyman, D.K. Strickland, R.E. Tanzi. Dept. of Neurology, Massachusetts General Hospital, MA 02129 and Biochemistry Lab., American Red Cross, Rockville, MD 20855.

Apolipoprotein E (apoE) has been implicated in neuronal plasticity and regeneration following peripheral and CNS injury. Recent studies indicate that the Apo- $\epsilon 4$  allele greatly increases the risk of late-onset sporadic and familial Alzheimer's disease (AD). Moreover, apoE knock-out mice display significant synaptic loss and structural alterations, indicating that neuronal uptake of apoE may be critical to maintain structural integrity of the synapse. Among members of the low-density lipoprotein (LDL) receptor family, LDL receptor-related protein (LRP) is the only identified major neuronal receptor for apoE. LRP binds and mediates the internalization of a diverse array of ligands, such as  $\alpha 2$ -macroglobulin and plasminogen activator. LRP immunoreactivity has been demonstrated in plaques, where its multiple LRP ligands are also found, as well as in reactive astrocytes in the AD brain. We now report that LRP is significantly enriched in isolated synaptic nerve terminals from the human cerebral cortex. LRP is localized sub-synaptically to synaptic plasma membrane but was not detectable in the postsynaptic density or light membrane (LP2) fractions. The synaptic localization and the multiple ligand binding properties of LRP suggest that apoE may be taken up directly in the synaptic terminals, raising the possibility that dysfunction of lipoprotein metabolism and protease clearance at the synapses may lead to the loss of synaptic integrity or to synaptic degeneration that is characteristic of AD.

## 400.6

Form and function of apoE-containing lipoproteins in the CNS. G.W. Rebeck\*, H. Chung, A. Mendez, J.H. Growdon and B.T. Hyman. The Neurology Service and Cardiac Unit of the Massachusetts General Hospital, Boston, MA.

Genetic data have indicated that apolipoprotein E (apoE) plays a role in the pathophysiology of Alzheimer's disease. We analyzed apoE in human CSF to determine the normal function of apoE in the CNS. ApoE is present on high density lipoproteins (HDL) in CSF. We isolated lipoproteins from post-mortem CSF of seven AD patients by ultracentrifugation. CSF HDL consisted of 38% protein, 34% phospholipid, 13% free cholesterol and 15% cholesterol esters. The protein component of CSF HDL was almost entirely apoE and apoA1. In order to test whether these particles could deliver lipids to cells, we radioactively iodinated ApoE3-containing CSF HDL and incubated them with fibroblast and PC12 cells in culture. CSF HDL were taken up and degraded in a dose dependent manner, with significant uptake occurring at physiologically relevant concentrations (1-10  $\mu$ g/ml). As comparison, plasma HDL were not taken up by cells in culture. We analyzed which receptors might mediate CSF HDL uptake by examining fibroblasts that expressed the LDL receptor and the LDL receptor-related protein (LRP) and fibroblasts that expressed only the LDL receptor. These two cell lines did not differ in CSF HDL uptake, suggesting that LRP did not affect metabolism of CSF HDL in fibroblasts.

These data are the first showing a function of the CSF lipoprotein and address how apoE complexes are cleared from CSF.

## 400.8

EXPRESSION OF HUMAN APOLOPOPROTEIN E IN RODENT BRAIN VIA AN ADENO-ASSOCIATED VIRUS VECTOR. M.G. Kaplitt<sup>1,2</sup>, J. Smith<sup>1</sup>, F. Ferran<sup>3</sup>, R. J. Samulski<sup>3</sup>, D.W. Platt<sup>1</sup>, M.J. During<sup>4</sup>, S. Gandy<sup>2</sup> and J. Breslow<sup>1</sup>. <sup>1</sup>The Rockefeller University, New York, NY 10021; <sup>2</sup>Cornell University Medical College, New York, NY 10021; <sup>3</sup>U of N. Carolina, Chapel Hill, NC 27599; <sup>4</sup>Yale Univ. School of Medicine, New Haven, CT 06520.

We report the first expression of human apolipoprotein E (Apo E) in the rodent brain using an adeno-associated virus (AAV) vector. Although transgenic mice have been created which either express no endogenous apoE or overexpress human apoE, to date expression of human apoE has not been reported in the rodent brain. Previously we have demonstrated that an AAV vector can safely and stably transfer and express foreign genes in the rodent and primate brain, and therapeutic improvement has been achieved in animal models of Parkinson's disease. We have now created AAV vectors containing human ApoE2 or ApoE4 isoforms under the control of the human cytomegalovirus promoter. Following packaging of AAV-ApoE, expression of both isoforms was demonstrated in a tissue culture cell line (293T) using a goat-anti human ApoE antibody. Purified AAV-ApoE2 vector was then unilaterally injected into cerebral cortex and hippocampus of the rat brain. After 3 days, cells expressing human apoE were observed within these regions, while there was a complete absence of positive cells on the contralateral hemisphere which had been injected with a control vector expressing the lacZ gene. Studies examining long-term expression and gene transfer into Apo E-deficient mice are currently in progress. Given recent advances in the development of animal models of Alzheimer's disease, these results present the opportunity to examine whether specific ApoE isoforms promote or prevent neuropathology and suggest the possibility of a novel gene therapy approach to this disorder.

## 400.9

THE INHIBITION OF NEURITE OUTGROWTH BY APOLIPOPROTEIN E4 IS MEDIATED THROUGH THE LOW DENSITY LIPOPROTEIN RECEPTOR-RELATED PROTEIN. B. P. Nathan\*, K.-C. Chang, S. Bellosta, R. W. Mahley,† and R. E. Pitas†. Gladstone Institute of Cardiovascular Disease, Cardiovascular Research Institute, Departments of †Medicine and †Pathology, University of California, San Francisco, CA 94141-9100.

Apolipoprotein (apo) E4 inhibits neurite outgrowth from murine neuroblastoma (Neuro-2a) cells. The inhibitory effect of apoE4 was observed only in the presence of lipoproteins and was blocked by a monoclonal antibody to the lipoprotein receptor-binding domain of apoE, suggesting that the interaction of apoE with lipoprotein receptors is important in eliciting the effect. In the present study, we treated cells with reagents that inhibit binding and uptake of lipoproteins by the low density lipoprotein (LDL) receptor-related protein (LRP), but not by the LDL receptor, and examined the effect on apoE4-mediated inhibition of neurite outgrowth. Neuro-2a cells were preincubated for 1 hour in serum-free medium alone or in medium containing either heparinase (10 units/ml) and chlorate (30 mM), or the receptor-associated protein (RAP) (5 µg/ml). Heparinase and chlorate deplete cell-surface heparan sulfate proteoglycans that bind apoE-enriched lipoproteins prior to internalization via the LRP, whereas the RAP competitively inhibits the binding of lipoproteins to the LRP. Following preincubation, β-migrating very low density lipoproteins (β-VLDL) (40 µg cholesterol/ml) and apoE4 (30 µg/ml) were added to the medium, and the cells were incubated for 24 hours in the presence of the inhibitors. After this incubation, inhibitors were re-added to the medium, and the cells were incubated for an additional 24 hours. Heparinase and chlorate or RAP alone, in the absence of β-VLDL and apoE4, did not have any effect on neurite outgrowth. Consistent with our previous studies, apoE4 in the presence of β-VLDL alone inhibited neurite outgrowth. However, when cells were treated with heparinase and chlorate or with RAP, the inhibitory effect of apoE4 with β-VLDL on neurite outgrowth was abolished. The data suggest that binding of apoE4-enriched lipoproteins by the LRP is necessary for the inhibitory effect on neurite outgrowth.

## 400.11

DNA DAMAGE IN ALZHEIMER'S DISEASE: COLOCALIZATION WITH C-JUN IMMUNOREACTIVITY, AND EFFECT OF BRAIN AREA AND POSTMORTEM DELAY. Aileen J. Anderson\*, Joseph H. Su and Carl W. Cotman. Brain Aging and Dementia Institute. University of California, Irvine, Irvine, CA 92717-4550.

Neurons in Alzheimer's disease (AD) exhibit terminal deoxynucleotidyl transferase (TdT) labeling for DNA strand breaks with a distribution suggestive of apoptosis in many cells (Su et al., 1994). We have previously shown that immunoreactivity for the immediate early gene c-Jun is elevated in AD, and found in association with neuronal pathology (Anderson et al., 1994). In addition, cultured neurons undergoing β-amyloid-mediated apoptosis exhibit a selective and prolonged induction of c-Jun (Anderson et al., in press). Consequently, we examined whether c-Jun is associated with DNA damage in AD tissue by double-labeling for DNA damage and c-Jun in 8 AD and 5 control cases. We observed a strong colocalization of these markers, supporting a relationship between the expression of c-Jun and neuronal risk and/or cell death. In order to examine the relationship of TdT labeling to brain area, we compared TdT labeling in the hippocampal formation and cerebellum of 5 individuals with AD. As would be predicted if the DNA damage detected with TdT is associated specifically with AD-related neuronal risk/cell loss, these results revealed low to absent TdT labeling the cerebellum. Gel electrophoresis of the genomic DNA from 4 AD and 4 control cases revealed no evidence for either an apoptotic or necrotic mechanism of cell death in AD. Although the above studies were conducted in tissues with very short postmortem delay (PMD), we also examined the effect of PMD on TdT labeling. In contrast to recent reports, our results suggest that PMD does affect TdT labeling at later timepoints.

## 400.10

LRP MEDIATES APOLIPOPROTEIN E-DEPENDENT NEURITE OUTGROWTH IN A CNS-DERIVED NEURONAL CELL LINE. D. M. Holtzman\*, R. E. Pitas\*, J. Kilbridge\*, Y. Sun\*, B. Nathan\*, R. W. Mahley\*, G. Bu\*, A. L. Schwarz\*, Washington University\*, St. Louis, MO, 63110, Gladstone Institute\*, UCSF, San Francisco, CA, 94141, UCSF\*, San Francisco, CA, 94143.

The ε4 allele of apolipoprotein E (apoE) is a major risk factor for Alzheimer disease (AD) suggesting that apoE may directly influence neurons in the aging brain. Recent data suggest that apoE-containing lipoproteins can influence neurite-outgrowth in an isoform-specific fashion. The neuronal mediators of apoE effects have not been clarified. Herein, we show that in a CNS-derived neuronal cell line (GT1-1 trk9), apoE3 but not apoE4 increases neurite extension. The effect of apoE3 required the presence of lipoproteins (β-VLDL) and was blocked at low nM concentrations by purified 39-kDa protein which regulates ligand binding to the low density lipoprotein receptor-related protein (LRP). Anti-LRP antibody also completely abolished the neurite promoting effect of apoE3. Understanding isoform specific cell biological processes mediated by apoE-LRP interactions in CNS neurons may provide insight into AD pathogenesis.

## 400.12

CANDIDATE GENES FOR THE MAJOR EARLY ONSET FAMILIAL ALZHEIMER'S DISEASE GENE ON CHROMOSOME 14 INCLUDING A NOVEL PROTEASE. R.E. Tanzi\*, D.M. Romano, W. Pettingell, P. Jondro, S. Schmidt, A.C. Crowley, J. Murrell, A. Buckler, K. Felsenstein, W. Wasco. Genetics and Aging Unit, Mass. General Hospital, Charlestown, MA; Bristol Myers-Squibb, Wallingford, CT.

The gene defect responsible for over 80% of familial Alzheimer's disease (*FAD3*) lies in an approximately 3 million bp region on chromosome 14 between markers *D14S61* and *D14S289*. In this region, we have assessed a number of candidate genes including the E2k component of α-ketoglutarate dehydrogenase (*DLST*), transforming growth factor β3 (*TGFB3*), and latent transforming growth factor-beta binding protein (*LTBP-2*). Of these genes, only *TGFB3* has been excluded. We have also isolated full-length cDNAs for a novel protease using "trapped exons" from the candidate region. This gene is ubiquitously expressed, differentially spliced, and has been shown to be active in its ability to cleave APP. We are currently in the process of searching for pathogenic mutations in this gene.

## BETA-AMYLOID: NEUROTOXICITY

## 401.1

EXPRESSION OF MEMBRANE ATTACK COMPLEX CONTRIBUTES TO THE INCREASED β-AMYLOID PROTEIN INDUCED NEURONAL CELL DEATH BY INTERRUPTION OF COMPLEMENT INHIBITOR CD59. Y. Shen\*, T. Sullivan, S. Magnuson, K. Shiosaki and C.W. Lin. Neuroscience Department, Abbott Laboratories, Abbott Park, Illinois 60064, USA

Evidence that β-amyloid protein (Aβ) is detected in normal brain tissues and cultures, and that synthetic Aβ is not highly neurotoxic, suggests Aβ alone may not be sufficient to cause Alzheimer's disease (AD). In addition to Aβ, focal immunoreactivity for various complement components has been found in senile plaques, tangles and dystrophic neurites in AD brains. Recently, we reported that complement activation causes neuronal cell death, and this degenerative process is regulated by homologous restriction (*Brain Res.* 671:282,1995). Furthermore, blockade of complement inhibitor CD59 (endogenous inhibitor of reactive lysis) resulted in increased vulnerability of differentiated SH-SY5Y human neuroblastoma cells to Aβ toxicity (*Neurosci. Abstr.* #676.10, 1994). This evidence has led to our hypothesis that interruption of CD59 increases neuronal vulnerability to Aβ by activating endogenous complement components and forming membrane attack complexes (MAC) on the cell membranes. To test this hypothesis, we were able to utilize techniques of reverse transcriptase polymerase chain reaction (RT-PCR) and PCR-Southern hybridization to detect the expression of message for the major complement components (C1q, C3, C4, C5, C6, C7, C8 and C9) in SH-SY5Y cells as well as in human brains. The results indicate that SH-SY5Y cells and human brains are able to synthesize the major complement components required to form MAC. Immunocytochemical studies demonstrated the presence of MAC on SH-SY5Y cells after treatment with Aβ or human serum in combination with either CD59 antibody or the enzyme which cleaves complement inhibitors on cell membranes (PI-specific phospholipase, PI-PLC). The results suggest that in SH-SY5Y cells, Aβ can activate complement cascade, and that MAC can be detected following depletion of CD59. MAC observed in senile plaque may be a consequence of Aβ action on neurons with dysfunctional endogenous complement inhibitors.

## 401.2

COAGULATION FACTOR XIa CLEAVAGE OF THE AMYLOID β-PROTEIN (Aβ) ALTERS ITS PATHOLOGICAL PROPERTIES. Susan M. Saporito-Irwin\* and William E. Van Nostrand. Department of Microbiology and Molecular Genetics, College of Medicine, University of California, Irvine, CA 92717-4025.

Deposition of Aβ in senile plaques in the neuropil and in the walls of cerebral blood vessels is one the hallmark features of Alzheimer's disease. Aβ is proteolytically derived from its transmembrane parent protein, the amyloid β-protein precursor (AβPP). AβPP is a multidomain protein which can be translated from alternatively spliced transcripts from a single gene on chromosome 21. The major mRNA species encode proteins of 695, 751 and 770 amino acids. The latter two isoforms contain a 56 amino acid domain that is homologous to Kunitz-type serine protease inhibitors (KPI). Recently, we have shown that Aβ1-42 induces cellular degeneration which is accompanied by a striking increase in its precursor, AβPP, in cultured human cerebrovascular smooth muscle cells. Here we show that coagulation factor XIa, a target protease for inhibition by the KPI domain of AβPP, proteolytically cleaves Aβ between residues Arg<sup>5</sup> and His<sup>6</sup> of the peptide. Proteolytic processing of Aβ1-42 at this site abolishes its ability to induce cellular degeneration and increased levels of cellular AβPP in the cultured cerebrovascular smooth muscle cells. These results suggest that the amino terminus of Aβ1-42 is important for eliciting pathologic changes in these cells. In addition, these findings indicate that the KPI domain of AβPP can regulate the activity of proteases that can process and alter the pathologic and possible physiologic properties of Aβ.

## 401.3

AMYLOID  $\beta$  PROTEIN TOXICITY AND ACTIVATED GLUCOCORTICOID RECEPTORS IN HIPPOCAMPAL NEURONS

Behl C., Trapp T., Skutella T., and Holsboer F.

Max-Planck Institute of Psychiatry, Clinical Institute, 80804 Munich

Amyloid  $\beta$  protein (A $\beta$ ), which accumulates in the central nervous system plaques, the characteristic feature of Alzheimer's disease (AD), is cytotoxic to clonal neuronal cells as well as to primary neurons. Addition of A $\beta$  to cultured neurons initially induces accumulation of hydrogen peroxide and finally results in lipid peroxidation and cell death. Dramatic cell death occurs in the hippocampus of AD patients. Since hippocampal neurons express high levels of glucocorticoid receptors, and the activation of these receptors has been proposed to exacerbate neuronal injury in the rat brain following ischemia and other metabolic insults, it was investigated if activated glucocorticoid receptors play also a role in A $\beta$  induced cell death. HT22 and HNI0e, two clonal mouse hippocampal cell lines express endogenous glucocorticoid receptors as shown by functional transactivation assays, western blot analysis, and immunocytochemistry. These cells are sensitive to A $\beta$ : 63  $\pm$  8 % of HT22, 78  $\pm$  5 % of HNI0e, and 30  $\pm$  6 % of primary neurons are surviving a 24 h exposure to A $\beta$ <sub>25-35</sub> as measured by MTT and trypan blue exclusion assays. When these hippocampal cells are preexposed to 10<sup>-5</sup> to 10<sup>-9</sup> M corticosterone or dexamethasone, cell death is further increased by up to 20 %. Cell death induced by the excitotoxin glutamate, which generates oxidative stress in a non receptor mediated fashion in HT22 cells, is also increased by up to 40 % after a 24 h exposure to 1 mM glutamate when endogenous glucocorticoid receptors have been activated. These data show that the activation of glucocorticoid receptors may increase oxidative injury induced by glutamate as well as by A $\beta$  in hippocampal neurons.

## 401.5

ALZHEIMER'S DISEASE  $\beta$ -AMYLOID PEPTIDE 25-35 IS LOCATED IN THE MEMBRANE HYDROCARBON CORE: X-RAY DIFFRACTION ANALYSIS. P.E. Mason\*, L. Shajenko, J. Estermyer and R.P. Mason. Neurosciences Research Center, Allegheny Campus, Medical College of Pennsylvania and Hahnemann University, Pittsburgh, PA 15212.

Previous studies have demonstrated that Alzheimer's disease  $\beta$ -amyloid ( $\beta$ /A4) 25-35 contributes to neurotoxicity by modulating the activity of membrane-bound proteins, including calcium channels. Small angle x-ray diffraction was used to explore the structural interactions of  $\beta$ /A4 (25-35) with membrane lipid bilayers. Multilamellar vesicles composed of 1-palmitoyl-2-oleoyl lecithin (POPC) were mixed with  $\beta$ /A4 (25-35) at varying concentrations in HEPES buffer (2.0 mM NaCl, pH 7.3). At 37°C, the *d*-space of control POPC membrane bilayers was 51.4 Å and the intrabilayer headgroup separation was 39 Å. One-dimensional electron density profiles generated from the data demonstrated that addition of  $\beta$ /A4 (25-35) produced a broad, concentration-dependent increase in electron density 0-12 Å from the center of the membrane bilayer. Increases in electron density associated with the interbilayer water space were not observed. These data provide direct evidence for a strong hydrophobic association of  $\beta$ /A4 (25-35) with the membrane hydrocarbon core as opposed to an electrostatic membrane surface interaction. These interactions of  $\beta$ /A4 (25-35) with the lipid bilayer hydrocarbon core may induce conformational changes in the structure of membrane-bound proteins, which could contribute to perturbations in ion channel activity.

## 401.7

TEA SENSITIVITY OF HIPPOCAMPAL K<sup>+</sup> CHANNELS IS REDUCED IN  $\beta$ -AMYLOID INJECTED RATS. J.L. Paynet, N. Meiri, D.L. Alkon and R. Eicheberrigaray\*. Laboratory of Adaptive Systems-NINDS, National Institutes of Health, Bethesda MD 20892. iHHMI-NIH Research Scholar

We have recently shown that  $\beta$ -amyloid, the main component of Alzheimer's Disease (AD) plaques induces some of the changes consistently observed in fibroblasts from AD patients, namely alterations in K<sup>+</sup> channels and reductions of Cp20 (a memory-associated GTP binding protein). Nevertheless, it remained important to establish whether or not the alterations observed in peripheral tissue (particularly those mimicked by  $\beta$ -amyloid treatment), could take place in brain cells, the main target of the disease process. Adult rats were cannulated and injected with 100  $\mu$ M  $\beta$ -amyloid orringer solution for three consecutive days. Hippocampal cells were acutely dissociated 24 h after the last injection and conventional patch-clamp techniques were used to assess K<sup>+</sup> channel function. Overall, the number of patches with observable K<sup>+</sup> channels in the  $\beta$ -amyloid treated group was somewhat reduced (62%) as compared to active patches in controls (85%). A large conductance K<sup>+</sup> channel ( $\approx$  180 pS) showed significant differences in TEA sensitivity in cells from control and  $\beta$ -amyloid treated animals. The activity of this channel was eliminated or greatly reduced by TEA (50-100 mM) in cells from ringer injected animals (N= 9 rats), while it was preserved in all cells from  $\beta$ -amyloid treated animals (N= 7 rats), *p* < 0.01 (contingency table). This reduced TEA sensitivity has been previously observed in fibroblasts and olfactory neuroblasts from AD patients. The frequency of appearance of this K<sup>+</sup> channel was also reduced in treated cells (60%) as compared to 82% in control patches. These preliminary observations provide evidence that alterations in K<sup>+</sup> function/regulation do occur in brain cells, and they can be induced by  $\beta$ -amyloid treatment.

## 401.4

MEMBRANE INTERACTIONS AND TOXICITY OF ALZHEIMER'S  $\beta$ -AMYLOID.

N. N. Dewji. \* University of California, San Diego, Department of Medicine, La Jolla, CA 92093.

$\beta$ -Amyloid is a 39-43 amino acid peptide derived from an integral membrane glycoprotein precursor, the amyloid precursor protein. Deposits of  $\beta$ -amyloid peptide accumulate in Alzheimer's disease (AD) brain, but their precise contribution to the subsequent neuropathology is presently unclear. A primary role for  $\beta$ -amyloid in AD pathology was suggested by reports that  $\beta$ -amyloid was directly toxic to neurons in vitro and in-vivo. However contradictory observations regarding the neurotoxic effects of  $\beta$ -amyloid have been reported, and the mechanism by which these peptides cause toxicity have not been adequately explained. In this work synthetic peptides to  $\beta$ -amyloid 1-40 and 1-42 and their fragments (1-28, 10-20, 25-35 and scrambled sequences) were used to study their interaction with a membrane bilayer system. In such a system, two halves of a closed membrane bilayer may respond differently to various perturbations while remaining coupled to one another. The same fragments were also used in a tissue culture system to study their effect on differentiated neurons and on undifferentiated cells. The extent of membrane damage was measured by lactate dehydrogenase released into the media. The work identifies precise regions of  $\beta$ -amyloid that interact with the membrane in a closed bilayer system and in cultured cells and suggests mechanisms involved in the interaction.

## 401.6

$\beta$ -AMYLOID PEPTIDE MODULATES CALCIUM CURRENTS IN hNT CELLS. K.L. Sanderson and V.M. Ingram\*, Dept. of Biology, Mass. Institute of Technology, Cambridge, MA, 02139.

hNT cells are produced from NT2 teratocarcinoma precursor cells by differentiation with retinoic acid. Whole cell patch clamp recordings under our conditions indicate that calcium currents in these cells are 30-80% of the dihydropyridine-sensitive type. We find that external application of the  $\beta$ -AP<sub>1-40</sub> peptide at 140  $\mu$ M causes a rapid and reversible increase in inward calcium current in most hNT cells. However, low concentrations of the peptide [20-50  $\mu$ M] caused a rapid decrease in calcium current, usually reversible. The effect of the  $\beta$ -AP<sub>1-40</sub> peptide might well be the initial step in the neurotoxic response of neuronal cells to high concentrations of  $\beta$ -AP<sub>1-40</sub> [Yankner, et al., Science, 1990, 250:279-282], since this would interfere with the ability of neuronal cells to maintain normal calcium homeostasis.

## 401.8

NITRIC OXIDE MEDIATES A COMPONENT OF  $\beta$ -AMYLOID NEUROTOXICITY IN PRIMARY CORTICAL NEURONAL CULTURES. A.M. Resink, H.P. Brahmabhatt, B. Cordell, V.L. Dawson<sup>1,2</sup>, T.M. Dawson<sup>1,2</sup>. Departments of Neurology<sup>1</sup>, Neuroscience<sup>2</sup> and Physiology<sup>3</sup>, Johns Hopkins University School of Medicine, Baltimore, MD 21287; SciosNova<sup>4</sup>, CA.

Derangements in glutamate neurotransmission have been implicated in several neurodegenerative disorders including Alzheimer's disease (AD). AD is characterized by progressive neurodegeneration of unknown etiology, but may be associated with the abnormal metabolism or deposition of the  $\beta$ -amyloid protein. In primary neuronal cultures fragments of the  $\beta$ -amyloid protein ( $\beta$ -amyloid 1-40 and  $\beta$ -amyloid 25-35) when preaggregated, are directly toxic to neurons with cell death occurring within 12 hours. The soluble peptides enhance glutamate induced neurotoxicity predominantly through activation of the N-methyl-D-aspartate (NMDA) receptor subtype of glutamate receptors. NMDA receptor activation causes an influx of calcium which binds calmodulin and activates neuronal nitric oxide (NO) synthase to convert L-arginine to citrulline and NO. NO has many roles in the central nervous system as a messenger molecule, however, when generated in excess NO can be neurotoxic. Inhibitors of NOS and scavengers of superoxide anion provide neuroprotection against  $\beta$ -amyloid and NMDA induced neurotoxicity but not against the neurotoxicity induced by preaggregated  $\beta$ -amyloid. Thus NO may play a role in neurotoxicity induced by the soluble  $\beta$ -amyloid peptide. It is possible that neuronally derived NO contributes to the neurodegeneration associated with AD.

401.9

# ABERRANT PROCESSING OF AMYLOID PRECURSOR PROTEIN IN DOWN'S SYNDROME

ASTROCYTES. J. Busciglio\* and B.A. Yankner. Dept. of Neurology, Harvard Medical School and The Children's Hospital, Boston, MA 02115.

The development of Alzheimer's disease in individuals with Down's syndrome (DS) has been attributed to overexpression of amyloid precursor protein (APP) due to increased gene dosage. To examine the processing of APP in the DS brain, we have established primary astrocyte cultures from DS and control cortex. DS and control astrocytes were similarly viable in culture. Metabolic labeling showed increased holo-APP in DS astrocytes relative to matched controls ( $214 \pm 40\%$  of control,  $P < 0.05$ ). Despite increased APP, the level of soluble APP in the medium was decreased in DS astrocytes ( $60 \pm 2\%$  of control,  $P < 0.01$ ), a finding that was replicated in cultures derived from 4 different DS brains. Pulse-chase labeling showed that the rate of APP secretion was markedly decreased in DS astrocytes. Holo-APP was synthesized at higher levels in DS astrocytes, but in addition showed increased stability relative to controls, correlating with decreased proteolytic degradation. This was accompanied by increased levels of the potentially amyloidogenic 11.5 kD C-terminal fragment of APP. These results suggest that APP processing is altered in DS astrocytes, and raise the possibility that an APP processing defect independent of APP overexpression may contribute to the development of Alzheimer's disease in adults with DS.

401.11

# CHRYSAMINE G, A CONGO RED ANALOGUE WHICH ENTERS THE BRAIN, PREVENTS A $\beta$ -INDUCED TOXICITY IN CELL CULTURE. WE Klunk<sup>1</sup>\*, AM Koros<sup>2</sup>, ML Debnath<sup>1</sup>, & JW Pettegrew<sup>1</sup>.

<sup>1</sup>Lab. of Neurophysics, Dept. of Psychiatry, WPIC, and

<sup>2</sup>Dept of Inf. Dis. & Microbiol, Univ. of Pittsburgh, Pittsburgh, PA 15261

Considerable data has accumulated to suggest that, at least in cell culture, beta-amyloid (A $\beta$ ) is toxic to a variety of cell types. This toxicity is dependent on aggregation into beta-sheet fibrils. Congo red is a histologic dye that binds to a wide variety of amyloid deposits, all of which have in common a beta-sheet fibril structure (Klunk et al., J.Histochem.Cytochem. 1989;37:1273). Recently, Congo red has been shown to prevent A $\beta$ -induced toxicity in primary rat hippocampal culture (Lorenzo and Yankner, PNAS 1994;91:12243) and rat PC12 cells (Pollack et al., Neurosci. Lett. 1995;184:113). However, Congo red is a highly acidic di-sulfonic acid which does not readily enter the brain. We have previously reported the development of Chrysamine G (CG), a carboxylic acid analogue of Congo red which partitions well into normal mouse brain (Klunk et al., Neurobiol. Aging 1994;15:691). In this study, we show that CG, like Congo red, can prevent A $\beta$ -induced toxicity in rat PC12 cells and a human small cell lung carcinoma cell line with neuroendocrine properties (SHP-77). In both cell lines, CG and Congo red prevented A $\beta$ -induced toxicity at concentrations similar to their IC<sub>50</sub> for binding to synthetic A $\beta$  in vitro. These results suggest that CG may be useful in the treatment of Alzheimer's disease.

401.10

# $\beta$ -AMYLOID PEPTIDES WITH AMINO-TERMINAL DELETIONS EXHIBIT NEUROTOXICITY AND INCREASED AGGREGATION IN VITRO. C.J. Pike\* and C.W. Cotman.

Institute for Brain Aging & Dementia, Univ. of California, Irvine, CA 92717 USA.

$\beta$ -amyloid protein (A $\beta$ ) isolated from senile plaques exhibits substantial COOH- and NH<sub>3</sub>-terminal heterogeneity. Since COOH-terminal heterogeneity significantly affects A $\beta$  structure/activity relationships, we examined whether NH<sub>3</sub>-terminal heterogeneity also affects A $\beta$  bioactivity and/or aggregation. To address this issue, we synthesized a series of peptides with progressively shortened NH<sub>3</sub>-termini (initial residues at positions  $\beta$ 1,  $\beta$ 4,  $\beta$ 8,  $\beta$ 12, and  $\beta$ 17) and COOH-termini extending to residue  $\beta$ 40 or  $\beta$ 42. Peptides were assayed for i) neurotoxicity in primary neuron cultures, ii) aggregation levels by sedimentation analysis, iii) secondary structure by circular dichroism, and iv) fibrillar structure by electron microscopy. Consistent with our previous observations, we found that all aggregating A $\beta$  peptides induced significant neurotoxicity *in vitro*. More importantly, we report that A $\beta$  peptides with NH<sub>3</sub>-terminal deletions exhibit enhanced aggregation levels relative to full-length species. This trend of increased aggregation with decreased NH<sub>3</sub>-terminus length was observed in peptides terminating both at  $\beta$ 40 and at  $\beta$ 42, although the  $\beta$ 42 peptides showed higher overall sedimentation levels. Peptides exhibiting significant aggregation were characterized by predominant  $\beta$ -sheet structure and fibrillar morphology. The increased ability of A $\beta$  peptides with NH<sub>3</sub>-terminal deletions to aggregate into  $\beta$ -sheet fibrils suggests that these A $\beta$  species may initiate and/or nucleate pathological A $\beta$  deposition and predict that events which promote generation of A $\beta$  NH<sub>3</sub>-terminal heterogeneity represent potential risk factors for Alzheimer's disease.

401.12

# POTENCY OF CONGO RED NEUROPROTECTION AGAINST AMYLOID- $\beta$ NEUROTOXICITY VARIES WITH A $\beta$ PEPTIDE LOT. P.C. May<sup>1</sup>, K.S.

Fuson<sup>1</sup>, J.N. Boggs<sup>1</sup>, B. Brigham<sup>2</sup>, S. Wright<sup>2</sup>, M. Wogulski<sup>2</sup>, K.

Tomaselli<sup>2</sup> and B.E. Rydel<sup>2</sup>, <sup>1</sup>CNS/GI/GU Division, Lilly Research

Labs, Eli Lilly and Co., Indianapolis, IN 46285, <sup>2</sup>Athena

Neurosciences, So. San Francisco, CA 94080

Peptide conformation and aggregation state of amyloid- $\beta$  (A $\beta$ ) appear to be important determinants for neurotoxicity. For example, "fresh" peptide lots of A $\beta$  with minimal structure have modest to moderate neurotoxic activity at 50 $\mu$ M, but little toxicity at 25 $\mu$ M unless "aged" for a period of days. In contrast, "pre-aged" lots of A $\beta$  already have some structure and show maximal toxicity at 25 $\mu$ M without aging. To further address these variables, we have compared the potency of Congo Red (CR) in affording neuroprotection against various lots of A $\beta$ . Mature, primary rat hippocampal cultures were co-treated with synthetic A $\beta$ (1-40) and CR. Cell viability was assessed 3-4 days later by an LDH release assay. As observed by others, near equimolar concentrations of CR (5-10 $\mu$ M) were required to block neurotoxicity of 25 $\mu$ M "pre-aged" lots of A $\beta$  peptide. In contrast, CR at a 100 fold lower concentration (50-100nM) provided complete protection in cultures treated with 50 $\mu$ M "fresh" A $\beta$  lots. Moreover, brief alkaline-treatment of A $\beta$  converted the toxicity profile of a pre-aged peptide into that of a "fresh" peptide with the concomitant shift from micromolar to nanomolar CR protection. These data suggest that maturation of A $\beta$  into a neurotoxic species occurs via a multi-step process and that early on, the initiating A $\beta$  species may be present at low nanomolar concentrations.

## PEPTIDE RECEPTOR STRUCTURE AND FUNCTION I

402.1

# Characterization of neuropeptide Y (NPY) receptors in discrete rat brain areas: subtype-related differences in affinity and sensitivity to ions and guanine nucleotides

S.L. Parker\*, B.L. Carroll, T. Sweetman and W. R. Crowley, Department of

Pharmacology, University of Tennessee College of Medicine, Memphis, TN 38163

NPY receptors [NPY-Rs] were characterized in microdissected hypothalamic and cortical areas of rat brain employing both subtype-nonselective and subtype-specific agonists. Synaptosomal fractions contained  $\geq 90\%$  of specific binding sites for either of the NPY-R subtypes. NPY receptors from all areas studied showed essentially homogenous high-affinity binding of a Y-1 subtype-selective NPY analog, (Pro34)hPPY, with K<sub>diss</sub> range of 80-150 pM. High-affinity Y-2 subtype binding of [125I]-human PYY(3-36) (hPYY(3-36)) was especially strong in circumventricular anterior hypothalamus. The Y-2 binding could be resolved into a high-affinity component (K<sub>diss</sub>  $\leq 10$  pM), and a highly variable lower-affinity component which could be augmented by preincubation. The Y-1 subtype binding of (Pro34)hPPY and (Leu31,Pro34)hPPY was much more sensitive than Y-2 binding of hPYY(3-36) to inhibition by Ca<sup>2+</sup> removal, by increases in [Na<sup>+</sup>] (affinity decrease of up to 5 pM/mM Na<sup>+</sup>), by nonionic chaotropes (urea), and by disulfide bond destabilizers (benzethamine, dithiothreitol). The Y-1 binding was strongly inhibited by all guanosine (but not adenosine) di- and triphosphates tested. Particulates from circumventricular hypothalamic areas and from piriform cortex showed a considerable Y-2 receptor activation by G-protein inactivator guanosine-5'-O-(2-thiodiophosphate) (GDP $\beta$ S), and also by GDP and GTP, but not by the corresponding adenine nucleotides. Y-2 receptor binding in all areas was  $\leq 30\%$  inhibited by hydrolyzable G-protein agonist guanosine-5'-O-(3'-thiotriphosphate) (GTP $\gamma$ S), or by selective chelation of Ca<sup>2+</sup>. The binding of subtype-nonselective NPY-R agonists [125I]hNPY and [125I]hPPY to membranes from areas with predominance of Y-1 subtype was much more sensitive to ionic and nucleotide inhibitors than the binding of these ligands to particles from Y-2 subtype-enriched areas, indicating that the observed differences in inhibition profiles generalize to receptor subtypes. Thus, the binding activity of Y-1 subtype NPY-Rs depends directly on association with G-protein(s), and is strongly modulated by changes in concentration of common ions. The activity of Y-2 receptors shows little direct dependence on ions or nucleotides, and could be mainly regulated through interactions with effector proteins and changes in receptor organization (microaggregation or clustering) and synaptic availability (sequestration, internalization, and extrusion).

402.2

# INHIBITION OF SYMPATHETIC VASOCONSTRICTION BY THE NEUROPEPTIDE Y-Y1 RECEPTOR ANTAGONIST BIBP 3226. J.M. Lundberg\* and A. Modin.

Division of Pharmacology, Department of Physiology and Pharmacology, Karolinska Institute, S-171 77 Stockholm, Sweden.

The non-peptide neuropeptide Y (NPY) - Y1 receptor antagonist BIBP 3226 (Rudolf et al., Eur. J. Pharmacol., 1994, 271, R11-R13) specifically displaced [125I]-NPY binding with IC50 value of about 10 nM in pig hypothalamus and renal arteries (Y1 receptors) with minor effects in the spleen (Y2 receptor). In anesthetized pigs in vivo BIBP 3226 inhibited the vasoconstrictor effects of a Y1 receptor agonist without influencing the responses to a Y2 receptor agonist, noradrenaline,  $\alpha$ , $\beta$ -methylene ATP or angiotensin II. A major reduction (about 50%) of the long-lasting vasoconstrictor responses to sympathetic nerve stimulation at high frequency (40 impulses at 20 Hz) in nasal mucosa and hind limb of control pigs occurred after BIBP 3226 (1 mg/kg). BIBP 3226 (1 mg/kg) markedly reduced (by 55-70%) the vascular response (total integrated blood flow reduction) evoked by sympathetic nerve stimulation at high frequency (40 impulses at 20 Hz) in spleen, kidney, nasal mucosa and hind limb of reserpinized pigs lacking noradrenaline. Furthermore, the maximal amplitude of the vasoconstriction was reduced especially in the kidney. BIBP 3226 did not influence stimulation-evoked NPY release. It is concluded that BIBP 3226 can act as a selective Y1 receptor antagonist in the pig. A role of endogenous NPY for the long-lasting duration of sympathetic vasoconstrictor effects in nasal mucosa and hind limb of pigs is highly suggested.

## 402.3

EXPRESSION CLONING AND PHARMACOLOGICAL CHARACTERIZATION OF A HUMAN HIPPOCAMPAL NPY/PYY Y2 RECEPTOR SUBTYPE. C. Gerald\*, M.W. Walker, J.A. Bard, C. He, Z. Shaposhnik, P.J.-J. Vaysse, T.A. Branchek and R.L. Weinshank. Synaptic Pharmaceutical Corporation, Paramus, NJ 07652

Neuropeptide Y (NPY) and related peptides elicit a diverse range of important physiological activities through activation of membrane bound receptors. Previous functional and binding data support the existence of multiple receptor subtypes including Y1, "atypical" Y1, Y2, Y3 and PP. To date, only the rat, human and various other species homologs of the Y1 receptor subtype cDNAs have been cloned and characterized. We now report the expression cloning and full pharmacological characterization of a human hippocampal cDNA encoding a Y2 receptor subtype. Protein sequence analysis reveals that this Y2 receptor is a member of the G protein-coupled superfamily. When compared to the Y1 subtype, the Y2 receptor displays an amino acid identity of only 31% overall and 41% in the seven membrane spanning regions. <sup>125</sup>I-PYY bound specifically to membranes from COS-7 cells transiently transfected with the cDNA expression clone. Upon extensive pharmacological characterization, the receptor encoded by this cDNA clone exhibits features of a Y2 receptor, including 1) binding affinity for PYY equal to or greater than that for NPY, 2) relative insensitivity to N-terminal deletion of NPY/PYY and 3) low tolerance for modification of Gln<sup>34</sup> in NPY and NPY-like peptides. Northern blot analysis reveals a broad distribution of the Y2 mRNA in human brain. RT-PCR analysis yielded positive signals in most human peripheral tissues tested except in the atrium of the heart, the liver and the uterus. Southern blot analysis is consistent with the human genome containing a single Y2 receptor gene. The isolation of a human Y2 receptor allows, for the first time, the ability to develop subtype specific ligands and will greatly facilitate the analysis of NPY-mediated physiological processes.

## 402.5

BINDING OF NPY, PYY AND PP ANALOGS TO CLONED HUMAN Y2 AND Y4 RECEPTORS. M.W. Walker, C. Gerald, J.A. Bard, P.J.-J. Vaysse, W.E. Heydon\*, R.L. Weinshank and T.A. Branchek. Synaptic Pharmaceutical Corporation, Paramus, NJ 07652.

Neuropeptide Y (NPY), peptide YY (PYY) and pancreatic polypeptide (PP) are members of the pancreatic polypeptide family. These peptides function as neurotransmitters and hormones through activation of membrane bound receptors. Pharmacological data support the existence of at least 5 receptor subtypes, known as Y1 (previously cloned from vertebrates), Y2, Y3, PP and Y1-like "feeding" receptors. We recently isolated human cDNAs encoding two novel Y-type receptors by expression and homology cloning techniques (Gerald et al., Bard et al., Soc. Neurosci. Abstr. 1995). Each cDNA was transiently expressed in COS-7 cells and evaluated in radioligand binding assays. The receptor clones were classified as Y2 and Y4 subtypes based on peptide binding profiles. The Y2 receptor bound porcine [<sup>125</sup>I]-PYY (K<sub>d</sub> = 0.07 nM) and human pancreatic polypeptides in rank order: PYY (K<sub>i</sub> = 0.4 nM) > NPY (K<sub>i</sub> = 0.7 nM) >> PP (K<sub>i</sub> > 1000 nM). The Y2 also bound C-terminal fragments PYY3-36 (K<sub>i</sub> = 0.7 nM), PYY13-36 (K<sub>i</sub> = 1.5 nM), NPY2-36 (K<sub>i</sub> = 2.0 nM), and NPY20-36 (K<sub>i</sub> = 3.6 nM), plus the Y2-selective cyclic disulfide analog C2-NPY (K<sub>i</sub> = 3.5 nM). Y2 binding was disrupted by replacement of Gln<sup>34</sup> in NPY or PYY with Pro, as in [Pro<sup>34</sup>]-PYY (K<sub>i</sub> > 300 nM). This binding profile matches that for the pharmacologically defined Y2 subtype. The Y4 receptor bound porcine [<sup>125</sup>I]-PYY (K<sub>d</sub> = 0.11 nM) and human pancreatic polypeptides in rank order: PP (K<sub>i</sub> = 0.06 nM) > PYY (K<sub>i</sub> = 0.9 nM) > NPY (K<sub>i</sub> = 2.2 nM). Y4 affinity for PYY or NPY analogs could be enhanced by inserting PP residues into positions 31 and 34, K<sub>i</sub> = 0.1 nM for [Pro<sup>34</sup>]-PYY and 1.1 nM for [Leu<sup>31</sup>,Pro<sup>34</sup>]-NPY. PP2-36 was well tolerated (K<sub>i</sub> = 0.06 nM), but further N-terminal deletion was disruptive (K<sub>i</sub> = 39 nM for PP13-36). The Y4 binding profile resembles that of the pharmacologically defined PP receptor. We propose the name "Y4" to account for the narrow range of K<sub>i</sub> values for all human pancreatic polypeptides, and to extend the Y-type nomenclature established for Y1, Y2 and Y3 receptors.

## 402.7

TACHYKININ NK-3 RECEPTOR MECHANISMS IN GUINEA PIG ILEUM. E. Burcher\*, C.J. Mussap, I.E. Apostolopoulos and S.K. Syd. Sch. Physiol. Pharmacol., Univ. of New South Wales, NSW 2052, Australia.

We recently found that [<sup>125</sup>I]-Bolton-Hunter (BH) scylorhynchin II (SCYII) labelled autoradiographically the myenteric plexus of guinea pig ileum, but in membranes, characterization to a definitive tachykinin receptor type was not possible (Mussap & Burcher, Naun-Sch Arch Pharmacol 350, 301, 1994). Here, we have used binding and functional techniques to further investigate the receptors interacting with SCYII, its non-radioactive BH derivatives (mono-BHSCYII and di-BHSCYII) and other analogues and antagonists including SR 142801 (NK-3 antagonist). In homogenates of ileum containing longitudinal muscle and myenteric plexus only, binding of 100 pM [<sup>125</sup>I]-BHSCYII was inhibited by SR 142801 ≥ senktide ≥ di-BHSCYII ≥ SCYII ≥ mono-BHSCYII > eledoisin > neuropeptide γ >> neuropeptide K > [Sar<sup>9</sup>,Met(O<sub>2</sub>)<sup>11</sup>]-SP ≥ [pGlu<sup>6</sup>,Pro<sup>9</sup>]-SP(6-11) (septide), CP 96345 and SR 48968 were ineffective competitors. This indicates binding to a definitive NK-3 site, in contrast to our earlier anomalous binding pattern. [<sup>125</sup>I]-BHSCYII also bound with high affinity to brain homogenates: SR 142801 was a much weaker competitor in rat compared with guinea pig brain. In segments of ileum suspended longitudinally in Krebs solution, these agonists typically produced both an initial fast response and a slower sustained contractile response. Initial but not late responses to mono-BHSCYII, di-BHSCYII, [Sar<sup>9</sup>,Met(O<sub>2</sub>)<sup>11</sup>]-SP and septide were inhibited by atropine and phenoxymethylamine (both 1 μM), whereas late but not initial responses were inhibited by 1 μM CP 99994. SR 142801 (0.1 μM) partially inhibited responses to senktide, SCYII and mono-BHSCYII. Both techniques demonstrate the existence of NK-3 receptors in guinea pig ileum myenteric neurons. However the functional studies illustrate the complexity of tachykinin contractile mechanisms.

## 402.4

CLONING AND CHARACTERIZATION OF A NOVEL HUMAN NEUROPEPTIDE Y/PEPTIDE YY/PANCREATIC PEPTIDE RECEPTOR SUBTYPE (Y4). J.A. Bard\*, M.W. Walker, T.A. Branchek and R.L. Weinshank. Synaptic Pharmaceutical Corporation, Paramus, NJ 07652.

The pancreatic polypeptide (PP) family of polypeptides contains NPY, PYY and PP, all consisting of 36 amino acids and shown to influence a range of physiological parameters, including food intake, psychomotor activity, central endocrine secretion and vasoactivity in the cardiovascular system. To date, only one receptor within this family, Y1, has been cloned. Here, we describe the cloning of a new member of this family, designated Y4, obtained from homology screening of a human placental genomic library, using transmembrane (TM) probes derived from the Y1 gene. The Y4 gene encodes for a predicted protein of 375 amino acids and contains several conserved structural features/residues found among the members of the neuropeptide family, including the greatest homology to the cloned human/rat/mouse Y1 gene (42% overall; 55% within TM's). Y4-transiently transfected COS-7 cells displayed high affinity binding of the PP family agonist [<sup>125</sup>I]-PYY(porcine), with a K<sub>d</sub>=0.11 nM (B<sub>max</sub>=1.4 pmol/mg protein), and similar high affinity to three other PP family agonists (human): NPY, PYY and PP (K<sub>d</sub>=2.2nM, 0.87nM, and 0.06nM, respectively). Pharmacological characterization of Y4 indicated a rank order of potency of the PP family of peptides, including selective truncated peptides, to be PP>[Leu<sup>31</sup>,Pro<sup>34</sup>]-NPY>PYY>NPY>NPY<sub>2-36</sub>>NPY<sub>13-36</sub>>NPY<sub>18-36</sub> NPY<sub>20-36</sub> and NPY<sub>free acid</sub>. Additionally, activation of the human Y4 with PP results in decreased cAMP accumulation, very likely through inhibition of adenylate cyclase, as well as increased calcium mobilization. Y4 mRNA was detected by RT-PCR in human total brain, coronary artery, and ileum, suggesting a potential role for Y4 receptors in CNS function, cardiovascular regulation, and gastrointestinal physiology.

## 402.6

SPECIES AND NK1 VERSUS NK2 TACHYKININ RECEPTOR SPECIFICITIES OF PERHYDROISOINDOLES. V. Fardin, L. Pradier\*, A. Morgat, S.M. Moussaoui, J. Menager, A. Carriette, J.F. Sabuco, S. Grisoni, J.L. Malleron, M. Tabart, J.F. Peyronel and C. Garret, Rhône-Poulenc Rorer S.A., CRVA, CNS Research Program, 94400 Vitry-sur-Seine, France.

Following the discovery of RP 67580, a selective non-peptide Substance P antagonist having preferential affinity for the rat and mouse NK1 receptor, chemical modifications in the perhydroisindole series led to the design of new sub-classes of NK1 antagonists with high affinity for the human receptor. Thus, RPR 100893, a triarylperhydroisindolol derivative, potently inhibits the binding of <sup>3</sup>H-SP to the NK1 receptor in guinea-pig, dog, monkey and human tissues. In contrast to RP 67580, it has low affinity for the rat and mouse NK1 receptors. Following molecular modelling analysis of RPR 100893, we synthesized new compounds without the gemdiphenyl moiety that retain affinity and selectivity for the human NK1 receptor. For example, RPR 107880 displayed a K<sub>i</sub> of 4 nM for the NK1 receptor of IM9 cells. RPR 100893 and RPR 107880 potentially antagonize SP-evoked inositol phosphate responses in human cells and contractions induced by SP in the guinea-pig ileum. *In vivo*, as *in vitro*, these two compounds were more potent in the guinea-pig than in the rat, as revealed by their inhibition of plasma extravasation induced by septide in peripheral tissues. In addition, triarylperhydroisindolol derivatives with high affinity for the human NK2 receptor could also be obtained from this chemical series (ex: RPR 106145 - K<sub>i</sub> = 16 nM). Here again, marked variations in affinity between species were observed since RPR 106145 was a poor inhibitor of the binding of <sup>125</sup>I-NK A to NK2 receptors in rat duodenum. Finally, the absolute configuration of the heterobicyclic core and the stereochemistry of substituents of perhydroisindoles are crucial to the species and NK1 vs NK2 specificity.

## 402.8

NATURAL ZINC-SITE IN THE TACHYKININ NK<sub>2</sub> RECEPTOR MODULATION OF AGONIST BINDING POPULATION.

Maria Lucibello, Mette M. Rosenkilde, Anders Blomquist\*, Birgitte H. Hansen, Christian E. Elling, Siv A. Hjorth, and Thue W. Schwartz, Laboratory for Molecular Pharmacology, Rigshospitalet 6321, Blegdamsvej 9, DK-2100, Copenhagen, Denmark.

**Background:** High affinity metal-ion sites are constructed by introducing His residues at positions *i* and *i*+4 at the outer part of TM-V in 7TM receptors (Nature, 1995, 374:74-77). In the NK-3 receptor, two His residues are naturally found in such a structure. **Methods and results:** HisV:01 (His<sup>100</sup>) was substituted with Ala and receptors were probed for ligand binding ([<sup>125</sup>I]His<sup>3</sup>-MePhe<sup>7</sup>-neurokinin B) and inositolphosphate turnover. On both wild-type and mutant receptor Zn<sup>2+</sup> acted only as an 'antagonist' when applied in millimolar conc. However, on the wildtype receptor in contrast to the H194A-NK<sub>2</sub> receptor the dose-response curve for Zn<sup>2+</sup> was biphasic as the metal-ion increased NK<sub>2</sub> binding between 10<sup>-6</sup> and 10<sup>-4</sup> mol/l. Competition binding curves in the presence of variable Zn<sup>2+</sup> cons. demonstrated that it increases the B<sub>max</sub> without affecting the K<sub>i</sub>. The two His residues are conserved in the NK<sub>2</sub>-like receptor (NK<sub>2B</sub>), which originally was cloned as a putative opiate receptor. A similar biphasic (stimulatory - inhibitory) dose-response curve is found for Zn<sup>2+</sup> in the NMDA glutamate receptor. **Conclusion:** A metal-ion site is located at the border between extracellular loop-2 and TM-V in the NK<sub>2</sub> receptor; coordination of physiological concentrations zinc-ions at this site increases the binding of the natural ligand, NK<sub>2</sub>, by increasing the B<sub>max</sub> without altering the K<sub>i</sub>.

## 402.9

## CONSTRUCTION OF AN ANTAGONISTIC ZINC-SWITCH IN THE KAPPA OPIATE RECEPTOR.

Kenneth Thirstrup, Christian E. Elling, Hans T. Schambye\*, Siv A. Hjorth, and Thue W. Schwartz. Laboratory for Molecular Pharmacology, Rigshospitalet 6321, DK-2100, Copenhagen, Denmark.

**Background:** The kappa opiate receptor was chosen as target for introduction of a metal-ion switch due to the availability of a diversity of high affinity and selective ligands. **Method:** Based on a metal-ion site previously constructed in the binding site for a non-peptide antagonist in the tachykinin NK-1 receptor (Nature, 1995, 374:74-77), histidyl residues were introduced in the rat kappa-opiate receptor. **Results:** His residues at positions V:01 (Asp<sup>223</sup>), V:05 (Lys<sup>227</sup>), and VI:24 (Ala<sup>296</sup>) alone and in combination had no direct effect on the binding of radioligands (antagonists <sup>3</sup>H-DIP and agonist <sup>3</sup>H-CI977). However, zinc-ions in a dose-dependent manner prevented binding of both agonist and antagonist ligands with an apparent affinity for the metal-ion which gradually was built up to 0.5 x 10<sup>-7</sup> mol/l (a 1000 fold increase in zinc-ion sensitivity). The zinc-site was relatively specific for Zn<sup>2+</sup> versus Cu<sup>2+</sup> (only 10-fold increase in affinity). **Conclusion:** A high affinity metal-ion binding site consisting of three histidyl residues has been introduced in the kappa-opiate receptor without altering ligand-binding characteristics; however, coordination of zinc-ions at this silent 'metal-ion switch' between the outer segments of TM-V and VI prevents ligand binding to the receptor. The direct transfer of this metal-ion site from a tachykinin to an opiate receptor indicate that the overall arrangements of the seven-helical bundle is common among 7TM receptors of the rhodopsin family.

## 402.11

CENTRAL HYPOTHYROIDISM CAUSED BY INACTIVATING MUTATIONS IN THE THYROTROPIN-RELEASING HORMONE RECEPTOR (TRHR) GENE. R. Collu\*, J.Q. Tang, J. Castagné, G. Lagacé, N. Masson, C. Deal, C. Huot and G. Van Vliet. Res. Unit on Reprod. Develop. Biol., Pediatr. Res. Center, Ste-Justine Hosp. and U. de Montréal, Montréal, Qué. H3T 1C5.

Central hypothyroidism, characterized by insufficient thyrotropin (TSH) production resulting in low circulating levels of thyroid hormones (T<sub>4</sub>, T<sub>3</sub>), is rare and has various etiologies. We have investigated a 12 year-old boy who had been treated with T<sub>4</sub> since 9 years of age for central hypothyroidism of unknown origin. His two brothers (10 and 15 years old) and unrelated parents were also investigated. The propositus, after one month off therapy, had a T<sub>4</sub> concentration of 42 nmol/L (normal 58-148) and a TSH concentration of 2.2 mIU/L (normal 0.1 - 5.0). TRH 200 µg iv induced no change in either plasma TSH or prolactin concentrations. His two brothers and both parents had normal plasma T<sub>4</sub> and TSH concentrations and normal TSH and prolactin responses to TRH. Genomic DNA was isolated from peripheral-blood leucocytes and the coding regions of the TRHR gene directly sequenced. Different mutations were detected in each of the propositus TRHR gene alleles. In one allele, identified as maternal, cytosine at position 49 was replaced by thymidine resulting in a premature stop codon. In the paternal allele, codons 343-351 were deleted and guanine at position 352 was replaced by adenine, resulting in the substitution of alanine by threonine at position 118. These mutations created new restriction sites that allowed us to haplotype the family and thus determine that the older brother had inherited the mutated maternal allele. Hormonal responses to TRH clearly show the presence of both mutated alleles is necessary and sufficient to induce refractoriness to TRH. These results indicate that central hypothyroidism may be due to inactivating mutations of the TRHR; the incidence of such mutations in the general population is under investigation.

## 402.13

PACAP HYBRID: A NEW ANTAGONIST FOR PACAP RECEPTOR SPLICED VARIANTS. T. Moody\*, T. Hida, S. Jakowlew, M. Birrer, J. Pisegna, S. Wank, M. Fridkin and I. Gozes. Biomarkers & Prevention Research Branch, NCI, Rockville, MD 20850, Digestive Diseases Branch, NIDDKD, Bethesda, MD 20892 and Dept. Clinical Biochemistry, Sackler School of Medicine, Tel Aviv, Israel.

Pituitary adenylate cyclase activating peptide (PACAP) receptor is a 27 amino acid peptide with sequence homology to vasoactive intestinal peptide (VIP). Distinct receptors for PACAP and VIP have been identified and the PACAP receptor is a G-protein coupled receptor with splice variants (basic, hip, hopl and hip/hopl) at the third cytosolic domain. Here the effects of a new PACAP receptor antagonist, neurotensin<sup>6-11</sup>PACAP<sup>7-27</sup>, PACAPhybrid, on PACAP receptor splice variants was investigated. All PACAP receptor splice variants bound PACAP with high affinity (IC<sub>50</sub> = 10 nM) and VIP with low affinity (IC<sub>50</sub> = >1000 nM). PACAP, 100 nM, transiently increased c-fos, c-jun and c-myc gene expression after 1 hour. Surprisingly the "hopl" PACAP receptor variant strongly, the "hip/hopl" variant moderately and the "basic" as well as "hip" variant weakly increased nuclear oncogene mRNA. Similar results were observed for cAMP and phosphatidylinositol turnover. PACAPhybrid (IC<sub>50</sub> = 100 nM) was more potent than PACAP(6-38) (IC<sub>50</sub> = 200 nM) at inhibiting <sup>125</sup>I-PACAP binding to the stably transfected NIH 3T3 cells. PACAPhybrid, 1 µM, inhibited the increase in nuclear oncogene mRNA caused by PACAP. These data indicate that PACAPhybrid antagonizes PACAP receptor splice variants.

## 402.10

## METAL-ION SITES AS STRUCTURAL AND FUNCTIONAL PROBES OF HELIX-HELIX INTERACTIONS IN 7TM-RECEPTORS

Christian E. Elling, Kenneth Thirstrup and Thue W. Schwartz\*. Laboratory for Molecular Pharmacology, Rigshospitalet 6321, Blegdamsvej 9, DK-2100, Copenhagen, Denmark.

**Background:** A high affinity antagonistic zinc-site, consisting of two His residues at the top of TM-V and one at the top of TM-VI, was previously built into the binding site for a non-peptide antagonist in the tachykinin NK-1 receptor (Nature, 1995, 374:74-77). **Methods & Results:** The possible involvement of other residues in the receptor structure (including His residues located further down in TM-VI and in TM-III) in the coordination of the zinc-ion was excluded by Ala substitutions. Details of the antagonistic property of the zinc-ion was studied by analysis of inositolphosphate turnover. The initial zinc-site was expanded to reach out to TM-III by systematic His substitutions at this location. The helical connectivity and overall arrangement of the seven-helical bundle was probed by additional metal-ion sites around the central TM-III column. The metal-ion sites also give functional informations: for example, a zinc-site around the top of TM-II prevents binding of agonist, substance P, but not binding of non-peptide antagonist, CP96,345. Based on the results from the tachykinin receptors, similar metal-ion sites were constructed in the beta-adrenergic receptor to test the general importance of the observations. **Conclusion:** High affinity metal-ion sites can be introduced at various sites in 7TM, G-protein coupled receptors whereby the overall helical arrangement and the helix-helix interactions can be probed. These metal-ion sites impose important triangular distance and angular constraints on the molecular models of 7TM receptors.

## 402.12

IDENTIFICATION OF RESIDUES IMPLICATED IN THE BINDING AND INTERNALIZATION OF THE RAT NEUROTENSIN RECEPTOR. J.M. Boulo, J. Chabry, D. Nouel<sup>1</sup>, A. Beaudet<sup>1</sup>, J.P. Vincent and J. Mazella IPMC, UPR411 CNRS, 660 route des Lucioles, 06560 Valbonne, FRANCE. <sup>1</sup>Institut Neurologique de Montréal, 3901 University, Montréal, Québec, H4A 2B4, CANADA.

We modified by site directed mutagenesis the cDNA encoding the rat neurotensin (NT) receptor and examined the binding and internalization properties of the mutant receptors after their transfection into COS-7 cells. The mutation of charged residues located in the first extracellular loop (Glu124, Asp139 and Arg143) and in the sixth transmembrane domain (TM) (Arg327-Arg328) totally abolished <sup>125</sup>I-NT binding. Confocal and electron microscopic immunocytochemical studies of mutated transfectants tagged with an immunogenic peptide sequence indicated that this loss of binding was not due to altered receptor expression or to a lack of insertion of the receptor into the plasma membrane as both the wild type and mutated forms of the receptor showed identical sub-cellular localizations. We therefore conclude from these results that charged residues located in the first extracellular loop and in the sixth TM of the rat NT receptor are implicated in the recognition of NT.

Deletion of the C-terminal tail of the NT receptor distal to the Trp391 residue did not affect <sup>125</sup>I-NT binding but resulted in a 90% loss in the capacity of the cells to internalize receptor-ligand complexes. Sequential deletions of Ser and Thr clusters in this region indicated that the cluster closest to the C-terminus was responsible for this effect. Within this cluster, combined point mutations of Thr422 and Tyr424 residues were sufficient to almost completely abolish ligand internalization. Confocal microscopy confirmed that cells transfected with the wild type receptor internalized a fluorescent analog of NT in a temperature dependent fashion, whereas cells transfected with a receptor truncated at the carboxyl terminus only showed a clustering of the fluorescent peptide at the cell surface. We conclude from these results that the Thr422 and Tyr424 residues are critical for NT induced receptor internalization.

## 402.14

MOLECULAR CLONING AND EXPRESSION OF THE RAT TYPE I GALANIN RECEPTOR. M.S. Jasper\*, N. Bhat and L.M. Kaplan

Neuroendocrine Lab, Gastrointestinal Unit, Massachusetts General Hospital, Boston, MA 02114.

Galanin is a 29-amino acid neuropeptide with multiple physiologic activities, including inhibition of insulin secretion from pancreatic β-cells and stimulation of fat ingestion via hypothalamic receptors. We report the isolation of cDNAs encoding the rat galanin receptor using expression- and polymerase chain reaction (PCR)-based approaches. Three independent clones isolated from rat hypothalamic libraries encoded cDNAs that span identical protein-coding sequences. The predicted sequence of the rat galanin receptor is 87% identical to the human type I galanin receptor. Hydrophobicity analysis revealed that, like the human receptor, the rat galanin receptor has 7 transmembrane domains. Local homology analysis revealed interspecies sequence similarities of >90% for transmembrane (TM) domains 1-4, between 80% and 90% for TM 5-7, and >90% for extracellular domains 1 and 2. This strong sequence conservation is consistent with the similar ligand-binding characteristics of the predominant galanin receptors in rat and human brain. Intracellular domains 1-3 also exhibited >90% similarity, suggesting that the two receptors utilize similar intracellular signaling mechanisms. Northern blot analysis revealed two mRNA species of approximately 7.5 and 4 kbp, respectively. High levels of galanin receptor expression were observed in whole brain and hypothalamus. Studies of normal, castrated and ovariectomized rats demonstrate that in contrast to the regulation of galanin itself, galanin receptor gene expression is strongly inhibited by sex steroid hormones.

## 402.15

IDENTIFICATION OF A NOVEL RECEPTOR SELECTIVE FOR PARATHYROID HORMONE WHICH IS EXPRESSED IN THE BRAIN: THE PTH2 RECEPTOR. T. B. Usdin\*, E. Mezey, and T. I. Bonner. Lab. of Cell Biol., NIMH, and Clin. Neurosci. Branch, NINDS (E.M.), Bethesda MD 20892-4090.

PTH (parathyroid hormone) regulation of peripheral mineral homeostasis is well studied, but little is known regarding the role of PTH in the brain. Authentic PTH has been reported in the hypothalamus of several species. PTH acts at the PTH/PTHrP receptor which does not discriminate between PTH and PTHrP (parathyroid hormone-related peptide, *nec* hypercalcemia of malignancy factor). PTHrP and the PTH/PTHrP receptor are widely distributed in the brain making identification of PTH-specific effects difficult. Using a homology based approach we identified a cDNA encoding a novel PTH receptor which we call the PTH2 receptor. It is a G-protein coupled receptor which stimulates cAMP accumulation, and is a member of the secretin receptor family. Its similarity to previously known receptors ranges from 60% amino-acid sequence identity with the PTH/PTHrP receptor to 30% identity with the CRF receptor. The PTH2 receptor is activated by PTH and not PTHrP. The PTH2 receptor is quite limited in distribution and its mRNA is particularly abundant in the hippocampus and the bed nucleus of the stria terminalis. This receptor should facilitate investigation of the CNS role of PTH.

## 402.16

EXPRESSION OF THE GONADOTROPIN RELEASING HORMONE (GNRH) RECEPTOR IN THE BACULOVIRUS/INSECT CELL (Sf9) SYSTEM. J.D. Neill, J.C. Sellers and L.W. Duck. Dept. of Physiology and Biophysics, Schools of Medicine and Dentistry, Univ. of Alabama at Birmingham, AL 35294.

The GnRH-receptor is expressed on the gonadotrope cells of the anterior pituitary; it binds the hypothalamic neuropeptide GnRH and stimulates the release of the gonadotropic hormones, FSH and LH. Molecular cloning and nucleotide sequencing of its cDNA revealed a 327 amino acid protein having a 7-transmembrane topology. Previously we reported that antibodies to receptor peptide segments failed to bind the native protein; thus we constructed a GnRH-receptor cDNA encoding an epitope tag (HA-1 antigen) at the amino terminus which is recognized by a commercially available antibody. Though this approach permits study of the heterologously expressed receptor, it does not allow detection of the native receptor. In the present study, we expressed the GnRH-receptor in the baculovirus/insect cell (Sf9) system; the epitope-tagged GnRH-receptor cDNA was used so that the expressed receptor could be immunoaffinity purified. The epitope tagged GnRH-receptor expressed in Sf9 cells is functional, having an affinity of 1.4 nM ( $IC_{50}$ ) for  $^{125}$ I-D-Ala<sup>6</sup>-des-Gly<sup>10</sup>-GnRH; when expressed in COS-1 cells it has an affinity of 0.47 nM ( $IC_{50}$ ). In Western blots, the epitope tagged GnRH-receptor in Sf9 cells is detected as a band at about 65 kDa which is similar with two bands at 67 kDa and 57 kDa found in COS-1 cells. Since the primary molecular weight of the GnRH-receptor is 37 kDa and the relative molecular mass of the endogenous receptor is reported to be 50-60 kDa, these results suggest that the Sf9 cells glycosylate the receptor to a slightly greater extent than do pituitary cells. The availability of large amounts of purified GnRH-receptor should permit production of antibodies that detect the native receptor and also allow studies of putative homodimerization of the GnRH-receptor molecule.

## CARDIOVASCULAR REGULATION: SPINALMEDULLARY MECHANISMS

## 403.1

EVIDENCE FOR AT1-MEDIATED SYMPATHOINHIBITORY AND SYMPATHOEXCITATORY ROLE OF BRAINSTEM ANGIOTENSIN IN CONSCIOUS RABBITS. GA Head, RD Bendle, SC Malpas, Y Hirooka\*, P. Potts\* and RAL Dampney\*\* Baker Medical Research Institute, Prahran, Victoria and \*Department of Physiology, University of Sydney, N.S.W., Australia.

The present study examined the cardiovascular effects of fourth ventricular (4V) administration of angiotensin II (Ang II) to conscious rabbits and the contribution of AT1 or AT2 receptors by treatment with losartan or PD123319 respectively. Ang II (1 to 125 pmol) into the 4V caused a maximum increase in mean arterial pressure (MAP) of  $17.3 \pm 1.5$  mmHg ( $n=8$ ). Losartan (0.001 to 10  $\mu$ g) caused a dose-dependent blockade of the pressor effect of Ang II, with complete blockade produced by 10  $\mu$ g. This effect lasted for at least 2 hours. PD123319 (0.1 to 1000  $\mu$ g) or vehicle had no effect on the Ang II pressor response. Following a 60 minute infusion of Ang II into the 4V of conscious rabbits and subsequent immunohistochemical staining for c-Fos protein, regions such as the rostral ventrolateral medulla pressor area and caudal ventrolateral medulla depressor area were heavily stained as were other regions such as the nucleus of the solitary tract and A5 area. In another 8 conscious rabbits implanted with 4V catheters and an electrode for recording renal sympathetic nerve activity (RSNA), the effect of losartan on the baroreceptor reflexes was examined. Baroreflex curves were determined by ramp increases and decreases in MAP using i.v. phenylephrine and nitroprusside before and after 10  $\mu$ g of losartan or vehicle, each on a separate day. Losartan did not alter MAP but increased resting RSNA ( $67 \pm 21\%$ ) and the range of the RSNA baroreflex curve by  $46 \pm 15\%$ . Vehicle had no significant effects. The effect of losartan in conscious rabbits suggests that the net effect of endogenous Ang II is a tonic inhibition of sympathetic vasomotor tone in contrast to exogenous Ang II which increases blood pressure and RSNA. Both of these actions are mediated by AT1 receptors.

## 403.3

EXCITATION OF C1 NEURONS IN ROSTRAL VENTROLATERAL MEDULLA (RVLM) BY ANGIOTENSIN II IS DUE TO CLOSURE OF A PERSISTENT K<sup>+</sup> CONDUCTANCE. Yu-Wen Li\* and P. G. Guyenet. Dept. Pharmacology, Univ. of Virginia, Charlottesville, VA 22908.

The RVLM is rich in angiotensin II (Ang II) receptors. The distribution of Ang II receptors overlaps with C1 cells. Activation of these receptors in RVLM increases sympathetic outflow and blood pressure. Fluorescent latex microspheres were injected into the thoracic spinal cord of neonatal rats (1-3 day-old). After 3-10 days, retrogradely labeled neurons in the RVLM were visualized by epifluorescence and recorded in cell-attached extracellular and/or whole-cell patch-clamp mode. Neurons were labeled with Lucifer Yellow. Tyrosine hydroxylase (TH) immunohistochemistry was later performed to identify phenotype of recorded cells. Sixty of 67 bulbospinal RVLM neurons were spontaneously active ( $2.7 \pm 0.2$  spikes/s), with 'resting' membrane potential of  $-55 \pm 0.5$  mV and input resistance of  $857 \pm 59$  M $\Omega$ . Ang II (1  $\mu$ M) increased firing rate to 250% of control in 28 of 39 neurons tested in cell-attached recordings. In current-clamp, Ang II depolarized the cells ( $+6 \pm 0.7$  mV,  $n=35$ ) and increased input resistance ( $+21 \pm 3\%$ ,  $n=20$ ). In voltage-clamp, Ang II induced an inward current ( $9.1 \pm 1.2$  pA,  $n=15$ ) at a holding potential around -50 mV. Ang II-evoked current was voltage-independent in the range of -40 to -120 mV, and had a reversal potential close to EK. The Ang II effect was abolished by the AT1 receptor antagonist losartan (3  $\mu$ M), but persisted in the presence of low Ca<sup>2+</sup>/high Mg<sup>2+</sup> solution or TTX. Ang II-sensitive neurons were inhibited by  $\alpha_2$ -adrenoceptor agonists (12/15). Ang II activated 24 of 26 TH-ir neurons. In conclusion, Ang II excites bulbospinal C1 cells in the RVLM, at least in part, by closing a persistent K<sup>+</sup> conductance. Supported by NIH (HL 28785) and AHA.

## 403.2

NEURAL MECHANISMS UNDERLYING THE CENTRALLY INITIATED PRESSOR RESPONSE ELICITED BY ANGIOTENSIN II IN RATS: A STUDY *IN VIVO*. M.-K. Sun\* & D.J. Reis. Div. of Neurobiol., Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, NY 10021.

Much interest has been raised as to the role of angiotensin II (Ang II) in generation and maintenance of hypertension. Its centrally initiated cardiovascular responses have been proposed to depend on responses of neurons in either (a) the area postrema or subfornical organ; (b) the rostral ventrolateral reticular nucleus (RVL) of the medulla oblongata to increase arterial pressure or (c) the caudal ventrolateral medulla or the nucleus tractus solitarius to decrease arterial pressure. We investigated whether a rapid activation of RVL-spinal vasomotor neurons underlies the Ang II-induced central pressor response. Ang II (1-100 nmol), applied intracranially (i.c.), dose-dependently and dramatically increased arterial pressure. The pressor response was neither preceded by any detectable excitatory responses of the singly identified RVL-spinal vasomotor neurons with slow and fast-conducting axons nor increased discharges of sympathetic nerves, but abolished by [Sar<sup>1</sup>, Thr<sup>8</sup>]-Ang II (100 nmol, i.c.), an Ang II receptor antagonist. Both types of RVL vasomotor neurons and sympathetic nerves were actually inhibited, due to their baroreflex sensitivity. The Ang II-induced pressor response was attenuated neither by a ganglionic blocker hexamethonium (250 mg, i.v.) nor by a complete cervical transection of the spinal cord (with i.v. infusion of L-phenylephrine to maintain arterial pressure to control level) but largely attenuated by [ $\beta$ -Mercapto- $\beta$ , $\beta$ -cyclopentamethylphenyl]-O-Et-Tyr<sup>1</sup>, Val<sup>4</sup>, Arg<sup>8</sup>]-vasopressin (1 mg, i.v.), a vasopressin antagonist. We conclude that (a) responses of RVL-spinal vasomotor and sympathetic neurons do not underlie the Ang II-induced central pressor response and (b) the pressor response depends on release of vasopressin into the circulation.

## 403.4

K<sup>+</sup> CURRENTS IN SPONTANEOUSLY ACTIVE AND SILENT RVLM NEURONS OF IMMATURE RAT BRAINSTEM SLICES.

N. J. Dun\* and T. Miyazaki.\*\* Dept. of Anat. & Neurobiol., Medical College of Ohio, Toledo, OH 43614. \*\*Present address: Dept. of Physiol., Tokyo Medical College, Tokyo, Japan.

Coronal 500  $\mu$ m brainstem slices were prepared from 8-12 day old rats. Whole-cell patch-clamp recordings were made from rostral-ventrolateral medulla (RVLM) neurons. At the resting membrane potential of about -60 mV, two types of RVLM neurons were noted: spontaneously active and silent neurons. The types of K<sup>+</sup> currents present in these two groups of neurons were the focus of these studies. The resting membrane potential and input resistance among these two types of neurons were not statistically different. Tetrodotoxin (TTX, 0.5  $\mu$ M) abolished the spontaneous discharges. In the presence of TTX, depolarizing step commands from the holding potential of -60 mV evoked in all RVLM neurons a TEA-sensitive outward current. The outward current had a mean reversal potential of -87.8 mV. All RVLM neurons exhibited a 4-aminopyridine (1 mM)-sensitive A-type current and a Cs<sup>+</sup>-sensitive H-type current. A Ca<sup>2+</sup>-activated K<sup>+</sup> current was present in most of the spontaneously active and silent RVLM neurons. The results show that these two types of RVLM neurons seem to have the same complement of K<sup>+</sup> currents and suggest that the spontaneous activity may be a network-related event. (Supported by NIH Grant HL51314).

## 403.5

**VENTRAL MEDULLARY SURFACE ACTIVITY CHANGES DURING MOMENTARY BLOOD PRESSURE VARIATION WITHIN SLEEP STATES.** R.M. Harper\*, D.M. Rector, G. Poe, H.V. Forster, P.J. Ohtake, L.G. Pan, T.F. Lowry and D. Gozal. Dept. of Anatomy and Cell Biology, UCLA, Los Angeles, CA 90095; Dept. of Physiology, Medical College of Wisconsin and Zablocki VA Hospital, Milwaukee, WI 53226.

We examined activity changes on the rostral ventral medullary surface (VMS) during sleep in a chronic goat preparation with imaging procedures. Under sterile surgery, five adult goats were instrumented with electrodes to monitor sleep physiology, arterial and venous cannulae to assess blood pressure, a tracheostomy to assess ventilatory measures, and a miniaturized video camera coupled to a coherent fiber probe and a narrow bandwidth illuminator (660 nm) to measure VMS activity. The probes were placed over a rostral VMS region which elicited ventilatory and blood pressure depression when cooled. Arterial pressure and 320 x 100 pixel images were collected at 1 Hz during an all-night sleep recording, and arterial pressure values were cross-correlated with overall image reflectance. Pronounced episodic activity transients occurred on the VMS, particularly during REM sleep and waking. Phasic arterial pressure variation during REM sleep followed VMS activity changes in a closely-coupled fashion (1-3 sec), while blood pressure changes during quiet sleep and waking followed image changes with more substantial or variable lags. We speculate that (1) momentary changes in VMS activity play a role in initiating large blood pressure transients during REM sleep, and (2) the timing of VMS activity changes to blood pressure transients during some states or others suggests a more prominent role for the VMS in modulating blood pressure in particular states. (Supported by HL-22418, NIDR DE-07212, and USPHS-25739; G.P. is supported by a Howard Hughes predoctoral fellowship).

## 403.7

**EFFECT OF SPINAL CORD INJURY ON CARDIOVASCULAR NEURONS IN THE ROSTROVENTROLATERAL MEDULLA.** A.V. Krassioukov\* & M.G. Fehlings\*. John P. Roberts Research. Inst. & Dept. of Physiol. Univ. of Western Ontario, London, Ont., Canada, N6A 5K8, and \*Playfair Neuroscience Unit, The Toronto Hospital Research Inst., 399 Bathurst St., Toronto, Ont., Canada M5T 2S8.

Deranged cardiovascular control in patients with paraplegia or quadriplegia can be directly linked to abnormalities within the autonomic nervous system. However, mechanisms for changes in central control of the cardiovascular system after spinal cord injury (SCI) have not been investigated. We studied changes within cardiovascular neurons in the rostral ventrolateral medulla (RVLM) after compression SCI. Neurons in the RVLM has been shown to be most critical for cardiovascular control. Numbers of RVLM neurons surviving after SCI in rats were identified by retrograde labelling with Fluoro Gold after T6 introduction and counts were performed eight weeks after different degrees of SCI (20g, 35g and 50 g compression) of the cord at T1. The RVLM neurons were counted in four control and nine cord-injured rats. The numbers of labelled RVLM neurons in control rats were 296±18; the numbers in cord-injured rats were markedly reduced and 144±17 neurons were found after 20g compression, 24±6 neurons after 35g compression and finally 9±1 neurons after 50g compression. These neurons must have retained an intact bulbospinal axon after the compression injury. A rim of subpial white matter usually is preserved after SCI in humans and in the rat model of compression injury. These tracts can be in the dorsolateral funiculus, the region of most descending sympathetic vasomotor pathways to the SPNs. These surviving bulbospinal RVLM neurons also were characterized by their expression of the enzyme phenylethanolamine-N-methyltransferase. They must project to spinal sympathetic neurons caudal to the site of injury and potentially could be a source of new innervation to other sympathetic neurons in these spinal segments. (Support: Ontario Heart & Stroke Foundation)

## 403.9

**MODULATION OF THE FREQUENCY AND AMPLITUDE COMPONENTS OF SYMPATHETIC ACTIVITY BY BAROREFLEXES AND CHEMOREFLEXES IN CONSCIOUS RABBITS.** S.C. Malpas, J.H. Ricketts, R.D. Bendle, G.A. Head, K. SHEPPARD\* Baker Medical Research Institute, Prahran, Victoria 3181, Australia.

Sympathetic discharges (SND) exhibit two distinct components, the frequency at which discharges occur and their relative amplitude (reflecting the number of activated nerve fibres within each burst). These may respond independently to different afferent inputs indicating separate central controlling processes. We examined the response in the frequency and amplitude of renal SND to baroreceptor and chemoreceptor activation in 8 conscious rabbits. Rabbits breathed either room air or a hypoxic gas mixture for 10 min, baroreflexes were then stimulated by ramp increases and then decreases in arterial pressure using i.v. phenylephrine (0.5mg/ml) and nitroprusside (1mg/ml) (total arterial pressure range induced 80mmHg). Hypoxia significantly increased the resting frequency, prior to baroreflex modifications, from  $1.94 \pm 0.33$  to  $2.82 \pm 0.31$  discharges per second and amplitude of SND  $21 \pm 7\%$ , although arterial pressure was unchanged. The baroreflex curve for the frequency of SND under normoxia was sigmoidal. The gain of this curve was significantly increased by hypoxia although not the range of frequencies occurring. The arterial pressure range over which these changes occurred was unaltered by hypoxia. The baroreflex curve for the amplitude of SND was also sigmoidal occurring over a similar arterial pressure range as the frequency curve. However under hypoxia the range of the amplitude curve was increased  $81 \pm 3\%$  ( $p < 0.05$ ), but the gain unaltered. These results indicate that baroreceptor afferents affect both the frequency and amplitude of SND similarly but when combined with chemoreceptor stimulation they display different responses. These findings support the hypothesis that there are independent controlling processes for the frequency and amplitude components of SND.

## 403.6

**DIRECT PROJECTIONS FROM A VASODEPRESSOR AREA IN THE MEDULLARY GIGANTOCYLLULAR RETICULAR NUCLEUS ONTO SYMPATHOADRENAL PREGANGLIONIC NEURONS IN THE THORACIC SPINAL CORD.** S.A. Aicher\*, D.J. Reis, and T.A. Milner. Dept. of Neurol. & Neurosci., Cornell Univ. Med. College, NY, NY 10021.

A vasodepressor area within the caudal ventral medullary gigantocellular reticular nucleus, the gigantocellular depressor area (GiDA), is topographically distinct from other vasoactive sites in the rostral ventromedial medullary reticular formation (RVM) and the GiDA innervates the thoracic spinal cord (Aicher, et al., *Neurosci.* 60: 761-779). We investigated whether these efferent fibers monosynaptically contact retrogradely-labeled sympathoadrenal preganglionic neurons of the thoracic spinal cord. The anterograde tracer biotinylated dextran amine (BDA) was iontophoresed into the GiDA of rats and the retrograde tracer Fluoro-Gold was injected into medulla of the ipsilateral adrenal gland. Fourteen days later, rats were anesthetized and perfused with acrolein and paraformaldehyde. Sections of the thoracic spinal cord (T7-T12) were processed for immuno-gold localization of Fluoro-Gold retrograde transport and peroxidase localization of anterogradely transported BDA. BDA injection sites were confined to the GiDA. In the thoracic spinal cord, BDA-labeled axons were both myelinated and unmyelinated. BDA-labeled terminals contained small, clear vesicles and formed symmetric synaptic contacts primarily on large and small dendrites. Some of the somata and large dendritic targets of BDA terminals contained immuno-gold reaction product associated with lysosomes and multivesicular bodies in the cytoplasm indicating they were retrogradely-labeled from the adrenal medulla. We conclude that GiDA neurons project directly onto sympathoadrenal preganglionic neurons in the thoracic spinal cord. The pathway may represent a direct medullary reticulospinal sympathoinhibitory pathway. (Support: NIH #HL18974; Amer. Heart Assoc. Grant-in-Aid to SAA).

## 403.8

**RENAL SYMPATHETIC ACTIVITY IN CONSCIOUS SPINAL INJURED RATS.** D.N. Majorov\*, L.C. Weaver and A.V. Krassioukov, John P. Roberts Research. Inst. & Dept. of Physiol. Univ. of Western Ontario, London, Ont., N6A 5K8, Canada.

Episodic hypertension in quadriplegics and high paraplegics can be induced by spinally-mediated reflex increases in sympathetic nerve activity in response to visceral stimuli. However, direct evidence for a neurogenic origin of autonomic dysreflexia does not exist. To evaluate the role of sympathetic activity in dysreflexia we studied the responses of mean arterial pressure (MAP), heart rate (HR) and renal nerve activity (RNA) to colon distension in unanesthetized rats 1-4 days after thoracic spinal cord transection (SCT). One day after SCT MAP and RNA were significantly decreased from that recorded in the 11 intact, pentobarbital anesthetized rats. In the ensuing days MAP partially recovered, whereas RNA declined further approaching levels indistinguishable from noise by day 4.

	Before SCT (under anesthesia)	After SCT (conscious)			
		24h(n=8)	48h(n=4)	72h(n=3)	96h(n=3)
MAP (mmHg)	93±4	69±7	77±6	77±12	97±3
HR (bpm)	422±18	390±34	390±4	395±48	365±66
RNA ( $\mu V \cdot s$ )	16±2	9±4	10±4	7±4	3±3

Colon distension elevated MAP by  $31 \pm 7$  mmHg and RNA by  $33 \pm 5 \mu V \cdot s$  on day 1 after SCT. On day 2 of testing, MAP and RNA increased by  $20 \pm 6$  mmHg and  $32 \pm 13 \mu V \cdot s$ , respectively. On day 3 colon distension increased MAP by  $22 \pm 7$  mmHg and RNA by  $18 \pm 5 \mu V \cdot s$ . On day 4 these responses did not differ significantly from those on day 3. On all four days of testing ganglionic blockade with hexamethonium abolished the responses in MAP and reduced the responses in RNA by 85±5%. These results demonstrated a) the absence of baseline RNA in awake rats 3-4 days after SCT, b) the neurogenic origin of autonomic dysreflexia in cord-injured rats.

## 403.10

**INTERCONNECTIONS OF CAUDAL VENTROLATERAL MEDULLARY (CVLM) AND RAPHE (R) NEURONS WITH ACTIVITY CORRELATED TO THE 10-HZ RHYTHM IN SYMPATHETIC NERVE DISCHARGE (SND) OF URETHANE-ANESTHETIZED CATS.** S.M. Barman\*, H.S. Orer, and G.L. Gebber. Dept. Pharmacol. & Toxicol., Michigan State Univ., E. Lansing, MI 48824.

We used spike-triggered averaging to identify CVLM and R neurons with activity correlated to the 10-Hz rhythm in SND. Nineteen of 47 CVLM neurons were antidromically activated by R stimulation. The longest onset latency (OL) of antidromic activation (AA) was  $19.9 \pm 2.8$  ms, a value similar to the difference (17 ms on the average) in firing times of CVLM and R neurons during the 10-Hz slow wave in SND. These responses likely reflected activation of axonal branches since the OL was decreased dramatically by moving the stimulating microelectrode within the R or by using suprathreshold current. The axons of CVLM neurons likely terminated on and excited R neurons since: 1) CVLM neurons could not be activated by stimulation of sites lateral to the midline, contralateral to the recording site; thus their axons did not cross the midline. 2) AA of some CVLM neurons was limited to stimulation of sites in one track through the midline; thus, their axons did not project to more rostral or caudal portions of the medulla. 3) 37% of R neurons were synaptically excited by CVLM stimulation (minimum OL:  $18.1 \pm 2.6$  ms). Eight of 41 R neurons were antidromically activated by CVLM stimulation. The OL of AA was decreased by moving the stimulating microelectrode within the CVLM or by using suprathreshold current. The axons of R neurons likely terminated in the CVLM since: 1) Higher current was needed to activate them from sites 0.5 mm further lateral or rostral. 2) 32% of the CVLM neurons were synaptically excited by R stimulation (minimum OL:  $18.3 \pm 4.2$  ms). These data raise the possibility that interconnections of CVLM and R neurons contribute to the expression of the 10-Hz rhythm in SND. (Supported by NIH grants HL-33266 and HL-13187.)

## 403.11

**GABAergic and Hypothalamic involvement in the 10 Hz Sympathetic Rhythm.** ME Clement\* and RB McCall. The Upjohn Company, Kalamazoo, MI.

The neurotransmitters GABA and glycine have been implicated in inhibitory neurotransmission in a number of central nervous pathways. Microinjection of these compounds into the caudal depressor area or the rostral pressor area of the ventrolateral medulla increases or decreases sympathetic outflow, respectively. Administration of antagonists to these neurotransmitters increases sympathetic nerve discharge. Recent experiments in our laboratory have investigated the effects of the glycinergic antagonist strychnine and the GABAergic antagonist picrotoxin on the frequency distribution of SND. While strychnine caused an overall increase in SND, picrotoxin selectively increased the power in the 10 Hz rhythm. Picrotoxin also caused a rightward shift of the 10 Hz band in the power spectrum. Thus the current study implicates a role for the two endogenous inhibitory neurotransmitters GABA and glycine in the modulation of the frequency spectra of SND. GABA in particular seems to be involved in the intrinsic circuitry regulating the central oscillator responsible for the generation of 10 Hz activity, while glycine appears to have a more general effect on power frequency spectra of SND.

Previous investigators have reported modulation of sympathetic nerve discharge by a hypothalamic GABAergic mechanism. The current study examined the coherence between field potential activity recorded from the hypothalamic area and sympathetic nerve activity recorded from the inferior cardiac nerve. Low doses (0.1-0.3 mg/kg) of picrotoxin increased the coherence in the 10 Hz band, while higher doses (1 mg/kg) increased the coherence in the lower frequencies. The 10 Hz rhythm is not dependent on the hypothalamus however, indicating the 10 Hz activity in the hypothalamus and the inferior cardiac nerve share an input from a common generator.

## 403.13

**NICOTINIC RECEPTORS ENHANCE SPONTANEOUS GABAERGIC SYNAPTIC CURRENTS IN RAT DORSAL MOTOR NUCLEUS OF THE VAGUS (DMV) NEURONS.** M. Bertolino\*, K.J. Kellar and R. Gillis. Department of Pharmacology, Georgetown University School of Medicine, Washington DC 20007.

Spontaneous synaptic currents were studied in thin (200  $\mu$ m) coronal slices of rat brainstem containing the DMV region. The effect of nicotine was investigated by measuring the frequency of the spontaneous events before and after bath application of the agonist using the patch clamp technique. Nicotine (1-30  $\mu$ M) increased the frequency of the synaptic currents in a dose-dependent way, but it failed to activate a postsynaptic current. The effect was observed also when epibatidine (0.1-10 nM) and cytosine (10  $\mu$ M), two potent nicotinic agonists, were applied. In the presence of the nicotinic receptor antagonist mecamylamine (20  $\mu$ M), the effect of 3  $\mu$ M nicotine on the frequency was decreased by 50%. Tetrodotoxin (1  $\mu$ M) completely blocked the effect of 3  $\mu$ M nicotine. To identify the neurotransmitter involved in the increased frequency, we tested blockers of the GABA and glutamate receptors. The effect of 3  $\mu$ M nicotine was blocked by 25  $\mu$ M bicuculline, a GABA antagonist; in contrast, it was not affected by 1 mM kynurenic acid, a glutamate antagonist. These data suggest the existence of presynaptic nicotinic receptors that increase GABA release in a tetrodotoxin-sensitive manner. These findings are similar to recent results showing that nicotinic receptors may mediate GABA release in the interpeduncular nucleus (Léna et al. J. Neurosci. 13:2680-2688, 1993). This effect of the nicotinic receptors on the GABA release in the DMV may have an important role in the control of gastrointestinal motility.

## 403.15

**EVIDENCE FOR OPPOSING EFFECTS OF VASOACTIVE INTESTINAL POLYPEPTIDE (VIP) ON GASTRIC MOTOR FUNCTION IN THE DORSAL VAGAL COMPLEX (DVC) AND NUCLEUS RAPHE OBSCURUS (nRO) OF THE RAT.** Z.K. Krowicki\* and P.J. Hornby, Dept. of Pharmacology, Louisiana State University Medical Center, New Orleans, LA 70112.

Specific binding sites for VIP and/or VIP-immunoreactive fibers have been found in the DVC and raphe nuclei. These findings prompted us to investigate the effect of VIP (0.1 - 100 pmol; 30 nl) and vehicle (30 nl) in the DVC and nRO of  $\alpha$ -chloralose-anesthetized rats on gastric motor function, heart rate (HR), and blood pressure (MBP). Peak changes in intragastric pressure (IGP) and areas of the response (ARIGP) as well as changes in pyloric (PMMI) and greater curvature (GCMMI) minute motility indexes, HR, and MBP vs. preinjection values in response to VIP at a dose of 10 pmol are shown as means  $\pm$  SE for 5 - 6 animals.

	DVC	nRO
Peak IGP (cm H <sub>2</sub> O)	+5.92 $\pm$ 1.54*	-1.75 $\pm$ 0.21*
ARIGP (cm <sup>2</sup> )	+1.98 $\pm$ 0.41*	-2.09 $\pm$ 0.56*
PMMI	+2.88 $\pm$ 0.61*	-4.07 $\pm$ 1.12*
GCMMI	+1.12 $\pm$ 0.57	-1.36 $\pm$ 0.52*
HR (bpm)	-33 $\pm$ 15	0 $\pm$ 0
MBP (mm Hg)	+13 $\pm$ 4*	+5 (median)

\* P<0.05 vs. corresponding vehicle (Student-Newman-Keuls test)

Activation of VIP receptors in the DVC increases, whereas microinjection of VIP into the nRO decreases gastric tone and inhibits gastric motility. These data show for the first time that the same neuropeptide may produce opposite gastric motor responses on its microinjection into different medullary nuclei. Supported by PHS grant DK42714.

## 403.12

**BICOHERENCE ANALYSIS OF SYMPATHETIC NERVE DISCHARGE (SND).** G.L. Gebber\* and Y. Paitel. Dept. Pharmacol./Tox., Michigan State Univ., E. Lansing, MI 48824

The bicoherence function (normalized bispectrum) was used to test for nonlinear quadratic coupling (i.e. phase-locking) of the cardiac-related and 10-Hz rhythms (baroreceptor-innervated) or  $\sim$ 5-Hz and 10-Hz rhythms (baroreceptor-denervated) in SND of urethane-anesthetized cats. Such higher-order power spectra identify coupling of frequency triples where the third frequency is the sum of the other two. Recordings were made from the inferior cardiac nerve. We found that the cardiac-related and 10-Hz or  $\sim$ 5-Hz and 10-Hz rhythms always were nonlinearly coupled when the higher frequency component was a multiple of the lower. This suggests stable phase-locking of the central generators responsible for these rhythmic components of SND. The presence of stable 2:1 or 3:1 phase-locking was confirmed by plotting the time evolution of voltage changes in the 10-Hz band of SND against those of the lower frequencies (selectively filtered). Such orbital plots were "stationary." The bicoherence function also showed coupling of the low and high frequency rhythms in some cases when they were not harmonically related. Since the orbital plots were "non-stationary", such cases of nonlinear coupling might reflect unstable phase-locking (i.e., relative coordination) of the low and high frequency rhythm generators or convergence of their outputs onto follower circuits. Either of these models could account for the modulated frequencies,  $f_1 \pm f_2$ . The conditions leading to the nonlinear coupling of the generators of the low and high frequency rhythms in SND remain to be defined. (Supported by NIH grant HL-13187.)

## 403.14

**NEUROCHEMICAL CHARACTERIZATION OF DORSAL VAGAL COMPLEX NEURONS RECEIVING INPUT FROM GASTRIC TENSION RECEPTORS IN RATS.** A.E. Willing, D.A. York\*, H.-R. Berthoud. Pennington Biomedical Research Center, Louisiana State University, Baton Rouge, Louisiana, 70808.

Important negative feedback information from gastrointestinal mechanoreceptors relevant to the control of digestive processes and food intake reaches the brain via vagal afferents that terminate in the nucleus of the solitary tract (nts) and dorsal motor nucleus (dmnX). To characterize the neurochemical identity of second order nts and dmnX neurons receiving input from gastric tension receptors, we measured c-fos induction in combination with catecholamine enzyme immunocytochemistry. A latex balloon was inserted into the fundic stomach of awake, freely moving male SD rats through a previously implanted chronic gastric fistula. The stomach was distended in a pattern that mimicked normal ingestion as described by Fraser & Davison (AJP 268, 1995). The large majority of neurons with c-fos positive nuclei were concentrated at the level of the area postrema, within the medial nts (mnts, 44 $\pm$ 3 neurons/40  $\mu$ m-section), commissural nts (15 $\pm$ 1), dorsomedial nts (13 $\pm$ 2), interstitial and intermediate nts (13 $\pm$ 2), and dmnX (28 $\pm$ 1). Sham-control manipulation resulted in few labeled cell nuclei (mnts: 5 $\pm$ 2/section). The distribution of tyrosine hydroxylase (TH) and dopamine  $\beta$ -hydroxylase (DBH) positive perikarya was similar, with the highest numbers in mnts and dmnX. The dmnX contained the highest proportion of gastric distension activated neurons with TH (13.1 $\pm$ 2.3%) and DBH (12.3 $\pm$ 7.6%), followed by the mnts: TH (7.8 $\pm$ 2.9%), DBH (7.3 $\pm$ 7.2%). These results suggest that nts noradrenergic and/or adrenergic neurons are involved in the dissemination of gastric tension cues to higher brain areas and in the dmnX they are involved in gastric tension dependent vago-vagal reflexes. Supported by NIH grant DK 47348.

## 404.1

Anti-oscillatory effects of adenosine in the thalamus. Daniel Ulrich\* and John B. Huguenard, Dept. of Neurology and Neurological Sciences, Stanford University School of Medicine, Stanford CA.

Adenosine has well established depressant effects in the central nervous system with both pre- and postsynaptic actions. We examined the effects of exogenously applied adenosine on thalamic network activity and on evoked synaptic responses *in vitro*. Thalamic oscillations were studied in acute slices by extracellular multi-unit recordings in the ventrobasal complex (VB) of the rat somatosensory thalamus and the adjacent GABAergic nucleus reticularis thalami (nRt). Phasic oscillations (3 - 4 Hz) in VB and nRt were evoked by extracellular stimulation of cortico - thalamic fibres. Adenosine (50  $\mu$ M) reversibly decreased the total number of spikes within these oscillations in VB to (mean  $\pm$  s.e.m)  $46 \pm 14$  % of control ( $n = 5$  experiments) and in nRt to  $53 \pm 9$  %. In addition, adenosine reduced the duration of these oscillations without disrupting their periodicity. In a similar preparation, evoked monosynaptic inhibitory (IPSCs) and excitatory (EPSCs) synaptic currents were recorded by whole cell patch clamp recordings. In both VB and nRt cells, adenosine decreased IPSCs to (mean  $\pm$  s.e.m)  $33 \pm 8$  % ( $n = 7$ ) of control and to  $39 \pm 7$  % ( $n = 8$ ), respectively. EPSCs in nRt elicited by stimulation of thalamo-cortical and corticothalamic axons in VB were reduced to  $16.7 \pm 7.4$  % ( $n = 5$ ) of control. With both excitatory and inhibitory synaptic responses, the adenosine effect was accompanied by an increase in failures of synaptic transmission indicating a presynaptic site of action and was reversed by the purinergic A1 receptor antagonist 8-cyclopentylthiophylline (CPT, 1  $\mu$ M).

We conclude that unlike in hippocampus where presynaptic effects of adenosine are restricted to EPSCs, in the thalamus both EPSCs and IPSCs are reduced. These multiple effects of adenosine contribute to robust depressant effects on thalamic network activity. ## 404.3

GABAergic autoinhibition in the thalamus John B. Huguenard\* and Daniel Ulrich, Dept. Neurology and Neurological Sciences, Stanford University School of Medicine, Stanford, CA.

Presynaptic inhibition of GABAergic synapses in the thalamus was studied in thin slices of rats at postnatal age P9 - P14 by whole cell patch clamp recordings with Cs-gluconate in the pipette. Monosynaptic inhibitory synaptic currents (IPSCs) were elicited by focal stimulation (1.5 - 2x threshold) of axons and recorded in relay cells of the ventrobasal complex (VB) of the somatosensory thalamus as well as in GABAergic neurons of the nucleus reticularis thalami (nRt). The IPSCs were reversibly blocked by bicuculline methiodide (10  $\mu$ M) and had a reversal potential close to the expected chloride equilibrium potential. (R)-Baclofen (10  $\mu$ M) decreased IPSCs in relay cells to (mean  $\pm$  s.e.m)  $11.8 \pm 2.6$  % of control ( $n = 11$  cells) and in nRt cells to  $10.8 \pm 1.6$  % ( $n = 12$ ). In both nuclei, the reduction of IPSCs was reversed (> 60 %) by the GABA<sub>A</sub> receptor antagonist CGP 35348 (10  $\mu$ M). In contrast, Phaclofen (1 mM) and 2-Hydroxysaclofen (0.5 mM) were less potent (< 40 %) in reversing the Baclofen induced reduction of IPSCs. In the same cell types, Baclofen also decreased the frequency of TTX resistant miniature IPSCs (mIPSCs) in VB to  $39 \pm 8$  % of control ( $n = 8$ ) and in nRt to  $69 \pm 16$  % ( $n = 6$ ). However, in both cell types, the cumulative amplitude distributions of mIPSCs remained unaltered by Baclofen (KS test,  $Q > 0.01$ ) indicating that the postsynaptic sensitivity to GABA was unaltered.

We conclude that both evoked and spontaneous release of GABA from inhibitory neurons of nRt in the thalamus is inhibited by presynaptic GABA<sub>A</sub> receptors. The potential role for autoinhibition in regulating thalamic network activity will be discussed. (Supported by NINDS NS 06477, the Pimley Research Fund and the Swiss National Science Foundation.)

## 404.5

MECHANISMS OF THE AUGMENTING RESPONSE IN THALAMOCORTICAL PATHWAYS. M.A. Castro-Alamancos\* and B.W. Connors, Department of Neuroscience, Brown University, Providence RI 02912.

During the classic "augmenting response", thalamus-evoked potentials in neocortex increase during paired stimuli or trains of between 5 and 20 Hz. We investigated the temporal, spatial and mechanistic properties of potentials in the frontoparietal cortex evoked from the ventrolateral (VL) and ventroposterior lateral (VPL) nuclei in the ketamine-anesthetized rat. Stimulation of VL produced strong augmenting responses, but repetitive stimulation of VPL yielded only depression. Current-source density analysis of VPL responses showed a primary current sink in layers III-IV, while VL produced a primary current sink in layer V. Inactivation of the thalamus with GABA or kynurenic acid did not affect the augmenting response. Recordings from a grid of 30 cortical sites showed that the augmenting response was generated in the projection field of the VL afferents and then spread into adjacent cortex. Intracellular recordings *in vivo* and *in vitro* revealed a population of intrinsically bursting cells in layer V that have  $I_h$  and  $I_T$  currents. A thalamic stimulus induced a small, brief EPSP followed by a strong, protracted IPSP in these cells; a second stimulus delivered during the IPSP induced a strong burst intracellularly and a concomitant augmenting response in the extracellular field potential. Blockade of the IPSP with low doses of GABA<sub>A</sub> receptor antagonists (but not GABA<sub>A</sub> antagonists), or local application of  $Ni^{2+}$  (a blocker of  $I_h$ ) suppressed the augmenting response. In slices *in vitro*, thalamocortical EPSPs did not generate paired-pulse facilitation. The results indicate that the augmenting response is generated within the cortex when thalamic axons from a layer V-projecting nucleus produce a strong hyperpolarizing IPSP that deactivates  $I_h$  in a subpopulation of layer V bursting cells. A subsequent thalamic EPSP that occurs during the hyperpolarization can then evoke a rebound  $Ca^{2+}$ -dependent depolarization that triggers a burst of action potentials; the spread of this enhanced activity to other cortical neurons completes the augmenting response. Supported by the NIH and ONR.

## 404.2

CHOLECYSTOKININ MODULATES INTRATHALAMIC OSCILLATIONS. C.L. Cox\*, J.B. Huguenard and D.A. Prince, Dept. Neurology and Neurological Sciences, Stanford University School of Medicine, Stanford, CA 94305.

The reciprocal synaptic connectivity between the thalamic reticular nucleus (nRt) and dorsal thalamus is implicated in intrathalamic rhythms associated with slow-wave sleep and pathophysiological conditions such as absence epilepsy. As cholecystokinin (CCK) is localized in thalamocortical and/or corticothalamic neurons, and has been found to selectively depolarize nRt neurons by suppressing a linear  $K_{max}$  conductance, we have examined CCK actions on intrathalamic oscillations.

Simultaneous extracellular multiple-unit recordings from nRt and ventrobasal nucleus (VB) were obtained from *in vitro* thalamic slices of young rats (P10-20). Electrical stimulation of nRt evoked oscillatory activity (2-3.5 Hz) involving both nuclei. CCK (10-1000 nM, bath applied) produced dose-dependent effects upon the oscillations. High [CCK] (>100 nM) shortened the oscillations ( $n=5$  slices), whereas lower [CCK] (10-100 nM) prolonged them ( $n=7$ ).

Current- and voltage-clamp recordings using whole cell patch techniques were employed to test the hypothesis that CCK-mediated actions on synaptic potentials contribute to modification of oscillatory activity. Stimulation of nRt evoked multiple-peak, burst-like IPSCs in VB neurons. CCK (>400 nM) reversibly reduced IPSC amplitude and eliminated the multiple-peak shape. In contrast, low [CCK] (<100 nM) did not modify the IPSCs. EPSPs in nRt neurons evoked by stimulation of VB or internal capsule were usually suppressed during the depolarization induced by high [CCK] (>100 nM); however, low [CCK] had a mixed effect upon the EPSPs (40% facilitated, 60% suppressed).

Our findings indicate that CCK exerts a fine level of control over these intrathalamic rhythmic activities. At low concentrations, CCK depolarizes nRt neurons towards spike threshold without changing their spike discharge mode, thus increasing the probability of burst discharge from nRt neurons. As indicated by reduction of the multiple-peak IPSCs in VB, high [CCK] depolarizes nRt neurons, shifting these cells from burst- to single-spike mode, thereby reducing their phasic inhibitory output. The reduced inhibition onto VB neurons decreases the probability of burst discharge from these cells which, in turn, dampens the oscillatory activity. Reduction of the EPSPs, presumably due to dendritic depolarization by CCK, would also contribute to dampening of the oscillation; however in some cells, the EPSP is enhanced, likely a result of increased input resistance produced by CCK, and thus may contribute to facilitation of the oscillation. Supported by NIH grants NS06477 and NS07280, and the Pimley Training Fund.

## 404.4

SHORT-TERM SYNAPTIC ENHANCEMENT PREDICTS LONG-TERM POTENTIATION IN NEOCORTEX. B.W. Connors\* and M.A. Castro-Alamancos, Department of Neuroscience, Brown University, Providence RI 02912.

Pathways of the cerebral cortex vary in their ability to generate short- and long-term forms of synaptic enhancement. Induction of NMDA receptor-dependent long-term potentiation (LTP) depends upon adequate postsynaptic activation during the conditioning period. We tested the hypothesis that short-term forms of enhancement, which operate during conditioning, might influence a pathway's ability to generate LTP. Using rat slices *in vitro*, theta-burst stimuli applied to layer IV reliably induced long-term potentiation (LTP) in the upper layers of the somatosensory (SI) cortex, but not in motor (MI) cortex (Castro-Alamancos et al., *J. Neurosci.*, in press). In SI cortex, synaptic responses were strongly enhanced during theta-burst conditioning; in contrast, short-term enhancement was very weak in MI. Both short-term enhancement and LTP were abolished by AP5, an antagonist of NMDA receptors. The magnitude of short-term enhancement during conditioning stimulation was strongly correlated with the magnitude of LTP across slices from both cortical areas. Pharmacologically isolated IPSPs were slightly depressed during theta-burst stimulation, to a similar extent in the two cortical areas. Thus, frequency sensitivity of inhibition does not explain the strong enhancement in SI. Pharmacologically isolated NMDA receptor-dependent EPSPs showed strong short-term enhancement in SI, but not in MI, indicating that enhancement reflects an increase in NMDA receptor-mediated currents. Short-term synaptic enhancement per se was not enough to induce LTP, because one theta-burst sequence produced strong enhancement, followed only by short-term potentiation without LTP; three theta-burst sequences reliably induced LTP. We suggest that, 1) the capacity for short-term synaptic enhancement may vary widely in different neocortical pathways and areas, 2) short-term synaptic enhancement promotes the induction of long-term potentiation, 3) variations in short-term enhancement may account for some of the variability of LTP induction in neocortex. Supported by the NIH and ONR.

## 404.6

BASAL FOREBRAIN TRANSPLANTS AMELIORATE THE EFFECTS OF BASAL FOREBRAIN LESIONS IN RAT BARREL CORTEX. O. Rahimi\*, G. Hill III, L.L. Porter, S.L. Juliano, Anatomy & Neuroscience, USUHS, Bethesda, MD.

Acetylcholine (ACh) is implicated in mediating functions including cortical arousal, learning and memory, and synaptic plasticity. Recent studies also demonstrate that neocortical depletion of ACh in rodents results in reduced 2-deoxyglucose uptake in response to whisker stimulation. Transplants of embryonic basal forebrain, however, restore stimulus-evoked activity toward normal. To verify previous observations that cholinergic depletion resulted in decreased stimulus-evoked activity, electrophysiological recordings were performed on rats that received unilateral basal forebrain lesions. A cortical whisker representation was selected and an electrode advanced while manually stimulating the whisker. As single units responded to the stimulation, a switching device was attached to the whisker and displaced in an upward direction for a fixed duration and amplitude. Unit responses were recorded over 30 stimulus trials for corresponding whiskers in both hemispheres. The response magnitude of each neuron was measured as spikes/stimulus during a fixed window of 8-50 msec post-trigger epoch. In the ACh-depleted hemisphere, the evoked response magnitude was significantly lower as compared to normal (unpaired t test,  $p < 0.01$ ). To assess the ability of embryonic basal forebrain transplants to ameliorate the effect of basal forebrain lesions, the above recording procedure was used to assess neuronal activity in rats that received basal forebrain lesions followed by embryonic basal forebrain transplants. The evoked response magnitude, recording from neurons in matched barrels in both hemispheres, in the grafted animals was dramatically improved compared to the lesioned animals. These results suggest that ACh plays a significant role in mediating neuronal activity and its modulatory control of cortical function.

## 404.7

SENSITIVITY OF SI CORTICAL INTRINSIC SIGNALS TO MODE AND PARAMETERS OF NATURAL SKIN STIMULATION. M. Tommerdahl\*, O. Favorov, and B. Whitsel. Departments of Biomedical Engineering and Physiology, University of North Carolina, Chapel Hill, NC 27599.

Stimulus-evoked intrinsic signals in SI of cats and monkeys were recorded in order to characterize the cortical response to three different modes of skin stimulation: brushing, vibrotactile and thermal. In anesthetized cats and monkeys, a recording chamber containing an optical window was mounted over the contralateral forelimb region of SI. The cortex was illuminated with near infrared light (840 nm), and images were obtained (slow scan CCD camera) before and during periods of tactile stimulation. Averaged stimulus - nonstimulus difference images were examined to detect the effects of changes in stimulus parameters (e.g., location, frequency, amplitude, direction of motion, temperature). A discrete vibrotactile skin stimulus initially evoked a relatively homogenous decrease in IR reflectance within an extensive SI region. As time of exposure to the stimulus increased (5-30 secs), however, a (modular) pattern of activation emerged, usually within 3-10 secs of stimulus onset. Brushing and thermal stimuli to the same skin site also evoked reflectance changes within a large SI region, but the patterns obtained with the different stimuli were substantially different. Following the optical imaging session, extracellular single unit recordings were obtained from areas selected on the basis of stimulus-evoked reflectance values. The results indicate that regions of stimulus-evoked decreases in IR reflectance correspond to regions in which stimuli enhance single neuron spike discharge, and that regions of stimulus-evoked increases in IR reflectance correspond to regions in which stimuli inhibit single neuron spike discharge. The intrinsic signal patterns were reproducible when the same stimulus conditions were used, and while the IR reflectance patterns evoked in the same SI region by different stimuli to the same skin site could be very different, all patterns shared common features. Supported by NIH NINDS R29 NS32358 and the Whitehall Foundation.

UTILIZATION OF TEMPORALLY-ENCODED VS. SPATIALLY-ENCODED INFORMATION DURING THE PERFORMANCE OF A TACTILE DISCRIMINATION TASK. E. Ahissar\* and E. Gamzu, Dept. of Neurobiology, The Weizmann Institute, Rehovot, Israel

Whether the finger velocity, and thus the temporal information, is of any importance in tactile identification is still controversial. Naive subjects were required to indicate which of two gratings, each presented to a different hand, is more dense. Spatial frequencies (SFs) spanned the range between 0.2 to 0.8 bars/mm. Finger velocities (V) were measured with a resolution of 0.1 mm / 40 ms. We compared the correlation between decision and spatial information to the correlation between decision and temporal information. The decision was more similar to the temporal information than to the spatial information, especially in the more difficult range of SFs (0.4 - 0.8 bars/mm). The tactile temporal frequency deviates from  $V \cdot SF$  as the stimulus intervals become close in size to the diameters of the receptive fields (aliasing). We have simulated two possible neuronal mechanisms operating on the predicted neuronal input: A low-pass filter (LPF) and a phase-locked loop (PLL). The outcome of both mechanisms showed better fitness with the decision than the temporal frequency per se within certain regimes of receptive field sizes. This fitness is better as the task becomes more difficult. We conclude that temporal information plays a significant role in tactile texture processing and that this information is further processed by central "temporally oriented" mechanisms. These conclusions are further supported by the following: at SFs around 0.7 bars/mm there is a consistent reversal of perception leading to a confusion between the higher and lower SFs. This reversal can be fully explained by the PLL mechanism. Supported by: MJHF Germany and USA-Israel BSF.

EVIDENCES FROM EXPERIMENTS AND COMPUTER MODELLING INDICATE A NOVEL MECHANISM FOR SIGNAL PROCESSING. M.T. Huber\*, S. M. Petersen§§, H.A. Braun and K. Voigt. § Department of Psychiatry, Univ. Marburg, R. Bultmannstr.; Institute of Physiology, Univ. Marburg, Deutschhausstr. 1-2, D-35037 Marburg; §§ Dept. of Physiology, Univ. Würzburg, D-97070 Würzburg, Germany.

Neuronal oscillations are of great interest and also controversy because of their possible functional implications for neuronal information processing. Here we present a simple computer model which bases on findings on ionic conductances found in certain cortical neurons and also incorporates noise to account for stochastic features. We show that the model remarkably well can reproduce findings from certain cortical neurons. Moreover we show own experimental work from two another and very different systems: spinal ganglion cells and shark electroreceptors, both of which clearly exhibit oscillatory activity very similar to those found in the cortical cells. We demonstrate that with the given set of "cortical" ionic conductances the experimental results from the ganglion cells and electroreceptors can be reproduced to great detail by the model. We present evidence that all the three systems might make use of oscillations and noise in principally the same way although they obviously have to deal with very different input modalities. The key finding is, that differential encoding of stimuli can occur because the noisy oscillator can be modulated in its firing probability per oscillation cycle or in its oscillation frequency depending on the stimulus modality. We conclude that neuronal oscillations per se can be advantageous for information processing at different levels of the nervous system. In this context noise is an essential feature for encoding with oscillations.

## HYPOTHALAMIC-PITUITARY-GONADAL REGULATION III

## 405.1

AN INCREASE IN HYPOTHALAMIC NEU (HER-2) PROTOONCOGENE RECEPTOR GENE EXPRESSION ACCOMPANIES THE INITIATION OF FEMALE PUBERTY. Y.J. Ma\*, D.F. Hill, M.E. Costa and S.R. Ojeda, Div. Neuroscience, Oregon Regional Primate Research Center, Beaverton, OR 97006.

Activation of epidermal growth factor receptors (EGFR) has been implicated as one of the mechanisms by which transforming growth factor alpha (TGF $\alpha$ ) produced by astroglial cells facilitates the increase in LHRH secretion that leads to the onset of female puberty. However, other members of the EGF family may also be involved in the central control of sexual maturation. *Neu* differentiation factors (NDFs) are EGF-related proteins that interact with an EGFR-related receptor known as *neu* or HER-2. In the present experiments we found that the genes for both NDF and *neu* are expressed in hypothalamic astrocytes. Like TGF $\alpha$ , NDF $\beta$ 2 (a NDF isoform found in brain) effected the release of prostaglandin  $E_2$  (a LHRH secretagogue) from hypothalamic astrocytes, indicating that activation of *neu* or EGFR results in at least one common cellular response. The abundance of *neu* mRNA in the female rat hypothalamus increases markedly at the time of puberty, reaching maximal values at the time of the first preovulatory surge of gonadotropins. These changes may be partially attributed to ovarian steroids, as evidenced by the increase in *neu* mRNA induced by the sequential administration of estradiol and progesterone to ovariectomized immature rats. In contrast to the peripubertal changes in *neu* mRNA levels, hypothalamic NDF mRNA content was exceedingly low and did not change at puberty, suggesting that activation of *neu* receptors at puberty may involve mechanisms other than increased ligand availability. Exposure of hypothalamic astrocytes to either TGF $\alpha$  or NDF resulted in *neu* tyrosine phosphorylation indicating that TGF $\alpha$ , which does not bind to *neu*, transactivates *neu* receptors via EGFR. Thus, the NDF/*neu* receptor signaling system in the neuroendocrine brain appears to function tightly coupled to that of TGF $\alpha$ /EGFR during female sexual development. Supported by NIH grants HD25123, HD07133, HD18185 and RR00163.

## 405.2

ESTROGEN AND PROGESTERONE RECEPTOR EXPRESSION AT PUBERTY IN NEUROENDOCRINE AND RELATED NEURONS OF THE FEMALE MONKEY HYPOTHALAMUS. P.C. Goldsmith\* and K.K. Thind, Reproductive Endocrinology Center, Univ. California Sch. of Med., San Francisco, CA 94143-0556.

Nuclear expression of estrogen receptors (ER) and progesterone receptors (PR) connotes transcriptional regulation by these gonadal steroids. In hypothalamic neurons of monkeys, ER and PR expression at puberty coincides with activation of pituitary function. To identify neuroendocrine (NEU) neurons affecting the pituitary directly, we microinjected retrograde tracer into the median eminence of pubertal female monkeys. To detect ER and PR expression, we immunostained vibratome sections for ER (mouse IgG C-314) or PR (rabbit IgG C-20, Santa Cruz Biotech) using DAB. Retrograde label was visible in the cytoplasm of NEU neurons after immunostaining. In the *supraoptic nucleus* (SON), nearly all NEU neurons had ER+PR, a few were NEU or had ER only, but no neurons had PR alone. Lateral to the SON, all NEU neurons had ER but not PR. In the *paraventricular nucleus* (PVN), ER neurons >> NEU+ER (half also had cytoplasmic ER), while very few were NEU+PR or had PR alone. Dorsal to PVN, NEU neurons >> NEU+PR or PR neurons, while ventral to PVN, the three groups appeared equal. In the anterior *periventricular zone* (PVZ), all NEU neurons had ER+PR. In the more posterior PVZ, all NEU neurons had PR and most had ER, but ventrally half were NEU+ER and half had ER alone. In the *arcuate* (ARC) region and adjacent PVZ, virtually all NEU neurons had PR. In the *premamillary* PVZ, ER neurons >> NEU neurons, but laterally the few NEU neurons all had ER. Our data indicate that in pubertal female monkeys, nearly all NEU neurons in the SON express ER+PR, most in the PVN express ER, and all in the ARC express PR. In the PVZ anteriorly, NEU neurons express PR+ER, posteriorly, PR, and more laterally, ER. This expression of ER/PR in NEU and related neurons correlates with changes in neural control of hormone secretion occurring at puberty. Supported by HD10907 and HD11979.

## 405.3

A "WINDOW" FOR THYROID HORMONE ACTION IN REGULATING SEASONAL REPRODUCTION IN SHEEP L.A. Thrun, G. E. Dahl and E. J. Karsch\*. Repro. Sci. Prog., Dept. of Biology, and Dept. of Physiol., Univ. of Michigan, Ann Arbor, MI 48109.

Thyroid hormones are essential for the neuroendocrine changes that lead to anestrus in the ewe. Previous studies involving thyroidectomy and timed thyroxine (T4) replacement suggest that thyroid hormones only need to be present late in the breeding season for anestrus to develop. This study tested the hypothesis that there is a limited "window" of time, late in the breeding season, when thyroid hormones must be present for progression of the neuroendocrine changes that lead to anestrus. Two approaches were used: 1) ewes were thyroidectomized (THX) late in the breeding season (mid-Dec.), just prior to the postulated "window" and 2) groups of 6-7 ewes were THX early in the breeding season (Oct.) and later received a physiological replacement of T4 at selected times during the hypothesized "window" (Jan.-Mar., either 30 or 90 days treatment). The effect of these treatments on anestrus was determined by monitoring changes in reproductive neuroendocrine activity. For this purpose, ewes were ovariectomized and received estradiol implants. In this animal model, serum LH decreases 10-20 fold marking the onset of anestrus. Serum levels of LH and total T4 were monitored in twice weekly samples. In the first approach (THX just prior to the postulated "window"), LH remained elevated well beyond the natural transition to anestrus, indicating that ewes were deprived of thyroid hormones during a time critical to development of anestrus. In the second approach (THX early in the breeding season followed by selected timed T4 replacement), LH remained elevated in ewes given 30 days of T4 during the hypothesized "window." In contrast, LH fell around day 80 in 5 of 7 ewes receiving the 90-day T4 replacement, indicating that thyroid hormones during this period were sufficient for development of anestrus. We conclude, therefore, that thyroid hormones influence seasonal changes in reproduction in the ewe only during a restricted "window" of about 80 days late in the breeding season to promote the neuroendocrine changes that lead to anestrus. (Supported by NIH HD18337 and MH10506; USDA 37203-0760).

## 405.5

FSH SECRETION FROM PERFUSED OVINE PITUITARY CELLS CHANGES MARKEDLY WITH CHANGING INHIBIN / ACTIVIN TONE. Yasanthia Padmanabhan\*, Judy Van Cleeff, Paul A. Favreau, and A. Rees Midgley Jr. Department of Pediatrics and the Reproductive Sciences Program, University of Michigan, Ann Arbor, MI 48109.

Previous studies with dispersed ovine anterior pituitary cells have shown that i) pituitary FSH secretion remains elevated or increases with time during long-term perfusion, ii) activin (A) potentiates FSH release minimally (~20%), iii) follistatin (F) suppresses FSH release, and iv) F pretreatment markedly enhances subsequent FSH responses to A (Padmanabhan et al., 77th Annual Meetings of the Endocrine Society, 1995, Washington DC). Because F is an A-binding protein, we postulated that the suppressive effects of F on FSH secretion are mediated via blockade of endogenous pituitary A action. If this were true, by virtue of inhibin (I)'s ability to compete for A receptor, the effects of I on FSH secretion should be similar to that seen with F. Two million ovine anterior pituitary cells were loaded immediately after dispersion into each of four, micro-perfusion chambers along with SoloHill glass-coated microcarrier beads and perfused at a flow rate of 35 mL/min. Hourly pulses of GnRH (1 nM for 4 min) were administered throughout the course of the study by means of computer-driven syringe pumps. The experimental paradigm consisted sequentially of 16h stabilization, 4h baseline, 20h I pre-treatment and 24h treatment (medium control, I, A or A+I). Recombinant human I (10 ng/ml) decreased FSH secretion ~30%. Removal of I during treatment caused FSH to rebound to values approximating initial baseline secretion. Activin (10 ng/ml) increased FSH secretion markedly (~2-fold), and this stimulatory effect was blocked by I co-treatment. These results suggest that: i) suppressive effects of I, like F, may be mediated via blockade of endogenous pituitary A action and ii) changes in pituitary A and I tone may be major contributing factors in the control of FSH secretion. Supported by NIH grants U54 HD 29184 & P30 HD 18258.

## 405.7

ROLE OF GONADAL STEROID INDUCED CHANGES IN VENTROMEDIAL NUCLEUS OXYTOCIN RECEPTORS IN THE PREOVULATORY LH SURGE IN THE CYCLING FEMALE RAT. C. A. Johnston\*, J. Gelineau-van Waas and V. Hardy. School of Pharmacy, Univ. of Montana, Missoula, MT 59812-1075.

Central oxytocin (OT) plays a physiologically important, stimulatory role in the expression of the preovulatory LH surge which is highly dependent on changes in plasma gonadal steroids (Neurosci. Lett. 120: 256, 1990). We have recently demonstrated changes in OT receptor mRNA expression in the ventromedial hypothalamic nucleus (VMN) throughout the estrous cycle which correlate temporally with the ability of centrally administered OT to stimulate LH secretion (Bale et al., J. Neurosci., In Press). The present study evaluated the physiological relevance of the changes in VMN OT receptor expression on the preovulatory LH surge by administering 200 ng/ul antisense oligonucleotide to the OT receptor into the VMN via stereotactically placed, bilateral, 26 gauge stainless steel cannulae in order to determine whether preventing synthesis of OT receptors in the VMN on proestrus prevents the LH surge. The preliminary data suggest that changes in OT receptor expression in the VMN may be critical to OT's stimulatory influence on plasma LH. This work was supported by NIH grant, MH48228.

## 405.4

CIRCULATING INHIBIN CONCENTRATIONS INCREASE PRIOR TO THE DECLINE IN PERIPHERAL FSH LEVELS IN SHORT PHOTOPERIOD-EXPOSED FEMALE SYRIAN HAMSTERS. M. E. McAssey and B. Benson\*. Dept. of Cell Biology and Anatomy, The University of Arizona, Tucson, AZ 85724

Female hamsters transferred from long photoperiod (LP) to short photoperiod (SP) exhibit a decline in circulating FSH concentrations and cessation of estrous cyclicity. Because inhibin may regulate FSH synthesis and secretion and hence follicle recruitment and maturation, we hypothesized that inhibin contributes to the suppression of serum levels of FSH during SP exposure and the onset of anestrus. Adult LSH/SsLak hamsters were maintained in LP (L14:D10 h) and monitored for regular four-day estrous cycles. Hamsters were transferred to SP (L8:D16 h) on estrus and groups of animals killed by rapid decapitation at either 1600 h on proestrus or 0800 h on estrus during each of five consecutive estrous cycles after transfer; groups of LP control animals were killed at comparable times. Additionally, groups of anestrus females were killed at 0800 or 1600 h 12 days after the last observed estrous discharge. One ovary from each animal was used for inhibin RIA; contralateral ovaries were reserved for inhibin mRNA analysis or processed for morphometry. Compared to estrous LP controls, serum FSH levels increased significantly ( $p < 0.05$ ) during the first two cycles in SP then declined to concentrations that, at the fifth cycle of SP, were significantly ( $p < 0.05$ ) lower than control values. Serum inhibin levels increased significantly by the third SP estrous cycle and remained elevated in anestrus animals. Regression analysis revealed an inverse correlation between serum inhibin and FSH levels on estrus ( $p < 0.001$ ) but not on proestrus. Ovarian inhibin concentrations were significantly ( $p < 0.05$ ) decreased only in ovaries from anestrus females when compared to those of LP controls. Relative levels of inhibin  $\alpha$ - and  $\beta$ A-subunit mRNAs were lower in ovaries from SP proestrus and anestrus females when compared to those from proestrus LP controls, but elevated in ovaries from SP estrous and anestrus females when compared to those from estrous LP controls. The absence of antral follicles on estrus in the last two cycles of SP suggests that the increase in circulating inhibin and inhibin mRNAs is not from antral follicles which failed to ovulate but may be derived from the hyperplastic interstitium. The inverse relationship observed between inhibin and FSH suggests that inhibin may exert a regulatory role in suppressing FSH concentrations during SP-induced anestrus in hamsters. Supported in part by NIH grant #HD19521.

## 405.6

THE IN-VIVO RELEASE OF NOREPINEPHRINE IN THE MEDIAL PREOPTIC AREA OF STEROID-PRIMED OVARIECTOMIZED RATS Sheba M. J. MohanKumar, P. S. MohanKumar, Deryl L. Trover\*, and S. K. Quadri, Department of Anatomy and Physiology, Kansas State University, Manhattan, KS 66506.

The afternoon of proestrus in young rats is marked by a surge in the release of luteinizing hormone (LH). This change in LH release is believed to be under the control of neurotransmitters, particularly the hypothalamic catecholamines. Norepinephrine (NE) is generally believed to have a stimulatory role in LH secretion. Recently we reported that, concomitant with the LH surge, NE release increases progressively during the afternoon of proestrus. The purpose of the present study was to investigate if a similar change in NE release accompanies the LH surge in steroid-primed ovariectomized rats. Female Sprague-Dawley rats (4-5 months) were implanted with a push-pull cannula in the medial preoptic area and ovariectomized bilaterally. On the seventh day after ovariectomy, they were injected with estrogen (30  $\mu$ g/100  $\mu$ l oil; s.c.) at 1000 hrs. On the ninth day they were injected with progesterone (2 mg/100  $\mu$ l oil; s.c.) at 1000 hrs and subjected to push-pull perfusion. Perfusate samples were collected at the rate of 10  $\mu$ l/min every 30 min from 1130-1730 hrs. They were analyzed for NE concentrations using high performance liquid chromatography with electrochemical detection. NE release was  $6.9 \pm 1.4$  pg/min at 1430 hrs but increased significantly ( $p < 0.05$ ) to  $16.2 \pm 3.9$  pg/min at about the time of the LH surge (1630 hrs) and then declined to  $12.0 \pm 1.9$  pg/min at 1730 hrs. It is concluded that this increase in NE release plays a role in bringing about the surge in LH in estrogen and progesterone primed ovariectomized rats.

$\alpha_1$ -ADRENERGIC RECEPTORS MEDIATE INOSITOL PHOSPHATE METABOLISM, AND PROSTAGLANDIN  $E_2$  AND LHRH SECRETION FROM IMMORTALIZED HYPOTHALAMIC NEURONS. S.M. Kreda<sup>1</sup>, M.T. Sumner<sup>1</sup>, S. Fillo<sup>1</sup>, S.B. Shears<sup>1</sup>, S. Collins<sup>2</sup> and W.C. Wetzel<sup>1</sup>, <sup>1</sup>Lab. of Cell. and Mol. Pharm., NIEHS, Research Triangle Park, NC 27709, and <sup>2</sup>Dept. of Psychiatry, Duke Univ. Med. Ctr., Durham, NC 27710.

Activation of  $\alpha_1$ -adrenoceptors ( $\alpha_1$ ARs) stimulates LHRH secretion *in vitro* and LH secretion *in vivo*. The purpose of the present study was to determine whether immortalized hypothalamic LHRH neurons (GT1 cells) possess  $\alpha_1$ ARs, which second messenger pathways are stimulated by these receptors, and whether activation of these  $\alpha_1$ ARs affects LHRH secretion. Ligand binding studies with [<sup>125</sup>I]-HEAT and WB4101 or ( $\pm$ )-niguldipine revealed that the GT1 cells contain two populations of receptors which correspond to the  $\alpha_{1A}$  (23%) and  $\alpha_{1B}$  (77%) subtypes. Northern blots confirmed that these neurons contain transcripts for the  $\alpha_{1A}$  and  $\alpha_{1B}$  receptors. Activation of  $\alpha_1$ ARs with phenylephrine or with norepinephrine in the presence of a  $\beta$ -blocker (1-alprenolol) stimulated inositol phosphate production, and prostaglandin  $E_2$  and LHRH secretion in a dose-dependent manner. These data suggest that LHRH neurons *in situ* may contain several different  $\alpha_1$ AR subtypes, that  $\alpha_1$ AR activation is coupled to two different intracellular signaling pathways, and that these actions may regulate LHRH secretion.

## 405.9

THE ROLE OF  $Ca^{2+}$  IN PULSATILE RELEASE OF LHRH FROM CULTURED LHRH NEURONS DERIVED FROM EMBRYONIC OLFACTORY PLACODE OF THE RHESUS MONKEY. K.L. Keen, P. Claude, L.L. Luchansky, and E. Terasawa. Wisconsin Regional Primate Research Center & Neuroscience Training Program, University Wisconsin, Madison, WI 53715

In a previous study we have reported that cultured LHRH neurons derived from the olfactory placode of monkey embryos release LHRH into media in a pulsatile manner at approx. 50 min intervals (Neuroscience Abst. 272.4, 1994). To further study the mechanism of LHRH pulse generation, in this experiment we have examined the role of calcium and the LHRH agonist, Des-Gly<sup>10</sup>, (D-Ala<sup>6</sup>)-LHRH Ethylamide, in LHRH release. The olfactory placode and the migratory pathway of LHRH neurons from monkey embryos at E35-37 were dissected out and cultured on collagen-coated coverslips in a growth medium. Two to four weeks later coverslips with cultured cells were mounted in Sykes-Moore chambers and perfused with a Krebs-Ringer phosphate buffer solution containing BSA and glucose (pH=7.4). Perfusates were collected in 10-min fractions for 5-6 h and LHRH was measured by RIA. After the perfusion experiment, cells were fixed and immunostained for LHRH and neuron-specific enolase. LHRH cells released the decapeptide hormone in a pulsatile manner at the interpulse interval  $47.3 \pm 3.5$  min (N=18). LHRH release from cultured LHRH cells was stimulated by  $1 \mu M$  Bay K 8644 as well as 30 and 56 mM  $K^+$ , while it was suppressed by  $1 \mu M$  nifedipine. Exposing the cells to a low  $Ca^{2+}$  (10 nM) buffer solution suppressed LHRH release after  $117 \pm 29$  min (N=11). Finally, the LHRH agonist at 10 nM consistently stimulated LHRH release. These results suggest that 1) release of LHRH is influenced by the state of  $Ca^{2+}$  channels, and the presence of extracellular  $Ca^{2+}$  is necessary for LHRH pulsatility, although intracellular mobilization of  $Ca^{2+}$  may be able to maintain the pulsatile release of LHRH for a short time, and that 2) LHRH itself may modify its pulsatility in these neurons, as shown in GT-1 cells. We are currently examining how intracellular  $Ca^{2+}$  oscillations correlate with the pulsatility of LHRH release. (Supported by NIH grants, HD15433, HD11355 & RR00167).

## 405.11

AMPLIFIED LH SECRETORY BURST FREQUENCY WITH SELECTIVE ATTENUATION OF PULSATILE (BUT NOT BASAL) TESTOSTERONE SECRETION IN HEALTHY OLDER MEN: POSSIBLE LEYDIG CELL DESENSITIZATION TO ENDOGENOUS LH SIGNALING. T. Mulligan,<sup>1</sup> A. Iranmanesh,<sup>2</sup> S. Gheorghiu,<sup>1</sup> M. Godschalk,<sup>1</sup> S. Pincus,<sup>3</sup> J.D. Veldhuis.<sup>4</sup> Hunter Holmes McGuire VA MC, Richmond, VA 23249, <sup>2</sup>Salem VA MC, Salem, VA 24153, <sup>3</sup>990 Moose Hill RD, Guilford, CT 06437, and <sup>4</sup>Div Endocrinology, Univ of Virginia, Charlottesville, VA 22908.

The specific mechanisms underlying the relative hypogonadism of aging remain to be elucidated fully. We used frequent venous sampling (every 2.5 min), sensitive and specific LH and testosterone assays, and deconvolution analysis (*Proc.Natl.Acad.Sci.* 84:7686, 1987) of the LH time series to assess overnight LH and testosterone (T) secretion in healthy young (N = 10, ages 21-34 years) and older (N = 8, ages 62-74 years) men. Elderly men had more frequent bursts of LH secretion (1.4 vs 0.9 per hr, P = 0.003), less T secreted per burst (265 vs 490 ng/dL, P = 0.021), and per hour (308 vs 721 ng/dL/hr, P = 0.05). Basal T secretion was similar. The frequency of LH and T secretory bursts correlated inversely (R = -0.746, P = 0.034). An approximate entropy (ApEn) statistic (*Proc.Natl.Acad.Sci.* 88:2297, 1991) was used as a scale-invariant measure of the orderliness of LH and T release. ApEn values for LH in older men ( $1.50 \pm 0.12$ ) were significantly higher (P = 0.0008, rank-sum) than those in young ( $1.17 \pm 0.21$ ), which indicates greater process randomness in LH secretion. We conclude that healthy aging in men is associated with: (i) diminished T production due to a decrement in the mass of T released per burst; (ii) an attenuated ability of the gonad to augment T production despite an accelerated LH secretory pulse frequency, suggesting partial desensitization of Leydig cells to available LH; and (iii) increased process irregularity in the time-structure of LH release.

## 406.1

SPROUTING OF ENDPLATES IN TRANSGENIC ANIMALS CONSTITUTIVELY EXPRESSING NCAM IN SKELETAL MUSCLE M.S.Fazeli\*, C. Hobbs, D.J.Wells, and E.S.Walsh. Exp. Path., UMDS, Guy's Hosp. & Dept. Basic Vet Sci., Royal Vet. Coll., London, U.K.

The neuromuscular junction is a versatile model system for the analysis of the role of cell adhesion molecules in synapse formation and plasticity. Neural cell adhesion molecule (NCAM) has been postulated to play an important role during the development and regeneration of the neuromuscular system. We have generated animals expressing the lipid-anchored isoform of human NCAM (125kD) under the control of skeletal muscle specific  $\alpha$ -actin promoter. Examination of the EDL of transgenic mice revealed a significant number of endplates with fine terminal and nodal sprouts (21% compared with 1.17% in the non-transgenic littermates;  $16.23 \mu m \pm 1.35$ ). Sprouting in the soleus muscle was also noted, however this was at a lower rate than in the EDL. A significant number of nerve terminals in the EDL displayed an altered morphology, with most terminal branches ending in conspicuous enlargements. Nerve terminals in both the soleus and EDL of transgenic mice displayed an increased arborization, as indicated by an increase in the number of branch points from  $2.82 \pm 0.21$  to  $4.25 \pm 0.13$  in the soleus. Endplate size was also increased in the Soleus and EDL by 30.5% and 50.7% respectively, compared with littermates. At the ultrastructural level, junctions in transgenic animals displayed an increase in the number of postsynaptic folds ( $8.7 \pm 0.52$  compared with  $6.85 \pm 0.57$ ). The number of terminals with greater than 7 folds increased from 35% in the non-transgenic animals to 76% in the transgenics. The cross sectional area of the nerve terminal in these junctions was not significantly altered. Botulinum toxin induced paralysis of the EDL of transgenic animals resulted in terminal sprouts that were 67% longer than those in non-transgenic animals. Our observations indicate a role for NCAM in the development of neuromuscular junctions.

## 405.10

DOPAMINE INCREASES TRANSFORMING GROWTH FACTOR- $\beta$ 1 SYNTHESIS AND SECRETION IN THE ANTERIOR PITUITARY GLAND. D.K. Sarkar\*, M. Pastorcic, A. De and N. Boyadjieva. Department of Veterinary and Comparative Anatomy, Pharmacology and Physiology, Washington State University, Pullman, WA 99164-6520.

We have previously shown that transforming growth factor  $\beta$ 1 (TGF $\beta$ 1) is produced and secreted from the lactotrophs of the anterior pituitary gland, and controls prolactin secretion and lactotropic growth. Since dopamine is known to be a physiological regulator of lactotropic function, we determined the action of dopamine and its agonist bromocriptine on TGF $\beta$ 1 synthesis and secretion. Determination of dopamine action on PRL and TGF $\beta$ 1 secretion from anterior pituitary cells in primary cultures revealed that dopamine concentration-dependently inhibited PRL secretion but stimulated TGF $\beta$ 1 secretion from these cells. When these cultured cells were treated with bromocriptine in the presence of estrogen, this dopamine agonist also stimulated TGF $\beta$ 1 secretion. In addition, bromocriptine increased TGF $\beta$ 1 mRNA levels in cultures in the presence of estrogen. Determination of bromocriptine action on TGF $\beta$ 1 protein and mRNA levels in the pituitary of estrogen-primed ovariectomized rats indicated that the agonist increased anterior pituitary content of TGF $\beta$ 1 protein and mRNA. These data suggest that dopamine and TGF $\beta$ 1 may interact to control lactotropic function. Supported by the National Institutes of Health Grant CA 56056.

## 406.2

SELECTIVE INTERACTION BETWEEN SRC-FAMILY TYROSINE KINASES AND NEURAL CELL ADHESION MOLECULES. P.F. Maness\*, S.G. Klinz, H.E. Beggs and W.R. Morse. Dept. of Biochemistry, UNC Chapel Hill School of Medicine, Chapel Hill, NC 27599-7260.

Members of the src-family of tyrosine kinases participate in neural cell adhesion molecule (CAM) mediated neurite outgrowth. Specifically, L1-dependent neurite outgrowth is mediated by the *c-src* gene product (pp60<sup>c-src</sup>), whereas NCAM-dependent neurite outgrowth is mediated by the *fyn*-protein (p59<sup>fyn</sup>). To elucidate the molecular basis for this selectivity we investigated interactions among neural CAMs and src-family kinases.

Physical association between pp60<sup>c-src</sup> and L1 in growth cone-enriched membranes from fetal (E18) rat brain was demonstrated by coimmunoprecipitation from Brij96-solubilized extracts. This interaction was specific as pp60<sup>c-src</sup> was not observed in immunoprecipitates with NCAM antibodies. However, overexpression of pp60<sup>c-src</sup> and L1 in transiently transfected COS cells did not result in detectable levels of association, indicating that their interaction in growth cones may involve an additional neuronal molecule. In contrast, overexpression of p59<sup>fyn</sup> and NCAM in transfected COS cells did result in an association demonstrated by coimmunoprecipitation. The physiological relevance of these findings was underlined by *in vivo* immunostaining that revealed L1 and pp60<sup>c-src</sup> and NCAM and p59<sup>fyn</sup> coexpression on primary olfactory axons during axonogenesis in the mouse embryo (E11).

A principal substrate for pp60<sup>c-src</sup> in growth cones is tubulin. We also demonstrate that tyrosine phosphorylation of tubulin in a fetal rat brain cytosolic extract influences the dynamics of microtubule assembly, suggesting that CAM-src kinase interactions regulate cytoskeletal properties affecting axonal outgrowth.

## 406.3

**FOCAL ADHESION KINASE (PP125<sup>FAK</sup>) IS TYROSINE PHOSPHORYLATED DURING THE INITIAL FORMATION OF NEURITES ON LAMININ.** P.S. Leventhal\* and E.L. Feldman, Dept. of Neurology, University of Michigan, Ann Arbor, MI 48109-0688

In SH-SY5Y human neuroblastoma cells, an *in vitro* model of neuronal growth and differentiation, adhesion to laminin (LN) induces rapid neurite outgrowth (NTO). This has previously been shown to correspond to tyrosine phosphorylation of pp125<sup>FAK</sup>, although the role of this protein is not clear. We found that adhesion of SH-SY5Y cells to LN-coated tissue culture plates resulted in tyrosine phosphorylation of pp125<sup>FAK</sup> before there was measurable NTO. Tyrosine phosphorylation of pp125<sup>FAK</sup> was maximal as the rate of neurite formation peaked, but phosphorylation of pp125<sup>FAK</sup> decreased thereafter, even as the neurites continued to lengthen. Colchicine, which eliminates elongation but not formation of neurites on LN, had no effect on the stimulation of pp125<sup>FAK</sup> phosphorylation. Finally, cytochalasin D inhibited LN-stimulated tyrosine phosphorylation of pp125<sup>FAK</sup> at levels that prevent initial neurite formation. These results suggest that the tyrosine phosphorylation of pp125<sup>FAK</sup> is related to changes in the actin cytoskeleton that occur during initial neurite formation and that its phosphorylation is not directly associated with the elongation of neurites.

## 406.5

**GROWTH CONES AND FIBROBLASTS EXHIBIT SUBSTRATE PREFERENCE IN THE ABSENCE OF DIFFERENTIAL ADHESION**

A. Soekarno\*, B. Lom, and P. E. Hockberger\*<sup>#</sup> Inst. for Neuroscience and <sup>#</sup>Dept. of Physiology, Northwestern Univ. Med. Sch., Chicago, IL, 60611.

The guidance of cells to distant locations is an important process during development of organisms as well as throughout adulthood. Growth cones, for example, must find and form synapses with distant neurons for proper functioning of the nervous system. Following injury, the normally stationary fibroblasts migrate to the wound site to aid in the healing process. The mechanism by which these cells are guided, however, is still poorly understood. An influential model suggests that cells and growth cones are guided by "differential adhesion" whereby guidance is mediated by either the most or least adhesive surface. The role of differential adhesion in substrate preference was examined using a combination of patterned substrates and interference reflection microscopy (IRM). N1E-115 neuroblastoma growth cones and 3T3 fibroblasts exhibited preferences for laminin and fibronectin, respectively, over amine, and amine over alkane. A quantitative analysis of cell-substrate adhesion was developed using digital image processing techniques and correlative immunofluorescence microscopy. The results revealed that substrate preference was not correlated with substrate adhesivity. Further, the adhesion profiles on the preferred and non-preferred substrates were indistinguishable, showing that differential adhesion did not mediate preference on patterned substrates. Moreover, the adhesion profiles as well as the general cell morphology and cytoskeletal organization were determined by the context in which the chemicals were presented, i.e., singly or alongside another. These results are, therefore, consistent with the notion that substrate preference and guidance may be mediated by some signal transduction mechanism.

This research was supported by a grant from The Whitaker Foundation.

## 406.7

**DISTINCT TENASCIN-C DOMAINS INFLUENCE NEURON ADHESION, NEURON REPULSION AND PROMOTION OF NEURITE OUTGROWTH.** A. Faissner\*, A. Scholze, A. Clement, A. Joester, K. Schütte, F. Wigger, R. Frank<sup>2</sup>, P. Ekblom<sup>3</sup> and B. Götz, Department of Neurobiology, INF 364,

<sup>2</sup>Center of Molecular Biology (ZMBH), INF 282, University of Heidelberg, D-69120 Heidelberg, Germany, <sup>3</sup>Department of Animal Physiology, Uppsala University Biomedical Center, S-75124 Uppsala, Sweden.

The glia-derived extracellular matrix protein tenascin (TN-C) exhibits modular structure with aminoterminal EGF type-1 followed by fibronectin type III (FN III)-repeats and homologies to fibrinogen  $\beta$  and  $\gamma$  at the carboxyterminus. Isoforms are distinguished by alternatively spliced FN III motifs between FN III repeats 5 and 6 of the basic structure. Functionally, TN-C promotes neuron-astrocyte adhesion, neuron migration and neurite extension. On the other hand, the glycoprotein displays repulsive properties for some neurons and their growth cones. Antibody perturbation studies suggest that these functions are encoded by distinct sites on TN-C. In order to characterize these further, bacterially expressed fusion proteins were generated to map domains adhesive, counteradhesive and neurite outgrowth promoting for neuronal cells. In short term (1 hour) assays, several recombinant proteins proved adhesive for postnatal day 6 (P6) cerebellar and embryonic day 18 (E18) hippocampal neurons, but only TNfn1-3 supported the development of a monolayer of cerebellar neurons within 24 hours. In contrast, TNegf and the alternatively spliced segment TNfnA1,A2,A4 exposed on patterned substrates displayed repulsive properties for both types of neurons and for growth cones leaving P6 cerebellar explants. Finally, neurite outgrowth promoting properties for E18 hippocampal neurons and P1 DRG explants could be attributed to TNfnB,D, TNfnD,6 and TNfn6, a region centered around the distal splice site of TN-C. The functional properties of isoform-specific FNIII variants indicate functional relevance of the alternative splicing of TN-C. Supported by DFG (SFB 317/A2 and Graduiertenkolleg).

## 406.4

**POSTTRANSCRIPTIONAL REGULATION OF LAMININ RECEPTORS IN SENSORY NEURONS IS DETERMINED BY LIGAND CONCENTRATION.** M. L. Condic\*, and P. C. Letourneau, Cell Biology and Neuroanatomy, University of Minnesota, Minneapolis, MN 55455.

Neurons are able to extend axons on Laminin (LM) absorbed to the substratum over a wide range of concentrations. This is somewhat surprising, in that LM is known to be an adhesive extracellular matrix molecule, and most cells need to maintain a precise balance between cell-substratum adhesion and deadhesion in order to remain motile. The most likely explanation for the ability of neurons to extend processes on a wide range of LM concentrations is that the levels of extracellular LM a growth cone encounters can induce a compensatory regulation of LM receptors (LM-Rs), such that high levels of LM cause a decrease in the amount of LM-R expressed (to prevent excessive adhesion to the substratum), and low levels of LM increase the expression of LM-R (to maintain cell motility).

We have examined the RNA and protein levels for two LM-Rs,  $\alpha 6$  and  $\alpha 3$  integrin. Dorsal root ganglia neurons from E12 chick embryos were dissociated and cultured on glass coverslips coated with either Hi- or Lo-LM (20 or 1  $\mu$ g/ml). Quantitation of the absorbance of LM using 3H-labeled LM indicated that there was a ten-fold difference in the concentration of bound LM between the two conditions. Neurons extend axons under both conditions. Overnight cultures were either processed *in situ* for RNA, or total cellular proteins were metabolically labeled and cell surface proteins were biotinylated prior to extraction for immunoprecipitation. Surprisingly, the levels of LM-R RNA were consistently lower in cells cultured on Lo-LM relative to those grown on Hi-LM (~60%). However, the amount of LM-R expressed at the cell surface was on average 3.4 fold greater in cells grown on Lo-LM. Total cellular integrin  $\alpha 6$  protein was approximately equal in the two conditions. Controls cultured on Fibronectin showed RNA and protein levels similar to those seen on Hi-LM. These results suggest that LM regulates its own receptor, both at the level of translation and posttranslationally through an effect on protein stability or transport to the surface.

## 406.6

**MECHANISMS OF INTRARETINAL AXON GUIDANCE.** B. Schlosshauer\* and H. Stier, Naturwissenschaftliches und Medizinisches Institut an der Universität Tübingen (NMI), 72762 Reutlingen, FRG.

During development ganglion cell axons are guided into the inner optic fiber layer (OFL) by a dual mechanism. Using tissue explants on retinal cryosections, we have shown that in the OFL endfeet of radial glia/neuroepithelial cells provide a permissive substratum, whereas outer retina layers are inhibitory (Development, 121 (1995)). Similarly, isolated endfeet used as substratum *in vitro*, are permissive in contrast to cell somata of radial glia purified by complement mediated cell lysis. Axonal outgrowth on glial somata is smaller by 2 orders of magnitude compared with glial endfeet. In addition, scanning electron microscopy shows axons to grow in a highly fasciculated manner avoiding contact with glial cell somata. When outgrowing axons approach outer layers of retinal cryosections, growth cone collapses are induced. Exposure of axon tips to purified retinal membrane fractions yields similar results as shown by time lapse video recording. In both cases the collapse inducing activity can be inactivated by heat denaturation. Because radial glia appears to be a likely candidate, cytoplasmic membranes are currently enriched from purified glial cells for collapse assays. In control experiments, cytoplasmic membranes from the synaptic target region (tectum opticum) of retinal ganglion cell axons do not significantly induce growth cone collapses. The biochemical characterization of the inhibitory activity is under way.

The data suggest that radial glia/neuroepithelial cells are instructive in guiding ganglion cell axons. Radial cells appear to be polarized having permissive endfeet and inhibitory somata which affect axon growth differentially. Supported by DFG.

## 406.8

**SOLUBLE CHONDROITIN SULFATE PROTEOGLYCAN REDUCES DORSAL ROOT GANGLION NEURITE LENGTH AND RATE OF ELONGATION ON FIBRONECTIN, BUT NOT ON LAMININ, BY BINDING DIRECTLY TO GROWTH CONES.** D.M. Snow\*, E.M. Brown, and P.C. Letourneau, The University of Minnesota, Cell Biology and Neuroanatomy, Minneapolis, MN 55455.

Chondroitin sulfate proteoglycan (CSPG) is a complex macromolecule having a wide variety of effects on neurons *in vivo* and *in vitro*. Studies on CSPG function have involved the use of both soluble and substratum-bound forms. Therefore, this study examined whether soluble CSPG influenced neurite outgrowth differently than substratum-bound CSPG. Previous reports (Snow et al., 1990, Exp. Neurol. 109:111; Snow et al., 1994, Dev. Biol., 106:87), showed that bound, but not soluble, CSPG inhibited neurite outgrowth, and induced the elevation of intracellular calcium in neurons grown on laminin (LN). A further report (Snow, D.M., 1994, ASCB Abst. 364a) showed that the addition of soluble CSPG at physiological concentrations had little effect on the attachment of dorsal root ganglion neurons (DRGs), or on their filopodial lifespan or length, when DRGs were grown on fibronectin (FN) or laminin. Interestingly, however, soluble CSPG reduced neurite length of DRG neurons grown on FN, but not on LN.

In the present study, we grew DRGs on either of two FN peptides, CS-1 (Humphries et al., 1987, J. Biol. Chem. 262:6886), or recombinant 9.5GST (Maejine, A. et al., *in prep.*), both of which permit DRG attachment and outgrowth, but do not bind CSPG, and compared neuronal behavior to DRGs grown on intact FN. Our results suggest that: 1) soluble CSPG reduces neurite outgrowth on FN or FN peptides up to 80%, and reduces elongation rate on FN up to 50%, and 2) soluble CSPG regulates neuronal behavior by binding directly to growth cones elongating on FN. Therefore, CSPG may affect growth cone behavior by either binding to the substratum, i.e. LN, or by binding directly to growth cones and not the substratum ligand, i.e. FN. Supported by NIH grant EY10545 to DMS, and HD19950 to PCL.

## 406.9

ENDOGENOUS CHONDROITIN SULFATE MODULATES LAMINAR-DEPENDENT INTERACTIONS OF THALAMIC NEURONS WITH CULTURED SLICES OF DEVELOPING CEREBRAL NEOCORTEX. D. E. Emerling\* & A. D. Lander, Dept. of Brain and Cognitive Sciences, Massachusetts Institute of Technology, Cambridge, MA 02139.

In the embryonic mouse brain, thalamic axons extend within the intermediate zone (IZ) and subplate (SP) layers of the cerebral cortex but do not enter the adjacent cortical plate layer (CP) until the latter begins to differentiate, eventually becoming layers 2-6 in the adult. Previously, we found that dissociated, embryonic mouse thalamic neurons attach well to the IZ and SP of living, vibratome-cut slices of embryonic cerebral cortex, but attach poorly to the CP. On postnatal slices, attachment to the CP improves markedly. (Development 120, 2811-2822, 1994). We now find that treatment of embryonic cortical slices with chondroitinase ABC (which degrades chondroitin sulfate [CS]), causes the CP to support thalamic neuron attachment at levels comparable with the other layers. Interestingly, such treatment also causes the IZ and SP to become less permissive for attachment. Both effects are dose-dependent and correlate with the disappearance of CS-immunoreactivity. Treatment of slices with another glycosaminoglycan lyase, hyaluronidase, fails to produce any of the effects seen with chondroitinase. These results suggest that CS, within different cortical laminae, may contribute both to local inhibition and local promotion of neuronal adhesion and may thereby differentially regulate axon growth during development. Whether these actions result from direct effects of CS on neurons, or indirectly, via interactions of CS with other molecules in the neural environment is under investigation.

## 406.11

THE MURINE SEMAPHORINS: A DIVERSE GENE FAMILY ENCODING GROWTH CONE GUIDANCE CUES. A. W. Püschel, R. H. Adams and H. Betz\*, Abteilung Neurochemie, Max-Planck-Institut für Hirnforschung, Deutschordenstr. 46, D-60528 Frankfurt/Main, FRG.

During development vertebrate spinal sensory and motor axons navigate with remarkable specificity to their peripheral targets. Members of the semaphorin gene family have been proposed to act as growth cone guidance signals in vertebrates and invertebrates. To identify candidate molecules involved in axonal pathfinding during mouse embryogenesis we isolated cDNAs encoding seven new members of the semaphorin family (sema - G). Four subgroups can be distinguished by comparison of the murine semaphorins to known vertebrate and invertebrate sequences. In situ hybridization analysis shows that the murine semaphorin genes are differentially expressed in mesoderm and neuroectoderm before and during the time when axons select their pathways in the embryo (E9 - E15).

In explant cultures recombinant Sem D/collapsin converts a matrix permissive for axonal growth into one that is inhibitory for neurites of peripheral ganglia. Our data demonstrate that semaphorins may provide local signals to specify territories inaccessible for growing axons.

## 406.13

AXONAL GUIDANCE OF MOTOR NEURONS INVESTIGATED IN VIVO AND IN VITRO. S. Guthrie\*, A. Tucker and A. Pini\*, Division of Anatomy and Cell Biology, UMDS, Guy's Hospital, London SE1 9RT

+Department of Genetic and Biometry, UCL, Wolfson House, 4 Stephenson Way, London NW1 2HE

In the developing nervous system, motor axons grow away from the ventral midline floor plate, suggesting that the latter may be a source of repulsive axon guidance cues. Transplantation experiments in the chick hindbrain showed that motor axons diverted from their normal pathways to avoid grafted floor plates, often traversing abnormally long circuitous trajectories to reach exit points. When ventral explants of rat or chick hindbrain or rat spinal cord were co-cultured at a distance from floor plate explants within collagen gels, the outgrowth of motor axons was dramatically reduced from explant regions that faced the floor plate. Thus, the floor plate secretes diffusible repulsive cues, which may exclude motor axons from the midline during development. Chick hindbrain motor neurons showed increased axon outgrowth when cultured with cranial sensory ganglia, which are an intermediate target for some cranial motor neurons. This suggests that ganglia may provide a trophic influence for growing motor axons.

## 406.10

CHARACTERIZATION OF *C. ELEGANS* SEMAPHORIN I AND II. P. J. Roy, H. Zheng, A. Roach\*, and J. Culotti, Samuel Lunenfeld Research Institute, 600 University Ave., Toronto, On, M5G 1X5, Canada.

Semaphorins are a family of proteins implicated in nerve guidance, and are found in both invertebrates and vertebrates, as described by Kolodkin *et al.*, (1993 Cell 75, 1389-1399). Using *C. elegans*, we wish to understand how the semaphorins help guide axons to their proper targets. To this end, we have identified a *C. elegans* semaphorin cDNA fragment through degenerate PCR. By splicing a partial clone we isolated from a cDNA library together with one obtained from a *C. elegans* cDNA sequencing project (Waterston *et al.*, 1992 Nature Genet. 1, 114-123), we constructed a full length cDNA (2.7kb) which corresponds to the size on the mRNA on Northern blots. Ce-sema cDNA sequence analysis elucidated a signal sequence and a transmembrane domain, similar to the Semal class of semaphorins, hence the designation Ce-Semal. Ce-Semal was mapped to cosmid F14B11 on chromosome I. A 12.8 KB subclone of F14B11 contains most of the *Ce-sema* gene; it has sufficient promoter elements to drive the expression of Lac-Z in a defined set of cells, and has the entire Ce-Semal coding sequence and 3' UTR. *Ce-sema* maps within 80 KB to the left of *unc-54*. We are currently using the 12.8 KB subclone to try to rescue prospective mutants which lie to the left of *unc-54*.

3.8 KB of *Ce-sema* predicted promoter sequence was fused to both nuclear and cytoplasmic lac-Z reporter constructs. Preliminary staining analysis of several stable lines of animals with the reporter constructs shows lac-Z expression early in embryogenesis, and strong posterior hypodermal staining in early larval stages, which is decreasingly maintained into adulthood. Weak staining is also seen in the head, among other cells.

Y. Kohara's cDNA sequencing project (Kohara *et al.*, 1994, p.comm.) yielded a second *C. elegans* semaphorin cDNA fragment. In combination with Kohara's clone, we have generated and used a 5'RACE product to construct a full length cDNA (2.4KB), which matches the predicted size indicated by Northern analysis. Our sequence analysis revealed a signal sequence, and an IG domain, placing this protein within the second class of semaphorins, hence the designation Ce-SemII.

## 406.12

DECORIN IN THE DEVELOPING MOUSE NERVOUS SYSTEM: EXPRESSION IN THE FLOORPLATE, AND BINDING TO NETRIN-1. Litwack, E.D.\*, M.J. Galko, K. Danielson, M. Tessier-Lavigne, R.V. Jozzo, and A.D. Lander. <sup>1</sup>Dept. of Biology & Dept. of Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139. <sup>2</sup>Dept. of Anatomy, UCSF, San Francisco, CA 94143. <sup>3</sup>Dept. of Pathology and Cell Biology, Thomas Jefferson University, Philadelphia, PA 19107.

Decorin, a small extracellular matrix proteoglycan with a single chondroitin sulfate (CS) or dermatan sulfate (DS) chain, is a major component of several connective tissues, and binds via its core protein to collagen fibrils. Both *in situ* hybridization and immunohistochemistry revealed that decorin is also expressed in the developing central nervous system: Decorin mRNA and protein occur uniquely in and are present throughout the floorplate of E11 mouse neural tube, a midline structure important for the guidance of commissural axons. Since the floorplate has little obvious extracellular matrix, it seemed likely that decorin's function there might involve interactions with ligands other than collagens. The recently described protein netrin-1 is specifically expressed by the developing floorplate, and is a secreted chemoattractant for commissural axons. To test whether netrin-1 and decorin might interact, salt extracts of cells expressing epitope-tagged netrin-1 were passed over a column prepared from bovine skin decorin (gift of L. Rosenberg). Netrin-1 was retained and could be eluted with 1M NaCl. In contrast, no netrin-1 bound a BSA column. Affinity coelectrophoresis experiments indicate that netrin-1 binds decorin with an apparent  $K_d$  of 0.035  $\mu$ M, near the apparent  $K_d$  of netrin-1 for heparin (0.030  $\mu$ M). Neither CS nor DS bound netrin-1 as tightly (apparent  $K_{ds}$  of 2.2  $\mu$ M for bovine tracheal CS and 1.1  $\mu$ M for porcine skin DS). Consistent with this view, DS released from decorin by  $\beta$ -elimination showed no binding of netrin-1 (up to 0.5  $\mu$ M DS). The data suggest that decorin's core protein may bind netrin-1 directly, a hypothesis now being tested. The idea that netrin-1 binds to decorin in the developing nervous system raises the possibility that decorin may regulate the diffusibility of netrin-1, or influence its chemotropic effects on axons. HOMOSYNAPTIC LONG-TERM DEPRESSION OF *APLYSIA* SENSORIMOTOR SYNAPSES IN CELL CULTURE. X. Y. Lin\* and D. L. Glanzman. Dept. of Physiological Science, UCLA, Los Angeles, CA 90024.

Although synapses between sensory and motor neurons of *Aplysia* exhibit short-term depression in response to low-frequency presynaptic stimulation, long-term depression (LTD) of sensorimotor synapses in cell culture has not been demonstrated. Indeed, it has been reported (Montarolo et al., 1988) that in vitro *Aplysia* sensorimotor synapses lack the capacity for LTD due solely to homosynaptic activation. Based on this result, it was suggested that the long-lasting depression of sensorimotor synapses in the abdominal ganglion of *Aplysia* induced by repetitive stimulation of the siphon or branchial nerve—which is thought to play a role in long-term habituation of the defensive withdrawal reflex (Carew and Kandel, 1973)—is due to heterosynaptic inhibitory pathways recruited by nerve shock.

We have previously shown that sensorimotor synapses in cell culture can exhibit homosynaptic long-term potentiation (LTP) (Lin and Glanzman, 1993, 1994a, 1994b). Moreover, induction of this LTP appears to be mechanistically similar to induction of LTP of synapses in the CA1 region of the mammalian hippocampus. We therefore examined whether in vitro *Aplysia* sensorimotor synapses, like CA1 synapses, can exhibit homosynaptic LTD. To induce LTD of sensorimotor synapses in cell culture, we stimulated the sensory neuron at 2 Hz. Compared to control stimulation, the 2-Hz presynaptic stimulation produced significant LTD of the sensorimotor EPSP. The EPSPs in synapses which received 2-Hz stimulation were significantly smaller than the EPSPs in control synapses 90 min after the end of the experimental stimulation period ( $p < 0.02$ , Mann-Whitney  $U$  test). Because there were no interneurons in our cell cultures, these results demonstrate that *Aplysia* sensorimotor synapses can undergo LTD that is independent of heterosynaptic input. Future experiments will investigate whether the induction of homosynaptic LTD of sensorimotor synapses requires a postsynaptic rise in  $Ca^{2+}$  and activation of NMDA-related receptors.

## 407.3

ROLE OF ADENYLYL CYCLASE AND cAMP IN ASSOCIATIVE SYNAPTIC FACILITATION AT SENSORY NEURON SYNAPSES IN *APLYSIA*. T. W. Abrams\* and J. E. Galun. Department of Neuroscience, University of Pennsylvania, Phila., PA 19104-6018.

Activity-dependent facilitation has been proposed to result from enhancement by paired spike activity of the modulatory effects produced by facilitatory transmitter in the presynaptic SNs. Several cAMP-mediated effects of the facilitatory transmitter 5HT have been found to be enhanced when paired SN activity and  $Ca^{2+}$  influx immediately precede the arrival of 5HT.  $Ca^{2+}$ /CaM-sensitive cyclase is a candidate site of stimulus convergence since its properties would enable it to integrate two temporally paired stimuli,  $Ca^{2+}$  and 5HT, with optimal cyclase activation occurring when  $Ca^{2+}$  precedes 5HT. Murphy and Glanzman (1994) found  $Ca^{2+}$  elevation in the postsynaptic MN may be critical in triggering activity-dependent facilitation. To investigate the role of presynaptic cAMP in activity-dependent facilitation, we injected the competitive antagonist Rp-cAMPS into a SN soma. 30 min were allowed for diffusion of the inhibitor throughout the presynaptic processes. Associative synaptic facilitation was produced by pairing a 0.5 sec 10 Hz SN spike train with a 1 sec train of mantle nerve stimuli. 15 min after the end of 5 pairing trials, EPSPs from Rp-cAMPS-injected SNs were <35% of their pre-pairing amplitude. In contrast, at the 15 min posttest, EPSPs from control paired SNs were significantly facilitated. These results suggest that if an increase in postsynaptic  $Ca^{2+}$  is a necessary signal in the initiation of associative synaptic facilitation at these SN synapses, then there must be a trans-synaptic interaction between this postsynaptic signal and the presynaptic cAMP cascade.

## 407.5

PRELIMINARY EVIDENCE FOR SYNAPSE-SPECIFIC LONG-TERM FACILITATION AT CONNECTIONS OF *APLYSIA* SIPHON SENSORY NEURONS. C. M. Gooch\* and G. A. Clark. Program in Neuroscience, Department of Psychology, Princeton Univ., Princeton, NJ 08544.

Synapse-specific plasticity provides a potentially precise means of modifying neural pathways. Although short-term facilitation in *Aplysia* LE siphon sensory cells can be synapse-specific (Clark & Kandel, PNAS 81: 2577-2581, 1984), long-term facilitation (lasting  $\geq 24$  hr) requires protein synthesis and probably the modification of gene expression. To investigate whether long-term facilitation can also be synapse-specific, we recorded the intracellular monosynaptic excitatory synaptic potentials (EPSPs) evoked simultaneously in a central and peripheral motor neuron by stimulation of individual sensory cells. We then examined whether 1-hr, 40-min applications of 10-30  $\mu$ M serotonin (5-HT), restricted to either the central or peripheral synapses, could produce differential increases in synaptic strength at these two sites when tested 24 hours later. For each sensory cell in a preparation, difference scores were calculated by subtracting the amount of facilitation at peripheral synapses from the amount of facilitation at central synapses. We found that 5-HT application to the central synapses and soma of the sensory cell produced a greater increase in synaptic strength at central synapses than at peripheral ones, relative to effects of application of 5-HT restricted to peripheral synapses (all  $n$ s = 5,  $P < 0.05$ , one-tailed). In contrast, control applications of artificial seawater produced a difference score that was intermediate between the effects of central and peripheral 5-HT applications. These results provide preliminary evidence that long-term heterosynaptic facilitation may be in part synapse-specific.

## 407.2

THE NMDA RECEPTOR ANTAGONIST APV DISRUPTS THE CELLULAR ANALOGUE OF CLASSICAL CONDITIONING IN *APLYSIA*. G. G. Murphy\* and D. L. Glanzman. Interdepartmental Program in Neurosci., Sch. of Med., and Physiological Sci., UCLA Los Angeles, CA 90024.

Classical conditioning of the *Aplysia* siphon-withdrawal reflex (Carew et al. 1981, 1983) is generally thought to be due to a presynaptic mechanism—activity-dependent presynaptic facilitation of sensorimotor connections (Hawkins et al. 1983; Walters and Byrne, 1983). Recently, however, it has been found that, contrary to an earlier report (Carew et al., 1984), *Aplysia* sensorimotor synapses possess the capacity for Hebbian LTP (Lin and Glanzman, 1994). Furthermore, the induction of Hebbian LTP of sensorimotor synapses requires a rise in postsynaptic  $Ca^{2+}$  and activation of NMDA-related receptors.

To determine whether classical conditioning in *Aplysia*—like LTP of sensorimotor synapses—might involve activation of NMDA-related receptors, we utilized the cellular analogue of classical conditioning of siphon withdrawal (Hawkins et al., 1983). The preparation we used consisted of the CNS of *Aplysia* together with two posterior pedal nerves (P9) which connect the animal's tail to the CNS. During training brief activation of a siphon sensory neuron (the CS) was paired with strong shocks delivered to the pedal nerves (the US). Paired stimulation carried out in normal artificial seawater (ASW) produced significant enhancement of the monosynaptic sensorimotor EPSP measured 60 min after the end of training (mean EPSP = 194  $\pm$  29% of the pretest EPSP,  $n = 4$ ). By contrast, paired stimulation carried out in ASW which contained the specific NMDA receptor antagonist APV (100  $\mu$ M) produced significantly less enhancement of the monosynaptic EPSP (mean EPSP = 111  $\pm$  18% of the pretest EPSP,  $n = 5$ ,  $p < 0.05$ ,  $t$ -test). These results—together with our previous finding that postsynaptic infusion of the  $Ca^{2+}$  chelator BAPTA completely blocks the cellular analogue of classical conditioning of siphon withdrawal (Murphy and Glanzman, Soc. Neurosci. Abstr. 20:1072, 1994)—suggest that classical conditioning in *Aplysia* is mediated, at least in part, by LTP-related modulation of sensorimotor connections.

## 407.4

HEBBIAN SYNAPSE-SPECIFIC FACILITATION AT *APLYSIA* SENSORIMOTOR CONNECTIONS: A POSSIBLE MECHANISM FOR CONDITIONED RESPONSE SPECIFICITY. G. A. Clark\*, P. M. Balaban, and X. Fang. Program in Neuroscience, Psychology Dept., Princeton Univ., Princeton, NJ 08544.

The *Aplysia* siphon-withdrawal response exhibits conditioned response (CR) specificity: following training with different unconditioned stimuli (USs) (e.g., tail or mantle shock), animals exhibit different forms of CRs which resemble the unconditioned response to the particular US used. One possible neural mechanism is synapse-specific facilitation, which could preferentially enhance connections onto one motor neuron relative to others. To explore this possibility, here we examined whether Hebbian facilitation at sensorimotor connections (Lin and Glanzman, 1994) in the abdominal ganglion could be synapse-specific. In each preparation, we recorded intracellularly from an individual LE siphon sensory cell which connected to two different LF<sub>S</sub> siphon motor neurons. We then paired spike train conditioned stimuli in the sensory neuron (12 spikes, 25 Hz) with simultaneous depolarization (3 nA) of one siphon motor neuron, and hyperpolarization of the other motor neuron. This manipulation of postsynaptic voltage was meant to mimic the effects with behavioral training with tail and mantle USs, which excite specific motor neurons but inhibit others. Following cellular training, EPSPs elicited by intracellular stimulation of the siphon sensory cell were preferentially enhanced at connections onto the depolarized motor neuron, relative to connections of the same sensory cell onto the hyperpolarized motor neuron ( $P < 0.01$ ). These results indicate that Hebbian facilitation at sensorimotor connections can be synapse-specific, and thus might serve as one associative mechanism for conditioned response specificity.

## 407.6

APL-EF1 $\alpha$ : A CANDIDATE MODULATORY FACTOR FOR UBIQUITIN-MEDIATED DEGRADATION OF PROTEINS DURING DEVELOPMENT OF LONG-TERM FACILITATION IN *APLYSIA* SENSORY NEURONS. K. Inokuchi, W. Pei, E. R. Kandel, J. H. Schwartz\*, and A. N. Hegde. Center for Neurobiology & Behavior and Howard Hughes Medical Institute, Columbia University College of Physicians & Surgeons, New York, NY, 10032.

The cAMP-dependent protein kinase becomes persistently active during the maintenance of long-term presynaptic facilitation (LTF) of sensory-to-motor neuron synapses underlying sensitization of defensive reflexes in the marine mollusk *Aplysia*. Kinase activity persists for at least 24 h, requires new protein synthesis, and results from proteolysis of regulatory (R) subunits. Hegde et al. (PNAS 90: 7436, 1993) presented evidence that this proteolysis is mediated by the ATP-ubiquitin-proteasome pathway. Based on these and earlier data, we postulated that among the new proteins synthesized would be specific regulatory components for the ubiquitin pathway. Earlier, we found that a ubiquitin carboxyl-terminal hydrolase (Hegde et al., in preparation) is induced in sensory neurons by the facilitatory neurotransmitter 5-HT. Now, using LTF-producing protocols, we show that a protein similar to vertebrate elongation factor 1  $\alpha$  (EF1 $\alpha$ ) is also induced in sensory neurons by 5-HT. Conventionally, the elongation factor, a GTP-binding protein, participates in the formation of the peptide bond between nascent proteins and amino acyl tRNAs on ribosomes. *Aplysia* EF1 $\alpha$  (Apl-EF1 $\alpha$ ) may be needed for the increased synthesis of new protein required for LTF (Winicov et al., Cold Spring Harbor Symp. on Learning and Memory, 1993). In addition, Gonen et al. (PNAS 91: 7648, 1994) have demonstrated a role for an EF1 $\alpha$  in ubiquitin-mediated degradation of proteins with blocked N-termini in rabbit reticulocyte lysates. We obtained full-length cDNA clones for Apl-EF1 $\alpha$  and raised anti-peptide antibodies based on its inferred amino acid sequence. These antibodies recognize an Mr 50,000 protein in nervous tissue. Our working hypothesis is that this factor facilitates regulated proteolysis of R subunits and other protein substrates with blocked N-termini that are necessary for the maintenance of LTF.

## 407.7

EXPRESSION OF THE IMMEDIATE-EARLY GENE *ApC/EBP* IS REQUIRED FOR THE STRUCTURAL CHANGES THAT ACCOMPANY LONG-TERM FACILITATION IN *APLYSIA*. C. H. Bailey\*, M. Chen, M. Ghirardi, C. M. Alberini, and E. R. Kandel. Ctr. Neurobiol. & Behav., Columbia Univ., HHMI, NY, NY 10032.

Activation of the *C/EBP* immediate-early gene is part of the molecular switch required for consolidation of long-term facilitation in *Aplysia* (Alberini et al., 1994). To explore the role of *ApC/EBP* in the induction of learning-related synaptic growth, we have examined in parallel the effects of blocking the expression of this gene on the 5-HT-induced long-term increases in both the functional strength of the sensory-to-motor neuron connection and on the number of fluorescently-labeled sensory neuron varicosities in dissociated cell culture. To compete for the binding activity of *ApC/EBP* to its target sequence we injected into sensory neurons an oligonucleotide encoding the enhancer response element (ERE). Control cells were injected with an ERE oligonucleotide mutated at two bases (ERE mutant) and unable to bind to *ApC/EBP*. Sensory neurons injected with the ERE mutant showed a significant long-term increase 24 hrs following the application of 5-HT in both the amplitude of the evoked EPSP in the motor neuron L7 ( $79\% \pm 14$ ,  $n = 7$ ) and in the number of sensory neuron varicosities contacting the major axons of L7 ( $54\% \pm 12$ ,  $n = 7$ ). By contrast, injection of the ERE oligonucleotide completely blocked both the 5-HT-induced long-term increase in EPSP amplitude ( $2\% \pm 6$ ,  $n = 9$ ,  $p < 0.001$ ) and in the number of sensory varicosities ( $0.1\% \pm 3$ ,  $n = 9$ ,  $p < 0.001$ ). These findings suggest that the induction of *ApC/EBP* (and perhaps other immediate-early genes) may constitute a necessary and intermediate step for the structural changes, which might then carry the memory stably into the long-term stage.

## 407.9

CONTRIBUTION OF LE SIPHON SENSORY NEURONS TO HABITUATION, DISHABITUATION AND SENSITIZATION OF THE GILL-WITHDRAWAL REFLEX IN *APLYSIA*. R. D. Hawkins\* and L. Frost. Ctr. Neurobiol. & Behav., Columbia Univ., NY, NY 10032.

We have developed a simplified preparation, consisting of the isolated mantle organs of *Aplysia*, that undergoes habituation, dishabituation, sensitization, and classical conditioning of the gill-withdrawal reflex. We previously found that the LE siphon sensory neurons contribute to the reflex elicited by controlled force stimulation of the siphon. However, a weak water movement stimulus that can produce PSPs in motor neurons and withdrawal of the gill does not cause the LE cells to fire, suggesting that other, unidentified sensory neurons can also contribute to the reflex (Cohen et al., 1991). Using a more sensitive mechanical stimulator (Byrne, 1975), we have replicated these results, and in addition have found that the unidentified neurons have lower thresholds than the LE cells. We previously recorded evoked spiking, the hyperpolarized complex PSP, and the PSP in high divalents in the gill motor neuron LDG1 in response to controlled force stimulation of the siphon during habituation, dishabituation, and sensitization of the reflex (Hawkins et al., 1992; Kaplan et al., 1993, 1994). Computer modeling of these results suggests that: (1) habituation can be accounted for by depression of sensory neurons PSPs; (2) dishabituation and sensitization by mantle shock involve heterosynaptic facilitation of the sensory neurons, and both facilitation and inhibition of interneurons; (3) 2.5 min after shock, inhibition of both excitatory and inhibitory interneurons produces net inhibition of the complex PSP, but contributes less to changes in evoked spiking; (4) 12.5 min after shock, facilitation of excitatory interneurons and inhibition of inhibitory interneurons contribute importantly to facilitation of evoked spiking.

## 407.11

ANATOMICAL EVIDENCE THAT SENSITIZATION OF MULTIPLE REFLEXES MAY BE MEDIATED BY AN IDENTIFIED CELL. W. G. Wright\*, K. Jones, P. Sharp, & B. Maynard, Department of Biology, Colorado State University, Ft. Collins, CO 80523.

Although sensitization-related changes in the neural circuitry of withdrawal reflexes in *Aplysia* are well studied, relatively few studies address the organization of the modulatory components of sensitization. In particular, it is not known whether individual modulatory loci can simultaneously effect change in multiple reflex circuits. There is, however, evidence that a single modulatory transmitter, serotonin, plays a pivotal role in facilitating several different reflex circuits during sensitization. Furthermore, it is known that activation of a pair of serotonergic neurons, the CB1s, produces heterosynaptic facilitation of the sensorimotor connections of one of these reflex circuits. These data together raise the possibility that the CB1s may produce changes in the neural elements of other reflex circuits, thereby effecting sensitization of multiple reflex systems simultaneously. In the present study, we utilized immunocytochemistry and intracellular labeling to obtain anatomical evidence of CB1's possible role in modulating other reflex circuits. We found 1) profuse fine processes given off by CB1 in the posterior neuropile of the cerebral ganglion, 2) extensive branching and fine processes in the pleural ganglion, and 3) a branch of CB1 that projects into the pedal ganglion. These three observations are consistent with, but do not prove, the hypothesis that CB1 modulates synaptic connections between 1) the sensory and motor neurons of the tentacle withdrawal reflex, 2) the sensory and interneurons of the tail and tail/siphon withdrawal reflex, and 3) the sensory and motor neurons of the tail withdrawal reflex.

## 407.8

LONG-TERM FACILITATION IN *APLYSIA* REQUIRES COORDINATE TRANSCRIPTIONAL ACTIVATION BY *AF-1* AND CONCOMITANT DEREPRESSION OF *CREB-2*. D. Bartsch, M. Ghirardi, P. Skehel, C. H. Bailey, M. Chen\*, S. Herder, K. Karl, and E. R. Kandel. HHMI, Ctr. Neurobiol. & Behav., Columbia Univ., NY, NY 10032.

The learning-related synaptic plasticity in the monosynaptic sensory-motor connection of the *Aplysia* gill-withdrawal reflex requires new protein and mRNA synthesis during the consolidation phase in which the short-term synaptic facilitation is transformed into a long-term form. During this period the transcription factor *ApC/EBP* is rapidly induced as an immediate-early gene by serotonin and cAMP. Perturbation of *ApC/EBP* function selectively blocks long-term facilitation (Alberini et al., Cell 76:109, 1994). Using the yeast two-hybrid cloning system, we have identified two constitutively expressed b-Zip domain transcription factors (*AF-1* and *CREB-2*) that specifically interact with *ApC/EBP*. Both *AF-1* and *CREB-2* interact with *ApC/EBP* and each other via C-terminal leucine-zipper domains and can be coprecipitated from *Aplysia* neuron extracts. Injection of *AF-1*-specific antisera into the presynaptic neuron of *Aplysia* sensory-motor neuron coculture selectively inhibits long-term facilitation induced by serotonin but has no effect on short-term facilitation. Injection of *CREB-2*-specific antisera has no effect on long-term facilitation induced by repeated 5-HT stimulation, but potentiates the effect of 5-HT, such that in contrast to control a single stimulus is now sufficient to induce long-term facilitation. Therefore *CREB-2* appears to act as a repressor of the transcription required for long-term facilitation. These data indicate that the transition from short- to long-term facilitation requires the coordinated positive regulation of the activator *AF-1* and concomitant inactivation of the repressor *CREB-2*.

## 407.10

A POSTSYNAPTIC CONTRIBUTION TO POSTTETANIC POTENTIATION (PTP) AND PAIRING-SPECIFIC FACILITATION AT *APLYSIA* SENSORY-MOTOR SYNAPSES IN CELL CULTURE. J.-X. Bao\* and R. D. Hawkins. Ctr. Neurobiol. & Behav., Columbia Univ., NY, NY 10032.

Infusion of the  $Ca^{2+}$  chelator BAPTA into the postsynaptic neuron or postsynaptic hyperpolarization during tetanic stimulation reduces long-term potentiation (LTP) at *Aplysia* sensory-motor synapses (Lin and Glanzman, 1994). We have examined whether these treatments also affect PTP and pairing-specific facilitation at these synapses in isolated cell culture. The excitatory postsynaptic potential (EPSP) between a pleural sensory neuron and a gill or siphon motor neuron (L7 or LFS) was tested at 5 min intervals for 40 min. In test-alone controls, the evoked EPSPs declined over time (homosynaptic depression). When the sensory neuron was stimulated with a tetanus (20 Hz for 2 s), EPSPs were potentiated for about 15 min. Infusion of BAPTA (200 mM) into the postsynaptic neuron or strong postsynaptic hyperpolarization (2-4 nA) during the tetanus reduced the amplitude and duration of PTP. Pairing tetanus with a single puff of 5-HT (50  $\mu$ M), which by itself produced short-lasting facilitation, induced greater facilitation than unpaired tetanus and 5-HT. Postsynaptic BAPTA reduced this pairing-specific facilitation, but did not affect facilitation by 5-HT alone. BAPTA also did not affect the amplitude of EPSPs after BAPTA infusion, homosynaptic depression, or paired-pulse facilitation, suggesting that BAPTA does not diffuse from the motor neuron to the sensory neuron. Since both PTP and pairing-specific facilitation are expressed presynaptically (Eliot et al., 1994), these results suggest that a postsynaptic increase in intracellular  $Ca^{2+}$  may lead to formation of some retrograde messenger, which participates in presynaptic facilitation of transmitter release.

## 408.1

## NEUROSTEROIDS IN BRAIN MICRODIALYSATES.

A. Guidotti\*, J. Aulá, D. Uzunov, D. Cheney, T. Cooper and E. Costa.  
\*N.S. Kline Institute for Psychiatric Research, Center for Neuropharmacology, Orangeburg, N.Y. 10962, and Dept. of Psychiatry, NYU, N.Y.

Coupling high performance liquid chromatography with gas chromatography-mass fragmentography (GC-MF) using negative ion detection, it has been possible to measure simultaneously subpicogram concentrations of allopregnanolone (ALLO) and of its parent compounds [pregnenolone (PREG), progesterone (PROG) and 5 $\alpha$ -dihydroprogesterone (5 $\alpha$ -DHP)] in discrete brain regions. Because measurements of neurosteroid steady state in brain may not reflect the dynamic state of neurosteroids at the synaptic level, we have used implanted microdialysis probes in the striatum and used the sensitive GC-MF method to establish whether neurosteroids are released and detected in the CNS extracellular fluid of awake freely moving rats. To this end, normal or adrenalectomized castrated (ADX/CX) rats were implanted stereotactically with microdialysis probes. Continuous probe perfusion with Ringer solution (pH6, 1  $\mu$ l/min, 30 min fraction collection) in normal rats revealed a basal efflux of PROG of 25 to 30 pg and of ALLO of 4 to 6 pg/fraction. This efflux was constant for 240 min of dialysis. In ADX/CX rats the efflux of PROG was reduced to approximately 5 pg but that of ALLO was maintained between 3.5 and 5 pg/fraction. The intravenous infusion of PREG-SO<sub>4</sub> (20 mg/kg) in ADX/CX rats elicited a 7 to 8 fold increase in the content of ALLO in brain but not in plasma. In the first hour following PREG-SO<sub>4</sub> infusion the microdialysate content of ALLO increased from 3.5 to 15 pg/fraction. These experiments indicate that: 1. Neurosteroids are released in significant amounts from brain stores into the extracellular fluid and 2. The stable baseline release of neurosteroids can be utilized to study the mechanism of action of agents which modify synthesis and release of neurosteroids. (Supported by Grant MH49489-03).

## 408.3

BIOCHEMICAL SENSITIZATION TO THE NEUROSTEROID, 3 $\alpha$ -HYDROXY-5 $\alpha$ -PREGNAN-20-ONE (3 $\alpha$ 5 $\alpha$ -THP) DURING ETHANOL WITHDRAWAL IN RATS. A. Leslie Morrow\* and Leslie L. Devaud. UNC School of Medicine, Chapel Hill, NC 27599.

Neurosteroids are potent modulators of GABA<sub>A</sub> receptors in the CNS. Behavioral and neurochemical cross-tolerance to most positive modulators of GABA<sub>A</sub> receptors have been observed in ethanol dependent rats. We recently demonstrated sensitization to the anticonvulsant effects of 3 $\alpha$ 5 $\alpha$ -THP during ethanol withdrawal (Alc. Clin. Exp. Res. 19: 350, 1995). We now report enhancement of 3 $\alpha$ 5 $\alpha$ -THP potentiation of GABA<sub>A</sub> receptor-mediated Cl<sup>-</sup> uptake in cerebral cortical microsacs of ethanol withdrawn rats. Rats were administered ethanol by liquid diet for 2 wks using a pair-fed design and tested 6 hrs following the removal of diet. GABA<sub>A</sub> receptor-mediated Cl<sup>-</sup> uptake was measured 5 sec after the addition of GABA (20  $\mu$ M) and various concentrations of 3 $\alpha$ -THP (5-600 nM). GABA mediated Cl<sup>-</sup> flux was reduced by 28%. 3 $\alpha$ 5 $\alpha$ -THP potentiation of the GABA response was enhanced by 44.8 $\pm$ 7.2% in ethanol withdrawn rats. Neurosteroid sensitivity in recombinant GABA<sub>A</sub> receptors is enhanced by the expression of  $\gamma$ 1 vs.  $\gamma$ 2 subunits. The level of  $\gamma$ 1 subunit mRNAs (measured by competitive RT/PCR) was increased 70% in cerebral cortex (3.5  $\pm$  0.6 vs. 6.0  $\pm$  1.3 pg/ $\mu$ g total RNA). These results suggest that neurosteroid sensitization may be mediated by alterations in GABA<sub>A</sub> receptor subunit assembly in ethanol dependent rats. Interactions between ethanol and 3 $\alpha$ 5 $\alpha$ -THP may influence the development of ethanol dependence. (Supported by AA09013, AA00191 and N.C. Governor's Institute).

## 408.5

ALLOPREGNANOLONE REDUCES BASAL AND STRESS-INDUCED RELEASE OF ACETYLCHOLINE AND DOPAMINE IN DIFFERENT BRAIN AREAS OF FREELY MOVING RATS. L. Dazzi, C. Motzo, M.L. Porceddu, A. Concas, M.L. Barbaccia† and G. Biggio\*, Dept. of Exp. Biol., University of Cagliari, Italy and †Dept. of Exp. Med. University of Rome "Tor Vergata", Italy.

Pharmacological, biochemical and electrophysiological evidences suggest that neurosteroids possess anxiolytic activity, possibly via a direct interaction with the GABA-gated chloride ion channel (GABA<sub>A</sub> receptor). As agonists and antagonists of GABA<sub>A</sub> receptor modulate in opposite manner the basal release of acetylcholine (ACh) and dopamine (DA) in the rat brain, we investigated using the microdialysis technique the effect of 3 $\alpha$ -hydroxy-5 $\alpha$ -pregnan-20-one (allopregnanolone) (AP) on basal and stress-induced release of these neurotransmitters in the prefrontal cortex and other brain areas of freely moving rats. AP (5, 10, 15  $\mu$ g/5  $\mu$ l, i.c.v.) dose dependently decreased the basal output of both cortical ACh and DA. This effect was maximal (~50%) 40 min after injection, lasted for about 60 min and returned to basal values within 120 min. AP also significantly decreased the basal output of ACh and DA in the hippocampus and nucleus accumbens, respectively. Footshock (0.2 mA/500 ms per s) is a stressful stimulus known to induce a rapid and marked increase in ACh (~90%) and DA (~100%) release in the above brain areas, an effect that lasts for at least 30-40 min. AP, at a dose (5  $\mu$ g/5  $\mu$ l) per se ineffective on basal ACh and DA release, prevented the effect induced by footshock stress in the output of these neurotransmitters, an effect mimicked by anxiolytic drugs like diazepam. Our results show that AP shares with anxiolytic drugs the capability to modulate ACh and DA release and to prevent the stress-induced enhancement in the release of these neurotransmitters. This pharmacological finding supports the idea that endogenous neurosteroids participate in the modulation of central cholinergic and dopaminergic function during and following stressful conditions.

## 408.2

FLUOXETINE TREATMENT SELECTIVELY CAUSES BRAIN ACCUMULATION OF ALLOPREGNANOLONE (ALLO) IN RATS.

D. P. Uzunov, D. L. Cheney\*, E. Costa and A. Guidotti; Center for Neuropharmacology, Nathan S. Kline Institute for Psychiatric Research, Orangeburg, and Department of Psychiatry, NYU.

Fluoxetine (20 mg/kg, i.p., 1 hr.) administered to normal and adrenalectomized/castrated (ADX/CX) male rats increased by 2-3 fold the brain content of the neurosteroid ALLO measured by gas chromatography-mass fragmentography in the selected negative ion monitoring mode (J. Neuro. 1995). The extent of fluoxetine-induced ALLO increase was identical in normal (from 3 to 9 pmol/g) and ADX/CX rats (from 2 to 8 pmol/g). Incubation of brain slices of normal and ADX/CX male rats with fluoxetine (10  $\mu$ M; 15 min) followed by addition of 10  $\mu$ M 5 $\alpha$ -dihydroprogesterone (5 $\alpha$ -DHP), the immediate precursor of ALLO, resulted in a significant time-dependent accumulation of ALLO as compared to vehicle treated brain slices. Interestingly, conversion of ALLO to 5 $\alpha$ -DHP by brain slices or by cultured glial cells was inhibited by 10  $\mu$ M fluoxetine. Since the content of progesterone and pregnenolone in brain slices or glial cells was not altered by fluoxetine, the data support the hypothesis that fluoxetine induces an accumulation of brain ALLO by inhibiting the 3 $\alpha$ -hydroxysteroid oxidoreductase which is the brain enzyme responsible for the conversion of ALLO to 5 $\alpha$ -DHP. The observation that in fluoxetine treated ADX/CX rats the extent of brain ALLO accumulation is comparable to that occurring in normal rats suggests that the effect of fluoxetine is brain specific and that it is independent from peripheral hormone mobilization sources. The high potency of ALLO to decrease neuronal excitability via an action on GABA<sub>A</sub> receptors supports the working hypothesis that GABA<sub>A</sub> receptors may participate in the antidepressant, antipsychotic action of fluoxetine. Supported by Grant MH49486-03.

INTRACEREBROVENTRICULAR INJECTION OF ALLOPREGNANOLONE ANTAGONIZES THE NEGATIVE EFFECTS OF ISONIAZID AND PTZ ON GABA<sub>A</sub> RECEPTOR FUNCTION. A. Concas\*, M.C. Mostallino, C. Perra, M.L. Barbaccia†, G. Roscetti†, R.H. Purdy\* and G. Biggio. Dept. Exp. Biology, Univ. of Cagliari, 09123 Cagliari Italy and †Dept. of Epx. Med. Univ. of Rome "Tor Vergata", 00133 Rome Italy, \*Dept. of Psych. UCSD, San Diego, 92161 CA, USA.

The effect of intracerebroventricular (i.c.v.) administration of 3 $\alpha$ -hydroxy-5 $\alpha$ -pregnan-20-one (allopregnanolone; AP), a neurosteroid endowed with anxiolytic and anticonvulsant properties, on the function of GABA<sub>A</sub> receptors has been investigated in the rat brain. AP dissolved in 45% 2-hydroxypropyl- $\beta$ -cyclodextrin induced a dose-dependent (5-15  $\mu$ g/5  $\mu$ l i.c.v.) decrease (maximal effect ~55% at 15  $\mu$ g) of [<sup>35</sup>S]TBPS binding measured "ex vivo" in unwashed membrane preparations from various rat brain regions (cerebral cortex, striatum, cerebellum, thalamus, hypothalamus, hippocampus). The effect of AP on [<sup>35</sup>S]TBPS binding was evident within 2 min. after injection, lasted for at least 30 min. and returned to control values by 60 min. AP antagonized dose-dependently (2.5-15  $\mu$ g/5  $\mu$ l i.c.v.) both the increase of [<sup>35</sup>S]TBPS binding and the convulsions induced by isoniazid (375 mg/kg s.c.). The same treatment antagonized convulsions induced by pentylenetetrazole (PTZ) (75 mg/kg i.p.): 10  $\mu$ g of AP produced a marked delay (8 folds) in the latency of convulsions induced by pentylenetetrazole while at a dose of 15  $\mu$ g this drug completely prevented the appearance of seizures. These effects were evident 2 min. after AP administration and lasted for at least 30 min. The time course of these effects well correlated with the time-related changes in brain AP concentrations which were maximal within 5 min. after i.c.v. infusion and returned to control values by 60 min. These results provide evidence that pharmacological doses of AP enhance the function of the GABA<sub>A</sub> receptors. The correlation between physiological concentrations of AP and GABAergic transmission will be discussed.

MODULATORY EFFECTS OF THE NEUROACTIVE STEROID THDOC ON GABA-INDUCED CHLORIDE CURRENTS IN CULTURED RAT HYPOTHALAMIC NEURONS. C. H. R. Weizel, R. A. Deisz, H. Vedder and W. Ziegler\*, Max-Planck-Institute of Psychiatry, Clinical Institute, 80804 Munich, Germany.

Steroid hormones control a variety of physiological functions, utilizing both, genomic and non-genomic mechanisms in the central nervous system. The neuroactive steroid 5 $\alpha$ -pregnane-3 $\alpha$ ,21-diol-20-one (THDOC) exerts its action either via activation of the progesterone receptor, following oxidation of THDOC to 5 $\alpha$ -pregnane-21-ol-3,20-dione (Rupprecht et al., Neuron, 11:523-530, 1993) or through direct membrane actions via modulation of the GABA(A) receptor-mediated chloride currents. We investigated the modulatory potency of THDOC on the GABA(A)-induced chloride currents in serum-free cultured rat hypothalamic neurons, employing the whole-cell voltage-clamp technique. GABA (1 - 10  $\mu$ M) and/or THDOC (10 nM - 1  $\mu$ M) were locally applied via a multibarrel/single tip superfusion device. The amplitudes of the GABA-induced chloride currents were measured at a holding potential of -70 mV. The effect of various concentrations of THDOC (10 nM - 1  $\mu$ M) on different concentrations of exogenously applied GABA (1  $\mu$ M and 10  $\mu$ M) was tested. Currents induced by 10  $\mu$ M GABA were increased to 128% and 125% of control, by simultaneous application of 100 nM and 1  $\mu$ M THDOC, respectively. Ten nM THDOC had no consistent effect on the GABA-induced chloride currents. However, responses to 1  $\mu$ M GABA were dose-dependently modulated: 10 nM THDOC reduced the GABA-induced current to 80% of control, whereas 100 nM and 1  $\mu$ M THDOC enhanced the GABA response to 115% and 180% of control, respectively. In summary, the naturally occurring metabolite THDOC exhibited marked effects on the GABA-induced chloride currents in cultured rat hypothalamic neurons. The bidirectional modulatory action of THDOC depended on the concentration of exogenously applied GABA and THDOC. Through this mechanism, THDOC may modulate the signal to noise ratio of the GABAergic inhibitory synaptic transmission.

## 408.7

CO 2-1970: A PARTIAL AGONIST FOR THE NEUROACTIVE STEROID BINDING SITE OF THE GABA<sub>A</sub> RECEPTOR. J.A. Drews\*, E.R. Whittemore, C.L. Kimbrough, J.-S. Chen, D. Hogenkamp, R.M. Woodward and J.E. Hawkinson. CoCensys Inc., Irvine, CA 92718

Neuroactive steroids bind to a unique site on the GABA<sub>A</sub> receptor complex and allosterically modulate the binding of [<sup>35</sup>S]TBPS, GABA ([<sup>3</sup>H]muscimol) and benzodiazepine ([<sup>3</sup>H]FLU) site ligands. 3 $\alpha$ ,5 $\alpha$ -P is a full agonist at the neuroactive steroid site inhibiting 100% of [<sup>35</sup>S]TBPS binding, enhancing [<sup>3</sup>H]FLU binding to 180% and  $\approx$ 225% of control in rat cortical and recombinant  $\alpha$ 1 $\beta$ 1 $\gamma$ 2L membrane preparations, respectively, as well as enhancing [<sup>3</sup>H]muscimol binding to 160% in rat cortical membrane. Numerous synthetic neuroactive steroids have been examined, one of which denoted CO 2-1970 having limited efficacy for allosteric modulation [<sup>35</sup>S]TBPS binding, displacing maximally 45% and  $\approx$ 55%, enhancing [<sup>3</sup>H]FLU binding, 140% and  $\approx$ 160% in rat and  $\alpha$ 1 $\beta$ 1 $\gamma$ 2L, respectively, and enhancing [<sup>3</sup>H]muscimol binding to  $<$ 110%. To experimentally verify that CO 2-1970 is a partial agonist, competition studies were performed between 3 $\alpha$ ,5 $\alpha$ -P and CO 2-1970. CO 2-1970 reduced the apparent potency of 3 $\alpha$ ,5 $\alpha$ -P for modulating the binding of all three radioligands in rat cortex and for [<sup>3</sup>H]FLU and [<sup>35</sup>S]TBPS in recombinant  $\alpha$ 1 $\beta$ 1 $\gamma$ 2L membranes. In *Xenopus* oocytes expressing the  $\alpha$ 1 $\beta$ 1 $\gamma$ 2L subunit combination, Cl<sup>-</sup> currents constituting 5% of the maximum GABA response were potentiated to 90% by 3 $\alpha$ ,5 $\alpha$ -P, but to only 25% by CO 2-1970. Levels of potentiation induced by 3 $\alpha$ ,5 $\alpha$ -P were reduced by coapplication of CO 2-1970 with a decrease in apparent affinity for 3 $\alpha$ ,5 $\alpha$ -P. Collectively, these data provide compelling *in vitro* evidence that CO 2-1970 is a partial agonist for the neuroactive steroid binding site of the GABA<sub>A</sub> receptor.

## 408.9

DIFFERENTIAL MODULATION OF GABA<sub>A</sub> RECEPTOR BY LORECEZOLE, PROPOFOL AND DIAZEPAM. M. Serra\*, C.A. Ghiani, G. Tuligi, E. Maciocco and G. Biggio. Dept. Exp. Biology, University of Cagliari, Cagliari Italy.

Recently, molecular biology and functional studies have shown that, differently to benzodiazepines and more similar to barbiturate, the broad spectrum anticonvulsant loreceazole (LRC) acts via a specific modulatory site on the  $\beta$  subunit of the GABA<sub>A</sub> receptor complex. A similar specificity for the  $\beta$  subunit has also been shown for the action of the general anesthetic propofol (PPF). On the basis of these data, the effect of LRC on the function of GABA<sub>A</sub> receptor complex in the rat cerebral cortical membrane preparation was compared with those of PPF and the benzodiazepine receptor full agonist diazepam (DZ). LRC and PPF modulated [<sup>3</sup>H]muscimol and [<sup>35</sup>S]TBPS binding with potencies and efficacies greater than those of DZ. The combination of LRC and PPF or DZ resulted in additive effect on [<sup>3</sup>H]muscimol binding, suggesting different sites of action for these drugs. Both LRC and PPF showed biphasic effects on [<sup>35</sup>S]TBPS binding to well washed membranes (in the absence of endogenous GABA): at low concentrations (5 or 10  $\mu$ M) both drugs enhanced [<sup>35</sup>S]TBPS binding, whereas at higher concentrations (30 to 100  $\mu$ M) they inhibited this biochemical parameter. In contrast, DZ enhanced [<sup>35</sup>S]TBPS binding to washed membranes at all concentrations tested. The combination of LRC with GABA, at concentration (0.3  $\mu$ M) that alone only slightly increased [<sup>35</sup>S]TBPS binding to washed membranes, not only abolished but reversed the increase in binding elicited by low concentrations (5 to 10  $\mu$ M) of LRC and significantly potentiated the inhibitory effect exerted by higher concentrations (30 to 100  $\mu$ M) of this drug. Similar effects were observed with the combination of GABA with PPF. However, GABA had no effect on the enhancement of [<sup>35</sup>S]TBPS binding induced by DZ. Since LRC modulates GABA<sub>A</sub> function receptor with higher efficacy than DZ its lack of sedative and hypnotic effects may depend from the capability to interact with selective GABA<sub>A</sub> receptor subtypes. Moreover, the lack of anesthetic action of LRC may reflect its much weaker capability to directly activate the chloride channel compared to PPF.

## 408.11

EVIDENCE FOR A POSITIVE MODULATORY SITE OF THE  $\gamma$ -BUTYROLACTONES ON THE GABA<sub>A</sub> RECEPTOR DISTINCT FROM THE PICROTOXIN SITE. K.L. Williams<sup>1</sup>, D.A. Gurley<sup>2</sup>, D.S. Weiss<sup>3</sup>, G. White<sup>3</sup>, D.F. Covey<sup>1</sup>, J.A. Ferrendelli<sup>1</sup> and S.M. Rothman<sup>1</sup>. <sup>1</sup>Washington Univ. Sch. of Med., St. Louis, MO 63110; <sup>2</sup>Neurogen Corp., Branford, CT 06405; <sup>3</sup>Univ. of South Florida College of Medicine, Tampa, FL 33612.

$\gamma$ -Butyrolactones and related compounds target the GABA<sub>A</sub> receptor and modulate GABA-induced chloride flux.  $\alpha$ -Substituted compounds generally potentiate, while  $\beta$ -substituted compounds potently inhibit GABA-induced currents. Both modulatory effects were believed to be mediated through opposite effects on the picrotoxin site. To test this hypothesis, a picrotoxin-insensitive GABA<sub>A</sub> receptor was created by introducing two point mutations in the second transmembrane domain of the  $\alpha$ 1,  $\beta$ 2, and  $\gamma$ 2 subunits of the rat GABA<sub>A</sub> receptor, to make them identical to the glycine  $\beta$  subunit. Only the presence of a single mutated subunit ( $\alpha$ ,  $\beta$ , or  $\gamma$ ) was required for picrotoxin insensitivity.

We examined the responses to  $\alpha$ - and  $\beta$ -ethyl, methyl-thiobutyrolactone ( $\alpha$ -EMTBL and  $\beta$ -EMTBL) of *Xenopus* oocytes injected with rat  $\alpha$ 1,  $\beta$ 2, and  $\gamma$ 2 RNA. Concentration responses were determined for each compound at the GABA EC<sub>10</sub>.  $\alpha$ -EMTBL (3-5,000  $\mu$ M) potentiated GABA-induced currents in both wild-type  $\alpha$ 1 $\beta$ 2 $\gamma$ 2-injected cells and in cells containing the mutated  $\beta$ 2 subunit (i.e.,  $\alpha$ 1 $\beta$ 2 $\gamma$ 2<sup>mut</sup>). In contrast,  $\beta$ -EMTBL, which inhibited GABA-induced currents at concentrations below 1 mM and potentiated GABA currents above 1 mM, in the  $\alpha$ 1 $\beta$ 2 $\gamma$ 2-injected cells only potentiated over the entire concentration range in the oocytes injected with the  $\alpha$ 1 $\beta$ 2 $\gamma$ 2 subunits. Additionally,  $\beta$ -EMTBL potentiated GABA-induced currents at 100 and 1000  $\mu$ M in cells injected with the mutated  $\gamma$ 2 subunit (i.e.,  $\alpha$ 1 $\beta$ 2 $\gamma$ 2<sup>mut</sup>). These results indicate that the lactones act through two distinct effector sites: a negative modulatory (picrotoxin) and positive modulatory (undefined) site.

STEROID RECEPTOR MEDIATED EFFECTS OF NEUROACTIVE STEROIDS: CHARACTERIZATION OF STRUCTURE ACTIVITY RELATIONSHIP. R. Rupprecht\*, J.M.H.M. Reul, B. Bering, C.A.E. Hauser and F. Holsboer. Max Planck Institute of Psychiatry, Clinical Institute, Kraepelinstr. 10, 80804 Munich, Germany.

Neuroactive steroids rapidly alter neuronal excitability through binding sites on neurotransmitter-gated ion channels. The 3 $\alpha$ -hydroxy ring A-reduced pregnane steroids enhance  $\gamma$ -aminobutyric acid (GABA)-mediated chloride currents while pregnenolone sulfate and dehydroepiandrosterone display functional antagonistic properties. Based on our previous findings that the 3 $\alpha$ -hydroxy ring A-reduced pregnane steroids allotetrahydroprogesterone and allotetrahydrodeoxycorticosterone may regulate also gene expression via the progesterone receptor after intracellular oxidation, we have characterized the effects of a series of natural and synthetic neuroactive steroids at the genomic level using a cotransfection system. Pregnanolone and pregnenolone were able to activate both the chicken and the human progesterone receptor while the synthetic 3 $\alpha$ -hydroxylated derivative alphaxalone and dehydroepiandrosterone were only active via the chicken progesterone receptor. Moreover, the antigluocorticoid activity of dehydroepiandrosterone reported at the systemic level could not be reconstituted in the cellular cotransfection system. This study provides evidence for differential genomic effects of neuroactive steroids in a structure specific manner which may have impact on the development of these steroids for therapeutic application in neurology and psychiatry.

## 408.10

DUAL MODULATION OF THE GABA<sub>A</sub> RECEPTOR/IONOPHORE BY  $\alpha$ -SUBSTITUTED  $\gamma$ -BUTYROLACTONES. K.D. Holland, G.C. Mathews, A.M. Bolos-Sy, J.B. Tucker, P.A. Reddy, D.F. Covey\*, J.A. Ferrendelli, and S.M. Rothman. Department of Molecular Biology & Pharmacology and Department of Neurology & Neurosurgery, Washington University School of Medicine, St. Louis, MO 63110.

Alkyl-substituted  $\gamma$ -butyrolactones (GBLs) and  $\gamma$ -thiobutyrolactones exhibit convulsant or anticonvulsant activity depending on the alkyl-substituents. Alpha-substituted lactones with small alkyl substituents are anticonvulsant and potentiate GABA-mediated chloride currents, while  $\beta$ -substituted compounds are usually convulsant and block GABA<sub>A</sub> currents. We have now found that this distinction is not so clearcut, in that some compounds can both block and augment GABA<sub>A</sub> currents, but with different time courses. For example,  $\alpha$ , $\alpha$ -disopropyl-GBL ( $\alpha$ -DIGBL) potentiates exogenous GABA currents in cultured rat hippocampal neurons, but diminishes GABA-mediated inhibitory postsynaptic currents. A more detailed analysis demonstrates a triphasic effect of  $\alpha$ -DIGBL on GABA currents, with a rapid inhibitory phase, a slower potentiating phase, and then an "off-response" when the GABA/ $\alpha$ -DIGBL perfusion is stopped. Thus,  $\alpha$ -DIGBL can inhibit and potentiate GABA currents with kinetically different time courses. Inhibition is more rapid, but at steady-state potentiation dominates. Using a simplified model of the GABA<sub>A</sub> receptor/ionophore, we have simulated our experimental observations with  $\alpha$ -DIGBL. Another lactone,  $\beta$ -ethyl- $\beta$ -methyl- $\gamma$ -thiobutyrolactone, also has dual actions, with inhibition predominating at low concentrations and potentiation predominating at high concentrations. We propose two distinct  $\gamma$ -butyrolactone modulatory sites on the GABA<sub>A</sub> receptor: an inhibitory "picrotoxin" site and an enhancing "lactone site". New information on the structure of the GABA<sub>A</sub> receptor/ionophore may allow the molecular dissection of these two sites.

Supported by NS-14834-17, 5T32GM0708, and the Seay Fellowship.

## 409.1

NEURONS AND ASTROCYTES CONTAIN THE MITOCHONDRIAL PERMEABILITY TRANSITION PORE. Janet M. Dubinsky\*, Dept. of Physiology, University of Minnesota, Minneapolis, MN 55455.

The permeability transition pore (PTP) is a mitochondrial channel associated with hypoxia in liver, that opens in response to calcium and oxidation, resulting in swelling of mitochondria in isolated preparations (Thomas et al '94 Am J Physiol 267:C313). Since both calcium and oxidation are required for delayed glutamate neurotoxicity (Kristal et al., Nsci. Abstr. 20:649) and mitochondrial swelling follows both excitotoxic and ischemic injury, I have hypothesized that the PTP exists in neural mitochondria and may participate in the pathogenesis of excitotoxic injury. To determine if nervous tissue contains the PTP, mitochondria in cultured astroglia and hippocampal neurons were visualized using conventional and confocal microscopy with nonyl acridine orange, a dye that partitions into mitochondrial membranes irrespective of mitochondrial membrane potential. Plasma membranes were permeabilized by a 5' exposure to 0.0005-0.001% digitonin in a high potassium or predominantly sucrose containing medium. Under these conditions, mitochondria were observed to change from rod shaped to rounded in response to calcium. Addition of an excess of EGTA could restore a rod-like shape. Phenylarsine oxide, a PTP activator, also produced shape changes in healthy mitochondria. Thus neuronal and astroglial mitochondria behave similarly to liver mitochondria under conditions that stimulate the PTP. Supported by the Mn. Medical Foundation and the Mn. American Heart Association.

## 409.3

GLUTAMATE EXCITOTOXICITY AND MITOCHONDRIAL MEMBRANE POTENTIAL. L. Kiedrowski\*. The Nathan S. Kline Institute for Psychiatric Research, New York University, Orangeburg, NY 10962.

Young cultures of cerebellar granule cells are less susceptible to glutamate excitotoxicity than older ones in spite of the fact that application of glutamate in a  $Mg^{2+}$  free medium leads to an influx of similar amounts of  $^{45}Ca^{2+}$  (Eimerl & Schramm, J. Neurochem. 62 (1994) 1223-26). The  $Ca^{2+}$  influx that is diverted to mitochondria during glutamate pulse may compromise mitochondrial function. Therefore, the mitochondrial ability to retain the inner mitochondrial membrane potential ( $\Delta\psi$ ) in younger and older cultures was studied. Cerebellar granule cells were simultaneously loaded with Fura-2 and tetramethylrhodamine (TMR) to study  $[Ca^{2+}]_i$  and  $\Delta\psi$ , respectively. In the 7 day old cultures an exposure to 1  $\mu M$  antimycin A1 for 30 min failed to dissipate  $\Delta\psi$ . In contrast, in the 10 day old cultures an incubation with antimycin A1 for only 7 min was sufficient to dissipate  $\Delta\psi$  and release TMR from mitochondria to cytoplasm. Hence, the inability to retain  $\Delta\psi$  may account for the increased susceptibility to excitotoxicity in older cultures. In fact, with the increasing age of cultures a progressively larger percentage of cerebellar granule cells failed to buffer  $[Ca^{2+}]_i$  during 15 min exposure to 100  $\mu M$  glutamate and 10  $\mu M$  glycine in a  $Mg^{2+}$  free medium; after glutamate withdrawal, the neurons that failed to buffer  $[Ca^{2+}]_i$  also failed to reaccumulate TMR in mitochondria. This indicates that in cerebellar granule cells that are more susceptible to excitotoxicity, the  $\Delta\psi$  collapses during the exposure to glutamate. A possible cause of the  $\Delta\psi$  collapse in these neurons may be an excessive  $Ca^{2+}$  uptake by mitochondria. Supported by NIH grant NS 28130-05.

## 409.5

MK-801 REDUCES UPTAKE AND STIMULATES EFFLUX OF EXCITATORY AMINO ACIDS VIA MEMBRANE DEPOLARIZATION. M.C. Longuemare\*, E.C. Keung, F.R. Sharp, P.H. Chan, R.A. Swanson, University of California and Veterans Affairs Medical Center, San Francisco, CA 94121.

MK-801 blocks excitotoxic neuronal injury by preventing  $Ca^{2+}$  flux through NMDA receptor (NMDA-R) gated ion channels. MK-801 and related compounds also have other effects, such as neuronal vacuolization and blockade of glutamate-induced astrocyte swelling, that may be unrelated their action at the NMDA-R. One mechanism by which these agents may act on neurons and glia is through impairment of glutamate uptake. In the present study, MK-801 inhibited glutamate uptake in both astrocyte and neuronal cultures in a dose-dependent manner. MK-801 (500  $\mu M$ ) reduced astrocyte glutamate uptake from  $24.0 \pm 0.6$  to  $16.8 \pm 0.5$  nmol/mg protein/minute for [glutamate] = 100  $\mu M$ . Both the  $V_{max}$  and  $K_M$  were reduced by 45%, suggesting uncompetitive inhibition. In addition, astrocyte GABA uptake was inhibited by more than 50%. The related NMDA-R channel blockers, PCP and ketamine, also inhibited glutamate uptake, while NMDA-R antagonists which block the glutamate-binding site or the glycine site showed no effect. Since glutamate and GABA uptake are electrogenic, blockade of ion channels leading to membrane depolarization could indirectly inhibit uptake. Whole-cell patch clamping demonstrated a  $35 \pm 3$  mV depolarization by MK-801 (1mM), suggesting that MK-801 inhibits uptake by reducing membrane potential. As predicted by models of glutamate transport, MK-801-induced depolarization caused excitatory amino acid efflux from astrocytes. It is possible that depolarization and subsequent impairment of glutamate transport may contribute to neurotoxic effects of NMDA-R channel blockers.

## 409.2

CGP 37157: A NEW TOOL FOR STUDYING MITOCHONDRIAL BUFFERING OF GLUTAMATE-INDUCED CALCIUM INFLUX IN CULTURED FOREBRAIN NEURONS. R.J. White\* and I.J. Reynolds, Center for Neuroscience and Department of Pharmacology, University of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

Mitochondria are a potentially relevant target for  $Ca^{2+}$ -mediated damage following excitotoxic stimuli, and we have previously documented the importance of mitochondria in buffering modest calcium loads induced by 15 seconds of 3  $\mu M$  glutamate (glu). Using indo-1 microfluorimetry to measure  $[Ca^{2+}]_i$  in single cells, we now report the effect of CGP-37157 (CGP), a reversible, specific inhibitor of the mitochondrial  $Na^+/Ca^{2+}$ -exchange. Following application of a control (15s, 3  $\mu M$ ) glu pulse, we stimulated primary cultures of rat forebrain neurons with an identical dose of glu and then washed the glu-containing buffer out with 2 minutes of 25  $\mu M$  CGP. We consistently observed that  $[Ca^{2+}]_i$  returned to baseline more rapidly than in controls. Rarely, we observed a small  $[Ca^{2+}]_i$  "hump" while washing the CGP out with  $Ca^{2+}$ -free buffer, presumably reflecting reactivation of the mitochondrial  $Na^+/Ca^{2+}$ -exchange and subsequent  $Ca^{2+}$  release from the mitochondria.

To explore mitochondrial  $Ca^{2+}$  buffering processes in paradigms relevant to excitotoxicity, we exposed neurons to 100  $\mu M$  glu for 5 minutes. Under control conditions, recovery of  $[Ca^{2+}]_i$  to baseline took up to an hour. In contrast, when glu stimulation was terminated with a  $Ca^{2+}$ -free solution containing CGP, some cells were able to buffer  $[Ca^{2+}]_i$  to baseline within minutes. Thus, by preventing  $Ca^{2+}$  movement from the mitochondria to the cytoplasm, CGP revealed a large mitochondrial contribution to the prolonged elevation of  $[Ca^{2+}]_i$  following this intense glu stimulus. In each experiment with the 100  $\mu M$  glu treatment, we observed a  $[Ca^{2+}]_i$  "hump" after we washed the CGP away with  $Ca^{2+}$ -free buffer; the "hump" was long-lasting and presumably reflected the substantial store of  $Ca^{2+}$  which the mitochondria had taken up during the glu stimulus. Our data reveal a significant, novel cellular transport process and establish the importance of mitochondria in buffering a glutamate-induced  $Ca^{2+}$  influx. CGP will prove to be an invaluable tool for further defining the role of mitochondria in excitotoxic neuronal injury.

PHOSPHOCREATINE-DEPENDENT GLUTAMATE UPTAKE BY SYNAPTIC VESICLES. C.J. Xu\*\*, W.E. Klunk\*, Q. Xiong\*, J.N. Kanfer\*, J.W. Pettigrew\* a: Laboratory of Neurophysics, University of Pittsburgh Medical Center, Pittsburgh, PA 15213. b: Department of Biochemistry and Molecular Biology, University of Manitoba, Winnipeg, Canada.

Glutamate is a major excitatory neurotransmitter in the vertebrate central nervous system. Glutamate is taken up by synaptic vesicles in an ATP-dependent manner, which is markedly stimulated by low concentrations of chloride and magnesium. Phosphocreatine (PCr) is an important high-energy phosphate that is a substrate for the creatine kinase catalyzed conversion of ADP to ATP. PCr was found to strongly stimulate glutamate uptake by bovine synaptic vesicles (about 180%) in the presence of 50  $\mu M$  glutamate. Furthermore, we found that: (1) PCr could stimulate glutamate uptake by synaptic vesicles even in the absence of exogenous ATP; (2) ATP alone at maximal concentration (2 mM) could only achieve 60% of the maximal PCr-stimulated uptake; (3) 0.5 mM of iodoacetamide completely inhibits creatine kinase activity, but does not inhibit glutamate uptake activity, suggesting that the effect of PCr on the glutamate uptake activity is not due to the conversion of ADP to ATP by creatine kinase; (4) PCr-dependent glutamate uptake, in contrast to ATP-dependent glutamate uptake, is not magnesium or chloride-dependent; (5) 0.5 mM of N-ethylmaleimide (NEM), a selective  $H^+$ -ATPase inhibitor, completely inhibits ATP-dependent glutamate uptake, but only slightly inhibits PCr-dependent glutamate uptake activity. We conclude that in addition to an ATP-dependent glutamate uptake system, there is a previously unrecognized PCr-dependent glutamate uptake system in the synaptic vesicles that appears to be able to stimulate greater uptake than the ATP-dependent system. (This work is supported by NIA grant AG08974)

## 409.6

LUBELUZOLE REDUCES EXTRACELLULAR GLUTAMATE IN THE PERI-INFARCT ZONE OF A THROMBOTIC INFARCT IN RATS. D. Scheller, M. De Ryck, A. Lesage\*, G. Clinckx and F. Tegetmeier, Janssen Research Foundation, D-41470 Neuss, Germany and B-2340 Beerse, Belgium.

Lubeluzole, the S-isomer of a novel benzothiazole, is a compound aimed at the treatment of acute stroke. It protected neurologic function and reduced infarct size in thrombotic infarction. The R-isomer was inactive. As excess extracellular glutamate (glu) is known to exert cytotoxic phenomena, we determined extracellular glu changes in the peri-infarct zone and measured the possible effect of both compounds on that parameter. A microdialysis probe (2x0.5 mm, perfusate: aCSF; flow rate: 2  $\mu l/min$ ) was implanted into the histologically verified peri-infarct area of male Wistar rats (250 g, urethane 1.55-1.95 g/kg). After 90 min, Rose Bengal was given i.v. (70 mg/kg) and illuminated through the skull for 5 min. Either lubeluzole (1.25 mg/kg), its R-isomer (1.25 mg/kg) or vehicle solution (10% cyclodextrin, pH 5) were infused 10 min afterwards. Amino acids were determined using HPLC with fluorescence detection. Extracellular glutamate rose from  $0.844 \pm 0.409$  ( $\mu mol/l$ , mean  $\pm$  SD, n=8) to  $4.578 \pm 1.772$  (6 h after infarction) in controls and increased from  $0.869 \pm 0.385$  to  $1.119 \pm 0.685$  (n=9) in the lubeluzole treated group (p=0.007, ANOVA for repeated measures). In the R-isomer series, glutamate rose from  $0.603 \pm 0.362$  to  $4.782 \pm 2.002$  (n=6) in the controls and increased from  $0.668 \pm 0.354$  to  $2.016 \pm 1.265$  (n=9) in the treated group (p=0.19). In conclusion, lubeluzole prevented the slow rise of extracellular glutamate in the peri-infarct zone of a thrombotic infarct. Thus, lubeluzole may, by preventing the rise of extracellular glu, contribute to an improved neurological outcome after infarction.

## N-METHYL-D-ASPARTATE- AND OXIDANT-INDUCED LUNG INJURY: CRITICAL ROLE OF POLY(ADP-RIBOSE) POLYMERASE. S. I. Said\*, H. Pakbaz, and H. I. Berisha.

Poly(ADP-ribose)polymerase (PARP), a nuclear enzyme that is activated by DNA damage and catalyzes the polymerization of poly (ADP-ribose), is involved in cell differentiation, proliferation, and DNA repair. Excessive activation of PARP may lead to depletion of cellular NAD and ATP, and eventual cell death. We have investigated the importance of PARP activation in the production of acute lung injury due to oxidant stress caused by: 1) N-methyl-D-aspartate (NMDA, 1 mM) in the presence of L-arginine (10 mM), in rat lungs; 2) Infusion of paraquat (100mg/kg) in guinea pig lungs; and 3) Combination of xanthine (1mM) and xanthine oxidase (0.15 U/ml) in rat lungs. The lungs were mechanically ventilated with air or O<sub>2</sub> + 5% CO<sub>2</sub>, and perfused at constant flow with Krebs solution containing 4% BSA. The importance of PARP activation was assessed by the use of either of 2 selective inhibitors of this enzyme, benzamide or 6(5H)-phenanthridinone. In all 3 models, injury occurred within 1 h, as evidenced by marked increases in airway and perfusion pressures, wet/dry lung weight ratio, and protein leakage into bronchoalveolar lavage fluid; lung tissue NAD levels decreased. Infusion of benzamide (1 mM) or 6(5H)-phenanthridinone (1 mM) greatly attenuated or totally prevented all signs of lung injury in each model (n=4-6). All 3 forms of injury were also prevented by the neuropeptide VIP, infused at 10 µg/kg. min.<sup>-1</sup>. The results suggest that: 1) poly(ADP)-ribosylation, through PARP activation, is an essential step on a common pathway leading to tissue injury from NMDA and oxidants; and 2) VIP may act in part as a PARP inhibitor.

## 409.9

HIGH-POTASSIUM-INDUCED NEURONAL DAMAGE *IN VIVO*: EFFECTS OF NMDA-RECEPTOR BLOCKADE. D. G. Fujikawa\* and T.B. Sohn. Exp. Neurol. Lab., VA Med. Ctr., Sepulveda, CA and Dept. of Neurology and Brain Res. Inst., UCLA Sch. of Med., Los Angeles, CA.

We have found that microdialysis probe delivery of 12 mM K<sup>+</sup> to the rat amygdala for 60-70 min produces edema, neuronal necrosis and elevations of extracellular glutamate to 262-322% and aspartate to 186-198% of baseline, without inducing local seizure discharges. In this study we investigated the effects of the competitive NMDA-receptor-antagonist CGP 40116. Bilateral CMA/11 guide cannulae with attached bipolar electrodes were placed in the basolateral amygdaloid nuclei of adult Wistar rats (n=6). The next day microdialysis probes were inserted and perfused with Krebs-Ringer-bicarbonate (KRB) solution for 2 h in freely-moving rats. The solution was then switched to 100 mM KCl in modified KRB (delivering 12 mM K<sup>+</sup> to tissue) bilaterally for 60 min; one side contained 36 µM CGP 40116. Preliminary data suggest that about 12 µM (29%) of the CGP 40116 was delivered to tissue, more than 100-fold greater than its *in vitro* K<sup>+</sup> for inhibition of NMDA-sensitive L-[<sup>3</sup>H]-GLU binding. Five of 6 normally-behaving rats had amygdalar epileptiform discharges on the CGP 40116 side during high-K<sup>+</sup> perfusion, with a latency to onset of 40.0 ± 7.4 min (mean ± S.E.M) and a total spike-wave duration of 8.0 ± 2.9 min. After *in situ* brain perfusion-fixation and removal, 6-µm-thick coronal brain sections stained with H & E were prepared and examined. Cells were counted in 270 × 540 µm areas immediately medial and lateral to each probe. Tissue edema was graded on a 0-3 scale. On the control high-K<sup>+</sup> side there were 45 ± 6 acidophilic and 86 ± 14 normal neurons, compared to 39 ± 5 acidophilic and 97 ± 8 normal neurons on the side exposed to CGP 40116 (p = 0.17 and 0.50 respectively). Severe edema was also present bilaterally: 3.0 ± 0.0 on the control side and 2.9 ± 0.1 on the CGP 40116 side (p = 0.36). Delivery of CGP 40116 to the amygdala during high-K<sup>+</sup> perfusion induced local epileptiform activity and was not neuroprotective.

## 409.8

## IDENTIFICATION OF A NOVEL NMDA AGONIST C.L. Willis\*, J. Humphrey\*, A.R. Chamberlin\*, R.J. Bridges. Dept. of Pharm. Sci., Univ. of Montana, Missoula, MT 59812, Dept. of Chem., Univ. of Calif., Irvine, CA 92717

During the course of studies aimed at the design and synthesis of conformationally constrained EAA analogues, we prepared the novel compound L-trans-2,3-pyrrolidine dicarboxylate (L-trans-2,3-PDC). Consistent with its action as an NMDA agonist, earlier studies with L-trans-2,3-PDC demonstrated that it blocked <sup>3</sup>H-L-glutamate binding to NMDA receptors and produced an excitotoxic response in rat cortical cultures that was blocked by MK-801. In the current study we examined the *in vivo* neurotoxicity of L-trans-2,3-PDC, as well as that of its newly synthesized 5-methyl derivative, by focal injection into the dorsal hippocampus of male Sprague-Dawley rats. Cellular damage in the pyramidal (CA1-CA4) and dentate granule (DG) neurons induced by L-trans-2,3-PDC or 5-Me-L-trans-2,3-PDC was assessed histologically and compared to pathology produced by NMDA, AMPA, and kainate. Although the two novel analogues exhibited similar potencies in blocking of <sup>3</sup>H-L-glutamate binding to NMDA receptors (IC<sub>50</sub> values of 1-3 µM), a significant difference was observed in their ability to induce excitotoxicity *in vivo*. Thus, while an injection of 20 nmols of L-trans-2,3-PDC produced little or no damage in the hippocampus, 0.25 nmols of 5-Me-L-trans-2,3-PDC induced a significant level of neuronal injury. CA1, CA3 and CA4 subfields exhibited between 70-90% neuronal injury, whereas only 10-30% CA2 and DG were damaged. The pattern and extent of pathology was comparable to that produced by 25 nmols of NMDA. The neuronal damage induced by 5-Me-L-trans-2,3-PDC was prevented by MK-801 (3mg/kg i.p.), but not by NBQX (25 nmols: a dose that protects against 1 nmol of AMPA). These results identify 5-Me-L-trans-2,3-PDC as a very potent NMDA agonist and highlight its utility in studying NMDA receptor-mediated neurodegeneration. This work was supported in part by NIH/NINDS NS30570 and NS27600.

## SPECIES DIFFERENCES IN QUINOLINIC ACID SYNTHESIS AND RESPONSES TO SPINAL CORD INJURY A.R. Blight\*, E.C. LeRoy, Jr., K. Saito\*, and M.P. Hayes\*, Div. Neurosurgery, Univ. North Carolina, Chapel Hill, NC 27599, and Lab. of Clinical Science, NIMH, Bethesda, MD 20892.

Experimental contusion injury to the spinal cord of guinea pigs results in delayed neurologic deficits that continue to increase in severity for several days following trauma, coincident with the invasion of the lesion by mononuclear phagocytes and increased levels of the neurotoxin quinolinic acid (QUIN), which is synthesized by macrophages. Inflammatory responses and accumulations of QUIN also occur following spinal cord contusion in rats, yet there is little or no indication of delayed onset of neurologic deficits. In this study, the responses of guinea pigs and rats to closely similar injuries of the spinal cord were examined. Tissue levels of QUIN were measured using mass spectrometry and gas chromatography at various times post-injury. In guinea pigs, increases in QUIN levels at the lesion site began at 1 day post injury, rose steeply during the first week, achieved potentially neurotoxic, maximal values, well in excess of serum levels, by 12 days, and remained elevated above serum levels at 25 days post-injury. A similar profile of increases in QUIN occurred in adjacent areas of the spinal cord, with lower peak levels. In rats, increases in tissue QUIN were much smaller, remaining below serum concentrations at all times, approached a plateau within 24 hours and decreased slowly over the succeeding weeks. Correlated with these observations, peritoneal macrophages from guinea pigs were shown to convert L-tryptophan to both L-kynurenine and QUIN *in vitro*, while rat macrophages show a much smaller capacity, and only under conditions of intense activation. Behavioral measurements confirmed the striking difference in the time course of functional deficits in the two species. QUIN accumulations in spinal cord following contusion injury may be of direct pathophysiological significance. (Supported in part by grant NS21122 from NIH, NINDS).

## 410.1

## TOTAL BUT NOT SPARED-GASTRIC VAGOTOMY REVERSES OLEIC ACID-INDUCED SATIETY. D. Greenberg\*, J. McCaffery, D.L. Lewis, G.P. Smith and A.J. Strohmayr. Bourne Laboratory, and Departments of Psychiatry and Neurology, Cornell Univ. Medical College, White Plains, NY 10605 USA.

Total subdiaphragmatic vagotomy attenuates the satiating effects of intestinal nutrients (Yox et al. 1992). To further investigate the neural mediation of satiation elicited by intestinally infused fats, we tested the satiating potency of intestinal infusions of the long chain fatty acid oleic acid (OL) in sham feeding rats with total abdominal vagotomy or with spared-gastric vagotomy.

Rats received total vagotomy where both the right and left vagal trunks were severed (n=8), spared gastric vagotomy where all branches of the abdominal vagus except the two gastric branches were severed (n=10), or sham vagotomy (n=8). All rats were subsequently fitted with gastric cannulas and duodenal catheters to allow duodenal infusions during sham feeding. Rats were food deprived overnight and given access to liquid food for 90 min. Sham fed intakes were measured every 5 min. Intestinal infusions (10ml) were delivered at a rate of 0.44 ml/min and began 12 min after sham feeding and were of sodium oleate (0.65 or 0.325 kcal) or 0.15M NaCl.

Intestinal infusions of both concentrations of OL rapidly suppressed sham feeding in the sham operated and spared-gastric vagotomy groups but not in the total vagotomy group [F(2,41)=p<.005]. We conclude that the gastric vagal nerves, presumably the afferent fibers are sufficient to mediate the satiating effect of intestinal infusions of OL.

## 410.2

## SYNERGISTIC INCREASE IN FOOD INTAKE AND BRAIN FOS-LIKE IMMUNOREACTIVITY (FOS-LI) AFTER TREATMENT WITH METHYL PALMOXIRATE (MP) AND 2,5-ANHYDRO-D-MANNITOL (2,5-AM). C.C. Horn\* and M.I. Friedman. Monell Chemical Senses Center, Philadelphia, PA, 19104.

We investigated the neural mechanism that integrates signals from carbohydrate (CHO) and fat metabolism to control food intake. Rats maintained on a diet providing equal amounts of calories from CHO and fat were given p.o. 5 mg/kg MP, a fatty acid oxidation inhibitor, or vehicle (methyl cellulose). Three hr later rats were injected i.p. with 150 mg/kg 2,5-AM, a fructose analogue that inhibits liver CHO metabolism, or saline. By 2 hr after i.p. injection, rats treated with MP and 2,5-AM showed a synergistic increase in food intake (MP+2,5-AM=2.0±0.3 gm, Veh.+2,5-AM=0.4±0.2, MP+Sal.=0.6±0.3, and Veh.+Sal.=0; n's=8; interaction, p<0.05). Fos immunocytochemistry was employed to investigate the neural pathways involved in this synergistic response. Groups of rats were treated as above (n's = 4). Brains from rats given MP+2,5-AM showed a large amount of Fos-li in the solitary tract nucleus and paraventricular nucleus of the hypothalamus whereas the other groups showed little or no Fos-li in these areas. These findings suggest that signals for feeding produced by MP and 2,5-AM treatment are integrated in the brain stem or peripherally. (This research was supported by NIH grants DK36339 and DC00014, and a grant from the Howard Heinz Endowment.)

## 410.3

DIET-RELATED EFFECTS OF 2,5-ANHYDRO-D-MANNITOL (2,5-AM) ON FOOD INTAKE AND LIVER ATP. J.E. Koch\*, G. Graczyk-Milbrandt, M.D. Osbakken, H. Blum, M.A. Ketchum, J.L. Nuss & M.I. Friedman. Monell Chemical Senses Center, Philadelphia, PA 19104.

2,5-AM, a fructose analogue, stimulates eating by its action in liver and decreases liver ATP. The eating response is attenuated by a high-fat diet. To determine whether this diet effect was related to liver ATP, 300 or 400 mg/kg 2,5-AM was injected (i.p.) into rats fed either a chow, low fat/high carbohydrate (LF/HC), or high fat/low carbohydrate (HF/LC) diet. 2,5-AM increased food intake compared with saline, but rats fed the LF/HC diet increased food intake more than rats fed the HF/LC diet or chow. One week later rats were re-injected, livers were freeze-clamped in liquid N<sub>2</sub> 30 min later, and assayed for ATP. Relative to saline, 2,5-AM decreased liver ATP in all diet groups; however, the drop was greater in rats fed LF/HC (82%) than in rats fed chow (43%) or HF/LC diets (46%). In vivo <sup>31</sup>P NMR spectroscopy also revealed diet-related changes in liver phosphate metabolism during i.v. infusion of 2,5-AM. Results are consistent with the hypothesis that the signal for eating after 2,5-AM is related to hepatic ATP levels. (Supported by NIH grant MH-50363)

## 410.5

CELIAC VAGAL AFFERENTS DETECT INTESTINAL MACRO-NUTRIENT INFUSIONS THAT SUPPRESS MEAL SIZE. E.K. Walls\*, R.J. Phillips, F.B. Wang, M.C. Holst and T.L. Powley. Psychological Sciences, Purdue Univ. West Lafayette, IN 47907.

Examination of the chemosensory functions of gastrointestinal vagal afferents has been facilitated by the recent development of a surgery that achieves highly specific deafferentation of vagal projection fields in the abdomen. Concurrent use of a WGA-HRP nodose ganglion injection and i.p. Fluorogold provide histological verification of the surgeries (Walls, et al. 1993, Soc. Neur. Abst. 19, 816). To specify more clearly the locations and pathways of chemosensory functions, the suppression of first meal size following acute intraduodenal infusion of 11 different macronutrients was compared in sham surgical control rats (SH, n=15) and rats that had received unilateral intracranial vagal afferent rhizotomy combined with contralateral celiac vagal branch cauterization (CV, n=22). Only data from rats with verified surgeries were used for statistical analysis. Duetodenal nutrient infusions (1.2 or 2.4 kcal/10ml/10min) immediately prior to the first (30 min) evening meal produced three distinct profiles of response. 1. Infusions of isotonic saline, 3% fructose, 3% D-phenylalanine or 5.6% glycerol failed to suppress first meal intake in either group. 2. Equicaloric 1.2 kcal infusions of 3% glucose, 3% maltose, 3% L-phenylalanine, 12% Isocal, and 1.4% oleic acid significantly reduced intake in SH but not in CV rats. 3. Intestinal infusion of 3% casein hydrolysate or 24% Isocal significantly reduced meal size in both SH and CV groups but the elimination of celiac afferents in CV rats blunted this response. Measures of baseline intake on noninfusion days also revealed that celiac deafferentation reduces the size of the first meal without affecting overall daily food intake or body weight. The finding that some nutrients failed to reduce intake shows that detection is nutrient-specific. The loss of suppression of meal size in CV rats suggests that afferents of the celiac vagus are critical for intestinal preabsorptive detection of macronutrients. The blunted nutrient-induced reduction in meal size reveals that when celiac vagal afferents have been eliminated some macronutrients are still detectable. NIH DK27627 and NIMH MH01023.

## 410.7

EFFECT OF HINDBRAIN LESIONS ON WATER AND SALINE INTAKE AFTER SHORT TERM SODIUM DEPLETION. G.L. Edwards\* and J.D. Power. Dept. of Physiol. & Pharmacol., Coll. of Vet. Med., Univ. of Georgia, Athens, GA 30602.

Treatment with a single dose of furosemide (10 mg/kg) and a low dose of captopril (5 mg/kg) results in an increase in sodium appetite in rats (Am. J. Physiol. 267: R171, 1994). We have found that overnight sodium depletion causes an increase in saline intake in rats with lesions of the area postrema/immediately adjacent nucleus of the solitary tract (AP/mNTS-lesions) (Am. J. Physiol. 264: R1242, 1993). In these studies, we examined the effect of short term sodium depletion with furosemide and captopril on water and 2% saline intake in rats with AP/mNTS-lesioned rats and SHAM-lesioned rats. We have found that this protocol stimulates increased water and saline intake in SHAM-lesioned rats (baseline: water 0.8±0.5 ml, saline 0.7±0.4 ml vs. depletion: water 6.4±0.7 ml, saline 4.1±0.9 ml) as previously reported. Interestingly, saline intake was not increased in AP/mNTS-lesioned rats (baseline: 26.4±3.8 ml vs depletion: 28.5±2.2 ml). However, water intake was significantly elevated in the AP/mNTS-lesioned rats after furosemide/captopril treatment (baseline: 4.8±1.0 ml vs depletion: 12.1±1.7 ml). These data provide further evidence for a role of the AP/mNTS in the control of fluid and electrolyte balance. (Supported by NIH DK 42533)

## 410.4

METABOLIC ACTIVITY IN THE BRAINSTEM ASSOCIATED WITH INTESTINAL INFUSIONS OF GLUCOSE VERSUS SALINE IN RAT PUPS. C.B. Phifer\* and C.A. Crady. Louisiana Scholars' College, Northwestern State University, Natchitoches LA 71457.

Responsiveness to ingested nutrients develops in rats during the second week of life. In a recent study involving independent ingestion by 15-day-old rat pups, direct duodenal infusions of 0.6M glucose decreased intake more than 50% relative to saline infusions. In the present study, [<sup>14</sup>C]-2-deoxyglucose autoradiography was used to study brainstem regions mediating inhibition of ingestion by intestinal glucose.

Polyethylene cannulas were implanted in the duodenum 4mm from the pylorus. Following [<sup>14</sup>C]-2-DG injections, pups were allowed to ingest milk for 30min. During the first 8min of the test, pups received duodenal infusions of 0.6M glucose or isotonic saline at 0.25% BW/min. Average autoradiograms were made from brainstem sections of eight pups in each treatment group. Images showing differences in activity were obtained by subtracting one average image from the other average image.

Pups that received glucose infusions showed lower relative metabolic activity in the lateral lemniscus, lateral parabrachial nu, principal sensory nu of the trigeminal n. oral portion of the spinal trigeminal nu, nu of the solitary tract, and medullary reticular fields. Glucose-infused pups showed higher activity than saline-infused pups in inferior colliculus, parabrachial regions, prepositus hypoglossal nu, medial vestibular nu, cuneate nu, and interpolar regions of the spinal trigeminal nu. These results will be discussed in relation to earlier studies on gastric distension and to nutrient-induced satiety.

## 410.6

RAPID STIMULATION OF SALT APPETITE BY INTRAVENOUS ANGIOTENSIN II IN RATS. R.L. Thunhorst\*, J.R. Lane, and D.A. Fitts. Dept. of Psychology, Univ. Iowa, Iowa City, IA 52242 and Dept. Psychology, Univ. Washington, Seattle, WA 98195.

A role for the renal renin-angiotensin system in the direct stimulation of salt appetite in the rat remains controversial because attempts to stimulate salt appetite by intravenous (iv) administration of angiotensin II (ANG II) have been unconvincing. Our recent demonstration that circulating ANG II is critical for the expression of sodium depletion-induced salt appetite calls for a re-examination of the role of renally-derived ANG II. The present experiment replicates our finding that depletion-induced salt appetite is prevented by selective blockade of ANG II synthesis with an iv dose of converting-enzyme inhibitor (captopril, CAP) that does not cross the blood-brain barrier. We now show that iv ANG II rapidly re-establishes salt appetite in CAP-blocked rats. Rats maintained on regular food, water and 0.3 M NaCl were depleted in the afternoon by furosemide (10 mg/kg sc) and were placed into metabolism cages with only water available. CAP infusions (2.5 mg/h iv) began just before the furosemide injections and continued overnight. The next morning, all rats received access to saline and water in graduated burettes. For the first 90 min of saline access, iv CAP continued in all rats. For the next 90 min, Group 1 received iv ANG II (30 ng/min, n = 4), and Group 2 continued on iv CAP (n = 6). For the last 90 min, all rats received iv ANG II.

	CAP	Group 1 ANG	ANG	CAP	Group 2 CAP	ANG
water	0.1±0.1	4.0±1.6*	3.5±2.5	0.2±0.2	0.0±0.0	3.4±1.1*
saline	0.4±0.4	4.3±1.3*	1.0±0.4	0.5±0.4	0.7±0.5	2.6±0.8*

\*p<0.05, ml/90 min, M and SE. The results suggest that ANG acts on the blood side of the blood-brain barrier to stimulate salt appetite in the sodium-depleted rat.

Supported by NS22274 to DAF.

## 410.8

EVIDENCE THAT GLYCINE COTRANSMISSION MAY BE ESSENTIAL TO FEEDING STIMULATION BY LATERAL HYPOTHALAMIC (LH) NMDA RECEPTORS. B.G. Stanley\* and B.S. Butterfield. Departments of Neuroscience & Psychology, University of California, Riverside, CA 92521.

We have recently shown that intense eating is elicited by LH injection of N-methyl-D-aspartic acid (NMDA), and that LH pretreatment with NMDA receptor antagonists suppresses both NMDA-elicited and natural eating. Cell physiology studies have suggested that NMDA receptor activation requires costimulation by glycine and glutamate. To examine whether glycine cotransmission might participate in NMDA-elicited eating, LH injection of 7-CK (7-chlorokynurenic acid), an NMDA-receptor glycine site antagonist, was tested in cannulated adult male Sprague-Dawley rats. First, we examined whether LH injection of 7-CK suppressed eating elicited by LH injection of NMDA (10 nmol), and found that the 6-10 gm elicited eating response was abolished by doses of 7-CK above 10 nmol. To examine behavioral specificity, 7-CK pretreatment was tested on eating elicited by LH injection of kainic acid (1 nmol). In contrast to its block of NMDA-elicited eating, 7-CK actually potentiated eating elicited by kainic acid, demonstrating the behavioral specificity of its actions. To confirm that 7-CK's effects were actually due to its actions at the glycine site, we tested whether pretreatment with LH injection of glycine would reverse 7-CK's block of NMDA-elicited eating. Glycine at doses above 20 nmol reversed 7-CK's effects. Finally, bilateral LH injection of 7-CK suppressed eating in 24 hr fasted rats. These findings support a role for NMDA receptors in LH feeding control mechanisms, and argue that glycine may act as a cotransmitter at these receptors.

## 410.9

REMNANTS OF A CTA PERSIST IN RAT NTS AFTER FULL BEHAVIORAL EXTINCTION. S.A. McCaughy<sup>1</sup>, B.K. Giza<sup>1</sup>, L.J. Nolan<sup>2</sup>, J.C. Smith<sup>1</sup>, J.A. Rhinehart-Doty<sup>1</sup>, and T.R. Scott<sup>1</sup>. (<sup>1</sup>Dept. of Psych., Univ. of Delaware, Newark, DE 19716; <sup>2</sup>St. Luke's/Roosevelt Hospital and Columbia University, NY, NY 10025; <sup>3</sup>Dept. of Psych., Florida State Univ., Tallahassee, FL 32306)

The development of a conditioned taste aversion (CTA) to saccharin in rats is accompanied by changes in taste-evoked activity in nucleus tractus solitarius (NTS). Responses to the CS are increased in a burst of activity that peaks 950 msec after stimulus application and that is restricted to a sugar-sensitive subgroup of cells. While a CTA can prevent ingestion of toxins, it also risks eliminating the ingestion of nutrients that were only coincidentally paired with illness. Thus, the ingestion of the CS without subsequent illness should extinguish the CTA. The aim of this study was to extinguish a CTA thoroughly and observe whether NTS responses return to normal. Subjects were female Wistar rats. One group (experimental) was conditioned to avoid 2.5 mM saccharin (the CS) by pairing its taste three times with intraperitoneal LiCl. The other group (control) received isotonic saline injections after the CS. Experimental rats were then given 10 min per day access to the CS after 23 hours of fluid deprivation until they accepted the CS at pre-CTA levels. Control rats were given access to the CS for the same length of time. All subjects were then tested in a two-bottle preference situation until the experimental rats preferred the CS over water to the same extent as the control rats. All behavioral vestiges of the aversion were extinguished after 13 daily sessions. Recording then took place from single neurons in NTS in response to 13 stimuli, including the CS. Responses to the saccharin CS in the experimental group still included a burst of activity, limited to the sugar-sensitive subgroup of cells, that peaked 1200 msec after stimulus onset. Thus, even after total behavioral extinction of a CTA, a neural vestige of the experience remains in the hindbrain. This may support the rapid relearning of an aversion that occurs upon a subsequent pairing of the CS with illness. (Supported by grant DK30964 from the NIDDKD.)

## 410.11

PREFERENCE OR AVERSION FOR ETHANOL OR SACCHARIN AFTER BILE DUCT LIGATION IN RATS. J.R. Lane\*, E.M. Starbuck, & D.A. Fitts. Dept. of Psychology, University of Washington, Seattle, WA 98195.

A bile duct ligation (BDL) in rats produces cholestasis, cirrhosis, portal hypertension, hyperkinetic circulation, and eventual hepatorenal failure. This syndrome is superficially similar to alcoholic cirrhosis, and thus yields the opportunity to observe the effects of cirrhosis on ethanol intake in relatively alcohol-naïve subjects. Rats that were allowed to drink 6% (v/v) ethanol for 3 wk persistently reduced their daily intake of ethanol by about 50% after BDL. The ethanol intakes of sham ligated rats did not change. To determine whether BDL-treated rats associate the taste of a completely novel, non-drug solution with the ill-effects of the BDL, dehydrated rats were given access to a 0.06% saccharin solution for 2 hr either immediately (paired) or 2 days (unpaired) before BDL or sham ligation surgery. Sham ligated rats all drank copious amounts of saccharin regardless of the pairing. All BDL rats avoided saccharin for about the first week, and after that the unpaired BDL rats developed a high preference for saccharin. The aversion in paired BDL rats persisted until the termination of the experiment at 27 days. When the association between ethanol and the BDL surgery was broken by providing either ethanol alone or ethanol with saccharin 15 days after BDL, the BDL groups drank as much as the sham ligated groups. Thus, BDL appears to induce a chronic aversion for either saccharin or ethanol when these flavors are paired with the onset of the illness. The reduction in ethanol intake does not seem to result from reduced ethanol metabolism, because chronic BDL rats drank large amounts of saccharin-flavored ethanol when it was unpaired with the BDL surgery. The results support the view that chronic illnesses can produce persistent aversions for flavors. Supported by NS22274, AA05390, and the U.W. Alcohol and Drug Abuse Institute.

## 410.10

COLOCALIZATION OF bZIP PROTEINS AND THEIR REGULATION BY CONDITIONED AND UNCONDITIONED STIMULI IN RAT BRAINSTEM SUGGEST A ROLE IN TASTE AVERSION LEARNING. C.A. Wilson and M.W. Swank\*. Department of Psychology, Furman University, Greenville, SC 29613.

Expression of the bZIP transcription factor c-Fos in the intermediate region of the nucleus tractus solitarius (intNTS) is a reliable correlate of both unconditioned stimulus (US) and post-training conditioned stimulus (CS) presentation during taste aversion learning. Because cFos must dimerize with other bZIP proteins to regulate putative genes involved in plasticity, examination of other bZIP proteins is a crucial step in understanding the role of cFos in this learning paradigm.

Although previous studies have shown expression of FosB, JunB, and JunD throughout the brainstem, the present study examined whether FosB is regulated by CS saccharin or US LiCl. Relative to control animals which received saline injections or ingested water, LiCl ( $p < .001$ ) and novel saccharin ( $p < .05$ ) caused an increase in FosB expression within intermediate NTS. In contrast to the effects of these two salient stimuli, familiar saccharin did not produce an increase in FosB above control, suggesting that regulation of FosB by novel saccharin is a crucial component of bZIP-mediated plasticity.

Colocalization of bZIP proteins is an obvious prerequisite for dimerization and interaction. To examine this, fluorochrome-avidin was used to sequentially label cells for c-Fos followed by FosB, JunB, or JunD. Within the intermediate NTS almost complete colocalization of c-Fos with FosB, JunB and JunD was found. We propose a model in which cFos and FosB compete for dimerization with JunB and/or JunD as part of a computational network of transcription factors which mediate plastic events associated with taste aversion learning.

## 410.12

ADRENALECTOMIZED RATS DEFEND A NEW, LOWERED BODY WEIGHT FOR AT LEAST 10 WEEKS. A.M. Strack\*, C. Horsley, M.F. Dallman. Dept. Physiology, UCSF, San Francisco, CA 94143-0444.

After adrenalectomy (ADX), the rates of body weight gain and food intake decrease over the first few weeks. To determine whether these decreases continue or whether they represent an altered set point for body weight (Green et al. Endocrinology 130:269, 1992), we studied ADX and sham-operated (SHAM) male rats through 10 wks after surgery on wk 4 of life. Body weight, food intake, ACTH, corticosterone (B) and insulin were measured at 1-2 wk intervals. Groups of 6-8 rats were killed 1, 3, 5 and 10 wks after surgery and tissues were weighed; DNA and protein were measured in brown adipose tissue (BAT).

Throughout the 10 wk period, plasma B levels at the PM peak or after 30 min restraint stress were  $< 1 \mu\text{g/dl}$  in all ADX rats used in these studies, demonstrating complete surgery. Body weight of ADX decreased to ~70% SHAM by 3 wks and remained at this level through 10 wks. Food intake in ADX was decreased by 2 d and remained at 75-80% of SHAM through wk 5 then it increased to ~90% SHAM in wks 7-10. BAT DNA increased by 40% between 1 and 3 wks and remained at this level until 10 wks; BAT protein ( $\mu\text{g/mg}$  wet weight) increased ~50% at 5 wks and 123% of SHAM at 10 wks. These increases in BAT indicate persistently increasing activity of the sympathetic nervous system after ADX. By contrast, white fat weight decreased by ~50-70% over 10 wks and plasma insulin levels were reduced by ~50-70% compared to SHAM at all times.

The increase in food intake, which coincided with the further increase in sympathetic activity, resulted in maintaining the reduced body weight constant in ADX rats. These results strongly suggest that ADX does reduce the reference, or set-point for body weight. (Supported in part by DK28172)

## ISCHEMIA: NEUROPROTECTION AND TROPHIC FACTORS

## 411.1

EFFECTS OF MILD AND MODERATE HYPOTHERMIA ON NEUROLOGIC OUTCOME, INFARCT SIZE AND ADENYLATE LEVELS FOLLOWING TRANSIENT MCA OCCLUSION IN RATS. C.M. Maier\*, K.V.B. Ahern, B.B. Gonzalez, and G.K. Steinberg. Dept. of Neurosurgery, Stanford University Medical Center, Stanford, CA 94305.

We studied 24 male Wistar rats who underwent a 2 hour occlusion of the ICA, MCA, and ACA by an intraluminal suture placed 18-22 mm into the ICA. During occlusion the animal's rectal and brain temperature were kept either normothermic (36.5-37.5°C; n=8), mildly hypothermic (32.5-33.5°C; n=8), or moderately hypothermic (29.5-30.5°C; n=8). After suture removal the animals were returned to normothermia and allowed to reperfuse for 24 hours. The animals were closely monitored throughout the recovery period and evaluated for neurological findings at 24 h post-ischemia. Average post-anesthesia recovery time showed that animals in the 33°C group recovered at a significantly faster rate (21±11 min;  $p < 0.05$ ) compared with the normothermic animals (37±12 min), but no significant improvement was found in the 30°C group. Neurological outcome showed that hypothermic animals in the 33°C group scored consistently higher (40±3.9) than either the normothermic (34±8.5) or the 30°C group (36±7.4). Histopathology revealed an 83% and 68% reduction in the area of cortical ischemic neuronal damage for the 33°C group (6.5±11.5%;  $p < 0.01$ ) and the 30°C group (11.9±17%;  $p < 0.025$ ), respectively, compared with the normothermic animals (37±20.5%). Using the intraluminal suture model, a separate group of animals was studied to determine brain adenylyte levels. After the animals were anesthetized, the brains were frozen *in situ* with liquid nitrogen, removed, sectioned into 3 coronal slices and the homogenates processed for extraction of adenylytes. Initial results of HPLC elution profiles in control animals show that this method assays adenylytes with a high degree of accuracy and thus may be useful in studying the mechanisms of neuroprotection by mild hypothermia.

## 411.2

BODY TEMPERATURE IN ACUTE HUMAN STROKE: RELATION TO STROKE SEVERITY, MORTALITY AND OUTCOME. J. Reith\*, H.S. Jørgensen, P.M. Pedersen, L.L. Jeppesen, H. Nakayama, H.O. Raaschou and T.S. Olsen. Dep. of Neurology, Bispebjerg Hospital, Copenhagen, Denmark, 2400.

Despite substantial experimental evidence of the benefit of peri- and postischemic hypothermia and the dangers of hypothermia, the validity of these claims in man is unproven. In the Copenhagen Stroke Study, which is a community-based, consecutive and prospective study of acute stroke, we measured body temperature on admission in 1197 patients. Stroke severity was measured using the Scandinavian Stroke Scale (SSS), on admission, weekly and at discharge. The CAT-scan rate was 82%. Multiple logistic and linear regression analyses were used. Among confounding factors recorded and taken into account were: Age, gender, stroke severity (SSS), Prior stroke, diabetes, hypertension, atrial fibrillation, ischemic heart disease, comorbidity, smoking, infections and leukocyte counts of blood. For patients admitted within 6 (n=390), 12 (n=556), and 24 (n=788) hours, body temperature was significantly and independently related to stroke severity, mortality and outcome. Although our investigation does not provide evidence of a causal relationship between early body temperature and outcome in acute human stroke, such a relationship explain our findings.

## 411.3

**NEURONAL N-TYPE CALCIUM CHANNEL ANTAGONIST, SNX-111, PREVENTS APOPTOSIS IN A FOCAL MODEL OF ISCHEMIA.** K. Gohil\*, T. Singh, D. Xue, G. Miljanich, R.B. Luther, C.M. Bitler, and S.S. Bowersox. NEUREX Corporation, Menlo Park, CA 94025.

The mechanisms of delayed neuronal death after a reversible ischemic insult are poorly understood. Recent studies in rodents have shown that apoptosis may play an important role in this process. A commonly used indicator of apoptosis is the presence of fragmented DNA (f-DNA), formed by the action of calcium-activated endonucleases. We have, therefore, examined the effects of SNX-111 (synthetic  $\omega$ -conopeptide MVIIA), a selective N-type neuronal calcium channel blocker, on ischemia-induced DNA fragmentation in spontaneously hypertensive rats. Temporary focal cerebral ischemia was produced by transient occlusion of the middle cerebral artery and permanent occlusion of the right common carotid artery. Rats were given either saline or a single dose of 5 mg/kg SNX-111 (infused intravenously over 30 minutes) immediately following 90 minutes of focal cerebral ischemia. Animals were sacrificed 24 hours after reperfusion, and their brains were rapidly removed and frozen. Coronal sections were analyzed for f-DNA using digoxigenin-dUTP and terminal transferase. Neurons with f-DNA were present only on the ipsilateral side of the injury. The highest densities of apoptotic nuclei (1800-3000) occurred in penumbral regions of parietal and insular cortices. Although total cell counts were comparable in saline and SNX-111 treated animals, the number of apoptotic neurons in brain sections from rats infused with SNX-111 was decreased by 63%. These findings suggest that the previously demonstrated neuroprotective actions of N-type calcium channel blockers (Buchan et al. *J. Cereb Metab Blood Flow* 14:903, 1994) may be due, in part, to suppression of apoptosis.

## 411.5

**PROTECTION FROM DELAYED HYPOXIC NEURONAL INJURY WITH THE NOS INHIBITOR, METHYLARGININE.** R.A. Wallis\* and K.L. Panizzon, Dept. of Neuro., UCLA and Sepulveda VAMC, Sepulveda, CA 91343.

During stroke, neurons appear to be injured by mechanisms of both acute and delayed injury. Nitric oxide has been demonstrated to mediate both hypoxic- and NMDA-induced acute neuronal injury. Since NMDA-receptor activation has been shown to induce delayed neuronal injury, we evaluated the effectiveness of the nitric oxide synthase (NOS) inhibitor, methylarginine against delayed neuronal injury from hypoxia in the hippocampal slice. Subjecting hippocampal slices to hypoxic exposure which was acutely sublethal, produced later evidence of CA1 delayed neuronal injury. To induce hypoxia, slice perfusion was changed to artificial CSF saturated with 95% N<sub>2</sub>/5% CO<sub>2</sub>. Hypoxia was discontinued at the peak appearance of the Hypoxic Injury Potential, which is an electrophysiological marker of acute irreversible hypoxic injury in this preparation. Slices given hypoxia recovered 100 ± 0% of initial CA1 PS amplitude after 1 hour. Thereafter, however, they lost all CA1 PS activity at a mean 7.3 ± 1.2 hours following hypoxia. In contrast, paired slices not receiving hypoxia, maintained PS activity for 19.8 ± 0.5 hours. The appearance of delayed neuronal injury from hypoxia was prevented with L-methylarginine (170  $\mu$ M) treatment, a concentration also protecting against acute neuronal injury in this preparation. When L-methylarginine was given for 35 mins. after hypoxia, CA1 PS response could be elicited thereafter for 21 ± 1.4 hours after, compared to paired slices exposed to hypoxia alone in which CA1 PS response could be elicited for only 7.7 ± 0.1 hours. The protection seen in these studies with L-methylarginine, a stereospecific inhibitor of NOS, indicates the involvement of nitric oxide mechanisms in CA1 delayed neuronal injury induced by hypoxia. Supported by the VA Research Service.

## 411.7

**LUBELUZOLE IMPROVES ISCHEMIC PENUMBRA MEASURED BY CORTICAL SPREADING DEPRESSIONS IN RATS.**

M. De Ryck\*, E. De Prins, C. Nolten, R. Marrannes and G. Clinck. Janssen Res. Found., Dept. Neuropsychopharmacol., Beerse, Belgium.

A photochemical thrombotic infarct was induced in rat parietal cortex (n=30). Two glass microelectrodes recorded extracellular [K<sup>+</sup>] and/or DC. A platinum electrode was placed frontally for electrical stimulation. In vehicle-treated rats (n=14), in sites up to 900  $\mu$ m proximal (P) to the infarct edge, infarct-related spreading depressions (SDs) progressively increased in duration, decreased in amplitude, and developed slower de- and/or repolarization slopes. By contrast, in sites 1-3 mm distal (D), SDs maintained a sharp profile, while somewhat increasing in duration. Following a one-hour SD-free period, an elicited SD, propagating towards the infarct, revealed further penumbral worsening, i.e., further changes in SD profile. The novel neuroprotective benzothiazole lubeluzole (R087926; 0.63 or 1.25 mg/kg iv; 5 min after irradiation; n=8/dose) did not reduce the number of infarct-related SDs (it is not an NMDA blocker), but following the one-hour SD-free period, lubeluzole protected against penumbral worsening. Lubeluzole (1.25 mg/kg iv) increased the penumbral SD amplitude by 24 % (p < 0.05) and accelerated the de- and repolarization rates by 89 % (p < 0.05) and 100 % (p < 0.01), resp., towards normal values. Lubeluzole prevents the increase of extracellular glutamate and normalizes neuronal excitability in the penumbra. It inhibits the glutamate-activated nitric oxide pathway.

## 411.4

**NPS 102, A NOVEL NMDA RECEPTOR ANTAGONIST, REDUCES ISCHEMIC DAMAGE IN RATS WITH INTRALUMINAL MIDDLE CEREBRAL ARTERY OCCLUSION.** Y. Chen, L.D. Arman, N. Alasti, J.L. Raszkiewicz\*, and A.L. Mueller. NPS Pharmaceuticals, Inc., Salt Lake City, UT 84108.

NPS 102 is a synthetic polyamine spider toxin analog that blocks NMDA/glycine-induced Ca<sup>2+</sup> influx noncompetitively in cultured rat cerebellar granule cells (IC<sub>50</sub> = 93 nM). NPS 102 produces marked neuroprotection (90%) of hippocampal CA1 pyramidal cells in a gerbil model of global ischemia. In order to study the potential neuroprotective effects of NPS 102 in focal cerebral ischemia, we administered NPS 102 (10 mg/kg, i.p. given immediately after the onset of ischemia) in male adult Wistar rats subjected to either permanent or temporary (2 hour) occlusion of the middle cerebral artery with an intraluminal suture. Cerebral infarct volumes were measured with triphenyltetrazolium staining 24 hours after permanent, or 72 hours after temporary occlusions. Compared with the control group which received saline, NPS 102 reduced the total infarcted volume by 20% in the permanent occlusion group (mean ± SEM). 286 ± 18 (control, n = 9) vs 229 ± 16 (NPS 102, n = 11) mm<sup>3</sup>, p < 0.03; and 37% in the temporary occlusion group: 150 ± 20 (control, n = 9) vs 94 ± 14 (NPS 102, n = 9) mm<sup>3</sup>, p < 0.05. The reduction in infarct volume involved both cortical and subcortical areas, and was most apparent in the striatum; this profile distinguishes NPS 102 from most other NMDA receptor antagonists. Moderate reduction in arterial pressure (25-30 mm Hg lasting 2 hours) was noted, while no PCP-like or other behavioral effects were observed. The results indicate that NPS 102, administered immediately after ischemic insult, reduces the infarct size in rats with focal cerebral ischemia, and that the neuroprotection is more effective in the setting of temporary ischemia followed by reperfusion.

## 411.6

**INDUCIBLE NITRIC OXIDE SYNTHASE GENE EXPRESSION IN TRANSIENT FOCAL CEREBRAL ISCHEMIA: PROTECTION BY AMINOGLUTAMINE.** C. Iadecola\*, X. Xu, F. Zhang, R. Casey, H. B. Clark and M. E. Ross, Dept. of Neurology, Univ. of MN, Minneapolis, MN 55455.

We have demonstrated that in permanent focal cerebral ischemia there is expression of inducible nitric oxide (NO) synthase (iNOS) and that the resulting NO production contributes to the secondary phase of tissue damage (AJP 268, R286, 1995; JCBF&M 15, 378, 1995). In the present study we investigated whether iNOS is expressed also after transient focal ischemia and, if so, we sought to define its role in the mechanism of brain injury. The middle cerebral artery was occluded for 2 hrs by an intraluminal filament in Sprague-Dawley rats and iNOS message was determined by the reverse-transcription polymerase chain reaction (RT-PCR) in the ischemic neocortex 6 hrs to 7 days after reperfusion. After transient ischemia iNOS mRNA was maximally expressed at 12 hrs after reperfusion and then began to decline. No expression was observed in non-ischemic cortex. iNOS immunoreactivity in the infarct was found in cells associated with the wall of small blood vessels at 12-48 hrs after reperfusion and in inflammatory cells as well at 48-96 hrs. To determine whether iNOS contributes to ischemic damage rats were treated for 4 days with the iNOS inhibitor aminoguanidine (AG) starting 6 hours after reperfusion. AG treatment (n=10) reduced infarct size in neocortex by 32±7% (p<0.05). Thus, transient focal ischemia leads to iNOS expression in selected cells. The observation that AG treatment reduces ischemic damage suggests that NO produced by iNOS contribute to the tissue damage. Interestingly, in transient ischemia maximal iNOS mRNA expression occurs 36 hrs earlier than in permanent ischemia (JCBF&M above). Perhaps, reperfusion of previously ischemic tissue triggers the release inflammatory cytokines which, in turn, induce iNOS in susceptible cells. We conclude that iNOS expression is an important determinant of ischemic brain damage and that AG may be a useful agent for the treatment of ischemic stroke. (Supported by AHA and NIH)

## 411.8

**NEUROTROPHINS INDUCE NMDA RECEPTOR EXPRESSION IN CULTURED RAT NEOCORTICAL NEURONS.** H.S. Ying\*, B.J. Gwag, M.M. Behrens, J. Koh, D. Lobner, and D.W. Choi. Dept. of Neurology and Center for the Study of Nervous System Injury, Washington Univ. School of Medicine, St. Louis, MO 63110.

Neurotrophin pretreatment increases the vulnerability of cultured mouse cortical neurons to oxygen-glucose deprivation-induced neuronal death, via an NMDA receptor-mediated mechanism (Koh et al., *Science* 268:573-575, 1995). Here, we used RT-PCR (30-35 cycles) to examine the effect of neurotrophin pretreatment on NMDA receptor expression in rat cortical cell cultures. 24 hr pretreatment with 100 ng/ml BDNF, NT-3, or NT-4/5 (but not NGF) increased mRNA levels of NMDAR-2A relative to cyclophilin, neurofilament light chain, or GFAP, whereas NMDAR-1 mRNA levels were unchanged. Consistent with this neurotrophin agonist profile, high levels of trk B and trk C mRNA, but not of trk A or p75 mRNA, were present in the cultures. Immunoblots revealed that the same neurotrophins selectively upregulated NMDAR-2A/B protein over NMDAR-1 protein. <sup>35</sup>S-methionine incorporation during neurotrophin application confirmed that the increased immunoreactivity corresponded to newly synthesized protein. These experiments suggest that the ability of neurotrophins to potentiate oxygen-glucose deprivation-induced neuronal death may be explained in part by an upregulation of NMDA receptor gene expression.

Supported by NIH NINDS grants NS 30337 and NS 322626 (DWC); Spanish Ministry of Science and Education (MMB). Neurotrophins were a generous gift from Genentech.

## 411.9

**BDNF POTENTIATION OF OXYGEN-GLUCOSE DEPRIVATION-INDUCED NEURONAL DEATH: INVOLVEMENT OF GENE EXPRESSION AND NITRIC OXIDE SYNTHASE** D. Lobner\*, B.J. Gwag, J. Koh, H.S. Ying, M.M. Behrens, and D.W. Choi. Dept. of Neurology and the Center for the Study of Nervous System Injury, Washington Univ. Sch. of Med., St. Louis, MO 63110.

We have shown previously that the neurotrophins BDNF, NT-3, and NT-4/5, but not NGF, potentiate neuronal necrosis induced by oxygen-glucose deprivation or addition of NMDA in murine cortical cell culture (Koh et al., *Science*, 268: 573-575, 1995). Murine cortical cell cultures briefly (30-40 min) deprived of oxygen and glucose normally developed little neuronal degeneration by the next day, but more neuronal death occurred in cultures treated with BDNF (50-100 ng/ml). This BDNF injury potentiation was associated with increased neuronal cell body swelling and was not blocked by late addition of cycloheximide, consistent with increased necrosis. BDNF injury potentiation was largely dependent on multi-hour pretreatment exposure, a small potentiation was induced by acute addition of BDNF during oxygen-glucose deprivation alone, and posttreatment had no effect. The large potentiating effect of 24 hr BDNF pretreatment was blocked by concomitant addition of 100 ng/ml actinomycin-D. Acute addition of inhibitors of nitric oxide synthase (NOS), 1 mM  $N^G$ -Nitro-L-arginine (N-Arg) or 1 mM  $N^G$ -Nitro-L-arginine methyl ester (L-NAME), during oxygen-glucose deprivation did not itself reduce neuronal death caused by longer oxygen-glucose deprivation (50-55 min), but attenuated BDNF-potentiated death by about 50%. These data suggest that BDNF potentiation of oxygen-glucose deprivation-induced neuronal cell death is dependent on gene expression and at least in part on NOS activity.

Supported by NIH NINDS NS 30337 (DWC), Spanish Ministry of Science and Education (MMB). BDNF was a generous gift from Genentech.

## 411.11

**INDUCTION OF NGFI-B EXPRESSION AFTER FOCAL CEREBRAL ISCHEMIA.** T.N. Lin\*, J.J. Chen, S.J. Wang, J.T. Cheng, S.I. Chi. Institute of Biomedical Sciences, Academia Sinica, Taipei and Tzu-Chi Medical College, Hualien, Taiwan, ROC

NGFI-B (also known as nur77) is a nuclear receptor, membrane of the thyroid/steroid receptor family, which is rapidly induced in cells stimulated with nerve growth factor (NGF). Altered expression of NGF mRNA has been reported after ischemia challenge. In the present study, the temporal and spatial expression of NGFI-B was investigated, using a three-vessel occlusion focal cerebral ischemia model. Northern blot analysis showed that, in the ischemic cortex, transient increased expression of NGFI-B immediately following ischemia-reperfusion and peaked (15-fold increase) at 30 min after reperfusion. Ipsilateral hippocampus also showed a similar induction of NGFI-B. Interestingly, increased expression of NGFI-B was also noted, with less extent, in the contralateral cortex which was sustained only very mild ischemia. On the other hand, there was no obvious increase in the contralateral hippocampus region. These results were in lined with the results from in situ hybridization studies. Which further revealed that enhanced expression of NGFI-B were also observed in the ipsilateral subcortical region but not the contralateral side. These results suggest that NGFI-B may play a crucial role in ischemia induced neuronal injury and/or recovery.

## 411.10

**Suppression of Specific Nerve Growth Factor Genes by Antisense DNA to c-fos.** PK Liu\*, JK Cui, YY He, CY Hsu. Div. Restorative Neurology and Human Neurobiology, Baylor College of Medicine, Houston, TX 77030 and Dept. of Neurology, Washington University St. Louis, MO 63110

In a rat stroke model, expression of immediate early genes (c-fos, c-jun and junB), late effector genes (neurotrophin genes: nerve growth factor [NGF] and brain-derived neurotrophic factor [BDNF]) and transcription factors (AP-1, and cyclic AMP response element binding [CREB]) increase within 2 hr after focal cerebral ischemia (FCI). Transcription factor activator protein-1 (AP-1) is a DNA-binding complex that recognizes the enhancer site of several late effector genes, including NGF. AP-1 dimeric complex contains proteins of Fos and Jun families. Cerebral ischemia increases the levels of AP-1 DNA binding activity. To investigate the effect of AP-1 activation on the regulation of late effector genes, we synthesized a 26-mer DNA (*mcfosr<sub>115</sub>*) in both antisense and sense orientation to the c-fos mRNA. *mcfosr<sub>115</sub>* was infused into the left lateral ventricle of adult male Long-Evans rats (n=20). Brain uptake and distribution of oligo DNA were studied using digoxigenin- or biotin- labeled *mcfosr<sub>115</sub>*. Neuronal uptake in the hippocampus was noted as early as 6 hr, and lasted for at least 41 hr. A 30-min ischemia with a 90-min reperfusion were induced 16 hr post *mcfosr<sub>115</sub>* infusion. We determined the effect of *mcfosr<sub>115</sub>* on the expression of transcription factor activities, and of neurotrophin mRNA after FCI. We observed inhibition of Fos/AP-1 activities and suppression of NGF mRNA by antisense *mcfosr<sub>115</sub>*, but not CREB activities or the expression of  $\gamma$ -actin and neurotrophin-3 genes in the hippocampus. We concluded that post ischemic NGF expression *in vivo* is dependent upon Fos/AP-1 activities, and this model is suitable for studying the regulation of effector genes controlled by AP-1 binding activities.

## 411.12

**THE NEUROPROTECTIVE EFFECT OF CLENBUTEROL IS MEDIATED BY NGF.** J. Krieglstein\*, I. Semkova and M. Schilling. Department of Pharmacology, Philipps-University, Ketzertbach 63, D-35032 Marburg, Germany

Adrenergic stimulation is known to induce NGF synthesis in the brain. Therefore, we attempted to find out whether the  $\beta_2$ -mimetic clenbuterol could protect neurons against damage by increasing NGF synthesis. In primary cultures of hippocampal neurons obtained from newborn rats we tested NGF induction and neuroprotection by clenbuterol. In the mouse model of focal cerebral ischemia the capacity of clenbuterol was examined to reduce the infarct size. Exposure of the hippocampal cells to 100  $\mu$ M clenbuterol for 4 h enhanced the level of NGF in the culture medium five-fold as measured by two-site ELISA. Furthermore, 1-100  $\mu$ M clenbuterol was capable of protecting concentration-dependently the hippocampal neurons against damage caused by 1 mM glutamate added to the medium for 1 h. When NGF was bound in the medium of the hippocampal cells by an antibody the neuroprotective effect of clenbuterol was no longer demonstrable. Doses of 0.3 or 1 mg/kg clenbuterol injected intraperitoneally 5 h prior to occlusion of the middle cerebral artery reduced significantly the infarct area on the mouse brain surface. The results offer strong evidence that the neuroprotective effect of clenbuterol demonstrated *in vitro* and *in vivo* is mediated by NGF. The induction of NGF in the brain by lipophilic drugs could become an elegant approach to the treatment of neurodegenerative diseases.

## POTASSIUM CHANNEL STRUCTURE, FUNCTION AND EXPRESSION II

## 412.1

**MACROSCOPIC PROPERTIES OF MSLO CA-ACTIVATED  $K^+$  CURRENTS** J. Cui\*, D.H. Cox, and R.W. Aldrich. Dept. of Mol. and Cell. Physiol., HHMI, Stanford University School of Medicine, Stanford CA 94305

Previous studies of the gating of Ca-activated  $K^+$  channels have focused primarily on the calcium dependence of steady-state single-channel recordings. To address the relationship between Ca-dependent and voltage-dependent gating, we have studied the kinetic and steady state properties of macroscopic currents from mSlo Ca-activated  $K^+$  channels expressed in excised macropatches from *Xenopus* oocyte membranes. In response to voltage steps activation and deactivation kinetics were sensitive to both internal  $Ca^{2+}$  ( $[Ca]_i$ ) and membrane voltage over a wide range of  $[Ca]_i$  (1 to 1000  $\mu$ M) and voltages (-180 to +200 mV). Activation rates increased, and deactivation rates decreased with increasing  $[Ca]_i$  or voltage. Both activation and deactivation could be approximated by a single exponential function. G-V plots could be fitted with a simple Boltzman function which maintained a similar shape as  $[Ca]_i$  was varied. The position of the G-V curve shifted in the hyperpolarizing direction along the voltage axis as  $[Ca]_i$  was increased. The magnitude of the G-V curve shift was not constant as  $[Ca]_i$  was increased in 10 fold increments, but rather was larger at low  $[Ca]_i$ . These results suggest that mSlo gating involves a voltage dependent process that is intrinsic to the channel protein and is cooperative among the subunits. Further supporting the existence of an intrinsic voltage dependent gating transition, the rate of activation at each test potential increased with  $[Ca]_i$  reaching a plateau at high  $[Ca]_i$  whose level was voltage dependent. Also, at voltages greater than +90 mV activation of the mSlo channel could be observed in solutions whose free  $Ca^{2+}$  was buffered to as low as ~2 nM. The activation rate under these conditions is much faster than the diffusion limit for  $Ca^{2+}$  binding, indicating that the channel can open without binding to  $Ca^{2+}$ . From measurements of the voltage-dependence of channel activity at Popen between  $10^4$  to  $10^{-2}$  we have estimated the amount of charge associated with mSlo gating to be between 1 to 1.5 charges per channel, an amount approximately equal to the sum of the charges associated with the rate limiting steps in activation and deactivation. These data lead us to favor a model in which each channel must undergo a single, intrinsic voltage dependent conformational change separate from  $Ca^{2+}$  binding before opening.

## 412.2

**A KINETIC MODEL FOR THE MSLO CA-ACTIVATED  $K^+$  CHANNEL** D.H. Cox, J. Cui, and R.W. Aldrich\*, Dept. of Mol. and Cell. Physiol., HHMI, Stanford University School of Medicine, Stanford CA 94305

We have studied macroscopic currents from mSlo Ca-activated  $K^+$  channels expressed in *Xenopus* oocytes. These studies have revealed several constraints on any system designed to model the behavior of this channel (see accompanying abstract). Among these constraints are the following: 1) In response to voltage steps, activation and deactivation kinetics are sensitive to both  $[Ca]_i$  and voltage over a wide range of these stimuli, and yet maintain approximately single exponential kinetics. 2) Conductance vs  $[Ca]_i$  curves are best fit to the hill equation using coefficients between 1 and 3 (depending on membrane voltage) suggesting that at least 3  $Ca^{2+}$  ions bind to the channel and affect activation. 3) There appears to be a single, intrinsic voltage dependent conformational change which the channel must undergo in order to open. And 4), even at very low  $[Ca]_i$  (~2 nM), activation is observed at voltages greater than +90 mV. We have used the general kinetic scheme below to model the behavior of this channel.

Horizontal transitions represent  $Ca^{2+}$  binding steps. No voltage dependence has been assigned to these steps. Vertical transitions represent a single voltage dependent conformational change necessary for channel opening.  $Ca^{2+}$  can bind to both closed (C) and open (O) conformations, but binds with higher affinity to O thus favoring channel opening. Models of this type can account for the major properties of our data. In one form of this scheme the affinities of all  $Ca^{2+}$  binding sites in any one conformation are the same. In this case the model amounts to a voltage dependent version of the MWC model of allosteric proteins replacing the T and R nomenclature with C and O respectively.

## 412.3

TISSUE-SPECIFIC TRANSCRIPTIONAL REGULATION OF THE SLOWPOKE  $Ca^{2+}$ -ACTIVATED  $K^+$  CHANNEL GENE. N. S. Atkinson\* and R. Brenner. Dept. of Zoology., The University of Texas at Austin, Austin TX 78712-1064.

The stereotypical properties of an electrically excitable cell result from the coordinated activity of different transmembrane ion channels. Little is known about the gene-regulation of the ion channel genes which underlie a cell's electrical profile. We are studying transcriptional control of the slowpoke  $Ca^{2+}$ -activated  $K^+$  channel gene. We have shown that slowpoke has both neuronal and muscle/gut/tracheal cell specific promoters. Each promoter causes the production of mRNAs that differ slightly in the 5' end and therefore encode slightly different polypeptides. For each of these tissue types we have also identified promoter proximal and/or enhancer elements that direct expression of the promoters. Furthermore, developmental-stage specific and eye specific enhancer elements have been discovered.

## 412.5

EVIDENCE THAT NEURONAL G PROTEIN-GATED INWARDLY RECTIFYING  $K^+$  CHANNELS ARE ACTIVATED BY  $G\beta\gamma$  SUBUNITS AND FUNCTION AS HETEROMULTIMERS. Paulo Kofuji, Craig Doupnik\*, Norman Davidson and Henry A. Lester. Division of Biology 156-29, Caltech, Pasadena, CA 91125

Guanine nucleotide-binding proteins (G proteins) activate  $K^+$  conductances in cardiac atrial cells to slow heart rate and in neurons to decrease excitability. Complementary DNAs encoding three isoforms of a G protein-coupled inwardly rectifying  $K^+$  channel have recently been cloned from cardiac (GIRK1) and brain cDNA libraries (GIRK2 and GIRK3). Here we report that GIRK2 but not GIRK3 can be activated by G protein subunits  $G\beta_1$  and  $G\gamma_2$  in *Xenopus* oocytes. Furthermore when either GIRK3 or GIRK2 was coexpressed with GIRK1 and activated either by muscarinic receptors or by  $G\beta\gamma$  subunits, G protein-mediated inward currents were increased by 5 to 40 fold. The single-channel conductance for GIRK1 plus GIRK2 coexpression was intermediate between those for GIRK1 alone and for GIRK2 alone, and voltage-jump kinetics for the coexpressed channels displayed new kinetic properties. On the other hand, coexpression of GIRK3 with GIRK2 suppressed the GIRK2 alone response. These studies suggest that formation of heteromultimers involving the several GIRKs is an important mechanism for generating diversity in expression level and function of neurotransmitter-coupled inward rectifier  $K^+$  channels. Supported by NIH, AHA and ICAgen Inc.

## 412.7

STRUCTURE OF THE PORE REGION OF CYCLIC NUCLEOTIDE-GATED CHANNELS AND ITS FUNCTION IN GATING. Z.-P. Sun\*, M.H. Akabas, F.H. Goulding, A. Karlin and S.A. Siegelbaum. Depts. Pharmacol., Physiol., Biochem., Ctr. Neuro. & Behav. & Ctr. Molec. Recog., HHMI, Columbia University, N.Y., NY 10032

The P-region (or H5) linking the extracellular ends of the S5 and S6 transmembrane segments of cyclic nucleotide-gated (CNG) ion channels is the major determinant of their ion-permeation properties and forms the channel pore. The P-region of the voltage-gated ion channels, which is homologous to the P-region of the CNG channels, has been proposed to fold into and out of the membrane as a  $\beta$  hairpin. We have applied the substituted-cysteine accessibility method (SCAM) to investigate the structure of the P-region. Each P-region residue (positions R345-S371, numbered R1-S27 here) of the cloned bovine retinal channel (BRET) was substituted with cysteine individually. The accessibility of each cysteine substitute to charged, sulfhydryl-specific reagents applied to either side of the membrane, in both the open and closed states, was studied in inside-out and outside-out patch-clamp recordings of the mutant channels expressed in *Xenopus* oocytes. V4C, T20C and P22C were accessible to reagents applied to either side of the membrane, V4C only in the closed state, and T20 and P22C in both the open and closed states. L7C and V24C were accessible to reagents in the closed state only from the cytoplasmic side. The two sided accessibility of V4C, T20C, P22C indicates that the P-region is a loop which extends towards the central axis of the channel. Together, the P-regions of the subunits of the oligomeric CNG channel form an iris that is the permeability barrier or gate in the closed state and the cation-selectivity filter in the open state.

## 412.4

N-terminal domain of GIRK1 muscarinic potassium channel facilitates activation by muscarinic receptors. P.A. Slesinger\*, E. Reuveny, Y.N. Jan and L.Y. Jan. Howard Hughes Med. Instit. and Dept. of Physiology, Univ. of California, San Francisco, San Francisco, CA 94143.

Stimulation of G-protein coupled receptors leads to the dissociation of the G-protein trimer into activated  $G\alpha$  and  $G\beta\gamma$  subunits which can each interact with various effectors. Although the specificity of this interaction for  $G\alpha$  effectors can be determined by the kind of  $G\alpha$  subunit, it is unclear what determines the specificity for effectors which respond to  $G\beta\gamma$  subunits. For example, the muscarinic potassium channel ( $I_{K_{ACM}}$ ) in the heart can be activated by a variety of different recombinant  $G\beta\gamma$  subunits, yet stimulation of muscarinic receptors but not beta-adrenergic receptors activates  $I_{K_{ACM}}$ . Expression of GIRK1, a cloned subunit of  $I_{K_{ACM}}$ , in *Xenopus* oocytes generates  $G\beta\gamma$ -sensitive inwardly rectifying potassium channels which couple to muscarinic receptors and have many properties similar to those of  $I_{K_{ACM}}$ . To identify structures involved in the activation of GIRK1 by muscarinic receptor stimulation, we have constructed chimeras of GIRK1 and IRK1, a G-protein-insensitive inward rectifier. In oocytes expressing GIRK1 and the m2 receptor, the m2 agonist carbachol rapidly induces an inwardly rectifying potassium current ( $\tau = \sim 7$  s.). Replacing the hydrophobic core (M1-H5-M2) and part of the C-terminal domain of IRK1 with the corresponding region of GIRK1 produces a chimeric channel which is  $G\beta\gamma$ -sensitive but activates slowly ( $\tau = 44$  s.) after m2 stimulation and has a high agonist-independent (basal) current. Adding the N-terminal domain of GIRK1 to this chimeric channel restores fast activation by m2 stimulation ( $\tau = \sim 7$  s.) and reduces the basal current. Our results demonstrate that the N-terminal domain of GIRK1 serves two roles: facilitating rapid activation by m2 stimulation and reducing the agonist-independent current. The interaction of the N-terminal domain with G-proteins provides one mechanism for ensuring specific activation of  $I_{K_{ACM}}$  in the heart.

## 412.6

DETERMINATION OF THE SUBUNIT STOICHIOMETRY OF AN INWARD RECTIFIER POTASSIUM CHANNEL. J. Yang, Y.N. Jan and L.Y. Jan\*. HHMI, Dept. of Physiol., Univ. of California, San Francisco, CA 94143

Inward rectifier  $K^+$  channels have a distinct architecture that is different from voltage-gated  $K^+$  channels: they contain only two putative transmembrane segments instead of six. It has been shown that voltage-gated  $K^+$  channels are composed of four subunits. We examined the stoichiometry of an inward rectifier  $K^+$  channel, IRK1, by linking together the coding sequences of three or four identical subunits and tagging the expression of an individual subunit with a mutation (D172N E224K) that weakens rectification and reduces single-channel conductance. Tandem trimers or tetramers with 0-3 tagged subunits at various positions were examined alone or in coexpression with the mutant monomer in *Xenopus* oocytes. We found that the four subunits in a tandem tetramer are equivalent and are all incorporated into the functional channel. More compellingly, whereas the tandem tetramer made up of four wild-type (wt) subunits behaved the same with or without coexpression of the mutant monomer, the macroscopic and single-channel properties of the wt tandem trimer coexpressed with the mutant monomer differ from those of the wt tandem tetramer, but are similar to those of the tandem tetramers with one mutant subunit at any of the four positions. These results indicate that IRK1 channel expressed in oocyte is composed of four identical subunits. Surprisingly, the tandem tetramers made up of three mutant (in this case, D172N-E224G) subunits and one wt subunit retain nearly identical sensitivity to  $Mg^{2+}$  and  $\sim 1/6$  of the sensitivity to spermidine as compared to the wt channel, suggesting that  $Mg^{2+}$  and spermidine can interact with only one subunit in a tetrameric channel. The tetrameric structure of both inwardly rectifying and voltage-gated  $K^+$  channels is consistent with an evolutionary linkage between these two families of channels.

## 412.8

A ROLE FOR THE "PRE-PORE" REGION OF VOLTAGE-DEPENDENT  $K^+$  CHANNELS IN GATING AND ZINC MODULATION.

G. Talukder\*, M.M. Tamkun\*, and N.L. Harrison\*

<sup>1</sup>Anes and Crit Care & Pharm/Phys., U of Chicago, Chicago IL 60637.

<sup>2</sup>Mol. Phys. and Biophys., Vanderbilt U., Nashville TN.

$Zn^{2+}$  modulates the gating of certain cloned voltage-gated  $K^+$  channels, such as Kv1.5 (Harrison et al. 1993 Mol. Pharm. 43:482-486). Two cloned potassium channels, Kv1.2 and Kv2.1, show decreased sensitivity to zinc. The amino acid sequence in the pre-pore domain between S5 and S6 is quite variable between these channels and Kv1.5. We have studied mutations of Kv1.5 in the pre-pore domain which affect gating, activation kinetics and zinc modulation. Whole cell recordings were made at 25°C, using intracellular solutions based on K gluconate and extracellular perfusion with saline containing 3mM  $K^+$ . All channels were transiently expressed in HEK 293 cells. Measurements of  $t_{1/2}$  (activation) were conducted at or as near as possible to  $V_{1/2}$  (midpoint of activation). We have studied several mutations of Kv1.5, including A455K, H461K, and E454Q. The gating of E454Q, A455K, and H461K is shifted in the depolarized direction relative to the wild type (w.t.) channel ( $V_{1/2}$ : w.t. =  $4.5 \pm 1.8$  mV; E454Q =  $19.5 \pm 3.1$ ; A455K =  $19.6 \pm 1.9$ ; H461K =  $18.9 \pm 2.3$ ). There is approximately a two-fold slowing of the activation kinetics of E454Q relative to the wild type channel ( $t_{1/2}$ : w.t. =  $5.33 \pm 0.7$  ms; E454Q =  $11.75 \pm 2.6$  ms [ $p < 0.01$ ]). The three mutations also show a decreased sensitivity to zinc, especially E454Q, which shows a ten-fold lower affinity for zinc. Based on these data, we suggest that the region of the channel protein between S5 and the pore may interact with extracellular ions and the "voltage sensor" in the S4 region to modulate channel gating.

## 412.9

**IN SITU OXIDATION OF AN ENGINEERED CYSTEINE IN THE K<sup>+</sup> CHANNEL Kv2.1 (DRK1) SUGGESTS CONTACT BETWEEN THE PORE AND S6.** R.H. Joho\*, Y. Liu, R.D. Zuhke and H.-J. Zhang. Department of Cell Biology and Neuroscience, The University of Texas Southwestern Medical Center, Dallas, Texas 75235.

The segment between S5 and S6 of voltage-gated K<sup>+</sup> channels has been implicated to form the major part of the ion conduction pathway. Little is known about the conformation of this region although various models have been proposed. To gain insight into the secondary structure, we used cysteine-substitution mutagenesis to probe side-chain accessibilities of mutated amino acids in the pore region of Kv2.1 and to monitor possible disulfide formation between cysteines by *in situ* oxidation. Of 28 cysteine substitutions, we identified one mutant, I379C, that showed >90% current reduction after superfusion of channel-expressing *Xenopus* oocytes with 0.1% H<sub>2</sub>O<sub>2</sub>. The effect could be reversed by 1 mM DTT. This finding suggested that the new cysteine at position 379 might form a disulfide either with the same cysteine of another subunit or with one of the three cysteines (C232, C393, and C394) present in the hydrophobic core (S1 - S6) of the channel, rendering the channel nonfunctional after *in situ* oxidation. To show if any of the three cysteines might interact with position 379, we mutated either singly or in combination C232, C393, and C394 to serine. The "cysteineless" mutant C232S/C393S/C394S/I379C was H<sub>2</sub>O<sub>2</sub> resistant. The double mutants C232S/I379C and C393S/I379C were still H<sub>2</sub>O<sub>2</sub> sensitive, in contrast, C394S/I379C was H<sub>2</sub>O<sub>2</sub> resistant, suggesting that positions 379 and 394 are close enough to support formation of a disulfide bridge after *in situ* oxidation. ## 412.10

**ACIDIC AMINO ACID E283 IN S2 SEGMENT INTERACTS ELECTROSTATICALLY WITH S4 BASIC RESIDUES IN SHAKER K<sup>+</sup> CHANNEL.** S.K. Tivari-Woodruff and D.M. Papazian\*, Department of Physiology, UCLA School of Medicine, Los Angeles, CA 90024-1751.

Electrostatic interactions between conserved acidic residues in putative transmembrane segments and basic amino acids of the voltage-sensing S4 segment stabilize the structure of voltage-dependent Shaker K<sup>+</sup> channels (Papazian et al., *Neuron* in press, 1995). Using charge reversal mutations, we have now identified likely short range electrostatic interactions of E283 in S2 with R368 and R371 in the S4 segment.

Single and double mutations (in an inactivation-removed [IR] background) were expressed in *Xenopus* oocytes for analysis of protein maturation and channel function. The mutation E283R-IR eliminated functional expression and significantly reduced maturation of the protein, suggesting that E283R affects proper folding. The double mutant combinations E283R+R368E-IR and E283R+R371E-IR restored efficient maturation. In contrast, charge reversal mutations at other S4 mutations did not rescue E283R. Only the double mutant combination E283R-R371E-IR restored functional expression; the activation curve was shifted to the right. These results suggest that E283 interacts electrostatically with R368 and R371. However, these two S4 positions are not equivalent because R371E restores channel activity to E283R whereas R368E does not. Perhaps the interactions are not of equal strength or E283 interacts with R368 and R371 in different channel conformations. The latter possibility would be consistent with the need for charged amino acids to undergo conformational changes during voltage-dependent activation.

## 413.1

**A METABOTROPIC GLUTAMATE RECEPTOR ON GANGLION CELLS IN CAT AND PRIMATE RETINAL SLICES** E.D. Cohen. Dept. of Ophthalmology and Visual Science, Yale Univ. Med. School, New Haven, CT 06520-8061. Bipolar cells transduce the visual signal through release of glutamate onto the dendrites of ganglion cells. I have examined the effect of glutamate agonists upon voltage-gated calcium currents of cat and primate ganglion cells in a slice preparation. Calcium currents were enhanced by 10mM barium, Na<sup>+</sup> channels were blocked by the addition of 200nM TTX, and NBQX 5μM blocked AMPA/kainate receptors. Ganglion cells were recorded using whole-cell and perforated patch clamp techniques. When held at -80mV and stepped to -10mV, application of 10μM glutamate depressed voltage gated calcium currents on cat and primate ganglion cells up to 50%, while evoking little inward current at rest. Quisqualate (10-30μM) and t-ACPD (10-100μM) produced similar depressions. An agonist potency series for this effect revealed glutamate=quisqualate >ACPD. Depression of calcium currents were observed on both on- and off-center midget/β ganglion cells and on α/parval cells. This suggests that regulation of calcium influx by metabotropic receptors could play an important role in modulating the light-evoked responses of retinal ganglion cells. Supported by EY10617.

## 413.2

**NICOTINIC ACETYLCHOLINE RECEPTORS ARE EXPRESSED BY AMACRINE AND GANGLION CELLS IN THE RABBIT RETINA.** Kent I. Keyser<sup>1</sup>, Agnieszka Brzozowska-Preci<sup>1</sup>, Jon M. Lindstrom<sup>2</sup>, and Richard H. Masland<sup>3</sup>. Department of Neurosciences, University of California, San Diego CA<sup>1</sup>; The Institute of Neurological Sciences, University of Pennsylvania, Philadelphia PA<sup>2</sup>; Howard Hughes Medical Institute, Mass. General Hospital, Boston MA<sup>3</sup>.

Acetylcholine (ACh) is a transmitter in the retina that affects the response properties of many ganglion cells, including those that display directional selectivity. Three structural (β) and eight ligand binding (α) subunits of neuronal nicotinic acetylcholine receptors have been purified and antibodies have been raised against some of them. As part of a continuing effort to understand the cholinergic circuitry in the retina, we used a monoclonal antibody that recognizes native α3 or α5 subunits to determine the pattern of expression of these subunits in the rabbit retina. Immunoreactive cells in the Inner Nuclear Layer were restricted to the first one or two tiers of cells. They ranged from 7 to 14 μm in diameter in dehydrated and cleared sections, and comprised at least three distinct populations based upon somata size and intensity of immunoreactivity. Several populations of cells in the Ganglion Cell Layer were distinguishable on these bases as well. The labeled cells in this layer ranged from 8 to 16 μm. The dendrites of some of the immunoreactive cells could be traced until they entered one of two dense bands of immunoreactive processes in the Inner Plexiform Layer. These bands divided the IPL roughly into thirds. They overlap the levels of stratification of the starburst (cholinergic) amacrine cells, but were wider and less sharply defined than the strata defined by starburst processes. Viewed in horizontal sections, the nAChR-positive plexi had a honeycomb appearance resembling the mosaic of starburst dendrites. These results are consistent with the known location of nicotinic synapses upon ganglion cells. The identity of the nAChR-containing amacrine cells remains to be learned.

## 413.3

**VOLTAGE-GATED NON-SELECTIVE ION CURRENT IN RETINAL GANGLION CELLS.** T. Tabata & A.T. Ishida\*. Section of Neurobiology Physiology & Behavior, University of California, Davis CA 95616.

Using whole-cell patch-clamp methods, we have found a voltage-gated non-selective ion current (I<sub>non</sub>) in retinal ganglion cell (RGC) somata dissociated from adult goldfish. Both rapidly and gradually rising components of I<sub>non</sub> were more activated at more depolarized voltages; the activation of these components was apparent at command potentials between -50 mV and +50 mV. The current-voltage curve of I<sub>non</sub> did not shift upon replacement of monovalent cations or anions in the superfusate saline by other small inorganic ions or by large organic ions (e.g., N-methyl-D-glucamine and D-glucuronate). These measurements suggest that I<sub>non</sub> can be carried by small as well as large ions and that the corresponding conductance has little ion selectivity. I<sub>non</sub> was resistant to 3 μM tetrodotoxin (TTX), 30 mM tetraethylammonium (TEA) plus 10 mM 4-aminopyridine (4AP), and 2.4 mM Co<sup>2+</sup>, which are effective blockers in goldfish RGCs against Na, K, and Ca currents, respectively. However, I<sub>non</sub> could be reduced in amplitude by roughly 50% with 1 mM halothane. When depolarized by exposure to high-K<sup>+</sup> saline containing Lucifer yellow (10 mM), TTX, TEA, 4AP, and Co<sup>2+</sup>, dissociated RGCs could be loaded with Lucifer yellow within several minutes. Some, if not all, of I<sub>non</sub> may therefore pass through channel-like hemi-gap junctions. Whether these form gap junctions *in situ* or function otherwise (e.g., spike shaping) remains to be established.

Supported by NIH grant EY 08120.

## 413.4

**CAN WE DETERMINE THE CONTRIBUTION OF NMDA AND KA/AMPA RECEPTORS TO EPSPs IN GANGLION CELLS?** T.J. Velte\*, W. Yu\*, and R.F. Miller\*. Dept. of Physiol., Grad. Program in Neuroscience, Univ. of Minnesota, Mpls, MN 55455; Johns Hopkins Univ., Sch. of Med., Baltimore, MD 21205.

Both NMDA and KA/AMPA receptors contribute to light evoked synaptic inputs of most retinal ganglion cells. However, the role and magnitude of each receptor subtype to EPSP generation has not been determined. We used NBQX and D-AP7 to segregate NMDA and KA/AMPA receptors, and study the relative contribution of each class, examined under voltage-clamp conditions in the slice preparation of the amphibian retina. Synaptically evoked currents were measured alternately in NBQX vs. D-AP7. Algebraic summation of the two currents were compared to the control response in standard Ringer. Most often the KA/AMPA + NMDA sum was less than the control, although occasionally the sum exceeded the control.

Computer simulations were carried out to understand the confounding summation experiments. We used an equivalent cylinder or a realistic compartmental model of a ganglion cell, with a passive membrane (R<sub>m</sub>=70,000 Ω cm<sup>2</sup>), a linear KA/AMPA current, and a non-linear NMDA current. We could duplicate the physiological summation data under the following conditions: when the stimulus was placed on or near the soma, the synaptic response was well clamped and the currents summed to produce the same current magnitude seen in the control. When the stimulus was located on a proximal dendrite, there was significant local escape voltage which caused the membrane potential to approach the peak potential for maximum NMDA current, which augmented the response. When the stimulus was placed distally, the escape voltage moved beyond the NMDA peak potential and closer to the reversal potential for both channel types (0 mV) which attenuated the overall current. Thus both clamp failures and non-linear summation may account for our observations.

## 413.5

MODULATION OF VOLTAGE-GATED Na<sup>+</sup> CURRENTS IN RETINAL GANGLION CELLS BY SEROTONIN RECEPTOR ACTIVATION.

S. Hidaka, M. Sutter\*, and A.T. Ishida. Section of Neurobiology Physiology & Behavior, University of California, Davis, CA 95616.

It is unknown whether serotonin (5HT) directly affects retinal ganglion cells, although it is known that serotonergic amacrine cells densely ramify in the inner plexiform layer, and that exogenous 5HT can modulate retinal ganglion cell light responses. We have tested for effects of 5HT on whole-cell currents in retinal ganglion cell somata dissociated from adult goldfish (*Carassius auratus*), using amphotericin-B-perforated patch-clamp methods. No pronounced change in holding current was produced by 5HT agonists at E<sub>rev</sub> between -65 mV and -90 mV. We therefore tested for effects of these ligands on voltage-activated currents, beginning with regenerative Na<sup>+</sup> currents. Under control conditions, maximal Na<sup>+</sup> current (-4 nA to -10 nA) was elicited by depolarizations from -90 mV to -10 mV. The decay of these currents could be fit by double exponential functions, with fast and slow time constants of 0.6 msec and 2-5 msec, respectively. Application of 5HT<sub>1</sub> receptor agonist [1-(2-methoxyphenyl) piperazine; 3 μM] and 5HT<sub>2A</sub> receptor agonist [8-hydroxydipropylaminotetralin; 3 μM] decreased maximal Na<sup>+</sup> current amplitude by 35% and slowed its decay, without markedly altering voltage-dependence of current activation. Current decay could then be fit by a time constant of roughly 1.5 msec. These effects developed over 1-10 min, could be reversed by washing with control saline, and resemble effects we recently reported of cAMP- (but not cGMP-) analogs on Na<sup>+</sup> currents in these cells. These results show that activation of 5HT<sub>1A</sub> receptors in retinal ganglion cells can modulate Na<sup>+</sup> currents in these cells. We are now studying mechanisms coupling 5HT receptors to Na<sup>+</sup> channels, and functional consequences of their activation.

## 413.7

ZINC ENHANCES GABA<sub>A</sub> CURRENTS OF SKATE MÜLLER CELLS.

R.L. Chappell\*, H. Qian\*, R.P. Malchow\*, and J.L. Ripps\*. Hunter College and Graduate School, CUNY\*, Harvard University\*, Department of Ophthalmology and Visual Sciences, University of Illinois Chicago\*, Marine Biological Laboratory, Woods Hole, MA 02543\*2,3

Perforated (amphotericin B) patch recordings were used to examine the modulatory effects of zinc on the GABA-induced currents of Müller cells (radial glia) isolated from the skate retina. Earlier studies indicated that the GABA currents of these elements are mediated solely by GABA<sub>A</sub> receptors.

We report here pharmacological data suggesting that the modulatory sites on the GABA<sub>A</sub> receptors of skate Müller cells exhibit several unique features. First, the benzodiazepine inverse agonists (10 μM DMCM or 10 μM CCB) potentiated the GABA-mediated responses. Second, 10 μM zinc greatly enhanced the current elicited by 1 μM GABA. Perhaps even more surprising was the fact that zinc alone induced a current comparable to that elicited by GABA; the reversal potential was the same as for the GABA current, the current was blocked by bicuculline, and the I-V relation was virtually indistinguishable from that produced by GABA. Moreover, cell-attached patch recordings showed that spontaneous channel activity was almost completely abolished by 100 μM bicuculline, whereas the frequency of channel openings was significantly enhanced by 10 μM zinc. These findings suggest that zinc acts directly on the GABA<sub>A</sub> receptors of Müller cells, and raise the possibility that the subunit composition of the GABA<sub>A</sub> receptor of the Müller cell differs from that of neuronal GABA<sub>A</sub> receptors studied previously in the CNS. It is noteworthy that zinc could be detected in skate photoreceptors using the Neo-Timm sulfide-silver method. These results support the notion that zinc may play a role in modulating GABAergic activity in the vertebrate retina.

Supported by a Bernard Davis Fellowship (to H.Q.), and by grants (EY-00777, EY-09411, and EY-06516) from the National Eye Institute and (N00014-92-J-1954) from the Office of Naval Research.

## 413.9

GABA ρ SUBUNITS IN RAT RETINA: STRUCTURE AND FUNCTION. Dongxian Zhang\*, Zhuo-Hua Pan, Amy D. Brideau, and Stuart A. Lipton. Dept. of Neurology, Children's Hospital, and Program in Neuroscience, Harvard Medical School, Boston, MA 02115.

Unlike the human GABA ρ receptors (Cutting et al., *PNAS* 1991) and GABA<sub>C</sub> receptors found in other species (Qian and Dowling, *Nature* 1993), the rat GABA<sub>C</sub> receptor is uniquely picrotoxinin-insensitive (Feigenspan et al., *Nature* 1993). We previously isolated from a rat retinal cDNA library two clones, homologous to the human p1 and p2 subunits. A unique single amino acid substitution (methionine instead of threonine) was identified in the second membrane region (M2) of the p2 clone compared to the p1 clone. Here, we undertook a systematic site-directed mutagenesis study involving 6 amino acid residues in the M2 region and found that the native met/thr site on p2 is critical for picrotoxinin-insensitivity. We characterized the expression levels of p1 and p2 transcripts in the rat retina. Northern blot analysis of either total RNA or poly (A)-selected RNA with a p1-specific probe labeled a band of 4.2 kb. A p2-specific probe labeled a predominant band of 2.2 kb in total RNA and an additional weak band of 3.4 kb in poly (A)-selected RNA. In addition, using a probe derived from a conserved region of p1 and p2 subunits, we found that p2 subunit mRNA appeared to be more abundant than that of the p1 subunit. This difference in expression levels was confirmed by combining primer extension in the presence of dideoxynucleotide, leading to early chain termination; in this method, the two p subunits could be distinguished by differences in the lengths of their products. If protein levels approximately mirror mRNA expression, our results suggest that an adequate amount of the p2 subunit is present in the rat retina to form native p1/p2 heteromeric receptors that are insensitive to picrotoxinin.

## 413.6

DIFFERENTIAL DISTRIBUTION OF GABA<sub>A</sub> RECEPTORS IN IDENTIFIED AMACRINE CELL TYPES IN THE RABBIT RETINA. Berndt Ehinger and Charles L. Zuckert\*, Department of Ophthalmology, University of Lund, Sweden, and Schepens Eye Research Institute, Harvard Medical School, Boston, MA.

GABA<sub>A</sub> receptor synapses are known to participate in movement detection in the retina, for which acetylcholine (ACh) containing starburst amacrine cells also play a role. However, the circuitry involved is not well understood. We have studied the distribution of GABA<sub>A</sub> receptor subunit proteins in rabbit retina, taking advantage of the improved resolution attainable by confocal microscopy and the availability of monoclonal GABA<sub>A</sub> receptor subunit antibodies. Further, starburst amacrine cells and other cells in the inner nuclear and ganglion cell layers of the retina stained by intraocular injection of DAPI were classified by intracellular injections of Lucifer yellow in living tissue. Immunohistochemical staining for choline acetyltransferase was also used to identify starburst amacrine cells in rabbit retina.

Starburst amacrine cells were found to contain no or only very little GABA<sub>A</sub> receptors of the α<sub>1</sub> and β<sub>1</sub>/β<sub>2</sub> subtypes. On the other hand, such receptors occur in high concentration in a cell type with morphologically characteristic features, called the DAPI-3 cell. This cell can be stained by an intraocular injection of DAPI, which is an aid for finding it for intracellular dye injection. Perikarya of the DAPI-3 cells are in the proximal cell rows of the inner nuclear layer and send processes into two sublayers in the inner plexiform layer, where they abut the processes of the two mirror symmetric populations of starburst amacrine cells. The high GABA<sub>A</sub> receptor content of the DAPI-3 cells can be used to identifying them immunohistochemically. They occur with roughly the same density as OFF starburst amacrine cells. GABA<sub>A</sub> receptor proteins appear also in other cell types in the retina, most notably in indoleamine accumulating S2 cells. The observations suggest that movement detection is accomplished by complex circuits formed by several different cells, and presumably comprising at least starburst amacrine cells as well as a second GABA<sub>A</sub> receptive amacrine cell type, perhaps the DAPI-3 cells. Supported by NIH grant EY07552 to CLZ.

## 413.8

MOLECULAR CLONING AND NITRIC OXIDE MODULATION OF KAINATE/AMPA-TYPE GLUTAMATE RECEPTOR IN THE HYBRID BASS RETINA. L.V. Ponomareva and D.G. McMahon\*. Department of Physiology, University of Kentucky, Lexington KY 40536-0084

Emerging evidence suggests that kainate/AMPA-type glutamate receptors (KA GluR) are widespread in the retina. We have used 0.5 kbp PCR-generated fragment from the coding region of a rat KA GluR (RGluR1) as a probe to investigate whether the bass retina expresses a KA GluR gene. In parallel, we studied the effects of the nitric oxide/cGMP pathway on the KA GluR of dissociated bass horizontal cells (HC). A clone BGluR1 was isolated by screening a bass retinal cDNA library. It was sequenced and compared to previously sequenced mammalian GluR genes. BGluR1 represents 3 kbp and shows 68% identity to rat GluR1 and GluR2 at the nucleotide and 40% identity at the amino acid level. BGluR1 contains the same regions of high homology as are found in all previously sequenced cDNA of ionotropic GluRs from mammals, frog and chicken. It includes 4 homologous transmembrane domains and the "flop" region, which also exists in RGluR2. Retinal HC were dissociated and maintained in culture using standard techniques. Whole-cell patch-clamp recordings were made from HC while kainate (10 or 50 μM) was applied by pressure ejection and test agents were applied by adding to the bath. The current traces elicited by application of L-glutamate, AMPA and kainate on HC support our conclusion that bass HC have KA/AMPA GluRs. Application of 1 mM sodium nitroprusside (SNP) or 100 μM S-nitroso-N-acetylpenicillamine (SNAP) reduced the overall responsiveness of HC GluR to KA, reducing the peak amplitude of the response to a standard puff of kainate by approximately 50% (N=8 and 7). The effects of SNP were mimicked by application of 2 mM 8-Br-cGMP (-63%, N=5) and were blocked by addition of cGMP cyclase inhibitor LY 83,583 (N=3). Future experiments will focus on cell localization of BGluR1, its expression and defining the mechanisms of nitric oxide modulation.

## 413.10

THE ACTIN-BASED CYTOSKELETON REGULATES VOLTAGE-GATED POTASSIUM CHANNEL ACTIVITY IN RETINAL BIPOLAR NEURONS. G. Maguire\*, V. Connaughton\*, A. Pratt\*, R. Jackson\*, and H. Cantello\*. # Department of Neurobiology & Anatomy, University of Texas Medical School, Houston, TX 77030, and @The Renal Unit, Massachusetts General Hospital, Charlestown, MA 02129 and Department of Medicine, Harvard Medical School.

The actin-based cytoskeleton is a rich intracellular network linked either directly or indirectly to membrane ion channels. Actin filaments exhibit ionic condensation and support the propagation of ionic charge waves along their longitudinal axis. Although actin has been well documented to play a role in regulating ion channel activity in epithelial cells, its role in regulating ion channels in neurons is less well understood.

We used whole-cell and single channel recording techniques in the retinal slice and in isolated retinal neurons to examine the effects of manipulating the actin-based cytoskeleton on voltage gated K<sup>+</sup> channel activity in retinal bipolar neurons.

Under whole cell recording conditions, the addition of cytochalasin D to the bath, an agent that disrupts the actin-based cytoskeleton, breaking actin into shorter filaments, led to an increase in the amplitude of the macroscopic voltage gated K<sup>+</sup> channel currents as compared to control. The onset of this effect was about 5 min. following cytochalasin D application and the maximal effect was at about 15 min. Single K<sup>+</sup> channel activity was similarly affected under cell-attached conditions. i.e. the frequency of K<sup>+</sup> channel opening greatly increased about 5 min. following cytochalasin D application to the bath. Inside-out patches demonstrated that the addition of medium length actin filaments to the bath also increased the frequency of single K<sup>+</sup> channel openings. These findings are consistent with actin filaments existing in a dynamic equilibrium, with long actin filaments in a cytoskeleton network leading to decreased channel opening, and shorter actin filaments leading to an increased frequency of opening.

MULTIPLE ROLES OF CALMODULIN IN MELATONIN BIOSYNTHESIS BY PHOTORECEPTOR CELLS: REGULATION OF CALCIUM INFLUX AND ADENYLATE CYCLASE ACTIVITY. P.M. Juvone\* and A.L. Alonso-Gómez. Dept. of Pharmacology, Emory Univ. Sch. of Med., Atlanta, GA 30302.

Serotonin *N*-acetyltransferase (NAT), a key regulatory enzyme in melatonin biosynthesis, is induced in depolarized photoreceptors. Induction of NAT activity by depolarization involves a signaling cascade that requires calcium influx through dihydropyridine-sensitive voltage-gated channels, stimulation of adenylate cyclase activity, cAMP-dependent protein phosphorylation, and *de novo* RNA and protein synthesis. Calcium influx is required for all subsequent steps in the cascade. The objective of this study was to examine the possible role of calmodulin in this intracellular signaling cascade. In photoreceptor-enriched chick retinal cell cultures, CGS 9343B and KN-62, selective inhibitors of calmodulin and CaM kinase II respectively, inhibit K<sup>+</sup>-evoked "Ca<sup>2+</sup>" influx through dihydropyridine-sensitive channels, cAMP accumulation, and induction of NAT activity. In contrast, they have no effect on induction of NAT activity by cAMP analogues, indicating a site of action prior to activation of protein kinase A. The inhibition of K<sup>+</sup>-evoked "Ca<sup>2+</sup>" influx by CGS 9343B, KN-62, and K55970, a structurally dissimilar CaM kinase II inhibitor, was blocked by Bay K 8644, a dihydropyridine channel agonist. CGS 9343B, but not KN-62, inhibited induction of NAT activity elicited by the calcium ionophore A23187, suggesting a site of action distal to the channel. Membranes prepared from photoreceptor-enriched cell cultures contain calmodulin-sensitive adenylate cyclase that is inhibited by CGS 9343B. These results suggest that Ca<sup>2+</sup>/calmodulin modulates two steps in the cascade regulating induction of NAT activity, enhancing Ca<sup>2+</sup> channel activity via a CaM kinase II-dependent mechanism and directly stimulating adenylate cyclase.

## 413.12

THE RETINAL NIGHT-DAY SWITCH: A NEURONAL FLIP-FLOP DEVICE. M.K. Boelen<sup>1</sup>, P.L. Mcgaw<sup>1</sup>, I.G. Morgan<sup>2</sup> and D.W. Marshak<sup>1\*</sup>. <sup>1</sup>La Trobe University, VIC 3550, Australia, <sup>2</sup>Australian National University, ACT 2601, Australia, <sup>3</sup>University of Texas Medical School, Houston, Texas 77225.

Reciprocal inhibitory circuits act as flip-flop devices with only one of the two elements active at any time. In chicken retina, photoreceptors (PRs) are involved in reciprocal inhibitory interactions like these with dopaminergic amacrine cells (DACs). Melatonin, synthesized and released by PRs in the dark, inhibits the DACs. Dopamine, released by the DACs in the light, inhibits the synthesis and release of melatonin by the PRs (1). The DACs are involved in a second set of reciprocal inhibitory interactions with the enkephalin-, neurotensin- and somatostatin-like immunoreactive amacrine cells (ENSLIACs). Here, dopamine, released by the DACs in the light, inhibits the ENSLIACs, and the enkephalins, released by the ENSLIACs in the dark, inhibit the DACs. A similar circuit may operate in primate retinas although the peptidergic element is different. In macaques, there are associational amacrine cells immunoreactive for both somatostatin and corticotropin releasing factor but not for the enkephalins. These cells co-stratify with DACs, and the majority of their contacts are with amacrine cells. In addition, somatostatin's effects resemble those of dopaminergic antagonists in rabbit retina (2,3). This PR/DAC-peptide triad exhibits two states. In the dark, the PRs and peptidergic amacrine cells are active, releasing melatonin and a combination of peptides while the DACs are inactive. In the light, the DACs release dopamine, while the PRs and peptidergic amacrine cells are inactive. The switch is flipped from the dark state to the light state by withdrawal of melatonin inhibition of the DACs plus light-induced drive to the DACs through an ON-bipolar cell pathway.

## CELL DIFFERENTIATION AND MIGRATION IV

## 414.1

CEREBELLAR GRANULE CELL DIFFERENTIATION IN MUTANT AND X-IRRADIATED RODENTS AS REVEALED BY THE NEURAL ADHESION MOLECULE TAG-1 D. Karagogeos\*<sup>1</sup>, K. Kyriakopoulou<sup>1</sup>, N. Delhaye, Bouchaud<sup>2</sup>, J. Mariani<sup>2</sup> and Y. Bailly<sup>2</sup>

<sup>1</sup> Dept of Basic Sciences, P.O. Box 1393, University of Crete Medical School, Heraklion 711 10, Crete, Greece

<sup>2</sup> Laboratoire de Neurobiologie du Développement, CNRS URA 1488, Université P. & M. Curie, Paris 75005, France

In the external granular layer (EGL) of the cerebellum, the granule cell (GC) precursors express the axonal glycoprotein TAG-1, a molecule involved in adhesion and neurite outgrowth. GC express TAG-1 transiently just as they extend neurites prior to migrating over the radial glia. We studied *in vivo* models in which Purkinje and/or GC defects occur during postnatal development to test whether such defects influence the premigratory phase of TAG-1 expression. These models include the cerebellar mutant mice *staggerer* and *huncher* as well as rats irradiated during early postnatal development.

Neither alterations in Purkinje cell differentiation nor the related GC loss in the mouse mutants impair the ability of the surviving GC precursors to express TAG-1. Also, early GC loss in the X-irradiated rats does not alter the normal pattern of TAG-1 expression in the surviving precursors. In the adult cerebellum of X-irradiated rats, ectopic GC remain located superficially in the molecular layer and stop expressing TAG-1 beyond the first 3 weeks of postnatal development.

Thus, the transient expression of the molecule is maintained as long as the GC precursors are in a postmitotic, premigratory state, even if this state is prolonged as is the case in *sg/sq*. We suggest that TAG-1 expression is regulated primarily by factors intrinsic to the GC and is unaffected by epigenetic events that kill the GC without altering their gene expression program.

## 414.3

THE EXPRESSION OF MEF2 GENES IS IMPLICATED IN NEURONAL DIFFERENTIATION X. Lin\* and R.F. Bulllett Dept. of Pharmacology, Univ. of Maryland Sch. of Med., Baltimore, MD21202

We cloned a cDNA encoding the mouse homologue of the transcription factor MEF2A from a postnatal mouse cerebellar cDNA library. In the adult mouse, MEF2A RNA expression occurs throughout the brain with high levels of expression in olfactory bulb, hippocampus and cerebellum. A similar pattern of protein expression was observed in immunostaining of brain sections using a polyclonal antibody generated against 21 amino acids at the C-terminal of MEF2A. Because the polyclonal antibody may crossreact with MEF2C and MEF2D isoforms, we also examined the expression of RNA for these two isoforms. By using PCR we obtained mouse cDNA clones of MEF2C and MEF2D. The pattern of MEF2D RNA expression resembles MEF2A in adult mouse brain; MEF2C differs with a high level of RNA expression in the cortex and a low level of expression in the cerebellum. In developing cerebellum, MEF2A and MEF2D RNA levels increase after birth reaching a peak at postnatal day 12 and are maintained in adults. More interestingly, this time course of MEF2A and MEF2D RNA expression coincides with that of GABA<sub>A</sub>6, a marker of the mature cerebellar granule cell phenotype. We further observed by using the polyclonal antibody, in the developing cerebellum, that MEF2 expression only occurs after granule cells have migrated into the internal granule layer (IGL). Thus, like in skeletal muscle, the products of MEF2 genes may be involved in determining the mature phenotype of cerebellar granule neurons. MEF2A and MEF2D may be particularly important in turning on a set of neuronal specific genes in these cells.

## 414.2

GENE EXPRESSION WITHIN THE DEVELOPING RAT CEREBELLUM. V. Narayanan\*, B. Ripeni, S. Olinisky, and W. Weng. Department of Pediatrics, Neurology, and Neurobiology, University of Pittsburgh, Pittsburgh, PA.

The most numerous of the cell types in the cerebellum, the granule cells, are derived from the external germinal layer, a structure that persists until P21 in the rat. The goal of our research is to isolate and characterize molecules that are expressed at specific stages of granule cell development, and eventually study the genetic control of neuronal differentiation. We ablated the cerebellar granule cells and the germinal cells by low dose X-irradiation of newborn rat pups. We next prepared a subtracted cDNA library (CONTROL - IRRADIATED), the expectation being that this would be enriched in genes expressed in the granule cells. We have identified 20 genes that are differentially expressed (by Northern blot analysis), about half of these being novel genes and the rest corresponding to cloned cDNAs. We present here our *in situ* hybridization data on the cellular distribution of mRNAs corresponding to two of these genes, that may have important functions in the cytoskeletal rearrangements that accompany granule cell differentiation. The first (clone GCE.B5) is the rat MARCKS cDNA, which encodes a protein kinase C substrate. MARCKS is expressed in a variety of cells within the cerebellum and cerebrum, including the granule cells, cells within the Purkinje layer, as well as in the hippocampus. MARCKS is known to interact with calmodulin and the cytoskeleton, and this interaction is modified by phosphorylation. The second gene we have studied (clone GCA.H2) corresponds to elongation factor-1 $\alpha$ . This gene is strongly expressed in the external germinal layer, and is down-regulated during cell differentiation and migration. It has recently been determined that this protein is involved in the dissolution of microtubules.

## 414.4

GRANULE NEURONS OF THE MIGRATION DEFICIENT WEAVER MOUSE MUTANT LACK A FUNCTIONAL NMDA-RECEPTOR. Päivi Liesi\* and Jerry M. Wright. LMCN, NIAAA, NIH, 12501 Washington Ave, Rockville, MD 20852.

The cerebellar granule neurons of the homozygous weaver mouse mutant fail to migrate and die within the first two weeks of postnatal life. The weaver gene is mapped in the chromosome 16 in the mouse, but the defective gene(s) has not yet been identified.

P7-P9 normal and homozygous weaver granule neurons were cultured on a laminin substratum for 24-48 hrs. Within this time period, the normal granule neurons extended long neurites whereas the weaver granule neurons showed impaired neurite outgrowth. Immunocytochemistry for NMDAR1 subunit (mouse  $\Sigma$ 1) of the receptor showed expression of the R1-subunit in both the weaver and the normal granule neurons. The mRNA levels for the NMDAR1 subunit were comparable in the normal and homozygous weaver mutant brain tissues. Patch clamp studies showed, however, that the homozygous weaver granule neurons differed from their normal counterparts with respect of the expression of a functional NMDA receptor. The normal neurons expressed a functional NMDA receptor whereas the homozygous weaver neurons failed to express the functional receptor.

These results indicate that the migration deficiency of the weaver granule neurons may be related to their lack of expression of the functional NMDA receptor. The mechanisms of neuronal dying and subunit composition of the NMDA receptor of the normal and homozygous weaver mouse cerebellum are further discussed.

## 414.5

MORPHOLOGICAL AND IMMUNOCYTOCHEMICAL STUDIES OF CEREBELLAR GRANULE CELLS ASSOCIATED WITH INHIBITION OF MIGRATION INDUCED BY K252a IN VITRO. S. Tanaka, S. Kobayashi and T. Shirao\*. Department of Neurobiology and Behavior, Gunma University School of Medicine, Maebashi, 371, Japan.

We examined the migration of cerebellar granule cells on laminin in primary reaggregation cultures. we found that K252a, a potent protein kinase inhibitor, specifically inhibited the migration through signal pathway other than protein kinase A, protein kinase C and CaM kinase II. In the absence of K252a, neurites extended from aggregations of granule cells and the cells migrated on the neurites. Most of the migrating cells were small spindle shaped. Immunocytochemical study demonstrated that both of actin filament and actin-binding protein drebrin were co-localized in submembranous regions of migrating cells. While in the presence of K252a, migration was significantly inhibited. Within five minutes after the addition of K252a, the shapes of most migrating cells started to change their forms. Within thirty minutes migrating cells slipped off the neurites and their shapes changed into large polygonal shapes with many filopodia-like process. Immunocytochemical study demonstrated that drebrin distributed diffusely in the cytoplasm, while actin filament formed stress fiber-like structures. These results suggested that the signal transductions in the cells for the dissociation of drebrin from actin filament were associated with protein kinase. Then actin filament formed into stress fiber-like structures, and thereby the migration was inhibited.

## 414.7

DYNAMICS OF CALCIUM OSCILLATIONS IN NEURONAL CELL MIGRATION. H. Komuro\* and P. Rakic, Section of Neurobiology, Yale University School of Medicine, New Haven, CT 06510

During neuronal cell migration, extension of the leading process and translocation of cell soma are regulated by a cooperated activity of voltage- and ligand-gated channels (Komuro & Rakic, Science 257: 806, 1992; 260: 95, 1993). Moreover, the movement of migrating neurons is characterized by alternations of short stationary phases with saltatory forward or backward movement (Komuro & Rakic, J. Neurosci. 15: 1110, 1995). Here, we examined the role of intracellular calcium ions as candidate intracellular second messengers that may control saltatory movement of migrating neurons. Rectangular pieces of cerebella from 2-6 day-old mice were placed on poly-L-lysine and laminin-coated Petri dishes containing serum-supplemented culture medium. After a 2-3 day incubation, cells were bathed in serum-free, defined culture medium with 1-3  $\mu$ M Fluo-3/AM,  $Ca^{2+}$  indicator dye, for 30 min at 37 °C. After rinsing with defined culture medium, changes in the rate of cell movement and the levels of intracellular  $Ca^{2+}$  of migrating granule cells were examined using confocal laser scanning microscopy. During saltatory movement, intracellular  $Ca^{2+}$  levels of cell somas spontaneously increased an average of  $14.2 \pm 3.2\%$  of baseline intensity, for an average duration of  $1.3 \pm 0.4$  min, with average frequencies of  $13.2 \pm 3.6$ /hr. This frequency is comparable to the cycle of saltatory movements of cell soma. Fast-moving cells exhibited a larger amplitude and higher frequency of  $Ca^{2+}$  oscillations than slow-moving cells. Blockade of  $Ca^{2+}$  influx by antagonists to voltage- and ligand-gated channels depressed these oscillatory responses, and resulted in a retardation of cell movement. Blockade of  $Ca^{2+}$  release from intracellular  $Ca^{2+}$  stores slightly decreased the amplitude of  $Ca^{2+}$  elevations and slowed cell movement. Moreover,  $Ca^{2+}$  levels within leading process of migrating cells fluctuated spontaneously; although the amplitude and frequency of  $Ca^{2+}$  oscillations of the leading process differed from that of the cell somas. Therefore, our results suggest that the amplitude and frequency of  $Ca^{2+}$  oscillations of the somas are positively correlated with the saltatory movement of migrating cell. ## 414.9

A ROLE FOR THE CELL ADHESION MOLECULE FASCICLIN II DURING NEURONAL MIGRATION IN THE INSECT ENTERIC NERVOUS SYSTEM. P.F. Copenhaver\*, M. Snyder, and A. Horgan, Cell Biology L215, Oregon Health Sciences U., Portland, OR 97201.

The directed migration of embryonic neurons in the developing nervous system requires the specification of their migratory pathways by extrinsic guidance cues. In the enteric nervous system (ENS) of the moth, *Manduca sexta*, this process guides a population of ~300 neurons (the EP cells) along a well-defined set of visceral muscle bands that form on the gut surface during embryogenesis. We have now found that both the EP cells and these muscle bands express a protein related to the cell adhesion molecule fasciclin II (named MFas II), an immunoglobulin-related cell adhesion receptor. Antisera against this protein stained both the EP cells and the muscle bands during the migratory period. An affinity-purified fraction of this antiserum caused a dose-dependent inhibition of migration in embryo culture. Microsequence data obtained from the purified protein revealed strong homology with forms of fasciclin II that have been described in other species. Immunoblot analyses of proteins extracted from the developing ENS revealed several putative isoforms of MFas II, including a ~91 kd form that (by analogy to fasciclins in other species) may be a glycosyl phosphoinositol-linked form of MFas II. Brief exposure of the developing ENS to PI-specific phospholipase C (but not other phospholipases) caused a loss of MFas II immunostaining in the ENS, a defasciculation of the visceral muscle bands, and a dose-dependent inhibition of EP cell migration. We are currently cloning the moth form of MFas II to clarify the role of this cell adhesion molecule in the guidance of EP cell migration both *in vitro* and *in vivo*. Supported by NIH # MH51833-01 and a grant from the MRF of Oregon.

## 414.6

LAMININ-1 IS NON-PREFERRED AND ANTI-ADHESIVE FOR DEVELOPING CEREBELLAR CELLS. B. Lom\* and P. E. Hockberger, Northwestern Univ., Chicago, IL 60611. Previous studies have indicated that the extracellular matrix molecule laminin-1 (EHS laminin) may be involved in guiding granule cell migration along radial glial fibers in the postnatal rodent cerebellum. This conclusion was based primarily upon three observations: *in situ* immunolocalization of laminin-1 along Bergmann glial fibers, *in vitro* studies showing that cerebellar neurite outgrowth, cell adhesion, and cell migration were enhanced on laminin-1 coated surfaces when polyamino acids were present, and inhibition of neurite outgrowth and cell migration in culture by laminin-1 antibodies. Other immunostaining and antibody blocking observations have produced contrary results. We have reinvestigated these observations and found that laminin-1 was not associated with radial glia, but rather, immunolocalized to blood vessels and meninges in postnatal cerebella by three different laminin antibodies. In culture, it was an anti-adhesive and non-preferred substrate for developing cerebellar cells, and laminin-1 antibodies did not influence cell adhesion or preference. Specifically, dissociated cerebellar cells adhered poorly to culture surfaces coated with laminin-1, compared with collagen IV, fibronectin, simple amines, or glass. Avoidance of laminin-1 regions on chemically patterned culture surfaces was not affected by the addition of laminin-1 antibodies. In comparison, neuroblastoma cells preferred laminin regions over glass and this preference could be eliminated by the addition of laminin-1 antibodies. Cerebellar cells preferred and adhered to laminin-1 regions only when it was combined with polylysine. These results suggest that laminin-1 acts as an anti-adhesive, non-preferred molecule for developing cerebellar cells.

## 414.8

NMDA-MEDIATED DEPOLARIZATION CAN ACT AS A STOP SIGNAL DURING NEURONAL MIGRATION IN VITRO TAURINE MODULATES. E. Trenkner\*, C. Harris, W. Hou, S. Gartenberg, NYS Institute for Basic Research in Developmental Disabilities, Staten Island, NY 10314.

Early postnatal mouse cerebellar granule cells (GC) migrate *in vitro* as they would *in vivo* under 'non-depolarizing' conditions. Here, we have studied granule cell migration after 2 DIV in the presence of various concentrations of depolarizing reagents NMDA, glutamate and their antagonists APV, MK801, CCP as well as  $K^+$ . We found that NMDA in concentrations higher than  $10^{-4}$ M arrested ~85% of migrating granule cells in less than 3 min. Similarly,  $K^+$  inhibited migration in osmolarity corrected depolarizing conditions ( $> 7$  mM) in our medium (BME, HS, 2  $\mu$ M  $Ca^{2+}$ ). While the effect of  $K^+$  could not be prevented, migration continued with NMDA-antagonists for more than 16 h. Furthermore, after pre-treatment of cultures with  $Ca^{2+}$  ionophore A23187 as well as with taurine, GC continued to migrate. We also demonstrate that physiological concentrations of taurine regulate intracellular  $Ca^{2+}$  concentrations to approximately 3-5  $\mu$ M during NMDA or glutamate induced depolarization, suggesting that intracellular  $Ca^{2+}$  concentrations determine the degree of GC migration.  $K^+$ -depolarization was unaffected. We propose that both the expression of NMDA type glutamate receptors on migrating GC and the event of depolarization through synapse formation with incoming mossy fibers determine the spatial distribution of individual granule cells after migration. Taurine seems to play a crucial role in modulating or even controlling intracellular  $Ca^{2+}$  concentrations and thus the extent of migration.

Supported by NSF Grant BNS - 8910218.

## 414.10

PARTICIPATION OF THE HETEROTRIMERIC G PROTEIN  $G_o$  AND POTENTIAL DOWNSTREAM EFFECTORS IN REGULATING NEURONAL MIGRATION. A.M. Horgan\* and P.F. Copenhaver, Cell Biol. & Anat. L215, Oregon Health Sciences U. Portland, OR 97201.

The intracellular signaling molecules responsible for regulating neuronal migration in an embryo are poorly understood. In the enteric nervous system of *Manduca sexta*, ~300 neurons (the EP cells) migrate along defined pathways to form the enteric plexus. One member of the heterotrimeric G protein family,  $G_o$ , is expressed in the EP cells coincident with their migration. Manipulations of G protein activity in a semi-intact embryonic preparation suggests an inhibitory role for this signaling molecule during migration. Intracellular injections of mastoparan caused a marked decrease in migration, whereas injections of pertussis toxin (PTX) had no effect. However, when the toxins were co-injected, the inhibitory effect of mastoparan was eliminated. Two likely candidate downstream effector systems that may be affected by  $G_o$  are intracellular calcium and components of the cytoskeleton. When intracellular calcium was elevated in the EP cells, we saw an inhibition of migration, but neuronal motility was not obviously affected by injections of the calcium buffer BAPTA. We are now examining whether  $G_o$  stimulation requires intracellular changes in calcium to down-regulate migration. Increased polymerization of both actin and tubulin have also been shown to coincide with EP cell migration, while transient exposure to cytochalasin D inhibited migration. We are now investigating whether  $G_o$  stimulation in the EP cells acts via the regulation of specific classes of actin binding proteins in the course of neuronal migration. Supported by NIH # MH51833-01 and a grant from the MRF of Oregon.

## 414.11

## MIGRATION OF OLIGODENDROCYTE PRECURSORS ON ASTROCYTES AND MENINGEAL CELLS

L. Fok-Seang, G.A. Mathews, C. French-Constant\*, J. Trotter and J.W. Fawcett

Physiological laboratory, Wellcome/CRC Institute of Developmental Biology and Cancer, MRC Cambridge Centre for Brain Repair, Cambridge University, England, and Department of Neurobiology, University of Heidelberg, Germany.

During development oligodendrocyte precursors migrate extensively through a CNS environment consisting mainly of astrocytes and neurones. However in some demyelinating conditions such as MS, remyelination fails in a predominantly astrocytic environment. In order to determine whether failure of oligodendrocyte precursor migration might be responsible we have examined *in vitro* the effects of astrocytes and meningeal cells on migration.

Migration rates were measured by time lapse microscopy, and by attaching precursors to shards of coverslip, inverting them on the test surface, and observing migration distances. Oligodendrocyte precursors and the CG4 and Oli-neu precursor cell lines migrate rapidly on laminin, very slowly on mature astrocytes and meningeal cells, but rapidly on embryonic astrocytes and EHS sarcoma cells. Astrocyte extracellular matrix, whether derived from mature cells, astrocyte cell lines whose matrix is inhibitory to axon growth or embryonic astrocytes, promotes migration as well as laminin, and migration on laminin is not affected by astrocyte conditioned medium. No correlation was found between adhesiveness and rate of migration. Time lapse microscopy showed that oligodendrocyte precursor contacts with meningeal cells were followed by rapid collapse and withdrawal of the process, while contacts with astrocytes were long-lasting, with flattening of the contacting process

## 414.13

EXPRESSION OF 9-O-ACETYLATED GANGLIOSIDES IS CORRELATED WITH TANGENTIAL CELL MIGRATION. R. Mendez-Otero and L. A. Cavalcante\*. Depart. Neurobiology, Instituto de Biofísica Carlos Chagas Filho, Universidade Federal do Rio de Janeiro, Rio de Janeiro, RJ 21941-590, Brazil.

9-O-acetylated gangliosides (9-O-aG) are expressed in regions of the developing brain during radial neuronal migration such as occurring during histogenesis of the cerebral cortex and the cerebellar granular cell layer (Mendez-Otero et al., J. Neurosci., 8: 564, 1988). In addition, we have demonstrated that an antibody against 9-O-aG (Jones mAb) interferes with axonal growth (Mendez-Otero et al., Soc. Neurosci. Abs., 18:36, 1992). To determine the generality of 9-O-aGs expression in directional movements, we have examined 9-O-aG immunoreactivity in the cell stream from the telencephalic subventricular zone (SVZ) to the olfactory bulb in developing and adult rats. Our results demonstrate that Jones antigens are expressed in the subventricular zone of the lateral ventricle of developing (postnatal) and adult rats and along the pathway purported to be followed by newly generated cells to their final destination in the olfactory bulb. Our present observation thus support the hypothesis that 9-O-acetylated gangliosides are expressed by neurons capable of dynamic changes and may contribute to the molecular mechanisms permitting cell migration not only during development but also in the adult.

## 414.15

MULTIPLE CLASSES OF GABA RECEPTORS MEDIATE EMBRYONIC RAT CORTICAL CELL MOTILITY *IN VITRO*. T.N. Behar\*, C.A. Scott, and J.L. Barker. Lab. of Neurophysiology, NINDS, NIH, Bethesda, Md. 20892

Embryonic rat cortical cell migration to  $\mu$ M GABA was analyzed *in vitro* using a chemotaxis chamber. GABA stimulated chemokinesis that was partially inhibited by saclofen and picrotoxin, but was unaffected by bicuculline. Agonists of GABA<sub>B</sub> (R-baclofen) and GABA<sub>C</sub> (CACA and TACA) receptors also stimulated chemokinesis. Baclofen-induced motility was only blocked by saclofen. Motility induced by CACA or TACA was blocked by picrotoxin, but not by bicuculline or saclofen. Bicuculline potentiated migration to CACA or TACA, suggesting that GABA<sub>A</sub> receptor activation may arrest chemokinesis in a subpopulation of cells. Whereas picrotoxin and saclofen each partially inhibited chemokinesis to GABA, significant levels of motility were completely attenuated in the combined presence of the two antagonists. Taken together, these results suggest that GABA's chemokinetic effects involve both GABA<sub>B</sub> and GABA<sub>C</sub> receptor proteins.

## 414.12

GLIAL PROGENITORS FROM THE POSTNATAL SUBVENTRICULAR ZONE MIGRATE ALONG RADIAL GLIA *IN VITRO*. S.R. Newman, M. Zerlin, and J.E. Goldman\*. Dept. Of Pathology, Columbia Univ., College of Physicians & Surgeons, NY, NY 10032.

Glial cells of the mammalian forebrain arise from the subventricular zone (SVZ), a germinal matrix that lies adjacent to the lateral ventricles. Migration of glial progenitors from the SVZ into gray and white matter may be guided by radial glia. *In vivo*, the collapse of radial glia coincides temporally with the inability of SVZ cells to migrate out into the cortex, and columns of SVZ-derived cells oriented perpendicularly to the pial surface have been observed in postnatal cortex. We report here that postnatal SVZ-derived cells migrate along radial glial cables *in vitro* using a model system of postnatal SVZ cell development, combined with high resolution time-lapse video microscopy and immunocytochemistry. We establish cultures from early postnatal rat forebrain in which aggregates of SVZ cells are connected by cables made up of processes that resemble radial glia, morphologically and antigenically. Immature cells migrate along cables, and even translocate between neighboring tracks. The cells that are apposed to the cables are unipolar and bipolar, and many express the immature neuroepithelial cell markers GD3 and A2B5. In addition, cells that express the oligodendrocyte (OL) markers O4 and O1 also align along the cables. The O4+ and O1+ that align along the cables display a unipolar or bipolar morphology, in contrast to the complex, branched O4+ and O1+ cells that lie directly on the culture dish. This difference in morphology between OL progenitors associated with cables and those on the culture substrate suggests that contact with the cable inhibits the morphological transformations of the progenitors. We suggest a model in which postnatal SVZ cells migrate along radial glia into gray and white matter. Radial glia may provide a permissive, preferential track that allows intrinsically migratory cells to disperse throughout the CNS.

## 414.14

A SEX COMPARISON OF NEURONAL MIGRATION INTO THE FERRET SEXUALLY DIMORPHIC PREOPTIC AREA/ANTERIOR HYPOTHALAMUS. J.-J. Park\*, R.G. Paredes, M.J. Baum and S.A. Tobet. Dept. of Biology, Boston University, Boston, MA 02215 and The Shriver Center, Waltham, MA 02254

The sexually dimorphic male nucleus of the dorsal preoptic area/anterior hypothalamus (Mn-POA/AH) is formed in male ferrets due to the action of estradiol during the last quarter of the 41-day gestation. We (Tobet et al., J. Neurobiol. 26:75, 1995) previously suggested that neurons migrate along radial glial guides into the POA/AH from proliferative zones lining the lateral as well as the third ventricles. We attempted to compare the routes and rate of this migration by a cohort of cells born in male and female fetuses on embryonic (E) day 24. Fetuses were injected with the thymidine analog, bromodeoxyuridine (BrdU) on E24 and subsequently killed on E30, E34, or E38. Brains were sectioned and processed immunocytochemically for BrdU as well as glial fibrillary acidic protein (GFAP), which is found in radial glial fibers. The distribution of BrdU immunoreactivity throughout the POA/AH was analyzed by quantitative image analysis in equivalent brain sections of ferrets of each sex killed at these fetal ages, which bracket the period when the Mn-POA/AH is formed in males. The results support our previous suggestion that neurons migrate into the dorsal POA/AH from proliferative zones lining the lateral as well as the third ventricles. There was no indication, however, that the migration of cells born on day E24 differs in males and females. Thus the action of estradiol in promoting the formation of the male's Mn-POA/AH may depend on other processes, such as cell specification or differential cell death. ## CELL DISPERSION PATTERNS IN THE MOUSE RETINA

BE Faulkner-Jones\*, BE Reese, L. Godinho and S-S Tan. Department of Anatomy and Cell Biology, University of Melbourne, Melbourne, Victoria 3052, Australia.

How retinal neurons acquire their phenotype is not yet determined. The cell's birth date, lineage, migration path and interactions with surrounding cells and the microenvironment may all influence its fate. The relative role of each of these factors remains controversial. We are interested in the relationships between cell lineage, their dispersion patterns and cell-cell interactions, and how these may determine cell fate.

We have generated a transgenic mouse carrying the *lacZ* gene on the X chromosome. In hemizygous female transgenic mice, clones of *lacZ* +ve or -ve cells are formed as a consequence of early X inactivation. In retina, each clonal cluster is composed of a radially-aligned column of cells spanning the retinal layers and invariably contains rod photoreceptors, bipolar and Muller glial cells. The remaining 15% of retinal neuroblasts, forming the ganglion, amacrine, horizontal and cone photoreceptor cells are tangentially displaced from the radial columns. As all seven cell classes share a common lineage those dispersion patterns must be linked to fate rather than lineage.

We are interested in identifying those forces which maintain the radial columns as a clonal cluster. Likely candidates are the cell-surface-expressed cell-cell adhesion molecules. We have focused on the cadherin superfamily using reverse-transcriptase PCR analysis of eye RNA and oligonucleotide primers directed towards conserved consensus sequences in the cytoplasmic domain. Of the currently known cadherins, E, K, OB-1, P, N, R and VE-cadherins are expressed at the mRNA level in the developing mouse eye. In addition, a novel cadherin most closely related to human cadherin 8 has been isolated from post-natal eyes. Differential expression of cell-cell adhesion molecules may determine the dispersion patterns of retinal neuroblasts.

## MIGRATION OF FACIAL MOTONEURONS IN THE DEVELOPING BRAZILIAN OPOSSUM BRAIN.

J. J. Swanson\*, J. Iqbal, and C. D. Jacobson. Department of Veterinary Anatomy and Neuroscience Program, Iowa State University, Ames, IA 50011.

The Brazilian opossum, *Monodelphis domestica*, is a small marsupial whose young are born in an extremely immature state with a protracted postnatal period of neurogenesis. We have previously shown that the facial motor nucleus (FMN) demonstrates a transient expression of cholecystokinin (CCK)-binding sites during development (Kuehl-Kovarik et al., Soc. Neurosci. Abstr. 19: 729, 1993). In addition we have also shown, using markers of synapse-associated proteins, that the FMN does not receive afferent innervation until postnatal day 15 (15 PN) and mature synapses are formed between 15 and 25 PN (Swanson et al., Soc. Neurosci. Abstr. 19: 644, 1993). In this study we have used postnatal injection of the retrograde tracer cholera toxin subunit B (CtB) and immunohistochemical detection of CtB to describe the migration of facial motoneurons in the developing brainstem. Injections of CtB were made into the cheek or lip region of opossum pups. Facial motoneurons in newborn opossum pups (1 PN) exhibited CtB labeling and their cell bodies were localized near the developing genu. At 3 and 5 PN, CtB labeled facial motoneurons were observed in and migrating to the region of the adult FMN. Between 7 and 10 PN, facial motoneurons had all migrated to their final destination. During postnatal days 1 through 5 the CtB labeled facial motoneurons appeared to migrate from the genu ventrally and laterally to where the motor nucleus will be located. These results indicate that facial motoneurons innervate their targets by 1 PN and migrate to their destination in the brainstem thereafter. Studies are underway examining the relationship of the location of facial motoneurons to the distribution of the markers of synaptic development.

## 414.18

## DORSAL MIGRATION OF NEURONS OF THE "U-SHAPED" GROUP CAN BE PERTURBED IN SPINAL CORD SLICE CULTURES. P.E. Phelps\*, R.B. Barber, and J.E. Vaughn. Div. of Neurosciences, Beckman Res. Inst. of City of Hope, Duarte, CA 91010.

Developing rat spinal cord contains a "U-shaped" group of neurons that surrounds the ventral 50% of the ventricular zone on E16 and that expresses both choline acetyltransferase and NADPH-diaphorase. Over a 2-3 day period, some of these cells appear to migrate into the dorsal horn *in vivo*. A relatively histotypic dorsal migration of the "U-shaped" group has been replicated in *in vitro* slice cultures of E16 cervical spinal cord. To attempt to perturb this migration, E16 slice cultures were microscopically divided into dorsal and ventral parts. After removing the ventral cord, the isolated dorsal cord was cultured for 3 days. Both parts were processed for diaphorase histochemistry to determine the amount of ventral cord removed, as well as the presence and location of the "U-shaped" group. All dorsal cultures contained a late-forming medial cluster of diaphorase cells (Wetts et al., Dev. Dyn. 202:215), but the number and position of cells derived from the "U-shaped" group varied with the amount of spinal cord excised. When the ventral 40% of cord was removed, numerous cells from the "U-shaped" group were present in dorsal cultures, but had disoriented processes and uncharacteristic locations. If over 55% of the spinal cord was removed ventrally, none of the diaphorase cells derived from the "U-shaped" group were present in dorsal cultures. Intermediate excisions produced a mixture of the above results. These findings demonstrate that the "U-shaped" group originates in ventral spinal cord, whereas the late-forming medial diaphorase cells originate dorsally. The disoriented processes and lack of migration of the "U-shaped" group may have resulted from the surgically induced loss of commissural axons, supporting our hypothesis that these axons may guide dorsal migration in spinal cord. Supported by NIH grant NS 18858.

## CELL DIFFERENTIATION AND MIGRATION V

## 415.1

MIGRATION AND MATURATION OF CELLS OF THE EARLY NEOCORTEX IN RODENT CENTRAL NERVOUS SYSTEM MAINTAINED IN CULTURE. G.W. Knott<sup>1</sup>, W.L. Weller<sup>2</sup>, K.M. Dziegielewska<sup>1</sup>, N.R. Saunders<sup>1</sup>. Departments of Physiology<sup>1</sup> and Anatomy<sup>2</sup>, University of Tasmania, GPO Box 252C, Hobart, Tasmania, 7001.

The entire central nervous system from the fetal rat (E15) has been shown to survive in culture for periods of up to 10 days. The details of the dissection and culture conditions have been published previously (Saunders et al., 1992, Proc. Roy. Soc. (B) 250, 171). The level of protein in the medium was adjusted to one which was similar to what would normally be present in the CSF of the fetal rat *in vivo*. After periods of up to 24 hours in culture preparations were fixed for light microscopy using Bouin's fixative and processed using histological and immunocytochemical techniques (Saunders et al., 1992, Anat. Embryol. 186, 477). During the first 24 hours ventricular zone cells of the neocortex, in the presence of 10% fetal calf serum (FCS), continued to divide and proliferate as they would *in vivo*. These newly formed cells were then able to migrate to more superficial regions of the neocortex. Although the neocortical wall had increased in thickness the cells accumulated outside the ventricular zone and there was no clearly defined cortical plate. However, one known marker for cells in the early cortical plate, fetuin, was identified in cells in the outer region of the cultured neocortex. The position of fetuin positive cells corresponded to that of the early cortical plate, *in situ*. Additionally, specific staining for fetuin, a protein derived from FCS, confirmed the integrity of the CSF/brain barrier even after 24 hours in culture. This was demonstrated by the total lack of fetuin and albumin (medium-derived) staining in the extracellular spaces of the brain. Although the overall morphological appearance of the neocortical wall was not preserved *in vitro* (E15 + 24 hours), the characteristic ability of early cortical plate cells to specifically take up fetuin was maintained in this model.

## 415.2

## GENETIC ENGINEERING OF HUMAN EMBRYONIC BRAIN CELLS BY RETROVIRAL VECTOR-MEDIATED GENE TRANSFER.

P. Almqvist<sup>1</sup>, L. Wahlberg<sup>2</sup>, S. Dilber<sup>3</sup>, A. Kjaeldgaard<sup>2</sup>, Å. Seiger<sup>1</sup>, J. Boethius<sup>3</sup>, K.G. Xanthopoulos<sup>3</sup>. Dept. of Clinical Neuroscience, Sections of Neurosurgery and Geriatric Medicine<sup>1</sup>, Dept. of Obstetrics & Gynecology<sup>2</sup>, and The Centre for Biotechnology<sup>3</sup>, Karolinska Institute, S-171 77 Stockholm, Sweden.

In contrast to chemical and physical cellular transfection methods, replication deficient murine retroviruses have proven to be extremely efficient vectors to transfer genes into proliferating mammalian cells. Embryonic cells are highly mitotically active and can be transfected *in vitro* with retroviral DNA that integrates into the host genome and is subsequently expressed. We have established a procedure for the *in vitro* transduction of first trimester embryonic brain cells of different gestational ages in primary culture. An 80-100% transduction efficiency was detected when *E.coli LacZ* reporter gene expression was driven by the 5'LTR viral promoter, and the cell proliferation was stimulated by the addition of bFGF and/or TGF- $\alpha$  to the culture medium. Recombinant gene expression in cultured cells was qualitatively studied by use of a modified retroviral vector encoding nuclear expression of the bacterial  $\beta$ -galactosidase enzyme, with subsequent X-gal staining. In long-term dissociated cell culture, X-gal co-staining with cytoplasmic cell type-specific markers revealed the expression of either neuronal or glial phenotypic markers in recombinant brain cells. The temporal pattern of recombinant gene expression was studied by CPRG spectrophotometric analysis of cytoplasmic  $\beta$ -galactosidase expression. Preliminary results from the current study indicate possible future clinical utility of *in vitro* genetically modified embryonic human cells for replacement cell therapy in neurodegenerative diseases including Parkinson's disease.

## 415.3

## NEURONAL DEVELOPMENT AND MIGRATION IN EXPLANT CULTURES OF CEREBRAL CORTEX OF THE MOUSE.

W. Hendelman\*, P. Humphreys, S. Jones. Departments of Anatomy & Neurobiology and Pediatrics, University of Ottawa, Ottawa, Ontario. K1H 8M5, Canada.

Explant cultures may be used to investigate mechanisms of neuronal migration. Fragments (250-350  $\mu$ m thick) taken from the cerebral mantle of 16 day embryonic mouse (E16) were grown *in vitro* on a membrane with large pores. The tissue fragment was embedded in a collagen 'sandwich', with medium placed both above and below the membrane. The plates were rocked slowly so that the surface of the explants was intermittently exposed to the ambient environment (5% CO<sub>2</sub> and 20% oxygen). At 7 days *in vitro*, culture thickness was on average 172  $\mu$ m; other cultures were maintained for up to 14 days. Immunohistochemical staining for GluR1, a glutamate receptor subunit, and A-60, (NeuN, neuron-specific nucleoprotein), indicated a high density of viable neurons throughout the explant at day 7 and at day 14. Glial cells were plentiful as seen with GFAP immunohistochemistry. Explants also stained intensely for GAD, glutamic acid decarboxylase, a GABA precursor, and GABA at days 7 and 14 in culture. Neurons also stained positively for microtubule-associated protein (MAP-2) at day 7. Time-pregnant mice were injected the day prior to implanting with 5-bromo-deoxy-uridine (BrdU) which becomes incorporated into the thymidine of dividing cells. Using a histochemical reaction with an antibody to BrdU, labeled cells were found at E16 in the ventricular zone. At 7-14 days in culture, labeled cells were found throughout the cortical plate, indicating that the neuronal cells had migrated *in vitro*, although it was not possible to differentiate cortical layers. In summary, this culture system permits embryonic cortical tissue to survive and differentiate for up to two weeks *in vitro*, while neuronal migration is occurring. ## 415.4

## CELLULAR PROPERTIES OF LEECH RETZIUS NEURONS CO-CULTURED WITH VARIOUS TARGET TISSUES. K.A. French\*, J.A. Murphy, and W.B. Kristan, Jr., Biology Dept., UCSD., La Jolla, CA 92093.

Retzius (Rz) neurons of *Hirudo medicinalis* differentiate into one of two possible phenotypes--which differ with respect to peripheral target, central morphology, synaptic inputs, and response to ACh applied to the soma--depending upon the environment in which they develop. Normally the peripheral processes of Rz neurons in the 5th and 6th midbody segment [Rz(5,6)] contact embryonic reproductive ducts, whereas all other Rz neurons [Rz(X)] contact body wall muscles; ablating the reproductive ducts at 30-35% of development causes Rz(5,6) neurons to adopt the properties of Rz(X).

To explore the interaction between Rz neurons and their targets, we cultured adult Rz neurons with several target tissues and then evaluated their morphology and physiological responses. Rz neurons were dissected from standard or reproductive ganglia and placed into culture, either in isolation on concanavalin A or directly on top of a target: body wall muscle, juvenile male reproductive duct, juvenile female reproductive duct, or germinal plate from an embryo at 30-35% of development. Cultures were maintained 3-17 days; then each neuron was impaled, its electrical properties and response to ACh were recorded, and it was filled with Lucifer Yellow. Filled cells were treated with anti-Lucifer antibody and HRP-conjugated second antibody, drawn with *camera lucida*, and digitized; the length of the processes was then measured. As a control, pressure-sensitive mechanoreceptor neurons (P cells) were cultured under the same conditions.

Rz(X) and Rz(5,6) neurons responded to the targets similarly. Neurons grew more processes on some targets than on others, in the order: germinal plate > female duct > male duct > body wall. Surviving neurons responded to ACh, even after 17 days in culture, and no neuron changed the sign of its response to ACh, whether it was grown on its usual target or on the "wrong" target and regardless of its process length. We conclude that the ACh response of Rz neurons is a very robust cellular property that is maintained even when the cells produce large amounts of new cell membrane. Supported by NIH Grant NS25916.

**CYTOSKELETAL DYNAMICS IN GROWTH CONE RETRACTION INDUCED BY THE mAb JONES** H.M. Araujo, and R. Mendez-Otero\*. Instituto de Biofísica Carlos Chagas Filho, UFRJ, Rio de Janeiro, RJ 21941-590 Brasil.

During development axons must find their targets navigating through environments with both attractive and repulsive cues. The ganglioside 9-O-acetyl GD3 may be one of these cues (Mendez-Otero et al., J. Neurosci. 8:564-579, 1988). Through blockage of this ganglioside with the JONES mAb, axonal migration is inhibited and growth cone collapse can be seen in primary culture. We have treated dorsal root ganglion (DRG) neurons *in vitro* with JONES, as a model to investigate intracellular events mediated by the ganglioside. We have utilized cytoskeleton-interfering drugs to characterize cytoskeletal filaments target or driving growth cone retraction. Adding taxol or nocodazole to the culture medium we show that microtubule rearrangements play an important role in JONES-induced retraction. On the other hand, cytochalasin D, which depolymerizes F-actin, induces axonal retraction with a pattern similar to that seen with JONES. We were able to establish two domains of JONES action: the proximal portion of the axon where rearrangements are dependent of microtubule dynamics, and the distal portion where microfilaments have an important role. We conclude that JONES-induced retraction involves changes in both tubulin and actin-based filaments.

## 415.7

**SHORT EXPOSURE TO METHYLAZOXYMETHANOL (MAM) CAUSES A LONG-TERM INHIBITION OF AXONAL OUTGROWTH FROM CULTURED EMBRYONIC RAT HIPPOCAMPAL NEURONS.** J.R. Hoffman\*, L.J. Boyne, P.R. Levitt, I. Fischer. Beaver College, Glenside PA, 19038; Med. Coll. of Penn. & Hahnemann Univ., Phila. PA, 19129; UMDNJ-Robert Wood Johnson Med. Sch., Piscataway NJ, 08854.

MAM is an antimetabolic, alkylating agent that is used to induce microencephaly, but its direct effects on developing neurons are not known. We examined the outcome of short exposure to MAM on postmitotic embryonic hippocampal cultures during the early stages of establishment of axonal polarity. At 0, 1, or 2 days *in vitro* (DIV), neurons were treated with 0.1mM-1mM MAM for 3 hr and then transferred to glial conditioned media. At 3 DIV, the cells were fixed and analyzed by immunofluorescent staining for viability and neurite differentiation. Control cells initiate several minor processes, one process elongates rapidly at about 1 DIV eventually becoming an axon, while extensive dendritic growth occurs after 3-4 DIV. Neurons treated with 1mM MAM at 0 or 1 DIV showed a withdrawal of axons and marked inhibition of neurite growth without affecting cell viability. Cells achieved only minimal recovery of neurite length at 7 DIV, even when transferred to a glial co-culture. In contrast, cells treated initially with MAM at 2 DIV showed no effect on axonal growth. To determine the effects of MAM on the neuronal cytoskeleton, we performed *in vitro* microtubule assembly assays using brain extracts. There were no changes in the total amount of microtubules assembled in the presence of MAM. However, MAM caused a decrease in the coassembly of MAP2, but not MAP1b, with microtubules. These results demonstrate that MAM can directly affect developing neurons, indicating that an early disruption of axonal outgrowth can have long-term effects.

## 415.9

**ROLE OF TARGET CELLS IN THE SURVIVAL AND DIFFERENTIATION OF PURIFIED PURKINJE CELLS IN VITRO.** C. Carroll, M.E. Morrison, and C.A. Mason\*. Dept. Path., Coll. P&S, Columbia Univ., NY, NY 10032.

Cell-cell interactions between afferents and their target neurons comprise a general class of mechanisms controlling cell survival and differentiation. Previous results from our lab (Baptista et al., 1994, Neuron 12:243) show that in isolation, Purkinje cell survival is poor, but is improved by neuronal contacts with either purified granule neurons or with high densities of other Purkinje cells. Moreover, proper Purkinje cell differentiation is driven only by co-culture with granule cells, the presynaptic afferents of Purkinje cells, producing dendrites with spines receiving synapses.

To address the role of postsynaptic or target cell influences on Purkinje cell survival and differentiation, we cocultured purified rodent Purkinje cells with their target cells, the deep cerebellar nuclei. Results to date show a twofold increase in the survival of Purkinje cells cocultured with enriched cell fractions of deep nuclei neurons, compared to survival of Purkinje cells cocultured with granule neurons. Furthermore, Purkinje cell axonal outgrowth and arborization is enhanced by coculture with deep nuclei cells, even though dendritic differentiation does not progress beyond immature forms. These results suggest that targets of the Purkinje cells, the deep cerebellar nuclei, regulate Purkinje cell survival and axonal, but not dendritic, outgrowth. Experiments are in progress to further characterize the relative contributions of pre- and postsynaptic cells at different developmental stages to the survival and differentiation of the Purkinje cell, and to assess the potential contribution of growth factors from the deep nuclei targets.

Supported by NIH grant NS16951 to CAM.

## 415.6

**INCOMPLETE TARGET SEGREGATION OF FACIAL, VESTIBULAR AND COCHLEAR Efferents IN RODENTS.** D.H. Nichols\*, J.D. Kingsley, L.L. Bruce and B. Fritzsche. Creighton Univ., Dept. Biomed. Sci., Omaha, NE 68104.

Otic efferents of many non-mammalian vertebrates share both fiber pathways and perikaryal position with facial motoneurons. Moreover, developmental studies in chicken and mice showed that postmitotic efferents and facial motoneurons first colocalize then segregate by differential migration (Fritzsche et al., 1993, J. Neurobiol. 24: 1481). Here we report that subpopulations of rodent facial motor, vestibular and cochlear efferent neurons possess collaterals to each other's target areas. Specifically, Dil applied to the facial nerve distal to the geniculate ganglion labeled collaterals to the horizontal canal and occasionally the utricle. A few contralateral facial motoneurons were labeled as well. Applications of Dil to the: 1) utricle labeled collaterals to the facial nerve, saccule and posterior vertical canal and 2) saccule labeled collaterals to the first turn of the cochlea. These saccular collateral branches had terminal swellings in the vicinity of spiral ganglion cells. Thus, subpopulations of otic efferent and facial branchiomotor neurons project to the same peripheral targets during development until at least postnatal day 9. This branching pattern varied quantitatively between individuals.

Supported by NIH DC00215-12 and NASA NCC2-861 grants.

## 415.8

**GRANULE NEURON REGULATION OF PURKINJE CELL DEVELOPMENT: ROLE OF NEUROTROPHINS AND cAMP.** M.E. Morrison, R.C. Marcus\*, and C.A. Mason. Dept. of Path., Coll. P & S, Columbia Univ., NY, NY 10032.

Previous work in our laboratory established a method for purification of cerebellar Purkinje cells (Baptista et al., 1994, Neuron 12:243), and demonstrated that granule neurons, presynaptic afferents of Purkinje cells, are potent regulators of Purkinje cell differentiation. Purified Purkinje cells cultured alone survive poorly, never developing dendrites, while Purkinje cells cocultured with granule neurons undergo full dendritic development. This model system allows us to identify factors supplied by granule neurons that induce Purkinje cell differentiation *in vitro*. Purkinje cell survival and development were assessed in three culture combinations: purified Purkinje cells cultured alone or with purified granule cells, or unpurified Purkinje cells in cultures of whole dissociated cerebellum. Neurotrophins were included in the culture medium at all times. Cultures were fixed at various times up to 3 weeks *in vitro*, and Purkinje cells were visualized with an antibody against calbindin. Results to date indicate that in cultures from perinatal animals, NT-3 and CNTF decrease Purkinje cell survival, while BDNF improves Purkinje cell survival and may accelerate dendritic spine development when Purkinje cells are cocultured with granule neurons. Preliminary results from embryonic and perinatal mixed cultures also reveal a developmental switch in Purkinje cell neurotrophin responsiveness.

Addition of a chlorophenylthio derivative of cAMP to the culture medium increased the survival of purified Purkinje cells, and enhanced dendritic development of purified Purkinje cells cultured with granule cells. Experiments are under way to test the specificity of these effects, and to examine the hypothesis that cAMP is one of the second messengers involved in granule cell-triggered Purkinje cell dendritic development.

## 415.10

**NEUROTROPHIN-3 IS ESSENTIAL FOR THE DEVELOPMENT OF THE CHICK RETINA.** A. Rodríguez-Tébar\*, J.M. Frade, E. Martí, M.A. Rodríguez-Peña and P. Bovolenta. Instituto Cajal, CSIC, Madrid, Spain, 28002.

Chicken embryos treated with a monoclonal antibody specifically blocking the activity of neurotrophin-3 (NT-3) showed severe alterations in the development of the retina, presenting abnormalities in all layers. Early in retinogenesis, fewer differentiated neurons were identified in NT-3 deprived embryos. The impairment of differentiation affected all types of neurons, and the undifferentiated precursors proliferated for longer. Accordingly, optic nerves from treated embryos contained 30-50% of axons with respect to controls. At earlier developmental ages, NT-3 is mostly located in the pigment epithelium, as assessed by both immunohistochemistry and northern analysis. As development proceeds, NT-3 expression shifts towards the neural retina. The NT-3 receptor trkC is expressed early in development and was found in most undifferentiated cells of the neural retina.

Together this data indicates that NT-3 is a decisive factor for differentiation and the survival of the different phenotypes of retinal neurons, and for the control of the final cell number in the vertebrate retina.

## 415.11

ROLE OF CYTOKINES IN NEURODEVELOPMENT: RELEVANCE TO DEVELOPMENTAL MODEL OF SCHIZOPHRENIA. B. Garimella, A. Jazayeri, C.M. Spangler, K. Essani, and K.M. Merchant\*, Dept of Biological Sciences, Western Michigan Univ., and \*CNS Diseases Research, The Upjohn Co., Kalamazoo, MI 49001

The role of a cytokine in neurodifferentiation is evident in earlier studies demonstrating that IL-6 exposure of PC12 cells produces morphological and biochemical markers of differentiation (neurite outgrowth, *c-fos* gene expression, and expression of Na<sup>+</sup> channels) similar to that seen after NGF treatment. The present study characterized further the neurodifferentiation effects of IL-6 and other cytokines. Exposure of PC12 cells to IL-6 (300 to 1000 ng) in the absence of serum did not appear to have a significant mitogenic effect as detected by uptake of <sup>3</sup>H-thymidine. However, uptake of <sup>3</sup>H-methionine was increased 8- to 10-fold after IL-6 treatment in the absence of serum. Interestingly, in the presence of IL-6, PC12 cells also remained viable for 8-10 d in the absence of serum. These data support the role of IL-6 in differentiation. Neurodevelopmental effects of immune system components were also examined *in vivo* by endotoxin treatment (S. enteritidis, 0.5 µg/rat, i.p.) of rat pups on postnatal days 1, 3 and 5. We compared the expression of genes thought to be involved in apoptotic processes or differentiation (Bcl-2, Bax, *c-fos*) in distinct brain regions in rats pretreated with endotoxin or vehicle at various times (2, 4, 6, 14 or 21 days) after the treatment. Finally, the relationship between developmental abnormalities produced by immune system modulation and psychotic disorders was evaluated by examining the responses of endotoxin-treated rats to amphetamine and clozapine. (Supported by Scottish Rite Research Foundation and Stanley Research Foundation).

## 415.13

A NOVEL HEPARAN SULFATE PROTEOGLYCAN INVOLVED IN THE REGULATION OF FGFs IN MOUSE EMBRYONIC BRAIN IS A PUTATIVE PERLECAN HOMOLOGUE. S.J. Joseph\*, M.D. Ford and V. Nurcombe, Department of Anatomy, Univ. of Melbourne, Vic. 3052.

A novel heparan sulfate proteoglycan (HSPG); called HSPG-BRM, for Brain Regulated Molecule, is expressed in embryonic mouse neuroepithelial tissue. This proteoglycan has been shown to differentially bind and activate FGF-1 and FGF-2 during the respective stages of neural proliferation and differentiation (1). The HSPG-BRM core protein has been purified from embryonic mouse brain, and partial peptide sequence indicates unique regions but also amino acid homology to Perlecan(2), a large HSPG that has been recently shown to bind to bFGF (3). Oligonucleotide primers have been designed from the amino acid data for the use in Polymerase Chain Reaction (PCR). The PCR derived products have been subcloned and sequenced. A 96bp PCR product, homologous to both HSPG-BRM and Perlecan was used as a probe in Northern analysis of poly(A<sup>+</sup>) RNA from the embryonic day 10 neuroepithelium-derived cell line, 2.3D. The expected 12.6kb mRNA species of Perlecan was detected, as well as two other variants: a 6kb and 3.5kb mRNA species. This latter species we believe to be the putative HSPG-BRM mRNA as it is expressed in relatively high abundance and is the expected size for a 45kD protein. Results from the PCR studies indicate the existence of alternatively spliced variants of Perlecan in the embryonic mouse brain, and that HSPG-BRM is a putative homologue of Perlecan.

## 415.12

IN VIVO INJECTION OF FGF2 INCREASES BRAIN WEIGHT AND CORTICAL VOLUME IN RAT EMBRYOS. E.M. Vaccarino\*, D.L. Stull and M.L. Schwartz, Child Study Center and Section of Neurobiology, Yale University School of Medicine, New Haven, CT 06520.

Growth factors may regulate both the number and the commitment of progenitor cells to different lineages. We have previously reported that basic fibroblast growth factor (FGF2) increases the number of neurons containing glutamate, but not of those containing GABA, in primary cultures of embryonic telencephalon (Vaccarino *et al.*, 95). This action is due in part to an increase in the proliferation of progenitors which is selective for the glutamate lineage. To test whether FGF2 exerts a similar effect *in vivo*, FGF2 was microinjected into the cerebral ventricles of E15.5 rat embryos. FGF2-injected fetuses (N=10), sacrificed at E21, had a mean increase in cerebral weight of 6% compared to littermate controls (N=13) (*p*<0.05). In addition, the volume of the cerebral cortex of FGF2-injected fetuses was increased by 5-13% over that of control littermates due to an increased thickness of both the intermediate zone and cortical plate. To identify the cells responding to FGF2, *in situ* hybridization was used to determine the distribution of two FGF receptor types, FGFR-2(bek) and FGFR-3. At E15.5, these receptors were found primarily in cells of the germinative and marginal zones of cortex. At E21, FGFR-2 and FGFR-3 were restricted primarily to cells of the cortical plate. FGF2 injections greatly increased the number of FGFR-2 and FGFR-3 expressing cells, which were mainly found in the intermediate zone and morphologically resembled migrating neurons. In both control and FGF2-injected brains, FGFR-2 and FGFR-3 were only occasionally present in the subventricular zone, suggesting that these receptors may not be involved in gliogenesis. These data are consistent with the *in vitro* results suggesting a role for FGF2 in the regulation of neuronal number and cortical size during fetal development.

## 415.14

INVOLVEMENT OF JANUS KINASES IN SIGNAL TRANSDUCTION OF AN IMMORTALIZED DIENTEPHALIC CELL LINE. K. Shimoda\*, T. Oshima, K. Inoue, D. Kaneto, T. Kitagawa, H. Takahashi\* and J.W. Commissiong\*\*, Div. of Neurology, National Nishitottori Hospital, Tottori 68902, JAPAN. #Lab. Histochem., Mitsubishi-kasei, Inst. of Life Sci. Machida 163, JAPAN. ##NTU, LMCN, NINDS, NIH, Bethesda, MD 20892, USA.

Many cytokines have recently been identified in the CNS. However, for many, their physiological functions have not been elucidated. We have prepared an immortalized cell line from E13 diencephalic region of rat, tested the hypothesis that IL-3 and bFGF may be involved in signal transduction mechanisms. E13 diencephalic cells were immortalized by transfection with the SV40 LT antigen temperature sensitive mutant, carried by a retroviral vector. Degenerate oligonucleotides were amplified by PCR methods, and used to clone PTKs. The clones from one cell line designated S1 were sequenced, and used to identify the following PTKs: Jak1, Jak2, bFGFR, hck/bmk and Try10. Using the Northern blotting technique, we identified the following Janus kinases: Jak1, Jak2, Jak3 and Tyk2. When the S1 cells were cultured and treated with bFGF and IL-3, both of which were coupled to Jak2, they extended processes and differentiated into cells with a neuron like morphology. The result strongly suggested that PTKs are involved in signal transduction mechanisms in the S1 cell lines. They might also have a similar function during development in the CNS. The S1 cell line that we have described may therefore become a model for studies of the molecular mechanisms involved in neuronal differentiation and signal transduction in the CNS.

## PATTERN FORMATION, COMPARTMENTS AND BOUNDARIES III

IDENTIFICATION OF CHICK PAX GENES LOCALIZED IN THE SPECIFIC NEURON CIRCUITS.

A. Kawakami\*, M. Kimura-Kawakami, M. Numura, H. Fujisawa, Dept of Mol Biol, Sch Sci, Nagoya Univ., Nagoya, 464-01, Japan

In the development of nervous system, several distinct cellular and molecular mechanisms cooperate to ensure correct neuronal network formation. Identification of the relevant molecules and their functions is our main goal. Pax molecules are the vertebrate homologues of *Drosophila* paired box containing genes and expressed regionally in the vertebrate brains. As those contain the paired box or both the paired and homeo boxes, it can be postulated that they are the transcription regulators involved in the development of specific neuronal cells.

To investigate the roles of pax molecules in the neuronal network formation, we screened for pax molecules expressed during middle-late stages of neuronal development in the chick brain, and identified two molecules, pax 6 and 7. Using *in situ* hybridization and immunohistochemical staining, we clarified that in the late stage of chick neuronal development pax 6 and 7 were expressed extensively in the retina and optic tectum, respectively, and scarcely in other part of the embryo. Expression was observed in the differentiated neuronal cells in these tissues. From these expression patterns, it was suggested that pax 6 and 7 molecules might regulate genes involved in the neuronal circuit formation.

## 416.2

SEGMENTAL DIFFERENCES IN SMALL CARDIOACTIVE PEPTIDE-CONTAINING NEURONS CORRELATE WITH EXPRESSION OF *Lox2*, A LEECH *Hox* GENE. V. Berezovskii\* and M. Shankland, Department of Neurobiology, Harvard Medical School, Boston, MA 02115

Expression of *Hox* genes at the level of single neurons may play a significant role in establishing their segmental identity, and we therefore studied cellular colocalization of *Lox2* protein and Small Cardioactive Peptide (SCP)-like immunoreactivity in the leech *Helobdella triseriatis*. *Lox2* is expressed at embryonic stage 10, and its expression remains stable until adulthood. The onset of SCP expression was later, and varied greatly for different neurons. Immunostaining revealed that the Medial Paired SCP (MPS) neurons located in the midbody segments 7-15 of the adult express *Lox2* protein. In the 11th-15th ganglia large MPS neurons begin to accumulate SCP shortly after the end of embryonic development, while in the 7th-10th ganglia the MPS neurons are smaller and begin to express SCP at a later stage. In the 16th and 17th ganglia we saw large MPS neurons which express lower levels of SCP starting from mid-juvenile stage, but these cells did not show detectable *Lox2* expression. Lineage tracer injections showed that the MPS neurons are descended from the O-teloblast stem cell. Two medial O-derived neurons in ganglia 11-15 contained *Lox2* protein on each side of the nerve cord, while in ganglia 16 and 17 we found only one such neuron. In ganglia 1-6 and 18-21 these neurons did not express *Lox2* protein or SCP. The results suggest that some segmental differences in the MPS neuron correlate with the segmental pattern of *Lox2* expression.

## 416.3

THE RXR $\alpha$  GENE IS EXPRESSED IN A MEDIOLATERAL GRADIENT IN THE VENTRICULAR ZONE OF A DISCRETE STRETCH OF THE CHICKEN EMBRYO NEURAL TUBE. F. Hoover\*, E.A.P. Seletro, P. Brickell & J. C. Glover. Dept. of Anatomy, Univ. of Oslo, 0317 Norway.

Characterization of the expression patterns of the various retinoid receptors (RAR $\alpha$ ,  $\beta$ ,  $\gamma$  and RXR $\alpha$ ,  $\beta$ ,  $\gamma$ ) is a prerequisite to an understanding of the regulation of pattern formation by retinoids. We have used non-radioactive *in situ* hybridization to localize RXR $\alpha$  transcripts in whole mounts of chicken embryos. The highest levels of expression are found in the neural tube. At the earliest stage yet examined (stage 10 = 11 somites), expression is localized to a short stretch of the neural tube adjacent to somites 4 and 5. Between stages 10 and 15 the domain of expression expands into the hindbrain to a sharp rostral border just caudal to the otic vesicle, remaining high to about the level of somite 8, and then gradually decreasing along the spinal cord. This pattern is maintained at least until stage 22, the latest stage yet examined. As the hindbrain develops, expression as seen in whole mounts is clearly predominant in the rhombic lip. Transverse sections show expression throughout the ventricular zone, in a mediolateral gradient peaking at the rhombic lip. The level of expression outside the ventricular zone is markedly lower if not absent. These results suggest that the RXR $\alpha$  gene is selectively expressed in progenitor cells along a specific stretch of the neural tube. The mediolateral gradient of expression in this progenitor cell population may be related to the mediolateral gradient of proliferative activity previously described in the hindbrain neural tube (Hemond and Glover (1993) J. Neurosci. 13:1387-1402).

## 416.5

CEREBELLAR COMPARTMENTS IN TRANSGENIC MICE EXPRESSING AN OLFACTORY MARKER PROTEIN-LacZ FUSION GENE. M.G. Nunzi<sup>1</sup>\*, M. Grillo<sup>2</sup>, F.L. Margolis<sup>2</sup> and E. Mugnaini<sup>1</sup>. <sup>1</sup>Neuromorphology Lab., Univ. of Conn., Storrs, CT 06269 and <sup>2</sup>Roche Inst. Molec. Biol., Nutley, NJ 07110.

The organization of the cerebellar cortex into compartments defined by distinct Purkinje cell (PC) phenotypes is an hallmark of the mammalian cerebellum, possibly linked to functional modules within the cerebellar circuitry. The molecular basis underlying PC diversity has been previously explored in transgenic mouse lines bearing different constructs of the PC specific gene *L7/Pcp-2* (Vandaele, et al., 1991; Oberdick et al., 1993). We report that a murine line (HpY-1) with a *lacZ* transgene containing 0.3kb of upstream and 0.35kb of downstream sequence from the olfactory marker protein (OMP) gene ectopically expresses the *lacZ* reporter within restricted cerebellar PC domains. The spatial pattern of expression was analyzed from embryonic to adult life in whole mount cerebella and sections with X-gal or anti-beta-galactosidase staining. At E13, a cluster of *lacZ*-positive cells outlined the PC plate in the cerebellar primordium. By E17, PCs expressing *lacZ* showed a banded pattern more evident in the caudal and lateral cerebellum than in the anterior lobe. Between P5 and P20, on and off parasagittal bands of *lacZ* expression became more prominent in the posterior vermis and hemispheres, and a wide expression region marked the rostral paraflocculus, whilst *lacZ* expression in the anterior vermis and crus I subsided. By P30, *lacZ* expression was detectable within parasagittal bands in the posterior cerebellum with a boundary slightly rostral to the primary fissure. These data suggest that the transgene contains regulatory elements recognized by transacting factors present in specific PC subsets and involved in the formation of cerebellar parasagittal and anterior-posterior compartments, or that the site of integration has placed the transgene under the control of such regulatory elements (Supported in part by NIH Grant NS 09904).

## 416.7

BrDU BIRTHDATING AND THE PURKINJE CELL COMPARTMENTATION OF THE MOUSE CEREBELLUM

K. Ozol\* and R. Hawkes. Dept. Anatomy and Neuroscience Research Group, U. of Calgary, Calgary, Alberta T2N 4N1, Canada.

Zebrin II is a 35 kDa polypeptide antigen in rat cerebellum, identified by using a monoclonal antibody. Zebrin II immunoreactivity is confined to a subset of Purkinje cells that form 14 rostrocaudal parasagittal bands interspersed by non-immunoreactive Purkinje cells. To explore the origins of compartmentation in the adult mouse cerebellum, pregnant dams were injected once with 0.05 mg/g BrdU at different gestation periods between E10 - E14. From each litter, pups were taken at three stages: at 4 h after injection, at P6 and as adults (>P30). The animals were ethanol-fixed, paraffin-embedded, sectioned, and immunostained for zebrin II + BrdU (adult), calbindin + BrdU (P6), or for BrdU alone (embryos). Statistical comparisons revealed a strong correlation between zebrin II<sup>+</sup> compartments and Purkinje cell birthdates. By comparing the BrdU labeling in animals from the same litter as embryos, neonates and adults, it is possible to correlate specific zebrin compartments with early Purkinje cell clusters and with the organization of the cerebellar anlage. The data support the hypothesis that birthdate-related Purkinje cells share a common zebrin II phenotype.

## 416.4

DISRUPTION OF BF-2 WINGED HELIX GENE BY HOMOLOGOUS RECOMBINATION IN ES CELLS. Hatini V.\* Huh S. Q., Balas G., Soares V., and Lai E. Cornell University Graduate School of Medical Sciences, Memorial Sloan-Kettering Cancer Center, New York, N.Y. 10021

Several members of transcription factor families are expressed in restricted domains within the developing forebrain and are believed to control their fate, growth and differentiation. We have previously shown that BF-1 and BF-2, winged helix (WH) transcription factors, are expressed in the telencephalon and rostral diencephalon, respectively. Their expression forms a boundary within the rostral forebrain and divides the optic stalk and retina into adjacent domains. The expression of BF-2 is the highest in the ventricular zone suggesting a role in the control of cell fate and cell proliferation within this region of the neuroepithelium. To examine the role of BF-2 during development we deleted the BF-2 gene by homologous recombination in the mouse. A targeting vector in which most of the BF-2 coding region was replaced by a *lacZ* neo cassette was constructed. Both J1 and C17 ES cell lines were electroporated with the BF-2 targeting vector and 4 correctly targeted clones were isolated. These clones were injected into blastocysts and one of the C17 clones contributed the mouse germ line. Analysis of heterozygote animals reveals that the  $\beta$ -galactosidase activity is identical to the *in situ* expression and may be useful in the analysis of the BF-2 mutant phenotype. Heterozygote animals were bred to generate BF-2 homozygote animals. Preliminary analysis of E11 litters of heterozygote intercrosses reveals that the homozygote animals are viable until this stage. Homozygote animals will be analyzed to determine the molecular basis of the putative developmental abnormalities and the possible mode of action of BF-2 within the developing neuroepithelium.

## 416.6

EXPRESSION OF AN OLFACTORY MARKER PROTEIN-LacZ CONSTRUCT MARKS GRANULE CELLS IN CEREBELLAR CORTEX AND COCHLEAR NUCLEAR COMPLEX. E. Mugnaini\*, C. Stein-Isak<sup>2</sup>, E.L. Margolis<sup>2</sup> and M.G. Nunzi<sup>1</sup>. <sup>1</sup>Lab. of Neuromorphology, Univ. of Connecticut, Storrs, CT 06269 and <sup>2</sup>Roche Inst. Molec. Biol., Nutley, NJ 07110.

Embryological investigations have shown that cerebellum and dorsal cochlear nucleus (DCoN) originate from nearby regions of the embryonic metencephalon and may share in common precursors of different cell types. Accordingly, the DCoN contains cerebellar-like granule, stellate, Golgi and unipolar brush cells, as well as cells analogous to the Purkinje cells, the cartwheel neurons. In the cerebellum, granule cells originate postnatally from the external granular layer, and then migrate inward through the molecular and Purkinje cell layers to form the granular layer. In the DCoN the granule cells show a similar developmental pathway, while in the ventral cochlear nucleus they maintain, for the most part, a superficial position. Histochemical analysis of the spatial and temporal distribution of an olfactory marker protein-*lacZ* fusion gene in a line of transgenic mice (B-OMP-1; Walters et al., submitted) has revealed ectopic *lacZ* expression within the granule cell populations of both cerebellum and cochlear nuclei. In the cerebellum, the transgene expression appears developmentally regulated. At P4, X-gal marks differentiating granule cells in all lobules. By P7, granule cells show stronger *lacZ* expression in vestibulocerebellar folia than in the rest of the cerebellum. In the adult, *lacZ* expression appears exclusively in the vestibulocerebellum. In the cochlear nuclear complex, *lacZ* is expressed at high levels at all stages of development and appears substantial also in the adult. Taken together, these data corroborate the notion that the granule cells systems of the vestibulocerebellum and cochlear nuclear complex form analogous systems that share in common not only morphological phenotypes, but also aspects of gene regulation. (Supported by NIH grant NIDCD 01805 and NS 09904).

## 416.8

THE EFFECTS OF THE MURINE MUTATION, meander tail, ON CEREBELLAR PURKINJE AND GOLGI EPITHELIAL CELLS ARE SECONDARY TO THE LOSS OF GRANULE CELLS. K.M. Hamre\* and D. Goldowitz. Dept. of Anat. & Neurobiol., Univ. of Tenn. Coll. of Med., Memphis, TN 38163.

The murine mutation meander tail (symbol: *mea*) results in numerous anterior lobe cerebellar perturbations including misorientation of Purkinje cell dendrites and somas, distorted and shortened radial glial fibers, foliation abnormalities, and the loss of virtually all granule cells. Previously, we presented evidence that the loss of granule cells in *mea* mice may be intrinsic to the granule cells or their precursors. In the present study, we further examine this issue, and additionally examine whether the glial and Purkinje cell abnormalities are also intrinsic defects to these cells or whether they are secondary to another target of the mutant gene such as the loss of granule cells. To address this issue, experimental murine chimeras were made between homozygous *mea* embryos and wild-type embryos. All chimeric mice were allowed to survive until 3-4 weeks of age. Cell genotype and phenotype were labeled in the same section. Cell genotype was identified with *in situ* hybridization. Subsequently, cell phenotype was immunocytochemically identified with antibodies to calcium-binding protein to label Purkinje cells or GFAP to label radial glial processes. In the cerebellums of chimeric mice, no obvious evidence of abnormal Purkinje cell alignment or dendritic arborization was found. Serial reconstructions of 22 genotypically *mea* Purkinje cells demonstrated that each of these cells was normally positioned with normally projecting dendritic arbors. Likewise, evaluation of Golgi epithelial cells showed no evidence of abnormal glial processes within the cerebellum of chimeric mice and genotypically *mea* Golgi epithelial cells had phenotypically normal radial glial processes. In contrast to the normal appearance of genotypically mutant Purkinje cells and radial glial processes, mutant granule cells were selectively deleted in the chimeric cerebellum. Thus, *mea* gene action is extrinsic to cerebellar Purkinje cells and Golgi epithelial cells but intrinsic to cerebellar granule cells. Support: NS23475.

SAGITTAL COMPARTMENTS OF THE CEREBELLUM ARE DISRUPTED IN *EN-2* MUTANT MICE

B. Kuemerle, K. Millen, A. Joyner and K. Herrup.\* Alzheimer Research Lab/Neurology Case Western Reserve, Cleveland, Rockefeller University, NY and Skirball Institute, New York University, NY

The mouse *Engrailed-2* gene (*En-2*) is a homologue of the *Drosophila en* gene that functions in establishing the posterior identity of compartments. Null alleles of mouse *En-2* have distinct effects on cerebellar foliation, which may reflect defects in anterior/posterior (A/P) patterning. We wished to know whether *En-2* might also play a role in mediolateral organization. Three markers of sagittal compartmentation were used: Zebirin II and ppath, antibodies that reveal the adult banding pattern, and a transgene, L7:Bgal, whose expression reveals a transient perinatal pattern of sagittal stripes. In the adult, the thin-anterior/thick-posterior pattern of the sagittal bands is preserved, but many individual bands are fragmented or attenuated. In the neonate, the basic temporal pattern of the marker is preserved (staining begins medially and spreads laterally), but distinct differences are also found. *En-2* mutant mice are always more lightly stained than age matched controls; there is an unusual fusion of the two most medial bands; and there is a precocious appearance of a band in the Crus I folium. The observed disruption of M/L banding in *En-2* mutants is consistent with our finding that *En-2* is expressed in the embryonic cerebellum in a pattern of sagittal bands. Our data suggest that *En-2*, which has previously been associated with A/P organization, also has important functions in specifying the M/L pattern of the mouse cerebellum.

## SPECIFIC ADHESION DIVIDES ODD- AND EVEN-NUMBERED RHOMBOMERES

A. Wizenmann and A.G.S.Lumsden\*.

Dep of Anatomy, UMDS, Guy's Hospital, London Bridge, London

Although neuroepithelial cells can move freely within a rhombomere, cell mingling between rhombomeres is almost negligible. To address the question of what cellular mechanisms are responsible for restricting cell movements between rhombomeres, we have established two *in vitro* culture systems. The first system was designed to assess if cells from different rhombomeres would adhere to membranes prepared from individual rhombomeres. The results showed that cells from any given rhombomere exhibited a preferential adhesion to their own membranes and, to a lesser degree, to those of alternate rhombomeres. The second system was based on the aggregation of dissociated rhombomere cells. Cells were allowed to aggregate with cells of the same rhombomere or with cells of neighbouring rhombomeres. Screening the aggregates revealed that mixtures of cells from both even- and odd-numbered rhombomeres either formed separate aggregates or became segregated within mixed aggregates. Selective removal of classes of adhesion molecules by different enzymatic treatments (Urushima et al., 1979) was used to uncover the adhesion systems involved. The general adhesion between hindbrain cells relies on Ca<sup>2+</sup>-dependent (CDS) and Ca<sup>2+</sup>-independent (CIDS) mechanisms. In contrast, the selective adhesion was only seen when CDS were left on the surface and not when only CIDS were present. The introduction of an RGD peptide, which interferes with integrin mediated adhesion, to aggregation cultures did not effect this selective adhesion. Our results suggest that cells from even- and odd-numbered rhombomeres differ in their adhesive properties as to a lesser extent do cells from different even or odd-numbered rhombomeres. Our experiments also suggest that the specific adhesion between cells of the same rhombomeric origin is due to a Ca<sup>2+</sup>-dependent mechanism, probably involving Cadherins. These functional adhesion assay systems provide a useful tool to dissect the molecular basis of these interactions.

## 416.13

## DEVELOPMENT OF THE NEOSTRIATAL MOSAIC IN THE MOUSE.

A.A. Ardelt\* and K.A. Roth. Dept. of Pathology, Washington University School of Medicine, St. Louis, MO 63110.

The patch/matrix organization of the striatum has been demonstrated in primates and rodents. Many studies have characterized these compartments in terms of connectivity and expression of transmitters, receptors, enzymes, and glycoconjugates. Elegant studies in the rat have addressed the development of the two compartments. We have undertaken the investigation of the development of this compartmentation in the mouse. We are studying the distribution and time course of expression of several markers of the patch/matrix compartments in perinatal mice. Markers that we are currently investigating include glycoconjugates recognized by a lectin, peanut agglutinin (PNA); tyrosine hydroxylase (TH)-containing nigrostriatal fibers; and birth dates of striatal cells, established by incorporation of the thymidine analog, 5-bromo-2'-deoxyuridine. In the embryonic day 18 (E18) mouse, the patch compartment can be identified as focal concentrations of TH fibers. As in previous studies in other species, there is a caudal-to-rostral gradient of TH fiber patch formation. This can be seen around the time of birth, when anterior regions of the striatum have a homogeneous distribution of TH fibers while more posterior regions show emerging TH fiber patches. Patches of PNA staining correspond to patches of TH fibers, and PNA staining is absent in striatal areas where TH fibers are homogeneously distributed. Interestingly, in areas where TH patches are just beginning to appear, patching of the PNA label is already clearly visible. We are also investigating how striatal cell birth date correlates with the appearance of PNA-positive patches. We have established that on P3, cells which become postmitotic on E12 are found in patches, while cells born on E14 are found in the matrix of the same striatal region. In addition, the caudal-to-rostral gradient of birth dates of patch neurons reported for the rat is evident in the mouse.

## 416.10

*Tlx-1* (*Hox11*) EXPRESSION IS ASSOCIATED WITH SENSORY AXON INNERVATION OF THE DEVELOPING CHICK HINDBRAIN.

R.J.T. Wingate\*, C.C. Logan, I.J. McKay and A.G.S. Lumsden. Division of Anatomy & Cell Biology, UMDS, Guy's Hospital, London SE1 9RT, UK.

We have isolated and characterised the chick homologue of *Tlx-1* (*Hox11*), a divergent homeobox-containing gene. *Tlx-1* was originally identified in human due to chromosomal translocations which resulted in its deregulated expression. The corresponding mouse homologue has a very complex pattern of expression within the developing embryo and plays a critical role in normal development of the spleen. The predicted protein sequence (297 aa) of the chick gene shares 73% and 71% identity overall with the human and mouse homologues respectively. Transcripts are first detected at HH stage 7 within the developing branchial region and later within several components of first the peripheral (HH stage 16) and then central nervous system (HH stage 20) including the trigeminal and facial ganglia and subsequently within the developing hindbrain.

We have begun to investigate the association between *Tlx-1* expression within the hindbrain and the ingrowth of sensory axons. The central pathways of sensory axons from the trigeminal and facial nerves at various stages (E5-E9) were mapped by injection of Dil into the respective ganglia of fixed hindbrains and axon morphologies reconstructed using confocal microscopy. Each respective sensory tract was found to occupy a successively more lateral position parallel to the marginal expression of *Tlx-1*. Axonal sidebranches of the afferent trigeminal axons extend medially into the *Tlx-1* expressing region. Deafferentation of the developing hindbrain at HH stages 14-16, either by ablation of the fifth ganglion, or by insertion of tantalum foil between the ganglion and hindbrain, will allow us to test the functional relationship between *Tlx-1* expression and distribution of trigeminal sensory axons.

## 416.12

## CHANGES IN DENDRITIC BRANCH PATTERN OF THE MEDIUM SPINY NEURONS IN THE STRIATUM OF THE WEAVER MOUSE: A GOLGI STUDY. D.E. Smith\*, B. Glover and C. Henry. Department of Anatomy, LSU Medical School, New Orleans, LA 70112.

In order to determine if there were changes in the dendritic arbor of the medium spiny neurons of the striatum as a result of the loss of dopaminergic input which is seen in the weaver neurological mutant mouse, a series of animals were prepared for Golgi analysis. Weavers and homozygous littermate controls were perfused with 2% glutaraldehyde - 2% paraformaldehyde in a 0.1M phosphate buffer and processed following the method of Shimono and Tsuji (JCN 259:122-130, 1987). The centrifugal method of numbering the first, second, etc., order dendritic branches was used in the count. There were no statistical differences in cell size or total dendritic area, but there were significantly fewer third and fifth order dendrites in weaver. These findings suggest that the loss of dopamine input alters the formation of the characteristic branch pattern of the dendritic arbor in the medium spiny neurons.

## 416.14

## TEMPORAL AND SPATIAL REGULATION OF TRANSCRIPTION FACTOR EXPRESSION IN THE DEVELOPING STRIATUM. E. Fusco\* and A.M. Graybiel. Dept. Brain &amp; Cognitive Sciences, MIT, Cambridge, MA 02139.

We have found that in the prenatal rodent striatum, NGFI-A, FRA and FOS expression follow temporal and spatial patterns typical of developing striosomes. We now have tested the precision of this match pre- and post-natally. There was, at E19, a strict match of the TF cell clusters with DARPP-32 and TH-positive patches, and double staining for FRA and NGFI-A showed that NGFI-A was expressed by a large majority of the FRA-positive cells both before and after the cells formed clusters. In contrast to the tight linkage of the TFs prenatally, their expression patterns diverged postnatally. FOS expression rapidly declined, FRA expression remained predominantly striosomal until P7 and then decreased, and NGFI-A expression increased and then spread to the matrix. Thus, although the three TFs are early markers of the striosomal compartment, they lose compartmental constraints as the striatum matures postnatally.

To test whether the early striosome-association of the TFs could be related to the early differentiation of this compartment relative to that of the matrix, we tested whether MAP-2 expression, which marks the differentiation of neurons as they acquire dendrites, would be linked to that of the TFs. MAP-2 immunostaining of striatal processes first appeared diffuse, but, by E17, MAP-2 clusters began to form and they then predominated until after P7. Throughout this period, virtually every MAP-2 cluster matched a TF-positive cluster. We suggest that early, selective TF expression in striosomes may reflect the early, time-shifted differentiation of this compartment relative to that of the matrix. We thank Drs. J. Milbrandt, M. Iadorola, H. Hemmings Jr. and P. Greengard for antisera, and acknowledge NIH 1 R01 HD28341.

## 416.15

EXPRESSION OF THE NMDA RECEPTOR NR1 SPLICED VARIANTS AND NR2 MRNAs IN THE STRIATUM DURING PRENATAL DEVELOPMENT. C.H. Lam\*, A. Sadikot. Department of Neurology and Neurosurgery, Montreal Neurological Institute, McGill University, Montreal, PQ H3A 2B4

Excitatory amino acids are thought to play an important role in the development of the mammalian central nervous system. Of the variety of glutamate receptors, NMDA is the best known. The subtype NR1 as well as NR2B and NR2D are expressed in the rat prenatal period. We found that this was true in the developing striatum in particular, but in addition found that the alternatively spliced variants, cassette insertion I (exon 5) and the deletion I (exon 21) (Sugihara et al., 1992) were expressed differentially. Using *in situ* hybridization technique, with oligonucleotide probes for the NMDA receptor subtypes NR1 InsI, NR1 DelI, NR2A, NR2B, NR2C, and NR2D, we studied the expression of the receptor mRNA in the prenatal period from E14 to E20 at two day intervals of the prenatal rat striatum. InsI mRNA was seen as early as E14 particularly in the periventricular area. By E18, the differentiating field in the striatum exhibited the densest signal. DelI expression was not observed in the prenatal period. NR2A expression also was not seen during this period. NR2B expression was seen in the striatum as early as E16. Density was uniform in all axes and across the neuroepithelium, subventricular zone and the differentiating field of the striatum up to E20. NR2C expression was low, but at E18 was noted in the striatum to be slightly denser than hippocampus, thalamus, and pallidum. NR2D expression showed a medial to lateral gradient with the periventricular zones being the densest in mRNA expression. This was seen as early as E16. The specialization of the NMDA receptor subtype and the variable expression in the prenatal period, particularly of the alternative spliced variants of NR1 may suggest a role in the early genesis of the rat striatum.

## 416.17

CELL DISSOCIATION OF THE CEREBRAL CORTEX AND CHEMOSENSITIVE AREAS BY THE TISSUE PRINT METHOD. J.W. Peters<sup>1</sup>, J.M. Wright<sup>2</sup>, D.W. Frederick<sup>3</sup>, and C.O. Trouth<sup>1</sup>. Dept. of Physiology & Biophysics<sup>1</sup>, Dept. of Psychology<sup>2</sup>, Howard Univ., Wash., DC 20059, Lab. of Molecular and Cellular Neurobiology<sup>3</sup>, NIAAA, NIH, Bethesda, MD 20892.

As a prelude to ion channel studies on the cerebral cortex and chemosensitive areas of the ventrolateral medulla neurons of Postnatal (P)1 to P3 rats, neural cells and their respective processes were isolated through tissue printing dissociation (Barres, et al. (1990) Neuron 5:527-544). Tissue slices were incubated in 0.2% papain (Worthington) for 5-30 minutes, and washed with a soybean trypsin inhibitor (Worthington, 50% solution). Tissues were placed on nitrocellulose paper and transferred to glass coverslips treated with 1% collodion solution (Ladd). Time trial studies were conducted to yield intact axonal and dendritic processes. Results have yielded patch-clamp recordable cells. Studies are in progress to define their respective ion channel properties.

ONTOGENETIC DISTRIBUTION OF NADPH-DIAPHORASE IN MOUSE SOMATOSENSORY CORTEX. Nadia Mitrovic\* and Melitta Schachner. Neurobiology, Swiss Federal Institute of Technology Hönggerberg, CH-8093 Zürich, Switzerland.

We have investigated the expression of NO synthase activity (NOS) during development of the mouse somatosensory cortex using NADPH-diaphorase histochemistry. Diffuse distribution of NOS was detectable in the entire width and over the entire area of the somatosensory cortex at birth but appeared more concentrated in the lower part of the cortical plate. At postnatal day 3 (P3) soon after layer 4 has started to develop the typical barrel field pattern, NOS accumulated in the hollows of barrel fields. Maximal expression of NOS in the hollows was reached at P6. At P9, NOS expression was decreased when compared to P6 and barrel fields could not be seen P15. In addition to the diffuse distribution of NOS, NOS was accumulated at all ages studied in individual cells, possibly interneurons, which were sparse in layer 4, where they were mostly located in the septa. These strongly NOS positive cells were more abundant in the deeper layers of the cortex. After ablation of the C row of whiskers at P1, NOS expression at P6 reflected the altered barrel fields. The somatotopic distribution of NOS was also observed in barrel fields and barrelettes at P6. Our experiments show that expression of NOS correlates with the establishment of connections in the somatosensory pathway and with other activity dependent changes during stabilization of synaptic contacts.

A NOVEL TRANSGENIC MOUSE LINE IDENTIFIES CELLS IN THE DEVELOPING AND MATURE CEREBRAL CORTEX. J. Zhang\*, M.-S. Hsu, P. Levitt, J.E. Pinar. Dept. Neurosci. and Cell Biol., UMDNJ -Robert Wood Johnson, Piscataway, NJ 08854.

Molecular approaches have been used recently to investigate the mechanisms underlying pattern formation in the vertebrate brain. This issue is of particular interest in the telencephalon, which is comprised of the cerebral cortex and subcortical areas such as the basal ganglia. We report further characterization of a transgenic mouse line in which a reporter gene is expressed exclusively in cells of the cerebral cortex. This line was established (Lee et al., Mol. Reprod. Develop. 35:382) in studies investigating the expression of IGF-2, in which a construct containing 30kb upstream from the IGF-2 initiation site was fused to the lacZ reporter. Expression patterns of lacZ in this line were mapped from e10 through birth. Cells expressing lacZ were first observed at e10.5 in the developing cerebral wall while all other regions were lacZ-negative. The positive cells were located underneath the pial surface, where the earliest neurons settle. A large increase in lacZ-positive cells was evident in the wall at e11.5. At subsequent ages, the anatomical pattern of lacZ expression suggests that differentiating, nonproliferative cells are the predominant, if not the only, lacZ-positive cells. Almost all lacZ expression was confined to cells within the borders of the cerebral cortex and absent subcortically, although a few labelled cells were present in the diencephalon at early ages. Homozygous offspring from matings of hemizygotes do not reach adulthood; preliminary evidence indicates that homozygotes die near the time of birth. In summary, ontogenetic analysis of this transgenic line indicates intergration into a site that drives unique expression in cells related by a common origin in the cerebral wall of the developing telencephalon. Supported by NS-21970 (JP) and MH-45507 (PL).

RESTRICTED CEREBRAL CORTEX EXPRESSION OF A CANDIDATE G-PROTEIN COUPLED RECEPTOR ISOLATED BY PCR DIFFERENTIAL DISPLAY. Margaret E. Levin, Anjen Chenn, and Susan K. McConnell\*. Department of Biological Sciences, Stanford University, Stanford, CA 94305.

We are interested in studying the mechanisms by which neurons within the cerebral cortex attain their lamina-specific identities during development. We hypothesize that genes involved in laminar determination will be expressed in layer-specific patterns, and are thus using PCR differential display techniques (Liang and Pardee, 1992) to identify candidate genes. In order to isolate differentially-expressed mRNAs, we have compared mRNAs obtained separately from the upper layers (1-4) and the lower layers (4-6) of P6 rat cortex. Of 15 differentially-expressed PCR products, *in situ* hybridization revealed that the expression of one candidate (1A) is localized within layers 2/3 and 4 in sections of P6 and P15 rat cortex. This mRNA is also expressed in the striatum in P6, P15, and adult rat brains. The 1A PCR product was used to isolate a cDNA clone from an upper layer cortical cDNA library. Sequencing and examination of the data bank revealed that 1A encodes a candidate G-coupled receptor for which the ligand is unknown (Song et al., 1994). We are currently continuing our search for layer specific genes using both PCR differential display and subtractive hybridization. Supported by NEI EY06524, NIH GM07365, and McKnight Scholars.

DEVELOPMENTAL CHANGES ALTER THE ABILITY OF MOSSY FIBERS TO REESTABLISH THEIR NORMAL INNERVATION PATTERN IN HIPPOCAMPAL SLICE CULTURES. L. B. Nguyen, T. N. Ricciardi and A. T. Malouf\*. Department of Neurological Surgery RI-20, University of Washington Seattle, WA 98195

Mossy fibers (MF) from dentate gyrus (DG) granule cells establish synapses on CA3 pyramidal neurons during the first 3 postnatal weeks in the rat (Gaarskjaer, 1986). Cultured hippocampal slices from postnatal day 4 rat pups show a similar MF termination pattern in stratum lucidum (SL) when examined by Timm stain after 10-14 days *in vitro*. Thus, axon guidance cues used by MF appear to be preserved in these cultured slices. Three experimental manipulations were performed on hippocampal slice cultures to examine whether the axon guidance cues used by MF are developmentally regulated. First, MF were transected on the day of culture or day 7 *in vitro*. MF transected on either day were able to reestablish their synaptic pattern in SL of CA3. Second, DGs and hippocampi (H) of same age or different age were co-cultured. Same-age co-cultures (P4 DG to P4 H or P11 DG to P11 H) showed good MF reinnervation of SL, as did different age co-cultures from P4 DG to P11 H. However, P11 DG to P4 H co-cultures showed little MF reinnervation of SL. Third, new P4 or P11 DG were co-cultured onto hippocampal slices in which MF had been allowed to degenerate. New MF reinnervated these hippocampi, but did not reestablish their normal synaptic pattern in SL. These 3 experimental manipulations suggest that the expression of axon guidance molecules in the hippocampus and on MF growth cones are developmentally regulated, and that existing MF play a role in directing MF reinnervation of SL.

This study was supported by The PEW Memorial Trust.

## 417.1

INDUCTION OF NF $\kappa$ B MEDIATES REGULATION OF NERVE GROWTH FACTOR MRNA BY IL-1 IN RAT HIPPOCAMPAL ASTROCYTES Wilma J. Friedman<sup>1</sup>, Sanjay Thakur<sup>3</sup> and Arnold B. Rabson<sup>2,3</sup> Departments of <sup>1</sup>Neuroscience and Cell Biology, and <sup>2</sup>Molecular Genetics and Microbiology, UMDNJ/Robert Wood Johnson Medical School, and <sup>3</sup>CABM Piscataway, N.J.

Cytokines such as interleukin-1 $\beta$  (IL-1) are produced in the brain during development and during inflammatory processes which result from lesions or disease. One function of IL-1 in the brain appears to be the stimulation of astrocytes to proliferate and produce a variety of cytokines and trophic factors, including nerve growth factor (NGF). The mechanisms by which IL-1 exerts its actions on astrocytes remain poorly defined. We present evidence that this cytokine elicits activation of the NF $\kappa$ B transcription factor in astrocytes, in particular the p50 and p65 subunits. Moreover, this transcription factor mediates effects of IL-1 on NGF mRNA expression. Inhibition of NF $\kappa$ B activation prevents the induction of NGF mRNA by IL-1. Elucidation of the processes by which cytokines activate astrocytes and influence trophic factor expression may provide insight into mechanisms governing inflammatory processes within the CNS. Supported by NIH grant NS 31357-02 to WJF.

## 417.3

REGULATION OF NGF SYNTHESIS BY DEXAMETHASONE IN HUMAN CELL LINES OF NEURONAL ORIGIN. R. Otmann, B. Hengeler, D. Mathé, A. Schade, J.-G. Meisburger and G. Fagg\* CNS Research Department, Pharmaceutical Division, Ciba, CH-4002 Basel, Switzerland.

Dexamethasone (DEX) increases and inhibits NGF synthesis in cultured hippocampal neurons and in astrocytes, respectively. We studied the effect of DEX on NGF expression in a series of established neuroblastoma and astrocytoma cell lines in order to find a cell line with an 'neuronal-type' up-regulation of NGF synthesis by DEX.

Levels of NGF mRNA and NGF protein were measured by Northern blotting and ELISA respectively (detection limits 1pg NGF mRNA and 1pg NGF, respectively). NGF mRNA and NGF protein levels were below detection limits in most of the neuroblastoma cell lines studied (SH-SY5Y, SK-N-SH, SK-N-MC, IMR-32). In most astrocytoma cell lines (U-373MG, U-118MG, U-87MG, T-98G), basal NGF protein and NGF mRNA levels were between 10-20pg NGF/ml and 1-5pg/10<sup>6</sup> cells, respectively. DEX (0.01-10 $\mu$ M) increased NGF protein and mRNA levels only in U-373MG astrocytoma cells (2-4fold and 4-5fold, respectively). Under the same experimental conditions DEX had no effect or inhibited NGF mRNA and NGF protein in all other astrocytoma cell lines studied. In the absence of fetal calf serum (fcs), or in the presence of dialyzed fcs during the drug treatment period DEX did not increase protein levels of U-373MG cells. Cell viability was not affected under these experimental conditions. Our data suggest that fcs contains a molecule acting as a cofactor for the up-regulation of NGF synthesis by DEX in human U-373MG cells. In conclusion, in a series of astrocytoma and neuroblastoma cells tested, only U-373MG cells increased NGF synthesis in response to DEX.

## 417.5

REGULATION OF FGF-1 AND FGF-2 GENE EXPRESSION IN RAT CORTICAL ASTROCYTES. M.A. Riva <sup>a,\*</sup>, R. Molteni <sup>b</sup>, E. Lovati <sup>b</sup>, F. Fumagalli <sup>b</sup> and G. Racagni <sup>b</sup>, <sup>a</sup> Di.Bi.T., San Raffaele Hospital, and <sup>b</sup> Center for Neuropharmacology, University of Milan, Via Balzaretti 9, 20133 Milan, Italy.

Neurotrophic factors play a major role in the maturation of specific neuronal pathways as well as in the maintenance of cell homeostasis. Moreover trophic molecules can be useful for the treatment of neurodegenerative disorders, as indicated by several observations showing that they can protect neurons against different types of damage. The present study was undertaken to investigate the regulatory mechanisms of FGF-1 and FGF-2 gene expression, as compared to other trophic molecules, in rat cortical astrocytes. We found that glucocorticoid hormones and the beta adrenergic receptor (BAR) agonist isoproterenol are potent inducers of FGF-2 gene expression in type I astrocytes. The effect of isoproterenol is mimicked by cAMP analogues or IBMX, a cAMP phosphodiesterase inhibitor, to indicate that intracellular elevation of this second messenger is indeed related to the induction of FGF-2 gene expression. On the contrary, the gene expression for FGF-1 and CNTF is markedly reduced after exposure to isoproterenol. However, different mechanisms may be involved in the modulation of trophic factor expression by these agents. The induction of FGF-2 mRNA by dexamethasone and isoproterenol does not depend upon new protein synthesis, while the reduction of CNTF expression following exposure to the BAR agonist was blocked by concomitant incubation of the protein synthesis inhibitor cycloheximide. Moreover experiments with actinomycin D, an inhibitor of gene transcription, suggest that the effects of isoproterenol on FGF-2 expression do not depend only on transcription activation, but may be the result of mRNA stabilization. These data suggest that complex mechanisms may contribute to the regulation of neurotrophic factor biosynthesis in astroglial cells. These mechanisms can be important in the maintenance of neuronal homeostasis and may provide useful informations to develop new therapeutical agents able to modulate the expression of trophic molecules, as an alternative strategy for the treatment of acute and chronic neurodegenerative disorders.

## 417.2

INDUCTION OF bFGF GENE EXPRESSION *in vivo* IN RAT PHOTORECEPTORS BY THE  $\alpha_2$ -ADRENERGIC AGONISTS XYLAZINE AND CLONIDINE. Rong Wen<sup>1</sup>\*, Tong Cheng<sup>1</sup>\*, Yiwen Li<sup>1</sup>, and Roy H. Steinberg<sup>2,3</sup>, Depts of <sup>1</sup>Physiology, <sup>2</sup>Ophthalmology, and <sup>3</sup>Neurology, University of California, San Francisco, CA 94143.

We observed an induction of bFGF mRNA in the rat retina following systemic administration of the  $\alpha_2$ -adrenergic agonists xylazine and clonidine. A single injection of xylazine (6mg/kg, i.m.) resulted in a more than 5-fold increase in bFGF mRNA in the retina by 12 hrs, which then declined to the baseline in 48 hrs. This increase in bFGF mRNA was completely inhibited by pre-injection of yohimbine, a specific  $\alpha_2$ -adrenergic antagonist (5mg/kg, i.p., 20 min before xylazine). Injection of another  $\alpha_2$ -adrenergic agonist, clonidine (0.5 mg/kg, i.p.), also up-regulated bFGF mRNA in the retina with a similar temporal pattern. Pre-treatment with yohimbine (15 mg/kg, i.p., 20 min before xylazine) completely abolished the effect of clonidine. A higher dosage of yohimbine (15 mg/kg, i.p.) also inhibited the normal expression of bFGF in the retina by 40%, indicating that  $\alpha_2$ -adrenergic stimulation was of physiological importance in regulating bFGF expression in the retina. Of particular interest is the finding that the xylazine-induced bFGF expression was found almost exclusively in the inner-segment region of photoreceptors, as accessed by *in situ* hybridization. However, in the eight different brain regions examined: septum, striatum, thalamus, hypothalamus, hippocampus, olfactory bulb, cerebellum, and cerebral cortex, there was virtually no change in bFGF mRNA expression after either xylazine or clonidine treatment. These findings indicate that bFGF expression in photoreceptors can be regulated by  $\alpha_2$ -adrenergic stimulation, and may provide new insights into the mechanisms that regulate bFGF expression in general.

## 417.4

EXPRESSION AND REGULATION OF FGF-2 AND FGFR-1 mRNAs IN PC12 AND CHROMAFFIN CELLS: EFFECTS OF NGF AND GLUCOCORTICOID. C. Meisinger and C. Grothe\*, Institute of Anatomy, University of Freiburg, D-79104 Freiburg, Germany.

FGF-2 and FGF receptor (FGFR)-1 mRNAs are present in the adrenal cortex and the adrenal medulla of rat and bovine glands as we have shown after ribonuclease protection assay. *In situ* hybridization studies reveal that both FGF-2 and FGFR-1 mRNAs are localized to a chromaffin subpopulation in the medulla.

In order to help to elucidate the physiological function of FGF-2 for chromaffin cells we analyzed the expression of both mRNAs in PC12 cells under different culture conditions. FGF-2 and FGFR-1 transcripts are expressed in PC12 cells under serum-containing and serum-free culture conditions. Neither application of growth factors in serum-free cultures (FGF-2, NGF, FGF-2/NGF, dexamethasone), nor stimulation of cholinergic receptors with carbachol or of adenylate cyclase with forskolin does affect FGFR-1 expression. In serum-containing cultures, however, NGF stimulates a significant increase of FGFR-1 mRNA as compared to untreated cultures suggesting that NGF could increase the sensitivity of PC12 cells for FGF. Dexamethasone stimulates a significant increase of the FGF-2 transcript level in serum-free and serum-containing cultures of PC12 cells suggesting that the glucocorticoid-effect on catecholamine synthesis could be mediated via the endogenous FGF. According to our results an autocrine/paracrine role of FGF-2 as a maintenance and differentiation factor for chromaffin cells is conceivable. Supported by DFG Gr 857/8-1

## 417.6

GLUCOCORTICOIDS REGULATE THE GENE EXPRESSION OF NEUROTROPHIC FACTORS: NGF $\beta$ , S100 $\beta$ , AND FGF-2 IN CULTURED HIPPOCAMPAL ASTROCYTES. H. Niu, D.A. Hinkle, D.F. Speck\*, P.M. Wise, Dept. of Physiology, Univ. of Kentucky College of Medicine, Lexington, KY 40536.

Glucocorticoids are major mediators of hippocampal functions in the adult as well as during development and aging. Astrocytes can synthesize a variety of neurotrophic factors which may mediate neuron-astrocyte interactions. We hypothesized that glucocorticoids may regulate the expression of neurotrophic factors in hippocampal astrocytes. In this study, three neurotrophic factors known to be important for hippocampal neuron development and survival were investigated: NGF $\beta$ , S100 $\beta$ , and FGF-2. Enriched type I astrocyte cultures from hippocampus were treated with 1 $\mu$ M dexamethasone (DEX), a synthetic glucocorticoid, for up to 120 hours. Total RNAs were isolated at 6, 12, 24, 48, 72, 96 and 120 hours after the initiation of the treatment. The neurotrophic factor mRNAs were measured by solution hybridization-RNase protection assays using highly specific cRNA probes for rat NGF $\beta$ , S100 $\beta$ , and FGF-2 with cyclophilin as an internal standard. The mRNA levels were quantitated with a PhosphorImager and 4 to 8 independent cultures were analyzed. We report that DEX suppressed NGF $\beta$  mRNA continuously over the 120-hour treatment, with a significant decrease detectable as early as 6 hours. In contrast, there were transient increases of approximately 1.5-fold in the S100 $\beta$  and FGF-2 mRNA levels which peaked at 24 hours. At 96 and 120 hours of treatment, S100 $\beta$  mRNA levels decreased approximately 2.5-fold. In addition, since GFAP is considered a marker of the functional status of astrocytes, GFAP mRNA levels were monitored. DEX suppressed GFAP mRNA level continuously over the 120-hour treatment, but a significant decrease was not detected until 48 hours into the treatment. Our results demonstrate that glucocorticoids can differentially regulate the gene expression of important neurotrophic factors in hippocampal astrocytes *in vitro*. This suggests that one of the mechanisms through which glucocorticoids affect hippocampal functions may be through regulation of neurotrophic factors gene expression (supported by NIH AG02224 to PMW).

## 417.7

TRANSCRIPTIONAL REGULATION OF BRAIN-DERIVED NEUROTROPHIC FACTOR mRNA LEVELS IN HIPPOCAMPUS BY KAINIC ACID IS INDEPENDENT OF PROTEIN SYNTHESIS AND ACTIVATION OF CALMODULIN KINASE II $\alpha$ . Eero Castrén<sup>\*</sup>, Benedikt Berninger, Axel Leingärtner, Dan Lindholm and Hans Thoenen. <sup>\*</sup>A.I. Virtanen Institute, University of Kuopio, Finland, Department of Neurochemistry, Max Planck Institute for Psychiatry, Martinsried, Germany.

We have investigated the pathways through which kainic acid increases brain-derived neurotrophic factor (BDNF) mRNA levels in cultured hippocampal neurons and in transgenic mice. Kainic acid induced the transcription of BDNF mRNA without influencing the mRNA stability. BDNF gene produces two transcripts with identical coding regions but with the 3' untranslated regions of different length. Interestingly, the half-life of the 4.2 kb BDNF transcript was much shorter than that of the 1.6 kb transcript (234 min. vs. 132±30 in), indicating that the 3' untranslated region of BDNF mRNA regulates mRNA stability. Increase in the BDNF mRNA levels by kainic acid was not blocked by the protein synthesis inhibitor cycloheximide demonstrating that BDNF is regulated as an immediate early gene in hippocampal neurons. Although calmodulin antagonists are known to abolish the effect of kainic acid on BDNF mRNA, this effect was very similar in Ca<sup>2+</sup>-calmodulin-dependent protein kinase II $\alpha$  knock-out mice and in wild-type mice suggesting that either other CAM-kinase subtypes can compensate for the lack of the  $\alpha$  type in these mice or that BDNF mRNA regulation is mediated by other calmodulin-dependent pathways than that involving CAM kinases.

## 417.9

EFFECTS OF ELEVATED INTRACELLULAR CALCIUM ON GDNF GENE EXPRESSION. J. F. Bishop, W. Wang, G. P. Mueller<sup>\*</sup> and M. M. Mouradian, Genetic Pharmacology Unit, Experimental Therapeutics Branch, NINDS, and Department of Physiology, USUHS, Bethesda, MD 20892.

Glial cell line-derived neurotrophic factor (GDNF) has both protective and restorative effects on nigrostriatal dopaminergic neurons *in vivo* (Tomac et al., Nature 373:335-339, 1995) and is therefore an important candidate for treatment of Parkinson's disease. In the present study, the role of calcium in the regulation of GDNF gene expression in rat C6 glioma cells was investigated. Confluent C6 cells were exposed to the Ca<sup>2+</sup> ionophore A23187 and GDNF mRNA levels were measured by reverse transcription (RT) followed by quantitative PCR (QPCR). Cells were incubated with A23187 (10<sup>-5</sup> M) or vehicle for 1 or 4 hours, and total RNA was extracted. QPCR results indicated that GDNF transcripts were elevated between 5 and 10 fold compared with vehicle treated controls. Inclusion of the RNA polymerase inhibitor actinomycin D (10  $\mu$ g/ml) in the culture medium for 4 hours abolished basal GDNF expression, suggesting that GDNF mRNA turnover is rapid in C6 cells. Actinomycin D decreased but did not abolish A23187-stimulated GDNF expression, suggesting that a calcium-dependent mechanism increases transcript stability. These results indicate that calcium is a prominent second messenger involved in the regulation of GDNF gene expression in C6 cells. The degree to which these observations can be extended to other cell types remains to be determined.

## 417.11

REGULATED SECRETION AND VECTORIAL TARGETING OF NEUROTROPHINS IN NEUROENDOCRINE AND EPITHELIAL CELLS. J.V. Heymach Jr., A. Krüttgen, U. Suter, and E.M. Shooter<sup>\*</sup>, Dept. of Neurobiology, Stanford Univ. School of Medicine, Stanford, CA 94305.

As a first step towards understanding how neurotrophins are targeted and secreted by neurons, we have investigated these questions in two model cell lines which mimic certain aspects of neuronal protein sorting: MDCK cells, a polarized epithelial cell line which targets proteins to either its apical or basolateral membranes; and AtT-20 cells, a neuroendocrine cell line which sorts secreted proteins to either regulated or constitutive pathways. When stably or transiently expressed in MDCK cells, NGF (both long and short splice variants) and NT-3 were secreted predominantly via the basolateral membrane, which is believed to correspond to the somatodendritic domain of neurons. In AtT-20 cells, both neurotrophins were sorted to the regulated secretory pathway as demonstrated by their release upon stimulation with 8-bromocyclic AMP. To determine if the NGF propeptide directs the sorting of mature NGF, we used site directed mutagenesis to generate mutants in which regions of the propeptide were deleted; in every case in which expression could be detected, these mutants were sorted similarly as wild-type NGF in both cell lines. Furthermore, NGF sorting was not significantly altered by mutations which specifically abolished N-linked glycosylation or proteolytic processing sites within the NGF precursor. These results indicate that NGF and NT-3 are vectorially targeted and secreted in a similar manner in the model cell lines examined, and suggest that the determinants of neurotrophin sorting are likely to be present within the mature neurotrophin moiety.

## 417.8

DIFFERENTIAL REGULATION OF BDNF TRANSCRIPTS THROUGH A CALCIUM/CALMODULIN-DEPENDENT PROTEIN KINASE PATHWAY. V. Y. Hayes<sup>\*1</sup>, K. D. Murray<sup>2</sup> and P. J. Isackson<sup>2</sup>.

<sup>1</sup>Dept. of Molecular Neuroscience and <sup>2</sup>Dept. of Biochemistry and Molecular Biology, Mayo Clinic, Jacksonville, FL 32224.

BDNF mRNA dramatically increases in cortical and hippocampal regions of the rat brain following recurrent seizures. The BDNF gene consist of at least four distinct 5' exons (exon I-IV) with different transcription initiation sites and a 3' exon (exon V) encoding preproBDNF (Timmusk et al., Neuron 10:475). Transcripts containing exon I and III are primarily responsible for increased BDNF mRNA expression following seizure induced by intraperitoneal injection of kainic acid, however they are distinctly regulated in different neuronal populations. Intracerebroventricular injection of KN62, an inhibitor of calcium/calmodulin-dependent kinase activity, results in a blockade of BDNF mRNA (exon V) induction in the neocortex, but not significantly in the hippocampus (Murray et al., Soc. Neurosci. Abstr. 19:111.15). In this study we have used *in situ* hybridization to demonstrate that seizure-induced BDNF transcripts containing exon I and II are inhibited in neocortex and to a lesser extent in hippocampus. In contrast, expression of transcripts containing exons III and IV are unaffected by KN62. These results provide further insight into mechanisms regulating CNS expression of BDNF mRNA.

## 417.10

DIFFERENTIAL EFFECTS OF INTERLEUKIN-6 ON CALCIUM RESPONSE AND MEMBRANE RESPONSE TO NMDA IN DEVELOPING CNS NEURONS. Z. Qiu<sup>\*</sup>, J.G. Netzeband and D.L. Gruol, Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037

We previously found that the amplitude of the calcium response to NMDA in cultured rat cerebellar granule neurons was significantly enhanced by chronic treatment with interleukin-6 (IL-6) during development, and that calcium influx and calcium release from intracellular stores contributed to mechanism mediating such increases. To determine the role of the calcium influx via various pathways to this enhancement, we have examined (a) calcium influx through voltage-sensitive calcium channels in response to NMDA, domoate and K<sup>+</sup> depolarization, (b) the membrane response to NMDA and K<sup>+</sup> depolarization and (c) membrane passive properties in both control and IL-6 treated neurons at different ages. The granule neuron cultures were exposed to IL-6 (5 ng/ml) by addition to the culture medium. Blocking L-type, N-type and P-type calcium channels with nimodipine,  $\omega$ -conotoxin GVIA and  $\omega$ -Aga-IVA toxin respectively all significantly decreased the amplitude of the calcium response to NMDA and K<sup>+</sup> in control and IL-6 treated neurons. However, the effects were more pronounced for the IL-6 treated neurons compared to controls and age dependent differences in the sensitivity of control and IL-6 neurons to these manipulations were observed. The sensitivity of the calcium responses to calcium channel blockers was similar for K<sup>+</sup> and domoate in both control and IL-6 treated neurons but differed from that observed for NMDA. Electrophysiological recordings from the granule neurons showed that at 11 days *in vitro* (DIV) there were differences in membrane input resistance and resting membrane potential between control and IL-6 treated neurons. These differences were not observed at 4 DIV. However, the membrane depolarizations to NMDA stimulation were similar in control and IL-6 treated neurons at all ages studied. These results suggested voltage-sensitive calcium channel play a role in the IL-6 induced enhancement of calcium response to NMDA, whereas a larger membrane response to NMDA does not. Supported by MH47680.

## 417.12

CHARACTERIZATION OF BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF) SECRETION FROM HIPPOCAMPAL NEURONS.

O. Griesbeck<sup>1</sup>, A. Blöchl<sup>1</sup>, J.F. Camahan<sup>2</sup>, H. Nawa<sup>3</sup> and H. Thoenen<sup>1\*</sup>. Max-Planck-Institut für Psychiatrie, Abteilung Neurochemie, 82152 Martinsried, Germany<sup>1</sup>; Amgen Inc., Thousand Oaks, CA 91320, USA<sup>2</sup> and Beckman Neuroscience Center, Cold Spring Harbour Laboratory, Cold Spring Harbour, NY 11724, USA<sup>3</sup>

In previous experiments it has been demonstrated that the activity-dependent secretion of NGF from hippocampal neurons (slices and primary cultures) showed very unusual characteristics. In contrast to the activity-mediated secretion of neurotransmitters and neuropeptides, the high potassium-, veratridine- and glutamate-initiated release of NGF was independent of extracellular calcium. It could be blocked by tetrodotoxin and depended on extracellular sodium and intact intracellular calcium stores (Blöchl and Thoenen, 1995, Eur. J. Neurosci., in press). It was important to know whether these unusual characteristics of activity-dependent secretion of NGF are unique for this molecule or whether other members of the same gene family show the same features of secretion. Using a novel two-site enzyme immunoassay for BDNF, we also found an activity-dependent release of BDNF from hippocampal slices of adult rats induced by high potassium (50 mM) or glutamate (100  $\mu$ M) which could be blocked by tetrodotoxin, but not by the high-affinity extracellular calcium chelator BAPTA. However, BAPTA/AM which penetrates the neuronal membrane abolished the activity-dependent release of BDNF, indicating that the observations made on the activity-dependent secretion of NGF are representative also for the other members of the NGF gene family.

## 417.13

CNTF RELEASE FROM CULTURED RAT HIPPOCAMPAL ASTROCYTES AND ITS REGULATION BY CYTOKINES. H. Kamiguchi\*, K. Yoshida, M. Sagoh, H. Wakamoto, M. Inaba, H. Sasaki, M. Otani and S. Toya. Department of Neurosurgery, Keio University, Tokyo 160, Japan.

Ciliary neurotrophic factor (CNTF) has been shown to rescue various types of lesioned neurons, and it needs to be released from astrocytes into the extracellular space to have an effect on neurons. However, direct evidence for CNTF release has not been unequivocally demonstrated. We hypothesized that the rapid sequestration by CNTF receptor present on cultured astrocytes might be the cause of the inability to detect CNTF released from astrocytes into the medium. Therefore, by two-site ELISA, we measured CNTF immunoreactivity in medium conditioned by astrocytes treated with phosphatidylinositol-specific phospholipase C (PI-PLC) which was used to prevent released CNTF from binding to the CNTF receptor on cultured astrocytes, since PI-PLC cleaves the glycosyl-phosphatidylinositol anchor of CNTFR $\alpha$ , the unique component involved in CNTF binding. CNTF immunoreactivity was not detectable in untreated astrocyte-conditioned medium (ACM), but was detectable in PI-PLC-treated ACM. These results together with the evidence that PI-PLC treatment used in this experiment did not have a toxic effect on astrocytes prove the fact that CNTF can be released from astrocytes without cell lysis. Subsequently, the effects of cytokines such as interleukin-1 $\beta$  (IL-1 $\beta$ ), tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), and epidermal growth factor (EGF), which are likely to be present in the brain following injury, were examined on CNTF release. Those cytokines increased CNTF protein levels in PI-PLC-treated ACMs without increasing CNTF protein levels in astrocyte-extracts, indicating that those cytokines enhance CNTF release from astrocytes.

## 417.15

INTRAVENTRICULAR AND INTRASTRIATAL INFUSION OF BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF) IN THE CYNOMOLGUS MONKEY: RETROGRADE TRANSPORT AND COLOCALIZATION WITH DOPAMINE CONTAINING SUBSTANTIA NIGRA NEURONS. E. J. Mufson\*, J. S. Kroin<sup>2</sup>, Y. T. Liu<sup>1</sup>, T. Sobrevieja<sup>1</sup>, R. D. Penn<sup>2</sup>, J. A. Miller<sup>2</sup> and J. H. Kordower<sup>1</sup>. Depts. Neurol. Sci.<sup>1</sup> and Neurosurg.<sup>2</sup>, Rush Med. Ctr., Chicago, IL 60612 and Amgen Inc.<sup>3</sup>, CA.

The distribution and retrograde transport of BDNF was examined using MRI guided stereotaxic intracerebroventricular (ICV) and intrastriatal infusion in the cynomolgus monkey. Two ICV animals were infused with BDNF at a dose of 3  $\mu$ g/h for 21 and 28 days and a third ICV animal received sequential infusions of 15, 30 and 60  $\mu$ g/h BDNF each for 7 days using an Alzet minipump. For the multiple intrastriatal animals (n=5) a dose of 3  $\mu$ g/h was infused into each site. Following the lower dose ICV infusion, BDNF immunoreactivity was confined to the ventricular ependymal layer. In the sequential higher dose ICV case the cannula was located mainly within the lateral ventricle, although there was damage to the ependymal wall and adjacent caudate nucleus. BDNF immunoreactivity revealed spread of injectate within the ipsilateral and to a lesser extent the contralateral caudate nucleus, septum, orbital cortex and ventricular ependymal wall. In this case, retrogradely labeled BDNF neurons were found within the parafascicular thalamus and substantia nigra, pars compacta, as well as within cortex and basal forebrain. BDNF intrastriatal infusion retrogradely labeled perikarya within sensory motor cortex, parafascicular thalamus and substantia nigra, pars compacta. Sections from these cases dual immunoreacted for BDNF and tyrosine hydroxylase, the synthesizing enzyme for dopamine, revealed a subpopulation of pars compacta dopaminergic neurons which contained retrogradely transported BDNF. These findings indicate that a select subgroup of nigral dopamine neurons retrogradely transport BDNF in the primate and that a subpopulation of nigral cells may be responsive to the trophic influences of BDNF in the normal and pathologic state.

## 417.17

NEUROLOGIC SYMPTOMS EXHIBITED BY TRANSGENIC MICE EXPRESSING ANTISENSE INTERLEUKIN 3 (IL3) RNA. Y. Sugita\*, C.E. Dunbar<sup>1</sup>, S. Dorent<sup>1</sup>, D.M. Cockayne<sup>1</sup>, J.P. Schwartz, Clinical Neuroscience Branch, NINDS, <sup>†</sup>Hematology Branch, NHLBI, NIH, Bethesda, MD 20892 and <sup>‡</sup>DNAX Res. Inst., Palo Alto, CA 94131.

IL3 is an important mediator in physiological and pathophysiological processes affecting the central nervous system (CNS). Microglia react to brain injury or inflammation with proliferation, migration and differentiation. IL3 stimulates proliferation of microglia, but also is a trophic factor for central cholinergic neurons. The major source of IL3 in the CNS is activated astrocytes and microglia. To examine the role of IL3 in the CNS, transgenic mice expressing murine antisense IL3 (AS-IL3) RNA were generated. RT-PCR confirmed expression of the AS-IL3 transgene in the CNS and hematopoietic tissues, and ELISA showed decreased IL3 levels in the periphery. AS-IL3 transgenic mice exhibit either progressive neurologic dysfunction or a lymphoproliferative syndrome: occasional mice with the neurologic syndrome show splenomegaly. Neurologic symptoms include paralysis (mono-, para- or hemiplegia) and ataxia or bradykinesia, followed by wasting and death resulting from an inability to eat or drink. Histopathological examination shows multifocal proliferation/infiltration of activated microglia in the brain stem and spinal cord, with some astrogliosis. In addition, B lymphocytes infiltrate around the brain and spinal cord, resulting in compression of the parenchyma. However, AS-IL3 transgenic mice do not exhibit abnormalities of the neuronal network or altered cell number in the hematopoietic system. Thus, IL3 may be required for appropriate expression of other cytokines/growth factors, which in turn regulate the environment of the CNS.

## 417.14

IDENTIFICATION OF A STRUCTURAL DOMAIN RESPONSIBLE FOR SECRETION OF A NEUROTROPHIC FACTOR FOR CILIARY GANGLION NEURONS. C. Gary Reiness\*, Sean Sweeney, and Rae Nishi<sup>†</sup>, Dept. of Biology, Lewis & Clark College, Portland, OR 97219 and <sup>‡</sup>Dept. of Cell Biology & Anatomy, Oregon Health Sciences University, Portland, OR 97201

Although growth promoting activity (GPA) and ciliary neurotrophic factor (CNTF) are both potent trophic factors for chick ciliary ganglion neurons in vitro, they differ in their abilities to be released from cells. The present study was undertaken in order to determine the structural basis for this difference in release between GPA and CNTF. GPA is homologous (50% amino acid identity) to CNTF; however, when GPA and CNTF were expressed by transfected cells, biological activity due to GPA was detectable in the medium, whereas CNTF was not (Leung et al., Neuron, 8: 1045, 1992). Neither GPA nor CNTF contains an N-terminal signal sequence for secretion, but GPA contains a sequence between positions 43-63 that is significantly more hydrophobic than the corresponding sequence in CNTF. We hypothesized that this internal hydrophobic domain might serve as a signal for secretion. To test this hypothesis, we generated a chimeric sequence that coded for the N-terminal 57 amino acids of GPA and the C-terminal 143 amino acids of CNTF. COS cells transfected with this vector expressed and secreted a protein that supported the survival of embryonic chick ciliary neurons in culture and was recognized by anti-rat CNTF antisera in an immunoblot assay. When CNTF was expressed in the same vector in COS cells, neurotrophic activity was found within cell extracts and no detectable activity was found in the culture medium. Thus the first 57 amino acids of GPA contain a signal that can target the molecule into a secretory pathway. We are currently conducting experiments to characterize the pathway by which the chimeric neurotrophic factor is secreted by COS cells. Supported by the Murdock College Science Program (CGR), the American Heart Association, Oregon Affiliate (CGR), and NINDS (RN).

## 417.16

RETROGRADE TRANSPORT OF rhBDNF FOLLOWING NEO AND LIMBIC CORTX INFUSION IN RAT. T. Sobrevieja\*, M. Pagcatipunan<sup>2</sup>, J. S. Kroin<sup>2</sup>, R. D. Penn<sup>2</sup>, J. Miller<sup>2</sup> and E. J. Mufson<sup>1</sup>, Depts. of Neurol. Sci.<sup>1</sup>, Neurosurgery<sup>2</sup>, Rush Presbyterian Med. Ctr., Chicago, IL 60612, Univ. Illinois<sup>3</sup>, Chicago and Amgen<sup>4</sup>, CA.

Brain-derived neurotrophic factor (BDNF) mRNA distribution differs from that of other members of the NGF family of neurotrophins within the central nervous system. To determine those neuronal populations which transport BDNF, rats were infused with rhBDNF at a dose of 3  $\mu$ g/h for 7 days using an Alzet 2002 minipump into the frontal, occipital, entorhinal cortex, amygdala and lateral ventricle. Immunohistochemistry was performed using a turkey anti-BDNF antibody. Frontal cortex infusion revealed retrogradely labeled neurons within frontoparietal, cingulate and perirhinal cortex, endopiriform nucleus, diagonal band, nucleus basalis, dorsal thalamus, lateral hypothalamus and locus coeruleus. Occipital infusion retrogradely labeled neurons in the temporal, ento/perirhinal, retrosplenial and occipital cortex as well as the claustrum, medial septum, diagonal band, dorsal thalamus, dorsolateral geniculate and hypothalamus. Entorhinal infusion retrogradely labeled neurons in the frontal, temporal, perirhinal cortex, CA fields, subiculum, endopiriform nucleus, septal/diagonal band complex, amygdala, dorsal thalamus, nucleus basalis, lateral hypothalamus, supramammillary region, brainstem tegmentum, raphe nuclei and locus coeruleus. Amygdaloid infusion retrogradely labeled neurons in the diagonal band/nucleus basalis, intra-amygdaloid nuclei, piriform, ento/perirhinal and occipital cortex as well as dorsal and epithalamus, hypothalamus, substantia nigra pars compacta, dorsal raphe and parabrachial regions. In contrast, after intracerebroventricular rhBDNF infusion, immunoreactivity was restricted to the ependymal wall of the ventricular system. These findings indicate that selective neuronal subgroups retrogradely transport BDNF. Moreover, these neurons may respond to this neurotrophin in the normal or pathologic condition.

## 418.1

**DIFFERENT CELLULAR MECHANISMS UNDERLIE THE POTENTIATION OF TRANSMITTER SECRETION AT DEVELOPING NEUROMUSCULAR JUNCTIONS BY BDNF AND CNTF.** R. Stoop\* and M.-m. Poo. Dept. Biol. Sci., Columbia Univ., N.Y., NY 10027.

Extracellular application of brain-derived neurotrophic factor (BDNF) and ciliary neurotrophic factor (CNTF) have been shown to cause rapid potentiation of spontaneous and evoked transmitter secretion from presynaptic nerve terminals at developing neuromuscular junctions. Three lines of evidence suggest that these two factors may potentiate the transmitter secretion by acting on different sites in the secretory machinery. First, CNTF requires signaling with the cell body for its potentiating effect, whereas BDNF can still potentiate secretion from a presynaptic nerve terminal transected from the cell body. Second, at a concentration of 100 ng/ml of BDNF or CNTF, which produces saturating effects on potentiating transmitter secretion, addition of CNTF or BDNF (100 ng/ml), respectively, further increases the potentiation significantly. The two factors may act synergistically, since addition of a low concentration (1 ng/ml) of CNTF, which by itself was ineffective, greatly elevated the potentiation effect of a low concentration (1 ng/ml) of BDNF. Third, application of BDNF (100 ng/ml) significantly reduces the paired-pulse facilitation at these synapses, while CNTF at the same concentration is without effect. Since distinct receptors and transduction mechanisms are involved in the actions of BDNF and CNTF, these neurotrophic factors may act in an additive or synergistic manner in promoting the synaptic functions at developing synapses.

## 418.3

**NEUROTROPHINS MODULATE SYMPATHETIC CONNECTIONS TO CARDIAC MYOCYTES.** G.G. Turrigiano\*, S. Lockhart, S.J. Birren. Dept. of Biology and Center for Complex Systems, Brandeis University, Waltham, MA, 02254.

The classic role for neurotrophins in the nervous system are as target-derived survival factors. Recent evidence suggest that neurotrophins also act to modulate synaptic strengths at the neuromuscular junction and between central synapses. We are interested in the role of neurotrophins in the formation and modulation of synaptic connections between sympathetic neurons and their cardiac myocyte targets. We have established co-cultures of rat neonatal superior cervical ganglia (SCG) neurons and ventricular myocytes. The myocytes form clusters that spontaneously beat in culture. Functional connections between SCG neurons and myocytes were assayed by stimulating SCG neurons intracellularly and monitoring myocyte beat frequency. At early times in culture (2-3 days) stimulation of SCG neurons accelerated myocyte beat frequency. At later times (2-3 weeks) the effect was inhibitory and was blocked by atropine, indicating that the neurons had undergone a switch to a cholinergic phenotype as previously described (Furshpan, Macleish, O'Laugue, and Potter 1976, PNAS 73:4225-4229). We examined the effect of NGF on synapse strength after 2-3 days in culture. NGF strongly potentiated the acceleration of myocyte beat frequency induced by SCG stimulation. The effects were rapid (2-5 minutes in onset), and reversed within 5-20 minutes of NGF washout. These results suggest that neurotrophins act to acutely modulate sympathetic synapses in culture. This modulation may be important for the initial formation and consolidation of synapses during early development.

## 418.5

**NON-TROPHIC EFFECTS OF NERVE GROWTH FACTOR (NGF) ON NEURONS OF THE MESENCEPHALIC TRIGEMINAL NUCLEUS (MES-V).** J. Yamuy\*, C. Pedroarena, I. Pose, F.R. Morales and M.H. Chase. Departamento de Fisiología, Facultad de Medicina, Montevideo, Uruguay and Department of Physiology and the Brain Research Institute, UCLA School of Medicine, Los Angeles, CA, 90024.

Microinjection of NGF into the rostral portion of the pontine reticular formation elicits, within a short latency, an active sleep-like state (1, 2) similar to that induced by cholinergic agonists. This finding led us to hypothesize that neurotrophins may directly affect neuronal excitability. In the present study, we examined this hypothesis with respect to neurons of the Mes-V, in which we have previously reported that fast (80-120 Hz) oscillations of the membrane potential develop upon membrane depolarization and may trigger bursts of rhythmic action potentials (3).

Intracellular recordings from Mes-V neurons were obtained utilizing brainstem slices of adult rats. Microdroplets of NGF, at a concentration of 1 µg/µl, were applied locally by pressure ejection. Following NGF application, the amplitude of the oscillations increased. In addition, the threshold for their occurrence was reduced. The augmented oscillations could also elicit the discharge of previously silent neurons. Rheobase was lower, which was probably due to the NGF-induced enhancement of the oscillations evoked by depolarizing pulses. No consistent changes in membrane potential were detected. The configuration of the spike and the action potential's afterhyperpolarization remained unchanged. These effects occurred 5 to 30 seconds after the application of NGF and persisted for 15 to 20 minutes.

These data suggest that NGF, in addition to its well defined role in regulating the survival and phenotype of neurons, has the potential for exerting modulatory actions on their intrinsic electrophysiological properties. This work was supported by USPHS Grants NS 23426, MH 43362 and NS 09999.

**MECHANISM OF POTASSIUM CHANNEL REGULATION BY NEUROTROPHINS AND CNTF.** S.S. Lesser\* and D.C. Lo. Department of Neurobiology, Box 3209, Duke University Medical Center, Durham, NC 27710.

Neurotrophic factors strongly influence the development and maintenance of neuronal excitability through the regulation of ion channel and neurotransmitter receptor expression. In this study, using electrophysiological and molecular techniques, we have focused on potassium channel regulation in the human neuroblastoma cell line SK-N-SH. This sympathetic-like cell line is responsive to several neurotrophic factors, including the neurotrophin nerve growth factor (NGF) and the unrelated neural cytokine ciliary neurotrophic factor (CNTF). In addition, we found that retinoic acid treatment induces TrkB and TrkC expression in SK-N-SH cells, and thus confers additional responsiveness in these cells to brain derived neurotrophic factor (BDNF), neurotrophin-3 (NT-3), and NT-4.

Treatments with NGF, NT-3, NT-4, or CNTF all increase a delayed rectifier potassium current in SK-N-SH cells. Using non-stationary fluctuation analysis on whole-cell currents we provide evidence that the predominant channel species in outside-out patches underlies the macroscopic current, supporting our hypothesis that these neurotrophic factors lead to increased expression of functional channels. To test whether transcriptional regulation mediates the regulation of potassium channels by NGF, NT-3, NT-4, and CNTF we used RT-PCR with degenerate primers to identify which potassium channels are expressed in SK-N-SH cells before and after neurotrophic treatments. With this method we have identified two human potassium channels, Kv1.1 and Kv1.3, which are expressed in these cells.

This work was supported by awards from the Ruth K. Broad Foundation, the Klingenstein Fund, the Alfred P. Sloan Foundation, and NIH grant NS32742. Neurotrophic factors were generously provided by Regeneron Pharmaceuticals.

**NERVE GROWTH FACTOR ACUTELY ENHANCES HIGH-VOLTAGE ACTIVATED  $Ca^{2+}$  CURRENTS IN ADULT MOLLUSCAN NEURONS.** W.C. Wildering\*, J.C. Lodder\*, K.S. Kits\* and A.G.M. Bulloch\*. Neuroscience Research Group, Faculty of Medicine, University of Calgary, Calgary, Alberta, Canada\* and Graduate School of Neurosciences Amsterdam, Research Institute Vrije Universiteit, Faculty of Biology, Amsterdam, The Netherlands\*.

Murine NGF induces sprouting in specific types of *Lymnaea* neurons, trophic actions that occur over a time course of hours to days. The present study investigated acute effects of NGF in identified motoneurons previously shown to sprout in response to NGF. Right Parietal A group (RPA) neurons were isolated from adult animals and plated on a poly-L-lysine substrate in a defined medium (DM). Using standard whole-cell voltage clamp techniques, the effect of NGF on  $Ca^{2+}$  currents in RPA neurons were studied within 1 to 5 hours after plating. RPA neurons predominantly express a high-voltage activated (HVA) sustained  $Ca^{2+}$  current. Superfusion of murine 2.5S NGF evoked a rapid and reversible increase of this HVA  $Ca^{2+}$  current ( $n=31$ ). In a typical experiment, the introduction of 1 ng/ml NGF in the bath induced a maximal increase in peak inward HVA current of 67% within 2 minutes. The effect completely reversed within minutes after the withdrawal of NGF. Although similar effects were observed in the majority of RPA neurons tested ( $n=31$ ), the responsivity varied considerably between neurons. Data suggest that in some cells the threshold dose may be as low as 1 pg/ml. Since both the disruption of NGF's tertiary structure by alkylation of its cysteine residues, as well as preabsorption of NGF with an anti-NGF IgG abolished NGF's activity, the effect on HVA  $Ca^{2+}$  currents is unlikely to be non-specific. These data indicate that enhancement of transmembrane  $Ca^{2+}$  currents is one of the early events in NGF signal transduction in *Lymnaea* neurons. Moreover, the low threshold dose of the effect suggests the involvement of a high-affinity receptor. Supported by NCE (Canada) and MRC (Canada).

## 418.6

**ACTIVATION OF SPHINGOSINE KINASE DIFFERENTIATES THE SIGNALING PATHWAYS OF EPIDERMAL AND NERVE GROWTH FACTORS IN PC12 CELLS.** R.A. Rius\* and S. Spiegel. Dept. of Biochemistry and Molecular Biology, Georgetown University School of Medicine, Washington, DC 20007.

Nerve growth factor (NGF) leads to neurite outgrowth and cessation of cell growth of rat pheochromocytoma (PC12) cells, whereas epidermal growth factor (EGF) stimulates cell proliferation. However, no major differences have yet been identified in the intracellular signal transduction pathways activated by the receptors for these growth factors. We have now found that NGF transiently activates cytosolic sphingosine kinase, which catalyzes the phosphorylation of the primary hydroxyl group of sphingosine to produce sphingosine-1-phosphate (SPP). SPP is a putative second messenger which mobilizes calcium in an inositol trisphosphate-independent manner, that has been implicated in the mitogenic action of platelet derived growth factor and serum (Olivera and Spiegel, *Nature*, 365: 557, 1993). In contrast to NGF, EGF had only a small effect on the activity of this kinase. Furthermore, long term treatment of PC12 cells with NGF induced marked increase in sphingosine kinase activity. This increase of nearly 2 fold was found after 2 days and reached a maximum of 5 fold after 3 days and remained elevated even after 2 weeks of treatment with NGF. Similar stimulations were observed in serum or serum-free media. Kinetic characterization indicated an increased  $V_{max}$ . In contrast to NGF, chronic treatment of PC12 cells with EGF, phorbol myristate acetate, or KCl had little or no effect on sphingosine kinase activity. However, agents that increase intracellular levels of cAMP uniformly lead to increases in sphingosine kinase activity. These results indicate that activation of sphingosine kinase and subsequent production of SPP might have an important biological role in signal transduction pathways activated by NGF. Further involvement of sphingolipid metabolites in NGF action is under investigation.

**MODIFICATION OF NGF SIGNALLING BY EXTRACELLULAR MATRIX ADHESION IN PC12 CELLS**  
**H.W. Harris\***, Laboratory of Neuroscience, National Institute on Aging, NIH, Bethesda, MD 20892.

Adhesion to extracellular matrix proteins is known to exert widespread influences over many cellular processes including differentiation, cytoskeletal organization, and cell cycle progression. Many of these processes are also regulated by growth factors such as NGF. We therefore investigated the responses to NGF treatment of adherent and nonadherent PC12 cells. For these studies, PC12 cells were grown either on collagen-coated or agarose-coated dishes. Nonadherent cells grown on agarose-coated dishes showed reduced long term viability as compared to adherent cells. Treatment of adherent cells with NGF reduced proliferation rate as measured by thymidine uptake that was associated with neuronal differentiation. In contrast, proliferation of nonadherent cells was increased by NGF treatment. NGF-associated signalling was investigated by phosphotyrosine immunoblotting of cell extracts from adherent and nonadherent cells in the presence and absence of NGF. Adherent cells showed patterns of NGF-induced tyrosine kinase activity that differed from those seen in nonadherent cells. These results suggest that signal transduction events and cellular responses to NGF are modified by extracellular matrix adhesion.

## 418.9

**DIFFERENTIAL EFFECTS OF NGF AND CALPHOSTIN C IN PC12 CELLS.** D. Maysinger\*, S. Panarello, A.L. Padjen, T. Hashiguchi & M. Hashiguchi, Dept. of Pharmacology & Therapeutics, McGill University, Montreal, QC H3G 1Y6, Canada & Dept. of Physiology, Tokyo Medical College, Shinjuku-ku, Tokyo 160, Japan.

Phaeochromocytoma cells (PC12) differentiate in the presence of nerve growth factor (NGF). Furthermore, this trophic factor also enhances enzymatic activity of Na<sup>+</sup>/K<sup>+</sup>-ATPase which is responsible for active transport of Na<sup>+</sup> and K<sup>+</sup> in most animal cells. The enzyme plays a central role in mediating electrical activity in the nervous system. A selective protein kinase C (PKC) inhibitor, calphostin C, also enhances the enzymatic activity of Na<sup>+</sup>/K<sup>+</sup>-ATPase *in vivo*.

The aim of this study was to assess the possible interaction between NGF and calphostin C effects. We examined the changes in Na<sup>+</sup>/K<sup>+</sup>-ATPase activity, expression of catalytic  $\alpha$  subunit and the extent of phosphorylation and used image analysis to study differentiation as well as electrophysiological measures of Na<sup>+</sup>/K<sup>+</sup> pumping and excitability. Results show that: [1] Unlike NGF which induces neurite outgrowth in both serum containing and serum-free medium calphostin C had no effects; [2] Both NGF and calphostin C moderately enhanced Na<sup>+</sup>/K<sup>+</sup>-ATPase activity when administered individually; in combination they exert remarkable morphologic effects in PC12 cells (increased length and decreased number of neurites per cell - appearance of spindle-like cells) and also enhance significantly Na<sup>+</sup>/K<sup>+</sup>-ATPase enzymatic activity. [3] The effects of calphostin C was concentration-dependent and bimodal: higher concentrations (>50 nM) caused general neurite retraction whereas lower concentrations had selective effect on distal neurites.

In conclusion these results suggest that NGF and calphostin C exert their effects on morphological changes, enzymatic activity and phosphorylation pattern in PC12 cells via different mechanisms. In addition, exposure to light seems to play a role in the phototoxic effect of calphostin C. (Supported by in part by MRC).

## 418.11

**CHARACTERIZATION OF AN mRNA REQUIRED FOR NEURITE REGENERATION IN NGF-PRIMED PC12 CELLS.** J.L. Twiss\* and E.M. Shooter, Depts. of Neurobiology and Pathology, Stanford Univ. Medical School, Stanford, CA 94305.

Neurite regeneration from NGF-primed PC12 cells is independent of RNA synthesis, but requires new protein synthesis. Regeneration is initiated by translation of proteins from short-lived mRNAs ( $t_{1/2} \leq 5-6$  h) produced during the NGF-priming period. Despite a careful search for short-lived mRNAs in NGF-primed PC12 cells, we found that those encoding structural proteins thought essential for neuritegenesis are all long-lived. To identify short-lived mRNAs in PC12 cells, we produced cDNA libraries from NGF-primed PC12 cells under conditions permissive and non-permissive for neurite regeneration. The permissive library [NGF x 10 d, RNA synthesis inhibition x 5 h] was screened with a subtracted probe enriched for short-lived mRNAs. The probe was generated by hybridizing cRNAs from the non-permissive libraries [NGF x 3 d and NGF x 10 d, RNA synthesis inhibition x 12 h] to <sup>32</sup>P-labeled single-stranded cDNA inserts from the permissive library to an  $R_0 > 1000$ . Thus far, we have identified a single clone, NSL8, with a remarkably short mRNA half-life in NGF-primed PC12 cells ( $t_{1/2} \leq 4.5$  h). Antisense NSL8 oligonucleotides diminish neurite regeneration from NGF-primed PC12 cells while sense NSL8 oligonucleotides are without effect. Sequence analysis shows that NSL8 cDNA likely represents the rat homologue of the human ribosomal associated protein, L4. It is probable that rapid translation of NSL8 mRNA following neurite injury provides translational competence to regenerate neurites from a large pool of long-lived mRNAs encoding structural proteins.

## 418.8

**PROMOTING EFFECTS OF EXTRACELLULAR MATRIX IN NEURONAL REGENERATION. SELECTIVE ROLE OF GLYCOSAMINOGLYCANS.** A.M. Di Giulio\*, L. Vergani, E. Germani, B. Tenconi, G. Prino and A. Gorio, Lab for Research on Pharmacology of Neurodegenerative Disorders, Dept Medical Pharmacology, Via Vanvitelli 32, Milano 20129, Italy.

The extracellular matrix plays a significant role in nerve regeneration and neurite formation and guidance *in vitro*. We have tested *in vitro* the ability of a variety of glycosaminoglycans upon promoting neurite formation in 5YSY neuroblastoma cells after exposure to serum-free medium. Heparin sulfate, chondroitin sulfate and a mixture, named Atracid, were the most effective glycosaminoglycans in promoting neurite formation. The effective concentrations were as low as 1pM. We have assayed the *in vitro* active glycosaminoglycans *in vivo* after permanent axotomy of the sciatic nerve in the rat. Twentyone days after nerve lesion substance P content in the lumbar cord drops from 10.1 to 6.6 ng/mg protein; treatment with glycosaminoglycans by daily intraperitoneal injection at the dose of 0.2 mg/kg counteracts the loss and promotes a huge increase to 18.5 ng/mg protein. A similar effect is observed for met-enkephalin lumbar cord content. Seven and twenty days after sciatic nerve injury the abundance of NGF mRNA increased by 6 fold in the proximal stump at the site of lesion, glycosaminoglycan treatment promoted a 15 fold increase in the lesioned nerve and 10 fold in the unlesioned contralateral. The abundance of p75 NGF receptor mRNA increased 10 fold after nerve lesioning, in animals treated with glycosaminoglycans the increase was 4 fold. Also the levels of brain derived neurotrophic factor and neurotrophin-3 mRNAs increased markedly 20 days after nerve transection, in animals treated with glycosaminoglycans a similar increase also occurred in the contralateral nerve. These data suggest that glycosaminoglycans promote neurite growth and prevent retrograde degeneration, the latter effect may be mediated by an increased production of neurotrophic factors.

## 418.10

**NGF Inducible Regulatory Elements in the Rat Cyclin D1 Promoter.** G-Z.

Yan\* and E. B. Ziff, Howard Hughes Medical Institute, and Department of Biochemistry, New York University Medical Center, New York NY 10016. Nerve growth factor (NGF) causes growth arrest and promotes rat PC12 cells to differentiate into sympathetic neuron-like cells. Our previous studies have indicated that NGF regulates the PC12 cell cycle machinery through specific inhibition of the Cdk kinases by p21, a cdk inhibitory protein, and induction of cyclin D1. Over expression of cyclin D1 in PC12 which leads to inhibition of PCNA expression is sufficient on its own to arrest the cells in G1 phase. Our recent studies show that constitutive expression of the *c-myc* gene in PC12 cells leads to a reduced level of cyclin D1 protein, while PCNA protein remains at high levels, suggesting that *c-myc* protein may be involved in mediating the regulation of cyclin D1 following NGF treatment. To further understand the mechanisms by which NGF regulates cyclin D1 during NGF control of PC12 cell cycle machinery, we have cloned the rat cyclin D1 promoter and analyzed the structure and function of 3kb of its 5'-flanking region. We find the upstream sequences of rat cyclin D1 gene are highly homologous to those of the human cyclin D1 gene. The cyclin D1 promoter is inducible by NGF in PC12 cells, which is similar to the induction of cyclin D1 by NGF *in vivo*. Repression by *c-myc* is also observed with the cyclin D1 promoter in PC12 cells. Deletion analysis has identified several regulatory regions which are involved in both basal level and NGF-induced cyclin D1 expression. We are now performing tests to determine the functional significance of these elements and the factors which interact with these elements in regulation of cyclin D1 expression.

**CHANGES IN ANTIOXIDANT HOMEOSTASIS AND CELL VIABILITY IN NGF-PRODUCING SY5Y.** D.P. Pizzo\* and J.R. Perez-Polo, Dept of Human Biological Chemistry and Genetics, Univ. of Texas Medical Branch, Galveston, TX 77555-0652

Nerve growth factor (NGF) regulates survival of several cell types both *in vivo* and *in vitro*. Protection from cell death occurs through a variety of mechanisms, including the regulation of antioxidant homeostasis. Here we describe an autocrine NGF model system consisting of NGF responsive SK-N-SH-SY5Y cells infected with a retroviral vector containing the NGF gene. The resulting cell line (SY5Y<sup>NGF</sup>) secretes NGF at a lower rate than that measured in fibroblast cell lines infected with the same NGF construct. The SY5Y<sup>NGF</sup> has altered growth properties, and significant changes in several aspects of glutathione metabolism. The rate limiting enzyme in glutathione synthesis, gamma-glutamylcysteine synthetase was reduced by greater than fifty percent in two different SY5Y<sup>NGF</sup> cell lines while the corresponding levels of glutathione were slightly but not significantly reduced. The protective enzyme, glutathione peroxidase, however, was slightly elevated in one of two SY5Y<sup>NGF</sup> clonal lines. The cells also had a diminished viability in defined media and a rapid onset of cell death as compared to the parental SY5Y. Within two days in defined media there was a noticeable change in morphology that resembled that typically seen in apoptotic cells. Compounds that inhibit the cell death of PC12 cells in serum free media such as NGF or cAMP did not protect the SY5Y<sup>NGF</sup> cultures. However, aurintricarboxylic acid and the phorbol ester TPA enhanced cell viability. These clonal lines should be useful in studies on cell death regulation as well as the effects of chronic neurotrophin treatment. Supported by a grant from the NASA/Texas Space Grant Consortium to DPP and NS18708 to JRPP.

**NGF COUPLES PROTEIN SYNTHESIS AND DEGRADATION IN SYMPATHETIC NEURONS.** J. L. Franklin\* and E. M. Johnson, Jr. Dept. of Molecular Biology and Pharmacology, Washington Univ. Sch. of Med., St. Louis, MO 63110.

Inhibitors of macromolecular synthesis are generally assumed to exert their effects on cells solely through inhibition of protein synthesis. We report here that the translational inhibitor, cycloheximide (CHX), and the transcriptional inhibitor, actinomycin D (ACT-D), also cause profound suppression of protein turnover in sympathetic neurons maintained in cell culture in the presence, but not absence of NGF. Superior cervical ganglia were dissected from embryonic-day-21 rats. Neurons were enzymatically and mechanically dissociated from the ganglia and maintained in culture in the presence of NGF for a week. For twenty-four hours before the beginning of the experiment neurons were incubated in medium containing  $^{35}\text{S}$  cysteine/methionine Trans label to allow ample time for incorporation of the labeled amino acids into cellular proteins. The label was then washed out and the cells were incubated in cold medium for 6 hours to remove labile proteins from the analyzed pool. They were then exposed for 72 hours to either CHX or ACT-D in the presence or absence of NGF. Neurons were then lysed and proteins precipitated with TCA. Both CHX and ACT-D caused a dose-dependent suppression of turnover in cells maintained in NGF. Total turnover in untreated cells during this time was about 40% either in the presence or absence of NGF. In cells maintained for this period in medium containing NGF and either CHX or ACT-D protein turnover was suppressed by 70-80%. The  $\text{IC}_{50}$  for suppression by both CHX and ACT-D was about 100 ng/ml of medium. In neurons maintained in the absence of NGF the inhibitors did not prevent turnover. These data indicate that a biological effect of neurotrophic factors is to maintain coupling of protein synthesis and protein degradation in neurons. Supported by the Ronald McDonald foundation.

## 418.14

**TROPHIC FACTORS ALTER CELLULAR METABOLISM AND EXPRESSION OF THE GLUCOSE TRANSPORTERS GLUT1 AND GLUT3 DURING NITRIC OXIDE TOXICITY.** K. Maiese\*, S. J. Vannucci, T. M. Davis-Hill, L. Boccone, and J. A. Simpson. Dept. of Neurology, Wayne State University School of Medicine, Detroit, MI, 48201, and NIDDK, NIH, Bethesda, MD, 20816

The trophic factors basic fibroblast growth factor (bFGF) and epidermal growth factor (EGF) are neuroprotective during anoxia and nitric oxide (NO) toxicity (Maiese, et al. *J Neurosci* 13: 3034-3040, 1993) and have been shown to alter the expression of glucose transporters. Facilitated glucose transport across cellular membranes is mediated by a family of transporter proteins that include the transporters GLUT1 and GLUT3 expressed in the central nervous system (Maher, F., et al. *FASEB J* 8: 1003-1011, 1994). Given the link between metabolism, NO toxicity, and neuroprotection by trophic factors, we examined the role of metabolism and the transporters GLUT1 and GLUT3 in the protective mechanisms of bFGF and EGF during a five minute exposure to 300  $\mu\text{M}$  of the NO generator sodium nitroprusside in primary hippocampal neuronal cultures. Exposure to NO reduced neuronal survival from approximately 95% to 30% and increased glucose consumption ( $8 \pm 3$  (normoxia) to  $23 \pm 3$  (NO),  $\mu\text{M} \times 10^3/\text{cell}$ ,  $n=10$ ,  $p<0.001$ ) and lactate production ( $23 \pm 3$  (normoxia) to  $74 \pm 5$  (NO),  $\mu\text{M} \times 10^3/\text{cell}$ ,  $n=10$ ,  $p<0.001$ ). In contrast, 24 hour pretreatment with bFGF or EGF during NO exposure protected neurons (increased survival from  $28 \pm 5\%$  (NO) to  $65 \pm 5\%$  (NO + bFGF/EGF),  $n=10$ ,  $p<0.001$ ) and decreased glucose consumption ( $23 \pm 3$  (NO) to  $18 \pm 4$  (NO + bFGF/EGF),  $\mu\text{M} \times 10^3/\text{cell}$ ,  $n=10$ ,  $p<0.001$ ) and lactate production ( $74 \pm 5$  (NO) to  $40 \pm 4$  (NO + bFGF/EGF),  $\mu\text{M} \times 10^3/\text{cell}$ ,  $n=10$ ,  $p<0.001$ ). In comparison to normoxic cultures, NO decreased the expression of GLUT1 by approximately 10% and GLUT3 by approximately 45%. Yet, a 24 hour pretreatment with bFGF or EGF during NO exposure restored the expression of GLUT1 and GLUT3 similar to that observed with normoxic cultures. Our results demonstrate that during NO exposure, bFGF and EGF reduce glucose consumption and lactate production and restore the expression of GLUT1 and GLUT3 similar to that observed in normoxic cultures. Further study of NO, cellular glucose transport, and trophic factor neuroprotection may direct future therapy for neurodegenerative disease.

## NEUROTROPHIC FACTORS: BIOLOGIC EFFECTS VII

## 419.1

**DIFFERENTIATION OF EMBRYONAL CARCINOMA CELLS BY NEUROTROPHIC FACTORS AND RETINOIC ACID.** W. M. W. Cheung\*, A. H. Chu, M. F. Leung and N. Y. Ip. Department of Biology, Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong.

Previous studies have demonstrated that cloned human embryonal carcinoma (EC) cells (NTera-2 cl.D1 or NT2/D1) could be induced to differentiate into several morphologically distinct cell types by treatment with retinoic acid. Such differentiating actions of retinoic acid may be mediated by the induction of neurotrophic factor receptors, as suggested by a recent study with neuroblastoma cells. We have used the NT2/D1 EC cells as a model system to examine whether neurotrophic factors alone, or in combination with retinoic acid, could effect neuronal differentiation. Neurotrophic factors were found to induce differentiation of NT2/D1 EC cells in a manner similar to that observed with retinoic acid. Following treatment with specific combinations of neurotrophic factors, NT2/D1 EC cells showed a disappearance of EC phenotype and neuronal cell morphology were observed within two weeks. Of the various neurotrophic factors examined, brain-derived neurotrophic factor (BDNF) appeared to be the most critical component involved in the differentiating process. Thus, similar to the recent findings with the sympathoadrenal progenitor (MAH) cells, collaboration of neurotrophic factors plays an important role in the process of neuronal differentiation.

## 419.3

**REGULATION OF EARLY PHOTORECEPTOR DEVELOPMENT BY CNTF.** S. Fuhrmann, M. Kirsch and H.-D. Hofmann\*. Institute of Anatomy, University of Freiburg, P.O.B. 111, D-79001 Freiburg, Germany.

Ciliary neurotrophic factor (CNTF) originally purified as a survival factor for ciliary ganglion neurons has been shown to have multiple effects on central and peripheral neurons. We are interested in a possible function of CNTF in the regulation of retinal development. In the present study we have investigated the influence of CNTF on photoreceptor development in dissociated retinal cultures from embryonic chick. Using opsin-immunoreactivity as a differentiation marker for photoreceptor cells we found a 2.3-4fold increase of the number of opsin-positive cells (rods) in the presence of CNTF. Other neurotrophic factors expressed in the retina had no effect (NGF, BDNF, and bFGF). Stimulation by CNTF was dose dependent ( $\text{EC}_{50}$  2.6 pM). Conditioned medium of glia-enriched cultures had identical effects indicating the production of a CNTF-like molecule by cultured retinal cells. CNTF exerted no effect on proliferation but acted during early stages of photoreceptor development. However, it was not capable of preventing a decrease of opsin expression during prolonged culture periods suggesting the involvement of additional factors in photoreceptor maturation. Among the agents tested only retinol prevented the disappearance of CNTF-stimulated photoreceptor cells.

We conclude that CNTF plays an important role in the determination of the rod phenotype or during its early differentiation. Retinol may be one of the factors required for further maturation and/or survival. Our results suggest a sequential action of different diffusible factors regulating photoreceptor development.

## 419.2

**DIFFERENTIATION OF THE DRG: EFFECTS OF NEUROTROPHIN-3 AND LIMB BUD ABLATION PRIOR TO POST-MITOTIC NEURONAL CELL DEATH.** N.E. Fox\*, A.C. Rusoff\*, S. Hapner\*, D. Edmo\*, D.O. Clary\*, L.F. Reichardt\*, and E. Lefcort\*. Dept. of Biology and WAMI, Montana State Univ., Bozeman, MT. Sugen, Inc., Redwood City, CA\* and HHMI, UCSF, San Francisco, CA\*\*.

We are studying the cellular and molecular mechanisms involved in the differentiation of the avian Dorsal Root Ganglia, prior to the period of post-mitotic neuronal cell death. Our previous work has pointed to a role for TrkC in DRG differentiation (Lefcort et al., Soc. NS 20: 238). TrkC is expressed throughout the formation of the DRG, with its onset in migrating neural crest cells and by E4-5 is expressed by ca 70% of the DRG cells (Lefcort et al., manuscript in preparation). In the chick, NT-3 has been shown to be expressed in the developing limb bud during the period of DRG differentiation. In that brachial DRG are larger than more rostral DRG from the onset of their formation, we are testing the effects of limb bud ablation and of exogenously supplied NT-3 on the brachial DRG prior to the period of neuronal programmed cell death. Following unilateral wing bud ablation at St. 18 (E 2.5-3), embryos are fixed at St.25 (E 4.5). We have found that even at this early stage, brachial DRG on the transected side have 22% ( $n=4$ ) fewer cells than their contralateral control-side DRG. Brachial DRG in embryos treated with NT-3 from St.17 and fixed at St.25, undergo an increase of 33% in cell number ( $n=4$ ) relative to controls. Since the time course for these treatments is occurring well before post-mitotic neuronal cell death is underway, our data point to a role for NT-3 and/or other factor(s) associated with the developing limb bud in the early formation of the DRG. We are now in the process of determining whether NT-3 can rescue DRG cells from limb-bud ablation. Further, we are determining what the effects of NT-3 are on DRG development: proliferation or prevention of cell death of neuroblasts, and/or promotion of their differentiation or maturation. We thank Genentech, South San Francisco, CA for NT-3. Supported by MONTS, ACS, NIH and HHMI.

## 419.4

**EFFECT OF NGF ON THERMAL NOCICEPTIVE THRESHOLD AND NEUROPEPTIDE SYNTHESIS IN PRIMARY AFFERENT NEURONS OF THE ADULT RAT.** R. Amann\*, R. Schulzgen, G. Herzog and J. Donnerer. Dept. Exp. & Clin. Pharmacology, Graz Univ., A-8010 Graz

The aim of this study was to investigate the functional and biochemical effects of unilateral intraplantar injections (1/d on 3 consecutive days) of NGF into the rat hind paw. On each day of treatment, NGF (4  $\mu\text{g}$ ) caused a unilateral decrease in thermal nociceptive threshold which was apparent 10 min after injection and lasted for less than 3 h. Capsaicin desensitization, but not treatment with compound 48/80 (which reduced skin histamine by > 90%) or with indomethacin (which blocked bradykinin-induced thermal hyperalgesia) abolished NGF-induced hyperalgesia. 24 h after the 3rd NGF injection, thermal nociceptive threshold was not different from control values. However, 24 h after the 3rd NGF injection neuropeptide content of the sciatic nerve was elevated: 0.5  $\mu\text{g}$  NGF (but not 0.1  $\mu\text{g}$ ) caused an increase of CGRP in the ipsilateral sciatic nerve. 4  $\mu\text{g}$  NGF produced a bilateral increase of CGRP and SP, while the CGRP and SP content of the trigeminal ganglion and several viscera was not significantly affected. Intraplantar NGF (4  $\mu\text{g}$ ) caused a bilateral increase of number of L-5 DRG neurons expressing CGRP- or pre-protachykinin (PPT)-mRNA. In rats which were treated with capsaicin as neonates, the number of CGRP-mRNA expressing neurons was reduced. In these rats, NGF had no detectable effect of the number of expressing cells nor on expression density per cell.

This indicates that unilateral intraplantar NGF stimulated CGRP and tachykinin synthesis exclusively in capsaicin-sensitive neurons of ipsi- and contralateral DRGs. This effect of NGF was not related to the observed immediate hyperalgesia following intraplantar injections. We assume that NGF caused sensitization of peripheral afferent nerve endings by a mechanism which was independent from mast cells degranulation or cyclooxygenase stimulation.

## 419.5

NEUROTROPHINS INDUCE THE NADPH DIAPHORASE PHENOTYPE IN CULTURED SPINAL CORD NEURONS. K. Huber, K. Kriegstein, and K. Unsicker\*, Dept. of Anatomy & Cell Biology; Univ. Heidelberg, INF 307, D-69120 Heidelberg, Germany

Neurotrophins are essential in the regulation of neuron survival and differentiation. One important aspect of neuron development is the acquisition of a transmitter phenotype. We have studied the influence of neurotrophins on the expression of NADPH diaphorase (NADPHd), an enzyme of the nitric oxide synthase pathway, in spinal cord cultures of 16 day old rat embryos. At this age we found NADPHd-reactivity becoming apparent in the spinal cord and predominantly expressed in preganglionic sympathetic nuclei. Spinal cords were dissociated, plated at a density of 260,000 cells/cm<sup>2</sup> and cultured under serum free conditions. NGF, BDNF, NT-3, or NT-4, (10 ng/ml each) were applied 24 h, 3 days or 5 days after plating. Counts of NADPHd+ neurons were obtained at various time points. Numbers of NADPHd+ neurons were very low 24 h after plating and did not change significantly until day 4 *in vitro*. Application of BDNF, NT-3, and NT-4 significantly increased their numbers within 24 h. BDNF, NT-3, and NT-4 were also effective when first applied after 3 or 5 days in culture. Cotreatment with NT-4 and NT-3 had no additive effect. NGF was not effective. Our findings suggest that neurotrophins are involved in the developmental regulation of NADPHd-activity in neuron populations of the spinal cord, which may include motor and preganglionic autonomic neurons. NADPHd-activity may be induced in neurons expressing the enzyme constitutively, yet at undetectable levels, or may be induced *de novo*. Supported by DFG, SFB 317/C8

## 419.7

CYTOKINES SUCH AS INTERLEUKIN(IL)-2, IL-4, IL-7, IL-15 AND LIF ON THE EXPRESSION OF THE CHOLINERGIC PHENOTYPE IN RAT SEPTAL NEURONAL CULTURES: A SPECIFIC EFFECT OF IL-2. E. Mennicken\* and R. Quirion, Douglas Hospital Research Center, Dept Psychiatry, McGill University, Montréal, Québec, Canada, H4H 1R3.

We have recently shown that IL-2 increases choline acetyltransferase (ChAT) activity in embryonic septal rat neuronal cell cultures (Soc. Neurosci. Abst., 20, 667, 1994). The aim of the present study was to determine a) the specificity of the effect of IL-2 by evaluating other cytokines and b) if the effect of IL-2 on ChAT activity was due to an increase in the growth of cholinergic cells or to a direct modulation of ChAT activity per cholinergic neuron. Cultures were obtained by dissecting septa of 17-day old rat embryos. Following dissociation, cells were grown in a chemically defined serum-free medium for 5 days with IL-2 (10<sup>-14</sup> to 10<sup>-8</sup>M, Sigma) or other cytokines such as IL-4, IL-7, IL-15 and LIF (0.01 to 40 ng/ml, PeproTech) added after plating. Acetylcholinesterase (AChE) staining was used to visualize cholinergic cells which represented less than 2% of all neurons in culture. Length of the neurites of AChE-positive neurons, number of primary neurites by cell and size of perikaryon were measured using computerized image analysis. No significant changes in the morphological features and the number of AChE-positive cells were observed using various concentrations of the cytokines tested, except for ChAT activity which was significantly increased only by IL-2 (10<sup>-13</sup> to 10<sup>-10</sup>M). Thus, IL-2 apparently acts by directly increasing the synthetic capacity of cholinergic neurons, not their survival or growth. Moreover, the effect of IL-2 is not shared by other cytokines also expressed in the CNS such as IL-4, IL-15 and LIF. Finally, in order to increase basal ChAT activity, NGF (10 and 100 ng/ml) was added to the culture medium (Harikaka and Hefti, J. Neurosci., 8, 2967, 1988). Under such conditions of highly increased (100%) ChAT activity, IL-2 failed to stimulate further the enzymatic activity. Taken together, these results suggest that IL-2 can directly modulate cholinergic neurons in the rat brain and likely sharesP metabolic pathways with NGF to induced ChAT activity. (Supported by FRSQ and MRCC).

## 419.9

DOES BDNF REGULATE THE FUNCTIONAL EXPRESSION OF NEUROPEPTIDE Y (NPY) NEURONS IN HUMAN FETAL BRAIN CULTURES? A. Barnea\* and H.N. Aguila-Mansilla, Dept. OB/GYN, UT Southwestern, Dallas, TX 75235-9032.

BDNF can regulate the human fetal NPY neuron in two possible ways: promote neuronal survival and induce functional expression. To address the latter possibility, we have used a culture model system of aggregates, formed from dissociated human fetal (12.5-18 wks old) cortical hemispheres, maintained in serum-free medium. We varied the dose of BDNF (10-50 ng/ml), the culture age (1-3 wks) and duration of BDNF exposure (2-11 days) and assayed NPY production. Under none of these conditions did we observe an increase in NPY production. These protocols were repeated in media containing 10% FCS or conditioned media derived from glia-enriched cultures and again there was no effect of BDNF. Furthermore, neither NT-3, NT-4/5, nor NGF induced NPY production. The lack of effect of BDNF is not due to poor viability/functional state of the NPY neurons, since forskolin+phorbol ester induced a dramatic 3-5-fold increase in NPY production under each of these culture conditions. Moreover, this lack of response is not due to aberrant behavior of NPY neurons in aggregate cultures, since BDNF induced a 2-3-fold increase in NPY production by aggregate cultures derived from the rat fetal cortex. Moreover, the latter positive response was observed under each of the conditions tested for the human cultures. In addition, BDNF was much more effective than NT-3 and NGF was ineffective in inducing NPY production; consistent with TrkB mediating BDNF action in the rat aggregate cultures. In summary, neither of the neurotrophins (BDNF, NT-3, NT-4/5, NGF) induced NPY production in human fetal cortical neurons in culture. If TrkB is expressed in these human

## 419.6

MULTIPLE NEUROTROPHIC FACTORS CONTROL THE MATURATION OF SEROTONERGIC NEURONS.

M.J. Eaton<sup>1,2</sup> and S.R. Whitemore<sup>1,3</sup>

The Miami Project<sup>1</sup>, Departments of Neurological Surgery<sup>2</sup> and Physiology & Biophysics<sup>3</sup>, University of Miami School of Medicine, Miami, FL 33136.

We utilized RN46A cells, an immortalized serotonergic neuronal cell line derived from the E13 raphe (White *et al.*, J. Neurosci. 14:6744-53, 1994), as a model for the maturation of embryonic raphe neurons. Differentiated RN46A cells express the low affinity neurotrophin receptor (p75<sup>NTR</sup>), the BDNF receptor (trkB), the ACTH receptor, and tryptophan hydroxylase (TPH), but little 5HT synthesis was detectable. BDNF, ACTH<sub>4-10</sub>, and adenylyl cyclase activation increase the expression of TPH but the initiation of 5HT synthesis requires initial treatment with BDNF, ACTH<sub>4-10</sub>, or adenylyl cyclase activation followed by partial membrane depolarization. The L- and N-type Ca<sup>2+</sup>-channel blockers reduce depolarization-dependent RN46A cell survival and eliminate the initiation of 5HT synthesis. BDNF and ACTH<sub>4-10</sub> increase cell survival independently of depolarization. The vesicular monoamine transporter (VMAT) and the 5HT<sub>1A</sub> receptor increase with differentiation, but high-affinity 5HT re-uptake remains unchanged unless RN46A cells are treated with ACTH<sub>4-10</sub>, forskolin, or S100 $\beta$ . 5HT release in differentiated RN46A cells is constitutive and is not potentiated by depolarization. Collectively, these data suggest a temporal regulation of serotonergic maturation by distinct yet partially overlapping biochemical pathways: BDNF induction of trkB autophosphorylation, adenylyl cyclase activation by ACTH<sub>4-10</sub>, and voltage-gated Ca<sup>2+</sup>-channel opening by partial membrane depolarization. This work was supported by The Miami Project to Cure Paralysis, General Reinsurance, and NS26887.

## 419.8

SELECTIVE INDUCTION OF NA CHANNEL GENE EXPRESSION IN EMBRYONIC STRIATAL NEURONS *IN VITRO* IN RESPONSE TO BDNF, NT-3, AND NT-4/5. R. A. Mauge<sup>1,2\*</sup>, R. Ventimiglia<sup>3</sup>, P. E. Mather<sup>3</sup>, R. M. Lindsay<sup>3</sup>, and G.R. Fanger<sup>1</sup>, Departments of <sup>1</sup>Biochemistry and <sup>2</sup>Physiology, Dartmouth Medical School, Hanover, NH 03755, and <sup>3</sup>Regeneron, Inc., Tarrytown, NY 10591.

There is considerable interest in understanding the mechanisms by which neurotrophins affect neuronal differentiation, including electrical excitability. As part of this, we have begun to assess the actions of neurotrophins on ion channel expression in striatal neurons, a neuronal population that undergoes degeneration during Huntington's disease. Neurons isolated from the striatum of E17 rats were maintained *in vitro* in the absence or presence of neurotrophins (50 ng/ml) before probes specific for type I, II, and III Na channel  $\alpha$  subunit mRNA were used in RNase protection assays to analyze expression of these transcripts, and whole-cell patch clamp recording used to measure Na current density. In untreated cells, both type I and type II  $\alpha$  subunit mRNA were clearly expressed, while type III  $\alpha$  subunit mRNA was only barely detectable. In response to BDNF, NT-3, or NT-4/5, but not NGF, there was a significant increase in the level of both type I and type II  $\alpha$  subunit mRNA, while expression of type III  $\alpha$  subunit mRNA did not change. Furthermore, there was a significant difference in the time course of the BDNF-mediated inductions of type I and type II  $\alpha$  subunit mRNA. The changes in  $\alpha$  subunit gene expression were accompanied by increased expression of functional Na channels, as there was a significant increase in Na current density in the striatal neurons in response to BDNF. The results extend previous evidence from cultured cell lines that neurotrophins can regulate Na channel expression by providing the first demonstration that this can occur in primary neurons of the central nervous system as well. In addition, we provide the first indication that neurotrophins can induce type I  $\alpha$  subunit mRNA as well as type II, and from the difference in kinetics suggest these inductions occur by distinct mechanisms. The results provide a basis for investigating the biochemical mechanisms underlying the induction of Na channel expression in striatal neurons, as well as for analysis of the functional consequences of these changes on their electrical properties. Supported by the Hitchcock Foundation and NS28767 to RAM.

## 419.10

ELEVATED GLUCOSE OXIDATION AND mRNA EXPRESSION OF GLYCOLYTIC ENZYMES BY NEUROTROPHINS IN RAT CEREBRAL CORTICAL NEURONS. H. Gao\*, K. Pong, C. Peterson, T. Yoshida, F. Hefti and B. Knusel, Andrus Gerontology Center, University of Southern California, Los Angeles, CA 90089.

The mechanisms of neuroprotection by trophic factors are not known. Aim of the current study was to investigate whether neurotrophins might regulate energy metabolism and free radical detoxification in brain cells. Primary cultures of embryonic rat cortex were treated with neurotrophins and mRNA was measured for phosphoglycerate kinase (PGK), phosphofructokinase (PFK) and superoxide dismutase (SOD). Cellular metabolic activity was determined by measuring production of CO<sub>2</sub> from cultured neurons incubated with <sup>14</sup>C-glucose. In cultures treated with BDNF or NT-4/5, mRNA levels for PGK and PFK were increased approximately twofold compared to untreated controls. NT-3 treatment resulted in a smaller increase, NGF treatment in no change. For maximal effect, the factors had to be present for at least 1 day. Very little increase was observed after 5hr treatment. However, presence of BDNF for only 4hr during <sup>14</sup>C-glucose incubation resulted in significant stimulation of CO<sub>2</sub> production. Further increase was observed when cultures were pretreated with BDNF for 1 to 3 days before the assay. In contrast to the stimulation of PGK and PFK expression and of cellular metabolic activity, neurotrophin treatment did not result in changes of mRNA for SOD. Our results suggest that neurotrophins might become useful in treating brain metabolic hypofunction which is observed in some neurodegenerative diseases, e.g. Alzheimer's disease.

## 419.11

**DIFFERENTIAL EFFECTS OF LONG-TERM AND SHORT-TERM NGF TREATMENT ON NEUROPEPTIDE EXPRESSION IN AXOTOMIZED SUPERIOR CERVICAL GANGLIA (SCG) *IN VIVO*.** Y. Sun\* and R. E. Zigmond. Dept. of Neurosci., Case Western Reserve Univ., Cleveland, OH 44106.

Transection of postganglionic nerve trunks deprives sympathetic neurons of target-derived NGF and causes changes in their neuropeptide (NP) expression. NGF deprivation could contribute to triggering the changes in NP expression. As one test of this hypothesis, we examined whether local application of NGF to the axotomized SCG would prevent, at least partially, the changes in NP expression. At the time of axotomy, slow release pellets containing NGF or control pellets were placed in contact with the SCG. Two days after the lesion, the substance P (SP), galanin (Gal) and vasoactive intestinal peptide (VIP) immunoreactivities increased in the placebo group. NGF treatment further increased SP and VIP, but had no effect on Gal. At 7 d, however, NGF decreased Gal, increased SP, but had no effect on VIP, and by 14 d NGF decreased both Gal and VIP by more than 50%, while still increasing SP. Corresponding effects of NGF treatment on peptide mRNA levels were also observed. The longer term effect of NGF, that is, inhibition of the axotomy-induced increases in VIP and Gal, raises the possibility that in uninjured SCG, the constant retrograde transport of NGF is involved in the suppression of VIP and Gal expression, but not SP. Since the initial effects of NGF, the increase in VIP and no effect on Gal at day 2, could be due to the interactions with acute injury responses, we examined the effect of 2 d NGF treatment on ganglia that had been axotomized for 12 d, and found NGF increased VIP but did not affect Gal. These data suggest that the duration of NGF treatment, but not when it is applied, determines the nature of its effects on NP. NGF treatment (for 10 d but not 2 d) also inhibited the small increases in VIP and Gal induced by sialectomy (which causes axotomy near the nerve endings). In summary, we found NGF had different effects on NP expression depending on the duration of treatment. Whether different signal transducing pathways of NGF or different sites of NGF action generate the differences in long- and short-term NGF effects remains to be determined.

## 419.13

**THE ROLE OF AFFERENT INPUT TO THE SUPERIOR CERVICAL GANGLION IN NGF-INDUCED PLASTICITY OF CEREBROVASCULAR INNERVATION.** S.C. Billieu<sup>1</sup>, K.L. Schwenk<sup>1</sup>, K.A. Crutcher<sup>2</sup>, and L.G. Isaacson<sup>1\*</sup> <sup>1</sup>Center for Neurosci Res, Dept Zoology, Miami Univ, Oxford, OH 45056; <sup>2</sup>Dept Neurosurg, Univ of Cincinnati College of Med, Cincinnati, OH 45267.

Following a 2 week intracranial infusion of nerve growth factor (NGF; 15 µg) into the adult rat, we observe a sprouting response by sympathetic perivascular axons associated with intradural internal carotid artery (ICA), most of which originate in the superior cervical ganglion (SCG). An increase (33% and 31% respectively) in total catecholamines (µg/g protein) and the amount of norepinephrine (NE)/total catecholamines accompanies the response. Our goal was to use EM and HPLC-ECD to determine whether removal of afferent input affects the NGF-induced sympathetic response. Compared with controls, deafferentation of the SCG (dVEH) did not affect mean number of axons/µm vascular wall or total catecholamine content of the ICA, but resulted in an increase (400%) in DOPAC, a dopamine metabolite. The number of axons/µm wall following deafferentation and subsequent NGF infusion (dNGF; 15 µg) was similar to NGF cases, indicating a sprouting response in the dNGF treatment. In contrast, dNGF rats showed no corresponding increase in total catecholamines or in the proportion of NE/total but remained similar to dVEH cases. Thus, deafferentation of the SCG does not affect the morphological response elicited by exogenous NGF but apparently blocks the increase in catecholamines observed following NGF infusion. (Supported by NS17131 and NS32876)

## 419.15

**EFFECT OF NERVE GROWTH FACTOR ON THE EXPRESSION OF CHOLINE ACETYLTRANSFERASE-mRNA IN PC12 CELLS.** J.L. Pongrac<sup>1</sup> and R.J. Rylett. Departments of Pharmacology and Physiology, University of Western Ontario, London, ON, CANADA, N6A 5C1.

Nerve growth factor (NGF), a neurotrophic agent, enhances cholinergic phenotypic expression. NGF increases choline acetyltransferase (ChAT) activity following *in vivo* administration, and *in vitro* in pheochromocytoma (PC12) cells and primary cultures of basal forebrain; these increases in ChAT activity are accompanied by apparent increases in steady-state levels of ChAT-mRNA. As there are multiple mRNA transcripts of the ChAT gene produced by alternative splicing, the purpose of the present study was to investigate whether NGF alters expression of all splice variants. These transcripts are variable in the promoter region as opposed to the coding region, thus translation produces a single protein product. The expression of various transcripts with different promoter regions may impact on the ability of different growth factors to elicit responses through specific transcription factors. Selective reverse transcription with polymerase chain reaction (RT-PCR) was used to amplify different upstream regions of ChAT-mRNA followed by Southern blot analysis and hybridization with a <sup>32</sup>P-labelled oligomer specific to the coding region of ChAT transcripts. We show that ChAT-mRNA transcripts associated with the M- and N-exons are expressed in PC12 cells. We also show that there is an increase in the expression of the ChAT transcript associated with the M-exon following NGF treatment. This suggests that NGF promotes the transcription of the ChAT gene in part through this variant. (Supported by MRC Canada and Ontario Mental Health Foundation)

## 419.12

**ANTISERUM TO NERVE GROWTH FACTOR (NGF) ALTERS NEUROPEPTIDE EXPRESSION IN THE SUPERIOR CERVICAL GANGLION (SCG) AND DORSAL ROOT GANGLION (DRG) *IN VIVO*.** R. E. Zigmond\*, A. M. Shadiack, and Y. Sun. Dept of Neurosciences, Sch of Med, Case Western Reserve University, Cleveland, OH 44106-4975.

Axotomy of sympathetic and sensory neurons leads to a decrease in their content of the target-derived factor NGF, an increase in immunoreactivity (IR) and mRNA of certain neuropeptides including galanin (GAL), vasoactive intestinal peptide (VIP), and substance P (SP), and a decrease in mRNA for neuropeptide Y (NPY) and tyrosine hydroxylase (TH). Axotomy of the DRG leads to an increase in GAL and a decrease in SP. Administration of exogenous NGF has been shown to reverse some of the effects of axotomy for example it decreases chromatolysis (West & Bunge, 1976) and synaptic stripping (Purves & Nja, 1976) in the SCG. Also, NGF partially inhibits the increase in GAL in the SCG in culture (Sun et al., 1993) and in the SCG (Sun et al., this volume) and DRG (Verge et al., 1995) *in vivo* after axotomy. We tested whether the effects of axotomy, in adult rats, could be mimicked by decreasing endogenous NGF by daily systemic treatment with an antiserum against NGF (a gift from Dr. J. Diamond). These animals show an increase in GAL and VIP mRNA in the SCG as compared to the normal serum-treated controls at 3 d after treatment. Although, TH and NPY mRNA is unchanged at 3 d, both mRNAs show a decrease at 14 d after treatment. In the DRG, there is a doubling in GAL, VIP, and a small increase in SP mRNA by 14 d. At 14 d by immunohistochemical analysis, GAL-IR is detected in some principal neurons in the SCG and some small neurons of the DRG. No apparent change in VIP- and SP-IR was observed in the SCG or DRG at this time. A decrease in NPY-IR was observed in the SCG. The apparent lack of a decrease in TH-IR in the SCG may reflect the non-linearity of the histochemical method. These data suggest that the loss of endogenous NGF is partly, but not wholly, responsible for some of the axotomy-induced neurotransmitter changes in the SCG and DRG.

## 419.14

**DIFFERENTIAL REGULATION OF SUBSTANCE P BY NEUROTROPHINS IN AVIAN DORSAL ROOT GANGLIA THROUGHOUT DEVELOPMENT.** P. Berndt<sup>1\*</sup>, S.C. Apfel<sup>2</sup>, J.A. Kessler<sup>2</sup>, and L. Yao<sup>3</sup>. Departments of Anatomy and Cell Biology<sup>1,3</sup> and Otolaryngology<sup>1</sup>, State University of New York, Health Science Center, Brooklyn, NY 11203, and Departments of Neurology and Neuroscience<sup>2</sup>, Albert Einstein College of Medicine, Bronx, NY 10461.

This study examined the effects of nerve growth factor (NGF), brain-derived neurotrophic factor (BDNF), neurotrophin-3 (NT-3) and neurotrophin-4/5 (NT-4/5) on substance P (SP) levels in dorsal root ganglia (DRG) shortly after their formation (stage 26, E4.5), during mid development (stage 33, E7.5) and during late development (stage 44, E14). The neurotrophin receptors, *trkA*, *trkB* and *trkC*, have been shown to be present at all these stages. NGF has already been shown to increase levels of SP during mid and late development. DRG were isolated, rinsed with defined medium in order to dilute endogenous neurotrophins, exposed to neurotrophins for 4 hrs (100 ng/ml; 37°C), and subjected to either RIA or EIA for measurement of SP. The results showed that the levels of SP increased throughout development (2 ng/mg protein at E4.5, 3 ng/mg protein at E7.5 and 11 ng/mg protein at E14). At E4.5, none of the neurotrophins had a significant effect on levels of SP. The same was true even if DRG were incubated for 20 hrs with neurotrophins. At E7.5, both NGF and NT-3 increased SP levels by nearly 50%, while NT-4/5 did not appear to have an effect (no results were obtained for BDNF). The effects of NGF and NT-3 were blocked by their respective antibodies. At E14, all neurotrophins had significant effects on SP levels, with NT-3's effect being more pronounced (140% above control) than that of NGF (48% above control), NT-4/5 (30% above control) and BDNF (15% above control). The increases in SP following neurotrophin treatment probably reflect increases on a per cell basis, since total cell number should not be altered after a 4 hr incubation. Supported by grants from the Dysautonomia Foundation and the National Science Foundation (IBN 92-22027).

**PERIOSTEAL CELLS INDUCE CHOLINE ACETYLTRANSFERASE IN CULTURED SYMPATHETIC NEURONS.** S.E. Asmus\* and S.C. Landis. Dept. of Neuroscience, Case Western Reserve Univ., Cleveland, OH 44106.

Periosteum, the connective tissue covering of bone, contains osteoblasts and their progenitor cells. The transmitter phenotype of its sympathetic innervation is altered developmentally. Although initially noradrenergic, sympathetic fibers in adult rat periosteum contain vasoactive intestinal peptide (VIP) immunoreactivity and acetylcholinesterase (AChE) activity. Heterotopically-transplanted periosteum suppresses catecholamines and induces VIP immunoreactivity in fibers that would otherwise express noradrenergic traits. Assays of choline acetyltransferase (ChAT) activity have been confounded in this tissue by attached skeletal muscle. Therefore, to test whether periosteum induces cholinergic function, we cocultured rat periosteal cells and sympathetic neurons. Periosteal cells dissected from postnatal day (P) 3 rats were either grown alone or added to sympathetic neurons. Periosteal cells attained a fibroblast-like morphology and reached confluence approximately 1 week after plating. After several weeks, alkaline phosphatase, an enzyme expressed in osteoblasts, was histochemically detected in some cells. Neurons cocultured for 1 week with periosteal cells or with explants of periosteum displayed a 5-6-fold induction in ChAT activity over neurons cultured alone. Because transgenic mice with a disruption in the gene for leukemia inhibitory factor (LIF), a cholinergic differentiation factor, contained identical distributions of VIP and AChE periosteal fibers, LIF is not responsible for the switch *in vivo*. Whether LIF expression by periosteal fibroblasts *in vitro* accounts for some of the ChAT induction seen here will be addressed by coculturing neurons and periosteal cells from LIF deficient mice. Taken together with previous findings, these results suggest that periosteum, in addition to sweat glands, can regulate the neurochemical phenotype of sympathetic neurons. Supported by NS0970901 (SEA) and NS2367811 (SCL).

INDUCTIVE INFLUENCES OF CNTF ON NEURONAL GENE AND PHENOTYPE EXPRESSION: BIOCHEMICAL AND FUNCTIONAL CORRELATES. L.H. Zimman<sup>1</sup>, G. Lawrance<sup>2</sup>, V.M.K. Verge<sup>3</sup>, K.E. Dow<sup>2</sup>, P.M. Richardson<sup>4</sup>, D.H. Maurice<sup>1</sup>, R.J. Riopelle<sup>1</sup>. <sup>1</sup>Dept. of Pharm. and <sup>2</sup>Med., Queen's Univ., Kingston, Ontario; <sup>3</sup>Dept. of Anat., Univ. of Saskatchewan, Saskatoon; <sup>4</sup>Dept. of Neurology, McGill Univ., Montreal, Que.

CNTF induces neuronal differentiation in the human LA-N-2 neuroblastoma cell line by activating its tripartite receptor complex (Lawrance et al., 1995, J. Neurochem. 64, 1483). We have also observed that CNTF-induced increases in ChAT specific activity were time-dependent, and that changes in ChAT activity correlate with changes in ChAT protein levels. Characterization of CNTF effects on ChAT mRNA were examined by *in situ* hybridization (ISH) using a 48 bp cDNA probe for rat ChAT and Northern analysis using a 340 bp human cDNA fragment generated by RT-PCR amplification techniques. CNTF-induced increases in ChAT specific activity and protein also correlate with changes in ChAT gene expression.

In naive LA-N-2 cells, low levels of trkA and p75 mRNA are detectable, p75 protein can be chemically cross-linked to <sup>125</sup>I-NGF, and NGF-mediated trkA phosphorylation can be detected. NGF-mediated neurite growth is observed only following priming of the LA-N-2 cells by CNTF. In this setting, trkA mRNA levels and NGF-mediated trkA phosphorylation are increased, while chemical cross-linking of the trkA receptor to <sup>125</sup>I-NGF is now detectable. The observation that CNTF and NGF have additive effects on neurite growth by CNTF-primed LA-N-2 cells suggests activation of non-convergent signalling pathways subserving neurite growth. Such additive effects are not observed for ChAT induction, and NGF does not induce an adrenergic phenotype in CNTF-primed LA-N-2 cells.

SYNERGY BETWEEN GROWTH FACTORS AND CATECHOLAMINES (CA) REQUIRED FOR NOVEL EXPRESSION OF TYROSINE HYDROXYLASE IN NON-CA BRAIN NEURONS. X. Du<sup>\*</sup> and L. Jaccovitti Dept. of Anatomy and Neurobiology, Medical College of Pennsylvania and Hahnemann University, Philadelphia, PA. 19102

We have previously demonstrated that induction of the catecholamine (CA) biosynthetic enzyme tyrosine hydroxylase (TH) in cultured non-CA neurons from the mouse striatum requires the cooperative interaction of two partner substances; neither of which is active alone. One agent is the growth factor, acidic fibroblast growth factor (aFGF), the other an unknown substance(s) present in several tissue extracts, including that of adult mouse midbrain. In this study, we examined 1) whether CA neurotransmitters present in the midbrain fraction were serving as aFGF partners; and 2) if so, whether other growth factors could be similarly activated by CAs to induce TH. The phenotypically plastic neurons of the embryonic mouse striatum (E13) were treated in culture with aFGF, bFGF, BDNF, CNTF, GDNF, TGF $\beta$ , IGF, NGF, PDGF or IL1 in the presence or absence of potential partners. Growth factors alone were powerless to induce TH. However, in the presence of an appropriate partner, aFGF, and to a lesser extent bFGF and BDNF, induced the novel expression of TH. Of the many potential activating substances tested, only those which contained an amine group separated from a catechol nucleus by two carbons, such as dopa, dopamine, the D1 receptor agonist SKF38393, norepinephrine and the beta adrenoceptor agonist isoproterenol were effective partners to the growth factors. However, since no receptor antagonists (SCH-23390; spiperone; haloperidol; yohimbine; prazosin; propranolol) or transport blockers (mazindol; nomifensine; indatraline; nipecotic acid) could inhibit the CA effect, the mechanism of action remains obscure. We conclude that TH expression can be novelly induced by the synergistic interaction of aFGF, and to a lesser extent bFGF and BDNF, and a variety of CA-containing partner molecules. We speculate that a similar association between growth factor and transmitter may be required during development for the differentiation of a CA phenotype in brain neurons. (Supported by NIH NS 24204).

## 419.21

CO-EXPRESSION OF TYROSINE HYDROXYLASE (TH) AND GLUTAMIC ACID DECARBOXYLASE (GAD) IN DOPAMINE DIFFERENTIATION FACTOR (DDF)-TREATED STRIATAL NEURONS IN CULTURE. S.R. Max<sup>\*</sup>, A. Bossio, and L. Jaccovitti, Depts., of Neurology and Biochemistry, Medical College of PA and Hahnemann Univ., Philadelphia, PA 19102

During differentiation, neurons acquire cell-specific traits that constitute their phenotype. One critical "decision" developing neurons must make is the neurotransmitter(s) they will produce. We have shown that DDF (i.e., aFGF + Dopamine; aFGF + mazindol; aFGF + Dopamine + mazindol) can stimulate expression of TH in striatal neurons, which normally do not express TH, since they are thought to be GABAergic neurons. In the present study, immunocytochemistry showed GAD and TH to be co-expressed in striatal neurons; this result was confirmed by assay of TH and GAD activities in extracts of DDF-treated neurons. Treatment of striatal neurons with DDF resulted in a striking increase in TH expression, as revealed by immunocytochemistry and by direct enzyme assay. Assay of GAD in these neuronal extracts did not show a significant change in activity with any of the treatments. Our results indicate that those striatal neurons that can be induced by DDF to express TH are GAD-positive GABAergic neurons. The co-expression of TH and GAD in the same neurons further suggests that induction of a novel neurotransmitter phenotype does not occur at the expense of existing traits. (Supported by NIH-NS24204 awarded to LJ).

## 419.18

EFFECTS OF FK-506, RAPAMYCIN AND CYCLOSPORIN A ON THE IN VITRO DIFFERENTIATION OF DORSAL ROOT GANGLIA EXPLANTS AND SEPTAL CHOLINERGIC NEURONS. A. CARREAU, J. GUEUGNON, J. BENAVIDES AND X. VIGÉ. Synthelabo Recherche, CNS Research Department, BP 110, 92225 Bagneux Cedex, France.

There is increasing evidence that immunophilins (targets of some immunosuppressant drugs) play a role in neural development and differentiation. We have studied the effects of FK-506, rapamycin and cyclosporin A on dorsal root ganglia (DRG) from different segmental levels and on septal cholinergic neurons in culture from rat embryo. Low concentrations of FK-506 (1 nM) significantly increased (+83%) the number of neurites of thoracic DRG explants. Higher concentration (100 nM) also enhanced the neurogenesis of thoracic (+100%) and lumbar/sacral (+57%) DRG, but no significant effect was observed on cervical explants. Rapamycin displayed an opposite effect, reducing the development of DRG explants from cervical and thoracic segments (-78% at 1 nM in thoracic DRG). Cyclosporin A (from 1 to 100 nM) was without effect on DRG neurogenesis. Both, FK-506 and rapamycin failed to affect neurite length under our experimental conditions. In cultured septal cells, FK-506 enhanced the differentiation of cholinergic neurons, as assessed by the measurement of ChAT activity, with a bell-shaped concentration-effect relationship. The maximal increase in ChAT activity (+40%) was obtained with 10 nM and 100 nM. The effect of FK-506 was additive to that of NGF. Rapamycin had no effect *per se*, but prevented the NGF-induced increase in ChAT activity.

These results demonstrate that immunophilin ligands affect neuronal differentiation. The differential sensitivity of DRG taken at various segmental levels to FK-506 and rapamycin is in agreement with the view that these drugs activate distinct transduction mechanisms. The lack of effect of cyclosporin A suggests that its receptors (cyclophilins) are not expressed by DRG.

## 419.20

ACIDIC FIBROBLAST GROWTH FACTOR AND CATECHOLAMINES (CA) TOGETHER UP-REGULATE TYROSINE HYDROXYLASE ACTIVITY IN DEVELOPING AND/OR DAMAGED DOPAMINE NEURONS. N.D. Stull<sup>\*</sup> and L. Jaccovitti Dept. of Anatomy and Neurobiology, Medical College of Pennsylvania and Hahnemann University, Philadelphia, PA. 19102

Our previous studies indicate that, in certain non-CA neurons, expression of the gene for the CA biosynthetic enzyme tyrosine hydroxylase (TH) can be initiated by the obligatory interaction of acidic fibroblast growth factor (aFGF) and a CA activator (See adjacent abstract). In this study, we sought to determine whether these same differentiation factors also play a role in maintaining and regulating existing TH expression in CA neurons. To do so, we studied the effects of exogenous application of aFGF and CA on TH in developing or damaged (MPP<sup>+</sup>-treated) dopamine (DA) neurons where endogenous levels of these agents were likely to be at physiologically low levels. DA neurons from the E15 rat ventral midbrain were grown in culture on defined media  $\pm$  2.5  $\mu$ M MPP<sup>+</sup> (24hrs); rinsed; treated for 4hrs with aFGF (10ng/ml) and DA (10 $\mu$ M), harvested and TH activity measured. In developing DA neurons (- MPP<sup>+</sup>), treatment with aFGF + DA resulted in a 40-62% increase in TH activity over controls (media only). In damaged DA neurons (+MPP<sup>+</sup>), aFGF and DA reversed the 30% loss in TH activity caused by toxin, returning TH to control levels. Since these effects were observed within 4 hrs of treatment, they were most likely due to the biochemical rather than trophic properties of these reagents. Several other CAs, such as dopa and norepinephrine, when combined with aFGF, also up-regulated TH activity levels; while the non-CA transmitter GABA did not. We conclude that the DA differentiation factors (aFGF and CAs) which are capable of first initiating expression of a quiescent TH gene may also be involved in the regulation of the enzyme during development or after damage. Although CAs have long been considered feedback inhibitors of TH, our results suggest, that in combination with aFGF, they may also serve as feedback inducers of TH transcription and/or translation. ## 420.1

NEUROTROPHIN-4/5 PROMOTES SURVIVAL OF CULTURED PRIMARY AUDITORY AND VESTIBULAR NEURONS AND PROTECTS THEM FROM OTOTOXINS. J.L. Zheng<sup>1</sup>, R.R. Steward<sup>2</sup> and W.-Q. Gao<sup>1</sup>. <sup>1</sup>Dept. of Neurosci., Genentech, Inc., South San Francisco, CA 94080 and <sup>2</sup>Dept. of Anatomy, George Washington Univ. Med. Ctr., Washington, DC 20037.

Destruction of spiral and vestibular ganglion neurons (SGNs and VGNs) induced by injury and toxins is one of the major causes for hearing and balance impairments. Here we report that neurotrophin-4/5 (NT-4/5), a member of the nerve growth factor (NGF) family, promoted survival of postnatal rat SGNs and VGNs in dissociated cell cultures. The survival-promoting potency of NT-4/5 was equivalent to that of brain-derived neurotrophic factor (BDNF) and stronger than that of neurotrophin-3 (NT-3). In contrast, NGF showed no detectable effects. Immunohistochemistry with TrkB and TrkA antisera revealed that these neurons produced TrkB protein, the functional receptor for NT-4/5 and BDNF, but not TrkA protein, the high affinity receptor for NGF. The survival-promoting activity of NT-4/5 was completely inhibited by TrkB-IgG (a fusion protein of extracellular domain of TrkB and Fc fragment of immunoglobulin). In addition, NT-4/5 protected the two types of neurons from neurotoxicity of ototoxins including cisplatin, a widely used chemotherapeutic drug, and gentamicin, a commonly used aminoglycoside. Thus, NT-4/5 is a specific survival factor for SGNs and VGNs and has therapeutic value in preventing hearing and balance impairments caused by injury or ototoxins on primary auditory and vestibular afferent neurons.

## 420.3

OVEREXPRESSION OF BDNF IN EPIDERMIS OF TRANSGENIC MICE CAUSES CHANGES IN TRK RECEPTOR EXPRESSION IN SENSORY GANGLIA AND ALTERATIONS IN SKIN INNERVATION. A.M. LeMaster\*, B.M. Davis, and K.M. Albers. Depts of Anatomy and Neurobiology and Pathology, Univ. of Kentucky Sch. of Med., Lexington, KY 40536.

Brain-derived neurotrophic factor (BDNF) is expressed in mouse skin at approximately embryonic day 10 (E10), expression peaks at E12, and then falls to low levels which are maintained throughout adulthood. BDNF expression in skin may promote neuronal survival during a period of programmed apoptotic cell death. To examine the effect of BDNF on neuronal survival and development, two lines of transgenic mice that overexpress BDNF in the epidermis have been examined. Transgene expression is driven by the promoter and enhancer elements of the human keratin 14 (K14) gene. To characterize the K14-BDNF transgenic mice, *in situ* hybridization was used to examine trk receptor expression in trigeminal and dorsal root ganglia. Transgenic line 733 had an approximate 1.7-fold increase in trk B expressing neurons of the trigeminal ganglion. Line 632 exhibited an approximate 3-fold and 2-fold increase in trk B expressing neurons of the trigeminal and dorsal root ganglia, respectively. A 1.5-fold increase in trk A expressing neurons was also found in trigeminal ganglion of line 632. Changes in trk receptor expression correlate with changes found in whisker pad skin innervation. Immunocytochemical analysis using an antibody against PGP 9.5, a ubiquitin carboxyl terminal hydroxylase which detects both myelinated and unmyelinated nerve fibers, revealed a dense plexus of small nerve fibers in areas of dermis subjacent to the epidermis. The increased number of fibers may be derived from the superficial vibrissa nerve since it is primarily composed of small-caliber fibers. Immunolabeling of skin using an anti-neurofilament 150 antibody which detects primarily myelinated innervation, also showed an increase in fiber density. These results indicate that BDNF influences the density and character of neuronal innervation to the skin. Supported by AR40873 (KMA) and NS31826 (BMD).

COMPARISON OF BDNF-, NT4-, BDNF/NT4- AND TRKB-DEFICIENT MICE: GENE DOSING EFFECTS AND COMPENSATION. J.T. Erickson<sup>1</sup>, J.C. Conover<sup>2</sup>, R.J. Smevne<sup>3</sup>, T.M. DeChiara<sup>2</sup>, M. Barbacid<sup>1</sup>, G.D. Yancopoulos<sup>4</sup> and D.M. Katz<sup>1</sup>. <sup>1</sup>Department of Neurosciences, Case Western Reserve University School of Medicine, Cleveland, OH 44106, <sup>2</sup>Regeneron Pharmaceuticals, Inc., Tarrytown, NY, 10591 and <sup>3</sup>Department of Molecular Biology, Bristol-Myers Squibb, Princeton, NJ 08543.

We recently reported (Conover et al., *Nature*, In Press) that mice lacking the trkB ligands NT4 or BDNF exhibit distinct sensory neuron deficits. In particular, the nodose/petrolal ganglion complex (NPG), which relays sensory information critical for regulation of autonomic functions, requires both BDNF and NT4 for survival of the full complement of neurons, although total cell counts from P14 BDNF, NT4 and BDNF/NT4 knockout mice revealed no obvious compensation by either factor for loss of the other in supporting survival of NPG neurons overall. This is not the case, however, for specific subsets of neurons. Analysis of tyrosine hydroxylase-containing (TH<sup>+</sup>) dopaminergic neuronal profiles in the NPG of P1 wild type, BDNF-, NT4-, BDNF/NT4- and trkB-deficient mice revealed TH<sup>+</sup> cell losses that were dependent on the number of functional BDNF, but not NT4, alleles. Furthermore, the sum of the TH<sup>+</sup> profile losses observed following disruption of either BDNF or NT4 individually (64%) was substantially less than the loss observed following disruption of both neurotrophins simultaneously (83%). These results provide the first evidence for compensatory actions on neuron survival by trkB ligands *in vivo*. Moreover, these data indicate that different subsets of trkB-expressing neurons in the NPG may be supported by either BDNF, NT4, or both. Finally, the fact that TH<sup>+</sup> neuron survival was related to the number of BDNF alleles provides direct confirmation of a central tenet of the neurotrophic hypothesis, i.e., that growth factor concentration is limiting for neuronal survival *in vivo*. Supported by HL-42131 (DMK) and in part by HL-25830 (Proj. 4, DMK).

## 420.2

DIFFERENTIAL OTOTOXICITY OF SALICYLATE, GENTAMICIN AND CISPLATIN AND PROTECTIVE EFFECTS OF SPECIFIC NEUROTROPHINS IN COCHLEAR EXPLANT CULTURES. W.-Q. Gao<sup>1</sup> and J.L. Zheng, Dept. of Neuroscience, Genentech, Inc., South San Francisco, CA 94080.

In organotypic cultures of postnatal cochlear explants in which the afferent innervation of hair cells by primary auditory neurons are intact, we have examined ototoxicity of three different classes of clinical drugs. These include sodium salicylate, an analog of aspirin, gentamicin, a commonly used aminoglycoside, and cisplatin, a widely used chemotherapeutic agent. Differential damages on auditory neurons and hair cells by the three types of drugs were observed by double labeling with a monoclonal antibody against neurofilament protein (200 kd) and a phalloidin-FITC conjugate. Sodium salicylate (3-10 mM) induced specifically degeneration of auditory neurons, but not hair cell loss. Gentamicin (0.01-0.5 mM) preferentially caused hair cell death, though loss of auditory neurons was also seen at higher concentration (1-5 mM). In contrast, addition of cisplatin to the culture resulted in degeneration of both auditory neurons and hair cells at a wide range of doses tested (1-8 µg), with a more profound damage on auditory neurons than on hair cells. When neurotrophins, members of nerve growth factor (NGF) family, were added together with sodium salicylate, gentamicin or cisplatin to the culture, neuronal degeneration was protected by neurotrophin-4/5, brain-derived neurotrophic factor and neurotrophin-3, but not by NGF or other growth factors. On the other hand, hair cell loss caused by gentamicin and cisplatin was not prevented by the presence of neurotrophins. These results suggest that ototoxic mechanisms by salicylates, aminoglycosides and chemotherapeutic agents are different and specific neurotrophins may be useful for prevention of auditory neuronal loss induced by ototoxic therapeutic drugs.

## 420.4

TRANSGENIC MICE THAT OVEREXPRESS NT-3 EXHIBIT ENHANCED INNERVATION OF TOUCH DOMES AND INCREASED NUMBERS OF TRK C EXPRESSING NEURONS. K.M. Albers\*, T.N. Perrone and B.M. Davis. Depts. of Pathology and Anatomy and Neurobiology, Univ. of Kentucky Sch. of Med., Lexington, KY 40536.

The family of neurotrophins is comprised of NT-3, NGF, BDNF, and NT4/5. Each of these compounds is expressed in target tissues during the development of the mammalian nervous system and in the adult. To examine the influence of neurotrophic compounds on the development and differentiation of neurons in the peripheral nervous system, we isolated transgenic mice that overexpress these compounds in the skin target tissue. NT-3 overexpressing mice have a phenotype unique from NGF and BDNF overexpressing mice. Flank skin of NT-3 mice stained with hematoxylin and eosin exhibited larger touch dome units associated with hair follicles. Immunolabeling using an NF-150 antibody showed innervation to touch domes was substantially increased in the number of neuronal processes and complexity. NF-150 labeling also showed an increase in the density of fibers comprising the circular component of the piloneuronal innervation. Numerous lanceolate endings were also observed in the transgenic skin. Immunolabeling using an anti-PGP 9.5 antibody showed a similar pattern of innervation and also revealed an increase in the density of fine caliber processes in the NT-3 expressing skin. *In situ* hybridization analysis of high affinity neurotrophin receptor expression in sensory ganglia indicated an approximate doubling in the number of cells expressing the trk C receptor mRNA. Measures of neuronal size showed no significant difference between trk C expressing neurons of transgenics and aged-matched controls. Supported by AR40873 (KMA) and NS 31826 (BMD).

## 420.6

ELECTROPHYSIOLOGICAL ANALYSIS OF CUTANEOUS SENSORY NEURONS IN NEONATAL WILDTYPE MICE AND TRANSGENIC ANIMALS LACKING BDNF. Martin Koltzenburg\*, Gary R. Lewin<sup>3</sup>, Klaus V. Toyka, Hans Thoenen<sup>4</sup>, Patrick Carroll<sup>1</sup>. Dept. Neurology, University of Würzburg, D-97080 Würzburg, Depts. <sup>2</sup>Neurobiochemistry & <sup>3</sup>Neurochemistry, Max-Planck Institute for Psychiatry, D-82152 Martinsried, Germany.

Brain derived neurotrophic factor (BDNF) is a member of the neurotrophin family which affects survival and differentiation of sensory neurons. Transgenic mice lacking BDNF die within the first month of life and show a 30% depletion of dorsal root ganglion cells compared to wildtypes mice (WT). Here we used electrophysiological techniques to analyze the functional properties of primary afferents. The saphenous nerve was dissected out together with the skin and single myelinated units (n=71) were studied *in vitro* using standard teased fiber techniques from the second postnatal week until adulthood in WT mice and during the 2nd and 3rd week of life in BDNF -/- animals. In both groups conduction velocity was considerably slower during the first 3 weeks than in adults. In WT mice there was a gradual increase of conduction velocity until the 6th postnatal week when values resembled those found at 8-10 months. Thin myelinated (Aδ) afferents were classified as either nociceptive high threshold mechanoreceptors or sensitive D-hair receptors from the 2nd postnatal week onward in both BDNF -/- and WT animals. Adaptation characteristics of large myelinated (Aβ) fibres appeared not to be fully mature within the first two postnatal weeks. While normal rapidly adapting afferents are found at this developmental stage, there are afferents in both BDNF -/- and WT mice which exhibit rapidly adapting responses at threshold intensities, but slowly adapting discharges at higher intensities. Since such units are not found in WT animals at 6 weeks and as slowly adapting afferents are functionally impaired in adult +/- animals (Carroll et al. Soc. Neurosci. Abstr. 20, 1994, 451.5), BDNF may be involved in the functional maturation of these afferents. (Supported by the DFG, SFB 353)

## 420.7

**NEUROTROPHIN-3 IS REQUIRED FOR THE DEVELOPMENT OF SUBPOPULATIONS OF CUTANEOUS MECHANORECEPTORS** G. R. Lewin\*, M. Koltzenburgs, M. S. Airaksinen, K. V. Toyka, H. Thoenen and M. Meyer  
Dept. Neurochemistry, Max-Planck Institute for Psychiatry D-82152, Martinsried.  
§Dept. Neurology, University of Würzburg, D-97080 Würzburg, Germany.

Elimination of the neurotrophin-3 (NT-3) gene in mice leads to a substantial loss of sensory neurons from the dorsal root ganglia. Using anatomical techniques it has been shown that at least some of the neurons lost are proprioceptive afferents. Here we have used an *in vitro* preparation to record from single neurons in the cutaneous saphenous nerve in normal and transgenic animals to ask whether specific sub-populations of skin afferents require NT-3 (Carroll et al. 1994 Neurosci. Abst 451.5). The number of myelinated axons in this nerve was reduced by 38% in NT-3 homozygous (-/-) and 24% in heterozygote mice compared to wild type littermates, indicating a gene dosing effect. Recordings were made from a total of 103 and 93 single afferents in wild type and NT3 (+/-) animals, respectively. In control and transgenic mice these afferents could be classified as high threshold mechanoreceptors, D-hair receptors, rapidly adapting mechanoreceptors, and slowly adapting mechanoreceptors. The physiological properties of all these afferent types appeared normal in NT-3 (+/-) animals. However, there was a dramatic and significant decrease in the incidence of slowly adapting mechanoreceptors (>70%) and also D-hair receptors (50%), indicating that these two sensory neuron types require NT-3 during development. These losses were very well accounted for by the loss of myelinated axons. We examined specialized Merkel cells in the touch dome complex of the skin which are the end-organs of slowly adapting mechanoreceptors and are dependent on an intact innervation. These cells were completely absent in (-/-) mice and substantially reduced in (+/-) mice. Thus NT-3 appears to be required for the development of a numerically large number of specialized sensory neurons innervating the skin.

## 420.9

**ASSESSMENT OF PAIN THRESHOLDS IN BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF) AND NEUROTROPHIN-4 (NT-4) KNOCKOUT MICE.** Judith A. Siuciak\*, Dacie Lewis, Joanne Conover and G. Yancopoulos, Ronald M. Lindsay, Regeneron Pharmaceuticals, Tarrytown, NY. 10591

BDNF and NT-4 are members of the nerve growth factor (NGF) family of neurotrophic factors and both signal via the TrkB receptor. Mice heterozygous for a mutation in their endogenous BDNF loci (*bdnf* +/-) or homozygous for a NT-4 mutation (*nt4* -/-) (Conover et al., Nature, 1995) were assessed for alterations in nociceptive responses using standard tests. The tail-flick and the hot-plate tests were used to measure responsiveness to acute, noxious thermal stimuli. The formalin test examined prolonged nociceptive response to a noxious chemical stimulus. In the tail-flick test, responses in *bdnf* +/- mice and those lacking NT-4 (*nt4* -/-) were similar to wild-type control mice. However, in the hot-plate test, *bdnf* +/- mice showed a significant increase in the nociceptive threshold compared to their wild-type controls, i.e., they were hypoalgesic. Latencies from *bdnf* +/- mice were increased by 60% ( $p < 0.0001$ ). In contrast, the *nt4* -/- mice showed similar hot plate latencies to wild-type controls. In the formalin test, *bdnf* +/- mice showed a decreased response to an injection of 2.5% formalin into the dorsal surface of the hindpaw. The number of flinches/min was decreased in both the early and late phases of the test. Again, *nt4* -/- mice showed no changes in response. Although the mechanism is unclear at the present time, these data suggest that endogenous BDNF, but not NT-4, may play a role in the development of nociceptive systems. Furthermore, the lack of change in tail-flick latencies suggests the involvement of central pathways.

## 420.11

**NEUROTROPHIN-3 PROMOTES THE SURVIVAL AND DIFFERENTIATION OF MUSCLE SPINDLE AFFERENTS IN THE ABSENCE OF PERIPHERAL TARGETS** R. A. Oakley\*, F. B. Lefcort, D. O. Clary, L. F. Reichardt and E. Frank  
Dept. of Neurobiology, Univ. of Pittsburgh, Pittsburgh, PA 15261; Dept. of Biology, Montana State Univ., Bozeman, MT 59717; Sugen Inc., Redwood City, CA, and Neurosci. Unit, HHMI, UCSF, San Francisco CA 94143.

Our previous work has shown that NT3 from limb tissues is necessary for the survival of the sensory neurons that supply muscle spindles (Oakley et al., *Development* in press). To determine if NT3 is sufficient for the development of these neurons in the absence of limb targets, we studied the effect of chronic NT3 treatments following early limb bud deletion. Limb buds were unilaterally removed from E2.5 chick embryos, prior to sensory outgrowth. These embryos were then treated with either cytochrome-c (control) or NT3 from E5 to E10, during the period of target interaction and cell death. The survival and differentiation of muscle spindle afferents was assessed using antibodies to trkC and Dil injections of the dorsal roots.

In control embryos, limb bud deletion resulted in a loss of nearly 90% of the trkC-positive neurons in the lumbar dorsal root ganglia (DRG), with a concomitant loss of the A fiber projection to motoneurons in the spinal cord. Treatment of limb-deleted embryos with NT3 restored the normal complement of trkC-positive neurons in lumbar DRG on the deleted side and nearly doubled the number of trkC positive neurons on the contralateral side. This treatment also quadrupled the number of trkC positive neurons in thoracic DRG of unoperated segments. NT3 treatment resulted in an apparently normal A fiber projection on the deleted side, despite the loss of limb motoneurons ipsilateral to the deletion. Furthermore, NT3 treatment caused an obvious increase in Ia collaterals contralateral to the deletion and in thoracic segments. These results indicate that NT3 is necessary and sufficient for the survival and differentiation of muscle spindle afferents, implicating NT3 as a factor responsible for the specification of this sensory phenotype. Supported by the NIH and the MDA.

## 420.8

**DIFFERENTIAL EFFECT OF NEUROTROPHINS ON INJURY-INDUCED PLASTICITY OF GABA<sub>A</sub> RECEPTORS AND SODIUM CURRENTS IN CUTANEOUS AFFERENT DRG NEURONS.** A. A. Oyler\*, M. A. Rizzo, S. G. Waxman and J. D. Kocsis. Dept. of Neurology, Yale Med. Sch., New Haven, CT 06510, and Neuroscience Res. Ctr., VAMC, West Haven, CT 06516.

Axotomy enhances GABA<sub>A</sub> receptor-mediated conductances, alters action potential waveform in medium-sized DRG neurons and induces a phenotypic shift of sodium currents in cutaneous afferent DRG neurons. The present study was undertaken to determine whether the observed injury-induced changes in GABA<sub>A</sub> receptor-mediated conductance, action potential waveform and sodium currents represent changes within a specific functional class of DRG neurons (i.e. cutaneous vs muscle afferents) and to determine whether neurotrophic factors play a role in the regulation of these injury-induced changes. Whole cell recordings were obtained from cutaneous and muscle afferent DRG neurons in culture, identified by retrograde labeling with Fluoro-gold. Muscle afferent neurons had larger GABA-induced conductances and fewer action potentials with inflections on the falling phase as compared to cutaneous afferent neurons. Cutaneous, but not muscle afferent neurons, increased their GABA-induced conductances and altered their action potential waveform in response to sciatic nerve injury. *In vivo* application of NGF to the nerve stump via an osmotic pump reversed the effects of axotomy on action potential waveform and also led to an increase in the expression of kinetically slow sodium currents in cutaneous afferent neurons without affecting GABA-induced conductances. *In vivo* application of BDNF reduced the increase in GABA-induced conductance without affecting action potential waveform. These results demonstrate a differential regulation of GABA<sub>A</sub> receptor and sodium channel expression in response to axotomy in cutaneous afferent neurons by different neurotrophic factors. Supported in part by the NIH and VA.

**Comparison of rhNGF and rhNT4/5 for Modulating Capsaicin-Evoked Release of iCGRP From Peripheral Sensory Neurons** WR Bowles<sup>1</sup>, CA Harding-Rose<sup>1</sup>, BC Rogers<sup>2</sup>, KM Hargreaves<sup>1</sup> (<sup>1</sup>Dept Rest Sci, Univ of MN, Mpls, MN 55455; and <sup>2</sup>Genentech, S SF, CA)

Recent studies suggest that nerve growth factor (NGF) may modulate neurogenic inflammation through alteration of peripheral neuropeptide secretion. Evidence implicating NGF in hyperalgesia includes behavioral studies in rats (Lewin et al., J Neurosci 13:2136, 1993; Woolf et al., Neurosci 62(2):327, 1994), and increased levels of iNGF during inflammation (Byers et al., Proc. Finn Dent Soc 88(Suppl 1):73: 1992). Accordingly, we compared NGF (whose preferred receptor is trk A), to NT4/5 (a preferred ligand for trk B) for altering capsaicin-evoked release of iCGRP from peripheral terminals of sensory neurons. Bovine dental pulp was chopped into 200 µm cubes, placed into 1 cc superfusion chambers, and perfused with oxygenated Krebs buffer (0.32 ml/min). After a recovery period, rhNGF or rhNT4/5 (Genentech) in concentrations of 10pM - 3µM (n=8-10/group) was added to the buffer 21 minutes before and during stimulation with 30µM capsaicin (which stimulates certain nociceptive fibers). The superfusate was collected over 7 minute periods, and iCGRP was measured using RIA. Data were analyzed using ANOVA. rhNGF pre-treatment significantly suppressed the capsaicin-evoked release of iCGRP (80.7 ± 20.6% suppression at 7.4 pM rhNGF vs control,  $p < 0.05$ ). In contrast, rhNT4/5 suppressed the capsaicin-evoked release of iCGRP, but only at concentrations of 1µM (by 59.3 ± 30.2% vs control). The results indicate that both rhNGF and rhNT4/5 pre-treatment inhibit capsaicin-sensitive fibers. Further, the high potency of NGF and low potency of NT4/5 are consistent with a primary mechanism of action mediated by activation of the trk A receptor. This research was supported in part by Genentech, DE07014 and DE09860.

**NEUROTROPIN-3 (NT-3) TREATMENT MAINTAINS MYELINATED NERVE FIBER PROFILES AND PREVENTS A-FIBER FUNCTION LOSS IN DIABETIC RATS.** K. A. Elias, N. Shinsky, G. Ingle, N. Desjardins, A. Shaheen, J. W. Winslow, M. J. Cronin\* and W.-Q. Gao. Genentech Inc., S. San Francisco, CA 94080

We have previously shown that NT-3 reverses cisplatin-induced peripheral sensory neuropathy. We now report that NT-3 treatment prevents pathological changes in sensory fibers observed in diabetic neuropathy. Female Wistar rats were made diabetic by streptozotocin (STZ; 75 mg/kg, ip). One week after STZ injection, rats were divided into 3 groups and injected 3x week s.c. for 15 weeks: non-diabetic + vehicle (n=18), diabetic + vehicle (n=16) and diabetic + NT-3 (1 mg/kg; n=12). Sensory conduction velocities (CV) were determined via the H-reflex at monthly intervals. At 15 weeks, peroneal nerves were removed for direct recordings of the A fibers and both peroneal and sural nerves removed for histologic analysis. At 3 months, the compound sensory CV, as defined by the H-reflex, was significantly decreased in diabetic rats regardless of treatment (vehicle, 46 ± 3; NT-3, 46 ± 2 m/s) compared to non-diabetic controls (57 ± 2 m/s;  $P < 0.05$ ). Diabetic nerve A-fiber CVs, determined directly from peroneal nerves, were significantly decreased ( $P < 0.05$ ; 54.7 ± 1.9 m/s; n=13) compared to non-diabetic controls (67.9 ± 3.5 m/s; n=12), while NT-3 treatment prevented this decrease in diabetics (65.6 ± 2.4 m/s; n=9). A-fiber amplitude and integral tended to be decreased in diabetics but not significantly. Morphometric measurements of sural nerves (n=3) demonstrated the characteristic shift in fiber size frequency to smaller fibers in diabetic (81.5 ± 3.7% of myelinated nerves ≤ 35 µm) vs non-diabetics (68.8 ± 3.7%,  $P < 0.05$ ). This shift was prevented by NT-3 treatment (61.5 ± 2.2%,  $P < 0.05$ ). These results demonstrate that NT-3 can protect A-fiber CV in diabetic animals, maintain myelinated nerve profiles, and suggest NT-3 as a therapeutic in diabetic neuropathy.

## 420.13

FURTHER STUDIES ON THE ROLE OF NT-3 IN INTACT & INJURED PRIMARY SENSORY NEURONS. K.A. Gratto<sup>1</sup>, B. Friedman<sup>2</sup>, L. Liu<sup>2</sup>, R.M. Lindsay<sup>2</sup> & V.M.K. Verge<sup>1</sup>. <sup>1</sup>Dept of Anatomy, University of Saskatchewan, Canada S7N 5E5. <sup>2</sup>Regeneron Pharmaceuticals Inc., Tarrytown NY 10591

The hypothesis that NT-3 plays a role in maintaining the differentiated state of responsive trkC-expressing neurons and may be responsible for reversing changes observed after injury, *in vivo* was tested further. Adult rat right sciatic nerves were proximally cut. 14d after injury NT-3 was intrathecally infused for an additional 7d in half of the rats. Cryostat sections of intact and injured DRG with and without NT-3 infusion were processed for *in situ* hybridization to detect mRNAs encoding its receptors trkC and p75, neurofilament-medium (NFM), the immediate-early gene (IEG) cjun, and peptides galanin, SP, SOM and VIP. Results indicate that in intact neurons trkC, p75, NFM, SP and SOM are abundantly and heterogeneously expressed, whereas few if any neurons express detectable galanin, VIP or abundant cjun mRNA. Two weeks after injury levels of trkC, p75, NFM, SP and SOM mRNA are dramatically reduced, while many neurons now express high levels of cjun, galanin and VIP mRNA. Infusion of NT-3 partially counteracts injury-induced decreases in trkC, p75, and NFM mRNA in primarily medium- to large-sized neurons and is also effective in downregulating the injury-induced expression of cjun and galanin in a similar neuronal subpopulation. NT-3 infusion has no apparent qualitative effect on the injury-induced changes in hybridization signal for SP, SOM and VIP. The lack of detectable influence of NT-3 on these peptides is consistent with their localization in a size range not normally associated with trkC expression, although this has not been rigorously tested. In conclusion, the ability of exogenous NT-3 to modulate expression of the receptors trkC and p75, the cytoskeletal protein NFM, the IEG cjun, and the peptide galanin, in addition to expression of the peptides NPY and  $\alpha$ -CGRP reported previously, strongly supports a role for NT-3 in maintaining aspects of the differentiated state of responsive adult primary sensory neurons. Canadian MRC and Saskatchewan HSURC supported.

## NEUROTROPHIC FACTORS: BIOLOGIC EFFECTS IX

## 421.1

NEUROTROPHIC FACTORS INCREASE AXONAL GROWTH AFTER SPINAL CORD LESIONS AND TRANSPLANTS IN ADULT RATS. B.S. Bregman<sup>\*</sup> and M. McAtee, Georgetown University, School of Medicine, Washington, DC 20007.

The capacity of CNS neurons for axonal regrowth after injury decreases as the age of the animal at time of injury increases. After spinal cord lesions and transplants at birth, there is extensive regenerative growth into and beyond a transplant of fetal spinal cord tissue placed at the injury site. After injury in the adult, however, although host corticospinal and brainstem-spinal axons project into the transplant, their distribution is restricted to within 1-2mm of the host/transplant border. The aim of this study was to determine if the administration of neurotrophic factors could increase the capacity of mature CNS neurons for regrowth after injury. Spinal cord over-hemisection lesions were made at T6 in adult rats. Transplants of E14 fetal spinal cord tissue were placed into the lesion site. BDNF, NT-3, NT-4, CNTF or vehicle alone were administered at the site of the transplant at the time of injury and transplantation. After 1-2 months survival, neuroanatomical tracing and immunocytochemical methods were used to examine the growth of host axons within the transplants. NT-3 increased both the density and extent of serotonergic axonal ingrowth into the transplants dramatically, but had relatively little effect on the growth of noradrenergic axons. BDNF, like NT-3, also substantially increased the growth of serotonergic axons into the transplants. Noradrenergic axons increased their projection in response to BDNF and NT-4. Although NT-4 influenced noradrenergic axons, it had no effect on the growth of serotonergic axons. The influence of the administration of the neurotrophins on the growth of injured CNS axons was not a generalized effect of growth factors per se, since the administration of CNTF had no effect on the growth of any of the descending CNS axons tested. These results indicate that in addition to influencing the survival of developing CNS and PNS neurons, neurotrophic factors are able to exert a neurotrophic influence on injured mature CNS neurons by increasing their axonal growth within a transplant. The influence of the neurotrophins on mature injured CNS neurons is not uniform. Rather, particular populations of neurons appear to respond preferentially to particular members of the neurotrophin family. Supported by NIH-NINDS NS 19259; neurotrophins supplied by Regeneron.

## 421.3

BDNF REVERSES THE ATROPHY OF CHRONICALLY INJURED RAT RUBROSPINAL NEURONS AFTER CERVICAL (C3) AXOTOMY. N.R. Kobayashi<sup>\*</sup>, A.M. Bedard and W. Tetzlaff. Dept. of Physiology and Neuroscience, Univ. of Ottawa, Ottawa, Ontario, K1G 8M5, Canada

Rat rubrospinal neurons undergo severe atrophy during the second week after axotomy at the cervical level (C3) of the spinal cord. This atrophy is accompanied by a decrease in the expression of regeneration associated genes i.e. tubulins, actin and GAP-43 (Tetzlaff et al., J. Neurosci. 11:2528-2544, 1991). We have previously shown that the application of BDNF (500 ng/ $\mu$ l/hr) into the vicinity of the red nucleus from day 7 to 14 fully prevented this atrophy and sustained GAP-43 mRNA expression. (Soc. Neurosci. abstr., Vol 19, 455.7). We have now tested whether BDNF can reverse the atrophy of these neurons after they had been chronically injured. We allowed rubrospinal neurons to undergo atrophy for 5, 7, 16, 24, and 52 weeks after cervical axotomy. Subsequently, BDNF (500 ng/ $\mu$ l/hr) was infused for 7 days i.e. during the 6th, 8th, 17th, 25th and 53rd week, respectively. The mean cross sectional soma area of the BDNF treated group was 88% of contralateral at 6 weeks, compared to 58% in the vehicle treated animals. After 17 weeks, the neurons of the BDNF treated group showed the cross sectional area of 72% of contralateral, while the vehicle treated group was found at 49% of contralateral. Furthermore, our preliminary *in situ* hybridization results indicate that GAP-43 mRNA is re-expressed and the decrease in  $\alpha$ 1-tubulin expression is reversed in the BDNF treated group, which is not seen after vehicle treatment only. It remains to be shown whether this approach can be exploited to promote regeneration after chronic injury.

BDNF was kindly supplied by Regeneron Pharmaceutical Inc.. Supported by the Medical Research Council of Canada (W.T.), the American Paralysis Association, USA (W.T.), and the Government of Canada Award (N.R.K.).

## 420.14

LOW-AFFINITY NEUROTROPHIN RECEPTOR p75 IS REQUIRED FOR THE DEVELOPMENT OF SOME MECHANORECEPTORS. K.-F. Lee<sup>1</sup>, H. Dickinson-Anson<sup>2</sup>, F.H. Gage<sup>2</sup>, and M. Byers<sup>3</sup>. <sup>1</sup>The Salk Institute, La Jolla, CA 92037, <sup>2</sup>Dept. Neurosciences, UCSD, La Jolla, CA 92037, <sup>3</sup>Dept. Anesthesiology, Univ. Washington, Seattle, WA 98195

Because p75 binds all neurotrophins and is capable of interacting with each of the trk receptors in potentiating the activity of neurotrophins in several culture systems, mutation of the p75 gene may affect the development of both NGF-dependent and NGF-independent neurons. In the present study p75-deficient mice were tested in a battery of sensorimotor tests. Results indicated that the mutant mice were impaired on several measures compared with controls. In particular, when placed on a raised small wooden dowel bridge midway between two escape platforms, the mutant mice were unable to traverse the bridge and escape without falling off. In contrast, 100% of control mice rapidly traversed the bridge to escape. These results suggest a deficit in sensory (or sensorimotor) function. Because the skin mechanoreceptor end organs, the Meissner's corpuscles, contains p75, we examined the possibility that the phenotype is in part due to a deficit in innervation of Meissner's corpuscles in glabrous skin. Sections of glabrous skin were immunostained with an antibody to protein gene product 9.5 (PGP9.5). Meissner's corpuscle innervation is almost absent in mutant animals as compared to control animals. Thus, the loss of mechanoreceptor innervation at least explains the behavioral deficits. Defects in motor neurons could also contribute to the phenotype. Preliminary counts of lumbar motor neurons, however, revealed no loss.

Similar results were obtained when hair follicle mechanoreceptors were examined with the same antibody. Meissner's corpuscles are rapidly-adapting sensory receptors and are innervated by (highly myelinated) A $\alpha$  neurons while hair follicles are innervated by A $\beta$  neurons. It has been suggested that the survival of mechanoreceptor neurons is dependent on neurotrophins other than NGF such as BDNF, because BDNF is expressed in deeper skin layers. Our results therefore provide evidence that p75 is important for the development of some NGF-dependent and NGF-independent sensory neurons.

## 421.2

TROPHIC FACTOR ENHANCED REGENERATION BY CHRONICALLY INJURED SUPRASPINAL NEURONS FOLLOWING CERVICAL SPINAL CORD INJURY. J.-H. Ye<sup>\*</sup> and J.D. Houle, Department of Anatomy, University of Arkansas for Medical Sciences, Little Rock, AR. 72205

Whether the regenerative response of chronically injured neurons could be enhanced by exposure to specific trophic factors was examined. Supraspinal neurons were retrogradely labeled with True Blue (TB) at the time of a C3 hemisection lesion of the adult rat spinal cord. Four weeks later gel foam soaked with insulin-like growth factor 1 (IGF-1), combined brain derived neurotrophic factor and neurotrophic factor 3 (BDNF/NT-3) or saline as a control was placed into the lesion cavity. The gel foam was replaced after 3 days with fresh factor and 4 days later (35 days after injury) an autologous peripheral nerve graft (PNG) was apposed to the rostral surface of the cavity. The distal end of the PNG was exposed to Nuclear Yellow (NY) 4 weeks after grafting. Animals were sacrificed 2 days later and serial vibratome sections examined for the presence of regenerative neurons labeled with TB/NY or NY only.

The mean total number of regenerating neurons significantly increased over control values with BDNF/NT-3 (353 vs 256) or IGF-1 (555 vs 256) treatment. The percentage of regenerating neurons that were chronically injured was: BDNF/NT-3 (75%), IGF-1 (61%), control (55%). Enhanced regenerative capacity was greatest within the reticular formation, lateral vestibular nucleus and hypothalamus with either BDNF/NT-3 or IGF-1. Treatment with BDNF/NT-3, but not IGF-1, increased the mean number of regenerating neurons within the locus coeruleus and red nucleus. No effects were found on raphe or spinal trigeminal tract neurons with either factor. These results demonstrate the potential to increase the regenerative response of specific chronically injured supraspinal neurons with a short term exposure to BDNF/NT-3 or IGF-1. BDNF and NT-3 were supplied by Regeneron Pharmaceuticals, Inc. Supported by NIH Grant NS 26380.

## 421.4

BDNF AND NT-3 EXERT DIFFERENTIAL AND OVERLAPPING EFFECTS ON GAP-43 AND  $\alpha$ 1-TUBULIN EXPRESSION IN AXOTOMIZED CORTICOSPINAL NEURONS OF THE RAT.

K. Giehl<sup>1,2</sup>, P. Mestres<sup>2</sup>, and W. Tetzlaff<sup>1</sup>. <sup>1</sup>Department of Physiology, University of Ottawa, 451 Smyth Rd., Ottawa, Ontario, Canada;

<sup>2</sup>Universität des Saarlandes, Anatomisches Institut, 66421 Homburg, Germany

In the peripheral nervous system, regeneration is correlated with increased expression of regeneration associated genes (RAG), e.g. GAP-43 and  $\alpha$ 1-Tubulin. In contrast, RAG expression is decreased in corticospinal neurons (CSN) after axotomy (Giehl et al., 1993, Soc. Neurosci. Abstr. 283.9). CSN, retrogradely labelled with Fast Blue, were axotomized at the internal capsule and the neurotrophins BDNF and NT-3 were applied intracortically via an osmotic minipump for 7 days. As shown with *in situ* hybridization, both BDNF and NT-3 increase  $\alpha$ 1-Tubulin expression in axotomized CSN. This is consistent with the expression of trkB and trkC in these neurons (Giehl and Tetzlaff, 1994, Soc. Neurosci. Abstr. 253.14). However, only BDNF but not NT-3 increases GAP-43 expression. In agreement with the lack of trkA expression in CSN, NGF did not have an effect. Thus, BDNF and NT-3 have overlapping as well as differential effects on RAG expression in axotomized CSN.

## 421.5

NEUROTROPHIN-3 (NT-3) PREVENTS DEATH OF CLARKE'S NUCLEUS NEURONS IN ADULT RATS. M. Shibayama<sup>1,2</sup>, S. Hattori<sup>1,2</sup>, B. T. Himes<sup>1,3</sup>, N. Matsui<sup>2</sup>, M. Murray<sup>1</sup>, and A. Tessier<sup>1,3</sup>. <sup>1</sup>Dept. of Anatomy & Neurobiology, Medical College of Pennsylvania and Hahnemann University, 3200 Henry Ave. Philadelphia, PA. 19129. <sup>2</sup>Dept. of Orthopedic Surgery, Nagoya City Univ. School of Medicine, Nagoya, Aichi, Japan. <sup>3</sup>Philadelphia VA Hospital

Fetal transplants placed into the site of hemisection in adults as well as neonates rescue all Clarke's nucleus (CN) neurons destined for retrograde cell death. One reason for retrograde cell death after axotomy is loss of neurotrophic factors. It has been proposed that transplants provide these neurotrophins. We studied whether NT-3 delivered exogenously to adult rats with spinal cord injury can rescue axotomized CN neurons otherwise destined to die. Female Sprague-Dawley rats (250-300g) underwent laminectomy at the mid-thoracic level with interruption of the right dorsal spinal spinocerebellar tract by spinal cord hemisection. This injury transects the axons of the right CN neurons and spares the neurons of the left CN as an intact control. At the time of the hemisection rats had either gelfoam soaked in NT-3 (10 µg, generously provided by Regeneron) or gelfoam soaked in saline placed into the hemisection cavity. Two months after surgery the rats were perfused, and CN neurons at the L1 segment were counted and measured. Rats receiving saline showed 30% loss of CN neurons ipsilateral to the hemisection; average cell area was reduced by 60%. Rats receiving NT-3 showed 15% neuron loss and greater average neuron area than after saline alone. Bioassay of the gelfoam in additional rats showed NT-3 activity at 1 day after surgery but not at 3 days. These results indicate that brief exposure of axotomized CN neurons to NT-3 suffices to produce long-term rescue of 50% of axotomized CN neurons that were destined to die in adult rats; to determine whether continuous availability of neurotrophic factor increases the number of rescued cells, we are administering NT-3 into the hemisection site by Alzet Osmotic Mini-pump. Supported by the VA Medical Research Service and NS 24707.

## 421.7

CLONING AND EXPRESSION OF BRAIN-DERIVED NEUROTROPHIC FACTOR IN BRAIN AND SPINAL CORD OF NEONATAL OPOSSUM. H.A. Vischer\* and E. Reinhard. Dept. Pharmacology, Biozentrum, University of Basel, 4056 Basel, Switzerland.

Crushed or cut spinal cord of neonatal opossum *Monodelphis domestica* has the ability to repair morphologically and physiologically *in vivo* and *in vitro* (Woodward et al., 1993; Saunders et al., 1995). In order to investigate the possible role of neurotrophins in this process, we partially cloned the opossum brain-derived neurotrophic factor (BDNF). BDNF has been shown to prevent cell death of motor neurons *in vivo* and *in vitro* in the brain and spinal cord (Oppenheim, 1992; Yin, 1994) and might therefore be upregulated during the period of spinal cord repair. Opossum BDNF was cloned by RT-PCR using primers to highly conserved regions of BDNF of different vertebrate species. A 266 bp long fragment was obtained that showed 83% identity on the nucleotide level to chick BDNF, 82% to human BDNF, 81% to pig BDNF and 77% to rat BDNF. Due to this high homology we used a full-length rat BDNF cDNA (gift from Regeneron) as a probe to determine the sites of expression in opossum. Whole-mount *in situ* hybridization studies were performed on isolated CNS preparations, using a digoxigenin-labeled single-stranded BDNF cRNA-probe. In those preparations where the spinal cord was crushed, BDNF was expressed at higher levels in the medulla oblongata. No BDNF was expressed at the crush site. We are currently studying the presence of other neurotrophic factors and their corresponding receptors during spinal cord repair.

## 421.9

BDNF PROMOTES THE SPROUTING OF NEUROTOXIN-LESIONED SEROTONERGIC AXONS IN RAT BRAIN. L.A. Mamounas\*, M.E. Blue, K.J. Axt and C.A. Altar. National Institute on Aging, GRC, Baltimore, MD 21224; Kennedy-Krieger Inst., Baltimore, MD; Johns Hopkins Univ. Sch. of Med., Baltimore, MD; and Regeneron Pharm., Tarrytown, NY.

Brain-derived neurotrophic factor (BDNF) was recently found to prevent the severe degenerative loss of serotonergic (5-HT) axons normally caused by the selective 5-HT neurotoxin p-chloroamphetamine (PCA) in adult rat neocortex (Mamounas et al., 1995). In our initial study, continuous three-week intracortical infusions of BDNF were started one week before subcutaneous administration of PCA, and continued for another two weeks after treatment with the neurotoxin. Thus, it remained to be determined whether BDNF 1) prevents the degeneration of 5-HT axons normally caused by PCA or 2) dramatically facilitates and accelerates the endogenous sprouting of 5-HT axons after PCA-induced degeneration, or both. The present study evaluated this question by manipulating the temporal parameters of BDNF and PCA delivery, followed by immunocytochemical staining of 5-HT axons using antisera directed against serotonin or the serotonin transporter. Two-week intracortical infusions of BDNF (12 µg/day) started four days after PCA administration (10 mg/kg, s.c.) caused a marked increase in 5-HT axon density near the BDNF infusion cannula when compared to control infusions, suggesting that BDNF accelerates and enhances the normally slow sprouting of 5-HT axons after PCA-induced degeneration. When BDNF infusions were started one week before PCA administration and terminated one day after PCA, an evaluation of the 5-HT innervation 2 days later revealed only a partial sparing of 5-HT axons near the BDNF infusion cannula. Thus, BDNF only partially prevents the PCA-induced degeneration of serotonergic axons, but causes a robust sprouting of 5-HT axons when administered after degeneration by PCA. These results support our initial finding that BDNF causes sprouting of uninjured 5-HT axons in intact (non PCA-lesioned) animals and suggest that BDNF given after injury has a tropic role in promoting serotonergic axonal growth in the adult nervous system.

## 421.6

SPINAL CORD GRAFTS IN OCULO: EFFECTS OF TREATMENT WITH BDNF, CNTF, GDNF OR NT-3. K. Trok\*, B. Hoffer and L. Olson. Department of Neuroscience, Karolinska Institutet, Stockholm, Sweden.

Intraocular transplantation of neural tissue provides a method to examine *in vivo* effects of trophic factors. We have previously demonstrated that fetal spinal cord tissue survives grafting to the anterior chamber of the eye. Such transplants receive functional inputs from cogafts of brain stem areas containing serotonin or noradrenaline neurons. Intraocular spinal cord tissue also becomes functionally connected with cortex cerebri, spinal cord and skeletal muscle cogafts. Because spinal cord maturation and connectivity involve the influence of trophic factors, in the present study we have investigated the influence of brain-derived neurotrophic factor (BDNF), ciliary neurotrophic factor (CNTF), glial cell line-derived neurotrophic factor (GDNF) and neurotrophin-3 (NT-3) on such grafts. Spinal cord tissue from E14, E18, P0-1, P7 and P14 rats was transplanted to the anterior eye chamber of adult host rats after incubation in 100 µg/ml of BDNF, CNTF, GDNF, NT-3, or cytochrome C (cyt C) in PBS or vehicle. On days 5, 10, 15, 20 and 25 postgrafting 5 µl of a similar solution was injected into the anterior eye chamber. Treatment with BDNF augmented growth of transplanted spinal cord of all donor stages compared to controls, although this effect appeared transient. Treatment with CNTF enhanced growth of grafts from P1 and P14 donors in an apparently permanent manner. Effects of NT-3 on postnatal spinal cord grafts appeared to be smaller than those of BDNF, and although they manifested later in graft maturation, they appeared to be more permanent. GDNF-treated P1 grafts grew to volumes larger than their initial size at grafting. P7 and P14 grafts treated with GDNF also responded with increased growth compared with controls but did not exceed their initial size at transplantation. Morphological characterization of grafted spinal cord tissue will be described.

## 421.8

WITHDRAWAL OF TRANSIENT SEROTONERGIC PROJECTIONS FROM NON-TARGET TRANSPLANTS IS REGULATED BY THE AVAILABILITY OF NEUROTROPHIC FACTORS. H. Bernstein-Goral\* and B.S. Bregman. Georgetown University, School of Medicine, Washington, DC 20007.

Axotomized serotonergic (5HT) raphe-spinal neurons permanently regenerate axons into target-specific fetal spinal cord transplants placed into either a spinal cord hemisection or transection in the newborn rat. While target-specific transplants permit regeneration, non-target transplants placed into a spinal cord lesion support only transient ingrowth of 5HT axons that is completely withdrawn from the transplant by one month after transplantation. This transient innervation arises from collateral sprouting of intact 5HT axons from the host spinal cord. Transient 5HT axons form synapses within the non-target transplant that are indistinguishable from those in appropriate targets. This suggests that synaptogenesis within the transplant does not regulate the maintenance of innervation. Signals arising from the non-target transplant itself appear to direct the withdrawal of axon collaterals. We hypothesize that specific neurotrophic factors that are critical for the maintenance of axonal ingrowth into the transplant are lacking in the non-target tissues. To test this, non-target transplants (fetal rat hippocampus) placed into a neonatal thoracic spinal cord hemisection, were supplemented with exogenous neurotrophins BDNF (n=11) or NT3 (n=8) or with saline (n=4). At one month post-transplantation, 5HT axonal ingrowth into the non-target transplant is maintained in animals that received either exogenous BDNF or NT3, but not in controls with non-target transplant alone. The pattern and density of ingrowth into non-target transplants with either exogenous BDNF or NT3 is comparable to the permanent regenerative growth of axons into target-specific transplants. Administration of neurotrophins also appears to affect the development of the hippocampus transplants directly; transplants are strikingly well differentiated and larger in the presence of neurotrophins than in transplants without additional neurotrophins. Our studies suggest that the availability of specific neurotrophins within the transplant may 1) enhance axonal elongation after CNS injury and 2) promote the long-term maintenance of newly formed pathways. Supported by NIH-NINDS NS 19259.

## 421.10

EXOGENOUS BDNF AND NT-4/5 UPREGULATE EXPRESSION OF BDNF mRNA IN MIDBRAIN NEURONS. K.D. Anderson\*, J.-Y. Cho, T.L. Corcoran, R.M. Lindsay, and S.J. Wiegand. Regeneron Pharmaceuticals, Inc., Tarrytown, NY 10591.

Intracerebral delivery of neurotrophins induces changes in neuropeptide levels and electrical activity of neurons, augments neurotransmitter turnover, and alters behavior. To investigate potential mechanisms whereby intracerebral delivery of neurotrophins influences neuron function, we determined the effect of exogenous neurotrophins on the expression of BDNF and NT-3 mRNAs by *in situ* hybridization in adult male rats. Neurotrophins were delivered intracerebrally for 12 days by an osmotic pump connected to a cannula implanted into the right mesencephalon and extending to the center of the substantia nigra pars compacta. Continuous infusion of BDNF (12 µg/day) or NT-4/5 (7.2 µg/day), but not NT-3, NGF (each at 12 µg/day) or saline (12 µl/day), induced a unilateral increase in neuronal expression of BDNF mRNA, but only in structures normally expressing it in untreated rats. Structures exhibiting neuronal BDNF mRNA upregulation included the superior colliculus, the central gray, ventral tegmental area, the substantia nigra pars compacta, the peripeduncular nucleus, and the red nucleus. An increase in NT-3 mRNA was not detected after infusion of BDNF, NT-3, NGF or saline. These results suggest that BDNF mRNA production may be regulated by a TrkB-mediated positive feedback loop. However, enhanced production of BDNF mRNA by NT-3, or enhanced production of NT-3 mRNA by BDNF, are not part of the mechanisms involved in the regulation of neuron function by exogenous neurotrophins.

## 421.11

THE NEUROTROPHIC ACTIONS OF BDNF IN THE DEVELOPING PONTINE-CEREBELLAR SYSTEM. S.A. Rabacchi, S.L. Meyer, D.H. Baird, and J.E. Springer\*. Department of Anatomy, Medical College of Pennsylvania and Hahnemann University, Philadelphia, PA. 19129, and Cephalon, Inc. West Chester, PA. 19380 (SLM)

The cellular events involved in regulating neuron survival, neurite outgrowth, and target contact rely, in part, on the expression of target-derived neurotrophic factors. One family of neurotrophic factors, the neurotrophins, have been shown to play a role in the development and survival of several PNS and CNS neuronal populations. In the developing cerebellum, granule cells have been shown to both synthesize and respond to BDNF, and express trkB. Granule cells are the major target of pontine-derived mossy fibers that innervate the cerebellum in early postnatal stages of development. In the present study we tested the effects of BDNF on trkB mRNA expression in granule cells, as well as the ability of BDNF to promote the outgrowth of mossy fibers in pontine explants. In the first experiment, purified granule cells were prepared from postnatal day 6 rats, cultured in serum-free conditions, and exposed to 1, 10, or 100 ng/ml of BDNF for a period of 4 or 24 hours. Using *in situ* hybridization, and increase trkB mRNA expression was observed in individual granule cells within 4 hr following treatment with 100 ng/ml of BDNF. The levels of trkB mRNA were still elevated in granule cells treated for 24 hours, although the effect was not as great as that observed at 4 hr. In the second experiment, pontine explants from neonates were treated with 1, 10, or 100 ng/ml of BDNF, NGF, or NT-3 for 2 days. BDNF, but not NGF or NT-3, increased the amount of neurite outgrowth from pontine explants at the 10 ng/ml concentration. This effect of BDNF is consistent with the expression of trkB mRNA in the pontine explants as determined using PCR analysis. Furthermore, BDNF treatment increased growth cone area by 2-fold. We propose that, in addition to acting as an autocrine/paracrine survival factor for the granule cells, BDNF also plays a role as a target-derived promoter of mossy fiber extension. Supported by NIH grants NS33214 (DHB) and NS30502 (JES).

THE BIOLOGICAL EFFECTS OF BDNF OVEREXPRESSION IN DOPAMINE- $\beta$ -HYDROXYLASE:BDNF TRANSGENIC MICE

C. Causing\*, E. Chang, S. Bamji, A. Gloster, A. Speelman, R. Varma, H. Majdan, J. Fawcett, T. A. Reader, A. R. Ase, and F.D. Miller. Centre For Neuronal Survival, Montreal Neurological Institute, Montreal, Quebec, H3A 2B4, \*Department of Physiology, University of Montreal, Quebec

We have examined transgenic mice that express BDNF from the dopamine- $\beta$ -hydroxylase (DBH) promoter which directs gene expression to adrenergic and noradrenergic neurons. Transgenic lines appropriately overexpress BDNF mRNA in the superior cervical ganglia (SCG), adrenals, and brainstem. Using an anti-BDNF antibody, BDNF protein is overexpressed in neurons of the SCG and locus coeruleus (LC). Innervation density within the SCG derived from cholinergic preganglionic inputs was increased as demonstrated by ChAT and synapsin immunostaining. trkB immunoreactivity has been localized to preganglionic neurons, and there is an increase in cell size in a preganglionic subpopulation. In the CNS, neurons of the LC are hypertrophied 40% relative to control which is accompanied by an increase in TH mRNA expression. Immunocytochemistry for DBH in the hippocampus shows an increase in DBH-positive fibers and preliminary evidence indicates changes in catecholamine content within discrete brain regions as demonstrated by HPLC measurements. The observed changes in catecholamine content in regions that contain trkB suggests these neurons may be responding to BDNF secreted from the LC. Based on these results we have hypothesized that sympathetic neuron-derived BDNF regulates its input innervation density via a feedback mechanism whereas, in the CNS, BDNF regulates the growth and survival of LC neurons via a potential autocrine mechanism.

## 421.15

CHANGING RESPONSIVENESS OF DEVELOPING MIDBRAIN DOPAMINERGIC NEURONS FOR EXTRACELLULAR GROWTH FACTORS. J. Engle\*, Dept. Anatomy and Cell Biology, University of Ulm, 89069 Ulm, Germany.

Previous studies have demonstrated that a vast array of growth factors support the survival of dopaminergic neurons in cultures of the early embryonic mesencephalon by either a direct or an indirect, glial-mediated, mechanism. To further characterize the functional role of these multiple growth factor influences for dopaminergic cell development, various purified growth factors as well as mesencephalic glial-conditioned medium (CM) were screened for their effects on dopaminergic cell survival in serum-free low-density cultures of the dissociated embryonic day (E)15 and E17 rat mesencephalon. Treatment of E15 mesencephalic cultures with FGF-2 (25 ng/ml), TGF $\alpha$  (50 ng/ml), IGF-1 (100 ng/ml), BDNF (50 ng/ml), PDGF-BB (30 ng/ml), interleukin-6 (25 U/ml), GDNF (1 ng/ml), and glial-CM (50%) all increased the number of surviving tyrosine hydroxylase-immunoreactive dopaminergic neurons at 6 days when compared to controls. In contrast, with E17 mesencephalic cultures, survival promoting effects on dopaminergic neurons were restricted to FGF-2, BDNF, and GDNF.

These findings demonstrate that, during embryonic development, dopaminergic cell survival sequentially depends on different sets of growth factors. The concomitant loss of sensitivity of developing dopaminergic neurons for mesencephalic glial-CM as well as TGF $\alpha$ , IGF-1, PDGF-BB, and interleukin-6 further suggests that the survival promoting effects of these growth factors on early embryonic dopaminergic neurons are indirectly mediated through resident mesencephalic glia. Supported by DFG, En 187/2-2.

## 421.12

BRAIN DERIVED NEUROTROPHIC FACTOR (BDNF) STIMULATES RAT CEREBELLAR GRANULE NEUROBLAST MITOSIS IN CULTURE AND *IN VIVO*. E. DiCicco-Bloom\*, J. P. Wagner, and J.B. Black. Dep't Neurosci. & Cell Biol. UMDNJ/Rob. Wood Johnson Med. Sch. Piscataway, NJ.

While neurotrophins play critical roles in target-dependent survival, expression in developing brain suggests that the factors regulate neurogenesis. Recent neurogenetic studies *in vitro* indicate two distinct mechanisms by which signals enhance proliferation, including (i) directly stimulating neuroblasts to enter the mitotic cycle (mitogenesis) and (ii) promoting survival of dividing precursors (trophism). We previously defined a trophic role for NT3 in stimulating sympathoblast proliferation. We now characterize mitogenic actions of BDNF in cerebellar granule neurogenesis.

We employed on a highly enriched population of postnatal day 7 rat cerebellar granule neuroblasts cultured in defined medium, and assessed [<sup>3</sup>H]thymidine ([<sup>3</sup>H]dT) incorporation, a marker of DNA synthesis, and cell number. BDNF increased [<sup>3</sup>H]dT incorporation 3-fold at 24 hr, with an EC<sub>50</sub> of  $\sim 0.08$  ng/ml and peak effects at 0.3-1 ng/ml. Enhanced DNA synthesis reflected a 50% increase in the proportion of neuroblasts in the mitotic cycle, revealed by [<sup>3</sup>H]dT autoradiography (labeling index, LI: Con=1 $\pm$ 0.8%; BDNF=17 $\pm$ 0.4%; p<0.003). In addition, BDNF increased cell number by 80%, though only at higher doses (30-100 ng/ml). To examine mitogenesis in the absence of trophism, cultures were assessed prior to cell death, at 6 hr, when numbers of trypan blue excluding cells were equal among groups. BDNF (3 ng/ml) increased the LI by 40%, indicating that the factor directly stimulated granule neuroblast mitosis, independent of trophic action.

To define activity *in vivo*, animals received 100 ng BDNF intracranially, and after subcutaneous [<sup>3</sup>H]dT injection at 6 hr, were sacrificed at 8 hr. BDNF increased DNA synthesis 4-fold in isolated neuroblasts, suggesting that the factor directly stimulates mitogenesis in the brain. Our observations indicate that neurotrophins exert both mitogenic and trophic regulation of neurogenesis, acting in population-specific fashion. (Support: NICHD23315; Trophix Pharm.)

## 421.14

MAPPING BDNF-RESPONSIVE NEURONS IN THE MATURE CNS: USE OF TAI:LACZ TRANSGENIC MICE S. Bamji\*, D. Matchett, and F.D. Miller. Centre For Neuronal Survival, Montreal Neurological Institute, Montreal, Canada, H3A 2B4

We have previously demonstrated that a 1.1 kb of 5' upstream region from the Tal  $\alpha$ -tubulin gene was sufficient to direct expression of a nuclear  $\beta$ -galactosidase marker gene to neurons of the peripheral and central nervous systems (Gloster et al., 1994). Moreover, we demonstrated that the absolute levels of expression of this transgene were regulated as a function of morphological growth in both developing and mature neurons. Interestingly, in the mature nervous system, the Tal:nlacZ transgene was not expressed homogeneously in a panneuronal fashion. To examine this phenomenon further, we have characterized the distribution of the Tal:nlacZ transgene in the mature central nervous system, and have compared its expression to that of the endogenous Tal  $\alpha$ -tubulin mRNA. Our results show that there is a strong correlation between the pattern of transgene expression and the pattern of Tal  $\alpha$ -tubulin mRNA expression indicating that even in the mature nervous system, the 1.1 kb Tal promoter fragment is sufficient to drive transcription as a function of neuronal growth potential. When Tal:nlacZ mice were crossed with a mouse line that overexpresses BDNF from the DBH promoter,  $\beta$ -galactosidase expression in distinct regions of the brain increased dramatically. This indicates that the 1.1 kb Tal promoter fragment contains elements necessary for BDNF-responsiveness. This system enabled us to rapidly map BDNF-responsive neurons in the mature mouse brain, and provides an ideal system to examine the function of BDNF in the brain.

## 421.16

ROLE OF NEUROTROPHIC FACTOR SIGNAL TRANSDUCTION PATHWAYS IN THE ACTIONS OF DRUGS OF ABUSE IN THE MESOLIMBIC DOPAMINE SYSTEM. M. Berhow\* and E.J. Nestler. Laboratory of Molecular Psychiatry, Yale Univ Sch of Med, Dept of Psychiatry, New Haven, CT

Chronic morphine and cocaine treatments have been shown to regulate levels of tyrosine hydroxylase (TH) and other proteins in the ventral tegmental area (VTA) of the adult rat brain. Recent research has demonstrated that direct infusion of BDNF or NT4 (2.5  $\mu$ g/day) midline into the VTA could prevent as well as reverse these biochemical changes associated with chronic morphine and cocaine treatments. In contrast, CNTF (1.5  $\mu$ g/day) infusions mimicked these biochemical changes (Berhow et al, Neuroscience, 1995, in press).

Present studies are focusing on the possibility that morphine and cocaine regulate TH and other target proteins via actions on neurotrophic factors signaling pathways within the VTA. One major pathway involves the activation of ERKs (extracellular signal regulated kinases). We are using an antisense oligonucleotide strategy to study the role of these kinases in drug action. Infusion of ERK1 antisense oligonucleotide (10  $\mu$ g/day) into the VTA for seven days resulted in a 60% decrease in ERK1, with no effect on ERK2. This treatment led to a 45% decrease in TH levels in the VTA, however numerous cytoskeletal and signaling proteins showed no change. The possibility that the ERKs mediate morphine and neurotrophin regulation of TH expression is under current investigation. A second major pathway involves activation of the JAK-STAT cascade. To date, we have found that chronic cocaine treatment increases JAK immunoreactivity by 40-50% in the VTA, whereas chronic morphine treatment produces no change in JAK levels. Gel shift assays are currently underway to determine whether there is also an alteration in STAT DNA binding activity with cocaine treatment. These studies promise to elucidate novel mechanisms by which drugs of abuse induce biochemical adaptations in the VTA potentially involved in addiction.

## 421.17

**MORPHOLOGICAL EVIDENCE OF CHANGES INDUCED IN THE VENTRAL TEGMENTAL AREA (VTA) BY CHRONIC MORPHINE TREATMENT.** L. Sklar-Tayron, W.-X. Shi, H.W. Harris, B.S. Bunney, and E.J. Nestler. Laboratory of Molecular Psychiatry, Depts of Psychiatry and Pharmacology, Yale Univ School of Medicine, New Haven, CT 06508.

The VTA and its dopaminergic projections to the limbic forebrain have been implicated in the reinforcing properties of opiates and other drugs of abuse and may be a site where the drugs produce long-term adaptations that underlie aspects of addiction. For example, we have shown that chronic morphine treatment increases levels of tyrosine hydroxylase (TH) and glial fibrillary acidic protein (GFAP), and decreases levels of neurofilament proteins, in the VTA. We have proposed, based on these biochemical findings, that prominent structural changes may occur within this brain region in the chronic morphine-treated state (Neuron 11, 995-1006, 1995). The aim of the present study was to investigate this possibility directly. Immunocytochemical studies revealed an increase in levels of GFAP immunoreactivity specific to the VTA. Higher magnification revealed a dramatic increase in the number of astrocytes in this brain region. Immunocytochemical analysis also revealed no difference in the number of TH<sup>+</sup> neurons following chronic morphine treatment. Morphometric analysis was used to evaluate whether chronic morphine treatment is associated with alterations in the shape and size of dopaminergic neurons in the VTA. Neurons in fixed brain slices were injected with lucifer yellow, and TH<sup>+</sup> cells were identified by immunocytochemistry. Preliminary studies have revealed a significant reduction in the mean area and perimeter of VTA dopaminergic (TH<sup>+</sup>) neurons in slices from chronic morphine-treated rats. In contrast, such changes were not apparent in non-dopaminergic (TH<sup>-</sup>) neurons. These findings support interpretations of our biochemical data that chronic morphine treatment is associated with prominent structural changes in the VTA, which may underlie some of the long-term behavioral effects of this drug.

## 421.19

**IL-1 $\beta$ , IL-6, AND TNF $\alpha$  DIFFERENTIALLY REGULATE THE SURVIVAL OF FETAL SEROTONIN AND DOPAMINE NEURON *IN VITRO*.** J.H. Gilmore\*, H. Xiao, M.B. Wilkie, J.M. Lauder. Depts. of Psychiatry and Anatomy and Cell Biology, University of North Carolina School of Medicine, Chapel Hill, NC 27599

*In utero* exposure to infection is associated with a variety of neurodevelopmental diseases, including schizophrenia. It is hypothesized that this association is mediated in part by cytokines, as it has been shown that cytokines can regulate neuronal survival and differentiation. The effects of IL-1 $\beta$ , IL-6, and TNF $\alpha$  on neuronal survival were studied as these cytokines have systemic effects and their concentrations in maternal and fetal blood, as well as in amniotic fluid, are altered in pregnancies complicated by infection. Dissociated cell cultures of rat embryonic day 14 rat substantia nigra (SN) and rostral raphe (RR) were grown for two days in the presence of three concentrations of human or murine rIL-1 $\beta$  or rIL-6 (1, 10, 100 units/ml) or rTNF $\alpha$  (0.1, 1.0, 10 ng). mIL-1 $\beta$  and mTNF $\alpha$  significantly decreased the survival of tyrosine hydroxylase (TH) immunoreactive neurons in SN cultures and 5-HT immunoreactive neurons in RR cultures, while mIL-6 significantly enhanced survival of both neuron phenotypes. All murine cytokines had effects at the lowest concentrations studied. In contrast, human cytokines had no effects on 5-HT neurons and required higher concentrations for effects on TH neurons. These findings suggest that human and murine cytokines have different effects on fetal neurons derived from rats. The results also indicate that these cytokines can regulate the survival of the monoaminergic neurons at physiologically relevant concentrations and provide support for the hypothesis that cytokines play a role in the altered neurodevelopment found in schizophrenia.

## 421.18

**NEUROTROPHIC EFFECT OF NEONATAL PROLACTIN (PRL) TREATMENT ON GROWTH HORMONE-RELEASING HORMONE (GHRH) EXPRESSION IN HYPOTHALAMIC NEURONS OF NORMAL AND AMES DWARF MICE.**

M.L. Romero\* and C.J. Phelps. Neuroscience Training Program and Department of Anatomy, Tulane University School of Medicine, New Orleans, LA 70112.

The absence of pituitary GH and PRL in Ames dwarf mice coincides with reduction in the number of dopaminergic neurons (catecholaminergic area A12; Phelps et al., J. Neuroendocrinology, 1994) and an increase in the number of GHRH-expressing neurons (Phelps et al., Endocrinology, 1993) which project to hypophyseal portal vessels to inhibit PRL and stimulate GH secretion. The increase in GHRH and the reduction in A12 neuron number in dwarfs both occur in the hypothalamic arcuate nucleus (ARC). This observation, combined with evidence in retrograde tract-tracing studies that the total number of ARC projection neurons is not reduced in dwarfs compared to normal mice, led to the hypothesis that ARC neurons that are originally dopamine (DA)-producing switch phenotype during early postnatal development to GHRH-producing cells. In order to test this theory, the present experimental design took advantage of the previous finding that the A12 deficiency can be prevented by treating neonatal dwarfs with PRL (Romero and Phelps, Endocrinology, 1993). This regimen of PRL replacement was repeated, in the expectation that the GHRH population would be reduced by preservation of the A12 cells. Alternatively, increased co-expression of DA and GHRH could occur, and this possibility is also being examined. Dwarf and normal siblings were treated beginning at 12 days postnatally with oPRL (50  $\mu$ g/day) and brains were evaluated by formaldehyde-induced catecholamine fluorescence for DA and immunostaining for mGHRH after i.c.v. colchicine (1.5  $\mu$ g/g). As previously reported, perikaryal fluorescence in A12 was comparable to that in normal mice. However, the number of GHRH<sup>+</sup> cells was significantly ( $p < 0.005$ ) increased in both normal (913 $\pm$ 61) and dwarf (1703 $\pm$ 158) mice, when compared to those observed previously in untreated normal (343 $\pm$ 54) and dwarf (976 $\pm$ 123) mice. This effect appeared to regress 15 d after PRL withdrawal. These results imply that PRL may be neurotrophic for GHRH as well as DA expression in neurons in the hypothalamic ARC. Supported by PHS grant NS35987.

## NEUROTROPHIC FACTORS: RECEPTORS AND CELLULAR MECHANISMS II

## 422.1

**BDNF-MEDIATED DOWN-REGULATION OF TRK-B RECEPTOR PROTEIN AND mRNA IN CULTURED HIPPOCAMPAL NEURONS.** L. Frank, R.M. Lindsay, R. Ventimiglia and J.S. Rudge\*. Regeneron Pharmaceuticals Inc., Tarrytown, New York 10591.

Given the interest in the clinical potential of peptide growth factors to ameliorate neurodegenerative disease, it is important to gain further knowledge about the effects of using such factors at pharmacological doses on CNS neurons. We decided to investigate how the neurotrophins brain-derived neurotrophic factor (BDNF), neurotrophin-3 (NT-3) and neurotrophin-4/5 (NT-4/5) affected the expression of the neurotrophin receptors TrkB and TrkC in responsive neurons. Regulation of Trk receptors was investigated in dissociated cultures of embryonic day 18 (E18) rat hippocampal neurons. Cultures were exposed to 50 ng/ml BDNF, NT-3 or NT-4/5 for 24 h upon plating followed by factor washout. As determined by immunohistochemical staining and phosphotyrosine blotting, the functional responses to acute stimulation with BDNF, NT-3 and NT-4/5, including c-Fos induction and phosphorylation of Trk and ERK proteins, were significantly decreased after 6 days in culture by prior exposure to BDNF. As determined by Western and Northern blot analysis, respectively, there was a parallel down-regulation of TrkB protein as well as trkB and trkC mRNA levels in BDNF pretreated cultures. Exposure to NT-3 or NT-4/5 at the same concentrations as BDNF did not down-regulate any of the measured cellular responses or TrkB protein and/or trkB and trkC mRNA levels. None of these effects were accompanied by any change in total cell number or percentage of NSE positive cells in our cultures, indicating that BDNF has no effect on gross survival of late embryonic hippocampal neurons. The present data show that exposure of developing hippocampal neurons *in vitro* to BDNF produces a long-term functional desensitization to the BDNF, NT-3 and NT-4/5, possibly resulting from down-regulation of TrkB protein and mRNA expression as well as down-regulation of trkC mRNA.

## 422.2

**CNTF INDUCES DOWN-REGULATION OF ITS RECEPTOR AND SIGNAL TRANSDUCTION PATHWAYS *IN VIVO*: NON-EQUIVALENCE WITH PHARMACOLOGICAL ACTIVITY.** P.S. DiStefano\*, T.G. Boulton, J. L. Stark and R.M. Lindsay. Regeneron Pharmaceuticals, Tarrytown, NY 10591.

A hallmark of polypeptide growth factors is ligand-induced down-regulation of cell surface receptors. We addressed this issue with the neurotrophic molecule, ciliary neurotrophic factor (CNTF), *in vivo*. A single injection of CNTF (1.0 mg/kg, s.c.) increased tyrosine phosphorylation of LIFR $\beta$  and gp130, and induction of the immediate-early gene, *c-fos*, in skeletal muscle. Continued administration resulted in down-regulation of CNTFR $\alpha$  mRNA, as well. Injections of CNTF 3-7 hr after an initial injection failed to re-stimulate receptor tyrosine phosphorylation and *c-fos* induction, indicative of a biochemical desensitization of the immediate-early responses to CNTF. When injections were spaced 24 or 48 hr apart, the full induction of immediate-early responses was once again obtained. Cross-desensitization experiments showed that a prior exposure to LIF, which does not utilize CNTFR $\alpha$ , resulted in desensitization to stimulation with CNTF in muscle and DRG; however, CNTF did not cause desensitization to LIF, suggesting that biochemical desensitization mechanisms may lie downstream from the specific CNTF receptor (CNTFR $\alpha$ ). To determine if the CNTF-induced down-regulation of CNTF receptor and immediate-early responses resulted in a functional desensitization, we assessed the ability of multiple daily injections of CNTF to prevent the denervation-induced atrophy of skeletal muscle (Helgren et al, 1994). Surprisingly, injections of CNTF every 6 hr, which falls within the putative refractory period for biochemical responses, resulted in equal or greater efficacy compared to once-daily injections. These results suggest that, although CNTF down-regulates its entire signal transduction system, biological signals continue to be recognized and interpreted by the cell.

## 422.3

**TRUNCATED TRKB RESTRICTS BDNF AVAILABILITY DURING DEVELOPMENT: EXPRESSION PATTERN AND BIOCHEMICAL PROPERTIES.** S. Biffi\*, B. Carter, N. Offenhäuser, and Y.-A. Barde. DIBIT. Istol. Molec., V. Olgettina 58, 20132, Milano, ITALY; MPI. Dept. Neurobiochem. 82152 Martinsried, FRG..

BDNF (Brain-derived neurotrophic factor) plays an important role in neuronal survival. Its biological effect is mediated by the tyrosine kinase receptor trkB that is expressed by a variety of neurons during development. Truncated trkB molecules lacking the tyrosine kinase domain have also been described, but their functions remain elusive. In order to gain insight into their role, we studied the pattern of expression and properties of these truncated receptors in the chick embryo. Truncated trkB mRNA was detected already early during neurogenesis, and in situ hybridisation experiments indicated that the expression was in non-neuronal cell. Ependymal and leptomeningeal cells expressing truncated trkB completely surrounded the developing brain and the spinal cord throughout development. In the otic vesicle, mesenchymal cells expressing truncated trkB surround cells producing BDNF, as well as neurons expressing trkB with its tyrosine kinase domain. Non-neuronal cells were found not to express trkB mRNA coding for the tyrosine kinase domain. Studies with radiolabelled BDNF performed on frozen sections of the chick embryo and on freshly dissociated leptomeningeal cells revealed that non-neuronal cells expressing truncated trkB bind BDNF with high affinity and selectivity. In addition, experiments with dissociated leptomeningeal cells showed that BDNF binding is rapidly followed by its internalisation. Finally, the cytoplasmic sequence of chick truncated trkB is highly homologous to the mammalian, thus suggesting a common signal transducing pathway. The yeast interaction trap/2-hybrid system is currently being used to detect possible interactors of truncated trkB. Taken together, our results suggest that truncated trkB forms an efficient and selective barrier preventing the diffusion of BDNF and eliminating it by internalisation. This barrier might be necessitated by the multiplicity of developing structures producing BDNF, and by the large number of diverse neuronal populations responding to it.

## 422.5

**REGULATION OF CEREBELLAR GRANULE CELL DEVELOPMENT BY BDNF AND DEPOLARISATION.** E. T. Coffey\*, K. E. O. Åkerman and M. J. Courtney. Dept. of Biochemistry and Pharmacy Åbo Akademi University, Turku, Finland.

Cerebellar granule cells in serum-based culture are a much exploited system for the study of neuronal development. They are particularly suited for studying the intracellular signalling pathways underlying neuronal development as they can be prepared in large quantities; however, this aspect has been little studied. Their survival is known to be regulated by elevation of intracellular calcium levels by, for example, depolarising culture conditions. We are investigating the regulation of neurotrophic factors and depolarisation on neuronal development and the signalling cascades involved. Development is measured at the level of (i) cell survival and (ii) expression of neurite and synaptic proteins. Cell survival is measured by cell permeant and impermeant DNA dyes, and expression of proteins such as synaptophysin,  $\beta$ -tubulin, tau, GAP-43 and c-Fos and tyrosine phosphorylation levels are measured by immunoblotting.

We have observed that death of cells grown in non-depolarising conditions, which is reported to be apoptotic, is not prevented by the presence of BDNF, NGF, or NT-3; glutamate-evoked neuronal death, however, is reduced by BDNF. Moreover, BDNF increases synaptophysin expression. We have also observed that BDNF evokes rapid tyrosine phosphorylation of a number of proteins and elevated expression of the immediate early gene, c-Fos. The basal level of expression of c-Fos in these cells appears to be developmentally regulated, peaking at 3 days in vitro; this peak is further increased by the presence of BDNF.

We conclude that BDNF modulates neuronal development in a specific manner, affecting the levels of a component of synaptic machinery and certain forms of cell death, but not apoptotic cell death.

## 422.7

**TRK B ACTIVATION IN SCIATIC NERVE DETECTED WITH PHOSPHORYLATION STATE-SENSITIVE ANTIBODIES TO SH2 RECOGNITION SITES.** A. Bhattacharyya\*, R.A. Segal, L. Rua, K.S. Thress, S.L. Pomeroy and C.D. Stiles. Dept. Micro. & Molec. Genetics, Harvard Medical School and Dana-Farber Cancer Institute; Dept. Neurology, Harvard Medical School, Beth Israel Hospital and Children's Hospital, Boston MA 02115.

Using synthetic tyrosine phosphopeptides as immunogens, we generated a panel of antibodies that report the phosphorylation state of four tyrosines common to the cytoplasmic domain of the high affinity neurotrophin receptors, Trks A, B and C. The targeted tyrosines are known autophosphorylation sites for Trk A *in vitro*. Two of them (corresponding to Y674/675 in Trk A) are within the catalytic domain. The other two (Y490 and Y785 in Trk A) flank that domain and, in the phosphorylated state, serve as recognition sites for SHC and PLC- $\gamma$ .

These positionally specific antiphosphotyrosine antibodies allow us to ask fundamental questions about Trk signaling in primary neuronal cell cultures and complex nervous tissue such as sciatic nerve that cannot be resolved using conventional antibodies and labeling protocols. By immunoprecipitating normal sciatic nerve extracts from adult rats with anti-Y490, we can detect Trk B phosphorylated at the SHC recognition site. When BDNF is injected into the hindleg muscle of these rats, we detect an increase in Trk B phosphorylation at the SHC recognition site. In nerves that are cut prior to BDNF injection, the Trk B phosphorylation is decreased, verifying that the Trk B activation is due to signals coming through the nerve.

## 422.4

**EXPRESSION OF CNTF RECEPTOR  $\alpha$  IN NORMAL, DENERVATED, AND DYSTROPHIC HUMAN SKELETAL MUSCLE.**

J. Weis\*, D. C. Lie<sup>1</sup>, P. C. Heinrich<sup>1</sup>, H.-G. Joost<sup>1</sup>, G. D. Yancopoulos<sup>2</sup>, J. M. Schröder<sup>1</sup>. Technical University<sup>1</sup>, Aachen, Germany, and Regeneron Pharmaceuticals<sup>2</sup>, Tarrytown, NY.

Ciliary Neurotrophic Factor (CNTF) is a trophic factor for a variety of cell types including motor neurons and a candidate molecule for the treatment of human motor neuron diseases. Within the tripartite CNTF receptor complex, CNTFR $\alpha$  is the component specific for CNTF. CNTFR $\alpha$  can be released from the cell surface; soluble CNTFR $\alpha$  is still bioactive. CNTFR $\alpha$  is crucial for the effects of CNTF. However, its expression pattern in normal, denervated and dystrophic human muscle is unknown.

In muscle biopsies from 5 normal subjects, 12 cases of neurogenic muscular atrophy, and 7 cases of Duchenne muscular dystrophy, CNTFR $\alpha$  mRNA levels were determined by Northern blotting. Transcript levels were markedly increased in denervated muscle compared to controls and dystrophic muscle.

These results suggest that the expression of CNTFR $\alpha$  is regulated by innervation. This regulation appears to be selective, because CNTFR $\alpha$  mRNA was not increased in dystrophic human muscle. Increased CNTFR $\alpha$  could confer higher sensitivity to CNTF on denervated muscle fibers and other cell types involved in nerve fiber regeneration.

## 422.6

**REGULATION OF CILIARY NEUROTROPHIC FACTOR RECEPTORS ON DIFFERENTIATING NEUROBLASTOMA CELLS.** R. Malek\* and S.W. Halvorsen. Dept. of Biochem. Pharmacol. State Univ. of New York at Buffalo, Buffalo, NY 14260.

The cytokine, CNTF, is a putative injury response/target derived trophic factor for motor, CNS, sensory and autonomic neurons. The SH-SY5Y neuroblastoma cell line serves as an *in vitro* model for studying the regulation of CNTF receptor expression during neuronal differentiation. We used retinoic acid, 12-O-tetradecanoyl-phorbol-13-acetate (TPA) or cAMP to differentiate SH-SY5Y cells. We found differences between retinoic acid and TPA induced differentiation manifested in the regulation of <sup>125</sup>I-CNTF binding whereas cAMP treatment had no effect on CNTF binding. Retinoic acid caused a two-fold increase in CNTF binding after 24 hours while TPA induced a transient 30% decrease in CNTF binding after 3-5 hours that recovered to control levels after 7 hours. In addition, the retinoic acid induced increase in CNTF binding could be prevented by either cycloheximide or actinomycin D, whereas neither inhibitor prevented the TPA induced decrease in CNTF binding. However, the PKC inhibitor, bisindolylmaleimide, prevented the TPA induced decrease in CNTF binding, consistent with PKC involvement in regulating CNTF binding levels. These results suggest retinoic acid and TPA regulate CNTF binding by different mechanisms. We are further analyzing retinoic acid and TPA effects to determine if the molecular mechanisms involve changes in expression of the receptor subunits, CNTFR $\alpha$ , LIFR $\beta$  and gp130 at either the protein or mRNA level.

## 422.8

**SIGNAL TRANSDUCTION OF TRKB IN PC12 CELLS.** Y. Iwasaki and S. Koizumi\*. Bio-organics Res. Dept., International Research Laboratories, CIBA-GEIGY (Japan) Ltd., Takarazuka 665, Japan.

A cell line expressing mouse *trkB* was established from PC12 cells to investigate the signal transduction of TrkB, a receptor of brain-derived neurotrophic factor (BDNF). The TrkB/PC12 cells responded to BDNF as well as nerve growth factor (NGF) by neurite outgrowth. However, the BDNF-induced morphological changes of TrkB/PC12 cells were markedly different from that induced by NGF. Cells treated with BDNF for 48 hr exhibited intensive somatic hypertrophy with longer and thicker neurites compared with NGF-treated cells at the same time point. This is not due to the overexpression of TrkB because the extent of BDNF-induced TrkB autophosphorylation was almost the same as NGF-induced TrkA autophosphorylation in this cell line. The tyrosine phosphorylation of signal proteins such as PI3 kinase, PLC $\gamma$ , Shc and MAP kinase was stimulated by both BDNF and NGF treatments. However, a 38 kDa tyrosine-phosphorylated protein which was co-immunoprecipitated with TrkA after NGF treatment of the cells was not associated with TrkB stimulated by BDNF. These data suggest that the intracellular signals from TrkB are not completely the same as TrkA, even though they share the most of known signal transduction pathways.

## 422.9

NATURALLY-OCCURRING TRUNCATED TRKB RECEPTORS HAVE DOMINANT INHIBITORY EFFECTS ON BDNF SIGNALLING. F.F. Eide\*, B.L. Eide, K. Zhang, X.-Y. Wang and L.F. Reichardt. Dept. of Physiology, U. of California, San Francisco, San Francisco, CA 94143.

A *Xenopus* oocyte microinjection assay was used to study the signalling properties and interactions of gp145trkB, and its naturally-occurring kinase-deficient isoforms, trkB.T1 and trkB.T2. When either trkB.T1 or trkB.T2 were co-expressed with gp145trkB, they inhibited BDNF-induced <sup>45</sup>Ca<sup>2+</sup> efflux responses. Quantitative tyrosine phosphorylation studies revealed that the truncated isoforms inhibited the BDNF signal by forming non-functional heterodimers with full-length receptors. An ATP binding mutant of gp145trkB had similar dominant inhibitory effects.

Our data suggest that naturally-occurring truncated trkB receptors function as inhibitory modulators of neurotrophin responsiveness. Furthermore, the homodimerization of gp145trkB appeared to be an essential step in the activation of the BDNF signalling cascade.

## 422.11

**Identification and characterization of receptor recognition sites of ciliary neurotrophic factor (CNTF)**  
Makoto Inoue, Kaoru Kikuchi, Tohru Tatsuno\*, Chikao Nakayama and Hiroshi Noguchi

Sumitomo Pharmaceuticals Research Center, 1-19, Kasugadenaka 3-chome, Konohana-ku, Osaka 554, Japan

Human ciliary neurotrophic factor (hCNTF) was subjected to tertiary structure modeling and site-directed mutagenesis to analyze its structure-function relationship. Cell survival activities and receptor binding abilities of hCNTF mutants, constructed from the PCR mutagenesis, were determined in an assay system of chick DRG neuron and human neuroblastoma cells (SH-SY5Y), respectively. The substitution of D1 cap region (around the boundary between the CD loop and helix D) of hCNTF, including both E153 and K155, resulted in drastic change of cell survival activity<sup>1</sup> but not of receptor binding ability reflecting low-affinity binding. K155 could not permit any substitutions for cell survival activity, and some E153 mutants had increased biological activity. On the other hand, the substitution of Q63 to R resulted in increment of both cell survival activity<sup>2</sup> and low-affinity receptor binding ability. That is, "siteI" around Q63 residue and "siteII" around the D1 cap region participates in low-affinity receptor binding and high-affinity receptor binding, respectively. Whereas, V170 in helix D also participates in receptor binding for its hydrophobic character. Many regions of hCNTF are responsible for receptor binding. Those were grouped and expected to be the binding sites correspond to respective receptor components.

## 422.13

IDENTIFICATION OF FUNCTIONAL CILIARY NEUROTROPHIC FACTOR RECEPTORS ON CHICK CILIARY GANGLION NEURONS. S. Koshlukova\*, I. Finn, R. Nishi and S. W. Halvorsen. Dept. Biochem. Pharmacol., SUNY at Buffalo, Buffalo, NY 14260 and Dept. of Cell Biol. and Anat., OHSU, Portland, OR 97201.

Embryonic ciliary ganglion neurons in culture are the fundamental system used to define the ciliary neurotrophic factor (CNTF)/growth promoting activity (GPA) family of factors, yet despite extensive efforts, their receptors have not been detected nor have their biological mechanism(s) been elucidated on these cells. We have examined the interaction of CNTF with its receptors by performing binding studies on ciliary ganglion neurons and have begun to characterize the intracellular pathways activated. <sup>125</sup>I-rat CNTF binding indicate that rat CNTF and avian GPA bind to neurons with a single affinity, while human CNTF recognizes the same sites with both a high and a low affinity. Comparison of the relative potency in biological assays indicates that GPA is 3-5 times more active than human CNTF in promoting survival and in regulating acetylcholine receptors. The binding of CNTF is specific, sensitive to phosphatidylinositol-specific phospholipase C (PI-PLC) and partially inhibited by leukemia inhibitory factor, but not by other members of the cytokine/neurokinin family including interleukin-6, interleukin-11 and oncostatin M. Cross-linking of <sup>125</sup>I-rat CNTF to ciliary neurons results in the specific labeling of three proteins with estimated molecular masses of 153, 81 and 72 kDa. The 81 kDa component was released from the cells after treatment with PI-PLC, suggesting a membrane attachment via a glycosylphosphatidylinositol linkage. Stimulation with CNTF or GPA for 5 minutes results in the tyrosine phosphorylation of a 90 kDa protein. Consistent with the binding and cross-linking data the phosphorylation is inhibited by pretreatment with PI-PLC and is not stimulated by the other cytokines. In conclusion, we report here pharmacological and functional properties of CNTF receptors on embryonic ciliary ganglion neurons. Our results provide the means for using chick ciliary ganglia for elaborating the molecular mechanisms of CNTF/GPA action and understanding their physiological role in a defined neuronal population.

## 422.10

Functional importance of the amino termini of neurotrophins. Gene Burton\*, Charles Schmelzer, Mike Sadic, Franz Hefti, James Treanor. Department of Neuroscience, Department of Recovery Process, Bioanalytical Technology, Genentech, 640 Pt San Bruno Blvd, S. San Francisco CA 94080

The neurotrophin family consists of a group of highly conserved small basic proteins, including nerve growth factor (NGF), brain-derived neurotrophic factor (BDNF), neurotrophin-3 (NT-3) and neurotrophin-4/5 (NT4/5). These molecules are critical for the development and maintenance of a wide range of neuronal populations in both the peripheral and central nervous system. The proteins exert their biological effects through interactions with two types of cell surface receptor, a family of selective tyrosine kinase (trk) receptors and a promiscuous 75kDa receptor (p75). Physical and mutagenesis studies have identified regions of NGF and NT-3 important in their receptor interactions.

This study attempts to investigate the role of the amino terminus by analyzing a battery of proteolytically cleaved or heterodimeric neurotrophin molecules. Neurotrophins contain a conserved proteolytic cleavage site several residues from the NH<sub>2</sub>-terminus. NH<sub>2</sub>-terminally truncated NGF ( $\Delta$ 5-NGF and  $\Delta$ 9-NGF), BDNF ( $\Delta$ 6-BDNF), NT-3 ( $\Delta$ 5-NT3 and  $\Delta$ 7-NT3) and NT4/5 ( $\Delta$ 10-NT4/5) were generated. Heterodimers of NGF and  $\Delta$ 9-NGF, NT4/5 and  $\Delta$ 10-NT4/5 and  $\Delta$ 9-NGF and NT4/5 were also made. These hybrid molecules were analyzed and compared to wild-type homodimeric neurotrophins in their interactions with both their cognate trk receptor and the p75 receptor. Phosphorylation of trk receptors by these molecules were also analyzed using a novel kinase-immunosorbant receptor assay (KIRA). The results suggest that the amino terminus of all neurotrophins is a critical binding domain for tyrosine kinase receptor but not p75 receptor interactions. The presence of a single intact amino terminus within the confines of the native dimer is sufficient to endow the hybrid molecule with almost wild type trk receptor affinity and signalling capability.

## 422.12

EFFECT OF p140<sup>trkA</sup> SUPPRESSION ON NGF AND BDNF RESCUE OF APOPTOTIC PC12 CELLS. G. Tagliatela\*, K. Wernbach-Perez, R. Perez-Polo. Dept of HBC&G, Univ. of Texas Med. Branch at Galveston, TX 77550.

Programmed cell death, the intrinsic form of apoptosis, plays an integral role in those neurodegenerative events associated with age-related neuropathology. Neurotrophins (NT) such as nerve growth factor (NGF), brain derived neurotrophic factor (BDNF), and NT-3 are required for survival of certain CNS neurons, although mechanistic descriptions for NT cell rescue from apoptosis are not definitive. Here we isolated the individual actions of high-affinity tyrosine kinase (Trk) receptors and p75<sup>NFR</sup>, the common low-affinity NT receptor, in NT rescue of apoptotic PC12 cells. Our results showed that the inhibition of Trk receptor phosphorylation abolishes NGF rescue of serum-deprived PC12 cells from apoptosis, but that TrkA suppression with antisense oligonucleotides did not. Also, while BDNF did not rescue naive serumless PC12 cells which lack the BDNF-specific trkB receptor, it significantly increased survival of TrkA-suppressed serum-starved PC12. These data support the hypothesis that while binding of any neurotrophin to Trk-free p75<sup>NFR</sup> bearing PC12 cells blocks apoptosis, reducing cognate ligand binding or Trk phosphorylation in Trk-bearing PC12 cells inhibits cell rescue. Supported by the AFAR and by NIH grant NS18708. This is publication no. 34A of the PPG AG10514 awarded by NIA.

## 422.14

EFFECTS OF GM1 GANGLIOSIDE ON Trk B RECEPTOR EXPRESSION IN MPTP-TREATED MICE. Carl Chiang\* and J.S. Schneider. Depts. of Anat. and Neurobiol. and Neurology, MCP and Hahnemann University, Philadelphia, PA 19102.

While previous work in our laboratory has shown that GM1 ganglioside treatment promotes biochemical and behavioral recovery in MPTP models of Parkinson's disease, the mechanism through which GM1 exerts its effect is unknown. One hypothesis suggests that GM1 may influence the nigrostriatal dopamine (DA) system indirectly through regulation of neurotrophic factors and/or their receptors. Specifically, brain-derived neurotrophic factor (BDNF) has been shown to increase the survival of DA neurons in vitro, both alone and in concert with GM1. In the present study, we used *in situ* hybridization (<sup>35</sup>S-labeled cRNA probe) to examine GM1 effects on the BDNF receptor, Trk B, in the mouse model of MPTP-induced parkinsonism. Mice were divided into three groups: MPTP (20 mg/kg s.c., 4x/day, 1 day) and subsequent GM1 (30 mg/kg i.p., 1x/day, 7 days), MPTP/saline, and untreated controls. Our preliminary data shows that, compared to controls, Trk B mRNA is almost absent in cells of the dorsomedial and ventromedial caudate and downregulated in the medially adjacent septal nucleus of MPTP/saline mice. In contrast, MPTP/GM1 mice showed an upregulation of Trk B mRNA in these three areas compared to control, indicating that GM1 may upregulate Trk B expression above normal levels after MPTP lesions. Interestingly, sparse labeling for Trk B was seen in the substantia nigra pars compacta (SNc) of normal and lesioned mice, unlike data reporting high levels of expression in normal rat SNc. It is possible that GM1 effects on Trk B expression in the striatum may relate to BDNF rescue of DA neurons and/or normalization of striatal neuronal function as a consequence of GM1 treatment. Further studies are ongoing to elucidate the nature of GM1's influence on BDNF and its receptor and the nigrostriatal DA system. Supported by NIH grant AG 10280.

## 422.15

DEVELOPMENTAL EXPRESSION AND DOWNREGULATION OF THE  $\alpha$  COMPONENT OF CHICK CNTF RECEPTOR IN DENERVATED SKELETAL MUSCLE. E.C.F. Ip, A.K.Y. Fu, K.W. K. Tsim and N.Y. Ip\*. Department of Biology, Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong.

A full length cDNA clone encoding for the chick CNTFR $\alpha$  (362 amino acids) was isolated by screening an embryonic day 13 chick brain cDNA library with a rat CNTFR $\alpha$  probe. The designation of this clone as chick CNTFR $\alpha$  was based on its relatively high homology in amino acid sequence (~70%) with the rat and human CNTFR $\alpha$ . While the carboxyl terminus of the chick CNTFR $\alpha$  exhibits the least degree of identity as compared to mammalian CNTFR $\alpha$ , the chick CNTFR $\alpha$  also lacks the cytoplasmic domain. The expression of chick CNTFR $\alpha$  was examined in various tissues at different developmental stages of the chick by Northern blot analysis. A single transcript encoding for the chick CNTFR $\alpha$  was detected in neural tissues such as brain and spinal cord, and in the skeletal muscle of the periphery. The level of the chick CNTFR $\alpha$  transcript in these tissues was found to be developmentally regulated. In addition, the expression of the chick CNTFR $\alpha$  in skeletal muscle was dramatically decreased by ~10-fold at 36 hours after denervation. Downregulation of the chick CNTFR $\alpha$  transcript was observed in different types of leg muscle examined, albeit with different time course. This is in sharp contrast to the result previously obtained with CNTFR $\alpha$  in denervated rat muscle.

## 422.17

INDUCTION OF FULL-LENGTH TrkB AND TrkC EXPRESSION IN THE ADULT SPINAL CORD. Connor, H., Palm, K., Neuman, T., Nornes, H.O.\*. Department of Anatomy and Neurobiology, Colorado State University, Fort Collins, CO 80523.

The neurotrophic factor system is downregulated in the adult nervous system in comparison to its expression during development. In regions of low plasticity, such as in the spinal cord, a truncated form of TrkB is expressed, and TrkC is expressed at low levels. Since lack of functional receptors for neurotrophic factors could contribute to lack of regeneration of the adult CNS, we studied the possibility of inducing TrkB and TrkC in the adult spinal cord. Analysis of promoter sequences of BDNF and TrkB and transient CAT assays demonstrated that these genes have response elements to retinoids, cyclic AMP and elevated levels of Ca<sup>2+</sup>. All these response elements function in different types of neuronal cells to stimulate expression of BDNF and TrkB genes. Based on this molecular analysis, we treated the adult spinal cord with the combination of all-trans retinoic acid (10  $\mu$ M), dibutyryl cAMP (2mM) and KCl (50mM) using intraspinal cannulation at a flow rate of 5  $\mu$ l/hr. Eight hours posttreatment, RNase protection analysis shows a 10x increase in full length TrkB and a 35x increase in TrkC expression. Experiments are in progress to determine if the induction of the neurotrophic factor receptors promotes survival and regeneration of lesioned neurons. (Supported by the Spinal Cord Society).

## 422.19

BONE MORPHOGENETIC PROTEIN-2 AND RETINOIC ACID SYNERGISTICALLY INDUCE TrkC RECEPTOR IN CULTURED SYMPATHETIC NEURONS. I. Matsuo\*, M. Kobayashi, and K. Kurihara. Faculty of Pharm. Sci. Hokkaido Univ. Sapporo 060 Japan

Sympathetic neurons undergo a developmental switch in trophic factor dependence from NT-3 to NGF by the sequential expression of trkC and trkA receptors. Recently, it was reported that both NT-3 and NGF promote the switching of neurotrophin dependence. However, the mechanism controlling the expression of trkC receptor at the initial developmental stage has not been clarified. Our previous work indicated that retinoic acid (RA) induces functional trkB receptor while it suppresses the trkA receptor expression in cultured sympathetic neurons isolated from superior cervical ganglia (SCG) of newborn rats. In the present study, by using RT-PCR, we examined further the effects of RA and members of TGF $\beta$  super family on the expression of trk receptors of the SCG neurons in culture. Treatment of the SCG neurons with BMP-2 (bone morphogenetic protein-2, 5 ng/ml) in the presence of NGF for 6 days induced the expression of trkC-mRNA without affecting the trkA-mRNA level. RA (100 nM) and activin A (5 ng/ml) had smaller effects on the induction of trkC-mRNA, while bFGF and TGF $\beta$  had no effect. RA enhanced the effect of BMP-2 on the trkC-mRNA induction 6-fold, while BMP-2 enhanced the RA-suppression of the trkA-mRNA level. Induction of functional trkC receptor was confirmed by the increase in the number of neurons surviving on NT-3 from 3% to 64% of the original population after the BMP-2/RA-pretreatment. These results suggest that BMP and RA *in vivo* synergistically induce the NT-3-dependence of developing sympathetic neurons.

## 422.16

INCREASED EXPRESSION OF trkB mRNA IN RAT CAUDATE-PUTAMEN FOLLOWING 6-OHDA LESIONS OF THE NIGROSTRIATAL PATHWAY. S. Numan\* and K.B. Seroogy. Department of Anatomy & Neurobiology, University of Kentucky, Lexington, KY 40536.

The tyrosine kinase receptors trkB and trkC are high affinity receptors for members of the neurotrophin family, including brain-derived neurotrophic factor (BDNF) and neurotrophin-3 (NT-3), respectively. Both neurotrophin receptor mRNAs are broadly distributed throughout the caudate-putamen. Loss of dopaminergic nigrostriatal afferents has been shown to alter the expression of peptides, neurotransmitter-synthesizing enzymes, and receptors in striatal neurons. To determine if expression of trkB and trkC mRNAs is also regulated by the integrity of dopaminergic afferents, adult rats received a unilateral injection of 6-hydroxydopamine (6-OHDA), a selective catecholamine neurotoxin, or vehicle into the ascending medial forebrain bundle. Following a two-week survival period, *in situ* hybridization with <sup>35</sup>S-labeled cRNA probes for trkB and trkC mRNAs was performed in striatal sections. A significant increase in the hybridization density for trkB mRNA was observed in the caudate-putamen ipsilateral to the 6-OHDA injection, as compared to the uninjected control side ( $P < .001$ ). In contrast, no alteration in the hybridization density for trkC mRNA was observed in the striatum of 6-OHDA-treated rats. Furthermore, no alterations in trkB or trkC mRNA levels were observed in the striatum of vehicle-treated animals. These data suggest that midbrain dopaminergic afferents selectively regulate the expression of trkB mRNA in the caudate-putamen. Alternatively, since BDNF is expressed by midbrain dopamine neurons, the increased expression of trkB mRNA in the striatum may reflect a compensatory response of striatonigral projection neurons due to a loss of target-derived trophic support. Supported by NIMH fellowship MH10806 (S.N.) and the National Parkinson Foundation (K.B.S.).

## 422.18

SITE DIRECTED MUTAGENESIS OF THE TRKB RECEPTOR TYROSINE KINASE. Joseph H. McCarty and Stuart C. Feinstein\*. Neuroscience Research Institute, University of California, Santa Barbara, CA 93106.

The trkB protein tyrosine kinase is a high affinity receptor for the neurotrophins BDNF and NT-4/5. Neurotrophin binding to the trkB extracellular region leads to activation of the receptor's intracellular tyrosine kinase domain, resulting in the rapid and transient autophosphorylation of specific tyrosine residues. This activation initiates a series of poorly understood cytoplasmic and nuclear signal transduction events, which lead to differentiative or proliferative responses, depending on the cellular context.

In order to assess the functional roles of known autophosphorylation sites, we have constructed a panel of tyrosine to phenylalanine substitutions within the intracellular region of trkB. Specifically, substitutions were introduced at the single juxtamembrane phosphorylation site (Y484F), within the proposed "regulatory region" of the kinase domain (Y670/674/675F), and at the lone carboxy terminal tyrosine residue (Y785F). Transfectants stably expressing each of these mutant constructs have been generated. The functional consequences of each point mutation on specific gene inductions will be presented. Supported by American Heart Association #94-421.

## 422.20

DISTINCT BIOCHEMICAL PROPERTIES AND SURVIVAL EFFECTS BDNF AND NT-3 ON CULTURED CEREBELLAR GRANULE CELLS. T. Nonomura, K. Shimoke, T. Oka, M. Yamada, T. Kubo and H. Hatanaka\*. Institute for Protein Research, Osaka Univ., 3-2 Yamadaoka, Suita, Osaka 565, Japan.

Brain-derived neurotrophic factor (BDNF) and neurotrophin-3 (NT-3), interact with receptor tyrosine kinases, TrkB and TrkC, leading to various intracellular signaling events and the trophic actions. We investigated the signaling pathways exerted by BDNF and NT-3 in relation to their survival promoting effects on dissociated cultures of cerebellar granule cells prepared from postnatal 9-day-old (P9) rats. The granule neurons in culture were strongly supported for their survival by BDNF, but not significantly by NGF nor NT-3. BDNF and NT-3 treatments resulted in not only respective autophosphorylation of TrkB and TrkC receptors but also tyrosine phosphorylation of SHC, a protein involved in controlling p21<sup>ras</sup> activity, and p42 and p44 proteins of mitogen-activated protein kinases (MAPKs). NT-3 induced the tyrosine phosphorylation of these proteins to a lesser extent than BDNF did, which might reflect the difference of expression level between trkB and trkC. We also observed transient induction of c-fos mRNA by BDNF and NT-3. However, NT-3 did not absolutely induce the tyrosine phosphorylation of phospholipase C $\gamma$  (PLC $\gamma$ ), while BDNF promoted the phosphorylation of PLC $\gamma$ .

The characteristics of signaling and survival effects of NT-3 on the granule neurons indicate a correlation with biochemical properties of insert-containing forms of TrkC (TrkC(ki)) when expressed in cell lines. Our present studies may provide the first evidence for the inhibitory function of TrkC(ki) that was demonstrated in primary CNS neurons.

## 422.21

CROSS-TALK BETWEEN THE PTPase SH-PTP2 AND TrkB. B.A. Goldsmith\*, N. Okada and S. Koizumi. Bio-organics Res. Dept., Int'l Research Laboratories, Ciba Geigy (Japan) Ltd., Takarazuka 665, Japan.

Increasing evidence suggests that protein tyrosine phosphatases (PTPases) play important roles in regulating signal transduction by growth factor receptors. One class of PTPases contains Src homology 2 domains (SH2) which may target these PTPases to activated growth factor receptors. Such localization may result in specific dephosphorylation of receptors or associated tyrosine-phosphorylated proteins. Localization may also result in tyrosine phosphorylation of PTPases by activated receptors, thus modulating PTPase activity. The SH2-containing PTPase SH-PTP2 has been found to associate with activated growth factor receptors and is tyrosine phosphorylated by receptor activation. However, interaction of SH-PTP2 with the Trk receptor family has not been characterized.

We have examined the interaction between SH-PTP2 and TrkB by utilizing an expressed intracellular kinase domain of TrkB (ICD-TrkB) and a GST fusion protein of SH-PTP2. We found that autophosphorylated ICD-TrkB (pICD-TrkB) associates *in vitro* with the SH-PTP2 fusion protein. In the presence of ATP and  $Mg^{2+}$ , SH-PTP2 is rapidly phosphorylated on tyrosine residues by pICD-TrkB. In the absence of ATP and  $Mg^{2+}$ , pICD-TrkB is rapidly dephosphorylated by SH-PTP2. Additionally, SH-PTP2 phosphorylated by pICD-TrkB can undergo autodephosphorylation to reverse tyrosine phosphorylation. Our results demonstrate that TrkB effectively phosphorylates SH-PTP2 and that pICD-TrkB is a target of SH-PTP2 activity. Phosphorylation of SH-PTP2 may modulate the ability of SH-PTP2 to dephosphorylate or associate with its targets. Our evidence suggests that cross talk between TrkB and SH-PTP2 may play a role in modulating signal transduction by TrkB.

## HORMONES AND DEVELOPMENT II

## 423.1

NO SUPPRESSION OF GROWTH HORMONE PULSATILITY IN EXERCISING PREGNANT HAMSTERS. S. Yeo, K. Borer\*, G. Beherent, and D. Mauger The University of Michigan, Ann Arbor, MI 48109-0482

In human pregnancy, pulsatile secretion of pituitary growth hormone (GH) ceases by mid gestation due to progressive increase in tonic secretion of a placental growth hormone variant. This hormonal adaptation may interfere with phenomena induced by exercise or food restriction. Pituitary GH takes a critical role linked to these phenomena. Previously we reported that Golden Syrian hamsters expressed somatic growth due to increased exercise-induced GH secretion in the presence of abundant food. When food was restricted, expression of exercise-induced growth was not observed. To determine whether pregnancy in hamsters blocks pituitary GH secretion, forty-seven Golden Syrian female hamsters were assigned to eight groups differing in three variables: pregnancy, food availability, and exercise. Voluntary exercise started 10 days prior to mating and continued through gestation (about 15 days). Food was restricted in REST group by 10% until mating, and by 20% through the remainders of gestation. Lighting was off at 14:00 h and on at 00:00 h. Hamsters were cannulated on day 13 of gestation and 24 hours blood sampling was performed on day 15. During the 24 h sampling, 20  $\mu$ l of blood was collected every 15 min. GH concentrations were measured in the homologous RIA for hamster GH. Cluster analysis and ANOVA were applied to log-transformed GH data. We found that exercise increased average GH concentration in both pregnant and non-pregnant hamsters ( $p=0.08$ ). Increase in GH pulsatility was expressed most strongly when exercising hamsters were fed ad libitum ( $p=0.0563$ ) than when their food was restricted (REST) ( $p=0.8$ ). Exercising hamsters indicated a higher increase (22.96 ng/ml) than sedentary animals (17.42 ng/ml) of GH concentration. We conclude that in the hamsters, pregnancy does not block exercise-induced increase in the GH pulsatility. However unlimited food intake is necessary to induce GH increases. Thus secretion of a placental GH variant probably does not occur in pregnant hamsters. (Supported partially by the Office of Vice President for Research University of Michigan and NIH, 1K07NR00047-01A1).

## 423.3

DEVELOPMENTAL CONSEQUENCES OF *IN UTERO* EXPOSURE TO 2,3,7,8-TETRACHLORODIBENZO-P-DIOXIN (TCDD): COMPARISONS WITH THE THYROID HORMONE INHIBITING AGENT PROPYLTHIOURACIL (PTU) AND THE ALKYLATING AGENT BUSULFAN (BU) IN THE LONG-EVANS RAT. D.B. Müller\*, J.P. O'Callaghan and L.E. Gray. U.S. Environmental Protection Agency, Research Triangle Park, NC 27711

Recent work (Gray et al., Toxicol. Appl. Pharmacol. 131, 1995; Mably et al., Toxicol. Appl. Pharmacol. 114, 1992) indicates marked reproductive abnormalities are produced in offspring of dams exposed to TCDD on gestational day (GD) 8 or 15 but there is little information on the consequences of these treatment regimens for brain development. To determine the impact of GD15 exposure to TCDD on brain development, offspring of TCDD dams were compared to offspring of dams treated with agents known to compromise development of the CNS by interfering with the actions of thyroid hormone (PTU) or by direct cytotoxicity to dividing cells (BU). Long-Evans dams received TCDD (1  $\mu$ g/kg) on GD-8 or 15, BU (5 or 10 mg/kg) on GD15 or PTU (0.8 or 8.8 mg/kg) in the drinking water from GD-15 through PND21. All 3 agents reduced body size. BU and PTU produced major reductions in brain size. TCDD produced minor decreases in brain size. Measurement of GFAP, the astrocyte-localized protein was used to evaluate the ontogeny of astrocytes as well as determine if these compounds would produce reactive gliosis, a reaction indicative of injury. GFAP changes were evident in offspring of dams treated with PTU and BU but not TCDD. Delayed synaptogenesis, as measured by the synapse-localized protein, synaptophysin, was evident in PTU offspring. Alterations in general motor activity were found with BU but not PTU or TCDD. Decreased cognitive ability, as measured by performance in the Morris water maze, was found with PTU or BU but not TCDD. Gestational exposure to TCDD does not appear to alter brain development in a manner similar to the changes produced by alterations in thyroid hormone or cytotoxicity to dividing cells.

## 423.2

EFFECTS OF PERINATAL HYPOTHYROIDISM ON GENE EXPRESSION OF CYTOCHROME C OXIDASE IN THE RAT CEREBELLUM. N. Koibuchi\*, S. Matsuzaki, H. Ohtake and S. Yamaoka. Dept. of Physiology and Biochemistry, Dokkyo Univ. Sch. Med., Mibu, Tochigi 321-02, Japan.

Neonatal hypothyroidism has been known to dramatically affect neurogenesis of the rat cerebellum. To identify the genes whose expressions are changed in association with perinatal hypothyroidism, we have applied the differential plaque screening method using cDNA library of 15 day-old newborn rat cerebellum. Although we could not isolate novel gene, we cloned cytochrome c oxidase subunit I (COX I) gene, which is located in mitochondrial DNA. Northern blot analysis showed that the expression of COX I gene was decreased in the cerebellum of the rats, which had been rendered hypothyroid by administering 0.05% methimazole in drinking water to their mothers. This decrease was restored by daily subcutaneous administration of thyroxine (2  $\mu$ g/100 g body weight). Then we have applied quantitative *in situ* hybridization using  $^{35}$ S-labeled RNA probe for COX I mRNA to examine the effect of perinatal hypothyroidism on COX I gene expression within each area of the cerebellar cortex. A marked change in COX I gene expression was observed not only in the external granule cell layer (EGL) and internal granule cell layer (IGL) but also in the molecular layer (ML). In the EGL of the control animals, a significant rise in COX I gene expression in 5 day-old rats and a gradual decrease in its expression in 10 and 15 day-old rats were observed. Such marked change was not observed in the hypothyroid rats. In the ML of control animals, hybridization signals were concentrated within the lower half, whereas in the hypothyroid animals, the signals were distributed evenly. In the IGL of the hypothyroid rats, a marked decrease in COX I gene expression within the Purkinje cells was observed. So far, because thyroid hormone treatment does not alter oxygen consumption of brain slices, oxidative phosphorylation in the central nervous system is thought to be unresponsive to thyroid hormone. However, the results of present study have demonstrated that thyroid hormone is involved in regulating COX I gene expression.

## 423.4

COMPARISON OF THYROTROPIN-RELEASING HORMONE (TRH) RECEPTOR KINETICS IN THE ADULT AND DEVELOPING AMPHIBIAN BRAIN. C.L. Mitchell\* and S.K. Boyd. Dept. of Biological Sciences, Univ. of Notre Dame, Notre Dame, IN 46556.

Quantitative receptor autoradiography was used to characterize binding sites for thyrotropin-releasing hormone (TRH) in the brain of adult and developing *Xenopus laevis*. Frozen brain sections (18  $\mu$ m) from adult males, and from representative stages of premetamorphic, prometamorphic and climax tadpoles, were incubated with  $^3$ H-MeTRH (5 nM) to determine total binding. Alternate sections were incubated with addition of 2000-fold excess unlabelled TRH for non-specific binding. Sections were exposed to film for 8 to 12 months then developed and quantified using Image 1. Kinetic studies of hypothalamic sites showed that binding of  $^3$ H-MeTRH was specific, saturable and reversible at all developmental stages tested. Equilibrium dissociation constants ( $K_D$ ) were similar at all stages, suggesting that the same receptor is present through development, but association ( $K_{on}$ ) and dissociation ( $K_{off}$ ) rate constants differed between adults and tadpoles. Compared to adult receptors, TRH dissociation in all stages of tadpoles was significantly faster, and association significantly slower, suggesting some primary difference in receptor binding during development. Most notably, binding was differentially temperature-dependent; in the adult hypothalamus, maximal specific binding at 4°C exceeded that at 23°C by two-fold, while in tadpoles, maximal specific binding at 4°C was reduced to 50 to 70% of that at 23°C. This altered binding may reflect a role for TRH in regulation of rate of metamorphosis, since low temperature significantly delays development.

## 423.5

LOCAL DEGENERATION WITHIN MUSCLE DEO1 TRIGGERS LOCAL ENDPLATE LOSS AND AXON RETRACTION IN THE MOTH, *MANDUCA SEXTA*. C. D. Hegstrom\* and J. W. Truman, Department of Zoology, University of Washington, Seattle, WA 98195-1800

During metamorphosis in the moth, *Manduca sexta*, the larval abdominal body-wall muscle DEO1 is remodeled to form the adult muscle DE5. The motoneuron innervating DEO1 prunes its axon arbor over most of the degenerating muscle, while maintaining two contact sites. It is from these sites that axon branches sprout over the developing adult muscle DE5 (Truman and Reiss, 1995).

Using ligation between thorax and abdomen to remove the prothoracic glands, the source of endogenous ecdysteroids, we have shown that muscle degeneration requires the pre-pupal peak of ecdysteroids. In ligated animals, local application of the ecdysteroid analog RH 5992 results in a gradient of degeneration within the muscle. This local degeneration results in endplate loss and branch retraction from the affected region. We conclude that a cue released by the degenerating muscle triggers local pruning of the axon.

POLYCLONAL ANTIBODY TO THE RAT GLUCOCORTICOID RECEPTOR EXPRESSED IN *E. COLI* USING GST GENE FUSION SYSTEM

N. Morita\*, M. Morimoto and M. Kawata, Dept. Anat. and Neurobiol., Kyoto Pref. Univ. Med., Kyoto 602, Japan

To study the development and differentiation of glucocorticoid receptor-immunoreactive cells in the nervous system, we made trials to produce a specific polyclonal antibody to the glucocorticoid receptor, which would be used for highly sensitive and multiple histochemical observation.

The rat liver glucocorticoid receptor cDNA fragment, which encodes 173 amino acids in the transcription modulation domain of the receptor protein, was inserted to the pGEX vector to express a rat glucocorticoid receptor-GST fusion protein in *E. coli*. After the purification of the fusion protein, the receptor protein domain was cleaved out. By immunization with the purified protein, a polyclonal antibody was raised in a rabbit. In immunoblot analysis of rat liver and brain homogenates, a single band of Mr 97000, the size deduced from the rat glucocorticoid receptor, was detected by this antibody. Moreover, the antibody clearly revealed the localization of immunoreactive neurons and glial cells in specific regions of the rat CNS with having low background.

These results demonstrate that the polyclonal antibody obtained in this study has high specificity and immunoreactivity to the glucocorticoid receptor, and that it would be particularly useful for our neuroanatomical pursuits.

## 423.9

A NOVEL MEMBER OF THE STEROID HORMONE RECEPTOR FAMILY IS REGULATED BY SYNAPTIC ACTIVITY AND IN THE DEVELOPING CENTRAL NERVOUS SYSTEM. K.I. Andreasson\*, A. Lanahan, P. Brakeman, C.A. Barnes and P. E. Worley. Depts of Neurology and Neuroscience, Johns Hopkins Univ. Sch. of Medicine, Baltimore, MD 21205 and Depts. of Neurology, Psychology and Div. of Neural Systems, Univ. of Arizona, Tucson, AZ 84724.

We have utilized differential cDNA cloning to identify genes regulated by activity in the rat hippocampus. One of the cDNAs isolated has an open reading frame that encodes a predicted protein which shows homology to the steroid receptor transcription factors. Northern blotting, analysis of cDNA clones, and PCR analysis reveal that alternative processing of the RNA transcript results in the presence of at least two forms of the mRNA in the hippocampus following stimulation. The mRNA for IEG59 is regulated by a variety of natural stimuli in developing and adult rats. Four hours following a maximal electroconvulsive seizure expression is induced by Northern analysis and *in situ* hybridization in the dentate gyrus. IEG59 mRNA is induced in NMDA dependent synaptic stimulation. In chronically implanted animals, IEG59 activin mRNA was strongly induced in hippocampal granule cells ipsilateral to high frequency LTP stimulus four hours after treatment. This induction was eliminated with pretreatment of the animals with MK-801. During fetal and postnatal development, IEG59 is expressed in discrete patterns in developing cortex and spinal cord. Supported by M206826, MH53608, AG9219, and M442187.

## 423.6

LONG TERM EFFECT OF INCREASE OF MATERNAL CORTICOSTERONE DURING LACTATION ON HIPPOCAMPAL CORTICOSTEROID RECEPTORS, STRESS RESPONSE AND LEARNING IN THE OFFSPRING. A. Catalani, P. Casolini, G. Cigliana, F.R. Patacchioli, M.R. Domenici, S. Sagratella, S. Scaccianoce, S. Keni\*† and L. Angelucci. Farmacologia 2, Università "La Sapienza" Medical Faculty, Rome 00185, Italy. † INSERM U394, 33077 Bordeaux, France.

There is a frequent association between a deregulation of glucocorticoid (GC) secretion and affective disorders in humans, cognitive impairment during ageing and self drug administration in animal research. As GCs are an important link between events occurring during the early stages of life and maturation of CNS, we investigated the influence of the increase ( $4 \pm 0.5$  to  $9.5 \pm 0.8 \mu\text{g}/100\text{ml}$ ) of maternal corticosterone (B) during lactation on the hippocampal corticosteroid receptors, hypothalamo-pituitary-adrenal axis (HPAA) activity and behavior in rat progeny from 11 days to 1 year of life. We added the hormone (200  $\mu\text{g}/\text{ml}$ ) to the dams' drinking water, thus avoiding any interference with the mother-pups relationship. The results were: a) lower stress-induced B secretion at 12 months, but not at 11 and 16 days; b) increase of hippocampal type I receptors at 1 and 15 months, but not at 11 and 16 days; c) better learning ability at 12 months in active avoidance, but not at 16 days in the water maze; d) changes in the expression of *in vitro* long-term potentiation at 2 months. Our results: i) indicate that the effects of the increase of maternal B is apparent only after weaning; ii) suggest that the increase of corticosteroid receptors may at least in part, be responsible for the lower stress response and the better learning ability of the progeny; and iii) confirm our previous data on stress response and learning observed at 1-3 months and extend them up to one year of life. It is tempting to find similarities between the endocrine and cognitive profile of our controls and some characteristics of HPAA and learning observable in certain human psychoaffective disorders. Our results suggest that the lack of arousal in infancy may have a negative influence in shaping some characteristics of the CNS of the future individual. Supported by CNR 94.00479 PF40 grant.

## 423.8

DISTRIBUTION OF MRNA AND PROTEIN OF GLUCOCORTICOID RECEPTOR IN RAT CENTRAL NERVOUS SYSTEM.

M. Morimoto, K. Yokoyama, D.T.M. Visser, N. Morita and M. Kawata\*, Dept. of Anat. and Neurobiol., Kyoto Prefec. Univ. Med., Kyoto 602, JAPAN.

Glucocorticoids play an important role in the development and the differentiation of the nervous system. The effects of glucocorticoids are mainly mediated by the glucocorticoid receptor (GR), which is distributed in various regions of the central nervous system. In this study, the cellular localization of GR mRNA and GR immunoreactivity in the adult rat brain was examined by *in situ* hybridization and immunohistochemistry. In the hybridization study, fluorescein-labeled RNA probes, complementary to about 500 base pairs coding the 5' untranslated region and a part of the transcription modulation domain in the rat GR cDNA were used. In immunohistochemistry, polyclonal antibodies against the transcription modulation domain of rat GR were used. Those have been obtained from rabbits, immunized with the GR protein produced by a gene fusion vector.

The expression of GR mRNA was detected in the cytoplasm and GR immunoreactivity was predominantly localized in the nucleus. GR mRNA-expressing and GR-immunoreactive cells were observed in various regions of the rat brain, especially in the tel- and diencephalon and the cerebellar cortex. The distributional pattern of GR mRNA in many regions of the rat brain was correlated with the distribution of GR immunoreactivity but in certain areas different localization could be found.

## 423.10

EFFECT OF PROGESTERONE AND TESTOSTERONE METABOLITES ON GFAP GENE EXPRESSION IN TYPE 1 ASTROCYTES.

R.C. Melcangi\*, M.A. Riva, F. Fumagalli\*, V. Magnaghi\*, G. Racagni\* and L. Martini\*. \* Dep. Endocrinology, Univ. of Milan; † Di.Bi.T., San Raffaele Hospital, Milan; ‡ Center of Neuropharmacology, Inst. of Pharmacol. Sci., Univ. of Milan, Italy.

Recent data obtained in this laboratory have indicated that in the central nervous system, the enzyme 5 $\alpha$ -reductase which converts testosterone (T) and progesterone (P) into their respective 5 $\alpha$ -reduced metabolites, is preferentially localized in neurons, but is present also in type 1 astrocytes (Melcangi et al. Endocrinology, 132:1252-1259, 1993; Brain Res. 639:202-206, 1994). On the basis of these observations, it was deemed of interest to analyze whether the original hormones T and P, and their 5 $\alpha$ -reduced metabolites dihydrotestosterone (DHT) and dihydroprogesterone (DHP) might exert some effects on the expression of the most typical astrocytic marker, i.e. the glial fibrillary acidic protein (GFAP). Cultures of rat type 1 astrocytes were exposed to the various steroids for 2, 6, and 24 hours, and the variations of GFAP mRNA were measured by Northern blot analysis. A significant elevation of GFAP mRNA levels was observed after exposure to either P or DHP; the effect of DHP appeared more promptly (at 2 h) than that of P (at 6 h), a result which suggests that the effect of P is linked to its conversion into DHP; this hypothesis has been confirmed by showing that the addition of finasteride (a specific blocker of the 5 $\alpha$ -reductase) is able to completely abolish the effect of P. After exposure to either progestagen, a decrease of GFAP gene expression was observed at later intervals (24 h). In the case of androgens, the data indicate that T does not change GFAP expression at any time of exposure, while DHT produced a significant decrease of GFAP mRNA only after 24 hours of exposure. The data suggest that beyond P, the 5 $\alpha$ -reduced metabolites of T and P may modulate the expression of GFAP in type 1 astrocytes. (Supported by CNR through BTBS n. 93.01103, PF70 and ACRO n. 94.01162, PF39).

## 423.11

THE SEXUALLY DIMORPHIC BEHAVIOR OF SWEET SOLUTION CONSUMPTION IS MEDIATED BY TESTOSTERONE.

Pizzi\*, W., Poskozm, J., Bellucci, C., Andrews, R. Northeastern Illinois University, Chicago, IL.

Two experiments were conducted to elucidate the hormonal mechanism controlling the sexually dimorphic behavior of sweet solution consumption. In exp. 1, cyproterone (cyp) 2 mg/kg, sc. in oil was administered to pregnant rats from gestation days 15-17. The offspring did not show differences in saccharin preference (SP) when tested prior to puberty. After puberty the vehicle control (VC) males showed a significant reduction in SP, while the cyp-exposed males did not show a reduction. The cyp-exposed females showed a dramatic increase in SP. A reproductive screen showed the cyp-exposed males to be impaired ( $p < 0.05$ ). A necropsy showed reduced testis ( $p < 0.02$ ) and seminal vesicle ( $p < 0.001$ ) weights. Exp. 2 was conducted on normal adult male rats treated with a single injection of cyp (5 mg/kg, sc), or female rats treated with tamoxifen (1 mg/kg, sc). Cyp-treated males showed a decreased SP over a 5-day period ( $p < 0.05$ ), while tamoxifen-treated females were unaffected. These results suggest that the sexually dimorphic behavior of sweet-solution consumption is mediated by testosterone.

## 423.13

**DEVELOPMENTAL PROFILE OF ANDROGEN RECEPTOR (AR) mRNA EXPRESSION IN THE FOREBRAIN OF PERINATAL RATS.** M. McAbee\*, R.J. Handa and L.L. DonCarlos. Dept. Cell Biol., Neurobio., & Anat., Loyola Univ, Maywood, IL 60153.

Testosterone (T) is essential for the normal masculinization of the rat brain. The primary metabolite of T responsible for masculinization is estrogen (E), acting via estrogen receptors. However, AR antagonists partially disrupt sexual differentiation, suggesting that T and its androgenic metabolites exert additional masculinizing effects via ARs. To determine the sites and magnitude of sensitivity to androgens during sexual differentiation of the forebrain, we used *in situ* hybridization to investigate the development of AR mRNA expression in regions prominent in sexually differentiated functions. Perinatal male and female rats were sacrificed on embryonic day 20 (ED-20; ED-0=day of conception), and postnatal days 0, 4, 10 or 20 (PND; PND-0=day of birth). *In situ* hybridization was performed on brain sections using an  $^{35}$ S-labeled riboprobe for rat AR mRNA. The lateral septum (LS), bed nucleus of the stria terminalis (BNST), medial preoptic area (MPOA), ventromedial (VMH) and arcuate (ARC) hypothalamic nuclei were analyzed. AR mRNA was present in all cell groups by ED-20. Relative amounts of AR mRNA followed the general gradient: caudal BNST >> MPOA > rostral BNST > LS > VMH. AR mRNA was not different on ED-20, PND-0 and PND-4 (although levels were slightly higher on PND-4). AR mRNA levels were significantly greater on PND-10 and PND-20 than at earlier ages. Furthermore, there was a sex difference at ages PND-4, 10, and 20, with males having higher levels of AR mRNA in the MPOA and BNST than females. This ontogenetic profile of AR mRNA expression parallels previous steroid binding studies (Lieberburg et al, Brain Res, 1980; Vito and Fox, Dev Brain Res, 1982). The presence of AR mRNA in these forebrain regions provides the requisite transcriptional machinery for T and its metabolites to play a role in sexual differentiation. Supported by NIMH grant MH48794.

## 423.15

**FRONTAL CORTICAL BRAIN AROMATASE ENZYME ACTIVITY IN MALE AND FEMALE RATS DURING PERINATAL DEVELOPMENT.** E. D. Lephart and R. W. Rhee\*. Dept. Zoology, Cellular Biology Division, Brigham Young Univ., Provo, UT 84602.

The conversion of androgens to estrogens is catalyzed by an enzyme complex termed aromatase. The presence of the aromatase enzyme in brain is thought to be responsible for the establishment of sexual dimorphic patterns in diencephalic and limbic structures during perinatal development. However, the presence and function of the aromatase enzyme in cortical tissues is not as well characterized. In this study, frontal cortical brain aromatase enzyme activity was measured in male and female Sprague-Dawley rats during perinatal development [from gestational day (GD) 17 to postnatal day 6]. In preliminary studies, brain aromatase activity was linear with time of incubation and protein content of the assayed tissue. The results from the 'tritiated water' release assay were confirmed by the estrogen product isolation assay. In both males and females the activity was highest (@ 320 fmol/hr/mg protein) at GD 17. In general, the aromatase levels declined in a linear fashion from GD 17 to GD 21 (@ 280 fmol/hr/mg protein) and continued to decrease by postnatal day 6. These results provide evidence for the presence of the aromatase enzyme in cortical tissue. Furthermore, the pattern and profile displayed in cortical tissue is different compared to hypothalamic aromatase activity which suggests that an alternative mechanism may regulate the aromatase enzyme in frontal cortical tissue during perinatal development.

## 423.12

THE GROSS SIZE OF THE SPLENIUM OF THE RAT CORPUS CALLOSUM : SEX DIFFERENCES, HORMONES AND POSSIBLE CORRELATES WITH AXON NUMBER J. L. Nunez\*, J. H. Y. Kim and J. M. Juraska Neuroscience Program and Department of Psychology, University of Illinois at Champaign, Urbana Champaign, IL 61820

Previously, we have not found significant sex differences in the gross size of the rat corpus callosum or the splenium (posterior 1/5) with n's of 8-10 per sex, but males have consistently had larger means than females. Here we found that by expanding our sample to 15-24 per sex, males have a significantly larger splenium and corpus callosum overall. Neither neonatal castration of the males nor neonatal testosterone injections of females altered the size of the splenium or the total corpus callosum. There were some preliminary indications that control manipulations for the hormone groups increased callosa in comparison to undisturbed litters. One must be cautious in interpreting measures of callosal size: in spite of males having a larger splenium, there are no sex differences in axon number when the splenium is thoroughly sampled (means favor females); nor does splenial size consistently correlate with the number of axons within it across age and sex. ## 423.14

REGIONAL LOCALIZATION OF 5 $\alpha$ -REDUCTASE TYPE 1 mRNA IN THE DEVELOPING RAT BRAIN. M. E. Lauber and W. Lichtensteiger. Institute of Pharmacology, University of Zürich, Switzerland.

Steroid hormones are essential for normal development and function of the central nervous system (CNS). In the adult rat brain, androgens are involved in the activation of male typical behaviors and the regulation of food intake. In order to precisely elucidate the molecular basis of such androgen action and to examine potential effects of these hormones in CNS development, we studied 5 $\alpha$ -reductase type 1 mRNA expression in fetal, postnatal and adult rat brain by means of *in situ* hybridization. Our results indicate that 5 $\alpha$ -reductase mRNA is expressed in two distinct patterns depending on the developmental stage. In early postnatal (PN15) and older animals, 5 $\alpha$ -reductase mRNA is detected predominantly in white matter structures, such as optic chiasm, lateral olfactory tract, corpus callosum and internal capsule. Specific mRNA is also detected in thalamic regions and low levels of mRNA appear to be distributed uniformly in the entire brain. These findings are in agreement with previous studies reporting 5 $\alpha$ -reductase activity in many regions of the rat brain including myelinated structures. A completely different pattern of 5 $\alpha$ -reductase mRNA expression was detected in the rat brain during fetal and early postnatal development (gestational day 14 to PN6). At these stages, high levels of 5 $\alpha$ -reductase mRNA were present in the neuroepithelium of many regions, including cortex, basal telencephalon, retina and spinal cord. Abundant mRNA was also detected in the pituitary, nasal epithelium, liver and lens of the developing eye. These results suggest that 5 $\alpha$ -reductase may serve different functions in the developing and adult nervous system.

## 423.16

**SEX DIFFERENCE IN THE DISTRIBUTION OF ESTROGEN RECEPTOR AND AROMATASE IN THE RAT BRAIN.** M. Yokosuka\* and S. Ilayashi

Dept. Anat. Embryol, Tokyo Metropol. Inst. Neurosci, Tokyo 183.

Distribution patterns of the neurons containing estrogen receptor (ER) and/or aromatase (AROM) immunoreactivity were studied in the newborn and adult rat brain by immunohistochemistry. In the newborn rat, AROM and ER were found in the anterior medial preoptic nucleus (AMPN), the dorso-caudal region of medial preoptic nucleus and its continuation to the bed nucleus of the stria terminalis (MPNdc-BST), the ventro-lateral part of the ventromedial hypothalamic nucleus (VMHvl) and the medial amygdaloid nucleus (MEA). In the VMHvl, most of the AROM immunoreactive (-IR) cells contained ER-IR in their cell nuclei. In the adult brain, AROM-IR in MPNdc-BST and MEA stayed at high level, while that in AMPN and VMHvl was diminished. Moreover, in both newborn and adult, sex difference in AROM- and ER-IR was found in MPNdc-BST: intensity of AROM-IR, female < male; density of ER-IR, female > male. These results suggest that, (I) AMPN and VMHvl seem to be actively involved in the sex differentiation of the brain during the neonatal life, (II) In VMHvl, aromatization and binding of estrogen to its cognate receptor seem to occur in the same neurons, (III) Active aromatization and estrogen binding occur also in MPNdc-BST. This intimate relationship between AROM- and ER-IR in these regions is likely related to reproductive functions.

## 423.17

3 $\beta$ -HYDROXYSTEROID DEHYDROGENASE/ $\Delta^5$ - $\Delta^4$  ISOMERASE. A KEY ENZYME IN THE BIOSYNTHESIS OF NEUROSTEROIDS. IS EXPRESSED IN THE RAT NERVOUS SYSTEM. R. Guennoun\*, M. Schumacher, M. Gouézou, F. Robert, K. Shazand, P. Robel, E.-E. Baulieu. INSERM U33, 94276 Le Kremlin-Bicêtre Cedex, France.

The 3 $\beta$ -hydroxysteroid dehydrogenase/ $\Delta^5$ - $\Delta^4$  isomerase (3 $\beta$ -HSD) enzyme can convert pregnenolone (PREG) into progesterone (PROG). We here show, by reverse transcriptase-polymerase chain reaction (RT-PCR), *in situ* hybridization and immunohistochemistry, for the first time, that sensory neurons of rat peripheral nervous system (PNS) express 3 $\beta$ -HSD. 3 $\beta$ -HSD is expressed in dorsal root ganglia (DRG) neurons during embryonic development and in adulthood. Sensory neurons cultures prepared from embryonic (E15) rat DRG can convert [ $^3$ H]PREG into [ $^3$ H]PROG. [ $^3$ H]PROG is further converted to its 5 $\alpha$ -reduced metabolite 5 $\alpha$ -pregnan-3,20-dione (5 $\alpha$ -DH PROG). Cultures of sensory neurons on a microporous membrane on top of a feeder layer of Schwann cells results in three-fold increase of the [ $^3$ H]PREG  $\rightarrow$  [ $^3$ H]PROG conversion. The identity of both [ $^3$ H]PROG and [ $^3$ H]DH-PROG was confirmed by high pressure liquid chromatography (HPLC) and crystallizations to constant specific activity after reverse isotopic dilution.

*In situ* hybridization showed that 3 $\beta$ -HSD mRNA is also expressed in neurons of defined regions of the central nervous system (CNS). RT-PCR amplification and nucleotide sequencing of the amplified products are in progress, to identify the isoform(s) of 3 $\beta$ -HSD expressed in the CNS.

In conclusion, our results give evidence of the CNS and PNS capacity to synthesize progesterone, an active neurosteroid, which may be involved in the control of myelin synthesis.

## 423.19

PRENATAL EXPOSURE TO ETHANOL DECREASES THE DEVELOPMENTAL EXPRESSION OF ESTROGEN RECEPTOR mRNA IN THE MEDIAL PREOPTIC AREA OF THE RAT. Y.B. Li\*, L.L. DonCarlos, D. Stancik and R.J. Handa. Dept. of Cell Biology, Neurobiology and Anatomy, Loyola Univ. Chicago, Maywood, IL, 60153.

Fetal alcohol exposure disturbs the development of the hypothalamo-pituitary-ovarian axis and results in neuroendocrine disorders in adult female offspring. To determine if these neuroendocrine deficits arise as a result of changes in estrogen sensitivity, we examined the effect of fetal exposure to ethanol on the development of estrogen receptor (ER) mRNA in the rat medial preoptic area using *in situ* hybridization histochemistry. Timed pregnant dams were fed a liquid diet with 35% ethanol derived calories from gestational day 14 to parturition. Control animals were either pair fed an isocaloric diet with sucrose substituted for ethanol or maintained on regular laboratory chow. On postnatal days 0 (day of birth), 4, 10, or 21, animals were sacrificed by nembutal and intracardiac perfusion with 4% paraformaldehyde. Brains were cut on a cryostat. *In situ* hybridization was performed using a  $^{35}$ S-labelled cRNA probe for rat ER mRNA. The levels of ER mRNA in the medial preoptic area were highest on postnatal day 0, 4 and 10, and underwent a dramatic decline after postnatal day 10 to adult levels by postnatal day 21 ( $p < 0.05$ ). As previously observed, ER mRNA expression in the medial preoptic area was higher in females than males on postnatal day 0, 4 and 10 ( $p < 0.05$ ). ER mRNA levels in the medial preoptic area were reduced by prenatal alcohol exposure both in male and female rats on postnatal day 0, 4 and 10 ( $p < 0.05$ ). The reduced expression of ER mRNA in the preoptic area by prenatal alcohol exposure may underlie the observed neuroendocrine disorders which appear later in life in female rats. Supported by USPHS AA08696, NSF IBN 94-08890 and MH 48794

## 423.18

LOCALIZATION OF ESTROGEN RECEPTOR mRNA IN THE DEVELOPING BRAZILIAN OPOSSUM AND RAT BRAIN. M.C. Kuehl-Kovarik\*, M.R. Bollnow\*, R.J. Handa\* and C.D. Jacobson. Dept. of Veterinary Anatomy and Neuroscience Program, Iowa State University, Ames, IA 50011, and \*Dept. Cell Biology, Neurobiology, and Anatomy, Loyola University, Chicago, IL 60153.

Estrogen receptor-like immunoreactivity (ER-LI) has been reported in the facial motor nucleus of rats from one to eleven days of postnatal age, but not in adults. We have not detected ER-LI in the facial motor nucleus of the Brazilian opossum at any age, although other receptor types are transiently expressed in this nucleus. In this study, we have used *in situ* hybridization to detect estrogen receptor mRNA in the developing rat and opossum brain. An  $^{35}$ S-labeled cRNA probe against the rat estrogen receptor (nucleotides 1542-1713) was utilized to detect estrogen receptor mRNA in both rat and opossum brain slices. Estrogen receptor mRNA (ER mRNA) was not detected in the midbrain or hindbrain of the embryonic day 19 rat. However, by eight days postnatal, ER mRNA was abundant in the facial motor nucleus. By 25 PN, no ER mRNA was detected in the rat facial, although it was abundant in forebrain areas. Estrogen receptor mRNA was not detected in the 5 or 10 PN Brazilian opossum brain. By 25 PN, ER mRNA was detected in the opossum forebrain and midbrain. At 70 PN, ER mRNA was detected in multiple forebrain areas, including the lateral septum and medial preoptic area. However, no estrogen binding sites were detected in the opossum brainstem at any age studied. These results agree very well with what our laboratory and others have found using immunohistochemistry, demonstrating that our rat probe effectively recognizes opossum mRNA. The estrogen receptor mRNA and protein are expressed transiently in the facial motor nucleus of the neonatal rat. However, neither the mRNA or the protein are detected in the facial motor nucleus of the Brazilian opossum at any age we have studied so far. The significance of transient ER expression in the neonatal rat facial motor nucleus remains to be elucidated.

## 423.20

Identification of genes regulated by estrogen in adult forebrain neurons using PCR-differential display. F. Sohrabji\* and R. C. Miranda. Department of Human Anatomy and Medical Neurobiology, Texas A&M University, College Station, TX 77843.

We are interested in the role of estrogen on the survival and maintenance of neurons in the basal forebrain cholinergic system and its forebrain targets. In adult animals, estrogen rapidly regulates the expression of BDNF mRNA in two forebrain targets, the cerebral cortex and olfactory bulb, suggesting that the expression of this neurotrophin gene may be an early event in an estrogen-stimulated cascade regulating cellular function. Since the estrogen receptor is a ligand-dependent transcription factor, the present study analyzed the expression of other novel downstream genes regulated by estrogen, using a PCR-based differential display technique. Cortical and olfactory bulb RNA was obtained from adult ovariectomized females exposed to either estradiol or vehicle and sacrificed 4 or 52 hours later. DNase-treated RNA was reverse transcribed and amplified using a modification of the previously-described technique (Liang and Pardee, 1992). While the majority of amplified transcripts were present in all groups, a doublet of approximately 1 kb and two smaller (450 and 300 bp) transcripts were regulated by estrogen. While the 1 kb transcript(s) had an early onset and stable expression in the olfactory bulb, its expression in the cerebral cortex was comparatively delayed. The smaller transcripts (450 bp in the cortex, 300 bp in the olfactory bulb) were expressed only in the group that received a 4 hour exposure to estrogen, and may represent genes that are transiently stimulated by estrogen. Characterization of these differentially-regulated genes may yield insight into the actions of estrogen, and also shed light on the downstream effects of estrogen-dependent stimulation of the neurotrophins.

## NEURONAL DEATH V

## 424.1

IDENTIFICATION OF GENES DISPLAYING ALTERED EXPRESSION IN CEREBELLAR GRANULE NEURONS DURING APOPTOSIS. S.R. D'Mello\*, A. Yan\*, K. Borodez\*, G. Rompato\*, and M. Cartwright\*. Dept. of Physiology and Neurobiology, University of Connecticut, Storrs, CT 06269, and Section of Biomolecular Medicine, Boston University Medical Center, Boston, MA 02118.

Cultured cerebellar granule neurons undergo apoptosis when switched from a medium containing high K $^{+}$  (25 mM) to one containing a low K $^{+}$  concentration (5 mM). Death resulting from the lowering of extracellular K $^{+}$  can be prevented by IGF-I, cyclic AMP, lithium, and the calcium-ATPase inhibitor thapsigargin. Apoptosis can also be inhibited by transcriptional and translational inhibitors suggesting the necessity for newly synthesized gene in the death process. Work in other systems has suggested that in addition to "killer genes" that are induced during cell death, apoptosis results from the downregulation of "survival genes" that normally serve to suppress cell death. In an effort to identify genes involved in the induction or suppression of apoptosis in granule neurons we have used the PCR-based differential display technique. Total RNA from granule neurons switched to medium containing low K $^{+}$ , high K $^{+}$ , IGF-I, or forskolin (adenylate cyclase activator) was analyzed. Complementary cDNAs representing several mRNA were detected that showed altered expression in low K $^{+}$  treated cells (primed to die), as compared to the cells maintained in one of the three survival promoting factors. That the expression of these mRNAs is altered during cell death is presently being confirmed by Northern blot analysis. Results concerning the characterization of these putative killer and survival genes will be presented (Supported by grants from the Whitehall Foundation and the A-T Children's Project).

## 424.2

DIFFERENTIAL DISPLAY INDICATES NOVEL ACTIONS OF PROSTAGLANDINS ON CENTRAL NEURONS. M. Cartwright<sup>1,3</sup>, P. Jackson<sup>4</sup>, S. D'Mello<sup>5</sup>, and G. Heinrich<sup>2,3</sup>. 1 Dept. of Pharmacol. and 2 Dept. of Med., Boston Univ. Med. Center, Boston, MA. 3 GRECC, VAH., Bedford, MA. 4 Mayo Clinic, Jacksonville, FL. 5 Dept. Neurobiol. and Physiol., UConn. Storrs, CT.

The predominant prostaglandins (PGs) synthesized in the brain are PGD $_2$ , PGE $_2$ , and PGF $_{2\alpha}$ . The rate-limiting enzyme in PG synthesis is cyclooxygenase (COX). Using Northern and Western blot analyses, we showed that kainic acid upregulates COX2 mRNA and COX2 in central neurons. PGs act via G-protein linked seven transmembrane domain receptors. Three PGE $_2$  receptor subtypes have been cloned (EP1, 2, and 3). Four variants of the EP3 subtype (A through D) arise via differential splicing of EP3 transcripts. These EP3 variants are coupled to different G-proteins.

We used RT-PCR assays to show EP1 and EP3A and B mRNAs in intact rat cortex as well as cultured cortical and cerebellar neurons. The identity of each mRNA was confirmed by restriction digest or cloning followed by nucleotide sequence analysis of the PCR products. Using RT-PCR we could not detect EP2 mRNA nor the mRNA that encodes the PGF $_{2\alpha}$  receptor (FP) in the intact cortex or cultured neurons.

The expression of EP1 and EP3 mRNAs by neurons raised the possibility that PGE $_2$  may regulate transcription of neuronal genes. To address this possibility cultured cortical and cerebellar neurons were treated with 1  $\mu$ M PGE $_2$  for 1h or 6h. Rats received intra-ventricular(iv) injections of PGE $_2$  and PGE $_2$  for 3h. Total RNA was extracted from cultured neurons, and rat hippocampus and cortex and analyzed by differential display. 14 of the visualized mRNAs differed between treated and untreated cells and animals. The corresponding cDNAs were cloned. None of 14 clones matched known nucleotide sequences. A clone downregulated by iv PGE $_2$ , derived from rat cortex, hybridized to an abundant, 2.3 kb mRNA on Northern blots.

These results indicate that PGR mRNAs are expressed in neurons and that PGs regulate mRNA levels in neurons. Future experiments will study these regulated mRNAs to further understand the molecular mechanisms of PG action in the brain.

## 424.3

## MULTIPLE GENES ARE REGULATED BY THE INDUCTION AND SUPPRESSION OF APOPTOSIS IN CEREBELLAR GRANULE NEURONS.

Tomio Ono, Yoshihisa Kudo, Kaoru Inokuchi, Akio Sato\*, Seiichi Kawashima. Dep. of Mol. Biol., Tokyo Metropolitan Inst. of Med. Sci. 3-18-22 Honkomagome, Bunkyo-ku, Tokyo 137, Japan.

Activity dependent modification of neural functions and neuronal differentiation are considered to be cellular bases of developmental plasticity. One of the activity dependent phenomenon during the neural network formation is the activity dependent regulation of survival and death of neuronal cells. The primary culture of cerebellar granule neuron provides an excellent model for studying the regulatory mechanisms of the activity dependent survival and death. In the absence of depolarization reagent(s) such as high concentration of KCl or NMDA in the culture medium, the granule neurons gradually undergoes to die with apoptosis within a few days. On the other hand, the addition of these reagents to the culture medium before 2.5 days *in vitro* (DIV.) suppresses the apoptosis of this neuron but does not suppress it if they are added after 3.0 DIV. We have been interested in gene regulation during this critical period of induction / suppression of the apoptosis in this system. In order to search regulated genes during this critical period, we have employed mRNA differential display technique and found that multiple genes are regulated at this critical period of induction / suppression of the apoptosis.

## NEUROLOGIC EFFECTS OF BCL-2 GENE ABLATION IN MICE.

J.T. Henderson<sup>1</sup>, Cindi M. Morshead<sup>2</sup>, Derek van der Kooy<sup>2</sup>, D.Y. Loh<sup>3</sup>, and J.C. Roder<sup>1</sup>. <sup>1</sup>Samuel Lunenfeld Research Institute, Mount Sinai Hospital; <sup>2</sup>Dept. of Anatomy, University of Toronto; and <sup>3</sup>Howard Hughes Medical Institute, Washington University.

Bcl-2 and its homologs have been shown to play a key role in the control of cell survival, from *C. elegans* to man. Over-expression of bcl-2 has been shown to protect a number of different cell types from programmed cell death. Within the vertebrate nervous system, bcl-2 is widely expressed during the period of neurogenesis, and this expression continues within restricted neural populations postnatally. In order to better understand the properties of bcl-2 *in vivo*, we have examined the nervous system of mice which are homozygous for a null mutation in the bcl-2 (alpha/beta) gene. These animals proceed through development normally and all major organ systems are functional at birth. However, they are noticeably smaller than their heterozygous littermates, and exhibit a substantially reduced lifespan.

With respect to the nervous system, bcl-2<sup>-/-</sup> mice exhibit all major neuro-anatomic structures. However, they exhibit a disproportionate reduction in the volume of their neocortex and cerebellum compared to heterozygous littermates. Preliminary analysis of the constitutively proliferating subependymal cells within the rostral forebrain indicate a reduction of this population. In addition, morphometric analysis of motor axons in these mice (L4 ventral root versus facial nerve) indicates that bcl-2<sup>-/-</sup> animals undergo a dramatic reduction their population of gamma motor neurons, in addition to an overall reduction in motor axon caliber. In contrast, the L4 dorsal root and optic nerve of these animals do not show marked alterations. These results demonstrate that loss of bcl-2 activity has subtle, yet specific, functional consequences *in vivo*.

## DEREGULATED INSULIN-LIKE GROWTH FACTOR-II EXPRESSION IN HUMAN NEUROBLASTOMA CELLS. J.R. Singleton, A. Randolph and E.L. Feldman\*. Department of Neurology, University of Michigan, Ann Arbor, MI 48109.

Insulin-like growth factor-II (IGF-II) promotes autocrine growth in human neuroblastoma cells via the type I IGF receptor. SK-N-SH human neuroblastoma cells have been cloned into two distinct cell lines: SH-SY5Y cells and SHEP cells. Autonomous growth in SH-SY5Y cells is dependent on IGF-II mediated autocrine growth. In contrast, SHEP cells lack IGF-II gene and protein expression and require serum for growth. In the current study, we determined whether deregulated expression of IGF-II alters the phenotype of SHEP cells and permits autonomous neuronal growth.

An 854 bp IGF-II cDNA was inserted into pSFSV plasmids containing a single copy of IGF-II were selected by *SalI* digest prior to SHEP cell transfection with lipofectin. Neomycin resistant transfectants were selected and screened for IGF-II production by enhanced chemiluminescence Western blotting. Four stable transfectants expressed the 2.2 kb IGF-II mRNA transcript and immunoreactive IGF-II. Cell growth was measured after 1, 2 and 3 days using a colorimetric assay that detects reduction of the tetrazolium salt MTT. Unlike SH-SY5Y cells, IGF-II transfected SHEP cells remained dependent on serum for growth in spite of autocrine IGF-II production. These results imply that 1) IGF-II alone is insufficient to support autocrine neuronal growth, and 2) an additional permissive factor present in either serum or the extracellular matrix is required for growth.

## 424.4

## ISOLATION OF BCL-Y, A NOVEL BCL-2 HOMOLOGUE, FROM RAT AND HUMAN BRAIN. J. Guastella, E. Weber\* and L. Zhang. Aeca Pharmaceuticals, Inc., (a subsidiary of CoCensys, Inc.) 213 Technology Dr., Irvine, CA 92718

The bcl-2/ced-9 gene family is composed of ten known genes which play a critical role in the regulation of cell survival. Some members of this family (such as bcl-2, ced-9 and bcl-x) are cell death blockers, while others (such as BAX and BAK) are cell death promoters. In order to understand better the molecular basis of cell death in the nervous system, we have used degenerate RT-PCR to search for additional members of this family in the brain. Using this approach, we have identified a novel bcl-2 homologue that is expressed in both rat and human brain.

Degenerate oligonucleotides were designed based on conserved sequences in bcl-2 homology domains 1 and 2 (BH1 and BH2). These oligos were used as primers in the PCR with rat brain cDNA and rat genomic DNA templates. PCR products of the predicted size were cloned and sequenced. Among these products were DNA fragments corresponding to bcl-2, bcl-x and BAX, all of which are known to be expressed in the nervous system. In addition, a novel sequence, with approximately 70% homology to bcl-2 and bcl-x at the amino acid level, was identified. This PCR product was designated bcl-y and was used to isolate full-length rat and human cDNA clones. Bcl-y is homologous to all known members of the bcl-2 family and is most similar to bcl-2 and bcl-x. Significant homology is observed throughout the length of the protein, but is most pronounced in the C-terminal half, particularly in BH1 and BH2. The C-terminal end of the protein contains residues predicted to form a mitochondrial membrane targeting sequence, suggesting that, like bcl-2 and bcl-x, bcl-y may be located at organelle membranes. We are in the process of constructing stable cell lines expressing bcl-y and producing polyclonal antibodies to the recombinant protein in order to establish the function and cellular distribution of this molecule.

## TRANSCRIPTION FACTOR INTERACTIONS FOLLOWING STRIATAL INJURY. K.M. Hollen, C.A. Walker, and S.W. Davies (SPON: Brain Research Association) University College London, London, WC1E 6BT, United Kingdom

Acute neuronal injury is characterised both by the rapid induction of a range of immediate early genes (IEG) and by the concomitant activation of the glucocorticoid receptor (GR) by increased circulating steroids. In this study, we investigated the induction of IEG of the AP-1 family (c-Jun, Jun-B, Jun-D, c-Fos, Fos-B, Fra-1, Fra-2) in the rat striatum by quinolinic acid (QA) injection *in vivo* and the effects of GR activation or antagonism on the expression of these IEG.

Induction of c-Fos and Jun-B mRNA and protein is rapid and transient at two hours post-lesion and distributed around the medial and ventral margins of the striatum. A delayed, extended upregulation of c-Jun, Jun-D, and Fos-B message and protein occurs in the dorso-central portion of the striatum. We additionally show the expression of ΔFos-B, an alternatively spliced truncated form of Fos-B, which is the predominant isoform in the striatum. Results show Fra-1 and Fra-2 are constitutively expressed and never induced by striatal QA lesion. We also observe three previously unreported Fos-specific proteins which are also constitutively expressed. Data shown here illustrates that ΔFos-B is involved in an AP-1 complex that binds to a nerve growth factor AP-1 DNA binding site in increased levels following striatal QA lesion. Interestingly, co-injection of either the synthetic glucocorticoid dexamethasone or the GR-antagonist RU38486 with QA does not significantly alter the temporal and spatial expression patterns or levels of Jun and Fos IEG. The ability of glucocorticoids to markedly enhance glutamate-induced neuronal death may therefore be due to direct protein-protein interactions between GR and AP-1, which may reduce the transcriptional activation capacity of AP-1, rather than have any direct effect on AP-1 expression.

## 424.8

## IN VIVO CELL MIXING EXPERIMENTS DEMONSTRATE THE CELL AUTONOMOUS ACTION OF THE WEAVER GENE ON CEREBELLAR GRANULE CELL SURVIVAL. D. Goldowitz\* and K. M. Hamre, Dept Anat. &amp; Neurobiol., Univ. of Tennessee Health Sci. Ctr., Memphis, TN 38163

The cellular event that defines the weaver mutation is the death of nearly all of the midline cerebellar granule cells. We are quantitatively re-examining adult chimeric cerebella and examining early postnatal chimeric cerebella (days 7 and 15) to determine if increased numbers of *+/+* cells help genetically *wv* cells to survive. The genotype of IGL and EGL cells was determined using strain specific DNA probes and *in situ* hybridization. In adult weaver chimeric cerebella, there are regional differences in the numbers of granule cells in the internal granule layer (IGL) that strongly correlates with the percentage of chimerism in the animal. In these weaver chimeras IGL granule cells are always predominantly of the *+/+* genotype indicating that the variation in granule cell number in different regions of a chimeric cerebellum is due to the variable donation of *+/+* granule cells. Surviving weaver granule are present in numbers similar to that found in a weaver cerebellum. Thus, there is little enhanced survival of weaver granule cells in regions where many *+/+* granule cells have colonized the IGL.

In postnatal day 7 and 15 weaver chimeras, the external granule layer (EGL) shows a regionally graded mixture of genotypically mutant and wild-type cells, from a preponderance of *+/+* cells to a predominance of *wv/wv* cells to percentage mixtures in-between. In all instances, however, the vast majority of granule cells in the IGL is of the *+/+* genotype with only a few surviving *wv* granule cells. Thus genotypically *wv* EGL cells do not successfully translocate to the IGL. In addition, an increased presence of pyknotic nuclei in the EGL, a characteristic of the weaver cerebellum, is found in the chimeric cerebellum.

We conclude that a wild-type environment does not promote increased survival of *wv* granule cells. Thus while other features of the *wv* granule cell may be ameliorated, such as axonal outgrowth (Gao & Hatten), the defining phenotype of the *wv* granule cell -- that of cell death -- is unaltered. The conclusion from these *in vivo* cell mixing studies is that the *wv* gene not only intrinsically targets granule cell survival, but this action is cell-autonomous. Supported by NINDS.

## 424.9

DIFFERENTIAL REGULATION OF BAX AND BCL-X EXPRESSION DURING DIFFERENTIATION OF PC12 CELLS. K. Vekrellis, L.L. Rubin\* and J. Ham. Eisai London Research Laboratories, Bernard Katz Building, University College London, Gower Street, London WC1E 6BT, UK.

We are studying the pattern of expression of members of the Bcl-2 family during neuronal differentiation and neuronal cell death. Bcl-2 and Bcl-xL have been shown to suppress apoptosis in a variety of cell types including sympathetic neurons deprived of survival factors. Bcl-x, in particular, plays an important role in the nervous system in that disruption of the Bcl-x gene in mice by homologous recombination leads to extensive cell death in the developing nervous system. In contrast to Bcl-2 and Bcl-xL, the Bax protein antagonizes Bcl-2 and accelerates cell death. To study the pattern of expression of these proteins in the nervous system, we have developed antibodies that specifically recognize Bcl-x and Bax. As a simple model system for studying neuronal differentiation and survival we have used the rat PC12 cell line, which can be induced by nerve growth factor (NGF) treatment to differentiate into cells that resemble sympathetic neurons. NGF also promotes PC12 survival.

We have found in western blotting experiments that PC12 cells express Bcl-x and Bax, but not Bcl-2. We have also demonstrated in co-immunoprecipitation experiments that, like Bcl-2, Bcl-x also interacts with Bax. When PC12 cells are treated with NGF, Bax protein levels decrease by at least 5 fold, whereas Bcl-x levels are unaffected. Downregulation of Bax occurs within 8 hours of NGF treatment. Other agents which promote neurite formation and survival of PC12 cells, such as cPT-cAMP, also cause a specific decrease in Bax levels. In contrast, serum or insulin, which promote PC12 survival but do not cause differentiation, do not affect the level of Bax. These results suggest that Bax downregulation is associated with PC12 differentiation. We have also observed that Bax is preferentially downregulated during development of the brain and cerebellum. We are currently studying the molecular mechanism by which NGF causes Bax levels to decrease. We are also investigating the biological consequences of the change in the ratio of Bax to Bcl-x that occurs during PC12 differentiation.

## 424.11

GENERATION OF TRANSGENIC MICE OVEREXPRESSING BCL-2 OR BAX UNDER THE MOUSE CHOLINE ACETYLTRANSFERASE (ChAT) PROMOTER. J.D. Cooper\*, T. Michaelidis, G. Tzimogiorgis, D. Lindholm and H. Thoenen Department of Neurochemistry, Max-Planck-Institute for Psychiatry, 82152 Martinsried, Germany.

Although bcl-2 and bax appear to play a key role in respectively suppressing or enhancing the process of apoptotic cell death, the role of these molecules in the CNS remains unclear. To study the effect of overexpressing bcl-2 or bax in defined populations of neurons we have generated transgenic mice in which expression of these molecules is driven by the promoter region of the murine choline acetyltransferase (ChAT) gene. We have previously shown that a 4kb EcoRI/HindIII fragment of the 5' flanking sequence of the murine ChAT gene confers NGF-inducible expression of reporter genes in transiently transfected PC12 cells but not NIH 3T3 fibroblasts. This 4kb ChAT promoter fragment was linked to a murine bcl-2 mini-gene containing both coding exons of bcl-2. The same ChAT promoter fragment was also linked to a construct containing coding and endogenous intronic sequences of the mouse bax gene. Pronuclear injections of these constructs have generated several lines of ChAT-bcl-2 and ChAT-bax transgenic mice, some of which also express the reporter gene LacZ under the ChAT promoter. RT-PCR of F1 generation ChAT bcl-2 mice indicates that the region of the murine ChAT promoter used in our constructs is capable of driving transgenes within particular regions of the CNS. We are currently mapping the pattern of transgene and reporter gene expression to determine their specificity and the relative levels of transgenic vs. endogenous expression of bcl-2 or bax. ChAT-bcl-2 and ChAT-bax mice will subsequently be used in studies of naturally occurring developmental cell death and the assessment of the mechanism of cell death after neurotrophin withdrawal or neurotoxic insult in defined *in vitro* and *in vivo* manipulations.

## 424.13

NUMERICAL MATCHING OF GRANULE CELLS WITH PURKINJE CELL TARGET SIZE IN TRANSGENICS OVEREXPRESSING THE BCL-2 ONCOGENE. M. W. Vogel\*, H. S. Zanjani, J.C. Martinou, N. Delhay-Bouchaud, and J. Mariani. MPRC, Univ. MD Med. School., Baltimore, MD 21228, Inst. des Neurosciences., UPMC and CNRS, Paris, France and Glaxo Imb., Geneva, Switzerland.

Naturally occurring cell death is an ubiquitous feature of neuronal development involving the matching of neuronal numbers with trophic factor support. The proto-oncogene Bcl-2 has been shown to protect neurons from programmed cell death by blocking apoptosis. Zanjani et al. (1994) have shown that Purkinje cell (PC) numbers are increased by 50% in transgenics overexpressing Hu-Bcl-2 embryonically, while normal PC numbers are found in Hu-Bcl-2 transgenics with postnatal overexpression. The Hu-Bcl-2 transgene is overexpressed in PCs, but not in granule cells (GC). To determine the effect of overexpression of Hu-Bcl-2 in target neurons and larger target size on the survival of afferent neurons, we have analyzed GC numbers in both the embryonic and postnatal expressing lines of Hu-Bcl-2 transgenic mice. GC numbers were counted in serial sagittal paraffin sections of the fixed transgenic and control brains that had previously been analyzed for PC numbers. The number of GCs is increased by 28% (t-test;  $p < 0.05$ ) in the transgenic line overexpressing Bcl-2 embryonically, while GC numbers are normal in the postnatally overexpressing line. The ratio of GCs to PCs in both lines is similar to controls. The results indicate that the increased target size in the early expressing line provides for increased numbers of granule cells, but overexpression of the Bcl-2 oncogene in target neurons alone does not rescue afferent neurons.

## 424.10

BCL-2 SUPPRESSES APOPTOSIS AND ACTIVATION OF NF-KAPPA B INDUCED BY SINDBIS VIRUS INFECTION. K-I Lin, J.M. Baraban, J.M. Hardwick, M. Veluona, B. Levine, R. Narayanan and R.R. Ratan\* Johns Hopkins Univ., Baltimore, MD 21205

Infection of mice with Sindbis virus (SV) results in encephalitis and has thus been used to model human encephalitis due to alphaviruses. SV infection causes apoptosis in most cultured cell lines and primary neurons; overexpression of the human proto-oncogene bcl-2 suppresses SV-induced apoptosis. In previous studies, we have shown that NF-kappa B activation is necessary for SV-induced apoptosis in AT3 Neo prostate carcinoma cells. We now report that the activation of NF-kappa B is suppressed in AT3 Bcl-2 cells infected with SV as well as AT3 Neo cells infected with a recombinant SV carrying the bcl-2 gene. These observations suggest that Bcl-2's anti-apoptotic action may derive from inhibition of an NF-kappa B signaling pathway. Current studies are underway to define the precise mechanism by which Bcl-2 inhibits SV-induced NF-kappa B activation.

## 424.12

POSTNATAL OVEREXPRESSION OF HU-BCL-2 GENE IN LURCHER MUTANT MICE PROTECTS INFERIOR OLIVARY NEURONS FROM TARGET-RELATED CELL DEATH. H. Zanjani\*, J.C. Martinou, N. Delhay-Bouchaud, and J. Mariani. Institut des Neurosciences, UPMC and CNRS, Paris, France and Glaxo Imb., Geneva, Switzerland.

It has been shown that the human proto-oncogene Bcl-2 can protect cells from apoptosis. Overexpression of Hu-Bcl-2 in transgenic mice protects both Purkinje cells (PC) and inferior olivary neurons (ION) from naturally occurring cell death (Zanjani et al., 1994). In the *lurcher* mutant, almost 100% of the PCs and 75% of the IONs die due to the intrinsic degeneration of the +Lc PCs. To study whether Bcl-2 protects neurons from pathological death we introduced this gene in *lurcher* mutant mice by crossing NSEb-Hu-Bcl-2 transgenics with + + /Lc  $Mi^{Wh}$  mutant mice. Hu-Bcl-2 expressing +Lc offspring were identified by PCR for Hu-Bcl-2 gene expression and by the presence of a white coat spot indicating linkage to the *Lc* locus. +Lc genotype was also confirmed histologically. We have analyzed four adult mice that overexpressed the Hu-Bcl-2 gene and are +Lc in genotype. ION numbers were analyzed in serial coronal paraffin sections and the counts compared to ION numbers in Hu-Bcl-2 transgenic mice and +Lc mutant mice. The number of IONs in the Hu-Bcl-2 overexpressing +Lc mutants was similar to C57BL/6J wild type controls and increased 78% compared to +Lc mutant mice. The number of rescued IONs was 15% lower than the number of IONs in Hu-Bcl-2 transgenic mice (t-test;  $p < 0.02$ ). Hu-Bcl-2 +Lc cerebella resemble +Lc cerebella so postnatal Hu-Bcl-2 overexpression did not prevent the death of +Lc Purkinje cells. We suggest that the genetic pathway for +Lc PC death may be initiated prenatally as in Lc/Lc mice and/or is independent of Hu-bcl-2 gene action. The rescue of IONs in Hu-Bcl-2 +Lc mice shows that bcl-2 gene overexpression can prevent target related cell death.

## 424.14

AXOTOMY-INDUCED MOTONEURON DEATH IN Cu/Zn SOD KNOCKOUT MICE. J.L. Elliott<sup>1</sup>\*, J. Harding<sup>1</sup>, A. Reaume<sup>2</sup>, E.K. Hoffman<sup>2</sup>, R. Scott<sup>2</sup>, and W.D. Snider<sup>1</sup>, Dept. of Neurology<sup>1</sup>, Washington University, St. Louis, Mo, 63110; Cephalon Inc.<sup>2</sup>, N.J.

Missense mutations in the gene encoding Cu/Zn superoxide dismutase (SOD1) are responsible for one form of familial amyotrophic lateral sclerosis (FALS). Unclear however, is the mechanism by which abnormalities in SOD1 lead to motoneuron loss. Experiments using transgenic mice overexpressing the mutant human SOD1 provide support for a toxic gain of function model. An alternative hypothesis is that motoneuron survival is dependent on levels of SOD1 and that decreases in overall levels of SOD1 activity lead to motoneuron loss. Previously this hypothesis has been difficult to test *in vivo*, but we have now gene-targeted mice heterozygous and homozygous for deletions in the murine SOD1 gene. These mice have 50% and 0-5% of normal SOD1 activity respectively and are ideal for definitively addressing this hypothesis. At 2.5 months of age, gene-targeted mice heterozygous for a SOD1 appeared phenotypically normal. To examine the vulnerability of adult motoneurons in adult SOD1 deficient mice, a right facial axotomy was performed on female (+/-) knockout and age matched (+/+) controls. At 5 weeks post-axotomy, the degree of facial motoneuron loss in control and heterozygote mice was similar (37% in control vs. 42% in heterozygotes). At 10 weeks post axotomy there was a trend toward more significant loss of facial motoneurons in heterozygotes (68%) than control (59%) but the results did not achieve statistical significance. Interestingly the degree of facial motoneuron loss in control (+/+) mice following axotomy was considerably higher than has been previously observed in adult rats. Experiments to date suggest that gene-targeted mice with 50% of normal SOD1 activity do not exhibit increased motoneuron loss following axotomy compared to controls, at least during the time frame studied. The consequences of further lowering SOD1 activity on motoneuron survival are now being addressed with similar experiments in mice homozygous for the SOD1 knockout.

## 424.15

**NEURONAL CELL DEATH IN WEAVER SUBSTANTIA NIGRA IS NON-APOPTOTIC.** TF Oo<sup>1</sup>, C Henchcliffe<sup>1</sup>, SWM Harrison<sup>2</sup>, SK Roffler-Tarlov<sup>2</sup>, RE Burke<sup>1</sup>\*, <sup>1</sup>Dept Neurology, Columbia University, NYC, NY; <sup>2</sup>Dept of Neuroscience and Dept of Anatomy & Cell Biology, Tufts University, Boston, Mass.

Weaver (wv/wv) is a murine mutation which results in the spontaneous loss of several cell populations during postnatal development including dopamine neurons in the substantia nigra (SN). The mechanism of cell death is unknown. We have shown in rat that developmental cell death with the morphology of apoptosis occurs in SN. We therefore sought to determine whether augmented apoptotic cell death may occur in wv/wv. We used silver staining to identify dying cells in wv/wv, wv/+ and +/+ mice at postnatal days (PNDs) 7, 14, 24/25 and adults. As in normal rats, natural cell death with the morphology of apoptosis was observed in SN in all mouse genotypes during postnatal development. However, we did not observe augmented apoptotic cell death in wv/wv. At PND 24/25 wv/wv =  $4.4 \pm 0.9$  (N=3), wv/+ =  $3.2 \pm 0.5$  (N=4), +/+ =  $3.1 \pm 0.6$  (N=4) apoptotic cells/SN section. Unique to the wv/wv genotype was the occurrence of non-apoptotic cell death in SN. Degrating cells appeared neuronal, with an argyrophilic nucleus and cytoplasmic silver deposits. These cells appeared on PND 14, were most numerous on PNDs 24/25, and were very rare in adult animals. Rarely degenerating cells were observed in wv/+ mice on PND 24. Degrating cells could also be identified by abnormal nuclear Nissl stain, but they were not TH-positive, possibly due to loss of phenotype expression. In situ 3'-end labeling of midbrain sections from wv/wv revealed no evidence for apoptotic cell death. In conclusion, the morphology of cell death in wv/wv SN is non-apoptotic and it remains to be determined whether it is necrotic or an alternate morphology of programmed cell death. NS26836, NS20181, PDF.

**APOPTOSIS IN WEAVER AND LURCHER MUTANT MICE**

U. Wüllner\*, P.-A. Löschmann, F. Eblen, D. Otto, M. Weller and T. Klockgether, Dept. of Neurology, Eberhard-Karls-University, Tübingen, Germany

Few *in vivo* data are available on apoptosis in neurodegenerative disease and an appropriate animal model is lacking. Apoptotic programmed cell death in the developing nervous system is associated with a characteristic DNA fragmentation. We used *in situ* end labeling to study apoptosis in mutant weaver (wv) and lurcher (lc) mice. Lc is an autosomal dominant mutation that resembles adult dominant ataxia in its histological and clinical features; Purkinje cells degenerate from P6 onwards and affected animals show symptoms at about P12. Apoptosis occurred in Purkinje and granule cells of affected lc mice; labeled cells were also found in brain stem nuclei. Wv is an autosomal recessive mutation leading to cerebellar granule cell loss and - in homozygous animals - to impairment of the nigrostriatal system. A single litter of wv mice (heterozygous parents) at P9 segregates in two groups on the basis of the number of apoptotic granule cells (average number of positive cells per midsagittal 8µm section:  $94 \pm 5$  vs.  $24 \pm 7$ ). Purkinje cells appeared to be affected to a much lesser extent.

## 424.19

**A MUTATION OF THE pRB-BINDING REGION OF SV40 T-ANTIGEN (Tag) ALTERS TARGETED PURKINJE CELL DEATH IN TRANSGENIC MICE** W.S. Yunis\*, H.B. Clark, H.T. Orr, T.J. Ebner, A.J. Beitz, C. Iadecola, and R.M. Feddersen, University of Minnesota, Minneapolis, MN 55455.

We have shown previously that intact SV40 Tag and the T147 form of Tag with the pRB-binding region intact result in Purkinje cell (PC) death and ataxia when their expression is directed transgenically to murine PCs by the *pcp-2* promoter. To test whether other portions of the Tag molecule are sufficient to induce PC death, transgenic mice were made using the PVU-Tag mutation (Tag unable to bind pRB) with the *pcp-2* promoter. Six PVU lines have been generated, four of which develop ataxia by three weeks of life. These mice differ from our previous Tag transgenic lines in that the PVU mice have minimal loss of PCs at the onset of ataxia. There is some loss of PCs over time in most lines, but not as severe as seen in lines made with intact Tag or T147. Two PVU-expressing lines are not ataxic and have no PC loss. One of these nonataxic lines has a single copy of the transgene which has a 3'-end deletion which may affect the ability of the Tag to bind p53. The other nonataxic line has expression of Tag in only some PCs. Although there is loss of PCs in the ataxic PVU lines, it occurs late in the disease course and cannot account for the onset of ataxia, particularly when compared to the degree of PC loss necessary for ataxia in the other Tag transgenic lines. The PC loss appears to be apoptotic but differs from that in the other Tag-transgenic mice in that cell death is not preceded by DNA synthesis. In one ataxic PVU line, P03, there is a decrease in 2-deoxyglucose uptake in the cerebellar cortex and deep cerebellar nuclei after the onset of ataxia but prior to significant loss of PCs. There is evidence that there is a failure of maturation of the cerebellar cortex in the ataxic PVU-transgenic mice. We conclude that in transgenically targeted PCs, SV40 Tag without its pRB-binding activity can induce sublethal alterations in PC development/function sufficient to produce ataxia. In PVU mice onset of ataxia is independent of PC loss, while in Tag transgenic lines with intact pRB binding sites, ataxia occurs only after significant PC loss. (Supported by P01 NS31318)

## 424.16

**APOPTOTIC AND NON-APOPTOTIC CELL DEATH IN THE MOUSE MUTANT WEAVER.** S.M.W. Harrison\* and S. Roffler-Tarlov. Dept. of Neuroscience & Dept. of Anatomy and Cell Biology, Tufts Univ. Sch. of Med. Boston, MA 02111.

The postnatal development of at least four cell populations are affected by the murine autosomal recessive mutation *weaver*. Large numbers of dopamine-containing neurons in the midbrain, granule and Purkinje cells in the cerebellum, and male germ cells fail to complete terminal differentiation and many die. To better understand the consequences of the *weaver* mutation, we have begun to study the death of the affected cell populations.

The death of a cell can be generally categorized as apoptotic, non-apoptotic non-necrotic, or necrotic by morphological characteristics. One of the properties that most consistently defines an apoptotic cell death is the fragmentation of the cell's DNA into nucleosomal sized pieces. Apoptotic cells can be detected in tissue sections by *in situ* end-labeling (ISEL) of the free DNA ends generated by this type of fragmentation. We have used this technique to determine whether the cells vulnerable to the actions of *weaver* die by apoptosis. We have also examined the morphological details of *weaver* cell death using standard microscopic techniques.

Cell death in the brain of the homozygous *weaver* (wv/wv) takes place within the first few postnatal weeks and after postnatal day (P) 28 in the testis. We have been unable to detect apoptotic cells by ISEL in the midbrain of P14 wv/wv mice. ISEL has, however, revealed extensive apoptosis within the wv/wv granule cell population at P7 and P14. Germ cells in the wv/wv male appear to undergo both apoptotic and non-apoptotic, non-necrotic deaths as determined by ISEL, thin-section light microscopy, and EM. Necrosis was not observed in any of the affected cell populations. These results suggest that lack of the normal *weaver* gene product provides a signal that leads to apoptotic and non-apoptotic modes of cell death but not necrosis. The program of cell death followed may differ between cell types as well as within a single cell type. NIH NS 20181.

## 424.18

**IDENTIFICATION OF GENES THAT CHANGE EXPRESSION IN DYING MOTONEURONS DEPRIVED OF TROPHIC SUPPORT.**

C.E. Milligant, H.A. Masont, R.W. Oppenheim<sup>§</sup> and L.M. Schwartz\*  
\*Department of Biology, Univ. of Massachusetts, Amherst, MA and  
§Department of Neurobiology and Anatomy, Bowman Gray Medical School, Winston-Salem, NC.

One population of neurons in which cell death has been extensively studied is spinal motoneurons in the developing chick spinal cord. The difficulty in studying molecular changes in this tissue, or any complex tissue displaying cell death, is that condemned cells are interspersed among viable ones. For these studies, we have used and characterized a primary tissue culture system that yields a pure population of motoneurons that survive in the presence of trophic support (muscle extract, MEx) and die when deprived of it. RNA was collected from motoneurons 16-18 hours after plating with or without MEx, a time when cells deprived of MEx are committed to die. After amplification of antisense RNA and conversion to double stranded cDNA, messages that are potentially up- or down-regulated in death-committed motoneurons were cloned using a PCR based subtractive hybridization paradigm. After the first round of subtraction several up-regulated messages have been identified. These appear to include a novel sequence, a "DEAD" box gene, and a Bcl-2 family member. Identification and characterization of the genes involved in motoneuron cell death will contribute to the understanding of normal developmental processes as well as the pathological cell death of motoneurons.

This work was supported by a grant from the Spinal Cord Research Foundation to CEM, NS20402 to RWO and GM40458 to LMS.

INTRACELLULAR SIGNALLING MECHANISMS MEDIATING MICROGLIAL MOTILITY INDUCED BY COMPLEMENT 5A (C5a) Ch. Nölke, Th. Möller, T. Walter, H. Kettenmann\* Cellular Neurosciences, Max-Delbrück-Center for Molecular Medicine, Robert-Rössle-Str.10, D-13125 Berlin, FRG.

Microglial cells are considered as the resident macrophages of the central nervous system. They respond to most pathological events by rapid transformation from a quiescent into an activated phenotype being characterized by increased cytotoxicity and motile activity. To search for motility controlling factors, we tested the complement factor C5a by time lapse videomicroscopy and a computer-based motility assay. Upon stimulation with C5a microglial cells responded by transient motility enhancement as characterized by intense ruffling of the cytoplasmic membrane and spreading on the substrate. This process was driven by actin polymerisation since cytochalasin B was able to inhibit the C5a-induced motility. C5a-receptor activation induced the release of  $Ca^{2+}$  from IP3-sensitive intracellular stores as recorded by a Fluo-3 based imaging system. However, conditions mimicking intracellular  $Ca^{2+}$ -transients like incubation with thapsigargin or addition of the calcium ionophore A23187 were not able to induce the motility reaction in microglia suggesting that  $Ca^{2+}$ -changes are not necessary for, but merely associated with, microglial motility. Both  $Ca^{2+}$  transients and motility were sensitive to preincubation with pertussis toxin (PTX) suggesting that a PTX-sensitive G-protein is involved in intracellular signalling after C5a-receptor activation. However, the C5a-induced motility reaction was markedly attenuated by Wortmannin, an inhibitor of PI3K 3-kinase (PI3-K), but the  $Ca^{2+}$ -transients were not affected by this treatment. PI-3K, activated by G-protein subunits, may therefore play a role in actin rearrangement via its products. These data imply that the signal transduction pathways for motility/chemotaxis and  $Ca^{2+}$ -regulated cellular responses, respectively, diverge downstream the C5a-receptor associated G-protein. Since complement factors are released at pathological sites, the PI3-K dependent signal cascade could serve to direct microglial cells to the lesioned or damaged brain areas.

## 425.3

MICROGLIA EXPRESS NEUROTROPHINS AND RESPOND TO BDNF AND NT-3. S. Elkabes\*, E.M. DiCicco-Bloom and J.B. Black, Neurosci. Cell Biol., RWJMS/UMDNJ, Piscataway, NJ 08854

Although microglia-mediated cytotoxicity has been extensively investigated, little is known about the potential microglial role in neuronal and glial support. Characterization of trophic elaboration by microglia and identification of responsive populations may define novel functions. We now report that microglia/brain macrophages express neurotrophins of the NGF gene family *in vitro* and *in vivo*, suggesting that these cells promote development and normal function of neurons and glia. Moreover, neurotrophins appear to act on microglia themselves, promoting mitosis and survival *in vitro*.

Our observations indicated that microglia express neurotrophins in a region-specific manner and that within any region only subpopulations elaborate trophins. Using an antiserum specific for NT-3 with the microglial/macrophage marker OX-42, we identified double-labelled cells in microglial subpopulations of the cerebral cortex, globus pallidus and medulla; NT-3 was undetectable in OX-42 positive cells in the ependyma, external capsule, meninges and choroid plexus. *In situ* hybridization studies on purified microglial cultures suggested that neurotrophins are synthesized by microglia. They also confirmed that only subpopulations express the NGF and NT-3 genes, substantiating the notion of microglial heterogeneity.

PCR analysis indicated that *trk* tyrosine kinase receptor genes are expressed by microglia *in vitro*, implicating responsiveness to neurotrophins. Indeed, BDNF and NT-3 increased  $^3H$ -thymidine incorporation two-fold in cultures grown in serum free medium suggesting stimulation of microglial mitosis. Moreover, in serum containing cultures, NT-3 increased total cell number, indicating synergism between factors present in serum and NT-3 to promote proliferation. NGF was ineffective. Our results indicate microglial expression of select neurotrophins which in turn differentially regulate microglial proliferation.

## 425.5

LIGHT MICROSCOPIC AND ULTRASTRUCTURAL DETECTION OF DNA FRAGMENTATION IN ACTIVATED MICROGLIA: *IN SITU* CELL DEATH AS A POSSIBLE MECHANISM FOR POPULATION CONTROL OF MICROGLIA L. L. Jones<sup>1</sup>, R. Banati<sup>1,2\*</sup>, L. Bonfanti<sup>3</sup> and G. W. Kreutzberg<sup>1</sup>. <sup>1</sup>Max-Planck-Institute of Psychiatry, Dept. of Neuromorphology, Martinsried, Germany 82152; <sup>2</sup>MRC-Clinical Sciences Center, Neurology Group, Cyclotron Unit Royal Postgraduate Medical School, Hammersmith Hospital, London, England W120HS; <sup>3</sup>Scuola Normale Superiore and Istituto di Neurofisiologia del CNR, Pisa, Italy 56127.

Microglia are the main immune effector cells of the CNS and it has been suggested that they play a vital role in the neuronal regeneration process. Shortly after injury, microglia begin to accumulate at the lesion site through *in situ* proliferation, as well as in the projection areas of the lesioned neurons. At the peak of their proliferation, approximately four days after lesion, the microglia population has increased four fold and many microglia cells occupy a distinct perineuronal position. However, within three weeks of this dominating presence, the microglial population tapers down once again to a resting state. Previous studies have suggested the possibility that the microglia may migrate away from the affected area and leave the CNS through blood vessels. Another possibility would be that the microglia population is regulated by programmed cell death. We investigated the possible role of programmed cell death in the down regulation of the microglial population.

Facial nerve axotomy or the injection of toxic ricin into the facial nerve was performed on adult Wistar rats, with survival periods from 1 to 120 days. Both coronal sections of the facial nucleus and primary cell culture from microglia were submitted to *in situ* terminal transferase labelling. DNA fragmentation labelling was observed both at the level of light microscopy as well as at the level of electron microscopy. These results were verified by the presence of DNA laddering observed through gel electrophoresis.

We demonstrate, through the use of *in situ* terminal transferase labelling, the specific delayed presence of DNA fragments in the facial nucleus after peripheral transection of the nerve. Our results show that microglia undergo DNA fragmentation and suggest programmed cell death as a mechanism to control activated microglia following injury.

## 425.2

SELECTIVE BINDING OF TERMINAL N-ACETYL-GALACTOSAMINE-SEPCIFIC LECTINS (SBA AND VVA) TO MICROGLIA IN EMBRYONIC MOUSE BRAIN. I. Nagata<sup>1</sup> and K. Ono<sup>2\*</sup> <sup>1</sup>Dept. of Cell Biology, Tokyo Metro. Inst. Neurosci., 2-6 Musashidai, Fuchu 183; <sup>2</sup>Dept. of Anatomy, Okayama Univ. Med. Sch., Shikadamachi, 2-5-1 Okayama 700, Japan

To obtain specific surface markers on immature glia, embryonic mouse brains were immersed in fixatives containing glutaraldehyde. Frozen sections were made and stained with various fluorescein-conjugated (F) lectins. F-SBA and -VVA (Vector, 1:100), both of which react to the terminal N-acetylgalactosamine, bound specifically to "amoeboid" and "ramified" types of cells presumed to be microglia. They were localized mainly in the subventricular zone and gray matter in the cerebral cortex, respectively, and emerged from ca. embryonic day 14, increased during the prenatal stage, decreased at the postnatal stage and disappeared at ca. postnatal day 10. In the EM study, these labeled cells showed features characteristic of microglia. Thus, such spatially and temporally defined bindings of SBA and VVA to microglia in embryonic brain may serve as good markers for elucidating the origin and differentiation of microglia.

## 425.4

THREE-DIMENSIONAL MORPHOLOGY OF RESIDENTIAL AND REACTIVE MICROGLIA IMMUNOSTAINED BY ANTI- $\beta$ -THYMOSIN ANTIBODY. K. Tohyama\*, T. Morita, N. Sato<sup>2</sup>, K. Sano, H. Yaginuma<sup>1</sup> and Y. Uchiyama<sup>2</sup>, Dept. of Cell Biology and Neuroanatomy, Iwate Medical Univ. School of Medicine, Morioka, Iwate 020 Japan, <sup>1</sup>Dept. of Anatomy, Institute of Basic Medical Science, University of Tsukuba, Tsukuba, Ibaragi 305 Japan, and <sup>2</sup>Dept. of Anatomy, Osaka Univ. School of Medicine, Suita, Osaka 565 Japan.

We have studied the 3-dimensional morphology of residential and reactive microglia, in reconstructions of confocal laser images taken at 0.2-0.5  $\mu$ m intervals from 50-80  $\mu$ m-thick sections of adult rat spinal cord or facial nucleus, immunostained by anti- $\beta$ -thymosin antibody ( $\beta$ -Th; Dev. Brain Res. 79:177-185, 1994). In normal tissues, residential microglia showed a ramified morphology, with long, slender, immunostained processes, in both gray and white matter. Such morphological characteristics of  $\beta$ -Th-immunoreactive cells correspond with those of OX-42 immunopositive Hortege cells in rat CNS. Reactive microglia immunopositive for  $\beta$ -Th were enormously increased in number in the dorsal and ventral horns of ipsilateral L4-L5 spinal cord or in the ipsilateral facial nucleus following sciatic nerve or facial nerve transection. However, these peripheral nerve injury (PNI)-induced microglia did not show amoeboid morphology; most continued to display the ramified morphology of residential microglia. These morphological characteristics of PNI-induced reactive microglial cells suggest that they possess non-phagocytic properties. These findings raise the question of the non-phagocytic role of microglial cells and also show that the  $\beta$ -Th antibody is a good marker for both residential and reactive microglial cells.

## 425.6

MACROPHAGE RESPONSES FOLLOWING SCIATIC NERVE INJURY IN TRANSGENIC MICE DEFICIENT FOR IL-1 OR TNF- $\alpha$  RECEPTORS. AT Dailey<sup>1\*</sup>, M. Carpenter<sup>2</sup>, AM. Avellino<sup>1</sup>, J. Peschon<sup>2</sup>, M. Glaccum<sup>2</sup>, M. Klotz<sup>1</sup>. <sup>1</sup>Dept. Neurosurgery, University of Washington, Seattle WA 98115, <sup>2</sup>Immunex Corporation, Seattle WA

During Wallerian degeneration in the peripheral nervous system (PNS), there is a pattern of axonal degeneration followed by a monocyte/macrophage (M $\phi$ ) response beginning on day 1 (Avellino et al., 1994, Griffin et al., 1993). Successful completion of degeneration and possibly regeneration are dependent upon the arrival of peripheral blood monocyte/M $\phi$ . The recruitment and activation of monocyte/M $\phi$  is controlled by growth factors and cytokines with pleiotropic effects. Previously, we have found differences in monocyte/M $\phi$  response in the osteopetrotic mouse (deficient in macrophage colony stimulating factor) during PNS Wallerian degeneration (Dailey et al., 1994). However, the precise mechanisms responsible for the M $\phi$  recruitment seen during Wallerian degeneration are not understood.

To further determine the role of specific cytokines in M $\phi$  responses during PNS Wallerian degeneration, we employed mice with targeted gene deletions of either the high affinity IL-1 receptor or the p60 and p80 components of the TNF- $\alpha$  receptor. M $\phi$ 's were identified with the F 4/80 monoclonal antibody. Degenerating sciatic nerve segments were harvested at 3, 7, and 14 days following transection. No differences in M $\phi$  counts (expressed as cells / 0.1 mm<sup>2</sup>) were observed in uncut nerves (control 13 $\pm$ 1, IL-1 11 $\pm$ 1, TNF- $\alpha$  10 $\pm$ 1; p>.05) or 7 and 14 days (control 123 $\pm$ 4, IL-1 118 $\pm$ 5, TNF- $\alpha$  115 $\pm$ 6; p>.05) following transection. However, at 3 days following transection fewer M $\phi$  were observed in both the IL-1 and TNF- $\alpha$  receptor deficient mice as compared to the response in normal control animals (control 30 $\pm$ 2, IL-1 22 $\pm$ 2, TNF- $\alpha$  20 $\pm$ 2; p<.005).

In addition, sciatic crush was used as a model for regeneration in the three groups. Although axons successfully regenerated in the transgenic mice, there was a decrease in the number of cells staining with antibody to nerve growth factor (NGF) in the distal portions of regenerating nerves in the IL-1 receptor deficient animals. These findings suggest that these cytokines may play a role in cellular responses in axonal degeneration and regeneration. However, the demonstration of only a partial effect points to the importance of other cytokines and their receptors. Supported by a CIDA grant to MK and VA funding.

**SYNERGETIC EFFECTS OF NEURON-DERIVED FACTORS AND COLONY-STIMULATING FACTOR 1 (CSF-1) ON MACROPHAGE PROLIFERATION** A. Dobbertin and M. Mallat\*, INSERM U114, Paris, France.

Infiltration and proliferation of bone marrow-derived macrophages (BMM) in the CNS contribute to growth and reactions of microglia during development or following lesions. *In vitro* cultures were used to investigate influences of rat or mouse CNS cells on purified BMM derived from adult rodent bone marrow. Survival and proliferation of isolated BMM required addition of CSF-1 to culture medium. A coculture system allowing exposure of BMM to soluble compounds released by CNS-derived cells, indicated that neurons from different developing brain regions produce factors which dramatically enhance mitogenic effect of CSF-1. Using saturating concentration of CSF-1 (10ng/ml of human recombinant CSF-1), the presence of neurons led to a 2-fold increase of the number of BMM within 72h. In contrast, cultured astrocytes or microglia failed to enhance CSF-1 mitogenic effect. <sup>3</sup>H-thymidine labeling of synchronized BMM indicated that the neuronal stimulation involved shortening of the cell cycle rather than induction of proliferation of a BMM subpopulation unresponsive to CSF-1 alone. Moreover, neuron-derived factors failed to rescue BMM from death in the absence of exogenous CSF-1. Potentialisation of CSF-1 mitogenic effect by neurons was also observed using cultured ameboid microglia or peritoneal macrophages instead of BMM. Considering that astrocytes can produce CSF-1, our results suggest a cooperation between different CNS cell lineages in promoting microglial growth or reactions.

## 425.9

**THE EFFECT OF PINEAL MICROGLIA ON CULTURED PINEALOCYTES** S.-Y. Tsai\* and I. A. McNulty, Department of Cell Biology, Neurobiology and Anatomy, Loyola University Medical Center, Maywood, IL, 60153

Microglia play important roles during neural development and damage through expression of trophic factors and adhesion molecules (Piani, Constam et al. 1994). Earlier studies have shown that microglia comprise an important part of the pineal gland in the adult rat (Kelly, Fox et al. 1993; Pedersen, Fox et al. 1993). However, the effects of microglia on pinealocytes have not been studied. The presence of microglia in 1 day Sprague-Dawley (S/D) neonate was verified by Dil-acetylated-LDL uptake cells in pineal cell suspension and OX-42 immunocytochemistry on pineal sections. In order to investigate the effects of microglia on pinealocyte development, microglia-depleted and microglia-enriched pineal cell cultures were generated from 1-day-old S/D neonate pineal cells by fluorescence activated cell sorting (FACS). Pineal cells (1X10<sup>5</sup> cells/coverslip) were plated in the following groups: 1) control pineal cells prepared before FACS, 2) microglia-depleted pineal cells, 3) microglia-enriched pineal cells and 4) combined culture of microglia-depleted and enriched pineal cells. After 7 days of culture (humidified 5% CO<sub>2</sub>, 95% air, 37°C), tissues were fixed (4% paraformaldehyde) and processed for S-Ag immunocytochemistry followed by morphometric analysis of pinealocyte neurite length. Our data indicate that microglia comprise 5-10% of the total cells in the pineal gland of the neonate. Pinealocytes neurite extension is enhanced in a microglia-depleted environment and inhibited in a microglia-enriched environment (Anova, p<0.01). The results of this study suggest that microglia play important roles in pinealocyte development.

## 425.11

**GLIAL CELL LINES DERIVED FROM MX-1-T-ANTIGEN TRANSGENIC MICE EXHIBIT INDUCIBLE ONCOGENE EXPRESSION.** J. P. Hamman<sup>1</sup>, C. B. Greco<sup>1</sup>, W. C. Kisseberth<sup>2</sup>, J. Y. Garbern<sup>3</sup> and A. Messing<sup>2</sup>. 1) CytoTherapeutics, Inc., Providence, RI, 02906, and 2) University of Wisconsin-Madison, Madison, WI, 53706, 3) University of Pennsylvania, Philadelphia, PA, 19104.

The regulation of oncogene expression in neural cell lines offers a valuable mechanism for controlling cellular differentiation. In order to derive neural cell lines with regulatable oncogene expression, we produced a line of transgenic mice in which the mouse Mx-1 promoter directs the expression of the SV40 Large T-antigen. The Mx-1 promoter has been previously shown to be highly inducible by interferon (IF). EGF-responsive neural stem cells that have the capacity to generate astrocytes, oligodendrocytes and neurons *in vitro* were derived from these animals. A portion of the stem cells were forced to differentiate by removing EGF and adding FBS. With the addition of 1000 Units/ml of alpha/beta IF, clusters of flat, astrocyte-like cells began to proliferate and eventually filled the culture dishes. The cells have been continuously maintained in IF for over 70 passages and have maintained a doubling rate of 24-36 hours over this period. When probed with a panel of neural and glial-specific antibodies, these IF-treated cells were virtually all nestin- and T-antigen-positive but were weakly immunoreactive for glutamine synthetase and were GFAP-negative. Upon removal of the IF, these flat cells rapidly decreased their rate of division, lost T-antigen immunoreactivity and gradually increased glutamine synthetase and GFAP immunoreactivity. These cells survive for several months *in vitro* and little or no proliferation is evident in the continued absence of IF. Interestingly, T-antigen immunoreactivity and cellular proliferation can be re-induced with the addition of IF. Cell lines with the capacity to proliferate or differentiate in a controlled fashion are useful tools for the study of developmental gene expression.

## 425.8

**A QUANTITATIVE IMMUNOHISTOCHEMICAL DESCRIPTION OF THE MACROPHAGE RESPONSE DURING PERIPHERAL NERVE WALLERIAN DEGENERATION**

A.M. AVELLINO\*, D. HART, A. DAILEY, M. GROSS, K. ANDRUS, & M. KLIOT, DEPARTMENT OF NEUROLOGICAL SURGERY, UNIVERSITY OF WASHINGTON SCHOOL OF MEDICINE & SEATTLE VAMC, SEATTLE, WA, 98104.

Following axotomy in the peripheral nervous system, blood-borne monocytes rapidly invade the site of injury and, after a delay, the distal Wallerian degenerating segment of nerve where they differentiate into activated macrophages that remove degenerating axonal and myelin debris (Friede & Beuche, 1993; Griffin et al., 1992; Perry et al., 1993; Stoll et al., 1989). The mechanisms responsible for this invasion remain incompletely understood.

We characterized quantitatively temporal and spatial aspects of the macrophage response following transection of the rat sciatic nerve. Immunohistochemistry was performed on longitudinal frozen sciatic nerve sections from 50 male Lewis rats sacrificed from 4 hours to 35 days after nerve transection using the commercially available ED-1, ED-2, and OX-42 as well as the CD11a (ICCS Corp.) monoclonal antibodies. We observed the following: 1) ED-1 positive macrophages began to increase in number in the external epineurium at 4 hours and peaked at 7 days, before declining to baseline control levels at 14 days; 2) a statistically significant two-fold increase in the number of intraneural ED-1 positive macrophages was seen by 1 day in the distal Wallerian degenerating segment of nerve; 3) intraneural ED-1 positive macrophages increased in number synchronously along the length of degenerating nerve over a 21 day period; 4) the morphology of infiltrating intraneural ED-1 positive macrophages changed over time from small slender ramified cells to large elongated multivacuolated cells; 5) intraneural OX-42 positive macrophages increased in number at 2 days and peaked at 14 days before leveling off; 6) intraneural ED-2 positive macrophages increased in number at 2 days and peaked at 14 days, before declining; and 7) intraneural CD11a positive macrophages increased in number at 2 days and peaked at 14 days, before declining.

Differences in the macrophage response as determined by different antibodies may reflect subpopulations and/or functional states of activation. Supported by NIH and VA funds as well as a CIDA grant to MK.

## 425.10

**CO-LOCALIZATION OF THE B2-CHAIN OF LAMININ AND AMYLOID PRECURSOR PROTEIN IN THE DEVELOPING AND ADULT CNS OF THE RAT**

G. Hager<sup>1</sup>, G. Kerber<sup>1</sup>, R. Banati<sup>1</sup>, P. Liesi<sup>2</sup>, and G. W. Kreutzberg<sup>1\*</sup>. <sup>1</sup>Max-Planck-Institute of Psychiatry, Dept. of Neuromorphology, D-82152 Martinsried FRG; <sup>2</sup>Lab. of Molecular and Cellular Neurobiol., National Institute on Alcohol Abuse and Alcoholism, NIH, 12501 Washington Avenue, Rockville, MD 20852

The ECM-molecule laminin plays a role in brain development as well as in neurodegeneration and regeneration in the mature CNS. Laminin is increased in glial cells during Alzheimers disease and has binding sites for amyloid precursor protein (APP). Recently we have shown that a synthetic peptide derived from a neurite outgrowth-promoting domain on the B2-chain of laminin modulates the electrical activity of pyramidal cells in adult rat neocortex and increases the excitotoxic vulnerability of neurons. With antibodies against the B2-chain of laminin and APP we show co-localisation of both molecules in the CNS.

Cryostat sections were fixed in p-benzochinone and double labelled with antibodies against the B2-chain of laminin or APP and GFAP. The sections were observed with confocal laser scanning microscopy.

Immunoreactivity against both the B2-chain of laminin and APP was co-localized on GFAP-positive radial glial fibers and on astrocytes in the developing cerebellum. Punctuated labelling of antibodies against both antigens could be seen on neurons and in the neuropil. Labelling for both antigens persisted in neurons and the neuropil of adult rats but was confined to perivascular astrocytes, Bergmann glial fibers and GFAP-positive astrocytes in the white matter of the cerebellum. In the corpus callosum and in a subpopulation of GFAP-positive astrocytes in the hippocampus of adult rats, GFAP positive astrocytes displayed immunoreactivity for the B2-chain of laminin but not for APP.

Our results suggest that the B2-chain of laminin and APP are co-localized and widely distributed in different patterns in developing and adult CNS. This may be relevant for the functional role of both molecules in the developing and adult CNS.

## 425.12

**ELECTROPHYSIOLOGICAL FEATURES OF MÜLLER GLIAL CELLS FROM HEALTHY AND PATHOLOGICAL HUMAN RETINA.** T. Pannicke, M. Francke, B. Biedermann, P. Wiedemann, F. Faude, and W. Reichelt\*, Paul-Flechsig-Institute for Brain Research, #Eye Hospital, University of Leipzig, 04109 Leipzig, Germany.

We intended to compare the electrophysiological features of Müller cells (MC) from healthy and pathologically changed human retinas. To this end we performed whole-cell voltage-clamp and patch-clamp experiments on acutely enzymatically isolated MC. The study was approved by the ethic committee of the University of Leipzig.

A clear loss of inwardly rectifying K<sup>+</sup> currents was found in the pathological MC. This caused a dramatic increase of the input resistance (ir). Of the healthy MC 92% had an ir of less than 0.5 GΩ, whereas of the pathological MC 55% and 23% had an ir higher than 1 GΩ and between 0.5 and 1 GΩ, respectively. The transient Na<sup>+</sup> current amplitudes were clearly increased in pathological MC.

Pathological as well as healthy MC possessed a high affinity Na<sup>+</sup>/glutamate uptake, but no glutamate receptor currents. The high affinity Na<sup>+</sup>/GABA uptake found on MC of other mammals was also present on human MC. However, the human MC additionally displayed GABA<sub>A</sub> receptor currents, which could not be found in guinea pig, mouse and horse MC. Interestingly, in a recent paper GABA<sub>A</sub> receptor currents were reported for the skate MC (Malchow, R.P. et al. (1986) Proc. Natl. Acad. Sci. USA 86, 4326-4330). We are not yet able to decide whether or not there is a different density of glutamate- and GABA-transporters as well as GABA<sub>A</sub> receptors between healthy and pathological MC.

The loss of inwardly rectifying K<sup>+</sup> currents must severely interfere with the normal MC function, i.e. K<sup>+</sup> spatial buffering to maintain normal [K<sup>+</sup>]<sub>o</sub>. Supported by 0316916A and 01ZZ9103/2.23 (Bundesministerium für Bildung und Forschung, Germany).

## 425.13

A GLIAL POPULATION IDENTIFIED *IN VIVO* BY ANTIBODIES TO NG2 PROTEOGLYCAN AND PDGF ALPHA RECEPTOR. Akiko Nishiyama<sup>1</sup> and William B. Stallcup<sup>2</sup> Dept. of Neurosciences<sup>1</sup>, The Cleveland Clinic Foundation, Cleveland, OH 44195 and La Jolla Cancer Res Foundation<sup>2</sup>.

We have used antibodies against the NG2 proteoglycan and PDGF  $\alpha$  receptor to identify a unique population of cells in the developing and mature rat cerebellum *in vivo*. Both NG2 and PDGF  $\alpha$  receptor have previously been shown to be expressed by O2A progenitor cells *in vitro* and down-regulated as they differentiate into mature oligodendrocytes. During late embryonic and early postnatal stages *in vivo*, NG2 and PDGF  $\alpha$  receptor are colocalized on cells that share the features described previously for oligodendrocyte precursors. The immunoreactive cells, which are scattered throughout the central nervous system, continue to increase in number until the first postnatal week, which marks a peak in both the density of immuno-reactive cells and the extent of colocalization of the two molecules. The immunoreactive cells decrease in number after the second postnatal week but can still be detected in significant numbers in both gray and white matter of the mature brain. In the mature brain NG2 is localized on both cell bodies and processes, while PDGF  $\alpha$  receptor becomes mostly confined to cell bodies. The NG2-positive cells in the mature brain display a complex morphology with multiple processes. Cells in the white matter extend processes parallel to axon tracts, whereas those in the gray matter extend multiple, fine processes in all directions giving them the appearance of astrocytes. Confocal laser microscopy of sections double-labeled for NG2 and GFA reveals no overlap between NG2+ and GFA+ cells but shows that NG2-positive processes are closely apposed to those of GFA-positive astrocytes. The processes from each NG2-positive cell in gray matter surround several neuronal cell bodies. These findings indicate that in addition to their properties as oligodendrocyte precursors, the NG2+ / PDGF  $\alpha$  receptor+ cells have a unique physiological relationship between astrocytes and neurons.

## 425.15

VIMENTIN EXPRESSION AND INCREASED GFAP IN THE HIPPOCAMPUS AFTER REPEATED SEIZURES. J. L. Stringer\* Department of Pharmacology, Baylor College of Medicine, Houston TX 77030

Reactive gliosis is characterized by hypertrophy of the cell bodies and processes of astrocytes and an increase in the expression of glial fibrillary acidic protein (GFAP). The signal that regulates the transition to the reactive state is unknown, as is the role of vimentin. This study used a model of repeated seizures in the hippocampal-parahippocampal circuits of the anesthetized rat to determine the extent and time course of reactive gliosis in response to seizures. The appearance of vimentin after seizures was also examined. Reactive gliosis, detected by immunohistochemistry for the presence of GFAP and vimentin, was present 2-7 days after the repeated seizures. At least 9 seizures, or at least 250 sec of total seizure discharge, were needed to induce reactive gliosis. After seizures, cells staining for vimentin were found in the dentate gyrus molecular layer and hilar region, as well as in the molecular layer of CA1. Fewer cells were stained in the CA3 region. Sections stained for GFAP immunoreactivity showed cell staining throughout the hippocampus. These experiments demonstrate that repeated discrete seizures of the hippocampal-parahippocampal circuits can cause reactive gliosis and can induce expression of a glial protein (vimentin) that is not normally expressed in the adult brain. If the appearance of vimentin protein can be taken as a marker for reactivation of the vimentin gene, then the data demonstrate that seizures can alter gene expression in glia. Supported by NINDS NS28871 and NS01784.

## 425.17

PHENOTYPIC AND FUNCTIONAL STUDIES OF OLFACTORY NERVE ENSHEATHING CELLS. Isabelle A. Franceschini and Susan C. Barnett\*. Depts. of Neurol./Med. Onc., Univ. of Glasgow, Switchback Road, Glasgow G61 1BD, U.K.

Olfactory nerve ensheathing cells (ONECs) are a specialised type of glial cell, residing in the primary olfactory system, which are believed to play a role in the exceptional regenerative capacity of this tissue. We have developed a culture system in which ONECs closely resemble their *in vivo* counterparts and have assessed their ability to support neurite outgrowth as compared to astrocytes and Schwann cells.

ONECs were purified from neonatal rat olfactory bulbs using the O4 antibody and fluorescence activated cell sorting. Their antigenic profile was characterised with a large panel of neural markers under various culture conditions and compared to that observed during development. The serum-free medium (DMEM-BS) but not the serum-containing medium (DMEM-FCS) maintained the cells with a heterogeneous phenotype that closely resembled their *in vivo* counterparts. In the former medium, two classes of ONECs were observed, characterised on the basis of their morphology and antigenic profile using antibodies to polysialic acid and to the low affinity nerve growth factor receptor. Both cell types were detected *in vivo* from embryonic day 14. It is likely that they belong to the same lineage as two cell types of similar morphology and antigenic profile were detected in a retrovirus-infected ONEC cell line shown to be clonal by Southern blot analysis.

ONECs could be expanded *in vitro* in DMEM-FCS but also with a partially purified and yet unidentified factor(s) present in DMEM-BS conditioned by type I astrocytes (ACM). ONECs grown in either media supported greater neurite outgrowth, attachment and/or survival of cerebellar granule neurons than astrocytes or Schwann cells. Although the average neurite outgrowth-promoting activity of ONECs was constant regardless of the culture medium it was found that ONECs grown in ACM supported greater neuronal attachment and/or survival than ONECs grown in DMEM-FCS. This emphasises the importance of optimising the culture conditions for the study of ONEC-neuronal interactions if comparison are to be made with the *in vivo* situation.

NOVEL ZINC FINGER PROTEINS EXPRESSED IN THE NERVOUS SYSTEM. C. Wiese\*, J. Kim, A. Warrington and L. Hudson. Lab. of Developmental Neurogenetics, NINDS, National Institutes of Health, Bethesda, MD 20892, U.S.A.

Cells in the early stages of the oligodendrocyte lineage express a novel gene of the zinc finger superfamily, MyT1, that can bind to the cis-regulatory region of the myelin proteolipid protein (PLP) gene. By a random site selection assay, MyT1 was found to recognize a G-rich consensus sequence (GGTGGGGPuPuPu) that is present in a number of myelin genes. MyT1 contains six fingers of the C2HC class present in two widely separated clusters of two and four fingers each. The four finger cluster is associated with an acidic domain, whereas a large second acidic domain (88% glutamate residues) precedes the two finger cluster. MyT1 is encoded by a single gene, but a family member that is closely related to MyT1 was also found to be expressed in early CNS development. This MyT1 family member displays 92% amino acid identity with MyT1 in the DNA binding domains, although it is missing one finger. But unlike MyT1, the transcripts of the family member are not detectable in the oligodendrocyte lineage cells based on Northern and RT-PCR analysis. The coding regions of the mouse MyT1 are highly homologous to the human MyT1 (95% amino acid identity). MyT1 has been mapped to human chromosome 20 by a Southern analysis of a panel of monochromosomal human/rodent hybrid cell lines, whereas the family member has been localized on chromosome 2. To examine the function of this class of zinc finger proteins in the nervous system, a targeted mutation in MyT1 is being created in transgenic mice. A construct carrying the genomic MyT1 with the insertion of the lacZ gene and the neo and tk selectable markers has been electroporated into embryonic stem cells and at least one correctly targeted ES clone has been identified by PCR. Further studies should illuminate the role that MyT1 plays in the specification and maturation of oligodendroglia cells.

## 425.16

INFLUENCE OF FUNCTIONAL GLIA ON THE ELECTROPHYSIOLOGY OF PURKINJE CELLS IN ORGANOTYPIC CEREBELLAR CULTURES. R. Drake-Baumann<sup>1,2</sup> and F.J. Seft<sup>1,2,3</sup>, Neurology Research<sup>1</sup>, VA Medical Center and Departments of Neurology<sup>2</sup> and Cell Biology & Anatomy<sup>3</sup>, Oregon Health Sciences University, Portland, OR 97201.

Previous studies have shown that exposure of explant cultures of neonatal mouse cerebellum to cytosine arabinoside (Ara C-Sigma), for the first 5 days *in vitro* (DIV) drastically reduced the granule cell population and compromised glial function (Seft, F.J. *et al.*, Brain Res. 186:393-408, 1980). Myelination was absent and astrocytes failed to ensheath Purkinje cells (PC). More recent studies have shown that exposure of cerebellar cultures to a different formulation of cytosine arabinoside (Ara C-Pfanztehl) also destroyed oligodendrocytes and the granule cell population but did not affect astrocytes (Seft, F.J. *et al.*, Neuroscience 51:149-158, 1992). These two formulations of Ara C provide the opportunity to examine the role of astrocytes in the development of electrophysiological properties of PCs.

Intracellular studies have shown that PCs in normal cultures exhibit spike activity consisting of a mixture of complex and simple action potentials, which is the characteristic of mature Purkinje cells *in vivo* and *in vitro*. By contrast, PCs in cultures exposed to Ara C-Sigma of similar age have a lower input resistance and generate only simple spike activity, reminiscent of the type of activity seen in immature PCs. After two weeks *in vitro*, PCs in cultures exposed to Ara C-Pfanztehl express membrane conductances and spike activity similar to those of PCs of control cultures. These include TTX sensitive fast and slowly inactivating sodium conductances, and potassium and calcium conductances. These studies suggest that the presence of functional glia and/or astrocytic ensheathment of PCs influences their electrophysiological maturation. (Supported by the U.S. Department of Veterans Affairs and NIH grant NS 17493).

## 425.18

REGULATION OF GLIAL CELL NUMBERS IN OPTIC NERVE OF MICE EXPRESSING A HUMAN BCL-2 TRANSGENE FROM A NEURON-SPECIFIC ENOLASE PROMOTER. J.F. Burne\* and M.C. Raff, MRC LMCB, University College London, London, UK.

We are interested in how the number and proportions of glial cells are controlled in the rodent optic nerve.

In the present study we analysed glial cells in the optic nerves of transgenic mice that express the human *bcl-2* gene from a neuron-specific enolase promoter (Martinou 1994). The *bcl-2* transgene suppresses normal neuronal cell death and, as a result, the mouse contains 70% more RGC axons in the optic nerve. DNA measurements indicate that the nerve also contains about twice as many glial cells. EM analysis of the glial population shows that there are twice as many oligodendrocytes, astrocytes and microglial cells so that the relative proportions of the axons and each glial cell type are preserved. We present evidence that oligodendrocyte numbers are increased by a reduction in normal oligodendrocyte death, whereas astrocyte numbers are increased by an increase in cell division.

Surprisingly, we find that the expression of the *bcl-2* transgene is not confined to neurons but is also expressed in mature oligodendrocytes and astrocytes. We provide evidence however, that the increase in oligodendrocyte and astrocyte number in the transgenic optic nerve is probably not directly related to the expression of the transgene in the glial cells but is probably secondary to the increase in the number of axons.

These findings suggest that complex interactions between axons and developing glial cells ensure that optimal numbers of each type of glial cell are generated in the optic nerve.

## 425.19

**K<sup>+</sup> CURRENTS IN THE ENDEFT OF MÜLLER (GLIAL) CELLS ISOLATED FROM FROG RETINA. EFFECT OF CUTTING THE OPTIC NERVE.**

S.N. Skatchkov, L. Vyklický, T. Clasen, P.M. Orkand\* and R.K. Orkand. Institute of Neurobiology /Dept. of Physiology, M S C, Univ. of PR, San Juan, PR 00901

Müller cells are radial glial cells which span the whole retina and play a role in transferring K<sup>+</sup> away from regions where it has accumulated due to impulse activity in the neurons. Such a function requires both inward (I<sub>KIR</sub>) and outward (I<sub>K</sub>) currents via K<sup>+</sup> channels in the Müller cell membrane. >95% of these channels are located in the endfeet. To understand the nature of potassium membrane currents in the endfeet of isolated Müller cells from the amphibian, *Rana pipiens*, we used simultaneously whole cell patch clamp applied to the endfeet of Müller cells as well as rapid changes in external K<sup>+</sup> ([K<sup>+</sup>]<sub>o</sub>). Changing [K<sup>+</sup>]<sub>o</sub> from 3 to 10 mM at E<sub>K</sub> for [K<sup>+</sup>]<sub>o</sub> 3 mM induced an inward current that was 5.48 (± 0.89 SD, n=9) fold larger than I<sub>o</sub> induced by application of 1 mM [K<sup>+</sup>]<sub>o</sub>. The inward current is linear from holding potentials of -140 to -40 mV, while the outward current displays a different behavior and has maximal amplitude at physiological potentials close to -80 mV. Both the outward and the inward currents were completely blocked by blockers of the K<sup>+</sup>-inward rectifier, 0.3 mM Ba<sup>2+</sup> and 5 mM Cs<sup>+</sup>. Other K<sup>+</sup>-channels did not appear to be present (TEA<sup>+</sup>, 30 mM or Cd<sup>2+</sup>, 2 mM had no effect on the currents). Inward and outward currents in Müller cells appear to flow only through the inward rectifying K<sup>+</sup> channel. 40-60 days after cutting the optic nerve, leaving blood vessels intact, without allowing regeneration, isolated Müller cells appeared normal. However, the ratio of the inward current to the outward current in the endfeet was markedly depressed. In 98 mM K<sup>+</sup> this ratio was 2.86 ± 1.03 SD n=24 in controls and 1.13 ± 0.59 SD n=21 in Müller cells from denervated retinae. The results suggest that the behaviour of K<sup>+</sup> channels in endfeet depends on the integrity of the closely apposed ganglion cells.

**CELL IDENTIFICATION OF LONG SURVIVING MURINE SPINAL CORD CULTURES. L.S. Gargan, J.L. Fuchs\*, and G.W. Gross. Center for Network Neuroscience, Dept. of Biological Sciences, University of North Texas, Denton, TX 76203.**

Our culturing methods have generated neuronal networks that have remained electrically active and pharmacologically responsive up to 312 days in vitro. Although much electrical data have been analyzed through recordings using array techniques, the cellular characterization of these stable culture systems has so far received less attention. We have begun to characterize the cellular components of the carpet layer that is situated between the electrode array and the neurons. Using immunofluorescence and electron microscopy, we found 40% astrocytes, 9% oligodendrocytes, and 4% neurons. Just beneath these identified cells, a "cobble-stone" layer composed of the remaining 47% of the cells, were non-neuronal and did not stain for astrocyte-specific glial fibrillary acid protein or oligodendrocyte-specific galactocerebroside. It is these cells that adhere primarily to the poly-D-lysine and laminin surface of the recording electrode plate. We anticipate that the lower layer of the carpet may consist of confluent fibroblasts, but could also be derived from pia or endothelial tissue fragments. The longevity of these cultures might be attributed to this layer of cells. (Supported by the Communities Foundation of Texas.)

## MOLECULAR CHANGES AFTER LESIONS

## 426.1

**THE EXPRESSION AND LOCALIZATION OF A FATTY ACID LIPID BINDING PROTEIN (FABP) IN THE RAT DORSAL ROOT GANGLIA AFTER SCIATIC NERVE TRANSECTION. C.A. Molina†, A.A. Welcher\*, M. De Leon†, †Dept. of Physiol. Loma Linda Sch. of Med., Loma Linda CA 92350; \*Amgen Inc., Thousand Oaks, CA 91320.**

The present study used immunocytochemistry (ICC) and Western blots analysis to examine the expression and localization of DA11, a rat FABP isolated from a dorsal root ganglia (DRG) cDNA library. The predicted amino acid sequence of DA11 was elucidated and peptide polyclonal antibodies were generated. Adult male Sprague Dawley rats received a left ipsilateral (ipsi) sciatic nerve transection and a right contralateral (contra) sham operation. The L<sub>4</sub>-L<sub>5</sub> ipsi and contra DRG were harvested, their respective proteins extracted, electrophoresed in a polyacrylamide gel, electroblotted to nitrocellulose and immunodetected with the DA11 antiserum. The Western blots showed the presence of a single ± 15.1 kD immunoreactive band in protein extracted from the DRG tissue. The DRG ipsi to the sciatic nerve transection showed a two-three-fold elevation in DA11 protein as compared with contra or naive controls. Additional animals were surgically manipulated as described above and processed for ICC. Neurons in contra and naive DRG showed a basal level of cytoplasmic expression of DA11-like immunoreactivity, with very few neurons exhibiting nuclear staining. In contrast, neurons in the DRG ipsi to the sciatic nerve transection showed a marked DA11-like immunoreactivity in the cell nuclei. Our data indicate that DA11 protein is up-regulated in axotomized DRG neurons after sciatic nerve transection.

## 426.2

**THE EXPRESSION OF A NOVEL FABP (DA11) IN RAT CNS DURING DEVELOPMENT. Y. Liu\*, C.A. Molina†, A.A. Welcher\*, M. De Leon†, \*Dept. Pathol. & Hum. Anat. and †Dept. Physiol. Loma Linda Univ., Sch. of Med., Loma Linda, CA 92350; #Amgen Inc., Thousand Oaks, CA, 91320.**

The identification of genes whose expression is regulated during neuronal injury and nerve regeneration is one way to study the molecular mechanism associated with neuronal plasticity and axon growth. In previous studies we reported the cloning and characterization of DA11, a full length of cDNA isolated from a rat dorsal root ganglia cDNA library that encodes for a novel rat fatty acid lipid binding protein. The sequence analysis revealed that DA11 is the rat homologue of human psoriasis-associated fatty acid-binding protein (PA-FABP). We now report the expression of DA11 mRNA and protein during the embryonic and neonatal development of the rat central nervous system (CNS). Total RNA was extracted from different rat CNS tissues and analyzed using Northern and Western blots. Our results show that DA11 mRNA is significantly elevated in all the neonatal and embryonic tissues analyzed. DA11 mRNA had a maximum elevation of 159-fold in the cerebellum, 87-fold in the brain stem, 34-fold in the hippocampus and 12-fold in the cerebrum during late embryonic and early post-natal period as compared to adult levels. Similarly, Western blots experiments showed that the DA11 protein was up-regulated in embryonic and neonatal rat CNS, as compared with adult. We conclude that DA11 may play a role during the development of the rat CNS.

## 426.3

**Induction of Embryonic GAD Transcripts and Nestin Following Hippocampal Injury: Recapitulation of Developmental Programs**

R. Somogyi\*, X. Wen\*, M.M. Dugich-Djordjevic†, O. Giorgi\*, R.D. McKay†, J.L. Barker\* Laboratory of Neurophysiology\*, Laboratory of Molecular Biology†, NINDS, Bethesda, MD

Repair of damaged CNS tissue is expected to involve the reactivation of genes necessary for "building" the CNS, i.e. genes usually expressed during development. Nestin is an intermediate filament protein expressed in proliferating stem cells of the CNS but not in terminally differentiated neurons. Several GAD (glutamic acid decarboxylase) 67-derived mRNAs and protein forms, collectively referred to as G67180/86, are transiently expressed during CNS development in the phase of neurogenesis. Here we have investigated the regulation of nestin and embryonic GADs in injured adult CNS. Systemic treatment of male adult rats with kainic acid (KA), a glutamatergic agonist, results in seizures, excitotoxicity and cell death, accompanied by gliosis and sprouting. We have used a high-sensitivity quantitative RTPCR protocol to analyze the expression of mRNAs for nestin and the known forms of GAD. Induction of embryonic G67180/86 was measured after 3h, followed by maximal expression at 6h, and a gradual decline at 24h to basal levels at 48h. Nestin mRNA expression increased at 3h, declined at 6h and increased again at 24h and 48h following KA administration. In situ hybridization with <sup>35</sup>S nestin cRNA and immunocytochemistry using the 130 nestin polyclonal antibody confirmed that nestin was upregulated at early time points following seizure activation in neuronal regions of the hippocampus and in both neuronal and non-neuronal cell populations at longer time points, corresponding to the onset of kainic-acid induced neurodegeneration. Thus, selective and transient overexpression of nestin and embryonic GAD forms may reflect the activation of repair mechanisms which involve genes previously associated with neurogenesis.

## 426.4

**The level of hemopexin, a glycoprotein absent from the CNS, increases after lesion and inflammation in the rat sciatic nerve. L. Camborieu\*, N. Madore, J. Smith\* and J.-P. Swerts. Centre de Biologie du Développement UMR CNRS 9925, Université Paul Sabatier 31062 TOULOUSE - FRANCE.**

We have previously demonstrated that a serum glycoprotein, hemopexin (HPX), is synthesised in the rat sciatic nerve. After axotomy, HPX levels increase. They remain high in permanently degenerated sciatic nerve but return to normal if regeneration is allowed to occur. Thus the hemopexin content seems closely correlated with the degeneration status of the nerve.

To get further insight into the role of HPX in nerve regeneration, we have studied the distribution of the protein in PNS and CNS. In sciatic (mixed), hypoglossal (motor) and cervical sympathetic trunk (unmyelinated) nerves, HPX labeling is detected around axonal units and blood vessels, partly colocalised with laminin. After lesion, HPX immunoreactivity increases drastically in the distal part of all peripheral nerves analysed, without change in its localisation. In the intact optic nerve and in the brain, HPX is found exclusively in blood vessels. In the transected optic nerve, no modification of the localisation or amount of HPX is observed. These findings indicate that the presence and the accumulation of HPX after injury is a general feature of the PNS, whereas the protein is absent from the CNS even after lesion.

One of the differences between the PNS and the CNS after lesion lies in the importance of the resulting inflammatory reaction. We hypothesised that accumulation of HPX may be dependent on macrophages. This idea is supported by the observation that enhanced HPX immunoreactivity is correlated with the presence of macrophages during inflammation induced by lipopolysaccharide in the sciatic nerve. Thus, as neither axons nor Schwann cells are injured in this process, inflammation alone seems to be sufficient to induce accumulation of HPX in PNS nerves.

## 426.5

**DIFFERENTIAL EXPRESSION OF JAK FAMILY GENES IN RAT HYPOGLOSSAL MOTONEURONS AFTER NERVE INJURY.** G. L. Yao, H. Kato, S. Shimada\* and H. Kiyama. Dept. of Neuroanatomy, Biomedical Research Center, Osaka Univ. Sch. of Med., Yamadaoka, Suita, Osaka 565, JAPAN.

Some lines of studies suggested that growth factors and cytokines play important role in the peripheral nerve regeneration, therefore it is likely that intracellular signaling pathways following growth factor and cytokine receptors can be crucial for peripheral nerve regeneration. Since it has been demonstrated that JAK family tyrosine kinases (JAK1, JAK2, JAK3 and TYK2) play a crucial role in intracellular signaling particularly downstream the cytokines' receptors, we studied regulation of JAK family genes expression following the peripheral nerve injury by *in situ* hybridization histochemistry. Unilateral hypoglossal nerve of rat was axotomized, and the mRNA level of these JAK family in the hypoglossal nucleus after post-operative time of 1, 3, 5, 7, 14, 21, 28 and 35 days was examined. Among JAK family, JAK2 and JAK3 mRNAs' level was substantially increased in the operated hypoglossal nucleus after nerve injury, whereas such significant increase was not observed in JAK1 and TYK2. These results suggest that intracellular signaling pathway which involves JAK2 and/or JAK3 could be important for the nerve regeneration.

## 426.7

**UP-REGULATION OF CYCLIN G EXPRESSION IN MOTONEURONS AFTER NERVE INJURY.** N. Morita, S. Kiryu and H. Kiyama\*. Dept. of Neuroanatomy, Biomed. Res. Center, Osaka Univ. Med. Sch., Suita, Osaka 565, Japan.

The differential display PCR (DD-PCR) technique was used to isolate nerve regeneration associated genes. Unilateral hypoglossal nerve of Wistar rats were cut, and total RNAs from control and operated sides of hypoglossal nuclei were extracted 7 days after the operation. DD-PCR was performed by using single arbitrary primer. The amplified cDNA fragments which were more abundant in the operated side than in the control side were subcloned, and checked by *in situ* hybridization (ISH) using unilaterally transected section. The positive clones confirmed by ISH were then sequenced. One of the up-regulated gene was identical to the cyclin G. Although the cyclin G belongs to G1-cycline family, it was suggested that the cyclin G was associated with growth stimuli but not with the cell cycle. Present result suggests that the cyclin G was closely associated with nerve regeneration event.

## 426.9

**C-JUN EXPRESSION IN AXOTOMIZED MEDIAL SEPTAL NEURONS IS NOT RELATED TO NEURONAL DEGENERATION.** C. A. Haas, J. Lübke\* and M. Frotscher. Institute of Anatomy, University of Freiburg, 79001 Freiburg, FRG.

The transcriptional control of neuronal regeneration/degeneration is of great interest for the understanding of neurodegenerative disorders. We use the anatomically well-defined fimbria-fornix system as a paradigm to study the molecular events involved in neuronal degeneration. The expression of three immediate early genes, c-fos, c-jun and jun B, was investigated in rat medial septal neurons following bilateral fimbria-fornix transection (FFT). Moreover, the degree of retrograde degeneration was assessed by measuring the DNA fragmentation in these injured neurons. A detailed post-operative time-course was performed ranging from 1 day to 9 weeks following bilateral FFT. A strong increase of c-jun immunoreactivity (IR) was observed in the nuclei of medial septal neurons as early as 2 days postaxotomy. The number of c-jun-positive neurons stayed high over 6 days, followed by a decline at day 12. Nine weeks after FFT c-jun-IR had disappeared. c-Fos or jun B immunoreactivity was neither detectable in unoperated nor in lesioned medial septal neurons. In addition, a massive induction of c-jun mRNA could be localized in the medial septal nucleus by *in situ* hybridization histochemistry. Experiments using the TUNEL technique (TdT-mediated dUTP nick-end-labelling), designed to detect DNA fragmentation in degenerating neurons complemented this study. Within three weeks postaxotomy medial septal neurons did not exhibit any DNA fragmentation. Taken together, the strong and long-term c-jun expression in axotomized medial septal neurons and the lack of DNA fragmentation in these cells suggests a strong survival capacity of this neuronal population.

(Supported by the Deutsche Forschungsgemeinschaft)

## 426.6

**NERVE INJURY ENHANCES RAT NEURONAL GLUTAMATE TRANSPORTER EXPRESSION: IDENTIFICATION BY DIFFERENTIAL DISPLAY PCR.** S. Kiryu\*, G. L. Yao, N. Morita, H. Kato, H. Kiyama. Dept. of Neuroanatomy, Biomedical Research Center, Osaka Univ. Med. Sch., Suita, Osaka, 565 JAPAN.

Using the differential display PCR (DD-PCR), we have compared differentially expressed genes between normal and nerve injured hypoglossal nuclei. Expression of several cDNA fragments were up-regulated on the displayed gel. *In situ* hybridization using those derived cDNA fragments showed that only five fragments among the candidates were apparently up-regulated in the injured nuclei. The five cDNA fragments were further used as probes to screen a rat cDNA library and isolate their corresponding complementary DNA clones.

Among cloned cDNAs, one clone showed high similarity to rabbit high affinity glutamate transporter (EAAC1). Since it is suggested that CNS injury such as ischemia induces an excess extracellular glutamate accumulation which causes severe neuronal damage, the up-regulation of glutamate transporter expression could be a response against the neuronal cell death caused by the glutamate toxicity. Therefore, activation of the glutamate uptake system might play an important role for damaged neurons to survive.

## 426.8

**Immunoreactivity for NGF and low affinity NGF receptor (p75) in the medial septal nucleus: a time course following fimbria-fornix transection** T. Naumann\*, A. Straube, E. M. Kasper and M. Frotscher. Institute of Anatomy, University of Freiburg, D-79001 Freiburg, Germany.

Many cholinergic neurons in the medial septal nucleus (MS) are able to restore the synthesis of their marker protein choline acetyltransferase (ChAT) after bilateral fimbria-fornix transection (ff-t) without exogenous treatment with nerve growth factor (NGF) (Naumann et al. 1994). It is still unknown whether these axotomized neurons receive NGF from other sources than the hippocampal formation which normally provides them with this trophic factor. To this end we have investigated changes in immunoreactivity for NGF and the low affinity receptor in axotomized cells. We looked at local axonal arborizations of MS neurons after different survival times following ff-t in both immunostained neurons (p75) as well as cells filled intracellularly with biocytin.

50 adult Sprague-Dawley rats received a bilateral ff-t. After defined survival times these animals and age-matched controls were processed for NGF and p75 immunocytochemistry. Another group of rats received multiple tracer injections (Fast Blue, Fluoro-Gold, Rhodamine) into different brain regions in order to identify different targets of MS neurons.

3 weeks postlesion the number of NGF positive neurons was decreased to 11% of control. There was no recovery after long survival times (6 months). A similar time course was found for p75-immunoreactive cells in the MS. As reported by others (Sofroniew et al. 1990) septohippocampal neurons have only one axonal target, but p75 immunocytochemistry as well as intracellular biocytin injections revealed extensive local axonal arborizations. We conclude that cholinergic neurons in the MS maintain local axonal arborizations following ff-t. The loss of NGF immunoreactivity in MS neurons after ff-t suggests that these cells do not receive NGF from other sources but the hippocampus.

## 426.10

**TENASCIN-C mRNA AND PROTEIN DISTRIBUTION IN THE RAT SPINAL CORD FOLLOWING UNILATERAL DORSAL COLUMN INJURY** Yi Zhang, P. N. Anderson, H. Mohajeri\*, M. Schachner<sup>1</sup>, J. Winterbottom and A. R. Lieberman\*. Dept. of Anatomy and Dev. Biology, University College London, WC1E 6BT and Neurobiology, Swiss Federal Institute of Technology, Zurich<sup>1</sup>.

Tenascin-C is a developmentally regulated ECM molecule. In rat spinal cord it is produced by glial cells and by a small subset of neurons. Tenascin-C expression patterns vary in different parts of the CNS after injury and there is controversy as to whether injury-induced tenascin-C inhibits or has the potential to support axonal regeneration. We have studied the expression and distribution of tenascin-C by *in situ* hybridization and immunofluorescence (with antibodies against tenascin-C, GFAP, OX-42 and the 200KD NF) in the spinal cord after stab wounds of the thoracic dorsal column in halothane anaesthetized adult rats. Between 3 and 30d after injury, lesion areas were largely devoid of GFAP+ astrocytes and often packed with OX-42+ macrophages and GFAP/OX-42- cells. A zone of diffuse tenascin-C immunoreactivity was found around the lesion site and in the degenerating dorsal column rostral to the lesion. Stronger immunoreactivity, sometimes with a filamentous appearance, was present around cells in and close to the lesion, most of which were GFAP- and OX-42-, and on some capillaries in the same region. Only a few of the GFAP+ astrocyte processes forming the glia limitans bordering the lesion were tenascin-C+. Many NF+ axons were present in the zone of diffuse tenascin-C immunoreactivity; some appeared to traverse this zone and enter the lesion area, but none was tenascin-C+. Tenascin-C mRNA+ cells were present in and around the lesion 3-14 days after injury but had disappeared by 30d, although tenascin-C was still present at this time. A minority of these cells were GFAP+ astrocytes. Thus the distribution of tenascin-C around lesion sites is compatible with it influencing axon regeneration, but sprouting NF+ dorsal column axons, unlike regenerating axons in the thalamus, do not appear to bind the molecule. Tenascin-C is produced at the lesion site by a population of cells which may be meningeal cells and/or Schwann cells, and by a subpopulation of reactive astrocytes. (Supported by the MRC)

## 426.11

QUANTIFIABLE DETECTION OF PROTEIN AND GENE EXPRESSION CHANGES IN ADULT RAT DORSAL ROOT GANGLIA AFTER SCIATIC NERVE TRANSECTION. A.M. Kenney and J.D. Kocsis\*. Dept. of Neurology, Yale Univ. Med. Sch., New Haven, CT. 06510, and Neuroscience Res. Ctr., VAMC, West Haven, CT. 06516

Immunohistochemistry and *in situ* hybridization studies of adult rat dorsal root ganglia (DRG) have been used to study genes regulated in response to sciatic nerve axotomy. Increased c-jun protein and mRNA levels in neurons 10-12 hours after injury has been identified as one of the first indications that a molecular program for reacting to axotomy has been initiated. Using the techniques of Western blotting with enhanced chemiluminescent (ECL) detection and northern blotting with radiolabelled probes, we quantified changes in gene expression in DRG following sciatic nerve transection with chronic target disconnection. Anesthetized 200 g adult female Wistar rats underwent unilateral sciatic nerve axotomy and contralateral sham surgery at the mid-thigh level. The nerve stump was drawn into a silicon cuff. From 1 hour to 30 days after surgery, the rats were sacrificed. Protein or total RNA was prepared from L4 and L5 DRGs. Protein was analyzed by SDS-PAGE and Western blotting. Elevated c-jun protein levels were detectable within 5 hours of axotomy, peaked at 5 days, and remained above constitutive levels through 30 days after axotomy. No elevation in c-jun was detected in sham controls. Message regulation was studied by northern blotting. We are using these techniques to measure changes in gene expression after axotomy with various treatments to elucidate signals that regulate the axon reaction and subsequent cell death or neurite outgrowth. Current results indicate that the techniques used here, while not cell specific, are quantifiable and useful for measuring subtle changes in gene expression, as evidenced by the increased c-jun protein levels seen here at 5 hours, rather than 10 hours, after sciatic nerve transection. Supported in part by the VA and the NIH.

## 426.13

MOLECULAR MECHANISMS OF NEURONAL REGENERATION. J.A. Davies\*, S. Korneev, A. Fedorov and S.F. Blackshaw<sup>1</sup>. Sussex Centre for Neuroscience, Sussex University, Falmer, Brighton BN1 9QG, U.K and <sup>1</sup>Laboratory of Cell Biology, University of Glasgow, Glasgow G12 8QQ, Scotland.

We are investigating the changes in gene expression that occur during neuronal regeneration in the leech, *Hirudo medicinalis*, by isolating and characterising molecules specific to regenerating neurons. Our previous studies have demonstrated the successful use of PCR technology in the construction of cDNA libraries from individually dissected, identified regenerating and non-regenerating neurons (Korneev et al., Progress in Neurobiology, 42: 339-346). Subtraction hybridisation has been used to create a library enriched in sequences from regenerating Retzius cells and its quality has been confirmed by both differential hybridisation and hybridisation with a subtracted probe. Sequence analysis of the recombinants has identified both known and novel sequences. Homologies include  $\alpha$ - and  $\beta$ -tubulin, a calmodulin-like protein and a clone encoding a protein homologous to the CCAAT/enhancer-binding protein (C/EBP) family of transcription factors. Further characterisation of the clones is underway and will enable us to explore the mechanisms which axons use to find and synapse with their target cells during normal and regenerative growth.

## 426.15

BROMODEOXYURIDINE (BRDU)- LABELED MACROPHAGES IN THE SUPERIOR CERVICAL GANGLION (SCG) AFTER AXOTOMY. R.C. Schreiber\*, S.A. Vaccariello, and R.E. Zigmond. Dept. of Neurosciences, Sch. of Med., Case Western Reserve University, Cleveland, OH 44106-4975.

Transection of the facial nerve results in proliferation of microglial cells but not astrocytes in the facial nerve nucleus (Graeber et al., 1988). Our laboratory has shown that postganglionic nerve transection results in increased expression of neuropeptides, increased immunoreactivity for glial fibrillary acidic protein (GFAP) and certain macrophage antigens (Bachoo et al., 1992; Schreiber et al., 1995), as well as proliferation of non-neuronal cells (Bachoo et al., 1992) in the SCG. This study examines the extent to which macrophages contribute to the proliferating cell population in the SCG. Rat SCG were axotomized and the animals injected every 6 h for 2 d with BrdU. SCG sections were immunostained for BrdU and GFAP or a cocktail of macrophage markers (ED1, ED2, and OX6). Confocal microscopy confirmed our earlier findings that many of the BrdU+ nuclei are present in GFAP+ cells (Bachoo et al., 1992). In addition, 20% of the BrdU+ nuclei was present in macrophages. Analysis of individual macrophage markers revealed that both the total number of ED1+ cells and the number of these cells containing BrdU+ nuclei increased 4-fold. While the number of OX6+ and ED2+ cells did not change appreciably 2 d after axotomy, there was a 3- and 11-fold increase, respectively, in the number of these cells which contained BrdU+ nuclei. Transecting the afferent input to the SCG (decentralization) results in extensive nerve terminal degeneration with little increase in neuropeptides. Preliminary studies indicate that there is little change in the number of macrophages after decentralization. BrdU studies on decentralized SCG will be reported. The data with colocalization of BrdU and ED2 (which identifies resident macrophages) are evidence that these cells, in addition to elicited (ED1+) macrophages, are affected by axotomy. The difference in the macrophage response to axotomy and decentralization raises interesting questions with regard to the signals affecting macrophages and the physiological functions of these cells in situations involving neural damage.

## 426.12

TISSUE PLASMINOGEN ACTIVATOR (TPA) BUT NOT UROKINASE (UPA) IS INDUCED IN PERIPHERAL NERVE INJURY. I.V. Smirnova, J.Y. Ma, D. Hantai, B.A. Citron\* and B.W. Festoff. Neurobiology Research Lab., VA Med. Cent., Kansas City, MO 64128, Dept. of Neurology, Univ. of Kansas Med. Cent., Kansas City, KS 66103, and INSERM U. 153, Paris, FRANCE

Serine proteases play crucial roles in development, maintenance and regeneration of the nervous system. Neurite outgrowth is dependent on components of the plasminogen-plasmin system. PAs, both tPA and uPA, are critical factors in this system. uPA, but not tPA, is altered in muscle after axotomy. In contrast, tPA, more than uPA, is involved in neurite outgrowth in both ganglionic and CNS neurons in culture. We sought to determine whether tPA or uPA activities are altered in murine sciatic nerve after crush injury. Highly sensitive chromogenic assays with specific protease substrates were employed to measure PA activities in nerve extracts by plasminogen activation to plasmin followed by determination of plasmin activity with the synthetic substrate, S-2251. Addition of fibrin monomer (FM), which modulates tPA activity, allowed us to distinguish tPA from uPA. We found rapid increase of activity (in the presence of FM) in the distal nerve segment after crush from day 1-4, when it peaked, declining by day 9-21, reaching basal levels on day 30, and remaining at this same level 60 days following injury. Nerve extracts showed no detectable activity in the absence of FM. No uPA activity was found by direct amidolytic assay with the substrate S-2444, relatively specific for uPA. Contralateral controls did not show measurable tPA activity. Our findings demonstrate that tPA, but not uPA, activity is significantly elevated in early stages (day 4) of nerve injury and may precede potential regeneration. (Supported by Association Française contre les Myopathies, INSERM, NATO, the Marion Merrell Dow Foundation/SEP, and the Medical Research Service of the Department of Veterans Affairs)

## 426.14

THE AXOTOMY-INDUCED NEUROPEPTIDE GALANIN IS ANTROGRADELY TRANSPORTED IN AXOTOMIZED SYMPATHETIC NEURONS. A.M. Shadiack\* and R.E. Zigmond. Dept. of Neurosciences, Sch. of Med., Case Western Reserve University, Cleveland, OH 44106-4975.

Axotomized sympathetic neurons reduce their production of molecules necessary for transmission and begin producing proteins which may aid in survival or regeneration. Among these newly produced proteins, are certain neuropeptides such as galanin (GAL). After axotomy of the middle and inferior cervical ganglion (MIG), GAL is produced in the axotomized neurons and later found in postganglionic axons in the cervical sympathetic trunk (CST). We have previously found that the amount of GAL-immunoreactivity (IR) in the MIG increases 2-3-fold between 7 and 14 days after axotomy (Shadiack, et al., 1994). It is possible that more neurons begin to produce GAL or the same cells produce more GAL. We now report that this change is not accompanied by a further increase in GAL mRNA. Quantitation of GAL-IR cells colocalized with fast blue, a fluorescent retrograde marker, after axotomy shows no change in GAL+ cell number between 7 and 14 days. We have studied the appearance of GAL-IR in the CST at 2, 4, and 7 days after axotomy with special reference to regionality within the CST. At earlier times, GAL-IR is localized to the region most distal to the ganglion, near the site of transection. At later times, GAL-IR was identified throughout the CST though the highest concentration remains distal to the ganglion. Using confocal laser microscopy, the GAL-IR could be further localized to synaptic vesicle-like structures within fibers. These data taken together suggest that the galanin produced by the axotomized neurons is actively transported toward the site of the transection perhaps to aid in regeneration. Furthermore, the secondary increase in GAL-IR at 14 days post-axotomy may be due to GAL, which would otherwise be transported away from the ganglion, building up in the sympathetic cell bodies due to a saturated transport system.

## 426.16

EXPRESSION OF SEVERAL GROWTH FACTORS AND DETECTION OF DNA FRAGMENTATION AFTER CORTICAL ABLATION IN RATS. M. Isono\*, Y. Wakabayashi, K. Asakuno, M. Fujiki, T. Mori, S. Hori. Dpt. of Neurosurgery, Oita Medical Univ. Oita, Japan, 879-55

To investigate the molecular changes due to deafferentation *in vivo*, expression of several growth factors and peptides were studied in rat brain after unilateral sensorio-motor cortical ablation. Also, whether DNA fragmentation and apoptosis related peptides might appear was investigated in the same model. Immunoreactivities of GFAP, bFGF, Syntaxin, OX-42, bcl-2 were studied by ABC method and compared with non-lesioned site. DNA fragmentation was detected by TUNNEL method. The observation period was ranged from 3 hrs to 3 months after the ablation surgery. Throughout the whole period, TUNNEL positive cells was not found, although routine staining revealed deformity of the nucleus in certain area. Relatively strong expression of bFGF in ipsilateral cortex was observed one day after the surgery, but only little expression was observed in the target area such as striatum or thalamus, where GFAP was positively expressed, throughout the period. Interestingly, rather strong expression of Syntaxin was observed in ipsilateral site. These results suggest that changes in the target area after deafferentation do not include apoptosis and are only little compared to those in area nearby the primary lesion.

## 426.17

**INJURY-ASSOCIATED CHANGES IN GLYCOSAMINOGLYCANS AND THEIR EFFECTS ON THE REGENERATION OF TRANSECTED SCIATIC NERVES OF GUINEA PIGS.** D.K.Y. Shum<sup>1</sup>, C.H. Chau<sup>1</sup>, K.F. So<sup>2</sup>, Y.S. Chan<sup>3</sup>. Depts of Biochemistry<sup>1</sup>, Anatomy<sup>2</sup> and Physiology<sup>3</sup>, The University of Hong Kong, Hong Kong. (SPON: The Hong Kong Society of Neurosciences)

The glycosaminoglycan (GAG) composition and content of sciatic nerves during recovery from crush-injury were studied in adult guinea pigs and compared with those of untreated controls. The GAGs were recovered from the 1,900 g supernatant and pellet of the tissue homogenate and assayed for hexuronate contents and susceptibilities to hyaluronidase, chondroitinase ABC and nitrous acid. In the untreated controls, GAGs were found only in the pellet which showed heparan sulphate (HS) as a major GAG class. In the 2 weeks post-crush, the GAG extracts indicated progressive increase in hexuronate which was due mainly to additional GAGs in the supernatant where chondroitin sulphate (CS) was the major GAG class found. The pellet fraction of crushed nerves in the same period was however similar to the untreated controls in relative abundance of GAG classes and hexuronate content. At 4 weeks post-crush, although the total hexuronate returned to the control level, a significant proportion of GAGs remained in the supernatant fraction. To study the effects of increased soluble GAGs in the neural environment, an 8-10 mm silicone tube, filled with solutions of CS, HS, or saline, was used to bridge transected sciatic nerves in halothane-anaesthetized animals. The animals were allowed to recover. At timed periods, they were re-anaesthetized for EMG measurements - electrical stimuli were applied at defined positions flanking the bridge on the transected nerve and the difference in latency for EMG to be recorded from the gastrocnemius muscle was used to determine conduction velocity across the bridge. Sections of the bridge were also histologically examined for nerve fibres. With saline as the bridge material, 3-4 weeks were required for histological indications and 9-10 weeks, for electrophysiological indications of regeneration. At these times, indications resulting from application of CS and HS will be compared to reach conclusions regarding their effects on neural regeneration.

## 426.19

**THE ROLE OF C-JUN IN REGULATING VIP AND OTHER PEPTIDES IN SENSORY NEURONS: IMPLICATIONS FOR THE RESPONSE TO AXOTOMY.** P.K. Mulderry & S.P. Dobson. SPON: Brain Research Association. MRC Brain Metabolism Unit, Royal Edinburgh Hospital, Edinburgh EH10 5HF, U.K.

Adult rat dorsal root ganglion (DRG) neurons express both VIP and c-Jun in response to axotomy *in vivo* and when the cells are placed in culture. We have used cultured DRG neurons to investigate the role of c-Jun in regulating expression of VIP and other peptides associated with the axotomy response. To demonstrate that VIP expression was dependent on c-Jun, we blocked neuronal c-Jun expression by microinjecting a c-jun antisense oligonucleotide. Quantitative immunofluorescence measurements in individual neurons confirmed that the antisense oligo specifically reduced c-Jun levels and also revealed a reduction in VIP immunofluorescence. This effect was selective, since neither substance P nor CGRP levels were reduced. To find sites of interaction between c-Jun and the VIP gene, we performed gel retard experiments. These demonstrated that c-Jun could bind the rat VIP cyclic AMP responsive element (CRE) in the presence of c-Fos, though not on its own, and we therefore tested whether VIP expression in DRG requires transcription factor binding to the CRE. Microinjection of a plasmid containing multiple copies of the CRE sequence, designed to sequester DRG transcription factors occupying the endogenous VIP CRE, selectively reduced VIP expression. Thus, c-Jun appears to activate VIP gene transcription in cultured DRG neurons by binding to the CRE in combination with other factor(s). We suggest that the same mechanism could account for VIP induction after axotomy *in vivo*. Accordingly, we examined the effects of the c-jun antisense oligo on other peptides induced by axotomy. The oligo reduced neuropeptide Y immunofluorescence but left galanin unaffected. We conclude that while c-Jun may mediate the induction of VIP and neuropeptide Y after axotomy, it is not necessarily required for galanin expression.

## 426.21

**GAP-43 AND SYNAPTIC VESICLE PROTEINS IN RAT AXOTOMIZED SCG NEURONS.** Xiu-E Hou<sup>1</sup> and Annica B. Dahlström. Dept. of Anatomy & Cell Biology, Göteborg University, Göteborg, Sweden.

Rat superior cervical ganglia (SCG) were used as a model to study GAP-43 and synaptic vesicle proteins in axotomized adrenergic neurons in the PNS. One, 3 or 8 days after cutting the internal and external carotid nerves, sections were incubated for immunofluorescence. Confocal laser scanning microscopy was used to study and semiquantitate immunoreactivities (IR). One day post axotomy many perikarya, normally GAP-43-negative, became GAP-43 positive, and nerve fibers and terminals around principal neurons became weakly GAP-43-IR, compared with the strong IR in control. Three and 8 days post axotomy GAP-43-IR in perikarya was stronger as compared with 1 day post-axotomy, but limited to neurons located in the middle and caudal parts of the SCG. The GAP-43 IR in the neurons was distributed as small granules in addition to diffuse GAP-43-fluorescence. Nerve fibers in the cranial part were intensely GAP-43 positive, due to accumulations in the cut axons. The neurons in the cranial part appeared to be degenerating, since the normal morphology of the synaptophysin- and synaptotagmin-positive Golgi complex had become diffuse and since they no longer contained detectable GAP-43-IR.

In 1 day irides GAP-43-IR was much decreased, especially in the terminals in the dilator. Synaptophysin-positive nerve fibers and nerve bundles became thinner, but did not disappear. In 3 and 8 days irides the intensity of GAP-43-IR increased, but intensity of synaptophysin-IR did not change.

The results show 1) that GAP-43-IR is up-regulated in the neurons undergoing regeneration, 2) that axotomy results in death in neurons close to the cut, 3) that most GAP-43-IR normally present in the iris terminals, emanate from the SCG; 4) that GAP-43-IR is upregulated in parasympathetic terminals of the iris after adrenergic denervation. Also, 5) synthesis of synaptophysin is probably altered, since the normal appearance of synaptophysin-positive Golgi complex disappeared at 3 and 8 days post axotomy.

## 426.18

**UNILATERAL PERIPHERAL NERVE INJURY IN THE RAT INDUCES TIME-DEPENDENT BILATERAL CHANGES IN mRNA LEVELS OF THE AXONAL GROWTH ASSOCIATED PROTEIN GAP-43 IN MOTONEURONS.** E. W. McNally, C. E. Blanco, T. Mosconi, P. E. Micevych and L. Kruger\*. Dept. of Neurobiology, UCLA School of Medicine, Los Angeles, CA 90095.

Relative GAP-43 mRNA levels were determined in motoneurons of spinal cord segments L4-L6 innervating their targets via the sciatic nerve using *in situ* hybridization histochemistry. In intact adult male Sprague-Dawley rats, GAP-43 mRNA was undetectable in L4 motoneurons and expressed at low levels in L5-L6 motoneurons. Unilateral axotomy or placement of a loose polyethylene cuff on the sciatic nerve increases the number of motoneurons expressing GAP-43 mRNA in a time dependent, asymmetric bilateral manner. Levels were examined at post-operative intervals of 0, 1, 3, 7, 10, 14 and 28 days. GAP-43 mRNA levels of motoneurons ipsilateral to the axotomy increase and remain elevated to four times normal levels 28 days after injury. The nerve cuff resulted in peak GAP-43 mRNA levels (three times greater than control levels) within seven days in the ipsilateral lateral motor column and decline thereafter. Both sciatic axotomy and nerve cuff result in expression in contralateral L4 motoneurons, but not in L5 or L6.

These results indicate that unilateral peripheral nerve injuries increase the GAP-43 mRNA levels of motoneurons whose axons are directly injured as well as in motoneurons which innervate the contralateral limb. The expression of GAP-43 in uninjured motoneurons suggests the nerve-injury induced changes in weight bearing and in locomotion may underlie axonal outgrowth and synaptic remodeling.

This research was supported by NS-5685, HL-34817 and NS-21220.

## 426.20

**GAP-43 mRNA LEVELS ARE UNCHANGED BY PROXIMAL AXOTOMY IN MOUSE CORTICAL NEURONS.** E.J. Elliott\*, D.A. Parks, P.S. Fishman. Research Service, VA Medical Center, Baltimore, MD 21201.

Neurons in the mammalian cerebral cortex do not regenerate successfully after axotomy. In those neurons of the mammalian CNS which do show some regenerative growth following axotomy, the extent of sprouting and the degree of upregulation of growth-associated proteins and mRNAs are correlated with the proximity of the axonal lesion. Lesions closer to the cell body are more effective in stimulating a regenerative response. We wished to determine whether close axotomy of cortical neurons in the mouse results in upregulation of GAP-43 mRNA.

Cortical pyramidal neurons that project across the callosum were labeled retrogradely by applying the fluorescent dye Fluorogold to the contralateral side of the cortex. A week later, a knife wound was made through the cortex and corpus callosum on the ipsilateral side. This wound divided the fluorescently labelled neurons into a lateral population of cells which were axotomized near their cell bodies and a medial population which had their axons intact.

*In situ* hybridization experiments, using a <sup>33</sup>P-labeled oligonucleotide probe, showed no detectable increase in GAP-43 mRNA in the axotomized cortical neurons compared to the un-axotomized cells, at 1 day, 3 days or 7 days after injury. Thus close axotomy alone does not result in biologically significant upregulation of GAP-43 mRNA in these neurons. We are currently investigating the potential of neurotrophic factors to enhance the response of cortical pyramidal cells to axotomy.

## 427.1

**A LOW-POWER EPIFLUORESCENCE MICROSCOPE FOR NEUROPHYSIOLOGISTS.** D.R. McPherson<sup>1</sup> and J.T. Buchanan<sup>2</sup>, <sup>1</sup>SUNY Geneseo, Geneseo, NY 14454 and <sup>2</sup>Marquette U., Milwaukee, WI 53233.

For studies of the synaptic organization of lamprey spinal cord, we wish to use fluorescent retrograde labelling to identify and then impale labelled fluorescent neurons *in vitro*. As inverted microscopes do not work well with the lamprey spinal cord-notochord preparation, we have developed a low power, upright epifluorescent microscope that has long working distance like a stereo dissecting scope (40-80 mm) and light-gathering power comparable to a compound microscope operating at similar magnification. The design uses off-the-shelf modular components, along with a conventional camera lens mounted in reverse. Magnification depends upon the separation between camera lens and microscope nosepiece, and working distance depends upon the choice of camera lens. With a medium format lens, working distance is about 80 mm. Medium-sized labelled neurons are readily distinguishable and their impalement is facilitated by this device. Compared to previously published descriptions of low-power epifluorescent microscopes (Ratzlaff & Grinvald, *J. Neurosci. Methods* 36:127), our design requires a minimum of specialized machining. A schematic design of the microscope will be available. Supported by NIH NS09111 to D.R.M. and NS28369 to J.T.B.

## 427.3

**TWO-PHOTON IMAGING OF CULTURED RAT HIPPOCAMPAL NEURONS STAINED WITH DII, DIO, DIA, AND BODIPY CERAMIDE.** S.M. Potter<sup>\*</sup> and S.E. Fraser, Biological Imaging Center, 156-29, California Institute of Technology, Pasadena, CA 91125

In order to observe morphological changes in single living neurons over time, relatively non-invasive, high-resolution imaging techniques must be employed. Confocal laser-scanning microscopy offers high resolution, but its use has been limited by phototoxicity and by photobleaching of the fluorophore. Two-photon laser-scanning microscopy (TPLSM) greatly reduces these limitations; fluorescence, and thus bleaching and phototoxicity are limited to the focal plane. Due to the lack of a pinhole aperture, and the easy separation of excitation (infrared) and emission (visible) light, TPLSM systems have inherently better signal throughput than standard confocal microscopes. Excitation of UV dyes and molecular uncaging are also possible without UV lasers and special UV-transparent optics.

We have modified a standard confocal microscope (Molecular Dynamics Sarastro 2000) to use excitation light from a pulsed Ti:Sapphire laser (Coherent Mira 900), continuously tunable from 710-970nm. Using pulsed infrared illumination, we have imaged live rat hippocampal neurons in dissociated cultures and in cultured slices, obtaining better-than-confocal resolution, using a variety of neuronal tracers, such as DII, DIO, DIA, and BODIPY ceramide. Two-photon excitation spectra in these specimens were determined, since the excitation wavelength maxima are not simply twice the one-photon maxima. We have observed little or no photobleaching or phototoxicity with continued scanning of specimens.

Thus, extended time-lapse or long-term 3-dimensional imaging of single living neurons at high resolution using standard neuronal tracers is now feasible, using TPLSM.

## 427.5

**CONFIRMATION OF IMMUNOHISTOCHEMICAL REAGENT PENETRATION IN THICK SECTIONS BY 3D MICROSCOPY**

D.F. Siwek<sup>\*</sup>, P.B. Cipolloni, E.N.R.M. VA Hospital, Bedford, MA 01730, T. Woerner and B. Hearl, Kirkegaard and Perry Inc., Gaithersburg, MD, 20879

Iontophoretic injections of biotinylated dextran were made into the auditory cortex of the rat to label somata and neuronal profiles in the ipsi- and contralateral cortex. These tissues as well as skin and egg membrane samples were processed with conventional Streptavidin-biotin and histochemical methods to visualize: biocytin stained structures, keratin and salmonella respectively. These tissues were then examined and photographed using 3 dimensional light microscopic techniques.

The thickness of histological tissue sections vary widely (1 to 800 um) depending on the particular stain protocol. An overriding concern in all methods which require thick section is the question of complete reagent penetration. One approach for confirming reagent penetration is to attempt to visualize stained structures through the entire section. However, as the thickness of tissue sections viewed by conventional light microscopy increases to the point where it exceeds the depth of focus, the plane of focus must be continually adjusted. The 3 dimensional light microscope (Edge Scientific Inst. Corp.) has considerable depth of focus, permitting viewing of sections as thick as 120 um without continuous focus adjustments.

The results showed that this type of microscope is very useful when it is necessary to view microscopic structures which pass through the thickness of the entire section (e.g. axons, dendrites, ducts, vessels). In addition, with conventional light microscopes, linear structures appear as puncta, whereas the 3D microscope reveals them to be linear structures passing through the tissue section orthogonal to the cut surface. Supported by Kirkegaard and Perry Laboratories and the Veterans Administration.

## 427.2

**Automated Recognition and Mapping of Immunolabeled Neurons in Developing Cortex.** L.S. Hibbard<sup>1,2</sup>, J.S. McCasland<sup>3</sup>, J.E. Bruystrom<sup>1</sup>, and A.L. Pearlman<sup>1,2</sup>, <sup>1</sup>Dept. of Neurology<sup>1</sup> and Cell Biology<sup>2</sup>, Washington University School of Medicine, St. Louis, MO 63110, and Dept. of Anatomy<sup>3</sup>, SUNY HSC, Syracuse, NY 13210

During development, neocortical laminae are populated by neurons that have migrated from the ventricular zone. To aid in evaluating experimental perturbations that are applied to an organotypic slice preparation of embryonic cortex, we have developed a digital image analysis system to assess the migration of BrdU labeled neurons quantitatively. Entire cortical sections are digitized as mosaics of 500X fields using a computer-controlled scanning stage microscope, and the cortical zone is identified interactively as a region-of-interest (ROI) in a low magnification mosaic-image. The ROI delimits the parts of all the high magnification tile-images which intersect the cortical zone. All significant stained objects in the tile-images (inside the ROI) are detected by template correlation, and the detected objects are classified as either true neurons or non-neurons by a minimum risk, Bayesian decision rule designed to produce the minimum error (19% currently) on training and test data consisting of several thousand expert-identified cells. Functions of Gabor wavelets formed some of the features used by the decision rule. Plots of detected neuron densities provide a quantitative record of migration patterns that can be used in assessing the molecular signals that guide neuronal migration. (Support: NIH P01 NS 17763)

## 427.4

**A COMPUTER TECHNIQUE TO ESTIMATE GOLD PARTICLE DENSITIES FOR ELECTRON MICROSCOPE POST-EMBEDDING IMMUNOCYTOCHEMISTRY** A.P. Barnes<sup>\*</sup>, C.A. Dietze, and R.R. Mize, Department of Anatomy and the Neuroscience Center, Louisiana State University Medical Center, New Orleans LA 70112

Post-embedding immunocytochemistry employs gold particles to mark the location of antibodies within brain. Counts of these particles can be used to estimate antibody labeling density. We have developed a computer routine which allows the counting of gold particles using image analysis techniques. Images were captured on a JEOL 1210 electron microscope using a Kodak 1K CCD camera and JEOL Temcam 2.3 digital archiving software, transferred across a local area network to a Macintosh Ilii computer, and stored on optical disks. A macro task list developed using NIH Image was employed to count particles and compute particle density. Contrast and brightness were first manipulated using the look up table function in Image. The image was further processed with three enhancement filters: sharpen, convolve, and smooth. A 3 X 3 sharpening matrix was used to sharpen particle edges. A 9 X 9 'mexican hat' convolution was used to isolate particles. A 3 X 3 smoothing matrix was used to blur the background. A freehand selection tool was then used to draw around a profile or other region of interest (ROI) that contained gold particles. A routine then measured the area of the ROI. The isolated gold particles within the ROI were then captured as a binary image by thresholding the particles using the density slice command. Two binary operators (erode and dilate) were then applied to disconnect adjacent particles and a measurement command was employed to count the number of particles and mark their position. We analyzed three profile types in 83 digital micrographs taken from the cat superior colliculus after application of a glutamate antibody. Retinal terminals (RT) with round synaptic vesicles; profiles containing pleomorphic or flattened vesicles (Fs or PSDs); and myelinated axons (A). Analysis revealed that RT terminals contained approximately 2.5 times the density of particles contained in F or PSD profiles. Comparison of automated and manual counts showed a high correlation between the two methods of counting particles. Supported by NIH NEI R01-02973.

## 427.6

**HIGH QUALITY ELECTRONIC IMAGES OF STAINED BRAIN SECTIONS.**

J. I. Johnson<sup>\*</sup>, W. I. Welker, and R. C. Switzer III, Anatomy Dept. and Neuroscience Program, Michigan State Univ., East Lansing, MI 48824; Dept. of Neurophysiology, Univ. of Wisconsin-Madison, Madison, WI 53706; Neuroscience Associates, Knoxville, TN 37922.

Our purpose was to determine the optimal means of capturing electronic images of stained sections of mammalian brains, at both high and low magnifications (whole sections). Three methods proved optimal, depending on the size of the field to be imaged. 1) For sections or fields over 25 mm in length or width, direct scanning of the tissue in a good quality desktop scanner (e.g. the LaCie SilverScanner II), using the Transparency mode; 2) For those less than 15 mm in length or width, a microscope is used with either a film camera (to make 35 mm slides for subsequent scanning) or a digital camera (in our tests, the Kodak DCS 200); 3) For those between 15 mm and 25 mm, optimal results are obtained using a camera (film or digital), our Leitz series (or their equivalents by Nikon) of "macro" (24 to 80 mm) lenses, and a specially designed, portable, slide holder and illuminator.

Images obtained from the desktop scanner or the digital camera had two advantages over those captured from film and subsequently scanned: 1) much less editing was needed to produce good final results, and 2) the electronic images were immediately available, avoiding the time-consuming processes of film development and subsequent scanning.

It was further determined that for our brain sections, computer image files of 150 pixels per inch, with a maximum dimension of 1050 pixels, stored as PICT files, compressed by the "high-quality" level of JPEG compression included in the PICT file creation module of the Adobe Photoshop program, proved best for economical electronic storage and transmission, for on-screen viewing, and for making good quality prints. An electronic version of this poster is in preparation for viewing on the Internet at <http://www.neurophys.wisc.edu/brain/brain.html> (Supported by NSF grants BNS 9111952, IBN 9318819, and BNS 899438.)

## 427.7

**COMPUTER MATCHING HOMOLOGOUS HISTOLOGICAL SECTIONS.** F.S. Cohen, Z. Yang, J. Nissanov, Z. Huang & D.L. McEachron\*. Computer Vision Center for Vertebrate Brain Mapping, Drexel Univ. Philadelphia, PA 19104.

An objective of computer vision based brain mapping is to develop techniques which will automatically combine images of sectional material derived from different animals. One step in the process is assigning the correct brain level of a given section. We report here on a coarse navigator which matches rat sections to a reference atlas using only external section contours. To assess its performance we employed an atlas consisting of 121 evenly spaced coronal sections extending across the length of one brain and 15 randomly selected coronal sections from each of 10 other brains. A semi-automatic procedure, thresholding followed by a minimum of manual editing, was utilized to generate the section contours. This did not always generate a perfect outline – for many images extraneous extensions from the section proper were also delineated – and as such this generated a realistic contour data set very much of the quality which will be encountered in normal laboratory settings. Identification of the homologous atlas section relied on B-spline modeling of the contours using a similarity measure which is based on the knot points associated with the B-spline curves, and the use of the B-spline affine invariant moments for alignment. The results were compared to classification by a human expert. Despite imprecision in the contour outlines, and variability between the different rat brains, 57% of the test cases were classified 12 sections or less from the correct section. This performance is adequate for a coarse navigator. Finer navigation will require consideration of some internal contours and a 3D reference atlas set. (Supported by NIH award P41RR01638, a Biomedical Technology Resource grant).

## 427.9

**NEUROZOOM: COMPUTER SOFTWARE FOR QUANTITATIVE NEUROANATOMY MAPPING AND STEREOLOGY.** W.G. Young\*, E.A. Nimchinsky†, P.R. Hoff, F.E. Bloom, and J.H. Morrison†. Department of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037. †Fishberg Research Center for Neurobiology, Mount Sinai School of Medicine, NY, NY 10029.

Using SmalltalkAgents®, an object oriented programming environment, we developed NeuroZoom, a platform-independent set of programs designed to map molecular markers across multiple levels of resolution (i.e., from macro to ultrastructural) into 3D coordinate space. NeuroZoom appears as a standard Macintosh application with multiple document windows, floating palettes, and import and export features to standard file formats. Data layers, object hiding, cutting, pasting, and copying are supported.

By controlling the XYZ axes, NeuroZoom maps structures across the entire extent of the tissue section. Morphometric data tools map locations, rectangles, ovals, contours, and bezier curves. Biological tools map specialized structures, such as somata, nuclei, dendrites, axons, spines, etc. A database dictionary maintains the definitions of all structural objects, characterized by color, line thicknesses, symbols or icons. Specialized functions in NeuroZoom support automatic movement of the stage to adjacent fields of view, automatic splicing of fields, and storing locations of regions of interest when browsing sections. Quenching is minimized by using digital maps instead of live video. Live links to database repositories on the Internet and on local atlas templates are available, as well as 3D expression and manipulation of data objects.

Stereology in NeuroZoom creates collections of stereological disectors of known thickness in a specified volume of tissue, moving the stage to align and focus on each disector, and collecting data in a manner that is constrained by stereology protocols. Statistical analyses are performed and updated as data are entered. An unbiased estimate of the cell densities is then calculated for the area or volume of tissue section. Stereological quantification of length, surface area, and volume will be added. Supported by the Human Brain Project Consortium grant MHDA 52154.

## 427.11

**SIMULTANEOUS MULTI-SITE RECORDING WITH TWO FLUORESCENT PROBES USING HIGH-SPEED LASER RANDOM-SCANNING MICROSCOPY.** S.S. Patel\*, A. Bullen and P. Saggau. Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

The design and implementation of a high-speed random-scanning laser fluorescence microscope configured for simultaneous recording from dual optical indicators is presented. Previously, we have described a random-scanning system capable of high-speed, high-resolution measurements from small dendritic processes stained with voltage-sensitive dye (Bullen & Saggau, 1994). Here we extend this system to allow simultaneous recording of two fluorescent probes with similar excitation but separate emission spectra. This instrument is comprised of an argon laser (488 nm; Spectra-Physics) and an inverted epifluorescence system equipped with a 100X objective (N.A. 1.3; Zeiss). Two acousto-optical deflectors (1205C-2; Isomet) under computer-control were employed to randomly scan the laser beam at high frequency (>200 kHz). A DIC image was used to interactively select multiple points for optical recording. Emission light was processed by two dichroic mirrors (505 nm & 580 nm) and two emission filters (OG590 & 535/45 bandpass). Two photodiodes were used to capture the resulting fluorescent signals (S). A separate photodiode was used to sample the excitation beam reference (R). Each signal was digitized with 16-bit resolution at a frequency up to 133 kHz per detector. At submaximal scanning rates each scanning point was oversampled up to 8 times to improve the signal-to-noise ratio. Cultured hippocampal neurons were stained with two indicators. A voltage-sensitive dye (Di-8-ANEPPS, 100  $\mu$ M) was applied by bath application. In parallel, an intracellular indicator (CaGreen or NaGreen; 25-100  $\mu$ M) was introduced through a patch pipette. The fractional changes in fluorescence ( $\Delta F/F$ ) were obtained by normalizing the ratio of S/R by its mean. Typically recordings were made at 6 kHz sampling rate (per scanning spot) and digitally filtered at 1.5 kHz. Spatial resolution was limited by spot size at the level of the preparation (7  $\mu$ m). Representative dual wavelength recordings from neurons under current-clamp conditions will be presented.

**AN INTERACTIVE SYSTEM FOR VISUALIZATION OF THREE-DIMENSIONAL BIOLOGICAL STRUCTURES**

D. Hessler, S. J. Young\* and M. H. Ellisman. Dept. of Neurosciences, University of California San Diego, La Jolla, CA 92093-0603.

The increasing availability of three-dimensional (3D) digital data on biological structures acquired with electron microscope (EM) tomography or serial sections as well as confocal microscopy (CM) and other biomedical techniques has led to considerable interest in software for 3D analysis and visualization. Understanding 3D biological structures in volume data is an important and a difficult problem. Structures of interest are often spatially complex, intricately textured and may be obscured by other components. To facilitate 3D analysis and visualization, we have recently developed "DUCKY", a flexible and versatile software system for processing, rendering, and animating 3D datasets. DUCKY is based on a run-time interpreter that executes ordinary text scripts expressing a powerful language with features similar to those in C++. An interpreter provides several advantages including rapid modification and debugging of processing and rendering operations as well as improving portability. To maximize speed, precompiled functions are included for compute-intensive operations such as rendering. An interactive menu and window-based visualization environment is provided for executing scripts, manipulating renderings, debugging and modifying scripts. Because the system is interpreter based, changes in script parameters or operations are immediately evident in the 3D rendering. Scripts are provided for many common tasks. Additional scripts can be written to create new interactive environments and processes for unique tasks. Since volume or surface rendering may be optimal for revealing particular structures, both rendering methods are provided and may be combined in a single visualization. DUCKY can create animations of a sequence of different views of a structure either within a 3D volume or across volumes acquired in a CM time-series. Demonstrations will include: (1) combined volume rendering of correlated 3D datasets of spiny dendrites imaged by CM and electron tomography; (2) an animated walk-through of a segment of smooth endoplasmic reticulum from a Purkinje cell dendrite; and (3) combined surface and volume rendering.

**MAPPING THE SURFACE OF INTACT FROZEN BRAINS USING A STRUCTURED LIGHT BASED 3D SCANNER.** J. Nissanov\*, C. Ozturk, D. Kozinska. Computer Vision Center for Vertebrate Brain Mapping, Drexel Univ. Philadelphia, PA 19104.

A significant problem in 3D reconstruction of brain tissue from histological material is alignment of the individual sections. Due to the intrinsic curvature of the brain, sequential registration of consecutive sections is inappropriate. Alignment based on blockface imaging, an approach with potentially very high accuracy, is quite expensive to implement. We are developing an alternative approach in which the surface of the tissue is obtained prior to cryosectioning and then utilized to guide registration. Toward that end, we have developed a structured light based technique for imaging frozen rat brains which we describe here.

In structured light imaging, the object is illuminated with a pattern of light while viewed with a camera from a different vantage point. The 3D location of given point within this pattern is computed by comparing its position in the camera image with that on the slide plane of the projector. Our approach relies on a novel coding scheme for the projected light which is based on 2D perfect submaps. Perfect submaps are rxv c-ary arrays in which every nxm c-ary submatrix is unique. In this application, the matrix consists of a 2D pattern of color dots with each uniquely defined by its color and that of its nearest neighbors.

To evaluate performance of this system we imaged 3 frozen rat brains. Each brain was placed on a turntable, rotated and images acquired at 10 degrees intervals to generate 36 views. On average each brain was sampled at over 1000 points. The result matched well the surface of the brain as evaluated by reconstruction from blockface images. (Supported by NIH award P41RR01638, a Biomedical Technology Resource grant).

## 427.12

**DERIVATION OF NEURON GEOMETRY FROM CONFOCAL SCANS** Stephen Senft\*, Department of Psychology and Center for Theoretical and Applied Neuroscience (CTAN), Yale University, New Haven, CT 06511.

Neuronal geometry is a limiting constraint on our understanding of brain architecture and function. Traditionally, such data has been extracted by tedious camera-lucida techniques.

We report an automatic computerized method (based on a thinning approach of Gong and Bertrand, 1990) for deriving the geometries of branched objects from high-resolution 3D confocal scans. Scanned data are partitioned into distinct collections of contiguous volume elements (voxels), and morphometric results are derived from the voxel subsets. The technique is demonstrated using scans of mammalian cerebral cortex.

The advantages of this method include: [1] volumetric data rapidly can be reduced to much more compact skeletal (medial axis) representations; [2] accurate coordinate and diameter information are retained for every voxel that is part of a neurite; [3] skeletons can be traversed automatically to characterize arbor topologies in terms of the number and location of branch and end points; [4] multiple arbors can be analyzed in a single data set; [5] the resulting geometries can be viewed in the context of the original scan and exported in formats useful as input to biophysical simulators.

Several unsolved problems remain that require operator assistance: in practice it can be difficult to automatically identify all voxels of a scanned object in the presence of noise. Loops resulting from inadequate resolution may need to be converted manually to branched structures. Skeletons from distinct scans may need to be annealed into one object. Certain fiducial features can be difficult to identify automatically. Supported by CTAN.

## 427.13

**DENDRITIC GEOMETRY IN EPILEPTOGENIC CORTEX FROM THERAPY RESISTANT PARTIAL EPILEPSY (TRPE) AND RETT SYNDROME (RS) PATIENTS. A 3-D CONFOCAL LASER SCANNING MICROSCOPY STUDY** P.V. Belichenko and A.B. Dahlström\*. Russian Brain Res. Inst., Moscow, Russia; \* Dept. of Anatomy & Cell Biology, Göteborg Univ., Medicinareg. 3-5, S-413 90, Göteborg, Sweden

Recently we described a strategy for studying the 3-D dendritic geometry at the microscopic level (1). Using this approach we have investigated biopsy material from the epileptogenic zone of 15 patients with TRPE, undergoing epilepsy surgery and compared these to autopsy brain material from 4 patients with epileptic RS and with 8 normal control cases. Different types of dendritic abnormalities were observed in these diseases (2,3). In the TRPE cases the results show different types of dendritic abnormalities on single pyramidal cells in the epileptogenic cortex in layers I, II, III and V, and in the subcortical white matter. Many cells were observed to have two or three dendrites originating from the apical part, rather than, as in normal cases, one single apical dendrite. In RS cases the results demonstrated somewhat different types of dendritic abnormalities as compared to TRPE and control cases. The normally occurring specialization in pyramidal architecture in different cortical areas was absent in RS. Studies on the cytoarchitecture (Nissl staining) revealed neuronal migration disorders (microdysgenesis) in TRPE, but was not observed in RS. Rather, RS appears to be a postnatal developmental, probably genetic, disorder.

Supported by Swedish MRC (2207, 10808), Royal Swed. Acad. Sci., Stockholm, Royal Soc. Arts Sci., Göteborg, and ISF (33000).

## 427.15

**MAGNETIC RESONANCE AXONOGRAPHY (MRX) OF THE HUMAN CENTRAL NERVOUS SYSTEM.** T. Nakada\*, H. Matsuzawa<sup>1,2</sup>, N. Nakayama<sup>2,3</sup>, I. L. Kwee<sup>1</sup>, T. Kashiwaba<sup>3</sup>, and H. Abe<sup>2</sup>. Dept. of Neurol., Univ. of Calif., Davis, CA 95616<sup>1</sup>, Dept. of Neurosurg., Univ. of Hokkaido, Sapporo 060<sup>2</sup>, Kashiwaba Neurosurg. Hosp., Sapporo 062<sup>3</sup>

Anisotropy of apparent diffusivities ( $D_{app}$ ) of water molecules is known to be an excellent means of elucidating detailed information regarding neuronal fiber direction and density in live subjects (axonography). We have recently developed a simple algorithm which allows for the extraction of the anisotropic term vector,  $D_{app}^A$ , from diffusion tensor,  $D_{app}^S$ , in pictorial form, which in turn provides a novel color-coded contrast for magnetic resonance imaging (MRI). MRI images obtained using this technique, three dimensional anisotropy contrast (3DAC), provided detailed anatomic resolution of the central nervous system (CNS), comparable to *in vitro* histology (NeuroReport 5:2053, 1994). In this study, we extended our investigations to the human CNS utilizing standard MRI systems (1.5T) widely available at clinical institutions. MRX appears to possess immediate applications not only in standard clinical settings but also in various aspects of human neuroscience.

## 427.17

**QUANTITATION OF MICROVASCULAR ENZYME ACTIVITY IN RAT BRAIN SECTIONS BY IMAGE CYTOMETRY.** L.E. De Bault\*. Department of Pathology, University of Oklahoma Health Sciences Center, Oklahoma City, OK 73190.

Alkaline Phosphatase is one of several enzymes that have a very high expression in brain microvessels. The purpose of these experiments is to demonstrate the feasibility of performing enzyme cytochemistry in real time and quantitate the amount of enzyme by a kinetic method on a DISCOVERY™ Fluorobance Image Cytometry System. Formalin-fixed, paraffin-embedded brain sections were incubated at 20°C in Tris buffer containing the sodium salt of 1-naphthyl phosphate as the substrate and fast blue BB as the simultaneous chromogen/coupling agent. Measurements of the same areas were taken at 5 or more time points, and the change in absorbance at 540nm recorded. Units of enzyme activity are calculated by first-order rate reaction method. It can be shown that microvessels of the subfornical organ, microvessels in surrounding brain tissue, as well as vessels in the choroid plexus are high but show varying amounts of enzyme activity. Further work on simultaneous kinetic measurements of 2 or more enzymes is in progress. When properly controlled this enzymecytochemical procedure combined with quantitative Image Cytometry can be used to monitor a variety of cytochemical procedures that use enzymes as indicators. (Supported in part by NIH grant NS-18775 and an OCAST to L.E.D.)

## 427.14

**AUTOMATED COMPUTER TRACING AND MORPHOMETRY OF NEURONS: QUANTITATIVE ANALYSIS OF 3-D CONFOCAL IMAGES**

Badrinath Roysam<sup>1</sup>, Seetha Kodiyalam<sup>1</sup>, Andrew R. Cohen<sup>1</sup>, and James N. Turner<sup>2\*</sup>. <sup>1</sup>Rensselaer Polytechnic Institute, Troy, NY 12180, USA; <sup>2</sup>Wadsworth Center for Laboratories and Research, Albany, NY 12201, USA.

Current manual and semi-automated methods for tracing and performing morphometry of neurons are tedious and time consuming, and require geometric assumptions that limit their morphometric accuracy. We have developed 3-D image analysis methods for fully automated tracing and analysis of neurons that are labeled with space filling dyes such as Lucifer yellow and HRP. Hippocampal pyramidal cells are impaled, classified electrically, filled with dye, fixed, cleared and imaged using a Bio-Rad MRC-600 confocal attachment and an Olympus microscope. The results of the computer analysis is a labelled laser printout of the tracing, and a computer database representation containing: i) location of all branching and end points, and neuronal spines, ii) spatial adjacency patterns, and voxel-by-voxel path representations, iii) lengths, tortuosities, volume and surface areas of all dendritic and axonal segments, iv) location, volume, and surface area of soma, and v) statistical analysis of all measured features. Comparison of automated results with manual tracing has shown excellent correlation and will be quantitatively compared at the meeting. Support: NSF DIR 9108492 and NIH RR01219.

## 427.16

**NEAR-INFRARED SPECTROSCOPY (NIRS) OF THE HUMAN BRAIN WITH IMPROVED SPECTRAL AND TEMPORAL RESOLUTION.** A. Villringer\*, H. Obrig, Ch. Hirth, T. Wolf, U. Lindauer, U. Dirnagl, Dept. Neurology, Charité Hospital, Berlin

NIRS permits the noninvasive assessment of human brain oxygenation. Most studies so far have employed apparatus using between 2 and 7 different distinct wavelengths of light between 700 and 1000 nm. In order to improve spectral and temporal resolution, in the present study we implemented a whole spectrum CCD approach as previously described by Cope et al. (Adv. Exp. Med. Biol. 247:33). We used a MPP EEV-CCD camera (256x1024), the light source was a halogen lamp. While the spectral resolution was 0.6 nm (at one second sampling time), the best temporal resolution was 37 ms. Using this prototype system, in preliminary human studies, we were able to detect changes in hemoglobin oxygenation occurring during Valsalva maneuver and during oxygen breathing. In the rat, we were able to detect the hemoglobin oxygenation changes associated with spreading depression. When performing a Fourier-analysis of a series of spectra acquired of the human brain with a temporal resolution of 37 ms, we were able to detect frequencies between 60 and 80/min probably corresponding to the heart frequency. In some subjects, we also detected oscillations of approx. 7 Hz and 9-11Hz. We conclude that the CCD-camera approach is a promising technical improvement in NIRS.

## 428.1

**NITRIC OXIDE INDUCTION IN HUMAN GLIA.** M. Ding,\* B.A. St.Pierre, K. He, J.E. Merrill, Dept. of Neurology, UCLA School of Medicine, Los Angeles, CA 90024.

Although the importance and a fair understanding of nitric oxide (NO) synthesis in rodent cells has been well established, the induction of NO and regulation of inducible nitric oxide synthase (iNOS) in human cells appears to be substantially different and much less is understood about it. In the present study, we undertook to study the induction of iNOS and NO in human microglia and mixed astrocytes and microglia cell cultures generated from brains taken from fetal, neonatal and adult. By immunohistochemistry and *in situ* hybridization, we identified that both human microglia and astrocytes express iNOS in response to the combination of interleukin-1 (IL-1) and interferon-gamma (IFN- $\gamma$ ) stimulation, but the expression was greater when antibody-opsonized myelin was added to the cytokines, especially in neonatal and adult cultures. Northern blot analysis also revealed the expression of 4.1 kb iNOS mRNA in these cultures. Moreover, the studies of the kinetics of NO induction in fetal mixed cultures suggested a delay of NO production after enzyme expression. The expression of mRNA coding for iNOS peaked at 6 hours but was always gone at 24 hours after stimulation, while the enzyme itself appeared at 24 hours, and the maximal level was at day 3, but was still evident at day 7. However, significant amounts of NO were not evident in the supernatant until day 3. NADPH diaphorase staining and nitro-tyrosine as detected by antibody were not observed until day 7. Taking these data together, we suggest that (1) both human microglia and astrocytes are able to express iNOS; (2) the induction of NO in human glia is developmentally controlled; (3) Antigen-antibodies complexes containing myelin induces NO; (4) the delay of production of NO, NADPH diaphorase and nitro-tyrosine suggests a possible post-translational regulation for human iNOS enzyme to be functional.

## 428.3

**TETRAHYDROBIOPTERIN BIOSYNTHESIS IS REQUIRED FOR LIPOPOLYSACCHARIDE AND CYTOKINE-INDUCED NITRIC OXIDE PRODUCTION IN C6 GLIOMA CELLS.** Carol D'Sa, Anthony West, Maurcen Hahn, Kei Hirayama and Gregory Kapatos. Cellular and Clinical Neurobiology Program, Department of Psychiatry and Behavioral Neuroscience, Wayne State University School of Med., Detroit, MI. 48201.

Tetrahydrobiopterin (BH4) is the essential cofactor for nitric oxide synthase and GTP cyclohydrolase I (GTPCH) is the first and rate-limiting enzyme in BH4 biosynthesis. We have examined the requirement of BH4 biosynthesis for the induction of nitric oxide (NO) by LPS and TNF- $\alpha$  in the astrocytic-C6 glioma cell line. Treatment with 10  $\mu$ g/ml LPS and 50 ng/ml TNF- $\alpha$  caused a time-dependent thirteen-fold increase in the levels of BH4 which preceded NO production. The same stimuli led to a twenty-five-fold increase in GTPCH activity, with a corresponding increase in protein levels as indicated by Western blots. Northern blot analysis showed that levels of GTPCH mRNA were detectable by 3 hrs, reached maximal 25 hrs after activation and were sustained at high levels for at least 50 hrs. 2,4-diamino-6-hydroxypyrimidine, a competitive inhibitor of GTPCH, caused an 83% inhibition of the LPS and TNF- $\alpha$  induced BH4 levels with a corresponding 88% suppression of induced NO production. These results demonstrate that generation of NO from activated C6 cells is dependent on BH4 biosynthesis and suggest that pterin-synthesis inhibitors may be useful for therapy in certain pathophysiological conditions. (Supported by NIH NS26081 and The Joe Young Sr. Research Fund)

## 428.5

**CYTOKINE-ACTIVATED ASTROCYTES INDUCE NITRIC OXIDE SYNTHASE TYPE II IN CEREBROVASCULAR ENDOTHELIAL CELLS.** R. Borgerding and S. Murphy\*. Dept. of Pharmacology, Univ. of Iowa, Iowa City, IA 52242.

Astrocytes and cells of the cerebrovasculature can be induced by cytokines to express nitric oxide (NO) synthase type II (NOS). However, cerebral vessel-derived endothelial cells exposed to NO from either chemical or cellular sources prior to cytokines are markedly resistant to inducers of NOS. In addition, cytokine-activated astrocytes brought into close proximity with naive endothelium cause a marked induction of NOS in these cells, as revealed by northern blotting for NOS mRNA and their release of nitrite into the medium. Cytokines do not evoke the release of this 'inducing factor' from actinomycin D pretreated astrocytes, suggesting that it is dependent upon transcription. While TNF $\alpha$  is released from astrocytes under these conditions and will transcriptionally activate the type II NOS gene in endothelium, the use of pentoxifylline and neutralizing antibodies indicate that this is not the inducing factor. Using cultures of cytokine-activated cerebrovascular smooth muscle, endothelium and RAW macrophages we can also demonstrate their NOS-inducing activity in naive endothelial cells.

These observations suggest that the expression of NOS type II in cerebral vessels *in vivo* may be regulated by adjacent cells.

## 428.2

**EFFECTS OF EICOSANOID & NITRIC OXIDE MEDIATORS ON MICROGLIAL REACTION TO SPREADING DEPRESSION.** A.O. Caggiano\* and R.P. Kraig, Dept. of Neurology, The University of Chicago, Chicago, IL 60637

To begin examining the mechanisms of gliosis, we studied the effects of inflammatory mediators on microglia made reactive (e.g. microgliosis) by spreading depression (SD), a benign perturbation that lacks cell necrosis.

We elicited SD in 63 halothane anesthetized male Wistar rats by micro-injection of 0.5 M potassium chloride (or 0.5 M sodium chloride, shams) to the parietal cortex for 3 hr at 9 minute intervals, with or without a single treatment with anti-inflammatory agents one hour prior to surgery. SD was confirmed by monitoring DC potentials in frontal neocortices. After a 3 day recovery, brains were removed, sectioned and processed immunohistologically with an antibody to the complement type III receptor, OX-42. Analysis of staining intensity was assessed using a computer-based image analysis system based on a 12-bit cooled CCD camera. The log ratio (lr) of optical density of the experimental cortex divided by the contralateral control cortex was used as a measure of microgliosis. SD induced a significant increase in the log ratio of OX-42 staining intensity (lr = 0.144, p < .001). Significant values were not induced, however in animals pre-treated with a single-dose of dexamethasone, a phospholipase A<sub>2</sub> inhibitor, nordihydroguaiaretic acid, a lipoxygenase inhibitor, L-NAM, a NO synthase antagonist (lr's = 0.055, 0.103, 0.092; p's > .05, .05, .05) or sodium nitroprusside, a NO donor, with ephedrine (lr = 0.07, statistics incomplete). Pre-treatment with mepacrine or indomethacin, both cyclooxygenase inhibitors, or ephedrine alone did not prevent significant log ratios (p's < .05, .05 and .001, respectively).

We have demonstrated that the induction of microgliosis is sensitive to eicosanoids, particularly those generated by lipoxygenase, and NO. Gliosis, a component of brain inflammation, modulates not only the severity of brain injury but perhaps normal phenomena such as learning. Thus, inflammatory mediators (e.g., eicosanoids & NO) are likely factors which influence glia in their modulation of brain injury and remodeling associated with learning.

## 428.4

**INDUCTION OF GTP CYCLOHYDROLASE I GENE EXPRESSION CONTROLS NITRIC OXIDE SYNTHASE ACTIVITY IN C6 GLIOMA CELLS.** Kei Hirayama\* and Gregory Kapatos, Cellular and Clinical Neurobiology Program, Department of Psychiatry and Behavioral Neuroscience, Wayne State University School of Med., Detroit, MI. 48201

Tetrahydrobiopterin (BH4) is the essential cofactor for all nitric oxide synthases (NOS), enzymes that produce nitric oxide (NO) from arginine. GTP cyclohydrolase I (GTPCH) is the first and rate-limiting enzyme in BH4 biosynthesis. Treatment of C6 glioma cells with LPS and cytokines such as TNF- $\alpha$  is able to induce NOS activity. We have recently shown that this treatment also induces GTPCH activity and BH4 levels. In order to study the interaction between BH4 and NOS, we have stably transfected C6 cells with rat GTPCH cDNA so that they constitutively express BH4. While BH4 was not detected in non-transfected C6 cells, transfected C6 cells synthesized large amounts of BH4 (0.98 ng/1x10<sup>5</sup> cells). Both transfected and non-transfected cells were treated with 10  $\mu$ g/ml of LPS and 50 ng/ml of TNF- $\alpha$  for 0-50 hrs and NOS activity in intact cells was measured. In transfected cells, induction of NOS activity was first detected following 2 hrs of treatment. In non-transfected cells NOS activity was not detectable until 7.5 hrs. The level of NOS activity induced by LPS and TNF- $\alpha$  was 3-fold higher in transfected cells than in non-transfected cells. Constitutive expression of BH4 in C6 glioma cells therefore results in a more rapid and robust induction of NOS activity following cytokine treatment, suggesting that in non-transfected C6 cells the level of expression of induced NOS activity is controlled by GTPCH gene expression. (Supported by NIH NS26081)

## 428.6

**NITRIC OXIDE LIMITS TRANSCRIPTIONAL INDUCTION OF NITRIC OXIDE SYNTHASE TYPE II IN ASTROCYTES.**

S.K. Park\*, H.L. Lin and S. Murphy. Dept. of Pharmacology, Univ. of Iowa, Iowa City, IA 52242.

Expression of nitric oxide (NO) synthase type II (NOS) mRNA in astrocytes in response to cytokines is transient but can be amplified by NOS inhibitors or NO-trapping agents (Biochem. Biophys. Res. Commun. 201, 762, 1994) and stabilized by cycloheximide. The regulation by NO appears to be on transcription rather than destabilizing mRNA because: (a) actinomycin D abolished the effect, (b) nuclear run-on experiments reveal increased rate of transcription in the presence of NO-trapping agents, and (c) NO donors did not affect NOS mRNA stabilized by actinomycin D or cycloheximide.

From western blotting, using an antibody against the p65 subunit, we determined that antioxidants such as N-acetylcysteine and DMPO blocked induction of the NOS gene at a step downstream from translocation of the transcription factor NF $\kappa$ B to the nucleus. Exogenous NO (spermine NONoate) alone evoked activation and translocation of NF $\kappa$ B but did not affect translocation of NF $\kappa$ B evoked by cytokines.

These results suggest that NO might regulate NOS gene activation at the level of transcription factor interaction with the promoter, possibly via a redox mechanism.

Supported by NS29226.

## 428.7

**SODIUM CHANNEL DISTRIBUTION IS ALTERED IN EXPERIMENTAL ALLERGIC NEURITIS (EAN).** S.D. Novaković\*, S.R. Levinson\*, and P. Shrager. Depts. of Physiol., Univ. of Rochester, Rochester, NY 14642 & \*Univ. of Colorado, Denver, CO 80262.

Compromised axonal conduction produces well recognized clinical symptoms in EAN. Lewis rats were immunized with bovine root myelin + adjuvant. Using immunofluorescence, we have shown an alteration in Na<sup>+</sup> channel distribution in diseased spinal roots. There is a decrease in Na<sup>+</sup> channel density at the nodes of Ranvier, primarily in large axons, that is observable very early in the disease. The labeling changes from a highly focused fluorescent ring to a more diffuse axonal pattern and, as the disease proceeds, eventually becomes undetectable at the nodes. Clinical symptoms in most rats progress to complete hind limb paralysis, followed by complete recovery within a few weeks. In the second phase of the disease, a few days before clinical recovery starts, new clusters of Na<sup>+</sup> channels are seen. As in our previous study on lysolecithin demyelinated nerve (J.Neurosci. 15:492-502, 1995), these new aggregates form at the edges of newly adhering Schwann cells in regions that previously were internodal. Na<sup>+</sup> channel clusters associated with neighboring Schwann cells then appear to fuse, forming new nodes. In addition, some original nodes of Ranvier seem to regain Na<sup>+</sup> channels, probably due to some influence of associated Schwann cells. Supported by Natl. Multiple Sclerosis Society and NIH.

## 428.9

**THE GLUTAMATE TRANSPORTER GLT-1 IS DOWNREGULATED IN HYPERAMMONEMIA AND ACUTE LIVER FAILURE.**

Z. Huo, J.T. Neary, C.K. Petito\*, and M.D. Norenberg. Departments of Pathology and Biochemistry & Molecular Biology, University of Miami School of Medicine and VA Medical Center, Miami, FL 33101.

Recent studies in our laboratory have indicated that ammonia impairs the ability of cultured astrocytes to take up glutamate [J. Neurochem 64 (Suppl):66,1995]. Since ammonia is believed to be a major toxin involved in the pathogenesis of hepatic encephalopathy (HE), we examined whether the glutamate transporter was also affected in animal models of HE as well as in hyperammonemia. Rats were treated with either saline, thioacetamide (TAA) (300 mg/kg; i.p.) or ammonium acetate (5 mmole/kg; i.p.) daily and sacrificed 2 hr after the fourth injection. RNA was extracted from the cerebral cortex and striatum by the guanidinium-thiocyanate-phenol-chloroform method. A 513 bp glutamate transporter (GLT-1) oligonucleotide probe was generated by RT/PCR based on the sequence of Pines et al [Nature 360:464,1992]. Northern blot analysis revealed that GLT-1 mRNA was significantly reduced by 22% and 21% in the cortex of TAA and ammonia-treated rats, respectively. GLT-1 mRNA was reduced to an even greater extent in the striatum (TAA, 47%; ammonia, 40%). Our findings indicate that in acute liver failure and in hyperammonemia, there is decreased expression of the glial glutamate transporter. Such a defect could result in elevated extracellular levels of glutamate and possibly contribute to abnormal glutamate neurotransmission and/or excitotoxicity. (Supported by NIH grants DK38153 and NS30291, VA and GRECC)

## 428.11

**AMMONIA INHIBITS THE METABOTROPIC GLUTAMATE RECEPTOR IN CULTURED ASTROCYTES.**

J.H. Bruce\*, J.T. Neary, Y. Itzhak and M.D. Norenberg. Departments of Pathology and Biochemistry & Molecular Biology, University of Miami School of Medicine and VA Medical Center, Miami, FL 33101.

Current evidence suggests that ammonia and related abnormalities in glutamate (GLU) neurotransmission play a major role in the pathogenesis of hepatic encephalopathy (HE). While changes in GLU receptors have been described in various models of HE, nothing is known about the properties of astrocytic GLU receptors in HE/hyperammonemia. Since astrocytes are believed to be critically involved in HE, we have initiated studies on the effects of ammonia on the astrocytic metabotropic GLU receptor (mGluR). Cultured astrocytes derived from neonatal rats were treated with 5 mM NH<sub>4</sub>Cl for 4 days and properties of the mGluR were determined. GLU-stimulated inositol phosphate formation, which is mediated by mGluRs, was reduced by 60% following ammonia treatment. In fura-2 loaded cells, the transient Ca<sup>2+</sup> peak response to quisqualate, an agonist for the mGluR, was reduced by approximately 50% and the number of cells responding to quisqualate was also reduced. Saturation binding experiments indicated a 35% decrease in the number of AP-3 sensitive [<sup>3</sup>H]GLU-binding sites in ammonia-treated cells (control B<sub>max</sub> = 1010 ± 20 vs. ammonia B<sub>max</sub> = 658 ± 59 fmol/mg protein). Our findings indicate that ammonia downregulates the astroglial metabotropic glutamate receptor. This may alter glial function, possibly affecting neuronal excitability, and play a role in hepatic encephalopathy. (Supported by NIH grants DK38153, NS30291, VA and GRECC)

## 428.8

**GLIAL CELL INTERCELLULAR PERMEABILITY IS INCREASED BY NERVE IMPULSES.** R.K. Orkand\* and H. Marrero. Institute of Neurobiology, University of Puerto Rico Medical Sciences Campus, 201 Blvd. del Valle, San Juan PR 00901, USA.

In the intact nervous system, glial cells form gap junctions with one another that permit the exchange of ions and small molecules important for their function in regulating the composition of the neuronal microenvironment. We have measured glial intercellular permeability by injecting the fluorescent dye, Lucifer Yellow (LY), into glial cells in the isolated intact optic nerve of the frog, *Rana pipiens*, and monitoring its diffusion into surrounding glial cells with a fluorescence microscope. Normally, 48% of the injections (n = 140) stained only one cell. In 44%, 2 - 10 cells were stained and in 8% the dye spread profusely staining more than 20 glial nuclei. Dye coupling increased with electrical stimulation of the axons during the injection (10 Hz for 1 sec/2 sec for 2 min). Raising [K<sup>+</sup>]<sub>o</sub> to 18-20 mM or adding 0.5 mM Ba<sup>2+</sup> to block K channels, which also depolarized glial cells, also increased gap junction permeability. Axonal stimulation in the presence of Ba<sup>2+</sup> further increased coupling without additional glial depolarization. Thus, it appears that dye coupling of glial cells is increased by nerve impulses not only because of glial depolarization but also by an additional factor released from stimulated axons. The increased coupling helps the role of the glial cells in extracellular homeostasis.

## 428.10

**INTRACELLULAR GLUTAMINE AS A FACTOR IN AMMONIA-INDUCED ASTROCYTE SWELLING.** R.S. Dombro\*, A.S. Bender, D.G. Hutson and M.D. Norenberg. VA Med. Ctr., Miami, FL 33125 and Depts. Surg., Pathol., Biochem. & Mol. Biol., Univ. Miami School of Med., Miami, FL 33101

Fulminant hepatic failure is associated with brain edema and astrocytic swelling. The mechanism for this swelling is poorly understood. Takahashi et al. (Am. J. Physiol. 261, H825, 1991) have proposed that ammonia-stimulated production of glutamine (GLN) may play a role in glial swelling by acting as an osmolyte. To test this idea, the effects of ammonia alone, and ammonia plus glutamate (GLU) on GLN levels were determined in cultured astrocytes by HPLC. Experiments were performed using GLN-free DMEM. Cell and medium concentrations of GLN were determined at 10 min, 1, 3, and 24 hr after treatment. Incubation with 1 and 5mM ammonia increased cell GLN at 24 hr by 2.6- and 2.1-fold, respectively. In the presence of 100μM GLU, the corresponding increases were 2.9- and 3-fold. With 1mM GLU, ammonia caused appreciably greater increases in cell GLN content, and these were observed at earlier time points (1 and 3 hr). Medium GLN was markedly decreased at 24 hr by ammonia (55% with 1mM and 76% with 5mM ammonia), suggesting that ammonia may inhibit GLN release. This was confirmed by loading cells with GLN-[<sup>14</sup>C] and measuring its efflux. Treatment with 5mM ammonia for 1 day caused a 13% decrease, whereas 3 day treatment caused a 46% decrease of GLN release from astrocytes. Our findings indicate that glutamine accumulates in astrocytes following ammonia treatment and that one factor in this accumulation is the diminished efflux of this amino acid. Such accumulation of GLN may contribute to glial swelling and the brain edema associated with acute liver failure. (Supported by VA Medical Research Service, NIH grants DK38153 and NS 30291 and GRECC).

**PHARMACOLOGICAL CHARACTERIZATION OF GLUTAMATE-INDUCED ASTROCYTE SWELLING.** A.S. Bender\*, A. Schousboe\*, and M.D. Norenberg. Lab. of Neuropathology, Univ. of Miami Sch. of Med. & VA Med Ctr., Miami, FL 33101 and Dept of Biol. Sci. PharmaBiotec Res. Ctr., Royal Danish School of Pharmacy, DK-2100 Copenhagen, Denmark

L-Glutamate (L-GLU) is well known to induce astrocyte swelling; however, the mechanism is not well understood. In this study, we examined whether such swelling is mediated through GLU receptors, GLU uptake or K<sup>+</sup> channels. Cell volume was measured in cultured astrocytes using 3-O-methyl[<sup>3</sup>H]-D-glucose method as described by Kletzien et al. (Anal. Biochem. 68:537,1975). L-GLU (1 mM) induced a two-fold increase in astrocyte cell volume, which was not stereospecific, since D-GLU, L-aspartate and D-aspartate at 1 mM induced swelling to about the same degree as L-GLU. K<sup>+</sup>-channel inhibitors such as barium, TEA and 4-aminopyridine at 1 mM did not prevent L-GLU swelling, suggesting that K<sup>+</sup> channels are not involved in this process. With the exception of dihydrokainate, L-GLU uptake inhibitors (e.g., β-methylene aspartate, DL-threo-β-hydroxyaspartic acid and L-trans-2,4-PDC) at 1 mM all caused a comparable increase in cell volume when given alone, and did not prevent L-GLU induced swelling. L-GLU receptor agonists such as kainic acid, trans-(1S,3R)-ACPD, AMPA and ibotenic acid at 1 mM did not affect cell volume, whereas swelling was observed with the metabotropic receptor agonists, AP4 and quisqualate. Although involvement of glutamate uptake cannot be completely excluded, our studies indicate that activation of certain metabotropic glutamate receptors may play a role in the mechanism of glutamate-induced astrocyte swelling. (Supported by NIH grants DK38153, NS30291, VA and GRECC)

## 428.13

THE ROLE OF EXTRACELLULAR IONIC CHANGES IN UPREGULATING mRNA FOR GFAP FOLLOWING SPREADING DEPRESSION. D.J. Bonthuis\*, E.W. Lothman and O. Steward, Departments of Neurology and Neuroscience, Univ. of Virginia, Charlottesville, VA 22908.

While spreading depression has been shown to upregulate glial fibrillary acidic protein (GFAP) mRNA expression, the specific physiological signal underlying the upregulation is unknown. During spreading depression, extracellular ionic concentrations are altered markedly. This study evaluates the role of these ionic changes as signals influencing GFAP mRNA expression. Gel foam pledgets saturated with artificial cerebrospinal fluid solutions in which  $[Na^+]$ ,  $[Ca^{++}]$ ,  $[K^+]$  and  $[H^+]$  were altered one at a time to match concentrations seen in spreading depression were applied to exposed parietal cortex for one hour. Dot blot and in situ hybridization techniques were used to evaluate GFAP mRNA levels. Alteration of  $[K^+]$  was the only ionic change that altered GFAP mRNA expression and led to a many-fold increase in GFAP mRNA levels at the time of maximum expression four days post-exposure. However, the upregulation in GFAP mRNA induced by the potassium exposure was totally blocked by prior administration of MK-801, an NMDA antagonist that blocks spreading depression. This suggests that the upregulation of GFAP mRNA was not due directly to the increased  $[K^+]$ , but to the spreading depression that the elevated  $[K^+]$  induced. A further finding was that application to the cortex of 60 mM KCl can elicit spreading depression without detectable tissue damage and induces a large transient increase in GFAP mRNA content. This finding demonstrates that an upregulation in GFAP mRNA can occur in the absence of degeneration debris and that the initiating events can be related to physiological changes.

AGMATINE AND ARGININE DECARBOXYLASE ACTIVITY ARE EXPRESSED IN GLIAL CELLS. S. Regunathan\*, D.L. Feinstein, L. Lyandvert, W. Raasch and D.J. Reis, Div. of Neurobiol., Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, NY 10021.

Agmatine, decarboxylated arginine, an endogenous ligand for imidazole ( $I_1$ ) and  $\alpha_2$ -adrenergic receptors has, with its biosynthetic enzyme arginine decarboxylase (ADC), been discovered in mammalian brain (Li et al., *Science* 263:966, 1994). While agmatine is stored in some central neurons, its cellular localization in CNS is not fully known. We investigated whether astrocytes store and synthesize the amine and whether it binds to astrocytic  $I_1$ -receptors (Regunathan et al., *J. Neurosci. Res.* 34:681, 1993). By HPLC measurement, the amount of agmatine was found to be  $8.5 \pm 1.4$  and  $1.8 \pm 0.6$  nmol/mg protein in astrocytes and C6 cells, respectively. Agmatine was immunocytochemically localized with a specific polyclonal antibody to cytoplasm of astrocytes cultured from neonatal rat cortex and in rat C6 glioma cells. ADC activity was present in membranes of astrocytes ( $85.4 \pm 9.2$ ) and C6 cells ( $18.2 \pm 3.12$  nmol/hr/mg protein) indicating that the amine was locally synthesized. Exposure to bacterial lipopolysaccharide (LPS; 1  $\mu$ g/ml) decreased ADC activity in C6 cells (to 70% of control) but did not affect astrocytic ADC. Interferon- $\gamma$  (20 Units/ml) significantly ( $p < 0.05$ ) increased ADC activity in astrocytes to 130% and C6 cells to 150% of controls.  $^3H$ -idazoxan binds with high affinity to  $I_2$  receptors on membranes of cultured astrocytes ( $K_D$ : 6.2 nM;  $B_{max}$ : 210 fmol/mg protein) but not C6 cells. Astrocytic binding was inhibited by agmatine ( $K_i$ : 450 nM). We conclude: (a) agmatine is synthesized and stored in astrocytes; (b) astrocytic ADC can be regulated by cytokines; (c) agmatine binds to astrocytic  $I_2$  receptors; (d) agmatine may be an autocrine message in astrocytes.

## 428.17

AUGMENTATION OF EXTRACELLULAR  $H^+$  BUFFERING BY EXOGENOUS CARBONIC ANHYDRASE IN VITRO & IN VIVO. M. Chesler\*, W. Huang and S.E. Smith, Depts. Physiol./Neurosurg. NYU Med. Ctr., 550 1st Ave., NY, NY 10016.

In brain, rapid pH buffering is insured by extracellular carbonic anhydrase (CA) [1,2]. We tested whether buffering can be increased by adding CA to Ringer superfused over rat brain slices or cerebral cortex. Artificial alkaline shifts were created by  $OH^-$  iontophoresis near a pH microelectrode. Endogenous alkaline shifts were evoked by AMPA ejection. At  $\sim 0.01 \mu$ M, CA had no effect, but at  $\sim 0.10 \mu$ M, CA reversibly decreased the alkaline shifts within 5-10 min. ( $-61 \pm 4\%$   $n=11$  slices &  $-60 \pm 9\%$ ,  $n=6$  slices for  $OH^-$  and AMPA responses respectively). In HEPES Ringer, CA had no effect on the pH shifts. AMPA-evoked alkaline shifts were also decreased ( $-53 \pm 6\%$ ,  $n=4$  rats) when  $\sim 0.10 \mu$ M CA was superfused over rat cortex *in vivo*. Our data show that CA readily diffuses in brain extracellular space. Thus, endogenous CA activity is unlikely to be an artifact of CA persisting from cell damage. Our results suggest that endogenous [CA] is low, equivalent to exogenous enzyme concentrations of  $\sim 0.01$  -  $0.10 \mu$ M. These data are consistent with previous  $PCO_2$  and  $HCO_3^-$  recordings during alkaline shifts [3], which suggested low extracellular CA activity, insufficient for rapid  $CO_2$ - $HCO_3^-$  equilibration. Supported by NIH grants NS32123 & NS10164. [1] Chen & Chesler. *PNAS* 89:7786 [2] Kaila et al. *NeuroReport* 3:105. [3] Chesler & Chen. *Soc. Neurosci. Abstr.* 19:267.

## 428.14

HETEROGENEITY OF BRAIN PEROXISOMES. A.M. Cimini\*, I. Singh\*, S. Moreno and M.P. Ceru\*. Dept. of Basic and Applied Biology, University of L'Aquila, L'Aquila, Italy 67100 \*Dept. of Pediatrics, Medical University of South Carolina, Charleston, S.C. 29425

Peroxisomes, a recently recognized subcellular organelle, is known to perform various functions including the metabolism of myelin lipids (plasmalogens and very long chain fatty acid). Morphological studies have previously suggested that peroxisomal functions in brain may be different in different neural cell types (Holtzman et al., 1979). We provide biochemical evidence that brain contains at least two subpopulations of peroxisomes based on their density in a gradient and that these two populations of peroxisomes have different enzyme composition. In a Nycodenz density gradient, we observed two different peroxisomal populations characterized by different equilibrium densities and different size. The peroxisomes equilibrated at a density of 1.12 gm/ml were of smaller size (0.12  $\mu$ m diameter) and the peroxisomes equilibrated at a higher density of 1.175 gm/ml had a large size (0.24  $\mu$ m diameter). The two populations seem to be different also in the enzymatic composition. The lighter peroxisomes ( $d=1.12$  gm/ml) had activity for dihydroxyacetone phosphate acyl-transferase (DHAP-AT) and D-amino acid oxidase activities; whereas heavier peroxisomes ( $d=1.175$  gm/ml) had high activities for catalase and D-amino acid oxidase. We also examined the latency of these enzymes in these two populations of peroxisomes. Catalase, acyl-CoA oxidase had a latency of 80 to 90 percent; whereas D-amino acid oxidase and DHAP-AT showed no detectable latency. We postulate that peroxisomes with different enzymatic composition for specific functions may be present in different neural cell types. Studies are in progress to characterize peroxisomes in different cell types in brain.

## 428.16

CHARACTERIZATION OF AN INWARDLY RECTIFYING CHLORIDE CONDUCTANCE IN DIBUTYRYL-CYCLOIC-AMP TREATED CORTICAL ASTROCYTES. S. Ferroni, C. Marchini, M. Nobile\* and C. Rapisarda, Department of Human and General Physiology, University of Bologna, 40127 Bologna, Italy.\*Institute of Cybernetic and Biophysics, CNR, 16149 Genova, Italy. (Spon. E.N.A.)

Prolonged incubation (1-3 weeks) with dibutyryl-cAMP of new-born rat cortical astrocytes in culture induces the expression of inwardly rectifying chloride ( $Cl^-$ ) and potassium ( $K^+$ ) conductances. We characterized with the whole-cell patch-clamp technique the gating and pharmacological properties of the  $Cl^-$  conductance using intra- and extracellular solutions with symmetrical  $Cl^-$  and with monovalent cations substituted by N-methyl-D-glucamine. Hyperpolarizing steps from an holding potential ( $V_h$ ) of 0 mV activated inward currents which had a slow activation kinetic and did not inactivate. The conductance activation was described by a Boltzmann equation. The calculated half conductance was at -70 mV, the slope 18 mV and the gating valence 1.5. Varying  $V_h$  of  $\pm 30$  mV did not change the amplitude of the currents. Tail currents analysis performed using different extracellular  $Cl^-$  concentrations confirmed the anion selectivity. The pharmacological profile showed that extracellular application of 1 mM DIDS and SITS did not affect the currents. In contrast 1 mM anthracene-9-carboxylate or 1 mM niflumic acid decreased the currents of  $\sim 50\%$ . Moreover, cadmium and zinc blocked the currents with an half inhibitory concentration of 0.2 and 0.5 mM respectively. These data suggest that the strengthening of the cAMP signalling induces the expression of a  $Cl^-$  conductance which can be involved together with the inward rectifying  $K^+$  conductance in the process of the extracellular  $K^+$  buffering via the mechanism of the local accumulation. Supported by grants from C.N.R. and M.U.R.S.T. (Italy).

ENDOGENOUS, PROLIFERATING CELLS IN ADULT RAT WHITE MATTER RESPOND TO INJURY. J.M. Gensert, G.R. Tibbs\* and J.E. Goldman, Depts. of Pathology & Physiology, Columbia Univ., NY, NY 10032.

Dividing cells persist in the adult mammalian CNS. Although the antigenic profile of at least a subpopulation of these cells is known, their response to injury has not been described previously. Proliferating cells in adult rat subcortical white matter were examined *in vivo* using stereotactic injections of a replication-deficient retrovirus that expresses  $\beta$ -galactosidase. These cells were visualized by X-gal histochemistry or by immunocytochemistry with anti- $\beta$ gal antibodies. An antigenic profile of the labeled cells was established, and their response to injury was examined. The initially labeled population of proliferating cells exhibited an immature morphology and did not express markers of mature glia 2 dpi. Nestin colocalized with  $\beta$ gal in approximately half of the labeled cells, and GST-Yp immunoreactivity was detected in approximately half of the  $\beta$ gal labeled cells; morphologically, these represented distinct populations of proliferating cells. Thirty days after introduction of retrovirus, however, approximately 20% of the labeled cells expressed Rip demonstrating that at least some members of the population of proliferating cells in adult CNS retain the capacity to differentiate and express markers of mature glia *in vivo*. The response of these cells to lesions was examined by disrupting cytoarchitecture with stab wounds and by demyelinating with lysolecithin. These cells responded to injury *in vivo* with an increase in proliferation as assayed by cell counts and BrdU incorporation. At longer time points, many of the  $\beta$ gal labeled cells differentiated into cells with astrocytic and myelinating oligodendrocytic morphologies. Thus, endogenous cells can develop through oligodendrocyte and astrocyte lineage pathways *in vivo* in response to CNS injury in the adult brain. The signals responsible for proliferation and differentiation of these cells in response to injury remain to be determined.

**TAURINE TRANSPORT KINETICS OF ASTROCYTES EXPOSED TO HYPER-OSMOTIC CONDITIONS.** J.W. Beetsch\* and J.E. Olson. Departments of Emergency Medicine and Physiology and Biophysics, Wright State University School of Medicine, Dayton, OH 45401.

Hyperosmotic exposure of cultured cerebral astrocytes leads to persistent increases in intracellular taurine content. Taurine uptake rates increase after 24 hr, but then decrease after 2 weeks of hyperosmotic exposure. These results indicate multiple mechanisms contribute to the accumulation and maintenance of high intracellular taurine after hyperosmotic exposure. In this study, we examined changes in taurine regulation in cultured rat astrocytes by comparing rates of uptake and release after growth in isosmotic and hyperosmotic conditions. Confluent cultures of cerebral rat astrocytes were exposed to control (300 mOsm) medium or hyperosmotic (350, 400, 450 mOsm) medium adjusted with NaCl. After 1, 24, or 48 hr, kinetic parameters of taurine uptake were determined using <sup>3</sup>H-taurine together with unlabeled taurine (5-1000 µM). Efflux of preloaded <sup>3</sup>H-taurine was measured in parallel studies at these same times. Intracellular taurine content was determined in efflux cultures by HPLC. Compared to control cultures grown in 300 mOsm medium, K<sub>m</sub> of taurine uptake was not altered after 48 hr hyperosmotic exposure. V<sub>max</sub> increased 39% after 24 hr exposure to 450 mOsm medium. After 48 hr exposure to this medium, V<sub>max</sub> returned to control values. Taurine release from cultures exposed to 450 mOsm medium for 1 and 8 hr increased 2.8 and 3.8 fold, respectively, when compared to control cultures. After 24 and 48 hr, release rates decreased to levels significantly (p<0.01) lower than control cultures. Thus, taurine accumulation by cultured cerebral astrocytes exposed to hyperosmotic conditions is due to an alteration in the rates of influx and efflux. Short term hyperosmotic exposure induces an uptake from the extracellular space while prolonged exposure decreases the amount of taurine lost from the cells. Supported by NIH (NS 23218).

## 428.20

**APOLIPOPROTEIN E RECEPTOR PHENOTYPE CHANGES WITH ASTROCYTIC AND OLIGODENDROCYTIC DIFFERENTIATION OF THE 4C8 MOUSE GLIAL CELL LINE.** M.C. Izarray, G.W. Rebeck, D. Strickland, B.T. Hyman, G.W. Van Hoesen\*, and C.A. Dyer. Neurology, Mass. Gen. Hosp., Boston, MA 02114; Anatomy, Univ. of Iowa, Iowa City, IA 52242; American Red Cross, Bethesda, MD 20855; and Biomedical Sciences, E. K. Shriver Center, Waltham, MA 02254.

The physiologic actions of apolipoprotein E (apoE) in the brain are mediated by apoE receptors—low density lipoprotein receptor (LDL-r), low density lipoprotein receptor-related protein (LRP), very low density lipoprotein receptor (VLDL-r), and GP-330. The 4C8 cell line was subcloned from the glioblastoma cell line MOCH-1 derived from a myelin basic protein/*c-neu* transgenic mouse. 4C8 cells cultured in low serum conditions resemble O-2A glial progenitor cells morphologically and possess immature myelin markers. LRP and VLDL-r are weakly expressed in these cells. Cells cultured in defined media without serum have the morphologic appearance of mature oligodendrocytes, express all the known major myelin markers, and lack astrocytic markers (GFAP). These oligodendrocytic cells strongly express VLDL-r and weakly express LRP. VLDL-r immunostaining is confined to vesicles in the cell body. 4C8 cells grown in 10% serum resemble reactive astrocytes, expressing GFAP but no myelin markers. These cells strongly express LRP and only weakly express VLDL-r. LRP immunostaining is present in vesicles predominantly located within the cytoplasm and at the tips of processes. Astrocytic 4C8 cells secrete apoE and a soluble form of LRP into the media. All three forms of 4C8 cells express LDL-r and lack GP-330. These results suggest that VLDL-r and LRP serve distinct roles in oligodendrocyte and astrocyte function.

## BLOOD-BRAIN BARRIER: PATHOLOGY AND DISEASE

## 429.1

**NEUROCHEMICAL AND CELLULAR MECHANISMS OF RMP-7: A TUMOR-SELECTIVE ADJUVANT TREATMENT FOR NEURO-ONCOLOGY.** R.L. Dean<sup>1</sup>\*, P.J. Elliott<sup>1</sup>, C.M. Oyler<sup>1</sup>, S.K. Fisher<sup>2</sup>, E.L. McEwen<sup>2</sup> & R.T. Bartus<sup>1</sup>. Alkermes Inc.,<sup>1</sup> 64 Sidney St., Cambridge, MA 02139 and Neuroscience Laboratory,<sup>2</sup> University of Michigan, Ann Arbor, MI 48104.

The blood brain barrier (BBB) severely limits diffusion of chemotherapeutics from the vasculature to brain and brain tumors. To overcome this therapeutic obstacle the bradykinin B2 analog, RMP-7, was designed to have a longer half life and improved selectivity compared to bradykinin. Recent data in a rat glioma (RG2) model (Inamura et al., *J. Neurosurg.*, 1994) not only demonstrated that RMP-7 could permeate the BBB, but that selective permeation of the blood tumor barrier was induced, providing several-fold greater uptake of labeled compounds into the tumor, relative to normal brain. The current work investigates the mechanism(s) of action of RMP-7, as well as gains insight into the nature of its selectivity for permeating brain tumor barriers.

We have demonstrated that in SH EP cells, a human neuroblastoma x epithelial cell line: (1) RMP-7 induced a B2 receptor-mediated PI response as a key intracellular signal in a dose-dependent manner (EC50 = 30-50 nM); this EC50 is equivalent to that induced by bradykinin. (2) RMP-7 resulted in a marked rise in cytosolic calcium ([Ca<sup>2+</sup>]<sub>i</sub>) levels (approx. 500nM). The subsequent addition of bradykinin (1 µM) did not elicit any further increase in [Ca<sup>2+</sup>]<sub>i</sub>. The rise in [Ca<sup>2+</sup>]<sub>i</sub> induced by RMP-7 was largely independent of extracellular Ca<sup>2+</sup> (EC50=40nM). In both series of studies, these responses were abolished by the selective B2 antagonist, HOE-140 (0.1-1.0µM), but not by the selective B1 antagonist, des Arg<sup>10</sup>-HOE-140 (0.1-1.0µM). These data, thus, provide direct empirical support for biochemical and cellular mechanisms of action of RMP-7.

## 429.3

**BRADYKININ PERMEATION OF THE BBB: EVIDENCE FOR A SENSITIVE, AUTO-REGULATED, RECEPTOR-MEDIATED SYSTEM.** R.T. Bartus<sup>1</sup>\*, P. Elliott<sup>1</sup>, N. Hayward<sup>1</sup>, K. Matsukado<sup>2</sup>, & K. Black<sup>2</sup>. Alkermes Inc.,<sup>1</sup> Cambridge, MA and UCLA Med Ctr,<sup>2</sup> Los Angeles, CA.

The cytoarchitecture of vessels supplying the brain excludes hydrophilic substances from diffusing into the brain. A primary component of this blood brain barrier (BBB) is the tight junctions between membranes of opposing endothelial cells. The endothelial cells comprising the BBB have a variety of peptide receptors linked to intracellular second messengers (implying complex and sensitive signal transduction systems) and an unusually high concentration of mitochondria (implying high energy demand). Recent data also suggests that one peptide, bradykinin, can cause permeability of the BBB through a B2 receptor-mediated pathway. Using RMP-7, a bradykinin analog that has greater B2 selectivity and plasma stability, we have previously shown that bradykinin permeates the mouse BBB by opening its tight junctions (Sanovich et al., Soc. Neurosci., '94). Corroborating data for RMP-7's ability to permeabilize vascular barriers in brain and eye has been obtained in rats, guinea pigs, dogs and humans.

In the present studies, we used continuous carotid infusions of RMP-7 (0.1 µg/kg/min), in conjunction with quantitative autoradiography, to study the kinetics of bradykinin's permeation of the BBB to radio-labeled 70kDa dextran. RMP-7 caused a rapid opening of the barrier (e.g., 3-fold increase in Ki within 10min; p<.0001) but this permeability was short-lasting (BBB integrity restored within 10 min of cessation of RMP-7; p>.10). The response also appeared to be auto-regulated, for permeability decreased rapidly (i.e., to <1/3 Ki within 30min; p<.001), even with constant carotid infusion of RMP-7. These studies suggest a very sensitive, but tightly regulated bradykinin system which transiently opens the BBB, for still unknown physiologic purposes.

## 429.2

**INTRAVENOUS ADMINISTRATION OF RMP-7 SELECTIVELY INCREASES UPTAKE OF CARBOPLATIN INTO RAT BRAIN TUMORS.** P. Elliott\*, N. Hayward, M. Huff, T. Nagle, R. Dean, D. Blunt, C. Kim, C. Oyler, A. Schutz, K. Black<sup>1</sup> & R. Bartus. Alkermes Inc., Cambridge, MA 02139 and UCLA Med. Center,<sup>1</sup> Los Angeles, CA 90024.

The brain is isolated from blood-borne agents by the tight intercellular junctions between the vascular endothelial cells that comprise the blood-brain barrier (BBB). A similar barrier exists around brain tumors, creating a formidable obstacle to effective treatment with chemotherapeutic agents. Intra-arterial administration of the hyper-osmotic agents mannitol and arabinose have been used clinically and are associated with lasting damage to the barrier and increased drug delivery to normal brain, relative to brain tumor. Thus, these methods can increase the neurotoxicity of the CNS.

An alternative approach employs the selective bradykinin B2 agonist RMP-7 which has been shown to selectively open the blood-tumor barrier in a rat glioma (RG2) model (Inamura et al., *J. Neurosurg.*, 1994). This selectively in permeating the blood-tumor barrier offers significant potential advantages for chemotherapy. The present study replicates and extends these earlier observations by: (1) illustrating a significant (p<.001) increase (1.5 fold) in uptake of the chemotherapeutic, <sup>14</sup>C-carboplatin, into brain tumor with IV administration of RMP-7 (4.5 µg/kg continuously infused for 15min), (2) demonstrating enhanced carboplatin uptake into the brain area immediately surrounding the tumor with substantially lower amounts in brain tissue distal to the tumor, (3) demonstrating no increase in uptake into peripheral (sciatic) nerve, and (4) characterizing the physiologic state (e.g., blood pressure, body temperature, blood gases, etc.) of brain-tumor-bearing animals treated with RMP-7 versus vehicle, thereby demonstrating that conventional hemodynamic bradykinin responses are not associated with enhanced permeability. These data are discussed as they relate to current attempts to treat gliomas in humans.

## 429.4

**RMP-7 SELECTIVELY INCREASES UPTAKE OF CARBOPLATIN INTO RAT BRAIN TUMORS AND SURROUNDING BRAIN.**

N. Hayward<sup>1</sup>\*, P. Elliott<sup>1</sup>, M. Huff<sup>1</sup>, T. Nagle<sup>1</sup>, A. Schutz<sup>1</sup>, K. Matsukado<sup>2</sup>, K. Black<sup>2</sup> & R.T. Bartus<sup>1</sup>. Alkermes Inc.,<sup>1</sup> Cambridge, MA 02139 and UCLA Medical Center,<sup>2</sup> Los Angeles, CA 90024.

Many agents in the blood are restricted from entering the brain by an anatomical barrier (BBB) comprised of tight intercellular junctions between the endothelial cells of the microvasculature. A similar barrier is found around brain tumors, creating a formidable obstacle to their treatment. The blood-tumor barrier can be selectively permeated by the peptidic bradykinin agonist RMP-7 in a rodent brain glioma (RG2) model (Inamura et al., *J. Neurosurg.*, 1994).

The present study replicates and extends these observations by demonstrating: (1) enhanced uptake of <sup>14</sup>C-carboplatin into brain tumor (1.5-2.0 fold; p<.01) following intracarotid infusion of RMP-7 (0.5-1.5 µg/kg for 5-15min); (2) enhanced uptake of <sup>14</sup>C-carboplatin into brain surrounding tumor (up to 2 mm<sup>3</sup> by RMP-7; although the Ki was lower than in tumor, it was significantly higher in RMP-7-treated relative to vehicle-treated animals (2.0 fold; p<.01); (3) enhanced efficacy when RMP-7 was combined with carboplatin (10 mg/kg, IA), reflected in increased survival rates of glioma animals; and (4) that changes in hemodynamic variables often associated with systemic bradykinin (e.g., decreased blood pressure, alterations in blood gases, etc) can be dissociated from the BBB permeability effects and thus are not responsible. These data are discussed as they relate to current attempts to treat recurrent gliomas in humans.

## 429.5

INTRAVENOUS RMP-7 SELECTIVELY OPENS THE GUINEA PIG BLOOD-RETINAL BARRIER. J. Mackic<sup>1</sup>\*, P. Elliott<sup>2</sup>, R. Barus<sup>2</sup> & B. Zlokovic<sup>1</sup>. Dept. Neurol. Surg., USC, Los Angeles, CA 90033 <sup>1</sup>, Alkermes Inc., Cambridge, MA 02139 <sup>2</sup>

RMP-7 is a selective B2 agonist with a longer in vivo half life than bradykinin. It has been shown to selectively increase the permeability of the blood-tumor barrier in rats to a number of different molecular weight compounds (Inamura et al., 1994). As such, it is currently in clinical trials as an adjunct to the chemotherapeutic agent carboplatin. RMP-7 is believed to achieve its effects through the opening of tight junctions between endothelial cells via activation of B2 receptors. We have recently shown that intracarotid infusions of RMP-7 can permeate the blood-retinal barrier (BRB) of the guinea pig (Elliott et al., 1995). Currently there are many eye disorders for which treatment is impeded by the BRB, such as cytomegalovirus retinitis (CMV). This study investigated the effects of intravenous (IV) infusion of RMP-7 on uptake of the anti-viral agent, ganciclovir, into the guinea pig eye and brain.

RMP-7 (1µg/kg; IV infusion) was given to guinea pigs as a 5min pretreatment, followed immediately by an IV infusion of 3H-ganciclovir for periods of 15sec to 10min. At the end of the radiolabel administration, the animals were sacrificed and the brain and eyes were rapidly removed and dissected. Levels of radioactivity within various eye segments and the brain were then determined using liquid scintillation counting.

Results illustrate that IV administered RMP-7 significantly increases the uptake of ganciclovir (up to 2 fold) into the guinea pig retina and lens epithelium but did not increase uptake into the brain of the same animals. Significant uptake into the retina and lens was also evident 30 min after cessation of the ganciclovir (5min) infusion. These data highlight the selective nature of RMP-7's effect and support its potential clinical use as an adjunctive treatment to various eye disorders, including CMV.

## 429.7

AN AGED RAT STUDY OF ALTERATIONS IN CHOROID PLEXUS EPITHELIUM AFTER ISCHEMIA INDUCED BY CAROTID OCCLUSION. C. Johanson\*, D. Palm, M. Primiano, P. Chan, N. Knuckey, and E. Stopa. Dept. Clin. Neurosci., Prog. in Neurosurg., Brown U. & RI Hospital, Providence, RI 02903

In late stages of life, the appearance in choroid plexus (CP) of calcification and hyalinization of connective tissue and blood vessels, undoubtedly alters the secretory and vascular functions of the blood-CSF barrier. Thus, in both elderly humans and aged rats, there are substantial reductions in baseline cerebrospinal fluid (CSF) production rate. Given the important role of the choroid epithelium in CNS extracellular fluid (CSF) homeostasis, it is important to know how the aging CP recovers from insults such as interruption of its blood supply.

We used the bilateral carotid occlusion model with hypotension, i.e., 40-45 mmHg, to induce transient forebrain ischemia (TFI). Sprague-Dawley rats, 1.5 to 2 yr of age, were anesthetized with halothane and subjected to carotid flow interruption for 10 min; following reperfusion of the carotids, the animals were then allowed to recover for 30 min or 24 hr. Sham surgical controls were also run.

At 30 min, the lateral ventricle plexus epithelium in aged rats was severely damaged, as evidenced by swollen mitochondria, extensive vacuolization of the cytoplasm, and disappearance of intact apical microvilli. However, by 24 hr of reperfusion following the ischemic insult, the ultrastructure of the choroid epithelium was restored to a near-normal state. The findings indicate that the blood-CSF barrier in aged rats is resilient, and it is apparently as capable of recovering from TFI (10 min) as is the case for young adult rats subjected to a similar degree of blood flow interruption.

## 429.9

EFFECT OF ATRIAL NATRIURETIC PEPTIDE AND STEROIDS ON TNF-INDUCED BLOOD-BRAIN BARRIER INJURY. G.A. Rosenberg\*, E. Estrada, and J.E. Dencoff. Depart. of Neurology, Univ. of New Mexico, and Neurology Service, and VA Medical Center, Albuquerque, NM 87131.

Delayed proteolytic damage to the blood-brain barrier (BBB) is important in inflammation and ischemia. Atrial natriuretic peptide (ANP) and methylprednisolone decrease BBB damage, possibly by altering proteolytic balance. Therefore, we used intracerebral injection of tumor necrosis factor- $\alpha$  to induce BBB damage and studied the effect of ANP and steroids on capillary permeability and MMP production. Adult rats had TNF (100,000U) infused into both hemispheres. BBB permeability was measured with <sup>14</sup>C-sucrose 24 hrs later. Two groups of rats had either ANP (0.8mg/kg/24hrs) or methylprednisolone (14mg/kg) given intraperitoneally. Control rats had TNF only. Sucrose uptake into brain was significantly reduced by both agents (3.72±0.30% and 4.27±0.33%, respectively, compared with 5.94±0.35% in controls; p<0.05). Production of 92-kD type IV collagenase was measured by zymography in TNF-injected rats. Both ANP and steroids significantly reduced MMP production compared with controls. Reduction of proteolytic activity by ANP and steroids may explain their beneficial actions in vasogenic brain edema.

THROMBIN PROTECTS THE BLOOD-BRAIN BARRIER DURING ACUTE HYPERTENSION. J. L. Williams\* and C. A. Hathaway. Univ. of South Dakota School of Medicine, Vermillion, SD 57069

Thrombin increases endothelial permeability in cell culture, and pretreatment with L-NAME further increases permeability (*Circ. Res.* 76:199, 1995). Our experiments examined the effects of thrombin alone and combined with L-NAME on blood brain barrier (BBB) permeability in vivo. Evans blue dye was used as a marker for permeability of the BBB in Sprague Dawley rats. Evans blue (3 ml/kg of 2.5% solution) was given intravenously to anesthetized rats and allowed 5 min to circulate. The BBB was then compromised by an abrupt increase in arterial pressure with a bolus of phenylephrine (15 µg IV). Mean arterial pressure (MAP) increased 63.4 ± 21 mmHg (mean ± SD) in control rats and 56.8 ± 11 mmHg in thrombin-treated rats. When MAP started to fall, control rats received a 1 ml bolus of saline, and treated rats received 80 units of thrombin. After the rats were killed, their brains were removed and examined and graded for coloration by a blinded observer. In five pairs of experiments, the brains of the thrombin-treated rats had less staining than sham-treated brains (p<0.05). In a similar set of experiments, either 30 mg/kg of L-NAME or saline was given IV to thrombin-treated rats. L-NAME was allowed to circulate for 30 min and MAP rose 18 ± 12 mmHg after treatment. Phenylephrine produced a rise in MAP of 78 ± 11 mmHg in control rats and 83 ± 16 mmHg in L-NAME-treated rats. Both groups were given 80 units of thrombin as soon as MAP started to return towards baseline. The rat brains were evaluated and graded for coloration by a blinded observer. In five groups of experiments, the rats that were treated with L-NAME had brains that were darker than sham-treated rats (p<0.05). These findings suggest that thrombin has a protective action on BBB by reducing the increase in permeability caused by an abrupt increase in MAP, possibly by increasing the release of nitric oxide.

## 429.8

BLOOD BRAIN BARRIER PERMEABILITY TO IL-1RA AND BSA AFTER FOCAL CEREBRAL ISCHEMIA IN THE RAT. J.K. Relton\* and K. Ash. Dept. Biology, Amgen Inc., 3200 Walnut St., Boulder, CO 80301.

Blood brain barrier (BBB) permeability to the recombinant human protein interleukin-1 receptor antagonist radiolabelled with <sup>125</sup>Iodine (I-IL-1ra) and <sup>125</sup>I-bovine serum albumin (I-BSA) were compared after focal cerebral ischemia in the rat. The timecourse of cerebral edema formation was also measured. Ischemia was induced by permanent occlusion of the left middle cerebral artery (MCAO) under fluorothane anesthesia (2% in O<sub>2</sub>). 2, 24, 48 or 72h later rats were anesthetized with sodium pentobarbital (60mg/kg ip) and the femoral vein and artery cannulated. 13µCi I-BSA or 2µCi I-IL-1ra was injected iv. 1h later arterial blood was collected and the vascular space cleared by cardiac perfusion with 30ml 0.9% saline prior to removal of the brain. 0.5g of cortical and striatal tissue was homogenized in 4.5mL 0.9% saline and radioactivity of plasma and brain samples measured in a Beckman γ-counter. Cerebral tissue H<sub>2</sub>O composition was determined from non-perfused rat brains by dry and wet weight measurement of right and left hemispheres as an index of edema. BBB permeability to I-BSA and I-IL-1ra was similar for both proteins at 0h in unoperated control rats (I-BSA: 19.7±5.5x10<sup>-3</sup>% Total count injected (T<sub>i</sub>); I-IL-1ra: 19.55±6.02x10<sup>-3</sup>% T<sub>i</sub>, n=6). BBB permeability to I-BSA correlated with the timecourse of edema formation. Both were evident 24h after MCAO and peaked at 72h (2.3±0.78% increase in %H<sub>2</sub>O, n=4; 49.9±10.8x10<sup>-3</sup>% T<sub>i</sub>, n=7). In contrast, increased BBB permeability to I-IL-1ra was evident at 24h, peaked 48h after MCAO (38.5±13.2x10<sup>-3</sup>% T<sub>i</sub>, n=7) and returned to control levels by 72h. These data indicate that different mechanisms may be responsible for I-BSA and I-IL-1ra entry into the brain after focal cerebral ischemia.

## 429.10

AMINO ACID EFFECTS ON CEREBRAL ENDOTHELIAL CELL (EC) INJURY FOLLOWING OXYGEN-GLUCOSE DEPRIVATION (OGD). J. Xu\*, M.P. Goldberg, J.S. Beckman, C.Y. Hsu. Dept. Neurology, Washington Univ Sch Med, St. Louis, MO 63110 and Dept. Anesthesiology, Univ Alabama, Birmingham, AL 35233.

The endothelium is a primary target of hypoxic or ischemic insult. We studied EC injury following oxygen-glucose deprivation in vitro using cultured bovine cerebral microvascular ECs. The extent of EC injury, based on cell viability (trypan blue exclusion) and LDH release (% of total cell death caused by a calcium ionophore), was dependent upon OGD duration. Cell viability was reduced from 78% to 7% and LDH release increased from 18% to 46% when OGD was extended from 1 to 6 hr. ECs in Dulbecco's modified Eagle's medium (DMEM) sustained greater injury than those in Hank's balanced salt solution. The 15 individual amino acids in DMEM were each tested for its potential deleterious effect on ECs under OGD. The only amino acid showing a substantial effect was L-cyst(e)ine which exerted a concentration-dependent protective effect with an EC50 of approximately 15 µM. ECs after OGD showed nitrotyrosine immunoreactivity suggesting the possible involvement of nitric oxide (NO) derivative in cell injury. However, L-arginine (0.004 - 0.4 mM) was without effect and the addition of L-nitro-arginine, an NO synthase inhibitor, was detrimental. L-arginine at concentrations of 1.2 mM or greater also exaggerated EC injury. Results suggest that amino acids individually and in combination may affect OGD induced EC injury which may be partly related to NO and free radical formation.

## 429.11

## EFFECT OF HYPOXIA ON POTASSIUM TRANSPORT SYSTEMS IN CULTURED BRAIN CAPILLARY ENDOTHELIAL CELLS OF THE RAT.

N. KAWAI, R. M. MCCARRON, and M. SPATZ.  
Stroke Branch, NINDS, NIH, Bethesda, MD 20892-4128

The specific ion transport systems localized in the brain capillary endothelium have been implicated in the regulation of water-electrolyte homeostasis in the brain. This report describes that hypoxia alters K<sup>+</sup> transport systems in cultured rat brain capillary endothelial cells (RBEC). Uptake of <sup>86</sup>Rb<sup>+</sup> (a tracer for K<sup>+</sup>, 2.5  $\mu$ Ci/ml) into RBEC was measured in HEPES-buffered Medium 199 at room temperature for 10 min; ouabain-sensitive and bumetanide-sensitive K<sup>+</sup>-uptake was defined as Na<sup>+</sup>-K<sup>+</sup>-ATPase and Na<sup>+</sup>-K<sup>+</sup>-Cl<sup>-</sup> cotransport activity, respectively. Hypoxia (95% N<sub>2</sub>/5% CO<sub>2</sub>, 24hr) reduced (61% of control) the Na<sup>+</sup>-K<sup>+</sup>-ATPase activity, whereas it increased (149% of control) the Na<sup>+</sup>-K<sup>+</sup>-Cl<sup>-</sup> cotransport activity (respective control values = 4.6 and 5.5 nmol/mg protein/min, n = 8). Oligomycin, a metabolic inhibitor (1  $\mu$ g/ml), similarly affected both ion transport systems in a time-dependent manner, which caused an increased (133% of control) total K<sup>+</sup>-uptake. Oligomycin also increased the rate of K<sup>+</sup>-efflux up to 129% of control without altering the total intracellular K<sup>+</sup> content (values in  $\mu$ mol/mg protein; control = 0.96, oligomycin = 0.93). The oligomycin-augmented Na<sup>+</sup>-K<sup>+</sup>-Cl<sup>-</sup> cotransport activity was reduced by protein-tyrosine kinase inhibitors (genistein, 50  $\mu$ M; herbimycin A, 10  $\mu$ M) without being affected by an inhibitor of protein kinase C (bisindolylmaleimide, 500 nM) or protein kinase A (H8, 20  $\mu$ M), indicating the involvement of protein-tyrosine phosphorylation. The data indicate that the up-regulated K<sup>+</sup>-uptake during hypoxia is due to an increased Na<sup>+</sup>-K<sup>+</sup>-Cl<sup>-</sup> cotransport activity. It is suggested that a similar mechanism may play a role in the disturbance of water-electrolyte homeostasis described in ischemic brain.

## 429.13

## EFFECT OF CAP37 ON BRAIN ENDOTHELIAL CELL PHOSPHATIDYL CHOLINE (PC) HYDROLYSIS. P. Grammas\*, T. Botchlet and H.A. Pereira. Dept. of Pathology, Univ. of Oklahoma HSC, Oklahoma City OK 73104

CAP37 is a multifunctional protein important in inflammatory and immune responses. We have previously shown, using specific CAP37 antibody, immunohistochemical staining of brain blood vessels in Alzheimer's brain but not in age-matched non-demented controls. The objective of this study was to elucidate what signalling cascades in brain endothelial cells are regulated by CAP37. Rat cerebral resistance vessels were isolated, collagenase treated, and vessel fragments seeded as explant cultures. Endothelial cells that emerged from the fragments were subsequently cloned to achieve a homogenous population and passages 10-15 were utilized in this study. Confluent monolayers were incubated with serum-free media containing 1  $\mu$ Ci [<sup>3</sup>H] choline chloride and cells treated with 1  $\mu$ g/ml CAP37 for 30 minutes. Lipids were extracted using chloroform/methanol/HCl and phospholipids separated by thin layer chromatography. The results demonstrated that CAP37 caused a significant (P<0.02) decrease in labelled PC suggesting receptor-mediated hydrolysis of this phospholipid. The data support the notion that CAP37 activates membrane phospholipases that hydrolyze PC and that the mediators released by PC hydrolysis (e.g., diacylglycerol) may mediate CAP37 actions in the cerebral microcirculation. Blood-brain barrier endothelial cell cultures from post-mortem Alzheimer brains. J. M. Wells<sup>1,2</sup>, A. Armaratunga<sup>1</sup>, A. McKee<sup>1,2</sup>, C. Abraham<sup>1</sup>, D. McKenna<sup>1,2</sup>, R. Fine<sup>1,2</sup>.  
<sup>1</sup>Boston University School of Medicine, Boston, MA and <sup>2</sup>ENRM VA Hospital Bedford, MA 01730.

A number of investigators have suggested that the blood brain barrier is disrupted in Alzheimer's disease. To examine this issue we have developed an *in vitro* model of the human blood brain barrier. Primary cultures of cerebral endothelial cells were established from microvessels isolated from brains obtained at autopsy from patients with Alzheimer's disease. The cells were able to proliferate and maintain their endothelial characteristics. Doubling time for these cells was between 1.5 and 2 days. Cells stained positive for Factor VIII antigen and formed tight junctions. We have also shown that these cells produce APP and secrete ApoE. We have evidence of proteases that may be involved in APP processing in these cells. We are now examining the role of cerebral endothelial cells in Alzheimer's disease. Supported by the Department of Veterans Affairs.

## 429.12

## NEUROTOXIC AND IMMUNOTOXIC EFFECTS OF LEAD IN RELATION TO BLOOD-BRAIN BARRIER PERMEABILITY IN A MURINE MODEL OF GENETIC SUSCEPTIBILITY. L. Claudio\*, R.V. Rosal, H.A.N. El-Fawal, A. Little, J.G. Wetmur, and D.P. Perl Div. of Environmental Medicine, Mount Sinai Med. Ctr., &amp; Institute of Environmental Medicine, NYU Med. Ctr. New York, NY 10029.

We hypothesize that one mechanism of lead neurotoxicity involves disruption of the blood-brain barrier (BBB), which exposes neural epitopes to the immune system. To explore this hypothesis, we have used two mouse strains which differ in the gene for  $\delta$ -aminolevulinic dehydratase (ALAD), an enzyme implicated in susceptibility to lead intoxication. We have shown that mice with a duplication of the ALAD gene (strain D) accumulate twice the blood lead levels than mice with a single copy of the gene (strain C) when exposed to the same acute oral doses. This may produce increased accumulation of lead in the brain, kidney and liver as observed by atomic absorption spectrometry. Strain D mice also show increased BBB permeability when exposed to lead. In brain, lead accumulated in astrocytes, as observed by laser microprobe mass analysis (LAMMA).

Exposure to lead increased circulating antibody titers to neural proteins, particularly glial fibrillary acidic protein (GFAP). This effect was higher in strain D mice which showed increased BBB permeability.

These data suggest that lead may induce increased BBB permeability in susceptible animals. Increased BBB permeability may allow exposure of neural epitopes thus raising the production of antibodies against these proteins. Astrocytes may be a primary target for lead toxicity as evidenced by the presence of lead in these cells and increased antibody titers to GFAP. This murine model may be useful for the study of genetic susceptibility to lead-induced toxicity as observed in humans.

## 429.14

VECTOR-MEDIATED DELIVERY OF [<sup>125</sup>I]-A $\beta$ <sup>1-40</sup> THROUGH THE BLOOD-BRAIN BARRIER (BBB) AND BINDING TO ALZHEIMER'S DISEASE AMYLOID OF THE [<sup>125</sup>I]-A $\beta$ <sup>1-40</sup>/VECTOR COMPLEX. Y. Saito, J. Buciak, K. Faulstich, and W.M. Pardridge. Depts. of Medicine and Psychiatry and Biobehavioral Sciences, UCLA School of Medicine, Los Angeles, CA 90024.

The brain amyloid of Alzheimer's disease (AD) may potentially be imaged in patients with AD using neuroimaging technology and a radiolabeled form of A $\beta$ <sup>1-40</sup> that is enabled to undergo transport through the brain capillary endothelial wall, which makes up the BBB *in vivo*. [<sup>125</sup>I]-A $\beta$ <sup>1-40</sup> transport through the BBB in the absence of vector-mediated delivery was negligible based on experiments with both an intravenous injection technique and an internal carotid artery perfusion method in rats. Unconjugated [<sup>125</sup>I]-A $\beta$ <sup>1-40</sup> was rapidly metabolized following either intravenous injection or internal carotid artery perfusion. To conjugate A $\beta$ <sup>1-40</sup> to a vector-mediated drug delivery system, [<sup>125</sup>I]-A $\beta$ <sup>1-40</sup> was monobiotinylated with NHS-XX-biotin, and bound to a conjugate of streptavidin (SA) and the OX26 monoclonal antibody to the rat transferrin receptor. The OX26 antibody undergoes receptor-mediated transcytosis through the BBB and the OX26/SA conjugate mediates drug delivery of biotinylated peptides through the BBB (Proc. Natl. Acad. Sci., 90, 2618, 1993). Both the rapid systemic clearance and peripheral metabolism of [<sup>125</sup>I]-A $\beta$ <sup>1-40</sup> was inhibited by conjugation to the OX26/SA vector. The brain uptake, expressed as % injected dose (ID) per g brain, of the [<sup>125</sup>I]-bio-A $\beta$ <sup>1-40</sup>/OX26-SA conjugate was 0.15  $\pm$  0.01 %ID/g, a level that is 2-fold greater than the brain uptake of morphine. The binding of the [<sup>125</sup>I]-bio-A $\beta$ <sup>1-40</sup>/OX26-SA conjugate to the amyloid of AD was demonstrated by film and emulsion autoradiography performed on frozen sections of AD brain. Binding of the [<sup>125</sup>I]-bio-A $\beta$ <sup>1-40</sup>/OX26-SA conjugate to the amyloid of AD brain was completely inhibited by saturation with high concentrations of unlabeled A $\beta$ <sup>1-40</sup>. In conclusion, these studies show that BBB transport and access to amyloid within brain may be achieved by conjugation of A $\beta$ <sup>1-40</sup> to vector-mediated BBB drug delivery systems.

## 429.16

LOCALIZATION OF SERUM PROTEINS IN THE BRAINS OF SIV MONKEYS L.A. Raymond\*, P.D. Cheney\*, S. Joag\*, O. Narayan\*, N.E.J. Berman\*. Dept. Physiol<sup>1</sup>, Microbiol, Molec Gene & Immunol<sup>2</sup>, Anat & Cell Biol<sup>3</sup>, Univ. Kansas Med Ctr, Kansas City, KS 66160 USA.

Symptoms of the human immunodeficiency virus (HIV) include psychomotor slowing and cognitive deficits. For HIV or its animal model, the simian immunodeficiency virus (SIV), to enter the central nervous system, it must traverse the brain-blood barrier (BBB). In human HIV patients, serum proteins have been localized in the brain (Petito & Cash, *Ann. Neurol.* 32:658-666, 1992). The brains of a normal sex and age-matched *Macaca nemestrina* (92424) and another (PHt) infected with neurovirulent SIV-7F, were frozen sectioned and labeled with polyclonal antibodies against serum proteins: fibrinogen, albumin, and IgG. 92424 had positive staining for all three proteins that was confined to the blood vessels of the choroid plexus and microvasculature of the brain with occasional staining surrounding blood vessels causing a "halo" effect. PHt also showed positive staining for all three proteins producing a similar "halo" effect but fibrinogen and albumin localized in many microglia producing large patches of high intensity staining indicating disruption of the BBB. The disruption of the BBB may contribute to the neurological symptoms and cognitive deficits seen in HIV patients and the SIV model will allow for further study. (Supported by HD02528, NS32202, NS32203, RR00166.)

## 429.17

EFFECT OF LIPOPOLYSACCHARIDE ON 92KD TYPE IV COLLAGENASE IN RAT BRAIN. S. Mun-Bryce\* and G.A. Rosenberg. Dept. of Neurology, Univ. of New Mexico School of Medicine, Albuquerque, NM 87131.

Bacterial infection of the brain increases capillary permeability with delayed secondary damage. Matrix metalloproteinases (MMP) mediate proteolysis of the blood-brain barrier, which is comprised of several extracellular matrix components including type IV collagen. We investigated the effect of lipopolysaccharide (LPS) on MMP production in the brain. Adult male rats received an intracerebral injection of either LPS, tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) or sterile saline. Production of MMPs was measured 24 hrs post-injection, using gelatin-substrate polyacrylamide zymography. LPS-injection produced a significant increase in 92-kD type IV collagenase (gelatinase B, MMP-9) as compared to saline injection. TNF- $\alpha$  also stimulated MMP-9 production to a lesser extent than LPS. The time course of LPS-stimulated MMP proteolysis in the brain was characterized by a marked rise in MMP-9 at 6 hrs post-injection in both saline and LPS animals. By 8 hrs, the MMP-9 lysis area in saline animals diminished, as compared to the continued intense MMP-9 lysis seen in LPS animals. Levels of MMP-9 remained elevated 24 hrs after LPS injection. These results show that LPS mediates MMP production, linking LPS with blood-brain barrier damage.

## 429.19

EFFECTS OF TNF- $\alpha$  ON THE PRODUCTION OF VASOACTIVE SUBSTANCES BY CEREBRAL ENDOTHELIAL AND SMOOTH MUSCLE CELLS IN CULTURE. C. Estrada\*, C. Gómez, and C. Martín. Department of Physiology, Faculty of Medicine, Universidad Autónoma de Madrid, Spain. The effects of TNF- $\alpha$  on the production of the vasoactive substances nitric oxide (NO) and endothelin-1 (ET-1) were investigated in cerebrovascular cells in culture. Bovine cerebral endothelial cells (BCEC) stained positively for NADPH-diaphorase/NO synthase activity and spontaneously produced nitrite, a stable NO oxidation product, which accumulated in the culture medium in a linear way for 48 hours. Low concentrations of TNF- $\alpha$  (0.5-2 ng/ml) significantly enhanced nitrite production after a 24 hour incubation. Higher concentrations or longer exposure times resulted in a cytotoxic effect which altered cell morphology, released LDH to the culture medium, and reduced the protein content. Dexamethasone, but not the NO synthase inhibitor N-ethylmaleimide-L-ornithine (L-NIO), prevented the cytotoxic effect of TNF- $\alpha$  in BCEC. TNF- $\alpha$  also significantly enhanced nitrite production in bovine cerebral smooth muscle cells (BCSMC). The enhancement was detected at all times between 8 and 72 hours and at all concentrations tested (2-100 ng/ml). Signs of cytotoxicity were not observed in BCSMC after incubation with TNF- $\alpha$ . ET-1 was constitutively secreted by BCEC. The production of ET-1 was stimulated by thrombin. TNF- $\alpha$  enhanced the release of ET-1 in BCEC, and this enhancement was not modified by the simultaneous addition of IFN- $\gamma$ . BCSMC did not produce ET-1, either spontaneously, or in the presence of TNF- $\alpha$ , IFN- $\gamma$ , or of both together. These effects of TNF- $\alpha$  on cerebrovascular cells may explain the microvascular alterations found in some inflammatory or traumatic conditions in which this cytokine is increased in the cerebral tissue. This work was supported by grants 92/0290 and 94/0388 from FIS, Spain.

## 429.18

STIMULATION OF IL-1 $\beta$ , TNF $\alpha$ , IL-6 AND iNOS mRNAs EXPRESSION BY LPS IN THE CULTURED RAT GLIAL AND CEREBRAL MICROVASCULAR ENDOTHELIAL CELLS. Z. Y. Hu\*, J. Xu, Y. Q. Yang and C. Y. Hsu. Dept. Neurology, Washington Univ. Sch. Med., St. Louis, MO 63110

Cytokines (such as IL-1 $\beta$ , TNF $\alpha$ , IL-6) and iNOS are produced by blood-borne and resident brain inflammatory cells. Cytokines mediate the bidirectional communication between cells to facilitate and perpetuate the inflammatory processes. Endotoxin and selected cytokines are known to be the major stimuli to induce iNOS expression in inflammation. Glia and endothelial cells may participate in post-ischemic inflammatory reaction and contribute to the breakdown of blood brain barrier and pathogenesis of vasogenic brain edema. The expression of IL-1 $\beta$ , TNF $\alpha$  and IL-6 mRNAs is studied by quantitative TR-PCR and Western blot in the glial, endothelial cell or mix cultures following incubation with lipopolysaccharide (LPS). Relative change in mRNA content of each gene was calculated after normalization based on endogenous  $\beta$ -actin mRNA. The endogenous IL-1 $\beta$ , TNF $\alpha$  and IL-6 levels were higher in glial cells and mix cultures than in endothelial cells. LPS increased the expression of IL-1 $\beta$ , TNF $\alpha$ , IL-6 and iNOS mRNAs to variable degrees in the glial cell and mix cultured cells. In endothelial culture, only IL-6 mRNA was increased by LPS. No additive effect was noted in cytokine expression in co-cultures. LPS stimulated glial iNOS expression. A synergistic effect of glial-endothelial interaction on iNOS expression was noted following LPS stimulation. IL-1 $\beta$ , TNF $\alpha$  and IL-6 were also detected by Western blot analysis in media of the glial, endothelial and mix cultures stimulated by LPS. Results suggest LPS-stimulated glial-endothelial interaction differentially augments iNOS but not cytokine expression.

## 429.20

GLYCOSHINGOLIPID ANTIGENS IN CULTURED BOVINE MICROVASCULAR ENDOTHELIAL CELLS OF ENDONEURIAL ORIGIN. T. Kanda\*, M. Yamawaki and T. Iwasaki. Department of Neurology, Tokyo Medical and Dental University, Tokyo 113, Japan.

Since a number of anti-glycosphingolipid antibody activities have been demonstrated in patients with peripheral neuropathies including Guillain-Barré syndrome, CIDP and macroglobulinemic neuropathy, the presence of common antigens between endoneurial microvascular endothelial cells (ENMEC) and the peripheral nervous tissues presents a potential mechanism for the penetration of macromolecules from the circulation to the peripheral nervous system parenchyma. To investigate the glycosphingolipid antigens in ENMEC, we first established the method to culture bovine ENMECs using a modified method of Kanda *et al.* (1994; originally for brain microvascular endothelial cells). Bovine ENMEC express GM3 (NeuGc) and GM3 (NeuAc) as the major gangliosides, and GM1, GD1a, GD1b, GT1b, as well as sialyl paragalactoside as the minor species. Neutral glycosphingolipids were extremely low and galactosylceramide was not detected. Our study is the first report to describe the successful cell culture method of ENMEC, and revealed that ENMEC and peripheral nervous tissues shared many glycosphingolipids as common antigens. Hence, the presumed cascade of pathological processes - immunological attack of ENMECs, destruction or malfunction of blood-nerve barrier, leakage of immunoglobulins into the endoneurial space and the subsequent destruction of peripheral nerve - can be logically explained in patients with anti-glycolipid antibody.

## PRESYNAPTIC MECHANISMS VI

## 430.1

PRESYNAPTIC MECHANISMS REGULATING CA<sup>2+</sup> CONCENTRATION TRIGGERING ACETYLCHOLINE RELEASE AT AN IDENTIFIED SYNAPSE OF *ALPISIA*. J.P. Mothet, P. Fossier, J. Stinnakre and G. Baux. Lab. Neurobiol. cellulaire et moléculaire, CNRS, 91198 Gif-sur-Yvette cedex, France.

The build up of a high concentration of Ca<sup>2+</sup> in the presynaptic terminal appears as the main trigger of ACh release. We show that both N- and P-type Ca<sup>2+</sup> channels, sensitive to  $\omega$ -conotoxin and Funnel Web spider toxin (FTx) respectively, are involved in transmitter release. The Ca<sup>2+</sup> influx through N-type Ca<sup>2+</sup> channels and consequently ACh release are modulated by FMRFamide, histamine and buccalin. FMRFamide increases the Ca<sup>2+</sup> influx by increasing the voltage-sensitivity of N-type Ca<sup>2+</sup> channels via the production of DAG, the activation of PKC and then the phosphorylation of the channels. Histamine has the opposite effect and reduces the voltage-sensitivity of the N-type Ca<sup>2+</sup> channels, most probably by reducing their rate of phosphorylation. Buccalin decreases the number of available N-type Ca<sup>2+</sup> channels. The Ca<sup>2+</sup> influx through P-type Ca<sup>2+</sup> channels appears unchanged by these neuromodulators. The injection of polyclonal antibodies raised against syntaxin into the presynaptic neuron decreases both ACh release and the Ca<sup>2+</sup> influx through N- and P-type Ca<sup>2+</sup> channels. This indicates that some proteins proposed to be involved in transmitter release could interfere with the Ca<sup>2+</sup> influx, because of their tight association with presynaptic Ca<sup>2+</sup> channels. Finally the Ca<sup>2+</sup> concentration which actually triggers ACh release may also depend on the activity of presynaptic Ca<sup>2+</sup> buffers. A blocker of the reticulum Ca<sup>2+</sup> pump, 2,5-diterbutyl 1,4-benzohydroquinone (BtBHQ), facilitates ACh release by increasing the intracellular concentration of Ca<sup>2+</sup> (detected with aequorin) without affecting the presynaptic Ca<sup>2+</sup> influx. This indicates that a presynaptic structure sequesters a part of Ca<sup>2+</sup> ions flowing into the terminal during the presynaptic depolarization, preventing this fraction to participate in ACh release. Nitric oxide which decreases ACh release without modifying the presynaptic Ca<sup>2+</sup> influx, could act on the activity of these presynaptic Ca<sup>2+</sup> buffers.

## 430.2

ON THE QUANTAL CO-RELEASE OF ATP AND ACETYLCHOLINE FROM FROG MOTOR NERVE ENDINGS AS MEASURED BY THE "PATCH-SNIFF" TECHNIQUE. R.S. Redman\*, T. Searl, E.M. Silinsky. Dept. of Molecular Pharmacology and Biological Chemistry, Northwestern University Medical School, Chicago, IL 60611.

At the skeletal neuromuscular junction, recent studies have suggested that upon the co-release of the neuromodulator, ATP, with the neurotransmitter, acetylcholine (ACh), ATP is hydrolyzed to adenosine and acts as the primary mediator of neuromuscular depression. While these studies imply that ATP release occurs in a quantal manner, there is little evidence demonstrating that ATP can be released rapidly enough and in temporal harmony with a single nerve impulse under physiological conditions to mediate neuromuscular depression. We used outside-out patches from sympathetic neurons in guinea pig celiac ganglia, which possess ATP-gated ion channels as well as ACh receptors, to test for the co-release of ATP and ACh. Specifically, a coverslip containing acutely dissociated celiac neurons was placed in a chamber in which a cutaneous pectoris nerve-muscle preparation (pretreated with a collagenase-protease digestion protocol) was pinned. Excised patches under voltage clamp were then moved to within 10  $\mu$ m of the motor nerve ending and single channel currents were recorded both before and after electrical stimulation of the motor nerve. Using this technique, it is possible to demonstrate the rapid (latency <5 msec) release of ATP by discrete nerve impulses in conjunction with ACh. Such release is blocked by the ATP antagonist, suramin (50  $\mu$ M). Preliminary experiments were made under conditions in which spontaneous ATP release was compared to evoked release; evoked ATP release appeared as integral multiples of the spontaneous events suggesting that ATP is released in a quantal manner from a vesicular store.

## 430.3

## SYNAPTIC STRENGTH OF DEVELOPING GABAERGIC SYNAPSES DEPENDS ON THE ACTIVATION STATUS OF PRESYNAPTIC GLUTAMATE RECEPTORS

R. Grantyn\*, I. Melnick and N.S. Veselovsky. Developmental Neurobiology Group, Physiological Institute of the Humboldt University Berlin, D-10117 Berlin

GABAergic synapses between cultured collicular neurons were studied by pair patch clamp recording. Using a local superfusion technique the number of participating terminals was artificially reduced rendering maximal amplitudes of evoked IPSCs 4-8 times the quantal size. Up to 10 neighbouring boutons were determined in the active window by histological techniques. Using this reduced synapse it was possible to apply unconstrained binomial analysis to estimate the release probability of individual terminals. It was found that the majority of terminals released GABA with low probability ( $p < 0.2$ ). We therefore looked for conditions that could transfer GABAergic terminals from a low-efficacy to a high-efficacy release state. Experiments with chronic exposure to the glutamate receptor blockers MK-801 (1  $\mu$ M), DNQX (10  $\mu$ M) and CPG (200  $\mu$ M) increased the average amplitude of evoked IPSCs and reduced the coefficient of variation. Differences between treated and untreated cultures were statistically significant after 9-12 days *in vitro*. Evaluation of amplitude distributions showed that failures were common in untreated pairs, but very rare in treated pairs. These results suggest that the strength of inhibitory coupling may be influenced by heteronymous synaptic input via glutamate receptors.

## PREJUNCTIONAL MODULATION BY ANGIOTENSIN I, II AND III OF NOREPINEPHRINE RELEASE FROM SYMPATHETIC NEURONS. O.A. Nedergaard\* and T. Storgaard. Department of Pharmacology, Odense University, DK-5000 Odense C, Denmark.

The aim of the present work was to examine the modulating effect of angiotensin I, II and III (AI, AII and AIII) on stimulation-evoked norepinephrine release from postganglionic sympathetic neurons in rabbit isolated aorta. Rings of aorta were preloaded with (-)-<sup>3</sup>H-norepinephrine (10<sup>-6</sup>M) and subsequently washed with physiological salt solution. The rings were subjected to electrical-field stimulation (S<sub>1</sub>-S<sub>4</sub>; 200 mA; 300 pulses; 0.5 ms; 1 Hz). The spontaneous <sup>3</sup>H-outflow and stimulation-evoked <sup>3</sup>H-overflow were collected in fractions (2 ml; 5 min). Cumulative addition of AI (10<sup>-6</sup>-10<sup>-4</sup>M), AII (3x10<sup>-11</sup>-10<sup>-6</sup>M) and AIII (3x10<sup>-10</sup>-10<sup>-6</sup>M) enhanced the stimulation-evoked <sup>3</sup>H-overflow up to 154, 169 and 193%, respectively. The order of potency was AII > AIII > AI. Captopril (10<sup>-6</sup>M) markedly attenuated the facilitating effect of AI (10<sup>-6</sup>-10<sup>-7</sup>M) but did not alter the facilitation seen with AII (10<sup>-10</sup>-10<sup>-6</sup>M). Captopril (10<sup>-7</sup>-10<sup>-4</sup>M) alone did not alter the stimulation-evoked <sup>3</sup>H-overflow. Edetate disodium (Na<sub>2</sub>EDTA; 3x10<sup>-3</sup>M) did not alter the enhancing effect of AI (10<sup>-6</sup>-10<sup>-7</sup>M). The enhancement seen with AII (3x10<sup>-11</sup>-10<sup>-6</sup>M) was independent of stimulation frequency (1-10 Hz). The facilitation induced by single concentrations (10<sup>-6</sup>-10<sup>-7</sup>M) of AI, AII and AIII on repeated stimulations waned with time, i.e. development of tachyphylaxis. Cocaine (3x10<sup>-3</sup>M) plus corticosterone (4x10<sup>-3</sup>M) did not alter the enhancing effect of AII. We conclude that the AII-induced enhancement of <sup>3</sup>H-overflow is due to an increased release of <sup>3</sup>H-norepinephrine rather than inhibition of neuronal and extraneuronal uptake and that the enhancing effect of AI is mainly due to its conversion to AII.

## 430.7

## PROTEIN KINASE INHIBITORS BLOCK SYNAPTIC TRANSMISSION IN XENOPUS EMBRYO SPINAL CORD. D.Gilday\* and N. Dale, School of Biological Sciences, University of Bristol, BS8 1UG, U.K.

Glycinergic inhibition plays a key role in the generation of the swimming motor pattern in the *Xenopus* embryo and can be modulated by GABA<sub>A</sub> receptors. As well as decreasing the Ca<sup>2+</sup> currents involved in transmitter release (Wall & Dale, 1994, *J. Neurosci.*, 14, 6248), GABA<sub>A</sub> receptors also reduce the frequency of glycinergic mIPSPs recorded in the presence of TTX and 100  $\mu$ M Cd<sup>2+</sup> (Wall & Dale, 1993, *J. Physiol.*, 469, 275).

To examine the possible mechanisms underlying this direct modulation of transmitter release, we applied the protein kinase inhibitors H7 and HA-1004 to the embryo spinal cord while recording both spontaneous glycinergic mIPSPs (with Cd<sup>2+</sup> and TTX present) and evoked glycinergic IPSPs in motoneurons. Both 1-10  $\mu$ M H7 and 100  $\mu$ M HA-1004 mimicked the actions of GABA<sub>A</sub> agonists, by causing a large reversible reduction in the frequency of spontaneous mIPSPs (in some cases abolishing spontaneous mIPSPs completely during the period of drug application). There was no significant change in the size of the spontaneous mIPSPs, suggesting that H7 and HA-1004 act presynaptically. H7 (10  $\mu$ M) also reduced the size of evoked glycinergic IPSPs by 43.1  $\pm$  4.32% ( $\pm$ SEM, n=19). However, patch-clamp recordings from acutely isolated *Xenopus* spinal neurons showed that Ca<sup>2+</sup> currents were not reduced by 10  $\mu$ M H7.

Since H7 and HA-1004 reduce transmitter release without altering the Ca<sup>2+</sup> currents, we propose that phosphorylation of vesicle proteins by a constitutively active kinase may be necessary to move vesicles into a releasable pool. Presynaptic inhibition by GABA<sub>A</sub> receptors may thus involve reduction of the activity of this kinase and hence the number of vesicles in the releasable pool.

## 430.4

## A CORRELATION EXISTS BETWEEN REDUCED CATECHOLAMINE RELEASE AND SUPPRESSED DIACYLGLYCEROL GENERATION BY C-TYPE NATRIURETIC PEPTIDE. S. Kanwal\* and G.J. Trachte. Dept of Pharmacology, Univ. of Minnesota-Duluth, Duluth, MN 55812.

C-type natriuretic peptide (CNP) reduces depolarization induced catecholamine release from rat differentiated pheochromocytoma (PC12) cells. We tested the hypothesis that CNP reduces evoked catecholamine release by inhibiting phospholipase C (PLC) activity. Calcium (10  $\mu$ M) was used to stimulate PLC. We measured changes in DAG generation as an indicator of PLC activity. CNP (0.1 to 100 nM) suppressed calcium stimulated DAG production concentration dependently. Maximal suppression of DAG production was 34  $\pm$  5 % at a CNP concentration of 10 nM. CNP (0.1 to 100 nM) also dose dependently reduced calcium evoked dopamine release with a maximal inhibition of 31  $\pm$  11 % at a concentration of 10 nM. There was a significant correlation between DAG production and dopamine release in response to CNP. DAG is an activator of protein kinase C which potentiates catecholamine release. Since CNP reduced both calcium stimulated DAG generation and dopamine release from PC12 cells, the neuromodulatory effects of CNP are related to a suppression of PLC activity. (Supported by Grant RO1 HL42525 from the PHS)

## 430.6

CONTRIBUTION OF PROTEIN KINASE ACTIVATION TO 5-HT<sub>4</sub>-MEDIATED FACILITATION OF FAST EXCITATORY SYNAPTIC POTENTIALS (fEPSPs) IN ENTERIC NEURONS. E. Messori and J. J. Galligan\*. Department of Pharmacology and Toxicology, Michigan State University, E. Lansing, MI 48824

5-HT<sub>4</sub> receptors couple to adenylate cyclase in smooth muscle and in neurons. In the present study we tested the contribution of protein kinase activation to fEPSP facilitation caused by the 5-HT<sub>4</sub> receptor agonist, renzapride. Intracellular electrophysiological methods were used to record fEPSPs from neurons in guinea pig myenteric plexus *in vitro*. The stimulus intensity was adjusted to the minimum needed to evoke a stable amplitude fEPSP. Renzapride (10-100 nM) produced an increase in fEPSP amplitude (EC<sub>50</sub>, 6 nM). The maximum increase was 110  $\pm$  14% over control (n=14). SDZ 205-557, a 5-HT<sub>4</sub> receptor antagonist, caused a rightward shift in the renzapride concentration-response curve (K<sub>d</sub>, 8 nM). Forskolin (0.1-1  $\mu$ M) increased fEPSP amplitude (EC<sub>50</sub>=126 nM) but the maximum response (55  $\pm$  10%) was less than that of renzapride. The protein kinase inhibitor, staurosporine, at 1 and 3  $\mu$ M reduced fEPSP facilitation caused by 100 nM renzapride by 40 and 60% respectively. These data suggest that 5-HT<sub>4</sub> receptors may mediate facilitation fEPSPs via an increase in cAMP and activation of a staurosporine-sensitive protein kinase. (supported by DK40210 and NS01738)

## 430.8

## COMPARISON BETWEEN HISTAMINE- AND CAFFEINE-INDUCED SECRETION IN INDIVIDUAL RAT ADRENAL CHROMAFFIN CELLS J. Kim\*, Wonil Kim and S. J. Kim Department of Physiology and Biophysics, Seoul Nat'l Univ. Coll. of Med., Seoul, Korea, 110-799

To investigate the effects of intracellular Ca stores on exocytosis, we applied histamine and caffeine, which are considered to stimulate IP<sub>3</sub>-induced intracellular Ca release and Ca-induced Ca release, to primarily cultured rat chromaffin cells. The change in membrane capacitance (C<sub>m</sub>) was monitored as an assay of the resultant exocytosis along the change in cell membrane conductance (G). Cells with positive exocytosis to membrane potential depolarization (-70 mV, 500 ms) were analyzed.

In histamine (100  $\mu$ M, 45 sec) treated cells with free external Ca, 24 out of 31 cell showed C<sub>m</sub> increases (140.4  $\pm$  17.8 fF, mean  $\pm$  S.E.M.) while majority of responded cells showed no difference in G trace (0.03  $\pm$  0.10 nS). Neomycin (1 mM, 5 min pretreatment) blocked histamine-induced C<sub>m</sub> increase reversibly. On the contrary, caffeine (10 mM, 45 sec) treated cells showed C<sub>m</sub> increases (110.6  $\pm$  20.4 fF) in 33 out of 49 treated cells accompanying changes in G trace (1.78  $\pm$  0.37 nS). The changes in G trace were blocked by the K channel blockers. The maximum rate of secretion (ff/sec) was also comparable between histamine- (17.1  $\pm$  1.3 ff/sec) and caffeine-induced secretion (40.7  $\pm$  5.1 ff/sec).

From the heterogeneity in the responses of chromaffin cells to histamine and caffeine, it is concluded that there are sub-populations of rat adrenal chromaffin cells according to the intracellular Ca stores.

## 430.9

A NOVEL FAMILY OF PKC SUBSTRATE PROTEINS IN RAT BRAIN AND ITS DEVELOPMENTAL CHANGES. H.H. Miao, C.W. Chak, X.F. Chen, Y.C. Du, F.S. Sheu and Y.F. Han. (SPON: The Hong Kong Society of Neurosciences) Dept. Biochem. Hong Kong Univ. Sci. & Technol., Hong Kong; <sup>1</sup>Shanghai Inst. Physiology; <sup>2</sup>Shanghai Inst. Biochem. Chinese Acad. Sciences, Shanghai, China.

Protein phosphorylation represents a common pathway in the molecular mechanisms through which neurotransmitters, hormones and the nerve impulse produce many of their physiological effects, and elucidation of the precise mechanisms involved in neuronal signalling depends upon the identification and characterization of the *in vivo* substrates for the various protein kinases. Protein kinase C (PKC) and its substrates have received extensive attention since the activation of PKC is coupled to regulations of neuronal development and synaptic plasticity. Here we presented the findings on the identification, distribution and developmental changes of a family of new neuron-specific and membrane-associated PKC substrates with low molecular weights from 12K-16K. Crude membrane of tissues and synaptic plasma membranes (SPM) from male rats of an inbred SD strain were prepared according to Dokas *et al* with minor modifications. PKC was purified from rat brain as previously described by Sheu *et al*. The SPMs were labelled with  $\gamma^{32}$ P-ATP by either endogenous or exogenous PKC, and phosphoproteins were separated by 13 or 15% SDS-PAGE. By means of this approach, it was detected in brain synaptic membranes a family of phosphoproteins, i.e. P12, P15, and P16, with apparent molecular weights of 12K, 15K and 16K, respectively. They have been found to be present in spinal cord, midbrain and cerebellum, but not in peripheral tissues. The phosphorylation of these proteins was selectively inhibited by PKC<sub>(9,31)</sub>, a specific PKC inhibitor, and by  $\text{Ca}^{2+}$ -chelator EDTA and EGTA, or stimulated by PKC activator phorbol 12,13-dibutyrate. Two-dimensional electrophoresis indicated that these small PKC substrates possess the similar neutral property with isoelectric points of approximate to 7. In contrast to the developmental decrease of GAP43 level in rat brain, it was found that the concentrations of P12, P15 and P16 ontogenetically increased in rat cerebral cortex.

## 430.11

INHIBITION OF TYROSINE KINASE BLOCKS POTENTIATION IN THE CEREBRAL GANGLION OF APLYSIA. S.M. Freedman\*, Dept. of Physiology, Meharry Medical College, Nashville, TN 37208.

The A-B neuron synapse in the cerebral ganglion of *Aplysia* exhibits multiple forms of activity-dependent plasticity. Low frequency stimulation of the presynaptic A neurons produces synaptic depression (LFSD) of their EPSPs in B neurons. Brief high frequency A neuron stimulation evokes a long-lasting increase in synaptic transmission, slow developing potentiation (SDP). Work to date indicates that SD is mediated by PKA and can be mimicked by cAMP and its activators. SDP appears due, at least in part to the activation of PKC. Both LFSD and SDP are due to changes in the presynaptic A neurons. Recently evidence has been obtained indicating that a tyrosine kinase (TK) may also contribute to SDP.

Experiments were done on isolated cerebral ganglia in high divalent cation seawater (55 mM  $\text{Ca}^{2+}$ , 150 mM  $\text{Mg}^{2+}$ ) to suppress polysynaptic connections. Individual A neurons were stimulated with single test pulses every 3 min. SDP was induced after the 3rd test pulse with 4, 500 msec 20 Hz trains. This was followed by 15 additional test pulses. After obtaining a control level of SDP, TK inhibitors were added to the bath. Both 1  $\mu\text{M}$  genistein and 1  $\mu\text{M}$  erbstatin analog gave similar, highly selective, results. In the presence of either inhibitor, there was no significant change in test EPSPs prior to the tetanic stimulation. However, SDP following the high frequency trains was largely eliminated. These inhibitors act at different sites on the kinase. Genistein blocks at the catalytic site, while erbstatin preferentially inhibits the regulatory site of the EGF receptor class of TKs. This suggests that SDP may be in part mediated by a receptor TK. Work is in progress to try and identify potential endogenous ligands and to further characterize the receptor.

## 430.13

FURTHER CHARACTERIZATION OF mGluR MODULATION OF SYNAPTIC TRANSMISSION AT SYNAPSES IN CORTICOSTRIATAL CO-CULTURES. E.C. Tyler\*, R.L. Popp, and D.M. Lovinger. Dept. of Molecular Physiology and Biophysics, Vanderbilt Medical School, Nashville, TN 37232.

Previously, we described a corticostriatal co-culture system in which both stimulus evoked and spontaneous, calcium influx independent, synaptic transmission were modulated by mGluR activation. We showed that inhibition of evoked EPSCs (eEPSCs) by application of mGluR agonists exhibited a pharmacology consistent with modulation by class II mGluRs. Application of 50  $\mu\text{M}$  L-ACPD produced 32.5 $\pm$ 4.6% (n=10) inhibition of eEPSC amplitude. In the same cells, application of 2  $\mu\text{M}$  DCG-IV and 5  $\mu\text{M}$  L-CCG-I produced 31.7% (n=2) and 34.2 $\pm$ 3.7% (n=9) inhibition of the eEPSC, respectively. In 4 of 5 cells examined, 100  $\mu\text{M}$  AP4 reduced the eEPSC by less than 10% (4.2 $\pm$ 1.3%). We also demonstrated that modulation of evoked synaptic transmission by mGluR activation is mediated via a pertussis toxin (PTX) sensitive G-protein. PTX pre-treatment of culture dishes (500 ng/ml, 20-27 hr) blocked the ability of 50  $\mu\text{M}$  L-ACPD to reduce the eEPSC (3.8 $\pm$ 2.7% inhibition, n=5) compared to untreated controls. In controls from the same set of cultures, 50  $\mu\text{M}$  L-ACPD reduced the eEPSC by 20.3 $\pm$ 3.8% (n=5). By comparing manipulations that affect modulation of evoked and spontaneous transmission we hope to determine if modulation of synaptic transmission is mediated via calcium channels or via a mechanism downstream of calcium influx. Previously, we showed that phorbol esters were able to block inhibition of eEPSCs by mGluR activation. We have now shown that phorbol esters also have a similar effect on calcium influx independent miniature EPSCs (mEPSCs). Application of 1  $\mu\text{M}$  PDAC significantly decreased the interval between mEPSCs in all neurons examined (n=4, range 20-40% of control) without affecting mEPSC amplitude. Application of 50  $\mu\text{M}$  L-ACPD in the presence of PDAC had no significant effect in 3 of the 4 neurons examined. In the one neuron showing an effect it was significantly smaller than ACPD effects before PDAC treatment. Our current data suggest that modulation of synaptic transmission at synapses in corticostriatal co-cultures is mediated via a class II mGluR and that this receptor is acting, at least in part, via a pertussis toxin sensitive G-protein. (Supported by NS 30870 and MSTP 5-T32-GM07347-14).

## 430.10

SYNAPTIC AND CELLULAR PROPERTIES OF HIPPOCAMPAL NEURONS IN CALBINDIN-D28K DEFICIENT MICE. S. Vietia\*, L. Mody\*, M. Meyer\*, M.S. Airaksinen\*, and H. Thoenen\*. Dept. of Neurology, UCLA School of Medicine, Los Angeles, CA, and <sup>2</sup>Dept. of Neurochemistry, Max-Planck Institut für Psychiatrie, Martinsried, F.R. Germany

To date, little is known about the function of high-affinity neuronal  $\text{Ca}^{2+}$ -binding proteins, but some experimental evidence is consistent with their role as intracellular  $\text{Ca}^{2+}$ -buffers. We have examined the possible  $\text{Ca}^{2+}$  sequestering role of the cytosolic  $\text{Ca}^{2+}$ -binding protein calbindin-D28K (CB). Electrophysiological experiments were carried out in brain slices obtained from female control (CB<sup>+/+</sup>, n=4) and genetically engineered mice that lacked the gene for CB (CB<sup>-/-</sup>, n=4). Immunohistochemical labeling of slices not used for physiology confirmed the loss of CB from various neurons of the hippocampal formation.

First we studied the role of CB in  $\text{Ca}^{2+}$ -sequestration in presynaptic terminals. In the CA3 and CA1 regions, we recorded extracellular field EPSPs evoked by stimulation of the mossy and Schaffer collateral/commissural fibers respectively. The recordings were done in 50  $\mu\text{M}$  bicuculline, 50  $\mu\text{M}$  AP5 and 4 mM  $\text{MgCl}_2$  to reduce the probability of polysynaptic activation of pyramidal cells. In CB<sup>-/-</sup> mice, the rates of potentiation of EPSPs during the first 10 pulses of a 33 Hz tetanus were decreased by 66.4% and 36.6% in the CA3 and CA1 regions respectively. Paired-pulse potentiation at inter-stimulus intervals (ISI) between 20-1000 ms was also reduced in CB<sup>-/-</sup> animals (e.g., at 50 ms ISI, there was 38% and 21% less potentiation in the CA3 and CA1 regions respectively). Second, we examined the effect of a short (3 min) anoxia on synaptic transmission in the CA1 region. No differences were found in the anoxia-induced depression of field EPSPs between CB<sup>+/+</sup> and CB<sup>-/-</sup> mice. Third, we studied the firing properties of dentate granule cells in whole cell recordings. The frequency of action potential firing elicited by depolarizing current pulses (200-400 ms) was significantly lower in CB<sup>-/-</sup> mice.

Our findings are consistent with an enhanced activation of a  $\text{Ca}^{2+}$ -dependent  $\text{K}^+$  conductance in the absence of CB, and thus indicate an active role for CB in the regulation of neuronal  $\text{Ca}^{2+}$  homeostasis.

## 430.12

MECHANISM OF FREQUENCY DEPENDENT FACILITATION OF NICOTINIC TRANSMISSION IN RABBIT PARASYMPATHETIC GANGLIA. T. Nishimura\* and T. Akasu. Dept. of Physiology, Kurume Univ. Sch. of Med., Kurume 830, Japan

Fast excitatory postsynaptic current (EPSC) was recorded from neurons in rabbit vesicular parasympathetic ganglia (VPG) at 36 $\pm$ 1°C *in vitro*, using single electrode voltage clamp techniques. A holding potential ranged between -50 and -60 mV. The fast EPSC was evoked by stimulation of the pelvic nerve at various frequencies (0.03-10 Hz). The amplitude of fast EPSC typically ranged from 0.1 to 0.6 nA at 0.03 Hz. When the frequency of preganglionic nerve stimulation was increased to 3 Hz, the fast EPSC gradually increased in amplitude and then reached 1.5-2 nA at a 10-15th stimulus from the beginning of a 3 Hz train. The facilitation lasted for 1-5 min after the tetanic stimulation (3 Hz for 10 sec). During the frequency facilitation, the amplitude of an inward current evoked by pressure application of acetylcholine (ACh) was not changed in the presence of atropine (1  $\mu\text{M}$ ). The amplitude of fast EPSC was depressed and the number of failures was increased in low calcium (0.8 mM) solutions or after the application of BAPTA-AM (200  $\mu\text{M}$ ) for 20 min. In these neurons the frequency facilitation still occurred in some extent, however the decay of facilitation was significantly faster than the control. The frequency facilitation occurred even at low temperature (22°C). Contrary dibutyryl cyclic AMP (1-6 mM) and forskolin (10  $\mu\text{M}$ ) presynaptically increased the amplitude of fast EPSC at 36°C but not at 22°C. These data suggest that the frequency dependent increase in the ACh-release is responsible for the frequency facilitation of the fast EPSC. The frequency facilitation is explained at least in part by "residual calcium" hypothesis. Also it is independent of cyclic AMP. The frequency facilitation of the fast EPSC may be one of the mechanisms of the high pass filter of nicotinic transmission in the rabbit VPG (Neurosci. Lett., 103: 179-184, 1989).

## 430.14

EFFECTS OF L-ARGININE ON GABA SYNAPTIC CURRENTS IN DOPAMINE NEURONS OF RAT MIDBRAIN SLICE. B.A. Cox\*, K.-Z. Shen and S.W. Johnson, Department of Pharmacology, Oregon Health Sciences University, Portland, OR, 97201.

Dopamine neurons were recorded with patch pipettes in the whole-cell configuration from rat midbrain slices, and synaptic currents were evoked by focal electrical stimulation of the slice. The amplitude of the GABA<sub>A</sub>-mediated inhibitory postsynaptic current (IPSC), recorded in bicuculline (30  $\mu\text{M}$ ), APV (50  $\mu\text{M}$ ) and CNQX (10  $\mu\text{M}$ ), was increased 21  $\pm$  4% by L-arginine (10 mM), whereas the duration of the current at half amplitude was prolonged 50  $\pm$  11%. L- $\omega$ -nitro-L-arginine methyl ester (L-NAME; 10 mM), an inhibitor of nitric oxide synthase, reduced the amplitude of the GABA<sub>A</sub> IPSC by 58  $\pm$  4%, whereas the addition of L-arginine to L-NAME raised the amplitude of the GABA<sub>A</sub> IPSC back to the control level. L-lysine (10 mM), a competitive inhibitor of L-arginine uptake, reduced the GABA<sub>A</sub> IPSC by 64  $\pm$  5%. The GABA uptake inhibitor NO-711 (1  $\mu\text{M}$ ) mimicked L-arginine by increasing the GABA<sub>A</sub> IPSC amplitude by 13  $\pm$  4% and increasing its duration at half-amplitude by 117  $\pm$  22%. Outward current evoked by GABA, applied locally by pressure-ejection with bicuculline (30  $\mu\text{M}$ ) in the superfusate, was increased 57  $\pm$  16% by L-arginine. However, L-arginine failed to increase outward current evoked by locally applied baclofen, a GABA<sub>B</sub> agonist. These results suggest a presynaptic site of action for the potentiation by L-arginine of GABA<sub>A</sub> synaptic transmission. The action of L-arginine may be mediated by release of nitric oxide. INOSITOL 1,4,5-TRISPHOSPHATE MASS MEASUREMENT IN TORPEDO CHOLINERGIC SYNAPTOSOMES UNDER CONDITIONS THAT RELEASE ACETYLCHOLINE. M.A. Carrasco<sup>1</sup>, Y. Morot-Gaudry<sup>2</sup>, Talarmin<sup>1</sup>, J. Molgo<sup>1</sup> and P. Caviedes<sup>1</sup>. <sup>1</sup>Lab. Neurobiologie Cellulaire et Moléculaire, CNRS, 91198 Gif-sur-Yvette Cedex, France; <sup>2</sup>Dept. Fisiol. Biofis., Fac. Medicina, U. Chile, Casilla 70005, Santiago, Chile.

The cholinergic nerve endings isolated from the electric organ of *Torpedo marmorata* retain most of their metabolic and physiological properties (Israel et al., *Biochem. J.*, 160, 113-115, 1976). The intracellular messenger inositol 1,4,5-trisphosphate (IP<sub>3</sub>), has not been described in this preparation. We measured both IP<sub>3</sub> mass using a radioreceptor assay and acetylcholine (ACh) release by a choline-oxidase chemiluminiscent method with various agents that trigger ACh release.

IP<sub>3</sub> mass under resting conditions ( $471.3 \pm 25.6$  pmol/mg of protein) was independent of external [Ca<sup>2+</sup>]. IP<sub>3</sub> mass and ACh release increased with [K<sup>+</sup>] provided Ca<sup>2+</sup> was present, as determined in parallel experiments. The threshold for IP<sub>3</sub> mass increase was different from that found for ACh release since 30 mM K<sup>+</sup> which did not modify significantly IP<sub>3</sub> levels with respect to controls, already increased ACh release. The Ca<sup>2+</sup>-ionophore A23187 and gramicidin-D, induced a significant IP<sub>3</sub> mass increase and a parallel marked increase of ACh release in the presence of Ca<sup>2+</sup>. Hence, changes in IP<sub>3</sub> mass and ACh release seem to depend on both Ca<sup>2+</sup> influx and intracellular Ca<sup>2+</sup> levels.

## 430.17

ACTIVATION OF GABA<sub>A</sub> RECEPTORS INHIBITS CALCIUM CHANNELS IN LATERAL ENTORHINAL CORTICAL NEURONS, BUT NOT TRANSMISSION AT THE LATERAL PERFORANT PATH. Nevin A. Lambert<sup>\*</sup> and Wilkie A. Wilson. Department of Pharmacology, Duke Univ. Med. Ctr. and VAMC, Durham, NC 27705.

Transmitters and modulators that inhibit transmission at various synapses often inhibit voltage-gated Ca<sup>2+</sup> channels in the cell bodies of the presynaptic neurons. We asked if Ca<sup>2+</sup> channels were ever inhibited in neurons that make synapses that are not affected by a given transmitter. Lateral perforant path (LPP) fibers arise from neurons in layer II of the lateral entorhinal cortex (LEC) and terminate in the outer molecular layer (OML) of the dentate gyrus<sup>2</sup>. LPP synaptic responses are unaffected by activation of GABA<sub>A</sub> receptors<sup>1</sup>.

Field potential recordings in the OML confirmed that LPP responses were not inhibited by the GABA<sub>A</sub> receptor agonists baclofen or CGP 27492 in slices from young (P14-21) rats; LPP responses were reversibly inhibited by adenosine (n=3). Whole-cell voltage-clamp recordings were made from visually-identified neurons in layer II of the LEC. With K<sup>+</sup>-based internal solutions, GABA<sub>A</sub> and adenosine receptor agonists induced currents which were outward at -60mV, reversed near -90mV and were associated with an increase in conductance (n=6). With Cs<sup>+</sup>-based internal solutions and TEA and TTX in the bath, GABA<sub>A</sub> and adenosine receptor agonists reversibly inhibited inward currents elicited by depolarizing commands from a holding potential of -80mV (n=25; Figure). These results suggest that activation of GABA<sub>A</sub> receptors inhibits Ca<sup>2+</sup> channels in LEC neurons, but not transmission at their terminals. Thus, regulation of somatic Ca<sup>2+</sup> channels is not a reliable predictor of regulation of transmission.

## 430.19

FACILITATION OF <sup>3</sup>H-NE RELEASE FROM CEREBRAL CORTICAL SLICES IS MEDIATED PRIMARILY BY  $\beta$ 2-ADRENERGIC RECEPTORS. K.D. Murugaiah and J.M. O'Donnell<sup>\*</sup>. Dept. of Pharmacology, L.S.U. Medical Center, Shreveport, LA 71130.

The facilitatory effect of isoproterenol (0.1-10 nM), a nonselective  $\beta$ -adrenergic receptor agonist, on electrical stimulation-evoked release of <sup>3</sup>H-NE from cerebral cortical brain slices was antagonized by the nonselective, the  $\beta$ 1- and the  $\beta$ 2-selective adrenergic antagonists, propranolol, ICI 89,406 and ICI 118,551, respectively. Preliminary data indicated that the  $\beta$ 1- and  $\beta$ 2-selective adrenergic agonists prenalterol and albuterol (0.1-100 nM) both enhanced electrically-evoked release of tritium. These results were extended to the present study which examined whether the facilitatory effects of prenalterol and albuterol were antagonized by propranolol, ICI 89,406 and ICI 118,551. Rat cerebral cortical slices were preloaded with <sup>3</sup>H-NE and superfused with Krebs Ringer buffer for 100 min and electrically stimulated (1 Hz, 20 mA, 2 ms, 2 min) at S1 (20 min) and S2 (70 min). Tritium outflow was evaluated as % radioactivity present in each 5 min fraction; results were expressed as S2/S1 ratios. Drugs were added 10 min prior to S2. Prenalterol and albuterol 1) did not alter basal outflow of tritium, 2) enhanced evoked overflow of tritium in a concentration-dependent manner but with differing potency and efficacy (S2/S1 ratios at 10 nM prenalterol =  $126 \pm 5\%$ ; albuterol =  $142 \pm 6\%$  of control), and 3) antagonism of the effects of both agonists was greater with ICI 118,551 than with propranolol or ICI 89,406. These results suggest that the facilitation of <sup>3</sup>H-NE release by  $\beta$ -adrenergic agonists primarily involves  $\beta$ 2-adrenergic receptors. ## 430.16

DOES ADENOSINE CONTRIBUTE TO TETANIC FADE AT THE MAMMALIAN NEUROMUSCULAR JUNCTION? D.F. Wilson<sup>\*</sup>, K.V. Schmit, J.W. Schrock, and P.M. Barr. Zog Dept., Miami Univ., Oxford, OH 45056.

In the amphibian it has been suggested that the major basis for tetanic fade at the neuromuscular junction is due to a feedback action of adenosine that is coupled with neurotransmitter release during repetitive stimulation. Evidence supporting this hypothesis is lacking in the mammalian system. We were interested in determining if a similar mechanism could be operating at the neuromuscular junction of the rat. The presynaptic effect of blocking adenosine A<sub>1</sub>-receptors on tetanic fade in the rat diaphragm was examined by testing 100 and 200 pM 8-cyclopentyl-1,3-dipropylxanthine (DPCPX) on evoked transmitter release. Intracellular recording techniques were used to monitor end-plate potentials and miniature end-plate potentials in the isolated cut-muscle rat diaphragm-phrenic nerve preparation (40 stimuli of 1, 25, and 50 Hz were used). Quantal release and tetanic fade in the presence and absence of the antagonist were examined. DPCPX failed to reduce tetanic fade or alter quantal release. These results do not support the hypothesis that adenosine causes tetanic fade by acting on presynaptic adenosine A<sub>1</sub>-receptors.

## 430.18

EFFECT OF CAFFEINE ON SYNAPTIC PERFORMANCE AT CRAYFISH NEUROMUSCULAR JUNCTIONS. K. Judd and S.J. Velez<sup>\*</sup>. Dept. of Biological Sciences, Dartmouth College, Hanover, NH 03755.

We had previously reported that caffeine decreased the facilitation of neurotransmitter released during constant 10 Hz stimulation of neuromuscular synapses in the crayfish superficial flexor muscles (*Soc. Neurosci. Abstr.* 20:1338). A dosage-response curve was now obtained for the largest excitator to this system (axon 6), at a constant 1 Hz or 10 Hz stimulation, while recording junction potential sizes (jp's) from several muscle fibers. Maximum reduction of jp size, within 5 minutes of exposure, was obtained for a .05M solution of caffeine in Ringers; no effect was observed for concentrations lower than .001M. Both jp's generated at 1 Hz and at 10 Hz were affected, as was the facilitation ratio (jp 10Hz/jp 1Hz) of the terminals. Experiments were repeated using .01M caffeine in Ringers that contained 30% or 200% normal calcium concentrations, with no effects observed on caffeine's reduction in jp sizes or time course of action. It appears that caffeine is lowering the intracellular free-calcium ion concentration in this system. Experiments in progress using .01M caffeine in Ringers containing the calcium ionophore A23187 indicate that even after internal calcium stores are compromised by the enhanced calcium permeability induced by the ionophore, caffeine's effects are still observed. This suggests that caffeine is not increasing calcium pumping into intracellular compartments but could be activating molecules that remove free-calcium ions from solution.

MODULATORY EFFECT OF BRADYKININ BY B<sub>1</sub> AND B<sub>2</sub> RECEPTORS ON NORADRENALINE RELEASE IN ISOLATED MOUSE ATRIA. C. Chulak<sup>\*</sup>, R. Couture and S. Foucart. Groupe de Recherche sur le Système Nerveux Autonome, Département de physiologie, Université de Montréal, Montréal, Canada, H3C 3J7.

The aim of this study was to investigate the modulatory effect of bradykinin (BK) on the release of noradrenaline (NA) from isolated mouse atria. Atria from CD1 mice were isolated and incubated with [<sup>3</sup>H]-NA and then inserted in a superfusion system (6 pairs of atria in parallel). After a washing period, the radioactivity was collected at every 5 min for 60 min. During this collecting period, the atria were electrically stimulated (5 Hz, 2 ms, 50 mA, 60 sec) at 10 min (S<sub>1</sub>) and at 45 min (S<sub>2</sub>). At the end of the experiments, the radioactivity was counted and the results were expressed by the ratio S<sub>2</sub>/S<sub>1</sub>. The drugs were added 20 min before S<sub>2</sub>. The results show that BK (10 nM) alone did not affect significantly [<sup>3</sup>H]-NA release induced by electrical stimulation. However, in the presence of a B<sub>1</sub> receptor antagonist, [Leu<sup>8</sup>]-des-Arg<sup>9</sup>-BK (100 nM), BK (10 nM) had a facilitatory effect on [<sup>3</sup>H]-NA release. This facilitatory action of BK (10 nM) was inhibited by HOE 140 (10 nM), a B<sub>2</sub> receptor antagonist. The B<sub>1</sub> agonist, des-Arg<sup>9</sup>-BK (10 nM) had an inhibitory effect on [<sup>3</sup>H]-NA release when used with the B<sub>2</sub> antagonist (100 nM). Moreover, BK had a facilitatory effect on [<sup>3</sup>H]-NA release when administered with a cyclooxygenase inhibitor, diclofenac (1  $\mu$ M). These results suggest that BK had a facilitatory effect through the activation of prejunctional B<sub>2</sub> receptors and also had an inhibitory effect through the activation of B<sub>1</sub> receptors linked to production of prostaglandins.

## 431.1

TRANSMITTER RELEASE PROBABILITY FUNCTION: A CONTINUOUS DISTRIBUTION. E. P. Huang\* and C. F. Stevens. Salk Institute, La Jolla, CA 92037.

Whole cell recording in rat hippocampal CA1 region was performed to examine the distribution of synaptic transmitter release probabilities. Cells in slices were clamped at -40mV, and NMDA receptor mediated EPSCs were isolated by stimulating in the stratum radiatum in the presence of 5  $\mu$ M DNQX. After application of NMDA receptor open channel blocker MK-801, the amplitude of EPSCs decreases with repeated stimuli as receptor block accumulates; the rate of decrease is determined by the synaptic release probability (Hessler et al., *Nature*, 366: 569 (1993); Rosenmund et al., *Science*, 262: 754 (1993)). The blocking rate is also determined by MK-801 concentration; we measured the dose response of NMDA receptor block at 10, 20, and 40  $\mu$ M MK-801. The fitted  $K_i$  is 20  $\mu$ M. Theoretical analysis shows EPSC amplitude decline in MK-801 is well fitted by a model incorporating a continuous distribution of release probabilities, such as previously reported (Allen et al., *PNAS*, 91:10380 (1994)). To further characterize this distribution we compared MK-801 block of synapses with release probabilities altered under two conditions: (1) paired pulse facilitation (PPF) and (2) increased or decreased  $Ca^{2+}$  concentration. PPF synapses show faster EPSC amplitude decline than control due to increased release probability. The facilitation ratio is measured during the blocking and found to be constant across synapses of all probabilities. Our model of MK-801 block predicts a relationship between the change in decline and the measured PPF ratio; our results are in good agreement with these predictions. The change of release probability in different  $[Ca^{2+}]$  is predicted by the Dodge-Rahamimoff model. We measured MK-801 block of synapses in  $[Ca^{2+}]$  of 1.0, 1.75, 2.5, and 6.0 mM. We fit the rate of decline versus  $[Ca^{2+}]$  to the D-R equation; fitted constants  $K_m$  and  $K_c$  are 3.4 mM and 0.8 mM, respectively.

## 431.3

MODELING THE CO-LOCALIZATION OF  $Ca^{2+}$  CHANNELS AND  $Ca^{2+}$  RECEPTORS: CORRECT HANDLING OF  $Ca^{2+}$  DOMAINS. R. Bertram\* and A. Sherman. Mathematical Research Branch, NIDDK, NIH, Bethesda, MD 20892.

$Ca^{2+}$  channels and  $Ca^{2+}$  receptors are often co-localized, so that receptor proteins are influenced almost exclusively by the  $Ca^{2+}$  from one or more adjacent channels. Examples include the co-localization of N-type  $Ca^{2+}$  channels and vesicle fusion proteins (Stanley, *Neuron*, 11:1007) and the co-localization of  $Ca^{2+}$  channels and calcium-activated  $K^+$  channels (Gola and Crest, *Neuron*, 10:689). This co-localization makes the modeling of transmitter release from a synaptic terminal or the total  $K(Ca)$  conductance of a patch of membrane problematic, due to the stochastic nature of channel openings which gives each binding complex a different history of exposure to  $Ca^{2+}$ . We describe a deterministic method which accounts for this stochasticity. Using a model of transmitter release based on single-channel  $Ca^{2+}$  domains (Bertram et al., *Biophys. J.*, 68:A396) we show that it is not valid to approximate the domain  $Ca^{2+}$  concentration by the average domain  $Ca^{2+}$  concentration if one or more of the binding sites comprising the receptor complex has kinetics which are slow compared to the time constant of the channel. Such slow  $Ca^{2+}$  binding sites are now thought to be crucial for fast synaptic facilitation (Stanley, *J. Neurosci.*, 6:782). We use this model in conjunction with a model for bursting in dopamine neurons (Li et al., *Soc. Neurosci. Abstr.*, 20:1507) to demonstrate that more transmitter is released when the cell is in bursting mode than when it fires tonically, even though bulk cytosolic  $Ca^{2+}$  does not accumulate.

## 431.5

MICROMOLAR 4-AMINOPYRIDINE ENHANCES INVASION OF A NEUROSECRETORY TERMINAL ARBORIZATION: OPTICAL RECORDING OF ACTION POTENTIAL PROPAGATION USING A PHOTODIODE ARRAY AND AN ULTRAFAST PHOTODIODE-MOSFET CAMERA. A.L. Obaid and B.M. Salzberg\*, Department of Neuroscience, UPENN School of Medicine, Phila., PA 19104-6074.

The vertebrate hypothalamo-neurohypophyseal system is a useful model for the study of excitation-secretion coupling. Magnocellular neurons located in the hypothalamus project their axons as bundles of fibers through the median eminence and infundibular stalk to arborize and terminate in the neurohypophysis, where the neurohypophyseal peptides and proteins are released into the circulation by a Ca-dependent mechanism. Elevating  $[Ca^{2+}]_o$  from 2 to 5 mM enhances release of arginine vasopressin from these terminals, as does the addition of 4-aminopyridine (4-AP) in micromolar concentrations. However, preliminary evidence based on the rapid changes in light scattering that accompany release from these terminals (Salzberg, Obaid, & Gainer, *J. Gen. Physiol.* 86: 395, 1985; Obaid, Flores & Salzberg, *J. Gen. Physiol.* 90: 32a, 1987), suggested that while Ca increases the amount of peptide released per active terminal, 4-AP acts by increasing the number of active terminals through a mechanism of enhanced invasion of the terminal arborization. Here, we show directly, using the voltage-sensitive dye NK 2761 and a differential photodiode-MOSFET camera (HR Deltaron 1700, Fuji Photo Co.), having 16,384 pixels (128 x 128) and operating at a frame rate of 1.7 kHz, that 10  $\mu$ M 4-AP dramatically increases the spatio-temporal spread of the action potential in the neurohypophysis of the frog *Xenopus*. We will show moving pictures of the enhanced invasion of the neurosecretory terminal arborization in micromolar 4-AP, together with evidence that elevated Ca has no effect on the pattern of action potential propagation.

We are grateful to Fuji Medical Systems (Stamford, CT) for the loan of the HR Deltaron 1700 and to the NINDS for USPHS grant NS16824.

## 431.2

MONTE CARLO SIMULATION OF FAST EXCITATORY SYNAPTIC TRANSMISSION AT A HIPPOCAMPAL SYNAPSE. L. M. Wahl, C. Pouzat, and K. J. Stratford\*, Univ. Lab. of Physiology, Parks Rd., Oxford, OX1 3PT, UK.

Fast excitatory synaptic transmission at the hippocampus has been simulated by modelling individual neurotransmitter molecules as they diffuse through the synaptic cleft and interact with postsynaptic receptors. 4000 neurotransmitter molecules are simultaneously released at a point source 15 nm above a rectangular array of 14x14 postsynaptic receptors. The model is able to reproduce published results of patch clamp experiments on CA3 pyramidal cells at room temperature, predicting an excitatory postsynaptic current (EPSC) with a 10-90 rise time ( $t_r$ ) of 0.28 ms, a peak open probability ( $P_o$ ) of 0.27, and a decay time constant ( $\tau_d$ ) of 2.33 ms. The coefficient of variation (CV) at the peak of the EPSC is 9.4%. At 37°C,  $t_r$  is 0.07 ms,  $P_o$  is 0.56, and  $\tau_d$  is 0.70 ms. The CV at the peak is 6.6%. Slower rates of diffusion of neurotransmitter in the cleft increase the peak response and slow the time course of decay. Random variations in release site position have little effect on the time course of the average EPSC or the peak response, whereas changes to the width of the synaptic cleft, or to the number or spacing of postsynaptic receptors, have marked effects on the peak amplitude of the simulated EPSC. Variations in the number of neurotransmitter molecules released also affect EPSC peak amplitude, but the magnitude of this effect is strongly dependent on the number of postsynaptic receptors and the rate of neurotransmitter diffusion in the cleft.

SPATIALLY RESOLVED MEASUREMENTS OF THE ENDOGENOUS CALCIUM BUFFERING CAPACITY IN ADRENAL CHROMAFFIN CELLS

M. Naraghi, T.H. Müller\*, M. Oheim and E. Neher  
Max-Planck-Institute for Biophysical Chemistry, Dept. of Membrane Biophysics, 37077 Göttingen, Germany

In calcium imaging experiments, theoretical considerations predict that the indicator dye, in addition to acting as an exogenous calcium buffer, also contributes to the diffusional equilibration of calcium gradients by virtue of its own mobility. In order to accurately assess its role and that of the endogenous calcium buffers in shaping the spatiotemporal dynamics of intracellular calcium signals, we have measured the diffusional dissipation of calcium gradients introduced by short depolarising voltage clamp pulses in chromaffin cells at different concentrations of the indicator dyes Fura-2 or Fura-2-Dextran or a combination of Calcium-Green-1 and Brilliant-Sulfaflavin.

We use a slow-scan CCD imaging system with an acquisition rate of 40-50 Hz. To improve the signal-to-noise-ratio we increase the excitation intensity by means of a pulsed power supply within the period of 200-300 ms during which the calcium gradients disappear. As the intracellular diffusion of calcium and indicator dye is inherently a three-dimensional process, its observation using a two-dimensional detector was achieved by obtaining responses at several planes of focus. The blurring introduced by the optical system was compensated for by using an iterative deconvolution algorithm based on regularisation theory. Using a diffusion model we calculate the endogenous buffering capacities in a spatially resolved manner.

## 431.6

ANALOG CIRCUIT OF A PASSIVE BRANCH POINT. M.D. Goldfinger\* and K. Moradmand, Dept. Physiology & Biophysics, Wright State U., Dayton, OH.

We solved the cable equation for a 1-dimensional core-conductor consisting of a parent fiber and two daughter branches using a series of connected compartments each of which corresponded to 0.0165  $\lambda$  of a 620- $\mu$ m-diameter squid axon ( $\lambda=4.8216$  mm) with  $R_m=1453.5 \Omega\text{-cm}^2$ ,  $C_m=1.0 \mu\text{F/cm}^2$ ,  $\rho_i=108.5 \Omega\text{-cm}$ , and 12 msec-duration constant current pulses. In unbranched configuration, transient and steady-state responses were well-fit by analytic solutions (1) including the shortening of the charging transient when total electrotonic length increased from 1 to 11 $\lambda$ ; errors >5% were restricted to the first 0.3  $t/\tau$  of the transient. The branch-point circuit (BPC) consisted of a 2.0 $\lambda$  parent and two 2.0 $\lambda$  branches. The second branch attenuated the magnitude of transient and steady-state voltages at any x but did not alter the time course, as reconstructed with a numerical literal compartmental model (LCM) using trapezoidal integration (2) with  $\Delta x=0.0165\lambda$  and  $\Delta t=50$  nanosec.

With parent distal-end stimulation, BPC and LCM steady-state potentials declined monotonically with x. Rall's Equivalent Circuit (REC3) underestimated these voltage changes. BPC and LCM steady-state axial current declined monotonically to the branch point and was equally divided into each branch. REC steady-state axial current increased discontinuously at and because of the diameter expansion. Close to ( $\pm 0.075\lambda$ ) the branch point, BPC transients were reconstructed by LCM but not by REC. BPC and LCM axial currents flowing from the parent were twice that flowing into each branch; compared to LCM, REC overestimated the entire axial current waveform at the geometrical transition.

Thus, while LCM accurately reconstructed the passive properties of the BPC, REC was not the electrical equivalent of BPC. Supported by NSF BCS-9315856(MDG). ## 431.7

## FOUR MODES OF GABAERGIC SYNAPTIC TRANSMISSION IN CULTURED EMBRYONIC RAT HIPPOCAMPAL NEURONES.

J. Vautrin,\* A.E. Schaffner and J.L. Barker.

Lab. of Neurophysiology, NINDS, NIH, Bethesda, MD 20892.

Most of the current to clamp at -80mV (whole-cell patch configuration, symmetrical [Cl<sup>-</sup>]) hippocampal neurones from 18-22 day old rat embryos with CsCl electrodes represents the activity of GABA receptor-coupled Cl<sup>-</sup> channels. Analysis of baseline and transient Cl<sup>-</sup> currents reveals that GABA is secreted from these neurones according to four modes as reported for ACh secretion from motor terminals. 1) Tonic secretion is characterized by a baseline noise corresponding to random openings of the Cl<sup>-</sup> channels. 2) One or a group of a few poorly synchronized transmitter discharges is characterized by TTX-resistant, small mode Cl<sup>-</sup> transient signals with highly variable peak amplitude (PA) and rise-time (RT). Elementary discharges peak at 10-20pA. 3) Well synchronized transmitter discharges (10-30) are characterized by medium mode (100-300pA), temporarily (15min) TTX-resistant, transient signals with moderately variable PA and RT. 4) Presynaptic action potential-evoked release is characterized by large mode (800-1200pA), TTX-sensitive, transient signals with little variability in PA and RT. Reversible, rapid or progressive interconversions between tonic and pulsatile secretory modes and between poorly and well-synchronized pulsatile modes occur spontaneously or are induced by conditions known to modify [Ca<sup>2+</sup>]<sub>i</sub>. Spontaneous or action potential-triggered presynaptic intracellular Ca<sup>2+</sup> transients are proposed to synchronize transmitter secretion to produce postsynaptic transient currents.

## 431.9

ONTOGENY OF ADRENERGIC MODULATION OF GABA<sub>A</sub> RECEPTOR-MEDIATED INHIBITION IN SOMATOSENSORY CORTEX OF RAT. B.D. Bennett, J.R. Huganard and D.A. Prince\*.

Dept. Neurol. and Neurolog. Sci., Stanford Univ. Med. Ctr., Stanford CA 94305

Adrenergic agonists decrease evoked inhibitory postsynaptic currents (eIPSCs) in hippocampal CA1 pyramidal neurons by decreasing the efficacy of excitatory synaptic input to presynaptic GABAergic interneurons (Doze et al., *Neuron* 6:889). We used whole-cell voltage-clamp techniques in slices of somatosensory cortex to study adrenergic modulation of monosynaptic eIPSCs in layer V pyramidal neurons. Experiments were designed to determine 1) whether adrenergic effects on eIPSCs might differ from those in hippocampus and, 2) to examine the ontogeny of this modulation. Monosynaptic IPSCs were evoked by layer V stimulation in slices bathed with ACSF containing 20 μM DNQX and 50 μM APV. Of 21 neurons studied in slices from animals aged P9-P12, 15 were responsive to 10 μM noradrenaline or adrenaline (bath application). Thirteen displayed a pronounced depression of eIPSCs that was reversible in 5 cells (43%±11%) and irreversible in 8 cells. An enhancement of eIPSCs was seen in 2 neurons and was reversible in 1. By contrast, adrenergic stimulation in 6 neurons from animals aged P15-P18 produced either a reversible enhancement (23%±13%) of eIPSCs (3 of 5 responsive cells) or an irreversible depression of eIPSCs (2 of 5). Adrenergic agonists increased spontaneous IPSCs in almost all neurons of both age groups but did not alter the baseline holding current in any cells. In contrast to findings in the hippocampus, these data indicate that adrenergic agonists directly modulate eIPSCs presumably through actions on presynaptic GABAergic neurons. The effects appear to be age-dependent so that reversible actions change from predominantly a depression of eIPSCs at P9-P12 to an enhancement of GABA<sub>A</sub>-mediated inhibition in the older age group (p<0.02, Mann Whitney U test). These studies were supported by NIH Grant NS12151 from the NINDS and a Pinley fellowship to BDB.

## 431.11

## DOPAMINERGIC INHIBITION OF SYNAPTIC CURRENTS IN CHOLINERGIC MAGNOCELLULAR NEURONS IN THE BASAL FOREBRAIN. T. Momiyama, J.A. Sim\* &amp; D.A. Brown. Dept. of Pharmacology, Univ. Coll. Lond., London WC1E 6BT.

Magnocellular cholinergic neurons in the basal forebrain, which form the main source of cholinergic projection to cortical and subcortical regions of the mammalian brain, receive dopaminergic inputs from both the substantia nigra pars compacta and ventral tegmental area. In the present study whole-cell recording experiments were carried out on thin slice preparations of the rat brain to elucidate the effect of dopamine on postsynaptic currents in the magnocellular basal forebrain neurons. Coronal slices (200 μm) of the horizontal limb of the diagonal band of Broca and substantia innominata/nucleus basalis were cut from 12-14 day old rats. After whole-cell configuration was made from visualised magnocellular basal forebrain neurons (>20 μm, considered to be cholinergic from morphological studies) a stimulating electrode was placed within the nucleus or on a nearby neuron to evoke synaptic currents. Both glutamatergic EPSCs, which were blocked by CNQX, and GABAergic IPSCs, blocked by bicuculline, were recorded. Dopamine suppressed both EPSCs and IPSCs in a concentration-dependent manner between 10 and 100 μM. SKF 81297, a D<sub>1</sub> agonist (10-30 μM), mimicked the action of dopamine, whereas (-)-JNPA, a D<sub>2</sub> agonist, had little effect at concentrations up to 30 μM. Dopamine-induced suppression of EPSCs and IPSCs was antagonized by SCH 23390, a D<sub>1</sub> antagonist, while antagonism by eticlopride, a D<sub>2</sub> antagonist, was less prominent. In addition, the frequency of miniature EPSCs and IPSCs, recorded in the presence of TTX (0.5 μM), was reduced by dopamine (10-30 μM), whereas their mean amplitude was unaffected.

These findings suggest that afferent inputs to magnocellular cholinergic neurons in the basal forebrain express mainly D<sub>1</sub> receptors to modulate excitatory and inhibitory transmission.

## 431.8

## SYNCHRONOUS AND ASYNCHRONOUS EPSCs EVOKED IN HIPPOCAMPAL SLICES: A TEST OF THE QUANTAL MODEL OF NEUROTRANSMISSION.

J.M. Bekkers\*, Division of Neuroscience, John Curtin School of Medical Research, Australian National University, Canberra, Australia.

The classical quantal model of synaptic transmission proposes that the amplitudes of evoked excitatory postsynaptic currents (EPSCs) occur as integral multiples of the amplitude of miniature EPSCs (mEPSCs). mEPSCs occur spontaneously in the postsynaptic cell following the asynchronous release of a single vesicle, or 'quantum', of neurotransmitter. Apparent quantization of EPSCs at central synapses has been reported, but mEPSCs generally had too broad an amplitude distribution to underlie the tight quantization of the evoked EPSCs, possibly because the mEPSCs and evoked EPSCs did not originate from the same population of synapses. The goal of this work is to test the quantal model at a central synapse under conditions in which evoked and miniature EPSCs originate at the same release site(s).

Whole-cell patch clamping was used to record EPSCs in dentate granule cells in 400 μm hippocampal slices from juvenile rats while weakly stimulating the perforant path. EPSCs evoked in control external solution (containing 2 mM Ca) showed predominantly synchronous release with short latency (<8 ms). Exchanging the external Ca for 8 mM strontium (Sr) produced EPSCs with a similar mean amplitude of synchronous release, but in addition a pronounced phase of asynchronous release lasting hundreds of milliseconds. This effect of Sr has been reported for the endplate (*Nature* 212:1233, 1966) and cultured hippocampal neurons (*PNAS* 91:12942, 1994) and is presumably due to residual Sr remaining in the stimulated presynaptic terminals. These asynchronous currents resembled mEPSCs in having no obvious inflections in their rising edges. Rise time and amplitude distributions for mEPSCs were similar to those of the synchronous EPSCs. Amplitude distributions for each were skewed (coefficient of variation 0.4-0.5) and had means of 3-6 pA (at -70 mV). These distributions will be subjected to quantal analysis using robust statistical techniques (*Biophys. J.* 67:532, 1994).

## 431.10

## NICOTINE FACILITATION OF GLUTAMATERGIC SYNAPTIC TRANSMISSION IS MEDIATED BY PRESYNAPTIC CALCIUM INFLUX D.S. McGehee\* &amp; L.W. Role. Dept. of Anat. &amp; Cell Biol., Columbia Univ., 722 W 168th St, NY, NY 10032.

Both the medial habenula (MHN) and the site of its primary projections, the interpeduncular nucleus (IPN), express nicotinic ACh receptors (nAChRs) and choline acetyltransferase. In recordings from dispersed IPN neurons innervated by explants of MHN, we find that the transmission is glutamatergic but that nAChR activation facilitates both evoked and spontaneous transmission by a presynaptic mechanism. The EC<sub>50</sub> for nicotine-induced facilitation is 170 nM, and it is blocked by pretreatment with α-bungarotoxin (100 nM). Thus it is likely that the α7 or α8 nAChR subunits are components of the receptors mediating this facilitation. We are utilizing antisense oligonucleotide deletion of the α7 subunit to characterize further the role of this subunit in presynaptic facilitation by nicotine. Since α7 nAChRs expressed in *Xenopus* oocytes are highly Ca<sup>2+</sup>-permeable, channels whose composition includes this subunit would be ideal regulators of synaptic transmission, particularly if expressed near sites of transmitter release. We have determined that the facilitation induced by nicotine is dependent upon the presence of Ca<sup>2+</sup> in the external solution. Therefore, we have used fura 2 imaging of intracellular [Ca<sup>2+</sup>]<sub>i</sub> in the cocultures and in dispersed MHN neurons to examine the subcellular localization of these receptors as well as the intracellular mechanisms involved in this response. In dispersed habenula neurons nicotine induces a concentration-dependent increase in [Ca<sup>2+</sup>]<sub>i</sub> with an EC<sub>50</sub> of approximately 1 μM. To test whether Ca<sup>2+</sup> enters the cells through nAChRs *per se* or through voltage-gated Ca<sup>2+</sup> channels (VGCC) we are testing the effects of various VGCC blockers (at concentrations that do not effect nAChR channels). Preliminary data indicate that VGCCs contribute to this response. Experiments are underway to test whether the nAChRs expressed in the periphery of these neurons differ in their Ca<sup>2+</sup>-permeability or in their concentration-dependence of activation from those found on the somata. Supported by NS22061, Cncl. Tobacco Res. & McKnight Found. grants to LR and NS09395 to DM.

## 431.12

## POSSIBLE MECHANISMS UNDERLYING PATTERNS OF ELECTRIC ACTIVITY IN NEUROHYPOPHYSIAL TERMINALS. G. Wang\* &amp; J.R. Lemos. Worcester Found. Exptl. Biology, Shrewsbury, MA 01545.

The different bursting patterns of action potentials (APs) in the hypothalamic magnocellular cells are important for neurohypophyseal peptide release. Properties of APs in the neurohypophyseal terminals, however, are still poorly understood. Recent characterization of the major voltage-activated ion channels allows us to gain insights into the mechanisms underlying AP patterns in the isolated terminals. Current-clamping with conventional and perforated 'whole-terminal' configurations shows that APs can be elicited from resting potentials (Vm) of -70 to -85 mV. The duration (12.7 ms) of AP (APD) was increased in a frequency- and Vm-dependent manner. The depolarizing phase of the AP was dependent only on Na<sup>+</sup> channel activity, but the repolarizing phase could be divided into an early, fast and a late, slow phase. The first phase was affected by the K<sup>+</sup>(A) channel blocker 4AP, producing a substantial prolongation of the APD. Using the perforated configuration or with low (0-50 nM) intraterminal Ca<sup>2+</sup> concentrations ([Ca<sup>2+</sup>]<sub>i</sub>), the second phase was even slower. Acceleration of this slow phase by high (10 μM) [Ca<sup>2+</sup>]<sub>i</sub> could be strongly antagonized by the K<sup>+</sup>(Ca) channel blockers Ba<sup>2+</sup>, tetrandrine and TEA. In addition, the K<sup>+</sup>(A) and K<sup>+</sup>(Ca) channel blockers had opposite effects on the Vm: the former increased it whereas the latter decreased it. These data suggest that: (1) the fast and slow repolarizing phases of the terminal's AP are dependent on K<sup>+</sup>(A) and K<sup>+</sup>(Ca) channel activities, respectively; (2) the genesis of bursting patterns might be due to an initially low [Ca<sup>2+</sup>]<sub>i</sub> which would result in a slower repolarization of the second phase and make the next AP trigger easier, while gradually accumulating high [Ca<sup>2+</sup>]<sub>i</sub> would eventually terminate the burst. (Supported by NIH NS29240)

**KAPPA-OPIOID RECEPTOR ACTIVATION MODULATES  $Ca^{2+}$  CURRENTS AND SECRETION IN ISOLATED NEUROENDOCRINE NERVE TERMINALS.** K.I. Rusin\*, D.R. Giovannucci, H.C. Moises and E.L. Stuenkel. Department of Physiology, University of Michigan, Ann Arbor, MI 48109-0622.

Whole cell patch clamp recordings were obtained from nerve terminals acutely dissociated from neurohypophysis of adult rats to investigate modulation of calcium currents and secretion by activation of opioid receptors. External and internal solutions were chosen to suppress sodium and potassium currents and calcium (10 mM) or barium (10 mM) was used as the charge carrier through calcium channels. Observed currents were characterized as high-threshold calcium currents. Bath administration of the  $\kappa$ -opioid agonists U-50488 (1-10  $\mu$ M) and U-69593 (1  $\mu$ M) suppressed peak amplitude of the calcium currents by  $32.8 \pm 12.9\%$  (n=4) and  $43.1 \pm 24.7\%$  (n=3), respectively. Measurements of cell capacitance showed that  $\kappa$ -opioids reduce depolarization-induced exocytosis in nerve terminals of the neurohypophysis. In contrast, administration of the  $\mu$ -opioid agonist H-Tyr-D-Ala-Gly-Phe(N-Me)-Gly-ol (DAGO, 3  $\mu$ M) did not effect calcium currents (n=6). These data suggest that  $\kappa$ - but not  $\mu$ -opioid receptors are negatively coupled to calcium channels in nerve endings of the rat neurohypophysis and may regulate release of oxytocin and vasopressin from these terminals. (Supported by NSF 9410834 to ELS and DA 03365 to HCM).

**EXCITATORY SYNAPTIC INPUT TO AXONS IN THE SPINAL CORD.** Amanda J. Holt\* and Simon Alford. Dept. of Physiology, Northwestern University Medical School, Chicago IL 60611.

In axons, release of transmitter follows transmission of action potentials from the soma to presynaptic terminals. The traffic of signals in axons is considered unidirectional, originating in the soma and ending at the axon termination. Release is subject to modification by autoreceptors and axo-axonic presynaptic inhibition, however there is evidence that vertebrate axons receive excitatory inputs. Recordings from cat primary afferents (Gossard et al 1989, J. Neurophysiol. 62:1177) indicate that the spinal cord is capable of causing antidromic spike activity. Additionally, synaptosomes release transmitter following application of excitatory amino acids (Barnes et al 1994, Br. J. Pharmacol. 113:339). We made whole cell patch recordings from reticulospinal axons in the spinal cord of the lamprey in which the cell body was removed. Axons ranged in input impedance from 350 to 12 M $\Omega$  and in diameter from 20 to 4  $\mu$ m, as identified by dye filling. Upon achieving whole-cell access, spontaneous transient inward currents are readily apparent which show variable rise times (range: 2 to 20 ms). Fictive locomotion was activated by bath application of 200  $\mu$ M NMDA. This caused a marked increase in the frequency of these events. Pressure ejection of AMPA over the spinal cord in the presence of TTX caused an immediate inward current in these axons whilst, in contrast, kainate and NMDA pressure ejection had no effect. In 32 recordings, a stimulation electrode was placed over the spinal ventromedial tracts. Stimulation evoked transient inward currents in axons whose rise times ranged from 1.1 to 23 ms. The responses showed a reversal potential markedly positive to resting membrane potential. Inward currents were abolished by the application of the AMPA receptor antagonist CNQX (10  $\mu$ M) in all cells tested (n=14). In 7 cells the recording method was switched to whole-cell current clamp. Spinal cord stimulation, subthreshold to direct stimulation of the axon, was then capable of evoking a spike in 6 of the 7 recorded axons. In summary, large descending excitatory axons of the spinal cord receive excitatory synaptic input mediated by AMPA/kainate receptors. This input is capable of depolarizing the axon to initiate an action potential. Supported by NINDS grant NS31713.

**PRESYNAPTIC METABOTROPIC INHIBITORY EFFECT INDUCED BY BACLOFEN AT THE CRAYFISH EXCITATORY SYNAPSES.** B. Alkahe, H. Golan and Y. Grossman\*. Department of Physiology, Faculty of Health sciences, Ben - Gurion University of the Negev, Beer - Sheva 84105, Israel.

Mechanisms of presynaptic inhibition were studied in the crayfish neuromuscular synapses. Excitatory post synaptic currents (EPSCs) were recorded by using a macropatch clamp technique. Inhibition was induced by either stimulating the inhibitory axon a few ms before the evoked EPSC or, by application of 5-50  $\mu$ M GABA to the bath solution for a period of 1-2 min. Short train of stimuli to the inhibitor usually decreased the potentiated EPSC by 43%. Application of 10, 30 and 50  $\mu$ M GABA caused 30%, 50% or 100% reduction in EPSC amplitude, respectively. Application of 100  $\mu$ M baclofen, a known GABA<sub>B</sub> agonist, did not affect the single EPSC amplitude. However it increased the efficacy of the evoked inhibition by 22% (n=4). Moreover, baclofen induced full recovery of evoked inhibition in synapses treated (for 60 - 90 min) with aminooxy acetic acid, a known glutamate decarboxylase blocker, which depressed inhibition efficacy by 38% (n=4). Baclofen effects were observed after 60 - 90 min incubation, and blocked by application of 50  $\mu$ M picrotoxin to the bath solution. These results suggest a modulatory effect by a presynaptic metabotropic GABA receptor whose activation increases the efficacy of a picrotoxin-sensitive GABA-dependent chloride inhibition.

## 431.14

**PRESYNAPTIC MUSCARINIC INHIBITION OF NICOTINIC TRANSMISSION IN BULLFROG SYMPATHETIC GANGLIA.** W-X Shen\* and JP Horn. Department of Neurobiology, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

Presynaptic muscarinic modulation was analyzed by recording nicotinic EPSCs from bullfrog sympathetic neurons under 2-electrode voltage-clamp in normal Ringer. Muscarine was bath-applied to cells in which EPSCs were evoked at 0.10 - 0.17 Hz. In B cells, EPSC amplitude was reduced by 60% ( $EC_{50} = 105$  nM, n = 8). Muscarine (0.3 to 3  $\mu$ M) had no effect on EPSCs in 4 C cells. Results from two types of experiment suggest that muscarine acts presynaptically to inhibit evoked acetylcholine (ACh) release. First, in 4 B cells, muscarine did not change nicotinic currents produced by iontophoresis of ACh. Second, when the coefficient of variation (CV) of EPSC amplitude was measured in the presence and absence of muscarine (10 B cells), the CV increased in proportion to the mean level of EPSC inhibition.

Presynaptic muscarinic receptors are activated by ACh that is released during repetitive nerve stimulation. Trains of 40 EPSCs were recorded in control Ringer and 300 nM atropine. Their difference was used to estimate the time course and magnitude of muscarinic inhibition. At 1 Hz, EPSC amplitude progressively declined by 10 - 15% with a latency of 4 - 5 s. At 5 Hz, the latency decreased to 2 s and EPSC inhibition increased to 40%. However, at 20 Hz, EPSC amplitude remained unaltered.

These results show that presynaptic muscarinic receptors in a subclass of preganglionic sympathetic nerve terminals inhibit ACh release during low-frequency stimulation. (Supported by NIH NS21065 and a Grant-in-Aid from the AHA, PA Affiliate).

## 431.16

**$\omega$ -CONOTOXIN GVIA-INSENSITIVE NEUROTRANSMITTER RELEASE IN THE ISOLATED RAT ANOCOCYGEUS MUSCLE: AN ELECTRO-PHYSIOLOGICAL STUDY.** A. B. Smith, R. S. G. Jones\* and T. C. Cunnane. Univ. Dept. of Pharmacology, Mansfield Rd, Oxford, OX1 3QT, U.K.

It is generally accepted that N-type calcium channels control action potential-evoked neurotransmitter release in sympathetic nerve terminals. Low concentrations of the N-type calcium channel blocker  $\omega$ -conotoxin GVIA ( $\omega$ -CTX) irreversibly abolished excitatory junction potentials (EJPs) evoked by nerve stimulation at  $\leq 10$  Hz ( $\leq 5$  stimuli). In the present study we have investigated the effects of  $\omega$ -CTX on EJPs evoked by higher frequencies of nerve stimulation.

Conventional intracellular microelectrode techniques were used and changes in membrane potential of individual smooth muscle cells were recorded to monitor neurotransmitter release. Trains of stimuli at 5-50 Hz were delivered through Ag/AgCl electrodes positioned close to the point of insertion of the pelvic nerves supplying the anococcygeus muscle.

Low concentrations of  $\omega$ -CTX (10 nM) greatly reduced all EJPs in trains of 3 to 5 stimuli at 10 Hz. When the frequency of stimulation was increased (10-50 Hz) trains of stimuli evoked EJPs even in the presence of 1  $\mu$ M  $\omega$ -CTX. We have termed this  $\omega$ -CTX-resistant release 'residual release'. EJP amplitude depended on both the frequency and number of stimuli in a train.

'Residual release' was inhibited to some extent by the P-type calcium channel blocker  $\omega$ -Agatoxin IVA (100 nM). However, even in the presence of both toxins, longer trains of stimulation could still evoke neurotransmitter release.

Therefore, it would appear that a heterogeneous population of calcium channels is involved in mediating norepinephrine release from these sympathetic nerve terminals.

## 431.18

**NMDA-INDUCED CHLORIDE CURRENT IN PC12 CELLS**

A. Yoshida\*, H. Takagi, Y. Kudoh and T. Yoshioka. Department of Molecular Neurobiology, Waseda University, Tokorozawa, Saitama 359, JAPAN. \*Tokyo University of Pharmacy and Life Science, Hachioji, Tokyo 192-03 JAPAN.

NMDA receptors have been shown to participate in synaptic plasticity and neuronal cell death. This type of glutamate receptor has a high permeability to  $Ca^{2+}$ . In this study, we found a novel NMDA-evoked inward current which was a slowly activated after NMDA application to whole-cell voltage-clamped PC12 cells, and these responses appeared in the presence of up to 10  $\mu$ M NMDA. The inward current induced by 100  $\mu$ M NMDA was blocked by the competitive NMDA antagonists AP7 and APV (100  $\mu$ M). However, no NMDA-dependent increase in  $[Ca^{2+}]_i$  was detected by fura-2- $Ca^{2+}$  measurement, and unusually the reversal potential of the NMDA-dependent current was nearly -40 mV. To determine whether  $Cl^-$  could cause the NMDA-evoked current, the reversal potential was measured at various  $[Cl^-]_i$ . The reversal potentials were shifted to the positive side by increasing  $[Cl^-]_i$  and fitted the calculated value. It was previously reported that syntaxin 1B forms an NMDA receptor channel in a *Xenopus* oocyte expression system. The properties of the syntaxin channel were similar to the NMDA-dependent  $Cl^-$  channel in PC12 cells detected in this study. To examine whether syntaxin forms this  $Cl^-$  channel, we treated the PC12 cells with botulinum neurotoxin C1 (BoTx C1) which specifically cleaves syntaxin and blocks transmitter release. The treatment of toxin prevented the NMDA-induced inward current. However, the treatment of BoTx A and C, which don't cleave syntaxin but block transmitter release, also blocked this current. These results suggest that the NMDA stimulation opened  $Cl^-$  channels in relation to exocytotic events in PC12 cells.

## 431.19

SEROTONIN PROLONGS ACTIVITY-DEPENDENT SYNAPTIC ENHANCEMENT AT CRAYFISH NEUROMUSCULAR JUNCTION S.-M. Qian\* and K.R. Delaney Dept. of Biosciences, Simon Fraser University, Burnaby, B.C., Canada V5A 1S6

Recovery of activity-dependent synaptic enhancement (ADSE) after moderate trains of action potentials (30 secs, 15 Hz) exhibits characteristic rapid ( $\tau < 1$  sec; facilitation) and slow ( $\tau \approx 10$  secs at 15.5°C; augmentation) phases. Serotonin (5-HT) increases the amplitude of excitatory junctional potentials (ejps) at crayfish neuromuscular junction (nmj) by 2-5 fold through presynaptic mechanisms (e.g. Dixon and Atwood 1985; 1989). To explore possible neuromodulation of ADSE, we have examined the effect of 5-HT on ejps after trains of action potentials. 5-HT (1  $\mu$ M) slows the recovery of the slow phase of ADSE up to 4.5 fold ( $2.92 \pm 1.20$ , mean  $\pm$  sd;  $n=16$ ) without changing the initial magnitude of slow ADSE measured immediately after the train. Reducing extracellular  $[Ca^{2+}]$  by 50% reduces transmitter release but has little or no effect on the prolongation of ADSE by 5-HT, suggesting the prolongation is not an artifact of saturation of transmitter release. The prolongation of ADSE and enhancement of eip amplitudes reverse with a similar time course during several hours of washing (linear correlation,  $r=0.84$ ). Preliminary data indicate that the effects of 5HT on the slow phase of ADSE may result from increased intracellular  $Ca^{2+}$  buffering, either the amount or the affinity of endogenous  $Ca^{2+}$  buffer. However, it is not consistent with a slowing of  $Ca^{2+}$  removal by pumps. Such neuromodulation of the time course of decay of ADSE may be important for the implementation of time-integrative properties of neural networks particularly for storage of short-term memory "traces". ## 431.20

DIRECT RECORDING OF A HIGHLY CALCIUM-SENSITIVE POTASSIUM CHANNEL ON THE PRESYNAPTIC NERVE TERMINAL OF THE CHICK CILIARY GANGLION. Sun, X.P.\* and Stanley, E.F. SMS, NINDS, NIH, Bethesda, MD 20892.

$Ca^{2+}$ -activated potassium channels have been localized to presynaptic nerve terminals (Robitaille, et al.: *Neuron*, 11:645) where they are believed to be important in the termination of action potential gated transmitter release. We have examined these channels by patch clamping on the calyx presynaptic nerve terminal of chick ciliary ganglion. A  $Ca^{2+}$  and voltage-sensitive potassium channel was recorded with a single channel conductance of  $219 \pm 15.1$  pS ( $n=8$ ). The open probability of the channel was half maximal in 100 nM  $Ca^{2+}$  at +40 mV and exhibited an e-fold change over  $33.5 \pm 6.5$  mV ( $n=3$ ). The channel was blocked by charybdotoxin (10 nM) but not by apamin. The high calcium sensitivity of the presynaptic terminal maxi-K<sup>+</sup> channel suggests that it plays an important role in defining the time course of transmitter release.

EFFECTS OF THE PESTICIDE ALDICARB ON CHOLINERGIC TRANSMISSION M.F.M. Braga, O.V. Sousa, M.D. Santos, L.E.F. Almeida, W.S. Cortes, W.M. Cintra, Y. Aracava\*, and E.X. Albuquerque Lab. Mol. Pharmacol., IBCCF, UFRJ, Rio de Janeiro, RJ 21944, Brazil; Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201, USA.

The carbamate aldicarb (ALD), like other cholinesterase (ChE) inhibitors, has been reported to interact directly with the muscle nicotinic receptor (nAChR, *Soc. Neurosci. Abs.* 20: 1138, 1994). In the present study, we investigated the effects of ALD on the neuromuscular transmission in various preparations. In  $Mg^{2+}$ -paralyzed sciatic nerve-sartorius muscle preparation from frog (*L. ocellatus*), ALD (0.1-300  $\mu$ M) increased the amplitude and prolonged the decay time constant of evoked and spontaneous end-plate potentials (EPP) in a concentration-dependent manner. These effects could not be fully explained by the anti-ChE activity of ALD, because maximal ChE inhibition could be obtained with 10  $\mu$ M ALD. To investigate whether the effects of ALD (30-300  $\mu$ M) could be attributed to a direct interaction of this compound with the muscle nAChR, we applied the whole-cell and the cell-attached modes of the patch-clamp technique to cultured rat myoballs and to frog single muscle fibers, respectively. In rat myoballs, ALD (1-50  $\mu$ M) increased the peak amplitude of ACh (1  $\mu$ M)- or anatoxin-a (1  $\mu$ M)-evoked whole-cell currents, although ALD alone was unable to elicit macroscopic currents. Thus, the potentiating effect of ALD could be the result of its interaction with an allosteric site on the nAChRs. In frog muscle fibers, ALD (1-100  $\mu$ M) decreased the mean open time of ACh-activated single channels and increased the number of brief closures within a burst, indicating that ALD can act as an open-channel blocker at muscle nAChRs. Our findings indicate that in addition to acting as a ChE inhibitor, ALD could facilitate the neuromuscular transmission by acting on an allosteric site on the muscle nAChRs, and that such a facilitation may be counteracted by its open-channel blocking activity. Support: FINEP/UMAB, FINEP, and CNPq.

## 432.3

EFFECTS OF PARAOXON ON HIPPOCAMPAL GABAERGIC-SYNAPTIC TRANSMISSION. Y. Aracava<sup>1,2</sup>, E.S. Rocha<sup>1</sup>, K.L. Swanson<sup>1</sup> and E.X. Albuquerque<sup>1,2</sup> <sup>1</sup>Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., USA; <sup>2</sup>Lab. Mol. Pharmacol. II, IBCCF, UFRJ, Rio de Janeiro, Brazil.

Several studies have suggested that the toxicity of paraoxon, mainly its convulsant properties, are not solely related to the irreversible inhibition of acetylcholinesterase. In the present study, we used the GABA-mediated transmission system in the mammalian central nervous system as a model to study the effects of paraoxon that are not correlated with cholinesterase inhibition. The whole-cell patch-clamp technique was applied to cultured rat hippocampal neurons, and spontaneous miniature postsynaptic currents (sMPSCs) mediated by GABA were pharmacologically identified and recorded. Paraoxon at several concentrations was applied for 5 to 10 min to the neurons. Each concentration was delivered through one of six parallel barrels placed 100  $\mu$ m away from the soma. The frequency, peak amplitude, and decay time constant of the sMPSCs were determined. Paraoxon (300 nM) irreversibly increased the frequency of GABA-mediated sMPSCs to  $180 \pm 15\%$  (mean  $\pm$  SE,  $n=5$ ) of control by a local presynaptic mechanism that was independent of either cholinesterase inhibition or action potential activity. In addition, exposure of neurons to paraoxon (3  $\mu$ M to 1 mM) caused a 30 - 50% reduction of the peak amplitude and decay time constant of the sMPSCs ( $n=9$ ). These blocking properties of paraoxon were immediately reversed upon washing. These data suggest that the marked potentiation of transmitter release and the blockade of GABA<sub>A</sub> postsynaptic receptors may contribute to the toxicity of paraoxon in the mammalian central nervous system. (USPHS Grants NS 25296, ES05730 and T32-ES07263).

## 432.2

DOES (+)-AMPHETAMINE FACILITATE THE TRANSMITTER RELEASE OF MOTOR NERVE ENDING? M.C. Tsai\*, Y.H. Chen, and C.C. Ho. Department of Pharmacology College of Medicine, National Taiwan University, Taipei, Taiwan R.O.C.

(+)-Amphetamine has powerful CNS stimulant action and causing dopamine release in the brain. However, it decreased the amplitude of end plate potential (EPP). The effect of (+)-amphetamine on synaptic transmission and motor nerve terminal activity were assessed on mouse *triangularis sterni* nerve-muscle preparations. The perineural waveforms were recorded with extracellular electrodes placed in the perineural sheath of motor nerves. (+)-Amphetamine (13.6  $\mu$ M) decreased the components of waveforms associated with potassium current and the slow potassium current of nerve terminal while it had no effect on that associated with the sodium, calcium and the calcium activated potassium currents of the nerve terminal. (+)-Amphetamine also increased the frequency of spontaneously generated MEPP and the quantal content of EPP. However, (+)-amphetamine decreased the amplitude of EPP. The MEPP was diminished in amplitude to the extent that the EPP was reduced despite an increase in quantal content. It is concluded that amphetamine decreased the potassium current in the nerve terminal. The effect may contribute to the pharmacological actions of amphetamine on synaptic transmission (Supported by NSC-82-0420-B002-M10 and NSC-84-2331-B002-107).

## 432.4

N-ETHYLMALIMIDE (NEM) BLOCKS DEPOLARIZATION-INDUCED SUPPRESSION OF INHIBITION IN RAT HIPPOCAMPAL PYRAMIDAL CELLS. B.E. Alger\*, T.A. Pitler, and J.J. Wagner Univ. Maryland Sch. Med., Baltimore, MD 21201.

Depolarization-induced suppression of inhibition (DSI) is the transient decrease in GABA<sub>A</sub> IPSCs that follows the activation of CA1 pyramidal cells or Purkinje cells with brief trains of action potentials or a voltage step (Pitler and Alger, 1994, *Neuron*, 13:1447-55). DSI lasts 60-120 s and is mediated by a retrograde signalling process (Pitler, et al., *Soc. Neurosci. Abstr.*, 1995). DSI is blocked in slices from pertussis-toxin-treated hippocampi, implying the existence of a G-protein-linked step somewhere in the DSI process. It will be useful to apply the criterion of G protein sensitivity in future studies of DSI, but treatment with pertussis toxin itself is laborious, and the technique does not permit confirmation of the capability for DSI in any given pertussis-toxin-exposed cell.

N-ethylmaleimide is a sulfhydryl alkylating agent that inhibits certain G-protein-mediated actions (e.g., Shapiro et al., 1994, *J. Neurosci.*, 14:7109-16). We now report that bath-applied NEM blocks DSI of spontaneous inhibitory postsynaptic currents (sIPSCs) recorded under whole-cell voltage clamp in neurons recorded from rat hippocampal slices. A high-[Cl<sup>-</sup>]-containing intracellular solution was used, and DSI was induced by 1-s, 60-mV depolarizing steps from -70 mV. NEM did not alter IPSCs or passive cell properties, although it did block G-protein-mediated baclofen responses. The NEM method is easy to apply and permits study of DSI in a cell prior to and after the G proteins are blocked. These results support the hypothesis of G protein involvement in DSI. Supported by NS30219 and NS22010 to B.E.A.

## 432.5

ZINC MODULATES INTRACELLULAR CALCIUM IN SALAMANDER ROD PHOTORECEPTORS. I.U. Willcockson<sup>1</sup>, P. Saggau<sup>2</sup> and S.M. Wu<sup>2\*</sup>. Dept. of Molecular Physiology & Biophysics<sup>1</sup>, Division of Neuroscience<sup>2</sup>, Cullen Eye Institute, Baylor College of Medicine, Houston, Tx 77030.

Dim background light increases the gain between rod photoreceptors and second-order neurons in the salamander retina. One possible mechanism involves modulation of the presynaptic calcium current, via neurotransmitters/modulators. Using retinal whole mounts,  $Zn^{2+}$  (5-50  $\mu M$ ) blocked synaptic transmission from photoreceptors to second-order neurons. Patch-clamping rods in retinal slices showed that  $Zn^{2+}$  reversibly and dose-dependently inhibits the  $Ba^{2+}$  current with an  $IC_{50}$  of 20 - 50  $\mu M$ .

To measure presynaptic calcium, rods were isolated enzymatically from the retina of larval tiger salamanders (*Ambystoma tigrinum*), and plated onto dishes coated with Sal-1 antibody (courtesy of P. MacLeish). Cells were bath-loaded for 10-20 min with the calcium indicator Fura-2 AM (5 mM) and examined on an inverted microscope. Fluorescence, excited at 380 nm, 360 nm and 340 nm, was recorded from the synaptic terminal of individual rods using a single photodiode. Changes in intracellular calcium were measured using fluorescence ratios.

Perfusing the cells for 2 - 4 min with saline containing 15 mM  $K^+$  and 1.8 mM  $Ca^{2+}$  (high  $K^+$  saline) resulted in an increase in intracellular calcium in the terminal which could be reversed upon washing the cells for several minutes with normal saline. Addition of 100  $\mu M$   $Zn^{2+}$  to high  $K^+$  saline resulted in reduced intracellular calcium increase. Present studies are examining the dose-response for zinc as it affects changes in intracellular calcium levels in the synaptic terminal as well as other potential sites of  $Zn^{2+}$  action.

## 432.7

INTRACELLULAR CADMIUM REDUCES PAIRED-PULSE FACILITATION AT A SYNAPSE BETWEEN IDENTIFIED LEECH NEURONS IN CULTURE. Y. Liu<sup>\*</sup> and E. F. Stanley. Synaptic Mechanisms Section, NINDS, NIH, Bethesda, MD 20892.

Previous studies have indicated that cadmium affects neurotransmitter release but examining the mechanism of this effect is severely limited by the low permeability of  $Cd^{2+}$  through calcium channels. We have used the cultured leech Retzius cell-pair preparation to inject  $Cd^{2+}$  directly into a presynaptic neuron. Neurons were impaled by intracellular electrodes filled with either 3M KCl (control) or 3M KCl plus 0.1M  $CdCl_2$ . One neuron was stimulated with brief duration single or paired-pulses while postsynaptic potentials (PP) were recorded from the other. Facilitation (PP<sub>2</sub>/PP<sub>1</sub>) was significantly lower with  $Cd^{2+}$  in the electrode,  $1.97 \pm 0.32$  (SD; n=3), than in controls,  $3.32 \pm 0.49$  (n=3;  $p < 0.02$ ).

Since facilitation is believed to reflect a step subsequent to calcium entry, this result suggests that cadmium affects synaptic transmission by competing for a calcium binding site.

## 432.9

ZINC INCREASES INTRINSIC EXCITABILITY OF CA3 INTERNEURONS IN ORGANOTYPIC SLICE CULTURES OF RAT HIPPOCAMPUS. Ricciardi, T.N.<sup>\*</sup> and Malouf, A.T. Neurological Surgery R1-20, University of Washington, Seattle, WA 98195.

$Zn^{2+}$  is a modulator of GABAergic synaptic transmission in the hippocampus. Application of exogenous  $Zn^{2+}$  (300  $\mu M$ ) results in net excitation and GABAergic giant depolarizing potentials (GDPs) in hippocampal neurons. GABA can cause depolarizations in pyramidal cells when it is focally applied to the dendrites. Thus, GDPs may arise from activation of GABAergic neurotransmission to dendrites of pyramidal neurons. In this study, whole-cell patch and sharp intracellular recordings were used to study the actions of  $Zn^{2+}$  on CA3 interneurons in slice cultures of hippocampus. Interneurons were recorded from stratum pyramidale (SP), stratum oriens (SO), and stratum radiatum (SR). Interneurons were physiologically identified by their characteristic fast spikes, large spike afterhyperpolarization, and lack of spike frequency adaptation. Interneurons were filled with biocytin for subsequent morphological identification. All interneurons showed an increase in intrinsic excitability in the presence of  $Zn^{2+}$ , as determined by an increase in the slope of the input-output response to intracellular current injection.  $Zn^{2+}$  dramatically reduced the spike afterhyperpolarization, which could contribute to the enhanced intrinsic excitability.  $Zn^{2+}$  reduced anomalous rectification (sag), prolonged the membrane time constant, and increased the input resistance. In the majority of interneurons,  $Zn^{2+}$  caused rhythmic bursting and giant depolarizing potentials (GDPs) similar to those previously seen in pyramidal neurons. These data suggest that  $Zn^{2+}$  can alter interneuron activity by increasing their intrinsic excitability and synaptic drive. Supported by NIH-NS28650 (A.T.M.) and NIH-T32NS-07144-15 (T.N.R.).

## 432.6

INHIBITION BY  $Zn^{2+}$  OF URIDINE 5'-TRIPHOSPHATE-INDUCED  $Ca^{2+}$ -INFLUX BUT NOT  $Ca^{2+}$ -MOBILIZATION IN PC12 CELLS. S. Koizumi, K. Nakazawa and K. Inoue<sup>\*</sup>. Div. Pharmacol., Natl. Inst. Health Sci., Kamiyoga, Setagaya, Tokyo 158, Japan

We previously demonstrated that  $Zn^{2+}$  potentiated the responses mediated by P2X<sub>2</sub>-purinoceptors forming non-selective cation channels using rat pheochromocytoma PC12 cells. In the present study, we show that the effects of  $Zn^{2+}$  on the responses mediated by G-protein coupled P<sub>2</sub>-purinoceptors in the cells. Uridine 5'-triphosphate (UTP; 1-100  $\mu M$ ) stimulated a rise in intracellular  $Ca^{2+}$  concentration ([Ca]<sub>i</sub>). This response was decreased to about 30 % by external  $Ca^{2+}$ -depletion, but not abolished. This [Ca]<sub>i</sub> rise was mimicked by 100  $\mu M$  ATP but not by 2-methyl-thio-ATP or  $\alpha, \beta$ -methylene-ATP in the absence of external  $Ca^{2+}$ , suggesting that the response was mediated by P<sub>2</sub>U-purinoceptors, a subclass of P<sub>2</sub>-purinoceptors. The UTP-evoked [Ca]<sub>i</sub> rise consisted of two components; a transient and a sustained one. When external  $Ca^{2+}$  was removed, the sustained component was abolished, on the other hand, the transient component was decreased by about 70 % but did not disappear. These results suggest that UTP induces  $Ca^{2+}$ -mobilization and, subsequently,  $Ca^{2+}$ -influx. The UTP-evoked increase in [Ca]<sub>i</sub> was not affected by  $Cd^{2+}$  (100 & 300  $\mu M$ ) or nifedipine (30  $\mu M$ ), inhibitors of voltage-gated  $Ca^{2+}$  channels, but was significantly inhibited by  $Zn^{2+}$  (10-300  $\mu M$ ) in the presence of external  $Ca^{2+}$ .  $Zn^{2+}$ , however, did not affect the  $Ca^{2+}$  response to UTP in the absence of external  $Ca^{2+}$ . UTP evoked the release of dopamine from the cells. This dopamine release was abolished by  $Ca^{2+}$ -depletion or  $Zn^{2+}$ , but not by  $Cd^{2+}$  or nifedipine. Taken together, the data demonstrate that UTP stimulates P<sub>2</sub>U-purinoceptors and induces a rise in [Ca]<sub>i</sub> both by  $Ca^{2+}$ -mobilization and  $Ca^{2+}$ -influx in PC12 cells. The UTP-evoked dopamine release requires external  $Ca^{2+}$  which may enter the cells through pathway sensitive to  $Zn^{2+}$ , but insensitive to  $Cd^{2+}$  or nifedipine.

$NH_4^+$  DECREASES FREQUENCY BUT NOT AMPLITUDE OF MINI-EPSCS IN CEREBELLAR NEURONS IN TISSUE CULTURE. W. Raabe<sup>\*</sup>. Depts. Neurology and Physiology, VA Medical Center and University of Minnesota, Minneapolis, MN.

$NH_4^+$  plays a role in the pathogenesis of hepatic encephalopathy. To study effects of  $NH_4^+$  on excitatory synaptic transmission, effects on action potential-independent, spontaneous EPSCs (miniEPSCs) were investigated in cerebellar neurons in tissue culture. Whole cell patch clamp recordings were obtained from large neurons (> 15  $\mu m$  Ø) presumed to be Purkinje cells. Extracellular solutions contained TTX (1  $\mu M$ ) and bicuculline (10  $\mu M$ ) to block action potential generation and IPSCs. CNQX (10  $\mu M$ ) completely abolished miniEPSCs indicating that these were generated by glutamate acting on AMPA receptors.  $NH_4^+$  (2.5-5 mM) did not affect the amplitude, however, decreased the frequency of miniEPSCs. Intracellular alkalization with trimethylamine (5 mM) had no effect on amplitude or frequency of miniEPSCs.

$NH_4^+ \geq 2.5$  mM decreases spontaneous transmitter release from cerebellar granule cells, the only excitatory neuron in the experimental preparation, independent of a change in intracellular proton concentrations. The mechanisms by which  $NH_4^+$  decreases transmitter release are currently further investigated. The lack of an effect of  $NH_4^+$  on the amplitude of miniEPSCs indicates that  $NH_4^+$  has no effect on the sensitivity to glutamate of cerebellar postsynaptic AMPA-receptors. This result contrasts with a report that  $NH_4^+$  decreases excitatory synaptic transmission in hippocampus by affecting AMPA-receptors (Brain Res. 632: 225, 1993).

MECHANISMS OF MOSSY FIBER ASYNCHRONY IN THE RAT HIPPOCAMPUS. D.A. Henze<sup>\*</sup> and G. Barrionuevo. Dept of Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.

Previous studies have reported that mossy fiber (MF) excitatory postsynaptic currents (EPSCs) recorded from CA3 pyramidal cells may show inflections during the rising phase suggesting an inherent asynchrony of neurotransmission at this synapse. Two different mechanisms have been proposed to underlie the observed asynchrony: Asynchronous release of quanta (Jonas et al., 1993), and asynchronous MF bouton spiking (Langdon et al., 1993). Asynchronous spiking could reflect heterogeneous conduction velocities, heterogeneous conduction distances, or differential bouton invasion delays. We have studied the MF fiber volley to determine if the MFs exhibit heterogeneous conduction velocities and conduction distances in the hippocampal slice. MF fiber volley recordings were made at 22 °C in the presence of Kynurenic acid (10 mM) or CNQX (10  $\mu M$ ) and MK801 (10  $\mu M$ ) to block synaptic transmission. Stimulation of the *s. granulosum* in the suprapyramidal blade of the dentate gyrus (DG) caused asynchronous MF fiber volleys in area CA3. Following the placement of extensive cuts which removed the hilus, the *s. oriens* and the *s. radiatum*, a synchronous MF fiber volley was observed by direct stimulation and recording in the *s. lucidum* of area CA3. The synchronous MF fiber volley had a conduction velocity of 0.3 m/sec for both anti- and orthodromic conduction. It was also possible to obtain synchronous MF fiber volleys in the intact slice by stimulating the *s. moleculare* in the DG adjacent to the hippocampal fissure. Stimulating the DG at locations progressively closer to the hilus lead to an increasing asynchrony in the MF fiber volley recorded in CA3. We conclude that asynchrony observed in the MF fiber volley is solely due to heterogeneous conduction distances arising from the anti/orthodromic activation of hilar MF collaterals and is not due to different MF fiber conduction velocities. We also conclude that the mechanism underlying the asynchronous unitary MF EPSCs as observed by Jonas et al. (1993) must occur at the level of the bouton and remains to be determined. ## REGULATION OF HIPPOCAMPAL CA3-CA1 PRESYNAPTIC FUNCTION ACROSS DEVELOPMENT T.C. Dumas\* and T.C. Foster, Dept. of Psychology, Univ. of Virginia, Charlottesville, VA, 22903.

Excitatory synaptic transmission increases postnatally in area CA1 of the developing rat hippocampus due, in part, to an increase in presynaptic function. Decreased transmitter release in younger animals might be due to differences in presynaptic receptors. We have measured changes in paired-pulse facilitation of CA3-CA1 synaptic responses during application of putative presynaptic receptor agonists and antagonists to investigate the development of presynaptic inhibition. Evoked field EPSPs (~1mV, 0.1Hz) were recorded in hippocampal slices taken from 3 and 5 week old rats. Paired-pulse stimulation (50ms ISI) was applied in order to measure changes in facilitation before and after bath application (5min) of adenosine (50uM), 1S,3R-ACPD (50uM), or baclofen (15uM). Recording was performed for 10min before and continued for at least 30min after drug application. All three agonists increased facilitation over baseline in the older animals suggesting functional presynaptic modulatory systems at week 5. In contrast to 1S,3R-ACPD which increased facilitation in the younger animals, adenosine and baclofen showed little to no effect at week 3. Decreased effects on facilitation could be due to lack of presynaptic receptors, saturation by endogenous ligands, or basement levels of release probability. After increasing probability with increased  $Ca^{2+}$ , adenosine and baclofen significantly increased facilitation in week 3 slices, indicating the presence of functional presynaptic receptors that are not saturated. Receptor antagonists, (+)-MCPG (250uM), phaclofen (800uM), or DPCPX (1uM), were without effect suggesting no tonic receptor activity. However, theophylline (25uM) decreased facilitation at both ages and the effect was larger in the younger animals. Theophylline could be acting at adenosine receptors or on second messenger systems. Current work addresses these possibilities. Supported by NS31830 to TCF.

## 432.13

## SHORT TERM SYNAPTIC POTENTIATION AND DEPRESSION IN THE PERFORANT PATH - DENTATE GYRUS SYNAPSE.

A. E. Talpalar\* and Y. Grossman, Department of Physiology, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva 84105, Israel.

Synaptic response depends on the amount of neurotransmitter released, and on the availability of postsynaptic receptors. Both factors are affected by previous use. Short term synaptic activity was studied in rat cortico-hippocampal slices. The perforant path was stimulated in the subiculum with series of 5 stimuli at frequencies from 0.1 to 100 Hz, and extracellular field potentials were recorded at the molecular layer of the dentate gyrus. Under these conditions, the responses of the perforant path axons and the presynaptic volley were stable, whereas the population excitatory post synaptic potentials (pEPSP) displayed frequency and time dependent depression. The slope of the fifth pEPSP declined by 5, 14, 32, 61, and 82 % (normalized to the first pEPSP), at 1, 10, 25, 50, and 100 Hz respectively. The synaptic decline was enhanced at 4-8 mM  $[Ca^{2+}]_o$ , and attenuated either at 1mM  $[Ca^{2+}]_o$ , or when  $[Mg^{2+}]_o$  was raised in normal solution containing 2 mM  $[Ca^{2+}]_o$ . At 0.5 mM  $[Ca^{2+}]_o$ , pEPSPs were reduced but were frequency - potentiated. 3.4  $\mu$ M  $\omega$ -conotoxin reduced the synaptic potentials by 50 %. but failed to prevent the frequency-dependent decline. Nifedipine (10-45  $\mu$ M) did not affect synaptic activity. Blockers of calcium dependent potassium channels, apamin (100 nM), charybdotoxin (10-30 nM), and quinidine (75-200  $\mu$ M) were ineffective in reducing the synaptic decline. The modulators of AMPA receptors desensitization, aniracetam (0.7 mM), and cyclothiazide (0.1 mM) prolonged the time course of the single pEPSP, but paradoxically increased its paired pulse depression. Synaptic decline was not affected by the GABA<sub>A</sub> blocker bicuculline methiodide (10 $\mu$ M), nor by the GABA<sub>B</sub> blocker saclofen (0.5 mM). In contrast, the GABA<sub>B</sub> agonist baclofen (1-25 $\mu$ M) and the non- NMDA-R blocker CNQX (0.5  $\mu$ M) diminished the decline. A calcium dependent, glutamate and GABA<sub>B</sub>-modulated mechanism, possibly a specific presynaptic potassium channel, may be responsible for this synaptic depression.

## HETEROGENEITY BETWEEN NON-NMDA SYNAPTIC SITES IN PAIRED-PULSE SYNAPTIC RESPONSES IN CA1 HIPPOCAMPAL NEURONS. D.A. Turner\*, Y. Chen, J. Isaac, M. West and H.V. Wheal, Neurosurg., Neurobiol. and ISDS, Duke Univ., Durham VAMC, Durham, NC, 27710. Physiol. and Pharmacol., Univ. Southampton, Southampton, SO16 7PX, UK.

Dynamic changes in synaptic release probability and synaptic amplitude are critical aspects of neural plasticity. We have developed a Bayesian statistical method which predicts both the likely number of activated synapses (k) and synaptic amplitude and probability without assuming a statistical model (SITE analysis). We analyzed single synaptic site parameters during paired-pulse changes using this approach.

Non-NMDA excitatory synapses onto CA1 hippocampal neurons were activated using microstimulation, block of inhibition, a paired-pulse stimulus protocol and whole-cell recording (n=16 ensembles exhibiting stationarity and <1.5 pA  $\sigma_{noise}$ ). EPSC ensembles (n=375±130) showed 1st pulse=4.61±3.67 pA and 2nd pulse=5.03±3.61 pA, with an average of  $k_1=3.0$  and  $k_2=3.4$  synaptic sites, respectively [to a marginal  $P(k;D)>0.5$ ]. These synapses exhibited significant heterogeneity of both site probability (range 0.03-0.99; mean 1st=0.43±0.31, mean 2nd=0.46±0.32) and site amplitude (range 1.09-19.4; mean 1st=5.20±2.82, mean 2nd=4.75±2.68 pA). There was greater inter-site amplitude variability (CV=77%) than that found at the same site over time (6.5%). Paired-pulse plasticity (depression, potentiation) primarily included alterations in the number of activated synapses and their release probabilities.

Heterogeneity between non-NMDA synapses onto CA1 neurons may preclude use of Poisson or compound binomial statistical models. These data suggest that a wide array of mechanisms may contribute to synaptic plasticity in the CNS, including alterations in the number of synaptic sites as well as parameter values (amplitude, probability) at each site. The Bayesian SITE analysis may also be extended to a time series approach which may give clues to dynamic synaptic plasticity. Supported by NSF (DAT, MW), VAMC (DAT), Wellcome Trust (HVW) and MRC (HVW).

## 432.12

## MUSCARINIC ENHANCEMENT OF DEPOLARIZATION-INDUCED SUPPRESSION OF INHIBITION IN RAT HIPPOCAMPAL PYRAMIDAL CELLS. L.A. Martin, T.A. Pitler, R.A. Lenz, J.J. Wagner\*, and B.E. Alger, Dept. Physiol., Univ. Maryland, Sch. Med., Baltimore, MD, 21201.

Depolarization-induced suppression of inhibition (DSI) is the transient decrease in GABA<sub>A</sub> IPSCs that follows the activation of a hippocampal CA1 pyramidal cell with brief trains of action potentials or voltage steps (Pitler and Alger, 1994, *Neuron*, 13:1447-55). DSI of spontaneous IPSCs is often absent or weak under normal conditions. However, activation of muscarinic receptors with carbachol can enhance or induce DSI. To investigate the mechanism of this effect we examined the dose-response relationship between carbachol (0.1-30  $\mu$ M) and DSI in pyramidal cells in hippocampal slices. We used whole-cell recording pipettes filled with a high-[Cl<sup>-</sup>]-containing solution and studied the ability of a 1-s depolarizing voltage pulse ( $V_H = -70$  mV) to cause DSI of sIPSCs.

At concentrations  $\leq 1$   $\mu$ M, carbachol inhibited the slow outward AHP current elicited by the voltage step and increased the frequency of small to medium sIPSCs (50-200 pA). DSI was not induced by these low levels of carbachol. At 1-3  $\mu$ M, carbachol typically induced the onset of large sIPSCs (>300 pA) and DSI. Further increases in carbachol concentration had little additional effect. In general, however, muscarinic receptor activation is neither necessary nor sufficient for DSI since in some cells carbachol did not induce large sIPSCs or DSI at any dose, and, in other cells, atropine did not block DSI when it occurred in the absence of carbachol. We conclude that muscarinic agonists primarily activate a set of interneurons whose output is particularly susceptible to DSI. Supported by NS 30219 and 22010 to B.E.A.

## 432.14

PATHWAY-SELECTIVE  $\beta$ -ISOPROTERENOL POTENTIATION OF PYRAMIDAL CELL ACTIVATION IN FIELD CA1 OF THE RAT HIPPOCAMPAL SLICE. D. Cooper, D. Dahl, G. Epling, V. Neitek, and G. Moushegian\*, School of Human Development, The University of Texas-Dallas, Richardson, TX 75083.

Norepinephrine or  $\beta$ -isoproterenol (a  $\beta$ -adrenergic agonist) produces potentiation of pyramidal cell activation by the Schaffer Collateral pathway (SC) in hippocampal field CA1. Whether this potentiation is due to direct effects of adrenergic agonists on pyramidal cells, or indirectly via modulation of SC is not known.

The locus of adrenergic potentiation was investigated in the rat hippocampal slice. Independent pathways activating field CA1 pyramidal cells were stimulated by monopolar electrodes placed in mid-stratum radiatum (to activate SC) and in the heavily myelinated perforant pathway (PP) proximal to the hippocampal fissure. After Colbert and Levy, field potential profiles and baclofen were employed to verify isolation of the SC and PP. Intracellular recordings of excitatory postsynaptic potentials (EPSPs) were taken to alternating SC and PP stimulation. Activation of pyramidal cells by the weak PP to field CA1 was enhanced by application of bicuculline methiodide (a  $\gamma$ -amino butyric acid<sub>A</sub> antagonist [1.0  $\mu$ M]).

Concentrations of  $\beta$ -isoproterenol in the range 500 nM - 1.0  $\mu$ M produced significant potentiation of SC-evoked EPSPs, but were without effect on PP-evoked EPSPs. In no experiment did PP-evoked EPSPs undergo potentiation in parallel to potentiation of the SC. Initial EPSPs of only a few mV frequently potentiated to well beyond action potential threshold.

These results are consistent with the hypothesis that adrenergic potentiation of pyramidal cell activation in field CA1 probably involves a pre-synaptic locus.

Supported by grants to DD from the Whitehall Foundation and NSF.

## 432.16

## DIFFERENTIAL MODULATION OF NEUROTRANSMITTER LEVELS IN RAT HIPPOCAMPUS BY ARACHIDONIC ACID. A.J.M. Breukel, E. Besselsen, V.M. Wiegant, C.M.A. Pennartz\*, F.H. Lopes da Silva and W.E.J.M. Ghijsen, Graduate School for the Neurosciences, Institute of Neurobiology, University of Amsterdam, Kruislaan 320, 1098 SM, Amsterdam, The Netherlands.

Glutamate and GABA play an important role in signal transduction in the hippocampus. Release and clearance of these neurotransmitters are regulated by specific messengers. We investigated the modulatory role of arachidonic acid (AA), which may act as a retrograde messenger in synaptic plasticity. Purified nerve terminals (synaptosomes) isolated from rat hippocampus were used to study AA effects on basal release of glutamate, aspartate and GABA and also of the neuropeptide cholecystokinin (CCK).

AA (25  $\mu$ M) increased the extracellular levels of glutamate, aspartate, GABA, and also of CCK under basal conditions. This effect was not due to nonspecific disturbances in the synaptosomal energetic balance (ATP/ADP ratio) or membrane integrity (LDH leakage). The AA-effect on the amino acid levels was completely Ca-independent, suggesting that the fatty acid acts on the cytoplasmic amino acid pool. Although AA is a potent presynaptic PKC activator, no effects of the inhibitors H-7 and sphingosine on Ca-independent amino acid release could be observed, excluding PKC involvement on this process. In contrast, AA-mediated enhancement of CCK release was blocked by these drugs. Possible effects of AA on re-uptake of spontaneously released amino acids were investigated by measuring accumulation of [<sup>3</sup>H]-GABA or [<sup>3</sup>H]-D-aspartate in synaptosomes. Under these conditions, AA inhibited the net Na-dependent uptake of [<sup>3</sup>H]-GABA by 20% and of [<sup>3</sup>H]-D-aspartate by 30%. In addition to its reported effects on stimulated release, especially of glutamate, we conclude that AA enhances basal, extracellular levels of amino acids by inhibition of their Na-dependent uptake, whereas it enhances those of the neuropeptide CCK via presynaptic PKC activation.

## 432.17

CORRELATED PHYSIOLOGY AND ANATOMY OF PYRAMID TO BURST FIRING INTERNEURONE CONNECTIONS IN RAT NEOCORTEX IN VITRO. Jim Deuchars and Alex Thomson, SPON:Brain Research Association, Dept. of Physiology, Royal Free Hospital School of Medicine, London, NW3 2PF, U.K.

Paired intracellular recordings were made using conventional sharp microelectrodes (2M KMeSO<sub>4</sub>/2% biocytin) in rat neocortex in vitro. Synaptic connections from pyramidal cells to spiny, burst firing interneurons were recorded and the cells filled with biocytin for histological analysis. In one pair the average EPSP amplitude recorded in the burst firing interneurone at a postsynaptic membrane potential of -79mV in response to single action potentials was  $1.12 \pm 0.66$  mV. Between 30 and 40% of presynaptic spikes failed to elicit discernable EPSPs in the interneurone. Light microscopic examination revealed 12 close appositions between pyramidal axon and interneurone dendrites. Electron microscopic examination of 6 of these 12 close appositions revealed that they were synaptic contacts. In another pyramidal to burst firing interneurone pair the average EPSP amplitude of  $0.12 \pm 0.21$  mV was associated with 80% apparent failures of transmission to single presynaptic spikes. Electron microscopic examination revealed that 3 of 6 close appositions were synaptic contacts. In response to pairs of presynaptic spikes profound paired pulse facilitation was evident in both pairs. These correlated data indicate that pyramidal terminals onto spiny, burst firing interneurons exhibit a low probability of release.

## 432.19

PRESYNAPTIC CALCIUM INFLUX IS MODULATED DURING MUSCARINIC RECEPTOR-INDUCED PRESYNAPTIC INHIBITION AND LTP AT CA3-CA1 SYNAPSES IN THE GUINEA PIG HIPPOCAMPUS. J. Ojan, L.G. Wu, and P. Saggau\* Div. Neuroscience, Baylor College of Medicine, Houston, TX 77030; \*Dept. Physiology, University of Colorado HSC, Denver, CO 80262.

Cholinergic receptors are involved in the regulation of synaptic transmission. The muscarinic receptor agonist carbachol (CCh) was previously shown to inhibit synaptic transmission and to modulate stimulation-induced LTP. Recently, CCh was found to induce by itself a novel form of LTP (muscarinic LTP, LTP<sub>m</sub>, Auerbach and Segal, *J. Neurophysiol.*, 1994). Ca<sup>2+</sup> influx through voltage-dependent calcium channels (VDCCs) plays a key role in transmitter release. In this study, presynaptic Ca<sup>2+</sup> influx at CA3-CA1 synapses was measured, using a previously developed optical technique (Wu and Saggau, *J. Neurosci.*, 1994), to address the role of presynaptic VDCCs in these modulations of synaptic transmission.

Bath application of 5  $\mu$ M CCh for 20 min inhibited synaptic transmission to less than 10% of baseline (slope of the extracellular field EPSP, low frequency stimulation), during which the presynaptic Ca<sup>2+</sup> influx was reduced to 40-50% of baseline. About 30 min after such CCh application, a long-lasting potentiation developed. This LTP<sub>m</sub> was 150-200% of baseline and lasted for more than 2 hours, during which the presynaptic Ca<sup>2+</sup> influx was enhanced by 20-40% of baseline. Administration of 10  $\mu$ M CNQX and 50  $\mu$ M APV did block glutamatergic transmission, however, this did not prevent the expression of LTP<sub>m</sub>, which developed even without any stimulation. Both CCh effects could be completely blocked by application of the muscarinic receptor antagonist atropine (10  $\mu$ M). Bath application of 1  $\mu$ M CCh produced the same LTP but showed less inhibitory effect.

These results suggest that presynaptic inhibition caused by activation of muscarinic receptors and LTP<sub>m</sub> are both at least partially due to a modulation of presynaptic Ca<sup>2+</sup> influx. Presynaptic inhibition and LTP<sub>m</sub> of synaptic transmission may be differentially regulated by activation of different subtypes of muscarinic receptors.

## 432.18

SINGLE AXON PYRAMID-PYRAMID AND PYRAMID-INTERNEURONE EPSPS COMPARED IN AREA CA1 OF RAT HIPPOCAMPAL SLICES. A. Barclay, J. Deuchars and A.M. Thomson\* Department of Physiology, Royal Free Hospital School of Medicine, London NW3 2PF, UK.

Paired intracellular recordings were made in 450  $\mu$ m thick slices of adult hippocampus from CA1 pyramidal cells and from interneurons at the stratum oriens/alveus border whose axons ramified in stratum lacunosum-moleculare. Of 12 pyramidal-interneurone pairs tested, four were monosynaptically connected. EPSPs elicited in the interneurons by single pyramidal action potentials had mean amplitudes of 0.2-1.1 mV. The proportion of apparent failures of transmission at these connections could be high (16-50%) and paired pulse facilitation was profound (>100%). In contrast, in the one CA1 pyramidal-pyramidal connection studied to date, EPSPs with a mean amplitude of 0.8 mV displayed no apparent failures of transmission under similar conditions and paired pulse depression was apparent. This pyramidal-pyramidal connection appeared to be partially mediated by NMDA receptors.

After recording, cells were filled with biocytin which was visualized using Avidin-HRP and recorded cells identified. Morphological analysis is in progress, but one presynaptic CA1 pyramidal axon appears to contact several basal dendrites of the postsynaptic CA1 pyramidal cell.

NOREPINEPHRINE DIFFERENTIALLY REGULATES SYNAPTIC INHIBITION IN THE RAT HIPPOCAMPUS. V. A. Doze\*, D. E. Bergles, S. J. Smith, and D. V. Madison. Department of Molecular and Cellular Physiology, Beckman Center, Stanford University School of Medicine, Stanford, CA 94305-5426.

Inhibition in the hippocampus is generated by a diverse group of local circuit interneurons which release GABA onto the principal cells. Numerous anatomical studies have suggested that these inhibitory interneurons are a primary target of the dense noradrenergic projection to this area. We have previously shown that norepinephrine (NE) reduced evoked polysynaptic IPSPs in hippocampal slices; however, monosynaptic IPSPs elicited in stratum radiatum were not affected.

In this study, we investigated the actions of NE on evoked monosynaptic IPSPs elicited in the various strata of area CA1 of the rat hippocampus, and compared these to the responses of identified interneurons to NE found in these same strata. Monosynaptic IPSPs elicited in stratum oriens consisted of a fast early IPSP only, whereas IPSPs evoked in stratum lacunosum-moleculare (L-M) near the hippocampal fissure consisted of a GABA<sub>A</sub>-mediated IPSP with a slow time-course (slow early IPSP) followed by a late GABA<sub>B</sub>-mediated IPSP. NE (10  $\mu$ M) caused a small increase (~10%) in the size of monosynaptic fast early IPSPs elicited in stratum oriens. In contrast, both the slow early and late IPSPs produced by L-M stimulation were decreased by >35% in NE (10  $\mu$ M). These results correlate with recordings from identified interneurons showing that those in stratum oriens depolarized in response to NE, while those located in stratum L-M were hyperpolarized by NE.

These results point to an important role for NE in regulating the efficacy of synaptic inputs in both spatial and temporal domains.

## LONG-TERM POTENTIATION: PHYSIOLOGY III

## 433.1

ANALYSIS OF Sr<sup>2+</sup>-INDUCED ASYNCHRONOUS RELEASE IN CA1 HIPPOCAMPAL NEURONS REVEALS CHANGES IN QUANTAL SIZE ASSOCIATED WITH BOTH LTP AND LTD. Stéphane H.R. Oliet\*, Robert C. Malenka and Roger A. Nicoll. Depts. of Cellular & Molecular Pharmacology, Physiology and Psychiatry, University of California, San Francisco CA 94143-0450.

At central synapses extracellular Sr<sup>2+</sup> has recently been shown to reduce the "synchronous" component of excitatory postsynaptic currents and facilitate the "asynchronous" phase of the synaptic response (Goda & Stevens, *PNAS* 91:12942-12946, 1994). The latter is characterized by a tail of quantal events following the decreased synchronous response which originate from the stimulated synapses. We took advantage of this observation to measure the changes in quantal size associated with homosynaptic LTP and LTD of synaptic transmission at Schaffer/collateral-CA1 synapses. When compared to the unitary events associated with the asynchronous component of the evoked response in an independent naive pathway, those originating from potentiated synapses (n=8) showed a significant increase in amplitude (+29.1  $\pm$  2.3%) and frequency (+62.0  $\pm$  26.2%). At depressed synapses the amplitude and frequency of these events were reduced by 18.4  $\pm$  2.3% and 12.4  $\pm$  7.2% respectively (n=7). In 6 cells where the stimulus strength of one pathway was increased, the frequency of unitary events associated with asynchronous release was increased significantly (+165.3  $\pm$  39.4%) whereas their size was unaffected (+3.0  $\pm$  1.2%). The changes in quantal size reported here are consistent with a post-synaptic site for expression of both homosynaptic LTP and LTD while the variations in frequency could reflect either pre- or post-synaptic modifications. Supported by the International Human Frontier Science Program and the NIMH.

## 433.2

HETEROSYNAPTIC LONG TERM DEPRESSION IN THE HIPPOCAMPUS. M. Scanziani\*, R.C. Malenka and R.A. Nicoll. Depts. of Cellular & Molecular Pharmacology, Physiology & Psychiatry; UCSF, San Francisco, CA 94143-0450.

Long term heterosynaptic depression (LTD<sub>H</sub>) of excitatory postsynaptic potentials was studied in the CA1 region of hippocampal slices of 2-4 week old rats using both field and whole cell recordings. Two independent afferent pathways were stimulated by either placing two bipolar electrodes in the radiatum or by placing one in the radiatum and one in the oriens. After blockade of GABAergic transmission, four tetani of 100Hz for 1s delivered to one of the pathways induced LTD<sub>H</sub> of the other synaptic input. LTD<sub>H</sub> could be followed up to 40 min and averaged 85% of baseline. Saturation of homosynaptic LTD (1Hz stim; 10 min; 4x) prevented subsequent generation of LTD<sub>H</sub>. D-APV (25  $\mu$ M) blocked LTD<sub>H</sub> but MCPG (500  $\mu$ M) and nimodipine (50  $\mu$ M) did not.

The NMDA receptors responsible for the induction of LTD<sub>H</sub> could be located either at the synapses of the tetanized pathway or at those synapses which express LTD<sub>H</sub>. The latter case would occur if ambient glutamate levels are high enough to activate NMDA receptors while the cell is being depolarized by the tetanus. We distinguished between these two possibilities by selectively blocking the NMDA receptors of one input with the use-dependent NMDA receptor channel-blocker MK801. LTD<sub>H</sub> could be expressed at synapses functionally devoid of NMDA receptors indicating that NMDA receptor activation at the tetanized synapse is sufficient to induce LTD<sub>H</sub>. Swiss National Science Fund and NIMH.

## 433.3

**INDUCTION OF LTD IN HIPPOCAMPUS *IN VIVO* BY PAIRED-PULSE STIMULATION: ROLE OF PAIRED-PULSE INHIBITION.** E. Thiels<sup>1</sup>, G. Barrionuevo<sup>2</sup>, T.W. Berger<sup>1</sup>. <sup>1</sup>Dept. of Neuroscience, U. Pittsburgh, Pittsburgh PA 15260, and <sup>2</sup>Dept. of Biomedical Engineering and Programs in Neurobiology and Neuroscience, U. Southern California, Los Angeles CA 90089.

We demonstrated that repeated paired-pulse stimulation (PPS; 0.5 Hz) of commissural afferents to area CA1 in hippocampus of anesthetized rats produces NMDA receptor-dependent long-term depression (LTD) at the commissural-CA1 pyramidal cell synapse (Thiels et al., 1994). The stimulation paradigm effective for producing LTD included 200 paired pulses with a 25-ms interstimulus interval (ISI). At this ISI, CA1 pyramidal cell firing to the second pulse of a pair was inhibited completely during most of the train. When the train was delivered in the presence of the GABA<sub>A</sub> receptor antagonist, bicuculline, paired-pulse inhibition during the train was largely abolished and LTD failed to develop. When the ISI was lengthened to 1000 ms, paired-pulse inhibition was absent and, again, LTD failed to develop. To characterize the relation between paired-pulse inhibition and the ability of PPS to induce LTD in intact hippocampus, we assessed the effect of various ISI durations on pyramidal cell firing to the second pulse of a pair and on the induction of LTD.

During a train with either a 75-ms or a 125-ms ISI, paired-pulse inhibition was present during only the first half of the train and significantly reduced compared to that seen with a 25-ms ISI. The amplitude of the CA1 population spike (PS) evoked by the second pulse of a pair for the first 100 pairs was 70±22% of pre-train baseline level for the 75-ms ISI (n=8) and 67±20% for the 125-ms ISI (n=8). In parallel with the attenuated amount of inhibition, the train with a 75-ms ISI caused a smaller reduction in the amplitude of the PS evoked 30 min after the train (-46±8%, compared to -76±6% for the 25-ms ISI). However, the train with a 125-ms ISI failed to produce a lasting depression in PS amplitude (-10±9%). During a train with a 200-ms ISI, paired-pulse inhibition was absent (the PS amplitude evoked by the second pulse for the first 100 pairs was 141±24% of baseline; n=6), and this train produced no change in PS amplitude (-3±7%). These findings indicate that temporal overlap of postsynaptic inhibition and excitatory synaptic activation of CA1 pyramidal cells alone is not sufficient to induce LTD *in vivo*. (Supported by ONR, NIMH, NIH, and BMSR).

**QUANTAL ANALYSIS OF LONG TERM DEPRESSION AT EXCITATORY SYNAPSES ON CA1 PYRAMIDAL NEURONES.** S.P. Perrett<sup>1</sup>, C. Stricker and S.J. Redman. Division of Neuroscience, John Curtin School of Medical Research, Australian National University, Canberra, Australia.

Long term depression (LTD) of transmission at CA1 synapses is thought to be the complementary process to long term potentiation (LTP) that can allow synaptic weights to remain flexible in response to different patterns of afferent activity. However, the precise mechanisms through which such changes in synaptic strength occur are unknown. The changes that occur in EPSCs of pyramidal cells following the induction of LTD were investigated using quantal analysis. Hippocampal slices obtained from young rats (17-24 days) were prepared using conventional techniques and maintained at 30°C. Small EPSCs (average peak amplitude <10 pA) were evoked by extracellular stimulation of stratum radiatum and recorded using whole cell techniques. Control records were obtained at 0.33 Hz, and homosynaptic LTD was then induced by a prolonged period of 1 Hz stimulation with the membrane potential maintained at -70 mV. When a noticeable reduction of the EPSC had occurred, 0.33 Hz stimulation was resumed, and conditioned responses were recorded for at least 30 mins. Probability density functions of the peak amplitudes of the control and conditioned EPSCs were constructed and quantal analysis followed the procedures described in Stricker *et al.*<sup>1</sup>. Four EPSCs have been analysed for which the control responses were clearly quantised, and for which a significant and stable reduction of the EPSC was maintained for >30 min. For three EPSCs, the quantal current decreased following conditioning (21%, 21%, and 51%), while no change occurred in the fourth. The probability of response failures increased and the probability of multiquantal responses decreased for all EPSCs following conditioning. These results are very similar, though opposite in direction, to changes recently observed for quantal analysis of LTP, and suggest that the mechanisms responsible for LTP and LTD may be complementary.

## 433.7

**HOMOSYNAPTIC LONG TERM DEPRESSION IN THE DEVELOPING RAT DENTATE GYRUS.** L. Kojic<sup>\*</sup>, R.M. Douglas, M.S. Cynader. Department of Ophthalmology, University of British Columbia, 2550 Willow St., Vancouver, B.C. Canada V5Z 3N9.

Long-term depression (LTD), an activity-dependent decrease in the strength of synaptic transmission, has been described in several brain regions. Heterosynaptic LTD has been frequently reported in dentate gyrus (DG) granule cells, indicating that synaptic efficacy could be decreased in nonactive synapses. However, homosynaptic LTD induced by prolonged low frequency stimulation of perforant path-granule cell synapses has been proven difficult to obtain, either *in vivo* or *in vitro*. The aim of this study was to examine the age as a factor in the induction of homosynaptic LTD in the DG *in vitro*. Recordings of field potentials were made from the molecular and granule cell layers of hippocampal slices from Wistar rats 4-93 days of age. Dentate granule cells were synaptically activated by electrical stimulation of the molecular layer (0.067 Hz), while LTD was induced by using prolonged low frequency (LFS) afferent stimulation (1 Hz, 900 pulses). This form of LTD was input specific, was saturable upon repeated stimulation and was reversible by induction of LTP. Homosynaptic LTD was most frequently induced in young animals at up to 3 weeks of age (21/29=72%). In the first two weeks LTD was clearly seen in the granule cell layer, expressed mostly as a long-lasting depression of the population spike. At the same age, LFS could induce either LTD or LTP of the molecular layer EPSP, simultaneously with the LTD observed in the granule cell layer. Later in DG development (3-8 weeks), homosynaptic LTD was produced in both molecular and granule cell layers, but at a lower frequency (12/23=52%) than it was in younger animals. In mature animals (8-12 weeks) this LTD was not inducible in either layer of the dentate gyrus (0/4=0%). Modulation of GABAergic transmission by bicuculline (0.1-10 μM) and muscimol (1-10 μM), during the first five weeks of age, did not significantly change the occurrence of homosynaptic LTD. The results suggest that this form of synaptic plasticity is developmentally regulated in the DG, in a manner complementary to the developmental pattern of dentate gyrus LTP.

## 433.4

**MAINTENANCE OF LTD IN HIPPOCAMPUS *IN VIVO* IS ACCOMPANIED BY INCREASED PROTEIN PHOSPHATASE ACTIVITY.** E.D. Norman<sup>\*</sup>, G. Barrionuevo, E. Klann, E. Thiels. Department of Neuroscience, University of Pittsburgh, Pittsburgh PA 15260.

Repeated paired-pulse stimulation (PPS; 0.5 Hz) of the commissural fibers has been shown to induce NMDA receptor-dependent long-term depression (LTD) of the commissural input to CA1 pyramidal neurons in the hippocampus of anesthetized rats (Thiels et al., 1994). It has been suggested that protein phosphatase (PPase) activity participates in NMDA receptor-dependent LTD induced by low-frequency stimulation in hippocampal slices (e.g., Mulkey et al., 1993). To determine whether an increase of PPase activity accompanies LTD induced by PPS in hippocampus *in vivo*, we measured PPase activity in homogenates of dorsal area CA1 (recording site) 30 min after the final train of 200 paired pulses (25-ms interpulse interval) delivered to the contralateral dorsal area CA3.

Tissue from dorsal and ventral (control) area CA1 was homogenized in buffer and added to reaction mixtures that included phosphorylase kinase (PK), a general PPase substrate. Incorporation of <sup>32</sup>P into the α and β subunits of PK was quantified using autoradiography and densitometry. Initial experiments indicated no difference in PPase activity between dorsal and control tissue using this assay. Three trains of PPS produced a significant reduction in the amplitude of the evoked CA1 population spike (PS; 22±8% of baseline; n=8). This effect was accompanied by a significant decrease in the phosphorylation of the α subunit of PK (<sup>32</sup>P remaining = 79±7% for dorsal and 94±7% for ventral) but not of the corresponding β subunit (90±3% and 98±3%, respectively). These findings indicate that LTD induced by PPS in intact hippocampus is associated with an increase in PPase activity. Injection of the NMDA receptor antagonist, D-APV (100 μM), near the recording site blocked the induction of LTD (evoked PS amplitude: 88.5±11.2% of baseline; n=3) and attenuated the increase in PPase activity (<sup>32</sup>P remaining on the α subunit of PK = 93±7% for dorsal and 92±4% for ventral). These findings indicate that NMDA receptor activation is necessary for the enhancement of PPase activity associated with LTD. Taken together, our findings suggest that PPase activity plays a role in the maintenance of NMDA receptor-dependent LTD in hippocampus *in vivo*. (Supported by NIMH and NINDS).

## 433.6

**PROPERTIES OF LTP AND LTD DURING THE CHOLINERGIC THETA STATE.** P.T. Huerta<sup>\*</sup> and J.E. Lisman. Center for Complex Systems, Brandeis University, Waltham, MA 02254-9110.

Cholinergic modulation (50 μM) of the rat hippocampal slice activates a theta (θ) network oscillation and makes CA1 synapses highly plastic. In this state, a single burst of only 4 pulses (100 Hz) to the Schaffer inputs induces LTP if given at the peak of θ. In potentiated pathways, two types of LTD can be elicited by a burst. Homosynaptic LTD is produced by a burst at the trough of θ; heterosynaptic LTD is obtained in inactive synapses when other synapses are stimulated at the peak of θ. The scheme below summarizes the synaptic changes during θ. Numbers indicate % of maximal LTP, or % of total reversal in stimulated (s) and unstimulated (ns) pathways (n=10, each).

These synaptic modifications can be saturated and require muscarinic receptors since they are blocked by scopolamine (1-5 μM). Cholinergic LTP occludes with standard LTP and like standard LTP, exhibits a cooperativity requirement (threshold for LTP was ~20% maximal stimulation). We conclude that the similar bursts observed during θ *in vivo* may be a natural stimulus for synaptic modifications, and that it is the timing rather than the frequency of stimulation that determines the sign of the change.

## 433.8

**THE INVOLVEMENT OF ADENOSINE A1 RECEPTOR ACTIVITY IN THE INDUCTION OF LONG-TERM DEPRESSION** Kunio Kato<sup>\*</sup>, Anne Williamson. Dept. of Surgery, Yale University School of Medicine, New Haven, CT 06520, U.S.A.

Long-term potentiation (LTP) is a widespread phenomenon in the central nervous system and is proposed as a mechanism for memory formation. Long-term depression (LTD) is another form of synaptic plasticity, which decreases the synaptic response. LTD is regarded as a 'forgetting' mechanism, since LTP and LTD are induced alternately. We investigated the role of adenosine receptor activation in LTD induction. 500 μM hippocampal slices were prepared from 20-25 days old rats, and field EPSPs and EPSCs were monitored using field and whole cell recordings. 2 Hz stimulation was applied for 15 min (low frequency stimulation; LFS) to induce LTD (-19.8 ± 0.9%; N=20). 8-Cyclopentyl-1,3-dipropylxanthine (DPCPX) 0.1 μM and 2 μM 8-Cyclopentyl-1,3-dimethylxanthine (CPT), adenosine A1 receptor antagonists, blocked LTD induction (+3.5 ± 0.3%; N=8). Adenosine deaminase 2 IU/ml also blocked the induction of LTD (N=3). 0.2 μM DPCPX and 5 μM CPT which is applied after LTD induction reversed LTD. This reversal effect was more obvious when these drugs were applied closer to the time of LTD induction. These data suggest that adenosine A1 receptor activity is essential for the induction of LTD. The site of LTD expression was investigated using a failure study under whole cell voltage clamp. These data indicated that the site of LTD expression is presynaptic. Application of 0.1 μM DPCPX with LFS prevented the induction of LTD and decreased the number of synaptic failures, suggesting enhancement of transmitter release. APV 50 μM, an NMDA receptor antagonist, also blocked the induction of LTD. Application of 50 nM N6-cyclohexyladenosine (CHA), an A1 adenosine receptor agonist, reversed the blocking effect of APV and induced LTD (-15.2 ± 2.8%; N=5). These data suggest that A1 receptor activity which is enhanced by NMDA activation, contributes to the induction of LTD.

## 433.9

REVERSAL OF LONG-TERM POTENTIATION IS DIFFERENT FROM LONG-TERM DEPRESSION. U. Staubli\*, D. Chun, F. Xu & X. Li. Center for Neural Science, New York University, New York 10003.

Previous studies (Staubli & Lynch, 1987, 1990) have shown that theta burst stimulation produces an extremely stable form of hippocampal LTP in area CA1 of awake rats that can be reversed with single pulse stimulation patterned at the frequency of the theta rhythm (5 Hz or theta pulse stimulation). The present set of *in vitro* studies extended these results by demonstrating that reversal of LTP is time dependent and does not require NMDA receptor activation. Specifically, a 1-min episode of theta pulse stimulation delivered 30 sec after LTP induction consistently produced nearly complete reversal. The same stimulation was progressively less effective at causing depotentiation at longer delays with virtually no impact at 15 min. Theta pulse stimulation never produced any depression when delivered to naive (non-potentiated) pathways, consistent with the idea that depotentiation is an active process that reverses increments in synaptic strength of recently potentiated synapses and is effective up to the time at which LTP stabilization is complete. In contrast, we found that a 15-min episode of low-frequency stimulation at 1 Hz produced a 15-20% stable homosynaptic depression (LTD) in adult slices, independent of whether the stimulated pathway was naive or potentiated. Unlike LTP reversal, this LTD effect was not time dependent and was blocked by APV. Moreover, while reversal of LTP by theta pulse stimulation (1 min) is readily obtained both *in vitro* and *in vivo*, we so far have been unable to produce LTD in the awake chronic CA1 preparation, despite the use of extended trains (up to 15 min) of low-frequency stimulation at 1 Hz, 5 Hz or 10 Hz. In sum, the above results do not support the notion that reversal of LTP represents a weak version of LTD, but suggest that the mechanisms underlying LTP reversal and LTD are qualitatively different.

## 433.11

### IMPAIRED MAINTENANCE OF HIPPOCAMPAL LONG-TERM POTENTIATION (LTP) IN MAP 1B-DEFICIENT MICE. M. Zervas<sup>1</sup>, W. Edelmann<sup>2</sup>, R. Kucherlapati<sup>2</sup>, Bruce Wainer<sup>1</sup>\*, and P.K. Stanton<sup>1</sup>. Departments of <sup>1</sup>Pathology, <sup>2</sup>Molecular Genetics, and <sup>3</sup>Neuroscience and Neurosurgery, Albert Einstein Coll. Med., Bronx, NY, 10461.

Mutant MAP 1B/- mice are deficient in the expression of microtubule associated protein 1B (MAP 1B) in the hippocampus, cerebellum, and olfactory cortex, and display a range of clinical phenotypes including tremor, ataxia, and slow growth rates. Electrophysiological recordings of Schaffer collateral-evoked excitatory post synaptic potentials (epps) from field CA1 of hippocampal slices reveals that MAP 1B/- mice (n = 16) display normal short-term potentiation, but show a decremental loss of long-term potentiation (LTP) when compared to slices from wildtype littermates (n = 8). The largest decrement in LTP was observed between 60 and 90 minutes post-tetanus. A separate set of littermates were examined for an extended time of four hours post-tetanus in response to saturating LTP stimulation (100 Hz/2Sec x 3, 5 min apart). Slices from MAP 1B/- mice (n = 6) showed smaller LTP that decayed more rapidly than age-matched wildtype littermates (n = 6). These data indicate that the dendritic expression of the cytoskeletal protein, MAP 1B, is important in the long term maintenance of LTP in hippocampal field CA1.

## 433.13

THE BASOLATERAL AMYGDALA MODULATES THE FORMATION OF HIPPOCAMPAL LONG-TERM POTENTIATION IN VIVO. Y. Ikegaya, K. Abe, H. Saito and N. Nishiyama. Dept. of Chem. Pharmacol., Fac. of Pharmaceut. Sci., The Univ. of Tokyo, Bunkyo-ku, Tokyo 113.

Long-term potentiation (LTP) of evoked potentials in the hippocampus is a form of activity-dependent synaptic plasticity which may underlie learning and memory. The amygdala is involved in emotional and motivational aspects of behavior. Recent behavioral studies have provided evidence that the amygdala modulates hippocampal-dependent memory. Therefore, in the present study, we investigated whether the amygdala contributes to hippocampal long-term potentiation. Male Wistar rats 8-9 weeks old were anesthetized with urethane and  $\alpha$ -chloralose. A bipolar electrode was placed in the entorhinal cortex to stimulate the medial perforant path, and the evoked potential was extracellularly recorded from the granule cell layer of the dentate gyrus. We first examined the effect of surgical lesions (80 °C for 10 sec) of the basolateral amygdala (BLA) on LTP. Synaptic potential evoked by low-frequency test stimulation did not change following lesion of the ipsilateral BLA. However, when tetanic stimulation (30 pulses at 60 Hz) of the perforant path was applied 60 min after BLA lesion, the magnitude of LTP was significantly attenuated. This LTP-attenuating effect of BLA lesion was an ipsilateral and unilateral phenomenon. Lesion of the BLA 20 min after tetanic stimulation did not affect the established LTP. Next, we tested the effect of high-frequency stimulation of BLA on LTP. Although a conditioning stimulation (100 pulses at 100 Hz) of the ipsilateral BLA had no influence on basal transmissions in the perforant path-dentate gyrus synapses, the magnitude of LTP was significantly facilitated, when the BLA conditioning stimulation was applied simultaneously with tetanic stimulation of the perforant path. The BLA conditioning stimulation did not enhance contralateral LTP. The BLA stimulation 1 sec - 10 min prior to tetanic stimulation did not affect LTP. These results suggest that the ipsilateral BLA neurons modulate the induction of LTP in the hippocampal dentate gyrus *in vivo*. Activity-dependent facilitation of hippocampal LTP by the amygdala may underlie associative memory processing with emotion.

## 433.10

SEX DIFFERENCES IN THE EXPRESSION OF HIPPOCAMPAL LTP IN CHRONICALLY PREPARED RATS. T.L. Ivanco\*, C. Trepel, and R.J. Racine. Department of Psychology, McMaster University, Hamilton, ON, Canada, L8S-4K1.

Recent evidence in anesthetized animals indicates that there are sex differences in hippocampal LTP, possibly modulated by hormonal fluctuations during the estrus cycle. We investigated LTP in awake rats to determine the long-term effect of sex on plasticity in the hippocampus. Female rats were chronically implanted with stimulating and recording electrodes in the perforant path and ipsilateral dentate gyrus under somnolent anaesthesia. Baseline input/output evoked response tests were run, and vaginal smears were taken, daily for ten days. Only those females with regular cycles were included in the experiment. Animals were divided into one of three groups: proestrus, estrus, and diestrus. Baseline measures continued until stable I/Os had been collected and smears indicated that the animal was in the appropriate phase of the estrus cycle. High frequency trains at 125  $\mu$ A (pairs of 400 Hz bursts with burst durations of 35 ms, separated by 200ms) were then delivered to the perforant path to induce LTP. Baseline responses were retested 20 minutes, 24 hrs, and 48 hrs following trains. A group of males underwent the same electrophysiological manipulations and served as controls. There were no significant differences in baseline measures between the four groups. All groups showed similar short term potentiation effects in response to the trains. No potentiation was seen in females given trains during the estrus or diestrus phase, whereas both the females stimulated during the proestrus phase and the males showed significant LTP up to 48 hrs after the trains. The stimulation effects in females were not due to the shift from one phase of the estrus cycle to another following trains. We conclude that the induction of LTP here is consistent with the literature based on anesthetized preparations. The difference in LTP induction between males and females is a result of the phase of the estrus cycle the females are in when given trains to induce LTP.

## 433.12

RE-DISTRIBUTION OF DENDRITIC SPINES FOLLOWING LONG-TERM POTENTIATION (LTP) IN THE HIPPOCAMPUS OF THE AWAKE RAT. M.G. Stewart, D.A. Rusakov, G. Richter-Levin, and T.V.P. Bliss. Open University, Milton Keynes, MK7 6AA, and NIMR, Mill Hill, London NW7 1AA, U.K. (SPON: BRA)

The fine composition of dendritic spine populations in hippocampal dentate gyrus was studied 24h after LTP was induced and maintained unilaterally in 7 awake rats. Hippocampi were dissected, and Golgi preparations of granule cells from both potentiated and control hemispheres were analyzed via computerized microscopy. A multifactorial statistical design included paired blocks (potentiated vs control hemispheres), 7-19 neurons per hemisphere, 3 dendritic branch orders per neuron, and 1-5 dendritic fragments (normal to the viewer's sight) per branch order. Identification of spines and quantification of branch-spine geometry was performed using an image recognition algorithm and standard image analysis methods<sup>1</sup>.

Statistical analysis of data obtained from light microscopic images revealed the existence of dense clusters of spines (spine collars) in potentiated and unpotentiated preparations. The frequency of spine collars decreased in 2nd and 3rd branch orders. Comparing potentiated and unpotentiated tissue with unbiased stereological estimators (the tilting disector<sup>1</sup>), we have found: (i) no significant changes in the mean spine density along dendrites; and (ii) a significant change in the variability of dendritic-spine geometry towards less variable spine densities, and more variable spine lengths after LTP, as revealed by principal component analysis.

These results suggest that long-term potentiation in rat hippocampus is accompanied by specific re-arrangement of synaptic connections. [1] Rusakov DA, Stewart MG (1995) *J Neurosci. Meth* (in press)

## 433.14

SELECTIVE BLOCKADE OF THE LATE PHASE OF LTP IN TRANSGENIC MICE EXPRESSING AN INHIBITORY FORM OF THE REGULATORY SUBUNIT OF PROTEIN KINASE A. P. V. Nguyen\*, T. Abel, M. Barad, and E.R. Kandel. Ctr. Neurobiol. & Behav., Columbia Univ., HHMI, New York, New York 10032.

LTP in the CA1 region of the hippocampus can persist for up to 8 hr in slices and for days in intact animals. The late phase of LTP (L-LTP) in CA1 differs from short-term LTP in requiring protein kinase A activity, protein synthesis, and transcription. Indeed, pharmacological inhibitors of PKA selectively block L-LTP. To genetically reduce PKA activity in the hippocampus, we generated transgenic mice that express an inhibitory form of the regulatory subunit of PKA. Expression of this subunit in the hippocampus, cortex, striatum and thalamus was driven by the promoter from the  $Ca^{2+}$ /calmodulin protein kinase II gene. We found that L-LTP was significantly decreased in area CA1 of transgenic mice: the mean field EPSP slope measured 30 min and 3 hrs post-induction in transgenic mice were  $173 \pm 14\%$  and  $105 \pm 6\%$  of pre-tetanus baseline, respectively (n = 6 mice, 22 slices), while wild-type values were  $226 \pm 24\%$  and  $171 \pm 13\%$ , respectively (n = 5 mice, 13 slices, p < 0.05). These results show that targeted suppression of PKA activity eliminates a late phase of LTP in CA1. These transgenic mice provide us with a model system with which to probe the behavioral roles of cAMP, PKA, and L-LTP in the mammalian hippocampus. Biochemical experiments are in progress to determine the effects of this inhibitory subunit on PKA activity, and behavioral studies are underway to investigate effects on spatial learning. [Supported by MRC Canada, Runyon-Winchell Fdn., NIH, and HHMI.]

## 433.15

TETRACYCLINE REGULATED EXPRESSION OF AN ACTIVATED FORM OF CaM KINASE II IN THE FOREBRAIN OF TRANSGENIC MICE. M. Mayford<sup>\*</sup>, L. Wang, K. Podsypanina, and E. R. Kandel<sup>1</sup>. Ctr. Neurobiol. & Behav., Columbia Univ., HHMI, NY, NY 10032.

One of the drawbacks of using genetically modified mice in the study of learning and memory is the lack of temporal control over the expression of the genetic change (Mayford et al., 1995). Recently, Furth et al. (1994) have described a binary system for the regulation of transgene expression in peripheral tissue using tetracycline. We have used this system to drive expression of an activated form of CaM kinase II, that is  $\text{Ca}^{2+}$ -independent due to the introduction of an aspartate at amino acid 286. Previous studies have shown that expression of this mutant form of the kinase shifts the response of hippocampal synapses to low-frequency trains in the 5-10 Hz range, so that LTD is enhanced and LTP is reduced (Mayford et al., *Cell*, in press). Using the tetracycline system combined with the CaMKIIa promoter, we generated mice that show strong transgene expression, which is limited to specific regions of the forebrain. Preliminary results indicate that transgene expression can be blocked by the administration of tetracycline analogs to the mice. The use of this system should allow the developmental consequences of transgene expression to be distinguished from the consequences of acute expression at both the electrophysiological and behavioral level.

## 433.17

#### AGED RATS SHOW INCREASED SENSITIVITY TO LTD-INDUCING STIMULATION

C.M. Norris<sup>#\*</sup> and T.C. Foster<sup>#\*</sup>.  
<sup>#</sup>Neuroscience Program and <sup>\*</sup>Dept. of Psychology, Univ. of Virginia, Charlottesville, VA, 22903

We tested the hypothesis that the rapid decay of long term potentiation (LTP) in aged animals is due to enhanced long term depression (LTD). Low frequency stimulation (LFS) (900 pulses at 1 Hz) depressed CA3-CA1 EPSPs more in slices from aged (21-24 mos) vs young (6-8 mos) Fischer 344 rats (p 05). No age-related differences were found in the magnitude of LTP and LFS delivered 15-20 min post LTP induction significantly reversed LTP in both age groups. However, only aged slices completely reversed to pre-LTP levels. LFS delivered 1 hr after LTP tended to reduce responses more in aged animals. To determine potential changes in the sensitivity to LTP-reversal, multiple short-duration episodes of LFS (6 sets, 30 pulses, separated by 10 min baselines) were employed. Aged rats showed significant reversal after the 1st set of LFS and responses were completely reversed by the 5th set of LFS. Young rats did not show significant reversal until the 5th set of LFS and at no time were responses reversed to pre-LTP levels (see Figure). The results indicate (1) LTD/LTP-reversal can be observed in CA1 of aged rats and (2) aged rats are more sensitive to LTD-inducing stimulation. Together, the findings suggest that LTD mechanisms could play a role in the rapid rate of LTP decay and the rapid rate of forgetting observed in aged animals. Supported by NS31830 to TCF.

## 433.19

#### LONG TERM POTENTIATION (LTP) IS IMPAIRED IN BDNF-DEFECTIVE MICE.

M. Korte, P. Carroll, H. Thoenen, and T. Bonhoeffer<sup>\*</sup>, Max Planck Institute for Psychiatry, D-82152 Munich-Martinsried, Germany.

There is increasing evidence that neurotrophins might be involved in neuronal plasticity. Application of BDNF (brain-derived neurotrophic factor) can induce synaptic strengthening, synthesis of BDNF and of NGF (nerve-growth factor) can rapidly be regulated by physiological stimuli, and secretion can occur from axonal and dendritic processes in an activity-dependent manner. To determine whether BDNF has a function in processes like long-term potentiation (LTP), we produced a strain of mice with a deletion in the coding sequence of the BDNF-gene. We then used hippocampal slices from these mice to investigate whether LTP is affected by this mutation. Homozygous mutant mice show significantly reduced LTP in terms of the magnitude of the potentiation as well as the percentage of cases in which LTP could be induced successfully. This was true intra- and extracellularly. In a number of electrophysiological control experiments we measured responses to the application of GABA, AMPA, and NMDA. Furthermore we measured important anatomical and morphological parameters, like cell shape, cell size, dendritic branching, and spine density. No differences could be detected between wildtype and mutant animals. Paired pulse facilitation as an important parameter for normal synaptic function was also not affected in mutant animals. Since no obvious developmental deficits seem to be responsible for the failure to induce LTP in BDNF-deficient mice we suggest that BDNF is causally involved in the expression of LTP. In an attempt to obtain further support for this notion we are currently testing whether LTP can be "rescued" by re-introducing the BDNF-gene with an adenovirus construct in slices from BDNF-deficient animals.

## 433.16

RESCUING IMPAIRMENT OF LONG-TERM POTENTIATION IN FYN DEFICIENT MICE BY INTRODUCING THE FYN TRANSGENE. N. Kojima<sup>1</sup>, J. Mansuy<sup>2</sup>, J. Wang<sup>2</sup>, M. Pragnell<sup>2\*</sup>, and E. R. Kandel<sup>1</sup>. <sup>1</sup>Lab. Neurochem., Natl. Inst. Physiol. Sci., Okazaki 444, Japan; <sup>2</sup>HHMI, Ctr. Neurobiol. & Behav., Columbia Univ., NY, NY 10032.

To understand the physiological roles of the tyrosine kinase Fyn in the brain, we generated transgenic mice expressing fynB cDNA under the control of calmodulin kinase IIa promoter. Regional distribution and time course of transgene expression were very similar to those of calmodulin kinase IIa mRNA. Strong expression of the transgene was observed in the adult forebrain, but hardly detected in the neonatal brain. To determine whether the impairment of long-term potentiation (LTP) in Fyn deficient mice is caused by the lack of Fyn in the adult hippocampus or by the developmental abnormality observed in neuronal connections, we generated Fyn deficient mice carrying the Fyn transgene. We were able to rescue LTP, at least partially, in the hippocampal slices from these mice, even though we did not rescue the characteristic morphological abnormalities in the hippocampus. These results suggest that Fyn contributes, in part, to the molecular mechanisms of LTP induction.

## 433.18

#### REPEATED CO-ACTIVATION OF THE CORPUS CALLOSUM AND HYPOTHALAMUS INDUCES A LONG-TERM POTENTIATION OF THE NEOCORTEX IN AWAKE BEHAVING RATS.

P.A. Valentine<sup>\*</sup> and G.C. Teskey. Behav. Neurosci. Res. Grp., Dept. of Psychology, Univ. of Calgary, Calgary, AB, Canada T2N 1N4.

The neocortex of the awake, behaving, adult rat has been found to be highly resistant to the induction of long-term potentiation (LTP). However, LTP of the neocortical evoked response has been observed when several sessions of high frequency stimulation (HFS) were applied to the corpus callosum over several days. It has also been shown that modulatory systems, which project to the cerebral cortex, play a role in LTP. This study was undertaken to examine the effects of co-activation of the ascending endogenous modulatory systems and corpus callosum on LTP of the neocortex. Male, Long-Evans hooded rats were chronically implanted with bipolar stimulating electrodes in the corpus callosum and the region of the dorsomedial-posterior hypothalamus (DMPH), and recording electrodes in the neocortex. Following a two-week recovery, baseline input/output (I/O) response curves were generated. These were based on the application of rectangular 200  $\mu$ sec pulses at 11 intensities through the callosal electrodes. The potentials evoked in the neocortex were analyzed for changes in the size (area) of the negative component. This was calculated by subtracting baseline field potentials from post-treatment field potentials. Experimental animals received HFS trains to the callosum concurrent with DMPH stimulation once a day for a total of five days. Post-treatment I/O's were recorded for several weeks. We report potentiation of a late component of the neocortical evoked response to concurrent application of HFS to the corpus callosum and stimulation of the DMPH. Animals that received either HFS to the corpus callosum alone or DMPH stimulation alone showed no change in the evoked response. Supported by NSERC.

## 434.1

## CHANGES IN EARLY AND LATE IPSPs IN CA1 PYRAMIDAL CELLS AFTER HIGH FREQUENCY STIMULATION OF SCHAFER COLLATERALS.

Y. Perez\* and J.-C. Lacaille. Center for Research in Neurological Sciences and Department of Physiology, University of Montréal, Montréal, Qc, Canada, H3C 3J7.

Stimulation paradigms inducing long-term potentiation in hippocampal pyramidal cells will also affect local inhibitory circuits. To investigate plasticity in these circuits, the effect of high frequency stimulation of Schaffer collaterals (100Hz, 1s) was examined on early and late IPSPs using intracellular recordings from CA1 pyramidal cells in conventional rat hippocampal slices. In a first series of experiments with K-acetate containing microelectrodes, the mean amplitude of early IPSPs 30 min after tetanization was increased to  $129 \pm 8.4\%$  of control in 37.5% of cells ( $p \leq .005$ ), decreased to  $67 \pm 4.0\%$  of control in 37.5% of cells ( $p \leq .001$ ) and unchanged in the other 25% of cells. The mean amplitude of late IPSPs was increased to  $142 \pm 4.3\%$  of control in 50% of cells ( $p \leq .04$ ), decreased to  $64 \pm 9.5\%$  of control in 25% of cells ( $p \leq .0001$ ) and unchanged in the remaining 25%. For the pooled data ( $n=8$  cells), mean amplitude of early and late IPSPs were unchanged. In another series of experiments, microelectrodes containing 200mM BAPTA were used to chelate intracellular  $\text{Ca}^{2+}$ . In these conditions,  $\text{Ca}^{2+}$ -dependent afterhyperpolarizations and accommodation were eliminated, and the mean amplitude of early IPSPs was increased 25-30 min after tetanization to  $141 \pm 3.5\%$  of control in all cells tested ( $n=5$ ;  $p < .0001$ ). The amplitude of late IPSPs was increased to  $172 \pm 28.2\%$  of control in 40% of cells ( $p \leq .0001$ ) and unchanged in the other 60%. For pooled cells, the late IPSPs were increased to  $138 \pm 7.2\%$  of control ( $p \leq .0001$ ). These preliminary results suggest that tetanization may result in either potentiation or depression of inhibition in pyramidal cells. Preventing  $\text{Ca}^{2+}$  rises in pyramidal cells blocked the depression and unmasked a reliable potentiation of both early and late IPSPs. Thus, tetanization may produce persistent changes within inhibitory circuits resulting in potentiation of inhibition in pyramidal cells.

## PLASTICITY AT 'SILENT' SYNAPSES EXPRESSING FUNCTIONAL NMDA RECEPTORS ONLY. J.T. Isaac\*, R.A. Nicoll and R.C. Malenka, Depts. of Psychiatry, Physiology and Cellular and Molecular Pharmacology, University of California, San Francisco, CA 94143.

NMDA receptor (NMDAR) activation is required for the induction of homosynaptic LTP and LTD in the hippocampal CA1 region. A recent study on CA1 using the analysis of coefficient of variation suggested that synapses may exist which express functional NMDARs only (Kullmann, *Neuron* 1994, 12, 1111-1120). To examine this possibility, whole-cell recordings were made from CA1 pyramidal neurons in rat hippocampal slices (12-20 day-old) in the presence of 100  $\mu\text{M}$  picrotoxin, and synaptic responses were elicited by minimal stimulation in the stratum radiatum. In 27/73 cells, synaptic events were detected at holding potentials between +30 and +60 mV, at a stimulus intensity which elicited no detectable synaptic response at -60 mV. The responses at positive potentials were completely blocked by D-APV. A comparison of spontaneous activity at -60 mV and +60 mV, using Fourier analysis, also revealed a much higher number of events at +60 mV. These additional events had the same frequency spectrum as evoked NMDAR-mediated EPSCs, and were completely blocked by D-APV. In 10/14 cells at a stimulus intensity which initially elicited no synaptic events at -60mV, AMPA receptor- (AMPA) mediated responses appeared following a pairing protocol (100 stimuli, 1Hz, -10mV). In the 4 cells in which pairing did not cause the appearance of events at -60mV, the existence of NMDAR-mediated responses was confirmed at the end of the experiment. This form of potentiation was stable for the duration of recordings, and in a series of interleaved experiments, was blocked by D-APV. These data demonstrate the existence of synapses that express functional NMDARs but no detectable AMPARs, and suggest that these synapses can undergo a form of LTP in which functional AMPARs are uncovered or inserted into the postsynaptic membrane. THE SPATIAL DISTRIBUTION OF LONG-TERM POTENTIATION IN THE HIPPOCAMPAL CA1 AREA DEPENDS ON THE TEMPORAL INFORMATION T. Aihara<sup>1</sup>\*, M. Mizuno<sup>1</sup>, M. Tsukada<sup>2</sup>, and H. Kato<sup>2</sup>

<sup>1</sup>Dept. of Information-Communication Engineering, Tamagawa Univ., Machida, Tokyo, 194, and <sup>2</sup>Dept. of Physiology, Yamagata Univ., School of Medicine, Yamagata, 999-23, Japan.

Long-term potentiation (LTP) in the CA1 area of hippocampus are highly sensitive to the higher order statistical characteristics of the stimulus (correlation between successive pairs of inter-stimulus intervals) (Tsukada et al. 1994). We observed the change of the spatial distribution of LTP depended on the number of stimulus in a slice preparation from the hippocampus of a guinea-pig by using the optical-imaging method. And we compared the spatial distribution of LTP induced by the temporal-pattern stimuli which have the same mean frequency but different time structure, different correlation, in inter-stimulus intervals.

As the results that the number of the stimulus increase, consequently, the area of LTP came more wide and shifted far from the stimulation site. And the spatial pattern of LTP in CA1 area was made in the area corresponding to the number of stimulus and the temporal-pattern sensitivity in LTP was identified in the area. And they differed depending on the temporal pattern of stimulus; positively correlated sequences were much more effective (large area) in producing LTP, while negatively correlated sequences were ineffective (small area), and randomly correlated sequence were medium. These results suggest that there is a transformation from the temporal pattern into the spatial pattern in the coding process of the hippocampal learning system.

## 434.2

## SATURATED HIPPOCAMPAL LTP IN RATS DOES NOT PRECLUDE ADDITIONAL POTENTIATION AT LATER PHASES. U. Frey\*, K. Schollmeier, K.G. Reymann\* and T. Seidenbecher\*, Inst. Neurobiol., Gene Regul. &amp; Plasticity, \*Neurophysiology, Brennekestr. 6, P.O. Box 1860, 39008 Magdeburg, Germany.

Hippocampal long-term potentiation may serve as an elementary process underlying certain forms of learning and memory in vertebrates. As is the case with behavioural memory, hippocampal long-term potentiation in the CA1 region and in the dentate gyrus exhibits distinct phases. These comprise a short-term early potentiation which lasts 1 to 3 hours and is independent of protein synthesis and is characterized in general by the activation of NMDA-receptors and protein kinases; and a later, longer lasting phase, which can be separated by inhibitors of protein synthesis.

Here, we report that the prior induction of long-term potentiation, both in the dentate gyrus in vivo and in the CA1-region in vitro, precludes further long-term but not short-term potentiation by means of a newly delivered conditioning stimulus to a subset of the same activated synapse population during the early stage (~1-3 hours post tetanus). In contrast, a subsequent, long-lasting potentiation can be induced after the establishment of the late phase of potentiation (>4 hours). Thus, the system preserves the capacity for short-term LTP immediately after potentiation, but the capacity for the induction of longer lasting plastic changes is recovered only after about 4 hours. Our results demonstrate that, once long-term potentiation has been established, hippocampal neurons do not lose their capacity for functional plasticity during certain phases of the maintenance of long-term potentiation.

## 434.4

## INDEPENDENT MECHANISMS FOR LTD OF AMPA AND NMDA RECEPTOR MEDIATED SYNAPTIC TRANSMISSION IN AREA CA1 OF RAT HIPPOCAMPUS. D.K. Selig, G.O. Hjelmstad, C. Herron\*, R.A. Nicoll, R.C. Malenka, Departments of Psychiatry, Physiology, &amp; Pharmacology, University of California, San Francisco, CA 94143.

Long-term depression (LTD) of excitatory synaptic transmission is a long lasting, activity dependent decrease in synaptic strength thought to be important for learning, memory, and neural development. Although LTD of AMPA responses (AMPA LTD) has been well characterized, relatively little is known about LTD of NMDA responses (NMDA LTD). We therefore decided to characterize NMDA LTD and compare its mechanism to that of AMPA LTD.

Using standard electrophysiological techniques to make field and whole cell recordings from area CA1 of the hippocampus, we produced input-specific NMDA LTD (-23±4%) by pharmacologically isolating the NMDA responses (0.1  $\text{Mg}^{2+}$ , 10  $\mu\text{M}$  CNQX, 100  $\mu\text{M}$  picrotoxin) and by applying low frequency stimulation (LFS; 1 Hz, 5-10 min). To determine whether NMDA LTD occurs under more physiological conditions, we first obtained AMPA LTD using LFS (-28±4%), and then pharmacologically isolated the NMDA responses. We found that the NMDA response in the test pathway was reduced relative to the control pathway (-41±5%). This NMDA LTD was blocked when D-APV (50  $\mu\text{M}$ ) was present during LFS.

To assess the mechanism responsible for NMDA LTD, we measured the coefficient of variation (CV) during whole cell voltage clamp recordings in which LTD was induced on pharmacologically isolated NMDA responses. We found that  $(1/\text{CV})^2$  was unchanged following NMDA LTD, implying a decrease in  $q$ , the unquantal NMDA response. Repeating this experiment under normal recording conditions, we obtained simultaneous AMPA and NMDA LTD and found that while AMPA LTD resulted in a proportional decrease in  $(1/\text{CV})^2$ , implying a decrease in  $n$  or  $p$ ,  $(1/\text{CV})^2$  of the NMDA response was again unchanged.

These results suggest that NMDA responses undergo LTD under physiological conditions, and that this LTD has a mechanism different from that of AMPA LTD.

## 434.6

THE LONG-TERM SUPPRESSIVE EFFECTS OF LOW-FREQUENCY STIMULATION ON THE INDUCTION OF LONG-TERM POTENTIATION IN CA1 NEURONS OF GUINEA PIG HIPPOCAMPAL SLICES. S. FUJII<sup>1</sup>), Y. KURODA<sup>2</sup>), K. Ito<sup>1</sup>), Z. CHEN<sup>1</sup>), H. KATO<sup>1</sup>), <sup>1</sup>Dept. of Physiology, Yamagata Univ. Sch. of Medicine, Yamagata 990-23, JAPAN and <sup>2</sup>Dept. of Molecular and Cellular Neurobiology, Tokyo Metropolitan Inst. for Neuroscience, Fuchu-shi, Tokyo 183, JAPAN.

Low-frequency afferent stimuli (LFS) erases LTP (depression); Fujii, et al. Brain Research, 555, 112, 1991) but also suppresses the induction of LTP in CA1 neurons of guinea pig hippocampal slices. The parameters of the LFS (frequencies of 1 and 5 Hz; number of pulses of 80, 200 and 1000; and time-lag prior to tetanus of 20, 60 and 100 min) were altered systematically and their effects on the induction of LTP were evaluated. When the LFS of 1000 pulses at 1 Hz was delivered, the slope of the field EPSP (S-EPSP) and the amplitude of population spike (A-PS) 50-60 min after the LFS were reduced by 3.0 % and 7.5 %, respectively (n=6). Tetanus (100 Hz, 1 s) given 60 min after the LFS failed to induce LTP leaving a short-term potentiation which declined gradually close to the pre-tetanic level within at most 40-50 min. Significantly less effectiveness was observed for the LFS at 5 Hz and the LFS at 1 Hz with either a shorter (20 min) or a longer (100 min) time-lag before tetanus. When the LFS of 1000 pulses at 1 Hz was delivered in the presence of 50  $\mu\text{M}$  APV (D,L-4-amino-5-phosphonovaleate), the S-EPSP and the A-PS 50-60 min after the LFS were considerably potentiated by 24.8 % and 31.8 %, respectively (n=6) and tetanus given 60 min after the LFS resulted in the induction of LTP. Therefore, the mechanisms of this particular form of synaptic plasticity may involve in the activation of NMDA receptor /  $\text{Ca}^{2+}$  channels by low-frequency synaptic inputs.

## 434.7

INTRACELLULAR CORRELATES OF EPSP-TO-SPIKE POTENTIATION. L.W. Campbell\* and T.J. Sejnowski. Howard Hughes Medical Institute, The Salk Institute for Biological Studies, La Jolla, CA 92037

EPSP-to-Spike (E-S) potentiation has been observed in the rat hippocampus following stimulation trains which lead to LTP in the CA1 cell layer. Most commonly, E-S potentiation is noted as a potentiation in the population spike amplitude in excess of that predicted by the potentiation of the field EPSP slope. Jester, *et al.* (J Physiol., 1995) reported an associative stimulation paradigm which directly produces an E-S potentiation with no change to the EPSP slope. Further work with field potentials recordings and GABA<sub>A</sub> antagonists suggest that GABA<sub>A</sub> receptors are necessary for the expression of this associative E-S potentiation. What are the intracellular correlates of associative E-S potentiation and in what way are GABA<sub>A</sub> receptors involved in its expression?

Intracellular recordings were made from 75 g male Sprague-Dawley rats using sharp electrodes filled with 2M potassium acetate. In order to measure Na spike excitability and accommodation, a series of intracellular depolarizing 150 ms D-C current injections were given at approximately 5 minute intervals. The population spike amplitude and EPSP slope were monitored every 20 seconds with a single shock to the Schaffer-Collateral pathway. The associative tetanization consisted of 50 bursts of 5 antidromic pulses at 100 Hz with an interburst interval of 200 ms, paired with one shock to the Schaffer-Collaterals per antidromic burst.

Tetanization resulted in a slowly developing depolarization of the RMP and an increase in spikes generated in the intracellular current injection series. Counteracting the depolarization with holding current did not fully counteract the increase in spikes generated in the series. Changes in the GABA<sub>A</sub>-mediated IPSP do not appear to contribute to the expression of E-S potentiation.

## 434.9

CA2 REGION MODULATES ACTIVITY PROPAGATION FROM CA3 TO CA1 IN RAT HIPPOCAMPAL SLICES. Y. Sekino<sup>1</sup> and K. Ohata<sup>2\*</sup>. <sup>1</sup>PRESTO Res. Develop. Co. of Japan, c/o Mitsubishi-kasei Inst. of Life Sci., Machida, Tokyo 194, <sup>2</sup>Lab. Neurochem., National Inst. for Physiol. Science, Okazaki 444, Japan.

Many electrophysiological studies on hippocampal slices and theoretical analysis of hippocampal function have been performed on the basis of a classical trisynaptic circuit from the perforant path to CA1 in the transverse section. We previously reported the existence of a delayed synaptic transmission between CA3 and CA1 in rat hippocampal slices cut rather obliquely along alveus fibers and suggested the involvement of the CA2 region (Soc. Neurosci. abst. 907,19,1993). In the present study, we investigated the pharmacological properties of this local circuit around the CA2 region with an optical measurement system (Fuji SD1001). Slices were stained with a potential sensitive dye, RH-482, and mossy fibers were electrically stimulated to produce synaptic excitation of CA3 and CA1 neurons. In some slices the delayed CA1 activity was not induced by the CA3 activation. When those tissues were treated with disinhibitory agents, the activity around the CA2 region was induced and the CA1 region was activated. These data suggest that the region including CA2 usually has a high threshold of excitation that is controlled by GABAergic and/or purinergic inhibitory systems. We propose that the CA2 region acts as a gate for the information processing along the longitudinal propagation in the hippocampal formation.

STIMULATION-DEPENDENT DIFFERENTIAL EXPRESSION OF LTP IN CA1 INTERNEURONS AND PYRAMIDAL CELLS. A. Stelzer\* & S. Karnup, Department of Pharmacology, SUNY Brooklyn, Brooklyn, NY 11203.

Double intracellular recordings were performed in basket or axo-axonic cells (identified by biocytin labelling) and apical dendrites of CA1 pyramidal cells in hippocampal slices to compare tetanization effects. In recording pairs, elicitation of orthodromic postsynaptic potentials (PSPs) in interneurons was implemented with lower stimulation intensities (ranging from 7-160  $\mu$ A for exclusive PSPs in interneurons, denoted I(i)). PSP elicitation in pyramidal cell dendrites required intensities from 80 - 430  $\mu$ A, denoted I(p). When I(i) stimulation intensities were used during tetanization (n=10 pairs), 8/10 interneurons exhibited LTP of orthodromic EPSPs, whereas no PSPs could be evoked in pyramidal cells at any point of time following tetanization. In contrast, when I(p) stimulation intensities were used during tetanization (n=7 pairs), pyramidal cells exhibited LTP of EPSPs in 6/7 recordings, whereas interneuron excitability was depressed in all 7 cells. These data show (1) stimulation-dependent differential LTP in pyramidal cells and interneurons, (2) a presynaptic strengthening of synaptic inhibition via interneuron LTP at I(i) tetanization stimulation intensities and (3) a presynaptic mechanism of disinhibition via interneuron depression at I(p) tetanization stimulation intensities at which pyramidal cell LTP was generated.

## 434.8

LONG-TERM POTENTIATION INITIATED BY EPILEPTIFORM ACTIVITY. V. Valenzuela & L.S. Benardo\*. Departments of Neurology and Pharmacology, State University of New York Health Science Center, Brooklyn, NY 11203.

We have developed an *in vitro* model of epileptogenesis in neocortex in which paroxysmal activity persists for several hours after a limited exposure to magnesium-free solution. We have investigated whether similar activity is observed in hippocampal slices following such treatment.

Rat hippocampal slices (P20-P36) were exposed to magnesium-free solution for 30 min and then returned to normal saline. Interictal spiking in CA1 led by activity in CA3 occurred during exposure to magnesium-free media, and for 2-6 hrs after slices were returned to normal media. In addition, evoked extracellular field potentials recorded in CA1 and CA3 in response to single electrical stimuli applied to stratum radiatum remained potentiated for the duration of the experiment (up to 6 hrs) by 75-100%.

Exposure to the NMDA receptor antagonist CPP (10  $\mu$ M) did not alter the potentiated field potentials, nor the spontaneous activity. However, the non-NMDA receptor antagonist CNQX (10  $\mu$ M) abolished both of them. These results show that long-term potentiation mediated through non-NMDA receptors occurs after a brief period of epileptic activity. This has implications for the role of synaptic plasticity in the process of epileptogenesis.

## 434.10

LONG-TERM TRANSFORMATION OF HIPPOCAMPAL GABAergic SYNAPSES SHARES MECHANISMS WITH PAIRING-INDUCED LTP, BUT NOT TETANUS-INDUCED LTP. D. Dahl<sup>1</sup>, C. Collin<sup>1</sup>, W. Devane<sup>1</sup>, J. Axelrod<sup>2</sup>, and D.L. Alkon<sup>1</sup>. School of Human Development, The University of Texas @ Dallas, Richardson, TX 75080 and the Laboratory of Adaptive Systems, NINDS, Bethesda, MD 20814.

Long-term potentiation (LTP) is the enhancement of excitatory synaptic transmission following afferent tetanization. Afferent tetanization may be paired with intracellular injection of depolarizing current (pairing-induced LTP) or not (tetanus-induced LTP). Here we present new evidence for the long-term transformation (LTT) of GABAergic inhibitory synaptic transmission into synaptic excitation by a pairing-specific paradigm. The mechanisms underlying LTT, pairing-induced LTP, and tetanus-induced LTP have not previously been distinguished.

Tetanus of the GABAergic afferents on to CA1 somata paired with injection of depolarizing current induces LTT in hippocampal field CA1 pyramidal neurons. The transformation response is not blocked by the glutamatergic antagonists CNQX and AP5. However, furosemide (600  $\mu$ M), a chloride-pump blocker, decreases or eliminates LTT and pairing-induced LTP. This result is in contrast to furosemide's enhancement of tetanus-induced LTP. Similarly, anandamide (1  $\mu$ M), an endogenous cannabinoid ligand, prevents LTT and pairing-induced LTP, but variably affected tetanus-induced LTP.

The results of the furosemide experiments suggest that LTT significantly contributes to pairing-induced LTP, but not to tetanus-induced LTP. Anandamide/cannabinoid receptor activation inhibits adenylate cyclase and N-type Ca<sup>2+</sup> channels and thus provides a possible link between LTT and pairing-induced LTP.

## 434.12

LTP INDUCED BY A PAIRING PROTOCOL REVEALS CELLULAR PLASTICITY IN ONLY ONE OF THREE CELL TYPES LOCATED OUTSIDE ST. PYRAMIDALE. C.J. McBain\* and G. Maccaferri NICHD-LCMN, NIH, Bethesda, MD, 20892.

We have studied the effect of pairing low frequency stimulation (1 Hz, 1 min.) of st. radiatum afferent fibers with cell depolarization (-20 mV) in three different populations of cells of the rat hippocampal slice preparation. Excitatory post-synaptic potentials (EPSPs) were recorded from single cells of CA1 under whole-cell current clamp conditions and field population spikes (fPSs) were simultaneously monitored in st. pyramidale. After establishing a stable EPSP baseline, the pairing procedure was applied to the cell under study. Long-term potentiation (LTP) could be induced in a subpopulation of st. radiatum cells, yielding a ~50% increase of the EPSP slope, while the fPS amplitude was decreased of ~40%. A second population of morphologically distinct st. Radiatum cells was totally insensitive to this protocol, and no change of the EPSP slope could be observed, while the fPS amplitude was again decreased. Finally, the effect of the pairing protocol on st. oriens-alveus cells elicited a depression of the EPSP slope, similar in magnitude to the decrease of the fPS amplitude. However, in this latter kind of cells LTP could be subsequently obtained by repeated tetanic stimulation (4X100 Hz, 1s) concomitant with an increase in the fPS amplitude. These results suggest the occurrence of: i) a "conventional" form of LTP in one cell type in st. Radiatum, independent of pyramidal cell activity, ii) the absence of synaptic plasticity in a second distinct st. Radiatum population, and iii) a "passive propagation" of synaptic plasticity from pyramidal to st. oriens-alveus cells (Maccaferri & McBain, Neuron 1995).

## 434.13

TETANUS-INDUCED LTP IN HIPPOCAMPAL PYRAMIDAL CELLS IS ACCOMPANIED BY SYNAPTIC DEPRESSION IN NEIGHBORING INTERNEURONS. L.L. McMahon\* and J.A. Kauer. Dept. of Neurobiology, Duke University Medical Center, Durham, NC 27710

Previous work in hippocampal slices suggests that after tetanic stimulation in s. radiatum (s.r.) that induces LTP, GABAergic transmission is significantly impaired (Abraham, et al., *J. Physiol.*, 394:367, '87; Miles and Wong, *Nature* 329:724, '87). We directly examined the effects of tetanus on excitatory synaptic transmission in inhibitory interneurons in s.r. Whole-cell recordings were made from CA1 s.r. interneurons in slices from 16-22 day old rats. Simultaneous field recordings in CA1 monitored synaptic transmission onto pyramidal cells. Tetani (100 Hz, 1 second at 1.5X test intensity) were delivered twice 20 seconds apart through electrodes in s.r. Tetanic stimulation triggered LTP in pyramidal cells, but depressed excitatory transmission onto the interneurons. Interneuron EPSCs were depressed by  $-34\pm7\%$  ( $n=8$ ) at 1 min.,  $-33\pm7\%$  ( $n=8$ ) at 10 min., and  $-40\pm10\%$  ( $n=3$ ) at 40 min. post-tetanus. Depression was maximal just after tetanus, and usually lasted throughout the experiment, as long as 69 minutes post-tetanus. Similar depression was observed in current-clamp, showing that changes in series resistance do not account for the reduced EPSC size (EPSP at 1 min. post-tetanus was  $-27\pm9\%$ ,  $n=7$ ; at 10 min.,  $-21\pm9\%$ ,  $n=7$ ). Neighboring synapses on pyramidal cells were simultaneously potentiated (EPSP at 10 minutes was  $+140\pm9\%$ ,  $n=5$ ; LTP is persistent under our recording conditions (30-40 minutes post-tetanus,  $+130\pm6\%$ ,  $n=6$ ). A second afferent pathway onto the interneuron (stim. electrodes averaged 870  $\mu$ m apart), unstimulated during the tetanus, nonetheless was also depressed, suggesting a postsynaptic locus of depression (unstimulated pathway,  $-25\pm7\%$  at 10 min. post-tetanus,  $n=7$ ). These data suggest a mechanism to decrease feedforward inhibition of pyramidal cells that reinforces the effects of LTP and may contribute to epileptiform activity. Supported by NIH grant NS30500-03.

## 434.15

LONG-LASTING FACILITATION OF EXCITATORY TRANSMISSION INDUCED BY STIMULATION OF A MONOSYNAPTIC INHIBITORY PATHWAY IN THE RAT HIPPOCAMPAL SLICE. T. Taira<sup>1,2\*</sup>, K. Lamsä<sup>1</sup> and K. Kaila<sup>1</sup>. <sup>1</sup>Department of Biosciences, Division of Animal Physiology, P.O. Box 17 and <sup>2</sup>Institute of Biomedicine, Department of Physiology, 00014 University of Helsinki, Finland.

Depolarizing inhibitory postsynaptic potentials (dIPSPs) can be evoked in CA1 pyramidal cells of the rat hippocampal slice upon monosynaptic high-frequency activation of GABAergic interneurons in the absence of excitatory transmission. We have previously shown that large dIPSPs trigger spikes accompanied by activation of voltage-gated calcium channels (VGCCs). We now show that pharmacologically-isolated dIPSPs exert a long-term modulatory influence on glutamatergic transmission. Tetanic (100 Hz/1 s) stimulation applied at s. radiatum close to the recording site in the presence of the glutamate antagonists AP5 (80  $\mu$ M) and CNQX (40  $\mu$ M) facilitated the recovery of field excitatory postsynaptic potentials (EPSPs) following washout ( $>70$  min) of the antagonists. In the tetanized pathway the recovery of the EPSPs was consistently faster and the synaptic responses larger (by up to 50%) than those recorded simultaneously in a separate control pathway which received the test stimuli only (given at 0.05 Hz). If the tetanization was given in the simultaneous presence of the glutamate antagonists and the GABA<sub>A</sub>-receptor antagonist PTX (100  $\mu$ M), no difference in the recovery of the EPSPs between the two pathways was seen. This indicates that activation of GABA<sub>A</sub> receptors during tetanization is required for the facilitated recovery of the EPSPs. Application of  $\text{Ni}^{2+}$  (50  $\mu$ M) during the high-frequency stimulation also prevented the facilitation of the EPSPs thus indicating an involvement of VGCCs. The results provide the first evidence for the idea that excitatory synaptic transmission can be potentiated upon activation of VGCCs by GABA-mediated depolarizing responses.

## 434.17

USE OF TS-TM-CALIX[4]ARENE FOR INTRACELLULAR BLOCKADE OF GABA<sub>A</sub>-MEDIATED INHIBITION IN VISUAL CORTICAL LAYER IV NEURONS. S.M. Dudek\* and M.J. Friedlander. Neurobiology Research Center, Univ. of Alabama at Birmingham, AL 35294.

Since many forms of synaptic potentiation and depression are dependent on activation of NMDA receptors and/or voltage-gated calcium channels for their induction, postsynaptic inhibition has been extensively studied as a possible modulator of these types of plasticity. Previously, we have shown that the presence of inhibitory postsynaptic potentials (IPSPs) that are evoked with white-matter stimulation is negatively correlated with the ability to induce long-term depression of postsynaptic potentials recorded from visual cortical layer IV neurons maintained *in vitro* (Dudek & Friedlander, *Soc. for Neurosci. Abstr.*, 19:894, 1993). Previous studies investigating the role of synaptic inhibition in the induction and maintenance of synaptic plasticity primarily have used extracellular application of various GABA receptor blockers by bath application or iontophoresis in order to reduce synaptic inhibition. These procedures have the disadvantage that entire networks of neurons are influenced, often leading to hyperexcitable states. Thus, introducing an agent intracellularly offers the advantage that only the neuron impaled is influenced by the blockade of synaptic inhibition directly onto that cell. We and others have determined that such studies are feasible for determining the effects of blocking GABA conductances both *in vitro* (DNDS: Dudek, et al., *Soc. for Neurosci. Abstr.*, 20:1471, 1994) and *in vivo* (DIDS: Nelson, et al., *Science*, 265:774-777, 1994). Here we present the use of a novel compound for the intracellular blockade of GABA<sub>A</sub>-mediated IPSPs. Although first described for the blockade of colonic chloride channels (Singh, et al., *Biophys. J.*, 64, 2(2):A17, 1993), 5,11,17,23-tetrasulfonato-25,26,27,28-tetramethoxy-calix[4]arene was found to potentially inhibit the early IPSPs evoked by stimulation of white matter in slices of visual cortex ( $n=8$ ). This study suggests that use of TS-TM-calix[4]arene may facilitate our understanding of the role of GABA<sub>A</sub> channels in modulating the induction and maintenance of synaptic potentiation and depression.

## 434.14

ROLE OF GABA<sub>A</sub> MEDIATED INHIBITION IN THE INITIATION AND MAINTENANCE OF LTD AND LTP IN RAT HIPPOCAMPAL PYRAMIDAL CELLS. S.V. Tisi, R.J. Holland, H.V. Wheal & J.E. Chad\*. Department of Physiology and Pharmacology, University of Southampton, Hants., UK. SO16 7PX.

Long Term Depression and Long Term Potentiation were investigated in the hippocampus of adult Wistar rats (200g). A simple LTD/LTP protocol was carried out on slices, 400  $\mu$ m thick, which had had the CA3 pyramidal cell layer removed. The Schaffer collateral pathway was routinely stimulated every 30 seconds with a bipolar stimulating electrode. Stimulus strength was set to the level required to elicit half-maximal population spike response under control conditions. Population responses were recorded from CA1 and radiatum. Under control conditions, population spike depolarisations in CA1 were  $2.42\pm0.28$  mV (mean $\pm$ SD) while in radiatum initial population epsp slopes were  $0.12\pm0.02$  mV/ms. LTD was generated by delivering 500 pulses at 1Hz producing a reduction in the slope of  $38\pm0.03$  and a reduction in the spike of  $48\pm0.26$ . Paired pulse inhibition at 20ms IPI was abolished. Following LTD, LTP could be produced by five 1 second bursts of 100Hz stimulation causing an increase in the measured slope of  $34\pm0.03$  and an increase in the spike of  $43\pm0.33$ . We are investigating the role of inhibition in controlling synaptic plasticity. Bicuculline (10  $\mu$ M) was used to block GABA<sub>A</sub> mediated effects, increasing population spike amplitude ( $55\pm0.18$ ) and causing multiple spiking. From this baseline, both LTD and LTP could be initiated. In the majority of slices, the level of depression reached a maximum immediately after the LTD stimulus and there was a recovery to a stable LTD level. The LTP stimulus increased population spike amplitude ( $55\pm0.171$ ) and epsp slope ( $20\pm0.019$ ). Intracellular recordings of spontaneous and evoked ipscs are being used to investigate modulation of synaptic inhibition and its effects on synaptic plasticity. Supported by the MRC and the Wellcome Trust.

EXPRESSION OF SYNAPTIC POTENTIATION IN THE VISUAL CORTEX IS DUE TO ENHANCEMENT OF EXCITATORY SYNAPTIC TRANSMISSION AND NOT DUE TO A REDUCTION IN CHLORIDE-DEPENDENT INHIBITORY SYNAPTIC TRANSMISSION. K. Harsanyi\* and M.J. Friedlander. Neurobiology Research Center, University of Alabama at Birmingham, AL 35294, USA.

Our laboratory has previously shown that potentiation of compound postsynaptic potentials (PSPs) in adult visual cortical slices can be induced by low frequency pairings of presynaptic afferent stimulation and coincident postsynaptic depolarization (Harsanyi and Friedlander, *Soc. Neurosci. Abstr.*, 20: 1471, 1994). Stimulation at the white matter/layer VI border at 0.1 Hz was paired with postsynaptic depolarizing pulses ( $2.1\pm0.1$  nA; 80 ms; 60 pairings). Fifty eight percent ( $n=35/60$ ) of the pairing protocols evoked potentiation of the PSP peak amplitude ( $26.5\pm3.1$  percent change) in visual cortical slices from adult guinea pigs (31-90 days). In the present study, we evaluated whether the expression of this type of potentiation is due to a reduction in the IPSP, or a pure enhancement of the EPSP. Conventional intracellular recordings were made from cortical slices of adult animals (35-45 days). To selectively inhibit IPSPs only onto the neuron that participates in the pairing, a combination of cesium to block potassium channels, and the disulfonic stilbene, DNDS (4,4'-dinitro-stilbene-2,2'-disulfonic acid; 500  $\mu$ M) to block chloride channels, was added to the micropipette filling solution (Dudek, et al. *Soc. Neurosci. Abstr.*, 20: 1471, 1994). DNDS is an organic acid compound that acts as an open-channel flicker-type blocker of chloride channels and decreases open probability in a concentration dependent manner (Singh et al. *Am. J. Physiol.*, 260, C51-C63, 1991). Diffusion of DNDS from the micropipette into the cell greatly reduced or eliminated early IPSPs, that are known to be mediated by movement of chloride ions through the GABA<sub>A</sub> channels. The probability of potentiation is similar with ( $n=6/9$ ) or without ( $n=35/60$ ) the intracellular block of chloride channels. Our data suggest that our pairing protocol induces an enhancement of compound PSPs by potentiating excitatory synaptic transmission. Supported by NIH grant EY 05116 and HFSP RG-69/93

BLOCKADE OF GABA<sub>A</sub> RECEPTORS FACILITATES INDUCTION OF NMDA-RECEPTOR INDEPENDENT LTP. Lawrence M. Grover\*, Dept. Physiology, Marshall Univ. Sch. Med., Huntington, WV 25755.

High frequency (200 Hz) tetanization can induce a slow onset, NMDA-receptor independent LTP in hippocampal area CA1. This LTP requires  $\text{Ca}^{2+}$  influx through postsynaptic voltage-dependent  $\text{Ca}^{2+}$  channels (VDCCs). During tetanization, GABAergic inhibition limits the degree of postsynaptic depolarization, and thus the magnitude of  $\text{Ca}^{2+}$  influx through VDCCs. Relief from inhibition might therefore enhance NMDA-receptor independent LTP. To test this possibility, extracellular field potentials were recorded from CA1 stratum radiatum of rat hippocampal slices. Slices were tetanized with a single 25 Hz, 1 sec stimulus train, or four 200 Hz, 0.5 sec stimulus trains. APV (50  $\mu$ M) was applied to all slices to prevent induction of NMDA-receptor dependent LTP. In some slices the GABA<sub>A</sub> antagonist, bicuculline (10  $\mu$ M), was applied with APV. 200 Hz tetanization in APV produced a mean EPSP potentiation of  $28.2\pm2.5\%$  ( $n=13$ ). The same 200 Hz stimulation delivered in APV and bicuculline induced significantly greater potentiation (mean EPSP increase of  $50.5\pm11.0\%$ ,  $n=11$ ). Bicuculline reduced the time required for maximal expression of LTP from 25 min (in APV alone) to 15 min (in APV and bicuculline). 25 Hz tetanization in APV did not induce LTP ( $-3.1\pm6.3\%$  change in EPSP,  $n=7$ ), but 25 Hz tetanization in APV and bicuculline induced a slow onset LTP in 5 of 11 slices (mean EPSP increase in these 5 slices was  $31.0\pm4.6\%$ , mean increase for all 11 slices was  $10.7\pm6.5\%$ ). These data show that GABA<sub>A</sub> inhibition can regulate the magnitude, kinetics, and probability of induction of NMDA-receptor independent LTP. Neuromodulatory control of inhibitory circuitry might therefore be important in regulating NMDA-receptor independent LTP *in situ*.

**DOES THE LATE MAINTENANCE OF CA1-LTP DEPEND ON GABA-ERGIC INHIBITION?** K. Schollmeier\*, F. Schollmeier and U. Frey. Inst. Neurobiol., Gene Regul. & Plasticity, Brenneckstr. 6, P.O. Box 1860, 39008 Magdeburg, Germany

LTP serves as a model for the investigation of distinct forms of learning and memory formation. LTP consists at least of three phases: a potentiation lasting up to one hour precedes an early stage lasting three to four hours and a third stage which maintains the potentiation for at least eight hours and which depends on protein synthesis.

We examined hippocampal CA1-LTP *in vitro* of male wistar rats as previously described (Frey et al., *Brain Res.* 452, 57-65, 1988).

We have investigated, whether the GABAergic system plays a role in mechanisms responsible for the prolonged maintenance of hippocampal CA1-LTP. When GABA<sub>A</sub>- and GABA<sub>B</sub>-antagonists were applied simultaneously, the induction of LTP was facilitated for the two recorded parameters, the population spike and the field-EPSP. The late phase of LTP was not negatively influenced. Interestingly, a slight additional potentiation was observed 3-4 hours after LTP induction. Our recent studies (Frey et al., *Neurosci.* in press) demonstrated that persistent LTP does not preclude further potentiation 4 hours after LTP-induction. We have now investigated, whether spontaneous, intrinsic bursts, which occur after application of GABA-receptor antagonists, are able to induce a potentiation by themselves. Therefore we used a low-frequency stimulation protocol. In these experiments we observed a delayed, developing potentiation after about 3-6 hours. This delayed potentiation induced via spontaneous, intrinsic bursts in the presence of GABA-receptor inhibitors may mask a possible blockade of a late phase of hippocampal LTP, when the inhibitory system is blocked during LTP-induction.

**MODULATION OF PAIRED PULSE DEPRESSION ASSOCIATED WITH LONG-TERM POTENTIATION OF INHIBITORY SYNAPTIC TRANSMISSION IN RAT VISUAL CORTEX.** Y. Komatsu\*. Dep. of Physiology, Kyoto Prefectural Univ. of Med., Kamigyoku, Kyoto 602, Japan.

To study the expression mechanism for long-term potentiation (LTP) of GABAergic inhibitory synaptic transmission in rat visual cortex, paired pulse depression (PPD) was compared before and after the induction of LTP. Inhibitory postsynaptic currents (IPSCs) evoked by layer IV stimulation were recorded from layer V cells while excitatory synaptic transmission was pharmacologically blocked. LTP of IPSCs induced by high-frequency stimulation accompanied no change in the mean value of PPD (ratio of the 2nd to the 1st IPSC amplitude), but did a significant reduction in the variation of PPD in all tested cells. The same change was observed when transmitter release was facilitated by bath application of a K<sup>+</sup> channel blocker 4-aminopyridine. In contrast, the changes of IPSC amplitude produced by changing the holding potential of postsynaptic cells accompanied no change in PPD. These results suggest that the expression of LTP involves an increase of transmitter release.

**DUAL ACTION OF CYCLOTHIAZIDE ON QUISQUALATE-STIMULATED PHOSPHOINOSITIDE HYDROLYSIS IN CEREBELLAR NEURONS.** J.T. Wroblewski\*, E. Surina and S. Pshenichkin. Department of Pharmacology, Georgetown University School of Medicine, Washington D.C. 20007

In primary cultures of cerebellar granule cells quisqualate stimulates phosphoinositide (PI) hydrolysis by acting at metabotropic glutamate receptors (mGluRs). Quisqualate is also known to be the most potent agonist at mGluR1 and mGluR5 receptors, both coupled to PI hydrolysis in CHO cells transfected with these receptors. In addition, quisqualate acts also as an agonist of ionotropic AMPA receptors. We have previously observed that in cerebellar neurons the action of quisqualate on PI hydrolysis can be enhanced by the presence of concanavalin A, a lectin known to decrease the desensitization of AMPA receptors. Hence, the stimulation of PI hydrolysis by quisqualate may include both a metabotropic and ionotropic component. In order to study further the possible contribution of AMPA receptors to the stimulation of PI hydrolysis we used cyclothiazide (CTZ) which decreases the desensitization of AMPA receptors. In addition, we used cerebellar neurons cultured in presence of 10 mM (K10) and 25 mM K<sup>+</sup> (K25) which express a different pharmacology of PI hydrolysis stimulation. Quisqualate enhances PI hydrolysis in both cultures, while *trans*-ACPD acts potently only in K10 cells. In K10 cells CTZ produced a biphasic effect on the basal PI hydrolysis, causing an increase at concentrations up to 10  $\mu$ M, followed by an inhibition at higher concentrations. CTZ, at concentrations above 10  $\mu$ M also inhibited the stimulation of PI hydrolysis induced by both quisqualate and ACPD. In K-25 cells, CTZ had little effect on basal PI hydrolysis, however, at low concentrations (10  $\mu$ M) it potently enhanced PI hydrolysis stimulated by quisqualate. This effect of CTZ was inhibited by NBQX, a selective antagonist of AMPA receptors. These results suggest that in K25 granule cells the stimulation of PI hydrolysis by quisqualate is mediated by both mGluRs and by ionotropic AMPA receptors. In contrast, in K10 the contribution of the ionotropic AMPA receptors to PI hydrolysis appears negligible. Instead, in these cells CTZ inhibits quisqualate stimulated PI hydrolysis, possibly through a direct action at mGluRs. In fact, the application of CTZ to CHO cells transfected with mGluR1 caused an inhibition of both quisqualate and ACPD-induced PI hydrolysis, similar to that observed in K10 cerebellar granule cells.

**STRUCTURE FUNCTION ANALYSIS OF THE COUPLING BETWEEN METABOTROPIC GLUTAMATE RECEPTORS AND SECOND MESSENGER PATHWAYS.** A. Francesconi\* and B. M. Duvoisin. Margaret M. Dyson Vision Research Institute, Department of Ophthalmology, Cornell University Medical College, New York, NY.

The function of metabotropic glutamate receptors (mGluRs) is dependent on the specific second messenger pathway(s) activated and thus on the specificity of coupling to different G proteins. To determine which regions of the receptor are involved in this interaction, we have introduced specific amino acid substitutions in the second and third intracellular domains of mGluR1a by site-directed mutagenesis. Messenger RNA, encoding wild-type and mutant receptors was synthesized *in vitro* and injected into *Xenopus* oocytes. The injected oocytes were challenged with 1 mM L-glutamate (Glu) for 15 sec to activate the receptors. The ability of the wild-type and mutant receptors to couple to G proteins was tested by recording the Ca<sup>2+</sup>-gated chloride current resulting from the activation of a second messenger pathway involving phospholipase C, IP<sub>3</sub> turnover, and intracellular Ca<sup>2+</sup> release. Since mGluR1a activity is partially sensitive to Pertussis toxin (PTX), we also tested the mutant receptors for their PTX sensitivity by pretreating the injected oocytes with PTX (2  $\mu$ g/ml) for 24 hours before the recording. Two of the receptors mutated in the third intracellular loop showed no response following Glu stimulation, indicating that this domain is probably essential for the coupling to G proteins. One of the receptors mutated in the second intracellular loop showed a different response profile and PTX sensitivity compared to the wild type mGluR1a, suggesting that this domain is important in determining the specificity of the coupling to G proteins. **MODULATION OF THE RETINAL ON-BIPOLAR CELL mGluR6 CASCADE BY PHOSPHORYLATION.** R.J. Walters & S. Nawy\*. Dept. of Ophthalmology and Visual Science, Albert Einstein College of Medicine, N.Y. 10461.

The ON-bipolar cell metabotropic glutamate receptor (mGluR6) is thought to be coupled to a cGMP-phosphodiesterase (PDE) via a G-protein. Receptor binding leads to the closure of a cGMP-regulated cation channel. Intracellular dialysis of the tiger salamander on-bipolar cell with 1mM cGMP and 2mM ATP causes the development of an inward cation current that is reversibly suppressed by the glutamate analog L-AP4. The inward current and L-AP<sub>4</sub> responses run-down with time (n=12) despite the continued presence of cGMP, suggesting that cGMP is not sufficient for maintaining the channel in the open state. We find that the rate of run-down increased when ATP was excluded from the pipette (n=14) or when ATP was replaced by ATP- $\gamma$ -S (n=6), indicating a requirement for ATP, and by extension phosphorylation. The PDE inhibitor IBMX (100  $\mu$ M) failed to enhance the size of the inward current in the presence of 1mM ATP- $\gamma$ -S, indicating that ATP- $\gamma$ -S did not merely enhance PDE activity. This concentration of IBMX restored the inward current in the presence of GTP- $\gamma$ -S which should maximally activate PDE, indicating that IBMX was capable of PDE inhibition. These results provide evidence that at least one site of phosphorylation is at the level of the channel. The specific cyclic-nucleotide dependent-protein kinase inhibitor HAI1077 (50  $\mu$ M, n=6) decreased not only the inward current (P<0.05) and L-AP<sub>4</sub> response (P<0.01) but also the fraction of current suppressed by L-AP<sub>4</sub>. The current evidence is consistent with the presence of phosphorylation sites associated with both the channel and the mGluR6-PDE pathway that may be important in adaptation state. ## 435.4

**ACTIVATION OF PHOSPHOLIPASE D MEDIATED BY A NOVEL METABOTROPIC GLUTAMATE RECEPTOR DOES NOT DEPEND ON PHOSPHOINOSITIDE HYDROLYSIS.** D.E. Pellegrini-Giampietro\*, S. Albani, G. Lombardi and F. Moroni. Dipartimento di Farmacologia, Università di Firenze, Italy.

We (*Soc. Neurosci. Abstr.* 20: 487, 1994) and others (Holler et al., *J. Neurochem.* 61: 1569, 1993; Boss et al., *Mol. Pharmacol.* 45: 1177, 1994) have shown that metabotropic glutamate receptor (mGluR) agonists stimulate phospholipase D (PLD): their rank order of potencies in adult rat hippocampal slices (quisqualate > ibotenate > L-CCG-I > IS,3R-ACPD > L-cysteinyl sulfinate = L-AP3 = L-glutamate) indicates that the response is not mediated by a II or III group mGluR. In order to investigate the relationship between PLD activity and the stimulation of phospholipase C (PLC) induced by mGluRs of the I group (mGluR1 and mGluR5), we examined the effects of a series of agents on i) the formation of inositol phosphates and ii) the PLD-specific transphosphatidyl transfer reaction resulting in the formation of [<sup>3</sup>H]phosphatidylethanol ([<sup>3</sup>H]P<sub>2</sub>). In rat hippocampal slices, the selective mGluR1 and mGluR5 agonist (RS)-DHPG (100  $\mu$ M) stimulated inositol phosphate formation but had no effect on PLD activity. Conversely, L-AP3 (1mM) and the phorbol ester TPA (100 nM) antagonized mGluRs linked to PLC but stimulated the mGluR1 linked to PLD. (RS)-MCPG (0.5-1 mM), an antagonist of mGluRs linked to PLC, stimulated the formation of [<sup>3</sup>H]P<sub>2</sub> and decreased the PLD response induced by IS,3R-ACPD, acting as a partial agonist on this receptor. The aminoindane derivative UPF-523, a selective mGluR1 antagonist (see Lombardi et al., these proceedings), had no effect on PLD activity. Finally, in cultured granule cells and in cerebellar slices, IS,3R-ACPD promoted inositol phosphate but not [<sup>3</sup>H]P<sub>2</sub> formation, which was instead stimulated by the Ca<sup>2+</sup> ionophore A23187. Our results indicate that the mGluR coupled to PLD does not belong to any of the three mGluR groups identified so far and that mGluRs may activate PLD and PLC via separate transduction pathways. Independent activation of PLD may be an important and specific mGluR mechanism to increase diacylglycerol formation in brain tissue.

## 435.5

Characterization of metabotropic glutamate receptors linked to IP<sub>3</sub>/Ca<sup>2+</sup> cascade in transfected cells.

S. Kawabata\*, R. Tsutsumi, A. Kohara, M. Okada and T. Yamaguchi. Yamanouchi Pharmaceutical Co., LTD. Tsukuba-city, 305 Japan.

Among metabotropic glutamate receptors, mGluR1 and R5 are coupled to IP<sub>3</sub>/Ca<sup>2+</sup> cascade. These receptors share more than 60% of amino acid identity, and show similar pharmacological properties when expressed in CHO cells. We transfected two types of cells, HEK293 and NIH3T3 cells with cDNA encoding either rat mGluR1α or mGluR5α and studied the activation of PI hydrolysis in response to glutamate and its agonists. In accord with the results in CHO cells, inositol phosphates formation increased 3- to 6-fold over basal levels in these cells. The coupling system of these receptors therefore are consistent among different cell types. Both rank order and potencies of agonists in inducing PI hydrolysis were closely similar in both receptors. We also studied the increases in [Ca<sup>2+</sup>]<sub>i</sub> triggered by glutamate exposure. The patterns of increase in [Ca<sup>2+</sup>]<sub>i</sub> were carefully examined by the single cell calcium recording technique. We will present these results in the meeting.

## 435.7

CHANGES IN [Ca<sup>2+</sup>]<sub>i</sub> INDUCED BY ACTIVATION OF GLUTAMATE RECEPTORS IN CULTURED RAT HIPPOCAMPAL NEURONES. L.S. Khiroug, P.R. Andrus, E. Cherubini and A. Nistri. Biophysics Sector, International School for Advanced Studies (S.I.S.S.A.), 34014 Trieste, Italy.

Confocal laser scanning microscopy was used to study changes in [Ca<sup>2+</sup>]<sub>i</sub> produced by pressure ejection of glutamate to rat cultured hippocampal neurones. Cells were pre-loaded at 37°C with the fluorescent calcium-sensitive dye fluo-3 (2 μM for 45-60 min). TTX (0.5 μM) was routinely used to block fast sodium currents. Glutamate (0.1 mM) induced a transient increase in [Ca<sup>2+</sup>]<sub>i</sub> as shown by a 3-5 fold rise in fluorescence which reached a peak in 2-5 s and exponentially declined in 10-20 s. The response was abolished in Ca<sup>2+</sup>-free solution. The Ca<sup>2+</sup> increase signal was strongly and reversibly depressed (72 ± 6%, n=17) by CPP (20 μM). The residual response was completely (6/9 cells) and reversibly blocked by CNQX (20 μM). However, CNQX alone caused a full inhibition (5/8 cells) of the glutamate-induced response. When 100 μM glycine was added to CNQX the block was only 30%, suggesting that CNQX acted also on glycine binding sites of the NMDA receptors. In addition, the metabotropic glutamate receptor antagonist MCPG (1 mM), significantly and reversibly decreased the background level of [Ca<sup>2+</sup>]<sub>i</sub> by 17 ± 1% (n=8) and reduced the effect of glutamate by 25 ± 6% (n=8). The latter effect was probably indirectly mediated since a complete suppression of calcium signalling was obtained when ionotropic glutamate receptor antagonists were applied after MCPG was washed out.

These data suggest that the rise in intracellular calcium by glutamate was dependent on extracellular calcium and involved mainly NMDA receptor activation.

Supported by Telethon, Italy

## 435.9

GLUTAMATE-STIMULATED MAGNESIUM INFLUX AND SUBSEQUENT MAGNESIUM EFFLUX IN NEURONS. A.K. Stout\*, Y. Li-Smerin, J.W. Johnson, and J.J. Reynolds. Depts. Pharmacol. & Neurosci., Univ. Pittsburgh, Pittsburgh, PA 15261.

Previous magfura-2 fluorescence microscopy studies using cultured rat forebrain neurons have demonstrated that glutamate exposures which trigger excitotoxicity (100 μM, 5 min) can also produce large increases in intracellular free magnesium concentrations ([Mg]<sub>i</sub>). A large component of the glutamate-induced increase in [Mg]<sub>i</sub> is probably due to displacement of bound intracellular Mg by influx of Ca ions through the NMDA receptor channel (Brocard *et al.* 1993). In this study we have investigated a smaller glutamate-stimulated increase in [Mg]<sub>i</sub> which remains in the absence of external Ca ([Ca]<sub>o</sub>) and Na ([Na]<sub>o</sub>). This glutamate-stimulated increase in [Mg]<sub>i</sub> was not significantly reduced by prior depletion of intracellular Na (induced by a fifteen-minute pretreatment of neurons with Na-free buffer), suggesting that the increase in [Mg]<sub>i</sub> does not occur via reverse Na-Mg exchange. The increase in [Mg]<sub>i</sub> was blocked by the NMDA channel blocker MK-801 (Brocard *et al.* 1993) and was enhanced by increasing external Mg ([Mg]<sub>o</sub>). Furthermore, the increase in [Mg]<sub>i</sub> was reduced when NMDA channel-permeant Cs or K ions were used as a Na substitute instead of the presumably NMDA channel-impermeant ion N-methyl-D-glucamine (NMDG). These results suggest that the glutamate-stimulated increases in [Mg]<sub>i</sub> that occur in the absence of [Ca]<sub>o</sub> and [Na]<sub>o</sub> result from Mg entry through NMDA-gated ion channels. Consistent with this hypothesis, application of NMDA + glycine in an extracellular solution containing Mg (70 mM) and NMDG (31 mM) as the only cations induced inward currents at negative membrane potentials in whole-cell patch-clamp experiments (see Li-Smerin *et al.*, this volume). The initial rate of recovery of [Mg]<sub>i</sub> after glutamate stimulation was significantly inhibited either by complete removal of [Na]<sub>o</sub> (31% of control) or by elevation of [Mg]<sub>o</sub> to 30 mM (36% of control), suggesting that Na-Mg exchange plays a role in Mg efflux. If the alterations of Mg homeostasis that occur upon glutamate stimulation contribute to excitotoxicity, then modulation of these Mg fluxes may provide a possible therapy for ischemic brain injury. Supported by the American Heart Association and NIH grants MH18273, MH45817, MH00944, DA07409, and NS34138.

## 435.6

NITRIC OXIDE SYNTHASE INHIBITORS DECREASE NMDA-INDUCED ELEVATIONS OF EXTRACELLULAR GLUTAMATE AND INTRA CELLULAR CALCIUM ([Ca<sup>2+</sup>]<sub>i</sub>) VIA A cGMP INDEPENDENT IN CULTURED CELLS. Seikwan Oh\* and P. P. McCaslin<sup>1</sup>. Dept. Pharmacol. & Toxicol., University of Miss. Med. Ctr., Jackson, MS 39216, and <sup>1</sup>Alton Ochsner Medical Foundation, Div. Res., 1615 Jefferson Hwy., New Orleans, LA 70121

These studies were designed to examine the effect of nitric oxide (NO) on glutamate neurotransmission. In primary cultures of cerebellar granule cells the glutamate receptor agonist, N-methyl-D-aspartate (NMDA), stimulates an elevation of intracellular calcium ([Ca<sup>2+</sup>]<sub>i</sub>), the release of glutamate, the synthesis of nitric oxide (NO) and an increase in cGMP. Although it is clear that NMDA-induced NO stimulates guanylyl cyclase, it is unclear whether NO augments the NMDA-induced elevations of extracellular glutamate or [Ca<sup>2+</sup>]<sub>i</sub> levels. We show that the NO synthase inhibitor, N<sup>G</sup>-monomethyl-L-arginine (MMA), partially prevents the NMDA-induced extracellular glutamate and [Ca<sup>2+</sup>]<sub>i</sub>, and with complete blocking of cGMP elevations. These effects of NO on glutamate release and [Ca<sup>2+</sup>]<sub>i</sub> elevation are unlikely to be secondary to cGMP elevations as evidenced the cGMP analogue, dibutyl cGMP (dBcGMP), does not augment NMDA-induced elevations of extracellular glutamate or [Ca<sup>2+</sup>]<sub>i</sub> levels. MMA was unable to suppress the kainate- or KCl-induced elevations of extracellular glutamate. Furthermore, MMA did not affect glutamate uptake. This results suggest that physiological concentrations of NO has a role in maintaining the NMDA receptor activation in a cGMP independent manner.

## 435.8

EXTRACELLULAR MG<sup>2+</sup> CAN CARRY CURRENT THROUGH THE NMDA-ACTIVATED CHANNEL. Y. Li-Smerin\*, A. K. Stout, J. J. Reynolds and J. W. Johnson. Depts. of Neuroscience and Pharmacology, University of Pittsburgh, Pittsburgh, PA 15260.

Glutamate increases the free intracellular [Mg<sup>2+</sup>] in cultured rat cortical neurons in the absence of extracellular Ca<sup>2+</sup> and Na<sup>+</sup>. The characteristics of this increase suggest that Mg<sup>2+</sup> can enter neurons through NMDA channels (see Stout *et al.*, this volume). In this study we directly measured NMDA-activated whole-cell currents in extracellular solutions in which Mg<sup>2+</sup> and NMDG were the only cations.

When 130 mM Cs<sup>+</sup> was included in the pipette solution, application of 100 μM NMDA plus 10 μM glycine activated an inward current in an extracellular solution containing 70 mM Mg<sup>2+</sup> and 31 mM NMDG (n = 13) at potentials from -40 to -120 mV. At potentials more positive than -75 mV, the NMDA solution activated an outward current in a solution containing 2 mM Mg<sup>2+</sup> and 140 mM NMDG (n = 6). Addition of 200 μM DL-APV to the NMDA solution inhibited the inward current by 95 ± 2.7% (n = 5). When the internal Cs<sup>+</sup> was entirely replaced by 130 mM NMDG, the NMDA solution activated an inward current in the 70 mM Mg<sup>2+</sup> solution at potentials more negative than +20 to +30 mV. The amplitude of the inward current ranged from -20 pA to -280 pA. In individual neurons, the amplitude of the Mg<sup>2+</sup> current was proportional to that of the control current (recorded in 140 mM extracellular Na<sup>+</sup>). The correlation between the two currents was highly significant (r<sup>2</sup> = 0.98, P < 0.001, n = 9), indicating that Mg<sup>2+</sup> and Na<sup>+</sup> permeate the same population of NMDA channels. Further analysis shows that the current recorded near -55 mV in 70, 2, or 0.9 mM Mg<sup>2+</sup> solution was 7.3 ± 0.5 (n = 9), 2.5 ± 1.4 (n = 5), and 0.9 ± 0.4% (n = 3) of the control current. The influx of Mg<sup>2+</sup> through NMDA channels may explain the glutamate-stimulated increase in the intracellular [Mg<sup>2+</sup>] in the absence of extracellular Ca<sup>2+</sup> and Na<sup>+</sup>. Supported by NIH grants MH00944, MH45817, MH18273, DA07409 and NS34138 and the American Heart Association.

## 435.10

DEVELOPMENT OF GLUTAMATE-INDUCED [Ca<sup>2+</sup>]<sub>i</sub> AND [Mg<sup>2+</sup>]<sub>i</sub> CHANGES IN CULTURED FOREBRAIN NEURONS. C. Cheng\*, F.A. Boeckman, E. Aizenman, and J.J. Reynolds. Depts. of Pharmacology and Neurobiology, University of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

Glutamate acting through the NMDA receptor produces a characteristic excitotoxic profile: a transient increase in [Ca<sup>2+</sup>]<sub>i</sub> during the toxic stimulus and cell death can be detected 24 hrs later. It has been suggested that both [Ca<sup>2+</sup>]<sub>i</sub> and [Mg<sup>2+</sup>]<sub>i</sub> may be important in this type of excitotoxic neuronal injury. The aim of this study was to look at the development of agonist-induced changes in [Ca<sup>2+</sup>]<sub>i</sub> and [Mg<sup>2+</sup>]<sub>i</sub> (using fura-2 and magfura-2, respectively) in cultured rat forebrain neurons at 5, 10, 14, 18, 21, 28 days in culture. A non-toxic stimulation with NMDA, AMPA, kainate, glutamate, or depolarization produces a change in [Ca<sup>2+</sup>]<sub>i</sub> at day 5 that was lower than the other developmental days. A toxic stimulation with glutamate appears to induce a change in [Ca<sup>2+</sup>]<sub>i</sub> that is lower at day 5 than at day 28, whereas glutamate seems to produce an increasing change in [Mg<sup>2+</sup>]<sub>i</sub> up to day 14. Our preliminary results indicate that after 20 days in culture, it took longer for the cells to recover to basal [Ca<sup>2+</sup>]<sub>i</sub> and [Mg<sup>2+</sup>]<sub>i</sub> after an excitotoxic stimulus compared to less mature cells. We are also currently investigating the relationship between the expression of various NMDA receptor subunits and sensitivity of these cells to excitotoxicity over this developmental time course. These results indicate that the neurons in our culture are functional and responsive to the various agonists tested, even at the earliest day studied. Although there does not appear to be a good correlation between glutamate-induced changes in [Ca<sup>2+</sup>]<sub>i</sub> or [Mg<sup>2+</sup>]<sub>i</sub> and sensitivity to excitotoxicity during the maturation of these cells, the difference in recovery times suggests a change in homeostatic mechanisms of the more mature neurons in buffering these ions upon glutamate stimulation.

**IBOGAINE BLOCKS NMDA RECEPTOR CURRENT BY AN OPEN CHANNEL MECHANISM.** K. Chen, T.G. Kokate, S. Yamaguchi\*, F.L. Carroll† and M.A. Rogawski. Neuronal Excitability Section, Epilepsy Research Branch, NINDS, NIH, Bethesda, MD 20892, and †Research Triangle Institute, Research Triangle Park, NC 27709.

Ibogaine is a hallucinatory indole alkaloid with antiaddictive properties that is under investigation as a treatment for chemical dependency. Recently, ibogaine was reported to be a competitive inhibitor of [<sup>3</sup>H]dizocilpine binding (Popik et al., *Psychopharmacology* 114: 672-674, 1994), suggesting that it interacts with the channel blocking site of NMDA receptors. We further investigated the effects of ibogaine on NMDA receptors in whole cell voltage-clamp recordings from cultured rat hippocampal neurons. At a holding potential of -60 mV, ibogaine caused a concentration-dependent block of NMDA-evoked currents (IC<sub>50</sub>, 3.1 μM). In contrast, ibogaine failed to affect either kainate- or GABA-evoked currents. The blockade of NMDA currents by ibogaine was use-dependent, long lasting and highly voltage-dependent, being significantly relieved at positive holding potentials. The block could be substantially reduced by co-application of Mg<sup>2+</sup>, indicating that ibogaine is an open channel blocker. In confirmation of previous studies, ibogaine produced a concentration-dependent inhibition of [<sup>3</sup>H]dizocilpine binding to rat brain membranes (IC<sub>50</sub>, 2.5 ± 0.9 μM). Finally, in mice, ibogaine had a dose-dependent protective effect against NMDA-induced lethality. These data indicate that ibogaine is a channel blocking antagonist of the NMDA receptor complex. Whether this contributes to its acute behavioral effects or reported ability to modify drug-seeking behavior remains to be determined.

**IN VIVO EFFECTS OF THE SELECTIVE KYNURENINE 3-HYDROXYLASE INHIBITOR FCE 28833 IN THE RAT.** A. Molinari, M. Cini, M. Marconi, H.-O. Wu, R. Schwarcz, A. Bonsignori, R.A. McArthur\*, M. Varasi and C. Speciale, Pharmacia R&D CNS, Nerviano, Italy and Maryland Psychiatric Research Center, Baltimore, MD 21228.

A shift in the equilibrium between the neuroprotectant kynurenate (KYNA) and the neurotoxin quinolinic acid (QUIN) towards the latter has been proposed to increase excitotoxic vulnerability in the CNS. The inhibition of kynurenine 3-hydroxylase (KYN 3-OHase), an enzyme of the kynurenine pathway, could conceivably attenuate kynurenine degradation to QUIN and at the same time increase the synthesis of KYNA. FCE 28833 [(R,S)-2-amino-4-oxo-4-(3'-4'-dichlorophenyl)butanoic acid] was identified *in vitro* as a specific and potent inhibitor of KYN 3-OHase (IC<sub>50</sub> = 0.2 μM). Drug effects were tested *in vivo* using male Wistar rats (200-250 g). After a single oral dose of 50-400 mg/kg, FCE 28833 caused increases in KYNA content in all tissues investigated (plasma, liver, kidney, brain). Brain KYNA increased approximately 14-fold by 8 hr after the administration of 400 mg/kg FCE 28833, p.o. The time course of this effect was further examined by intrahippocampal microdialysis in freely moving rats. A 10-fold increase in extracellular KYNA was thus obtained between 3 and 10 hr after 400 mg/kg FCE 28833, p.o. Data returned to baseline values by 20 hr after drug administration. FCE 28833 (400 mg/kg, p.o.) also reduced the duration of maximal electroshock-induced tonic-clonic convulsions by approximately 30%, without affecting motor coordination on the rotarod. FCE 28833 is a novel KYN 3-OHase inhibitor which constitutes a useful tool to investigate the neurobiological relevance of modulating kynurenine pathway function in the brain.

**MICROSPECTROFLUORIMETRIC STUDIES OF UNCOMPETITIVE NMDA ANTAGONISTS.** D. Sawyer, J.G. McLamon, and J. Church\*, Departments of Pharmacology & Therapeutics and Anatomy, The University of British Columbia, Vancouver, BC, Canada V6T 1Z3.

Cultured rat cortical neurons loaded with the calcium-sensitive fluorescence indicator Fura-2 responded to 20 s applications of NMDA, AMPA, kainate or 50 mM potassium with transient increases in intracellular free calcium ([Ca<sup>2+</sup>]<sub>i</sub>). Superfusion of the cultures with either the non-opioid antitussive dextromethorphan or the benzomorphan opiate (-)-β-cyclazocine resulted in suppression of responses to NMDA but not to AMPA or kainate. Responses to high K<sup>+</sup> were also unaffected by (-)-β-cyclazocine, whereas a slight decrease was observed with dextromethorphan, consistent with its known blockade of high-voltage activated Ca<sup>2+</sup> channels. Concentration-effect curves showed dextromethorphan and (-)-β-cyclazocine to inhibit NMDA-evoked responses with IC<sub>50</sub>'s near 5 μM and 0.2 μM, respectively. The actions of β-cyclazocine on NMDA-evoked [Ca<sup>2+</sup>]<sub>i</sub> increases were stereoselective, as the (+)-enantiomer at 5 μM decreased NMDA responses by only 18±2%. The actions of (-)-β-cyclazocine exhibited use-dependence in that several applications of agonist were required in order to achieve a steady-state block. On the other hand, with dextromethorphan an equilibrium level of blockade was apparent with the initial application of agonist. The results show that while both compounds are inhibitors of NMDA-evoked responses in cultured rat cortical neurons, there may be important differences in their mechanism of block.

## 436.2

**BIII 277 CL AND BIIL 281 CL, TWO ENANTIOMERIC NMDA OPEN-CHANNEL BLOCKERS: ELECTROPHYSIOLOGICAL CHARACTERIZATION.** M. Grauert, J.M. Rho, M.A. Rogawski\*, Epilepsy Research Branch, NINDS, NIH, Bethesda, MD 20892.

BIIL 277 CL (2R-[2α,3(R'),6α-1,2,3,4,5,6-hexahydro-3-(2-methoxypropyl)-6,11,11-trimethyl-2,6-methano-3-bezazocin-9-ol hydrochloride]) is a potent antagonist of the NMDA receptor-channel complex which is currently under preclinical evaluation as a treatment for acute thrombotic stroke. We investigated the mechanism by which BIIL 277 CL and its enantiomer BIIL 281 CL block NMDA receptors using whole-cell and single channel recording techniques in cultured hippocampal neurons; for comparison we also examined the effect of the drugs on AMPA and GABA<sub>A</sub> receptor currents. In whole-cell recordings, both compounds produced a long lasting, use-dependent block of NMDA-evoked currents that could be substantially reduced by coapplication with Mg<sup>2+</sup>. In contrast, the compounds had no effect on currents evoked by kainate, AMPA or GABA. The block of NMDA-activated current by BIIL 281 CL occurred in a concentration-dependent fashion with IC<sub>50</sub> of 63.5 nM (Hill coefficient, 1.1). The data obtained with BIIL 277 CL was fit better to a two binding site model, with IC<sub>50</sub>'s of 1.96 and 58.4 nM. In single-channel recording from outside-out patches, BIIL 281 CL caused rapid flickering of NMDA-evoked unitary currents, compatible with a channel blocking mechanism. In contrast, BIIL 277 CL caused flickering early in the drug application, but then virtually eliminated all channel currents, possibly because of slow binding to a high affinity blocking site. We conclude that both enantiomers selectively block NMDA receptors by an open-channel mechanism. BIIL 281 CL likely interacts with the NMDA receptor at one site, whereas BIIL 277 CL seems to interact with two sites, one of which may correspond to the BIIL 281 CL blocking site.

## 436.4

**DERIVATIVES OF KYNURENINE AS INHIBITORS OF RAT BRAIN KYNURENINE AMINOTRANSFERASE.** M. Varasi\*, P. Pevarello, C. Speciale, P. Guidetti, D.R. Wells and R. Schwarcz, Pharmacia R&D CNS, Nerviano, Italy and Maryland Psychiatric Research Center, Baltimore, MD 21228.

Previous studies have indicated that a single enzyme, kynurenine aminotransferase (KAT), is responsible for the synthesis of the neuro-inhibitory metabolite kynurenic acid (KYNA) in the rat brain. The structural requirements of the enzyme's catalytic site were now examined using analogs and derivatives of L-kynurenine (KYN), the natural substrate of KAT. KYNA production from KYN was routinely monitored in rat brain homogenates and brain tissue slices in the presence or absence of the novel compounds. Any modification of KYN's alanine side chain or its ring amino group resulted in compounds which (up to 1 mM) did not affect KYNA synthesis from KYN. In contrast, ring chlorination in positions 3, 4, 6 and 5 yielded KYN analogs which interfered with KYNA synthesis with increasing potency. L-5-Cl-KYN was found to be the most active of several 5-substituted kynurenes. Using partially purified rat KAT, L-5-Cl-KYN was shown to be an excellent substrate of KAT, yielding 6-Cl-KYNA. In kinetic studies using partially purified KAT, L-5-Cl-KYN was found to have an approximately 5 times higher affinity to the enzyme than KYN (K<sub>i</sub> for L-5-Cl-KYN: 5.4 μM vs. K<sub>m</sub> for KYN: 28.3 μM). Ongoing studies are designed to examine the usefulness of L-5-Cl-KYN as a tool for the study of brain kynurenes.

Supported by USPHS grants NS 16102 and NS 28236.

## 436.6

**CEREBRAL PRODUCTION OF 7-CHLOROKYNURENIC ACID AFTER SYSTEMIC ADMINISTRATION OF ITS BIOPRECURSOR 4-CHLOROKYNURENINE IN MICE.** H.-O. Wu\* and R. Schwarcz, Maryland Psychiatric Research Center, Baltimore, MD 21228.

We have demonstrated previously that 4-chlorokynurenine (4-Cl-KYN) can be enzymatically converted into the specific NMDA/glycine antagonist 7-chlorokynurenic acid (7-Cl-KYNA) in the rat brain (J. Med. Chem., 37: 334, 1994). Through conversion to 7-Cl-KYNA, 4-Cl-KYN exhibits potent neuroprotective properties *in vivo* (Soc. Neurosci. Abstr. 19: 554.7, 1993). We now explored the effects of systemically administered 4-Cl-KYN (300 mg/kg, i.p.) on cerebral 7-Cl-KYNA synthesis using hippocampal microdialysis in unanesthetized CD-1 mice. Extracellular 7-Cl-KYNA was found to rise rapidly, reaching a plateau of 600 nM at 3 h. 7-Cl-KYNA levels declined slowly over the next 20 h. Infusion of 1 mM aminooxyacetic acid through the dialysis probe reduced the levels of 7-Cl-KYNA by 90%, indicating that enzymatic production of 7-Cl-KYNA occurs in the brain. Systemic administration of 4-Cl-KYN also increased endogenous extracellular kynurenic acid levels two-fold. Tissue levels of 7-Cl-KYNA were examined in separate animals which were killed 4 h after the i.p. administration of 4-Cl-KYN (100-1000 mg/kg). 7-Cl-KYNA was measured in the hippocampus and striatum of these saline-perfused mice and was found to increase linearly with the dose of 4-Cl-KYN. Unexpectedly, the 7-Cl-KYNA content was almost twice as high in the hippocampus as in the striatum (1.3±0.2 vs. 0.7±0.1 pmol/mg prot. after 300 mg/kg 4-Cl-KYN; P < 0.05). These data indicate that systemically administered 4-Cl-KYN may provide region-selective NMDA/glycine receptor antagonism in the brain.

Supported by USPHS grants NS 16102 and NS 28236.

## 436.7

**ACEA 1021: AN ANTAGONIST AT THE STRYCHNINE-INSENSITIVE GLYCINE RECEPTOR - ELECTROPHYSIOLOGICAL CHARACTERIZATION *IN VIVO*.** K. Lingenhöhl\*, T. Ferrat, and R. Hiltcher. Ciba, 4002 Basel, Switzerland.

ACEA 1021 is an antagonist at the strychnine-insensitive glycine receptor site of the NMDA receptor and has been shown to exhibit neuroprotective, anticonvulsant and analgesic properties *in vivo* (Woodward et al. 93, Soc. Neurosci. Abstr., 19: p. 718).

In the present study the effects of ACEA 1021 were examined on NMDA induced as well as acoustically induced excitation in the rat *in vivo*. Single and multibarrel electrodes were used for extracellular recordings and the application of NMDA. ACEA 1021 was either iontophoretically or intravenously applied. In the CA1 region iontophoretically applied ACEA 1021 abolished NMDA induced excitation. In the same area of the brain systemically applied ACEA 1021 dose-dependently reduced NMDA induced excitation. At 30 mg/kg the NMDA induced excitation was reduced to 5.4 %. In the inferior colliculus acoustically induced excitation, which is NMDA and non-NMDA mediated, was maximally reduced by iontophoretically applied ACEA 1021 to 32.1 %. Intravenously applied ACEA 1021 reduced acoustically induced excitation at 30 mg/kg to 35.0 %. In summary, these data show that following systemic application ACEA 1021 is centrally active on exogenously evoked NMDA responses as well as endogenously mediated NMDA responses.

## 436.9

**PHARMACOLOGICAL CHARACTERIZATION OF MDL 105,519, A SYSTEMICALLY ACTIVE ANTAGONIST OF THE NMDA RECEPTOR-ASSOCIATED GLYCINE RECOGNITION SITE.** B.M. Baron\*, B.W. Siegel, B.L. Harrison, J.H. Kehne, T.C. McCloskey, C.J. Schmidt, V.L. Taylor, G.M. Fadavel, M.K. Murawsky, P.L.M. van Giersbergen, H.S. White<sup>1</sup>, and F.G. Salituro. Marion Merrell Dow Research Institute, Cincinnati, OH, 45215 and Strasbourg, France; University of Utah, Salt Lake City, UT 84108

MDL 105,519 ((Z)-2-(phenyl)-3-(4,6-dichloroindol-3-yl-2-carboxylic acid)propenoic acid) is a potent inhibitor of [<sup>3</sup>H]glycine binding to the NMDA receptor ( $K_i = 11$  nM) exhibiting > 1,000-fold binding selectivity vs. a panel of 16 ionotropic and G-protein coupled receptors. Antagonism was evident in that MDL 105,519 prevented both NMDA-dependent increases in [<sup>3</sup>H]TJCP binding and NMDA-elicited biochemical responses. The  $IC_{50}$  value vs NMDA-stimulated cGMP accumulation in cerebellar slices was 282 nM. Inhibition was non-competitive and could be nullified with D-serine. MDL 105,519 (1  $\mu$ M) reversibly inhibited by ~90% NMDA-induced elevations in cytosolic calcium and whole cell currents.

Inhibition of harmaline-stimulated increases in cerebellar cGMP content (CD-1 mouse,  $ED_{50}$  56 mg/kg i.v.) provided evidence of NMDA antagonism *in vivo*. Anticonvulsant activity was quantitated vs audiogenic seizures (DBA/2J mouse,  $ED_{50}$  12 mg/kg ip), ivc quinolinic acid (CD-1 mouse,  $ED_{50}$  = 37 mg/kg iv), and maximal electroshock (CDF rat,  $ED_{50}$  29 mg/kg iv). Duration ( $t_{1/2}$ ) was 1-3 h in the various models. MDL 105,519 showed anxiolytic activity in the rat separation-induced vocalization model ( $ED_{50}$  40 mg/kg ip) but muscle relaxant activity was evident at lower doses ( $ED_{50}$  28 mg/kg ip). Side effect liability was also evaluated using the mouse rotarod test ( $ED_{50}$  73 mg/kg iv), rat mesolimbic dopamine turnover or release (no effect at  $\leq 100$  mg/kg ip), and prepulse inhibition of the rat startle reflex (inhibited baseline response but did not abolish prepulse inhibition even at doses up to 200 mg/kg).

## 436.11

**PHARMACOLOGICAL STUDIES OF AMINO ACID NEUROTRANSMITTERS USING SILICON SUBSTRATE DRUG DELIVERY PROBES.** J.F. Hetke, S.C. Bledsoe, Jr.\*, J. Chen, J.A. Wiler, K.D. Wise and D.J. Anderson. Dept. Elec. Engin. & Comp. Sci. and Kresge Hearing Res. Inst., Univ. of Michigan, Ann Arbor, MI 48109

Traditionally, *in vivo* pharmacological studies of the nervous system have largely relied on microiontophoretic and micropressure techniques. With this approach multibarrel pipettes are used to apply drugs in the vicinity of a single neuron. An improvement would be the ability to record simultaneously multiple neurons at different locations while applying the drug at a given site.

Toward this end, we report on the development and utilization of silicon substrate drug delivery "puffer" probes. These probes, fabricated using integrated-circuit processing techniques, bury microchannels within the substrate. The process is compatible with the inclusion of multiple recording sites on the same substrate, permitting multipoint drug delivery and multichannel recording with minimal tissue disruption. Separations between the electrode sites and outlet ports can be as small as 2.5  $\mu$ m.

Utilization of puffer probes reveals that kainic acid, a neural excitant, produces excitation in the superior colliculus but not the inferior colliculus (IC). We also have preliminary results that the application of  $\gamma$ -aminobutyric acid (GABA), a known inhibitory transmitter in the (IC), produces both inhibition and excitation of IC neurons. This new technology should prove useful for connectivity studies in neural networks and for pharmacological manipulation of tissue reactions in chronic electrophysiological studies.

## 436.8

**FREE L-ASPARTATE, L-GLUTAMATE, D-SERINE AND GLYCINE CONCENTRATIONS IN THE DISCRETE BRAIN AREAS OF MK-801(DIZOCILPINE)-TREATED RAT.**

S. Kumashiro, and T. Nishikawa\*, Dept. of Mental Disorder Res., Natl. Inst. of Neurosci., NCNP, Tokyo 187, Japan.

Concentrations of free L-aspartate, L-glutamate, D-serine and glycine have been measured in the rat cerebral cortex, hippocampus and striatum using high-performance liquid chromatography with fluorometric detection after the blockade of the N-methyl-D-aspartate (NMDA) receptor. Systemic administration of a selective and non-competitive antagonist of the NMDA receptor, MK-801 (0.05-0.15 mg/kg, S.C.), decreased and increased the levels of L-aspartate and L-glutamate, respectively, in the three areas at 90 min post-injection. The contents of D-serine were found to be increased in the striatum. There was no change in glycine concentration in the three areas. These results indicate that contents of endogenous amino acids acting at the excitatory amino acid site (L-aspartate and L-glutamate) and the glycine site (D-serine) of the NMDA receptor might depend upon the NMDA receptor-mediated neurotransmission.

## 436.10

**[<sup>3</sup>H]MDL 105,519, A HIGH AFFINITY RADIOLIGAND FOR THE NMDA RECEPTOR-ASSOCIATED GLYCINE RECOGNITION SITE.** B.W. Siegel\*, B.M. Baron, B.L. Harrison, R.S. Gross, C. Hawes<sup>1</sup>, and P. Towers<sup>1</sup>. Marion Merrell Dow Research Institute, Cincinnati, OH, 45215; <sup>1</sup>Amersham International plc, Cardiff Laboratories, Whitechurch, Cardiff CF4 7YT, Wales UK.

MDL 105,519 ((Z)-2-(phenyl)-3-(4,6-dichloroindol-3-yl-2-carboxylic acid)propenoic acid) is a potent ligand at the NMDA receptor-associated glycine recognition site. For purposes of characterizing its action at the glycine binding site, a halogenated analog was reduced with tritium to form radiolabeled MDL 105,519. [<sup>3</sup>H]MDL 105,519 bound to a rat brain membrane P2 fraction with high affinity ( $K_d = 3.77$  nM) and capacity ( $B_{max} = 12.1$  pmol / mg protein). Specific binding was ~90% of total binding. Centrifugation and filtration gave identical levels of specific binding.

The kinetics of the binding reaction were studied. Association was monophasic with  $k_{on}$  equal to  $7.0 \times 10^7$  M<sup>-1</sup>min<sup>-1</sup>. Dissociation was also monophasic with the  $k_{off}$  value calculated from association experiments (0.257 min<sup>-1</sup>) being similar to that measured directly in dissociation experiments (0.232 min<sup>-1</sup>). A kinetically-derived value for the equilibrium dissociation constant was calculated using the two values for  $k_{off}$  and the association rate constant. The values ( $K_d = 3.67$  and 3.31 nM, respectively) agreed well with those obtained from the saturation experiments.

Comparing the  $pK_i$  values for a series of glycine site agonists, partial agonists, and antagonists, the pharmacology of the site labeled by [<sup>3</sup>H]MDL 105,519 matched that of the recognition site labeled by [<sup>3</sup>H]glycine ( $r = 0.90$ ). With the exception of HA-966, Hill slopes were not significantly different from unity. No effect on specific binding was observed with ligands interacting with other sites on the NMDA receptor complex or with non-NMDA glutamate recognition sites.

## 436.12

**BIOCHEMICAL, PHARMACOLOGICAL AND STRUCTURAL CHARACTERIZATION OF KAINATE RECEPTORS.** Z.G. Wo, M.J. Sutcliffe\*, and R.E. Oswald\*. Dept. Pharmacology, Cornell Univ., Ithaca, NY 14853 USA; <sup>§</sup>Dept. Chemistry, Univ. Leicester, UK.

Based on the studies of two goldfish kainate receptor subunits (GFKAR $\alpha$  and GFKAR $\beta$ ), we have previously proposed a model with three transmembrane segments (3-TMs) for the topology of ionotropic glutamate receptor family (Wo, Z.G. and Oswald, R.E. *TINS* 18, 161-8, 1995). In the present study, GFKAR $\alpha$  and GFKAR $\beta$  were transiently expressed in transfected HEK293 cells either alone or in combination. [<sup>3</sup>H]kainate saturation binding analysis showed that GFKAR $\alpha$  and GFKAR $\beta$  have  $K_D$ 's for kainate of 20 nM and 35 nM, respectively. The affinity of GFKAR $\alpha$  and GFKAR $\beta$  for various glutamatergic ligands (L-glutamate, quisqualate, domoate, AMPA and CNQX) was measured by the inhibition of [<sup>3</sup>H]kainate binding. While GFKAR $\alpha$  and GFKAR $\beta$  have similar affinity for quisqualate, domoate, AMPA and CNQX, these two subunits showed marked difference (> 20-fold) in the affinity for L-glutamate. When co-expressed, GFKAR $\alpha$  and GFKAR $\beta$  assemble into hetero-oligomers as indicated by the changes in ligand binding profiles. Thus, these two kainate receptor subunits (sharing 55% identity) provide an interesting system for the identification of the residues determining ligand binding specificity. The affinity for [<sup>3</sup>H]kainate was increased upon treatment with the reducing agent dithiothreitol (DTT). Detailed analysis indicated the presence of S-S bond in GFKAR $\alpha$  and GFKAR $\beta$ . Given the 3-TM model for the transmembrane topology and a body of structural information available, we will present a three dimensional structural model of non-NMDA glutamate receptors.

## 436.13

## PHENYLGLYCINE ANALOGUES CAN EVOKE THE AP6 "PRIMING" RESPONSE IN RAT CINGULATE CORTEX.

M.J. Sheardown\* and C. Thomsen. Novo Nordisk A/S, Neuroscience, Novo Nordisk Park, DK-2760 Måløv, Denmark.

The priming or AP6 response following quisqualate application to slices of rat cingulate cortex can be evoked in a dose dependent manner by L-AP4 and L-AP6. A series of phenylglycine analogues, which have no intrinsic depolarizing activity, can evoke large depolarizations of rat cingulate cortex slices, when administered 20 min following a 2 min application of 30  $\mu$ M quisqualate. These depolarizations were inhibited by NBQX (0.3–1.0  $\mu$ M). The most potent compound was (S)-4C3HPG (MEC 3  $\mu$ M). The order of potency was (S)-4C3HPG  $\geq$  (S)-3C4HPG > (S)-4CPG > (S)-3HPG > (RS)- $\alpha$ -M4CPG. None of these compounds showed any significant affinity for the AMPA or CPP binding sites, and their pharmacology at mGluR subtypes was heterogeneous. All of the compounds showed affinity for a low affinity [ $^3$ H] AP4 binding site. The potency at this site was correlated to (P = 0.001) the MEC in the AP6 response in the cortex. None of the compounds have affinity for mGluR4 receptors.

## 436.15

## KINETIC ANALYSIS OF AMPA RECEPTOR AND EPSC MODULATION BY NON-SATURATING DOSES OF CYCLOTHIAZIDE. R. Baehring, D. K. Patnaik, L. Vyklicky Jr and M. L. Mayer\*. LCMN, NICHD, National Institutes of Health, Bethesda, MD 20892; and #Department of Pharmacological &amp; Physiological Sciences, University of Chicago, Chicago, IL 60637.

In whole cell experiments on cultured hippocampal neurons AMPA receptors show 90–95% desensitization ( $\tau$  8–15 ms) in response to fast superfusion of 1 mM glutamate. The amount of desensitization was reduced by cyclothiazide in a concentration-dependent manner ( $IC_{50}$  1  $\mu$ M). For equilibrium responses to non-saturating concentrations of cyclothiazide the desensitization time constant of the initial component of the glutamate response was indistinguishable from control values. Similar results were obtained during both wash-in and wash-out of cyclothiazide. Thus, at low concentrations of cyclothiazide two distinct receptor populations could be distinguished, one with cyclothiazide bound, showing block of desensitization, and a second receptor population which desensitized normally.

We have also studied effects of cyclothiazide on evoked excitatory postsynaptic currents (EPSCs). The decay of EPSCs was prolonged in a dose-dependent manner, but with the most pronounced effect at concentrations of cyclothiazide greater than those required to fully block desensitization. Assuming that receptor deactivation is the main factor for determining the decay kinetics of EPSCs we expected cyclothiazide to exhibit comparable effects on responses to brief glutamate applications (1 ms) recorded in outside-out patches. Indeed, we found that deactivation was prolonged by cyclothiazide, however, at 100  $\mu$ M the slowing of deactivation did not match the effects on EPSC decay kinetics. In the presence of cyclothiazide a fast component of EPSC decay was followed by a pronounced slow component ( $\tau$  50 ms; relative weight 40% of the total current decay). In contrast, the slow component of deactivation ( $\tau$  12 ms) was considerably more rapid than for EPSC decay and contributed only 25% to the total amplitude. Together, these results suggest more than one mechanism for modulation of EPSCs by cyclothiazide. The examination of lower concentrations of cyclothiazide on deactivation kinetics are in progress and should shed further light on this issue.

## 436.17

## IN VITRO ACTIVITY OF THE NOVEL NMDA RECEPTOR GLYCINE SITE ANTAGONIST ACEA 1021. J.E. Hawkinson\*, C.L. Kimbrough, Z.O. Egbuwoku, and R.M. Woodward. CoCensys, Inc., 213 Technology Dr., Irvine, CA 92718.

ACEA 1021 is a systemically active quinoxalinedione currently under clinical evaluation as a neuroprotectant. Electrophysiological data indicates that ACEA 1021 is a selective antagonist of the NMDA receptor glycine site. In this report, we compare the electrophysiological, neurochemical, and binding properties of ACEA 1021 with R(+)-HA-966, a systemically active glycine site partial agonist/antagonist. ACEA 1021 and R(+)-HA-966 inhibit NMDA/glycine currents in *Xenopus* oocytes expressing rat brain NMDA receptors with  $K_b$  values of ~ 5 nM and ~ 15  $\mu$ M, respectively, and inhibit the binding of the glycine site antagonist ligand [ $^3$ H]5,7-dichlorokynurenic acid ([ $^3$ H]DCKA) to rat cortical membranes with  $IC_{50}$  values of 3 nM and 8  $\mu$ M, respectively. In neonatal rat cerebellar slices *in vitro*, ACEA 1021 and R(+)-HA-966 block NMDA-stimulated cGMP accumulation with  $IC_{50}$  values of 2  $\mu$ M and 1 mM, respectively. Thus, ACEA 1021 inhibits NMDA/glycine currents and [ $^3$ H]DCKA binding with high affinity and is > 2000-fold more potent than R(+)-HA-966. Although less active in cerebellar slices, ACEA 1021 retains 500-fold greater potency than R(+)-HA-966 in blocking cGMP accumulation. These electrophysiological, neurochemical, and binding data provide further evidence for ACEA 1021 antagonism of glycine sites associated with the NMDA receptor.

## 436.14

## EFFECTS OF CYCLOTHIAZIDE AND GYKI 52466 ON BINDING PROPERTIES OF AMPA RECEPTORS. M. Kessler\*, A. Arai, A. Quan, and G. Lynch. Ctr. for the Neurobiology of Learning and Memory, Univ. of California, Irvine CA 92717.

The binding affinity of the AMPA receptor for [ $^3$ H]AMPA was shown in an earlier report to be reduced about five-fold by cyclothiazide (Hall *et al.*, Brain Res. 628 (1993) 345–348). Binding in that study had been measured in the presence of the chaotropic ion thiocyanate. When similar tests were carried out without thiocyanate, cyclothiazide was found to have minimal effects on [ $^3$ H]AMPA binding or on the displacement of [ $^3$ H]CNQX binding by AMPA and glutamate. The interaction of cyclothiazide with the receptor itself seemed not to be affected by thiocyanate. The results, when interpreted in a five-state receptor model, suggest that cyclothiazide does not reduce receptor desensitization by making the desensitized state inaccessible but rather by increasing the affinity of the active (non-desensitized) state for agonists to such an extent that the active state becomes energetically more stable than the desensitized state.

The inhibition of AMPA receptor currents by GYKI 52466 has been reported to be reversed by cyclothiazide in an apparently competitive manner. The interaction between these two compounds was examined further by testing whether the effects on binding that cyclothiazide produces in the presence of thiocyanate are influenced by GYKI. This was not the case with GYKI concentrations up to 400  $\mu$ M, i.e., concentrations far exceeding those effective in physiological experiments. The lack of effect of GYKI is not likely to be due to a negative interaction with thiocyanate since AMPA-induced currents in patches excised from hippocampal pyramidal cells were inhibited to a similar extent in the absence and presence of the latter. The results suggest that GYKI and cyclothiazide do not bind to the same site on the AMPA receptor. (Supported by grants from AFOSR and Cortex Pharmaceuticals).

## THE POLYAMINE SITE ANTAGONIST IFENPRODIL BLOCKS THE EXCITATORY EFFECTS OF DYNORPHIN ON NMDA RECEPTOR-MEDIATED SYNAPTIC CURRENTS IN THE CA3 REGION OF THE GUINEA PIG HIPPOCAMPUS. R.M. Caudle\* and R. Dubner. Neurobiology and Anesthesiology Branch, National Institute of Dental Research, National Institutes of Health, Bethesda, Maryland 20892.

In a previous study we demonstrated that dynorphin had a biphasic concentration response relationship on N-methyl-D-aspartate (NMDA) receptor-mediated synaptic currents in guinea pig CA3 pyramidal cells (J. Neurosci. 14:5580, 1994). Concentrations of dynorphin < 1  $\mu$ M enhanced the synaptic current whereas concentrations > 1  $\mu$ M inhibited the current. In our previous study, we demonstrated that the inhibitory effects of dynorphin were blocked by naloxone while the excitatory effects of dynorphin were non-opioid. The inhibitory effects were demonstrated to be mediated by  $\kappa_{2}$  opioid receptors. The present study focused on the excitatory actions of dynorphin on NMDA receptor-mediated synaptic currents. Synaptic currents were evoked by stimulating the Schaffer collateral pathway while voltage clamping the CA3 pyramidal cell. Non-NMDA excitatory amino acid receptors were blocked by CNQX (10  $\mu$ M) and GABA receptors were blocked by bicuculline (20  $\mu$ M). The patch electrode contained cesium and tetraethylammonium chloride to block potassium currents. In the absence of any antagonists dynorphin 1–17 had a biphasic concentration response relationship as previously described. When the NMDA receptor polyamine site antagonist ifenprodil (10  $\mu$ M) was included in the superfusion buffer, dynorphin's concentration response relationship was monotonic and inhibitory. The  $IC_{50}$  for dynorphin was shifted from approximately 1.1  $\mu$ M to 28 nM by the addition of ifenprodil. Ifenprodil alone had no effect on NMDA mediated synaptic currents. The inhibitory effect of dynorphin in the presence of ifenprodil was blocked by naloxone. These findings indicate that dynorphin can act as an agonist at the polyamine site of the NMDA receptor in the guinea pig hippocampus.

## 437.1

## EFFECT OF THIOCYANATE ON AMPA RECEPTOR MEDIATED RESPONSES IN EXCISED PATCHES AND HIPPOCAMPAL SLICES

A. Arai\*, J. Silberg, M. Kessler and G. Lynch. Center for the Neurobiology of Learning and Memory, University of California Irvine CA 92717.

The binding affinity of AMPA receptors for [<sup>3</sup>H] AMPA is increased 10-30-fold by the chaotropic anion thiocyanate. The present experiments tested if thiocyanate alters AMPA receptor mediated currents and if any such effects are reflected in the waveform of synaptic responses. Currents induced by glutamate and AMPA were measured in patches excised from pyramidal cells of hippocampal slice cultures. Thiocyanate accelerated the decay of AMPA responses two-fold and reduced the peak current by 30-50% with an EC<sub>50</sub> of 3.2 mM which is comparable to its EC<sub>50</sub> for enhancing binding. Effects on the desensitization of glutamate induced responses were much smaller and only evident at the highest thiocyanate concentration. Binding and physiological effects can be adequately explained by assuming that thiocyanate enhances conversion from the sensitive to the desensitized state of the receptor and reduces ligand dissociation from the desensitized state. Synaptic responses were measured in disinhibited hippocampal slices. Thiocyanate increased the slope of the field excitatory postsynaptic potential by 45 ± 4% and reduced its decay time by 10 ± 4%. The former effect appears to result at least in part from an increase in transmitter release. The decrease in the decay time constant points to an effect of thiocyanate on AMPA receptors *in situ* which is similar to that seen in excised patches. These results demonstrate that an increase in binding affinity may be indicative of reduced rather than enhanced current flow through AMPA receptors. In addition, the results provide further evidence that the kinetics of the AMPA receptor channel contribute significantly to at least the decay phase of fast excitatory synaptic responses. (Supported by AFOSR).

## 437.3

## MODULATION OF DOPAMINE (DA), NORADRENALINE (NAD) AND SEROTONIN (5-HT) RELEASE IN FRONTAL CORTEX, ACCUMBENS AND STRIATUM OF FREELY-MOVING RATS BY PSYCHOSTIMULANT DRUGS. A. Gobert\*, J.-M. Rivet, S. Maurel-Remy, L. Cistarelli and M. J. Millan. Institut de Recherches Servier, 125 Chemin de Ronde, 78290 Croissy, France.

A perturbation of mesolimbic and mesocortical monoaminergic transmission is implicated in the etiology of schizophrenia. Here, we compared the influence of several psychostimulants upon the release of DA, NAD and 5-HT in freely-moving male Wistar rats implanted with a single cannula in the frontal cortex, or with a cannula in the accumbens and the contralateral striatum. Rats were dialysed and monoamines measured by HPLC with coulometric detection. Samples were taken every 20 min. Three basal values were taken, then amphetamine (2.5 mg/kg, i.p.), phenylclidine (PCP) (20.0 mg/kg, s.c.) or dizocilpine (0.16 mg/kg, s.c.) injected and samples taken for a further 180 min.

	Frontal Cortex			Nucleus Accumbens			Striatum	
	DA (1.2)	NAD (1.8)	5-HT (0.8)	DA (4.9)	NAD (0.6)	5-HT (0.8)	DA (9.2)	5-HT (0.8)
PCP	1085	436	447	383	1037	246	268	372
DIZO	163	263	896	108	217	138	105	129
AMPH	817	1560	293	922	4391	220	915	954

Absolute, basal levels are given (pg/20 min) in parentheses. Maximum mean % change is expressed relative to basal levels (= 100%).

Vehicle (water) did not significantly modify release (not shown). For PCP and dizocilpine, but not amphetamine, the increase in DA and 5-HT release was more marked in cortex than elsewhere. These findings reveal distinctive patterns of modulation of monoaminergic transmission by several psychostimulant drugs.

## 437.5

## PROLINE-INDUCED POTENTIATION OF SYNAPTIC TRANSMISSION IS LONG-LASTING AND NMDA RECEPTOR-DEPENDENT. S.M. Cohen\* and J.V. Nadler. Depts. Pharmacology and Neurobiology, Duke Univ. Med. Ctr., Durham, NC 27710.

We previously reported that concentrations of proline known to be present in CSF enhance synaptic transmission at Schaffer collateral-commissural synapses in rat hippocampal slices, when proline is continuously present in the medium. At high concentrations, proline can activate NMDA receptors. We are therefore investigating the relationship between proline-induced potentiation and NMDA-dependent LTP. Two concentrations of proline were used: a concentration typical of normal CSF (3 μM) and a concentration present in the CSF of persons with hyperprolinemia type II (30 μM). When proline was added to the superfusion medium for 20 min, the initial slope of the field EPSP began to increase after about 10 min in 85% of rat hippocampal slices and continued to increase after proline was removed. Plateau values, reached in 50-60 min, were 36% and 46% greater than baseline for 3 and 30 μM proline, respectively. In the absence of proline, field EPSP slope declined slightly during the same time period. When applied concurrently with proline, 50 μM D-AP5 blocked proline-induced potentiation. When 25 nM NMDA was added to the superfusion medium for 20 min, it increased the field EPSP slope to a comparable degree. However, the effect of NMDA was immediate and, unlike proline, it increased the amplitude of the fiber volley. In addition, proline-induced potentiation did not reduce the amplitude of subsequent electrically-evoked LTP.

These results suggest that proline-induced potentiation is long-lasting, requires the activation of NMDA receptors and is separable from electrically-evoked LTP.

## 437.2

## HALOTHANE INDUCED SYNAPTIC DEPRESSION AND METABOTROPIC GLUTAMATE RECEPTORS. M.D. Sokoll\*, E. Narimatsu, S. Kamath, T. Gerhold, L. Davies. Dept. of Anesthesia, Univ. of Iowa College of Medicine, Iowa City, IA 52242.

We examined the effect of metabotropic glutamate receptor (mGluR) activation by trans-(±)-1-amino-1,3-cyclopentanedicarboxylic acid (ACPD) on control and halothane depressed population spikes (PS's) in the rat hippocampal slice. Hippocampal slices 400 μm thick were cut and placed in a submersion type bath. The stratum radiatum was stimulated at the CA1-CA2 boundary with PS recorded from the CA1 stratum pyramidale and the field EPSP from the stratum radiatum. PS's were analyzed for amplitude and latency EPSP for slope of onset. In some studies staurosporine was added to examine the possible interaction of protein kinase C. ACPD 100 μM produced a biphasic effect on the PS consisting of a transient increase in amplitude followed by a decline to about 4.3% of the control value. Prior application of halothane prevented the initial increase in PS amplitude produced by ACPD but did not alter the later decrease. The slope of the EPSP was only reduced without a preceding enhancement. The prior application of staurosporine did not alter the effect of ACPD.

The initial increase in amplitude caused by ACPD is reported to be related to enhanced excitability of the CA1 pyramidal cell. The secondary decrease in amplitude is reported to be related to decreased glutamate release. Halothane prevented the primary increase in amplitude but did not alter the secondary decrease. Halothane action was not altered by the prior application of staurosporine. Part of the action of ACPD may be related to a reduction of inhibitory mechanisms.

## 437.4

## GLUTAMATE MODULATES SPINAL CORD NOREPINEPHRINE RELEASE.

D. W. Glasser, H. Mukai and D. J. Jones\*. Depts Pharmacol. and Anesth., Univ. of TX Hlth. Sci. Ctr., San Antonio, TX 78284.

Previous studies have demonstrated that glutamate (GLU), via N-methyl-D-aspartate (NMDA) receptors modulates the release of various neurotransmitters including dopamine, acetylcholine and norepinephrine (NE) from brain regions. In the spinal cord, the presence of GLU terminals in anatomically similar areas where NE and serotonin (5-HT) terminals are located suggests a possible interaction between these neurotransmitter systems. The present studies, therefore were undertaken to determine if GLU modulates the release of spinal neurotransmitters such as 5-HT and NE.

Spinal cords from male Sprague-Dawley rats (250-300g) were harvested and chopped into 300 μm slices. The slices were incubated with 0.025 μM [<sup>3</sup>H]NE or [<sup>3</sup>H]5-HT and tissue aliquots placed in 1 ml chambers and then perfused with Mg<sup>++</sup> free Krebs-bicarbonate buffer. GLU agonists were added to the perfusion buffer and fractions of perfusate collected. When included, drugs were added 15 min prior to stimulation with glutamate agonists. [<sup>3</sup>H]NE or [<sup>3</sup>H]5-HT release was expressed as a percentage of the total tissue radioactivity remaining at the beginning of that fraction.

In the absence of Mg<sup>++</sup>, NMDA induced a concentration dependent increase in the release of [<sup>3</sup>H]NE but not of [<sup>3</sup>H]5-HT. [<sup>3</sup>H]NE release was Ca<sup>++</sup>-dependent and blocked by Mg<sup>++</sup> and the NMDA antagonists MK-801, APV and ketamine. NMDA was more efficient at inducing [<sup>3</sup>H]NE release than was kainate or glutamate. NMDA-stimulated [<sup>3</sup>H]NE release from dorsal spinal cord was 2-fold greater than from ventral cord. These findings suggest an interaction between GLU and NE that may be involved in spinal sensory processing.

## 437.6

MODULATION OF GLUTAMATE AND ASPARTATE RELEASE FROM HIPPOCAMPAL SYNAPTOSOMES BY ARACHIDONIC ACID AND THROMBOXANE A<sub>2</sub>. C.L. Peterson\* and J.V. Nadler. Depts. Pharmacology and Neurobiology, Duke Univ. Med. Ctr., Durham, NC 27710.

Previous studies on slices of hippocampal area CA1 that utilized inhibitors of eicosanoid metabolism suggested that arachidonic acid and/or platelet-activating factor (PAF) enhances the K<sup>+</sup>-evoked, Ca<sup>2+</sup>-dependent release of glutamate and aspartate and that a prostaglandin or thromboxane inhibits the release of glutamate. To identify the specific eicosanoids involved in regulating glutamate/aspartate release, we tested the effects of these compounds on release from rat hippocampal synaptosomes. Arachidonic acid (60 μM), but not linoleic acid (300 μM), enhanced the K<sup>+</sup>-evoked, Ca<sup>2+</sup>-dependent release of glutamate and aspartate. The PLA<sub>2</sub> inhibitor aristolochic acid (50 μM) reduced the release of these amino acids. c-PAF (3-10 μM), in contrast, enhanced the release of aspartate only. Flurbiprofen (100 μM), an inhibitor of both isoforms of cyclooxygenase, selectively enhanced glutamate release from both CA1 slices and hippocampal synaptosomes. In synaptosomes, prostaglandins D<sub>2</sub> (1 and 10 μM), E<sub>2</sub> (1 and 10 μM), F<sub>2α</sub> (1 μM) and c-12 (10 μM) did not alter the release of aspartate or glutamate. However, two metabolically-stable forms of thromboxane A<sub>2</sub> (1 and 20 μM c-TXA<sub>2</sub> and 20 μM p-TXA<sub>2</sub>) inhibited the release of both amino acids. SQ 29,548 (5 μM), an antagonist of TXA<sub>2</sub> in other systems, partially reversed the depression of aspartate release and fully reversed the depression of glutamate release.

These results suggest that arachidonic acid and TXA<sub>2</sub> act as modulators of excitatory transmitter release in the rat hippocampus. Arachidonic acid enhances and TXA<sub>2</sub> depresses release. These effects may be especially important during seizures and cerebral ischemia, when these lipids are released in large quantities.

PHENCYCLIDINE AND MK801 PRODUCE TIME-DEPENDENT REGIONAL ALTERATION IN GAD mRNA IN RAT BRAIN. T. Hashimoto\*, X.-M. Gao and C.A. Tamminga. Maryland Psychiatric Research Center, University of Maryland School of Medicine, Baltimore MD 21228

Interactions between glutamatergic and GABAergic transmission in CNS have been previously demonstrated. We have studied this interaction in rat brain pharmacologically by measuring GAD mRNA after blockade of glutamate transmission at the NMDA receptor with PCP or MK801. These non-competitive antagonists at the NMDA receptor have extended, time-dependent actions in rat brain on regional cerebral glucose utilization, hippocampal glutamate receptor density and expression of multiple immediate early genes. In this study, we report the extended actions of PCP (8.6 mg/kg) and MK801 (1 mg/kg) on the expression of GAD<sub>67</sub> mRNA at 1, 3, 6, 24, and 48 hours after drug administration. We employed *in situ* hybridization with a specific GAD cRNA probe and quantified the film densities autoradiographically. Expression of GAD<sub>67</sub> mRNA was reduced by 15%-25% in neocortex including anterior cingulate, medial prefrontal (MPC), dorsolateral frontal (DFC) and sensorimotor cortices (P<0.05) 24 hours after PCP. The caudate also showed a decrease in the expression of GAD<sub>67</sub> mRNA (P<0.05) 24 hours after PCP. After MK801 GAD<sub>67</sub> mRNA was reduced in MPC and DFC 24 hours after dosing. Data from additional times and drug doses will be reported. At higher PCP doses, this reduction in inhibitory transmission might be the basis of the PCP-induced signs of neurotoxicity, like intracellular vacuolization (Olney et al. 1989) and HSP elevation (Sharp et al. 1991, 1992). This action of PCP and MK801 in inhibiting GAD mRNA production, suggests that glutamatergic stimulation at the NMDA receptor activates GAD activity regionally and maintains inhibitory transmission.

## 437.9

EVALUATION OF NEUROSTEROID MODULATION OF KAINATE RECEPTORS USING AN AUTOMATED SYSTEM FOR OOCYTE ELECTROPHYSIOLOGY. N. Yaghoubi\*, T.T. Gibbs, and D.H. Farb. Laboratory of Molecular Neurobiology, Department of Pharmacology, Boston University School of Medicine, Boston, MA 02118.

Recent studies from our laboratory have shown that neurosteroids can directly modulate glutamate-gated ion channels. Although modulation of NMDA receptors has been well documented, modulation of kainate receptors has not been studied in detail. To characterize neurosteroid modulation of the kainate response, kainate receptors expressed in *Xenopus* oocytes from rat brain mRNA were evaluated using a novel automated system for oocyte electrophysiology. To provide precise control over voltage and drug application protocols during data acquisition, an automated system was developed that integrates drug application, instrument control, data acquisition, and waveform analysis through a computer-based "virtual instrument." The apparatus consists of a custom recording chamber that is coupled through a multi-barrel manifold to a programmable perfusion system that is controlled by a Mac-based data acquisition and instrument control platform running SuperScope II software (GW Instruments). Automated protocols have been implemented to generate dose-response curves, reversal potential determinations, and modulation studies while automatically measuring waveform parameters and generating session transcripts. The neurosteroids pregnenolone sulfate and 3 $\beta$ -hydroxy-5 $\beta$ -pregnan-20-one sulfate were found to act as negative allosteric modulators at the kainate receptor, with respective IC<sub>50</sub> values of approximately 142  $\mu$ M and 270  $\mu$ M. Various other steroids, including progesterone, corticosterone, and 17 $\beta$ -estradiol, were evaluated and found to be without effect on the kainate receptor. These studies may provide a basis for using neurosteroids in the clinical management of disorders involving glutamatergic neurotransmission. The automation techniques that have been developed significantly improve the efficiency of oocyte electrophysiology while enabling the development of more complex protocols and are amenable to implementation with patch-clamp recording rigs.

## 437.11

CNQX-AND APV-RESISTANT, G PROTEIN-UNCOUPLED SLOW EPSCS IN SUBSTANTIA GELATINOSA NEURONS OF THE ADULT RAT SPINAL CORD SLICES. Y. Yajiri\*, M. Yoshimura, H. Baba and H. Higashi. Dept. Physiol., Kurume Univ. Sch. Med., Kurume 830, Japan and Dept. Orthop. Surg. Niigata Univ. Sch. Med., Niigata 951, Japan

To characterize the slow EPSCs evoked by A $\delta$  afferent fibers, blind patch clamp recordings were made from SG neurons in the adult rat spinal cord slices in which an attached dorsal root was retained. The slow EPSC evoked by A $\delta$  afferent fibers reversed polarity at holding potential of +15mV which was similar to that of fast EPSC. The slow EPSC evoked by primary afferents was abolished by CNQX (10-20  $\mu$ M), while the slow EPSC evoked by focal stimulation was depressed but not abolished by CNQX. The slow EPSC could be elicited for up to two hours after establishing whole cell configuration and was insensitive to injection of GDP- $\beta$ -S. These observations suggest that the slow EPSC is mediated by a ligand-gated channel. However, none of the antagonists for the known ligand gated channels had significant effect on the slow EPSC. Currents produced by glutamate or aspartate revealed similar properties to those of slow EPSC and were depressed but not abolished by CNQX and APV (CNQX, 40  $\mu$ M; APV, 100  $\mu$ M). Furthermore, the slow EPSC was occluded during the aspartate induced current but not during the glutamate induced current. These observations suggest that the slow EPSC is mediated by a transmitter released from interneurons through CNQX and APV-resistant receptors and that this slow synaptic response may contribute to processing nociceptive information in the spinal dorsal horn.

## 437.8

POTENTIATION OF SPONTANEOUS EXCITATORY POSTSYNAPTIC CURRENTS BY PREGNENOLONE SULFATE IN CULTURED NEURONS. M. Park-Chung\*, T.T. Gibbs and D.H. Farb. Laboratory of Molecular Neurobiology, Department of Pharmacology, Boston University School of Medicine, Boston, MA 02118.

We have shown recently that the naturally occurring sulfated neurosteroids pregnenolone sulfate (PS) and 3 $\alpha$ -hydroxy-5 $\beta$ -pregnane-20-one sulfate (5 $\beta$ 3 $\alpha$ S) are glutamate receptor modulators. PS potentiates and 5 $\beta$ 3 $\alpha$ S inhibits the response to exogenously applied N-methyl-D-aspartate (NMDA), and both PS and 5 $\beta$ 3 $\alpha$ S inhibit responses to kainate and  $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionate (AMPA). However, the effects of steroids on glutamate-mediated synaptic responses have not been studied. Here we report that PS potentiates spontaneous excitatory post synaptic currents (EPSCs) in cultures of rat hippocampal neurons. Using whole-cell recording methods, cells were voltage-clamped at -70 mV. Drug solutions were applied to single neurons by pressure ejection from 7-barrel pipets. EPSC potentiation by PS is concentration-dependent, with an EC<sub>50</sub> of 5.6  $\mu$ M and maximum potentiation of 198.2 %. An analog of PS, 11-keto PS, has no effect on EPSCs, suggesting the effect of PS on EPSCs is specific. When EPSCs mediated by NMDA receptors are blocked with the specific NMDA receptor antagonist APV (40  $\mu$ M), the potentiation of EPSCs by 100  $\mu$ M PS is reduced. Conversely, when EPSCs mediated by non-NMDA glutamate receptors are blocked with the specific non-NMDA receptor antagonist DNQX (10  $\mu$ M), 100  $\mu$ M PS produces a greater potentiation of EPSCs (453 %). These results indicate that PS primarily potentiates EPSCs mediated by NMDA receptors. The effects of PS on EPSCs agree with those of PS on the response induced by exogenously applied NMDA. These observations provide further evidence that neurosteroids such as PS can exert direct neuromodulatory effects on excitatory synaptic transmission in the CNS.

## 437.10

CHRONIC EXPOSURE OF MOUSE CORTICAL NEURONS TO NMDAR ANTAGONISTS DIFFERENTIALLY REGULATES NMDAR SUBUNIT mRNA AND POLYPEPTIDE EXPRESSION. P. Follés\*, and M.K. Ticku. Department of Pharmacology, University of Texas Health Science Center, San Antonio, TX 78284-7764.

Chronic exposure of neurons to N-methyl-D-aspartate receptor (NMDAR) antagonists produced upregulation as measured by radioligand binding. In this study we examined the possibility of changes in mRNA and polypeptide expression encoding for the R1, R2A and R2B subunits of the NMDAR after chronic antagonist D(-)-2-Amino-5-phosphopentanoic acid (AP-5) exposure in cultured mouse cortical neurons. Exposure of neurons to AP-5 (100  $\mu$ M, 5 days) produced a 45% increase in the levels of mRNA encoding for the R2B subunit. There was no significant change in the mRNA levels encoding for the R1 and R2A subunits. Using different antibodies against NMDAR subunits, we observed 40-60% increase in R1 polypeptide despite no apparent change in the levels of mRNA encoding for the R1 subunit. More pronounced increase was observed for the R2A-B polypeptide (2-3 fold). The effect of chronic antagonist treatment was time and concentration dependent and reversible after 48 h removal of the antagonist. Concomitant exposure of neurons to AP-5 and NMDA (1mM) was able to block the increase in gene expression of the NMDAR subunits. Noncompetitive antagonist of the NMDAR, MK-801 (1  $\mu$ M), was also able to upregulate the NMDAR. In contrast non-NMDAR antagonists such as CNQX did not have any effect on NMDAR expression. These data suggest that the upregulation of the NMDAR induced by AP-5 is due to a selective increase in NMDAR mRNA and polypeptide expression by a translational or posttranslational regulation for the R1 subunit and a transcriptional regulation for the R2 subunits.

Supported by NIH-NIAAA grant # AA10852.

## 437.12

DESCENDING AND SEGMENTAL EXCITATORY AMINO ACID-MEDIATED SYNAPTIC TRANSMISSION TO RAT SYMPATHETIC PREGANGLIONIC NEURONS (SPN). D. Spanswick, S.D. Logan and L.P. Renaud\*. Neuroscience Unit, Loeb Research Institute, Ottawa Civic Hospital, Ottawa, Canada K1Y 4E9 and Univ. of Aberdeen, Dept Biomedical Science, Marischal College, Aberdeen, AB91AS, U.K.

Thoracolumbar SPN receive both segmental and supraspinal afferents. To investigate their nature and source we utilized whole-cell recording techniques from SPN in neonatal rat spinal cord slices maintained *in-vitro*. Electrical stimulation of ipsilateral dorsal horn (DH), ipsi- and contralateral lateral funiculus (iLF, cLF) evoked fast EPSPs in all SPN tested. EPSPs displayed constant latencies, rise-times and no failures at 10Hz, suggesting a monosynaptic origin. Bath application of the non-NMDA receptor antagonist CNQX (5-12 $\mu$ M) or NBQX (1-2 $\mu$ M) reduced all EPSPs. An NMDA receptor-mediated component was evident by sensitivity of EPSPs to D-CPP (5-12 $\mu$ M) and extracellular magnesium. D-CPP reduced EPSPs in some SPN during low frequency (0.03Hz) stimulation of DH, iLF and cLF. However, a D-CPP-sensitive component was observed during repetitive 10 Hz stimulation, or uncovered during low frequency stimulation following removal of magnesium from the media. These observations demonstrate a role for excitatory amino acids, acting through both NMDA and non-NMDA receptors, in synaptic transmission in descending inputs from both sides of the spinal cord, and from ipsilateral segmental inputs. Supported by MRC, Heart and Stroke Foundation of Canada, British Heart Foundation and Wellcome Trust.

## 437.13

## KINETIC PROPERTIES OF RECOMBINANT NMDA RECEPTORS IN OUTSIDE-OUT PATCHES

D. Wyllie\*, B. Edmonds, M. Nassar, R. Schoepfer &amp; D. Colquhoun

Dept. Pharmacology, University College London, London WC1E 6BT, UK.

The NMDA component of excitatory synaptic currents mediated by glutamate is long-lasting (~100-300 ms). This slow decay can be mimicked by brief (1 ms) applications of glutamate to NMDA receptors in outside-out patches from hippocampal granule cells (13 day-old rats), suggesting that the slow decay arises from the fact that glutamate remains bound to the receptors for a prolonged period after the 1 ms exposure. To investigate the single-channel basis for the slow decay, we have attempted to obtain ensemble currents with only a single channel in the patch, and the results from one such patch suggest that a long latency to first opening (after agonist binding) is a major contributor to the slow decay. Obtaining single-channel patches from granule cells has, however, proved extremely difficult, making it difficult to substantiate our observations. Therefore, we are now pursuing this problem by performing concentration jump experiments on recombinant NMDA receptors (NR-1 plus NR-2A, -2B, -2C or -2D) expressed in *Xenopus* oocytes. Preliminary data suggests that it is possible to reduce the density of receptor expression by altering the amount of mRNA injected into the oocyte. Thus, we hope to increase the probability of obtaining single-channel patches using this strategy. Moreover, since NMDA receptors with different subunit compositions are known to have different macroscopic decay kinetics, the results of jump experiments on a variety of recombinant receptors expressed at low density will allow us to compare the single-channel mechanisms underlying the decay timecourses.

Supported by the Royal Society, Medical Research Council and Wellcome Trust.

## 437.14

## THE ROLE OF SYNAPTIC GEOMETRY IN NEURAL TRANSMISSION: A MODELING STUDY. J.-S. Liaw\*, M. Baudry, G.A. Chauvet, and T.W. Berger. Depts. of Biomedical Eng. and Biological Sciences, Program in Neuroscience, University of Southern California, Los Angeles, CA 90089-2520

We have developed a computational model of a glutamatergic synapse to study the structural correlates of synaptic transmission. In particular, we examine factors that contribute to the differential expression of short-term potentiation (STP) in AMPA and NMDA-mediated conductances. It has been demonstrated that during the expression of STP, the evoked responses of both AMPA and NMDA components are greatly increased. Furthermore, sensitivity to microinjection of exogenous agonist is selectively enhanced for NMDA; responses to microinjection of AMPA are unchanged (Xie & Berger *Soc. Neurosci. Abstr.*, 1994). We investigated the role of the relative positions of presynaptic release site and postsynaptic receptor-channels in determining the magnitude and time course of the EPSCs. Our simulations show that AMPA-mediated EPSC is 42% higher while NMDA-mediated EPSC is 17% higher when the receptors are right underneath the release site than when they are 40 nm away. Furthermore, the rising and decaying phases of AMPA-mediated EPSC becomes faster, consistent with experimental data. NMDA receptor has a high affinity and is thus less sensitive to the relative position. If glutamate is delivered to the synapse by means of perfusion, then its distribution becomes more uniform and the influence of receptor location should be reduced for both AMPA and NMDA-mediated EPSCs. Surprisingly, AMPA-mediated EPSC is 7% lower when the receptor and the release site are aligned. The simulations strongly support the hypothesis that the potentiation of AMPA-mediated EPSC is due to the relocation of the receptor on the postsynaptic membrane while changes in the kinetic parameters underlies the potentiation of NMDA-mediated EPSC. ## 438.1

## CHARACTERIZATION OF NATIVE NMDA RECEPTOR CHANNELS IN ADULT RAT HIPPOCAMPUS. P. Miu\*, L. Zhang, &amp; P.L. Carlen

Playfair Neuroscience unit, Bloorview Epilepsy Program, Toronto Hospital, Rm 12-413, 399 Bathurst St., Toronto, Ontario, Canada M5T 2S8.

Earlier studies using outside-out patch clamp configuration have shown that the selective agonist NMDA activates multiple single channel conductances, which can be categorized into small (5-15 pS), medium (20-35 pS), and large (40-50 pS) opening events. Since the outside-out configuration may alter the functional integrity of NMDA receptors, we compared the NMDA-evoked single channel events recorded in both outside-out and cell attached patch clamp configurations of hippocampal CA1 neurons of mature rat brain slices.

In the outside-out configuration, 5  $\mu$ M NMDA evoked predominately one main conductance level of  $42.9 \pm 3.6$  pS at -80 mV. The slope conductance of the main conductance state, determined by fitting a first order regression line through the data in the current-voltage plot, was  $48.3 \pm 1.7$  pS, which is consistent with previous findings for the large opening events. However in the cell attached configuration, the single channel main conductance level was consistently higher ( $66.7 \pm 1.4$  pS, at -70 mV) than that of outside-out configuration. The slope conductance of the main conductance state obtained from four cells was  $61.7 \pm 7.1$  pS. We also found that when the recording temperature was increased from room temperature (22° C) to 33° C, the NMDA main conductance level was further increased to  $97.9 \pm 9.3$  pS.

We hypothesize that the larger NMDA-evoked single channel events observed in the cell attached mode, particularly in mature rat brain slices, reflect the preservation of intracellular modulation of the NMDA receptor channel activity.

Supported by the MRC of Canada and Bloorview Epilepsy Program.

## 438.2

## DEVELOPMENTAL AND REGIONAL EXPRESSION PATTERN OF A NOVEL NMDA RECEPTOR-LIKE SUBUNIT (NMDAR-L) IN THE RODENT BRAIN. Nikolaus J. Sucher\*, Schahram Akbarian, Carlin L. Chi, Cynthia L. Leclerc, Marc Awobuluyi, David L. Deitcher, Michele K. Wu, Joseph P. Yuan, Edward G. Jones, and Stuart A. Lipton. Dept. of Neurology, Children's Hospital and Harvard Medical School, Boston, MA 02115; Dept. of Anatomy and Neurobiology, Univ. of California, Irvine, CA 92717.

NMDAR-L shares ~27% identity with NMDA receptor subunits. *In situ* hybridization experiments indicate that NMDAR-L mRNA is expressed in the developing rodent CNS. On postnatal day 1 (P1), NMDAR-L mRNA expression was pronounced in the entorhinal cortex (Ec), the subiculum (Su) and the thalamus (Th), in layer V of the developing neocortex (Nc), in the superior and inferior colliculi, and the hindbrain excluding the cerebellum. On P5, NMDAR-L mRNA was expressed in layer V of the Nc, in the Ec, in the Su, and in the Th. On P14, NMDAR-L mRNA was expressed in layers II-VI of the Nc, in the Ec and piriform cortex, in the Su and CA1 field, and in the nucleus of the lateral olfactory tract (NLOT). In the adult brain, NMDAR-L mRNA was detected exclusively in the NLOT. Injection of NMDAR-L cRNA into *Xenopus* oocytes did not lead to the expression of homomeric glutamate-activated channels. However, co-injection of the triple combination of NMDAR-L with NMDAR1 and NMDAR2B cRNAs led to a striking decrease in the current magnitude compared to currents obtained after co-expression of the double combination of NMDAR1 with NMDAR2B. While the function of NMDAR-L remains to be established, its developmental and regional expression pattern suggests that NMDAR-L may play an important role in brain development.

## 438.3

CLONING OF  $\chi$ -2: A PUTATIVE MEMBER OF THE IONOTROPIC GLUTAMATE RECEPTOR SUPERFAMILY.

M.S. Forcina, A.M. Ciabarra, and K.A. Sevarino\*. Div. of Molecular Psychiatry, Dept. of Psychiatry, Yale School of Medicine, New Haven, CT 06508

Synaptic transmission is mediated by ligand-gated ion channels which transduce ligand binding into electrical stimuli; glutamate plays the major role in excitatory signalling in the mammalian brain. Molecular cloning techniques have been employed to identify 16 rat glutamate receptor subunits. As reported elsewhere in these abstracts, Ciabarra et al. and Sucher et al. used degenerate PCR to isolate and characterize  $\chi$ -1, the first member of a new class of ionotropic glutamate receptors.

For this study, degenerate primers were designed based on the sequences of  $\chi$ -1 and the NMDA receptors. Degenerate PCR was used in concert with homology screening to identify 8 novel PCR fragments, 7 of which possess 40-71% identity to residues 575 to 688 in  $\chi$ -1. These data strongly suggest that the novel clones are members of the  $\chi$  class of glutamate receptors. The fragment possessing 71% identity has been identified as  $\chi$ -2.

Further sequencing is necessary to establish whether  $\chi$ -2 and other clones represent one or several different  $\chi$  relatives. Northern blot analysis, *in situ* hybridization, ligand binding and electrophysiological studies with  $\chi$ -2 and other  $\chi$ -1 relatives will elucidate the function of  $\chi$  receptors in neuronal development and may allow pharmacological characterization of this new class.

## 438.4

CHARACTERIZATION OF A MEMBER OF A NOVEL CLASS OF THE GLUTAMATE RECEPTOR FAMILY. A. M. Ciabarra<sup>1</sup>, J. M. Sullivan<sup>2</sup>, L. G. Gahn<sup>1</sup>, G. Pecht<sup>2</sup>, S. Heinemann<sup>2</sup>, and K. A. Sevarino<sup>1</sup>

<sup>1</sup>Division of Molecular Psychiatry, Departments of Pharmacology and Psychiatry, Yale University School of Medicine, 34 Park Street, New Haven, CT 06508; <sup>2</sup>Molecular Neurobiology Laboratory, The Salk Institute, La Jolla, CA 92037.

Ionotropic glutamate receptors mediate the majority of rapid excitatory transmission in the CNS. We have cloned a novel member of the rat glutamate receptor family that has an average amino acid identity of 27% to NMDA receptor subunits and 23% to non-NMDA receptor subunits. *In situ* hybridization experiments reveal that the regional transcript levels of this subunit are elevated just prior to and during the first postnatal week, with the highest levels present in the spinal cord, brainstem, hypothalamus, thalamus, and CA1 field of the hippocampus. Transcript levels decline after postnatal day 7 (P7) and are very low in the adult brain. This subunit does not form functional homomeric channels when expressed in *Xenopus* oocytes. However, co-expression studies have demonstrated that this subunit diminishes the current responses of NMDA channels, but not non-NMDA channels, suggesting a functional interaction with NMDA subunits. Ligand binding experiments conducted in HEK-293 cells did not demonstrate detectable binding of this subunit to [<sup>3</sup>H]CGP 39653 or [<sup>3</sup>H]DCKA. A C-terminal antisera has been developed which recognizes a 135 kDa protein in membranes from transfected HEK-293 cells and from P7 brain. Immunoprecipitation experiments to determine if this subunit assembles with NMDA subunits are in progress. This receptor is also being studied by Sucher et al. Further characterization will be required to establish the precise role of this subunit in neuronal signaling.

## 438.5

**REGIONAL EXPRESSION AND CLONING OF THE HUMAN NMDA NR2C SUBUNIT.** Y.J. Lin\*, J. Carver, and T. Giordano. Symphony Pharmaceuticals, Inc., Malvern, PA 19355.

The NMDA glutamate receptor family is composed of at least five subunits, NR1 (present in various splice variants), NR2A, NR2B, NR2C and NR2D as determined by cloning of cDNAs from rat and mouse. We have cloned cDNAs from human hippocampal and cortical libraries representing the complete coding sequence of the human NR2C. Sequence analysis of approximately 1/3 of the > 4 kb nucleic acid contig in the coding region has shown 90% and 97% identity to the rat NR2C at the nucleic acid and amino acid levels, respectively. When compared to the human NR2A subunit, this homology is decreased to 70% and 75%. Northern analysis has demonstrated highest levels of expression in the cerebellum, moderate levels of expression in the amygdala, caudate nucleus, corpus callosum, hippocampus, subthalamic nuclei and thalamus, and low abundance levels in the hypothalamus and substantia nigra. This is in contrast to previously published reports suggesting the lack of expression of NR2C in the rat hippocampus. The NR1 subunit is also detected in all nine brain regions analyzed, with the highest levels observed in the hippocampus and hypothalamus. In the human periphery, NR2C was detected in the heart, skeletal muscle and pancreas by Northern analysis. In contrast, NR1 was not detected in any peripheral tissues. Further work is required to elucidate the function of NR2C in the periphery.

## 438.7

**NOVEL HUMAN NMDA RECEPTOR SUBUNITS: CLONING AND IMMUNOLOGICAL CHARACTERIZATION OF EXON 5 CONTAINING ISOFORMS.** N.R. Nash\*, C.J. Heilman, H.D. Rees, A.I. Levey. Dept. of Neurology, Emory Univ. Sch. of Med. Atlanta, GA 30322.

The NMDA subtype of the glutamate receptor family is important in neuronal plasticity and neurotoxicity. Nine isoforms of the rat NMDAR1 receptor subunit have been previously distinguished, based on alternatively spliced exons. In four of the isoforms, exon 5 (encoding 21 amino acids) is spliced into the N-terminus. This insert has a high charge density (9 of 21 amino acids), is predicted to be located at the surface of the receptor, and has been implicated in both H<sup>+</sup> sensitivity and regulation by polyamines.

The cloning of the human homologue to NMDAR1-3b and a second isoform NMDAR1-4b are reported here; both of these contain the N-terminal insert, but differ in their C-termini as a result of differential splicing. An *E. coli* expression construct was made splicing amino acids 22-268 behind glutathione S-transferase in pGEX2T. The resulting fusion protein was used to generate rabbit antisera, which recognize at least two distinct protein bands (~115 kD) by Western blot analysis of human and rat brain. A rat monoclonal antibody has also been obtained using this antigen. Epitope mapping demonstrated the recognition site is within the 21 amino acid N-terminal insert. Immunocytochemistry and immunoblotting show insert containing NMDA receptor subunits are heterogeneously distributed in brain.

## 438.9

**BIOPHYSICAL PROPERTIES OF HUMAN NMDA RECEPTORS STABLY EXPRESSED IN MAMMALIAN CELLS.** S.D. Hess\*, C. Deal, M. Urcan, R. Skvoretz, E.C. Johnson and G. Veliczelebi. SIBIA Inc., La Jolla, CA 92037.

Mouse Ltk<sup>+</sup> cells were stably transfected using cDNAs encoding human NMDAR1A/2A or NMDAR1A/2B receptors. Subclones that reliably displayed an increase in [Ca<sup>2+</sup>]<sub>i</sub> following application of NMDA and glycine (see Varney *et al.*, these abstracts) were examined using the whole-cell mode of the patch-clamp technique. Cells were typically held at -60 mV in mammalian Ringer with 0 external Mg<sup>2+</sup> and tested with saturating concentrations of NMDA (1 mM) and glycine (100 μM) delivered via a pressure pipette positioned within 20-30 μm of the cell. The recording pipette contained (in mM): 135 CsCl<sub>2</sub>, 10 EGTA, 1 MgCl<sub>2</sub>, 10 HEPES and 4 ATP. For NMDAR1A/2A-expressing cells, currents ranged from 10 to 408 pA, and the mean (± S.D.) current density was 2.6 ± 2.7 pA/pF (n = 27 cells). Analysis of currents elicited by voltage ramps showed a reversal potential of approximately 0 mV, and the maximal inward current in the presence of 1 mM external Mg<sup>2+</sup> occurred at -23.6 ± 1.4 mV (mean ± S.D., n = 3 cells). Currents ranged from 9 to 1390 pA for NMDAR1A/2B-expressing cells, and the current density was 5.9 ± 6.8 pA/pF (mean ± S.D., n = 14 cells). The reversal potential in Ringer was approximately 0 mV, and the maximal inward current with external Mg<sup>2+</sup> present occurred at -24.3 ± 7.7 mV (mean ± S.D., n = 3 cells). These current densities were observed over 6 and 13 cell passages for the hNMDAR1A/2A and hNMDAR1A/2B lines, respectively. The NMDA-site competitive antagonist CGS19755 (30 μM) reversibly blocked 90-100% of the current elicited with 100 μM NMDA and 30 μM glycine for either the hNMDAR1A/2A or hNMDAR1A/2B-expressing cells. Based on these results, these cell lines represent useful experimental systems to study the functional and pharmacological properties of human NMDA receptor subtypes.

## 438.6

**ISOLATION AND ANALYSIS OF TWO SPLICE VARIANTS OF A HUMAN METABOTROPIC GLUTAMATE RECEPTOR.** P.J. Flor, P. Grandes, D. Rüegg, S. Lukic, T. Leonhardt, T. Knöpfel and R. Kuhn\*. CNS Research, Pharmaceuticals Division R & D, Ciba, CH-4002 Basel, Switzerland and Departamento de Neurociencias, Universidad del Pais Vasco, Apdo. 699-48080 Bilbao, Spain.

The metabotropic glutamate receptor subtype 7 has previously been isolated from rat brain (mGluR7) and is a member of a family of at least eight G-protein coupled receptors (Okamoto *et al.*, 1994; Saugstad *et al.*, 1994).

Here we report the isolation of two full-length cDNA clones encoding two splice variants of human mGluR7 (hmGluR7a and -b). hmGluR7b differs by 23 amino acids from hmGluR7a and is generated by alternative splicing at the C-terminus. hmGluR7b stably expressed in Chinese hamster ovary cells mediates depression of forskolin-stimulated cAMP accumulation. The rank order of potency of five agonists is comparable to that described for mGluR7a (L-SOP ≥ L-AP4 > L-glutamate >> 1S,3R-ACPD, quisqualate). Northern blot analysis shows a strong expression of hmGluR7 in human fetal brain and a wide distribution in adult human brain. Immunohistochemical studies with polyclonal antibodies raised against the different C-termini of hmGluR7a and -b demonstrate distinct and differential distribution of the two splice variants in rat brain.

## 438.8

**MOLECULAR CLONING AND CHARACTERISATION OF THE HUMAN mGlu<sub>1</sub>, mGlu<sub>2</sub> AND mGlu<sub>3</sub> RECEPTORS** B. Sommer\*, H. Boddeke, P. Schoeffter, K. Stockli, K.-H. Wiederholt, T. Tölle\*, D.J. Laurie. Sandoz Pharma AG, Basle, Switzerland and \*Max-Planck Institute for Psychiatry, Munich, Germany.

Glutamate receptors in the mammalian CNS are categorised as ionotropic or metabotropic receptors. Seven rat metabotropic receptor sequences have been published and allocated to three main groups, based on pharmacological preferences and sequence homologies (Nakanishi, 1994, Neuron 13: 1031). In CHO cells, group I receptors (mGlu<sub>1</sub> and -2) positively couple to phospholipase C, while receptors of groups II (mGlu<sub>2</sub> and -3) and III (mGlu<sub>3</sub>, -4 and -5) negatively couple to adenylate cyclase. Sequences for the human mGlu<sub>1</sub> and -2 receptors have recently been described (Flor *et al.*, 1994, Eur. J. Neurosci. (Suppl. 7), Abstr. 47.01; Minakima *et al.*, 1994, Biochem. Biophys. Res. Commun. 199: 1136). We here report the cloning of cDNAs encoding three human metabotropic receptors, hmGlu<sub>1</sub>, -2, and -3, one from each group. These were obtained from human brain and retina cDNA libraries by homology screening using radiolabelled fragments of the rat mGlu<sub>1</sub> and -2 receptors. The deduced amino acid sequences are 846, 1180 and 866 residues in length, respectively, and display ~95% homology to the published rat sequences. *In situ* hybridisation on human brain sections revealed that hmGlu<sub>1</sub> mRNA is widely expressed and hmGlu<sub>2</sub> mRNA is strongly expressed in the hippocampus, but no hmGlu<sub>3</sub> mRNA is expressed. PCR analysis showed that, as in the rat, hmGlu<sub>1</sub> mRNA is virtually restricted to the retina. In CHO cells stably expressing hmGlu<sub>1</sub> receptors, glutamate raised intracellular [Ca<sup>2+</sup>]<sub>i</sub> (detected by aequorin luminescence), while in cells expressing hmGlu<sub>2</sub> and -3 receptors glutamate lowered the forskolin-elevated intracellular cAMP concentration. L-CCG-1, quisqualate and L-AP4 were, respectively, the most potent agonists at the hmGlu<sub>1</sub>, -2, and -3 receptors, in agreement with published studies on the corresponding rat receptors. The pharmacological preferences and coupling mechanisms of these receptors are currently under study.

## 438.10

**STABLE EXPRESSION AND CHARACTERIZATION OF RECOMBINANT HUMAN DIMERIC NMDA RECEPTOR SUBTYPES 1A/2A AND 1A/2B IN MAMMALIAN CELLS.** M.A. Varney\*, M. Urcan, C. Jachec, R. Skvoretz, L.P. Daggett, F.F. Lin, T. Moran\*, J. Morrison\*, E.C. Johnson, G. Veliczelebi. SIBIA, La Jolla, CA 92037, and \*Mount Sinai School of Medicine, New York, NY 10029.

Human hippocampal and fetal brain cDNA libraries were screened with rat or human NMDA receptor sequences, and overlapping cDNAs obtained corresponding to the human NMDAR1A, 2A and 2B subunits. These cDNAs were subcloned into plasmids containing the MMTV inducible promoter, and stable co-transfections initiated in mouse fibroblast Ltk<sup>+</sup> cells. After G418 selection, transfected cells were cloned by limiting dilution and cells screened for NMDA/glycine-stimulated [Ca<sup>2+</sup>]<sub>i</sub> responses in Mg<sup>2+</sup>-free buffer. Clones expressing hNMDAR1A/2B displayed peak [Ca<sup>2+</sup>]<sub>i</sub> responses of approximately 3 to 4-fold above basal levels. Functional expression was also confirmed by measurement of NMDA-induced currents in whole-cell patch-clamp recordings (Hess *et al.*, this meeting). The presence of both subunits in the receptor complex was confirmed by non-denaturing detergent-solubilization of membranes and immunoprecipitation of receptor complexes using an antibody to the 1A subunit, followed by Western blotting and detection of the 2B subunit.

The pharmacology of recombinant hNMDAR1A/2B in Ltk<sup>+</sup> cells, as measured by the Ca<sup>2+</sup> response in Mg<sup>2+</sup>-free buffer, is consistent with that reported from *Xenopus* oocyte expression. NMDA increased [Ca<sup>2+</sup>]<sub>i</sub> with an EC<sub>50</sub> value of 10.4 ± 2.3 μM, and responses to submaximal concentrations of NMDA were inhibited by the competitive NMDA antagonist CGS19755, and by the noncompetitive channel blockers MK801 and ketamine. The glycine-site antagonist 5,7-DCKA also inhibited [Ca<sup>2+</sup>]<sub>i</sub> responses to NMDA. The same strategy has been used for the stable expression of hNMDAR1A/2A receptor subunits, and functional clones are currently undergoing stability tests and pharmacological characterization.

## 438.11

**CLONING AND FUNCTIONAL EXPRESSION OF THE HUMAN GLUR3-FLIP IONOTROPIC GLUTAMATE RECEPTOR.** L.P. Daggett, F.F. Lin, C. Jachec, C.R. Deal, S. Rao, C.-C. Lu, E. Santori, M.A. Varney, S.D. Hess, E.C. Johnson and G. Velicelebi. SIBIA, Inc., La Jolla, CA 92037.

A full-length human GluR3-flip cDNA (hGluR3) was constructed using two overlapping cDNA fragments isolated from human hippocampal and human fetal brain cDNA libraries. The deduced amino acid sequence of the hGluR3 receptor is 894 amino acid residues which is 6 amino acids longer than rat GluR3.

Human embryonic kidney (HEK293) cells were transiently transfected with hGluR3, and tested for functional expression of the receptor in several assays. A 110-kDa immunoreactive species was identified in membranes prepared from hGluR3-transfected cells when probed with anti-rat GluR2/3 antibody in Western blots. This is the expected size for a full-length GluR3 polypeptide. Treatment of the hGluR3-transfected cells with 100  $\mu$ M AMPA in the presence of 100  $\mu$ M cyclothiazide elicited inward currents of  $285 \pm 116$  pA (mean  $\pm$  S.D.,  $n=5$  cells) that were reversibly blocked by 10  $\mu$ M CNQX. Treatment of cells with 100  $\mu$ M AMPA or kainate stimulated intracellular calcium levels ( $[Ca^{2+}]_i$ ) 3- to 4-fold above basal levels in the presence of cyclothiazide. Both the AMPA- and kainate-induced  $[Ca^{2+}]_i$  responses were inhibited by CNQX. No increase in  $[Ca^{2+}]_i$  was detected in the absence of cyclothiazide. Stable transfections of cells with hGluR3, have been initiated with the aim of using these cells as targets in drug screening.

## 438.13

**CLONING AND EXPRESSION A HUMAN CELL LINE cDNA WHICH ENCODES A GLUTAMATE-GENERATING NEUROPEPTIDASE ACTIVITY.** R.E. Carter\*, A. Feldman, and J.T. Coyle. Laboratory of Molecular and Developmental Neuroscience, Massachusetts General Hospital and Consolidated Department of Psychiatry, Harvard Medical School, Boston, MA.

The N-acetylated alpha-linked acidic dipeptidase (NAALADase) is a novel membrane hydrolase which has been characterized in the mammalian nervous system on the basis of its catabolism of the neuropeptide N-acetylaspartylglutamate (NAAG) to N-acetylaspartate (NAA) and glutamate. The isolation of a similar rat brain cDNA has led us to discover that the cDNA for an investigational prostate cancer marker known as the prostate-specific membrane antigen (PSM) encodes a hydrolase with the substrate and pharmacologic properties of NAALADase (Carter et al. [1994] Soc. Neurosci. Abstr. 308.13, Israeli et al. [1993] *Cancer Res.* 53, 227-230). We have recently cloned a cDNA containing the 2250-base PSM open reading frame by RT-PCR from the human prostatic carcinoma cell line LNCaP. Transfection assays of this cDNA demonstrate NAAG-hydrolyzing activity which is inhibited by the specific NAALADase inhibitors quisqualic acid and  $\beta$ -NAG. Thus, as defined by activity and pharmacology, PSM is a NAALADase enzyme, and its corresponding cDNA is the first full-length NAALADase species to be identified. Northern analyses detect at least six transcripts which hybridize to both the rat brain and human cell line cDNA clones. These RNAs are variably expressed in rat brain and other NAALADase-positive but not in NAALADase-negative rat tissues and human cell lines. Our findings indicate that PSM and/or species which share molecular similarities to PSM account for the NAAG-hydrolyzing activity characterized previously in the nervous system.

## 438.15

**EXPRESSION OF THE GLUTAMATE-BINDING PROTEIN IN CEREBELLAR GRANULE CELLS: A RECEPTOR PROTEIN MEDIATING NMDA-INDUCED CELL DEATH AND NMDA-DEPENDENT SYNAPTOGENESIS.** Y. Xia\*, R. Ragan, L. Shen, M. L. Michaelis and E. K. Michaelis. Dept. of Pharmacol. & Toxicol. and the Higuchi Biosciences Center, Univ. of Kansas, Lawrence, KS 66045

The glutamate-binding protein (GBP) is a subunit of an NMDA receptor-like complex isolated from rat brain synaptic membranes (Kumar et al., *J. Biol. Chem.* 269, 1994, 27384-27393). Cerebellar (CB) granule cell cultures were previously used as a model system to study the role of the GBP in NMDA-induced neuronal development and neurodegeneration (Xia et al., *Neurochem. Res.* 20, 1995, 545-557). At 14 days *in vitro*, NMDA caused significant cell damage. Anti-GBP and anti-NMDAR1 antisense oligonucleotides were used to inhibit the expression of GBP and NMDAR1. Following a 20 hr incubation with the antisense oligos, the expression of both proteins was inhibited by about 30% as detected by immunoblot analyses for the GBP and NMDAR1. However, only the anti-GBP antisense oligos produced significant inhibition of the NMDA-induced cell death ( $P < 0.01$ ), whereas the anti-NMDAR1 antisense and the missense oligos for both proteins had no effect. NMDA also has a trophic effect on CB granule cells in culture. These cells survive under non-depolarizing conditions when NMDA is present. The expression level of GBP was regulated by the presence of NMDA in the culture medium and this effect was sensitive to the presence of the antagonist 2-AP-5. Confocal images of cells labeled with fluorescently-tagged antibodies showed clear localization of the GBP on the growth cones of CB granule cells at 4.5 and 18 hr in culture. NMDA also increased the levels of intracellular calcium at the growth cones of CB granule cells. These data indicate that the GBP may play an important role in both neuronal survival and synaptogenesis (Supported by an NMDA fellowship and grant and by grant AA04732 from NIAAA).

## 438.12

**CHARACTERIZATION AND TIME-COURSE OF AGONIST-INDUCED DESENSITIZATION OF HUMAN mGLUR1 $\alpha$ .** M.A. Desai\*, J.P. Burnett, N.G. Mayne and D.D. Schoepp. Central Nervous System Research, Eli Lilly & Co., Indianapolis, IN 46285.

We have studied the properties of a human mGluR1 $\alpha$  (HmGluR1 $\alpha$ ) receptor in a novel cell line (AV12-664; ATCC CRL 9595) and examined its pharmacological profile when co-expressed with a rat glutamate/aspartate transporter (GLAST). Using RT-PCR to compare mRNA levels, we found that HmGluR1 $\alpha$  was similarly expressed in AV12 cells with or without co-expression of GLAST. However, HmGluR1 $\alpha$ -mediated phosphoinositide (PI) hydrolysis was appreciably elicited only in cells co-expressing the rat GLAST transporter (RGT cells). Pre-treatment and subsequent washout of RGT cells with the glutamate uptake blocker, L-trans-pyrrolidine-2,4-dicarboxylic acid (L-PDC), had no effect on agonist-stimulated PI hydrolysis at 6 or 12 hours; whereas similar pre-treatment with 3,5-dihydroxyphenylglycine (DHPG), an mGluR1 agonist, inhibited glutamate-stimulated PI hydrolysis by 15% and 47%, respectively. Upon 24 hour pre-treatment with L-PDC, glutamate-stimulated PI hydrolysis was inhibited by 40%. These effects were reversed by (+)- $\alpha$ -methyl-4-carboxyphenylglycine (MCPG), an mGluR1 antagonist. These studies demonstrate that activation of HmGluR1 $\alpha$ , either through inhibition of transport and resulting accumulation of glutamate in the extracellular medium or through direct activation of the receptor, elicits a time-dependent, receptor-mediated inhibition of agonist-stimulated PI hydrolysis.

## 438.14

**CLONING OF A 3.8 kb cDNA FOR A BRAIN SYNAPTIC MEMBRANE PROTEIN THAT BINDS NMDA RECEPTOR ANTAGONISTS.** K.N. Kumar\*, X.Y. Chen, P.S. Johnson, M. Ahmad and E.K. Michaelis. Dept. of Pharmacol. & Toxicol. and the Center for Neurobiol. & Immunol. Res., Univ. of Kansas, Lawrence, KS 66045.

We have previously reported on the purification and the immunological and pharmacological characterization of a complex of four proteins having the characteristics of an NMDA receptor (Kumar et al. *J. Biol. Chem.* 269, 27384, 1994). This complex consists of an ~70 kDa glutamate-binding protein, an ~80 kDa CPP-binding protein, and an ~60 kDa glycine/TCP-binding protein. In the present studies, we have used the polyclonal antibodies raised against the ~80 kDa antagonist-binding protein to screen hippocampal cDNA libraries for clones expressing the antigenic protein. The largest cDNA clone identified, pNRA2, had a size equal to 3.8 kb. This clone was sequenced and found to contain a unique sequence. An open reading frame for a protein of similar size to the synaptic membrane CPP-binding protein was identified. In Northern blot analyses, an ~3.9 kb mRNA hybridized with the cDNA for this protein. Based on the Northern blot analyses, the mRNA levels for this protein were approximately equal in hippocampus, cerebral cortex, and cerebellum. The properties of ligand binding to the protein expressed in *E. coli* following transformation with the pNRA2 clone were distinguishable from those of the NMDA receptor protein NMDAR1 but were similar to those of the CPP-binding protein purified from rat brain synaptic membranes (Cunningham and Michaelis, *J. Biol. Chem.* 265, 7768, 1990). These results indicate the presence of proteins that differ from the NMDAR1/R2 families yet have the ligand recognition sites associated with brain NMDA receptors. [Supported by grants AA 04732, DAAL 031-91-G-0167, and an unrestricted grant from PARKE-DAVIS]

## 439.1

THE FAILURE OF NO DONORS TO MODULATE AMPA BINDING IN THE ABSENCE OF THE CHAOTROPIC AGENT, POTASSIUM THIOCYANATE. L.M. Hawkins and P.J. Roberts (SPON: Brain Research Association)\*. Department of Pharmacology, University of Bristol, Bristol, BS8 1TD U.K.

In several regions of the rat brain  $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptor mediated synaptic transmission has been shown to undergo both long-term potentiation (LTP) and long-term depression (LTD). The mechanisms underlying these changes in the functional responsiveness of AMPA receptors are not yet understood. However, the ability of phosphorylation and dephosphorylation to alter the responsiveness of glutamate receptor gated ion channels in opposing ways suggests a role for protein kinases.

Both nitric oxide (NO) donors and cyclic GMP analogues have been shown to increase the affinity of [ $^3$ H]AMPA binding in rat cerebellum, suggesting that a cyclic GMP-dependent protein kinase can modulate the AMPA receptor. In those studies [ $^3$ H]AMPA binding was performed in the presence of the chaotropic agent potassium thiocyanate (KSCN), which enhances AMPA binding by an unknown mechanism. We have recently described a new radioligand, (S)-[ $^3$ H]-5-fluorowillardiine, which, in contrast to [ $^3$ H]AMPA, displays high levels of specific binding in the absence of KSCN.

In this study we assessed the ability of NO donors to modulate the binding of 20nM (S)-[ $^3$ H]-5-fluorowillardiine to sections (10 $\mu$ m) of rat brain. The specific binding in the forebrain represented 97.0  $\pm$  4.5% and 97.5  $\pm$  4.9% of control binding in the presence of the NO donors N-nitroso-N-acetylpenicillamine (SNAP) (200 $\mu$ M) and sodium nitroprusside (SNP) (1mM) respectively. Similarly in the cerebellum binding in the presence of 200 $\mu$ M SNAP and 1mM SNP represented 98.7  $\pm$  7.2% and 93.4  $\pm$  4.7% of control binding. Therefore we conclude that the binding of (S)-[ $^3$ H]-5-fluorowillardiine to rat brain, in the absence of KSCN, cannot be modulated by compounds which release NO in physiological tissues.

## 439.3

WATER DEPRIVATION INCREASES THE NUMBER OF NON SYNAPTIC AMPA/GLUR RECEPTORS IN RAT TELENCEPHALON. S. Standley\*, S. Maren, K. Aquino, R. F. Thompson, and M. Baudry, University of Southern California, HEDCO Neurosciences Bldg., Los Angeles, CA 90089-2520

Water deprivation increases the degree of long-term potentiation (LTP) of synaptic transmission in hippocampus and performance in cognitive tasks in rats. This study examined the effects of water deprivation on the properties and subcellular distribution of AMPA receptors. Long Evans rats were water deprived for 3 days and sacrificed. Crude synaptic (P2) and microsomal (P3) fractions from telencephalon were prepared by differential centrifugation. Binding properties were determined by saturation kinetics with [ $^3$ H]-AMPA, and relative amounts of receptor subunits were obtained with Western blots using antibodies against GluR1, and GluR2/3.

As previously reported, greater numbers of high affinity binding sites were found in P3 fractions than in P2 fractions. Water deprivation resulted in a significant increase in the number of high affinity binding sites in both P3 and P2 fractions. P3 fractions also showed an increased amount of GluR2/3 subunits compared to controls. Neither number of low affinity binding sites nor amount of receptor subunits in P2 fractions were altered. Our results indicate that water deprivation alters the number of non-synaptic AMPA receptors in rat telencephalon. The increased number of receptors might provide the basis for the increased degree of synaptic plasticity and learning. ## 439.5

PRESYNAPTIC NMDA AND AMPA BUT NOT KAINIC ACID RECEPTORS EVOKE RELEASE OF PRELOADED NORADRENALINE FROM RAT SPINAL CORD SLICES. E. Sundström\*, L. Holmberg, L.-L. Mo and F. Söuverbie. Dept. of Clin. Neurosci., Karolinska Institutet, Huddinge Univ. Hosp., S-141 86 Huddinge, Sweden.

Presynaptic excitatory amino acid (EAA) receptors have been shown to induce release of noradrenaline (NA) in several supraspinal regions. To determine if EAA receptors exist on spinal NA terminals we studied release of [ $^3$ H]NA from preloaded slices in a superfusion system. We found that NMDA at concentrations similar to those that stimulated binding of [ $^3$ H]MK-801 to spinal cord synaptic membranes gave a potentiation of NA release induced by 10 mM K $^+$ . NMDA-induced release was inhibited by  $\mu$ M concentrations of MK-801, whereas [ $^3$ H]MK-801 showed a nM affinity for binding to spinal NMDA receptors. AMPA gave an evoked release of NA only when 300  $\mu$ M cyclothiazide was used to prevent receptor desensitization. AMPA-mediated release was apparently mediated by the low affinity AMPA receptor since high  $\mu$ M concentrations were necessary to evoke release. AMPA-evoked NA was inhibited by NBQX indicating that similar to the NMDA-stimulated release these processes are receptor mediated. Kainic acid at concentrations of up to 100  $\mu$ M failed to induce release of NA even when the lectin Concanavalin A was used to prevent receptor desensitization. It has previously been shown that presynaptic  $\alpha_2$  receptors inhibit release of glutamate in the spinal cord. Considering the present data it is possible that glutamate released from primary afferents, interneurons or descending axon terminals increase extracellular levels of NA which in turn inhibits release of glutamate thereby creating a negative feed-back loop in the spinal cord.

## 439.2

REGIONAL HETEROGENEITY IN AGONIST ENHANCED [ $^3$ H]MK-801 BINDING FOLLOWING VARIABLE PREWASH CONDITIONS IN RAT BRAIN. L. McCoy\*, and E.K. Richfield. Departments of Psychiatry, Neurology and Pharmacology, University of Rochester School of Medicine, Rochester, NY 14642

NMDA receptor function is modulated through distinct sites that regulate channel opening. The objectives of the present study in Sprague Dawley rat were threefold: (i) determine the contribution of prewash variables on agonist stimulation of the NMDA receptor, (ii) compare regional differences in functional glycine, spermidine and NMDA binding sites under optimized prewash conditions, and (iii) attempt to define the effects of endogenous factors at the different NMDA modulatory sites. The effect of prewash on [ $^3$ H]MK-801 binding in rat tissue sections was volume, temperature, and time dependent and regionally variable. Variations in prewash time and temperature at a constant volume and agonist concentration produced a wide range (0-700% increase) of agonist enhanced binding values. Prolonged prewash caused a regionally specific decrease in unenhanced [ $^3$ H]MK-801 binding, which was restored to unenhanced binding levels with exogenously added glycine, NMDA or spermidine. Short prewash times caused a regionally specific biphasic effect on enhanced [ $^3$ H]MK-801 binding supporting the presence of both endogenous agonists and antagonists at the various NMDA modulatory sites. To detect regional differences in NMDA binding, a 4 $^{\circ}$ C prewash of at least 120 min using a minimum volume of 25 ml/section is suggested. The regional heterogeneity both in [ $^3$ H]MK-801 binding following washout of endogenous factors and in agonist modulation of binding following a prolonged prewash supports the hypothesis that NMDA receptor function is dependent on the interaction of the specific receptor subtype expressed and the concentrations of one or more endogenous factors. ## 439.4

KINDLING-INDUCED LONG-LASTING PROLONGATION OF SINGLE NMDA CHANNEL OPENINGS OCCCLUDES THE EFFECT OF PHOSPHATASE INHIBITION. D.N. Lieberman\* and I. Mody. Dept. of Neurology, UCLA School of Medicine, Los Angeles, CA

We previously reported that the kinetics of single NMDA receptor-channel openings are profoundly altered by kindling-induced epilepsy, and that the openings are similarly prolonged following inhibition of the Ca $^{2+}$ -dependent phosphatase calcineurin by okadaic acid (OA). We have now investigated the persistence of these kindling-induced modifications in the NMDA receptor-channel complex.

Adult rats were implanted with stimulating electrodes in the hippocampal commissures and were either stimulated daily or were handled but not stimulated. Cell-attached recordings in acutely dissociated control and kindled dentate gyrus granule cells were obtained in Mg $^{2+}$ -free medium using 1-aspartic acid (250-500 nM) and glycine (3-8  $\mu$ M) to elicit openings primarily to the 50 pS level. We previously showed that in kindled neurons 2 days after the last seizure, channel openings were significantly prolonged compared to controls. We now examined the longevity of the plastic changes induced by kindling. NMDA channel openings recorded in granule cells 28 days after the last seizure showed a 67% increase in mean open time, a 127% increase in burst duration, a 78% increase in cluster duration, and a 76% increase in supercluster duration. These effects were comparable to those seen 2 days after the last seizure. Thus, the molecular mechanisms responsible for the alteration in NMDA channel function must persist for at least four weeks *in vivo*.

In control granule cells, serine/threonine phosphatase inhibitors produce an enhancement of NMDA channel openings comparable to that induced by kindling. When 10  $\mu$ M OA was perfused onto control neurons, channel activity was enhanced as has been reported previously. In contrast, granule cells obtained from rats 28 days after the last seizure did not respond to OA. The occlusion of the OA effect on NMDA channel openings in epileptic neurons is consistent with a profound and long-lasting alteration in the phosphorylation/dephosphorylation machinery.

## 439.6

BINDING OF [ $^3$ H]CGP-39653 AT THE NMDA RECEPTOR IN PRESENCE OF GLYCINE AND ANTAGONISTS IN THREE BRAIN REGIONS OF THE RAT BRAIN. R. Robichon\*, P.K. Randall and S.W. Leslie. Div. of Pharmacol. and Toxicol., The Univ. of Texas at Austin, Austin, TX 78712.

Previous studies have shown that glycine agonists and antagonists differentially affect the binding of antagonists and agonists at the glutamate site of the NMDA receptor. To further elucidate the relationship between the glutamate and the glycine sites, we studied the effect of glycine and its antagonists on the binding of [ $^3$ H]CGP-39653 in cortex, hippocampus and cerebellum of adult male rats.

Cortex, hippocampus and cerebellum membrane preparations were prepared according to the method of Sills et al. (Eur. J. Pharmacol. 192:19-24, 1991). The tissue (0.10 - 0.15 mg protein) was incubated with 10 nM [ $^3$ H]CGP-39653 and 10 concentrations of glycine or DCKA (10 $^{-4}$  - 10 $^{-8}$  M) for 2 hrs at 4 $^{\circ}$ C. For saturation experiments, 11 concentrations of [ $^3$ H]CGP-39653 (0.5 - 60 nM) and 10 $^{-5}$  M glycine or 10 $^{-6}$  M DCKA were used. Non-specific binding was determined with 10  $\mu$ M glutamate.

Glycine decreased the binding of [ $^3$ H]CGP-39653 with an IC $_{50}$  of 261 and 290 nM in cortex and hippocampus, respectively. In the cerebellum, only 3 x 10 $^{-5}$  and 10 $^{-4}$  M of DCKA decreased [ $^3$ H]CGP-39653 binding. The decrease in binding was due to a lower B $_{max}$  and affinity of [ $^3$ H]CGP-39653 at the NMDA site in presence of glycine. The glycine antagonist DCKA decreased [ $^3$ H]CGP-39653 binding with an IC $_{50}$  of 41 and 36 nM in cortex and hippocampus, respectively, with no effect on the cerebellum. The decrease in [ $^3$ H]CGP-39653 binding was due to a lower affinity of [ $^3$ H]CGP-39653 for the NMDA receptor in cortex and hippocampus without any change in the B $_{max}$ . These results suggest that cerebellum behaves differently from cortex and hippocampus regarding the effect of glycine and its antagonists on the binding of [ $^3$ H]CGP-39653. It appears that at low concentrations glycine increases the binding of [ $^3$ H]CGP-39653 but that at higher concentrations it decreases [ $^3$ H]CGP-39653 binding. Thus, glycine may modulate the antagonist binding. (Supported by NIAAA grants RO1 AA05809 and RO1 AA09337).

## 439.7

CP-101,606, A POTENT AND SELECTIVE ANTAGONIST OF FOREBRAIN NMDA RECEPTORS: BINDING TO A NOVEL RECOGNITION SITE. W. F. White\*, M. F. Ducat, B. L. Chenard, T. W. Butler, R. T. Ronau. Pfizer Inc., Central Research Division, Groton, CT, 06340.

CP-101,606, the dextrorotatory (+) enantiomer of (1S,2S)-1-(4-hydroxyphenyl)-2-(4-hydroxy-4-phenylpiperidino)-1-propanol, is a potent and selective antagonist of NMDA-mediated responses *in vitro* and *in vivo*. However, binding studies indicate that CP-101,606 does not interact with the glutamate, glycine, or TCP modulatory sites on the NMDA receptor. Thus, the NMDA antagonist activity of CP-101,606 is not mediated through interaction with these sites. CP-101,606 is also essentially inactive at a variety of other neurotransmitter receptors, enzymes, and uptake systems. Instead, CP-101,606 interacts specifically at a novel regulatory site on the NMDA receptor. The affinity of racemic CP-101,606 for its binding site in membranes from rat cortex is  $12 \pm 2$  nM and the  $B_{max}$  is  $1.7 \pm 0.2$  pmols/mg protein. In membranes from human frontal cortex these values are  $18 \pm 4$  and  $0.7 \pm 0.1$ . The potency of CP-101,606 analogs to displace racemic  $^3H$ -CP-101,606 binding correlates with potency in protecting hippocampal neurons from glutamate toxicity. This strongly suggests that the mechanism of neuroprotective activity is mediated through interactions at this binding site. *In vitro* autoradiographic studies on sections from rat brain reveal that the racemic  $^3H$ -CP-101,606 binding site has a much more restricted distribution than do ligands acting at the glutamate, glycine, or TCP modulatory sites on the NMDA receptor. The binding site is most dense in hippocampus and cortex with low to very low densities seen in more posterior regions of the brain. Thus, these data are consistent with CP-101,606 acting at NMDA receptors containing the NR2B subunit through a novel mechanism.

## 439.9

CP-101,606, A POTENT AND SELECTIVE ANTAGONIST OF FOREBRAIN NMDA RECEPTORS: *IN VIVO* ACTIVITY. M. J. Pagnozzi\*, L. K. Chambers, F. S. Menniti, B. L. Chenard, W. F. White. Pfizer Inc., Central Research Division, Groton, CT, 06340.

NMDA antagonists have been shown to have neuroprotective effects in animal models of disease. However, the adverse behavioral effects of the available agents may limit their therapeutic usefulness. CP-101,606 acts to selectively inhibit forebrain NMDA receptor function through a novel mechanism. This agent retains the neuroprotective effects but appears to be very well tolerated. The immediate early gene *c-fos* is induced in rats following a stab wound to the brain and the *fos* gene product is elevated in mice following subconvulsant doses of NMDA. Both of these responses are blocked by CP-101,606 ( $ED_{50} = 4$  mg/kg *iv* and 1 mg/kg *ip* in rat and mouse model, respectively). The  $ED_{50}$  for MK-801 in both models is approximately 1 mg/kg. SL-82,0715 was inactive in the mouse model at doses up to 56 mg/kg. CP-101,606 also blocks haloperidol induced catalepsy with an  $ED_{50}$  of 0.3 mg/kg SC. MK-801 is approximately 10x more potent whereas neither SL-82,0715 or ifenprodil were active at doses up to 32 mg/kg. The noncompetitive NMDA antagonist MK-801 at doses greater than 0.1 mg/kg SC caused marked stimulation of locomotor activity in rats. It also disrupted memory consolidation in a mouse step-through passive avoidance paradigm at doses greater than 1 mg/kg *ip*. CP-101,606 had neither effect at the highest doses tested, 56 mg/kg SC and 100 mg/kg *ip*. Unlike both competitive and noncompetitive NMDA antagonists, CP-101,606 does not produce neuronal vacuolization in the cingulate or retrosplenial cortex. These data support the NMDA antagonist activity of CP-101,606 in a number of animal models and suggest that it may be better tolerated and/or more efficacious than other available NMDA antagonists.

## 439.11

POLYAMINE INTERACTIONS WITH IFENPRODIL'S HIGH AFFINITY INHIBITION OF  $[^3H]$ TCP BINDING. L. L. Coughenour, J. J. Cordon and P. A. Boxer\*. Parke-Davis Pharmaceutical Research Division, Warner-Lambert Company, Ann Arbor MI, 48106.

Ifenprodil's high affinity inhibition of the binding of channel blockers such as thienylcyclohexylpiperidine (TCP) and dizolcipine to the NMDA complex have been reported to reflect its selectivity to the NR2B subtype of the receptor. Ifenprodil also has been characterized as a polyamine antagonist. Using  $[^3H]$ TCP binding under nonequilibrium conditions we found that the addition of spermidine at a concentration that enhances the binding (10  $\mu M$ ) or the addition of arcaine at a concentration (10  $\mu M$ ) which inhibits 50% of the binding did not significantly shift the  $IC_{50}$  of the high or low affinity inhibition of ifenprodil. Spermidine significantly increased the percentage of high affinity binding by 15%. High affinity binding disappeared as  $[^3H]$ TCP was allowed to come to equilibrium with only 7% of the sites detectable at 3 h. Increasing the concentration of spermidine to 100  $\mu M$  also eliminated the high affinity binding. Under both these conditions we could again detect high affinity inhibition by ifenprodil by adjusting the equilibrium time of the  $[^3H]$ TCP. This suggests that spermidine does not interact at ifenprodil's high affinity (NR2B selective) site but alters the binding kinetics of  $[^3H]$ TCP. Assay parameters that increase the access or binding within the channel may mask the detection of this high affinity site without direct interaction.

## 439.8

CP-101,606, A POTENT AND SELECTIVE FOREBRAIN NMDA RECEPTOR ANTAGONIST: EFFECTS ON NMDA RECEPTOR-MEDIATED ION FLUX. A. H. Ganong\*, J. T. Lazzaro, K. E. G. Richter, L. H. Tang, E. Aizenman, F. S. Menniti, W. F. White. Pfizer Inc. Groton, CT 06340, Dept. Neurobiology, University of Pittsburgh, PA 15261.

The effects of CP-101,606 on NMDA receptor-mediated responses were studied using patch clamp recording and single cell calcium imaging. Whole cell recordings from rat cortical cells 12-14 days in culture showed dose-dependent inhibition of 100  $\mu M$  NMDA-induced responses by 32 nM - 10  $\mu M$  CP-101,606. NMDA responses were inhibited maximally by 76% by CP-101,606 with an  $IC_{50}$  value of 196 nM. Inhibition by CP-101,606 was slow to develop and did not reverse with 5-10 min of washout. The inhibition of NMDA responses by CP-101,606 appeared to be noncompetitive since increasing concentrations of NMDA did not overcome the block. 1  $\mu M$  CP-101,606 blocked kainate-induced currents by  $8 \pm 2\%$  ( $n=3$ ). CP-101,606 had heterogeneous effects on single NMDA receptor channels studied in patches taken from cultured cortical neurons. CP-101,606 (0.3-3  $\mu M$ ) decreased the frequency of channel opening in 14/17 patches and decreased single channel conductance in 9/17 patches. There were no consistent effects on single channel open time. Single cell calcium imaging in cultured cortical cells revealed that CP-101,606 decreased NMDA-induced calcium influx in about 80% of the cortical neurons (100 nM, 57% inhibition; 1  $\mu M$ , 72%; 114 cells on 5 coverslips). There was large variability in the inhibition by CP-101,606 in the population of cells sensitive to the drug. NMDA receptor-mediated synaptic field potentials recorded in the Schaffer-CA1 pathway in rat hippocampal slices were also inhibited by CP-101,606 with maximal inhibition of 84% and an  $IC_{50}$  value of 212 nM. The results of these studies are consistent with the hypothesis that CP-101,606 differentially affects NMDA receptor subtypes.

## 439.10

PUTATIVE COGNITION ENHANCERS REVERSE INHIBITION BY KYNURENATE OF  $[^3H]$ MK-801 BINDING. John C. Lehmann\* and Servane Hamelin. Dept. Neurosurgery MS 407, Medical College of Pennsylvania and Hahnemann University, Philadelphia PA 19102-1192.

Pittaluga and co-workers have reported that nootropics such as aniracetam reverse the inhibition by kynurenate (100  $\mu M$ ) of release of  $[^3H]$ norepinephrine stimulated by NMDA (100  $\mu M$ ) from hippocampal slices (Eur. J. Pharm. 272:203, 1995). To further elucidate this effect, we attempted to replicate the findings in a simpler system, namely,  $[^3H]$ MK-801 binding in rat brain membranes.

Kynurenate (100  $\mu M$ ) inhibited this binding 75 %. The addition of D-cycloserine, piracetam, or aniracetam reversed this inhibition in a concentration dependent manner. Neither D-cycloserine nor aniracetam increased  $[^3H]$ MK-801 binding in the absence of kynurenate, although piracetam represented an exception and stimulated  $[^3H]$ MK-801 binding in the absence of kynurenate. The maximal reversal obtained by the nootropics was less than that observed by Pittaluga et al., possibly due to a different population of NMDA-type receptors residing on noradrenergic terminals as opposed to those found in total brain, which may have different pharmacological responses to nootropics. These findings have relevance for determining potentially efficacious cognition-enhancing compounds in a quantitative, mechanistic manner.

## 439.12

CHARACTERIZATION OF PD 158473, AN ORALLY ACTIVE COMPETITIVE ANTAGONIST OF THE NMDA RECEPTOR, AS MEASURED BY  $[^3H]$ TCP BINDING.

C. F. Bigge\*, J. Li, J. J. Cordon and L. L. Coughenour. Parke-Davis Pharmaceutical Research Division, Warner-Lambert Company, Ann Arbor MI, 48106.

The competitive antagonist, -Amino-3-(3-naphthalen-1-yl-5-phosphonomethyl-phenyl)-propionic acid (PD 158473), inhibits the binding of  $[^3H]$  CGP 39653 to the NMDA recognition site and the release of lactate dehydrogenase, as a measure of cell death, in cell cultures exposed to application of NMDA *in vitro*. *In vivo* it is orally active in preventing seizures caused by maximal electroshock. This study investigated the mechanism of action of PD 158473 using  $[^3H]$  thienylcyclohexylpiperidine (TCP), a high potency blocker of the NMDA channel, as a probe for measuring NMDA receptor activation. PD 158473 inhibited the binding of  $[^3H]$ TCP in well-washed, frozen/thawed, rat forebrain membranes;  $IC_{50} = 0.021 \mu M$ . In comparison, the  $IC_{50}$  for reference NMDA antagonists was SDZ-515 (S), 0.29  $\mu M$ ; CGS 19755, 0.508  $\mu M$ ; and CPP 1.55  $\mu M$ . In the presence of PD 158473 (0.01  $\mu M$  to 1  $\mu M$ ) and glycine 0.03  $\mu M$  the  $EC_{50}$  for the enhancement of  $[^3H]$ TCP binding by glutamate was increased from 0.256  $\mu M$  to 11.5  $\mu M$ . The enhancement of  $[^3H]$ TCP binding by glycine in the presence of glutamate (0.1  $\mu M$ ) was inhibited in a concentration dependent manner by PD 158473 (0.01 to 1  $\mu M$ ) without altering the  $EC_{50}$  of glycine.

## 439.13

RPR 104632: A POTENT AND SPECIFIC GLYCINE-SITE NMDA RECEPTOR ANTAGONIST AND NEUROPROTECTIVE AGENT. S. Mignani, G.A. Böhme\*, A. Boireau, G. Birraux, M.C. Burgevin, A. Doble, P. Jimonet, C. Malgoures, J.C.R. Randle and J.C. Blanchard, Rhône-Poulenc Rorer Central Research, CNS Pharmaceuticals Research Program, 94400 Vitry-sur-Seine, France.

RPR 104632 (2H-1,2,4-benzothiadiazine-1-dioxide-3-carboxylic acid) is a novel ligand of the glycine-site of NMDA receptors that displaces [<sup>3</sup>H]-dichlorokynurenic acid binding to rat cortical membranes with a K<sub>i</sub> of 4.9 nM. In cerebellar slices from immature rats, RPR 104632 blocked the NMDA-induced increase in cGMP levels (IC<sub>50</sub> = 0.9 μM) and [<sup>3</sup>H]-thienylcyclohexylpiperidine (TCP) binding to the NMDA receptor/channel (IC<sub>50</sub> = 55 nM) in a glycine-sensitive manner. In rat hippocampal slices, long-term potentiation (LTP) of the Schaffer collateral-CA1 pathway EPSP was reduced from 163 ± 8% (n=6) to 105 ± 7% when 10 μM RPR 104632 was applied 30 min before tetanic stimulation, an effect that was not seen in the presence of 1 mM glycine (LTP = 147 ± 4%). In anesthetized rats, RPR 104632 (1-30 mg/kg iv.) inhibited (up to 70% and for 30-60 min) the excitatory responses of thalamic neurons to repetitive iontophoretic NMDA ejections. In hippocampal slices from immature rats, RPR 104632 (1 and 10 μM) reduced pyramidal cell necrosis induced by NMDA (100 μM) by 50 and 100%, respectively, an effect that was reversed by 1 mM glycine. In 8 day-old primary cultures of rat cortical neurons, RPR 104632 concentration-dependently (EC<sub>50</sub> = 0.5 μM) protected against cell death caused by NMDA (1 mM) as measured by trypan blue exclusion and MTT staining, an effect that was also sensitive to 1 mM glycine. Therefore, RPR 104632 is a potent antagonist at the glycine-site of the NMDA receptor/channel and an effective neuroprotective agent.

Supported by Rhône-Poulenc with the participation of the French Ministries of Research and Industry (Bio-Avenir Program).

## 439.14

BEHAVIORAL AND NEUROCHEMICAL ASSESSMENT OF THE PSYCHOTOMIMETIC POTENTIAL OF THE COMPETITIVE NMDA ANTAGONIST MDL 100,453. T.C. McCloskey\*, R.A. Padich, V.L. Taylor, C.J. Schmidt and J.H. Kehne. Marion Merrell Dow Research Institute, 2110 E. Galbraith Road, Cincinnati, Ohio 45215.

MDL 100,453, a competitive NMDA antagonist being developed for the treatment of stroke, was evaluated for duration of action using baseline startle depression, psychotomimetic potential using disruption of prepulse inhibition and stimulation of rat forebrain dopamine synthesis. Time course studies showed that MDL 100,453 has a considerably shorter duration of action than either D-CPPene or CGS 19755, suggesting the potential for improved control over possible side effects. Dose-response studies showed that the ion channel blockers phencyclidine, MK-801, and CNS 1102 consistently disrupted auditory and visual prepulse inhibition, and stimulated dopamine synthesis, indicative of high psychotomimetic potential. MDL 100,453, CGS 19755 and D-CPPene all depressed baseline startle but did not produce a channel blocker-like disruption of prepulse inhibition or stimulation of dopamine synthesis. There was a trend in both behavioral and biochemical studies for an improved psychotomimetic profile of MDL 100,453 relative to CGS 19755 and D-CPPene. Glycine antagonists resembled competitive NMDA antagonists in having minimal effects on prepulse inhibition and on dopamine synthesis. These data suggest that MDL 100,453 has a desirable pharmacokinetic and psychotomimetic side-effect profile relative to other competitive and uncompetitive NMDA antagonists.

## NEUROPEPTIDE LOCALIZATION: SENSORY PEPTIDES

## 440.1

IMMUNOHISTOCHEMICAL DETERMINATION OF SUBSTANCE P RECEPTORS IN RAT CENTRAL NERVOUS SYSTEM.

Y. Takeda<sup>1</sup>, H. Kawano<sup>2</sup>, K. Kawamura<sup>2</sup>, H. Asou<sup>1\*</sup> and K. Uyemura<sup>1</sup>. Departments of Physiology<sup>1</sup> and Anatomy<sup>2</sup>, Keio University School of Medicine, Shinjuku-ku, Tokyo 160, Japan.

Localization of substance P receptor (SPR) in mammals are extensively studied by radiolabeled binding assays. In this study, we immunohistochemically characterized a distribution of SPR in rat central nervous system. An antiserum against rat SPR was obtained by immunizing rabbits with C-terminal peptide (SPR<sub>398-407</sub>) of SPR and was characterized by using CHO cells transfected with rat SPR cDNA. A strong immunoreactivity was detected on the membranes of CHO cells stably expressing rat SPR. The immunoreaction on the membranes of cell bodies and processes in distinct populations of neurons were found throughout the central nervous system, such as olfactory bulb, septum, hypothalamus, cerebral cortex, hippocampus, superior colliculus, locus coeruleus, dorsal parabrachial nucleus and dorsal horn of the spinal cord in adult rat. In the primary culture of astrocytes isolated from neonatal rat cerebral cortex, SPR immunoreactivity was detected in O-2A progenitor cells and type-2 astrocytes, but not in type-1 astrocytes. Immunostaining with the anti-SPR antiserum preabsorbed with antigen peptide (10 μM) completely abolished all of the positive reactions.

The distribution of the SPR-like immunoreactivity detected in neuronal and glial cells coincides well with that of SP binding sites previously reported, indicating that the antibodies generated in this study recognize the physiologically active SPRs in rat central nervous system.

## 440.3

SUBSTANCE P AND ITS RECEPTOR NK-1 IN RAT DURA MATER ENCEPHAL-AN IMMUNOCYTOCHEMICAL STUDY. U. Hänesch, S. Moussaoui<sup>1</sup>, R.F. Schmidt\*. Physiologisches Institut, Röntgenring 9, D-97070 Würzburg, Germany. <sup>1</sup>Dept. of Biology, Rhône-Poulenc Rorer, 13, quai Jules Guesde, 94403 Vitry-sur-Seine, France.

Neurogenic inflammation of the meninges that is characterized by vasodilatation and plasma extravasation has been proposed as a pathogenic mechanism in headache and migraine pain. It is mainly mediated by the release of the sensory neuropeptides substance P (SP) and calcitonin gene-related peptide (CGRP) from afferent nerve fibers. While the vasodilatation seems to be mediated by CGRP, the plasma extravasation is very likely caused by SP, since it can be markedly attenuated by application of SP-antagonists that act at the NK-1 receptor.

The aim of the present study was to characterize the types of the target cells bearing the NK-1 receptor and to investigate the relationship between the site of release of SP (the primary afferents) and its site of action in the dura mater encephali. Therefore, single and double immunostaining with antibodies directed against SP and the NK-1 receptor was performed on whole mount preparations of the rat dura mater by using the ABC-method and the immunogold-silver staining.

NK-1 receptor immunoreaction product was found in the inner layer of venous vessels, on cells that resemble immune cells, mast cells and fibroblasts, and on Schwann cells of small nerves and nerve bundles. SP-immunopositive nerve fibers terminated as free nerve endings not only in close association to blood vessels, but also within the connective tissue between vessels. To now, no clear correlation could be found between terminals of SP-containing fibers and the localization of the NK-1 receptor.

We conclude that SP released from afferent fibers in the dura mater may have multiple effects when activating its receptor NK-1 found associated with different cell types. SP may mediate plasma extravasation by acting on the endothelial layer of venules, stimulate inflammatory mediators (e.g. prostaglandins) by activating fibroblasts and regulate the metabolism and excitability of nerve fibers by binding to Schwann cells.

## 440.2

NEUROKININ-3 RECEPTOR (NK-3R) DISTRIBUTION IN RAT AND HUMAN BRAIN: AN IMMUNOHISTOCHEMICAL STUDY. D. Mileusnic, D. J. Magnuson, M. J. Heins, J. B. Lorenz, S. A. Lorenz and J. M. Lee. Depts. Pharmacology and Pathology, Loyola Univ. Medical Center (Bldg. 135), Maywood IL 60153; Department of Molecular Biology, University of Bergen, Norway.

Autoradiographic studies have shown that the NK-3R is widely distributed in the rodent CNS. Expression of the NK-3R in human brain, however, has been debated, mainly due to low levels of the receptor mRNA. We examined <sup>3</sup>H-senktide binding in homologous cortical areas of the human and rat brain. Autoradiography in rat showed dense binding in the middle cortical layers and the ventral CA3 hippocampal region. The autoradiographic analysis of the human frontal cortex revealed a distinct superficial cortical binding, limited to only the glia limitans. The conflicting findings between the two species as well as the inadequate autoradiographic image resolution prompted us to develop a primary polyclonal antibody against both rat and human NK-3R. We used an oligopeptide derived from the carboxy-terminus (EASTSSFISSPTSSVDEYS; amino acids 434-452 of the rat receptor; the underlined Cys was added). The C-terminus was considered the best candidate for generation of the antibody since it is highly conserved between species, while divergent between different neurokinin receptors. NK-3R autoradiography and immunohistochemistry in young rat brain (4 mo) were highly correlated, with the highest concentrations of the receptor in cortical layers II-IV and the hippocampal CA2 and CA3 regions. In contrast, NK-3R immunoreactivity in normal humans (mean age 80 years) was found in the superficial cortical layers, mainly in cells that appear to be astrocytes. The Western blot analysis of the human frontal cortex and hippocampus as well as rat hippocampus revealed a major band in the molecular weight range of 60,000 to 70,000 D which corresponds to the proposed molecular weight of the NK-3R, based on the amino acid sequence. These findings suggest that there may be interspecies differences with regard to NK-3R expression and distribution. However, because there were major age differences between the human and rodent subjects in the present study, we are investigating the effects of aging on NK-3R expression.

## 440.4

LOCALISATION OF NK1 RECEPTOR IMMUNOREACTIVITY IN NEURONS AND INTERSTITIAL CELLS OF THE GUINEA-PIG GASTROINTESTINAL TRACT. A.L. Portbury\*, J.B. Furness, H.M. Young and S.R. Vigna\*. Department of Anatomy and Cell Biology, University of Melbourne, Parkville, Victoria, Australia, 3052 and \*Department of Cell Biology, Duke University Medical Centre, Durham, North Carolina 27710, USA.

The localisation and distribution of the NK1 receptor was studied throughout the gastrointestinal tract of the guinea-pig using a polyclonal antiserum raised against the C-terminal 15 amino acids of the NK1 receptor. NK1-immunoreactive nerve cell bodies were found in the myenteric and submucosal plexuses as well as in the interstitial cells of Cajal, at the level of the deep muscular plexus. No immunoreactivity was seen in either the circular or longitudinal muscle layers in any of the regions examined. Immunoreactivity was largely confined to the cell surface. The majority of NK1-immunoreactive nerve cells had Dogiel type 1 morphology. About two-thirds of NK1 reactive nerve cells were also reactive for nitric oxide synthase. NK1 was located in neuropeptide Y-containing secretomotor neurons of the myenteric and submucosal plexuses. A population of substance P-containing neurons in submucosal ganglia also exhibited NK1 receptors.

## 440.5

## RECEPTOR ENDOCYTOSIS OF THE SUBSTANCE P RECEPTOR AND DENDRITE RESHAPING IN SPINAL NEURONS AFTER SOMATOSENSORY STIMULATION

SD Rogers, JR Ghilardi, E DeMaster, H Liu, Al Basbaum, CR Mantyh, SR Vigna, GR Strichartz\*, JE Maggio, A Malhotra, DA Simone, PW Mantyh. Mol. Neurobiol. Lab (151), VA Med. Cntr., Mpls., MN 55417; Dept. Anatomy, UCSF, SF, CA 90024; Depts. Cell Biol. & Med., Duke Univ. Med. Cntr., Durham, NC 27710; Dept. Biol. Chem. Molec. Pharmacol., Harvard Med. School, Boston, MA 02115; Dept. Psychiatry, Univ. Minn., Mpls., MN 55455

Neurons in the mammalian brain express postsynaptic receptors that mediate responses to extracellular signals. The largest class of transmitters in the brain is the G protein-coupled receptor family, which includes adrenergic and muscarinic receptors and nearly all neuropeptide receptors, including the substance P (SP) receptor. Here we show that in vivo somatosensory stimuli, which evoke release of SP from primary afferent neurons terminating in the dorsal spinal cord, stimulate rapid and massive endocytosis of SP receptors in dorsal spinal neurons. In addition, thin distal dendrites which show SP receptor internalization undergo a morphological reorganization, from a roughly tubular structure to one of large swollen varicosities connected by thin segments. This internalization and dendritic structural rearrangement provides a pharmacologically specific image of neurons activated by SP. These data suggest that receptor internalization can drive reversible structural changes in neurons of the central nervous system in vivo. Both of these processes may be involved in neuronal plasticity. Supported by the NIH and the VA.

## 440.7

CHOLINE ACETYLTRANSFERASE AND NEUROKININ B mRNAs ARE COLocalized IN NEURONS OF THE HUMAN MAGNOCELLULAR BASAL FOREBRAIN COMPLEX. M.K. Chawla\*, G.M. Gutierrez, G.L. Wenk and N.E. Rance, Department of Pathology, College of Medicine and Division of Neural Systems, Memory & Aging, University of Arizona, Tucson, AZ 85724.

Our previous mapping study of the location of substance P and neurokinin B (NKB) mRNAs in the human hypothalamus and basal forebrain identified numerous NKB neurons in the magnocellular basal forebrain complex (Soc. Neurosci. Abstr., 20:516, 1994). In the present study, we determined if there is colocalization of choline acetyltransferase (ChAT) and NKB mRNAs in this region. Basal forebrains were collected from 3 adults without histories of neurological disease. Coronal blocks were snap frozen and serially sectioned at 10  $\mu$ m thickness. *In situ* hybridization was performed on every 10<sup>th</sup> (ChAT) and 11<sup>th</sup> (NKB) section using <sup>35</sup>S-labeled 48-base synthetic cDNA probes. In the nucleus basalis of Meynert, 216 labeled (> 5X background) magnocellular neurons were identified in adjacent sections hybridized for ChAT and NKB. Of these neurons, 41% contained both ChAT and NKB mRNAs, 50% contained only ChAT mRNA, 3% contained only NKB mRNA, and 6% were unlabeled. In the diagonal band of Broca, of 189 magnocellular neurons, 34% were double-labeled, 56% contained only ChAT mRNA, 4% contained only NKB mRNA, and 6% were unlabeled. Because the basal forebrain cholinergic system degenerates in Alzheimer's disease, it will of interest to determine if the cholinergic NKB neurons are also affected (Supported by NIH AG-09214).

## 440.9

QUANTITATIVE THREE-DIMENSIONAL MAPPING OF HUMAN BRAINSTEM SEROTONERGIC SYSTEMS. D. P. McLaughlin\*, J. E. Lopez, K. Y. Little, R. Pavlic and S. J. Watson. Mental Health Research Institute & V.A. Medical Center, University of Michigan, Ann Arbor, MI 48109-0720.

Investigation of the serotonergic systems of the human brainstem is necessary not only from a basic scientific point of view, but also from a clinical standpoint. 'Atypical' antipsychotics such as clozapine and risperidone have clear actions on 5-HT receptors, which may be the key to their usefulness as therapeutic agents in certain cases of schizophrenia. One cannot hope to determine their site(s) of action and develop even more useful therapies without a greater knowledge of the serotonergic circuits of the brain. To this end, we have developed a method for the generation of a three-dimensional (3-D) map of expression of key genes in the serotonergic systems of the human brainstem.

Brainstem blocks were obtained *post mortem* from seven normal controls, frozen rapidly on dry ice, and stored at -80°C until use. Tissues were then mounted on individual chucks and four fiducial holes were drilled in the blocks prior to sectioning, using a #55 wire drill bit (0.052"). These fiducial holes allow tissue autoradiograms to be placed in register, using specially-developed macros incorporated into the latest version of NIH IMAGE. This generates a 3-D map of gene expression in specific subregions of this area of the brain. Quantitative, digitized data are left intact and easily accessible. *In situ* hybridization protocols utilizing cRNA probes for tryptophan hydroxylase, the serotonin transporter and 5-HT<sub>1A</sub> 'autoreceptor' have been developed to allow quantitation of the levels of mRNA encoding these molecules, the three main components determining the concentration of any given monoamine transmitter in the synapse: the biosynthetic enzyme, transporter and autoreceptor.

It is hoped that this normative 3-D map of gene expression in the human brainstem will become the basis for future studies of the serotonin system, including studies into schizophrenia and depression.

## 440.6

ORGANIZATION OF TACHYKININ PEPTIDE mRNAs WITH OPIOID AND DOPAMINE SYSTEMS IN THE NUCLEUS ACCUMBENS OF THE RAT. E.J. Curran\* and S.J. Watson, Mental Health Research Institute, The University of Michigan, Ann Arbor MI 48109.

There are two genes that encode the tachykinins; preprotachykinin A encodes the precursors for both substance P (SP) and neurokinin A (NKA), and preprotachykinin B encodes the precursor for neurokinin B (NKB). The mRNAs for both of these tachykinin genes are expressed in the nucleus accumbens (NAcc). The distribution pattern for SP/NKA mRNA within the NAcc is rather homogeneous although there are regional variances in the magnitude of expression. In contrast, the distribution pattern for NKB mRNA is more distinct. NKB-positive cells are primarily observed in the rostral pole and shell where they aggregate together to form a patch-like pattern.

The interaction of the tachykinins with dopamine and opioid systems within the NAcc is thought to play a role in the motivational and motor properties of dopaminergic and opiate drugs. In a series of double in situ hybridization studies, we analyzed the colocalization patterns of SP and NKB mRNAs with opioid peptide, opioid receptor, and dopamine receptor mRNAs in the NAcc of Sprague-Dawley rats. Complex and distinguishable patterns of colocalization were observed for SP and NKB. The distribution pattern of NKB mRNA overlaps extensively with mu opioid receptor mRNA. Previously described substructures within the rostral pole and shell of the NAcc that uniquely coexpress proenkephalin and prodynorphin also overlap with NKB cell groups. Ongoing studies combining tract-tracing with in situ hybridization will determine how these different cell types are related to specific efferents of the NAcc. [This work was supported by DA 02265 and DA 08920]

## 440.8

THE DISTRIBUTION OF NEUROKININ B RECEPTOR (NK-3) mRNA IN THE FEMALE RAT CNS. P.J. Shughrue\*, M.V. Lane and J. Merchenthaler. Women's Health Research Institute, Wyeth-Ayerst Research, Radnor, PA 19087.

The tachykinins, substance P, neurokinin A and neurokinin B, are a family of neuroactive peptides that appear to have three distinct receptors termed NK-1, NK-2 and NK-3. While the distribution of the NK-1 receptor has been elucidated, little is known about the topography of NK-2 and NK-3 in the rodent brain. Autoradiographic binding studies with tachykinin agonists have provided some insight about the distribution of NK-3 receptors in the rat brain, however the results of these studies varied with different agonists. With the cloning of the rat NK-3 cDNA, it is now possible to evaluate the distribution of NK-3 mRNA in the rat brain. The brains of female rats were frozen and 20  $\mu$ m cryostat sections collected on microscope slides, hybridized with a <sup>35</sup>S-labeled antisense riboprobe complementary to NK-3 mRNA, stringently washed and apposed to emulsion. The results of these studies revealed an extensive distribution of NK-3 mRNA throughout the rostral-caudal extent of the brain. In agreement with previous binding studies, we observed NK-3 mRNA in the cerebral cortex; amygdala; hippocampus; medial habenula; zona incerta; the paraventricular and supraoptic nuclei of the hypothalamus; substantia nigra; ventral tegmental area; interpeduncular nuclei; raphe nuclei, dorsal tegmental nucleus and the nucleus of the solitary tract. In contrast with binding data, only a few NK-3 mRNA cells were detected in the striatum. In addition, the results of the present studies have demonstrated the presence of NK-3 mRNA in the olfactory bulb; dentate gyrus and subiculum of the hippocampus; medial septum; diagonal band of Broca; ventral pallidum; globus pallidus; bed nucleus of the stria terminalis; the arcuate, premammillary and mammillary nuclei and the dorsal and lateral regions of the posterior hypothalamus; central gray; cerebellar cortex; parabrachial nuclei; pontine gray; nucleus of the spinal trigeminal tract and the dorsal horn of the spinal cord. The results of these *in situ* hybridization histochemical studies have provided detailed and novel information about the distribution of NK-3 mRNA in the rat central nervous system. This morphological data also elucidates the putative sites of neurokinin B action in the central nervous system which is an important step towards understanding the neuronal systems modulated by this neuropeptide.

## 440.10

COMPARATIVE DISTRIBUTION OF AMYLIN AND CALCITONIN GENE RELATED PEPTIDE (CGRP) IMMUNOREACTIVITIES IN THE ADULT RAT BRAIN. Roger P. Dilts\*, Julie Phelps, Joy Koda and Kevin Beaumont. Amylin Pharmaceuticals Inc., San Diego, CA 92121

Calcitonin gene related peptides (CGRP) and amylin share almost 50% sequence identity and can interact at receptors within the rat brain. While CGRP-like immunoreactivity (CGRP-IR) has been extensively studied, comparatively little is known about the distribution of amylin-like immunoreactivity (amylin-IR). Therefore, we investigated the distribution of amylin-IR within the rat brain using monoclonal antibodies, F024-4.4 and F055-24, raised against human amylin, and compared this to CGRP-IR. Serial 40 micron sections of perfusion fixed rat brains were prepared. Sections were exposed to a 1:5000 dilution of guinea pig anti-CGRP serum (Accurate Chemical Co., Westbury, NY) and/or a monoclonal antibody concentration of 1  $\mu$ g/ml. Primary antibodies were detected using biotinylated donkey anti-guinea pig IgG and/or anti-mouse IgG (Jackson Immunoresearch Laboratories Inc., West Grove, PA) coupled with either streptavidin-peroxidase, DAB reaction product intensified with cobalt and imidazole, or with fluorescence utilizing streptavidin-Cy3 or FITC. Amylin-IR was most notable within the spinal trigeminal tract and sparsely distributed within the area postrema and solitary tract nucleus. No amylin-IR was observed within the superior olivary nucleus where CGRP-IR fibers, as well as cell bodies, were easily discerned. Amylin-IR was also observed within the central amygdaloid nucleus. Thus, it appears that amylin-IR represents a highly localized subset of CGRP-IR fibers and cell bodies within the rat brain.

## 440.11

**ENKEPHALINS IN THE DEVELOPING CENTRAL NERVOUS SYSTEM OF THE AXOLOTL, *Ambystoma mexicanum*.** Sánchez-Islas E., Sánchez-Alvarez M., Pellicer F.\* and León-Olea M. Div. de Investigación en Neurociencias, Instituto Mexicano de Psiquiatría, Tlalpan México, D.F. C.P. 14370.

Endogenous opioid systems have been shown to play an important role in the regulation of neural development. This system may serve as a trophic factor that regulates cell proliferation and influences cell differentiation and neurobehavioral ontogeny through inhibitory mechanisms (Hess and Zagon. Brain Res. Bull. 20:473-478, 1978). In this study we determined the existence and anatomical localization of the immunoreactive neurons (IRN) and fibres (IRF) to enkephalins (LE, ME) and the octapeptide (MERGL) in the developing central nervous system of the axolotl until it reaches two months old. We carried out experiments using the indirect immunofluorescence method with antibodies directed against LE, ME and MERGL. The results shown cover the days 10, 21, 26, 33 and 49 after the first cleavage. Our main results show no immunoreactivity (IR) present in the brain at day 10. At day 21, we found IRF in the motor zone (MZ) of the ventral part of rhombencephalon and a low density of IRF in the reticular formation. At day 33, IRN were clustered in groups covering all brain regions, and there was an appreciable increase in the density of IRF compared to previous stages. A high density of IRF to ME were found in the thalamic paraventricular nucleus (TPv) and hypothalamus, whereas in amygdala, preoptic nuclei, ventral thalamus and ventral tegmentum a moderate density was present. A moderate density of IRF to MERGL was localized in TPv and hypothalamic nuclei (HthN). The rhombencephalon presented IRF to ME in the ventral part of MZ. At day 49, an increase in the density of IRF and IRN to LE, ME and MERGL localized in the ventral part of the brain was observed, especially a high density of IRF in the HthN. Our results show that enkephalins are present in early stages of ontogeny, suggesting an important role in the organization and development of the CNS. ## 440.13

**TRANSIENT APPEARANCE DURING TOOTH TURNOVER OF GALANIN PEPTIDE AND C-FOS PROTEIN IN TRIGEMINAL GANGLION NEURONS PROJECTING TO GINGIVA AND TOOTH PULPS IN A POLYPHYODONT SPECIES.** E. TUISKU\* AND K. EDOFF, DEPT. CELLBIOLOGY, FAC. HEALTH SCI., LINKÖPING UNIVERSITY, S-581 85 LINKÖPING, SWEDEN.

It has become apparent that neuropeptides and transcription factors contained in specific populations of neurons are not necessarily detectable at all times. Changes in the levels of these factors commonly occur during development. In the polyphyodont cichlid *Tilapia mariae* nerve fibers influence the regular formation of new tooth germs. In view of this, it appeared of interest to analyse if the cytochemical characteristics of tooth-related trigeminal ganglion (TG) neurons in *T. mariae* change during tooth turnover (i. e. when the functional teeth are shed, a new generation erupts, and the development of a third one is initiated). In anesthetized animals fluorescent latex microspheres were injected into gingiva or tooth pulps. After a survival period the animals were reanesthetized and perfusion fixed. The TG was dissected out bilaterally and cryosectioned. Fluorescence microscopic analysis revealed retrogradely labeled TG neurons in the distal half of the ganglion. TG neurons projecting to the gingiva exhibited a unimodal size distribution with a diameter range of 8-14  $\mu$ m (peak at 11  $\mu$ m). TG neurons innervating tooth pulps displayed a bimodal size distribution with a diameter range of 10-30  $\mu$ m (peaks at 12 and 25  $\mu$ m). Following tracer analysis the same sections were processed for peroxidase-antiperoxidase immunohistochemistry against a selected set of neuropeptides or transcription factors. Light microscopic analysis revealed a galanin peptide (Gal)-like immunoreactivity (LI) in TG neurons projecting to gingiva and tooth pulps. This Gal-LI was exclusively present during tooth turnover. Other gingival and pulpal TG neurons displayed a c-fos-LI with the same temporal appearance as the Gal-LI. It is concluded that the cytochemical characteristics of some tooth-related TG neurons in *T. mariae* change during tooth turnover.

## 440.15

**A RAT GALANIN RECEPTOR: ITS CLONING AND DISTRIBUTION IN RAT FOREBRAIN.** E. Grafstein-Dunn, G. G. Cadd, D. K. Clifton, and R. A. Steiner\*. Depts. of Ob-Gyn and PBio, University of Washington, Seattle, WA 98195.

The neuropeptide galanin (GAL) is thought to play an important modulatory role as a cotransmitter in a variety of classical and peptidergic pathways. In the hypothalamus, GAL is coexpressed with gonadotropin-releasing hormone (GnRH) and with growth hormone-releasing hormone (GHRH) and may modulate their release through undefined mechanisms. Although evidence for both pre- and post-synaptic actions of GAL has been found, GAL's target cells in the brain have not been clearly identified. Therefore, we have 1) cloned a fragment of a rat GAL receptor (Gal-R), 2) mapped its distribution in the forebrain, and 3) assessed possible coexpression of Gal-R in GnRH and GHRH neurons to determine whether GAL could directly regulate the activity of these cells. We cloned a 400 bp fragment of a GAL receptor cDNA by PCR from a rat brain cDNA library and found it to be 85% identical to the published human GAL receptor sequence. We synthesized a <sup>33</sup>P-labeled riboprobe and performed double-label *in situ* hybridization on brain sections of adult male and female rats. Neurons expressing Gal-R mRNA were identified in several regions previously reported to contain GAL binding sites. These included: preoptic regions, basal forebrain, hypothalamus, thalamus, amygdala, and hippocampus. We found no evidence for coexpression of Gal-R mRNA in GnRH or GHRH neurons in either sex. In conclusion, the distribution of Gal-R mRNA parallels that of GAL binding sites in several regions. A direct action of GAL on either GnRH or GHRH neurons does not seem likely since neither cell type expressed the Gal-R.

## 440.12

**RAT PINEAL CELLS EXPRESSING PREPROENKEPHALIN mRNA ARE NOT SEROTONIN-PRODUCING PINEALOCYTES: EVIDENCE USING *IN SITU* HYBRIDIZATION COMBINED WITH IMMUNOCYTOCHEMISTRY FOR SEROTONIN** X.-T. Wang\*, G. D. Pappas, J. Sagen and J. R. Unnerstall, Dept. of Anat. & Cell Bio., Univ. of Illinois at Chicago College of Med., Chicago, IL 60612.

The localization and physiological function of bioactive peptides and growth factors in the mammalian pineal gland has received considerable attention. In the present study, the preproenkephalin (PPEnk) mRNA expressing cells have been identified in rat pineal gland using radioactive *in situ* hybridization histochemistry. Approximately seven percent of the cells in the pineal gland ( $7.5 \pm 0.86$ , mean  $\pm 95\%$  C.I.) express PPEnk mRNA. These cells are distributed throughout the pineal either as scattered single cells or small groups of cells with large round or oval nuclei. Using ABC immunocytochemistry for serotonin (5-HT), the majority of cells in the pineal gland are found to be 5-HT positive. However, using *in situ* hybridization combined with 5-HT immunocytochemistry in the same pineal sections, the PPEnk mRNA labeling cells are found not to be serotonin immunoreactive cells. These data indicate that the PPEnk mRNA is expressed in certain discrete subpopulation of cells in rat pineal gland and these cells are not serotonin-producing pinealocytes. The physiologic role of PPEnk-derived peptides in the pineal remains unknown. It is possible that these peptides are either synthesized and secreted as hormones or act as pineal paracrine signals. Supported by NIMH MH47491

## 440.14

**AUTORADIOGRAPHIC STUDY OF GALANIN BINDING IN THE PRIMATE BRAIN: REGIONAL DIFFERENCES IN THE RESPONSE TO GTP PRETREATMENT.** J.B. Leverenz\*, B. Planas, M.A. Raskind and M.A. Miller. Depts. Medicine and Psych. & Behav. Sci., Univ. Washington, Seattle, WA 98195.

In humans, galanin (GAL) is a 30 amino acid neuropeptide implicated in a variety of neuroendocrine and behavioral functions. GAL exerts its effects via interactions with a specific G-protein coupled receptor. In crude membrane preparations of human hypothalamus, guanine nucleotides reduce GAL binding by inducing dissociation of the ligand-receptor complexes. We have recently reported that preincubation of adult rat brain slices with guanosine-5'-triphosphate (GTP) enhances GAL binding in specific regions including hypothalamus (Planas et al., 1994). GTP pretreatment may enhance binding density in slices by inducing dissociation of endogenous GAL from its binding sites and thereby unmasking previously occupied receptors. Here, we assessed the effects of GTP preincubation on GAL binding in human and non-human primate brain slices. Fresh frozen coronal sections (20  $\mu$ m) from normal human (n=4) and Macaca nemestrina (n=3) brains were sampled at the level of the paraventricular nucleus of the hypothalamus, amygdala, and hippocampus. Sections were preincubated with or without GTP ( $10^{-4}$  M) and then incubated in 0.25 nM [<sup>125</sup>I]-GAL (porcine). Non-specific binding was assessed by the addition of 0.25  $\mu$ M unlabeled GAL (porcine). GAL binding in several hypothalamic regions was robustly enhanced following GTP pretreatment (e.g., human lateral hypothalamus R.O.D.: GTP preat 0.42  $\pm$  0.03, no GTP 0.11  $\pm$  0.03, p<0.001). Preliminary findings in extrahypothalamic regions including the amygdala and hippocampus indicated that these regions differ from hypothalamus in their response to GTP pretreatment. This regional specificity of response to GTP parallels our previous observations in the adult rat and suggests that GAL release and receptor occupancy are also increased in the primate hypothalamus compared to other brain regions. These findings indicate that pretreatment with GTP may be necessary for accurate assessment of GAL binding site density in primate brain slices and may provide information about receptor occupancy by endogenous GAL.

## 441.1

FOUR DOPAMINE D<sub>1</sub>-LIKE RECEPTORS ARE EXPRESSED IN THE EEL BRAIN. Cardinaud, B., Kukstas, L.A., Vincent, J.D. & Vernier, P. Inst. Alfred Fessard, UPR 2212, CNRS, 91198, Gif/Yvette, France.

The phylogenetical analysis of bioamine receptor sequences suggests that the main classes of receptors were generated by gene duplication at a period close to the divergence of vertebrates from invertebrates. To test this hypothesis, we analyzed the molecular diversity of dopamine D<sub>1</sub>-like receptors in a fish, the european eel *Anguilla anguilla*. The combined use of PCR cloning and screening of an eel brain cDNA library led us to isolate four subtypes of D<sub>1</sub>-like receptor cDNA. Two of them are homologous to the vertebrate D<sub>1A</sub> receptors (D<sub>1A</sub> and D<sub>1A'</sub>), one is a D<sub>1B</sub> orthologue, and one is clearly homologous to the D<sub>1C</sub> receptor found in fishes and amphibians. These results indicate that the three main classes of D<sub>1</sub>-like receptors were generated before the divergence of fishes from the other vertebrates and that the D<sub>1A</sub> receptor was duplicated in the *Anguilla* phylum. The D<sub>1A'</sub> receptor is expressed at a much lower level than its sister gene. The pharmacological profiles of these fish D<sub>1</sub> receptors, transiently transfected in COS cells, closely resemble those of their vertebrate homologues. The D<sub>1A</sub> and D<sub>1B</sub> receptors are clearly discriminated by ligands such as butaclamol or flupentixol. *In-situ* hybridization of the D<sub>1A</sub> receptors showed a distribution restricted to areas such as pituitary, stratum periventriculare, torus semicircularis and especially the ventricular wall. The analysis of the molecular data in terms of anatomical homology will be extended to gain a better understanding of the genetic events which gave rise to the bioamine receptor diversity in vertebrates.

## 441.3

DIFFERENTIAL DESENSITIZATION OF D<sub>1</sub> DOPAMINE RECEPTOR FOLLOWING A81686 AND DOPAMINE TREATMENT. S.E. Côté\*, P.J. Bédard, P. Falardeau, Médecine Génétique et Moléculaire, CHUL, Université Laval, Ste-Foy, Québec, G1V 4G2, Canada.

The motor effects of D<sub>1</sub> receptor stimulation in Parkinson's disease seems to be a better therapeutic profil. However, specific D<sub>1</sub> receptor stimulation leads to a rapid and extensive desensitization. Interestingly, this desensitization is different according to the agonist used. Desensitization mechanisms induced by a new selective dopamine agonist (A81686) compare to dopamine was investigated using mouse fibroblast Ltk- cells expressing human D<sub>1</sub> receptors. Cells were treated with A81686 or dopamine and receptor levels, G protein coupling and adenylyl cyclase activation were examined. Exposure of Ltk-#20 cells to 10 $\mu$ M dopamine or A81686 for 4 hours resulted in a 17% decrease of total number of D<sub>1</sub> receptors, as assessed by [<sup>3</sup>H] SCH 23390 binding. Competition experiments of dopamine on [<sup>3</sup>H] SCH 23390 binding revealed no significant difference in the relative proportion of high affinity state receptors after pretreatment with dopamine (51%). In contrast, this proportion drop to 31% following A81686 treatment. Dopamine stimulated the activity of adenylyl cyclase in membranes of D<sub>1</sub> receptor expressing cells (4.7-folds over basal). Following dopamine treatment, the potency of dopamine to stimulate AC remained comparable to untreated cells (4.2-fold over basal). In contrast, this potency was decreased after pretreatment with A81686 (1.8-fold over basal). These results showed that A81686 is more potent to induce D<sub>1</sub> receptors desensitization than dopamine and suggested that the molecular mechanisms involved in desensitization can be dependent of the agonist used.

## 441.5

DOPAMINE D<sub>1</sub> RECEPTORS ARE NOT INVOLVED IN THE ACUTE TOLERANCE TO NICOTINE IN THE RAT. X. Zhang, J.R. James\*, C. Liu, Z.H. Gong, and A. Nordberg, Dept. of Clinical Neuroscience and Family Medicine, Division of Nicotine Research, Karolinska Institute, Huddinge University Hospital, 141 86, Sweden

Acute tolerance to nicotine was assessed in a two lever operant drug discrimination paradigm to study nicotine's mechanism(s) of action in the central nervous system. Rats were trained to discriminate nicotine (400 ug/kg, s.c.) from saline. A challenge dose of nicotine (800 ug/kg) administered 90-180 minutes prior to the training dose significantly attenuated drug lever responding in a subpopulation of the rats (desensitized) but not in another subpopulation (non-desensitized). Quantitative [<sup>125</sup>I]-SCH 23982 (dopamine D<sub>1</sub> receptor antagonist) autoradiography revealed that there is no significant difference in the number of dopamine D<sub>1</sub> receptors in caudate putamen (Cpu), accumbens nucleus (Acb), ventral tegmental area (VTA) and substantia nigra (SNR) between desensitized and non-desensitized rats. This result suggests that dopamine D<sub>1</sub> receptors are not involved in the acute tolerance to nicotine in the rat.

## 441.2

THE D<sub>1</sub> AGONIST SKF 82958 PREVENTS NALOXONE-INDUCED SEIZURES IN RATS INFECTED WITH BORNA DISEASE VIRUS. M. V. Solbrig, G. F. Koob and W. I. Lipkin\*, Lab for Neurovirology, University of California, Irvine CA 92717

Borna disease (BD) virus is a neurotropic RNA virus that causes movement and behavior disorders in immunocompetent animals. Infected rats have orofacial dyskinesias resembling the medical condition, tardive dyskinesia, that may follow exposure to neuroleptic drugs. Because dopamine and opiate systems may mediate perioral movements in rats, the effects of a selective D<sub>1</sub> agonist, SKF 82958, and the opiate antagonist, naloxone, were examined in the BD rat model of tardive dyskinesia.

BD rats had behavioral sensitivity to SKF 82958 (0.25, 0.50, and 1.00 mg/kg) as shown by continuous cage gnawing and self-biting. Naloxone (0.04, 0.20, and 1.00 mg/kg) caused myoclonic, generalized clonic, or atonic seizures, behavior arrest and staring spells, masking any effect on perioral movements. Naloxone-induced seizures were prevented by pretreatment with 1.00 mg/kg SKF 82958. These results demonstrate a convulsant action of naloxone in the BD rat and suggest that the seizures may be mediated by activity in D<sub>1</sub> circuits.

## 441.4

CHIMERIC DOPAMINE D<sub>1A</sub>, D<sub>1B</sub> AND D<sub>1C</sub> RECEPTORS: PHARMACOLOGICAL & FUNCTIONAL CHARACTERIZATION. K.S. Sugamori\*, M. Chung, and H.B. Niznik, Dept. of Pharmacology and Psychiatry, University of Toronto, and the Molecular Neurobiology Laboratory, Clarke Institute of Psychiatry, Toronto, Ontario, M5T 1R8

We previously reported the cloning and characterization of three dopamine D<sub>1</sub>-like receptor subtypes (D<sub>1A</sub>, D<sub>1B</sub>, D<sub>1C</sub>) from *Xenopus laevis*. The isolation of the novel D<sub>1</sub> receptor subtype, D<sub>1C</sub>, which lacks appreciable structural similarity but displays pharmacological homology to mammalian D<sub>1</sub> receptors may facilitate the identification of regions or structural motifs regulating D<sub>1</sub> ligand binding specificity and signal transduction. Using PCR-generated splicing by overlap extension, chimeras were constructed in which the variable carboxy tail regions were exchanged. Six chimeric receptors (D<sub>1A</sub>/D<sub>1B</sub>Ct, D<sub>1A</sub>/D<sub>1C</sub>Ct, D<sub>1B</sub>/D<sub>1A</sub>Ct, D<sub>1B</sub>/D<sub>1C</sub>Ct, D<sub>1C</sub>/D<sub>1A</sub>Ct, D<sub>1C</sub>/D<sub>1B</sub>Ct) have been generated, sequenced and expressed in COS-7 cells. Since the parent receptors differ in their affinities for the agonists DA and 6,7-ADTN, we have first determined the binding affinities (K<sub>i</sub>'s) for these chimeras. A rightward shift to wild type parent affinity for DA and ADTN was noted for the D<sub>1B</sub>/D<sub>1A</sub>Ct and D<sub>1B</sub>/D<sub>1C</sub>Ct chimeras indicating that sequences in the carboxy tail region of the D<sub>1B</sub> receptor may confer high affinity binding for certain D<sub>1</sub> receptor agonists. The K<sub>d</sub> for [<sup>3</sup>H]SCH-23390 was unchanged for these chimeras. The reciprocal of this effect, however, could not be tested as the D<sub>1A</sub>/D<sub>1B</sub>Ct and D<sub>1C</sub>/D<sub>1B</sub>Ct receptor chimeras did not show any detectable [<sup>3</sup>H]SCH-23390 binding, despite stimulation of cAMP accumulation in response to DA and high affinity SCH-23390 inhibition of DA-stimulated cAMP accumulation. None of the mutant receptors caused any appreciable shift in EC<sub>50</sub> for DA-stimulated cAMP accumulation confirming that sequence-specific domains conferring functional responsiveness may reside in the third intracellular loop. Since the carboxy tail regions may in turn play a role in receptor desensitization, the effect of short term desensitization is currently under investigation.

## 441.6

SCH 23390 IS A PARTIAL AGONIST AT RAT D<sub>1A</sub> AND D<sub>1B</sub> DOPAMINE RECEPTORS EXPRESSED IN SF9 CELLS. <sup>1</sup>M.W. Martin\*, <sup>1</sup>A.W. Scott, <sup>1</sup>S.A. Griffin, <sup>2</sup>S. Chumpradit, <sup>2</sup>H.F. Kung, <sup>3</sup>S.T. Elder, <sup>3</sup>R.H. Mach\* and <sup>1</sup>R.R. Luedtke <sup>1</sup>Department of Pharmacology, University of North Texas Health Science Center at Fort Worth, Fort Worth, TX 76107, <sup>2</sup>Department of Radiology, University of Pennsylvania School of Medicine, Philadelphia, PA 19104 and <sup>3</sup>Department of Radiology, Bowman Gray School of Medicine, Winston-Salem, NC 27157.

The baculovirus system was used to express the rat D<sub>1A</sub> and the rat D<sub>1B</sub> receptors in Sf9 cells. Rat D<sub>1A</sub> and D<sub>1B</sub> dopamine receptors expressed in Sf9 cells appear to be linked to endogenous Gs protein since a dose dependent stimulation of adenylyl cyclase activity can be achieved using dopamine. The dopamine receptor antagonists cis- $\alpha$ -flupentixol and fluphenazine inhibit a) dopamine dependent stimulation of adenylyl cyclase and b) basal enzyme activity in Sf9 cells expressing D<sub>1</sub>-like receptors. The benzazepine SCH 23390 stimulates adenylyl cyclase activity in Sf9 cells expressing rat D<sub>1A</sub> and D<sub>1B</sub> dopamine receptors with nanomolar EC<sub>50</sub> values. A panel of benzazepines structurally related to 7-chloro-8-hydroxy-1-(3'-iodophenyl)-3-methyl-2,3,4,5-tetrahydro-1H-3-benzazepine (TISCH) were also agonists at rat D<sub>1A</sub> and D<sub>1B</sub> receptors and their potency for stimulation correlates with their affinity for D<sub>1</sub>-like receptors. (Supported by NINDS 30507 and the National Alliance for Research on Schizophrenia and Depression).

## 441.7

CONSTITUTIVE ACTIVITY OF THE D<sub>1</sub> DOPAMINE RECEPTOR BY MUTATIONS NEAR PROLINES W. Cho\*, L. P. Taylor, A. Mansour and H. Akil. Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109.

Proline is highly conserved in the  $\alpha$ -helices of 7-transmembrane, guanine-nucleotide binding protein-coupled receptors. The peculiar properties of this imino acid have led to speculations that proline may be both structurally and dynamically important for 7TM function. As an alternative to the potentially deleterious consequences of proline-directed mutagenesis, substitutions were created in the X residue of X-pro peptide bonds (where X = the adjacent residue to the amino terminal side of proline) which may influence static geometries and possibly agonist-induced conformational changes at the X-pro peptide bond. In the fifth helix of the human D<sub>1</sub> receptor, isoleucine205 was substituted with either an alanine (I205A) or a tyrosine (I205Y). Similarly, in the sixth helix, leucine286 was substituted with either an alanine (L286A) or a tyrosine (L286Y). L286A resulted in a constitutively active receptor characterized by elevated basal cAMP levels and increased agonist potencies. This is the first report of a constitutively active receptor due to this novel point mutation. I205A resulted in subtle changes in the D<sub>1</sub> pharmacological profile and some deficits in signal transduction. I205Y and L286Y produced comparatively drastic impairments in both binding and signal transduction. While affinity shifts may reflect static alterations in ligand binding topography, modification of signal transduction properties may be due altered energetics of isomerizations or other conformational changes about the X-pro peptide bond necessary for linking agonist binding with G protein coupling.

## 441.9

DINAPSOLINE: A NOVEL FULL D<sub>1</sub> AGONIST. D.E. Nichols<sup>2</sup>, V.J. Watts<sup>1</sup>, C.P. Lawler<sup>1</sup>, D. Ghosh<sup>1</sup>, C. Stripplin<sup>2</sup> and R.B. Mailman<sup>1</sup>. Univ. of North Carolina<sup>1</sup>, Chapel Hill, NC 27599, and Purdue Univ.<sup>2</sup>, W. Lafayette, IN. 47907.

Despite the widespread clinical use of dopaminergic ligands (e.g., Parkinson's Disease or schizophrenia), it is generally recognized that more selective drugs, or drugs with unusual functional effects, may be of great utility. Several years ago, we synthesized the first high affinity, bioavailable, full D<sub>1</sub> agonist dihydroxidine (DHX; *trans*-10,11-dihydroxy-5,6,6a,7,8,12b-hexahydrobenzo[*a*]phenanthridine, a drug later shown to have profound antiparkinsonian effects in MPTP-treated monkeys. DHX also provided a semi-rigid structural backbone that allowed refinement of a D<sub>1</sub> agonist pharmacophore model. We now report the pharmacological properties of 8,9-dihydroxy-2,3,7,11b-tetrahydro-1H-naph[1,2,3-*de*]isoquinoline (dinapsoline). This compound was designed by tethering the two phenyl rings of dihydroxidine through a methylene bridge and removing the C(7)-C(8) ethanobridge. Preliminary molecular modeling studies demonstrated that these modifications conserved the relative orientation of all the essential elements of the D<sub>1</sub> pharmacophore (position and orientation of the nitrogen, hydroxyls, and phenyl rings). Dinapsoline had slightly higher affinity than DHX at rat striatal D<sub>1</sub> receptors ( $K_i = 5.9$  nM), and a Hill slope of 0.66, suggesting agonist characteristics. Consistent with this, in both rat striatum and C-6-mD<sub>1</sub> cells, dinapsoline was a full agonist with an EC<sub>50</sub> of 30 nM. These data provide a powerful test of the model of the D<sub>1</sub> pharmacophore we have developed, and provide another tool for the functional study of D<sub>1</sub> receptors. Moreover, DHX is interesting in that it has relatively high D<sub>2</sub> affinity ( $K_{0.5} = 100$  nM) despite the accessory phenyl ring usually thought to convey D<sub>1</sub> selectivity. DHX is unusual in that it is an agonist at some D<sub>2</sub> receptors, but an antagonist at others (so called "functional selectivity"). Dinapsoline had even higher affinity for the D<sub>2</sub> receptor ( $K_{0.5} = 31$  nM) than DHX. Studies are underway to determine whether dinapsoline retains the D<sub>2</sub> "functional selectivity" of DHX.

## 441.11

DOPAMINE D<sub>1</sub> RECEPTOR ACTIVATION PRODUCES OPPOSITE EFFECTS ON GABA RELEASE IN VENTRAL TEGMENTAL AREA BEFORE AND AFTER CHRONIC COCAINE. A. Bonci, D. Grandy\* and J. T. Williams. Vollum Institute for Advanced Biomedical Research, Oregon Health Science University, Portland, OR 97201.

The dopamine D<sub>1</sub>-mediated modulation of the GABAB IPSP in ventral tegmental area of guinea pig was studied before and after chronic cocaine treatment. Electrically evoked GABAB-mediated IPSPs were isolated pharmacologically by applying 2-amino-5-phosphonopentanoic acid (AP-5), 6-cyano-2,3-dihydroxy-7-nitro-quinoxaline (CNQX), picrotoxin, strychnine and tetrodotoxin. Our experiments show that in controls the D<sub>1</sub> receptor activation produced an increase in the GABAB IPSP, while in animals tested one week after the last cocaine injection we observed a decrease on GABAB IPSP. The effect of forskolin, an adenylyl cyclase activator, was likewise opposite in the two groups of animals, producing in controls and in cocaine treated animals respectively an increase and a decrease in the GABAB IPSP amplitude. It is known from other works that increased extracellular levels of adenosine can result from metabolism of cAMP. It has also been demonstrated that presynaptic A<sub>1</sub>-adenosine receptor activation inhibits GABA release in VTA. The A<sub>1</sub> adenosine antagonist, 8-CPT, and drugs able to decrease the extracellular adenosine levels such as RO-201724, probenecid and adenosine deaminase, reversed the inhibition of GABA release caused by D<sub>1</sub> receptor activation or by forskolin. This suggests that one week after chronic cocaine treatment the extracellular levels of adenosine in ventral tegmental area are increased. These results support the hypothesis that the D<sub>1</sub>/adenosine balance in the ventral tegmental area is profoundly altered after chronic cocaine and that this interaction could play a crucial role in sensitization to psychostimulants.

## 441.8

PURSUIT OF A SELECTIVE D<sub>5</sub> ANTAGONIST. BT Hoffman, SD Wyrick, MA Mayleben, PS Charifson, DL Minor, RB Mailman\*. Division of Medicinal Chemistry, School of Pharmacy, and Brain Development Research Center, School of Medicine, UNC-Chapel Hill, NC, 27599.

We have previously reported the binding affinities at the D<sub>1</sub> dopamine receptor of several tetrahydroisoquinoline ring-contracted analogs of the D<sub>1</sub> antagonist SCH23390. These analogs were synthesized in order to further characterize the antagonist binding pharmacophore of the D<sub>1</sub> receptor. The binding affinities of these compounds for the D<sub>1</sub> receptor were determined by conducting competition binding studies using rat striatal membranes labeled with [<sup>3</sup>H]SCH23390. ( $\pm$ )-N-methyl-6-chloro-7-hydroxy-1-phenyl-1,2,3,4-tetrahydroisoquinoline (R=H) exhibited a  $K_i$  of 12.5 nM. In order to assess the effects on affinity of substituents

on the appended phenyl ring, several analogs were synthesized. The ( $\pm$ )-*ortho*-methyl analog (R=CH<sub>3</sub>) had a higher affinity than the unsubstituted (R=H) analog, with a  $K_i$  of 8.4 nM. Methyl substituents in other ring positions decreased affinity; the ( $\pm$ )-*meta*-methyl and ( $\pm$ )-*para*-methyl analogs had  $K_i$ 's of 30 nM and 18 nM, respectively. An electron-withdrawing substituent in the *ortho* position decreased affinity, as was observed with the *ortho*-chloro analog (R=Cl), which had a  $K_i$  of 16 nM.

The D<sub>1</sub> and D<sub>5</sub> receptors are 80% homologous within the transmembrane regions, and radioligand binding experiments have shown that agonists and antagonists exhibit similar affinities for the D<sub>1</sub> and D<sub>5</sub> receptors. We are currently assessing the affinity of these compounds and novel analogs for the D<sub>5</sub> receptor. Discovery of a selective D<sub>1</sub> or D<sub>5</sub> ligand would be beneficial in delineating the pharmacological and biological differences between these dopamine receptor subtypes. This work was supported by PHS grant MH40537.

## 441.10

A-77636 INDUCES PERSISTENT ACTIVATION AND PROLONGED DENSITIZATION OF THE DOPAMINE D<sub>1</sub> RECEPTOR C.W. Lin\*, B.R. Bianchi, T.R. Miller, M.A. Stashko, P. Curzon, L. Hodges, K.E. Asin and Don Britton. Neuroscience Area, Abbott Labs, Abbott Park IL 60064

A-77636 is a D<sub>1</sub> receptor selective agonist that was shown to elicit beneficial responses in animal models of Parkinson's disease (Eur. J. Pharmacol. 229: 203, 1992). However, A-77636 is of limited potential for PD therapy because it rapidly induces tolerance *in vivo*. To understand how A-77636 induces tolerance, we studied the *in vitro* properties of A-77636 and A-81686, a related compound that did not lead to tolerance after repeated administration. Using a neuroblastoma cell line, SK-N-MC, as a model for the D<sub>1</sub> receptor, we found that A-77636 persistently activated the receptor. One h pretreatment with A-77636 resulted in significant residual cAMP production even after the drug solution was removed and the cells were washed. The residual cAMP activity was selectively inhibited by SCH 23390, a selective D<sub>1</sub> antagonist. The residual cAMP activity declined with pretreatment time and, after 4 h pretreatment, little residual cAMP production was observed. A-77636-treated cells were devoid of agonist response 4 hr after drug removal. In contrast, A-81686 did not elicit residual cAMP production in SK-N-MC cells. Receptor binding studies showed that pre-incubation of rat striatal membranes with A-77636 led to a large decrease (>80%) in D<sub>1</sub> receptor density, despite repeated washings. We conclude that A-77636 dissociates slowly from the D<sub>1</sub> receptor. The continued activation of the D<sub>1</sub> receptor leads to inability of the receptor to restore its responsiveness, and may explain the behavioral tolerance seen after A-77636 treatment.

## 441.12

SITE-DIRECTED MUTAGENESIS STUDY OF PALMITOYLATION SITES ON DOPAMINE D<sub>1</sub> RECEPTOR. H. Jin, R. Zastawny, H. Moldofsky\*, S. R. George and B. E. O'Dowd\*. Departments of Pharmacology and Psychiatry, University of Toronto; Addiction Research Foundation, Ontario, Canada.

Elimination of palmitoylation site(s) has been shown to produce different functional effects on several G protein coupled receptors. Two cysteines (Cys347 and Cys351) exist at the carboxyl terminus of the human D<sub>1</sub> receptor. To investigate the role of palmitoylation in G protein-coupling and desensitization of D<sub>1</sub> receptor, one or both cysteines were replaced by alanine using site-directed mutagenesis. In addition, a hemagglutinin epitope was tagged to both the wild type and mutant D<sub>1</sub> receptors. DNA constructs encoding the epitope-tagged wild type and Cys347Ala mutant receptors were individually transfected into the BHK3 cell line. In the two stable cell lines (BHK14 for the wild type and BHK25 for the mutant) selected and characterized, K<sub>d</sub> values of SCH23390 were: 590.9±65.1 pM for BHK14 and 527.9±75.5 pM for BHK25. Ki rank orders were the same for both clones: dopamine>SKF38393>5-HT>isoproterenol for agonists and SCH23390>butaclamol>haloperidol for antagonists. Therefore, introduction of both the epitope and mutation did not interfere with ligand binding. Two agonist affinity states were demonstrated by dopamine competition indicating the presence of G protein coupling, which was completely abolished in the presence of GppNHp. In addition, pretreatment of both cell lines with dopamine (10  $\mu$ M for 15 min) also caused a complete conversion of high affinity sites to low affinity and a similar 2-3 fold increase in EC<sub>50</sub> of adenylyl cyclase activity. Thus, the single mutation of Cys347Ala did not affect G protein coupling or agonist-induced adenylyl cyclase desensitization. Studies are currently being carried out to determine if the other single mutation (Cys351Ala) and the double mutation (Cys347Ala/Cys351Ala) will produce any different effects.

## 441.13

THE EFFECT OF GTP ON THE DISPLACEMENT OF [3H]SCH 23390 BY DA AGONISTS IN RHESUS MONKEY STRIATA. M.R. Weed, W.L. Woolverton\* and J.A. Paul. Dept of Psychiatry, Univ of Miss Med Ctr, Jackson, MS 39216.

Guanyl nucleotides alter agonist displacement of antagonist binding to G-protein-coupled receptors by reducing the high affinity binding component. The efficacy of guanyl nucleotides to shift the displacement potency of an agonist may be related to the intrinsic activity of the agonist. The present study describes the effect of 100  $\mu$ M GTP on binding to the dopamine (DA) D<sub>1</sub> receptor in rhesus monkey striata. Tissue was thawed in phosphate buffer (pH 7.4), homogenized, separated by centrifugation and used to initiate assays containing buffer, 4 mM MgCl<sub>2</sub>, 0.05 nM [3H]SCH 23390 and 16 concentrations of test compound. Assays were incubated at 37°C for 60 min, terminated by rapid filtration, soaked in 500  $\mu$ l of Packard Microscint cocktail, and bound radioactivity was measured using a Packard Top Count scintillation counter. 100  $\mu$ M cis-Flupentixol defined NSB. In the absence of GTP, D<sub>1</sub> agonists (i.e. compounds which stimulate cAMP production in rat striata) displaced [3H]SCH 23390 in a manner best fit with a 2-site model (Prism, GraphPad). For agonists, GTP addition reduced the percent high affinity binding without changing the affinity of either binding site. One-site

Compound	Fold Shift
Dopamine	6.14
SKF 81297	2.99
R(+)-Br APB	2.56
SKF 82958	2.35
SKF 77434	2.33
SKF 38393	2.23
S(-)-Br APB	1.84
SCH 39166	0.68
SCH 23390	0.51

models were fit to displacement curves in the presence and absence of GTP and the ratio between these two IC<sub>50</sub>'s is presented for each compound as the "fold-shift" induced by GTP. D<sub>1</sub> agonists with higher efficacies in cAMP assays had larger shifts than lower-efficacy agonists and antagonists. These data are generally consistent with the hypothesis that an agonist's sensitivity to guanyl nucleotides is related to its intrinsic efficacy. However, the differences in the effect of GTP on D<sub>1</sub> agonists were not as large as the differences of these same compounds to stimulate cAMP production in rat striata. Supported by DA-05616 and DA-08731.

## 441.15

INVESTIGATION OF CYCLIC AMP-MEDIATED REGULATION OF THE RAT D<sub>1A</sub> DOPAMINE RECEPTOR USING SITE-DIRECTED MUTAGENESIS TECHNIQUES. Dong Jiang and David R. Sibley. Molecular Neuropharmacology Section, ETB/NINDS/NIH, Bethesda, MD 20892.

Previous investigations of D<sub>1A</sub> receptor regulation have suggested a role for the cAMP-dependent protein kinase (PKA) in agonist-induced desensitization and down-regulation of receptor expression. Given the presence of at least three possible consensus recognition sites for PKA on the D<sub>1A</sub> receptor protein, a reasonable hypothesis is that some of these PKA-mediated effects are due to direct phosphorylation of the receptor. In order to investigate this possibility, we have used site-directed mutagenesis techniques to alter each of three potential phosphorylation sites to determine the subsequent effects on agonist-induced regulation of the receptor. Using a PCR-based mutagenesis method, we modified the following amino acids as indicated: Thr<sup>135</sup>→Val<sup>135</sup>, Ser<sup>229</sup>→Ala<sup>229</sup>, and Thr<sup>268</sup>→Val<sup>268</sup>. Residue 135 is found within the second intracellular loop of the receptor whereas residues 229 and 268 are present in the third intracellular loop. Preliminary characterization of the mutated receptors was achieved by lipofectamine-mediated transient transfection of COS cells. Both the wild type and mutant receptors were expressed at identical levels (Bmax values ranged from 1.5-4 pmol/mg between experiments) and there were no differences in the affinity of [3H]SCH-23390 (K<sub>D</sub> ~140 - 170 pM). Similarly, dopamine was found to compete for [3H]SCH-23390 binding and stimulate cAMP production in a identical fashion for all of the receptors. These data suggest that the mutations have no effect on receptor expression, antagonist or agonist affinities, or on functional coupling with Gs. Preliminary experiments indicate that dopamine preincubation of the transfected COS cells results in desensitization of the wild type receptor with no alteration in [3H]SCH-23390 binding. We are currently evaluating this response for the mutant receptors as well as preparing stably transfected cell lines for further analysis.

## 441.17

PRELIMINARY CHARACTERIZATION OF A MONOCLONAL ANTIBODY THAT BINDS A RECOMBINANT PROTEIN CORRESPONDING TO THE CARBOXY TERMINUS OF THE RAT D<sub>1b</sub> DOPAMINE RECEPTOR. R.R. Luedtke\*, S.A.Griffin, X.Jin and S.Summers, Department of Pharmacology, University of North Texas Health Science Center at Fort Worth, Fort Worth, TX 76107.

PCR was used to amplify a segment of DNA that codes for the carboxy terminus of the rat D<sub>1b</sub> dopamine receptor. Bam HI restriction sites were engineered into the primers to facilitate subcloning the amplified fragment into the pET expression system vectors. Plasmid containing the receptor gene fragment was used to transform BL21plysS DE3 *E. Coli* cells. Several colonies were evaluated using analytical SDS-PAGE for the ability to express a recombinant peptide following induction with 1 mM isopropyl- $\beta$ -D-thiogalactopyranoside. A recombinant protein corresponding to the carboxy terminus of the rat D<sub>1b</sub> receptor (rD<sub>1b</sub>-COOH) was partially purified by preparative SDS-PAGE and used to immunize BALB/c mice. Splenocytes from immunized mice were used for the preparation of hybridomas. Tissue culture media from the hybridomas was screened using recombinant protein with an ELISA and an immunoblot assay. One monoclonal antibody, designated SG5D1b bound rD<sub>1b</sub>-COOH but did not cross-react with the corresponding rD<sub>1a</sub>-COOH peptide. Research is ongoing to determine whether SG5D1b can specifically bind to the native receptor protein. (Supported by NINDS 30507, the Scottish Rite Schizophrenia Research Program and the National Alliance for Research on Schizophrenia and Depression).

## 441.14

DESENSITIZATION AND DOWN-REGULATION OF D<sub>1A</sub> DOPAMINE RECEPTORS IN MUTANT CHO CELLS DEFICIENT IN CYCLIC AMP-DEPENDENT PROTEIN KINASE. Ana L. M. Ventura\* and David R. Sibley. Molecular Neuropharmacology Section, ETB/NINDS/NIH, Bethesda, MD 20892.

In order to investigate the role of the cAMP-dependent protein kinase (PKA) in the desensitization and down-regulation of the D<sub>1A</sub> dopamine receptor, we stably expressed the rat cDNA for this receptor in mutant CHO cell lines deficient in PKA activity. The 10260 mutant CHO cell line has been characterized as expressing less than 10% of type I and type II PKA activities relative to the parental 10001 CHO cell line. The 10248 mutant CHO line lacks type II PKA activity but expresses type I PKA. The transfected parental and mutant cell lines were found to express between 1-3 pmol/mg of D<sub>1A</sub> receptor binding activity (Bmax) as determined using [3H]SCH23390. All three cell lines demonstrated similar levels of dopamine-stimulated adenylyl cyclase activity. Treatment of all three CHO cells with dopamine resulted in a similar (>90%) desensitization of the dopamine-stimulated adenylyl cyclase response. Dopamine also promoted, in a time- and dose-dependent fashion, a >90% down-regulation of D<sub>1A</sub> receptors in the parental cell line, but only a ~50% decrease in both mutant lines. Similarly, treatment of the cells with CPT-cAMP and 8-Bromo-cAMP, membrane permeable analogs of cAMP, decreased the receptor binding activity in the parental cell line by ~50%, however, the decrease was smaller for the 10260 mutant (~25%) and not significant (<5%) with mutant 10248. A similar result was obtained by treating the cells with forskolin which down-regulated the D<sub>1A</sub> receptors by ~50% in the parental cells, ~25% in the 10260 mutant cells and ~10% in the 10248 cell line. Our results suggest that PKA significantly contributes to the down-regulation of D<sub>1A</sub> receptors in CHO cells but may not be essential for desensitization of the adenylyl cyclase response by dopamine.

## 441.16

DOPAMINE D<sub>1</sub> RECEPTORS COUPLING TO ACTIVATION OF ADENYLYL CYCLASE IS MEDIATED BY Gs BUT NOT GOLF PROTEINS. H.-Y. Wang, G.-P. Cai and E. Friedman. Department of Pharmacology, Medical College of Pennsylvania/EPPi, Philadelphia, PA 19129.

Previously, the possible role of Golf in dopamine D<sub>1</sub> receptor stimulated striatal adenylyl cyclase was suggested by the enrichment and its colocalization with D<sub>1</sub> binding sites in striatal tissues (Herve et al., 1993). The involvement of guanine nucleotide binding proteins, Gs and Golf in regulating the dopamine stimulated adenylyl cyclase was therefore investigated in rat striata. Incubation of striatal membranes with antisera against  $\alpha$ -subunit of Gs but not Golf attenuated dopamine-stimulated cAMP accumulation by 50%. Furthermore, the association between those G proteins with dopamine D<sub>1</sub> receptor was examined by the ability of dopamine to stimulate [<sup>35</sup>S]GTP $\gamma$ S and [ $\alpha$ -<sup>32</sup>P]GTP to the two G $\alpha$  proteins in striatum. Dopamine increased [<sup>35</sup>S]GTP $\gamma$ S to Gs but not to Golf. Analysis of immunoprecipitated [<sup>32</sup>P]guanine nucleotide associated G $\alpha$  protein revealed that dopamine activated Gs (45-KDa) but not Golf (42-KDa) in striatum. Similarly, antisera against Gs but not Golf precipitated D<sub>1</sub> receptors as indicated by specific [3H]SCH23390 binding. These results thus suggest that dopamine D<sub>1</sub> receptors are coupled with Gs but not with Golf to stimulate adenylyl cyclases.

## 441.18

CO-LOCALIZATION OF THE D<sub>1</sub> DOPAMINE RECEPTOR IN A SUBSET OF DARPP-32-CONTAINING NEURONS IN RAT CAUDATE-PUTAMEN. K.C. Langley\*, C. Bergson† and C.C. Ouimet. Program in Neuroscience, Florida State University, Tallahassee, FL 32306, †Department of Pharmacology, Pennsylvania State College of Medicine, Hershey, PA 17033

DARPP-32 is a dopamine and cAMP-regulated phosphoprotein that is enriched in dopaminergic brain regions high in D<sub>1</sub> dopamine receptor binding. We used double-labeling immunofluorescence to localize both the D<sub>1</sub> receptor and DARPP-32 in the rat caudate-putamen. As expected, both D<sub>1</sub> and DARPP-32 antibodies heavily labeled fibers in the neuropil. Many medium-sized neuronal cell bodies were weakly immunoreactive for the D<sub>1</sub> receptor and a larger number were strongly immunoreactive for DARPP-32. All cell bodies immunopositive for the D<sub>1</sub> receptor appeared to be immunopositive for DARPP-32. The D<sub>1</sub> receptor was not detectable, however, in a subpopulation of DARPP-32-containing cell bodies.

These findings are consistent with the known regulation of DARPP-32 phosphorylation by D<sub>1</sub> receptor activation. The lack of detectable D<sub>1</sub> receptor in a subset of DARPP-32-positive cell bodies supports the idea that in these cells other receptors may regulate DARPP-32 phosphorylation.

## 441.19

DOPAMINE (D<sub>1</sub>) RECEPTOR IN THE CHICK FOREBRAIN. A LIGHT- AND ELECTRONMICROSCOPIC STUDY: R. Schnabel<sup>1</sup>, S. Jiang<sup>1</sup>, K. Braun<sup>1</sup>, H. Stark<sup>1\*</sup>, H. C. Hemmings<sup>2</sup> and P. Greengard<sup>3</sup>. <sup>1</sup>Fed. Inst. for Neurobiology, Magdeburg, Germany, <sup>2</sup>Cornell Medical Center, New York, <sup>3</sup>Rockefeller University, New York.

Auditory imprinting induces an increased metabolic activity in associative forebrain regions. In the mediorostral neostriatum/hyperstriatum ventrale (MNH) the type I neurons show a reduction of spine synapses and prolonged postsynaptic densities of the remaining synapses. From other experiments we have some evidence for the involvement of dopamine in this synaptic selection process. The physiological effects of dopamine are mediated by two distinct receptor types. We compared the localization of D<sub>1</sub> receptors in imprinting relevant forebrain areas of the chick detected by ligand autoradiography with the immunohistochemical demonstration of D<sub>1</sub> receptors. Using autoradiography the highest D<sub>1</sub> receptor densities were observed in the basal ganglia (lobus parolfactorius, paleostriatum augmentatum), amygdala (dorsal archistriatum) and dorsal and lateral caudal parts of the neostriatum and hyperstriatum ventrale. The MNH revealed moderate labeling. In general, the autoradiographical results are in accordance with the immunohistochemical pattern. Discrepancies were found in the HV including the hyperstriatal part of the MNH, which shows a high ligand binding but only few immunoreactive cell bodies and fibers. In the MNH and caudal neostriatum the immunoreaction product was found postsynaptically in symmetric and asymmetric synapses which are located on cell bodies and dendritic shafts and spines.

This work was supported by grants GSF 07 NBL 06 and 0310651 of the BMBF and Schn 505/1-2 of DFG.

## SEROTONIN RECEPTORS: STRUCTURE AND STRUCTURE/FUNCTION

## 442.1

RARE NON-CONSERVATIVE AMINO ACID SUBSTITUTION IN THE 5-HT<sub>2</sub> RECEPTOR GENE FOUND IN ALCOHOLICS WITH ANTISOCIAL PERSONALITY DISORDER. U. Pesonen<sup>\*</sup>, M. Koulou, M. Eggert, M. Virkkunen, M. Linnoila and D. Goldman. Laboratory of Neurogenetics, DICBR, NIAAA, Rockville, MD, USA.

Reduced central serotonergic neurotransmission has been associated with increased aggression and impaired impulse control in humans. The distribution and pharmacological properties of the serotonin 5-HT<sub>2</sub> receptor suggest that it may play a role in psychiatric disorders. We screened using PCR-SSCP method the coding sequence of the 5-HT<sub>2</sub> receptor gene for sequence variants within a Finnish population of alcoholics with violent behavior. Subjects included in the study are alcoholic offenders who were ordered to undergo forensic psychiatric examination. The controls are a random sample of healthy volunteers. In three patients with antisocial personality disorder we discovered a non-conservative amino acid substitution in the putative third intracellular loop of the receptor protein while none of the ethnically matched healthy controls had this mutation. The study provides evidence for the involvement of the 5-HT<sub>2</sub> receptor in antisocial personality disorder in violent alcoholic offenders.

## 442.2

STRUCTURE AND FUNCTION OF NATURALLY OCCURRING MUTATIONS IN THE HUMAN SEROTONIN<sub>1A</sub> RECEPTOR GENE. Bita Nakhai, David A. Nielsen, Bridget Giblin, Alessandro Rotondo, Gary Jenkins and David Goldman<sup>\*</sup>. Section of Molecular Genetics, LN, NIAAA, Bethesda, MD 20892.

The serotonin 1A (5-hydroxytryptamine) receptor gene codes for the 5-HT<sub>1A</sub> receptor. It is expressed both presynaptically in serotonergic cell bodies and in dendrites of the dorsal raphe nucleus and postsynaptically in hippocampus. Serotonin plays a key role in many physiological and behavioral functions including aggressive behavior, intolerance to delay, impulsivity, appetite and control of temperature and sleep. Serotonergic activity is regulated, in part, by binding of serotonin to the 5-HT<sub>1A</sub> receptor.

Two relatively rare polymorphisms were identified in the human 5-HT<sub>1A</sub> gene by SSCP analysis. Both amino acid substitutions alter the extracellular amino terminal domain. The polymorphisms encode amino acid substitutions in the 5-HT<sub>1A</sub> receptor of a glycine to serine at amino acid 22 and an isoleucine to valine at amino acid 28, respectively. The polymorphic 5-HT<sub>1A</sub> alleles were found in American and Finnish Caucasians and in Native Americans. To study the biological function and biochemical properties of these allelic variants we subcloned them in a eukaryotic expression vector, under the control of the CMV promoter. They were further transiently transfected into mammalian COS-7 cells to characterize 5HT<sub>1A</sub> receptor function by various methods including receptor binding assays. The allelic variants did not show a remarkable difference in binding to the 5-HT<sub>1A</sub> specific ligand 8-OH DPAT compared to the wild type receptor. Studies of the stably expressed variants are under way and these studies will allow us to assess effects on signal transduction and receptor regulation.

## 442.3

GENOMIC CLONING AND HETEROLOGOUS EXPRESSION OF A RECOMBINANT GUINEA PIG SEROTONIN 5-HT<sub>1Dα</sub> RECEPTOR. W.H.M.L. Luyten<sup>\*</sup>, J. Van de Weyer, G. Nobels, P. Van Gompel, W. Gommeren, A. Lesage and J.E. Leysen. Dept. of Biochem. Pharmacol., Janssen Research Foundation, Beerse, B2340 Belgium.

Significant differences exist between the pharmacological properties of 5-HT<sub>1D</sub> receptors (Rs) in various species, rendering extrapolation of e.g. rodent data to humans hazardous. Human 5-HT<sub>1Dα</sub> and 1Dβ-R subtypes are very similar pharmacologically, but the ligand-binding properties of the latter differ significantly from those of their rat or mouse homologues, which are therefore called 5-HT<sub>1B</sub>-Rs. Guinea pigs are also used frequently for pharmacological studies but their 5-HT<sub>1D</sub>-Rs have not yet been cloned or expressed; only small partial sequences of their 5-HT<sub>1Dα</sub>-R have been published so far (C.R. Acad. Sc. III 314: 429 (92); Proc. Natl. Acad. Sc. U.S.A. 91: 3666 (94)).

PCR-primers based on the published guinea pig 5-HT<sub>1Dα</sub>-R sequence were used to amplify a ±350 bp fragment of the coding region (including transmembrane domains II through IV) starting from cDNA prepared from total RNA of guinea pig trigeminal ganglion and cerebellum. This fragment was verified by restriction digests and labelled with 32P-dCTP by random-priming. A λEMBL-3 guinea pig genomic library was screened with this probe and two clearly positive plaques were identified amongst 750,000 plated (±3.5 genome equivalents). Both λ-clones were plaque-purified and partially sequenced by primer-walking (cycle-sequencing followed by resolving the reaction products on an ABI 373 automated fluorescent sequencer). The coding region was subsequently PCR-amplified with Pfu (Stratagene), subcloned into the SmaI site of pBluescript (Stratagene) and the sequence verified once more. The insert was then subcloned into the pSVL expression vector (Pharmacia) yielding pSVL/5-HT<sub>1Dα</sub>-R. Membranes from COS-cells transiently transfected with pSVL/5-HT<sub>1Dα</sub>-R were used for radioligand binding studies and the data were compared with those from guinea pig cerebellum membranes. The same insert was subcloned into the pRc/CMV vector (Invitrogen) and CHO-K1 cells were permanently transfected with this construct. Membranes prepared from transfectants were used for radioligand binding studies and inhibition of forskolin-stimulated cAMP formation was measured in intact CHO-cells.

## 442.4

CLONING AND CHARACTERIZATION OF RABBIT 5-HT<sub>1Dα</sub> AND 5-HT<sub>1Dβ</sub> RECEPTOR SUBTYPES: A COMPARISON OF THE PHARMACOLOGICAL PROFILE TO THE HUMAN SPECIES HOMOLOGUES. S.A. Kucharewicz, J.A. Bard, R.L. Weinshank, T.A. Branchek<sup>\*</sup>. Synaptic Pharmaceutical Corporation, Paramus, NJ 07652.

Species differences in the pharmacology of 5-HT<sub>1D</sub> binding sites have long been observed. In order to further explore this issue, we have cloned the rabbit 5-HT<sub>1Dα</sub> and 5-HT<sub>1Dβ</sub> genes, transiently transfected them into Cos-7 cells, and assessed membrane preparations in relationship to the pharmacology of the previously cloned human homologues. The K<sub>d</sub> of [<sup>3</sup>H]-5-HT determined from saturation experiments for the rabbit 5-HT<sub>1Dα</sub> and 5-HT<sub>1Dβ</sub> receptors was 4.02 nM and 6.46 nM, respectively. The B<sub>max</sub> for rabbit 5-HT<sub>1Dα</sub> and 5-HT<sub>1Dβ</sub> was determined to be 235 fmol/mg and 740 fmol/mg protein respectively. The rank order of binding affinities determined from competition experiments is as follows: rabbit 1Dα, 5-CT>5-HT>5-CH<sub>3</sub>O-tryptamine=5-CH<sub>3</sub>-tryptamine>sumatriptan>α-CH<sub>3</sub>-5-HT>8-OH DPAT>mCPP; rabbit 1Dβ, 5-CT=5-HT>5-CH<sub>3</sub>O-tryptamine>5-CH<sub>3</sub>-tryptamine>sumatriptan>α-CH<sub>3</sub>-5-HT>8-OH DPAT>mCPP; human 1Dα, 5-CT>5-HT>sumatriptan=5-CH<sub>3</sub>O-tryptamine>8-OH DPAT>α-CH<sub>3</sub>-5-HT>5-CH<sub>3</sub> tryptamine=mCPP; human 1Dβ, 5-CT>5-HT>sumatriptan>5-CH<sub>3</sub>O-tryptamine>α-CH<sub>3</sub>-5-HT>8-OH DPAT>mCPP>5-CH<sub>3</sub> tryptamine. The differences in the rank order of binding affinities observed when comparing the cloned rabbit to the cloned human 5-HT<sub>1D</sub> subtypes may be attributed to species differences in the amino acid sequences within the transmembrane domains of the species homologues. Correlation plots for rabbit vs. human 5-HT<sub>1Dα</sub> (r = 0.82) and 5-HT<sub>1Dβ</sub> (r = 0.80) demonstrates the similarity of the pharmacology of the species homologues. Finally, the rabbit 5-HT<sub>1Dα</sub> and 5-HT<sub>1Dβ</sub> receptors show considerable similarity in their pharmacological profiles (r = 0.86).

## 442.5

**SITE-DIRECTED MUTAGENESIS OF THE HUMAN 5-HT<sub>1D</sub> RECEPTOR FOR IDENTIFICATION OF AMINO ACIDS INVOLVED IN LIGAND BINDING.** C. Gránäs\*, G. Nordvall, D. Larhammar. Dept. of Medical Pharmacology, Box 593, #Dept. of Organic Pharmaceutical Chemistry, Uppsala University, S-751 24 Uppsala, Sweden.

The precise structure of the 5-HT<sub>1D</sub> receptor and the molecular mechanisms for ligand binding are unknown. We have made a three-dimensional model of the 5-HT<sub>1D</sub> receptor based on the high-resolution structure of bacteriorhodopsin and energy minimized this model with ligands docked into the binding pocket. To evaluate the usefulness of this model and to determine the ligand-binding properties of the 5-HT<sub>1D</sub> receptor we have performed site-directed mutagenesis in TM4 (Ser181 to Ala, Phe185 to Ala or Met), TM5 (Ser212 to Ala), TM6 (Phe331 to Ala or Tyr, Ser334 to Ala) and TM7 (Phe354 to Ala or Tyr). According to the model these amino acids may all interact with ligands. The indol part of 5-HT may interact with Ser181 and there may be a H-bond to sumatriptan with Ser212. An aromatic ring interaction with Phe331 is predicted and Ser334 might have a specific interaction with sumatriptan, hence a mutation to Ala (as in the 5-HT<sub>1A</sub> receptor) should give more 5-HT<sub>1A</sub>-like binding properties. Phe354 is adjacent to Asn/Thr355 that accounts for the pharmacological differences between the human HT<sub>1D</sub> and rodent 5-HT<sub>1B</sub> receptor. Phe185 differs between 5-HT<sub>1</sub> receptor subtypes; we have introduced the Leu present at the corresponding position of the 5-HT<sub>1D</sub> receptor. The influence of these residues on binding of various ligands and the accuracy of the model predictions will be reported.

## 442.7

**MOLECULAR CLONING AND PHARMACOLOGICAL ANALYSIS OF NEUROTRANSMITTER RECEPTORS FROM THE CENTRAL NERVOUS SYSTEM OF LYMNAEA STAGNALIS.** C.C. Gerhardt, J. Leysen, R. J. Planta, E. Vreugdenhil and H. van Heerikhuizen\*. Graduate School of Neurosciences Amsterdam, Research Institute Neurosciences Vrije Universiteit, Faculty of Chemistry, Department of Biochemistry and Molecular Biology, Vrije Universiteit, De Boelelaan 1083, 1081 HV Amsterdam, The Netherlands. I)Department of Biochemistry and Pharmacology, Janssen Research Foundation, Turnhoutseweg 30, B2340 Beerse, Belgium.

G-protein-mediated signal-transduction pathways are crucial in neuronal communication. To study the in vivo molecular mechanisms underlying these pathways we have adopted the giant neurons of the pond snail *Lymanaea stagnalis* as a model system. Because of their large size these neurons are extremely suitable for perturbation of signaling components by injection of specific 'molecular tools' (e.g. expression plasmids, antisense oligonucleotides, antibodies, etc.). As a first step to generate such tools we have applied the PCR technique to amplify cDNA fragments encoding neurotransmitter receptors. Here we present data on the cloning and functional expression of three such receptors.

One of these receptors exhibits the highest similarity to the vertebrate subfamily of 5-HT<sub>2</sub> receptors and was therefore designated 5-HT<sub>2</sub>lym2. The identity of 5-HT<sub>2</sub>lym2 was further investigated by its expression in HEK293 cells. As with the vertebrate 5-HT<sub>2</sub> receptors, application of 5-HT induces an increase in intracellular IP<sub>3</sub> concentration. Furthermore, [3H] mesulergine, a specific antagonist for mammalian 5-HT<sub>2C</sub> receptors, binds with high affinity to 5-HT<sub>2</sub>lym2. This binding can be competed for by several mixed 5-HT<sub>2A/2B/2C</sub> antagonists and agonists, showing a pharmacological profile most closely related to 5-HT<sub>2B</sub> and 5-HT<sub>2C</sub> receptors.

Two other neurotransmitter receptors, GRI004 and GRI007, exhibit significant sequence similarity with the tyramine receptor from *Drosophila* and mammalian adrenergic receptors. Expression studies show that [3H] rauwolfine, an antagonist for mammalian  $\alpha$ -adrenergic receptors, binds to both receptors in the nanomolar range. Both adrenaline and noradrenaline are able to elicit an increase in intracellular cAMP levels. However, octopamine (the putative evolutionary precursor to adrenaline and nor-adrenaline) induces a strong increase in cAMP in GRI007 but not in GRI004, indicating that the former is likely to be the *Lymanaea* octopamine receptor.

## 442.9

**IDENTIFICATION, MOLECULAR CLONING, AND DISTRIBUTION OF A SHORT VARIANT OF THE SEROTONIN 5-HT<sub>2C</sub> RECEPTOR PRODUCED BY ALTERNATIVE SPLICING.** H. Canton\*, R.B. Emerson, E.L. Barker, J.T. Lu, M.S. Chang, and E. Sanders-Bush. Dpt. of Pharmacology, Vanderbilt University Medical School, Nashville, TN 37232.

S1 nuclease protection of the rat serotonin<sub>2C</sub> (5-HT<sub>2C</sub>) receptor mRNA revealed a second short transcript. The short form was expressed in the same structures as the 5-HT<sub>2C</sub> mRNA, for example, choroid plexus, striatum, hippocampus, hypothalamus, olfactory tubercles, and spinal cord. However, the ratio of the short form over 5-HT<sub>2C</sub> mRNA varied from 0.6 in an epithelial tissue (choroid plexus) to 0.25 in striatum showing differential regulation. Cloning and sequencing revealed a second clone with a 95 nucleotide deletion in the region coding for the putative second intracellular loop and the fourth transmembrane domain of the 5-HT<sub>2C</sub> receptor. This deletion leads to a frameshift in the downstream sequence coding region and a premature stop codon. The deduced protein contains 172 amino-acids, with 153 residues at the amino-terminal identical to the 5-HT<sub>2C</sub> receptor, and 19 carboxy-terminal amino-acids that are specific. Expression of the short form in different cell types failed to reveal any serotonergic ligand binding. The two transcripts arise from a single gene by alternative splicing using two different donor sites and a common acceptor. PCR amplification of mouse or human brain cDNAs showed the occurrence of the same splicing pattern. Due to nucleotide sequence differences, the human short form encodes a putative 248 amino-acid protein with 96 specific residues on the amino-terminus. In conclusion, this study demonstrates the occurrence in rat, mouse and human of two 5-HT<sub>2C</sub> mRNA spliced-variants with apparent tissue-specific regulations. The functional significance of the short form remains to be established (supported by NIH research grant MH 34007).

## 442.6

**MOLECULAR CLONING OF PLANARIAN SEROTONIN RECEPTORS** O. Saitoh<sup>1</sup>, H. Orii<sup>2</sup>, K. Agata<sup>2</sup>, K. Watanabe<sup>2</sup> and H. Nakata<sup>1</sup>. <sup>1</sup>Dept. of Mol. & Cell. Neurobiol., Tokyo Metropolitan Inst. for Neuroscience, Fuchu-shi, Tokyo 183 and <sup>2</sup>Dept. of Life Science, Fac. of Science, Himeji Inst. Tech., Hyogo 678-12, Japan.

Planarians are well known for their ability of regeneration. Although previous studies suggest a significant role of serotonin for the planarian regeneration, its molecular and cellular mechanisms are not well understood. We therefore explored the possibility that the planarians express novel serotonin receptors which are responsible for the regeneration process. We first analyzed ligand binding properties of crude planarian membranes and found that they possessed high affinity binding sites with the serotonergic ligand, [<sup>3</sup>H]LSD (K<sub>d</sub>=2.6 nM). The ligand binding specificity of the planarian membranes was similar to that of *Drosophila* serotonin receptor 1 (5HT-dro1). We then tried to clone the corresponding receptor gene by PCR using degenerate primers. Four individual clones which contained consensus sequences of the G-protein coupled receptors were amplified from planarian cDNA. Judging from the homology comparison, all the four clones (PLAR1-4) appeared to be classified into the serotonin receptor family. A full-length cDNA clone for PLAR4 clone, which seems to be most abundantly expressed in planarians, was isolated from a planarian cDNA library. This cDNA clone encoded 478 amino acids that can be organized into seven transmembrane stretches. This amino acid sequence also showed a significant similarity with a human 5-HT<sub>1A</sub> serotonin receptor. Its physiological functions are currently under investigation.

## 442.8

**IDENTIFICATION OF RAT SEROTONIN 5-HT<sub>2C</sub> RECEPTORS AS GLYCOPROTEINS CONTAINING N-LINKED OLIGOSACCHARIDES.** J. R. Backstrom\*, R. S. Westphal, H. Canton, and E. Sanders-Bush. Dept. of Pharmacology, Vanderbilt University School of Medicine, Nashville, TN 37232.

Antibodies against a portion of the rat 5-HT<sub>2C</sub> receptor third intracellular loop were generated and used to identify receptors solubilized from cell lines and rat brain. Western blots of CHAPS-soluble proteins were probed with affinity-purified anti-2C antibodies. The specificity of anti-2C was demonstrated with extracts prepared from NIH/3T3 fibroblasts which stably express functional rat 5-HT<sub>2C</sub> or 5-HT<sub>2A</sub> receptors. Extracts from the 5-HT<sub>2C</sub> cell line, but not the 5-HT<sub>2A</sub> cell line, contained immunoreactive proteins with masses of 51-52 kDa and 58-68 kDa. In the brain, the highest relative amount of immunoreactive proteins was identified in choroid plexus, with masses of 51 kDa and 58-62 kDa. The 5-HT<sub>2C</sub> receptor cell line (3T3/2C) was grown in the presence of tunicamycin to metabolically inhibit N-linked glycosylation. Proteins from the cell extracts were detected with masses of 40 and 41 kDa. Extracts prepared from 3T3/2C cells (grown in the absence of tunicamycin) and from choroid plexus were incubated with N-glycosidase F to enzymatically remove available N-linked sugars. Immunoreactive proteins were detected with masses of 41 and 42 kDa from 3T3/2C cells and 41 kDa from choroid plexus. Neuraminidase reduced the mass of the 51 and 58-62 kDa proteins from the choroid plexus to 50 and 54-58 kDa. In contrast, the proteins from 3T3/2C cells were not affected by treatment with neuraminidase. These results demonstrate that 5-HT<sub>2C</sub> receptors contain N-linked sugars and suggest that 5-HT<sub>2C</sub> receptors in the choroid plexus contain sialic acid residues. (Supported by NIH research grant MH34007).

## 442.10

**SERINE<sup>159</sup> OF THE HUMAN 5HT<sub>2A</sub> RECEPTOR INTERACTS WITH 5HT BUT NOT LSD.** N. Alaula\*, B.J. Ebersole, D. Zhang, H. Weinstein, and S.C. Sealfon. Mount Sinai School of Medicine, New York, N.Y. 10029.

The 5HT<sub>2</sub> receptor subtypes have been implicated in mediating the effects of hallucinogenic drugs of abuse. Mutant receptors were constructed to identify the determinants underlying the specificity of ligand interaction with the human 5HT<sub>2A</sub> receptor. We have identified a serine residue in transmembrane helix 3 which differentially affects the binding affinity of 5HT, tryptamine and LSD. Substitution of S3.36(159) by alanine causes an approximately 10 fold decrease in the affinity of 5HT and tryptamine, whereas the binding affinity of LSD remains unaffected. Replacement by cysteine has an intermediate effect on 5HT and tryptamine affinity whereas the affinity of the structurally unrelated ligand DOI for both mutant receptors was decreased approximately 20 fold. Ketanserin had wild-type high affinity for both mutant receptors. These results are interpreted with respect to a three dimensional molecular model of the human 5HT<sub>2A</sub> receptor, in terms of the different orientations of the various agonists. (Supported by NIH-NIDA DA09088, K05 DA00060 and T32 DA07135).

## 442.11

**DETERMINANTS OF COUPLING EFFICIENCY AND SIGNAL SPECIFICITY IN THE TMH 6 ADJACENT DOMAIN OF THE HUMAN 5-HT<sub>2A</sub> RECEPTOR.** B.J. Ebersole\*, N. Almazul, J.A. Ballesteros, H. Weinstein and S.C. Scalfon. Departments of Anesthesiology, Pharmacology, Neurology, Physiology and Biophysics, and Fishberg Center in Neurobiology, Mount Sinai School of Medicine New York, NY.

Chimeras of the third cytoplasmic loop of several G-protein coupled receptors have been found to alter coupling specificity and one chimera involving only the membrane proximal segment of TMH6 of the  $\beta$ -adrenergic /  $\alpha_1$  adrenergic receptor generated a constitutively active  $\beta$ -adrenergic receptor (Samama et al., J.Biol.Chem.268:4625, 1993). In the 5-HT receptors, there are three residues which differ in this domain between the human 5-HT<sub>2A</sub> and 5-HT<sub>1A</sub> subtypes. We studied the effects of exchanging these residues in the 5-HT<sub>2A</sub> receptor for the corresponding 5-HT<sub>1A</sub> receptor residues. A V6.36(324)T mutation caused no change in E<sub>max</sub> or EC<sub>50</sub> for 5-HT-stimulated phosphatidylinositol (PI) turnover, nor in binding affinities for [<sup>3</sup>H]-Ketanserin or 5-HT in comparison to wild type receptor expressed transiently in COS-1 cells. Simultaneous alteration of all three residues in which the receptor subtypes differ [A6.33(321)T, C6.34(322)V, and V6.36(324)T] did not result in changes in binding affinities or receptor expression levels, but did lead to a 100-fold increase in EC<sub>50</sub> and 50% reduction in E<sub>max</sub> for 5-HT-stimulated PI turnover. Neither of these constructs showed significant changes in the basal level of PI turnover. These results and studies on other systems implicate this domain as a critical structural determinant in the efficiency of receptor coupling. Some mutations increase efficiency and generate constitutively active mutants whereas others, like the triple amino acid mutation, decrease coupling efficiency. The effect of these and additional mutations in this domain on coupling efficiency and specificity will be presented from the exploration of effects on PI turnover and cAMP accumulation. Supported by NIH grants DA09088, DA09083, KO5 DA00060, and NIDA training grant DA07135.

## 442.12

**IDENTIFICATION OF RESIDUES WHICH ALTER KETANSERIN BINDING AFFINITY TO 5-HT<sub>2A</sub> RECEPTORS: Comparison with binding models for ketanserin.** MS Choudhary\*, N Khan\*, RA Glennon\* and BL Roth\*. Departments of Biochemistry and Psychiatry, Case Western Reserve University School of Medicine, Cleveland, OH 44106 #Department of Medicinal Chemistry, MCV/VCU, Richmond, VA

The elucidation of the mode(s) of drug binding to neurotransmitter receptors remains a major unsolved problem for modern molecular pharmacology. The approach we have taken to clarify this issue is to combine molecular modelling and molecular biology techniques. We now report our results in which more than 40 mutant 5-HT<sub>2A</sub> receptors were constructed and characterized and in which the results were compared with previously published models of ketanserin binding to 5-HT<sub>2A</sub> receptors. In addition, several ketanserin analogues were tested at mutant receptors to clarify the mode(s) of binding at the implicated sites. Chimeric receptor studies suggested that ketanserin bound to multiple helices; specific interactions were implicated between helices II-III and VI-VII. Point mutations of both conserved and non-conserved residues identified at least 5 sites which altered ketanserin's affinity for the 5-HT<sub>2A</sub> receptor (F339, M132, W336, W367, Y370). Preliminary results suggest that the nature of the substituent on the benzyl moiety strongly affects binding to F339. The results were compared with a model for ketanserin binding (Kristiansen et al, 1994) and, in general, a good correspondence was found comparing residues predicted to be important for ketanserin binding and residues found to alter ketanserin's affinity for the 5-HT<sub>2A</sub> receptor. It was significant that residues which were found experimentally to affect ketanserin's affinity for the 5-HT<sub>2A</sub> receptor were found clustered around the predicted central core of the receptor. Supported by GM52213 (BLR).

SEROTONIN RECEPTORS: 5-HT<sub>2</sub>

## 443.1

**THE EFFECTS OF SELECTED 5-HT RECEPTOR AGONISTS ON NEURONAL NETWORK ACTIVITY IN MURINE SPINAL CORD CULTURES.** M.H. Droge\*, S. Laufer, G. Gross, L. Uphouse. Dept. of Biol., Texas Woman's Univ., Denton, TX 76204; Dept. of Biol. Sci., Univ. of North Texas, Denton, TX 76203.

The effects of 5-HT<sub>1A</sub> and 5-HT<sub>2</sub> receptor activation on mouse spinal neurons were tested in 4-8 week old, spontaneously active monolayer networks. The cultures were grown on photoetched electrode arrays featuring 64 thin film electrodes for extracellular recordings. Spike activity was integrated for display and analysis. Bath applications of the 5-HT<sub>1A</sub> receptor agonist 8-hydroxy-2-(di-N-propylamino)tetralin-HBr (8-OH-DPAT, 10-30  $\mu$ M) resulted in prolonged episodes of repetitive bursting. Compared to pre-test activity, the 8-OH-DPAT-induced pattern had increased burst durations and increased interburst intervals, which produced a lower frequency of bursting. Applications of the 5-HT<sub>2</sub> receptor agonist [1(2,5-dimethoxy-4-iodophenyl)-2-amino-propane-HCl (DOI, 0.2 mM) resulted in a cessation of activity that was reversible with a medium change. The 8-OH-DPAT results are consistent with the reported inhibitory action of 5-HT<sub>1A</sub> agonists. DOI's blockade of activity is surprising, but may indicate 5-HT<sub>2</sub>-receptor activation of inhibitory interneurons. Supported by the Federation of North Texas Area Universities, RO1 HD 28419 and GM 08256.

## 443.2

**SEROTONIN EXCITES DORSAL VAGAL MOTONEURONS VIA 5-HT<sub>2A</sub> RECEPTORS.** A.P. Albert, P.A. Brooks. Dept. Physiology, Royal Free Hospital School of Medicine, LONDON, NW3 2PF, UK.

In the rat, *in vitro* studies have shown that serotonin (5-HT) increases the excitability of dorsal vagal motoneurons (DVMs) by eliciting a direct, postsynaptic slow depolarization mediated via a reduction in K<sup>+</sup> conductance (Albert & Brooks, J. Physiol. 481, 23P, 1994). This study investigates in greater detail the receptor subtypes involved using selective 5-HT antagonists.

Whole-cell patch recordings in current-clamp mode were made from visually identified DVMs in 175-200  $\mu$ m thick brainstem slices from 17-21 day old rats. The DVMs were identified as clusters of fusiform shaped cells between 20-30  $\mu$ m in diameter.

From a holding potential of -60 mV control responses to bath applications (5ml/min) of 5-HT were obtained ( $6.9 \pm 0.27$  mV,  $n=35$ , 20  $\mu$ M). Antagonists were preincubated for between 5-60 mins. The selective 5-HT<sub>2A/2C</sub> antagonists ketanserin (1  $\mu$ M) and LY 53,857 (1  $\mu$ M) both significantly blocked the response to 5-HT (20  $\mu$ M) as did the 5-HT<sub>1A/2A</sub> antagonist, spiperone (1  $\mu$ M), whereas pindolol (5  $\mu$ M), a selective 5-HT<sub>1A</sub> antagonist, had no effect. The selective 5-HT<sub>2</sub> antagonists MDL 72222 (10  $\mu$ M) and ICS-205-930 (1  $\mu$ M) had a small partial blocking effect. ICS-205-930 at higher concentrations (10  $\mu$ M) produced an increase in this partial antagonism, however, complete block was never obtained.

We conclude that 5-HT increases the excitability of DVMs via a 5-HT<sub>2</sub> receptor, probably the 5-HT<sub>2A</sub> subtype. Also, a small component could involve a 5-HT<sub>1</sub> response, although this requires further analysis. The involvement of 5-HT<sub>1</sub> receptors in this response is unlikely as ICS-205-930 was only a partial antagonist at high concentrations.

The research was supported by the Wellcome Trust.

## 443.3

**INHIBITION OF THE 5HT<sub>2A</sub> RECEPTOR-MEDIATED STIMULATION OF PHOSPHOINOSITIDE (PI) HYDROLYSIS BY AN ANTISENSE OLIGODEOXYNUCLEOTIDE IN A NEURONAL CELL LINE.** J.M. Scalzitti\*, K.A. Berg and J.G. Hensler. Department of Pharmacology, University of Texas Health Science Center at San Antonio, San Antonio, TX 78284.

The A1A1 variant cell line, is a descendant of the A1A1 clone which is derived from 16 day rat cortical cultures by retroviral transduction of the wildtype simian virus 40. The A1A1 variant cells endogenously express the 5HT<sub>2A</sub>, adenosine-2, and bradykinin receptors and exhibit an amplified second messenger response as compared to the parent line (see Berg et al. Mol. Pharm. 45:826, 1994). In A1A1 variant cells quipazine acted as a partial agonist (intrinsic activity of 0.75 in reference to the full agonist 5HT) with an EC<sub>50</sub> of 713 nM and E<sub>max</sub> 119% above basal. Cells were treated with vehicle, antisense or control oligos (0.2  $\mu$ M cumulative) for 5 days in a serum-free medium. Cells were pre-labelled with 2  $\mu$ Ci of [<sup>3</sup>H]-myo-inositol for PI hydrolysis assays or 1  $\mu$ Ci of [<sup>3</sup>H]-thymidine to assess oligo-induced cytotoxicity. On the sixth day [<sup>3</sup>H]-thymidine uptake was measured or cells were stimulated with quipazine and total inositol phosphate (IP) accumulation determined. The antisense oligo treatment decreased the efficacy of the partial agonist quipazine (antisense: E<sub>max</sub> =  $55.3 \pm 4.4$  % of control E<sub>max</sub>) with no change in the potency (antisense: pEC<sub>50</sub> =  $5.71 \pm 0.21$ ; vehicle: pEC<sub>50</sub> =  $6.15 \pm 0.16$ ; p<0.1). The sense, random and mismatch controls had no effect on the E<sub>max</sub> or EC<sub>50</sub> of quipazine to stimulate PI hydrolysis. [<sup>3</sup>H]-thymidine uptake was unaffected by the presence of either the antisense or control oligos. The data indicate that an 18-base antisense oligo attenuates 5HT<sub>2A</sub> receptor-mediated second messenger function without affecting cell proliferation. Currently, the effect of the antisense oligo on receptor number, the bradykinin receptor response and ribonuclease protection assays are being performed. Antisense oligodeoxynucleotides may prove to be more selective tools than traditional agonists and antagonists for investigations into the role of central 5HT<sub>2A</sub> receptors *in vivo*. Supported by USPHS grant MH52369.

## 443.4

**5-HT<sub>2A</sub> ACTIVATION PRODUCES VARIABLE EFFECTS ON SEROTONIN FIBER GROWTH AND SURVIVAL AFTER LESIONING BY PCA OR MDMA.** B. Liao\*, J.C. Rios, L. Corrente, E.C. Azmitia, H.K. Kramer and J.C. Pobleto. Dept. of Biology, New York Univ., NY, NY, 10003.

Substituted amphetamines (SA) like 3,4-methylenedioxymethamphetamine (MDMA) and p-chloroamphetamine (pCA) are specific serotonergic (5-HT) neurotoxins which promote the release of monoamines (5-HT and DA). We have proposed the involvement of the 5-HT-2a/2c receptor in the mechanisms that promote the degeneration of fine 5-HT axons in the forebrain. This receptor has been shown to become transiently downregulated after chronic MDMA-exposure; possibly through increased synaptic 5-HT levels. MDMA and 5-HT have also been shown to increase cerebral glycogenolysis and promote PKC activation in whole brain and cortical astrocytes via this receptor. Consequently, SA's may deplete 5-HT synapses of vital energy reserves after the prolonged activation of this receptor. We now examine the effect of 5-HT-2a/2c receptor activation after a SA-mediated de-afferentation of 5-HT fibers, to observe how an increase in glucose availability to injured 5-HT axons influences their re-innervation.

Male Sprague-Dawley rats were injected (s.c.) with MDMA (6 x 20 mg/kg), pCA (1 x 10 mg/kg) or saline. One week later, rats received saline or the 5-HT-2 agonist, ( $\pm$ )-DOI-HCl (0.5, 2.5, or 5.0 mg/kg), for 3 days. Seven days later, the density and activity of forebrain and brainstem 5-HT nerve terminals were quantified by [<sup>3</sup>H]-paroxetine ([<sup>3</sup>H]-PAR) binding and [<sup>3</sup>H]-5-HT uptake.

MDMA and pCA exposure significantly reduced the density of forebrain (cortical) [<sup>3</sup>H]-PAR binding sites by 45.5% and 85.3%, respectively. Post-lesion DOI exposure significantly (p<0.01) returned both the activity and density of forebrain 5-HT axons after MDMA to levels comparable to saline treated controls. Conversely, DOI potentiated the loss of CTX and HIP 5-HT terminals after pCA in a dose-dependent fashion. However, in the brainstem, where the extent of the pCA lesion is lower (< 40%), DOI post-treatment only enhanced neurotoxicity by 29.3% compared to pCA alone. These results indicate that 5-HT axons lesioned by MDMA or pCA show differences in their potential for and rate of re-innervation. This effect may be related to the extent of the initial denervation, and to the density of astrocytes which increase glucose availability to damaged fibers through activation of the 5-HT-2 receptor. (NIDA# 271-90-7403)

## 443.5

**PCA AND MDMA ACTIVATE RAT GLYCOGEN PHOSPHORYLASE *IN VIVO* VIA THE 5-HT<sub>2A</sub> RECEPTOR.** J.C. Poblete\*, J.C. Brios\*, E.C. Azmitia\*, and C.W. Harley\*. 1-Biology Dept., New York Univ., NY, NY 10003; 2-Psych Dept., Memorial Univ., St. John's, Newfoundland, Canada A1B 3X9.

Glycogen levels in the brain are regulated by neurotransmitters, neuropeptides, and ions. Glycogen is mainly localized in astroglial cells in the CNS. Functional serotonin (5-HT) receptors are expressed in these astrocytes, and 5-HT is known to stimulate glycogenolysis in astrocytes. Substituted amphetamines (SA), like 3,4-methylenedioxymethamphetamine (MDMA) and p-chloroamphetamine (PCA), are potent 5-HT releasers that also inhibit 5-HT reuptake and monoamine oxidase A (MAO-A) activity. As a consequence of MDMA or PCA administration, extracellular levels of 5-HT are increased acutely. Recently, we reported that 5-HT and MDMA activate glycogen phosphorylase (GPase) in cortical astroglial-rich primary cultures, which can be attenuated by mianserin, a 5-HT<sub>2</sub> antagonist. In addition, 1-(2,5-dimethoxy-4-bromophenyl)-2-aminopropane (DOB), a 5-HT<sub>2</sub> agonist, also activates GPase in these cultures. These results indicate that astroglial glycogenolysis is controlled by the 5-HT<sub>2A</sub> receptor.

In the present study, the activation of GPase *in vivo* was assessed after the administration of PCA (10 mg/kg, sc.) or (+)MDMA (40 mg/kg, sc.) into adult Sprague-Dawley rats. Active glycogen phosphorylase ( $\alpha$ GPase) was assayed histochemically 15 min. and 30 min. after MDMA and PCA, respectively. The relative optical densities (ROD) were determined using a computer-assisted densitometric software (Optimas). PCA and MDMA increased  $\alpha$ GPase activity in layers 4, 5b and 6 of the neocortex compared to corresponding saline-treated controls. In addition, PCA produced a longer activation profile than MDMA. The activation of GPase was most significant in the parietal cortex, in which PCA increased the ROD in layer 4 (26%), layer 5b (29%), and layer 6 (69%).

Our results indicate that 5-HT releasers, like PCA and MDMA, activate glycogen phosphorylase *in vivo*. The pattern of  $\alpha$ GPase activation parallels the cortical distribution of 5-HT<sub>2A</sub> mRNA, and the decreases in 5-HT-IR axo + s produced by PCA and MDMA. These findings suggest that increased extracellular 5-HT activates GPase in cortical astrocytes via the 5-HT<sub>2A</sub> receptor. The possible relationship between GPase activation and SA-induced neuropathology will be discussed. (NIA Grant # PO1 AG10208)

## 443.7

**NOVEL STRUCTURAL CLASS OF COMPOUNDS INHIBITING SEROTONIN INDUCED RAT PAW INFLAMMATION; IDENTIFICATION OF 5HT<sub>2</sub> SUBTYPE RECEPTOR ANTAGONISTS.** G. Koppel, D. Nelson, J. Reel, R. Simon, D. B. Wainscott, C. Whitesitt, H. Cole and H. Bryant\*. Lilly Research Laboratories, CNS & Endocrine Divisions, Indianapolis, IN 46285.

Serotonin (5HT) is an important mediator of acute inflammatory responses due to its role in altering vascular tone and permeability which contribute to fluid extravasation. Intraplantar injection of 5HT produces a rapid, concentration dependent increase in paw weight and volume which is prevented by non-selective 5HT<sub>2</sub> antagonists (i.e. ketanserin, mianserin). While the pro-inflammatory activity of 5HT is likely mediated by 5HT<sub>2</sub> receptors, the subtype involved is unclear. Here we report the effects of a new structural class with relative selectivity for 5HT<sub>2A</sub> receptors which show potent activity at inhibiting 5HT-induced paw edema in the rat. Radioligand binding studies were performed with 125I DOI on human 5HT<sub>2A</sub> and 5HT<sub>2C</sub> receptors and with [<sup>3</sup>H]-5HT on human 5HT<sub>2B</sub> receptors. LY314228, LY320951 and LY320954 displayed higher affinity for the 5HT<sub>2A</sub> receptor. When compared to binding at other 5HT receptor subtypes, LY314228 had a 21 fold greater affinity for the 5HT<sub>2A</sub> site over the 5HT<sub>2B</sub> site, and 2.4 fold greater at the 5HT<sub>2C</sub> site. The compounds were also evaluated for effects on paw swelling in SD rats. With this model, all three compounds displayed potent inhibition of 5HT-induced swelling with ED<sub>50</sub>'s of 2, 3.1 and 5.5 mg/kg (for LY314228, LY320951 and LY320954, respectively). These studies demonstrate the anti-inflammatory activity of a novel class of pharmacophores for the 5HT receptor family which show greater relative affinities for the 5HT<sub>2A</sub> receptor subclass.

## 443.9

**[<sup>3</sup>H]RAUWOLSCINE AS AN ANTAGONIST RADIOLIGAND FOR THE CLONED HUMAN SEROTONIN<sub>2B</sub> (5-HT<sub>2B</sub>) RECEPTOR.** D.L. Nelson\*, M. Baez, J.D. Kursar, D.A. Sasso, and D.B. Wainscott. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285.

We have previously reported the cloning and pharmacologic characterization of the cloned rat and human 5-HT<sub>2B</sub> receptors, using [<sup>3</sup>H]-5-HT. One limitation to the use of agonist radioligands is that they typically do not readily allow the study of the agonist low-affinity state of G protein-coupled receptors. Since no high affinity antagonist radioligand had been reported for the 5-HT<sub>2B</sub> receptor, the present work was undertaken. When examining the pharmacologic profile of the 5-HT<sub>2B</sub> receptor, it was found that rauwolfscine had sufficiently high affinity for the human receptor (K<sub>i</sub> human = 14.6 ± 1.2 nM, compared to K<sub>i</sub> rat = 35.8 ± 3.8 nM). Therefore, [<sup>3</sup>H]rauwolfscine was examined for its usefulness as a radioligand for the cloned human 5-HT<sub>2B</sub> receptor expressed in AV12 cells. Initially, biphasic competition curves were obtained against [<sup>3</sup>H]rauwolfscine binding. This was due to [<sup>3</sup>H]rauwolfscine binding to an  $\alpha$ 2-adrenergic receptor present in the AV12 cell line. Efaroxan was found to block [<sup>3</sup>H]rauwolfscine binding to the  $\alpha$ 2-adrenergic receptor without significantly affecting binding to the 5-HT<sub>2B</sub> receptor and was therefore included in all subsequent studies. In saturation studies, [<sup>3</sup>H]rauwolfscine labeled a single population of binding sites, K<sub>d</sub> = 3.32 ± 0.21 nM and B<sub>max</sub> = 383 ± 69 fmol of 5-HT<sub>2B</sub> receptors / mg of protein. This compares to 331 ± 43 fmol of 5-HT<sub>2B</sub> receptors / mg of protein for [<sup>3</sup>H]-5-HT binding. Certain antagonist structures displayed higher affinity for [<sup>3</sup>H]rauwolfscine than for [<sup>3</sup>H]-5-HT labeled 5-HT<sub>2B</sub> receptors. Competition curves for antagonists had slope values of unity, which was not the case for agonists. [<sup>3</sup>H]Rauwolfscine is a useful antagonist radioligand for the cloned human 5-HT<sub>2B</sub> receptor and will aid in characterizing the properties of both the agonist high- and low-affinity states of this G protein-coupled receptor.

## 443.6

**IN VIVO STUDIES OF 5-HT<sub>2A</sub> RECEPTORS USING [C-11]-LABELLED MDL 100907.** C.A. Mathis\*, J.M. Gerdes, N.R. Simpson, J.C. Price, Y. Huang, K. Mahmood, K. Urso, M.A. Mintun. PET Facility, University of Pittsburgh Medical Center, Pittsburgh, PA 15213

MDL 100907, a potent and selective 5-HT<sub>2A</sub> antagonist, was radiolabelled with carbon-11 (20 min half-life) at either the 2- or 3-methoxy positions and evaluated in rats and rhesus monkeys. MDL 100907 is highly selective for the 5-HT<sub>2A</sub> receptor, possessing a 300-fold *in vitro* binding selectivity for this site over 5-HT<sub>2C</sub>,  $\alpha$ -1, and D2 receptors. The less active C-11-labelled (S)-(-)-enantiomer (termed MDL 100009) was also evaluated.

*In vivo* distribution studies in male Sprague-Dawley rats indicated that both C-11-labelled MDL 100907 radioligands were taken up and regionally distributed in rat brain in a manner consistent with the known distribution of 5-HT<sub>2A</sub> receptors. Frontal cortex-to-cerebellum ratios (a measure of total-to-nonspecific binding) reached values >10:1 at 90 min post injection. Their specific uptake was blocked by pretreatment with altanserin (2 mg/kg) 5 min prior to their *in vivo* injection. The *in vivo* brain distribution of C-11-labelled MDL 100009 indicated the lack of regional localization in brain areas known to contain high concentrations of 5-HT<sub>2A</sub> receptors such as the frontal cortex.

*In vivo* PET imaging studies in rhesus monkeys with the two C-11-MDL 100907 radioligands resulted in high uptake and regional localization for both compounds consistent with the known distribution of 5-HT<sub>2A</sub> receptors in primate brain. The regional brain concentrations of these two radioligands in monkeys were similar with frontal cortex-to-cerebellum ratios >3:1 at 90 min post injection. Radiolabelled metabolites in the plasma of monkeys were determined for both of the C-11-MDL 100907 radioligands, and the 2-methoxy-labelled compound led to the formation of a lipophilic metabolite which was absent with the 3-methoxy-labelled compound. Injection of C-11-MDL 100009 in monkeys resulted in a uniform brain distribution without regional localization consistent with the lower affinity of this enantiomer for 5-HT<sub>2A</sub> receptors. These results indicate that C-11-MDL 100907 labelled in the 3-methoxy position is a useful agent to image 5-HT<sub>2A</sub> receptors *in vivo* using PET.

## 443.8

**HALLUCINOGENS ARE POTENT PARTIAL AGONISTS AT 5-HT<sub>2A</sub> RECEPTORS ON INTERNEURONS IN RAT PIRIFORM CORTEX.** G.J. Marek\* and G.K. Aghajanian. Depts. of Psychiatry and Pharmacology, Yale School of Medicine, New Haven, CT 06508.

A subpopulation of interneurons in rat piriform cortex are excited by 5-HT via 5-HT<sub>2A</sub> receptors. Since controversy exists regarding whether LSD is a partial agonist (Sanders-Bush et al., 1988) vs antagonist (Pierce & Peroutka, 1990) at cortical 5-HT<sub>2A</sub> receptors, we explored whether LSD and a phenethylamine hallucinogen, DOI, are agonists, partial agonists or antagonists at 5-HT<sub>2A</sub> receptors on interneurons in piriform cortex. Extracellular studies were performed on interneurons excited by 5-HT near the borders of layers II and III while intracellular voltage-clamp studies were performed on pyramidal neurons in layer II. Low concentrations of LSD (10-100 nM) and DOI (0.3-3  $\mu$ M) applied for 10 min excited almost every interneuron that was excited by 5-HT. The maximal excitation achieved with LSD and DOI was 44 and 54%, respectively, of that observed after a near maximal concentration of 5-HT (100  $\mu$ M). Consistent with a partial agonist action, only the highest concentration of the hallucinogens occluded the maximal excitation by 5-HT. The excitation by NE was not affected by the hallucinogens while the excitation by the excitatory amino acid agonist AMPA was potentiated. MDL 100,907 (30 nM), a selective 5-HT<sub>2A</sub> antagonist, blocked the excitation of interneurons by LSD and DOI as well as the potentiation of excitation by AMPA. The excitation of interneurons by 5-HT and DOI induced inhibitory post-synaptic currents (IPSPs) in pyramidal cells. As expected from the extracellular studies, DOI (10  $\mu$ M) induced fewer IPSCs than did 5-HT (100  $\mu$ M). These findings suggest that the effects of hallucinogens at 5-HT<sub>2A</sub> receptors in the cortex are due to a potent partial agonist rather than antagonist action.

## 443.10

**COMPARISON OF 5- AND 7-SUBSTITUTED TRYPTAMINES AND DERIVED TETRAHYDRO-8-CARBOLINES AT THE CLONED RAT SEROTONIN<sub>2B</sub> (5-HT<sub>2B</sub>) RECEPTOR.** J.S. Nissen, J.J. Droste, D.B. Wainscott, V.L. Lucchesi, D.L. Nelson and J.E. Audia\*. Lilly Research Laboratories, Eli Lilly & Company, Indianapolis, IN 46285.

Previous studies from these laboratories have demonstrated high affinity binding of 5-substituted tryptamines at the cloned rat 5HT<sub>2B</sub> receptor (Wainscott et al., *Mol. Pharmacol.* 1993, 43, 419). The current work broadens the investigation of structure activity relationships to include both 5- and 7-substituted tryptamines and their derived 6- and 8-substituted tetrahydro-8-carbolines. Simple 5-substituents such as halogen (F, Cl, Br), OMe and OH confer high affinity upon the tryptamines. Analogous 6-substitution of the tetrahydro-8-carbolines, however, gives rise to relatively low affinity binding at the 5HT<sub>2B</sub> receptor, with little correlation to the tryptamine SAR. High affinity binding was also observed with the 7-substituted tryptamines. In this case, conversion to the 8-substituted tetrahydro-8-carbolines increased affinity approximately 2-3 fold relative to the tryptamines, while maintaining identical rank-order of potency. Functionally, these tryptamines showed agonist effects while the tetrahydro-8-carbolines lacked intrinsic activity (IP<sub>3</sub> response). These studies provide insights into recognition and activation requirements for the rat serotonin 5HT<sub>2B</sub> receptor and the binding orientation of ligands at this site.

## 443.11

SB 206553: IN VITRO AND IN VIVO CHARACTERIZATION OF A POTENT 5-HT<sub>2C/2B</sub> RECEPTOR ANTAGONIST.

T.P. Blackburn, G.A. Kennett, G.S. Baxter, M.D. Wood, P. Ham and I.T. Forbes. SmithKline Beecham Pharmaceuticals, Discovery Research, New Frontiers Science Park, Third Avenue, Harlow, Essex, England, CM19 5AW.

We have previously reported on the synthesis and characterization of SB 20646A the first selective 5-HT<sub>2C/2B</sub> receptor antagonist (Forbes et al., 1994: *J. Med. Chem.* 36, 1104). We now report on the pharmacological characterization of a more potent, high affinity compound SB 206553A (5-methyl-1-(3-pyridylcarbamoyl)-1,2,3,5-tetrahydropyrrolo[2,3-f]indole) with approximately 100 fold selectivity for the 5-HT<sub>2C/2B</sub> receptor over other neurotransmitter receptors. Characterisation of SB 206553 in functional studies measuring 5-HT-stimulated phosphoinositol hydrolysis as a model of 5-HT<sub>2C</sub> receptor activation revealed the compound to be a competitive antagonist with a pK<sub>B</sub> 8.8 compared to a pK<sub>i</sub> of 8.7 as measured against [<sup>3</sup>H]-mesulergine binding in human HEK 293 cells transfected with the 5-HT<sub>2C</sub> receptor. SB 206553 was also shown to be a competitive antagonist (pA<sub>2</sub> 8.4) of 5-HT<sub>2B</sub> receptors in the rat stomach fundus assay. In vivo, SB 206553 was approximately 3-4 fold more potent than SB 20646A at blocking m-CPP-induced hypolocomotion (ID<sub>50</sub> 5.5 vs 19.2 mg/kg p.o. respectively). Also, like SB 20646A, SB 206553 was shown to possess anxiolytic-like properties in rodent models. Thus SB 206553 represents an important tool to probe the therapeutic potential of 5-HT<sub>2C/5-HT<sub>2B</sub></sub> receptor antagonists.

## 443.13

REGULATION OF SEROTONIN 5-HT<sub>2</sub> RECEPTORS BY A SIGMA LIGAND NE-100. N. Narita\*, K. Hashimoto, S. Tomitaka, Y. Minabe and K. Yamazaki. Natl. Inst. Neurosci., NCNP, Tokyo 187 and Dept. of Psychiatry, Tokai Univ. Sch. of Med., Kanagawa, Japan.

There is evidence that sigma receptors may play a role in psychosis, and might be involved in the pathophysiology of schizophrenia. Some studies suggest that sigma ligands and serotonin 5-HT<sub>2</sub> receptor antagonists lack the extrapyramidal side effects associated with dopamine D<sub>2</sub> receptor antagonists. Therefore, sigma ligands and 5-HT<sub>2</sub> receptor antagonists are a target for the development of atypical antipsychotic drugs. It is reported recently that NE-100 (Taisho Pharmaceutical Co. Ltd.) is a novel selective and high potent ligand for sigma receptors. In this study, we examined the effects of NE-100 on the serotonergic neurons in rat brain. A single administration of NE-100 (3 and 10 mg/kg, i.p.) did not affect the contents of monoamines (5-HT and dopamine) and their metabolites (5-HIAA, DOPAC, HVA) in the brain. However, the K<sub>d</sub> values of [<sup>3</sup>H]ketanserin binding to 5-HT<sub>2</sub> receptors were increased significantly by a single injection of NE-100. Furthermore, subchronic administration of NE-100 (3 mg/kg, i.p., twice daily, 14 days) also did not affect the contents of monoamines and its metabolites. However, the K<sub>d</sub> values of [<sup>3</sup>H]ketanserin binding were significantly increased. At 24 hrs, 7 days and 14 days after final administration of NE-100. These results suggest that a sigma ligand NE-100 may regulate 5-HT<sub>2</sub> receptor function in the brain. Thus, the regulation of 5-HT<sub>2</sub> receptors by NE-100 suggests that this new potential antipsychotic drug may exert antipsychotic effects without producing significant extrapyramidal side effects.

## 443.15

## ATYPICAL ANTIPSYCHOTICS BLOCK 5-HT-MEDIATED EXCITATIONS IN SEPTOHIPPOCAMPAL GABAergic NEURONS. W. Liu\* and M. Alreja. Dept. of Psychiatry, Yale Univ. Sch. of Medicine, CMHC, New Haven, CT 06508.

We recently reported that 5-HT excites GABAergic neurons in the rat medial septum/diagonal band complex (MSDB) via multiple 5-HT receptors, including the 5-HT<sub>2A</sub> subtype (Alreja, in press). Since a sub-population of MSDB GABAergic neurons projects to the hippocampus, we tested the effect of 5-HT on antidromically-activated septohippocampal neurons (SHNs) using extracellular recording techniques in a sagittal brain slice preparation that contained the MSDB and the dorsal fornix. Additionally, since atypical antipsychotics have been reported to target the 5-HT<sub>2A</sub> and other 5-HT receptor subtypes, we examined the effect of these drugs on 5-HT-mediated excitations in MSDB neurons.

The effect of bath-applied 5-HT (10-100 μM) was tested in a total of 119 neurons out of which 97 were antidromically identified as SHNs. Antidromic latency measurements indicated that the 5-HT-responsive SHNs had fast conducting fibers (presumably, GABAergic; mean conduction velocity - 1.62 ± 0.08 m/s; range - 0.2 to 3.7 m/s; n=76). 79% of the SHNs tested were excited by 5-HT, 18% were inhibited and 3% showed no response to 5-HT. A 20 min bath application of MDL 100,907 (30 nM), a highly selective and potent 5-HT<sub>2A</sub> receptor antagonist, blocked 5-HT-induced excitations in 78% of the SHNs tested with a mean pA<sub>2</sub> value of 8.51 ± 0.14 (n=19). The atypical antipsychotics, risperidone and clozapine also blocked 5-HT-mediated excitations with pA<sub>2</sub> values of 8.82 ± 0.17 (n=4) and 7.06 ± 0.11 (n=7), respectively. Haloperidol, a typical antipsychotic, blocked 5-HT-mediated excitations with a relatively lower pA<sub>2</sub> value of 5.49 ± 0.3 (n=3). In conclusion, 5-HT excites septohippocampal GABAergic neurons and the MSDB may represent an important site of action for the atypical antipsychotic drugs.

## 443.12

FURTHER IN VIVO CHARACTERISATION OF SB 206553, A 5-HT<sub>2C/2B</sub> RECEPTOR ANTAGONIST. G.A. Kennett, F. Bright, J. Cilia, D. C. Piper, N. Upton, M. L. Evans\* and T.P. Blackburn. Dept of Psychiatry Research, SmithKline Beecham Pharmaceuticals, New Frontiers Science Park, Third Avenue, Harlow, Essex, CM19 5AW, U.K.

SB 206553 is a high affinity 5-HT<sub>2C</sub> and 5-HT<sub>2B</sub> receptor antagonist with over 100 fold selectivity over the 5-HT<sub>2A</sub> and other sites (see Blackburn et al., this meeting). It is also a potent antagonist (ID<sub>50</sub> 5.5 mg/kg p.o.) of mCPP-induced hypolocomotion, a model of 5-HT<sub>2C/2B</sub> receptor function in vivo (Kennett et al., 1994, *Brit. J. Pharmacol.*, 111: 797). SB 206553 increased total interaction scores in a 15 min rat social interaction test (method as in Kennett et al., 1994) under high light unfamiliar conditions over a dose range of 2-20 mg/kg p.o. given 1 h pretest. This profile may be consistent with anxiolysis. In a rat Geller-Seifter conflict test of anxiety (method as in Kennett et al., 1995, *Psychopharmacol.*, 118: 178), SB 206553 increased punished responding between 2-40 mg/kg p.o. given 1 h pretest, but had little effect on unpunished responding. In a third model of anxiety using a second species, the marmoset conflict test (method as in Kennett et al., 1995), SB 206553 also increased suppressed responding. The anxiolytic-like profile of SB 206553 in three models of anxiety with different aversive and motivational components is compelling evidence that SB 206553 may be anxiolytic.

Recently, mutant mice lacking 5-HT<sub>2C</sub> receptors were reported to suffer from epilepsy and obesity (Tecott et al., 1995, *Nature* 374: 542). However, chronic administration of SB 206553 (5 or 40 mg/kg p.o. b.i.d. x 14) had no effect on rat body weight compared to vehicle treated controls, while acutely, 50 or 100 mg/kg p.o. 1 h pretest, had no effect in the mouse maximal electroshock (MES) threshold test (method as in Loscher and Schmidt 1988, *Epilepsy Res.* 2: 145).

## 443.14

## OLANZAPINE EXHIBITS SIMILAR ACTIVITIES TO CLOZAPINE AT CLONED HUMAN SEROTONIN 2A, 2B, 2C AND MUSCARINIC RECEPTORS. V.L. Lucaites, F. P. Bymaster\*, D. B. Wainscott, J. F. Falcone, M. Baez and D. L. Nelson. Lilly Research Laboratories, Eli Lilly and Company, Lilly Corporate Center, Indianapolis, IN 46285

Antipsychotic agents are believed to control the positive symptoms of schizophrenia by blocking dopamine D<sub>2</sub> receptors. Control of the negative symptoms of schizophrenia is one of the benefits of the so-called "atypical" antipsychotics and may involve drug interaction at other neurotransmitter receptor systems. This study compares the binding and second messenger profiles of the atypical antipsychotics clozapine and olanzapine, as well as risperidone and haloperidol, at the human 5-HT<sub>2</sub> receptor family and the human muscarinic receptor subtypes. Clozapine and olanzapine showed no agonist activity at any serotonergic or muscarinic receptors. At the 5-HT<sub>2A</sub> receptor, olanzapine exhibited higher binding affinity (K<sub>i</sub>) and greater potency in blocking 5-HT-stimulated increases in IP<sub>3</sub> (IC<sub>50</sub>) than clozapine, with less difference at the 5-HT<sub>2B</sub> receptor.

	5-HT <sub>2A</sub> K <sub>i</sub> (nM)	5-HT <sub>2A</sub> IP <sub>3</sub> IC <sub>50</sub> (nM)	5-HT <sub>2B</sub> K <sub>i</sub> (nM)	5-HT <sub>2B</sub> IP <sub>3</sub> IC <sub>50</sub> (nM)
Olanzapine	2.5 ± 0.3	36.3 ± 11	11 ± 1.7	42 ± 7.8
Clozapine	6.5 ± 0.3	154 ± 22	7.3 ± 1.0	29 ± 7.4

Olanzapine showed lower binding affinity than clozapine (K<sub>i</sub> = 2.5 ± 0.3 and 1.4 ± 0.3 nM) and less potency in blocking oxotremorine-M induced stimulation of [<sup>3</sup>H]-arachidonic acid release in m1 muscarinic receptors (IC<sub>50</sub> = 680 ± 295 and 272 ± 69 nM respectively) with similar results at m3 and m5 receptors. Thus olanzapine shows a profile similar to clozapine with these receptors.

## 443.16

DIFFERENCES IN THE INOSITOL 1,4,5-TRISPHOSPHATE PROFILES OF TRANSFECTED HUMAN 5-HT<sub>2A</sub> AND 5-HT<sub>2C</sub> RECEPTORS. S.L. Briddon, R.A. Leslie\* and I.M. Elliott. Dept. Clinical Pharmacology, University of Oxford, Radcliffe Infirmary, Oxford, England. OX2 6HE.

We have used the human neuroblastoma cell line SH-SY5Y, transfected with the cDNAs for the human 5-HT<sub>2A</sub> and 5-HT<sub>2C</sub> receptors to study the adaptive response of these receptors to 5-HT stimulation. Clones were isolated which expressed similar numbers of receptors and gave a dose-dependent production of inositol 1,4,5-trisphosphate in response to 5-HT. The time-course of 5-HT stimulated Ins(1,4,5)P<sub>3</sub> production consisted, in both cases, of an initial peak falling rapidly to a plateau level of Ins(1,4,5)P<sub>3</sub> production. However, the peak in Ins(1,4,5)P<sub>3</sub> levels occurred earlier for the 5-HT<sub>2C</sub> receptor (~5s) than for the 5-HT<sub>2A</sub> receptor (~20s). A similar response has also been described for the endogenous muscarinic-m3 receptor in this cell line, and is caused by a desensitization at the receptor level. We have confirmed this difference in desensitization between the two 5-HT<sub>2</sub> receptors by measuring the accumulation of total [<sup>3</sup>H]inositol phosphates in the presence of lithium. For both receptors, prolonged exposure to 5-HT caused homologous desensitization of the resulting PI response which was both time and concentration dependent. When exposed to 1 μM 5-HT for up to 120 min, both the rate and extent of 5-HT<sub>2C</sub> receptor desensitization was markedly greater than that for the 5-HT<sub>2A</sub> receptor (t<sub>1/2</sub> = 12.5 min vs. t<sub>1/2</sub> = 110 min).

This data suggests that the human 5-HT<sub>2C</sub> receptor is more susceptible to agonist-induced desensitization than the 5-HT<sub>2A</sub> receptor when expressed in this cell line.

## 443.17

FURTHER CHARACTERIZATION OF AGONIST-INDUCED 5-HT<sub>2A</sub> RECEPTOR UP-REGULATION IN CEREBELLAR GRANULE CELLS. H. Li\*, H. Chen, C. Hough, K.-G. Zhang and D.-M. Chuang. Section on Molecular Neurobiology, Biological Psychiatry Branch, NIMH, NIH, Bethesda, MD 20892

We have reported that the levels of 5-HT<sub>2A</sub> receptor binding sites and mRNA are up-regulated following persistent stimulation of 5-HT<sub>2A</sub> receptors in cerebellar granule cells (CGC) (Mol. Pharmacol. 43:349-355, 1993). The present study was undertaken to further characterize this up-regulation process in CGC. The increase in the B<sub>max</sub> of 5-HT<sub>2A</sub> receptor binding sites induced by DOI, a 5-HT<sub>2A</sub> receptor agonist, was reversible; the up-regulated 5-HT<sub>2A</sub> receptor sites returned to basal level within 32 hours after DOI wash-out. The DOI up-regulation decreased, while basal level of 5-HT<sub>2A</sub> receptor sites increased with the age of CGC in culture. The up-regulation was blocked by ritanserin, a 5-HT<sub>2A</sub> receptor antagonist, indicating that it is receptor-mediated. The increase was also largely inhibited by depletion of extracellular Ca<sup>2+</sup> or inclusion of SK&F 96365 or LaCl<sub>3</sub> during DOI stimulation. Moreover, calmidazolium prevents DOI-induced increase of 5-HT<sub>2A</sub> receptor sites and mRNA. These results suggest an involvement of Ca<sup>2+</sup> influx and a Ca<sup>2+</sup>/calmodulin dependent process in the agonist-induced 5-HT<sub>2A</sub> receptor up-regulation in CGC, possibly at the level of transcription.

## 443.19

EFFECT OF 5-HT<sub>2A</sub> RECEPTOR DOWNREGULATION ON 5-HT<sub>1A</sub> RECEPTOR SENSITIVITY *IN VIVO*. K.A. Truett\* and J.G. Hensler. Dept. of Pharmacology, Univ. of Texas Health Sci. Center, San Antonio, TX 78284.

Treatment of rats with antidepressant drugs, 5-HT<sub>1A</sub> agonists, or 5-HT<sub>2A</sub> agonists results in the downregulation and desensitization of 5-HT<sub>2A</sub> receptors and the desensitization of 5-HT<sub>1A</sub> responses. The goal of these studies was to determine whether the desensitization of 5-HT<sub>1A</sub> receptors *in vivo* occurs as a result of 5-HT<sub>2A</sub> receptor downregulation. Rats were treated with the 5-HT<sub>2A</sub> receptor antagonist ketanserin (10 mg/kg, i.p., b.i.d., for 21 days). 5-HT<sub>1A</sub> receptor sensitivity was assessed by measuring DPAT-induced hypothermia (0.05 mg/kg, sc.) twenty-four hours after the last ketanserin injection. [<sup>3</sup>H]-ketanserin binding to 5-HT<sub>2A</sub> receptors in cortical homogenates revealed a decrease in B<sub>max</sub> (saline-treated: 166±10 fmol/mg protein; ketanserin-treated: 106±6 fmol/mg protein) with no change in K<sub>D</sub> as a result of ketanserin treatment. Chronic ketanserin treatment did not alter DPAT-induced hypothermia (maximal decrease in body temperature for saline = 1.9±0.3°C; for ketanserin = 1.8±0.2°C; n=5). In a second study, rats were treated with mianserin, a 5-HT<sub>2A</sub> antagonist that downregulates 5-HT<sub>2A</sub> receptors after a single injection (10 mg/kg, sc.). [<sup>3</sup>H]-ketanserin binding showed that a single injection of mianserin resulted in the downregulation of cortical 5-HT<sub>2A</sub> receptors (B<sub>max</sub>: saline-treated: 182±12 fmol/mg protein; mianserin-treated: 76±4 fmol/mg protein). Twenty-four hours after mianserin injection, DPAT-induced (1 mg/kg, sc.) forepaw treading was used as a measure of 5-HT<sub>1A</sub> receptor sensitivity. Repeated measures ANOVA found no treatment effect of mianserin on DPAT-induced forepaw treading (p = 0.13; n = 6). These data indicate that 5-HT<sub>2A</sub> receptor downregulation alone is not sufficient to cause 5-HT<sub>1A</sub> receptor desensitization. Future studies will test whether 5-HT<sub>2A</sub> receptor activation, which may subsequently downregulate 5-HT<sub>2A</sub> receptors, is required to desensitize 5-HT<sub>1A</sub> responses. Supported by USPHS grant MH52369.

## 443.21

5HT<sub>2</sub> RECEPTORS AGONIST  $\alpha$ -METHYL-5HT POTENTIATES THE GLYCINE-RECEPTOR MEDIATED Cl<sup>-</sup> CURRENTS IN TRIGEMINAL NEURONS. S.L. Lai<sup>1</sup>, J.M. Chung<sup>2\*</sup> and L.-Y.M. Huang<sup>2</sup>. Kaohsiung Medical College Hospital, Kaohsiung, Taiwan, R.O.C.<sup>1</sup> and Marine Biomedical Institute, Department of Physiology and Biophysics, The University of Texas Medical Branch, Galveston, Texas 77555-1069<sup>2</sup>.

Serotonin (5HT) is released from nerve terminals in the descending pathways and inhibits the activities of dorsal horn neurons. To understand the mechanism actions of 5HT, we studied the effects of 5HT on glycine-receptor mediated Cl<sup>-</sup> currents in medullary dorsal horn neurons isolated from the spinal trigeminal subnucleus caudalis. Whole cell currents were recorded using the patch clamp technique. The 5HT<sub>2</sub> agonist,  $\alpha$ -methyl-5HT, increased glycine-receptor mediated Cl<sup>-</sup> currents in 40% (24/60) of the cells. The agonist was effective at a concentration as low as 0.1 nM. The glycine responses rose by 40% at 100 nM  $\alpha$ -methyl-5HT. The action of  $\alpha$ -methyl-5HT was sustained. The glycine-activated currents stayed elevated for 20 min after the agonist was washed out. The enhancing effect of  $\alpha$ -methyl-5HT could be blocked by a high concentration of the 5HT<sub>1A/2</sub> antagonist, spiperone (1  $\mu$ M). The 5HT<sub>1</sub> antagonist, pindolol, had no effect on the action of  $\alpha$ -methyl-5HT. These results suggest that  $\alpha$ -methyl-5HT activates 5HT<sub>2</sub> receptors and brings about a sustained potentiation of glycine responses (Supported by NIH grants NS11255, NS30045, NS23061).

## 443.18

DIFFERENTIAL REGULATION BY CORTICOSTEROIDS OF 5-HT<sub>2A</sub> RECEPTORS IN P-11 AND C-6 CELLS. E. Saif<sup>1\*</sup>, J. Goska<sup>1</sup>, E. Sibille<sup>1</sup>, M. Toth<sup>2</sup>, L. Pohorecky<sup>2</sup>, D. Benjamin<sup>1</sup>. <sup>1</sup>Ramapo College, Mahwah, N.J. 07430. <sup>2</sup>Cornell University Medical College, N.Y., N.Y. 10024. <sup>3</sup>Rutgers University Center of Alcohol Studies, Piscataway, N.J. 08855.

Individual variations in the functioning of both the central serotonergic (5HT) system and the hypothalamic-pituitary-adrenal axis (HPA) have been implicated in the etiology of affective disorder, drug addiction and alcoholism. Understanding 5HT-HPA interactions is essential for the understanding and effective treatment of these disorders. Hypercortisolemia and an increase in 5-HT<sub>2A</sub> binding are frequently-reported biological correlates of depression. 5-HT release activates the HPA via 5-HT<sub>2A</sub> receptors, and there is evidence for 5-HT<sub>2A</sub> upregulation in response to glucocorticoids (GCCs) *in vivo*; we speculate that a high HPA response to chronic stress is the basis of a positive feedback cycle contributing to the pathogenesis of depression.

P-11 cells, isolated from rat pituitary tumor, and C-6 rat glioma cells express the 5-HT<sub>2A</sub> receptor and are convenient models for study of 5-HT<sub>2A</sub> regulation *in vitro*. We report that 50 hours of incubation with dexamethasone (DEX), or corticosterone upregulate the 5-HT<sub>2A</sub> receptor in P-11 cells two to three fold. 5-HT<sub>2A</sub> mRNA is also increased. DEX downregulates 5-HT<sub>2A</sub> receptors and mRNA approximately 50% in C-6 cells.

Demonstration of a cell-type dependent, differential regulation of 5-HT<sub>2A</sub> expression by GCCs may contribute to an eventual understanding of physiological mechanisms underlying the behavioral consequences of exposure to chronic stress.

## 443.20

DEVELOPMENT OF MONOCLONAL ANTIBODIES TO THE SEROTONIN 5-HT<sub>2A</sub> RECEPTOR. C. Wu, E. Yoder\*, L. Shi, J. Wei, P. Dias, C.R. Monell, M. H. Ellisman\*, and S. Singh\*. PharMingen, San Diego, CA 92121 and \*San Diego Microscopy and Imaging Resource, Department of Neurosciences, UCSD School of Medicine, La Jolla CA 92093.

Serotonin (5-Hydroxytryptamine; 5-HT) mediates many nervous system functions by its interaction with specific receptors. Physiological, pharmacological, and molecular cloning studies have identified fourteen serotonin receptors belonging to seven families. We have developed monoclonal antibodies (mAbs) directed against one of these receptors, the 5-HT<sub>2A</sub>. To generate mAbs against the 5-HT<sub>2A</sub> receptor (5-HT<sub>2AR</sub>), mice were immunized with GST-fusion proteins containing either the N- or C-terminus domain of the 5-HT<sub>2AR</sub>. The hybridomas were initially screened by ELISA against the corresponding recombinant proteins or the GST protein. Hybridomas positive for only GST-5-HT<sub>2AR</sub> were selected for reactivity in western blots to identify clones which specifically reacted with insect cell expressed recombinant proteins. Subsequently, 12 and 7 hybridomas containing antibodies against the C-terminus and the N-terminus, respectively were tested for suitability as immunocytochemical reagents by screening with cultured rat Schwann cells known to express the 5-HT<sub>2AR</sub>. Parallel coverslips were processed as controls. The expression of 5-HT receptors was monitored using calcium imaging. Several clones that labeled strongly and specifically were identified, and their IgG fractions were purified. Current studies test these purified antibodies in Schwann cell cultures and rat brain sections using immunofluorescence.

## 444.1

**INTERCELLULAR CALCIUM WAVES PROPAGATED VIA GAP JUNCTIONS IN NEURONS** A.C. Charles<sup>1</sup> and R.F. Tyndale<sup>2</sup> Dept. Of Neurology, UCLA, Los Angeles, CA 90024 and Addiction Research Foundation and Dept. Of Pharmacology, Univ. Of Toronto, Canada M5S 2S1

Spontaneous waves of increased intracellular calcium concentration were rapidly propagated over groups of primary mouse cortical neurons and immortalized hypothalamic (GT1-1) neurons in culture.  $\text{Ca}^{2+}$  waves were propagated at a rate of 100-200  $\mu\text{m}/\text{sec}$  over 10-200 cells.  $\text{Ca}^{2+}$  waves were abolished by the removal of extracellular calcium and by TTX. Similar intercellular  $\text{Ca}^{2+}$  waves were induced by mechanical stimulation of a single cell. GT1-1 neurons showed fluorescence recovery after photobleaching of a single cell, and intercellular  $\text{Ca}^{2+}$  waves were abolished by the gap junction blocker octanol. By contrast, a different clone of the GT1 neurons (GT1-7) showed frequent spontaneous  $\text{Ca}^{2+}$  oscillations but no intercellular  $\text{Ca}^{2+}$  waves, no intercellular communication of the response to mechanical stimulation, and no fluorescence recovery after photobleaching. Comparison of expression of connexin mRNA in the GT1-1 and GT1-7 lines using RT-PCR revealed a 5-fold greater level of connexin26 mRNA in the GT1-1 line, but no difference in the levels of connexin32 or connexin43 mRNA. These results show that neurons are capable of extensive  $\text{Ca}^{2+}$  signaling via gap junctions, and suggest that connexin26 is the gap junction protein which enables intercellular  $\text{Ca}^{2+}$  signaling in GT1 neurons. Intercellular  $\text{Ca}^{2+}$  waves in cultured neurons may represent a model for gap-junctional signaling between neurons in the developing nervous system, and between subsets of neurons in the adult brain.

## 444.3

**ASSOCIATION OF TYPE I AND TYPE III INOSITOL 1,4,5 TRISPHOSPHATE RECEPTORS.**

E.C. Nucifora Jr., A.H. Sharp, S.L. Milgram<sup>1</sup>, R.E. Mains\*, C.A. Ross. Laboratory of Molecular Neurobiology, Johns Hopkins University, School of Medicine, 720 Rutland Ave., Ross 615, Baltimore, MD 21205. 1. Department of Physiology University of North Carolina.

The Inositol 1,4,5-trisphosphate receptor (IP<sub>3</sub>R) is an intracellular calcium channel involved in coupling cell membrane receptors to calcium signal transduction pathways within the cell. The IP<sub>3</sub>R is believed to form a tetrameric structure to produce the calcium channel in endoplasmic reticulum membranes. Several isoforms (I, II, III) of IP<sub>3</sub>Rs have been identified which are coded by separate genes, and are expressed in many tissues with differing patterns of cellular expression. We have generated specific affinity purified polyclonal anti-peptide antibodies to each of the three isoforms. Western Blot analysis of R1Nm5F and AT120 cells shows high levels of endogenously expressed type I and type III IP<sub>3</sub>R, but undetectable levels of type II. Co-immunoprecipitation experiments were performed by immunoprecipitating from these cells with the type I specific antibody and Western Blotting with the type III specific antibody, or by immunoprecipitating with the type III specific antibody and Western Blotting with the type I specific antibody. Both experiments yielded a band at 260 kDa, the appropriate size of both the type I and type III IP<sub>3</sub>R. Immunocytochemistry performed on these cell lines with either antibody demonstrated similar ER staining patterns. The type III IP<sub>3</sub>R was absent from the secretory granules of AT120 cells. These data indicate that type I and type III IP<sub>3</sub>Rs can associate into a molecular complex.

**CLONING AND SEQUENCING OF AN IP<sub>3</sub>-RECEPTOR cDNA FROM LOBSTER OLFACTORY ORGAN.** S.D. Munger<sup>1,2</sup>, B.W. Ache<sup>1,2,3</sup> and R.M. Greenberg<sup>1</sup>, Whitney Laboratory<sup>1</sup> and Depts. of Neuroscience<sup>2</sup> and Zoology<sup>3</sup>, Univ. of Florida, St. Augustine, FL 32086.

Several lines of evidence suggest that inositol 1,4,5-trisphosphate (IP<sub>3</sub>)-receptors (IP<sub>3</sub>Rs) occur in the plasma membrane of neuronal and nonneuronal cells, but little is known about the structural similarities of these plasma membrane IP<sub>3</sub>Rs to the better known intracellular IP<sub>3</sub>Rs. IP<sub>3</sub> directly gates two types of ion channels in the plasma membrane of lobster olfactory receptor neurons (ORNs); these channels are functionally similar to IP<sub>3</sub>Rs localized to endoplasmic reticulum (ER) and nuclear membranes in vertebrates (Fadool & Ache, *Neuron*, 9: 907; Hatt & Ache, *PNAS*, 91: 6264). A polyclonal antibody directed against the ER IP<sub>3</sub>R of rat cerebellum recognizes membrane proteins of appropriate size in lobster ORNs; this antibody also perturbs function of the lobster IP<sub>3</sub>Rs in excised patch recordings (Fadool & Ache, *ibid.*). We have exploited the suggested structural similarities between plasma membrane and ER IP<sub>3</sub>Rs by amplifying a partial cDNA, homologous to known IP<sub>3</sub>Rs, from reverse transcribed lobster olfactory organ RNA using degenerate primers and PCR. We extended the clone to the 3'-noncoding region using 3'-RACE (Rapid Amplification of cDNA Ends). We have constructed an IP<sub>3</sub>R mini-cDNA library, and have isolated overlapping clones by plaque hybridization and PCR. The open reading frame of the cDNA isolated to date, which codes for 1400 amino acids and comprises ca. 50% of the anticipated coding region, exhibits 40-45% identity to known IP<sub>3</sub>Rs. While Northern analysis demonstrates a low level of expression of a >10 kb message in the brain, but none in the nose, the more sensitive ribonuclease protection assay shows the message to be expressed in the nose and, at higher levels, in the brain. We are currently working to extend the cDNA to the 5'-end and to localize the receptor by *in situ* hybridization and immunohistochemistry. {This work supported by ONR grant N00014-90-J-1566}

## 444.2

**THYROID HORMONE CONTROL OF CALCIUM WAVES IN XENOPUS LAEVIS OOCYTES.** L.M. John, J.D. Lechleiter, and P. Camacho<sup>2</sup>. Dep't of Neuroscience, Univ. of Virginia, Charlottesville, VA 22903.

Inositol 1,4,5 trisphosphate (IP<sub>3</sub>)-induced intracellular  $\text{Ca}^{2+}$  release mediates the action of many neurotransmitter signalling pathways. Spiral  $\text{Ca}^{2+}$  wave propagation and annihilation of IP<sub>3</sub>-induced  $\text{Ca}^{2+}$  release reveals an underlying excitable process which can be accounted for by the  $\text{Ca}^{2+}$  dependent properties of the IP<sub>3</sub>-bound IP<sub>3</sub> receptor (IP<sub>3</sub>R). We previously demonstrated the importance of cytosolic  $\text{Ca}^{2+}$  buffering on this dynamic process by overexpression of sarco-endoplasmic reticulum  $\text{Ca}^{2+}$ -ATPases (SERCAs) in *Xenopus* oocytes (*Science* 260, 226-229). Thyroid hormones and growth hormones have been shown to increase the expression of  $\text{Ca}^{2+}$ -ATPases in smooth muscles and cardiac myocytes. Additionally, thyroid hormones have been implicated in the regulation of  $\text{Ca}^{2+}$  uptake and/or release in mitochondria. Given the importance of  $\text{Ca}^{2+}$  sequestration in the dynamics of  $\text{Ca}^{2+}$  wave activity, we examined the effects of thyroid hormones on IP<sub>3</sub>-induced  $\text{Ca}^{2+}$  signalling in *Xenopus* oocytes. To accomplish this, oocytes were injected with mRNA encoding the *Xenopus* thyroid receptor (TRBA1) and assayed for IP<sub>3</sub>-induced  $\text{Ca}^{2+}$  wave activity 1-3 days later using confocal imaging. Exposure of oocytes expressing TRBA1s to L-3,3',5-triiodothyronine ( $\text{T}_3$ , 50-100  $\mu\text{M}$  for 20-60 min before recording) resulted in an increase in the number of oocytes exhibiting IP<sub>3</sub>-induced regenerative  $\text{Ca}^{2+}$  wave activity (58%; n=65) compared with control, non-mRNA injected oocytes (21%; n=24). In addition, TRBA1 expressing oocytes showed an increase in  $\text{Ca}^{2+}$  wave amplitude from 0.77±0.49 ( $\Delta F/F$ ) to 0.95±0.41 and an increase in interwave periods from 24.4±11.3 to 64.9±42s in the presence of  $\text{T}_3$ . We conclude that acute exposure to thyroid hormone dynamically modulates IP<sub>3</sub>-mediating  $\text{Ca}^{2+}$  signalling. These data will be discussed in relation to the action of thyroid hormone on mitochondrial  $\text{Ca}^{2+}$  buffering. The work was supported by NIH GM48451 and AHA878.

## 444.4

**CONFOCAL MEASUREMENTS OF BASELINE NUCLEAR AND CYTOPLASMIC FLUORESCENCE: COMPARISON OF  $\text{Ca}^{2+}$  INDICATOR AND NON- $\text{Ca}^{2+}$  INDICATOR DYES.** M.N. Rand\*, S. Aguilan, & J.D. Kocsis. Dept. of Neurology and Sect. Neurobiology, Yale Medical School, New Haven, CT 06510; and VAMC, West Haven, CT 06516.

At baseline resting potentials, neurons which have been loaded with  $\text{Ca}^{2+}$  indicator dyes using a micropipette have higher levels of fluorescence in the nucleus than in the cytoplasm, and it has been suggested that this effect is due to the presence of more dye in the nucleus. To evaluate this idea confocal microscopy was used to compare nuclear to cytoplasmic fluorescence ratios (N/C ratios) of cultured adult rat dorsal root ganglion neurons filled by micropipette with either  $\text{Ca}^{2+}$  indicator or non- $\text{Ca}^{2+}$  indicator dyes. Both 10 kD dextran-conjugated and free forms of the  $\text{Ca}^{2+}$  indicator and non- $\text{Ca}^{2+}$  indicator dyes were used. In all cases, N/C ratios of  $\text{Ca}^{2+}$  indicator dyes were significantly higher than those of the non- $\text{Ca}^{2+}$  indicator dyes (dextran-conjugated: 1.89 vs 1.11; free dye: 3.30 vs 1.58). N/C ratios of the non- $\text{Ca}^{2+}$  indicator dyes remained constant whereas N/C ratios of  $\text{Ca}^{2+}$  indicator dyes varied significantly over time. Some of the neurons also developed blebs on their plasma membrane which filled with water, aqueous solutes and dye; for non- $\text{Ca}^{2+}$  indicator dyes bleb fluorescence was always higher than nuclear fluorescence, and for  $\text{Ca}^{2+}$  indicator dyes nuclear fluorescence was always higher than bleb fluorescence. These results suggest that micropipette dye-loaded neurons have higher levels of nuclear  $\text{Ca}^{2+}$  at baseline resting potentials, and have important implications for the evaluation of depolarization-induced intracellular  $\text{Ca}^{2+}$  signals. Supported in part by the NIH and Department of Veterans Affairs.

## 444.6

**PLATELET-ACTIVATING FACTOR INDUCED INTRACELLULAR CALCIUM OSCILLATIONS IN RAT HIPPOCAMPAL NEURONS.** M.A. DeCoster, H.E.P. Bazan\*, and N.G. Bazan. LSU Medical Center, Neuroscience Center, New Orleans, LA 70112-2234

As has been previously shown, we have found using confocal microscopy and fluorescent calcium indicators, that intracellular calcium concentration ( $[\text{Ca}^{2+}]_i$ ) oscillates spontaneously in rat hippocampal neurons *in vitro*. While addition of glutamate (GLU) to these hippocampal cultures causes distinct  $[\text{Ca}^{2+}]_i$  changes ranging from transient, single spikes (100-500 nM GLU) to sustained increases (20-80  $\mu\text{M}$  GLU), GLU does not appear to induce  $[\text{Ca}^{2+}]_i$  oscillations. We have investigated the ability of the potent lipid mediator platelet activating factor (PAF) to affect  $[\text{Ca}^{2+}]_i$  dynamics in hippocampal neurons. When 4  $\mu\text{M}$  methylcarbaryl PAF (mcPAF) was added to the hippocampal neurons, the average  $[\text{Ca}^{2+}]_i$  was increased slightly in cells. Furthermore, the variance of fluorescence values after mcPAF additions was 8-fold higher than before additions, indicating an increase in oscillatory  $[\text{Ca}^{2+}]_i$  dynamics induced by PAF. Neurons not spontaneously oscillating were observed to be induced to oscillate by PAF addition, and neurons spontaneously oscillating increased in oscillatory behavior upon PAF addition. In agreement with Bito *et al.* (*Neuron*, 9:285, 1992) we found that not all neurons responded to acute PAF application. In contrast, long-term effects of PAF treatment on hippocampal cultures appeared to affect the majority of cells. Overnight treatment with PAF (200-400 nM) and mcPAF (2-4  $\mu\text{M}$ ) reduced the neuronal  $[\text{Ca}^{2+}]_i$  changes induced by GLU the next day when compared with cells pretreated with lysoPAF (2-4  $\mu\text{M}$ ) or the vehicle alone. In two cases, the  $[\text{Ca}^{2+}]_i$  increases in response to 500 nM GLU were completely inhibited by PAF pretreatment. Since PAF has been shown to enhance hippocampal excitatory synaptic transmission (Clark *et al.*, *Neuron* 9:1211, 1992) we postulate that induction of  $[\text{Ca}^{2+}]_i$  oscillations by PAF may be an early signal of GLU release, resulting in GLU receptor desensitization (Supported by DAMD-17-93-V-3013).

## 444.7

**LOCALIZATION OF THE RYANODINE RECEPTOR IN ALPHA MOTOR NEURONS IN THE CHICK SPINAL CORD.** Y. Qiyang\*, P. A. Cole, M. E. Martone, V. M. Edelman, J. A. Airey\*, J. L. Sultko\* and M. H. Ellisman. Dept. of Neurosciences, Univ. California, San Diego, CA 92093-0608 and \*Dept. of Pharmacology, Univ. Nevada, Reno, NV 89557-0046.

The ryanodine receptor is an intracellular calcium release channel localized to the membranes of the endoplasmic reticulum (ER) in neurons and other cell types. The subcellular localization of this channel has been most extensively studied in Purkinje neurons, which possess an abundant and elaborate intracellular membrane system that likely functions in the uptake, storage and release of intracellular calcium. Alpha motor neurons also possess abundant ER and are known to contain the ryanodine receptor (Qiyang et al., Brain Res. 620:269, 1993) but the subcellular distribution of this channel has not been investigated in this cell type. We employed light and electron microscopic immunolabeling techniques to investigate the organization of the ryanodine receptor in motor neurons in the chick spinal cord. Three monoclonal antibodies against the ryanodine receptor were employed: mAB34C which recognizes all forms of the ryanodine receptor thus far described in chick, mAB110F which specifically recognizes the alpha skeletal muscle isoform and mAB110E, which recognizes both the beta and the cardiac form but does not distinguish between the two. Immunofluorescence studies in chicks aged 1 day to 2 weeks indicated that motor neurons in the ventral horn contain the beta/cardiac but not the alpha skeletal muscle form of the ryanodine receptor. Labeling was seen throughout the cell soma but was most concentrated in a bright band underneath the plasma membrane. At the electron microscopic level, the prominent subplasmalemmal labeling was associated with the hypolemmal and subsurface cisternae. In order to determine whether the ryanodine receptor was localized within the motor nerve terminals, cryostat sections of muscle were double labeled using mAB34C labeled with FITC and rhodamine-labeled alpha bungarotoxin, to mark the neuromuscular junction (NMJ). Preliminary results indicate that labeling for the ryanodine receptor may be present within the pre-synaptic terminal at the NMJ. Thus, the ryanodine receptor may contribute to intracellular calcium regulation in motor neurons and their terminals.

## 444.9

**CALCINEURIN ASSOCIATED WITH THE INOSITOL 1,4,5-TRISPHOSPHATE RECEPTOR-FKBP12 COMPLEX MODULATES CALCIUM FLUX.** A. M. Cameron\*, J. P. Steiner, A. J. Roskams, S. M. Ali, G. V. Ronnett, and S. H. Snyder. Department of Neuroscience, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

FK506 Binding Protein 12 (FKBP) is a small, nearly ubiquitous cellular protein which possesses prolyl isomerase activity and was first identified as the target of the immunosuppressant drug FK506. When bound to FK506, FKBP binds to and inhibits the  $Ca^{2+}$  activated phosphatase calcineurin. In the absence of FK506, FKBP has been identified in complexes with the Ryanodine receptor (RyR) and Inositol trisphosphate receptor (IP<sub>3</sub>R), both of which are large intracellular calcium release channels. FKBP modulates the  $Ca^{2+}$  release properties of these channels apparently through a mechanism independent of its prolyl isomerase activity. We now report that calcineurin is present in these  $Ca^{2+}$  channel-FKBP complexes and may be anchored to these channels by an interaction with FKBP. Calcineurin is catalytically active in these complexes and is thus able to dynamically modulate phosphorylation status of the IP<sub>3</sub>R, most actively towards the protein kinase C (PKC) site of phosphorylation, suggesting a  $Ca^{2+}$  sensitive feedforward and feedback regulation of intracellular calcium flux and thus a possible substrate for observed intracellular  $Ca^{2+}$  oscillations.

## 444.11

**NADH SELECTIVE STIMULATION OF INOSITOL 1, 4, 5-TRISPHOSPHATE RECEPTORS MEDIATES HYPOXIC MOBILIZATION OF CALCIUM.** Adam I. Kaplin\*, Solomon H. Snyder, and David J. Linden. Dept. of Neurosci., Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

To evaluate the relationship of inositol 1, 4, 5-trisphosphate (IP<sub>3</sub>) receptor-mediated signal transduction and cellular energy dynamics, we have characterized effects of nucleotides on IP<sub>3</sub> receptor (IP<sub>3</sub>R)-mediated calcium ( $Ca^{2+}$ ) flux in purified IP<sub>3</sub> receptors reconstituted in lipid vesicles (IP<sub>3</sub>RV) and examined hypoxia-induced augmentation of intracellular  $Ca^{2+}$ . NADH increases IP<sub>3</sub>-mediated  $Ca^{2+}$  flux in IP<sub>3</sub>RV. This effect is highly specific for NADH and is quantal. Hypoxia elicited by brief exposure of PC12 cells or cerebellar Purkinje cells to cyanide elicits increases in internal [ $Ca^{2+}$ ]. The augmented  $Ca^{2+}$  derives from IP<sub>3</sub>-sensitive stores. Blockade of this effect by 2-deoxyglucose and inhibition of glyceraldehyde-3-phosphate dehydrogenase implicate enhanced glycolytic production of NADH in the  $Ca^{2+}$  stimulation. Internal [ $Ca^{2+}$ ] is markedly augmented by lactate, which elevates [NADH], and by direct intracellular injection of NADH. These findings indicate that direct regulation of IP<sub>3</sub>R by NADH is responsible for elevated cytoplasmic [ $Ca^{2+}$ ] occurring in hypoxia. This link of IP<sub>3</sub>R activity with cellular energy dynamics may be relevant to hypoxic damage and energy provision for IP<sub>3</sub> signaling processes.

## 444.8

**CALCIUM OSCILLATIONS AND WAVES IN C2C12 CELLS.** P. Lorenzon,<sup>1</sup> F. Eusebi,<sup>2</sup> A. Giovannelli,<sup>2</sup> D. Ragozzino<sup>2</sup> and F. Ruzzier<sup>1</sup>\*, <sup>1</sup>Inst. of Physiology, Univ. of Trieste, I-34127 Trieste and <sup>2</sup>Lab. of Biophysics, C.R.S. Regina Elena, I-00158 Rome, Italy.

It is known that spontaneous oscillations and/or waves of [ $Ca^{2+}$ ] are present in many cells. Using confocal and video-microscopy techniques, we studied these two phenomena in the mouse C2C12 line myotubes. Oscillations have been observed in 20% of differentiated cells, with variable frequency in the range 0.01 - 2 Hz. About 80% of the cells showing oscillations had silent periods lasting several minutes. The activity was reversibly blocked using EGTA 5 mM, KCl 5 mM or TEA 10 mM. Ryanodine 1  $\mu$ M, heparin 5 mg/ml or thapsigargin 1  $\mu$ M did not allowed the appearance of oscillations. On the contrary, caffeine 2 - 5 mM inhibited pre-existing oscillations whilst inducing a transitory (10 - 50 s) activity in silent cells. In the majority of the cells,  $Ca^{2+}$  waves could be detected along the whole myotube when caffeine 40 mM was applied in the presence of EGTA. In some cells, sub maximal caffeine concentrations (2 - 5 mM) elicited waves confined in restricted regions. These observations suggest that spontaneous oscillations of [ $Ca^{2+}$ ] in C2C12 myotubes are related to two different mechanisms: changes in  $Ca^{2+}$  permeability of the cell membrane, and  $Ca^{2+}$  movements from intracellular stores. Furthermore, we suggest that the autoregenerative  $Ca^{2+}$  propagation is sustained by a calcium-induced calcium release mechanism.

## 444.10

**CHARACTERIZATION OF THE RAFT-1 PROTEIN, THE MAMMALIAN TARGET OF THE G1-ARREST COMPLEX, FKBP12-RAPAMYCIN.** D.M. Sabatini\*, B. Pierchala, R. Barrow, D. J. Liss, N.A. Cohen and S.H. Snyder. Dept. of Neuroscience, Johns Hopkins Univ. Sch. of Med., Baltimore MD 21205.

The macrolide drugs rapamycin and FK506 were first identified as potent immunosuppressants which block T-cell mediated immunity. These drugs have been used as probes in a variety of cell types, including PC12 cells, for studying intermediate steps in signal transduction pathways from the cell surface to the nucleus.

FK506 acts by binding to a soluble intracellular receptor, FKBP12, and endowing this drug-receptor complex with the capacity to interact with and inhibit the  $Ca^{2+}$  activated phosphatase, calcineurin. FKBP12 and calcineurin are enriched in the mammalian nervous system and have been implicated in the control of neurite outgrowth and neurotransmitter release.

Rapamycin also mediates its effects by binding to FKBP12. The rapamycin-FKBP12 complex does not interact with calcineurin, but instead with a protein that we have termed RAFT-1 (for Rapamycin And FKBP12 Target). We have recently purified the 220 kDa RAFT-1 protein and cloned its cDNA. We now show that RAFT-1 from brain has lipid kinase activity. Using *in situ* hybridization and immunohistochemistry we have localized the RAFT-1 mRNA and protein in the adult and embryonic central nervous system. In addition, we have identified the subcellular localization of RAFT-1 and are studying the effect of rapamycin on this localization.

## 444.12

**THE ROLE OF INOSITOL TETRAPHOSPHATE IN  $Ca^{2+}$  MOBILIZATION IN XENOPUS OOCYTES.** B. Paul\*, Y. Yao, R.F. Irvine, and I. Parker. Laboratory Cellular and Molecular Neurobiology, Dept. of Psychobiology, University of California Irvine, Irvine, CA., 92717, USA. The Babraham Institute, Babraham, Cambridge CB2 4AT, UK.

Although the  $Ca^{2+}$  mobilizing role of inositol 1,4,5-trisphosphate (InsP<sub>3</sub>) in the phosphoinositide signaling pathway is well established, possible functions of inositol 1,3,4,5-tetrakisphosphate (InsP<sub>4</sub>), formed via phosphorylation of InsP<sub>3</sub>, are less clear. Studies of InsP<sub>4</sub> actions have been confounded by the finding that InsP<sub>4</sub> is back-converted to InsP<sub>3</sub> via InsP<sub>4</sub> 3-phosphatase (R.F. Irvine, 1992, *Inositol Phosphates and  $Ca^{2+}$  Signaling*, Raven Press, pp.161-185). We show that InsP<sub>4</sub> can mobilize  $Ca^{2+}$  from intracellular stores in *Xenopus* oocytes, even when co-injected with InsP<sub>6</sub>, a highly effective substrate for the InsP<sub>4</sub> 3-phosphatase, which thereby acts as a potent inhibitor of its actions on InsP<sub>4</sub> (S.B. Shears, 1992, *ibid.*, pp.63-92). When injected alone, InsP<sub>4</sub> elicited  $Ca^{2+}$ -activated membrane  $Cl^-$  currents resulting from intracellular  $Ca^{2+}$  mobilization, whereas injections of InsP<sub>6</sub> (up to 0.75 pmol) failed to evoke responses. Co-injection of InsP<sub>4</sub> and InsP<sub>6</sub> (8-50 fold excess InsP<sub>6</sub>) elicited currents of similar sizes to those evoked by comparable amounts of InsP<sub>4</sub> alone, indicating that previously reported mobilization of intracellular  $Ca^{2+}$  by InsP<sub>4</sub> (I. Parker & I. Ivorra, 1991, *J. Physiol.*, 433:207-27) arose through actions of InsP<sub>4</sub> itself, and not InsP<sub>3</sub> formed from it. Although InsP<sub>4</sub>, injected together with InsP<sub>6</sub>, evoked robust  $Ca^{2+}$  release from intracellular stores, it frequently failed to induce  $Ca^{2+}$  influx, as assessed by appearance of a transient inward ( $I_{in}$ ) current in response to hyperpolarization. Thus, internal  $Ca^{2+}$  store depletion appears not to be a sufficient stimulus for plasma membrane  $Ca^{2+}$  influx. However, a role for InsP<sub>4</sub> in regulation of  $Ca^{2+}$  influx cannot be ruled out, since  $I_{in}$  currents were induced by InsP<sub>4</sub> following 'priming' injections of InsP<sub>3</sub> (I. Parker & R. Miledi, 1987, *Proc. R. Soc. Lond. B*, 232:59-70).

NEURONAL CALCIUM HOMEOSTASIS AND THE REGULATION OF THE PLASMA MEMBRANE CALCIUM ATPASE: D.A. Zacharias\* and E.E. Strehler Mayo Grad. School, Dept. of Molecular Neuroscience, Rochester, Mn 55905.

Ca<sup>2+</sup> dyshomeostasis has been implicated as an underlying factor in the development and progression of neuronal degeneration occurring in disorders such as Alzheimer's Disease (AD). Of all the cellular systems that participate in Ca<sup>2+</sup> homeostasis, extrusion mechanisms have hitherto received little attention as a factor contributing to the Ca<sup>2+</sup> dyshomeostasis that occurs in neurodegenerative diseases. ATP-driven plasma membrane Ca<sup>2+</sup> ATPases (PMCA) are responsible for the fine-tuning of [Ca<sup>2+</sup>]<sub>i</sub> and represent a ubiquitous system for transmembrane Ca<sup>2+</sup> extrusion. Changes in the levels and distribution of differentially regulated PMCA isoforms in normal vs. diseased brains may provide clues regarding the reasons for the observed dysregulation of Ca<sup>2+</sup> in the disease state. In the first part of this study, we present a comparison of normal and AD brains as analysed by reverse transcription (RT)-PCR, quantitative ribonuclease protection assay (Q-RPA) and *in situ* hybridization analysis of the PMCA expression. In the second part of the study, our aim is to identify some of the mechanisms by which altered PMCA expression may occur. We have developed a human-derived cell culture (IMR-32 neuroblastoma) system in which we are able to vary [Ca<sup>2+</sup>]<sub>i</sub> in a controlled fashion and analyse the changes that occur as a result. Our preliminary results indicate that Ca<sup>2+</sup>-related signalling pathways regulate the expression of the PMCA at the level of alternative splicing and that calcineurin may be involved in this regulation pathway.

## 444.15

INCREASED <sup>45</sup>Ca<sup>2+</sup>-ACCUMULATION AND INOSITOL 1,4,5-TRISPHOSPHATE (IP<sub>3</sub>) RECEPTOR BINDING BY ORTHO-SUBSTITUTED POLYCHLORINATED BIPHENYLS (PCBs) IN RAT CEREBELLUM *IN VITRO*. P.R.S. Kodavanti, W.R. Mundy, S. Willig, and H.A. Tilson\* Neurotox. Div., NHEERL/USEPA, Research Triangle Park, NC 27711.

Previous reports from our laboratory indicate that *ortho*-substituted PCB congeners increase intracellular Ca<sup>2+</sup>, alter agonist-stimulated phosphoinositide hydrolysis, and cause protein kinase C translocation at concentrations where no cytotoxicity is observed; the effects of non-*ortho*-substituted PCB congeners on these phenomena are minimal. The present research extends these findings and examines the possible sources of intracellular Ca<sup>2+</sup> rise following PCB exposure. We studied the effects of two PCB congeners on <sup>45</sup>Ca<sup>2+</sup> accumulation in cerebellar granule cells to determine the contribution of Ca<sup>2+</sup> from external source and inositol 1,4,5-trisphosphate (IP<sub>3</sub>) receptor binding which is known to be associated with the Ca<sup>2+</sup> release from intracellular stores. <sup>45</sup>Ca<sup>2+</sup> accumulation was studied by incubating cerebellar granule cells with radioactive <sup>45</sup>CaCl<sub>2</sub>. IP<sub>3</sub> receptor binding was studied by incubating brain cerebellar microsomes with radioactive IP<sub>3</sub>, D-[inositol-1-<sup>3</sup>H]. Both 2,2'-dichlorobiphenyl (DCB), an *ortho*-substituted non-coplanar congener and 3,3',4,4',5-pentachlorobiphenyl (PeCB), a non-*ortho*-substituted coplanar congener, increased <sup>45</sup>Ca<sup>2+</sup> accumulation significantly at 100 μM indicating that both types of PCBs increase Ca<sup>2+</sup> accumulation in cerebellar granule cells from external source. However, DCB (at 30-100 μM), but not PeCB (even at 100 μM) enhanced IP<sub>3</sub> receptor binding significantly suggesting that interaction of *ortho* PCBs with cerebellar endoplasmic reticular membranes may be a mechanism by which *ortho* PCBs can mobilize intracellular Ca<sup>2+</sup> and contribute to altered cellular Ca<sup>2+</sup> signaling. These results suggest that both Ca<sup>2+</sup> accumulation from extracellular source and Ca<sup>2+</sup> release from intracellular stores are involved in the intracellular Ca<sup>2+</sup> rise by *ortho* PCBs.

## 444.17

DIRECT MEASUREMENT OF MITOCHONDRIAL Ca<sup>2+</sup> IN NORMAL AND PYRUVATE DEHYDROGENASE-DEFICIENT HUMAN DIPLOID FIBROBLASTS. R.A. Padua\*, M. Shen, C. Campbell and S.A. Thayer Dept. of Pharmacology, Univ. of Minnesota, Minneapolis, MN, 55455.

Mitochondrial Ca<sup>2+</sup> concentration ([Ca<sup>2+</sup>]<sub>mt</sub>) was directly measured in control and pyruvate dehydrogenase-deficient (pdh<sup>-</sup>) human diploid fibroblasts expressing mitochondrial-targeted apoaequorin (mt-aq). In both cell types, bradykinin (BK, 100 nM) was able to elicit a reproducible cytosolic Ca<sup>2+</sup> ([Ca<sup>2+</sup>]<sub>i</sub>) transient as shown by indo-1 microfluorimetric measurements. BK-induced [Ca<sup>2+</sup>]<sub>i</sub> increases were not significantly different in the presence and absence of the mitochondrial uncoupler FCCP. In control fibroblasts, a transient increase in [Ca<sup>2+</sup>]<sub>i</sub> induced by BK was paralleled by an increase in normalized luminescent signal (response counts/total counts; 0.237±0.031) indicative of a rise in [Ca<sup>2+</sup>]<sub>mt</sub>. FCCP blocked the BK-induced [Ca<sup>2+</sup>]<sub>mt</sub> transient and this effect was reversible because subsequent BK application elicited a [Ca<sup>2+</sup>]<sub>mt</sub> transient (0.097±0.012). In pdh<sup>-</sup> fibroblasts, the BK-induced [Ca<sup>2+</sup>]<sub>mt</sub> transient (0.027±0.003) was greatly reduced relative to control. However, mt-aq expression in pdh<sup>-</sup> cells was 27% of control. During transfection, treatment of pdh<sup>-</sup> cells with β-hydroxybutyrate (2 mM), an alternative substrate for aerobic metabolism, increased mt-aq expression by 35%, enhanced mitochondrial cytochrome C oxidase activity by 4-fold and restored BK-induced [Ca<sup>2+</sup>]<sub>mt</sub> transients (0.072±0.013) to 30% of control. Taken together, our results suggest that cells with compromised aerobic metabolism have a reduced ability to sequester Ca<sup>2+</sup> into mitochondria.

## 444.14

TRANSFECTED PC-12 CELLS EXPRESS CALRETININ: DOES ALTERED Ca<sup>2+</sup>-HOMEOSTASIS AFFECT PC-12 CELL DIFFERENTIATION, SURVIVAL, AND APOPTOSIS? J. Kuźnicki, K. Strauss, K.R. Isaacs, and D.M. Jacobowitz, NIMH/LCS, Bethesda, MD 20892-1266

Calretinin (CR), a calcium binding protein homologous to calbindin D28k, is present in subsets of brain neurons. The role of this protein is unknown. We report that PC-12 cells do not express endogenous CR either before or after NGF-induced differentiation. We transfected PC12 cells to determine whether CR functions as a Ca<sup>2+</sup> buffer to alter Ca<sup>2+</sup>-homeostasis, and if CR affects neuronal differentiation, vulnerability to Ca<sup>2+</sup> overload, or apoptosis. We devised a vector with the CMV promoter upstream of the CR coding region (pBK-CMVCR). Transformed *E. coli* induced with IPTG produced a 22 kDa protein that was recognized by CR-specific antisera and bound Ca<sup>2+</sup> in overlay assays. Undifferentiated PC-12 cells transfected with Transfectam and pBK-CMVCR (minus the lacZ promoter and ATG) yielded CR-immunoreactive cells, found frequently grouped in pairs. To produce a line of stable transfectants, cells were treated with geneticin. Ca<sup>2+</sup>-imaging and immunohistochemistry will be used to evaluate the fate of transfected PC-12 cells treated with A23187, excitatory amino acids or serum depletion. Changes in NGF-induced differentiation will also be analyzed.

## 444.16

PROPERTIES OF CA<sup>2+</sup> STORES IN TYPE 1 AND TYPE 2 ASTROCYTES. P.B. Simpson, C.A. Sheppard and J. T. Russell LCMN, NICHD, NIH.

In this study, we have investigated the Ca<sup>2+</sup> stores present in cultured rat cortical type 1 and type 2 astrocytes. Immunocytochemical analysis with specific antibodies indicated that both type of astrocyte express subtypes of inositol trisphosphate receptors, ryanodine receptors (RyRs) and Ca<sup>2+</sup>ATPases. Both cell types responded to bradykinin with a peak and plateau or oscillatory [Ca<sup>2+</sup>]<sub>i</sub> elevation, which was markedly inhibited by pretreatment with cyclopiazonic acid (CPA). CPA alone evoked a transient [Ca<sup>2+</sup>]<sub>i</sub> elevation in both types of glial cell in nominally Ca<sup>2+</sup>-free medium, whereas a sustained elevation was apparent in normal [Ca<sup>2+</sup>]<sub>i</sub>, consistent with store depletion in both cell types activating Ca<sup>2+</sup> entry. Despite widespread expression of RyRs, perfusion of type 1 astrocytes with caffeine evoked an elevation of [Ca<sup>2+</sup>]<sub>i</sub> in only a small number of the cells examined (5 out of 143 cells, 4%). However, in type 2 cultures caffeine evoked a peak elevation in a much higher proportion of cells (16 out of 70 cells, 23%). This response was still present in type 2 astrocytes, and indeed often of greater magnitude, subsequent to activation of Ca<sup>2+</sup> entry using kainate. These findings indicate that while type 1 and type 2 astrocyte Ca<sup>2+</sup> stores appear to have considerable similarities in terms of their inositol trisphosphate receptor and capacitative entry properties, there is a marked difference in their responsiveness to caffeine. The reason for this difference, and its putative relevance for astrocyte RyR-mediated signalling, remains to be established.

## 444.18

PDGF-BB INDUCED Ca<sup>2+</sup> RESPONSES IN CELLS OF THE OLIGODENDROCYTE LINEAGE ARE MODULATED BY SPHINGOLIPIDS. Alessandro Fatatis\* and Richard J. Miller Department of Pharmacological and Physiological Sciences, The University of Chicago, Chicago (IL).

CEINCE cl 3 is a cell clone which was obtained through the infection of rat embryo neural cells with the murine leukemia virus carrying the polyoma middle T oncogene. These cells stain with immunofluorescent antibodies directed against galactocerebroside C, myelin basic protein and cyclic nucleotide phosphodiesterase, three specific markers for oligodendroglia. Exposure of these cells to PDGF-BB (10ng/ml) for 5 minutes induced two types of [Ca<sup>2+</sup>]<sub>i</sub> response, monitored through fura-2 single-cell videoimaging. The first type was observed in 56% of the responding cells with a delay of 187±6 seconds and was characterized by a non oscillatory increase in [Ca<sup>2+</sup>]<sub>i</sub>. The other 44% of the responding cells showed an oscillatory [Ca<sup>2+</sup>]<sub>i</sub> response with a delay of 289±9 seconds. Both [Ca<sup>2+</sup>]<sub>i</sub> responses were partially dependent on the presence of extracellular Ca<sup>2+</sup>. It has been demonstrated in fibroblasts that PDGF-BB exposure induces the increase of the intracellular levels of sphingosine and sphingosine-1-phosphate (SPP), which appear to be correlated with cell proliferation. When CEINCE cl 3 were incubated for 10 minutes with 10μM DL-threo dihydrosphingosine, which inhibits the phosphorylation of sphingosine in SPP, 90 % of the responding cells showed oscillatory [Ca<sup>2+</sup>]<sub>i</sub> responses to following PDGF-BB perfusion. Furthermore, when 10μM DL-threo dihydrosphingosine was added between two consecutive PDGF-BB pulses, cells showing a monophasic response to the first pulse responded with an oscillatory pattern to the second PDGF exposure. Finally, when sphingosine (10μM) and SPP (1μM) were separately perfused, more than 90% of the responsive cells showed an oscillatory and a non-oscillatory Ca<sup>2+</sup> response, respectively. These results showed that in CEINCE cl3 cells Ca<sup>2+</sup> signalling following PDGF-BB stimulation is differently modulated by sphingosine and SPP.

## 444.19

HISTAMINE  $H_1$ -RECEPTOR ACTIVATION INDUCES  $[^3H]$ GABA RELEASE FROM HUMAN U373 MG ASTROCYTOMA CELLS. L.E. Soria, Q. Martinez-Fong\* and J.A. Anas-Montano. Departamento de Neurociencias, CINVESTAV-IPN. Apdo. postal 14-740, 07000 Mexico, D.F., Mexico.

Amino acidic neurotransmitters can be released from glial cells in a  $Ca^{2+}$ -independent manner (Bernath, Prog. Neurobiol. 38: 57-91, 1992). Since glial and glia-derived cells often express histamine  $H_1$ -receptors coupled to phosphoinositide hydrolysis (Inagaki and Wada. Glia, 11: 102-109, 1994) we set out to study whether agonist-induced increase in intracellular  $Ca^{2+}$  concentration ( $[Ca^{2+}]_i$ ) results in neurotransmitter release from U373 MG cells, a cell line derived from a human astrocytoma. Cells grown in 12-well plates were incubated with  $[^3H]$ GABA (80 nM) for 30 min at 37°C. After washing out the excess of  $[^3H]$ GABA, the medium (1 ml) was changed every 2 min and radioactivity measured in each fraction. In the fraction exposed to histamine  $[^3H]$ GABA release was increased in a concentration dependent-manner (maximum  $306 \pm 23\%$  of controls). Neither  $Ca^{2+}$  removal nor  $Cd^{2+}$  (100  $\mu$ M) affected histamine-induced  $[^3H]$ GABA release. In cells labelled (24 hr) with  $[^3H]$ inositol and exposed to histamine for 2 min, total  $[^3H]$ inositol phosphates accumulation increased in a concentration dependent-manner ( $EC_{50}$ ,  $17 \pm 2$   $\mu$ M, maximum  $203 \pm 4\%$  of basal). Histamine (100  $\mu$ M) also increased  $[Ca^{2+}]_i$  ( $\Delta [Ca^{2+}]_i = 242 \pm 12$  nM) in a thapsigargin-sensitive manner. The  $H_1$ -selective antagonist mepyramine blocked the actions of histamine on  $[^3H]$ GABA release,  $[^3H]$ inositol phosphates accumulation and  $[Ca^{2+}]_i$ . Taken together our results indicate that  $Ca^{2+}$  ions released from intracellular stores are responsible for histamine  $H_1$ -receptor induced  $[^3H]$ GABA release from U373 MG cells.

## BEHAVIORAL PHARMACOLOGY: SEROTONIN AND DOPAMINE

## 445.1

EFFECTS OF 5-HT<sub>2</sub> AND DA ANTAGONISM ON THE STIMULUS PROPERTIES OF LSD. W.B. West, D.M. Millis, J. Buggy\*, and J.B. Appel. Behavioral Pharmacology Lab., Dept. of Psychology, Univ. of S. Carolina, Columbia, SC, 29208. Because the only drugs that substitute for LSD are 5-HT<sub>2</sub> agonists or congeners of LSD and the only drugs that block the LSD cue are 5-HT<sub>2</sub> antagonists, we concluded that the LSD cue is mediated primarily by the 5-HT<sub>2</sub> receptor. However, several findings suggest that other neuronal systems may at least modulate this effect: 1) Spiperone, probably the most selective 5-HT<sub>2</sub> antagonist does not block the LSD cue, and 2) both ritanserin and risperidone, which are potent and selective antagonists of LSD and have strong affinity for 5-HT<sub>2</sub> receptors, have substantial affinity for DA receptors. In light of these data, we studied the effects of LY 237733, a selective 5-HT<sub>2</sub> antagonist with only weak affinity for DA receptors, ritanserin, MDL 72222, a 5-HT<sub>2</sub> antagonist and haloperidol, a DA antagonist, on the stimulus effects of LSD. Rats were trained to discriminate i.p. injections of LSD (0.08 mg/kg) using a standard, two-lever drug discrimination paradigm. They were then given two kinds of combination (antagonism) tests: 1) several doses of each putative antagonist were given in combination with a single dose of LSD or, 2) a single dose of each antagonist was given in combination with three cumulative doses of LSD (0.02, 0.04, 0.08 mg/kg). Under both test conditions, sufficiently high doses of LY 237733 (4 mg/kg) and ritanserin (2 - 4 mg/kg) blocked the LSD cue completely; neither MDL 72222 nor haloperidol had any antagonistic effect. These results suggest that whatever affinity ritanserin (and probably risperidone) may have for DA is not as important as their actions at 5-HT<sub>2</sub> receptors in mediating the LSD cue. Drugs that act predominantly at either 5-HT<sub>2</sub> or DA receptors do not appear to play any role in the stimulus effects of LSD.

Supported by USPHS Research Grant 5 R37 DA02543, from the National Institute on Drug Abuse.

## 445.3

SEROTONIN-2A ANTAGONISTS DECREASE APOMORPHINE-INDUCED STEREOTYPIC BEHAVIOR WITHOUT AFFECTING LOCOMOTOR ACTIVITY. P. Hicks\*, K. Young, R. Zavodny and T. Richter. Department of Psychiatry and Behavioral Sciences, Scott and White Clinic, Temple, TX 76708.

We have previously demonstrated the role of serotonin-2C (5-HT-2C) receptors in modulation of apomorphine-induced locomotor activity (AILA) at an apomorphine dose of 0.25 mg/kg. The 5-HT-2A/2C antagonist mesulergine potentiated AILA and suppressed apomorphine-induced stereotypic behaviors (AIS). To further characterize the role of the 5-HT-2A and 5-HT-2C receptors in modulation of AIS, we have studied the effects of several substances active at these receptor sites.

Male Sprague-Dawley rats were given apomorphine (0.5 mg/kg) and test compounds (vehicle or serotonergic agents) subcutaneously at time zero. Locomotor activity was monitored in 5-min intervals for 30 min (San Diego Instruments). Baseline crossings in the 15-25 min post-treatment interval were used for comparisons. Stereotypic behavior was rated at 5-min intervals for 30 min by an observer blind to the treatment using a 0-5 scale. The sum total of stereotypic behavior scores for all six observation intervals was used for comparisons.

The 5-HT-2A antagonists ketanserin (0.02 mg/kg), MDL 100,907 (0.02 and 0.1 mg/kg) and ritanserin (0.02 mg/kg) all suppressed AIS without significant effects on locomotor behavior. The specific 5-HT-2C antagonist SER 082 had no effect on either AILA or AIS.

These findings suggest that serotonergic modulation of locomotor activity and stereotypic behavior is complex. The 5-HT-2A receptor appears to be more important as a modulator of stereotypic behaviors. The lack of effect of the specific 5-HT-2C antagonist SER 082 on either AILA or AIS suggests that the previous findings of potentiation of AILA with mesulergine may reflect activity at a receptor site other than the 5-HT-2A or 5-HT-2C receptor.

## 445.2

DOPAMINERGIC AND SEROTONERGIC PROPERTIES OF FLUOXETINE. B.B. Simon and J.B. Appel\*, Behavioral Pharmacology Lab., Dept. of Psychology, Univ. of S. Carolina, Columbia, SC, 29208.

Fluoxetine (Prozac) has been used to treat a variety of complaints including depression, obsessive-compulsive disorders, and drug abuse, each of which has been attributed to disturbances in central reward mechanisms. Since these mechanisms are thought to be dopaminergic, the reason why their behavioral expression is altered by a selective 5-HT reuptake inhibitor is unclear. This problem was analyzed indirectly in the present experiment by training rats to discriminate i.p. injections of a 5-HT agonist, LSD (0.08 mg/kg, n = 11) and a DA agonist, cocaine (10 mg/kg, n = 16) from saline in a standard two-lever, drug discrimination situation. All animals were then tested with fluoxetine (0.625 - 10 mg/kg) alone and in combination (0.625 - 2.5 mg/kg) with the training drugs.

A 2 x 5 mixed analysis of variance on percentage of drug-appropriate responding indicated that fluoxetine did not substitute for either LSD or cocaine at any of the doses tested [ $F_{(4,56)} = 1.52$ ,  $p > .21$ ]. Moderate dose of fluoxetine (1.25 mg/kg) appeared to potentiate the discriminability of cocaine (2.5 mg/kg) of but not of LSD (0.02 mg/kg). These data suggest that inhibition of 5-HT reuptake has little, if any effect on the behavioral effects of LSD, which probably involve 5-HT<sub>2C</sub> receptors. The ability of fluoxetine to potentiate the cocaine cue (but not to substitute for cocaine) suggests that fluoxetine does not inhibit DA reuptake but may have dopaminergic actions such as increasing DA receptor density. Alternatively, cocaine may have serotonergic properties, which result in the combination of relatively low doses of fluoxetine and cocaine being additive or synergistic.

## 445.4

DIFFERENT EFFECTS OF TROPISETRON (ICS 205-930) AND ONDANSETRON IN LEARNING AND MEMORY PARADIGMS. BEHAVIORAL EVIDENCE FOR DIVERSE 5-HT<sub>3</sub> RECEPTOR SUBTYPES? N. Pitsikas\* and F. Borsini. Department of Biology, Boehringer Ingelheim Italia S.p.A. 20139 Milan, Italy.

The 5-HT<sub>3</sub> receptor antagonists tropisetron (ICS 205-930) and ondansetron were tested in different memory tasks in which scopolamine (0.2 mg/kg, SC) was used as amnesic agent. Pretreatment with ondansetron (0.01 and 1  $\mu$ g/kg, IP) but not with tropisetron (1, 10 and 30  $\mu$ g/kg, IP) reversed scopolamine-induced memory deficits in the step-through passive avoidance task.

When the effects of these 5-HT<sub>3</sub> receptor antagonists on cognition were assessed in the Morris water maze, ondansetron (0.01, 1 and 10  $\mu$ g/kg, IP) did not antagonize the amnesia induced by scopolamine. On the contrary, pretreatment with tropisetron (10 and 30  $\mu$ g/kg, but not 1  $\mu$ g/kg, IP) counteracted the learning and memory impairment due to scopolamine treatment.

It is suggested that different subtypes of the 5-HT<sub>3</sub> receptor may underlie the different effects on cognition displayed by compounds which belong to the same pharmacological class.

## 445.5

COMPARISON OF PUNISHED RESPONDING AND CONDITIONED SUPPRESSION IN PIGEONS AND RATS. C.D. Overshiner, M.J. Benvenia, and J.D. Leander\* Lilly Research Laboratories, Eli Lilly & Co., Lilly Corporate Center, Indianapolis, IN 46207

Two procedures, punished responding and CER, that are used to study anxiolytic activity of drugs were examined in two species, rat and pigeon. Chlordiazepoxide, 8OHDPAT and pentobarbital significantly increased punished responding in both species. In the CER paradigm, chlordiazepoxide, 8OHDPAT, and pentobarbital slightly increased suppressed responding in both species, with only chlordiazepoxide in the pigeon producing a statistically significant increase in suppressed responding. WAY100635, a 5HT<sub>1A</sub> antagonist, did not significantly affect responding in either procedure or species. Buspirone and diazepam, tested only in rats, significantly increased punished responding, with only the highest dose of diazepam producing a significant increase in suppressed responding.

Punished responding was a more sensitive measure of anxiolytic effects than conditioned suppression in both species. Effects of compounds on conditioned suppression paralleled that of punished responding but with less magnitude and higher variability.

## 445.7

BESPIRIDINE HCL (HP 749) AND HP 184 REDUCE SCHEDULE-INDUCED POLYDIPSIA (SIP) IN THE ABSENCE OF SELECTIVE SEROTONIN (5HT) UPTAKE INHIBITION. A.T. Woods, C.P. Smith, R. Corbett, G. Bores, W. Petko, J.E. Roehr, L. Davis, J.T. Klein, R.C. Effland and S. Kongsamut, Neuroscience Product Group Unit, Hoechst-Roussel Pharmaceuticals, Inc., Somerville, NJ 08876.

The polydipsia (SIP) model may have relevance for the prediction of efficacy of compounds useful in the treatment of obsessive compulsive disorder. Previous results (Woods et al., *Psychopharmacol.* 112: 195-198, 1993) have shown that only selective 5HT re-uptake inhibitors such as clomipramine and fluoxetine decrease SIP after a 14-21 day treatment. In these experiments, food-deprived rats were exposed to a fixed-time feeding schedule (FT=60sec) for 150 min per day. After 3 weeks of training, rats considered polydipsic drank >60 ml of water during the 150 min session (vs. 17 ml for food deprived controls). Besipirdine and HP 184 both decreased SIP beginning with the first treatment and this reduction was maintained for 28 days. Notably, neither compound was a selective 5HT uptake inhibitor. Besipirdine is a weak, non-selective inhibitor of biogenic amine uptake, and HP 184 has no uptake inhibitory properties at all. However, besipirdine and HP 184 did enhance the release of [<sup>3</sup>H]5HT from rat hippocampal slices, but these effects were not blocked by the selective 5HT uptake inhibitor citalopram (10  $\mu$ M). Thus, for besipirdine and HP 184, mechanisms independent of selective 5HT uptake inhibition can successfully reduce SIP.

## 445.9

EFFECTS OF ACUTE TREATMENT WITH INDIRECT-ACTING SEROTONERGIC AGONISTS ON ANXIETY-LIKE (CONFLICT) BEHAVIOR IN MAUDSLEY RATS. M.W. Lewis, D.E. Nichols, M.A. Ritter, J.S. Verbanac and R.L. Commissaris\*, Purdue Univ., West Lafayette, IND and Wayne State University, Detroit, MI.

The Maudsley Reactive (MR; 'anxious') and NonReactive (MNRA; 'non-anxious') rat strains may represent a genetically-based model for differences in anxiety-like behavior. Serotonin (5HT) has been suggested to play a role in anxiety. The present studies examined the effects of acute treatment with the 5HT reuptake blocker fluoxetine (FLU) and the 5HT releaser 5-methoxy-6-methyl-2-aminindan (MMAI) on anxiety-like behavior in the Maudsley rats. MR and MNRA rats were trained in a conditioned suppression of drinking conflict paradigm. After several weeks of baseline conflict sessions, rats received challenges with MMAI (0.0625 - 8.0 mg/kg) and FLU (2.5 - 20 mg/kg) over the course of several weeks. In addition, challenges with phenobarbital (PHENO: 10, 20 mg/kg) and alprazolam (ALP: 0.25, 0.5 mg/kg) served as reference anticonflict standards. As expected, conflict-trained MNRA rats accepted more shocks (i.e., were less 'anxious') than MR rats in non-drug conflict sessions; PHENO or ALP produced robust increases in shocks received in both rat strains. At low doses, neither MMAI nor FLU significantly affected shocks received or water intake. Higher doses of both agents significantly reduced water intake (i.e., disrupted behavior) with a concomitant decrease in shocks received. There were no MR -v- MNRA strain differences in the response to either agent for either shocks received or water intake. These data suggest that acute manipulations of 5HT neurotransmission via reuptake blockade or increased release do not affect conflict behavior. Moreover, these data suggest that the Maudsley rats do not differ in their sensitivity to acute treatments which alter 5HT neurotransmission.

## 445.6

DRUG DISCRIMINATION STUDIES OF THE INTEROCEPTIVE CUES PRODUCED BY SELECTIVE SEROTONIN UPTAKE INHIBITORS AND SELECTIVE SEROTONIN RELEASING AGENTS. D. Marona-Lewicka\* and D.E. Nichols, Departments of Pharmacology and Toxicology and Medicinal Chemistry and Pharmacognosy, Purdue University, West Lafayette, Indiana 47907

MMAI (5-Methoxy-6-methyl-2-aminindan) is a non-neurotoxic, highly selective neuronal serotonin (5-HT) releasing agent. MMAI and other 5-HT releasing agents produce a robust discriminative cue in drug discrimination (DD) studies. In vitro, 5-HT release can be blocked by selective 5-HT uptake inhibitors. However, in the present DD studies, pretreatment with fluoxetine, sertraline, or citalopram 60 minutes before the training drugs MMAI or (+)-MBDB produced only slight inhibition of the discriminative cue. In substitution tests, sertraline and citalopram partially mimicked the training drugs, whereas only 40% substitution occurred with fluoxetine in MMAI or (+)-MBDB trained rats. Since acute systemic administration of 5-HT releasing agents is known preferentially to increase extracellular 5-HT in forebrain structures, while the extracellular 5-HT increase induced by a single dose of an uptake inhibitor is several-fold higher in the raphe nuclei than in the frontal cortex, activation of forebrain serotonergic systems may be an important factor for the discriminative stimulus properties of drugs with 5-HT releasing and uptake blocking properties.

## 445.8

COMPARATIVE ANTIDEPRESSANT- AND ANTIANXIETY-LIKE EFFECTS OF 5-HT<sub>1A</sub> AGONISTS IN MICE AND RATS. Roger D. Porsolt, Joseph G. Wettstein\* and Sylvain Roux, I.T.E.M.-Labo, 93 avenue de Fontainebleau, 94276 Le Kremlin-Bicêtre, France.

One primary indication for 5-HT<sub>1A</sub> agonists is the treatment of anxiety yet such compounds may also possess antidepressant activity. The purpose of the present study was to examine the behavioral effects of two novel 5-HT<sub>1A</sub> agonists flesinoxan and alnespirone (S 20499), the prototype 5-HT<sub>1A</sub> agonists buspirone and 8-OH-DPAT, and the conventional drugs imipramine and diazepam in procedures designed to detect antidepressant and anxiolytic activity. In the mouse tail suspension test, all 5-HT<sub>1A</sub> agonists along with diazepam increased and imipramine decreased the duration of immobility. In the rat behavioral despair test, imipramine and the 5-HT<sub>1A</sub> agonists (except buspirone) decreased immobility duration. In the mouse behavioral despair test, imipramine clearly decreased, alnespirone and 8-OH-DPAT partially decreased, and flesinoxan increased immobility; buspirone had no effect. In the Cook-Davidson conflict procedure, diazepam but not buspirone increased suppressed responding whereas both diazepam and buspirone increased suppressed drinking in the Vogel conflict test. Together, these results support the idea that the mouse tail suspension test is sensitive to an anxiolytic-like action of 5-HT<sub>1A</sub> agonists. In comparison, the behavioral despair test with rats may be useful in detecting potential antidepressant activity of such compounds.

## 445.10

INVOLVEMENT OF SEROTONIN<sub>1A</sub> RECEPTORS SUPPRESS DEFENSIVE RAGE BEHAVIOR IN THE CAT. M.B. Shaikh\*, N. Simpson, and A. Siegel, Lab. of Limbic System and Behavior, Dept. of Neurosciences, N.J. Medical School, UMDNJ, Newark, N.J. 07103.

The midbrain periaqueductal gray (PAG), a primary brainstem site for the integration of defensive rage behavior (DR), receives converging inputs from medial hypothalamus (MH) which mediates DR and serotonergic inputs from the raphe system. The present study was designed to test the hypothesis that activation of 5-HT<sub>1A</sub> receptors within the PAG inhibits DR elicited from the MH. Stimulating electrodes were implanted into DR sites within MH and cannula electrodes were implanted into DR sites in the PAG for drug infusion. Following microinfusion of the selective agonist for 5-HT<sub>1A</sub> receptors, 8-OHDPAT (50 pmole, 2.0, 3.0 nmole) into the PAG, response latencies for MH-elicited DR were significantly increased above baseline at the highest dose level ( $p < 0.01$ ) in a dose- and time-dependent manner at 5 min postinjection. At a dose of 2.0 nmole, microinjections of 8-OHDPAT also resulted in an increase in response latencies but of lesser magnitude. Pretreatment with the 5-HT<sub>1A</sub> receptor antagonist, p-MPPI, (1.5, 3.0 nmole), blocked the suppressive effects of 8-OHDPAT. The results demonstrate the inhibitory role of 5-HT<sub>1A</sub> receptors within the PAG in modulating defensive rage behavior.

## 445.11

**EFFECTS OF DOPAMINE AGONISTS AND ANTAGONISTS ON BODY TEMPERATURE, ACTIVITY AND ULTRASONIC VOCALIZATIONS OF RAT PUPS.** B.E. Brown\*, F. Dastur, D. Wiles and J. McGregor(1). Depts of Psychology, Dalhousie University, Halifax, N.S. Canada B3H 4J1 and (1) University of Sydney, Sydney, NSW 2006, Australia.

As D1 agonists induce hyperthermia, while D2 and D3 agonists induce hypothermia, we predicted that the D1 agonist SKF 81297 (SKF) would reduce USVs while D2 (Quinpirole) and D3 agonists (7-OH-DPAT) would increase USVs in 11-13 day old rat pups. The axillary temperature of pups given SKF (2.5 mg/kg) was lower than saline injected controls and the pups emitted fewer ultrasonic vocalizations (USVs) and had decreased activity levels in a 5 min. test. As SKF increases body temperature in adults, the reduced body temperature in pups was unexpected. SCH 23390 (0.3 mg/kg) but not Raclopride (0.3 mg/kg) reversed the effect on temperature. Quinpirole decreased body temperature at low (0.3 mg/kg) and high (3.0 mg/kg) doses and both doses increased activity levels, but only the high dose reduced USVs. These effects were reversed by Raclopride, but not SCH. 7-OH-DPAT reduced temperature at high (1. mg/kg) but not low doses (0.1 mg/kg). Both doses increased activity levels and this effect was reversed by both antagonists. Only the high dose of 7-OH-DPAT reduced USVs and this effect was reversed by Raclopride but not by SCH. Neither SCH (0.3 mg/kg) nor Raclopride (0.3 mg/kg) alone altered body temperature or USVs, but SCH reduced activity levels. The drop in body temperature during the 5 min. test was not the most important stimulus for emission of USVs. The reduction in USVs by the D1, D2 and D3 agonists suggests that the antianxiety or antidepressant actions of these drugs, their reinforcing properties, or their effects on respiration alter USV emission in infant rats, rather than their thermoregulatory actions.

## 445.13

**TRIHENXYPHENIDYL ATTENUATES DEFICITS PRODUCED BY CHRONIC DOSING OF RACLOPRIDE BUT NOT SCH 23390 IN RATS TRAINED TO PERFORM A SUSTAINED ATTENTION TASK.** B.J. Brockel\*, S.C. Fowler. University of Mississippi, University, MS 38677.

Sixty rats were trained to respond to 1 of 3 briefly presented light stimuli with a nose poke response. Using a between groups design, each subject received either vehicle or its own dose of SCH 23390 (0.02-0.16 mg/kg) or raclopride (0.2-0.8 mg/kg) daily for 7-21 days. After chronic dosing, the effects of chronic treatment were challenged with the anticholinergic trihexyphenidyl (0.5 mg/kg). Chronic SCH 23390 and raclopride treatment lengthened reaction time, increased errors of omission, and decreased earned reinforcers. Head exits, a possible model of akathisia, were increased by raclopride but not by SCH 23390. Trihexyphenidyl attenuated reaction time deficits produced by raclopride but not by SCH 23390. The results of this study indicate that both SCH 23390 and raclopride could have antipsychotic properties. Raclopride may be more likely to produce motor side effects such as parkinsonism and akathisia, but anticholinergic cotreatment may not alleviate side effects produced by SCH 23390. Supported by MH43429.

## 445.15

**CARBAMAZEPINE REDUCES DOPAMINE-MEDIATED BEHAVIOR IN NORMAL AND CHRONIC NEUROLEPTIC-TREATED RATS: IMPLICATIONS FOR TREATMENT OF TARDIVE DYSKINESIA.** T. Wigal<sup>1</sup>, G.J. LaHoste<sup>2</sup>, B.H. King<sup>3</sup>, N. Khouzam<sup>1</sup>, S.J. O'Dell<sup>1</sup>, F.M. Crinella<sup>1</sup> and J.M. Swanson<sup>1</sup>. Depts. of <sup>1</sup>Pediatrics, <sup>2</sup>Phys. Med. & Rehab., and <sup>3</sup>Psychobiology, Univ. California, Irvine, CA 92717; <sup>4</sup>Dept. Psychiatry, Univ. Calif. Los Angeles.

We have recently found in developmentally disabled patients that tardive dyskinesia (TD) following withdrawal from long-term neuroleptic treatment occurs less frequently in patients that had concurrently received anticonvulsants, principally carbamazepine (CBZ). To determine whether this protective effect is due to anticonvulsant treatment *per se*, we employed an animal model of TD, based on chronic treatment with the neuroleptic haloperidol (HAL). In this model rats develop up-regulated dopamine D2 receptors and behavioral supersensitivity, effects which many investigators believe underlie TD. Twenty-nine adult rats received in their drinking water: HAL (1.2 mg/kg/day; n=6), HAL+CBZ (1.2 + 25 mg/kg/day; n=7), CBZ (25 mg/kg/day; n=6), 1/2HAL (0.6 mg/kg/day; n=5), or lactic acid (0.77%; n=5). After eight weeks, drugs were withdrawn and 96 h later all rats were tested for behavioral responsiveness to combined treatment with the selective D1 agonist SKF 38393 (20 mg/kg, i.p.) and the selective D2 agonist quinpirole (0.125 mg/kg, i.p.). Chronic HAL treatment resulted in elevated stereotypy rating scores, as expected, for both the full and the half dose ( $P < 0.04$ ). Chronic CBZ significantly reduced stereotypy scores regardless of whether HAL was given concomitantly or not ( $P < 0.01$ ). The present behavioral data parallel the human data and suggest that carbamazepine may be effective in lowering the incidence of TD and in treating hyperdopaminergic states. To help elucidate the biological basis of these findings, we are currently assessing whether CBZ alters the effects of HAL on striatal D2 receptor binding.

## 445.12

**IMPROVED SENSITIVITY OF A WATER WHEEL AUTOMATED BEHAVIORAL DESPAIR TEST USING WISTAR-KYOTO RATS.** F.W. Ninteman\*, D.J. Johnston, J.N. Wiley, A.E. Corbin, and T.G. Heffner. Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Co., Ann Arbor, MI 48105.

Although the forced swim behavioral despair test has been used to identify antidepressant drugs, selective serotonin reuptake inhibitors (SSRI) are often inactive in this test. In order to improve the sensitivity of the test, we compared the behavior of Wistar-Kyoto (WKY) and Sprague-Dawley (SD) rats in an automated behavioral despair test that employs a wire mesh wheel mounted in a tank of water to enable recording of escape activity as wheel rotations. Drugs were given after a 15 min exposure to the apparatus on day 1 and again 24 hrs later, one hour prior to a 15 min test. The control behavior of WKY rats was significantly lower than that of SD rats (approx. 6 vs 50 rotations). WKY rats showed larger percentage increases in rotations than SD rats in response to the antidepressants, imipramine, desipramine, phenylzine, and mianserin. WKY rats, but not SD rats, also showed a significant increase in rotations after the SSRI fluoxetine. The SSRI paroxetine also produced significant effects in WKY rats. While the anxiolytic, diazepam, appeared to be a false-positive in SD rats, WKY rats did not show this effect. Both WKY and SD rats showed reduced rotations in response to the antipsychotic, haloperidol. Although amphetamine, scopolamine, and phencyclidine increased rotations in both WKY and SD rats, these drugs could be distinguished from antidepressants by their stimulant profiles in locomotor tests. These data indicate that WKY rats enhance the sensitivity and selectivity of the behavioral despair test and support previous suggestions that WKY rats represent a potential animal model of depression.

## 445.14

**EVIDENCE FOR GENETICALLY MEDIATED DYSFUNCTION OF THE CENTRAL DOPAMINERGIC SYSTEM IN THE STARGAZER RAT.** J.W. Brock\* and C.R. Ashby, Jr. Brain and Development Research Center, The University of North Carolina at Chapel Hill, Chapel Hill, NC, 27599; Medical Department, Brookhaven National Laboratory, Upton, NY, 11973. The stargazer rat is an autosomal recessive mutant (homozygous *stg/stg*) that displays abnormal behavior, characterized by stereotypic head-movement, circling, and a high level of ambulatory activity. Heterozygous (*stg/+*) littermates display normal spontaneous behaviors. In this study, stargazers and their unaffected littermates were compared in their behavioral responses to both stimulation and inhibition of dopamine D<sub>2</sub>/D<sub>3</sub> receptors, using quinpirole and haloperidol. Stargazers were observed to yawn a significantly fewer number of times than littermates in response to (-) quinpirole (50 µg/kg i.p.). Haloperidol (HAL, 0.1 and 0.3 mg/kg s.c.) caused a significant decrease in stereotypic head-movement in the mutants that was both time- and dose-dependent. In normal littermates, HAL inhibited locomotor activity and produced catalepsy in a time- and dose-dependent manner. In stargazers, both doses of HAL inhibited locomotor activity to a similar degree as in the normal littermates. However, no catalepsy was detectable in the mutants using 0.1 mg/kg of HAL, and 0.3 mg/kg was only weakly cataleptogenic. Overall, the spectrum of abnormal behaviors expressed by the stargazers and the present evidence of D<sub>2</sub>/D<sub>3</sub> receptor subsensitivity suggest that stargazers possess a genetically mediated dysfunction of the central dopaminergic system.

## 445.16

**CLOSE CORRELATION BETWEEN INTRASTRIATAL CONCENTRATION OF SULPIRIDE AND CATALEPSY AS STUDIED BY IN VIVO VOLTAMMETRY.** H.P.M. Horikawa<sup>1,2</sup>, T. Nakazato<sup>2</sup> and O. Hikosaka<sup>2</sup>. <sup>1</sup>Dept. of Neurochem. Brain Res. Inst. Niigata Univ. 1-757 Asahimachi-dori, Niigata, Japan, <sup>2</sup>Dept. of Physiol., Juntendo Univ. Sch. of Med., 2-1-1 Hongo, Tokyo Japan.

To investigate the correlation between intrastriatal dopamine (DA) and its behavioral effects, we injected a dopamine D2 antagonist (sulpiride) locally into the rat striatum and measured its kinetics using *in vivo* voltammetry and examined behavioral changes due to the injection. First, we found that sulpiride could be measured *in vitro* with this technique. The measured current intensity selective for sulpiride increased dose-dependently ( $1 \times 10^{-7}$  M to  $2 \times 10^{-6}$  M). We then applied this method to the *in vivo* examination. Sulpiride ( $10^{-3}$  M, 7.5 µl) was administered into the striatum of freely moving rats over 30 min. Sulpiride began to be detected approximately 12 min after the start of injection, and remained higher than the baseline for more than 3 h. Sulpiride-induced catalepsy appeared 45 min after the start of injection and continued for 3 h. For comparison, DA and 1-methyl-4-phenyl-pyridinium (MPP<sup>+</sup>) were administered intrastrially, and these drugs disappeared soon after the end of injection. When MPP<sup>+</sup> and its uptake inhibitor were co-administered intrastrially, the concentration of extracellular MPP<sup>+</sup> remained high for a longer period than in the case of MPP<sup>+</sup> only. These results indicate that the time course of exogenous sulpiride in the striatum was closely correlated with that of cataleptic changes. The effects were prolonged probably because sulpiride is taken up or metabolized only slowly.

## 445.17

## EFFECTS OF CLOZAPINE AND A DOPAMINE D1 ANTAGONIST ON DIZOCILPINE-INDUCED LOCOMOTION AND STEREOTYPY IN RATS.

H.A. Al-Amin, and S.B. Schwarzkopf\*. Departments of Psychiatry and Psychology, University of Rochester, Rochester, NY 14620.

Dizocilpine (MK-801) is a PCP analog that acts as a noncompetitive NMDA receptor antagonist. It induces specific abnormalities of sensory gating, locomotion and stereotypy that have been used to develop animal models of schizophrenia and to test the efficacy of neuroleptics. Dopaminergic and serotonergic systems are known to modulate the MK-801-induced hypermotility and stereotypy.

This study evaluated the time course and dose response of the effects of MK-801 on automated motility measures in rats. Testing started immediately after injection of MK-801 and lasted for 30 minutes. MK-801 0.2 and 0.5 mg/kg but not 0.05mg/kg significantly increased motility and stereotypic behaviors. Effects of MK-801 0.2mg/kg were very similar to 0.5mg/kg. The MK-801-induced behaviors were not evident until 12-18 min after injection with the effect stabilizing between 18-24 min. The selective D1 antagonist SCH23390 (SCH) 0.05mg/kg blocked the effects of MK-801 on all behavioral measures. This blockade was evident during the whole session. Pretreatment with Clozapine (CLOZ) 10mg/kg reduced the hyperactivity induced by MK-801 0.2mg/kg and had a similar pattern as SCH. The relative blockade of MK-801-induced stereotypy by CLOZ was significantly less than that by SCH.

These findings demonstrate that MK-801 effects on stereotypy and locomotion reach their maximum in about 20 minutes and that doses above 0.2mg/kg do not increase the magnitude of these effects in rats. These data also support the role of D1 receptors in modulating the activity of noncompetitive NMDA receptors. The results further support the differential effects of CLOZ on locomotion and stereotypy induced by MK-801.

## 445.19

DIFFERENCES BETWEEN THE HIGH POTENCIES OF THE D1/D2 ANTAGONISTS HALOPERIDOL AND *cis*-FLUPENTHIXOL TO AFFECT BEHAVIORAL VIGILANCE IN INTACT RATS. M. Sarter, J. McGaughy and A.M. Frostholt\*. Department of Psychology & Neuroscience Program, The Ohio State Univ., Columbus, OH 43210.

The determination of the role of mesolimbic dopamine in attentional functions is of significance for the understanding of the potential consequences of dopaminergic dysfunctions on attention. Our hypothesis suggests that cortical cholinergic hyperactivity is necessarily associated with an overactive dopaminergic transmission in the nucleus accumbens (via GABAergic projections to the basal forebrain), and that the attentional dysfunctions that are due to cortical cholinergic hyperfunction contribute to the emergence of psychotic symptoms in schizophrenia (Sarter, Psychopharmacol., 1994, 114:539-550; Holley et al., Psychopharmacol., 1995, in press). In a first step to study the role of dopaminergic systems in attention, the effects of the D1/D2 antagonists haloperidol and *cis*(Z)-flupenthixol on behavioral vigilance were studied using the task previously characterized (McGaughy et al., Psychopharmacol., 1995, 117:340-357). Administration of haloperidol (0.001 - 0.05 mg/kg; 2.6 - 133  $\mu$ mol) potently impaired the animals' ability to detect visual signals (presented for 25 - 500 msec) and to correctly reject non-signal trials. Although flupenthixol has significantly greater affinity for D1 and D2 receptors than haloperidol, no significant effects were found (0.01 - 0.05 mg/kg; 19 - 98  $\mu$ mol). These findings question the role of D1/D2 receptors in the effects of haloperidol.

## 445.18

PHARMACOLOGICAL CHARACTERISATION OF VARIOUS DOPAMINE (DA) AGONISTS IN TWO PUTATIVE MODELS OF D<sub>3</sub> RECEPTOR FUNCTION: COMPARISON WITH EFFECT ON PREPULSE INHIBITION (PPI). G.B. Varty, A.G. Hayes\* and G.A. Higgins. Glaxo Unit for Behav. Psychopharmacol., Div. of Biosci., Univ. of Herts, Hatfield, Herts, UK, and Pharmacology 1 and 2, Glaxo Research & Development Ltd, Ware, Herts, UK.

We have evaluated the potency of various dopamine (DA) agonists, 7-OH-DPAT (7-OH), quinpirole, quinlorane, PD128907 (PD), apomorphine (apo) and SKF38393 (SKF) in two putative models of D<sub>3</sub> function: DA agonist-induced hypothermia (Millan et al (1994) Eur. J. Pharmacol. 260: R3-R5) and 7-OH-DPAT-induced drug discrimination (McElroy (1994) Pharmacol. Biochem. Behav. 48: 531-533). Drug potencies in these models were compared with that required to disrupt prepulse inhibition (PPI). The objective being to establish whether D<sub>3</sub> receptors may be involved in the modulation of PPI.

Male, Wistar rats (250-400g) were used throughout. The high affinity D<sub>3</sub> agonist, 7-OH inhibited PPI (0.03-1mg/kg sc) and reduced body temperature (0.03-0.3mg/kg sc). Both responses were blocked following pretreatment with the D<sub>2/3</sub> antagonist raclopride (0.3mg/kg sc). Rats were successfully trained to discriminate 7-OH (0.03mg/kg) from saline using a two lever operant procedure (final ratio, FR10). Raclopride (0.03mg/kg) attenuated this discrimination (vel/7-OH: 91 $\pm$ 4%, rac/7-OH: 53 $\pm$ 9%). In tests of substitution, quinpirole, PD, quinlorane, apo all completely generalised to the 7-OH cue. The rank order of potency for generalisation to the 7-OH cue was similar to that required to reduce body temperature and disrupt PPI; i.e. quinlorane>quinpirole>7-OH>PD>apo>>SKF. Thus the similar order of potencies in the PPI model may be consistent with a D<sub>3</sub> receptor mediated event, although a D<sub>2</sub> receptor involvement cannot be excluded.

## 445.20

## PINEALECTOMY, MELATONIN AND 5-HYDROXYTRYPTOPHOL EFFECTS ON ANXIETY IN RATS. E.B. Naranjo-Rodriguez, E. Hernández-Avilia, B. Barrera-Mera\* and C. Reyes-Vázquez. Department of Physiology, Faculty of Medicine, UNAM, Mexico City, CP. 04510

Anticonvulsive, hypnotic and sedative effects had been described after melatonin (MEL) systemic administration. However, the mechanism of action used by MEL to produce such effects are unknown. A GABA-ergic like mechanism has been proposed, because MEL enhances GABA binding "In Vitro" and elicits some biochemical effects those produced by diazepam (DIAZ), chlordiazepoxide (CDP) and buspirone (BUS). These data suggest MEL could exert other effects of this kind of drugs like, anxiolysis. In the present study we analyze comparatively the anxiolytic action of MEL, 5-hydroxytryptofol (5-Hol), DIAZ and CDP, in pinealectomized and control rats. Male Wistar rats (180-230 g) were deprived of water for 48 h before testing on Vogel conflict chamber. A drinkometer circuit was connected between a drinking tube of a water bottle and the grid of the floor of a Plexiglas box, the rat completed the circuit whenever it licked the tube. Each time, the rat closed the circuit, an electrical pulse (0.7 mA/2 sec), was delivered. The effects of two classical anxiolytic drugs, DIAZ (2 and 5 mg/Kg) and CDP (5 and 10 mg/Kg), were compared with MEL (1 and 2 mg/Kg) and 5-Hol (1 and 2 mg/Kg). Anxiolytic drugs as well as MEL and 5-Hol, produced a dose dependent increase in the number shocks, being MEL more potent. When the drugs were applied in pinealectomized rats, the effects were more significant. These results suggest that the two pineal indols used in this work, are involved in the modulation of the stress responses.

## CATECHOLAMINES: BIOSYNTHETIC ENZYMES

## 446.1

## MELATONIN INCREASES THE IN SITU ACTIVITY OF TYROSINE HYDROXYLASE IN THE MEDIAN EMINENCE/ARCuate REGION OF CASTRATED SYRIAN HAMSTERS. N.A.M. Alexiuk\* and J.P. Vriend. Department of Anatomy, University of Manitoba, Winnipeg, Canada R3E 0W3.

Daily late afternoon melatonin injections have been shown to increase the *in situ* activity of tyrosine hydroxylase (TH) and to decrease dopamine (DA) content in the median eminence (ME)/arcuate region of the mediobasal hypothalamus (MBH) of male Syrian hamsters (Alexiuk & Vriend, 1994). In the present study, the effects of melatonin injections (for 9.5 weeks) on TH activity were examined in the ME/arcuate region and in the neurointermediate lobe (NIL) of the pituitary of gonadectomized (GX) male hamsters. The tissues were sampled from animals sacrificed at nighttime, since previous data showed that the most significant effect of melatonin on DA levels occurred during the dark phase of the light-dark cycle. TH activity was determined by measuring the accumulation of L-DOPA following administration of the aromatic L-amino acid decarboxylase inhibitor, NSD-1015. As previously shown in intact hamsters, a marked elevation ( $p < 0.001$ ) in ME/arcuate TH activity was demonstrated in castrated hamsters injected with melatonin, compared to saline-treated GX controls. This melatonin-induced increase in TH occurred concomitantly with a significant reduction in DA content of the ME/arcuate region ( $p < 0.001$ ) and of the NIL ( $p < 0.01$ ). However, no significant effect of melatonin on TH activity of the NIL was demonstrated. Melatonin administration had no detectable effects on nighttime norepinephrine concentrations. The present data are consistent with the interpretation that melatonin increased the synthesis/release (turnover) of tuberoinfundibular DA neurons of the MBH. Since all of the animals in this study were castrated, the effects of melatonin on TH activity and on DA content could not be secondary to melatonin-induced changes in circulating levels of testosterone.

## 446.2

IN VIVO AND IN SITU STUDY OF TYROSINE HYDROXYLASE (TH) ACTIVITY MODULATIONS IN THE RAT BRAIN USING [3,5-<sup>3</sup>H]- $\alpha$ -FLUOROMETHYL-TYROSINE (<sup>3</sup>H<sub>2</sub>- $\alpha$ -FMT). L. Bezin, C. Garcia, D. Blum, P. Lafargue, J.P. Lelouche, J.F. Pujol and D. Weissmann\*. Lab. CNRS-UCBL UMR105, Fac. de Médecine A. Carrel, rue G. Paradin, F-69008 Lyon, France.

TH activity can be modified by changes in its specific activity (SA) or in the levels of active enzyme. We have developed a methodology which allows to measure with an excellent anatomical resolution TH enzymatic activity and protein quantity by quantitative radioautography and immunautoradiography respectively, from adjacent sections taken at serial intervals along the longitudinal extent of a same brain. SA of TH was estimated by the slope of correlation curves established between TH quantity and activity. To evaluate TH activity, we have used the <sup>3</sup>H<sub>2</sub>- $\alpha$ -FMT, which is transformed by TH into <sup>3</sup>H<sub>2</sub>- $\alpha$ -fluoromethyl-dopa. This last compound is suggested to be a potent and irreversible substrate for aromatic amino acid decarboxylase. Indeed: (1) intracisternal injection of 20  $\mu$ Ci of <sup>3</sup>H<sub>2</sub>- $\alpha$ -FMT was followed by a rapid disappearance of <sup>3</sup>H<sub>2</sub>- $\alpha$ -FMT ( $t_{1/2} = 1.5$  h) and by specific accumulation of radioactivity into the locus caeruleus (LC) cell body limits; (2) following hemilateral 6-hydroxydopamine-induced lesion of the nigrostriatal pathway, the bilateral injection of <sup>3</sup>H<sub>2</sub>- $\alpha$ -FMT into the neostriatum revealed a specific accumulation of radioactivity in the intact side only. The study of the tissue distribution of SA of TH in the LC region revealed that this SA was 48% higher in the LC cell body limits (PKA) than in the pericaerulean neuropil (PCN). Only 12% of TH contained in the PCN exhibited a detectable level of enzymatic activity. We have finally examined short (15 min) and long term (72 h) increases in TH activity in the LC region, following Vindébumol treatment (30 mg/kg, i.p.), which is also known to induce long term increase in TH protein levels. Two distinct mechanisms have been observed: short term effect was due to an increase in the SA of TH in the PKA only; long term effect was due to an increase in active TH protein quantity in the PCN only.

## 446.3

POSTNATAL DEVELOPMENT OF THE DOPAMINERGIC INNERVATION OF MONKEY ENTORHINAL CORTEX. S.L. Erickson\*, M. Akil, A.I. Levey and D.A. Lewis. Depts. of Neuroscience and Psychiatry, University of Pittsburgh, Pittsburgh, PA, 15260 and Dept. of Neurology, Emory University, Atlanta, GA, 30322.

The rostral portions of the entorhinal cortex (ERC) of the adult monkey receive a dense dopaminergic innervation (Akil and Lewis, *Cerebral Cortex*, 1993). The postnatal maturation of the dopaminergic innervation of limbic cortical areas has not been examined, but the development of this afferent system in primate frontal cortex has been shown to be protracted and region-specific (Rosenberg and Lewis, *J. Comp. Neurol.*, 1995). Antibodies against the dopamine transporter and tyrosine hydroxylase (TH) were used to study the laminar distribution and density of dopaminergic axons in the rostral subdivision ER in 22 rhesus monkeys (*Macaca mulatta*) ranging in age from 2 days to over 18 years. With both antibodies, the density of labeled axons in layers I and III increased from birth to peak at the middle of the first year of life, then declined over the next year to relatively stable levels, which were maintained through adulthood. In contrast, the density of labeled axons in layer VI appeared to remain stable throughout postnatal development. Preliminary quantitative measurements of TH-labeled axons revealed that these developmental changes were more pronounced in layer III, with peak values representing a 10-fold increase over those observed in the newborn, whereas the peak in layer I represents a 3-fold increase. In contrast to frontal cortex, no increase in DA axon density was observed in the ERC in the animals 2-3 years of age, the peripubertal period. These findings suggest that the role of dopamine in the development of the ERC may be functionally distinct from that in frontal cortex.

## 446.5

MEASURES OF TYROSINE HYDROXYLASE PROTEIN SYNTHESIS AND TURNOVER IN THE RAT LOCUS COERULEUS NUCLEUS USING A PULSE-RADIOLABELING PARADIGM. T.G. Sherman\*, J.T. Curtis, S. Ito, and A.E. Svjed. Department of Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.

The expression of tyrosine hydroxylase (TH) is important for the functioning of noradrenergic neurons of the locus coeruleus (LC). A variety of stimuli, such as stress, have been shown to alter the level of TH mRNA and TH protein in these neurons; however, the impact of these treatments on the synthesis, stability, and transport of TH to nerve terminals have never been directly examined. In order to address these issues, we have developed a strategy for studies on the synthesis, turnover, and transport of TH in the LC that involves the pulse-radiolabeling of TH *in vivo*. 90  $\mu$ Ci of [35S]-methionine (1175 Ci/mmol) in 2  $\mu$ l is infused during 20 min into the left LC of halothane anesthetized male Sprague-Dawley rats. Following injection, the rat is allowed to recover for 30 min to 7 d prior to sacrifice. The LC is dissected from a 2 mm frozen section of pons. The relative specific radioactivity of TH ([radiolabeled TH]/[total TH]) in the LC is determined by the quantitative immunoprecipitation of tissue TH, autoradiography, and indirect Western quantitation. The incorporation of [35S]-methionine into immunoprecipitable TH is ~70% of maximal levels at 30 min after injection. Levels of radiolabeled TH plateau within 3 hrs and remain stable for ~1 d. After 1d, levels of radiolabeled TH in the LC decrease with first-order kinetics with a half-life of ~2 days ( $k = 0.36/d$ ). The relative contributions of axonal transport and protein turnover to this first-order decay have yet to be determined. These data demonstrate the feasibility of a pulse-labeling strategy for studies of TH expression in nuclei of the CNS, and will permit a comprehensive examination of the contributions of TH to catecholamine expression. (Supported by NINDS NS19608 and NIMH MH29670 grants.)

## 446.7

TYROSINE HYDROXYLASE IMMUNOREACTIVE CELLS IN THE RAT NEOCORTEX AND HIPPOCAMPUS. A.H. Siddiqui\*, W.H. Pilcher, S.A. Joseph. Division of Neurological Surgery, University of Rochester School of Medicine and Dentistry, Rochester, NY 14642.

Catecholamines have been implicated as integral neurochemicals in a variety of neuronal functions including: motor, biobehavioral, neuroendocrine, and cognition among others. Their presence in brain is primarily identified by immunocytochemical localization of their rate limiting enzyme Tyrosine Hydroxylase.

We have identified Tyrosine Hydroxylase immunoreactive cells in colchicine treated adult rat neocortex and hippocampus. Similar findings have been reported in human, monkey and developing rat brain. We have also demonstrated a non colchicine enhanced tyrosine hydroxylase immunoreactivity in neonatal rat cortex which appears to disappear during early stages of development. Our results indicate that these cells persist throughout adulthood and form part of an endogenous cortical catecholaminergic system in addition to the exogenous fiber projections from the locus coeruleus, ventral tegmental area and the zona incerta as determined from our tract tracing studies.

These findings assume greater importance in light of the recently reported work by Zhu et al who report that patients with complex partial seizures express aberrant hippocampal tyrosine hydroxylase immunoreactive cells as compared to controls. These findings have been confirmed and extended in our lab. Anti epileptogenic characteristics of catecholamines have been well recognized in neuropharmacological, and neurophysiological studies utilizing catecholaminergic cell groups in the brain stem and various agonists and antagonists. Our results indicate the presence of this inherent cortical catecholaminergic system in normal adult rats and provides basis for studies which address these cortical cells and their possible role in modulation of epilepsy.

## 446.4

LIGHT AND ELECTRON MICROSCOPIC COMPARISON OF AXONS IMMUNOREACTIVE FOR DOPAMINE TRANSPORTER OR TYROSINE HYDROXYLASE IN MONKEY NEOCORTEX. R.E. Whitehead\*, D.S. Melchitzky, S.R. Sesack, A.I. Levey and D.A. Lewis. Depts. of Psychiatry and Neuroscience, University of Pittsburgh, PA 15213 and Dept. of Neurology, Emory University, Atlanta, GA 30322.

The influence of dopamine (DA) on neocortical function is in part determined by the activity of two major proteins: tyrosine hydroxylase (TH), the rate-limiting enzyme in DA biosynthesis, and the specific dopamine transporter (DAT), the uptake carrier that terminates the action of DA. We used immunocytochemistry to compare the light microscopic organization and ultrastructural features of axons and terminals immunoreactive for DAT or TH in the neocortex of adult cynomolgus (*Macaca fascicularis*) monkeys. By light microscopy, the majority of DAT-IR axons were similar in morphology to TH-IR axons, although DAT-IR axons generally appeared to be less varicose. The density of DAT-IR axons was greatest in motor regions, intermediate in association areas, and lowest in primary sensory areas. DAT-labeled axons were distributed across all layers in the densely innervated regions, and typically were located in layers 1-2 and 5-6 in the other regions. With few exceptions, the relative regional density and laminar distribution of DAT-IR axons were quite similar to those of TH-IR axons. At the ultrastructural level, both DAT- and TH-IR terminals formed primarily symmetric synapses. However, TH label was seen in both axons and terminals, whereas DAT label was more often found in pre-terminal axons. These findings suggest that the use of specific antibodies directed against proteins with different roles in DA neurotransmission may provide new insights into the function of cortical DA systems in normal development and psychopathology.

## 446.6

TYROSINE HYDROXYLASE (TH) PHENOTYPE EXPRESSION WITHIN CONTROL AND VINDEBURNOL-TREATED BALB/C (C) AND C57BLACK/6 (B6) MOUSE LOCUS COERULEUS (LC). D. Marcel, N. Ginovart, L. Bezin, J.F. Pujol\* and D. Weissmann. Lab. CNRS-UCBL UMR105, Fac. de Médecine A. Carrel, rue G. Paradin, F-69008 Lyon, France.

TH phenotype expression and its plasticity after Vindéburnol treatment (known to induce long term increase in TH level within the LC) was investigated in the two compartments of the LC of pure inbred strains of mice, the perikarya-delimited space and the surrounding neuropile. Serial coronal sections were selected along the caudo-rostral extent of the LC of control and Vindéburnol-treated C and B6 mice; and were processed for TH immunocytochemistry or TH immunoradiography. Three days after the single intraperitoneal injection of the drug (20mg/kg), we observed: 1) an increase in the number of cells expressing the enzyme in the C strain only, which equalized the catecholaminergic neuronal population of the two strains; 2) an increase in the enzyme level in the two compartments of the structure of both strains. In the perikarya-delimited space, two mechanisms of this pharmacologically-induced protein modulation were demonstrated: in C strain, the increase was obviously explained by the subset of additional TH expressing cells; whereas in B6 strain, the mean TH quantity provided by each cell was increased. Furthermore, a similar response to Vindéburnol treatment was observed in the surrounding neuropile of the two strains: a significant increase in the TH level was measured, resulting in a significant increase in the immunoradiolabeled volume. These results demonstrate 1) a different regulation of the TH phenotype expression between the perikarya area and the surrounding neuropile of the LC of each strain; 2) a strain-dependant difference in the response to the Vindéburnol treatment.

## 446.8

TYROSINE HYDROXYLASE AND AROMATIC L-AMINO ACID DECARBOXYLASE ACTIVITIES DURING ETHANOL WITHDRAWAL. N.H. Neff\*, M. Hadjiconstantinou, T.A. Wemlinger and Z.L. Rossetti. Department of Pharmacology and Psychiatry and The Neuroscience Program, The Ohio State University College of Medicine, Columbus, OH 43210, U.S.A.

The mechanism(s) underlying the long-lasting inhibition of dopaminergic (DA) function during ethanol withdrawal is unclear. To study whether ethanol withdrawal was associated with alterations in the DA biosynthetic pathway we measured tyrosine hydroxylase (TH) and aromatic L-amino acid decarboxylase (AAAD) activities in terminal areas of the DA system of ethanol-withdrawn rats. Ten hr following withdrawal, i.e. the time at which overt physical signs of withdrawal were manifested, TH activity was increased to 195 % of control in the nucleus accumbens (NAS) and was unchanged in the striatum (CS). In contrast, AAAD activity was reduced to 49% in NAS and to 83% in CS. Concomitant with increased TH and decreased AAAD was an increase of approximately 200% of control in mRNA for the two enzymes in the midbrain. All parameters returned to control values 36 hr following withdrawal. It is possible that AAAD may become rate-limiting under these conditions and the increase in mRNA in the midbrain for the two enzymes may represent a compensatory response to maintain a normal level of DA function. The reduction of AAAD activity provides additional evidence of functional modulation of this enzyme and may represent another mechanism for the reduction of DA availability during ethanol withdrawal. Supported by Grant NS34571.

## 446.9

MODULATION OF TYROSINE HYDROXYLASE AND AROMATIC L-AMINO ACID DECARBOXYLASE IN MOUSE STRIATUM AFTER INHIBITION OF MONOAMINE OXIDASE S. Cho\*, M. Hadjiconstantinou and N.H. Neff Dept. Pharmacol., Neurosci. Program, Ohio State Univ. Coll. of Med., Columbus, OH 43210

After the administration of the monoamine oxidase (MAO) inhibitors clorgyline (MAO-A), or pargyline (MAO-A and -B) there is a transient reduction of tyrosine hydroxylase (TH) and a long-lasting reduction of aromatic L-amino acid decarboxylase (AAAD) activity in the mouse striatum. Deprenyl, a MAO-B inhibitor, had no effect on these two enzymes except at high doses, doses that apparently inhibit MAO-A. The MAO inhibitors altered the expression of TH and AAAD mRNA in the midbrain. Pargyline and high doses of deprenyl increased AAAD mRNA, while clorgyline initially decrease and then increase expression. In contrast, TH mRNA transiently decreased following clorgyline or deprenyl (a high dose) administration. The acidic metabolites of dopamine appeared most effected by pargyline and clorgyline, suggesting deamination of striatal dopamine by MAO-A. Our results suggest that striatal TH and AAAD are modulated differently in response to perturbation of dopamine metabolism. The observation that MAO inhibitors decrease AAAD activity might have clinical implications, as current therapy for Parkinson's disease might include deprenyl alone or combined with L-DOPA. Supported, in part, by Grant NS34571.

## 446.11

PROTEIN TYROSINE PHOSPHORYLATION IN THREE MODELS OF NIGROSTRIATAL DOPAMINE DEPLETION: WEAVER MOUSE, MPTP AND 6-OHDA. J.A. Richter\*, B. Ghetti and D.J. Bare. Indiana University Sch. Med., Indianapolis, IN 46202.

The weaver mutant mouse has a 70% loss of nigrostriatal dopaminergic neurons and of striatal dopamine. We have found that the tyrosine kinase inhibitor genistein stimulates fractional dopamine release from striatal slices in vitro and does so to a greater extent from weaver compared to normal striatal slices (Soc. Neurosci. Abs. 20:285,1994). Therefore we examined the phosphorylation of proteins on tyrosine in weaver and normal mouse striatum. Striatal proteins were extracted in lysis buffer and separated by SDS-PAGE. In a Western blot striatal proteins were reacted with the mouse monoclonal anti-phosphotyrosine antibody (4G10) and HRP-conjugated secondary antibody and processed for detection by enhanced chemiluminescence. We found no differences in the level of phosphorylation on tyrosine in weaver striatum compared to normal mouse striatum. For comparison we treated mice with MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine) given s.c. Striatal dopamine depletions of 80-92% by MPTP did not result in alterations of phosphotyrosine levels in striatal proteins. In contrast, in preliminary studies, unilateral nigral injections of 6-OHDA (6-hydroxydopamine) in rats resulting in >99% loss of dopamine on the lesioned side resulted in an increase in pp180 and perhaps other bands as previously shown by Girault et al. (1992). Further experiments will evaluate whether the key difference is the species, the degree of dopamine depletion or the 6-OHDA itself. Supported by USPHS R01-NS14426.

## 446.13

THE EFFECTS OF OKADAIC ACID, HIGH POTASSIUM, OR FORSKOLIN ON *IN SITU* L-DOPA SYNTHESIS AND ON PHOSPHORYLATION OF TYROSINE HYDROXYLASE (TH) IN AIT20 CELLS. K. Harada\*, J.Y. Lew, M. Goldstein, J. Wu and J.W. Haycock\*, Neurochem. Res. Labs., NYU Med. Ctr., New York, NY, \*Dept. Biochem. Molec. Biol., LSU Med. Ctr., New Orleans, LA

It was reported that protein phosphatase 2A (PP2A) is involved in dephosphorylation of TH (Haavik, et al, FEBS Letters, 251, 36-42, 1989), and therefore we have studied effects of okadaic acid (OKA), a PP2A inhibitor, on phosphorylation of TH and on biosynthesis of L-dopa in AIT20 cells which express recombinant TH. The cultured cells were treated for various time periods with OKA, high potassium (60mM), or forskolin (1μM) alone or in combination. The exposure of the cells for 10min to OKA had no effect, while high potassium or forskolin increased L-dopa biosynthesis. The treatment of cells with OKA in combination with high potassium had no additional effect on the high potassium-elicited increase of L-dopa production. The effects of these treatments on phosphorylation of TH at serine 40 (Ser40) were determined by Western analysis using anti-pTH32-47, an antibody which selectively recognizes the TH phosphorylated at Ser40 (Goldstein, et al, J. Neurochem. 64, 2281-87, 1995). The exposure of the cells to OKA for 10min did not increase, while that for 20min increased the phosphorylation of TH. High potassium treatment for 10min increased phosphorylation of TH, but the increase was diminished in the cells treated for 20min. The exposure of the cells to high potassium in combination with OKA for 20min resulted in a greater increase of phosphorylated TH at Ser40 than individual treatments. The potentiating effect of this combination treatment was not detected in the cells exposed for 10min. These results show that OKA affects L-dopa biosynthesis and phosphorylation of TH at Ser40 in the cells treated for 20min. Our findings suggest that the levels of phosphorylated TH at Ser40 are critical for dephosphorylation, and therefore we postulate that PP2A plays a role in the regulation of TH under activated condition.

## 446.10

AROMATIC L-AMINO ACID DECARBOXYLASE ACTIVITY IS REGULATED VIA PHOSPHORYLATION. M.D. Berry\*, M.Hadjiconstantinou and N.H.Neff, Dept. Pharmacology and Psychiatry and the Neuroscience Program, Ohio State University College of Medicine, Columbus, Ohio 43210.

Recent studies have suggested that aromatic L-amino acid decarboxylase (AAAD) activity can be modified by treatment with dopamine receptor agonists and antagonists. Similar changes have also been shown to occur following administration of compounds which stimulate/inhibit protein kinases, suggesting that regulation may occur via phosphorylation. We investigated this possibility directly by examining the effects of cAMP-dependant protein kinase (PKA) on the phosphorylation and activity of AAAD. Crude P<sub>2</sub> synaptosomal tissue preparations from rat striatum were incubated at 37°C under a variety of phosphorylating conditions. AAAD protein was identified by immunoblot and AAAD bands were cut out and counted for <sup>32</sup>P. Purified PKA catalytic sub-unit caused a concentration-dependant increase in <sup>32</sup>P incorporation into AAAD. Increases were also seen following incubation with okadaic acid, forskolin or 8-bromo-cAMP. The effects of forskolin and 8-bromo-cAMP were prevented by the protein kinase inhibitor H-7. Incorporation of <sup>32</sup>P was increased following prior dephosphorylation. Using L-dopa as a substrate, conditions which increased phosphorylation were also found to increase AAAD activity. These studies provide the first direct demonstration that AAAD activity can be regulated by phosphorylation. That such a regulation of AAAD activity occurs under physiological conditions is suggested by the effect of okadaic acid alone on phosphorylation and AAAD activity, and the effect of prior dephosphorylation on <sup>32</sup>P incorporation. Such a regulation of AAAD may be of importance in the normal control of monoaminergic neurotransmission, and in Parkinson's disease, during L-dopa administration. Supported in part by NINDS grant NS 34571.

## 446.12

PHOSPHORYLATION-SPECIFIC ANTIBODIES TO THE SERINE 19 SITE IN TYROSINE HYDROXYLASE (TH). M. Goldstein\*, K. Harada, J.Y. Lew, J. Wu, J.W. Haycock\*, Neurochem. Res. Labs., NYU Med. Ctr., New York, NY and \*Dept. Biochem. Molec. Biol., LSU Med. Ctr., New Orleans, LA

Activation of catecholaminergic cells increase the phosphorylation of TH at Ser19 (mediated by Ca/CaM PKII), Ser31 (mediated by ERK), and Ser40 (mediated by PKA). For the study of multiple-site TH phosphorylation, immunoblot analyses with antibodies (Abs) that selectively recognize the phospho-forms of each site offer a facile alternative to HPLC/β detection of tryptic peptides from <sup>32</sup>P-TH, isolated by immunoprecipitation after *Pi* prelabeling of cells/tissue. In a previous report, Abs specific for Ser40-P were developed (Goldstein, et al., J. Neurochem. 64:2281,1995). In the present report, we describe analogous Abs that are specific for Ser19-P. Rabbits were immunized with a chemically phosphorylated, synthetic Ser19 peptide (ARAVSEQDAK) conjugated to KLW. In immunoblots of extracts from AIT20 cells expressing recombinant TH (rTH), robust labeling of wild type rTH by anti-Ser19-P was observed with okadaic acid-treated (but not untreated) cells, whereas labeling of the site-mutant S19L rTH was not detected with either treated or untreated cells. The reactivities of anti-Ser19-P and anti-Ser40-P were compared in blots of extracts from PC12 cells. Elevated KCL (40mM, 30s) produced a large increase in anti-Ser19-P labeling but only a small increase in anti-Ser40-P. Conversely, forskolin (5μM, 10min) selectively increased anti-Ser40-P reactivity. Combined treatment increased labeling by both of the Abs. Such data indicate that the site-specific, phospho-specific Abs will be useful for studying multiple-site TH phosphorylation.

## 446.14

PHOSPHORYLATION OF TYROSINE HYDROXYLASE ISOFORMS IN HUMAN NEUROBLASTOMA CELLS. John W. Haycock\*, Dept. Biochem. & Molec. Biology, LSU Medical Center, New Orleans, LA 70119.

In most mammalian species, tyrosine hydroxylase (TH) is a M<sub>r</sub>~240,000 homotetramer, and activation of catecholaminergic cells increases the phosphorylation of TH subunits at Ser19 (mediated by Ca/CaM PKII), Ser31 (mediated by ERK), and Ser40 (mediated by PKA). In primates and humans, alternative RNA splicing produces an additional TH isoform (TH-2) which contains four extra amino acids (-Val-Arg-Gly-Gln-) between Met30 and Ser31, thus creating a consensus recognition motif for Ca/CaM PKII (-R-X-Y-S-) at the ERK site of TH-1. In order to determine whether alternative splicing changes the signaling pathway involved in regulating the phosphorylation of this site, two human neuroblastoma cell lines [BE(2)M17, CHP234] were preincubated with <sup>32</sup>P, and then treated with activators of the three signaling pathways. <sup>32</sup>P incorporation into TH-1 and TH-2 at the multiple sites was analyzed by on-line radiochemical detection of tryptic TH phosphopeptides separated by HPLC. Veratridine and forskolin increased Ser19 and Ser40 (TH-1, TH-2) phosphorylation, respectively, and phorbol dibutyrate increased <sup>32</sup>P incorporation into Ser31 of TH-1. <sup>32</sup>P incorporation into "Ser31" of TH-2 was disproportionately low relative to the amount of TH-2 protein present, irrespective of the treatment condition. Thus, rather than altering its regulation, alternative splicing appears to eliminate this residue as a phosphorylation site in TH-2, the major alternative splicing variant present in humans and monkeys. [Supported by NS25134]

## 446.15

NEUROPEPTIDE Y INHIBITS NICOTINIC RECEPTOR STIMULATED TYROSINE HYDROXYLASE PHOSPHORYLATION. J. Zheng and T.D. Hexum\*. Department of Pharmacology, University of Nebraska College of Med., Omaha, NE 68198-6260.

Increased catecholamine secretion is accompanied by a corresponding increase in catecholamine biosynthesis to keep pace with secretory demands of the neuron. The increase in biosynthesis occurs, in part through the activation of tyrosine hydroxylase. The immediate activation of tyrosine hydroxylase after neuronal stimulation occurs as a result of the receptor-mediated phosphorylation of the enzyme resulting in the activation of various protein kinases. The extent of enzyme phosphorylation correlates directly with an increase in enzyme activation. Correspondingly, inhibition of enzyme phosphorylation should result in decreased enzyme activity. We have demonstrated that neuropeptide Y (NPY) inhibits forskolin-stimulated cyclic AMP accumulation in chromaffin cells through a pertussis toxin-sensitive process (Zhu, J., W. Li, M.L. Toews and T.D. Hexum, 1992, J. Pharmacol. Exp. Ther., 263:1479-1486). Chromaffin cells were prelabeled with [<sup>32</sup>P]PO<sub>4</sub> (90 min, 37°C) washed and incubated in the presence or absence of nicotine (1-100 μM) for 4 min. The medium was aspirated and the cells solubilized in 1% NaDodSO<sub>4</sub>, containing 1 mM EDTA, pH 8. Proteins (50 μg) were separated by polyacrylamide gel (7.5%) electrophoresis. After autoradiography of stained and dried gels, [<sup>32</sup>P] incorporation was quantitated by phosphorimetry. This procedure characteristically labels several proteins of which the 100 kDa, 87 kDa, 74 kDa, 60 kDa and 55 kDa are the most prominent. The 60 kDa protein, tyrosine hydroxylase, is easily identified by its characteristic increase in [<sup>32</sup>P] incorporation in the presence of nicotine. The [<sup>32</sup>P] labeling of tyrosine hydroxylase was confirmed by Western blot analysis and immunoprecipitation. A significant increase in [<sup>32</sup>P] incorporation into tyrosine hydroxylase occurred in the presence of increasing nicotine concentrations compared to that seen in the absence of nicotine. NPY (0.3-300 nM) produced a concentration dependent, pertussis toxin-sensitive, decrease in [<sup>32</sup>P] incorporation into tyrosine hydroxylase (IC<sub>50</sub> = 3.02 nM) when present during nicotine (100 μM) stimulation. (Supported by NIH grant # NS26479.)

## 446.17

TYROSINE HYDROXYLASE IMMUNOREACTIVITY (TH-IR) MAY NOT RELIABLY MARK CATECHOLAMINE NEURONS IN THE MEDULLA.

G. Aston-Jones\* and Y. Zhu, Div. Behavioral Neurobiology, Dept. Psychiatry, Hahnemann University, Philadelphia, PA 19102.

Brains of 30 adult male Sprague-Dawley rats were prepared for immunohistochemistry using antibodies against TH, dopamine beta hydroxylase (DBH), phenylethanolamine-N-methyl transferase (PNMT), dopamine (DA), or dihydroxyphenylalanine (L-DOPA). Double labeling was conducted using either rhodamine + fluorescein or DAB + SG substrate (Vector).

Numerous neurons in the ventral and dorsal medulla stained for TH but not for DBH, DA or L-DOPA. Virtually all TH-ir neurons in the caudal ventral medulla (A1 cell group) also stained for DBH. However, cell counts in 3 rats revealed that 7%, 21% and 53% of TH+ neurons in the caudal, mid- and rostral levels of the nucleus paragigantocellularis (PGi), respectively, did not stain for DBH. Thus, in the ventral medulla TH+/DBH- cells were most frequent at rostral levels where more than half of the TH+ neurons in the area of the C1 cell group did not stain for DBH. Such TH+ neurons also did not stain for DA or L-DOPA, indicating that they may not be catecholaminergic. Triple labeling with retrograde transport of Fluoro-Gold (FG) indicated that many of these TH-only neurons projected to the spinal cord. Many TH+/DBH- neurons were also identified in the Xth cranial nucleus, whereas virtually all TH+ neurons in the NTS also stained for DBH. Some TH+/DBH- neurons in X stained for DA, indicating that a small population of dopaminergic neurons may exist in this cranial nucleus. It appeared that many TH+/DBH- neurons in the ventral and dorsal medulla may also stain for PNMT. A group of neurons in the medial A5 region stained for DBH but not TH, and other cells in the caudal NTS were PNMT+ but TH-.

These results indicate that immunoreactivity for TH, DBH or PNMT may not reliably identify catecholaminergic neurons in certain regions of the medulla. While it is possible that these neurons contain undetectably low levels of other catecholamine chemicals, these findings identify populations of neurons with unusual properties. Supported by PHS grants NS 24698 and DA 06214.

## 446.19

TETRAZEBINE BINDING TO SYNAPTIC LIKE MICROVESICLES

FROM ADRENAL MEDULLA. I. Llona<sup>1</sup>, W.G. Annaert<sup>2</sup>, W.P. De Potter<sup>2</sup>, Gysling K.\* <sup>1</sup>Facultad de Ciencias Médicas, Universidad de Santiago de Chile, <sup>2</sup>Lab. Farmacología Bioquímica, Facultad de Ciencias Biológicas, Universidad Católica de Chile, <sup>3</sup>Lab. Neurofarmacología, Dept. Geneeskunde, Universiteit Antwerpen (UIA), België.

We have previously described the presence of catecholamines in a synaptic like microvesicles (SLMV) enriched fraction from bovine adrenal medulla (Annaert et al., (1993) J. Neurochem. 60,1746). However, in PC12 cells SLMV store acetylcholine but not monoamines. In order to assess the presence of the catecholamine carrier in SLMV we studied the binding of [<sup>3</sup>H]-dihydro-tetrazebine (TBZ) to a SLMV purified fraction from adrenal medulla.

SLMV fraction was obtained after centrifugation in sucrose and urografin gradients. SLMV can be separated from plasma membranes, chromaffin granules (CG) and Golgi membranes as indicated by the distribution of synaptophysin (P38), 5' nucleotidase, dopamine β hydroxylase (DBH) and cytochrome b561 (CYT) and galactosyl transferase.

Membrane fragments from CG equilibrated at lower density than P38. TBZ binding presented a bimodal distribution with a peak coincident with CG markers (CYT and DBH) and the other peak with P38. The specific activity of TBZ binding in SLMV was lower compared to CG, however the dissociation constant determined by kinetic analysis was similar. These results indicate that SLMV contain a catecholamine carrier similar to CG, supporting the presence of catecholamines in SLMV.

PROTEIN SYNTHESIS INHIBITORS STABILIZE TYROSINE HYDROXYLASE (TH) IN ISOLATED BOVINE CHROMAFFIN CELLS. E. Fernandez and G.L. Craviso\*. Dept. Pharmacology, Univ. Nevada Sch. Med., Reno, NV 89557.

Reports of independent regulation of TH mRNA and TH protein levels raise the issue of post-translational control of TH turnover. To address this possibility, we have been studying the regulation of TH half-life (t<sub>1/2</sub>) in primary cultures of bovine adrenal chromaffin cells. Using two different methodological strategies, approach to steady-state and pulse-chase analyses, an apparent t<sub>1/2</sub> value of 17-30 hours was estimated for TH in non-stimulated chromaffin cells. To establish whether ongoing protein synthesis has a role in regulating TH turnover, TH levels were examined in chromaffin cells treated with two mechanistically distinct inhibitors of protein synthesis, puromycin (100 μM) and cycloheximide (20 μM). After 3 days of treatment, neither inhibitor reduced the activity of TH or the amount of the 59-60 kD TH subunit, even though incorporation of [<sup>3</sup>H]leucine into trichloroacetic acid precipitable protein was inhibited 90-97% at 1-2 hours as well as throughout the duration of the treatment. This lack of effect on TH level contrasted with the decline in glucose-6-phosphate dehydrogenase, an enzyme reported to have a similar subunit size (63 kD) and a similar t<sub>1/2</sub> (15 hrs) as TH. These results suggest that TH is selectively stabilized under conditions in which protein synthesis is blocked. One possibility that could explain TH stabilization is that protein synthesis inhibitors prevent the synthesis of a factor(s) that is involved in regulating TH turnover. Supported by the AHA Nevada Affiliate and the AAUW.

## 446.18

A NOVEL SUBSTRATE FOR Ca<sup>2+</sup>/CALMODULIN-DEPENDENT PROTEIN KINASE II IN BOVINE ADRENAL MEDULLARY CELLS. N. Yanagihara\*, H. Yamamoto, Y. Ohishi, E. Miyamoto, M. Tsutsui, Y. Toyohira, Y. Uezono and F. Izumi. Dept. of Pharmacol. Univ. of Occup. & Env. Health, Sch. of Med., Kitakyushu 807 and \*Dept. of Pharmacol. Univ. of Kumamoto Sch. of Med., Kumamoto 860, Japan.

We have recently reported the isolation of a novel substrate (70-kDa protein) for Ca<sup>2+</sup>/calmodulin-dependent protein kinase II (CaM kinase II) from bovine adrenal medullary cells (Mol. Pharmacol., 46, 423-430, 1994). In the present study, we examined the interactions among CaM kinase II, the 70-kDa protein and tyrosine hydroxylase (TH), and studied whether the 70-kDa protein would be phosphorylated by several other protein kinases.

1) When TH and the 70-kDa protein were incubated with CaM kinase II, TH protein enhanced the phosphorylation of the 70-kDa protein by CaM kinase II, but the 70-kDa protein attenuated the phosphorylation of TH. The autophosphorylation of CaM kinase II was stimulated by the presence of TH or the 70-kDa protein.

2) The 70-kDa protein was phosphorylated by cyclic AMP-dependent protein kinase and protein kinase C.

These results suggest that interactions among CaM kinase II, TH and the 70-kDa protein occur during the stimulation of adrenal medullary cells and that the 70-kDa protein is the substrate for several multifunctional protein kinases.

MULTIPLE FORMS OF PHENYLETHANOLAMINE N-METHYL TRANSFERASE IN RAT ADRENAL AND BRAIN. J.L. Rozycki, T.D. Gbadebo, and J.K. Stewart.\* Dept. of Biology, Virginia Commonwealth Univ., Richmond, VA 23284

Recently investigators detected two closely migrating forms of PNMT mRNA in the rat adrenal, but it is unclear whether there is more than one form of the enzyme in rat adrenal or brain. In this study, four different antibodies to bovine PNMT detected a major and minor immunoreactive protein (M<sub>r</sub> 31,500 and 30,500, respectively) on Western blots of rat adrenal samples. Optical density (O.D.) of each of these proteins correlated significantly with PNMT activity, and O.D. of other adrenal proteins cross-reacting with one of the antibodies exhibited no correlation with enzymatic activity. Neither of the adrenal proteins was observed on Western blots of rat brainstem, but two of the antibodies detected a lower molecular weight protein (M<sub>r</sub> 29,500) in brainstem samples. The brainstem protein was not evident in cerebellum, a tissue with little or no PNMT activity. All immunoreactive proteins were present in both frozen and freshly prepared samples homogenized with or without proteolytic inhibitors or dithiothreitol. These findings provide immunochemical evidence for two closely migrating forms of PNMT in the rat adrenal and a third form of PNMT in the rat brainstem.

## 447.1

UTILIZING "CAGED-DOPAMINE" IN MEASUREMENT OF DOPAMINE UPTAKE IN BRAIN SLICES. T.H. Lee, K. Gee, E.H. Ellinwood, and F.J. Seidler. Dept. of Psychiatry and Pharmacology, Duke U. Med. Ctr., Durham, NC 27710 and Molecular Probes, Eugene, OR, 97402.

In order to facilitate examining altered dopamine (DA) uptake kinetics following chronic cocaine pretreatment, we have developed a methodology which evokes an "instantaneous" rise in extracellular DA concentrations without electrical stimulation. The uptake can be then measured in "real-time," using fast scan cyclic voltammetry at a 10-Hz sampling rate. In a recording chamber mounted on a Nikon Optiphot epifluorescent microscope, coronal rat brain slices containing both the caudate nucleus and nucleus accumbens were perfused with artificial CSF containing 150 - 200  $\mu$ M of "caged-DA" (MPR 71012 synthesized by K.G.). UV illumination (0.5-1 sec) focused at the tip of the recording electrode (exposure timing controlled by an Uniblitz shutter) produced an "instantaneous" rise in extracellular DA concentrations; a peak DA concentration, 4-8  $\mu$ M, was detected immediately following shutter closure (within 100 msec). This rise was followed by uptake with a "half-width" time of  $1.2 \pm 0.08$  sec. The uptake could be inhibited by cocaine in a concentration-dependent manner ( $1.9 \pm 0.2$  and  $2.9 \pm 0.3$  sec at 10 and 20  $\mu$ M, respectively). The main advantages of our methodology include: (1) similar initial DA concentrations (by varying UV exposure time) achievable for uptake measurement regardless of endogenous DA content in the region (e.g., caudate vs. prefrontal cortex) and (2) elimination of diffusional delay (seconds to minutes) inherent in pressure and microiontophoretic application techniques. Regional differences in uptake kinetics and effects of various uptake blockers will be presented.

## 447.3

IN VIVO DIFFERENTIATION OF DA SYNTHESIS FROM DA RELEASE ALTERATIONS USING PUSH-PULL SUPERFUSION AND DIFFERENTIAL PULSE AMPEROMETRY. V. Leviel\*, V. Olivier and B. Guibert. Inst. A. Fessard, CNRS, 91198 Gif sur Yvette, France.

A push-pull canula supplied with artificial CSF was implanted in the striatum of anesthetized rats, and the basal extracellular dopamine (DA) was assayed in the superfusates using HPLC and electrochemical detection. Simultaneously a carbon fiber electrode was implanted in close proximity (300  $\mu$ m) of the canula and the evoked DA release was detected by differential pulse amperometry (DPA) during stimulation of the DA axons at the level of the medial forebrain bundle (MFB). The absence of calcium in the superfusing fluid induced a complete disappearance of the response to MFB stimulation detected by DPA. The same effect resulted from an i.p. injection of reserpine (10 mg/kg). This confirmed previous results showing that DPA allows to detect the release of DA from vesicular stores by a calcium dependent mechanism. In contrast, the DA collected through the push-pull canula during the same period of time was only reduced by 50% (CaO) and 40% (reserpine). This demonstrates, that DA detected in extracellular space by superfusion with a push-pull canula is only partially coming from vesicular stores. In addition, the absence of calcium ions produced a decrease of the DA release that was not additive with the effect of  $\alpha$ -methyl-p-tyrosine (0.1 mM), blocking the DA synthesis. This suggests that superfusion without calcium reduces extracellular DA by a mechanism different from exocytosis and involving alterations of DA synthesis. These results show that basal extracellular DA, coming from a non exocytotic process of release, and highly sensitive to DA synthesis, can be monitored simultaneously with the firing-dependent release.

## 447.5

INTERACTIONS BETWEEN (-)DS 121 AND COCAINE ON GLUCOSE METABOLISM AND EXTRACELLULAR DOPAMINE IN THE RAT BRAIN. Susanne Koch<sup>1,2</sup>, Montford F. Piercey<sup>1</sup>, Kjell A. Svensson<sup>1</sup>, and Matthew P. Galloway<sup>2</sup>. The Upjohn Co., CNS Res, Kalamazoo, and Wayne State U Sch Med<sup>2</sup>, CCN Program, Dept Psych & Behav Neurosci, Detroit, MI

The phenylpiperidine (-)DS 121 is a dopamine (DA) antagonist that has a preferential action at terminal DA autoreceptors and stimulates locomotor activity. Interestingly, (-)DS 121 decreases cocaine self-administration in rats and is not self-administered. In the present study, (-)DS 121 was tested for its ability to affect cocaine-induced changes in extracellular DA and local cerebral glucose utilization (LCGU) in rats. Using Sokoloff's 2-deoxyglucose (2-DG) autoradiography technique, cocaine administration (5mg/kg, iv) increased LCGU in the frontal cortex, motor cortex, caudate, substantia nigra reticulata and mammillary body. By itself, (-)DS 121 (15mg/kg, ip) did not significantly alter metabolism in any brain region, however, in combination with cocaine, (-)DS 121 antagonized the stimulant effects of cocaine on LCGU, particularly in cortical areas. Using *in vivo* microdialysis in freely moving rats, administration of either cocaine (5mg/kg, iv) or (-)DS 121 (15mg/kg, ip) increased extracellular striatal DA. When combined with cocaine, (-)DS 121 prolonged the cocaine-induced increase in extracellular striatal DA. Our results with 2-DG support the hypothesis that (-)DS 121 blocks postsynaptic DA sites. Furthermore, prolongation of cocaine's effect on striatal DA may reflect (-)DS 121 antagonism of terminal DA autoreceptors. Because (-)DS 121 has both cocaine-mimetic and cocaine antagonist properties, it may be beneficial in treating both cocaine craving and bingeing. Supported by The Upjohn Co., DA 04120, and the Joe Young Sr. Research Fund.

## 447.2

EXPERIMENTAL STUDY TOWARDS DEVELOPING DOPAMINE RELEASING DRUG DELIVERY SYSTEM (DDS). K.Nishino\*, M.Kowada, Y. Tabata, Y. Ikada. Dept. of Neurosurgery, Akita University & Kakunodate General Hospital, Akita, Japan. Research Center for Biomedical Engineering, Kyoto University. 50 mg/ml of Dopamine(DA) was encapsulated in silicon polymer(DK 38 fluid, DDS-1) or biodegradable polylactate polymer (DDS-2) to develop DA releasing drug delivery system and was determined *in vitro* and *in vivo* as for duration and characteristic of DA release to test whether DDS was implantable in the brain or not. Both DDS was immersed in test tubes filled with 1 ml of lactate Ringer solution. Every day solution of the test tube was exchanged for from a week to 5 months. The samples were stored at -40 °C deep freezer until the amount of DA release was measured by HPLC and ECD. Paradigm of *in vitro* DA release from DDS-1 was sequentially determined by microdialysis technique. In test tube for a couple of hours. *In vitro* DDS-1(N=3) released DA for a week and DDS-2 (N=5) for more than five months at 20 °C. The amount of DA release at 20 °C was 10 times higher than at 4 °C. *In vitro* microdialysis indicated that DDS-1 showed DA release at constant rate for at least a couple of hours. DDS-2 was microscopically implanted in the right frontal (N=2) and the parietal paraventricular region(N=5) of male SD rat (BW; 250-350 gm) subjected to stereotactic insertion and fixation of steel catheter into right caudate-putamen under nembutal anesthesia. Then the extracellular levels of DA were sequentially monitored with *in vivo* microdialysis system(Eicom Co Ltd, Tokyo, Japan). Using another animal with inserted probe, the sequential monitor of extracellular DA level was performed after intraventricular injection of 10  $\mu$ l of 50  $\mu$ M DA. Extracellular DA levels were  $1.07 \pm 0.22$  (m  $\pm$  SEM, pg/10  $\mu$ l) at 4 th day post surgery in normal control (N=3),  $5.4 \pm 1.8$  (N=3) at 4 th day and  $37.1 \pm 16.6$  (N=5) at 7-18 days in paraventricular implantation group, while 1.2 (N=2) at 4 th day post frontal implantation. The intraventricular injection of DA caused rapid increase in extracellular level of DA in the right caudate putamen without marked changes in metabolite levels of catecholamine. We conclude that DA was stable after polymer encapsulation and its implantation of ventricle was helpful to boost extracellular DA level in the caudate-putamen.

## 447.4

SIMULTANEOUS MEASUREMENT OF SUBFEMTOMOLE AMOUNTS OF NOREPINEPHRINE, DOPAMINE AND SEROTONIN IN MICRODIALYSIS SAMPLES USING HPLC-EC. P.K. Mishra<sup>1</sup>, R.L. Burger<sup>1</sup>, J.K. Cullison<sup>2</sup>, M.J. Bowers<sup>2</sup>, J.N. Acworth<sup>2</sup> and P.C. Jobe<sup>1</sup>. <sup>1</sup>Department of Basic Sciences, University of Illinois College of Medicine, Peoria, IL 61656 and <sup>2</sup>ESA, Inc., Chelmsford, MA 01824.

Among the *in-vivo* sampling methods, voltammetry offers extremely high temporal resolution but it lacks specificity and does not allow simultaneous quantitation of several neurotransmitters. These factors limit its applicability to selected areas of the brain that have a dominant neurotransmitter. In contrast, samples from *in-vivo* microdialysis are analyzed *ex-vivo* and therefore several compounds can be measured concurrently from a single dialysate. However, microdialysis has been regarded as lacking in temporal resolution. We now report successful, reproducible, and simultaneous analysis of subfemtomole quantities of monoamines and metabolites. This assay allows routine quantitation of these compounds in one minute microdialysates.

A microbore-microflow HPLC system (1 mm X 150 mm column at 75  $\mu$ l/min) was used with a 5  $\mu$ l injection loop and a low dispersion sample valve. A high sensitivity microbore electrochemical detector cell with glassy carbon electrode was used for detection. Detectable levels of norepinephrine, dopamine and serotonin were observed in one minute basal microdialysate samples from superior colliculus and cortex using a 3 mm loop type microdialysis probe. The samples were collected at 4.5  $\mu$ l/min and acidified continuously with 0.5  $\mu$ l/min 0.01N HClO<sub>4</sub> using a Y-connector. Factors influencing HPLC-EC in this assay are: pH of the samples, chemically reactive components of the injection valve and duration of exposure of dialysate to non-inert components. While variations in sample pH produce subtle effects on the retention of components, certain injection valve materials can produce artifact peaks and contribute to a large solvent front. Proper handling of samples insures the stability of monoamines in the microdialysate, which otherwise degrade rapidly at low volume and in nanomolar concentration.

## 447.6

INCREASES IN EXTRACELLULAR DOPAMINE FOLLOWING ELEVATED KCL - A NORMALIZING FACTOR FOR DRUG RESPONSES? T.L. Ripley, P.K. Randall\* and R.A. Gonzales. Division of Pharmacology, University of Texas, Austin, TX 78712

We have previously shown that there is a good correlation between increases in extracellular dopamine (DA) following stimulation with high potassium (K<sup>+</sup>) and that induced by other mechanisms causing depolarization. Here we investigate whether this correlation remains for drugs affecting extracellular DA by different mechanisms. Male Sprague-Dawley rats (250-280g) were implanted with a guide cannula in the left striatum 7-10 days before experimentation. Concentric dialysis probes (diameter 270 $\mu$ m; length 3mm) were inserted 18h before the experiment. Following 3 basal samples (sample = 15min, 2 $\mu$ l/min, ACSF 4mM K<sup>+</sup>), 50mM K<sup>+</sup> ACSF was perfused for 10min, followed an hour later by a 10min perfusion with the test drug (n=3-6). The change in DA from basal (pg/ $\mu$ l) was calculated for the K<sup>+</sup> and drug induced responses, and the Pearson correlation coefficient (r) calculated. Calcium free ACSF decreased extracellular DA by at least 50%.

Test drug	r	Test drug	r
50mM K <sup>+</sup>	0.940	5% Ethanol	1.000
10 $\mu$ M Amphetamine	-0.594	1mM NMDA	0.990
20 $\mu$ M Cocaine	0.322	10mM NMDA	0.962
1 $\mu$ M Tetrodotoxin	0.205		

The increase in DA following the first 50mM K<sup>+</sup> perfusion was not significantly different between the test groups (p>0.05, ANOVA). The mean value across all the groups was  $0.608 \pm 0.083$  pg/ $\mu$ l (n=27). A high positive correlation was seen when the second drug administered was K<sup>+</sup>, NMDA or ethanol. The magnitude of the test drug response altered the slope of the correlation, irrespective of the correlation value. The other drugs investigated showed little to moderate correlation to the initial K<sup>+</sup> response at the concentrations tested, amphetamine being the only drug to show a negative correlation. Haloperidol was also tested (5 $\mu$ M) but the increase in extracellular DA followed a much slower time course and therefore was not included in the analysis. These results suggest that not all drugs that change extracellular DA can be correlated with the animal's response to K<sup>+</sup>. Further work will reveal if those drugs that correlate with the K<sup>+</sup> response act through similar neuronal mechanisms. Work supported by NIAAA (AA08484 and AA00147).

## IN-VIVO MONITORING OF NEOSTRIATAL DOPAMINE ACTIVITY AFTER NASAL DRUG ADMINISTRATION IN THE RAT: RELEVANCE TO PARKINSON'S DISEASE AND ADDICTION

P.J.C. Nogueira, M.A. De Souza Silva, C. Mattern\*, R. Häcker\*, J.P. Huston and R.K.W. Schwarting. Institute of Physiological Psychology I, University of Düsseldorf, 40225 Düsseldorf, \*Mattern et Partner, Enzianstr. 4a, 82319 Starnberg, FRG (EBBS)

Pharmacological treatments aimed at the brain, like DOPA for the treatment of Parkinson's disease, are usually performed by administering drugs orally or iv; however, limited effectiveness and inconveniences for the patient call for using other ways of drug delivery. Here, the nasal route may be an interesting approach, not the least, since its effectiveness to affect brain mechanisms is vividly illustrated by drug abuse which is often performed via the nose. However, regarding the neurochemical effectiveness of nasal drug intake, experimental evidence is sparse. Thus, we used *in vivo* microdialysis to monitor neurochemical activity of the neostriatum in urethane-anesthetized rats, which received drug treatments ip or nasally. When using the nasal route, saline-dissolved drugs (5-10 µl) were administered into one nostril using a blunt microsyringe. In a first study, where methyl-DOPA (50 mg/kg) was given without prior inhibition of peripheral DOPA decarboxylase, both, ip and nasal administration of methyl-DOPA increased extracellular DOPAC and HVA levels in the neostriatum by about 200-500%. In a next study with prior enzyme inhibition (benzazide), the effects on DA metabolites were confirmed and, furthermore, pronounced increases of extracellular DA were found. Thus, nasal administration of methyl-DOPA or similar drugs may serve as an interesting drug route in the treatment of Parkinson's disease. Further studies with nasal administration of amphetamine (5 mg/kg) and cocaine (15 mg/kg) yielded huge increases of extracellular DA in the neostriatum. These data indicate that studying neurochemical effects after nasal drug administration may be useful with respect to further improving drug therapies against brain disease, and may also serve as an interesting approach for studying neuronal mechanisms of drug abuse.

## 447.9

## REGULATION OF STRIATAL ACETYLCHOLINE RELEASE: ROLE OF DOPAMINE D1/D2 RECEPTORS AND EFFECT OF CHRONIC AMPHETAMINE

Michael J. Bickerdike\* & Elizabeth D. Abercrombie, Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102.

A reciprocal relationship between acetylcholine (ACh) and dopamine (DA) appears to modulate basal ganglia-related behavior. Striatal ACh efflux is directly inhibited by D2 receptor activation but increased by activity at extrastriatal D1 receptors<sup>1,2</sup>. These opposing DAergic influences on ACh suggest a D1/D2 balance exists; thus while systemic D2 agonists inhibit ACh release, amphetamine (AMPH), activating both D1 and D2 receptors, has little effect. We hypothesize that chronic AMPH produces behavioral sensitization via changes in striatal DA/ACh interactions, determined by alterations in the D1/D2 balance. Male rats received AMPH (4 mg/kg i.p.; b.i.d., 14 days) or were untreated (controls). Behavioral sensitization, defined as a shift from hyperactivity to predominant stereotypy in response to AMPH, was produced. After chronic treatment, microdialysis was used to monitor striatal ACh efflux (10 nM neostigmine). In control rats, striatal AMPH infusion (10 µM) decreased ACh output by 35%, from 59±8 to 38±5 fmol/20 µl. This local inhibitory effect was reversed (63±5 fmol/20 µl) by systemic AMPH (2 mg/kg i.p.). In AMPH-treated rats, ACh output was decreased by 61%, from 46±1 to 18±1 fmol/20 µl, by local AMPH application. This decrease was significantly greater than that observed in control rats. Systemic AMPH also reversed the inhibitory local effect of the drug in the AMPH-treated group (44±3 fmol/20 µl). Basal DA levels in the two groups did not differ. Extracellular DA increased in response to local AMPH ~30-fold in control rats and ~23-fold in AMPH-treated rats. These results suggest chronic AMPH produces a shift in the balance of D1/D2 receptor influences upon striatal ACh efflux in favor of D2-mediated inhibition. This shift did not result from increased DA release but may instead reflect changes in D1/D2 receptor mechanisms. An apparent hyperdopaminergic state, in terms of behavior, may thus be brought about by altered DA/ACh interactions in the absence of changes in striatal DA itself. (Supported by NIDA 08086)

## 447.11

## MODULATION OF NITRIC OXIDE-MEDIATED STRIATAL DOPAMINE RELEASE IN VIVO

Anthony R. West\* and Matthew P. Galloway CCN

Program, Dept of Psychiatry and Behavioral Neurosciences, Wayne State University School of Medicine, Detroit, MI 48202

The existence of both nitric oxide synthase (NOS) and excitatory amino acid transmitter mediated nitric oxide (NO) release in the striatum has suggested a role for NO in modulating striatal function. Using microdialysis, we report that both NOS substrate and NO-donors increase striatal dopamine (DA) release *in vivo*. Intra-striatal infusion with N<sup>G</sup>-hydroxy-L-arginine (100 µM for 120 min) increased DA release to 57 ± 5% above basal levels. Perfusion with sodium nitroprusside (SNP) (cumulative-dose 1.7 mM) increased extracellular (EC) DA to 331 ± 76% over basal concentrations. Local perfusion of (±)-S-nitroso-N-acetylpenicillamine (SNAP, 1 mM), elevated EC DA levels to 472 ± 120% above baseline levels. This effect of SNAP was not mimicked by perfusion with 1 mM (±)-penicillamine indicating that this NO-carrier compound is not responsible for SNAP-mediated DA release. The DA releasing effect of SNAP was abolished in rats pretreated with reserpine (5 mg/kg) implicating a vesicular dependent release process. The guanylyl cyclase inhibitor LY-83583 (100 µM) administered 100 minutes prior to and during the SNAP pulse, elevated EC DA levels approximately 6-fold by itself and potentiated the DA releasing effect of SNAP to 2598 ± 551% above basal DA levels. While similar pretreatments with antagonists such as methiothepin (10 µM), bicuculline (100 µM), or atropine (100 µM) were without effect, the NMDA antagonists MK-801 (10 µM) and  $\pm$ CPP (100 µM) blocked SNAP-mediated DA release. These results suggest that both endogenous and exogenous NO releases vesicular stores of striatal DA via an NMDA-receptor mediated mechanism and independent of guanylyl cyclase activation. Supported by NIDA-04120 and Joe Young Sr. Research Fund.

## 447.8

## D2 RECEPTOR MODULATION OF SOMATODENDRITIC RELEASE OF DOPAMINE IN THE SUBSTANTIA NIGRA: THE ROLE OF NIGRAL AND EXTRANIGRAL SITES

Marten J. Heeringa\* and Elizabeth D. Abercrombie, Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102, USA.

Dopaminergic neurons of the substantia nigra (SN) can release dopamine (DA) at both the nerve terminal level in striatum and at the somatodendritic level in SN. Based on the effects of systemic administration of D2 antagonists, somatodendritic DA release in the SN has been suggested to be under tonic autoreceptor control. However, this approach does not discriminate between different sites of action of the antagonists. In the present studies, we used *in vivo* microdialysis in awake rats to examine the effects of systemic administration of haloperidol (HAL) and the effects of local administration of this drug, in both SN and striatum, on somatodendritic DA release in SN. Systemic administration of HAL (0.5 mg/kg i.p.) increased DA output in SN by 34% (from 1.1±0.2 to 1.5±0.3 pg/20 µl; n=4). This effect was maximal since a higher dose (1 mg/kg i.p.) did not induce a further increase. Local administration of HAL (1 µM) in SN via the microdialysis probe did not alter the DA output in SN. However, this treatment abolished the decrease in DA output induced by local administration of the D2 agonist quinpirole (1 µM), thus demonstrating effective pharmacological blockade of D2 receptors. In contrast to local administration in the SN, local application of HAL in striatum via microinjection (50 µg/2.5 µl) increased DA output in SN by 27% (from 1.7±0.2 to 2.2±0.2 pg/20 µl; n=5), similar to the increase observed after systemic administration of the drug. This effect was maximal since a higher dose (75 µg/2.5 µl) of HAL caused a similar increase. The effect of local HAL (50 µg/2.5 µl) in striatum on DA output in SN was not further increased by simultaneous administration of HAL (0.5 mg/kg) via the systemic route (30% of basal values; from 1.3±0.1 to 1.7±0.1 pg/20 µl; n=4). These data fail to support the concept of autoregulation of somatodendritic DA release in the SN by local D2 receptors, at least under resting conditions. The effect of systemic administration of D2 antagonists on the release of somatodendritic DA in SN results from D2 receptor blockade in striatum, rather than from a blockade of nigral D2 receptors (support: USPHS Grants NS19608/DA08086).

## 447.10

## STEREISOMERS OF CARBIDINE AS D3 DOPAMINE RECEPTOR PREFERRED ANTAGONISTS

R.R. Gainetdinov, H. Shoemaker\*, V.A. Zagorevsky, N.M. Sipilina, T.D. Sotnikova, T.V. Grekhova, K.S. Rayevsky\*, Institute of Pharmacology RAMS, Baltiyskaya str., 8, Moscow, 125315, Russia; \*Synthelabo Recherche 31, Av. Paul Vaillant-Couturier BP110 92225 Bagneux - Cedex, France.

Carbidine ((+)-cis-3,6-dimethyl-1,2,3,4,4a,9b-hexahydro-γ-carboline dihydrochloride) was introduced into clinical use as an atypical neuroleptic drug with stimulatory and thymoleptic properties. The drug in clinical trials has been shown to possess antidepressant action alongside its antipsychotic efficacy and has been used in the treatment of patients with some forms of schizophrenia and alcoholism. Trans-isomer of carbidine synthesized according to V.A. Zagorevsky et al. (Zh. Vses. Khim. Obshchest., 27(1), pp.102-104, 1982) has been found to possess a higher potency in behavioral and neurochemical studies as regard to dopamine (DA) receptor blocking ability vs. cis-carbidine. In microdialysis studies both compounds were shown to increase DA release more than its synthesis/metabolism and to produce certain behavioral activation in rats at low doses. Cis- and trans-isomers of carbidine were studied in the screening tests for the native rat striatal DA D2 using [<sup>3</sup>H]spiperone and bovine D3 receptor using [<sup>3</sup>H]7-OH-DPAT. In two independent experiments, cis-carbidine showed IC<sub>50</sub> 10 µM against [<sup>3</sup>H]spiperone binding to rat striatal membranes (maximal inhibition of 0 and 13% at 10 µM) and against [<sup>3</sup>H]7-OH-DPAT binding to membranes from the bovine caudate (maximal inhibition of 46.6 and 38.8% at 10 µM). Trans-carbidine showed IC<sub>50</sub> values of 4.5 and 4.9 µM against [<sup>3</sup>H]spiperone and 0.33 and 0.20 µM against [<sup>3</sup>H]7-OH-DPAT. Thus binding data as well as behavioural and *in vivo* neurochemical profiles of the drugs demonstrate D3 vs D2 DA receptor preference of both cis- and trans-isomers of carbidine.

## 447.12

## UNUSUAL NEUROCHEMICAL PROPERTIES OF THE NOVEL ANTIPSYCHOTIC OPC-14597 IN RAT STRIATUM

C. Priolau, D.M. Montague, N.Y. Choksi, S.B. Southerland, C.P. Lawler\* and R.B. Mailman Univ. of North Carolina, Chapel Hill, NC 27599

OPC-14597 (OPC) is a novel antipsychotic from a unique structural class. It binds with high affinity to rat striatal D<sub>2</sub>-like dopamine receptors, and exhibits functional antagonist properties at measures of postsynaptic receptor function. OPC also has nanomolar affinity for cloned D<sub>2</sub> receptors where it behaves functionally as an antagonist. Preliminary clinical data also indicate that this drug may be a new atypical antipsychotic having good efficacy, yet little tendency to induce extrapyramidal side effects. Thus, it was surprising that in rat brain slices OPC actually had, at high concentrations, a modest inhibitory effect on dopamine synthesis, suggesting possible agonist presynaptic actions. The present studies were aimed at investigating the actions of OPC on another measure of presynaptic function, dopamine release. The effects of OPC on dopamine release in rat striatum were compared to those of the D<sub>2</sub> selective antagonist sulpiride using two distinct preparations. The first of these utilized *in vivo* cerebral microdialysis in freely moving animals. We have previously shown that OPC (12 mg/kg) had little or no effect on the concentration of DA or its metabolites HVA and DOPAC, whereas haloperidol markedly increased all three. In the present studies, 1 µM OPC was infused directly into the dialysis cannula. Sulpiride, as expected, increased the efflux of dopamine and its metabolites DOPAC and HVA. Surprisingly, OPC increased dopamine overflow but, unlike sulpiride, had no effect whatsoever on the overflow of HVA and DOPAC. This was investigated further using superfused rat striatal slices preloaded with [<sup>3</sup>H]dopamine. As expected, apomorphine inhibited [<sup>3</sup>H] efflux, and this effect was blocked by sulpiride. Yet whereas sulpiride alone had no effect, OPC [1 µM] alone dramatically increased basal [<sup>3</sup>H]dopamine release. These data demonstrate that OPC has neurochemical functional effects distinct from those of other antipsychotic candidates, and that this may play a role in its actions *in vivo*.

## 447.13

EVALUATION OF D<sub>3</sub> RECEPTOR FUNCTION IN VIVO: A MICRODIALYSIS STUDY \*C. Routledge, L. Thorn, T. Ashmeade and S. Taylor. SmithKline Beecham Pharmaceuticals, Discovery Research, New Frontiers Science Park North, Third Avenue, Harlow, Essex, England, CM19 5AW

It was recently suggested that dopamine D<sub>3</sub> receptors may function as autoreceptors on nigrostriatal and mesolimbic dopaminergic neurones (Sokoloff *et al.*, 1990, *Nature* 347: 146), this was supported by data demonstrating that the D<sub>3</sub> receptor agonist 7-OH-DPAT induced a decrease in dopamine release in the striatum (Damsma *et al.*, 1993, *Eur. J. Pharm.* 249: R9). In the present study we have further characterised D<sub>3</sub> receptor function by determining the effects of the D<sub>3</sub> receptor agonists quinpirole and quinpirole (EC<sub>50</sub> D<sub>2</sub>/D<sub>3</sub>=21.4; EC<sub>50</sub> D<sub>2</sub>/D<sub>3</sub>=3.3 respectively, Sautel *et al.*, 1995, *NeuroReport* 6: 329) on dopamine release in the nucleus accumbens and striatum (the nucleus accumbens having a higher D<sub>2</sub>/D<sub>3</sub> receptor density than the striatum) using microdialysis in the conscious rat.

Quinpirole (30 µg/kg s.c.) significantly ( $p<0.01$ ) decreased dopamine release in both the nucleus accumbens and the striatum to  $40.0\pm7.0$  and  $45.0\pm7.0$  % of preinjection control levels respectively but was without effect at lower doses (0.1-10.0 µg/kg s.c.). Maximum effects were observed 60 min post-drug administration. Similarly quinpirole (30 µg/kg s.c.) significantly ( $p<0.01$ ) decreased dopamine release in both the nucleus accumbens and striatum to  $42.0\pm2.0$  and  $26.4\pm12.0$  respectively but was without effect at lower doses (0.0-10.0 µg/kg s.c.). Again maximum effects were observed at 60 min post-drug administration. That there was no differentiation between the effects of these ligands in the nucleus accumbens and striatum, and the relatively high doses of agonists used to elicit the decrease in dopamine release suggest that this response may be mediated via D<sub>2</sub> rather than D<sub>3</sub> receptors.

## 447.15

BURST STIMULATION OF THE MEDIAL FOREBRAIN BUNDLE SELECTIVELY INCREASES FOS IMMUNOREACTIVITY IN THE LIMBIC FOREBRAIN OF THE RAT. K. Chergui, G. G. Nonikos, J. M. Mathé, F. Gonon and T. H. Svensson\*, Dept. of Physiology & Pharmacology, Div. of Pharmacology, Karolinska Institutet, S-171 77 Stockholm, Sweden.

The present study was designed to evaluate the postsynaptic, functional consequences of different presynaptic activity patterns in midbrain dopamine (DA) systems using electrical stimulation of the rat medial forebrain bundle (MFB) and subsequent determination of *c-fos* expression, used as a marker for neuronal activation, in DA target areas, by means of Fos immunohistochemistry. Nerve terminal DA release evoked by electrical stimulation of the MFB was monitored in the same animals using *in vivo* voltammetry. A 5 Hz stimulation consisting of 60 trains of 5 pulses and lasting 1 min was applied to the MFB. This stimulation was repeated 15 times every 3 min. Its pattern was defined by the interpulse interval which was either 70 ms or 200 ms for burst or regularly spaced stimulation, respectively. Our results show that burst stimulation of the MFB, which increases release of DA in target areas, increases the basal expression of Fos in the stimulated hemisphere, while regular stimulation does not affect expression of this protein. Moreover, the increased expression of Fos induced by burst stimulation is restricted to limbic related structures, i.e. nucleus accumbens shell and intermediate aspect of the lateral septum, and the major island of Calleja, but is not observed in motor related structures (nucleus accumbens core and striatum). Finally, pretreatment with the D<sub>1</sub>-D<sub>2</sub> receptor antagonist, SCH23390 (0.1 mg/kg i.p.), blocked the increased expression of Fos induced by burst stimulation of the MFB, suggesting a role for these receptors in the observed effects. The present data indicate that, rather than the absolute mean discharge rate of midbrain DA neurons, the temporal organization of the action potentials they generate conveys information to their target areas.

## 447.17

EFFECT OF A TETRODOTOXIN PULSE VIA A MICRODIALYSIS PROBE ON DOPAMINE AND SEROTONIN SYNTHESIS AND METABOLISM IN RAT STRIATUM. K. W. Perry and R. W. Fuller\*, Lilly Research Laboratories, Eli Lilly and Co., Lilly Corporate Center, Indianapolis, IN 46285.

Tetrodotoxin (TTX) has been widely used in microdialysis experiments to demonstrate that the substance being measured is released from neurons, because TTX is known to block the impulse-induced release of neurotransmitters (Westerink *et al.*, Naunyn-Schmied. Arch. Pharmacol. 336, 502-507, 1987). Consistent with previous literature, we found that there was an immediate decline in extracellular dopamine and serotonin in rat striatal microdialysate upon infusion of TTX (3 µM) through the probe. The duration of the decrease was dependent on the length of the TTX pulse (15 or 60 min). Both serotonin and dopamine gradually returned to normal after the TTX infusions ended with serotonin recovering faster than dopamine. Extracellular concentrations of DOPAC did not change significantly while the TTX was present in the perfusate, but when TTX infusions ended extracellular DOPAC increased to approximately 300 and 400% over baseline after infusion durations of 15 and 60 min, respectively. Extracellular 5-HIAA decreased by 9% and 17% after TTX infusions of 15 and 60 min respectively, then returned to baseline. To determine if the changes observed in the dopamine and serotonin metabolites reflected changes in synthesis, a decarboxylase inhibitor was included in the perfusate along with TTX which enabled the measurement of L-DOPA and 5-HTP. Extracellular levels of L-DOPA measured in this way increased to 170% of baseline in the presence of TTX and returned toward normal after TTX infusion had ended. Extracellular levels of 5-HTP were measured at the same time and, after a 30 min delay, decreased by about 25%. The increase in dopamine synthesis after TTX infusion probably occurred due to a lack of dopamine at the presynaptic autoreceptor. In contrast, serotonin synthesis was decreased after TTX, indicating that the serotonin autoreceptor does not exert an influence similar to the dopamine autoreceptor in the rat striatum.

## 447.14

DIFFERENCES IN EFFECTS OF PUTATIVE D<sub>3</sub> DOPAMINE RECEPTOR AGONIST 7-OH-DPAT ON DOPAMINE RELEASE AND SYNTHESIS IN RAT BASAL GANGLIA *IN VIVO* T.D. Solnikova\*, R.R. Gametdinov, T.V. Grckhova and K.S. Rayevsky. Inst. of Pharmacology RAMS, Baltiyskaya 8, Moscow, 125315, Russia.

To study the role of D<sub>2</sub> and D<sub>3</sub> dopamine (DA) autoreceptors in presynaptic regulation of DA synthesis and release in mesolimbic and nigrostriatal targeting regions we investigated *in vivo* neurochemical effects of putative D<sub>3</sub> DA receptor agonist 7-OH-DPAT using transcranial microdialysis on awake rats. The drug dose-dependently decreases DA release, metabolism and synthesis of DA in nucleus accumbens (NAC) and dorsal striatum (DS). However the potency of 7-OH-DPAT in decreasing of DA release was higher in the NAC vs. DS. DA metabolism assessed by DOPAC level and synthesis determined as extracellular L-DOPA following NSD-1015 perturbation ( $10^{-5}$  M) were decreased at higher dose ranges of 7-OH-DPAT. Importantly, that no difference between DS and NAC in this regard was observed. The hypomotility induced by 7-OH-DPAT well corresponds to decrease of DA release in NAC. Infusion of the drug into the brain also resulted in preferential decrease of DA release in NAC vs. DS. Pretreatment with 7-OH-DPAT at putative D<sub>3</sub> DA receptor "selective" dose 0.05 mg/kg i.p. prior haloperidol or (+) A776 was found to prevent the increase of striatal DA release but not DOPAC level produced by both DA receptor antagonists. The present results give further support to the hypothesis that DA D<sub>3</sub> terminal autoreceptor preferentially involved in regulation of DA release while D<sub>2</sub> one regulates DA synthesis in rat basal ganglia *in vivo*.

involved in regulation of DA release while D<sub>2</sub> one regulates DA synthesis in rat basal ganglia *in vivo*.

## 447.16

CHRONIC CLOZAPINE ADMINISTRATION REDUCES STIMULUS-EVOKED DOPAMINE OVERFLOW IN THE RAT NUCLEUS ACCUMBENS IN VIVO.

K. J. Feasey-Truger, C. Alzheim and G. ten Bruggencate\*, Institute of Physiology, University of Munich, Pettenkoferstr. 12, 80336 Munich, Germany.

The antipsychotic effects of neuroleptic drugs appear to arise from long-term adaptive changes in the mesolimbic dopamine (DA) system. A number of studies have shown that chronic treatment with the atypical neuroleptic, clozapine (CLOZ) selectively decreases basal DA levels in the nucleus accumbens (Acb), but not in the striatum. In this study, we have used fast cyclic voltammetry (FCV) to examine the effects of chronic CLOZ treatment on stimulus-induced i.e. impulse-dependent mesolimbic DA overflow in the Acb of the anaesthetized rat *in vivo*.

Treated rats (n=7) received CLOZ (20 mg/kg/d) in their drinking water for 21 days; control rats (n=8) received tap water alone. Electrochemical studies were performed under urethane anaesthesia. DA overflow was evoked via stimulus trains delivered every 5 min to the VTA (350 µs, 60 pulses, 60 Hz), and detected via a carbon fibre microelectrode positioned in the ipsilateral Acb. DA overflow in response to a range of stimulus intensities (0.2-1.0 mA) was compared in each group. Evoked DA overflow was significantly reduced in treated rats ( $p<0.0001$ ). The effects of the DA autoreceptor agonist, quinpirole (QUIN), were also studied in treated and control rats. Quin (1.0 mg/kg, i.p.) significantly reduced evoked DA overflow in both groups; however, the magnitude and time course of the reduction in DA overflow did not differ significantly between the groups.

These results show for the first time that chronic CLOZ administration reduces stimulus-induced DA overflow in the rat Acb *in vivo*. This effect does not appear to be due to DA autoreceptor supersensitivity, since the QUIN-induced decrease in DA overflow was unchanged in CLOZ-treated rats. The mechanism underlying the observed reduction in DA overflow will be the subject of further study.

## 447.18

EFFECTS OF THE SIGMA LIGAND PENTAZOCINE ON THE EXTRACELLULAR CONCENTRATION OF DOPAMINE (DA) IN THE STRIATUM OF THE RAT. Gary A. Gudelsky\*, College of Pharmacy, University of Cincinnati Medical Center, Cincinnati, OH. 45267

Sigma ( $\sigma$ ) binding sites are characterized by their high affinity for certain opiates, antipsychotic drugs, steroids and guanidines. Data from behavioral and neurochemical studies are supportive of the view that  $\sigma$  ligands interact with dopaminergic systems in the brain. The present studies were undertaken to assess the effects of the  $\sigma$  ligand pentazocine on the release of DA from nigrostriatal neurons using *in vivo* microdialysis. The systemic administration of (+)-pentazocine (10-20 mg/kg, sc) produced approximately a 50% increase in the extracellular concentration of DA in the striatum; (-)-pentazocine was less effective. The administration of (+)-pentazocine (1 mM) through the dialysis probe for 120 min resulted in a biphasic effect on DA release: a brief increase of 75% was followed by a prolonged decrease of approximately 70%. The local perfusion of (-)-pentazocine (1 mM) also produced a biphasic response similar in magnitude to that produced by the (+)-isomer. Furthermore, the intrastriatal administration of the NMDA antagonist CPP (100 µM) diminished the initial increase but not the subsequent decrease in DA release elicited by the intrastriatal administration of (+)-pentazocine. These data are suggestive that DA release may be modulated by multiple  $\sigma$  receptor subtypes and that NMDA receptors also may mediate the stimulatory effect of  $\sigma$  ligands on DA release in the striatum.

## 447.19

METHYLENEDIOXYMETHAMPHETAMINE (MDMA)-INDUCED DOPAMINE RELEASE IN RATS: EFFECTS OF RESERPINE PRETREATMENT AND ALTERATIONS IN CORE BODY TEMPERATURE. K.E. Sabol\*, M. Balcells, L.S. Seiden. Dept. Pharm./Phys. Sci., University of Chicago, Chicago, IL 60637

MDMA increases dopamine release. Pretreatment with reserpine (RES), which depletes vesicular dopamine stores, attenuates the MDMA-induced dopamine release. RES also decreases core body temperature. The purpose of this report was to determine whether the RES-induced reduction in body temperature is responsible for the attenuation in MDMA-induced dopamine release. Using in vivo dialysis, dopamine release was measured in three treatment groups: 1.) MDMA alone (N=5); 2.) MDMA plus RES (N=5); and 3.) MDMA, RES, plus heat (N=8). Animals were implanted with guide cannulae (above striatum) one week before testing. The evening before testing, dialysis probes were lowered into the guides, and the animals were connected to the dialysis perfusion system. RES (10.0 mg/kg) was administered 18 hr prior to MDMA (10.0 mg/kg) treatment. At the start of the experiment the average core temperature of all the RES pretreated rats was 32.2 ( $\pm$  0.5 SEM) degrees C. In the group receiving heat treatment, core temperature was maintained between 37 and 39 degrees C (range of normal body temperature) using a heat lamp. As was previously found, RES significantly attenuated the MDMA-induced dopamine release. When the core temperature in RES pretreated animals was maintained at 38 degrees C, the MDMA-induced dopamine release was intermediate between the MDMA alone and the RES pretreated groups. The heated reserpinized group however, was not significantly different from either the RES (not heated) pretreated or the MDMA alone groups. The heated reserpinized group demonstrated substantial variability, with some animals overlapping with the RES (not heated) rats and some animals overlapping with the MDMA alone groups. Although cooling may be responsible for some of the attenuation of MDMA-induced dopamine release in reserpinized animals, other important variables appear to be involved (Supported by NIDA DA-00085 & RSA 10562, L.S. Seiden).

## 447.20

RESERPINE DOES NOT AFFECT THE ACCUMULATION OF 3-METHOXYTYRAMINE FOLLOWING PARGYLINE IN THE DIALYSATE FROM THE SUBSTANTIA NIGRA. A. Elverfors\*, J. Jonason and H. Nissbrandt. Department of Pharmacology, Göteborg University, Medicinaregatan 7, S-413 90 Göteborg, Sweden.

Indirect biochemical methods, as accumulation of the dopamine (DA) metabolite 3-methoxytyramine (3-MT) after monoamine oxidase inhibition has been used as an indirect measurement of DA release. Results obtained with this indirect method are in accordance with results obtained with more direct methods, as microdialysis technique, when DA release is measured in terminal regions, as the striatum, but not when measured in somatodendritic regions, as the substantia nigra (SN). This study was undertaken to further investigate the discrepancy in the SN between the different methods to measure DA release. The DA and 3-MT concentrations were measured by microdialysis in freely moving rats in the SN and in the striatum following pargyline (75 mg/kg) treatment and reserpine (5 mg/kg) plus pargyline treatment. Pargyline treatment only increased the DA concentrations to 180% of basal levels in the striatum and to 310% of basal levels in the SN. Combined treatment with pargyline and reserpine decreased the DA concentrations to 6% of basal levels in the striatum and to 13% of basal level in the SN. In the striatum, the 3-MT concentrations in the dialysate decreased when the animals were treated with reserpine plus pargyline as compared to when treated with pargyline only. However, in the SN the 3-MT concentrations following pargyline plus reserpine was equal with the concentrations following pargyline only. This suggest that pargyline-induced 3-MT accumulation in the SN does not reflect extracellular concentrations of DA. A possible explanation for this discrepancy between the striatum and the SN could be that the metabolic enzyme COMT is located in dopaminergic neurons in the SN but not in the striatum.

## CATECHOLAMINES: ELECTROPHYSIOLOGICAL STUDIES

## 448.1

DIFFERENTIAL EFFECTS OF ACUTE AND CHRONIC FLUOXETINE ON THE ELECTRICAL ACTIVITY OF DOPAMINERGIC NEURONS IN THE VENTRAL TEGMENTAL AREA. E. Esposito\* and S. Prisco. Istituto di Ricerche Farmacologiche "Mario Negri", Consorzio "Mario Negri" Sud, Santa Maria Imbaro (Chieti), Italy.

There is extensive evidence that the activity of midbrain dopamine (DA) neurons is modulated by the serotonergic system. Electrophysiological studies have shown that serotonin (5-HT) exerts an inhibitory action on the firing rate of DA neurons in the ventral tegmental area (VTA) and the substantia nigra, pars compacta (SNc). Thus, it is conceivable that selective 5-HT reuptake inhibitors, such as the antidepressant fluoxetine, may affect DA function. In order to investigate this point, we have studied the effects of acute and chronic administration of fluoxetine on the electrical activity of DA neurons in both the VTA and the SNc. Extracellular single unit recordings were performed in vivo on male Sprague Dawley rats, anesthetized with chloral hydrate. DA neurons in the VTA and SNc were identified by their location, waveform, firing rate and pattern. Acute i.v. injection of fluoxetine (20-1280  $\mu$ g/kg) caused a dose-dependent inhibition of the firing rate of VTA DA neurons, but it did not affect the activity of DA cells in the SNc. Pretreatment with the specific 5-HT<sub>2c</sub> receptor antagonist mesulergine (80  $\mu$ g/kg, i.v.) blocked the inhibitory effect of fluoxetine on VTA DA cells. Selective lesions of 5-HT neurons by the neurotoxin 5,7-dihydroxytryptamine abolished the reduction of VTA DA activity induced by fluoxetine. In another series of experiments, i.p. fluoxetine (10 mg/kg) or saline was administered once daily for 21 consecutive days. Acute i.v. administration of fluoxetine (20-1280  $\mu$ g/kg, 72 hours after the last i.p. injection) did not modify the basal firing rate of VTA DA neurons in treated rats, whereas it induced the typical inhibitory effect in control animals. A group of rats chronically treated with fluoxetine, received i.v. m-chlorophenylpiperazine (10-200  $\mu$ g/kg), a 5-HT<sub>2c</sub> receptor agonist. This drug significantly inhibited VTA DA function in control rats, but it did not modify the basal activity of DA cells in animals given chronic fluoxetine. On the basis of these findings it is possible to argue that prolonged administration of fluoxetine induces a down-regulation of 5-HT<sub>2c</sub> receptors.

## 448.2

THE ELECTROPHYSIOLOGICAL EFFECTS OF MONOAMINO OXIDASE INHIBITORS ON RAT DOPAMINERGIC NEURONS INTRACELLULARLY RECORDED IN VITRO. N. B. Mercuri, P. Calabresi, A. Bonci, A. Pisani, R. Vagnozzi, G. Bernardi. Clinica Neurologica, Univ. Tor Vergata, 00173, Roma, Italy.

The effects of unspecific and specific monoamine oxidase (MAO) inhibitors were studied on the spontaneous firing of the dopaminergic neurons intracellularly recorded in slices of the ventral midbrain. The non-specific MAO inhibitor pargyline superfused at a concentration of 30- 100  $\mu$ M irreversibly inhibited within 5 - 15 minutes of application the spontaneous firing discharge of the neurons either in the substantia nigra pars compacta and/or in the ventral tegmental area. The D2 receptor antagonist sulpiride (100 - 300 nM) reversed the effect of pargyline. The selective inhibitor for MAO A, clorgyline (30 - 100  $\mu$ M) slightly depressed the firing rate of the DA neurons. Contrariwise, the MAO B inhibitor deprenyl (30 - 100  $\mu$ M) reduced or blocked the spontaneous discharge of dopaminergic cells and this effect was at least in part reversible. Our electrophysiological data suggest that only a mixed inhibition of type A and type B MAO is able to profoundly inhibit the dopamine-containing neurones of the rat mesencephalon. This effect is probably due to an increased action of endogenous dopamine on DA autoreceptors. The transient inhibition produced by l-deprenyl could be due to an amphetamine-like effect of this compound.

## 448.3

CHARACTERIZATION OF HUMAN MIDBRAIN NEURONS IN CULTURE. W.-X. Shi, H.G. Foellmer, C.L. Pun, D.E. Redmond, Jr and B.S. Bunney\*. Depts of Psychiatry and Pharmacology, Yale Univ Sch of Med, New Haven, CT 06510

Our knowledge of brain neurons has come largely from studies in non-human species. To study human neurons directly, we have developed a technique for culturing human fetal midbrain neurons and have begun to compare their properties with those of rat neurons. Human fetal tissue was collected following termination of pregnancy (7-11 wks; Redmond et al., *Science* 242:768, 1988). Ventral mesencephalon neurons from either freshly collected or cryopreserved fetal tissue were cultured using methods similar to those previously described for rat neurons (Rayport et al., *J Neurosci*, 12:4264, 1992). They had cell bodies 5.8-14.7  $\mu$ m in diameter (mean  $\pm$  SEM = 8.35  $\pm$  0.31, n=43), exhibiting different shapes, and extensive processes. Whole cell recordings were made from 33 human neurons cultured for an average of 20 days. All fired action potentials either spontaneously or during current injection. TTX (1  $\mu$ g/ml, n=5) blocked the action potential and Co<sup>2+</sup> (2 mM) reduced its size (7/8 cells), suggesting the involvement of both Na<sup>+</sup> and Ca<sup>2+</sup> in the action potential of these cells. Spontaneous synaptic potentials (both IPSPs and EPSPs) were frequently observed, indicating that human fetal neurons were capable of making synaptic connections in the culture. Application of glutamate and GABA evoked robust responses in all cells tested, suggesting the presence of receptors for both transmitters on these neurons.

## 448.4

FURTHER CHARACTERIZATION OF DOPAMINE-INDUCED DEPOLARIZATION OF NEURONS IN THE PREFRONTAL CORTEX. X.-F. Liang, B.S. Bunney and W.-X. Shi\*. Depts of Psychiatry and Pharmacology, Yale Univ Sch of Med, New Haven, CT 06510

Last year, we reported that dopamine (DA) dose-dependently depolarized both pyramidal and non-pyramidal neurons in the prefrontal cortex (PFC) and increased their excitability (Shi and Bunney, *Soc Neurosci Abstr* 20:1354, 1994). However, this effect was not mimicked by either D1- or D2-like receptor agonists or blocked by D1- or D2-like receptor antagonists. It was, thus, suggested that the depolarizing effect of DA in the PFC may be mediated non-specifically by non-DA receptors, such as those for norepinephrine (NE) and serotonin (5-HT). To test this possibility, the effect of DA on PFC neurons was reexamined in the presence of the antagonists for these non-DA receptors. PFC slices (400  $\mu$ m) were prepared from male Sprague-Dawley rats weighting between 75 and 170 g and maintained in an interface slice chamber. Neurons in layers V and VI of the medial PFC were recorded in whole cell mode and drugs were applied through the bath. Confirming the previous finding, DA dose-dependently depolarized most neurons tested. Surprisingly, this effect was not blocked by either the  $\alpha$  antagonist phentolamine (10  $\mu$ M, n=8) or the  $\beta$  antagonist alprenolol (10  $\mu$ M, n=12), or a mix of the two (n=3). The effect also persisted in the presence of high concentrations of clozapine (10  $\mu$ M, n=5; 100  $\mu$ M, n=11), an atypical antipsychotic drug that blocks multiple receptors including those of DA and 5-HT. These results again (Sesack & Bunney, *JPET* 248:1323, 1989) suggest the existence of an as yet uncharacterized class of DA receptors in the PFC, which may be responsible for the observed depolarizing effect of DA.

## 448.5

REPETITIVE FIRING PROPERTIES OF NIGRAL DOPAMINE (DA)-CONTAINING NEURONS *IN VITRO*. H.X. Ping and P.D. Shepard\* MD Psychiatric Res. Cntr. & Univ. of MD School of Med., Baltimore, MD 21228.

DA-containing neurons *in vivo* exhibit an adaptive response to long duration depolarizing pulses consisting of a progressive reduction in firing frequency (Grace & Bunney, 1984). This phenomena, referred to as spike frequency adaptation (SFA), is reported to be considerably less pronounced *in vitro*. In the present study, intracellular recording techniques were used to investigate the voltage dependence and pharmacological sensitivity of spike frequency modulation exhibited by these neurons *in vitro*. In agreement with previous studies, DA neurons showed little evidence of SFA in response to low intensity stimuli applied during spontaneous spiking. Further increases in stimulus strength reduced the intervals between initial spikes in the train after which firing frequency rapidly adapted to a steady state value that was maintained for the duration of the stimulus. In marked contrast to this response, 14 of 18 cells depolarized from a holding potential of -64 mV exhibited a progressive increase in firing frequency. Bath application of TEA (20 mM, n=5) increased spike width as well as the number of spikes evoked in response to membrane depolarization but had no effect on the temporal organization of spike trains.  $\text{Cd}^{2+}$  (200  $\mu\text{M}$ ; n=5) prevented the paradoxical increase in firing frequency but failed to induce SFA. These effects were accompanied by an increase in spike width and a reduction in the amplitude of the post-spike afterhyperpolarization (AHPs;  $17.6 \pm 3\%$  decrease). A further reduction in AHPs amplitude was observed following 100 nM apamin ( $88.7 \pm 8.7\%$ ) and was associated with both a marked increase in neuronal excitability and the appearance of SFA. These data suggest that the repetitive firing properties of DA neurons are modulated principally by AHPs. It is further suggested that loss of SFA *in vitro* may reflect an increase in the apamin-sensitive conductance responsible for generating AHPs.

## 448.7

THE EFFECTS OF PD 128907 ON THE FIRING ACTIVITY OF SUBSTANTIA NIGRA ZONA COMPACTA DOPAMINE (DA) AND ZONA RETICULATA (ZR) NEURONS. L.T. Meltzer\*, C.L. Christoffersen and K.A. Serpa. Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Co., Ann Arbor, MI 48105.

PD 128907(R-(-)-trans-3,4,4a,10b-tetrahydro-4-propyl-2H,5H-[4,3-b]-1,4-oxazin-9-ol) has an 18-fold higher affinity for DA D3 vs. DA D2 receptors *in vitro* (DeMattos, et al., Soc. Neurosci. Abst. 19:77,1993). Thus, it represents a potential tool for discriminating the relative functional roles of D3 versus D2 receptors. In the present studies we compared the inhibitory effects of PD 128907 (PD), quinpirole (Q; 9-fold D3/D2) and apomorphine (A; 3-fold D2/D3), administered *i.v.* in a cumulative dose-response, on the firing activity of substantia nigra DA and ZR neurons in chloral hydrate anesthetized rats. The ability of various DA antagonists to selectively block the effects of PD versus A, both tested at 0.1 mg/kg *i.p.*, was also evaluated.

PD, Q and A all produced similar, complete inhibitory effects on DA neuronal activity. The dose-response curves for all three agents overlapped. Thus, D3 versus D2 selectivity did not alter the DA autoreceptor agonist effects.

A and PD, both at 0.1 mg/kg *i.p.*, produced similar decreases in DA neuronal activity. Pretreatment with haloperidol (0.03 & 0.1 mg/kg *i.p.*, 5-fold D2/D3), (-)-sulpiride (10 mg/kg *i.p.*, 2-fold D2/D3) or remoxipride (2 mg/kg *i.p.*, 10-fold D2/D3) produced similar antagonism of the PD- or A-induced inhibition of DA neuronal activity. Thus, these studies utilizing antagonists with varying selectivity for D2 and D3 receptors did not reveal a preferential role for D2 or D3 receptors in mediating the agonist effects of A or PD.

PD and Q produced a dose-related biphasic effect on ZR neuronal firing. Relatively low doses (0.5-16  $\mu\text{g}/\text{kg}$  *i.v.*) produced an increase in activity, which was returned to or below baseline with higher doses ( $> 32 \mu\text{g}/\text{kg}$  *i.v.*). However, in control recordings there was also a slow spontaneous increase in neuronal firing. Thus, only relatively high doses of PD and Q, which are unlikely to show D3 vs D2 receptor selectivity, produced measurable effects on ZR neuronal activity. H (0.3 mg/kg *i.p.*), antagonized the secondary decrease in activity. In conclusion, these studies did not clearly differentiate between D2 or D3 mediated actions of DA agonists.

## 448.9

LACK OF PACEMAKER ACTIVITY IN THE NIGRAL DOPAMINE NEURONS OF NEONATES: EXTRACELLULAR ELECTROPHYSIOLOGICAL STUDIES *IN VITRO*. J. Zhang\*, M.W. Lewis and D.K. Pitts. Department of Pharmaceutical Sciences, College of Pharmacy, Wayne State University Detroit, MI 48202.

Midbrain slices containing the substantia nigra and ventral tegmental area were obtained from rats anesthetized with chloral hydrate (400 mg/kg *i.p.*). The activity of single nigral dopamine (DA)-containing neurons was sampled *in vitro* from midbrain slices at the postnatal ages of 1-2 days old, 1-, 2- and 4-weeks old, and from juveniles (approximately 7 weeks old) using standard electrophysiological techniques. The distribution of spontaneously active DA neurons was found to differ in an age-dependent manner. A proportionately greater number of spontaneously active DA neurons was found in both the pars reticulata and pars compacta of midbrain slices from animals 2-weeks-old or less than from slices in juvenile rats. In the slices from animals 2-weeks-old or less there was also a greater proportion of spontaneously active non-DA neurons in both the pars reticulata and pars compacta relative to juveniles. The discharge rate of the nigral DA neurons progressively increased in slices from 1-2 day-old to juvenile animals in an age-dependent manner ( $P < 0.001$ ). The nigral DA neurons from slices older than 2-weeks-old discharged in a very regular pattern characteristic of pacemaker activity. However, as earlier postnatal ages were examined the discharge pattern of DA neurons became progressively less regular. The average coefficient of variation (CV) for interspike intervals of nigral DA neurons from slices less than 2-weeks old was significantly ( $P < 0.001$ ) greater (2x to 6x) than the average CV of DA neurons from older slices. Preliminary evidence suggests that DA neurons from 1-week-old slices have somatodendritic autoreceptors that are less sensitive to the inhibitory effects of DA agonists than those from juvenile animals. These studies suggest that electrophysiological properties intrinsic to DA neurons are still developing during the postnatal period. Supported by MH47857 (DKP).

## 448.6

DIFFERING EFFECTS OF HALOPERIDOL VERSUS MK-801 ON NONLINEAR SEQUENTIAL STRUCTURE OF DOPAMINE NEURON FIRING PATTERNS. R.E. Hoffman\*, W.-X. Shi, B.S. Bunney. Dept. of Psychiatry, Yale Univ. Sch. of Med. New Haven, CT 06520.

The acute effects of systemic haloperidol on deterministic structure of interspike interval (ISI) patterns of dopamine (DA) neurons were studied using an analysis of dynamical complexity. Data consisted in single unit extracellular recordings of A9 and A10 DA neurons in rats anesthetized with chloral hydrate. Haloperidol (5mg/kg) produced increased nonlinear sequential structure of single unit extracellular ISI firing patterns in 6/6 A9 and 5/6 A10 DA neurons. Nonlinear organization is known to enhance flexibility of dynamical systems. Our preliminary investigation of MK-801 (2mg/kg), a drug with psychotomimetic properties, demonstrated an opposite effect, namely reductions in nonlinear firing pattern structure in 5/6 A9 cells. Altered nonlinear structure was not secondary to activation *per se* since both haloperidol and MK-801 increased firing rate of DA cells. Is it possible that antipsychotic effects of haloperidol include enhancement of nonlinear organization and functional flexibility of neural networks incorporating DA cells?

IBOTENIC ACID LESIONS OF THE VENTRAL HIPPOCAMPUS INCREASES THE PROPORTION OF BURSTING MIDBRAIN DOPAMINE NEURONS IN THE A10 AREA OF THE RAT. L. Wang, J. Zhang and D.K. Pitts\*. Dept. of Pharmaceutical Sciences, College of Pharmacy, Wayne State University, Detroit, MI 48202.

An excitotoxic lesion was produced in 6-week-old rats by infusing ibotenic acid into the ventral hippocampus (VH). One experimental group had bilateral microinjections of ibotenic acid (n=18) into the VH while the other had bilateral vehicle (saline; n=16) injections. After a one month recovery period rats were anesthetized with chloral hydrate and prepared for standard *in vivo* extracellular electrophysiological recording. The number of spontaneously active midbrain dopamine (DA) neurons in the A9 and A10 areas was determined within a stereotactically defined block of tissue created by 9 equally separated (200 $\mu\text{m}$ ) electrode tracks per nucleus. No significant treatment-dependent difference in the number of DA neurons per electrode track was found (ANOVA,  $P > 0.20$  for main effects and interaction). A three-way frequency (log-linear) analysis was used to examine the distribution of cells according to three factors: cell type (A9/A10), treatment group (lesion/control) and discharge pattern (bursting/non-bursting). Significant marginal/partial associations were found for the cell type x discharge pattern ( $P < 0.001$ ),  $P < 0.001$ ) and treatment x discharge pattern ( $P < 0.01$ ),  $P < 0.02$ ) interactions. This result indicated that overall there was a greater proportion of bursting neurons in the A10 (75%) vs A9 (59%) cell groups, and that for the A10 cell group, but not the A9 cell group, there was a greater proportion of bursting neurons in lesioned animals (81%) relative to control animals (68%). No significant treatment-dependent differences were found for seven parameters used to describe the pattern displayed by bursting neurons. These results suggest that bilateral VH lesions may increase the proportion of bursting DA neurons associated with the mesolimbic and/or mesocortical DA pathways. Supported by MH47857 (DKP).

## 448.10

PRENATAL ETHANOL EXPOSURE DECREASES THE ELECTRICAL ACTIVITY OF A9 AND A10 DOPAMINE NEURONS IN ADULT RATS. Roh-Yu Shen\*. Cellular and Clinical Neurobiology Program, Department of Psychiatry and Behavioral Neuroscience, Wayne State University School of Medicine, Detroit, MI 48201.

Prenatal ethanol exposure has been observed to alter dopamine (DA) content, turnover, and receptors in the striatum as well as DA receptor-mediated behaviors. Because the function of the midbrain DA systems is related to the electrical activity of DA neurons, we investigated the effect of prenatal ethanol exposure on the electrical activity of DA neurons in the substantia nigra (A9) and ventral tegmental area (A10). Pregnant rats were intubated by 0, 3, or 5 g/kg of ethanol once daily from gestation day 8 - 20. Rats in the *ad lib* group received no intubation. At 2-4 months of age, male offspring from each group were anesthetized with chloral hydrate and the electrical activity of A9 and A10 DA neurons was sampled by extracellular single-unit recording and cells-per-track sampling techniques. There were no differences in the electrical activity of DA neurons between the *ad lib* and 0 g groups in either A9 or A10. In A9, prenatal ethanol treatment decreased the number of spontaneously active DA neurons by 30%. In A10, the numbers of spontaneously active DA neurons were reduced by 25% and 47% in 3 g and 5 g groups respectively. The average firing rates of DA neurons were not changed by prenatal ethanol exposure. These observations suggest that the decreased DA content and turnover in the striatum after prenatal ethanol exposure may result from decreased electrical activity of midbrain DA neurons. The hypofunction in midbrain systems also support the view that the treatment effect of amphetamine-like stimulants on attention problems often observed in fetal alcohol children is due to their ability to increase the release of DA. ## 448.11

CYCLIC AMP-SENSITIVE SUBCONDUCTANCE STATE OF DOPAMINE-MODULATED K<sup>+</sup> CHANNELS ON RAT CAUDATE-PUTAMEN NEURONS. Gabriela J. Greif\*, Yong-Jian Lin, and Jonathan E. Freedman. Dept. Pharmaceutical Sciences, Northeastern Univ., Boston, MA 02115.

We are characterizing the properties of an 85 pS K<sup>+</sup> channel which is modulated by D<sub>2</sub>-like dopamine receptors on freshly dissociated rat corpus striatum neurons, using cell-attached patch-clamp recording. Previous studies indicated that this channel has an absolute requirement for the presence of D<sub>2</sub>-like dopamine agonists within the patch pipette for activation, but can also be activated by the G-protein stimulating peptide mastoparan. Agonists applied outside the cell-attached patch pipette were ineffective at channel activation, arguing against a direct role for a diffusible second messenger in receptor-channel coupling. We now report that the membrane-permeable cyclic AMP analog Sp-cAMPS and the cAMP blocker Rp-cAMPS (each at 100  $\mu$ M) were ineffective at either activating or inhibiting this channel, making it unlikely that changes in cAMP levels mediate this action of D<sub>2</sub> receptors. However, Sp-cAMPS (but not Rp-cAMPS) reduced channel closed time, while increasing channel dwell time in a subconductance state. This implies a more subtle role for cAMP in dopamine receptor signal transduction than previously anticipated, and suggests the existence of another receptor on these cells acting cooperatively with D<sub>2</sub> receptors via the cAMP system. If this other receptor were a D<sub>1</sub> receptor, our results could provide a simple molecular model for D<sub>1</sub>-D<sub>2</sub> receptor cooperativity. (Supported by MH-48545.)

## 448.13

THE FUNCTIONAL PHARMACOLOGY OF D<sub>3</sub> RECEPTORS: SINGLE NEURON ANALYSIS OF THE VENTRAL PALLIDUM. A. Javed\*, F. Rehman, B.A. Heidenreich, E.R. Larson\*, M.A. Ariano\*, and J.C. Napier. Dept. Pharmacol., Loyola Univ. Chicago, Sch. Med., Maywood, IL 60153; and <sup>1</sup>Dept. Neurosci., Univ. of Health Sci./Chicago Med. Sch., North Chicago, IL 60064.

Using polyclonal antibodies selectively generated against unique peptide fragments of the native dopamine (DA) D<sub>3</sub> receptor protein, D<sub>3</sub> receptors were identified in both perikarya and fibers throughout the basal forebrain, including the ventral pallidum (VP). To ascertain if D<sub>3</sub> receptors regulate VP neuronal firing, extracellular single-unit recordings were obtained from >200 neurons in chloral hydrate-anesthetized rats and responses to D<sub>3</sub>-preferring agents were monitored. Intravenous administration of the D<sub>3</sub>-preferring agonist PD128907 (30  $\mu$ g/kg) or 7OHDPAT (0.3-38  $\mu$ g/kg) altered firing in 74% and 56% of the neurons tested, respectively. Both rate increases and decreases were observed. The D<sub>3</sub>-preferring antagonists (+)A776 (0.6 mg/kg) or U99194A (0.14 mg/kg), antagonized these effects in 70% and 73% of the neurons, respectively. In contrast, 0.6 mg/kg of (+)A776 attenuated only 12% of the VP responses to the D<sub>2</sub> agonist, U91356 (30  $\mu$ g/kg); 1.2 mg/kg (+)A776 was less specific, in that this dose antagonized 80% of the responses to 100  $\mu$ g/kg of U91356. To verify that the activated receptors were located within the VP itself, microiontophoresis was used to locally apply DA agonists. Iontophoresis of PD128907 altered firing in 48% of the VP neurons tested. Sixty percent of these were antagonized by 0.6 mg/kg i.v. (+)A776. Responses evoked by PD128907 differed from those evoked by iontophoresis of DA or the D<sub>2</sub>/D<sub>3</sub> agonist quinpirole. These results support an important functional role for the D<sub>3</sub> DA receptor subtype in the regulation of basal forebrain neuronal activity, and demonstrate that at the appropriate concentrations, D<sub>3</sub>-preferring agents can be selective for this receptor subtype. Work made possible by gifts from Upjohn and RBI, and grants MH45180 to TCN and NS23079 to RCH.

## 448.15

MODULATORY ACTION OF DOPAMINE ON STRIATAL AND ACCUMBAL NEURONS: IONTOPHORESIS IN AWAKE, UNRESTRAINED RATS. G. V. Rebec\* and E. A. Kiyatkin. Prog. in Neural Science, Dept. Psychology, Indiana University, Bloomington, IN 47405.

Although monitoring dopamine (DA) neuronal activity or fluctuations in terminal DA release may help identify the role of the DA system in goal-directed behavior, it is equally important to know the effects of released DA on its targets under natural conditions. To assess this issue, single-unit recording was combined with iontophoresis to study the effects of DA and glutamate (Glu) on spontaneous impulse activity in the striatum and nucleus accumbens in awake, unrestrained rats.

Approximately half of the recorded striatal and accumbal cells were inhibited by a brief DA application (20-30 s) at low ejection currents (10-30 nA). Although small in magnitude, this effect occurred with short onset and offset latencies and was dependent upon basal impulse activity and ongoing behavior. The DA-induced inhibition was attenuated or disappeared entirely when neurons were physically activated during spontaneous motor behavior. Prolonged DA application (120-180 s) not only inhibited basal impulse activity but enhanced the signal-to-noise ratio of Glu responses. In most cases, this DA-induced enhancement was associated with a depression of both basal impulse activity and Glu responses (40%), an inhibition of basal impulse activity only (37%), or with a slight increase in Glu-response magnitude (23%). The enhancing effect was maximal at relatively low DA ejection currents (10-30 nA), on cells with moderate rate of basal impulse activity, which had an initially small and moderate magnitude of Glu responses. Because Glu afferents appear to provide the major excitatory input to striatal and accumbal cells from widespread areas of cerebral cortex, a DA-induced modulation of Glu responses may serve as a mechanism for enhancing the transmission of a wide range of behaviorally significant information.

## 448.12

D<sub>2</sub> DOPAMINE-MODULATED K<sup>+</sup> CHANNEL EXPRESSION ON RAT STRIATOPALLIDAL AND STRIATONIGRAL NEURONS. Lynn P. Martin\*, Gabriela J. Greif, Jonathan E. Freedman and Barbara L. Waszczak. Dept. Pharmaceutical Sciences, Northeastern Univ., Boston, MA 02115.

Medium spiny neurons of the caudate-putamen can be classified as projecting to either the globus pallidus or the substantia nigra. The distribution of D<sub>1</sub>-like and D<sub>2</sub>-like dopamine receptors between these two cell populations is a matter of controversy. We have previously used cell-attached patch-clamp recording to describe an 85 pS K<sup>+</sup> channel which is modulated by D<sub>2</sub>-like dopamine receptors on a subpopulation of freshly dissociated rat corpus striatum neurons. This channel was observed in about half of patches from cells with a characteristic shape, which were immunoreactive for neuron-specific enolase and for GABA. We are now using retrograde labeling with fluorescent latex microspheres in order to identify projection neurons during our electrophysiological recordings. We found that the 85 pS channel was expressed in a significant proportion of recordings from neurons projecting to the globus pallidus, demonstrating the presence of this channel on medium spiny neurons, and consistent with some models of D<sub>1</sub>-D<sub>2</sub> receptor distribution. There were often multiple channels per patch when present. We are currently assessing whether the D<sub>2</sub>-modulated K<sup>+</sup> channel is also expressed on neurons projecting to the substantia nigra.

ELECTROPHYSIOLOGICAL EVIDENCE ASSOCIATING LIMBIC PREFERENCE WITH PRAMIPEXOLE, A D<sub>2</sub>-PREFERRING DOPAMINE AGONIST. W.E. Hoffmann, M.W. Smith, D.K. Hyslop\*, and M.F. Piercey. The Upjohn Company, Kalamazoo, MI 49001.

*In situ* mRNA hybridization experiments suggest a preferential distribution of D<sub>2</sub> receptors in the mesolimbic dopaminergic (DA) pathways (Bouthenet *et al.*, Br Res 564:203, 1991). Pramipexole (PPx), a D<sub>2</sub>-preferring DA agonist, was evaluated for its effects on firing of neurons in substantia nigra pars compacta (SNPC), ventral tegmental area (VTA), substantia nigra pars reticulata (SNPR) and nucleus accumbens (NA). PPx was equipotent in inhibiting SNPC and mesolimbic VTA DA neurons. PPx effects were antagonized by haloperidol, a D<sub>2</sub>-preferring DA antagonist (Sokoloff *et al.*, Nature 347:146, 1990) and U-99194A, a D<sub>2</sub> dopamine antagonist (Waters *et al.*, J. Neural Transm 94:11, 1993). In SNPC, U-99194A was more potent in antagonizing PPx than in blocking U-91356A, a D<sub>2</sub>-preferring DA agonist. In SNPR, the output target of striatal efferents, PPx inhibited approximately half the cells; a few were stimulated. PPx doses required in SNPR were much larger than those required in SNPC. Even large doses of haloperidol only partially reversed PPx inhibitions in SNPR. However, U-99194A was as potent in reversing PPx inhibitions in SNPR as it was in SNPC. In the NA, PPx again inhibited about half the cells, although approximately 20% were stimulated. PPx was more potent in depressing NA neurons than in depressing SNPR neurons; potencies for depressing NA approximated those for depressing VTA. U-99194A tended to more commonly antagonize PPx inhibitory effects than did haloperidol. Overall, the data suggest that pramipexole has a mesolimbic preference and exerts most of its biological effects via the D<sub>2</sub> receptor.

## 448.16

DIHREXIDINE DEMONSTRATES FUNCTIONAL SELECTIVITY AT D<sub>2</sub> DOPAMINE RECEPTOR MEDIATED PROCESSES. H.P. Smith<sup>1</sup>\*, G.S. Oxford<sup>1</sup>, D.E. Nichols<sup>2</sup>, R.B. Mailman<sup>1</sup> and C.P. Lawler<sup>1</sup>. Univ. of North Carolina<sup>1</sup>, Chapel Hill, NC 27599, and Purdue Univ.<sup>2</sup>, W. Lafayette, IN 47907.

Dihydroxidine (DHX), a member of the novel hexahydrobenzo[a]phenanthridine dopamine agonists, is best known as a full intrinsic activity D<sub>1</sub> agonist (Mottola *et al.*, 1992) that has potent antiparkinsonian effects in MPTP-treated primates (Taylor *et al.*, 1991). Although ten-fold D<sub>1</sub> selective, DHX also has high affinity for the D<sub>2</sub> receptor (K<sub>D</sub> 80 nM), yet its functional profile is unusual: In all assays that represent functions mediated by "postsynaptic" D<sub>2</sub> receptors (e.g., inhibition of adenylyl cyclase activity in striatal slices), DHX demonstrates clear agonist activity. Conversely, in D<sub>2</sub>-mediated "presynaptic" functions (e.g., inhibition of nigral cell firing, or inhibition of dopamine synthesis or release), DHX is inactive even though it binds with similar affinity to both pre- and post-synaptic receptors. Despite this unusual functional profile, DHX apparently binds equally well to both pre- and post-synaptic receptors. Thus, we hypothesized that the functional selectivity of DHX at D<sub>2</sub> receptors may depend on the nature of the transduction mechanism (e.g., D<sub>2</sub> coupled cyclase vs. D<sub>2</sub> mediated opening of inwardly-rectifying potassium ion channels). This hypothesis was tested by performing full DHX dose-response experiments using both whole-cell and perforated patch clamp methods in single pituitary lactotrophs *in vitro*. Compared to dopamine, DHX demonstrates only partial agonist efficacy to elicit potassium currents, with a peak current value only one-fourth that of dopamine. As with dopamine, this response is specifically blocked by the selective D<sub>2</sub> antagonist (-)-sulpiride (30  $\mu$ M). The combination of DHX plus dopamine results in a significant decrease in the current caused by dopamine alone, consistent with the idea that the drugs are competing for the same receptor. If DHX inhibits cAMP synthesis in these cells as it does in striatum, it would provide a mechanistic explanation for the unusual functional discrimination of this class of agonists.

## 448.17

ACTIVATION OF DARPP-32, AN INHIBITOR OF PROTEIN PHOSPHATASE 1, MODULATES THE VOLTAGE-GATED SODIUM CURRENT IN STRIATAL NEURONS. S.N. Schiffmann<sup>1</sup>, P.-M. Lledo<sup>2</sup>, F. Desdouis<sup>3</sup>, P. Greengard<sup>4</sup>, J.J. Vanderhaghen<sup>1</sup>, J.-D. Vincent<sup>2</sup> & J.-A. Girault<sup>3</sup> (Brain Research Unit, ULB, Brussels, Belgium, <sup>2</sup>Inst. A. Fessard, CNRS, Gif-sur-Yvette, France, <sup>3</sup>INSERM U114, Paris, France, <sup>4</sup>Rockefeller University, NY, NY, USA)

Dopamine D1 receptor stimulation reduces sodium current ( $I_{Na}$ ) by promoting activation of cAMP-dependent protein kinase (PKA) in striatal neurons which results in a reduction of neuronal excitability (Schiffmann *et al.*, J. Physiol. 483:95-107, 1995). From these results, we concluded that direct phosphorylation of voltage-gated sodium channels by PKA leads to this reduction. It seems possible that phosphorylation of DARPP-32 (dopamine- and cAMP-regulated phosphoprotein, Mr = 32000) by PKA in response to D1 receptor stimulation might result in a similar effect through its inhibition of protein phosphatase 1 (PP1) and therefore the stabilization of phosphorylated states of the sodium channels. Therefore, we used whole-cell patch-clamp recordings of striatal neurons to study the effect of phospho-DARPP-32 and dephospho-DARPP-32 on  $I_{Na}$ . Phospho- or non-phospho- recombinant DARPP-32 (0.5 mg/ml) was loaded into the cytosol of neurons by simple diffusion from the pipette solution. Loading of phospho-DARPP-32 resulted in a time-dependent decrease in  $I_{Na}$  ( $19.2 \pm 3.0\%$ , mean  $\pm$  S.E.M.) whilst dephospho-DARPP-32 did not significantly reduce  $I_{Na}$  ( $3.7 \pm 1.3\%$ ). To ascertain whether this effect may result from an inhibition of PP1 activity, okadaic acid (1  $\mu$ M) was similarly loaded into striatal neurons and this led to a significant decrease of  $I_{Na}$  ( $23.1 \pm 2.9\%$ ) as compared to a control solution ( $3.6 \pm 0.7\%$ ). We therefore propose that, in striatal neurons, phospho-DARPP-32 reduces sodium current by inhibiting dephosphorylation of voltage-gated sodium channels and that this contributes to the regulation of these channels by D1 receptors.

## RECEPTOR MODULATION, UP- AND DOWN-REGULATION II

## 449.1

ADENOSINE A2a RECEPTORS SELECTIVELY AND ANTAGONISTICALLY REGULATE DOPAMINE D2 (LONG-FORM) RECEPTORS IN STABLY COTRANFECTED FIBROBLAST CELLS. S. Ferré<sup>\*</sup>, S. Dasgupta, S.-N. Yang, P. B. Hedlund, U.-B. Finnman, S. Ahlberg, E. Arenas, B. B. Fredholm and K. Fuxe, Department of Neuroscience, Karolinska Institute, Stockholm.

In membrane preparations from rat striatum, where adenosine A2a and dopamine D2 receptors are coexpressed, stimulation of A2a receptors was found to decrease the affinity of D2 receptors. We now demonstrate the existence of this antagonistic interaction at the cellular level, by using a fibroblast cell line stably transfected with the human D2 (long-form) and the dog A2a receptors. Stimulation of A2a receptors with the selective A2a agonist CGS 21680 decreased the affinity of D2 receptors 2-3 fold, as shown in competition experiments with dopamine versus the selective D2 antagonist [3H]raclopride. CGS 21680 was however ineffective in control cells expressing D2 but not A2a receptors. The effect of CGS 21680 was counteracted by the adenosine antagonist 8-phenyltheophylline and was independent of the effect of the GTP analogue Gpp(NH)p suggesting that a GTP-independent mechanism mediates this A2a-D2 receptor interaction. In cotransfected cells both A2a and D2 receptors were found to be coupled to adenylate cyclase. CGS 21680 induced a small but significant increase and dopamine induced a significant decrease of cAMP accumulation. In control cells forskolin did not induce any change in the binding characteristics of D2 receptors. Furthermore, activation of the constitutively expressed A2b receptors with the non-selective adenosine agonist NECA, which also induced a high cAMP accumulation, did not modify dopamine D2 binding. Therefore, the A2a-induced modulation of D2 receptor affinity seems to be independent of adenylate cyclase activation. With calcium image analysis experiments a functional A2a-D2 interaction was also demonstrated in cotransfected cells. CGS 21680 was found to counteract the increase in intracellular calcium levels mediated by the selective D2 agonist quinpirole.

## 449.3

REGULATION OF A1 ADENOSINE RECEPTOR EXPRESSION IN CEREBELLAR GRANULE CELLS AFFECTS SENSITIVITY TO ADENOSINE ANALOG-INDUCED INHIBITION OF ADENYLYL CYCLASE. B.D. Hettinger-Smith<sup>\*</sup>, M. Leid and T.F. Murray, College of Pharmacy, Oregon State University, Corvallis, OR 97331.

Adenosine acts as a neuromodulator in the central nervous system via its actions at A1, A2a, A2b, and A3 adenosine receptors which belong to the superfamily of G protein coupled receptors. The A1 adenosine receptor (A1AR) is antagonized by caffeine and related methylxanthines and is coupled to the inhibition of adenylyl cyclase. Chronic exposure to caffeine leads to a tolerance to its stimulatory effects and the basis of this tolerance may, in part, be due to an upregulation of A1AR. Primary cultures of cerebellar granule cells from 8 day old Sprague Dawley rat pups were established and used to study A1AR regulation in response to chronic exposure to agonists and antagonists. In addition, the sensitivity of adenylyl cyclase to A1AR agonist-induced inhibition was assessed. A 72-hour treatment of cultures with the A1AR agonist, cyclopentyladenosine (CPA) resulted in a decreased Bmax with no change in receptor affinity as measured by saturation binding of [3H]dipropylcyclopentylxanthine (DPCPX, an A1 selective antagonist) in cerebellar granule cell membranes. Down regulation could also be demonstrated in whole cell binding experiments. Desensitization of the CPA-induced decrease in adenylyl cyclase activity accompanied this down regulation of A1AR. Chronic antagonism of A1AR by caffeine or 8-para-sulphophenyltheophylline (8-pSPT) resulted in an increased Bmax with no change in affinity of A1AR; a sensitization to CPA-induced decrease in adenylyl cyclase activity accompanied this upregulation. Parallel A1AR regulation studies in P19 cells stably transfected with A1AR have been performed. (Supported by NIDA grant F31 DA05631-01 to BHS).

## 449.2

STIMULATION OF ADENOSINE A<sub>2</sub> RECEPTORS INDUCES FOS-LIKE IMMUNOREACTIVITY PREFERENTIALLY IN THE NUCLEUS ACCUMBENS: POSSIBLE ANTIPSYCHOTIC EFFECTS. M. Morelli<sup>\*</sup>, A. Pinna, J. Wardas<sup>\*</sup>, Dpt. Toxicology, Univ. of Cagliari, Italy <sup>\*</sup> Inst. Pharmac. Polish Acad. Science, Cracow, Poland.

Administration of typical neuroleptics like haloperidol is known to induce Fos-like immunoreactivity (FLI) in several rat brain areas including the nucleus accumbens and the striatum, while atypical neuroleptics like clozapine induced FLI in the nucleus accumbens but not in the striatum. It was therefore proposed that the different clinical profile of haloperidol and clozapine might be related to their different targets in the brain (Robertson and Fibiger, 1992). Adenosine A<sub>2</sub> receptor agonists, like neuroleptics, antagonize the motor hyperactivity induced by dopamine agonists, moreover A<sub>2</sub> receptors are strictly localized in areas rich of dopamine innervation like the striatum, nucleus accumbens and olfactory tubercle. Here we show that administration of the selective A<sub>2</sub> agonist CGS 21680 dose-dependently (5-20 mg/kg s.c.) induced FLI in the shell of rat nucleus accumbens while even at the higher dose used, no FLI was observed in the core of the nucleus accumbens and in the striatum. CGS 21680-induced FLI was abolished by a 6-hydroxydopamine lesion of the medial-forebrain-bundle and by stimulation of dopamine D2 receptors. The results suggest that A<sub>2</sub> receptor agonists, like atypical neuroleptics, might have antipsychotic effects without producing extrapyramidal side effects.

## 449.4

REGULATION OF TYPE-1 AND TYPE-2 ANGIOTENSIN II RECEPTOR mRNA DURING DIFFERENTIATION OF NG108-15 NEUROBLASTOMA CELLS. W.R. Schchman, S.G. Soltyz, J.L. Kurth, R.L. Berdeaux and J.A. Weyhenmeyer<sup>\*</sup>, Dept. of Cell and Structural Biology, University of Illinois, Urbana, IL, 61801.

The murine neuroblastoma x glioma NG108-15 cell line possesses both AT<sub>1</sub> and AT<sub>2</sub> angiotensin II (AngII) receptor subtypes. We have previously shown that AT<sub>1</sub> and AT<sub>2</sub> binding is increased following DMSO differentiation of NG108-15 cells. Binding studies performed on membranes from undifferentiated and differentiated (maintained in medium containing 1.5% DMSO and 0.5% FBS for 4 days) NG108-15 cells revealed a single K<sub>D</sub> of  $0.64 \pm 0.12$  nM, and B<sub>max</sub> of  $26.8 \pm 0.12$  fmol/mg protein and  $607 \pm 139$  fmol/mg protein, respectively. Further, undifferentiated cells predominantly express the AT<sub>1</sub> receptor subtype, while differentiated cells contain a majority of AT<sub>2</sub> receptors suggesting that AT receptors play a role in neuronal growth and differentiation. In the present studies, we investigated the regulation of AT<sub>1</sub> and AT<sub>2</sub> mRNA during DMSO differentiation of NG108 cells. Northern blot analysis was used to determine AT<sub>2</sub> mRNA levels in cells treated from 0-4 days. AT<sub>2</sub> levels increased threefold from 0 to 2 days of treatment. Transcript levels then remained relatively constant between days 2-4. To examine AT<sub>1</sub> mRNA levels, a competitive PCR method was used. Preliminary data suggests that AT<sub>1</sub> mRNA is also increased during DMSO differentiation; however, an exact time-course has not been established. Taken together, these findings suggest that the increase in AT binding during differentiation is due to *de novo* transcription and, presumably, translation. (Supported by NSF, W.R.S. is supported by an American Heart Association Student Stipend).

**REPEATED POSTNATAL PCP EXPOSURE DOES NOT ALTER SIGMA RECEPTOR BINDING IN RAT CEREBELLUM** C.-S. Li, H.-J. He\* and R. Sircar. Laboratory for Developmental Neuroscience, Departments of Psychiatry and Neurology, Albert Einstein College of Medicine, Bronx, New York.

We have earlier demonstrated that postnatal PCP treatment in rats produce long-term changes in seizure susceptibility. Although PCP binds to specific brain PCP receptor, at high concentrations it is known to interact with a large number of molecular target sites -  $\sigma$  binding site, monoamine uptake sites,  $K^+$  channel, acetylcholine receptor,  $\gamma$ -aminobutyric acid (GABA) regulated chloride channel. To test the hypothesis that the behavioral effects of postnatal PCP exposure are mediated via the sigma receptor, we carried out experiments to measure sigma receptor binding in postnatal PCP-treated rats and compared the data from those obtained from saline-treated controls. Rat pups were treated with PCP (5 mg/kg/day) for 11 days from postnatal days 5 to 15, intraperitoneally. Control pups received equivalent volume of saline. On postnatal day 21, groups of saline- and PCP-treated rats were sacrificed, their brains removed, dissected and cerebellum immediately frozen. [ $^3H$ ](+) pentazocine binding was measured in drug-treated and control rat cerebellum. Saturation analyses of the binding data showed no significant difference in any of the binding characteristics between chronic PCP-treated rats and saline-treated controls suggesting that mechanisms other than alterations in  $\sigma_1$  binding underlie the behavioral effects of repeated postnatal PCP administration in immature rats.

## 449.7

**MECHANISM OF HISTAMINE  $H_2$  RECEPTOR DOWNREGULATION IN CHINESE HAMSTER OVARY CELLS** E. Roovers, M.J. Smit\*, J. Blauw, A. Alewijnse, H. Timmerman, and R. Leurs. Leiden/Amsterdam Center for Drug Research, Department of Pharmacochimistry, De Boelelaan 1083, 1081 HV Amsterdam, The Netherlands.

Under several pathophysiological conditions, where histamine is released in large quantities, or during treatment with histaminergic drugs in various disorders, regulatory processes such as desensitization and downregulation may become apparent.

Exposure of Chinese Hamster Ovary cells (CHO) expressing the histamine  $H_2$  receptor to histamine leads to a dose dependent and time dependent decrease in the number of cell surface receptors (up to 44% reduction after 24 hours of exposure) without affecting receptor affinity. RNA slot blotting hybridization analysis was used to evaluate the levels of receptor mRNA. Stimulation of the cells with histamine caused a rapid decrease in histamine  $H_2$  receptor mRNA levels (up to 80% reduction within 4 hours), which is due, at least partly, to an increased turnover of the transcript. Stimulation with forskolin also induced downregulation of the  $H_2$  receptor and its mRNA in a manner similar to the histamine-induced downregulation. This suggests the involvement of protein kinase A in  $H_2$  receptor downregulation. Yet, stimulation of a mutant  $H_2$  receptor with a truncated C-terminus displacing normal adenylyl cyclase activity, was even more susceptible to histamine-induced downregulation than the wild type receptor. This suggests that an other signaling pathway is involved in  $H_2$  receptor downregulation.

To investigate whether this alternative pathway is G-protein dependent or independent, we are currently in the process of generating receptor mutants that are unable to couple to G-proteins.

## 449.9

**THE SYNTHESIS AND BIOLOGICAL ACTIVITY OF A NOVEL CLASS OF ANTAGONISTS FOR THE BRAIN CB1 CANNABINOID RECEPTOR** K. Fahey, M. Chaney, G. Cullinan, D. Hunden, D. Johnson, G. Koppel\*. Lilly Research Laboratories, CNS & Endocrine Divisions, Indianapolis, IN 46285. C.C. Felder<sup>1</sup>, K.E. Joyce<sup>1</sup>, E.M. Briley<sup>1</sup>, K. Mackie<sup>2</sup>, J.N. Crawley<sup>2</sup>, B.R. Martin<sup>4</sup>, M.J. Brownstein<sup>1</sup>. <sup>1</sup>Laboratory of Cell Biology, National Institute of Mental Health, National Institutes of Health, Bethesda, MD 20892. <sup>2</sup>Section on Behavioral Neuropharmacology, National Institute of Mental Health, Bethesda, MD 20892. <sup>3</sup>Department of Physiology and Anesthesiology, University of Washington, Seattle, WA 98195. <sup>4</sup>Department of Pharmacology and Toxicology, Medical College of Virginia, Richmond, VA 23298-0613.

A new structural series of compounds were synthesized and their binding affinities to the brain CB1 receptor were determined. In addition, their ability to functionally antagonize the anandamide mediated adenylyl cyclase inhibition in CHO cells stably expressing the CB1 receptor were evaluated. The lead compound in the series, LY320135, is a selective antagonist for the brain CB1 receptor, having a 16 fold higher affinity for the CB1 compared to the peripheral CB2 receptor. The  $K_i$  values for LY320135 at the CB1 and CB2 receptors, transfected and stably expressed in cell lines, was 203 nM and 3340 nM, respectively. Similar  $K_i$  values were measured in binding studies performed on cerebellum and spleen membrane preparations endogenously expressing the CB1(204 nM) and CB2(>1  $\mu$ M) receptors, respectively. Finally, molecular modeling comparisons with other selective CB1 binding substrates have been completed. LY320135, also, potentially reversed cannabinoid-mediated modulation of  $K^+$  and  $Ca^{2+}$  currents.

**CHRONIC NEONATAL PCP DIFFERENTIALLY REGULATES mRNA LEVELS FOR NMDA RECEPTOR SUBUNITS** R. Sircar\*, P. Collesse, M.K. Ticku. Laboratory for Developmental Neuroscience, Departments of Psychiatry and Neurology, Albert Einstein College of Medicine, Bronx, New York; \*Department of Pharmacology, University of Texas Health Science Center, San Antonio.

The NMDA receptor has been implicated in developmental plasticity. We have earlier demonstrated that postnatal PCP treatment in rats produce long-term changes in seizure susceptibility. In Day 21 rats, [ $^3H$ ]MK-801 binding was decreased in selective brain areas. To test the hypothesis that this selective decrease in [ $^3H$ ]MK-801 binding is due to the downregulation of NMDA receptor subunits, NMDAR1, NMDAR2A-C mRNA levels in specific brain regions in PCP-treated and control rats were measured. Rat pups were treated with PCP (5 mg/kg/day) for 11 days from postnatal days 5 to 15, intraperitoneally. Control pups received saline (1 ml/100 g). On postnatal day 21, groups of saline- and PCP-treated rats were sacrificed, their brains removed, dissected and brain regions immediately frozen. Using the RNase protection assay we compared the levels of different NMDAR subunit mRNAs in postnatal PCP-treated rat brain with those from saline-treated controls. Our results indicate, that in both male and female PCP-treated pups mRNA encoding for NMDAR2B subunit was selectively reduced in the frontal cortex. There was no significant effect on the NMDAR1 subunit levels in the hippocampus, striatum and frontal cortex. Also, we did not find any change in the NMDAR2A or 2C levels in any of the regions studied. These results suggest that the decrease in [ $^3H$ ]MK-801 binding in the frontal cortex seen in neonatal PCP-treated rats is associated with the downregulation of the gene encoding for specific NMDAR subunits.

**REGULATION OF THE HUMAN  $H_1$  HISTAMINE RECEPTOR IN HeLa CELLS AND IN STABLY TRANSFECTED CHO-K1 CELLS** Steven J. Max\* and Claire M. Fraser. Department of Cellular and Molecular Biology, The Institute for Genomic Research, 932 Clopper Road, Gaithersburg, MD 20878.

A gene encoding the human  $H_1$  histamine receptor was recently cloned from a human genomic library prepared from blood leukocytes. The coding region was cloned into the mammalian expression vector, pcDNA3, and transfected into CHO-K1 cells. Membranes prepared from the transfected cells specifically bound the radioligand [ $^3H$ ]-pyrilamine with a  $K_d$  of 0.6 nM and  $B_{max}$  values ranging from 150-1800 fmol/mg protein. A stably transfected CHO clone expressing the  $H_1$  receptor (CHO/ $H_1$ R) at a density of 150 fmol/mg protein was selected and compared to human HeLa cells which endogenously express the  $H_1$  receptor at a similar level. Exposure to the agonist histamine resulted in a dose-dependent increase in inositol phosphates production with an  $EC_{50}$  of 0.75  $\mu$ M. The maximum response in the HeLa cell line was 5-fold, whereas, in CHO/ $H_1$ R cells, the maximum response was 2-fold. Pretreatment of the cells with 1 mM histamine for 30 min resulted in a 50 percent reduction in the maximal response in the transfected CHO line, while the maximal response in the HeLa cells was reduced to basal levels. Long-term exposure (24 hrs) of HeLa cells and CHO/ $H_1$ R cells to histamine in the presence of 0.2 mM sodium metabisulfite resulted in 80 percent and 60 percent decreases, respectively, in the density of binding sites for [ $^3H$ ]-pyrilamine as compared to untreated cells. A ribonuclease protection assay employing an  $H_1$ -specific 32P-antisense RNA probe was used to evaluate the levels of receptor mRNA in histamine-treated vs. control HeLa cells. There appeared to be a significant decrease (65 percent) in steady-state levels of  $H_1$  receptor mRNA in the treated HeLa cells. Overall, these results indicate that although CHO/ $H_1$ R cells express a functional protein, they are coupled to second messenger systems less efficiently than the naturally expressed receptor in HeLa cells. Furthermore,  $H_1$  histamine receptor down-regulation may be due, in part, to changes in mRNA levels.

## 449.10

**NEUROTROPHIN AND RETINOID REGULATION OF NEURONAL B<sub>2</sub> BRADYKININ RECEPTOR EXPRESSION IN DEFINED AFFINITY FORMS** Y.-J. I. Jong and N. L. Baenziger\*. Dept. of Anatomy and Neurobiology, Washington Univ., St. Louis, MO 63110.

We have defined regulation of expression of B<sub>2</sub> subtype receptors for the neuropeptide bradykinin (BK) upon differentiation of human and rat neuronal cell lines. In SH-SY5Y neuroblastoma and PC12 pheochromocytoma cells we identify B<sub>2</sub> receptors equivalent to and recognized by MABs selective for Intermediate (I,  $K_d$  5.6 nM) and Low (L,  $K_d$  42 nM) affinity B<sub>2</sub> receptor forms in human lung fibroblasts (Jong et al, Proc Natl. Acad. Sci. 90:10994,1994). Receptors of 78-82 kDa comparable to the human fibroblast receptors are immunoprecipitated from detergent lysates of neuronal cells with I and L form specific MAbs, and [ $^3H$ ]-BK binding reveals 2 sites with respective  $K_d$  values of 3 nM and 55 nM, corresponding to known *in vivo* BK levels. A 2- to 3-fold induction of BK receptors accompanies neuronal differentiation by NGF and retinoic acid (RA), in a cell- and context-specific manner. In PC12 cells only the I form is enhanced: L form expression remains unchanged from its initial constitutive levels. In SH-SY5Y cells both I and L forms increase upon neuronal differentiation. The time course of BK receptor augmentation relative to neurite outgrowth also differs in the 2 cell lines. It directly matches the pace of neurite outgrowth in PC12. However it precedes the bulk of neurite outgrowth in SH-SY5Y; augmented expression is minimal at 7-17 hr of differentiation, then increases sharply to maximal levels from 17-24 hr, whereas neurite outgrowth is maximal at 72-96 hr. Induction thus represents a mechanism of cross-talk between the BK branch of the G-protein-coupled receptor family, the Trk family of membrane Tyr kinase receptors, and the RA family of cytosolic translocating - nuclear receptors which exert their activity at the transcriptional level. BK receptor induction by NGF and RA in SH-SY5Y cells is not additive, indicating that NGF and RA actions both funnel into a final common pathway governing BK receptor expression.

AGONIST-INDUCED DESENSITIZATION OF  $P_2U$  PURINOCEPTORS. S.M. Sromek\*, E.R. Lazarowski† and T.K. Harden†. Curr. of Neurobiology\* and Dept. of Pharmacology†, Univ. of North Carolina, Chapel Hill NC 27599.

The  $P_2U$  purinergic receptor is a 377 amino acid G protein-coupled receptor which is activated by ATP and UTP and stimulates phospholipase C (PLC). Preincubation of CF/T43 human airway epithelial cells with  $P_2U$  receptor agonists results in desensitization, i.e. uncoupling of the receptor from PLC activation. Recovery of agonist-promoted PLC response is rapid (<10 min) after drug washout. When stably expressed in 1321N1 human astrocytoma cells, the human  $P_2U$  receptor displays a similar pharmacological profile for PLC activation compared with CF/T43 cells, although agonists are 30- to 100-fold more potent than with the natively expressed receptor. Pretreatment of  $P_2U$ -1321N1 cells with agonist for 8 h results in a decrease in apparent potency of agonists without decreasing the maximal effect on PLC.

An epitope-tagged  $P_2U$  receptor has been created by addition of 9 amino acids at the amino terminus. This receptor is currently being expressed in 1321N1 cells to determine the fidelity with which this receptor reflects the signalling properties of the native receptor. The tagged receptor will be utilized to study the role of receptor trafficking in  $P_2U$  purinoceptor desensitization and resensitization.

## 449.13

DOPAMINE AND 5-HT MODULATION OF SYNAPTIC TRANSMISSION IN THE LAMPREY SPINAL CORD. M. Wikström, A. El Manira, W. Zhang, R.H. Hill and S. Grillner\*. Nobel Institute for Neurophysiology, Department of Neuroscience, Karolinska Institute, S - 171 77 Stockholm, Sweden

Using the lamprey spinal cord *in vitro* preparation we have investigated the effects of 5-HT on the synaptic transmission from primary sensory neurons to relay giant interneurons as well as the effects of dopamine (DA) on the reticulospinal input to the spinal cord. Both 5-HT and DA are important modulatory transmitters in the lamprey spinal cord. To a large degree these transmitters act in a complementary fashion on the cellular and locomotor network levels. DA and 5-HT are colocalized and co-released from a ventromedial plexus (Schotland et al. *Nature* 374, 266-269, 1995). 5-HT immunoreactive fibers (without DA-ir) are also present in the dorsal column and dorsolateral areas. Application of 5-HT depressed the glutamatergic monosynaptic excitatory postsynaptic potentials (EPSP) recorded in giant interneurons which were evoked by stimulation of the dorsal column or the dorsal roots. 5-HT had no effect on the input resistance of giant interneurons, suggesting that 5-HT acts presynaptically on sensory axons to depress synaptic transmission. 5-HT has a similar effect at synapses between reticulospinal axons and motoneurons in the ventral spinal cord which are located close to the 5-HT/DA plexus (Buchanan and Grillner. *Neurosci. Lett.* 112, 71-74, 1991; Shupliakov et al. *Eur. J. Neurosci.* in press). DA also modulates synaptic efficacy between reticulospinal axons and spinal neurons. The amplitude of monosynaptic postsynaptic potentials (PSP) evoked by stimulation of reticulospinal axons is reduced upon application of DA. The effect is considered to be presynaptic as no significant change in input resistance occurs in the target cells. The selective  $D_2$  receptor agonist  $R(-)-2,10,11$ -Trihydroxy-N-propyl-noraporphine HBr mimicked the effects mediated by DA. DA reduces calcium-currents in spinal neurons through activation of dopamine  $D_2$  receptors which might be a mechanism through which transmitter release is modulated also at the presynaptic terminal. DA and 5-HT thus both act to reduce glutamatergic synaptic transmission from reticulospinal axons.

## 449.15

CORTICAL NMDA RECEPTOR LEVELS ARE INCREASED IN ADULT RATS FOLLOWING NEONATAL EXCITOTOXIC LESIONS OF THE VENTRAL HIPPOCAMPUS. Z. Albo, G. Flores, D. Barbeau, R. Quirion and L.K. Srivastava\*. Douglas Hospital Research Center, Departments of Psychiatry, and Pharmacology and Therapeutics, McGill University, Montreal, Quebec, Canada, H4H 1R3.

Neonatal bilateral excitotoxic lesion of the ventral hippocampus in rats results in hyperlocomotor behavior induced by dopamine agonists, and hyperresponsiveness to stress-induced behaviors in adult animals (Lipska et al. *Neuropsychopharm.* 9:67, 1993). These neonatally hippocampal-lesioned rats have accordingly been proposed as an animal model of schizophrenia. Glutamate plays a prominent role in locomotor behavior and has been implicated in schizophrenia (Ellison, *Brain Res. Rev.* 23:250, 1995). We have compared the level of N-methyl-D-aspartate (NMDA) receptors in cortical areas, striatum and nucleus accumbens of rats that underwent either bilateral ibotenic acid lesions or sham-lesion of the ventral hippocampus at postnatal day 7 (PD7). Hippocampal-lesioned rats at PD56 but not PD35, showed increased locomotor activities induced by swim-stress or exposure to a novel environment, as well as after D-amphetamine or apomorphine injections. The density of NMDA receptors as measured by ligand autoradiography using [<sup>125</sup>I]MK801 (200pM), was found to be significantly increased in the inner layers of frontal and cingulate cortices at PD62 in the hippocampal-lesioned group compared to the sham-lesioned controls of same age. No significant difference in binding was observed between sham and lesioned groups at PD41. Other brain areas studied showed no significant change in [<sup>125</sup>I]MK801 binding between the two groups. The results suggest that alterations in the levels of cortical NMDA receptors could underlie some of the behavioral changes at adulthood observed in neonatally hippocampal-lesioned rats. ## 449.12

CARBAMAZEPINE ACTS THROUGH THE PERIPHERAL BENZODIAZEPINE RECEPTOR TO UP-REGULATE  $\beta$ -ADRENERGIC RECEPTOR mRNA.

C. Hough\*, D.-M. Chuang Section on Molecular Neurobiology, Biological Psychiatry Branch, NIMH Bethesda, MD 20892

We have previously shown that chronic treatment (6 days) of C6 glioma cells with carbamazepine (CBZ) causes a time- and concentration-dependent increase in the expression of  $\beta$ -adrenergic receptor ( $\beta$ -AR) protein and mRNA. To determine the mechanism of this up-regulation, we investigated the possibility that CBZ acts at the peripheral benzodiazepine receptor to change  $\beta$ -AR mRNA levels. C6 glioma cells were treated for 7 days with ligands of the peripheral benzodiazepine receptor, PK 11195, RO 5-4864, and FGIN 1-27, at concentrations ranging from 1 nM to 10  $\mu$ M. All three ligands caused concentration-dependent increases in levels of both  $\beta_1$ - and  $\beta_2$ -AR mRNA at concentrations between 1 and 100 nM. Above this, the effect of the ligands to cause  $\beta$ -AR mRNA up-regulation diminished in a concentration-dependent manner. The addition of 50  $\mu$ M CBZ to these same treatments antagonized the up-regulation of  $\beta$ -AR mRNA at low concentrations of ligand and potentiated the diminution of their effect at high concentrations. There were some differences in the effects of CBZ and the peripheral benzodiazepine ligands on  $\beta_1$ - and  $\beta_2$ -AR mRNA levels. Simultaneously, CBZ displayed a clear ability to alter the level of  $\beta$ -AR mRNA on its own. These results suggest that CBZ acts as a partial agonist at the peripheral benzodiazepine receptor to cause  $\beta$ -AR mRNA up-regulation.

## 449.14

DECREASED EXPRESSION OF DOPAMINE  $D_3$  RECEPTORS IN THE LIMBIC SUBREGIONS OF RAT BRAIN FOLLOWING NEONATAL EXCITOTOXIC LESION OF THE VENTRAL HIPPOCAMPUS. G. Flores\*, D. Barbeau, J.J. Liang, R. Quirion and L.K. Srivastava. Douglas Hospital Research Center, McGill University, Montreal, Qc, Canada, H4H 1R3.

Neonatal, bilateral lesion of the ventral hippocampus in rats has been proposed as a model of schizophrenia as these animals show postpubertal hypersensitivity to stress and dopamine agonists that can be reversed by neuroleptic treatment (Lipska et al. *Neuropsychopharmacology*, 9, 67, 1993). To investigate the mechanisms of abnormal dopamine related behaviours in these animals, we have evaluated the expression of dopamine  $D_1$ ,  $D_2$  and  $D_3$  receptors in various striatal and limbic subregions of rats that had received bilateral ibotenic acid lesion of the ventral hippocampus at postnatal day 7 (PD7). Locomotor activity of the hippocampal and sham-lesioned rats were measured at prepubertal (PD35) and postpubertal (PD56) ages. In accordance with previous reports, an increased locomotor activity was observed at PD56 in the hippocampal-lesioned group following exposure to novelty and swim-stress test, as well as after D-amphetamine (1 mg/kg) or apomorphine (0.5 mg/kg) injections. The density of dopamine receptor subtypes were then estimated by ligand autoradiography at PD41 and PD62. The density of dopamine  $D_3$  receptors, as measured by [<sup>3</sup>H]-OH-DPAT binding, is markedly reduced in the nucleus accumbens and the island of Calleja of hippocampal-lesioned rats with the changes being more pronounced at PD62. A small, but significant, increase in  $D_1$  receptors ([<sup>3</sup>H]-SCH23390 binding) was also observed in the dorsal striatum of PD62 hippocampal-lesioned animals, while no significant changes in [<sup>3</sup>H]-spiperone binding (representing total  $D_2$ -like receptors) were noted. In view of the inhibitory role of  $D_3$  receptors in locomotion, the results suggest that some of the delayed behavioral changes seen in the neonatal hippocampal-lesioned rats may be mediated by decreased  $D_3$  receptor levels. (Supported by the MRC, FRSQ and the Low-Beer Foundation).

## 449.16

DOWN-REGULATION OF GABA  $\rho$  RECEPTOR CHANNELS BY PROTEIN KINASE C. T. Kusama\*, M. Sakurai, Y. Kizawa, G.R. Uhl and H. Murakami. <sup>1</sup>Dept. of Physiol. Anat., Nihon Univ. Coll. of Pharmacy, Chiba 274, Japan; <sup>2</sup>Mol. Neurobiol., ARC/NIDA/NIH & Nsci., JHUSM, Baltimore, MD 21224.

Several ligand gated ion channels are robustly regulated by phosphorylation events. In the present study, we investigated the effect of protein kinase C (PKC) activators on GABA  $\rho_1$  and  $\rho_2$  receptor, newly cloned from human retina, in expressing *Xenopus* oocytes under voltage clamp.

Phorbol 12-myristate 13-acetate (PMA), exogenously applied for 3 min, inhibited more than 80 % of the  $\rho_1$  and  $\rho_2$  receptor currents. This inhibition developed slowly, reaching a maximum about 40-70 min, and was concentration-dependent, with EC<sub>50</sub> for PMA of 6 nM. PMA inhibition decrease GABA efficacy, but not its potency. 100 nM phorbol 12-monomyristate, an inactive analog of PMA, did not exhibit such an inhibitory effect. 3 min application of 10 nM mezerein, a non-phorbol ester PKC activator, also inhibited the  $\rho_1$  responses more effectively than 25 nM PMA. However, 1 mM 8-chlorophenylthio-cyclic AMP, an effective activator of oocyte protein kinase A, failed to effect  $\rho_1$  responses. The inhibition by 25 nM PMA was blocked by 20 min pretreatment with 1  $\mu$ M staurosporine, a PKC inhibitor.

These results suggest that GABA  $\rho$  receptor function may be dramatically regulated by PKC-mediated phosphorylation events in retinal and other neurons that express  $\rho_1$  and/or  $\rho_2$  receptors. Current mutagenesis experiments may determine the PKC site responsible for down-regulation of  $\rho$  receptors.

## 449.17

FLUNITRAZEPAM INDUCES A BI-PHASIC DOWN-REGULATION OF THE GABA<sub>A</sub> RECEPTOR  $\alpha_1$  SUBUNIT PROTEIN. M.J. Brown and D.R. Bristow\*. Division of Neuroscience, University of Manchester, Manchester, M13 9PT.

Prolonged benzodiazepine administration results in tolerance to some of their therapeutic effects. Studies on the molecular mechanisms underlying tolerance to benzodiazepines have reported a down-regulation of certain GABA<sub>A</sub> receptor subunit mRNA species ( $\alpha_1$  and  $\gamma_2$ ). In the present study, the short-term effect on the expression of the GABA<sub>A</sub> receptor  $\alpha_1$  subunit protein by the benzodiazepine agonist, flunitrazepam, was examined in primary cultures of cerebellar granule cells. Cerebellar granule cells were prepared and treated with 1  $\mu$ M flunitrazepam (1-48 hours) and then the protein extracted. Proteins were separated by 10% (w/v) SDS-PAGE. Western blotted onto nitrocellulose membrane and probed with subunit-specific  $\alpha_1$  antibody. Membranes were incubated with HRP secondary antibody, and protein bands detected using ECL. The optical density of the protein bands were quantitated using a OmniMedia flatbed 600dpi scanner.

This study demonstrates that after 1, 2, 4, and 8 hours stimulation with 1  $\mu$ M flunitrazepam, the  $\alpha_1$  subunit protein is reduced (-24 $\pm$ 16, -64 $\pm$ 25, -26 $\pm$ 11 and -51 $\pm$ 14, mean $\pm$ SEM, respectively, compared to controls, n=4-8, p<0.05, Wilcoxon Rank). Following 12 hours exposure, the  $\alpha_1$  subunit protein expression recovers to control values (0 $\pm$ 22%, mean $\pm$ SEM, n=4). However, by 24, 30 and 48 hours, the  $\alpha_1$  subunit protein is reduced again (-38 $\pm$ 12%, -26 $\pm$ 10% and -40 $\pm$ 3%, mean $\pm$ SEM, respectively, compared to controls, n=4-11, p<0.05, Wilcoxon Rank). This study will further explore the mechanism underlying the two phase response to benzodiazepines by examining the  $\alpha_1$  subunit RNA over a similar time course of flunitrazepam treatment. This study provides a better understanding of the molecular events occurring at the GABA<sub>A</sub> receptor upon benzodiazepine stimulation.

## 449.19

LACK OF RECYCLING OF INTERNALIZED NEUROTENSIN RECEPTORS IN PRIMARY CULTURED NEURONS.

E. Hermans, M.A. Vanisberg, M.K. Luabeya, J.M. Maloteaux. Lab. of Neurochemistry (1080), Université Catholique de Louvain, B-1200, Brussels, Belgium. (SPON: SONA)

Both short-term and long-term regulation processes induced by neurotensin on its receptor were studied in rat primary cultured neurons. After incubation of intact neurons with unlabelled neurotensin (3 nM) for 1 or 24 h at 37°C, the [<sup>3</sup>H]-neurotensin specific binding measured in cell homogenates was decreased to about 35 and 65% of control values respectively. In these experiments, the decreases in binding corresponded to reductions of B<sub>max</sub> value, without significant changes in the affinity. The neurotensin-induced receptor down-regulation is thought to result from receptor degradation since it was reduced by lysosomotropic drugs and because no agonist-induced change in neurotensin mRNA level could be measured. After short term incubations, internalized receptors slowly reappeared at the cell surface during further incubation in the absence of the peptide. Such receptor reappearance did not occur in the presence of the protein synthesis inhibitor cycloheximide and is therefore thought to result from the new-synthesis and not from the recycling of internalized receptors. These results indicate that the neurotensin-induced receptor internalization in cultured neurons is irreversible and that it is followed by a down-regulation of the receptor through a degradative process.

## 449.18

REGULATION OF MUSCARINIC M1 AND ADRENERGIC  $\alpha_1$  RECEPTOR EXPRESSION IN LIVING VISUAL CORTEX NEURONAL CULTURES. Y.H. Wang\*, O. Gu and M. S. Cynader. Dept. of Ophthalmology, Univ. of British Columbia, Vancouver, B.C. Canada V5Z 3N9

We have demonstrated the regulation of expression and distribution of muscarinic m1 receptors and adrenergic  $\alpha_1$  receptors, respectively, in living visual cortex neuronal cultures by using confocal microscopy and fluorescently labelled analogues of receptor-specific ligands. Here, our goals were to study the specificity of receptor regulation to the blockade of a particular receptor class. We approached this by comparing the effects of treatment with the  $\alpha_1$  receptor antagonist prazosin and m1 receptor antagonist pirenzepine on the expression of  $\alpha_1$  and m1 receptors in cultured cortical neurons. Neurons were either pretreated with (a) 10 nM pirenzepine alone, (b) 50 nM prazosin alone, and (c) 50 nM prazosin and 10 nM pirenzepine for 5 days in culture. The results showed that blockade of muscarinic receptors with pirenzepine upregulates muscarinic receptor expression selectively without changing  $\alpha_1$  receptor expression. Conversely blockade of  $\alpha_1$  receptors upregulates  $\alpha_1$  expression but not muscarinic receptor expression. This implies that the expression levels of m1 and  $\alpha_1$  receptors are both regulated through specific signal transduction pathway. We have previously found that tetrodotoxin (TTX) treatment decreases expression of muscarinic receptor in cultured neurons.

To study the interactions between neuronal activity and receptor activation (or blockade) on receptor number, we compared the effects of TTX, prazosin, and noradrenaline on the expression of  $\alpha_1$  and m1 receptors in our cultured neurons. In these experiments, neurons were pretreated either with (a) 0.1  $\mu$ M TTX (b) 0.1  $\mu$ M TTX and 50 nM prazosin and (c) 0.1  $\mu$ M TTX and 1  $\mu$ M noradrenaline for 7 days in culture. The results show that TTX exposure reduces both  $\alpha_1$  and m1 receptor expression regardless of the presence of the receptor agonists or antagonists. This implies that the activity-dependent regulation of receptor number is predominantly regulated by neuronal activity rather than receptor occupancy.

## 449.20

FACTORS REGULATING THE EXPRESSION OF THE Y1 RECEPTOR FOR NEUROPEPTIDE Y IN PC12 CELLS.

J. C. Bournat and J. M. Allen\*. Division of Biochemistry and Molecular Biology, Davidson Building, University of Glasgow, Glasgow G12 8QQ, Scotland, UK.

The region of the Y1 receptor gene that lies 5' to the first exon has been attached to the reporter function, luciferase, such that the expression of this enzyme has been placed under the control of the 5' flanking region of the Y1 receptor. It is thus possible to measure the activity of the gene and the factors that regulate its expression in cells that constitutively express the endogenous gene. Luciferase activity can be readily measured in cell extracts by providing substrate and measuring luminescence in a luminometer. The fusion gene has been transfected into PC12 cells, which express low levels of the Y1 receptor. Activity of the gene promoter region was measured by analysing the activity of the luciferase enzyme in cell extracts 48 hours after transfection. Very low levels of luciferase activity were observed in cells transfected with the promoterless control plasmid indicating that the vector itself contained no sequences that activate gene expression in PC12 cells. Maximal activity was assessed by transfecting PC12 cells with a control plasmid in which the luciferase has been placed under the control of a viral promoter. Transfection of the fusion gene (in which the enzyme was placed under the control of the 5' flanking region of the Y1 receptor) resulted in slightly higher levels of luciferase activity compared to the promoterless plasmid but were considerably less than the maximal activity. These results indicate a low basal level of Y1 receptor gene transcription in these cells. We have started to analyse the factors that regulate Y1 receptor gene activity in PC12 cells. Preliminary data indicates that the gene for the Y1 receptor is regulated in a similar fashion to that for the peptide itself. Thus, Nerve Growth Factor and activators of cAMP dependent protein kinase both stimulate Y1 receptor gene transcription.

## NEUROENDOCRINE REGULATION: VASOPRESSIN AND OXYTOCIN

## 450.1

SINOARTIC DENERVATION INCREASES OSMOTICALLY STIMULATED PEPTIDE RELEASE WITHIN SUPRAOPTIC NUCLEUS (SON). M.F. Callahan, M. Ludwig, C. Barrett and M. Morris. Dept. of Physiology/ Pharmacology, Wake Forest University Medical Center, Winston-Salem, NC, 27157-1083.

Removal of baroreceptor function by sinoaortic denervation (SAD) results in increased plasma peptide response to osmotic stimulation. We examined whether chronic SAD alters vasopressin (VP) and oxytocin (OT) release into the SON. Urethane anesthetized SAD or sham operated male Sprague Dawley rats were given arterial and venous catheters and bilateral microdialysis probes into the SON. Baroreceptor testing was accomplished by examining bradycardia following phenylephrine induced pressor responses. Successful SAD (< 0.5 bpm bradycardia/mmHg increase in arterial pressure) was observed in 7 of 9 SAD rats. Dialysis probes were perfused with artificial CSF (3  $\mu$ L/min) over nine 30-minute periods. After a one-hour baseline, animals were given an i.p. osmotic challenge (3.5M, 600  $\mu$ L/100g body wt). The osmotic stimulus caused an increase in VP and OT peptide release in both groups of animals with the peak occurring during 30-60 minutes post stimulation. In sham operated rats, dialysate VP increased from 0.28 $\pm$ 0.15 pg/sample in baseline to 4.4 $\pm$ 3 following stimulation. SAD rats showed an exaggerated response to osmotic stimulation with dialysate VP increasing from a baseline of 0.15 $\pm$ 0.02 to 9.3 $\pm$ 2.8 pg/sample. OT release was also exaggerated in the SAD group. This supports previous research which showed that intranuclear peptide release to direct osmotic stimulation was also exaggerated in SAD rats. These results indicate that intranuclear peptide release in response to osmotic stimulation is under control of arterial baroreceptor function. (Supported by NHLBI Grant # HL-43178).

## 450.2

MECHANISMS INVOLVED IN SUCKLING-INDUCED INHIBITION OF MILK EJECTION IN RATS. M.T. Morales, E. Shapiro and F. Mena. (SPON: S. Diaz-Cintra\*). Centro de Neurobiología, Universidad Nacional Autónoma de México, México D.F. 04510, México.

Milk ejection in rats results from interactions of antagonistic mechanisms activated by suckling, i.e., oxytocin (OT) and catecholamines (CAs), from neural or adrenal origin, upon the motor apparatus of the mammary gland. We know from previous work that neural regulation of the gland (facilitation or inhibition of milk ejection) may be activated by central administration of CAs or by peptides like prolactin (PRL), but it is unclear the role that suckling may have on its activation. In the present study, we analyzed whether suckling may inhibit milk ejection induced by IV doses of OT in anesthetized lactating rats, and to what extent it may result from adrenal or neural CAs. **Methods:** Wistar lactating rats (pp days 12-16) chronically implanted with cannulae into each lateral cerebral ventricle (ICV) were used. The day of the experiment the mothers were separated from their pups for 8h and then anesthetized with urethane. Groups of rats were either hypophysectomized, adrenalectomized, spinal cord transected (T3-T4), or had the nipple area locally anesthetized before suckling. IV doses of OT (0.8 mU every two min) were injected to the mother during 10 min periods of suckling by the pups. Milk yield was determined by weighing the litter after each period of suckling. **Results:** 1) Milk yield was greatly depressed in either control intact, sham operated or saline ICV-injected rats. This inhibition was counteracted by IV or ICV administration of the  $\beta$ -adrenergic blocker propranolol, spinal-cord transection or local anesthesia of the nipple area; and was partially prevented by bilateral adrenalectomy. 2) During suckling, no facilitation of milk ejection occurred after ICV administration of PRL. In fact, inhibition instead of facilitation was observed when suckling was applied after PRL, and this effect was counteracted by IP propranolol. These results indicate that suckling inhibits milk ejection in the anesthetized rat through the reflex activation of central  $\beta$ -adrenergic mechanisms, involving both, adrenal and neural CAs. Also, they suggest that the inhibition of PRL on milk ejection occurred by potentiation of suckling stimulation.

**EFFECT OF BILATERAL ADMINISTRATION OF  $\beta$ -ACTIN ANTISENSE INTO THE SUPRAOPTIC NUCLEI ON THE MILK-EJECTION REFLEX IN THE CONSCIOUS RAT.** Q. J. Pittman\*, Y. Takahashi & B. C. Wilson. Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada T2N-4N1.

Antisense oligonucleotides (oligos) are used experimentally as specific inhibitors of gene expression. Bilateral injection of antisense directed against oxytocin (OT) mRNA into the supraoptic nuclei (SON) was recently shown to reduce pup weight gain and reduce the total number of milk-ejections of conscious dams 4 hours post-injection. While these effects were specific for OT-antisense (OT-as) and not mimicked by VP-as or mixed bases (which would not hybridize in an OT cell), the question arose if similar effects would result from hybridization with a different active transcript in the OT cell. Nineteen mer antisense (TCGTCATCCATGGCGAACT) or sense (AGTTGCGCATGGATGACGA, as control) oligos were directed against a region of the mRNA spanning the start codon of the precursor of the microfilament protein,  $\beta$ -actin. Injections ( $1\mu\text{g}/0.5\mu\text{l}$ ) were given bilaterally into the SON of conscious Day 9 lactating rats implanted with guide cannulae. Four hours post-injection, 10 pups were re-introduced into the cage of each dam and assessments were made of maternal behaviour, pup weight gain and the number of milk-ejections occurring in a 30 min period after suckling was established. There was no significant ( $p > 0.05$ ) difference between maternal behavior, pup weight gain or the number of milk-ejections of dams receiving sense or antisense for  $\beta$ -actin into the SON (verified histologically) or rats receiving injections of either substance into adjacent brain tissue. These data indicate that short latency actions of antisense nucleotides may be specific to secreted protein and are not seen after hybridization with mRNA for another cellular constituent. Our data also suggests that short-term disruption of  $\beta$ -actin synthesis does not affect milk delivery to rat pups.

**OXYTOCIN AND VASOPRESSIN GENE EXPRESSION IN THE INTERMEDIATE LOBE OF RAT PITUITARY.** Q. Sun, S. Pretel\*, D. Piekut. Dept. of Neurobiology & Anatomy, Univ. of Roch., Rochester, NY 14642

One important function of the pituitary is to modulate the body's stress-response through secretion of ACTH. Corticotrophin releasing factor, oxytocin (OX) and vasopressin (VAS) are known to stimulate ACTH release; their synthesis and release are increased in many stressful conditions. Two pathways by which OX and VAS may modulate the corticotrophin cells in the anterior lobe of the pituitary have been hypothesized. One is via the long portal veins, through which OX and VAS, released from parvocellular neurons into the median eminence, are carried to the anterior lobe. The other is via the short portal veins, which transport the OX and VAS, released by magnocellular neurons at the posterior lobe, to the anterior lobe. The presence of OX and VAS peptide in posterior lobe is well known. Recently the presence of VAS, but not OX mRNA, has also been reported; however, the location of VAS mRNA in the pituitary is unclear. The goal of the current study was to localize the expression of OX and VAS mRNA, as well as their peptide, in specific components of the pituitary of normal and kainate treated rats. In situ hybridization was performed on frozen sections with  $[35\text{S}]$ -labeled oligonucleotide probes (generously provided by Dr. S. Young, NIH). In this study, strong OX and VAS immunoreactivity (ir) was demonstrated in nerve endings and Harris bodies in the posterior lobe; no mRNA for either OX or VAS was present. In the anterior lobe, only a few weakly labeled OX-ir cells were found; no VAS-ir cells, and no OX or VAS mRNA labeling was present. However, in the intermediate lobe, positive labeling for OX and VAS mRNA was present in the majority of cells in normal and kainate treated rats. The OX-ir and VAS-ir labeling were weak, but clearly detectable. Since the intermediate lobe has much less blood supply, its secretion of OX and VAS might stimulate the ACTH release through paracrine mechanism. Supported by NIH grant NS 18626

## 450.7

**EFFECTS OF ESTROGEN ON NORADRENERGIC AND VASOPRESSIN CELL RESPONSES TO HYPOXIA.** K.M. Buller\* & T.A. Day. Dept. of Physiology & Pharmacology, University of Queensland, Australia.

This laboratory has recently shown that in male rats systemic hypoxia produces an activation of neurosecretory vasopressin (VP) cells that is mediated by an input from the A1 noradrenergic (NA) cell group of the caudal medulla. In the female rat this system may be influenced by the ovarian hormone estrogen (E). Thus, in the ovariectomized (OVX) rat, the excitability of A1 cells is reportedly enhanced by E administration, while in the intact rat it has been shown that the VP response to haemorrhage varies in accord with circulating E levels. We therefore hypothesized that variations in E levels might both alter the basal activity of brainstem NA and hypothalamic VP cells and influence the responsiveness of these cells to systemic hypoxia (10% O<sub>2</sub>). Using the *c-fos* neuronal activity mapping technique we have investigated in the OVX rat the effects of both a single E bolus (100  $\mu\text{g}/\text{kg}$ , s.c.) and repeated daily E injections (day 1, 5  $\mu\text{g}$ ; day 2, 50  $\mu\text{g}$ ; day 3, 50  $\mu\text{g}$ ), compared to injections of vehicle at matching times. Neither single nor multiple injections of E ( $n = 4$ ) significantly changed the basal levels of *c-fos* expression in A1 or A2 NA cells, or supraoptic nucleus VP cells. With regard to responsiveness to 10% O<sub>2</sub>, single E treatment had no significant effect on A1, A2 or SON *c-fos* expression. Multiple injections of E also failed to alter the A2 cell group response to hypoxia, but significantly increased the A1 cell response ( $40.7 \pm 3.9\%$  versus  $19.2 \pm 9.4\%$  of caudal ventrolateral medulla tyrosine hydroxylase positive cells being Fos-positive). However, despite the well established link between A1 cell activation and VP cell activity, multiple injections of E had no significant effect upon the frequency of *c-fos* expression in supraoptic VP cells.

## 450.4

**RESPONSE OF PLASMA AVP AND FOS IMMUNOREACTIVITY TO INTRAGASTRIC HYPERTONIC SALINE IN CONSCIOUS RATS**

S. H. Carlson and J. W. Osborn\*. Departments of Physiology and Animal Science, University of Minnesota, Twin Cities, 55455

Some studies have suggested peripheral osmoreceptor control of arginine vasopressin (AVP) release in the rat. The afferent pathway mediating this response is unclear. Experiments were conducted to examine the effects of intragastric administration of isotonic (290 mOsm/L) and hypertonic (600 mOsm/L) saline on plasma AVP (PAPV) and *fos* immunoreactivity within various central nuclei. In the first study, rats were chronically instrumented with arterial and gastric catheters. Two days later, rats received an intragastric infusion of either isotonic ( $n = 7$ ) or hypertonic ( $n = 9$ ) saline (59 ml/min). Blood samples were taken before and after infusion to measure plasma osmolality (POSM) and PAPV. Isotonic saline did not affect PAPV ( $4.1 \pm 1.4$  to  $3.9 \pm 0.4$  pg/ml), while hypertonic saline resulted in a significant increase in PAPV ( $3.5 \pm 1.1$  to  $5.8 \pm 1.7$  pg/ml;  $P < 0.05$ ). Hypertonic saline did not affect POSM, indicating that the central osmoreceptors were not stimulated. In a second study, chronically instrumented rats ( $n = 10$ ) were examined for changes in *fos* immunoreactivity in selected brain nuclei in response to intragastric isotonic and hypertonic saline infusions. Hypertonic saline increased *fos* immunoreactivity in the area postrema, nucleus tractus solitarius, lateral parabrachial nucleus, and the paraventricular and supraoptic hypothalamic nuclei. These results indicate that intragastric hypertonic saline stimulates AVP release in the absence of central osmoreceptor activation, which is consistent with the hypothesized peripheral osmoreceptor control of AVP release. Additionally, *fos* immunoreactivity results indicate that the hypertonic gastric saline activates central nuclei apart from the hypothalamic nuclei associated with AVP release, including the area postrema, nucleus tractus solitarius and lateral parabrachial nucleus. Whether these nuclei are associated with the observed AVP release is unknown, and their exact role in the response to gastric hypertonic saline remains to be determined.

## 450.6

**PROFILE OF CATECHOLAMINE AND AMINO ACID NEUROTRANSMITTER CONCENTRATIONS IN RAT SUPRAOPTIC NUCLEUS DURING PARTURITION** D. Voisin<sup>1</sup>, C. Chapman<sup>1</sup>, A. Douglas<sup>2</sup> and A. Herbison<sup>1</sup>. (SPON: Brain Research Association) <sup>1</sup>Lab. of Neuroendocrinology, Babraham Institute, Cambridge and <sup>2</sup>Dept. Physiology, University of Edinburgh, U.K.

The magnocellular oxytocin neurones of the supraoptic (SON) and paraventricular nuclei of the hypothalamus are believed to play an important role in the initiation of parturition in the rat. However, little is known about the neural inputs regulating oxytocin neurone activity at the time of parturition. In the present study we have used the technique of intracerebral microdialysis to monitor the extracellular concentrations of a variety of catecholamines and amino acid neurotransmitters within the SON prior to and during parturition.

Microdialysis probes were implanted under halothane anaesthesia into the SON of pregnant rats ( $n=5$ ) on the day preceding parturition and 15 min dialysate samples were collected from freely moving rats over the following two days until 3h after birth of the last pup. Dialysate samples were analysed by electrochemical and fluorescence HPLC for glutamate, aspartate, GABA, norepinephrine, dopamine and serotonin.

On the day of parturition, extracellular concentrations of norepinephrine were significantly ( $p < 0.05$ ) increased in the hour leading up to and including the birth of the first 2-3 pups but then fell to basal levels only to increase again in a transient fashion at the termination of parturition. Dopamine levels remained unchanged but increases in serotonin were noted during parturition in some rats. An increase in glutamate levels was observed immediately preceding and during the initiation of parturition although this change was not significant ( $n=4$ ). No differences in aspartate or GABA levels were observed at this time although GABA concentrations were elevated in an inconsistent manner during the course of parturition.

These results indicate that norepinephrine, and possibly glutamate, may be involved in the activation of SON oxytocin neurones at the initiation of parturition but not during its maintenance.

## 450.8

**EFFECTS OF SELECTIVE HYPOVOLAEMIA & HYPOTENSION ON A1 NORADRENERGIC & NEUROSECRETORY VASOPRESSIN CELLS.** D.W. Smith\*, K.M. Buller and T.A. Day. Dept. of Physiology & Pharmacology, University of Queensland, Australia.

Hypotensive haemorrhage elicits a vasopressin (VP) cell response that depends on a relay from the A1 noradrenergic cell group. There has been considerable debate as to the importance of arterial baroreceptors versus cardiac volume receptors in this response. By applying stimuli that recruit receptors selectively, we have investigated their contributions to A1 and neurosecretory cell responses to the component stimuli of haemorrhage. Animals received either i.p. injections of polyethylene glycol (PEG; 20-30% w/v in dH<sub>2</sub>O; 20 ml/kg;  $n=6$ ) or the ganglionic blocker pentolinium (PENT; 10 mg/kg;  $n=5$ ). Controls received similar volumes of isotonic saline. After 2 h animals were sacrificed and brains processed for Fos, VP, oxytocin (OT) and tyrosine hydroxylase immunocytochemistry. Parallel groups of animals, chronically instrumented for blood pressure recording, received identical treatments. PEG, but not PENT treated animals, showed a significant reduction in plasma volume (20%) as estimated by haematocrit. PENT, but not PEG treated animals, showed a significant reduction in MAP (40 mmHg), suggesting that PEG is a non-hypotensive hypovolaemic stimulus and PENT is an isovolaemic hypotensive stimulus. Both stimuli caused significant increases in VP and OT neurosecretory cell *c-fos* expression, although these responses were substantially greater in the supraoptic nucleus. Both stimuli significantly increased A1 noradrenergic cell group *c-fos* expression with a similar distribution of activated cells along the rostro-caudal axis of the A1 column. These data suggest that both arterial baroreceptor and cardiac volume receptor populations contribute to the VP and OT responses to haemorrhage and that the A1 cell group has a role in these responses.

## 450.9

FUNCTIONAL ROLE OF ATRIAL NATRIURETIC PEPTIDE RECEPTORS ON NEURONAL AND GLIAL ELEMENTS IN THE RAT NEUROHYPOPHYSIS. M. Hlubek, K.D. Ramsell and P. Cobbett.\* Dept. Pharmacol./Toxicol. and Neuroscience Program, Michigan State Univ., E. Lansing, MI 48824.

Activation of atrial natriuretic peptide (ANP) receptors increases cGMP within axon terminals and pituitary cells (astrocytes) of the neurohypophysis (Rambotti *et al.*, Brain Res:644,52-58,1994). We have therefore investigated the effect of ANP on vasopressin (AVP) secretion from neurosecretory cells (isolated neurohypophyseal axon terminals) and on the morphology of cultured pituitary cells. ANP (1 $\mu$ M) significantly elevated AVP secretion evoked by potassium-induced depolarizations of neurosecretory cells but had no effect on basal secretion of AVP. In contrast, 8-bromo-cGMP (20-100 $\mu$ M) did not appear to affect depolarization-evoked secretion but appeared to increase basal secretion. In cultures of pituitary cells, the fraction of stellate cells was significantly increased by incubation in medium containing ANP (1 $\mu$ M) or 8-bromo-cGMP (100 $\mu$ M) compared to control medium. These data indicate that ANP may act at the level of the neurohypophysis to modulate AVP secretion. Supported by NINDS (NS28206).

## 450.11

CHANGES IN THE ELECTROPHYSIOLOGICAL PROPERTIES OF OXYTOCIN AND VASOPRESSIN NEURONS DURING LACTATION.

W.E. Armstrong\* and J.E. Stern, Dept. of Anat. & Neurobiol., Univ. Tenn., Memphis, TN 38163.

During lactation, oxytocin (OT) neurons adopt a synchronized and intermittent high frequency bursting firing pattern, which optimizes the release of OT at the neural lobe and the resulting milk ejection. Furthermore, profound rearrangements in the ultrastructure of the supraoptic nucleus (SON) have been observed in association with parturition and lactation. In the present study we sought to determine whether the intrinsic membrane properties of supraoptic nucleus (SON) magnocellular neurons were altered as a function of lactation, and if so whether changes were selective to OT neurons. Conventional intracellular recordings from SON neurons were combined with immunohistochemical identification of OT and vasopressin (VP) neurons using hypothalamo-neurohypophyseal explants taken from virgin diestrous and lactating rats, both of which have low circulating estrogens. Resting membrane potential, input resistance, and spike height were not different between lactating and diestrous females. OT, but not VP neurons showed a lactation-dependent increase in the amount of afterhyperpolarization per spike following spike trains. The presence of a depolarizing after-potential (DAP) was increased by 20% in OT neurons during lactation, but the differences were not statistically significant. The repetitive firing properties of SON neurons also changed during lactation. Neurons from lactating rats had a less steep F-I slope for early interspike intervals than those in diestrous rats, but reached significance only in OT neurons. Individual spikes were wider in OT neurons during lactation and showed more spike broadening during trains. In both cell types the number of spikes for a given positive current injection was decreased during lactation. These results indicate that the state of lactation can affect some properties of both neuron types but has a more pronounced effect on OT neurons. Supported by NIH NS 23941 (WEA) and the Neuroscience Center for Excellence.

## 450.13

INDUCTION OF FOS-LIKE IMMUNOREACTIVITY BY NITRIC OXIDE IN THE HYPOTHALAMIC MAGNOCELLULAR NEUROSECRETORY NEURONS OF THE RAT. E. Shen\*, Z.J. Yang and X. Sun, Shanghai Brain Research Institute, 320 Yueyang Rd, Shanghai 200031, China.

High concentration of nitric oxide synthase (NOS) in the hypothalamic magnocellular neurosecretory neurons (MCNs) in the rat has been documented. Its function remains unknown. In the present study we tried to investigate whether nitric oxide (NO) synthesized in the MCNs could induce c-fos or not. The substrate of NOS, L-arginine (10 nM, 5  $\mu$ l), was slowly microinfused in a period of 50 min into the supraoptic nucleus (SON) of adult male Sprague-Dawley rats under sodium pentobarbital anesthesia. Eighty min after the start of microinfusion the rats were sacrificed. Fos-like immunoreactivity (FLI) could be seen in the nuclei of a subpopulation of MCNs in the SON. A majority of the FLI-positive nuclei were not in the NADPH-diaphorase-positive cells. Only about 7% were colocalized with them. The FLI-positive nuclei could be found in both the oxytocin cells and vasopressin cells. However the percentage of FLI expressed in the oxytocin cells was higher. It is suggested that the NO synthesized in the NOS-containing MCNs diffuses out of the cells and induces FLI in the nearby MCNs. ## 450.10

ELECTROPHYSIOLOGICAL DIFFERENCES BETWEEN OXYTOCIN AND VASOPRESSIN NEURONS IN FEMALE RATS. J.E. Stern\* and W.E. Armstrong, Dept. of Anat. & Neurobiol., Univ. Tenn., Memphis, TN 38163.

Oxytocin (OT) and vasopressin (VP) neurons display different firing patterns during hormone release. The extent to which these patterns result from intrinsic membrane properties, particularly in OT neurons, is incompletely known. In addition, most intracellular recording studies in rats have focused on males. In the present study, the membrane properties of immunohistochemically identified supraoptic nucleus neurons in hypothalamo-neurohypophyseal explants were studied in lactating and virgin female rats. Resting membrane potential and input resistance didn't differ between OT and VP neurons, but spike threshold was 5 mV more depolarized in OT neurons. When the great majority (94%) of OT, but not VP (93%) neurons were current-clamped at depolarized voltages (<50 mV), small hyperpolarizing pulses revealed a time- and voltage-dependent outward rectification which decreased with increasing hyperpolarization. A rebound depolarization (RD) followed the offset of pulses associated with strong rectification. Both the outward rectification and RD were abolished by TEA (10 mM) and increased by 4-AP (6 mM). Ba<sup>2+</sup> (0.1-1 mM) but not Cs<sup>+</sup> (2 mM) blocked the outward rectification. The RD was partially blocked by Cd<sup>2+</sup> (0.5 mM) but not by Ni<sup>2+</sup> (0.2-0.5 mM). In general, the outward rectification and RD were reminiscent of behavior seen in sympathetic ganglion cells and attributed to M-current. An additional difference between OT and VP neurons was seen in the amount of transient outward rectification, which was stronger in VP neurons. These results indicate the presence of significant differences in the intrinsic membrane properties, probably K<sup>+</sup> currents, between OT and VP neurons in both lactating and virgin female rats. Experiments in progress are testing whether these differences affect the firing pattern of these neurons, and whether they are amenable to neurotransmitter modulation. Supported by NIH NS 23941 (WEA) and the Neuroscience Center for Excellence.

## 450.12

INCREASED INTESTINAL TRANSIT AFTER LiCl TREATMENT IN RATS MAY BE MEDIATED BY OXYTOCIN. E.A. Baker, K.S. Curtis, J.G. Verbalis and E.M. Stricker\*, Departments of Neuroscience and Medicine, University of Pittsburgh, Pittsburgh, PA 15260.

The ingestion of toxins by animals is known to reduce food intake and slow gastric emptying. These same adaptive responses can be produced by systemic administration of agents such as LiCl. This study evaluated intestinal transit after LiCl treatment in rats. Control rats given ip injections of isotonic NaCl solution required 7.3  $\pm$  0.6 h (n=9) to pass a dye contained in a consumed meal; in contrast, rats injected ip with LiCl (3 mEq/kg) 45 min after eating had a significantly faster IT time of 4.0  $\pm$  0.7 h (n=25; p<0.01 compared to controls). Previous studies indicated that LiCl-induced anorexia was potentiated by administration of the opioid antagonist naloxone, so we also evaluated the effects of this agent on LiCl-induced changes in IT. Whereas injection of either a low dose of LiCl (1.5 mEq/kg ip) or naloxone (2.5 mg/kg ip) separately had no effect on IT (8.8  $\pm$  0.5 h, n=9, and 7.3  $\pm$  0.4 h, n=9, respectively), combined treatment with naloxone and this low dose of LiCl significantly decreased IT time to 4.8  $\pm$  0.9 h (n=9; p<0.01 compared to controls). Because LiCl stimulates pituitary OT secretion in rats, an effect which is potentiated by naloxone, we pretreated rats with the OT receptor antagonist [d(CH<sub>2</sub>)<sub>5</sub>, Tyr(OMe)<sup>2</sup>, Orn<sup>4</sup>] vasotocin (OVT; 50  $\mu$ g/kg) 30 min before LiCl administration (3 mEq/kg); OVT pretreatment abolished the LiCl-induced changes in IT (8.0  $\pm$  0.7 h, n=6; p<0.01 compared to rats treated with this dose of LiCl alone). Collectively, these results indicate that toxins such as LiCl increase intestinal transit in rats, and suggest that this effect may be mediated by the increase in plasma OT levels known to accompany the administration of LiCl and other toxins in this species.

## 450.14

Age Interferes with the Response of the Hypothalamo-neurohypophyseal System to Hypertonic Saline Injection. Gwyneth Hill Reagley\*, Department of Psychology, Alma College, Alma MI 48801

The Hypothalamo-neurohypophyseal System (HNS) shows characteristic morphological changes in response to a large systemic injection of hypertonic saline. In the posterior pituitary, cytoplasmic processes of astrocytic glial cells (pituicytes) typically retract, allowing decreased enclosure of axons and increased apposition of neuropeptide terminals with the basal lamina (BL). This facilitates increased release of oxytocin and vasopressin into the bloodstream. The present study investigated the effect of age on the HNS response. Male Sprague-Dawley rats aged 4-5 months (young) and 20-24 months (old) were given 18 ml/kg injections of either hypertonic (1.5 M NaCl) or normal (0.15 M NaCl) saline and sacrificed after 5 h. HNSs were removed for examination with a transmission electron microscope. Morphological analysis of micrographs of the neural lobes showed:

1. Terminal apposition in the neural lobes of both groups of older rats was lower than in young control rats (old 0.15 M NaCl = 17.2 $\pm$ 2.9%; old 1.5 M NaCl = 13.2 $\pm$ 7.9%; young 0.15 M NaCl = 30 $\pm$ 3%).

2. Pituicytes in the neural lobe of older rats did not retract from the BL in response to the hypertonic saline injection (pituicyte apposition in young 1.5 M NaCl rats = 41 $\pm$ 1.9%; in old 1.5 M NaCl rats = 87 $\pm$ 2.5%).

3. Many terminals in the hypertonically stimulated older rats were still enclosed by pituicytes, but were only partially filled with neuropeptide containing vesicles.

These findings suggest that although a hypertonic saline injection may stimulate neuropeptide release from the neural lobe of older rats, the pituicytes do not respond to the challenge with retraction characteristic of pituicytes in younger animals. This suggests increased age could result in decreased effectiveness in the response of the HNS to acute and chronic dehydration.

## 450.15

Oxytocin Receptor mRNA and Binding in the Ventromedial Hypothalamus of Male and Female Rats: Effects of Androgens and Progesterone Tracy L. Bale\* and Daniel M. Dorsa, Depts. of Pharmacology and Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA 98195

In situ hybridization and radioligand binding techniques were used to demonstrate correlations between changes in oxytocin receptor (OR) mRNA and binding levels in the ventromedial hypothalamus (VMH) in both males and females in response to gonadal steroids. Previous reports have shown that estrogen (E) increases OR binding in the VMH in both males and females, and testosterone (T) also increases binding in males. The E induced increase in OR binding in females has been reported to be further modulated by progesterone (P), as P was shown to increase OR binding area. We have previously reported that E treatment of ovariectomized females results in a significant increase in OR mRNA expression in the VMH. The present studies were designed to 1) determine if the reported increases in OR binding in the VMH in males is preceded by increases in OR mRNA expression, 2) to determine the effect of P and E on OR mRNA in the VMH in females, and 3) to correlate these findings in the VMH with radioligand OR binding. Castrated males were treated with T or its metabolites, E and dihydrotestosterone (DHT). Autoradiographic results from in situ hybridization indicate that T and E can both significantly increase OR mRNA expression in the VMH. However, DHT when administered with E, reduced the induction observed with E alone. <sup>125</sup>I-OTA binding in the VMH confirmed this inhibition. Ovariectomized females were treated with E, P, or E and P (E/P). Results from this study confirmed our previous report of increases in OR mRNA expression with E treatment. P alone had no effect, nor did it alter expression seen with E alone (E/P). <sup>125</sup>I-OTA binding measured in adjacent sections of these animals showed no difference in OR binding site density or distribution between the two groups. These findings contrast with previous reports of an increase in the area involved in OR binding in the VMH. These results confirm a stimulatory role for E, but indicate a negative effect of DHT and no effect of P on OR regulation. We are presently sequencing the promoter region of the OR gene to identify enhancer elements which might mediate these hormonal effects. (Supported by NS-20311, NS-07332)

NITRIC OXIDE DEPOLARIZES PARVOCELLULAR, NOT MAGNOCELLULAR NEURONS IN PARAVENTRICULAR NUCLEUS. J.S. Bains\* and A.V. Ferguson, Department of Physiology, Queen's University, Kingston, ON, Canada K7L 3N6.

Nitric oxide (NO) has been implicated in playing a pivotal role in an increasing number of neuronal functions. The localization of NO synthase in the paraventricular nucleus of the hypothalamus (PVN), led us to investigate the putative role of NO within this structure. Previous work from our laboratory has reported that administration of NO depolarizes cells within PVN. Since PVN is a heterogeneous structure composed of at least two different cell types, we have now extended this work to clarify the types of cells affected by NO and the underlying mechanisms responsible for the observed response.

Using patch electrodes filled with potassium-gluconate, recordings were made from PVN neurons in coronal brain slices (400 µm thickness) of adult, male Sprague-Dawley rats. Cells were classified into type I (putative magnocellular) or type II (putative parvocellular) according to the criteria of Tasker and Dudek (J. Physiol. 434: 273-294). Bath application of NO ( $\leq 10^{-7}$ ) or the NO donor N-Acetyl-S-nitroso-D-penicillamine (SNAP) ( $10^{-9}$  -  $10^{-6}$ ) elicited a mean depolarization of  $4.5 \pm 1.1$  mV (mean  $\pm$  SEM) (n=19) and a mean decrease in input resistance of  $140 \pm 41$  MΩ. Application of the NO precursor L-arginine (L-ARG) (n=14) also elicited a mean depolarization ( $5.2 \pm 1.2$  mV), and an accompanying decrease in input resistance ( $246 \pm 71$  MΩ). Type I cells, however, were unaffected by administration of NO, SNAP or L-ARG (n=10). Type II cells tested in TTX exhibited a mean depolarization of  $6.2 \pm 1.9$  mV (n=6) in response to NO or SNAP, but did not respond in a zero calcium solution (n=5). Preliminary evidence suggests that NO actions may be the result of activation of cyclic GMP (cGMP), as SNAP has no effect on the membrane potential of type II cells in the presence of the cGMP inhibitor LY83583 (n=2).

BRAIN MAST CELL DEGRANULATION BY COMPOUND 48/80 OPENS THE BLOOD-BRAIN BARRIER X. Zhuang<sup>1</sup>\*, A.-J. Silverman<sup>2</sup>, and R. Silver<sup>1,3</sup>, <sup>1</sup>Dept. Psychology, <sup>2</sup>Dept. Anat. & Cell Biol., P&S, 10032, and <sup>3</sup>Barnard College, Columbia Univ., New York, NY 10027

Mast cells (MC) are well known for their production and secretion of vasoactive substances. MC are particularly numerous in the medial habenula (MH) of the ring dove at the peripubertal age of 5-7 mo. In this study we asked if MC activation causes alterations in the permeability of the blood-brain barrier (BBB). Thus, the mast cell degranulator, compound 48/80 (C48/80) was injected i.m. into 6 mo. old birds followed 2 hrs later by i.v. injection of the fluorescent dye, Evans blue (EB). This dye does not cross the BBB. Control animals were injected with saline followed by EB. All birds were perfused 30 min after EB injection. Frozen sections (50 micron) were examined for the distribution of EB in the brain parenchyma using fluorescence microscopy. The optical density of the fluorescent signal was quantified by digital imaging (Image NIH). Images of brain sections containing the MH, paraventricular nucleus (PVN), and a circumventricular organ - the lateral septal organ (LSO) were captured and stored. Brain sections were then stained with toluidine blue to delimit the foregoing nuclei for quantification. C48/80 treatment significantly increased the spread of the tracer in the MH (p<0.01). In contrast, there was no leakage of tracer into the PVN in either group. There was leakage of EB into the brain around the LSO in both groups but the extent of leakage does not differ between groups. Degranulation of mast cells after C48/80 treatment was confirmed histochemically and ultrastructurally. The result supports the hypothesis that mast cell activation can open the BBB. Supported by NSF grant SGER and NIMH grant 29380 (RS) and HD 10665 (AJS).

## 451.3

Is Activated Complement Neurotoxic to Rat Hippocampal Neurons? C. Raby\*, K. Spiegel and M.R. Emmerling, Parke-Davis Pharmaceutical Research Center, Warner Lambert Co., Ann Arbor, MI 48103.

Alzheimer disease (AD) is characterized by excessive deposition of the  $\beta$ -amyloid peptide in the central nervous system. Several proteins in addition to the  $\beta$ -amyloid protein have been found in close association with both diffuse and classical neuritic plaques. Immunocytochemical studies have demonstrated the presence of complement proteins. Senile plaques and extracellular tangles are decorated with complement proteins of the classical pathway indicating activation of this cascade in AD brain. It has been shown that the  $\beta$ -amyloid protein which is the chief component of the senile plaques is capable of activating the complement cascade. To determine whether complement is neurotoxic, we treated neuronal hippocampal cultures with human serum. Hippocampal neurons were prepared from day 17 rat embryos and cultured on poly-D-lysine coated plastic in serum free neural basal medium with B27 supplements. Treatment with increasing concentrations of sera showed a concentration dependent increased neural toxicity, as indicated by reduced conversion of calcein AM to the fluorescent "live" dye calcein and by decreased reduction of the dye Alamar Blue, an indicator of mitochondrial function. The neurons appear compromised or stressed as indicated by Alamar Blue, yet the cells remain viable as indicated by Calcein AM. Sera depleted of the C1q and C3 component was also toxic to these cells suggesting that complement is not the only component of sera to be toxic to neurons. Further work will examine the effect of activated complement on rat hippocampal neurons and whether we can inhibit activation and slow the progression of neuronal death by complement.

## 451.2

STUDY OF DE NOVO SYNTHESIS OF C1q PROTEIN IN KAINIC ACID TREATED RAT BRAIN. S.K. Goldsmith\* and C.E. Finch, Ethel Andrus Gerontology Center, Biological Sciences, Univ. South. Calif. Los Angeles, CA 90089.

C1q has been found in it's activated form in senile plaques in Alzheimer disease (AD) (Eikelenboom et al., 1994; Johnson et al., 1992; Lampert-Etchells et al., 1993; Rogers et al., 1992). Aggregated  $\beta$ -amyloid may be consequent, among other possibilities, to activation of C1q (Jiang et al., 1994). We are studying rodent models of these complex processes. Lesions of limbic and cortical pathways in rats result in increased levels of C1q protein and C1qB mRNA *in vivo* (Johnson et al., 1992; Rozovsky et al., 1994). The present studies test for *de novo* synthesis of C1q in KA treated rat brain. Increases in C1q protein are observed after 2 lesions: systemic KA (10mg/kg); and neocortical ablation. Batch chromatography modified from the methods of Tenner et al. (1981) revealed three C1q monomers of expected size (approx. 26 kd) as identified on Western blots, which were identical to those from rat sera. Brains processed 3 days after KA had approx. 6-fold increases in C1q vs. controls (KA+ pentobarbital, pentobarbital alone, saline(SAL)). Ten days after neocortical ablation, ipsilateral striatum only showed increased C1q. *De novo* synthesis was studied using <sup>3</sup>H-proline or <sup>35</sup>S-methionine. Pilot data indicate a 5 fold increase in incorporation of the <sup>3</sup>H-proline into the purified C1q fraction of KA slices, incubated for 3 h as compared to controls (KA 0 incorp. time; SAL 0 incorp. time; SAL 3 h incorp.). SDS-PAGE gels of purified C1q from KA slices incubated in <sup>35</sup>S-methionine resulted in labeled monomers in the 26Kd range. (Supported by AG 07909.)

## 451.4

INVOLVEMENT OF AMOEBOID MICROGLIA IN NEURODEGENERATION IN ORGANOTYPIC SLICE CULTURES OF MOUSE HIPPOCAMPUS B.W. Colman\* and C.F. Ide, Dept. of Cell and Molecular Biology, Tulane University, New Orleans, LA 70118

Microglia, the resident macrophages of the brain, are widely recognized as immunocompetent cells of the CNS. In response to injury or disease, microglia become activated and are drawn to the site of damage and acquire macrophage-like characteristics. Current *in vitro* models of neuroglial inflammatory responses offer a limited approach to the complex interactions between neurons and glia because functional neuroimmune networks are either absent or greatly simplified. This obstacle is overcome in slice cultures which may be manipulated *in vitro* while maintaining the complex *in situ* environment of the brain. To further investigate the role of microglia during neurodegenerative events, we have characterized the temporal and spatial distribution of activated and quiescent microglial cells associated with necrotic sites in culture using the *Griffonia simplicifolia* lectin. Initially, out of 76 cultures, spontaneous neurodegenerative sites occurred in approximately 43% of slices within six days *in vitro* (DIV). In a subset of the group that formed holes, after 3-4 DIV, 82% developed necrotic centers in CA3, 18% in CA1 and no necrotic sites were observed in the dentate gyrus. After 5-6 DIV, 87% of necrotic sites were found in CA3, 33% in CA1 and again, no necrotic centers were observed in the dentate gyrus. In all cultures, amoeboid microglia were closely associated with the retracting necrotic edge of the forming hole. Resting microglia were confined primarily to sites devoid of tissue. A temporal and spatial propensity for specific sites of neurodegenerative events occurs *in vitro*, and appears to follow *in vivo* patterns. Thus, organotypic slice cultures may serve as an excellent model for elucidating neuroglial inflammatory responses to disease or injury. Supported by DOD grant DOD93DNA-2 and DOE grant DE FG01-93 EW 53023.

## 451.5

Ultrastructural Localization of Quinolate in Human Monocytes/Macrophages. V. Sung<sup>1</sup>, C. Venkateshan<sup>2</sup>, L. Williamson<sup>3</sup>, M.G. Espey<sup>1</sup>, E. Neale<sup>3</sup>, C.G. Gibbs<sup>2</sup> Jr., J.R. Moffett<sup>1</sup> and M.A.A. Nambodiri<sup>1</sup>. Dept. Biology, Georgetown Univ., Washington, DC, LCNSS<sup>2</sup>, NINDS, and LDN<sup>3</sup>, NICHHD, NIH Bethesda, MD 20892.

Quinolate (QUIN), a tryptophan derived excitotoxin, was localized in human monocytes/macrophages (MQ) by immunoelectron microscopy. A combined carbodiimide/glutaraldehyde/formaldehyde based fixation procedure was developed for optimal retention of intracellular QUIN while minimizing loss of ultrastructure, and a silver enhanced colloidal gold detection was used to visualize QUIN. QUIN-immunoreactivity was detectable at the cell periphery and in association with the inner face of the plasma membrane in normal MQ, and increased significantly on treatment with 1) IFN- $\gamma$ , an immune activator and 2) kynurenine, a precursor. Dense aggregations of gold particles representing QUIN were especially present in the pseudopodia of stimulated MQ. The specific localization of QUIN near the plasma membrane and its reported release suggest a possible role for QUIN as an immune regulator.

## 451.7

MODULATION OF MACROPHAGE PHAGOCYTOSIS BY OPIOID PEPTIDE, ENDORPHIN. M. Sawada\* and M. Ichinose. Dept. Physiology, Shimane Med. Univ. Izumo 693, Japan.

The effects of  $\beta$ -Endorphin ( $\beta$ End) on phagocytosis in peritoneal macrophages were examined by using flow cytometry (FCM).  $\beta$ End enhanced phagocytosis in a dose-dependent manner. Leucine-enkephalin (Leu-Enk), methionine-enkephalin (Met-Enk),  $\alpha$ -endorphin ( $\alpha$ End),  $\gamma$ -endorphin ( $\gamma$ End),  $\alpha$ End(18-31) and  $\beta$ End(28-31) had no such activity.  $\beta$ End(1-27) and  $\beta$ End(6-31) enhanced phagocytosis less effectively than did  $\beta$ End. Naloxone did not inhibit the enhancement of phagocytosis induced by  $\beta$ End. Unstimulated control phagocytosis was partially suppressed in  $\text{Ca}^{2+}$ -free EGTA-containing solution and even in this solution  $\beta$ End enhanced phagocytosis. However, the enhancement was suppressed in the solution containing BAPTA-AM. The present study showed that  $\beta$ End enhanced extracellular  $\text{Ca}^{2+}$  ( $[\text{Ca}^{2+}]_o$ ) dependent and independent phagocytosis and that the enhancement is largely dependent on intracellular  $\text{Ca}^{2+}$  ( $[\text{Ca}^{2+}]_i$ ). These results support  $\beta$ End being one of the mediators that modulates the immune system.

## 451.9

IMMUNE EFFECTS OF PRENATAL ETHANOL EXPOSURE (PEE) ARE MODULATED BY NEUROACTIVE DRUGS IN C57BL/6 MICE. B. Günther, P. Clausen, A. Emmendorfer, and M.-L. Lohmann-Matthes. Dept. Lab. Animals, F.-S.-University, 07745 Jena, Germany.

In order to determine if an altered neurotransmission plays any role in fetal alcohol effects on the immune system, mice prenatally exposed to ethanol (PEE, 1.69 g/kg, po, twice daily, gestational days 14-18) were treated postnatally with the  $\beta$ -adrenergic agonist isoproterenol (IPR, 6  $\mu$ g/kg, im) or the  $\alpha$ -adrenergic antagonist yohimbine (YO, 2.6 mg/kg im) prior to assessing contact sensitivity (CS) to picryl chloride and analysis of lymphocyte subsets in spleen and cervical lymph node (CLN) at 4 or 12 w of age. The norepinephrine concentration was also determined in these organs. In spleen PEE increased significantly the portion of the L374 and B220 subsets of 4 w old mice. Postnatal treatment with IPR or YO abolished this effect. PEE decreased these subset portions as well as Thy1.2 and the cell count in 12 w old mice. Postnatal treatment with IPR aggravated these decreases in the 12 w old subjects. In CLN PEE alone did not affect lymphocyte subsets in 4 w old mice. Postnatal treatment of such individuals with IPR or YO decreased the L374, Thy1.2, B220 portions and the cell count. In 12 w old mice these parameters were significantly increased after PEE. IPR and YO did not affect the alterations induced by PEE. CS was unaffected by PEE in 4 w old subjects, however in 12 w old PEE-mice CS was significantly decreased. There was a significant positive over all correlation ( $r=0.672$ ,  $n=52$ ) between the intensity of CS and the norepinephrine concentration in the CLN. It is concluded that the adrenergic system is involved in PEE induced immune changes in an age-related manner.

## 451.6

ENHANCEMENT OF MACROPHAGE FUNCTION BY DYNOPRIN A. M. Ichinose\* and M. Sawada. Dept. Physiology, Shimane Med. Univ. Izumo 693, Japan.

The effects of the opioid peptide dynorphin A (DynA) on phagocytosis in peritoneal macrophages was examined by flow cytometry (FCM). DynA enhanced phagocytosis in a dose-dependent manner. Leucine-enkephalin (Leu-Enk), methionine-enkephalin (Met-Enk),  $\beta$ -neo-endorphin ( $\beta$ Neo-End), DynA(9-17) and DynA(13-17) had no such activity.  $\alpha$ -Neo-endorphin ( $\alpha$ Neo-End), dynorphin B (DynB), DynA(1-13) and DynA(6-17) enhanced phagocytosis less effectively than DynA. Naloxone did not inhibit the enhancement of phagocytosis induced by DynA. Unstimulated control phagocytosis was partially suppressed in  $\text{Ca}^{2+}$ -free EGTA-containing solution and even in this solution DynA enhanced phagocytosis. However, the enhancement by DynA was suppressed in EGTA- and BAPTA-AM-containing  $\text{Ca}^{2+}$ -free solution. The present study showed that enhancement of phagocytosis by DynA was independent of extracellular  $\text{Ca}^{2+}$  ( $[\text{Ca}^{2+}]_o$ ) and dependent on intracellular  $\text{Ca}^{2+}$  ( $[\text{Ca}^{2+}]_i$ ). The present results support DynA being one of the mediators from the nervous system that modulates the immune system.

## 451.8

FETAL THYMIC EXPRESSION OF CRF AND POMC IS AFFECTED BY MATERNAL ALCOHOL CONSUMPTION IN MALE RATS, SELECTIVELY. S. Revskoy, L. Halasz and E. Redei\*. Depts. of Pharmacology and Psychiatry, University of Pennsylvania, Philadelphia, PA 19104.

CRF and POMC have been shown to be expressed in the adult thymus. However, no data to date is available on the expression of these genes in the fetal thymus. Early environmental stressors such as maternal alcohol exposure deleteriously affect immune function of the offspring and alters the expression of CRF and POMC in the hypothalamus and pituitary. Thus, we have hypothesized that changes of thymic POMC and CRF expression can reflect the altered fetal thymic milieu in these animals. In the present study, we have measured thymic CRF and POMC mRNA levels on days 19 and 21 of embryonic life in male and female fetuses. Fetal thymi were obtained from fetuses of control dams maintained on liquid diet and from dams consuming an alcohol-containing liquid diet from day 8 of gestation. CRF and POMC mRNA levels were measured by reverse-transcription-polymerase chain reaction method in individual thymic tissue. The levels of expression were estimated as a ratio of the levels of CRF and POMC to GAPDH mRNAs, respectively. In general, CRF and POMC transcript levels were higher on embryonic day 19 compared to day 21. CRF gene expression was similar in the fetal rat thymus of both sexes. However, thymic POMC expression was substantially higher in males on day 19. Maternal alcohol exposure significantly increased CRF and lowered POMC expression in male thymus on day 19; this effect was not observed in females and it disappeared by day 21. Therefore, the data also suggest that fetal thymic CRF and POMC are developmentally regulated and that environmental stimuli can modulate their expression. The differential response of CRF and POMC genes in fetal thymus to alcohol exposure in utero suggest that POMC transcription in the fetal thymus is regulated differently from pituitary. FETAL ALCOHOL EXPOSURE ATTENUATES INTERLEUKIN-1 $\beta$ -INDUCED FEVER. A.N. Taylor\*, M.L. Pilati, D.L. Tio, F. Chiappelli and R. Yirmiya. Dept. of Anatomy and Cell Biology, and Sch. of Dentistry, University of California, Los Angeles, and West Los Angeles VA Medical Center, Brentwood Div., Los Angeles, CA 90024; and Dept. of Psychology, The Hebrew University of Jerusalem, Mount Scopus, Jerusalem 91905, Israel.

Exposure to alcohol in utero can lead to long-lasting impairments of immune functions and to decreased resistance to infectious agents. We have previously reported that fetal alcohol exposed (FAE) rats show markedly decreased lipopolysaccharide-induced fever. Based on this finding, as well as on data from other laboratories, we hypothesized that FAE impairs the communication between the immune and the nervous systems. In the present study we assessed this hypothesis by examining the effects of interleukin-1 $\beta$  on body temperature in FAE and control rats. Transmitters for biotelemetric recording of body temperature were calibrated and implanted i.p. in normal (N) adult male rats, age- and sex-matched offspring of dams fed a liquid diet supplemented with ethanol (35% caloric equivalent) during the last two weeks of gestation (FAE) and pair-fed control offspring (P). Baseline recording began 2 weeks after the operation. After 24 hr of baseline recording, all rats were injected with IL-1 $\beta$  (2  $\mu$ g/kg, i.p.). And body temperature was recorded for an additional 24 hr. IL-1 produced a significant increase in body temperature, starting about 2 hr and ending 7 hr following the injection. The febrile response in FAE rats was significantly lower than in P and N rats. These results indicate that FAE produces an impairment in the pyrogenic effects of IL-1. This impairment may account for some of the decreased resistance to infections observed in FAE animals and humans. (Supported by NIH/NIAAA AA09850 and VA Medical Research Service.)

## 451.11

**Retinoic Acid Potentiates the ability of Interferon  $\beta$ -1B to augment Non-Specific Suppressor T Cell function *in vitro* in Multiple Sclerosis.** Z. X. Qu, M. A. Jensen and Barry G.W. Arnason\*, Dept. of Neurology, Univ. Chicago, Chicago, IL 60637.

The Diverse effects of Retinoids on the immune system make them important immunomodulators. Interferons (IFNs) exert anti-viral, anti-proliferative and immunomodulatory effects. IFNs have been used in combination with vitamin A and its analogues to treat various diseases. IFN  $\beta$ -1B is used to treat Multiple Sclerosis (MS). Deficient non-specific suppressor T-cell function in MS is partially restored by IFN  $\beta$ -1B. We studied the effect of IFN  $\beta$ -1B and Retinoic Acid (RA) on Con A-induced suppressor function *in vitro*. Peripheral blood mononuclear cells (PBMC) from 14 healthy controls (8 female and 6 male) and 14 patients (12 female and 2 male) with MS were incubated with IFN  $\beta$ -1B, RA (prepared in dimethyl sulfoxide) or both plus Con A for 48hrs and then treated with mitomycin C to arrest cell proliferation. MMC treated PBMC were washed three times and incubated with fresh PBMC ( $1 \times 10^5/100 \mu$ l for both) in medium alone or with Con A for 72 hrs. Cultures were set up in quadruplicate in a final volume of 220  $\mu$ l. One  $\mu$ Ci of [ $^3$ H]-thymidine was added during the final 5 hrs of incubation. Incorporated radioactivity was measured using liquid scintillation spectroscopy. The results indicate that: 1. RA, at a non-toxic concentration ( $<5 \times 10^{-5}$ M), has no effect on Con A-induced PBMC proliferation; 2. IFN  $\beta$ -1B inhibits lymphocyte proliferation and enhances suppressor function in controls and in MS ( $P < 0.001$ ); 3. Suppressor function in controls is higher than in MS ( $17.13 \pm 2.81$  v.s.  $9.01 \pm 1.83$  ( $P < 0.02$ )); 4. RA ( $5 \times 10^{-5}$  -  $5 \times 10^{-7}$  M) does not augment suppressor function significantly; 5. RA ( $5 \times 10^{-5}$  -  $5 \times 10^{-7}$  M) combined with IFN  $\beta$ -1B (100 to 1000 u/ml) significantly increases suppressor function compared to IFN  $\beta$ -1B alone ( $39.30 \pm 2.73$  v.s.  $31.33 \pm 2.53$  in controls ( $P < 0.04$ );  $35.69 \pm 3.13$  v.s.  $23.77 \pm 2.54$  in MS ( $P < 0.005$ )).

## 451.13

**DIFFERENTIAL UP-REGULATION OF ANTI-VIRAL STATE GENES IN NEURAL CELLS.** L.A. Ward\* and P.T. Massa, Ph.D

Neurons express high levels of interferon-beta (IFN- $\beta$ ) but not MHC class I molecules following viral infection. The non-coordinate induction of these two genes is the result of differential binding of transcription factors at cis-regulatory sites (KB and ISRE sites) common to the promoter regions of these and other anti-viral genes. In addition, the IFN- $\beta$  produced by neurons acts in an autocrine fashion to induce an anti-viral state but not MHC class I gene expression. As a result, it was of interest to determine: 1) what anti-viral state genes are induced in neural cells following viral infection or IFN treatment, and 2) how these genes are differentially regulated via KB and ISRE binding regions. Therefore, we have examined the expression and regulation of the 2'-5' oligoadenylate synthetase (OAS) and inducible nitric oxide synthase (iNOS) genes within neural cells. Northern blot analysis of RNA derived from primary cultures of neurons and astrocytes show that both cell types are induced to express the OAS gene following viral infection or treatment with IFN- $\beta$ . In contrast, astrocytes but not neurons are induced to express the iNOS gene following treatment with virus but not IFN- $\beta$ . This suggests that multiple anti-viral genes can be differentially regulated in neural cells. The cis-regulatory regions and transcription factors responsible for the non-coordinate induction of these genes are being investigated. (Supported by the National Multiple Sclerosis Society.)

**SIGNIFICANCE OF CERVICAL LYMPH NODES IN BRAIN TUMOR IMMUNITY IN THE RAT.** Y. Okamoto\*, S. Kida, J. Yamashita, Dept. of Neurosurgery, Kanazawa Univ., School of Med., Kanazawa, Japan, 920

Recent physiological and anatomical studies have demonstrated that a major fraction of brain interstitial and cerebrospinal fluid drains into cervical lymph nodes in a number of experimental animals. To investigate the role of cervical lymph nodes in brain tumor immunity, temporal profiles of T lymphocyte subsets in brain tumor, cervical lymph nodes and other lymphoid tissues were analyzed by immunohistochemistry and flow cytometry. **Methods:** A total of 37 male Wistar rats were used. 1) Intracranial transplantation models (n=16) 2) Extracranial transplantation models (n=12) 3) Intracranial transplantation with cervical lymphadenectomy models (n=9). 1, 2, 3 and 4 weeks after transplantation, brain, cervical lymph nodes, peritoneal lymph nodes and spleen were removed. Immunohistochemistry was performed by using following antibodies: OX6 (MHC class II), ED-1 (macrophage, microglia), W3/25 (CD4+ T cells) and OX8 (CD8+ T cells). Tumor infiltrating lymphocytes were isolated and were analyzed by flow cytometry. **Results:** Two weeks after the transplantation of C6 glioma cells into the rat brain, expression of MHC class II was induced in the brain and all lymphoid tissues examined. However, the following activation of CD4+ or CD8+ cells was firmly confined to cervical lymph nodes, which coincided with the infiltration of such cells in the brain tumor 2 weeks after the transplantation. Extracranial transplantation of C6 glioma cells showed less reaction of cervical lymph nodes, in which delayed increase of the number of CD4+ cells was observed 4 weeks after the transplantation. In the animal group of cervical lymphadenectomy followed by intracerebral transplantation of C6 glioma cells, there was a delayed infiltration of CD4+ cells in the brain tumor 3 weeks after the transplantation, and the production of such cells was substituted by the spleen. These results suggest that cervical lymph nodes act as draining lymph nodes of the brain and play a crucial role of regional lymph nodes in brain tumor immunity.

## 451.12

**THE IMPACT OF DIFFERENT VIRAL INFECTIONS ON CORTICOSTERONE SECRETION IN MICE** A.H. Miller\*, B.D. Pearce, T.L. Pisell, J.S. Orange, H.C. Su, J.J. Leung, C.A. Biron, Emory Univ. Sch. of Med., Atlanta, GA 30322 and Brown Univ., Providence, RI 02912.

Although there is ample data to suggest that the neuroendocrine and immune systems reciprocally interact, little is known about the specifics of these interactions in the context of ongoing immune responses such as during a viral infection. We have been evaluating cytokine and cellular immune responses to different experimental infections with murine cytomegalovirus (MCMV) and 2 distinct clones of lymphocytic choriomeningitis virus (LCMV). The immune responses to these agents differ both qualitatively and quantitatively. To examine the impact of these infections on the neuroendocrine system, male C57BL/6 mice were infected ip with either MCMV or LCMV clone E350 or iv with LCMV clone 13, and plasma corticosterone was measured at the am nadir on days 1, 2, 3, 5 and 7 post infection (n=3 or more per time point). Each viral infection exhibited a distinct pattern of corticosterone secretion. LCMV clone E350 gave a modest rise in corticosterone with a peak response of  $2.3 \pm 0.4 \mu$ g/dl on day 5 post infection. MCMV infection resulted in a peak response of  $6.9 \pm 1.9 \mu$ g/dl on day 2 post infection followed by a concentration of  $6.2 \pm 3.9 \mu$ g/dl on day 3 post infection. LCMV clone 13 gave the greatest corticosterone response with a sharp rise to  $18.3 \pm 2.8 \mu$ g/dl on day 7 post infection. Baseline corticosterone concentrations in uninfected animals were 1  $\mu$ g/dl or lower in all experiments. These results demonstrate that the corticosterone response to a viral infection is highly specific. Moreover, they suggest that within a given infection there may be critical periods when endogenous immune responses induce glucocorticoids which, in turn, serve to regulate particular cellular and/or cytokine responses to the virus. ## 451.14

**CORRELATION OF HERPESVIRUS NEUROVIRULENCE WITH ALTERATION OF INTRACEREBRAL CYTOKINE PRODUCTION.** G. Lewandowski\*, Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

In general, herpes simplex virus type 2 (HSV-2) is more neurovirulent than closely related strains of HSV-1. The basis for the increased neurovirulence of type 2 is unclear. However, our previous work comparing an avirulent strain of HSV-1 and an extremely neurovirulent strain of HSV-2 suggest that the neurovirulence of HSV-2 results from deficiencies and/or alterations in intracerebral cytokine production. Moreover, the alteration of intracerebral cytokine production results from HSV-2-mediated suppression of class II major histocompatibility complex (MHC)-restricted antigen presentation.

To test this hypothesis the following parameters were used to evaluate several strains of HSV-1 and HSV-2: (i) lethality, (ii) neuroinvasiveness and extent of viral replication in the PNS and CNS, (iii) cellular localization of MHC class II proteins, and (iv) intracerebral cytokine production. Following ocular inoculation of immunocompetent mice, all strains of HSV-1 and HSV-2 invaded the trigeminal ganglia and brain. All strains of HSV-2 were neurovirulent with LD50 values ranging from 3 plaque forming units (pfu) to 66 pfu. Four of 7 strains of HSV-1 were avirulent with LD50's ranging from 7000 pfu to  $>8 \times 10^5$  pfu. Two strains of HSV-1 had LD50's that were within the HSV-2 range (19 and 60 pfu). Expression of MHC class II antigens at the cell membrane was inhibited in CNS and PNS tissues from all mice infected with strains of HSV-2, but not in mice infected with avirulent strains of HSV-1. Most importantly, we observed that the production of intracerebral IFN- $\gamma$  was significantly inhibited in mice infected with all strains of HSV-2, and in those mice infected with strains of HSV-1 that had low LD50 values (neurovirulent strains). In summary, our data suggest that the neurovirulence of HSV-2 (and some strains of HSV-1) may result from significantly suppressed production of intracerebral IFN- $\gamma$ . The inhibition of intracerebral IFN- $\gamma$  is likely caused by HSV-2-mediated suppression of class II MHC-restricted antigen presentation in the PNS and CNS.

## 451.16

**INDUCTION OF INTERLEUKIN-1 BIOACTIVITY AFTER INTRACEREBRAL INFUSION OF NATIVE GP120 AND GP160.** J.M. Weiss\*, Z. Zhang, M. Emery, E. Lai, R. Bonsall, V.S. Kalyanaram\*, and N. Quan, Dept. of Psychiatry and Behavioral Sciences, Emory Univ. Sch. of Med., Georgia Mental Health Institute, 1256 Briarcliff Rd, Atlanta, GA 30306. \*Advanced BioScience Laboratories, Inc., Kensington, MD.

We reported previously that intracerebral infusion of recombinant gp120 (r-gp120 Intracel; formerly American Bio-Technologies, Inc.) induced IL-1 bioactivity in rat brain (Sundar et al., (1991) *PNAS*, 88, 11246-11250). To test whether IL-1 is also induced by native HIV envelope proteins, we used native gp120 (n-gp120) and gp160 (n-gp160), which were purified from the conditioned medium of HIV-1<sub>AD5</sub>-infected HUT78 cells (Advanced BioScience Laboratories, Inc.). Under halothane anesthesia, 10  $\mu$ l of one of the following solutions was slowly infused (over 10 min.) into the hippocampus of pathogen-free Sprague-Dawley rats: pyrogen-free saline, 0.1 or 0.5  $\mu$ g r-gp120, 0.5  $\mu$ g n-gp120, 0.5  $\mu$ g n-gp160, or 1 ng LPS. Three hours later, animals were sacrificed, brains removed, and 5 mm $^3$  tissue surrounding the infusion site dissected. Samples were processed by liquid chromatography and IL-1-containing fractions analyzed by D10 assay (see Quan, N. et al., this meeting). IL-1 bioactivity was found in the extracellular fluid (EC) of tissue infused with LPS and all gp120 and gp160 preparations. IL-1 bioactivity was not found in the saline-infused tissue; the small amount of tissue in the sample likely accounts for absence of IL-1 bioactivity in saline-infused tissue. IL-1 bioactivity was confirmed by the blockade of the stimulation of D10 cells after addition of antibody to IL-1 receptor. To assess whether IL-1 bioactivity might have been due to endotoxin contamination, LPS, r-gp120, n-gp120, and n-gp160 were also infused into the brain of LPS-resistant C3H/HeJ mice. In these animals, IL-1 bioactivity was detected in gp120- and gp160- but not in LPS-infused tissue. Furthermore, infusion of carboxy methylated r-gp120 and r-gp160 (CM-gp120 and CM-gp160; Advanced BioScience Laboratories, Inc), which have original amino acid sequence but altered structure, produced no IL-1 bioactivity. Thus, native HIV envelope protein gp120 and gp160 induced brain IL-1 activity; this effect depends on the intact structure of these proteins. (Supported by NIH grant 50420)

## 451.17

DETECTION OF IL-1 BIOACTIVITY IN VARIOUS BRAIN REGIONS OF NORMAL HEALTHY RATS. N. Quan\*, Z. Zhang, M. Emery, R. Bonsall, and J.M. Weiss. Dept. of Psychiatry and Behavioral Sciences, Emory Univ. Sch. of Med., Georgia Mental Health Institute, 1256 Briarcliff Rd., Atlanta, GA 30306.

Although interleukin-1 (IL-1) has been implicated in an array of brain functions, it is generally not detected in brain unless viral or bacterial stimulation is present (e.g., by lipopolysaccharide). But in view of the potency of IL-1 in brain, small amounts of this cytokine may normally act in brain and such quantities can escape detection by assay methods usually employed. Bioassays that are currently most sensitive to IL-1 can be compromised by molecules in brain tissue other than IL-1 and attempts to purify IL-1 from brain tissue can result in significant loss of IL-1 from samples. In studies reported here, we have refined techniques sufficiently to reliably detect IL-1 bioactivity in both extracellular fluid (EC) and tissue lysate (LY) of normal, healthy rat brain. After pathogen-free Sprague-Dawley rats were perfused by cardiac puncture to eliminate blood from brain tissue, brainstem, cortex, diencephalon, and hippocampus were dissected immediately on ice [for dissection, see Quan et al. (1994) *J. Neuroimmunol.*, 49, 125-134]. EC from brain regions was extracted by segregating brain cells with a nylon mesh in culture medium and collecting supernatant after centrifugation. Additional samples of LY were produced by ultrasonic sonification of tissue residue. IL-1 in EC and LY was isolated by running samples through a 9x95 mm G-50 sephadex mini-column equilibrated with culture medium after which fractions containing IL-1 were subjected to assay using D10 cells, which detects rhIL-1 at the level of 1 pg/ml in our hands. The short G-50 columns minimized loss of IL-1 (more than 40% IL-1 can be recovered from a starting sample load of 50 pg of IL-1). IL-1 bioactivity was reliably detectable, i.e., D10 growth was greater in IL-1 containing fractions relative to baseline (incubation with medium alone), in EC of all brain regions examined. Furthermore, IL-1 bioactivity was blockable in all brain regions by addition to the D10 cell bioassay of monoclonal antibody against type I IL-1 receptor. Hence, low levels of IL-1 appear to be present in most brain regions of normal healthy rats. (Supported by NIH grant 50420)

EXPRESSION OF NITRIC OXIDE SYNTHASE TYPE II IN THE CNS DURING ACUTE AND PERSISTENT HEPATITIS VIRUS INFECTION. A. Lojhl\*, D. Grzybicki\*, S. Kardos, S. Perlman\* and S. Murphy. Depts. of Pharmacology, Pathology\* and Pediatrics\*, Univ. of Iowa, Iowa City, IA 52242.

Transcriptional induction of nitric oxide synthase type II (NOS II) requires cellular exposure to proinflammatory cytokines, suggesting that NOS II is active under pathophysiological conditions. In this study we determined whether, and in which cell types, NOS II was induced during acute and/or persistent mouse hepatitis virus (MHV-JHM) infection in the CNS.

Intranasal inoculation with MHV-JHM in C57BL/6 mice results in an acute, rapidly fatal encephalitis. We find expression of NOS II mRNA in brains of infected (but not uninfected) animals by RT-PCR and ribonuclease protection assay on day 6 after infection when all mice become clinically ill, and this continues through day 7, when all mice expire. Western blotting reveals NOS II protein in infected brain. Expression is in macrophages diffusely infiltrating in the late stages of infection. In persistent MHV-JHM infection NOS II mRNA and protein were expressed in brain and spinal cord of mice exhibiting hindlimb paralysis. Immunohistochemical studies are in progress to localize the cell type(s) expressing NOS II.

The results suggest that NO plays a role in the pathologies occurring with acute and persistent MHV infection. In acute infection, NO production does not appear to be a first-line defense mechanism. Supported by NS29226.

CHARACTERIZATION OF THE PERIPHERAL IMMUNE RESPONSE TO OVALBUMIN MICROINFUSED INTO THE NORMAL MOUSE BRAIN. J.T. Park, C.J. Harling-Berg, P.M. Knopf\*. Physiology and Molecular Microbiology and Immunology, Brown University, Providence, RI 02912.

We have demonstrated in a normal rat model, that CNS immunity involves a significant, persistent and enhanced specific antibody response elicited in the periphery of rats receiving a microinfusion of antigen into brain (Cserr and Knopf, *Imm. Today*, 13(12): 507-512, 1992). Antigen was administered through an indwelling cannula implanted 7 days earlier to allow for the recovery of the blood-brain barrier. Our current studies extend findings to an outbred (CD1) mouse strain. The peripheral humoral and delayed-type hypersensitivity (DTH) responses to OVA infused into ventricular CSF were characterized and compared to subcutaneous (SC) injections of OVA in the presence and absence of complete adjuvant. Antibody and DTH responses were measured using an ELISA and standard ear-swelling assay, respectively. Following a CSF-injection of OVA, serum anti-OVA antibody titers were elevated and sustained for at least 10 weeks post-immunization. A response was measured for all OVA doses: 10µg (n=12), 20µg (n=4), and 50µg (n=4). CSF immunizations yielded significantly ( $P<0.01$ ) greater serum titers (mean log titer = 3.655) than comparable (50µg) SC-administered doses (n=6, mean log titer = 2.143). CSF and SC immunization protocols elicit predominantly IgG1 and IgG2b isotypes with relatively little IgM, IgG2a, and IgA. However, immunization via CSF elicited a greater percentage of IgG2b than SC immunization. Both CSF and SC immunizations with OVA alone did not generate a DTH response as compared to negative controls at 21 days. Data indicates that the afferent limb of the immune response to brain-administered antigen is intact in the mouse. Results, consistent with our rat model, support the concept that CNS immunity favors a strong humoral response and down-regulates potentially damaging cell-mediated inflammatory responses.

INDUCTION OF ICE mRNA AND ENZYME ACTIVITY IN THE RAT BRAIN AND ADRENAL GLAND. M. Schultzberg\*, S. Tingsborg, C. Eriksson, M. Zetterström, K. Alheim and T. Bartfai\*. Dept. of Clin. Neurosci., Geriatric Med., Karolinska Institute, Novum & Dept. of Neurochem. and Neurotoxicol., Stockholm Univ., Stockholm, Sweden.

The overexpression of interleukin-1β converting enzyme (ICE) has been shown to cause apoptotic cell death in transfected fibroblasts and dorsal root ganglion neurons. The present study analyzes the distribution and inducibility of ICE enzyme activity and mRNA in the adult rat brain, the pituitary and the adrenal gland. Using an artificial fluorescence substrate, DABCYL-Tyr-Val-Ala-Asp-Ala-Pro-Val-EDANS, the specific activity of ICE, under non stimulated conditions, was highest in the hypothalamus, followed by the pituitary and hippocampus. The  $K_m$  values for ICE:  $25 \pm 15 \mu M$  using the fluorescence substrate, were similar in all tissues. ICE enzyme activity was significantly induced in the pituitary 4 hours after intraperitoneal (i.p.) injection of *E. coli* lipopolysaccharides (LPS; 2 mg/kg), while the same treatment did not affect hypothalamic, and slightly suppressed hippocampal and adrenal gland enzyme activity. Constitutive expression of ICE mRNA was found in all brain regions, the pituitary and the adrenal gland, and an increase was found in the pituitary and adrenal gland after the LPS treatment, as was pro-interleukin-1β (pro-IL-1β) mRNA expression. ICE mRNA levels in the hypothalamus and hippocampus were not affected at the 4 hour time point after LPS injection. The results are discussed in relation to LPS-stimulated production of mature IL-1β by ICE. The constitutive and regionally specific distribution of ICE in the rat brain suggests that ICE at least partly is neuronally expressed. DIFFERENTIAL RESPONSES TO BACTERIAL ENDOTOXIN OF SPLENIC AND RENAL SYMPATHETIC NERVES. B.J. MacNeil\*, A.H. Jansen, A.H. Greenberg, and D.M. Nance. Dept. of Pathology and Manitoba Institute of Cell Biology, Univ. of Manitoba, Winnipeg, Manitoba, Canada R3E 0W3.

Regulatory interactions and neuroanatomical pathways exist between the sympathetic nervous system (SNS) and the immune system. It is not clear whether these pathways are selectively active in immune organs during immune responses. We tested whether systemic injection of endotoxin (LPS) induces sympathetic outflow to an immune organ (spleen). Sympathetic nerve activity was recorded in adult male rats from either the splenic or renal nerve. Splenic nerve activity increased in a dose dependent manner up to 175% of control 17.1 to 23.5 minutes following i.v. injections of LPS. In contrast, renal nerve recordings showed a significantly slower onset of 37.1 to 52.6 minutes at the same doses, despite a similar magnitude of increase. In addition, splenic nerve recordings of 8/8 rats responded to 10 µg of LPS, whereas only 4/11 positive renal nerve responses were observed at this dose. Spectral analysis of sympathetic nerve activity (35 contiguous 5 s windows, percent area under the average FFT curve calculated) revealed baseline splenic nerve activity had greater power in the 0-2 Hz bandwidth compared to renal nerve activity ( $0.333 \pm 0.013$  vs  $0.271 \pm 0.007$ ,  $p=0.015$ ). The renal nerve had a greater proportion of power in the 6-8 Hz range relative to the splenic nerve ( $0.135 \pm 0.003$  vs  $0.101 \pm 0.009$ ,  $p=0.028$ ). LPS enhanced these differences, albeit, nonsignificantly. In summary, splenic nerve activity, which differs in discharge pattern from the renal nerve, is more sensitive to LPS-induced sympathetic activation regarding the latency and rate of responses. Thus, differential sympathetic outflow can be directed to an immune organ in response to a stimulus known to activate the immune system. Supported by MRC (Canada), MHRC (Manitoba) and NIMH.

CENTRAL NITRIC OXIDE SYNTHASE INHIBITION BLOCKS ENDO-TOXIN-INDUCED C-FOS PROTEIN IN THE HYPOTHALAMUS.

A.T.K. Jackson\*, L. Janz, A.H. Greenberg and D.M. Nance. Depts. of Pathology and Physiology and Manitoba Institute of Cell Biology, University of Manitoba, Winnipeg, MB, Canada R3E 0W3

Endotoxin is a potent stimulator of numerous immunological and physiological systems. It has been shown that injection of lipopolysaccharide (LPS), a powerful bacterial endotoxin, results in the expression of the proto-oncogene c-fos in the brain (Wan et al. *B.R.B.* 32:581, 1993). We report here that central injections of L-NAME, a nitric oxide synthase inhibitor, inhibited LPS-induced c-fos in the paraventricular nucleus and this inhibition was LPS dose-dependent. Male S-D rats were pretreated by i.c.v. infusion of L-NAME (50µg) and then treated with an i.v. LPS dose of either 10, 20, 40, 50, or 100µg. All doses of LPS induced c-fos in the brain, but only the 10 and 20µg doses were significantly inhibited by L-NAME. This suggests a functional role for central nitric oxide in low dose LPS-induced neuronal changes. The lack of inhibition at higher doses may be due to extra-immunological effects induced by high doses of LPS. In preliminary work, centrally administered PGE<sub>2</sub> induced c-fos in a pattern similar to that produced by i.v. LPS and this PGE<sub>2</sub>-induced c-fos also was inhibited by i.c.v. L-NAME. This suggests a role for nitric oxide in the neuronal signalling produced by LPS, and that PGE<sub>2</sub> is a likely mediator in this pathway. Supported by MRC and NIMH.
