Peripheral injection of lipopolysaccharide (LPS), a potent bacterial endotoxin, results in the central expression of the proto-oncogene c-fos. Areas of the brain that have increased c-fos expression include the paraventricular nucleus of the hypothalamus (PVN) and the catecholamine cell groups located in the dorsal and ventrolateral regions of the medulla (Wan et al, B.R.B. 32:581,1993). To investigate further the potential role of catecholamines in the central expression of c-fos, unilateral posteriorlateral hypothalamic knife cuts were used to eliminate ascending catecholamine input to the hypothalamus. After i.v. LPS treatment (50µg), c-fos induction in the PVN was inhibited on the cut side of the brain and the knife-cuts produced an ipsilateral reduction in dopamine-β-hydroxylase staining in the hypothalamus. Preliminary work with unilateral knife cuts of catecholamine tracts in the mesencephalic pontine region produce a similar ipsilateral reduction of endotoxin-induced c-fos staining in the PVN. These results suggest a functional neural role for catecholamines in the central processing of the LPS immune stimulus. Supported by MRC and NIMH.

## THE ROLE OF INTERLEUKIN-6 IN THE NEUROCHEMICAL AND HPA CHANGES INDUCED BY ENDOTOXIN.

J.P. Wang, Nick Goeders\* and A.J. Dunn.

Dept Pharmacology, Louisiana State University Medical Center, Shreveport, LA 71130.

Interleukin-6 (IL-6) is produced by immune cells early in the response to antigenic stimulation. IL-6 has been reported to activate the hypothalamo-pituitary-adrenocortical (HPA) axis. Our data show that IL-6 concentrations in the plasma rise after endotoxin (LPS) administration, with a peak at 2-3 hours. Administration of purified recombinant mouse IL-6 intraperitoneally activated the HPA axis as indicated by increases in plasma ACTH and corticosterone. IL-6 was significantly less potent than IL-1. The peak effect occurred at around one hour. We observed no effects on catecholamines or metabolites in the brain. However, tryptophan and 5-hydroxyindoleacetic acid (5-HIAA) were elevated at several time points after mL-6 injection. Experiments with monoclonal antibodies to mouse IL-6 have indicated attenuation of the HPA response to LPS. These results suggest that IL-6 may play a role in the responses to LPS, but the lack of effect of IL-6 on cerebral norepinephrine, suggests that it is not the only factor.

## LONG-TERM I.C.V. CORTICOTROPIN-RELEASING HORMONE INFUSION OF RATS ALTERS ENDOTOXIN-INDUCED AUTONOMIC AND NEURAL RESPONSES A.C.E. Linthorst\*, M.S. Labeur and J.M.H.M. Reul, Max Planck Institute of Psychiatry, Clinical Institute, Dept. of Neuroendocrinology, Munich, Germany.

Recently, we reported on the effects of long-term i.c.v. corticotropin-releasing hormone (CRH; 1 µg/µl/h via an Alzet minipump) infusion of male rats on the hypothalamic-pituitary-adrenocortical (HPA) axis and the immune system (Labeur et al., *Endocrinology* May 1995). A sustained HPA axis hyperactivity was observed, as indicated by increased plasma ACTH and corticosterone (CORT) levels, increased anterior pituitary POMC mRNA expression and adrenal enlargement. Moreover, the i.c.v. CRH treatment suppressed *in vitro* splenocyte activation and enhanced IL-1β and IL-2 expression. In this study, experiments were performed to investigate whether the increased HPA axis activity and the altered cytokine expression in the CRH-infused rats has *in vivo* physiological consequences. In one set of experiments, biotelemetric transmitters were i.p. implanted to monitor body temperature and locomotion, and in another set a microdialysis probe was implanted in the hippocampus to measure serotonergic neurotransmission and free CORT levels. Compared to control animals, CRH-treated rats showed an overall increase in body temperature with a flattening of the circadian rhythm, a marked increase in locomotion and elevated free CORT levels. I.p. administration of endotoxin (lipopolysaccharide) is known to induce fever, and to increase HPA axis activity and hippocampal serotonergic neurotransmission. However, after an i.p. endotoxin injection the CRH-treated rats produced markedly reduced elevations in both body temperature and hippocampal serotonergic neurotransmission whereas the attained free CORT levels were similar. Summarizing, our results demonstrate that chronic activation of the HPA axis has profound consequences for the autonomic and neural responses to an endotoxic challenge.

## 452.4

## ENDOTOXIN INCREASES NITRIC OXIDE SYNTHASE mRNA LEVELS IN THE PARAVENTRICULAR NUCLEUS OF THE RAT HYPOTHALAMUS.

Soon Lee\*, Gérard Barbanel and Catherine Rivier, Clayton Fndn. Laboratories for Peptide Biol., The Salk Institute, 10010 N. Torrey Pines Road, La Jolla, CA 92037.

Nitric oxide synthase (NOS), the enzyme responsible for nitric oxide (NO) formation, is found in hypothalamic neurons that control ACTH secretion. This led to the hypothesis that brain NO may modulate the response of the hypothalamic-pituitary axis (H-P) to various stimuli. We tested this hypothesis by measuring changes in constitutive (c) NOS mRNA levels in the hypothalamus of rats systemically injected with endotoxin, a lipopolysaccharide (LPS) that releases endogenous cytokines, and analyzed these results in the context of the appearance of corticotropin-releasing factor (CRF) and vasopressin (VP).

Following LPS injection (100 µg/kg, iv), cNOS mRNA levels increased dramatically 3-4 h in the paraventricular nucleus. LPS treatment also rapidly upregulated CRF heteronuclear RNA, and increased mRNA levels of the immediate early genes, *c-fos* and *NGFI-B*, as well as CRF and its receptors. On the other hand, no changes in cytoplasmic VP mRNA levels were noted following LPS injection. At present, the prevailing concept is that iv administered LPS influences both the activity of nerve terminals and that of hypothalamic cell bodies, a phenomenon believed to reflect the concerted action of the various neurotransmitters and cytokines released by endotoxin. Our results indicate the involvement of several circuitries of potential importance for ACTH secretion in rats injected with endotoxin, though it is premature to invoke a causal relationship between the increased gene expression of cNOS and CRF.

These studies indicate that systemic LPS produces rapid increases in neuronal activity of hypothalamic regions known for their involvement in the responses of the H-P axis. While the role of CRF and its receptors is fairly well understood, the observation of increased cNOS gene expression following LPS treatment, and the presence of this enzyme in neurons that regulate ACTH secretion, bring support to the hypothesis that this gas also plays an important function in mediating the H-P axis response to an immune challenge.

## 452.6

## THE EFFECTS OF HIGH FAT DIET AND EXERCISE ON THE RESPONSE TO BACTERIAL ENDOTOXIN IN FEMALE SPRAGUE DAWLEY RATS.

P.J. Rowsey\*, T.A. Lennie and B.L. Metzger, The University of Michigan, Ann Arbor, MI 48109-0482

The hypothesis that exercise induces clinically significant functional changes in the immune system is supported by data from several studies showing that moderate to intense exercise is associated with an increased number of lymphocytes, especially natural killer cells (NK cells). We studied the relationship between diet and exercise-induced increase in natural immune function. Female Sprague Dawley rats (12:12 reverse photoperiod) with access to running wheels were fed a high fat diet (HF, 62% Kcal from fat). Ten rats had access to running wheels for 6 weeks and 10 were sedentary controls. At the end of a six week period, the response to a challenge of bacterial endotoxin (lipopolysaccharide, LPS 50 µg/kg) was examined. Food intake (FI), body temperature (BT), and activity were recorded for four hours. At the end of 4 hour period, animals were sacrificed and spleens were taken for immune profile studies. During the 4 hours following LPS injection, there were no differences in FI, BT, or activity between the two groups. In the presence of a HF diet, total spleen lymphocytes were higher in sedentary animals (35.7% positive cells) as measured by flow cytometry when compared to the sedentary animals fed a normal diet (27.8% positive cells). There were no differences in the number of T helper (CD4) and T suppressor (CD8b) cells in the spleens of exercise and sedentary animals. However, in the presence of a high fat diet, exercise animals showed lower number of total lymphocytes as well as lymphocytes with cytotoxic function (CD8a). This decreased expression of cytotoxic lymphocytes in the exercised group differs from that found in previous studies. These results indicate that animals given a high fat diet, regardless of activity level, do not express the usual immune response to LPS, either behaviorally or via their immune profile.

## 452.8

## NONHYPOTENSIVE ENDOTOXEMIA INCREASES PLASMA NOREPINEPHRINE AND INDUCES FOS IN THE CENTRAL NUCLEUS OF THE AMYGDALA. N. Tkacs\* and J. Li, Depts. of Psychiatry and Neurosciences, UMDNJ-New Jersey Medical School, Newark NJ 07103.

Conscious, chronically instrumented male Sprague-Dawley rats were studied for blood pressure, heart rate and plasma norepinephrine responses to E. coli endotoxin (ETX). For 6 hours following bolus injection of ETX 10 µg/kg or 50 µg/kg intravenously, no hypotension was observed, however, there was significant tachycardia from 2 hours to 6 hours post-ETX. Plasma norepinephrine was significantly elevated after both doses of ETX, indicating prolonged sympathetic activation.

We chose 25 µg/kg, a dose within this nonhypotensive, sympatho-excitatory range to study Fos expression in the central nucleus of the amygdala (CeA). At time points 1 hour to 4 hours after ETX, rats were deeply anesthetized and perfused, with removal of the brains for Fos-ICC using standard techniques. Counts of Fos-stained nuclei were increased at 4 rostrocaudal levels of the CeA beginning at one hour and persisting for 4 hours after ETX. Fos expression in the medial amygdala was minimal after this stressor. This raises the possibility that the CeA, a limbic and autonomic related nucleus, may be involved in the behavioral and autonomic responses to mild acute endotoxemia. Supported by NR03801.

## 452.9

INDUCTION OF THE INFLAMMATORY CYTOKINES IL-1, IL-6 AND TNF $\alpha$  IN MICE FOLLOWING EXOGENOUS ADMINISTRATION OF INFLAMMATORY AGENTS. L.K. Jackson<sup>1</sup>, R. Kulmer<sup>2</sup>, S.W. Rogers<sup>1,2,3</sup> and L.C. Gabring<sup>1,2,4</sup>. S.L.C. VA GRECC, <sup>1</sup> Depts of Neurobiology and Anatomy<sup>2</sup>, Human Molec. Biol. and Genetics<sup>3</sup> and Medicine<sup>4</sup>, Univ. of Utah, S.L.C., UT.

The inflammatory cytokines IL-1, IL-6, and TNF $\alpha$  are expressed in the CNS and there is increasing interest in the role of these mediators in neuronal function during health and disease. We have examined the expression of these cytokines in the peripheral immune system and the CNS following intravenous administration of lipopolysaccharide (LPS). At specific times after LPS administration, mice were perfused with saline to remove contaminating blood cells and the brains were dissected into cortex, hippocampus, cerebellum, midbrain and hypothalamus. Spleens from these animals were also isolated. RNA was extracted and RT-PCR performed using cytokine specific primers. All results were quantified by measuring EtBr incorporation into PCR products as determined by fluorimetry, and normalized to  $\beta$ -actin expression. Injection of LPS induces elevations in the expression of cytokine mRNA which peaks at 2 hrs post LPS administration and decreases to normal levels by 6 hrs. All regions of the brain examined by RT-PCR demonstrated a similar pattern of cytokine mRNA induction. We investigated the expression of cytokine protein by immunohistochemistry. Results demonstrate that protein expression is more limited in distribution and associated with specific neuronal neurotransmitter receptors systems. Regions of the CNS that contain cytokine expressing cells include the globus pallidus, hippocampus and thalamus. Cytokine expressing cells are also present in some white matter tracts. Therefore, both glial and neuronal-like cells produce these inflammatory cytokines, and levels are sensitive to peripheral insult. Supported by NIH grants AG04418, NS0990, and the American Federation for Aging Research.

## 452.11

EFFECT OF  $\beta$ -ENDORPHIN ON ENDOTOXIN-INDUCED FORMATION OF IL-1 $\alpha$ , IL-1 $\beta$  AND IL-6 IN FETAL MIXED BRAIN CELLS *in vitro* K. P. Das\*, M. K. McMillan, B. C. Wilson, P. M. Hudson and J. S. Hong. Laboratory of Environmental Neuroscience, NIEHS-NIH, Research Triangle Park, NC 27709.

Opioids have been shown to have diverse effects on the peripheral immune system, both *in vivo* and *in vitro*, but their interactions with the glial cells of the central nervous system (CNS) have not been well studied. In the present study, we have examined the effect of opioid peptide  $\beta$ -endorphin (61-91) ( $\beta$ -end) on lipopolysaccharide (LPS)-induced production and release of IL-1 $\alpha$ , IL-1 $\beta$  and IL-6 from mouse embryonic mixed brain cell cultures. Two-week-old mixed embryonic brain cell cultures were treated with LPS (1  $\mu$ g/ml) and  $\beta$ -end ( $10^{-14}$  M to  $10^{-6}$  M) alone and/or together for 3 h, 6 h, 12 h, 24 h, and 48 h, and cytokines were measured by ELISA. None of the  $\beta$ -end concentrations examined significantly altered the production or release of IL-6, and the release of IL-1 $\alpha$  and IL-1 $\beta$  were not detectable; LPS significantly induced both the formation and release of all three cytokines.  $\beta$ -endorphin ( $10^{-14}$  M to  $10^{-6}$  M), however, suppressed the LPS-induced increases of all three cytokines in the media after 48 h of treatment. These data indicate that the opioid peptide  $\beta$ -end has an inhibitory role in regulating the endotoxin-induced release of inflammatory cytokines, and further suggests possible roles for opioid peptides in the regulation of neuroimmune function in the CNS.

## 452.13

INFLAMMATORY STRESS MODULATES CORTICOTROPIN-RELEASING FACTOR RECEPTOR A (CRF-RA) mRNA LEVELS IN RAT PITUITARY. J.M. Aubry\*, G. Pozzoli, A.V. Turnbull, Catherine Rivier and W.W. Vale. Clayton Foundation Labs. for Peptide Biol., The Salk Institute, La Jolla CA 92037, USA.

Inflammatory stress produces profound activation of the hypothalamo-pituitary-adrenal (HPA) axis. The majority of evidence indicates that inflammatory mediators (i.e. cytokines) act at the level of the hypothalamus to stimulate the secretion of CRF, the major adrenocorticotropin (ACTH) secretagogue. However, while a number of studies have described direct pituitary actions, the effects of inflammatory stimuli on corticotrope sensitivity to CRF remain to be elucidated. The aim of this study was to determine the effects of systemic or local inflammation on the levels of mRNA for the rat pituitary CRF receptor (CRF-RA).

Both systemic (intravenous lipopolysaccharide, LPS, 5 $\mu$ g/kg) and local inflammation (intramuscular turpentine, 50  $\mu$ l/100 g BW) increased plasma concentrations of ACTH and the cytokine, interleukin-6 (IL-6). Although systemic LPS induced much higher levels of ACTH (4 fold) and IL-6 (50 fold) than local inflammation, these responses were of shorter duration (LPS approximately 6h, turpentine>12h). RNase protection assay analysis of total RNA isolated from whole pituitary, indicated that systemic LPS produced a decrease in CRF-RA mRNA, that was evident by 2h after injection (to 65% of controls) and more marked by 6h (to 40% of controls). Similarly, local inflammation produced a reduction in pituitary CRF-RA mRNA levels (to 45% of controls at 8h).

These data indicate that CRF receptor mRNA levels in the pituitary of the rat are markedly reduced during both systemic and local inflammation, suggesting that pituitary sensitivity to CRF may be altered by these stimuli. Whether the modulation of pituitary CRF-RA is due to direct effects of inflammatory mediators or results from changes in HPA activity (eg. increased exposure to CRF), remains to be determined.

## 452.10

CYTOKINE REGULATION OF PROENKEPHALIN GENE EXPRESSION IN THE PARAVENTRICULAR NUCLEUS (PVN) S. E. Hyman, S. E. Lewis\*, O. Falkowski, K. Van Kuoghnet, D. Borsook. Molecular and Developmental Neurobiology Laboratory, Mass. Gen. Hospital, Boston MA 02114

Lipopolysaccharide (LPS), the principal component of endotoxin, has profound physiological effects on the central nervous system and on neuroendocrine systems. These effects are thought to be mediated by various cytokines including interleukin-1 $\beta$  (IL-1 $\beta$ ). We have produced transgenic mice expressing a human proenkephalin- $\beta$ -galactosidase fusion gene which is correctly expressed and regulated by stress in the hypothalamus. Intraperitoneal (i.p.) injections of LPS (4mg/kg) produced an increase in transgene expression in the PVN but not in the supraoptic nucleus (SON). Following a single i.p. injection of LPS transgene induction is seen within 2 hrs, is maximal at 12 hrs, and decreases at 24 and 48 hrs to below basal levels. Surprisingly, transgene induction by LPS is inhibited by pretreatment with naloxone. Induction of transgene expression in the PVN also correlates with c-Fos induction following LPS. In preliminary experiments, i.p. (0.1 $\mu$ g in 0.2ml NS) or i.c.v. (2ng) injections of interleukin-1 $\beta$  also produced a significant increase in the transgene expression. Gel-shift analysis with nuclear extracts from the hypothalamus containing the PVN shows induction of binding to putative cytokine response elements in the proenkephalin gene. Supershift analysis showed that STAT 3 binding is induced. Binding of other cytokine regulated proteins within the proenkephalin gene is being analyzed. These results suggest a model in which proenkephalin gene expression in the PVN may be regulated in part by specific cytokine response elements.

## 452.12

TUMOR NECROSIS FACTOR  $\alpha$  (TNF $\alpha$ ) MEDIATES THE RAT HYPOTHALAMO-PITUITARY-ADRENAL (HPA) RESPONSE TO ACUTE LOCAL INFLAMMATION BY AN ACTION IN BRAIN. A.V. Turnbull\* and Catherine Rivier. Clayton Fdn. Labs. for Peptide Biol., The Salk Institute, La Jolla CA 92037, USA.

Inflammatory processes have a profound impact on neuroendocrine function, an effect which is thought to be mediated by cytokines. However, the precise role of individual cytokines in different inflammatory conditions (systemic versus local and acute versus chronic), and their site of action (within the brain or periphery) remains to be established. The present study investigated the role of TNF $\alpha$  within the brain in activation of the HPA axis by acute local inflammation in the rat.

Injection of a small volume (50  $\mu$ l/100 g body weight) of the mineral oil turpentine into the hindlimb produced an initial and brief (within the first hour) stress-induced increase in plasma adrenocorticotropin (ACTH). This was followed by a swelling of the limb, a rise in plasma interleukin-6 concentration and a secondary rise in plasma ACTH, which peaked at around 8h. Immunoneutralization of corticotropin-releasing factor or arginine vasopressin indicated that this secondary, inflammation-induced, rise in ACTH was mediated by a combination of both these hypothalamic neuropeptides.

Prior central (intracerebroventricular) administration of either a soluble TNF receptor construct (rhTNFR(p80):Fc, 1-50  $\mu$ g, Immunex, Seattle) or a neutralizing rabbit anti-mouse TNF $\alpha$  (5  $\mu$ l) antiserum, inhibited the secondary peak rise in plasma ACTH induced by local inflammation by 62-72%. In contrast, these treatments administered intravenously, at the same doses, had no significant effect on the ACTH response.

These data indicate that acute local inflammation in the rat induces activation of the HPA axis which is dependent on the action of TNF $\alpha$  within the brain. Whether TNF $\alpha$  is synthesized within the brain, or is derived from peripheral sources, remains to be determined.

## 452.14

INFLAMMATORY RESPONSES TO ADENOVIRUS VECTOR GENE THERAPY IN THE BRAIN. A.P. Byrnes\*, M.J.A. Wood and H.M. Charlton. Dept. of Human Anatomy, Univ. Oxford, Oxford OX1 3QX, UK

Non-replicating viral vectors are being widely considered for gene therapy in the brain, but few studies have examined the immune response to these vectors and whether it results in any pathology. The lengthy expression that is possible from E1-deleted adenovirus in the adult brain deserves special attention, as in most other organs a T cell immune response eliminates the virus within weeks. We have used a variety of approaches to characterize the inflammation which follows an injection of adenovirus vector.

- By depleting CD4<sup>+</sup> or CD8<sup>+</sup> T cells, we have determined that adenovirus vectors in the brain induce both an early phase of inflammation that is independent of T cells, and a later phase that depends on T cells, particularly of the CD4<sup>+</sup> subset. This second phase includes extensive recruitment of leukocytes into the brain and perivascular cuffing.

- By two months after an injection of vector into the brain, inflammation has essentially ceased. If a peripheral injection of adenovirus vector is then given, a much more severe immune response resumes in the brain around the original injection site, leading to demyelination.

We conclude that the inflammatory response to adenovirus vectors, although severe, probably does not result in damage to the brain and is not sufficiently strong to eliminate the virus. However, the virus which remains in the brain is still potentially a target of the immune system, as after a second injection of virus in the periphery a strong T cell response develops which causes damage in the brain. In addition to their implications for gene therapy, these studies may form a basis for the better understanding of immune responses to persistent viruses in the brain, as well as the role of T cells in demyelinating pathology.

## 452.15

CRF AND IL-1 RECEPTOR UPREGULATION IN LOCALIZED INFLAMMATION. S. Mousa<sup>1,2</sup>, M. Schäfer<sup>1,2</sup>, W. Mitchell<sup>2\*</sup>, C. Stein<sup>1</sup>, <sup>1</sup>Dep. Anesthesiology, Johns Hopkins University, <sup>2</sup>NIDA/Addiction Research Center, Baltimore, MD 21224.

Previously, we showed that injecting CRF or IL-1 $\beta$  into inflamed tissue caused local release of opioid peptides by a receptor specific mechanism, and opioids in turn produce antinociceptive effects. In the present study we examined CRF and IL-1 $\beta$  binding with regard to specificity, anatomical localization and quantitative differences in inflamed and non-inflamed tissue by means of *in vitro* receptor autoradiography. Four days after intraplantar injection of Freund's complete adjuvant, sections from subcutaneous paw tissue, popliteal lymph nodes and spleen were examined autoradiographically using <sup>125</sup>I-oCRF and <sup>125</sup>I-IL-1 $\beta$  as ligands. CRF and IL-1 $\beta$  binding sites were present on immune cells in the inflamed subcutaneous paw tissue and lymph node but were practically absent on nerves and in non-inflamed subcutaneous paw tissue. The number of CRF and IL-1 $\beta$  receptors, as detected by densitometry and counting of autoradiographic grains is greatly enhanced in inflamed paws and lymph node but it does change in the contralateral paw, lymph node or spleen. These findings are consistent with our *in vivo* studies that have shown potent antinociceptive effects of locally applied CRF or IL-1 $\beta$  in inflamed but not in non-inflamed tissue.

## 452.17

CENTRAL  $\alpha$ -MSH EFFECTS ON TWO MODELS OF PERIPHERAL INFLAMMATION IN THE RAT. E. D. Milligan, P. G. Green, J. D. Levine and M. F. Dallman\*. Dept. of Physio UCSF, San Francisco, CA., 94143.

When injected *i.v.*,  $\alpha$ -melanocyte-stimulating hormone ( $\alpha$ -MSH), a pro-opiomelanocortin derivative, reduces both picryl-chloride-induced and intradermal cytokine-induced inflammation of mouse ears. (Lipton et al, 1991, Peptides, 12:795-798) To test the effects of central  $\alpha$ -MSH on inflammation in rats, we administered 3rd ventricular injections of  $\alpha$ -MSH<sub>(1-13)</sub> at 0.1, 0.25, 0.5, 1.0, or 2.5, in 2.5  $\mu$ l, or 5.0  $\mu$ g in 5.0  $\mu$ l to alter xylene-induced inflammation of an ear. Anti-inflammatory effects of 3rd ventricular injections of  $\alpha$ -MSH were measured by changes in ear thickness (with a spring-loaded micrometer) prior to and 2, 4, and 6 hours after xylene application. Results revealed a U-shaped, dose effect of  $\alpha$ -MSH<sub>(1-13)</sub> on inflammation. Maximal anti-inflammatory effects were observed at 0.5 and 1.0  $\mu$ g of  $\alpha$ -MSH. Additionally, we tested the effects of a 3rd ventricular injection of  $\alpha$ -MSH at 0.1, 0.25, 0.5, or 1.0  $\mu$ g on bradykinin-induced plasma extravasation in the knee joint assessed by measurement of Evans blue dye in the fluid perfusing the rat knee joint. Central  $\alpha$ -MSH dose-dependently inhibited bradykinin-induced plasma extravasation within 10 minutes of 3rd ventricular administration. We conclude that central  $\alpha$ -MSH<sub>(1-13)</sub> has anti-inflammatory effects on two rat models of inflammation: xylene-induced inflammation of the ear and bradykinin infused into the knee joint.

Supported in part, by KD28172.

## 452.16

A NEW MODEL OF NEUROGENIC INFLAMMATION USING A NEUROTROPIC VIRUS. H. Guo<sup>1</sup>, D. Goff<sup>1</sup>, R. Schmidt<sup>2</sup>, L. Jasmin<sup>1\*</sup>

<sup>1</sup>Neurosurgery & Cell Biology Georgetown Univ., Washington DC, <sup>2</sup>Urology, Univ. of Colorado, Denver CO.

Interstitial cystitis is a chronic painful disease of unknown etiology in which there is evidence for a neurogenic component to the inflammation. To explore this possibility we have devised a model in which infection of the spinal cord with a herpes virus, pseudorabies virus (PRV), induces an inflammatory cystitis. Injection of PRV (2x10<sup>5</sup> pfu) in a tail muscle led to retrograde infection of the spinal cord segments innervating the bladder. On day 3 post-inoculation clear signs of sacral myelitis were found without any bladder inflammation (n=12). On day 4, the animals exhibited signs of urinary retention. On day 5, they presented hematuria and a hemorrhagic, inflamed, and distended bladder. The surrounding viscera appeared normal. Animals in which PRV was injected at a site other than the tail, such as a cervical myotome (n=3) or in the bladder wall (n=3), manifested systemic viral disease after 5 days, yet their bladder remained normal. After Evans Blue injection (*iv.*), animals with an inflamed bladder exhibited significant ( $p < 0.01$ ) retention of the dye in the bladder wall compared to controls and short survivals. In addition to establishing this model of cystitis we studied the neural pathways involved in its induction. Intravesical application of resiniferatoxin, or lumbosacral sympathectomies prevented the appearance of the cystitis but not of the myelitis as confirmed with immunocytochemistry for PRV. Sensory denervation of the bladder by dorsal rhizotomies did not prevent the appearance of the cystitis. From these results we conclude that PRV can induce visceral inflammation after inoculation at a somatic site and that this inflammation is dependent on the sympathetic efferent pathway.

## SOMATIC AND VISCERAL AFFERENTS: VISCERAL AFFERENTS

NITRIC OXIDE OF PRIMARY SENSORY ORIGIN IS A NEUROMODULATOR IN SYMPATHETIC GANGLIA AND BLOOD VESSELS. Z.L. Zheng, B. Satterfield, R.D. Dey, T.L. Anthony, R. Hendriks, D.L. Kreulen\*. Depts of Physiology and Anatomy, West Virginia Univ., Morgantown, WV, 26506.

A sensory nerve-mediated vasodilatation in guinea pig inferior mesenteric artery can be attenuated by treatment of *in vitro* preparations with nitric oxide synthase inhibitors. The purpose of this study was to determine the localization of NOS in primary sensory neurons. Adult guinea pig thoracic and lumbar dorsal root ganglia (DRG) (n=2) were dissected, fixed, sectioned and stained for immunofluorescence. Using a rabbit polyclonal antibody, neuronal nitric oxide synthase-like immunoreactivity was localized in 12% of cells (38/328) of DRG. In these same ganglia 23% (78/339) of neurons stained for substance P (SP). In the inferior mesenteric ganglion (IMG) there was an extensive network of NOS-positive nerve fibers surrounding principal ganglion cells, but sympathetic neuron perikarya were not stained. To test the hypothesis that NO modulates synaptic transmission in sympathetic ganglia, synaptic potentials were recorded with intercellular microelectrodes before and after the administration of a NOS inhibitor. N $\omega$ -nitro-L-arginine methyl ester (L-NAME) (10  $\mu$ M) increased the amplitude and duration of the slow EPSP (sEPSP) by 59% and 43%, respectively (n=18,  $p < 0.01$ ) and hyperpolarized the membrane of principal ganglion cells by 2-10 mV. These studies suggest that primary sensory nerves are a source of NO in sympathetic ganglia and blood vessels. They further suggest that the DRG is a source of NOS-containing fibers in IMG and mesenteric blood vessels. Support: NIH-HL 27781.

## 453.2

RENAL SYMPATHETIC RESPONSES TO SOMATIC AND VISCERAL STIMULATION IN SPINALLY-TRANSECTED RATS. L.P. Schramm\* and D. Chau. Dept. of Neuroscience, The Johns Hopkins University, Baltimore, MD 21205.

These experiments provide a detailed mapping of the responses of renal sympathetic nerve activity (RSA) to cutaneous stimulation and to several forms of visceral stimulation. The effects of dorsal rhizotomy on responses were also examined. Experiments were conducted on 24 male, chloralose-anesthetized, C<sub>1</sub>-transected, paralyzed, artificially-respired, Sprague-Dawley rats. Arterial pressure was measured via a right femoral arterial cannula. RSA was recorded from the left renal nerves, rectified, and quantified. Rats were shaved and marked with a uniform reference grid. Two types of cutaneous stimuli, light brushing and pinching with toothed forceps, were delivered for periods of 3 seconds. Magnitudes of responses in RSA were noted for 44 stimulated sites on an identical map for each rat. Responses were considered significant if they represented a 10 % change in activity. Light brushing of all sites inhibited RSA. Pinching of the caudal left flank increased RSA. Pinching of all other sites inhibited RSA. Pressure on the renal pelvis and traction on either the rectal temperature probe or the arterial cannula produced large increases in RSA. Increases in RSA elicited from the left flank were surprisingly resistant to dorsal rhizotomy. Increases in RSA were mapped before and after concurrent section of 3 or 4 left dorsal roots. Responses were most markedly reduced by concurrent section of roots T<sub>13</sub>, L<sub>1</sub>, and L<sub>2</sub>. However, reduced responses remained even after section of all dorsal roots between T<sub>1</sub> and S<sub>4</sub> in one rat. We conclude that in the spinally-transected rat, RSA is increased by stimulation of only a small portion of the body surface but that these portions affect the spinal cord via a wide range of dorsal roots and, perhaps, via ventral root afferents. More widely distributed visceral afferents are capable of exciting RSA. Supported in part by NIH grant HL16315.

## 453.3

DYNAMIC RESPONSES OF RENAL R2 CHEMORECEPTORS TO INTRAPELVIC PRESSURE INCREASES. N.G. Moss and J.V. Karastioianova\* Department of Physiology UNC Chapel Hill NC. 27599.

R2 chemoreceptors are sensitive to the ionic composition of intrapelvic urine and thus, indirectly, to pressure gradients across the pelvic epithelium that cause backflux of urine into the renal interstitium. These studies have investigated the dynamic components of this relationship by recording afferent renal nerve activity (ARNA) in anesthetized rats during intrapelvic pressure increases of 0.05 (slow), 0.15 (medium), 0.3 (fast) mmHg/sec with diuretic (DU) and non-diuretic (NDU) urine. In 7 rats pressure increases with NDU caused multiunit ARNA to increase in a direct, linear relationship with pressure. Rate of increase in ARNA (% of control) correlated with the rates of pressure increase (slow = 5.1% per mmHg, medium = 8.1% per mmHg, fast = 12.4% per mmHg,  $p < 0.001$  for all comparisons). The same preparations were not activated by backflow of isotonic saline, confirming that these were chemoreceptor responses. Pressure increases with DU were also excitatory but the ARNA responses were not different between each of the three filling rates and the response showed a pressure threshold of 5 mmHg before excitation began. Analysis of single unit activity from 17 R2 chemoreceptors in 7 rats showed a similar relationship with filling rates. However, the R2 response to pressure increases was curvilinear, suggesting that the multiunit response results from a heterogeneous receptor population. Thus, renal chemoreceptor responses to intrapelvic pressure increases have a dynamic component modulated by the rate of pelvic filling and urine composition.

ELECTROPHYSIOLOGICAL AND PHARMACOLOGICAL FEATURES OF PELVIC AFFERENTS INNERVATING THE RAT URINARY BLADDER. W. Jiang and J.F.B. Morrison, (Spon: Brain Research Association), University of Leeds, Leeds, LS2 9NQ, United Kingdom.

Recordings from 100 pelvic nerve bladder afferents were made in pentobarbitone anaesthetized rats during slow distensions with saline (controls), and using artificial urine containing high potassium, osmolar or proton concentrations, or capsaicin, for up to 6 hours. The urinary bladder was distended at 0.16 ml/min for four minutes, the maximum intravesical pressure was generally below 40 mmHg. Fibres that did not respond to this distension were termed 'silent' afferents. Three functional different types of afferents were found: Aδ and C low threshold mechanoreceptors, a few high threshold mechanoreceptors and 'silent' units. 44% of units were unmyelinated. The range of thresholds of the Aδ and C units overlapped, but the mean threshold of the C fibres is greater ( $15.0 \pm 0.3$  vs  $9.48 \pm 0.5$  mmHg, mean  $\pm$  SE); the slope of the stimulus response curve was also less in the C-fibres. 75% of the Aδ and 86% of C-fibres can be excited by intravesical chemical stimulation and showed sensitisation: the slope of their stimulus response curves increased, and 'silent' afferents became mechanosensitive, with thresholds of  $17.6 \pm 0.4$  mmHg. 42% of units showed initial sensitisation and then depression with 400 to 500 nM KCl only, which is presumably due to depolarisation block of potassium. The slope of the stimulus response curve was less in the C-fibres. 18% of the studied units did not respond to any chemical stimulus. Aδ and C-mechanosensitive afferents showed biphasic responses to the intravesical capsaicin injection. Acute capsaicin caused excitation in 80% of units and this lasted at least 1.5 hours. Desensitisation was never seen before 1.5-2.0 hours had elapsed. The majority of mechanosensory receptors in this study respond to intravesical chemical stimuli, some of which (potassium and protons) can occur within the physiological range. 'Silent' afferents develop mechanosensitivity following chemical stimulation. It is possible that some of these sensory endings are present in the bladder epithelium.

## 453.7

VAGAL AFFERENT ELECTRICAL STIMULATION PRODUCES PUPIL DILATION IN THE RAT. Barry R. Komisaruk<sup>1,2</sup>, Rafael Cueva-Rolon<sup>2</sup>, Lisbeth Gomez<sup>2</sup>, Maria Ganduglia-Piruvano<sup>1</sup>, Giorgio Sansone<sup>1</sup> and Ralph Bianca<sup>1</sup>, Institute of Animal Behavior, Rutgers, The State University of New Jersey, Newark, NJ 07102<sup>1</sup> and Center for Research in Animal Reproduction (CIRA), CINVESTAV, Unidad Tlaxcala, Mexico<sup>2</sup>.

Previous studies in this laboratory have shown that, in the rat, vaginocervical stimulation (VS) produces an immediate and marked dilatation of the pupil of the eye (PD). VS-produced PD is reduced but not abolished by a) bilateral transection of all known genito-spinal nerves (pelvic, hypogastric and pudendal) or b) complete transection of the spinal cord at the level of vertebra Thoracic 7. Subsequent bilateral subdiaphragmatic vagotomy abolished the residual VS-produced PD. Based on these findings, we hypothesized that electrical stimulation of vagus nerve afferents would produce pupil dilatation. To test this hypothesis, rats were anesthetized with pentobarbital (3.9 mg/100g bw). The left vagus nerve was transected near the clavicle. The proximal (central) stump of the nerve was placed on a pair of silver wire electrodes and stimulated by 1 sec trains of 0.1 msec duration biphasic square wave pulses at 50 Hz. The pupil image (ipsilateral eye) was recorded via a close-up video camera, and pupil diameter was measured from a monitor. Pupil dilatation was directly proportional to stimulation intensity, ranging from 5.6% above baseline diameter at 1.0 V to 47% above baseline diameter at 40 V. The magnitude of the PD was calibrated against force of VS. The magnitude of PD produced by 5V or 40V electrical stimulation applied to the vagus nerve central stump was equivalent to that produced by 100g or 350g vaginocervical mechanical force, respectively. The present findings provide further evidence that vaginocervical stimulation can be conveyed directly to the brain via vagus nerve afferents, thereby bypassing the spinal cord. Support: NIH - Fogarty International Center - 1R03-TW00394 (BRK).

## 453.4

C-FOS IMMUNOCYTOCHEMICAL LABELING WITHIN THE RAT DORSAL HORN AFTER RENAL AFFERENT STIMULATION. G.K. Fitch, K.P. Patel and M.L. Weiss\*, Dept. of Anatomy and Physiology, Kansas State University, Manhattan, KS 66506-5602

Retrograde labeling studies using the rat indicated that dorsal root ganglion cells from T<sub>1</sub> to L<sub>2</sub> innervate the left kidney. Further, electrical stimulation of renal afferents influences dorsal horn neurons in spinal segments T<sub>10</sub> to L<sub>1</sub>. To investigate the spinal neurons influenced by renal afferent stimulation, we used c-fos immunocytochemistry following renal afferent stimulation to indicate neuronal activation. In anesthetized rats, a left renal nerve branch was located and either unstimulated (sham) or electrically stimulated (12 volt, 2 ms pulses at 7 Hz; 30 s on / 30 s off; repeated 30 times). In rats with flank incisions, the renal nerve was sectioned or crushed and electrical stimulation was applied to the proximal end of the nerve. After the stimulation protocol, the rat survived for 1.5 hour prior to perfusion. The brain and spinal cord were harvested and histologically processed. Immunocytochemistry using antibody directed against the fos protein was performed on free-floating sections. Electrical stimulation of renal afferents produced a 64% increase in the number of labeled cells in spinal cord dorsal horns relative to sham stimulated animals. Most labeled cells were found in the left dorsal horn of spinal segments T<sub>11</sub> and T<sub>12</sub>. In rats with ventral midline incisions, renal afferents were activated either electrically or by selective activation of renal mechanoreceptors. The renal nerve was not sectioned or crushed before stimulation. Following stimulation in these animals, the left dorsal horn had more labeled cells than the right dorsal horn. Renal denervation greatly reduced the number of fos labeled cells in the dorsal horn after mechanoreceptor activation. Our results indicate that activation of renal afferents can induce c-fos expression in the dorsal horn. Sponsored by the American Heart Association, Kansas Affiliate.

## 453.6

MODIFICATIONS OF MOTOR RESPONSES IN THE RAT URINARY BLADDER FOLLOWING PERIGANGLIAR INJECTION OF COLCHICINE. A. Lecci, R. Patacchini, S. Giuliani, E. Theodorsson<sup>1</sup> and C.A. Maggi\*, Pharmacol. Res. Dept. "A. Menarini" Pharmaceuticals, Florence, Italy, and <sup>1</sup> Dept. of Clin. Chem. Karolinska Hosp., Stockholm, Sweden.

The aim of this study was to assess the effect of blocking the axonal transport by local injection of colchicine at pelvic ganglia level on the sensory and "efferent" function mediated by capsaicin-sensitive primary afferent neurons innervating the urinary bladder in rats. Bilateral injection of colchicine (125 nmol/ganglion) in the prostatic tissue underneath the pelvic ganglia of male rats induced a time-dependent reduction (maximal effect at 72 h, 100% of reduction) of the contraction of the rat isolated bladder induced by capsaicin (1 μM). The response to electrical field stimulation (0.1-20 Hz) was also reduced, although at a lesser extent, the direct bladder contractions induced by substance P (100 nM) or KCl (80 mM) were not affected by colchicine pretreatment. In vivo, periganglionic injection of colchicine (72 h before) increased bladder capacity, and reduced the amplitude of micturition contractions during the cystometrogram in urethane-anesthetized rats. Topical application of capsaicin (15 nmol/rat) onto the bladder or onto the stomach induced a cardiovascular pressor reflex in urethane-anesthetized, spinal cord transected rats. Colchicine pretreatment reduced by 50% the pressor response elicited by chemoceptive stimulation of the bladder but not that arising from the stomach. Colchicine pretreatment abolished capsaicin-induced release of CGRP-i.r. from the urinary bladder and time-dependently reduced bladder levels of SP-, NKA-, CGRP-, NPY-, but not of VIP-i.r. Present findings demonstrate that blockade of axoplasmic transport completely eliminates the "efferent" but only partially affects the sensory function of capsaicin-sensitive neurons.

## 453.8

LOCALIZATION OF ADENOSINE (A1) RECEPTORS TO CARDIAC AFFERENT NEURONS IN ADULT RATS. H.R. Middlekauff, S.A. Rivkees +, H.E. Raybould\*, S. Sampaio, E.A. Mayer, UCLA Sch of Med, Los Angeles, California 90024, and + + Indiana University Sch of Med, Indianapolis, IN 46202.

**Background:** Adenosine stimulates afferent neurons in a variety of tissues, including the myocardium, producing ischemic-like pain. Unmyelinated spinal afferents mediate visceral pain, while vagal afferents play a role in pain modulation and reflex regulation. It is unknown if adenosine activates sensory afferent neurons directly, or through intermediaries.

**Aim:** To determine if adenosine receptors (A1R) are located on cardiac spinal and/or vagal afferent neurons.

**Methods:** Bilateral nodose ganglia (NG) and C7-T5 dorsal root ganglia (DRG) from 8 adult Sprague-Dawley rats (180-200g) were used in the following studies: 1) radioligand binding performed in quadruplicate with [<sup>3</sup>H]DPCPX, a highly selective A1R agonist (n=5); 2) *in situ* hybridization probes using <sup>32</sup>S labeled cRNA probes (n=3); and 3) following retrograde labeling of cardiac afferent neurons with fluorogold, immunocytochemistry (ICC) with polyclonal antisera against A1R (n=3). **Results:** 1) Specific binding for [<sup>3</sup>H]DPCPX (fmol/mg protein) was present: DRG  $12.2 \pm 0.07$ , NG  $39.6 \pm 1.2$ . 2) A1R mRNA was detectable in both NGs and DRGs. 3) Fluorogold labeled a subset of small and large nerve bodies within bilateral NGs and C7-T5 DRGs. A1R ICC labeling was found in the majority of both large and small neurons, both in fluorogold labeled and unlabeled cells.

**Conclusion:** A1R are present in both spinal and vagal afferent neurons, including those innervating the heart. Thus these afferents are likely to participate in the generation of ischemic pain in response to endogenously released adenosine, and may play a role in the mediation of viscerovisceral reflex responses associated with cardiac ischemia.

## 453.9

**PRESENCE AND LOCALIZATION OF NEUROTROPHIN RECEPTOR TYROSINE KINASE (TrkA, TrkB, TrkC) mRNAs IN VISCERAL AFFERENT NEURONS OF THE NODOSE AND PETROSAL GANGLIA.** H. Zhuo<sup>1</sup>\* and C.J. Helke<sup>1,2</sup>. <sup>1</sup>Dept. of Pharmacol. & <sup>2</sup>Neurosci. Program, Uniformed Services University of the Health Sciences, Bethesda, MD 20814.

This study was conducted to reveal the expression of the high affinity tyrosine kinase (Trk) receptors for neurotrophins in visceral afferent neurons of the nodose and petrosal ganglia of adult and neonatal rats. We used *in situ* hybridization histochemistry with [<sup>35</sup>S]-labeled oligonucleotide probes to Trk mRNAs. Neurons containing TrkA mRNA were found in the adult nodose and petrosal ganglia. About 10% of nodose ganglion neurons and 38% of petrosal ganglion neurons contained TrkA mRNA. The nodose and petrosal ganglia from 1 day old neonates also expressed TrkA mRNA. No TrkB mRNA-containing neurons were detected in the adult nodose and petrosal ganglia, whereas TrkB mRNA was detected in 1 day old neonatal nodose and petrosal ganglia. TrkC mRNA was found in about 9% of nodose ganglion neurons and 11% of petrosal ganglion neurons of adult rats. Likewise, low but detectable levels of TrkC mRNA were seen in 1 day old neonatal nodose and petrosal ganglia. These data demonstrate the presence of TrkA and TrkC in the adult nodose and petrosal ganglia and provide a substrate for the ongoing neurotrophin-induced regulation of neuronal function. The presence of TrkC in the nodose ganglion is consistent with the transport of [<sup>125</sup>I]-NT-3, the neurotrophin ligand for TrkC, by vagal afferent neurons of the nodose ganglion (Helke et al., this meeting). The presence of TrkB mRNA in neonatal but not in adult nodose and petrosal ganglia suggests a developmental down-regulation of TrkB receptor expression in these placodally-derived visceral afferent neurons. (supported by NIH Grant R01 NS20991)

## 453.11

**CAPSAICIN-RESISTANT VAGAL AFFERENTS: MORPHOLOGICAL EVIDENCE USING DII AND HRP TRACING.** H.-R. Berthoud\*, A.E. Willing, D.C. Irminger, K. Mueller, and W.L. Neuhuber. Pennington Biomedical Research Center, Louisiana State Univ., Baton Rouge, LA, 70808, USA, and Anatomy Institute, Univ. of Erlangen, D-91054 Erlangen, Germany.

In order to identify the peripheral and central projections of putative capsaicin-resistant vagal afferents we used the carbocyanine dye DiI and HRP injected into the nodose ganglia or the cut cervical vagus, respectively. In the first experiment capsaicin or vehicle was administered to neonatal Wistar rats (50 mg/kg) or young adult SD rats (3 injections over 36 h, 12.5, 30, and 75 mg/kg, i.p.), followed 10 days later by DiI or WGA-HRP injections into the left nodose ganglion. Behavioral effectiveness of capsaicin treatment was tested by means of the eye-wiping test. There was no difference in the number of DiI-labeled vagal intraganglionic laminar endings (IGLEs) in esophagus and stomach between capsaicin and vehicle treated rats, but a substantial reduction of IGLEs in the duodenum of capsaicin treated animals. In the second experiment capsaicin was administered to neonatal Wistar rats (50 mg/kg), followed 3 months later by HRP application to the central cut ends of either the left cervical vagus or the left splanchnic nerves. Following cervical vagal HRP application there was no noticeable difference in labeled perikarya of the ipsilateral nodose ganglion or afferent axon terminals throughout the NTS, between capsaicin and vehicle treated rats. In contrast, splanchnic nerve application of HRP in capsaicin pretreated rats resulted in a 60-80% reduction in labeled T9-T11 dorsal root ganglion cells and a drastic reduction of labeled afferent axon terminals in the spinal cord. These results demonstrate that unlike spinal afferents, abdominal vagal afferents are less sensitive to capsaicin, and that the capsaicin sensitive vagal afferents may be restricted to a population that innervates the small intestine but not the esophagus and stomach. Supported by NIH grant DK 47348 and DFG-SFB grant 353/B9.

## 453.13

**THE ROLE OF THE SYMPATHETIC NERVOUS SYSTEM IN CHRONIC VISCERAL PAIN.** U. Wesselmann<sup>1</sup>, A.L. Burner<sup>2</sup> and J. N. Campbell<sup>1</sup>. <sup>1</sup>Blaustein Pain Treatment Center and <sup>2</sup>James Buchanan Brady Urological Institute, Johns Hopkins Hospital, Baltimore, MD 21287.

Chronic visceral pain is a challenging problem because of the wide differential diagnosis and lack of successful treatment options. The reproductive organs, which have a very dense sympathetic innervation, seem to be more prone to chronic pain states than other visceral organs with a predominantly parasympathetic innervation. Chronic pain can sometimes even persist despite the surgical removal of the organ that was thought to be the source of pain (persistent pain after hysterectomy or orchiectomy). In contrast chronic visceral pain associated with organs with a predominantly parasympathetic supply is usually cured when the organ is surgically removed (persistent pain after tonsillectomy or cholecystectomy is rare). We have tested the hypothesis that chronic testicular pain is sympathetically maintained. The testis was chosen as a model for visceral pain, since it is the only visceral organ that can easily be examined clinically. We treated 5 patients with chronic unilateral non-malignant testicular pain ( $\geq 6$  mo duration) with sympathetic blockade including lumbar sympathetic blocks with local anesthetic, placebo-controlled phenolamine infusions and oral alpha-1 adrenergic antagonists. All patients had undergone a full urological exam (including ultrasound and evaluation for infection) and psychological evaluation. All patients had significant pain relief from sympathetic blockade, reducing pain from 6/10 to 1/10 on a verbal pain scale. Duration of pain relief varied between patients and depending on the modality of sympathetic blockade, ranging from 3hrs to persistent pain relief. The preliminary results support the hypothesis that the concept of sympathetically maintained pain can be extended to certain visceral chronic pain syndromes.

## 453.10

**RETROGRADE AXONAL TRANSPORT OF NEUROTROPHIN-3 (NT-3) BY THE CERVICAL VAGUS NERVE TO THE NODOSE GANGLION IN THE RAT.** C.J. Helke<sup>1</sup>\*, K. Adryan<sup>1</sup>, R. Curtis<sup>2</sup>, H. Zhuo<sup>1</sup>, and P.S. DiStefano<sup>2</sup>. <sup>1</sup>Dept. of Pharmacol., Uniformed Services Univ. of the Health Sciences, Bethesda, MD, 20814, and <sup>2</sup>Regeneron Pharmaceuticals, Inc., Tarrytown, NY, 10591.

Placodally-derived visceral sensory neurons of the nodose ganglion in the rat are responsive to the trophic effects of NT-3 during development. However, little is known of the responsiveness of mature nodose ganglion neurons to NT-3. Because retrograde transport of a neurotrophin is thought to be predictive of neuronal responsiveness, we have studied the transport of NT-3 by neurons of the nodose ganglion which comprise the afferent vagus nerve. [<sup>125</sup>I]-NT-3 or [<sup>125</sup>I]-cytochrome C was administered to the cut-end of the cervical vagus nerve of adult rats. In competition studies, [<sup>125</sup>I]-NT-3 was administered with an excess of unlabeled NT-3, NGF, BDNF, or NT-4. After 17 hours, ganglia were dissected and [<sup>125</sup>I] was determined by gamma counting followed by emulsion autoradiography of tissue sections. [<sup>125</sup>I]-NT-3 was retrogradely transported from the cervical vagus nerve to neuronal perikarya in the ipsilateral nodose ganglion. [<sup>125</sup>I]-NT-3 labeling was not found in the ipsilateral superior cervical or contralateral nodose ganglia. [<sup>125</sup>I]-cytochrome C (physically similar to NT-3) was not significantly transported. The transport of [<sup>125</sup>I]-NT-3 to the nodose ganglion was reduced by 85% in the presence of unlabeled NT-3 and by 40% in the presence of unlabeled NGF. Unlabeled BDNF and NT-4 had no significant effect on the transport of [<sup>125</sup>I]-NT-3 to the nodose ganglion. Preliminary data also showed the transport of [<sup>125</sup>I]-NT-3 by the efferent vagus nerve to perikarya in the dorsal motor nucleus of the vagus and nucleus ambiguus.

These data demonstrate the receptor-mediated retrograde axonal transport of [<sup>125</sup>I]-NT-3 by vagal afferent neurons of the nodose ganglion. The profile of the competition studies suggests an involvement of neurotrophin receptors, TrkC and perhaps TrkA, in the transport. (Supported by NIH grant NS20991 to C.J.H.)

## 453.12

**DISSOCIATION OF GASTRIC PRESSURE AND TENSION RESPONSES FROM GASTRIC VAGAL AFFERENT RESPONSES TO CHOLECYSTOKININ AND NEUROMEDIN C IN RAT.** G.J. Schwartz\*, E.E. Ladenheim, and T.H. Moran. Dept. Psychiatry & Behav. Sci., Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205.

Exogenous administration of a range of brain-gut peptides, including cholecystokinin (CCK) and the mammalian bombesin-like peptide neuromedin C (NMC) have been demonstrated to suppress feeding. To evaluate the potential role for peripheral peptide elicited gastrointestinal neuromuscular events in the suppression of food intake produced by these peptides, we examined the changes in gastric pressure and gastric wall tension produced by intravenous (jugular vein, i.v.) and close celiac arterial (i.a.) infusion of a dose range of CCK and NMC (10 - 1000 pmol) in anesthetized rats. We simultaneously recorded the neurophysiological activity of gastric load-sensitive single vagal afferent fibers to evaluate the correlation between peptide-induced gastrointestinal events and the production of gastric vagal afferent signals. Both i.a. and i.v. CCK and NMC elicited dose-dependent increases in the neurophysiological discharge rates of a population of single vagal afferent fibers with gastric receptive fields. NMC also elicited dose-dependent increases in both intragastric pressure and gastric wall tension, while CCK elicited a modest reduction in intragastric pressure, and no changes in gastric tension. These data suggest that different mechanisms underlie the ability of these peptides to elicit vagal afferent signals. Supported by NIH DK 47208 and DK46448.

## 453.14

**RESPONSE CHARACTERISTICS OF ABDOMINAL VAGAL AFFERENTS DURING ISCHEMIA** H.-L. Pan, Z.B. Zeisse, L.-X. Zhang\* and J.C. Longhurst. Cardiovascular Medicine, Univ. of Calif., Davis, CA 95616

Activation of abdominal sympathetic visceral afferents elicits nociception and autonomic cardiovascular reflexes during ischemia. It is not known, however, whether and how abdominal vagal afferents respond to ischemia. Single-unit activity of abdominal vagal afferents (n=29) was recorded from decentralized right thoracic vagus nerve in anesthetized cats during 15 min of ischemia. Afferent nerve endings were located on the stomach, pancreas and duodenum with conduction velocity ranging from 0.30 to 1.15 m/sec. Occlusion of the thoracic descending aorta gradually increased the discharge activity of 5 afferents from 0.16±0.04 to 0.45±0.06 imp/sec (p<0.05). Discharge frequency of 14 afferents was mainly inhibited during 15 min of ischemia (0.85±0.28 to 0.13±0.04 imp/sec, p<0.05) although the activity displayed transient increase for the first 5 min of ischemia in 4/14 afferents. In the remaining 10 afferents, the discharge frequency was not altered significantly during ischemia (0.12±0.05 to 0.13±0.04 imp/sec). Intra-arterial injection (1 µg/kg) but not serosal application (10 µg/ml) of bradykinin activated 19 of 29 afferents from 0.58±0.08 to 1.72±0.23 imp/sec (p<0.05). These data indicate that although most abdominal vagal afferents lack the capacity to encode ischemic event, a subgroup of afferents are capable of conveying ischemic information to the central nervous system.

(Supported by NIH HL-36527 and AHA-CA 93-39).

## 453 15

CENTRAL ACTION OF TRH ACTIVATES CAPSAICIN-SENSITIVE SPLANCHNIC AFFERENTS WITH RECEPTIVE FIELDS IN THE STOMACH. T.J.O-Lee, J.Y. Wei, & Y. Taché, CURE/Gastroenteric Biol. Ctr., VA Wadsworth Med. Ctr. & Dept. of Med. & Brain Res. Inst., UCLA, Los Angeles, CA 90073.

It has been demonstrated that the gastric hyperemic response to central vagal activation induced by intracisternal TRH analog RX-77368 is mediated by local effector function of capsaicin-sensitive afferent fibers releasing calcitonin-gene related peptide (CGRP) (Am J Physiol 267:G1041-G1049, 1994). In this study, we investigated the way low doses of TRH analog (1.5 ng / rat) injected into the cisterna magna altered the afferent activities of the celiac branch of the left splanchnic nerve. The celiac nerve is approached by laparotomy. By first locating the super-renal ganglia, the celiac branch can be identified with little difficulty. Unit action potentials of the nerve filament were recorded with bipolar platinum electrodes (dia. 30  $\mu$ m). Single unit analysis was done by separating each unit with a window discriminator based on the amplitude and wave-form of each spike. Nine units from 3 separate animals have thus far been analysed. Seven of the 9 units exhibited spontaneous firing activities, and among these, significant increases in activity ( $287 \pm 49\%$ ,  $\text{mean} \pm \text{SE}$ ;  $P < 0.02$ , unpaired Student's t-test) were observed after ic injection of TRH. The results were compared against the activity change after ic injection of saline ( $136 \pm 21\%$ ). The 2 units that had no spontaneous activity were unaffected by ic saline but were activated by ic TRH (firing at 20-50 pulses/min after injection). To ensure that the units investigated originated from the stomach, we perfused capsaicin intraluminally (640 nmol/ml, 0.69-0.84 ml/min) for 15-20 min. in each experiment. The activity of all nine units increased during capsaicin perfusion ( $144 \pm 15\%$ ). In addition to the perfusion, we also distended the stomach with 5 ml of saline. All nine units also responded to stomach distension with an increase in activity ( $202 \pm 19\%$ ). These data suggest that splanchnic afferents with receptive fields in the stomach are activated by central administration of TRH analog. The pathway for this activation is likely to involve gastric-vagal efferents, but the exact mechanism remains to be further investigated.

PERITONEAL IRRITATION-INDUCED ILEUS IN RATS INVOLVEMENT OF CRF PATHWAYS. B. Bonaz, N. Cristina and C. Feuerstein INSERM-LAPSEN U318 38043 Grenoble cedex 09 France

Peritoneal irritation induced by acetic acid (AA) is a noxious visceral stimulus resulting in digestive ileus in rats. central injection of the CRF antagonist reverses this ileus (1). Aims to study in rat brain 1) the effect of AA on the expression of Fos mRNA, 2) the localization of this transcript in CRF perikarya of the paraventricular nucleus (PVN) of the hypothalamus. Methods male SD rats received an ip injection of either AA (0.6 vol% 10 ml/kg) or saline (controls). Animals were perfused (4% paraformaldehyde-borax) 1h 2h 3h 4h and 6h after ip injections and brains processed for *in situ* hybridization (ISH) using  $^{35}$ S riboprobes. Colocalization of the transcript within CRF immunoreactive neurons of the PVN was determined using a combination of immunocytochemistry and ISH. Results AA induced Fos mRNA expression in the NTS and ventrolateral medulla parabrachial nucleus locus coeruleus cerebellar cortex PVN (mainly parvocellular part) and supraoptic nucleus of the hypothalamus. This expression peaked 1h after the injection of AA, decreased at 2h and totally vanished 6h after injection. In the parvo PVN CRF-immunoreactive neurons expressed the Fos transcript. Conclusions AA induces Fos expression in nuclei (PVN locus coeruleus NTS) controlling digestive motility in rats. In the parvo-PVN CRF immunoreactive neurons expressed Fos mRNA thus confirming the involvement of CRF pathways in peritoneal irritation-induced ileus (1) Rivière et al J Pharmacol Exp Ther 1995 (in press)

GFAP-IMMUNOREACTIVITY IN PULP CELLS, PRETERMINAL AXOPLASM, AND SCHWANN CELLS OF RAT AND MONKEY DENTAL TISSUE. M.R. Byers\*, T. Maeda, F.F. Solca. Anesthesiology and Biochemistry Univ Washington; Oral Anatomy Niigata University Japan

Patch clamp studies have recently identified potassium and sodium currents in cultured human pulp cells as well as immunoreactivity (IR) for substance P and glial fibrillary acidic protein (GFAP) (Davidson et al., J. Dent. Res. 73:121 '94). Our study was done to identify GFAP-IR cells in jaw tissue of young and old rats and monkeys using light and electron microscopy and western blot techniques. Rats (aged 1 wk to 1 yr) and monkeys (1 & 6 yr) were perfusion fixed; jaw tissues were decalcified and analyzed by standard ABC immuno techniques using polyclonal anti-GFAP and monoclonal anti neurofilament. Western blot demonstrated that there was no cross-reactivity of the GFAP antibodies with neurofilament protein. GFAP-IR was found in pulp cells of immature teeth, but not in adults; and odontoblasts were never labeled. Preterminal axoplasm of dental and gingival nerves had intense GFAP-IR, associated with axonal cytoskeletal filaments. Schwann cell label was variable: some pulpal Schwann cells had GFAP-IR while others did not; periodontal Ruffini terminal Schwann cells were not labeled. GFAP-IR was weak or absent in trigeminal ganglion cell bodies, but intense in perivascular fibers in the adjacent fascia. We conclude that GFAP-IR intermediate filaments characterize preterminal axoplasm of some types of sensory nerve fiber, some Schwann cells and immature non-odontoblast pulp cells. Supported by NIH DE05159.

NEURAL PATHWAYS INVOLVED IN EMESIS IN *SUNCUS MURINUS*. N. Matsuki\*, M. Saito and H. Saito, Department of Chemical Pharmacology Faculty of Pharmaceutical Sciences, The University of Tokyo, Tokyo 113, JAPAN.

To investigate the neural pathways that cause emesis, expression of c-Fos protein was investigated immunohistochemically in *Suncus murinus*. Cisplatin or motion was used as an emetic stimulus. Cisplatin enhanced the expression of c-Fos-like immunoreactivity (FLI) strongly in the nucleus tractus solitarius (NTS) and the dorsal motor nucleus of the vagus (DMV) and slightly in the area postrema (AP). FLI was not detected in other brain regions. Pretreatment of the animals with a 5-HT<sub>3</sub> receptor antagonist, tropisetron, abolished the emesis caused by cisplatin completely and reduced FLI in the NTS and the DMV strongly. Abdominal vagotomy also abolished the emesis completely but suppressed FLI partially. Administration of cisplatin into mice did not cause emesis nor retch but FLI was observed in AP and NTS. The motion caused FLI in the NTS and DMV but not in AP. Pretreatment of animals with a 5-HT<sub>1A</sub> receptor agonist, 8-OH-DPAT abolished motion-induced emesis and partially reduced FLI in NTS and DMV. These results suggest that NTS and DMV are part of "vomiting center" in *Suncus murinus* because they were similarly activated by two completely different emetogenic stimuli. Cisplatin may have a direct effect on NTS and DMV through 5-HT<sub>3</sub> receptors but the stimulation is either not strong enough to cause emesis or independent from emetogenic effect.

TEMPERATURE AND ANION SPECIES MODIFY THE CHORDA TYMPANI NERVE RESPONSE TO SALT STIMULATION IN RATS. R. F. LUNDY, JR.\* and R. J. CONTRERAS, Program in Neuroscience, Florida State Univ., Tallahassee, FL 32306-1051.

The goal of the present study was to extend the work of previous research on the neural mechanism(s) of salt taste using a novel stimulus delivery system. We investigated the effects of tongue adaptation temperature (25° vs. 35° C) on the summated responses of the whole chorda tympani nerve to a broad range of salts mixed with and without 100  $\mu$ M amiloride hydrochloride in male Sprague-Dawley rats using a novel stimulus delivery system. The stimuli consisted of 500 mM concentrations of NaCl, Na<sub>2</sub>SO<sub>4</sub>, sodium acetate (NaAc), KCl, K<sub>2</sub>SO<sub>4</sub>, potassium acetate (KAc), NH<sub>4</sub>Cl, (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, ammonium acetate (NH<sub>4</sub>Ac), and CHCl<sub>3</sub>. Each stimulus was presented twice: first by itself for 45 s (protocol A), and second with the first 15 s by itself, the next 15 s mixed with amiloride, and the last 15 s by itself again with uninterrupted flow (protocol B). In the absence of amiloride, the phasic response magnitudes of the chorda tympani nerve to all stimuli were smaller at 25° than at 35° C; except for KCl and KAc. Similarly, the tonic response magnitudes to the same stimuli, except NaCl, were also smaller at 25° than at 35° C. Amiloride suppressed the chorda tympani nerve responses to all stimuli so that NaAc > Na<sub>2</sub>SO<sub>4</sub> = KAc = NaCl > K<sub>2</sub>SO<sub>4</sub> = KCl = CHCl<sub>3</sub> > NH<sub>4</sub>Ac = (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> = NH<sub>4</sub>Cl. However, the degree of amiloride suppression for NaCl, Na<sub>2</sub>SO<sub>4</sub>, and the ammonium salts was greater at 25° than at 35° C. Amiloride completely suppressed the chorda tympani nerve responses to NaAc at 25° and 35° C. Substituting SO<sub>4</sub> for Cl in sodium salts, and Ac for Cl in both sodium and potassium salts increased amiloride suppression. Taken altogether, the findings suggest that: (1) the degree of amiloride suppression of the chorda tympani nerve to all salt stimuli is a function of lingual mucosal temperature and/or anion species; and (2) amiloride's ability to block ion channels is either not as specific as previously suspected or many taste stimuli express various affinities for amiloride-sensitive Na<sup>+</sup> channels.

RECORDINGS OF AFFERENT AND EFFERENT C-FIBRE ACTIVITY FOLLOWING CUTANEOUS ARGON LASER STIMULATION IN MAN. B. Olsson<sup>1</sup>, J. O. Skarphedinnsson<sup>2</sup>, M. Elam<sup>1</sup>, Gunnar Wallin<sup>1</sup> & B. C. Shyu<sup>3,4</sup>. <sup>1</sup>Dept. Clin. Neurophysiol., Sahlgren Univ. Hosp., S-414 45 Göteborg, Sweden, <sup>2</sup>Dept. Physiol. Univ. of Island, <sup>3</sup>Academia Sinica, Taipei, ROC. Stimulation of the skin in man by high intensity carbon dioxide laser can induce pain sensations which has been correlated to evoked C-fibre activity recorded in the peripheral nerve. The present study aimed to investigate the reaction pattern in cutaneous C-fibre afferents and reflex sympathetic activity following cutaneous argon laser stimulation in man. Microneurographic nerve recordings were performed in the peroneal nerve in healthy volunteers (n=11). Single C-fibre afferents were identified. In the same recording sites efferent multiunit thin fibre activity were simultaneously recorded. Sympathetic effector organ responses were monitored with laser doppler flowmetry and skin resistance recordings. The pain perception was measured with a visual analogue scale. Mechano-heat sensitive nociceptive C-fibre units were activated by the argon laser. Linear relations were found between the subjective pain rating, the intensity of the laser stimulation and the number of action potentials following laser stimulation, respectively. The latency shift in the electrically evoked activity was related to the number of action potentials evoked by, and the time elapsed, since the laser stimulation. The temporal profile of the reflex sympathetic nervous responses suggest laser induced activity also in A-delta afferents. Cutaneous argon laser stimulation induced selective activity in polymodal nociceptive afferent C-fibres. The degree of activation was linked to the psychophysical pain report. The nociceptive stimulation induced a reflex activity in the skin sympathetic fibres suggesting laser induced activity in A-delta afferents.

## 454.3

ELECTROPHYSIOLOGICAL EVIDENCE THAT MENINGEAL AFFERENTS ARE NOCICEPTIVE. Geoffrey Bove\*, Michael Moskowitz\*, Massachusetts General Hospital, CNY 149-6403, Charlestown, MA 02129.

The meninges possess a rich supply of small diameter afferent fibers that are presumed to be nociceptive. Using classical teased fiber recordings, we have recorded from single axons of the guinea pig nasociliary nerve innervating the dura mater covering the frontal lobe and olfactory bulb. The fibers were characterized according to their conduction velocity (CV) and response to mechanical stimulation with sharp forceps or sharpened 0.5 mm pin. All mechanically sensitive fibers had CVs of  $<1$  m/s, indicating that they were unmyelinated (C-fiber). The receptive fields were punctate and occasionally multiple, located in close relation to either blood vessels or the ethmoidal nerve. The discharges were slowly or non-adapting during the stimulus, and stopped abruptly when the stimulus was removed. Sustained discharge rates were as high as 40 Hz, with instantaneous frequencies as high as 100 Hz, and roughly paralleled the mechanical stimulus intensity. No units had ongoing discharge when isolated, but one did develop activity after repeated mechanical stimulation (0.5 Hz). The mechanical threshold, CVs, and absence of background discharge are similar to those reported for mechanically sensitive nociceptors from cutaneous and deep tissues.

These data demonstrate that the meninges are innervated by fibers that share properties with nociceptors from other tissues. The receptive field locations correlate with data collected from human volunteers. These nociceptors are likely to be involved in the transmission of intracranial pain, including migraine.

## 454.5

ELECTROPHYSIOLOGICAL CHARACTERIZATION OF TRIGEMINAL GANGLION CELLS THAT INNERVATE INTRACRANIAL DURAL VENOUS SINUSES IN THE RAT. A.M. Strassman\*, S.A. Raymond and R. Burstein, Dept. Anesthes., Beth Israel Hosp. and Harvard Med. Sch., Boston, MA 02115.

Major intracranial blood vessels of the dura and pia receive an afferent innervation from the trigeminal nerve which has been postulated to play a critical role in the mediation of vascular headache syndromes such as migraine. Although the trigeminal afferents that supply this innervation have been the subject of intense study by anatomical and pharmacological approaches, direct information on their physiological response properties is lacking. In order to examine more directly the physiological properties that underlie sensory signalling in this pathway, single unit extracellular recording techniques were used to identify and characterize cells in the trigeminal ganglion that innervate dural blood vessels in urethane-anesthetized rats. Such cells were initially identified by their constant latency response ( $<1$  msec jitter) to single shock electrical stimuli (0.1-0.5 msec pulses) delivered to the dural surface overlying the ipsilateral transverse sinus. Response latencies were 0.8 - 13 msec, indicative of conduction velocities of approximately 1.2 - 19 m/sec. Dural stimulation sites of lowest threshold (typically 20-100  $\mu$ A) were always on the ipsilateral transverse sinus or sinus confluens and were surrounded by dural sites that exhibited higher thresholds or were ineffective ( $>5$  mA). A subset of neurons exhibited mechanical sensitivity. Some neurons could be activated by light stroking within a restricted field overlying the transverse sinus, whereas others were activated only by more intense mechanical probing or traction. Further characterization of the neurons' response properties, including possible chemosensitivity, will be important for understanding their role in cranial vascular sensation. (Supported in part by the National Headache Foundation, NINDS (NIH), and Beth Israel Hospital Dept. Anesthesia.)

## 454.2

ACTIVATION OF MENINGEAL AFFERENTS IN THE RAT: RESPONSES OF TRIGEMINAL BRAIN STEM NEURONS AND DURAL ARTERIAL FLOW. K. Meßlinger\*, A. Ebersberger, M. Pawlak, K. Scheepelmann, R.F. Schmidt, Dept. of Physiology, University of Würzburg, D-97070 Würzburg, Germany.

Severe headaches such as migraine pain result from a massive activation of nociceptive afferents in meningeal structures, where neurogenic inflammatory processes may play a significant role. The noxious stimuli initially involved are unknown. A preparation was developed in the rat in which the activation of meningeal afferents could be examined by two methods: electrophysiological recordings from trigeminal brain stem neurons and monitoring of dural blood flow changes indicating neurogenic inflammation.

The dura mater encephali was exposed by removing the parietal bone up to the sagittal superior sinus. Meningeal afferents were stimulated with electrical pulses using bipolar electrodes lowered on the dura. Chemical stimuli were applied topically or by injection through a catheter into the sagittal sinus. Extracellular recordings were made from neurons in the subnucleus caudalis of the spinal trigeminal tract. The blood flow was monitored with a laser Doppler flowmeter around branches of the medial meningeal artery.

Neurons in deeper laminae of the nucleus caudalis driven by meningeal afferents were identified by electrical stimulation and by probing the receptive fields on the dura. Most of these units had convergent input from the cornea and/or from the periorbital skin. A proportion of them could be activated by injection of bradykinin, prostaglandin  $E_2$ , and a combination of several inflammatory mediators into the sagittal sinus. The dural arterial flow was locally increased by series of electrical stimuli which were able to activate dural afferents. These increases in flow depended on the polarity, the strength and the frequency of stimuli and could be abolished by local anesthetics.

We conclude that local electrical stimulation of dural structures activates meningeal afferents and causes neurogenic inflammatory responses. These afferents project to trigeminal brain stem neurons and may be activated by inflammatory mediators accumulated in the intracranial venous compartment. The preparation presented here may be a valuable model for studying the processes which are involved in the activation of meningeal afferents and the pathophysiological changes that lead to headaches.

## 454.4

PROTONS ALTER INTRACELLULAR  $Ca^{2+}$  IN A SUBPOPULATION OF CULTURED TRIGEMINAL GANGLION NEURONS. X.-S. Zhang and B. P. Bryant\*, Monell Chemical Senses Center, Philadelphia PA, 19104

Psychophysical studies demonstrate that a subcutaneous pH of 6.2 is sufficient to cause pain in humans and that the perception of pain increases with increasing hydrogen ion concentration (Lindahl, 1962). Single-unit recordings from mammalian nerves show that protons activate a subpopulation of afferents innervating skin and cornea (Steen et al., 1992; Belmonte et al., 1991). In single trigeminal ganglion (TG) neurons, inward currents activated by protons at pH 6 share similarities with capsaicin (CAP)-activated inward currents (Liu and Simon, 1994). To further elucidate the cellular mechanisms by which protons and CAP are transduced to cause pain and irritation we have examined the effect of these stimuli on intracellular  $Ca^{2+}$ .

In cultured neonatal rat TG neurons, 60% of the neurons are sensitive to CAP, and a subpopulation of the CAP-sensitive neurons expressed CGRP using a cobalt uptake assay and immunocytochemical technique. Proton-sensitive neurons were not detected. This suggested that CAP and proton sensitivity may be mediated by different mechanisms or that the cobalt assay was not suitable. Using the  $Ca^{2+}$ -sensitive indicator FURA-2 to measure intracellular  $[Ca^{2+}]$  in TG neurons, we have found that 0.25  $\mu$ M CAP elevated the concentration of intracellular free  $Ca^{2+}$  in 62% of cultured neonatal TG neurons. 20% of the neurons responded only to low pH. Protons (pH 6.6) caused a decrease or increase of intracellular  $[Ca^{2+}]$  in different neurons. The percentage of CAP-sensitive neurons which responded to protons with a decrease in intracellular  $[Ca^{2+}]$  was concentration dependent in the range of pH 6.5 to pH 5. All neurons which responded to protons with an increase in intracellular  $[Ca^{2+}]$  were also sensitive to 0.25  $\mu$ M CAP. The percentage of neurons which responded to protons with an increase in intracellular  $[Ca^{2+}]$  was constant across the range of pH 6.5 to pH 5. While this heterogeneity may reflect acid-sensitive processes on the cell body, it may also reflect the presence of an additional proton sensitive transduction mechanism that is independent from CAP sensitivity. Supported by DC01921 and Kirin Brewery Co. Ltd.

## 454.6

MODULATION OF TRIGEMINAL SENSITIVITY TO IRRITANTS. T.K. Baumann\*<sup>1,2</sup> and M.E. Martenson<sup>1</sup>, Division of Neurosurgery<sup>1</sup> & Department of Pharmacology<sup>2</sup>, Oregon Health Sciences University, Portland, OR 97201

Both trigeminal and spinal ganglion neurons show a strong potentiation of responses to the irritant capsaicin in an acidic environment. The present study revealed that there is also a strong interaction between protons and piperine, another vanilloid irritant. We studied the mechanism of the interaction between protons and the vanilloids. Whole-cell patch clamp recordings were performed on cultured adult rat TG neurons clamped near their resting membrane potential (-60 mV). Piperine (10  $\mu$ M) caused a sustained inward current associated with an increase in membrane conductance. When protons and piperine were co-applied, the membrane currents evoked in piperine-sensitive TG neurons far exceeded the algebraic sum of the responses to the two stimuli applied in isolation. Capsazepine blocked the response of TG neurons to piperine (or capsaicin) at both physiological and acidic pH. In the presence of capsazepine, responses to the mixture of a vanilloid and protons resembled the response to the low pH stimulus applied alone. These findings suggest that protons either increase the availability or affinity of the vanilloid receptor, change the kinetics of the receptor/channel complex or carry a substantial current. (Supported by the National Headache Foundation)

## 454.7

**LECTIN STAINING OF UNMYELINATED AXONS IN VARIOUS SKIN REGIONS OF MALE RATS.** J.C. Petruska\*, W.J. Streit, and R.D. Johnson. Depts. of Neurosci. & Physiol. Sci., Univ. of Florida, Gainesville, FL 32610.

Characterization of various plant lectins has revealed specific binding to distinct neuronal populations. In peripheral nerves, it has been shown by others that the lectin *Griffonia* (or *Bandeiraea*) *simplicifolia* I-B<sub>4</sub> nearly exclusively labels unmyelinated visceral and somatic afferent fibers and their cell bodies of origin, but also labels myelinated gustatory afferents and a small percentage of sympathetic postganglionic cell bodies. The DRG cells giving rise to unmyelinated peripheral and central processes that are positive for the GS-I-B<sub>4</sub> lectin are nearly all fluoride-resistant acid phosphatase (FRAP, a major sensory neuron marker) positive and also include most C-fibers that are negative for the known neuropeptides (e.g. CGRP, SP, etc.). The purpose of the present study was to anatomically characterize the GS-I-B<sub>4</sub> positive fibers in various types of skin. The specificity of GS-I-B<sub>4</sub> in frozen and paraffin sections was examined in the glabrous and hairy skin of the foot, hairy skin of the scrotum, and the mucocutaneous skin surrounding the external urethral orifice. Both Remak bundles present in small dermal nerve branches and single unmyelinated fibers were clearly stained. Lectin-positive axons coursed through the subepithelial tissue, and in some cases, amongst the epithelial cells. Serial section analysis of GS-I-B<sub>4</sub> and CGRP-IR upheld the findings in peripheral nerves and ganglia that the two markers minimally colocalize. Use of the GS-I-B<sub>4</sub> isolectin in conjunction with markers for other neuronal populations (i.e. autonomic and peptidergic fibers) may enable the specific visualization of C-fiber afferents in various skin targets. Such specific visualization in the target tissue of this population will enable more detailed study of cutaneous C-fiber function, morphology, and plasticity.

## 454.9

**DESENSITIZATION OF THE CAPSAICIN-ACTIVATED CURRENT IN RAT DORSAL ROOT GANGLION NEURONS.** P.A. Koplas\*, G.S. Oxford, and R.L. Rosenberg. Curriculum in Neurobiology, University of North Carolina, Chapel Hill, NC 27599.

Capsaicin (8-methyl N-vanillyl 6-nonenamide) has proven to be a valuable tool in the study of primary sensory afferents. This pungent component of the *Capsicum* pepper family activates a non-selective cation channel in nociceptive neurons. The whole-cell patch clamp technique was used to investigate the desensitization of capsaicin-activated currents in cultured neonatal rat dorsal root ganglion (DRG) neurons. Ion substitution experiments demonstrated calcium permeation through the capsaicin-activated channels, with a calculated  $P_{Ca}/P_{Na}$  of 4.0. Barium is less permeant in comparison to calcium, and magnesium supports relatively little current through these channels. The following two types of desensitization behavior were examined: (1) **acute desensitization**, the current inactivation occurring during a prolonged capsaicin exposure; and, (2) **tachyphylaxis**, the reduction in the amplitude of current responses for repeated capsaicin applications. Both categories of desensitization were dependent on the external calcium concentration and degree of internal calcium chelation, and insensitive to changes in capsaicin concentration. Barium supported both acute desensitization and tachyphylaxis, but to a lesser extent than that observed for calcium. The manipulation of intracellular nucleotides indicated acute desensitization was not dependent on ATP and GTP, whereas the degree of tachyphylaxis was enhanced by the exclusion of ATP from the internal solution. Overall, these results provide a detailed characterization of the regulation of capsaicin responses by desensitization processes in cultured DRG neurons.

## 454.11

**PHOSPHOLIPASE A<sub>2</sub> SENSITIVITY OF THE DORSAL ROOT AND DORSAL ROOT GANGLION. AC OZAKTAY, S KALLAKURI, JM CAVANAUGH.** Bioengineering Center, Wayne State University, Detroit, MI 48202, U.S.A.

The aim of this study was to investigate the electrophysiological effects of phospholipase A<sub>2</sub> (PLA<sub>2</sub>) applied to lumbar dorsal roots and dorsal root ganglia (DRG). **METHODS:** Rabbits (3-4 kg, male) were anesthetized and an L5-L7 laminectomy was performed. Recordings were made from split L6 or L7 dorsal roots using dual bipolar electrodes. Latency between the electrodes was used to determine conduction velocity (CV). PLA<sub>2</sub> (150-450 U, *naja naja* venom, Sigma) in a buffered carrier solution (100  $\mu$ l, pH 7.5) was then applied to the dorsal roots and DRG. The spontaneous discharge rates (SDRs) were recorded on analog tape for later computer analysis. **RESULTS:** *Multi-unit:* SDR decreased within 10 min for 6 of 10 PLA<sub>2</sub> applications. In 2 applications (200 U of PLA<sub>2</sub>), SDR showed either frequent bursting or a steady increase over 20 min. *Single units:* The most prominent findings were in the *silent units*. They (n=8) were activated after PLA<sub>2</sub> application and had a peak SDR after 15-20 min. *Group II units* (n=3) disappeared within 10 min. In one of the 4 *group III units* SDR increased and stayed stable over 25 min while the other 3 showed a decrease within 10 min of PLA<sub>2</sub> application. These results suggest chemosensitivity of dorsal roots and DRG to PLA<sub>2</sub>. Supported by NIH Grant AR41739 (JMC).

## 454.8

**SEPARATE AND OVERLAPPING POPULATIONS OF LUMBAR DORSAL ROOT GANGLION CELLS ARE REVEALED BY RETROGRADE TRANSPORT OF A MIXTURE OF TWO LECTINS.** H. Wang, P. Shortland, H. Johnsson\* & C. Molander. Dept. of Neuroscience, Karolinska Institutet, S-171 77 Stockholm, Sweden.

The plant lectins soybean agglutinin (SBA) and *Griffonia simplicifolia* (B4) exhibit specific binding to terminal  $\alpha$ -D-galactose groups that are expressed on subsets of small sized dorsal root ganglia (DRG) cells (Plenderleith et al., '90; Wang et al., '94). Binding studies indicate that SBA & B4 label the same cell populations (Streit et al., '86) but a review of the literature suggests that the 2 lectins may react differently to peripheral nerve injury. As a first step in identifying the responses of these lectins to injury, the distribution & possible colocalisation of these 2 markers were examined in the L4-5 DRGs in normal adult rats. A mixture of 2-5% B4 & SBA was injected into the sciatic nerve and 3 days later the relevant DRGs and spinal cord segments processed using double labelling immunofluorescent techniques. In the DRGs, cell profiles with a visible nucleus that were immunofluorescent for only SBA or B4 and for those that were double labeled were counted. Preliminary results indicate that approximately twice as many cell profiles were labelled by SBA compared to B4. Of the SBA population, 20.3% were also B4 positive while 36.5% of the B4 population were also SBA immunoreactive. B4 and SBA labelled terminals in the dorsal horn were predominately located in lamina II. The present results indicate that SBA and B4 lectins label separate and partially overlapping populations of C fibers and may provide a useful tool for studying the effects of peripheral nerve injury on different subpopulations of C-fibers. Supported by Åke Wibergs stiftelse.

## 454.10

**CHARACTERIZATION OF CAPSAICIN RESPONSES IN INTACT RAT DORSAL ROOT GANGLION NEURONS.** G.S. Oxford\*, P.A. Koplas, and R.L. Rosenberg. Curriculum in Neurobiology, University of North Carolina, Chapel Hill, NC 27599.

Capsaicin is the pungent component of the *Capsicum* pepper family which activates a non-selective cation channel in nociceptive neurons. The two techniques of intracellular calcium imaging and nystatin perforated-patch clamp recording were used to characterize capsaicin responses in intact cultured neonatal rat dorsal root ganglion (DRG) neurons. For the calcium imaging experiments, DRG neurons were loaded with the fluorescent dye fluo-3 AM (5  $\mu$ M). Capsaicin (0.03-1  $\mu$ M) caused an increase in the internal calcium signal, which was dependent on the presence of external calcium. The calcium signals produced by capsaicin and caffeine (10 mM) were additive, suggesting that capsaicin stimulation does not directly lead to calcium release from internal caffeine-sensitive stores. The addition of external cadmium to block voltage-gated calcium channels did not prevent the increase in internal calcium, suggesting that calcium can enter the neurons through capsaicin-gated channels. In the nystatin perforated-patch experiments, the desensitization of capsaicin responses was not significantly different from the whole-cell behavior, indicating that desensitization processes are not compromised by whole-cell dialysis of the intracellular environment. (Supported by NIH NS18788 and HL49449).

## 454.12

**BRADYKININ SENSITIZES RAT CUTANEOUS C-FIBRE POLYMODAL NOCICEPTORS TO INTERLEUKIN-2.** H.A. Martin\*. Div. of Neurobiology, University School of Medicine, Newcastle upon Tyne NE2 4HH, U.K.

We have recently reported that interleukin-2 (IL-2) activates a third of rat cutaneous polymodal nociceptors (Martin & Murphy, *Arch. Physiol. Biochem.* 103, 1995). These nociceptors were subsequently activated by histamine, bradykinin (BK) and topical acetic acid (AA), respectively in this order. However, the cross-reactivity between agents was not assessed due to experimental limitation. Curiously, we found in preliminary studies that units tested with BK (75ng/3 $\mu$ l) responded better to subsequent IL-2 (0.06U/3 $\mu$ l). This observation needed further investigation.

Nociceptors were isolated in an *in vivo* rat saphenous nerve preparation (Martin et al., *Neurosci.* 22, 1987) and characterized by their responsiveness to mechanical, thermal heat and chemical stimuli (rat IL-2: 1.2 U/3 $\mu$ l; BK: 75 ng/3 $\mu$ l; AA; Sigma). IL-2 and BK were injected (3 $\mu$ l) into individual receptive fields. Two series of experiments were conducted: 1) Two IL-2 injections preceded BK. Then, two other IL-2 injections followed BK; 2) BK was injected first and two IL-2 injections followed later. Injections were separated by 10 min when units were silent. Data were analyzed using Spike2 and statistical significance was assessed in a paired-sample t-test. Mean response of the first IL-2 injection equals 100% (reference).

In the first series of experiments, mean response to the 2nd IL-2 (prior to BK) decreased to 55% of the reference level. After BK, mean response to 3rd and 4th IL-2 increased to 155% of reference ( $p < 0.02$ ). In the second series, vigorous IL-2 responses were sustained without tachyphylaxis.

In conclusion, BK sensitizes cutaneous polymodal nociceptors to IL-2, which may explain the occurrence of pruritus in inflamed skin.

## 454.13

SPONTANEOUS FIRING IN ISOLATED RAT DORSAL ROOT GANGLION NEURONS FROM RATS WITH A PAINFUL NEUROPATHY. R.E. Study\*, M.G. Kral, Pain Research Group, Dept. of Anesthesia, Brigham & Women's Hospital, Boston, MA, 02115

Neuropathic pain from nerve injury has been associated with spontaneous action potential (AP) activity in primary afferents, which may be involved in the induction and maintenance of this condition. We show here that such spontaneous activity is maintained in DRG neuron somata after isolation and AP threshold is lower.

A neuropathic pain state was induced in male Sprague-Dawley rats by chronic constriction injury (CCI), applying four loose ligatures to the sciatic nerve as described by Bennett and Xie (*Pain* 33:87-107, 1988). DRG of L4 and L5 were removed from anesthetized animals 3-21 days postop. Neurons were dissociated enzymatically and cells were then plated to culture dishes and used within 6 hours. Recordings were done using whole cell patch clamp under current clamp conditions.

Results show a 20% incidence of spontaneous activity in CCI neurons in comparison to a 3% incidence in controls. This difference is significant ( $P < 0.01$  with Fischer's exact test). These results are maintained over the several hours of the cell prep. Spontaneously firing cells exhibited two types of electrical activity: a regular rapid firing and random firing of single or short bursts of 2-4 APs. Firing was often triggered by spontaneous membrane potential fluctuations. The AP threshold for spontaneously active cells was  $-34.5 \pm 2.7$  mV compared to  $-18.7 \pm 1.5$  mV for quiescent CCI neurons and  $-20.5 \pm 2.2$  mV for control cells. The threshold for spontaneously active cells is significantly lower in comparison to both quiescent CCI and control cells ( $P < 0.001$  with student's t-test). The basis of this lower threshold is unknown, but it may be the cause of the higher incidence of spontaneous firing in these neurons.

## 454.15

PSYCHOPHYSICAL MEASURES OF COLD PAIN SENSATION IN HUMANS: COMPARISON WITH EVOKED RESPONSES OF PRIMARY AFFERENT NOCICEPTORS. D.A. Simone<sup>1</sup>, J. Li<sup>1</sup>, E.R. Stevens<sup>1</sup>, B. Allen<sup>1</sup> and K.C. Kajander<sup>2</sup>. Depts. of <sup>1</sup>Psychiatry and <sup>2</sup>Oral Science, University of Minnesota, Minneapolis MN 55455.

Psychophysical characteristics and the underlying neural mechanisms of pain sensation evoked by cold temperatures below 0° C have not been thoroughly investigated. In the present study, comparisons were made between psychophysical measures of cold pain sensation in humans and evoked activity of primary afferent nociceptors in monkeys. Six subjects judged the magnitude and quality of cold pain sensation evoked by stimulus temperatures between 20° C and -12° C. Stimuli were delivered in descending order of 2° increments to the volar forearm via a 1 cm<sup>2</sup> Peltier stimulator. Each stimulus was of 5 sec duration and applied every 3 min. Thresholds for cold pain were > 10° C for 5 of 6 subjects. Using regression analysis, in 4 of 6 subjects, pain produced by stimuli above -2° C increased at a significantly slower rate than the pain evoked by temperatures below -2° C. The quality of cold sensation changed dramatically at temperatures below 0° C, from one of dull aching to one of sharp, pricking pain. In correlative electrophysiological studies, thresholds of all C nociceptors (n=20) were  $\geq -2^\circ\text{C}$ , whereas thresholds of 12 of 24 A $\delta$  nociceptors were  $\leq -2^\circ\text{C}$ . These data suggest that C and some A $\delta$  nociceptors contribute to cold pain sensation at stimulus temperatures above -2° C. The sharp pricking sensation evoked by stimulus temperatures below -2° C is likely to be mediated by the recruitment of additional A $\delta$  nociceptors.

## 454.17

MECHANICAL RECEPTIVE FIELD STRUCTURE FOR CUTANEOUS C- AND A-FIBER NOCICEPTORS IN THE MONKEY DETERMINED WITH GRADED INTENSITY STIMULI. R.M. Slugg\*, R.A. Meyer, and J.N. Campbell, School of Medicine, Johns Hopkins Univ., Balto., MD 21287

Receptive field (RF) maps have traditionally been determined with hand-held von Frey probes. With use of a new, computer-controlled mechanical stimulator system, we are now able to obtain high-resolution, quantitative maps of nociceptor response at different stimulus intensities. Standard teased fiber techniques were used to record from 18 C-fiber and 7 A-fiber nociceptors that innervate hairy skin in the anesthetized monkey. Force-controlled stimuli (2-64 gm, 1 s) were delivered to the skin via thin (100  $\mu\text{m}$ ) blade-shaped probes. The stimuli were delivered in 100  $\mu\text{m}$  increments along a line through the middle of the RF and orthogonal to the blade. Blade-shaped probes were chosen to activate the whole RF in one dimension (along the length of the blade) and to permit high spatial resolution maps in the other dimension (perpendicular to the blade). This allows functional mapping of two dimensional structures from data obtained in one dimension. The one-dimensional RF maps were obtained by plotting the response as a function of probe location. Various RF architectures were observed including 1) multiple, fine, punctate structures with dimensions less than 200  $\mu\text{m}$  wide, 2) several broad, rounded structures with dimensions greater than 500  $\mu\text{m}$ , and 3) combinations of these. As stimulus intensity increased, the response at the peaks increased, the punctate structures became broader, and the valleys between adjacent peaks became less distinct. The RF architecture was reproducible with repeated mapping. This technique will allow investigations of alterations in RF architecture that follow cutaneous injury.

## 454.14

THE ROLE OF NON-SPECIFIC CATION CHANNELS IN COLD TRANSDUCTION

D.L. Tanelian\*, and S. Monroe, Dept. Anesthesiology and Pain Management Southwestern Medical Center, Dallas, Texas 75235-9068

The molecular and cellular processes involved in cold transduction remain unknown due to the small size, and restricted accessibility of cold fiber terminals. The goal of this study was to investigate the role of Na<sup>+</sup>, K<sup>+</sup>, Ca<sup>2+</sup>, non-specific cation channels, as well as Na-K ATPase, in cold transduction. Single unit extracellular recordings were obtained from 59 corneal cold nociceptors in 26 rabbits. The adapting temperature was 35°C in all experiments. Thermal responsiveness for each fiber was characterized with a -5°C temperature ramp (-1°C/sec). Pharmacological channel blockers ( $\mu\text{M}$ ), diltiazem (10), 4-aminopyridine (10), quinine (100), glibenclamide (10), TEA (20), Cs<sup>+</sup> (2), ouabain (10), Ni/Cd (50 & 200), quinidine (100), apamin (10), were then applied to the terminal field of the recorded cold receptor. Neural activity was characterized by 5 parameters: tonic firing rate, cold evoked maximum action potential (AP) frequency, evoked adapted AP frequency, and rate of neural activation and adaptation. Our previous work identified the rate of neural activation as being the best reflection of the dynamic cold transduction process. The dynamic cold response was attenuated by all compounds that block nonspecific cation channels (diltiazem, 4-AP, and quinine). Tonic cold fiber activity was increased by all compounds tested and known to cause neural depolarization (TEA, Cs<sup>+</sup>, ouabain, and glibenclamide). Nonspecific depression of all cold fiber activity was seen when using a Na<sup>+</sup> channel blocking concentration of Ni/Cd and quinidine. Ni/Cd (50  $\mu\text{M}$ ), which blocks all voltage dependent Ca<sup>2+</sup> channels, and apamin, had no effect upon cold fiber activity. The results of this study implicate a non-specific cation channel in the transduction process of dynamic cooling.

ACTIVITY-DEPENDENT VARIATIONS IN CONDUCTION VELOCITY OF A-DELTA FIBERS OF RAT SCIATIC NERVE S.C. Nam<sup>1</sup>, C.K. Won<sup>2</sup>, M.Y. Park<sup>2</sup>, H.S. Park<sup>2</sup>, and H.C. Shin<sup>2</sup>. Dept. of Oral Physiology, Coll. of Dentistry, Seoul National Univ., Seoul & Dept. of Physiology<sup>2</sup>, Coll. of Med., Hallym Univ., Chunchon, Korea

Previously, we have demonstrated different profiles of the activity-dependent changes in conduction velocity (CV) of C-fibers of rat sciatic nerve. In the present study, changes of the CV and subsequent conduction block (CB) were characterized following impulse activity (0.5, 1.0, 5.0, 10.0, 25.0, 50.0, 100.0 and 200.0 Hz, 1 min) in single A-delta fibers (n=19, range of resting CVs: 2.15 - 18.64 m/sec, at 0.5 Hz) of isolated rat sciatic nerves. A-delta fibers which had similar resting CVs often exhibited quite different profiles of the activity-dependent latency change and/or CB following impulses. Although A-delta fibers showed only small (1.17 $\pm$ 0.5%) decrease of CV at the lowest activity rate (1.0 Hz), they exhibited much extensive increase of latencies at higher activity states (10.0 Hz: 11.54 $\pm$ 2.9%, 25.0 Hz: 28.03 $\pm$ 6.1%, 50.0 Hz: 22.81 $\pm$ 4.8%, 100.0 Hz: 23.38 $\pm$ 5.0%). The frequency of CB increased dramatically as the activity rate rose (5.0 Hz: 10.5%, 10.0 Hz: 21.1%, 25.0 Hz: 31.6%, 50.0 Hz: 36.8%, 100.0 Hz: 68.4% and 200 Hz: 89.5%). Five of 19 fibers showed intermittent CB prior to the occurrence of the complete block, whereas 14 of 19 fibers exhibited direct CB without showing intermittent firing activities. These results imply underlying variation among A-delta fibers in the activity-dependent excitability changes, especially in the buildup and recovery of the hypoeccitable phases (supported by KOSEF 94-0403-15-02-3).

## 454.18

PLASMA EXTRAVASATION IS REDUCED ON THE PLANTAR SURFACE OF THE RAT HIND PAW FOLLOWING LIGATION OF THE L5 AND L6 SPINAL NERVES Z. Ali<sup>1</sup>, M. Ringkamp<sup>2</sup>, R.A. Meyer<sup>1,3\*</sup> and S.N. Raja<sup>2</sup>. Dept. of Neurosurgery<sup>1</sup>, Anesthesiology<sup>2</sup>, Applied Physics Lab<sup>3</sup>, Johns Hopkins University, Baltimore, MD 21287

Ligation of spinal nerves L5 & L6 leads to behavioral signs of hyperalgesia on the plantar surface of the rat hind paw. In this study plasma extravasation was used to examine C-fiber innervation of the paw following spinal nerve ligation. Spinal nerves L5 and L6 were ligated in 8 male Sprague-Dawley rats. Three weeks after surgery the rats were anaesthetized with pentobarbital, paralysed and artificially ventilated. Both sciatic nerves were exposed and cut at the sciatic notch. An intravenous bolus of Evans blue (50 mg/kg) was administered 5 min before both sciatic nerves were stimulated (80 V, 1 ms, 5 Hz) for 10 min. The rats were perfused and fixed with formalin. Plasma extravasation was markedly reduced in the paw ipsilateral to the nerve ligations when compared to the equivalent paw of 8 concurrent, non-lesioned control rats. Within the L5 dermatome which covers the lateral aspect of the foot, extravasation was almost abolished on both dorsal and plantar surfaces. Surprisingly, extravasation also appeared to be abolished on the plantar surface in the region of the footpads, an area predominantly innervated by the non-lesioned, L4 spinal nerve. In contrast, plasma extravasation in the L4 distribution on the dorsum of the foot was not decreased. The decreased extravasation near the footpads may be explained by: 1) a change in function of nociceptors in the L4 spinal nerve, 2) a substantial denervation of the footpad region by the L5 lesion, or 3) an enhanced vasoconstriction associated with stimulation of sympathetic fibers in the sciatic nerve.

## 454.19

TIME COURSE OF FORMALIN-INDUCED RESPONSE OF C-FIBERS IN THE SAPHENOUS NERVE OF RAT. W.D. McCall, Jr.\*, Kimberly D. Tanner, and Jon D. Levine SUNY Buffalo & UCSF.

While the formalin test is a widely used behavioral model of tonic chemogenic pain and is well characterized, little is known about the response of peripheral afferent fibers to formalin.

Single C-fiber primary afferents were isolated from the saphenous nerve of pentobarbital-anesthetized rats. C-fibers were identified by having conduction velocities less than 2 m/s and a positive collision test. Formalin (2.5 %, 50  $\mu$ l) was injected in the vicinity of the fiber's mechanical receptive field. Activity of the fiber was recorded from 10 minutes prior to the injection to 60 minutes after the injection. Action potentials were counted in 3-minute bins.

Following formalin injection, the average number of spikes per bin in C-fibers ( $n=26$ ) showed two peaks. The first peak was  $70.5 \pm 28.5$  (mean  $\pm$  s.e.m.) spikes per bin at 3 min, which declined to pre-injection levels at 9 to 12 min, then rose gradually to a second peak of  $39.0 \pm 23.1$  at 48 min. The average of 8 saline-injected C-fibers showed no significant increase of activity.

The time course of the response to formalin of C-fiber afferents is similar to that of the behavioral response, is not explained by the injection of vehicle, and suggests that C-fiber activity could contribute to the behavioral response in phase 2 as well as phase 1 of the formalin test.

## SOMATIC AND VISCERAL AFFERENTS: MECHANORECEPTORS

## 455.1

MECHANICAL STATES ENCODED BY JOINT CAPSULE AFFERENTS. P.S. Khalsa\*, and P. Grigg, Phys. Dept., Univ. Mass. Med. Sch., Worcester, MA 01655

Joint capsule afferents from the cat knee posterior capsule were studied for their sensitivity to in-plane stretch. The posterior joint capsule was excised from the knee and subjected to stretching *in vitro*. Forces were applied through tabs along the edges (3 tabs / edge) of the capsule (Fig. 1), using an apparatus that allowed for independent control of each load on each tab. By appropriately loading the tissue margins, it was possible to establish states of uniaxial and biaxial tension, as well as shear. Plane stresses were calculated from the loads along the tissue margins. Strains were calculated from deformations of the capsule measured by tracking markers on its surface. Full characterization of tissue stresses and strains made it possible to determine strain energy density and the magnitudes of other coordinate invariant mechanical states. Single afferents were recorded from filaments of the posterior articular nerve. All afferents had conduction velocities in the group 2 or group 3 range. Individual afferents exhibited pronounced directional sensitivity. There was no overall preferred orientation. Linear multiple regression of the combined stress and strain components on the neuronal response revealed high correlation ( $R = 0.84$ ), indicating that the measured mechanical states strongly determine neuronal response. Correlation analysis between neuronal discharge and individual stress or strain components revealed no consistent relationship between neuronal response and any single tensor component. However, there was a much stronger relationship between neuronal discharge and stress variables than with strain variables. The strongest relationship was observed between neuronal response and the first invariant of the stress tensor. Supported by NIH grants NS-10783, 5-F32-AR08225, and FCER grant 92-6-2.

## 455.2

MECHANICAL TUNING OF THE PACINIAN CORPUSCLE'S ACCESSORY CAPSULE AND ITS RELATIONSHIP TO TRANSDUCTION MECHANISMS. B. Pietras\*, and S.J. Bolanowski, Institute for Sensory Research and Department of Bioengineering and Neuroscience, Syracuse University, Syracuse, New York 13244.

The magnitude of receptor potentials recorded from isolated Pacinian corpuscles in response to sinusoidal vibrations display a U-shaped frequency response curve, centered around 300 Hz. The low frequency portion of this curve can be partially explained by the mechanical properties of the accessory capsule, while the high-frequency portion of the curve it thought to be due to transduction channel kinetics. To assess the mechanical contribution of the accessory capsule to the Pacinian corpuscle's frequency response, individual Pacinian corpuscles were mechanically stimulated with a cylindrical probe (diameter  $\approx 250 \mu$ m) statically, and with sinusoidal vibrations ranging from 1 to 900 Hz, allowing for video analysis of the lamellar motion in response to the mechanical stimuli. It was found that the lamellae motion had a band-pass characteristic whereby the peak-to-peak change of the interlamellar spacing as a function of frequency displayed a U-shaped function analogous to the physiological frequency response. Thus the mechanical properties of the accessory capsule contribute not only to the low-frequency portion of the physiological frequency response, but also to the high-frequency portion. It is possible that the Pacinian corpuscle's reduced sensitivity at high frequency is due to the mechanics of the capsule and not transduction channel kinetics. Work supported by NSF, IBN-9211561.

## 455.3

QUANTITATIVE CHARACTERIZATION OF RAPIDLY ADAPTING CORNEAL MECHANO-RECEPTORS.

S. Monroe\*, B. Kane, G. Kovacs, D. Jackson, and D.L. Tanelian, <sup>1</sup>Dept. Anesthesiology and Pain Mgt., Southwestern Medical Center, Dallas, Texas 75235-9068, and <sup>2</sup>Dept. of Elect. Eng., AEL 132, Stanford Univ., \*Stanford, CA 94305

Measurement of force thresholds in intact vertebrate mechanoreceptors is complicated by their surrounding tissue medium. This situation is greatly simplified in the cornea where the mechanoreceptors are embedded in a homogenous avascular non-keratinized epithelium. Single unit extracellular recordings were obtained from 7 corneal mechano-sensitive nociceptors from 5 rabbits. A newly developed polysilicon, piezo resistive, force sensing microprobe was used to determine the sensitivity of these fibers. The microprobe (25  $\mu$ m width) was force-feedback closed-loop controlled and allowed independent control of the duration, force, and rate of force of the stimulation probe. Cornea mechano-sensitive fibers displayed characteristics common with other rapidly adapting mechano-receptors. The fibers are normally silent, but in response to a rapidly applied force will display a dynamic response followed by a tonic response which lasts up to 4 sec. In general, the greater the magnitude and rate of change of the stimulating force the greater the number of evoked action potentials, and the longer the duration of the sustained tonic response. Short intertrial intervals ( $< 20$  sec) with repeat stimulation leads to a decrement in response. Ascending force trials, over the range of 0 - 1.25 mN, in steps of 0.5 mN (100 mN/sec, 4 sec duration and 20 sec inter trial interval), were used to determine that the response threshold of these mechanoreceptors was  $0.1 \text{ mN} \pm 0.09 \text{ mN}$ . This threshold is significantly lower than previously reported for any population of cutaneous mechanosensitive fibers, including the cornea, which was previously estimated with von Frey Hairs to be 0.64 to 1.2 mN. An "off response" appeared in some mechanoreceptors after the sustained application of forces  $> 1 \text{ mN}$ . This corneal mechanoreceptor preparation will allow further quantitative studies of mechanical transduction mechanisms.

## 455.4

PERIPHERAL NEURAL REPRESENTATION OF THE SHAPES AND ORIENTATIONS OF THREE-DIMENSIONAL OBJECTS STROKED ACROSS THE MONKEY FINGERPAD. R.H. LaMotte\*, C. Lu and M.A. Srinivasan, Dept. of Anesthesiology, Yale University School of Medicine, New Haven, CT 06510 and Research Laboratory of Electronics, MIT, Cambridge, MA 02139

The neural representation of object shape and orientation was studied in responses of rapidly and slowly adapting mechanoreceptive primary afferent fibers (SAs and RAs) to ellipsoidally shaped objects stroked across the fingerpad of the anesthetized monkey. Each ellipsoid, 0.5 mm high and mounted on a flat plate, had a radius of 5 mm on the major axis and 1, 3 or 5 mm on the minor. A servocontrolled stimulator stroked the object back and forth across the skin in the horizontal plane (x,y) along a series of laterally shifted parallel linear trajectories while maintaining a contact force of 5, 10 or 20 g-wt. Orientation of the object and direction and velocity of stroking were varied. 3-D "Spatial event plots" (SEPs) of impulses/0.2 mm bin plotted as height over object position (x,y) were interpreted as instantaneous, spatially distributed responses of a population of fibers. The contour of the base of the SEPs of RAs and SAs encoded the 2-D outline of the object in contact with the skin. The orientation of the outline, determined by a principal component analysis, was closely related to the physical orientation of the object on the skin.

An average of 5 central, vertical cross-sections through the SEP parallel to the minor axes of the ellipsoids revealed a contour that was related non-isomorphically to object shape. Peak height of this contour (maximum spatial discharge rate) increased and width of its base (extent of receptor activity in the skin) decreased with increasing object eccentricity for both RAs and SAs. Peak height also changed with changes in contact force, object orientation, and stroke velocity and direction. When peak heights were normalized, object curvature was correlated with the rate of decline of the falling phase in the response profiles for 11 of 16 SAs, but not for the 11 RAs tested. The spatial response measures of shape were more resistant than the intensive measures (discharge rate) to changes in contact force and the direction and velocity of stroking. Supported by NIH grant NS15888 and ONR grant N00014-92-J-1814.

## 455.5

## PREDICTING THE RESPONSE OF A POPULATION OF MECHANORECEPTORS USING 3D FINITE ELEMENT MODELS OF PRIMATE FINGER TIPS.

K. Dandekar and M. A. Srinivasan\*, Department of Mechanical Engineering and Research Laboratory of Electronics, MIT, Cambridge, MA 02139.

Geometrically accurate 3-dimensional finite element models of human and monkey finger tips were developed based on data obtained using a video-microscopy system. The differences in the mechanical properties of various layers of the skin, the adipose tissues and the bone was accounted for by modeling the fingertip in layers such that each layer could be assigned distinct material properties. To accurately predict the experimentally observed *in vivo* surface deformations of human and monkey finger tips under a line load, at least three distinct layers were found to be necessary. The epidermis and dermis were represented by a stiff outer layer, the adipose tissue was modeled by a relatively compliant intermediate layer, and the bone was modeled as the rigid innermost layer. This model also predicted very well the experimentally observed *in vivo* surface deformations of human finger tips under cylindrical indentors of various radii.

The stresses and strains at typical receptor locations calculated from the models were correlated with electrophysiologically recorded responses of slowly adapting (SA-I) afferents in monkeys to indentations by rectangular bars, cylinders, and sinusoidal step shapes. The strain energy density and the maximum compressive strain at the receptor locations were found to be directly related to the experimentally recorded neural response. Thus, the predictions of the finite element models matched the data from both biomechanical and neurophysiological experiments. The spatial response profile, obtained from the neural data recorded from single afferent nerve fibers, was found to be significantly different from the population response predicted by the model, owing to the differences in the location of the receptors in the population. These empirically validated models can also be used for hypothesizing how the CNS might infer object shape from tactile neural input. ## 455.7

## IDENTIFYING SENSORY RECEPTORS FROM SOMAL SPIKES USING

NEURAL NETS AND DISCRIMINATE ANALYSIS. RD Rose\* & WJ Karnavas, Center for Clinical Neurophysiology, Department of Neurosurgery, CHP, University of Pittsburgh, PA 15213; and Transarc Corporation, Pgh PA 15219.

Retrospective analysis of somal electrophysiology from intracellularly recorded, physiologically identified cat DRG somata demonstrates that both neural nets and discriminate analysis (DA) provide adequate tools for specifying peripheral receptor type from measurable parameters of individual somal spikes. Specifically, somata could be identified as innervating muscle spindles, hairs or high threshold mechanoreceptors (HTMRs). 156 units were selected and analyzed from a database for all units with spikes  $\geq 60$  mV initial rising phase and entries for at least 6 of the following 12 parameters: spike duration, risetime, falltime, half amplitude duration, half amplitude after hyperpolarization duration, spike amplitude, overshoot amplitude, after hyperpolarization amplitude, resting membrane potential, peripheral fiber conduction velocity (PFCV), convexity of shoulder on spike depolarization phase, and convexity of shoulder on repolarization phase.

Conventional analysis of these same spike parameters showed statistical differences among afferent types (ANOVA, corrections for multiple comparisons, Rose 1986) but was of little predictive value. Our back propagation neural net with 12 input nodes, 10 nodes in one hidden layer and 4 output nodes, and trained with 1% random noise added to each input during training, readily reached our criterion of 100% correct identification using a pseudo jack-knife procedure. Moreover, hairs and HTMRs could be segregated into Down, G1 & G2, and A $\beta$ , A $\delta$  & C, respectively, even when PFCV was omitted. DA did as well, but also indicated that almost equal results could be obtained with but 4 parameters. DA has the additional feature of providing the relative value/contribution of each parameter in the analysis.

Coupling these mathematical tools with computer controlled data acquisition should greatly improve efficiency of animal use and investigators.

## 455.9

## RESPONSIVENESS OF MESENCEPHALIC TRIGEMINAL NUCLEUS NEURONS TO EXCITATORY AMINO ACIDS. K.A. Pelkey and K.C. Marshall\*, Dept. of Physiology, Univ. of Ottawa, Ottawa, Ontario, Canada, K1H 8M5.

The central location of the mesencephalic trigeminal nucleus (MeV) makes the cell somas of the primary sensory afferents that compose this nucleus accessible targets for modulation of sensory input by fibres projecting from other parts of the central nervous system. In fact, modulation of the activity of MeV neurons has been reported in response to fictive mastication, although the modulatory mechanism was undetermined (Kolta et al. (1990) J. Neurophysiol. 64, 1067-1076). Immunocytochemistry studies have revealed a prominent innervation of MeV cell bodies by nerve terminals containing a variety of putative neurotransmitters including, but not limited to, histamine, dopamine, serotonin, noradrenaline, and adenosine. However, when tested electrophysiologically none of these putative neurotransmitters have elicited changes in the activity of MeV cells.

We have performed intracellular recordings from MeV neurons in a rat brain slice preparation to determine if exogenously applied excitatory amino acids (EAAs) can alter the membrane properties of these cells. The recorded neurons were found to exhibit glutamate responsiveness that was composed of both an N-methyl-D-aspartate (NMDA) component and a non-NMDA component. The NMDA-mediated response consisted of a slowly rising depolarization that frequently reached threshold for action potential generation. Furthermore, this response displayed typical  $Mg^{2+}$  sensitivity and could be abolished by the potent and selective NMDA antagonist 3-(R)-2-carboxypiperazin-4-yl-propyl-1-phosphonate (CPP). The non-NMDA component of the glutamate response could be antagonized by 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX). Kainate (KA) application caused a slow depolarizing response that was CNQX sensitive suggesting that the non-NMDA component of the glutamate response is, at least in part, mediated by the KA subtype of glutamate receptor. This report documents for the first time responsiveness of MeV neurons to EAAs and may provide insight into the mechanisms responsible for modulation of their activity. (Supported by MRC Canada)

## 455.6

## SPATIAL SUMMATION OF THRESHOLDS FOR PERCEIVED PRESSURE, SHARPNESS, AND MECHANICALLY EVOKED CUTANEOUS PAIN.

J.D. Greenspan\*, M. Thomadaki, and S.L.B. McGillie. Dept. of Neurosurgery & Physiology, SUNY Health Science Center, Syracuse, NY 13210, USA.

Psychophysically, spatial summation can be defined as a decrease in threshold accompanying an increased area of stimulation. The present study examined to what extent different mechanically evoked percepts (pressure, sharpness, and pain) demonstrate spatial summation. Various probes were used to apply prescribed forces to the dorsal surface of the digits of 19 healthy subjects. Some tests used a single probe (circular contact area of 0.05 or 0.1 mm<sup>2</sup>), while other tests used two probes of the same size, separated by 5 mm. This distance provided for stimulation of two largely separate sets of receptors, yet was perceived as a single stimulation site.

The three perceptual qualities showed differing degrees of spatial summation: sharpness averaged 18% summation, pain averaged 46%, while pressure averaged 76%. The small degree of spatial summation for sharpness threshold is consistent with the theory that perceived sharpness is based on near threshold activity of a small number of nociceptors. The modest amount of spatial summation for pain suggests that distinctly suprathreshold activation of nociceptors is required for mechanically evoked pain perception. However, spatial summation for nociceptors appears to be less than that for slowly adapting mechanoreceptors, as evidenced by the greater spatial summation observed for pressure vs. pain thresholds. (Supported by NIH grant NS-28559).

## 455.8

## MECHANORECEPTOR ACTIVITY RECORDED FROM THE HUMAN LINGUAL NERVE. M. Trulsson, G. Essick, S. Vines and J. Zuniga. Dental Research Center, Univ. of North Carolina, Chapel Hill, NC 27599-7455.

The human tongue is exquisitely sensitive to tactile stimulation. Very little, however, is known about the peripheral neural mechanisms underlying lingual sensation. The present study sought to explore the mechanoreceptive innervation of the tip of the tongue. The lingual nerve was approached intraorally using a microneurographic technique similar to that employed to study the human inferior alveolar nerve (Trulsson et al., J. Physiol. 447:373-389, 1992). Tactile stimulation of the lingual mucosa was provided by blunt probes and von Frey hairs mounted to a force transducer. To date, 6 healthy young adult subjects have been studied.

The innervation territories of 9 nerve fascicles were mapped. The fields always included the tip of the tongue and extended at least 3 cm posteriorly. No field extended more than 1-2 mm across the midline.

Twelve single mechanoreceptive afferents were isolated and classified. Each exhibited an extremely small, well defined receptive field (RF; median = 2 mm<sup>2</sup>; range = 1 - 20 mm<sup>2</sup>) and responded to very low forces (median threshold = 0.19 mN; range = 0.03 - 2 mN). Seven of the 12 afferents adapted rapidly to suprathreshold forces applied to the RF. Responses at both the onset and offset of sustained indentation were observed. Since no afferent was sensitive to tapping stimuli applied remote to the RF, all seven resembled the fast adapting type I afferents supplying the glabrous skin of the human hand. Five of the 12 afferents adapted slowly to suprathreshold forces applied to the RF. Two of these afferents exhibited irregular responses to sustained indentation and were particularly sensitive to changes in deformation of the mucosa. Three afferents exhibited highly regular responses and were spontaneously active. As such, these two groups correspond to the type I and II slowly adapting afferents of the hand. Supported by the Swedish Medical Research Council (grants no. 8667, 11087) and NIH (grants no. DE10141, DE07509).

## 456.1

MICROSTIMULATION ON TRIGEMINAL SUBNUCLEUS CAUDALIS (Vc) PRODUCES EXCITATORY EFFECTS ON RAT JAW MUSCLES. C.-M. Tsai\*, B.J. Sessle, and J.W. Hu. Dept. of Oral Physiology, Fac. of Dentistry, Univ. of Toronto, Toronto, Canada. M5G 1G6

We have shown in rats that lesions of Vc, an important brainstem relay of orofacial nociceptive information, interfere with the increases of electromyographic (EMG) activity in digastric (DIG) and masseter (MASS) muscles reflexly evoked by injection of mustard oil into the temporomandibular joint region. This study was initiated to test whether microstimulation of Vc produces excitatory effects on DIG and MASS. In 8 male Sprague-Dawley rats (250-350 g) anesthetized with halothane/N<sub>2</sub>O/O<sub>2</sub>, microstimulation (1-ms duration train of three 50- $\mu$ s cathodal pulses; <1 mA; train frequency 0.3 Hz) was applied via a microelectrode (0.2-3 M $\Omega$  at 1 kHz) introduced into the exposed caudal brainstem at 4 rostrocaudal planes (0.5 mm rostral, and 1.0, 2.5 and 4.0 mm caudal to obex); stimuli were delivered at different depths within medial and lateral Vc and adjacent reticular formation. EMG activity was recorded from ipsilateral DIG and MASS for measurement of incidence, threshold and latency of evoked EMG activity. EMG activity in DIG and MASS could be readily evoked in all animals, with the lowest threshold sites (mean  $\pm$  S.D., 153.1  $\pm$  63.1  $\mu$ A for DIG and 157.8  $\pm$  59.0  $\mu$ A for MASS) being superficial loci within the medial portion of Vc in the most caudal plane. The threshold for evoking EMG activity in both DIG and MASS gradually decreased from rostral to caudal planes and was significantly lower (i) in the most caudal plane than the more rostral planes (Repeated-measures ANOVA,  $p < 0.001$ ), (ii) in medial Vc than lateral Vc or reticular formation ( $p < 0.01$ ), and (iii) in superficial layers than deep layers of Vc ( $p < 0.001$ ). The shortest latency of EMG activity evoked by 3xT stimulation was also significantly lower in the most caudal plane (4.43  $\pm$  0.81 ms for DIG and 4.8  $\pm$  0.89 ms for MASS) than the most rostral plane (7.18  $\pm$  2.68 ms for DIG and 8.28  $\pm$  3.31 ms for MASS,  $p < 0.05$ ). These findings indicate that Vc may produce excitatory effects on jaw muscles, and the latency values suggest that these effects involve multisynaptic or slowly conducting pathways from Vc to DIG and MASS motoneurons. Supported by Canadian MRC MT12286.

## 456.3

ASCENDING NOCICEPTIVE CONTROL SYSTEM IS MEDIATED IN THE ROSTRAL VENTRAL MEDULLA RW Gear\* and JD Levine, Depts. of Stomatology and Oral and Maxillofacial Surgery, Univ. of Calif., San Francisco

We have previously shown that lumbar intrathecal (i.t.) administration of the  $\mu$ -receptor selective opioid DAMGO in the rat attenuates (i.e., is antinociceptive to) the trigeminal jaw-opening reflex (JOR) and, further, that naloxone microinjected into the nucleus accumbens blocks attenuation of the JOR by i.t. administered DAMGO. To explain these results, we proposed the existence of an ascending spino-supraspinal nociceptive control system that is mediated by an opioid link in the nucleus accumbens (J Neurosci 15(1995):3154-61). Since naloxone microinjected into either the periaqueductal gray (PAG) or the rostral ventral medulla (RVM) does not block the effect of i.t. DAMGO on the JOR, opioidergic circuitry in these sites does not appear not to be involved in this proposed ascending pathway. In contrast, we now report the GABA<sub>A</sub> agonist, muscimol (20 ng), microinjected into the RVM completely blocks the attenuation of the JOR by i.t. DAMGO. Also, suppression of the JOR by DAMGO (60 ng) microinjected in the PAG is antagonized by naloxone (2  $\mu$ g) microinjected in the RVM, confirming previous reports that activation of a descending nociceptive control system by opioids injected into the PAG is mediated, at least in part, by opioidergic circuitry in the RVM. These results suggest that nonopioidergic circuitry, possibly subject to GABA inhibition, in RVM is required to mediate the antinociceptive effect of i.t. DAMGO on the JOR and that the RVM is an important site in the ascending nociceptive control system. Furthermore, since opioidergic circuits in the RVM are implicated in antinociception produced by DAMGO microinjected in the PAG but not by DAMGO administered i.t., the classic descending nociceptive control system appears to be mediated by different supraspinal circuitry than the proposed ascending nociceptive control system.

NEUROPEPTIDES IN SPINAL PATHWAYS TO THE RAT INTERNAL LATERAL PARABRACHIAL NUCLEUS. K. Feil\* & H. Herbert. Dept. Animal Physiol., Univ. Tübingen, Auf der Morgenstelle 28, D-72076 Tübingen, Germany.

The parabrachial complex receives topographically organized somatosensory inputs from the spinal cord and the spinal trigeminal nuclei (Sp5). In the present study we analyzed the afferents to the internal lateral (il) PB in more detail by using retrograde tracing with Fluoro-Gold (FG) combined with fluorescence immunocytochemistry for vasoactive intestinal polypeptide (VIP) and substance P (SP).

Following FG injections into the PBil retrogradely labeled neurons were observed in the lateral spinal nucleus (LSN) and the lateral reticular area (LRA). The majority was present in the LSN of cervical and lumbo-sacral spinal segments, whereas in the thoracic spinal cord only few labeled neurons were seen. Retrogradely labeled neurons that were also immunoreactive (ir) for VIP were predominantly found in the LSN of lumbo-sacral segments while in the LSN of upper spinal segments only few double labeled neurons were found. In the LRA we observed in all spinal segments only occasionally VIP-ir neurons. In contrast, neurons double labeled for SP were almost exclusively present in the LSN of upper cervical spinal segments while the LSN of thoracic and lumbo-sacral segments was largely devoid of double labeled cells. Sections through the parabrachial complex stained for VIP and SP also showed a differential pattern of staining in the PBil. VIP-ir fibers were predominantly found in a bowl-shaped area bordering the PBil ventrally, while SP-ir fibers were found within the PBil proper. A similar pattern of termination of spinal fibers in the PBil was already previously observed.

Our data indicate that the projections from the LSN to the PBil consist of two different pathways: a VIP-ergic pathway which originates in the lumbo-sacral LSN and terminates in the ventral aspects of the PBil and a SP-ergic pathway which originates in the upper cervical LSN and terminates in the PBil proper. It is conceivable that they represent two functionally different routes which are coded by two different neuropeptides. (Supported by DFG He 1842/3-2)

## 456.2

DYNORPHIN-IMMUNOREACTIVITY IS INCREASED IN THE SPINAL TRIGEMINAL NUCLEUS IN AN ANIMAL MODEL OF OROFACIAL INFLAMMATION. Y.-O. Lee<sup>1</sup>\* and A.J. Beitz<sup>2</sup>. Graduate Programs in Oral Biology<sup>1</sup> and Neuroscience<sup>2</sup>, University of Minnesota, St. Paul, MN 55108.

We have utilized an animal model of orofacial inflammation (Haas *et al.*, 1992) to assess possible changes in dynorphin immunostaining in the spinal trigeminal nucleus (STN). Inflammation of the temporomandibular joint (TMJ) was induced by paraperiosteal injection of mustard oil (30  $\mu$ l of 20 % allyl isothiocyanate in mineral oil; Aldrich Chemicals Co.; Milwaukee, WI) into the periarticular TMJ tissue of the anesthetized rat.

Twelve animals were randomly assigned into one of the following three groups after initial baseline testing for mechanical hyperalgesia using von Frey hairs (Vos *et al.*, 1994): 1) mustard oil (MO) injection group, 2) saline (SAL) injection group, and 3) a control group not subjected to TMJ injection. Animals were tested for mechanical hyperalgesia at one, three, five, and seven days post-injection. Following behavioral testing on day seven, animals were perfused transcardially with 4 % paraformaldehyde and subsequently processed for immunocytochemical staining using an antiserum against dynorphin A1-17 (Peninsula; Belmont, CA).

Animals with MO injection into TMJ demonstrated behavioral signs of mechanical hyperalgesia at all post-injection testing timepoints as determined by larger difference scores compared to the SAL-injected group or the control group. A difference score was obtained through subtraction of the contralateral response score (non-injected side) from the ipsilateral response score (injected side). In the MO injection group, there was a significant increase in the number of dynorphin-immunoreactive (DYN-IR) cell bodies in the ipsilateral subnucleus caudalis of the STN where primary afferents from the inflamed TMJs presumably terminate. These data suggest that dynorphin-containing neurons in the STN play a role in the response of this nucleus to TMJ inflammation. Possible changes in DYN-IR fibers are currently being investigated using a computerized image analysis system. (Supported by NIH grant D106682)

## 456.4

IS THE PARABRACHIAL NUCLEUS ESSENTIAL FOR REFLEX AUTONOMIC RESPONSES ELICITED BY NOXIOUS ELECTRICAL STIMULATION OF TOOTH DENTIN?

G.V. Allen\*, M.J. Esser and S. Pronych, Department of Anatomy and Neurobiology, Dalhousie University, N.S., Canada, B3H 4H7.

Noxious stimulation of trigeminal sensory nerves induces reflex changes in arterial blood pressure and heart rate. Previous studies in this laboratory determined that nociceptive neurons in the spinal trigeminal nucleus have dense projections to the lateral parabrachial nucleus and moderate to light projections to the ventral lateral medulla and the A5 region. However, the relative importance of trigeminal projections to the lateral parabrachial nucleus and the other brain stem autonomic cell groups, in the autonomic reflex response, remains to be determined.

In one series of experiments, arterial blood pressure was monitored during noxious electrical stimulation of the rat mandibular incisor before and after infracollicular and mid-pons coronal knife cuts. Infracollicular knife cuts had little or no effect on the pressor responses to tooth stimulation whereas the mid-pons knife cuts abolished the pressor responses. In all cases, the mid-pons knife cuts were near the caudal end of the facial nucleus. In a second series of experiments, injections (300 nl) of 2% lidocaine or 10mM cobaltous chloride into the A5 region completely blocked the pressor response. In contrast, injections of lidocaine or cobalt into the lateral parabrachial region produced only slight attenuation of the pressor responses elicited by noxious electrical stimulation of the tooth dentin. The results suggest that reflex autonomic changes in blood pressure induced by noxious stimulation of tooth dentin are mediated, predominantly, in the A5 region and to a lesser extent in the lateral parabrachial nucleus. Supported by the New Brunswick Heart and Stroke Foundation.

## 456.6

THALAMIC PROJECTIONS FROM THE MEDULLARY SUBNUCLEUS RETICULARIS DORSALIS (SRD) OF THE RAT STUDIED WITH THE PHA-L METHOD. L. Villanueva, J.E. Bernard and D. Le Bars (SPON: European Neuroscience Association), INSERM, U-161, 2, rue d'Alsia, Paris, (France).

SRD is a caudal area within the brainstem that processes specifically cutaneous and visceral nociceptive information from the whole body. Their neurones are exclusively activated by A $\delta$ - and C- fibre inputs and encode cutaneous and visceral stimuli within the noxious range. We examined the distribution and organization of thalamic projections from the SRD following injections of Phaseolus vulgaris Leucoagglutinin (PHA-L).

Male Sprague-Dawley rats were anaesthetized with chloral hydrate and PHA-L (5%) was electrophoretically injected into the SRD. Two weeks later, the rats were perfused transcardially, the brain was removed and cut in serial sections which were reacted with PHA-L antibody and ABC complex.

SRD projections were observed in several thalamic nuclei, and terminal labelling was almost exclusively contralateral. In the ventral complex, dense labelled terminals were found in the ventromedial and ventrolateral nuclei. In the intralaminar complex, terminal labelling was observed in the parafascicular and central lateral nuclei. Labelling was also found in the midline reunions nucleus. The highest density of labelling was observed in the ventromedial nucleus, throughout all its rostrocaudal extent.

Together with our previous electrophysiological and anatomical data, this study suggests that the SRD provides a link in spino-reticulo-thalamic pathways implicated in the processing of pain.

## 456.7

**DIRECT PROJECTION OF TRIGEMINAL BRAINSTEM NEURONS TO THE HYPOTHALAMUS OF THE RAT.** A. Malik\* and R. Burstein. Department of Neurobiology, Harvard Medical School, Boston, MA 02115.

Somatosensory stimulation of structures innervated by the trigeminal nerve is capable of inducing changes in the activity of hypothalamic neurons associated with neuroendocrine and autonomic functions. To understand how such sensory signals reach these neurons, we examined the possibility that cells in the different nuclei of the trigeminal brainstem nuclear complex (TBNC) and upper cervical spinal cord (C1-2) project directly to different hypothalamic areas.

In three groups of rats the retrograde tracer Fluoro-Gold was injected unilaterally into the rostral hypothalamus, caudal hypothalamus, or entire hypothalamus. One week later the brainstem and upper cervical segments were processed, and the TBNC and dorsal horn of C1-2 examined for labelled cells. Following unilateral injections of the entire hypothalamus 941 neurons were counted bilaterally (66% contra) within SpVp (3%), SpVo (5%), SpVi (6%), SpVi/Vc (13%), SpVc (28%), and the dorsal horn of C1 (24%), and C2 (20%). Following injections centered in the rostral and caudal hypothalamus, 856 and 398 neurons were found in the examined trigeminal areas, respectively. In these cases, labelled cells were also distributed bilaterally throughout the length of the TBNC and C1-2. The majority of neurons found in SpVc and C1-2 dorsal horn of all three groups were located within laminae I-II and V, areas known to participate in nociceptive transmission.

The findings of this study suggest that neurons located throughout the TBNC and dorsal horn of C1-2 project directly to the rostral and caudal hypothalamus. These cells may participate in relaying somatosensory information from trigeminal primary afferents to hypothalamic regions involved in autonomic and neuroendocrine regulation. ## 456.9

**Changes in Regional Cerebral Blood Flow Associated with Painful Peripheral Mononeuropathy in the Rat.** Thomas Morrow, Pamela Paulson and Kenneth Casey. Depts of Neurology, Physiology, Univ of Michigan and VAMC, Ann Arbor, MI 48105

Chronic constriction injury (CCI) produced by loose ligation of the common sciatic nerve in the rat is a widely used model of chronic neuropathic pain (CNP). Extensive investigations with this model have demonstrated the occurrence of spontaneous pain, thermal hyperalgesia and mechanical allodynia. These alterations in pain perception are thought to reflect a functional reorganization in CNS structures forming a neural network for pain, which may be responsible for the development and maintenance of CNP. We quantified changes in forebrain activation by injecting  $^{99m}\text{Tc}$ -HMPAO to measure regional cerebral blood flow (rCBF) in rats. rCBF was measured in 4 male S-D rats 2-4 weeks after CCI, the period when CNP is reported to be maximum. Under halothane, a 24-ga catheter was placed in the tail vein. Subjects were then placed in soft restraint and allowed to recover from anesthesia for 45 minutes. 10 mCi of  $^{99m}\text{Tc}$ -HMPAO was injected through the catheter. Five minutes later the rats were overdosed with chloral hydrate and the brain removed. Twenty micron frozen sections were cut and mounted. Standard autoradiographic images of brain sections were then analyzed for relative optical density. Regions of interest were sampled and statistically analyzed (t-tests) for differences. In the absence of overt stimulation, we found increased rCBF within structures known to be part of the forebrain network for pain. These structures include: cingulate cortex, somatosensory cortex and lateral thalamus. In addition, although not yet statistically significant because of small sample size, the anterior dorsal thalamus also showed a tendency toward increased activation bilaterally during CNP. This thalamic nucleus has connections to the limbic system, including connections to the cingulate cortex. The findings that forebrain patterns of rCBF change in association with the behavioral signs of CNP provide new insight into the central mechanisms of CNP.

## 456.11

**RESPONSES OF PRIMATE NOCICEPTIVE SI NEURONS TO INTRADERMAL CAPSAICIN INJECTIONS.** D.K. Douglass\*, M. Sholas, R. Dubner, D.A. Thomas and D.R. Kenshalo, Jr. Neurobiology and Anesthesiology Branch, NIDR, NIH, Bethesda, MD 20892.

In humans intradermal injection of capsaicin produces burning pain, cutaneous hyperalgesia and allodynia. In the present study we examined the changes in response characteristics of nociceptive neurons in the primary somatosensory cortex (SI) after an intradermal injection of capsaicin. The monkeys were anesthetized with alpha-chloralose and supplemented by Nembutal. A craniotomy was performed over the foot or hand representation and single units were isolated using tungsten microelectrodes. Each unit with slowly adapting responses to mechanical stimulation was tested for responses to a brush, pressure and pinch stimulus and the size of the receptive field determined. Neurons that responded maximally to the pinch stimulus received an intradermal injection of capsaicin (200 µg). The receptive field size and the responses to the graded series of mechanical stimuli were then determined at 5, 15 and 25 min. post-injection. After the injection, the discharge rate of all neurons increased dramatically and remained higher than the pre-injection discharge rate for an average of 75 s. Capsaicin injected into the receptive field produced an expansion in receptive field size in 22 of 30 nociceptive neurons. The expansion (10-1500%) was present within 5 min. of the injection and persisted for at least 25 min. The responses to the series of mechanical stimuli also increased after capsaicin injection with the largest relative increase to the pressure stimulus. These results indicate that nociceptive neurons in the primate SI cortex respond to intradermal injection of capsaicin and that tonic activity in nociceptive pathways can alter receptive field size and responses to mechanical stimulation. We conclude that many of the receptive field changes seen in nociceptive SI neurons can account for the burning pain, cutaneous hyperalgesia and allodynia in humans after injection of capsaicin.

## 456.8

**CORTICAL PROJECTIONS OF VMpo, A SPECIFIC PAIN AND TEMPERATURE RELAY IN PRIMATE THALAMUS.** A.D. (Bud) Craig\*, K. Krout, and E.-T. Zhang. Div. of Neurobiol., Barrow Neurol. Inst., Phoenix, AZ.

Anatomical and physiological work in the macaque has demonstrated that VMpo is a cyto- and chemo-architecturally distinct nucleus that receives dense, topographic lamina I spino- and trigemino-thalamic input and contains a concentration of nociceptive- and thermoreceptive-specific neurons; further, VMpo in the human thalamus is located in the region associated with pain and temperature sensation by stimulation, lesion and recording data (Craig et al., 1994, *Nature* 372:770). We have used multiple anterograde tracers to examine the cortical projections of VMpo in the cynomolgus macaque.

Localization of VMpo in 7 anesthetized monkeys was based on recordings from topographically organized single units and clusters of nociceptive- and thermoreceptive-specific neurons. Ionophoretic or hydraulic injections of labeled dextrans (biotin or fluorescent red or green) or PHA-L were made with micropipettes. Animals survived 3-6 wks. Dense, topographic terminal labeling observed in the dorsal part of the anterior insula that extended beyond the fundus of the limiting sulcus, anterior to SII, was ascribed to VMpo projections. Light labeling was also found in SII, and a small, dense burst occurred in the fundus of the central sulcus in most cases. Adjacent regions of posterior thalamus appear to project strongly to SII, RI, lateral area 6, and the granular insula, consistent with earlier studies by others.

These observations indicate that the primate anterior insula receives input associated with specific pain and temperature sensation. This provides a structural basis for the strong activation of this region by noxious and thermal stimuli in human PET studies, and it is consistent with the limbic afferent role proposed for lamina I. ## 456.10

**REDUCTION OF AUTOTOMY BEHAVIOUR FOLLOWING PERIPHERAL NEURECTOMY BY A SINGLE INJECTION OF BUPIVACAINE INTO THE CINGULUM BUNDLE OF RATS** Jane E. Magnusson\* and Anthony L. Vaccarino. Department of Psychology, University of New Orleans, LA 70148.

Peripheral neurectomy in rats is followed by autotomy of the denervated zone, which is assumed to represent an index of pain or dysesthesia. We previously demonstrated that periodic anesthetic blockade of the cingulum bundle reduces the amount of autotomy following peripheral neurectomy. In the present study, we examined whether a single injection of a local anesthetic (bupivacaine) into the cingulum given immediately prior to or shortly after peripheral neurectomy could reduce autotomy behaviour. Under sodium pentobarbital anesthesia, male Long-Evans rats were implanted bilaterally with cannulae aimed at the anterior cingulum bundle. Following a 7-14 day recovery period, the rats were anesthetized and the sciatic and saphenous nerves were sectioned free, ligated and cut. Starting immediately prior to or 20 minutes after nerve section, rats were infused bilaterally into the cingulum bundle with 1 µl of 0.75% bupivacaine or saline over a 2-min period. Beginning the day after nerve section the rats were examined daily for signs of autotomy. Anesthetic blockade of the cingulum bundle at the time of nerve section, or shortly after nerve section, was found to delay the onset and reduce the overall degree of autotomy behaviour. These results demonstrate that a single injection of bupivacaine reduces autotomy behaviour for periods that far exceed the duration of the anesthetic block. This research was supported by a Louisiana Education Quality Support Fund (LEQSF).

## 456.12

**SI RECEPTIVE FIELD CHANGES PRODUCED BY INTRADERMAL INJECTION OF CAPSAICIN ARE REVERSED BY MK-801, A NMDA RECEPTOR ANTAGONIST.** M. Sholas\*, D.K. Douglass, R. Dubner, and D.R. Kenshalo, Jr. Neurobiology & Anesthesiology Branch, NIDR, NIH, Bethesda, MD. 20892.

Intradermal injection of capsaicin produces burning pain and mechanical hyperalgesia in humans. In this study, we attempted to determine if NMDA receptors were involved in the expansion of the receptive field (RF), and in the increase in responses to mechanical stimulation that is likely involved in these sensations. The monkeys were anesthetized and a craniotomy was performed over SI. Tungsten microelectrodes were used to record from single units responding preferentially to noxious stimulation of glabrous skin. Once isolated, a graded series of mechanical stimuli -- brush (camel hair brush), pressure (large arterial clamp), and pinch (small arterial clamp) -- was delivered to the RF. Capsaicin (200 µg) was intradermally injected, and the RF was again characterized at five minutes post injection. Finally, the animal received an IV injection of the NMDA channel blocker, MK-801 (0.1 mg/kg), and the neuronal response properties were re-evaluated 25-45 minutes after capsaicin injection.

Ten of twelve units included in the study showed a RF expansion after capsaicin, which averaged 381% ( $\pm 139$ ) of the original size. Baseline activity of the units increased from 11 ( $\pm 1.48$ ) to 34 ( $\pm 7.50$ ) Hz. Responses to all mechanical stimuli increased. Once expanded, IV injection of MK-801 reduced the average RF of the ten cells that responded to capsaicin to an area only 253% ( $\pm 102$ ) of the original area. Baseline activity decreased after MK-801 to 17 ( $\pm 7.29$ ) Hz, which was similar to control values. After MK-801, neuronal responses to the series of graded mechanical stimuli were decreased as compared to capsaicin, and were equivalent to control responses. Two cells which did not respond to capsaicin were not affected by injection of MK-801. The findings suggest that NMDA-receptors are involved in the hyperexcitability of SI neurons caused by intradermal capsaicin.

## 456.13

CHEMICAL LESIONS IN THE STRIATUM INHIBIT NOCICEPTIVE REFLEXES IN RATS. N.E. Saadé, S.A. Shbeir, S.J. Jabbur and S.F. Atweh\*. Fac. of Medicine, American Univ. of Beirut - Lebanon.

Previous work from our laboratory has shown that chemical lesions of the neostriatum inhibited deafferentation pain in rats by reducing the incidence and delaying the onset of autotomy following leg denervation (Saadé et al. Society for Neuroscience, 1994: 20, 1573). The aim of this study was to investigate whether similar chemical lesions affect the latencies of acute pain tests such as the tail immersion (TI) and the hot plate (HP) tests.

Two groups of rats were subjected to TI and HP tests for two weeks prior to injections in the left striatum of either 9 µl of saline (sham group, n=7) or of 2 µg of kainic acid (striatum-lesioned group, n=12). After 3 weeks of testing, both groups received similar injections of saline and kainic acid in their right striatum and were subjected to pain tests for another period of three weeks. Sham injected group did not show any significant changes in the latencies of both pain tests. Unilateral lesion of striatum produced a 22% and 33% increase of TF and HP latencies, respectively. While bilateral lesions of striatum increased the latencies of TF and HP tests by 50% and 93% respectively. These results suggest that the basal ganglia play a role in processing nociceptive information and in modulating pain related reflexes even at spinal level.

(Supported by a grant from the Diana Tamari Sabbagh Fund and LNRC).

## 456.15

SPINOHYPOTHALAMIC TRACT (SHT) NEURONS IN THE CERVICAL ENLARGEMENT OF RATS: LOCATIONS OF ANTIDROMICALLY IDENTIFIED AXONS IN THE CONTRALATERAL BRAINS. E. Kostarczyk\*, X. Zhang and G.J. Giesler, Jr., Dept. of Cell Biol. & Neuroanat., Univ. of Minnesota, Minneapolis, MN 55455.

Many nociceptive spinal neurons in rats project directly to hypothalamus. In this study, the course of ascending SHT axons and the possible existence of branches from them were examined in the medulla, pons and midbrain. Ninety-eight neurons were antidromically activated from the contralateral hypothalamus. Their axons were antidromically activated at 568 low threshold points at multiple anterior-posterior levels of the contralateral brain and rostral spinal cord. In caudal segment C1, axons ascended in the ventral lateral funiculus. As the axons projected rostrally, they shifted into the dorsal lateral funiculus of rostral C1. In the caudal medulla, parent SHT axons ascended near ventrolateral reticular n and n ambiguus. Evidence for numerous branches from SHT axons was seen in the medulla. These branches appeared to be located in n. ambiguus (11 branches), medullary reticular field (19), parvocellular n (6), gigantocellular (4) reticular n, cuneate n (4) and n solitary tract (3). In the rostral medulla, SHT parent axons were concentrated near the lateral paragigantocellular n. In the pons, parent SHT axons were located within and surrounding the facial n and branches of the SHT axons were noted in the pontine reticular formation (3). In the caudal midbrain, parent SHT axons coursed dorsally adjacent to the lateral lemniscus. They then traveled toward the thalamus in the brachium of inferior colliculus. SHT parent axons ascended through the posterior nucleus of thalamus, medial to the medial geniculate n. These axons then entered supraoptic decussation and coursed toward the hypothalamus. Each of 45 tested neurons responded preferentially or specifically (38%) to noxious mechanical stimuli. These studies provide evidence that SHT axons may provide nociceptive information to a variety of brainstem nuclei. Supported by NS25932.

## 456.14

RESPONSES OF NEURONS IN THE CAUDAL INTRALAMINAR THALAMIC COMPLEX OF THE RAT TO STIMULATION OF THE UTERUS, CERVIX, COLON AND SKIN. G. Guilbaud\*, K.J. Berkley, J.-M. Benoist and M. Gautron. Unité de Recherches de Physiopharmacologie du Système Nerveux, INSERM U. 161, 2 rue d'Alésia, 75014 Paris, France.

Neurons in the lateral thalamus in and near the ventrobasal complex have recently been shown by several groups to respond to both skin and visceral stimulation. Given that neurons in lateral and medial thalamus have long been thought to subserve different aspects of pain sensation, the present study examined responses of neurons in the caudal intralaminar complex (IL) to skin and visceral stimuli so that their response characteristics could be compared with those of lateral thalamic neurons to identical stimuli studied earlier (Berkley, et al, *J. Neurophysiol.*, 69, 1993). In 12 adult rats anesthetized with halothane (2-2.5%) and nitrous oxide (2/3) in oxygen (1/3), responses of 35 caudal IL neurons were tested to mechanical stimulation of skin (brush, pressure, noxious pinch) and 4 pelvic visceral stimuli (noxious distension of uterine horn and vaginal canal, gentle distension of colon and probing cervix). As previous studies of IL in males and other species have shown, many neurons (24/35) responded to frankly noxious stimulation of skin in several body regions; only 3 of them responded to gentle skin stimulation. Here it was also found that some neurons (16/24) additionally responded to one or more visceral stimuli, while 4/35 responded only to a visceral stimulus. The most effective visceral stimuli were the noxious ones. Thus, in contrast with neurons in lateral thalamus that exhibit a variety of response characteristics to both noxious and nonnoxious somatic and visceral stimuli, neurons in medial thalamus appear to be signalling information mainly when intense somatic and visceral stimuli are frankly above the noxious threshold, providing further support for the concept that pain-related functions of these two regions differ.

Supported by INSERM and NIH grant NS 11892.

## PAIN MODULATION: PHARMACOLOGY—OPIOIDS I

## 457.1

OPIOIDS MODULATE NMDA-EVOKED RESPONSES OF NEURONS IN THE SUPERFICIAL AND THE DEEPER DORSAL HORN OF THE MEDULLA. K.M. Zhang, X.-M. Wang, A.M. Peterson, S. Bhattacharjee, and S.S. Mokha\*. Dept. of Physiology, Meharry Medical College, Nashville, TN 37208.

We have previously reported, based on systemic studies, that multiple opioid receptors ( $\mu$ ,  $\delta$  and  $\kappa$ ) modulate nociceptive and non-nociceptive inputs in the superficial and the deeper dorsal horn of the medulla (trigeminal nucleus caudalis). The effects of iontophoretically applied receptor-selective opioid agonists have not been investigated previously either on the natural stimuli-evoked or the N-methyl-D-aspartate (NMDA)-evoked responses of physiologically characterized neurons in the superficial and the deeper dorsal horn of the medulla. The present study was, therefore, designed to investigate the role of  $\mu$  (DAMGO) and  $\delta$  (DPDPE) opioid receptor selective agonists in modulating the NMDA-evoked responses of neurons in the trigeminal nucleus caudalis. Extracellular single unit recordings were made with the central barrel of a seven barreled microelectrode in rats anesthetized with urethane (1.5 g/kg, i.p.). The other barrels contained freshly made solutions of [D-Ala<sup>2</sup>, N-Me-Phe<sup>4</sup>, Gly<sup>5</sup>-ol]enkephalin (DAMGO, 25 mM, pH 4.5), [D-Pen<sup>2</sup>]enkephalin (DPDPE, 10 mM, pH 4.5), NMDA (50 mM, pH 8.2), DL-2-Amino-5-Phosphonopivalic acid (AP-5, 50 mM, pH 8.0), naloxone hydrochloride (50 mM, pH 4.5), and NaCl for current balancing. Neurons were characterized nociceptive specific (NS), wide dynamic range (WDR), low threshold (LTH) using natural stimuli (brush, pressure, pinch, squeeze, heat). Opioids were ejected with positive current whereas NMDA and AP-5 were ejected with negative current. DAMGO (40-120 nA) and DPDPE (40-80 nA) primarily produced reduction in the NMDA (15-90 nA, cycle) evoked responses of NS, WDR and LTH neurons in the superficial and the deeper dorsal horn of the medulla. However, excitatory or biphasic effects were also observed. It is concluded that  $\mu$  and  $\delta$  opioid receptor selective agonists produce modulation of the NMDA-evoked responses of nociceptive and non-nociceptive neurons in the medullary dorsal horn.

## 457.2

TOLERANCE, CROSS-TOLERANCE AND DEPENDENCE FOR  $\mu$ -OPIOID AND A<sub>1</sub>-ADENOSINE PERIPHERAL ANTINOCICEPTION IN THE RAT. K. O. Aley, P. G. Green\* and J. D. Levine

Depts. of Medicine and Oral Surgery, and Division of Neurosciences, UCSF, Box 0452A, San Francisco, CA 94143.

The selective  $\mu$ -opioid agonist, DAMGO, or the selective A<sub>1</sub>-adenosine agonist CPA, when co-injected intradermally with prostaglandin E<sub>2</sub> (PGE<sub>2</sub>) into the rat hind paw, dose-dependently inhibited PGE<sub>2</sub>-induced mechanical hyperalgesia in the Randall-Selitto paw-withdrawal test in the rat. Repeated (3 hourly) intradermal injections of DAMGO or CPA produced tolerance to their antinociceptive effects. Furthermore, repeated (3 hourly) intradermal injections of DAMGO produced cross-tolerance to the antinociceptive effect of CPA, and vice versa. The demonstration of cross-tolerance between the peripheral antinociceptive effects of DAMGO and CPA supports the suggestion that both DAMGO and CPA produce antinociception by acting on the same cell, presumably the primary afferent nociceptor, and that tolerance requires changes subsequent to activation of  $\mu$ -opioid and A<sub>1</sub>-adenosine receptors. When injected alone in normal rats, the opioid antagonist naloxone had no effect on paw-withdrawal threshold, but it produced withdrawal hyperalgesia in DAMGO-tolerant rats. This naloxone-induced hyperalgesia was reversed when naloxone was co-injected with DAMGO, but not when it was co-injected with CPA. Similarly, the A<sub>1</sub>-adenosine antagonist, PACPX, produced hyperalgesia in CPA tolerant paws, which was prevented by a co-injection of CPA with PACPX, but not when co-injected with DAMGO. Naloxone elicited withdrawal responses (reduction in paw-withdrawal threshold) in CPA as well as DAMGO tolerant paws and PACPX elicited withdrawal responses in DAMGO as well as CPA tolerant paws. These observations suggest that dependence to  $\mu$ -opioid and A<sub>1</sub>-adenosine agonists involves changes mediated by a common second messenger system.

## 457.3

ACUTE OPIOID TOLERANCE IN MOUSE SPINAL CORD: INVOLVEMENT OF NMDA RECEPTORS AND CONTRAST WITH ALPHA-2 ADRENERGIC RECEPTORS. C.A. Fairbanks<sup>1</sup>, K.F. Kito<sup>1</sup>, H.H. Wu<sup>3</sup>, G.L. Wilcox<sup>1,2</sup>. <sup>1</sup>Department of Pharmacology, <sup>2</sup>Graduate Program in Neuroscience, <sup>3</sup>Dept. of Cell Biology and Neuroanatomy, University of Minnesota, Minneapolis, MN, U.S.A.

Both NMDA and  $\alpha_2$  adrenergic receptors have been implicated in spinal opioid antinociception and the development of opioid tolerance. The present experiments sought to test whether acute morphine tolerance shares the dependence on NMDA receptors previously shown with chronic tolerance and whether acute or chronic opioid tolerance generalizes to the  $\alpha_2$  receptor.

Acute tolerance to morphine was induced in male ICR mice (15-20g) by intrathecal (i.t.) injection of morphine (20 nmol). Chronic tolerance to  $\beta$ -endorphin (previously defined as  $\mu$  opioid tolerance) was induced by i.t. implantation of  $10^5$  AIT20 cells. Selective action of  $\alpha_2$  receptors was accomplished by a administration of a mixture of  $\alpha_2$  adrenergic agonist UK14801 (3, 10, 30 nmol) and  $\alpha_2$ C antagonist prazosin (1  $\mu$ M) was used to selectively activate  $\alpha_2$ A receptors. Antinociception was detected via the hot water (55°C) tail flick test.

I Coinjection (i.t.) of the NMDA antagonist MK801 (1  $\mu$ g) with morphine (20 nmol) prevented acute tolerance to morphine measured 6 h later. II Acute tolerance to morphine was not accompanied by cross tolerance to UK; in fact, it appeared to enhance the efficacy of UK + prazosin. III Chronic opioid tolerance (AIT20 cell implanted mice) did not alter the UK dose response curve.

The evidence presented here supports a role for NMDA receptors in the development of acute opioid tolerance extending other studies with repeated morphine injection. In agreement with other studies in rat, chronic opioid tolerance is not accompanied by cross tolerance at  $\alpha_2$  adrenergic receptors and may, in fact, enhance  $\alpha_2$ A mediated spinal antinociception. (Supported by NIH/K02-DA-00145 & NIH/R01-DA-04274)

## 457.5

DIFFERENTIAL EFFECTS OF MORPHINE ON DESCENDING CONTROLS MODULATING THE SENSORY AND MOTOR FACETS OF A NOCICEPTIVE SPINAL REFLEX. D. Brouhassira, D. Chitour, F. Guirmand and D. Le Bars (SPON: Eur. Neurosci. Ass.) INSERM U-161, 2, rue d'Alésia 75014 Paris, France.

Intravenous morphine exhibits a dose-dependent biphasic effect on electromyographic (EMG) recordings of a nociceptive flexion reflex in the anaesthetized rat: low (< 2 mg/kg) and higher doses elicit facilitatory and depressive effect respectively. The former, a priori paradoxical, effect could be due to an action on the motor limb of the reflex arc, either directly at the spinal level or, indirectly via an action at supraspinal sites, on descending controls.

We investigated in anaesthetized rats (halothane 1%) the effects of 0.5 mg/kg i.v. morphine on both a nociceptive flexion reflex and the responses of dorsal horn convergent neurones. These effects were compared in sham-operated and rats with lesion of the nucleus raphe magnus (NRM), a supraspinal site for morphine action and a source of descending controls modulating the spinal transmission of nociceptive signals at both sensory and motor levels.

EMG recordings of a C-fibre reflex elicited by electrical stimulation of the sural nerve territory were made from the ipsilateral biceps femoris muscle. Convergent neurones with excitatory receptive field in the territory of the sural nerve were simultaneously recorded from the ipsilateral dorsal horn. Recruitment curves for C-fibre evoked reflexes and neuronal responses were built by varying the stimulus intensity from 0 to 40 mA, before and 20 minutes after morphine. In sham-operated animals, morphine had no significant effect on the threshold but facilitated (> 150%), in a naloxone-reversible fashion, the reflex elicited by suprathreshold stimuli (> 3 X threshold). The facilitations disappeared in animals with NRM lesions. No significant effects of morphine were observed on the C-fibre evoked responses of convergent neurones in either group of animals.

These results revealed a differential effect of morphine on sensory and motor facets of a nociceptive reflex. Facilitations of the EMG responses elicited by low systemic doses of morphine were probably related to an action on descending controls of the motor limb of the reflex arc through the NRM.

RELATIONSHIP BETWEEN NEUROENDOCRINE ACTIVITY, PAIN, STRESS, AND THE DEVELOPMENT OF MORPHINE TOLERANCE: A STRAIN COMPARISON. Leland C. Couret, Jr. and Anthony L. Vaccaro<sup>2</sup>. Department of Psychology, University of New Orleans, LA 70148.

We previously reported that morphine fails to produce analgesic tolerance and dependence when administered in the presence of formalin-induced pain. The hypothalamic-pituitary-adrenal (HPA) axis is known to respond to stressful stimuli, including pain. To examine whether the blockade of tolerance by pain is related to HPA activity, we assessed the development of tolerance to morphine analgesia in an inbred strain of rats that lack typical stress-induced HPA responses (Lewis strain). Female Lewis rats were injected with morphine (20 mg/kg) or saline for four consecutive days in the presence or absence of formalin-induced pain. The analgesic effect of test doses of morphine (5, 10 or 20 mg/kg) was then measured in the tail-flick test 24 h after tolerance induction. Female Fischer rats, which show typical stress-induced HPA responses, were used for comparison. Analgesic tolerance was produced in both strains when morphine was delivered in the absence of pain. However, the presence of pain during tolerance induction prevented the development of analgesic tolerance in Fischer rats, but not Lewis rats. The differential effects of pain on the development of morphine tolerance are suggested to be related to genetically determined differences in stress-induced HPA activity. This research was supported by a LSU Neuroscience Incentive Grant and a UNO Research Council Grant.

TAIL-FLICK: TEST INTERVAL CAN MODIFY THE DEVELOPMENT OF BOTH SENSITIZATION AND MORPHINE ANALGESIA.

R.J. Brennan, J.P. O'Brien, P.J. DeMarco, A.E. Baldwin, & J.T. Cannon\*. Dept. of Psychology & Neuroscience Program, University of Scranton, Scranton, PA 18510-4596.

The tail-flick response to heating is one of the most widely used indices of nociception in rodents. Several lines of evidence, however, suggest that this test may possess some undesirable characteristics. For example, it may be altered both qualitatively and quantitatively by variations in heat intensity (e.g., Cannon et al., 1990; Kelly, 1983; Ness & Gebhart, 1986). It also interacts with tail temperature (e.g., Hole & Tjølsen, 1990). In anesthetized animals, inter-flick interval (IFI, 1 vs. 10 min) can affect the degree to which latencies decrease across the first 10-20 min of testing (O'Brien et al., 1994). Using a 1 min IFI, Baldwin et al. (1992) found that exposing rats to a single prolonged tail-flick stimulus can produce long lasting reductions of flick latencies. The first study reported here compares the degree of sensitization that a single suprathreshold stimulus produces in animals tested at either 1 or 10 min IFIs. The second study examines the analgesic effects of morphine in animals tested at these IFIs.

In the first study, 48 pentobarbital-anesthetized male albino rats (8/group) were tested at either a 1 or 10 min IFI, with half of the animals receiving a single prolonged trial (10 sec. approximately 100% above baseline latencies) after 10 min of baseline testing. Baseline latencies were shorter with a 1 min IFI. The prolonged trial produced clear sensitization only in animals tested at the 1 min IFI, with decreases in latencies being seen at all tail spots tested, but the greatest decrease evidenced at the spot that received suprathreshold stimulation.

In the second study, 64 pentobarbital-anesthetized male albino rats (8/group) were tested at either 1 or 10 min IFI. After 10 min of baseline testing, animals received an injection of either saline or morphine (2.5, 5, or 10 mg/kg, s.c.). When comparing 1 and 10 min IFIs: shorter latencies were exhibited by saline injected animals tested with a 1 min IFI; maximal levels of analgesia were comparable for each of the morphine doses; and analgesia developed significantly more slowly in animals that were injected with 5 mg/kg of morphine and tested at the 10 min IFI. Tail temperature was a significant covariate for several analyses; it does not, however, explain the IFI effect in the 5 mg/kg morphine condition.

## 457.6

INTRAPLANTAR MORPHINE DEPRESSES SPINAL c-FOS EXPRESSION INDUCED DURING INFLAMMATORY PAIN STATES IN THE RAT P. Ilonori\*, J. Buritova, V. Chapman and J.-M. Besson, INSERM U.161, 75014 Paris, France.

This study evaluated the effect of pharmacological modulations of peripheral  $\mu$ -opioid receptors on Fos-like immunoreactivity (FLI) in rat lumbar spinal cord neurons induced 1h30 and 3h after intraplantar carrageenin injection.

One and half hours (h) after intraplantar injection of carrageenin (6 mg/150  $\mu$ l), in the hind paw, FLI neurons (76 $\pm$ 2 neurons/section) were observed in the dorsal horn, predominantly in the superficial laminae (74 $\pm$ 2%), of the L4 -5 segments of the spinal cord. Three hours after carrageenin injection considerably more FLI neurons were observed in the dorsal horn of the spinal cord (241 $\pm$ 8 neurons/section), at this time point both superficial (I-II) and deep laminae (V-VI) were densely labelled (45 $\pm$ 2% and 37 $\pm$ 1% of carrageenin induced FLI neurons, respectively).

Co-administration of intraplantar morphine (10, 25 or 50  $\mu$ g/50  $\mu$ l of saline), dose-dependently ( $r^2=0.366$ ,  $p<0.05$ ) decreased the number of superficial FLI neurons induced at 1h30 after intraplantar carrageenin, without influencing the peripheral inflammation. The effects of the highest dose of morphine (45 $\pm$ 4% reduction,  $p<0.01$ ) were significantly blocked by co-administered intraplantar methiodine naloxone (20  $\mu$ g/50  $\mu$ l of saline), which injected alone had no effect. The highest dose of morphine (50  $\mu$ g), injected intravenously, did not influence either spinal c-Fos expression or peripheral inflammation. In addition, co-administration of intraplantar morphine (10, 25 or 50  $\mu$ g/50  $\mu$ l of saline), dose-dependently ( $r^2=0.705$ ,  $p<0.0001$ ) decreased the total number of FLI neurons induced at 3h after intraplantar carrageenin and reduced the peripheral inflammation. The highest concentration of morphine significantly reduced both the total expression of c-Fos (37 $\pm$ 3%,  $p<0.0001$ , reduction of control) and the enhanced paw and ankle diameter (50 $\pm$ 2% reduction,  $p<0.0001$ , 70 $\pm$ 1%,  $p<0.0001$ , reduction of control, respectively). These effects were blocked by a co-administration of intraplantar methiodine naloxone.

These results demonstrate that intraplantar morphine reduces peripheral inflammation and the subsequent spinal expression of c-Fos, thus illustrating the role of peripheral opioid receptors during inflammatory nociception.

## 457.8

LOSS OF EFFICACY AND POTENCY OF SPINAL MORPHINE TO INHIBIT THE TAIL-FLICK REFLEX IN RATS WITH A NERVE CONSTRICTION INJURY. Michael H. Ossipov, Yvan Lopez, Michael L. Nichols, Di Bian and Frank Porreca\*. Department of Pharmacology, University of Arizona Health Sciences Center, Tucson, AZ 85724.

Nerve constriction injury produces thermal hyperalgesia and mechanical allodynia analogous to clinical conditions of neuropathic pain. However, the effect of neuropathic injury on acute nociception has not been studied. Nerve constriction injury was produced by unilateral ligation of the L5/L6 spinal roots of the sciatic nerve of male Sprague-Dawley rats. Intrathecal (i.th.) catheters were inserted for spinal drug administration. Response to acute nociception was measured by determining the tail flick (TF) latency to immersion of the tail into a 55°C water bath before (control) and after (treatment) i.th. morphine administration. A cut-off latency of 15 sec was employed. Data were converted to % maximal possible effect (%MPE) by the equation:  $100 \times ((\text{test latency} - \text{control latency}) / (15 - \text{control latency}))$ . In sham-operated rats, morphine produced dose-dependent antinociception with a maximal effect of 100% MPE at 60  $\mu$ g; the  $A_{50}$  (95% C.L.) was 22 (17 - 30)  $\mu$ g. In nerve-ligated rats, morphine also produced dose-dependent increase in TF latency, but with a maximal effect of only 60  $\pm$  17% obtained at 100  $\mu$ g; the calculated  $A_{50}$  (95% C.L.) from the lower portion of the dose-effect curve was 82 (46 - 146)  $\mu$ g, representing at least a 4-fold decrease in potency compared to controls. Antinociception in both sham and nerve-injured animals was readily reversed by naloxone (5 mg/kg, i.p.). These data indicate that nerve constriction injury substantially reduces the potency and efficacy of i.th. morphine in affecting acute nociceptive input. Conceivably, degeneration of primary afferents subsequent to nerve constriction injury results in a loss of  $\mu$  opioid receptors in the dorsal horn. The data also imply that a major part of normally observed morphine antinociception is related to activity at presynaptic opioid receptors.

## 457.9

"REKINDLING" EFFECT OF INTRATHECAL INJECTION OF NALOXONE ON JAW MUSCLE ACTIVITY EVOKED BY MUSTARD OIL APPLICATION TO TEMPOROMANDIBULAR JOINT IN RAT: POSSIBLE INVOLVEMENT OF TRIGEMINAL SUBNUCLEUS CAUDALIS (V<sub>c</sub>). K. Seo, B.J. Sessle, D.A. Haas\* and J.W. Hu, Faculty of Dentistry, University of Toronto, M5G 1G6, Canada

We have recently reported that systemic administration of the opioid antagonist naloxone can induce a recurrence ("rekindling") of increased electromyographic (EMG) activity evoked in jaw muscles by injection of the C-fibre excitant and inflammatory irritant mustard oil (MO) into the temporomandibular joint (TMJ) region of rats. A likely site of opioid action is V<sub>c</sub> which is integrally involved in orofacial nociceptive transmission. This possibility was tested in 24 male rats anesthetized with halothane/N<sub>2</sub>O/O<sub>2</sub> by injecting naloxone intrathecally (i.t.) via a cannula (PE-10) introduced into the brainstem subarachnoid space and placed near the brainstem surface overlying the left (ipsilateral, IP) V<sub>c</sub>. EMG activity was recorded bilaterally from digastric (DIG) and masseter (MASS) muscles, and MO (20%, 20μl) was injected into the IP-TMJ region. Naloxone (1μg, 10μg, 30μg) or saline (as vehicle control) was applied (10μl, i.t.) 30 minutes after MO application by which time the MO-evoked activity had subsided. Naloxone induced a significant dose-dependent increase in EMG activity in IP-MASS, IP-DIG and contralateral (CL)-DIG ( $p < 0.05$  ANOVA), but not in CL-MASS ( $p > 0.05$ ). The change in peak EMG activity was dose-dependent for IP- and CL-DIG ( $p < 0.05$ ), but not for either IP- or CL-MASS ( $p > 0.05$ ). The duration of the naloxone-induced "rekindling" effect was dose-dependent for IP-DIG and IP-MASS ( $p < 0.05$ ), but not for either CL-DIG or CL-MASS ( $p > 0.05$ ); the latency of the "rekindling" effect also did not appear to be affected by the different dose levels. These results suggest that V<sub>c</sub>, or an adjacent brainstem region, may be a site of action of the opioid "rekindling" effect on MO-evoked jaw muscle activities. Supported by Can. MRC MT-12286 and NIH DE-09559.

## 457.11

A NON-PEPTIDE NEUROTENSIN ANTAGONIST (SR48692) POTENTIATES THE ANTINOCICEPTIVE ACTION OF MORPHINE IN RATS. Smith, D.J., Smith, D.L., Monroe, P.J., Urban, M.O. and Gully, D. Dept. Anesth. WVU, Morgantown WV 26506, and Sanofi Recherche, Toulouse Cedex, France.

Neurotensin's neuronal projections from the periaqueductal gray (PAG) to the rostroventral medial medulla (RVM) function in a pain facilitatory fashion following the microinjection of an antinociceptive dose of morphine into the PAG of rats (Neurosci. Lett. 174: 21, 1994). Microinjection of an antagonistic dose of the peptidergic neurotensin partial agonist D-trp-11-neurotensin into the RVM potentiates the antinociceptive response to PAG morphine (6nmol). Similarly, the microinjection of the non-peptide neurotensin antagonist SR48692 into the RVM enhances PAG morphine (Can. J. Physiol. Pharmacol. 72 (S1): 414, 1994). Since the non-peptide neurotensin antagonist penetrates the blood-brain-barrier, the current study was undertaken to determine if systemically administered SR48692 would enhance the antinociceptive action (i.e. heat-induced tail flick test; TFL) of morphine in rats. In this regard, i.p. administered SR48692 caused a marked potentiation of the response to PAG morphine (6 nmol), essentially doubling the magnitude and duration of the opioid's antinociceptive effect. The dose response relationship for the antagonist was bell-shaped with 0.1 and 0.3 mg/kg (i.p.) producing the effect, while higher doses were ineffective. Furthermore, systemically administered SR48692 produced a distinct potentiation of the action of systemically administered morphine (2 mg/kg, i.p.). Again the magnitude and duration of the response to the opioid was doubled, with the dose response relationship for the effect of SR48692 being bell-shaped (effective doses range, 0.03-0.3 mg/kg, i.p.). These data suggest that the novel non-peptide neurotensin antagonist, SR48692, may be useful as an adjunct to analgesic therapy to enhance narcotic efficacy.

EFFECTS OF MORPHINE OR NERVE INJURY ON MECHANICAL, THERMAL AND CHEMICAL RESPONSE THRESHOLDS IN FROGS. S. Willenbring\* and C.W. Stevens, OSU-Coll. Osteo. Med., Tulsa, OK 74107

Hind paw withdrawal responses to mechanical and thermal stimuli serve as quantifiable methods of assessing hypersensitivity following peripheral nerve injury in rodent models of neuropathic pain. The acetic acid test (AAT) provides a similar morphine-sensitive test in amphibians, although it has thus far been used only in studies of acute pain. We evaluated mechanical and thermal responses and their sensitivity to systemic morphine administration in the northern grass frog, *Rana pipiens* with comparison to AAT. Frogs were randomly divided into 3 groups, which received systemic (sc) injections of saline (control, n=12) or morphine at 100 (n=10) or 300 (n=10) nmol/g. Mechanical, thermal and AAT response thresholds were measured at 1, 2 and 3 hours post-injection and compared to prior baseline values. Morphine produced dose-dependent elevations in all three tests ( $p < .05$ , 100 nmol;  $p < .01$ , 300 nmol). Additionally, we evaluated changes in mechanical, thermal and AAT responses following sciatic nerve injury in a separate group of frogs. Following the establishment of baseline responses, frogs were randomly divided into 3 groups, which were subsequently subjected to chronic constriction injury (CCI; n=13), sciatic cryoneurolysis (SCN; n=13) or sham surgery (control; n=6). Responses were then measured 3 times per week for 4 weeks. Preliminary results indicate a significant decrease in acetic acid ( $p < .01$ ) and mechanical ( $p < .05$ ) response thresholds following either lesion at 2 weeks post-injury. These results suggest a potential usefulness of the amphibian for future investigations of the neural and pharmacological mechanisms of acute and neuropathic pain states. (support: NIH 1-F32-NS09732-01)

## 457.10

MORPHINE SENSITIVITY OF SPINAL- AND SUPRASPINAL-MEDIATED NOCICEPTIVE RESPONSES USING A NOVEL FOCAL ELECTRICAL STIMULATION PARADIGM. M. Vincler\*, W. Majner\*, C. J. Vierck\*, and A.R. Light\*, Departments of Pharmacology\* and Physiology†, University of North Carolina, Chapel Hill, NC 27599-7545.

The antinociceptive effects of morphine in rats have been established using a variety of techniques utilizing different nociceptive stimuli such as heat, electric shock, and algogenic chemicals. Among these stimuli, electric shock has been one of the most poorly characterized. We have developed a technique which allows us to use focal electrical stimulation of the hindpaw and measure both spinal-mediated and supraspinal-mediated responses. This was accomplished by suspending the rat and attaching two small electrodes to the hindpaws. The hindlimbs were tethered to a force transducer allowing the measurement of a spinal-mediated response (hindlimb reflex). The right forepaw rested on a lever which, when pressed, terminated the shock and allowed the measurement of a supraspinal-mediated response (latency). Using this paradigm, we examined the effects of morphine (0.3, 1.0, 3.0, and 10.0 mg/kg) on bar press latency and hindlimb reflex force at various intensities of electric shock (0.05 - 0.8 mA). The 2 lower doses of morphine did not alter bar press latency or hindlimb reflex at any of the stimulus intensities tested. Morphine at 3.0 mg/kg increased bar press latency for stimulus intensities ranging from 0.05-0.6 mA, but had no effect at 0.7 and 0.8 mA. Hindlimb reflex force, however, was attenuated from 0.2-0.8 mA. Morphine at 10.0 mg/kg increased bar press latency and attenuated hindlimb reflex force at all stimulus intensities. These data suggest that focal electrical stimulation can be used to test the antinociceptive effects of opioids and that morphine is more effective at attenuating spinal-mediated nociceptive responses than supraspinal-mediated responses in this paradigm. Supported by NIDA grant DA04420 (A.R.L.) and NIDA grant DA07244 (L.A. Dykstra).

## 457.12

STUDIES OF OPIOID AND ALPHA2 ANALGESIA AFTER SPINAL ADMINISTRATION IN AMPHIBIANS. C. W. Stevens\* and G.M. Brenner Oklahoma State University, College of Osteopathic Medicine, Tulsa, OK 74107-1898.

Spinal administration of opioid and alpha-adrenergic agents in mammals produces potent and dose-dependent analgesic effects. To further characterize spinal sites of analgesic action in non-mammalian vertebrates, we used an alternative model for assessing analgesia in the Northern grass frog, *Rana pipiens*. Pain thresholds were estimated using the acetic acid test. Log-spaced doses of opioid agonists (*mu*: dermorphin, DAMGO, fentanyl, morphine; *delta*: DSLET, DADLE, DPDPE, deltorphin; and *kappa*: C1977, bremazocine, U50488, nalorphine) or alpha-adrenergic (dexmedetomidine, epinephrine, norepinephrine, clonidine) agonists were administered intraspinally at the level of the lumbar spinal cord using a hand-held microsyringe. All agents produced a dose-dependent analgesia which lasted at least four hours. ED50 values for the 12 opioids ranged from 0.04 nmol/frog for dermorphin to 43.1 nmol/frog for nalorphine. ED50 values for the alpha-adrenergic agents ranged from 6.4 nmol/frog for dexmedetomidine to 248 nmol/frog for clonidine. These data suggest that *mu*, *delta*, and *kappa* opioid receptors, as well as *alpha*<sub>2</sub>-adrenergic receptors, mediate analgesia in the frog spinal cord. Supported by the Whitehall Foundation and NIH grant DA07326.

## 457.14

THE NEURONAL PATHWAYS THAT MEDIATE THE ANTINOCICEPTION PRODUCED BY MICROINJECTION OF MORPHINE IN THE RAT PERIAQUEDUCTAL GRAY. Herbert K. Proudfit\* and Fang Fang, Dept. of Pharmacology, Univ. of Illinois at Chicago, Chicago, IL 60612.

Experiments were done to determine the neurotransmitters involved in mediating the antinociception produced by microinjecting morphine in the periaqueductal gray (PAG). The antinociceptive effects of morphine microinjected into the ventrolateral PAG were determined using both the tail flick and the foot withdrawal responses to noxious radiant heat in lightly anesthetized rats. The increase in the foot withdrawal response latency produced by morphine was reversed by intrathecal injection of the cholinergic muscarinic antagonist atropine, but was not affected by the  $\alpha_2$ -adrenoceptor antagonist yohimbine, the serotonergic receptor antagonist methysergide, or the opioid receptor antagonist naloxone. In contrast, the increase in the tail flick response latency produced by morphine was reduced by either yohimbine, methysergide or atropine. In summary,  $\alpha_2$ -adrenoceptors, serotonergic, and cholinergic muscarinic appear to mediate the antinociception produced by morphine using the tail flick test, but only cholinergic muscarinic receptors appear to modulate the antinociceptive effects of morphine using the foot withdrawal response. These results indicate that the nociception produced by noxious heating of the feet is modulated by different neuronal systems than that produced by noxious heating of the tail. This work was supported by grant DA03980 from the National Institute on Drug Abuse.

## 457.15

EFFECT OF TRANSIENT ANTAGONISM ON SPINAL MORPHINE TOLERANCE AND SPINAL RELEASE OF GLUTAMATE. Takae Ibuki\*, Stuart A. Dunbar and Tony L. Yaksh, Dept. of Anesthesiol, Univ. of Ca San Diego, La Jolla, CA 92093

To confirm whether tolerance development depends on duration of receptor occupancy or is influenced by receptor onset and offset, rats were implanted with intrathecal (IT) catheters connected to osmotic minipumps to receive morphine (MOR 20 nmol/hr) or saline (SAL) infusions for 7 days. Rats were tested daily on hot plate (HP) and then daily injected with naloxone (NAL 0.6 mg/kg) or SAL subcutaneously (SQ). On day 7 infusion was terminated and on day 8 HP response to a single IT probe-bolus of MOR (60 nmol) was observed. In separate rats a spinal loop dialysis catheter was also placed to measure glu (GLU) release before and after daily SQ NAL injection in MOR or SAL-infused rats. ITMOR infusion evoked a maximum increase on HP which diminished over ensuing days (Fig 1). ITSAL was without effect. Day 8 response to IT-probe MOR was ITSAL>SQSAL>ITSAL>SQNAL>ITMOR>SQSAL>ITMOR>SQNAL (Fig 2 shows ITMOR-infused rats results). Daily resting spinal GLU release increased modestly in rats with ITMOR and was significantly elevated in rats receiving IT MOR>SQNAL (Fig 3). Results indicate that transient naloxone antagonism aggravates spinal tolerance development by enhancing spinal GLU release (DA0210/NS16541).

## 457.16

MORPHINE ANALGESIA OF THERMAL HYPERALGESIA, TOLERANCE AND PHYSICAL DEPENDENCE. M. Backonia\*, M.F. Fabbrocini, and C.V. Levenick, Dept. of Neurology, Univ. of Wisconsin, Madison, WI, 53792.

Thermal hyperalgesia, a sign of neuropathic pain, can be effectively relieved with an opioid analgesic such as morphine, in a dose dependent fashion without the loss of analgesic effect, i.e. without the development of tolerance, as demonstrated in our earlier study. In this study the form of tolerance, the response to an acute single dose of morphine in animals chronically treated with morphine, and physical dependence precipitated with administration of naloxone were investigated. Thermal hyperalgesia was induced with loose ligation of the sciatic nerve, as per Bennett and Xie (1988), and a control group of rats received sham surgery. Morphine in doses of 20mg/kg/day was continuously delivered for seven days via osmotic pumps (Alza) and produced analgesia in ligated and sham-operated rats. Control groups of ligated and sham-operated rats were treated with placebo, received normal saline via osmotic pumps. Foot withdrawal latencies from radiant heat, as per Hargreaves et al (1988), were obtained by examiners who were blinded as to what treatment animals received. Tolerance was tested on the last day of morphine infusion with administration of a single 5mg/kg dose of morphine to all rats. Physical dependence signs was precipitated with administration of 1mg/kg of naloxone. A single dose of 5mg/kg of morphine produced the greatest analgesia in ligated rats treated with saline, modest analgesia in ligated rats treated with morphine and sham rats treated with saline, and no effect on sham rats treated with morphine, suggesting tolerance only in the latter group. Physical dependence induced naloxone precipitated signs of withdrawal in all rats but signs were more pronounced in rats chronically treated with morphine. In conclusion, this study demonstrates that tolerance to an opioid in the case of neuropathic, measured by a couple of methods, is not an inevitable outcome.

## PAIN MODULATION: PHARMACOLOGY—OPIOIDS II

## 458.1

BIOCHEMICAL AND PHARMACOLOGICAL CHARACTERIZATION OF MULTIPLE  $\beta$ -ENDORPHINERGIC SYSTEMS IN THE RAT PAG: IDENTIFICATION OF FACILITORY AS WELL AS INHIBITORY NOCICEPTIVE MECHANISMS. P.J. Monroe\*, A.A. Hawranko, D.L. Smith, and D.J. Smith, Depts. of Anesthesiology & Pharm./Tox., WV Univ., Morgantown, WV 26506-9134

The administration of  $\beta$ -endorphin and morphine into the periaqueductal gray (PAG) of rats results in profound antinociception. We have previously demonstrated that in addition to activating neuronal mechanisms common to both agonists,  $\beta$ -endorphin interacts with unique mechanisms which can be discriminated based on their differential sensitivities to the opioid antagonists CTP (D-Phe-Cys-Tyr-D-Trp-Lys-Thr-Pen-Thr-NH<sub>2</sub>) and naltrexone (Smith et al., Reg. Peptides 50S: 199, 1994). Consistent with these results, [<sup>125</sup>I]- $\beta$ -endorphin was shown in the current study to label a population of sites which (compared to those labelled by [<sup>3</sup>H]-morphine) displayed a significantly higher affinity for CTP. In addition, a naltrexone insensitive binding component was identified in the [<sup>125</sup>I]- $\beta$ -endorphin, but not [<sup>3</sup>H]-morphine assays. Furthermore, comparable competitor affinities were determined across assays, suggesting an interaction of the two radioligands with common PAG sites. A naltrexone insensitive component to  $\beta$ -endorphin antinociception was also identified in studies which evaluated the ability of the antagonist to shift the  $\beta$ -endorphin dose response curve. Interestingly, the ability of low doses of CTP and naltrexone to inhibit increasing doses of  $\beta$ -endorphin was described by a U shaped dose effect curve. The response to low (0.1 and 0.3 nmol) and high (10 nmol), but not intermediate (1 and 3 nmol) doses of  $\beta$ -endorphin were antagonized by a 1 pmol dose of CTP, or a 30 pmol dose of naltrexone. As there was no evidence for allosteric interactions between [<sup>125</sup>I]- $\beta$ -endorphin binding sites in the PAG, these results suggest that  $\beta$ -endorphin may be activating pain facilitory mechanisms which counterbalance the overall antinociceptive effect of the peptide. Moreover, these pain facilitory mechanisms appear to be involved in the modulation of antinociceptive responses in animals exposed to stress. (see accompanying abstract by Hawranko et al.).

## 458.2

PAIN FACILITORY AND INHIBITORY SYSTEMS ARE ACTIVATED BY  $\beta$ -ENDORPHIN: STRESS ENHANCES FACILITATION. A.A. Hawranko\*, P.J. Monroe, and D.J. Smith, Depts. of Anes. & Pharm., WVU, Morgantown, WV 26506

Opioids produce pain facilitation, as well as pain inhibition (see Parvini et al., JPET. 265: 286, 1993). We have previously shown that repetitive exposure of rats to the noxious heat associated with hot-plate testing (52.5°C) causes stress induced analgesia (i.e. a 1.5 - 2 sec increase in tail flick latency, TFL), and an alteration in the ability to pharmacologically distinguish neuronal processes involved in  $\beta$ -endorphin's antinociceptive actions in the periaqueductal gray (PAG) region of the midbrain (Hawranko et al., Brain Res. 667:283, 1994). Currently, we report that occurring concomitantly with the stress are a reduction in the antinociceptive potency of  $\beta$ -endorphin, and the demonstration of a pain facilitory role for the peptide at doses lower than those associated with antinociception. That is, when stereotactically microinjected into the PAG of awake male rats not exposed to hot plate testing,  $\beta$ -endorphin produces a dose dependent (0.1 - 10 nmol) increase in TFL. Multiple neuronal mechanisms account for this response, one of which is naltrexone resistant (Smith et al., Reg. Peptides 50S:99, 1994). However, the antinociceptive mechanisms appear to change with hot plate stress. The maximal antinociception resulting from PAG microinjections of  $\beta$ -endorphin is sharply reduced from 70% in the nonexposed rats to 15% above baseline in the hot plate exposed rats, and can be completely blocked by naltrexone. Moreover, a naltrexone sensitive pain facilitation (about 2 sec reduction in latency) is observed with doses of  $\beta$ -endorphin (0.03 nmol) which were inactive in the non stressed rat. This facilitation is blocked by low doses of the opioid antagonist CTP, resulting in a marked enhancement of  $\beta$ -endorphin antinociception to levels greater than those observed in nonstressed rats. Thus, opioid pain facilitation occurs at least in part via spinopetal neuronal processes originating in the PAG. In addition, facilitation of pain responses may be a more prominent effect of opioids under some environmental conditions.

## 458.3

SPINAL ANTINOCICEPTION FOLLOWING STIMULATION OF THE AMYGDALA DEPENDS ON OPIOID RECEPTORS IN THE VENTRAL PERIAQUEDUCTAL GRAY. S.A. Tershner\* and F.J. Helmstetter, Department of Psychology, University of Wisconsin, Milwaukee, WI 53201.

The presence of certain environmental stressors activates a descending antinociceptive neural system which includes the amygdala, periaqueductal gray (PAG), and rostroventral medulla (RVM). Lesions of each of these brain sites as well as the application of  $\mu$  opioid receptor antagonists to the PAG have been shown to be effective in blocking stress-induced hypoalgesia in behaving rats. Recent studies conducted in our laboratory have shown that microinjection of  $\mu$  receptor agonists into the anterior basolateral nucleus of the amygdala (BLA) will inhibit the tail flick (TF) reflex evoked by radiant heat in barbiturate anesthetized rats, and this effect is blocked by lesions of the PAG. The purpose of this experiment was to determine if the antinociception following forebrain opioid injection is expressed through a second opioid synapse located in the PAG. Rats maintained under constant barbiturate infusion were implanted with cannulae aimed at the BLA and ventrolateral PAG. Radiant heat TF latency was recorded at 2 min intervals. As we have previously shown, DAMGO (0.5  $\mu$ g  $\times$  2) applied to the BLA inhibited TF. This inhibition of TF was prevented by pretreatment of the vPAG with naltrexone (NTX, 5.0  $\mu$ g). However, NTX injections in the vPAG made after DAMGO treatment did not reverse the effect. Pretreatment with the selective  $\mu$  antagonist CTOP (0.05  $\mu$ g) in vPAG was also effective supporting a role for  $\mu$  opioids in this structure. Unlike CTOP, the putative epsilon receptor antagonist beta-endorphin<sub>27</sub> (6.0  $\mu$ g) failed to block TF inhibition. These findings together with other recent data suggest that  $\mu$  opioid receptors located within multiple CNS structures from the telencephalon to the dorsal horn may be important for antinociception. Our ability to activate PAG neurons presumably via an intact functional subset of their forebrain inputs will allow for more detailed study of the physiology of this structure.

## 458.4

DYNORPHIN (1-8) MODULATES THE BASAL AND MECHANICALLY EVOKED RELEASE OF SUBSTANCE P IN THE DORSAL HORN OF THE RAT. V. Zachariou\* and B.D. Goldstein, Department of Pharmacology and Toxicology, Medical College of Georgia, Augusta GA 30912.

Substance P (SP) is an 11 amino-acid peptide found in high concentrations in the dorsal horn of the spinal cord, primarily in the terminals of the unmyelinated primary afferent fibers. Evidence suggests that SP is a modulator of nociceptive information. Dynorphin (1-8) is an opioid peptide also found in the superficial laminae of the dorsal horn, which possesses higher selectivity for the  $\kappa$ -receptor. Previous studies in this laboratory showed that dynorphin (1-8) prevented the increase in the release of SP like-immunoreactivity (SPLI) during the application of a noxious thermal stimulus. The aim of this study was to investigate the effect of dynorphin (1-8) on the release of SPLI during the application of a noxious mechanical stimulus. A push-pull cannula was stereotactically introduced into the superficial dorsal horn in decerebrate/spinal transected rats and the dorsal horn was perfused with artificial CSF. Noxious mechanical stimuli were applied to different areas of the ipsilateral hind paw and lower limb. The perfusate was collected and assayed for SPLI using RIA. Dynorphin (1-8) applied to the dorsal horn (1  $\mu$ M) prevented the mechanically evoked release of SPLI. The effect of dynorphin (1-8) was blocked by the  $\kappa$ -opioid receptor antagonist, nor-BNI. The effect of dynorphin (1-8) on the release of SPLI during the application of the mechanical stimulus was similar to that seen during the application of a thermal stimulus. Nor-BNI alone increased the basal release of SPLI, in agreement with previous studies. However, unlike the prolonged increase in the release of SPLI in the presence of nor-BNI following the thermal stimulus, the release of the peptide following the mechanical stimulus returned to baseline almost immediately. The above data suggest that the  $\kappa$ -receptor differentially regulates the release of SPLI following thermal or mechanical stimuli.

**EFFECTS OF SNX-111, A HIGH-AFFINITY N-TYPE VOLTAGE-SENSITIVE CALCIUM CHANNEL ANTAGONIST ON MORPHINE-INDUCED RESPIRATORY DEPRESSION IN RATS.** R.R. Dean\*, S. S. Bowersox, and R.R. Luther. NEUREX Corporation, Menlo Park, CA 94025.

The influence of SNX-111 (synthetic  $\omega$ -conopeptide MVIIA, a high-affinity antagonist of N-type voltage-sensitive calcium channels) on respiratory depression induced by morphine sulfate was studied in awake, male Sprague Dawley rats. Using whole-body plethysmography, respiratory minute-volume responses to breathing air containing 10% CO<sub>2</sub> were measured before, and 30, 60, 90, and 120 minutes after administering a combination of morphine sulfate (10 mg/kg or 30 mg/kg) or saline subcutaneously and SNX-111 (0.1  $\mu$ g) or saline intrathecally. Intrathecal bolus injections of SNX-111 both attenuated and shortened the duration of respiratory depression induced by 10 mg/kg morphine but had little or no effect on respiratory depression induced by 30 mg/kg morphine sulfate. SNX-111 did not affect respiratory minute-volume responses to CO<sub>2</sub> inhalation when it was administered after subcutaneous injections of saline. These findings indicate that intrathecal administration of SNX-111 does not depress respiration nor does it potentiate the respiratory depressant actions of morphine sulfate in rats.

## 458.7

**EFFECT OF U50,488 ON MECHANOSENSITIVE AFFERENT FIBERS IN THE PELVIC NERVE INNERVATING THE URINARY BLADDER OF RAT.** J. N. Sengupta\*, X. Su and G. F. Gebhart. The University of Iowa, Department of Pharmacology, Bowen Science Building, Iowa City, Iowa 52242

Pelvic afferent fibers innervating the lower urinary tract travel in L6 and S1 dorsal roots. In the present study, 306 afferent fibers in the decentralized L6 dorsal root were identified by pelvic nerve stimulation; 163 (53.27%) responded to noxious urinary bladder distension (UBD; 80mmHg). Fifty-seven fibers were unmyelinated C-fibers (mean:  $2.03 \pm 0.04$  m/s) and 106 were myelinated A $\delta$ -fibers (mean:  $8.31 \pm 0.05$  m/s). Stimulus-response functions of 13 fibers were tested to graded UBD (5 to 100 mmHg, 30 sec.) and seven of them were also tested after instillation of 0.5 ml of 30% xylene in silicone oil into the bladder. The effect of U50,488, a  $\kappa$ -opioid receptor agonist, was tested on responses to noxious UBD (80mmHg, 30 sec, every 4 min). U50,488 produced dose-dependent inhibition of responses to noxious UBD. The mean inhibition produced by U50,488 (16mg/kg) was to  $41.2 \pm 2.2\%$  ( $n=5$ ) and  $33.4 \pm 5.9\%$  ( $n=9$ ) of control from untreated and xylene-treated bladders, respectively. There was no apparent difference in the dose-response functions of U50,488 between afferents studied from untreated and treated bladder. The inhibition of responses of fibers by U50,488H suggests an activation of peripheral  $\kappa$ -opioid receptors.

## 458.9

**INTRATHECAL DELTORPHIN OR DPDPE PRODUCES ANTINOCICEPTION, BUT DOES NOT SUPPRESS FOS-LIKE IMMUNOREACTIVITY (FLI) IN THE RAT SPINAL CORD.** D.L. Hammond\*, H. Wang\*, N. Nakashima\* and A.I. Basbaum\*, Dept. of Anes. & Crit. Care, Univ. of Chicago, Chicago, IL 60637 and \*Dept. of Anat. and Physiol., Keck Cntr. for Integr. Neurosci., UCSF, San Francisco, CA 94143

This study examined the ability of i.t. administration of the  $\delta$ -1 receptor agonist DPDPE or the  $\delta$ -2 receptor agonist [D-Ala<sup>2</sup>, Glu<sup>1</sup>]deltorphin (DELT) to inhibit the behavioral response and the expression of FLI in the spinal cord induced by i.p. injection of formalin in the rat. Five days after implantation of i.t. catheters, male S-D rats were i.t.-injected with either vehicle, DPDPE (10-60  $\mu$ g), DELT (3-30  $\mu$ g), or the  $\mu$  receptor agonist DAMGO (0.3  $\mu$ g). Ten min later, 100  $\mu$ l of 5% formalin was injected i.p. in one hindpaw and the number of flinches that occurred in the next hr was counted. The rats were then perfused with fixative and the spinal cord processed for FLI by standard immunocytochemical methods. Although DPDPE and DELT each dose-dependently suppressed formalin-evoked pain behaviors, FLI was not reduced by DELT and was only marginally reduced in the deep dorsal horn and ventral horn by the highest dose of DPDPE. However, FLI was nearly completely inhibited by an equianalgesic dose of DAMGO. In the absence of formalin, FLI-neurons were not evident in vehicle-, DPDPE or DELT-treated rats. These data suggest that (1) the production of antinociception by  $\delta$  opioid receptor agonists is independent of the suppression of FLI in the spinal cord and (2) the intracellular mechanisms responsible for  $\delta$ -mediated opioid antinociception differ from those responsible for  $\mu$ -mediated opioid antinociception. ## 458.6

**EFFECTS OF KAPPA-OPIOID RECEPTOR AGONISTS ON MECHANOSENSITIVE PELVIC NERVE AFFERENT FIBERS INNERVATING COLON OF RAT.** X. Su\*, J. N. Sengupta and G. F. Gebhart. The University of Iowa, Department of Pharmacology, Bowen Science Building, Iowa City, Iowa 52242

Pelvic nerve afferent fibers from the colon travel primarily in the S1 dorsal roots. In the present study, 177 fibers in the S1 dorsal root were identified by electrical stimulation of the pelvic nerve; 53 (30%) responded to noxious colorectal distension (CRD; 80mmHg). Stimulus-response functions of 23 fibers were tested to graded CRD (5 to 100 mmHg, 30 sec.) and eight were tested after colonic instillation of 5% acetic acid ( $n=3$ ) or 5% mustard oil ( $n=5$ ). The effects of U50,488, U69,593, U62,066, and ICI204,488 were tested on responses of 31 fibers (15 untreated and 16 treated) to noxious CRD (80 mmHg, 30sec., every 4 min.). Of 15 fibers studied from untreated colon, 13 were inhibited by U50,488 ( $n=5$ ), U69,593 ( $n=4$ ), or U62,066 ( $n=4$ ) in a dose-related manner. The ED<sub>50</sub>s for U50,488, U69,593, and U62,066 were  $8.1 \pm 0.8$ ,  $8.4 \pm 2.2$ , and  $5.7 \pm 1.2$  mg/kg, respectively. ICI204,488, a peripheral  $\kappa$ -opioid receptor agonist, had no effect on two fibers studied to date. Responses of 16 fibers pretreated with acetic acid or mustard oil were tested with U50,488 ( $n=9$ ), U69,593 ( $n=3$ ), or U62,066 ( $n=4$ ). There was no apparent difference in the inhibitory effect on these compounds on untreated and treated colon. The results suggest that  $\kappa$ -opioid agonists inhibit the responses of pelvic nerve afferents by activation of peripheral  $\kappa$ -opioid receptors.

## 458.8

**$\kappa$ -OPIOID RECEPTOR AGONISTS ATTENUATE RESPONSES TO COLORECTAL DISTENSION IN RATS WITH NORMAL OR INFLAMED COLONS.** M.B. Burton\*, and G.F. Gebhart. University of Iowa, Iowa City, IA, 52246.

Recently,  $\kappa$ -opioid receptor agonists have been reported to significantly attenuate responses of pelvic nerve afferents to noxious colorectal distension (CRD) (see Xu *et al.*, and Sengupta *et al.*, this meeting). The aim of this study was to evaluate the effects of the  $\kappa$ -opioid receptor agonists U-50,488, U-69,593, and ICI-204,448 on pseudoreflexive (visceromotor and pressor) responses to CRD in awake, unrestrained rats. The effects of these drugs were studied in rats with normal and with inflamed colons.

Rats with externalized femoral arterial and venous catheters and EMG electrodes (peritoneal musculature) were given 1 ml of either saline or 5% acetic acid (HAc) intracolonic 6 hours prior to testing. CRD was administered as a staircase function (0-80 mmHg) over 70s at 4 min intervals. Drugs were administered i.v. using a cumulative dose regimen. All three agonists dose-dependently attenuated the pseudoreflexive responses to CRD in rats with normal or with inflamed colons. U-50,488 U-69,593 and ICI-204,448 all produced rightward shifts of the stimulus-response curve and significantly increased the extrapolated response thresholds. The slopes of these curves were decreased after U-50,488 and U-69,593, but not after ICI-204,448. At doses producing near maximal antinociceptive effects, U-69,593 and U-50,488 (but not ICI-204,448) also produced agitation.

These results indicate: first, that  $\kappa$ -opioid agonists can attenuate responses to noxious visceral stimuli; second, the actions of these agonists are, at least in part, mediated through peripheral receptors; and third,  $\kappa$ -opioid agonists may be useful in the treatment of visceral pain.

## 458.10

**ANTINOCICEPTIVE EFFECT OF KAPPA- AND MU-OPIOID AGONISTS ON THE CARDIOVASCULAR RESPONSE INDUCED BY VAGINAL DISTENSION** L. Diop\*, N. Friese, S.G. Dahl and P.J.M. Riviere. Dept. of Gastroenterology, Institut de Recherche Jouvain, 3-9, rue de la Loge, 94265 Fresnes, France.

Both uterine and vaginal distensions increase spinal and supraspinal neuronal activity and induce an escape behavior in response to this painful stimulus. The cardiovascular reflex (CVR) response has been widely used to measure the intensity of pain induced by distension of visceral hollow organs. The present study used the CVR response to evaluate the antinociceptive activity of  $\mu$ - and  $\kappa$ -opioid agonists against pain induced by vaginal distension (VD) in anesthetized rats.

The CVR responses induced by VD were measured in pentobarbital (60 mg/kg i.p.) anesthetized female rats. VD, by the inflation of a 1 cm length latex balloon placed in the vagina with 1.5 mL of water for 1 min, were performed every 5 min.

VD induced a reproducible hypotensive response ( $27.5 \pm 1.6$  mm Hg). Morphine (0.03 - 1 mg/kg i.v.) and U-50,488H (0.08 - 1.6 mg/kg i.v.) produced a dose-related inhibition of the CVR induced by VD. ED<sub>50</sub> were 0.16 and 0.49 mg/kg i.v. respectively. Morphine (0.3 - 10  $\mu$ g/rat) administered i.c.v. displayed an antinociceptive effect ( $81.4 \pm 7.9\%$  at 0.3  $\mu$ g/rat) whereas U-50,488H (30 - 300  $\mu$ g/rat) was inactive by this route. A low dose of naloxone (30  $\mu$ g/kg i.v.) blocked the response to morphine but not to U-50,488H. The  $\kappa$ -opioid antagonist, nor-BNI (10 mg/kg s.c.) abolished the response to U-50,488H but not to morphine.

This demonstrates that CVR response is a reliable parameter to assess the antinociceptive activity of opioids in distension-induced vaginal pain and that the  $\kappa$ -opioid agonist, U-50,488H, blocks vaginal nociception by acting on peripheral  $\kappa$ -opioid receptors. In contrast, both central and peripheral  $\mu$ -opioid receptors may be involved in morphine-induced antinociception. To our knowledge, this is the first demonstration of a  $\kappa$ -opioid receptor mediated antinociceptive effect in VD.

## 458.11

EFFECT OF FENTANYL AND NALOXONE ON THALAMICALLY INDUCED PAIN IN HUMANS. A.L. Velasco\*, F. Brito, M. Gallegos, F. Jiménez, F. Velasco and M. Velasco. Unit of Neurology and Neurosurgery, General Hospital of Mexico, S.S. and UMR Neurophysiology, National Medical Center, IMSS, Mexico City 73032

This work was performed on epileptic patients with intractable generalized tonic clonic seizures and chronically implanted electrodes in the Centro Median Thalamic Nuclei (CM) as a neuroaugmentative procedure for seizure control. As a collateral observation, we found that acute unilateral electrical stimulation of CM (10 sec trains of rectangular square pulses, frequency 60/sec, duration 1.0 msec and threshold intensity=1200-2000 $\mu$ A) in its more medial and basal portion close to nucleus parafascicularis (coordinates: AP=10, lat=2/10 and H=+1/10 of the AC-PC line length) produced an intense pain response on the contralateral face neck and arm characterized by long lasting (9-13 min) EEG desynchronization, tachycardia and hypertonia of the chin muscles.

In these patients, single 5.0  $\mu$ g/kg i.v. injections of fentanyl completely blocked the threshold to pain response and was increased from 1200-2000 $\mu$ A to 5000 $\mu$ A. This effect was reversed by naloxone (3.0 $\mu$ g/kg) which was administered 30 min after fentanyl.

In contrast, no changes in threshold and intensity of the pain response were observed after comparative injections of saline solution.

These data suggest that fentanyl (opioid antagonist) is able to interfere with pain at the level of the thalamus in addition to its well known effect at the spinal cord.

## 458.13

OPIOID INVOLVEMENT IN ELECTROMYOGRAPHIC (EMG) RESPONSES INDUCED BY INJECTION OF INFLAMMATORY IRRITANT INTO DEEP NECK TISSUES. J.W. Hu\*, J. Tatourian and H. Vernon. Faculty of Dentistry, University of Toronto, and Canadian Memorial Chiropractic College, Toronto, Ontario, Canada.

We previously demonstrated that injection of the inflammatory irritant and C-fiber excitant mustard oil (MO, 20%, 20  $\mu$ L) into the C2 paravertebral region produces an EMG activity increase in various neck and jaw muscles (Hu et al, Pain 1993;55:234). To determine if endogenous opioids are involved in these MO-induced EMG responses, experiments were performed in 23 anesthetized (halothane/N<sub>2</sub>O/O<sub>2</sub>) rats in which bipolar EMG electrodes were inserted into bilateral deep neck muscles, ipsilateral trapezius muscle and ipsilateral masseter muscle. The opiate antagonist naloxone (0.6 mg/kg, n=7; 1.2 mg/kg, n=7; 2.5 mg/kg, n=9) administered (i.v.) 30 minutes after MO injection (or after the EMG response level had returned to baseline level) produced dose-dependent EMG activity increases in all 4 muscles. The two higher doses of naloxone produced higher incidences (>50% vs <15% for the lowest dose) of EMG activity increases at a relative constant latency (13.3  $\pm$  5.7 min, mean  $\pm$  S.D.) and duration (12.6  $\pm$  5.8 min); repeated doses of naloxone provoked higher incidences and larger EMG responses than the initial naloxone administration. The MO-induced EMG activity increase is consistent with the concept of "central sensitization", and the ability of the opioid antagonist naloxone to "rekindle" this increase is consistent with our other findings (Yu et al, J. Neurophysiol. 1994;72:1430) of the involvement of endogenous opioids in modulatory mechanisms underlying central sensitization. Opioid peptide gene delivery to mouse sensory neurons using herpes virus vectors. G. Davar\*, B.P. Vos, R. Day, W. Dong, D. Coen, L. Fang, W.R. Bebrin. Dept. of Anesthesia, Brigham and Women's Hosp., Dept. of Biol. Chem. and Molec. Pharm., Harvard Medical School, Boston, MA 02115 USA, and Clin. Research Institute of Montreal, Montreal, Quebec, Canada.

Herpes simplex viruses are potentially useful vectors for the delivery of genes encoding opioid peptides to sensory neurons in vivo. To explore the potential of such vectors, a herpes simplex virus (HSV) recombinant,  $\alpha$ LTDRdyB (see Davar et al., '93), containing the full length coding sequence for rat prodynorphin inserted into the herpes simplex thymidine kinase gene and downstream of the MoMLV-LTR promoter, was inoculated onto the mouse cornea. Evidence of prodynorphin gene expression was observed in rostromedial trigeminal ganglion neurons 4 and 8 days following inoculation by in situ hybridization. Markedly greater numbers of prodynorphin-labeled neurons were observed in  $\alpha$ LTDRdyB-infected animals than were observed in control virus- or mock-infected animals. Prodynorphin expression occurred only in neurons that expressed HSV latency-associated transcripts (LAT), a marker of HSV infection.

In a separate preliminary experiment,  $\alpha$ LTDRdyB was inoculated onto the skin of mice in the periocular region. Low intensity mechanical stimulation of this area 3 days after infection produced a higher frequency of directed face wiping than was observed after infection with a similarly-constructed lacZ-containing TK<sup>-</sup> virus (Wilcoxon Signed Rank Test, p<.05).

These data are evidence that the gene for prodynorphin can be delivered to and expressed in mouse sensory neurons in vivo using an HSV vector. Our working hypothesis is that release of dynorphin peptides from HSV-infected sensory neurons can contribute to changes in the behavioral response to mechanical stimulation.

## PAIN MODULATION: PHARMACOLOGY—ALLODYNIA

## 459.1

MEXILETINE INHIBITS INTRATHECAL STRYCHNINE-INDUCED ALLODYNIA AND NOXIOUS PAW PINCH IN THE RAT. S.E. Sherman\*, C.W. Loomis and E.M. Hodge. School of Pharmacy & Division of Basic Medical Sciences, Memorial University, St. John's, Newfoundland, Canada A1B 3X6

The blockade of spinal glycine receptors with intrathecal (i.t.) strychnine (STR) produces a reversible, segmentally localized allodynia-like state in the rat. The purpose of this study was to investigate the effect of mexiletine, a sodium channel blocker used in the management of clinical allodynia, on STR-induced allodynia, and to compare its effect on mechanical nociception. Male, Sprague-Dawley rats, fitted with chronic i.t. catheters, were lightly-anesthetized with urethane. Stimulus-evoked changes in blood pressure and heart rate were recorded from the left carotid artery and cortical electroencephalographic (EEG) activity was continuously monitored using subdermal needle electrodes. After i.t. STR (40  $\mu$ g), normally innocuous hair deflection (HD) elicited a marked increase in mean arterial pressure and heart rate, an abrupt motor withdrawal response, and desynchronization of the EEG, comparable to those observed with calibrated, bilateral noxious hind-paw pinch (without STR). Mexiletine (5-30 mg/kg i.v.), given 5 min before i.t. STR, dose dependently inhibited the pressor, heart rate and motor withdrawal responses evoked by HD; these effects were significantly different from control at 15 and 30 mg/kg. A similar mexiletine dose-response curve was observed against noxious hind-paw pinch. The percent synchrony in the EEG was significantly increased with i.v. mexiletine at 30 mg/kg, suggesting the inhibition at this dose was a non-specific effect. In conclusion, systemic mexiletine attenuates the cardiovascular and motor withdrawal responses evoked by HD in the presence of i.t. STR, and by noxious mechanical stimulation (without STR), with comparable potency. These results are consistent with the effect of mexiletine in clinical allodynia and in a focal spinal ischemia model of allodynia. (Supported by MRC of Canada)

DYNORPHIN AND NMDA RECEPTOR-MEDIATED GLUTAMATE IN ALLODYNIA DEVELOPMENT. R. Wagner\* and J.A. DeLeo. Dept. of Pharmacology and Toxicology, Dartmouth Medical School, Hanover, NH, 03755.

Spinal glutamate, via the NMDA receptor, and the  $\kappa$ opioid dynorphin are implicated in the development of neuropathic pain following peripheral nerve injury. In addition, dynorphin has nonopioid functions that involve the NMDA receptor. Sciatic cryoneurolysis (SCN) is a complete but transient injury to the sciatic nerve that produces mechanical allodynia at 21-28 days. Since allodynia appears later in SCN than in other neuropathy models, we questioned if it was NMDA receptor-dependent. We also explored an interrelationship of spinal dynorphin and glutamate following SCN using quantitative immunohistochemistry. Rats received 0.25 mg/kg MK-801 i.p. twice daily from 0-7 or 0-21 days post-SCN to preemptively block the NMDA receptor. In different rats, an antibody to dynorphin (1-13) was given i.p. at 16.6 mg/kg twice daily from 14-21 days post-SCN. Allodynia outcome at 42 days was assessed using von Frey hairs, and dynorphin (DYN) and glutamate (GLUT) immunoreactivity was quantitated at 42 days in laminae II-III by measuring proportional area stained and relative optical density, respectively. Only 0-7 day MK-801 increased mechanical thresholds (mean  $\pm$  S.E.M., 7g  $\pm$  1.2) from saline controls (3.9g  $\pm$  0.6) by Student's t-test [p<0.05]. However, this did not prevent allodynia since baseline thresholds were 12 or 15g. However, pharmacological treatments did alter resulting DYN and GLUT. Dynorphin antibody increased GLUT as compared with saline controls (807.2  $\pm$  3.61 vs. 779.6  $\pm$  8.3) [p<0.01]. MK-801 from 0-21 days decreased DYN compared to controls, but not significantly. This study suggests that allodynia development following SCN involves only an early and limited NMDA receptor contribution, and that decreasing available dynorphin had significant and lasting effects on spinal glutamate expression.

## 459.3

## PHARMACOLOGY OF TACTILE ALLODYNIA IN THE STREPTOZOTOCIN DIABETIC RAT

S. R. Chaplan<sup>1</sup>\*, N.A. Calcetti<sup>2</sup> and T.L. Yaksh<sup>1</sup>, Depts. of Anesthesiology<sup>1</sup> and Pathology<sup>2</sup>, UCSD, 9500 Gilman Drive, La Jolla CA 92093.

Tactile allodynia (light mechanical stimulus perceived as painful) is a prominent abnormality in painful diabetic neuropathy; investigations in rat models of diabetes to date have focused on pressure hyperalgesia and thermal stimuli. We have recently reported the finding of hyperglycemia-related tactile allodynia in the streptozotocin (STZ) diabetic rat, which may be prevented by systemic insulin treatment. In this study we report investigations on the spinal pharmacology of the allodynia. Adult female Sprague Dawley rats were rendered diabetic with a single dose of STZ, 50 mg/kg, i.p. At 3 weeks of diabetes, lumbar intrathecal catheters were implanted. At 4 to 6 weeks of diabetes, paw withdrawal thresholds (PWT) to graded von Frey hairs were measured in awake, unrestrained rats before and after spinal drug applications. Acute treatments with intrathecal dexmedetomidine (alpha-2 agonist), AP5 (NMDA antagonist), CP96345 (NK1 antagonist) and morphine ( $\mu$  agonist) normalized PWT in a dose-response fashion; ketorolac (COX inhibitor) also had significant efficacy. These results strongly suggest the presence of synaptic facilitation at the spinal level in this model. However, the spinal pharmacology of this diabetic allodynia is not identical to other models of allodynia or spinal facilitation. This model promises to be useful in the study of hyperglycemia-related abnormalities of afferent processing in diabetes, and in the search for treatments for painful diabetic neuropathy in humans. (Support: NIH, RSDSA)

## 459.5

## MODULATION OF SPINAL OPIOID EFFICACY IN A MODEL OF NEUROPATHIC PAIN IN RATS. M.L. Nichols, D. Bian, M.H. Ossipov, E.D. French\* and F. Porreca, Dept. Pharmacology, Univ. of Arizona HSC, Tucson, AZ 85724

Neuropathic pains have often been classified as opioid resistant. The present studies have investigated the antiallodynic actions of intrathecal (*ith*) opioids in a nerve constriction model of neuropathic pain in rats. Morphine, at doses up to 300 nmol (100  $\mu$ g), was ineffective at altering allodynia. In contrast, [D-Ala<sup>2</sup>, NMPhe<sup>4</sup>, Gly-ol]enkephalin (DAMGO) produced dose-related antiallodynic actions with an  $A_{50}$  value (95% C.L.) of 1.2 (0.8-1.8) nmol. Furthermore, [D-Ala<sup>2</sup>, Glu<sup>4</sup>]deltorphin (DELT) was able to produce a significant antiallodynic effect (~70% of the maximum) at 300 nmol; the  $A_{50}$  (95% C.L.) for DELT was 111 (91-136) nmol. Co-administration of morphine (90 nmol) with an ineffective dose of DELT (10 nmol) was able to produce a significant, long-lasting antiallodynic action; this apparently synergistic effect was antagonized by *ith* naltrindole (NTI) at a dose selective for opioid  $\delta$  receptors (67 nmol). Blockade of cholecystokinin-B (CCK<sub>B</sub>) receptors with L365,260 (6.3 pmol, *ith*) did not produce any effects alone; however, coadministration of morphine (90 nmol) with L365,260 resulted in significant antiallodynic actions (~65% of maximum); this effect was also antagonized by a  $\delta$ -receptor selective dose of *ith* NTI. Both an opioid  $\delta$  agonist, and a CCK<sub>B</sub> antagonist, though ineffective alone, increased morphine efficacy in an NTI-sensitive fashion. These findings suggest that blockade of CCK<sub>B</sub> receptors may enhance the availability of endogenous enkephalins which increase morphine efficacy via a  $\mu$ - $\delta$  interaction. Additionally, the finding that DAMGO, but not morphine, was able to attenuate allodynia suggest that the actions of  $\mu$  opioids in this model may be related to efficacy and that morphine may be unable to produce antiallodynic effects in this model due, in part, to a reduction in available  $\mu$  receptors which may occur as a result of presumed degeneration of primary afferents following nerve constriction injury. The data suggest that the use of high efficacy  $\mu$  opioids may be more effective in the treatment of allodynia associated with neuropathies and that CCK<sub>B</sub> antagonists, and eventually, opioid  $\delta$  agonists, may be useful adjuncts.

INVOLVEMENT OF  $\alpha_2$ -ADRENOCEPTORS IN THE PERIAQUEDUCTAL GRAY-INDUCED INHIBITION OF DORSAL HORN CELL ACTIVITY IN RATS. Y.B. PENG\*, Q. LIN, W.D. WILLIS, Dept. of Anatomy and Neuroscience, The University of Texas Medical Branch, Galveston, Texas 77555-1069

Serotonergic, opioid, and noradrenergic systems are considered the major descending analgesic systems. The relationship between stimulating PAG and the likely effect on the noradrenergic system is of great interest. Brain stem cell groups containing noradrenergic neurons that project to the spinal cord include the locus coeruleus, subcoeruleus, Kölliker-Fuse nucleus, parabrachial nuclei and the more caudal A5 cell group. A projection from the PAG to the locus coeruleus and parabrachial region has been reported. Kwiat et al demonstrated that there are noradrenergic neurons that send axon branches both to the spinal cord and to the PAG. It is possible that electrical stimulation of the PAG might activate bulbospinal noradrenergic controls via antidromic activation of the noradrenergic axons which project to the PAG, and subsequent orthodromic activation of the spinally projecting collaterals of the noradrenergic cells in A5, locus coeruleus, subcoeruleus and A7/Kölliker-Fuse nucleus. The current experiment was designed to study the effect of  $\alpha_2$ -adrenoceptors on spinal dorsal horn cells on PAG-induced inhibition. Male Sprague-Dawley rats (270-360g) were used in the study. A microdialysis fiber was introduced into the dorsal horn of the lumbar enlargement for drug administration. An electrode was placed in the vicinity of the microdialysis fiber for extracellular single unit recording. When stimulating the PAG, responses to mechanical stimuli applied to the skin (brush, press, and pinch) were inhibited. When a  $\alpha_2$ -adrenoceptor antagonist, idazoxan (1 mM), was administered, the background activity and the responses of the cell to brush, press, and pinch stimuli increased. Interestingly, the PAG-induced inhibition to mechanical stimuli was reduced by idazoxan. This result suggests an involvement of  $\alpha_2$ -adrenoceptors in PAG-induced inhibition of dorsal horn cell activity. This study was supported by NIH Grants NS09743 and NS11255.

## 459.4

## CHARACTERIZATION OF THE ANTIALLODYNIC EFFICACY OF MORPHINE IN A MODEL OF NEUROPATHIC PAIN IN RATS. D. Bian, M.L. Nichols, M.H. Ossipov, R.B. Raffa\* and F. Porreca, Department of Pharmacology, University of Arizona Health Sciences Center, Tucson, AZ 85724 and \*Drug Discovery Research, R.W. Johnson, Pharmaceutical Research Institute, Spring House, PA 19477.

Neuropathic pains have often been classified as opioid-resistant. The present studies have investigated systemic (intraperitoneal; *i.p.*), intrathecal (*ith*) and intracerebroventricular (*i.c.v.*) antiallodynic actions of morphine in a nerve constriction model (L5-L6) of neuropathic pain in rats. Allodynia was assessed by determining the response threshold to stimulation with von Frey filaments. Morphine administered *i.p.* (3-30 mg/kg) or *i.c.v.* (1-10  $\mu$ g) produced dose-dependent antiallodynic effects which were readily antagonized by naloxone (5 mg/kg, *i.p.* at -10 min). The *i.p.* and *i.c.v.* morphine antiallodynic  $A_{50}$  values (and 95% confidence limits) were 6.4 (5.3-7.6) mg/kg and 2.2 (1.0-4.6)  $\mu$ g, respectively. Morphine administered *ith* (3-100  $\mu$ g) did not produce any antiallodynic actions. These data suggest that the failures of morphine to produce antiallodynic effects when administered *ith* in this model may be due, in part, to a decrease in available spinal  $\mu$  opioid receptors which may result from degeneration of primary afferent fibers after nerve constriction injury. In contrast, the antiallodynic actions of *i.p.* or *i.c.v.* morphine appear to depend on supraspinal activation of opioid ( $\mu$ ) receptors and subsequent activation of descending modulatory systems. The inconsistent data seen clinically with morphine in neuropathic pains may be related to the lack of supraspinal/spinal synergy that is normally associated with morphine efficacy in conditions of acute pain.

## 459.6

## NEW PAIN MODEL INDUCED BY A MONOCLONAL ANTIBODY. CHEMOTHERAPEUTIC AGENT. L.S. Sorkin\*, R. Slart, T.L. Yaksh and A.L. Yu, Depts of Anesthesiology and Pediatrics, UCSD, La Jolla, CA, 92093

Systemic administration of an antibody against the GD2 ganglioside is a promising treatment for neuroblastoma. A serious side effect is the development of an opiate resistant pain state. We sought to determine if antibody administration to rats would also lead to a quantifiable pain state, thus producing a model for developing better pain management.

Halothane anesthetized rats (Sprague-Dawley 300-350 g male) were implanted with jugular catheters and allowed to recover for 3 hrs. After acclimation to a test chamber, withdrawal threshold (WT) to mechanical stimulation was measured with von Frey hairs applied to the hindpaws. An index of whole body touch evoked agitation was also obtained. Following baseline measurements, saline, 0.1, 1.0, 3.0 or 10 mg/kg of antibody was administered through the catheter. Behavioral responses were measured every 15 min for the next 3 hours. The experimenter was blinded to the syringe contents. Another group of rats given 1.0 mg/kg antibody were monitored for blood pressure (BP) and heart rate (HR). Saline and 0.1 mg/kg antibody both initiated a small drop in WT (allodynia). WT returned to baseline for the controls and was maintained for the experimental group. All 3 higher doses of antibody caused a large, precipitous drop in WT for the entire observation period. Touch evoked agitation was produced by all doses of antibody. Resting BP and HR following 1.0 mg/kg antibody increased (mean change 14 mm Hg and 30 beats/min, respectively).

These results indicate that systemic administration of GD2 antibody in the rat reliably produces mechanical allodynia and may serve as a model for assessing the pharmacology of this clinically relevant pain state.

## 459.8

## PROTEIN KINASE C INFLUENCES THE EFFECTIVENESS OF PERIAQUEDUCTAL GRAY-INDUCED INHIBITION OF PRIMATE SPINOTHALAMIC TRACT NEURONS BY DESENSITIZING SPINAL GLYCINE AND GABA RECEPTORS. Q. Lin\*, Y.B. Peng and W.D. Willis, Dept. of Anatomy and Neurosciences, UTMB, Galveston, TX 77555-1069.

Previously we demonstrated that spinal glycinergic and GABAergic interneurons are involved in the inhibition of primate spinothalamic tract (STT) neurons by stimulation in the periaqueductal gray (PAG). In this study, we examined the changes in the inhibition mediated by glycine and GABA that occur when STT cells were sensitized by intradermal (i.d.) injection of capsaicin and the involvement of protein kinase C (PKC) in this process. Recordings were made from STT cells in anesthetized monkeys (*M. fascicularis*) using a multi-barreled microelectrode. Responses of STT neurons to innocuous and noxious mechanical stimuli applied to the skin were inhibited by iontophoretic application of glycine, GABA and muscimol and by stimulation in PAG. Sensitization of responses of STT cells to mechanical stimuli was accompanied by a reduction in glycine and PAG inhibition, but GABA inhibition was only attenuated in some cells, and muscimol inhibition was unchanged or increased. Similar results were observed when PKC activator, phorbol ester (12-O-tetradecanoylphorbol-13-acetate) was infused within the spinal dorsal horn by microdialysis. Conversely, spinal cord administration of the selective PKC inhibitor, NPC-15437, prevented the capsaicin-induced sensitization and glycine, GABA and PAG inhibition of STT cells. Our results provide evidence that i.d. injection of capsaicin may result in the desensitization of glycine and perhaps GABA<sub>B</sub>, but not GABA<sub>A</sub>, receptors in the spinal cord, and this reduces the effectiveness of PAG inhibition. These events are likely to contribute to allodynia and hyperalgesia seen after i.d. injection of capsaicin, and PKC may mediate the desensitization of some inhibitory amino acid receptors. (Supported by NIH grants NS 09743 and NS11255).

## 459.9

EXCITATORY AMINO ACIDS (EAA) IN THE PERIPHERY CONTRIBUTE TO THE DEVELOPMENT OF ALLODYNIA AND THERMAL HYPERALGESIA IN ARTHRITIC RATS. K.N. Westlund\*, N.B. Lawand, and W.D. Willis Dept. of Anatomy and Neurosciences, Univ. of Texas Med. Branch, Galveston, TX 77555.

EAA receptors are thought to mediate fast excitatory synaptic transmission in the mammalian CNS. However, EAAs may have specific, receptor mediated functions in the periphery also. The aim of the present study is to investigate the role of peripherally released EAAs in the development of hyperalgesia and allodynia. Inflammation was induced in one group of rats by injection of kaolin/carrageenan into the knee joint. With a CMA-20 microdialysis probe inserted in the knee joint cavity, it was determined that glutamate, aspartate and arginine concentrations were increased with inflammation. A second group of rats was injected with L-aspartate (ASP), L-glutamate (GLU) and arginine (ARG) either alone or in different combinations. Paw withdrawal latencies (PWL) to radiant heat and withdrawal thresholds (WT) for innocuous mechanical stimuli were measured before and after intraarticular administration of the AAs. When administered alone, the AAs did not have any effect on withdrawal from noxious and innocuous stimuli. However, when combinations of ASP/GLU, ASP/ARG or ASP/GLU/ARG were applied, a significant decrease in PWL and WT was observed as compared to baseline. Therefore, hyperalgesia could be induced by intraarticular injection of combinations of AAs, although the joint did not become inflamed. NMDA (AP7) and non-NMDA (CNQX) receptor antagonists applied intraarticularly in arthritic animals as well as rats injected with ASP/GLU/ARG reversed the mechanical allodynia and thermal hyperalgesia. Our data suggest that EAAs injected or released in the synovial fluid may act on glutamate receptors in the knee joint capsule to produce mechanical allodynia and thermal hyperalgesia but not inflammation. (Supported by NS32778, NS11255, and NS09743.)

LIGHT-MEDIATED RETINOIC ACID PRODUCTION. E. Wagner, P. McCaffery, J. Mey and U. C. Dräger\*, E.K. Shriver Center, Waltham, MA 02254 and Harvard Medical School, Boston MA.

The transcriptional activator retinoic acid (RA) is generated from retinaldehyde by retinaldehyde dehydrogenases. In most tissues we find a quantitative correlation between levels of retinaldehyde dehydrogenases and levels of endogenous RA, but the postnatal eye shows an anomaly: while under dark-adapted conditions the two parameters correlate well, illumination of the eye results in a disproportional increase in RA synthesis. Appearance of this light-induced RA production in the developing eye coincides with maturation of rhodopsin, indicating that it is due to all-*trans* retinaldehyde, released from bleached rhodopsin, becoming accessible to the dehydrogenases. Although the main fate of released all-*trans* retinaldehyde is capture by retinoid binding proteins for regeneration of 11-*cis* retinaldehyde, bright light is likely to transiently saturate the visual recycling mechanism. As the vertebrate eye contains high levels of cytosolic retinaldehyde dehydrogenases, and as the oxidation of retinaldehyde to RA is an irreversible reaction, RA production is probably an unavoidable by-product of bright illumination, providing a mechanism by which light can directly influence gene transcription. Transcription of several ocular proteins is known to respond to light, including arrestin. We find that RA injection into mice causes a dose-dependent increase in arrestin immunoreactivity in the outer nuclear layer. Light-mediated RA production due to precursor release from bleached rhodopsin provides a plausible and general mechanism for light effects in the vertebrate eye which cannot be explained by electric activity. Supported by R01 EY03819 and a gift from Johnson & Johnson.

## 460.2

LIGHT-INDUCED FOS EXPRESSION IN THE VISUAL SYSTEM OF THE *RD* MOUSE. C.M. Araki<sup>1</sup>, N.M. Hossokawa<sup>2</sup>, L.R.G. Britto<sup>2</sup>, and D.E. Hamassaki-Britto<sup>1\*</sup>. Depts. <sup>1</sup>Histology and Embryology and <sup>2</sup>Physiology and Biophysics, Institute of Biomedical Sciences, University of São Paulo, São Paulo (SP), 05508-900, Brazil.

Several mutations in the gene encoding the rod cGMP-phosphodiesterase during early development are responsible for the degeneration of photoreceptors in the *rd* mouse. This study was undertaken to evaluate the possibility that the remaining retinal cells and cells in central visual areas could be activated by visual stimuli. Normal (C57BL/6) and *rd* (C3H) adult mice were dark-adapted, and just before the visual stimulation an occluder was placed over one of the eyes (control). The visual stimulus consisted of flashes or diffuse light that were presented for 1-1.5 h to the opened eye. An antibody against the Fos protein (Oncogene) was used with the avidin-biotin-peroxidase method to determine the cells that were activated using this protocol. Fos-positive cells were observed in the inner third of the inner nuclear layer and in the ganglion cell layer of both normal and *rd* mice. Only a few Fos-positive cells were seen in control retinæ of either normal or *rd* mice. Fos-positive cells were also observed in the superficial layers of the contralateral superior colliculus and ventral lateral geniculate nucleus of both strains of mice, whereas the correspondent ipsilateral regions contained a very small number of stained cells. Taken together with previous behavioral data indicative of residual vision in *rd* mouse, our data suggest that the *rd* mouse visual system retains some functional characteristics. Supported by: FAPESP and CNPq (Brazil).

## 460.3

PHOTORECEPTOR DEVELOPMENT IN CULTURE. ARNOLD G. HYNDMAN\*, DEPARTMENT OF BIOLOGICAL SCIENCES, RUTGERS UNIV., PISCATAWAY, NJ 08855

INTRINSIC FACTORS IN THE NEURAL RETINA ARE BELIEVED TO PLAY AN IMPORTANT ROLE IN DETERMINING WHETHER PRECURSORS WILL DIFFERENTIATE INTO EITHER NEURONS OR PHOTORECEPTORS. IN ORDER TO FURTHER EXAMINE THIS PHENOMENON, CULTURES FROM EMBRYONIC DAY 6 CHICK NEURAL RETINAE WERE DISSECTED, DISSOCIATED AND CULTURED IN CONDITIONS KNOWN TO YIELD A HIGH PERCENTAGE OF PHOTORECEPTORS. FOR THE FIRST TWO DAYS *IN VITRO* CULTURE MEDIA WAS SUPPLEMENTED WITH 5% FETAL BOVINE SERUM (FBS). AT THE END OF THIS PERIOD, SOME CULTURES WERE PLACED IN A SERUM-FREE MEDIUM SUPPLEMENTED WITH ONLY CATALASE AND INSULIN (CI). ALL CULTURES WERE EXAMINED AT 3 DAYS *IN VITRO*. CELL SURVIVAL WAS 50% GREATER IN CI CULTURES COMPARED TO FBS CULTURES. THIS INCREASE WAS DUE TO AN INCREASE IN THE NUMBER OF PHOTORECEPTORS PRESENT. THE ADDITION OF TRANSFERRIN, BASIC FIBROBLAST GROWTH FACTOR AND TAURINE TO CI CULTURES RESULTED IN SURVIVAL OF NEURONS AND PHOTORECEPTORS SIMILAR THAT OF CULTURES SUPPLEMENTED WITH CI ALONE. PHOTORECEPTORS (PHR) WERE CLASSIFIED BASED ON THEIR *IN VITRO* MORPHOLOGY. PHR WITH A SMALL FILOPODIA (A RUDIMENTARY OUTER SEGMENT?) AND LITTLE NEURITE DEVELOPMENT WAS CALLED TYPE 1. TYPE 2 PHR WAS SIMILAR, HOWEVER, THERE WAS NOTABLY MORE NEURITE DEVELOPMENT ORIGINATING FROM THE FILOPODIA AND FROM THE OPPOSITE END OF THE CELL. TYPE 3 PHR LACKED A FILOPODIA, BUT THERE WERE NEURITES PRESENT AT EACH END OF THE CELL. FBS CULTURES CONTAINED 60% TYPE 1 PHR, 36% TYPE 2 PHR AND 4% TYPE 3 PHR. CI CULTURES CONTAINED 49% TYPE 1 PHR, 48% TYPE 2 PHR AND 3% PHR. FROM THESE STUDIES, IT CAN BE CONCLUDED THAT FACTORS IN SERUM CAN INFLUENCE THE DIFFERENTIATION AND/OR SURVIVAL OF PHOTORECEPTOR CELLS OR THEIR PRECURSORS. TRANSFERRIN, BASIC FIBROBLAST GROWTH FACTOR AND TAURINE WHICH MAY HAVE IMPORTANT ROLES IN PHOTORECEPTOR DEVELOPMENT DID NOT AFFECT THESE INITIAL STAGES OF SURVIVAL OR DIFFERENTIATION.

## 460.4

SPECIFIC PHAGOCYTOSIS TRIGGERS EXPRESSION OF IMMEDIATE EARLY TRANSCRIPTION FACTORS IN RETINAL PIGMENT EPITHELIUM (RPE) CELLS. A.V. Ershov, W.J. Lukiw, D.M. Linn\*, N.G. Bazan, Eye and Neuroscience Center, LSU Medical Center, New Orleans, LA.

Phagocytosis of used tips of rod outer segments (ROS) by RPE cells is vitally important for maintaining structural and functional integrity of the retina. Phagocytosis deficiency in dystrophic RCS-*p*<sup>+</sup> rat RPE cells leads to degeneration of the retina and complete blindness. We studied the expression of immediate early gene mRNAs and their gene products during the phagocytosis of ROS by normal Long Evans (LE) and RCS-*rdy*<sup>+</sup>*p*<sup>+</sup> rats, and by dystrophic RCS-*p*<sup>+</sup> rat RPE cells in primary cell culture, using Northern blot analysis and electrophoretic mobility shift assay (EMSA). Northern analysis revealed that the levels of c-FOS, TIS1 and ZIF268 mRNA were rapidly, strongly and transiently increased in normal RPE cells during ROS phagocytosis, but not during phagocytosis of non-specific latex particles. No increase in the gene expression was found in RCS-*p*<sup>+</sup> dystrophic RPE cells challenged with ROS. As shown by EMSA, a prominent short-term increase in the intensity of gel shifted band was detected using nuclear protein extract derived from ROS-challenged normal LE RPE cells and ZIF268 or AP-2 consensus oligonucleotides. No such increase was detected when using NFκB consensus oligonucleotide. At any time point, neither expression of COX2 mRNA was detected by Northern analysis, nor any shifted band was revealed by EMSA using COX2 promoter region DNA. As a positive control, COX2 mRNA band could be revealed on Northern blots after treatment of LE RPE cells with TPA or PDGF. The results suggest that in RPE cells ROS-specific phagocytosis is accompanied by a short-term over-expression of immediate early genes, coding transcription factors, as well as their gene products. The specific pattern of the expression of these transcription factors would then be able to further modify the expression of other genes in a gene cascade. Supported by NIH grant EY05121.

## 460.5

ULTRAVIOLET LIGHT INDUCES FOS PROTEIN EXPRESSION IN THE RAT VISUAL SYSTEM. B. Robinson\* and S. Amir. Center for Studies in Behavioral Neurobiology, Concordia University, Montreal, Quebec, Canada.

Electrophysiological evidence that the spectral sensitivity of the retina in rodents extends into the ultraviolet range and behavioral evidence that rodents can detect ultraviolet wavelengths suggests that ultraviolet light plays a role in vision. Little is known, however, about the effect of ultraviolet light on the rodent visual system. Here we used immunostaining for the cellular phosphoprotein Fos to examine the effect of ultraviolet light exposure on patterns of neuronal activation in rat brain. Nighttime exposure to diffuse monochromatic ultraviolet light (1-30 min,  $\lambda$  max 360 nm; half bandwidth, 8.8 nm; irradiance at eye level, 10  $\mu$ W/cm<sup>2</sup>) induced extensive Fos expression in visual cortex and lateral geniculate complex. Within the lateral geniculate, ultraviolet light induced Fos expression in the ventrolateral, but not dorsolateral, nucleus and in the intergeniculate leaflet. The effect of ultraviolet light on Fos expression was blocked by either bilateral orbital enucleation or bilateral optic nerve transection, and it appeared to be mediated by a mechanism bearing characteristics of a specific ultraviolet receptor. This is the first demonstration that ultraviolet stimuli detected by a receptor in the retina can gain access to, and stimulates neuronal activity in, brain centers involved in visual perception (visual cortex) and luminance detection (ventral lateral geniculate nucleus and intergeniculate leaflet).

## 460.7

RET 1, A *CIS*-ACTING ELEMENT THAT IS SUFFICIENT TO DIRECT OPSIN EXPRESSION IN ROD PHOTORECEPTORS J. Martinez, X. Yu, J. Leconte, C.J. Barnstable\*. Neuroscience Program, Yale University, New Haven, CT.

RET 1 is a binding site for retinal nuclear proteins located at -136 to -110 bp in the rat opsin promoter (Morabito et al., J Biol. Chem. 266:9667, 1991). A similar sequence is found in the upstream regions of many other photoreceptor genes. Alignment of these sequences has allowed the definition of a 7 base consensus sequence, CAATTAG, which exhibits the binding activity of the full length RET 1 element. A 40 kD protein that binds to RET 1 has been purified over 2 X 10<sup>5</sup> to apparent homogeneity. The function of RET 1 has been tested in two sets of transgenic mice. In one set, a mutant RET 1 in an otherwise normal rat opsin promoter failed to drive expression of a *lacZ* marker gene in 8 of 10 lines. In 2 lines very faint expression in photoreceptors was detected. In the second set, RET 1 elements alone were used to direct expression of *lacZ*. Expression of *lacZ* was detected in 9 out of 12 lines. In all 9 lines expression was found in photoreceptors. In 2 lines expression was also detected in the ganglion cell layer and the ciliary epithelium. In 3 lines a characteristic pattern of expression was found in the embryo CNS in addition to the normal retinal expression. The results suggest that interaction of a 40 kD protein with RET 1 is both necessary and sufficient to drive gene expression in rod photoreceptors. Further, our results indicate that RET 1-like elements may also be important in the developing nervous system. Supported by NS 20483 and the RP foundation.

## 460.9

CLONING OF A NOVEL EXTRARETINAL OPSIN FROM CATFISH BARBEL. Seth Blackshaw, Yonatan H. Grad, and Solomon H. Snyder\*. Department of Neuroscience, Johns Hopkins University School of Medicine, 725 N. Wolfe St., Baltimore, MD 21205.

Extraretinal and extrapineal photosensitivity has been implicated in contributing to camouflage and circadian processes in a variety of lower vertebrates, including fish, amphibians, and reptiles. Very little, however, is known about the molecular mechanism of this photosensitivity, and it is unclear whether and receptor-mediated mechanisms are involved. In the course of attempting to clone G-protein coupled taste receptors from channel catfish, we obtained a PCR product encoding a novel opsin from barbel cDNA. A putative full-length genomic clone showed roughly 40% amino acid identity to both chicken pinopsin and fish red and green cone pigments over the region excluding the amino and carboxy terminal domains, in addition to exhibiting an intron-exon structure not seen in any other vertebrate photopigment. All residues implicated in directly contacting retinal via site-directed mutagenesis of rhodopsin are conserved. Northern analysis showed two transcripts in ventral skin, but not in retina or barbel RNA. Attempts to localize transcript via *in situ* hybridization, and attempts to reconstitute spectrally active protein are underway, and will be discussed.

## 460.6

LOCALIZATION OF *DROSOPHILA* RETINOID BINDING PROTEIN IN THE COMPOUND EYE. K. Shim<sup>1</sup>, J. Polizzi<sup>1</sup>, C. F. Thomas<sup>2</sup>, B. N. Wigger<sup>3</sup>, G. Kutty<sup>3</sup>, T. Duncan<sup>3</sup>, K. Kutty<sup>3</sup>, and W.S. Stark<sup>1</sup>. <sup>1</sup>Biology Dept., Saint Louis Uni. (SLU), St. Louis, MO 63103, <sup>2</sup>Integrated Micros. Resource (IMR), Univ. of Wisconsin, Madison, WI 53706, <sup>3</sup>Natl Eye Institute, 9000 Rockville Pike, Bethesda, MD 20892.

Carotenoid deprivation decreases proteins relevant to *Drosophila* vision (Western analyses, R.D.Lee, MS Thesis, SLU Biology, 1994). We used antibodies and FITC conjugated anti-IgG secondaries to localize proteins using fluorescence and confocal microscopes. An antibody to Rh1 (R1-6 opsin), made in collaboration with S. J. Fliester, Ophthalmology, SLU, helped us to optimize our methodology. DRBP (*Drosophila* retinoid binding protein, Duncan et al., 1994 *Arch. Biochem. Biophys.* 312:158-166, 1994) may be a *Drosophila* homologue of vertebrate IRBP (interphotoreceptor RBP) well-known as a transporter of retinoids between retinal pigment epithelium (RPE) and photoreceptors. DRBP is expressed specifically in cone (Semper) cells, four per ommatidium, between photoreceptor cells and the dioptric pseudocone with processes extending to basement membrane. Deprived flies have lower staining, consistent with Western analyses (Lee). Pre-immune staining gave the expected result of a negative control. The deprivation result suggests that DRBP is relevant to retinoid handling. Localization implies that cone cells may be analogous to vertebrate RPE in cell to cell retinoid transport. Earlier, in *Calliphora*, vitamin A and photoisomerase were localized to tissue near the cornea (Schwemer, in *Facets of Vision* Stavenga & Hardie eds. Berlin, Springer, 112-133, 1989), consistent with our finding. Support: NIH grants RO1 EY07192 to WSS & DRR-570 at the IMR.

## 460.8

SIMULTANEOUS DETECTION OF MULTIPLE OPSIN mRNAs IN GOLDFISH RETINA WITH NONISOTOPIC *IN SITU* HYBRIDIZATION. L.K. Barthel and P.A. Raymond\*. Dept. of Anat. & Cell Bio., University of Michigan, Ann Arbor, MI 48109.

It is generally believed that individual photoreceptor cells express a single opsin gene, and the spectral absorption properties of the resultant visual pigment establishes the spectral identity of that cell. Recent evidence from microspectrophotometric measurements in some species of fishes and from immunocytochemical analyses of developing cones in rodents has suggested that individual photoreceptors might express a combination of opsin genes or might switch from one opsin to another during development. In tetraploid species, such as goldfish, it is likely that each of the opsin genes is duplicated, but it is not yet known whether multiple genes are expressed in each photoreceptor of a given spectral subtype or whether the spectral subclasses are heterogeneous.

We sought to explore techniques to allow the simultaneous detection of more than one opsin mRNA in the goldfish retina. cRNA probes labeled with either digoxigenin-UTP (DIG-RNA) or fluorescein-UTP (FL-RNA) were generated by *in vitro* transcription from goldfish opsin cDNA clones. The probes were combined, hybridized to retinal tissues, and detected with antibodies to digoxigenin and fluorescein. Alkaline phosphatase (AP) and horseradish peroxidase (HRP) enzymatic histochemistry was used to detect the antibodies. One successful combination was DIG-RNA probes to goldfish blue cone opsin visualized with HRP/DAB combined with FL-RNA probes to goldfish red cone opsins revealed by AP/Vector Blue. The brown HRP reaction product was confined to short single cones, and the blue AP reaction product was only in long single and double cones with no overlap in signals, consistent with the known spectral identities of goldfish cones. Further experiments will use additional combinations of opsin probes, in both mature and developing retina, with special attention to temporal order and patterning at onset of expression and to photoreceptors that might express more than one opsin. Supported by NIH EY 04318 and NSF IBN 9222046.

## 460.10

ISOLATION AND CHARACTERISATION OF VISUAL PIGMENT GENES FROM STOMATOPOD CRUSTACEA. A.J.H. Brown, N.J. Marshall, M.F. Land and J.F. Burke\*. Sussex Centre for Neuroscience, School of Biological Sciences, University of Sussex, Brighton BN1 9QG, UK.

Colour vision in many species is based upon the differential light absorption by visual pigments. Microspectrophotometric and electrophysiological data suggest the retina of stomatopod crustacea contains up to 16 different photoreceptor cell types including 6 UV receptors covering the spectral range from 325nm to 700nm.

We have employed RT-PCR techniques to obtain two different full length cDNA clones from the mantis shrimp, *Gonodactylus oerstedii*. Comparison of deduced amino acid sequences has revealed 70% and 60% sequence identity to Mantis and Crayfish opsins.

Northern blot and *in situ* hybridisation techniques were used to study mRNA expression within the retina. Preliminary data suggest a localisation of one sequence within the proximal row 2 photoreceptor cell of the enlarged retinal midband region, absorbing maximally at 525nm.

In order to explain the number of visual pigments required to produce the electrophysiological recordings obtained, we have undertaken PCR amplification of the *G. oerstedii* genomic DNA with the same primers as used in RT-PCR. These data and Southern blot hybridisations suggest that at least one of these genes may be present in multiple copies that differ in the organisation of the intron/exon boundaries. This leaves open the possibility that multiple visual pigments could arise by alternative splicing.

This work is supported by a BBSRC grant to Prof. M. O'Shea.

## 460.11

RETINAL TOPOGRAPHY AND PUTATIVE ULTRAVIOLET-SENSITIVE CONES IN ADULT SPAWNING SALMONID FISHES. C.W. Hawryshyn\*, L. Beaudet and J. Novales Flamarique. Dept. Biology, U. Victoria, P.O. Box 1700, Victoria, B.C. Canada V8W 2Y2

Ultraviolet-sensitive cones (UV cones) disappear from the retina during the course of ontogeny in several species of salmonid fishes. In juveniles, the putative UV cones occupy the corner position within the retinal cone square mosaic and are thus referred to as corner cones. In this project, we used conventional histological techniques to study the distribution, densities and dimensions of the different cone types in the retinas of wild adult spawning fishes from four species of salmonids (*Oncorhynchus nerka*, *O. keta*, *O. tshawytscha* and *O. mykiss*). Two areas of higher cone density were located in the ventral and the dorso-nasal retina. In contrast to previous hypotheses, corner cones were present over extensive areas. In all species studied, corner cones were found in the temporal retina, dorsally and ventrally. The distribution of these cones was not associated with the regions of higher cone densities. We also found some areas where the cone arrangement did not allow the corner cones to be identified. In these cases, however, single/double cone ratios were consistent with those found in areas containing corner cones. Experimental work has indicated the possibility of UV cones reintegrating the retina subsequent to their loss (Brownman and Hawryshyn, 1994, Vision Research, 11:1397-1406). Our results are consistent with these findings. Finally, the location of the putative UV cones with respect to the zones of higher photoreceptor density indicates that they are probably not used for visual tasks requiring higher visual acuity. ## 460.13

CALCIUM IS A REQUISITE FOR RHABDOM SHEDDING UNDER NATURAL LIGHTING IN *Limulus*. R.N. Links\* and S.C. Chamberlain. Department of Bioengineering & Neuroscience and Institute for Sensory Research, Syracuse University, Syracuse, NY 13244.

Photoreceptors of the lateral eye of the horseshoe crab, *Limulus*, shed their photosensitive membrane at dawn each morning under natural lighting. Protein kinase C (PKC) activators (phorbol esters and diacylglycerol (DAG) analogs), injected intraretinally, initiate rhabdom shedding in the absence of a light trigger. Inositol triphosphate (IP<sub>3</sub>), when injected simultaneously with DAG analog, decreases the concentration of DAG analog required for the triggering of rhabdom shedding by 10 times, implicating a Ca<sup>2+</sup>-dependent PKC isozyme in the cascade that communicates down to the intracellular machinery responsible for the breakdown of the rhabdom. Immunocytochemical evidence suggests a PKC  $\beta$ -like isozyme. DAG and IP<sub>3</sub> are produced naturally in the lateral eye in response to light (*Nature* 311: 160). If the PKC isozyme that mediates light-triggered rhabdom turnover is Ca<sup>2+</sup>-sensitive, then chelating the intracellular free Ca<sup>2+</sup> in the photoreceptor cells of the intact eye at dawn should inhibit activation of the PKC and thereby inhibit rhabdom shedding.

Adult male *Limulus*, maintained under natural lighting, were placed in complete darkness at sunset. One eye of each animal was injected intraretinally the following morning in darkness with 2.0 ml of 500  $\mu$ M BAPTA-AM, a cell-permeant Ca<sup>2+</sup> chelator, in Ca<sup>2+</sup>-free *Limulus* Ringer's. The other eye served as an untreated internal control. Retinas incubated with BAPTA-AM in the dark for 30-45 min prior to exposure to direct sunlight for 15 min displayed a marked decrease in rhabdom shedding (8.3% of the ommatidia shed their rhabdoms) in comparison with the control retinas in which >90% of the ommatidia shed. Eyes were fixed in direct sunlight 15 min after light onset by intraretinal injection of our standard EM fix. Rhabdom shedding in the BAPTA-AM loaded retinas was limited to fewer than 5 photoreceptors within each of the 8.3% of the ommatidia that displayed lamellar whorls of shed membrane along the internal margin of the rhabdom.

Inhibition of natural light-triggered rhabdom shedding by buffering the first morning light-induced rise in intracellular Ca<sup>2+</sup> implies that shedding requires Ca<sup>2+</sup>. Either the Ca<sup>2+</sup>-sensitive PKC presumed to mediate light-triggered shedding was not activated under these conditions, or a separate, unknown Ca<sup>2+</sup>-sensitive mechanism exists downstream from PKC in this cascade. We are currently developing PKC assays to investigate both of these possibilities. Supported by NIH EY-04446 and Syracuse University.

PHOTORECEPTOR MOSAIC AND ESTIMATE OF VISUAL ACUITY IN THE CEBUS MONKEY. Andrade da Costa, B.L.S. and J.N. Hokoç\*. Lab. Neurobiologia da Retina, IBCCF/UFRJ-RJ 21949-900, Brazil.

The retinal photoreceptor mosaic was studied in the diurnal New World primate *Cebus apella*. Parameters such as the spatial density of cones and rods, the geometry of the sampling array, the cone inner segment diameter and the inter-cone spacing were analyzed. Video-enhanced differential interference contrast optics (Curcio et al., 1987) were used to analyze retinas of six adult animals. The total number of cones and rods estimated was  $3.8 \pm 0.07$  and  $48 \pm 0.10$  millions, respectively. Peak fovea cone density averages  $152,023$  cones/mm<sup>2</sup> and decreases about 20-40 fold towards the periphery. The cone density increases in the retina's far periphery, adjacent to ora serrata, with a more pronounced peak in the nasal quadrant. The cone density is asymmetrical along the horizontal meridian but not along the vertical meridian. The highest rod densities are located along an elliptical ring at eccentricities between 3.5 to 5.0 mm of the foveola. Asymmetries in this density distribution were observed along the vertical and horizontal meridians. The cone center-to-center spacing obtained from the nearest-neighbor analysis reveals a minimal spacing at the foveola ranging of 2.2 to 3.5  $\mu$ m. Assuming a RMF= 197.3  $\mu$ m/degree and a hexagonal array, the Nyquist limit estimated in the foveola ranged from the 30.0 to 56.2 cycles/degree, decreasing about 2.5 X by 2 degrees of eccentricity. Compared to Old World primates the optical parameters of the *Cebus*' eye are scaled relative to *Macaca fascicularis*. However, in despite of differences in the resolution grain and in the strategies for capturing light, the majority of qualitative and quantitative aspects of the photoreceptor mosaic is more similar to that described in human. ## 460.14

USE OF A RETROVIRAL VECTOR WITH AN INTERNAL OPSIN PROMOTER TO DIRECT GENE EXPRESSION TO RETINAL PHOTORECEPTOR CELLS. M. Kido, K.A. Rich, G. Yang, E. Barron, D.B. Kohn\*, M.R. Al-Ubaidi\*, and J.C. Blanks\*. Doheny Eye Institute and Depts. Ophthalmology and Pediatrics, USC School of Medicine, Los Angeles, CA and \*Dept. of Ophthalmology, University of Illinois, Chicago, IL.

Viral-mediated gene transfer holds promise as a potential treatment for inherited retinal degeneration. We have evaluated the potential of a retroviral vector with an internal opsin promoter fragment to direct gene expression to retinal photoreceptor (PR) cells. Two recombinant retroviral vectors were prepared, each carrying a 1.4 kb fragment of the mouse opsin promoter, which was placed downstream from the neo<sup>R</sup> gene in the MMuLV-based vector GINA. One vector contained the bacterial lacZ gene, and the other the cDNA for mouse rod PR phosphodiesterase (PDE)  $\beta$ -subunit, each linked to the opsin promoter fragment. These vectors were tested for their ability to direct gene expression after infection of 3T3 cells, or of neonatal mouse retinal cells and explants in primary culture. Both lacZ and PDE  $\beta$ -subunit mRNA were expressed only at low levels in 3T3 fibroblasts. Northern analysis indicated that these were LTR-driven transcripts. Infection of neonatal mouse retinal cells or explants with BAG retrovirus, in which lacZ is driven by the viral LTR, resulted in expression in many cell types, while in contrast the opsin-lacZ retrovirus mediated the transfer and expression of the lacZ reporter gene specifically to PR cells. We are now evaluating the potential therapeutic effect of the opsin-PDE retrovirus following subretinal injections in newborn *rd* mice. **In conclusion**, the internal opsin promoter fragment appears capable of selectively directing gene expression to PR cells after retroviral-mediated gene transfer and may also allow for developmentally-appropriate timing of expression of PR-specific genes following gene therapy *in vivo*.

## AUDITORY SYSTEMS: CENTRAL PHYSIOLOGY V

## 461.1

Corticothalamic inputs to the rat medial geniculate body. Ed Bartlett\* and Phil Smith. Dept. of Anatomy and Neuroscience Training Program. University of Wisconsin Medical School, Madison, WI, 53706.

The auditory thalamus or medial geniculate body (MGB) receives a strong corticothalamic input. In visual and somatosensory systems, corticothalamic inputs arise from layer VI and V pyramidal cells which give rise, respectively, to small terminals on distal dendrites of thalamocortical cells and large glomerular-like terminals on primary dendrites in specific areas of "extralemiscal" thalamus. Our *in vivo* gross injections of neurobiotin in auditory cortex confirmed preliminary data (Welker and Rouiller, '91) that corticothalamic axons projecting to MGB give rise to small or large swellings. E.M. analysis showed that the small swellings are terminals on small dendritic profiles while the large swellings are glomerular, terminating on a large dendrite and its specializations. To determine the effects of these corticothalamic inputs we have begun to record intracellularly from rat MGB cells in an *in vitro* slice preparation using neurobiotin-filled sharp glass electrodes. In dorsal MGB cells, single shocks to corticothalamic afferents often caused a short latency (2-4 ms) epsp, followed in some cases by a long ipsp (50-600 ms). High shock strengths generated a second, slower epsp component. Simultaneous bath application of DNQX and APV abolished the epsp while DNQX or APV alone reduced the first and second components of the epsp, respectively. Bicuculline did not block the ipsp. Repetitive shocking of the corticothalamic input resulted in a prolonged depolarization lasting 2-5 s after stimulus offset which persisted in DNQX, APV, or both drugs simultaneously and could not be duplicated by repetitive brief depolarizing current pulses. Thus, corticothalamic inputs can activate rapidly acting ionotropic non-NMDA and NMDA receptors as well as an additional long lasting response. We are presently testing whether this lasting response occurs due to activation of postsynaptic metabotropic glutamate receptors at the small, layer VI synapses. Supported by NSF grant BNS-8901993 and NIH grant RO1-DC01999 to P. Smith.

## 461.2

THE CONTROL OF MEMBRANE POTENTIAL AND MODE OF SYNAPTIC TRANSMISSION IN AUDITORY THALAMUS. B. Hu\*, V. Senatorov, D. Mooney, and A. Miller. Loeb Research Institute, Ottawa Civic Hospital, Ottawa, ON, Canada, K1Y 4E9.

The primary and nonprimary auditory thalami display distinct modes of synaptic transmission *in vivo*. Neurons in the latter pathway are characterized by low-excitability, a slow synaptic response and a low responding speed (below 10 Hz). Here, we propose a theoretical model to account for this phenomenon.

We used the Mullins-Noda and Morton equations to model the resting membrane potential of medial geniculate body (MGB) neurons. Four families of membrane conductances were considered: the Na<sup>+</sup>/K<sup>+</sup>-ATPase, the voltage-dependent inward rectifying cation channel (I<sub>h</sub>), the muscarinic-gated potassium conductance and the leak potassium conductance. The K<sup>+</sup> and Na<sup>+</sup> membrane permeabilities/conductances were based on experimental data obtained *in vitro* (see this meeting). In this model, the "resting" membrane potential of nonprimary MGB cells was found to be below -70mV, 5-10mV more negative than in the primary pathway. This moderate membrane hyperpolarization changed the mode of synaptic activity in nonprimary cells in three ways: 1) It significantly reduced spontaneous or random spiking of the cell, thereby creating a low-excitability/low-noise state. 2) It allowed compounded EPSPs to activate an intrinsic, low-threshold calcium conductance (or LTS). This EPSP-LTS coupling gave rise to a slow, ramp-like membrane depolarization and a delayed bursting discharge. 3) It limited the responding rate of the cell to below 5 responses/s due partly to the LTS refractoriness. These features are comparable to the response properties of nonprimary thalamic neurons observed *in vivo* and may represent a non-stochastic mode of synaptic transmission for sensory event detection and integration. Supported by MRC of Canada

## 461.3

**DIFFERENTIAL RESTING MEMBRANE POTENTIAL REGULATION IN PRIMARY AND NONPRIMARY AUDITORY THALAMUS: INTRINSIC MECHANISM MEDIATED BY NA,K-ATPase.** V.Senatorov\* and Bin Hu. Loeb Research Institute, Ottawa Civic Hospital, Ottawa, ON, Canada, K1Y 4E9.

Primary (ventral) and nonprimary (dorsal) thalamic relay neurons of the rat medial geniculate body (MGB) exhibit a different average resting membrane potential *in vitro*, with the latter being 5-10 mV more hyperpolarized. To explore the underlying mechanism, we examined the role of Na,K-ATPase. Whole-cell patch clamp recordings were obtained from MGB neurons in explants from adult rats at 32°C. Bath application of Na,K-ATPase inhibitors strophanthidin or dihydropyridine at concentrations of 30-200  $\mu$ M for 10s produced a transient, dose-dependent inward current in 80% of cells ( $I_{Na,K}$  = 20-100 pA) or, under current clamp, a 2-10 mV membrane depolarization. The drug-evoked inward current displayed no clear voltage-dependence and was not abolished by various blockers acting on voltage-activated K<sup>+</sup> or Na<sup>+</sup> channels. A similar membrane inward current was induced after pump activity was inhibited using dialysis of the cell with pipette solution containing zero-[Na<sup>+</sup>] or following removal of extracellular K<sup>+</sup>. The average peak current induced by pump inhibitors was ~50% larger in the nonprimary MGB cells than that recorded in primary MGB neurons. Neurons exhibiting a larger pump current usually had a more negative resting membrane potential (the difference ranged from 5 to 10 mV).

Incubation of enzymatically dissociated MGB neurons with monoclonal antibodies against  $\alpha$ 1,  $\alpha$ 2 or  $\alpha$ 3 pump subunits revealed strong immunoreactivity for only the  $\alpha$ 3 subunit. Overall immunoreactivity was significantly stronger in dorsal MGB neurons than in their ventral counterparts. It appears, therefore, that a gradient of Na,K-ATPase expression may be partly responsible for the resting membrane potential gradient between ventral and dorsal MGB pathways. ## 461.5

**ELEVATION SENSITIVITY OF SINGLE NEURONS IN THE MEDIAL GENICULATE BODY (MGB) OF THE CAT.** P.Poirier\*, F.K.Samson and T.J.Jimig. Dept. of Physiology, Kansas Univ. Med. Ctr., Kansas City, KS, 66103.

Elevation tuning of high-frequency MGB neurons (N=70; BF:4-37kHz) that derive their azimuth sensitivity from monaural spectral (MD) or binaural disparity (BD) cues was studied in barbiturate-anesthetized cats. Noise bursts that varied in azimuth, elevation and SPL were presented throughout the frontal field, and spatial receptive fields (SRFs; N=48) were defined as areas in which responses exceeded 50% of maximum. An elevation function, averaged over SPL, was obtained for each cell at a preferred azimuth (response  $\geq$  75% at 0° elevation), and units with modulation  $\geq$ 75% were classified as elevation sensitive. MD and BD cells differed in SRF location, shape, size and in elevation sensitivity. Most MD cells had focal SRFs that were restricted in azimuth and elevation. Almost all MD SRFs became smaller with increasing SPL. A great majority of MD cells was elevation sensitive, and as a group MD cells were more narrowly tuned than BD cells. The elevation tuning of MD cells was similar under monaural and binaural conditions showing that it derived from monaural cues. SRF size was significantly smaller for MD than for BD cells. BD cells comprised three sub-groups. SRFs of BD-EI cells covered one hemifield, typically the contralateral one. BD-FAC cells, characterized by binaural facilitation, had SRFs that were located either on the midline (BD-MID) or lateral to it (BD-LF). SRF size was significantly greater for BD-LF than for BD-EI or BD-MID groups (BD-LF > BD-EI > BD-MID). In contrast to MD cells, SRF size of most BD units expanded or was unaffected by increasing SPL. The vast majority of BD cells was elevation insensitive, and the sensitive ones were broadly tuned. These results indicate that MD cells are more sensitive and more narrowly tuned to elevation than BD cells, and that they derive elevation tuning from monaural spectral cues (supported by FCAR, FRSQ and NIDCD #DC00173).

## 461.7

**PERIODICITY PITCH AND PARTY EFFECT: TEMPORAL PROCESSING, INTRINSIC OSCILLATIONS AND BINDING IN THE AUDITORY SYSTEM** G.Langner\*, Zoological Institute of THD, 64287 Darmstadt, Germany

An important clue for detection of acoustic signals in noisy environments (e.g. cocktail parties) is periodicity. Signals with the same periodicity have the same pitch, independent of waveform and spectral content. Broadband signals are typical for human and animal communication and are decomposed by the cochlear frequency filter in different components. The resulting binding problem is comparable to that in visual perception. The present paper provides evidence for the hypothesis that the same temporal processing-synchronized neuronal representations, intrinsic oscillations and neural integration delays followed by coincidence mechanisms- underlies pitch perception and auditory binding. Due to their oscillatory and integrative membrane properties, chopper and pauser neurons in the cochlear nucleus provide synchronized and delayed responses to periodic envelopes. Their convergence on coincidence neurons in the auditory midbrain transforms temporal into rate information. Low frequency neurons were found which may contribute to binding by integrating over a broad frequency range. The transformation of the temporal into a rate code is supplemented by a transformation into a spatial code with the result that periodicity information is represented at the level of the midbrain orthogonal to the tonotopic map. Since temporal information about high modulation frequencies is essentially lost in the midbrain, the auditory cortex is provided predominantly with spatial information. Correspondingly, frequency and periodicity pitch are represented in orthogonal maps in the forebrain of mynah bird. Furthermore, magnetoencephalographic investigations provided evidence for an orthogonal representation of pitch and frequency information in the auditory cortex of human subjects.

## 461.4

**DIFFERENTIAL RESTING MEMBRANE POTENTIAL REGULATION IN PRIMARY AND NONPRIMARY AUDITORY THALAMUS: EXTRINSIC MECHANISM MEDIATED BY MUSCARINIC RECEPTOR** D.M.Mooney\* and Bin Hu. Loeb Research Institute, Ottawa Civic Hospital, Ottawa, ON, Canada, K1Y 4E9.

To determine the physiological role of cholinergic reticular input to primary (MGv) and nonprimary (MGd) auditory thalamus, we examined the membrane effect of (+)muscarine *in vitro*. Bath application at concentrations of 20 to 90  $\mu$ M for 20 sec produced membrane depolarization in MGv neurons (15/20). In contrast, application of muscarine to MGd cells at the same concentrations caused a membrane hyperpolarization (12/13). The membrane depolarization response in MGv cells was associated with an average 21% reduction in membrane conductance (n=12), whereas the membrane hyperpolarization in MGd cells was accompanied by an average 15% increase in membrane conductance (n=11). Both muscarinic membrane depolarization and hyperpolarization were unaffected following blockade of synaptic transmission by TTX; they were reversibly blocked by pirenzepine (1 to 10  $\mu$ M) when moderate concentrations (10 to 30  $\mu$ M) of muscarine were applied. Preliminary evidence suggests that the hyperpolarizing effect was mediated by the opening of a membrane potassium conductance. The effects of muscarine on MGv/d neurons were further examined through extracellular recordings of synaptically-evoked responses. In MGv, the burst synaptic response elicited by stimulation of collicular input was largely abolished by muscarine (22/32). In contrast, bursting synaptic response in the majority of MGd cells remained unblocked (21/32). Hence, muscarinic receptor activation seems capable of regulating the resting membrane potential and the firing mode of thalamic relay neurons in a pathway-specific manner. Supported by MRC of Canada.

## 461.6

**EFFECT OF BASELINE LEVEL ON SENSITIVITY TO RATE OF RISE OF MEDIAL GENICULATE NEURONS IN THE SQUIRREL MONKEY.** J.E. Olsen\*, Lab. Neurophysiology, NIMH, Poolesville, MD 20837.

The responses of most neurons in the medial geniculate (MGN) to a broadband noise burst are determined by rate of rise (peak amplitude/rise time; Olsen, *Soc. Neurosci. Abstr.* 20: 321, 1994). This study examines the effect of baseline level on the responses of MGN neurons to linear amplitude increments of a broadband noise. Baseline level (0-73 dB SPL), step amplitude (6-24 dB re. baseline), and step rise time (3-96 ms) were varied independently. Extracellular recordings were made from 42 MGN neurons in halothane-anesthetized monkeys. For most neurons, response probability increased as a linear function of the step's rate of rise, and was independent of peak level (baseline level + step amplitude). Responses were 100% modulated by rate of rise, regardless of baseline amplitude. At low baseline amplitudes (generally below 40 dB SPL), there was little effect of baseline amplitude on threshold rate of rise. At higher baseline amplitudes, threshold rate of rise increased at least 1 dB per dB increase in baseline level. The rate of rise at saturation also increased, such that the range of rates over which neural responses were modulated increased linearly with baseline amplitude. Thus, MGN neurons signal amplitude increments over a wide range of baseline levels with no loss of responsiveness. The data suggest that baseline level is represented by an adaptation level in these neurons.

## 461.8

**MICROSTIMULATION OF AUDITORY CORTEX FOR A POTENTIAL NEUROPROSTHETIC USING A 100-ELECTRODE ARRAY.** Patrick J. Rousche\*, Craig T. Nordhausen, and Richard A. Normann, Moran Laboratories, Department of Bioengineering, University of Utah, Salt Lake City, Utah, 84112, USA

We propose that a cortical auditory prosthetic could be based upon intracortical microstimulation of auditory cortex using an array of penetrating electrodes. This approach hinges upon 3 key issues: tonotopicity, electrical activation, and chronic threshold stability. To address these issues, we have conducted neural recording and stimulation experiments using the Utah Intracortical Electrode Array in the feline primary auditory cortex (AI).

The Utah array consists of 100, 1 mm platinum-tipped electrodes positioned in a 10x10 matrix, with an interelectrode spacing of 400  $\mu$ m. This array can be used acutely, for recording from all one hundred electrode sites or chronically, where 10 electrodes are accessed through a percutaneous connector.

**Tonotopicity:** Acute recording studies with this array have verified the existence of a tonotopic map in cat AI over an investigated frequency range of 5-35 KHz. Characteristic frequencies were recorded from an average of 85 of the 100 electrode sites in each of 4 preparations. **Electrical activation:** Cats implanted in AI with a chronic electrode array were trained to identify the presence or absence of auditory stimuli. Trials were then introduced in which AI was electrically stimulated in the absence of external auditory stimuli. Minimum current levels required to evoke an auditory detection response ranged from 20-120  $\mu$ Amps (biphasic, cathodic first, current pulses of width 150  $\mu$ sec delivered at 250 Hz for .6 sec, total charge from 3-18 nC). **Chronic stability:** Behavioral responses to stimulation were obtained up to 8 weeks post-implant. However, threshold current and thus charge levels were not constant from electrode to electrode or from week to week. If chronic stability can be assured with electrical activation through tonotopically placed electrodes, then a cortical auditory prosthesis may be possible.

## 461.9

**THE FUNCTIONAL ORGANIZATION OF THE BARN OWL AUDITORY FOREBRAIN (FIELD L).** Y.E. Cohen\* and E.J. Knudsen. Dept. Neurobiology, Stanford Univ. School of Med. Stanford, CA 94305.

The barn owl forebrain is critical for certain aspects of sound localization behavior. We are examining how auditory spatial information is organized in the primary forebrain auditory area, Field L, the avian analogue of mammalian auditory cortex. In particular, we are interested in determining whether regions of Field L are specialized to process binaural localization cues, such as interaural phase differences (IPD) and interaural level differences (ILD).

Neuronal activity in Field L was recorded extracellularly during dichotic presentation of digitally synthesized noise or tone bursts. Field L contains at least two functionally distinct regions: (1) a tonotopic region located rostrally and (2) a non-tonotopic "belt" region which adjoins the tonotopic region at its caudal and medial borders. The tonotopic region was distinguished by a caudorostral progression of frequency tuning, sharp tuning for frequencies above 3 kHz, and unit tuning for both ILD and IPD. In contrast, units in the non-tonotopic belt region often had complex frequency tuning and were tuned very rarely for both ILD and IPD.

The auditory properties of the tonotopic region suggest that it is specialized for processing spatial information. The properties of units in the belt region suggest that it may process non-spatial features of the auditory scene such as vocalizations.

Supported by grants from the NIH and the Bank of America-Giannini Foundation.

## 461.11

**ELECTRICAL STIMULATION OF AI MODULATES NEURONAL RESPONSES TO PURE-TONES IN THE CAT MEDIAL GENICULATE BODY** J. He<sup>1</sup>\*, T. Fujimi<sup>1</sup>, T. Hashikawa<sup>1</sup>, E. G. Jones<sup>1,2</sup>. <sup>1</sup>Lab. for Neural Systems, Frontier Research Program, The Institute of Physical and Chemical Research (RIKEN), Saitama 351-01, Japan and <sup>2</sup>Dept. of Anatomy and Neurobiology, University of California, Irvine, CA 92717.

The corticothalamic projection has been suggested to modulate information processing in the thalamus. We studied the effect of corticofugal modulation of neuronal responses to sound stimuli in the medial geniculate body (MGB) by electrical activation of the primary auditory cortex. Single- and multi-unit responses to pure-tones were recorded in the ventral nucleus of the MGB in sodium pentobarbital anesthetized cats. Pulse burst electrical stimulation was applied to different sites around a single isofrequency band or to different isofrequency bands in AI. Tuning curves in firing rate at varied sound intensity were recorded before and during AI stimulation. The corticofugal connection between AI stimulation sites and the recording sites was confirmed histologically in anterograde tracer experiments.

Stimulation of the cortex enhanced the responses of most MGB neurons at the same best-frequency site to their best frequency and sharpened their tuning curves in some cases. Stimulation of different isofrequency bands inhibited the neuronal responses to their best-frequencies and shifted the tuning curves of some MGB neurons. The corticofugal modulation effect was stronger to low-intensity sound stimuli than to high-intensity sound stimuli.

The results suggest the presence of a variety of modulations of responses in thalamic neurons by the corticothalamic fiber system.

## 461.13

**REPRESENTATION BY SPIKE COINCIDENCE IN PRIMARY SENSORY CORTEX.** R.C. deCharms, C.E. Schreiner\* and M.M. Merzenich. Keck Center for Integrative Neuroscience, UCSF, San Francisco, CA 94143.

These experiments investigated the hypothesis that the coincident firing of large populations of cortical neurons may constitute a fundamental element of primary cortical stimulus representation, particularly relevant during continuous stimuli. Neurons in the primary cortical areas AI, SI and VI respond in a predominantly phasic fashion, which is strikingly mismatched to the ongoing percepts evoked by continuous stimuli. We therefore explored whether coincidence-based coding is being employed, and whether it can be clearly dissociated from firing rate coding using these stimuli.

We recorded single or multiple supragranular neurons from groups of 2-6 sites at once (at .1-.5mm separations) in the primary auditory cortex of three pentobarbital anesthetized common marmoset monkeys, using conventional microelectrode recording methods and spike sorting.

The mean firing rate time course of many locations is nearly identical following a brief (50msec) tone burst as during a four second continuous tone; there is typically little or no information about the ongoing stimulus present in individual firing rates during the tonic phase of the stimulus. However, spikes from pairs of locations with no tonic firing rate change often very reliably indicate the presence of a stimulus during this time by the degree of spike coincidence from the two locations. Modulation of spike coordination during the tonic phase of continuous stimuli satisfies a number of additional criteria of a representational system: 1) it is stimulus specific and frequency tuned for each pair of locations; 2) it can increase or decrease from background depending upon the stimulus presented; 3) it can follow the time course of long stimuli when individual firing rate does not; and 4) it forms an organized topographic map across the cortical surface. (Funded by NIH grant NS-10414; NSF Graduate Fellowship).

## 461.10

**DOES BINAURAL INTERACTION INCREASE FREQUENCY SELECTIVITY IN GUINEA PIG AUDITORY CORTEX ?**

K. Fukunishi\*, N. Murai, B. Tokioka. Advanced Research Laboratory, Hitachi Ltd., Hatoyama, Saitama, 350-03 Japan

The relation between the tonotopic arrangements and the binaurality in the guinea pig auditory cortex AI was investigated by using optical recording with a voltage sensitive dye (RH795). Spatio-temporal neural response pattern to acoustic stimuli of tone bursts of 4 kHz and 8 kHz with different sound intensities on each ear were measured in AI of the anaesthetized animal and compared. That is, topographic imaging of neural response to interaural intensity differences (IIDs) was evaluated in relation with the tonotopic arrangements in AI of the left hemisphere of the animal. The tonotopic arrangements appear in the form of island-like clusters that become larger with higher peak amplitude with increasing sound pressure level (SPL), but stable regarding the peak amplitude position (as discussed before at the previous meetings). These clusters of the responses were weakened, contracted and delayed for ipsilaterally dominant stimuli, the SPL at the ipsilateral ear being stronger than that at the contralateral ear compared to the response to the same SPL as both ears. On the other hand, the responses for contralaterally dominant stimuli showed shorter latencies but similar amplitude as the control with similarly equal SPL. The distribution of the time delay of the correlation functions between the responses for the contralaterally dominant stimuli or of the ipsilaterally dominant stimuli and the responses for the binaural equal intensity stimuli at 128 recording pixels showed significantly larger in the rim of the tonotopic cluster. Considering the longer delay time of the neural responses to contralateral stimulation as compared to ipsilateral stimulation and predominant inhibitory inputs from ipsilateral ear, the results indicate that the topographic organization of neural sensitivity to IIDs account for increased tuning sensitivity for coding of sound frequencies. Thus, another important aspect related to frequency tuning of the binaural interaction of the primary auditory cortex in the guinea pig is demonstrated.

## 461.12

**MONAURAL AUDITORY DEPRIVATION FROM ONSET OF HEARING AFFECTS DEVELOPMENT OF AUDITORY CORTICAL FIELDS IN THE MONGOLIAN GERBIL (*MERIONES UNGUICULATUS*)**

I.W. Stürmer\* and H. Scheich. Federal Institute for Neurobiology (IFN), Brennekestr.6, D-39118 Magdeburg, Germany.

In auditory cortex (AC) of the Mongolian Gerbil the primary auditory field (AI), the anterior auditory field (AAF) and additional activity in an intermediate zone (IZ) between AI and AAF could be distinguished at P 15 using the fluoro-2-deoxyglucose (2DG) mapping technique. Tonotopic activity in AI and AAF appeared at P 19. Here, we investigated the effects of preauditory induction of peripheral hearing loss on the development of activity pattern from P 19 to P 27. We prevented development and opening of the left external ear canal surgically under anesthesia at P 9. Auditory deprivation could be maintained for life or reversed by surgical opening of an artificial external ear canal.

2DG-Experiments were performed at P 19 and P 27 in alert animals deprived since P 9. After injection of 9  $\mu$ Ci <sup>14</sup>C-fluoro-2-deoxyglucose i. p., gerbils were stimulated for 45 minutes with tones continuously alternating between 1 and 2 kHz (250 ms each frequency, 70 dB SPL free field). The left external ear canal was either closed (END), or it was quickly reconstructed under anesthesia 15 minutes before the 2DG injection, allowing air transduction during acoustical stimulation (REC). Control groups consisted of gerbils which received foam ear plugs in the left external ear canal 15 minutes before 2DG injection (PLU) and animals with normal hearing abilities (NOR).

At P 19, monaurally deprived animals (END, REC) showed no obvious asymmetry in metabolic activity of AI and AAF but a frequent lack of IZ in the right AC. Left and right secondary auditory fields showed no or low activity. Monaural deprivation may thus retard the functional maturation of some cortical fields in both hemispheres. Effects of monaural deprivation on the contralateral (right) AC could be detected in END and REC at P 27. Right AI showed increased metabolic activity as well as expansion of its rostrocaudal extent. Metabolic activity in IZ could be identified in the left AC but was missing in the right AC. PLU animals in contrast showed more or less reduced activity in right AC.

Obviously, imbalance of auditory input, due to preauditory monaural deprivation, interferes with normal development of auditory cortex. Low metabolic activity in secondary auditory fields at P 19 may indicate a role in processing of binaural input. Increased activity in AI and absence of activity in IZ contralateral to the deprived ear at P 27 may be due to disturbed balance of excitatory and inhibitory mechanisms after a critical period.

## 462.1

**FUNCTIONAL ACITIVATION OF AUDITORY CORTEX: A PET STUDY IN JAPANESE MACAQUE.** T. Hashikawa<sup>1</sup>, J. He<sup>1</sup>, T. Kakiuchi<sup>2</sup>, H. Tsukada<sup>2,3</sup>, M. Molinari<sup>1</sup>, and E. G. Jones<sup>1,4</sup>. <sup>1</sup>Lab. for Neural Systems, RIKEN, Wako, Japan, <sup>2</sup>Centr. Res. Lab., Hamamatsu Photonics, Shizuoka, Japan, <sup>3</sup>Subfemtomole Biorecog. Proj., JRDC, Osaka, Japan, and <sup>4</sup>Dept. of Anat. and Neurobiol., Univ. of California, Irvine, CA 92717.

The primary auditory cortex of Japanese monkey is located in the center of the supratemporal plane of the superior temporal gyrus, being coincident with an annectant gyrus typical of this species, and characterized by dense immunostaining for a calcium binding protein, parvalbumin (Hashikawa et al., 1994, Soc. Neurosci. Abstr., 20). To evaluate its functional state in vivo, tonal stimuli were applied to anesthetized monkeys and the activated regions were examined by positron emission tomography (PET) using H<sub>2</sub><sup>15</sup>O to measure regional cerebral blood flow. In comparison with activities in the control state (white noise stimulation), pure tone stimulation activated multiple cortical regions, including those on the supratemporal plane, the posterodorsal inferotemporal cortex, the posterior lip of the lunale sulcus, and the dorsal prefrontal cortex. The central core of the activated region varied when a coo sound, a species-specific communication sound, was used as a stimulation. Coo stimulation produced activation sites in peripheral regions of the supratemporal plane, e.g., the anterior lip of the superior temporal sulcus and the medial wall of the annectant gyrus, as well as in the central portion of the plane. In contrast, reversed (nonsense) coo sounds evoked stronger activation in the insular and ventral prefrontal cortex than on the supratemporal plane.

The present results confirm the anatomically defined auditory regions on the supratemporal plane and suggest that extensive cortical regions are involved in auditory information processing having potentially differentiated functions.

## 462.3

**A NEUROPHYSIOLOGIC CORRELATE OF COMODULATION MASKING RELEASE (CMR).** C. King, T. Nicol, T. Carrell, T. McGee and N. Kraus\*, Auditory Neuroscience Lab., Northwestern University, Evanston, IL 60202.

Hall et al. (JASA 76:50-56, 1984) first demonstrated an increase in the release from masking (i.e. better threshold) for a signal centered in amplitude modulated (AM) noise as the noise bandwidth is widened. This increase was seen even when the bandwidth was wider than the critical band for the signal. This effect has been termed comodulation masking release (CMR) because the key element for obtaining the release from masking is the correlated or coherent AM rates of noisebands. It is thought that the auditory system can use CMR to improve the detectability of signals in noisy listening situations.

There have been numerous human psychophysical experiments examining the nature of CMR, but to date, nothing has been published regarding the possible underlying neurophysiology. The purpose of this study is to demonstrate a neurophysiologic correlate in a guinea pig model to the behavioral psychophysical measures of CMR, using the mismatch negativity (MMN), an auditory evoked potential. The MMN is seen as a negativity in the response to an infrequent stimulus presented in a train of frequent stimuli (an oddball paradigm).

In this experiment, two 75 dB, 400 Hz-wide noisebands centered at 2 kHz and 2.7 kHz were comodulated at 30 Hz for the infrequent stimulus in the oddball paradigm. For the frequent stimulus, the noiseband centered at 2 kHz was modulated at 30 Hz and the noiseband centered at 2.7 kHz was modulated at 51 Hz (conflicting modulation). In an experimental condition, a 2 kHz tone was added to both the frequent (conflicting modulation) and the infrequent (comodulation) stimuli. This 2 kHz tone was set at threshold for the conflicting modulated stimulus. (This threshold was determined earlier using human subjects in a psychophysical task.) In a control condition, no tone was present in order to demonstrate that any differences seen in the experimental condition were due to CMR and not to differences in the comodulated and conflicting modulated noisebands themselves.

Epidural electrodes were placed on anesthetized albino guinea pigs over the primary auditory cortex and over the posterior midline. Previous work in our lab has shown that the posterior midline is the best site for recording the MMN in guinea pigs. Results revealed a mismatch negativity at the midline recording site for the experimental condition, but not for the control condition. Therefore, differences seen in the experimental condition appear to represent a neurophysiologic reflection of CMR.

## 462.5

**SPATIO-TEMPORAL ANALYSIS, NEOCORTICAL EEGs AND BEHAVIORAL ANALYSIS OF CONDITIONED RABBITS.**

J.L. Chin, D.R. Graham-Squire, S.N. Truong, W.J. Freeman, and E. Marg\*, Dept. of Molecular and Cell Biology, School of Optometry, University of California, Berkeley CA 94720.

Rabbits with 8x8 epidural arrays (0.5-0.8 mm spacing) on the auditory cortex were conditioned to respond to stimuli in a classical aversive paradigm. Stimuli consisted of short tones of various frequencies. 64 EEG traces were recorded during a 6 second period. Respiratory waves were simultaneously recorded using a pneumograph belt placed around the trunk. Changes in respiration were used as the conditioned response to the conditioned stimulus. Patterns of behavioral responses were followed and probabilities of a response occurring were calculated to determine whether habituation to the stimulus was achieved. The EEG traces were subsequently classified into groups based on stimulus type and order of presentation. Root mean square amplitude was calculated to represent each spatial pattern by a 64x1 column vector. Euclidean distance in 64 space was used to classify spatial patterns of those groupings. We conclude that distinct spatial patterns existed for each presented stimuli. Comparisons of control periods within sessions did not separate but between sessions, control periods displayed sustained differences across days, indicating long term changes. Analysis of behavioral responses yielded a gradual decrease in the response probability as stimuli presentations continued. We wish to determine whether spatial patterns change with habituation and whether changes in behavioral responses reflect prior changes in the cortex.

## 462.2

**A COMPARISON OF EVOKED POTENTIALS AND HIGH FREQUENCY (GAMMA-BAND) OSCILLATING POTENTIALS IN RAT AUDITORY CORTEX.** D.S. Barth\* and M.N. Franowicz, Dept. of Psychology, Univ. of Colorado, Boulder, CO 80309.

Middle latency auditory evoked potentials (MAEP) and steady-state (40-Hz) evoked potentials, as well as spontaneous and click-evoked gamma-band oscillations, were recorded from 15 lightly anesthetized rats using an 8x8 electrode array covering auditory cortex and adjacent areas to determine and compare the spatiotemporal distributions of these four phenomena.

Results indicate that both the MAEP complex, and the steady-state 40-Hz response with its associated slow potential, are highly stereotyped in lightly anesthetized rodent cortex. Their spatiotemporal distributions are probably determined in large part by asynchronous activation of parallel thalamocortical projection systems.

No direct link was found between either the MAEP or the steady-state 40-Hz response to spontaneous or evoked gamma-band oscillations in auditory cortex. A notable spatiotemporal variability of gamma oscillations, with rapid spread within areas 41, 36 and 20, suggests a neural generator within the cortex independent of direct thalamocortical pacemaker influence. This hypothesis is further supported by the observation that neither the spatial distribution nor the phase of ongoing gamma oscillations were influenced by auditory stimulation. However, post-inhibitory enhancement of gamma oscillations following auditory stimulation may indicate a role in auditory information processing that is not reflected in either a stimulus specific spatial distribution or phase relationship.

## 462.4

**THE P13 MIDDLE LATENCY AUDITORY EVOKED POTENTIAL IN A RAT MODEL OF ANXIETY USING CHRONIC CORTICOSTERONE INJECTION.** H. Miyazato, R.D. Skinner\* and E. Garcia-Rill, Dept. of Anatomy, University of Arkansas for Medical Sciences, Little Rock, AR 72205.

The human P1 (or P50) middle latency auditory evoked potential, which is characterized by: 1) sleep state dependence, 2) rapid habituation, and 3) blockade by scopolamine, is a useful tool in assessing psychiatric disorders. Post-traumatic stress disorder (PTSD) patients have markedly decreased habituation of the P1 potential (Gillette, et al., 1995). Also, preliminary results suggest a decrease in locus coeruleus (LC) cell number in post-mortem human brains from anxiety disorder patients (Freeman, et al., 1993). Because of the link between PTSD and stress, we studied the effects of chronic corticosterone injection on the P13 potential, which has been demonstrated to be a rat model of the human P1 potential (Miyazato, et al., Brain Res. Bull. 37:247-255, 1995).

Under anesthesia, adult male Sprague-Dawley rats were implanted with epidural screws at the vertex (Vx) and the auditory cortex (ACx). Three weeks after surgery, rats were injected (s.c.) daily with corticosterone 5mg (CORT) or vehicle (CTL) and recordings were performed weekly using a paired click paradigm (ISI=0.25 and 1.0sec, 0.03Hz stimulation rate). Results showed that CORT markedly decreased habituation of the Vx P13 potential. After four weeks of injections, there was no significant difference between CORT and CTL rats at an ISI of 0.25sec. However, at an ISI of 1.0sec, CORT animals showed a 101±15% amplitude in the P13 potential following the second of two click stimuli, compared to a 25±19% amplitude in CTL animals (p<0.0001). After nine weeks of injections, CORT animals showed 95±21% (vs CTL 6±8%, p<0.0001) and 114±21% (vs CTL 22±13%, p<0.0001) amplitude at ISIs of 0.25 and 1.0sec, respectively. In contrast to the dramatic change in the P13 potential, the ACx Pa potential showed no changes after CORT.

These preliminary results suggest that cholinergic mesopontine neurons (which participate in the manifestation of the P13 potential) undergo decreased habituation following chronic corticosterone injection, possibly due to decreased inhibitory LC input. Supported by USPHS Grant NS20246.

## 462.6

**CHRONIC MICROELECTRODE INVESTIGATIONS OF HUMAN AUDITORY CORTEX.** M. Howard\*, J. Volkov, M. Ollendieck, H. Damasio, P. Abbas, C. Brown, B. Gantz, Univ. of Iowa Sch. of Medicine, Iowa City, IA 52242.

A new method has been developed which enables investigators to chronically record individual neuron activity from MRI defined anatomical locations in the human brain. Hybrid depth electrodes (HDE) are stereotactically placed in patients requiring depth electrode (DE) evaluation as part of their treatment for medically intractable epilepsy. Each HDE has standard clinical recording sites and eight pairs of high impedance bipolar microelectrode recording sites positioned along the shaft. Using a HDE does not increase risk to the patient. To date, eleven HDEs have been placed in three patients. Single unit activity was recorded from each of the microelectrode recording contacts for periods ranging from 5 to 14 days. Post-implantation stereotaxic imaging identified recording site locations.

One HDE was positioned along the length of a patient's right transverse temporal (Heschl's) gyrus (HG). Evoked potentials (EP) and single-unit recordings were obtained as clicks and tone bursts were presented to the left ear. EPs demonstrated an initial cortical response 15 ms following onset of sound stimuli, and the magnitude of the EPs were frequency dependent. A tonotopic pattern was observed with best frequencies systematically increasing as more medial-caudal recording sites were sampled. Single units from multiple recording sites along the HDE shaft displayed frequency dependent responses to tones. Responses were predominantly tonic in nature and single unit best frequencies displayed a tonotopic pattern similar to that observed with EPs. These results unambiguously demonstrate a tonotopic organization within human auditory cortex similar to that reported in monkey (Merzenich and Brugge, 1973). This new method appears suitable for future investigations of more complex issues related to auditory cortex plasticity.

## 462.7

A COMPARISON OF LAMINAR EVOKED POTENTIALS, STEADY-STATE (40 HZ) EVOKED POTENTIALS AND HIGH FREQUENCY (GAMMA-BAND) OSCILLATING POTENTIALS IN RAT AUDITORY CORTEX. B. BRETT\* AND D.S. BARTH Dept. of Psychology, University of Colorado, Boulder, Co. 80309

Mid-latency auditory evoked potentials (MAEPs), steady-state (40-Hz) evoked potentials, and spontaneous gamma-band oscillating potentials were recorded from lightly anesthetized rats using a 16 channel laminar electrode array positioned in area 41 to compare the spatiotemporal characteristics of these potentials in the cortical lamina.

Current source density (CSD) and principle component analysis (PCA) of MAEPs recorded in the cortical lamina provide evidence of dynamic interactions between supragranular and infragranular neuronal subpopulations in primary auditory cortex. Analysis of steady-state 40 Hz evoked potentials indicates that these potentials exhibit dynamic interactions similar to those of MAEPs, suggesting that the same populations of cells which produce MAEPs also produce steady-state 40 Hz evoked potentials. Analysis of spontaneous gamma-band oscillations indicates that these potentials display different spatiotemporal characteristics.

We propose that MAEPs and steady-state 40 Hz evoked potentials result primarily from the asynchronous activation of parallel thalamocortical projections from the medial geniculate (MG), while spontaneous gamma-band oscillations have a more complex neurogenesis which may involve different thalamocortical and intracortical circuitry.

## 462.9

THE DECOMPOSITION OF EVOKED SCALP POTENTIAL DATA INTO PARAMETRIC EQUIVALENT DIPOLE COMPONENTS: APPLICATION TO THE AUDITORY P50. H. L. Gillary\* Department of Physiology, University of Hawaii, Honolulu, HI 96822.

A procedure has been developed to represent multi-channel averaged evoked scalp electrical potential data in terms of potentials generated on a homogeneous spherical volume conductor by overlapping parametric spatio-temporal equivalent dipole current sources designed to facilitate inferences about real intracranial sources. For the simplest (8 parameter) dipole component (DC), the magnitude function of time is Gaussian and the location and orientation constant over time; added parameters can allow rotation and a more flexible magnitude function. The data are first segmented at time points of minimum variance and constrained DCs successively fitted to them using a simplex algorithm to minimize residual variance. Ultimately each data segment is represented as the sum of a few principal DCs with maxima within the segment, the tails of DCs in adjacent segments, and a residual.

The procedure has been applied to segments of 14-channel band-pass filtered auditory evoked potential data that include the P50 wave, obtained using a protocol in which two clicks 500 ms apart were presented every 7-8 s. The respective responses to the two clicks could differ markedly in topography. For example, for one subject the P50 segment to click 1 was well explained primarily by one principal DC whereas that to click 2 required two quite dissimilar principal DCs (one of which, although smaller in amplitude, showed marked similarity to the major DC for click 1) and displayed a much larger residual that resisted further DC decomposition. The procedure, readily modified with regard to head and current source model and minimization algorithm, shows promise as a general means to summarize and explore scalp potential dynamics, and to identify components that correlate with specific clinical conditions.

## 462.11

BINAURAL AND MONAURAL SOUND LOCALIZATION IN ACALLOSA HUMAN LISTENERS. N. Lessard, F. Lepore\*, P. Poirier, J. Villemagne and M. Lassonde, Groupe de Recherche en Neuropsychologie Expérimentale, Univ. de Montréal, Canada.

In order to elucidate the callosal involvement in sound localization in free-field space, the present study examined response accuracy to monaurally and binaurally presented auditory targets in acallosal subjects (Ss). In these Ss, binaural cues to localization ( $\Delta I$ ,  $\Delta T$ ) are integrated at the cortical and subcortical level without the additional support of the telencephalic commissure. Because acallosal Ss developed with this reduced source of binaural activation of cortical cells, moreover, they might have perfected their ability to use monaural cues to sound localization. This hypothesis was tested by examining localization performance using monaural stimulation. Three Ss with callosal agenesis and 14 controls were asked to localize broad band noise bursts (BBN) of fixed intensity in the horizontal plane in an anechoic chamber. BBN were delivered randomly through 16 loudspeakers, which were mounted at 10° intervals on a calibrated perimeter frame. Two conditions were tested: i) localization of a fixed-sound source; ii) localization of the beginning and the end of a simulated moving sound. Listeners had to report the apparent stimulus location by pointing with the index finger the position on the sound perimeter. The results indicated that there was a small tendency for the acallosal Ss to be somewhat less accurate than the controls in binaural localization. However, under monaural testing conditions, the acallosals performed significantly better than the controls. The latter data suggest that because of their lack of corpus callosum, acallosal Ss compensate for their reduced access to cortical binaural cues by making greater use of monaural cues.

## 462.8

AUDITORY MISMATCH NEGATIVITY EVOKED RESPONSES HAVE BOTH TEMPORAL AND FRONTAL GENERATORS. R.E. Greenblatt, D. Voreades Source/Signal Imaging, San Diego CA 92102, H. Gould, Memphis Univ. Memphis TN 38105 and D.F. Rose\*, LeBonheur Children's Medical Center and Univ. Tenn., Memphis TN 38105.

Mismatch negativity (MMN) is observed in scalp electrical recordings in response to a rare deviant tone following a sequence of standard tones, and is thought to be an electrical correlate of auditory novelty detection. In order to estimate the cortical generators for this and other components of the auditory evoked potential, we have obtained 64 channel electrical recordings from 10 normal adult subjects for whom volumetric magnetic resonance images were also available.

For each subject, tone burst stimuli sequences were presented unilaterally with identical standard tones, and deviant tones (10%) which varied either in duration, intensity, or pitch. Data were averaged off-line to produce artifact free estimates of the evoked responses to the standard and deviant tones. The MMN signal was then obtained as the difference of the deviant response less the standard response. Source estimates were obtained from the voltage data using generalized linear inverse techniques with Laplacian regularization. Head shape information was obtained from digitized electrode locations and used as the basis for a three shell forward solution.

Source estimates from individuals show some variation, but certain general features are apparent. Sources derived from the N1 peak have a contralateral maximum in a location consistent with a superior temporal generator. Additional, secondary, N1 generators may also be inferred. The MMN signal appears to have at least three generators, one in contralateral (left) temporal cortex (at a similar location to the principal N1 cortical source), a second which is in right frontal cortex, and a third near ipsilateral (right) temporal cortex.

## 462.10

COMPARISON OF RELATIVE AND ABSOLUTE SOUND LOCALIZATION ABILITY IN NORMAL HUMAN SUBJECTS. S.D.R.R. Makhama, D.C. Guard, P. Geiger, and G.H. Recanzone\* Center for Neuroscience and Dept. Neurobiol. Physiol. & Behav., University of California at Davis, Davis, CA 95616.

Sound localization paradigms have been used by others to either define the minimum audible angle (relative localization), or measure the subject's judgments of sound source locations (absolute localization). Comparisons between these paradigms are difficult due to differences in acoustic stimuli, subjects, etc. In this study, the same apparatus and stimuli were used in order to directly compare performance between absolute and relative localization paradigms in the same subjects.

All experiments were performed in a darkened sound booth on four normal hearing subjects (aged 20-32 yr.). Tonal (1 kHz and 4 kHz) or gaussian noise stimuli were presented for 200 msec (5 msec rise/fall) at 30 +/- 2 dB re threshold for that subject. Stimuli were presented from 8 degrees to the left, to 56 degrees to the right along the horizontal meridian. For the relative localization task, stimuli were sequentially presented 3-9 times from a single speaker every 800 msec, then the same acoustic stimulus was presented at one of 14 other possible locations. For the absolute localization task, a single stimulus was presented from one of 15 possible locations, and the subjects were required to face that speaker location.

Minimum audible angle (MAA) measurements were smallest for noise (2-3 deg) and 1 kHz tones (10-15 deg) with little effect of eccentricity of the starting speaker. MAAs for 4 kHz tones were larger (15-30 deg) and increased with increasing eccentricity. Absolute localization judgments ranged over 20 deg for noise, 20-50 degrees for 1 kHz tones, and 30-60 degrees for 4 kHz tones. These ranges increased with increasing eccentricity for both 1 kHz and 4 kHz tones, but not noise.

These data indicate that subjects are better at determining that a stimulus has changed location than at determining the precise location of the stimulus in space, and suggests that absolute localization tasks may provide a better metric in comparisons of perceptual acuity with spatial receptive fields recorded from neurons in the central auditory nervous system.

## 462.12

\*SPATIAL AND TEMPORAL CHANGES OF THE MAGNETIC FIELD PRODUCED BY THE CEREBRAL CORTEX DURING 40 HZ AUDITORY EXCITATION. K.H. Knuth, J.Dh. Broadhurst Dept. of Physics, Univ. of Minnesota, Minneapolis MN 55455, B.J. Schwartz, C.C. Gallen\* MEG Laboratory, Scripps Research Institute, La Jolla, CA 92037

\* The magnetic fields from steady-state auditory responses driven by clicks at approximately 40 Hz were examined using a 37-channel biomagnetometer. The magnetic fields were found to be periodic in time, oscillating at the stimulation frequency. Initially in the cycle, the magnetic fields exhibited a bipolar form consistent with a single current dipole. At longer post-stimulus latencies, however, this bipolar form dissipated leaving a multipole field. Examination of the differences between the phases of the response detected in the individual sensors showed that a stationary equivalent current dipole is not an accurate model of the neural magnetic field generators. However, the location of the active tissue was found to change in a coherent manner.

## 462.13

NEUROMAGNETIC FIELD RESPONSES TO CHANGES OF INTERAURAL TIME DIFFERENCE IN THE HUMAN AUDITORY CORTEX. K. Mori<sup>1</sup>, S. Imaizumi<sup>1</sup>, S. Kiritani<sup>1</sup> and M. Yamoto<sup>2</sup>. <sup>1</sup>Research Institute of Logopedics and Phoniatrics, and <sup>2</sup>University of Tokyo Hospital, Faculty of Medicine, University of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo 113 Japan.

Representation of external space in the human auditory cortex still remains elusive, in spite of evoked response studies to interaural time differences (ITD) by electroencephalography (EEG) (Picton *et al.*, 1991), as well as by magnetoencephalography (MEG) (McEvoy *et al.*, 1993). We recorded neuromagnetic responses from the left and right temporal cortices using a 37-channel magnetogradiometer (BTI) in 6 normal-hearing adult volunteers. Use of continuous, binaurally-correlated gaussian noise stimuli and selective averaging eliminated components unrelated to ITD shifts from the recording. ITD was changed between 0 and 400  $\mu$ s, with the steps either 200 or 400  $\mu$ s. Amplitude peaks of the root mean square (RMS) of the evoked magnetic fields were observed typically at or around 80, 140, and 240 ms latencies, replicating previous EEG results. ITD shifts representing virtual sound movements to the contralateral direction evoked larger responses than those to the ipsilateral to the recorded hemisphere, although the movements in the far ipsilateral virtual field evoked smaller responses. The evoked magnetic field waveshapes of responses to 0→200 and 200→400  $\mu$ s ITD transitions were more similar than any other pair of responses, like those to 200→0 and 200→400  $\mu$ s or 0→200 and 400→200  $\mu$ s transitions, suggesting that the relative sound movement rather than movement origin or destination is the primary contributor to the MEG response, which in turn may correspond to the psychophysical lower threshold for sound movement detection than absolute localization errors. However, since estimated current dipole positions for the responses to 0→200 and 200→400  $\mu$ s transitions of ITD were slightly offset by several millimeters from each other, depending on subjects and recorded sides, absolute places in virtual space may also be mapped in the temporal auditory cortex.

## 462.15

AUDITORY SALTATION: HEARING BACKWARDS IN TIME. R. Hari<sup>\*</sup>. Low Temperature Laboratory, Helsinki University of Technology, 02150 Espoo, Finland.

Sensory integration and backwards masking studies indicate that the nervous system collects information for 100–200 ms before conscious perception takes place. The present study shows similar sluggishness in an experiment of directional hearing in which the subjects mislocalized sounds which followed each other in rapid succession.

Fourteen healthy adults listened to trains of 8 binaural clicks, 4 left-ear leading (interaural difference 0.8 ms) followed by 4 right-ear-leading. The clicks were separated by 30–500 ms in different sequences. At ISIs of less than 120 ms the subjects perceived illusorily that the clicks jumped in equidistant steps from left to right. The perception was symmetrical without any bias towards the more recent stimuli. Monaural clicks, left-sided followed by right-sided ones, did not produce a similar illusion. Since impulses activating overlapping neuronal populations in close succession, as the binaural clicks evidently did, have a high probability of arising from the same source, the occurrence of the illusion for the binaural but not for the (ecologically nonvalid) monaural trains may reflect neuronal constraints of interpretative brain processes.

These data suggest that the brain integrates sound locations for 100–150 ms and that the conscious perception may be delayed by about 500 ms.

Supported by the Academy of Finland.

## 462.17

THE RESPONSES OF LEFT AND RIGHT HESCHL'S GYRI TO THE FORMANT TRANSITIONS OF AUDITORY STIMULI: A PET STUDY. Belin P., Zilbovicius M.<sup>\*</sup>, Fontaine A., Garnier M., d'Alessandro C., Chantome B., Frouin V., Mangin J.F., Zouaoui A., Dormont D., Masure M.C., Samson S., Marsault C., Neel F., Samson Y., CEA-SHFI, and LIMSI, Orsay, UCV Salpêtrière, Paris.

The perception of consonants depends on brief formant transitions (FT) of auditory stimuli, which in turn may be selectively processed by left hemisphere cortical regions (Schwartz & Tallal, Science 1980). Here, we used H2O15 PET stimulation studies to investigate the responses of left and right primary auditory cortices (Heschl's gyri) induced by brief auditory stimuli with and without formant transitions. rCBF was measured in 6 right-handed normal volunteers, at rest and in five passive listening conditions: 1) Consonant-vowel-consonant (CVC)-like stimuli with short FT (C:40ms, V:200ms) 2) CVC-like stimuli with long FT (C:200ms, V:200ms) FT, 3) Vowel-like stimuli (V: 200ms) 4) Short-duration 750hz bursts (40ms), and 5) Long-duration 750hz bursts (200 ms). Heschl's gyri were localized on individual coregistered PET-MR images.

The short FT stimulus significantly activated both left (10.5±7%) and right (7.7±7%) Heschl's gyri, as well as the long FT stimulus (L:10.1±4% vs R:11.6±6%). The differences between left-right activations, and short-long FT were not significant. The vowel-like stimulus produces an activation that was significant in the right Heschl's gyrus (5.6±4%, p<0.02), but not in the left (4.9±5%, ns). Bursts also activated both Heschl's gyri. Yet, Heschl's activation was significantly higher for FT stimuli (10±6%), than for vowel-like stimuli (5.2±4%) or bursts (5.8±5%).

In summary, as expected, Heschl's gyri are more sensitive to formant transitions than to steady-state stimuli, but we found no evidence for asymmetrical processing at this early cortical level. (supported in part by a DRC grant of AP-HP)

## 462.14

EFFECTS OF PSYCHOPHYSICAL TRAINING ON THE ENTRAINMENT OF PRIMARY AUDITORY CORTICAL NEURONS TO AMPLITUDE MODULATED TONES. R. Beitel<sup>\*</sup>, C. Schreiner, X. Wang, S. Cheung, W. Jenkins and M. Merzenich. Keck Center, UCSF, San Francisco, CA 94143.

We have tested the hypothesis that the entrained response of neurons in the primary auditory cortex (A1) can be modified by reward-contingent stimulation with amplitude modulated (AM) tones over the range of temporal modulation rates that occur naturally in the vocalizations of an adult primate. Owl monkeys were trained to report a change in the modulation rate of a 1.0 kHz tonal carrier when the rate changed from a standard frequency (4Hz or 10Hz) to higher, comparison frequencies. Following training, the monkeys were anesthetized with pentobarbital sodium, and the 1.0 kHz isofrequency region of A1 mapped with tungsten microelectrodes. Free-field signals were either sequential AM tones (standard-comparison) that simulated the stimuli used in psychophysical training, or simple (2Hz-96Hz) AM tones. Digitized multiunit neuronal responses were analyzed as periodic functions of the AM signals (events/cycle) to derive temporal modulation transfer functions (tMTFs). Based on a preliminary analysis of data, results indicate that: 1) psychophysical thresholds for detection were 3 or 4 Hz above the standard AM rates used in training; 2) tMTFs were bandpass in form with a median best modulation frequency significantly higher than those reported by other investigators for untrained cats and monkeys; and 3) relative to the entrained response to the standard AM tone, the response entrained to the comparison AM tone was smaller when the modulation rate was below psychophysical threshold and larger when the modulation rate was above psychophysical threshold. The results suggest that behavioral performance is reflected in the entrainment of neuronal responses in A1, which is modified by training. (Supported by NIH Grant NS-10414 and ONR.)

AUDITORY EVOKED FIELDS TO ATTENDED AND NON-ATTENDED ILLUSORY SOUND MOTION. L. McEvoy<sup>\*</sup> and J.P. Mäkelä. Low Temperature Lab, Helsinki Univ of Tech. 02150 Espoo, Finland.

Auditory motion can be simulated by presenting binaural sounds with time-varying interaural intensity differences. The illusion of motion in 4 directions was produced by varying a 6 dB intensity difference between the two ears in the middle of a 600ms, 1 kHz tone. To examine human cortical responses to this correlate of auditory motion, magnetic fields were recorded from 7 subjects with a 122-channel whole-head magnetometer while subjects ignored or attended to the stimuli. The stimuli elicited clear responses in auditory cortices of both hemispheres, with strongest responses occurring about 100 ms after stimulus and transition onsets. A sustained field was also present throughout the tone. Over each hemisphere, the largest transition responses occurred to stimuli that appeared to move into the contralateral field and the smallest to stimuli that appeared to move away from the subject. The variation of response amplitude with simulated motion suggests that the responses are mediated by directionally selective cells in human auditory cortex. Attention to the stimuli elicited activity in frontal, parietal, and midline regions, as well as enhancing the sustained response from auditory areas of supratemporal cortex.

## 462.18

A SELF-ORGANIZING MODEL OF AUDITORY CORTICAL TOPOGRAPHY: EMERGENCE OF FUNCTIONAL SEGREGATION DIVERSITY. K. Sameshima<sup>\*</sup> and C.E. Schreiner<sup>2</sup>. <sup>1</sup>School of Medicine Univ. São Paulo, 01246-903 São Paulo SP, Brazil. <sup>2</sup>Coleman Laboratory, UCSF, San Francisco, CA 94143-0732.

The primary auditory cortex (A1) of cats, ferrets, and monkeys shows a number of systematic topographic segregations for different sound parameters along the isofrequency dimension, such as bandwidth, threshold, latency etc. We investigated the emergence of topographic organizations in the auditory cortex using a self-organizing single-compartmental neural network model with normalizing Hebbian pre- and post-synaptic cells activity dependent plasticity rule. Our model consists of five layers representing one cochlear (excitatory), two subcortical (excitatory and inhibitory) and two cortical (excitatory and inhibitory) levels. The model incorporates a novel feature, namely an ontogenetically predetermined increasing spread of subcortico-cortical connections in the isofrequency domain. The network was trained with sets of randomly or sequentially ordered inputs with different temporal patterns. Integration among two or more tone stimuli occurs if inputs generate temporo-spatially coincident activation. After training sessions, keeping synaptic weights constant, cortical excitatory cell responses were measured by applying single tones or tone sequences. In general, the ventral portion of the isofrequency dimension emerged as sharply tuned and the dorsal-half as broadly tuned. Occasionally, the center of the isofrequency domain was the most sharply tuned region. For nets trained with randomly sequenced tones with short interstimulus intervals, stronger responses were found in the ventral half. Thus, the model provides a variety of specific topographic patterns that can be quite similar to those observed in physiological experiments. A variety of topographic functional segregation patterns can emerge by manipulating the input stimulus patterns. (Supported by HCFMUSP, FAPESP 91/2182-8, CNPq 301059/94-2 and ONR Grant N00014-91-J-1317)

COMPUTATIONAL PRINCIPLES OF MULTISENSORY INTEGRATION: STUDIES OF ADAPTATION TO NOVEL VISUO-AUDITORY REMAPPINGS. Z. Ghahramani\*, D.M. Wolpert & M.I. Jordan. Department of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139.

To explore the computational principles of human multisensory integration we have examined subjects' localization pointing errors in the azimuth to randomly interleaved visual, auditory and combined visuo-auditory targets. In a baseline study the visual and auditory stimuli coincided both temporally and spatially. In two remapping studies the normal relationship between the visual and auditory spatial maps was altered. In the first remapping study, a 15° bias was introduced between the maps by offsetting the relative locations of auditory and visual targets during combined presentation. In a second study, variance was introduced by adding zero-mean, 10° s.d. Gaussian noise between the location of the auditory and visual stimuli. Results on the baseline bias and variance of localization responses and the adaptation induced by the two perturbation paradigms are discussed in the context of cooperative (e.g. minimum variance) and competitive (e.g. winner-take-all) statistically-based fusion models.

PARALLEL HABITUATION AND SENSITIZATION OF AUDITORY EVOKED RESPONSES IN CHILDREN J. Karhu\*, E. Herrgård, A. Pääkkönen, and J. Partanen. Kuopio University Hospital, Kuopio, Finland.

Developmental changes modulate auditory event-related potentials (ERPs). Latency decreases with age may reflect increased efficiency in receiving networks, and changes in topographic distribution may indicate changes in the mode of auditory processing. In adults, detection of any sound activates auditory cortices and frontal areas at 100 ms (N100). A novel sound elicits N100, which coincides in time with vertex response belonging to automatic orienting reaction.

We compared the auditory processing during the detection of novel input and subsequent repetitions of stimuli in 45 school-aged children (age 9 years) and in 20 adults (mean age 28 years; range 23–49 years). Subjects received trains of identical tones separated by 12 s silence, which exceeds the putative duration of sensory (echoic) memory. Evoked electric signals were monitored continuously from 21 scalp electrodes and analysed off-line.

In both children and adults, a prominent 100 ms response at vertex followed the first tone in train, and decreased to half in size after the second tone. In children, the amplitude of a 150–180 ms response over temporal auditory areas diminished similarly. In parallel, a frontal-central response at 260–300 ms enhanced markedly.

ERPs over temporal areas were significantly larger in children than in adults but habituated similarly as the vertex response suggesting that wider auditory networks activate automatically during orientation to novel input. Furthermore, sensitization of a temporally and topographically separate neuronal population to repeated input was obvious. We hypothesize that this dual behaviour reflects building of neural representations in networks instrumental in elementary auditory perception and may reveal plastic capacity in developing brain.

## OLFACTORY SENSES: ACCESSORY OLFACTORY SYSTEM

## 463.1

REPLACEMENT OF SENSORY CELLS IN VOMERONASAL EPITHELIUM OF ADULT HAMSTER AFTER NERVE TRANSECTION. M. Ichikawa, T. Osada, R. M. Costanzo\*. Tokyo Metropolitan Institute for Neuroscience, Tokyo, Japan and Virginia Commonwealth University, Medical College of Virginia, Richmond, VA 23298-0551.

Sensory cells in the vomeronasal epithelium are replaced following experimentally induced degeneration. Transection of vomeronasal nerves results in degeneration of sensory cells followed by replacement of the receptor cell population. A quantitative analysis was made to determine the time course and degree of cell replacement in the vomeronasal epithelium following unilateral section of vomeronasal nerves in adult hamsters. Histological measurements of the number of sensory cells and epithelial thickness were made for up to 50 days postoperatively. Results for each experimental animal were expressed as a percentage of the contralateral control side. There was gradual degeneration of sensory cells, the number ranging from 60–100% on day 4 and 30–40% by day 7. During days 7–15 sensory cell replacement was observed. Cell number increased and reached a level of 80% by day 21. Epithelial thickness decreased to 70% during the degeneration period and did not return to control levels by day 21. This study confirms that vomeronasal sensory cells are capable of replacement following degeneration. However, the observed recovery did not reach control levels. Assessment of the functional capacity of replacement cells requires further study.

## 463.2

DIFFERENTIAL LOCALIZATION OF NADPH-DIAPHORASE ACTIVITY IN THE MOUSE VOMERONASAL SYSTEM M. Halpern\* and C. Jia. Program in Neural and Behavioral Science, SUNY Hlth Sci. Ctr. at Brooklyn, 450 Clarkson Ave., Brooklyn, NY 11203.

The anterior and posterior portions of the accessory olfactory bulb (AOB) of some mammals differentially express a number of cell markers including the lectin VVA, olfactory marker protein (OMP), G proteins and NADPH-diaphorase activity. In the opossum AOB all of these markers are differentially expressed, whereas in the rat AOB the VVA lectin and G proteins only are differentially expressed and OMP and NADPH-diaphorase activity are homogeneously expressed. The distribution of NADPH-diaphorase activity was examined in the vomeronasal system of the mouse using a direct histochemical staining technique. In the AOB, the somata and neuropil in the granule cell layer and neuropil in the mitral-tufted cell layer were labeled. In the nerve-glomerular layers, only the anterior half was labeled. The boundary between the labeled anterior half and unlabeled posterior half of the nerve-glomerular layers was very sharp. In the sensory epithelium of the vomeronasal organ, the receptor neurons located in the middle layer were more darkly labeled than receptor neurons more basally situated. This finding is consistent with our previous observation in opossums suggesting that the receptor neurons in the middle layer of the sensory epithelium project to the anterior part of the AOB. Since NADPH-diaphorase activity indicates the presence of enzymes that require NADPH as a cofactor, this finding also suggests that the receptor neurons in the middle layer that project to the anterior part of the AOB may be functionally different from the receptor neurons in the basal layers.

## 463.3

DIFFERENTIAL EXPRESSION OF G PROTEINS IN SUBCLASSES OF VOMERONASAL RECEPTOR NEURONS AND THEIR SEPARATE TERMINATIONS IN THE ACCESSORY OLFACTORY BULB OF THE RAT AND MOUSE. C. Jia\* and M. Halpern. Program in Neural and Behavioral Sci., SUNY Hlth. Sci. Ctr. at Brooklyn, 450 Clarkson Ave., Brooklyn, NY 11203.

It has previously been reported that the G proteins are differentially expressed in the nerve-glomerular layers of the accessory olfactory bulb (AOB) of rats (Shinohara et al. J. Neurosci., 1992). In order to understand the possible significance of the heterogeneity in the AOB, the AOB and vomeronasal (VN) organ of rats and mice were stained using antibodies to G proteins (anti-Gαi2 and anti-Gαo). In the nerve-glomerular layers of the AOB of rats and mice, anti-Gαi2 stains only the anterior half, and anti-Gαo stains only the posterior half. Since the nerve-glomerular layers contain axons and the terminals of VN receptor neurons, cross sections of the VN organ were processed for staining with the same antibodies. Anti-Gαi2 stains the neurons in the middle layers (middle 1/3) of the VN epithelium and anti-Gαo stains neurons in the deep layers (basal 1/3) of the VN epithelium. Staining is located in dendrites, the microvillar surface, cell bodies and axon bundles. The axon bundles stained by anti-Gαi2 can be followed from the VN organ to the anterior half of the nerve-glomerular layers of the AOB, while the axons stained by anti-Gαo can be followed from VN organ to the posterior half of the nerve-glomerular layers. The axons stained by the two antibodies are intermingled near the VN organ but gradually sort out toward the AOB. These results suggest that (1) there are two populations of mature receptor neurons in the VN organ, one expressing Gαi2 and the other expressing Gαo; (2) the Gαi2-expressing receptor neurons in the middle layers of the VN epithelium project to the anterior half of the AOB, and Gαo-expressing receptor neurons in the deep layers of the VN epithelium project to the posterior half of the AOB; and (3) this pattern of projections may be a common feature of organization in the mammalian VN system since similar results have been observed in the opossum.

## 463.4

PHYSIOLOGICAL PROPERTIES OF VOMERONASAL RECEPTOR CELLS IN AQUATIC SALAMANDERS (*AMBYSTOMA*).

H.L. Eisten\*, R.J. Delay and V.E. Dionne. Boston University Marine Program, Marine Biological Laboratory, Woods Hole, MA 02543.

The vomeronasal system is an accessory olfactory system that originated in tetrapods; the sensory epithelium is innervated by terminal nerve fibers that contain gonadotropin releasing hormone (GnRH). The function of the vomeronasal system in aquatic amphibians is not known. As a first step toward understanding the modulation of vomeronasal receptor cell activity by odorants and by GnRH, we are characterizing the conductances present in these cells. Using a slice preparation, whole-cell recordings were made from vomeronasal receptor cells in two subspecies of tiger salamanders (*A. tigrinum mavortium* and *A. t. mexicanum*). Application of tetrodotoxin revealed that a large portion of the inward current was carried by Na<sup>+</sup>. The contribution of Na<sup>+</sup> varied among cells, ranging from 60 to 100% of the inward current (n = 10). The remainder of the inward current was carried by Ca<sup>2+</sup>, as demonstrated by the use of Ca<sup>2+</sup> substitutes (Ba<sup>2+</sup>) and blockers (Co<sup>2+</sup>, Cd<sup>2+</sup>). The magnitude of the outward current was greatly reduced in the presence of Cs<sup>+</sup>, a K<sup>+</sup> channel blocker (n = 62). Furthermore, extracellular application of Ba<sup>2+</sup> reduced the outward current in the presence of Cs<sup>+</sup>, suggesting the additional presence of both Ca<sup>2+</sup>-dependent and -independent outward currents (n = 23). We are currently examining the contribution of Cl<sup>-</sup> and a nonselective cation conductance to both the voltage-activated and Ca<sup>2+</sup>-dependent components of the outward current in these cells.

## 463.5

## EVIDENCE FOR DIFFERENT MECHANISMS OF SENSORY TRANSDUCTION IN THE VOMERONASAL ORGAN AND OLFACTORY EPITHELIUM.

A. Berghard, E. Liman\* and L. B. Buck. Dept. of Neurobiology, Harvard Medical School, 220 Longwood Ave., Boston, MA 02115

The olfactory system of mammals is divided into two parts: the main olfactory system and the accessory olfactory system. The sensory neurons of the accessory system are located in the neuroepithelium of the vomeronasal organ (VNO), a tubular structure that lies beneath the nasal cavity and opens into it. Previous studies indicate that the VNO is involved in the sensing of pheromones that regulate sexual and social behaviors and endocrine function. At present, nothing is known about the mechanisms underlying the transduction of pheromonal signals in the VNO. One important issue is whether sensory transduction in the VNO proceeds via a G protein coupled mechanism as it does in the olfactory epithelium (OE) of the nasal cavity. To address this question, we have isolated cDNAs encoding G protein  $\alpha$  subunits expressed in the VNO and have examined their patterns of expression. Our results indicate that G $\alpha$ olf, which is highly expressed in OE neurons and is thought to mediate sensory transduction in these cells, is not expressed in VNO neurons. Instead, we observe high level expression of genes encoding two other G $\alpha$  subunits, G $\alpha$ o and G $\alpha$ i2 in VNO neurons. Immunostaining reveals that G $\alpha$ o and G $\alpha$ i proteins are present at the microvillar surface of the VNO neuroepithelium, the expected location of molecules involved in sensory transduction. Our results indicate that there are two distinct subpopulations of VNO neurons, one of which expresses high levels of G $\alpha$ o and the other high levels of G $\alpha$ i2, and that these two subpopulations of cells are located in different parts of the VNO epithelium. These findings suggest that: 1) VNO neurons transduce signals via mechanisms different from those used by neurons in the OE, 2) sensory transduction in the VNO proceeds via mechanisms involving G proteins, and 3) there are two different types of VNO neurons that have distinct locations in the neuroepithelium and use different G proteins to transduce sensory signals.

## APHRODISIN IMMUNOREACTIVE EPITHELIAL CELLS ARE ASSOCIATED WITH NERVE TERMINALS IN THE REPRODUCTIVE TRACT OF THE FEMALE HAMSTER.

T. Jang\*, A.G. Singer and F. Macrides. Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545 and Monell Chemical Senses Center, Philadelphia, PA 19104

Aphrodisin, a 17 kD protein purified from hamster vaginal discharge, elicits copulatory behavior and increases c-fos immunoreactivity in the accessory olfactory bulb of the male hamster. In this study, we localized the protein in the female hamster reproductive tract with the ABC-DAB immunolabeling technique using aphrodisin antiserum. Aphrodisin immunoreactivity was found in the oviduct and uterus. In the oviduct, the aphrodisin containing cells were located at the epithelium. The cells were mostly goblet in shape with a constricted base. Their slender basal ends reached to the basal laminae with either a bulbar or bifurcated ending. Nerve terminals with synaptic profiles were observed to contact these cells. In the uterus, immunoreactivity was located in the epithelial cells and uterine glands. In the estrous animal, the endometrium exhibited strong aphrodisin immunoreactivity, but the shedding process caused the immunopositive cells to be unrecognizable. These results indicate that the secretory cells of the oviductal and uterine epithelium, and uterine glands are the main source of aphrodisin, and may be neurally regulated. Supported by PHS grant NS12344.

## 463.6

## MORPHOLOGY OF SYNAPTIC PLASTICITY INDUCED BY URINARY STIMULATION IN ACCESSORY OLFACTORY BULB.

M. Matsuoka<sup>1,2</sup>, Y. Mori<sup>2</sup> and M. Ichikawa\*<sup>1</sup>. <sup>1</sup>Tokyo Metropoli. Inst. for Neurosci., Fuchu, Tokyo 183, <sup>2</sup>Univ. of Tokyo, Bunkyo-ku, Tokyo 113.

We have studied whether natural stimuli through sensory systems to which animals are exposed affect synaptic structure of the vomeronasal system. This system, consisting of the vomeronasal organ, the accessory olfactory bulb (AOB) and the higher vomeronasal centers receiving afferents from the AOB, is known to play a critical role in the perception and processing of conspecific chemical signals (pheromones) in mammals. The axons of vomeronasal sensory cells make synapses on the dendrites of mitral/tufted cells in the glomeruli of the AOB. The effects of urinary stimuli on synapses were examined in the AOB of adult male golden hamsters. At 30 days of age, male littermates were divided to three groups and exposed to one of three materials: 1) the female hamster urine, 2) the female rat urine, 3) and the control (distilled water), each animal was reared independently. After two weeks, the AOBs of animals from each group were prepared for electron microscopic examination. The length of synaptic active zone and the length of synaptic apposition zone in the glomeruli of AOB were measured: the synaptic active zone was characterized by the postsynaptic thickenings and the synaptic apposition zone was characterized by the close apposition area between pre and postsynaptic membranes. The length of synaptic active zone was longer in both the hamster urine group and the rat urine group compared with the control group. The length of synaptic apposition zone was longer in the control group compared with the rat urine group, there was no difference between hamster urine group and control group. These results demonstrate that exposure to the female urine induces morphological changes of synapses in the AOB of adult male hamster.

## 464.1

SPATIO-TEMPORAL DISTRIBUTION OF Ca<sup>2+</sup> TRANSIENTS AND LATE DEPOLARIZATIONS IN SALAMANDER MITRAL/TUFTED (M/T) CELLS A.R. Cinelli\*. Dept. Anatomy & Cell Biol., SUNY Brooklyn, NY 11203.

Relative long lasting depolarizations at glomerular and subglomerular levels of the olfactory bulb has been associated to Ca<sup>2+</sup> currents. Using voltage sensitive dyes, optical signals evoked either by electrical or odor stimulations consist on slow components which have been related to dendritic Ca<sup>2+</sup> transients. In M/T intracellular recordings, conditions which reduce inhibitory actions can unmask late depolarizations at the soma probably also related to Ca<sup>2+</sup> transients. In the present study, calcium-sensitive probes were used to determine the role of Ca<sup>2+</sup> transients in these long lasting dendritic depolarizations. Experiments were conducted in isolated epithelium-bulb preparations. Horizontal slices of the bulb with the olfactory nerve fibers attached to the epithelium were put in a split-bath tissue chamber. In single M/T cells injected with non-permeant forms of FURA-2, FLUO-3 or CALCIUM GREEN, olfactory nerve electrical stimulation gave rise to relatively long-lasting Ca<sup>2+</sup> transients distributed predominantly across the dendritic arborization. Odor stimuli also evoked Ca<sup>2+</sup> transients on M/T dendrites. In both cases, Ca<sup>2+</sup> transients were non-homogeneously distributed throughout M/T dendrites, suggesting the activation of multifocal dendritic electrogenic zones. The spatio-temporal distribution of these Ca<sup>2+</sup> transients depended on (a) the sites of activity at the epithelium and (b) the activation of inhibitory circuits. Blockade of inhibitory feedbacks using either bicuculline and/or phaclofen increased the magnitude, duration and spatial distribution of these Ca<sup>2+</sup> transients. These conditions also facilitated the propagation of these transients to the soma level. These data support the notion that the activation of Ca<sup>2+</sup> transients regulate the spatio-temporal distribution of the activity in M/T dendrites and might have implications in the generation of long lasting excitability changes that occur in M/T cells either following odor or electric-elicited activity. ## SPATIO-TEMPORAL DYNAMICS OF OSCILLATORY ACTIVITY IN FROG OLFACTORY BULB K.R. Delaney\* and D. Kleinfeld Dept. of Biosciences, Simon Fraser Univ., Burnaby, B.C. Canada V5A1S6; AT&amp;T Bell Laboratories, Murray Hill, NJ, USA 07974.

Odor stimulation of the nasal epithelium evokes an oscillatory field potential (FP) in olfactory bulbs (OBs) of virtually all vertebrates. Odor-evoked responses at 8-12 Hz (T=21°C) as well as broad-band spontaneous activity (peak ~2-4 Hz) are known, distinctive features of FPs from frog OB. We recorded odor-evoked and spontaneous activity *in vivo* using the voltage-sensitive dye RH795 and linear arrays of 2-7 photodiodes or a high speed CCD camera to image the ventral surface of OBs (frogs are pithed, paralyzed and perfused with high osmolarity Ringer to reduce movement artifacts). Power spectra of simultaneous FP and optical measurements from 100x200  $\mu$ m spots are essentially equivalent during spontaneous and odor-evoked activity. Multi-site optical measurements indicate odor-evoked oscillations are spatially coherent, typically with no phase shifts along the rostral-caudal axis of the OB, although in some instances shifts of up to  $\pi$  were seen. During spontaneous activity spatial coherence is less than that during odor-evoked activity and exhibits phase jitter, i.e., irregular waves whose direction of propagation along the rostral-caudal axis fluctuates. Interestingly, after odor stimulation the frequency of oscillations returns to its spontaneous range while the spatial coherence remains high for many seconds. Intracellular recordings from mitral cells in an *in vitro* nose-forebrain preparation reveal that most mitral cells show odor-evoked membrane potential oscillations synchronized to the FP but there is considerable variation between cells in the extent of firing during each depolarizing phase of the oscillation. ## 464.3

## LOCALIZATION OF THE GLUTAMATE-RECEPTOR SUBUNITS NMDAR1 AND GLUR1 IN THE RAT OLFACTORY BULB.

M. Giustetto<sup>1</sup>, A. Fasolo<sup>2</sup>, D. Cantino<sup>1</sup>, P. Bovolin<sup>1,2</sup>, M. Bonino<sup>2</sup>, and M. Sassò-Pognetto<sup>1</sup>. <sup>1</sup>Dept. of Human Anatomy and Physiology, and <sup>2</sup>Dept. of Animal Biology, Univ. of Turin, I-10126 Turin, Italy.

Recent immunocytochemical and electrophysiological data indicate that glutamate may be the neurotransmitter released by olfactory nerve fibers. In the present study, we have investigated the expression and localization of two glutamate-receptor subunits (NMDAR1 and GLUR1) in the rat olfactory bulb (OB) using Reverse Transcriptase-Polymerase Chain Reaction (RT-PCR) and immunocytochemistry.

Semiquantitative RT-PCR experiments showed that both the GLUR1 and the NMDAR1 mRNAs are abundantly expressed and that the NMDAR1-a splicing variant approximately doubles the NMDAR1-b mRNA. NMDAR1-immunoreactivity was present in mitral and tufted cells, as well as in interneurons (granular and periglomerular cells). In the olfactory glomeruli, a punctate immunoreactivity was observed. The AMPA-binding subunit GLUR1 was expressed by short-axon cells, by mitral/tufted cells, and by neurons located in the periglomerular region. The external plexiform layer and the glomeruli were also immunoreactive. Electron-microscopic immunocytochemistry showed that both NMDAR1 and GLUR1 can be present at the synapses established by olfactory nerve terminals with the dendrites of mitral/tufted and periglomerular cells. However, only a few of these synapses were labelled. NMDAR1 was also present at some dendro-dendritic synapses between mitral/tufted and periglomerular cells, and GLUR1 was found in glial cell processes.

These results are consistent with the assumption that glutamate is a neurotransmitter released by olfactory nerve fibers, and indicate a high heterogeneity in the expression of glutamate receptors by the postsynaptic neurons. (Study supported by M.U.R.S.T. 40% and 60%, C.N.R.).

## 464.5

## INTRINSIC FIRING PROPERTIES OF OLFACTORY BULB NEURONS IN AN IN VITRO BRAIN SLICE PREPARATION IN RAT. A. Elaagouby\*, D. W. Tanki) and J. M. Bower CALTECH Div. Biol. Pasadena, CA 91125 and 1) AT&amp;T Bell Labs Murray Hill, NJ 07974

Understanding the dynamics of a neural network such as the mammalian olfactory bulb (OB) requires a precise knowledge of the intrinsic properties of its neuronal components. We have undertaken experiments to describe the intrinsic firing properties of OB neurons. Using *in vitro* brain slice techniques, we performed intra- and extracellular recordings of the neuronal spontaneous activity and response to electrical stimulation of the olfactory nerve (ON) of relay cells and interneurons. Recordings were also performed in the presence of blockers for most excitatory and inhibitory synapses known in the OB, in order to artificially disconnect the neurons from the rest of the network.

In this preparation OB neurons were found to have high levels of spontaneous activity. Based on the pattern of their spontaneous firing, neurons can be classified into three distinct categories: intermittent firing (IM), sustained regular (SR) and fast bursting (FB) neurons. The IM neurons are found in the mitral and external plexiform layers. These neurons fire every 6-10 sec for a duration of 2-3 sec at average firing rates of 5-50 Hz. They are often responsive to ON stimulation. Synaptic blockage induce a tremendous increase in the firing rate. The SR neurons are found in all OB layers except the glomerular layer (GL). They fire at constant rates in the range of 5 to 20 Hz. Finally, the FB neurons, found exclusively in the GL, fire bursts of 4-7 spikes (at 140-180 Hz) every 350-1000 ms. The FB neurons spontaneously synchronize their bursting activity resulting in deflections of the local field potential (LFP). Occasionally, the LFP acquires an oscillatory rhythm. These results may be important to validate realistic models of the OB neurons, and guide the steps toward building a network model of the OB.

## 464.7

## INCREASED EXPRESSION OF THE BCL-2 PROTO-ONCOGENE IN THE DEVELOPING OLFACTORY BULB AFTER OLFACTORY DEPRIVATION. J. Naibauer, E. Ibrahim and M. Leon\*. Dept. of Psychobiology, University of California, Irvine, CA 92717-4550

The Bcl-2 gene is a key regulator of cell survival in the developing nervous system. The olfactory bulbs are a prominent site of Bcl-2 expression, with highest levels in the mitral and glomerular layers. We showed earlier that apoptosis accompanies the normal development of the olfactory bulb and that olfactory experience can modulate the number of cells that undergo apoptosis in the bulb. Here we determined whether olfactory deprivation can affect the levels of the Bcl-2 mRNA in the olfactory bulb. The external nares of rat pups were unilaterally occluded on postnatal day (PND) 2. Littermates with nonoccluded nares were used as controls. At PND 15, coronal sections from the bulbs were subjected to *in situ* hybridization assays for Bcl-2 mRNA. Naris closure resulted in overall increased expression of Bcl-2 in the occluded bulb when compared to the contralateral bulb ( $p < 0.05$ , paired t-test,  $n = 10$  animals). The individual layers of the lateral portion of the occluded bulb showed increased expression of Bcl-2 (glomerular layer,  $p < 0.05$ ; external plexiform,  $p < 0.05$ ; mitral,  $p < 0.01$ , granule,  $p < 0.05$ ), while in the medial portion, the external plexiform layer had increased levels of Bcl-2 ( $p < 0.001$ ). There were no significant differences detected in any of the bulb layers in the unoperated control group. These results indicate that olfactory experience can modulate the level of Bcl-2 expression in the olfactory bulb, and thus an increase in Bcl-2 may allow many cells to survive after olfactory deprivation. Funded by grant MH48950 from NIMH.

## ANALYSIS OF EXCITATORY SYNAPTIC TRANSMISSION IN RAT OLFACTORY BULB SLICES. W. Chen\*, K. Kato and G.M. Shepherd. Section of Neurobiology and Neurosurgery, Yale University School of Medicine, New Haven, CT 06510

Most of our knowledge of synaptic transmission in olfactory bulb has been obtained from the *in vitro* turtle preparation. Here we extend the analysis by developing an *in vitro* slice preparation of rat olfactory bulb.

Slices were cut either horizontally or parasagittally from olfactory bulbs of 20-40 day old rats. Both whole-cell and sharp electrode intracellular recordings were obtained from cells in the mitral cell layer, some of which were identified as mitral cells by biocytin staining. Excitatory synaptic responses to ONL stimulation have been evoked in 22 of 31 recorded cells. These neurons generally responded with a long lasting depolarization (ranging from 200 ms to 5 s). Bath application of 20  $\mu$ M bicuculline methiodide ( $n = 3$ ) had little effect on this depolarization, excluding the possible synaptic contribution of other bulbar neurons to this depolarization. The ONL-evoked EPSPs in mitral cells were completely blocked by 20  $\mu$ M CNQX plus 100  $\mu$ M APV ( $n = 6$ ), suggesting that excitatory amino acids are the main transmitter of rat olfactory axon terminals in the glomeruli, consistent with previous findings in the turtle (Berkowicz et al, 1994). LOT stimulation evoked antidromic impulses, accompanied in 9 cells by a depolarizing wave lasting up to 150 msec, resembling the self-excitatory depolarization described by Nicoll and Jahr (1982) in the turtle. Supported by grants from NIDCD and NIMH, NASA & NIDCD (Human Brain Project)

## 464.6

## EFFICACY OF DENDRODENDRITIC INTERACTIONS MODULATED BY VAGINOCERVICAL STIMULATION IN THE RAT OLFACTORY BULB. E. Okutani, S. Matsutani\*, H. Kaba, and T. Higuchi. Dept. of Physiology, Kochi Med. Sch., Nankoku, Kochi 783, Japan.

Vaginal stimulation at parturition plays a critical role in the induction of maternal behavior in rats, because mothers show maternal behavior immediately after parturition although they found pup odors aversive before parturition. We thus examined if vaginocervical stimulation (VCS) influences the dendrodendritic inhibition from granule cells to mitral cells in the rat olfactory bulb (OB). VCS was carried out using a rubber balloon which was inserted into the vagina and was inflated to increase intravaginal pressure to 100 mmHg for 2.5 min. The dendrodendritic inhibition does not change during VCS, but it is significantly enhanced immediately after the stimulation. Infusion of timolol (20mM, 1.0  $\mu$ l), a  $\beta$ -blocker, into the OB blocked the VCS effect, but phentolamine (20 mM, 1.0  $\mu$ l), an  $\alpha$ -blocker, did not. These results suggest that the somatosensory stimulation to the vagina modulates the dendrodendritic inhibition from the granule to mitral cells in OB through  $\beta$ -receptors.

## 464.8

LOCUS COERULEUS LESIONS INCREASE DENSITY OF  $\beta$ -ADRENERGIC RECEPTORS IN THE MAIN OLFACTORY BULB OF YOUNG RATS. C.C. Woo\*, C. Lemon, D.A. Wilson, R.M. Sullivan and M. Leon. Dept. of Psychobiology, University of California, Irvine, CA 92717 and Dept. of Zoology, University of Oklahoma, Norman, OK 73019.

Beta adrenergic receptors are located in nearly all bulb lamina, with a particularly high density of beta-1 and beta-2 adrenoceptors present in the glomerular layer. Early olfactory experiences that increase norepinephrine levels in the bulb decrease the density of both beta-1 and beta-2 adrenoceptors, as well as the number of high density beta-2 foci in the glomerular layer of the bulb. It therefore seems possible that changes in norepinephrine levels can affect the density of beta adrenoceptors in the bulb. To test this hypothesis, we performed unilateral lesions of the locus coeruleus on PND 4, and examined the density of beta-1 and beta-2 adrenergic receptors in the main olfactory bulb on PND 19 using [<sup>125</sup>I]-iodopindolol receptor autoradiography. Beta-1 and beta-2 receptors were visualized using the specific receptor subtype antagonists ICI 118,551 and ICI 89,406, respectively. Locus coeruleus deafferentation resulted in a statistically significant increase in the density of beta adrenergic receptors in the ipsilateral bulb compared to the contralateral bulb. Both beta-1 and beta-2 adrenoceptor subtypes increased in density with locus coeruleus lesion, although the number of glomerular-layer, high density beta-2 foci was not significantly different between the two bulbs. Thus, changes in the level of norepinephrine in the olfactory bulb can regulate the density of beta adrenoceptors in the bulb.

## 464.9

**QUANTITATIVE 2-DIMENSIONAL MAPS OF GLOMERULAR 2-DEOXYGLUCOSE UPTAKE REVEAL DISTINCT RESPONSES TO CLOSELY RELATED ODORANTS.** B.A. Johnson\* and M. Leon.

Department of Psychobiology, University of California, Irvine, CA 92717.

Recent receptor-based models of olfactory coding predict that each odor should evoke a unique pattern of glomerular activation in the bulb. Also, the overlap between patterns evoked by related odorants should be in proportion to their chemical similarities. In order to explore these and other questions regarding olfactory processing, we have mapped glomerular uptake of [<sup>14</sup>C]2-deoxyglucose in rat pups exposed to odors of the major components of peppermint: L-menthol, L-menthone, and L-menthyl acetate (4 pups/odor). Quantitative 2-D maps of relative uptake were generated by taking discrete readings at 10° increments around autoradiographic images of coronal sections collected throughout the rostral-caudal extent of the bulb. After correcting for bulb size, the resultant arrays for left and right bulbs of each brain were averaged (~2500 data points/bulb). Different odors were compared by using statistical analyses of cell arrays. We found that each odor induces multiple areas of contiguous cells showing significantly increased uptake, compared to pups not exposed to an odorant. Coherent areas of decreased uptake also occur. When the minty odors are compared, 92-97% of the glomerular layer gives a similar response. Despite the widespread similarities, each odor produces areas of uptake that are significantly different from the other two odors. Menthol yields 2 unique areas of increased uptake; menthone gives 2 unique areas of increased uptake as well as 2 unique areas of decreased uptake; and menthyl acetate yields 1 unique area of increased and 1 of decreased uptake. These data are consistent with receptor-based, combinatorial models of odor coding. They also provide a means to relate chemical features of odorants to spatial patterns of olfactory bulb responses. Funded by grant HD24236 from NICHD.

## 464.11

**SUBCOMPARTMENTAL ORGANIZATION OF THE RAT OLFACTORY BULB GLOMERULUS.** Charles A. Greer\*, Hanna Kim and Kenneth Chiu. Sections of Neurosurgery and Neurobiology, Yale University School of Medicine, New Haven, CT 06510.

Olfactory receptor cell (ORC) axons terminate in the glomerular neuropil of the olfactory bulb where they make synaptic connections with target dendrites of mitral, tufted and periglomerular neurons. We have investigated the organization of the glomerular neuropil using antibodies or the lipophilic dye Dil to label constituents for analyses using confocal microscopy. In parallel, we have used electron microscopy to assess the distribution of synaptic appositions within the glomerulus. Sprague-Dawley rats, 30-50 days postnatal, were perfused with 4% paraformaldehyde and processed for immunocytochemistry of olfactory marker protein (OMP) and MAP-2 or crystals of Dil were implanted into the olfactory nerve for tract tracing. Equivalent rats were perfused with 4% paraformaldehyde and 1% glutaraldehyde and processed for routine transmission electron microscopy. ORC axons stained with Dil occupied restricted regions within the glomeruli. OMP staining confirmed that observation. Double labeling for OMP and MAP-2 revealed a distinct interdigitation of axonal and dendritic processes within glomeruli. OMP staining, though present throughout the glomerulus, was strongest in the shell or outermost portion, an impression also gained from the Dil stained ORC axons. MAP-2 staining was less extensive and not apparent in the glomerular shell. Reconstructions of the area occupied by ORC axons versus dendrites from EM montages revealed continuous islands of axons within the glomerulus, accounting for 28.24% +/- 1.34 of the total area, with bundles of dendritic processes interspersed. The distribution of synapses within the glomerulus further suggested the segregation of axo- and dendrodendritic interactions. The results support the hypothesis of a subcompartmental organization of the olfactory bulb glomerular neuropil.

**REGULATION OF c-FOS mRNA AND PROTEIN EXPRESSION IN OLFACTORY BULBS FROM UNILATERALLY ODOR-DEPRIVED, ADULT MICE.** B.K. Lin\*, L. Franzen and H. Baker. Cornell Univ. Med. Coll. at The Burke Med. Res. Inst., White Plains, NY 10605.

Odorant deprivation, produced by unilateral naris closure, profoundly reduces tyrosine hydroxylase (TH) expression within intrinsic olfactory bulb dopamine neurons. An AP-1 site, present in the TH gene, interacts with the product of the immediate early gene (IEG), c-fos, regulated by neuronal activity. To test the hypothesis that odorant stimulation and deprivation modify c-fos expression in TH neurons, adult CD-1 mice were subjected to unilateral naris closure. After two months, naris closed and control mice were exposed to either clean air for 60 min or clean air for 30 min followed by 30 min of alternating exposure to 10% isoamyl acetate (1 min) and air (4 min). TH mRNA and immunoreactivity decreased in the olfactory bulb ipsilateral to closure as previously observed. A parallel reduction occurred in c-fos mRNA and Fos-like immunoreactivity (FLI) in the glomerular as well as mitral and granule cell layers in olfactory bulbs ipsilateral to closure. Odor stimulation induced a short-lived increase in c-fos mRNA and FLI in olfactory bulbs contralateral to closure. The increase in Fos expression was region-specific in the glomerular layer but diffuse in mitral and granule cell layers. Interestingly, odor stimulation also induced strong c-fos expression in the mitral and granule cell layers and sparsely within limited periglomerular regions of olfactory bulbs ipsilateral to closure. These results suggest that c-fos expression, as in other systems, is an indicator of neuronal activity. Odor induced expression in mitral and granule cell layers may reflect increased centrifugal activity. The altered periglomerular cell Fos expression supports a role for this early gene in regulation of the TH gene. Supported by AG09686.

## 464.10

**SYNAPTOPHYSIN-LIKE IMMUNOREACTIVITY IN THE RAT OLFACTORY BULB AFTER RESTRICTED EARLY OLFACTORY EXPERIENCE.** K. Ninomiya-Tsuboi, B.A. Johnson, C.C. Woo, J. Leon\* and M. Leon. Dept. of Psychobiology, Univ. of California, Irvine, CA 92717

Synaptophysin is a synaptic vesicle protein that provides a marker of synapse distribution in the brain. Intensely stained particles initially are distributed evenly throughout olfactory bulb glomeruli, although beginning around PND 12, such particles tend to be located along the glomerular perimeter (Johnson et al. '93). To determine if this developmental pattern is affected by early olfactory experience, PND 19 bulbs were reacted with an antibody to synaptophysin after naris closure on PND 1. In spite of the negative impact of this unilateral olfactory restriction on laminar size, no difference was detected in synaptophysin immunoreactivity in any of the laminar measurements (glomeruli, external plexiform layer, internal plexiform layer or granule cell layer). Although the staining measured across entire glomeruli does not change with odor restriction, the distribution of immunoreactivity within individual glomeruli is affected by naris closure. Glomeruli of the deprived bulbs are stained homogeneously, while glomeruli of both contralateral and unoperated bulbs are stained more darkly along the perimeter than the glomerular core. Further study showed that the difference in staining between the olfactory nerve/glomerular border and glomerular core is significantly less in deprived bulbs than in either contralateral glomeruli or glomeruli from unoperated animals. These results indicate that early olfactory experience affects the developmental change in the distribution of synaptophysin immunoreactivity within glomeruli. Funded by grant HD 24236 from NICHD.

Evidence for a stereotyped and highly organized spatial map of sensory input in the olfactory bulb.

Kerry Bessler, Susan Sullivan, Huntington Potter\*, and Linda Buck

Howard Hughes Medical Institute

Department of Neurobiology

Harvard Medical School

The odorant receptor gene family contains ~1000 members, each of which is expressed by only a small fraction of olfactory sensory neurons. Neurons that express the same odorant receptor gene are confined to one of four distinct odorant receptor expression zones in the olfactory epithelium. However, within that zone, those neurons appear to be randomly distributed, such that each zone is a mosaic of sensory neurons expressing different receptor types. Thus there may be an initial broad organization of sensory information in the nose into zones, but information within every zone is still highly distributed. We have found that odorant receptor mRNAs are present in the axons of olfactory sensory neurons. This has allowed us to examine the patterns of synapses formed in the olfactory bulb by neurons that express the same odorant receptor gene. Using *in situ* hybridization with specific odorant receptor probes, we find high concentrations of individual receptor mRNAs within small subsets of glomeruli in the olfactory bulb. Different odorant receptor probes hybridize to different glomeruli. Each odorant receptor probe that we have examined hybridizes to only 2-5 of the ~2000 glomeruli in each mouse olfactory bulb. The glomeruli are located at two distinct sites in each olfactory bulb, one lateral and the other medial. Furthermore, they appear to be located at approximately the same place in each olfactory bulb and in the bulbs of different animals. Our results suggest that in the olfactory bulb, sensory information that is highly distributed within a single zone in the nose is transformed into a highly organized and spatially stereotyped information map.

## 464.14

**ALTERED PLASTICITY OF TYROSINE HYDROXYLASE EXPRESSION IN OLFACTORY BULB OF OLD MICE.** J.H. Baker\*, J.L. Franzen, M. Grillo and J.L. Margolis. <sup>1</sup>Cornell Univ. Med. Coll., Burke Med. Res. Inst., White Plains, NY 10605 and <sup>2</sup>Roche Inst. Mol. Biol., Nutley, NJ 07110.

Tyrosine hydroxylase (TH) is the rate-limiting enzyme in the catecholamine biosynthetic pathway. In contrast to other brain regions, we demonstrated that age-related losses in TH expression do not occur in periglomerular neurons intrinsic to the rodent olfactory bulb. We also showed that deafferentation produced in young mice by intranasal irrigation with Triton X-100 results in marked, but reversible, reductions in TH expression suggesting that the deficits are not associated with cell death. The current studies tested the hypothesis that the ability to re-express TH would be compromised in old animals. Both young (6 months) and old (20-21 months) C57BL/6JNIA mice were intranasally irrigated with either Triton X-100 in saline (100µl), to produce a reversible deafferentation, or with saline alone (control). TH expression was examined biochemically, immunocytochemically and by *in situ* hybridization. At both 10 and 30 days post-irrigation, TH expression was dramatically reduced (to about 30% of control levels) in mice of both ages. At 42 days post-treatment, TH activity recovered to 60% and 44% of control (saline) values in young and old mice, respectively. In replicate experiments at 60 days post-treatment, TH activity returned to 65% and 87% of control levels in young mice but to only 48% and 55% of control values in old mice. Olfactory marker protein levels, an indicator of reinnervation, showed similar reductions to 55% and 41% in young and old mice, respectively. These data suggest that plasticity of reinnervation and the consequent induction of TH expression is compromised in the olfactory system of old mice. Supported in part by AG09686.

## 464.15

DECREASED NGF AND INCREASED NGF-RECEPTOR LEVELS IN OLFACTORY BULBS OF DEVELOPING HYPOTHYROID RATS AND REVERSAL OF THIS RESPONSE BY RECOVERY. T. J. Sendera\* and E. Meisami (Dept. of Physiology & Biophysics, Univ. of Illinois, Urbana, IL 61801).

Effects of early thyroid deficiency [propylthiouracil (PTU) in liter's drinking water (1g/L)] and recovery from this condition on NGF levels and expression of low-affinity-NGF-receptor (p75NGFR=NGF-R) in rat olfactory bulbs (OB) were studied using an ELISA assay for NGF and immunocytochemistry for NGF-R. We have shown previously that neonatal hypothyroidism results in up to 70% deficit in total number of olfactory receptor neurons (ORNs) and a 24% loss of mitral cells. Withdrawal of PTU results in complete recovery of ORN number and OB volume. In 25- & 50-day-old hypothyroid rats, NGF levels per OB were reduced by >50%. Withdrawal of PTU doubled NGF levels in hypothyroid OBs- although recovery was incomplete by day 50. In normal OB, NGF-R expression was moderate, patchy and limited to glomeruli. NGF-R response to hypothyroidism was opposite to NGF, i.e., widespread and markedly elevated in OB glomeruli of hypothyroid rats. Upon recovery, expression returned to low, i.e., normal levels. Results suggest that thyroid hormones regulate NGF and NGF-R levels in OB: in hypothyroidism, NGF is reduced while NGF-R is up-regulated. Thyroidal normalization restores NGF and NGF-R levels. Changes in NGF and NGF-R may also follow altered proliferation and maturation of ORNs (Paternostro & Meisami, *Dev. Brain Res.* 76:151-161,93; *ibid* 83:151-162,94). *Supp: NIH grant (GM07143) and UIUC Research Funds*

## 464.17

THE OLFACTORY SYSTEM IN GANGLIOSIDE STORAGE DISEASE CATS. E. E. Morrison\* and J. C. Dennis. Department of Anatomy and Histology, College of Veterinary Medicine, Auburn University, AL 36849-5518.

We examined the olfactory epithelium and bulb in cats carrying the neuronal storage disease GM1 gangliosidosis in cats. Gangliosides are glycosphingolipids located mainly on the outer lipid bilayer of the neurolemma and are thought to be involved in differentiation and synaptogenesis. Gangliosidosis is a metabolic disorder affecting normal mechanisms of surface membrane production and regulation and can result in the appearance of aberrant neuronal plasticity, e.g. meganeurites. Ten matched pairs of control and mutant cats (provided by Dr. H. Baker) were euthanized and the nasal cavity and olfactory bulb immersion fixed for light and electron microscopic examination. The olfactory neuroepithelium appeared normal by LM inspection. Slides immunostained for olfactory marker protein, (OMP) a characteristic biochemical marker for mature olfactory neurons, showed mutant ORN's capable of expressing OMP. TEM examination showed ORN's cell bodies to contain large numbers of storage vesicles. Olfactory bulb mitral and tufted cells appeared abnormal by LM. Cell bodies were swollen and contained vacuoles. At the TEM level, the most conspicuous feature was the large number of storage vesicles within the cell body and dendritic processes. Where Golgi impregnation was successful, mitral and tufted cells showed no apparent development of meganeurite. These results indicate that the olfactory system of animals with gangliosidosis show characteristic storage disease pathology but not aberrant neuronal plasticity. Olfactory receptor neurons show cellular pathology but still express the biochemical marker olfactory marker protein. Supported by grant #DC01532 (EEM) and Scott-Ritchey Research Center, Auburn University.

## 464.16

IN VIVO VOLUMETRIC QUANTIFICATION OF NEURAL DEGENERATION IN RAT OLFACTORY BULB USING MAGNETIC RESONANCE IMAGING (MRI). Saied Agahi, Esmail Meisami\*, and Paul C. Lauterbur (Dept. Physiol & Biophys. & Biomedical Magnetic Resonance Lab., Univ. Illinois, Urbana, IL 61801)

We used MRI to delineate laminar organization of olfactory bulb (OB) and convolutions of olfactory conchae and to see whether atrophic responses of OB to olfactory nerve degeneration in developing rats can be visualized *in vivo*. 1% zinc sulfate was irrigated intranasally in neonatal rats resulting in destruction of olfactory epithelium. Rats were anesthetized with ketamine, xylazine and acepromazine cocktail and placed in especially constructed plastic cylindrical chambers wound with an Alderman-Grant rf coil 6.3 cm in diameter. Using a 4.7T/33 cm bore magnet and a SISCO imaging spectrometer, OB and nasal cavities were imaged using moderately T2 weighed images. Imaging data sets were processed and displayed using the NCSA supercomputers and *Viewit* visualization software. MRI images of olfactory cavities revealed highly intricate details of conchae from coronal 0.3 mm thick images. Images of normal OB revealed 4 zones corresponding to olfactory nerve-glomerular, external plexiform, internal granular and ventricular-ependymal layers. Thickness of these layers from MRI images could be measured. Denervation studies indicated a reduction in size and volume of OB, accompanied with about 20-30% reductions in thickness of superficial OB layers. Thus MRI imaging allows us to visualize *in vivo* not only the laminar details of OB but also to quantify the effects of degeneration of olfactory nerves in the developing OB. *Supp: NSF DIR 89-20133COOP, NIH PHS 5 P41 RR05964, Servants United Foundation, UIUC Research Funds.*

## OLFACTORY SENSES: OLFACTORY CORTEX

## 465.1

INHIBITION OF OLFACTORY BULB MITRAL CELLS BY STIMULATION OF PIRIFORM CORTEX ASSOCIATION FIBERS IS ENHANCED FOLLOWING LTP. J. S. Stripling\*, J. L. Cauthron, and M. P. Galupo. Department of Psychology, University of Arkansas, Fayetteville, AR 72701.

Stimulation of association fibers in the piriform cortex (PC) evokes a late negative wave in the granule cell layer of the olfactory bulb (OB) which appears to represent synaptic excitation of granule cells by PC association fibers. We have previously demonstrated that this negative wave undergoes long-term potentiation (LTP) following high-frequency stimulation of PC association fibers, and have proposed that this potentiation is due to LTP at synapses between cortical association fibers and OB granule cells. Because granule cells inhibit mitral cells, it follows that mitral cells should be inhibited by stimulation of PC association fibers, and that this inhibition should be enhanced following LTP. The present study was designed to test this hypothesis. LTP was induced in male Long-Evans rats by daily high-frequency stimulation of PC association fibers. Extracellular recordings of individual mitral cells were then made under urethane anesthesia (1.4 g/kg). Inhibition of mitral cell firing by stimulation of the lateral olfactory tract (LOT) and the PC association fiber system was monitored before and after LTP was reinstated by high-frequency stimulation of PC association fibers. Prior to reinstatement of LTP, stimulation of either the LOT or the PC association fiber system produced a brief inhibition of mitral cell firing. Following reinstatement of LTP, mitral cell inhibition by PC association fiber stimulation was increased in duration (typically two-fold or more), while inhibition by LOT stimulation was unaffected. This supports the conclusion that PC pyramidal cells exert substantial inhibitory control over mitral cells, and that the strength of this control can be altered by LTP at pyramidal cell synapses on granule cells. These observations emphasize the potential importance of feed-back inhibition from the PC to the OB, and its modification by experience, in olfactory processing. Supported by NIH grant DC02271 and the Marie Wilson Howells Fund.

## 465.2

ALL-OR-NONE THRESHOLD FOR EXPRESSION OF LTP IN THE OLFACTORY BULB AND PIRIFORM CORTEX: MODULATION BY BEHAVIORAL STATE. M. P. Galupo\* and J. S. Stripling. Department of Psychology, University of Arkansas, Fayetteville, AR 72701.

Previous research in this laboratory has documented the long-term potentiation (LTP) of late components in potentials evoked in the olfactory bulb (OB) and piriform cortex (PC) by stimulation of PC association fibers. The present research investigated the expression of this potentiation at near-threshold current intensities. LTP was induced in male Long-Evans rats by daily high-frequency stimulation (thirty 10-pulse trains at 100 Hz) of PC association fibers. Input/output testing was conducted both before and after daily high-frequency stimulation to determine the stimulation threshold for expression of the potentiated component of the evoked potential. In addition, behavioral effects on threshold were explored by conducting separate input/output tests during slow-wave sleep, awake immobility, and locomotion. Results indicate that the expression of LTP has a sharp current threshold, and that LTP expression occurs in an all-or-none fashion with near-threshold stimulation. Threshold is reduced following daily high-frequency stimulation and drops progressively across days as LTP develops. In addition, threshold is dependent upon behavioral state: it is lowest during slow-wave sleep, highest during locomotion, and has an intermediate value during awake immobility. These results demonstrate that the expression of this form of LTP in the OB and PC is powerfully modulated by behavioral state. Furthermore, the characteristics of LTP expression (all-or-none expression at threshold with a long latency) suggest that LTP expression is dependent upon reverberating positive feedback within a synaptically activated network.

Supported by NIH grant DC02271 and the Marie Wilson Howells Fund.

## 465.3

IS NOREPINEPHRINE DEPENDENT ON GABA IN ATTENUATING PYRAMIDAL POSTSYNAPTIC POTENTIALS IN THE PIRIFORM CORTEX? A.J. Rechs\* and D.W. Gietzen. Vet Med: Anatomy Physiology & Cell Biology, Univ Calif, Davis, Davis CA 95616.

It has been shown that norepinephrine (NE) decreases the amplitude of postsynaptic potentials (PSPs) of pyramidal cells located in layer III of the rat piriform cortex. The focus of this study was to ascertain whether this decrease is mediated by NE acting directly on the pyramidal cells, or by NE acting indirectly through GABAergic interneurons. Coronal brain slices 400 microns thick were taken from male adult rats (n=3), and perfused with ACSF. Stimulating and recording electrodes were placed approximately 1mm apart in layer III. Stimulation was applied for 100  $\mu$ sec at a constant current necessary to elicit a half-maximal PSP response. After recording a stable baseline for one hour, NE (31 $\mu$ M) was applied to the slice for 30 minutes and then washed out. NE caused a significant decrease in the amplitude of the PSP. Approximately an hour after restoration of baseline values, the GABA<sub>A</sub> antagonist bicucullin (30 $\mu$ M) was added to the ACSF medium, causing a dramatic increase in the amplitude of the PSP. An hour after recording a new baseline, NE (31 $\mu$ M) was reapplied, again decreasing the amplitude of the PSP. After 30 minutes the NE was washed out, returning the PSP amplitude to the bicucullin baseline level. The PSP response to NE in the presence of bicucullin suggests that NE's effect is not solely mediated by GABAergic interneurons. However, the response to NE in the presence of bicucullin was  $60 \pm 3\%$  smaller than that observed in the absence of bicucullin, suggesting that the GABAergic interneurons do play a role in the ability of NE to attenuate pyramidal PSPs in the piriform cortex. Supported by USDA NRI 94-37200-0655.

## 465.5

THE EFFECTS OF SYNAPTIC TIMING IN A REALISTIC MODEL OF A LAYER II PIRIFORM PYRAMIDAL CELL. A. Protopapas\* and J.M. Bower. Div. of Biology 216-76, Caltech, Pasadena, CA 91125

We constructed a compartmental model of a layer II pyramidal cell from piriform cortex based on the morphology of a stained cell from rat and using only membrane and synaptic currents known or suggested to exist in this cell type. Whole-cell recordings were made on a population of pyramidal cells in order to obtain experimental constraints for the passive properties of the neuron. Passive and active behavior (in the form of *I/V* curves) were used to match the model to experimental data.

In these simulations we were interested in exploring the consequences of different spatial and temporal synaptic patterns on the output of this type of neuron. Different synaptic pathways are known to terminate in different layers of the piriform cortex (afferent input in layer Ia; associative excitatory input in layer Ib; feedback inhibition in layer II). This was modeled by distributing synaptic inputs along the apical dendritic tree according to these data.

We varied the timing of synaptic input in layer Ib with respect to input arriving in layer Ia and found that EPSPs summed linearly when membrane resistance was at values based on passive *in vitro* experiments; however, when membrane resistance was lowered to simulate background synaptic activity, EPSPs did not summate linearly, and the peak of the summed EPSP shifted in time. Shifting the timing of inhibition in layer II with respect to EPSPs arriving in layer Ia, we found that as much as 40% of the inhibition was due to shunting even at depolarized resting potentials (-55mV). Peaks of summed responses were relatively stationary.

Supported by NIH-#5T32-GM07737-17.

## 465.7

A NEW ANATOMICALLY AND PHYSIOLOGICALLY DISTINCT SUBDIVISION OF THE PIRIFORM (OLFACTORY) CORTEX. M. Behan, D.M.G. Johnson, S.L. Feig, and L.B. Haberly\*. Dept. of Anatomy, Dept. of Comp. Biosciences, and Neurosci. Training Program, University of Wisconsin, Madison, Wisconsin 53706.

Current source-density analysis of 40-60 Hz oscillations in piriform cortex (PC) has revealed that each cycle contains a monosynaptic afferent-evoked EPSC followed by a disynaptic EPSC (KL Ketchum and LB Haberly, J Neurosci 13:3980). These 2 EPSCs are generated in adjacent distal and middle segments, respectively, of pyramidal cell apical dendrites at a fixed temporal relationship in all parts of the cortex. The demonstration of "associative LTP" between these 2 sets of synapses (ED Kanter and LB Haberly, J Neurosci 13:2477) suggests that the spatial and temporal juxtaposition during fast oscillations may play a role in learning-related adjustment of synaptic efficacies. Based on modeling analysis of propagation patterns it has been postulated that the disynaptic EPSC is mediated by cells in the ventral part of the anterior piriform cortex (APC) (KL Ketchum and LB Haberly, J Neurophysiol 69:261).

This hypothesis was tested by comparing projection patterns of pyramidal cells in dorsal and ventral parts of the APC using small extracellular injections of the anterogradely transported tracer, PHA-L. The results showed that a ventral region, consisting of a narrow strip of cortex deep to the medial half of the lateral olfactory tract (LOT) projects exclusively to a thin zone at the superficial margin of layer Ib (depth of mid-apical dendrites) where the disynaptic component is generated in oscillatory responses. From single small injections the projection is heavy throughout the full extent of the PC and all other olfactory areas. By contrast, the projection from the remainder of the APC is similar to that from the posterior PC (M Luskin and JL Price, J Comp Neur 216:292): it is concentrated in the deep part of layer Ib and in layer III of the posterior PC, with a much weaker projection to rostral regions of the PC and other olfactory areas. Physiological study of pyramidal cells deep to the LOT revealed additional distinctive features of this region: activation by afferent fibers occurs at lower thresholds and at shorter latencies with a greater degree of synchrony than in other parts of the PC (KL Ketchum, A Kapur and LB Haberly, unpublished). Based on the occurrence of the disynaptic EPSC at fixed latency relative to the afferent input in low amplitude oscillations, these features support the conclusion from the anatomical findings that this EPSC is mediated by the newly-distinguished ventral strip in the APC. Supported by NS19865 from NINDS.

## 465.4

GABAergic NEURONS IN THE MOLECULAR LAYER OF PIRIFORM (OLFACTORY) CORTEX HAVE LAMINA-SPECIFIC AXONAL ARBORS. J.J. Ekstrand\* and L.B. Haberly. Neuroscience Training Program, Dept. of Anatomy, and MD/PhD Program, University of Wisconsin, Madison, WI 53706.

Previous studies in the piriform cortex have provided evidence that, as in the hippocampus, different forms of inhibition are concentrated in dendritic and somatic regions of pyramidal cells. GABA<sub>B</sub>-mediated inhibition and the newly-distinguished slow GABA<sub>A</sub>-mediated IPSC (GABA<sub>A,slow</sub>; R Pearce, Neuron 10:189) are concentrated in apical dendrites, whereas cell bodies receive a higher proportion of GABA<sub>A,fast</sub> (A Kapur et al, Soc Neurosci Abs 19:1521). Physiological evidence for laminar specificity in axonal arbors (A Kapur et al, Soc Neurosci Abs 19:1521) suggests that these different inhibitory processes are mediated, at least in part, by different interneurons. The present study is the first step characterizing the populations of neurons that mediate different forms of inhibition in the piriform cortex. Goals are to understand the roles of inhibition in the regulation of NMDA-dependent synaptic plasticity (ED Kanter and LB Haberly, J Neurosci 13:2477; Kapur et al 20:652), integrative processes, and the prevention of epileptic bursting.

Cells were studied in layer I (molecular layer) where immunocytochemical studies have shown that most or all neurons are GABAergic (Haberly et al, JCN 26:269). Recordings were made with whole-cell patch pipettes placed under direct vision on cell bodies in slices from 1-3 week old rats. Cells were stained by diffusion of neurobiotin from the patch solution. Afferent and association fibers were stimulated with microelectrodes. This stimulation evoked prominent EPSPs, but weak IPSPs from all cells. Dendrites from all cells were varicose and sparsely spiny, but varied in form from vertically oriented arbors extending over the full depth of layer I to predominantly horizontal arbors that were restricted in laminar extent. Three distinctive axon branching patterns have been distinguished thus far: one that arborizes extensively in layer Ia (depth of afferent inputs to distal apical dendrites), one with extensive branching in the deep part of layer Ib (depth of association fiber inputs onto proximal apical dendrites), and one with axons that descend and arborize in layer II at the depth of pyramidal cell somata. The cells with arbors in deep Ib were distinctive physiologically by virtue of a rapid adaptation that limited depolarization-induced discharge to a single spike. Supported by NS19865 from NINDS.

## 465.6

INFORMATION PROCESSING IN THE RAT PIRIFORM CORTEX: INFLUENCE OF EXPERIENCE ON THE DISTRIBUTION OF ACTIVITY. P. Litaudon\*, A.M. Mouly, R. Sullivan, M. Cattarelli, <sup>1</sup>CNRS UA 180, UCB Lyon 1, 69622 Villeurbanne, France & <sup>2</sup>Department of Zoology, Univ. of Oklahoma, USA.

The piriform cortex (PC) is a brain area which has a potential role in olfactory learning. The current view of the neural basis of learning suggests that learning is coded by changes in neural network. Thus, we used the optical recording method which enables one to record neural activity simultaneously over the entire PC. Therefore, the effects of experience could be assessed on the distribution of activity optimizing the possibility of characterizing local changes in the neural circuitry. Rats were given olfactory experience via electrical stimulation of the olfactory bulb which has a massive projection to the PC. Moreover, this technique provides precise control over odor stimulation during both experience and testing.

Four electrodes were implanted in the olfactory bulb which were used to mimic odor stimulation. In a daily training paradigm, rats were trained to discriminate between spatially distinct electrical stimulation delivered to one olfactory bulb. Control rats received olfactory bulb electrical stimulation without discrimination training. The discrimination was acquired within 5-7 days. Following acquisition, piriform cortex responses to olfactory bulb electrical stimulation were mapped using optical recording with a voltage-sensitive dye. Each of the four olfactory bulb electrodes were individually electrically stimulated (single shock, 200  $\mu$ s, 0.05-1 mA), and the whole PC activity mapped using two recordings along the antero-posterior axis. The data indicate that the response of the PC to olfactory bulb stimulation was altered by olfactory experience. Specifically, a late wave component of the PC response to electrical stimulation of the olfactory bulb seems to be more frequent in rats that had received the olfactory experience. Further analysis of the data will determine whether this effect is localized to a specific area of the PC.

## 465.8

REAFFERENCE AND RHINENCEPHALIC MARKERS DURING OLFACTORY PERCEPTION IN RATS.

L.M. Kay\* and W.J. Freeman. Graduate Group in Biophysics and Department of Molecular and Cell Biology, Neurobiology Division, University of California at Berkeley, Berkeley, CA 94720

ReaffERENCE refers to the ability of a sensory system to expect input and carry out action based on the difference between expected and actual input. Simultaneous bipolar field potential recordings from the olfactory bulb (OB), prepiriform cortex (PPC), entorhinal cortex (EC), and dentate gyrus (DG) in rats during performance of an olfactory recognition operant task suggest a generalized model of reaffERENCE in olfactory perception: 1) "afference": a primary burst in the gamma band (40-120 Hz) is passed from the OB to PPC and to the limbic areas, the EC and DG (Kay and Freeman, Society for Neuroscience Abstracts, 1994); 2) "preafference" (similar to "efference copy"): before odor recognition a signal in the beta band (15-35 Hz) is passed from the EC to the OB; 3) "post-afference" (similar to "reafference"): after a primary burst in the OB during odor recognition a secondary nearly periodic burst is originated in the PPC at 3/4 to 5/6 the dominant frequency of the OB oscillation and is passed back to the bulb and inwardly to the limbic areas. This burst is correlated with the behavioral motor response (bar press). The afferent burst rides the crest of the low frequency oscillation (3-12 Hz) correlated with the inhalation phase of the respiratory cycle in the OB, while the post-afferent burst, which is often 3-4 times the amplitude of the afferent burst, occurs in the troughs of the respiratory wave. **CALRETININ GENE EXPRESSION IN THE HUMAN THALAMUS.** A. Parent\*, F. Cicchetti and P. V. Gould. Neurobiology Res. Cr. and Dept. of Pathol., Enfant-Jésus Hospital, Québec, Canada, G1J 1Z4.

Previous studies from this laboratory have provided evidence for the existence of calretinin (CR) in human basal ganglia. In order to study the localization and levels of expression of this calcium-binding protein in the human thalamus, we undertook an *in situ* hybridization study on formalin-fixed postmortem material from normal individuals. The brain slabs that were used contained a large portion of the diencephalon and parts of the basal ganglia. The slabs were cut with a freezing microtome into 50 µm-thick sections and processed for X-ray film radioautography and emulsion radioautography. The presence and levels of CR mRNA were detected with an antisense <sup>35</sup>S-labeled riboprobe synthesized by *in vitro* transcription of cDNA clones encoding for human CR. A sense riboprobe served as negative control. As visualized on X-ray film radioautographs, high concentrations of CR gene transcripts occurred in several thalamic nuclei, including the reticular nucleus, the centromedial nucleus, the paracentral nucleus, and several midline nuclei, as well as a number of hypothalamic nuclei. In the reticular thalamic nucleus, neurons expressing CR mRNA were few in number and formed typical clusters scattered throughout the rostrocaudal extent of the nucleus. Observations of emulsion radioautographs revealed that each neuron in these reticular nucleus clusters was heavily labeled. In contrast to the reticular nucleus, virtually all neurons in the intralaminar and midline nuclei expressed high levels of CR mRNA. When examined on X-ray films, these heavily labeled neurons formed a very prominent rim around the poorly labeled mediodorsal nucleus. This zone of intense labeling was continuous ventrally with the hypothalamus, whose neurons also contain high concentrations of CR gene transcripts. These results reveal that CR mRNA is expressed by specific thalamic nuclei in humans, particularly those nuclei projecting heavily to the basal ganglia, and that the presence of CR gene transcripts can easily be detected on formalin-fixed sections of the human brain. [Supported by the MRC of Canada].

## 466.3

**CALRETININ IN THE PRIMATE THALAMUS IS MAINLY LOCATED IN LIMBIC-ASSOCIATED TERRITORIES.** M.-C. Asselin\*, M. Fortin and A. Parent. Centre de recherche en Neurobiologie, Fac. of Med., Univ. Laval, Québec (Qc.), Canada, G1K 7P4.

A comparative immunohistochemical study of the distribution of the calcium-binding protein calretinin (CR) was undertaken in the thalamus of squirrel monkeys (*Saimiri sciureus*) and humans. In the anterior division of the thalamus, a moderate to dense immunostaining is observed in most of the nuclei, represented by the anterior ventral (AV), anterior dorsal (AD) and anterior medial (AM) nuclei. Exceptions reside in the human AD, where CR fibers are more densely stained and in the absence of a human AM nucleus. CR immunoreactivity (CR-IR) in the mediodorsal nucleus (MD) has an arrangement individual to human and non human primates. The human MD displays a weakly stained CR neuropil, and a few densely immunoreactive cell bodies concentrated in central and ventral regions of the nucleus rostrocaudally. In monkeys, moderately stained cells and fibers are concentrated in the central part of the MD where they form a patchy arrangement. In more caudal regions, these patches of immunoreactive perikarya and fibers extend to more lateral and medial areas. The CR cells found in the monkey MD are of small size and their distribution seem to be confined to the parvocellular division, the other parts of the MD being totally devoid of immunoreactive cell bodies. In both humans and monkeys, a much weaker CR-IR is seen in the ventral and posterior nuclear groups, as well as the centre median of the paralamina division. Features observed in both species include a very dense and uniform immunoreactivity in the midline nuclear group and its peripheral subdivisions, especially the anterior ventral and some members of the lateral group (Pt. CSL). Other common characteristics include heterogeneous distributions in the paracentral, central lateral with very few labeled cell bodies compared to the whole population. The parafascicular nucleus harbor a group of CR cells confined to its medial portion in both monkeys and humans. The main pattern of CR-IR displayed in both human and monkey seems to be closely related to the thalamic divisions that receive major inputs from CR-positive neurons in limbic structures such as the amygdala and the ventral striatum. The present data reveal that CR is a useful chemical marker for parts of the thalamus related to limbic function. [Supported by FRSQ and MRC].

**IONIC MECHANISMS UNDERLYING SYNCHRONIZED OSCILLATIONS AND TRAVELING WAVES IN A MODEL OF FERRET THALAMIC SLICES.** A. Destexhe\*, T. Balj, D.A. McCormick and T.J. Sejnowski

The Salk Institute, Computational Neurobiology Laboratory, PO Box 85800, San Diego, CA 92186, USA; † Section of Neurobiology, Yale University School of Medicine, 333 Cedar Street, New Haven CT 06510, USA.

A network model of thalamocortical (TC) and thalamic reticular (RE) neurons was developed based on electrophysiological measurements in ferret thalamic slices. Single-compartment TC and RE cells included voltage- and calcium-sensitive currents described by Hodgkin-Huxley type of kinetics. Synaptic currents were modeled by kinetic models of AMPA, GABA<sub>A</sub> and GABA<sub>B</sub> receptors. The model reproduced successfully the characteristics of spindle and slow bicuculline-induced (SBI) oscillations. The most critical parameters were: (a) the mutual recruitment between TC and RE cells, due to their reciprocal connectivity. The time course of GABAergic IPSPs from RE to TC determined the frequency of oscillations (8-12 Hz spindle or 2-4 Hz SBI). (b) Cooperativity in the activation of GABA<sub>B</sub> responses, which are absent during spindles. If the intra-RE GABA<sub>A</sub> IPSPs were suppressed, the stronger discharges of RE cells enhanced GABA<sub>B</sub> IPSPs in TC cells, recruiting TC and RE neurons in the slower highly synchronized SBI oscillations. (c) A TC origin for the "waning" of these oscillations, through the upregulation of I<sub>h</sub> by intracellular calcium, leading to a refractory period in these cells. (d) Local axonal arborization of the TC-RE and RE-TC projections, which allowed traveling phenomena to occur. The model predicts that intrinsic properties of TC and RE neurons and their reciprocal connectivity establish a highly excitable structure; stimulation at any location can induce an oscillatory travelling wave through the reciprocal recruitment of TC and RE cells. The presence of a refractory period in TC cells accounts for the waxing and waning properties of the traveling waves, collisions between waves and the slower propagation of highly synchronized SBI oscillations.

**NEURONS CONTAINING CALRETININ AND EXPRESSING SUBSTANCE P (NK1) RECEPTORS IN THE STRIATUM OF NORMAL AND HUNTINGTON'S DISEASE PATIENTS.** F. Cicchetti\*, P. V. Gould and A. Parent. Neurobiology Res. Cr. and Dept. of Pathol., Enfant-Jésus Hospital, Québec, Canada, G1J 1Z4.

Single immunohistochemical studies of the striatum in normal individuals have revealed the presence of both large and medium aspiny neurons enriched with the calcium-binding protein calretinin (CR). The medium CR neurons outnumbered the large CR neurons throughout the striatum, but the former were more abundant in the caudate nucleus whereas the latter predominated in the putamen. In addition, medium and large aspiny neurons displaying immunoreactivity for substance P (NK1) receptors were also detected in the human striatum. In contrast to CR neurons, however, the proportion of the two types of SPR neurons was about the same in the putamen and in the caudate nucleus. Double-immunostaining experiments have also shown that a significant proportion of the large CR neurons and a small contingent of medium CR neurons displayed SPR immunoreactivity. Furthermore, somatostatin was found to be colocalized in a subset of medium SPR neurons. Thus, the medium SPR neurons appear to correspond, at least in part, to the well characterized somatostatinergic striatal interneurons. On the basis of their morphological features and patterns of distribution, the large SPR and CR neurons are believed to represent subsets of the large cholinergic striatal interneurons. These normative data have allowed us to examine the status of the chemospecific striatal neurons in various neurodegenerative diseases. In the present study, analysis of the striatum in advance cases of Huntington's chorea have revealed that both CR and SPR immunoreactivities were unaltered, despite the marked atrophy of both caudate nucleus and putamen that characterizes this neurodegenerative disease. These findings provide the first evidence for the existence of CR and SPR neurons in the human striatum and indicate that these chemospecific neurons are selectively spared in Huntington's disease. [Supported by the MRC of Canada].

**IN VIVO, IN VITRO AND COMPUTATIONAL ANALYSIS OF DENDRITIC CURRENTS IN THALAMIC RETICULAR NEURONS.**

T.J. Sejnowski\*, A. Destexhe, D. Contreras†, M. Steriade† and J.R. Huguenard‡. The Salk Institute, Computational Neurobiology Laboratory, PO Box 85800, San Diego, CA 92186, USA; † Laboratory of Neurophysiology, Laval University, Québec, CANADA G1K 7P4; ‡ Department of Neurology and Neurological Sciences, Stanford University Medical Center, Stanford CA 94305, USA.

Thalamic reticular (RE) neurons are involved in the genesis of synchronized thalamocortical oscillations, which depend in part on their complex bursting properties. We have investigated the intrinsic bursting properties of RE cells using computational models based on morphological and electrophysiological data. Simulations of a reconstructed RE cell were compared directly to the recordings from the same cell, which allowed precise values for the passive parameters to be obtained. Voltage-clamp data were obtained on the low-threshold calcium current (I<sub>T</sub>) in acutely dissociated RE cells which lack most of their dendrites. Simulations based on a cell with truncated dendrites and Hodgkin-Huxley kinetics reproduced these recordings with a relatively low density of I<sub>T</sub>. In intact RE cells, high densities of I<sub>T</sub> in distal dendrites were required to generate the higher amplitudes of the current seen experimentally, as well as the typical properties of the burst of RE cells. More importantly, we found that, because of dendritic I<sub>T</sub>, synaptic bombardment in the dendrites had a strong impact on the genesis of the burst, and could generate the typical burst responses of RE cells *in vivo*. These findings suggest that synaptic integration on the dendrites of RE cells is significantly influenced by dendritic calcium currents. In addition, we were able to simulate the same behavior in simpler models with as few as three compartments, provided there was a high density of I<sub>T</sub> in the dendrites. These experiments provide firm evidence for resolving the difference observed in the intrinsic bursting properties of RE cells *in vivo* and *in vitro*, on the basis of dendritic calcium currents.

## 466.6

**SYNCHRONIZATION OF THALAMIC SPINDLE OSCILLATIONS IS ENHANCED BY CORTICAL FEEDBACK INPUT.** D. Contreras\*, A. Destexhe†, T. Sejnowski† and M. Steriade†. Lab. of Neurophysiol., School of Med., Laval University, Québec, CANADA, G1K 7P4. †The Salk Institute, Computational Neurobiology Laboratory, La Jolla, CA 92186, USA.

Synchronization of spindle waves was studied in intact cortex and decorticated cats under barbiturate anesthesia. Field potentials were recorded from the cortical suprasylvian gyrus (areas 5 and 7) with an array of 8 equidistant bipolar electrodes (surface-depth), with an interelectrode separation of 1 mm. Sequences of spindles at 7-12 Hz recurred every 5 to 10 seconds and they were simultaneous in all cortical leads. Interruption of corticocortical connections by a cut between recorded foci, in the middle suprasylvian gyrus, did not affect intracortical synchronization. In intact cortex animals, recordings from the thalamus, with the same array of bipolar electrodes (1 mm apart), revealed that most spindle sequences occur simultaneously over a distance of about 7 mm. Massive unilateral decortication decreased intrathalamic synchrony; however, many spindles still occurred simultaneously among the 8 electrodes. In decorticated animals, thalamic recordings with an array of 8 equidistant tungsten microelectrodes, separated by smaller interelectrode distances (0.4 mm), revealed that, when spindling propagated sequentially, thalamic reticular neurons recorded from the rostral pole consistently discharged typical spike-bursts, with acceleration-deceleration patterns, before thalamocortical neurons recorded from more posterior dorsal thalamic nuclei. These results demonstrate the important role of the cortex in enhancing the intrathalamic synchrony within the frequency range of spindles and emphasize the role of rostral reticular neurons in initiating and synchronizing spindling in decorticated animals.

Supported by MRC of Canada (grant MT-3689), the Savoy Foundation and The Howard Hughes Medical Institute.

## 466.7

CHANGES OF INPUT RESISTANCE AND SYNAPTIC EXCITABILITY OF CORTICAL AND THALAMIC NEURONS DURING VARIOUS COMPONENTS OF THE SLOW OSCILLATION IN CAT. L. Timofeev\*, D. Contreras and M. Steriade, Lab. of Neurophysiol., Univ. Laval, Sch. Med., Quebec, Canada G1K 7P4.

A slow oscillation characterizes the activity of cortical and thalamic network during anesthesia and natural slow-wave sleep. Typically, long-lasting (0.2 to 0.8 s) positive field potentials recorded from the cortical depth, recurring at a frequency below 1 Hz, are associated with prolonged hyperpolarization in cortical, thalamic reticular (RE) and thalamocortical (TC) cells. These hyperpolarizations are followed by a depolarizing phase associated with negative field potentials in the cortical depth. To shed light on the nature of cellular phenomena underlying the slow oscillation, intracellular recordings from cortical, RE and TC cells were performed in vivo in cats under ketamine & xylazine anesthesia. Hyperpolarizing current pulses showed that the hyperpolarizing phase of the spontaneous oscillation is accompanied by an increase in input resistance of 15-20% in all three types of cells. During the following depolarizing phase, input resistance decreased by 50 %. Testing synaptic excitability with stimuli applied to prethalamic paths revealed that during the hyperpolarizing phase of the oscillation, bisynaptic EPSPs in RE and cortical cells were virtually abolished. During the same phase, TC cells did not display a decrease in the prethalamic-evoked monosynaptic EPSP, but the hyperpolarization abolished the firing probability, so that the signal transmission through the dorsal thalamus was obliterated. During the depolarizing phases, the responses to prethalamic volleys were overwhelmed by the spontaneous synaptic activity. By contrast, the responsiveness to cortical stimuli was not altered during the slow oscillation. These results indicate that the messages from the periphery are blocked at the level of TC cells during slow oscillatory states, but also show that the responses to corticocortical and corticothalamic signals remain unaffected.

ORGANIZATION OF TERMINAL FIELDS OF SINGLE LABELED CEREBELLAR AXONS IN THE VENTROLATERAL NUCLEUS OF THE MONKEY THALAMUS. A. Mason, K. Kultas-Ilnsky and I.A. Ilnsky\*, Dept. of Anatomy, Univ. of Iowa Sch. Med., Iowa City, IA 52242.

The projection zone topography and ultrastructural features of cerebellothalamic terminals in nonhuman primates have been extensively studied earlier. However, the extent and geometry of the terminal fields of individual cerebellothalamic axons and their relationships to different groups of neurons in the ventrolateral nucleus (VL) are not known. To study these aspects small pressure injections of biotinylated dextran amine were centered on the dentate nucleus of the cerebellum, and after 4-5 weeks of survival time the tissue was processed with DAB for visualization of the tracer. The labeled fibers were traced and their relationships with thalamic neurons were analyzed in continuous series of sections using either a drawing tube or Eutectics system. Some of the material was also analyzed under confocal microscope in transmitted light mode. The thick afferent axons upon entering the VL divided into, on average, four primary branches that after running a similar course for 200-300  $\mu\text{m}$  divided each into 3-5 terminal branches. The latter either ended with irregular shape and size terminal enlargements spaced at irregular intervals or branched one more time before forming the terminals. Up to 10 enlargements could originate from the same terminal branch. The terminals of single afferent axons distributed within a relatively small space (apprx.  $5.6 \times 10^{-4} \mu\text{m}^3$ ) clustering around somata and proximal dendrites of only some neurons present within the space and completely avoiding others. The results suggest that the input to the monkey VL originating in the dentate nucleus is very focused, targets small groups of cells and appears to be directed preferentially to proximal parts of projection neurons. Supported by ROINS24188.

## 466.11

STRIATAL PROJECTIONS FROM THE ETHMOID NUCLEUS IN THE RAT. S. Gagnon\*, M. Levesque, J. Bourassa, M. Deschênes and A. Parent, Centre de recherche en neurobiologie, Hôpital de l'Enfant-Jésus, Univ. Laval, Québec, Canada, G1J 1Z4.

Posterior to the parafascicular (Pf) nucleus and anteroventral to the ventral part of the anterior pretectal area, lies a distinct group of large cells in a thalamic region perforated by vertically oriented fibers. This thalamic region is termed the Ethmoid nucleus (Eth). The axonal projection of Eth neurons was studied in rats after labeling small pools of cells with biocytin. The mapping of axonal arbors was made from serial horizontal sections that were also immunostained for calbindin D-28k, a specific marker of the striatal matrix compartment. Eth cells have a large perikarion from which emerge thick, long and poorly branched dendrites bearing spines and filamentous appendages. Their dendritic domain extends for up to 1.5 mm. Eth fibers project sparsely to the ventral wing of the thalamic reticular nucleus and to the globus pallidus, and arborize densely within the matrix compartment of the dorsal striatum. Most Eth cells also send an axonal branch towards the cortex but this projection appears light. The histological features of the dendrites and axonal terminals of Eth cells are reminiscent of those of Pf neurons. It appears that Eth and Pf neurons are representative of a distinct category of thalamic relay cells, different from those found in the rest of the thalamus, that constitutes the main component of the thalamostriatal pathway.

## 466.8

COMPARISON OF INPUTS FROM THE ENTOPEDUNCULAR NUCLEUS AND THE CEREBELLUM TO VA-VL NEURONS IN THE CAT THALAMUS. T. Futami\*, Y. Izawa<sup>1</sup>, Y. Shinoda<sup>1</sup> and E.G. Jones<sup>2</sup>, Frontier Research Program, The Institute of Physical and Chemical Research (RIKEN), Wako, 351-01, Japan, <sup>1</sup> Dept. of Physiology, School of Med., Tokyo Medical and Dental Univ. Tokyo, 113, Japan and <sup>2</sup> Dept. of Anatomy and Neurobiology, Univ. of California Irvine, CA 92717

Synaptic inputs from the entopeduncular nucleus (ENT) to thalamocortical neurons (TCNs) in the ventroanterior-ventrolateral complex (VA-VL) of the thalamus were characterized in anesthetized cats. Effects of stimulation of the ENT and the brachium conjunctivum (BC) were examined by recording intracellular potentials from VA-VL neurons. TCNs were identified by their antidromic responses to stimulation of the pericruciate cortex.

Stimulation of the ENT evoked monosynaptic IPSPs in TCNs, while stimulation of the BC evoked monosynaptic EPSPs followed by disynaptic IPSPs. Only IPSPs were evoked in virtually all TCNs receiving ENT input. Mapping experiments revealed that TCNs in the rostromedial part of the VA-VL predominantly received input from the ENT, while TCNs in the more caudomedial part of the VA-VL received input from the BC. Less than 10% of the TCNs examined received convergent inputs from both the ENT and BC and all were located at the border between ENT- and BC-receiving areas of the VA-VL. TCNs receiving ENT input projected to area 6, while TCNs receiving BC input projected to areas 4 and 6.

Supported by the Human Frontier Science Program and by the Frontier Research Program, RIKEN.

## 466.10

SEGREGATED VENTRAL PALLIDUM-THALAMIC PROJECTIONS FROM THE CORE AND SHELL REGIONS OF THE RAT NUCLEUS ACCUMBENS: TRANSYNAPTIC RETROGRADE LABELING USING PSEUDORABIES VIRUS. P. O'Donnell\*, A. Lavin, A. A. Grace, and J.P. Card, Depts. Neuroscience and Psychiatry, Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.

The primary output of the nucleus accumbens (NA) is known to exert regulatory control over the mediodorsal thalamic nucleus (MD) via its projections to the ventral pallidum (VP), with the *core* and *shell* regions of the NA projecting to the lateral and medial aspects of the VP, respectively. In this study, we assessed whether these projections remain segregated within the NA-VP-MD system. An attenuated strain of pseudorabies virus was injected into either the medial or lateral segments of the MD, or into the rostral or caudal aspects of the reticular thalamic nucleus (RTN). After appropriate survival times, infected neurons were labeled immunocytochemically using antiviral antibodies. These results show that the medial MD receive direct projections from the medial VP and other regions previously shown to project to this region of the thalamus. Transynaptic projections to the medial MD were observed to arise from the shell (but not the core) region of the NA. Injections into the lateral MD resulted in retrograde labeling of neurons in the globus pallidus (GP) but not the VP, and second order infections were absent from both regions of the NA. Viral injections into the rostral RTN resulted in labeling of cells in the lateral aspect of the rostral VP along with the amygdaloid, basal forebrain, and thalamic nuclei. In these cases, transynaptically infected cells were observed in the core, but not the shell, region of the NA. Injections in the caudal RTN resulted in direct retrograde labeling of cells within the GP (but not the VP), and transynaptic infections were found in cells located in the dorsolateral striatum (but not in the NA). These results suggest that the main output of VP cells receiving inputs from the shell of the accumbens is directed to the medial MD, whereas core neurons contact primarily VP cells that in turn project to the RTN, which is known to regulate thalamocortical activity.

## 466.12

STRIATAL AND CORTICAL PROJECTIONS OF SINGLE CELLS FROM THE CENTRAL LATERAL THALAMIC NUCLEUS IN THE RAT. M. Deschênes\*, J. Bourassa and A. Parent, Centre de recherche en neurobiologie, Hôpital de l'Enfant-Jésus, Univ. Laval, Québec, Canada G1J 1Z4.

The axonal projections of 15 cells from the caudal part of the central lateral thalamic nucleus (CL) were traced in the cerebral cortex and striatum of rats after labeling small pools of neurons with biocytin. CL neurons have a medium sized perikarion from which emerge numerous frequently branching dendrites bearing a few sessile spines. Their axons branch profusely in the thalamic reticular nucleus, and arborize sparsely in the striatum and massively in the cerebral cortex. At striatal level, CL fibers form a rather loosely organized network composed of axonal branches that appear to contact *en passant* several striatal neurons. In contrast, the cortical branch of CL axons forms multiple (4-5) patches of terminations in layers Va and III aligned along the rostrocaudal extent of the motor area. Projections to layers I and II are very sparse, consisting of occasional branches which do not show any ramifications. These results reveal that CL relay neurons, once thought to project diffusely to the superficial cortical layers, innervate mainly the mid cortical layers of a single cytoarchitectonic area. Therefore, it appears likely that the early surface negativity observed in the cortex after electrical stimulation of CL was due either to current diffusion or to activation of a disynaptic pathway.

This research was supported by the MRC of Canada.

## 466.13

STRIATAL AND CORTICAL PROJECTIONS OF SINGLE CELLS FROM THE PARAFASCICULAR NUCLEUS IN THE RAT. J. Bourassa\*, A. Parent and M. Deschênes. Centre de recherche en neurobiologie, Hôpital de l'Enfant-Jésus, Univ. Laval, Québec, Canada G1J 1Z4.

The thalamostriatal projection from the rat parafascicular nucleus (Pf) was studied by tracing anterogradely axons of small pools of thalamic neurons labeled with biocytin. A total of 21 Pf neurons were analyzed in the present study. Pf neurons have a large perikarion from which emerge thick, long and poorly branched dendrites bearing spines and filamentous appendages. The dendritic domain extends for up to 1.5 mm. After leaving the nucleus, Pf axons course through the thalamic reticular nucleus, where they emit two poorly branched collaterals, traverse the globus pallidus, where they also distribute collaterals, and arborize massively in the striatum and sparsely in the cerebral cortex. At striatal level 4-5 axon collaterals leave the main axon and terminate in clusters scattered over a large rostrocaudal sector of the striatum. These patches are located within the calbindin D-28k rich matrix compartment. The cortical branch forms small terminal puffs centered upon layer VI of the motor cortex. Before entering the striatum some Pf axons also give rise to descending collaterals that arborize in the entopeduncular nucleus, the subthalamic nucleus and the red nucleus. These findings provide the first direct evidence that virtually all Pf cells project to both striatum and cerebral cortex. They also reveal that, besides their massive projection to the striatum, Pf axons provide collaterals to other components of the basal ganglia.

This research was supported by the MRC of Canada.

## 466.15

SINGLE INJECTION OF GABA INTO RAT MOTOR THALAMUS (VL/VN) INCREASES STRIATAL GLUTAMATE RELEASE AND THE DENSITY OF NERVE TERMINAL GLUTAMATE IMMUNOREACTIVITY. C.K. Meshul\*, C. Allen, J.P. Riggan, and D.J. Feller. V.A. Medical Center and Oregon Health Sciences University, Portland, OR. 97201.

Subchronic injections of GABA ( $10^{-5}$  M, 0.5  $\mu$ l) into VL/VN for 21 days resulted in an increase in the percentage of striatal glutamatergic synapses with perforated postsynaptic densities (PSDs) and an increase in the density of glutamate immunoreactivity within nerve terminals of all asymmetric synapses (Meshul et al 1995). These findings are similar to those seen after subchronic haloperidol treatment. An acute injection of GABA (15  $\mu$ l) into VL/VN results in an increase in striatal glutamate release as measured by *in vivo* microdialysis. This may be due to stimulation of presynaptic GABA receptors within the thalamus, leading to a decrease in GABA release and activation of the thalamo-cortico-striatal pathway. There was no change in striatal glutamate synapses with perforated PSDs or in glutamate release if GABA was injected into the somatosensory thalamic nuclei (VPM/VPL). We determined if a single injection of GABA ( $10^{-5}$  M, 15  $\mu$ l) into VL/VN would also result in changes in glutamate synapses 1 day later. We found that there was a significant increase in the percentage of striatal synapses with perforated PSDs and an increase in the density of nerve terminal glutamate immunoreactivity. If these findings are due to activation of the thalamo-cortico-striatal pathway, then it is possible that the identical changes observed with haloperidol treatment may also be due to increased activity of corticostriatal synapses. Supported by Dept. of Veteran Affairs.

## 466.17

THE CHEMICAL ARCHITECTURE OF THE DORSOMEDIAL AND INTRALAMINAR THALAMIC NUCLEI AND ITS RELATIONSHIP WITH THE THALAMOSTRIATAL SYSTEM IN THE CAT. E. Mengual, S. de las Heras, J.L. Velazco and J.M. Giménez-Amaya\*. Departamento de Morfología, Facultad de Medicina, U.A.M., 28029 Madrid, Spain.

A great discrepancy is found among the different authors concerning the delineation of the mediodorsal (MD) and intralaminar (IL) thalamic nuclei in the cat, following cytoarchitectonic and/or connectional criteria. In this study, the distribution of acetylcholinesterase (AChE), NADPH-diaphorase (NADPH-d) and cytochrome oxidase (CO) histochemical activities was studied, together with cytoarchitectonic and myeloarchitectonic techniques, in order to further characterize these thalamic nuclei and to establish a clearer delineation between them. Additionally, this chemical architecture was correlated with the distribution of retrogradely labelled thalamostriatal neurones, after stereotaxic injections of either HRP-WGA or fluorescent tracers into the caudate nucleus. For this purpose, twenty four adult cats were used for the histochemical studies and twelve animals for the hodological ones. The main findings of this study were: 1) The heterogeneous distribution of AChE activity within these nuclei allowed to delineate MD from the adjacent nuclei rostrally, medially and, at rostral levels, also laterally. 2) The AChE activity showed a network of AChE-rich patches located in the midline, in the ventral and lateral portions of MD and in the dorsal portions of the paracentral nucleus, that crossed the cytoarchitectonic borders. 3) NADPH-d activity in MD and IL displayed a distribution pattern that overlapped that of AChE, except in the centromedian-parafascicular (Cm-Pf) complex and in the central medial nucleus. CO activity, also heterogeneous, proved to be very useful in the identification of the central lateral nucleus (CL). 4) The distribution of the thalamostriatal neurones confirmed the chemical architecture of DM and IL, being located at histochemically defined areas, such as the area dorsal to MD, rhomboidal nucleus with its lateral wing, Cm-Pf complex and moderately stained areas within CL.

## 466.14

UNILATERAL 6-HYDROXYDOPAMINE (6-OHDA) LESIONS OF THE SUBSTANTIA NIGRA INDUCE BILATERAL INCREASES IN GLUTAMIC ACID DECARBOXYLASE (GAD) mRNA IN THE RETICULAR THALAMIC NUCLEUS. J.M. Delfs\*, J.J. Soghomonian\*, Y.M. Ciaramitaro and M.F. Chesselet. Institute of Neurological Sciences and Dept. of Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, PA and \*Hopital De L'Enfant Jesus, Quebec, Canada.

The reticular thalamic nucleus (RTN) is a thin band of GABAergic neurons which surrounds the lateral border of the thalamus. Due to its extensive and reciprocal projections with the cortex and thalamus, the RTN is thought to be involved in attentional processes. The RTN also receives inputs from the basal ganglia, in particular the globus pallidus (GP, external segment) and the substantia nigra (SN) suggesting that it may be involved in relaying motor information to the thalamus and cortex. In order to explore the relationship between the basal ganglia and the RTN, rats received unilateral 6-OHDA lesions of the SN and were sacrificed 2 or 3 weeks after the lesion. Sections of the RTN at the level of entopeduncular nucleus were processed for *in situ* hybridization and emulsion autoradiography. A unilateral SN lesion resulted in a bilateral increase in GAD (Mr 67,000:GAD67) gene expression in neurons of the RTN. The level of mRNA encoding GAD (Mr 65,000:GAD65) was increased ipsilaterally to the SN lesion. Neither short-term (7 day) or long-term (8 month) haloperidol treatment, which induce catalepsy or orofacial dyskinesia, respectively, altered GAD67 mRNA levels in the RTN, indicating that changes in GAD mRNA in the RTN are not related to motor symptoms. The results reveal novel bilateral effects of unilateral dopamine depletion in the RTN. In view of the role of the RTN in attentional processes, this effect could be related to the non-motor effects of dopamine depletion. This work was supported by PHS grants MH 44896 and MH 17168.

THALAMIC ARBORIZATIONS OF AXONS ARISING IN THE MESOPONTINE RETICULAR FORMATION OF SQUIRREL MONKEYS. C. Asanuma\*. Laboratory of Neurophysiology, NIMH, NIH Animal Center, Poolesville, MD 20837.

The thalamic projections of the mesencephalic (MRF) and pontine (PRF) reticular formation were examined and compared using anterograde transport of wheat germ agglutinin-conjugated horseradish peroxidase (WGA-HRP) and tetramethylbenzidine (TMB) histochemistry in squirrel monkeys.

Injections of WGA-HRP directed into the rostral MRF result in diffusely scattered anterograde label (fine, dust-like particles of TMB reaction product) throughout the dorsal thalamus and thalamic reticular nucleus (TRN). Increased concentrations of diffuse anterograde label are evident bilaterally throughout the intralaminar nuclei, and patches of moderate label occur laterally in the ipsilateral mediodorsal nucleus (MD) and in parts of the anterior ventral lateral nucleus (VLO).

PRF injections of WGA-HRP, in contrast, result in a patchy distribution of anterograde label within ventral MD, at the level of the centromedian/parafascicular complex (CM/Pf). Dense clusters of label occur ventrally within the central lateral nucleus (CL) as well as at this level, whereas labeling elsewhere within CL and throughout the intralaminar nuclei is spread more evenly and occurs in only moderate density. Anterograde labeling elsewhere in the dorsal thalamus is light. As with the MRF cases, the anterograde labeling within the intralaminar nuclei resulting from PRF injections is bilateral. Prominent labeling in the ventral lateral geniculate nucleus extends dorsally along the medial margin of the TRN. However, only occasional axons are detected within the TRN itself.

When the CL labeling resulting from an MRF injection is examined at the EM level, the TMB reaction product is observed within both myelinated and unmyelinated axons and in terminal profiles that establish synaptic contact with unlabeled dendrites. The synaptic relations of terminals arising in different sectors of the mesopontine reticular formation as well as the relation of the ascending brainstem terminals with the GABA<sup>+</sup> and the GABA<sup>-</sup> synaptic profiles of the CL neuropil are currently being examined in more detail.

## 466.18

DOPAMINE AGONIST-EVOKED LOW THRESHOLD SPIKES IN MEDIODORSAL THALAMIC NUCLEUS NEURONS IN VITRO. A. Lavin\* and A.A. Grace. Depts. Neuroscience and Psychiatry, CNUP, Univ. Of Pittsburgh, Pittsburgh, PA. 15260.

The mediodorsal thalamic nucleus (MD) of the rat is reported to be innervated by dopaminergic and non-dopaminergic cells of the ventral tegmental area (VTA), and DA receptors have been shown to be present in the thalamus. Using intracellular recordings in 400  $\mu$ m sagittal slices, we studied the effect of the DA D2 agonist quinpirole (10  $\mu$ M) on the physiology of MD thalamic neurons. The D2 agonist applied into the bath caused a hyperpolarization of the membrane of 14/22 cells by  $5.8 \pm 4.4$  mV, and depolarized 4/22 for  $9.3 \pm 12.1$  mV. Following drug application there was an increase in the average input resistance of 9/16 neurons for 32% (all cells had exhibited a depolarizing response) and also a decreased in the input resistance by 17% in 7/16 cells (all cells had exhibited hyperpolarizing response) and also an increase in the time constant in 27% (7/10 cells, 6 of them hyperpolarized). In the majority of cells tested (17/22 cells), the D2 agonist caused an increase in the apparent spike threshold of the cells by  $8.1 \pm 3.8$  mV. Plotting I/V regression lines before and after quinpirole administration showed a reversal potential for this response averaging approximately -92 mV, which is consistent with the reversal of a K<sup>+</sup> conductance. When haloperidol was applied, a depolarization of the membrane ( $9.2 \pm 1.4$  mV, n=2) and a decrease in the input resistance (17%) were produced. In addition, a prominent (LTS)-like event was apparent in 11/18 cells following quinpirole administration. Thus, in MD thalamic cells D2 receptor stimulation was found to cause a hyperpolarization that may be due to an increase in K<sup>+</sup> conductance, which in turn may facilitate the expression of the LTS.

## 467.1

PROJECTIONS FROM DORSAL PARAFLOCCULUS TO CEREBELLAR NUCLEI OF MACAQUES. M. Glickstein, I. Krali-Hans, B. Mercier, C. Swales, N. Gerrits, J. Voogd, R. J. Krauzlis, and F. A. Miles\*. Department of Anatomy, University College London, London WC1E 6BT, England, Department of Anatomy, Erasmus University, Rotterdam, Netherlands, and Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

The dorsal parafoveus is a major target for visual input to the cerebellar cortex. To study the projections from dorsal parafoveus and adjacent areas of the cerebellar cortex, wheatgerm-agglutinin horseradish peroxidase injections of between 0.1 and 0.2 microliters were placed in the dorsal parafoveus of three monkeys, and in other cerebellar cortical areas of six others. We report here on the nuclear targets revealed by these injections. Injection into the dorsal parafoveus revealed a dense zone of terminals in a ventral, caudal region of the posterior interpositus nucleus and adjacent dentate nucleus. Cells in the dorsal parafoveus (Noda and Mikami, 1986) and in the ventral caudal region of nucleus interpositus (Van Kan et al., 1993) are known to discharge in relation to eye movements. Injections into paramedian lobule, Crus II, the ventral parafoveus, or vermal lobule VII revealed projections to other, non-overlapping nuclear targets.

Thus, in addition to other cerebellar circuits which involve the flocculus, ventral parafoveus, or vermal lobule VII, there is another pathway by which visual inputs can influence eye movements: Visual cells in the pontine nuclei receive an input from dorsal extrastriate visual areas and relay to the dorsal parafoveus, which in turn projects to the posterior interpositus nucleus.

## 467.3

SPINAL CONNECTIONS OF CAT POSTERIOR INTERPOSITUS.

K. M. Horn\*, C. M. Porter and A. R. Gibson. Barrow Neurological Institute, Phoenix, AZ 85013.

Injections of HRP into the spinal cord label neurons in medial regions of the cerebellar posterior interpositus (Matsushita & Hosoya, Br. Res. 142). Where does the interposito-spinal projection terminate, and does it target specific motor neuronal pools? To answer these questions, we injected WGA-HRP (.008 ul, 1%) into cat posterior interpositus.

Labeled fibers could be traced from the injection site through the decussation of the superior cerebellar peduncle. The fibers descended along the neuraxis as a widely spaced group passing above the inferior olive; at spinal levels, the fibers coursed in the ventrolateral funiculus. No motoneuronal pools were targeted by the projection, and labeling in the spinal gray was largely confined to Rexed's lamina VIII contralateral to the injection site. Although the labeled area decreased in size and moved medially at levels caudal to C3 (as does lamina VIII), some label was present as far caudally as T1. In addition to the anterograde label, large retrogradely labeled neurons were also present in lamina VIII.

Neurons in lamina VIII provide crossed spinal connections. Therefore, the interposito-spinal pathway may be involved with muscles requiring bilateral control, such as those of the neck or spine. Spinal neurons projecting back to interpositus could allow the cerebellum to respond to lamina VIII activity at very short latency.

## 467.5

PROJECTIONS FROM THE RED NUCLEUS TO THE INTERPOSITUS NUCLEUS IN THE RAT DEMONSTRATED BY THE RETROGRADE TRANSPORT OF FLUOROGOLD. J.M. Lockard\* and D.G. Lavond. Dept. of Neurobiology, Univ. of Southern California, Los Angeles, CA 90089

Injections of a 2% solution of Fluorogold (Fluorochrome, Inc.) in 0.9% saline were made through a glass micropipette (tip diameter 25 µm) in the cerebellar interpositus nucleus of Sprague-Dawley rats. Injections were made over a 10 minute period with a constant current unit, set to deliver a 7 second, +5 µA pulse, with 7-second interpulse durations. Survival times for the animals was 14 days. Animals were then deeply anesthetized with sodium pentobarbital (35-50 mg/kg) and then perfused transcardially with 400 ml of ice-cold 4.0% paraformaldehyde in 0.1 M sodium borate buffer at pH 9.5, following a brief saline rinse to remove most of the blood. The brains were then removed and postfixed for 24 hrs. at 4°C in the same fixative containing 10% sucrose. Serial 30 µm thick sections were collected, with one series being processed for immunohistochemistry with an anti-Fluorogold serum (Chemicon), at a concentration of 1:10,000. The primary antiserum is localized using a standard method for visualizing the avidin-biotin complex system. The second adjacent series is mounted and Nissl-stained for reference purposes. Retrograde cell labeling was seen throughout the rostral-caudal extent of the contralateral red nucleus. These findings support the earlier reports of Courville & Brodal (J. Comp. Neurol. 126:471-485, 1966) and more recently by Huisman et al. (Brain Res. 264:181-196, 1983) and further extends the key role played by the red nucleus in cerebellar functioning.

## 467.2

POSTSYNAPTIC TARGETS OF PURKINJE CELLS IN THE CEREBELLAR AND VESTIBULAR NUCLEI. A. S. Berrebi\* and C. I. DeZeeuw†, ENT Dept, West Virginia Univ School of Medicine, Morgantown, WV and †Dept of Anatomy, Erasmus Univ Rotterdam, Rotterdam, The Netherlands.

The cerebellar (CN) and vestibular nuclei (VN) consist of a heterogeneous group of inhibitory and excitatory neurons. A major proportion of the inhibitory neurons provide GABAergic feedback to the inferior olive, while the excitatory neurons exert more direct effects on motor control via non-olivary structures. It is not clear whether Purkinje cells (PCs) innervate all neuronal types in the CN and VN nor whether an individual PC axon can innervate different types of neurons.

We studied the postsynaptic targets of PC axons in the rat by combined preembedding immunolabeling with L7, a PC-specific marker, and postembedding GABA and glycine immunocytochemistry. In the CN and VN, and nucleus prepositus hypoglossi PC terminals were apposed to GABAergic and glycinergic (GLY) neurons as well as to larger nonGABAergic, nonGLY neurons. In the CN and VN individual PC terminals innervated both inhibitory and excitatory neurons. Both neuron types were not only contacted by GABAergic PC terminals, but also by GABA-containing terminals that were L7-negative and by nonGABAergic, nonGLY terminals that formed excitatory synapses. GLY-containing terminals were relatively scarce (<2% of the GABA-containing terminals) and frequently contacted larger nonGABAergic, nonGLY neurons.

In summary, PC axons modulate the activity of multiple cell types in the CN and VN complex. The observation that individual PCs can innervate both excitatory and inhibitory neurons suggests that the excitatory cerebellar output system and the inhibitory feedback to the inferior olive may be controlled simultaneously.

Supported, in part, by grants from DRF (ASB), NWO & KNAW (CID).

## 467.4

INFLUENCE OF UNILATERAL LABYRINTHECTOMY ON EXPRESSION OF PROTEIN KINASE C IN A CEREBELLAR-VESTIBULAR PATHWAY IN RAT. N.H. Barmack\*, J. Yoshimura, Z.-Y. Qian and H. Fushiki. R.S. Dow Neurological Sciences Inst., Portland, OR 97209.

Protein Kinase C-δ, a calcium-independent isoform of PKC, is found in sagittal banding patterns in the cerebellum of rat. In other systems, PKC has been linked to the regulation of ion channels related to signal transduction. Using immunohistochemical staining for PKC-δ, we have confirmed these banding patterns in the uvula-nodulus. Western blotting identifies a PKC-δ positive protein with a molecular weight of 75-80 KDa. In the present report we investigate the projection patterns of PKC-δ positive, uvula-nodular Purkinje cells.

In three rats, anesthetized with ketamine-xylazine-acepromazine, we made unilateral lesions of the uvula-nodulus and examined the distribution of PKC-δ positive terminals within the vestibular complex. Subtotal unilateral lesions deplete more than 50% of the terminals within the ipsilateral caudal medial vestibular nucleus (MVN) and nucleus prepositus hypoglossi (NPH). In fifteen anesthetized rats, we performed unilateral labyrinthectomies. The rats were sacrificed 6 hrs - 38 days after the labyrinthectomy. PKC-δ positive terminals within the MVN and NPH were counted. Unilateral labyrinthectomies caused a decreased count of PKC-δ positive terminals in the ipsilateral MVN and NPH. Paradoxically, unilateral labyrinthectomies caused no detectable decreases in labeling of Purkinje cell bodies in the ipsilateral nodulus. Nor, using hybridization histochemistry, could we detect a change in PKC-δ mRNA in nodular Purkinje cells. The decreased PKC-δ labeling in terminals within the ipsilateral vestibular complex may reflect a change in the regulation of a protein to which PKC-δ binds.

## 467.6

ELECTROPHYSIOLOGICAL PROPERTIES OF NEURONS IN THE RAT PONTINE NUCLEI IN VITRO. C. Schwarz\*, M. Möck and P. Thier. *Sekt. für Vis. Sensorik, Neurologische Universitätsklinik, 72076 Tübingen, Germany.*

The pontine nuclei are the major relay of cortical information destined for the cerebellum. We established a slice preparation of rat pontine brainstem in order to study the membrane and synaptic properties of pontine neurons using standard intracellular electrophysiological techniques. We recorded from 69 pontine neurons which displayed a resting potential of  $-63 \pm 5.8$  mV (mean  $\pm$  SD) and were not spontaneously active. The input resistance was  $50 \pm 28$  MΩ and the time constant was  $7.3 \pm 2.9$  ms (measured with injection of  $-1.0/-0.2$  nA respectively). Action potentials (amplitude  $70 \pm 7.7$  mV) were elicited with current pulses depolarizing the membrane potential to  $-41 \pm 8.7$  mV. Each spike was followed by a marked afterhyperpolarization. A salient property of pontine neurons was the adaptation of the firing rate when depolarized with long lasting current pulses.  $Ca^{2+}$  dependency of this phenomenon could be demonstrated by the reduction of the spike adaptation under substitution of extracellular  $Ca^{2+}$  by  $Mn^{2+}$  or  $Co^{2+}$  (2.4 mM).  $Ca^{2+}$  influx most probably takes place via voltage dependent  $Ca^{2+}$  channels as broad spikes could be elicited by depolarizing current pulses from rest during the block of  $K^{+}$  and fast  $Na^{+}$  channels by TEA (10 mM) and TTX (1 µM). These broad spikes were based on  $Ca^{2+}$  current as was shown by their sensitivity to substitution of extracellular  $Ca^{2+}$  by  $Mn^{2+}$ . We next studied the postsynaptic influences of cortical afferents by electrical stimulation of the pedunculi cerebri. Graded EPSPs could be elicited depending on the amplitude of stimulation currents (minimal 20 µA). The EPSPs were sensitive to DNQX (25 µM) suggesting glutamate as transmitter acting on AMPA receptors. In most cases the time of decay of the EPSPs increased markedly with depolarized membrane potentials. This may be due to an additional involvement of NMDA receptors, an issue which we are investigating currently. Supported by DFG SFB 307-A1

## 467.7

**CEREBELLAR AFFERENTS FROM THE SUPERIOR COLLICULUS AND A17 ARE KEPT SEGREGATED IN THE RAT PONTINE NUCLEI** *Anja Horowski, Cornelius Schwarz and Peter Thier* (SPON: European Neuroscience Association). *Sekt. für Vis. Sensomotorik, Neurologische Universitätsklinik, 72076 Tübingen, Germany.*

We investigated whether inputs to the cerebellum arising from the superior colliculus (SC) and the visual cortex (A17) are integrated in the pontine nuclei (PN). To this end we first used double anterograde tracing (DiI, DiAsp) from different points within each structure in order to clarify if a topographical organization of pontine afferents exists. The tectopontine terminal fields were then compared with those originating in A17. In a second step we used a combination of anterograde tracing and intracellular fills of identified projection neurons in fixed slices in order to investigate if projection neurons extend their dendrites into the terminal fields of both structures.

Independent of the location of the injection sites in the SC and A17, DiI and DiAsp-labeled terminal fields were largely congruent. Tectopontine fibers converge essentially in one pontine compartment while those arising from A17 were distributed among 3 to 4 compartments. Comparing tectal and visual-cortical terminal fields within the PN revealed that while located close to each other they in any case remain segregated. Moreover, intracellular fills showed that the dendrites of pontocerebellar neurons respect the borders of the labeled axon terminal fields and do not tend to cross them. We therefore conclude that visual information from cortical and subcortical sources destined for the cerebellum is kept segregated from each other in the PN. *Supported by DFG SFB 307-A1*

## 467.9

**CALRETININ IMMUNOREACTIVE UNIPOLAR BRUSH CELLS FORM PARASAGITTAL BANDS IN THE RABBIT CEREBELLUM.** *M.R. Dino\*, E. Mugnaini.* Neuromorphology Lab, U-154, Univ. of Conn., Storrs, CT. 06269-4154

Golgi and immunocytochemical methods have been used to anatomically characterize the unipolar brush cells (UBCs) in the granular layer of the rodent cerebellum. Intermediate in size between the granule and Golgi cells, UBCs are distinguished by a brush-like formation, consisting of several short branchlets, emanating from the tip of a single, relatively thick dendrite. The brush usually establishes a giant synapse with a single mossy fiber rosette, is postsynaptic to small boutons of the Golgi cell axon, and, in addition, is presynaptic to granule cell dendrites. Utilizing the calcium binding protein calretinin as a neuronal marker, we have mapped the distribution of UBCs in Brazilian opossum, mouse, rat, guinea pig, rabbit, cat, Rhesus monkey, and human by immunocytochemistry. The features of the unipolar brush cells are remarkably similar in all mammals analyzed, including human. As a general trend, the UBCs are distributed in cerebellar lobules that receive the least pontine nuclei input, are particularly enriched in the vestibulocerebellum, and are more prominent and widely distributed in cat, macaque and human than in rodents. A remarkable interspecies variation, however, was observed in the rabbit, where UBCs, in addition to the patterns observed in other species, were distributed in distinct alternating on-off compartments, reminiscent of the parasagittal zones described by others. Experiments are in progress with other cell population markers to establish whether calretinin-negative UBCs are present in the off-bands. In addition to UBCs, calretinin positive mossy and climbing fibers were also prominent in the rabbit cerebellum. *Supported by NIH grant NS09904.*

## 467.11

**CEREBELLAR MODULAR ORGANIZATION IS MAINTAINED IN NUCLEO-BULBAR PROJECTIONS: AN ANATOMICAL TRACER STUDY IN THE RAT.** *T.M. Teune, J. van der Burg, T.J.H. Ruigrok and J. Voogd.* Dept. of Anatomy, Erasmus University Rotterdam, 3000 DR, The Netherlands.

**Introduction.** Cerebellar circuitry is characterized by longitudinally arranged cortico-nuclear and olivo-cerebellar projections. Less is known to what extent this modular organization is preserved in the cerebellar output to the brainstem. The potential di- and convergence of projections from the cerebellar nuclei (CN) to four functionally different target areas (the inferior olive: IO; the nucleus reticularis tegmenti pontis: NRTP; the red nucleus: RN; the prerulear area: preRN) was investigated. Retrograde tracers (WGA-BSA-gold + CTb) were applied to CN target areas. Anterograde tracers (BDA + Pha-L) were applied to the CN.

**Retrograde labeling.** Cases with injection combinations that involved the IO resulted in very sparse double labeling (less than 0.5% of all labeled cells). Combinations of NRTP, RN and preRN injections showed up to 45% double labeled CN cells. The posterior interposed nucleus (PIN) remained relatively devoid of labeling from the NRTP.

**Anterograde labeling.** All cases with separate injection sites in the CN resulted in distinct patches of terminal labeling within the IO, NRTP, RN and preRN, even when both tracers were centered on the same subnucleus. PIN injections did not result in labeling within the NRTP. Injections centered on the anterior interposed nucleus (AIN) did not result in labeling within the preRN.

**Conclusions:** A) the nucleo-olivary neurons represent a distinct entity within the CN; B) AIN and lateral cerebellar nuclear (LCN) neurons collateralize to the NRTP, RN and/or preRN; C) The CN projections to the brainstem maintain a non-overlapping topographic organization.

## 467.8

**EXPRESSION OF aFGF AND A NOVEL PROTEIN TYROSINE PHOSPHATASE mRNA FOLLOWS A ROSTROCAUDAL BOUNDARY IN THE MURINE CEREBELLAR CORTEX.** *<sup>1</sup>A. Rotter\*, <sup>2</sup>P.E. McAndrew, <sup>2</sup>A.H.M. Burghes, <sup>3</sup>J.-M. Chiu, <sup>1</sup>J.E. Evans, <sup>1</sup>M. Sutter and <sup>1</sup>A. Frostholm.* Depts. of <sup>1</sup>Pharmacology, <sup>2</sup>Neurology and <sup>3</sup>Internal Medicine, The Ohio State University, Columbus, OH 43210.

The cerebellum is a highly compartmentalized structure, being organized into various layers, parasagittal zones and anterior-posterior compartments. While the segregation of molecular markers into lamina is indicative of differences in neuronal populations of the various layers, parasagittal zonal differences are a reflection of afferent and efferent connectivity. Recently, genes which specify cerebellar rostral-caudal compartments during development have been identified and have been shown to define a distinct boundary between anterior and posterior regions. We have used *in situ* hybridization with cRNA probes to define the distribution of acidic FGF mRNA and a novel protein tyrosine phosphatase (PTPase) mRNA in the cerebellar cortex. Within the cerebellar cortex, the expression of both genes was limited to the granule cell layer. Each signal was strong in the anterior region (lobules 1-6) and formed a distinct boundary with posterior lobules at the dorsal aspect of lobule 6. The expression of the two messages may be related to the homeobox gene, *Otx-1*, which has a similar developmental expression pattern. This developmental boundary was first noted in several mouse mutants, including meander tail, leaner, and swaying. The restricted pattern of acidic FGF and the novel PTPase implies that these molecules may have a specific signaling role in the anterior region of the cerebellum.

## 467.10

**Quantitative Anatomical Aspects of the Inhibitory Interneurons of the Rat Cerebellar Molecular Layer, A Light and Electron Microscopic Golgi Study.** *F. Sultan\*, M.H. Ellisman<sup>2</sup> and J.M. Bower<sup>1</sup>.*

<sup>1</sup>Div. of Biology 216-76, Caltech, Pasadena, CA 91125 and

<sup>2</sup>San Diego Microscopy and Imaging Resource, Dept. of Neurosciences, UC San Diego, La Jolla, CA 92093.

The basket and stellate cells are important elements in the cerebellar cortex circuit. Together, these cells form the second most numerous type of neuron in the cerebellar cortex. The long term goal of this study was to provide accurate anatomical data to construct a realistic model of these neurons.

Using the Eutectic Neuron Tracing System we reconstructed at the light microscopic level seven stellate and two basket cells stained with the Golgi-Rapid method. The average length of the stellate cell axon was 1150  $\mu$ m. The average axonal swelling or bouton density of the stellate cell axon was 0.13/ $\mu$ m. All stellate cells had local axonal collaterals. The majority (5/7) had a main axon that extended beyond the region occupied by the stellate cells dendritic tree (up to 550  $\mu$ m from the soma).

In addition to the light microscopic level, the dendrite of a Rapid-Golgi stained basket cell was serially sectioned for electron microscopy after gold-toning. A total of 41.9  $\mu$ m dendritic length was reconstructed and analyzed. The number of synapses per dendritic length calculated was 0.9 synapses/ $\mu$ m. The serial reconstruction of the dendrite is employed in order to facilitate the identification of the excitatory presynaptic structure, i. e., parallel or ascending part of the granule cell axon.

The two major functions which have been proposed for the inhibitory cells of the molecular layer are threshold control and lateral inhibition. If the overlap between the dendrite and the axon were large, then the former hypothesis would be favored. If the overlap were small, then the latter is more likely. A method is proposed that allows a quantitative comparison of the overlap between the two structures.

## 467.12

**Perioral Regions of Somatosensory Cortex Project to Corresponding Cerebellar Regions Through Spatially Restricted Domains Within the Pontine Nuclei.**

*J.H. Thompson\*, K.A. Lyngstad<sup>2</sup>, J.G. Bjaalie<sup>2</sup> and J.M. Bower<sup>1</sup>.*

<sup>1</sup>Division of Biology 216-76, Caltech, Pasadena, CA, 91125 and

<sup>2</sup>Dept. of Anatomy, University of Oslo, N-0317, Oslo, Norway.

We have been using electrophysiologically guided placement of punctate iontophoretic injections of tracers to reveal the details of how a somatotopic map in S1 of somatosensory cortex projects to a "fractured" somatotopic map in Crus IIa of the cerebellar hemisphere via the pontine nuclei. High density micromapping techniques in both cerebral cortex and the cerebellum have allowed precise localization of representations of specific regions of the body surface. Tracers were delivered with iontophoresis in the upper lip (UL) representation in S1, layer 5, and in an UL patch in the granule cell layer of Crus IIa. The distributions of anterogradely labeled corticopontine fibers and retrogradely labeled ponto-cerebellar cell bodies were computer reconstructed as point clouds inside a solid model representing the pontine nuclei. Using anatomical landmarks, the distribution patterns from several experiments were superimposed for comparison. Inspection of these and individual cases has revealed several important findings. The UL representation of corticopontine fibers occupies a much more restricted space than does the entire facial region. The ponto-cerebellar cell bodies which project to the UL patch are located in only a part of the domain for Crus IIa-projecting ponto-cerebellar cells. Fibers from the UL region of S1 and cells projecting to the UL patch of Crus IIa are not in completely overlapping regions, but appear to occupy adjacent subspaces. We find no evidence supporting the traditional concept of "columns" of cortico-pontine fibers.

## 467.13

NOS, NMDAR1 AND CYTOCHROME OXIDASE IN THE BRAIN-STEM-CEREBELLAR CIRCUIT OF MACACA MULATTA. B.J. Anderson, W.S. Liebl, B. Myklebust\* and M. Wong-Riley. Dept. of Cell. Biol. & Anat., Med. Coll. of Wisconsin, Milwaukee, WI 53226.

Nitric oxide (NO) is a gaseous intra- and inter-cellular messenger in the CNS. NO production can be triggered by the activation of NMDA or other glutamate receptors. The level of nitric oxide synthase (NOS) is high in the rodent cerebellum, but its localization is unknown in the monkey. The goal of the present study was to correlate the distribution of NOS with that of NMDAR1 (a major NMDA receptor subtype) and of cytochrome oxidase (C.O.; a metabolic marker) in the macaque cerebellum and precerebellar nuclei. Serial sections were reacted for NOS, NMDAR1, and C.O., respectively. All three labels were present in the cell bodies and dendrites of neurons in the inferior olive (IO), pontine nuclei (PN) and deep cerebellar nuclei (DCN). In the cerebellar cortex, Purkinje cell dendrites are labeled for NMDAR1, C.O. and lightly for NOS. Granule and basket/stellate cells and Purkinje cell bodies were labeled in a heterogeneous but spatially corresponding pattern for NMDAR1. NOS consistently labeled glomeruli in the granular cell layer and basket/stellate cells in their entirety in the molecular layer. The labeling patterns in the IO, PN and DCN are consistent with NMDA-triggered NO production in these regions. Unexpectedly, granule cells in the cerebellum were not labeled for NOS. The lack of a consistent co-localization of NOS and NMDAR1 is in agreement with earlier reports that non-NMDA receptors may also be involved in NO production. The high levels of C.O. in many NMDAR1+ structures suggests that excitatory input imposes a high energy demand on these neurons. (Supported by NIH NS18122)

## 467.15

PHYSIOLOGICAL EFFECTS OF CALCITONIN GENE-RELATED PEPTIDE IN THE MOUSE INFERIOR OLIVE. K.V. Gregg\* and G.A. Bishop. Neuroscience Program, The Ohio State University, Columbus, OH 43210.

We have previously shown that calcitonin gene-related peptide (CGRP) immunoreactive varicosities have a dense distribution throughout all subnuclei of the inferior olivary complex (IOC) of the mouse (Gregg et al., Soc. Neurosci., 24:714.2, 1994). The aim of the present study was to determine the physiological effects of CGRP on olivary neurons and to analyze interactions between the peptide and excitatory amino acids (EAAs) through the use of extracellular recordings in an *in vitro* slice preparation.

In the slice preparation, olivary neurons fire spontaneously at irregular intervals at a frequency of 0.2-1 Hz which is in general agreement with data obtained previously in other species (Armstrong, *Physiological Reviews* 53:358, 1974). Application of EAAs such as quisqualate or glutamate increased the firing rate to 2 Hz and induced neurons to fire more regularly. Application of CGRP to spontaneously active olivary neurons suppressed the firing rate. In some instances, after prolonged application of the peptide, neurons were able to recover. CGRP also suppressed EAA induced activity. Two different paradigms were used. In one, the EAA was applied first at levels that increased olivary activity. Application of CGRP during the EAA pulse reduced neuronal activity. If CGRP was applied first, the excitatory effects of quisqualate and glutamate were suppressed or delayed in their onset. As with spontaneous activity, in a few cases neuronal firing rate recovered during later stages of the CGRP pulse. These effects of CGRP on spontaneous and EAA induced activity suggest a neuromodulatory role for CGRP in the IOC. In the dorsal horn of the spinal cord, CGRP has been shown to modify  $Ca^{2+}$  currents (Ryu et al., *Brain Res.* 441:357, 1988).  $Ca^{2+}$  is responsible for generating specific portions of the olivary action potential (Llinas and Yarom, *J. Physiol.* 315:549, 1981a; Llinas and Yarom, *J. Physiol.* 315:569, 1981b) including an afterhyperpolarization. Future intracellular studies will allow us to determine if CGRP alters olivary activity by modulating  $Ca^{2+}$  currents in olivary neurons. (supported by NS-18028).

## 467.17

THE PHYSIOLOGICAL EFFECTS OF DOPAMINE (DA) ON PURKINJE CELLS IN MOUSE CEREBELLAR SLICES. T.E. Nelson\* and G.A. Bishop. Neuroscience Program, The Ohio State University, Columbus, OH 43210.

Recent studies have indicated that dopaminergic fibers and binding sites are present within the rodent cerebellar cortex (Panagopoulos et al., 1991, *Neurosci. Lett.* 130:208; Panagopoulos and Matsokis, 1994, *Gen. Pharmac.* 25:131) and that DA is released within the rat cerebellum (Chrapusta et al., 1994, *Brain Res.* 655:271). Furthermore, D3 receptor mRNA is present in Purkinje cells (Bouthenet et al., 1991, *Brain Res.* 564:203) and D3 receptor binding is found within the molecular layer (Levant et al., 1993, *J. Pharmacol. Exp. Therap.* 264:991) of lobules IX and X of the rat cerebellum. In this study, we investigated the physiological effects of this catecholamine on mouse cerebellar Purkinje cells using an *in vitro* slice preparation. Multibarrel glass electrodes were used to record the single-unit activity of Purkinje cells in lobules IX and X of the cerebellar vermis and to iontophoretically apply combinations of DA, glutamate, quisqualate and GABA, as well as the DA agonists, PPHT and 7-OH-DPAT, to the neurons. The effects of DA and its agonists on spontaneous activity, excitatory amino acid-mediated excitation, and GABA-mediated inhibition of Purkinje cells were tested.

Purkinje cell activity was decreased in response to DA although it never completely suppressed Purkinje cell firing. DA reduced the spontaneous firing rate of 57% of the Purkinje cells (n=54) while 37% were unaffected by DA. Only 6% of the cells responded to DA with an increase in spontaneous firing rate. A majority (94%) of Purkinje cells (n=36) showed a marked suppression of glutamate- or quisqualate-induced excitation in response to DA; the remaining 6% showed an enhancement of excitatory activity. The suppressive effect of DA on excitatory amino acid-induced activity was typically greater than its suppression of spontaneous activity. Nearly half (47%) of the Purkinje cells tested (n=17) exhibited no interaction between DA and GABA. In 29% of the cells the inhibition due to GABA was augmented by DA while in 24% GABA-mediated inhibition was reduced. Moreover, all of the suppressive effects of DA were mimicked by both PPHT (a nonselective D2-like receptor agonist) and 7-OH-DPAT (a D3-selective agonist) suggesting a D3 receptor mediation of these responses. This is in agreement with the reports of Bouthenet et al. (1991) and Levant et al. (1993) describing a population of D3 receptors on Purkinje cells in lobules IX and X of the rat cerebellum. In summary, DA acts as a neuromodulator to suppress the spontaneous activity of Purkinje cells and decrease their responsiveness to excitatory amino acids. This suppression of Purkinje cell activity would likely result in a higher firing rate of target neurons within the cerebellar nuclei, and thus a subsequent increase in cerebellar output. (Supported by NS18028 and NS08798.)

## 467.14

CEREBELLAR PURKINJE CELLS DISPLAY VARIATIONS IN PROTEIN CONTENT AND LOCALIZATION PATTERN. C.J. Tandler and A. Pellegrino de Iraldi\*. Inst. of Cell Biology & Neuroscience Prof. E. De Robertis, Buenos Aires School of Medicine, Paraguay 2155, 1121 Buenos Aires, Argentina.

Differences in Purkinje cells nuclei and perikarya in adult rats and chicken have been found as a result of cytochemical and conventional procedures. At ultrastructural level there were electron dense and light cells. Purkinje cells in which the nucleus was filled with abundant electron-dense material showed granular endoplasmic reticulum cisternae in lamellar arrays. Those with a clear appearance in their nuclei displayed clusters of ribosomes in polysomal configurations and a less developed granular endoplasmic reticulum. The contribution of proteins and nucleic acids to the electron opacity was indicated by selective blockage and extractive techniques. At light microscopy the mercury-silver method (*Biotech. Histochem.* 69: 329, 1994) also revealed dark and light Purkinje neurons in both nuclei and perikarya, according to their relative protein concentration. A direct relationship with extranuclear transcriptional rates is suggested. This work was supported by grants from CONICET and UBA.

## 467.16

THE EXPRESSION OF CORTICOTROPIN RELEASING FACTOR (CRF) mRNA AND CRF RECEPTOR mRNA IN THE MOUSE BRAINSTEM AND CEREBELLUM T.L. Overbeck\* and J.S. King Department of Cell Biology, Neurobiology and Anatomy and Neuroscience Program, The Ohio State University, Columbus, Ohio 43210 U.S.A.

Corticotropin releasing factor (CRF) has been immunocytochemically localized to climbing fibers and mossy fibers in the cerebellar cortex, and in varicosities in the cerebellar nuclei. In the present study we used *in situ* hybridization to detect CRF mRNA in brainstem nuclei that are the source of these afferents. A positive signal was present in all subnuclei of the inferior olivary complex, the source of climbing fibers. In addition, CRF mRNA hybridization signal is present in neurons located in brainstem nuclei previously shown to give rise to CRF mossy fibers (Errico and Barnack, 1993, *JCN* 336:307) including the nucleus prepositus hypoglossi, nucleus raphe magnus, nucleus reticularis gigantocellularis and the vestibular complex. Receptor binding studies show positive ligand binding over the molecular, Purkinje and granule cell layers in all lobules of the adult cerebellar cortex (Overbeck et al. 1994, *FASEB Journal Abstr.* 8:109). We used *in situ* hybridization to identify the neuronal elements in the cerebellum that express the CRF receptor mRNA. An antisense riboprobe corresponding to the full length sequence of the rat CRF receptor was used (Perrin et al. 1993, *Endocrinology* 133:3058). Positive hybridization is evident in Purkinje cells, granule cells and cerebellar nuclear neurons. No signal was detected in the molecular layer. *In vitro* physiological studies demonstrate that CRF acts as a neuromodulator by enhancing both the spontaneous and excitatory amino acid-induced activity of Purkinje cells (Nelson and Bishop, unpublished observations). Tissue culture experiments (Fox and Groul, 1993, *Neurosci. Lett.* 149:103) suggest that the effects of CRF is mediated through a cAMP second messenger system which acts to close calcium-dependent  $K^{+}$  channels, thereby depolarizing the cell. Taken together, these data suggest that CRF may modulate the activity of Purkinje cells, granule cells and nuclear neurons in the adult mouse cerebellum. Currently, we are investigating the temporal expression of CRF mRNA in the inferior olive and the expression of CRF receptor mRNA in the cerebellum of the developing mouse. (Supported by NS-08798)

## 467.18

INCREASE IN VELOCITY-SENSITIVITY OF FLOCCULAR PURKINJE CELLS BY ACETYLCHOLINE.

J. van der Steen and H.S. Tan Dept of Physiology, Faculty of Medicine, Erasmus University Rotterdam, Rotterdam, The Netherlands. (Spon: European Neuroscience Organisation)

Behavioural evidence is emerging suggesting a positive modulatory action of acetylcholine (ACh) in the cerebellum. The present study describes such action of ACh on floccular Purkinje cells (P-cell) in rabbit. Using a sinusoidal optokinetic stimulus (0.2 Hz; Amplitude 5°; max vel 6.3°/s) we tested simple-spike responses of P-cells sensitive to optokinetic stimulation about an earth-vertical axis (VA-cells) or a horizontal axis oriented at 135° azimuth (HA-cells). The firing rate of VA-cells (n=22) showed a drum-velocity sensitivity of 26 spikes/deg/s with stimulation in the excitatory direction. This excitatory direction corresponds with the temporal-to-nasal direction of optokinetic stimulation of the eye ipsilateral to recorded flocculus. In the inhibitory direction sensitivity was only 12 spikes/deg/s. Iontophoretic application of ACh enhanced sensitivity to 80 and 40 spikes/deg/s for the excitatory and inhibitory directions respectively. With drum velocities within the range of  $\pm 3^{\circ}$ /s the simple-spike rate of the HA-cells tested (n=17) showed a sensitivity of 7 spikes/deg/s in both directions. Higher velocities in both directions were cut off. ACh application increased sensitivity to 11 spikes/deg/s without affecting the cut-off level. Conclusion: The described pattern of velocity-sensitivity of floccular P-cells correlates with behavioural data on the optokinetic reflex. ACh enhances optokinetic responses of P-cells through increasing the P-cells' velocity-sensitivity, without extending their sensitivity range.

## 467.19

**EXTRINSICALLY DERIVED GABAERGIC INHIBITION MODULATES THE INFORMATION TRANSFER THROUGH RAT PONTINE NUCLEI.** M. Möck\*, C. Schwarz, P. Wahl\*, and P. Thier. *Sektion für visuelle Sensorik, Neurologische Universitätsklinik, 72076 Tübingen, Germany.* Lehrstuhl für Allg. Zoologie und Neurobiologie, Ruhr-Universität, 44780 Bochum, Germany.

In opposition to the traditional view as a pure relay station in the corticocerebellar pathway, the pontine nuclei (PN) contain a considerable number of GABAergic synapses. Immunohistochemistry suggests that the number of GABAergic neurons residing in the PN is substantially lower in the rat as compared to the monkey. We have asked whether this finding reflects a genuine species difference in the cellular composition of the PN. We have therefore reexamined the number of GABAergic neurons using the more sensitive technique of *in situ* hybridization which monitors the amount of mRNA for glutamic acid decarboxylase (GAD). Our finding of an almost complete absence of GAD mRNA expressing neurons in the PN confirmed the earlier results based on immunohistochemistry, suggesting that at least in rat the dense pontine network of GABA-positive fibers originates exclusively from extrinsic sources.

In order to study the synaptic characteristics of GABAergic inhibition of pontine neurons, we performed intracellular recordings from coronal and parasagittal slice preparations. IPSPs, elicited by electric stimulation (20-240  $\mu$ A) of distinct sites within the pontine tegmentum, could be demonstrated in the majority of neurons sufficiently tested. The precise location of these stimulation sites and their relationship to afferents of the PN are currently under investigation. On their way to the PN the inhibitory axons probably cross the pedunculi cerebri as stimulation there under blockade of glutamatergic transmission (DNQX 25  $\mu$ M) revealed IPSPs similar to those observed after tegmental stimulations. The IPSPs had amplitudes of up to 4.4 mV, latencies between 0.8 and 4.3 ms, a maximal duration of 40 ms, and a reversal potential of -75 to -79 mV. IPSPs were completely blocked by bicuculline (50  $\mu$ M) suggesting an involvement of the GABA<sub>A</sub> receptor. In conclusion, we have demonstrated that inhibition affecting the pontine information transfer originates from outside the PN. Supported by DFG SFB 307 A1.

## 467.20

**ABSENCE OF GABAERGIC FEEDBACK PROJECTION FROM THE RAT LATERAL CEREBELLAR NUCLEI ON PRECEREBELLAR NUCLEI.** Y. Schmitz\* and C. Schwarz, *Sekt. f. Vis. Sensorik, Neurologische, Universitätsklinik 72076 Tübingen, Germany.*

The pontine nuclei (PN) and the nucleus reticularis tegmenti pontis (NRTPT) are important targets of the lateral cerebellar nucleus (LCN). On the other hand these brainstem nuclei are sources of a direct excitatory projection to the cerebellar nuclei. It has been suggested that these backprojections from the LCN are partially GABAergic. In order to test this hypothesis we applied a combination of anterograde tracing (biotinylated dextran amine injection into the LCN) and postembedding GABA and glutamate immunogold histochemistry to the PN and NRTPT. The pattern of labeling was compared to that of cerebellonuclear terminals in two target structures which in turn project to the spinal cord and neocortex: the nucleus ruber (NR) and the thalamus (VM/VL). The projection to the inferior olive (IO) known to be predominantly GABAergic served as a control. Quite unexpectedly we did not find any GABA immunoreactive (ir) cerebellonuclear terminals neither in the PN, NRTPT nor in the NR and VM/VL. In contrast 73% of the terminals in the IO were GABA-ir. On the other hand, when applying glutamate immunohistochemistry more than 90% of the cerebellonuclear terminals in PN, NRTPT, NR and VM/VL were labeled contrasting with only 5% in the IO. The cerebellonuclear terminals in the feedback projections to the PN and NRTPT were smaller (1.1  $\mu$ m<sup>2</sup>), than those found in VL/VM and NR (1.75  $\mu$ m<sup>2</sup>). The smallest terminals were found in the IO (0.6  $\mu$ m<sup>2</sup>). Cerebellonuclear terminals in the PN, NRTPT, VL/VM, and NR reached predominantly proximal dendrites. In summary our data do neither support a role for GABAergic inhibition in the feedback systems from the LCN to the PN and NRTPT nor within the projections to the NR and VM/VL. Hence, the rat LCN and PN/NRTPT may be connected reciprocally through excitatory synapses only. Supported by DFG SFB 307-A1

## OCULOMOTOR SYSTEM: SACCADDES—SUPERIOR COLLICULUS

## 468.1

**INTRACOLICULAR CONNECTIONS OF THE OPTIC LAYER IN THE TREE SHREW.** P. Lee\*, R. Mirabal and W. C. Hall. Department of Neurobiology, Duke University, Durham, NC 27710

Intracellular injections of biocytin in living brain slices were used to study the connections of neurons in the optic layer of the superior colliculus. The results indicate that the neurons in this layer differ from those of the superficial gray layer in at least two ways. First, in contrast to the narrow and wide field vertical cells in the adjacent part of the superficial gray layer, which have apical dendrites that ascend toward collicular surface, the optic layer neurons have radiate dendrites. These dendrites often span the optic layer and sometimes extend into the adjacent superficial and intermediate gray layers. Second, whereas the intracollicular axons of the narrow and wide field vertical cells terminate primarily within the subjacent layer, the optic layer neurons project most profusely near their somas. Prominent but less dense projections terminate within the adjacent gray layers. Other optic layer neurons have axons that extend for considerable distances without terminating, and may project to structures outside of the superior colliculus. These results support the hypotheses that optic layer neurons are distinct from those in the adjacent layers and that many modulate the flow of information from the superficial to the deeper gray layers. Supported by NIH grant EY08233.

**INTERRUPTING SACCADDES BY ELECTRICAL STIMULATION OF THE SUPERIOR COLLICULUS DETERMINES AN EXTENDED FIXATION ZONE.** N.J. Gandhi\* and E.L. Keller. Graduate Group in Bioengineering, UCSF, San Francisco, CA 94143 and Smith-Kettlewell Eye Research Institute, San Francisco, CA 94115.

The spatial shift theory for control of saccades suggests that a organized wave of activity moves from caudal superior colliculus (SC) to the rostral pole. The wave starts in the buildup neurons (BUNs) and travels to the fixation neurons (FNs) whose activation serves to end the saccade. Results from rostral pole electrical microstimulation at saccade onset have supported this hypothesis. The effect of such stimulation is to briefly interrupt the ongoing movement, which resumes shortly after the termination of the stimulation and ends near the original target. This study attempts to determine the extent of the fixation zone, the SC region where stimulation produces interrupted saccades. We obtained interruption of saccades by stimulating the deep intermediate layers of the SC at locations caudal of the rostral pole. Prior to stimulation BUNs, not FNs, were recorded at these sites. One interpretation of these results is that fixation zone neurons (FNs and rostral BUNs) are actually one class of functional cells involved in saccade termination. Our reasoning is supported by an anatomic study which determined that direct projections to the omnipause neurons (OPNs) in the brainstem from the SC originate from the rostral SC but not exclusively the rostral pole.

Interrupted saccades are also produced by stimulation of the OPNs. While interrupted saccades produced by SC and OPN stimulations are similar, analysis showed some consistent differences. OPN stimulation induced interrupted saccades often overshoot the target position (behavior consistent with decay of a resettable integrator for eye position), but those due to SC stimulation were hypometric (behavior consistent with spatial averaging at the level of the SC). However, the pulse train durations needed to produce an interruptive effect on saccades were considerably shorter in the SC. Further increases in stimulus train duration in OPN truncated saccades, while increasing stimulus duration at some sites in SC produced a redirected saccade.

## 468.3

**SACCADIC REACTION TIME IN MONKEY. I. SPATIAL SELECTIVITY AND EFFECTS OF GAZE ANGLE.** M. Paré\* and D.P. Munoz, MRC Group in Sensory-Motor Physiology, Queen's University, Kingston, Ont., Canada K7L 3N6.

The introduction of a temporal gap between the disappearance of a fixation point and the appearance of a peripheral target causes a reduction of saccadic reaction times (SRT). In addition to this reduction of SRT, presumably due to a gap-related disengagement of fixation, the occurrence of express saccades having very short SRT is facilitated in this gap paradigm. The percentage of express saccades has been shown to increase with training, whose effect is spatially selective. The extent of this spatial selectivity, however, remains to be determined. Also relevant, the gap effect may depend on the eye position from which saccades are initiated. Two monkeys were trained to perform saccades to a single visual target (10° of eccentricity) presented either simultaneously with the disappearance of the fixation point (step task), or after a gap period (gap task). In both monkeys, SRT distribution in the gap task displayed bimodality, i.e., an express saccade peak at ~100ms and a regular saccade peak at ~150ms. After a period of training at this one target location, target location was randomly varied in either amplitude or direction. The monkeys made no express saccades to the novel target locations, unless they were nearby the previously trained target location: within about  $\pm 50^\circ$  or  $\pm 20^\circ$  of direction and  $\pm 5^\circ$  of amplitude. The gap-related reduction in SRT was nevertheless observed for all targets. The position of eye fixation was also randomly varied when the animals were required to make saccades to two targets presented randomly on either side of the fixation point. Varying the initial gaze angle changed the relative frequency of the different modes of SRT. The percentage of express saccades increased as the movements started more contralateral. To explain our results, we suggest that training-dependent express saccades are caused, at least in part, by local changes - coding for the trained movements - restricted to a specific locus in a neural map of saccades, e.g., superior colliculus. Furthermore, these local changes are modulated by a gaze angle signal such that movements toward central eye position are facilitated.

## 468.4

**SACCADIC REACTION TIMES IN MONKEY. II. NEURAL CORRELATES IN THE SUPERIOR COLLICULUS.** M.C. Dorris\*, M. Paré, P. Istvan, A. Lablans, D.P. Munoz. MRC Group in Sensory-Motor Physiology, Queen's University, Kingston, Ontario, CANADA K7L 3N6.

The reduction in saccadic reaction times associated with the introduction of a temporal gap of no stimuli between the disappearance of an initially fixated visual target and the appearance of a peripheral saccadic target is called the gap effect, and occurs irrespective of target location. Extremely short latency express saccades (reaction times ~ 100 ms) may be elicited using this gap paradigm after training to a specific target location. We recorded from single neurons in the intermediate layers of the superior colliculus (SC) of monkeys trained to generate saccades in the gap paradigm. Fixation neurons (FNs), located in the rostral SC, were tonically active during fixation and paused for saccades. During the gap, FN discharge rate decreased by about 50% to a minimum level 250 ms into the gap, and then slowly increased for longer gap durations. The level of FN discharge at target onset was highly correlated to the ensuing saccadic reaction times. Saccade-related burst neurons (BNs) and buildup neurons (BUNs), discharged visual and saccadic motor bursts following target appearance at a specific point in the visual field. During the gap, BNs remained silent, whereas BUNs, located at an SC site coding the amplitude and direction of a potential saccadic target, became tonically active. Prior to the generation of express saccades, the anticipatory BUN discharge rate during the gap was higher. We conclude that the reduction in FN discharge that occurs during the gap period partially disinhibits the entire SC saccade generating map leading to the 'global' reduction in saccadic reaction times known as the gap effect. The occurrence of express saccades, however, requires an additional gap-related increase in discharge of local populations of BUNs coding for trained target locations.

## 468.5

AUDIO-VISUAL INTEGRATION IN THE SUPERIOR COLLICULUS OF THE AWAKE MONKEY M.A. Frens<sup>1,2</sup> and A.J. van Opstal<sup>1</sup>.

<sup>1</sup> Dept. of Biophysics, Univ. of Nijmegen, The Netherlands

<sup>2</sup> Neurology Dept., University Hospital, Zürich, Switzerland.

We have recorded single-unit activity in the deep layers of the Superior Colliculus (SC) of two rhesus monkeys, trained to make saccadic eye movements towards visual targets, while ignoring a simultaneously presented auditory noise burst. The position of the sound stimulus relative to the visual target was systematically changed. The properties of these bimodal saccades were similar to saccades elicited by unimodal visual stimuli, except for a clear change in movement latency. Furthermore, the saccade reaction time was significantly modulated by the spatial distance between the visual and the auditory stimuli in 36% of the recordings. The timing of the saccade-related burst in SC units remained tightly locked to the saccade under unimodal and bimodal conditions. In most units, the saccade-related activity for otherwise identical saccades was significantly affected by the auditory distractor (mean enhancement of 95% in 26/50 units; mean suppression of 31% in 19/50). In 18/50 units, spatial separation of the stimuli induced a systematic change in the firing rate, which co-occurred strongly with the effect on saccade latency.

We conjecture that the audio-visual interaction effects on the activity in the SC result from (1) changes in the excitability of the cells, necessary to initiate the saccade-related burst, and (2) a change in the balance of various afferent signals. The observed large variations in SC activity were not related to either saccade kinematics or accuracy, and are thus incompatible with a dynamic motor error code.

COMPONENT STRETCHING DURING OBLIQUE SACCADDES: COMMON SOURCE VS. CROSS-COUPLED MODELS. M. James Nichols and D.L. Sparks.\* Institute of Neurological Sciences, and the Department of Psychology, University of Pennsylvania, Philadelphia, PA 19104.

Electrical stimulation at sites in the primate superior colliculus (SC) can evoke saccades with latencies down to 20 ms or shorter. For a given site and fixed stimulation parameters, evoked saccades have very stereotyped direction and amplitude. The activity at particular SC sites, then, provides a vectorial saccadic request that must subsequently be decomposed for downstream horizontal and vertical pulse generators. It has long been known, however, that the horizontal and vertical pulse generators do not operate independently during oblique saccades. Rather, the minor component is typically reduced in velocity and stretched in duration to better match the duration of the major component.

It has been proposed previously that component stretching might be accomplished by appropriate decomposition of a vectorial velocity signal ("common source model"; van Gisbergen et al., 1985). Furthermore, a growing body of evidence demonstrates that the level of SC activity systematically influences vectorial saccadic velocity. It therefore seems quite plausible that the SC could provide the common source vectorial velocity signal. An active site in the motor map would send a velocity command to each component burst generator that was weighted appropriately for the saccade direction normally specified by that site. Alternative models have proposed that independent horizontal and vertical pulse generators could be cross-coupled downstream from the SC to produce component stretching (e.g., Grossman and Robinson, 1988).

An experimental paradigm originally proposed by Nichols and Sparks (1994, 1995) to test other aspects of saccadic control can also distinguish between these two schemes for component stretching. Experimental results will be presented.

## 468.9

AFFERENT CONNECTION TO FIXATION ZONE OF MONKEY SUPERIOR COLLICULUS FROM FRONTAL CORTEX AND BASAL GANGLIA H. Aizawa\*, C. R. Gerfen, and R. H. Wurtz. Lab. of Sensorimotor Research, NEI, NIH, and Lab. of Systems Neuroscience, NIMH, NIH, Bethesda, MD 20892.

Recent experiments in the monkey identified fixation cells in the rostral pole of the superior colliculus (SC) with properties distinct from saccade related cells in the caudal SC (Munoz and Wurtz, 1993). The aim of this experiment is to determine whether the fixation cells of the SC receive projections distinct from those of the saccade related cells.

The rostral fixation cell area was distinguished from the caudal saccade area by recording single cells and by stimulating electrically. We identified the fixation area by recording cells that paused during saccades and by electrically stimulating to delay saccades. Using a 30 gauge syringe needle with a protruding micro wire to verify its tip location by recording and stimulation, we then pressure injected fastblue (FB; 2%, 0.2 - 0.4µl) and diaminodimethylbenzidine (DAB; 5%, 0.2 - 0.4µl) into the fixation cell area and the saccade cell area.

Retrogradely labeled cells were identified in ipsilateral frontal eye field (FEF) and substantia nigra pars reticulata (SNr) of rhesus monkeys. In FEF, cells labeled by rostral SC injection were found in the more lateral part of anterior bank of the arcuate sulcus and cells labeled by caudal SC injection were clustered more medially on the anterior bank in the arcuate sulcus. In SNr, cells labeled by rostral SC injection were found in the more caudal dorsolateral part, and cells labeled by caudal SC injection were found more ventromedially. We also found cells labeled by rostral SC injection in contralateral rostral SC. In contrast, none, if any, labeled cells were found in contralateral SC following caudal SC injection.

These findings show 1) that the projections to the fixation and saccade regions of SC receive input from different areas of FEF and SNr, and 2) that the cross connection between the two rostral SC could underlie the coordination of fixation activity on the two sides.

## 468.6

SUPERIOR COLLICULUS ACTIVITY DURING ORBITALLY DEPENDENT REMEMBERED SACCADDES. E.J. Barton, R.P. Kalesnykas, T.R. Stanford\*, D.L. Sparks. Univ of Pennsylvania, Philadelphia, PA. 19104

The direction and amplitude of visually-guided saccades in the light are relatively independent of the initial eye position, within the range +/- 20 deg. However, in monkeys, saccades to remembered target displacements result in horizontal and vertical biases, which are markedly influenced by the initial eye position (Barton and Sparks, *Neurosci. Abstr.*, 295.18, 92). The influence of the starting orbital position is large, systematic, and consistent across monkeys. The behavioral and neural data strongly suggest that the effect of orbital position during remembered saccades is a direct function of neural coding and not a function of the mechanical properties of the plant (Barton and Sparks, *Neurosci. Abstr.*, 321.8, 93).

We recorded from saccade related burst neurons (SRBNs) within the superior colliculus (SC) of a rhesus monkey to examine whether the SC codes the orbitally-dependent biases. If the SC activity includes the biases, the response of any SRBN should correspond to the amplitude and direction of the movement, whether or not the movement is an accurate visually-guided saccade or a deviated remembered saccade. Whereas, if the SC does not include the biases, the discharge will better correspond to the target location than to the amplitude and direction of the inaccurate remembered saccade. In the former case, changes in the starting position of remembered saccades will affect the discharge according to the magnitude of the bias introduced, but in the latter case, the activity will be independent of bias magnitude.

The activity of the SRBNs studied reflected the target location rather than the amplitude and direction of the movements. The cells fired similarly for the grossly inaccurate remembered saccades as for the accurate visually-guided saccades to the same targets. Furthermore, when the targets for the visually-guided and remembered trials were different, but the movements were of comparable amplitude and direction, the cells fired dissimilarly.

This suggests that the orbitally-dependent biases are introduced to the saccadic system after the level of the SC and represents yet another example of a dissociation between the SC command and the executed movement.

## 468.8

MULTIMODAL ADAPTIVE CONTROL OF SACCADIC EYE MOVEMENTS BY SUPERIOR COLLICULUS. (S. Grossberg<sup>1,2,3</sup>, K. Roberts<sup>1,2</sup>, and D. Bullock<sup>1</sup>). Department of Cognitive and Neural Systems, Boston University, Boston, MA 02215.

How does the saccadic eye movement system select a target when visual, auditory, and planned movement commands differ? Recent data on superior colliculus (SC) reveal a traveling wave of activation whose peak codes the current gaze error (Munoz et al., 1992). In contrast, Waitzman et al. (1991) found that a stationary locus of peak activity in SC decays as a function of residual gaze error. We develop a neural network model that answers the question posed while providing a functional rationale for both signals. Calibration between visual inputs and eye movement commands is learned early in development within a visually reactive saccade system. The accuracy of planned saccades derives from using the gains learned by the reactive system. Visually reactive locations on the SC motor map encode gaze error in retinotopic coordinates. Planned targets are coded in head-centered coordinates. These distinct types of signals must be adaptively aligned to ensure selection of a single target. For this, a transformation between a planned and a retinotopic target representation needs to be learned. The targets can then compete for attention to generate a movement command in motor error coordinates. In addition, converging, spatially-coincident, visual and auditory signals produce response enhancement in collicular cells that is greater than the sum of the responses to each signal, as well as response depression when paired auditory and visual stimuli are not spatially coincident. The model simulates this effect as well as cell profiles measured in visually guided, memory guided, overlap, and gap paradigms. <sup>1</sup>Supported in part by ONR (N00014-92-J-1309). <sup>2</sup>Supported in part by ARPA (ONR N00014-92-J-4015). <sup>3</sup>Supported in part by AFOSR (AFOSR F49620-92-J-0499).

## 469.1

THE FRONTAL EYE FIELDS OF THE AWAKE, BEHAVING CAT. T.G. Weyand\* and A.C. Gafka. Dept. Anatomy, LSU Medical Center, New Orleans, LA 70112

We have recorded the activity of > 300 isolated neurons in a region of cortex that corresponds to the frontal eye fields in the awake, behaving cat. In these experiments, head position is fixed and eye position (gaze) is determined using the scleral search coil technique (resolution < .2°). The cats were trained to fixate on a small red spot that could be positioned anywhere on a rear projection screen. Our assumption was that this cortical region was involved in generating saccadic eye movements. Towards that end, we were particularly concerned with evaluating activity of neurons prior to saccadic eye movements and during active fixation. Only a small fraction (< 3%) of the neurons exhibited clear pre-saccadic activity. Most neurons were modulated by fixation, with suppression of activity during fixation being the most common response. At least one third of the neurons were visually responsive. Most of these had huge (hemi-field) receptive fields with a preferred direction of motion either towards or away from the hemisphere we were recording from. Visual responsiveness tended to be profoundly suppressed when fixation was demanded in the behavioral tasks. We were unable to determine any modulation of activity in one third of the neurons encountered. This estimate is conservative, as we were attracted to study those neurons that appeared influenced by the tasks.

Although this region of cortex shares some common cell types with the primate frontal eye fields, its influence on oculomotor behavior appears less direct. Rather than dictate via pre-saccadic elements where gaze should be directed next, an important role of this area in gaze control is elimination of potential targets for saccadic eye movements. (Supported by NIH EY06818 and MRC Canada)

## 469.3

REVERSIBLE ACTIVATION AND INACTIVATION OF MONKEY FRONTAL EYE FIELD WITH GABAERGIC DRUGS. E.C. Dias\*, M. Kiesau and M.A. Segraves. Dept. of Neurobiol. and Physiol., Northwestern Univ., Evanston, IL 60208.

Although compelling anatomical and physiological evidence link the primate frontal eye field (FEF) to the generation of eye movements, chronic lesions produce minimal long-term oculomotor deficits. To test the effects of acute activation or inactivation of the FEF, we made microinjections of GABA-related substances in 2 rhesus monkeys and recorded the animal's spontaneous as well as task-related oculomotor performance.

Injections of muscimol, a GABA agonist with inhibitory effect, produced an oculomotor scotoma. When the monkey was performing a visually-guided saccade task it was unable to saccade to targets in the injection site's movement field, while easily making saccades to targets at other locations. In a memory-guided saccade task these effects were enhanced revealing at least two deficits in oculomotor performance. When the target appeared in the movement field of the injection site, the monkey failed to saccade towards it. When the target appeared in the opposite direction, the monkey made irrepressible saccades towards it, i.e. the monkey looked at the peripheral target as soon as it came on, not waiting for the go-signal, which in this task was the extinction of the central fixation target. The monkey also showed difficulty in maintaining fixation after the injection. In contrast, when bicuculline, a GABA antagonist that produces disinhibition of cortical cells, was injected at the same site, on a different day, the monkey's response to a target at any location in a visually-guided saccade task was to first make a saccade toward the movement field of the injection site followed by a saccade to the target. Difficulty in maintaining fixation prevented the monkeys from performing a memory-guided saccade task. When idle the monkey spontaneously produced series of short-latency saccades of approximately the same direction and amplitude as the saccade elicited electrically from the injection site, similar to the staircases of saccades obtained by electrically stimulating the FEF with long trains of electrical pulses. Control injections of saline did not produce observable changes in the monkey's performance.

These findings suggest monkeys with surgical FEF ablations show substantial recovery from the acute effects of FEF lesions and that FEF activity in the intact primate is important for the generation of all voluntary saccades and for fixation. Supported by NIH Grant EY08212.

## 469.5

THALAMOCORTICAL INPUT TO THE SLOW EYE MOVEMENT AND SACCADIC EYE MOVEMENT SUBREGIONS OF THE FRONTAL EYE FIELD IN CEBUS MONKEY. J.-R. Tian\*, Hao Liu<sup>1</sup> and J.C. Lynch<sup>1,2,3</sup>. Depts. of Anatomy<sup>1</sup>, Ophthalmology<sup>2</sup>, and Neurology<sup>3</sup>, University of Mississippi Medical Center, Jackson, MS 39216

Thalamocortical projections to the slow eye movement subregion (SEM) and the saccadic eye movement subregion (SAC) of the frontal eye field (FEF) were studied in 4 *cebus apella* monkeys. The SEM and SAC were localized using standard low-threshold (<50  $\mu$ A) electrical microstimulation procedures and Telazol anesthesia. The supplementary eye field (SEF) and the hand/arm region of dorsal premotor cortex (PMd) were also localized in some monkeys. Retrogradely-transported fluorescent dyes were then injected into these areas. Eye movements were recorded and later analyzed using a video recording system. The major sources of thalamic input to SEM were VA, VLc, and MD. In each of these, labeled neurons are clustered in the most dorsal part of the nucleus. In contrast, neurons labeled by SAC injections were concentrated in paralamina MD and in VA; neurons labeled from SEF were concentrated in VA and X; and neurons labeled from PMd were concentrated in ventral VLc, VLo, and VPLo. Although the SEM was adjacent to PMd<sub>(hand)</sub>, the connections of the two regions were clearly distinct. Previous studies have established that VA, rostral VLc, and MD receive input from the globus pallidus or substantia nigra, whereas caudal VLc, X, VPLo, and MD receive input from the cerebellum. Thus each oculomotor subregion, as well as PMd, receives a major neural input from both a basal ganglia target and a cerebellar target in the thalamus.

## 469.2

FRONTAL EYE FIELD ACTIVITY IN CONJUNCTION WITH SACCADDES MADE IN RESPONSE TO STEP-RAMP MOTION. D. Shi\*, H.R. Friedman, and C.J. Bruce. Section of Neurobiology, Yale Univ. Sch. Med., New Haven, CT 06520-8001.

Saccades to moving targets are accurately targeted despite the fact that saccades are executed ballistically and take 100–200 ms to program, being unaffected by target displacements occurring less than 100 ms prior to initiation of the saccade. Therefore, we studied saccade-related activity in the macaque monkey's FEF during saccades from stationary fixation to moving targets to determine if target velocity is predictively compensated for at the level of FEF. After the optimal vector for each cell's saccade-related response was estimated by testing with static targets, a parametric step-ramp experiment was conducted wherein targets moved towards the cell's response field along paths perpendicular to the cell's optimal vector (e.g., leftward and rightward ramps for an upward response field). The monkeys' saccadic behavior generally compensated fully for target velocity, and in many cases the saccades even ended slightly ahead of the targets. We then analyzed the neuronal data by modifying our previous Gaussian model for directional tuning of response fields by adding a single parameter (K) to quantify compensation for target velocity:  $R_i = B + R \cdot \text{EXP}(-0.5((\theta - S\theta_i + K \cdot d\theta_i)/d)^2)$  where  $R_i$  is the cell's spike rate for each trial,  $S\theta_i$  is the saccade's polar direction,  $d\theta_i$  is the target's angular velocity, and the remaining parameters are all to be fit, with  $\theta$  estimating the cell's optimal polar direction,  $d$  its directional tuning, and K estimating (in ms) the velocity compensation being added downstream of the FEF cell in question. Some FEF cells appeared to be upstream of all velocity compensation (e.g., K of 230±30 ms), but other cells had considerably smaller K, e.g., 90±20 ms, indicating that they were at an intermediate stage of velocity compensation. This data may help explain why projections from motion areas in posterior cortex (MT, MST, STP, etc.) are not confined to FEF's smooth pursuit representation in the depths of the arcuate sulcus, but terminate extensively in saccadic FEF as well. We hypothesize that these projections enable saccade-related FEF activity to begin the process of predictive compensation for target velocity. Supported by PHS grants EY04740 & MH44866.

METRICS OF SACCADDES EVOKED BY ELECTRICAL STIMULATION IN THE FRONTAL EYE FIELDS ARE NOT AFFECTED BY SHORT-TERM SACCADIC ADAPTATION. J.A. Edelman\* and M.E. Goldberg. Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

Monkeys and humans can rapidly adjust saccadic amplitude to compensate partially for intrasaccadic target perturbations. Previous work in this laboratory has shown both that the movement fields of saccade-related burst neurons in the primate superior colliculus (SC) change after such short-term saccadic adaptation (STSA), and that the metrics of saccades evoked by electrical stimulation of the SC are not affected by STSA. This paradox can be resolved if stimulation of the SC fails to entrain a corrective mechanism located in the deep cerebellar nuclei, lesions of which abolish STSA. To test whether stimulation of the frontal eye fields (FEF) entrains this corrective mechanism we stimulated in the FEF before, during and after STSA in two monkeys. A target was initially presented at the same location as the end-point of saccades evoked by low-current (<50  $\mu$ A) electrical stimulation. First, the monkey performed ~150 pre-adaptation trials. Next, at saccade onset the target was stepped back a fixed percentage (50%) of the initial target displacement. Adaptation was usually complete within ~400 trials, after which another ~150 target-displacement trials were performed. On ~10% of both kinds of trials no target was presented and stimulation was applied ~400ms after the central fixation point was extinguished. Eye movements were recorded during a block of trials before, during, and after saccadic adaptation at each of 7 stimulation sites. Across all sites, non-stimulated saccade amplitude decreased by an average of 27% while stimulated saccade amplitude increased by 1%. At all sites the time course of any change in stimulated saccade amplitude was not related to that of STSA. These data suggest that like SC stimulation FEF stimulation does not activate a cerebellar pathway that adjusts saccadic amplitude.

SUPPLEMENTARY EYE FIELD NEURONAL ACTIVITY DURING MONKEY PERFORMANCE OF ANTISACCADDE TASKS.

N. Amador, M. Schlag-Rey\*, J. Schlag & H. Sanchez. Brain Research Institute, UCLA, Los Angeles, Ca. 90095-1761

Human antisaccades made to look at a location opposite to that of a visual target are known to be selectively impaired by frontal lobe and basal ganglia lesions while visually guided prosaccades are not.

We studied neuronal activity in the monkey Supplementary Eye Field (SEF) during the performance of immediate and delayed anti- and prosaccades in directions chosen to coincide with each cell preferred or null direction (interleaved trials). The cue for making anti- or prosaccades was a small dot or square appearing as the initial fixation point. The saccade target (always a dot) was flashed during or after fixation of the instruction cue which, when turned off, provided the go signal for the eye movement. The cells studied were confined to the SEF region defined by low threshold electrically evoked saccades (some of them, goal-directed).

Unit responses to instruction cues did not differentiate pro- and antisaccades trials. Fixation cells, characteristic of the SEF area, were activated (or silenced) during the initial fixation period. Visuomotor cells, sustained (VM) or twice activated (V&M) revealed a dissociation of their visual and movement components as a function of the task. Some of these cells increased their firing more before antisaccades than before prosaccades having identical vectors. Such cells were not observed in the Frontal Eye Field of the same monkey performing the same task.

The results support the hypothesis of a distinct role for the SEF in initiating intentional saccades to goals internally rather than externally defined, i.e. in gaze behavior competing with visual reflexes. (Supported by USPHS grants EY02305 and EY05879).

## 469.7

RESPONSE FIELDS OF NEURONS IN AREA LIP DURING PERFORMANCE OF DELAYED SACCADDE AND SELECTION TASKS M.L. Platt\* and P.W. Glimcher, Center for Neural Science, New York University, New York, NY, 10003.

We examined the response fields of single LIP neurons in head-fixed rhesus macaques performing delayed saccade and selection tasks. Both tasks began with the fixation ( $\pm 2^\circ$ ) of a central yellow LED. In the delayed saccade task, a second yellow LED was then briefly illuminated (200-1000 msec). After 200-1000 msec, the fixation LED was then extinguished, cueing the monkey to align gaze with the no longer visible target ( $\pm 3^\circ$ ). In the selection task, fixation of the central LED was followed by the illumination, for 200-800 msec, of two yellow eccentric LEDs, one above and one below the horizontal meridian. The fixation LED then changed color to either red or green. Red indicated that the monkey would be rewarded for aligning gaze with the upper LED ( $\pm 3^\circ$ ) upon offset of the fixation LED, green specified the lower LED as the saccade goal. Eccentric targets were located at  $4^\circ$  intervals spanning  $40^\circ$  of horizontal and vertical visual angle. Neurons were also studied with a delayed version of the selection task in which potential targets were extinguished before the fixation LED changed color.

Cells studied typically had low baseline activity that increased to a maximum ( $<100$  Hz) during saccades of particular directions and amplitudes. For each delayed saccade trial, we measured activity during four canonical epochs: 1) 200 msec after the illumination of the eccentric target; 2) 200 msec after the offset of the eccentric target; 3) 100 msec before the beginning of the saccade; and 4) 200 msec after the beginning of the saccade. On selection trials, activity was also measured 200 msec after the color change cue. Detailed response fields were constructed for LIP units during each epoch. Some units showed a maintained increase in activity across measured epochs for particular target locations/movement metrics. Other cells displayed discrete bursts of activity after the illumination of particular target locations and immediately preceding saccades of particular amplitudes and directions. On selection and delayed selection trials, sensory non-movement response fields (Glimcher and Sparks, *Nature*, vol. 355, 1992) of unit activity during the epoch following the color change cue were not co-extensive with movement fields for the same epoch. Comparison of these target-movement and distractor non-movement response fields suggests that LIP neurons may be differentially sensitive to targets and distractors.

## THE CONTROL OF SACCADDES, SMOOTH PURSUIT EYE

MOVEMENTS AND FIXATION: A PET STUDY. E.P. O'Sullivan, R.C. Miall, P. Haggard, J.F. Stein, C. Kennard, D.J. Brooks SPON: Brain Research Association. MRC Cyclotron Unit, Hammersmith Hospital, London W12 0HS.

Visual fixation of a stationary object has been thought of as a smooth pursuit eye movement (SPEM) of zero velocity. However, there is electrophysiological and behavioural evidence suggesting that fixation affects the performance of both the saccadic system and the SPEM system, implying that it is not merely a specialised form of SPEM, but that it is derived from a separate neural pathway.

To investigate the neural substrates controlling these oculomotor systems, we studied 6 male volunteers using  $H_2^{15}O$  positron emission tomography (PET). Reflexive saccades to unpredictable targets, smooth pursuit at a range of velocities and fixation were tested.

Comparison of fixation with saccades, and of fixation with SPEM showed significant increases ( $p < 0.001$ ) in regional cerebral blood flow (rCBF) in the dorsolateral prefrontal cortex and the cingulate cortex.

Both the saccadic and SPEM tasks resulted in significant rCBF increases in the striate, extrastriate and temporal lobes relative to fixation. In addition, the saccadic task also showed increased rCBF in the posterior parietal lobe and the frontal eye fields. This pattern of activation was not seen for SPEM. The comparison of saccades and SPEM showed no overall significant change in rCBF.

This study suggests that the control of visual fixation includes a neural pathway which is separate from those controlling saccades and SPEM. It also demonstrates that there is much overlap between the pathways that control saccades and SPEM.

DIFFERENTIAL EFFECTS OF REPETITIVE TRANSCRANIAL MAGNETIC STIMULATION OVER CORTICAL VISUOMOTOR AREAS IN PREFRONTAL AND PARIETAL CORTEX IN MAN. S.A. Brandt, C.J. Ploner, B.-U. Meyer, P. Stoerig\*, and A. Villringer, Laboratory of Neurophysiology, Department of Neurology, Charité, 10098 Berlin, Germany.

In an earlier study we showed that repetitive, rapid-rate transcranial magnetic stimulation (rTMS) over the dorsolateral prefrontal cortex (DLPFC) impairs performance of memory-guided saccades in humans. Now we are using rTMS to compare the differential effects of stimulation over different cortical visuomotor areas during different phases of the premotor planning of saccades. Precision, latency and velocity of saccades to memorized locations were measured after rTMS (10 Hz) over the prefrontal and parietal cortex of either hemisphere. We compared rTMS shortly before or after presentation of a visual cue with rTMS performed at different intervals during the delay period before saccades had to be executed. Results show that prefrontal rTMS impairs saccade latency and precision maximally when performed during the delay period, whereas parietal rTMS had a maximal effect when performed shortly before or after cue presentation. Our findings are compatible with the hypothesis that the parietal cortex is a critical structure during the early phase of visuospatial delay tasks, and that the prefrontal cortex (area 46) is involved in the transient representation of visuospatial information in absence of the visual cue. rTMS is a powerful tool to study functions of visuomotor system by interfering with information processing in selected cortical areas non-invasively in humans.

## 469.8

NEURONS OF THE LATERAL GENICULATE (LGN) CARRY AN EYE POSITION-RELATED SIGNAL POST-SACCADICALLY. L. Chukoskie, A. Handel & P.W. Glimcher\*, Center for Neural Science, New York University, New York, NY, 10003.

Single units of the lateral geniculate were studied in two head-restrained awake-behaving rhesus monkeys while they performed delayed and memory saccade tasks in dim illumination and in total darkness. Units were found which burst vigorously after saccades. The magnitude of this burst, even when it occurred in total darkness, was correlated with the post-saccadic orbital position of the monkey's eye.

In our total-darkness memory-saccade task, an animal fixated a central LED ( $\pm 3^\circ$ ). A second eccentric LED was then illuminated for 600-900 msec and extinguished. After a further 300-500 msec, the fixation LED was extinguished, placing the animal in total darkness and cueing him to make a saccade (typically with a 200 msec reaction time) which aligned gaze with the remembered location of the eccentric target ( $\pm 4^\circ$ ).

We studied the first 300-400 msec of this post-saccadic burst by plotting the mean frequency of post-saccadic firing (as measured in the 300 msec interval that began 100 msec after saccade onset) as a function of final eye position with regard to the animal's fixed head. These LGN units were typically found to have a preferred final eye position for which they responded most vigorously. As final eye positions deviated from this preferred position, the magnitude of the post-saccadic response declined. By systematically varying the location of the initial fixation target, we were able to determine that the spatial tuning of these units did not correlate with the amplitude and direction of the just completed movement but did correlate with the final position of the eye.

To confirm that these LGN signals were correlated with eye position we performed an additional experiment in which units were studied both before and after an animal was mechanically rotated in the visually fixed environment of the experimental chamber. We found that this manipulation, which did not alter the animal's visual environment, did shift the position tuning of the unit in the direction predicted by the rotation of the monkey. Histological analysis of several marking lesions in one animal revealed that responses of this type were encountered within the magnocellular layers of the LGN.

## 469.10

VISUALLY-GUIDED SACCADIC EYE MOVEMENTS ELICIT ACTIVATION IN FRONTAL OCULOMOTOR AREAS IN HUMAN BRAIN USING FUNCTIONAL MAGNETIC RESONANCE IMAGING (fMRI). K.-M. Lee<sup>1,2</sup>, J. Hirsch<sup>1,2</sup>, K. Kim<sup>1,2</sup>, R. J. DeLaPaz<sup>1,3</sup>, N. Rekin<sup>1</sup>, Dept. of Neurology and Neuroscience, Cornell University Medical College<sup>1</sup>, Dept. of Neurology<sup>2</sup> and Radiology<sup>3</sup>, MSKCC, New York, NY 10021

We studied human cortical oculomotor systems with fMRI by the following parameters: 1.5 T magnetic resonance scanner (GE) retrofitted for echo-planar imaging (Advanced NMR Instancan), T2\*-weighted images by gradient echo sequence (TE = 60 ms, TR = 3 secs, flip angle =  $30^\circ$ ) with in-plane resolution of  $1.56 \times 1.56$  mm ( $128 \times 256$  matrix in  $20 \times 40$  cm FOV) and 16 contiguous 4.7 mm thick slices parallel to the AC-PC line. Independent t-test with requirement of replication was employed to compare the mean intensity of each voxel between baseline and activation periods. During activation periods, four right-handed healthy volunteers were asked to make saccadic eye movements to a small dot that was back-projected onto a screen. The direction and amplitude of saccades were controlled so as to obtain cortical activation as specific as possible for invariant-vector saccades vs. saccades to and from an invariant eye position. Activation was observed at punctate regions in the frontal cortex. There was an asymmetry of those regions in that the activated area was more dorsomedially located in the left hemisphere of all subjects. Furthermore, separate but adjacent areas were identified where the saccade-related activation depended upon eye position as well as the direction of eye movement. In summary, with fMRI, we have localized areas in the frontal cortex that show increased activity with visually-guided saccades and observed that some areas code for the direction of saccades without eye-position dependency, while others show activation that is dependent upon eye position as well as saccadic direction. TRANSCRANIAL MAGNETIC STIMULATION (TMS) ALTERS HUMAN SACCADDE INITIATION IN A COUNTERMANDING PARADIGM. J. D. Olson\*, S. Anandt and J. Holson†\*, Dept Neurology & Neurological Science, Stanford Univ Sch Med† and Calif Inst Med Res†, Stanford and San Jose, CA.

**Purpose:** Performance in a saccade countermanning paradigm can be modeled as a competition between initiation vs inhibition of saccades. Since TMS over frontal cortex delays saccade initiation, we asked whether TMS could selectively shift the balance between initiating and withholding saccades in this paradigm.

**Methods:** In  $>67\%$  of the trials, two subjects rapidly initiated a saccade to a go-signal target presented  $4.5^\circ$  to the right or left of a central fixation target that was simultaneously extinguished. Stop trials were interwoven in which the central fixation target reappeared as a signal to withhold the saccade. Stop signal delays (SSD) ranged from 0-250 ms after the onset of the go signal. Single pulse TMS was delivered at 80-100% maximum intensity with a butterfly coil 10, 25 and 50 ms after the onset of the stop signal. **Results:** In control trials without TMS, results were similar to those reported in the macaque monkey. Saccades were rarely initiated at SSD of 0-50 ms and were rarely stopped at SSD of 175-250 ms. Saccade gain was near unity for go trials. TMS over right or left dorsolateral frontal cortex (DLFC) or a midline parietal area reduced the frequency of normometric saccades at SSD of 125-200 ms when compared to control results. This effect was greatest for TMS 10 ms after the stop signal. At the shortest SSD, however, TMS delivered 10 ms after the stop signal tended to increase the frequency of saccade initiation. Saccade gain was less than 0.5 for TMS trials at the shortest SSD and increased at longer SSD. **Conclusion:** TMS can decrease saccade initiation at long SSD, but may also increase the initiation of hypometric saccades at short SSD. These responses are not unique to TMS delivered over DLFC.

## 469.13

**TRANSCRANIAL MAGNETIC STIMULATION OF THE POSTERIOR PARIETAL CORTEX AND PREFRONTAL CORTEX DURING MEMORY-GUIDED SACCAD—ES.** R.M. Muri\*, A.I. Vermersch, S. Rivaud, B. Gaymard, C. Pierrot-Deseilligny. INSERM 289, Hôp. de la Salpêtrière, 47 Bd de l'Hôpital, F-75651 Paris, France, and Dep. of Neurology, University of Bern, Inselspital, CH-3010 Bern, Switzerland

The posterior parietal cortex (PPC) and the dorsolateral prefrontal cortex (PFC) play an important role in the control of memory-guided saccades (1,2). In both regions, single cell recordings in monkeys have shown sustained activity during the different phases of the paradigm. In humans, however, only little is known about the functional and temporal organization of memory-guided saccades. Therefore, transcranial magnetic stimulation (TMS), which can disturb saccadic programming (3), was used to determine such organization. Single TMS was applied in 8 normal subjects over the right PPC and in 7 subjects over the right PFC. Temporal mapping of both regions was performed by stimulating 160ms, 260ms, 360ms after the flashed target, during the mid-memorization period (800 - 1400ms), and 100 ms after the go-signal, i.e. the extinguishing of the central fixation point. Horizontal component of saccades were recorded by electrooculography. Compared with the percentage of error in amplitude (PEA) without stimulation (mean: 8%), a significant increase of PEA was found for contralateral saccades if TMS was applied over the PPC 260ms after the flashed target (mean: 18%, Mann-Whitney,  $p < 0.0008$ ), and, secondly, if TMS was applied over the PFC during the mid-memorization period (mean: 27%,  $p < 0.0002$ ). Control experiments with stimulation over the occipital cortex during the same time intervals had no significant influence. These results suggest that the observed effect of TMS seems to be specific to the stimulated region. Furthermore, for the functional organization of memory-guided saccades, the PPC might play a major role during the early phase of the paradigm, whereas the PFC seems to be more important during the memorization phase.

## OCULOMOTOR SYSTEM: HEAD MOVEMENTS AND LISTING'S LAW

## 470.1

**CATS USE MULTIPLE COORDINATION PATTERNS TO ACHIEVE THE SAME MOTOR TASK.** K.D. Statler, E.A. Keshner, S.L. Delp, and B.W. Peterson\*. Sensory Motor Performance Program, Rehab. Inst. of Chicago, Dept. of Biomedical Engineering and Dept. of Physiology, Northwestern University, Chicago, IL 60611.

Simultaneous video-fluoroscopic and neck muscle EMG data were recorded from one cat performing  $\pm 15^\circ$  sinusoidal (0.25 Hz) head tracking movements in the sagittal plane. The cat performed the movement in two different body postures and with two different starting neck orientations. Radio-opaque markers were inserted into the anterior/posterior and lateral aspects of the occipital ridge and C1-C7 to measure vertebral displacement. Kinematic data of the head and neck were analyzed using a computer model. The model was used to characterize the limits of movement in the cervical spine and to estimate the moment arms of the neck muscles at different orientations of head-neck movement. Experimental results showed that the cat utilized different vertebral alignments, relative joint movements, and muscle activation patterns to achieve the same movement outcome. The model predicted that muscle moment arms would vary little for the different vertebral alignments chosen by the cat to complete the task varied as the movement was performed from different initial conditions. When the cat was standing, the movement was accomplished with joint movements about Skull-C1, joints on either side of C3, and joints on either side of C6. When the cat was prone, the movement was accomplished with joint movements about Skull-C1 and joints on either side of C3. Rectus capitis, complexus, and splenius EMG activity were similar in all positions of the neck and body. Biventer cervicis and occipitocapularis EMG activity had variable responses for different body positions. Although the model predicted that the tracking task could be accomplished in the same manner regardless of the initial conditions, the results suggest that the central nervous system engages in multiple strategies of musculoskeletal coordination to achieve the same gross movement outcome. Supported by grants BNS9109705 and NS22490.

## 470.3

**REDUCED PROPRIOCEPTIVE INPUT FROM CERVICAL AFFERENTS IN HUMANS IMPAIRS GAZE ACCURACY DURING LARGE COMBINED EYE-HEAD SACCAD—ES.** J.L. Johnston\*, G.T.D. Thomson, G.D. Miller, D. Ireland. Dept. of Medicine & Otolaryngology, University of Manitoba, Winnipeg, Canada R3E 0Z3

We measured head and gaze movements using magnetic search coil oculography in 14 patients with idiopathic fibromyalgia and compared them to normal subjects. Head-free saccades were made to a laser dot target that moved in random directions, timings and amplitudes of 30-60 deg under 2 conditions: 1) with no direction to the subject as to how to move their heads; and 2) with instructions to move their heads as fast as possible. Under condition 1, all fibromyalgia patients could be classified as non head-movers, compared to 50% of our control group. All normal control subjects and 13 of 14 patients increased the amplitude of head movements significantly under condition 2. Of these 13 fibromyalgia patients, 7 (Group A) had improved gaze accuracy, as measured by the gain (gaze/target amplitude) of the first head-free saccade, for condition 2 (mean gain 0.92) compared to condition 1 (mean gaze gain 0.81,  $p=0.04$ ). The remaining 6 patients (Group B), and all normal subjects did not show any change in gaze gain between conditions. Group A was more likely to employ synchronous eye and head movement of low amplitude during condition 1 (mean head latency 74ms) rather than suppress the head movement, or produce head motion at prolonged latency (188ms), as in Group B. During condition 2, Group A made larger amplitude head movements at shorter latency (about 7 ms). We conclude that musculoskeletal injury to the neck may impair gaze accuracy during large amplitude combined eye-head tracking by reducing proprioceptive inputs from neck afferents during a time when the VOR is suppressed. By voluntarily increasing head amplitude, a more head dominant strategy is employed, and the incorporation of neck afferent information during the initial gaze saccade improves accuracy.

## 470.2

**METRICS OF INCORRECT GAZE SHIFTS AND DISSOCIATED EYE-HEAD MOVEMENTS IN A DISTRACTOR PARADIGM IN HUMANS.** B.D. Corneil\*, D.P. Munoz. MRC Group in Sensory-Motor Physiology, Queen's University, Kingston, Ontario, CANADA K7L 3N6.

We studied the coupling of eye-head movements using a multimodal task in which human subjects were instructed to make a gaze shift to a target located  $40^\circ$  to the left or the right. In the distractor condition a distracting target was presented on the opposite side of the saccade target; in the enhancer condition the two targets were spatially coincident. Both auditory and visual stimuli were used as targets. Correct gaze shifts consisted of a coordinated eye and head movement directed to the saccade target. Incorrect gaze shifts were occasionally observed in the distractor condition, when the subject's gaze was initially directed to the distracting target. The frequency of these incorrect movements could be altered by presenting the distracting target earlier or later relative to saccade target onset. Incorrect gaze shifts initiated earlier relative to saccade target onset typically had larger amplitudes in the incorrect direction and had longer intervals before the correct gaze shift was initiated. Some correct gaze shifts in the distractor condition consisted of a dissociated early slow head movement directed to the distracting target, while the eyes made a compensatory movement to keep gaze aligned with the initial fixation position. Following a variable time, subjects then generated a correct gaze shift directed to the saccade target. The results provide support for a gaze control system wherein reflexive orienting is suppressed until a decision to make a gaze shift has been made. Incorrect gaze shifts occur when this suppression is released before the saccade target has been identified, and subjects orient to the first perceived stimulus. For correct gaze shifts with an early incorrect head movement, we hypothesize that the premotor area controlling head movements is receiving a separate localizing signal from the distracting target before the signal to initiate the gaze shift, and this signal is not under the same suppressive control as the gaze signal.

## 470.4

**Head-free primate gaze shifts in response to double target steps.** J.O. Phillips\*, L. Ling, and A.F. Fuchs. Department of Physiology and Biophysics, Univ. of Washington, Seattle, WA 98195

During shifts of gaze, the eye and head may either be driven by a common command producing an early eye saccade and a later head movement or be driven independently toward a common goal. To evaluate these two alternatives, we observed primate eye and head movements during gaze shifts in response to forward-forward or forward-backward double target steps, looking for reliable relationships between eye and head movement direction, amplitude and timing.

Short inter-step durations ( $\leq 100$  ms) reliably produced two movements of the head, the first of which varied considerably in size; the second brought it onto the final target. However, these double head movements were often accompanied by only a single saccade to the second target. When two saccades did occur, the second typically began after the start of the second head movement, even when the onset of the initial head movement trailed the onset of the first saccade. The minimum inter-saccadic interval was relatively constant, while the interval between head movements was quite variable. Longer inter-step durations ( $\geq 150$  ms) typically produced two saccades, which were often accompanied by a single head movement. Overall, there was a poor correspondence between eye and head movement amplitude for each step.

These data suggest that eye and head commands are separate in the primate. Further, they suggest that the minimum inter-saccadic interval is a feature of the eye movement system alone, and is not a function of sensory-motor processing common to both eye and head movement.

This work was supported by NIH grants EY00745 and RR00166.

## 470.5

TWO COMPONENTS OF HEAD MOVEMENTS DURING READING: PERCEPTUAL AND COGNITIVE ORIGINS. Choongkil Lee\*. Dept. of Psychology, Seoul National University, Seoul Korea, 151-742.

The procedures adopted in most studies measuring eye movements during text reading require immobilizing the head, and so the pattern of head movements and the consequent ocular compensations have been undetermined. If head movements are suppressed for fixation stability while the eyes remain within the oculomotor range, programming of a head movement is likely to be coupled with the programming of eye movements, because the head movement is based on information concerning the position of the eyes in the orbit. Alternatively, since the direction and expected excursion of impending gaze shifts are known, the head may be programmed independently of the eyes to move continuously with a predetermined velocity influenced by several factors such as text familiarity.

Simultaneous recording of eye and head movements while reading revealed that during forward gaze saccades, head movements consisted of two components: a constant velocity component, and a velocity-modulatory component which was coupled to gaze saccades as revealed by cross correlation analysis. The constant velocity, but not the amplitude of the velocity-modulatory component, increased as subjects repeatedly read the same text. These results suggest that these two components of head movements are controlled by separate processes: a perceptual process coordinating eye and head movements, and a cognitive process incorporating text familiarity, operating on a more global scale, and that the former is not influenced by the latter for head movements.

## 470.7

HEAD POSITION SPECIFIC ADAPTATION OF VERTICAL EYE ALIGNMENT. J.S Maxwell\* and C.S. Schor. University of California at Berkeley, Berkeley, CA 94720.

Previous experiments have shown that open loop vertical eye alignment (measured as vertical phoria) can be trained to vary with eye position. Such adaptation would be appropriate for compensating for muscle palsies wherein the magnitude of the misalignment varies with orbital eye position. Vertical deviation might also result from deficits in specific sensorimotor pathways. The ocular tilt reaction, for example, requires the coordination of head roll, ocular counterroll and vertical eye deviation. The present experiment demonstrates that vertical eye alignment can be trained to vary with head position. Subjects trained binocularly with different vertical disparities present at two different head positions. The disparities were created with base up and base down prisms. If a right over left disparity was presented with the head pitched up, for example, a left over right disparity was presented with the head pitched down. The head was stationary during training and testing. Changes in head position were in either pitch, roll or yaw. Roll rotations were about an earth-horizontal axis (EHA) and yaw rotations were about an earth-vertical axis (EVA). Pitch rotations were about either an EVA or an EHA. Head rotations were either by head-on-neck (HON) or whole body (WB) movements. All subjects adapted in all paradigms where rotation was about an EHA. Most also adapted to HO pitch rotation about an EVA. Head position specific adaptation would be expected to normally compensate for bilateral imbalances in otolith-ocular and, perhaps, cervical-ocular pathways. Supported by EY03532

## 470.9

ON LISTING'S LAW DURING SLEEP. Y Suzuki\*, K Hepp<sup>1</sup>, V Henn. Neurology Dept, University Hospital, CH-8091 Zürich, Switzerland

With the head erect and not moving, Listing's law confines conjugate eye positions to two degrees of freedom. Its validity has been shown for fixation, saccades, and pursuit. It has not been solved to what degree Listing's law is the result of orbital mechanics or is determined neurally. During light sleep, when the eyes drift, the coordinated activation of motoneurons deteriorates, and is finally lost during deeper stages of sleep, when eye movements cease. We measured the oculomotor range, the orientation and thickness of Listing's plane during alertness and compared it to periods of light sleep.

Rhesus monkeys were trained for a visual fixation task, and were chronically prepared with a head holder and a dual magnetic search coil to monitor eye position in three dimensions.

In light sleep, eye positions during slow drifting movements covered a range of about  $\pm 20$  deg in the horizontal and vertical directions with torsional components in a range of about  $\pm 10$  deg. The distribution of data points can often still be approximated by a plane which is similarly oriented to Listing's plane during alertness. However, torsional positions then show a variability of up to 5 deg standard deviation from the mean value as compared to less than 1 deg during alertness. Similar observations could also be obtained after bilateral riMLF lesions, which in the awake condition is characterized by a loss of vertical and torsional rapid eye movements.

We agree with Nakayama (1975) that the main factor responsible for the high precision of Listing's plane during alertness is neuronal, and not mechanical.

EYE AND HEAD COORDINATION DURING HEAD-FREE GAZE PURSUIT IN THE Rhesus MONKEY: PREDICTABLE vs. UNPREDICTABLE STIMULI.

W.A.D. Smith, B. Segal\*, and K.E. Cullen. Aerospace Medical Research Unit, McGill University, Montreal, Canada.

The relationship between the head and eye movements generated during head-free gaze pursuit of a moving visual target was investigated. *Rhesus fascicularis* monkeys were trained to track a target moving in either a "predictable" (a single sine wave: 0.25 - 2.5 Hz, 20 or 40°/s peak velocity) or an "unpredictable" (pseudorandom stimulus: the sum of five non-harmonic sinusoids; 10 or 20°/s component peak velocity) trajectory in the horizontal plane. Two specific series of studies were carried out. In the first, a monkey's ability to track target motion and pursuit strategy were compared across frequencies and between conditions. Monkeys were completely head-free and pursued either sinusoidal or pseudorandom target motion. Although the target remained well within its oculomotor range ( $\pm 50^\circ$ ), the monkey made significant use of both head and eye movements to maintain accurate pursuit, and these movements were well-coordinated. Overall tracking accuracy decreased with increasing stimulus frequency; gaze velocity gain decreased and phase lag increased relative to target velocity. Head velocity consistently lagged ( $> 15^\circ$ ) eye velocity in each paradigm. A prediction strategy, defined by a significant phase lead in gaze velocity relative to target velocity, was only observed systematically during sinusoidal pursuit at the lowest frequency tested (0.25 Hz). In the second series of studies, the functional state of the vestibulo-ocular reflex (VOR) was evaluated during head-free pursuit. VOR gain ( $G_{VOR}$ ) was assessed by temporarily braking head motion and evaluating the resultant short-latency (20-60 ms) eye movement responses. During both sinusoidal ( $> 0.25$  Hz) and pseudorandom pursuit,  $G_{VOR}$  was significantly attenuated at a very short latency ( $< 20$  ms;  $G_{VOR} \approx .40 - .69$ ), compared to control values ( $G_{VOR} = .84 - .98$ ). The reduction in  $G_{VOR}$  observed during gaze pursuit indicates that the strong degree of synergy between head and eye movements is beneficial to tracking, since head movements do, in fact, contribute to the displacement of the visual axis in space.

NEW CLUES TO THE COORDINATES OF THE OCULOMOTOR SYSTEM. D. Tweed\*. Depts. of Physiology and Ophthalmology, Univ. of Western Ontario, London, N6A 5C1, Canada.

This work deals with 3 interconnected puzzles involving oculomotor coordinates:

1. When humans are rotated in roll while supine, their eyes counterroll but then quickly drift back to zero torsion when the vestibular stimulation is over; this drift suggests that the oculomotor integrator is leaky in torsion (Seidman et al. 1995). I present a model to explain how the integrator can leak torsionally but hold vertically, even though torsional and vertical signals are mixed together in the integrator neurons of the interstitial nucleus of Cajal (Crawford et al. 1991).

2. Humans adopt nonzero torsional eye positions when they converge their eyes (Allen 1954). How can we hold these positions if our integrators are leaky in torsion? I suggest that this torsion is maintained by a separate vergence integrator. This does not imply that vergence is a 2D system, because its "horizontal" and "torsional" effects can both be explained by a 1D command. The resulting model is greatly simplified if vergence, saccades and pursuit all operate in a novel coordinate system which combines some of the advantages of quaternions, rotation vectors and Helmholtz angles.

3. During eye-head saccades, each eye rotates with 3 degrees of freedom, breaking Donders' law (Tweed et al. 1995). But saccadic commands from the superior colliculus are just 2D (van Opstal et al. 1991). I show that a 2D colliculus can drive the observed 3D eye-in-head motion if the variable coded in the collicular map is conjugate gaze shift in space. Together, these 3 puzzles suggest a model for binocular eye-head control whose predictions will be compared to those of other theories of saccades, pursuit, vergence and VOR.

THE GEOMETRY OF SACCADES AND LISTING'S LAW.

A. A. Handzel, T. Flash\*. Dept. of Applied Mathematics and Computer Science, Weizmann Institute of Science, Rehovot, 76100, Israel.

We have analysed the geometry of conjugate saccadic eye movements using basic Lie group theory and differential geometry. Normal saccades involve rotations about a single axis (Tweed and Vilis, 1990), hence they are described mathematically as geodesics in the manifold of the rotation group (Hepp, 1990). We show that trajectories of saccades follow curved arcs in the space of Rodriguez rotation vectors (coordinates in the 3D projective plane). In addition, we point to the relations between different parameterizations of rotations (Hepp and Henn, 1987), namely, rotation vectors (Rodriguez), gimbal systems (Fick and Helmholtz) and canonical coordinates in the Lie algebra of the rotations group,  $so(3)$ ; transformations between the coordinates can be computed using the Campbell-Baker-Hausdorff formula.

Further, Listing's law can be described by means of the Lie algebra  $so(3)$ , which is decomposed into Listing's plane and the orthogonal axis of torsion rotations. The axes of rotation in Listing's plane generate the geometrical structure of a 2D sphere  $S^2$ , which corresponds to the space of gaze directions, giving a direct connection to Donders' law. Although Donders' law admits many 2D submanifolds of the rotation group, only the sphere is an integral surface of the Lie algebra elements (i.e. translation invariant vector fields), which lie in Listing's plane. Finally, to rotate between two (non-primary) eye positions contained in Listing's plane, the rotation axis itself lies outside the plane; this reflects the structure of the rotation group, i.e. the rotations which correspond to Listing's plane do not form a subgroup of  $SO(3)$ .

## 470.11

DYNAMIC CONTROL OF PRIMARY EYE POSITION AND LISTING'S COORDINATES AS A FUNCTION OF HEAD POSITION IN SPACE IN RHESUS MONKEYS. B.J.M. Hess\* and D.E. Angelaki. Dept. of Neurology, University Hospital Zürich, CH-8091, Switzerland and Dept. of Surgery (Otolaryngology), University of Mississippi Medical Center, Jackson MS.

Primary eye position is defined on the basis of Listing's law under static conditions with the head upright (reference position) and undergoes systematic transformation as a sinusoidal function of head position relative to gravity. Thus, as the head assumes different static roll or pitch positions, the torsional and vertical coordinates of primary position transform relative to reference position according to the sine of the roll and pitch angle, respectively (Haslwanter et al. 1992). We investigated whether this transformation was maintained constant when head orientation changed dynamically relative to gravity at different speeds and whether it would be compatible with a generalized dynamic implementation of Listing's law. We studied 3d eye position and angular velocity of slow and fast phases of nystagmus as a function of head position during constant velocity and mid and high frequency oscillations about off-vertical axes in rhesus monkeys. It was found that modulation of torsional and vertical mean eye position was (a) independent of frequency up to at least 0.5 Hz suggesting a frequency independent control of the torsional and vertical coordinates of primary eye position (b) generated by slow eye movements only at low frequencies and mainly by saccadic, i.e. forward directed fast eye movements at higher frequencies. Furthermore, angular velocities of fast or saccadic eye movements followed on average the velocity criterion of Listing's law. The results show that Listing's coordinates are dynamically controlled by otolith input suggesting a tight link between oculomotor coordinates and vestibular signals related to absolute orientation in space.

## 470.12

WHY IS LISTING'S PLANE THICK? J.F.X. DeSouza, S. Mikael, D.A. Nicolle and T. Vilis\*. Neuroscience Program, Departments of Physiology and Ophthalmology, University of Western Ontario, London, Ontario, Canada N6A 5C1.

This study examined the precision with which the angular position of the eye is confined torsionally to Listing's Plane (LP) during and after saccades. Five normal subjects were asked to saccade to targets within a 30° square grid in different directions: horizontal (as in reading), vertical, radial, random, clockwise (CW) and counterclockwise (CCW). The thickness of LP was measured by fitting the 3D eye position data to a second order surface and then computing the variability in the torsional direction about this fitted surface. The thickness during the random task averaged 1° and was used as a reference. LP was 40% thinner in the Hor & Vert tasks and 25% thinner during the CW & CCW tasks. This decrease in thickness occurred for data sampled during a saccade, immediately after a saccade, and before the next saccade, suggesting that torsional "blips" (Twed et al., 1994) are not a major factor. We also examined the coefficients of the second order surface fit for indications of task dependent changes in shape. LP was more twisted, towards a surface produced by a Helmholtz gimbal, during the Vert task than during the Hor task. As observed by Ferman et al. (1987), we found that the surface shifted forward in the CCW task as compared to the CW task. When subjects were asked to orient their head towards the same targets, a similar reduction in the thickness of the plotted surfaces was observed for the head's Donders surface (DS) and this surface also exhibit task dependent changes in shape. In summary, both the eye's LP and the head's DS exhibits task dependent changes in shape. We propose that the surface in the random task is "thicker" because it is the combination of surfaces with different shapes.

## SPINAL CORD AND BRAINSTEM: FUNCTIONAL NEUROPHYSIOLOGY

## 471.1

DORSAL SPINOCEREBELLAR TRACT NEURONS CAN BE INFLUENCED BY THE NEURAL CIRCUITRY PRODUCING FICTIVE LOCOMOTION IN THE CAT. B. Fedirchuk\*, H. Hultborn, D.J. Bennett, and M. Gorassini. Dept. Med. Physiol., Univ. of Copenhagen, DK-2200, Denmark.

Dorsal spinocerebellar tract (DSCT) neurons have been reported *not* to be rhythmically active in a de-afferented locomoting cat (Arshavsky et al. 1984; *In Studies of Brain Function Vol 13: Cerebellum and Rhythmical Movements*). In contrast, the ventral spinocerebellar tract (VSCT) has been described to report activity in spinal motor circuitry (see Baldissera et al. 1981; *In Handbook of Physiology - The Nervous System II*).

Extra- and intracellular recordings were made from antidromically identified DSCT neurons within the L1 to L4 spinal segments in 9 precollular-postmammillary decerebrate cats. After paralysis, fictive locomotion was elicited by electrical stimulation of the mesencephalic locomotor region. 42 of 60 DSCT neurons exhibited rhythmic activity, either firing exclusively, or at higher frequencies, in one phase of the fictive step cycle. There was no relationship between the type of afferent input exciting the neuron and whether or not the cell was rhythmically modulated. 21 DSCT cells were more active during flexion, 21 were more active during extension. 14 of 17 intracellularly recorded DSCT cells exhibited locomotor drive potentials (LDPs) ranging from 0.4 to 6.0 mV in amplitude. 7 VSCT cells were also recorded and all 7 exhibited rhythmic activity during the fictive step cycle. VSCT neurons generally had higher firing frequencies and larger LDPs than DSCT neurons.

These results indicate that the motor circuitry producing locomotion can directly affect both DSCT and VSCT neurons and suggest that previous conceptions of the dorsal spinocerebellar pathway be re-assessed.

## 471.2

HOMOSYNAPTIC DEPRESSION OF ROSTRAL TRIGEMINAL SENSORY NEURONS IN THE CHRONIC CAT: A ROLE FOR PRESYNAPTIC INHIBITION? B.E. Cairns\*, M. Frago, and P.J. Soja. *Fac. of Pharm. Sci., UBC, Vancouver, BC, Canada V6T 1Z3.*

In acute anesthetized animal preparations, homosynaptic conditioning (HC) of V afferents exerts a suppressive influence on synaptic transmission through the trigeminal sensory nuclear complex (TSNC). Homosynaptic suppression of TSNC neuronal activity has been casually linked to a presynaptic inhibitory mechanism involving a process of primary afferent depolarization (PAD, *J. Neurophysiol.* 28: 695-709, 1965; *Brain Res.* 143: 369-372, 1978). In the present study, the association between neuronal suppression and PAD induced by such stimuli was examined in the chronic unanesthetized cat. Two adult cats were prepared for chronic recording as reported previously (*J. Neurophysiol.*, 1995, *in press*). Overall, the maxillary tooth pulp-evoked activity of 11 TSNC neurons was suppressed by 20% when HC stimuli (0.2ms, 50-100µA) were applied to the mandibular tooth pulp (CT interval: 30 ms). These HC stimuli did not alter the latency to spike onset (control: 4.6ms ± 0.3; conditioned: 4.4ms ± 0.3). Paired experiments were also performed to evaluate excitability changes resulting from HC in 7 TSNC neurons and their adjacent tooth pulp afferent terminals. Tooth pulp evoked activity was decreased (by 19-58%) in 4 neurons, increased (by 47%) in 1, and unchanged in 2 cells. The excitability of individual afferent terminals was examined using Wall's technique (*J. Physiol.*, 288: 437-447, 1979) at sites where these individual sensory neurons were previously recorded. While variable effects on TSNC neurons were observed, the same homosynaptic stimuli depolarized all the adjacent tooth pulp afferent terminals by a mean of 334%. Although V HC stimuli uniformly induce PAD in individual tooth pulp afferents, postsynaptic mechanisms, i.e., facilitation and/or inhibition, must also contribute to the V afferent modulation of TSNC neuronal activity observed in the chronic cat preparation. Supported by BChRF, MRC, and NIH (NS32306).

## 471.3

BARBITURATE-INDUCED SUPPRESSION OF DORSAL SPINOCEREBELLAR TRACT (DSCT) NEURONS IN THE CHRONIC CAT. M. Frago\*, G. Nixon, B. E. Cairns, and P.J. Soja. *Faculty of Pharm. Sci., UBC, Vancouver, BC, Canada V6T 1Z3.*

Barbiturates are often used to maintain the state of general anesthesia during electrophysiological studies of DSCT neurons (see *Brain Behav. Evol.*, 7: 34-83, 1973; *Prog. Neurobiol.*, 36: 391-423, 1991). The present study was performed to access the extent to which barbiturate anesthesia alters the excitability of individual DSCT neurons in the intact behaving cat. Three adult cats were prepared for chronic extracellular recording of DSCT neurons (*J. Neuroscience Meths.*, 1995, *in press*). Spontaneous and sciatic nerve-evoked spike activities from antidromically identified DSCT neurons were recorded during wakefulness (W, *ibid*), the induction into and recovery from the state of anesthesia induced by the short acting barbiturate thiopental. During control periods of W, ongoing DSCT neuron spike rate measured 13.2Hz ± 3 (SEM, n=8). Thiopental (15mg/kg, i.v.), infused over a 3 min period, rapidly induced unconsciousness that was accompanied by a sustained "slow wave" EEG wave pattern, miosis, areflexia, and generalized atonia. Five minutes following injection, spontaneous and sciatic nerve-evoked (0.05ms, 150-200µA) spike activities were maximally suppressed by 76.5%, and 33%, respectively ( $p < 0.05$ , ANOVA). Complete recovery from thiopental's effects on DSCT cellular activities occurred within 30 min. Antidromically propagated spikes remained secure in all but one DSCT neuron. These findings confirm that thiopental attenuates ongoing synaptic transmission through the DSCT accounting in part for the loss of proprio- and exteroceptive sensation during barbiturate anesthesia. Marked differences are also likely to occur in the electrical and integrative properties of DSCT neurons recorded in acute, anesthetized vs. chronic, unanesthetized cat preparations. Supported by MRC.

## 471.4

MEDULLARY RETICULAR CONTROL OF DORSAL SPINOCEREBELLAR TRACT (DSCT) NEURONS IN THE UNANESTHETIZED CAT. P.J. Soja\*, G. Nixon, and M.C. Frago. *Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada V6T 1Z3.*

The nucleus reticularis gigantocellularis (NRGc) is known to exert an inhibitory influence on ascending lumbar sensory tract neurons in anesthetized animal preparations. The present study was performed to characterize the effect of NRGc conditioning stimuli on the spontaneous activity of DSCT neurons in the chronic unanesthetized cat. Two adult cats were prepared for chronic extracellular recording of DSCT neurons (*J. Neuroscience Meths.*, 1995, *in press*). DSCT neurons were antidromically identified and a baseline level of spontaneous spike activity established (*ibid*). Short trains of stimuli (4 pulses, 0.8 msec, 400 Hz, 20-160 µA) were applied to the NRGc (HC: P 7.5-9, L 1.5-2.5, H -6.0 to -7) during states of wakefulness and quiet sleep. Computerized analyses indicated that DSCT baseline spike activity did not differ between wakefulness and quiet sleep (*Sleep Res.* 24: 1995, *in press*). NRGc stimulation suppressed (~50-90%) DSCT neuron spike activity in every cell examined (n=20). The latency-to-onset and duration of the suppression ranged from 5-15 msec and 20-60 msec, respectively. The degree of suppression was graded with the intensity of NRGc stimuli used. There was no difference in the onset or duration of the NRGc suppression during the state of wakefulness vs. quiet sleep. Strychnine (0.08-0.12mg/kg, i.v.), antagonized the NRGc-induced suppression of spontaneous spike activity in each of 3 DSCT neurons tested without altering baseline activity. The present findings indicate that synchronous activation of the NRGc exerts a potent, phasic suppression of ongoing transmission of sensory information through the DSCT in the chronic unanesthetized cat. A process of glycine-mediated postsynaptic inhibition may partly underlie DSCT neuronal suppression exerted by the NRGc during wakefulness and quiet sleep. Supported by BChRF and MRC.

## 471.5

**PAD AND PRESYNAPTIC INHIBITION ELICITED IN GROUP Ia MUSCLE AFFERENTS PERSIST 1-3 MONTHS AFTER CRUSHING THEIR AXONS IN THE PERIPHERAL NERVE.** E. Manjarrez, M. Enriquez & P. Rudomin\* Dep. Physiol. CINVESTAV-IPN, México, D.F. 07300.

Horch & Lisney (J. Physiol. 313: 287, 1981) showed that 1-3 months after crushing their peripheral axon, cutaneous fibers fail to show PAD following stimulation of other cutaneous nerves. In contrast, stimulation of the posterior biceps and semitendinosus nerve (PBSt) produces PAD in group Ia fibers of the medial gastrocnemius (MG) whose axons were crushed in the periphery 1-3 months before (Abst. Soc. Neurosci. 18: 217.17, 1992). We now report observations aimed to investigate if this PAD is associated with presynaptic inhibition. The experiments were performed in anesthetized, paralyzed and artificially ventilated cats, in which the left MG nerve was crushed 1-2 months previously, while the lateral gastrocnemius plus soleus (LGS) nerve was left intact. The left L6-S1 ventral roots were sectioned and a NaCl filled glass micropipette (2-5 MΩ) was placed within the GS motor nucleus, either to record the extracellular field potentials (EFP's) produced by MG or LGS stimulation, or to test the excitability of the intraspinal arborizations of the MG and LGS afferent fibers. In two experiments, conditioning stimulation of the PBSt nerve (3 pulses at 300 Hz applied 20 ms before the test pulse) increased the excitability of both the MG and LGS fibers (mean 167% and 170% of control, respectively). In 3 experiments, conditioning stimulation of the PBSt nerve applied 30-45 ms before, depressed both pre- and postsynaptic components of the EFP's evoked by stimulation of the MG nerve (to 75±27% and 60±15%, of control respectively). The pre- and postsynaptic EFP's produced by stimulation of the intact LGS nerve were depressed to about the same extent (to 58±14% and 62±5% of control, respectively). These results suggest that the PAD that is produced in muscle spindle afferents whose peripheral axons have been crushed 1-3 months before is associated with presynaptic inhibition. *Partly supported by NIH NS09196, and CONACyT 031N9107.*

## 471.7

**RUBROSPINAL PROJECTIONS TO FORELIMB MOTONEURONS AND PHRENIC MOTONEURONS IN CATS.** Y. Fujito\* and M. Aoki Dept. Physiol., Sch. Med., Sapporo Med. Univ., Sapporo 060, Japan

Rubrospinal projections to forelimb and phrenic motoneurons (Mns) in the cat were examined and compared with those of corticospinal projections electrophysiologically. Cats were anesthetized with Nembutal. Single pulse stimulation of the red nucleus (RN) produced EPSPs with a mean amplitude of about 0.35 mV in the majority of forelimb Mns (88/122). Half of forelimb Mns (23/46) of C8-T1 segments in which RN-EPSPs were detected by single shocks exhibited segmental latencies of RN-EPSPs shorter than 1 ms, while only 3 of 43 forelimb Mns in C6-7 segments showed such latencies. These results suggest that rubro-motoneuronal connections are, at least in part, monosynaptic for forelimb Mns that innervate in particular the wrist and digit muscles. When paired pulse stimuli (interpulse interval of 3 ms) were applied to RN, the second EPSPs were potentiated only moderately (mean facilitation ~24%) for EPSPs with short segmental latencies (<1.0 ms). Probable monosynaptic RN-EPSPs were still induced in distal forelimb Mns after acute transection of the ipsilateral ventral quadrant of the C4 spinal segment. Stimulation of the interstitiospinal tract did not produce any monosynaptic EPSPs in Mns. There was no evidence suggesting monosynaptic connections between RN and phrenic Mns, and between corticospinal fibers and forelimb Mns. Single shocks to the cerebral peduncle (CP) produced EPSPs in 18/57 phrenic Mns and their segmental latencies shorter than 1 ms were observed in 2 cells in which paired pulse facilitation of CP-EPSPs were not evident. The present results suggest the presence of preferential direct rubrospinal projection to Mns innervating distal forelimb muscles in the cat.

## 471.9

**INITIATION OF VOCALIZATION INDUCED BY DISINHIBITION OF THE RESPIRATORY NEURONS IN THE NUCLEUS OF THE SOLITARY TRACT IN CATS.** T. Sakamoto\*, A. Katada, T. Sugimoto and K. Kikuchi, Dept. of Physiol., Asahikawa Med. Col., 4-5 Nishikagura, Asahikawa, Japan 078

Repetitive electrical stimulation (20-100 μA, 0.2 ms, 100 Hz, lasting for 2 to 5 sec) delivered to the periaqueductal gray (PAG) in decerebrate cats resets the normal respiratory rhythm, and induces initial inspiration followed by alternate vocalization and inspiration. The changes in the neuronal activities of the medullary respiratory neurons induced by PAG stimulation were extracellularly recorded by tungsten microelectrodes to understand the initiation mechanisms for vocalization.

Under halothane nitrous oxide gas anesthesia, cats were decerebrated at precollular postmammillary level. The temperature of rectum was kept at 36-37°C by a radiant heat lamp.

When the PAG stimulation was delivered during the expiratory period, the augmenting expiratory neurons recorded from the retrofacial nucleus (E-aug neurons) ceased to discharge within 20 to 30 ms after the onset of the PAG stimulation. While the inspiratory neurons in the ventrolateral nucleus of the solitary tract (I-neurons) started to increase their discharge rate about 30 to 50 ms after the initiation of the PAG stimulation. However, none of these I-neuron was orthodromically activated by the PAG stimulation.

It has been known that the E-aug neurons exert the inhibitory effects upon the I-neurons, and most of those neurons are premotor neurons of the inspiratory muscles. The present results suggest that the preceding inspiration before vocalization is induced by disinhibitory process acting on the I-neurons from the E-aug neurons.

## 471.6

**Large inhibitory effects of single interneurons on the motoneurons in neonatal rat spinal cord.**

Morten Raastad\* and Ole Kiehn.

Department of Neurophysiology, University of Copenhagen, Denmark.

The effect of individual spinal interneurons on the motoneurons was investigated.

Compound synaptic potentials were recorded with good signal to noise ratio from the ventral roots L4 or L5 of isolated spinal cords from 0 to 5 day old rats. The cords were split mid-sagittally. Intracellular recordings from interneurons were obtained using the tight seal technique. Spikes were elicited either with steady current injection or 1 ms current pulses.

Individual action potentials in some interneurons medial to the motoneuron pool generated a large hyperpolarization in the ventral root recording. In order to quantify this hyperpolarization, its amplitude was compared to the amplitude of a monosynaptic excitation that was large enough to elicit spikes in the motoneurons. The absolute value of the amplitude of the inhibitory potential was up to 40% of the depolarization needed to discharge motoneurons. The delay between the spike in the interneurons and the inhibitory potential ranged from 25 to 40 ms in different cells, but varied by less than 7 ms in individual cells. The inhibitory potential was blocked by kynurenic acid and low Ca<sup>2+</sup>. These results together suggest a polysynaptic pathway for the inhibitory effect.

The interneurons were characterized by large afterhyperpolarizations and a stable firing over a wide range of frequencies. Several cells were spontaneously active. The firing frequency affected the shape of the inhibitory potential, and it was abruptly abolished at frequencies above 5-7 Hz.

These experiments suggest that individual neurons can have a powerful role in the complex network controlling the motoneurons.

This work was supported by The Human Frontier Program.

## 471.8

**BRAINSTEM CONTROL OF SENSORY INPUTS TO LUMBAR MOTONEURONS IN THE NEONATAL RAT.** L. Vinay\* and F. Clarac, Lab. Neurobiologie et Mouvements, CNRS, 31 chemin Joseph Aiguier, 13402 Marseille cedex 20, France.

The pathways descending from the brainstem to the spinal cord and the connections between dorsal root afferents and motoneurons are both present very early during development. In the present study the interactions between the brainstem and the peripheral inputs were investigated using intracellular recordings from lumbar motoneurons in the *in vitro* brainstem / spinal cord preparation of the neonatal (P0-5) rat.

The brainstem inputs to motoneurons were characterized by microstimulations delivered to the different funiculi of the spinal cord at the level of the brainstem spinal cord junction, in C1. Synaptic responses consisted of excitation and inhibition that were mediated mainly by NMDA, non-NMDA and glycine receptors. Stimulation of the ipsilateral dorsal root at long interstimulus intervals (30 s to avoid synaptic depression) evoked short-latency EPSPs assessed to be monosynaptic since they persisted under mephensin. In normal Ringer, stimulation of the ventromedial and ventrolateral funiculi of the spinal cord 40-130 ms prior to the peripheral stimulation resulted in a depression (up to 40%) of the dorsal root evoked EPSP. In some cases, stimulation of the rostral spinal cord at a low intensity reduced the amplitude of the dorsal root evoked potentials without any post-synaptic effect on the motoneuron suggesting that the modulation of the dorsal root evoked EPSP may occur at a presynaptic level. The inhibition of the dorsal root evoked EPSP was reduced markedly by bath application of GABA<sub>A</sub> (bicuculline) and GABA<sub>B</sub> (saclofen, phaclofen) antagonists.

These data suggest that pathways descending from the brainstem already exert a control on segmental afferents at birth.

## 471.10

**DESCENDING PROJECTIONS OF THE NUCLEUS RAPHE OBSCURUS (nRO): POSSIBLE ANATOMICAL BASIS OF ROLE IN LUMBOSACRAL REFLEXES** G.E. Hermann\*, G.M. Holmes, J.C. Bresnahan, M.S. Beattie, and R.C. Rogers, Depts. Cell. Biol., Neurobiol, and Anat., and Physiol., Ohio State University, Columbus, OH 43210

Our previous electrophysiological studies (Holmes, NS 1994) suggested that the nRO is an important source of descending control for lumbosacral reflexes. Therefore, anterograde labeling of nRO projections to the spinal cord and retrograde labeling of motoneurons (MN) innervating the external anal sphincter (EAS), bulbospongiosus (BS) and the ischioavernosus (IC) muscles was used to examine the neuroanatomical basis of these observations. Fluorescent labeling of the nRO ("fluororuby", Mole. Probes) demonstrated terminations in the intermediolateral cell column of the thoracic cord, and in the sacral parasympathetic nucleus, lamina X, dorsal commissural nucleus and ventral horn in the lumbosacral cord. We observed presumptive terminal contacts between fibers originating in the nRO and cell bodies and/or dendrites of motoneurons of the EAS (approx 25%) and BS (approx 11%) but not the IC. [Motoneurons were retrogradely labeled with either fluorogold or fluorescein.] These apparent direct connections to lumbar MN and to regions participating in sacral reflexes, suggest the nRO provides a pathway for descending control and/or integration of autonomic and somatic motor activity. The results substantiate physiological studies which indicated that the nRO provides potent input to caudal spinal cord regions controlling eliminative and sexual functions. (Support: NS-31193; PVA SCRF 1254)

## 471.11

PHYSIOLOGICAL AND BEHAVIORAL EFFECTS OF SEROTONIN OR THYROTROPIN RELEASING HORMONE ON RAT DORSOMEDIAL MOTONEURONS. G.M. Holmes\*, J.C. Bresnahan, R.C. Rogers, G.E. Hermann, M.S. Beattie. Depts. of Cell Biology, Neurobiology, and Anatomy, and Physiology. The Ohio State University, Columbus, OH 43210.

In the rat, motoneurons (MNs) innervating the external anal sphincter (EAS) and bulbospongiosus (BS) muscles lie within the dorsomedial (DM) motoneuron pool. Differences in spontaneous activity and response to nucleus raphe obscurus (NRO) stimulation of BS and EAS MNs suggest that BS and EAS MNs are differentially controlled by the NRO. Putative transmitters of NRO cells include serotonin (5-HT) and thyrotropin releasing hormone (TRH) both of which augment firing rates of classical  $\alpha$ -motoneurons. We have shown that intrathecal (IT) infusions of TRH augment both smooth muscle anorectal activity and EMG activity of the EAS but not the BS muscles. Experiment 1 sought to clarify the locus of TRH activation. Nanoliter volumes of TRH were intraspinally pressure injected directly into the DM nucleus of anesthetized rats. Intraspinal TRH profoundly increased EAS, but not BS, EMG activity. In Experiment 2, awake, chronically catheterized animals, were infused with IT TRH (10-500  $\mu$ M). All doses inhibited both corpus cavernosum and corpus spongiosum erections. Defecation rates were unaffected.

Unlike TRH, serotonin pressure injected into the DM eliminated firing of spontaneously active (presumably EAS) cells. Doses of IT 5-HT that inhibit urethro-genital reflexes in anesthetized acute preparations did not significantly affect penile reflexes (e.g. erection latency and erection total) in awake, chronically catheterized animals, despite the presence of "5-HT syndrome" hyperreactivity which would be expected to interfere with (i.e. inhibit) penile reflexes. These data suggest differential circuitry regulates adjacent DM motoneurons involved in sexual and eliminative reflexes. (Support: NIH, NS-31193; PVA, SCRF 1254).

ONUF'S NUCLEUS (ON) MOTONEURONS (MNs) HAVE MORE GABA-ERGIC SYNAPTIC COVERAGE THAN OTHER SOMATIC MNs: A QUANTITATIVE IMMUNOCYTOCHEMICAL STUDY IN THE CAT. Q. Li, M.S. Beattie, J.C. Bresnahan\*. Dept. of CBNA and Neuroscience Program, The Ohio State University, Columbus, OH 43210.

The pudendal motoneurons (PMNs) in ON are involved in visceral reflexes although they innervate somatic muscles. They have different properties than limb and other "classical" MNs (CMNs), e.g. they are more resistant to ALS. We compared the pattern of GABAergic input to these two populations of MNs in the cat (n=4) using EM immunocytochemistry. Quantitative analysis of was carried out in randomly selected plastic sections through ON, the dorsolateral nucleus (DLN) and the ventromedial nucleus (VMN). At the light microscopic (LM) level, PMNs in ON (n=169) had a mean (+/-SEM) synaptic coverage by GABA terminals of 43.3+/-0.56% vs. CMNs of 18.5+/-0.43% (n=129; p<.01). DLN did not differ from VMN. EM montages of the somatic surface of randomly selected MNs (20 cells/group) showed more GABA terminals apposed to PMNs vs. CMNs (mean no./cell= 4.45 vs. 0.7 respectively), and that a greater percent of the PMNs' cell perimeter (7.5+/-1.13%) was apposed to GABA terminals than the CMNs' (0.9+/-0.3%). The mean terminal apposition length and area of labeled terminals apposed to PMNs vs. CMNs did not differ (1.5+/-0.06um vs. 1.9+/-0.28um; area 0.9+/-0.07um<sup>2</sup> vs 1.3+/-0.23um<sup>2</sup>; p>0.05), nor did the active zone length (0.37+/-0.03um vs. 0.33+/-0.08um). The shape of the synaptic vesicles in the GABA terminals apposed to MNs was spherical (56.3%) or pleomorphic (41.8%); some DCVs were present. (Supported by NIH NS-10165 and NS-31193)

## 471.15

EFFECTIVE ELECTROMYCTURITION AND HISTOPATHOLOGIC CHANGES AFTER CHRONIC IMPLANTATION OF MICROELECTODES IN THE SACRAL CORD OF THE CAT. B.J. Woodford\*, R.R. Carter, D. M. McCreery, L.A. Bullara, W.F. Agnew, Huntington Medical Research Institutes, Pasadena, CA 91105

With the goal of designing a neural prosthesis for bladder control, we have implanted iridium microelectrodes into the sacral spinal cord of male cats, targeting parasympathetic preganglionic neurons. Electrodes were 50  $\mu$ m in diameter and 2.0 to 2.8 mm long. Through a support substrate on the dorsal surface of the cord, four electrodes were positioned one behind the other and directed to alternating sides. Stimulation-induced bladder pressure changes and electrode impedances were monitored on a weekly basis. At the termination of the experiment, the cats were perfused with fixative, and the electrodes were left *in situ* until autopsy. The final position of each electrode was determined by following patent tracks in 1  $\mu$ m serial transverse sections of epoxy-embedded sacral segments.

One out of five cats had histologic signs of chronic inflammation near the electrodes. The most consistent aspect of chronic implantation was a macrophagic and fibrous ensheathment of the support substrate, which sometimes involved dorsal roots and encroached into the dorsal cord along the path of the electrode entry. Other findings within the cord were varying thicknesses of glial ensheathment around the electrodes, axonal degeneration of varying severity in the dorsal columns, and neuronal loss in gray matter around the electrodes.

Electrophysiologic monitoring showed that the electrode array was electrically stable and that bladder pressure was controllable for at least 60 days. The effectiveness of stimulation decreased over time, however, and our results suggest that there may have been electrode migration away from the parasympathetic target, and/or trauma to spinal cord tissue that caused the neurons to be refractory to stimulation.

## 471.12

CHANGES IN THE EXPRESSION OF RAT MICROGLIAL IMMUNOMOLECULES AFTER UNILATERAL PUDENDAL NERVE SECTION OR CASTRATION. T. J. Brown\*, J.C. Bresnahan and M. S. Beattie, Dept. of Cell Biol., Neurobiol., and Anatomy; and Neuroscience Program, The Ohio State University, Columbus OH 43210.

The dorsolateral (DL) and dorsomedial (DM) motor nuclei innervate the perineal muscles of the rat via the pudendal nerve (PN), are androgen sensitive, and exhibit synaptic plasticity in response to lesions or castration. Previous studies using the plant lectin GSA I-B<sub>4</sub> showed that while pudendal nerve section resulted in microglial activation in all animals, only a percentage of the castrated animals showed this phenomenon and only at 3 days post-op. We decided to try more sensitive markers to determine whether or not castration results in microglial activation. The markers used were the monoclonal antibodies OX-42 (anti-CR3 receptor), OX-18 (anti-MHC I antigens), and OX-6 (anti-MHC II antigens). Animals were allowed to survive for 2, 3, 5, 6, 7 or 10 days following castration or PN section. Animals with nerve sections labeled with OX-42 showed activation in the dorsal horn (DH), DM and DL at all time points. Adjacent sections labeled with OX-18 showed activated microglia in the DH at 3 days post-op, DL at 5 days, and DM at 7 days post-op. Microglia stained with OX-6 did not appear until 10 days post-op. In the castrated animals no activated DH microglia were observed using any of the OX antibodies. At six days post-op activated microglia were observed in the DL and DM in sections labeled with OX-42 and OX-6 in one animal out of 15. Using microglial activation as an indicator, we conclude that the effects on motoneurons from removing androgen (castration), are not equivalent to the removal of target derived trophic factors (axotomy). (Support: NS31193 & NS10165).

## 471.14

EMERGENCE OF DISTENSION-EVOKED BLADDER CONTRACTIONS IN SPINAL CATS REQUIRES PERINEAL STIMULATION. J.W. Downie<sup>1,2</sup>, M.J. Espey<sup>1</sup>, and J.B. Gajewski<sup>2</sup>. Depts. Pharmacol.<sup>1</sup> and Urol.<sup>2</sup>, Dalhousie University, Halifax, Nova Scotia B3H 4H7, Canada.

Distension-evoked bladder contractions usually appear 2-8 weeks after spinal cord injury in cats. For a testing paradigm in our laboratory, cats had had chronically-implanted bladder cannulas. After spinal transection at T11/12, 3 cats failed to develop reflex bladder contractions in response to bladder distension up to 16 weeks post-transection when twice daily bladder drainage was accomplished through the implanted cannula. In two of these cats tested after decerebration, the bladder contracted in response to electrical stimulation of the S2 dorsal or ventral roots, indicating that appropriate spinal circuitry and a peripheral motor pathway were present. Four similarly-prepared cats managed by twice daily catheterization showed reflex bladder contractions within 2-4 weeks of spinalization. Five cats were then prepared with indwelling cannulas and were spinally transected. In these, tactile perineal stimulation was provided during bladder drainage through the implanted cannula. All 5 showed contractile activity in response to bladder distension within 1-3 weeks. In further experiments, 2 cats were prepared with sensory pudendal and superficial perineal neurectomies, 3 others were sham-operated controls. All were managed by headcap drainage plus tactile perineal stimulation. Controls showed rhythmic bladder contractions in response to bladder distension (up to 63-72 days post spinal transection). Cats with peripheral neurectomies showed no rhythmic contractions  $\geq 15$  cm H<sub>2</sub>O by 54 and 56 days post-spinalization. It is concluded that the emergence of distension-evoked bladder contractions in spinal cats is not an inevitable consequence of spinal cord transection but may depend on peripheral afferent activity from the perineum. ## 472.1

SYSTEMATIC CHANGES IN POSTURAL EQUILIBRIUM (HEAD STABILITY), GAZE NYSTAGMUS AND COGNITIVE PERFORMANCE WITH GRADED DOSAGES OF ALCOHOL. R.S. Kennedy\*, J.M. Drexler, Essex Corporation, Orlando, FL 32803; W.P. Dunlap, Tulane University, New Orleans, LA 70118; and J.M. Ordv, Memory Research Associates, Pittsford, NY 14534.

Postural equilibrium is used by clinical and experimental neuroscientists as a global index of central nervous system integrity. However, posturography devices are generally cumbersome, expensive, and follow a bottom-up (feet, knees, hips, etc.) measurement approach. In this study we measured and analyzed head kinematics (HK) (position, velocity and acceleration) using simple and low-cost equipment (video recording, PC-based framegrabber, head mounted reticle and specially written software) in a top-down approach. The effects of graded dosages of alcohol on the objectively scored video of postural stability was compared to performance on a standardized cognitive test (CT) battery and ratings by trained enforcement officers on the standardized roadside field sobriety tests (FST).

Eleven volunteers (male and female) were dosed with grain alcohol using the Widmark equation which expresses the relationship between distribution of alcohol, in the body as a whole, compared to the blood. After subjects reached a breath alcohol concentration (BAC) of .08% they were tested (HK, CT, FST) at each .02% BAC interval thereafter until .02% BAC was reached at which time subjects were again dosed to .08% BAC and the procedure was repeated. The results showed that all tests correlated with BAC levels. The best measure of alcohol intoxication was gaze nystagmus from the FST and the next best was y Velocity from HK. However, the gaze nystagmus test correlated minimally with y Velocity, the cognitive tests and the other FST posture measures. This means that aspects of y Velocity can add additional information not available from gaze nystagmus and performance alone and also provides support for our hypothesis that a video record of head position has promise as an index of alcohol dosage and perhaps other agents and treatments.

## 472.3

INTERACTION BETWEEN ATTENTION DEMANDING FOCAL TASKS AND POSTURAL SWAY. D.L. Weeks\*, R. Forget, L. Mochino, D. Gravel and D. Bourbonnais. Dept. of Physical Therapy, Regis Univ., Denver, CO, 80021, & Rehabilitation Inst., 6300 Dartington Ave., Montreal, Quebec, Canada, H3S 2J4.

The ability to simultaneously allocate attentional resources to both a postural and focal task is not well understood. Therefore, this study investigated the interaction between attention demanding cognitive and motor focal tasks, and postural sway during quiet stance with borders of the feet together in healthy young and healthy elderly subjects. The cognitive task involved silently solving an orally presented multi-step mathematics problem over 30 sec, while the motor task was a 30 sec bilateral static finger-thumb pinch task at 10% MVC. Each focal task was performed separately, and in a condition in which both tasks were performed simultaneously. Sway was recorded in a baseline (no focal task) condition, and during the performance of the focal tasks with full vision and with vision occluded on the premise that focal task performance would be degraded when attention devoted to postural control increased in the absence of vision. Analyses of cognitive task answers and RMS from the motor task target force revealed no Age Group, Gender, or Vision main effects. Thus, subjects adhered equally well to all focal tasks regardless of visual condition. Young subjects exhibited significantly less M-L sway, mean radial sway normalized for the height of the subject, and absolute sway velocity. Occlusion of vision significantly increased M-L and A-P sway, mean radial sway, and absolute sway velocity in the young and elderly. The single significant effect of the various focal tasks was on M-L sway in which the cognitive task resulted in significantly less sway than the motor task condition for the elderly subjects. Postural sway in the young subjects was not affected by the focal tasks. This suggests that for the elderly, M-L sway was influenced centrally during the cognitive task. In contrast, the increase in sway in the elderly during motor focal task performance suggests a reduced ability to suppress sway when the motor system is concurrently occupied with a voluntary task.

## 472.5

ARE ACCOMMODATIONS TO POSTURAL PERTURBATIONS AFFECTED BY FEAR OF FALLING? L.A. Brown\* and J.S. Frank. Neural Control Laboratory, Dept. of Kinesiology, University of Waterloo, Waterloo, Ontario Canada.

There is increasing evidence that many older adults are apprehensive about falling. Fear of falling is based on a perceived risk of instability leading to potential injury. Perceptions and fears are often reduced by familiarity with a situation. One possibility however, is that individuals apprehensive about falling do not adapt to familiar situations. This study addressed whether accommodations to postural perturbations are affected by fear of falling. In this study, fear of falling was simulated by manipulating the consequences of imbalance.

Eight healthy male subjects ( $23 \pm 5.7$  yrs) were exposed to 5 repeated external perturbations (force applied to the upper back) under conditions which manipulated the consequences of a loss of balance: (a) standing at ground level and (b) standing at the edge of a .83m high elevated platform. Whole body centre of mass (COM) kinematics and post-perturbation EMG activity of selected trunk and leg muscles were examined. The range of linear COM displacement was significantly lower during the elevated condition ( $p < .05$ ). In addition, COM displacement increased across trials in both testing conditions (statistical significance was noted between trial 1 and trials 4 and 5). Comparison of post-perturbation EMG activity revealed that the onset latency for the soleus muscle occurred significantly earlier for the elevated condition than for the ground-level condition. In addition, a progressive reduction in soleus EMG magnitude with repeated perturbations was revealed for the elevated condition only ( $p < .01$ ). Thus, despite the noted accommodation of postural responses in both conditions, the neural strategy underlying the resultant accommodation depended on the consequences of instability. These findings have implications for understanding how postural control is managed by individuals afflicted with a fear of falling. Supported by NSERC Canada.

## 472.2

THE INFLUENCE OF COGNITION ON BALANCE CONTROL IN PATIENTS WITH ALZHEIMER'S DISEASE. D. J. Beckley\*, V. P. Panzer, K.R. Thompson, B.R. Bloem, and M.P. Remler, Depts. of Neurology, UC Davis, CA 95616 and Leiden University Hospital, The Netherlands.

Falls are a significant problem in the elderly population and Alzheimer's disease (AD) is said to be a further risk factor. While exact mechanisms of postural instability are poorly understood in AD, one possible factor may be failure to use relevant environmental information. To assess the role of cognition on balance control in patients with dementia of the Alzheimer's type, eight patients with AD (5 female, mean age  $68.8 \pm 11.6$  (SD); Folstein MMSE  $16.4 \pm 6.9$ ) and eleven elderly normal subjects (4 female, mean age  $68.9 \pm 6.5$ ; MMSE  $29.6 \pm 0.5$ ) were tested with two sets of force plate perturbations (random mixture of small ( $5^\circ$ ) toe-up, toe-down, and large ( $15^\circ$ ) toe-up rotations). In one set, prior to each trial, subjects received perturbation pre-information. No pre-information was provided in the other set. The dependent variable was the frequency of two biomechanical markers of falls which occurred only during the  $15^\circ$  perturbations. There was no significant difference in the frequency of the biomechanical markers of falls between the AD and control group when no pre-information was provided (chi-square = 2.4). In contrast, a significant effect was noted when subjects received perturbation pre-information (chi-square = 22.3,  $p < .005$ ). The number of falls decreased in the control group while there was no improvement in the AD group. Our results suggest that the inability to use relevant environmental pre-information may be a potential mechanism leading to the higher incidence of falls in patients with AD. (Study supported by NIA-NIH)

## 472.4

ARE THERE VARYING ATTENTIONAL DEMANDS FOR DIFFERENT POSTURAL STRATEGIES? M.H. Woolacott\*, L.A. Brown and A. Shumway-Cook. Inst. of Neuroscience, Dept. of EMS, University of Oregon, Eugene OR.

Postural control is considered automatic, implying that sensorimotor processing requires minimal cognitive involvement. However, studies suggest that decreased neural function due to aging may increase postural attentional requirements. Consequently, postural control may be jeopardized if performing an attentionally demanding task. Attentional demands may also increase when the postural task becomes more difficult. This study examined the effects of attentional distraction on postural control as well as the attentional requirements associated with increasing postural demands. Six young adults participated in this study. Postural control and attentional performance were tested using a platform perturbation paradigm and an attentionally demanding counting task. The range of centre of mass displacement increased with increasing perturbation velocity, but did not significantly change when the secondary task was added. Attentional distraction therefore, did not disrupt the ability to control balance following unexpected perturbations. However, the findings confirmed that postural recovery is an attentionally demanding task: all subjects showed a decrease in attentional performance for the perturbation vs the control trials. This implies that, postural control takes precedence over a secondary task when the two are performed simultaneously. In addition, there did not appear to be varying attentional demands for different types of nonstep strategies; differences in attentional performance however, were noted when subjects executed a stepping response. For one subject in particular, there were no differences in attentional performance for the execution of an ankle-dominated or a hip-dominated postural response (mean subtraction duration was  $9.3 \pm 6.3$  sec for the control trial and,  $12.7 \pm 5.8$  vs  $12.6 \pm 5.6$  sec for the ankle and hip responses respectively). For this same subject however, the shift from a nonstep to a stepping strategy demanded additional attentional resources, and further reduced performance on the secondary task (mean subtraction duration was  $16.1 \pm 3.9$  sec for the stepping response). Thus, postural control is not automatic, but requires varying attentional resources depending on the postural response elicited.

## 472.6

POSTURAL ADAPTATIONS WHEN STANDING ON AN ELEVATED PLATFORM. J.S. Frank\*, D. Cockell and L.A. Brown. Department of Kinesiology, University of Waterloo, Waterloo, Ontario, Canada N2L 3G1.

The selection of a postural strategy to control upright stance can be influenced the cognitive set of an individual. A possible factor influencing cognitive set is the perceived threat to one's personal safety. We explored this factor by examining the control of stationary stance when standing at ground level and on a platform elevated to 0.81 metres above ground level. Eight adult males (17-34 years) of approximately the same height (1.8-1.9 metres) participated in the experiment. Subjects stood with their feet positioned side-by-side: when standing on the elevated platform, the toes were positioned at the edge of the platform. Postural control was examined during three consecutive 30-second intervals defined by three vision conditions: eyes open, eyes closed and return to eyes open. Measures of the root mean square of centre of pressure (CoP) and centre of mass (CoM) for the whole body showed little difference when standing with the eyes open at ground level versus on the elevated platform. However, removal of vision differentially influenced postural control for the two height conditions. Upon closing the eyes, CoP and CoM increased (58%) when standing at ground level and decreased (-40%) when standing on the elevated platform. The decrease in CoP and CoM for this latter condition was accompanied by a small increase in the mean level on soleus and tibialis anterior electromyographic activity. It appears that postural control is modified by perceived threat to safety and involves an increase in joint stiffness. Increase in joint stiffness would serve to limit displacement of the body to an impending perturbation.

Supported by a grant from NSERC.

## 472.7

REDUCED OR INAPPROPRIATE SENSORY INFORMATION INCREASES CENTER OF PRESSURE EXCURSION IN CHILDREN. H. Sveistrup\*, M. Trudel and R. Thibault. Program in Occupational Therapy, University of Ottawa, ON Canada K1H 8M5

The ability to regulate posture is a function of the detection and integration of inputs from the somatosensory, visual and vestibular systems. The challenge of maintaining balance increases when sensory information is removed or if information from one system is either distorted or in conflict with information from other systems. We recorded center of pressure excursion of children aged 4-6 (YC) and 7-10 (OC) under six conditions of altered sensory input obtained by modifying the support surface (normal, foam) and visual cues (normal, eyes closed, sway referenced). Center of pressure excursion increased from baseline in YC and OC when visual information alone was removed (8% and 54%) with slightly greater increases when somatosensory information alone was altered (23% and 69%). Altering inputs from both systems resulted in increased excursion from 43% and 110% (eyes closed, foam) and 63% and 165% (sway referenced, foam). The greatest increases in both YC and OC were recorded when both visual and somatosensory inputs conflicted suggesting that subjects had greater difficulty minimizing sway when inappropriate information was provided than when sensory information was removed.

## 472.9

RELIABILITY AND VALIDITY OF THE CTSIB AND BALANCE SYSTEM IN THE EVALUATION OF INDIVIDUALS WITH HEMIPARESIS D.S. Nichols\*, K.J. Hutchinson, L.A. Colby. Physical Therapy Division, The Ohio State University, Columbus, OH 43210.

Test-retest reliability and discriminant validity were evaluated for the Clinical Test for Sensory Interaction in Balance (CTSIB) and the sway index of the Balance System. 14 subjects with hemiplegia ( $x = 62.1$ , range 48-85) and 14 age and gender matched controls ( $x = 60.6$ , range = 48-83) participated. Each subject was tested using both the CTSIB and Balance System under 6 testing conditions: 2 support surfaces (CTSIB - firm, compliant; Balance System - firm, angular rotation) and 3 visual conditions (eyes open, eyes closed, visual conflict). Selected subjects were retested within 1 wk. ICC's (1,1) for the test-retest reliability ranged from .12-.82 for the Balance System and .20 to .97 for the CTSIB. Student's t-test comparisons identified significant differences between the 2 groups on both measures. A discriminant analysis using both measures correctly identified 12 of the 14 hemiplegic subjects. Pearson's correlation coefficients between the 2 tests were low to moderate.

## 472.11

SHORT-, MEDIUM-, AND LONG-LATENCY RESPONSES TO POSTURAL PERTURBATIONS IN PATIENTS WITH DIABETES MELLITUS. R. W. Simmons\*, C. Richardson and R. Pozos. Motor Control Lab, San Diego State Univ., San Diego CA 92182.

Insulin-dependent diabetes mellitus patients (IDDM:  $n = 23$ ), non-insulin dependent diabetes mellitus individuals (NIDDM:  $n = 10$ ), and diabetics with clinically apparent distal, symmetrical neuropathy (DN:  $n = 23$ ) were tested using dynamic posturography techniques. Diabetic subjects were matched to controls for age, weight and gender factors. For all subjects pre-amplified electromyographic (EMG) surface electrodes were placed over the anterior tibialis (AT) and medial gastrocnemius (GS) muscles of both legs. Subjects stood on dual forceplates that rotated upwards about the ankle joint 8 degrees in 400 ms. Twenty trials were completed separated by a randomly determined inter-trial delay of 1-5 s. Raw EMG signals were full-wave rectified and averaged for each subject. An interactive computer cursor device was used to determine the onset of the short-loop (SL), medium-loop (ML) and long-loop (LL) latencies manifested by the AT and GS muscles. For all pair-wise comparisons t-tests revealed no significant differences between diabetic and control groups for SL, ML, and LL latencies ( $p < .05$ ). Deficits in postural control associated with diabetic polyneuropathy are not attributable to delayed latencies in the lower limbs.

## 472.8

POSTURAL CONTROL DURING QUIET STANDING IN STROKE SUBJECTS. M. C. Verrier\*, D. Fogal Smith, A. Yuen, S. Dick, C.D. MacKinnon. Departments of Physical Therapy and Physiology, University of Toronto, Toronto, Ontario, M5T 1W5, Canada.

Centre of pressure (CP) is the point of application of the resultant ground reaction force vector and can indirectly represent the continuous neuromuscular control of the location of the body's centre of mass. To study the location and velocity of the CP, ground reaction forces and moments were recorded using a single AMTI force platform during three 20 second trials (eyes open) in stroke subjects (> than 6 months post-stroke) and normal subjects. In contrast to previous studies which forced subjects into a standardized foot position, stroke subjects stood on the force platform with their feet in the position that best reflected their perception of maximal stability. CP location and velocity were calculated post-hoc. Location of the CP was standardized to mid-ankle joint centre for each individual subject for inter-subject and group comparison. The mean CPx (anterior/posterior) and CPz (medial/lateral) locations were used to estimate weight-bearing relative to a mid-point between the two limbs (paretic and non-paretic). The mean CPx location was similar for both groups, but the mean CPz location was displaced laterally towards the non-paretic limb ( $\bar{x} = 1.3$ cm). The mean variance in the velocity of the excursion of CPx and CPz was calculated to provide an indicator of the 'rate of control of posture'. When CP velocity was compared in a sub-group of age- and anthropometrically-matched normal subjects who adopted the preferred standing position of their matched stroke subjects ( $n=9$ ), there was an increase in the mean variance of both the CPx (26%;  $p=0.059$ ) and CPz (65%;  $p=0.006$ ) velocity of stroke subjects. The marked increase in the variance of the CPz velocity indicates that preferred foot positioning does not adequately compensate for the medial/lateral instability seen in stroke. (Supported by NHRDP Grant # R6606-4547-59).

## 472.10

POSTURAL REFLEXES IN SUBJECTS WITH SOMATOSENSORY IMPAIRMENT. M. Zampoloni\*, A. Reali, M. Franceschini.

Department of Rehabilitation, Trevi, 06039, Perugia, Italy.

Balance reflexes elicited by a body sway produced by brisk movement of a platform are regulated by different afferent systems (somatosensory, visual and vestibular). In this study we investigated the role of the somatosensory system on the regulation of postural reflexes.

We studied four patients with specific somatosensory system lesions. Three were patients affected by spinal cord lesion limited mainly in the dorsal column pathway at dorsal or cervical level. The fourth patient was affected by a thalamic haemorrhage with proprioceptive impairment.

The subjects stood on a platform ("Dynamic Platform Apache BTH 1000") moved briskly backwards or forwards. The platform was moved by an engine stall holding force 60 Kgf and the displacement was regulated with a resolution of 1 mm using a computer with a RS232 interface. The activity of anterior tibialis (Tib) and medial gastrocnemius (Gast) was recorded by bipolar surface electrodes. The data were acquired using an A/D converter (Codas - 20 KHz). The body sway was backward and was induced with a series of 4 random acquisitions. Three different patterns of acceleration were used. All the series were studies with both open and closed eyes. The data were compared with the reference value of the normal subjects.

The data show a significant increase of the latency of Tib responses (18-35 ms) in all the patients. In the patient with thalamic lesion the latency on pathologic side was increased compared with the normal side. Measuring the postural responses during the follow-up (3 months later) the latency showed improvement.

The data indicate that the somatosensory system plays a pivotal role in regulating the postural reflexes through a long loop response.

This analysis could be used for monitoring the improvement of the postural adjustment during recovery after a central nervous system lesion.

## 472.12

DECREASING SWAY MAGNITUDE TO ENHANCE POSTURAL CONTROL IN OLDER, NON-FALLER ADULTS. S.L. Wolf\*, R.L. Segal, P.A. Catlin, C.A. Byrne, T.E. Palm, D.E. Sedgwick, A.H. Snyder. Department of Rehabilitation Medicine, Division of Physical Therapy, Emory University School of Medicine, Atlanta, GA 30322

The consequence of falls in the elderly is recognized as a severe public health issue. In part, falls may be due to disequilibrium. This study determined if sway magnitude in older adults following a toes-up perturbation could be conditioned using visual feedback. Ten healthy, non-faller adults (mean age: 73.1 years) received 30 toes-up perturbations during each of six baseline and six training sessions. Visual feedback of sway magnitude changes in center of pressure was provided during training. EMG data were gathered for training sessions to monitor subjects' responses to perturbation. Somatosensory and motor control tests were administered before baseline, between baseline and training sessions and following training. Sway magnitude was divided into response and maintenance intervals. The response interval was further divided into three 75 msec bins. During feedback training, sway magnitude increased within the first 75 msec, but decreased between 150-225 msec. Difference scores in somatosensory and motor control tests did not change significantly over time. Although adaptation may occur at a single joint, responses of the entire kinetic chain do not adapt. Visual feedback may have helped subjects decrease sway magnitude, but an extended baseline is needed to confirm this observation. Postural retraining of sway magnitude should be pursued more rigorously before ascertaining if this approach can improve postural dyscontrol in older individuals.

This study was supported by VA Merit Award #E723-RA awarded to Drs. Wolf and Segal.

## 472.13

OVERALL VS SELECTIVE DECLINE OF POSTURAL SUBSYSTEMS IN BALANCE-IMPAIRED OLDER ADULTS. S. Moore\*, M.H. Woollacott, M.S. Hu. Department of Exercise and Movement Science, University of Oregon, Eugene, OR 97403.

This study addressed the issue of whether balance impairment, unrelated to any known pathology in community dwelling older adults, involved overall vs selective decline of postural subsystems. Sensory and motor subsystems were evaluated. Two groups of 10 older adults (Balance Impaired, 80±8 yrs; Nonimpaired, 72±6 yrs) were selected from previous studies in our lab because they differed markedly in their ability to maintain balance when sensory information was manipulated. The Balance Impaired group experienced loss of balance 7±1 times on the Sensory Organization Test of Nashner (1982) whereas the Nonimpaired group did not experience any loss of balance. Both older groups, plus a Young adult control group (n=10, 31±5 yrs), were subjected to a test of motor coordination (sudden, unexpected support surface displacements) for which long loop muscle response latencies and organization were evaluated. The older groups also were screened neurologically.

The Nonimpaired and Young groups had significantly shorter distal agonist latencies than the Balance Impaired group (Young 88 ms, Nonimpaired 94 ms, Impaired 109 ms). Age was moderately correlated with distal agonist latency (Gastroc  $r = .51$ , Anterior Tib  $r = .66$ ). There were no group differences for orders of muscle onset, or for the symmetry of left and right agonist responses. Neurological screening revealed that the Impaired group had more impairment of vibration and position senses, and of tandem gait than the Nonimpaired group.

Evidence from this study suggests selective rather than overall decline of postural subsystems, and that this is partially explained by aging.

## 472.15

OPEN-LOOP AND CLOSED-LOOP POSTURAL CONTROL MECHANISMS IN PARKINSON'S DISEASE: INCREASED MEDIOLATERAL ACTIVITY DURING QUIET STANDING S.J. Mitchell, J.J. Collins, C.J. De Luca\*, A. Burrows, and L.A. Lipsitz Hebrew Rehab Center for Aged, Harvard University. NeuroMuscular Research Center, Boston University, Boston, MA 02215

The postural dyscontrol associated with Parkinson's Disease (PD) is a poorly understood phenomenon. In this study we used stabilogram-diffusion analysis (SDA) to gain insights into the postural impairments in PD. SDA is a technique based on a random-walk approach to quiet-standing center-of-pressure (COP) trajectories. SDA yields COP parameters which relate directly to the steady-state behavior of the neuromuscular mechanisms involved in maintaining erect stance. Posturographic data were obtained using a Kistler balance platform from 22 subjects with PD (72 ± 10 yrs) and 24 healthy elderly subjects (75 ± 2 yrs). Each subject performed ten 30s trials of quiet standing with eyes open. Effective diffusion coefficients, which reflect the level of effective stochastic activity of the postural control system, were calculated by plotting mean square COP displacements as a function of increasing time interval. Effective diffusion coefficients over short-term time intervals ( $D_s$ ) and long-term time intervals ( $D_l$ ) are proposed to represent an open-loop and closed-loop control system, respectively. The  $D_s$  ( $p < 0.0001$ ) and  $D_l$  ( $p = 0.002$ ) were significantly greater in the mediolateral (ML) direction for the PD subjects compared to the healthy elderly. These parameters did not distinguish the two groups in the anteroposterior (AP) direction. ML posturographic measures were also associated with a history of falls ( $p = 0.01$ ), difficulty arising from a chair ( $p < 0.001$ ), poor performance on a clinical scale of balance ( $p < 0.001$ ), and slower gait speed ( $p < 0.0001$ ). Thus, the postural control mechanisms in PD subjects, compared to healthy elderly, were characterized by an increase in effective stochastic activity in the ML direction. This may reflect an attempt to maintain potentially stabilizing movements during quiet stance in the face of impaired movement in the AP direction. This study suggests that ML activity is an important posturographic marker of functional balance impairment in PD during quiet standing.

## LIMBIC SYSTEM AND HYPOTHALAMUS: FUNCTION I

## 473.1

SINGLE UNIT ACTIVITY IN THE MEDIAL SEPTUM FOLLOWING SELECTIVE LESION OF THE SEPTOHIPPOCAMPAL CHOLINERGIC SYSTEM. E. Apatis, M.H. Bassant, F. Jazat-Poindessous and Y. Lamour\*. INSERM U 161, 2 Rue d'Alésia, 75014, Paris, France

The medial septum contains cholinergic and GABAergic neurons which project to the hippocampal formation. A significant proportion of the septohippocampal neurons exhibit a rhythmically bursting (RB) activity which is involved in the generation of the hippocampal theta rhythm. The neurochemical nature of septal RB neurons is not firmly established. To address this question, the cholinergic septal neurons were lesioned by an icv injection of the toxin 192 IgG-saporin (5µg), which destroys selectively the cholinergic neurons bearing the low-affinity NGF receptor (NGFr). The extracellular activity of the medial septal neurons was then studied in urethane anesthetized and unanesthetized rats 14 to 21 days after lesion. The loss of cholinergic neurons (assessed by NGFr immunohistochemistry) ranged from 80 to 100%. In urethane-anesthetized lesioned rats, the percentage of RB neurons decreased dramatically (8% (19/235) vs 20% (57/286) in controls,  $p < 0.001$ ). Even in rats with a complete cholinergic lesion, a few RB neurons were still recorded. The frequency of the RB neurons was higher in lesioned rats as compared to controls (4.5 vs 3.7 Hz,  $p < 0.0001$ ). In unanesthetized lesioned rats, no RB neurons were found out of the 51 neurons recorded during different behavioral states including REM sleep, whereas a high proportion of neurons recorded during REM sleep in control rats displayed RB activity. These data support the conclusion that RB septal neurons form two populations of unequal size: a cholinergic one, as shown by the decrease of RB activity in lesioned rats; a non-cholinergic one, as shown by the few RB neurons remaining in case of complete cholinergic lesion. (Supported by a grant from Bayer-Pharma, France).

POSTURAL RESPONSES TO A SLIP DURING WALKING IN HEALTHY OLDER AND YOUNG ADULTS. P.F. Tang\*, M.H. Woollacott, R. K-Y. Chong. Institute of Neuroscience, and Dept. of Exercise and Movement Science, University of Oregon, Eugene, OR 97403.

Slips are one of the major causes of falls in older adults. The present study compared postural responses to simulated slips during walking between healthy older and young adults. Subjects were perturbed during free-speed walking with an unexpected forward or backward translation of a movable platform incorporated into the center of a 5 m-long walkway. The onset of the platform movement (10 cm at 40 cm/s) was precisely timed to heel strike, midstance, or the late stance phase of the gait cycle, to induce various slip conditions. A total of 48 trials were tested, with the first 12 trials as a no-perturbation blocked condition, followed by 12 anterior perturbations (4 trials/phase), 12 posterior perturbations (4 trials/phase), and 12 additional no-perturbation trials in random order. Long-loop muscle response sequences from bilateral legs and the trunk, and the onset latency of distal leg muscles were investigated. Results from 4 healthy older (mean age = 77 ± 6 yrs) and 4 young (mean age = 24 ± 2 yrs) adults showed that the anterior platform translation at heel strike induced the most muscle responses, suggesting that this was the most challenging perturbation. In response to this anterior slip condition, both age groups revealed an increased activity of the tibialis anterior (TA), followed by increased activity of the quadriceps (Q), of the perturbed leg. These increased muscle activities were accompanied by decreased gastrocnemius (G) activity of the perturbed leg following heel strike, but a significant increase of G activity in late stance. Increased TA and Q activity was also found in the contralateral leg, but with a smaller magnitude. Unpaired t-test showed that the onset latency of the TA muscle in the perturbed leg was significantly longer ( $p = .01$ ) in the older adults (122 ± 5 ms) than in the young adults (106 ± 7 ms). These results demonstrate that healthy older and young adults have similar muscle sequencing in response to a slip during walking. The response from the distal muscle (TA), however, is delayed in older adults. (Supported by NIH AG05317 to Dr. Woollacott)

## 473.2

Non-cholinergic neurones of the medial septum display cluster firing at the theta frequency as well as 40 Hz (20-50 Hz) subthreshold oscillations. M. Serafin\*, S. Williams, B.E. Jones\* and M. Mühlethaler. Dept. of Physiology, CMU, 1211 Geneva 4, Switzerland and \*Montreal Neurological Inst., McGill University, Canada H3A 2B4.

We have recently demonstrated that nucleus basalis (NB) non-cholinergic neurones display high frequency (20-70 Hz) subthreshold oscillations and have the ability to discharge in rhythmic clusters (2-10 Hz) of action potentials (20-70 Hz during a cluster). In view of the possible rôle of the medial septum (MS) in conveying theta rhythmicity to the hippocampus as well as the recent evidence of "40 Hz" activity within that structure, we have reinvestigated the properties of non-cholinergic MS neurones, originally described by Griffith and Matthews (1986) in the guinea-pig and Markham and Segal (1990) in the rat. Using guinea-pig basal forebrain slices we found in the MS essentially two cell types. Out of 24 cells, 18 had properties characteristic of cholinergic neurones, that is a tonic discharge most probably subserved by a low-threshold calcium spike followed by a prominent slow afterhyperpolarization (AHP). Their firing rate could not exceed 10-15 Hz when depolarized. The remaining 6 cells were typically non-cholinergic with a fast AHP and fast spiking. We found that these cells, like the non-cholinergic NB cells could fire in rhythmic clusters at theta frequency when depolarized. Their firing frequency during the clusters was voltage-dependent and varied between 20 to 50 Hz. In addition subthreshold oscillations at the same frequency were observed between clusters. These results indicate that non-cholinergic (presumably GABAergic) MS neurones could convey to the hippocampus not only theta but also "40 Hz" rhythmicity. (Swiss NSF and Canadian MRC).

## 473.3

"SYNCHRONIZATION OF GAMMA OSCILLATIONS BY SYNAPTIC INHIBITION AMONG INTERNEURONS: A MODEL STUDY". X-J Wang\* (1), A. Sik (2) and G. Buzsáki (2), (1) Department of Mathematics, University of Pittsburgh, Pittsburgh, Pa. 15260. (2) Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, N.J. 07102

Rhythmic neural activity (gamma, 40-100 Hz) has been observed in the neocortex and hippocampus during behavioral arousal. We investigated the synchrony induced by inhibitory synaptic interactions among interneurons during gamma oscillations, using computer simulations. We show that the degree of synchrony is critically dependent on intrinsic cellular properties (in particular the amplitude of afterhyperpolarization (AHP)), as well as the network properties (especially the sparseness of connectivity). These two conditions appear to be fulfilled by fast spiking (basket or alveus/oriens) interneurons in the hippocampus. They display AHPs of less than 15 mV from the spike threshold. Furthermore, in vivo biocytin and parvalbumin double staining has allowed a direct estimate on the probability of contact between a pair of parvalbumin positive interneurons. This estimated probability is shown in the model to be sufficient but minimal for ensuring a high degree of synchronous firing in a local population of interneurons, which in turn are presumably capable of synchronizing the firing of the pyramidal cell populations.

## 473.5

ACTION POTENTIALS AND RELATIONS TO THETA RHYTHM OF SEPTOHIPPOCAMPAL NEURONS IN VIVO. S.E. Fox\* and E. Buzsáki. Dept. of Physiol., SUNY Health Sci. Ctr., Brooklyn, 11203.

Our previous intracellular studies distinguished three types of neurons in the medial septal nucleus / nucleus of the diagonal band (MS/DB) based upon duration of action potential (AP) and afterhyperpolarization (AHP). Two of the types are numerous: cholinergic septohippocampal neurons (long-AP, long-AHP) and GABAergic septohippocampal neurons (short-AP, short-AHP). Extracellularly recorded neurons are also divisible into two types based on AP duration. Both short-AP and long-AP cells can fire in rhythmic bursts phase-locked to the hippocampal theta rhythm. To better understand the neuronal organization of MS/DB we measured the phase relations to the theta rhythm, recorded at the hippocampal fissure, for intracellular recordings taken from urethane-anesthetized rats (n=30) and for extracellular recordings taken from freely moving rats (n=96).

Phase histograms of both intracellular and extracellular recordings from short-AP (putative GABAergic) cells showed that they fired mainly on the negative phase of the theta rhythm, whereas long-AP (putative cholinergic) cells fired on the positive phase. Rhythmic bursting of long-AP cells (n=5) was affected by local injection of GABA-A antagonist (picrotoxin, 1-1.5 µg), while the rhythmicity of short-AP cells was relatively unaffected (n=3). The results suggest that, for the theta rhythm that accompanies walking, the "GABAergic" septohippocampal neurons contribute to the phasic modulation of the "cholinergic" septohippocampal neurons. ## 473.7

MEDIAN RAPHE INFLUENCES ON HIPPOCAMPAL FIELD POTENTIALS AND NEURON SUBPOPULATIONS. K.Kao\*, M.J. Sanders and E.J. Green. Dept. of Psychology, University of Miami, Coral Gables, FL 33124

Prestimulation of the median raphe has been demonstrated to markedly augment the flow of information through the hippocampus. In the present experiments we investigated the mechanism underlying this phenomenon by assessing the influence of MR stimulation on the activity of different neuronal subpopulations.

Urethane anesthetized rats were prepared for stimulation of the perforant path (PP) and median raphe (MR), and recording of units and field potentials in the hippocampus. Prestimulation of the MR consistently produced substantial (> 50%) facilitation of the perforant path-evoked population spike without affecting the evoked field EPSP. Spontaneously active units were classified on the basis of location, spike duration, spontaneous firing rate, and response to paired stimulation of the perforant path. During the period of maximal spike facilitation (30-50 msec following the MR stimulus), MR stimulation produced suppression of many (50%) putative interneurons recorded in the stratum granulosum/hilus; the remainder of those cells were not consistently affected during this period. The majority (72%) of hilar complex spike cells were unaffected by MR stimulation, but 28% showed decreases in spontaneous activity. Similar effects were observed in CA1, where MR stimulation suppressed spontaneous firing in the majority (67%) of CA1 theta cells, and a smaller proportion (38%) of complex spike cells. Excitatory responses to MR stimulation during this interval were not observed.

The present results suggest that facilitation of hippocampal throughput by MR prestimulation likely results from inhibition of inhibitory interneurons. These data, taken with similar observations regarding the actions of other hippocampal afferents (e.g. medial septum) provides support for the idea that disinhibition is a common mechanism by which information flow through the hippocampus is facilitated.

## 473.4

MODELS OF GAMMA (40 HZ) AND THE LAMBDA RHYTHM IN THE RAT HIPPOCAMPUS IN VITRO AND IN VIVO R.D. Traub\*, J.G.R. Jefferys, M.A. Whittington, G. Buzsáki, M. Penttonen & S.B. Colling IBM Watson Res. Ctr., Yorktown Heights, NY 10598, St. Mary's Hospital Med. Sch., Imperial College, London W2 1PG, U.K. and Center for Neuroscience, Rutgers Univ., Newark, NJ 07102

Synchronized oscillations can be elicited in synaptically coupled networks of interneurons, by stimulation of metabotropic glutamate receptors and without a need for ionotropic glutamate receptors (Whittington, Traub & Jefferys, Nature, 1995). The network frequency is about 40 Hz. We studied further the oscillation mechanisms in a computer-simulated network (with 1,024 pyramidal cells and 256 inhibitory cells), in hippocampal slices and in anesthetized and behaving rats. 1) In the model and in slices, network frequency depends on 3 parameters - GABA<sub>A</sub> conductance and time constant in interneuron-interneuron synapses, and the driving current to the interneurons; 2) The model predicts a zero phase lag between pyramidal cell and interneuron firing during 40 Hz, in contrast to models dependent on recurrent excitation. *In vivo* data are consistent with our prediction; 3) The model can generate a 40 Hz rhythm that is frequency-modulated at theta frequency, using theta-modulated inputs to networks of chandelier, basket and dendritic interneurons. Firing patterns then resemble those recorded *in vivo*; 4) The model predicts that synchronized pyramidal cell bursts can be followed by a transient gamma-frequency tail. This phenomenon is observed in the rat following entorhinal cortex lesions. Simulated  $\theta + \gamma$ :

SIMILAR EFFECTS ON THE HIPPOCAMPAL EEG FOLLOWING INJECTIONS OF GABA AGONISTS AND ANTAGONISTS INTO THE MEDIAN RAPHE NUCLEUS. Jeffrey S. Thinschmidt<sup>1</sup>\*, Bernat Kocsis<sup>2</sup>, and Gene G. Kinney<sup>3</sup>. (1) University of Florida, College of Medicine, Dept. of Neuroscience, Gainesville, FL (2) National Institute of Neurosurgery, Budapest, Hungary (3) Fisons Pharmaceuticals, Dept. of Biology, Rochester, NY.

It has been shown that stimulation of the median raphe nucleus (MR) produces a desynchronized hippocampal EEG. We previously demonstrated that injections of 5-HT<sub>1A</sub> agonists (which inhibit 5-HT cell firing in the MR) and excitatory amino acid antagonists into the MR produce long trains of hippocampal theta rhythm (Vertes et al., *Neurosci.*, 60, 441, 1994; Kinney et al., *Brain Res.*, 654, 96, 1994). More recently, we found that injections of the GABA<sub>A</sub> agonist, muscimol, produced similar effects (Kinney et al., *Psychopharm.*, In Press). We now report that injections of the GABA antagonist, bicuculline, also produce long trains of hippocampal theta rhythm.

The hippocampal EEG of urethane anesthetized rats was recorded during baseline conditions (desynchronization), in response to sensory stimulation, and following a 0.1-1 µl injection of bicuculline methiodide or saline into the MR. Bicuculline (0.1-1.0 µg/0.1 µl of saline) produced theta with latencies of 0.5-5.6 min and durations of 23.5-76.34 min, while saline had no effect on the hippocampal EEG. By comparison, muscimol (0.5-3.0 µg/0.1 µl of saline) injections into the MR produce theta with latencies of 0-12.45 min and durations of 9.62-48.83 min (Kinney et al., *Psychopharm.*, In Press).

The unexpected finding that a GABA agonist and antagonist produce similar effects may indicate a complex GABAergic modulation of the hippocampal EEG at the level of the MR. This modulation may be mediated through the following mechanisms: (1) GABAergic receptors on 5-HT cells in the MR; (2) a population(s) of GABAergic interneurons in the MR; (3) an extrinsic GABAergic modulation of the MR. ## 473.8

THE INFLUENCE OF THE THALAMIC NUCLEUS REUNIENS ON HIPPOCAMPAL THETA AND SHARP-WAVE FIELD ACTIVITY IN URETHANE-ANESTHETIZED RATS L.M. Materi, L.J. Kirk, S.D. Oddie, R.S. Sainsbury and B.H. Bland. Behavioural Neuroscience Research Group, Dept. of Psychology, University of Calgary, Calgary, AB, Canada T2N 1N4.

There is considerable evidence that hippocampal theta (θ) activity is generated independently in CA1 and dentate gyrus cell populations. These two generators give rise to θ fields approximately 180° out of phase. The nucleus reuniens of the thalamus (Re) projects densely to the CA1 field of the hippocampus, but not to the dentate (Wouterlood et al., *J. Comp. Neurol.* 296:179, 1990). This raises the possibility of differential effects of Re inputs on θ activity generated in the CA1 and dentate. Previous electrophysiological work has established that electrical or pharmacological stimulation of the Re can elicit epileptiform activity in hippocampus (Vachon and Miliareiss, *Beh. Neurosci.* 106:981, 1992; Hirayasu and Wada, *Brain Res.* 577:36, 1992), although to date, no role in theta generation has been examined. In this study, hippocampal θ was recorded from close to the CA1 pyramidal layer and from the stratum moleculare of the dentate gyrus. Procaine (0.5 µl, 20%) infused into Re significantly reduced the amplitude of CA1 θ, but had less effect on dentate θ. Electrical stimulation of the Re elicited hippocampal θ in both generators at low intensity stimulation (100-300 µA). Systematically increasing the level of stimulation (up to 1000 µA) initially resulted in the appearance of epileptiform sharp-waves in CA1 (θ still present in dentate). Further increases in stimulation intensity resulted in sharp-wave activity in both CA1 and dentate. These results provide further support for the independence of CA1 and dentate θ generation, and suggest that the nucleus Re preferentially affects activity in the CA1 hippocampal region. (supported by NSERC and AHFMR).

## 473.9

SPONTANEOUSLY OCCURRING, RETICULARLY-ELICITED AND SEPTALLY-DRIVEN HIPPOCAMPAL THETA RHYTHM: A COMPARISON OF DEPTH AND CURRENT-SOURCE DENSITY PROFILES. I.J. Kirk\*, S.D. Oddie\*, N. McNaughton\* and B.H. Bland\*, Behavioural Neuroscience Research Group, Dept. of Psychology, University of Calgary, Calgary, AB, Canada T2N 1N4. \*Dept. Psychology and Neuroscience Research Group, University of Otago, PO Box 56, Dunedin, New Zealand.

Hippocampal theta ( $\theta$ ) can occur spontaneously in urethane anesthetized rats or can be elicited by high frequency (eg. 100 Hz) stimulation of the pontine reticular formation. High frequency stimulation of the medial septum desynchronizes hippocampal activity. However,  $\theta$ -like activity can also be driven by  $\theta$ -patterned stimulation of the medial septum. It has been suggested that the latter method may result in synchronous activation of septo-hippocampal fibres and fibres of passage and that the "driven  $\theta$ " is the sum of a variety of rhythmically evoked hippocampal field potentials that resemble  $\theta$ , rather than being analogous to actual  $\theta$  (Stewart and Fox, TINS 13:163,1990). In the present study, we analyzed the depth profiles (phase and amplitude) and the current-source density (CSD; Nicholson and Freeman, J. Neurophysiol. 38:356, 1975) profiles generated from them in spontaneously occurring, reticularly-elicited, and septally-driven hippocampal  $\theta$  (4-8 Hz). Consistent with previous research spontaneous and reticularly-elicited  $\theta$  reversed about an amplitude null zone in the stratum radiatum. Septally-driven  $\theta$  was found to reverse in phase at the same level. Also consistent with previous research, CSD analysis revealed predominant rhythmic sink-source pairs in the stratum oriens, stratum radiatum, and stratum lacunosum moleculare of CA1, and at, or just below the fissure in the stratum moleculare of the dentate gyrus. Again, CSD profiles derived from septally-driven  $\theta$  displayed essentially the same pattern. These results suggest that, at least in the urethane anesthetized rat, septally-driven hippocampal  $\theta$  is principally the result of activation septal projections normally active during spontaneous or reticularly-elicited  $\theta$ .

## 473.11

PHASIC THETA-ON CELLS IN THE MEDIAL MAMMILLARY NUCLEUS ARE SCULPTURED BY INHIBITORY INPUT DURING HIPPOCAMPAL THETA FIELD ACTIVITY IN URETHANE-ANESTHETIZED RATS. S.D. Oddie\*, I.J. Kirk\*, J. Konopacki, and B.H. Bland\*, Behavioural Neuroscience Research Group, Dept. of Psychology, University of Calgary, Calgary, AB, Canada T2N 1N4.

Hippocampal theta (HPC- $\theta$ ) results from the activation of synchronizing inputs which originate in the pons region (PO) and ascend via the posterior hypothalamic and supramammillary (SuM) nuclei to the septo-hippocampal system. Cells in these nuclei, and in the medial mammillary nucleus (MM), show distinct relationships to HPC- $\theta$  (Bland et al., 1995). Specifically, MM cells discharge rhythmically and in phase with HPC- $\theta$  (phasic  $\theta$ -ON). The linear relationships which  $\theta$ -related cells have to HPC- $\theta$  are used to characterize frequency coding in the hippocampal synchronizing system. The current study examined the linearity of MM cells during varying frequencies of HPC- $\theta$  produced by electrical stimulation in the PO. MM cell discharges were recorded during spontaneously-occurring HPC- $\theta$  and during HPC- $\theta$  elicited by 0.1 - 0.9 mA PO stimulation. For any recorded signal, the average discharge rate per  $\theta$ -wave and the frequency of the simultaneously-occurring HPC- $\theta$  were determined. For each MM neuron, cell discharge values were regressed onto the frequency values and the significance and type of linearity (i.e. negative, positive, or non-linear) were assessed. Of the 17 MM cells recorded, 12 revealed significant negative-linear relationships to HPC- $\theta$ . That is, as the frequency of HPC- $\theta$  increased, the rhythmic discharge rate of the MM neurons decreased linearly. Of the remaining 5 cells, two were positive-linear, and three were non-linear. All but one negative-linear MM neuron were found in the anterior portion of the MM, immediately ventral the SuM, whereas the remaining cells were located in the posterior MM. These findings indicate that most rhythmic MM cell discharge, in the 2-8 Hz bandwidth, results from a frequency-coded inhibitory input originating in the septo-hippocampal system.

## 473.13

TEMPORAL STRUCTURE IN THE DISCHARGE OF SUPERFICIAL LAYER (II-III) ENTORHINAL CORTICAL NEURONS. J.J. Chrobak\* & G. Buzsáki, Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102.

The superficial layers (II-III) of the entorhinal cortex (EC), parasubiculum and presubiculum provide the neocortical input to the hippocampus (HPC). Information about the activity of this cell population is crucial for understanding memory formation and the etiology of Alzheimer's dementia. The present study examined the discharge characteristics of these neurons in the freely-behaving rat.

During awake immobility and slow wave sleep, layer II-III neurons discharged single spikes that were phase-related to local high frequency field oscillations (~100Hz) during EC sharp potentials. Entorhinal sharp potentials were prominent throughout the deep and superficial layers of the EC and occur with greater frequency than hippocampal sharp waves. During exploratory activity and REM sleep, superficial neurons fired phase-related to EC gamma (~40-100Hz) oscillations that were coupled to EC theta waves. Most neurons fired in association with gamma for an irregular series of theta waves and then remained silent for indefinite periods. A single cell was observed that fired on each and every theta-nested gamma oscillation. Rhythmic and intermittent high-frequency oscillations associated with EC theta and EC sharp potentials, thus provide temporal structure to the discharge of these neurons. These patterns are analogous to neuronal activity observed at their targets within the dentate/hilar region of the HPC. This structured discharge suggests that functional coupling between these regions is mediated by network oscillations, when the discharge of neurons in each region is brought together in time within the millisecond range.

## 473.10

INTRASEPTAL MICROINFUSION OF MUSCIMOL: EFFECTS ON HIPPOCAMPAL FORMATION FIELD ACTIVITY AND PHASIC THETA-ON CELL DISCHARGES. B.H. Bland\*, C. Trepel, S.D. Oddie, & I.J. Kirk, Behavioural Neuroscience Research Group, Dept. of Psych., University of Calgary, Calgary, AB, Canada T2N 1N4.

The effect of intraseptal microinfusions of the GABA-A agonist muscimol on hippocampal (HPC) field activity, and simultaneously-occurring discharges of phasic theta-ON cells, was investigated in urethane-anesthetized rats. The microinfusion of 5.0 - 12.5 nmoles of muscimol into the medial septum (MS) resulted in a progressive reduction (beginning 5 min post-infusion) in the power (amplitude), and finally the total loss of theta field activity. In contrast, the frequency of the theta field activity remained unaffected until it was abolished. In the period immediately following the first 1 min intraseptal microinfusion of 5 nmoles muscimol, a brief period of phasic theta-ON cell excitability was manifested as an increase in the number of discharges per rhythmic burst. Subsequently, associated with the progressive reduction of the amplitude of theta field activity, phasic theta-ON cell discharge rates were progressively reduced for a period beginning 5 min post-infusion of 5 nmoles muscimol. Despite the progressive reduction in the number of discharges, phasic theta-ON cells maintained their preferred phase preferences while theta activity was present. Just prior to the complete abolishment of theta activity, phasic theta-ON cells ceased discharging. During the period when theta activity was replaced by low amplitude asynchronous activity, phasic theta-ON cells discharged in bursts correlated with every occurrence of sharp wave field activity. The results support previous suggestions that GABA-ergic neurons in the MS regulate the activity of cholinergic septohippocampal neurons, that the MS modulates theta amplitude primarily and theta frequency secondarily, and that HPC theta and sharp wave field activity represent separate neural inputs to phasic theta-ON cells. (Supported by NSERC & AHFMR).

## 473.12

RECOGNITION OF SPATIALLY SEPARATED FIELD POTENTIALS AND UNIT ACTIVITY BY "SPATIAL CLUSTERING" METHOD. Z. Nádasdy\*, A. Bragin and G. Buzsáki, CMBN, Rutgers University, Newark, NJ 07102.

Sixteen-channel recordings of spontaneous local field potentials, recorded from the CA1 and dentate regions of the hippocampus, were analyzed by a "spatial clustering" method using multiple site silicon probes (100  $\mu$ m intervals). The rationale of the method is that the amplitude ratios of the simultaneous field components are expected to change systematically with the distance of the electrodes from the actual current source of synaptic currents. Here we describe the utility of the method for known hippocampal field events, sharp waves (SPW) and two types of dentate spikes (DS1, DS2) which are known to be generated by spatially segregated synapses. The "spatial clustering" method could reliably cluster these events in the space-time domain.

The same rationale was applied to identify unit activity. Spatial separation was applied to four-channel multiunit recordings (25  $\mu$ m intervals) from the CA1 region of the hippocampus. A combination of different spatial descriptors of the spikes led to a convergence of spike localization. The correspondence of the spatial spike-clusters with single neuronal activity was attested by auto-correlation analyses. After single spike separation, we examined somadendritic spike propagation in individual neurons. During slow firing the amplitude ratio of extracellularly recorded spikes in the dendrites and soma were similar. However, during epileptic activity a gradual spike attenuation and failure was observed in the dendrites. The findings show that multiple site recording in the awake animals can be used to monitor spike propagation and network interactions.

## 473.14

ACTIVITY OF NUCLEUS TRIANGULARIS SEPTI (TS) NEURONS TO THETA AND SHARP WAVES IN THE BEHAVING RAT. D. Carpi, A. Sik and G. Buzsáki\*, CMBN, Rutgers University, Newark, NJ 07102.

The TS is a homogeneous group of neurons located in the fimbria-fornix. TS cells are immunoreactive for calcium binding proteins, calretinin and calbindin, and contain numerous peptides, including LHRH, neurophysin and GnRH. TS neurons may receive afferents from the hippocampal formation and through their efferent projections may convey endocrine information. The aim of this study was to investigate the relationship between firing patterns of TS neurons and hippocampal activity in the behaving rat, specifically during theta waves associated with exploration and sharp waves (SPW) associated with consummatory behaviors and slow wave sleep. Population firing of TS cells were phase-locked to the ascending part of CA1 theta waves. Isolated individual cells rarely fired rhythmically at theta frequency. All TS cells recorded were observed to powerfully increase their firing rates during SPW, indicated by large peaks in the cross-correlograms. The correlation between hippocampal population patterns and TS activity provides physiological support for an excitatory input from the hippocampal formation to this nucleus. The strongest population bursts in association with SPW may explain why several endocrine functions are most affected during sleep and we hypothesize that hippocampal SPW are instrumental in such operations.

## 473.15

**GAMMA FREQUENCY (30-100 Hz) PATTERNS IN THE HIPPOCAMPUS: PARTIAL COHERENCE ANALYSIS.** B. Kocsis\*, A. Bragin and G. Buzsáki. Natl. Inst. Neurosurgery, Budapest; CMBN, Rutgers University, Newark, NJ

We examined the cellular generation and spatial distribution of gamma frequency activity in the hippocampus of the awake rat. Multiple site recording techniques with silicon probes (16-site arrays) combined with wire electrodes were used. The power at gamma frequency was greater during theta than during immobility or slow wave sleep. Phase measurements indicated 180° reversal of gamma waves at two different locations: across the granule cell layer and across CA1 pyramidal layer. Partial coherence analysis revealed separate dipoles associated with the dentate gyrus (DG) (50-90 Hz), the stratum lacunosum-moleculare (lac-mol) and pyramidal layer (30-60 Hz). Mathematical elimination of the components coherent with electrical activity in the hilus from signals recorded at different depths in CA1 did not affect the coherence between gamma in lac-mol and str. oriens indicating that these oscillators were independent from the DG oscillator. Independence of the lac-mol and pyramidal oscillators was suggested by marked separation of coherences between CA1 electrodes placed above or below the pyramidal layer. Similarly, the coherence between oscillators in the hilus and the hippocampal fissure remained significant when allowance was made for gamma oscillations in CA1. The granule cell layer also separated coherent oscillations in the hilus and the molecular layer. Following surgical removal of the entorhinal cortex (EC), active generators of gamma activity were found in str. radiatum and pyramidal. The coherence between these oscillators could be eliminated by partialization on the signal recorded from CA3c region suggesting that the latter is transmitted from the CA3 region. We conclude that in the intact brain layers II and III of EC are coupled by gamma oscillators of DG and CA1 regions, respectively.

## 473.17

**DENTATE MOSSY CELL INVOLVEMENT IN TRANSIENT FOREBRAIN ISCHEMIA: AN IMMUNOCYTOCHEMICAL STUDY.**

M. Hsu<sup>†</sup>, C. Leran<sup>§</sup>, A. Sik<sup>†</sup> and G. Buzsáki<sup>†</sup>. <sup>†</sup>Ctr for Molec & Behav Neurosci, Rutgers Univ, Newark, NJ. <sup>§</sup>Dept Obstetrics & Gynecology, Yale Univ, New Haven, CT.

Previous studies have implicated the degeneration of dentate mossy cells after ischemia and epilepsy. Because mossy cells do not express the common neuropeptides and calcium-binding proteins known to date, they have been impossible to visualize other than using Golgi methods. Recently, we have shown, using the Gallyas silver stain for "dark" neurons and immunocytochemistry against heat-shock proteins (HSP72), that mossy cells are affected by ischemia. However, it is still controversial whether neurons expressing HSP72 actually degenerate, or whether the damage is reversible. In the companion abstract, we report that in the dentate hilus, only mossy cells stain for the GluR2/3 subunit of the AMPA receptor (Leran et al, 1995). This allowed us to directly visualize mossy cells in the posts ischemic hilus. Rats were made ischemic using the 4-vessel-occlusion method and allowed to survive for 4-12 mo. Their brains were then processed for immunocytochemistry against GluR2/3 and the calcium-binding proteins calbindin, calretinin, and parvalbumin. Non-overlapping hilar cell populations were immunostained using these antibodies. Electron microscopic examination revealed the presence of thorny excrescences on the thick proximal dendrites of the GluR2/3-positive cells, confirming that they were indeed mossy cells. Although a few mossy cells were still present in the posts ischemic hilus, their numbers were drastically reduced compared with controls. Yet, mossy cells could be seen even in ischemic brains where CA1 had completely degenerated. These results indicate that the extent of hilar and CA1 ischemic damage may not parallel each other, and that ischemic cell damage in the hilus and CA1 may occur by means of independent mechanisms.

**MAPPING HUMAN LIMBIC RESPONSES TO SUBANESTHETIC NITROUS OXIDE BY PET.**

F. Gyulai, L. Firestone, M. Mintun\*, P. Winter. Dept. of Anesthesiology/CCM, and PET Facility, University of Pittsburgh, PA 15261

Recent human behavioral studies have shown that even subanesthetic concentrations of nitrous oxide (N<sub>2</sub>O) impair psychomotor, cognitive performance and semantic learning and memory processes. To elucidate the cerebral areas mediating these effects, following IRB approval (#931063), 8 volunteers were studied by positron emission tomography (PET). <sup>15</sup>O-water was used to detect changes in regional cerebral blood flow (rCBF), that in turn reflected central neuronal activity, during room air or 20% N<sub>2</sub>O inhalation. In 4 subjects, N<sub>2</sub>O-related regional cerebral metabolic activity (rCMR) was also measured with <sup>18</sup>F-deoxyglucose, to control for possible effects of N<sub>2</sub>O on rCBF/rCMR coupling. Two rCBF and 1 rCMR scan was obtained in each of these conditions. The room air condition always preceded N<sub>2</sub>O administration. N<sub>2</sub>O-associated regional activity changes were identified using the statistical parametric mapping method at a significance level of 0.01. The magnitude of changes detected by the rCBF and rCMR scans were statistically analyzed (t-test) for differences (p<0.01).

Twenty percent N<sub>2</sub>O did not produce significant spatial or magnitude differences in rCBF/rCMR coupling. N<sub>2</sub>O inhalation was associated with significant activation in the anterior cingulate cortex and deactivation in the poster cingulate and hippocampal areas. The anterior cingulate cortex is associated with psychomotor and cognitive function, while the posterior cingulate and hippocampus mediate learning and memory. Thus these neuroanatomic findings strongly correlate with the behavioral effects of N<sub>2</sub>O. Supported by a grant from the IARS (LF), UACCMF, UPMC PET Facility.

**SEPTAL STIMULATION SUPPRESSES HIPPOCAMPAL SYNAPTIC INHIBITION IN A COMBINED SLICE PREPARATION.** K. Tóth, T.F. Freund and R. Miles\*. Institute of Experimental Medicine, Hungarian Academy of Sciences, Budapest, Hungary and Neurobiologie Cellulaire, Institut Pasteur, Paris, France.

The septohippocampal pathway includes, in addition to cholinergic afferents, GABAergic fibers which terminate specifically on hippocampal interneurons (Freund & Antal, 1988). We investigated the functional effects of this pathway using septohippocampal slices of mouse and rat. Immunocytochemical staining for parvalbumin and ChAT revealed the slices contained intact septohippocampal axons. The activity patterns of intracellularly recorded septal and hippocampal neurons were as described previously.

We examined the effect of septal stimulation on spontaneous IPSPs recorded with KCl-filled electrodes from CA3 hippocampal pyramidal cells in the presence of CNQX (20 μM), APV (100 μM) and atropine (1 μM). IPSP frequency was reduced by 73 ± 8 % during trains (20-50 Hz, duration 0.2-1 s) of septal stimuli (n=16 slices). Averages of responses to single septal shocks (n=4 cells) revealed a hyperpolarisation at membrane potentials of -65 to -80 mV, while IPSPs were depolarising at these potentials. In contrast, at potentials positive to the IPSP reversal in records with CsCl filled electrodes, averages showed a depolarisation (n=3 cells). These findings suggest that one functional effect of septal activity is hippocampal disinhibition.

## 473.18

**REGULATION OF EXCITATORY SYNAPTIC INPUT TO BASKET CELLS IN NEONATAL RAT DENTATE GYRUS DURING HYPOXIA.**

J. Doherty<sup>†</sup>, T. Kneisler and R. Dingledine. Dept. of Pharmacol., Emory Univ., Atlanta, GA.

Alterations in excitatory input to basket cells in the dentate gyrus of neonatal rat hippocampal slices resulting from brief hypoxic episodes (1-5 min, 95% N<sub>2</sub>/5% CO<sub>2</sub>) were examined under whole cell clamp. Basket cells were morphologically identified by a biocytin staining protocol following electrophysiological study. A brief hypoxic episode evoked two slow currents, a low amplitude (10-20 pA) hypoxic outward current, followed by a larger (40-60 pA) post-hypoxic outward current. Hypoxic episodes also increased the frequency of spontaneous EPSCs.

Minimal electrical stimulation of dentate granule cells, CA3 pyramidal cells, and the perforant path generated AMPA and NMDA receptor mediated excitatory postsynaptic currents (EPSCs) in basket cells. Brief hypoxic episodes rapidly and reversibly suppressed basket cell EPSCs evoked in response to all three inputs. Hypoxic episodes also suppressed CA3 evoked polysynaptic IPSCs in dentate granule cells, but did not suppress monosynaptic IPSCs evoked by stimulation in the granule cell layer. Adenosine A1 receptor antagonists (DPCPX, N-0840 1 μM) delayed, but did not block, hypoxia-induced suppression of basket cell excitatory input.

Adenosine (50 μM) rapidly and reversibly suppressed both evoked and spontaneous basket cell EPSCs, but did not generate slow postsynaptic currents. The metabotropic glutamate receptor agonist 1S,3R-ACPD (30-100 μM) also rapidly and reversibly suppressed evoked EPSCs, and sharply increased the frequency of spontaneous EPSCs. Application of 1S,3R-ACPD generated slow inward currents in 71% of basket cells. Loss of excitatory input to dentate basket cells may contribute significantly to hippocampal hyperexcitability following hypoxia. The extreme sensitivity of basket cell excitatory inputs to suppression under hypoxic conditions suggests that these inputs may be crucial in regulating hippocampal excitability.

## 473.20

**SELECTIVE ACTIVATION OF A LIMBIC NETWORK IN HUMANS** D. Servan-Schreiber\*, W. Perlestein, J.D. Cohen, & M. Mintun. Dpt. of Psychiatry and PET Facility, Univ. of Pittsburgh, Pittsburgh, PA, 15213.

Previous studies have suggested that Procaine HCl administered IV can reliably induce activation of limbic structures. In this PET O15 study, 10 normal human volunteers received two injections of placebo and two injections of procaine HCl 1.84 mg/Kg in a single scanning session (ABBA sequence). One minute scans were obtained two minutes after each injection. Subjects were instructed to pay attention to somatic, perceptual, cognitive and emotional effects and interviewed for 10 mins after each injection. Procaine induced powerful and varied subjective effects including anxiety, depression and euphoria, as well as somatic and perceptual changes. It also reliably increased plasma cortisol levels. Blood-flow increased very selectively in a bilateral anterior limbic network encompassing the insular cortex (IC), the anterior cingulate cortex (AC) and the amygdala/parahippocampal region (AMG/PHC). No neo-cortical region was comparably activated. Individual subject analyses showed that activation of this anterior limbic network occurred in all subjects. A principal component analysis with varimax rotation on selected neocortical and limbic voxels suggested three independent patterns of activation that together accounted for 77% of the variance in blood-flow among the selected voxels over all four scans. The first pattern reflected primarily anterior limbic activation (IC, AMG/PHC, and rostral AC). Exploratory correlations revealed a strong selective association with ratings of mood, somatic and perceptual symptoms, and with changes in plasma cortisol. The second pattern captured changes in blood-flow in the inferior frontal cortex (IF), with right and left IF loading in opposite directions. It was not associated with the subjective or physiological variables measured in this study but was related to time spent in the scanner. The third pattern captured primarily blood-flow changes in the caudal AC and was associated selectively with changes in heart rate.

**New CBF-based Functional MRI Technique, Seong-Gi Kim\***, Center for Magnetic Resonance Research, Dept. of Radiology, Univ. of Minn., Minneapolis, MN 55455. In order to measure relative cerebral blood flow (relCBF) changes quantitatively, we have developed a Flow-sensitive Alternating Inversion Recovery (FAIR) MRI technique (Kim, Magn. Reson. Med., accepted), in which perfusion-based functional images can be generated by subtracting two inversion recovery (IR) images, one with a non-slice-selective IR pulse and another with a slice-selective IR pulse. Consecutive FAIR echo planar images were collected, first under a resting state, then during a "task" period, and ending with a recovery state. Tasks are repetitive thumb-digit opposition movements. Imaging parameters are spatial resolution = 3.8x3.5 mm, inversion time = 1.4 s and inter-image time = 2.8 s. In all 4 subjects, the contralateral motor cortex was activated during finger movements, which is consistent with previous studies. The relCBF change of contralateral motor cortical area in four subjects detected by the FAIR technique was 49 +/- 16% SD. Although the FAIR technique provides the same relCBF information compared to PET, the MR method provides advantages due to availability of higher spatial and temporal resolution, ease of use and absence of any invasive procedures. Also, the FAIR technique is capable of generating microvascular-based functional maps and relatively independent of magnetic field strength. (Supported by NIH grants NS32919 and RR08079).

## 474.3

**FLUCTUATION IN SOMATOSENSORY OPTICAL SIGNAL DURING SUSTAINED STIMULATION, M. Hanagar, J. Dowling, D. Liu, J.C. Royvainen, T. Woolsey, R. Grubb\***, Departments of Neurosurgery and of Cell Biology and Physiology, Washington University School of Medicine, St. Louis, MO 63110

Measurable changes in optical characteristics of the cerebral cortex at various wavelengths accompany increased neural activity. Activity dependent changes in absorbance at 520-560 nm, are attributable to changes in blood volume and thus reveal fluctuation in blood flow or perfusion. Optical changes were monitored over the rat whisker-barrel cortex during whisker stimulation with a Macintosh computer, CCD camera with image intensifier, research microscope and public domain software (NIH Image 1.49). Somatosensory cortex was imaged through a closed cranial window (11mm, i.d.) in 300 g Wistar rats anesthetized with 1 g/kg urethane, ip. Single and C-row whiskers were stroked at 4-5 Hz for up to 30 minutes. Pixel by pixel comparisons of images obtained prior to, during and after stimulation revealed blood flow related changes in the optical characteristics of barrel cortex and of cerebral vessels. Arterial, parenchymal and venous responses were selected and analyzed at intervals as short as 133 ms directly from the CCD camera or *post hoc* from video tape recordings. These studies demonstrate the temporal and spatial fluctuations in optical signal which occur in response to prolonged stimulation.

This work supported by NIH Grants NS 07057, NS 17763, NS 26761, and HL 41075, the McDonnell Center for Studies of Higher Brain Function and an award from the Spastic Paralysis Foundation of the Illinois-Eastern Iowa District of the Kiwanis International.

## 474.5

**A METRIC FOR VALIDATING CROSS-MODALITY IMAGE REGISTRATION TECHNIQUES, K.J. Black\*, T.O. Videen, J.S. Perlmutter**, Departments of Radiology, Psychiatry and Neurology, Washington Univ. Sch. of Med., St. Louis, MO 63110.

We placed thin tubing in the shape of 3 N's in a rigid headholder used for imaging studies in primates. The headholder bolts firmly to a surgically implanted "cap" affixed to the skull. The tubing can be filled with a solution containing either  $^{18}\text{F}$  or  $\text{CuSO}_4$  for visualization with PET or MRI, respectively. Using manual segmentation of each limb of each N, followed by least-squares regression, we can locate the two "corner," or intersection, points on each fiducial. This gives 6 well-localized fixed points. Test-retest accuracy in a Siemens 953b PET scanner varied from 0.2mm (largest fiducial) to 1.1mm (smallest fiducial). Comparing the location of these fixed points in serial PET scans during a given study confirmed that there was no detectable movement over a period of several hours (mean error 0.4mm, or within the limits of test-retest accuracy). Accuracy was also assessed by computing distances between independently located fixed points. The method preserved distances across MR studies (<1% error), across PET studies (<1% error), and between modalities (<2% error). Given this validation of our ability to find these fixed points in either PET or MRI, we can test the accuracy of cross-modality image registration techniques which *do not* use these fiducials. We have applied this test to the AIR method of Woods et al. (J Comput Assist Tomogr 17:536-546, 1993) in our ongoing PET and MRI studies of baboons. Preliminary results show that summed blood flow images ( $\text{H}_2^{18}\text{O}$ -PET) can be aligned to MR anatomic images with an accuracy of 1.5mm-5.22mm (mean, 3.3mm), measured at the external fiducials. Maximum error in the brain is roughly 2mm. Single, unfiltered  $\text{H}_2^{18}\text{O}$  emission images are aligned with only slightly worse accuracy. In sum, we report validation of a stringent test which can be applied to any post-hoc method for intra- or cross-modality image registration.

## 474.2

**SUBTRACTION ANALYSIS OF FDG PET DATA: DESCRIPTION OF METHOD AND COMPARISON OF TWO AGE GROUPS, J.R. Ashher\*, (1,2), E.H. Fahey (3), C. Eades (3), E.B. Wood (1), Departments of Neurology (1), Psychiatry and Biobehavioral Sciences (2), and Radiology (3), Bowman Gray School of Medicine, Winston-Salem, N.C. 27157-1078, U.S.A..**

Worsley and colleagues described a technique for statistical analysis of PET activation experiments. We describe a modification of the technique for between-group comparisons, and report an analysis of 11 "old" and 20 "young" subjects. Normal volunteers were recruited from the community, and carefully screened for psychiatric, neurological, and neuropsychological problems. All subjects underwent  $^{18}\text{F}$  FDG PET scanning on a Siemens CTI 951/31 PET Scanner, following a standardized period of tracer uptake. All subjects performed a letter identification task during glucose uptake to reduce variability in glucose metabolism. The PET scans were registered to T-1 weighted MRI scans. MRI scans were automatically transformed to stereotaxic space using a cross correlation minimization procedure. All the PET scans were placed in stereotaxic space by combining transformation parameters for each step. Each PET surface was marked with a 3D contour so the degree of overlap among scans ("n image") could be computed. Between-group differences in glucose metabolism were computed for each voxel, along with the pooled variance for each group. The n image and the pooled variances were used to scale the difference image to the appropriate t value. Significant differences were identified as those exceeding the critical threshold. Significant age-related reductions ( $p < 0.01$ ) in glucose metabolism were noted bilaterally in the parietal, frontal, and prefrontal cortices, and caudate nuclei. The right putamen, right insula, left anterior cingulate, and left Heschl's gyrus also demonstrated age-related declines in glucose metabolism. We conclude that unpaired analysis of average  $^{18}\text{F}$  FDG PET scans is a viable analytic strategy.

## 474.4

**APPRAISAL OF UNIVARIATE AND MULTIVARIATE ANALYSIS TECHNIQUES FOR PET BRAIN IMAGE QUANTIFICATION**

**J.D. Van Horn\*, G. Esposito, B.S. Kirkby, D.R. Weinberger, and K.F. Berman**, Unit on PET, Clinical Brain Disorders Branch, NIMH, National Institutes of Health, Bethesda MD 20892

Analyses of PET brain image data currently quantify statistical effects using pixel-wise univariate comparisons within and/or between datasets. However, functional intercorrelation and multiple comparisons of rCBF measurements may complicate the interpretation of results obtained via this approach. Multivariate methods avoid these problems by measuring effects along latent dimensions present in the data. To date, no direct comparisons of univariate and multivariate methods of PET data analysis have been conducted. We assessed the relative performance of univariate and multivariate techniques in the analysis of  $\text{H}_2^{15}\text{O}$  PET data from age-, sex-, and performance-matched medicated ( $N=10$ , haloperidol 0.4mg/kg/d) and unmedicated ( $N=10$ ) schizophrenic groups and normal controls ( $N=10$ ) during the Wisconsin Card Sort test. In particular we contrasted: 1) multivariate discriminant analysis vs. pixel-wise t-tests, for measuring differences between subject groups; and 2) canonical correlation vs. pixel-wise correlations, for assessing the within-group relationships between task and control conditions. Discriminant analysis offered an index of the overall difference between the groups ( $F=4.13$ ,  $p=0.006$ ), a measure not offered by the pixel wise omnibus map, and indicated two separate dimensions presumably due to diagnostic and possibly medication related effects. Pixel-wise comparisons indicated similar results, but required multiple contrasts of the groups to draw similar conclusions. Canonical correlation analysis between task and control conditions suggested strong overall associations with variations across groups (with correlations highest in the medicated patient group) which were not as evident via pixel-wise correlations. Overall, multivariate methods were more robust and succinct than univariate methods in describing statistical effects present in the data, which in these clinical groups suggested effects of diagnosis and drug treatment on rCBF.

## 474.6

**THE TEMPORAL/SPATIAL EVOLUTION OF OPTICAL SIGNALS IN HUMANS, A.F. Canestro\*, A.W. Toga, K.L. Black**, Lab. of Neuro Imaging, Division of Brain Mapping, Department of Neurology, UCLA School of Medicine, Los Angeles, CA. 90095.

Human somatosensory and motor cortex was mapped in response to peripheral stimulation using optical reflectance imaging. Informed consent was obtained from patients whose tumor resection neurosurgeries required parietal cortex exposure. Upon reflection of the dura evoked potentials (EP) and optical images were collected in response to median and ulnar nerve stimulation. Non-contact image data acquisition was demonstrated by monitoring and synchronizing to electrocardiographic and respiratory waveforms. The spatial extent of the optical response correlated topographically with the electrophysiologic response to peripheral transcutaneous nerve stimulations. Activated regions were observed in both precentral (motor) and postcentral (sensory) contralateral cortex. The evolution of the signal demonstrated a genesis at 1-2 s, a peak at 3 s, and a return to baseline by 9 s. The optical response differed spatially when median and ulnar nerves were stimulated separately. Ulnar stimulation produced a more posterior response in the postcentral gyrus in relation to median nerve stimulation. When both median and ulnar nerve simultaneous stimulation was performed a larger and more focal response appeared than either nerve alone. The simultaneous median and ulnar nerve stimulation produced an optical response greater than the arithmetically additive response of separate stimulations. EP mapping generated a similar pattern. These optical reflectance maps, overlaid by the EP mapping of human somatosensory and motor cortex correlates neuronal firing, vascular and metabolic function.

## 474.7

A STUDY OF HUMAN SENSORIMOTOR AREAS USING WHOLE BRAIN ISOTROPIC FUNCTIONAL MRI WITH 0.05 ML RESOLUTION. B.H. Sexton<sup>1</sup>, V.S. Mattay<sup>1</sup>, A.K.S. Santha<sup>1</sup>, K.A. Tallent<sup>1</sup>, A.C. McLaughlin<sup>1</sup>, J. Pekar<sup>2</sup>, J. Ostuni<sup>2</sup>, P. Jezzard<sup>3</sup>, E.C. Wong<sup>4</sup>, J.A. Frank<sup>2</sup>, and D.R. Weinberger<sup>1</sup>, <sup>1</sup>CBDB/NIMH, <sup>2</sup>LDRR/OIR, and <sup>3</sup>LCE/NHLBI, National Institutes of Health, Bethesda, MD 20892; <sup>4</sup>Depts. of Radiology and Psychiatry, Univ. of California at San Diego.

In an attempt to map in 3-D space the response of human brain sensorimotor areas to a simple motor task, we performed whole-brain blood oxygenation level dependent functional Magnetic Resonance Imaging at 1.5 T in five normal volunteers. Sagittal gradient-echo echo planar images of the whole brain with 3.75 mm isotropic voxels were acquired continuously while the subjects performed sequential tapping of the thumb and fingers of one hand followed by a resting period. Each active/rest period lasted for 33 seconds. A complete study consisted of eight such pairs of active/rest segments.

The threshold for determination of "activation" was set at p value of 0.05 (two-tailed), Bonferroni-corrected for the ~20,000 pixels in the brain, yielding a Z score of ~4.7. Using this criterion, all five subjects showed activation in ~1% of brain pixels located predominantly in the contralateral sensorimotor cortex and the supplementary motor areas. The average signal change in these activated pixels was ~4%. These results demonstrate the potential of whole brain fMRI with EPI at 1.5 T for robust investigational brain mapping.

## 474.9

INTERNAL CAROTID AND VERTEBRAL ARTERIAL BLOOD FLOW SIMULTANEOUSLY AND CONTINUOUSLY MEASURED BY ULTRASONIC DOPPLER FLOWMETRY IN ANESTHETIZED AND CONSCIOUS RABBITS Ying-Hui Yu\*, B-S Zhu and W.W. Blessing. Centre for Neuroscience, Flinders University, Bedford Park, SA 5042, Australia.

Ultrasonic Doppler flowmeters, implanted around the internal carotid and vertebral arteries were used to continuously measure cerebral blood flow (CBF) in the rabbit, both in anesthetized and in conscious animals. Flow in these arteries was compared with sagittal sinus flow, simultaneously measured. All three flows increased in the expected manner with increases in the concentration of CO<sub>2</sub> (up to 10%) in the inspired gas. There were linear relationships with high correlation (0.83 to 0.96 in six animals) between mean internal carotid flow and mean sagittal sinus flow. The sagittal sinus blood flow increased to 205±27% of baseline (n=6, P<0.01). At the same time internal carotid and vertebral arterial flows also increased (to 200±31% of baseline for internal carotid flow, n=6, P<0.01 and to 139±7% of baseline for vertebral flow, n=6, P<0.01). When animals were breathing normal air (conscious animals) or oxygen and halothane (anesthetized animals) arterial pCO<sub>2</sub> was 39±2 mmHg (n=6). When inspired CO<sub>2</sub> was increased to 9%, arterial pCO<sub>2</sub> was 54±2 mmHg (n=6). The relationship between internal carotid flow and inspired CO<sub>2</sub> was different in conscious and anesthetized rabbits. Vertebral and internal carotid angiography demonstrated the recording probes and the cerebral distribution of the vessels around which they were implanted. Measurement of cerebral arterial inflow by chronically implanted ultrasonic Doppler flowmeters is quite feasible, accurate, relatively non-invasive, and suited to repeated measurements in different experimental conditions, particularly in the conscious rabbit. The similarity in cerebrovascular arrangements between rabbits and humans means that the rabbit may become an important model for studies of the control of CBF relevant to humans.

## 474.11

DIFFUSION OF [3]H<sub>2</sub>O AND [14]C-PEG IN ISCHEMIC BRAIN SLICES. G.Newman, F.E.Hospod, C.S.Patlak, Depts. of Neurology and Surgery, SUNY at Stony Brook, NY, and Northport VAMC, NY.

Spectacular advances in imaging of molecular diffusion in humans by diffusion-weighted MRI are finding immediate application in stroke management. However, interpretation of the apparent diffusion coefficient (ADC) is complicated because it reflects diffusion in the extracellular space (ECS) and intracellularly, capillary blood flow and CSF flow. Brain slices provide an opportunity to study diffusion without blood or CSF. Our model of ischemia employs 1050µm hippocampal brain slices which share features of *in vivo* ischemia including histology, increased water, lactate and glucose utilization and reduced adenylylates.

Both influx and efflux of [14]C-PEG(4000) and [3]H<sub>2</sub>O were studied in 450µm or 1050µm hippocampal brain slices in Krebs-Ringer with 3% dextran for periods of 30 sec to 3 hours with about 60 slices per data set. Slice radioactivity and times were analyzed with kinetic models which explicitly include diffusion in ECS and one serial compartment, using non-linear least squares methods. [14]C-PEG experiments were used to determine the size of the ECS for the [3]H<sub>2</sub>O experiments. Diffusion coefficients (D<sub>c</sub>) and transport rate constants, with calculated intracellular space, were determined by the best least squares fit.

Thick slices show a large reduction in ECS to 0.16, from 0.25 in thin slices, along with marked intracellular swelling (cytotoxic edema). Surprisingly, the D<sub>c</sub> of both tracers increase in the thick slices, contrary to the observed decrease in ADC of water by MRI in stroke patients. We will discuss this seeming paradox in light of ongoing experiments but these results emphasize the complexity of events that underlie the MRI ADC measurements. Support: VA Merit Review and NIH NS28429.

## 474.8

FMRI DEMONSTRATES SUSTAINED BLOOD OXYGENATION AND FLOW ENHANCEMENT DURING EXTENDED DURATION VISUAL AND MOTOR CORTEX ACTIVATION. P.A. Bandettini\*, K.K. Kwong, T. L. Davis, A. Jiang, J. R. Baker, J. W. Belliveau, R. M. Weisskoff, and B. R. Rosen, Massachusetts General Hospital - NMR Center, Charlestown MA

Sustained blood flow and oxygenation elevation during extended cortical stimulation was demonstrated using T1-weighted (blood flow sensitive) and T2\*-weighted (blood oxygenation sensitive) echo-planar MRI. Seven subjects were studied. Flow sensitive (inversion recovery EPI: TI = 1000ms, TR = 3000ms, TE=20ms: spin-echo) and blood oxygenation sensitive (gradient-echo EPI: TR = 3000ms, TE = 40ms) time course series were obtained using a 1.5 T GE Signa scanner retrofitted with an ANMR resonant gradient system. Five subjects underwent 10 Hz full field black and white alternating checkerboard visual stimulation. Timing was: 1 min.off, 1 min.on, 1 min.off, 20 min.on, 1 min.off, 1 min.on, 1 min.off. Two subjects performed repetitive finger tapping for up to 20 minutes during T2\*-weighted image collection. Motion correction was also performed.

All subjects demonstrated sustained elevation of flow and oxygenation during the 20 minute stimulation period. A post-stimulation undershoot was observed with the T2\*-weighted sequence but not with the T1-weighted sequence. These studies demonstrate that flow and oxygenation elevation are *not* transient effects for these types of stimuli. Minimal neuronal habituation occurs and oxygen extraction does not sufficiently increase to cause a decrease, over time, in blood oxygenation sensitive MR signal. Ongoing studies of extended duration stimulation of visual cortex tissue known to have high cytochrome oxidase concentrations, "blobs", and therefore higher oxidative metabolism, are being performed to determine the sensitivity of the blood oxygenation-sensitive MR signal to differences in oxidative metabolic rate.

## 474.10

LAMINAR ANALYSIS OF CEREBELLAR BLOOD FLOW BY A LASER-DOPPLER COMBINATION PROBE. M. Fabricius\*, N. Akgören and M. Lauritzen. Dep. of Med. Physiology, Univ. of Copenhagen, DK-2200 Copenh., Denmark.

Laser-Doppler flowmetry (LDF) estimates relative changes of cerebral blood flow (CBF). The measurement depth depends on the wavelength of the laser light and on the separation between the transmitting and recording optic fiber of the LDF probe. We used a LDF combination probe (Perimed, Sweden) holding four combinations of wavelength and fiber separation to measure CBF in four different depths in the cerebellar cortex of halothane anesthetized rats. The cortex was exposed to local electrical stimulation, hypercapnia, and adenosine applied topically or injected 1 mm into the tissue through a glass microelectrode.

Local tetanic stimulation, mainly of the parallel fibers, increased CBF by 78 ± 8% in the upper layer corresponding to the superficial part of the molecular layer in which these fibers and their synaptic connections are located. The CBF increase declined at increasing depth of measurement to 59 ± 8%, 43 ± 7%, 23 ± 3% (P = 0.001, ANOVA test). Hypercapnia increased CBF by 102 ± 14% and 94 ± 11% in the middle depths, but only by 44 ± 10% in the upper layer and by 77 ± 8% in the largest depth (P = 0.002). Topical adenosine (1mM) increased CBF by 118 ± 20% in the upper layer, the values decreasing steadily to 52 ± 5 in the largest depth (P = 0.004). Injection of 100 nl of adenosine (20mM) increased CBF by 38 ± 7% in the largest depth, the values decreasing steadily to 20 ± 6% in the upper layer (P < 0.001).

We conclude that the LDF combination probe is valid for laminar analysis of CBF with a resolution in depth of 2-300 µm. Important differences of laminar CBF reactivity is seen during hypercapnia.

## 474.12

GENERALIZED THEORY FOR INTERPRETING MICRODIALYSIS

P.M. Bungay\*, Biomedical Engineering & Instrumentation Program, NCR/NH, Building 13/3N17, Bethesda, MD 20892-5766

Previous mathematical modeling of microdialysis has been directed primarily at interpretation of measurements obtained with low-molecular-weight, hydrophilic solutes. For such solutes, movement through tissue is assumed to occur predominantly by diffusion through the interstitial fluid. The steady-state and transient models have now been extended to treat lipophilic solutes by incorporating transcellular solute movement. When applied to microdialysis measurements in muscle and brain for the lipophilic solute, ethanol, the steady-state model indicates a significant transcellular contribution.

The revised models suggest that a useful measure for characterizing microdialysis is the ratio,  $H = P_l \cdot r_o / D_l$  in which  $P_l$  and  $D_l$  are the permeability and diffusivity for the solute in the tissue of interest. The ratio is made nondimensional by including the outer radius of the microdialysis probe,  $r_o$ . The magnitude of this ratio is an increasing function of the nondimensional clearance rate,  $\theta = r_o \sqrt{k_l / D_l}$ , where  $k_l$  is the rate constant characterizing clearance of the solute from the tissue interstitium. The radial distance,  $r_l$ , over which microdialysis disturbs tissue concentrations exhibits a strong inverse relationship to  $\theta$ . The dominance of the nondimensional clearance rate,  $\theta$ , signifies the important role played by local clearance processes in microdialysis behavior. The influence of a third parameter ratio,  $L_m / r_o$ , involving the probe membrane length,  $L_m$ , has not yet been incorporated. Its effects are generally neglected, since  $L_m$  is typically much larger than  $r_o$ . This assumption may be questionable, at least for slowly cleared solutes.

The applicability of the generalized theory will be illustrated for a wide range of hydrophilic and lipophilic solutes and interstitial clearance mechanisms: very rapid active cellular uptake of dopamine, rapid utilization of glucose, active efflux-to-blood of dopamine metabolites, passive efflux of ethanol and tritiated water and slowly effluxing extracellular markers, such as sucrose.

## 475.1

A FUNCTIONAL MRI (fMRI) STUDY OF CEREBELLUM DURING MOTOR AND WORKING MEMORY TASKS. J.E. Desmond\*, J.D.E. Gabrieli, B.L. Ginier, J.B. Demb, A.D. Wagner, D.R. Enzmann, and G.H. Glover. Depts. of Radiology and Psychology, Stanford University, Stanford, CA 94305.

Recent studies have suggested cerebellar contributions to cognition as well as to motor performance. We investigated cerebellar activation in human volunteers using fMRI during two tasks: (1) A motor task consisting of finger-to-thumb movements of the right hand, and (2) A working memory task (Sternberg, Science, 153:652, 1966) in which difficult and easy conditions were alternated. For the difficult condition, an array of 6 different letters was presented on a screen for 0.5 sec, followed by a 5.5 sec no-stimulus delay, followed by a single letter probe. Subjects responded using a squeeze ball if the probe matched one of the letters in the 6-letter array. For the easy condition, the 6 letters were all the same. Subjects received 4 cycles of easy/difficult for the memory task and movement/rest for the motor task over a 6 min scan. Brain images of the cerebellum were collected continuously from 2-4 slices oriented parallel to the brain stem using a T2\*-weighted gradient echo spiral sequence (1.5T, 5-10mm thick slices, TR=75 ms, TE=40 ms, flip angle=23). Preliminary results from 4 subjects revealed that the motor task mostly ipsilateral increases in activation in lobules HIV and HV. Ipsilateral or bilateral dentate activation also appeared to be present. To a lesser degree, mostly bilateral activation was observed in HVIII. For the working memory task, hemispheric increases in activation for the difficult condition were observed in two locations: (1) mostly on the right side of lobule HVI, extending in two cases to superior portions of HVIIA; (2) bilaterally in inferior HVIIA and HVIIIB. These results suggest that fMRI can be used to study cerebellar contributions to cognition. Supported by NIH (F32NS09628), Stanford Office of Technology and Licensing, and the Lucas Foundation.

## 475.3

PERFORMANCE OF CONTINGENT OPERATIONS AND SHORT TERM MEMORY FOR A STIMULUS ACTIVATE DIFFERENT PARTS OF THE PRE-FRONTAL CORTEX T. Klingberg, B.T. O'Sullivan, P.E. Roland\* Division of Human Brain Research, Department of Neuroscience, Karolinska Institute, 171 77 Stockholm, Sweden

The prefrontal cortex is known to be important for the performance of consecutive operations according to a plan. We investigated if the number of contingencies in an instruction effects the cortical activity. Ten human subjects performed three short-term memory tasks with delayed matching of coloured patterns. Two of the tasks contained instructions with additional contingencies of how to alternate between the matching of colours and patterns. Regional cerebral blood flow was measured with PET, during the three tests and one control situation which contained the same type of visual stimulation and motor responses as the tests.

All three short-term memory tasks had two cortical activations in common: one in the left intraparietal sulcus, and one in the left inferior frontal sulcus. Keeping a stimulus representation in short-term memory was apparently carried out through the co-activation of these two areas. In the two tasks with additional contingencies, the right middle frontal gyrus was also activated. This activity was interpreted as underlying the ability to perform contingent, consecutive operations.

## 475.5

INVESTIGATING WORKING MEMORY IN HUMANS AS INDEXED BY COGNITIVE EVOKED POTENTIALS. G. S. Robinson\*, Dept. of Psychology, Skidmore College, Saratoga Springs, NY 12866

The utility of cognitive evoked potentials to objectively study memory processes in humans is on the rise. Cognitive evoked potentials were recorded from 20 college students, while they performed three different conditions designed to activate working memory. Condition one was the letter "x" as the target letter, and the rest of the letters as non-targets. Condition two was a two letter word task, in which the target letter was the last letter of any two letter word. Condition three was a three letter word task, in which the target letter was the last letter of any three letter word. The letters were presented one at a time in the center of the screen. Thus, for the word conditions, the subjects had to hold the last one or two letters in working memory in order to identify a two or three letter word.

Activity recorded from Cz, Fz and Pz, indicated an increase in P300 latency,  $F(2, 28) = 58.21$ ,  $p < .01$ , with increasing working memory demands. The P300 amplitude generally decreased with increasing working memory demands. However, there was a significant interaction for amplitude and scalp location. Results suggest that cognitive evoked potentials are sensitive to changes in working memory processes. Further, amplitude scalp locations, suggest different neural arrays for different levels and demands of working memory processing.

## 475.2

WORKING MEMORY AND DECISION-MAKING ARE MEDIATED BY TWO SEPARATE SECTORS OF THE PREFRONTAL CORTEX. A. Bechara\*, D. Tranel, H. Damasio, S.W. Anderson and A.R. Damasio, Div. of Cognitive Neuroscience, Dept. of Neuro., Univ. of Iowa, Iowa City, IA 52242.

The prefrontal cortex has been implicated in the mediation of both working memory and decision-making. How related or distinct are the respective operations? Do they depend on separate anatomical substrates? To approach these questions, we compared the performances of normal controls and frontal lobe patients on two sets of behavioral tasks. One included modified delay tasks (delayed response; delayed non-matching to sample), which test experimentally the role of prefrontal cortex in working memory as studied in nonhuman primates. The other included "gambling" tasks which we recently designed to study the real-life decision-making deficits expressed by frontal lobe patients.

Five patients with bilateral damage to the ventromedial prefrontal cortex, but without damage to the basal forebrain, were severely impaired on the decision-making tasks, but not on the working memory tasks. (When the damage included the basal forebrain, patients (n=4) were impaired on both the decision-making and memory tasks). By contrast, four patients with damage to the right dorsolateral sector of the prefrontal cortex were severely impaired on the working memory tasks, but less so on the decision-making tasks. Four patients with dorsolateral lesions on the left were only mildly impaired on the working memory tasks. These results suggest: (1) A relative segregation of the neural structures supporting working memory (right dorsolateral sector) and decision-making (ventromedial sector). (2) A relative asymmetry in the cognitive deficits observed after damage to each sector. Decision-making defects can occur in the absence of working memory defects; however, working memory defects are usually accompanied by some compromise in decision-making.

Supported by NINDS P01 NS 19632 and JSMF.

## 475.4

A PET STUDY OF IMMEDIATE AND MEMORIZED VISUOMOTOR TRANSFORMATIONS. E. Lacquaniti\*, E. Guigon, D. Perani, V. Bettinardi, E. Fazio Istituto Scientifico S. Lucia, 00179 Rome, Italy; INSERM CREARE, UPMC, 75005 Paris, France; INB-CNR, 20131 Milan, Italy; Cattedra di Medicina Nucleare, Università di Milano, 20132 Milan, Italy.

Positron emission tomography was used to reveal the neural bases of visuomotor transformations in the human brain. Subjects ( $n = 8$ ) were instructed to fixate a small spot displayed on a screen in front of them, to detect the appearance of a peripheral target (every 5 s) and to perform a movement using a stylus on a horizontally oriented table. In a first condition (*direct*), the movement was performed toward the current target. In the second conditions (*memory*), the movement was toward the previous target. The results show that different networks are involved in *direct* and *memory* conditions. Common processing pathways involved the contralateral sensorimotor cortex, the contralateral inferior frontal gyrus, the vermis and the cerebellar hemispheres bilaterally, the right fusiform gyrus. The *direct* condition involved specifically a focus in the left precentral gyrus, in the left middle occipital gyrus. The *memory* condition activated specifically the contralateral supplementary motor area, the anterior thalamus, the cingulate cortex, the lingual gyrus, the calcarine sulcus and the hippocampus, bilaterally. The *memory* condition is a spatial short-term memory task and activates a network (hippocampus, anterior thalamus, cingulate) generally associated with long-term memory. In the *memory* condition, the subject must simultaneously execute the appropriate movement toward the position of the previous, memorized target, and memorize the current target as the goal of the next movement. The present results indicate that the neural substrat of long-term memory might be involved when sensorimotor encoding and decoding processes are in competition.

## 475.6

NEUROPHYSIOLOGY OF SEMANTIC CONCEPTS. S.L. Provençal, J.D. Lewine, E.C. Benzel\*, P.C. Amrhein, C. Edgar, and K. Paulson New Mexico Institute of Neuroimaging and the Department of Psychology, University of New Mexico, Albuquerque, NM

The neural mechanisms that support the formation of, and access to, equivalent semantic representations (e.g., picture of a dog and printed word "dog") are poorly understood, although the issue has been studied with vigor within the behavioral context, especially with regards to the visual and cognitive processing of pictures and written words. This study augments the traditional behavioral approach by analysis of simultaneously collected electrophysiological (EEG) data. Cross-modal associations between visual pictures and auditory words were examined using a simple match-to-sample task. Behavioral and EEG (32 channel scalp electrodes) data were recorded as subjects responded to the sameness-of-meaning for two sequentially presented stimuli. Probes (second stimulus) could either be the same or different as the target (first stimulus). Within mode and cross-mode interactions could thus be examined in regards to the extent in which the pattern of brain activity evoked by stimulus two was a function of stimulus one. Behavioral data suggests no significant within mode advantage, other than that believed to be due to sensory priming effects. This is consistent with the notion of a common processing pathway for within and cross conditions. EEG data demonstrates that modality specific processing cascades exist, with activation determined mostly by probe rather than target stimulus. The EEG also demonstrates early differences in evoked responses that are a function of the target stimulus. This implies modality specific memory representations, rather than an amodal representation. Although an architectural model is available to explain these findings, higher resolution spatial data may aid in a better understanding of certain components of the model, as may magnetoencephalographic recordings.

## 475.7

SEMANTIC RETRIEVAL: A STUDY OF REGIONAL CEREBRAL BLOOD FLOW IN NORMALS. H.P. Ham, M.F. D'Souza, W.W. Beatty\*, and J.R. Prince. University of Oklahoma Health Sciences Center, Oklahoma City, OK 73104.

Regional cerebral blood flow (rCBF) for semantic retrieval was examined in 10 healthy, right handed normals using a split-dose  $^{99m}\text{Tc}$ -HMPAO Single Photon Emission Computed Tomography (SPECT) protocol. Subjects underwent back-to-back baseline (resting) and activation (verbal fluency task) scans on a triple-headed rotating gamma camera system. Co-registration using individual MRI images ensured anatomical accuracy for isolating functional areas of interest. As hypothesized, the most significant hyperperfusion was noted in left pre-frontal cortex, however, high flow was also found in left temporal and inferior parietal cortices (respectively, Broca's area [Brodmann's 44, 45, and 46], Wernicke's area [Brodmann's 21, 22, 37], and inferior parietal lobule [Brodmann's 39, 40]). Interestingly, significant hyperperfusion was also noted in inferior visual association cortices (Brodmann's 18, 19) even though subjects had their eyes closed throughout the entire imaging procedure. rCBF was negatively correlated with verbal fluency in the left pre-frontal area ( $r = -.37$ ,  $p = .2$ ) and the left temporal area ( $r = -.65$ ,  $p < .05$ ). Thus, high fluency subjects exhibited no or very low activation during the semantic task, whereas low fluency subjects revealed higher activation. These results are consistent with PET findings that have found inverse relationships for glucose metabolism with semantic retrieval and intelligence. One hypothesis for this somewhat counter intuitive phenomenon is that the "more efficient" brain requires less effort for certain tasks and thus lower blood flow (or glucose) to the appropriate cortex. Another closely related hypothesis suggests that the pre-frontal cortex may initially be directly involved in learning semantic retrieval tasks, but as these tasks become over-learned and more stimulus driven, alternate pathways may perform the task and thus reduce the effort (i.e., activation) of the pre-frontal cortex. ## 475.9

TEMPORAL IMAGING OF EEG COHERENCE SHOWS DISTINCT REGIONAL CHANGES FOR STORAGE AND RECALL DURING A VERBAL WORKING MEMORY TASK. D. Lacroix\*, T. M. Dung Vo, R. Lamer and Y. Chaput. Département de Psychiatrie, Hôpital Notre-Dame, Université de Montréal, 1560 Sherbrooke E., Montréal, CANADA H2L 4M1.

Working memory is used when short-term storage of information is needed to execute a cognitive task. EEG coherence is a measure of the synchrony of amplitude variations between two electrical signals. It is computed between each electrode paired to all electrodes and detects localized or inter-regional brain changes during a cognitive activation task. EEGs were obtained from 10 right-handed healthy males at rest-eyes opened- and during the following twelve-second task: 1- to memorize four words that were read on a computer screen and 2- to recall if a fifth presented word was part of the previous four words. Subjects used a mouse to answer. The task was repeated 20 times. 19 electrodes were used according to the 10/20 system. Signals were referenced to averaged signals from both ear lobes (TC 0.3s, Filter 35 Hz). Coherence values were computed for each component of the task and compared to those of the resting EEG. Probability mapping showed that: 1- when memorizing words, changes of inter-regional coherence were centralized on left medial (T3) and posterior (T5) temporal electrodes paired with left prefrontal (F7, F3, Fp1) and right centro-parietal electrodes (P4, C4). 2- when recognizing a word, changes of inter-regional coherence were mostly centralized on the left medial temporal (T3) and the left lateral prefrontal (F7) electrodes paired between themselves and with other prefrontal sites, mostly on the left. These results show that, during a verbal working memory task, short-term storage of information involves distinctively the left posterior temporal region in contrast to the left prefrontal lateral region during recall.

## 475.11

THE ROLE OF THE RIGHT HIPPOCAMPAL REGION IN THE ENCODING AND RECALL OF OBJECT-LOCATION: A PET STUDY. A. M. Owen\*, B. Milner, M. Petrides and A. C. Evans. Montreal Neurological Institute, McGill University, Montreal, H3A 2B4, Canada.

A plethora of studies, across many species, have demonstrated that the hippocampal region plays a critical role in memory for spatial location. In the present study, the functional anatomy of object-location memory was investigated further using PET. Regional cerebral blood flow (rCBF) was measured while 12 normal volunteers encoded, and then recalled, the locations of eight familiar objects presented on a computer screen. In two analogous conditions, the subjects were required to encode, and then to recall, eight distinct locations represented by identical white boxes on the screen. An increase in rCBF was observed in the caudal part of the right medial temporal region when the encoding-location condition was subtracted from the encoding-object-location condition. An increase in rCBF was observed more anteriorly in the region of the right parahippocampal gyrus corresponding to entorhinal cortex when the recalling-location condition was subtracted from the recalling-object-location condition. In addition, the two encoding conditions activated left-hemisphere regions preferentially, whereas the two recall conditions activated right-hemisphere regions.

Together, these findings suggest that the human right hippocampal region is critically involved in recalling information that links object to place. The secondary finding, that encoding and retrieval appear to be lateralized to the left and right hemispheres respectively, is discussed with reference to current models of episodic memory (cf. Tulving et al, 1994), and alternative hypotheses are considered.

## 475.8

GAMMA-BAND ACTIVITY (30-60 Hz) INDUCED BY A VISUAL RECOGNITION TASK IN HUMAN. C. Tallon-Baudry, O. Bertrand, M.-H. Giard\* and J. Pernier. Brain signals and processes laboratory INSERM U280, 151 cours A. Thomas, 69003 Lyon, France.

Various 40 Hz or near 40 Hz synchronized activities have been described in cat, monkey and human. According to the different authors, they are thought to be implied in perception (feature binding, figure-ground separation), attention, and/or consciousness. Our study aimed at testing in human the hypothesis of a role of gamma-band activity in feature binding.

Our paradigm used the famous "dalmatian dog" picture. In a first recording session, the subjects were not aware of the presence of the dog. Before the second recording session, they were trained at perceiving it. Our hypothesis was that feature binding occurred only in the second recording session, when the subject had to bind together the blobs to perceive the dog, thus inducing a specific 40 Hz activity.

We recorded continuous EEG from 8 subjects. During the first recording session, subjects were shown a neutral stimulus (randomly displayed blobs), the dalmatian dog with its head turned rightward (unperceived as a dog), and a target stimulus (twirled blobs) they had to count. During the second recording session, they were shown the same neutral condition, the same dog (perceived as a dog after training) and had to count a target which was a dalmatian dog with its head turned leftward.

A time-frequency analysis of single trial responses shows a significant increase in the second recording session of a non phase-locked activity peaking at 250 ms, centered at 35 Hz. It must be underlined that this activity differs significantly from the first recording session for both neutral and dog stimuli (Quade signed rank test,  $p < 0.03$ , occipital and parietal electrodes). No such effect could be found on the low frequency (0-25 Hz) averaged response.

These results cannot be solely interpreted in terms of visual integration, as the neutral stimulus also induced a gamma-band activity in the second part of the experiment. They could also be interpreted in terms of both increased attention and activation of a mental representation of the dog.

## 475.10

ERPS DISSOCIATE ITEM AND SOURCE MEMORY. E.L. Wilding, and M.D. Rugg, (SPON: European Brain and Behaviour Society). Wellcome Brain Research Group, Sch. of Psychology, Univ. of St Andrews, UK.

In two recognition memory tests, each of which employed 16 subjects, event-related potentials (ERPs) were recorded at midline and lateral scalp sites. At study, subjects heard a series of single words, half spoken in a male and half spoken in a female voice. At test, subjects saw a series of single words, half of which had been heard at study. Subjects made initial old/new judgments (item judgment) and, for words judged old, indicated whether the word had previously been spoken by the male or the female voice (source judgment).

The ERPs to words correctly judged old were separated according to the accuracy of the source judgment. Comparison of these ERPs with those evoked by words correctly judged new revealed that both were more positive between 500 and 800 msec post-stimulus, whilst post-800 msec this was true only for the ERPs to correct source judgments. The scalp distributions of the ERPs to correct and incorrect source judgments did not differ over the 500-800 msec latency region. However, the scalp topography of the differences between the ERPs to correct source judgments and the ERPs to words correctly judged new differed over time. Between 500 and 800 msec the largest differences between these ERPs were at left parietal sites, whilst post-900 msec the largest differences were at right frontal sites. The findings are consistent with the idea that multiple neural circuits contribute to recognition memory.

## 475.12

AN ELECTROPHYSIOLOGICAL INVESTIGATION OF STRATEGIC INFLUENCES ON CONCRETENESS EFFECTS. W.C. West and P.J. Holcomb\*. Dept. of Psychology, Tufts Univ., Medford, MA 02155

A variety of studies have demonstrated a distinct processing advantage for words representing concrete concepts than words that represent abstract concepts. One theory used to explain these effects is Paivio's dual-coding model, which proposes that both word types are represented in a verbal system, but that concrete words also benefit from referential connections to an image based system. Evidence supporting the dual-code model comes from studies of acquired dyslexics who have relatively greater problems with abstract words. This has led to the speculation that there may be distinct cognitive and therefore neural systems for processing the two word types. The aim of the present study was to determine the influences of different processing strategies on concreteness effects manifested in both a behavioral measurement (reaction time) and in a physiological measurement [event-related potentials (ERPs)]. Three groups of 12 subjects performed a sentence verification task in which the final word of each sentence was either concrete or abstract. For each group the truthfulness judgement involved either 1) imagery, 2) a semantic decision which is not aided by imagery, or 3) surface level processing (letter search). Response times were found to increase in the order: surface, semantic, imagery. ERPs to concrete and abstract final words did not differ for the surface group. Waveforms were more negative to concrete than to abstract words in the region of the N400 component for both the semantic and imagery groups. This effect was evident at locations across the entire scalp for the semantic group but were restricted to anterior sites for the imagery group. These results suggest a role for imagery in language processing and support the dual-coding model of semantic representation. The anterior spatial distribution of the N400 in these tasks suggests the existence of multiple neural generators which may contribute to this component.

## 475.13

**IMPLICIT WORD PRIMING: A NEW METHODOLOGY TO CIRCUMVENT EXPLICIT MEMORY CONTAMINATION.**

H. Chertkow; J. Benhamou, S. Leblanc, M. Beauregard. Lady Davis Institute, Jewish General Hospital; Centre Hospitalier Côte-des-Neiges.

An extensive literature suggests that priming effects and explicit memory are mediated by separate mechanisms. Some authors, however, have suggested that priming effects may be seriously contaminated by covert explicit strategies, limiting our ability to analyze potentially separable memory mechanisms in aging and brain disease states. We have devised a new priming methodology to circumvent such contamination. Subjects were tested for implicit priming on a speeded category membership decision task carried out in two blocks. In each block, the subject first studied 10 category members, and was then tested on a set of 40 word stimuli. Of these, 10 were the previously studied category members, 10 were new category members (20 "yes" responses), and 20 were category non-members. List study conditions were manipulated in two experiments. In experiment 1, 14 normal undergraduate subjects were presented in each block with the 10 study words, each shown twice for a one second duration. In experiment 2, carried out with 20 other normal undergrad subjects, the identical stimuli were presented. This time, however, word presentation consisted of a brief duration (17 ms) pattern masked exposure of the word. Each word was presented 10 times in succession at this exposure duration. No subject could reliably report the words seen. In both experiments, and for both semantic categories, the reaction time for "yes" decisions to the primed words was significantly faster ( $p < .001$ ) than to the unprimed words (priming effect of 52 ms in exp. 1 and 62 ms in exp. 2). Furthermore, there was no significant difference in the magnitude of the priming effect between the two experiments. These experiments establish that word priming effects can occur even in the absence of explicit recognition or recall of presented material in normal individuals. Furthermore, no evidence for additional priming from "covert explicit strategies" was found in experiment 1. This methodology may allow better evaluation of intact and impaired memory mechanisms in individuals with brain damage.

## 475.15

**EVENT-RELATED POTENTIAL MEASURES OF PRIMING AND RECOGNITION AS A FUNCTION OF LAG. J.V. Patterson<sup>1</sup>, C. Sandman<sup>2</sup>, C. Cotman<sup>1,2</sup>, and W.E. Bunney, Jr.<sup>2\*</sup>** Departments of <sup>1</sup>Neurology, <sup>2</sup>Psychobiology, and <sup>3</sup>Psychiatry and Human Behavior, University of California, Irvine, CA 92717

Event-related potential (ERP) measures of priming and recognition were compared in 10 young controls. Three lists of words matched for word frequency and length were prepared for 3 conditions (priming, recognition, target detection). Each list was presented in the auditory modality (digitized speech of the experimenter) and contained the following: (1) 40 words repeated immediately (0 lag); (2) 40 words repeated after 5 intervening words (5 lag); (3) 16 words not repeated (fillers); and (4) 34 infrequent target words (numbers) not repeated. In the recognition condition, subjects pressed one of 2 reaction time (RT) buttons to indicate whether each word was a first ("new") or second ("old") presentation of a word in the list. In the priming condition, subjects made syllable judgements of each word and were not required to recognize the words as new or old. In a target detection condition, subjects pressed one RT button to infrequent numbers interspersed among the list of words. RTs were longer to new than to old words in both the priming and recognition conditions (ANOVA,  $p < .001$ ). RT differences between new and old words were larger at 0 lag than at 5 lag for both the priming and recognition conditions. RTs in the priming and recognition conditions were not significantly different. ERP differences between new and old words were observed for each of the 3 conditions in the region of N400 and the late positive component (300-600 msec) (t-test,  $p < .05$ ). N400 was attenuated to old compared to new words and the late positive component was earlier and larger. ERP differences between new and old words were larger for 0 lag than 5 lag, and for recognition compared to priming. The late positive component to repeated words was delayed for 5 compared to 0 lag. These results show that the ERP can reflect memory processes and may differentiate between implicit (e.g., priming) and explicit (e.g., recognition) memory tasks.

## 475.14

**INFERIOR TEMPORAL-OCCIPITAL AND HIPPOCAMPAL CONTRIBUTIONS TO WORD PRIMING AND RECOGNITION MEMORY. D. Swick\* & R.T. Knight.** Dept. of Neurology & Center for Neuroscience, UC Davis, VAMC, Martinez, CA 94553.

Posterior cerebral artery stroke patients with unilateral damage to posterior hippocampus and adjacent inferior temporal and occipital structures can exhibit anterograde memory disturbances (Von Cramon et al., 1988). A case study has suggested that right occipital cortex is critical for word repetition priming (Gabrieli et al., 1995). Similarly, a PET study of young controls during word stem completion priming found decreased blood flow in right occipital cortex, centered in the region of the lingual gyrus (Squire et al., 1992). In the present experiment, electrophysiological (ERP) and behavioral data were recorded from age-matched controls and 3 patients with damage in right parahippocampal and lingual gyri, with variable extent into posterior hippocampus (n=2) and striate/extrastriate cortex (n=2). Words and pronounceable nonwords repeated after one of 3 delays: immediate (lag 0), 1-3 intervening items (lag 1-3), and lag 9-19. In separate sessions, subjects performed lexical decision (LD) or recognition memory (RM) tasks. Analysis of reaction time (RT) data from LD revealed a lag X group interaction ( $p < .01$ ). The patients failed to show significant RT priming at lag 1-3 and lag 9-19, but immediate priming was intact. Likewise, the late positive ERP component related to stimulus repetition was diminished at all scalp sites, implying the loss of a neural generator associated with priming. In RM, behavioral accuracy did not differ between groups ( $p > .2$ ), with only one of 3 patients showing a verbal memory deficit. The ERP repetition effect appeared reduced at posterior electrodes in this task as well, but to a lesser extent than in LD. These results demonstrate the importance of right inferior temporal-occipital cortex to behavioral and ERP measures of word priming.

## 476.1

**HUMAN PREFRONTAL CORTEX GATES DISTRACTING SENSORY INPUT**

L.L. Chao\* and R.T. Knight. Department of Neurology & Center for Neuroscience, U.C. Davis, VAMC, 150 Muir Road, Martinez, CA 94553-4685.

Jacobsen's (1935) seminal observation that monkeys with bilateral frontal lesions involving the sulcus principalis were impaired at delayed discrimination tasks was initially interpreted as a memory deficit. However, subsequent work by Malmö (1949) indicated that prefrontal monkeys were unable to gate irrelevant sensory information, which decremented their ability to maintain information in working memory over delay intervals. This finding supported an attentional deficit in the frontal monkeys. Experimental research has shown that humans with prefrontal lesions perform poorly on neuropsychological tests that require response inhibition; however, few studies have examined whether this inhibitory deficit extends to control of irrelevant sensory information. The present study examined the role of human dorsolateral prefrontal cortex, hippocampal region, and temporal-parietal junction in the gating of irrelevant auditory stimuli during an auditory working memory task.

Stroke patients with unilateral lesions located in either the dorsolateral prefrontal cortex, the temporal-parietal junction, or the posterior hippocampus and control subjects were tested on a task requiring short-term retention of environmental sounds. Subjects had to indicate whether initial presentation and subsequent test sounds were identical in two conditions. The initial and test sounds were separated by either a silent period varying from 4 to 12.6 seconds (no-distractor condition) or by a series of irrelevant tones (distractor condition). Prefrontal patients were significantly impaired by distractors at all delays, hippocampal patients were impaired only at longer delays, while temporal-parietal patients performed comparably to controls. The findings suggest that dorsolateral prefrontal cortex is crucial for gating of distracting information. Loss of this capacity may contribute to deficits in working memory observed after prefrontal damage. Supported by NIMH fellowship 1 F31 MH10958-01 and NINDS grant NS21135.

## 476.2

**PERFORMANCE OF PATIENTS WITH DORSOLATERAL FRONTAL LESIONS ON AN OLFACTORY IDENTIFICATION TASK. J. Baldo\* and A. Shimamura.** Psych. Dept., Univ. of California, Berkeley, CA 94720.

Studies of neurological patients have shown that lesions of the orbitofrontal and anterior temporal regions disrupt performance on olfactory discrimination tasks. Although such olfaction studies have not implicated more dorsal regions of prefrontal cortex, patients with lesions in this area are impaired on certain types of memory paradigms, such as free recall. The present study was undertaken to determine whether patients with unilateral dorsolateral prefrontal lesions would show deficits on a recall manipulation of a standardized olfactory, "scratch and sniff" test, the University of Pennsylvania Smell Identification Test (UPSIT). For each item, patients with dorsolateral prefrontal lesions and controls first attempted to name the odorant from memory (recall). This was followed by the four-alternative forced choice procedure (recognition). Subjects smelled 20 odors monorhinally and 20 odors with both nostrils. In the monorhinal condition, patients sniffed using the nostril associated with their lesioned hemisphere. It has been suggested that patients with dorsolateral frontal lesions are impaired at verbal recall and retrieval from remote memory due to decreased use of memory strategies and organization; they are generally less impaired on recognition tasks. Thus, we hypothesized that the patients would show deficits only on the recall portion of the experiment. Instead, we found that patients were impaired on both recall and recognition when they sniffed monorhinally, but not when they used both nostrils. These findings indicate olfactory memory impairment in patients with dorsolateral frontal lesions.

## 476.3

**THE PREFRONTAL INFERIOR CONVEXITY (IFC): INVOLVEMENT IN CATEGORICAL VS. SENSORY PROCESSING**  
 F.A.W. Wilson\*, S.P. O'Scalade & P.S. Goldman-Rakic. Neurobiology, Yale University Medical School, New Haven, CT 06510

In rhesus monkeys, gaze duration is greater for faces and objects than for color fields (Wilson & Goldman-Rakic, *Behav Br Res* 60). In order to examine the role of the frontal lobe in these behaviors, we compared the responses of 155 IFC stimulus-selective neurons to presentations of faces, objects and monochromatic color fields (CF). Each neuron was tested with sets of: 5 objects, 1 face and 1 CF (40 sets, 280 stimuli). Each stimulus was placed in 1 of 3 categories: faces, CF's, and objects.

IFC neurons responded selectively. For each neuron, the stimuli eliciting the maximal and minimal response were determined. Assuming that neuronal selectivity was based on arbitrary stimulus attributes, one would expect the face and CF categories to recruit approximately 22 neurons (155/7) for maximal and minimal responses. This assumption was clearly wrong: faces elicited maximal responses in 40 IFC neurons, almost double the incidence of other categories. Moreover, in 16 of 40 neurons with maximal responses to faces, the minimal response was to colour fields; this incidence was twice as great as found for any other stimulus category. One possible implication of these data is that the firing rate of IFC neurons reflects the degree to which a stimulus can be categorised. In contrast, the 8 neurons with maximal responses to color fields had minimal responses to faces, an incidence twice as large as for any other stimulus category. This second finding is consistent with separate mechanisms for color and face processing in prefrontal cortex.

## 476.5

**THE INTERFERENCE EFFECT OF TEMPORAL PROXIMITY CONTRIBUTES TO THE FRONTAL RESPONSE SEQUENCE DEFICIT**  
 Martin Lepage & François Richer. Labo. Neuroscience Cognition, Université du Québec, Montréal, QC, H3C-3P8.

Patients with frontal lesions have long been known to fail in the execution of response sequences while individual responses pose little problem. Among the many factors that could contribute to the sequencing deficit is the well-documented interference caused by the temporal proximity of responses, which may be increased in frontals. One test of the magnitude of this interference is the acceleration of sequential responses by stimulus preview which measures how much processes can be squeezed together or overlapped by making stimuli available in advance. We compared 9 patients with a frontal excision to 9 patients with a temporal excision and 9 controls in a task requiring rapid keypress responses to each of five letters in a sequence. The letters (A,B, or C) were randomly presented at adjacent positions on a computer screen and were mapped to three adjacent keys. In the no-preview condition, the five letters were presented one at a time, immediately following the previous response. In the full-preview condition, the five letters were presented simultaneously. Subjects were tested in 10 practice trials and 60 experimental trials in each condition. Frontals had slower response times than the other groups. In normals and temporals, stimulus preview produced the expected slowing of the first response and the acceleration of the next four responses in the series. In frontals, however, preview did not increase response speed and the slowing of the first response was exacerbated. The absence of facilitation by preview indicates that frontals show increased interference of adjacent responses which suggests a longer decision interval.

## 476.7

**SPATIAL REASONING AND PROBLEM-SOLVING IN THE RHESUS MONKEY.** E. Procyk and J-P. Joseph\*. INSERM U94, 16 av. Doyen Lepine, 69500 BRON, FRANCE.

A large body of experimental data indicates that Rhesus monkeys (*macaca mulatta*) can perform complex spatial tasks. They are able, for instance, to memorize the order of illumination of 3 fixed spatial targets and, after a delay, to press them in the same order. This task entails complex neural processes such as the capacity to integrate the spatio-temporal information given by the environment (the order of the targets) into a spatial plan.

The present report analyses the behavioural data obtained in two rhesus monkeys in a problem-solving situation derived from the spatial task described above. The task consisted in finding, by trial and error, the order (that the animal ignores) of touching 2 or 3 targets in a set of 3 or 4 fixed spatial targets. Whenever an order has been discovered and practised several times, a signal was sent to the animal indicating that a new order had to be discovered in the same set of targets.

The data show that monkeys are capable of conducting a methodic research of the hidden order and of finding the solution in a minimal number of trials. When the first target is found, it is kept in ongoing trials until the second target is found and so on, until the whole sequence is discovered. This optimal research seems to be guided by an integration of the location and rank of the successful and erroneous target-touches, i.e. by manipulations of internal representations of the environment.

It is concluded that the monkey brain is able, in a spatial problem solving task of this type, to construct complex cognitive structures which mimic a spatial reasoning. This reasoning is logic in as much as it reflects the logic of action ("get the reward as fast as possible"). It has a direct relationship with practical (success) or pre-symbolic intelligence.

## 476.4

**HUMAN REASONING AND THE FRONTAL CORTEX.** R. Adolphs\*, A.R. Damasio. Div. of Cognitive Neuroscience, Dept. of Neurology, Univ. of Iowa Coll. of Medicine, Iowa City, IA52242.

We have previously reported evidence that the human prefrontal cortex, especially its ventromedial sector (VMFC) appears necessary to re-create somatic states and associated feelings in response to stimuli that have had personal significance in prior experience. Those findings support a theoretical framework in which human reasoning, via the VMFC, can draw upon the outcomes of previous experience, by enacting "somatic states" that were engaged on those prior occasions (A.R. Damasio, *Descartes' Error*, New York: Putnam, 1994). The present study aims to test these ideas further by examining the performance of brain-damaged subjects on a conditional reasoning task, the Wason selection task. This task requires subjects to test the truth of a conditional ("If A then B") on the basis of the four possible conditions (A, not-A, B, not-B). Studies with normal subjects have revealed that (1) they often incorrectly choose A&B as the relevant conditions on abstract tasks, and (2) they often correctly choose A&not-B on certain concrete tasks. We found that patients with brain lesions outside of the VMFC (n=22) performed similarly to normal subjects. However, subjects with lesions to the VMFC (n=6) made significantly more errors on concrete, familiar conditionals (p<0.01, Fisher's exact test), while performing similarly to controls on abstract and unfamiliar conditionals. While correct choices on the task are facilitated for control subjects when the subject matter is familiar, no such facilitation is seen for subjects with VMFC lesions (their reasoning on unfamiliar and familiar subject matter are equivalent). These results show that the VMFC is important in relating the choices that can be made in reasoning to their real-life contingencies. We suggest that successful reasoning in real life requires the feelings (hunches, intuitions, gut-feelings) evoked by past experiences.

## 476.6

**FRONTAL LESIONS INCREASE THE PSYCHOLOGICAL REFRACTORY PERIOD IN HUMANS.** M.J. Chouinard\* & F. Richer. Hôpital Notre-Dame, Université du Québec, Montréal.

Simple decisions interfere with each other when executed in close sequence. This interference appears to be mainly due to a basic temporal limitation in systems involved in response selection known as the psychological refractory period (PRP). From evidence of response selection difficulties in patients with frontal lesions (Décary & Richer, 1993), we hypothesized that frontal lesions would be associated with longer response selection times which would produce an additive increase in the PRP. We compared 8 patients with a unilateral frontal excision to 8 patients with a temporal excision and 8 controls in a double decision task using visual stimuli. In each trial, a letter (A or B) was followed by a number (1 or 2) separated by either 55, 300 or 600 ms. After the number, the S made two rapid, grouped keypress responses (A or 1 = left, B or 2 = right). The PRP effect can be observed as increase in the response time of the second decision (RT2) with shorter delays. Compared to temporals and normals, frontals showed an increase (RT2) that was constant for all inter-stimulus delays. The data indicate that the interference between adjacent decisions is more durable in frontals, which agrees with an increased duration of response selection processes. The basic problem could contribute to a number of behavioral deficits of frontals such as those observed in sequential responses, categorization, and general behavioral planning.

## 476.8

**NEURONAL ACTIVITIES IN THE ORBITOFRONTAL CORTEX OF MONKEYS INVOLVED IN PERFORMING A VISUAL COGNITIVE BEHAVIOR.** K. Matsumoto, K. Nakamura, A. Mikami\* and K. Kubota. Dept. of behavioral and Brain Sciences, Primate Research Inst., Kyoto Univ., Inuyama, Aichi 484, Japan.

To determine the role of the monkey orbitofrontal cortex (OFC) in visual cognitive behavior, the activity of single neurons were recorded from the OFC while the monkeys (N=3) were performing a visual recognition memory task, with or without eye fixation, as employed in previous studies of the temporal cortices done in our laboratory (Nakamura *et al.*, 1994; Mikami *et al.*, 1994). In the task, a photograph (a human face, a monkey, food and non-food objects) was presented repeatedly 1 to 4 times as a sample stimulus (S) on a TV monitor with a 2 s interstimulus delay period, then another photograph was presented as a response stimulus (R). The monkeys memorized the S and discriminated it from the R by a non-matching rule. When the monkeys responded correctly to the R by releasing a holding lever, a drop of water was delivered to the mouth as a reward. In total, 161 neurons responded to the S. The stimulus selectivity of half of the neurons was lower than those in the temporal cortices, and the selectivity of the remainder were as high as those in the temporal cortices. The activity of 13% of the neurons (21/161) responding to S also changed during the delay period. In 38% of these, (8/21), the activity during the delay period gradually increased toward the end of the period. The activity of the remainder was similar to that of the neurons in the temporal cortices. Seventy-one percent of the neurons (114/161) responding to S also responded to R. When the same stimulus as S was presented as R, 18% (3/17) responded strongly and the peak of the responses was near the time of the lever release. Thirteen percent of the neurons (21/161) responding to S also responded to the reward. These neurons responded to a delivery of water while the monkeys were not performing the overtrained task. We also tested the responsiveness of the neurons responding to S, to the same stimulus as S in a task in which the monkeys were required to detect change of orientation of a fixation point. Both the responsiveness and the selectivity of the neurons to the stimulus were dramatically lowered. These behavior-related OFC neurons were different from the temporal neurons. These results suggest that the monkey OFC is involved in employing visual information to prepare for the upcoming behavior and in receiving information from the result of the behavior.

## 476.9

**CONSISTENCY AND SPECIFICITY OF ACQUIRED SOCIAL AND EMOTIONAL DEFECTS FOLLOWING VENTROMEDIAL FRONTAL LOBE DAMAGE.** S.W. Anderson,\* D. Tranel, H. Damasio, & A.R. Damasio. Dept. of Neurology, Univ. of Iowa, Iowa City, IA 52242.

Several case studies have documented striking impairments in social behavior and emotion following damage centered in orbital and mesial sectors of the human frontal lobes (ventromedial frontal lobe or VMFL), but no study to date has examined the consistency of this behavioral profile in a group of subjects with VMFL damage. Here, the intersubject reliability and consistency of a circumscribed defect in the realm of social and emotional functions were examined in a group of 13 subjects with focal VMFL lesions, and in 2 control groups, one with dorsolateral frontal lesions (DLFL; N=15) and one with posterior, nonfrontal lesions (NF; N=15). All subjects had normal developmental histories and focal lesions acquired in adulthood due to stroke or resection of a benign tumor. They were studied with standardized neuropsychological and neuroimaging protocols at least 2 years following lesion onset. We examined social behavior and emotion, intellect, attention and working memory, anterograde memory, visual perception and visual construction, and executive functions. We found that: (1) all 13 VMFL subjects had major impairments of social behavior, accompanied by emotional alterations (primarily blunting) and defects in decision-making and behavioral organization, in the context of otherwise well preserved cognitive abilities; (2) subjects in the control groups had generally normal social and emotional profiles despite significant and varied cognitive impairments. These findings indicate that the behavioral profile associated with human VMFL damage is highly consistent across subjects, and support further the hypothesis that this region is a critical component of the neural system which supports social and emotional behavior. (Supported by NINDS P01 NS19632).

### LEARNING AND MEMORY: SYSTEMS AND FUNCTIONS III

## 477.1

**LAMINAR ORGANIZATION OF THE RAT SUBICULUM.** N. Ishizuka\*. Dept. Cell Biol., Tokyo Metropol. Inst. for Neurosci., Fuchu, Tokyo 183, Japan.

The distribution of subcortically projecting subicular neurons was investigated with a retrograde labeling technique in the rat. Under chloral hydrate anesthesia, WGA-HRP was injected into the anterior thalamic nuclei (ATH), the nucleus accumbens (ACB), and the medial mammillary body (MB). To facilitate a cytoarchitectonic analysis of the hippocampal region, frozen sections were cut serially at perpendicular to the long axis of the extended hippocampus. This transverse plane revealed that subiculum coexisted with Ammon's horn (CA) and the dentate gyrus (DG) along the whole extent of long axis.

At all septotemporal levels, neurons projecting to the ATH (ATH cells), MB (MB cells), and ACB (ACB cells) were labeled in the pyramidal cell layer of the subiculum. However, few neurons of CA and DG were labeled in any cases of the present study. Arrangement of ATH, MB and ACB cells changed along the long axis. At the level of a septal quarter, each group of labeled neurons was organized in lamina parallel to the pial surface, i.e., ACB cells were located in the most superficial portion, MB cells were distributed in the upper two-thirds of the layer, and ATH cells were situated in the deepest portion. This laminar arrangement of the subicular neurons is quite similar to that of subcortically descending neurons in laminae V-VI of other cortices. At the more temporal levels, where gyrification of the hippocampal formation well developed, the vertical arrangement of the laminae gradually changed to the oblique arrangement: ACB cells were confined to the transitional part with CA1 sector and some of them penetrated beneath the CA1 pyramidal cell layer, while ATH cells were gradually accumulated in the distal portion of the subiculum and the adjacent lamina principalis interna of the presubiculum. MB cells were still located in between ACB and ATH cells in both vertical and proximodistal axis of the subiculum. It was suggested that the inrolling of hippocampus caused a slide of laminae in the subiculum, resulting a modification in cellular arrangement from vertical to oblique. Taken together, it was also suggested that the subiculum corresponds to the infragranular layer, while CA and DG are rather comparable to the supragranular layer of the cortex.

## 477.3

**CHOLINERGIC MODULATION MAY ALLOW COMBINATION OF SELF-ORGANIZING FEEDFORWARD CONNECTIONS AND ASSOCIATIVE FEEDBACK CONNECTIONS IN PIRIFORM CORTEX AND NEOCORTEX.**

R.E. Bergman\*, M. Cekic and M.E. Hasselmo. Department of Psychology and Program in Neuroscience, Harvard Univ. Cambridge MA 02138.

Different models of piriform cortex focus on either the competitive self-organization of lateral olfactory tract (LOT) synapses (Ambros-Ingerson et al., Science 247: 1344-1348, 1990) or on the associative memory function of excitatory intrinsic synapses (Hasselmo et al., J. Neurophysiol. 67: 1230-1246, 1992). Here we show that these functions can be combined, as long as cholinergic suppression of intrinsic synaptic transmission prevents associative recall during learning. A model with mean firing rate representations of pyramidal cells and inhibitory interneurons could store multiple different patterns as fixed point attractors without modification of afferent input. However, capacity was limited by interference between different overlapping patterns. With modifiable LOT synapses, self-organization decreased the overlap between stored input patterns, increasing capacity. This effect was also studied in a biophysical simulation of the piriform cortex developed using the GENESIS program (Barkai and Hasselmo, J. Neurophysiol. 72: 644-658, 1994).

In the neocortex, cholinergic modulation could allow self-organization of afferent and feedforward synapses terminating in layer IV to be combined with associative memory function of feedback synapses terminating in layer I. This would require selective suppression of synaptic transmission in layer I but not layer IV. In brain slice preparations of rat somatosensory cortex, we tested the amount of suppression of synaptic potentials recorded extracellularly in layer I or layer IV. Layer I synaptic potentials showed suppression during perfusion of 100  $\mu$ M carbachol (37.8% suppression, n=8), while layer IV synaptic potentials showed slight enhancement with 100  $\mu$ M carbachol (7.8% enhancement, n=5). This supports the theory that cholinergic modulation allows combination of self-organization and associative memory function in the neocortex. Supported by ONR N00014-93-1-595 and NIMH R29 MH52732-01.

**HIPPOCAMPAL LESIONS AND ACQUISITION OF A 5-CHOICE SELECTIVE ATTENTION TASK.** Bratt, A.M.\*, Stacey, K., Chase, R.M., Mittleman, G. Dept. Psychology, The University of Memphis, Memphis, TN 38152.

Neuropathological structural changes have been found in the brains of schizophrenics (Shapiro, 1993; *Schizophrenia Res.* 10: 187-239), with the hippocampus being particularly affected. It is thought that such developmental brain abnormalities may play an aetiological role in the progression of this complex disease. One of the behavioural deficits typically shown by schizophrenics is an impairment in selective attention (Mesulam & Geshwind, 1978; *J. Psychiat. Res.* 14: 249-259). Therefore, this experiment investigated the effects of lesions of subfields of the hippocampus on the acquisition of a task of selective attention (5-choice serial reaction time task, (Carli et al., 1983; *Behav. Brain Res.* 9:361-380) in the rat. Male Long-Evans rats received either total hippocampal ablations using multi-site bilateral intra-cerebral micro-injections of ibotenic acid, (Jarrard, 1993; *Behav. Brain Res.* 60:9-26), ibotenate lesions of the subiculum or dentate gyrus, electrolytic lesions of the fimbria-fornix or sham lesions. Rats were trained to discriminate a light stimulus randomly presented in 1 of 5 locations and to nose poke into the light to receive a food reward. Daily 30 min training sessions comprised a total of 100 trials in 4 x 25 trial blocks. Rats passed progressively through 5 individual test stages, upon attaining 75% correct responses at each stage, and the attentional demands of the task were incrementally increased. The task difficulty was elevated by altering the parameters from standard (stimulus duration [SD] 30s; inter-trial interval [ITI] 60s) to a criterion level of >75% correct; (SD 1s, ITI 10s). Preliminary data indicate that rats having total hippocampal and subiculum lesions required significantly more trials to reach criterion at the final test stage than sham controls, suggesting the presence of attentional deficits. These data may provide evidence for the role of the hippocampus in processes of selective attention in the rat.

## 477.4

**POLYSYNAPTIC POTENTIATION IN THE DENTATE GYRUS INDUCED BY LEARNING AND MEMORY OF AN OLFACTORY ASSOCIATIVE TASK.** F.A. Chaillan, E. Marchetti-Gauthier\*, F.S. Roman and B. Soumireu-Mourat. Lab. de Neurobiologie des Comportements, URA-CNRS 372, IBHOP, 13388 Marseille cedex 13, FRANCE.

Previous work showed that electrical high frequency stimulations applied to the lateral olfactory tract can be used as an artificial olfactory cue (olfacto-mimetic stimulations, OMS) in an olfactory discriminative task. Likewise a progressive long-term potentiation phenomenon was also induced in piriform (olfactory) cortex while rats were learning the meaning of these OMS (Roman et al., 1993). Electrophysiological recordings were used to study the dynamic of dentate gyrus (DG) involvement in learning and memory in an olfactory associative task. A first group of animals (OMS-group) was trained in discriminating a natural odor versus an OMS. A second group of pseudoconditioned animals was used to check that OMSs have no effect without a learning context. During the learning sessions, behavioral performances were gradually improved. The electrophysiological recordings, before and after each learning session, revealed the development and the potentiation of a long latency polysynaptic evoked potential in the DG. The changes of the electrical activity recorded in the DG were correlated to the performances only in the first learning sessions. The polysynaptic potentials evoked by a control electrode (which served only to deliver single test pulses) remained unchanged. No significant variation of the electrophysiological recordings was obtained in pseudoconditioned animals. The long onset latency of the potentiated polysynaptic response obtained in the DG suggests that its reactivation is mediated by a hippocampal loop via the entorhinal cortex. The fast development of the polysynaptic evoked potential observed in the sessions is consistent with an early involvement of the hippocampus during the learning. This early activation could induce long lasting changes in a specific neuronal network of the piriform cortex, which themselves could be one of the neurobiological substrates of the memorized information.

## 477.5

PROACTIVE INTERFERENCE AND SHORT-TERM MEMORY DURING PERFORMANCE OF A DNMS TASK IN NORMAL RATS AND RATS WITH HIPPOCAMPUS REMOVED  
Robert E. Hampson\*, Douglas R. Byrd, Joanne K. Konstantopoulos, Terence Bunn, Leonard E. Jarrard and Sam A. Deadwyler. Dept. of Physiology & Pharmacology, and Neuroscience Program, Bowman Gray School of Medicine, Winston-Salem, NC and Dept. of Psychology, Washington and Lee Univ., Lexington, VA.

Neural ensemble activity recorded from the hippocampus of rats performing a spatial Delayed-Nonmatch-to-Sample (DNMS) task has been shown to encode information specific to cognitive features of the task (Hampson *et al.* Soc. Neurosci. Abstr. 20:430, 1994). Recent studies with neurotoxic lesions confirm that this task is hippocampal dependent. Population analyses of hippocampal ensemble firing have identified two sources of errors in the DNMS task: 1) "Misencoding" of the sample response (lever position) by the ensemble, and 2) "Weakly encoded" sample information that decays at longer delays. Unlike the second source of errors, misencoding was not delay-dependent, and occurred consistently across all delays. The source of misencoding was likely proactive interference from the previous trial. Analyses were performed in normal rats ( $n=30$ ) and rats with confirmed ibotenate removal of the entire hippocampus ( $n=12$ ), to assess hippocampal involvement in trial-to-trial responding.

Trials were sorted on the basis of the same or different preceding trials and preceding trial delay. There was no proactive interference if the delay on the preceding trial was <10 sec. however there was a 5-20% decrement in correct responding if the preceding trial delay was >10 sec. When trials were the same, preceding delays of >10sec were slightly facilitatory. Similar analyses showed proactive interference in rats with hippocampal lesions, but it was not delay related. In these instances it was likely that other response strategies (i.e. maximizing on one lever) at longer delays, was the most prominent behavior exhibited by lesioned rats.

The DNMS task thus demonstrates serial memory (Hampson and Deadwyler 1990). It is likely that delay dependent hippocampal deficits result from increased interference of the previous trial, on the normal encoding by the hippocampus during sample phase of the current trial. When this fails to occur, as indicated by ensemble recording, normal animals respond like animals without a hippocampus.

## 477.7

EFFECTS OF SELECTIVE LESIONS ON CA3 AND DENTATE GYRUS UPON WORKING MEMORY OF RATS.  
O.F.A. Bueno\*, M. Costa, G.F. Xavier and M.G.M. Oliveira. Department of Psychobiology, Universidade Federal de São Paulo, São Paulo, SP, Brasil 04023-062

Although the hippocampus has been associated for some time with working memory process in rodents, less is known about the role of the hippocampal sub-areas. In the present study, we investigated the actions of colchicine-induced lesion on the dentate gyrus (DG), and kainic acid lesions on CA3 sub-area of the hippocampus on retention of Wistar rats pretrained to perform a win-shift task on an elevated T-maze. The task consisted of a series of two-run trials, the first one forced (information trial - I), and the other with free choice (C). The animals that reacquired criterion after the surgery were also tested after several delay intervals interposed between the I and C trials of the task. DG lesion initially disrupted performance in comparison to controls, but not the number of sessions required to reacquire criterion; an impairment was also seen in the delay tests with all intervals. CA3 lesion also disrupted performance, but in a more permanent way, since most of the CA3-lesioned rats did not reacquire criterion. It is suggested that CA3 and DG have different functions in mediating working-memory. Financial support: AFIP, CNPq, CAPES.

## 477.9

MEMORY IMPAIRMENT INDUCED BY LESIONS OF DOPAMINERGIC MESO-HIPPOCAMPAL PATHWAYS IN THE RAT. A. Gasbarri\*, A. Sulli, R. Innocenzi, C. Pacitti and J.D. Biondi. Department of Science and Biomedical Technology, Lab. of Human Physiology, University of L'Aquila, 67100 L'Aquila, Italy and <sup>2</sup> Neuroscience Research (D47W), Abbott Laboratories, Abbott Park, IL, 60064-3500.

The hippocampal formation (HF) has long been thought to play a role in learning and memory. Previous studies from our laboratory examined the organization of mesencephalic projections towards the HF in the rat. In order to evaluate the effects on learning and memory of retrograde selective lesions of mesencephalic dopaminergic neurons, following bilateral injection of 6-hydroxydopamine (6-OHDA) in dorsal and ventral subiculum and adjacent CA1 field of HF, young adult Sprague-Dawley rats were trained in: a) the classical inhibitory (passive) avoidance (IA), b) IA using a multiple-trial (training to criterion) and c) standard Morris water maze task (MWM), cued and spatial version. Concerning IA, retention was examined 1, 3, and 10 days after training. Concerning MWM task, 6-OHDA lesioned and sham-operated rats received 4 training trials on each of 4 days. After training sessions, the rats were tested during a 60s probe trial (free-swim trial) in which the platform is removed from the maze. During the free-swim we recorded: a) the time to cross the original platform position (latency); b) the time spent in the target quadrant (quadrant time), c) the number of crossings over the original platform position (platform crossings). After behavioral tests, the loss of mesencephalic dopaminergic neurons in the 6-OHDA lesioned rats, compared to sham-operated rats, was verified by tyrosine hydroxylase immunohistochemistry. Though the 6-OHDA lesioned rats were indistinguishable from sham-operated rats in performing the IA and cued version of MWM task, in the spatial version of MWM, lesioned rats, compared to controls, exhibited significantly differences in the latency ( $P<0.05$ ), quadrant time ( $P<0.01$ ) and platform crossings ( $P<0.05$ ). These results suggest that the rat's ability to acquire spatial learning and memory for place navigation in the MWM is likely dependent also on the integrity of meso-hippocampal dopaminergic connections.

## 477.6

HIPPOCAMPAL LESIONS DISRUPT THE RETENTION, BUT NOT ACQUISITION, OF OBJECT DISCRIMINATIONS. L.A. Rothblat\* and N. Vnek. Department of Psychology, The George Washington University, Washington, D.C., 20052.

A defining feature of the anterograde amnesia seen in patient populations is an impaired ability to retain information over long delay intervals despite the normal functioning of short-term memory. Animal models of human amnesic syndromes, however, have largely ignored the effect of neural trauma on long-term retention. We recently found that entorhinal-hippocampal disconnection from angular bundle transections does not affect rats' capacity for acquiring a series of object discrimination problems but does impair the retention of this information (*J. Neurosci.*, 15: 3193, 1994). The present study was designed to determine if direct damage to the hippocampus also leads to a selective impairment in the retention of object discriminations.

Rats with bilateral dorsal hippocampal lesions, rats with control lesions of overlying neocortex, and normal controls were trained on three successive object discrimination problems and then retrained on these problems after a 3 week delay interval. All three groups showed similar levels of performance during the training phase of testing. During retraining, normal and control animals showed robust -- and equivalent -- levels of retention. In contrast, animals with hippocampal lesions demonstrated impaired retention compared to normals and controls. This acquisition/retention dissociation, moreover, is consistent with that seen in rats with entorhinal-hippocampal disconnection. Together, these findings suggest that the hippocampus and anatomically related structures are not involved in establishing memories of complex visual discriminations, but are critical for maintaining this information for later use. Thus, the role of the hippocampus in nonspatial memory may be clarified by paradigms that employ measures of retention. Supported by Alzheimer's Association Grant PRG-94-172.

## 477.8

TIME OF DAY AS A CONDITIONAL CUE IS NOT DEPENDENT UPON THE HIPPOCAMPUS. A. Koerner\* & R.J. Sutherland. Dept. of Psychology, University of New Mexico, Albuquerque, NM 87131.

Rats were trained in a conditional discrimination based upon time of day in operant chambers. Rats were trained that the light cue, not the tone cue, is correct at Time 1, and that the tone cue, not the light cue, is correct at Time 2. This experiment showed that rats are capable of using time of day as a conditional cue after extensive training in an operant task using lever pressing. Hippocampal formation was damaged by multiple intrahippocampal NMDA microinjections and fornix lesions. Preliminary results indicate that the hippocampus is not necessary for this type of associative learning. The same rats were impaired at the fixed location hidden platform location of the Morris water task.

## 477.10

THE EFFECTS OF HIPPOCAMPAL AND PARIETAL CORTEX LESIONS ON MEMORY FOR AN OBJECT/SPATIAL LOCATION PAIRED ASSOCIATE TASK IN RATS. J.M. Long\*, R.P. Kesner. Dept. of Psychology, University of Utah, Salt Lake City, UT 84112.

Previous research in rats suggest that lesions of the hippocampus do not significantly impair object/object paired associate (PA) learning and result in facilitation of odor/odor PA learning. However, more "natural" PA learning is impaired by hippocampal damage (Eichenbaum and Bunsey, Curr. Dir. 1995).

In the present study Long-Evans rats were trained in a "natural" object/spatial location PA task. This was a successive discrimination, go/no-go task in which the rats had to remember which object/spatial location pairs had been associated with reward. Four objects and four spatial locations served as stimuli. This resulted in four PA's (reward condition) and twelve mispairs (non-reward condition). Five PA's and five mispair trials were given daily until rats reached criterion performance (a minimum of a 5 sec. difference between reward and non-reward trials based on 100 trials). Rats then received either hippocampal lesions, parietal cortex lesions, or control operations under Nembutal anesthesia. After a one-week recovery period they were given 300 additional test trials in order to assess retention of the PA task.

Preliminary data indicate that compared to controls, rats with hippocampal lesions have only a mild impairment, whereas rats with parietal cortex lesions are significantly impaired in their retention of the previously learned object/spatial location PA's. These results suggest that the parietal cortex, but perhaps not the hippocampus, is involved in memory for the more "natural" object/spatial location PA's. The involvement of the parietal cortex may be because either object, spatial location, or object plus spatial location needs to be represented in memory. Other data support the third possibility.

## 477.11

PARIETAL NEURAL ACTIVITY OF AWAKE RATS DURING DIRECTIONAL DELAYED NONMATCHING TO SAMPLE TASK IN FAMILIAR AND UNFAMILIAR CONDITIONS. K. Nakamura\*, T. Ono\*, T. Isaji and M. Yoshida, Dept. Electronics and Informatics, Toyama Prefectural Univ., Toyama 939-03, and \*Dept. Physiol., Fac. Med., Toyama Med. & Pharmaceu. Univ., Toyama 930-01, Japan.

To elucidate the involvement of parietal cortex (PG) in a spatial working memory function, rats were trained to perform a directional delayed nonmatching-to-sample (dDNMS) task. Six speakers surrounded the experimental field. In dDNMS, rat needed to remember the stimulus direction during 2 s delay. Neural activity in PG was in the first tested in familiar condition, then retested either by using unfamiliar tones, or after rotating the rat to the unfamiliar orientation. In total, 118 neurons were recorded during dDNMS in familiar condition and some (24 neurons) in both familiar and unfamiliar conditions. Forty two neurons responded to the directional first tones (39, differential; 3, non-differential). Of 39 differential PG neurons, 29 neurons had also significant activity during the delay period (memory related). Of 24 differential neurons (18 of these, memory related) which were also tested in unfamiliar conditions, 21 neurons had significant activity during delay period in unfamiliar conditions. Seven neurons had enhanced activity in unfamiliar conditions either to the first tone or both to the first tone and during delay. The response enhancement ratio were ranged from 1.4 to 4.3. The response tuning index (peak/mean) were usually reduced in unfamiliar conditions. These results suggest that PG neurons are involved in spatial working memory. The spatial memory in PG may be persistent, and spatial attention or learning mechanisms may be enhanced in unfamiliar conditions.

KAINIC ACID-INDUCED NEUROPATHOLOGY AND COGNITIVE DYSFUNCTION AS AN ANIMAL MODEL OF DEMENTIA. D.J. Fontana\*, M. Haraguchi, M. Rowe, R. Lewis and G.R. Stewart, Dept. Neurosciences, Syntex Research, Palo Alto, CA 94303.

Systemic injection of kainic acid (KA) causes an acute syndrome of seizures and seizure related brain damage. The present study characterized the long term effects of kainic acid-induced brain damage on cognitive and sensorimotor behaviors. Adult male Wistar-Furth rats were treated with KA (10 to 14mg/kg, ip). The majority of animals (63%) entered status epilepticus (STAT) and remained in a state of continuous seizure activity for six hours. Animals were then treated with MK-801 (0.5mg/kg, ip) and diazepam (2.5mg/kg, ip). Overt seizure activity abruptly ceased within 20 minutes and animals remained sedated for several hours. KA treated animals not entering status epilepticus (nonSTAT) were administered MK-801/diazepam and used as controls. Untreated, age-matched animals (AMC) were included as a second control group.

Following a one month recovery, all animals were subjected to a battery of tests to assess neurologic and cognitive status. STAT animals were significantly impaired on three distinct tests of learning and memory (passive avoidance, Morris Water Maze and habituation to a novel environment) and on a test of sensorimotor gating (pre-pulse inhibition to acoustic startle). General hyperactivity and increased responsiveness to acoustic stimuli were observed, but STAT animals were otherwise intact neurologically. NonSTAT animals performed similar to AMC on all tests. Histologically, STAT animals had bilaterally symmetrical damage to the hippocampus and piriform/entorhinal cortex. In some animals, there was damage to the thalamus including the presence of calcium deposits.

These results demonstrate that KA-induced seizure-disseminated brain damage yields animals in a state of global cognitive dysfunction and with underlying limbic pathology similar in many respects to that found in advanced Alzheimer's Disease.

## 477.15

HIPPOCAMPAL EVOKED POTENTIALS TO PITCH-DEVIANT AND TIME-DEVIANT TONES IN THE TRAIN OF AUDITORY STIMULI IN THE CAT: MISMATCH-LIKE NEGATIVITY (MMN) AND ITS CONNECTIONS TO THE NEURAL BASIS OF LEARNING AND MEMORY. K. Kivirikko\*, T. Korhonen, T. Ruusuvirta, J. Arikoski and P. Astikainen, Dept. of Psychol., Univ. of Jyväskylä, P.O. Box 35, 40351 Jyväskylä, Finland.

Hippocampal auditory evoked potentials elicited by pitch-deviant or time-deviant tones were recorded during a passive oddball situation in the cat. Experiment 1 showed that the hippocampal N130d recorded in the cat can be evoked by the presentation of a pitch-deviant tone (2500 Hz) in the sequence of repeated standard tones (2000 Hz) despite the lack of behavioral orientation to the stimuli. The recordings in CA1, CA3 and dentate fascia of the hippocampal formation showed that the main deflection in response to the deviant tone appeared in the latency range of 100-170 ms (N130d). The only similarity to the hippocampal MMN-like potentials previously reported in the cat, was N40d. No N130d was observed to the standard tones preceding the deviant tones. The stimulus parameters eliciting the N130 and its latency range support an assumption according to which the N130 may reflect the hippocampal neural orienting response. Consistent with the results obtained in the human cortical MMN studies concerning delayed noise bursts we could detect no N40 or N130 to the time-deviant tones following the pre-standard tones. The deviant event was a doubled interstimulus interval (ISI=1000 ms,  $p=.05$ ) which occurred randomly in a sequence where the regular ISI was 500 ms. High selectivity of the hippocampal N130, to be elicited only in response to the deviant tone, is consistent with an assumption that the hippocampal novelty detectors are responsible for the response to the deviant tone in the sequence of standard tones.

In experiment 2 our purpose is to examine whether a shortened (250 ms) or a doubled (1000 ms) ISI used as a deviance in a sequence of tones where the regular ISI is 500 ms produces hippocampal or cerebellar MMN in the rabbit.

## 477.12

HIPPOCAMPAL INSULTS PRODUCE MEMORY IMPAIRMENTS WHEREAS CHRONIC STRESS CAUSES FASTER EXTINCTION IN Y-MAZE BEHAVIOR. Y. Kuroda\*, C.D. Conrad, L.A.-M. Galea, B.S. McEwen, The Rockefeller University, New York, NY 10021

A recently modified version of the Y-maze has been shown to assess memory in rats (F. Dellu, et al., *Brain Res.* (1992) 588: 132-139). Advantages of this Y-maze is that memory can be assessed quickly (within hrs) and the task requires no food deprivation or pain.

The Y-maze consists of three identical arms. An arm was randomly blocked (novel) and a rat was allowed to investigate the other two arms for 15 minutes. After a delay of 2, 4, or 6 hrs, the rat was re-introduced in the maze with all arms available for investigation. The hippocampus was lesioned with kainic acid (KA) or colchicine (COL), i.c.v., in male rats. After 3 wk recovery, the rats were tested in the Y-maze. KA and COL groups showed no preference for the novel arm in the first choice (2 & 6 hr delay) whereas controls entered the novel arm first (93% = 2hr, 86% = 6 hr). Further, controls spent more time in the novel arm compared to the other arms relative to KA and COL rats (2 hr delay). None of the groups showed an arm preference at the 6 hr delay. These data indicate that the Y-maze is sensitive to hippocampal damage.

Because chronic restraint stress (STR, 6 hrs daily/21 days) can cause CA3 dendritic atrophy, we investigated whether such damage results in memory impairment. STR and controls entered the novel arm on first choice (80% preference for both, 4 hr delay). However, controls spent more time in the novel arm in the first two mins whereas the STR rats preferred the novel arm in the first min only. These results show that STR rats can perform a memory task but may have faster extinction rates than controls. Supp. by MH10804 to CC and MH41256 to BM.

## 477.14

HIPPOCAMPAL GRAFTS OF CELLS ENGINEERED TO PRODUCE ACH REVERSE SPATIAL MEMORY DEFICITS IN RATS WITH UNILATERAL FIMBRIA FORNIX LESIONS. H.A. Dickinson-Anson\*, F.H. Gage and L.J. Fisher, The Salk Institute, La Jolla, CA 92037-1099

Lesions of the fimbria fornix (FF) produce spatial memory deficits that can be attenuated by grafts of cholinergic tissue into denervated target regions or by systemic administration of cholinergic drugs. However, it has not been clarified if the presence of acetylcholine (ACh) in the hippocampus is a critical element for achieving improvements in spatial processing post-damage. We previously developed a genetically modified fibroblast population that expresses high levels of choline acetyltransferase, and produces and releases ACh both *in vitro* and *in vivo*. In the present study, we used these ACh-producing fibroblasts to directly test whether cholinergic function in the hippocampus is involved in spatial learning and memory.

Male Fischer 344 rats received unilateral grafts of either ACh-producing fibroblasts or  $\beta$ -galactosidase-expressing fibroblasts into the hippocampus. Immediately following the transplantation, the ipsilateral FF of the grafted rats was dissected by aspiration. Control groups consisted of unoperated rats or non-grafted rats with FF lesions. One week post-grafting, all rats were trained in a 2-day spatial water maze task. Rats with lesions of the FF showed a significant impairment in water maze performance compared to unoperated rats. Rats implanted with the ACh-producing cells, however, showed a performance in the water maze on the second day of training that was equal to that of unoperated controls. Since rats implanted with  $\beta$ gal fibroblasts did not improve post-grafting, these results indicate that ACh was a critical component in the recovery of spatial learning and memory. Further support for the role of hippocampal cholinergic function in spatial memory processing was provided in a second experiment in which ACh-producing fibroblasts were implanted into the hippocampus of normal, unlesioned rats. The performance of these animals in both the water maze and in a simple habituation task was enhanced compared to nongrafted controls. Taken together, these data suggest that hippocampal ACh is involved in spatial learning and memory, and that ACh replacement within the damaged hippocampus is sufficient to ameliorate some cognitive deficits.

## 477.16

BEHAVIORAL AND HIPPOCAMPAL EVOKED RESPONSES IN AN AUDITORY ODDBALL SITUATION WHEN AN UNCONDITIONED STIMULUS IS PAIRED WITH DEVIANT TONES IN CATS. T. Ruusuvirta\*, T. Korhonen, M. Penttonen, J. Arikoski, and K. Kivirikko, Dept. of Psychol., Univ. of Jyväskylä, Finland.

An acceleration of head movements and hippocampal event-related potentials (ERP) were measured in an oddball situation in freely moving cats. An electrical stimulation of the lateral hypothalamus (US) was paired with pitch deviant tones. In addition to the developing conditioned orienting head turns (orienting response, OR) towards the deviant stimuli, an amplitude increase of the parallelly elicited hippocampal ERPs was found. In fact, the changes in the ERP amplitude preceded the changes in the behavioral level. Both the behavioral and neural responses appeared not until the 50 ms latency range. Furthermore, time-amplitude characteristics of the ERPs corresponded to time-acceleration characteristics of the conditioned behavioral ORs indicating a close functional connection between the ERPs and the behavioral OR. The observed ERPs that were elicited at the latency range following the typical latency range of a hippocampal mismatch-like negativity in cats (30-50 ms) may represent a cat analogy of ERPs following a mismatch negativity (MMN) in humans (N2b, P3).

## 477.17

SYNAPTIC LOSS FOLLOWING REMOVAL OF SEROTONERGIC AND/OR CHOLINERGIC FIBERS IN THE RAT HIPPOCAMPUS. M. Ogawa, M. Matsukawa, and N. Okado\*. Dept. Anat., Inst. Basic Med. Sci., Univ. Tsukuba, Tsukuba, Ibaraki 305, Japan.

Serotonergic neurons innervate broad areas of the vertebrate central nervous system implicating an unique role in the brain. Indeed, serotonin (5-HT) has been shown to have an important role for synaptic formation and maintenance in developing and adult animals (J. Neurobiol. 24: 687-698, Neurosci. Res. 19: 111-115). In addition to 5-HT, acetylcholine (ACh) has shown involvement in memory formation in the hippocampus. The present study was undertaken to correlate between behavioural changes and synaptic structures following destruction of 5-HT and/or ACh systems in the hippocampus.

Following injections of AF64A (1 nmol/each lateral ventricle at once), ACh neurotoxin, or p-chlorophenylalanine methyl ester (pCPA, 100 mg/kg for every other day for two weeks), synthetase inhibitor for 5-HT, water maze learning was not significantly impaired, whereas simultaneous injections of AF64A and pCPA produced an apparent memory deficit. A slight reduction in the density of synapses (less than 10%) was found in the dorsal part of the stratum radiatum and stratum radiatum + stratum moleculare following injections of AF64A and pCPA, respectively. In contrast, synaptic density decreased in the dorsal part of the stratum radiatum by 20% following simultaneous injections of AF64A and pCPA.

This study has demonstrated that 5-HT and ACh have cooperative effects for synaptic structures and memory formation of the placement learning.

## 477.18

PAVLOVIAN AVERSIVE CONTEXT CONDITIONING USING CARBON DIOXIDE (CO<sub>2</sub>) AS AN UNCONDITIONAL STIMULUS (US): EXTINCTION OF CONDITIONED RESPONDING

DL. Mongeluzi\*, BJ. Caldarone, HS. Stock, RA. Rosellini. Dept. of Psychology, The University At Albany: SUNY, Albany, NY 12222.

Three experiments were conducted to examine the utility of CO<sub>2</sub> as an aversive US in a Pavlovian aversive context conditioning paradigm. The results of Experiment 1 indicated that animals which were exposed to CO<sub>2</sub> in a distinctive context showed elevated levels of freezing behavior in the conditioning context than control animals. Experiment 2 replicated this basic effect with a modified conditioning procedure and additionally demonstrated conditioned analgesia as indexed by increased tail flick latencies following removal from the conditioning context. Based on the outcomes of Experiments 1 and 2, it was important to begin to determine whether conditioning phenomena which have been demonstrated with shock can also be observed in the present CO<sub>2</sub> conditioning paradigm. Thus, the purpose of Experiment 3 was to investigate extinction and an extinction related phenomenon, renewal. The results of Experiment 3 indicated that repeated exposure to the context in the absence of CO<sub>2</sub> resulted in a decrease in the ability of the context to induce freezing behavior. In addition, animals which received CO<sub>2</sub> exposure in one context and extinguished in a different context showed an increase (renewal) in freezing behavior upon return to the original context.

## LEARNING AND MEMORY: SYSTEMS AND FUNCTIONS IV

## 478.1

DYNAMICS OF MESOLIMBIC AND NIGROSTRIATAL DOPAMINE ACTIVITY, DURING APPETITIVE PAVLOVIAN CONDITIONING, AS DETERMINED BY *IN VIVO* ELECTROCHEMICAL DETECTION. T.J. Brozoski\*, D.T. Brozoski, and M. Kim. Dept. of Psychology, Grinnell College, Grinnell, IA 50112.

There is considerable evidence that the mesolimbic (ML) and nigrostriatal (NS) dopamine (DA) systems of the mammalian brain are deeply involved in motivation and adaptive behavior. The ML is thought to be directly involved in mediating the effects of positive reinforcement, and the NS involved in the selection and maintenance of adaptive behavior. Pavlovian (Pav) conditioning is one of the fundamental processes through which many species acquire adaptive behaviors. The temporal dynamics of Pav conditioning are reasonably well known. The present experiment examined the temporal dynamics of DA activity in the ML and NS systems, in rats, during a simple appetitive Pav task. The objective was to discern the relationship between DA activity in these systems and behaviorally significant events in conditioning. DA activity, as indicated by *in vivo* electrochemical detection of DA metabolites, was rapidly and repeatedly measured throughout a course of Pav appetitive conditioning. The measures were obtained using chronic electrodes in freely behaving animals. Daily conditioning sessions consisted of 300 to 400 CS-US pairings, and extended over 10 to 20 consecutive days. A delay procedure was used, with an auditory cue as the CS and a food pellet as the US. Once conditioning developed, it was found that the ML system displayed a dramatic drop in DA activity during the CS and a prominent increase in DA activity immediately following the US. This was most clearly seen in the nucleus accumbens. The response of the NS system qualitatively resembled that of the ML system, but was more subtle and complex. The most notable difference between the two systems was that, in the NS system, DA activity increased only slightly, if at all, following the US. This corresponds to results previously reported by our laboratory, and suggests complementary and somewhat different roles for the ML and NS systems in the acquisition of adaptive behavior.

## 478.2

ACQUISITION OF OCCASION SETTING IN PREFRONTAL AND HIPPOCAMPAL LESIONED RATS. D.M. Skinner\*, A. Bechara and D. van der Kooy. Dept. of Anatomy and Cell Biology, University of Toronto, Toronto, Ontario, M5S 1A8. Dept. of Neurology, University of Iowa Hosp. & Clinics, Iowa City, IA 52242

In occasion setting one discriminative stimulus predicts whether or not a second, target stimulus will be followed by a motivational event (the US). We have previously suggested that most of the discriminative control is not due to simple, Pavlovian associations between the discriminative cue and the US or between the discriminative cue and the target stimulus, but to a more complex, higher-order type of association among all three elements. The hippocampus appears not to be essential for this type of complex associative learning. In a previous experiment, animals that had undergone aspiration lesions of the hippocampus were compared to sham lesioned controls on an occasion setting task employing contextual cues. While hippocampal lesioned rats were slower to acquire the occasion setting problem than sham controls, they eventually reached control levels and behavioral tests revealed that the two groups were solving the task using a similar strategy. We now report that lesions aimed at the prefrontal cortex do not impair performance on the same occasion setting task. In one distinct context, rats are given a novel flavored solution followed by an injection of LiCl. In a second distinct context, the same flavored solution is not followed by LiCl. Over time, both prefrontal and sham lesioned rats learn to suppress fluid consumption in the first context but consume large amounts in the second context. Prefrontal rats, unlike hippocampal rats, acquired the task at the same rate as controls rats. Behavioral tests, including a transfer test with a novel target solution and a choice test between the two training contexts, revealed that the prefrontal and control groups were solving the task in a similar manner. Surprisingly, the prefrontal cortex (or other cortical tissue, given previous findings of acquisition after neonatal decontamination) does not appear essential for acquiring occasion setting, although the delayed acquisition after hippocampal lesions may point to a role for the hippocampus in decreasing interference among cues.

## 478.3

THE EFFECTS OF HIPPOCAMPAL LESIONS ON PAVLOVIAN CONDITIONED ACTIVITY DEPEND ON AMOUNT OF REINFORCEMENT OF CONTEXT. I. L. Davidson, S. C. Benoit, and L. E. Jarrard\*. Purdue Univ., West Lafayette, IN 47907; Washington & Lee Univ., Lexington, VA 24450.

Rats with selective ibotenate lesions of the hippocampus and controls underwent Pavlovian conditioning in which a 10 sec tone conditioned stimulus (CS) terminated with the delivery of a food unconditioned stimulus (US). Behavioral activity during the CS and during the 10 sec period preceding the CS (Pre CS) was recorded by a computerized system. All rats received one CS-US trial during each of fifteen, 50 min sessions. The four groups differed with respect to the number of unsignaled USs received during training: Group 1-0 received no unsignaled USs, Group 3-1 received one unsignaled US every three sessions, Group 1-1 received one unsignaled US each session, and Group 1-3 received three unsignaled USs each session. Activity was greater during the CS than Pre CS periods for both hippocampal and control rats when the number of unsignaled USs was small (Groups 1-0 and 3-1). However, hippocampal rats were impaired when the number of unsignaled USs was relatively large (Groups 1-1 and 3-1). This difference was specific to the training context since both hippocampal and control rats showed greater activity during CS than during Pre CS periods when tested in a novel context. Furthermore, giving more unsignaled USs to Groups 1-0 and 3-1 increased Pre CS activity for hippocampal rats but not for controls. The results suggest that rats without a hippocampus may have difficulty suppressing activity in a highly reinforced context.

## 478.4

IBOTENATE LESIONS OF THE HIPPOCAMPUS DO NOT ATTENUATE THE EFFECTS OF US DEVALUATION FOLLOWING CS-US PAIRINGS IN RATS. J.R. Morell and S.E. Swithers\*. Dept. of Experimental Psychology, Duke University, Durham, NC 27706.

The role of the hippocampus in simple associative learning was examined using US devaluation. Of the 37 rats in the experiment 20 were given ibotenate lesions of the hippocampus, 10 served as sham controls and 7 were only anesthetized and allowed to recover. All rats were then allowed to recover for at least two weeks post surgery. The lesioned and control rats were then distributed between Paired and Unpaired groups. For both groups, initial tone conditioning was accomplished in standard skinner boxes by pairing a tone with a food US for 8 days. All animals then received 10 minute access to the food US in their home cages followed by intraperitoneal injections (5ml/kg) of .3M lithium chloride (LiCl). The paired rats received the injections immediately following access to the food US while the unpaired rats were injected 6 hours after access to the food US. The following day the rats were placed back in the skinner boxes and tested for responsiveness to the tone CS. Both control and lesioned animals in the paired group showed an attenuated CR to the tone in the last test while both control and lesioned animals in the unpaired group did not. These results suggest that the hippocampus is not necessary for tracking devaluations of the US. This task may be seen as a conditional logic task where the animals are taught that A=B and B=C and then asked if they know that A=C. While many have suggested that the hippocampus is necessary for the solution of such tasks, these data suggest that the hippocampus may not be necessary for solving such tasks in the rat.

## 478.5

**LATENT INHIBITION OF THE RABBIT CONDITIONED EYEBLINK IS NOT REFLECTED IN HIPPOCAMPAL ACTIVITY.** D.B. Katz\*, D.M. Shock, and J.E. Steinmetz. Dept. of Psychology/Neural Sciences, Indiana Univ., Bloomington, IN 47405.

Latent inhibition (LI) has been described as a robust effect whereby pre-exposure to a conditioned stimulus (CS) inhibits later learning of an association between the CS and an unconditioned stimulus (US). Several current neurobiological theories have suggested that the hippocampus mediates this phenomenon. In an examination of this possibility, male New Zealand White rabbits implanted with multiple-unit CA1 or dentate electrodes were pre-exposed to 1 kHz tones (120 per session) for eight sessions, after which they received standard delay eyeblink conditioning (pairings of the tone with a 3 psi air puff to the cornea). Pilot experiments with a 250 msec interstimulus interval (ISI) suggested that CS pre-exposure did not slow the learning rate of these animals compared to controls that had been exposed to the testing context for a similar amount of time. With the ISI set at 500 msec, however, CS pre-exposure caused a 120-trial delay in the acquisition of learning criterion. The hippocampus modeled the conditioned eyeblink in very few cases, regardless of whether the animal was pre-exposed to the CS or to the testing context only; when modeling did occur, it developed several sessions after the animal had reached criterion. These data stand in contrast to earlier work suggesting that as many as 75% of CA1-dentate pyramidal cells model the eyeblink in concert with learning. Our results suggest that the hippocampus may encode overall context, of which the CS is only a part. This last conclusion is in accord with recent lesion experiments suggesting that hippocampectomy may enhance or 'de-contextualize' LI.

## 478.7

**POST-CONDITIONING ISOLATION DISRUPTS CONTEXTUAL BUT NOT AUDITORY FEAR CONDITIONING** J.W. Rudy,\* Department of Psychology University of Colorado, Boulder, Co. 80309

Rats conditioned to an auditory cue paired with shock display a conditioned freezing response to both the cue and the context in which the shock occurred. Unlike cue conditioning, however, contextual conditioning appears to require a lengthy retention period before it is fully manifested. For example, 23-to-30-day-old rats display much less contextual conditioning when tested 10 min to 3 hrs after conditioning than when tested 24 hrs after conditioning, whereas freezing to the auditory cue is the same when animals are tested 10 min or 24 hrs after training (Rudy & Morledge, 1994, *Behav. Neurosci.* 108, 227-234). Rudy and Morledge proposed that this phenomenon reflects a lengthy consolidation period during which a representation of the context is constructed that can be used to evoke fear. To investigate this hypothesis, I compared 25-day-old rats that were either returned to their home-cage and littermates after conditioning with rats that were isolated in a novel room with food and water available. Consistent with the consolidation hypothesis, I found that (a) an isolation treatment lasting 1, 3, or 24 hrs disrupted contextual but not auditory fear conditioning, (b) a 15 min isolation treatment had no effect, (c) contextual conditioning was disrupted when the conditioning-isolation interval was 2 hrs but not when it was 24 hrs, and (d) preexposure to the conditioning context 24 hrs prior to the conditioning session prevented isolation from disrupting conditioning. These results support the consolidation hypothesis and provide additional evidence that contextual and auditory-cue fear conditioning depend on different processes.

## 478.9

**HIPPOCAMPAL LESIONS CAUSE LEARNING DEFICITS IN MORRIS WATER MAZE AND CONTEXTUAL CONDITIONED FEAR TASKS IN INBRED MICE.** S.F. Logue\*, R. Paylor and J.M. Wehner. Institute for Behavioral Genetics and School of Pharmacy, University of Colorado, Boulder, CO 80309.

C57BL/6 (C57) mice perform better than DBA/2 (DBA) mice on the hippocampal-dependent components of the Morris water maze task and a conditioned fear task while performance of the two inbred mice strains is not different on the hippocampal-independent components of these tasks (Paylor et al., *Behav. Neurosci.*, 108:1-8, 1994; Upchurch & Wehner, *Behav. Neurosci.*, 103:1251-1258, 1989). Although the differential performance between the strains on the hippocampal-dependent components of the tasks is thought to be due to functional differences in the hippocampi of these strains, it has not yet been demonstrated that the mice are actually using the hippocampus (HPC) to learn these tasks.

The current experiments examined the effect of kainic acid/colchicine lesions of the HPC on acquisition of the Morris task and/or conditioned fear responses. Groups of C57 and DBA mice were given HPC lesions or sham surgery and after recovery trained on the tasks. In the contextual fear test, lesions decreased freezing in both strains of mice. In the conditioned stimulus test this lesion effect was not seen. In the Morris task, based on probe trial data, the lesioned C57 mice failed to learn relative to the sham controls while both the lesion and sham DBA mice failed to learn the task. These data demonstrate that C57 mice do use the HPC to solve the Morris and conditioned fear tasks and that the DBA mice use the HPC in the conditioned fear task. (Supported by S.F.L.-5T32HD-07289; J.M.W.-MH-48663 & AA-00141)

## 478.6

**TRACE AND DELAY EYEBLINK CONDITIONING INDUCE ALTERATIONS IN THE IMMUNOREACTIVITY FOR PKC $\gamma$  IN THE RABBIT HIPPOCAMPUS.** E.A. Van der Zee\*, J.F. Palm, M.A. Kronforst, E.J. Maizels, M. Shanmugam, M. Hunzicker-Dunn, and J.E. Disterhoft. CM Biology, Northwestern University Med. Sch., 303 E. Chicago Ave., Chicago, IL 60611 USA.

Protein Kinase C (PKC) modulates neuronal activity in the hippocampus in relation to learning and memory. Previously, learning-induced changes for PKC $\gamma$  immunoreactivity (ir) were found in the hippocampus after spatial learning (Van der Zee et al., *J. Neurosci.* 12:4808-4815; 1992). The aim of the present study was to determine whether both hippocampally-dependent 500 ms trace and 250 ms delay eyeblink conditioning induce changes in the ir for calcium-dependent PKC isoforms. Young adult (2-3 months; n=37) female NZW rabbits were used. Trained animals were killed 24 h after reaching an 80% CRs/session criterion. Brain sections were stained for the PKC isoforms  $\alpha$ ,  $\beta$ ,  $\beta$ II and  $\gamma$ . The hypothalamus served as a control region.

	hippocampus staining	translocation	cerebellum staining	hypothalamus staining
pseudoconditioned (n=7)	+	-	nd	-
trace conditioned (n=7)	+++	-	nd	-
pseudoconditioned(n=8)	+	nd	-	-
delay conditioned(n=8)	++	nd	-	-

Comparison for PKC $\gamma$  with naive young adults (n=7). nd = not determined; - = no change

PKC $\gamma$  ir changed after conditioning. The smaller change after delay than trace conditioning might reflect differential hippocampal involvement. No gross changes in ir were observed for PKC $\alpha$ ,  $\beta$ I, or  $\beta$ II. Western blot results showed that the total amount of hippocampal PKC $\gamma$  did not change after conditioning, and no translocation occurred. These results suggest that PKC $\gamma$  is the crucial PKC isoform mediating hippocampal memory changes during eyeblink conditioning. The absence of PKC $\gamma$ -ir changes in the cerebellum may suggest that this isoform plays a role in declarative memory rather than procedural memory. (Supported by NIH RO1 MH47340, RO1 AG08796, and Dr. J.L. Dobberke Foundation for Comparative Psychology to I.F.P.)

## 478.8

**CONTEXTUAL FEAR CONDITIONING AND HIPPOCAMPUS** Robert J. McDonald\*, Amy Koerner and Robert J. Sutherland, Dept. of Psychology, University of New Mexico, Albuquerque, New Mexico, U.S.A.

Investigations directed at understanding the neural substrates underlying fear conditioning to context remain controversial. Many of these studies use different response measures to assess conditioning and provide no evidence for context discrimination. In this study we address these issues by assessing 4 responses (freezing, locomotion, defecation, preference) in a context discrimination. Rats with damage to the hippocampus and shams were trained on a 4 phase procedure: (1) Pre-exposure. Each rat exposed to the 2 chambers and a connecting alley. (2) Conditioning. Each rat placed into either chamber for 2 minutes and received 3 shocks (1.5 mA for 2 s) separated by 60 s. (3) Retention. All rats were placed for 5 minutes into the three chambers (black, white, novel). (4) Preference. Each rat was allowed to show a preference for one of the chambers. Rats with damage to hippocampus do/do not exhibit acquired fear to context depending on the response measure. These results suggest that multiple representations of context exist and are differentially connected to actions.

## 478.10

**EFFECTS OF HIPPOCAMPAL LESIONS ON A CONTEXTUAL DISCRIMINATION TASK.** P.D. Sparks\* and J.E. LeDoux. Department of Psychology and Center for Neural Science, NYU, NY, NY 10003.

Dorsal hippocampal lesions interfere with the conditioning of fear responses to contextual stimuli in rats. In the present study we examined the effects of such lesions on a contextual discrimination task, in which an auditory conditioned stimulus (CS: 10kHz, 72dB, 20 sec) was paired with footshock in one chamber and without footshock (0.5 ma, 500ms) in another. Two weeks after surgery, blocks of two trials consisting of tone-shock pairings were given twice a day (7 hrs apart), for 8-10 days.

Time spent freezing to context and tone were measured in each chamber in order to evaluate the animals' ability to discriminate between the chambers. After 7 days on average, controls spent less time freezing in the no shock chamber than in chamber the shock chamber. Hippocampal lesions reduced freezing to the context in the no shock chamber but not in the shock chamber. This result was unexpected, as it suggests that hippocampal lesions facilitated the learning of a contextual discrimination. The effects of septal lesions on contextual discrimination are currently under investigation. Supported by NSF9209646 and MH38774.

## 478.11

**UNILATERAL AMYGDALA LESIONS ATTENUATE CONDITIONED FEAR IN RATS** K.S. LaBar\* and J.E. LeDoux. Center for Neural Science, New York University, NY, NY

We recently demonstrated impaired fear conditioning in human patients with unilateral medial temporal lobe resection, including the amygdala, to control medically refractory epilepsy (LaBar et al., 1994). This human study differed from typical animal models in several ways, including that a loud white noise burst served as a US, and that the extent of amygdala damage was primarily unilateral. The present study was thus designed to test the efficacy of a white noise US for conditioning to both an explicit CS and to the context, and to compare the effects of unilateral vs. bilateral amygdala lesions on conditioned fear in rats.

Male Sprague-Dawley rats were randomly assigned to experimental (left/right unilateral or bilateral electrolytic amygdala lesion) or control (sham operated or unoperated) groups. One week following surgery, the rats received 2 days of CS-US acquisition training (2 trials/day: CS=10 kHz tone, 75 dB, 20 sec; US=white noise, 110 dB, 1 sec) and 5 days of CS-alone extinction training (2 trials/day). Rats with bilateral amygdala lesions showed a nearly complete lack of freezing to both the CS and the context. Rats with unilateral amygdala lesions froze significantly less than controls to the CS and the context; the context effect, however, was less pronounced due to low overall levels of contextual conditioning in the control groups. We conclude that white noise can serve as an effective US, especially for conditioning to an explicit CS, and that unilateral amygdala lesions attenuate but do not eliminate conditioned fear in rats.

**EFFECTS OF MUSCIMOL APPLIED TO THE DORSAL HIPPOCAMPUS ON THE ACQUISITION AND EXPRESSION OF CUED VERSUS CONTEXTUAL FEAR CONDITIONING**

P.S.F. Bellgowan\* & F.J. Helmstetter

Department of Psychology, University of Wisconsin, Milwaukee, WI 53201

Previous research has shown that rats with lesions of the dorsal hippocampus show dramatic deficits in Pavlovian fear conditioning when complex contextual stimuli are used as the CS but show normal learning when a discrete unimodal cue such as a tone is used to signal shock (Kim & Fanselow, 1992). In order to investigate whether the hippocampus was selectively involved in either the acquisition or the expression of contextual fear conditioning we prepared rats with chronic cannulae and injected the GABA agonist muscimol (MUS, 0.25 µg) into the hippocampus prior to a training session in which white noise (10 sec / 72 dB) and shock (2 mA / 1 sec) were paired within a distinctive observation chamber, or prior to testing sessions during which fear responses to a single 5 min presentation of white noise and the shock-associated training context were measured independently during extinction. When hippocampal activity was disrupted with MUS prior to the training session, freezing behavior subsequently measured in the training context was drastically reduced. Furthermore, fear responses to the contextual CS were also affected when MUS was injected prior to CR expression in animals trained with saline. Neither of these effects were due to "state-dependence." These results suggest that the hippocampus is important for both the acquisition and the expression of contextual fear conditioning. Pretraining MUS produced minimal disruption of fear to the auditory CS measured 24 or 48 hr after acquisition. However, when MUS was injected prior to testing we observed a substantial attenuation of performance to the discrete CS during the second testing session suggesting that hippocampal manipulations may affect performance of discrete CRs during extinction.

**SELECTIVE NEUROTOXIC LESIONS OF THE HIPPOCAMPUS BLOCK RETENTION OF A SOCIAL MEMORY.** H. Eichenbaum\* and M. Bunsey. Center for Behavioral Neuroscience, SUNY at Stony Brook, NY 11794-2575.

Previous studies have indicated that hippocampal lesions impair the memory for the social transmission of food preferences (Winocur, Behav. Brain. Res. 38:145, 1989; Bunsey & Eichenbaum, Soc. Neurosci. Abstr. 19:358, 1994). The present study assessed which subcomponents of the hippocampus are critical to support this form of memory.

Male Long Evans rats underwent control surgery or ibotenic acid-induced lesions of the hippocampus proper plus dentate gyrus (H+D), the subiculum (S), or all three hippocampal subfields (H+S+D). Following a three week recovery, subjects were briefly housed with a conspecific that had just consumed a distinctively scented diet. Either immediately or 24 hr after this social interaction, subjects were given a choice between a diet identical to that eaten by the conspecific and a different scented diet. Consistent with previous results, normal rats preferred the conspecific's diet following the interaction, and showed no forgetting over a 24 hr retention interval. Neither selective H+D nor selective S lesions affected performance at either delay. By contrast, the complete hippocampus lesion (H+D+S) completely blocked memory at the 24 hr test. This deficit was delay-dependent -- there was no effect at the immediate retention test -- thus indicating a specific memory impairment. These findings demonstrate a critical role for the hippocampus in a naturally-occurring, and distinctly nonspatial form of memory and provide further evidence that the functional unit underlying hippocampal-dependent memory includes all of its subfields. ## 478.12

**STIMULATION OF HIPPOCAMPAL KAPPA OPIOID RECEPTORS BLOCKS PAVLOVIAN FEAR CONDITIONING TO CONTEXTUAL STIMULI** F.J. Helmstetter\*, P.S.F. Bellgowan & E.A. Kasparsen, University of Wisconsin, Milwaukee, WI 53201

Endogenous opioid peptides that bind to  $\kappa$  receptors may act as retrograde inhibitory neurotransmitters which regulate excitatory synaptic transmission in the hippocampus. *In vitro* studies have shown that endogenously released and exogenously applied  $\kappa$  agonists will selectively block the induction of at least one form of LTP (e.g., Wagner, Terman & Chavkin, *Nature* 363:451). In the present study rats were prepared with chronic cannulae in the dorsal hippocampus and tested in a Pavlovian fear conditioning paradigm. Prior to training during which animals received a series of paired presentations of an auditory stimulus and foot shock in a distinctive observation chamber groups were pretreated with the  $\kappa$  agonist U50,488H (U50), the  $\kappa$  antagonist nornaltrorphimine (nBNI) or saline. Twenty four and 48 hours later fear conditioning to the shock-associated observation chamber (contextual CS) and the auditory signal (discrete CS) was assessed independently. Prior work has shown that hippocampal lesions or local infusion of NMDA antagonists block learning about the contextual but not the discrete CS. Rats treated with U50 showed a significant disruption in fear to the shock-associated context. Initial response to the auditory CS was intact in these animals although large decrements due to pretraining U50 were seen during extinction. nBNI failed to facilitate the acquisition of either response. The results generally support a role for  $\kappa$  opioids as regulators of hippocampal plasticity during learning in intact animals.

## 478.14

**IBOTENIC ACID HIPPOCAMPAL LESIONS REVERSE CONTEXT BUT NOT LATENT INHIBITION EFFECTS DURING APPETITIVE AND AVERSIVE SIGNALLED BARPRESS TRAINING.** D. P. Miller\* and J. E. Steinmetz<sup>2</sup>, Dept. of Psych., Carthage College<sup>1</sup>, Kenosha, WI 53140; Prog. in Neural Sci. and Dept. of Psych., Indiana University<sup>2</sup>, Bloomington, IN 47405.

A number of studies have demonstrated that conventional hippocampal lesions abolished latent inhibition in aversive (e.g., Solomon & Moore, *J. Comp. Physiol. Behav.*, 89:1192, 1975) and appetitive (Kaye & Pearce, *Quarterly J. Exper. Psychol.* 39B:107, 1987) tasks. Recently it was reported that ibotenic acid hippocampal lesions did not abolish latent inhibition in an appetitive Pavlovian conditioning task (Honey & Good, *Behav. Neurosci.* 107:23, 1993). In the present experiments we assessed the effects of ibotenic hippocampal lesions on appetitive and aversive signalled barpress conditioning following latent inhibition training. During appetitive training, rats that received pre-exposure to the tone signal exhibited a prolonged increase in latency to perform the signalled barpress response within trials. Hippocampal lesions did not disrupt this inhibitory effect. Latent inhibition training did not retard acquisition of the barpress response across trials. During aversive training, a separate group of rats with hippocampal lesions acquired the signalled avoidance response faster than rats with an intact hippocampus regardless of whether they had received pre-exposure to the tone signal or the conditioning chamber without the tone signal. Latent inhibition training retarded acquisition of the signalled escape response and hippocampal lesions did not reverse this retardation. Thus specific hippocampal lesions did not reverse inhibition related to processing the tone signal in either appetitive or aversive conditioning but did appear to reverse inhibition related to the processing of more general contextual cues in the aversive task. Supported by NIMH grant MH44052.

## 478.16

**SELECTIVE HIPPOCAMPAL LESIONS BLOCK ASSOCIATIVE TRANSITIVITY.** M. Bunsey\* and H. Eichenbaum. Center for Behavioral Neuroscience, SUNY at Stony Brook, NY 11794-2575.

The hippocampus is thought to support declarative memory processing. Defining characteristics that distinguish declarative memory is the representation of relations among items in memory and a capacity for representational flexibility, the ability to access memories in novel situations, independent of the circumstances of original learning. This study assessed the effects of selective hippocampal lesions on one such form of representational flexibility, i.e., associative transitivity.

Male Long Evans rats underwent ibotenic acid-induced lesions of the hippocampal subfields or control surgery. Subjects were then trained on two consecutive sets of odor paired associates with shared elements: Set 1 involved learning pairs A-B and X-Y, and set 2 involved pairs B-C and Y-Z. Associative transitivity between sets is demonstrated to the extent that subjects infer the associative relationships that exist across pairs, e.g., by judging an association to exist between A and C based on the shared element B. Controls quickly learned the paired associate problems and showed substantial transitivity on unrewarded probe trials in which inferential judgement was required. Rats with selective hippocampal lesions learned the paired associates as quickly as controls, but showed no evidence of transitive inference. Thus, despite intact acquisition of the paired associates, hippocampal rats developed an abnormal and inflexible representation of the odor pairings. These data add to growing evidence that the hippocampus itself is not critical to some forms of paired associate or conditional learning, but that it is crucial to the development of a "declarative" form of representation that supports relational and flexible memory expression. (Supported by NIMH, ONR, NIA)

## 478.17

**SPATIAL & TEMPORAL ORGANIZATION IN TRANSITIVE INFERENCE BY RATS.** J. Dusek\*, M. Bunsey, & H. Eichenbaum. Center for Behavioral Neuroscience, SUNY-Stony Brook, NY 11794.

The term "transitive inference" signifies the ability to infer a relationship between items that have not been previously experienced together, based on previous learning of the relations between overlapping subsets of the items. The present experiment is intended to extend the Roberts and Phelps (Psychol. Sci. 5:368, 1994) study in which transitive inference was exhibited in rats trained with odor stimuli presented in a linear spatial arrangement, but not when the same stimuli were randomly arranged. These findings were interpreted as consistent with the spatial hypothesis of transitive inference, that is, that the spatial ordering of stimuli provided the organization necessary for inferential judgments. The present study was aimed to determine if other, nonspatial orderings provided during training would also enable rats to encode an odor sequence and demonstrate transitive inference.

Three groups of male Long Evans rats (spatial, temporal, control) were trained with five adjacent pairs of odors (A+ vs B-, B+ vs C-, C+ vs D-, etc.) that formed a sequential hierarchy (A>B>C>D>E>F). After reaching criterion on the set of pairwise discriminations, rats were subsequently tested in a novel environment with the non-adjacent pair, BD, to assess capacity for transitive inference. Preliminary results suggest that the groups acquired the sequence in different ways and that the patterns of responses are consistent with the organization of the odors for spatial or temporal ordering. Supported by ONR.

## 478.19

**CATECHOLAMINE DEPLETION DOES NOT ATTENUATE CONSOLIDATION IN A SIMPLE PAVLOVIAN FEAR CONDITIONING PARADIGM**

S.G. Anagnostaras\* and Michael S. Fanselow. Department of Psychology, University of California, Los Angeles, CA 90024-1563.

Rats given signaled shocks in a particular context will later express conditional fear to that context or to the signal. Previous experiments in our laboratory have shown that contextual fear appears to be consolidated over a 4-wk period, such that hippocampal lesions given immediately after training produce a profound retrograde amnesia specific to contextual fear, but lesions given four weeks after training do not affect contextual fear memory. Although initial acquisition is dependent on NMDA receptor activation, the neurochemical events occurring during the 4-wk consolidation period are unknown. As a first step toward discovering the nature of consolidation, we are attempting to deplete particular neurotransmitter systems to determine which are necessary for consolidation. Studies by McGaugh and others have shown that catecholamines neurotransmitters are important in the modulation of consolidation. In order to test whether or not catecholamines are necessary for consolidation, rats were treated with *DL*- $\alpha$ -methyl-*p*-tyrosine methyl ester HCl (AMPT), a tyrosine hydroxylase inhibitor. On the conditioning day, the animals were given five tone-shock pairings in a particular context. *Anterograde* animals were given an injection of AMPT (200 mg/kg, i.p.) 1-hr prior to training. *Retrograde* animals received an injection of AMPT (200 mg/kg) immediately after training and twice daily for two additional days. *Saline Control* animals were treated similarly but received saline injections. Seven to eight days later, all animals were tested in the absence of the drug for conditional freezing to the training context and to the tone in a novel context. Although these treatments produce severe reductions in catecholamine levels, there was no effect of either AMPT treatment paradigm on the expression of conditional fear on either test. Thus, normal levels of catecholamines do not appear necessary for consolidation of simple Pavlovian fear conditioning. Studies are in progress examining other neurotransmitter systems on consolidation in this behavioral paradigm. Supported by NIMH grant (MH39786) to MSF.

## 478.21

**THE IMMEDIATE SHOCK FEAR DEFICIT: A TEST OF TIMING VS. ASSOCIATIVE ACCOUNTS.** M. S. Fanselow\* & D. Stote. Department of Psychology, University of California, Los Angeles, CA 90024-1563.

Rats that receive aversive footshock soon after placement in an observation chamber show conditional fear-induced responses to this shock paired context when they are reexposed to the observation chamber. This contextual fear increases with increases in the interval between placement in the chamber and shock. If shock is given immediately upon placement in the chamber no fear is observed, an effect called the immediate shock deficit (ISD). We have suggested that the ISD arises because there is insufficient time to process contextual cues prior to shock and therefore, the animal fails to associate the context with shock. However, if one makes the assumption that rats accurately learn the placement to shock interval, alternative accounts can be entertained. For example, rats that expect shock once every 5 sec may abandon this assumption during the shock-free test more readily than rats expecting shock once every minute (disconfirmation hypothesis). We tested the timing assumption by determining the latency to freeze and the time at which peak freezing occurred in rats that received different intervals between placement and shock (5, 20, 60, & 180 sec). The timing assumption predicts a positive relation between this interval and these two measures, while the associative account predicts an inverse relationship. Both measures supported the associative account. We also tested the disconfirmation hypothesis' prediction that the ISD function should be eliminated if preshock, postshock and testing times are held constant. There was a substantial ISD under these conditions, supporting the associative account. This pattern of results generalized to the freezing deficit obtained with multiple massed shocks. By administering naltrexone prior to shock, we also determined if the ISD results from a brief opioid analgesia that could accompany placement in the chamber, but the ISD was not affected by the opioid antagonist. Overall, the data support the hypothesis that the ISD results from an associative deficit that arises because of a failure to appreciate the context prior to shock, a process that is likely to depend on the hippocampus. Supported by NIMH grant (MH39786) to MSF.

## 478.18

**EXCITOTOXIC LESIONS IN THE BASOLATERAL AMYGDALA INDUCE A TEMPORALLY-STABLE RETROGRADE AMNESIA OF FEAR IN RATS.** S. Maren\*, G. Aharonov and M. S. Fanselow. Department of Psychology, University of California, Los Angeles, CA 90024-1563.

It is now generally agreed that the amygdala is required for the acquisition of conditional fear in a variety of learning tasks, but there is some debate concerning the role of the amygdala in the expression of learned fear following conditioning. Some investigators have suggested that the role of the amygdala is temporally-graded, because post-training amygdala inactivation disrupts retention only when performed shortly after training. In contrast, other investigators have found that electrolytic lesions of the amygdala produce deficits in the expression of conditional fear when given either 1 or 30 days following training, suggesting a temporally-stable role for the amygdala in the expression of conditional fear. Because the lesions used in the latter experiments included damage to the central nucleus, which is required for the performance of both conditioned and unconditioned fear, we have re-examined the retrograde gradient of Pavlovian fear conditioning using more selective *N*-methyl-D-aspartate (NMDA) lesions of the basolateral amygdala. On the conditioning day, rats were placed in observation chambers and three minutes later given three tone (90 dB, 2 kHz, 10 s)-footshock (1 mA, 2 s) pairings with a 74 s ISI. One, fourteen, or twenty-eight days following conditioning bilateral excitotoxic lesions were made in the basolateral amygdala using NMDA (20  $\mu$ g/ $\mu$ L, 0.3  $\mu$ L/site); control rats received sham surgery with no drug infusion. One week following surgery fear to the context of the conditioning chamber was assessed by returning the rats to the chambers and scoring freezing; fear to the tone was assessed in a different chamber the following day. Results showed that basolateral amygdala lesions produced an impairment of both context and tone fear that did not vary as a function of the training to lesion interval. This pattern of results reveals that the role of the amygdala in Pavlovian fear conditioning is not temporally-graded and suggests that neurons in the basolateral amygdala are the storage site for fear memories. These results will be contrasted with those obtained from excitotoxic lesions of the hippocampus. Supported by NIMH grant (MH39786) to MSF.

## 478.20

**EFFECTS OF LESIONS AND GLUTAMATE ANTAGONISTS IN THE VENTRAL AND DORSAL PAG ON THE LEARNING AND PERFORMANCE OF CONDITIONED FEAR.** B. M. De Oca\* and M. S. Fanselow. Dept. of Psychology, University of California, Los Angeles, CA 90024-1563.

The midbrain periaqueductal grey is involved in fear and defense-related behaviors. Lesion studies suggest that the caudal region dorsal and lateral to the aqueduct of the periaqueductal grey (D-PAG) is implicated in circa-strike defensive responding in rats while the caudal region ventral to the aqueduct (V-PAG) is implicated in defensive freezing. We have suggested that the D-PAG tonically inhibits the V-PAG. The purpose of this study was to: 1) Dissociate learning and performance effects of both the D-PAG and V-PAG on conditioned fear-induced freezing. 2) Ascertain that effects of lesions of the area are due to damage to neurons intrinsic to the PAG and not to the many fibers of passage which traverse the PAG. Pre-training lesions enhance defensive freezing to Pavlovian-conditioned fear cues, possibly by eliminating tonic inhibition of the V-PAG, while post-training lesions of the D-PAG have no effect. In other experiments, rats received the AMPA receptor antagonist, DNQX or vehicle prior to training and either DNQX or vehicle prior to testing of Pavlovian-conditioned fear. The results suggest that neurons within the PAG are not simply motor-output relays, but rather are critical for acquisition of conditioned fear. Supported by NIMH grant (MH39786) to MSF.

## 479.1

DOES REWARDING ELECTRICAL STIMULATION OF LATERAL HYPOTHALAMUS FACILITATE LEARNING OF CONDITIONED NICITATING MEMBRANE RESPONSE IN RABBITS? J. Arikoski\*, T. Korhonen, M. Penttonen, T. Ruusuvirta and J. Wikgren, Dept. of Psychol., Univ. of Jyväskylä, P.O. Box 35, SF-40351, Jyväskylä, Finland.

There are only few observations of rewarding effects of an electrical brain stimulation (ESB) on classical conditioning of nictitating membrane (NM) response in rabbits. There are also a few if not at all such studies in which both the rewarding pre- and post-ESB is present. In this study control rabbits (CC group) were classically conditioned with a tone conditioned stimulus (CS) and an airpuff unconditioned stimulus (US). In test groups, the ESB either preceded (CCpre group) or followed (CCpost group) the CS-US presentation.

Results indicated that during the CS periods of the CS test trials (an unpaired control tone) all the groups showed significant increase in the CR amplitude over days ( $F(1.50, 40) = 22.48, p < .001$ ). After five days of conditioning it could be identified that the CCpost group showed faster CR acquisition than the CC group, whereas only a slight CR could be identified from the CCpre group. In this phase a significant Treatment x Day interaction ( $F(2.99, 40) = 3.56, p < .05$ ) was observed.

Due to these facts we conclude that the ESB of the lateral hypothalamus given as post stimulation is sufficient to facilitate classical conditioning of the NM response. In this study also evoked potentials and multiple-unit recordings were obtained from hippocampus (CA1, CA3 and dentate gyrus). We are working on this data.

## 479.3

IMPAIRED CLASSICAL EYEBLINK CONDITIONING IN PURKINJE CELL DEGENERATION (*pcd*) MUTANT MICE. L. Chen\*, S. Bao, J. J. Kim and R. F. Thompson. Neuroscience Program, Univ. of Southern Calif., Los Angeles, CA 90089-2520.

An accumulating body of evidence from rabbit, rat and human studies strongly suggest the crucial involvement of cerebellum in classical eyeblink conditioning. Within the cerebellum, however, it has been difficult to dissociate the relative role of cerebellar cortex versus deep nuclei in eyeblink learning; it is practically impossible to lesion the entire cerebellar cortex while sparing the deep nuclei. In the present study, we employed mutant mice deficient of Purkinje cells, the exclusive output neurons of the cerebellar cortex, to further investigate eyeblink conditioning.

The subjects, adult male *pcd* mutant ( $n=11$ ) and normal littermate ( $n=10$ ) mice (C57BL/6J background), underwent a standard delay eyeblink conditioning paradigm (350-ms tone conditioned stimulus, 100-ms periorbital shock unconditioned stimulus, interstimulus interval = 250-ms). The eyelid muscle electromyograph (EMG) was recorded to score CRs. Our results indicate that *pcd* mice exhibited a profound impairment in the acquisition of delay eyeblink conditioning in comparison to their normal littermates. The *pcd* animals, nevertheless, did evidence partial learned eyeblink responses with extensive training. There were no differences between the groups in sensitivity to the unconditioned stimulus nor unconditioned responses to the periorbital shock. These results suggest that cerebellar cortex plays a critical role in eyeblink conditioning.

Supported by grants from NSF (IBN9215069), NIA (AF05142), and Sankyo to RFT.

## 479.5

NEURAL RESPONSES OF THE CEREBELLAR DEEP NUCLEI IN THE NAIVE AND WELL TRAINED RABBIT FOLLOWING NM CONDITIONING.

M.S. Berg\* & R.F. Thompson. Neurosciences Program, University of Southern California, Los Angeles, CA 90089-2520.

The cerebellar deep nuclei appears to be necessary for classical conditioning of the rabbit nictitating membrane (NM) response. Reversible lesions of the anterior interpositus (IPA) prevent acquisition of the learned behavior in naive animals, and abolish the learned response in trained animals (Krupa et al., 1993). Previous studies have shown that lateral IPA and the medial dentate receive convergent projections from peripheral auditory and somatosensory stimuli and produce neural models of the learned NM response following conditioning to a tone conditioned stimulus (CS). (Tracy et al, 1991, 1993, Neurosci Abs) This study replicates the same pattern of responses using a light stimuli, which is another effective CS.

Neural recordings were performed in the awake behaving rabbit. Naive rabbits received unpaired trials of light (350 msec) and air (100 msec, 3 psi). Trained rabbits were conditioned to a light (350 msec) that preceded and coterminated with an air puff to the eye (100 msec, 3 psi). Animals were trained to criteria with one day over-training. Recordings from the cerebellar deep nuclei in the naive rabbits show that the cerebellum receives projections from peripheral visual and somatosensory stimuli. Neurons throughout the deep nuclei respond to somatosensory information. The lateral IPA and the medial dentate respond to both visual and somatosensory information. In well trained animals, this same area that receives the convergence of visual and somatosensory information produces neural responses that precede and model the learned NM response. These neural models precede the learned behavior an average of 108 msec.

SUPPORTED BY: NSF (IBN9215069), NIA (AF05142), and Sankyo.

## 479.2

CEREBELLAR LESIONS PREVENT THE LEARNING OF CLASSICALLY CONDITIONED EYEBLINK RESPONSES IN MICE. S. Bao\*, L. Chen, J. J. Kim, R. F. Thompson. Neuroscience Program, Univ. of Southern Calif., Los Angeles, CA 90089-2520

Converging lines of evidence from rabbit, rat and human studies indicate that the cerebellum is essential for the delay eyeblink conditioning. In the present study, we examined whether eyeblink conditioning is feasible and whether the cerebellum is crucial for this type of learning in mice.

Adult male mice (C57BL/6J strain) were implanted with four wires (Teflon coated) subcutaneously to the left upper eyelid. Two of the wires were used to record differential electromyograph (EMG) from obicularis oculi and the other two wires were used to deliver periorbital shock. A four-pin strip connector to which the wires were soldered to was cemented to skull with dental acrylic. Animals were trained on a standard delay paradigm where conditioned stimulus (CS) was a 350-ms tone (1kHz, 83dB) and unconditioned stimulus (US) was a 100-ms periorbital shock coterminating with the CS (interstimulus interval = 250 ms). Eyelid EMG was recorded to score conditioned responses (CRs) to CS.

Eyeblink conditioning was examined in the following three groups of animals: paired, pseudo-random, and cerebellar lesioned. Animal that received paired CS-US gradually acquired CRs to the CS and reached asymptote within five days. When switched to CS-alone trials, they exhibited gradual extinction of the CRs. In contrast to paired group, animals that received pseudo-random presentations of CS and US did not acquire CRs. When switched to paired training, they gradually acquired CRs. Animals with cerebellar lesions failed to show CRs even with extensive training (10 days). Together, our results shows that eyeblink conditioning is feasible in mice and that the cerebellum plays a critical role in eyeblink conditioning. Supported by grants from NSF (IBN9215069), NIA (AF05142), and Sankyo to RFT.

## 479.4

SELECTIVE INCREASE IN HIPPOCAMPAL AMPA RECEPTOR LEVELS WITH TRACE EYE-BLINK CONDITIONING. W. Sun\*, L. Chen, S. Bao, S. Standley, G. Tocco, J. J. Kim, M. Baudry, and R. F. Thompson. Neurosciences Program, University of Southern California, Los Angeles, CA 90089-2520.

It has been shown previously that rabbits trained on the trace eye-blink conditioning paradigm showed an increase in  $^3\text{H}$ -AMPA binding in their hippocampal sections. The increase in  $^3\text{H}$ -AMPA binding may be due to an increase in the number of AMPA receptors or to an increase in the affinity of the receptor for its ligand. To distinguish the two different possibilities, we examined the hippocampal proteins for changes in AMPA receptor levels with conditioning by western blot analysis. Three groups of animals are analyzed: 1) 500 ms trace conditioning with paired tone-air, 2) pseudo-random tone-air, and 3) naive animals. Once the paired group was trained to criterion, the hippocampi from all the animals were removed. Synaptosomal fractions were prepared from each hippocampus and the protein concentrations were determined. Equal amounts of synaptosomal protein were subjected to SDS-PAGE and then transferred onto nitrocellulose. The filters were then incubated with antibodies (Chemicon) directed against specific AMPA receptor subunits GluR1-R4. Antibody against the 38 kD synaptophysin was also used as a control. The blots were scanned by HP ScanJet II and subjected to image analysis. Western blot analysis showed that in group 1 animals, there is a significant increase in the level of hippocampal GluR1 receptors as compared to those of the animals from groups 2 and 3. There is no significant difference in the level of synaptophysin among animals from the three groups. These results suggest that the increase in  $^3\text{H}$ -AMPA binding in the hippocampus associated with trace eye-blink conditioning is due to an increase in the number, rather than affinity for the ligand, of AMPA receptor GluR1.

## 479.6

INACTIVATION OF THE INTERPOSITUS NUCLEUS PREVENTS TRANSFER OF THE RABBIT'S CLASSICALLY CONDITIONED EYEBLINK RESPONSE FROM A LIGHT TO A TONE CS. B.D. Cipriano, D.J. Krupa, W. Almanza, and R.F. Thompson\*. Neurosciences program, USC, Los Angeles, CA 90089-2520.

To study the role of transfer training from one CS to another, the following procedure was used. Three groups of rabbits were each implanted with a cannula in the left interpositus (IP). Groups I and II received 7 daily sessions of paired light-airpuff training (120 trials/session). Group III was restrained during sessions 1-7 but presented with no stimuli. Prior to session 8, group I was infused with 200ng muscimol to inactivate the IP. Groups II and III were infused with saline. Session 8 for all groups consisted 120 paired tone-airpuff trials (with 20 interpolated light-airpuff trials). Group I performed no CRs to the tone or light during session 8. Session 9 (48 hrs later) was the same as session 8 with the addition with the addition of 30 tone alone trials prior to any paired trials. No infusions were given. The results of the 30 tone alone trials indicate that group I did not learn during session 8 (IP inactivated), as evidenced by baseline responding. Groups II and III both showed learning during session 8. However, the percentage of CRs performed by Group II to the tone CS during session 8 and subsequent 30 tone alone trials (session 9) was significantly higher than the percentage performed by group III, demonstrating a strong transfer of learning between the 2 CS conditions. These results indicate that the cerebellum is essential for transfer training from one CS to a second, contradicting a recent report by Welsh & Harvey (J. of Physiol, 1991). [Support: NSF (IBN9215069), NIA (AF05142), and Sankyo.]

## 479.7

**A STUDY OF HABITUATION IN THE RABBIT TO A CORNEAL AIRPUFF AT DIFFERENT INTERSTIMULUS INTERVALS AND STIMULUS INTENSITIES.** D. Iykovich\* and R.F. Thompson. Neuroscience Program, University of Southern California, Los Angeles, CA 90089-2520.

Peripheral airpuff stimulation is commonly used in classical conditioning of the defensive eyeblink response. Modulation of this response has been observed following both associative and non-associative training sessions. The present study addresses changes in reflexive eyeblink behavior to repeated airpuff stimulation in the absence of conditioned stimulus presentations.

Fifty New Zealand White rabbits were divided into 5 groups, each experiencing a different interstimulus interval (ISI): 1 s, 5 s, 10 s, 30 s, or 60 s. Each animal was given two consecutive days of unpaired airpuff alone stimulus exposure, a week of rest, then two more days of exposure. Within each group, half of the animals were presented in the first series with an airpuff intensity of 3 psi followed by 1 psi in the second series. The remaining animals experienced the reverse order. Each session consisted of 12 blocks of 9 trials (8 airpuff and 1 blank to test for anticipatory responding). Measures of response frequency and absolute and scaled (percentage change) amplitude were analyzed.

Animals responded above 90% to both stimulus intensities. Absolute response amplitudes to 3 psi were significantly higher overall. Significant response decrement (habituation) was observed within a session and the change on day 2 was greater than day 1. Scaled amplitude measures revealed an order effect for intensity: experiencing a strong stimulus facilitated later habituation to a weak one. There was no main effect of ISI on any measure, but there were complex interactions of ISI with intensity within and between days which suggest a balancing of sensitization and habituation processes described in previous electrophysiological preparations.

## 479.9

**INJECTIONS OF ANISOMYCIN INTO THE INTERPOSED NUCLEAR REGION AFFECT CONSOLIDATION OF THE CONDITIONED EYEBLINK RESPONSE.** V. Bracha\*, M.L. Webster, M.K. Stachowiak, J.R. Bloedel. Barrow Neurological Institute, Phoenix, AZ 85013.

The present experiments examined the effects of injecting anisomycin (ANI), a protein synthesis inhibitor, into the cerebellar interposed nucleus (IPN) on the acquisition and expression of the classically conditioned nictitating membrane response in the rabbit. Animals were conditioned for three days in a standard delay paradigm. Before each training session they were bilaterally injected into the IPN with 1 µl of an ANI solution. On the fourth day no drug was injected and the rabbits were tested for retention of conditioned responses (CR). All animals were further conditioned to test for any long-term effects of previous ANI applications.

The experimental group of rabbits injected with ANI during the three acquisition sessions exhibited a lower incidence of CRs than the control group of animals injected with vehicle. Importantly, animals in the experimental group exhibited a significantly lower incidence of CRs in the retention test. Animals showing ANI-affected retention of CRs acquired the CRs at a normal rate after the drug injections were discontinued. The ANI injections did not eliminate CR expression during either the initial training or in well trained animals. The results indicate that while anisomycin has few acute effects on the CR expression, it significantly reduces its retention, implying that the synthesis of new proteins in the IPN region is required for the process of consolidation of CRs between individual training sessions.

**CEREBELLAR CORTEX IS NECESSARY FOR ACQUISITION OF PAVLOVIAN EYELID RESPONSES.** Keith S. Garcia\* and Michael D. Mauk. Department of Neurobiology and Anatomy, University of Texas Medical School at Houston, Houston, TX 77030.

Recent work has shown lesions of the cerebellar cortex that include the anterior lobe disrupt the timing and prevent the extinction of Pavlovian eyelid responses (CRs). These results have motivated a reexamination of the role of the cerebellar cortex in CR acquisition with emphasis on the anterior lobe. Aspiration lesions of the cerebellar cortex were performed on well-trained rabbits. By training subjects prior to surgery the effects of aspiration lesions on CR timing can be used as a functional indication that lesions have damaged the anterior lobe and that input and output pathways necessary for CR expression remain intact. Rabbits that showed disrupted CR timing following surgery were unable to acquire CRs when trained for 15 days with a novel conditioned stimulus (CS), although this CS supported acquisition in the opposite eye. These data suggest that Pavlovian eyelid conditioning is mediated by converging CS and unconditioned stimulus pathways in the cerebellar cortex and support the notion of two sites of plasticity in the cerebellum -- one site in the cerebellar cortex important for timing, and one site in the cerebellar nucleus that mediates the short-latency CRs. In addition, this work provides evidence that inhibitory input from the cerebellar cortex regulates or contributes to the induction of plasticity in the cerebellar nuclei.

**SUPPRESSION OF RABBIT'S TRACE-CONDITIONING NICTITATING MEMBRANE RESPONSE BY SCOPOLAMINE.** T. Kaneko\* and R. F. Thompson, Neuroscience Program, Univ. of Southern California, Los Angeles, CA 90089-2520

It has been reported that scopolamine, a muscarinic acetylcholine receptor antagonist, delayed the rate of acquisition in classical conditioning of the rabbit nictitating membrane response on delay paradigm. However, no information is available concerning trace paradigm, even though an important role of the hippocampus, one of the main targets of cholinergic innervation in the brain, in trace conditioning has been suggested. In this study we have examined to what degree the cholinergic systems were involved in trace conditioning of rabbits by means of a simple pharmacological manipulation.

Rabbits were trained on a trace paradigm in which a 250 ms tone CS and a 100 ms airpuff US were presented with 500 ms i.s.i. Each training session a day was consisted of 10 tone alone, 10 airpuff alone and 80 paired trials. Scopolamine hydrobromide 0.03 or 0.1 mg/0.5 ml/kg, or saline 0.5 ml/kg was injected subcutaneously 15-20 min prior to daily training session.

In average, control animals having saline injections (n=5), showed more than 80% of CRs by training day 10. On the other hand, averaged CR percentage of rabbits having scopolamine 0.03 mg/kg (n=4) gained a plateau of about 60% after 12 days of training, and one of the animals failed to reach a criteria of learning (8 CRs out of consecutive 9 trials). None of 5 rabbits treated with the higher dose of scopolamine satisfied a criteria within 12 days of training. The averaged CR percentage of these animals remained about 10% through the period of training. On day 13, scopolamine 0.1 mg/kg, s.c. given to control animals decreased CRs, but still more than 50% of CRs was observed. CR percentage of these animals returned to the previous level on day 14 when rabbits treated with saline. In rabbits having treated with scopolamine 0.1 mg/kg, CR percentage gradually increased when scopolamine was switched to saline from day 13.

**STOCHASTIC SIMULATIONS OF CEREBELLAR-MEDIATED MOTOR ADAPTATION.** Javier F. Medina and Michael D. Mauk\*. Department of Neurobiology and Anatomy, University of Texas Medical School at Houston, Houston, TX 77030.

Our lab has previously developed a linear mathematical model to study synaptic plasticity in the cerebellum. This model is based on the well characterized cerebellar synaptic organization and specific synaptic plasticity rules at Granule to Purkinje (Gr→Pjk) and Mossy fiber to Nucleus (MF→Nuc) synapses. We use stochastic computer simulations to study the possible influences of biologically relevant non-linearities on the predictions of the linear model. Empirical data from eyelid conditioning, a simple form of cerebellar-mediated motor learning, is then used to test the results from these simulations. During an eyelid conditioning training trial, an unconditioned stimulus (US), which is simulated as an increase in the excitatory drive to climbing fibers, is paired with a conditioned stimulus (CS), modeled as consistent changes in the activities of specific subsets of Gr→Pjk and MF→Nuc synapses from their background activity levels.

Simulations show that after acquisition, the model is capable of acquiring conditioned responses (CRs) as measured by increases in nuclear cell activity. Previous theoretical work suggests that during a conditioning trial only one subset of MF→Nuc but many different subsets of Gr→Pjk synapses are active. Using this assumption, simulations are capable of reproducing not only the net effect of training on the strength of CS-US associations but also capture key behavioral features of eyelid conditioning such as the ISI function and the form and timing of the conditioned response.

**TEMPORARY INACTIVATION OF THE CEREBELLUM PREVENTS THE EXTINCTION OF CONDITIONED NICTITATING MEMBRANE RESPONSES.** Rammani N.\*, Hardiman M.J. and Yeo C.H. Neuroscience and Behaviour Group, Department of Anatomy, University College London, London WC1E 6BT, U.K.

The classically conditioned nictitating membrane response (NMR) of the rabbit is associative learning of a simple motor response and is critically dependent upon the cerebellum. Destructive lesions of parts of the olivo-cerebellar system abolish or impair conditioned responses (CRs) (Yeo, Ann. N.Y. Acad. Sci., 627:292-304, 1991). Such lesions may impair CRs either because the cerebellum is actively engaged in learning, or because lesions interfere with the execution of learned responses. Reversible lesions can be used to distinguish between these possibilities. One such study shows that acquisition is impaired during muscimol inactivation of the interpositus nucleus of the cerebellum, but subjects acquire CRs normally after the blockade (Krupa et al. Science 260:989-991, 1993). The cerebellum is therefore actively engaged in the acquisition of CRs. The same circuitry may also be essentially involved when there is extinction of NMR conditioning. Here we have examined the effects of muscimol blockade of the cerebellum during the extinction of previously acquired conditioning. Rabbits were implanted with cannula guides near the right interpositus nucleus of the cerebellum, and were given 4, daily sessions of NMR delay conditioning (tone CS, periorcular electrical stimulation US, 100 trials per session, 90 CS-US, 10 CS alone). 4 daily sessions of extinction training (100 trials, CS alone) under muscimol then began. 1 µl of muscimol (1.54 nmol) was infused over 1 min, 1 hour before each session. 4 more extinction sessions were then given without muscimol. Expression of CRs at the beginning of the first of these sessions was at the same maximal level as trained, unextinguished animals. These extinguished at the same rate as CRs of controls extinguishing for the first time. **Muscimol blockade of the interpositus nucleus prevented the extinction of conditioned NMRs, so normal cerebellar function is essential for extinction. The neural circuitry underlying acquisition and extinction of conditioned NMRs may be the same.**

## 479.13

REVERSIBLE INACTIVATION OF THE CEREBELLUM WITH MUSCIMOL PREVENTS THE ACQUISITION AND EXTINCTION OF CONDITIONED NICTITATING MEMBRANE RESPONSES IN RABBITS.

Hardiman, M.J., Ramnani, N., Gilbert, P.F.C., Yeo, C.H. Department of Anatomy, University College London, London WC1E 6BT, U.K.

We used muscimol to inactivate the cerebellum and test its involvement in acquisition and extinction of conditioned nictitating membrane responses. In 4 rabbits we implanted a guide cannula close to the interpositus nucleus of the cerebellum (Muscimol Group). In the acquisition phase of training each rabbit was injected with muscimol (1.54nmol in 1µl of PBS, pH7.4) 1 hour before delay conditioning. This procedure was repeated for 4 daily sessions of 100 trials (90 CS-US paired; 10 CS alone; CS - tone; US - periorcular electrical stimulation). There were very few conditioned responses (CRs) in these training sessions. After 3 days subjects were then trained for 4 more sessions without injections of muscimol. There were no CRs on initial trials of the first session of retraining but all subjects produced CRs by the end of this session. Three of these subjects then underwent 4 daily sessions (100 trials, CS alone) of extinction training with muscimol and no CRs were produced. After 3 days there were 4 daily sessions of extinction training without muscimol. On the first of these sessions, all subjects immediately produced high levels of CRs. These responses then extinguished within and between sessions with characteristic beginning-of-session spontaneous recovery. Control subjects either remained in their home cages (Naive Group, n=4) or were placed in the experimental chambers but received no stimuli (Sit Group, n=4) during sessions equivalent to those of the Muscimol Group when the muscimol was delivered. Muscimol subjects neither acquired nor extinguished under muscimol blockade, but when trained after the blockade had lifted then did so at rates similar to those of the appropriate controls. We conclude that circuitry essential for both the acquisition and extinction of this simple form of motor learning includes the cerebellum.

Effect of the Red Nucleus Lesion on the Hippocampal Multiple Unit Activity. J.W. Ryou\*, S.Y. Cho, and H.T. Kim. Dept. of Psychology, Korea Univ., Seoul, 136-701, Korea.

Sears et al. (Behav. Neurosci. 104, No. 5, 1990) showed that learning-related multiple unit activity (MUA) developing in the hippocampus during the classical conditioning of nictitating membrane response depends on the intactness of the cerebellar interpositus nucleus. The cerebellar interpositus nucleus is known to be an essential neural structure for this conditioning, and a place representing time-amplitude neural model of the conditioned response (CR). Lesioning the interpositus nucleus, therefore, obstructs the learning itself and as a result, the hippocampal MUA can not develop. In case the red nucleus receiving the projection from the interpositus nucleus is lesioned, the learning-related MUA in the interpositus nucleus can be recorded (Chapman et al., Brain Res. 537, 1990), which is possibly interpreted as the learning is established but the performance of CR is blocked. The present study was conducted to determine if the learning-related MUA could be developed in the hippocampus after lesioning the red nucleus in the output pathway of the interpositus nucleus. Rabbits were given unilateral electrolytic lesions of the red nucleus before the conditioning sessions (CS: 550msec tone, US: 100msec air puff, ISI: 450msec). They just showed 8% or less CRs by the end of the 8th session, whereas the control animals showed on an average 80% or more CRs by the 4th session ( $F(1,10)=187.84$ ,  $p<0.001$ ). The control group showed typical increases of hippocampal MUA in the process of learning, while the group with the red nucleus lesion did not show the increase of hippocampal MUA in the CS period ( $F(1,10)=10.67$ ,  $p<0.05$ ). These results suggest that the learning-related input from the interpositus nucleus via the red nucleus may be critical for the normal MUA development in the hippocampus.

TISSUE PLASMINOGEN ACTIVATOR INDUCTION DURING CEREBELLAR MOTOR LEARNING. N.W. Seeds\*, B.L. Williams and P.C. Bickford. Neuroscience Prog., MSTP, Depts. Biochem/B/Genetics and Pharmacology, Univ. Colorado H.S.C., Denver, CO 80262.

The cerebellar cortex is implicated in the learning of complex motor skills. Motor learning is thought to involve the modulation of mossy fiber input to cerebellar Purkinje neurons via climbing fiber activity. Studies suggest that this modulation may require synaptic remodeling of Purkinje cell inputs. The possibility that an extracellular serine protease, tissue plasminogen activator (tPA) which plays an important role in remodeling of various non-neural tissues and is associated with developing and regenerating neurons, may be activated during motor learning was explored. In situ hybridization shows that tPA mRNA expression is dramatically increased in Purkinje neurons within an hour of training rats for a complex motor task. By 4 hrs. after training tPA mRNA appears to spread into the molecular layer; however, this induction is transient and tPA mRNA levels are quite low by 24 hrs. after the learning task. Neither untrained animals nor exercised rats showed a specific increase in tPA mRNA expression. Similarly, antibody to tPA visualized the induction of tPA protein associated with cerebellar Purkinje cells. This induction of tPA mRNA and protein during motor learning may play a role in activity dependent synaptic plasticity and remodeling of Purkinje cell inputs. (Supported in part by grants from NIH, NSF, and NIMH)

## 479.14

PAIRING-SPECIFIC DEPRESSION OF PURKINJE CELL EPSPS RESULTS FROM A CLASSICAL CONDITIONING PROCEDURE IN THE RABBIT CEREBELLAR SLICE. B.G. Schreurs\*, M.M. Oh and D.L. Alkon. Lab. of Adaptive Systems, NINDS, NIH, Bethesda, MD 20892.

We simulated classical conditioning in a rabbit cerebellar slice by stimulating parallel fiber inputs to Purkinje cells using a brief, high frequency train of eight constant-current pulses 80 ms before climbing fiber inputs were stimulated using a brief, lower frequency train of three constant-current pulses. Intracellularly recorded Purkinje cell excitatory post synaptic potentials (EPSPs) underwent a long-term reduction in amplitude following paired stimulation (30%,  $n=10$ ,  $p<0.01$ ) but not following unpaired ( $n=11$ ) or parallel fiber alone stimulation ( $n=10$ ). We call this phenomenon pairing-specific depression (PSD). Facilitation of a second EPSP occurred both before and after paired stimulation, suggesting the locus of PSD was not presynaptic. Depression of a depolarizing response to focal application of glutamate following pairings added support to a postsynaptic locus for the PSD effect. Pairing-specific depression occurred both in the presence and absence of bicuculline. The potentiation of EPSPs by aniracetam (40%) was abolished after pairings. Removal of aniracetam from the bath 20 min following pairings revealed normal levels of PSD suggesting that the effect did not result from direct desensitization of AMPA receptors. Incubation in the protein kinase inhibitor H7 potentiated EPSPs (9%) but these values returned to baseline following pairings. The net reduction in EPSP amplitude of less than 10% following pairings suggested that H7 blocked PSD and that PSD may be mediated by protein kinases. Unlike LTD, PSD may be obtained using the sequencing and timing of stimulation appropriate for classical conditioning in the intact animal.

## 479.16

Kainic acid Lesions of the Cerebellar Interpositus Nucleus Abolished the Conditioned Neural Activity in the Hippocampus. H.T. Kim\*, K.J. Lee, and J.W. Ryou. Dept. of Psychology, Korea Univ., Seoul, 136-701, Korea.

The cerebellum and the hippocampus are known to be neural structures involved in the classical conditioning of nictitating membrane response of the rabbit. The neural activity related to learning, the conditioned multiple unit activity (MUA), can be observed in both the structures. It could be possible that the learning-related neural activity is established simultaneously in the interpositus nucleus and in the hippocampus, or hierarchically. The rabbits used in this study were chronically implanted with a 23 gauge of outer cannula in the region of the cerebellar interpositus nucleus and with a recording electrode (insulated insect pin #00) in the CA3 region of the hippocampus. The standard delay conditioning (CS: 400msec tone, US: 100msec air puff, ISI: 300msec) was performed. At the time when the learning rate reached 80%, kainic acid (0.3µL, 2mg/ml, Sigma) was injected into the interpositus nucleus of the experimental group while saline (0.9%, 0.3µL) the control group. And then training was resumed on the rabbit. Consequently, the injection of kainic acid abolished not only the conditioned behavioral response ( $F(1,11)=281.55$ ,  $p<0.01$ ) but also the conditioned increase in neural activity of hippocampus ( $F(1,11)=17.85$ ,  $p<0.01$ ), which had developed before the lesion. These results are consistent with those of Clark et al. study (Brain Res. 291, 1984), and suggest that the learning-related MUA in the hippocampus might depend on the input from the cerebellum.

## 479.18

CONDITIONED ENHANCEMENT OF THE EARLY COMPONENT OF THE RAT EYEBLINK REFLEX. Y.-W. Lam\*, A. Wong, T. Canli and T.H. Brown. Depts. of Psychology and Cellular and Molecular Physiology, Yale University, New Haven, CT. 06520.

The orbicularis oculi (oo) muscle contributes the main force for the closing phase during an eyeblink in the rat. The EMG response in the oo muscle during an eyeblink consists of early (R1) and late (R2) components. The circuitry underlying the rat R1 response is relatively simple, consisting of only two central synapses. Here we explored the effects of fear conditioning on the rat R1 response.

Forty-two male Sprague-Dawley rats were randomly divided into three groups: a CS-US paired group, where subjects were trained with paired presentations of a tone CS and a footshock US; a CS-US unpaired group, in which subjects received the same number of CS and US presentations but they were explicitly unpaired; and a CS-alone group, where subjects were preexposed to the same number of CS presentations but had no experience with the US. In the subsequent testing session, eyeblinks were elicited by directly stimulating the 5th nerve. The magnitude of the integral of the full-wave-rectified R1 response was compared in the presence and in the absence of the CS.

A one-way ANOVA revealed a significant group effect on the percentage enhancement,  $F(2,39)=5.93$ ,  $p<0.01$ . Planned contrasts showed significant CS-produced R1 enhancement in the CS-US paired group (61.1%) and the CS-alone group (16.7%) but not in the CS-US unpaired group (0.7%). Post hoc comparisons revealed significantly greater enhancement in the CS-US paired group than in the other two groups (Tukey HSD,  $p<0.05$ ), indicating a pairing-specific component of CS-produced R1 modulation in rat. Supported by NIH.

## 479.19

**Effects of Amygdala Lesions on Second-Order Pavlovian Conditioning.** T. Hatfield<sup>1</sup>, J. S. Han<sup>1</sup>, P. C. Holland<sup>2</sup> and M. Gallagher<sup>1</sup>, <sup>1</sup>Department of Psychology, University of North Carolina, Chapel Hill, NC 27599, <sup>2</sup>Department of Psychology, Duke University, Durham, NC 27706. Second-order conditioning is often used to measure whether a conditioned stimulus (CS) that had previously been paired with an unconditioned stimulus (US) can subsequently serve as a reinforcer. One function commonly attributed to the amygdala complex is learning the biological significance of events through which conditioned stimuli (CSs) acquire rewarding or aversive properties. As a further test of this idea, the present study examined the effects of neurotoxic amygdala lesions on appetitive second-order conditioning. In the second-order conditioning behavioral paradigm, following light-food pairings, rats are given tone-light pairings in the absence of food. Rats that received large neurotoxic lesions of the amygdala failed to acquire second-order conditioning. In a second experiment, rats with small neurotoxic lesions confined to the amygdala central nucleus acquired second-order conditioning indistinguishable from intact control rats. Currently, the effects of neurotoxic lesions confined to the amygdala basolateral complex are being examined. The results of this experiment in combination with the other studies should help to define whether a specific subsystem in the amygdala is critical for the acquisition of a CS's reinforcing properties in appetitive Pavlovian conditioning. Further, a differential behavioral effect of ABL and CN damage could support the idea that such reinforcing properties of a CS are mediated through amygdalo-ventral-striatal circuitry. Supported by an award from the Human Frontier Science Research Program and a Research Scientist Award (KO5-MH01149) to MG.

## 479.21

**HYPEREXCITABILITY: EXAGGERATED FEAR-POTENTIATED STARTLE PRODUCED BY PARTIAL AMYGDALA KINDLING.** J.B. Rosen<sup>1</sup>, E. Hamerman<sup>2</sup>, M. Sitcoske<sup>1</sup>, J.R. Glowa<sup>3</sup> and J. Schulkin<sup>2</sup>, <sup>1</sup>Biol. Psychiat. and <sup>2</sup>Clin. Neuroendocrinol. Brs., NIMH, and <sup>3</sup>Lab. Med. Chem., NIDDK, Bethesda, MD 20892.

The present study asked whether a hyperexcitable amygdala would have an effect on the expression of conditioned fear-potentiated startle. Rats were trained to be fearful of a light by pairing light and footshock together 5 times. During the following two days the amygdala or hippocampus was made hyperexcitable in half of the rats. Hyperexcitability was produced by delivering electrical stimulation bilaterally to the amygdala or hippocampus on two consecutive days which induced electrographic afterdischarges but no behavioral seizures (i.e., partial kindling). The following day, rats were tested for fear-potentiated startle. Amygdala kindled rats displayed more than twice the startle amplitude in the presence of the light compared to sham kindled rats, indicating exaggerated fear-potentiated startle in the amygdala kindled rats. Enhanced startle in the presence of the light was also found in the hippocampus kindled rats, but was no greater than the startle amplitude of sham kindled rats. Expression of c-fos mRNA, which was used as a marker for neuronal activation, was induced throughout the limbic and neocortex by partial amygdala kindling. In contrast, partial hippocampus kindling induced c-fos mRNA expression in the dentate gyrus, CA1, CA2 and CA3 only. These experiments demonstrate that following kindled-induced hyperexcitability of the amygdala and limbic cortices, rats exhibit exaggerated conditioned fear-potentiated startle. Hyperexcitability of amygdala fear circuits may be important for the evolution of fear states to pathological anxiety states.

## 479.23

**RELEASE OF CALCITONIN GENE-RELATED PEPTIDE IN THE LATERAL AMYGDALA MAY BE IMPORTANT FOR THE EXPRESSION OF AUDITORY FEAR CONDITIONING** L.H. Poore\* & F.J. Helmstetter  
Department of Psychology, University of Wisconsin, Milwaukee, WI 53201

Previous work has shown that the amygdala is critical for the acquisition and expression of Pavlovian fear conditioning in the rat. When auditory signals are used to predict the occurrence of a UCS this information reaches the lateral nucleus of the amygdala (LA) via the auditory cortex and via a direct projection to the amygdala from the medial geniculate nucleus (MG). This projection from MG to LA contains calcitonin gene-related peptide (CGRP) and we have recently shown that injections of CGRP into the LA of rats will produce behavioral effects which closely resemble normal fear responses. We have also shown that application of CGRP or the putative CGRP receptor antagonist hCGRP<sub>8-37</sub> to the LA prior to a training session in which auditory stimuli are paired with shock will affect the learning of fear responses measured 24 hr later. In the present study we investigated the effects of blocking CGRP receptors in the LA during the expression of fear-related CRs. Adult male rats were implanted with bilateral cannulae in the LA. During training rats received an injection of saline in LA and were exposed to 4 paired presentations of white noise (72dB/10sec) and foot shock (2mA/1sec) in a distinctive observation chamber. One the next day separate groups of rats were pretreated with hCGRP<sub>8-37</sub> (0.63nM, 0.63mM) or saline and observed for freezing behavior. One half of the animals were returned to the observation chamber in which training was conducted while the remaining rats were given a single white noise presentation in a distinctly different chamber. Blocking CGRP receptors selectively attenuated fear to the auditory CS. Since lesions of the lateral parabrachial nucleus (which provides the only other significant CGRP input to the amygdala) do not produce similar results these studies suggest that CGRP is released in LA by MG neurons during the expression of fear.

## 479.20

**CONDITIONED ORIENTING BEHAVIOR IS MEDIATED BY THE AMYGDALO-NIGROSTRIATAL PATHWAY.** J. S. Han<sup>1</sup>, R. W. McMahan<sup>1</sup>, P. C. Holland<sup>2</sup>, M. Gallagher<sup>1</sup>, <sup>1</sup>Dept. of Psychology, Univ. of North Carolina, Chapel Hill, NC 27599, <sup>2</sup>Dept. of Psychology, Duke University, Durham, NC 27706.

Rats with neurotoxic lesions of the amygdala central nucleus (CN) fail to acquire conditioned orienting responses that are normally learned with conditioned stimulus (CS)-unconditioned stimulus (US) pairings (Gallagher et al. J. Neurosci. 10: 1906, 1990). The CN projects ipsilaterally to an area of the substantia nigra (SN) that innervates dorsolateral striatum. Based on evidence that orienting to sensory cues depends on SN input to dorsolateral striatum, a crossed-lesion model was employed to determine whether this pathway is used to express conditioned orienting responses. Unconditioned orienting to a light (that was later used as the CS) was first tested. Rats were then conditioned for 10 days with 5 trials per day consisting of a 10-sec light (CS) followed by 2 food pellets (US). There were no differences between the control group and the unilateral lesion groups - either an ibotenic acid lesion of CN or unilateral 6-OHDA lesion of the striatum - in the occurrence or habituation of unconditioned orienting (rear to light), in acquisition of the conditioned orienting response, or learning to approach the food cup during the CS. Relative to those groups, rats with the crossed lesion consisting of a unilateral CN lesion and contralateral striatal lesion showed deficits only in the acquisition of the conditioned orienting response. These results support our proposal that conditioned orienting behavior is mediated by the amygdalo-nigrostriatal pathway. Supported by an award from the Human Frontier Science Research Program and a Research Scientist Award (KO5-MH01149) to MG.

## 479.22

**THE ROLES OF THE AMYGDALA AND BED NUCLEUS OF THE STRIA TERMINALIS (BNST) IN THE ACQUISITION OF FEAR POTENTIATED STARTLE USING BOTH EXPLICIT AND CONTEXTUAL CUES.** M. Davis\*, J. C. Gewirtz, K. A. McNish, and M. Kim, Depts. of Psychiatry and Psychology, Yale Univ. Sch. of Med., New Haven, CT 06508.

The effects of lesions of the central nucleus of the amygdala and the BNST on the acquisition of fear-potentiated startle to both explicit and contextual cues were examined in two experiments. Over repeated experimental sessions rats were given two presentations of a 3.7-s light CS which terminated with a 0.5-s, 0.6-mA footshock US. To assess fear-potentiated startle, each session also included presentations of a 50-ms, 95-dB startle-eliciting stimulus alone, and of the same stimulus in the presence of the visual CS. We previously reported that bilateral electrolytic lesions of the central nucleus of the amygdala blocked acquisition of fear-potentiated startle to the visual CS (explicit cue conditioning, Kim and Davis, 1993). In Experiment 1, these same lesions also blocked acquisition of fear-potentiated startle to the startle-eliciting stimulus alone (context conditioning). In Experiment 2, bilateral electrolytic lesions of the BNST had no effect on the acquisition of fear-potentiated startle to the visual CS. However, the same lesions completely blocked the acquisition of fear-potentiated startle to the experimental context. These data suggest that the acquisition of fear to an explicit cue is dependent upon processes involving the amygdala, whereas the acquisition of fear to contextual cues is dependent upon both the amygdala and the BNST.

Interestingly, the BNST receives extensive projections from the hippocampus, and projects to similar hypothalamic and brainstem targets as the amygdala. The BNST may therefore be critical for the elicitation of autonomic and behavioral responses associated with contextual fear conditioning, just as the amygdala is critical for the elicitation of similar responses associated with explicit cue conditioning.

## 480.1

LTP IN RECURRENT NETWORKS GENERATES SEQUENCE LEARNING AND PREDICTION Kenneth L. Blum<sup>1</sup> and L. F. Abbott<sup>2</sup>  
<sup>1</sup>Dept. Brain and Cognitive Sciences, MIT, Cambridge, MA 02139, and  
<sup>2</sup>Center for Complex Systems, Brandeis Univ., Waltham, MA 02254.

Neuronal ensembles with recurrent feedback connections can store and recall sequences of population-coded inputs if NMDA-mediated LTP is active. In our model the ensemble activity of a network of neurons initially encodes the current value of a sensory input. We then train the network with repeated presentations of a given sequence of inputs. We assume that synapses between encoding neurons are modified during training by NMDA-mediated LTP with properties similar to those seen in slice experiments. After training, the population firing pattern of the network shifts so that the ensemble response to sensory input predicts future inputs in the training sequence. This effect arises automatically from the temporal asymmetry of LTP induction.

If the output of the network we study is fed to a motor system, the predictive power of the network can be used to generate motor sequences. The motion is executed by a feedback loop: the motor system chases the target provided by the coding network which responds to the arm position generated by motor activity.

In the conventional analysis of recurrent networks, feedback dominates inputs and a briefly presented input evolves quickly to a fixed-point. In contrast, the 'response-driven' memory we propose involves weaker recurrent feedback, so input about the current state of the system dominates network activity. This means that motor sequences can be generated at any desired speed and that the resulting movement is stable to perturbations.

## 480.3

PATTERN RECOGNITION BY A CIRCUIT MODEL OF DENDRITIC SPINES. K.T. Blackwell<sup>1</sup>, T.P. Vogl<sup>1</sup>, D.L. Alkon<sup>2</sup>. <sup>1</sup>Environmental Research Institute of Michigan, Arlington, VA 22209; <sup>2</sup>Laboratory of Adaptive Systems, National Institute of Neurological Disorders and Stroke, NIH, Bethesda, MD 20892

The properties of biological pattern matching were investigated in a circuit model of a piece of dendritic membrane with a number (1-10) of dendritic spines. Each spine head is modeled as a synaptic conductance in parallel with a calcium dependent potassium conductance. Each spine neck is modeled as an axial resistor and all the spines are attached to a common dendritic membrane compartment. In *Hermisenda* and in hippocampal CA1 cells, classical conditioning causes a decrease in conductance of the calcium dependent potassium channel (Alkon, Science, 1984; Sanchez-Andres and Alkon, J. Neurophysiology, 1991). In the model, the effect of classical conditioning is represented by adaptation of the calcium dependent potassium channel to the intra-spine calcium concentration consequent to repeated stimulus presentations. Computer simulations show that the model's dendritic membrane depolarization is greater in response to a previously learned pattern of synaptic inputs than in response to a novel pattern of synaptic inputs. These simulations, in combination with analysis of the circuit equations, reveal that when the synaptic input pattern is similar to the learned pattern of synaptic inputs, total dendritic depolarization is a linear combination of dendritic depolarization contributed by individual spines. When as few as one synaptic input differs markedly from the learned value, dendritic depolarization is a non-linear combination of individual spine depolarizations. These properties are captured in a simplified set of equations which satisfies the computational requirements for a practical similarity measure for artificial neural networks.

MASSIVELY PARALLEL COMPUTER SIMULATIONS OF LARGE-SCALE NEURAL NETWORKS: APPLICATION TO GRANULE-GOLGI CELL DYNAMICS DURING EYELID CONDITIONING. G.T. Kenyon<sup>\*</sup> and M.D. Mauk. Department of Neurobiology and Anatomy, University of Texas Medical School, Houston, TX 77225.

We have implemented a general purpose neural simulator on a massively parallel computer (CM-5). Since many biological neural networks consist of a large number of neurons drawn from a limited number of types, massively parallel computers represent a natural platform for such systems. A considerable increase in computational performance is obtained since the massively parallel architecture allows the internal dynamical variables of all neurons of a given type to be updated simultaneously. Because synaptic interactions require general communication between processors, this step might be expected to be rate limiting. However, when multiple synapses converge on the same target, the associated impulses are summed linearly, which effectively addresses the problem of collisions. Membrane potentials are updated using a parallel version of the Hines algorithm for solving the multi-compartment diffusion equations and the threshold dynamics is modeled as an integrate-and-fire process. The simulator allows for the arbitrary specification of conductance kinetics, dendritic morphology, and connectivity patterns for each neuron type. The simulator additionally allows the user to configure arbitrary patterns of sensory input corresponding to different experimental protocols. An analysis package, fully optimized for the massively parallel architecture, allows the results of the simulation to be displayed using a variety of electrophysiological measures, including raster plots, intracellular records, and massed post-stimulus time and cross-correlation histograms. The simulator is currently being used to study the dynamics of granule-Golgi cell interactions in the cerebellar cortex during simulated eyelid conditioning. Preliminary results have better characterized the physiological factors that influence the response of the granule cell population vector to changes in the mossy fiber input elicited by the CS.

WHAT THINKING OF NEURONS AS BINARY UNITS MISSES OUT A. Treves<sup>1</sup>, S. Panzeri<sup>1</sup>, E.T. Rolls<sup>2</sup>, K.M. Gothard<sup>3</sup> and W.E. Skaggs<sup>3</sup>. <sup>1</sup>SISSA, Cognitive Neuroscience, via Beirut 2-4, 34013 Trieste, Italy  
<sup>2</sup>Dept. of Experimental Psychology, Univ. of Oxford, OX1 3UD, UK  
<sup>3</sup>Neural Systems, Memory and Aging, Arizona Res. Labs, Tucson, USA.

The all-or-none nature of the action potential has made attractive the notion that CNS neurons may be modelled, to a first approximation, as binary elements, that at any moment in time are either firing or quiescent. Connections have related these two states to the truth or falsehood of underlying predicates, computer scientists have considered neuronal circuits in the context of digital processing, and statistical physicists have imported mathematical techniques developed for spin systems. The complex set of time scales associated with neuronal processing obviously makes neuronal dynamics much richer than could be described in binary terms. One consequence is that, even when the same computational mechanisms may operate for both binary units and real neurons, they operate with very different efficiency. We have quantified the effect in some cases. a) The amount of information conveyed by the firing rate of single cells in the primate temporal cortex about visual stimuli is compared with what could be conveyed by ideal binary units, and with what would be conveyed by binary units that responded in the same way as real neurons. b) The information conveyed by populations of rat hippocampal cells about the rat location is measured for different time windows, from very short ones in which neurons can be regarded as effectively binary, through intermediate ones related to the theta rhythm, to windows as long as compatible with rat motion. c) The information that may be stored and retrieved with associative memories made of graded-response units is compared across different structures of memory representations, from binary to continuously graded.

These quantitative analyses yield insights on the differences, in general, between binary and neuronal processing.

## 480.4

RECOGNITION AND RECALL IN DISTRIBUTED MEMORY MODELS. M.J. Kahana<sup>\*</sup> & J. Lisman<sup>\*</sup>. Volen National Center for Complex Systems, Brandeis University, Waltham, MA 02254.

Distributed memory models have been able to provide a unified account of data on recognition and recall as well as numerous other effects in the human memory literature. These models are now challenged with accounting for data on the contingency relations between different memory tasks. Data from successive testing experiments yield moderate correlations (~0.5) when item recognition is followed by cued recall. In contrast, associative recognition followed by cued recall yield very high correlations (~0.9). A theoretical analysis demonstrated that models which assume separate representations for item-specific and relational information (e.g., Metcalfe, 1989; Murdock, 1989) predict independence between item recognition and cued recall and perfect dependence between associative recognition and cued recall. These models generally fail to consider the effects of encoding variability in storage and retrieval processes. Once included, these sources of variability have opposing effects on the correlations. Encoding variability increases the correlation whereas retrieval variability decreases it. Using a mixed-list / pure-list design we obtained experimental evidence supporting the claim that encoding variability actually increases the observed correlation between item recognition and cued recall.

## 480.6

A MODEL NETWORK THAT PERFORMS BOTH SHORT-TERM AND LONG-TERM MEMORY. O. Jensen, M.A.P. Idiart<sup>\*</sup> and J.E. Lisman<sup>\*</sup>. Center for Complex Systems, Brandeis University, Waltham MA 02254-9110

In a previous model we showed that the continued firing that maintains short-term memory might be due to a known intrinsic cell property, the depolarizing afterpotential that is triggered by action potentials. We showed that when neurons with this property are embedded in an oscillatory network, the network could maintain 7 different memories, each in a different ("40 Hz") subcycle of a theta-frequency oscillation (*Science* 267:1512, 1995). Here we extend this model by incorporating excitatory recurrent collaterals among neurons (as in Hopfield nets), with each synapse modified according to a Hebb rule. Our simulations show that this hybrid model preserves both the short-term memory capability of our original model and the long-term memory capability typical of Hopfield nets. Moreover, the repetition of firing patterns caused by the short-term mechanism causes a natural transition of information into the slowly modifiable synapses that encode long-term memory. Interestingly, the build up of long-term memory provides an error correction mechanism for the firing associated with short-term memory.

## 480.7

**MAXIMAL INFORMATION TRANSFER IN SPIKING NEURONS.** B.A. Pearlmutter\* and L.C. Parra. Siemens Corporate Research, 755 College Road East, Princeton, NJ 08540.

It is known that an exponential distribution of inter-spike intervals maximizes the rate of information transmitted by a spiking neuron. We first show that this holds even in the presence of a refractory period  $\Delta$ , giving a "front porch exponential" density

$$p(s) = \begin{cases} s < \Delta & 0 \\ s \geq \Delta & (1/\tau) \exp(-(s-\Delta)/\tau) \end{cases}$$

We then derive a relationship among the time constant  $\tau$ , the refractory period  $\Delta$ , and the standard deviation of the noise in spike timing  $\sigma$ , assuming  $\sigma \ll \Delta$ ,

$$\frac{\Delta}{\sigma} = \frac{\tau}{\sigma} \left( \log \frac{\tau}{\sigma} - \frac{1}{2} \log(2\pi e) \right)$$

If neurons truly maximize only their coding efficiency, the predicted relationship between the optimal time constant  $\tau$  and the physiological characteristics of the neuron should be observable. Somewhat surprisingly, if the neuron maximizes its bit rate under a limited energy budget, the ISI distribution retains its exponential form. An extra parameter  $\alpha$  that trades off energy against bits is introduced,

$$\frac{\Delta}{\tau} = \log \frac{\tau}{\sigma} - \frac{1}{2} \log(2\pi e) - \alpha \left( \frac{\tau}{\sigma} + \frac{\Delta}{\sigma} \right)^2$$

We are currently searching for a system sufficiently controlled and biophysically characterized to allow these relations to be tested.

## 480.9

**INCORPORATING SYNAPTIC FAILURES INTO A CA3 NEURAL NETWORK.** D.A. August\* and W.B. Levy. Dept. of Neurosurgery, Univ. of Virginia, Charlottesville, VA 22908.

Some brain areas may operate with a high rate of synaptic failure. We have investigated the effect of synaptic transmission failures on the sequence-learning and sequence-prediction ability of a simplified network model of hippocampal area CA3. The network consisted of input (EC) and output (CA3) layers, as well as feedforward and feedback inhibitory units. The CA3 layer had a sparse (10%) recurrent connectivity. During learning, a sequence of slowly-shifting input patterns was presented to the EC layer. After learning, the network was tested with the first pattern of this sequence, and then allowed to relax.

We performed two simulations to study the effects of quantal noise on this network. In the first experiment, synaptic weights were modified by a Hebbian rule, and transmission failures occurred stochastically with a fixed probability. Synaptic failure probability (at recurrent CA3-CA3 synapses, and CA3-inhibitory synapses) were varied between  $p = 0.125$  and  $p = 0.5$ . In the second experiment, the synaptic weights were fixed, and the probability of reliable synaptic transmission was modified with a Hebbian rule. Two properties were observed in both experiments. First, the noisy networks required less inhibition to properly recall a sequence than the noise-free networks. Second, for certain levels of recurrent inhibition (less than the amount needed for recall), the network performed sequence prediction. That is, network replayed the sequence faster than it was learned. Thus, the presence of quantal failures modulated the effect of inhibition. Supported by NIH grants MH10702 to DAA and MH00622 to WBL.

## 480.11

**A DYNAMICAL NEURAL NETWORK MODEL OF MISMATCH NEGATIVITY AND THE UNDERLYING MEMORY TRACE.** P. May<sup>(1)</sup>, J. G. Taylor<sup>(1)</sup>, H. Tiitinen<sup>(2)</sup>, I. Winkler<sup>(2)\*</sup>, and R. Näätänen<sup>(2)</sup>, (1) Dept. Mathematics, King's College London, WC2R 2LS, UK. (2) Cognitive Psychophysiology Research Unit, Dept. Psychology, FIN-00014 Univ. Helsinki, Finland.

Mismatch negativity (MMN), a component of the event-related potential elicited by changes in the auditory environment and indexing auditory sensory memory, was replicated for frequency and temporal changes in stimulation in a neural network model describing columnar cortical structure. Analyses of the non-linear dynamics of the system revealed that MMN can be explained as a transient state of the system due to a switch in the location of the attractor associated with the input. An experimentally measurable quantity is suggested for the strength of the underlying memory trace.

## 480.8

**A COMPUTATIONAL MODEL OF HIPPOCAMPAL REGION CA3 FOR FLEXIBLE LEARNING OF TEMPORAL SPATIAL ASSOCIATIONS.** W.B. Levy\*, X. B. Wu, & R. A. Baxter. Univ. of Virginia Health Sciences Ctr., Dept. of Neurosurgery, Charlottesville, VA 22908.

We have been studying an extremely simple and biologically motivated model of hippocampal region CA3. This model is distinguished by its sparse connectivity and local associative modification. This model is capable of a variety of forms of sequence learning which would be useful for solving problems in cognitive mapping. The problems solved by the network include sequence completion, goal finding without search, finding shortcuts, and piecing together separately learned subsequences. In finding goals without search, this model essentially imagines the path to the goal without the step-by-step changes of sensory inputs typical of other approaches that model an animal walking through an environment. The most notable aspect of neuronal firing in this network is the formation of a place cell analog. That is, different cells learn to recognize specific parts of the sequenced patterns that correspond to specific places. The cell firing patterns form spontaneously based on local associative modification. The firing of these cells is interleaved with one another such that the ability to predict sequences or to find goals exceeds the firing time of individual place cells. Thus, the network is able to solve the prediction problems mentioned above by virtue of one set of place cells passing off activity to another set of place cells.

Supported by MH00622 to WBL.

## 480.10

**THE TRANSIENT 40-Hz RESPONSE AND MISMATCH NEGATIVITY AS INDICES OF ATTENTIONAL PROCESSES.** H. Tiitinen\*. Cognitive Psychophysiology Research Unit, Dept. Psychology, FIN-00014 Univ. Helsinki, Finland.

The results of five recent EEG and MEG studies on the neurophysiological basis of selective attention and auditory sensory memory are reviewed. The results demonstrate that the transient 40-Hz response is enhanced by selective attention, attenuated in the course of long-term stimulation, and is not affected by qualitative changes in auditory stimuli. Therefore, the 40-Hz response seems to be closely related to selective and sustained attention whereas it can be dissociated from memory mechanisms. Changes in the auditory environment are registered by a pre-attentive sensory memory, as indexed by mismatch negativity (MMN). By this time, the 40-Hz oscillations have terminated or asynchronized. According to the present results, sensory memory for tone frequency is located in tonotopically organized auditory cortex and, more importantly, this pre-attentive memory mechanism governs attentive detection of changes in the auditory environment.

## 480.12

**CORRELATION-BASED INVERTIBLE ENCODING IN A MODEL OF HIPPOCAMPAL MEMORY.** N.H. Goddard, J.L. McClelland\*, R.C. O'Reilly. Dept. of Psychology, Carnegie Mellon Univ., and Center for the Neural Basis of Cognition, Carnegie Mellon Univ. and Univ. of Pittsburgh, Pittsburgh, PA 15213.

The extended temporal role of the hippocampal formation in memory suggests it forms stable traces of cortical activity lasting up to several years. We explore the role of EC-CA1-EC pathways in a model designed to meet this severe constraint [1]. In the model, a new experience is encoded twice, as independent orthogonalized sparse patterns in CA3 and in CA1. The sparsity and orthogonalization minimize interference between memories. Synaptic plasticity stores the experience in the EC-CA3 pathway and the recurrent CA3 collaterals. The bi-directional pathways between EC and CA1 implement a fixed encoder/decoder: The EC-CA1 connections map an EC input to a pattern in CA1 that returns the corresponding EC pattern via the CA1-EC connections. The CA1 and CA3 patterns are associated via plasticity in the Schaeffer collaterals. During retrieval, a partial cue arising in EC retrieves the stored CA3 pattern. The CA3 pattern then retrieves the associated CA1 pattern, which in turn completes the EC pattern.

Our simulations investigate the exploitation of correlations in the recovery of EC inputs from the CA1 patterns they produce. With symmetric, random EC-CA1 connections the model recovered only 67% of the EC cells active in the input pattern, using biologically realistic parameters, but performance improved dramatically when correlated activity between EC neurons was used in setting a subset of the connection weights. Recovery of the EC input increased to 96% for the optimal number of correlated connections. The results support the view that the EC-CA1-EC pathways could implement the proposed invertible encoding operation.

**MEAN-FIELD APPROACH TO MODELING INTERACTING NEURONS** J. C. Lin and D. M. Durand\*. Department of Biomedical Engineering, Applied Neural Control Laboratory, Case Western Reserve University, Cleveland, OH 44106

A mean-field theory is developed to describe the temporal behavior of interacting neurons. A 2-dimensional iterative map is obtained to estimate the membrane potentials of both excitatory and inhibitory neurons in a large neural network. This mapping function is derived using a mean-field approach that represents the average behavior of excitatory and inhibitory neurons. The threshold for excitation, the connectivity number, and the synaptic conductance are random variables with mean values and known distributions. By averaging over all the cells, the behavior of the network is captured by two nonlinear equations which give the membrane potentials of excitatory and inhibitory cells. This simple 2-dimensional iterative model can generate potential wave forms such as resting (no action potentials), spontaneous quasi periodic and chaotic pattern of neuronal firing, and spontaneous bursting similar to epileptiform activity. These various wave forms can be generated by adjusting the values of the model parameters such as the neural connectivity, the synaptic conductance, the threshold, and their fluctuations, etc. The ability of the model to simulate neuronal activity similar to what is observed physiologically will be helpful in determining the mechanisms underlying normal and abnormal neuronal network behaviors. Supported by NSF grant # IBN 9319591.

**THE ROLE OF GENETIC BACKGROUND IN ASSESSING THE BEHAVIOUR OF TRANSGENIC MICE** D.P. Woller\*, Marijana Bozicevic-Staglar, H.-P. Lipp. Department of Anatomy, University of Zürich, CH-8057 Zürich, Switzerland

Swimming navigation learning was studied in 743 mice using a standardised schedule. The paths of all mice were recorded digitally and analysed using an identical set of parameters. Large differences in performance were found among the inbred strains and crosses that have been studied so far: C57BL/6, DBA/2, CBA, BALB/c, I/Ln, 129/J, 129/Sv, Swiss Albino. 129/Sv, 129/J and BALB/c typically are the donor strains for embryonic stem cell lines used for gene targeting. In our hands, they are among the worst navigators and show peculiarities such as passive floating and behavioural instability. In addition, they suffer from dysgenesis of the corpus callosum and the 129/J strain also carries the *pink-eye dilute* mutation.

392 mice with total or partial gene knockouts (prion protein, tissue plasminogen activator, urokinase, myelin-associated glycoprotein, nectadrin, amyloid precursor protein) were tested in our setup. Most test samples were F2 generations of crosses between 129/Sv chimeras and C57BL/6 mice. Their genetic background contained variable and unknown proportions of C57BL/6 and 129/Sv alleles. Typically, behavioural performance in both mutants and wildtype controls varied on a large scale. In comparison, mutation effects, if present, were often subtle or even lacked complete penetrance.

In order to avoid false-positive results when studying small samples of knockout mice, the anatomical and behavioural peculiarities of the background strains must be evaluated. Ideally, behavioural effects of gene targeting should be tested against a constant genetic background with decent performance, e.g. by backcrossing to C57BL/6. A pure 129/Sv or 129/J background should be avoided. Negative results must be interpreted cautiously as well. Our group is currently establishing new approaches to verify behavioural profiles obtained in the laboratory by natural selection studies in large outdoor pens. Swiss NF 31-37497, 31-42347.94.

## 480.17

**GENETIC VARIATION IN THE SEPTOHIPPOCAMPAL CHOLINERGIC SYSTEM IN THE MOUSE: A POSSIBLE EXPLANATION FOR DIFFERENCES IN SPATIAL LEARNING AND MEMORY?** I.H. Schwegler, I.R. Linke, I.M. Boldyreva, and H.-P. Lipp\*. <sup>1</sup>Inst. Anatomy, University of Magdeburg, D-39120 Magdeburg, Germany, and <sup>2</sup>Inst. Anatomy, University of Zurich, CH-8057 Zurich, Switzerland

Lesion studies, pharmacological and electrophysiological experiments have shown that the septohippocampal cholinergic system is involved in learning and memory processes. In contrast to these invasive approaches, we were interested in genetic variation within the septohippocampal cholinergic system and correlations between cholinergic markers with behavioral data obtained in a water maze and different radial mazes. The following cholinergic variables were studied in eight different inbred mouse strains: i) the number of cholinergic neurons as revealed by choline acetyltransferase (ChAT) histochemistry, ii) the number of ChAT-positive, septohippocampal projection neurons (after retrograde labeling), and iii) the density of cholinergic fibers in different hippocampal subregions as revealed by acetylcholinesterase (AChE) histochemistry. For all cholinergic and behavioral variables studied significant strain differences were found. Furthermore, we also obtained significant morpho-behavioral correlations: i) the density of AChE-positive fibers in the dentate gyrus was positively correlated with activity-dependent learning in the water maze, ii) the number of septohippocampal cholinergic projection neurons was positively correlated with spatial working and reference memory capacities in an eight arm radial maze.

From these studies we conclude that the cholinergic system is essential for learning and memory processes and that strain differences in learning performance might be explained by variation within this system.

## 480.14

**ASSOCIATIVE PLASTICITY OF POLYSYNAPTIC INPUTS TO HIPPOCAMPAL CA1 NEURONS: IMPLICATIONS FOR TEMPORAL INFORMATION PROCESSING.** D. Buonomano\*, P. Hickmott, M. Merzenich. Keck Center, UCSF, San Francisco, CA 94143-0732.

Previous theoretical work (Buonomano and Merzenich, 1995) suggests that temporal information can be transformed into a spatial code as a result of the interaction between time-varying neuronal properties such as paired-pulse facilitation and slow inhibition, and local circuit properties. As an initial experimental test of this hypothesis we analyzed the plasticity of polysynaptic EPSPs (poly-EPSPs) in rat hippocampal slices. Our objectives were twofold: (1) To determine whether different subpopulations of neurons are activated by the first and second of two stimuli delivered 100 ms apart; (2) To determine whether it is possible to obtain order-sensitive synaptic plasticity.

Poly-EPSPs elicited by stimulation of the hilus or molecular layer of the dentate gyrus, were recorded intracellularly in CA1 neurons. Paired-pulses were delivered with an interstimulus interval of 100 ms. Our hypothesis was that the first and second pulses might activate overlapping but different subpopulations of neurons in the CA3 region. Rather than record simultaneously from a large population of CA3 neurons, we recorded poly-EPSPs from a single CA1 neuron, thus effectively sampling from a population of CA3 neurons. To determine whether the first and second poly-EPSPs were from different subpopulations of CA3 neurons we used associative LTP to "tag" the synapses. By depolarizing the postsynaptic cell during either the first or second pulse we analyzed whether it was possible to produce differential facilitation, that is, a change in the EPSP2/EPSP1 ratio. After stable poly-EPSPs were established and a 5 min baseline was obtained, either the first or second pulse was paired with depolarization for 20 - 40 trials. Synaptic changes were analyzed both 5 min and 20 min after training. Our results show that on average EPSP2/EPSP1 decreased when the first pulse was paired with depolarization ( $\Delta=0.858$  and  $0.873$ , at 5 and 20 min respectively) and increased when the second pulse was paired ( $\Delta=1.1$ ,  $1.22$ ). These differences were significant at both 5 and 20 min posttraining ( $t(20)=3.3$   $p<0.01$ ;  $t(17)=3.1$   $p<0.01$ ). These results support the hypothesis that as information flows through a neuronal layer temporal information can be converted into a spatial code. This mechanism could function as a basis for the formation of temporal combination-sensitive cells. [Supported by NIH grants NS10414 and MH10431, and HRJ].

## 480.16

**IDEAL GENETIC BACKGROUNDS FOR TRANSGENIC ANIMALS DEVELOPED FOR ASSESSMENT OF COGNITIVE FUNCTION.** E.W. Hanebuth, S.F. Logue, D.L. Rasmussen, and J.M. Wehner\*. Instit. for Behav. Genetics, Dept. of Psychology, University of Colorado, Boulder, CO, 80309-0447.

Recently, many inbred mouse strains have been used to create transgenic animals. Because complex learning is regulated by polygenic systems, the genetic background of these parental strains is important in evaluating the performance of transgenics. In an effort to look at learning performance in the context of genetic backgrounds, fourteen inbred mouse strains and seven F<sub>1</sub> crosses have been examined in multiple behavioral tasks. The tasks used in this study include: Morris Water task, conditioned fear responses, open field activity, Y-maze activity, startle response, and pre-pulse inhibition. The Morris task and contextual conditioned fear test an animal's ability to use complex information in a learning task, while the other tasks assess sensory and motor function.

Various strains were significantly different in their performance during these tasks. To highlight a few strains, C57/6J mice were capable of learning the Morris task and contextual conditioned fear. However, 129/SvJ mice, who are not visually impaired, only learn contextual conditioned fear. A visually impaired strain, FVB, was not capable of learning either task. Understanding the cognitive capabilities of the parental strains will aid in the selection of an appropriate parental strain for the transgenic animals modelling cognitive function. (Supported by MH-16880, MH-48663).

## 480.18

**THE DIFFERENT REACTIVITY OF C57BL/6 AND DBA/2 INBRED MICE TO SPATIAL AND NON SPATIAL CHANGE IS SUBSERVED BY A STRAIN DEPENDENT HIPPOCAMPAL AND POSTERIOR PARIENTAL CORTIX INTERPLAY.** M. Ammassari-Teule, E. Save, C. Rossi-Arnaud and C. Thinus-Blanc\*. Ist. Psychobiology and Psychopharmacology, Rome, Italy and Lab. Neurosciences Cognitives, Marseille, France.

Inbred mice such as C57BL/6 (C57) and DBA/2 (DBA) differently perform in a variety of spatial tasks with C57 doing better at such learning. The low spatial performance of DBA could, therefore, reflect defects of acquisition or, alternatively, deficits yet in the processing of spatial information. In order to test these hypotheses, mice from both strains were placed in an open field containing five objects and their reactivity to the displacement (spatial change) or the substitution (non spatial change) of some of these objects was examined. The results show that C57 mice react to spatial change by exploring more the displaced than the non displaced objects while DBA mice do not show any reaction. Conversely the two strains strongly react to the substituted object. Dorsal hippocampal lesions abolish the reactivity to spatial change in C57 and stress the disinterest towards the five objects in DBA. Posterior parietal cortex lesions also abolish selectively the reactivity to spatial change in C57 but do not produce any effect in DBA. Taken together, these results indicate that the high spatial learning performance of C57 mice could be based upon (1) the capability of perceiving and updating spatial relationships between objects and (2) the involvement of both the hippocampus and the posterior parietal cortex in such processes. Data concerning DBA mice suggest (1) a genetic defect in encoding of spatial relationships between objects (2) a non specific involvement of the hippocampus and (3) no involvement of the posterior parietal cortex in the exploration of object configurations.

## 480.19

**QUANTITATIVE TRAIT LOCUS MAPPING OF CONTEXTUAL AND CUED FEAR-CONDITIONED FREEZING IN C57BL/6J X DBA/2J RECOMBINANT INBRED STRAINS OF MICE.** S.C. Christensen\*, E.W. Hanebuth, S.F. Logue and J.M. Webner. Institute for Behavioral Genetics, Dept. of Psychology, and School of Pharmacy, University of Colorado, Boulder, CO, 80309-0447.

C57BL/6J (B6) and DBA/2J (D2) inbred strains have been shown to differ in conditioned fear responses with respect to contextual stimuli but not an auditory CS following a single, 0.35 mA shock (Paylor *et al.*, *Behav. Neurosci.*, 108(4):1-8, 1994). B6 mice freeze to contextual stimuli significantly more than D2 mice. Research from this laboratory supports the hypothesis that the decreased contextual freezing observed in D2 mice is the result of functional deficiencies of the hippocampus, where integration of spatial information and other complex cues involved in learning and memory processes are believed to take place.

Putative chromosomal loci responsible for the observed differences in conditioned fear responses between B6 and D2 parental strains have been mapped by quantitative trait locus (QTL) analyses of mean contextual, altered context and auditory CS freezing scores in 22 B6XD2 recombinant inbred (RI) strains. The analyses indicate a polygenic mode of inheritance for all measures, and heritability estimates are 0.25, 0.16 and 0.24 for the three freezing scores, respectively. Estimates of the minimum number of loci involved are 2.6 for context, 2.5 for altered context, and 4.5 for the auditory cue. QTLs were detected on mouse chromosomes 1, 9, 11, 13, 14 and 17. These data may be used in future studies to screen loci on these chromosomes for candidate genes that may be implicated in different fear-conditioned responses (Supported by MH-16880, AA-00141 and MH-48663).

**LEARNED HELPLESSNESS IN SHUTTLEBOX AVOIDANCE LEARNING IN AUTOIMMUNE BXSB MICE?** L.A. Hyde and V.H. Denenberg\*. Biobehavioral Sciences Graduate Degree Program, University of Connecticut, Storrs, CT 06269.

Autoimmune mice do not learn shuttlebox avoidance well. Due to the aversive nature of the avoidance task, it is always the last test administered in our battery of behavioral tests. We investigated whether learned helplessness was a possible explanation for the observed learning deficits. One group of mice was tested in avoidance first, a water version of the Lashley maze second, and water escape last, while a second group was given these tests in the reverse order. If the animals were experiencing learned helplessness, we would expect that this would transfer and the animals would show poorer learning in other tests following avoidance. Contrary to the predictions of this theory, animals who were exposed to avoidance first did not demonstrate any learning deficits in subsequent tests. This would suggest that the poor performance in shuttlebox learning demonstrated by autoimmune mice is not due to learned helplessness. Supported in part by NIH grant H-20806.

## LEARNING AND MEMORY: PHARMACOLOGY V

## 481.1

**THE EFFECT OF ACUTE FLUOXETINE AND BUSPIRONE ADMINISTRATION ON PERFORMANCE IN A LATENT INHIBITION (LI) TASK.** A. Jakob\* and J. Rochford. Douglas Hospital Research Center, Dept. Psychiatry, McGill University, Montreal, Quebec

LI reflects the decrement in the acquisition of Pavlovian conditioning evoked by extensive conditioned stimulus (CS) preexposure. LI has been suggested to be an animal model of selective attention in that it assesses the ability to ignore irrelevant stimuli. It has been shown that lesioning the mesolimbic serotonergic (5-HT) system abolishes LI. As yet, few studies have been performed to examine the effects of pharmacological manipulation of 5-HT transmission on LI. In the present experiments we assessed the effects of acute administration of the 5-HT reuptake inhibitor fluoxetine and the 5-HT<sub>1A</sub> receptor agonist buspirone in an LI task. Following lever press training, different groups of animals were preexposed to 0 (nonpreexposed, NPE), 10 or 40 presentations of a tone (the to be conditioned stimulus; CS). Over the following two conditioning days all animals were exposed to two tone-shock (0.6 mA, 0.5 sec) pairings and the acquisition of conditioned suppression was measured. Different groups received either 5 mg/kg fluoxetine, 5 mg/kg buspirone or vehicle (i.p.) prior to the preexposure day and the conditioning days or on the conditioning days only. The LI phenomenon occurred in that untreated animals preexposed to 40 tones learned the tone-shock association less rapidly than those not preexposed to the tone. Fluoxetine-treated animals preexposed to 40 tones performed similarly to vehicle-treated animals exposed to 40 tones. However, fluoxetine induced an LI-like effect in animals preexposed to 10 tones. Preexposure to 10 tones did not induce LI in untreated animals. Buspirone was without effect in animals administered 10 or 40 tones. These findings suggest that acute 5-HT reuptake blockade, but not acute 5-HT<sub>1A</sub> receptor activation, can augment LI. (Funded by the FRSQ).

**THE INCREASE IN LEARNING INDUCED BY INDORENATE AND 8-OH-DPAT WAS BLOCKED BY SILENT 5-HT<sub>1A</sub> ANTAGONISTS.** E. Hong\* & A. Meneses. Terapéutica Experimental, Depto. Farmacología y Toxicología, CINVESTAV-IPN. Ap. Postal 22026, México, D.F., 14000. MEXICO.

We have previously reported that the 5-HT<sub>1A</sub> agonist 8-OH-DPAT (D) enhanced consolidation of learning and such effect was reversed by PCPA pretreatment. In the present work, the effect of post-training i.p. injection of WAY 100135 (W) or S-UH-301 (S) plus D or indorenate (I) was determined in autoshaping. Animals were individually trained to find 30 pellets, the unconditioned stimulus (US) in the food magazine. Each session had 20 trials and a trial consisted of illumination of a retractable lever for 8 sec (conditioned stimulus, CS) followed by the delivery of a US after the 8 sec period that were carried out every 60 sec. If the animal pressed the lever (conditioned response, CR) the trial was shortened and the lever was retracted, the light was turned off and the US was delivered immediately. The results showed that D and I increased the CR. W (5.0-20.0 mg/Kg) or S (0.3-3.0 mg/Kg) did not alter CR by themselves, but antagonized the effect induced by D and I. PCA neither induced changes in learning, nor modified the silent characteristic of W and S. At behavioral active doses, ketanserin or ondansetron reversed the effect of D. The present data suggest that D and I are involved on learning through activation of 5-HT<sub>1A</sub> receptors. However, integrity of 5-HT<sub>2</sub> and 5-HT<sub>3</sub> receptors seem to be required in order that the stimulation of 5-HT<sub>1A</sub> receptors be able to enhance learning. Supported by CONACYT grant 4367-M9406

## 481.2

**PHARMACOLOGICAL ANALYSIS OF SEROTONERGIC RECEPTORS ACTIVATION OR BLOCKADE ON LEARNING.** A. Meneses\* & E. Hong. Terapéutica Experimental, Depto. Farmacología y Toxicología, CINVESTAV-IPN. Ap. Postal 22026, México, D.F., 14000. MEXICO.

We have tested several 5-HT selective agonists and antagonists (5-HT<sub>1A/1B</sub>, 5-HT<sub>2A/2B/2C</sub>, 5-HT<sub>3</sub> or 5-HT<sub>4</sub>), an uptake inhibitor and 5-HT depletors in the autoshaping learning task. The present work deals with the receptors which stimulation increases or decreases learning, as well as possible explanations for the coexistence of the two effects. Impaired consolidation of learning was observed after the presynaptic activation of 5-HT<sub>1B</sub>, 5-HT<sub>3</sub> or 5-HT<sub>4</sub>, or the blockade of postsynaptic 5-HT<sub>2C/2B</sub> receptors. On the other hand, improvement occurred after the presynaptic activation of 5-HT<sub>1A</sub>, 5-HT<sub>2C</sub>, and the blockade of presynaptic 5-HT<sub>2A</sub>, 5-HT<sub>2C</sub> and 5-HT<sub>3</sub> receptors. The blockade of postsynaptic 5-HT<sub>1A</sub>, 5-HT<sub>1B</sub>, 5-HT<sub>3</sub> or 5-HT<sub>4</sub> receptors and 5-HT inhibition of synthesis and depletion did not alter learning by themselves. The present data suggest that multiple pre- and postsynaptic serotonergic receptors are involved in the consolidation of learning. Stimulation of most 5-HT receptors increase learning, however, some of 5-HT subtypes seem to limit the data storage. Furthermore, the role of 5-HT receptors in learning seem to require an interaction with glutamatergic, GABAergic and cholinergic neurotransmission systems. Supported by CONACYT grant 4367-M9406

## 481.4

**STIMULATION OF 5-HT<sub>1A</sub> RECEPTORS INDUCES ANXIOLYTIC-LIKE EFFECTS AND FACILITATES ACQUISITION OF A SPATIAL DISCRIMINATION TASK IN MICE.** J. Micheau\*, B. Van Marrewijk and R. Jaffard. Lab. de Neurosciences Comportementales et Cognitives URA CNRS 339, Université de Bordeaux I, Ave des Facultés, 33405 TALENCE cedex, FRANCE.

Behavioural and pharmacological studies indicate that central 5-HT systems may mediate coping responses to acute and chronic stress. Consequently, the widespread action of 5-HT in anxiety related behaviour makes difficult to investigate the role of this transmitter on learning and memory. The aim of the present study was to investigate a possible relationship between the anxiolytic- or anxiogenic-like effects of 8-OH-DPAT, a 5-HT<sub>1A</sub> agonist, and its influence on memory processes.

Mice were tested in an elevated plus maze before being submitted to a spatial discrimination task in a 8-arm radial maze. The 8-OH-DPAT (1 mg/kg, ip) administered 30 min prior to the test of anxiety, induced anxiogenic-like effects. In addition, 8-OH-DPAT improved the acquisition of the spatial discrimination ( $p < 0.05$ ), probably by facilitating retrieval processes. Moreover, a regression analysis showed that the index of anxiety was positively correlated to the performance level reached at the fourth day of training. Because very high concentrations of 5-HT<sub>1A</sub> receptors are localized in the hippocampus, a possible interaction with the cholinergic septo-hippocampal system was investigated in the following experiment. Immediately after testing in the elevated plus maze, the animals were killed to measure the high-affinity sodium-dependent choline uptake (SDHACU) in hippocampal synaptosomes. The testing-induced activation of hippocampal SDHACU was reduced by the 8-OH-DPAT treatment (1 mg/kg) ( $p < 0.05$ ).

These results suggest that anxiogenic-like effects induced by the stimulation of 5-HT<sub>1A</sub> receptors may have a positive influence on the acquisition of a hippocampal-dependent learning task.

## 481.5

EFFECTS OF ONDANSETRON, AN ANTAGONIST OF THE 5-HT<sub>3</sub> RECEPTOR, ON HIPPOCAMPAL CELLULAR ACTIVITY *IN VIVO*.

J. Reznic\*, S.E. Fox<sup>1</sup> and U. Staubli, Center for Neural Science, New York University, New York, NY 10003; <sup>1</sup>Dept. Physiology, SUNY health Science Center, Brooklyn, NY 11203.

Serotonin has been shown to block hippocampal LTP in a dose-dependent fashion, and antagonists of the 5-HT<sub>3</sub> receptor have been demonstrated to enhance learning and memory in rodents and primates. Ondansetron (ON), a potent and specific 5-HT<sub>3</sub> receptor antagonist, has recently been found to facilitate LTP, to significantly increase the frequency of the EEG ('theta rhythm'), and to enhance performance on olfactory and spatial memory tasks in rats. The present study sought to characterize the mechanisms responsible for these changes. Male Long-Evans rats (250-300 g) were surgically implanted with chronic microelectrode bundles into the CA1 region of the hippocampus bilaterally, and extracellular single-unit activity and EEG were recorded. Pyramidal cells and interneurons ('theta cells') were identified based upon their action potential waveform and firing properties with respect to the EEG during open field, exploratory and wheel running activities. The exact locations of the recorded units within hippocampal strata were verified histologically upon termination of the study. Following baseline measurement of average firing rate, ON (0.5 and 1.0 mg/kg) was administered intraperitoneally fifteen minutes subsequent to an injection of an equal volume of physiological saline. Enhanced firing of pyramidal cells (4/8,  $p < 0.01$ ) was observed following ON injection when compared to both control and saline conditions, accompanied by a decrease (10/20,  $p < 0.01$ ) or increase (1/20,  $p < 0.01$ ) in the firing rate of interneurons. The peak effect occurred between 15 and 30 minutes post-injection, and is consistent with an inhibitory action of ondansetron on 5-HT<sub>3</sub> receptors present on interneurons and subsequent disinhibition of pyramidal cells, thereby promoting activity patterns appropriate for the occurrence of long-lasting synaptic changes thought to underlie certain forms of memory.

## 481.7

## INVOLVEMENT OF DOPAMINE IN THE CHICK STRIATUM IN ONE-TRIAL PASSIVE AVOIDANCE TRAINING. E. Harrison.

M.G. Stewart, P. Kabat, A. Csillag and G. Swanson\*, Dept. of Biology, Open University, Milton Keynes, MK7 6AA; Semmelweis University, Budapest IX, Hungary; TINS, Hills Road, Cambridge, CB2 1LA, UK.

One-trial passive avoidance training utilizes the ability of 1-day old domestic chicks (*Gallus domesticus*), to learn to distinguish between pleasant and unpleasant tasting substances such as methyl anthranilate (MeA). Major cellular changes following avoidance training occur in two forebrain regions, part of the hyperstriatum ventrale (IMHV), and the lobus parolfactorius (LPO). The LPO is a major component of the avian paleostriatal complex, equivalent to the medial striatum (caudate-putamen) of mammals, and is rich in dopamine receptors in pigeons. Dopamine has been implicated as a modulator of motivational behaviour, and contributes to the maintenance of avoidance responding in mammals. In birds, the striatum plays an important role in stereotyped behaviour, and alterations in dopamine binding may therefore be involved in modification of the pecking response in avoidance training.

The present study has used quantitative receptor autoradiography to investigate the binding of [<sup>3</sup>H]SCH 23390 to D<sub>1</sub> and [<sup>3</sup>H]spiroperone to D<sub>2</sub> receptors in chick forebrain. Our data show that D<sub>1</sub> and D<sub>2</sub> ligands bind at high levels to the striatum and pallidum of the 2-day old chick, as reported in the pigeon, turtle and rat. In addition, as in these species, the proportions of D<sub>1</sub> and D<sub>2</sub> receptors in the chick are relatively similar in the striatum and pallidum, apart from the paleostriatum augmentatum where D<sub>2</sub> receptors outnumber those of D<sub>1</sub> by a factor of two. In the passive avoidance experiments the data show a large and highly significant bilateral increase in binding to D<sub>1</sub> (but not D<sub>2</sub>) receptors in part of the striatum, the LPO.

## 481.9

## DOPAMINERGIC BEHAVIORAL DRUG SENSITIZATION AS A DUAL PROCESS PHENOMENON: MOTORIC ACTIVATION AND RESPONSE REORGANIZATION. Ernest N. Damianopoulos\*, Huiliang Dai and Robert J. Carey. Psychiatry, SUNY Health Science Center and Research and Development Service - 151, VA Medical Center, Syracuse, NY 13210

Previous apomorphine behavioral sensitization studies have shown that locomotor activation is enhanced by repeated apomorphine treatment. This effect, however, is not a simple enhancement of locomotor behavior but actually entails both locomotor stimulation and locomotor response reorganization. We have proposed that the reorganization component is mediated by a Pavlovian conditioning process and, therefore, it represents a quasi-permanent change in the behavioral action of the drug treatment. To further assess this issue and to determine whether the two drug sensitization components; i.e., motoric activation and response reorganization, are associated or dissociated processes, a time-course study was carried out to assess the relative durability of the locomotor reorganization vs. the locomotor activation effect resulting from the repeated apomorphine treatment. Using Sprague-Dawley rats matched into three sets of paired - unpaired treatment groups, the animals were administered 7 once/day saline/apomorphine (2.0 mg/kg sc) treatments paired or unpaired to a 20 min placement into the drug test environment. The three sets of animals were then tested separately for behavioral sensitization after 1, 7, and 28 days of withdrawal/non testing. The results showed that locomotor activation enhancement was retained after 1 and 7 but not after 28 days. In contrast, the acquired locomotor pattern changes were retained at all test intervals suggesting that the response pattern reorganization effect is dissociated from locomotor activation enhancement and displayed the relatively-permanent characteristics of a learned response uniquely marking the drug effect.

HALOPERIDOL- INDUCED CHANGES IN NEUROTRANSMISSION IN CHICK BRAIN: A MICRODIALYSIS STUDY. M. GRUSS<sup>1</sup>, G. POEGGEL<sup>2</sup> and K. BRAUN<sup>1</sup>. <sup>1</sup>Federal Institute for Neurobiology, 39118 Magdeburg, Germany

<sup>2</sup>University of Leipzig, 04103 Leipzig, Germany

We use auditory filial imprinting in chicks as an experimental model to study the mechanisms which underlie juvenile learning processes. We have previously reported an increase of extracellular glutamate in response to the acoustic imprinting stimulus in the associative forebrain region medio-rostral neostriatum/hyperstriatum (MNH) and to a lesser extent also in the basal ganglia. Anatomical investigations revealed a dopaminergic input into the MNH and basal ganglia and we speculate that dopaminergic modulation of the glutamatergic pathway may be critically involved in synaptic changes during auditory filial imprinting. Thus we tested the effect of acute application of the dopamine- antagonist haloperidol on the extracellular concentrations of catecholamines and amino acids. A CMA11 microdialysis probe was stereotactically implanted into the right MNH or the basal ganglia of 2 to 4 day old chicks. Haloperidol ( $10^{-5}$  -  $10^{-3}$  M) was infused locally through reverse microdialysis. In both regions haloperidol induced a concentration-dependent increase of dopamine, dihydroxyphenylacetic acid, homovanillic acid and hydroxyindoleacetic acid. In addition the extracellular levels of glutamate, aspartate and GABA were increased in a concentration-dependent manner. The increase of catecholamine metabolites was higher in the basal ganglia than in the MNH, which correlates with the higher densities of dopamine receptors in the basal ganglia.

We suggest that the blockade of D<sub>2</sub>-autoreceptors leads to a local increase of dopamine release and that this increased dopamine level enhances the release of amino acids via activation of presynaptic D<sub>1</sub>-receptors. These findings further support the hypothesis of a modulatory influence of dopamine on the glutamatergic transmission system.

## SENSITIZATION AND CONDITIONING WITH INTRASTRIATAL DOPAMINE AND DIBUTYRYL CYCLIC AMP IN RATS WITH NIGRAL LESIONS. P.B. Silverman\* Dept. of Psychiatry, Univ. of Texas HSC, Houston, TX 77030.

Previous work in this laboratory has shown that systemic D<sub>1</sub> and D<sub>2</sub> selective dopamine receptor agonists both induce rotation in unilateral nigral rats which sensitizes with repeated administration, but that only D<sub>1</sub> agonists result in rotation conditioned to the test environment which can be demonstrated weeks later. Here intrastriatal administration of dopamine and dibutyryl CAMP were tested for acute rotation, sensitization and conditioned rotation. Under pentobarbital anesthesia, female S-D rats were lesioned with 6-hydroxydopamine in one substantia nigra. At the same time, an indwelling cannula was implanted in the ipsilateral striatum. Two to three weeks later, they were injected intrastrially on 3 consecutive days with dopamine HCl or with dibutyryl cyclic AMP. Both dopamine and dibutyryl cyclic AMP induced rapid contralateral circling which increased significantly with repeated administration. Neither cyclic AMP sodium salt, which reportedly has limited intracellular penetration, nor butyrate induced circling. When tested, undrugged, in the rotation environment 2 or more weeks after administration of dopamine or dibutyryl cyclic AMP, rats exhibited a brief burst of conditioned rotation. The results show that acute rotation, sensitization to repeated administration of dopamine or dibutyryl CAMP and conditioned circling can all be demonstrated with intrastriatal administration alone. It is apparently possible to bypass stimulation of the D<sub>1</sub> receptor in this preparation and obtain classically conditioned behavior by direct administration of second messenger.

## A SMALL DOSE OF APOMORPHINE IMPROVES MEMORY ON A DIFFICULT SPATIAL TASK. A.G. Gittis\*, C. Rudy and M. Esch. Psychology Dept., Westminster College, New Wilmington, PA 16172.

Gittis and Falleroni (*SN Abs*, 1993) demonstrated that accuracy of conditioned alternation (CA) is closely related to the geometric arrangement of the choices. A model was developed that sees CA as a manifestation of a higher order motor program which permits maintenance of orientation. Neurally, this implies that CA is mediated by frontal-cortex striatal circuits rather than temporal/parietal-limbic circuits. Therefore, an injection of a dopaminergic agonist should accentuate the alternation motor pattern which would have the cost of interfering with CA in geometric configurations that are not congruent with the motor pattern.

Rats were trained in a CA paradigm in a Y-shaped maze in which the choice between two arms was systematically varied angularly and relative to midline. After training the animals received an injection of the dopaminergic agonist apomorphine (0.5 mg/kg) or a vehicle injection and then tested. It was predicted that apomorphine injections would interfere with performance particularly when an arm incompatible with the alternation motor pattern had to be selected, e.g., when both arms are positioned on the same side lateral to midline.

As observed in previous studies, pre-injection alternation between arms laterally positioned was poorer than when midline had to be crossed. Contrary to the prediction, injections of apomorphine improved CA performance in the laterally positioned arms. This pattern of improvement confirms a report of memory enhancing effects of low doses of apomorphine (White et al., 1993). These authors suggest that the memory improvement is mediated by the activation of presynaptic autoreceptors which functionally reduce dopaminergic transmission. Hence the improvement in performance on the most difficult CA choices may have arisen from a reduction of dopaminergic transmission.

## 481.11

DIFFERENTIAL EFFECTS OF BROMOCRIPTINE AND 7-OH-DPAT ON RESPONDING FOR CONDITIONED REWARD IN RATS. M.A. Sutton, P.L. Nakonechny, N.G. Rolfe and R.J. Beninger\*. Dept. Psychol., Queen's Univ., Kingston, K7L 3N6, Canada.

Previous studies have shown that receptor subtype-specific dopamine agonists differentially affect responding for conditioned reward; D1 agonists impair whereas D2 agonists selectively enhance responding. To compare the effects of the D2 agonist bromocriptine to the D3 agonist 7-OH-DPAT, food deprived rats (N=58) were pre-exposed to a chamber with two levers, one producing a tone (3 s) and the other lights-off (3 s), for 5 40-min sessions. Then, in 4 60-min sessions, with the levers removed, the lights-off stimulus was paired with food (80 pairings per session). During two 40-min test sessions, lever press responses again produced the tone and lights-off stimuli. (+)-Bromocriptine (5.0 mg/kg ip 30 min before) selectively enhanced responding on the lights-off lever. Animals treated with 7-OH-DPAT (0.1, 0.2, 0.5, 1.0 mg/kg 30 min before), although responding preferentially on the lights-off lever, did not show an enhancement. Results suggest that D2 and D3 receptors are differentially involved in the control of responding by conditioned rewards.

## 481.13

EFFECTS OF INTRA-CAUDATE NUCLEUS INJECTIONS OF PLATELET-ACTIVATING FACTOR AND BNS2021 ON MEMORY. L.A. Teather\*, M.G. Packard, & N.G. Bazan. Louisiana State Univ. Medical Center & Dept. of Psychology, Univ. of New Orleans, N. O., LA 70148.

Platelet-activating factor (PAF; 1-O-alkyl-2-acetyl-sn-glycero-3-phosphorylcholine) is a biologically active lipid metabolite derived from phospholipase A<sub>2</sub>, and is present in mammalian brain. PAF has recently been proposed as a retrograde messenger critical for the generation of long-term potentiation, and is involved in the formation of hippocampal-dependent and amygdala-dependent memory. The present experiments were designed to extend these findings by examining the effects of post-training intra-caudate nucleus injections of methylcarbaryl-PAF (mc-PAF) and the PAF antagonist BNS2021 on memory using a caudate-dependent visible platform water maze task.

Male Long-Evans rats received an eight trial (30 second ITI) training session in which a visibly cued escape platform was located in a different quadrant of the maze on each trial. Following trial 8, the rats received a unilateral post-training intra-caudate injection of mc-PAF (1 µg/0.5 µl), BNS2021 (0.5 µg/0.5 µl), or vehicle. On a retention test 24 hours later, latency to mount the escape platform was used as a measure of memory. The retention test escape latencies of rats receiving mc-PAF were significantly lower than those of vehicle-injected controls, indicating an enhancement of memory. The retention test escape latencies of rats receiving the PAF antagonist BNS2021 were significantly higher than those of vehicle-injected controls, indicating an impairment of memory. Injections of mc-PAF or BNS2021 did not affect retention when the injections were administered 2 hours post-training, indicating a time-dependent effect of the drugs on memory storage processes. The findings suggest that endogenous PAF plays a role in caudate nucleus dependent memory processes.

## 481.15

ENHANCEMENT OF MEMORY PROCESSING IN A Y-MAZE DISCRIMINATION TASK BY POSTTRAINING INFUSION OF CLENBUTEROL INTO THE NTS. C.L. Williams\* & J.L. McGaugh. Center for the Neurobiology of Learning & Memory and Dept. of Psychobiology, University of California, Irvine, CA 92717-3800.

It is well established that administration of noradrenergic agonists peripherally or into limbic brain regions improve retention in memory tasks. There is evidence to suggest that neurons in the nucleus of the solitary tract (NTS) may mediate some of the effects of norepinephrine (NE) on memory. Peripheral afferent nerve fibers containing (NE) innervate several regions of the NTS. In addition, NE neurons in the A2 region of the NTS send nerve terminals to brain structures such as the amygdala, where NE infusion is known to facilitate retention. This experiment examined whether memory processes are affected by NE activation of the NTS. Male Sprague-Dawley rats (225-275 grams) implanted with cannulae tips placed above the NTS were trained to obtain food pellets placed in 2 arms of a Y-maze and then given a footshock in one arm of the maze. Immediately after the footshock, the rats received bilateral injections of 0.5 µl of phosphate buffer or the NE agonist clenbuterol (10, 50, or 100ng) into the NTS. On the retention tests given 24 and 48 hours after training, the number of seconds to enter either alley of the maze and the time to consume all food in the alley where footshock was received served as indices of retention. The latencies of animals given posttraining injections of clenbuterol (100ng/0.5 µl) were significantly longer on these measures relative to phosphate buffer-treated controls. These findings suggest that NE activation of NTS neurons is one mechanism by which memory storage processes are regulated.

## 481.12

"SUPER" LATENT INHIBITION (LI) WITH HIGH DOSE OF AMPHETAMINE J. Feldon<sup>1</sup>\*, U. Shalev<sup>2</sup>, L. Weiner<sup>1</sup>\*, <sup>1</sup>Dept. Psychology, Tel-Aviv University, Tel-Aviv, Israel. <sup>2</sup>Lab. Behav. Biol. Funct. Toxicol., Institut. Toxicol., Schorenstrasse 16, Schwerzenbach 8603, Switzerland. (ENA)

LI is a two stage paradigm: in preexposure, the subject receives a series of stimuli (e.g. tones); in conditioning, this stimulus is followed by reinforcement. LI consists of slower conditioning in the preexposed as compared to nonpreexposed subjects, and is considered to measure organisms' ability to ignore irrelevant stimuli. In both rats and humans, LI is disrupted with low but not high doses of amphetamine (AMPH). We attributed the former effect to enhanced behavioral switching, whereby animals switch rapidly to respond according to the stimulus-reinforcement contingency in conditioning. Since at high doses, AMPH produces behavioral perseveration, we tested the hypothesis that in LI this will be reflected in perseveration in ignoring irrelevant stimuli. One way to demonstrate such "super-LI" is to increase the number of stimulus-reinforcement pairings in conditioning to a level at which normal animals switch to respond according to the new contingency, and thus cease to show LI; Under these conditions, AMPH treated animals should persevere in ignoring the stimulus, and continue to show LI. Two experiments were conducted, using a conditioned emotional response procedure, in which animals received 20 nonreinforced tone preexposures followed by 5 tone-shock pairings. In Exp.1, vehicle controls, as expected, did not show LI, whereas animals treated with 4mg/kg AMPH showed LI. In Exp.2, we showed that AMPH-produced "super LI" is identical to that produced by 0.2 mg/kg haloperidol. These results may have implications for the LI model of schizophrenia. Until now, the model has been based on the parallel between LI disruption in rats by low AMPH doses and in acute schizophrenics. However, LI reappears in schizophrenics as a function of chronicity of illness. The "reappearance" of LI under high doses of AMPH may provide an animal parallel to this puzzling clinical phenomenon.

## 481.14

NOREPINEPHRINE RELEASE IN THE AMYGDALA IN RESPONSE TO FOOTSHOCK STIMULATION USED IN INHIBITORY AVOIDANCE TRAINING. J.L. McGaugh\*, R. Galvez and M.H. Mesches. Center for the Neurobiology of Learning and Memory and Department of Psychobiology, University of California, Irvine, CA 92717-3800.

Extensive evidence indicates that the amygdala plays a major role in modulating memory storage induced by emotionally arousing stimulation such as footshock used in inhibitory avoidance training. Pharmacological evidence suggests that such memory modulating effects may be mediated by the release of norepinephrine (NE) in the amygdala. The present study examined NE levels released in the amygdala of freely moving rats in response to a single footshock comparable to that typically administered in inhibitory avoidance training.

One week prior to the experiment, male Sprague-Dawley rats were implanted bilaterally with guide cannula aimed at the dorsal side of the central nucleus of the amygdala. The microdialysis probe was inserted into the guide cannula 2 hours prior to collecting the first sample. One hour and thirty minutes after inserting the probe the rat was placed into a 30 X 30 cm box where footshock could be delivered through a grid floor. The flow of the artificial cerebrospinal fluid was 1 µl/min, and samples were collected every 15 minutes. After establishing a stable baseline, the rat was given a 0.55 mA / 1 sec shock. Samples were collected until NE levels returned to baseline. NE levels, as quantified by HPLC, increased significantly after the footshock. These results are consistent with previous pharmacological findings suggesting that NE release in the amygdala is involved in modulating memory storage.

## 481.16

THE EFFECTS OF CONTINUOUS INFUSION OF ATIPAMEZOLE ON BEHAVIOR AND CNS NEUROCHEMISTRY IN RATS A. Haapalinn, T. Viitamaa, E. MacDonald, J.S. Salonen, J. Sirviö\* and E. Heinonen. Orion Corporation, Orion-Farmos, P.O.Box 425, FIN 20101, Turku, Finland. Dept. of Pharmacology and Toxicology and A.I. Virtanen Institute, University of Kuopio, P.O.Box. 1627, FIN 70211, Finland.

Atipamezole (ATI) is a selective α<sub>2</sub>-adrenoceptor antagonist that, after acute dosing (0.3 mg/kg s.c.), stimulates release of central norepinephrine, potentiates neophobia, enhances maze learning, but impairs active (electric shock) avoidance learning. In the present work the effect of continuous ATI (100 µg/kg s.c./h) 6 -10 days infusion was tested on behavior and central monoamine turnover and compared with the effect of 24 h infusion. Also central α<sub>2</sub>-antagonism against detomidine in a rat mydriasis model and ATI concentration in serum and brain was measured. ATI 24 h infusion had no effect on motor activity, but decreased exploratory behavior in a staircase test. ATI after 6 days infusion had no effect on motor activity nor exploratory behavior. Active avoidance learning test was carried out at days 7, 8 and 9 of infusion and ATI treated animals made significantly more correct avoidance responses than control animals at day 9. Central α<sub>2</sub>-antagonism measurement and sacrifice of the animals were done after 24 h or 10 days of infusion. ATI 24 h infusion caused a marked increase in central norepinephrine, dopamine and serotonin turnover rate. ATI 10 days infusion had only a slight effect on central monoamine turnover rates, but shifted detomidine dose response curve to left with same potency than 24 h ATI infusion, indicating the same degree of α<sub>2</sub>-antagonism level. The mean ATI concentrations in serum and brain were 47 ng/ml and 84 ng/g after 24 h infusion and 47 ng/ml and 118 ng/g after 10 days infusion, respectively. These results indicate that after subchronic treatment with ATI, there was not longer potentiation of neophobia nor impairment, instead improvement in stressful learning test and only a slight stimulation of central monoamine turnover rate. However, the α<sub>2</sub>-antagonism potency was maintained and the concentration of ATI in brain was slightly increased.

## 481.17

ODOR PREFERENCES OF CONTROL RATS ARE ALTERED BY THE NUMBER OF DSP-4 TREATED RATS IN THE HOME CAGE. H.G. McFarlane, S. Henry, T.H. Dewey AND C.A. Cornwell. Dept. of Psychology, Syracuse University, Syracuse, NY 13244.

In a previous study, control rats showed an abnormal aversion to a new home cage odor when they were housed with an equal number of cagemates treated with the NE neurotoxin N-(2-chloroethyl)-N-ethyl-2-bromobenzylamine (DSP-4). The present study examined the effects of altering the ratio of DSP-4 treated rats to controls caged together. Male Sprague-Dawley rats were injected subcutaneously two days after birth with 50mg/kg of DSP-4 or vehicle (distilled water). After weaning, they were placed in one of three housing conditions: eight vehicle-injected controls; four vehicle-injected rats and four DSP-4-injected animals, or one vehicle-injected and seven DSP-4-injected animals. On postnatal day thirty-two, the bedding was switched from pine to cedar. Odor preferences for cedar versus pine were tested on postnatal day thirty-five. Social housing influenced odor preferences for the controls, but not for the DSP-4-injected rats. Controls housed with zero (0) or four (4) DSP-4-treated cagemates showed a significant aversion to cedar. In contrast, controls housed with 7 DSP-4-treated animals showed no preference between odors and had scores significantly higher than the other controls. Odor preferences for DSP-4-treated rats showed no trend toward a social effect. These data are consistent with the hypothesis and existing evidence that NE depletion reduces the effects of the social environment on odor preferences in rats. Since cage density was held constant, environmental effects on controls were not due to crowding.

## 481.19

SEXUALLY DIMORPHIC DSP-4 EFFECTS ON ODOR PREFERENCES AND WEIGHT LOSS IN MICE.

T.H. Dewey\*, S. Henry, R. Desai, A. Fijman, P. Hancock-Abel, M. Zavod, and C.A. Cornwell. Dept. of Psychology, Syracuse University, Syracuse, NY 13244.

Odor preferences were investigated in NE-depleted mice and their control cagemates. Same-sex living groups of 8 mice per cage were housed together from weaning over hardwood shavings. At 60 days of age, each group was subdivided into cohorts of 4 mice each, which were then housed in modified plastic cages (30 square inches) over either hardwood or pine shavings for the duration of the three day experimental period. 2 of the mice in each experimental cage were injected i.p. with 50 mg/kg of the NE neurotoxin, N-(2-chloroethyl)-N-ethyl-2-bromobenzylamine (DSP-4). Their cagemates and mice in control cages received injections of water vehicle. Odor preferences were tested 3 days after injection. Mice that were continuously housed over hardwood exhibited significant preferences for that odor. Exposure to a new odor, pine, reduced preferences for the hardwood odor in all groups with the exception of the DSP-4-treated females. An unexpected finding was that female mice in all groups demonstrated a significant reduction in weight during the 4 days between injection and testing while males did not show any significant weight changes. The data support previous evidence that norepinephrine facilitates olfactory learning in female mice but also suggest that the effect may be sexually dimorphic. The sex differences in weight changes imply that separation from their cagemates or the crowding conditions may have been more stressful to the female mice.

## 481.21

ADMINISTRATION OF L-TYROSINE PREVENTS COLD-INDUCED MEMORY DEFICITS IN NAVAL SPECIAL WARFARE PERSONNEL. J. Schrot\*, J.R. Thomas, and D. Shurtleff Naval Medical Research Institute, Bethesda, MD 20889-5607.

Administration of l-tyrosine has been shown to prevent cold-induced memory deficits in a laboratory environment. The present study extended those findings to a military field setting. Thirty-six active duty Naval Special Warfare Personnel volunteered to serve as subjects while conducting Arctic and Mountain Warfare Training in Alaska. The subjects were first trained on a computerized performance assessment test battery in Virginia approximately one month prior to deploying to Alaska. Once in Alaska the subjects were divided into two equivalent groups based on baseline test scores. Both groups were then exposed, on at least two occasions, to outdoor ambient cold temperatures, which ranged from -22°C to -3°C (-10°F to 28°F), for one hour subsequent to consuming either 6.0 g of tyrosine or an equal amount of placebo. At the end of the cold exposure the subjects were brought inside and were administered the test battery. On average the subjects who consumed placebo showed performance decrements following cold exposure while the subjects who consumed tyrosine had test scores comparable to those obtained under baseline conditions. The results indicate that consumption of a large dose of tyrosine can prevent cold-induced memory deficits.

## 481.18

SYMPATHETIC AFFERENTS DO NOT APPEAR TO PARTICIPATE IN THE MODULATION OF MEMORY STORAGE PROCESSES. M. Noyes\*, L.L. Murphy\*, and R.A. Jensen\*\*. Departments of Psychology\* and Physiology\*, Southern Illinois University at Carbondale, Carbondale, IL 62901.

Research from this laboratory indicate that vagotomy significantly attenuates the memory-enhancing effects of peripherally acting substances such as 4-OH amphetamine (Williams & Jensen, 1991, *Peripheral Signaling of the Brain*), and vagotomy also attenuates the memory-impairing effects of peripherally administered leu-enkephalin (Williams & Jensen, 1993, *Behav. and Neural Biol.*). These findings suggest that peripheral events, often associated with arousal, send messages to the brain via the vagus nerve to modulate the storage of memories. However, as vagotomy only attenuated and did not block these memory modulatory effects it is possible that other neural pathways from the periphery, such as those associated with the sympathetic system, may also participate in the modulation of memory consolidation. To test this idea, three groups of male Long-Evans rats -- nonoperated controls, sham-operated, and splanchnicectomized animals -- were prepared. The splanchnic nerves were cut bilaterally below the adrenal branch, leaving the innervation to the adrenal glands intact. This was done so that the release of adrenal epinephrine and norepinephrine in response to arousal would be unaffected. Following a seven-day recovery period, the animals were trained in an inhibitory avoidance task where they received a 0.75 mA footshock. Immediately after the training, either saline or 1.0 mg/kg 4-OH amphetamine was administered intraperitoneally, and a retention test was given 24 hours later. To verify the effectiveness of the surgery, only those rats that showed an increased rate of stomach emptying compared to controls were retained in the splanchnicectomy group. In each experimental group, median entrance latencies were significantly higher in the 4-OH amphetamine-treated groups than in the saline-treated groups. These data strongly suggest that splanchnic afferents do not participate in a significant way in the modulation of memory storage processes following peripheral arousal and that afferents of the vagus appear to be the primary route by which peripherally acting substances influence memory storage.

## 481.20

EFFECT OF IDAZOXAN (IDZ) IN CONTROL AND LEAD-EXPOSED RATS: EVIDENCE FOR THE ROLE OF NOREPINEPHRINE (NE) IN ATTENTION. L.E. Bayer\* & B.J. Strupp. Developmental Neuroscience Group & Div. Nutr. Sci., Cornell University, Ithaca, NY 14853.

The present study was conducted with a dual objective: (1) to assess adrenergic receptor involvement in Pb-induced cognitive dysfunction; & (2) to examine the role of noradrenergic activity in selective attention and distractibility. Pb-exposed and control rats were administered the  $\alpha$ -2 adrenergic antagonist IDZ (0, .1, .5, 1 mg/kg) and tested on a distraction task. This task assessed the ability of the S's to monitor an unpredictable light cue of either .5 or 1 sec duration, and maintain performance when presented with olfactory distractors. Preliminary analysis did not provide evidence for a differential effect of IDZ in Pb-exposed and control rats but did reveal specific attentional effects of both Pb exposure and IDZ. Pb-exposed rats made significantly more omission errors than control rats, specifically in the short light cue condition. IDZ (1 mg/ml) improved accuracy, specifically in the most attentionally demanding conditions: the short light cue and distraction conditions. This pattern of results rules out nonspecific alterations in performance as the basis of both the Pb and IDZ effects. These results provide evidence for the hypothesized role of the coeruleocortical NE pathway in attentional function.

## 482.1

ASSESSMENT OF HABITUATION TO A NOVEL ENVIRONMENT AS A MEMORY MODEL. H. Dai\*, E.N. Damanopoulos and R.J. Carey. Dept. of Psychiatry, SUNY HSC and VA Medical Center, Syracuse, NY 13210.

Habituation to a novel environment is a basic learning process manifested throughout the animal kingdom. Although widely used as an index of behavioral adaptation in many animal model studies, relatively few attempts have been made to systematically evaluate habituation as an index of memory. Toward this end, a series of studies were conducted in which rats were exposed to a novel environment for 10 minutes. Twenty four hours later the rats exhibited a decrease in locomotor behavior typical for an habituation effect. In order to develop this response to be relevant to memory, other sets of animals were exposed to the test environment for variable intervals of 2.5, 5, 7.5 or 10 min and then tested twenty four hours later for habituation. In addition, other groups were given a 10 min exposure but were not tested for habituation for 7 or 14 days. The results showed that habituation was positively related to exposure time but negatively related to the length of the inter-test interval. These manipulations provided an experimental means to enhance or attenuate habituation and thereby provide a context in which to assess other memory enhancement or amnesic properties of drugs. Consistent with this analysis, sets of animals were given their first test exposure with drugs known to induce amnesic effects scopolamine (0.5 mg/kg) or MK-801 (0.05-0.3 mg/kg). Both scopolamine and non-motoric doses of MK-801 (less than 0.2 mg/kg) induced deficits in habituation consistent with amnesic effects. Interestingly, higher doses of MK-801 (0.2-0.3 mg/kg) induced both hyperlocomotion and seemingly normative habituation and memory 24 hours later. These studies demonstrate the importance of monitoring the direct behavioral effects of a drug in any attempt to evaluate subsequent effects in memory.

## 482.3

EFFECTS OF THE NMDA ANTAGONIST MK-801 ON OLFACTORY DISCRIMINATION LEARNING AND VICARIOUS TRIAL-AND-ERROR. G. Griesbach\*, D. Hu & A. Amsel. Dept. of Psychology & Inst. for Neuroscience, University of Texas, Austin, TX 78712.

MK-801 (a noncompetitive NMDA receptor antagonist) has been shown to interfere with learning. MK-801 induced learning impairments appear to affect acquisition but not retention. The effects of MK-801 on simultaneous olfactory discrimination learning and vicarious trial-and-error (VTE) were observed. The term VTE was used by Tolman (*Psychol. Rev.* 1939), who described it as a conflict-like behavior at a choice point in discrimination learning. VTE takes the form of head movements from one stimulus to the other. It has been proposed as related to hippocampal function during learning (Amsel, *Hippocampus*, 1993). Twenty-two day-old Sprague-Dawley rats received systemic MK-801 that was injected intraperitoneally 30 min before the onset of training. Subjects were trained for a total of 9 sessions of 20 trials, 3 sessions per day. In the 10th session the odors were reversed. Reversal training was terminated after the 18th session. The present results were that the MK-801 treated animals needed significantly more sessions to reach a criterion of 18 out of 20 rewards per session, and that the control group obtained significantly more rewards per session than the MK-801 treated animals. Control animals also showed a significantly larger number of VTE's. In reversal learning there was no difference between the MK-801 and the control groups. There was also no difference for VTE between the 2 groups. The lack of significance in reversal learning suggests that the effects of MK-801 on olfactory discrimination learning and VTE are dependent on task familiarity obtained in the initial training. Because MK-801 acts on the NMDA receptors, the implication is that the NMDA receptor is more likely to be involved in attention or encoding rather than retention and retrieval. Supported by NIAAA grant AA07052.

## 482.5

RECONSOLIDATION AFTER REACTIVATION OF MEMORY. S.J. Sara, J. Przybylski and T. Alexinsky (SPON: European Brain and Behaviour Society) Institut des Neurosciences, Université P & M Curie, Paris, France.

Rats were trained in a radial maze to choose 3 fixed arms/8, a task requiring integration of distal spatial information contained in cues strategically placed around the maze. Pretrial injection of the noncompetitive NMDA receptor antagonist, MK-801, at a dose which had no effect on overt behavior, markedly disrupted the well-trained performance of the task. Surprisingly, the behavioral deficit persisted on subsequent drug-free trials, 24h and even 48h later. Posttrial injections produced the same proactive effects on performance on one or two subsequent daily trials. There was a temporal gradient of efficacy of drug treatment: delay of injection up to 2h post trial induced significant amnesia, when the rats were tested 24h later. A more difficult version of the task yielded a still longer temporal gradient. Thus it appears that activation of a well-established memory circuit triggers cellular events which depend upon NMDA receptors for more than 2h. To what extent the entire postacquisition cascade of intracellular events associated with long term memory consolidation is recapitulated each time a memory is activated and reorganised is probably a function of the age and complexity of the memory and the amount of new information to be integrated into the circuit. These results provide physiological evidence that memory, as a dynamic process, undergoes continual reorganisation as a function of the ongoing experience of the organism.

## 482.2

THE EFFECTS OF MK-801, A NON-COMPETITIVE ANTAGONIST OF THE NMDA RECEPTOR, ON THE PARTIAL REINFORCEMENT EXTINCTION EFFECT. S. Bland\* and A. Amsel. Dept. of Psychology and Inst. for Neuroscience, University of Texas at Austin, Austin, TX, 78712, USA.

The partial reinforcement extinction effect (PREE) is a paradoxical reward-schedule effect in which resistance to extinction (learned persistence) is increased after partial (PRF) but not continuous (CRF) reinforcement training. Hippocampal insults such as prenatal and early postnatal alcohol, x-irradiation, and electrolytic lesions attenuate the PREE, suggesting that this type of learning depends on the integrity of the hippocampal formation. The NMDA receptor, a subtype of glutamate receptors which is densely concentrated in areas CA1 and dentate gyrus of the hippocampus, has been implicated in a variety of learning and memory tasks as well as long-term potentiation (LTP), an experimental model of synaptic plasticity. To assess the effects of NMDA receptor blockade on the PREE, rat pups (15 days old) were injected with either MK-801 (dizocipine maleate, .05 ml/kg i.p.), a non-competitive antagonist of the NMDA receptor, or saline 30 minutes before either PRF or CRF training (two acquisition sessions and one extinction session) on a straight runway. An additional group was injected with saline before each acquisition session and with MK-801 before the extinction session. The PREE was attenuated in animals treated with MK-801; this difference was greatest in animals receiving MK-801 before both acquisition and extinction. These results suggest a role for the NMDA receptor in learned persistence. (Supported by NIAAA grant AA07052.)

## 482.4

EFFECTS OF MK-801 ON ACQUISITION AND RETENTION OF AN ACTIVE AVOIDANCE RESPONSE IN RATS. E.R. Delay\*, Dept. Psychology, Regis University, Denver, CO 80221.

Depending upon the task, MK-801, an NMDA noncompetitive antagonist, can either improve or disrupt learning and memory (e.g., Mondadori et al, *Exp. Brain Res.*, 75: 449-456, 1989). This study examined the effects of MK-801 on the acquisition and retention of rats trained to avoid shock cued by either a light or a noise intensity CS in a 4-way shuttle. In Experiment 1, four groups of rats were given 30 trials on each of 4 consecutive days with the noise CS. Each group of rats was injected with MK-801 (0.1 mg/kg, IP) 35-40 min prior to one of the 4 sessions. The drug blocked acquisition of the avoidance task only when administered before the first training session. In Experiment 2, rats received the drug within 1 min after completing the training session. No drug effects were found. In Experiment 3, rats were trained with the light CS in Session 1, and with the noise CS in Sessions 2 and 3. MK-801 (0.05 & 0.1 mg/kg) blocked learning in Session 1 and retarded performance in Session 2 but not in Session 3. Drug-induced increases in activity were not related to changes in avoidance behavior. MK-801 blocked acquisition (but not retention) of the active avoidance task and disrupted cross-modal transfer of learning.

## 482.6

SYSTEMIC AND INTRA-CAUDATE NUCLEUS INJECTION OF NMDA RECEPTOR ANTAGONISTS IMPAIR MEMORY IN A VISIBLE PLATFORM WATER MAZE TASK. R.J. Bennett\* & M.G. Packard. Dept. of Psychology, University of New Orleans, N.O., LA, 70148.

Lesion and post-training treatment studies demonstrating dissociations between the effects of lesions and post-training treatments of the hippocampus and caudate nucleus indicate that these two structures are parts of independent memory systems. The caudate nucleus receives glutamatergic input via corticostriatal projections, and it is hypothesized that such input provides sensory information critical to the role of the caudate in "stimulus-response" habit formation. Previous findings indicate a role for the glutamatergic NMDA receptor in hippocampal-based memory. The present study was designed to extend these findings by examining the role of NMDA receptors in the acquisition of a caudate-nucleus dependent cued water maze task.

In Exp. 1 rats received a single 8 trial (30 sec inter-trial interval) training session with a visibly cued escape platform located in a different quadrant of the maze on each trial. Following trial 8, rats received a post-training systemic injection of the non-competitive NMDA receptor antagonist MK-801 (0.1 mg/kg), or saline. On a retention test 24 hours later, latency to mount the escape platform was used as a measure of memory. The retention test escape latencies of rats receiving MK-801 were significantly higher than those of saline treated animals, indicating an impairment of memory. When injections of MK-801 were delayed 2 hours post-training, no effect on retention was observed, indicating a time-dependent effect of MK-801 on memory storage processes.

In Exp. 2, different groups of rats given identical training in the cued task received bilateral post-training intra-caudate nucleus injection of the competitive NMDA receptor antagonist AP5 (2.0, 5.0, 10.0 ug/0.5 ul), or saline. Intra-caudate injection of AP5 at a dose of 2.0 ug significantly impaired memory relative to saline injected controls. The findings suggest that the role of NMDA receptors in memory extends to caudate-nucleus dependent memory processes.

## 482.7

MK 801 BUT NOT HALOPERIDOL SPECIFICALLY ALTERS THE REACTIVITY OF MICE TO SPATIAL CHANGE. P. Rouillet, A. Mele and M. Ammassari-Teule\*. Ist. of Psychobiology and Psychopharmacology, Dip. Gen. e Biol. Mol. Università Roma I, Rome, Italy and Lab. of Psychophysiology, Univ. Tours, France.

NMDA as well as dopaminergic antagonists produce specific place but not cue learning deficits in the Morris water maze. The present work was, therefore, aimed at examining if the blockade of NMDA and dopaminergic receptors interfere with spatial information processing even in non associative tasks i.e. in tasks which do not involve an explicit reinforcing procedure. CDI mice injected with MK801 (.1 and .25 mg/kg), haloperidol (.04 and .08 mg/kg) or saline were placed in an open field containing five objects and their reactivity to the displacement (spatial change) or the substitution (non spatial change) of some of these objects was examined. The results show that saline injected mice react to spatial as well as to non spatial change, by increasing the time spent exploring the displaced objects or the substituted one. Both doses of MK 801 prevented the mice to discriminate between displaced and non displaced objects while their reactivity to the novel object was unchanged. Both doses of haloperidol did not affect the reactivity of mice to spatial or to non spatial change. These results indicate that NMDA antagonists specifically disrupt the capability to perceive and/or to update spatial relationships since they alter performance in associative as well as in non associative spatial tasks. Conversely, the fact that haloperidol produces deficits of performance limited to associative spatial tasks suggests that dopaminergic antagonists can interfere with spatial information processing only in the presence of a reinforcing event.

## 482.9

KETAMINE BLOCKS A CONDITIONED TASTE AVERSION (CTA) IN NEONATAL RATS. G.A. Mickley\*, M.A. Schaldach, K.J. Snyder, T. Len and S.A. Balogh. Department of Psychology, Baldwin-Wallace College, Berea, OH 44017-2088.

We have been exploring the effects of glutamate, NMDA receptor blockade on the formation and retention of CTA memories in young rats. Previous data from our laboratory (Mickley et al., *Dev. Brain Res.* 85, 1995, 119-127) suggested that ketamine administration potentiates the CTA of E18 rat fetuses. The current studies investigated this phenomenon in neonates.

On their day of birth, Sprague-Dawley rat pups received injections of 0.1 or 10 mg/kg ketamine, i.p. or a saline control injection. Pups were then injected orally with either saccharin (SAC; 10  $\mu$ l of 0.3%) or water followed by an injection of either Lithium Chloride (LiCl; 81mg/kg) or saline (i.p.). The CTA was evaluated in 2 different tests. Two weeks after conditioning, the dam was anesthetized and we measured the frequency with which pups attached to SAC-painted nipples vs nipples painted with water (nipple test). After weaning, we also evaluated the CTA by measuring the amount of SAC (0.3%) or water consumed during a 2-bottle test.

The data suggest that neonates receiving saline control injections can acquire CTAs. However, the ketamine-injected pups did not exhibit CTAs on either the nipple or bottle tests. Rats injected with ketamine and then SAC+LiCl drank more SAC than pups receiving saline before SAC+LiCl treatments.

These data reflecting a ketamine-induced blockade of neonatal CTAs are in contrast with findings in which ketamine potentiated fetal CTAs. This difference could reflect distinct dosing procedures employed in fetal vs neonatal rats. Alternatively, NMDA receptor blockade may shape memory formation in a manner that is dependent on the stage of brain development.

## 482.11

NEUROPEPTIDE Y AND CALCITONIN GENE-RELATED PEPTIDE ATTENUATE MEMORY IMPAIRMENT INDUCED BY MK-801 LIKELY VIA A SIGMA RECEPTOR-RELATED MECHANISM. P. Bouchard\*, S. St-Pierre, A. Privat and R. Quirion. <sup>1</sup>Douglas Hospital Research Center and McGill University, Montréal, Québec, Canada <sup>2</sup>I.N.S.E.R.M. U.336, Montpellier, France, and <sup>3</sup>Institut National de la Recherche Scientifique, Pointe-Claire, Québec, Canada.

It was recently shown that high affinity sigma ( $\sigma$ ) ligands (DTG, (+)NANM and (+)pentazocine) significantly attenuated the amnesia induced in mice by the systemic administration of the non-competitive NMDA receptor antagonist MK-801. The purported  $\sigma$  receptor antagonists BMY-14802 and NE-100 blocked the effect of  $\sigma$  ligands, suggesting the involvement of  $\sigma$  receptors in mnemonic processes mediated by the NMDA receptor (Maurice et al., 1994). It was also shown, using *in vivo* binding (Bouchard et al. 1993, 1994) and electrophysiological (Monnet et al., 1992; Bouchard et al., 1994) paradigms that neuropeptide Y (NPY) and calcitonin gene-related peptide (CGRP) modulate  $\sigma$  sites in the rat and mouse brain, *in vivo*. Taking into consideration these various results, we investigated the possible modulatory actions of NPY and CGRP on MK-801-induced amnesia in mice, using a well-established step-down passive avoidance test (Maurice et al., 1994). At time 0, male Swiss mice were injected i.p. with either saline, MK-801 (200  $\mu$ g/kg; i.p.) or MK-801 (200  $\mu$ g/kg; i.p.) in combination with BMY-14802 (5 mg/kg; i.p.) as  $\sigma$  blocker. Immediately thereafter, mice were injected i.c.v. (3  $\mu$ l) with either saline, NPY or CGRP. Ten min later, animals received their first training session. Step-down latency (SDL) and the number of flinching actions and vocalizations were recorded. The second training period was carried out 90 min after the first, with an upper limit of 60 sec. The retention test was carried out 24 hr after the second training, with an upper limit of 300 sec. Compared to control mice, SDL was substantially reduced following the preadministration of MK-801 suggesting a memory impairment. NPY (1000 pmol; i.c.v.) and CGRP (1000 and 1500 pmol; i.c.v.) while having no significant effect by themselves, attenuated the MK-801-induced amnesia as shown by increased SDL. Furthermore, when co-administered with MK-801, BMY-14802 prevented the effect of NPY and CGRP in the behavioral task suggesting the involvement of  $\sigma$  sites. Hence, while *in vitro* evidence for direct interaction between NPY or CGRP and  $\sigma$  sites have failed to be obtained thus far, various *in vivo* models have shown that these peptides can modulate  $\sigma$  receptor systems in the brain. (Supported by the NSERC and Jouveinal Laboratories)

## 482.8

CLASS I METABOTROPIC GLUTAMATE RECEPTOR AGONIST tADA FACILITATES LTP BUT BLOCKS MEMORY FORMATION IN RATS. G. Riedel\*, W. Wetzel\*, D. Manahan-Vaughan\*, M. Reiser\*, S. Vieweg\*, G. Behnisch\*, A.P. Kozikowski\* and K.G. Reyman\*, Dept. of Psychol., Univ. of York, York, YO1 5DD, United Kingdom, <sup>2</sup>Fed. Inst. for Neurobiol., Dept. Neurophysiol., P.O.Box 1860, D-39008 Magdeburg, Germany and <sup>3</sup>Neurochem. Res., 12 Mershon Drive, Princeton, NJ 08540, USA

As previously shown metabotropic glutamate receptors (mGluRs) are involved in LTP *in vitro* and *in vivo* as well as memory formation. In order to classify which subtypes may participate in such forms of plasticity, we invented the effects of trans-azetidine-2,4-dicarboxylic acid (tADA) in both LTP in the dentate gyrus and spatial alternation learning versus brightness discrimination. tADA selectively acts on class I mGluRs in hippocampal slice preparations, and had no effect on forskolin-stimulated cAMP formation.

Weak tetanization (3 bursts, 200 Hz, 75 ms) applied to chronically implanted and saline i.c.v. injected rats (bipolar stimulation electrodes in medial perforant path, monopolar recording electrode in granular cell layer of dentate gyrus, guide cannula in lateral ventricle) caused a 2 hr potentiation, which was significantly prolonged when tADA (20 mM/5  $\mu$ l) was i.c.v. injected 30 min. pretetanus. The same tADA concentration injected 30 min pretraining had no effect on acquisition performance in a shock-reinforced spatial alternation task in the Y-maze. When tested for retention 24 hr later tADA treated rats were amnesic. State-dependent effects could be excluded. No effect of tADA was observed in brightness discrimination learning.

These data suggest that mGluR activation, although it facilitates LTP maintenance, blocks spatial memory formation, possibly via an unspecific saturated activation of mGluRs. This saturation may in turn decrease the signal-to-noise ratio of synaptic transmission and thus block memory formation.

## 482.10

ADVERSE EFFECTS OF DEXTROMETHORPHAN ON THE SPATIAL LEARNING OF RATS IN THE MORRIS WATER MAZE. D.C. Rojas\*, A.J. Bane, K.I. Indermauer, T.L. Bennett, and D.D. Avery. Dept. of Psychology, Colorado State Univ., Ft. Collins, CO 80523.

The effects of dextromethorphan (DX), a common over-the-counter antitussive, on spatial learning were assessed using the Morris Water Maze procedure. DX was administered IP to 4 groups of rats in 10, 20, 30, 40 mg/kg doses, as well as a saline vehicle control group. DX, a non-competitive n-methyl-D-aspartate (NMDA) receptor antagonist, impaired learning dose-dependently in the initial training phase of the experiment. During the probe trial conducted after initial training, in which the animals swam for 60 seconds in the maze with no escape platform, dose-dependent performance deficits were noted in the first 15 seconds of the trial only. Strategy differences between the lowest and highest dose group were also observed during the probe trial, with the saline control group spending more time in the target quadrant than the 40 mg/kg group during the first 15 seconds, then searching other quadrants; the opposite pattern was observed in the 40 mg/kg group. During the reversal training phase, when the quadrant was moved to a location 180 degrees from the original location, the dose-dependent impairment was seen again, but the 40 mg/kg group perseverated to the former location longer than the other groups. A cued control trial, in which the platform could be seen by the animals, indicated that in addition to the learning impairment produced, the highest dose of DX may also impair motor coordination.

## 482.12

BEHAVIOURAL EVIDENCE FOR A MODULATING ROLE OF THE SIGMA LIGANDS JO 1784 AND 2-DTG IN MEMORY PROCESSES IN THE RAT.

B. Earley\*, M. Glennon\*, D. Kane\*, B.E. Leonard\*, and J.-L. Junien\*, Pharmacology Department\*, University College, Galway, Ireland and Institut de recherche Jouveinal\*, 94265, Fresnes, France.

The nature and extent of the behavioural changes induced by the non-competitive NMDA antagonist, dizocilpine (MK-801), were assessed in the eight arm radial maze task. Male Sprague-Dawley rats were trained on the eight-arm radial maze task for food reinforcement. The effects of various doses of 1,3-di(2-tolyl)guanidine (2-DTG) (1 and 3 mg/kg s.c.) and JO 1784 (0.1, 0.3, 1.0 and 3.0 mg/kg s.c.) were determined alone and in combination with MK-801 (0.25 mg/kg s.c.). Relative to vehicle controls, JO 1784 and 2-DTG alone did not affect performance in the radial arm maze. MK-801 alone decreased the number of correct responses in the first eight arm choices, while increasing both the number of errors and the time necessary to complete the maze. 2-DTG produced a slight attenuation of MK-801 induced amnesia. Moreover, JO 1784 attenuated MK-801 induced amnesia only after the administration of 2-DTG. These results suggest that sigma ligands are capable of modulating learning and memory processes.

## 482.13

DIFFERENTIAL EFFECTS ON SPATIAL LEARNING AND MEMORY BY THE NMDA RECEPTOR ANTAGONIST CGP 37849. L. J. Jeun, J. Baruch, and V. Luine\*. Department of Psychology, Hunter College of CUNY, New York, NY 10021

Using a spatial memory task, we assessed the behavioral effects of the NMDA receptor antagonist CGP 37849. CGP 37849 enhances cell birth in the dentate gyrus of the rat hippocampus and causes a 24% increase in the number of granule neurons one month post-treatment (Cameron et al., in press). Twelve adult male rats were administered one i.p. injection of 7 mg/kg CGP 37849 or saline. Two months after treatment, rats were trained and tested using the 8-arm radial maze (RAM). Overall, the CGP-treated rats did not perform as well as control rats. During regular trials, they made mistakes sooner and more frequently. During delay trials, CGP-treated subjects also exhibited impaired performance with 3, 4, 5, and 6 h delay intervals between the 4th and 5th choices.

In an attempt to determine whether impairments were due to learning or memory function, rats were tested with four arms baited. Surprisingly, in the first 10 of 25 trials, CGP-treated rats made fewer reference errors (entries into unbaited arms which represent acquisition of the procedural aspect of the maze), suggesting enhanced learning. In contrast, in the last 15 of 25 trials CGP-treated rats made more working errors (re-entries into baited arms which represent short term memory), suggesting impairments in working memory. These results show that a single injection of an NMDA receptor antagonist causes a long term effect on spatial memory performance. Moreover, CGP 37849 appears to differentially affect learning and memory, enhancing the former and impairing the latter. (NIMH MH16705 to H.C.)

## 482.15

THE EFFECTS OF BASAL FOREBRAIN LESIONS ON EXPECTANCY IN THE RAT. J.D. Stoehr\* and G.L. Wenk. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

A two-choice operant task was used to measure the effect of lesions of the basal forebrain on a task that requires shifting of attention between two visual stimuli. Discriminability between these two stimuli and response bias were determined in rats given injections of N-methyl-D-aspartate (NMDA) or a selective cholinergic toxin, IgG-192 saporin, into the basal forebrain. NMDA injections significantly reduced ChAT activity, a measure of basal forebrain cholinergic cell loss, in the frontal and parietal cortex, but not in the hippocampus or olfactory bulbs. IgG-192 saporin injections significantly reduced ChAT activity in all of these brain areas. Both toxins produced a significant shift in response bias that correlated with the degree of cholinergic cell loss in cortical and hippocampal areas. IgG-192 saporin injections produced a significantly greater impairment in choice accuracy and response bias compared to injections of NMDA. The results suggest that the cholinergic basal forebrain may influence the selection of response strategies in simple operant tasks involving motor responses to visuospatial stimuli.

## 482.14

NMDA RECEPTORS ARE INVOLVED IN LEARNING A SPATIAL TASK BUT MAY NOT BE NECESSARY FOR ENCODING A SPATIAL REPRESENTATION OF A SPECIFIC ENVIRONMENT. D.M. Bannerman, M.A. Good, M. Ramsay, S.P. Butcher, S.D. Iversen\*, R.G.M. Morris, Centre for Neuroscience and Dept of Pharmacology, Univ of Edinburgh, Edinburgh EH8 9JZ, Scotland.

Morris et al., (*Nature*, 1986, 319:774-776) found that chronic i.c.v. infusion of the competitive NMDA antagonist, D,L-2-amino-5-phosphopentanoate (AP5) impairs the acquisition of spatial learning in the watermaze and blocks the induction of LTP in the dentate gyrus *in vivo*. In contrast, both the retention of previously acquired spatial information and performance on a non-spatial visual discrimination task are unaffected by AP5. These results support the hypothesis that NMDA receptor-dependent changes in synaptic efficacy, similar to LTP, may contribute towards the neural mechanisms underlying spatial learning. However, in a subsequent study we found that, although a 30 mM dose of D-AP5 reliably impairs spatial learning in naive animals, the behavioural deficit is greatly reduced if spatial training in a different environment is given prior to the drug phase of the experiment. This outcome is not because of generalisation between the 2 laboratories, occurs despite the learning of the second task remaining dependent on the integrity of the hippocampus, and with intracerebral levels of D-AP5 well in excess of those required to block LTP *in vivo* in the same animals as tested behaviourally. In contrast, if rats are pretrained as normal animals in the first watermaze, under conditions that minimise spatial learning, the D-AP5 induced deficit in the second watermaze re-appears. These results suggest that spatial learning in the watermaze may involve NMDA receptor-dependent and -independent components, and that while NMDA receptors are required while learning a spatial task, they are not necessary for encoding the spatial representation of a specific environment.

## 482.16

EFFECTS OF A COMPETITIVE NMDA ANTAGONIST, CGP-39551, ON HIPPOCAMPAL LTP AND PLACE LEARNING. J.M. Hoising\*, A.D. Barnes, R.J. McDonald, and R.J. Sutherland. Dept. of Psychol. & Physiol., Univ. of New Mexico, Albuquerque, NM 87131-1161.

Manipulations which affect hippocampal LTP, such as blockade of NMDA receptors, have been shown to block place learning. In general, these results support the idea that NMDA-dependent hippocampal synaptic plasticity is necessary for the acquisition of certain types of information. In particular, the effects of CGP-39551, a competitive NMDA antagonist, on induction of hippocampal LTP and on the acquisition of spatial information in the Morris water task were examined. LTP was induced in urethane-anesthetized rats by electrical stimulation of perforant path-dentate gyrus synapses. CGP-39551 produced a dose-dependent deficit in LTP induction - at 12 mg/kg LTP was blocked. Experimentally naive rats treated with 12 mg/kg did not learn to swim to the fixed location of a hidden platform in the Morris water task. Experimentally sophisticated rats, trained in a place learning-set procedure, were able to acquire accurate place navigation in a novel room after having been treated with the same dose, 12 mg/kg. This suggests that acquisition of spatial information *per se* does not require NMDA-dependent synaptic processes.

## BIOLOGICAL RHYTHMS AND SLEEP: AGING

## 483.1

PATHOLOGICAL CORRELATES OF CIRCADIAN RHYTHM DISTURBANCES IN LATE-STAGE ALZHEIMER'S DISEASE. A. Satlin\*, E.G. Stopa, D.G. Harper, V. Kuo-LeBlanc, M. Rodriguez-Wolf, L. Volicer. Dept. of Psychiatry, McLean Hospital, Belmont, MA 02178; E.N. Rogers Memorial Veterans Hospital, Bedford, MA 01730; Dept. of Pathology, Brown Univ. Sch. of Med., Providence, RI 02903.

We previously reported a phase delay in the circadian rhythms of locomotor activity and core-body temperature in patients with late-stage Alzheimer's disease, and a decreased amplitude of the locomotor activity rhythm. Neuropathologic examination of the suprachiasmatic nucleus in patients with advanced AD has revealed a significant decrease in vasopressin-containing neurons and an increase in the glia/neuron ratio compared to age-matched controls. The present study sought correlations between disturbances in circadian rhythmicity and pathologic changes in the brains of 16 late-stage AD patients. Vasopressinergic neuronal loss was associated with decreased mean diurnal ( $r=0.81$ ;  $p<0.001$ ) and nocturnal ( $r=0.74$ ;  $p<0.01$ ) core-body temperature and with increased fragmentation of the locomotor activity rhythm (intradiurnal variability;  $r=0.62$ ;  $p<0.01$ ). Loss of neurotensin-containing neurons was associated with lower circadian temperature rhythm amplitude ( $r=0.57$ ;  $p<0.05$ ). There were no significant associations between loss of either cell population and the phase of the temperature or activity cycles. However, later phase of the temperature cycle was associated with axonal degeneration in the optic nerve ( $r=0.56$ ;  $p<0.05$ ). These findings confirm an association between degeneration in brain structures thought to mediate circadian rhythmicity and objective measures of circadian function in late-stage AD patients. They also suggest that differential degeneration in neuronal populations and structures in AD may have variable effects on circadian function. Supported by AG09301.

## 483.2

CIRCADIAN RHYTHMS AND AGING: A LONGITUDINAL STUDY OF FREERUNNING PERIOD AND ACTIVITY LEVEL IN SYRIAN HAMSTERS. N. Viswanathan\* and F.C. Davis. Dept. of Biology, Northeastern Univ., Boston, MA 02115.

Age-related changes in the regulation of circadian rhythms have been reported in humans and other animals. In Syrian hamsters the freerunning period of the activity/rest rhythm has been reported to shorten with age. Although this has been observed under a variety of experimental conditions (including blinded hamsters), continuous measurements of freerunning period over the life of animal have not been made in intact hamsters. In the present study, the wheel running activity/rest rhythm was continuously measured in male hamsters (*Mesocricetus auratus*) in dim constant light (< 1 lux) from 8 to 90 weeks of age. Freerunning period and activity level were analyzed beginning at 30 weeks of age to ensure that after-effects of the initial light/dark cycle had decayed and that the reproductive state of the hamsters had stabilized. Fifteen hamsters (28% of initial number) survived to at least 90 weeks. The average freerunning periods of these hamsters at 30, 50, 70 and 90 weeks of age were 24.08, 24.13, 24.11, and 24.10 respectively, and there was not a significant shortening of period ( $P=0.38$ , repeated measures ANOVA). Some individual hamsters showed a shortening of period while others showed no change or a lengthening. In contrast to freerunning period, average activity level showed a 60% decrease over the course of the study ( $P<0.001$ ). To determine whether period changed prior to death, the freerunning periods of hamsters that were at least a year old were measured at 2 weeks, 3 months, and 6 months prior to death ( $n=18$ ). There was also no change in average period in this group. These results demonstrate that the average freerunning period of the circadian activity/rest rhythm does not change with age in intact hamsters continuously maintained under constant conditions. Previous observations of a shortening of freerunning period with age may be related to the particular conditions of those studies. Supported by PHS grant P01 AG09975.

## 483.3

THE ROLE OF SUPRACHIASMATIC NUCLEUS IN AGE-RELATED CHANGES OF CIRCADIAN RHYTHM. S. Yamaoka\*, N. Koibuchi, and M. Sakai. Dept. of Physiology, Dokkyo Univ. Sch. of Med., Mibu, Tochigi, 321-02 Japan

Age-related changes in various circadian rhythms have been documented. However aging mechanisms in circadian system is still unknown. Previously we reported that the aging changes of circadian sleep rhythm in female rat correlated with the aging changes in sexual cycle. To clarify the role of suprachiasmatic nucleus (SCN) in correlation between aging mechanism and circadian system, we adapted the analyses of circadian locomotor activity and the quantitative immunohistochemistry. 1) Male rats (Sprague Dawley, SD) were divided into three groups: 2-5 months young rats, 12-16 middle aged rats, 18-30 months old rats. Zitter rat (*z*: a mutant rat), which shows spongy degeneration of the central nervous system and a generalized body tremor, divided two groups (1-3 months and 7-10 months). The circadian locomotor activity (LMA) was measured by infra-red area sensor. The free-running period under constant dark shortened with age in both strains. Three hours light pulse caused the phase shift depending on the applied circadian time in young SD rat, but not in old SD and 7-10 months *z* rat. In old SD rats, the re-entraining days to reverse lighting schedule also postponed with age. These aging effects of 7-10 months *z* rat were equivalent with over 24 months SD rats. 2) The Fos-like immunoreactive (Fos-IR) cells was diffusely located in SCN. Greater amount of Fos-IR cells were seen in light phase than dark phase under light-dark condition. This change was disrupted in old rat. Fos-IR cells were confined in the ventrolateral part of SCN by the light pulse during constant dark. This change did not show any difference with the age or the phase of activity. These results suggest that a part of aging mechanism in circadian rhythm due to the disruption of signal transduction from circadian oscillator, and the signal transduction from retina is not affected by aging.

## 483.5

AGE-RELATED CHANGES IN THE EXPRESSION OF BRAIN-DERIVED NEUROTROPHIC FACTOR mRNA IN THE RAT SCN. D. Earnest\*, B. Earnest and E. Sohrabji. Dept. of Human Anatomy and Medical Neurobiology, Texas A&M Univ., College of Medicine, College Station, TX 77843.

Aging of the circadian pacemaker in the rodent suprachiasmatic nucleus (SCN) is characterized by changes in period length and in responses to environmental stimuli. While the physiological or biochemical changes underlying this age-related deterioration of SCN circadian function are unknown, such changes may be associated with age-related alterations in specific growth factors that mediate structural or synaptic plasticity. Since recent data from our lab indicates that brain-derived neurotrophic factor (BDNF) mRNA is expressed within the rat SCN, the present study examined whether aging is associated with changes in SCN expression of this neurotrophin gene.

Total RNA from the SCN of 4-month and 21-month old male Fisher 344 rats was DNase-d and then assayed by semi-quantitative RT-PCR for BDNF mRNA. Template cDNA was formed using reverse primers specific for the rat BDNF gene (Exon V) and cyclophilin and then amplified by the addition of gene-specific, <sup>32</sup>P-labelled forward primers. Amplified product was size-fractionated and visualized by film autoradiography. The PCR product of BDNF primers was normalized to cyclophilin mRNA that had been concurrently reverse-transcribed and amplified. SCN expression of BDNF mRNA showed signs of age-dependent regulation, suggesting that aging may alter SCN plasticity in response to environmental stimuli. Continuing work will explore the relationship between this age-related alteration in BDNF expression and deterioration of SCN circadian function.

BASAL AND PHASE-SHIFTED NEURONAL RHYTHMS IN THE AGED SCN IN VITRO. V. H. Cao, D. M. Edgar, H. C. Heller, W. C. Dement and J. D. Miller\*. Cir. Sleep and Circadian Neurobiology, Stanford University, Stanford, CA 94305.

The mammalian suprachiasmatic nuclei (SCN) contain a circadian pacemaker that produces a 24hr rhythm in spontaneous neuronal activity *in vitro*. This *in vitro* rhythm can be phase-advanced by application of the 5HT1A/5HT7 receptor agonist, 8-OH-DPAT. Although numerous investigators have noted a decline in behavioral circadian rhythmicity *in vivo* with aging, it is not known whether this decline represents an alteration in afferent input to the SCN, intrinsic function of the SCN pacemaker, or SCN efferents. To address these questions we have examined basal and 8-OH-DPAT-phase-shifted single unit rhythms in SCN slices from behaviorally characterized (locomotor activity) aged Fischer 344 or Wistar male rats. Brain slices prepared during lights-on from 4-32 month old male rats, housed in 12:12 LD were maintained *in vitro*. In some experiments basal single unit rhythms were recorded. In other experiments slices were treated for one hr with 8-OH-DPAT (5 uM) at CT6 on the first day *in vitro*. Neuronal activity was recorded on day 2. In nearly all baseline studies (n=35 at present, including 20 rats from 12-32 mo old) the usual unimodal circadian rhythm was observed. In 8-OH-DPAT studies, phase advances of about 150% the magnitude of the usual advance in young rats (-4 hr, 2-4 mo old) were noted in the aged rats (-6.3 hr, 17-32 mo old, n=5). Robust phase advances and the usual unimodal single unit rhythms were observed, even from rats with very low amplitude behavioral rhythms. Our preliminary data suggest that the intrinsic circadian pacemaker in the SCN is relatively resistant to aging. The large phase advances to 8-OH-DPAT in aged slices suggest development of 5HT7 receptor supersensitivity. Frequently observed low amplitude behavioral rhythms in these studies further suggest that age-related degeneration in rhythmicity may largely reflect deficits in SCN efferents or downstream clock effector mechanisms. Supported by AG11084.

## 483.6

REDUCED CIRCADIAN RESPONSES TO LIGHT IN AGED C3H/HeN MICE. S. Benloucif, M. I. Masana, and M. L. Dubocovich. Dept. Mol. Pharmacol. Biol. Chem., Northwestern Univ. Med. Sch., Chicago, IL 60611.

Light-induced immediate early gene expression in the SCN of aged rodents is attenuated, suggesting decreased responsiveness by the circadian pacemaker (Neurobiol. Aging, 1993, 14:441). The present study examined the effect of age on phase shifting responses to light in C3H/HeN mice. Young and old male C3H/HeN mice (4 or 16 months at the beginning of the experiment, n = 9) were housed in constant darkness with circadian wheel running activity rhythms monitored by an online computer. Shifts in phase were assessed by comparing the steady state activity onset before (10 days) and after (14 days) the treatment. Light pulses of 15 min duration (30, 100, 300 or 1000 lux) were delivered every 3 weeks over a 6 month period and the magnitude of the phase shifts compared. Aging reduced the phase delaying effect of light at CT 14 at all light intensities (p < 0.001), with an interaction of age and intensity that approached significance (p = 0.06). A light pulse of 30 lux was saturating in the young mice, resulting in delays in phase of -2.79 ± 0.22 h (n = 6). In contrast, only one of 5 old mice shifted phase at this intensity (p < 0.001). In the old mice, light pulses of 100, 300, and 1000 lux induced phase delays of lower magnitude than young controls [1000 lux, young: -2.28 ± 0.13 (n = 5); old: -0.98 ± 0.47, p < 0.05 (n = 6)]. These results support reduced responses to light by the circadian pacemaker or its effector systems in aging. The molecular responsiveness of the pacemaker will be determined at the conclusion of behavioral testing by assessing the photic induction of immediate early genes (*c-fos* and *jun-B*) in the SCN. Supported by a Glaxo grant and NIH F32-AG05608.

## BIOLOGICAL RHYTHMS AND SLEEP: DISORDERS AND CLINICAL STUDIES

## 484.1

EVIDENCE FOR LOCALIZED NEURONAL DEGENERATION IN THE NARCOLEPTIC DOG. J. M. Siegel\*, R. Nienhuis, H. Fahringer, S. Gulyani, E. Mignot and R. C. Switzer III. Neurobiology Research Sepulveda VAMC, Dept of Psychiatry, UCLA School of Medicine, North Hills CA 91343 and \*Dept of Psychiatry, Stanford University, Stanford CA

Narcolepsy develops postnatally in both humans and animals. While changes in receptor levels have been reported, no underlying pathology responsible for these changes has been identified. We hypothesized that narcolepsy is caused by a transient degenerative process occurring at the age of symptom onset. We used the cupric silver technique to search for axonal degeneration shortly after symptom onset in four narcoleptic dobermans and four age and breed matched normal canines. All narcoleptic animals showed extensive degeneration in the medial septal nucleus and diagonal band region. None of the controls showed such degeneration (p < .001, 2 way ANOVA). The areas of degeneration are adjacent to basal forebrain neuronal systems known to be of primary importance in sleep initiation and motor control. Therefore this damage can explain the principle symptoms of narcolepsy.

## 484.2

BEHAVIOR DISRUPTION AND RECOVERY IN PORTACAVAL SHUNTED RATS. P. A. Hawkins, M. R. DeJoseph and R. A. Hawkins\*. Department of Physiology and Biophysics, Finch University of Health Sciences/The Chicago Medical School, North Chicago, IL 60064

Portacaval shunting causes liver atrophy and encephalopathy as evidenced by a variety of metabolic and behavioral abnormalities including a disruption of the normal circadian rhythm. Whether the changes associated with liver dysfunction are completely reversible has been hypothetical. We developed a rat model that allows blood circulation to be restored to the liver resulting in its re-growth to normal size and the elimination of many of the metabolic signs of liver dysfunction. The focus of this study was on behavioral activity before, during and after a period of portacaval shunting to determine whether the normal pattern of activity could be restored after a sustained period of liver dysfunction. Behavioral activity was monitored in a specially designed cage for 2 weeks to establish pre-shunt activity. Rats were then given side-to-side shunts and activity was monitored for 6 weeks. Finally, blood circulation was restored to the liver and behavioral activity was recorded for at least an additional 6 weeks. Portacaval shunted rats showed a depression in nighttime activity and the night-to-day ratio within 1 week. Redirecting blood flow to the liver resulted in restoration of normal behavior in all but 1 rat (n=10). The ability to reverse behavioral changes in rats with portacaval shunts of 6 weeks duration suggests a non-permanent nature of hepatic encephalopathy in this time period. Monitoring activity seems to be an efficient way to test potential therapies for chronic hepatic encephalopathy. Supported by NIH grant NS 16389.

## 484.3

EFFECTS OF OLFACTORY BULBECTOMY ON RUNNING-WHEEL ACTIVITY IN ADULT MALE RATS. M.E. Yagell, M.Y. McGinnis\*, B. Possidente, and A.R. Lumia. Depts. of Psych. & Bio., Skidmore College, Saratoga Springs, NY 12866. Dept. of Cell Bio./Anat., Mount Sinai School of Medicine, NY, NY 10029.

Bilateral olfactory bulbectomy (OBX) in rodents results in several behavioral and biochemical alterations leading to its development as a rodent model for depression. OBX mice entrained to 12:12 LD schedules increase both amplitude and mean running-wheel activity levels. The present study tests whether OBX affects running-wheel activity in adult male Long Evans rats as it does in mice. Wheel-running activity was measured with an automated system for counting revolutions per ten minute interval. Activity was measured for two weeks before OBX surgery, followed by two weeks of surgical recovery, and then measured for two final weeks. The data were analyzed using a linear COSINOR model with the frequency set for 1 cycle/day to determine amplitude and mean activity levels. Statistics were performed using the percent change from pre-surgical activity levels for each rat because of high inter-animal variability. We found that OBX rats showed significant increases in both amplitude and mean activity levels when compared to sham operated controls (Mann-Whitney U test). The data from the present study on OBX rats corresponds to other studies involving OBX mice. We conclude that in spite of the large individual differences in wheel-running activity, Long Evans rats are suitable for studying the chronobiological effects of OBX.

QUANTITATIVE ELECTROENCEPHALOGRAPHIC AND LOCOMOTOR ACTIVITIES IN THE GRAVID RAT. G. Livezey\* and C. Smith, Dept. of OB/GYN, University of Nebraska College of Medicine, Omaha, NE 68198-3255

In developing an animal model for the study of prenatal exposure to centrally acting drugs, we compared the electroencephalographic (EEG) and locomotor activities in the pregnant and nonpregnant rat. Mature female Sprague-Dawley rats were implanted with telemetry transmitters. EEG and locomotor activities were sampled every 10 minutes around the clock for 5 weeks prior to breeding, throughout their 21 day gestation and 3 weeks postpartum (weaning period). Contemporary controls consisted of those not bred. The EEG data was converted to the power spectra and averaged over 24 hours. We divided the spectra into delta (1-4 Hz), theta (4-8 Hz), alpha (8-12 Hz), middle beta (12-16 & 16-20 Hz), and fast beta (20-24, 24-28, & 28-32 Hz) frequency bands. Each band was converted to a percentage of the total spectra. Locomotor activity was analyzed by ANOVA and power spectral frequency bands by MANOVA. Data are presented as effects of circadian rhythm, menses cycle, progression of pregnancy and maternal behavior.

## 484.7

ONGOING AND INDUCED BRAIN RHYTHMS: MANIPULATION BY INVASIVE MAGNETIC PULSEFORMS. H. Stowell\*, HRT Brain & Behavior, Milledgeville GA 31061-3420.

In 1994 a new biomedical instrument arrived on the USA market from South Wales U.K. It claims unprecedented control of a magnetic field, by frequency and amplitude modulation of magnetic pulses peaking at 30 MW, entrained as 8 pulses from a single coil or 4 from a pair of coils independently timed; the coils are designed to sit bilaterally over human & other primate heads. Interpulse spacing permits entrainment of up to 8 pulses within a bandpass of 10 Hz to 2 KHz, by steps of 0.0001 Hz, which includes all but the lowest frequencies of human ongoing & induced rhythms in the brain (OIRB) or EEG & event related brain potential (EEG-ERBP). Its makers say that an FDA-IDE is necessary for "commercial use", but in 1994 the FDA claimed never to have heard of either makers or instrument; neuroscientists familiar with basic research on OIRB, earlier claims for behavioral modification by weak UHF-carrier, low-frequency modulated irradiation of nonhuman brains, traditional ECT, and the morally indignant response of AAS to the 1989 report of magnetic stimulation for epileptic relief [1], may be concerned at the claims and likely uses of this Magstim Quadropulse Magnetic Pulse Train Workstation.

AMPLITUDE OF WHEELRUNNING RHYTHMS IS DECREASED IN HAMSTERS TREATED WITH SCOPOLAMINE AS NEONATES. H. Klemfuss\*, P. R. Ramos and J. C. Gillin. Veterans Affairs Medical Center, San Diego, CA 92161 and Department of Psychiatry, University of California, San Diego.

Cholinergic-aminergic imbalance may be involved in mood and sleep disorders. Treatment of neonatal rats with monoamine uptake inhibitors can produce a depression-like syndrome in adults that includes REM sleep disturbances and alterations in the circadian rhythm amplitude. We tested effects of neonatal treatment with scopolamine HCl (SCOP), a muscarinic antagonist, on circadian running rhythms in the golden hamster.

Neonatal hamsters were housed with the mother on an LD14:10 cycle, with lights on at 6 am. From age 8-16 d, 3 ♂ and 3 ♀ were given sc injections of 1 mg/kg SCOP at 7 am and 7 pm, and 9 control hamsters (5 ♂, 4 ♀) received saline injections. Hamsters were weaned at d 16. 10 mg/L SCOP was added to the water of experimental hamsters from d 16-21. Starting on d 28 each hamster was housed in a running wheel cage and given water to drink.

There were no differences between groups in weight gain or appearance. Neonatal SCOP decreased the total harmonic amplitude of the wheelrunning rhythm in juvenile hamsters ( $p < .001$ ) and decreased goodness-of-fit by several methods ( $p < .001$ ). Harmonic amplitude was also increased when expressed as % of mesor ( $p < .01$ ). Circadian phase was not significantly altered (saline-control  $20:44 \pm 2$  hr; SCOP-treated  $19:89 \pm 4$  hr; lights off  $20:00$ ) ( $p = .11$ ). This preliminary work indicates that transient disturbance of muscarinic metabolism in developing hamsters can produce lasting effects on circadian oscillator amplitude.

## 484.6

EFFECT OF ZINC MALNOURISHMENT ON DIURNAL PHASE SHIFT IN ADOLESCENT RHESUS MONKEYS. M.S. Golub\*, L. A. Buck, M.E. Gershwin, and C.L. Keen. California Regional Primate Research Center, Univ. California, Davis, CA 95616.

Diurnal activity cycles were determined in female rhesus monkeys (22-39 months of age, premenarchal to sexually mature) as part of an evaluation of the effects of zinc deprivation on adolescence. An extension of the active period of the diurnal rest-activity cycle occurs in adolescence as reflected in longer nocturnal activity periods in rodents and later bedtimes in children. Monkeys were housed in indoor cage rooms with a 12:12 (lights on at 7 AM) light cycle. Activity was recorded for 2 consecutive 24-hr periods biweekly using a small commercial monitor consisting of a mercury switch with associated micro circuitry for data recording. The monitor was worn in a harness on the animal's back and could be removed to transfer data to a computer with custom software which generated plots of activity counts (switch closures) in 1 min intervals. Moderately zinc deprived (ZD) monkeys ( $n=4$ , 2  $\mu$ g Zn/g diet) were compared to controls ( $n=4$ , 50  $\mu$ g Zn/g diet). The extension of the daily active period during the 17 mo study period was  $79 \pm 15$  min for controls and  $21 \pm 20$  min for ZD monkeys ( $p=.059$ ). The increase in delay of phase shift (time to onset of nighttime rest period) was  $132 \pm 14$  min for controls and  $51 \pm 24$  min for ZD monkeys ( $p=.028$ ). ZD monkeys also exhibited growth retardation and one ZD monkey had delayed sexual development. The data suggest that dietary zinc deprivation can influence functional brain maturation in adolescent monkeys. Supported by HD14388.

## 484.8

DIURNAL VARIATION IN CEREBROSPINAL FLUID (CSF) NOR-EPINEPHRINE (NE) CONCENTRATIONS IN HEALTHY HUMANS. M.A. Kling\*, M.D. De Bellis, D. Hu, T.D. Geraciotti, D.S. Goldstein, E.H. Oldfield, and P.W. Gold. Clin. Neuroendo. Br., NIMH; Clin. Neurosci. and Surgical Neurology Brs., NINDS, Bethesda, MD 20892.

CSF concentrations of NE have been utilized extensively in studies of the pathophysiology of neurologic and psychiatric disorders. However, nearly all data are based on single time point measures of CSF NE obtained by lumbar puncture (LP). We report here the results of a study in which CSF NE concentrations were determined at hourly intervals over a 30-hour period in 7 healthy volunteers (4 male; ages 23-52 yr) undergoing continuous CSF sampling through indwelling lumbar catheters. In these volunteers, a 20-g epidural catheter was inserted in a low lumbar interspace through an 18-g Tuohy spinal needle under local anesthesia at 0900-1000 h. CSF was collected at a constant rate of 6 ml/h using a mini-roller pump; subjects remained flat in bed throughout the study. NE was measured by HPLC-EC in hourly aliquots (1 ml) for 30 hours beginning at 1100 h. A significant ( $p < 0.05$ ) diurnal rhythm in CSF NE was observed in 6 of the 7 volunteers by cosinor analysis; the mean CSF NE level in the 7 volunteers also showed a significant diurnal rhythm ( $p < 0.001$ ), with a fitted mean level of 99.1 pg/ml, a half-scale amplitude of 18.1 pg/ml, and acrophase at 11:55 am. These data are consistent with previous findings in patients who underwent LPs at different times of day. The finding of a diurnal variation in CSF NE has implications, not only for single time point studies of CSF NE, but also for the possible physiologic significance of CSF NE measurements in human subjects in states of health and disease.

## 484.9

## RELATIONSHIP BETWEEN AROUSAL LEVEL AT DAYTIME AND SLOW WAVE SLEEP IN HEALTHY YOUNG ADULTS.

K. Kancia, H. Hayasaka<sup>1</sup>, M. Ikemoto, S. Murakami, M. Watanabe, N. Takahata, S. Hata<sup>2</sup> and H. Ohshika<sup>2</sup> Dep. of Neuropsychiatry, Diagnostic Ultrasound & Medical Electronics<sup>1</sup> and Pharmacology<sup>2</sup>, Sapporo Med. Univ., Sapporo, 060 Japan

It's reported that the long arousal state makes Slow Wave Sleep (SWS) increasing and that physical and mental stress don't change the total time of SWS but move SWS to the first period. The background activity (BgA) in electroencephalogram (EEG) is important to decide the arousal level. In the relationship between the amplitude of EEG and the arousal level, it is reported that alpha amplitude is low in excited or stimulated state and alpha amplitude is high in relaxed state. This time, we studied polysomnographic characteristics at night and BgA of EEG at daytime.

Subjects: After approval of the study protocol, five male subjects between 20 and 25 years of age were recruited. They were in good, mental and physical health as determined by medical history, psychiatric evaluation, physical examination, clinical laboratory tests, electrocardiograph and chest X-p.

Procedures: A subject slept over 3-nights in the laboratory. The first and second nights are adaptation. The third night polysomnograph (PSG) is used for the basic PSG. The EEG at 5:00 PM on third day is used for the BgA. PSG was analyzed according to the roles of Rechtschaffen and Kales. We used the power spectrum program to analyze BgA. We examined Total sleep time, every stage latencies and every stage time. About the BgA, the peak of power spectrum, the mean alpha amplitude, the alpha 2/alpha 1 ratio (alpha 1; 8-10 Hz, alpha 2; 10-13 Hz) and % theta in frontal were examined.

Results: The amount of SWS related significantly to the mean alpha amplitude. The high alpha amplitude makes SWS increasing. These results suggest that relaxed state makes SWS increasing.

## 484.11

## 19-YEAR CHRONOBIOLOGIC STUDY OF A MIDDLE-AGED CYCLOTHYMIC MALE SUBJECT. D.A. Goodman\*, Newport Neuroscience Center, San Marcos, CA 92079-0803.

The long-term longitudinal study of single subjects is essential for human chronobiology. Generally, the n-of-1 study lasting decades is critical for the identification of long-duration infradian rhythms that might otherwise be undetected. In the present study, a white male, age 37, diagnosed as cyclothymic, in January 1977 agreed to keep a daily psychobiological journal of mental and physical states, also physiological health factors that could impact on biological rhythms. The subject agreed to restrictions in daily life that might increase the applicability of the findings, meaning that he lived alone, worked out of his own facilities, and avoided medications capable of altering biological rhythms. As of May 1, 1995, the subject has kept daily records for 6,694 consecutive days and nights, and has preserved archival data from more than 12,000 dreams.

Among the major findings from the 19-year study is the discovery that the subject's circatrigintan (about 28-day) rhythm observed during his 37th year over time increased monotonically in frequency until by the 55th year it easily overlapped the circadian. This shifting of a monthly rhythm to a daily rhythm (not the circadian) is of interest for two reasons: (1) Its use as a temporal reference makes possible statistical inference of future states; and (2) it establishes the value of longitudinal design, wherein data are collected serially to identify a novel infradian rhythm

## 484.13

## THE ANS ACTIVITIES IN ASSOCIATION WITH EEG SLEEP: Power spectrum components of heart rate variability highly correlated with delta-wave activity during sleep

Y. Kurokawa, H. Imai and M. Kabuto\*

Natl. Inst. Environ. Studies, 16-2 Onogawa, Tsukuba City, Ibaraki, 305 JAPAN.

Several characteristics of the changes in sympathetic and parasympathetic activities during sleep have been indicated in relation to EEG based on a method of power spectral analysis of heart rate variability (HRV), suggesting a possibility of a simple (non-invasive) and objective method other than EEG to evaluate sleep quality, which is often needed especially in epidemiologic studies on sleep disturbance. Therefore, investigated was the most suitable index to reflect sleep quality indicated especially by deep sleep component out of various parameters obtained from spectral analysis of HRV. Data on EEG at parietal region (bipolar) and R-R intervals (bipolar chest leads) were collected from six healthy subjects aged 24-29 yrs. during sleep in an insulated experimental room with mostly light off from 23:00 to 8:00. Spectral power of HRV as well as EEG were calculated using fast Fourier transformation method, with which three major powers in the ranges of 0.005-0.05 Hz (VLF), 0.05-0.15 Hz (LF) and 0.15-0.50 Hz (HF) for HRV and one in the range of  $\delta$  wave (0.5-4.0 Hz) for EEG were calculated. When correlations between amounts of  $\delta$  component of EEG and each of the three components of HRV were examined for a series of 300 sec-divided records, the strongest correlation ( $r=0.59$  for all subjects) was found between  $\delta$  wave component and spectral power in the VLF range of HRV, although there was rather large individual variation. Moreover, a tendency that correlation is stronger in the lower frequency even among the VLF was also found, which might be related to the decrease in the slope of the regression line relating 1/f plots (log amplitude vs. log frequency) of the spectra of single neuronal spontaneous activity in various sites of cat's brain during  $\delta$  wave sleep (Yamamoto et al in Brain Res. 366, 1986).

EFFECTS OF CL 284,846 AND TRIAZOLAM ON SLEEP EEG POWER SPECTRA IN SUBJECTS WITH PRIMARY INSOMNIA. Y. Kim<sup>1,2</sup>, H. Tachibana<sup>2</sup>, K. Emori<sup>2</sup>, G. Nino-Murcia<sup>1</sup> and C. Guilleminault<sup>3</sup>.

<sup>1</sup>Sleep Medicine and Neuroscience Institute, Palo Alto, CA 94303; <sup>2</sup>Dept. of Neuropsychiatry, Toyama Med. & Pharmaceut. Univ., Toyama 930-01, Japan; <sup>3</sup>Sleep Disorders Clinic and Research Center, Stanford University School of Medicine, Stanford, CA 94305.

CL 284,846 is a non-benzodiazepine compound for N-[3-(3-cyanopyrazolo[1,5-a]pyrimidin-7-yl)phenyl]-N-ethyl acetamide which was developed by the American Cyanamid Company. In this study, we investigated, with polysomnographic recordings, the effect of two dose levels of a non-benzodiazepine, CL 284,846 10 mg (CL-10) and CL 284,846 40 mg (CL-40), and one dose of triazolam 0.25 mg (TRZ) versus placebo on the results of visual scoring and FFT analysis of sleep EEG in subjects with primary insomnia.

Eight patients with primary insomnia (ages 40-59 years) were randomized in a double-blind design and the effects of 0.25-mg triazolam (TRZ), CL-10 and CL-40 on the sleep EEG were examined. In comparison of visual scoring, the significant differences between 3 drug nights were sleep onset latency and total wake time. FFT analysis revealed that 3 drugs had significant effects on sleep EEG power spectra. CL-10 significantly increased mean power density per NREM epoch (mean NREM power) for 2.0-8.0 Hz band than TRZ. CL-40 significantly increased mean NREM power for 0.0-6.0 Hz band than TRZ, and significantly decreased mean NREM power for 6.0-10.0 Hz than CL-10. Quantitative electroencephalography aids in differentiating specific effects of hypnotics on EEG power spectrum.

This study was supported in part by a grant from American Cyanamid Company, Pearl River, NY, USA.

## RECOGNITION OF REM SLEEP WITH ARTIFICIAL NEURAL NETWORKS BASED ON PREPROCESSED PERIODS OF 2.5 SECONDS OF EEG ACTIVITY. M. Grözinger\*, J. Rösche and C. Frank Dept. of Psychiatry, University of Mainz, Untere Zahlbacher Straße 8, 55131 Mainz, Germany.

For different scientific and clinical applications in psychiatry we have been working on a robust automatic online algorithm to detect Rapid Eye Movement (REM) sleep from single channel EEG data without using EMG or EOG information. The continuous signal was analysed in time periods of 20 seconds in order to be compatible with the manual evaluation, which is based on time periods of at least this length. For data preprocessing every EEG segment was digitally filtered in 6 frequency bands (0.5-4.5, 0.5-3.5, 3.5-7.5, 7.5-15, 15-35 and 35-45 Hz) and the RMS values of the filtered signals were calculated. This vector of 6 real numbers served as input to an artificial neural network. One output neuron was to indicate the presence of REM sleep. In 2 groups of 5 resp. 8 healthy volunteers this system was able to correctly classify close to 90% of the time intervals not belonging to the training set.

Unfortunately this kind of data preprocessing is dissipating information about short events like sleep spindles, because the calculation of the RMS values is averaging the signals over 20 seconds. The use of a shorter time basis of 2.5 seconds was considered to improve the results. The alpha band was divided by adding a 7th filter in the range of 7.5-11 Hz. Additionally the 3 layer backpropagation neural network had to be extended 8 fold to 56 input neurons for the time periods to remain compatible with the manual evaluation. 6 hidden neurons and 1 output neuron together with all possible feedforward connections completed the architecture. As compared to the 20 second time basis the percentage of misclassified time periods could be reduced by more than 20% for data not belonging to the training set.

ANGIOTENSIN II ANTAGONISTS BLOCK ETHANOL EFFECTS ON THE AERIAL RIGHTING REFLEX. H. Tracy, M.J. Wayner, D.L. Armstrong, and J. Polan-Curtain\*. Division of Life Sciences, The University of Texas at San Antonio, San Antonio, TX 78249.

The purpose of the present study was to determine the effects of an angiotensin II (AII) AT<sub>1</sub> antagonist, losartan 20 mg/kg i.p., and the AII AT<sub>2</sub> antagonist, PD 123319, 20 mg/kg i.p. on ethanol intoxication as measured by the aerial righting reflex in male rats. 25% ethanol, 2.0 g/kg, was administered by stomach tube under mild metaphane anesthesia and the aerial righting reflex was determined at 30 min intervals for 3.5 hours. The AII antagonists were administered intraperitoneally 2 hours before the ethanol. There were 4 groups of 10 rats each, 235 to 335 g in weight; ethanol alone, losartan plus ethanol, losartan plus PD 123319, and losartan alone. Data were analyzed by a two-way ANOVA with repeated measures on one factor. Results show a clear intoxicating effect on the aerial righting reflex that was blocked significantly by losartan and to a greater degree by both losartan and PD 123319. Losartan alone had no observable effect. The administration of both antagonists completely blocked the ethanol effect on the aerial righting reflex. The involvement of AII in the mediation of ethanol intoxication effects on the aerial righting reflex supports results of our earlier studies on the effects of ethanol on open field behavior, retention of an inhibitory shock avoidance response, and on hippocampal granule cell long term potentiation; all of which can be blocked by losartan.

## 485.3

STRESS CONTROLLABILITY BUT NOT PREDICTABILITY ALTERS THE ATAXIC POTENCY OF BOTH MIDAZOLAM AND ETHANOL IN THE RAT.

R.C. Drugan\*, T. Coyle, A. Cohen, D. Healy and S. Chen. Dept. of Psychology, Brown University, Providence, R.I. 02912

Last year we reported that exposure to escapable but not inescapable shock is associated with the release of a benzodiazepine-like compound in brain. Other research has indicated that a B-carboline-like substance may be released following uncontrollable stress. The present work examines the functional significance of these endogenous changes as they may influence subsequent drug reactivity at the benzodiazepine/GABA receptor complex (BGRC). Using a rotarod treadmill to assess motor ataxia, we find that uncontrollable but not controllable stress potentiates the motor incoordinating effects of both midazolam and ethanol in comparison to naive controls. Stressor predictability shows little effect on these indices. We are initiating *in vitro* binding analyses to complement these behavioral findings. These findings suggest that stress control and prediction (safety signals) may be working through different mechanisms in brain. Finally, psychological dynamics of stress markedly alters subsequent CNS depressant drug reactivity which may have implications for drug abuse and dependence. TASTE REACTIVITY TO ALCOHOL AND BASIC TASTES IN OUTBRED MICE. S.W. Kiefer\* and K.G. Hill. Dept. of Psychology, Kansas State Univ., Manhattan, KS 66506-5302.

The taste reactivity test was adapted for mice to determine their gustofacial responses to alcohol and basic taste solutions. Outbred mice (n=10) were implanted with an intraoral fistula and then tested for taste reactivity to distilled water, 0.1 M sucrose, 0.1 M sodium chloride, 0.00001 M quinine hydrochloride, 0.01 M hydrochloric acid, and to four concentrations of alcohol (3%, 6%, 9%, and 12%, v/v). Mice were given daily 1 min trials with a single solution at an infusion rate of 0.2 ml/min. Taste responses were scored as either ingestive or aversive. Results showed that the response profiles to the various solutions were quite similar. Mice made a substantial number of aversive responses to all solutions; the sucrose solution produced the lowest amount of aversive responding (X=13.5) whereas the other solutions elicited approximately 30 aversive responses. Ingestive responding was relatively consistent across solutions; there was a slightly higher rate of ingestive responding to sucrose and hydrochloric acid. The initial data from outbred mice suggest that these subjects do not show differential taste reactivity responses to a variety of taste solutions or to a range of alcohol concentrations. Supported by NIAAA grant R03 AA09335.

## 485.2

MODULATION OF ETHANOL-INDUCED MOTOR INCOORDINATION (EIMI) BY ADENOSINE (ADO) IN THE RAT MOTOR CORTEX. Y.S. Barwick and M. S. Dar\*. Department of Pharmacology, School of Medicine, East Carolina University, Greenville, NC 27858.

Previous studies in our lab showed that ADO uptake-blockers and antagonists enhanced and attenuated, respectively, EIMI. It was later found that EIMI was significantly enhanced and attenuated when ADO agonists and antagonists, respectively, were microinfused into the cerebral ventricles, striatum and cerebellum of rats and mice. The purpose of this study was to determine if ADO in the motor cortex would modulate EIMI. Using male rats, a unilateral guide cannula was implanted into the motor cortex. Each rat received a microinfusion of drug or artificial cerebrospinal fluid (ACSF) in a volume of 200 nl and ethanol (1.5 g/kg) or saline by i.p. injection. Microinfusion of the ADO A<sub>1</sub>- and the A<sub>2</sub>-selective agonists, CHA and CGS-21680, respectively, revealed significant and dose-dependent accentuation of EIMI when compared to the control group. CHA was 194-fold more potent in enhancing EIMI than CGS-21680 suggesting that motor cortical ADOergic modulation of EIMI may be mediated by the A<sub>1</sub> receptor. The A<sub>1</sub>-selective antagonist, DPCPX, significantly blocked the effect of CHA on EIMI. The non-selective ADO agonist, NECA, also significantly accentuated EIMI with an ED<sub>50</sub> higher than CHA but markedly lower than CGS-21680. Microinfusion of the ADO agonists followed by i.p. injection of saline had no effect on motor coordination suggesting a selective interaction between ethanol and ADO. To obtain further evidence for the role of the A<sub>1</sub> receptor in the modulation by ADO of EIMI, the effect of the R- and S-stereoisomers of PIA on EIMI were compared. R-PIA, the A<sub>1</sub>-selective stereoisomer, was significantly more potent in modulating EIMI than S-PIA. From these data, it may be inferred that ADOergic modulation of EIMI in the rat motor cortex may be via the A<sub>1</sub> receptor. This receptor is known to be negatively coupled to adenylyl cyclase via a pertussis toxin (PT)-sensitive G-protein (G<sub>i</sub>). Pretreatment of the motor cortex with PT significantly attenuated the effect of CHA on EIMI affirming a role for G<sub>i</sub> and indirectly supporting the supposition that ADO modulates EIMI through the A<sub>1</sub> receptor.

ETHANOL SELF-ADMINISTRATION PRODUCES CHANGES IN CIRCADIAN AND ULTRADIAN RHYTHMS. D.G. Harper\*, W. Tornatzky, J.C. Cole, and K.A. Miczek. Dept. of Psychology, Tufts University, Medford, MA 02155.

Many physiological and behavioral effects of ethanol may be due to disturbed rhythms of homeostatic functioning. It is the purpose of the present experiment to quantify the ability of ethanol to shift circadian and ultradian rhythms in 8, adult male Long-Evans Rats. Animals were studied in a reversed 12:12 D:L (lights off at 08:00) environment and implanted with a telemetry sender (Data-Sciences) which monitored heart rate and temperature. Following recovery from surgery, animals were food restricted to maintain stable body weight and induced to drink ethanol via the sucrose fading technique. Animals self-administered 10% ethanol at 10:30am for 30 min/day for 3 weeks and were tested for entrainment effects. Animals were then offered ethanol at differing concentrations (5%, 10%, and 20% counterbalanced) each for 5 days. Finally, animals were withdrawn from ethanol for 3 weeks. Preliminary results indicate discrete effects for both food restriction and ethanol. Food restriction caused an increase in the amplitudes of circadian and 2 cycle/day rhythms as well as an adjustment in the phase of the 2 cycle/day rhythm of heart rate and temperature. Ethanol self-administration caused an entrainment effect on the phase of the 5 cycle/day rhythm of heart rate but not of temperature. Goodness of fit measures indicate a shift in heart rate rhythms away from circadian control and towards ultradian rhythms. Manipulating ethanol concentrations induced a dose dependent diminution of amplitude and dose dependent phase advance of the circadian temperature rhythm. These results demonstrate that animals can adjust their rhythms to accommodate salient events such as daily access to ethanol.

## 485.6

OPERANT RESPONDING FOR ALCOHOL CHANGES ITS PALATABILITY IN RATS. K.G. Hill\*, D.R. Remmers-Roeber, S.W. Kiefer, and J. Frieman. Department of Psychology, Kansas State University, Manhattan, Kansas, 66506-5302.

Male Wistar rats were tested for initial taste reactivity responses to water and a 10% alcohol solution. Subjects were then trained in an operant box to press a lever for 10% alcohol that was delivered through an intraoral cannula. Subjects were tested for taste reactivity responses to 10% alcohol after they reached a fixed-ratio 5 (FR5) and fixed-ratio 10 (FR10) schedule. Ingestive responding to 10% alcohol was significantly higher after operant training. The average number of ingestive responses after operant training was nearly double those responses made prior to conditioning. There was no statistically significant difference between taste reactivity responding at FR5 and FR10. Aversive responding to alcohol was unchanged by the training procedure. Subsequent extinction trials failed to reduce ingestive responding. These data suggest that operant responding for 10% alcohol may alter its palatability by increasing its hedonic value.

## 485.7

BLOOD VERSUS BRAIN ETHANOL LEVELS AND ETHANOL-INDUCED LOCOMOTOR ACTIVITY IN DBA/2Abg AND C57BL/6Abg MOUSE STRAINS. T. Tritto\*, J.A. Clarke, and B.C. Dudek. Dept. of Psychology, Univ. at Albany, SUNY, Albany, NY 12222

Dose-response studies have shown that while most mouse strains, such as the DBA/2 (D2) strain, show a large degree of locomotor activation in response to 0-1.5 g/kg of ethanol, other strains, such as the C57BL/6 (B6) strain, show little or no activation (Dudek & Tritto, 1994). Genetic studies suggest that this variation is under simple genetic control with only a few genes responsible. Although CNS sites of ethanol action may be important for such differences, brain and blood absorption profiles of ethanol require examination in the D2 and B6 strains. Locomotor activity was measured for 15 min following an i.p. injection of either 0 or 1.5 g/kg of ethanol using a computerized activity monitoring system, and blood and brain ethanol levels were measured immediately afterward. The D2 strain showed the typical large degree of behavioral activation at the 1.5 g/kg dose, while the B6 strain showed no activation. Blood and brain ethanol levels were nearly identical for both strains, with the brain ethanol levels being approximately 80% of those of the blood levels. These results demonstrate that the differences between these strains do not arise from variations in alcohol absorption rates. [This work was supported by NIAAA grants K02-AA00170 and R01-AA09038.]

OPERANT RESPONDING FOR ETHANOL IN DEPENDENT VS. NON-DEPENDENT RATS: A.J. Roberts and G.F. Koob\*, Dept. Neuropharmacology, The Scripps Research Inst. La Jolla, CA. 92037.

Tolerance and dependence are potentially very important factors in the continued use of alcohol by alcoholics. Recently, our laboratory has been interested in producing models of ethanol (EtOH) intake in dependent animals. In this set of experiments, rats previously trained to lever press for oral EtOH and made dependent in alcohol vapor chambers were allowed to respond for EtOH over an extended period following withdrawal. In this way patterned operant responding for EtOH could be compared between dependent and non-dependent animals. Male Wistar rats were trained to lever press for 10% EtOH or water using a sweetened solution fading procedure. Rats were then housed for 2 weeks in EtOH vapor chambers with average blood alcohol levels of  $133 \pm 9$  mg%. Control animals were simultaneously exposed to air. Every 4 days rats were taken out of the vapor chambers and placed in operant boxes for their entire 12 hr dark (active) phase. Each box contained a full food dish and levers equipped to deliver water and 10% EtOH. In each of 4 trials, EtOH vapor exposed (dependent) rats responded more than air exposed (non-dependent) controls between 6 and 8 hr following withdrawal. This corresponds to the expected time of peak withdrawal symptomatology. In order to further examine responding in this time period, rats were withdrawn a 5th time, but left out of the operant boxes until hr 7. Dependent rats displayed visible signs of withdrawal at this time and again responded more than non-dependent rats for EtOH. Rats were then left out of the EtOH for 1 week and retested in order to determine whether response differences still existed in the absence of visible withdrawal signs. Again, rats previously exposed to EtOH vapor responded for EtOH to a greater degree than air exposed rats, however there was no obvious temporal pattern of responding. The results of this set of experiments suggest that rats experiencing acute withdrawal respond in a pattern consistent with the avoidance of withdrawal symptoms and that enhanced, but unpatterned, responding persists following abstinence. These two types of responding may represent models of EtOH intake associated with dependence and tolerance, respectively. Supported by grants AA08459 and AA06420.

## 485.11

EFFECT OF ETHANOL ON SPATIAL AND NON-SPATIAL LEARNING IN AN 8-ARM RADIAL ARM MAZE: COMPARISONS WITH DIAZEPAM AND MK-801. J.L. Vandergriff, D. B. Matthews, P.J. Best and P.E. Simson. Department of Psychology, Miami University, Oxford, OH 45056.

In addition to slowing reaction times and impairing coordination, ethanol (EtOH) can also impair performance on a number of learning and memory paradigms. For example, acute administration of EtOH impairs the use of spatial memory (Matthews et al., 1995). Additionally, chronic administration of EtOH impairs learning of a spatial task (Ardent et al., 1988) that is sensitive to hippocampal damage (Olton and Papas, 1979). More recently, our laboratory has reported that EtOH selectively impairs the learning of spatial, but not non-spatial, tasks (Vandergriff et al., 1995).

In the present study, we compared the effect of EtOH on spatial and non-spatial learning to those of diazepam and MK-801, two drugs that have been likened to EtOH on a number of behavioral and electrophysiological measures. The paradigm utilized in the present work does not require progressive training techniques, and has been shown to be dependent on an intact hippocampus (Matthews and Best, 1995). Ethanol (0.75 - 2.5 g/kg, i.p.) impaired learning of the spatial task to a greater extent than the non-spatial task. Diazepam (0.5 - 2.0 mg/kg, i.p.) impaired learning of the spatial task, while slightly facilitating learning of the non-spatial task. The effect of diazepam on spatial and non-spatial learning thus bears remarkable resemblance to the effect of lesions of the fimbria-fornix on these learning tasks (Matthews and Best, 1995). Finally, MK-801 (0.1 - 3.0 mg/kg, i.p.) markedly impaired learning of both the spatial and non-spatial tasks at all doses tested. These results suggest that EtOH shares characteristics of both diazepam and MK-801 on spatial and non-spatial learning.

## 485.8

ANALYSIS OF THE BIPHASIC LOCOMOTOR RESPONSE TO ETHANOL IN HIGH (HR) AND LOW (LR) RESPONDERS TO NOVELTY: A STUDY IN WISTAR RATS. M.A. Gingras\* and A.R. Cools. Psychoneuropharmacology, Univ. of Nijmegen, P.O. 9101, 6500HB Nijmegen, The Netherlands.

The purpose of the study was to investigate the biphasic locomotor response to ethanol in rats. Given the recent finding that HR and LR differ in ethanol intake and preference (1), it was initially investigated to what extent HR and LR differ in locomotor responses to ethanol. A dose-response curve (0.2-2.0 g/kg, i.p.) was established using standardized activity cages. HR showed a significant increase at 0.5 g/kg, followed by a significant decrease at doses 1.0-2.0 g/kg; LR showed only a decrease at doses 1.0-2.0 g/kg. Secondly, it was investigated to what extent stress altered the ethanol-induced increase and decrease, respectively. For that purpose, the ethanol-induced locomotor effects (0.5 & 1.0 g/kg) were analyzed in habituated and non-habituated (stressed) HR. Stress significantly enhanced the excitatory effects in HR, but had no effect on the sedative effects in HR and LR. Finally, the locomotor effects of a subchronic treatment (7 days) with an excitatory (0.5g/kg) or sedative (1.0 g/kg) dose were analyzed in HR and LR. The excitatory effect of 0.5 g/kg disappeared throughout this treatment in HR, whereas the sedative effects of 1.0 g/kg did not change in HR and LR. Apparently, the mechanisms underlying the ethanol-induced locomotor increase fully differ from those underlying the ethanol-induced locomotor decrease. Given the known differences in the make-up of the brain and endocrine system between HR and LR (2), HR and LR are suggested to be good models for studying the mechanisms underlying the biphasic locomotor response to ethanol.

CONCURRENT COCAINE (COC) AND ETHANOL (EtOH) EFFECTS: MICRODIALYSIS AND BEHAVIORAL STUDIES.

Aron N. Starosta\*, Gregory G. Blakley and Michael J. Lewis. Neurobehavioral Laboratory, Dept. of Psychology, Temple University, Philadelphia, PA 19122

The concurrent use of EtOH and COC has become a common abuse pattern. While both compounds administered alone produce reinforcing effects and increasing extracellular dopamine concentrations, little is known about their effects when administered together. The goal of this study was to investigate the effects in rats given IP injections of EtOH (0.1-0.5g/kg), COC (0.1-0.5mg/kg), or both given in combination, on concentration of monoamines in the nucleus accumbens and locomotor behavior. Monoamine levels were determined using high pressure liquid chromatography and electrochemical detection (HPLC-ECD). Open-field locomotor activity was measured using a computerized video system. Activity levels and monoamines were measured every ten minutes for 60 minutes. While EtOH and COC each elevated locomotor activity during the first 10 minute period, concomitant administration increased locomotion over the effects of either agent during the 10-30 minute time periods. Little effect was observed during the final 30 minutes of testing. Microdialysis measurement of dopamine levels in the nucleus accumbens showed increases consistent with behavioral changes. (NIDA #DA07237).

## 485.12

CHRONIC ETHANOL EXPOSURE ENHANCES PERFORMANCE OF ADULT RATS IN RADIAL ARM MAZE TASKS. E.S. Steigerwald and M.W. Miller\*. Res. Serv., V.A.M.C., Iowa City IA 52242, and Depts. of Psychiatry and Pharmacology, Univ. of Iowa Coll. of Med., Iowa City IA 52242.

The effect of chronic exposure to ethanol on learning and memory was assessed by examining the ability of adult male rats to learn radial arm maze tasks that depended upon either extra-maze cues (visual-spatial) or intra-maze cues (various odors) for solution. Rats were fed *ad libitum* with a liquid diet containing 6.7% (v/v) ethanol (Et) or pair-fed an isocaloric diet (Ct). Eight subjects per treatment group were tested after being on the diet for 14 or 20 wk. Rats were maintained on this diet throughout the behavioral testing, but limited to a 2 hr feeding period. Rats were tested in both the visual-spatial and odor cue conditions twice daily for 26 days. The latency required to successfully navigate the maze, and the number of reference memory (RM) and working memory (WM) errors was recorded. Et-fed rats performed significantly better than Ct-treated rats in both testing conditions by making fewer RM errors and requiring a shorter latency to navigate the maze successfully. The Et-fed rats initially made fewer WM errors, but this pattern disappeared with repeated testing. The results were obtained in rats fed Et for 14 or 20 wk. Thus, moderate amounts of ethanol consumption appear to improve performance in some learning and memory tasks. Supported by the V.A. and N.I.H. (DE07734, AA06916, and AA07568).

## 485.13

**ETHANOL IMPAIRS PERFORMANCE IN A NON-SPATIAL WORKING MEMORY TASK.** K. McMahon\*, T. Wallace, M. Ostrander and B. Givens. Department of Psychology, The Ohio State University, Columbus, OH, 43210.

Ethanol impairs spatial working memory in rats but its effects on non-spatial working memory have been difficult to assess. The difficulty in developing an operant model of non-spatial working memory has been in devising a task that does not allow any mediating behaviors during the delay. Trials began with either a signal (0.5 or 1.0 s center panel light), or a non-signal (absence of light). They were then required to match-to-sample (DMTS) in a choice phase, where one of two lights was illuminated. A lever was located beneath each light. Choice accuracy was significantly affected by delay (1 or 4 sec), but not by stimulus length (500 or 1000 msec). Following ethanol administration (0.25, 0.5, 0.75, and 1.0 g/kg), there was a dose-dependent change in choice accuracy and an interaction between dose and delay. Ethanol affected choice accuracy primarily at the 1 sec delay, with an increase at lower doses and a decrease at higher doses. These results demonstrate that performance in this task is both sensitive to the demands of working memory and is impaired by ethanol. A more detailed examination into the role of the prefrontal cortex in this task will be presented.

## 485.15

**GENETIC ANALYSIS OF ETHANOL-INDUCED HYPERGLYCEMIA USING RECOMBINANT INBRED BXD MICE.** F. O. Risinger\* and M. M. Brown. Oregon Health Sciences University, Portland, Oregon 97201-3098.

Sensitivity to ethanol's glycemic effect is influenced by genotype and may be related to the thermic and motivational effects of ethanol (Risinger and Cunningham, *Alcoholism Clin Exp Res.* 15, 1991; *Life Sci.* 50, 1992). In the present study, 16 recombinant inbred strains of the BXD/Ty series, derived from C57BL/6J (B6) and DBA/2J (D2) inbred mice, were acutely exposed to either 4 g/kg ethanol (IP) or saline (order of exposure counterbalanced). Tail blood samples were obtained immediately before injection and 120 min after injection. As expected, strains differed in the magnitude of ethanol-induced hyperglycemia (i.e., Strain x Drug Treatment x Time;  $F(18,222)=3.1, p<0.01$ ). Further, a continuous range of hyperglycemia was noted in the BXD strains, including levels above and below those seen in the progenitor B6 and D2 mice. Comparison of strain means with mapped genetic markers (Quantitative Trait Loci analysis) revealed associations with a number of regions located on chromosomes 3, 17 ( $p<0.01$ ) and 4 ( $p<0.02$ ). This pattern of strain differences suggests polygenic mediation of sensitivity to ethanol's glycemic effects.

## 485.17

**ACETALDEHYDE LEVELS IN ASIAN MEN WITH DIFFERENT ALDH2 GENOTYPES.** T.L. Wall\*, C.M. Peterson, K.P. Braun, M.L. Johnson, H.R. Thomasson and C.L. Ehlers. The Scripps Research Institute, La Jolla, CA 92037.

About half of Asian men and women have a genetically defined deficiency in the aldehyde dehydrogenase (ALDH2) isoenzyme responsible for metabolizing acetaldehyde, which results from the oxidation of alcohol. ALDH2 deficiency results from the inheritance of the mutant ALDH2\*2 allele, a dominant mutation that disrupts the function of the subunit polypeptide. Asians possessing one or both alleles of ALDH2\*2 drink less alcohol, are less likely to be alcoholic, and have more intense responses to alcohol, including a flushing reaction, than Asians homozygous for the ALDH2\*1 allele, which encodes the active subunit polypeptide. It is hypothesized that acetaldehyde mediates the more intense alcohol response. Few studies have measured acetaldehyde levels in Asians who have been genotyped for ALDH2 and past studies have not controlled for recent use of alcohol and tobacco. This study assessed healthy 21-25 year Asian American men following oral administration of placebo and 0.75 ml/kg alcohol. Subjects with ALDH2\*1/\*1 genotype (n=12) were matched to subjects with ALDH2\*1/\*2 genotype (n=8) on demographics and recent drinking and smoking history. Blood alcohol and blood acetaldehyde levels were measured before and 15, 30, 45, 60, 90, 120, and 150 minutes following beverage administration. The group with ALDH2\*1/\*2 genotype had significantly higher blood acetaldehyde levels at 45, 60, 90, 120, and 150 minutes after drinking alcohol compared to the group with ALDH2\*1/\*1 genotype, despite equivalent blood alcohol levels. These results suggest that post-alcohol acetaldehyde levels may, in part, mediate enhanced sensitivity to alcohol and may contribute to the decreased likelihood of alcohol intake and protection from alcoholism among Asians. Supported by grants AA00098, AA00155, AA06420, and RR00833.

## 485.14

**THE BEHAVIORAL AND NEUROPHYSIOLOGICAL EFFECTS OF ETHANOL ON SUSTAINED ATTENTION IN RATS.** B. Givens\*, K. Hutchinson, & K. McMahon. Dept. Psychology and Neuroscience Program, The Ohio State University, Columbus, OH 43210.

Investigations into the effects of acute alcohol intoxication on human performance consistently show deficits in continuous performance tasks that require sustained attention. Long-Evans rats were trained on an operantly-conditioned vigilance task that measures attentional abilities via manipulation of signal length (25, 50, and 500 msec) intertrial interval duration ( $9 \pm 3$  sec), and signal salience. Each trial began with the presence or absence of a signal (central panel light) followed 1 sec later with a tone which signaled lever activation. A correct response was a left lever press on a signal trial and a right lever press on a non-signal trial, and was rewarded with water. Ethanol (0.0, 0.5, 1.0, and 1.25 g/kg i.p.) increased reaction time, in a time- and stimulus length-dependent fashion. Reaction time for correct responses was substantially increased during the first half of the session, and were greatest at the shortest (25 ms) stimulus length. The only effect of ethanol on choice accuracy was a facilitation on signal trials but not on non-signal trials at the lowest dose (0.5 g/kg). The higher doses of ethanol (1.0 & 1.25 g/kg) increased omissions but this effect did not interact with signal length. Following ethanol testing, rats were surgically implanted with movable, fine-wire electrodes into the medial prefrontal cortex for single unit recording. Preliminary electrophysiological data suggest that only a small fraction of prefrontal neurons are engaged in performance aspects of the task. Neurons with evoked-activity were time-locked to the stimulus, and increased their activity during decreased signal salience, correlating with decreased choice accuracy. The results suggest that the prefrontal cortex may be involved in ethanol-induced changes in sustained attention.

**SEX DIFFERENCE IN ETHANOL INTOXICATION IN FAWN HOODED RATS.** C.M. Harris\* and D.S. Ritchel.

N.Y. Col. Osteo. Med., Old Westbury, NY 11568.

Male and female Fawn Hooded (FH) rats voluntarily consume ethanol (1.15 g/kg/day in our colony) whereas male and female Long Evans Hooded (LEH) rats do not. We gave these four groups ethanol, 15% w/v (or control) solution by gavage and rated intoxication severity on a 7-point scale. In two independent tests with ethanol, 2.6 g/kg (8/group) and 3.0 g/kg (5-7/group) scores differed significantly between groups (both p values <.005). FH females were least drunk and scores for FH males were intermediate between those of the two LEH groups consistently throughout 2 hrs of observations. In a 3rd test blood ethanol was measured and rank order for intoxication was replicated. Blood ethanol concentrations at 40 min after 3 g/kg (4/group) were lower in the FH strain (M+-SEM mg/dl: FH =113+-15; LEH=177+-10;  $p=.005$ ), but did not differ between sexes for either strain. Results suggest that sex difference for intoxication in FH rats was due not to pharmacokinetic factors, but rather to different neural responsiveness. These results are significant because FH males drink voluntarily despite high sensitivity to blood ethanol. Supported by DA06873 (NIDA).

**EVENT-RELATED POTENTIALS IN NATIVE AMERICAN CHILDREN** C.Garcia-Andrade, E.Phillips, E.Bisson, E.L.Battenburg\*, T.L.Wall and C.L.Ehlers. Department of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

The P300 component of the event-related potential (ERP) has been suggested to have predictive value as an index of vulnerability for alcoholism. Native Americans, as a group, are at higher risk for this disorder. ERP studies, however, have not been accomplished in this population. This study evaluated Native American children (NACH) between the ages of 10 and 13. Subjects were recruited from the Luiseño and Diegueño tribes in southern California. Data were available from 41 children, twenty-five (mean of age= 11.3 years) who were identified as Family History Positive (FHP) for alcoholism and 16 (mean of age= 11.2 years) as Family History Negative (FHN). None of the subjects had borderline IQs, abnormal EEGs, or first-degree relatives with major Axis I DSM-III-R disorders. FHP children had a father who met criteria for alcohol dependence. FHN children had no alcoholic relatives. Subjects were also evaluated by their percentage of Native American heritage (NAH). Fifteen subjects were  $\geq 50\%$  NAH (mean=68%) and 10 <50% NAH (mean=35%). ERPs were elicited using an auditory "oddball plus difficult discrimination" paradigm. EEG was analyzed from three derivations (Fz, Cz and Pz). Preliminary results showed a tendency for FHP children to have decreased P300 amplitudes [ $F(3,16), <.08$ ] in the parietal lead (Pz) in response to the non-difficult target tone. When data were evaluated based on NAH (n=25), there was a significant difference observed between groups in several late ERP components. Longer latency N2 components, elicited by the difficult to discriminate tone, were found at Fz and Cz in the  $\geq 50\%$  NAH group compared to the <50% NAH group ( $F=6.6$   $p<.02$  and  $F=11.9$   $p<.002$ ). Lower amplitude P300 components to the difficult to discriminate tone were also observed at Pz ( $F=10.5$   $p<.004$ ) in the  $\geq 50\%$  NAH group compared to the <50% NAH group. These studies suggest that ERPs might provide measures that along with other biological and psychological factors may be coupled with heritability to alcoholism. (Supported by NIAAA, 00098, 00155, 06420, 10201, and RR00833).

## 485.19

QUANTITATIVE MICRODIALYSIS OF ETHANOL IN RAT BRAIN - COMPARISON OF THEORY TO EXPERIMENT. R.A. Gonzales\*, T.L. Ripley, J. McNabb, and P.M. Bungay<sup>1</sup>. Univ. of Texas, Inst. of Neuroscience, Austin, TX 78712, and <sup>1</sup>Biomed. Eng. & Instr. Prog., NCR/NH, Bethesda, MD 20892-5766

Microdialysis is commonly used to study effects of drugs, including ethanol (EtOH), on levels of extracellular neurotransmitters *in vivo*. However, due to diffusional resistance, concentration gradients exist within the membrane and the tissue surrounding the probe, thus making tissue concentrations of specific analytes unknown. We have applied the steady-state theory of quantitative microdialysis (Bungay *et al.* Life Sci 46: 105, 1990) to simulate the EtOH concentration profiles when the probe is perfused with an EtOH solution. Microdialysis probes (3 mm long and 270  $\mu$ m o.d.) were perfused *in vitro* at 1.65  $\mu$ l/min in a stirred solution at 37°C. The measured steady-state extraction fraction (recovery),  $0.41 \pm 0.05$  (mean  $\pm$  SD, N=3), agreed with the predicted value of 0.41. *In vivo* experiments were conducted by placing probes into the striatum of rats which had been implanted with a guide cannula at least one week before. After perfusing overnight with artificial cerebrospinal fluid, the perfusing solution was changed to one that contained 1% EtOH (v/v) and samples were collected every 15 min for 1 hr. Following this period the rats were decapitated within 30 s and the heads frozen in liquid N<sub>2</sub>. Dialysate EtOH and brain tissue EtOH content was determined by GC headspace analysis. The *in vivo* EtOH extraction fraction,  $0.25 \pm 0.07$  (N=5), together with the *in vitro* value, were used to make several predictions: EtOH concentration at the probe-tissue interface was 40-50% of the inflow concentration, the extent of diffusion into the tissue was less than 1 mm from the probe, and the diffusivity of EtOH in striatum is  $8.3 \times 10^{-9}$  cm<sup>2</sup>/s. These predictions incorporate the effect of EtOH clearance by efflux to blood. The diffusivity estimate was then used to predict a value of 2.4  $\mu$ g for the tissue content of EtOH in the region surrounding the probe, including correction for washout of EtOH during the post-perfusion delay. A comparable experimental value of  $0.94 \pm 0.40$   $\mu$ g (N=3) was obtained. This work suggests that transcellular EtOH diffusion contributes substantially to rapid movement of EtOH through tissue. Work supported by NIAAA (AA08484 and AA00147) and the Alc. Bev. Med. Res. Found.

## 485.21

Induction and maintenance of moderate blood alcohol levels by atraumatic pulsatile gastric infusions in "experienced" rats: transient effects on hypothalamo-pituitary-adrenal (HPA) activation. Rasmussen, D.D.\*, Levin, N.\*, Lawson, P.T., Wilkinson, C.W. Univ. of Washington and Seattle/American Lake V.A. Med. Center, Tacoma WA, 98493; \*Genentech, Inc., South San Francisco CA, 94080.

Ethanol administration can stimulate HPA activity. However, paradigms commonly used to investigate this activation may elicit confounding non-specific stress responses. We have developed a model in which "experienced" rats (previously introduced to ethanol administration, so that the subjective response is not a novel stimulus) receive pulsatile intragastric ethanol infusions during the dark (active) photophase to produce and sustain (for 3 h) moderate (0, 50, 90-100, or 120-150 mg/dl) blood alcohol levels (BALs) in a range which has been demonstrated to be reinforcing. The lowest ethanol dosage (BAL: approx. 50 mg/dl) did not significantly alter plasma ACTH, corticosterone (CORT), or  $\beta$ -endorphin ( $\beta$ END) concentrations at any time point evaluated (30, 60, 180, 360 min). BALs of 90-100 mg/dl increased plasma ACTH, CORT, and  $\beta$ END concentrations at 30 min; these declined to control levels at 60 and 180 min, even though the BALs had been maintained. BALs of 120-150 mg/dl increased ACTH, CORT and  $\beta$ END levels at both 30 and 60 min; ACTH and CORT declined to control levels by 180 min, whereas  $\beta$ END levels remained moderately elevated. At 360 min (3 h after cessation of infusions), ACTH, CORT, and  $\beta$ END levels for all treatments were comparable to controls. We are also assaying paraventricular nucleus corticotropin-releasing factor (CRF) mRNA concentrations in these same rats as an index of CRF neurosecretion. These results demonstrate that, under relatively non-stressful conditions, induction of moderate BALs acutely activates the HPA axis, but that this activation is transient, diminishing even when BALs are maintained. (NIH/NIAAA AA10567)

## 486.1

DIFFERENTIAL NEURONAL SENSITIVITY TO ETHANOL IN THE CEREBELLUM AND HIPPOCAMPUS, BUT NOT NEOCORTEX OF HAS AND LAS RATS. R.K. Freund, B.J. Pearson, and M.R. Palmer\*. Dept. of Pharmacology, Univ. of Colorado Health Sci. Ctr., Denver, CO 80262.

We previously reported that cerebellar Purkinje neurons of low alcohol sensitive (LAS) and high alcohol sensitive (HAS) rats are differentially sensitive to the depressant effects of locally applied ethanol. In this study we determined if neurons in other brain areas also show a similar differential ethanol sensitivity. We studied electrophysiologically identified single neurons from layers V and VI of prefrontal neocortex, the CA1 region of the hippocampus and Purkinje neurons in the cerebellum from urethane-anesthetized LAS and HAS rats. Single neurons were recorded from one barrel of two-barrel micropipettes, and ethanol was locally applied by pressure ejection from the other barrel. We found higher ethanol sensitivity to the depressant effects of local ethanol applications in HAS rats than in LAS rats for cerebellar Purkinje neurons as well as both pyramidal and theta cells from hippocampus. The difference in the ethanol sensitivity of hippocampal pyramidal neurons between LAS and HAS was similar to that observed between cerebellar neurons in those two rat lines, whereas there was a much larger difference in the ethanol sensitivity of hippocampal theta cells. Neurons in prefrontal cortex, on the other hand showed a similar sensitivity to ethanol-induced depressions between the two rat lines. These data suggest that the neuronal ethanol sensitivity differences observed between LAS and HAS rats is not limited to the cerebellum, but is not found in all brain regions.

## 485.20

RAPID TOLERANCE AS A MODEL FOR CHRONIC TOLERANCE.

J.M. Khanna\* and H. Kalant. Dept. of Pharmacology, Univ. of Toronto, Addiction Research Foundation, Toronto, Canada M5S 1A8.

Development of tolerance is believed to increase alcohol consumption by reducing the aversive effects of alcohol relative to its rewarding effects. The most commonly studied form, called chronic tolerance, increases gradually over days or weeks of alcohol administration, and such studies are therefore slow and costly. Another form, called rapid tolerance, is seen in response to a second dose of alcohol given 8-24 hr after the effect of the first dose has disappeared. Rapid tolerance has been known for over 15 years, but its relation to chronic tolerance has not been studied systematically until recently (Khanna *et al.*, Pharmacol. Biochem. Behav., 41:355-360, 1992). In the present work, we have extended these investigations by examining the effects of various pharmacological interventions (i.e. protein synthesis inhibition with cycloheximide, 5-HT modification with p-chlorophenylalanine and L-tryptophan, modification of NMDA receptor system and use of calcium channel blockers) on rapid tolerance development. All these interventions, which are known to affect chronic tolerance development, affected rapid tolerance in exactly the same way. These findings suggest that rapid and chronic tolerance are two expressions of the same alterations in brain function, and that experiments on rapid tolerance can therefore be used to predict the effects of drug therapies on chronic tolerance, at a great saving in time and costs.

## 486.2

ETHANOL ALTERS THE RESPONSE PROPERTIES OF NEURONS IN THE STRIATUM OF THE AWAKE, BEHAVING RAT. P.H. Janak\*, M.G. Laubach and D.J. Woodward. Dept. of Physiology & Pharmacology, Bowman Gray School of Medicine, Wake Forest Univ., Winston-Salem NC 27157

Ethanol intoxication is known to impair the execution of sensorimotor behavior. To understand the underlying neuronal processes that are altered by ethanol, we studied the effects of ethanol on the spike activity of single neurons in the striatum of freely-moving rats during 1) open field behavior, 2) treadmill locomotion, and 3) reaction-time performance. Simultaneous recordings of the spike activity of 5-20 single units per subject were obtained from microwire electrode arrays chronically implanted into the striatum of adult male Long-Evans rats. Multiple measures of neuronal activity were compared following systemic ethanol or saline administration. Alterations in neuronal activity that accompanied the behavioral effects of systemic ethanol included dose-dependent changes in the firing rate and the firing mode (i.e., bursts versus single spikes) of striatal neurons, and alterations in the spatiotemporal patterns of firing within pairs and groups of neurons. In the drug-free animal, striatal neurons exhibit altered firing rates during one or two behaviors of the sequence that comprise task performance. A striking effect of ethanol was the emergence of responses by neurons during additional behaviors for which the neurons previously were quiescent. These observations suggest the hypothesis that ethanol may impair sensorimotor behavior by altering cortically-driven response properties of neurons in the striatum. ## 486.3

EFFECT OF CHRONIC ALCOHOL CONSUMPTION ON SPECIFIC STRESS-AXIS RESPONSIVE REGIONS IN THE CENTRAL NERVOUS SYSTEM OF THE MALE RAT. C. Hamelink, B. Daoud, T. Torda, J. Presson\*, T. Castonguay, and R. Eskay. Lab. of Clinical Studies, NIAAA, NIH, Bethesda, MD 20892

Chronic alcohol consumption (CAC) leads to degeneration of site-specific regions of the brain. Previous morphological analysis has revealed the hippocampus to be preferentially sensitive to the neurotoxic consequences of CAC. Preferential hippocampal damage also occurs over time in the presence of elevated glucocorticoids, which energetically weaken hippocampal neurons through a toxic cascade involving glutamate and calcium ions. Using the intragastric ethanol infusion model, blood alcohol levels were continuously maintained between 150-350 mg/dl for up to 4 weeks with a daily 2-10 fold ethanol-induced elevation of plasma corticosterone (CS) at the nadir of the CS rhythm. Considering that a change in corticosteroid receptor activity may reflect early neuronal degeneration in the hippocampus, we have analyzed steady-state glucocorticoid (GC) and mineralocorticoid (MC) receptor mRNA levels in specific subfields of the hippocampus. Initial findings in the dorsal hippocampus with *in situ* hybridization using antisense probes have revealed a 20-30% reduction of GC mRNA levels in the CA1, DG or CA3 subfield regions following 10 days of CAC. Similar reductions were observed in MC receptor mRNA levels in the hippocampal subfields. The effects of CAC appear not to preferentially endanger the CA3 subfield region of the hippocampus but additional analysis of prolonged (4 weeks) alcohol exposed brains will clarify this issue.

ETHANOL INDUCES APOPTOTIC CELL DEATH IN SCHWANN CELLS COCULTURED WITH SYMPATHETIC NEURONS. M.J. Johnson\*, J. Gilman, M. Collier, and M. Thompson. Dept. of Pediatr., Steele Mem. Child. Res. Cntr., Univ. of Arizona, Tucson, AZ 85724-0001.

Fetal alcohol exposure may result in striking craniofacial abnormalities as well as microcephaly and CNS dysfunction. The microcephaly may be secondary to reduced numbers of both glia and neurons. In prior studies we have shown that ethanol enhances axonal elongation but reduces the number of both total and dividing Schwann cells even after exposure times of less than 24 hours and levels of ethanol as low as 9 mg%. In these experiments we utilize the TUNEL procedure to identify nicked DNA in the nuclei of Schwann cells undergoing apoptotic cell death. Rat sympathetic ganglia were cultured for 4-5 days *in vitro* and treated 19-22 hours with ethanol before fixation and application of the TUNEL procedure. Increased numbers of apoptotic Schwann cells were seen with ethanol exposure, particularly at distances greater than 1 mm from the explant edge. In one experiment the percent of total Schwann cells that were TUNEL positive at 1.25 mm was  $2.7 \pm 1.1$  for controls and  $4.7 \pm 1.7$ ,  $19.3 \pm 4.9$ , and  $19.3 \pm 5.5$  for 50, 300, and 750 mg% ethanol respectively. (Mean  $\pm$  SEM;  $p < .004$  for both 300 and 750 mg%). The positive cells were often in clusters and just proximal to the tips of the axons. They frequently showed a very discrete positive area that appeared confined to the nucleus. In others the TUNEL positive material appeared to spill out of the nuclear area. In summary, preliminary experiments indicate that ethanol increases the number of apoptotic Schwann cells and this effect is dependent on both the concentration of ethanol and the distance from the edge of the explant. ## 486.7

CHANGES IN BRAIN ACTIN AND TUBULIN FOLLOWING CHRONIC ETHANOL TREATMENT. E. Fiková\*, H. Eason, K. Buellman, J. Joo, M. Morales. Dept. of Psychology, University of Colorado, Boulder, CO 80309 and Dept. of Neuropharmacology, Scripps Research Institute, La Jolla, CA 92037.

Ethanol-sensitive LSJBG mice (15) treated for 4 months with ethanol diet were compared to control mice (9). Pools of actin and tubulin were prepared by Triton-X to solubilization of brain homogenates prepared under microtubule-stabilizing conditions (Black et al., Brain Res., 225:255, 1984). After centrifugation of the homogenate (H) the Triton-soluble fraction containing unpolymerized cytoskeletal component was recovered in the supernatant (S-1) and the Triton-insoluble fraction containing polymerized cytoskeletal component was recovered in the pellet (P-1). The P-1 fraction was resuspended in calcium-containing buffer and incubated at 4° C and centrifugation yielded a calcium/cold-insoluble cytoskeletal component in the pellet (P-2). In each fraction the total protein was established. Following protein separation on SDS-PAGE, the amount of  $\alpha$ -tubulin and actin in each fraction was determined with a quantitative immunoblotting procedure (Black et al., J. Neurosci., 2:358, 1989). In the P-1 fraction both  $\alpha$ -tubulin and actin were significantly reduced following ethanol treatment. In addition  $\alpha$ -tubulin was also significantly reduced in the homogenate. Thus, both major components of the neuronal cytoskeleton are affected by chronic ethanol exposure. The loss of tubulin in the fraction containing polymerized components of the cytoskeleton corroborates our results showing a loss of microtubules following chronic ethanol treatment. Given that microtubules are essential for axonal transport, this loss could be implicated in the decreased axonal transport observed after chronic ethanol treatment (McLain, Alcohol, 4:385, 1987). In addition, the ethanol-related loss of actin an ubiquitous neuronal proteins implicated in cytoskeletal functions as well as in synaptic plasticity suggests that chronic ethanol significantly impairs basic neuronal functions. Supported by grants AA06196 and AA00130.

## 486.4

NEUROTOXICITY OF NITROPRUSSIDE AND ITS POTENTIATION BY CHRONIC ETHANOL IN BRAIN ORGANOTYPIC SLICES AND CEREBELLAR GRANULE CELL CULTURES. J.Y. Zou\*, E.J. Neafsey and M.A. Collins. Neuroscience Program, Loyola University of Chicago Medical Center, Maywood, IL 60153.

Our *in vivo* study demonstrates that chronic ethanol-induced selective neuronal degeneration in entorhinal cortex and dentate gyrus in adult rats is not prevented by blockade of endogenous nitric oxide (NO) production using nitric oxide synthase inhibitors. The present study uses *in vitro* models to examine the relationship between chronic ethanol and excessive NO neurotoxicity. Entorhinal-hippocampal complex slices were prepared from 8-10 day old neonatal rats and cultured on interface membranes (4-6 slices per membrane) for 2 weeks. Cerebellar granule cell cultures were prepared from 8 day old neonatal rats and maintained in cultures for 8 days. Neurotoxic effects of NO generator sodium nitroprusside (SNP) in these cultures were assessed by measuring LDH release 24 hr after treatment. In controls, SNP (300  $\mu$ M) treatment for 30 min produced obvious neurotoxicity in these cultures as indicated by increased LDH release. Ethanol (100mM) exposure for 4 days significantly increased SNP-induced LDH release compared to the SNP group. SNP neurotoxicity in both groups was partially blocked by poly (ADP-Ribose) synthase (PARS) inhibitor dihydroxyisoquinoline, but not by benzamide. Concurrent measurements indicated that SNP-induced neurotoxicity was accompanied by a dramatic increase in cGMP production. Chronic ethanol exposure significantly increased basal cGMP level and SNP-stimulated cGMP production compared to corresponding controls in both brain slice and cerebellar granule cell cultures, indicating that chronic ethanol may up-regulate guanylate cyclase. These results suggest the possible involvement of excessive NO in chronic alcohol-related neuronal damage. Supported by Loyola NSAI Postdoctoral Fellowship.

## 486.6

DENDRITIC MICROTUBULES IN THE DENTATE FASCIA ARE AFFECTED BY CHRONIC ETHANOL EXPOSURE. D. Lang\*, E. Fiková, M. Beno. Dept. of Psychology, University of Colorado, Boulder, CO 80309.

Ethanol-sensitive LSJBG and ethanol-insensitive SJSBG mice were exposed to ethanol diet (23.5% ethanol-derived calories) for 4 months. Half of the animals were sacrificed at this time and the other half was withdrawn from the ethanol diet for 1 month. Electron microscopy was used to estimate the density of dendritic microtubules in the dentate molecular layer (DML). In the LS line, the density of microtubules was significantly decreased in the middle and distal thirds of the DML during ethanol exposure. This change was normalized during withdrawal. In the SS line the microtubule density was decreased during ethanol exposure in the distal third only and was normalized during withdrawal. However, during withdrawal in the proximal and middle thirds a decreased and increased microtubule density, respectively was observed in the SS mice. The present observation on ethanol-related loss of neuronal microtubules is supported by ethanol-induced loss of microtubules in hepatocytes. Here acetaldehyde, the first metabolite of ethanol oxidation, forms stable adducts with tubulin dimers which markedly impairs microtubule assembly leading to a reduced number of microtubules (Tuma et al., Ann. NY Acad. Sci., 625:786,1991). *In vitro* acetaldehyde reacts with neuronal tubulin in a way similar to that of hepatic tubulin. The presence of acetaldehyde in the brain has been previously debated, however, recently acetaldehyde has been observed in the cerebrospinal fluid. This can be accounted for by alcohol metabolism that occurs directly in the brain (Anandatherthavarada et al., Brain Res., 601:279, 1993) as cytochrome P-45011E1 oxidizing ethanol into acetaldehyde can be induced by chronic ethanol intake, both in liver and in brain. Thus, acetaldehyde could be responsible for the loss of microtubules observed in the reported experiments. This loss is in agreement with the ethanol-related loss of tubulin in the brain. Moreover decreased density of microtubules may account for the decreased dendritic arborization found following chronic ethanol treatment (Paula-Barbosa et al., Addiction, 88:237, 1993). Supported by grants AA061196 and AA00130.

## 486.8

ETHANOL EFFECTS ON MEMBRANE RESPONSE PROPERTIES OF LAYER II-III NEURONS OF RAT SOMATOSENSORY CORTEX. E.-C. Hsu, J. Zhai, T.N. Felder, R.C.-S. Lin, A.E.K. Kosobud, S.J. Wieland, M.C. Kennedy\* and F.M. Sessler. Dept. of Anat. & Neurobiol., Med. Col. of Pennsylvania and Hahnemann Univ. Philadelphia, PA 19102, and Dept. of Psychol., Indiana Univ. IN 47405.

In a previous report we described acute and chronic actions of ethanol (EtOH) on membrane function of layer V somatosensory cortical pyramidal neurons. These experiments demonstrated various actions of EtOH on neocortical circuits that may underlie its effects on information-processing. The present experiments were conducted to examine the effects of EtOH on another cell population, i.e., layer II-III pyramidal neurons, which is known: 1) to express high levels of NMDA receptors and 2) to be involved in corticocortical functions. Experiments were done using an *in vitro* brain slice preparation from rat somatosensory cortex. Microelectrodes containing either neurobiotin (2-3%) or lucifer yellow (5%) were used for intracellular recording and morphological characterization of individual layer II-III neurons. Postsynaptic potentials (EPSP and IPSP) were evoked by electrical stimulation of either layer IV or the underlying white matter. Bath application of EtOH (1-100mM) produced dose dependent suppressant effects on EPSP amplitude, EPSP area and decreased the probability of spiking in response to threshold and suprathreshold synaptic stimulation. Basic membrane parameters were not affected to the same extent. Some cells were more sensitive than others to low concentrations of EtOH (1-10mM) suggesting a differential susceptibility to alcohol effects within the neocortical cell population. These data indicate that EtOH can affect signal processing capability and corticocortical transfer mechanisms through a direct action on layer II-III vulnerable neurons. (Supported by NIDA DA08405 and Allegheny-Singer Research Institute Award to FMS).

## 486.9

LONG-TERM ETHANOL EXPOSURE OR GAMMA-HYDROXYBUTYRATE EACH REDUCE LACTATE DEHYDROGENASE RELEASE FROM RAT ORGANOTYPIC HIPPOCAMPAL SLICES. King, M.A., Carlan, D.E., and Walker, D.W.\*, Department of Neuroscience and Brain Institute, University of Florida College of Medicine, and Veterans Administration Medical Center, Gainesville, FL 32610-0244.

Rats experiencing withdrawal from chronic ethanol demonstrate EEG hyperexcitability and transient increases in brain c-fos expression. These indices may reflect the occurrence of excitotoxic processes in the absence of overt seizures that could account for some of the brain pathology associated with chronic alcoholism. We used an organotypic interface slice culture model to assess cellular damage resulting from prolonged ethanol exposure or subsequent withdrawal, as reflected in the levels of lactate dehydrogenase (LDH) released into culture media.

Gammahydroxybutyrate (GHB) has recently been shown to ameliorate acute ethanol withdrawal symptoms in humans and rats. We also attempted to mimic whole animal and clinical effects of GHB on withdrawal. Slices from P7 Long-Evans rat pups, plated on Millipore culture plate inserts, were fed fresh media with or without 600 mg% ethanol (EtOH) daily for 7 days. Control and EtOH plates were then treated with fresh media containing EtOH, 20 mM GHB, both, or neither. Media were collected at 6 hrs for LDH assay. Ethanol and GHB alone each reduced LDH but were not additive. LDH in plates withdrawn from EtOH did not rise above control levels. GHB reduced LDH release in plates withdrawn from ethanol to levels observed in nonwithdrawal plates. This model system may be an efficient paradigm for the study of phenomena related to long-term ethanol exposure.

## 486.11

A CUT-OFF PHENOMENA FOR INHIBITION OF GLIAL INDUCIBLE NITRIC OXIDE SYNTHASE (iNOS) BY PRIMARY ALCOHOLS. P.J. Syapin\* and J.D. Militante, Department of Pharmacology, Texas Tech University Health Sciences Center, Lubbock, TX 79430.

Ethanol (C2) has been shown to dose-dependently inhibit glial iNOS expression in C6 glioma cells induced by treatment with phorbol ester + lipopolysaccharide. The inhibition appears transcriptional, but little is known about the underlying mechanism of action. The present study examined other primary alcohols for effects on iNOS activity. C6 glioma cells were exposed to primary alcohols (C1 to C8) during a 24 h induction period, and iNOS activity was estimated by nitrite accumulation, as described previously for C2 (Syapin, Alcohol Clin Exp Res, 19:262-267, 1995). Alcohols  $\leq$  C7 inhibit nitrite accumulation in proportion to measures of their hydrophobicity (e.g., carbon chain length and membrane/buffer partition coefficient), however, no inhibition is observed with C8 (1-octanol), a more hydrophobic alcohol. Experiments with C10 are under way to confirm this cut-off phenomena. Although significant correlations between potency and hydrophobicity suggest that alcohols  $\leq$  C7 inhibit iNOS in a manner similar to ethanol, experiments are being done to rule out a possible direct inhibition of enzymatic activity or indirect inhibition as a consequence of cytotoxicity. It is increasingly proposed that the actions of ethanol and other intoxicant-anesthetics are due to effects on hydrophobic regions of proteins, as opposed to membrane disordering effects on lipids. Our data supports the hypothesis that primary alcohols can interact directly with proteins to have biologically significant effects. (Supported by a Seed Research Grant and the Southwest Institute for Addictive Diseases)

## 486.13

INDUCTION OF RAT BRAIN CYTOCHROME P450 BY NICOTINE AND ETHANOL. R.B. Newton, R.M. France, L. Wecker\*, Department of Pharmacology and Therapeutics, University of South Florida, College of Medicine, Tampa, FL 33612.

The ability of nicotine and ethanol to induce cytochrome P450 in the rat brain was investigated. Twenty-four rats were assigned to four groups of six animals each and treated with nicotine alone, ethanol alone, nicotine and ethanol, or saline and water. Nicotine (1.76 mg/kg) was administered subcutaneously twice daily for ten days using an equivalent dose of saline as control. Ethanol (0.5 ml of 50% solution) was administered as a single dose by gastric gavage 18 hours prior to decapitation with normal drinking water administered as a control. Total P450 levels were determined by spectroscopic analysis. Administration of nicotine alone for ten days twice daily resulted in a 2-fold increase in total brain P450 levels. Administration of a single dose of ethanol 18 hours prior to decapitation resulted in a 2-fold increase in brain cytochrome P450 as well. Chronic subcutaneous administration of nicotine twice daily for ten days followed by a single administration of ethanol by gastric gavage resulted in a 3-fold increase in total brain cytochrome P450. Immunoblotting of pooled samples indicated that both nicotine and ethanol increased cytochrome P450B immunoreactive protein, and the combination treatment was equal to or greater than either treatment alone. These data indicate that treatment of rats with nicotine and ethanol alters brain cytochrome P450 levels and cytochrome P450B immunoreactivity, effects that may alter the metabolism of other psychoactive compounds.

## 486.10

CALCIUM HOMEOSTASIS IN CULTURED NGF-TREATED HIPPOCAMPAL NEURONS IS ALTERED BY ETHANOL. B. Webb\*, S.S. Suarez, M.B. Heaton, and D.W. Walker, University of Florida, V.A. Medical Center, Gainesville, FL 32610.

Acute ethanol treatment (AET) can cause changes in basal levels of intracellular calcium  $[Ca^{2+}]_i$  in hippocampal neurons. Nerve growth factor (NGF) may alter the effect of AET on calcium ( $Ca^{2+}$ ) homeostasis in hippocampal neurons. We cultured embryonic (E18) rat hippocampal neurons for 2 weeks. The cultures were treated with NGF (20 ng/ml) for 24 h and loaded with  $2\mu M$  indo-1. Baseline  $[Ca^{2+}]_i$  measurements were taken. The buffer for each group was exchanged for buffer containing NGF and control (no ethanol (EtOH)) or 100, 400, or 800 mg% EtOH. Fast responses were recorded for the first 6.4 sec and then at 10, 30, 45, 60 min. Overall,  $[Ca^{2+}]_i$  increased in hippocampal neurons treated with 100 or 800 mg% EtOH ( $p < 0.0001$ ). No change in  $[Ca^{2+}]_i$  was observed with 400 mg% EtOH. When EtOH-treated cultures were compared to control, 100 mg% EtOH increased resting  $[Ca^{2+}]_i$  from 3.2 sec until 10 min while the increase in  $[Ca^{2+}]_i$  persisted for 60 min in neurons treated with 800 mg% EtOH. We compared this data with previous data from hippocampal neurons treated with similar levels of EtOH but not with NGF. NGF treatment did not alter  $[Ca^{2+}]_i$ . NGF-treated neurons responded to 100 mg % ( $p < 0.0037$ ) or 800 mg% ( $p < 0.0001$ ) EtOH with greater increases in  $[Ca^{2+}]_i$  than did similarly treated non NGF-treated neurons. These results indicate that NGF enhanced the response of hippocampal neurons to AET, causing greater changes in  $[Ca^{2+}]_i$ . Both NGF and EtOH affect cellular mechanisms involved in the regulation of  $Ca^{2+}$  homeostasis. EtOH may alter the ability of NGF to regulate  $[Ca^{2+}]_i$  or NGF may alter the sensitivity of hippocampal neurons to EtOH. These alterations in  $[Ca^{2+}]_i$  may be an underlying mechanism of EtOH neurotoxicity. Supported by NIAAA grants AA00200, AA09128, and Fellowship #1F31AA05372-01; and Medical Research Service Department of Veterans Affairs.

## 486.12

ETHANOL ENHANCES RESTING AND STIMULATED SUPEROXIDE ANION PRODUCTION IN CULTURED MICROGLIA. C. Colton\*, O. Chernyshev, and J. Snell, Dept. Physiology, Georgetown University Medical School, Washington DC 20007.

Increased production of reactive oxygen species (ROS), i.e., superoxide anion, hydrogen peroxide, the hydroxyl free radical ( $OH\cdot$ ) and/or nitric oxide (NO), has been implicated as a causative factor in the tissue damage associated with ethanol-induced toxicity. Although a similar mechanism has been proposed for CNS damage, the source of ROS has not been clarified. Microglia, the CNS macrophages, are known to produce large quantities of ROS and are critical to normal development of the brain as well as the response of the brain to injury and infection. Using cultured neonatal hamster microglia, we have examined the effect of ethanol on microglial superoxide anion and NO production. Microglia were treated with 20 mM ethanol for 30 min, 3 hours, 24 hours and 48 hours and both resting (non-stimulated) and phorbol myristate acetate (PMA)-stimulated superoxide anion production examined for each time point. A significant increase in non-stimulated superoxide anion production was seen at 24 hours but not at the other time points studied. PMA-stimulated production was also significantly increased but only after 48 hours of continual treatment with 20 mM ethanol. Ethanol also altered the response of the microglia to lipopolysaccharide (LPS), a known inflammatory mediator. Treatment with both LPS and 20 mM ethanol for 24 hours produced a significantly greater resting release of superoxide anion than either LPS or ethanol alone. PMA stimulated release in ethanol and LPS treated microglia, however was not significantly greater. NO production was not induced by ethanol at any time point or concentration studied. These results suggest that microglia may be a significant factor in the production of oxidative stress induced by chronic exposure to ethanol.

## 486.14

BASAL AND PHORBOL ESTER - STIMULATED PHOSPHORYLATION OF MARCKS *IN SITU* ARE INCREASED IN ASTROCYTES CHRONICALLY EXPOSED TO ETHANOL. T.L. Smith\* and M.S. Bitrick, Research Service (151), Dept. of Veterans Affairs Med. Ctr., Tucson, AZ 85723

Chronic ethanol (E) exposure selectively inhibits metabotropic-glutamate receptor-stimulated polyphosphoinositide hydrolysis in astrocytes (Smith, Alcohol, 11:405, 1994). Because this receptor system is highly sensitive to modulation by protein kinase C (PKC), the aim of the present study was to determine whether chronic E affected PKC activity. PKC was monitored indirectly by determining the phosphorylation of MARCKS *in situ*. Type I astrocytes were grown in 96 well plates and exposed to either control media or media containing either 50 mM E or 100 mM E for 4 days. Cell wells were then rinsed with PBS and incubated at 25° for 12 mins. with a HEPES-buffered physiological salt solution containing: 50  $\mu M$  digitonin; 5mM EGTA; 100  $\mu M$  MARCKS; 100  $\mu M$  [ $^{32}P$ ] ATP (10<sup>3</sup> CPM/pmol). Reactions were stopped with TCA. Aliquots were spotted on phosphocellulose paper and counted for radioactivity. Phosphorylation of MARCKS expressed as pmoles P/mg protein/12 mins were: control, 633  $\pm$  18; 50 mM E, 909  $\pm$  39; 100 mM E, 983  $\pm$  53. Cells preincubated with 100 nM PMA for 15 mins: control, 2956  $\pm$  280; 50 mM E, 4948  $\pm$  677; 100 mM E, 5719  $\pm$  152. The results suggest that the ability of PKC to phosphorylate MARCKS *in situ* is significantly increased in a concentration-dependent manner by chronic E exposure employed in the present study. ALCOHOL REGULATION OF HYPOTHALAMIC-PITUITARY-ADRENAL ACTIVITY AND EXPRESSION OF ARGININE VASOPRESSIN MRNA IN MALE RATS BEARING LESIONS OF THE PARAVENTRICULAR NUCLEUS. K.M. Ogilvie\* and C. Rivier. Clayton Foundation Laboratories for Peptide Biology, The Salk Institute, 10010 North Torrey Pines Road, La Jolla, CA 92037.

Exposure to alcohol results in profound perturbations of homeostasis accompanied by activation of the hypothalamic-pituitary-adrenal (HPA) axis. The hypothalamic peptide corticotropin-releasing factor (CRF) is an essential modulator of this response. Previous work in this laboratory shows that in male rats, electrolytic lesions of the paraventricular nucleus of the hypothalamus (PVN) attenuate, but do not abolish, ACTH secretion in response to acute alcohol administration. Since the PVN is the major site of CRF neurons that project to the median eminence, this observation suggests that other brain areas, and perhaps ACTH secretagogues other than CRF (e.g. arginine vasopressin (AVP)), mediate HPA activation by alcohol.

In a preliminary experiment, injection of AVP antiserum (0.4 ml, iv) prior to injection of AVP (1.2 µg/kg BW, iv) completely blocked ACTH secretion. Use of the same antiserum attenuated the ACTH response to alcohol (3 g/kg BW, ip) in sham-lesioned animals. Immunoneutralization of AVP also diminished alcohol-evoked ACTH secretion in PVN-lesioned animals, indicating that endogenous AVP from outside of the PVN partially mediates the HPA response to alcohol. Because of the role of AVP in alcohol-stimulated ACTH secretion, we sought to determine whether alcohol also regulates AVP mRNA levels in the supraoptic nucleus (SON) and PVN using standard *in situ* hybridization techniques. Sham-lesioned animals sacrificed 3 hours after administration of alcohol (3g/kg BW, ip) had increased PVN levels of AVP mRNA in comparison to saline injected controls. In the SON, alcohol decreased levels of AVP mRNA in PVN-lesioned animals but had no effect in sham-lesioned animals.

The results demonstrate that in addition to CRF of PVN origin, the mechanisms by which alcohol elicits ACTH secretion involve AVP secretion from brain areas outside of the PVN. However, the precise manner in which alcohol stimulates the AVP response, especially in PVN-lesioned animals, has yet to be established.

## 486.16

INFLUENCE OF EXERCISE AND ETHANOL ON ACETYLCHOLINESTERASE ACTIVITY AND LIPID PEROXIDATION IN BRAIN REGIONS OF RAT. K. Husain, L.P. Rybak, S.M. Somani, R.J. Elble\*. Department of Pharmacology and Surgery, Southern Illinois University School of Medicine, Springfield, IL 62794-9230.

We have recently shown that exercise and ethanol increase lipid peroxidation (malondialdehyde-MDA) in the brain. AChE is lipid-dependent membrane bound enzyme. This study was sought to determine the effect of exercise and ethanol (Et) on AChE activity in specific brain regions. Male Fisher-344 rats were sacrificed after acute exercise (AE) (100% VO<sub>2max</sub>), Et 20% (1.6 gm/kg po), AE+Et and sedentary control (SC). Brain regions were isolated and AChE and MDA were determined. The results indicate that AE decreased AChE activity in corpus striatum (CS) (40%), medulla (M) (23%) and cerebral cortex (CC) (17%) compared to SC, and MDA increased 112%, 13% and 57% respectively. Ethanol increased AChE activity in CC (24%), and M (20%) and MDA increased 73% and 36% respectively compared to SC. However, the combined effect of AE+Et resulted in an increase activity in CC (26%), and decrease in CS (24%) with increased level of MDA 56% and 53% respectively. These results suggest that AE, Et and combination of both modulate AChE activity differentially in specific brain regions with enhanced lipid peroxidation.

## DEGENERATIVE DISEASE: PARKINSON'S—OTHER MODELS

## 487.1

CHARACTERIZATION OF A RAT MUTANT WITH SIMILARITIES TO PARKINSON'S DISEASE. R.W. Davies\*, R.G. Sutcliffe, P. Shiels, M. Duran Alonso, D.J. Clarke\*, D. Gilmore and A.P. Payne. \*Department of Human Anatomy, Oxford University, Oxford. Institute of Biomedical and Life Sciences, University of Glasgow, Glasgow G11 6NU, Scotland, U.K.

A mutant strain of rat (AS/AGU; Albino Swiss/Anatomy Glasgow University) with many phenotypic features similar to human Parkinson's disease is being characterized genetically and biochemically. AS/AGU rats show marked and progressive movement disorder and a loss, at one year, of 60% of tyrosine hydroxylase positive (dopaminergic) cells in the substantia nigra pars compacta (SNc). Dopamine levels are reduced by 45% in the SNc and by 26% in the dorsal caudate nucleus (DCN). HPLC measurements of dopamine levels in various regions of the caudate-putamen (CPu) show regional localization of dopamine depletion, and a precise correlation with the inheritance pattern of the mutation. Neurotransmitter level differences in the raphe nucleus (5HT) and locus coeruleus (NA) have also been analysed. An extensive programme of genetic mapping is underway.

## 487.2

PARTIAL-DEPLETION RODENT MODEL OF PARKINSON'S DISEASE. M.D. Lindner\*, D.F. Emerich, M.A. Plone, J.M. Francis, J.D. Salamone, and M.S. Hooks CytoTherapeutics Inc., Two Richmond Square, Providence, RI 02906

The discovery and development of new treatments with potential clinical efficacy in Parkinson's disease could be facilitated with a rodent model which simulates the clinical disorder more closely than the models currently available. Previous reports by Salamone et al. have demonstrated a pattern and degree of dopamine depletion analogous to the clinical disorder, and they have demonstrated a behavioral deficit with apparent clinical relevance (e.g. analogous to tapping speed). The present work replicates and extends their findings using rats with partial bilateral dopamine depletions by demonstrating that: (1) rats can be maintained following these partial bilateral dopamine depletions with low (0%) mortality, (2) the need for labor-intensive, time-consuming, manual forced-feedings following surgery is precluded by the use of sipper tubes and liquid diet, (3) clinically-relevant behavioral deficits can be quantified with simple, automated, fixed-ratio operant conditioning tasks, (4) these behavioral deficits are reliable, robust and long-lasting (>3mo). This model may prove useful in testing the effects of potential treatments including Sinemet and apomorphine.

## 487.3

FOREHAND ADJUSTMENT STEPPING IN DOPAMINE-DENERVATED RATS AS A MODEL FOR THE AKINESIA OF PARKINSON'S DISEASE. S.R. Wachtel\*, D. Young and U. J. Kang. Dept. of Neurology, University of Chicago, Chicago, IL 60637.

A paradigm characterizing non-drug-induced forelimb movements as a model for the akinesia of Parkinson's disease has recently been introduced by Norton et al. (NS Abs 1992) and Olsson et al. (NS Abs 1993). Of the parameters monitored, contralateral forehand adjusting steps in rats with unilateral 6-hydroxydopamine-induced denervation demonstrated the most consistent and robust deficit. In the present study, forehand steps over a fixed distance was used as simplified measure to characterize this behavior as a function of striatal dopamine (DA) depletion. Forehand steps showed two distinct levels as a function of the degree of DA loss. Whereas subjects with DA depletion <80% did not display any significant change in the number of contralateral forehand steps (11.1±3.0), stepping was essentially eliminated (0.3±0.4) in all rats with DA depletion >80% (p < 0.0001). The stepping deficits were evident by one week and remained stable up to 2 months after the lesion. Furthermore, the decrease in steps was partially restored by a low dose of L-DOPA (6.25 mg/kg i.p.). A similar biphasic response was noted by a comparison of lesion size with contralateral rotations induced by apomorphine (0.1 mg/kg); however, the appearance of apomorphine-induced rotation required greater (>95%) DA depletion than the loss of forehand stepping. Thus, reduced stepping behavior identified more animals with partial lesions than drug-induced behavior. In summary, forehand stepping changes provide a very consistent and reliable indicator of DA depletion, and reverses with pharmacological restoration of DA.

## 487.4

EFFECTS OF COMPLETE AND PARTIAL LESIONS OF THE DOPAMINERGIC MESOTELENCEPHALIC SYSTEM ON SKILLED FORELIMB USE IN THE RAT. S. Parmentier, M. Mazadier, J.M. Miquel, A. Boireau, P. Dubédat, J.-C. Blanchard, and P. Barnéoud\*. Rhône-Poulenc Rorer S.A., CRVA, Biology Department, 13 quai Jules Guesde, F-94403, Vitry-sur-Seine Cedex, France

This study compares certain behavioral consequences of partial and complete unilateral lesions of the dopaminergic mesotelencephalic system. We investigated skilled forelimb use, rotations induced by apomorphine and amphetamine, and dopaminergic metabolism of the nigrostriatal system of rats that had received a unilateral injection of 6-hydroxy-dopamine (2x6µg) into the medial forebrain bundle. The rats classified Apo(+), which rotated after the administration of apomorphine, had a complete lesion of the nigrostriatal system, whereas those classified Apo(-), which did not rotate after the administration of apomorphine, had a partial lesion of the nigrostriatal system. In the Apo(+) rats, 99.8% of the dopamine in the striatum was depleted, as was 85% of that in the substantia nigra. For the Apo(-) rats, 72% of the dopamine in the striatum was depleted as was 56% of that in the substantia nigra. When investigated with the staircase test, the animals with the most severe dopamine depletions were those most impaired in the paw reaching task. Complete and partial unilateral depletions of the dopaminergic mesotelencephalic system impaired the hierarchic phases of the paw reaching differently. A complete dopamine depletion, but not a partial one, decreased the number of attempts made with the contralateral paw, and induced a bias towards the ipsilateral paw. A partial dopamine lesion impaired the sensorimotor coordination of both paws, whereas the complete dopamine lesion had a greater effect on the contralateral paw than on the ipsilateral paw. The mild paw reaching impairments observed in animals with moderate depletions of dopamine are proposed as model of the early symptoms of Parkinson's disease that may be useful for the development of protective or restorative therapies.

## 487.5

DECREASES IN DOPAMINE RELEASE AND UPTAKE RATES IN THE PARTIALLY DENERVATED STRIATUM ARE PROPORTIONAL TO THE LOSS OF DOPAMINE TERMINALS. P. A. Garris\*, Q. D. Walker and R. M. Wightman. Department of Chemistry and Curriculum in Neurobiology, University of North Carolina, Chapel Hill, NC 27599-3290.

The present study tested the hypothesis that normal concentrations of extracellular dopamine can be generated in the partially denervated striatum without compensatory changes in dopamine uptake or release rates. One to four weeks after adult rats were unilaterally lesioned with 6-hydroxydopamine, fast-scan cyclic voltammetry at Nafion-coated, carbon-fiber microelectrodes was used to monitor extracellular dopamine levels *in vivo*, under urethane anesthesia. Simultaneous voltammetric recordings were collected in the lesioned striatum and contralateral control. Extracellular dopamine was elicited by bilateral electrical stimulation of the medial forebrain bundle. A 20 Hz stimulation evoked similar concentrations of extracellular dopamine in both lesioned and control striata, although tissue dopamine was decreased 30 to 70% in lesioned striata, as determined subsequently by HPLC-EC. However, kinetic analysis of the voltammetric recordings revealed that the concentration of dopamine released per stimulus pulse and  $V_{max}$  for dopamine uptake decreased in proportion to the magnitude of the lesion. These data support the hypothesis that normal extracellular dopamine levels can be generated in the partially lesioned striatum in the absence of active neuronal compensation. These results also suggest that passive mechanisms involved in the regulation of extracellular dopamine might play an important role in maintaining function during the preclinical phase of Parkinson's disease.

## 487.7

#### ELEVATED STRIATAL FOS IMMUNOREACTIVITY FOLLOWING 6-HYDROXYDOPAMINE LESIONS IS MEDIATED BY EXCITATORY AMINO ACID TRANSMISSION.

A. J. Cooper\*, S. Wooler and I. J. Mitchell. School of Psychology, University of Birmingham, Edgbaston, Birmingham, U.K., B15 2TT

Pharmacological depletion of dopaminergic neurotransmission can result in an elevation in striatal Fos levels. This elevation may occur as a direct result of decreased dopaminergic neurotransmission or indirectly via elevated cortico-striatal glutamatergic neurotransmission which occurs secondary to dopamine depletion. To test the hypothesis that elevated N-Methyl-D-Aspartate-mediated corticostriatal transmission may underlie the increase in striatal Fos levels upon dopamine depletion, rats were unilaterally 6-hydroxydopamine lesioned and either allowed to recover for 6 hours or maintained under anaesthesia for this period induced by the NMDA antagonist, ketamine. This was followed by sacrifice and quantification of striatal Fos immunoreactivity. The results demonstrate that dopamine depletion following 6-hydroxydopamine lesioning can result in elevated striatal Fos levels which can be attenuated by contiguous treatment with an NMDA antagonist. This suggests that the increase in striatal Fos levels observed following dopamine depletion may occur as a result of elevated cytoplasmic calcium levels in the striatal cells.

## 487.9

#### THE EFFECTS OF STRIATAL DOPAMINE DEPLETION ON CYTOCHROME OXIDASE ENZYME ACTIVITY IN THE RAT.

C. A. Baker\*, A. C. Grobin, & A. Y. Deutch. Departments of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06510.

Recent studies have demonstrated changes in mitochondrial enzyme activity and protein levels of constituents of the electron transport chain in selected brain areas in Parkinson's disease. Accordingly, we examined the activity of the mitochondrial enzyme cytochrome oxidase (CO) dorsolateral striatum and substantia nigra of rats and mice following treatment with MPTP, 3-acetylpyridine (3-AP), or 6-hydroxydopamine (6-OHDA)-induced striatal dopamine depletion. Our preliminary data suggest that 3-AP-treated rats sacrificed 7 days or 21 days after treatment did not show significant changes in CO activity in the striatum (CP) or substantia nigra (SN). Likewise, MPTP did not cause a significant change in CO activity in the CP or SN of C57BL6 mice sacrificed 21 days after treatment. Rats subjected to unilateral SN injections of 6-OHDA and sacrificed 21 days after treatment did not show a significant change in CO activity between the striata ipsilateral and contralateral to the lesion. These results contrast with our previous data demonstrating an increase in mitochondrial mRNAs for subunits of the electron transport chain following treatment with 6-OHDA, MPTP, or 3-AP. These data suggest that neurotoxin-induced alterations in mitochondrial gene transcription may not always be accompanied by a corresponding change in enzyme activity.

Supported by the National Parkinson Foundation Center for Excellence at Yale University.

## 487.6

REGIONAL STUDY OF STRIATAL LEVELS OF DA UPTAKE SITES, DA D<sub>1</sub> AND D<sub>2</sub> RECEPTORS, DA D<sub>2</sub> AND PREPROENKEPHALIN mRNAs AND FOS IMMUNOREACTIVITY AFTER PARTIAL DOPAMINERGIC DEGENERATION IN THE RAT BRAIN. M. Savasta<sup>1</sup>\*, V. Blanchard<sup>2</sup>, F. Javoy-Agid<sup>2</sup>, R. Raisman<sup>2</sup>, C. Feuerstein<sup>1</sup>

and M. Chritu<sup>1</sup>. 1. INSERM-LAPSEN U.318, Pavillon de Neurologie, CHU de Grenoble, Grenoble, France; 2. INSERM U.289, Hôpital Salpêtrière, Paris, France.

The presymptomatic situation of Parkinsonian patient has been reproduced in the rat by partially lesioning the nigrostriatal dopaminergic pathway. In this animal model, only the lateral part of the substantia nigra was destroyed by unilateral stereotaxic injection of 6-hydroxydopamine. Striatal levels of DA uptake sites, DA D<sub>1</sub> and D<sub>2</sub> receptors, DA D<sub>2</sub> and preproenkephalin (PPE) mRNAs and Fos immunoreactivity were studied one month after lesion by quantitative autoradiography, *in situ* hybridization and immunohistochemistry. Using an image analyser system, two striatal regions were differentiated: one corresponding to the denervated area and the other one being not affected by the lesion. Topographically, the disappearance of DA terminals as revealed by the <sup>3</sup>H-GBR 12935 (a marker of DA uptake sites) labelling, affects preferentially the lateral part of the striatum and concerns 30 to 70% of the total surface of this structure. Our results showed that in the denervated striatal subregion, no modification in D<sub>1</sub> and D<sub>2</sub> receptor densities or in D<sub>2</sub> receptor and PPE mRNA levels was detected, comparatively to ipsilateral control values. On the contrary, a differential Fos immunoreactivity has been evidenced according to the location of the striatal cells: the number of Fos reactive neurons induced by amphetamine was significantly reduced (-25%) in the deafferented part of the striatum whereas this number remained unchanged in the intact one. This last observation suggests that striatal cells located in the denervated part of the striatum are sensitized to the partial denervation. In conclusion, the fact that we did not observe any hypersensitivity of DA parameters suggests the existence of compensatory mechanisms induced by remaining DA neurons. Such mechanisms allow the maintenance of striatal dopaminergic transmission at post-synaptic level and could probably contribute to delay the appearance of neurological symptoms in Parkinsonian patients.

## 487.8

EFFECT OF LEVODOPA TREATMENT ON STRIATAL TYROSINE HYDROXYLASE FOLLOWING PARTIAL LESION OF THE SUBSTANTIA NIGRA. G. Dziewczapolski<sup>1</sup>, O. Gershanic<sup>1</sup>, S. Vyas<sup>2</sup>, Y. Agid<sup>2</sup> and R. Raisman-Vozari<sup>2</sup>. (1) Instituto de Investigaciones Farmacológicas, CONICET, Buenos Aires, Argentina; (2) INSERM U 289, 75013 Paris, France.

It is controversial whether levodopa (L-DOPA) therapy influences the progression of Parkinson's disease (PD) because of its toxic potential to dopaminergic neurons. This is also a reason for delay in L-DOPA administration at least in the early stages of PD.

Partial lesions of the substantia nigra (SN) in rat provide a model of the early stages of PD. We have recently demonstrated a spontaneous recovery of striatal tyrosine hydroxylase (TH) six months after partial lesions of the SN with 6-hydroxydopamine (6-OHDA) (Blanchard et al., J. Neurochem. 64, 1669, 1995). In the present study, we investigated the effects of chronic treatment with L-DOPA on TH on partially lesioned rats. Using immunohistochemical methods (Raisman-Vozari et al., J. Neurochem. 57, 1212, 1991) we quantified TH protein in the striatum (ST) from rats given L-DOPA + Carbidopa (170 and 17 mg/kg/day) for 7 months after partial (40-60% cell loss) unilateral 6-OHDA lesions of the SN.

In untreated lesioned rats (n=8), the decrease in striatal TH was 45.7 ± 4 % compared to the unlesioned side. Seven months after L-DOPA treatment, in lesioned rats (n= 7) the decrease of TH in the striatum was 15 ± 3 % compared to the unlesioned side. The exact mechanisms by which chronic treatment with L-DOPA increases TH in the ST in this animal model of PD remains to be clarified. However, our results demonstrate an absence of L-DOPA toxicity in the remaining dopaminergic neurons.

NOREPINEPHRINE LOSS ENHANCES METHAMPHETAMINE-INDUCED STRIATAL DOPAMINE DEPLETION IN MICE AND RATS. F. Fornai\*, M.T. Torracca, L. Bassi, F. Vaglini, R. Maggio and G.U. Corsini. Institute of Pharmacology, University of Pisa, 56126 Pisa, Italy.

Evidence is accumulating that norepinephrine depletion enhances the neurotoxic effect of the parkinsonism inducing neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP). In this study we investigated whether norepinephrine loss potentiates methamphetamine-induced striatal dopamine depletion.

Injection of C57BL/6N mice with methamphetamine (2 X 5 mg/Kg i.p., at two hour intervals) produced only a partial (50%) striatal dopamine depletion 7 days after drug administration. Pretreatment with the selective noradrenergic neurotoxin DSP-4 (50 mg/Kg, i.p.) enhanced methamphetamine-induced striatal dopamine depletion to 86%, without decreasing striatal dopamine levels when injected alone. Pretreatment of Sprague-Dawley rats with DSP-4 (50 mg/Kg, i.p.) did not decrease striatal dopamine levels when injected alone but produced a significant decrease in striatal dopamine levels when combined to a dose of methamphetamine (3 X 5 mg/Kg i.p., at two hour intervals) which did not change striatal DA levels when injected alone. There was a direct correlation between the degree of norepinephrine depletion in specific brain areas and the extent of enhancement of methamphetamine toxicity produced by DSP-4. Our results extend previous findings obtained with the dopaminergic neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine in DSP-4-pretreated mice and confirm that norepinephrine loss might enhance neurotoxic damage to nigrostriatal dopaminergic neurons.

## 487.11

THE DOPAMINERGIC NEUROTOXICITY OF METHAMPHETAMINE IS PREVENTED BY NITRONE SPIN TRAPPING AGENTS. C. J. Schmidt and V. L. Taylor. Marion Merrell Dow Research Institute, 2110 E. Galbraith Rd., Cincinnati, OH 45215.

A large body of indirect evidence suggests that oxidative damage may play a major role in the degeneration of dopaminergic nerve terminals observed following high doses of methamphetamine (METH). When coadministered with iprindole, a single of METH (20 mg/kg, s.c.) reduced striatal dopamine concentrations in the rat by 40 to 50% after one week. Pretreatment with the nitrone spin trap,  $\alpha$ -phenyl-*tert*-butylnitron (PBN) or the novel cyclic nitrone, MDL 101,002, prevented the METH-induced decline in dopamine concentrations. Previous research has demonstrated that neuroprotection in this model may be achieved by agents which interfere with METH-induced hyperthermia. Temperature studies were therefore conducted to determine if such a mechanism could account for the protective effects of the nitrones. Acute administration of METH (20 mg/kg, s.c.) resulted in a significant hyperthermia of 2 to 2.5 °C above baseline which lasted greater than 6 h. PBN alone (100 mg/kg, i.p.) produced a modest hypothermia (-1 to -1.5 °C) of 4 to 5 h duration but did not affect the hyperthermic response to METH. Although not neuroprotective, the same dose of MDL 101,002 produced a hypothermic response of similar duration to PBN but of greater magnitude (-2.5 °C). The neuroprotective dose of MDL 101,002 (300 mg/kg, i.p.) produced a profound hypothermia (-3.5 to -4 °C) but like PBN, did not alter the effect of METH. The results support the hypothesis that free radical damage is an important component of METH-induced neurotoxicity and further indicate that nitrone spin trapping agents are centrally effective antioxidants.

## 487.13

ANIMAL MODELS OF PARKINSONIAN SYMPTOMS: EFFECTS OF ACUTE AND REPEATED CLOZAPINE INJECTIONS ON CHOLINOMIMETIC-INDUCED TREMULOUS JAW MOVEMENTS. J.D. Salamone\*, and E. Chesler. Dept. of Psychology, U. of Connecticut, Storrs, CT 06269-1020 USA

Three studies were undertaken to investigate the effects of the atypical neuroleptic clozapine on the tremulous jaw movements induced by cholinergic stimulation in rats. In the first 2 studies, acute clozapine injections (2.0-16.0 mg/kg) produced a dose-related suppression of the tremulous jaw movements induced by either 0.4 mg/kg physostigmine or 4.0 mg/kg pilocarpine. The third study compared the effects of acute and repeated clozapine injections. Either acute or repeated injections of 16.0 mg/kg clozapine reduced tremulous jaw movements relative to rats that received pilocarpine alone, and the two clozapine-treated groups did not differ from each other. Sedation ratings indicated that acute injections of clozapine produced substantial drowsiness and sedation, whereas rats that had received clozapine for 14 days did not show substantial sedation. These results indicate that clozapine can suppress cholinomimetic-induced tremulous jaw movements, and that the suppression of pilocarpine-induced jaw movements is not merely an artifact of clozapine-induced sedation. Because pilocarpine-induced tremulous jaw movements share some characteristics with human parkinsonian symptoms, the present results are consistent with reports indicating that repeated injections of clozapine produce anti-parkinsonian effects.

## 487.15

ANIMAL MODELS OF PARKINSONIAN SYMPTOMS: FURTHER CHARACTERIZATION OF TREMULOUS JAW MOVEMENTS IN RATS. M. Finn\*, A. Jassen, P. Baskin, E. Chesler, M. Cousins and J.D. Salamone. Dept. of Psychology, U. of Connecticut, Storrs, CT 06269-1020 USA

Vacuous jaw movements are vertical deflections of the lower jaw that resemble chewing but are not directed at any stimulus. Because vacuous jaw movements in rats can be produced by dopamine (DA) antagonism, striatal DA depletion, and muscarinic stimulation, it has been suggested that vacuous jaw movements share some characteristics with parkinsonian symptoms. In order to determine if vacuous jaw movements are tremulous in nature, rats were videotaped in Plexiglas tubes for observation of jaw movements. The videotapes were observed at 1/6 normal speed, and the observed jaw movements were recorded by a computer program that measured the interresponse time of each jaw movement. These methods were used to study the jaw movements induced by 2.0 and 4.0 mg/kg pilocarpine, as well as the movements induced by depletion of DA. Analysis of interresponse times indicated that most of the jaw movements occur in the same frequency range as parkinsonian tremor (3-7 Hz). Additional studies showed that vacuous jaw movements can be induced by ventrolateral striatal (VLS) DA depletions, and that DA depletions in the ventral portion of the VLS were correlated with both jaw movements and feeding deficits. Haloperidol facilitated jaw movements in DA depleted rats on days 5 and 15 after surgery. The "vacuous" vertical jaw movements induced by cholinomimetics or DA depletion may be useful as a model of parkinsonian tremor.

## 487.12

ANIMAL MODELS OF PARKINSONIAN SYMPTOMS: THE ANTICHOLINESTERASE TACRINE INDUCES TREMULOUS JAW MOVEMENTS IN RATS. A.J. Mayorga\*, D. Carriero, G. Gianutsos and J.D. Salamone. Dept. of Psychology, U. of Connecticut, Storrs, CT 06269-1020 USA

Tacrine (Cognex) is an acetylcholinesterase inhibitor that is being widely used as a treatment for Alzheimer's disease. Some of the reported side effects of tacrine include parkinsonian symptoms such as tremor, akinesia, rigidity and gait disturbance. For these reasons, the effects of tacrine on tremulous jaw movements in rats were investigated. Intraperitoneal injections of tacrine induced tremulous jaw movements in the dose range of 1.25-10.0 mg/kg. These movements, like those produced by physostigmine and pilocarpine, tended to occur in rapid, repetitive bursts of jaw movement characterized by vertical deflections of the lower jaw. The jaw movements induced by 5.0 mg/kg tacrine were blocked by injections of the muscarinic antagonist scopolamine. These results indicate that tacrine can produce signs of extrapyramidal motor disturbance, which is consistent with some of the reported side effects of this drug. In addition, these results are consistent with the extensive literature indicating that muscarinic cholinergic stimulation can lead to parkinsonian symptoms, including tremor. Investigations of tremulous jaw movements in rats may be useful as a tool for investigating the neurochemical basis of the motor side effects of tacrine.

## 487.14

ANIMAL MODELS OF PARKINSONIAN SYMPTOMS: L-DOPA IMPROVES SKILLED MOTOR FUNCTION IN RATS WITH VENTROLATERAL STRIATAL DOPAMINE DEPLETIONS. M.S. Cousins\* and J.D. Salamone. Dept. of Psychology, U. of Connecticut, Storrs, CT 06269-1020 USA

Previous studies indicated that ventrolateral striatal (VLS) dopamine (DA) depletions produced profound motor deficits that interfered with lever pressing. DA depletions induced by VLS injections of 6-OHDA significantly reduced lever pressing on a fixed ratio 5 (FR5) operant schedule. This deficit was largely due to a dramatic increase in the average response initiation time, which was defined as the time from offset of one lever press to the onset of the next one. Analysis of the distribution of response initiation times indicated that VLS DA-depleted rats made relatively few responses with fast initiation times, and also that VLS DA depletions led to a dramatic increase in the number of pauses in responding. The observed lever pressing deficits produced by VLS DA depletions were partially reversible with L-DOPA. Systemic administration of 40.0 mg/kg L-DOPA significantly increased the number of responses in DA-depleted rats, whereas both 20.0 and 40.0 mg/kg L-DOPA partially reversed the response initiation deficits. The deficits in response initiation and execution produced by VLS DA depletions in rats could be related to the impairments in skilled motor usage that are characteristic of patients with Parkinson's disease. This paradigm may be useful for examining other potential antiparkinsonian agents such as D1 and D2 agonists, or cholinergic and excitatory amino acid antagonists.

## 487.16

RETROGRADE NEURONAL DAMAGE CAUSED BY LYSO-PHOSPHOTIDYLCHOLINE: ROLE OF METHYLATION IN NEURODEGENERATION. C. G. Charlton\*. Florida A&M University, College of Pharmacy, Tallahassee, Florida 32307.

The CNS injection of S-adenosyl-methionine (SAM) causes Parkinson's disease-like changes. The movement disorders may be caused by dopamine (DA) loss. The cause of SN damaged, however, is unknown. Products of methylation, like methyl-beta-carbolines were indicated, but other agents, like methylated phospholipids (PL), may be involved. Lyso-phosphatidylcholine (lyso-PTC) is a likely candidate, because it is a potent cytotoxic secondary product of SAM, that damages cell membranes and fibers and reduces DA receptor binding. To know if lyso-PTC may be involved in SAM-induced cell damage, the PL was injected into the brain of rats. Injections into the ventricle cause tremor, teeth chattering, hypokinesia, and dilation of the ventricles. Following injection into the caudate nucleus, neuronal membrane damage, gliosis, axonal swelling, tangle-like debris and filamentous remains of blood microvessels were seen close to the injection sites. Degeneration was traced, retrogradely, to the substantia nigra (SN), where Nissl staining showed degenerated neurons and silver staining identified damaged axonal stumps. PL methylation increases membrane solubility, and lyso-PTC was reported to be involved in ischemic cell death, therefore, methylated PL, which represent about 19% of dry cell mass, may play a role in neuronal damage and in cerebrovascular accidents. Supported by NIH RR 03020 and RO1 28432 and 31177.

## 487.17

**PARAQUAT ELICITED PARKINSON-LIKE EFFECT IN RATS: BEHAVIOR, NEUROCHEMISTRY AND HISTOLOGY.** H.H. Liou<sup>1,\*</sup>, M.C. Tsai<sup>2</sup>, Y.F. Tsai<sup>3</sup>, W.P. Chen<sup>1</sup>, Y.C. Chang<sup>1</sup> and R.C. Chen<sup>1</sup>

<sup>1</sup>Department of Neurology, <sup>2</sup>Pharmacology, <sup>3</sup>Physiology and <sup>4</sup>Anatomy, National Taiwan University, Taipei 100, Taiwan, ROC.

Epidemiologic studies point to a connection between paraquat exposure and parkinsonism. To evaluate a potential role for the paraquat, male Wistar rats were unilateral intranigral injection of paraquat (1.5 µg). This study showed: (1) behaviorally, apomorphine induced dose-related rotational behavior in rats contralaterally to the lesioned side 2 weeks after paraquat treatment. (2) neurochemically, ipsilateral striatal dopamine level was decreased to 91.5 % after 3 µg paraquat-treated. Paraquat also produced a dose-dependent depletion of dopamine in the ipsilateral striatum of rats 2 weeks following treatment. The decreased striatal dopamine is long-lasting and irreversible. (3) morphologically, marked decreased Nissl bodies and prominent gliosis in the substantia nigra were observed 2 weeks after paraquat injection. Whereas 3 µg paraquat caused a severe necrotic lesion in the injected area. The behavioral, neurochemical and histological results are identical to those observed following intranigral injection of 1-methyl-4-phenylpyridinium ion (MPP<sup>+</sup>). The structure resemblance of paraquat to MPP<sup>+</sup> makes the possible correlation between paraquat and Parkinson's disease more intriguing. The present results indicated that intranigral injected paraquat could possess a marked neurotoxicity and induce nigrostriatal dopaminergic system degeneration in rats. These findings suggested that paraquat should be investigated as a potential etiological agent of parkinsonism. (Supported by NSC-84-2331-B002-280, Taiwan)

## 487.19

**TYROSINE HYDROXYLASE IMMUNOREACTIVITY IS PRESERVED IN TWO SUBSETS OF NIGRAL NEURONS IN CULTURED RAT MIDBRAIN SLICES** T.R. Mhyre<sup>\*</sup>, S.N. Huber, and J. Holliday. Dept. of Neurobiology & Anatomy, Univ. of Rochester Medical Center, Rochester, NY 14642

The complexity of the nervous system presents unique problems in studying normal and pathologic processes in both *in vivo* and standard *in vitro* systems. A technique combining the relative ease of manipulation of culture experiments with the more physiologically relevant aspects of whole animal studies, therefore, is a highly desirable research tool. We wanted to devise a method that would allow midbrain slices to remain viable in culture for at least 3 days and at the same time maintain the appropriate nigral neuronal phenotypes.

Adult female Sprague Dawley rats received bilateral, intra-striatal injections of the retrograde tracer, dextran-conjugated lucifer yellow (LY). The animals were sacrificed after 7 to 8 days and 200 µm thick midbrain vibratome sections were cut. Slices containing the substantia nigra (SN) were then cultured on polycarbonate filters in deplanarizing medium. Following fixation on 0, 1, 2, and 3 days *in vitro* (DIV), the slices were resectioned (25 µm thickness) and stained for tyrosine hydroxylase (TH) or calbindin D (Cal D) immunoreactivity (IR). Fluorescence microscopy demonstrated that the retrogradely labeled neurons of the SN retained the LY through 3 DIV and were also double labeled for TH IR. However, only a subset of retrogradely labeled neurons double labeled with Cal D IR, a marker for dorsal tier neurons of the SN.

These results demonstrate that midbrain slices 1) survive in culture for at least 3 days and, more importantly, 2) appropriate dorsal tier and ventral tier neuronal pools are maintained in these cultures. Thus, this system provides a unique model for studying mature, subset-specific neurons in the SN without the inherent problems of standard *in vitro* and *in vivo* experiments. Supported by funds from the Patterson Trust and Rochester Area Pepper Center.

## 487.18

**TRANSGENIC MICE EXPRESSING HUMAN MONOAMINE OXIDASE B DRIVEN BY THE NEURON-SPECIFIC ENOLASE PROMOTER.** P. Matherbe<sup>\*</sup>, J. Gottowik, E. Borroni, J.G. Richards, A. Cesura, C. Kühn, R. Pink, H. Blüthmann and M. Da Prada. Pharma Division, Preclinical Research, F. Hoffmann-La Roche Ltd, CH-4002 Basel, Switzerland

To gain insight into the possible role of monoamine oxidase B (MAO-B) in dopaminergic cell death in Parkinson's disease, we have generated lines of transgenic mice in which neurons overexpress the human MAO-B protein under the control of the neuron-specific enolase promoter. The transgenic mice express 4-6 fold higher MAO-B activity in brain as compared to non-transgenic littermates, whereas the activity of MAO-B in the liver was equal to that of control animals. Analysis of brain monoamines in 5-8 weeks old transgenic mice showed a 30-40% increase in the basal levels of the dopamine metabolites DOPAC and HVA, whereas no changes were observed in the basal levels of dopamine (DA). Further analysis of brain regions showed an increase in the levels of DOPAC and HVA in the substantia nigra and striatum of transgenic mice, whereas no changes in neurotransmitter level were seen in the locus coeruleus and frontal cortex. The transgenic mice metabolize approximately 20% more DA than control animals under basal conditions. Thus, the increased rate of dopamine metabolism observed in mice overexpressing human MAO-B is likely to result in an increased oxidant stress since the conversion of DA to DOPAC, catalysed by MAO, is stoichiometrically linked to the production of hydrogen peroxide. Therefore, these animals could serve as an invaluable tool to study the etiology of Parkinson's neuro-pathologies in brain.

## 487.20

**HEMIPARKINSON RATS DISPLAY ACTIVE SUPPORT IN THE GOOD LIMBS VS PASSIVE SUPPORT IN THE BAD LIMBS ON A SKILLED REACHING TASK OF VARIABLE HEIGHT.** E. I. Miklyaeva<sup>\*</sup> and I. O. Whishaw. Dep. of Psychology, Univ. of Lethbridge, Lethbridge, AB, Canada, T1K 3M4

Control rats and rats with unilateral DA-depletion, produced by 6-hydroxydopamine (6-OHDA) injected into the nigrostriatal bundle, were tested in a skilled reaching task. The height to be reached was varied in order to force the rats to use their supporting limbs to assist them in reaching. Control rats used the contralateral-to-reaching rear limb to stretch their body at high heights and the contralateral-to-reaching forelimb to lower their body at low heights. The DA-depleted rats failed to use their bad hind limb to extend their reach at high heights and failed to lower their body with their bad forelimb in order to reach at low heights. Consequently, they failed to obtain a reward at the height extremes. At intermediate heights, for which use of the bad limbs was not essential, their reaching performance approximated that of the control rats. It is suggested that extensive DA-depletion may result in the loss of the ability to apply forces with affected limbs for both voluntary movements and for postural adjustments.

## DEGENERATIVE DISEASE: PARKINSON'S—CLINICAL

## 488.1

**PARKINSON STUDY GROUP DNA REPOSITORY.** C.M. Tanner<sup>▲</sup>, C.W. Shults<sup>★</sup>, P. Chan<sup>◆</sup>, J.S. Fink<sup>◆</sup>, M. Kurth<sup>+</sup>, K.L. Marek<sup>+</sup>, L.W. Elmer<sup>#</sup> and Parkinson Study Group. <sup>▲</sup> The Parkinson's Inst., Sunnyvale, CA; <sup>★</sup> Univ. Cal. San Diego, La Jolla, CA; <sup>◆</sup> Mass. Gen. Hosp., Boston, MA; <sup>+</sup> Barrow Neurol. Inst., Phoenix, AZ; <sup>+</sup> Yale Univ., New Haven, CT; <sup>#</sup> Univ. Mich., Ann Arbor, MI.

The Parkinson Study Group (PSG), a consortium of 34 centers across the United States and Canada has established a DNA repository with samples from over 400 persons who were clinically diagnosed as having typical early Parkinson's disease (PD) and enrolled in the DATATOP (Deprenyl and Tocopherol Antioxidative Therapy of Parkinsonism) clinical trial in 1987-88 (Arch. Neurol. 1989; 46:1052-1060). Evaluations of the patients were performed through 1995 and included measures of neurological function, severity of PD (including the Unified Parkinson's Disease Rating Scale, Schwab and England scale and Hoehn and Yahr scale), cognition, mood, drug treatment and drug-associated adverse events. Additional information includes gender, race and age of onset for PD. Investigators interested in use of this repository should contact Dr. C.W. Shults (Fax: 619-552-7513, e-mail: cwshults@vapop.ucsd.edu). Access to this resource will be determined by the PSG based on the scientific merit and appropriateness of the proposal. To our knowledge, this represents the largest collection of well characterized, uniformly followed PD patients from whom DNA has been collected. DNA from this repository is likely to be useful in investigations of genes that may be associated with PD.

## 488.2

**NIGRAL INFECTION BY INFLUENZA A VIRUS-A POSSIBLE CAUSE OF POSTENCEPHALITIC PARKINSONISM.** M. Takahashi, T. Yamada<sup>\*</sup>, S. Nakajima, K. Nakajima, T. Yamamoto and H. Okada. Choji Medical Institute, Noyori Fukushima Hospital, Toyohashi 441, Japan.

Clinical and immunohistochemical studies were done for 3-39 d on mice after intracerebral inoculation with the neurovirulent A/WSN/33 (H1N1; WSN) strain of influenza A virus, the nonneurovirulent A/Aichi/2/68 (H3N2; Aichi) strain, and two reassortant viruses (R96 and R404BP) between them. Both the WSN and R404BP strains, which contain the WSN gene segments coding for neuraminidase and matrix protein, were clearly neurovirulent both clinically and pathologically. On day 3 after inoculation, WSN-antigen was detected in meningeal areas and neurons of the substantia nigra zona compacta. On day 7, meningeal reactions as well as neuronal staining was still seen, and advanced accumulation of the viral antigen was evident in the substantia nigra zona compacta. Double immunostaining demonstrated that the WSN antigen was only seen in neurons. Immunostaining for a lectin, maackia amurensis agglutinin, that recognizes the Neu5Ac α2, 3 Gal sequence which serves as a binding site for influenza A virus on target cell membranes, showed that positive staining was localized in the ventral substantia nigra. These results suggest that neurovirulent influenza A viruses could be one of the causative agents for postencephalitic parkinsonism.

## 488.3

IS FAMILIAL PARKINSONISM ASSOCIATED WITH THE EXPANSION OF TRINUCLEOTIDE REPEATS? **K. Markopoulou<sup>1</sup>, R.F. Pfeiffer<sup>2</sup>, Z.K. Wszolek<sup>1</sup> and B.A. Chase<sup>3</sup>**. <sup>1</sup>Section of Neurology, University of Nebraska Medical Center, Omaha NE 68198-2045, <sup>2</sup>Dept. of Neurology, University of Tennessee, Memphis TN 38163, <sup>3</sup>Dept. of Biology, University of Nebraska at Omaha, Omaha NE 68182-0040.

Interest is increasing concerning the role of genetic factors in the etiology of Parkinson's disease. We report the analysis of a Greek-American kindred with levodopa responsive parkinsonism. Of the 98 individuals present in six generations of this pedigree, 16 individuals in three successive generations have developed parkinsonism. The phenotype of this pedigree is that of idiopathic Parkinson's disease and appears to be inherited in an autosomal dominant manner. Anticipation is present in this pedigree. The age of disease onset decreases, while the phenotypic severity appears to increase in successive generations. The affected members in the third generation developed symptoms at ages 50-71, in the fourth at ages 40-55 and in the fifth at age 31. This is another example of a neurodegenerative disease with autosomal dominant inheritance and anticipation. Diseases displaying anticipation have been associated with trinucleotide repeat expansion in their genes. The method of repeat expansion detection (RED) has been used to determine whether this pedigree is associated with trinucleotide repeat expansion. Preliminary findings will be presented.

## 488.5

CO-LOCALIZATION OF NEUROFILAMENT AND UBIQUITIN IN LEWY BODIES. **W.D. Hill<sup>1</sup> and G. Oblak<sup>2</sup>**. Dept. of Cellular Biology and Anatomy, Medical College of Georgia, Augusta, GA 30912.

Lewy bodies (LBs) are the pathological hallmarks of Lewy body associated disorders including Parkinson's disease and diffuse Lewy body disease. These filamentous neuronal inclusions characteristically label with antibodies to ubiquitin and with antibodies to neurofilament (NF) triplet proteins. Neurofilament proteins have been proposed as the major structural components of the filaments in Lewy bodies. However, several reports of NF antibody labeling of LBs suggest that not all LBs are labeled by NF antibodies. Additionally, the NF antibodies generally labeled only the outer portion of the LB. These observations have raised the possibility that NFs are not consistent features of LB filaments and therefore are not universal components of LBs.

In this study we provide further evidence that the Lewy body fibrils are composed of neurofilament proteins. Confocal microscopy was used in conjunction with immunoprobe to the neurofilament-M subunit and ubiquitin. Substantia nigra pars compacta neurons from 5 Parkinson's disease cases, 6 Alzheimer's/Parkinson's disease cases and 4 diffuse Lewy body disease cases were examined. The RMO32 neurofilament-M epitope is distributed throughout the Lewy bodies, wherever the filaments existed. Additionally, RMO32 labeling co-localized with anti-ubiquitin labeling. This demonstrates that NF containing Lewy bodies are not distinct from ubiquitinated Lewy bodies. Reported differences in NF labeling may be due to disease associated modifications to the NF epitopes and differences in antibody specificity and sensitivity.

## 488.7

PLASMA CATECHOLAMINE LEVELS OF ELDERLY MEN DURING EXERCISE: COMPARISON OF NORMALS WITH PARKINSONIAN PATIENTS. **Susan L. Stoddard, Todd D. Miller, Gertrude M. Tyce, J. Eric Ahlskog, Alan R. Zinsmeister, and Stephen W. Carmichael\***. Mayo Medical Ventures, Departments of Cardiology, Physiology, Neurology, Statistics, and Anatomy, Mayo Clinic/Foundation, Rochester, MN 55905.

Plasma levels of epinephrine (EPI), norepinephrine (NE), and dopamine (DA) were measured by HPLC with EC in 17 normal men (mean age 61 years; range 52 to 75) before, during, and 3 minutes after exercise to exhaustion on a cycle ergometer. The same measurements were made on a group of 8 men (mean age 48.3 years; range 38 to 58) with Parkinson's disease (PD), before and one year after autologous transplantation of the adrenal medulla to the caudate nucleus.

	PLASMA CATECHOLAMINES (CA) IN PG/ML - Median Values								
	EPI			NE			DA		
	Norm	Pre	Post	Norm	Pre	Post	Norm	Pre	Post
Rest	29*	54	60	253	268	436	26*	1043	1192
Sub-Max	63	43	70	871*	302	529	30*	895	842
Max	127	78	86	1648*	548	708	43*	880	831
3 Min	72	72	75	1451*	599	582	42*	1252	854

EPI in normals was significantly (\*) less than either PD group at rest. NE in normals was significantly greater than both PD groups during exercise, most likely due to the greater intensity of exercise possible in this group. DA was significantly lower in normals than either PD group for all measures, most likely due to the administration of L-dopa and carbidopa to PD patients. Pre-op and post-op PD patients had no differences in any CA for any measure, suggesting that the remaining adrenal medulla compensates following unilateral adrenalectomy.

## 488.4

PATTERN OF BRAIN ATROPHY IN DIFFERENT PARKINSONIAN SYNDROMES. **D.A. McRitchie, K.L. Double, G.M. Halliday, and E.M. McLachlan\***. Prince of Wales Medical Research Institute, Randwick, 2031, Australia.

There have been no previous studies of regional brain volumes in Parkinsonian syndromes, despite many patients having significant cortical signs in life. The present study analysed atrophy in brains collected from prospectively followed donors and controls with the clinical diagnosis of Parkinson's disease (PD) confirmed postmortem. The study was approved by the Human Ethics Committee. Four patients had idiopathic PD (with no cortical pathology), 9 patients had PD with dementia (4 with cortical plaque pathology; 5 with diffuse Lewy body disease), and 10 were age- and sex-matched controls. The brains were weighed and volumes calculated before and after fixation. The cerebrum volume was remeasured prior to cutting into 3mm coronal slices. Each brain slice was photographed and printed. Frontal, temporal and parieto/occipital cortices, amygdala/hippocampus, basal ganglia and white matter were delineated. The volume of each region was calculated in each slice by point counting (each point=0.05ml). Repeated measures gave a 1% maximum error with an inter-rater error of less than 1%. There was no atrophy of white matter or basal ganglia in any case. Patients with idiopathic PD had no atrophy of cortical structures but a significant volume loss in the amygdala/hippocampus (24%). In contrast, PD patients with dementia had significant losses of frontal (16%), temporal (17%) and parieto/occipital (11%) cortices. In addition, volume reduction of the amygdala/hippocampus was more marked (33% loss) compared to PD patients without dementia. The results show that PD patients with dementia have significant cortical atrophy, without concomitant Alzheimer's disease. Surprisingly, significant volume changes occur in deep temporal lobe structures without overt memory deficits.

## 488.6

UBIQUITIN AND MAP5 OCCUR SPECIFICALLY IN DEGENERATING NEURITES AND LEWY BODIES IN PARKINSON'S DISEASE AND DIFFUSE LEWY BODY DISEASE. **W.P. Gai\*, P.C. Blumbergs, and W.W. Blessing**. Depts. of Physiology and Medicine, Centre for Neuroscience, Flinders University, Bedford Park, SA 5042, Australia.

We examined degenerating neurites in serial sections of brainstem and forebrain regions from Parkinson's disease (PD, n=14), diffuse Lewy body disease (DLBD, n=7), Alzheimer's disease (n=6), multisystem atrophy (n=4), motor neuron disease (n=5), vascular parkinsonism (n=2), and neuropathologically normal aged controls (n=11). Sections were stained routinely for histopathological examination or immunocytochemically with antibodies to ubiquitin, tau, bA4, and other cytoskeletal proteins, including MAP5 and neurofilaments. Doubly immunostained sections were examined with a confocal microscope. Ubiquitin-positive, tau-negative degenerating neurites were found in PD and DLBD, largely confined to brain regions where Lewy bodies were present. Corresponding neurites were absent in normal controls, and in non-Lewy body degenerative conditions. In PD, density of degenerating neurites in the dorsal motor vagal nucleus inversely correlated with the duration of symptoms.

MAP5 was consistently present in Lewy bodies and degenerating neurites (identified by ubiquitin double staining) throughout the brain, including the neurites in hippocampal CA2 area. Confocal microscopy showed MAP5 and ubiquitin reactivities partially overlapped and both were located in the Lewy body core and in the central region of degenerating neurites. Neurofilaments were located in the periphery of the Lewy bodies and degenerating neurites in which they occurred. Our results suggest support the view that degenerating neurites and Lewy bodies may derive from the same pathogenic process.

## 488.8

A DEVICE FOR THE QUANTIFICATION OF PARKINSONIAN RIGIDITY

**S.K. Patrick\*, S.C. Naaman, M.J.A. Gauthier, A. Prochazka** Division of Neuroscience, University of Alberta, Edmonton, Alberta, Canada T6G 2S7

The subjective nature by which Parkinsonian rigidity is measured clinically makes inter- and perhaps intra-clinician comparison of rigidity scores difficult and unreliable. A device currently under development aims to overcome these problems by quantifying the rigidity elicited during the clinical exam. Portable, lightweight sensors are used to record the forces the clinician exerts as he manipulates the patient's arm about the elbow. In this way, the procedure retains the advantages of the conventional clinical exam, yet a more reliable, standardized rating of the rigidity is achieved (Prochazka, A., Bennett, D.J., Stephens, M.J., Sears-Duru, R., Roberts, T., Jhamandas, J.H., Movement Disorders (submitted)).

Recently, the device has undergone substantial improvement. Notably, a Windows™-based user interface and modifications to the hardware make use of the device straightforward and uncomplicated, while increasing its portability. A Motorola 68HC11 microprocessor is now used to sample the data. This replaces larger, more cumbersome equipment and allows the user easy adjustment of signal gain and offset. The computer interface displays the incoming data in real-time, manages all data files, and invokes Matlab® to perform the analysis. Results of the analysis, and information regarding the patients, examinations, and individual tests are easily accessible to the user for future reference.

Calculated stiffness scores correlate well with clinicians' ratings, and the rigidity is described as it changes with time, facilitating detection of drug effects. Preliminary investigations show that this device may also be applicable to measurement of spasticity; calculated stiffness scores agree better with clinicians' ratings than do those of the standard pendulum test.

Supported by the Alberta Paraplegic Foundation, the AHFMR, the Neuroscience Network, and the Canadian MRC.

## 488.9

## ABILITY TO PERFORM TWO MOTOR ACTS IS PRESERVED IN PROGRESSIVE SUPRANUCLEAR PALSY

K. Fujimoto\*, T. Kawakami, N. Ueno. Department of Neurology, Jichi Medical School, Minamikawachi-machi, Tochigi, 329-04, JAPAN

Progressive supranuclear palsy (PSP) is a sporadic neurodegenerative disorder characterized clinically by parkinsonism, supranuclear ophthalmoplegia, and dementia. In its earlier stages, PSP can be misdiagnosed as Parkinson's disease (PD). We tried to find a clinical sign to distinguish PSP from PD.

The subjects were 9 patients with PSP and 20 patients with idiopathic PD. All of them were clinically diagnosed under the consideration of neurological signs, imaging of the brain, and response to levodopa. Neurological symptoms of each patient were evaluated by modified united Parkinson's disease rating scale. Test battery consists of diadokokinesis and tapping of the hands. First, diadokokinesis and tapping were performed separately (single motor act). Second, diadokokinesis was performed in one hand and tapping was performed in the other hand (two motor acts). All movements were recorded by a video system. In some patients, finger tapping was recorded by a transducer and diadokokinesis was recorded by an X-Y recorder. The amplitude, frequency, and rhythm of the movement were evaluated.

Of these two groups, neurological symptoms were more strongly affected and ability of daily life was more limited in PD than PSP. The patients with rigidity in their wrist could not perform diadokokinesis well even in single motor act; 2 out of 9 with PSP and 4 out of 20 with PD could not perform it. Two motor acts were more difficult than single motor act. All 7 with PSP could perform two motor acts well also, while 15 out of 16 with PD failed to perform them. In their earlier stages, two motor acts seem to be one of a useful clinical sign to distinguish PSP from PD. The mechanism of the difference is difficult to explain. One possibility is a topographical difference of afferent dopaminergic neurons within the striatum between PSP and PD.

## 488.11

## LARYNGEAL ELECTROMYOGRAPHIC FINDINGS IN PARKINSON'S DISEASE C. Gracco\*, K.L. Marek, Walter Naito, Nancy Bryant. Depts Neurology, Surgery (ENT), Yale Univ/Haskins Laboratories, New Haven CT

The role of the intrinsic laryngeal musculature in voice production is well documented in normal human subjects. In particular, the thyroarytenoid (TA) and cricothyroid (CT) muscles are known to function in laryngeal adduction during modal phonation and pitch adjustment respectively. This investigation characterized laryngeal manifestations of Parkinson's Disease (PD) using complimentary instrumental techniques. Six subjects, 4 PD and 4 controls were evaluated. Simultaneous EMG recordings were made from TA and CT during speech and non speech maneuvers using hooked wire electrodes after the method by Hirano and Ohala (1970). Acoustic and aerodynamic measures were made in conjunction with EMG recordings from intrinsic laryngeal muscles to characterize vibratory cycles.

In patients with demonstrated vocal fold vibrational deficits, laryngeal EMG suggested the tendency for antagonistic co-contraction, reduced amplitude of vibration, and longer vibratory cycles in this population. In particular, the timing of activity in CT and Voc muscles differed for normal subjects and Parkinson's patients. Glottal closure and aperture for context based speech tasks showed reduction in activity of vocalis and increase in CT for voiceless tasks. The PD patients showed no depression of vocalis and a constant level of activity for CT. Further, these patients showed a premature increase in vocalis and CT activity which was sustained for longer periods during the consonant gesture. These findings support the notion that PD may affect the laryngeal musculature and the limbs similarly.

## 488.13

## HOW PARKINSONIANS POINT IN 3-DIMENSIONAL SPACE. Berkinblit, Michael, Fookson, Olga, Henning, Wayne\*, Poizner, Howard. Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102; Institute for Problems of Information Transmission, Russian Acad. of Sci., Moscow, Russia; Department of Neurology, Lyons Veterans Administration Medical Center, Lyons, NJ 07939

It is known that Parkinson's disease patients (PDPs) perform planar goal directed movements without visual control less accurately than healthy subjects. However it is not known whether PDPs are accurate in 3-dimensional space for unconstrained movements. We studied the accuracy and kinematics of pointing movements to memorized targets in three-dimensions for five PDPs (stage II and III) and five normal control subjects. Five target locations were presented in 3D space by a programmable robot arm. The subjects were required to memorize the target location, close their eyes, and point to the remembered location upon an auditory signal. Movements of multiple joints of the arm were recorded in three dimensions. Errors in azimuth, elevation, radial distance, and in absolute 3D distance of finger from target were measured as were kinematic parameters of the trajectories.

Although PDPs differed from controls in elevation, absolute 3D errors and did not differ significantly between the two groups. Likewise, peak velocities, velocity symmetry, and movement duration were not significantly different. Thus, under conditions of unconstrained, 3D pointing movements executed at a comfortable speed, PDPs were able to accurately control the final arm position in 3D space. PDPs thus appear to be able to plan one entire "ballistic" movement without vision of their moving arm or of the target.

## 488.10

MOVEMENT PREPARATION IN INITIATING GAIT IN PARKINSON'S DISEASE. E. Roy<sup>1,2</sup>, T. Sora<sup>1</sup>, J. Frank<sup>1</sup>, A. Patla<sup>1</sup>, J. Saint-Cyr<sup>1</sup>, A. Lang<sup>1</sup>. <sup>1</sup>Dept. of Kinesiology, University of Waterloo, Waterloo, Ontario and <sup>2</sup>Movement Disorders Clinic, Toronto Hospital, Toronto, Ontario

Reaction time in gait initiation was examined in patients with Parkinson's disease (PD, N=10) and in ten healthy elderly adults. The task involved a single step (SN) or a sequence of two steps (SEQ) initiated from a standing position to four targets placed on the floor directly ahead of the subject. The SN task involved two reaction time conditions, simple (SRT) and choice (CRT), in which the subject knew the stepping target in advance in the SRT but not the CRT condition. In the SEQ task the subject initiated one of three two step sequences in a CRT paradigm. Reaction time (the time to initiate the step), movement time (time from initiation to stepping on the target) and fractionated early and late components of reaction time, weight transfer to stepping leg (WT) and step initiation (SI), respectively, were the dependent variables. Analyses revealed no group differences in movement time, but the PD patients exhibited significantly longer reaction time. While the slowing in reaction time in the PD patients was of equal magnitude across tasks, slowing in the components of reaction time was not. The PD patients were slower in both components when initiating single movements but only in the late component when initiating movement sequences. These findings suggest that PD effects a general slowing in movement initiation but not movement execution. This slowing in movement initiation is unaffected by task complexity defined either by event uncertainty (SRT vs CRT tasks) or sequence length (SEQ tasks). Task demands, however, mediate the effects of PD on the components of reaction time.

## 488.12

IMPROVEMENT IN ACCURACY WITH PRACTICE: EFFECTS OF AGE AND PARKINSON'S DISEASE. W. A. Henning<sup>1,2,3</sup>, M. Roller<sup>1</sup>, and J. Gordon<sup>2,3</sup>. Neurology Depts., VAMC<sup>1</sup>, Lyons, NJ and UMDNJ-RWJohnson Med Sch<sup>2</sup>, New Brunswick, NJ; and Ctr for Neurobiology & Behavior<sup>3</sup>, Columbia Univ, NY, NY

We previously reported that practiced, but not unpracticed, Parkinsonian subjects show normal accuracy in a simple planar pointing task when deprived of task information (Neurosci Abstr 18:935; 20:1464). We have now examined performance in unpracticed normals (N=15), aged 20 to 79, and Parkinsonians (N=4), aged 63 to 71. Subjects made movements to match four randomized computer screen targets requiring 8 to 32 cm excursions of the draped arm over a digitizing tablet. In the No Information task, the subjects were shown a target which was blanked, together with a cursor indicating hand position, at a "Go" signal. No feedback about performance was provided. Subjects were studied in 2 sessions; the No Information task followed by trial blocks with task information. We analyzed accuracy and movement features (reaction time, movement duration, linearity), comparing the two sessions, subject age and normal vs. Parkinsonian performance. In the entire subject group, accuracy, but not movement features, improved with practice. Performance did not vary with age. Parkinsonian subjects were less accurate than normals in the first, but not the second, session. Their movement features were comparable to age matched controls. We conclude that all subjects, including Parkinsonians, can increase accuracy with practice when performing without task information, but show only modest changes in movement features. Parkinsonian subjects are less accurate only before practice. This research supported by the Dept. of Veterans Affairs Medical Research Council.

## 488.14

## VISUAL MOTION CUES AND PARADOXICAL MOVEMENTS IN PARKINSON'S DISEASE PATIENTS. M.J. Maisak, A.M. Gentile, J.R. Flanagan, and M.E. Boyd-Topolski\*. Teachers College, Columbia Univ., NYC, NY 10027 and Wheeling Jesuit College, Wheeling, WV 26003.

Individuals with Parkinson's disease (PD) frequently display bradykinesia (slowness in movement execution). However, paradoxical fast movements have been reported, sometimes anecdotally, when the environmental context provides visual cues of object- or self-motion (Purdon-Martin, 1967; Forssberg et al, 1984). Glickstein & Stein (1991) have described neural pathways that relay information about direction and velocity of rapidly moving targets from motion-detection cells in cortical visual areas to visual mossy fibers of the cerebellum via pontine projections. They proposed that PD patients can execute rapid movements when visual motion cues provide access to this cerebellar circuit. Thus, the intact cerebellar circuit permits an alternate mode of motor control less dependent on basal ganglia function. We tested these proposals in a task involving reaching to grasp a stationary or moving ball within a designated contact zone. The moving ball rolled down an inclined ramp (2.09m/sec) from left to right, in a plane parallel to the frontal plane of subjects at a distance equal to 80% of arm length. Six seated PD and 6 age/gender-matched, healthy subjects were tested under 4 conditions: (a) stationary ball at subject's preferred speed, (b) stationary ball at subject's maximum speed, (c) ball in motion, (d) retest of stationary/maximum speed. Kinematic analysis (2D) of hand trajectories showed that PD patients were slower than controls under all conditions. For PD patients ball motion produced faster movement times, higher peak velocities (PV), and faster time-to-PV than under stationary conditions. Indeed, these measures for PD patients approached those of controls under ball-motion conditions. Controls had sped up across testing conditions and showed carryover of speed set with retesting under stationary/maximum. In contrast, following tests with ball-motion, PD patients returned to prior levels observed under the stationary/maximum condition. These results offer support for Glickstein & Stein's proposals and implicate an alternative, cerebellar pathway for motor control in tasks involving visual motion cues.

## 488.15

A COMPARISON OF SENSORY PERCEPTION BETWEEN PATIENTS WITH PARKINSON'S DISEASE (PD) AND MATCHED CONTROLS. E. E. Jobst, M. E. Melnick\*, N. N. Byl, G. A. Dowling, M. J. Aminoff. Grad Program in Physical Therapy, UCSF/SFSU, San Francisco, CA, 94143.

The accurate interpretation of kinesthetic and proprioceptive information is critical to the control of voluntary movement. Recent evidence suggests that there is decreased sensation of the position and movement of the limbs and trunk in space in patients with PD. This may contribute to the motor disturbances. We compared sensory discrimination skills of patients with PD to age and gender-matched controls to further define the sensory disturbances. Ten subjects with PD and 10 age/gender-matched control subjects were tested on four subtests of the Sensory Integration and Praxis Test (SIPT): Finger Identification (FI), Graphesthesia (GRA), Localization of Tactile Stimuli (LTS) and Kinesthesia (KIN). Data were analyzed using paired t-test for ratio data and the paired Wilcoxon test for ordinal data. Patients with PD performed significantly worse ( $p_{KIN} = 0.0014$ ) on the test of kinesthesia than did the controls. There were no significant differences on the other tests. Thus, PD patients had no more difficulty than controls in identifying tactile input to the fingers, discriminating designs drawn on the hands or in making movements to a target located on the body surface. However, PD patients have significant difficulty in localizing a target outside the body, a task in which they must rely on the sensation of the movement itself (kinesthetic feedback). These results support the role of the basal ganglia in sensory processing and integration of sensory input into a motor task.

## DEGENERATIVE DISEASE: PARKINSON'S—MECHANISMS

## 489.1

NO-SYNTHASE AND NEURONAL VULNERABILITY IN PARKINSON'S DISEASE S. Hunot, B. Faucheux\*, F. Roissière, A. Mouat-Prigent, Y. Agid and E.C. Hirsch, INSERM U289, Salpêtrière hospital, 47 Bd de l'Hôpital, 75013 Paris, France.

Parkinson's disease is characterized by a loss of dopaminergic neurons in the substantia nigra. Yet, not all dopaminergic neurons of the mesencephalon degenerate during the disease. Indeed, the neuronal loss is severe in the substantia nigra pars compacta, intermediate in the ventral tegmental area and catecholaminergic cell group A8 and almost nil in the central grey substance. The mechanism of nerve cell death in Parkinson's disease is not known but oxidative stress may participate in the cascade of events leading to neuronal death. Because nitric oxide (NO) may be involved in the increased production of oxygen free radicals, we have analyzed the production mechanisms of NO in the mesencephalon of 3 patients with idiopathic Parkinson's disease and 3 matched control subjects.

Using histochemistry, we have analyzed the NADPH-diaphorase (NADPH-D) activity of NO-synthase (NOS), the enzyme involved in the synthesis of NO. NADPH-D activity has been detected in glial cells and neurons of the human mesencephalon. Using specific antibodies directed against the constitutive isoform of NOS and immunohistochemical techniques, we have evidenced that this isoform of NOS is solely present in neurons. By contrast, immunohistochemical analysis performed with an antibody against the inducible isoform of NOS solely revealed a glial staining. Quantitative analyses showed: 1) an increased density of NADPH-D positive glial cells in the dopaminergic regions characterized by a neuronal loss in Parkinson's disease, 2) an increased proportion of NADPH-D positive neurons among catecholaminergic neurons in the parkinsonian patients.

These data suggest a potential deleterious role of glial cells producing NO in Parkinson's disease on the one hand and the existence of subpopulations of dopaminergic neurons expressing NADPH-D which seem to be relatively preserved during the course of the disease on the other hand. The exact role of NO in this phenomenon remains to be analyzed.

## 489.3

APOPTOTIC DEGENERATION OF NIGRAL DOPAMINERGIC NEURONS IN PARKINSON'S DISEASE. P. Anglade, S. Vyas, F. Javoy-Agid, M. T. Herrero, P. P. Michel, J. Marquez, A. Mouat-Prigent, M. Ruberg, E. C. Hirsch\*, Y. Agid, INSERM U289, Hôpital de la Salpêtrière, Paris, France.

Parkinson's disease (PD) is a degenerative disorder of the central nervous system characterized by a selective and progressive loss of dopaminergic neurons in the substantia nigra. Oxidative stress and decreased activity of the complex I of the respiratory chain are probably involved in the process of degeneration. However, the mechanisms leading to neuronal death are still unknown. In this work, we searched to elucidate whether, in PD, dopaminergic neurons die by apoptosis (programmed cell death), already described during development and in experimental models of cell death. Nigral dopaminergic neurons were analyzed at the ultrastructural level in the substantia nigra of 3 PD patients and 3 control subjects. In PD patients, characteristics of apoptosis, such as chromatin condensation and cell shrinkage, were observed in 6 neurons on a total of 160 analyzed. Signs of autophagic degeneration were detected in 3 neurons, in only 1 patient. Neither apoptotic nor autophagic cell was observed in controls (90 cells examined). Factors known to intervene in programmed cell death, such as the apoptosis-preventing gene *bcl-2* in dopaminergic neurons and the cytokine  $TNF-\alpha$  in glial cells, were detected in the substantia nigra of PD patients. These results suggest that, in PD, dopaminergic neurons die through molecular mechanisms analogous to those described in programmed cell death.

## 488.16

WORKING MEMORY IN PATIENTS AT DIFFERENT STAGES OF PARKINSON'S DISEASE. J.L. Iddon<sup>1</sup>, A.M. Owen<sup>1</sup>, J.R. Hodges<sup>2</sup> & T.W. Robbins<sup>1</sup>\*. Departments of Experimental Psychology<sup>1</sup> and Neurology<sup>2</sup>, University of Cambridge, Downing Street, Cambridge, CB2 3EB, UK.

Groups of patients with Parkinson's disease (PD), either unmedicated and early in the course (n=8), medicated (mild) (n=7) or medicated (severe) (n=7), together with age- and IQ-matched control subjects (n=35) were tested on three analogous self ordered computerized searching tasks used to compare spatial, visual and verbal working memory.

In the spatial condition subjects were required to systematically search through a number of boxes presented on the screen to find 'tokens' whilst avoiding boxes in which a 'token' had previously been found. In the visual and verbal conditions, subjects were required to search in exactly the same manner, but through a number of abstract 'designs' and 'surnames', avoiding designs or names in which a token had previously been found without respect to their spatial location.

Results, (as analysed using MANOVA with between group effects tested using orthonormal contrast analysis) showed that the unmedicated PD patients were unimpaired on all three tests. Medicated (mild) PD patients were impaired only in terms of the number of returns to boxes in which a token had already been found ('between search' errors) on the spatial working memory task. However, the medicated (severe) patients had an impaired 'between search' errors score on all three tests of working memory. In addition on the test of visual working memory this group also made more returns to boxes previously unopened and shown to be empty ('within search' errors). The working memory deficits in patients with medicated Parkinson's disease could not be attributed to the inefficient use of a particular searching strategy in any of the three test conditions.

These results reveal (i) the progressive nature of the working memory impairment observed at different stages of Parkinson's disease. (ii) This impairment cannot be attributed to a deficit in the use of a strategy but (iii) can be contrasted with the lack of effect of frontal lesions on the visual and verbal memory tasks.

## 489.2

PATTERN OF CELL LOSS IN THE SUBSTANTIA NIGRA IN PARKINSON'S DISEASE P. Damier<sup>1,2</sup>, E.C. Hirsch<sup>2</sup>, Y. Agid<sup>2</sup> and A.M. Graybiel<sup>1</sup>. Dept. Brain & Cogn. Sci., MIT, Cambridge, MA 02139; <sup>2</sup>INSERM U289, Hôpital de la Salpêtrière, Paris, France.

To investigate the pattern of cell loss in the substantia nigra pars compacta (SNpc) in Parkinson's disease (PD), we developed a calbindin immunohistochemistry protocol. We showed that calbindin D<sub>28k</sub>-immunostaining is intense in the ventral midbrain and forms compartmental patterns with prominent bands and pockets of low staining where most of the dopaminergic neurons are densely packed. Moreover, these calbindin fibers survive in PD and thus can be used as landmarks both in control and parkinsonian midbrains.

Dopamine-containing neurons, identified by their tyrosine hydroxylase (TH) content, were mapped on regularly spaced sections (every 360  $\mu$ m) from three control and three parkinsonian midbrains, using an image analysis system (HistoRag, Biocom, France). Sets of adjacent sections were stained for calbindin immunoreactivity and were used to delineate the outlines of the calbindin-poor and -rich zones on the maps of TH-positive neurons. The outlines were added to each computerized chart of TH-positive neurons, and the number of TH-positive neurons in each subgroup defined by calbindin patterns was calculated. The total number of dopaminergic neurons per subgroup was obtained by integrating the number of neurons per section over the entire length of the SNpc. The percent cell loss in PD was calculated from these values.

The loss of dopaminergic neurons was significantly higher in calbindin-poor zones (92%) than in calbindin-rich areas (71%) ( $p < 0.02$ ). Moreover, analysis of the three-dimensional labyrinths formed by calbindin-poor zones allowed five calbindin-poor pockets to be defined. The cell loss appears to vary from one pocket to another: i.e. 97% in the main pocket, located in the caudal and medialateral part of SNpc, and only 56% in the rostral and medialateral pocket. This pattern of cell loss was consistent from one parkinsonian SNpc to another.

Compartmental patterns of calbindin immunohistochemistry allowed the loss of dopaminergic neurons to be defined with great accuracy in the SNpc and thus should permit investigations of the differences between nigral subgroups underlying the differential cell loss observed.

Supported by NIH Javits Award NS25529 and National Parkinson Foundation.

## 489.4

DIFFERENTIAL CELL DEATH IN MITOCHONDRIAL TRANSFORMED HUMAN NEUROBLASTOMA CELLS. J.P. Sheehan, J.B. Tuttle\*, P.A. Trimmer, R. Swerdlow, S. Miller, R.L. Davis, and W.D. Parker. Departments of Neurosurgery, Neuroscience, Urology, and Neurology, University of Virginia, Charlottesville, VA 22908 and Applied Genetics, San Diego, CA.

Significant evidence links Parkinson's disease and other neurodegenerative disorders to defects in mitochondrial DNA (mtDNA). However, the exact role, if any, of mtDNA in disease etiology is not yet defined. Starting with the human neuroblastoma cell line SY5Y, Rho<sup>0</sup> 118/5 cells (Applied Genetics, San Diego, CA) devoid of mtDNA were developed. Then, mtDNA from either control or Parkinson's patients' tissues was inserted into the Rho<sup>0</sup> 118/5 cells. Using these mtDNA transformed cells as an *in vitro* model, vulnerability to the mitochondrial complex I toxin 1-methyl-4-phenylpyridinium (MPP<sup>+</sup>) was examined. Both cell types were exposed to selected concentrations of MPP<sup>+</sup> for 24 and 48 hours and, subsequently, stained with bisbenzimidazole. The ratio of pyknotic to total nuclei was determined for each experimental condition, and the results are as follows:

MtDNA Type	Incubation Time	[MPP <sup>+</sup> ]	Ratio of Pyknotic:Total Nuclei
Parkinson's	24 hours	80 $\mu$ M	0.59
		40	0.13
		80	0.52
	48	40	0.80
		80	0.034
		40	0.018
Control	48	80	0.037
		40	0.43
		80	0.037

Cells with mtDNA from Parkinson's patients exhibited substantially increased cell death when exposed to MPP<sup>+</sup>. These data suggest that the mtDNA from Parkinson's patients confers a predilection for cell death when the cells containing such DNA are exposed to the neurotoxin MPP<sup>+</sup>.

## 489.5

**SOMATOSTATIN mRNA EXPRESSION IN PARKINSONIAN BASAL GANGLIA: A QUANTITATIVE IN SITU HYBRIDISATION STUDY**  
D.J. Eys, A.P. Nisbet, A. Kingsbury, C.D. Marsden and O.J.F. Foster\*  
United Kingdom Parkinson's Disease Society Brain Bank, 1 Wakefield Street, London WC1N 1PJ, UK

Levels of the neurotransmitter somatostatin (SS) have previously been shown to be reduced in the cortex and hippocampus of demented parkinsonian patients and patients with Alzheimer's disease. In the basal ganglia, SS has been demonstrated within striatal interneurons, colocalised with nitric oxide synthase (NOS) and neuropeptide Y, and in the medial medullary lamina of the globus pallidus (MML). *In situ* hybridisation histochemistry (ISHH) was used to examine SS mRNA expression within the striatum and MML in Parkinson's disease (PD) and in matched controls. ISHH was performed with a <sup>35</sup>S tail-labelled oligonucleotide DNA probe to human SS mRNA on 12µ coronal sections cryostat cut from flash-frozen human basal ganglia blocks (at approximately mamillary body level). Quantitation of SS mRNA expression from emulsion dipped sections revealed a significant increase of 82% in the MML of the globus pallidus in PD (56.5µ<sup>2</sup> of silver grain / cell, n=9 cases) compared to controls (26.3µ<sup>2</sup> / cell, n=13 cases, p<0.01, Student's *t*-test). No difference was detected in SS mRNA expression in putamen of PD cases (n=10) compared with controls (n=14). Upregulation of NOS mRNA has previously been demonstrated in MML neurons in PD cases and these results suggest that SS mRNA expression within MML cells is upregulated in parallel. Somatostatinergic neurons of the MML are thought to project to the striatum, and SS has been shown to enhance dopamine release in striatal slice preparations. The reported changes in MML SS mRNA expression in PD could therefore play a part in compensating for striatal dopamine depletion in this disorder.

## 489.7

**STRIATAL PROTEIN CONCENTRATION OF THE DOPAMINE TRANSPORTER IS MARKEDLY REDUCED IN IDIOPATHIC PARKINSON'S DISEASE.** S.J. Kish\*, A.I. Levey, O. Hornykiewicz and J.M. Wilson. Human Neurochemical Pathology Lab., Clarke Institute of Psychiatry, Toronto, Ontario and Department of Neurology, Emory University, Atlanta, Georgia.

We have recently developed a specific monoclonal antibody (McAb) directed to the N-terminus of the human dopamine (DA) transporter (hDAT) (Miller, et al., Soc. Neurosci. 1995). In order to determine whether hDAT McAb might be useful for the quantitative estimation of dopamine nerve terminal concentration in human brain disorders, we compared, in striata (caudate and putamen) of 12 patients with idiopathic Parkinson's disease (PD) and 10 matched controls, levels of DAT protein immunoreactivity (SDS-PAGE with rat hDAT McAb) vs. levels of three established markers of striatal DA nerve terminal integrity, namely, [<sup>3</sup>H]WIN 35,428 (WIN, 0.25-100nM) and [<sup>3</sup>H]dihydrotetrabenazine (TBZ, 0.25-30nM) binding and DA levels (HPLC). As compared with the controls, striatal concentrations of all four DAergic markers were markedly reduced in the PD patients, with DAT protein and DA levels being reduced similarly and to the greatest extent (see Fig). As expected, levels of the four DAergic markers were reduced to a greater extent in putamen vs. caudate.

Statistically significant (p<0.05) correlations were observed between striatal protein levels of DAT vs. WIN (r=0.46) and TBZ (r=0.43) binding. We conclude that blot immunolabelling analysis of hDAT protein in postmortem brain may provide a useful quantitative estimate of DA nerve terminal integrity in human disorders which involve DAergic systems. (Supported US NIDA DA 7182, DA 9484, NS 26034, NS 31937 and APDA).

## 489.9

**INTRASTRIALLY ADMINISTERED DOPAMINE, DOPA AND METHAMPHETAMINE: EVIDENCE OF NEUROTOXICITY.** T.G. Hastings\*, A.D. Rabinovic, M.J. Zigmond and D.A. Lewis. Neurology, Neuroscience and Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA

Dopamine (DA) neurons of the nigrostriatal pathway are selectively vulnerable to degeneration in Parkinson's disease. We have shown in vivo that intrastriatal DA resulted in a central region of nonspecific cytotoxicity surrounded by a region of selective decrease in tyrosine hydroxylase (TH) immunoreactivity. Toxicity was accompanied by DA oxidation as shown by the presence of protein-bound cysteinyl-DA and cysteinyl-DOPAC. The administration of exogenous antioxidants reduced the amount of cysteinyl-catechol formation and blocked the selective toxicity to DA terminals associated with exogenous DA exposure. The present study further explored the neurotoxic actions of DA by examining the time course of TH loss and by utilizing agents known to increase the availability of DA. DA (0.4 µmol), DOPA (0.4 µmol), and methamphetamine (MA; 1.0 µmol) were stereotactically injected into rat striatum. At 24 and 48 h following DA injections, TH labeled axons and terminals were enlarged and dystrophic. At later time points, the density of these dystrophic processes decreased in association with a general loss of TH immunoreactivity, suggesting the loss of DA terminals and not merely a decrease in TH immunoreactivity. At 7 d, intrastriatal injection of either DOPA or MA, like DA, resulted in nonspecific damage as indicated by staining for Nissl substance. However, unlike DA, neither DOPA nor MA showed a region of selective loss of TH immunoreactivity. These findings suggest that exogenous DA produces a degeneration of striatal DA axons, whereas exposure to agents that increase the availability of DA in vivo can cause generalized cytotoxicity. (Supported in part by USPHS grants NS19608 and AG05133.)

## 489.6

**ALTERED STRIATAL DOPAMINE TRANSPORTER IMMUNO-REACTIVITY IN PARKINSON'S DISEASE.** G.W. Miller, C.J. Heilman, J.T. Perez, J.K. Staley, D.C. Mash, D.B. Rye, A.I. Levey\* Department of Neurology, Emory University School of Medicine, Atlanta, GA 30322.

Ligand binding studies have demonstrated a selective loss of striatal dopamine transporter (DAT) in patients with Parkinson's disease (PD). Determination, however, of DAT protein expression in PD has awaited production of specific antibodies to DAT. In this study we describe the production and characterization of a highly specific rat monoclonal antibody to the N-terminus of human DAT (mDAT-Nt), and its use in Western blot analysis and immunocytochemistry. Homogenates of microdissected samples of caudate (Ca), putamen (Pu), and nucleus accumbens (NA), from control (n=3) and PD brains (n=6), were separated by SDS-PAGE, and analyzed by Western blotting and enhanced chemiluminescence (Amersham). DAT immunoreactivity was observed at high levels in Ca, Pu and NA of control brains, with marked reductions in Ca and Pu, and mild reductions in NA of PD brains. Immunocytochemistry performed on several of the same brains showed similar results. DAT immunoreactive fibers displayed puncta and were dense throughout the striatum of control brains, but were virtually non-existent in Pu in PD brains. Caudate showed modest densities of terminals, mostly along the border of the ventricle and appeared largely preserved in NA. Thus, the monoclonal antibody mDAT-Nt provides a novel means for characterizing DAT protein in PD and other disorders with improved sensitivity, specificity, and subcellular resolution, and also offers the potential for quantitation. Supported by APDA, DA9484 and NS31937.

## 489.8

**MODIFICATION OF PROTEIN FUNCTION BY DOPAMINE OXIDATION: EFFECT ON DOPAMINE TRANSPORT.** S.B. Berman\*, M.J. Zigmond and T.G. Hastings. Departments of Neuroscience and Neurology, University of Pittsburgh, Pittsburgh, PA 15260.

Dopamine (DA) can oxidize to form reactive oxygen species (ROS) and DA quinones, and we have previously shown that quinones formed from DA and its metabolite, dihydroxyphenylacetic acid (DOPAC) covalently bind to cysteinyl residues on proteins in striatum (Hastings and Zigmond, 1994; Hastings et al., 1994). It is possible that striatal proteins with a higher affinity for DA may be at greater risk for this modification. One such protein is the DA transporter, which contains cysteinyl residues that are critical to its function and which may be oxidized by O<sub>2</sub>, OH<sup>-</sup>, or quinones. In these studies, we tested whether DA transport in rat striatal synaptosomes could be modified by generators of ROS, including DA. We found that <sup>3</sup>H-DA uptake was reduced in the presence of ascorbate (0.85 mM), which can function as a prooxidant in the presence of iron, while the antioxidant, glutathione (1 mM), had no effect. This inhibition by ascorbate was prevented by DETAPAC (1 mM), an iron chelator. To examine this effect further, synaptosomes were preincubated under various oxidative conditions and washed, and then uptake of <sup>3</sup>H-DA (250 nM) was measured. Preincubation with ascorbate inhibited subsequent <sup>3</sup>H-DA uptake by 45%, and this effect was again prevented by DETAPAC. Xanthine (500 µM) + xanthine oxidase (50 mU/ml) reduced subsequent uptake of <sup>3</sup>H-DA by 80%. Preincubation with DA (100 µM) caused a 60% inhibition of subsequent <sup>3</sup>H-DA uptake, an inhibition attenuated by DETAPAC (1mM), which as an iron chelator prevents Fe-catalyzed oxidation of DA during the preincubation. These findings suggest that DA oxidation and ROS can modify DA transport function. Further experimentation is required to determine whether this transport inactivation might function to protect DA terminals or to act destructively by further promoting extracellular DA oxidation (Supported in part by USPHS grant NH19608).

## 489.10

**DOPAL: A POTENTIAL NEUROTOXIN FOR DOPAMINERGIC NEURONS IN PARKINSON'S DISEASE** M. B. Mattamall, H. D. Chung\*, J.H. Haring, S. Wulff, K.W. P. Yoon and R. Strong. Departments of Medicine, Neurology and Anatomy, St. Louis University and GRECC, VAMC, St. Louis, MO and Departments of Cellular and Structural Biology and Pharmacology, University of Texas Health Science Center and GRECC, Audie L. Murphy Memorial Veterans Hospital, San Antonio, TX, 78284.

It has been suggested that aberrant metabolism of dopamine plays a role in the pathogenesis of Parkinson's disease. The metabolism of dopamine by MAO-B liberates 3,4-dihydroxy-phenylacetaldehyde (DOPAL). We found that DOPAL is present in substantia nigra of individuals who had pathologically confirmed PD and is undetectable in SN of control cases. We hypothesized that DOPAL is a selective dopaminergic neurotoxin whose specific effects are mediated by the dopamine transporter. *In Vitro*, DOPAL selectively destroyed dopamine containing synaptosomes, while 5HT and glutamate containing synaptosomes were unaffected. The specific uptake of [<sup>3</sup>H]DOPAL in neostriatal synaptosomes was inhibited by mazindol, a specific dopamine uptake inhibitor. Moreover, exposure of cultured mesencephalic neurons to DOPAL caused a selective disappearance of TH-positive neurons. *In vivo*, DOPAL was delivered to the SN of rats. Immunocytochemistry and cell counts through the extent of the SN revealed that the number of TH-positive neurons in the SN receiving DOPAL injection was significantly reduced to 27 ± 4% of the control. GABA neurons in the SN were not affected. These data suggest that DOPAL is a selective dopaminergic neurotoxin that may have relevance to the neuronal degeneration observed in Parkinson's disease.

## 489.11

ISCHEMIC DAMAGE TO THE NIGROSTRIATAL TRACT: RELATIONSHIP TO INCREASED DOPAMINE RELEASE AND OXYGEN RADICAL GENERATION AND PROTECTION BY THE DOPAMINE AGONIST PRAMIPEXOLE. P.K.Andrus\*, T.J.Fleck, J.A.Oostveen, J.S.Althaus, G.J.Fici, P.F.VonVoigtlander and E.D.Hall. CNS Diseases Research, The Upjohn Company, Kalamazoo, MI 49007

We examined progressive retrograde degeneration of the dopaminergic nigrostriatal (NS) tract over 28 days in gerbils subjected to a 10-min period of forebrain ischemia. There was a 39% loss of NS cell bodies in the zona compacta (TH immunocytochemistry) over that time period. To explore the mechanism of this degeneration, we measured striatal levels of dopamine (DA) and DA metabolites (DOPAC, HVA, 3-MT) via HPLC-ECD and hydroxyl radical production ( $\bullet$ OH) via the salicylate trapping method during the first hr after reperfusion. DA levels did not change after reperfusion, but there was a significant increase in DOPAC (+537% at 5 min), 3-MT (+1300% at 1 min), and HVA (+185% at 5 min), indicative of an increased DA turnover. It is proposed that this post-reperfusion increase in striatal DA release/metabolism and the associated elevation in  $\bullet$ OH production (i.e., increased MAO activity) are responsible for oxidative damage to the NS dopaminergic nerve terminals and subsequent retrograde degeneration of the NS neurons. Pramipexole at 1 mg/kg was able to significantly reduce this increased dopamine turnover. Consistent with the acute attenuation of DA turnover, daily post-ischemic oral dosing (1 mg/kg p.o. BID beginning at 1 hr after insult) decreased 28-day post-ischemic loss of NS DA neurons by 36% ( $p < 0.01$  vs vehicle treated).

## 489.13

PROTECTION BY MANGANESE AGAINST FERROUS IRON-INDUCED NEUROTOXICITY IN THE BRAIN IN VIVO. I. Sziraki\*, P. Rauhala, D. L. Murphy & C. C. Chiueh. Unit on Neurotoxicology and Neuroprotection, Laboratory of Clinical Science, NIMH, NIH 10/3D41, Bethesda, MD 20892-1264.

It has been proposed that transition metals such as Fe and Mn can induce nigrostriatal degeneration through dopamine autooxidation and OH radical generation. However, ours and others' results indicate that Fe but not Mn can induce peroxidation of brain lipids. In fact, Mn inhibits peroxidation of brain lipids. Thus, we re-investigated the possible prooxidant and antioxidant roles of Fe and Mn in the brain in vivo.

Intrastriatal infusion of 4.2 nmol of Fe, but not Mn increased brain lipid peroxidation in the substantia nigra assayed by a fluorometric microassay procedure. Fe decreased striatal dopamine levels by 75%, while Mn caused no change. Mn completely blocked the Fe-induced lipid peroxidation and nigral injury as indicated by the absence of dopamine depletion in the nerve terminal region.

In summary, the present in vivo results demonstrated that manganese protects against oxidative injury of nigrostriatal neurons induced by ferrous iron complex. In conclusion, physiological levels of manganese may be a neuroprotective antioxidant in the brain.

## 489.15

PRELIMINARY CHARACTERIZATION OF  $\beta$ -CARBOLINE-2-N-METHYLTRANSFERASE FROM MAMMALIAN BRAIN. D.A. Gearhart\*, M.A. Collins and E.J. Neafsey. Neuroscience Program and Dept. of Biochemistry and Dept. of Anatomy, Loyola University Medical School, Maywood, IL 60153.

Brain  $\beta$ -carboline-2-N-methyltransferase ( $\beta$ C-2-NMT) catalyzes the S-adenosylmethionine (SAM)-dependent N-methylation of environmental  $\beta$ -carbolines ( $\beta$ Cs) to yield 2-N-methylated  $\beta$ -carbolinium ( $\beta$ MC<sup>+</sup>) derivatives which are structural analogs of 1-methyl-4-phenyl-pyridinium ion (MPP<sup>+</sup>). The activity of this enzyme leads to the formation of cationic products which may be trapped within the brain. Evaluation of  $\beta$ C-2-NMT is necessary since it generates potential neurotoxins that may play a role in idiopathic Parkinson's disease (Collins et al., *Brain Res.*, 1993). Our studies indicate that  $\beta$ C-2-NMT activity resides primarily in the cytosolic fraction of brain homogenates, but that nuclear activity is notable. As expected for SAM-dependent methyltransferases, the enzyme is inhibited by S-adenosylhomocysteine ( $K_i = 10 \mu$ M).  $\beta$ C-2-NMT activity in bovine brain cytosol exhibits a broad pH optimum ranging from pH 8-8.5 in potassium phosphate-bicine buffer. Apparent kinetic constants for  $\beta$ C-2-NMT with respect to SAM are:  $K_m = 137 \mu$ M and  $V_{max} = 100$  pmoles/mg protein/hr when 9-MeNH substrate is fixed at 540  $\mu$ M. Apparent kinetic constants for  $\beta$ C-2-NMT in regard to 9-MeNH are:  $K_m = 66 \mu$ M;  $V_{max} = 87$  pmoles/mg protein/hr with SAM fixed at 500  $\mu$ M. Preliminary characterization of  $\beta$ C-2-NMT is fundamental to assay optimization in preparation for enzyme purification as well as measurement of enzyme activity in normal and Parkinsonian brain. Research supported by NIH (NS23891).

## 489.12

S-NITROSO THIOLS: SNAP AND GSNO INHIBIT PER-OXIDATION OF BRAIN LIPIDS IN VIVO AND IN VITRO. P. Rauhala, I. Sziraki & C.C. Chiueh\*. Unit on Neurotoxicology & Neuroprotection, Laboratory of Clinical Science, NIMH, NIH, 10/3D-41, Bethesda, MD 20892-1264

We previously reported that sodium nitroprusside or nitroferricyanide (SNP) increases, while S-nitroso-N-acetylpenicillamine (SNAP) decreases  $\bullet$ OH formation induced by ferrous citrate iron-complexes. We compared further the effects of these two NO $\bullet$  donors as well as S-nitrosoglutathione (GSNO) on the peroxidation of rat brain lipids (assayed by a fluorometric microassay procedure) both in vivo and in vitro.

The present results demonstrated that SNP is a prooxidant while SNAP is antioxidant based upon their opposite effects on brain lipid peroxidation in the rat substantia nigra. Similar to SNAP, GSNO is a S-nitrosothiol compound and it also inhibited brain lipid peroxidation. However, SNP significantly increased brain lipid peroxidation since it is a nitroferricyanide complex leading to an increase in generation of  $\bullet$ OH (> 24 hr) and a brief release of NO $\bullet$  (<30 min). These effects of GSNO and SNAP but not SNP were blocked by light exposure.

In conclusion, S-nitrosothiols such as SNAP and GSNO, through the release of NO $\bullet$ , may protect brain neurons against oxidative injury caused by  $\bullet$ OH radicals. Furthermore, these results raise a new hypothesis that NO $\bullet$  and its S-nitrosothiol derivatives may be a new class of neuroprotective antioxidants.

## 489.14

SELECTIVE INDUCTION AND EXPRESSION OF HIPPOCAMPAL METALLOTHIONEIN ISOFORMS. M. Ebadi\* and M.P. Leuschen. Departments of Pharmacology and Cell Biology and Anatomy, Univ. Nebraska Coll. Med., 600 South 42nd Street, Omaha, NE 68198-6260.

Zinc induces the synthesis of metallothionein (MT) isoforms in hippocampal neurons in primary culture in a dose- and time-dependent manner. Moreover, the hippocampal MT becomes induced by agents causing oxidative stress, such as 6-hydroxydopamine (6-OHDA), and/or involved in inflammatory processes, such as interleukin-1. In addition, the *in situ* hybridization of <sup>35</sup>S-labeled cDNA showed that MT-1 mRNA is heavily localized in select areas of brain, including hippocampal formation. The induction of MT by zinc or neurotoxin is selective in that it occurs in some brain areas such as hippocampus, choroid plexus, and granular layer of cerebellum, but not in the caudate putamen.

The lack of induction of striatal MT by either zinc or 6-OHDA is of extreme clinical significance in Parkinson's disease and other movement disorders. In view of the fact that striatal tissue in patients with Parkinson's disease have a high concentration of iron (prooxidant) and a low concentration of ferritin (iron-binding protein which, in part, prevents the toxicity of excess iron), makes the striatum especially susceptible to oxidative stress. The evidence provided here suggests that the lack of induction of striatal metallothionein (antioxidant) by either zinc or 6-OHDA, along with high levels of iron, render the striatum especially susceptible to a high degree of oxidative stress. (Supported in part by a grant provided by USPHS NS 34566.)

## 489.16

ESTROGEN MAY PROTECT FEMALES FROM PARKINSON'S DISEASE. X.L. Chen, R. Li and M. Gupta\*. Dept. of Anat. Sci. & Neurobiology, U of Louisville Sch. of Med., Louisville, KY 40292, USA

Most studies have found that Parkinson's disease (PD) is more common in men than in women. Furthermore, striatal neurons have been shown physiologically to respond to direct applications of estrogen. In postnatal day 10 female rat, scattered striatal neurons have been shown to co-localize estrogen receptor mRNA and estrogen binding. Using the mouse Parkinsonian model, present studies were undertaken to determine if treatment of ovariectomized female mice with 17 $\beta$  estradiol, prior to MPTP treatment, would prevent MPTP-induced damage of the nigrostriatal system. Young adult female ovariectomized mice were treated with: (A) 17 $\beta$  estradiol (15  $\mu$ g/ mouse over 2d, s.c.), (B) vehicle, (C) 17 $\beta$  estradiol followed by MPTP, (D) vehicle followed by MPTP. Three days later, all the animals were sacrificed by decapitation to cause minimal stress. Brains were quickly removed. Striatum were dissected and frozen until neurochemical analysis to determine the levels of dopamine and its metabolites using LC/EC. Remaining brain pieces were immersed-fixed in 4% paraformaldehyde in 0.1M PO<sub>4</sub>. Frozen 40  $\mu$ m thick adjacent sections through the substantia nigra (SN) were stained immunocytochemically for tyrosine hydroxylase (TH) and the number of TH-positive neurons were quantitated. The data shows that treatment of ovariectomized mice with 17 $\beta$  estradiol, prior to MPTP, can reduce the MPTP-induced decrease in the number of dopaminergic neurons in the substantia nigra as well as dopamine levels in the striatum, thereby suggesting that estrogen may play a protective role in females against Parkinson's disease.

## 489.17

**RAT AND HUMAN LIVER ARE RICH SOURCES OF A NOVEL DOPAMINE RELEASING PROTEIN.** S. Kuhananthan\*, J. Hyson-Lee, C. Pullins, and V.D. Ramirez. Dept of Molecular and Integrative Physiology, Univ of Illinois, Urbana, IL.

A dopamine releasing protein (DARF) was first purified from rat adrenal gland and subsequently characterized as a multiunit glycoprotein of 200K. Monoclonal antibodies produced against this protein reduce brain dopamine levels when injected into newborn rats. These monoclonal antibodies immunostain specific areas in the rat adrenal and rat and human brain. DARF was also demonstrated to be present in human serum when tested on a direct ELISA assay. Interestingly, Parkinson's disease patients had higher concentrations of serum DARF when compared to age-matched controls. The first 36 N-terminal amino acids of DARF are already microsequenced and a synthetic peptide (DARF-36) is available.

We studied the concentrations of DARF in crude extracts of different rat tissues using a direct ELISA assay. Highest concentrations of DARF were found in liver and brain. Skeletal muscle did not contain significant amounts of DARF. Crude liver extract also competes with DARF-36 to bind anti-DARF in a competitive ELISA assay. Western blot analysis of crude liver extract (50 µg protein) under reducing and non reducing conditions reveal a strong band of 60K detected by anti-DARF. However, several other tissues including skeletal muscle did not elicit any immunostaining. Crude liver DARF was also biologically active in releasing dopamine from superfused rat corpus striatal fragments in a dose dependent manner. Human liver extract gives a strong ELISA response between 125-2000ng protein and also reveals the same 60K band in western blot analysis with monoclonal anti-DARF.

The above data suggests that liver could be the site of production of serum DARF.

## 489.19

**DOPAMINERGIC-INDUCED DYSKINESIA IN THE MPTP MONKEY MODEL IS ASSOCIATED WITH AN INCREASE IN ΔFosB IN THE STIATUM.** P.J. Bédard<sup>1</sup>, P.J. Blanchet<sup>1</sup>, J.-P. Doucet<sup>2</sup>, R. Grondin<sup>1</sup>, Y. Nakagawa<sup>3</sup>, M. Filion<sup>1</sup>, and G.S. Robertson<sup>1</sup>. Neurobiology Research Center, Laval Univ. 1401 18th St., Quebec City, Que, Canada G1J 1Z4, Dpt of Pharmacology, Univ. of Ottawa, Ottawa, Ont., Canada, K1H 8M5, and Dpt of Biochemistry<sup>3</sup>, Medical Institute of Bioregulation, Kyushu University 69, Fukuoka 812, Japan.

Dyskinesia is a frequent complication of treatment of Parkinson's disease with dopaminergic agents. Its appearance requires denervation and chronic DAergic treatment. Once established it is persistent, suggesting a learning phenomenon the nature of which has eluded us so far. We have previously shown, by Western Blot, using an antibody raised against the DNA binding region of Fos, that in rats, DA denervation by 6-OHDA is followed by a long-lasting increase in Fos-like immunoreactivity in striato-pallidal neurons and that it corresponds to a 38 kD Fos protein called ΔFosB. An even more important and persistent increase in ΔFosB is seen in striato-nigral neurons, in denervated rats treated chronically with a D<sub>1</sub> agonist. More recently, we examined the effects of chronic (one month) daily administration of D<sub>1</sub>-like and D<sub>2</sub>-like dopamine receptor agonists on striatal ΔFosB expression in the MPTP-primate model of Parkinson's disease. The animals were sacrificed four days after the last dose of DAergic agent. In monkeys rendered parkinsonian by MPTP, but left untreated, there was a modest increase of ΔFosB-like protein(s). Chronic administration of the D<sub>1</sub>-like agonist SKF-82958 by multiple daily injections, induced the development of dyskinesia and was accompanied by large increases of ΔFosB-like protein(s). Interestingly, the same total daily dose of the same D<sub>1</sub> agonist administered by minipump did not induce dyskinesia nor an increase in ΔFosB. In contrast, administration of the long acting D<sub>2</sub>-like agonist cabergoline which alleviated parkinsonian symptoms without producing dyskinesia reduced ΔFosB levels to near normal. Taken together, these results indicate that a persistent enhancement of ΔFosB-like protein(s) in striatopallidal and striatonigral neurons is associated with the development of parkinsonism and dyskinesia, respectively. ΔFosB-like protein(s) may therefore contribute to the development of these movement disorders by participating in gene signalling pathways activated by prolonged alterations in D<sub>1</sub>- and D<sub>2</sub>-like receptor stimulation. (Supported by the MRC of Canada).

## 489.18

**CHARACTERIZATION OF CATECHOLAMINE ABSORBING PROTEINS USING A NOVEL HIGH SPECIFIC ACTIVITY AFFINITY LIGAND.** R.K. Mishra<sup>1</sup>, B.E. McCarry<sup>2</sup>, V. Nair<sup>1</sup>, H. Niznik<sup>3</sup>, R.J. Riopelle<sup>4</sup> and G.M. Ross<sup>4</sup>. <sup>1</sup>Department of Biomed. Sci. and <sup>2</sup>Chemistry, McMaster Univ., Hamilton, Ontario, <sup>3</sup>Clark Inst. of Psychiatry, Toronto, Ontario and <sup>4</sup>Department of Medicine, Queen's Univ., Kingston, Ontario.

Catecholamine Absorbing Proteins (CATNAP's) are a family of CNS specific proteins which appear to play a role in oxidative processes within the brain. CATNAP's may represent a scavenging mechanism for highly reactive products of aberrant catecholamine metabolism which may arise from free radical mediated mechanisms. Such mechanisms have been implicated in the pathophysiology of several neurodegenerative diseases including Parkinsonism. We have synthesized a high specific activity CATNAP probe ([<sup>125</sup>I]-DATN) for pharmacological and biochemical characterization of these proteins, which had previously been identified using the ligand [<sup>3</sup>H]-N-propyl-norapomorphine (Ross et al., 1993, J. Mol. Neurosci. 4:3 141). The ligand [<sup>125</sup>I]-DATN labelled CATNAP proteins with the same tissue distribution, molecular weight distribution and pharmacological profile as the tritiated compound. Purification of these proteins was facilitated by the radioiodinated ligand, which has also allowed the generation of polyclonal antisera against purified CATNAP's. Antibodies specific to each of the various molecular weight CATNAP's have been used to characterize changes in expression of these proteins under a variety of pharmacological manipulations known to modulate free radical mediated mechanisms, including administration of MPTP and 6-OHDA.

Supported by MRC Canada.

**BEHAVIORAL AND BIOCHEMICAL EFFECTS OF CHRONIC TREATMENT WITH THE LONG-ACTING DOPAMINE D2 AGONIST CABERGOLINE IN PARKINSONIAN DRUG-NAIVE MONKEYS.** R. Grondin<sup>1</sup>, M. Goulet<sup>2</sup>, T. DiPaolo<sup>2</sup> and P.J. Bédard<sup>1</sup>. <sup>1</sup>Neurobiol. Res. Center, Enfant-Jésus Hosp., Laval University and <sup>2</sup>Dept. of Molecular Endocrinol., CHUL, Quebec, Canada.

Continuous dopaminergic stimulation is now considered as an interesting approach for the control of motor complications such as dyskinesias often seen in parkinsonian patients treated chronically with levodopa. There is some evidence that dopamine (DA) D1 receptors are more prone to tolerance than the DA D2 receptors under such continuous stimulation. A few clinical studies using cabergoline (CBG) which is a long-acting DA D2 receptor agonist have been completed so far with good results in parkinsonian patients who have been previously exposed to other drugs and in whom the current levodopa-therapy was maintained during the CBG treatment.

Therefore, the purpose of the present study was to test the effects of repeated s.c. administration of CBG at 0.25 mg/kg every 48h during a month in 3 drug-naive monkeys (*Macaca fascicularis*) rendered parkinsonian by MPTP to see whether or not CBG would have a sustained antiparkinsonian effect and would induce dyskinesias. The animals were rated to quantify the antiparkinsonian as well as the dyskinetic response and the motor activity was monitored by photocells. The locomotor response, initially greatly stimulated, decreased somewhat, but was thereafter maintained at a high level (more or less 5 times higher than control values). The parkinsonian features were improved in a sustained manner and transient dyskinesias were present in 2 monkeys. Receptor binding assays were then performed on striatal and pallidal tissues homogenates with tritiated selective antagonists and were compared with those of 3 healthy and 3 MPTP-exposed monkeys otherwise untreated. A decrease in striatal DA D2 receptor density (Bmax) and a reversal of the supersensitivity of GABA<sub>A</sub> receptors in the GPI were seen which may explain the behavioral effects mentioned above. Thus, continuous DA D2 receptor stimulation appears to be an interesting strategy of treatment especially in parkinsonian patients who are experiencing motor complications under levodopa-therapy. (Supported by Parkinson Foundation and MRC of Canada).

## DEGENERATIVE DISEASE: PARKINSON'S—PHARMACOLOGY

## 490.1

**CHARACTERIZATION OF AROMATIC L-AMINO ACID DECARBOXYLASE IN RAT STRIATUM.** M. Ahmed and U. J. Kang\*. Dept. of Neurology, Univ. of Chicago, Chicago, IL 60637.

L-Dihydroxyphenylalanine (L-DOPA) is the most effective treatment for Parkinson's Disease (PD). L-DOPA must be converted to dopamine by aromatic L-amino acid decarboxylase (AADC) to be effective, but the source of AADC in these patients and dopamine-depleted animal models are not known. The major source of AADC is terminals of dopaminergic neurons which are lost with dopaminergic lesions. This suggests that there are important sources of AADC outside dopaminergic neurons. Previous investigators have suggested intrinsic striatal neurons or striatal glial cells as the sources of AADC, but immunohistochemistry and *in situ* hybridization showed no evidence of AADC expressing cells (Kang et al., 1992). Recently, two different splicing variants of AADC messages have been found in neuronal and non-neuronal tissues (Hahn et al., 1993). Therefore, the present investigation attempted to examine the sources of AADC by characterizing the type of AADC mRNAs in the striatum. cDNA was synthesized from total RNA extracted from different areas of brain by using antisense primer specific to AADC axonal sequences common to neuronal and nonneuronal forms. The cDNA was amplified by Polymerase Chain reaction (PCR) using specific neuronal and nonneuronal primers respectively. Striatal tissue contained neuronal mRNA for AADC. Adrenal tissue and substantia nigra also contained exclusively neuronal RNA. In contrast, liver had only the nonneuronal mRNA of AADC. Our data suggest that intrinsic striatal neurons rather than glia may be the source of AADC that catalyze the conversion of L-DOPA to dopamine in the denervated striatum.

## 490.2

**L-DOPA IS CONVERTED TO DOPAMINE IN SEROTONERGIC TERMINALS IN THE RAT STRIATUM.** R. Arai\*, N. Karasawa, M. Geffard<sup>1</sup> and I. Nagatsu. Dept. of Anatomy, Fujita Health Univ. Sch. of Med. Toyoake, Aichi 470-11, Japan, <sup>1</sup>IDRPH and EPHE, 33400 Talence, France.

L-DOPA administration is the most effective drug treatment for the Parkinson's disease. The administered L-DOPA may be converted to dopamine by enzymatic decarboxylation and restore the dopamine depletion in the striatum. Serotonergic cell bodies in the raphe nuclei project their nerve terminals to the striatum. These serotonergic neurons contain aromatic L-amino acid decarboxylase. In the present study, we used a double immunofluorescence staining method and examined the possibility that a portion of the administered L-DOPA is converted to dopamine in serotonergic terminals of the striatum. After i.p. injection of L-DOPA into the rat, dopamine immunoreactivity was found in serotonergic cell bodies of the raphe nuclei and in their terminals of the striatum. This suggests that, in the striatum of parkinsonian patients, the serotonergic terminals are involved in the conversion of L-DOPA to dopamine.

## 490.3

**EFFECT OF CHRONIC LEVODOPA TREATMENT ON mRNA LEVELS OF D1 AND D2 DOPAMINE RECEPTORS IN THE BASAL GANGLIA OF MPTP-MONKEYS.** M. Morissette<sup>1</sup>, M. Goulet<sup>1</sup>, P.J. Blanchet<sup>1</sup>, P.J. Bédard<sup>1</sup>, and T. Di Paolo<sup>2</sup>. <sup>1</sup>Dept of Pharmacology, Faculty of Medicine, Laval Univ., Québec, G1K 7P4, and Neurobiology Res. Center, Enfant-Jésus Hospital; <sup>2</sup>Sch. of Pharmacy, Laval Univ., and Dept of Molecular Endocrinology, CHUL, Québec, G1V 4G2, CANADA.

The effect of levodopa on dopamine receptor gene expression in the basal ganglia of MPTP-monkeys was investigated using quantitative *in situ* hybridization. Seven ovariectomized female *macaca fascicularis* monkeys were rendered parkinsonian after subcutaneous administration of the toxin MPTP. Three MPTP-monkeys were treated with levodopa (100 mg) and the peripheral DOPA decarboxylase inhibitor Benserazide (25 mg) once daily for one month. Naive controls and untreated MPTP animals were also included in the experiment. Levodopa treatment produced very good motor recovery but caused progressive sensitization to treatment and, as expected, induced choreic dyskinesia. In MPTP-treated monkeys, a decrease of D1 receptor mRNAs was observed in the rostral part of the caudate and the putamen compared to control animals (-20% and -17% respectively). Chronic treatment of MPTP-monkeys with levodopa returned D1 receptors mRNA levels near to values for control monkeys. No such changes were observed in the more caudal parts of the striatum. A decrease of D1 receptor mRNA levels was observed in the olfactory tubercle (-21%) in MPTP-monkeys compared to control animals while no change was seen in the nucleus accumbens. An apparent increase in the levels of D2 receptor mRNAs was observed in the caudal part of the caudate and putamen (+24% and +23% respectively). Chronic levodopa treatment returned these levels to control values. No variation of D2 receptor mRNA levels was seen in the more rostral parts of the striatum. Our results show for the first time that levodopa can influence gene expression of D1 and D2 receptors in MPTP-monkeys. Supported by the MRC of Canada (to P.J.B.) and the Parkinson Foundation of Canada (to T.D.P. and P.J.B.).

## 490.5

**ASSESSMENT OF THE EFFECTS OF A D2-SPECIFIC DOPAMINE AGONIST (PRAMIPEXOLE) ON MOTOR BEHAVIOR OF PARKINSON'S DISEASE (PD) PATIENTS.** N.J. Greenberg\*, D.B. Willingham and J.P. Bennett. Dept. of Psychology, Univ. of Virginia, Charlottesville, VA 22903.

Treatment of Parkinson's Disease by drugs such as L-dihydroxyphenylalanine (L-DOPA) have helped alleviate bradykinesia and performance deficits in initiation and planning of motor movements. L-DOPA, however, affects both D1 or D2 receptor subtypes which restricts conclusions that can be drawn from these studies. The present study assessed the effects of a D2-specific agonist, Pramipexole. Comparisons of performance on motor tasks were designed to selectively investigate the effects of D2 on speed, planning, and execution of motor responses. Twelve patients in the early stages of PD participated in a drug trial with half randomly assigned to a placebo group and half to an active medication group. The study was double-blind. Dosage in the active group was ramped over the course of the study. Patients were tested on fifteen visits spanning three months on tests of tapping speed, simple (SRT) and choice (CRT) response time, and sequencing. Results indicate that the D2-specific agonist is effective in alleviating motor symptoms of PD, but its effectiveness varies by task.

## 490.7

**U-95666A. A POTENTIAL ANTI-PARKINSON DRUG.** V.H. Sethy\*, B.R. Ellerbrock and H.Wu. CNS Diseases Research, The Upjohn Company, Kalamazoo, MI 49001

U-95666A (U) is very selective for its binding to D<sub>2</sub> dopamine (DA) receptors. This compound has been investigated to determine its effect on striatal acetylcholine (ACh) and was compared with other DA agonists and antagonists. U, quinpirole, pergolide and bromocriptine significantly ( $p < 0.01$ ) increased, whereas haloperidol significantly ( $p < 0.01$ ) decreased striatal ACh levels. In rats with unilateral lesion of the substantia nigra (SN), U produced significantly ( $p < 0.02$ ) higher elevation in ACh on the lesioned side as compared to the intact side. Chronic treatment with U had no significant effects on U-induced increases in ACh either on the lesioned or intact striatum. U and diazepam decreased cerebellar cGMP and attenuated stress-induced elevation in this nucleotide. In conclusion, U is both a dopamine agonist and an anxiolytic, and would be useful for the treatment of Parkinson's disease.

## 490.4

**CHRONIC L-DOPA TREATMENT PREVENTS THE DERANGEMENT OF THE STRIATAL SYNAPTIC TERMINALS INDUCED BY 6-OHDA.** M.T. Pacheco-Cano, L. Colín-Barenque, M.R. Avila-Costa, V. Anaya-Martínez, J. Espinosa-Villanueva, E. Montiel-Flores, N. Manzano-León and F. García-Hernández\* Neuroscience, ENEP Iztacala UNAM, A.P. 314, Tlalneplan, México.

Unilateral lesioning of the nigrostriatal pathway with 6-hydroxydopamine (6-OHDA) produces a profound derangement of the striatal synaptic terminals. In the present study we analyzed the ultrastructural changes in the striatum of unilaterally 6-OHDA lesioned rats after chronic L-dopa treatment. Fourteen male Wistar rats were stereotactically injected with 8 µg of 6-OHDA into the left medial forebrain bundle. Control rats (n=10) received vehicle sham lesions. All 6-OHDA lesioned rats showed more than 200 turns/30 minutes when tested with 0.25 mg/kg of apomorphine. Also all rats were continuously tested in the narrow uphill beam test. The sham lesioned group received a daily oral dose of 0.9% NaCl for 30 days, the 6-OHDA lesioned rats were then divided into two groups, one of which remained untreated (n=5), while the second group (n=9) received a daily oral dose of L-dopa (50mg/kg) for 30 days. Rats were then sacrificed and the brain fragments obtained from the right (unlesion) and left (lesion) caudates were conventionally processed for electron microscopy. The ultrastructural analysis consisted of a) synaptic endings diameter, b) synaptic vesicles distribution and c) synaptic contact type. Our results confirm our previous observations about the dramatic derangement caused in the striatal synaptology by 6-OHDA, nevertheless in the 6-OHDA lesioned L-dopa treated group, almost all of the evaluated features remained not different from the values obtained from the sham lesioned group. The only difference between this to groups was a significant decrease of axospinous contacts made with the head of the spines. However, L-dopa treatment did not ameliorated the motor disturbances evaluated. These results indicate that L-dopa prevents the ultrastructural alterations that 6-OHDA produces.

SUPPORTED BY PAPIIT IN-203192 AND IN-205694 DGAPA, UNAM.

## 490.6

**IN SITU HYBRIDIZATION OF D1 AND D2 DOPAMINE RECEPTOR mRNAs IN THE CAUDATE-PUTAMEN OF MPTP MONKEYS: EFFECT OF CHRONIC TREATMENT WITH THE D2 AGONIST U91356A.** M. Goulet<sup>1</sup>, M. Morissette<sup>2</sup>, P.J. Blanchet<sup>2</sup>, P.J. Bédard<sup>2</sup> and T. Di Paolo<sup>1</sup>. <sup>1</sup>Sch. of Pharmacy, Laval Univ., and Dept of Molecular Endocrinology, CHUL, Québec, G1V 4G2, <sup>2</sup>Dept of Pharmacology, Faculty of Medicine, Laval Univ., Québec, G1K 7P4, and Neurobiology Res. Center, Enfant-Jésus Hospital, CANADA.

Quantitative *in situ* hybridization histochemistry (ISH) was used to analyze the effect of a chronic D2 receptor (D2R) agonist (U91356A) treatment on D1 and D2 dopamine receptor mRNAs. U91356A was administered to ovariectomized female *macaca fascicularis* MPTP-monkeys for 27 days using an intermittent (n=3) or continuous (n=3) schedule. Untreated MPTP as well as naive control animals were also studied. U91356A relieved parkinsonian symptoms and stimulated locomotion in all animals. Animals treated in a pulsatile mode with U91356A showed progressive sensitization and had dyskinesias whereas those receiving U91356A continuously developed behavioral tolerance and no dyskinesia. Density of D1 and D2 receptor mRNAs were examined by ISH using human-specific cRNA probes. Densitometric analysis of X-ray film demonstrated that in general D2R mRNA levels varied rostro-caudally with lower values in the posterior striatum. In addition higher D2R mRNA levels were observed in the lateral versus the medial caudate-putamen. D1 receptor mRNA in anterior caudate and putamen were lower in MPTP monkeys compared to control animals whereas D2R mRNA in the posterior striatum was increased. U91356A treatment whether continuous or pulsatile did not affect D1 receptor mRNA. Pulsatile administration of U91356A did not significantly decrease striatal D2R mRNA versus MPTP. Continuous administration of U91356A decreased D2R mRNA in the posterior striatum, more specifically in the putamen versus MPTP. These findings are consistent with our previous results on D1 and D2 receptor densities. The present results suggest that continuous but not intermittent administration of D2 agonist leads to a decrease of D2R expression in the putamen, that may be implicated in behavioral tolerance. Supported by the MRC, the Parkinson Foundation of Canada and the Upjohn Co., Kalamazoo, USA.

## 490.8

**D<sub>1</sub> DOPAMINE RECEPTOR ACTIVITY OF ANTI-PARKINSON DRUGS.** G.J. Fisi, H. Wu, P.F. VonVoigtlander\* and V.H. Sethy. CNS Diseases Research, Upjohn Laboratories, Kalamazoo, MI 49001.

Clinical and preclinical investigations suggest that stimulation of D<sub>1</sub> dopamine receptors may be responsible for dyskinesias induced by dopamine agonist treatment of Parkinson's Disease (PD) and that these dyskinesias may be decreased by treatment with a D<sub>1</sub> antagonist (clozapine). We have examined the effects of dopamine agonists and antagonists in a primary cerebellar granule cell model of cAMP formation that seems to be highly responsive and discerning for the D<sub>1</sub> receptors. A ~9-fold increase in cAMP was observed with the D<sub>1</sub> agonist SKF 38393 that was completely blocked by the D<sub>1</sub> antagonist SCH 23390 but there was no significant cAMP change with the D<sub>2</sub> agonist U-95666A. SKF 38393, lisuride, pergolide, dopamine, bromocriptine and 7-OH-DPAT showed concentration dependent increases in cAMP with EC<sub>50</sub> values of 0.013 µM, 0.053 µM, 1.04 µM, 2.18 µM, 50.9 µM and 54.4 µM, respectively. SKF 38393, dopamine and pergolide had similar intrinsic activity (100%) while the intrinsic activity of 7-OH-DPAT, bromocriptine and lisuride were 28.0%, 20.7% and 17.2%, respectively. The D<sub>2</sub> agonist U-95666A showed no significant effect (1-1000 µM), while the D<sub>1</sub> agonist pramipexole (0.1-100 µM) showed a slight but significant decrease in cAMP formation. Clozapine concentration dependently blocked pergolide-induced increases in cAMP and was ~1700-fold less potent than SCH 23390 (IC<sub>50</sub> values 0.97 µM and 0.56 nM, respectively). These data suggest that D<sub>1</sub>-induced cAMP formation may be predictive of dopamine agonist-induced dyskinesias in PD. We hypothesize that a D<sub>1</sub> or D<sub>2</sub> agonist with either low D<sub>1</sub> agonist activity or D<sub>1</sub> antagonist activity would be an effective anti-Parkinsons drug.

## 490.9

PHARMACOKINETICS OF THE FULL EFFICACY D<sub>1</sub> AGONIST DIHYDREXIDINE IN RATS AND MONKEYS. K.W. Locke\* Interneuron Pharmaceuticals Inc., Lexington, MA 02173.

The pharmacokinetic profile of dihydrexidine (DHX), a selective, full efficacy dopamine D<sub>1</sub> agonist undergoing clinical evaluation for the treatment of Parkinson's disease, was evaluated in rats and monkeys. In Sprague-Dawley rats administered a single 3.0 mg/kg 15 min iv infusion of <sup>14</sup>C-DHX, plasma radioactivity decreased in a biphasic manner, rapidly from maximal levels at 0 hr post-infusion and more slowly 3 hrs after the infusion. The elimination half-life of radioactivity from plasma was 6.8 hrs. Radioactivity distributed rapidly into all tissues, including brain, with significant concentrations observed 0 hr post-infusion. In general, clearance of radioactivity from tissues was greater than that from plasma. Radioactivity was excreted predominately by the urinary route, however, 18% of <sup>14</sup>C-DHX-derived radioactivity appeared to undergo biliary excretion. Plasma samples were collected on the last day from Cynomolgus monkeys administered 2.5, 7.5 or 15 mg/kg of DHX by 15 min iv infusion for 28 days. DHX was extracted from plasma using methyl-t-butyl ether and analyzed by HPLC-EC. DHX was rapidly eliminated from plasma by first order kinetics; the half-life of DHX ranged from 1.6 to 8.4 min. AUC values increased in proportion to the administered dose. As with other catechols, DHX appears to be rapidly metabolized by catechol-O-methyltransferase (COMT); this hypothesis is supported by mass spectrometry and by *in vivo* interaction experiments with COMT inhibitors. Pharmacodynamic studies demonstrate a much longer duration of action, than would be predicted from its relatively short plasma half-life.

## 490.11

CHRONIC ADMINISTRATION OF L-DEPRENYL INHIBITS MONOAMINE OXIDASE A ACTIVITY. D.A. Di Monte\*, J. Irwin, P. Chan, L.E. DeLanney and J.W. Langston. The Parkinson's Institute, Sunnyvale, CA 94089.

The monoamine oxidase (MAO) B inhibitor deprenyl has attracted considerable attention as an adjunctive drug and a possible neuroprotective agent in Parkinson's disease. The relationship between MAO B inhibition and the therapeutic action of deprenyl has been questioned, however, because (1) deprenyl possesses a number of additional properties which may contribute to its mechanism of action, and (2) the absence of MAO B within dopaminergic terminals does not support a major role of this enzyme in dopamine metabolism. The purpose of this study was to test the hypothesis that, since MAO A activity is expressed in dopaminergic terminals, chronic administration of deprenyl may also affect this enzyme. The action of deprenyl as a selective MAO B inhibitor was compared in C57BL/6 mice after a single injection and chronic treatment (three times per week for three consecutive weeks). Results of the study indicate that doses of deprenyl (1, 5 and 10 mg/kg) which cause selective inhibition of MAO B after a single injection also decrease MAO A activity when administered chronically. A slight but statistically significant increase in dopamine concentrations and a marked decrease in DOPAC levels were also measured in the striatum following chronic deprenyl administration, but not after a single injection of the drug. Thus, in the experimental conditions of this study, deprenyl loses its MAO B selectivity after repeated administration and, by acting as a MAO A inhibitor, affects striatal dopamine metabolism. These results support the view that MAO A plays a more relevant role than MAO B in striatal dopamine metabolism and raise the possibility that the delayed onset of symptomatic benefits after deprenyl treatment may be due, at least in part, to MAO A inhibition.

## 490.13

DEGENERATION OF DOPAMINERGIC NEURONS IN THE SUBSTANTIA NIGRA FOLLOWING HALOPERIDOL TREATMENT IN THE RAT.

S.M. Svedia, R.S. Bobba, E.T. Kiriakopoulos,

S. Garside, P. Rosebush, M. F. Mazurek\*. Neuropsychiatry Research Programme, McMaster University Medical Centre, Hamilton, Ontario. L8N 3Z5.

Chronic administration of the D<sub>2</sub> dopamine receptor antagonist haloperidol (HAL) is known to cause extrapyramidal side effects that may persist after the medication is withdrawn. In this study, we examined the effect of HAL on dopaminergic neurons of the substantia nigra (SN). Over 8 weeks, rats received daily intraperitoneal injections of either saline, low dose HAL (1mg/kg/day) or high dose HAL (10mg/kg/day). Two weeks after the final injection, the rats were sacrificed and the brains were immunostained for tyrosine hydroxylase (TH). There was a highly significant dose-dependent depletion of TH positive neurons in the SN of HAL treated rats (with a 32% reduction in the low HAL group and a 46% reduction in the high HAL animals). Also, there was a highly significant dose-dependent decrease in the density of TH neurons (19% reduction in low HAL, 31% in high HAL). These results indicate that HAL may be toxic to the dopaminergic neurons of the SN.

## 490.10

L-DEPRENYL DOES NOT AFFECT DOPAMINE DEPLETION WHEN ADMINISTERED AFTER MPTP. L.E. DeLanney\*, D.A. Di Monte, A.M. Janson<sup>1</sup>, P. Chan, J. Irwin and J.W. Langston. The Parkinson's Institute, Sunnyvale, CA 94089. <sup>1</sup>Dept. of Neuroscience, Karolinska Institute, S-171 77 Stockholm, Sweden.

Although it is known primarily as an inhibitor of monoamine oxidase (MAO) B, deprenyl possesses a number of additional properties which may contribute to its therapeutic effects in Parkinson's disease. In particular, it has recently been shown to rescue dopaminergic neurons from death caused by the parkinsonism-inducing neurotoxicant 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) without affecting the MAO-mediated MPTP metabolic activation. This rescue effect was demonstrated solely by counting neuronal cells in the substantia nigra of mice and has yet to be replicated by other research groups. Therefore, the levels of dopamine and dopamine metabolites were measured in this study as potential additional markers of the neuroprotective action of deprenyl in the same experimental conditions. C57BL/6 mice were first injected i.p. with 30 mg/kg/day MPTP for 5 consecutive days. Then, starting 72 hrs after the last MPTP injection, mice were treated with 10 mg/kg/day i.p. deprenyl three times per week for 3 consecutive weeks. Animals were killed and levels of dopamine and dopamine metabolites were measured in the striatum and ventral mesencephalon (v. m.). There were no differences between dopamine concentrations in the v. m. of mice treated with saline, deprenyl, MPTP or MPTP/deprenyl. In the striatum, dopamine levels were 20-30% higher in mice treated with deprenyl alone as compared with saline controls; MPTP alone decreased dopamine concentrations by 50% and dopamine values were 20-30% higher in the deprenyl/MPTP group as compared to the MPTP alone group. Thus, deprenyl did not affect MPTP-induced striatal dopamine depletion when values were expressed as per cent of the corresponding control groups. Neurochemical measurements do not reflect therefore the reported rescue effect of deprenyl on MPTP-induced neuronal death. Cell counting of dopaminergic neurons in the v. m. using an unbiased stereologic method is in progress.

## 490.12

INTRACRANIAL MICRODIALYSIS OF SALICYLIC ACID TO DETECT HYDROXYL RADICAL GENERATION IN THE RAT: EFFECT OF MONOAMINE OXIDASE INHIBITOR. T. Obata\*, and Y. Yamanaka. Department of Pharmacology, Oita Medical University, Hasama-machi, Oita 879-55, Japan

We examined the effect of pargyline, a monoamine oxidase inhibitor, on the generation of hydroxyl free radicals ( $\cdot\text{OH}$ ) using striatal microdialysis. The probe was washed with simple Ringer's solution for at least 30 min prior to stereotaxic implantation in the striatum and then the infusion was continued ( $1 \mu\text{l} \cdot \text{min}^{-1}$ ) for at least 60 min before switching to the experimental drug solution using liquid switch. The hydroxyl free radicals react with salicylate and generate 2,3- and 2,5-dihydroxybenzoic acid (DHBA) which can be measured electrochemically in picomole quantity by HPLC. When pargyline ( $100 \text{ nmole} \cdot \mu\text{l} \cdot \text{min}^{-1}$ ) was infused in rat brain, the level of 3,4-dihydroxyphenylacetic acid (DOPAC) gradually decreased in a time-dependent manner. In addition, a marked elevation of DHBA was observed. The present results indicate that accumulation of dopamine (DA) in the extracellular fluid elicited by pargyline can be auto-oxidized and in turn leads (possibly by an indirect mechanism) to the formation of cytotoxic  $\cdot\text{OH}$  free radicals.

## 490.14

SYMPTOMATIC EFFECTS OF N-METHYL-D-ASPARTATE (NMDA) RECEPTOR ANTAGONISM IN PARKINSON'S DISEASE. P.J. Blanchet\*, L. Verhagen-Metman, M.M. Mouradian and T.N. Chase. Experimental Therapeutics Branch, NINDS, Bethesda, MD 20892-1406.

Nigrostriatal dopaminergic cell loss in Parkinson's disease (PD) and oral levodopa (LD) replacement therapy alter the balance of excitatory amino acid transmission in the basal ganglia. Previous studies have shown that NMDA antagonists can potentiate the effects of LD in reserpinized rats (Klockgether and Turski, Ann Neurol 1990;28:539), 6-OHDA-lesioned rats (Engber et al., Neuro-Report 1994;5:2586) and MPTP-exposed monkeys (Wüllner et al., Neuropharmacology 1992;31:713; Greenamyre et al., 1994;35:655). We tested the hypothesis that NMDA antagonists might reduce motor response complications from LD with dextrophan hydrochloride (DX), a dextrorotatory morphinan (Hoffmann-La Roche Inc., Nutley, NJ), in a double-blind, placebo-controlled, dose-escalation design.

Two PD patients, chronically treated with LD and experiencing motor response complications and dyskinesias, first received incrementing i.v. infusions of DX as monotherapy for 6 hrs. Given alone, DX displayed no antiparkinsonian benefit and a deterioration in parkinsonian disability was documented in one patient in the higher dose range used. In combination with an optimal i.v. LD bolus dose, a well-tolerated DX infusion produced an apparent reduction in the intensity of LD-induced, peak-dose dyskinesia in both patients, but did not antagonize the LD antiparkinsonian response. Dose-limiting adverse effects occurred in both patients (dysarthria, inattention, dizziness, ataxia). These preliminary observations indirectly suggest that antiparkinsonian and dyskinesic effects of LD could be mediated by different mechanisms and that NMDA antagonists could be useful adjuncts for the treatment of LD-induced dyskinesias in PD. [Supported by a fellowship grant from The Parkinson Foundation of Canada to PJB]

## 490.15

**NEUROPROTECTIVE EFFECTS OF RILUZOLE ON A MODEL OF PARKINSON'S DISEASE IN THE RAT.** P. Barnéoud, M. Mazadier, J.-M. Miquet, S. Parmentier, P. Dubédat, A. Doble\* and A. Boireau, Rhône-Poulenc Rorer S.A., CRVA, Biology Department, 13 quai Jules Guesde, F-94403, Vitry-sur-Seine Cedex, France

The aim of the present study was to analyze whether riluzole, a compound that interacts with the voltage-dependent sodium channel and impairs glutamatergic transmission, would exhibit a neuroprotective activity in a model of Parkinson's disease in the rat. Impaired skilled forelimb use, circling behavior, and altered dopaminergic metabolism of the mesotelencephalic system were evaluated in unilaterally 6-hydroxy-dopamine-lesioned rats. Riluzole (2x5 mg/kg, i.p.) reduced (50%) both the contralateral rotations induced by apomorphine and the ipsilateral ones elicited by amphetamine. Moreover, the decreased dopaminergic metabolism seen after 6-hydroxy-dopamine injection was slightly attenuated in the riluzole-treated animals, both at the striatal and nigral levels. These biochemical and behavioral results demonstrate the ability of riluzole partially to protect the degeneration of the nigrostriatal dopaminergic neurons induced by the toxin 6-hydroxy-dopamine. Perhaps, the most telling evidence of the protection afforded by riluzole was that this compound improved the skilled paw use, a complex sensorimotor behavior which is not easily ameliorated by palliative therapies such as dopaminergic grafts. Noteworthy, riluzole protected the rats against the learning impairment of paw reaching induced by the unilateral 6-hydroxy-dopamine lesion. These results extend previous data showing that riluzole counteracts the toxicity induced by MPTP and MPP+ in rodent dopaminergic neurons. The use of riluzole may be considered of potential interest for the neuroprotective therapy of Parkinson's disease in humans.

## 490.17

**ANTIPARKINSONIAN EFFECTS OF THE NOVEL NMDA ANTAGONIST CP-101,606** Kathy Steece-Collier\*, Rodrigo Pazmino & J. Timothy Greenamyre Chicago Medical School & University of Rochester, Rochester, NY 14642.

After dopaminergic denervation of striatum, glutamate pathways from subthalamic nucleus to the basal ganglia output nuclei become overactive, and play a major role in the pathophysiology of Parkinson's disease. Therefore, pharmacological manipulation of the glutamatergic system may exert antiparkinsonian effects. In the current study, we examined the ability of CP-101,606 (CP), a selective antagonist of the NR2B subunit of the NMDA receptor, to produce antiparkinsonian effects in MPTP-treated rhesus monkeys with a longstanding, stable parkinsonian syndrome. One hour after injection of CP (1.0 mg/kg; s.c.), the parkinsonian clinical score decreased by 20% to a mean of  $7.91 \pm 0.54$ , compared to  $9.84 \pm 0.55$  after vehicle injection ( $p < 0.01$ ); the effect was still significant at 2 hours ( $p < 0.02$ ). Levodopa methylester (LD) alone (10 mg/kg) had a moderate antiparkinsonian effect at 1 hour, decreasing the score by 23% ( $p < 0.05$ ). The combination of CP (0.05 mg/kg) plus LD had a profound antiparkinsonian effect ( $5.54 \pm 0.43$ ) that was better than either vehicle (-44%;  $p < 0.0005$ ) or LD alone (-27%;  $p < 0.05$ ). At two hours, the effect of CP plus LD ( $5.86 \pm 0.62$ ) was still better than either vehicle (-47%;  $p < 0.0001$ ) or levodopa methylester (-33%;  $p < 0.002$ ). No side effects were seen. We conclude that CP alone has antiparkinsonian effects and that it enhances the therapeutic effects of LD. (Supported by Pfizer Inc., a Mallinckrodt Scholar Award, USPHS grant NS33779 and the National Parkinson Foundation Center of Excellence at the University of Rochester.)

## 490.16

**INTERACTIONS OF HU-211, A NOVEL NMDA ANTAGONIST WITH THE DOPAMINERGIC SYSTEM.** S. Striem, A. Bar-Joseph, Y. Berckovitch, V. Nadler\* and A. Biegon, Pharmos Corp., Kiryat Weizmann, Rehovot, 76326, Israel

HU-211 is a novel NMDA antagonist, devoid of the severe side effects characteristic of many other NMDA antagonists. In the present study, we examined its interaction with the dopaminergic system using *in vitro* and *in vivo* systems and comparing its activity to MK-801. Binding studies on forebrain membranes demonstrated that HU-211 (100  $\mu$ M) inhibited the binding of SCH 23390, a D<sub>1</sub> antagonist by  $51.8 \pm 6.3\%$ . HU-211 also enhanced the conversion of [<sup>3</sup>H] adenosine to cyclic AMP ( $51.8 \pm 29.7\%$ ). This increase was not reduced by SCH 23390. A synergistic effect ( $314.7 \pm 14.3\%$ ) was evident with a D<sub>1</sub> agonist. This effect is specific to the dopaminergic system. *In vivo* we examined the ability of HU-211 to reduce catalepsy induced by dopamine antagonists. BALB/c mice were treated with either HU-211 (10 mg/kg), or MK-801 (1 mg/kg), immediately after administration of either SCH 23390 (10 mg/kg), the D<sub>2</sub> antagonist clebopride (20 mg/kg) or the mixed D<sub>1</sub> and D<sub>2</sub> antagonist haloperidol (1 mg/kg). Catalepsy was then measured every hour for 6 hours. HU-211 significantly ( $p < 0.0001$ ) reduced the total catalepsy time induced by all dopamine antagonists in the present study. Catalepsy times were: SCH 23390;  $46 \pm 8$  for vehicle and  $11 \pm 4$  sec for HU-211, clebopride;  $58 \pm 8$  and  $22 \pm 7$  sec respectively and haloperidol;  $82 \pm 8$  and  $29 \pm 7$  sec. respectively. HU-211 reduced the dopamine antagonists-induced catalepsy in a similar manner to MK-801, but with no behavioural side effects. In conclusion, the present work describes the ability of HU-211 to inhibit the binding of D<sub>1</sub> receptor antagonist, to reduce catalepsy induced by D<sub>1</sub> and D<sub>2</sub> antagonists and to specifically cause an increase in dopamine receptor mediated CAMP production. This may have therapeutic implications in diseases involving disorders of the dopaminergic system, such as Parkinson disease.

## DEGENERATIVE DISEASE: PARKINSON'S—MPTP MODELS

## 491.1

**ACUTE EFFECT ON THE BASAL GANGLIA OF INTRACAROTID ADMINISTRATION OF 1-METHYL-4-PHENYL-1,2,3,6-TETRAHYDRO-PYRIDINE (MPTP) TO RHESUS MONKEYS** J.S. Forno\*, D. Nagy, J. Conway, M. Emborg, W. McLaughlin and K.S. Bankiewicz, Somatix Therapy Corporation, Alameda CA 94501 and #VA Medical Center, Palo Alto, CA 94304

Symptoms of Parkinson's disease are primarily related to the degeneration of the nigrostriatal dopaminergic system. MPTP administration to human and non-human primates produces selective dopaminergic neuron lesion in the nigrostriatal system and causes severe parkinsonian motor deficits. In this study we examined the acute cellular toxicity of high dose of MPTP.

Two rhesus monkeys were severely affected and died 3 days after unilateral intracarotid injection of 4 mg of MPTP-HCL. 40  $\mu$ m whole mount frozen sections were stained with hematoxylin-eosin and with antibodies to tyrosine hydroxylase (TH) and to glial acidic fibrillary protein (GFAP). There was grossly visible swelling of the neostriatum on the side of injection that correlates well with acute oedema seen on MRI. Reaction to the TH antibody was very weak in the putamen on the affected side, contrasting with the strong reaction on the uninjected which served as control. The caudate nucleus on the side of injection had only a mild reduction of staining for the TH antibody. There was no cell depletion in the substantia nigra seen on either side in these monkeys. Staining for GFAP was reduced, but mainly in the anterior putamen. The TH antibody reaction was mildly reduced in the substantia nigra. A puzzling finding was recent focal infarcts, one in each monkey, but located in the globus pallidus internus in one, and in the internal capsule and substantia nigra in the other. These lesions were interpreted as embolic infarcts, perhaps without direct relationship to MPTP or MPP+. The findings suggest that the acute effect of intracarotid administration of MPTP is complex and represents more than a simple degeneration of the dopaminergic terminals.

## 491.2

**THE DEVELOPMENT OF A NEW SQUIRREL MONKEY MODEL OF PARKINSON'S DISEASE.** S. L. Pinkston, L. De Lanney, M. Emborg\*, D. Nagy, J. W. Langston, I. Irwin, D. Kutzscher, F. Wu\* and K.S. Bankiewicz, The Parkinson's Institute, Sunnyvale, CA 94089 and #Somatix Therapy Corporation, Alameda, CA 94501.

The goal of this study was to develop a stable model of Parkinson's disease (PD) in squirrel monkeys. Unilateral intracarotid artery (ICA) infusion plus systemic administration of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) was carried out in 19 squirrel monkeys. Since MPTP toxicity is achieved by first pass ICA administration, the dose of MPTP-HCL was given per brain rather than per body weight: normal saline (n.s.) (n=1), 0.5 (n=2), 0.6 (n=3), 0.7 (n=12) and 1.0 (n=1) mg. 3 ICA infusion rates were tested: 1) 1.0 ml/min in 15 ml n.s., 2) 0.5 ml/min in 10 ml n.s., 3) 0.25 ml/min in 5 ml n.s. MRI brain scans showed lateral ventricle enlargement and hemorrhagic lesions in ipsilateral striata using rates 1 and 2 but no lesions using rate 3. The dose of 0.7 mg produced the most consistent signs of hemiparkinsonism (HPD) with some bilateral effects (e.g., bradykinesia). Additional systemic (s.c.) MPTP at 1-1.5 mg/kg produced progressive parkinsonian signs. L-dopa and apomorphine administration increased total body activity and contralateral turning dose-dependently. Histological, biochemical, and *in vivo* microdialysis examination of brains showed dose-dependent depletion of the dopaminergic system (DS). TH immunostaining revealed dramatic depletion of cells in the ipsilateral substantia nigra and fibers in the striatum with a mediolateral gradient of lesion contralaterally. Dopamine and dopa-decarboxylase measured in brain punches from striata was reduced 98% ipsilaterally and 50-80% contralaterally. Behavioral recovery was much less likely to occur using this technique than after systemic MPTP administration. The model appears to achieve a more stable level of DA depletion in the DS ipsilateral to the MPTP lesion characteristic of acute parkinsonism, while the contralateral partially lesioned side correlates with advanced parkinsonism. Therefore, this approach appears to be a more effective way to produce stable parkinsonism compared to systemic treatment alone. Because it also represents two models in one (partial lesion on one side and complete lesion on the other) this model should have many uses including the study of neurografting directed to DA replacement therapy on the ipsilateral side and/or trophic approach on the contralateral side.

## 491.3

REST TREMOR IN RHESUS MONKEYS WITH MPTP-INDUCED PARKINSONISM. M.E. Emborg, J.W. Tetrad\*, W.W. McLaughlin and K.S. Bankiewicz. Somatrix Therapy Corp., Alameda, CA 94501 and #The Parkinson's Institute, Sunnyvale, CA 94089.

Rest tremor is a characteristic feature of Parkinson's disease (PD) and can also be present in humans and monkeys with MPTP-induced parkinsonism. We quantified rest tremor in 3 rhesus monkeys who received an unilateral intracarotid artery (ICA) infusion of 2.5 mg MPTP-HCL followed by 2-4 doses i.v. of 0.3 mg/kg MPTP. The animals were trained to remain restrained in a primate chair for periods of 120 min. An angular rate sensor (26g) from a tremor monitor (Motus I, Motus Bioengineering, Benica, CA) was taped on the dorsum of each monkey's hand contralateral to the side of the ICA administration with the opposite arm restrained. The sampling time for each recording was 12 sec from which a frequency power spectrum was produced. Recordings began 45 min prior to and ended 45 min following administration of oral 25/250 mg carbidopa/levodopa (CD/LD). The mean peak of tremor frequency prior to CD/LD in the 3 animals was 7.9 Hz (SE:0.2) and following CD/LD, it was maintained (15min:8.1, SE:0.2; 30min:8.1, SE:0.3; 45min:7.8, SE:0.5), but there was a 75% reduction in tremor amplitude. We conclude that: (i) the mean rest tremor frequency in rhesus monkeys (7 to 8.5) is higher than in humans with PD (4 to 6 Hz), (ii) as in PD, tremor frequency in the monkey is maintained within a rather narrow band width, (iii) as in PD, the amplitude of rest tremor in the monkey is reduced by CD/LD, and (iv) the Motus I tremor monitor is a useful tool for objective characterization of tremor in the monkey and should provide objective assessment of tremor changes in experimental implantation of dopaminergic tissue, pallidotomy and thalamotomy.

## 491.5

STRIATAL SOMATOSENSORY ACTIVATION IN PRIMATES WITH OR WITHOUT PARKINSONIAN SIGNS. J.S. Schneider, L.L. Brown\*, D.S. Rothblat, D.M. Smith, M.G. Smith and T.I. Lidsky. Depts. of Anat. and Neurobiol. and Neurology, MCP and Hahnemann Univ., Phila., PA 19102; Depts. of Neurol. and Neurosci., Albert Einstein Coll. of Med., Bronx, NY 10461; Inst. for Basic Res., Staten Island, NY 10314.

Electrophysiological studies have suggested that parkinson-producing lesions alter the sensory responsiveness and response characteristics of striatal and pallidal neurons. Such a disruption of information processing may underlie some of the signs and symptoms of parkinsonism. To further examine sensory information processing in the primate striatum, and the influence of dopamine (DA) on the processing of this information, we performed [<sup>14</sup>C]-2-deoxyglucose autoradiographic mapping studies in M. fascicularis monkeys during somatosensory stimulation of the forearm. Two monkeys were intact, 2 were MPTP-treated and parkinsonian, and 1 was MPTP-treated and functionally recovered from parkinsonism. Forearm somatosensory stimuli caused 1) peak metabolic activation patterns consistent with known corticostriate projection patterns in many putamen regions in an intact animal, 2) a slightly greater area of activation in the recovered animal than in the intact animal, and 3) a remarkably widespread and metabolically greater activation pattern throughout the caudate and putamen in the parkinsonian monkey. Unlike other metabolic mapping studies of unstimulated MPTP-treated primates, the stimulated parkinsonian animal showed increased local cerebral glucose utilization in caudate and putamen that consisted of special, expanded patterns in comparison to a dopamine-intact animal and a DA depleted but asymptomatic animal. These results further emphasize and characterize the abnormal processing of somatosensory information in parkinsonian monkeys, and further emphasizes the DAergic regulation of the specificity and plasticity of afferent information processing in the striatum. Supported by MH 46531, NS 21356, and the F.M. Kirby Fdn.

## 491.7

DIFFERENCES IN STRIATAL DOPAMINE INNERVATION AND PREPROENKEPHALIN mRNA LEVELS IN MONKEYS WITH DIFFERENT DEGREES OF PARKINSONISM. L. DiStefano\*, C. Chang, A. Pope-Coleman and J.S. Schneider. Depts. of Anat. and Neurobiol. and Neurology, MCP and Hahnemann University, Philadelphia, PA 19102.

The nigrostriatal dopamine (DA) system in non-human primates appears to consist of several subsystems that display different degrees of vulnerability to MPTP and exert various effects upon peptide expression in different functional striatal territories. Most studies concerned with examining neurochemical changes associated with parkinsonism have concentrated on monkeys made acutely parkinsonian by MPTP and have provided no information concerning the relative contributions of different neurochemical systems in the striatum to cognitive or motor deficits of parkinsonism. In the present study, the DAergic innervation of the striatum (visualized by [<sup>3</sup>H]-mazindol autoradiography) and preproenkephalin (ENK) gene expression (visualized by *in situ* hybridization histochemistry) were examined in normal monkeys, MPTP-exposed parkinsonian monkeys (PD), and chronic low dose MPTP-exposed monkeys (CLD) with cognitive but no motor deficits. In PD monkeys, loss of striatal DA innervation was greatest in sensorimotor territories, and, in all striatal territories, exceeded the loss of DA innervation observed in CLD MPTP monkeys. In CLD MPTP monkeys, loss of striatal DA innervation was similar across functional striatal territories, although the loss was generally greater in dorsal vs. ventral regions. In PD monkeys, ENK mRNA expression increased dramatically, particularly in dorsal lateral putamen and caudate. Much smaller increases in ENK gene expression were observed in these areas in CLD MPTP monkeys. These data suggest that progression of parkinsonism from primarily a cognitive disorder to primarily a motor disorder is accompanied by increased regional loss of striatal DA innervation and regional increases in ENK gene expression, particularly in sensorimotor territories. Supported by grant MH-46531.

## 491.4

LONG-TERM COGNITIVE IMPAIRMENT IN MPTP-TREATED MONKEYS. J. Fernandez-Ruiz\*, D. Doudet and T. Aigner. Lab. of Neuropsychology, NIMH, NTH Bethesda, MD 20892-4415.

Administration of MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine) is known to induce a long-lasting Parkinson-like motor syndrome in monkeys. In addition, it has been shown that MPTP monkeys manifest cognitive deficits on tasks known to assess the fronto-striatal system; there are, however, no data regarding long-term cognitive effects. In this study, we examined the cognitive abilities of monkeys seven years after MPTP administration. Four MPTP-treated and four age-matched control male rhesus monkeys (*Macaca mulatta*) performed a delayed response spatial task under two different experimental conditions in a Wisconsin General Test Apparatus. In the first experiment each monkey started at 0-sec delay and had to achieve a criteria of 90% correct choices, after which 10 sec were added to the delay for the next 30-trial session. The experiment was concluded if the monkey could not reach the 90% criteria within 400 trials. For the second experiment, delays from 0 to 60 sec (in intervals of 10) were repeated four times each in a random manner during the daily session. The results of the first experiment showed a significant difference ( $p < 0.01$ ) between the maximum delay attained by the control group (37.5 sec) and that by the MPTP group (22.5 sec). In the second experiment, both groups performed equally well at 0-sec delay; with longer delays, the MPTP monkeys' performance declined leading to a statistically significant interaction between delay and drug ( $p < 0.05$ ). These results suggest that the MPTP-treated monkeys have a delay-sensitive spatial memory impairment that is apparent seven years after treatment. In this respect, the MPTP-treated primate displays spatial deficits similar to those observed in Parkinson's patients and thus may offer a useful model for evaluating novel therapeutic approaches to this disease.

QUANTITATIVE AUTORADIOGRAPHIC STUDY OF GM1 GANGLIOSIDE EFFECTS ON GABA<sub>A</sub> RECEPTORS IN AN EXPERIMENTAL MODEL OF PARKINSONISM IN MONKEYS. A. Pope-Coleman\* and J.S. Schneider. Depts. of Anat. and Neurobiol. and Neurology, MCP and Hahnemann University, Philadelphia, PA 19102.

GM1 ganglioside has been proposed as a possible therapeutic agent for the treatment of Parkinson's disease. Previous experiments have shown that GM1 treatment to monkeys can result in small but significant increases in striatal dopamine (DA) levels, increases in striatal DA transporter density, and a reversal of DA D1 receptor density upregulation. In view of the importance of dysfunction of GABAergic striatal projection neurons to the functional consequences of nigrostriatal DA denervation, the present study examined the effects of GM1 treatment on MPTP-induced changes in GABA-mediated neurotransmission. GABA<sub>A</sub> receptor density in striatum, pallidum, and substantia nigra was evaluated with [<sup>3</sup>H]-flunitrazepam (FLZ) binding to the benzodiazepine site of the GABA<sub>A</sub>/benzodiazepine receptor complex. In parkinsonian animals that received MPTP+saline treatments, there was a rostral-caudal gradient of decreased striatal [<sup>3</sup>H]-FLZ binding. The greatest decrease in [<sup>3</sup>H]-FLZ binding was observed in the substantia nigra (SN) and in the internal and external segments of the globus pallidus. Six weeks of GM1 treatment subsequent to the induction of parkinsonism by MPTP, resulted in a partial restoration of [<sup>3</sup>H]-FLZ binding in all regions sampled. In the striatum, GM1-induced increase of [<sup>3</sup>H]-FLZ binding was greatest at the caudal level. In the pallidum, GM1-induced increases in [<sup>3</sup>H]-FLZ binding were greater in the internal segment than the external segment. Restoration of SN [<sup>3</sup>H]-FLZ binding was of lesser magnitude than that observed in the pallidum. The present results suggest that GM1-induced functional recovery is accompanied by changes in the DAergic system that seem to normalize neurotransmission in striatal output circuits. Supported by the F.M. Kirby Foundation and Fidia Pharmaceutical Corp.

## 491.8

FACTORS AFFECTING STRIATAL DOPAMINE RELEASE IN NORMAL, SYMPTOMATIC AND RECOVERED MPTP-TREATED CATS. AN IN VIVO MICRODIALYSIS STUDY. Angeles Fernandez and J.S. Schneider\*. Depts. of Anat. and Neurobiol. and Neurology, MCP and Hahnemann University, Philadelphia, PA 19102.

MPTP administration to cats causes an initial parkinsonian condition that spontaneously recovers. These animals have more extensive striatal dopamine (DA) terminal loss dorsolaterally than ventromedially. Although extracellular fluid (ECF) levels of DA are significantly increased in recovered animals, the source of this DA and factors influencing its release remain in question. The present studies were conducted to further examine possible DAergic mechanisms contributing to functional recovery in MPTP-treated cats. Amphetamine (AMPH, 10μM), NMDA (1 mM), and KCl (60 mM) were locally infused into dorsolateral caudate (DL CD) or ventromedial caudate (VM CD) via microdialysis probes in normal, symptomatic, and recovered MPTP-treated cats, and effects on ECF DA and metabolite levels were examined. In normal animals, ECF DA levels increased significantly and similarly in response to all test compounds, with AMPH-induced release significantly outlasting the time course of NMDA or KCl-induced release. In symptomatic animals, AMPH, NMDA, and KCl-induced release was undetectable in both DL and VM CD. In animals functionally recovered from parkinsonism, DA release was observed in response to all compounds, but peak releases were significantly less than in normal animals. Peak AMPH-induced DA release greatly exceeded peak NMDA-induced DA release in both striatal regions sampled. The latency to release and clearance time for released DA was prolonged in recovered animals compared to normal animals. These results suggest that AMPH and NMDA may increase ECF DA levels through different mechanisms and that these mechanisms for DA release may be differentially affected during functional recovery from an extensive DA-depleting lesion. Supported by NIH grant NS 23980.

## 491.9

ALTERATIONS IN EXPRESSION OF DOPAMINE AND EXCITATORY AMINO ACID (EAA) RECEPTORS IN THE STRIATUM OF CATS SYMPTOMATIC FOR AND RECOVERED FROM MPTP-INDUCED PARKINSONISM. David S. Rothblatt\* and J.S. Schneider Depts. of Anat. and Neurobiol. and Neurology, MCP and Hahnemann University, Philadelphia, PA 19102.

Interactions between the two major sources of afferent input to the striatum, the dopaminergic input from the ventral mesencephalon and the glutamatergic input from the cerebral cortex and thalamus are not completely understood. Loss of striatal dopamine (DA) can have significant effects on behavior as well as the regulation of dopamine receptors. The present study was performed to examine the extent to which striatal DA loss affects expression of striatal D1 and D2 DA receptors and the levels of EAA receptors in the striatum of animals symptomatic for and spontaneously recovered from MPTP-induced parkinsonism. Striatal D1 receptor gene expression was upregulated in parkinsonian cats and further upregulated in recovered cats. Striatal D2 receptor gene expression did not differ from normal in either experimental condition.  $[^3H]$ -AMPA binding was decreased in the dorsal striatum and slightly less so in the ventral striatum in parkinsonian cats. There was no difference in striatal  $[^3H]$ -MK-801 binding (to NMDA receptors) between normal and parkinsonian cats. In cats recovered from parkinsonism,  $[^3H]$ -AMPA binding in the dorsal striatum partially recovered, while  $[^3H]$ -AMPA binding in the ventral striatum was similar to that observed in symptomatic animals.  $[^3H]$ -MK-801 binding in recovered cats did not differ from symptomatic or normal animals. These results suggest that changes in D1 receptor expression may be important for functional recovery and that striatal AMPA receptors, particularly in the dorsal or 'sensorimotor' striatum, may be more responsive to changes in DAergic tone and may better correlate with the functional status of the animal than NMDA receptors. Supported by NIH grant NS 23980.

## 491.11

SECOND MESSENGER MODULATION OF L-AROMATIC AMINO ACID DECARBOXYLASE AND TYROSINE HYDROXYLASE IN NORMAL AND MPTP-LESIONED MOUSE STRIATUM. E.A. Young\*, N.H. Neff and M.Hadjiconstantinou Departments of Pharmacology and Psychiatry and The Neuroscience Program, Ohio State University, Columbus OH 43210

Rapid and transient regulation of tyrosine hydroxylase (TH) activity by phosphorylation has been extensively studied, however, much less is known about regulation of L-aromatic amino acid decarboxylase (AADC) activity. We have previously demonstrated that AADC activity is transiently increased by activation of cyclic AMP and protein kinase C (PKC) dependent pathways in mouse striatum and midbrain (J. Neurochem. (1993) 60:2331-33 and (1994) 63:694-97). Under these same conditions of intracerebroventricular administration of forskolin or phorbol myristate acetate (PMA), TH activity increases transiently, presumably through phosphorylation. MPTP lesions have been shown to reduce both AADC and TH activities, but 2 weeks after the lesion, Northern blots reveal at least a 2-fold increase in both TH and AADC mRNA levels. The lesion also alters regulation of TH and AADC by cyclic AMP and PKC dependent pathways. Both TH and AADC are capable of further transient activation by forskolin. The increases are of greater magnitude and TH activity remains elevated longer. MPTP lesions abolish the response of AADC to PMA, and delays and abbreviates the response of TH. This work was supported in part by grants NS-34571 and MH-10629.

## 491.13

(+)-MK-801 DOES NOT PROTECT NIGRAL DOPAMINE NEURONS AGAINST MPTP-INDUCED LONG-TERM TOXICITY IN C57BL/6 MICE. J.W. Langston, A.M. Janson, D.A. Di Monte, W. Cao\* and P. Chan. The Parkinson's Inst., Sunnyvale, CA 94089; \*Dept of Neurosci., Karolinska Inst., Stockholm, Sweden.

Several studies have suggested that excitatory amino acids and activation of NMDA receptors may be involved in dopaminergic neurotoxicity caused by the neurotoxicant 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP), although other investigations reported contradictory results. The present study was designed to evaluate the effects of (+)-MK-801, an NMDA receptor antagonist, on MPTP neurotoxicity in the mouse substantia nigra. Six to 8 week old C57BL/6 mice were treated with a single dose of MPTP (40 mg/kg, s.c.). (+)-MK-801 (1 mg/kg, i.p.) was given to animals 30 min prior to the MPTP treatment and additional two injections were administered at 4 hr intervals following the first one. Levels of dopamine as well as the total number of dopamine neurons using an unbiased stereological cell counting method were determined at different time points after the exposure. In animals sacrificed one week after MPTP, (+)-MK-801 significantly prevented MPTP-induced decrease in levels of dopamine in the ventral mesencephalon (VME), and DOPAC and HVA in both VME and striatum. In contrast, there were no differences between the (+)-MK-801/MPTP and the MPTP-alone groups at three weeks. Although the total number of tyrosine hydroxylase positive neurons was slightly but not statistically significantly higher in (+)-MK-801 pretreated animals as compared to the MPTP-alone group at one week, their values were not different at three weeks. Furthermore, (+)-MK-801 did not affect the formation of MPP<sup>+</sup>, but it significantly delayed MPP<sup>+</sup> elimination from the VME. These data suggest that (+)-MK-801 does not have a long-term protection against MPTP-induced neurotoxicity in the mouse substantia nigra, although the possibility that excitatory amino acids are involved in MPTP toxicity cannot be ruled out.

## 491.10

CHANGE IN DOPAMINE TRANSPORTER (DAT) SITES AND mRNA LEVELS IN C57BL/6 MICE AFTER MPTP TREATMENT. A. Stadlin\*, P. Chan, H.L. Choi and L.A. Snider. Dept of Anatomy, Chinese Univ. Hong Kong. Shatin, N.T. Hong Kong and \*The Parkinson's Inst., Sunnyvale, CA 94089.

It has been shown that MPTP treatment results in the loss of dopaminergic neurons in the substantia nigra (SN) and a decrease in dopamine levels in the striatum of C57BL/6 mice. A significant recovery had been reported to occur after MPTP treatment in mice. The present study aims to determine the effects of MPTP on DAT and its relation to the recovery. 6-8 weeks old C57BL/6 mice were treated with a single injection of either MPTP (40mg/kg, s.c.) or saline and sacrificed at 1hr, 4hr, 1, 3 and 7 days after treatment. The striatal DAT binding sites were measured by Scatchard analysis using  $[^3H]$ WIN35,428 as a ligand. The DAT mRNA levels were determined in the SN by isolating poly(A)<sup>+</sup> total mRNA from the same animals used for DAT binding study and hybridized with a 496 bp DAT probe. Results showed that there was a very rapid increase in the no. of DAT during the first 4 hours after MPTP treatment. This was followed by a gradual decrease reaching a maximum of 54% decrease of DAT sites by day 3. At day 7, the no. of DAT sites had significantly recovered to only 26% less as compared to the control. The  $K_d$  for DAT was 1 fold higher in the MPTP-treated mice (control  $K_d = 19.19$ nM; MPTP-treated  $K_d = 42.19$ nM). Northern blot analysis revealed that there was a maximum decrease of 80% in the level of mRNA in day 3 MPTP-treated mice. However, the mRNA level had returned to normal value by day 7 when a marked decrease in striatal DA content was found. It can be concluded that MPTP treatment resulted in a maximum loss of DAT sites and mRNA levels at day 3 after MPTP exposure. However, a compensatory mechanism exists whereby the remaining neurons increase in DAT binding affinity and upregulate mRNA, which may contribute to the significant post-treatment recovery.

## 491.12

MPP<sup>+</sup> AND AN ENDOGENOUSLY FORMED ANALOG, N-METHYLATED  $\beta$ -CARBOLINUM, INHIBIT IN VIVO ACTIVITIES OF STRIATAL TYROSINE HYDROXYLASE AND MONOAMINE OXIDASE. K. Matsubara\*, T. Idzu, Y. Kobayashi, D. Nakahara\*, W. Maruyama\*, K. Kimura and M. Nao\*. Section of Neuroscience & Sense Organs, Shimane Med. Univ. Izumo 693, \*Dept. of Psychology, Hamamatsu Univ. Sch. of Med., and \*Dept. of Biosciences, NIT, Nagoya 466, Japan.

Intracerebral microdialysis in freely moving rats was used to compare the neurotoxic effects of 2,9-dimethylnorharmanium (2,9-Me2NH<sup>+</sup>) with those of MPP<sup>+</sup> in the striatum. Perfusion with either 2,9-Me2NH<sup>+</sup> or MPP<sup>+</sup> evoked a marked increase of dopamine (DA) and decreases of its acidic metabolites in the dialysate, even at low doses ( $\leq 0.1$  mM). The effects of both compounds ( $\leq 0.1$  mM) on 5-HT and 5-HIAA efflux were negligible. However, the 5-HT system was affected by perfusion with 1 mM of both compounds. As an index of the in situ activity of tyrosine hydroxylase (TH), the rat striatum was also perfused with NSD-1015, and extracellular DOPA levels were measured. MPP<sup>+</sup> irreversibly inhibited in situ TH activities almost completely, even at a dose as low as 0.05 mM. On the contrary, 1 mM 2,9-Me2NH<sup>+</sup> reduced TH activities to 10% of the basal level only during its perfusion. Although the modes of TH inhibition were different, these results suggested that both 2,9-Me2NH<sup>+</sup> and MPP<sup>+</sup> were selectively taken up into the dopaminergic nerve terminal, where these cations eventually inhibited DA synthesis by TH and metabolism by monoamine oxidase.

## 491.14

EVALUATION OF METALLOTHIONEIN INDUCERS AFTER MPTP. P. Rojas, C. Rios and R. Barroso\*. Dept. of Neurochemistry, Instituto Nacional de Neurología y Neurocirugía, México city, 14269.

MPTP induces selective damage in brain dopaminergic neurons and produces parkinsonian syndrome in human. In the present study the possible antiparkinsonian activity of metallothionein (MT) inducers was assessed in the MPTP model. Adult male swiss albino mice were injected with cadmium (Cd, 1 mg/Kg, i.p.) or dexamethasone (Dex, 5 mg/Kg, i.p.) and 5 hrs. later with MPTP (30 mg/Kg, i.p.) daily for 3 or 5 days. 7 days after the last MPTP injection all animals were sacrificed by decapitation, their brains were removed rapidly, and their striata were dissected out. Striatal dopamine concentrations were obtained by HPLC - electrochemical analysis. We found significant increases in striatal dopamine content as follows: MPTP (3 days) + Cd (38%); MPTP (3 days) + Dex, (28%); MPTP (5 days) + Cd, (48%) and MPTP (5 days) + Dex, (43%) versus animals - treated with MPTP alone. Results indicate that MT induction can protect against MPTP -induced neurotoxicity.

## 491.15

IN VITRO AND IN VIVO PREVENTION OF MPTP INDUCED NEUROTOXICITY BY A SYNTHETIC SUPEROXIDE SCAVENGER, EUK-134 C. Fonck\*, B. Malfroy\* and M. Baudry. Neurobiology Program, University of Southern California, Los Angeles, CA 90089-2520 and \* Eukarion Inc., Bedford, MA 01230.

Selective damage to neurons in the nigrostriatal pathway by 1-methyl 4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) has been proposed as a model to study Parkinson's disease. It has been suggested that MPTP's deleterious effects result from free radical production due to oxidation of MPTP to MPP<sup>+</sup> in the brain. The present study tested the ability of EUK-134, a synthetic free radical scavenger, to prevent striatal tissue damage produced by MPTP. In vitro experiments consisted in incubating mice striatal slices with MPTP (2 mM) and evaluating the extent of damage to dopaminergic terminals by measuring <sup>3</sup>H-dopamine uptake. Incubation with MPTP resulted in a large decrease in <sup>3</sup>H-dopamine uptake (> 80%) which was markedly reduced by a synthetic catalytic scavenger of free radicals, the salen-manganese complex EUK-134 (50 uM). Adult mice were injected twice subcutaneously with MPTP (40 mg/kg) and the extent of damage was assessed 7 days later by measuring <sup>3</sup>H-mazindol binding to striatal membranes. This regimen resulted in a 70% decrease in <sup>3</sup>H-mazindol binding. Chronic treatment with EUK-134 dissolved in drinking water starting two days before MPTP injection and lasting for the duration of the survival period produced a significant inhibition of the MPTP-induced decrease in <sup>3</sup>H-mazindol binding. These results confirm the involvement of free radicals in MPTP-mediated toxicity and show the potential useful therapeutic applications of salen-manganese complexes.

## 491.17

INHIBITORS OF NO SYNTHASE (NOS) AND POLY (ADP-RIBOSE) SYNTHASE (PARS) DO NOT BLOCK TOXIC ACTIONS OF 8-CARBOLINIUM CATIONS OR MPP<sup>+</sup> IN MESENCEPHALIC CULTURES. M.A. Collins, L. Slobodnik and E.J. Neafsey. Dept. of Biochem. and Dept. of Anatomy, Loyola Univ. Medical School, Maywood IL 60153.

Human brain contains N-methylated 8-carbolinium (MBC<sup>+</sup>) cations that structurally resemble the nigrostriatal toxin, MPP<sup>+</sup>. MBC<sup>+</sup> formation via enzymic N-methylation of environmental 8-carbolines (BCs) such as norharman (Nh) may occur in Parkinson's disease. Like MPP<sup>+</sup>, nigral injections of MBC<sup>+</sup>s damage nigrostriatal cells in rats, but MBC<sup>+</sup>s are less selective and potent in terms of dopamine (DA) neurons (Brain Res. 675: 279, 1995). Neurotoxic potencies toward DA and GABA neurons have been examined in G-15 fetal rat mesencephalic cells (6-d cultures). Exposure 2 d to MPP<sup>+</sup>, 2,9-dimethyl-Nh (2,9-dMNH<sup>+</sup>), 2-methyl-harmaline (2-MH1<sup>+</sup>) or 2-methyl-harmine (2-MH<sup>+</sup>) was followed with DA & GABA uptake and tyrosine H<sub>2</sub>Oase (TH) immunohistochemistry (uM IC<sub>50</sub>'s below).

Cation	IC <sub>50</sub> (DA uptake loss)	IC <sub>50</sub> (GABA uptake loss)
MPP <sup>+</sup>	0.4	~100
2,9-dMNH <sup>+</sup>	8.6	12.3
2-MH1 <sup>+</sup>	9.4	15.2
2-MH <sup>+</sup>	37.1	100

Toxicities of MPP<sup>+</sup>, 2,9-dMNH<sup>+</sup> and 2-MH1<sup>+</sup> were unaffected by nitroarginine methyl ester (30-100uM) or 7-nitroindazole (3-100uM)--inhibitors of NOS--or 1,5-dihydroxyisoquinoline (3-30uM), a potent inhibitor of PARS, indicating that NOS (NO production) and PARS do not mediate the mechanisms of MPP<sup>+</sup> or the MBC<sup>+</sup> analogs. TH assays indicate that DA uptake blocker GBR12909 inhibits most of MPP<sup>+</sup>'s toxicity, but less than 50% of the toxicity of 2,9-dMNH<sup>+</sup> and none of 2-MH1<sup>+</sup>. Other active uptake routes and and passive uptake may function for MBC<sup>+</sup>s, but these could be circumvented *in vivo* by BC N-methylation within DA neurons. Supported by NIH.

## 491.16

SEVERE REDUCTION OF DOPAMINE (DA) FORMATION AFTER CARBIDOPA/L-DOPA (CD/LD) ADMINISTRATION IN MPTP-TREATED MONKEYS. W.W. McLaughlin\*, M.E. Emborg, F.F. Wu, J. Irwin\* and K.S. Bankiewicz. Somatix Therapy Corp., Alameda, CA 94501, \*The Parkinson's Institute, Sunnyvale, CA 94089.

Unilateral intracarotid (ICA), plus systemic administration of MPTP reduces nigrostriatal DA levels in the ipsilateral (98%) and contralateral (50-80%) side, while inducing severe signs of Parkinson's disease (PD) that are stable over time. In order to examine the behavioral and biochemical effects of p.o. CD/LD, 5 rhesus monkeys were treated with ICA (2.5-4.0 mg) followed by 2-4 i.v. doses (0.3 mg/kg) of MPTP and studied for 8-20 months after ICA infusion. Four monkeys were given a single dose of CD/LD (10/100-35/350 mg) and 1 monkey was kept on chronic treatment of 25/250 mg. Clinical responses were recorded, animals were sacrificed 40 min after the last dose of CD/LD and their brains were removed. Tissue punches were obtained bilaterally from dorsal and ventral caudate nucleus (CN) and putamen (PUT), nucleus accumbens (NA) and temporal (TC) and occipital (OC) cortices, and were processed for LD, DA, homovanillic acid (HVA) and dopamine decarboxylase (DDC). Tyrosine hydroxylase immunostaining (TH-IR) was performed in adjacent blocks. Monkeys showed poor behavioral response to CD/LD while chronic animal (more severely affected) only responded to apomorphine administration (0.1 mg/kg, im). LD levels in acute monkeys were 4-12 ng/mg and in chronic one were between 25-60 ng/mg, in all the regions for both sides. DA levels on the ipsilateral side for acute, and on both sides for chronic animal, were below 3 ng/mg in all regions with the exception of NA where DA levels were significantly higher. DDC activity was depleted following the pattern of DA levels. The elevated levels of LD, low levels of DA and decreased DDC activity in CN/PUT indicate reduced decarboxylation of LD to DA. It further indicates that most DDC activity is present in nigrostriatal DA fibers and is related to high DA in NA where a partial lesion was observed on TH-IR. These findings may help to explain the low efficacy of LD treatment in advanced PD patients and validate this model for dopamine-replacement therapy using neurografting and gene therapy.

## TUESDAY PM

## SYMPOSIA

## 492

SYMPOSIUM. SENSORY CIRCUMVENTRICULAR ORGANS: BODY-BRAIN COUPLING AND MECHANISMS OF AFFERENT SIGNALING. A.K. Johnson, Univ. of Iowa (Chairperson); W.F. Ganong, Univ. of California, San Francisco; R.R. Miselis, Univ. of Pennsylvania; R. Gerstberger, MPI-W.G. Kerckhoff Institut; P.E. Sawchenko, The Salk Institute.

Circumventricular organs (CVOs) are small midline structures bordering the ventricles of the brain. They have common morphological features that distinguish them from the rest of the nervous system. In particular, they lack a blood-brain barrier. Early work on the 7 or 8 structures considered as CVOs in mammals focused on neurosecretory capacities. However, a neuroendocrine role for some CVOs has been difficult to establish. This is especially true for the subfornical organ, organum vasculosum of the lamina terminalis, and the area postrema. For these 3 structures, more recent results indicate that they function in a sensory mode to detect blood-borne factors. Detection of circulating signals by sensory CVOs has important functional implications for many physiological processes that include those involved in maintaining body fluid, cardiovascular and energy homeostasis and in protecting against infectious and toxic agents. The speakers in this symposium will review recent studies on the neurobiology and physiology of sensory CVOs. Particular attention will be paid to new methods for studying cellular mechanisms of CVOs signal transduction in sensory CVOs and the neural connectivity of CVOs with other brain structures.

## 493

SYMPOSIUM. GDNF: A NEW NEUROTROPHIC FACTOR WITH MULTIPLE ROLES. L. Olson, Karolinska Institute (Chairperson); F. Collins, Amgen Inc.; B.J. Hoffer, Univ. of Colorado Health Sciences Center; C.E. Henderson, INSERM.

GDNF is a TGFβ member with potent trophic effects on dopamine and motoneurons. The symposium will summarize current knowledge about the distribution and roles of GDNF and discuss how the new data may relate to the etiology and/or therapy of neurodegenerative diseases such as Parkinson's disease and ALS.

Dr. Frank Collins, who together with his team discovered GDNF, will present the molecular biology of GDNF and its position in the TGFβ family. He also has data on the effects of GDNF on both dopamine neurons and motoneurons which will complement the focused presentations of these two aspects given by Speakers 3 and 4.

Dr. Lars Olson will present an overview of the expression of GDNF in the organism, mainly as a result of *in situ* hybridization studies. Several new surprising aspects have been uncovered, suggesting that GDNF plays important roles not only in the developing nigrostriatal dopamine system and for the motoneurons, but also e.g. in cerebellum, thalamus, and spinal cord as well as in the GI-tract and in the kidney.

Dr. Barry Hoffer will present several lines of converging evidence suggesting that GDNF has potent trophic activity on dopaminergic (DA) ventral mesencephalic neurons *in vivo*. In nonlesioned rodents, intranigral injection of GDNF produces an increase in locomotor behavior and an upregulation of DA levels and TH immunoreactivity. In both the 6-OHDA rat model and the MPTP mouse model of DA neurodegeneration, GDNF exerts protective and restorative roles. Finally, GDNF augments DA neuron survival and fiber outgrowth in transplant models.

Dr. Chris Henderson will present the evidence that GDNF plays a biological role in regulating motoneuron survival during the cell death period in both chicken and rat embryos. In particular, the cellular origin of GDNF as compared to that of the neurotrophins BDNF and NT-3 will serve as the basis for a hypothesis to explain the multiplicity of factors that support motoneuron survival. The *in vivo* effects of GDNF on motoneurons are also striking: the relevance of experimental models to potential therapeutic strategies in motoneuron diseases will be discussed.

## 497.1

**NATURAL ANTISENSE TRANSCRIPTION IS INVOLVED IN PROENKEPHALIN REGULATION.** G. Weisinger<sup>1,2</sup>, O. Zinder<sup>1</sup>, J.D. DeCristofaro<sup>2</sup> & E.F. LaGamma<sup>2</sup>, Faculties of Medicine, Technion, Haifa, Israel<sup>1</sup> and SUNY, Stony Brook, N.Y.<sup>2</sup>.

The level of cholinergic induction of striatal preproenkephalin (ppEnk) RNA is 10-15 fold greater when measured at the level of RNA initiation compared with steady state mRNA levels. This was verified by experiments probing the same northern blots with different oligomeric fragments that hybridize to ppEnk exons 1 and 3. Hence, a novel transcriptional or posttranscriptional event occurred between the end of ppEnk exon 1 and the beginning of exon 3. To address this issue run-on transcription assays were initiated using single-stranded DNA (M13) probes derived from different regions of the rat ppEnk gene. The resulting data would indicate the relative rate of RNA transcription along the gene. Our data not only demonstrated the presence of the expected ppEnk sense RNA transcripts in four tissues (Striatum, Cerebellum, Olfactory Bulb & Adrenal Medulla), but also the presence of natural antisense RNA ppEnk transcripts showing a definite tissue specificity. Additionally, our data is also consistent with the presence of a new species of somatic ppEnk sense RNA, initiated from within the first intron of the gene. This transcript seems to be important following whole animal cholinergic agonist treatments. A mechanistic understanding of ppEnk regulation will require an understanding of these new findings.

## 497.3

**CLONING OF PUTATIVE PROOPOMELANOCORTIN STEM-LOOP RNA-BINDING PROTEINS USING A NORTHWESTERN SCREEN.** C.M. Spencer\*, S.D. Flagg and J. Eberwine, Department of Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, PA 19104

Regulation of proopiomelanocortin (POMC) gene expression is an important component of the body's response to stress. In previous studies, we have shown that a stable (-45 kcal) stem-loop structure in the protein coding region of rat or mouse POMC mRNA plays a role in the regulation of POMC translation in rabbit reticulocyte lysates. UV-crosslinking and RNA gel mobility shift assays have indicated that four protein-RNA complexes from mouse corticotroph AIT-20 cytoplasmic extracts are formed in a heparin-resistant and sequence-specific manner with radiolabeled riboprobes containing the POMC stem-loop sequence. At least two of the complexes are formed in a tissue-specific manner.

We are currently attempting to clone POMC stem-loop RNA-binding proteins from AIT-20 cells using a Northwestern screening technique. A lambda-ZAP cDNA expression library (300,000 clones) was screened using a radiolabeled 63-nt riboprobe that corresponds to the stem-loop structure of POMC. Seventy-two clones remained positive after two rounds of screening/plaque-purification and were partially sequenced. After sequences were compared to available databanks, ten novel clones were selected based upon sequence similarity to known DNA- and RNA-binding proteins. These clones were expressed in bacteria and tested further in UV-crosslinking and RNA gel shift assays. One clone, which has tested positive in preliminary assays, contains sequences that are highly similar to mouse adenine nucleotide translocase. This is interesting because a known stem-loop RNA-binding protein, the iron-responsive element binding protein, contains a consensus sequence for binding adenine nucleotides. A shorter sequence in this clone contains significant sequence similarity to FMR-1, another RNA-binding protein. This clone, as well as others, will be further analyzed for POMC stem-loop RNA-binding activity, appropriate tissue expression and the ability to regulate POMC mRNA translation in rabbit reticulocytes.

## 497.5

**CHARACTERIZATION OF THY-1 ENHANCER ELEMENTS IN TRANSGENIC MICE.** K.A. Kelley\*, A. Sonshine, and A. Ho, Fishberg Res. Ctr. for Neurobiology, The Mount Sinai School of Medicine, New York, NY 10029.

Previous studies of the mouse Thy-1 gene have suggested that the thymic enhancer is located within the third intron while the CNS enhancer is most likely in the first intron. We have further characterized the Thy-1 regulatory elements by deleting flanking sequences to leave only 388 bp 5' to the transcription start site and 154 bp 3' to the polyadenylation signal. The resulting 5.6 kb gene fragment was used to produce three transgenic mouse lines which all expressed the transgene at high levels in brain and thymus, indicating that very little flanking sequence is required for appropriate expression. The 374 bp third intron was then removed from this minimal gene fragment, and the resulting 5.3 kb gene was used to produce four transgenic mouse lines. While none of the lines expressed this transgene in the thymus, three of the four lines expressed very high levels of transgene message in the brain, confirming that the thymic enhancer is indeed in the third intron. A reciprocal construct (3.1 kb) from which the 2.5 kb first intron was removed was used to produce four transgenic lines. Surprisingly, this construct was not expressed in either the brain or thymus of any of the four lines, even though the known thymic enhancer within the third intron was retained in this gene fragment. Finally, thymic expression was also lost from a Thy-1/lacZ construct in which the lacZ coding region was inserted directly into the second exon (Soc. Neuro. Abst. 19: 1260, 1993). These data suggest that the spacing of the tissue-specific enhancers relative to the promoter may be crucial for appropriate expression, and that the previous putative identification of a brain enhancer within the first intron by deletion studies may not be accurate.

## 497.2

**THE BRN-4 POU DOMAIN MEDIATES PROTEIN-PROTEIN INTERACTIONS BETWEEN BRN-4 AND OTHER CLASS III POU FACTORS.** K.F. Malik\* and W.S. Young, III, Laboratory of Cell Biology, NIMH, NIH, Bethesda, MD 20892.

We previously demonstrated DNA-independent protein-protein interactions among class III POU factors (Malik et al., SFN Abstract, 1994). To determine Brn-4 domains important for these interactions, truncated Brn-4 constructs bacterially expressed as GST fusion proteins were used as both targets and radiolabeled probes in Farwestern blot assays. The Brn-4 POU domain (a.a.s 192-361) was able to interact with full length Brn-4 and itself but did not interact with GST, the Brn-4 N-terminal transactivating domain (N-Term; a.a.s 2-188), the Brn-4 POUspecific domain (POUs; a.a.s 192-275) or the Brn-4 POUhomeodomain (POUhd; a.a.s 261-361). To corroborate these findings a modified two-hybrid assay was used. Brn-4 constructs (same a.a.s as above) were expressed as fusions with GAL-4 DNA binding or VP-16 transactivating domains in CV-1 cells cotransfected with a reporter vector that contained the GAL-4 upstream activating sequence 5' to a viral Elb promoter driving luciferase expression. In these assays Brn-4 POU domain interacts with Brn-4, itself and POUhd but not N-Term or POUss. Together these findings indicate that: 1) the POU domain is critical for class III POU protein-protein interactions; 2) the POUhd may importantly contribute to these interactions; and 3) GST may interfere with POUhd binding in the Farwestern blot assay.

GST/Brn-4 was also used as a probe in Farwestern blot assays to screen nuclear extracts of several cell lines including HeLa, CV-1, and a Brn-4 expressing neuronal precursor cell line for factors that interact with Brn-4. A ~120 KDa Brn-4 interacting factor was found in all three cell lines. This Brn-4 interacting factor (BIF120) is highly enriched in the flow-through fraction of HeLa nuclear extracts passed over a phosphocellulose column. Experiments designed to determine the specificity of Brn-4 interactions with nonadenatured BIF120 and the identity of BIF120 are currently underway.

## 497.4

**GENETIC, PHYSICAL AND TRANSCRIPT MAPPING OF THE MOUSE VIBRATOR LOCUS: A JUVENILE TREMOR MUTANT WITH DEGENERATION OF SPINAL, BRAINSTEM AND DORSAL ROOT NEURONS.** B.A. Hamilton<sup>1</sup>, J.L. Nemhauser, R. T. Bronson<sup>1</sup>, and E.S. Lander. Whitehead Institute for Biomedical Research, Cambridge, MA 02142 and <sup>1</sup>Tufts University School of Medicine, Boston, MA and The Jackson Laboratory, Bar Harbor, ME.

*Vibrator* homozygotes exhibit a progressive action tremor beginning soon after they acquire coordinated locomotion. Vacuolated and faint-staining neurons are seen in the spinal cord, brainstem, and dorsal root ganglion after progression of the disease. Affected animals do not survive beyond postnatal day 40 on most inbred genetic backgrounds, although affected animals derived from outcrossings to one strain have survived beyond one year, suggesting the presence of suppressing alleles of at least one modifier locus in this strain.

We have genetically mapped *vibrator* to within a 0.5 cM interval on chromosome 11. This interval is spanned by a single yeast artificial chromosome. A contiguous set of bacteriophage P1 clones from this interval has been used to isolate brain, spinal, and neonate-derived cDNA fragments by direct selection. Preliminary sequence analysis of these clones has identified four previously known genes from GenBank, with one to six independent clones for each, as well as several novel transcribed sequences. Efforts to identify which of these genes is defective in *vibrator* are underway.

## 497.6

**THE ROLE OF A COMPLEX INTRON ELEMENT IN THE REGULATION OF HUMAN CT/GRP ALTERNATIVE SPLICING.** H. Lou<sup>1</sup>, Y. Yung<sup>1</sup>, Y. Zhang<sup>2</sup>, S.M. Berger<sup>2</sup> and R.E. Gagel<sup>1</sup>, Section of Endocrinology, University of Texas M.D. Anderson Cancer Center<sup>1</sup>, Division of Neuroscience<sup>2</sup> and Department of Biochemistry<sup>3</sup>, Baylor College of Medicine, Houston, TX 77030.

Cell-specific regulation of alternative RNA processing of the calcitonin/GRP (CT/GRP) gene is poorly understood. The key regulatory event in this alternative splice is inclusion or exclusion of exon 4, which codes for the peptide CT, from the final mRNA. Inclusion results in an exon order of 1, 2, 3, and 4 with utilization of the polyA site following exon 4. Exclusion results in an exon order of 1, 2, 3, 5 and 6 with utilization of the polyA site following exon 6. Although several regulatory sequences have been identified, no clear model exists for control of this processing choice. As a part of a continuing effort to understand this processing choice, we identified a highly conserved (among human, mouse and rat) intron element located 200 nt downstream of the exon 4 polyA hexanucleotide by deletion analysis of a minigenic construct containing exon 4 and flanking intronic sequence. This intron element is required for recognition and polyadenylation of exon 4. The intron element contains two 5' splice site sequences, the second flanked by two pyrimidine-rich sequences. Point mutations in these four motifs affected the inclusion of exon 4 differently. Disrupting the first 5' splice site increased the inclusion of exon 4 while disrupting the downstream 5' splice site resulted in skipping of the exon. Mutations in the two pyrimidine motifs decreased, but did not abolish, the inclusion of exon 4.

To determine if this intron element regulates polyadenylation of exon 4, we performed in vitro cleavage/polyadenylation assay in HeLa nuclear extract using the second half of CT exon 4 (250 nt) and first half of CT intron 4 (250 nt) as substrate. Point mutation of the upstream 5' splice site within the intron element increased polyadenylation slightly, whereas 2 different point mutations in the downstream 5' splice site reduced polyadenylation by 75%. Mutations in one of the pyrimidine motifs also decreased the cleavage activity more than 66%. Oligonucleotide-mediated-depletion of U1 snRNA from the HeLa nuclear extract abolished cleavage of the CT exon 4, but had no effect on a substrate derived from SV40. This result suggests a specific role for U1 snRNP in polyadenylation of CT exon 4. The possible roles of this intron element on the regulated exclusion of CT exon 4 in neuron cells are also being evaluated. We conclude that polyadenylation of CT exon 4 requires a novel and complex 5' splice containing intron element and provides a potential site for regulation of this splice choice.

## 497.7

HTLV-I TAX ACTIVATES THE cAMP-REGULATED ENHANCERS IN THE HTLV-I LTR AND CELLULAR GENES BY DIFFERENT MECHANISMS. R.P.S. Kwok\*, M.E. Lurance, J.R. Lundblad, P.S. Goldman, H.M. Shih, and R.H. Goodman. Vollum Institute, Oregon Health Sciences University, Portland, OR 97201.

Because tumor viruses typically co-opt host cell pathways for regulating viral replication, viral gene products can provide reagents for dissecting the mechanisms underlying cellular signaling processes. The human T cell lymphotropic virus (HTLV)-I LTR contains an enhancer that is regulated synergistically by the cellular transcription factor CREB and the viral co-factor, Tax. A pathway involving CREB and Tax also underlies the ability of HTLV-I to activate cellular genes that lead to transformation. Although Tax activates gene expression if fused to a heterologous DNA binding domain, the native protein does not contact DNA directly. Consequently, Tax is thought to function by increasing the dimerization and binding of CREB to DNA. Our observation that Tax converts the inhibitory protein CREM $\alpha$  into a transcriptional activator is not consistent with this hypothesis, however. Using fluorescence anisotropy measurements, we showed that Tax increases CREB and CREM $\alpha$  binding to the HTLV-I LTR, but not to the prototypical cellular CRE sequence. Furthermore, Tax increases the binding of CREB and CREM $\alpha$  to the cellular co-activator CBP, but only in the context of the HTLV-I CRE. Activation of cellular genes probably results from the ability of Tax to bind to CBP directly, which we showed by using both *in vitro* and *in vivo* binding assays. Thus, Tax activates viral and cellular enhancers through transcriptional pathways that involve CREB and the co-activator CBP. The virus can activate this system in the absence of protein kinase A (PKA)-stimulation, while the cellular CRE requires the simultaneous activation of PKA. The HTLV-I Tax system provides a useful paradigm for examining how viral transforming proteins interact with second messenger signaling pathways.

## 497.9

PROMOTER ELEMENTS AND SECOND MESSENGER PATHWAYS INVOLVED IN TRANSCRIPTIONAL ACTIVATION OF TYROSINE HYDROXYLASE BY IONOMYCIN. B. Nankova\*, B. Hiremagalur and E.L. Sabban, Dept. Biochem. & Mol. Biology, New York Medical College, Valhalla, NY 10595.

Membrane depolarization, or agents which increase intracellular calcium, elicit transcriptional activation of tyrosine hydroxylase (TH). In this study we analyze the factors involved in the regulation of the TH promoter by a calcium ionophore. PC12 cells were transiently transfected with plasmids containing wild type or mutated 5' flanking sequences of the rat TH gene, fused to bacterial chloramphenicol acetyl transferase (CAT). Point mutations introduced into the consensus cAMP-regulatory element (CRE) abolished the induction of CAT by ionomycin indicating that it is essential for mediating the calcium response. An intact and functional AP1 site did not confer calcium inducibility when the CRE/CaRE sequence was mutated. The extent and kinetics of the increase in intracellular calcium as well as the induction of CAT activity under the control of TH promoter by ionomycin were similar in PC12 cells and in the A123.7, protein kinase A (PKA) deficient cell line. In both cell lines addition of ionomycin rapidly increased the phosphorylation of transcription factor CREB at Ser 133. These results suggest that the activation of TH transcription by ionomycin does not require PKA. However, KN62 an inhibitor of Ca<sup>2+</sup>/calmodulin dependent (CaM) kinases prevented the induction indicating possible involvement of CAM kinases in the calcium response.

## 497.11

CELL LINE-SPECIFIC TRANSCRIPTIONAL AND POSTTRANSCRIPTIONAL REGULATION OF THE RAT CKB GENE BY ITS INTRONS. E. V. Kuzhikandathil\*, S. E. Ilvin, J. Zhao and G. R. Molloy, Department of Biology, University of Delaware, Newark, DE 19716.

The brain creatine kinase gene (CKB) is expressed in a range of tissues with expression being highest in glial cells of the brain (J. Neurochem. 58:1925-1932(1992)). The expression of the rat CKB gene is regulated by both distal and proximal promoter sequences in some cell types. However, in cell lines such as rat C8 glioma, rat RT4 B8 neuroblastoma, human U87 MG glioblastoma and human U251 glioma, our CKB gene promoter-deletion experiments have failed to identify any significant upstream promoter regulatory sequence. In this report, we show that certain introns of the rat CKB gene can regulate its expression at the transcriptional level in HeLa cells and at the posttranscriptional level in U87 and U251 glial cells. We demonstrate that an enhancer-like sequence in intron 1 of rat CKB has a negative regulatory effect in all cell lines tested. In addition, we also show that introns 3, 4, 5, and 6 has a positive regulatory effect on the transcription of the rat CKB gene in HeLa cells. In contrast to HeLa cells, in U87 and U251 glial cells, these introns affect the expression of the rat CKB gene at the posttranscriptional level by generating an altered form of rat CKB mRNA. This altered rat CKB mRNA retains only intron 7 and 145 nts of the 5' end of exon 8 of the rat CKB gene. The generation of this glial-specific altered CKB RNA and its possible physiological role is under investigation. These results further demonstrate the complex regulation of the rat CKB gene and the mechanisms by which introns can regulate gene expression.

## 497.8

UPSTREAM SEQUENCES DETERMINE CELL-SPECIFIC EXPRESSION OF THE PNMT GENE. M.J. Evinger\* and Y.S.E. Leg, Depts. of Pediatrics and Neurobiology & Behavior, SUNY at Stony Brook, Stony Brook, NY 11794

Cell-specific expression of genes for the catecholamine synthesizing enzymes is an important determinant of neurotransmitter phenotype. Although analogous sequences have been identified in the tyrosine hydroxylase and DBH genes, this report now characterizes those sequences responsible for cell-specific expression of the epinephrine-synthesizing enzyme phenylethanolamine N-methyltransferase (PNMT).

Expression of constructs containing nested deletions of the rat PNMT promoter has been compared following transient transfection into continuous cell lines. Luciferase reporter gene activity for each PNMT promoter construct in the cell lines is expressed relative to expression of that construct in primary bovine adrenal chromaffin cells, the system closest to expression *in vivo*.

We have identified sequences which restrict expression of the PNMT gene to cells of adrenergic and of neuronal lineage. Sequential deletion of these sequences enhances reporter gene expression 2 to 5-fold, depending upon the neural vs. non-neural origin of the cells. PNMT promoter expression in neuroblastoma lines is greater than in PC12 or TE671 cells or in non-neuronal C6 glioma or L6 fibroblast lines. The most distal element appears to be unique to the PNMT gene; its influence restricts expression to adrenal medullary cells. Two additional sequences share similarity with neural specific elements described in other genes. Removal of these portions of the promoter increases expression in non-neural cell lines, e.g. C6 and L6 cells.

The array of multiple adrenergic and neural specific sequences in the PNMT gene effectively restricts peripheral expression of PNMT to differentiated chromaffin cells. Cell-specific expression of the PNMT gene thereby constitutes the critical transcriptional event governing determination of the adrenergic phenotype. Supported by NIH GM46588 (MJE).

## 497.10

INTRACELLULAR CALCIUM AS A MEDIATOR OF INCREASED TYROSINE HYDROXYLASE GENE EXPRESSION IN PC12 CELLS. A. Menezes\*, R. Zeman, B. Hiremagalur and E.L. Sabban, New York Medical College, Valhalla, NY 10595.

Elevation in [Ca<sup>2+</sup>]<sub>i</sub> that occur in response to a variety of stimuli have been implicated in regulating cellular processes such as neurotransmitter secretion, neurite outgrowth and gene expression. The importance of the rise in [Ca<sup>2+</sup>]<sub>i</sub> for regulation of tyrosine hydroxylase (TH) gene expression for various treatments which elevate [Ca<sup>2+</sup>]<sub>i</sub> by different mechanisms was examined in PC12 cells. Spatial and temporal changes in [Ca<sup>2+</sup>]<sub>i</sub> were monitored by calcium imaging and confocal microscopy. Upon continuous depolarization with 50 mM KCl, [Ca<sup>2+</sup>]<sub>i</sub> was raised from 50-60 nM to about 120 nM for several hours. TH mRNA levels were elevated 3-4 fold, maximally after 2-12 hrs. Release of calcium from intracellular stores by bradykinin or thapsigargin, raised [Ca<sup>2+</sup>]<sub>i</sub> to about 250 nM, and also induced TH transcription with similar kinetics, even in low extracellular calcium. In contrast, nicotine treatment, which raised [Ca<sup>2+</sup>]<sub>i</sub> to similar levels and subcellular distribution, required over 12 hrs exposure to induce TH. All these agents utilize the Ca/CaRE region of the TH promoter to increase gene expression. Treatments with agents which block release of calcium from intra- and extra-cellular pools were used to determine the source of intracellular calcium required to elevate TH transcription.

Influx of calcium from intracellular or extracellular pools was found sufficient to initiate induction of TH gene expression. However, the results with nicotine indicate that the changes in gene expression are not simply due to a read-out of the rise in calcium. (Supported by NIH & STRC)

## 498.1

CHARACTERIZATION OF PICROTOXIN BLOCKADE OF GLUTAMATE-GATED CHLORIDE CHANNELS REVEALS STRUCTURAL AND FUNCTIONAL SIMILARITIES TO GABA<sub>A</sub> AND GLYCINE RECEPTORS. J.P. Arena\*, K.K. Liu, D.F. Cully, D.K. Vassiliadis, B.H. Reiss, J.M. Schaeffer, A. Etter. Dept. of Biochemistry and Physiology, Merck Research Labs, Rahway, NJ 07065.

The predicted protein sequences of the *Caenorhabditis elegans* glutamate-gated chloride channel subunits (GluCl $\alpha$  and GluCl $\beta$ ) contain the conserved motifs present in GABA<sub>A</sub> and glycine receptors. To establish a functional link between the GluCl family and other ligand-gated chloride channels we studied the properties of picrotoxin (PTX) blockade. *In vitro* RNA synthesized from pGluCl $\alpha$  and pGluCl $\beta$  and was either co-injected ( $\alpha\beta$ ) or injected individually ( $\alpha$  or  $\beta$ ) into *Xenopus* oocytes. Recordings were made under two electrode voltage clamp. Oocytes injected with  $\alpha\beta$  formed heteromeric channels which responded to glutamate and ivermectin (IVM), a widely used antiparasitic agent. These currents were weakly inhibited by PTX (EC<sub>50</sub> = 50  $\mu$ M). Homomeric  $\alpha$  and  $\beta$  channels were selectively activated by IVM and glutamate, respectively. The EC<sub>50</sub> for PTX block of homomeric  $\alpha$  channels was 50  $\mu$ M, and current from homomeric  $\beta$  channels was potently inhibited by PTX with an EC<sub>50</sub> of 50 nM. Opening of homomeric  $\beta$  channels with glutamate was required for PTX block and unblock. Resistance to PTX has been reported for a Ser to Ala mutation in the M2 domain of a *Drosophila* GABA receptor (Ifrench-Constant, R.H., et al. 1993, Nature 363, p449). To test this position for the GluCl family we substituted the Ala of GluCl $\beta$  with a Thr (as found in GluCl $\alpha$ ) and channels became resistant to PTX (20 % block at 1mM). In conclusion, resistance of the heteromeric  $\alpha\beta$  channel is conferred by a single subunit ( $\alpha$ ). Blockade and recovery from PTX block requires channel opening, and a single point mutation in M2 confers PTX resistance. These properties have been described for PTX blockade of glycine and GABA<sub>A</sub> receptors and demonstrate a functional as well as structural similarity of the GluCl family to these receptors.

## 498.3

STRUCTURAL DETERMINANTS OF ATP-GATED ION CHANNELS P. Werner, E.P. Seward\*, G. Buell and R.A. North.

Glaxo Institute for Molecular Biology, 1228 Plan-les-Ouates, Geneva, Switzerland.

P<sub>2</sub>X receptors cloned from rat vas deferens (Valera et al. 1994 Nature, 371, 516) and PC12 cells (Brake et al. 1994 Nature, 371, 519) differ in their pharmacological profiles and kinetics. PC12 P<sub>2</sub>X receptors are distinguished from the rapidly desensitizing smooth muscle form by their insensitivity to the agonists  $\alpha\beta$ meATP and ADP, and their lack of desensitization during a 10 s application of agonist. To probe the functional domains important for ligand-binding and channel gating, chimeric receptors were constructed and expressed in *Xenopus* oocytes. A major determinant of agonist selectivity was found to be the region between the two transmembrane domains, which is thought to form a large extracellular loop. The PC12 receptor became desensitizing with the introduction of vas deferens receptor segments corresponding to the transmembrane domains along with neighboring residues. The results indicate that regions controlling P<sub>2</sub>X ion channel gating are independent of the ligand-binding site, and that rapid desensitization can not be accounted for by any single domain.

## 498.5

SELECTIVITY OF ANTAGONISTS AT SUBTYPES OF CLONED P<sub>2</sub>X RECEPTOR EXPRESSED IN MAMMALIAN CELLS. C. Lewis, R.A. North, G. Buell and A. Surprenant\*. Glaxo Institute for Molecular Biology, Plan-les-Ouates, 1228 Geneva, Switzerland.

The effects of the antagonists suramin, pyridoxal 5-phosphate (P5P) and pyridoxal phosphate-6-axophenyl-2',4'-disulphonic acid (PPADS) were studied on the responses to ATP of HEK293 cells expressing four molecular species of P<sub>2</sub>X receptors (cloned from human bladder, rat PC12 cells, rat superior cervical ganglion (scg) and rat dorsal root ganglion (drg)). Suramin acted as an antagonist at bladder, PC12 and drg receptors; it was apparently competitive only up low dose-ratios (<10); it did not antagonise responses of this scg clone. P5P and PPADS acted as essentially irreversible antagonists at the bladder and PC12 receptors (50% inhibition by 3 - 10  $\mu$ M), had no effect (up to 100  $\mu$ M) at the scg receptor, and caused rapidly reversible antagonism (50% inhibition by 10  $\mu$ M) at the drg receptor. The differences in primary sequence that underlie these differences in antagonist sensitivity are being determined by expression of chimeric and point-mutated receptors. The results indicate that not all P<sub>2</sub>X receptors are sensitive to blockade by the usual antagonists suramin, P5P and PPADS.

## 498.2

LOCALIZATION OF A GEPHYRIN BINDING SITE ON GLYCINE RECEPTOR  $\beta$  SUBUNIT

D.Langosch, G.Meyer, J. Kirsch, S.Kröger\*, H. Betz, Max-Planck-Institut für Hirnforschung, 60496 Frankfurt, Germany.

The tubulin-binding protein gephyrin copurifies with the inhibitory glycine receptor (GlyR) and is essential for its postsynaptic localization. Gephyrin contributes to the formation of GlyR clusters in the postsynaptic membrane of spinal neurons, as antisense oligonucleotides interfering with gephyrin synthesis drastically reduce clustering. Here, we analyzed the interaction between the GlyR and different recombinant gephyrin isoforms (P1-P3) and identified a gephyrin binding site within a 49 amino acid sequence in the cytoplasmic loop between the third and fourth transmembrane segments of the  $\beta$  subunit. GlyR  $\alpha$  subunits and  $\gamma$ -aminobutyric acid<sub>A</sub> receptor proteins failed to bind recombinant gephyrin. However, insertion of a central 18 residue segment of the GlyR  $\beta$  49mer into a  $\gamma$ -aminobutyric acid<sub>A</sub> receptor  $\beta$ 1 subunit construct conferred gephyrin binding. This data defines a minimal gephyrin binding motif and suggests that  $\beta$  subunit expression is essential for formation of a postsynaptic GlyR matrix.

## 498.4

CLONING AND EXPRESSION OF A FAMILY OF ATP-GATED ION CHANNELS G. Buell, C. Lewis, G. Collo, R.A. North\* and A. Surprenant. Glaxo Institute for Molecular Biology, Plan-les-Ouates, 1228 Geneva, Switzerland.

P<sub>2</sub>X receptors cloned from the rat vas deferens and PC12 cells form cation-selective channels gated by extracellular ATP when expressed in heterologous cells (S. Valera et al. Nature 371, 516, 1994; A.J. Brake et al. Nature 371, 519, 1994). We have isolated further members of the P<sub>2</sub>X receptor family by a PCR-based approach, and expressed them by transfection into HEK293 cells. One was isolated from a rat superior cervical ganglion cell cDNA library; however, its RNA is found predominantly in epithelial tissues. It is generally similar in its functional properties to the PC12 form of the receptor (insensitive to  $\alpha\beta$ meATP, non-desensitizing). Another cDNA was cloned from a rat dorsal root ganglion library, and in situ hybridisation showed RNA also in trigeminal ganglia and retina. In HEK293 cells this clone has properties intermediate between those of the bladder and PC12 forms; it is sensitive to  $\alpha\beta$ meATP but shows less desensitization than the bladder receptor. All receptors are 40 - 55% identical at the amino acid level, indicating that P<sub>2</sub>X receptors belong to an extended gene family whose products quite distinct electrophysiological properties and tissue distribution.

## 498.6

CLONING AND FUNCTIONAL PROPERTIES OF A CENTRAL P<sub>2</sub>X ATP RECEPTOR. P. Séguéla<sup>1</sup>, A. Haghighi<sup>2</sup>, J.-J. Soghomonian<sup>3</sup> and E. Cooper<sup>2</sup>. <sup>1</sup>Montreal Neurological Institute, <sup>2</sup>Dept. Physiology, McGill University, Montreal, Qc, H3A 2B4 and <sup>3</sup>Neurobiology Res. Group, Laval University, Quebec City, Qc, G1J 1Z4, Canada.

Using a degenerate PCR strategy for cloning novel members of the P<sub>2</sub>X ATP-gated channel family, we report the primary structure of a new subtype expressed in the rat brain. This clone (P2x3) encodes a 388 aa protein which has the characteristic features of known ATP-gated channels according to their transmembrane topology, post-translational modifications and ion selectivity. The predicted sequence of this central receptor subunit has 47% identity with the rat smooth muscle subtype and 37% with the PC12 subtype. Functional homomeric P2x3 channels expressed in *Xenopus* oocytes present a distinct pharmacological profile (ATP > 2methylthioATP >  $\alpha\beta$ methyleneATP) and are sensitive to blockade by P2 antagonists. Their potentiation by Zn ions may be of particular functional relevance since P2x3 is localized by *in situ* hybridization in CA3 hippocampal pyramidal cells heavily afferented by Zn-containing terminals of mossy fibers. This central subtype is also expressed at high levels in cerebellum, limbic system and motor nuclei of brainstem. These data support the hypothesis that fast purinergic transmission mediated by extracellular ATP is widespread in the mammalian CNS. (Supported by MRC and NSERC)

## 498.7

ROLE OF THE METABOTROPIC GLUTAMATE RECEPTOR mGluR5 IN THE HIPPOCAMPUS REVEALED WITH ANTISENSE DEOXYNUCLEOTIDES. J.M. Wojtowicz\*, F. Dorri, D. Hampson and A. Baskys. Department of Physiology, University of Toronto, Toronto, ONT, M5S 1A8.

Several metabotropic glutamate receptor subtypes are expressed in the hippocampus but their functions are poorly understood due to the lack of specific ligands and blockers. We have used the antisense deoxynucleotide (oligo) technology to study the effects of mGluR5 on neuronal excitability and synaptic transmission in CA1 area of the rat hippocampus. The antisense oligos to mGluR5 were stereotactically injected into the CA1 area of the hippocampus of 30 day old male Wistar rats. After repeated injections *in vivo* for three days, standard hippocampal slices were prepared for electrophysiological and Western blott analysis. In uninjected controls two effects of a metabotropic agonist ACPD (50  $\mu$ M) were observed: a reduction in the evoked field EPSP and an increase of the population action potential. The antisense-treated animals showed a significantly reduced effect of ACPD on the action potential (ANOVA,  $P < .05$ ,  $n_c = 20$ ,  $n_{as} = 39$ ). The reduction was sequence and target specific since a mismatched oligo had no effect, and the response to ACPD of the field EPSP in the antisense-treated group was unchanged. Also, the magnitude of long-term potentiation in the affected slices was unchanged. Reduced expression of mGluR5 was confirmed by immunoblotting with a specific antibody. Supported by MRC of Canada.

## EXCITATORY AMINO ACIDS: PHARMACOLOGY—NMDA/AMPA RECEPTORS

## 499.1

METABOTROPIC GLUTAMATE RECEPTOR ACTIVATION MEDIATES NITRIC OXIDE (NO) PRODUCTION IN THE HIPPOCAMPUS *IN VIVO*. A. Bhardwaj\*, F.J. Northington, L.J. Martin, D.F. Hanley, R.J. Traystman, R.C. Koehler.

Johns Hopkins University School of Medicine, Baltimore, MD 21287.

Utilizing the technique of microdialysis we have demonstrated that NMDA and AMPA receptor stimulation and blockade modulates NO production *in vivo*. Because of the known role for G-protein coupled glutamate receptors in regulating intracellular calcium levels, we tested the hypothesis that metabotropic glutamate receptors modulate NO production *in vivo*. Under controlled conditions of normoxia, normocarbida and normothermia bilateral microdialysis probes were placed in the hippocampus of adult male Sprague-Dawley rats and perfused for 5 hours with perfusates containing 3  $\mu$ M [ $^{14}$ C]-L-arginine. Effluent [ $^{14}$ C]-L-citrulline was used as a marker of NO production. At 5 hours of perfusion, [ $^{14}$ C]-L-citrulline in the effluent (femtomoles/minute  $\pm$  S.E.M.) was greater on the side perfused with selective metabotropic receptor agonist, 1 mM trans-( $\pm$ )-1-amino-(1S,3R)-cyclopentanedicarboxylic acid (ACPD) ( $149 \pm 35$ ) than on the control side perfused with artificial CSF ( $81 \pm 16$ ) (N=5). ACPD enhanced [ $^{14}$ C]-L-citrulline recovery was attenuated by the addition of 1 mM metabotropic receptor antagonist ( $\pm$ )-alpha-methyl-4-carboxyphenylglycine (MCPG) ( $143 \pm 10$ ) as compared to ACPD alone ( $280 \pm 21$ ) (N=5). ACPD enhanced [ $^{14}$ C]-L-citrulline recovery was attenuated by 70% with the addition of 1 mM L-nitroarginine. ACPD + 1 mM dantrolene, an inhibitor of intracellular calcium release attenuated the citrulline recovery ( $93 \pm 18$ ) as compared to ACPD alone ( $179 \pm 18$ ) (N=6). These data indicate that the metabotropic glutamate receptor activation can mediate the production of NO *in vivo* by modulating intracellular calcium release.

Stable cell lines expressing recombinant human N-methyl-D-aspartate receptor subtypes.

P. J. Whiting\*, S. Grimwood, B. Le Bourdellès, W. Cockett, J. Myers, P. Hutson and C. I. Ragan. P. Laughton and T. Priestley. Neuroscience Research Centre, Merck Sharp and Dohme Research Laboratories, Harlow, Essex, U.K.

To enable detailed pharmacological and functional analysis of human N-methyl-D-aspartate (NMDA) type glutamate receptor subtypes we have established permanently transfected cell lines expressing recombinant human NR1a/NR2A and NR1a/NR2B heteromeric receptors. In order to overcome the cytotoxicity associated with expression of recombinant NMDA receptors in transfected cells, the subunit cDNAs were engineered so as to be under control of a dexamethasone inducible promoter. Radioligand binding studies allowed pharmacological analysis of the glycine, glutamate and channel (MK801) sites of recombinant receptors. Similarly, electrophysiological approaches allowed analysis of the functional pharmacology of these recombinant human receptor subtypes, and comparison with the properties of native rat NMDA receptors expressed by cultured neurons.

PHARMACOLOGY OF STABLY EXPRESSED RECOMBINANT HUMAN N-METHYL-D-ASPARTATE RECEPTORS USING A  $^{45}$ Ca $^{2+}$ -INFLUX ASSAY. S. Grimwood, E. Gilbert, J. Myers, B. Le Bourdellès, W. Cockett, N. Ruppia\*, C.I. Ragan, P.J. Whiting and P.H. Hutson. Merck Sharp & Dohme Research Laboratories, Neuroscience Research Centre, Terlings Park, Eastwick Road, Harlow, Essex CM20 2QR.

$^{45}$ Ca $^{2+}$ -influx experiments were performed on monolayers of cells stably expressing human NR1a/NR2A and NR1a/NR2B receptors under the control of a dexamethasone inducible promoter. Using this assay we have characterised in detail the pharmacology of the different modulatory sites of the NMDA receptor complex with a view to identifying sub-type selective compounds.  $^{45}$ Ca $^{2+}$ -influx was maximal in the presence of 100  $\mu$ M L-glutamate and 100  $\mu$ M glycine, addition of 100  $\mu$ M MK-801 determined background levels. No significant difference was observed between affinity values obtained with the two cell lines for the ion-channel ligands MK-801, phencyclidine and ketamine, whilst the polyamine-site antagonist ifenprodil was 600-fold more potent at NR1a/NR2B receptors (see Table).

	NR1a/NR2A	NR1a/NR2B
MK-801	0.191 (0.125, 0.291)	0.125 (0.098, 0.159)
Phencyclidine	2.14 (1.68, 2.74)	1.07 (0.652, 1.75)
Ketamine	10.1 (4.22, 24.0)	4.88 (3.35, 7.11)
Ifenprodil	298, 329*	0.491 (0.395, 0.612)

Data are  $K_i$  values (geometric mean ( $\pm$ SEM,  $\pm$ SEM)) ( $\mu$ M) ( $n \geq 3$ ,  $n = 2$ ).

These results show that  $^{45}$ Ca $^{2+}$ -influx can be used to characterise the pharmacology of stably expressed NMDA receptors, and that the sub-type selective compound ifenprodil will distinguish between recombinant human NR1a/NR2A and NR1a/NR2B receptors.

## 499.4

AMPA INDUCES THE ACTIVATION OF MAP KINASE IN RAT CORTICAL NEURONS BY A  $Ca^{2+}$ -DEPENDENT PROTEIN KINASE CASCADE. Y. Wang, M. Black, P. Morley, K. Chaundy\* and J.P. Durkin. Cellular Neurobiology Group, Institute for Biological Sciences, National Research Council of Canada, Ottawa, Ontario, Canada K1A 0R6.

AMPA ( $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid) receptors play important roles in plasticity, neurotransmission and neurotoxicity. Despite the importance of the AMPA receptor to normal and aberrant neuronal behavior, the signalling pathways coupled to the AMPA-mediated influx of  $Na^+$  and  $Ca^{2+}$  ions are only poorly understood. In this study we demonstrate that AMPA receptor stimulation in primary cortical neurons triggers a protein kinase cascade leading to the activation of MAP kinase (MAPK). 100  $\mu$ M AMPA caused a rapid 3-fold increase in MAPK activity within 3 min of stimulation and which slowly returned to basal levels over the ensuing 60 min. By contrast, KCl-induced depolarization caused a rapid but highly transient activation of MAPK which returned to basal levels within 10 min of stimulation. The AMPA-induced activation of MAPK was dependent on the presence of  $Ca^{2+}$ , but not  $Na^+$ , in the culture medium. While the L-type  $Ca^{2+}$ -channel blocker, nifedipine, effectively blocked the activation of MAPK by KCl-mediated depolarization, it had no effect on AMPA-induced MAPK activation. AMPA also stimulated *ras* activity in cortical neurons, as measured by an increase in the amount of GTP-bound *ras* relative to the inactive GDP-bound form of *ras*. Using an anti-*ras* antibody, it was determined that the coprecipitation of *ras* with *raf* kinase and the MAP kinase/ERK-activating kinase (MEK-1) increased within 3 min of AMPA stimulation. As was the case with MAPK activation, the association of *ras*, *raf* and MEK-1 was dependent on extracellular  $Ca^{2+}$ , but not  $Na^+$ . A gel mobility shift assay was used to determine that the phosphorylation and activation of MEK-1 occurred in an AMPA-concentration dependent manner. Collectively, these results suggest that the stimulation of the AMPA receptor triggers a  $Ca^{2+}$ -dependent kinase cascade in cultured cortical neurons in which *ras* activation leads to the activation of *raf* kinase, MEK-1 and MAPK.

SYNTHESIS AND PHARMACOLOGY OF HIGHLY SELECTIVE PHOSPHONO AMINO ACID AMPA RECEPTOR ANTAGONISTS. U. Madsen\*, B. Ebert and P. Krogsgaard-Larsen. Department of Medicinal Chemistry, Royal Danish School of Pharmacy, DK-2100 Copenhagen, Denmark.

Excitatory amino acid (EAA) receptors are subjects of extensive exploration as potential targets for drug intervention in different neurodegenerative disorders. Ligands for the *N*-methyl-D-aspartic acid (NMDA) and 2-amino-3-(3-hydroxy-5-methyl-4-isoxazolyl)propionic acid (AMPA) subtypes of EAA receptors are of interest in this regard as pharmacological tools and potential drugs. The availability of a broad spectrum of phosphono amino acids showing potent and highly selective competitive antagonism of NMDA receptor function has played a crucial role in the characterization of this subtype of EAA receptors. AMPA has previously been converted into the AMPA antagonist (RS)-2-amino-3-[(3-carboxymethoxy)-5-methyl-4-isoxazolyl]propionic acid (AMOA). In continuation of this line of research, structural hybrids containing a distal phosphono group and an isoxazole nucleus have been synthesized and tested pharmacologically. The pharmacology of the compounds has been investigated in electrophysiological and receptor binding assays using rat brain tissue. The most potent compound, (RS)-2-amino-3-[(3-phosphonomethoxy)-5-*tert*-butyl-4-isoxazolyl]propionic acid (ATPO), has a potency as AMPA antagonist ( $IC_{50} = 27 \mu M$ ) approximately 20 times greater than that of AMOA and shows higher selectivity for the AMPA receptors compared to the parent compound AMOA. In context with this series of AMPA antagonists, a parallel series of AMPA agonists was synthesized.

## 499.7

GLUTAMATE ANTAGONISTS PREVENT CONVULSIONS INDUCED BY INSECTICIDES. W.A. Turski\*, P. Blaszczyk, E. Urbanska and L. Turski. Institute of Agricultural Medicine, PL-20950 Lublin and Research Laboratories of Schering AG, 13342 Berlin

Human exposure to insecticides may occur in agriculture, during occupational exposure, their improper use in medicine, or by intake of contaminated foods. The symptoms of toxicity in humans in non-fatal cases are nausea, mental confusion, myoclonic jerks and severe convulsions. Current therapy of insecticide-poisoning is symptomatic and consists of removal of the poison, control and support of respiratory and cardiovascular systems, hemodynamic stabilization, and anticonvulsant treatment. Clinical experience suggests that antiepileptic drugs may not be sufficient to control insecticide-induced convulsions which may immensely affect clinical outcome. Therefore we examined whether glutamate antagonists (E)-4-(3-phosphoroprop-2-enyl)piperazine-2-carboxylic acid (D-CPPene, 20 mg/kg i.p.), dizocilpine (MK-801, 0.4 mg/kg i.p.), felbamate (400 mg/kg i.p.) and 2,3-dihydroxy-6-nitro-7-sulfamoylbenzo(F)quinoxaline (NBQX, 100 mg/kg i.p.) influence seizures induced by chlorinated hydrocarbon insecticides  $\gamma$ -lindane and dieldrin.  $\gamma$ -Lindane induced clonic seizures in Swiss mice, 20-25 g, with an ED50 of 27 mg/kg and tonic seizures with an ED50 of 47 mg/kg. Clonic seizures induced by  $\gamma$ -lindane were prevented by the non-NMDA antagonist NBQX but not by the NMDA antagonists D-CPPene, MK-801 and felbamate.  $\gamma$ -Lindane-induced tonic seizures were blocked by either type of glutamate antagonists. Dieldrin induced clonic seizures in mice with an ED50 of 21 mg/kg and tonic seizures with an ED50 of 29 mg/kg. Clonic seizures induced by dieldrin were prevented by both non-NMDA and NMDA antagonists. Dieldrin-induced tonic seizures were also sensitive to the treatment with glutamate antagonists. Such observations suggest that glutamate may be involved in the evolution of insecticide-induced convulsions, and that antagonism at glutamate receptors may offer a novel therapeutic approach for seizure prevention in insecticide poisoning.

## 499.9

NEURONAL ACTIVITIES OF IBOGAINE AND NORIBOGAINE AT THE NMDA RECEPTOR COMPLEX: LIGAND BINDING AND ELECTROPHYSIOLOGICAL STUDIES. I. Pablo\*, J.K. Staley, A.M. Holohan, J.C. Hackman, R.A. Davidoff, and D.C. Mash. Dept. of Neurology, Univ. of Miami Sch. of Med., Miami, FL, 33136.

Ibogaine is purported to be a naturally occurring anti-addiction agent based on preclinical studies and on anecdotal reports from addict self-help groups. Popik et al., (1994) have suggested that the anti-addictive properties of ibogaine are due to an interaction with NMDA receptor-coupled cation channels. The non-competitive NMDA receptor antagonist, MK-801, has been reported to block sensitization to the behavioral activating effects of cocaine and amphetamine. We report here a comparison of the activities of ibogaine and its O-demethylated metabolite (noribogaine) at the NMDA receptor complex. The potency of both drugs at [ $^3H$ ]MK-801 binding sites were compared to their electrophysiological actions on isolated frog spinal cord, using differential sucrose gap recording of the IXth ventral root. Ligand binding profiles demonstrate that ibogaine was six-fold more potent than noribogaine in competition assays with [ $^3H$ ]MK-801. Ibogaine (100  $\mu M$ ) and noribogaine (1 mM) blocked (85 to 90% of control values) the ability of NMDA (100  $\mu M$ , 5 sec.) to depolarize frog motoneurons in a non-competitive and use-dependent manner. The lower affinity of noribogaine may indicate that the dwell time for the metabolite in the ion channel is too brief to be additive to the activity of ibogaine. The molecular target(s) mediating the putative anti-addictive, psychotropic and neurotoxic properties of ibogaine are not completely understood. If ibogaine's interaction with the NMDA receptor-coupled cation channels contribute to its psychotropic and/or neurotoxic actions, the metabolite may have fewer adverse effects than the parent drug. Supported by NS 17577 and VA Medical Ctr (MRS 1769 & 3369).

## 499.6

PHARMACOLOGICAL INTERACTIONS OF THE AMPA ANTAGONIST NBQX WITH CNS DEPRESSANTS. G.H. Jones\*, A. Huth, E. Ottow and L. Turski, Research Laboratories of Schering AG, Müllerstr. 178, D-13342 Berlin, Germany.

AMPA receptor antagonists have been shown to have marked neuroprotective effects in variety of animal models of cerebral ischemia and trauma which indicates that this compound class may have clinical potential for the treatment of stroke or head trauma. AMPA receptor antagonists reduce excitatory synaptic neurotransmission in the CNS which leads at higher doses to sedation and loss of motor coordination. It is therefore important to investigate the potential interaction of these compounds with other commonly used CNS depressants. We examined the interactions between the competitive AMPA receptor antagonist 2,3-dihydroxy-6-nitro-7-sulfamoylbenzo(F)quinoxaline (NBQX, i.v.) and several CNS depressants, including ethanol, diazepam, morphine, hexobarbital and urethane on measures of motor coordination and toxicity in NMRI mice (20-25 g). Of particular interest was the finding that ethanol (3.125 g/kg, p.o.) potentiated the loss of righting reflex and impairment of rotarod performance, but did not increase the toxic effects, produced by NBQX. Diazepam (80 mg/kg, i.v.) also greatly increased the loss of righting reflex produced by NBQX. In contrast, the presence of hexobarbital (100 mg/kg, i.v.) greatly increased the toxic effects of NBQX, but there was no marked interaction between these two compounds on loss of righting reflex. In conclusion, these results indicate the specific nature of interactions of NBQX with other CNS depressants which may be of clinical importance.

## 499.8

CYCLOTHIAZIDE INTERACTIONS WITH AMPA AND KAINATE RECEPTOR ANTAGONISTS. K.A. Yamada\*, Depts of Neurology and Pediatrics, Washington Univ. Sch. of Med., St. Louis, MO 63110.

We studied interactions between cyclothiazide, GYKI 52466 (GYKI), and NBQX using native AMPA/Kainate receptors and whole-cell voltage-clamp recording. 30  $\mu M$  GYKI blocked Kainate-activated whole-cell currents in hippocampal neurons ( $16 \pm 8.3\%$  of control) and the onset of the block was best fit by a double exponential function ( $\tau_1 = 94 \pm 18$ ,  $\tau_2 = 388 \pm 228$  ms). The estimate for GYKI's  $IC_{50}$  against hippocampal Kainate currents was 15  $\mu M$ . 100  $\mu M$  cyclothiazide potentiated the Kainate current 2.6  $\pm$  1.0 fold and reduced the GYKI block ( $62 \pm 12\%$  of control). Moreover, the time course of onset of the block was slower ( $\tau_1 = 164 \pm 39$ ,  $\tau_2 = 861 \pm 455$  ms,  $P \leq 0.001$ ). NBQX blocked Kainate currents to  $6.2 \pm 4.4\%$  of control, and unlike GYKI the kinetics of block was more complex than a two exponential function. However, similar to GYKI, 100  $\mu M$  cyclothiazide reduced NBQX block to  $42 \pm 16\%$  of control and the time course of NBQX block was also slower. Kainate activated a slowly desensitizing current in DRG neurons which was unaffected by cyclothiazide. GYKI blocked DRG Kainate currents, but with lower affinity than for hippocampal AMPA receptors. Cyclothiazide did not affect GYKI's antagonism of DRG Kainate currents, against which GYKI's  $IC_{50}$  was between 120 and 400  $\mu M$ , several fold greater than for hippocampal neurons. These results suggest that the site of action of cyclothiazide is an important allosteric modulatory site on the AMPA receptor, affecting the actions of both competitive and non-competitive antagonists, and that receptor subunit composition influences the affinity of the non-competitive AMPA/Kainate antagonist GYKI. Because AMPA receptors mediate excitatory responses at central synapses and contribute to excitotoxic neuronal injury during hypoxia-ischemia, these findings may have both functional and therapeutic implications. Supported by NIH NS 01443.

## 499.10

MODULATION OF AMPA OR GABA<sub>A</sub> RECEPTORS ANTAGONIZES ALPRAZOLAM-INDUCED IMPAIRMENT OF LEARNING IN MONKEYS. J. Auta, D.M. Thompson, J.M. Moerschbacher\*, K. Varner\*, A. Guidotti, and E. Costa, N.S. Kline Institute for Psychiatry Research, Center for Neuropsychopharmacology, Orangeburg, NY and Dept. Psychiatry, NYU, NY. <sup>1</sup> Dept. Pharmacology, LSU Med. Center, New Orleans, LA.

A multiple schedule of repeated acquisition and performance of response chains was used to assess the effects of IDRA 21 (JPET 272: 300, 1995) and aniracetam (two allosteric modulators of AMPA receptor-induced desensitization) on alprazolam-induced impairment of acquisition in monkeys. Acquisition of the response chain was defined by a decrease in errors as the session progressed. Responding in each component was maintained by food presentation under a fixed-ratio schedule. Alprazolam (0.3 or 1  $\mu mol/kg$  p.o.), a full positive allosteric modulator of GABA action, when administered alone produced dose-related decreases in response rate in each component. Alprazolam also produced a dose-related increase in percent errors in acquisition while having a small effect on accuracy in performance. Imidazenil, a partial positive allosteric modulator of GABA action (JPET 266: 1018, 1993), had little or no effect when given alone (0.003 to 3  $\mu mol/kg$  p.o.) 60 min pre-session but dose dependently antagonized and at 0.03  $\mu mol/kg$  completely blocked the disruptive effects of alprazolam when given 60 min before alprazolam. IDRA 21 (13 and 24  $\mu mol/kg$  p.o.) and aniracetam (137  $\mu mol/kg$ ) administered alone had no effect on either rate of responding or accuracy in either component. However, 60 min pretreatment with IDRA 21 (13  $\mu mol/kg$  p.o.) or aniracetam (137  $\mu mol/kg$  p.o.) produced a dose-related attenuation of the effects of alprazolam in both components. These data suggest that in primates alprazolam impairment of learning may depend upon events coordinated by AMPA and GABA<sub>A</sub> receptors (Supported by Grant NS 28130-04).

## 499.11

EVIDENCE FOR REDOX MODULATION AND S-NITROSYLATION OF THE RAT BRAIN  $\text{Na}^+/\text{Ca}^{2+}$  EXCHANGER. R.A. Colvin\*, J. Schummers, N. Davis, and L.D. Hatem. Program in Neurobiology, Department of Biological Sciences, Ohio University, College of Osteopathic Medicine, Athens, OH 45701

When plasma membrane vesicles derived from whole rat brain were incubated with 1 mM DTT or ascorbic acid at 37°C for 1 hr., a maximal 35% decrease in  $\text{Na}^+/\text{Ca}^{2+}$  exchange activity was seen. Coincubation with 10 mM  $\text{H}_2\text{O}_2$  prevented the effect of DTT. Sodium nitroprusside (SNP) (0.1 mM) which in solution has the capability to generate NO and ferrocyanide, had no effect by itself, but when added in combination with DTT caused an additional 50% inhibition of the activity seen with DTT alone. The SNP effect was dose dependent with a half maximal effect seen at 2  $\mu\text{M}$ . Ferrocyanide did not cause inhibition when added in combination with DTT. The inhibitory effect of SNP could not be prevented by coincubation with Vitamin E (100  $\mu\text{g}/\text{ml}$ ). The initial velocity of  $\text{Na}^+/\text{Ca}^{2+}$  exchange was determined at various concentrations of  $\text{Ca}^{2+}$  and  $\text{V}_{\text{max}}$  and  $\text{K}_\text{m}$  determined. DTT inhibition resulted from a decrease in  $\text{V}_{\text{max}}$  with no effect on the  $\text{K}_\text{m}$  for  $\text{Ca}^{2+}$ . There was no additional effect of coincubation of DTT with SNP on either the  $\text{K}_\text{m}$  or  $\text{V}_{\text{max}}$ . There was no effect of DTT or DTT/SNP on membrane permeability to  $\text{Ca}^{2+}$ . Analysis of unidirectional fluxes for  $\text{Ca}^{2+}$  during a  $\text{Na}^+/\text{Ca}^{2+}$  exchange reaction showed that both DTT and DTT/SNP reduced  $\text{Ca}^{2+}$  influx.  $\text{Ca}^{2+}$  efflux was reduced only after preincubation with both DTT and SNP. Western analysis with an antibody specific for the  $\text{Na}^+/\text{Ca}^{2+}$  exchanger, showed a single band with a molecular weight of 116 kDa in the presence of NEM. Incubation with DTT resulted in the release of a 19 kDa protein fragment. In summary, the brain  $\text{Na}^+/\text{Ca}^{2+}$  exchanger appears to contain reactive thiol groups that modulate its activity and structure. The reduced exchanger may be inhibited by S-nitrosylation after exposure to NO. The  $\text{Na}^+/\text{Ca}^{2+}$  exchanger may be proteolytically cleaved *in situ*, and a peptide fragment released when disulfide bridges are reduced.

## 499.13

PRESYNAPTIC SYNTHESIS OF THE NMDA-ASSOCIATED GLYCINE RECEPTOR AGONIST, D-SERINE. P.L. Wood, D.B. Goodnough, J.E. Hawkinson, and R.P. Shank\*. Dept. of Pharmacology, CoCensys, Inc., 213 Technology Dr., Irvine, CA 92718

While glycine has been assumed to be the sole endogenous co-agonist at NMDA-associated glycine receptors, recent descriptions of endogenous D-serine levels in the brain force us to reassess this assumption. Indeed in more rostral brain regions, the levels of D-serine are greater than those of glycine. In the current studies, we assessed the levels and metabolic sources of D-serine in neocortical synaptosomal preparations. Previous studies have demonstrated that CNS serine and glycine are synthesized *de novo* via the phosphorylated pathway, originating with phosphoglycerate. The rate-limiting step in the synthesis of serine is the hydrolysis of phosphoserine by phosphoserine phosphatase (EC 3.1.3.3). In our synaptosomal preparations we have demonstrated the uptake of L-phosphoserine and its hydrolysis to both L-serine and D-serine. These data indicate that racemization can occur during or subsequent to the hydrolysis of L-phosphoserine. Another potential route for the generation of D-serine involves the glycine cleavage system (EC 2.1.2.10). In this case, experiments involving precursor loading with excess glycine or [ $^{13}\text{C}$ ,  $^{15}\text{N}$ ]glycine also demonstrated conversion to both L-serine and D-serine. In conclusion, these studies demonstrate that there may be alternate pathways for the synthesis of D-serine by neocortical synaptosomes.

## 499.15

SELECTIVE, HIGH POTENCY INHIBITION OF CLONED KAINATE RECEPTORS BY SYM 2081. K.A. Jones\*, Z.O. Gu, J.R. Howe, K.A. Yamada, and A.M. Costa. Symphony Pharmaceuticals Inc., Malvern, PA; <sup>1</sup>Dept. Pharmacology, Yale University Sch. Med., New Haven, CT; <sup>2</sup>Depts. Neurology and Pediatrics, Washington University Sch. Med., St. Louis, MO.

Among the four diastereoisomers, (2S,4R)-4-methylglutamate (SYM 2081) displays  $10^3$  fold higher affinity for kainate (KA) compared to AMPA or NMDA receptors in brain membranes. Here we report the functional activity of SYM 2081 at cloned GluR6 receptors expressed in HEK293 cells. Whole-cell currents elicited by KA (100  $\mu\text{M}$ ) in voltage clamped cells expressing GluR6 were reversibly abolished by preapplications of 300 nM SYM 2081. The dose response relationship for 1 minute preapplications of SYM 2081 yielded an  $\text{IC}_{50}$  of 10 nM. In contrast, no inhibition of AMPA currents elicited by KA in primary cultures of rat neocortex was observed at doses up to 10  $\mu\text{M}$ . Rapid applications of  $\mu\text{M}$  concentrations of SYM 2081 to HEK293 cells expressing GluR6 receptors resulted in rapidly desensitizing KA-like currents. The KA-like behavior of SYM 2081 at high doses (>30  $\mu\text{M}$ ) was confirmed in cortical neurons that responded to the drug with non-desensitizing currents. We tested the possibility that receptor desensitization was responsible for the inhibitory effects of SYM 2081 by treating cells with concanavalin A (Con A). Whereas untreated cells produced no detectable current in response to rapid applications of 30 nM SYM 2081, Con A-treated cells responded with a slowly developing, non-desensitizing current. In addition, Con A prevented the inhibition of KA currents by SYM 2081. SYM 2081 thus appears to act as an inhibitor of KA channel function by inducing receptor desensitization at doses well below that which cause macroscopic channel activation. The unique properties of this compound make it ideal for studying the physiological roles of the KA class of glutamate receptors.

## 499.12

PEROXYNITRITE DOWN REGULATES NMDA RECEPTOR ACTIVITY IN RAT CORTICAL NEURONS. Stuart A. Lipton\*, Won-Ki Kim, Posina V. Rayudu, Mark E. Mullins, and Jonathan S. Stamler. Depts. of Neurology and Chemistry, Harvard Medical School and Harvard Univ., Boston, MA 02115; Dept. of Medicine, Duke Univ. Medical Center, Durham, NC 27710.

Peroxynitrite ( $\text{ONOO}^-$ ), formed by reaction of nitric oxide with superoxide anion, is a potent oxidant and neurotoxin (Lipton, Choi et al., Nature 1993). The role of peroxynitrite as a potential second messenger or regulatory agent, however, remains controversial. Peroxynitrite has been reported to oxidize sulfhydryl groups (Radi, Beckman et al. JBC 1991), and NMDA-evoked responses can be modulated by sulfhydryl redox agents (Aizenman, Lipton et al., Neuron 1989; Sullivan et al., Neuron 1994). Therefore, the present study was undertaken to determine if peroxynitrite, at very low concentrations, could modulate the activity of the NMDA receptor. Peroxynitrite, synthesized by stopped flow reaction kinetics, was rapidly applied to rat cortical neurons in culture while monitoring their NMDA-evoked calcium responses with digital imaging of fura-2 or whole-cell recording with patch electrodes. Peroxynitrite, at micromolar concentrations or less ( $t_{1/2} \approx 1$  s), decreased NMDA responses. The effect was reversed by subsequent exposure to the reducing agent dithiothreitol. Peroxynitrite did not further decrease NMDA responses of neurons previously treated with another sulfhydryl oxidizing agent 5,5'-dithio-bis-(2-nitrobenzoic acid). Moreover, peroxynitrite had no effect on NMDA receptors irreversibly alkylated with N-ethylmaleimide. These data indicate that peroxynitrite can reversibly downregulate NMDA receptor activity by oxidizing critical sulfhydryl groups comprising the redox modulatory sites of the NMDA receptor.

## 499.14

THE NON-COMPETITIVE NMDA ANTAGONIST ACTIVITY OF THE OPIOID AGONIST KETOBEMIDONE IS POTENTIATED BY THE SPASMOLYTIC AGENT (RS)-3-DIMETHYLAMINO-1,1-DIPHENYLBUT-1-ENE (A29). B. Ebert\* and S. Andersen. <sup>a</sup>PharmaBiotec Research Center, Department of Medicinal Chemistry, The Royal Danish School of Pharmacy, DK-2100 Copenhagen, Denmark; <sup>b</sup>Department of Anaesthesiology, Hvidovre University Hospital, DK-2650 Hvidovre, Denmark.

The opioid ketobemidone has previously been shown to be a non-competitive N-methyl-D-aspartate (NMDA) antagonist. Ketobemidone is in Scandinavia available in a formulation (Ketogan®) which contains ketobemidone and a spasmolytic agent (RS)-3-dimethylamino-1,1-diphenylbut-1-ene, hydrochloride (A29) in a one to five ratio. Lately, however, ketobemidone has been introduced in a sustained release formulation without the spasmolytic (Ketodur®). Clinical observations indicate that Ketogan® is more potent than Ketodur® on a mg to mg basis suggesting that A29 might potentiate the effects of ketobemidone. Using the rat cortical wedge preparation and receptor binding studies, we investigated whether the potentiation of ketobemidone by A29 was caused by an interaction with the NMDA receptor, other glutamate receptors, the  $\gamma$  aminobutyric acid (GABA)<sub>A</sub> receptor or the GABA uptake system. A29 inhibited synaptosomal GABA uptake ( $\text{IC}_{50}$  value  $180 \pm 26$   $\mu\text{M}$ ) and [ $^3\text{H}$ ]MK-801 binding ( $\text{K}_i$  value  $16 \pm 4.5$   $\mu\text{M}$ ), but was inactive in assays measuring affinities for other glutamate receptors and the GABA<sub>A</sub> receptor complex. In the rat cortical wedge preparation A29 was a non-competitive NMDA antagonist. The inhibitory effects of 20  $\mu\text{M}$  ketobemidone and 100  $\mu\text{M}$  A29 on responses to 10  $\mu\text{M}$  NMDA were additive. NMDA activity was completely abolished by 1 mM A29. These results suggest that the potentiating effect of A29 may be a consequence of a combined blockade of the NMDA receptor and the GABA uptake system.

Ketogan®, thus, seems to exert its analgesic actions *via* interaction with three different neurotransmitter systems, namely the opioid system, the NMDA receptor and the GABA uptake system.

## 499.16

GLUTAMATE-MODULATED VERSUS SPONTANEOUS  $\text{Ca}^{2+}$  OSCILLATIONS IN HIPPOCAMPAL GLIA. P.P. McCaslin\* and G. Hammond. Div. Res., Ochsner Med. Found., New Orleans, LA 70121.

Cytoplasmic  $\text{Ca}^{2+}$  oscillations occur in hippocampal glia as well as other cell types. Oscillations are induced by ligands which activate a large variety of G-protein-linked receptors including ATP, glutamate and 5-HT, and do not require the movement of extracellular  $\text{Ca}^{2+}$ . We report that oscillations in glia are modulated by G-protein-linked receptors, but light is an important component of the oscillations. In non-perfused buffer, spontaneous oscillations occur in >99% of cultures of hippocampal glia in the absence of exogenous receptor ligands. At a light intensity of 50  $\text{cd}/\text{m}^2$ , oscillations begin within 20 min and last about 90 min; after oscillations have stopped, increases and decreases in  $[\text{Ca}^{2+}]_i$  (but not  $\text{Ca}^{2+}$  oscillations) are nevertheless induced by agents such as ionomycin and cytidine, respectively. If 20  $\mu\text{M}$  glutamate is added to non-perfused buffer and cells are then exposed to light, regular oscillations begin almost immediately and continue for about 60 min; when a new, non-light-exposed region (but glutamate-exposed for 60 min) on the same slide is exposed to light, oscillations begin within 5 min and continue for 60 min with a similar oscillation pattern to the previous cells. Similar results occur a third and fourth time even though cells were exposed to glutamate for 120-180 min before light exposure. Moreover, glutamate-modulated oscillations display a different pattern from spontaneous oscillations which is best illustrated by the return maps of the time series. Interestingly, if cells are perfused for one hour under 50  $\text{cd}/\text{m}^2$  light, they do not oscillate (as opposed to the above non-perfused cells); furthermore, they do not oscillate when exposed to glutamate. However if glutamate is added after 5-15 minute of light exposure in perfused cells, oscillations do occur. Collectively, these results suggest that light induces the release of a mediator which is necessary for cytoplasmic  $\text{Ca}^{2+}$  oscillations in glia. Glutamate apparently modulates oscillations in conjunction with this mediator.

## 500.1

**THRESHOLD PROPERTIES OF OPERANT CONDITIONING IN *LYMNAEA*.** K. Lukowiak\*, P.M. Hermann and A.G.M. Bulloch. Neuroscience Research Group, University of Calgary, Calgary, AB, Canada, T2N 4N1.

Lung ventilation in the pond snail *Lymnaea stagnalis* occurs at the water surface by opening and closing the pneumostome. In a previous study it was shown that *Lymnaea*'s respiratory behavior can be operantly conditioned. The operant conditioning procedure consisted of stimulating the pneumostome area with a sharp wooden stick each time the animal attempted to open its pneumostome. In successive training sessions of an hour per day, the animals learned to avoid the stimulus by changing their behavior in frequency and performance. The present study was designed to investigate threshold properties of the previously described learning procedure. Different groups of animals were, therefore, subjected to different regimes of reinforcement. Animals which had two operant conditioning training sessions of 1/2 hour per day showed the same behavioral changes compared with animals which were trained for one period of an hour per day. However, one training session of 1/2 hour per day did not induce overt behavioral changes. It seems, therefore, that animals need a total of one hour of conditioning training period per day to exhibit associative learning behavior. At the moment our experiments are focused on the question of whether exposure to a subliminal training scheme (i.e. one session of 1/2 hour per day), or to stimuli that are not contingent with pneumostome opening (i.e. random stimulation), affect the ability to exhibit associative learning in the future (i.e. whether this desensitizes the animal). Our data suggest that animals which have received the subliminal training scheme differ from naive animals in their ability to be operantly conditioned. Supported by MRC (Canada).

## 500.3

**CONTEXTUAL BLOCKING IS A CENTRALLY MEDIATED PHENOMENON IN THE MARINE INVERTEBRATE, *HERMISSENDA***  
R.F. Rogers\*, J.A. Muzzio, A.C. Talk and L.D. Matzel

Department of Psychology, Rutgers University, New Brunswick, NJ 08903

Contextual blocking of a CS-US association was investigated behaviorally and neurophysiologically in the marine mollusc *Hermisenda*. As indexed by the development of a conditioned foot contraction to a light CS, it was found in two experiments that US (rotation) preexposure within a diffuse chemosensory context (shell fish extract) blocked subsequent learning about a CS (light) paired with the US in that context, but not in a second, neutral context. In a subpopulation of these animals, the membrane resistance across the B photoreceptor soma (a cellular correlate of the light-rotation association) was investigated electrophysiologically. Despite their differential responding at the behavioral level, an equivalent increase in membrane resistance was found in blocked, and paired control animals relative to unpaired controls. A third experiment investigated light-induced multi-unit activity in a pedal nerve known to convey motor information to the foot and thought to participate in the behavioral expression of the CS-US association. Consistent with their behavioral expression of the CS-US association, light-induced nerve activity in paired controls was suppressed relative to the unpaired animals. In contrast, no difference was found in light-induced nerve activity between behaviorally blocked animals and their unpaired controls, despite the associative increase in B cell excitability.

One hypothesis to account for these results is that the development of a context-US association in the preexposure phase results in plastic modifications within a network of centrally located interneurons known to receive information from all three sensory systems. The result of this plasticity is a biasing of this central network toward contextual stimuli, such that the behavioral expression of the light-rotation association is blocked.

## 500.5

**GENE TRANSFER OF OCTOPAMINE RECEPTOR THAT IS LINKED TO THE ADENYLYL CYCLASE INTO THE SENSORY NEURONS OF *APLYSIA*.** B-K. Kaang\*, X.-C. Li, Ctr. Neurobiol. & Behav., Columbia Univ., HHMI, NY, NY 10032; \*IMBG, Seoul Natl. Univ., Seoul, Korea.

Several processes are thought to contribute to the short-term synaptic facilitation produced by 5-HT, including membrane depolarization, an increase in the duration of the action potential, enhanced membrane excitability and enhanced neurotransmitter release. To further analyze the role of a second messenger cAMP in these processes, we used the ectopic gene transfer into the sensory neurons of the novel octopamine receptor that is coupled to adenylyl cyclase (Li et al., 1994, *Soc. Neurosci. Abstr.* 20:1160). Since the pleural sensory clusters do not seem to express the octopamine receptor endogenously, we overexpressed this receptor gene in the sensory neurons by the microinjection method using the green fluorescent protein (GFP) as a marker for gene expression. We then activated the expressed receptor by the application of octopamine thereby resulting in the production of cAMP in the sensory neurons. In control experiments, the expression of GFP itself did not seem to affect the physiology of cells including resting potential, input resistance, and the response to 5-HT. The treatment of octopamine produced the spike broadening ( $37.3 \pm 5.0\%$ ,  $N = 14$ ) as well as the increase in the membrane excitability (number of spikes =  $11.8 \pm 0.5$ ;  $N = 22$ ) in the sensory cells that expressed the *Aplysia* octopamine receptor, all of which were observed by the treatment of 5-HT to the control cells expressing the GFP protein alone ( $45.6 \pm 10.3\%$ ,  $N = 6$ ). The occlusion experiments showed that cAMP produced by octopamine alone was responsible for at least 73.9% of maximum spike broadening achieved by both octopamine and 5-HT together. Supported by HHMI and SNU Daewoo.

## 500.2

**BEHAVIORAL AND NEURAL CHARACTERISTICS OF CONDITIONED INHIBITION IN *Hermisenda*.** Gabrielle Britton and Joseph Farley\*, Program in Neural Science, Indiana University, Bloomington, IN 47405

Most studies of Pavlovian conditioning in model systems have focused upon the learning produced by conditioned excitation procedures, viz. pairings of CS and US. For *Hermisenda* (H.c.), pairings of light and rotation result in suppression of phototactic behavior. A second major category of associative learning, which has been conspicuously neglected in model systems research, is that of conditioned inhibition, i.e. the learning which results when a CS signals the absence of a US. We report that H.c. learn to approach a light that has been explicitly unpaired with rotation, i.e. their phototactic behavior is enhanced when light signals the absence of rotation. The behavior of H.c. in a light gradient was time-sampled over a ten min period in an underwater open-field. Two measures of phototactic behavior were computed: 1) the average distance from the center of the light gradient, 2) the change in the animal's orientation (with respect to light) from one sample period to the next. On retention days following 3 consecutive training sessions of explicitly-unpaired presentations of light and rotation, animals moved closer to (and were more likely to be oriented towards) the center of the light gradient. Animals exposed to equivalent numbers of random presentations of light and rotation, or no training at all, failed to show these changes. Intracellular recordings from synaptically-intact Type B photoreceptors indicated that explicitly-unpaired training produced a selective reduction in the amplitude of the light-evoked generator potential, as well as a decrease in action potential frequency. Our results demonstrate the occurrence of conditioned inhibition in an invertebrate model system in which cellular mechanisms of learning and memory can be studied, and further suggest that some of the cellular changes underlying conditioned excitation and inhibition are localized to the same cells (Type B photoreceptors) but are apparently encoded in opposite fashion (increases and decreases in excitability, respectively).

## 500.4

**INCREMENTAL TRANSLOCATION OF PROTEIN KINASE C UNDERLIES THE ACQUISITION CURVE DURING *IN VITRO* ASSOCIATIVE CONDITIONING**

I. A. Muzzio (\*), A. Talk, R. Rogers and L.D. Matzel

Department of Psychology, Rutgers University, New Brunswick, NJ 08903

An ubiquitous characteristic of learning is the improvement in performance observed over successive acquisition trials. This acquisition curve is presumably based in biophysical and biochemical alterations within the nervous system. In the isolated nervous system of the marine mollusc *Hermisenda*, an *in vitro* conditioning preparation was employed that is analogous to associative conditioning in the intact animal. Pairings of light (CS) with mechanical stimulation of the vestibular hair cells (US) resulted in an incremental change in the excitability of the photoreceptors. This increase became asymptotic within 3-5 training trials. A single pairing of light and rotation produced a small increase in excitability that dissipated over time. The incremental step function observed as a result of successive training was not obtained in the presence of NPC-15437, a selective inhibitor of protein kinase C (PKC), or if the stimuli presentation occurred in an unpaired fashion.

Colorimetric analysis of PKC in the cytosol and membrane components extracted from groups of isolated eyes indicated that while total PKC activity remains constant under different training conditions (0, 1, 3, or 5 pairings of light and rotation), successive training trials produce an incremental translocation of PKC from the cytosolic to membrane fractions, that like the increase in excitability, asymptotes within 5 trials. Artificial translocation of the kinase by phorbol ester produced a redistribution of PKC analogous to asymptotic training. Unpaired training produced no such translocation, nor did paired training in the presence of NPC-15437. These results suggest that redistribution of PKC may play an important role in the acquisition of new learning.

## 500.6

**EGG MASSES ARE A SIGN STIMULUS FOR RELEASE OF BAG CELL PEPTIDES AND REPRODUCTIVE BEHAVIOR IN *APLYSIA*.**

Valerie L. Begnoche, Earl Mayeri\*, and Samuel K. Moore. Dept. of Physiology, University of California, San Francisco, CA 94143-0444 USA.

Many behaviors associated with reproduction are instinctive, or genetically determined, and involve a fixed action pattern that is triggered by a highly specific stimulus in the environment, the sign stimulus. The sequence of neural events between the sign stimulus and expression of the fixed action pattern is in many cases poorly understood. One idea is that the sign stimulus leads to release of endogenous peptide neurotransmitters. To test this idea we observed spontaneous reproductive behavior in groups of *Aplysia* in a recirculating sea water aquarium. We found that contact by the mouth with an existing egg mass is a sign stimulus for release of egg laying behavior and two other fixed action patterns in the same individual, mating as a female during egg laying, and mating as a male after egg laying.

In animals where electrical activity from the CNS was recorded, contact with the egg mass initiated repetitive spike activity in bag cell neurons, which are part of a peptidergic neural system and are known from previous work to modulate neuronal activity in the CNS for up to several hours and to initiate spontaneous egg laying in isolated individuals. Thus, the egg mass is a sign stimulus that initiates the release of neuropeptides and this serves as an innate releasing mechanism for control of the fixed action patterns.

## 500.7

**VISUALLY GUIDED NAVIGATION IN THE GIANT TROPICAL ANT, *PARAPONERA CLAVATA*.** A.P. Baader\*, Zoologisches Institut der Universität, Winterthurer Str. 190, CH-8057 Zurich, Switzerland. Scouts of the ponerine ant, *Paraponera clavata*, forage many meters away from the nest. They travel over the foliage of the forest ground as well as up in the trees, thus occupying an immense three-dimensional space in rain forests of Central America. Pheromone trails, although known to be used during foraging, homing, and recruitment, provide only limited information for long-distance explorations in complex terrain. This study investigated the use of visual cues by *P. clavata* scouts during foraging and homing, with the goal of characterizing the coding properties of visual pathways within the central nervous system.

Behavioral field experiments revealed that information from both the top and the sides of the visual fields was essential for successful homing of foragers, even when initially laid chemical trails were still present during the tests. The ants were capable of finding their way back to the nest even after nearby landmarks and pheromone cues had been eliminated, presumably by using distant visual cues and/or canopy information. There was no indication of vector-based orientation. Scouts which were spotted during their extended foraging excursions and transferred to a different place homed successfully, although their visual surroundings at the release site were different from their original site. This indicates that the foragers utilized more complex visual strategies than can be explained by the most common navigation theories.

Intracellular recordings were performed on tethered ants walking on a freely movable treadmill while stimulated with various visual signals. The electrophysiological investigation aims at characterizing descending neuronal visual pathways in behaving animals. (The behavioral part of the project was carried out with Esther Denzler at the Biological Station of the Organization for Tropical Studies (OTS) in La Selva, Costa Rica. Partly funded by the Swiss National Science Foundation).

## 500.9

**cAMP INCREASES AT THE INJURY SITE IN APLYSIA NERVES** R.T. Ambron\*, D. Ambrou, X.-P. Zhang, M. Poyelones, Anatomy and Cell Biology, Columbia University, New York, NY 10032

Crush injury to a peripheral nerve causes the transport of protein sp97 to the cell body. Sp97 is one of several axonal proteins that have a nuclear localization signal, but it alone changes direction in response to crush.

Sp97 accumulates at a ligation located proximal to the crush site. When axoplasm extruded from the ligation site is injected into the soma of non-injured neurons, it induces many of the changes seen when the axons of these cells are crushed. Thus, sp97 has the properties expected of an injury signal (Ambron et al. *J. Neurosci.* 1995). What causes sp97 to change direction? Sp97 is phosphorylated at the crush site. Since PKA is present in Aplysia nerves, we asked whether cAMP levels are elevated in the axon after injury. Nerves p6-p9 of anesthetized animals were crushed and frozen 1 min later. The cm segment of nerve proximal to the crush and the next proximal cm segment were collected separately and assayed for cAMP. Control nerves were not crushed. As seen (fig.), cAMP levels were significantly

higher (Wilcoxon matched pairs test) at the crush site (distal) than in either control segment or in the proximal segment of the crushed nerve. Axoplasm extruded from the crush site had roughly half of the total cAMP in the segment. PKA activated by cAMP could phosphorylate sp97 and the catalytic subunit would be available for transport to the nucleus to phosphorylate the transcription factor CREB.

## 500.11

**MODULATION OF A  $\text{Na}^+/\text{K}^+$  ELECTROGENIC PUMP AS NEW MOLECULAR MECHANISM UNDERLYING NON-ASSOCIATIVE LEARNING PROCESSES IN INVERTEBRATES** M. Brunelli\*, R. Scuri, R. Mozzachiodi, M. L. Zaccardi and M. Lazzerini, Dept. of Physiology and Biochemistry "G. Moruzzi", University of Pisa, Italy.

Electrophysiological experiments performed onto T sensory neuron of the leech *Hirudo medicinalis*, have demonstrated that the after-hyperpolarization (AHP) which follows the electrical activation of this cell may be modulated during non-associative learning processes. The AHP is mainly due to the activity of a  $\text{Na}^+/\text{K}^+$  electrogenic pump and partly to a  $\text{gK}/\text{Ca}$ . Serotonin, acting through cAMP, reduces the AHP amplitude by inhibiting this  $\text{Na}^+/\text{K}^+$  pump (*J. Physiol.* 462: 229-242, 1993). More recently we have demonstrated that low rate intracellular stimulation (L.R.I.S.) of T cell produces after 15 stimuli a lasting increase of AHP amplitude. This effect is still present when the  $\text{gK}/\text{Ca}$  is blocked by 0.1 mM  $\text{CdCl}_2$ . 5  $\mu\text{M}$  NDGA or 25  $\mu\text{M}$  nifedipine application blocks the AHP potentiation as well as the inhibition of the pump by serotonin. On the contrary, it is still possible to obtain AHP increase after 5  $\mu\text{M}$  indometacin application. Our data demonstrate that the increase in AHP amplitude after L.R.I.S. is due to a potentiation of the  $\text{Na}^+/\text{K}^+$  pump, is triggered by voltage-dependent L-calcium channels and is mediated by lipoxygenase metabolites of arachidonic acid. The increase in AHP amplitude may provide an interesting cellular mechanism underlying the habituation: it might block the traffic of action potentials along the sensory fibers, thus decreasing the synaptic efficacy of T neuron. By utilizing the experimental model of swim induction we have demonstrated that the leeches subjected to repetitive tactile or electrical stimulation exhibit habituation; this reduction of the response to tactile stimulation disappears when either 50  $\mu\text{M}$  NDGA or 1 mM nifedipine is injected into the animals.

## 500.8

**GENETIC MODULATION OF *SHAKER* CHANNELS CHANGES THE SENSITIVITY OF THE CNS OF *DROSOPHILA* TO GENERAL ANESTHETICS.** M. Lin\* and H. A. Nash, Laboratory of Molecular Biology, NIMH, NIH, Bethesda, MD 20892

This laboratory has reported that some channel mutations influence the sensitivity of *Drosophila* to volatile general anesthetics in behavioral assays. In our present study we use electrophysiological recording from flight and jump muscles to monitor the response of a particular neural pathway when different stimulating voltages are applied across the eyes to the brain. We find that the more distal part of the pathway (from giant fiber through one or two neurons to muscle), represented by a short latency response ( $<3$  msec) to high voltage, is very insensitive to halothane. However, synaptic transmission in the fly brain upstream of the giant fiber, represented by a long latency response (4-6 msec) to lower voltage, is inhibited by clinical doses of halothane. When *Sh* and *eag* mutants are assayed, there is a good correlation between the published effect of the mutations on the peak amplitude of the A-type current in larval muscle and their effect on halothane sensitivity of the long latency response. Genetic tests, such as outcrossing and deficiency mapping, indicate that the phenotype of these strains is due to the corresponding mutation in the potassium channel genes. These results indicate that the A-type  $\text{K}^+$  channel in CNS is a target for general anesthetics or at least influences the target.

## 500.10

**AXOTOMY CAUSES LONG-TERM HYPEREXCITABILITY OF SINGLE APLYSIA SENSORY NEURONS IN CELL CULTURE.** A. Salim and D. L. Glanzman\*, Dept. of Physiological Science, UCLA, Los Angeles, CA 90024.

Walters and Ambron (1995) have suggested that the cellular signals which mediate long-term memory may converge with those which mediate the effects of axonal injury. This suggestion is based on investigations of the effects of nerve crush on the excitability of sensory neurons in *Aplysia* pleural ganglia (Walters et al., 1991; Gunstream et al., 1995). When tested hours-to-days after nerve crush, axotomized sensory neurons are significantly more excitable than control sensory neurons. Similar hyperexcitability of *Aplysia* sensory neurons has been observed 24 hr after repeated applications of 5-HT (Dale et al., 1987), a transmitter which mediates behavioral sensitization in *Aplysia*. A question raised by the nerve crush experiments is whether the injury-induced changes in the properties of the sensory neurons are a direct consequence of trauma suffered by the sensory axons. The changes might be due, at least in part, to modulatory factors released from non-sensory neurons whose axons also run in the crushed nerves, or to nonneuronal substances produced by tissue damage.

To determine whether the cellular changes in *Aplysia* sensory neurons produced by nerve crush are due to intrinsic or extrinsic signals, we examined the long-term effects of axotomy on the excitability of individual pleural sensory neurons in dissociated cell culture. All of the neurons had been in cell culture for 2 days at the start of the experiments. Sensory neurons were impaled with intracellular microelectrodes and injected with 2-sec pulses of varying levels of depolarizing current. We recorded the number of action potentials generated by each sensory neuron in response to the current pulses. Following the current injections, some of the sensory neurons were axotomized. Approximately 24 hr later, the sensory neurons were reimpaled and their excitability retested. The axotomized sensory neurons exhibited a significant increase in their excitability, whereas the control sensory neurons did not. These *in vitro* results establish that the cellular changes in sensory neurons observed after nerve crush are, in part, an intrinsic effect of damage of the sensory axons.

## 501.1

THE IMMEDIATE EARLY GENE CYCLOOXYGENASE-2 IS EXPRESSED IN CA1 NEURONS DESTINED FOR APOPTOTIC DEATH FOLLOWING GLOBAL ISCHEMIA. M. Nakayama\*, J. Chen, T. Lowry, T. Asakura, S.H. Graham, Dept. Neurology, Univ. of Pittsburgh, PA 15261 and Dept. Neurosurgery, Univ. of Kagoshima, Kagoshima, Japan

Cyclooxygenase (COX) may play an important role in normal brain functions as well as in the pathogenesis of neurodegenerative diseases. COX-2, the inducible form of COX, is an immediate early gene that is expressed in brain neurons in response to increased synaptic activity.

We studied the temporal profile of COX-2 expression in brains following global ischemia. Anesthetized rats were subjected to 15 min of 4 vessel occlusion and 2h, 4h, 8h, 24h, 48h, or 72h of reperfusion. Transcriptional expression of COX-2 was studied by *in situ* hybridization using a 35S-labeled oligonucleotide probe, and protein expression was studied by immunocytochemistry using a monoclonal antibody against COX-2. Results were compared with TUNEL staining at 24h and cresyl violet staining at 72h after ischemia respectively. Forebrain ischemia induced COX-2 expression in a similar pattern at both the mRNA and protein levels. COX-2 was transiently expressed in neurons throughout CA1-4, dentate, caudate putamen and superficial cortex at 2-8h. However, COX-2 was persistently expressed in majority of CA1 neurons at 24-48h where positive TUNEL staining indicative of apoptosis were also found. In contrast, the stress protein HSP72 was not expressed in CA1 at these times. COX-2 expression was completely lost at 72h when there was near complete death of CA1 neurons.

COX-2 could play an important role in the expression of excitotoxicity since Ca++ activates phospholipases which provide arachidonic acid substrate for COX and each molecule of AA metabolized by COX produces an oxygen free radical. The persistent expression of COX-2 preceding DNA damage and cell death in CA1 following global ischemia are consistent with the hypothesis that COX-2 activity may contribute to oxidative stress and subsequent apoptotic cell death.

## 501.3

TARGET DISRUPTION OF CuZn-SUPEROXIDE DISMUTASE GENE IN MICE CAUSES EXACERBATION OF CEREBRAL INFARCTION AND NEUROLOGICAL DEFICITS AFTER FOCAL CEREBRAL ISCHEMIA AND REPERFUSION. Kondo T.<sup>1</sup>, Reaume A.<sup>2</sup>, Huang T.T.<sup>3</sup>, Carlson E.<sup>3</sup>, Chen S.<sup>1</sup>, Scott R.<sup>2</sup>, Epstein C.J.<sup>3</sup>, Chan P.H.<sup>1</sup> (Department of Neurosurgery and Neurology<sup>1</sup>, Pediatrics<sup>3</sup>, University of California, San Francisco, CA94143 and Cephalon, Inc<sup>2</sup>, 145 Brandywine Parkway, West Chester, PA19380.)

Oxygen radicals are involved in the pathogenesis of infarction, edema and neurological deficits following cerebral ischemia and reperfusion. We have previously demonstrated that these brain injuries are significantly reduced in transgenic mice overexpressing human CuZn-superoxide dismutase (CuZn-SOD). In order to confirm further the beneficial role of CuZn-SOD in neuronal protection against ischemic insult, we employed two independent lines of heterozygous knockout mutant mice that were generated by targeted disruption or deletion of the mouse CuZn-SOD (Sod-1) gene. Heterozygous male Sod-1 knockout mutant mice and wild-type littermates (34±4 g) were identified by the activity of Sod-1 in red blood cells (0.73 vs. 1.60 unit / mg protein). These mice were subjected to middle cerebral artery occlusion (MCAO) and reperfusion by intraluminal suture blockade, plus ipsilateral common carotid artery occlusion. At 24 h after 60 min MCAO, the mice (n=9) were evaluated for neurological deficits prior to decapitation. To evaluate infarct volume, one group of fresh brain sections (2 mm) were stained with 2,3,5-triphenyltetrazolium chloride (n=3). In another group, the frozen brain sections (20 µm) were stained with cresyl violet (n=6). The mutant mice showed significantly greater neurological deficits (17.9 vs. 11.1, p<0.05) and larger infarct volume (88.5±10.3 mm<sup>3</sup> vs. 41.6±6.1 mm<sup>3</sup>, p<0.05) than the wild-type mice. There were no differences between the mutant and the wild-type animals in cerebral blood flow (rCBF), systemic blood pressure and arterial blood-gas analysis. These results indicate that reduction of Sod-1 activity exacerbates the tissue damage after ischemic reperfusion injury without affecting the physiological status, including rCBF. It is suggested that without an adequate level of Sod-1, the overaccumulation of superoxide anions is deleterious to the brain after ischemia and reperfusion. (Supported by NS-14543, NS-25372, AG-08938.)

## 501.5

AN ANTISENSE OLIGONUCLEOTIDE TO TNF- $\alpha$  mRNA INCREASES THE SIZE OF CEREBRAL INFARCTS IN THE RAT. Q. Zhai, N. Futrell\*, F. Chen, M.J. Paredes, Cerebrovascular Laboratory, Medical College of Ohio, Toledo, OH 43614

Both TNF- $\alpha$  mRNA and protein are upregulated following brain injuries of various types. Our laboratory has documented TNF- $\alpha$  mRNA within cerebral infarcts, from 2-12 hours (peak 6 hours) following middle cerebral artery occlusion (MCAO) in the rat. Astrocytes and neurons are positive for TNF- $\alpha$  by double-labeled immunoperoxidase. To study the role of TNF- $\alpha$  in tissue damage following cerebral infarction, we used an antisense oligonucleotide to rat TNF- $\alpha$  mRNA. Sixteen male Fisher rats, 8-9 weeks old, were used. Intraventricular injection of 40 µl (5 nmol) of antisense oligo was given to 8 animals, with controls given 40 µl (5 nmol) of sense oligo (n=4) or 40 µl of normal saline (n=4). MCAO was produced 16 hours later, using a craniotomy and cauterization of the MCA. Animals were sacrificed 24 hours later. Coronal microtome sections were cut at 400 µm intervals and stained with H&E. Infarct volume was measured by computerized image analysis. Mean infarct volumes were 22.06 ± 17.10 mm<sup>3</sup> for normal saline controls and 34.07 ± 14.50 mm<sup>3</sup> for sense controls. Three of 8 antisense treated animals died at 2-3 hours following injection, before MCAO was performed. Five surviving animals had MCAO with a mean infarct volume of 118.00 ± 13.61 mm<sup>3</sup> (p<0.05, ANOVA and Newman-Keuls test). The early death of some antisense animals suggests a physiological role of TNF- $\alpha$  in brain homeostasis. Factors potentially contributing to larger infarct size in antisense animals include: 1) a rebound up regulation of TNF- $\alpha$ , which may function as a neurotoxic factor, may have occurred as the quantity of antisense oligo decreased during the study period (40 hours from injection to sacrifice), or 2) a neuroprotective effect of TNF- $\alpha$  is possible within cerebral infarcts, as TNF- $\alpha$  can induce nerve growth factor and calbindin-D<sub>28k</sub>. Alternate injection times and doses are being studied. The effects of the antisense oligo on mRNA expression and on protein synthesis of TNF- $\alpha$  are under investigation using RT-PCR and Western Blot, to clarify the overall role of TNF- $\alpha$  in cerebral infarction in the rat.

## 501.2

UPREGULATION OF BAX PROTEIN LEVELS IN NEURONS FOLLOWING GLOBAL CEREBRAL ISCHEMIA. S. Kraiowski, J.K. Mai\*, M. Kraiowska, M. Sikorska\*, M.J. Mossaakowski, S.M. Park\* and J.C. Reed, La Jolla Cancer Res. Fnd., La Jolla, CA 92037, \*Univ. of Duesseeldorf, @National Res. Council of Canada, Ottawa and \*Med. Res. Center, Warsaw.

The patterns of expression of the *bcl-2*, *bax*, and *bcl-X* genes were examined immunohistochemically in neurons of the adult rat brain before and after 10 min. of global ischemia induced by transient cardiac arrest. High levels of the cell death promoting protein Bax and concomitant low levels of the apoptosis-blocking protein Bcl-2 were found in some population of neurons that are particularly sensitive to cell death after ischemic incidence, such as CA1 sector of the hippocampus and Purkinje cells of the cerebellum. Moreover, within 0.5 to 3 hrs after cardiac arrest, immunostaining for Bax was markedly increased in neurons with morphological features of degeneration in many regions of the brain. Use of a two-color staining method for simultaneous analysis of Bax protein and *in situ* detection of DNA-strand breaks revealed high levels of Bax immunoreactivity in many neurons undergoing apoptosis. Post-ischemic elevations in Bax protein levels in the hippocampus, cerebral cortex and cerebellum were also demonstrated by immunoblotting. At early times after transient ischemia, regulation of Bcl-2 and Bcl-X protein levels varied among neuronal subpopulation, but from 3 hrs on, those neurons with morphological evidence of degeneration uniformly contained reduced levels of Bcl-2 and particularly Bcl-X immunoreactivity. The findings suggest that differential expression of some members of the Bcl-2 gene family may play an important role in determining the relative sensitivity of neuronal subpopulations to ischemia and that post-ischemic alterations in the expression of the *bax*, *bcl-2*, and *bcl-X* may contribute to the delayed neuronal cell death that occurs during reperfusion phase after a transient ischemic episode.

## 501.4

CEREBRAL INFARCTION IS EXACERBATED IN MITOCHONDRIAL MANGANESE SUPEROXIDE DISMUTASE (Sod-2) KNOCKOUT MUTANT MICE AFTER FOCAL CEREBRAL ISCHEMIA AND REPERFUSION. Mikawa, S.<sup>1</sup>, Li Y.<sup>1</sup>, Huang T.T.<sup>3</sup>, Carlson E.<sup>3</sup>, Chen S.<sup>1</sup>, Kondo T.<sup>1</sup>, Murakami K.<sup>1</sup>, Epstein C.J.<sup>3</sup>, Chan P.H.<sup>1,2</sup> Departments of Neurosurgery,<sup>1</sup> Neurology,<sup>2</sup> and Pediatrics,<sup>3</sup> University of California, San Francisco, CA 94143

Oxygen radicals have been shown to be involved in the development of cerebral infarction following cerebral ischemia and reperfusion in various experimental animal models. We have previously demonstrated that infarct volume, blood brain barrier breakdown, vasogenic edema and neurological deficits are significantly reduced in transgenic mice overexpressing CuZn-superoxide dismutase (Sod-1). Since mitochondria are known to be the site for oxygen radical formation during reperfusion, we sought to elucidate the role of manganese superoxide dismutase (Mn-SOD), a mitochondrial-specific antioxidant enzyme, in ischemic infarction. Targeted disruption of manganese superoxide dismutase gene (Sod-2) in mice by homologous recombination has been successfully achieved in our laboratory. The Sod-2 knockout animal (Sod-2<sup>mlucsf</sup>) contains the mutant gene as demonstrated by PCR and RT-PCR and by the enzymatic assays. The heterozygous mice were subjected to 30 minutes focal cerebral ischemia using intraluminal suture to block the middle cerebral artery and followed by 24 hr. reperfusion. There were no significant differences between the mutant and wild-type littermates in physiological parameters (pH, PCO<sub>2</sub>, PO<sub>2</sub> and MABP) before, during and after the onset of ischemia. However, infarct volume was significantly increased in mutant as compared to wild-type animals. Furthermore, mutant animals exhibited a greater severity in neurological deficit scores than those of the wild-type mice. These data suggest that deficiency in mitochondrial defense against oxidative stress in mutant mice results in exacerbation of ischemic infarction. Supported by NS 14543, NS 25372, and AG 08938.

## 501.6

Ischemia Increases Cyclin-dependent Kinase 5 Activity in Gerbil Brain. S.L. Green\*, and P.R. Vulliet, Dept. Molecular Biosciences, UC-Davis School of Vet. Med., Davis, CA 95616

Cyclin-dependent kinase 5 (CDK5) is the catalytic subunit of a recently characterized neuronal cdc2-like protein kinase. It may regulate the cytoskeleton rather than cell cycle control. We have examined the effects of transient global ischemia and reperfusion on CDK5 activity in gerbil brain. Activity increased by 2 to 5-fold in the cytosolic and particulate fractions in the hippocampus and neocortex after 5, 15, and 30 min reperfusion. There was a marked decline in activity after 2 hrs, followed by a return to control levels after 2 days. On western blot analysis, CDK5 immunoreactive bands increased in intensity at the time points in which an increase in activity was observed. There was no change in immunostaining of the hippocampus and neocortex early after ischemia. Loss of staining occurred after 2 days. This data suggests that CDK5 is altered following brain ischemia and may play a role in neuronal response to injury.

## 501.7

ASTROCYTE GLUTAMATE RELEASE UNDER "ISCHEMIC" CONDITIONS  
B.A. Swanson, and M.C. Longuemare, Dept. of Neurology, VAMC and University of California, San Francisco, CA 94121

Extracellular glutamate accumulation during cerebral ischemia results from both synaptic and non-synaptic glutamate release. Some studies, using animal models of stroke, suggest non-synaptic release of glutamate to be the major source, while other studies have found non-synaptic release to be minimal. We propose that these disparities may stem from differences in the metabolic disturbances caused by different ischemic models (e.g. complete vs. incomplete ischemia). This was tested using primary rat astrocyte cultures devoid of neurons. The cultures were exposed to metabolic stresses that occur during ischemia: glucose deprivation, oxygen deprivation, acidosis, and elevated potassium concentrations. Glutamate efflux was assessed by HPLC determinations of the culture media and by efflux of pre-loaded  $^3\text{H}$  D-aspartate (D-ASP). Potential routes of non-synaptic release were assessed by pre-loading the cells with specific inhibitors of glutamate transport pathways. Hypoxia caused modest (20-40%) reductions in ATP and did not cause glutamate release.  $1\text{K}^+$  up to  $60\text{mM}$  also failed to provoke glutamate release. Hypoxia plus glucose deprivation reduced ATP to below 25% of controls and caused a 10-fold increase in glutamate release. Release under these conditions was markedly reduced by pre-loading the cells with compounds that specifically block  $\text{Na}^+$ -dependent glutamate transport (TBHA or PDC). This reduction was more complete for D-ASP efflux than for glutamate efflux. These findings suggest (1) that residual glucose delivery, as occurs during incomplete ischemia, may prevent non-synaptic glutamate release; (2) that glutamate release from astrocytes during energy failure occurs primarily via reversal of  $\text{Na}^+$ -dependent uptake, and (3) that D-ASP transport does not always mimic glutamate transport.

## 501.9

EFFECT OF HYPOXIA ON ISCHEMIC AND NON-ISCHEMIC BRAIN.  
R.N. Auer and O. Miyamoto, Department of Pathology, University of Calgary, Calgary, AB T2N 4N1, Canada and Departments of Basic Sports Medicine and Anatomy, Kagawa Medical School, Kagawa, Japan.

The aim of these experiments was to study the potential of hypoxic hypoxia (i.e. hypoxia produced by lowering inspired oxygen content) in causing brain necrosis, with or without ischemia. Male Wistar rats were ventilated and in the first (hypoxia only,  $n=13$ ) group, arterial  $\text{pO}_2$  was decreased to  $25\text{ mm Hg}$  by lowering the oxygen content in the inspired gas mixture. When mean arterial blood pressure (MABP) spontaneously fell to  $30\text{ mm Hg}$ , the oxygen content was adjusted to keep MABP at  $30\text{ mm Hg}$  for 15 min. In a second (ischemia only,  $n=13$ ) group, MABP was decreased to  $30\text{ mm Hg}$  and kept there for 15 min by withdrawal or reinfusion of blood after ligation of right common carotid artery (CCA). In a third (hypoxia plus ischemia,  $n=9$ ) group, after ligation of the right CCA, MABP and  $\text{pO}_2$  were lowered to  $30$  and  $25\text{ mm Hg}$  respectively. To further study the contribution of hypoxia and hypotension, additional groups ( $n=57$ ) varied  $\text{pO}_2$  and MABP systematically in animals with unilateral carotid occlusion. Pathological examination was performed one week after the experiments.

Neuronal necrosis was absent in the hypoxia only group. Caudate and hippocampal necrosis was seen in all ischemia plus hypoxia groups. Subsequent groups showed that this depended on both MABP and  $\text{pO}_2$ . At a fixed MABP of  $30\text{ mm Hg}$ , hypoxia led to brain necrosis in 33%, 66%, 60% and 100% of animals at  $\text{pO}_2$  of  $>100$ , 45, 35 and  $25\text{ mm Hg}$  respectively. At a fixed  $\text{pO}_2$  of  $25\text{ mm Hg}$ , 20%, 60%, 88%, 78% and 100% of animals showed cerebral necrosis at MABP's of 70, 60, 50, 40, and  $30\text{ mm Hg}$  respectively. These results suggest that hypoxia augments brain damage when cerebral blood flow is impaired, but in the absence of arterial occlusion is incapable of causing brain damage by itself, even with lowering of the BP to  $30\text{ mm Hg}$  in the rat.

## 501.11

CHANGES IN PHOSPHORYLATION OF TAU INDUCED BY ISCHEMIA AND REPERFUSION.  
D.A. Shackelford, R.Y. Yeh, and J.A. Zivin, Dept. of Neurosciences, UCSD, La Jolla, CA 92093-0624.

The microtubule-associated protein tau plays an important role in the dynamics of microtubule assembly necessary for axonal growth and function. In this study the effect of ischemia and reperfusion on the expression and phosphorylation of tau was examined. Using a reversible model of spinal cord ischemia in rabbits, tau was found to be dephosphorylated in response to ischemia with a time course that closely matched the production of permanent paraplegia. Dephosphorylation of tau was observed only in the caudal lumbar spinal cord that is defined as ischemic by blood flow measurements. Similarly  $\text{Ca}^{2+}$ /calmodulin-dependent kinase II activity was reduced only in the caudal lumbar region. Thus dephosphorylation of tau and loss of  $\text{Ca}^{2+}$ /calmodulin-dependent kinase II activity are early markers of ischemia. Tau, however, was rapidly rephosphorylated during reperfusion, at site(s) that cause a reduction in its electrophoretic mobility, regardless of the neurological outcome. Changes in tau phosphorylation were monitored using both the phosphate-sensitive antibody Tau-1 and the phosphate-insensitive antibodies T14 and SE2. The observed dephosphorylation of tau during ischemia and its rephosphorylation during reperfusion were confirmed using a rat model of global cerebral ischemia. The activities of kinases that may phosphorylate tau during reperfusion is currently being investigated. Alterations in tau phosphorylation or degradation may affect microtubule stability, possibly contributing to disruption of axonal transport but also facilitating neurite regeneration.

## 501.8

MECHANISMS OF ACIDOSIS-INDUCED ASTROCYTE DEATH. B.A. Stein, K. Farrell, and B.A. Swanson, Dept. of Neurology, VAMC and University of California, San Francisco, 94121.

Rat cortical astrocyte cultures were employed to study the factors causing astrocyte death under conditions simulating incomplete cerebral ischemia. These conditions are characterized in part by acidosis accompanied by hypoxia and variably increased  $\text{K}^+$ . Astrocyte cultures were subjected to these conditions alone or in combination for periods of 2-6 hours and survival was assessed 24 hours later by measuring LDH activity in cell lysates. Astrocytes under normoxic conditions were resistant to acidosis injury over the range of pH 7.2 to pH 6.2. Hypoxia, produced either by  $\text{O}_2$  deprivation, azide, or antimycin A, similarly caused no cell death with exposures of up to 8 hours. Astrocyte sensitivity to acidosis was, however, markedly accentuated by hypoxia, with 4 hours at pH 6.2 killing 60-80% of the cells. Evaluation with the pH-sensitive fluorescent probe BCECF showed that hypoxia impaired intracellular pH regulation during acidosis, with  $\text{pH}_i$  in the presence of azide falling to values 0.5 to 1.0 pH unit below those reached in the absence of azide. The changes in  $\text{pH}_i$  were paralleled by reductions in glycolytic rate and ATP content.  $^3\text{H}$  2-deoxyglucose accumulation showed glycolytic rate during hypoxia at pH 6.2 plus to be only  $28 \pm 8\%$  of controls. ATP content fell to  $63 \pm 8\%$  of control after 30 minutes of hypoxia at pH 7.2 and to  $28.1 \pm 9\%$  at pH 6.2. The ATP depletion preceded irreversible cell injury by several hours, suggesting a causative role for energy failure. Both glycolytic rate and cell survival were increased in media containing  $40\text{mM K}^+$ . These findings suggest that the cause of astrocyte death under conditions of incomplete ischemia is energy failure resulting from intracellular acidosis impairing glycolytic production of ATP.

## 501.10

INDUCTION OF VASCULAR ENDOTHELIAL GROWTH FACTOR PROTEIN EXPRESSION BY TRANSIENT CEREBRAL ISCHEMIA IN RAT BRAIN. F.Y. Sun, W.L. Bao, W. Ni, and S.D. Shi, Dept. of Neurobiology, Shanghai Medical Univ., Shanghai, 200032, China.

Vascular endothelial growth factor (VEGF) expression in retina, heart and glial tumor can be upregulated by hypoxia or ischemia. To investigate possible role of VEGF in cerebral ischemia, immunohistochemical study was used to detect the induction of VEGF protein expression in the brain by a transient cerebral middle artery occlusion. In the present study, we observed that VEGF-like positive immunostain cells were widely expressed in rat brain. Highest density of VEGF-like positive immunostain cell in the brain was mainly located in superoptic and lateral dorsal septal nucleolus, caudate putamen and medium density, in thalamus, hypothalamus, molecular layer of cerebral cortex and pyramidal layer of hippocampus. The number of VEGF-like positive immunostain cell was dramatically and time-dependently increased in pyramidal layer of cerebral cortex and molecular layer of hippocampus after cerebral ischemia.

The results suggest that VEGF may play a role in the neuronal function and participate in the pathophysiological process after brain ischemia.

## 501.12

REDOX EFFECTS ON NO-MEDIATED POSTEXCITOTOXIC INJURY IN HIPPOCAMPAL SLICES. C.G. Wasterlain, D. Henry, R.A. Baldwin, VAMC, Sepulveda, CA91343-2099, dpt of Neurology and Brain Research Institute, UCLA School of Medicine

Transient exposure of hippocampal slices to high concentrations of excitatory amino acids (EAA) or to hypoxia is followed by a lasting increase in the rate of EAA release and of opening of NMDA receptor-gated ionic channels (NMDArc). These changes may play a role in the amplification phase of excitotoxic or hypoxic injury. We studied their mechanism by measuring EAA release by reverse phase HPLC and NMDArc opening by  $^3\text{H}$ -MK801 binding, 30 min. after a transient (5 min) exposure to  $10\text{ mM}$  glutamate+glycine.

Postexcitotoxic perfusion with  $100\mu\text{M}$  nitroarginine (NA) inhibited both EAA release and NMDArc opening. This was reversed by  $1\text{ mM}$  L-arginine but not by D-arginine, suggesting that it required NO synthesis. It was reduced by the free radical scavengers U74389G and SOD+catalase, but unaffected by  $8\text{br-cGMP}$ , methylene blue or by ADP ribosylation inhibitors. Sodium nitroprusside ( $500\mu\text{M}$ ) exposure mimicked the effects on NMDArc opening; this was increased by the reducing agent cysteine ( $1\text{mM}$ ) and reversed by SOD+catalase, suggesting mediation by  $\text{NO}^{\cdot}$  and/or peroxynitrite.

These results suggest that free radicals such as NO play an important role in this model of postexcitotoxic hippocampal injury. Supported by VHA research serv. and by grant NS13515 from NINDS

## 502.1

**EYE MOVEMENT DISORDERS AFTER PREFRONTAL CORTEX LESIONS IN HUMANS.** C. Pierrot-Deseilligny\*, R.M. Müri, S. Rivaud and B. Gaymard. INSERM 289, Hôpital de la Salpêtrière, 47 bd de l'Hôpital, 75651 Paris Cedex 13, France.

Eye movements were recorded electro-oculographically in 3 patients with a small ischemic lesion affecting the left dorsolateral prefrontal cortex (PFC), i.e. area 46 of Brodmann, and 10 control subjects. The frontal eye field was spared. Reflexive visually guided saccades (gap and overlap tasks), antisaccades, several paradigms of predictive saccades, memory-guided saccades, double-step saccades, sequences of memory-guided saccades (using 4 successively presented visual targets, which remained illuminated) and smooth pursuit were studied. In patients, latency was slightly shorter in the gap task (with more express saccades) and slightly longer in the overlap task, compared to controls. The difference between latencies in the overlap and gap tasks was greater in patients (contralaterally to the lesion), compared to controls. Saccades accuracy was normal in both tasks. The percentage of errors in the antisaccade task was significantly increased, bilaterally. For memory-guided saccades, latency (bilaterally) and the percentage of error in amplitude (contralaterally) were significantly increased. The chronological order of saccades in memory-guided saccade sequences and accuracy of double-step saccades (i.e. the first and second saccades) were normal. Smooth pursuit was also normal. These results suggest, for the first time in the same patients, that the PFC is involved in disengagement from fixation, inhibition of unwanted reflexive visually guided saccades, triggering of predictive saccades, and spatial working memory controlling saccades. In contrast, the PFC does not appear to be involved in temporal working memory controlling memory-guided saccade sequences, in double-step saccade control and smooth pursuit. Therefore, the PFC, which controls different types of cognitive mechanisms preparing saccades, could play a major role in human ocular motor behavior.

## 502.3

**EFFECTS OF FEATURE EXPECTANCY ON TARGET SELECTION IN MACAQUE FRONTAL EYE FIELD.** N.P. Bichot\*, K.G. Thompson & J.D. Schall. Department of Psychology, Vanderbilt University, Nashville, TN 37240

We have found that the initial visual responses of frontal eye field (FEF) neurons do not discriminate the target from distractors in the receptive field during visual search for a salient stimulus (e.g., red target among green distractors or green target among red distractors) (Schall & Hanes, 1993). In subsequent work with a monkey trained only to make a saccade to a red target among green distractors, we found that the initial visual response of a significant proportion of subcortical visuomotor neurons discriminated the red target from a green distractor in the receptive field (Schall & Thompson, 1994 *Soc Neuro Abstr*).

We now report findings from FEF of that monkey. Neurons with visual activity were recorded in the FEF of the monkey performing the search for a red target. When presented a search array with a green target among red distractors, the monkey never fixated the green target but instead directed gaze to the red distractors. A one-way ANOVA of the initial visual response of FEF cells during search trials indicated significant variation in a higher fraction of cells compared to the previous data. The timecourse of the selection decision was estimated by comparing spike density functions, constructed by convolving spike trains with a growth-decay pulse ( $\tau_{\text{growth}} = 1$  ms,  $\tau_{\text{decay}} = 20$  ms), across trials when the target or distractors were in the response field. For the cells showing significant variation of the initial visual response, the visual response latency averaged 95 ms, and the decision latency averaged 15 ms after the visual response began. For the cells showing no variation of initial visual response to the search display, the visual response latency averaged 65 ms, and the decision latency averaged 60 ms. These data indicate that neurons with later visual response latencies may be subject to more extraretinal modulation. (Supported by F32-EY06495, McDonnell-Pew and R01-EY08890)

**DISCHARGE OF SUPERIOR COLLICULUS FIXATION CELLS DURING GAZE SHIFTS IN THE HEAD-FREE CAT.** D. Guitton\* and H. Jiang. Montreal Neurological Institute and McGill University, Montreal, Quebec, Canada, H3A 2B4.

The tonic discharge of fixation cells (FCs) in the rostral superior colliculus (SC) may suppress gaze shifts initiated by the motor map. FCs tend to pause during gaze shifts; we studied how pauses are initiated and terminated. Cats faced an opaque barrier of variable width, and generated horizontal gaze shifts in response to a hidden food target that suddenly appeared on one side. Ambient light could be turned off 100 ms after target appearance. In some gaze shifts, head motion (hence gaze motion) was mechanically stopped for brief periods. **RESULTS: Ipsilateral gaze shifts:** FCs pause in light and dark. Activity is gradually reactivated as gaze approaches final desired position - with a burst at gaze end - irrespective of whether the overall displacement is made in a single step or a staircase series of multiple-steps. In the latter movements a few FCs discharge weakly during intersaccadic plateaus. Activity peaks at final position and then decreases to a lower level. FCs maintain their pause in light and dark during perturbed gaze shifts and are reactivated at gaze end, as in normal movements: i.e. head brakes increase the duration of both gaze shifts and pauses. Gaze rapidly moves to target after brake release. **Contralateral gaze shifts:** FCs that burst before small (e.g. 2°) contralateral gaze shifts may reduce their frequency or briefly pause during large gaze shifts. Activity increases and peaks just before final position is reached. FCs recorded more rostrally do not burst before small contra-movements. In large contra-movements they pause; more like ipsi-movements. Results support the hypothesis that FCs are reactivated by feedback when gaze motor error approaches zero.

## 502.2

**SPATIAL WORKING MEMORY AND OCULOMOTOR CONTROL IN THE ELDERLY**

J.A. Sweeney\*, R.A. Berman. University of Pittsburgh School of Medicine, Pittsburgh PA 15213

The evaluation of saccadic eye movements provides a promising strategy for studying changes in motor and cognitive processes over the age span. In this study, we examined eye movement activity in groups of 32 young (18-34 yrs) and 21 elderly (65-80 yrs) healthy subjects. The accuracy of visually-guided saccades of the elderly subjects was comparable to that of younger subjects. However, peak eye velocity was reduced in the elderly subjects, particularly for larger eye movements, indicating a decline in basic motor processes that maintain the main sequence of saccades.

Antisaccade and oculomotor delayed response tasks were administered to assess the capacity for voluntary response suppression and spatial working memory. Initiation of saccades in these tasks, as in the visually-guided saccade task, was delayed in the older subjects. Elderly subjects made more antisaccade errors, indicating some loss in the ability to inhibit responses to compelling visual stimuli. The delayed saccade initiation and the reduced ability to intentionally suppress saccadic eye movements suggest an age-related decline in the functional integrity of frontostriatal circuitry. In contrast, the accuracy of memory-guided saccades of elderly subjects was preserved with delays up to 8 seconds. The maintained accuracy of visually- and memory-guided saccades indicates that elderly subjects can make accurate saccades to both sensory cues and remembered spatial locations. Therefore, the widely distributed dorsal cortical circuitry which holds spatial information on-line for delayed oculomotor responses may be relatively unaffected by normal aging processes.

## 502.4

**TIME-COURSE OF TARGET SELECTION IN MACAQUE FRONTAL EYE FIELD DURING VISUAL SEARCH.** K.G. Thompson\*, D.P. Hanes & J.D. Schall. Department of Psychology, Vanderbilt University, Nashville, TN 37240

We have shown that during visual search the initial visual responses of frontal eye field (FEF) cells do not discriminate the target from distractors. After this initial indecision, the activity evolves to signal the location of the target (Schall & Hanes *Nature* 366:467, 1993; Thompson, Hanes, Tu & Schall *Soc. Neurosci. Abstr.* 19:27, 1993). The purpose of this study was to determine accurately the visual activation latency of FEF neurons and to determine when neural activity in FEF shows evidence of the decision whether the stimulus in the receptive field is the target of the impending saccade.

The visual activation latency, determined by a Poisson spike train analysis (Hanes, Thompson & Schall *Exp. Brain Res.* 103:85, 1995), averaged 70 ms after target presentation (range: 40 - 130 ms). On average, visual response latencies did not differ either between search and detection trials or between search trials when the target or distractors were in the cells' receptive field. To estimate the evolution of the target location decision, spike density functions, constructed by convolving spike trains with a growth-decay pulse ( $\tau_{\text{growth}} = 1$  ms,  $\tau_{\text{decay}} = 20$  ms), were compared across trials when the target or distractors were in the response field. The two spike density functions diverged on average 110 ms after search array presentation, corresponding to 50-80 ms before saccade initiation. The decision time was statistically more related to the time of stimulus presentation than to the time of saccade initiation. For some cells, the decision time tended to be later in trials with longer saccade latencies, suggesting that saccade initiation was postponed by the target decision delay. (Supported by F32-EY06495, T32-EY07135, McDonnell-Pew and R01-EY08890)

## 502.6

**VISUO-MOTOR TRANSFORMATION DEFICITS AFTER INACTIVATION OF THE CAUDAL FASTIGIAL NUCLEUS IN THE HEAD-FREE CAT.** D. Pélisson\* and L. Goffart. Vision et Motricité, INSERM U94, 16 av Doyen Lépine, 69500 Bron, France.

Unilateral inactivation of the caudal Fastigial Nucleus (cFN) in the cat strongly alters the accuracy of visually-triggered gaze shifts: ipsiversive movements are hypermetric whereas contraversive movements are hypometric (Goffart & Pélisson, *J. Neurophysiol.*, 1994). Whereas the systematic overshoot of ipsiversive movements likely reflects a spatial bias in planning the impending movement, the significance of hypometric contraversive gaze shifts was not clear and was further investigated.

First, it will be shown that gaze main sequence relationships and eye-head coordination stay unchanged. Second, we will present the effects of perturbations, resulting from transient electrical stimulation of the Superior Colliculus (SC), on orienting gaze shifts towards visual targets. Collicular stimulation was a train of pulses (0.2 ms, 500 Hz) applied during either the latency or the execution of the gaze shift. During the control session, gaze landed ultimately very close to the target, irrespective of whether the stimulation was applied during the latency or the movement period. In contrast, after muscimol injection in the cFN, contraversive gaze shifts were hypometric but ended at locations that depended on the stimulation period. When the SC was stimulated during the on-going movement, gaze landed at approximately the same spatial location as when no perturbation occurred. When applied during the reaction time, the stimulation led to a larger gaze inaccuracy; in fact, the position reached by these compensatory responses corresponded to the endpoint of unperturbed gaze shifts starting from the same position.

These data suggest that gaze hypometria induced by cFN inactivation does not result from deficits in processes that control the on-going movement but rather result from a disturbance in the processes that specify, during movement preparation, a desired gaze displacement command that will drive the movement generators.

## 502.7

SACCADIC ADAPTATION DEFICITS AFTER MUSCIMOL INACTIVATION OF THE CAUDAL FASTIGIAL NUCLEUS IN MACAQUE. F.R. Robinson\*, Albert Fuchs, and Andreas Straube.

Department of Physiology and Biophysics, University of Washington, Seattle, WA 98195 and Abteilung Neurologie, Klinikum Grosshadern, University of Munich, 8000 Munich 70, Germany

Saccade-related discharge of neurons in the caudal fastigial nucleus (CFN) of the monkey cerebellum helps assure saccade speed, accuracy and consistency. We show here that CFN activity also is necessary for adapting saccade gain to compensate for neuronal damage that makes saccades the wrong size. To simulate such damage by behavioral means, we jump the target backward as the monkey makes a targeting saccade. The initially overshooting saccade gradually decreases in size until after about 1000 trials, the saccadic gain (saccade amplitude/initial target amplitude) has decreased by an amount proportional to the backward step.

After we inactivate one CFN with the GABA<sub>A</sub> agonist muscimol, the monkey no longer can adapt its saccadic gain. For example, in one monkey an injection made ipsilateral saccades too big (avg. gain=1.87) and contralateral saccades too small (avg. gain=0.63). After 2200 saccades, these gains had changed little (ipsi gain=2.07, contra gain=0.73).

CFN inactivation blocks adaptation, not just expression of the gain change. If, after the above experiment, the monkey spends 20 hrs in the dark, the muscimol dissipates without the monkey making visually guided saccades to affect whatever adaptation that had occurred. Saccade gain retruns to normal (~1.0) after the drug dissipates so there is no evidence that the gain had adapted. We know that if gain had adapted covertly under the influence of muscimol the change would be evident after 20hrs in the dark because an uninjected animal retains gain adaptation after 20 hrs in the dark. ## 502.9

SHIFTS OF ATTENTION CHANGE THE SACCADES EVOKED BY STIMULATION OF THE MACAQUE SUPERIOR COLLICULUS Alexander A. Kustov\* and David Lee Robinson. Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

There has been considerable interest in the relationship of attentional shifts and visually guided saccadic eye movements. Some have argued that they are independent whereas others propose that attentional shifts accompany all visually guided saccades. The aim of the present experiments was to test the premotor theory of attention which claims the same mechanisms are involved in overt and covert orienting. The study was conducted in two monkeys trained to make saccadic eye movements and in two attentional tasks. Central and peripheral cues were used to direct the monkeys' attention to the location at which a visual target was most likely to appear (80% valid cues). The target onset was delayed for random times between 0 and 500 msec after the onset of the cue (cue-target-onset-asynchrony, CTOA).

We electrically stimulated the superior colliculus during the CTOA at twice threshold with trains of 40 msec. Stimulation during fixation always evoked fixed vector saccades. When the identical stimulation was applied before the monkey initiated a visually guided saccade, there was a shift of the evoked saccade towards the direction of the target. Similar effects were induced during the peripherally cued attention task as well as the centrally cued attention task. The stimulation evoked saccades deviated further from the fixed vector saccades as the stimulation was applied later within the CTOA. These time courses were similar to the changes in saccadic reaction times of the visually guided saccades in the two cuing tasks. These observations help to explain the effectiveness of cues in various psychological attentional experiments. The data also suggest that the superior colliculus mediates components of attentional shifts.

## 502.11

DIRECTIONAL EFFECTS OF EXTRAOCULAR MUSCLE AFFERENT SIGNALS ON SINGLE UNIT VISUAL RESPONSES IN THE OPTIC TECTUM OF THE PIGEON. Paul C. Knox (SPON: Brain Research Association) Centre for Neuroscience, University of Edinburgh, Crichton St., Edinburgh EH8 9LE

The role of afferent signals from the extraocular muscles (EOM) in both the oculomotor and visual systems remains unclear. However, having recently shown that EOM afferent signals are involved in both the vestibulo-ocular and vestibulo-colic reflexes, and therefore in the control of gaze, these present experiments were designed to investigate interactions between EOM afferent signals and visual signals in the superficial layers of the avian optic tectum (OT).

Adult pigeons were decerebrated under ether anaesthesia and paralysed with gallamine. Extracellular single unit visual responses were recorded from the superficial layers of the left OT with glass-coated tungsten microelectrodes. Visual stimuli were projected to the right eye. EOM afferent signals were induced by moving the left eye passively (PEM) by means of a suction contact lens. In initial experiments, in which the visual stimulus was always a horizontal bar moving vertically up through the visual receptive field, the visual responses of 33 of 56 single units (59%) were significantly modified (usually inhibited) by PEM. PEM in the horizontal plane produced the greatest modification of the visual responses of 21 (64%) of these 33 units. In subsequent experiments, the visual directional preference of a unit was first established, and then this direction of visual stimulus movement was combined with different directions of PEM. Of 27 units which responded best to a visual stimulus consisting of a horizontal bar moving vertically down, 23 (85%) preferred PEM with a horizontal component, only 4 preferred vertical PEM.

These results confirm that an EOM afferent signal reaches the superficial layers of the optic tectum in the pigeon and suggest that there is a relationship between the visual directional preference of a unit, and the direction of PEM which has the largest effect.

## 502.8

THE SUPERIOR COLLICULUS OF THE MACAQUE PRODUCES INDEPENDENT FUNCTIONAL CHANNELS FOR HEAD AND EYE MOVEMENTS Robert J. Cowie\* and David Lee Robinson. Department of Anatomy, Howard University, Washington, DC, and Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

Numerous studies have suggested that the superior colliculus provides a gaze signal for the combined movements of the head and eyes. Such a model suggests that an individual neuron has identifiable bursts for the head and eyes or that a single burst produces tightly coupled movements of the head and eyes. To test this hypothesis of a single gaze signal, we have electrically stimulated the superior colliculi of two monkeys, free to make head and eye movements. We made many penetrations normal to the collicular surface extending from the dorsal aspect through the deepest laminae and measured the threshold current for evoking eye movements and head movements. These two values varied as the penetration descended but the head and eye thresholds did not vary together, as might be expected if a single gaze signal were organized here. Furthermore, the individual head thresholds and eye thresholds did not have a systematic relationship. Also, at individual sites we stimulated using currents more than twice threshold for the head or eye movement. At one type of site we observed that latencies, amplitudes, and peak velocities for eye movements were very regular whereas the same stimuli evoked head movements of high variability. At other sites the latencies, amplitudes, and peak velocities of the head movements were relatively constant while those properties of the eye movements were quite variable. We conclude from these data that the colliculus of the monkey does not produce a single gaze signal but has separate channels for accessing head and eye premotor systems.

## 502.10

EVIDENCE FOR A CARTESIAN MODEL FOR THE GENERATION OF OBLIQUE SACCADES IN HUMANS K.G. Rottach, R.D. v Maydell, V.E. Das, A.Z. Zivotofsky, A.O. DiScenna, J.L. Gordon, D.M. Landis, L.F. Dell'Osso\*, R.J. Leigh Ocular Motor Lab., VA medical center and Case Western Reserve Univ., Cleveland, OH 44106

We measured horizontal, vertical, and oblique eye movements of three sisters with Niemann-Pick type C disease that caused a selective defect of vertical saccades, which were slow and hypometric. Horizontal saccades, smooth pursuit and vestibular eye movements in both planes were similar to control subjects. The defect was investigated further by examining the dynamic properties of oblique movements from primary to tertiary eye positions. The saccadic trajectory was strongly curved. The initial saccadic movement was mainly horizontal and most of the vertical component was achieved after the eye had completed the horizontal part; during this time the eye oscillated horizontally with a frequency of 10 to 17 Hz and an amplitude of 0.2 to 1.5 deg until the vertical component ended. In contrast, the onset of smooth pursuit with oblique step-ramp stimuli was characterized by a nearly-oblique movement; in some cases, the vertical component had a larger velocity than the horizontal - presumably representing an attempt to compensate for the saccadic defect. Using the model of Zee et al. (J Neurophysiol, 1992), for saccade generation we were able to closely simulate the characteristics of the patients' vertical saccades by reducing the asymptotic value of the burst response curve. Combining normal horizontal and "lesioned" vertical versions of the model in simple Cartesian addition yielded trajectories similar to the patients' oblique saccades. We conclude that Niemann-Pick type C disease selectively affects vertical burst neurons which lie in the riMLF and that oblique saccades are normally generated by independent horizontal and vertical burst cell populations. MOTOR ADAPTATION OF 2-D AND 3-D ASPECTS OF EYE-HEAD COORDINATION IN MONKEYS. J.D. Crawford\* and D. Guitton\*

(1) Depts. Psychology and Biology, York University, North York, Ontario, Canada, M3J-1P3. (2) Montreal Neurological Institute and Department of Neurology and Neurosurgery, McGill University, Montreal, Canada, H3A 2B4.

To un-couple the normally stereotyped coordination between eye and head, 3 *Macaca fascicularis* were trained to search "head only" for visual targets while wearing opaque goggles with a 10° aperture. A similar task employed acutely in humans produced modest kinematic effects (Tweed et al. *Soc. Neurosci. Abstr.* 1993). Our animals took 1, 4, and 7 weeks respectively of daily training sessions to learn the task for all movement directions. In the first two, dual search coils were implanted for 3-D recordings of eye and head position. For "head only" gaze shifts, eye-in-head quick phases were reduced in size, truncated early by slow phases that kept eye-in-head gaze near the aperture. The normal "head-mainly-horizontal, eye-mainly-vertical" strategy was changed to the "same-direction" strategy required to return the eye to the aperture. However, the behaviour was more complex than simply scaling the horizontal and vertical components of eye vs. head. When the location of the aperture was suddenly shifted, animals could not perform the task without re-training: surprisingly, they continued to drive the eye towards the location of the old (now covered) aperture. It thus appeared that a neural mapping from desired gaze direction onto desired eye-in-head position had been modified. Finally, whereas 3-D eye-in-space position was normally constrained to a curved 2-D surface, eye-in-space position now conformed to a plane, like Listing's plane for eye-in-head. Thus the neural operators for Listing's law and the analogous eye-in-space law may utilize a similar mechanism capable of parametric adjustments to suit the task.

## 503.1

**in situ RT-PCR DETECTION OF INFLUENZA VIRAL RNA**

S.H. Isaacson<sup>1,2</sup>, D.M. Asher<sup>1</sup>, C.J. Gibbs, Jr.<sup>1</sup>, D.C. Gajdusek<sup>1</sup>, and M.D. Yahr<sup>2\*</sup>  
<sup>1</sup>NIH, Bethesda MD 20892; and <sup>2</sup>Mount Sinai Medical Center, New York NY 10029

We have previously assessed the sensitivity, specificity, and reproducibility of *in situ* RT-PCR amplification with labeled-probe hybridization (*in situ* RT-PCR/LPH) to detect and localize viral RNA in archival paraffin-embedded CNS tissue sections from several neurological diseases of known viral origin (i.e. measles virus, poliovirus, HTLV-1). Some of these tissues were embedded over 25 years ago, and frozen specimens are not available.

The etiologic agent of encephalitis lethargica (von Economo's encephalitis) has never been identified. Although its temporal proximity to the 1918 influenza pandemic has suggested that this virus may be implicated, attempts to demonstrate influenza virus as the cause have been inconclusive. Since no frozen tissue is available, we used *in situ* RT-PCR/LPH to determine if influenza viral RNA could be detected in archival paraffin-embedded brain tissue from seven patients who died with postencephalitic parkinsonism as a sequela of encephalitis lethargica. We also studied mice experimentally infected with the neurotropic NWS strain of influenza A. Highly conserved influenza A genomic sequences were detected in the brains of these mice by *in situ* RT-PCR/LPH. We were unable to detect influenza RNA in simultaneously examined postencephalitic brains. Whether influenza RNA may have been present earlier in the disease course is not known. Alternatively, a different agent may have caused this pandemic.

## 503.3

**GDNF UPREGULATES NIGRAL DOPAMINE NEURONS AND IMPROVES MOTOR FUNCTIONS IN HEMIPARKINSONIAN RHESUS MONKEYS** D. M. Gash<sup>1\*</sup>, Z. Zhang<sup>1</sup>, A. Ostad<sup>1</sup>, W. Cass<sup>1</sup>, D. Russell<sup>2</sup>, D. Martin<sup>2</sup>, F. Collins<sup>2</sup>, B. Hoffer<sup>2</sup> and G. Gerhardt<sup>1</sup> 1. Univ. of Kentucky Medical Center, Lexington, KY; 2. AMGEN, Inc. Thousand Oaks, CA; 3. Univ. of Colorado Health Sci. Ctr., Denver, CO.

Glial cell line-derived neurotrophic factor (GDNF), a novel member of the TGF- $\beta$  superfamily, exerts potent effects on CNS dopamine neurons *in vitro* and *in vivo*. In the present study, the effects of either vehicle or human rGDNF-injected into the CNS of 19 adult female hemiparkinsonian rhesus monkeys were evaluated from standardized video taped tests by blinded raters using a primate parkinsonism rating scale. All animals were at least 3 months post MPTP treatment and consistently expressed moderate parkinsonian features. Baseline parkinsonian features were evaluated for at least four weeks prior to trophic factor treatment. Using sterile MRI-guided stereotaxic procedures, three routes of administration were evaluated: intranigral (150  $\mu$ g GDNF), intrastriatal (450  $\mu$ g GDNF) and intracerebroventricular (ICV, 100  $\mu$ g and 450  $\mu$ g GDNF). Animals were behaviorally evaluated for 3-19 weeks, then euthanized with their brain tissue recovered for neurochemical and immunohistochemical analysis.

No significant behavioral changes were measured in the seven vehicle injected animals during the period following treatment. However, the results from GDNF injections into the same sites were quite different. Improved motor functions lasting for at least four weeks were seen following all three routes of administration. ICV administrations repeated every four weeks maintained the functional improvements. Dopaminergic neurons in the lesioned nigra showed evidence of increased stimulation as revealed by immunohistochemical staining and increased levels of dopamine and its metabolites.

## 503.5

**INTRASTRIATAL IMPLANTATION OF BDNF-PRODUCING FIBROBLASTS PREVENTS NEURODEGENERATION IN A RAT MODEL OF PARKINSON'S DISEASE (PD)** M. Levivier<sup>1,\*</sup>, S. Przeglowski<sup>1</sup>, C. Bencsics<sup>1</sup>, U.J. Kang<sup>2</sup>, <sup>1</sup>Mov. Disorders Div., Neurology, Columbia Univ., New York, NY; <sup>2</sup>Neurosurgery, ULB-Hôp. Erasme, Brussels, Belgium; <sup>3</sup>Neurology, Univ. of Chicago, Chicago, IL.

We recently developed a rat model of partial lesion of the nigrostriatal pathway using intrastriatal injection of 6-OHDA. BDNF has neuroprotective properties on DA neurons *in vitro*. However, BDNF is difficult to deliver into the CNS and therefore its *in vivo* effects are not well defined. Herein, we tested the protective effect of grafts of fibroblasts genetically modified to produce BDNF (BDNF[+]) in our partial lesion model of PD. Control groups consisted of: (i) animals which received no grafts prior to the injection of 6-OHDA, (ii) animals which received BDNF[+] grafts only, and (iii) animals which received grafts of non-transduced fibroblasts prior to the injection of 6-OHDA. Lesions were assessed by [<sup>3</sup>H]mazindol binding quantitative autoradiography and cell count on Nissl staining. Compared to lesioned only animals, rats with BDNF[+] grafts were protected against 6-OHDA-induced neurodegeneration, while grafts of unmodified fibroblasts failed to protect against 6-OHDA. In animals that received only BDNF[+] grafts and no subsequent lesion, there was no difference in binding or cell count compared to the contralateral nonoperated side. This suggests that the neuroprotective effect of BDNF against 6-OHDA, which was evaluated quantitative autoradiography and cell counting, is not a reflection of a trophic effect of BDNF on remaining neurons. This study demonstrates that, in this model of partial lesion of the nigrostriatal pathway, grafts of fibroblasts genetically modified to produce BDNF protect against 6-OHDA. These results open new possible neuroprotective therapeutic avenues aiming at slowing down neurodegeneration in early stages of PD, using neurotrophic factors such as BDNF. (Supported by PDF & UPF, USA, and FNRS, Belgium, as well as NIH - Fogarty, Fulbright and NATO fellowships).

## 503.2

**DOPAMINE TRANSPORTER IMAGING IN PARKINSON'S DISEASE AND PARKINSON PLUS SYNDROMES** K.L. Marek\*, J.P. Seibyl, K. Sheff, B. Fussell, E.O. Smith, P.B. Hoffer, R.B. Innis. Depts Neurology, Psychiatry, Diagnostic Radiology, Yale Univ/VA Med Ctr, New Haven CT [<sup>123</sup>I]β-CIT (2β-carboxymethoxy-3β-(4-iodophenyl)tropane) labels monoamine transporters located on the terminals of dopaminergic projections from the substantia nigra to the striatum providing a marker for neurons which degenerate in Parkinson's disease (PD) and related neurodegenerative disorders. [<sup>123</sup>I]β-CIT SPECT imaging was performed in 42 idiopathic PD patients, 17 Parkinson's plus patients and 27 healthy subjects 18-24 hour post tracer administration. Data was analyzed relative to two outcome measures: ratio of specific:non-displaceable striatal activity and striatal uptake expressed as percent of injected dose. Disease severity was assessed by Hoehn and Yahr Staging, UPDRS scales and timed motor events following 12 hours off drug. In the PD patients striatal [<sup>123</sup>I]β-CIT uptake was dramatically reduced in an asymmetric and region specific manner. The reduction in age corrected transporter loss in PD patients was 70% in the putamen and 53% in the caudate contralateral to initial symptoms. In Parkinson's plus patients including MSA (SND and Shy-Dragers syndrome), and PSP [<sup>123</sup>I]β-CIT uptake was similarly, but more symmetrically reduced. The reduction in age corrected transporter loss in patients with Parkinson's plus syndromes ranged from 60-95% in putamen and from 40-90% in caudate. The loss of [<sup>123</sup>I]β-CIT uptake reflected the severity of the patient's motor deficit. These data suggest that imaging of the dopamine transporter may be a useful *in vivo* marker for idiopathic PD and Parkinsonian syndromes.

## 503.4

**INCREASED VIABILITY OF GENETICALLY MODIFIED PRIMARY RAT FIBROBLASTS PREPARED FOR IMPLANTATION IN THE BRAIN IN BUFFER CONTAINING N-ACETYL-L-CYSTEINE AND SERUM** K.G. Rendahl, D.G. Clevenger, T.M. Jaret\*, C. Unruh, D. Nagy, J. Conway, M. Morton, R. J. Mandel, and S. Leff. Somatix Therapy Corp., 850 Marina Village Pkwy., Alameda, CA 94501.

Optimizing *in vivo* cell viability after grafting is important for gene therapy protocols in which one desires to maximize the expression of gene product from a limited number of genetically modified cells. Experiments involving primary Fischer rat Dermal Fibroblasts (FDFs) prepared for implantation in the brain demonstrated that the choice of media used for the preparation of the cells is critical for their survival *in vitro*. The viability of both tyrosine-hydroxylase (TH) transduced and non-transduced cells after preparation in our standard buffer, PBS, was compared with that in a variety of buffers containing factors known to enhance cell growth in culture. The cells were trypsinized, washed and resuspended in a given buffer, passed through an injection cannula, and then assessed by propidium iodide (PI) exclusion via Fluorescence Activated Cell Sorting (FACS) over a four hour time course. Preparation of the cells in PBS yielded inconsistent results, ranging from a mean of better than 90% viability at the time of passage through the cannula, to less than 60% at four hours. PBS containing 10% heat-inactivated rat serum and 1 mM N-acetyl-L-cysteine (NAC), which regulates the redox state of the cell by potentiating intracellular glutathione levels, had the most significant protective effect. A robust 95% survival was observed in this media for the duration of a given experiment. Neither 10% serum nor 1 mM NAC was as effective, although both were significantly more protective than PBS alone. In addition, a high correlation between cell survival and intracellular glutathione levels was demonstrated. *In vivo* experiments with primary FDFs are in progress, in order to determine whether or not these modifications in the buffer composition will lead to the increased survival of implanted cells.

## 503.6

**COEXPRESSION OF HUMAN GTP CYCLOHYDROLASE I (GTPCHI) AND HUMAN TYROSINE HYDROXYLASE CDNAS TO POTENTIATE L-DOPA PRODUCTION BY FIBROBLASTS: APPLICATIONS TO PARKINSON'S DISEASE GENE THERAPY** S.E. Leff\*, F. Wu, C. Unruh, D. Clevenger, T. Jaret, K. Rendahl, K. Spratt, K. Bankiewicz, O. Danos, and R. J. Mandel, Somatix Therapy Corp., Alameda, CA, 94501.

We and others have been developing protocols for treating Parkinson's Disease using cells that have been genetically modified to express recombinant human tyrosine hydroxylase (hTH) with the aim of achieving local L-DOPA delivery in the CNS after grafting. However, efficient L-DOPA delivery using these protocols involving most cell types may be limited by the absence of "activating" levels of tetrahydrobiopterin (BH<sub>4</sub>), an essential cofactor for TH. To increase the efficiency of L-DOPA production, we are coexpressing cDNAs encoding the human GTPCHI, the rate-limiting enzyme for de-novo BH<sub>4</sub> synthesis, with the cDNA encoding hTH. Co-expression of the rat GTPCHI with TH cDNAs in rat fibroblasts was first reported by C. Bencsics *et al* (Soc. Neurosci. Abst., 20:176, 1994), who showed that L-DOPA production by these cells *in vitro* could be achieved in the absence of added BH<sub>4</sub>. We have cloned the full-length human GTPCHI cDNA using PCR of human liver cDNA. Our cDNA sequence corresponds to the active type I form described by Gutlich *et al*. The GTPCHI cDNA has been placed in a retroviral vector, MFG-s-GTPCHI, or in a bicistronic vector, MFG-s-hTH2-ires-GTPCHI, and retrovirus has been packaged using the  $\psi$ -CRIP line. Results on the ability of these systems to enhance L-DOPA production *in vitro* and *in vivo* after grafting will be presented.

## 503.7

**APOPTOTIC-LIKE CHANGES IN HUMAN SUBSTANTIA NIGRA** M.M. Tompkins\*, W.D. Hill. Department of Cellular Biology and Anatomy, Medical College of Georgia, Augusta, Georgia, 30912.

The substantia nigra (SN) undergoes cell death during aging and in neuropathological diseases such as Parkinson's disease (PD) and diffuse Lewy body disease (DLBD). The morphology of this cell death process has not been previously described in detail. We have found apoptotic-like changes in cells undergoing degeneration in the substantia nigra of control and diseased patients. Midbrains of 28 individuals (neurologically normal, 3 cases; Alzheimer's disease (AD), 7 cases; concomitant AD/PD, 4 cases; DLBD, 9 cases; and PD, 5 cases) were probed for DNA fragmentation with a TUNEL assay using an FITC label (Apotag kit, Oncor, Gaithersburg, MD), and counterstained for nucleic acid with propidium iodide. Nigral nuclei with an apparently normal morphology were seen stained with propidium iodide in the presence and absence of FITC labeling. Abnormal FITC(+) nuclei were divided into subgroups based on appearance of the chromatin and the neuromelanin (NM) pigment. The subgroups included condensed chromatin with normal-appearing NM, condensed chromatin with clumped NM resembling apoptotic bodies, and condensed chromatin with strands of DNA radiating away from the main body. Some morphologies resemble early-stage apoptosis, while others appear to be apoptotic cell fragments awaiting or undergoing phagocytosis. The percentage of apoptotic-like neurons was found to be lower in controls and AD cases as compared to AD/PD and DLBD cases, while the PD cases ranged from low to high percentage. Our observations suggest that in PD, AD/PD and DLBD neurons are dying by apoptosis. In this case, therapies aimed at interfering with the apoptotic mechanism may be useful in rescuing neurons.

## 503.9

**BIPHASIC PATTERN OF MPTP NEUROTOXICITY IN THE NIGROSTRIATAL SYSTEM IN MICE** P.Chan, D.A. Di Monte, A. Stadlin\* and J.W. Langston\*. The Parkinson's Inst., Sunnyvale, CA 94089, \*Dept of Anat., Chinese Univ. of Hong Kong, Hong Kong.

The cascade of events leading to MPTP neurotoxicity *in vivo*, particularly during the acute phase of toxicity, is still not fully understood. The purpose of the present study was to evaluate the temporal and possibly causal relationship between pharmacological and toxic events leading to neuronal degeneration after MPTP exposure. C57BL/6 mice were treated with a single injection of MPTP (40 mg/kg, s.c.) and killed at time points ranging from 30 min to 7 days. MPTP/MPP<sup>+</sup> pharmacokinetics and changes in levels of DA, ATP, GSH/GSSG, Glut/Asp, mRNA levels and binding sites of dopamine transporter (DAT) were determined in the nigrostriatal system. MPTP was fully converted to MPP<sup>+</sup> within 1 hr, which was selectively accumulated (peak concentration: 1.5 hr) in and then eliminated from striatum (within 16 hr). MPTP-induced changes occurred in a biphasic pattern based on the presence (first phase) and absence (second phase) of MPP<sup>+</sup>. The first phase was characterized by a rapid decrease in striatal levels of ATP which was followed by a marked decrease in Glut/Asp and DA, but without loss of the DAT binding sites. These changes returned to normal (ATP and Glut/Asp) or were recovered (DA) within 24 hr. However, a second and long-lasting decline of DA began at day 2; it was accompanied by a significant decrease in the number of DAT binding sites and mRNA levels (maximum decrease: 3 days). No changes in GSH and GSSG content were found at any time point studied. These data suggest that MPTP/MPP<sup>+</sup> causes an initial reversible changes followed by long-term neurotoxic effects. Although the precise relationship between these two phases remains unclear, it is likely that transient events in the first phase set in motion a process which may ultimately lead to neurotoxic damage. The MPTP model may provide a valuable tool to study factors which may initiate the neurodegenerative processes.

## 503.11

**ACUTE TREATMENT OF MICE WITH THE GLUTATHIONE SYNTHESIS INHIBITOR BUTHIONINE SULFOXIMIDE CAUSES DAMAGE TO THE NIGRO-STRIATAL SYSTEM REMINISCENT OF PARKINSON'S DISEASE** J.K. Andersen\*, J.Q. Mo, D.G. Hom, T.H. McNeill. Division of Neurogerontology, Ethel Percy Andrus Gerontology Center, University of Southern California, Los Angeles, California 90089-0191.

In this study, we have analyzed the acute effects of treatment with the compound buthionine sulfoximine (BSO), a synthesis inhibitor of the antioxidant glutathione, on the nervous system of C57Bl male mice. Following multiple injections of BSO, levels of GSH were found to be dramatically reduced in the substantia nigra (SN). The reduction in levels of GSH correlated with increases in brain levels of lipid peroxidation and oxidative stress. BSO treatment was found to have detrimental effects on the nigro-striatal system. These effects included decreased dopamine content per cell, increased lipofuscin accumulation, and increased numbers of dystrophic axons in dopaminergic fibers of the mesolimbic and nigrostriatal systems, as well as decreases in striatal dopamine (DA) and its metabolites, HVA and DOPAC. The detrimental effects of BSO treatment on these cell populations were not generalized to other catecholaminergic neurons. Results from our study suggest that BSO administration has effects on the nigro-striatal nervous system which are morphologically similar in appearance to those changes which occur with advancing age and following treatment with MPTP.

## 503.8

**APOPTOSIS-LIKE NEURONAL CELL DEATH *IN VIVO* IN THE 1-METHYL-4-PHENYL-1,2,3,6-TETRAHYDROPYRIDINE (MPTP) MOUSE MODEL OF PARKINSON'S DISEASE (PD)**

A.M. Janson\*. Dept of Neuroscience, Karolinska Institutet, Doktorsringen 17, S-171 77 Stockholm, Sweden.

Apoptosis may represent an important mechanism of cell death in some experimental models of neurodegeneration as well as in human neurodegenerative disorders. Although the MPTP mouse model of PD has been studied extensively over the last decade, the mechanism by which the neuron ultimately dies remains unknown.

A single dose of MPTP (40 mg/kg, sc) was given to 10 weeks' old male C57 Bl/6 mice. The nuclear alterations were studied in midbrain sections and analyzed with stereological unbiased quantitative techniques at various time-points after the lesion. Two different *in situ* labeling techniques analysing DNA fragments were compared. The first one uses DNA polymerase I, which detects the 3'-OH-ends of single-stranded DNA breaks. The second technique employs terminal deoxynucleotidyltransferase labeling the 3'-OH-ends of both single- and double-stranded DNA breaks.

The results for the first time indicate a role of apoptotic-like cell death mechanisms in the MPTP mouse model *in vivo*, possibly also related to the pathogenetic mechanism in PD.

## 503.10

**TRK-B EXPRESSION IN THE SUBSTANTIA NIGRA PARS COMPACTA (SNC) AND PARKINSONISM IN THE RAT** S.P. Jaw\*, D.D. Su, S. Wellman and D.D. Truong. Dept. of Neurology, Univ. of California Irvine, Irvine, CA 92717.

Roles of brain-derived neurotrophic factor (BDNF), neurotrophin-4/5 (NT-4/5), and their common high-affinity receptor, Trk-B, in the development of Parkinsonism were investigated in both young (2-month-old) and aged (30-month-old) male Sprague Dawley rats. As determined by reverse transcriptase followed by polymerase chain reaction (RT-PCR), significant reductions of BDNF and NT-4/5 gene expressions, were found in the SNC of old rats. The levels of Trk-B were also lower in the SNC of old rats as measured by immunoblot assays. Furthermore, following 6-hydroxydopamine (6-OHDA) lesion in the SNC, old rats developed apomorphine-induced rotational behaviors faster (5 days post lesion) than young ones (14 days post lesion). These results indicate that lower expressions of BDNF, NT-4/5, and their receptor, Trk-B may contribute to the temporal difference in the development of Parkinsonism in rats.

## 503.12

**BEHAVIORAL AND NEUROCHEMICAL DYSFUNCTION IN THE CIRCLING RAT. A NOVEL GENETIC ANIMAL MODEL OF PARKINSONISM?** W. Löscher<sup>1</sup>\*, A. Richter<sup>1</sup>, G. Nikkha<sup>2</sup>, C. Rosenthal<sup>2</sup>, U. Ebert<sup>1</sup>, and H.-J. Hedrich<sup>1</sup>. Department of Pharmacology, Toxicology and Pharmacy, School of Veterinary Medicine, <sup>2</sup>Neurosurgical Clinic, Nordstadt Hospital, and <sup>3</sup>Institute for Laboratory Animal Science, Medical School, D-30559 Hannover, Germany.

One of the crucial breakthroughs in research on parkinsonism was the observation of circling behavior in rodents after unilateral intranigral injection of 6-hydroxydopamine (6-OHDA). This Ungerstedt model still is one of the basic animal models of Parkinson's disease. We report here the first mutant rat strain with abnormal circling behavior and several other features reminiscent of the Ungerstedt Parkinson model. The neurological disorder in the novel mutant rat strain is determined monogenetically by a recessive autosomal gene termed circling (*ci*). Mutant rats of both sexes exhibit an intense asymmetric circling in an open-field or rotometer, which is enhanced by amphetamine. Neurochemical determinations show that mutants of both sexes have significantly lower dopamine and dopamine metabolites in the striatum ipsilateral to the preferred direction of rotation. Furthermore, in a forelimb reaching test for assessing the skilled motor capacities of rats, *ci* rats show a marked deficit on the side contralateral to the preferred direction of turning, which is analogous to motor deficits previously described for rats subjected to unilateral 6-OHDA lesions. The new mutant rat strain thus exhibits remarkable similarities to the Ungerstedt model and may serve to study the endogenous processes, particularly the genetic components, that might eventually lead to progressive neurological disorders such as idiopathic parkinsonism.

## 504.1

ORGANIZATION OF EXTRASTRIATE VISUAL AREAS IN HUMAN OCCIPITAL CORTEX INFERRED FROM CALLOSAL CONNECTIONS. D.C. Van Essen<sup>1</sup>, S. Clarke<sup>2</sup>, H.A. Drury<sup>1</sup>, N. Hadjikhani<sup>2</sup>, T. Coogan<sup>1</sup>, R. Kraftsik<sup>2</sup>. <sup>1</sup>Department of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, USA; <sup>2</sup>Institute of Physiology, University of Lausanne, Lausanne, Switzerland.

Callosal connections provide valuable markers for the borders of topographically organized visual areas, because they terminate preferentially along representations of the vertical meridian. We report here on the pattern of degenerating callosal fibers in the left hemisphere of a human brain that had a right occipital infarct. A computerized three-dimensional reconstruction of the entire occipital lobe was generated from a series of contours through cortical layer 4. Custom software was used for smoothing and flattening the cortical surface, thereby allowing ready visualization of buried cortex. Our results substantially extend the findings reported last year on a more restricted portion of a different hemisphere (Van Essen et al., Soc. Neurosci. Abstr. 20:428, 1994) as well as the original study of Clarke and Miklosy (J. Comp. Neurol., 1990).

Extrastriate visual cortex contains a pattern of callosal-free regions surrounded by callosal-recipient rings that has many similarities to the pattern known for the macaque monkey. We confirmed the presence of callosal-free regions adjoining V1 dorsally (presumed dorsal V2 and area V3) and ventrally (presumed ventral V2 and area VP). These callosal-free regions are separated by callosal-recipient regions at the representation of the fovea (occipital pole) and the far periphery (anterior calcarine sulcus). In ventral cortex, there is a more lateral callosal-free region in the inferior temporal gyrus, that is likely to include the ventral (upper-field) portion of area V4. In dorsal cortex, there are at least two additional callosal-free regions, including a dorso-medial one that may include area V3A and a dorso-lateral one that may include the dorsal (lower-field) portion of V4. These boundaries provide a useful anatomical framework for comparisons with activity foci revealed by PET and fMRI.

## 504.3

OPTIMAL HIERARCHIES FOR THE PRIMATE VISUAL SYSTEM DERIVED WITH A NOVEL NETWORK PROCESSOR. C.C. Hilgetag, M.A. O'Neill and M.P. Young\*. Neural Systems Group, Univ. Newcastle, Ridley Bldg., Newcastle upon Tyne NE1 7RU, UK.

Connections between visual cortical areas in primates can be classified as 'ascending', 'descending' or 'lateral' according to the pattern of their origins and terminations within cortical layers. This classification yields 318 pairwise hierarchical constraints that describe relations between 30 visual areas. The available anatomical constraints are incomplete, some of the constraints are unreliable, ambiguous, and inconsistent with others, and the number of possible orderings that might fit the constraints is very large ( $\sim 10^{37}$ ). Nonetheless, the data are widely assumed to contain important information about the organization of the visual system, and hierarchies have been derived by ordering the visual areas by hand while trying to satisfy the constraints as well as possible.

We have automated this procedure and analysed the data with stochastic optimization. This computational approach employed an annealing algorithm which was integrated with an algorithm for re-arranging the wiring of complex networks. The program searched for optimal hierarchical orderings of the visual system. Starting from an arbitrary structure, it proceeded by cumulative modification and cost evaluation of candidate solutions, where the cost related to the number of constraint violations.

The processor found optimal hierarchical orderings that possessed only a very low number of constraint violations, suggesting that the visual system is a surprisingly strict hierarchy. There were, however, at least 55000 different optimal orderings of the visual cortical areas. The presently-known hierarchical constraints were therefore not sufficient to constrain a unique hierarchy, and no single hierarchy can properly describe the organization of the system. Widely-reported hierarchical orderings of the primate visual system that were derived by hand have higher cost than the optimal solutions found by the processor. We also used the network processor for computer experiments to determine the causes of the few remaining violations in the optimal solutions. We found that solutions with an even lower cost could be derived under the assumption that one of the visual areas, FST, consists of two distinct sub-areas.

## 504.5

DISTINCT SYNAPTIC MECHANISMS IN FORWARD AND FEEDBACK CIRCUITS WITHIN RAT VISUAL CORTEX. Z. Shao, G.W. Harding and A. Burkhalter. Dept. Anatomy and Neurobiology, Washington Univ. Sch. of Med., St. Louis, MO 63110.

The multiple visual areas of mammalian visual cortex are reciprocally linked by forward and feedback connections. The function of forward pathways is to convey information from lower to higher cortical areas, whereas feedback pathways provide 'top-down' influences from higher to lower areas. Each of these functions is generated by anatomically distinct circuits in which 90% of forward inputs go to pyramidal cells and 10% of inputs are sent to GABAergic interneurons (Johnson and Burkhalter, 1994). In contrast 98% of feedback inputs go to pyramidal cells and only 2% to GABAergic neurons (Johnson and Burkhalter, 1992). Although this difference is significant, the absolute magnitude is small and the question arises whether different synaptic properties are generated.

Using slices of rat visual cortex we have performed intracellular recordings in secondary (area LM) and primary visual cortex after stimulation of forward and feedback connections, respectively. In addition these responses were compared to those evoked after stimulation of white matter and horizontal connections within area 17. In every case activation of forward inputs evoked monosynaptic EPSPs followed by undershooting disynaptic IPSPs and closely resembled responses after stimulation of geniculocortical and local horizontal connections. In contrast only 22% of feedback inputs showed undershooting IPSPs.

These results suggest that the synaptic mechanisms in forward and feedback circuits are distinct and that modest differences in the input to inhibitory circuitry can dramatically alter the function of cortical circuits.

## 504.2

CORTICAL MAPS AND MODULES AS A SOLUTION TO THE PROBLEM OF VOLUME MINIMIZATION. E. Todorov<sup>1</sup>, K. Zipser<sup>1</sup> and D. Zipser<sup>2</sup>. BCS, MIT, E25-634, Cambridge, MA 02139<sup>1</sup>; Cognitive Science Dept., UCSD, La Jolla, CA 92093-0515<sup>2</sup>.

The connections among cells, rather than the cell locations, determine the functionality of the brain. Assuming development could achieve the same connectivity with different cell locations, we may argue that cortical evolution will favor the configurations that result in minimal volume (i.e., minimal axonal or dendritic length). If this form of volume minimization is a dominant principle underlying cortical structure, it should be possible to explain the existence of both cortical visual maps and modules without reference to any specific developmental mechanisms. Here we design simulations in which connections among model cortical neurons and subcortical inputs are prespecified, and the positions of neurons in a model cortical sheet are varied (by starting at a random configuration and using simulated annealing) until a minimum of the connection length is found. In simulations in which cortical cells receive input from elongated patches of retinal (LGN) cells of different weight from each eye, ocular dominance columns, orientation columns, and retinotopic mapping resembling those in area V1 are obtained as a result of minimizing total connection length. In simulations in which cortical neurons are connected in a hierarchical manner so that "higher level" cells have larger receptive fields than their afferent cells, all cells are found in register in a single retinotopic map. If lateral connections among cells of each hierarchical level are added, separate retinotopic maps do arise, but only if the ratio of lateral to forward connections exceeds a threshold, which we show both through simulation and analytically to be approximately 20. Thus, functionally distinct groups of cells can be mixed, clustered into modules, or separated into areas, depending on the interplay between hierarchical and lateral connections.

## 504.4

SYNAPTIC INTEGRATION OF GENICULOCORTICAL AND INTRACORTICAL FEEDBACK INPUT IN RAT PRIMARY VISUAL CORTEX. A. Burkhalter, J.M. Nerbonne\* and Z. Shao. Dept. Anatomy and Neurobiology, Washington Univ. Sch. of Med., St. Louis, MO 63110.

Intracortical feedback connections that link higher to lower cortical areas are likely conduits for top-down influences by which attention modulates processing of visual features. How these higher order processes are synaptically integrated with afferent information supplied by the geniculocortical system is poorly understood. Feedback pathways constitute anatomically distinct microcircuits whose inputs to inhibitory interneurons are five times weaker than in forward circuits (Johnson and Burkhalter, 1992; 1994). This represents an imbalance of inputs to excitatory and inhibitory neurons which results in PSPs that are mainly excitatory (Shao et al., 1995). In contrast forward circuits show more balanced inputs to excitatory and inhibitory neurons and, similar to the geniculocortical system (LGN), activation evokes a sequence of monosynaptic EPSPs followed by disynaptic IPSPs (Douglas and Martin, 1991; Shao et al., 1995).

We have used intracellular recording in slices from rat visual cortex to study how feedback inputs from secondary visual cortex and LGN inputs interact in layer 2/3 pyramidal neurons of area 17. Electrical stimulation was employed for simultaneous activation of feedback inputs and LGN afferents. When stimulated separately, feedback pathways showed large EPSPs and no undershooting IPSPs. Stimulation of LGN inputs alone typically revealed EPSPs followed by IPSPs. For coincident activation, stimulus strengths in both pathways were adjusted to evoke EPSPs but no undershooting IPSPs. Surprisingly, with co-activation in every cell, the response was dominated by inhibition: EPSPs were smaller than the sum of responses to either pathway alone, whereas IPSPs were extremely large, indicating strong non-linear inhibition.

The results suggest that depending on the strength of coincident inputs feedback pathways can act to enhance or suppress striate cortical responses.

OPTICAL IMAGING OF ORIENTATION TUNING MAPS IN THE FOCALLY LESIONED CAT VISUAL CORTEX. U.T. Eysel\*, Z.F. Kisvárdy, M. Rausch. Department of Neurophysiology, Faculty of Medicine, Ruhr-Universität Bochum, D-44780 Bochum, F.R. Germany.

Photocoagulation of the cat visual cortex produces well defined heat lesions of 1-2 mm diameter and about 1500  $\mu$ m depth. Surrounding the lesion we have observed a zone of neuronal dysfunction (Eysel & Schmidt-Kastner, Neurosci Lett. 131:45, 1991). The functional disturbances of single cells included hyperactivity, reduced intracortical inhibition and weakening of orientation tuning. To further understand the spatial distribution of lesion-induced dysfunction we have applied optical recording of intrinsic signals (Grinvald et al., Nature 324:361, 1986) during stimulation with drifting gratings of variable direction and orientation (adult cats, pentobarbital anaesthesia, artificial respiration). Important vital parameters (blood pressure, body temperature, end-expiratory CO<sub>2</sub>, EEG) were monitored. The visual cortex (areae 17/18) was bilaterally exposed and a chamber filled with silicone oil attached. Several normal maps were recorded to ascertain the reproducibility. The heat lesion was produced through the intact chamber. After lesioning the cortex was remapped every 2 h for a period of 12-36 h. Postmortally the size of the lesion was measured in Nissl stained sections. Immunohistochemistry was used to estimate the extent of edema and neuronal damage.

Optical imaging of stimulus evoked intrinsic signals proved to be very sensitive for the detection of lesion effects with high spatial resolution. The maps were analysed for possible changes of the spatial distribution of orientation domains and centers. In addition, the strength and sharpness of orientation tuning was quantitatively evaluated. The functionally disturbed region (with a completely silent core and surrounding changes in the orientation map and in strength and specificity of tuning) surpassed the histologically verified border of the lesion by 0.5-1 mm. This spatial extent is closely related to the lateral range of effective intracortical inhibition and the size of the hypercolumns.

**FUNCTIONAL IMAGING AND CORTICAL CONNECTIONS OF V2 THIN AND INTERSTRIPE COMPARTMENTS.** Y. Xiao and D.J. Felleman. Department of Neurobiology and Anatomy, Univ. Texas Medical School, Houston, Texas 77030.

Previous evidence suggests that areas V4 and perhaps V3A of macaques contain distinctive modules that receive segregated input from V2 thin or interstripes. However, the number, size and organization of these modules is not known. In the current study, V2 thin- and interstripes were visualized, *in vivo*, according to their differential activations to isoluminant chromatic and luminance gratings of different temporal and spatial frequencies. Iontophoretic injections of anterograde and retrograde tracers (Pha-L, BDA, <sup>3</sup>H-proline, FITC and TRITC-dextran, WGA-HRP, BB, NY) were aimed at different stripes or different parts of the same stripe. Clustered intrinsic connections in V2 were most dense within 4 mm of the injection site, but were observed up to 9 mm away. Injections restricted to either V2 thin stripes or interstripes produced clustered terminal labeling in areas V3, V3A, and V4. Individual axons often branched in the white matter and traveled obliquely in gray matter before terminating in several areas. Labeled axons gave off terminal branches usually in layer 4 but occasionally extending to layer 1. Terminal fields in V4 were often restricted to 1-4 narrow foci ~250-500  $\mu$ m in width, but the total projection field often extended dorso-ventrally for 4-5 mm. Retrogradely labeled cells also formed patches which overlapped, but were not identical to the terminal patches. Terminal projections from thin- and interstripe injections appear to segregate in a complex, interdigitating pattern in V4. Injections at thin-interstripe borders labeled terminal fields in V4 that were wider than those originating from single stripe injections. Supported by RO1-EY08372 and Texas ARP 011618-025 to DJF, and P30-EY10608.

## 504.9

**RETINOTOPIC ORGANIZATION OF MULTIPLE VISUAL AREAS IN HUMANS REVEALED BY FUNCTIONAL MRI.** M.I. Sereno\*, A.M. Dale, R.B.H. Tootell, J.B. Reppas, K.K. Kwong, J.W. Belliveau, and B.R. Rosen. Cognitive Science Department 0515, University of California San Diego, La Jolla, CA 92093, University of Oslo, Oslo, Norway, and MGH NMR Center, 149 13th St., Charlestown, MA 02129.

We previously showed how four techniques (multislice fMRI, stimulus phase-encoding and Fourier analysis, cortical surface reconstruction, and visual field sign calculations) could be combined to reconstruct the internal retinotopic organization of visual areas V1, V2, VP, V3, and V4 in humans, and to accurately trace out the borders between these areas in the human brain (Sereno et al., 1995, *Science*).

This analysis was performed for a larger pool of subjects. We also used thin ray and ring stimuli in an attempt to recover retinotopy from areas with larger receptive fields. The resulting isoeccentricity, isopolar angle, and visual field sign maps were viewed on the partially unfolded cortical surface of each subject. We found a large amount of variability in the absolute size, relative size, and location relative to gyral landmarks of both striate cortex as well as extrastriate cortical areas.

Cortical magnification factor curves for striate and extrastriate cortical areas were also determined, which showed that human visual areas have a greater emphasis on the center of gaze than their counterparts in monkeys. An increase in the foveal density of human midlevel ganglion cells with respect to macaque monkeys could explain our result. This may also help to explain the increase in the size of the region between foveal V1 and MT in humans compared to monkey (relative to the size of V1).

One subject with early, unilateral, localized retinal damage (with foveal sparing) viewed the mapping stimuli with the damaged eye, and then with both eyes. V1 in this subject showed a localized region of reduced activation with damaged-eye-only stimulation that whose location was predicted in large part by the visual field defect measured for that eye.

**SPATIOTEMPORAL IMAGING OF PATTERN VERSUS MOTION SELECTIVE AREAS IN HUMAN VISUAL CORTEX.** S.P. Ahlfors1\*, H.J. Aronen2, J.W. Belliveau3, A. Dale4, M. Huotilainen5, R.J. Ilmoniemi6, W.A. Kennedy3, A. Korvenoja2, A.K. Liu3, R. Näätänen5, B.R. Rosen3, C-G. Standertskjöld-Nordenstam2, R.B.H. Tootell3, J. Virtanen5, G.V. Simpson1

1Albert Einstein College of Medicine, Bronx, NY, 2Radiology, Helsinki Univ. Central Hospital, Finland, 3Massachusetts General Hospital, NMR Center, Charlestown, MA, 4University of Oslo, Norway, 5Cognitive Brain Research Unit, Univ. of Helsinki, Finland, 6BioMag Laboratory, Helsinki Univ. Central Hospital, Finland

The purpose of the study was to isolate motion selective human visual cortical areas and to examine the dynamics of their activity. Five subjects were presented with two types of stimuli which consisted of onset-offset of small wedge-shaped patterns in the upper and lower left visual quadrants. One type had moving contrast-modulated radial bands within the wedge, the other had stationary bands. The same subjects were measured with fMRI and simultaneous EEG and MEG (32 and 122 channels). The combined measures revealed pattern onset responses in retinotopically organized visual cortical areas, whereas, motion specific responses were less sensitive to retinal location. Subtraction of responses to stationary stimuli from responses to moving stimuli revealed activity in two cortical regions, one corresponding to fMRI defined MT/V5, the other located in the temporal parietal junction. Initial motion-specific responses in these areas peaked at approximately 140-180 ms post-stimulus onset and again at 260-300 ms.

## 504.8

**EVIDENCE FOR THE PRESENCE OF THE DORSOMEDIAL VISUAL AREA (DM) IN FIVE PRIMATE SPECIES.** Pamela D. Beck\* and Jon H. Kaas. Department of Psychology, Vanderbilt University, Nashville, TN 37204.

The dorsomedial visual area (DM) in owl monkeys can be identified by its complete representation of the visual hemifield, dense myelination and high cytochrome oxidase reactivity, and distinct pattern of connections with other visual areas. Our goal in the present study was to determine if DM is an area common to other primates. We injected 1-4 tracers (wheatgerm agglutinin conjugated to horseradish peroxidase, fluororuby, diamidino yellow, fast blue, and fluorescein) into cortex in the expected location of DM, just rostral to dorsomedial V2, in one macaque monkey (*Macaca nemestrina*), two squirrel monkeys (*Saimiri sciureus*), two owl monkeys (*Aotus trivirgatus*), and one galago (*Galago crassicaudatus*). We examined the injection sites and resulting label, cytochrome oxidase staining, and myelination in tangential sections from unfolded, flattened cortex. In all these primates, a DM-like area could be identified by more dense myelination and cytochrome oxidase reactivity. Injections in this region labeled neurons in areas V1, V2, and MT. The labeled neurons in V1 were largely co-extensive with CO blobs. Other connections were with posterior parietal cortex, cortex caudal to MT, and cortex on the ventral surface of the occipital lobe. These similarities in cortical architecture and connections suggest that DM exists in most or all primates.

## 504.10

**SPATIOTEMPORAL IMAGING OF COHERENT MOTION SELECTIVE AREAS IN HUMAN CORTEX.** AM Dale1\*, SP Ahlfors2, HJ Aronen3, JW Belliveau4, M Huotilainen5, RJ Ilmoniemi6, WA Kennedy4, A Korvenoja3, AK Liu4, JB Reppas4, BR Rosen4, MI Sereno7, GV Simpson2, C-G Standertskjöld-Nordenstam3, J Virtanen1, RBH Tootell4. 1University of Oslo, Norway, 2Albert Einstein College of Medicine, Bronx, NY, 3Radiology, Helsinki Univ. Central Hospital, Finland, 4Massachusetts General Hospital, NMR Center, Charlestown, MA, 5Cognitive Brain Research Unit, Univ. of Helsinki, Finland, 6BioMag Laboratory, Helsinki Univ. Central Hospital, Finland, 7University of California-San Diego, CA

The purpose of the study was to demonstrate and characterize human visual areas sensitive to coherent vs. incoherent motion. Six subjects were presented with two classes of random dot rotation/dilation flow field stimuli. In one condition (coherent motion) each randomly placed dot moved as part of the same flow field, while in the other condition (incoherent motion) each dot moved independently, but with the same local statistics as the coherent case. The same subjects were measured using fMRI and simultaneous EEG/MEG (32/122 channels). The results from each measure converged to reveal activity in areas previously shown with fMRI to be retinotopically organized (Sereno et al., *Science* 1995) as well as in other areas sensitive to motion (Tootell et al., *J. Neuro.* 1995). In addition, at least two spatially disparate areas were found to exhibit coherent motion selectivity as early as 130ms post stimulus onset. These foci may be human homologues of visual areas identified in nonhuman primates, including MSTd and VIP.

## 504.12

**DOUBLE DISSOCIATION OF MOTION AND FORM PROCESSING IN VISUOPARIETAL AND VISUOTEMPORAL CORTEX OF THE BEHAVING CAT.** S. G. Lomber\*, B.R. Payne, P. Cornwell and K.D. Long. Laboratory for Visual Perception and Cognition, Department of Anatomy and Neurobiology, Boston University School of Medicine, Boston, MA 02118.

The purpose of this study was to elucidate functional differences between visuoparietal cortex lining the middle suprasylvian (MS) sulcus and visuotemporal cortex lying ventrally on the posterior suprasylvian (vPS) gyrus. Freely behaving cats were trained to perform a battery of four motion and/or form processing tasks. Following midline sections of the optic chiasm and visual fibers of the corpus callosum, cooling probes were permanently implanted into the MS sulcus of one hemisphere and over vPS cortex of the other hemisphere to permit reversible deactivation of each cortical site. Deactivation of MS, but not vPS, cortex resulted in a profound deficit in the discrimination of direction of motion. In contrast, deactivation of vPS, but not MS, cortex severely impaired retention of object discriminations. Two final tasks both involved two-dimensional static patterns with an overlying grid-mask. While the mask was in motion, deactivation of either MS or vPS cortex impaired discrimination of the underlying patterns. However, when the mask was static, like the underlying pattern, discrimination was only impaired by deactivation of vPS cortex. These double dissociations show that visuoparietal cortex contributes greatly to visual motion processing, while visuotemporal cortex contributes significantly to form recognition. These functional dissociations have many features in common with the visuoparietal and visuotemporal processing streams identified in monkey and humans. Supported by NS32137.

PRESYNAPTIC INHIBITION OF PROPRIOCEPTIVE SENSORY NEURONS DURING VOLUNTARY MOVEMENTS OF THE LOCUST. M. Burrows\* and B. Hedwig. Dept. of Zoology, Univ. of Cambridge, Cambridge CB2 3EJ, U.K.

The central terminals of sensory neurons from a proprioceptor at the femoro-tibial joint of a leg receive inhibitory depolarising synaptic inputs that are mediated by interneurons releasing GABA. During imposed movements of this joint the presynaptic inputs in a particular sensory neuron are greatest for movements that evoke its best spike response. To determine when presynaptic inputs occur during voluntary movements we recorded from the terminals of these sensory neurons during kicking. Locusts use a distinctive motor pattern to extend the tibia of a hind leg rapidly and the force for the movement is generated by an almost isometric co-contraction of the extensor and flexor tibiae muscles followed by a sudden release of the stored energy when the flexor motor neurons are inhibited. During this motor pattern, the spikes of the sensory neurons are superimposed on a depolarising synaptic potential generated near their output terminals that is linked to the time in the motor pattern when the sensory neurons spike. Flexion-sensitive neurons spike and their terminals are depolarised when the tibia is initially flexed. The depolarisation of the terminals precedes the spikes and persists during the co-contraction phase. Extension-sensitive neurons spike and their terminals are depolarised only when the tibia is rapidly extended, and they may repolarise during co-contraction. Some of these synaptic potentials occur before movements have started, suggesting that they may result from central elements of the motor pattern, whereas others are clearly consequent upon joint movements. The effect and timing of the presynaptic inhibition of the terminals during this voluntary movement should be to reduce the effectiveness of the sensory neurons in transmitting signals to their postsynaptic neurons. This could therefore be part of a mechanism that allows voluntary movements to proceed in the presence of self-generated sensory feedback which might impede that movement. Supported by NIH grant NS16058.

SPATIAL CODING OF A MECHANICAL STIMULUS BY THE LEECH LOCAL BEND NETWORK: MAPPING STIMULUS LOCATION TO BEHAVIORAL OUTPUT. J.E. Lewis\* and W.B. Kristan Jr., Biology Department., University of California, San Diego, 9500 Gilman Dr., La Jolla, CA, 92093-0357.

Local bending in the leech, *Hirudo medicinalis*, is a withdrawal reflex elicited by a mechanical stimulus to the body wall. Bending away from a stimulus results from the contraction of longitudinal muscles in the vicinity of the stimulus and relaxation of muscles opposite to the stimulus. Two classes of mechanosensory neurons mediate the reflex: low threshold T cells and higher threshold P cells. Previous work has described a subset of the neurons underlying the reflex, namely the interneurons and motor neurons responding to individual and paired electrical stimulation of P cells. We extend this work by using a more realistic mechanical stimulus that recruits both T cells and P cells. Video motion analysis of intact preparations and muscle tension measurements in semi-intact preparations reveal that the behavioral output varies smoothly with stimulus location around the circumference of the body wall. These results are consistent with a model involving the continuous coding of stimulus location by the local bend network. We are continuing this work by describing, as a function of stimulus location, the responses of the T cells, P cells, and motor neurons. A detailed characterization in this way will provide a framework for using the local bend network to investigate principles of sensory to motor transfer of spatial information.

## 505.5

DEVELOPMENT OF A MECHANOSENSORY PATHWAY IN LOCUSTS. H.J. Pflüger\*, S. Meuser, Freie Univ. Berlin, Inst. Neurobiologie, Koeningin-Luise-Str. 28-30, D-14195 Berlin, Germany.

A mechanosensory pathway has been identified in adult locusts that serves flight steering behaviour. It is comprised of filiform hairs on the locust frontal parts, a mediating projection interneuron in the ventral cord, and motor neurons to pleuroaxillary flight muscles. This pathway is found in all larval instars, although locust larvae do not possess functional wings. The receptive field of the interneuron comprises filiform hair receptors on the locust frontal part. In newly hatched first instars 30 filiform hairs are present, and in each larval instar new hairs are added, until in adults a full complement of 300 hairs is reached. The central nervous projections of these filiform hair receptors exhibit a structural dynamic during larval development, i.e. ipsilateral axon collaterals degenerate whereas contralateral ones are strengthened. Correspondingly, synapses to the ipsilateral interneuron are lost, those to the contralateral interneuron strengthened. This reorganisation is dependent on the neuronal activity of the receptors.

The pleuroaxillary target muscles are also reorganised: Each larval muscle consists of three discrete bundles whereas each adult muscle has only two discrete bundles. Correspondingly, larval muscles are innervated by three large motor neurones, adult muscles by only two motor neurons. This reorganisation correlates with the adult moult, and there is evidence that this reorganisation depends on a low juvenile hormone titre. This finding is supported by chemically induced precocious adults which possess only two muscle bundles and two large motor neurons.

## 505.2

HOW ARE LIMBS ON DIFFERENT SEGMENTS OF THE BODY COORDINATED? A TEST OF THE "EXCITABILITY GRADIENT" HYPOTHESIS IN THE SWIMMERET SYSTEM. B. Mulloney\* and W.M. Hall, Neurobiology, Physiology and Behavior, Univ. Calif. Davis, Davis CA 95616.

The swimmerets of crayfish are paired abdominal limbs that normally move rhythmically in a sequence of alternating power-stroke and return-stroke movements that thrust the animal forward. The phases of these movements in different segments lag progressively from posterior to anterior segments. To explain this metachronal progression and the observation that swimmeret beating normally begins with the most posterior pair, Ikeda and Wiersma (1964) proposed that posterior segments were intrinsically more excitable than anterior ones, and so reached threshold in each cycle before the anterior segments did. We tested this idea by comparing the periods of swimmeret motor patterns produced by isolated segments of the central nervous system of crayfish, *Pacifastacus leniusculus*, that were excited by carbachol.

When pairs of abdominal ganglia (A2-A3 and A4-A5) were exposed to the same concentrations of carbachol, we observed no significant differences in their periods. This lack of difference persisted in different concentrations of carbachol, and in different experiments that used TTX, or sucrose, or cutting to isolate pairs of ganglia.

We conclude that excitability of the modular swimmeret pattern-generating circuits do not differ systematically in different abdominal segments, and that another mechanism must account for the normal metachronal coordination that is characteristic of the swimmerets.

Supported by NSF grant IBN 92-22470.

## 505.4

A VISUALLY-SENSITIVE HALTERE CONTROL MUSCLE OF THE BLOWFLY, *CALLIPHORA*. M. H. Dickinson\*, Dept. of Organismal Biology & Anatomy, Univ. of Chicago, Chicago, IL 60637.

The metathoracic wings of all flies have been transformed during evolution into a pair of complex mechanosensory organs called halteres. The drumstick-shaped halteres beat anti-phase to the wings during flight, driven by their own asynchronous power muscles. The oscillations of each haltere are encoded by several hundred campaniform sensilla arranged in five fields at the base of the structure. Perturbations in the motion of the haltere caused by rotations of the animal during flight are thought produce compensatory alterations in wing kinematics via feedback from the campaniform afferents onto thoracic motoneurons.

The haltere afferents are thought to detect externally induced changes in haltere beating. Like the wing, however, each haltere possesses a discrete array of small synchronous control or 'steering' muscles, which could provide a mechanism for internally induced changes in haltere kinematics. Extracellular recordings from one of these muscles reveals strong descending visual input. This input shows a marked directionality, such that the haltere muscle is excited by rotation of large field visual stimuli towards the ipsilateral but not the contralateral side. The response elicited by a step change in pattern rotation is phasic-tonic: the muscle first adapts rapidly, but then maintains a low tonic discharge for the duration of the motion stimulus. The firing rate of the muscle is roughly proportional to the angular velocity of the visual stimulus.

These results have an important functional implication for the role of haltere in flight control. Given the strong monosynaptic input between haltere campaniforms and wing steering motoneurons, the haltere muscles could provide an alternative pathway for descending flight control interneurons. Instead of driving the wing steering muscles directly, descending visual input could change haltere beating which in turn could modify the output of wing muscles via feedback from haltere afferents.

## 505.6

REORGANIZATION OF PROPRIOCEPTIVE INPUT DURING MATURATION OF THE LOCUST FLIGHT SYSTEM. J.R. Gray\*, C.E. Gee & R.M. Robertson, Dept. Biology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

Current theories suggest that the flight circuitry of the locust is formed during embryogenesis and requires only appropriate activation at the imaginal moult. An alternative hypothesis is that adult maturation represents a time that is required to reorganize the circuits to produce effective flight. We tested the second hypothesis by examination of normal adult maturation of the flight system and maturation following removal of wing proprioceptors. During normal maturation an increase in the wingbeat frequency, from 15-25 Hz, is accompanied by growth of centrally projecting afferents and central flight interneurons. There is also an increase in the sensitivity of one of the afferents, the wing hinge stretch receptor (fSR), to rhythmic wing movements, demonstrating that proprioceptive input changes during maturation. Moreover, the ability of the fSR to entrain the flight motor pattern is greater in mature adults than in immature adults. Maturation following removal of proprioceptive input also results in reorganization of the flight circuitry. When the wing tegulae are ablated the wingbeat frequency decreases. During subsequent maturation the wingbeat frequency increases, approaching that of intact animals. There is, however, no difference in the central flight rhythm recorded from recovered and intact animals. This implies that changes in remaining proprioceptive input mediate functional recovery. We suggest that there is significant reorganization of the flight circuitry during adult maturation and most of these changes are manifested within the proprioceptive pathways.

## 505.7

**DYNAMICS OF CRICKET WIND-SENSING HAIRS: QUANTIFYING INPUT TO A MECHANORECEPTOR SYSTEM.** Leslie C. Osborne and John P. Miller\*, University of California at Berkeley, Berkeley, CA 94720

Crickets, like other orthoptera, are able to sense air disturbances caused by objects moving nearby. This sense is mediated by the cercal sensory system. The cricket has about two thousand mechanoreceptive filiform hairs on two antennal cerci projecting from the rear of the animal. Each hair's deflection is transduced into spikes by a single receptor neuron which carries this information to the cricket's CNS. The information about air movement direction, intensity, and frequency available to the cercal sensory system is determined by the mechanical properties of the filiform hairs. The mass, spring stiffness, and damping vary as a function of hair length, such that longer hairs have lower resonant frequencies than shorter hairs. Additionally, the boundary layer of dampened air movement near the surface of the cercus affects the amplitude and phase of a hair's response to oscillating flow.

Using a high-speed video microscope, we have characterized filiform hair responses to calibrated single frequency and bandpassed noise stimuli generated by speakers in an acoustically isolated laminar flow chamber. Near-field sound stimuli of variable direction, calibrated by a displacement sensitive microphone, were delivered by two speakers. Single hairs and groups of hairs of differing lengths were observed. Hair length was recorded, hair motion digitized, and angular motion over time extracted and analyzed. Tuning curves, power spectra, and the coherence of hair motion with the stimulus were computed. The results are interpreted in light of recent electrophysiological studies of signal encoding by the receptor neurons.

## 505.9

**SYNAPTIC DEPRESSION IN THE CRICKET CNS CAN BE CHARACTERIZED BY THE DEPLETION HYPOTHESIS.** A.A.V. Hill\*, P. Jin and R.K. Murphey, Neuroscience and Behavior Program, Biol. Dept., Univ. of Massachusetts, Amherst, MA 01003.

We have characterized synaptic depression at the synapses between wind-sensitive sensory neurons (SNs) and primary interneurons in cricket cercal sensory system. Identified SNs were stimulated with a train of 60 depolarizing pulses applied through a saline filled pipette placed over the cut end of a wind-sensitive filiform hair. The amplitude of the EPSP, recorded postsynaptically in either interneuron 10-3 or MGI, declined during the train at stimulus frequencies from 5 to 100 Hz. Based on the correspondence between the experimental results and the predictions of the depletion hypothesis this depression is most likely due to the depletion of transmitter (Liley and North, 1953, *J Neurophysiol* 16:509-527). According to the depletion hypothesis as the frequency of stimulation is increased the time constant of depression ( $\tau$ ) should decrease and the amplitude of the steady-state plateau should become lower. This prediction accurately describes the experimental data. For example, as the stimulus frequency was varied (5, 10, 20 Hz), for a synapse between SN 5p and MGI,  $\tau$  varied linearly (2500, 909, 588 ms). Also, the plateau EPSP amplitude was lower with higher stimulus frequencies. Additionally, we found that reducing the extracellular  $Ca^{++}$  concentration results in a decrease in the fraction of transmitter ( $F$ ) released with each stimulus and a change in the dynamics of depression that is consistent with transmitter depletion. When a synapse from SN 2c to 10-3 was stimulated in low  $Ca^{++}$  saline  $F$  was reduced by 50% and  $\tau$  increased by 150%. Our aim is to understand how synaptic dynamics shape the temporal response properties of the primary interneurons. Computer simulations suggest that differences in synaptic depression (Jin et al., 1995 Soc. Neurosci. Abstr.) and facilitation influence the phasic and tonic response properties of MGI and 10-3 respectively. Supported by NSF grant # IBN 9121063 to R.K.M.

## 505.11

**SENSORY INHIBITION OF PROLEG MOTOR ACTIVITY IN *Manduca sexta* LARVAE.** D.J. Fickbohm, S. Landau, and B.A. Trimmer\*, Dept. of Biology, Tufts University, Medford, MA 02155.

Our observations of *Manduca sexta* larvae suggest that control of proleg movement has both excitatory and inhibitory components. For example, proleg retraction normally evoked by stimulation of mechanosensory planta hairs (PHs) is often prevented during grasping. The excitatory factors are mediated, in part, by a monosynaptic reflex arc involving nicotinic and muscarinic mechanisms (e.g., Trimmer 1994 *J. Neurophysiol.* 72). Although inhibition of proleg reflexes is easy to see in freely moving larvae, it is harder to detect neurophysiologically. However, we made the following observations that suggest sensory input can inhibit motoneurons involved in proleg movement: 1) In extracellular recordings from sub-branches of the ventral motor nerve stimulation of lateral proleg hairs or PHs causes a decrease in the activity of motor units controlling proleg movement, 2) Similar mechanosensory stimulation can hyperpolarize and decrease the spike frequency of VPO and PDV motoneurons that control the ventral posterior oblique and the posterior dorsal ventral muscle groups.

To test the possible role of mAChRs in the inhibition of VPO we pressure-applied the muscarinic agonist, oxotremorine-M ( $1 \times 10^{-5}M$ ), into the ipsilateral neuropil. Rather than causing an inhibition, this depolarized VPO and increased its firing frequency. Therefore, it is likely that the inhibitory effects of mechanosensory hair stimulation on motor activity are mediated by polysynaptic pathways, perhaps employing a non-cholinergic neurotransmitter, such as GABA or 5-HT.

Supported by a Sloan Foundation Fellowship, Whitehall Foundation Grant, and NIH Grant NS 30566 to BAT.

## 505.8

**AIR CURRENT VELOCITY ENCODING BY ENSEMBLES OF FILIFORM MECHANORECEPTORS OF THE CRICKET CERCAI SENSORY SYSTEM.** J.C. Roddey and G.A. Jacobs\*, 195 LSA, Dept. of Molecular and Cell Biology, Univ. of California at Berkeley, Berkeley, CA 94720.

Techniques of stochastic systems analysis and principles of information theory were applied to analyze stimulus encoding by ensembles of wind-sensitive, filiform receptor neurons in the cricket cercal sensory system. White noise air current stimuli were presented to the cricket, and the spike train responses elicited by individual receptor neurons and pairs of receptors were recorded. The spike trains elicited in single cells by multiple presentations of the same stimulus waveform were combined to represent the simultaneous responses of an ensemble of receptors to a single stimulus presentation. The rate at which information about the stimulus could be encoded in ensemble responses was then estimated with the stimulus reconstruction technique. The information encoding rates of receptor ensembles were significantly higher than those of single neurons. Also, spike trains of pairs of receptors with different frequency response characteristics were simultaneously recorded in response to white noise air currents. Preliminary results confirm the hypothesis that such receptors have disparate phase response characteristics as well.

## 505.10

**ELEMENTARY COMPUTATION OF APPROACH IN A VISUAL INTERNEURON.** Nicholas Hatsopoulos\*, Fabrizio Gabbiani, & Gilles Laurent. CNS Program, 139-74, Caltech, Pasadena, CA 91125.

We investigated the coding properties of the descending contralateral motion detector (DCMD), a wide-field visual interneuron that extends from the brain to the metathoracic ganglion of the locust. We recorded its activity extracellularly while monocularly presenting objects on a computer screen that appeared to approach the animal.

The time of the post-stimulus histogram (PSH) peak correlated extremely well with the collision time of the stimulus despite variations in the object's physical size and approaching velocity. This suggested that DCMD may be warning the animal of impending collision, particularly for large and slow objects.

We developed a simple, mathematical model which matched the response profiles of DCMD quite well for a variety of different object sizes and velocities. Time-to-collision can be computed by taking the ratio of the angular velocity of an edge in the image to its angular distance from the focus of expansion. Our model replaces the denominator with the exponential of the angular extent of the image.

This non linearity was verified by presenting laterally moving objects of different sizes. Our model not only fit the PSH's resulting from objects moving at constant approaching velocities but also predicted the profiles from decelerating objects whose projected edges move at a constant angular velocity.

We also demonstrated that the critical variable in the denominator is the angular extent of the image and not its angular distance from the focus of expansion. We presented four approaching objects, all of the same size, surrounding the focus of expansion. The model fit the PSH's well only when the angular extent of each image was used.

# REGENERATION OF LESIONED NEONATAL MAMMALIAN SPINAL CORD IN CULTURE FOLLOWING APPLICATION OF ANTIBODY AGAINST GROWTH INHIBITORY PROTEIN.

Z. Varga, M. Schwab\* and J.G. Nicholls\*, Biozentrum, Univ. of Basel, 4056 Basel, Switzerland; #Brain Research Institute, 8029 Zürich, Switzerland

In the spinal cord of the neonatal opossum (*Monodelphis domestica*) in culture, neurites grow profusely and rapidly through a crush or a cut provided that the animal is less than 12 days old. At this critical period, oligodendrocytes, myelin, growth-inhibitory proteins and astrocytes have developed and regeneration stops. In the present experiments the antibody IN-1 was applied to the fluid bathing isolated lesioned spinal cords of animals after the critical period. This antibody blocks growth inhibitory actions of protein NI-35/250 which is associated with myelin. Penetration of antibody IN-1 into the tissue occurred rapidly and reliably under these conditions. Out of 33 preparations from animals aged 13-14 days without antibody none showed any outgrowth of fibers labeled by Dil into the crush. By contrast, in 17 out of 31 preparations from animals aged 13-17 days clear regeneration of axons occurred into and beyond the crush. The effect was specific for antibody IN-1; other antibodies failed to promote regeneration after the critical period even though they penetrated the CNS. These results suggest that the myelin associated antigen NI-35/250 plays a part in preventing regeneration as the animal matures. The use of an isolated central nervous system in culture permits assessment of the effects of trophic as well as inhibitory molecules singly or in combination.

## 506.3

# REGROWTH OF SPINAL MOTORAXONS AFTER SPINAL CORD INJURY: DISTRIBUTION OF PROSTAGLANDIN RECEPTORS AND G-PROTEINS IN THE CNS SCAR TISSUE.

M. Risling\*, M. Meier, S. Cullheim, A.-M. Sjögren and S. Lake, Department of Neuroscience, Karolinska institutet, S-171 77 Stockholm, Sweden and Pharmacia Biopharmaceutical Preclinical R&D, Stockholm, Sweden

Spinal motoneurons in the adult cat and rat have an ability to regenerate central nervous system (CNS)-type axons after a lesion in the ventral funiculus of the spinal cord. Regrowing motor axons penetrate the CNS-type of scar tissue and enter adjacent ventral root fascicles. This scar tissue is mainly composed of a loose trabecular web of astrocytic processes and invading leptomeningeal cells, which have high and low affinity receptors for NGF. The reactive astrocytes express NGF and a truncated species of *trkB*. Laminin, tenascin and collagens are upregulated in the extracellular matrix. In addition, there is a persistent defect in the blood-brain barrier function. Thus, blood-borne macrophages and trophic substances may have longterm access to the lesion area. Cytokines released from macrophages have been suggested to play a key role in the early response to CNS trauma, by regulating the synthesis of neurotrophins and matrix molecules in the scar tissue. Prostaglandins (PGs), induced by interleukins or transforming growth factor (TGF)  $\alpha$ , represent potent mediators in cytokine evoked actions and exert their effects via specific PG receptors, which are functionally linked with G-proteins. Many of the PG receptors have just recently been cloned. In the present study we have studied the distribution of PG receptors and (relevant)  $\alpha$  subunits of the trimeric G-proteins in CNS scar tissue using *in situ* hybridization and/or immunohistochemistry. Spinal motoneurons and astrocytes were shown to be labelled with markers for the PGF $_{2\alpha}$  receptor. 10 days after a lesion, could an upregulation of the  $\alpha$ 1,  $\alpha$ 2 and  $\alpha$ 11 subunits of trimeric G-proteins be observed in reactive glial cells and/or the blood vessels of the scar tissue. In addition, an upregulation of the receptor for TGF $\alpha$  was observed in the cicatrix. These findings are consistent with cytokine evoked effects during the formation of a traumatic CNS scar.

## 506.5

# ECTOPIC EXPRESSION OF THE NEURAL CELL ADHESION MOLECULE L1 BY MOUSE ASTROCYTES IMPROVES NEURITE OUTGROWTH.

H. Mohajeri\*, U. Bartsch, H. van der Putten<sup>1</sup>, G. Sansig<sup>1</sup>, L. Mücke<sup>2</sup> and M. Schachner, Neurobiology, Swiss Federal Institute of Technology, 8093 Zürich, Switzerland, 1: CNS Mol. Cell. Biol., Ciba, 4002 Basel, Switzerland, 2: Virology, RISC, 10666 N. Torrey Pines Rd., La Jolla, CA 92037 USA.

Transgenic mice lines were generated to test whether ectopic expression of L1, driven by GFAP regulatory elements, in astrocytes will overcome the inhibitory influences exerted by adult CNS tissue. *In situ* hybridization analysis of optic nerve sections from transgenic mice confirmed expression of L1 by astrocytes. Immunostaining of cultured astrocytes localized L1 protein to the cell surface. L1 protein expression in lesioned optic nerves of transgenic animals was up to 300% higher than in lesioned nerves of non-transgenic controls and up to 30% higher than in unlesioned optic nerves of transgenic animals. Mouse small cerebellar or chick DRG neurons extended up to 400% or 50% longer neurites on cryostat sections of lesioned optic nerves or astrocyte monolayers, respectively, when compared to similar preparations from non-transgenic controls. The potential to promote neurite outgrowth of different transgenic lines was proportional to the levels of L1 expression and was specifically inhibited by anti-mouse L1 antibodies. These observations demonstrate that L1 is able to overcome, at least in part, the non-permissive substrate properties of differentiated CNS glial cells and CNS tissue when expressed ectopically in astrocytes from transgenic mice.

## 506.2

# MECHANISM OF RECOVERY FROM SPINAL CORD INJURY IN NEONATAL MONDELPHIS DOMESTICA (S. AMERICAN OPOSSUM)

N. R. Saunders\*, P. Kitchener, G. W. Knott and J. G. Nicholls Dept. of Physiology, Uni. of Tasmania, GPO Box 252C, Hobart, Tasmania, 7001; <sup>1</sup>Dept. of Pharmacology, Biozentrum Uni. of Basel, Klingelbergstrasse 70, CH-4056 Basel, Switzerland.

There is increasing evidence that injury to the spinal cord in immature birds and mammals is followed by a significant degree of recovery and development of normal function providing injury is sufficiently early in development (eg. chick embryo, Hasan, *et al.* 1992, J. Neuroscience, 13, 492-507; opossum neonate, Saunders, *et al.* 1995, Clin. Exper. Pharm. Physiol. In press.). The extent to which this recovery and development in the opossum is dependent upon regeneration of neurites from damaged axons as opposed to growth of new axons not present at the time of injury is not known. Nor is it clear whether the remarkable degree of locomotor activity demonstrated in adult opossum that receive complete spinal transection in the first week of life, is due mainly to local circuits in the spinal cord, or whether the connections that develop following injury are normal. These problems have been studied in *Monodelphis domestica* whose spinal cords were crushed with fine forceps under anaesthetic and sterile conditions in the first week of life and allowed to develop to adulthood. Evoked potential and retrograde pathway tracing methods are being used to study the connectivity involved in walking and swimming movements in these animals. In order to remove tactile and proprioceptive inputs which may stimulate rhythmic walking in spinal operated animals, they were subjected to a swimming test and movements analysed on video. These experiments show that the animals are able to display rhythmic movements even when swimming, thus indicating that the activity is controlled at a supraspinal level.

# Growth Factors Increase PNS Regeneration Accuracy.

Roger D. Madison<sup>1,2,3</sup>, Victor Wang<sup>1</sup>, and Simon J. Archibald<sup>1</sup>. Division of Neurosurgery<sup>1</sup>, Department of Neurobiology<sup>2</sup>, Duke University Medical Center, and the Research Service of the VA Medical Center, Durham, NC<sup>3</sup>.

Preferential Motor Reinnervation (PMR) refers to the proven ability of regenerating motor axons in rat femoral nerve to preferentially, albeit incompletely, reinnervate motor vs. sensory distal nerve branches. We have now found that the addition of growth factors (aFGF & NGF) to the nerve transection site significantly increases PMR in the rat femoral nerve.

The motor and sensory neuronal pools projecting to the quadriceps muscle via the terminal motor branch of the femoral nerve were prelabeled with Dil (J. Neurosci. Meth., 39:123-129,1991) in 27 adult male Sprague Dawley rats. Ten animals served as controls for the double labeling method and seventeen animals received femoral nerve entubulation repair of a 4 mm nerve gap. The lumens of polyethylene nerve guides were flushed and filled with: A) N=10, control solution of lactated Ringers, USP (Abbott Labs.); or B) N=7, growth factor solution containing 100 ng/ml of 2.5S NGF and 400 ng/ml acidic-FGF. Following 4 weeks of regeneration, Fluorogold was applied to the motor branch. After 72 hrs the spinal cords and the L3 DRGs were processed to display retrogradely labeled neurons.

The accuracy of motor axon regeneration into the original terminal motor branch was profoundly increased from 51% to 90% (p<.001) by the addition of growth factors to the repair site. Sensory axon regeneration into the original terminal motor branch also increased from 59% to 69%, but this trend did not reach statistical significance. We propose that the increase in regeneration accuracy is due to increased axonal branching at the repair site.

Understanding the mechanisms of increased PMR may have significant benefits to clinical nerve repair. NS22404-09 and VA Merit Review (RDM).

## 506.6

# UP-REGULATION OF RECOGNITION MOLECULES DURING THE SUCCESSFUL REGENERATION OF THE FISH OPTIC PATHWAY.

R.R. Bernhardt\*, E. Tongiorgi, M. Schachner, Neurobiology, Swiss Federal Institute of Technology, 8093 Zürich, Switzerland.

Adult fish retinal ganglion cells (RGCs) can regenerate their axons. Here we correlate this capacity with the expression of mRNAs coding for L1.1, L1.2,  $\alpha$ -2, and N-CAM (homologs of mammalian cell recognition molecules), as detected by *in situ* hybridization. The mRNAs are expressed by developing RGCs, consistent with a role during axonogenesis. In adult RGCs, expression of the mRNAs appears reduced, most strikingly in the case of L1.1. RGCs react to an optic nerve lesion by up-regulating L1.1, L1.2, and possibly also N-CAM mRNA levels,  $\alpha$ -2 mRNA levels appear unchanged. The up-regulation seems to be part of a growth program that is re-activated after axotomy and may be an intrinsic determinant of a neuron's regenerative capacity. Presumptive glial cells in the optic pathway also respond to the lesion: L1.1, L1.2 and  $\alpha$ -2 mRNAs are detected in the regenerating but not the control optic pathways. N-CAM mRNA, which is constitutively expressed at low levels, is up-regulated. The mRNAs are expressed by only some of the cells in the pathway. These may be oligodendrocytes, reported to express related molecules in culture (Bastmeyer *et al.*, 1994). The up-regulation of the four mRNAs in the optic pathway could contribute to an environment that allows axonal regeneration.

## 506.7

**BRAIN NUCLEI WITH AXONS PROJECTING TO THE SPINAL CORD IN ZEBRAFISH: REGENERATIVE CAPACITY AND REGULATION OF CELL ADHESION MOLECULES.** Thomas Becker\*, Catherina G. Becker, Robert R. Bernhardt, Enrico Tongiorgi, Mario F. Wüllmann\*, Melitta Schachner. Neurobiology, Swiss Federal Institute of Technology, Hönggerberg, 8093 Zürich, Switzerland. +Brain Research Institute, University of Bremen, 28334 Bremen, Germany.

We studied axonal regrowth from brain nuclei projecting to the spinal cord of adult zebrafish after transection of the spinal cord. Axonal projections to the spinal cord in unlesioned animals were established for 20 distinct nuclei in the brain by retrograde labeling using biocytin, horseradish peroxidase, and fluorescent dextrans. Six weeks after spinal cord transection, most of these nuclei showed axonal regrowth. However, the n. ruber, n. tangentialis, n. raphes and the Mauthner cell did not or hardly show axonal regrowth.

To correlate axonal regrowth with expression of L1.1, a homolog of mouse L1, and of the neural cell adhesion molecule (NCAM), both known to promote neurite growth in mammals, the levels of expression of these molecules were investigated by *in situ* hybridization. L1.1 mRNA was strongly up-regulated in the nuclei with axonal regrowth, when compared to unlesioned animals. Up-regulation was first detectable 3 days after the lesion, remained high for 2 months, and had returned to control levels after 3 months. The nuclei with poor or no axonal regrowth did not show this up-regulation. NCAM mRNA was not up-regulated in any brain nuclei.

Our observation that axonal regrowth correlates with an up-regulation of L1.1 mRNA suggests that up-regulation of this molecule may contribute to regenerative axonal growth.

## 506.9

**MECHANISMS OF CONDITIONING LESION ENHANCEMENT OF NERVE REGENERATION** K. L. Lankford\* & J. D. Kocsis. Department of Neurology Yale University Medical School New Haven CT 06510 & Neuroscience and Regeneration Research Center West Haven CT 06516.

In this study, we assessed the mechanisms by which prior nerve injury enhances subsequent regeneration. To examine this issue, we compared the timing of neurite initiation, extent of outgrowth, and branching frequency of cultured adult rat DRG neurons from animals subjected to sciatic nerve injury one week before culture to control neurons and neurons exposed to conditioned media from ligated DRG or Schwann cells or treatments designed to alter intracellular calcium levels. Conditioning lesioned cultures had roughly twice as many process-bearing neurons after 1 day *in vitro* as controls although the average total neurite extension from neurons with neurites did not change. Retrograde labeling of cut neurons showed that precocious neurite initiation only occurred in neurons with previously ligated axons; neurons whose axons exited the sciatic nerve proximal to the site of injury were unaffected. Average interbranch distances also increased in conditioning lesioned cultures and increased with culture time for controls. Elevating intracellular calcium via depolarization or release from intracellular stores likewise increased neurite initiation at day 1, while thapsigargin, which indirectly blocks calcium transients, inhibited neurite initiation and reduced interbranch distances. By contrast, conditioned media from ligated neurons had no effect on any of the parameters measured and conditioned media from Schwann cell cultures increased the average total neurite extension, without affecting neurite initiation or branching frequency. These data suggest that at least one component of conditioning lesion enhancement of nerve regeneration is directly due to nerve injury, rather than changes in the trophic environment, and that calcium signals might be involved in triggering these changes.

**NEUROFILAMENT SPACING, PHOSPHORYLATION AND AXON DIAMETER IN REGENERATING AND UNINJURED LAMPREY AXONS.** D. S. Pijak, G. F. Hall, P. J. Tenicki, A. S. Boulas, D. I. Lurie and M. E. Selzer\*. Dept. of Neurology and the David Mahoney Inst. of Neurol. Sci., Univ. of Pa. Med. Ctr., Philadelphia, PA 19104-4283.

The relationships among NF phosphorylation, NF spacing and axon diameter were examined in uninjured and spinal cord-transected larval sea lampreys (*P. marinus*). Axon diameters in untransected spinal cords varied from 0.5-50µm. MABs specific for highly phosphorylated NFs labeled only large axons (>10µm), while mABs for lightly phosphorylated NFs labeled medium and small axons more darkly than large axons. For most axons in untransected animals, diameter was inversely related to NF packing density, but interfilament distances of the largest axons were only 1.5X those of the smallest axons. In addition, the NFs of the small axons in the dorsal columns were lightly phosphorylated but widely spaced. Regenerating neurites of giant reticulospinal axons (GRAs) have diameters only 5-10% that of their parent axons. While NFs in these slender regenerating neurites had packing densities twice those of their parent axons, they were highly phosphorylated. Following section of these same axons close to the cell body, axon-like neurites regenerated ectopically from dendritic tips. These neurites had NF packing densities 2.5X those of uncut GRAs, but were also highly phosphorylated. Thus NF phosphorylation probably does not control axon diameter directly through electrorepulsive charges that increase NF spacing. Phosphorylation of NFs might influence axon diameter through indirect mechanisms that can be over-ridden under some circumstances, e.g., during regeneration. NIH Grant # NS14837

## 506.8

**SILENCING OF THE GAP-43 GENE IN DIFFERENTIATED ZEBRAFISH RETINAL GANGLION CELLS DEPENDS ON AN INTACT CYTOSKELETON AND THE ACTIVATION OF A SIGNAL TRANSDUCTION PATHWAY INVOLVING PROTEIN PHOSPHATASES.** V. M. Zumsteg, P. Bormann and E. Reinhard\*. Dept. Pharmacology, Biozentrum of the University of Basel, 4056 Basel, Switzerland.

Neurite outgrowth and axon elongation depend largely on activation of a specific set of growth-associated genes. The single-copy GAP-43 gene is expressed strongly during neuronal development and then decreases drastically as synapses are formed. Axon interruption re-induces GAP-43 expression in nerve cells capable of regeneration. To explore the mechanisms that lead to silencing of the GAP-43 gene in differentiated neurons we studied its regulation in zebrafish retinal ganglion cells (RGCs) using *in situ* hybridization after optic nerve lesions and interference with intracellular structures in intact nerves. GAP-43 is not expressed in adult zebrafish retina. However, 24 hr after a crush of the optic nerve, RGCs start to re-induce GAP-43. Expression is maximal between day 6 and 10 after lesion, declines gradually thereafter and is absent 15 days after lesion. Prevention of functional regeneration by removing a part of the optic nerve results in sustained GAP-43 expression in RGCs up to 50 days after a lesion, suggesting that synapse formation triggers events that lead to silencing of the GAP-43 gene. To identify components of the signalling pathway we applied metal cuffs filled with agarose-embedded drugs to the intact zebrafish optic nerve. Vinblastine and colchicine, drugs that disrupt the axonal cytoskeleton resulted in GAP-43 induction in RGCs without optic nerve lesion. Similarly, inhibition of intracellular phosphatases by okadaic acid and calyculin A reinduced re-expression of the GAP-43 gene; kinase-inhibitors, such as staurosporine, had no effect. These results indicate that GAP-43 expression is actively repressed in differentiated zebrafish RGCs by retrogradely transported factors that may involve activation of phosphatases or inhibition of kinases. Supported by a grant from the SNF # 31-36266.92.

## 506.10

**EVIDENCE FOR GROWTH OF FASCICULUS GRACILIS AXONS THROUGH THE LESION AFTER TRANSECTION OF THE SPINAL CORD IN THE DEVELOPING OPOSSUM, *DIDELPHIS VIRGINIANA*.** G. F. Martin\*, J. R. Terman and X. M. Wang. Dept. Cell Biology, Neurobiology and Anatomy, The Ohio State Univ., Coll. of Med., Columbus, Ohio 43210.

We have shown previously that the spinal cord regenerates after transection during early development in the opossum and that brainstem axons grow through the lesion. We have since asked whether comparable growth of fasciculus gracilis axons occurs. In one experiment, the thoracic cord was transected at postnatal day (PD)5 or 12. The pups were maintained for approximately 30 days after which bilateral injections of Fast Blue (FB) were made several segments caudal to the lesion. Three to five days later, they were sacrificed and perfused so that their spinal cord and brainstem could be removed and sectioned for microscopic examination. In the animals subjected to transection at PD5, labeled axons were present in regenerated spinal cord at the lesion site and in the fasciculus gracilis rostral to it. Such axons could be traced to the nucleus gracilis. Labeled axons were not observed rostral to the lesion in the animals transected at PD12. In order to verify that some of the axons which crossed the lesion originated within dorsal root ganglia, we transected the thoracic cord at PD5 in a second group of animals and 7 days later made injections of cholera toxin conjugated to horseradish peroxidase (HRP) into the hindlimb on one side. The intent of the injections was to label dorsal root axons transganglionically. Three days after the injections, the pups were sacrificed and the removed spinal cords and brains were processed for HRP. In all cases, labeled axons could be traced through the lesion site to the nucleus gracilis. The results support our previous contention that the mammalian spinal cord regenerates after transection at early stages of development and show that axons of the fasciculus gracilis, like axons which originate within the brainstem, grow through the lesion. ## 506.12

**SPATIOTEMPORAL ASPECTS OF CRANIAL NEURAL CREST REGENERATION REVEALED BY DI1 LABELING AND *SLUG* EXPRESSION.** J. W. Sechrist\*, M. Angela Nieto, R. T. Zamanian and M. Bronner-Fraser. Dev. Biol. Ctr., UC Irvine, Irvine, CA 92717 and Instituto Cajal, CSIC, Avda. Doctor Arce 37, 28002 Madrid, Spain.

After unilateral ablation of avian cranial neural folds, the remaining neuroepithelial cells regulate to replace the missing neural crest population (Scherson et al., 1993). The effects of unilateral and bilateral ablations have now been compared using Di1, HNK-1 antibody labeling, and gene expression techniques. The results demonstrate that crest regeneration occurs only after apposition of the remaining neural fold and epidermis. We also discovered profound regional differences in the regenerative ability of the cranial neural tube; there is a robust regenerative response in the caudal midbrain/rostral hindbrain, but much less regulation in the caudal forebrain/rostral midbrain. Embryos with unilateral ablations recovered more completely, suggesting some contribution by the contralateral side. Bilateral ablations yielded significant numbers of neural crest cells, but deficits in neural crest-derived structures (i.e. trigeminal ganglion) were observed 3-4 days following ablation at the 4-7 somite stage. *Slug*, a transcription factor present in premigratory and migratory crest cells (Nieto et al., 1994), was expressed in cells proximal to the ablated region between 5-8 hours after surgery and prior to emergence of neural crest cells, indicating that up-regulation of *Slug* is an early response in crest regeneration. Our results demonstrate that the potential of the cranial neuroepithelium to regulate and replace the neural crest after ablation depends upon the timing, location, and extent of cranial neural fold ablation. Supported by USPHS HD 25138.

## 506.13

THE REGULATION OF ASTROCYTE GROWTH AND REACTIVITY. E.E. Geisert, Jr.\*<sup>1</sup>, L.J. Yang and N. Del Mar. Department of Anatomy and Neurobiology, University of Tennessee Health Science Center, Memphis TN, 38163.

Following an injury to the CNS, astrocytes become reactive to form a scar. Many investigators believe that this astroglial scar contributes in part to the lack of axonal regeneration and functional recovery. One approach to defining the role of reactive astrocytes in scar formation is to develop monoclonal antibodies to the surface proteins of astrocytes that will alter astrocytic growth. The present study centers around a monoclonal antibody, AMP1, that depresses the mitotic activity of glial cells, modulates astrocyte-astrocyte adhesion, and affects the morphology of cultured astrocytes. Previous studies demonstrated that the AMP1 antigen is found on the external surface of cultured astrocytes and is involved in adhesive interactions between these cells. Immunohistochemical studies reveal a dramatic increase in AMP1 immunoreactivity following cortical stab wounds, kainic acid lesions of the neostriatum, and focal ischemia. The monoclonal antibody AMP1 recognizes two proteins: a 106 kDa protein with a high degree of homology to non-muscle alpha actinin, and a 26 kDa protein that is related to the target of the antiproliferative antibody, TAPA-1. The characterization of these antigens indicates that the AMP1 antibody recognizes the 26 kDa protein on immunoblots and in tissue; while, the 106 kDa protein can be identified only on immunoblots and not in tissue or cells. Following CNS injury, the increase of immunoreactivity at the site of injury is due solely to the upregulation in the 26 kDa antigen, TAPA. Taken together these data indicate that TAPA plays a prominent role in regulating the astrocyte response to injury.

MATHEMATICAL MODEL OF FORMATION AND GROWTH OF SENILE PLAQUES IN ALZHEIMER DISEASE. S. Buldyrev, S. Havlin, E.T. Hedley-Whyte\*, H.E. Stanley and B.T. Hyman. Center for Polymer Studies and Dept Physics Boston University, Boston, MA 02215 & Neurology Service, Massachusetts General Hospital, Boston, MA 02114

Studying the geometrical properties of senile plaques may lead to insight into the various factors that contribute to amyloid deposition. Senile plaques are accumulations of a small amphipathic protein, A $\beta$ , in the cortex of individuals with Alzheimer disease (AD). Recently, the distribution of plaque size was found to be log-normal (1). This finding suggests that the growth mechanism of the plaques is a random multiplicative process. Neuropathological studies distinguish several different types of plaques, e.g., diffuse and compact, but the relationship among these is unknown. Since tracing the development of plaques *in vivo* is impossible, creating a biologically-motivated growth model is of interest. We developed a mathematical model of A $\beta$  amyloid aggregation that accurately models the stable log-normal distribution of plaque sizes and the geometrical morphology of both diffuse and compact plaques. Crucial aspects of this model are that there are both aggregation and dissociation kinetics of A $\beta$  interaction with plaques, and that these vary within defined ranges near a critical point.

## 507.3

A biotechnological method provides access to aggregation competent monomeric Alzheimer's 1-42 residue amyloid peptide (A $\beta_{1-42}$ )

H. Dobeli, D. Schmidt, B. Seilheimer\* and M. Zulauf. Hoffmann-La Roche, CH-4002 Basel, Switzerland.

Deposition of A $\beta_{1-42}$  appears to be fundamental for AD pathogenesis. In contrast to A $\beta_{1-40}$ , A $\beta_{1-42}$  is characterized by its extreme tendency to aggregate into fibres or amorphous precipitate. A tailored biotechnological method prevents aggregation of A $\beta_{1-42}$  monomers during its production. The method is based on a protein tail fused to the amino terminus of A $\beta$ . This tail leads to a high expression in *E. coli*, and a histidine affinity tag facilitates purification. Selective cleavage of the fusion tail is performed with cyanogen bromide by immobilizing the fusion protein on a reversed phase chromatography column. Cleavage then occurs only at the methionine positioned at the designed site but not at the methionine contained in the membrane anchor sequence of A $\beta$ . Furthermore, immobilization prevents aggregation of cleaved A $\beta$ . Elution from the HPLC column and all succeeding purification steps are optimized to preserve A $\beta_{1-42}$  as a monomer. Solutions of monomeric A $\beta_{1-42}$  spontaneously aggregate into fibres within hours. This permits the investigation of the transition of monomers into fibres and the correlation of physico-chemical properties with biological activities. Mutations of A $\beta_{1-42}$  at position 35 influence the aggregation properties. Wild-type A $\beta_{1-42}$  with methionine at position 35 has similar properties as A $\beta$  with a methionine sulfoxide residue. The fibre formation tendency, however, is reduced when position 35 is occupied by a serine, leucine or glutamic acid residue.

The biological effect has been investigated with rat PC12 cells using the MTT reduction assay as a measure. Inhibition of MTT reduction correlates with the presence of fibres: the EC $_{50}$  for the methionine sulfoxide derivative is ~1nM and for the glutamic acid mutant ~1 $\mu$ M.

## 507.2

KINETIC ANALYSIS OF A $\beta$  AGGREGATION

D.B. Teplow\*<sup>Δ†</sup>, A. Lomakin<sup>Δ†#</sup>, D.A. Kirschner<sup>††</sup>, and G.B. Benedek<sup>#</sup>.

<sup>Δ</sup>Department of Neurology, Brigham and Women's Hospital; <sup>†</sup>Neurology Research, Children's Hospital; and <sup>††</sup>Department of Neurology (Neuroscience), Harvard Medical School, Boston, MA 02115. <sup>#</sup>Department of Physics, and Center for Material Science and Engineering, Massachusetts Institute of Technology, Cambridge, MA, 02139.

Deposition of fibers of the amyloid  $\beta$ -protein (A $\beta$ ) in the cerebral parenchyma and vasculature is a major neuropathologic feature of Alzheimer's disease. Since A $\beta$  normally exists in a soluble form in human plasma and CSF, a key etiologic issue is how this soluble molecule is converted into amyloid fibers. Although fibrillogenesis has been studied extensively *in vitro*, the initial steps in this process are poorly understood. We have applied the techniques of quasielastic light scattering spectroscopy (QLS) to this question. We report here the results of kinetic studies of the aggregation of synthetic human A $\beta$ (1-40) and various structural analogues thereof. These studies have led to the development of a new theory describing A $\beta$  aggregation and fibrillogenesis.

## 507.4

QUANTIFICATION OF SOLUBLE AND AGGREGATED A $\beta$  USING A NOVEL METAL-COATED MICROTITER PLATE ELISA. R.D. Moir, A.J. Bush, K.M. Rosenkranz, L.A. Rodes, S. Guénette\* and R.E. Tanzi. Genetics and Aging Unit, Massachusetts General Hospital, Building 149, 13th St, Boston, MA 02114.

A $\beta$  is the principal component of cerebral amyloid in Alzheimer's disease (AD). Recent studies have identified A $\beta$  as a strong copper and zinc binding protein and have shown that physiological concentrations of Zn<sup>2+</sup> rapidly induce amyloid formation *in vitro*. We exploited these interactions to develop an ELISA which uses these metals to capture the A $\beta$  metalloprotein. Immobilized Cu<sup>2+</sup> or Zn<sup>2+</sup> ions replace bound antibodies used to capture A $\beta$  in conventional sandwich ELISA protocols. Both soluble and aggregated A $\beta_{1-40}$  and A $\beta_{1-42}$  are captured by the metal-coated microtiter plates. The present limit of sensitivity for A $\beta$  is 20 pg/ml (=5 pM).

We have also developed simple methods for enriching and purifying A $\beta$  from biological samples using filtration techniques, anion exchange and metal chelating chromatographic procedures. Using these techniques in combination with immunoblots, we have verified the specificity of the novel metal capture ELISA for CSF (20-35 ng/ml), neuronal cell culture media (0.5-1 ng/ml), brain extracts (0.1-0.5 ng/g) and plasma (0.5-1 ng/ml).

Preliminary findings indicate that, although there is considerable overlap, A $\beta$  levels in the CSF of patients diagnosed as having AD are decreased relative to controls. These novel technologies were also used to demonstrate that Zn<sup>2+</sup> induces A $\beta$  aggregation in the presence of CSF.

## 507.5

UNDERSTANDING NUCLEATION-DEPENDENT AGGREGATION OF  $\beta$ -AMYLOID PEPTIDE AND COMBINATORIAL SEARCHES FOR PEPTIDES THAT INTERACT WITH  $\beta$ -AMYLOID. S. R. Sahasrabudhe\*, J. E. Sun, S. Goyal, J. Knaeblein, P. Gonzalez-DeWhitt, M. A. Fortes, N. G. Riedel and S. R. Hughes, Neuroscience PGU, Hoechst-Roussel Pharmaceuticals Inc., P O Box 2500, Somerville, NJ 08876.

The kinetics of amyloid fibril formation by  $\beta$ -amyloid peptide ( $A\beta$ ) are typical of a nucleation-dependent polymerization mechanism. This type of mechanism suggests that the study of the interaction of  $A\beta$  with itself can provide some valuable insights into Alzheimer disease amyloidosis. Interaction of  $A\beta$  with itself *in vivo* was explored with the yeast interaction trap system. Fusion proteins were made by linking the  $A\beta$  fragment to a LexA DNA binding domain (bait) and also to a B42 trans-activation domain (prey). Protein-protein interactions were measured by expression of these fusion proteins in *Saccharomyces cerevisiae* harboring a lacZ ( $\beta$ -galactosidase) and LEU2 (leucine utilization) gene under the control of a LexA-dependent operator. This approach suggests that the  $A\beta$  molecule is capable of interacting with itself *in vivo*. LexA protein fused to the *Drosophila* protein bicoid (LexA-bicoid) failed to interact with B42 fragment fused to  $A\beta$ , indicating that the observed  $A\beta$ - $A\beta$  interaction was specific. Also no significant interaction was observed in yeast bearing LexA- $A\beta$  bait when the B42 trans-activation domain was fused to  $A\beta$  fragment with phenylalanine<sup>19</sup>, phenylalanine<sup>20</sup> substituted by threonine-threonine ( $A\beta$ TT). These findings suggest that the yeast system described above can be used to study the interactions of  $A\beta$  monomers and to define the peptide sequences that are important in nucleation-dependent aggregation. We have performed saturation mutagenesis in the VFFA region of  $A\beta$  in the context of the prey plasmid. This library screen identified several peptides that interact strongly with  $A\beta$ .

## 507.7

HOMOPHILIC- AND COLLAGEN-BINDING SITES OF APP ARE OVERLAPPING BUT DIFFERENTLY REGULATED. G. Multhaup, D. Beher, L. Hesse, A. Schlicksupp, J. Beer\*, C.L. Masters and K. Beyreuther. ZMBH-Center for Molecular Biology, Im Neuenheimer Feld 282, D-69120 Heidelberg, Germany. \*Department of Pathology, The University of Melbourne, Parkville, Victoria 3052, Australia.

The specific binding of the amyloid precursor protein (APP) to extracellular matrix molecules (ECM) suggests that APP regulates cell interactions and has a function as a cell adhesion molecule (CAM) and/or substrate adhesion molecule (SAM). On the molecular level APP has binding sites for collagen, laminin and glycosaminoglycans (GAG) which is a characteristic feature of cell-adhesion molecules. We have examined the interactions between the APP and collagen types I, III, IV and V and identified the corresponding binding sites on APP and collagen type I.

We show that <sup>125</sup>I-APP bound most efficiently to collagen type I in a concentration-dependent and specific manner in the native and heat denatured states suggesting an involvement of a contiguous binding site on collagen. This binding site was identified on the cyanogen bromide fragment  $\alpha$ 1(I) CB6 of collagen type I which also binds heparin. APP did not bind to collagen type I-heparin complexes which suggests that there are overlapping binding sites for heparin and APP on collagen.

Since a peptide encompassing residues 448-465 binds to collagen type I and inhibits APP-collagen type I binding in nanomolar concentrations, this region may comprise the major part of the collagen type I binding site of APP. Moreover, our data also indicate that the collagen binding site represents a homophilic binding site for APP that can be modulated by zinc(II), copper(II) and heparin. Taken together, the data suggest that the regulation of APP binding to collagen type I by heparin occurs through the competitive binding of heparin and APP to collagen, and the collagen binding sequence of APP competes with homophilic binding of APP.

## 507.9

EFFECTS OF CONGO RED ON  $A\beta$  PRODUCTION, STABILITY AND AGGREGATION IN CHO CELLS. M.B. Podlisny\*, B. Ostaszewski, C.H. Haass, D.J. Selkoe\* Harvard Med. Sch., Boston.

Fibrillar deposits of amyloid  $\beta$ -protein ( $A\beta$ ) characterize AD. Studies with synthetic  $A\beta$  peptides show that soluble, monomeric  $A\beta$  is relatively inert whereas fibrillar aggregates of  $A\beta$  are neurotoxic *in vitro*. These findings, along with genetic and transgenic mouse data, suggest that aggregated  $A\beta$  is pathogenic in AD.  $A\beta$  is proteolytically cleaved from its precursor protein ( $\beta$ APP) and constitutively secreted as a monomeric 4 kDa peptide. Understanding the processes that mediate the conversion of monomeric  $A\beta$  to aggregated  $A\beta$  is thus important. We have recently shown that  $\beta$ APP-transfected CHO cell conditioned medium contains small amounts ( $<10^{-9}$ M) of SDS-stable oligomers of  $A\beta$ , primarily dimers and trimers. Overnight metabolic labeling of these cells in the presence of 10  $\mu$ M Congo red (CR) leads to a marked increase in 4 kDa  $A\beta$  and a modest decrease in oligomeric  $A\beta$  in the medium. Experiments on the effect of CR on  $A\beta$  production, stability and aggregation were conducted. CR was found to stabilize  $A\beta$  only slightly from degradation by endogenous proteases in the medium. CR had no detectable effect on full-length  $\beta$ APP or soluble APP<sub>s</sub> levels. It produced a slight decrease in the amount of  $A\beta$  secreted during short-term pulse-chase experiments. CR also caused an increase in 12 and 14 kD C-terminal  $\beta$ APP fragments, which were subsequently turned over. These rather subtle effects of CR on  $A\beta$  production and stability cannot account for the large increase in  $A\beta$  monomer found after overnight labeling in CR. Therefore, CR may be inhibiting the aggregation of monomeric  $A\beta$  into higher molecular weight species that are currently not detectable by our immunoprecipitation protocol.

## 507.6

Zinc Induces Aggregation of PN2 and  $A\beta$  in Dog, Monkey and Human Cerebrospinal Fluid. A. M. Brown, D. M. Tummolo, J. Hofmann, J. S. Jacobsen\*, and J. Sonnenberg-Reines. Department of Central Nervous System Biological Research, Wyeth-Ayerst Research, American Home Products Corporation, Pearl River, NY 10965.

It has been suggested that abnormalities in zinc metabolism may play a role in the pathogenesis of senile dementias. Recently it was reported that addition of zinc to buffered solutions of  $A\beta$  induced accelerated formation of insoluble aggregate (Science 265, 1464-7, 1994). The studies reported the behavior of  $A\beta$  at concentrations of  $\sim 0.8 - 8 \mu$ M  $A\beta$  at 25  $\mu$ M Zn<sup>2+</sup>, or 1.6  $\mu$ M  $A\beta$  and 1-300 nM Zn<sup>2+</sup>. In contrast, the concentration of  $A\beta$  in cerebrospinal fluid (CSF) is typically 2-3 nM. Furthermore, the relevance to  $A\beta$  found in its native milieu, which includes many potential carriers of both  $A\beta$  and zinc, is unclear.

We have developed a highly sensitive western blotting system that allows detection and quantitation of PN2 and  $A\beta$  from 50  $\mu$ l samples of CSF. Using this technique we have examined the effect of added zinc upon the solubility of PN2 and  $A\beta$  in CSF, determined by sedimentation of aggregates by ultracentrifugation. We find that addition of  $\geq 50 \mu$ M zinc to CSF induces the rapid formation of sedimentable aggregates that include both PN2 and  $A\beta$ . The reaction is specific, since most ( $\geq 90\%$ ) of the CSF protein remains soluble under the same conditions. We also observe evidence of spontaneous aggregation of  $A\beta$  in CSF from different species without any additions. We are analyzing the structure of the amyloid-containing pellet to learn if there is evidence of fibril formation. Investigation of aggregation of  $A\beta$  in biological fluids will aid in assessing the biological relevance of agents that have been reported to accelerate fibril formation.

## 507.8

ZINC INDUCES AGGREGATION OF  $A\beta_{1-40/42}$  AT PHYSIOLOGICAL CONCENTRATIONS. A. I. Bush\*, R. D. Moir, K. M. Rosenkranz, L. A. Rhodes and R. E. Tanzi. Genetics and Aging Unit, Mass. Gen. Hospital, Boston, MA.

$A\beta_{1-42}$  is the main component of plaque amyloid in Alzheimer's disease (AD). We are systematically appraising neurochemical factors which promote  $A\beta$  amyloid formation *in vitro*. Among the biochemical lesions of AD is a cerebral and systemic defect of zinc metabolism. We have shown that  $A\beta$  specifically and saturably binds zinc, when, at physiological concentrations, it increases the peptide's adhesive properties, resistance to proteolysis and rapidly induces amyloid formation (Bush *et al.*, Science, 265, 1464, 1994). The rat homolog of  $A\beta$  is not sensitive to the effects of zinc, perhaps explaining why this species is not subject to cerebral amyloid deposition.

We have developed two novel technologies to study the differential effects of metal ions upon the physicochemical behaviour of the 1-40 and the 1-42  $A\beta$  species. We analysed the solubility of peptides using a filtration assay where the retention of aggregated peptide ( $>0.2 \mu$  diameter) permits the high-throughput quantification of metal-induced precipitation (Bush *et al.*, *ibid*; Bush *et al.*, Science, in press). Using this technique we determined that at 1.6  $\mu$ M, the spontaneous aggregation of the 1-42  $A\beta$  form exceeds that of the 1-40 form. However, seeding of 1-40 solutions with pre-aggregated 1-42 induces far less aggregation than incubation with Zn(II). Although Fe(II) and Cu(II) are capable of inducing some aggregation in this system, only Zn(II) induces a readily sedimentable, relatively large (10-40  $\mu$ m), conophilic reaction product.

Using Zn(II) or Cu(II) immobilized onto microtiter plates, we have developed a novel capture ELISA to quantify  $A\beta$  in biological fluids, and for characterizing the physicochemical interactions of metalloproteins. This capture assay can quantify aggregated  $A\beta$ , and was used to determine that aggregation of  $A\beta$  at low nM concentrations can be induced by physiological concentrations of zinc.

## 507.10

THE HEPARIN-BINDING OF  $A\beta_{WT}$  AND  $A\beta_{E22Q}$  DEPENDS ON THE AGGREGATION STATE OF  $A\beta$  AND IS DIFFERENTIALLY BLOCKED BY CONGO RED. D.J. Watson<sup>1</sup>, A.D. Lander<sup>2\*</sup> and D.J. Selkoe<sup>1</sup>, <sup>1</sup>Center for Neurologic Diseases, Brigham and Women's Hospital and Harvard Medical School and <sup>2</sup>Department of Brain and Cognitive Sciences, M.I.T., Boston, MA 02115.

Heparan sulfate proteoglycans (HSPGs) are components of many types of amyloid deposits, including the diffuse and cored plaques of Alzheimer's disease and the vascular amyloid of Hereditary Cerebral Hemorrhage with Amyloidosis, Dutch type. To help to understand the close association of  $A\beta$  fibrils with HSPGs in these amyloid deposits, we examined the binding of synthetic  $A\beta_{1-40}$  to a model glycosaminoglycan, <sup>125</sup>I - low molecular weight ( $<6$  kD) tyramine-heparin, using affinity coelectrophoresis (ACE) [Lee and Lander, PNAS 88(7), 1991]. Fibrils of Dutch mutant (E22Q) or wildtype  $A\beta_{1-40}$  were formed by resuspending lyophilized peptide in a phosphate-buffered salt solution to 100  $\mu$ M and rocking for 2 days at 25°C, then diluting and sonicating the resultant pellet. Fibrillar wildtype  $A\beta$  shifted the mobility of heparin half-maximally at about 1  $\mu$ M  $A\beta$ . Fibrillar mutant  $A\beta_{E22Q}$  had a slightly increased affinity for heparin. In addition, we found that pre-incubation of  $A\beta$  fibrils with the amyloid-binding dye Congo Red completely blocked the binding of heparin to wildtype fibrils but not to mutant E22Q fibrils. The importance of fibrillar  $A\beta$  structure for heparin binding is emphasized by the fact that freshly resuspended  $A\beta_{WT}$  did not shift the mobility of heparin, and by a reverse ACE experiment in which concentrations of Na-heparin up to 30 mg/ml did not shift the mobility of nonfibrillar E22Q or wildtype <sup>125</sup>I- $A\beta_{1-40}$ . However, freshly resuspended  $A\beta_{E22Q}$  in water or in 5 mM NaOH still produced a shift of heparin mobility similar to the shift caused by mutant fibrils. We are further characterizing these results by doing electron microscopy on the  $A\beta$  fibrils and by the use of different peptide preparations, aggregation protocols, glycosaminoglycans, and blocking agents.

## 507.11

EFFECTS OF APOLIPOPROTEIN E AND PERLECAN ON AGGREGATION AND TOXICITY OF  $\beta$ -AMYLOID PROTEIN EXPRESSED IN CULTURED CELLS. K. Fukuchi<sup>1</sup>, T. Ohman<sup>1</sup>, A.D. Snow<sup>2</sup>, R.C. LeBoeuf<sup>2</sup>, C.E. Furlong<sup>3</sup>, and J.R. Hassell<sup>4</sup>. <sup>1</sup>Dept. of Comparative Medicine, Univ. of Alabama at Birmingham, Birmingham, AL 35294; <sup>2</sup>Pathology and <sup>3</sup>Medicine, Univ. of Washington, Seattle, WA 98195; <sup>4</sup>Dept. of Ophthalmology, Univ. of Pittsburgh, Pittsburgh, PA 15213.

Characteristic pathological changes found in the brains of patients with Alzheimer's disease (AD) are deposits of  $\beta$ -amyloid protein (A $\beta$ ) aggregates and loss of selected neurons. A $\beta$  and its precursor protein (PP) are thought to play a causative role in the pathogenesis of AD. To study amyloidogenicity (aggregation) and neurotoxicity of A $\beta$ , we had previously established cell culture systems (COS and P19 cells) where overexpression of cDNA for a C-terminal region of PP brings about aggregation of the C-terminal fragments in COS cells and degeneration of neurons in P19 cells (Fukuchi et al., 1992, BBRC 182:165). Since apolipoprotein E (ApoE) and perlecan, a specific heparan sulfate proteoglycan, are intimately associated with A $\beta$  deposits in the brains of patients with AD, we have been using the cell culture systems to investigate the effects of these proteins on amyloidogenesis and  $\beta$ -amyloid-mediated neurotoxicity. When both ApoE3 and the C-terminal fragment of PP were overexpressed in COS cells, Western blot analyses revealed partial inhibition of A $\beta$ -aggregation. On the other hand, overexpression of perlecan domains I and II, or domain III, with the C-terminal fragment of PP appeared not to influence A $\beta$  aggregation. We are currently evaluating ApoE4 and other domains of perlecan to study their potential influence on A $\beta$  aggregation. The effects of ApoE and perlecan on A $\beta$ -mediated neurotoxicity are being studied using P19 cell cultures. This work was supported by the National Institute of Health and the Alzheimer's Association, Inc.

## CALCIUM CHANNEL STRUCTURE, FUNCTION AND EXPRESSION I

## 508.1

BIOPHYSICAL AND PHARMACOLOGICAL CHARACTERIZATION OF STABLY EXPRESSED CLASS B AND CLASS E  $Ca^{2+}$  CHANNELS IN HEK 293 CELLS. D.M. Rock<sup>1</sup>, S.J. Stoehr<sup>1</sup>, J. Offord<sup>2</sup> and A. Palma<sup>3</sup>. <sup>1</sup>Neuroscience Therapeutics and <sup>2</sup>Biotechnology, Parke-Davis Research, 2800 Plymouth Rd., Ann Arbor, MI 48105 and <sup>3</sup>Neurex Corporation, Menlo Park, CA 94025.

Molecular biological experiments have shown that several different subtypes of the  $\alpha_1$  subunit of  $Ca^{2+}$  channels exist. Co-expression of different  $\alpha_1$  subunits with  $\alpha_2$  and  $\beta$  subunits results in  $Ca^{2+}$  channels that have different biophysical and pharmacological properties. In these experiments, we have stably expressed the human  $\alpha_{1B}$  (Class B) or  $\alpha_{1E}$  (Class E) along with rabbit skeletal muscle  $\alpha_2$  and human neuronal  $\beta$  in HEK293 cells. We determined the biophysical and pharmacological properties of these expressed channels.

Conventional techniques were used to obtain whole-cell voltage-clamp recordings of  $Ca^{2+}$  currents, with 2 mM  $Ca^{2+}$  as the charge carrier. Both classes of  $Ca^{2+}$  channels were high voltage activated, with activation first occurring at a test potential of -20 to -10 mV, with peak current at a test potential of +10 to +20 mV. Steady state inactivation properties of both classes of channels were also similar, with channels becoming 50% inactivated at a holding potential of around -50 mV. However, the rate of inactivation of these two classes of  $Ca^{2+}$  channels was different. While both classes of  $Ca^{2+}$  channels showed voltage-dependent inactivation during test depolarizations, Class B channels inactivated more slowly than Class E channels. Similar to what has been previously reported in oocytes injected with the same subunits, Class B channels were sensitive to  $\omega$ -conopeptides and Class E channels blocked only by the nonselective toxin  $\omega$ -Aga-IIIa.

These biophysical and pharmacological properties of expressed channels will be compared with  $Ca^{2+}$  channels expressed in superior cervical ganglion neurons (N-type) and a subtype of  $Ca^{2+}$  channels expressed in cerebellar granule cells (R-type).

## 508.3

AN ESSENTIAL STRUCTURAL DOMAIN THAT DETERMINES THE BIOPHYSICAL PROPERTIES OF THE HUMAN  $\alpha_{1A}$  HIGH-VOLTAGE ACTIVATED CALCIUM CHANNEL. M.E. Williams, M. Hans\*, P. Sionit, E.C. Johnson and S.B. Ellis. SIBIA, Inc., La Jolla, CA 92037.

The human  $\alpha_{1A}$  and  $\alpha_{1B}$  type calcium channels have distinct biophysical properties. Transient expression of human  $\alpha_{1A}$ ,  $\alpha_{1B}$ , calcium channel subunits in HEK293 cells results in robust voltage-activated barium ( $Ba^{2+}$ ) currents ( $2.71 \pm 3.02$  nA,  $n=13$ ) which inactivate rapidly ( $\tau_{inact} = 200$  ms). In contrast, co-expression of the  $\alpha_{1A}$ ,  $\alpha_{1B}$ , calcium channel subunits result in relatively small inward  $Ba^{2+}$  currents ( $0.185 \pm 0.166$  nA,  $n=74$ ) that inactivate more slowly ( $\tau_{inact} = 346$  ms). The size of the  $\alpha_{1A}$ -type current is independent of the  $\alpha_{1A}$  splice variant or  $\beta$  subunit coexpressed. Moreover,  $\alpha_{1A}$  calcium channels expressed in *Xenopus* oocytes gave rise to robust  $Ba^{2+}$  currents ( $>1$   $\mu$ A). To identify structural elements within the  $\alpha_{1A}$  subunit responsible for the relatively small and slowly inactivating  $Ba^{2+}$  currents expressed in HEK293 cells, we constructed a series of chimeras combining portions of the  $\alpha_{1A}$  and  $\alpha_{1B}$  subunits and coexpressed them with  $\alpha_{1B}$  and  $\beta_{1,3}$  subunits.

Expression of an  $\alpha_{1A}$  subunit that contains the IVS3-COOH terminus of  $\alpha_{1B}$  resulted in macroscopic  $Ba^{2+}$  currents with  $\sim 10$ -fold larger current magnitude than the wild type  $\alpha_{1A}$  subunit. The inactivation kinetics of these  $Ba^{2+}$  currents were faster ( $\tau_{inact} = 108$  ms) compared to the wild type  $\alpha_{1A}$  or  $\alpha_{1B}$  calcium channel. In contrast, expression of an  $\alpha_{1A}$  subunit containing only the COOH terminus of  $\alpha_{1B}$  resulted in peak current amplitudes of  $<30$  pA. Whole cell recordings of subsequent chimeras revealed that substitution of the  $\alpha_{1B}$  IVS5-IVS6 region within the  $\alpha_{1A}$  subunit is sufficient to enhance  $Ba^{2+}$  current amplitude ( $>30$ -fold) and increase the rate of inactivation. Site specific mutations within the  $\alpha_{1B}$  IVS5-IVS6 segment are being used to help identify specific amino acids that affect the biophysical characteristics of human  $\alpha_{1A}$  calcium channels. Further analysis is required to determine whether the increase in current magnitude is a result of an increase in the expression of the number of functional channels or, alternatively, reflect changes in the open probability of the channel.

## 507.12

FURTHER STUDIES IMPLICATING THE IMPORTANCE OF PERLECAN (A SPECIFIC HEPARAN SULFATE PROTEOGLYCAN) IN AN ANIMAL MODEL OF FIBRILLAR A $\beta$  AMYLOID DEPOSITION IN VIVO: COMPARISON OF A $\beta$  (1-42) VERSUS A $\beta$  (1-40). A.D. Snow<sup>1</sup>, J.A. Cummings<sup>1</sup>, C.T. Ng<sup>1</sup>, W. Yang<sup>1</sup>, D. Noghin<sup>1</sup>, K. Rimvall<sup>2</sup>, M.J. Sheardown<sup>2</sup> and M. Judge<sup>2</sup>. <sup>1</sup>Dept. of Pathology, Neuropathology Labs Box 356480, University of Washington, Seattle, WA 98195 and <sup>2</sup>Novo Nordisk, 2760 Malov, Denmark.

Previously, we described a new consistent animal model to study the effects of fibrillar beta-amyloid protein (A $\beta$ ) in brain, by continuous coinfusion of perlecan and A $\beta$  into rodent brain (Neuron 12:219-234, 1994). In the present study, we have compared the effects of perlecan infusion into rat hippocampus in the presence of A $\beta$  (1-42) versus A $\beta$  (1-40). Sprague-Dawley rats (6 per group) were infused for 1 week with A $\beta$  (1-42), A $\beta$  (1-40), perlecan only, A $\beta$  (1-42) + perlecan, A $\beta$  (1-40) + perlecan, or vehicle only. 100% of animals (12 of 12) infused with perlecan plus A $\beta$  (1-42 or 1-40) demonstrated congophilic and Thioflavin S positive deposits (indicative of amyloid) at the infusion site and penetrating into brain parenchyma. Only 50% (6 of 12) of animals infused with A $\beta$  (1-42 or 1-40) showed any indication of amyloid deposition in brain. A significant 4-fold increase ( $p < 0.01$ ) in the extent of A $\beta$  amyloid deposition (as measured by blind scoring of Congo red stained sections) was observed in animals infused with A $\beta$  (1-42 or 1-40) + perlecan, versus A $\beta$  (1-42 or 1-40) only. No significant differences in congophilia were observed between A $\beta$  (1-42) versus A $\beta$  (1-40), in the presence of perlecan. Current analysis includes blind scoring of sections to evaluate potential neurotoxic effects, and evaluation of amyloid effects on glia and induction of Alzheimer's disease-like antigens. This study demonstrates that perlecan enhances A $\beta$  amyloid deposition *in vivo* regardless of the predominant A $\beta$  amyloid protein isoform (ie. 1-42 or 1-40) and reconfirms the importance of perlecan in A $\beta$  amyloidosis.

## 508.2

N-TYPE CALCIUM CHANNELS ASSOCIATE WITH MULTIPLE BETA SUBUNITS. V.E.S. Scott, M. De Waard, C.A. Gumett, H.Y. Liu, D.R. Wichter\*, V.A. Lennon\* and Campbell, K.P. Howard Hughes Medical Institute, Department of Physiology and Biophysics, University of Iowa, Iowa City, IA 52242; \*Neuroimmunology Laboratory, Mayo Clinic, Rochester, MN 55905.

The N-type  $Ca^{2+}$  channel is central to neurotransmitter release at the presynaptic membrane in mammalian neurons. Purification of the N-type  $Ca^{2+}$  channel shows that it contains  $\alpha_{1B}$ ,  $\alpha_{2\delta}$  and  $\beta$  subunits, together with a novel neuronal specific 95 kDa component. Monoclonal antibodies specific for the  $\alpha_{1B}$  subunit and polyclonal antibodies for each representative of four different  $\beta$  subunit genes have been exploited in further analyzing the subunit composition of these channels. Different  $\beta$  subunits were transiently transfected into COS7 cells. The cells were then harvested, subjected to SDS-PAGE and immunoblotted with affinity-purified antibodies to confirm the selectivity of each antibody. The  $\alpha_{1B}$  specific monoclonal antibody coupled to Avidin served to purify  $\omega$ -conotoxin GVIA receptor solubilized from bovine brain membranes. Protein eluted at pH 2.5 was subjected to SDS-PAGE followed by Western blot analysis with affinity-purified antibodies specific for  $\beta_1$ ,  $\beta_2$ ,  $\beta_3$  or  $\beta_4$ . This revealed that the  $\alpha_{1B}$  subunit is associated with both  $\beta_3$  and  $\beta_4$  subunits in brain. In addition, the affinity of  $\alpha_{1B}$  interaction domain (AID $\beta$ ) for each of the *in vitro* translated  $^{35}$ S-labeled  $\beta$  subunits was determined. The results demonstrate that  $\beta_3$  and  $\beta_4$  have similar affinities for the  $\alpha_{1B}$  subunit of the N-type  $Ca^{2+}$  channels. Our data suggest heterogeneity in the  $\beta$  subunit composition of N-type  $Ca^{2+}$  channels.

## 508.4

$Ca^{2+}$ -DEPENDENT INTERACTION OF N-TYPE CALCIUM CHANNELS WITH SYNAPTIC DOCKING/FUSION CORE-COMPLEX.

Z.-H. Sheng\*, J. Rettig, T. Cook, M. Takahashi#, and W. A. Catterall, Department of Pharmacology, University of Washington, Box 357280, Seattle, WA 98195-7280, USA, #Mitsubishi Kasei Institute of Life Sciences, Machida, Tokyo, Japan.

The specificity of  $Ca^{2+}$ -dependent exocytosis requires the tight structural and functional association of calcium channels with synaptic fusion machinery in the presynaptic active zone. To characterize this protein association, we performed binding experiments with recombinant proteins and partially purified,  $^{125}$ I- $\omega$ -CTx labeled native N-type calcium channels. We report here that a syntaxin- and SNAP25-binding site is located in the cytoplasmic loop (LII-III) between domains II and III of the N-type calcium channel ( $\alpha_{1B}$ ). The N-type calcium channels interact with syntaxin-SNAP25 heterodimer or syntaxin-SNAP25-VAMP trimeric complex in a  $Ca^{2+}$  dependent manner. These data suggest that the direct interaction of N-type calcium channels with synaptic core-complex is a  $Ca^{2+}$ -sensing process and may play a key role in docking and fusion of synaptic vesicles.

## 508.5

**IDENTIFICATION OF A VESICULAR POOL OF CALCIUM CHANNELS IN APLYSIA BAG CELL NEURONS.** *B.H. White\* and L.K. Kaczmarek.* Dept. of Pharmacology, Yale Univ. Sch. of Med., New Haven, CT 06520.

Protein Kinase C (PKC) acutely up-regulates one of two calcium conductances in bag cell neurons (BCNs). Previous evidence suggests that PKC may do so by selectively recruiting channels to the membrane surface. To test this hypothesis we have made antibody probes to calcium channels expressed in BCNs by first amplifying calcium channel fragments by RT-PCR and then using the fragments to make fusion proteins for the production of polyclonal antisera.

PCR amplification yielded two distinct fragments, one (BCCA-I) with ~65% sequence identity to the corresponding regions of mammalian  $\alpha_{1A}$  and  $\alpha_{1B}$  calcium channels, the other (BCCA-II) with ~65% identity to the corresponding region of  $\alpha_{1D}$  channels. Antibodies against the two fusion proteins specifically recognize distinct proteins of ~200 kD on immunoblots of BCN membranes, consistent with recognition of calcium channel  $\alpha_1$ -subunits. Immunofluorescent staining of cultured BCNs with the two antibodies yields strikingly different patterns.  $\alpha$ BCCA-II antibodies uniformly stain BCNs, apparently at the level of the plasma membrane as suggested by confocal analysis. In contrast,  $\alpha$ BCCA-I antibodies punctately stain the cytoplasm of BCNs, consistent with vesicular staining. Typically, BCN somata and growth cone core regions are stained, with variable staining of neurites. Occasional "hot spots" occur, often in regions of contact. We speculate that BCCA-I is the PKC-sensitive channel of BCNs.

## 508.7

**FUNCTIONAL EXPRESSION OF A RAT CALCIUM SENSING RECEPTOR AND LOCALIZATION TO NERVE TERMINALS.** *M. Ruat, A.M. Snowman\*, L.D. Hester, M.E. Molliver and S.H. Snyder.* Dept. of Neuroscience, Johns Hopkins U. Sch. of Med., Baltimore, MD.

Calcium ions play a key role in a variety of neuronal functions. Recently, we cloned a calcium sensing receptor (CaSR) from a rat brain library displaying seven putative transmembrane domains and significant homology with the metabotropic glutamate receptors.

Immunocytochemistry performed on rat brain sections using a polyclonal antiserum developed against a peptide designed from the N-terminal domain of rat CaSR, reveals discrete punctate localizations throughout the brain reflecting nerve fibers and terminals. For example, staining surrounding the Purkinje cell bodies reflects terminals of basket cells, while the Purkinje cells themselves are not stained. Pyramidal cell bodies in the hippocampus are not immunoreactive but are surrounded by intensely stained puncta in CA1 to CA3 regions indicating synaptic terminals. Ependymal cells of the third ventricle are not labeled but are surrounded by positive staining indicating that CaSR is associated with a dense plexus of nerve fibers located at the ependymal surface. CaSR in the ependymal zone may respond to changes in ventricular calcium concentration whereas CaSR on nerve terminals may regulate the disposition of neurotransmitter in response to calcium levels in the synaptic space.

A Chinese Hamster Ovary cell line, CHO(CaSR), permanently expressing CaSR proteins was selected by western blot analysis. Preliminary experiments suggest that calcium and magnesium in the millimolar range stimulate second messenger pathways in CHO(CaSR) cells. Experiments are underway to characterize the pharmacology of these transduction systems.

## 508.9

**VOLTAGE-DEPENDENT CALCIUM CHANNEL  $\alpha_1$  AND  $\beta$  SUBUNIT EXPRESSION AND INTERACTION IN PC12 CELLS.** *H.Y. Liu\*, M. De Waard, C.A. Gurnett, and K.P. Campbell.* HHMI, Dept. of Physiology and Biophysics, and Program in Neuroscience, University of Iowa, Iowa City, IA 52242

We have quantitatively studied the expression level of various voltage-dependent calcium channels in rat PC12 pheochromocytoma cell line. Ligand binding studies of [<sup>125</sup>I]  $\omega$ -conotoxin GVIA ( $\omega$ -CgTX) and [<sup>3</sup>H] PN200-110 demonstrate that these cells express about ten fold more N-type than L-type calcium channels. Purification data have demonstrated that both calcium channel types contain an  $\alpha_1$  and a  $\beta$  subunit. We have investigated the expression of various calcium channel  $\alpha_1$  and  $\beta$  subunits at the mRNA level by reverse-transcription polymerase chain reaction (RT-PCR). Sequencing of these RT-PCR products demonstrate that PC12 cells express at least three  $\beta$  genes ( $\beta_1$ ,  $\beta_2$  and  $\beta_3$ ) and three  $\alpha_1$  genes ( $\alpha_{1A}$ ,  $\alpha_{1B}$  and  $\alpha_{1C}$ ). In order to study the association of different  $\beta$  subunits with the  $\alpha_{1B}$  subunit of the N-type calcium channels, we have produced  $\beta$  subtype specific antibodies against fusion proteins containing  $\beta$  subtype specific regions. These  $\beta$  antibodies recognize native  $\beta_1$ ,  $\beta_2$ ,  $\beta_3$  and  $\beta_4$  subunits from rat tissues. We also used mAb VD2, which recognizes the skeletal muscle L-type and brain N-type calcium channel  $\beta$  subunits, and also *in vitro* translated  $\beta_{1B}$ ,  $\beta_{2A}$ ,  $\beta_3$  and  $\beta_4$  gene products. In immunoprecipitation studies, mAb VD2 and polyclonal antibodies to  $\beta_3$  and  $\alpha_{1B}$  subunits all immunoprecipitate equal amounts of [<sup>125</sup>I]  $\omega$ -CgTX labeled receptor from solubilized PC12 cell membranes. Currently research is undergoing to determine how the expression level of the  $\beta$  subunits affects their association with the  $\alpha_{1B}$  subunit in PC12 cells.

## 508.6

**A CALCIUM CHANNEL DENSITY GRADIENT IN NEUROBLASTOMA CELL GROWTH CONES** *Fritz Zimprich, Michael Duchon\* and Stephen Bolsover.* Department of Physiology, University College London, Gower Street, London WC1E 6BT.

Depolarization of N1E-115 neuroblastoma growth cones to voltages that activate L type calcium channels causes calcium to rise in spatially restricted hotspots. In the present study we selected non-branching growth cones in which the leading edge could be unequivocally identified. In these, a hotspot was usually located at the leading, distal edge so that on average the Fluo-3 fluorescence increase was significantly larger at the distal 5  $\mu$ m than in more proximal growth cone regions. Neither dantrolene at 40  $\mu$ M nor ryanodine at 200  $\mu$ M affected depolarization-induced calcium changes at the growth cone, indicating that calcium-induced calcium release from intracellular organelles can not account for the observed gradient.

Calcium channels of the T and L type were observed in cell-attached patches. L channels had a conductance of 24.8  $\pm$  0.8 pS (n=12) in 110 mM barium, but also displayed subconductances in the range 9 to 16 pS. L channel open probability was 0.011  $\pm$  0.003 (n=9) at +10 mV and was the same in all growth cone regions. The number of L channels per patch was six times greater in patches from the distal 4  $\mu$ m than in more proximal patches (taken 11 to 22  $\mu$ m from the tip). These results demonstrate directly that the calcium concentration gradient seen in depolarized growth cones has its origin in a gradient of L type calcium channel density.

## 508.8

**TRANSMEMBRANE TOPOLOGY AND FUNCTIONAL ORGANIZATION OF THE VOLTAGE SENSITIVE CALCIUM CHANNEL  $\alpha_2\delta$  SUBUNIT** *C.A. Gurnett, M. De Waard and K.P. Campbell\*.* Howard Hughes Medical Institute and Department of Physiology and Biophysics, University of Iowa College of Medicine, Iowa City, IA 52242.

Voltage dependent  $Ca^{2+}$  channels minimally consist of three subunits:  $\alpha_1$ ,  $\alpha_2\delta$ , and  $\beta$ . Functional effects of the  $\alpha_2\delta$  subunit on current amplitude appear dependent on coexpression of  $\beta$  subunits, suggesting either a direct interaction of the  $\alpha_2\delta$  and  $\beta$  subunits or a modification of  $\beta$  subunit regulation of channel activity by  $\alpha_2\delta$ - $\alpha_1$  interactions. Determination of the transmembrane topology of  $\alpha_2\delta$  would support or refute a possible direct interaction with the entirely cytoplasmic  $\beta$  subunit based on the cytoplasmic orientation of  $\alpha_2\delta$  in two different transmembrane models. We have utilized *in vitro* translation of full length and truncated  $\alpha_2\delta$  proteins in the presence of canine microsomal membranes to investigate the transmembrane topology of the  $\alpha_2\delta$  subunit. Deletion of sequences including the first and second hydrophobic domains have no effect on membrane association, suggesting that the hydrophobic region in  $\delta$  is the sole transmembrane domain. Moreover, tryptic fragments of native skeletal muscle  $\alpha_2\delta$  located between the first and second hydrophobic domains are shown to be glycosylated. These data support a model whereby all but the 5 carboxyl-terminal amino acids are extracellular and the  $\alpha_2\delta$  must interact with the  $\alpha_1$  subunit through either the transmembrane domain in  $\delta$  or extracellular sequences in  $\alpha_2\delta$ . Coexpression of these truncated  $\alpha_2\delta$  proteins in *Xenopus* oocytes are underway to further identify regions of interaction between the  $\alpha_2\delta$  and  $\alpha_1$  subunits.

## 508.10

**CHARACTERIZATION OF HUMAN N-TYPE VOLTAGE-GATED  $Ca^{2+}$  CHANNELS THAT BIND LAMBERT-EATON AND MONOCLONAL ANTIBODIES.** *V.A. Lennon, C.W. Zwizinski, T.J. Kryzer, E. Luoma, G.E. Griesmann, P.E. O'Suilleabhain, K.P. Campbell, E.H. Lambert\*.* Neuroimmunology Laboratory, Depts. of Immunology & Neurology, Mayo Foundation, Rochester, MN 55905, and Howard Hughes Medical Institute Research Laboratories, Univ. of Iowa, Iowa City, IA 52242.

The Lambert-Eaton myasthenic syndrome (LES) is an IgG-mediated presynaptic disorder of peripheral cholinergic neurotransmission that is highly associated with small cell lung carcinoma (SCLC). The targets of pathogenic autoantibodies are voltage-gated  $Ca^{2+}$  channels (VGCC) that control acetylcholine release at neuromuscular and autonomic synapses. By immunizing rats with a fusion protein containing a portion of the  $\alpha_{1B}$  sequence we have produced monoclonal antibodies against this subunit. The rats did not develop a defect of neuromuscular transmission. One monoclonal IgG (Mab CC18) selectively precipitates N-type VGCCs (high affinity receptors for [<sup>125</sup>I]-labeled  $\omega$ -peptide Gv1A) from membranes of human cerebral cortex and SCLC, and binds to denatured  $\alpha_{1B}$  (~230 kDa) in Western blots. Mab CC18 binds minimally to an  $\alpha_{1A}$  fusion protein, and exhibits 0.002% cross-reactivity with P/Q-type VGCC's (high affinity  $\omega$ -peptide Mv1C receptors) which are the presumptive neuromuscular target of LES IgG. The apparent molecular weight of the  $\omega$ -peptide Gv1A receptor (~900 kDa, by density sedimentation) increases more when complexed with LES IgG than with Mab CC18. This observation is consistent with binding of polyclonal IgG in LES serum to multiple epitopes on neuronal N-type VGCCs. These IgGs may be pertinent to the autonomic dysfunction of LES. Supported by NCI grant CA-37343.

## 509.1

**NEWBORN MONKEYS HAVE WELL-SEGREGATED OCULAR DOMINANCE COLUMNS ORGANIZED IN AN ADULT-LIKE MOSAIC PRIOR TO VISUAL EXPERIENCE.** J.C. Horton\*, D.R. Hocking. Dept. of Ophthalmology, UCSF, San Francisco, CA 94143-0730.

To determine if visual experience is required for the formation of ocular dominance columns, time-mated Rhesus monkeys were delivered prematurely by C-section at E-157. Animals were kept in complete darkness and all procedures were performed with the aid of infrared night-vision goggles to eliminate light exposure. A day after C-section, <sup>3</sup>H-proline was injected into the right eye. A week later, at the equivalent of P-0 (165 days of gestation), alternate sections of visual cortex were prepared for autoradiography and cytochrome oxidase (CO). All three babies studied had well-segregated ocular dominance columns in striate cortex of both hemispheres, organized into the characteristic mosaic present in adults. The columns were always crisper in the cortex ipsilateral to the injected eye, suggesting that axon terminals driven by the ipsilateral eye segregate earlier and/or more completely than those driven by the contralateral eye, or that there is greater tracer spillover in the contralateral geniculate body. In the upper layers, a mature pattern of CO patches was visible, aligned with the ocular dominance columns in layer IV. Every other row of CO patches in layers II & III was labelled by <sup>3</sup>H-proline. In V2 a regular system of distinct pale, thick, and thin CO stripes was present. These findings indicate that stimulation of the retina by light is not necessary for the development of columnar systems in the visual cortex. Ocular dominance columns, CO patches, and V2 stripes are all well formed in newborns, prior to visual experience. Even the thalamic input to the CO patches in the upper layers is segregated by ocular dominance in newborns. (Supported by NEI EY10217)

## 509.3

**NPY mRNA EXPRESSION IN ORGANOTYPIC RAT VISUAL CORTEX CULTURES IS REGULATED BY THALAMIC AFFERENTS.** K. Obst and P. Wahle\*. Ruhr-Universität, Zoologie und Neurobiologie, 44780 Bochum, Germany.

We have reported, that the number of NPY mRNA expressing neurons in the rat visual cortex declines dramatically between postnatal day (P) 30 and 70, from peak values at P21 of 2-4 % to 1-2 % at P70 (Obst and Wahle, Eur. J. Neurosci., submitted). In contrast, in cortical monocultures prepared at P0 and maintained for up to 90 days *in vitro* (DIV) we do not observe a reduction in NPY mRNA expressing neuronal number. Moreover, the percentage of NPY mRNA expressing neurons in monocultures is 6-8 % up to 90 DIV and thus exceeds by far the percentage observed *in vivo*.

In co-cultures of rat visual cortex and thalamus (including the LGN) prepared at P0 the number of NPY mRNA expressing neurons declines dramatically from peak values of 6-8 % at 30 DIV to 2-3 % at 60 DIV and later on. The reduction is not due to an overall cell death, because thionin counterstained OTCs revealed that the neuronal number / unit area remained fairly constant in mono- and co-cultures from 30 DIV onwards. This suggests that the reduction observed *in vivo* and *in vitro* is dependent on the thalamic innervation, although it occurred long after reciprocal connections between the two explants had been established.

In a triple arrangement consisting of one thalamus cortex co-culture and an additional cortex on the same coverslip, surprisingly 6-8 % of all neurons expressed NPY mRNA in both cortical explants. Further, medium from monocultures applied to co-cultures from 7 DIV onwards elicits an upregulation of NPY mRNA expression.

Therefore we suggest, that a noninnervated cortex releases a trophic factor into the medium, which leads to the NPY mRNA expression in a higher percentage of cortical neurons. In contrast *in vivo* or in pure co-cultures the production of this factor is progressively suppressed possibly by functional changes of the thalamic input later in development. Supported by DFG "Neurovision".

## 509.5

**SPATIAL PATTERNS OF INHIBITION IN DEVELOPING AND ADULT VISUAL CORTEX: IMPLICATIONS FOR CORTICAL PROCESSING.** M.B. Dalva\*, M. Weliky, and L.C. Katz. Department of Neurobiology, Duke University Medical Center, Durham, NC 27710.

Inhibition plays a central role in modulating response properties of visual cortical neurons, but little is known about the organization of inhibitory connections onto single cells. To investigate the adult organization and development of inhibitory connections in primary visual cortex, we used scanning laser photostimulation (Dalva and Katz, Science 265: 255 1994) to map the pattern of functional inhibitory synaptic inputs onto single neurons in coronal and tangential brain slices. At postnatal day 20 (P20), soon after layer 2/3 has formed, there are few inhibitory inputs onto pyramidal neurons (n=6 cells). These originate within 250µm of the cell body of the recorded neuron and are organized radially. Subsequently, the number and extent evoked inhibitory postsynaptic potentials (IPSCs) increases substantially, reaching a peak at eye-opening (P33-34, n=6). The density of inputs is highest near the cell body and decreases with distance, with no inputs of >1.5 mm. From eye-opening until adult (>P41), the number of IPSCs originating from sites >250 µm from the cell body declines dramatically (n=10), while the number of IPSCs evoked near to the cell body remains constant. In the adult (n=9), few IPSCs originate from >250µm from the cell body. Using coronal slices, inhibitory inputs to layer 2/3 pyramidal cells originate primarily from the supragranular layers of visual cortex (>80%, n=8). To examine the relationship between orientation selectivity and inhibitory connections, we determined the pattern of orientation tuning in striate cortex with optical imaging *in vivo*, and then recorded from single neurons with known orientation selectivity preference *in vitro* (n=1 animal, n=4 cells). As in other adult neurons, most inhibitory input was evoked from within 250µm of the cell body; the circular pattern of inhibition shows no clear relationship to the pattern of orientation selectivity. Taken together with our previous results, we conclude 1) that inhibitory inputs develop with a time course similar to excitatory connections, and 2) that inhibition arises from activation of all orientations, not just cross orientations. Supported by a McKnight Investigators Award (L.C.K.) and NIH grant EY07690 (L.C.K.).

## 509.2

**NORMAL OCULAR DOMINANCE PLASTICITY WITHOUT LONG-TERM POTENTIATION IN THE VISUAL CORTEX OF PKA R1B-DEFICIENT MICE.** J.A. Gordon\*, T.K. Hensch\*, E.P. Brandon\*, G.S. McKnight\*, R.L. Idzerda\*, and M.P. Stryker\*. \*Kek Center for Integrative Neuroscience, Univ. of California, San Francisco, CA 94143; and \*Dept. of Pharmacology, Univ. of Washington Schl. of Medicine, Seattle, WA 98195.

An activity-dependent competition between axons for common targets sculpt connections in the developing primary visual cortex (V1). Homosynaptic Long-Term Potentiation (LTP), studied *in vitro*, is an attractive cellular candidate for the mechanism underlying these changes. To test this hypothesis, visual cortical plasticity was examined both *in vitro* and *in vivo* in mice with a targeted disruption in the gene for protein kinase A regulatory subunit 1β (PKA R1β). All experiments were conducted using critical period-aged animals (P21-P32) and performed blind to genotype.

We have previously demonstrated (Hensch et al. (1995), IBRO Abstracts) a dissociation between LTP and monocular deprivation (MD) effects in PKA R1β knockouts (KOs). Layer IV theta-burst stimulation (TBS) failed to induce LTP in layer II/III field potentials in slices of V1 from KOs (post-TBS LTP=19±5% [WT] and 1±5% [KO]; p<0.05). 4 days of MD shifted cortical responses *in vivo* toward the open eye equally well in WT and KOs (p>0.8).

A shift toward the open eye after MD could result merely from a decrease in the efficacy of deprived eye inputs, without any potentiation of open eye inputs. Recovery of responses to the initially deprived eye, however, requires a potentiation mechanism. After MD for an initial 5 days, reverse suture allowed a similar recovery of responses to the initially deprived eye in KOs and WT, the extent of which increased with increasing time after the reversal.

In these mice, Hebbian potentiation of visual pathways *in vivo* occurred despite the absence of TBS-induced LTP during the critical period. Alternative cellular mechanisms of plasticity must, therefore, underlie the activity-dependent rearrangement of connections during visual cortical development. Supported by the HFSP, ARCS, and HHMI.

## 509.4

**NEUROTROPHINS AND ACTIVITY INTERACT TO MODULATE DENDRITIC GROWTH IN DEVELOPING FERRET VISUAL CORTEX.** A.K. McAllister\*, D.C. Lo, and L.C. Katz. Department of Neurobiology, Duke University Medical Center, Durham, NC, 27710.

The growth and rearrangement of neuronal circuits in visual cortex is strongly influenced by levels and patterns of neuronal activity, but little is known about the molecular signals that transduce activity into morphological changes. Neurotrophins are likely candidates for such molecular signals. To elucidate the influence of synaptic activity and its possible interactions with neurotrophins on dendritic growth, glutamate receptor antagonists—CNQX, a non-NMDA receptor antagonist, or APV, an NMDA receptor antagonist—were added alone or with particular neurotrophins to slices of P14 ferret visual cortex for 36 hours; dendrites of pyramidal neurons were visualized using biolistic transfection of a lacZ reporter construct. Glutamate receptor blockade alone enhanced growth and branching of basal dendrites in layers 4 and 6 (for example, total dendritic length (TDL) of layer 4 neurons: 243±20µm CNQX vs. 165±11µm for untreated (UT) cells, n=48 and 50, p<0.01). Brain-derived neurotrophic factor (BDNF) or neurotrophin-4 (NT-4) alone caused an even greater enhancement of dendritic growth and branching (TDL: 340±29 BDNF vs. 165±11 UT, n=52 and 50, p<0.001). However, glutamate receptor blockade completely prevented the BDNF-induced enhancement of growth (TDL: 156±19 BDNF+CNQX vs. 165±11 UT, n=52 and 50, p=0.7). Blockade of NMDA receptors alone similarly prevented NT-4-induced growth (TDL: 213±31 APV+NT-4 vs. 165±11 UT, n=45 and 50, p=0.2) while blockade of non-NMDA receptors was considerably less effective (TDL: 297±28 CNQX+NT-4 vs. 165±11 UT, n=45 and 50, p<0.001). These results suggest that neurotrophin effects on dendritic growth require glutamate receptor activation, implying that neurons require ongoing synaptic activity to be competent to respond to the growth-promoting effects of neurotrophins. Supported by NIH EY07690 (L.C.K.) and NIH NS32742, the Klingenstein Fund, the Alfred P. Sloan Foundation (D.C.L.) and by Sigma Xi (A.K.M.). Neurotrophins were generously provided by Regeneron, Inc.

## 509.6

**DISRUPTION OF HORIZONTAL CONNECTIONS IN DEVELOPING VISUAL CORTEX INDUCES ORIENTATION MAP DISCONTINUITIES.** M. Weliky\* and L.C. Katz. Department of Neurobiology, Duke University Medical Center, Durham, NC 27710.

Iso-orientation domains in visual cortex form a periodic pattern of patches and bands. A number of computational models suggest that lateral interactions are required to generate such periodic patterns. To assess whether horizontal connections shape the organization of orientation domains during postnatal development, these connections were severed by making shallow cuts through the upper layers of developing visual cortex in young ferrets (age p33-35, n=4). Thin Teflon sheets (2.5 mm long by .7-9 mm deep) were inserted into the cuts. At these ages, orientation tuning is still immature. Two to three weeks later, at which time orientation tuning has matured to an adult-like level, optical imaging of intrinsic signals was used to map the layout of iso-orientation domains. These maps revealed that iso-orientation domains were not continuous across the cut. Cross-correlation analysis demonstrated that the pattern of domains on either side of the cuts were uncorrelated. In contrast, when cuts were made at an age in which orientation tuning had matured to an adult-like level (>p43), orientation domains were more highly correlated across the cut, with correlations reaching random only relatively distant (~500µm) from the cut (n=2). To assist in interpreting these results, "cuts" were made in simulations of cortical map development incorporating lateral excitatory and lateral inhibitory interactions. Cuts in the simulations induced patterns of discontinuities similar to those observed in the visual cortex. These results suggest that prior to the onset of robust orientation tuning, and prior to fully developed clustered axon collaterals, intracortical horizontal connections contribute to organizing the layout of orientation domains in visual cortex. Supported by NIH grant EY07690 (L.C.K.).

## 509.7

**Mechanisms for initiation and propagation of intercellular calcium waves in the developing visual cortex.** K. Kandler\* and L.C. Katz. Department of Neurobiology, Duke University Medical Center, Durham, NC 27710.

During the development of the neocortex, many neurons are transiently coupled through gap junctions to form neuronal assemblies exhibiting coordinated activity in the form of intracellular  $\text{Ca}^{2+}$  transients (neuronal domains). To determine the identity of the intercellular signals, we investigated possible signaling molecules involved in gap junction communication between neurons of the visual cortex of early postnatal ferrets and rats. Patch pipettes were used to inject the gap junction permeable second messenger inositol trisphosphate ( $\text{IP}_3$ ) into individual neurons in slices loaded with the calcium indicator fura-2. In a second set of experiment we investigated the effects of the depletion of intracellular  $\text{Ca}^{2+}$  stores with thapsigargin (10  $\mu\text{M}$ ), the blockage of  $\text{Ca}^{2+}$  channels with  $\text{Ni}^{2+}$  (2 mM), and the stimulation of metabotropic glutamate receptors by t-ACPD (100  $\mu\text{M}$ ) on the occurrence of temperature drop (TD) elicited neuronal domains (Yuste et al. Neuron 14:7, 1995). Injection of  $\text{IP}_3$  into single neurons triggered intercellular  $\text{Ca}^{2+}$  waves which propagated to neighboring neurons. These waves covered an area of  $2011 \pm 438 \mu\text{m}^2$  (mean  $\pm$  SEM,  $n=14$  waves), which is similar to the area of TD elicited domains ( $2791 \pm 218 \mu\text{m}^2$ ,  $n=64$  waves). Depletion of  $\text{IP}_3$  sensitive stores by thapsigargin dramatically reduced the occurrence of neuronal domains (control:  $4.9 \pm 1.3$  domains/TD = 13 slices, thapsigargin:  $0.8 \pm 0.25$  domains/TD,  $n=24$ ,  $p<0.01$ ). In contrast, blockage of  $\text{Ca}^{2+}$  channels by  $\text{Ni}^{2+}$  had no significant effect ( $2.8 \pm 0.9$  domains/TD = 5,  $p>0.1$ ). Activation of metabotropic glutamate receptors by ACPD elicited neuronal domains (area  $1942 \mu\text{m}^2 \pm 201$ ,  $n=47$ ) probably by increasing the intracellular  $\text{IP}_3$  concentration. The present data, together with previous results demonstrate that cortical neurons can coordinate their behavior through biochemical signals, such as  $\text{IP}_3$ , before they begin to communicate via classical synaptic transmission. We suggest that this novel form of neuronal communication underlies the propagation of intercellular calcium waves present in the developing visual cortex. In addition, domains may be "triggered" by local release of glutamate that interacts with the metabotropic receptors. Supported by the Alexander von Humboldt Stiftung (KK) and NIH grant NS32396.

## 509.9

**DEVELOPMENTAL MECHANISMS UNDERLYING THE FORMATION OF LAYER-SPECIFIC CORTICAL CIRCUITS.** V. Castellani and J. Bolz\*. INSERM U.371 Cerveau et Vision, Bron, France.

There is compelling evidence that neuronal activity is required for the patterning of connectivity within individual cortical layers. In the visual cortex, for instance, neuronal activity controls the segregation of thalamic afferents into eye-specific patches in layer 4 and the formation of column-specific horizontal axonal projections in layers 2/3 (see Goodman and Shatz, Cell 72, 1993). In contrast, little is known about the mechanisms involved in the elaboration of the laminar specificity of cortical connections. Recent in vitro studies provided evidence for the existence of diffusible and substrate-bound guidance factors during the development of layer-specific afferent and efferent cortical projections (see Bolz et al., TINS 16, 1993). We examined whether molecules confined to specific cortical layers play a role in the construction of the intrinsic cortical circuitry. An important component of this circuitry are stereotyped vertical connections which link distinct cortical layers. For instance, axon collaterals of layer 6 neurons branch in layer 6 and the superficial layers, but there are very few branches in the intervening layer 5. In an in vitro assay, cortical explants from E15 or E16 rats (which contain layer 6 and subplate neurons) extended the same number of axons on cell membranes isolated either from layer 6, layer 5 or the superficial layers of P9-P11 rats. In contrast, when given a choice between membranes from superficial layers or layer 5, and likewise between membranes from layer 6 and layer 5, more than 80% and 70% respectively of the axons grew on membranes from the appropriate layer compared to layer 5. The most dramatic effect was observed on axonal arborizations: on layer 6 membranes, branching was 100%, and on membranes from superficial layers 110% more frequent than on layer 5 membranes. Thus substrate-bound molecules differentially expressed in cortical layers contribute to the laminar specificity of collateral branch formation of cortical neurons.

## 510.1

**THEORETICAL AND EXPERIMENTAL ANALYSES OF LATERAL INHIBITION AND THE ROLE OF NOTCH AND DELTA IN PATTERNING THE XENOPUS NEURAL PLATE.** A.B. Chitnis\*, D. Henrique and C.R. Kintner. MNL, The Salk Institute, La Jolla, CA 92037 and ICRF Developmental Biology Unit, Oxford OX1 3PS.

Lateral inhibition is a type of cell-cell interaction where a cell that adopts a particular fate inhibits its neighbors from adopting the same fate. This kind of interaction has been shown to play an important role in restricting the number of neural precursors in the *Drosophila* nervous system. Due to lateral inhibition only a single cell in each proneural cluster eventually delaminates and differentiates as a neuroblast while the rest adopt an epidermal fate. The process of lateral inhibition is mediated by the neurogenic genes Delta and Notch, which encode an inhibitory signal and receptor, respectively, in this process. In *Xenopus* the CNS is derived from a part of the ectoderm that segregates to form the neural plate; the rest of the ectoderm adopts an epidermal fate. Cells within specific longitudinal domains in the neural plate acquire the potential to differentiate as neurons. However, only a small subset of these cells eventually differentiate as neurons.

We have theoretically and experimentally explored the role of local interactions in patterning the early *Xenopus* CNS. Computer simulations show that, in principle, lateral inhibition alone could refine the limits of the neural plate, define longitudinal domains with neurogenic potential within the neural plate and select neuron precursors within these domains. Analysis of the effects of experimentally manipulating the activity of *Xenopus* Notch1 and *Xenopus* Delta1, however, suggests that these genes mainly restrict the number of neurons that differentiate within specific longitudinal domains in the neural plate. Supported by NIH.

## 509.8

**OPTICAL RECORDING OF EARLY CALCIUM RESPONSES TO ATP IN THE FERRET CORTICAL VENTRICULAR ZONE.** K. Herrmann\* and R.O.L. Wong. Lab. Neurophys., NIMH, Poolesville, MD 20837 and Dept. Anat. and Neurobiol., Washington Univ. Sch. Med., MO 63110.

Transmitter-like molecules are now believed to be involved in early aspects of neuronal development such as cell division, migration and differentiation. These molecules affect cell development often by regulating intracellular calcium levels ( $[\text{Ca}^{2+}]_i$ ). Recently, adenosine 5'-triphosphate (ATP) has been included in the list of extracellular ligands that mediate intercellular signaling in many cell types, including neurons. Here, we have examined whether cells in the mammalian cortical ventricular zone (VZ) are sensitive to ATP during the period of neurogenesis and early differentiation. We used optical recording techniques and calcium sensitive dyes to monitor the responses of cells in the VZ to exogenously applied ATP (0.05 mM to 1 mM) in acute slices of ferret neocortex between embryonic day E31 (gestation is 41 days) and postnatal day P8. ATP evoked an increase in  $[\text{Ca}^{2+}]_i$  in many cells in the VZ, both in the embryonic and neonatal neocortex. A larger proportion of cells in the VZ appeared responsive to ATP during the first postnatal week, than during the fetal ages. The magnitude of change in  $[\text{Ca}^{2+}]_i$  observed in the VZ varied between tens to hundreds of nM. The ATP-evoked  $[\text{Ca}^{2+}]_i$  rise resulted from an influx of  $\text{Ca}^{2+}$ , since it was blocked by BAPTA (2 mM) or  $\text{Ni}^{2+}$  (>3 mM). However, this response was not affected by the sodium channel blocker, tetrodotoxin (2  $\mu\text{M}$ ). Subsequent intracellular filling of ATP-responsive cells with lucifer yellow and neurobiotin revealed that they were predominantly progenitor cells, with thin processes that were oriented radially or tangentially. The fact that cells in the cortical ventricular zone are clearly responsive to ATP might indicate a role for this ligand in mitosis and/or early cell differentiation. Supported by a L.P. Markey Award to R.O.L.W.

## 509.10

**DEVELOPMENTAL MECHANISMS UNDERLYING THE SEGREGATION OF AFFERENT AND EFFERENT CORTICAL PROJECTIONS.** D. Bagnant<sup>1</sup>, E. Mann<sup>1</sup>, S. Henke-Fahle<sup>2</sup>, and J. Bolz<sup>1</sup>. <sup>1</sup>INSERM U.371 Cerveau et Vision, Bron, France; <sup>2</sup>Dept. Ophthalm., Univ. Tübingen, Germany.

The axonal pathway which links specific thalamic nuclei with distinct cortical areas precisely ordered. During cortical development, ascending thalamic axons travel in the subplate (SP) and in the outer region of the intermediate zone (IZ), whereas descending cortical axons grow in the deep region of the IZ towards their target. We have been studying the mechanisms that regulate the segregation of these reciprocal projections. As reported previously (Henke-Fahle et al., Neurosci. Abs. 1994), staining with different monoclonal antibodies directed against components of the extracellular matrix (ECM) transiently delineated the pathway of fibers running to and from the cortex. In a quantitative outgrowth assay, the antibody mab 10, which is concentrated in the SP and outer IZ, influenced thalamic and cortical axons in a 'push-pull' manner: it inhibited the growth of thalamic axons, but at the same time enhanced the outgrowth of cortical axons. However, this antibody did not interfere with the guidance of thalamic or cortical axons. We then used a co-culture system in combination with time-lapse video microscopy to examine potential interactions between individual cortical and thalamic axons. In cortex-cortex co-cultures prepared from E15 and E16 rats, over 60% of the axons encountering another cortical axon grew along each other. These results are consistent with the proposal that the corticofugal pathway is laid down by early pioneer fibers, and that later descending cortical axons extend along earlier-growing cortical fibers (McConnell et al., Science 245, 1989). In contrast, in cortex-thalamus co-cultures of the same developmental stage, in over 70% of the cases thalamic and cortical axons retracted from each other. Thus ECM components in the developing pathway, in concert with cues restricted to the surface of specific axonal populations, contribute to segregate afferent from efferent cortical projections.

## GENESIS OF NEURONS AND GLIA III

## 510.2

**THE ROLE OF THE XENOPUS SHAGGY KINASE IN NEURAL INDUCTION AND NOTCH-MEDIATED LATERAL INHIBITION.** E.A. Marcus\*, D.A. Wettstein, W.A. Harris and C.R. Kintner. Biology Department, UCSD and the Salk Institute, La Jolla, CA 92093.

In light of the recent demonstration that *Xenopus Notch* mediates lateral inhibition of cell fate in the neuroectoderm of developing *Xenopus* embryos, identification of the intracellular events downstream of *Notch* activation may provide insights into the molecular basis of primary neurogenesis in vertebrates. One candidate element for the signal transduction cascade triggered by *Notch* receptor activation comes from genetic analyses in *Drosophila* where it has been shown that a null mutation at the locus encoding the protein kinase *shaggy* mimics the neurogenic phenotype of a *Notch* loss-of-function mutation. Moreover, it has also been shown that the *shaggy* null phenotype is epistatic to a *Notch* gain-of-function phenotype in double mutants, suggesting that activity of *shaggy* is required for *Notch*-mediated signaling. In the present study we have cloned and sequenced the *Xenopus* homolog of *Drosophila shaggy* and are examining its role in neural induction and *Notch*-mediated lateral inhibition in *Xenopus* embryos.

The *Xenopus shaggy* homolog (*X-shaggy*) was cloned by low stringency screening of a *Xenopus* neurula cDNA library using a probe generated by random priming of a human homolog of *shaggy*, GSK3b. The isolated full-length cDNA was sequenced and used to generate a digoxigenin-labeled riboprobe for *in situ* hybridization. At the neural plate stage, *X-shaggy* mRNA is expressed in three dorsal longitudinal stripes. These stripes overlap with the expression of  $\beta$ -tubulin mRNA which selectively labels primary neurons. In later stage embryos, *X-shaggy* is expressed in the eye, cranial nerves, neural tube, notochord and somites. We are currently misexpressing wild-type *X-shaggy* and dominant negative *X-shaggy* DNA constructs alone and in combination with an activated *Notch* construct in *Xenopus* embryos to determine whether *X-shaggy* plays a role in *Notch*-mediated lateral inhibition during primary neurogenesis.

## 510.3

PITUITARY ADENYLATE CYCLASE ACTIVATING PEPTIDE (PACAP) IS AN AUTOCRINE REGULATOR OF CEREBRAL CORTICOGENESIS. N. Lu\* and E. DiCicco-Bloom, Dep't of Neuroscience & Cell Biology, UMDNJ/Robert Wood Johnson Medical School, Piscataway, NJ.

The sequence of cerebral cortex development has been characterized extensively *in vivo*: young neurons undergo radial migration and differentiation only after precursor proliferation in the ventricular zone has ceased. While molecules stimulating proliferation have been identified, including IGF-I and bFGF, little is known about factors signaling the transition from proliferation to differentiation. Previously, we found that PACAP promotes this ontogenetic switch, inducing mitotic arrest while enhancing neurite outgrowth and *trkB*. The expression of PACAP ligand and receptor mRNA and protein in embryonic brain raised the possibility of autocrine function of the peptide during ontogeny, for which we now provide evidence.

To examine autocrine function, a virtually pure population of MAP-2 positive precursors, derived from embryonic day 13.5 rat cerebral cortex, was cultured for 24 hr in defined medium. Using antiserum raised against PACAP, 83% of cells expressed immunoreactivity which was blocked by PACAP but not the related peptides VIP, Sec, and PHI. In addition to peptide, 67% of precursors expressed PACAP receptor, consistent with a possible autocrine role.

Since PACAP receptors activate cAMP pathways, we examined effects of peptide on nuclear expression of phosphorylated CREB, a well-characterized transcription factor downstream of cAMP. While 3% of control cells exhibited staining, PACAP treatment increased phosphorylated CREB immunoreactivity to 69%, corroborating receptor staining, and indicating that peptide elicits nuclear signaling in cortical precursors.

To establish an autocrine circuit, in which released PACAP inhibits ongoing mitosis, a specific antagonist, PACAP<sub>6-38</sub>, was employed. The antagonist control blocked PACAP-induced mitogenic stimulation in sympathetic cultures. In cortex cultures, antagonist increased by 57% the proportion of mitotic neuroblasts (Con= 10±0.3; Antag= 16±1.1), consistent with interruption of ongoing mitotic inhibition mediated by PACAP. These observations suggest that PACAP is an endogenous cortical factor regulating the transition from precursor proliferation to neuronal differentiation.

## 510.5

DIFFERENTIAL REQUIREMENT FOR BCL-X DURING THE DEVELOPMENT OF NEURONS AND GLIA. N. Motoyama\*, K. A. Roth†, S. Senju, D. Y. Loh, H. H. M. I., and †Department of Pathology, Washington Univ. Sch. of Med., St. Louis, MO 63110.

Regulation of programmed cell death (apoptosis) is thought to be important for the development and homeostasis of multicellular organisms. In the developing nervous system, more than 50% of neurons undergo programmed cell death. Bcl-x is one member of the Bcl-2 gene family, which regulates programmed cell death. Bcl-x is widely expressed in the nervous system during development and in the adult. Many differentiating immature neurons of central and peripheral nervous systems in Bcl-x-deficient embryos undergo apoptosis (N. Motoyama et al., Science, 267, 1506, 1995). Because of embryonic lethality, we could not analyze the role of Bcl-x in late-embryonic development or in the adult nervous system using germline mutant mice.

Here, we generated Bcl-x-deficient somatic mutant chimeras using the double knock-out method. We injected *bcl-x*<sup>-/-</sup> embryonic stem (ES) or control parental wild-type ES cells into blastocysts from C57BL/6 (B6) mice to generate chimeric animals. By glucose phosphate isomerase allozyme analysis, which allows us to distinguish between ES and B6-derived cells, we showed that the contribution of Bcl-x-deficient ES cells to the brain, spinal cord, sensory ganglia and eye was small compared to other organs such as kidney, heart, and lung. In situ hybridization for an ES cell-specific marker was performed to determine the cell-specific contribution of ES cells to the nervous system. In comparison to control chimeras, *bcl-x*<sup>-/-</sup> chimeric mice exhibited a marked decrease in the number of ES cell derived neurons in the brain, spinal cord, and sensory ganglia. ES cell derived glial cells were comparable in control and *bcl-x*<sup>-/-</sup> chimeric mice. These findings suggest that Bcl-x is required for the development and survival of the vast majority of neurons but not for glia.

## 510.7

IDENTIFICATION OF DIFFERENTIALLY EXPRESSED mRNA SPECIES IN THE DEVELOPING CENTRAL NERVOUS SYSTEM OF MOUSE. Nakayama K., Tomooka Y.<sup>2)</sup>, Okada G., Moriizumi T.<sup>3)</sup>, Iwai K., and Takahashi M. Dept. Immunobiology, Cancer Res. Inst. Kanazawa Univ., 13-1 Takaramachi, Kanazawa, Ishikawa 920, Japan., 2) Dept. Biological Science and Technology, Science Univ. of Tokyo, 3) Dept. Anatomy, Medical school, Shinsyu Univ.

Vertebrate central nervous system (CNS) derives from a neural tube, in which pluripotent neural precursor cells (NPCs) proliferate and differentiate into various types of neuronal and glial cells. The molecular mechanisms by which NPCs become committed to distinct lineages are not well understood. As a first step to clarify the mechanisms of NPCs differentiation, we screened for genes activated or inactivated during NPC differentiation. We isolated NPCs from mouse neural tube at embryonic day 10 for primary culture. In primary cultures, NPCs differentiate into neural and glial cells by following a time schedule similar to that observed in mouse embryos. Total RNAs were isolated from primary cultures at 2 day intervals, followed by differential display method using the four degenerated dT12MN primers in combination with 26 arbitrary 10mers. In general, each primer set could display more than 100 bands. Visual survey of the mRNA differential display with 104 primer set combinations revealed less than 0.5% bands that appeared to be differentially expressed during NPC differentiation. These bands were cloned for further analysis. Based on time courses of gene expressions, we classified differentially expressed genes under three classes: (1) inactivated genes (decreased expression), (2) activated genes (increased expression), (3) intermediate genes (expressed transiently). These genes should be useful as markers in the molecular dissection of neural development.

## 510.4

CELL PROLIFERATION OBSERVED WITHIN THE RAT CEREBRAL NEUROEPITHELIUM IN VITRO. Richard Adams\* MRC Research Centre in Brain and Behaviour, University Laboratory of Physiology, Parks Road, Oxford OX1 3PT, UK.

We know that the majority of neurons of the mammalian cerebral cortex are generated from precursor cells within the pseudostratified neuroepithelium but we know very little of the nature of the cell movements and interactions that underlie neurogenesis within this region. To address this problem a number of methodologies are being used to follow the behaviours of cells in the neuroepithelium of the developing rodent cerebral cortex *in vitro*. Organotypic cultures of sheets and slices of cortex continue to display mitotic activity for one or two days after explantation into a defined culture medium. Vital chromatin dyes and lineage tracers may then be applied *in vitro* and the stained cells followed by time lapse confocal microscopy over periods of several hours. The mitotic process at the ventricular surface may be followed in great detail. It has already been reported that the mitotic spindles of the vast majority of cells align parallel to the surface of the tissue and that the spindles of many cells actively rotate within the plane of the tissue through metaphase and but stop at the onset of anaphase (Adams, Soc Neurosci Abstr. 20:30 (1994)). The statistical alignment of rotating metaphase spindles is strongly biased parallel or antiparallel to the direction of anaphase and cell division. Consistent with the orientation of cell division being determined at the entry into mitosis. The fates of these dividing cells are now being investigated in more detail to related this process to the generation of post mitotic neurons.

## 510.6

LOCAL INDUCTION OF OLIGODENDROCYTE PRECURSORS IN EMBRYONIC CHICK SPINAL CORD BY THE NOTOCHORD. D. M. Orenias\* and R. H. Miller, Department of Neurosciences, Case Western Reserve University, Cleveland, Ohio, 44106.

During spinal cord development oligodendrocytes, the myelinating cells of the CNS, arise from precursors initially located in the ventral ventricular zone. In the chick spinal cord at E6 (stage 29) oligodendrocyte precursors, identified by the mAb O4, are neuroepithelial cells located directly dorsal to the floorplate. The dorsal-ventral polarity of the developing spinal cord appears to be established by signals derived from the notochord and such signals may also influence the initial location of oligodendrocyte progenitors. To determine whether the notochord had the capacity to locally induce spinal cord oligodendrocyte precursors, additional notochords were transplanted adjacent to the dorsal neural tube and host embryos allowed to develop to at least E6. O4+ cells developed in the dorsal neural tube adjacent to the transplanted notochord. Heterochronic transplants demonstrated that the notochord was capable of inducing O4+ oligodendrocyte precursors in the dorsal neural tube until stage 12 (E2). Similarly, dorsal neural tubes were competent to respond to notochord induction until the same stage. The localization of SC-1+ floorplate cells in experimental animals suggested that induction of floorplate did not directly correlate with the induction of O4+ oligodendrocyte precursors. To assess the requirement for the notochord during normal development of oligodendrocytes, the endogenous notochord was ablated at different developmental stages. Ablations subsequent to stage 12 did not perturb the pattern of oligodendrocyte precursor development. These data suggest that signals originating from the notochord are capable of inducing oligodendrocyte precursors from cells in the dorsal neural tube. Furthermore, after E2 signals from the notochord are not essential for the normal development of spinal cord oligodendrocytes at E6. The 4 day time lag between the signaling from the notochord and appearance of oligodendrocyte precursors in the spinal cord suggest an indirect mode of signaling. If the notochord was releasing a signal directly inducing O4+ cells, such a signal would be long acting and stable. If however, the notochord is directing ventralization of the neural tube, signals from the notochord may act upon intermediate structures which are then capable of inducing oligodendrocyte progenitors.

## 510.8

Screening for differentially expressed genes in CNS injury and development using multiplex arbitrarily primed PCR (MAPP)

C. Pázmán, J. Bengzon<sup>1</sup>, J. Castellí, C.A. Berki, X. Wen, R. Somogyi<sup>2\*</sup> Laboratory of Neurophysiology, Laboratory of Molecular Biology<sup>1</sup>, NINDS, Bethesda, MD

Investigating the genetic network program which underlies CNS development and which may become reactivated following CNS injury requires an efficient, unbiased screening technique for the identification of genes which participate in these processes at all levels. We have optimized an arbitrarily-primed PCR technique for this purpose. Since we have found that the principle of arbitrary priming also results in the production of artifacts during high-gain amplification, it is important that primers and reactions conditions are carefully matched. We have eliminated primer concatamer artifacts by using a high-fidelity, low-cycle PCR protocol with modified primers to amplify the first strand PCR products created under low fidelity conditions. This approach requires longer primers than used in the "differential display" protocol, but also takes advantage of the T12VN reverse transcription combined with arbitrary forward priming. We have found that T12VN priming is not confined to the poly-A tail and that forward primers can also operate in the reverse direction because of the inherent reverse transcriptase activity of the Taq polymerase. Nevertheless, we were able to generate diverse and reproducible gene expression spectra that enabled us to identify genes selectively regulated during spinal cord development, PC12 cell differentiation and in response of adult dentate gyrus to kainate-induced seizures. A variety of genes were identified related to redox metabolism and apoptosis, macromolecule synthesis and folding, transcriptional regulation, and neurotransmitter phenotype. Furthermore, we discovered many novel sequences not part of the Genbank database. The expression and regulation of these novel genes was confirmed by PCR using sequence specific primers.

## 510.9

LOCALIZATION OF mRNA FOR UDP-GALACTOSE: CERAMIDE GALACTO-SYLTRANSFERASE IN MOUSE BRAIN DURING DEVELOPMENT. Tetsushi Kagawa, Akio Oba, and Kazuhiro Ikenaka\*, Lab. of Neural Information, National Institute for Physiological Sciences, Okazaki, 444, JAPAN.

UDP-galactose: ceramide galactosyltransferase (CGT) is considered to be a key enzyme in the biosynthesis of galactocerebroside, which is absolutely enriched in oligodendrocyte in CNS and is the most frequently used marker of oligodendrocyte. Thus, CGT gene expression should be closely linked to oligodendrocyte development. We applied the *in situ* hybridization technique to determine the localization of CGT mRNA in mouse CNS during development. Serial paraffin sections were collected and hybridized with CGT cRNA probe labeled with digoxigenin-UTP (DIG-UTP) or with myelin proteolipid protein (PLP) DIG-cRNA probe which can detect both PLP and its isoform DM-20, a putative marker of the progenitor cells of oligodendrocytes. At postnatal day 20 (P20), CGT gene expression was highly restricted to the CNS white matter, which was a quite similar to the pattern of PLP/DM-20 gene expression. We could detect the CGT gene expression in the developing brain and spinal cord as early as embryonic day 17 (E17). The CGT-positive cells were restricted to a longitudinal column of cells in the basal half of ventricular zone around the ventricles quartus. The strongest signals were observed at the most caudal level of medulla oblongata. The PLP/DM-20 gene expression pattern is very similar to that of the CGT gene except in the anterior hypothalamus, where we detected only PLP/DM-20 signals. After birth, CGT-positive cells were distributed in caudal to rostral and ventral to dorsal gradient, for instance we detected the CGT mRNA from P2 in cerebellum.

## 510.11

CROOKED TAIL (Cd): A MOUSE MODEL OF BRAIN MALDEVELOPMENT & ROSTRAL NEURAL TUBE DEFECTS Y. Oofuji, M. Carter, C.J. MacNabb, & M.E. Ross\*, Dept of Neurology, Univ of Minnesota, Minneapolis, MN 55455.

Cd is a semidominant mutation in which heterozygote tails are kinked and homozygotes have a high incidence of exencephaly, a rostral neural tube (NT) defect related to anencephaly. We previously cloned a message form of the cell cycle regulatory gene, D2 cyclin (J. Neurosci., 14:6384, '94), which has a highly restricted temporal and anatomic expression pattern in brain during development. On a map of the mouse genome (Jenkins & Copeland, NCI) the MN20/D2 cyclin probe was localized to chromosome 6, near the purported locus for Cd (Lane, '72). To further investigate MN20/D2 cyclin as a potential candidate for the Cd allele, we compared the developmental anatomy of Cd exencephaly with the timing and sites of MN20 expression during normal embryogenesis. On whole mounts and sections of Cd embryos, NT closure was observed to fail at the level of the mesencephalic vesicle by embryonic day (E)10.5. By *in situ* hybridization, MN20/D2 cyclin mRNA was expressed heavily in the roof of the mesencephalic vesicle and was just detectable in the telencephalon at E10.5, the earliest age yet examined. By E12.5, MN20/D2 cyclin expression is shifted posteriorly to the tectum, and is heavily expressed at the top of the cerebral wall. To define more precisely the chromosome locus for Cd, further linkage analysis was carried out by PCR-based, simple sequence length polymorphism (SSLP) in an intraspecific backcross. Thus far, 30 N2, affected progeny have been genotyped, identifying a linkage group in which the D6Mit300 marker has a LOD score of 9 relative to Cd. We conclude that: (1) Cd exencephaly results from failure of NT closure at the mesencephalic level at ~E10; (2) the temporo-spatial pattern of MN20/D2 cyclin expression correlates well with the site of origin and developmental time-course of Cd exencephaly; (3) SSLP-based linkage analysis supports the MN20/D2 cyclin gene as a candidate for the Cd locus. Thus, abnormal expression of D2 cyclin may be the molecular substrate for the Cd phenotype.

## 510.13

SEX DIFFERENCES IN ADULT NEUROGENESIS IN THE WILD-TRAPPED MEADOW VOLE. L.A.M. Galea\* and B.S. McEwen, Laboratory of Neuroendocrinology, The Rockefeller University, New York, NY, USA.

Sex differences favoring males in spatial learning in the adult meadow vole appear to be related to gonadal hormone level and photoperiod. Dentate gyrus and hippocampal size differences are also associated with sex and hormone level in the meadow vole. Adult neurogenesis is seen in mice and rats in the dentate gyrus of the hippocampus. The purpose of this study is to examine the relationship of sex and reproductive status in adult neurogenesis in the dentate gyrus of wild-trapped meadow voles. Wild meadow voles, *Microtus pennsylvanicus*, were captured during a short photoperiod (November, January) in Millbrook, NY. Voles were injected 24 h following capture with <sup>3</sup>H-thymidine (5.0  $\mu$ Ci/g), a marker of DNA synthesis, and perfused 24 h following injection. Brains were processed for autoradiography and stained for cresyl violet. Significant sex differences favoring females in the number of dividing ( $p = .0006$ ) and degenerating cells ( $p = .028$ ) were shown in both the granule cell layer and the hilus of the dentate gyrus. Voles are also being trapped during the long photoperiod (May, June) in order to compare levels of adult neurogenesis with voles trapped during the short-photoperiod. The meadow vole model may help to elucidate the mechanisms underlying the dynamic nature of cell birth and death in the hippocampus. Research supported by an NSERC-PDF to LAMG and a MH41256 to BSM.

## 510.10

CELLULAR BASIS OF METHYLMERCURY POISONING IN MOUSE NEOCORTEX. N.L. Hayes\*, M. Philbert, K.R. Reuhl, and R.S. Nowakowski, Dept. of Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854 and Dept. of Pharmacology and Toxicology, Rutgers University, Piscataway, NJ 08854.

Methylmercury (MeHg), a widespread environmental neurotoxicant, has a profound effect on cell proliferation in the developing CNS. MeHg (5  $\mu$ g/g) was given intraperitoneally to pregnant CD-1 mice on embryonic day 14 (E14) either 4 hrs prior to double labeling with 2 S-phase markers (iododeoxyuridine (IdUdR) followed 2 hrs later by bromodeoxyuridine (BUDR)) or between the two S-phase markers (1 hr after IdUdR and 3 hrs before BUDR). Thirty minutes after the BUDR injection embryos were fixed and processed for immunohistochemical visualization of the two markers. Labeled and unlabeled cells in the ventricular zone of the neocortical anlage were counted and labeling indices (LI) calculated. The LI of all nuclei labeled by the second tracer (LI:BUDR) is a measure of the proportion of the total population in S-phase at the time of the BUDR injection, and a measure of the ratio of the S-phase to the total cell cycle, Ts/Tc. The LI of cells labeled by the first tracer only (LI:IdUdR) is a measure of the proportion of cells which left S-phase during the interinjection interval. We found a decrease in LI:BUDR in both experimental groups, indicating that, in acute MeHg-treated animals, the Ts/Tc ratio is reduced and the proportion of proliferating cells in S-phase is decreased. A small increase in the LI:IdUdR indicated that the effect on the cells exiting S-phase is minimal. The ratio LI:IdUdR/LI:BUDR showed that the change in LI:IdUdR is insufficient to account for the larger change in LI:BUDR. The most parsimonious explanation of these data is that MeHg reduces the number of cells entering S-phase by lengthening G1 and/or M.

Supported by grants from NINDS and EOHHS.

## 510.12

Developmental expression of novel gene(PK4) mapped on human chromosome 17p13

Sun-Hwa Park, Hyung-Lae Kim\*, Hyun-Sue Kim, Young-Hyuck Chun, Hye-Sun Chung and Hyun Kim

Department of Anatomy, Korea University College of Medicine; \*Department of Biochemistry, E-Hwa Women's University College of Medicine, Seoul, Korea

Recently, surmountable amounts of genes are being cloned and it has become necessary to develop new techniques for discovering genes with known chromosomal location and their possible functions.

We made cDNA library from 18 weeks old human fetal brain assuming it expresses many genes involved in neuronal development. To define the location on the chromosome we performed fluorescent *in situ* hybridization on human chromosome with these cDNAs. The bands that showed strong hybridization with our cDNAs were microdissected and amplified by PCR. PK4 was amplified from 17p13 and found to be the new gene by the sequence analysis. To predict the role of this gene, *in situ* hybridization histochemistry was performed on developing and adult rat.

In the nervous system, strong expression of PK4 close to the ventricle was observed in E13 to E16. In the dentate gyrus, PK4 was highly expressed in comparison with other areas of hippocampus in P21. From P7 to P14, PK4 was extensively expressed in the external granular layer.

From these results, we suspect that PK4, located on human chromosome 17p13, may be related with neurogenesis.

## 510.14

SYNAPSE FORMATION AND ESTABLISHMENT OF POLARITY BY NEURONS DERIVED FROM P19 EMBRYONIC CARCINOMA CELLS. MFA Finley\*, N Kulkarni, and JE Huettner, Department of Cell Biology & Physiology, Washington University, St. Louis, MO 63110.

P19 embryonic carcinoma cells adopt a neuronal phenotype following exposure to retinoic acid. We have used electrophysiology and immunofluorescence to study the development of synaptic connections and neuronal polarity by P19-derived neurons. Paired recordings from P19 cells grown on microislands of rat astrocytes revealed that about 25% of the cells evoked fast excitatory currents (Pair 1) while roughly 5% of the cells elicited rapid inhibitory currents (Pair 2). The remaining cells failed to evoke a detectable postsynaptic response. Nearly all of the epscs were blocked by CNQX; the ipscs were inhibited by bicuculline or in some cases by strychnine. The tau of single-exponential decay averaged 1.4  $\pm$  0.2 msec for epscs and 12  $\pm$  2 msec for ipscs. Evidence for synaptic connections was first recorded 10 days after plating.

Staining with antibodies to GAP-43 and MAP-2 in P19 mass cultures revealed clear segregation into separate axonal and somato-dendritic compartments, respectively. Consistent with our physiological evidence for synapse formation, we observed intense punctate staining with antibodies to the synaptic vesicle proteins SV2 and synaptophysin. Collectively, these data suggest that P19 neurons develop polarity and form functional synapses in a manner similar to normal CNS neurons.

## 510.15

GABA ELEVATES CYTOPLASMIC CALCIUM IN FRACTIONATED EMBRYONIC RAT CORTICAL CELLS **H. Xian, D. Maric, J. Maric and J.L. Barker\***, Lab. of Neurophysiology, NINDS, NIH, Bethesda, MD 20892

Modulation of calcium homeostasis by GABA may play an important role in the early developmental processes occurring in the CNS, such as cell proliferation, differentiation and migration. We have found that during CNS development, embryonic cells exhibit different buoyant densities reflecting differences in their ratio of nuclear mass to cytoplasmic volume. Subpopulations of cells can be isolated using gradients in buoyant density during both proliferative and differentiating periods. We have isolated cells according to their buoyant density from the telencephalon-cortex at different embryonic ages to study the developmental appearance of membrane properties. Here we have studied the effects of GABA on cytoplasmic  $\text{Ca}^{2+}$  ( $\text{Ca}^{2+}_i$ ) in several fractions at later embryonic ages using digital video-microscopy and fura 2. We found that GABA elevated  $\text{Ca}^{2+}_i$  in subpopulations of cells in the most buoyant fractions. The elevation in  $\text{Ca}^{2+}_i$  varied from 50 to 200 nM. At E16 - E19, this GABA-induced increase in  $\text{Ca}^{2+}_i$  depended entirely on extracellular  $\text{Ca}^{2+}$ , since the response was eliminated in  $\text{Ca}^{2+}$ -free medium. Moreover, the response appeared to be mediated through activation of GABA $_A$ -type receptors since the GABA $_A$  receptor antagonist bicuculline (100  $\mu\text{M}$ ) inhibited it completely and reversibly. Pretreatment of cells with thapsigargin (3  $\mu\text{M}$ ) or ryanodine (1 - 10  $\mu\text{M}$ ) did not prevent the GABA-induced increase in  $\text{Ca}^{2+}_i$  in most of the cells tested; however, in some cells, the GABA response was eliminated by ryanodine. Most GABA-responsive cells showed an increase in  $\text{Ca}^{2+}_i$  following exposure to 10 - 40 mM  $\text{K}^+$ . However, a small percentage did not increase  $\text{Ca}^{2+}_i$  over this range of  $[\text{K}^+]$ . These results suggest that GABA-induced increases in  $\text{Ca}^{2+}_i$  involve  $\text{Ca}^{2+}$  influx perhaps via voltage-dependent  $\text{Ca}^{2+}$  channels or receptor- and/or second messenger-operated mechanisms in the plasma membrane, as well as release of intracellular  $\text{Ca}^{2+}$  from ryanodine-sensitive stores.

## 510.17

PROLIFERATIVE AND DIFFERENTIATING STAGES OF NEOCORTICAL DEVELOPMENT CAN BE RAPIDLY ACCESSED BY CONTINUOUS PERCOLL GRADIENTS I. IMMUNOCYTOCHEMICAL CHARACTERIZATION. **J. Maric\*, D. Maric, and J.L. Barker** LNP, NINDS, NIH, Bethesda, MD

We evaluated specific proliferation/differentiation patterns in the embryonic (E) rat neocortex at a single cell level using continuous density gradients of Percoll, immunocytochemistry and flow cytometry. Timed pregnant E19 Sprague-Dawley rats were given a single intraperitoneal injection of BrdU (50  $\mu\text{g/g}$  b.w.) and sacrificed one hour later. The cortical region of the embryonic CNS was dissociated into a single cell suspension and subpopulations of cells further separated based on their natural specific buoyant density using continuous Percoll gradients. Cell proliferation was assessed by anti-BrdU-FITC immunoreaction, propidium iodide staining and two color flow cytometry. Cell differentiation was evaluated using single and double immunostaining with antibodies (Abs) against nestin, tetanus toxin (TnTx) and GFAP. Cortical cells separated reproducibly into multiple specific bands. After immunostaining, flow cytometric analysis revealed that fractionated cells showed a remarkable correlation between their buoyant densities and proliferative and differentiating stages of neocortical development. The most buoyant cells, accumulated in the bands at the top of the gradient, were all BrdU $^+$ , GFAP $^+$  and virtually all TnTx $^-$ , indicating that most were well-differentiated neurons. Double staining with TnTx and nestin Abs revealed that a small percentage of TnTx $^+$  cells were also nestin $^+$ . Going toward the bottom of the gradient, each subpopulation consisted of increasing number of smaller, less buoyant cells that were progressively more BrdU $^+$  and nestin $^+$  and less TnTx single positive. In contrast, the least buoyant cells isolated at the bottom of the gradient were all TnTx $^-$  mostly nestin $^+$  and about 15% of these cells incorporated BrdU during the one hour pulse. Thus, separation of cells according to their specific buoyant density using continuous Percoll gradients offers the opportunity of analysis of cells in different stages of maturation obtained from the same specific region of the developing CNS.

## 510.16

PROLIFERATIVE AND DIFFERENTIATING STAGES OF NEOCORTICAL DEVELOPMENT CAN BE RAPIDLY ACCESSED BY CONTINUOUS GRADIENTS IN BUOYANT DENSITY: II. A FUNCTIONAL CHARACTERIZATION. **D. Maric\*, J. Maric, and J.L. Barker** LNP, NINDS, NIH, Bethesda, MD

We have used the property of cellular buoyant density to selectively fractionate rat cerebral cortical cells with phenotypes ranging from proliferatively active, tetanus toxin receptor (TnTx-R) lacking to terminally postmitotic, high TnTx-R expressing. Here we test the expression of functional  $\text{Na}^+$  channels and GABA, glycine (GLY) and glutamate (GLU) receptors on 20 distinct buoyant density subpopulations of cortical cells isolated on continuous Percoll gradients at embryonic day 19. The cells were double-loaded with voltage-sensitive (oxonol) and  $\text{Ca}^{2+}$ -sensitive (Fluo-3) fluorescent indicator dyes and their responses to veratridine (VTD), a  $\text{Na}^+$  channel agonist, GABA, muscimol (MUSC), a GABA $_A$  receptor agonist, GLY, GLU and kainic acid (KA), an agonist of a subset of GLU receptors, recorded using a dual-laser flow cytometer. The least buoyant and most proliferative cell fraction produced depolarizing responses to VTD, GABA/MUSC and to GLY, but not to GLU or KA. However, none of these responses, with the exception of a subpopulation of cells depolarizing to VTD, involved an elevation of  $\text{Ca}^{2+}$  ions. As the cells became more buoyant and lost their proliferative potential, presumably due to their progressive commitment toward differentiation, the percentage of cells that depolarized to all of the above ligands increased, and the rises in intracellular  $\text{Ca}^{2+}$ , particularly in response to GLU and KA became more apparent. At the other end of the spectrum, almost every cell of the most buoyant and virtually completely postmitotic cortical subpopulations produced the most intensive depolarizing responses to all of the above ligands which were accompanied by submicromolar increases in intracellular  $\text{Ca}^{2+}$ . Most of this  $\text{Ca}^{2+}$  elevation was presumably achieved via activation of voltage-dependent  $\text{Ca}^{2+}$  channels which appear to be absent in the least buoyant, most proliferative cells. The results show that buoyant density can be used as a simple property in fractionating distinct cortical subpopulations based on their proliferation/differentiation status and can be readily applied in order to gain access to different stages of neocortical development.

## CELL LINEAGE AND DETERMINATION III

## 511.1

ROLE OF MIDLINE GENES IN THE DEVELOPMENT OF THE GRASSHOPPER CENTRAL NERVOUS SYSTEM. **K. Menon, T.-Y. Kung, A. Collazo\* and K. Zinn**, Division of Biology, Caltech, Pasadena, CA 91125.

In insects and in vertebrates a distinct group of cells located in the midline play an important role in guiding commissural axon pathways during development of the central nervous system (CNS). The median neuroblast (MNB) lineage in grasshopper gives rise to the majority of these midline cells. A set of 'midline genes' have been identified in *Drosophila* that affect the CNS midline. However, the precise roles of these genes in controlling cell fate is poorly understood. We are using the grasshopper system to address these questions.

We are examining how two midline genes, *single-minded (sim)* and *Toll*, control cell fate decisions in the MNB lineage of the developing CNS. Our progress towards this goal includes isolating and determining expression patterns of the grasshopper homologs of *Drosophila sim* and *Toll* genes. The *sim* clone encodes a protein that is approximately 75% identical to the *Drosophila* sequence within its N-terminus half (including the helix-loop-helix region). The *Toll* clones were isolated by J. Sane's group. We have also performed *in situ* hybridization experiments for both these genes in grasshopper embryos and results indicate that *sim* RNA is present in neuronal and glial progeny of the MNB cluster and in the MP3 progeny. *Toll* 2 RNA is present in the glial cells of the MNB progeny and in the adjacent neuroblasts. Currently we are trying to inhibit expression of *sim* and *Toll* genes with antisense oligonucleotides that are microinjected in the MNB nucleus of grasshopper embryos. Analyses of the perturbation experiments will be presented.

BrdU DETERMINATION OF PROLIFERATION RATES IN MEDIAN NEUROBLAST LINEAGES OF THE GRASSHOPPER CNS. **Mark A. Masino and Melody V.S. Siegler\***, Dept. Biology, Emory Univ., Atlanta GA 30322.

Incorporation of bromodeoxyuridine (BrdU), which labels actively dividing cells, was used to determine proliferation rates of segmental median neuroblasts (MNBs) of the grasshopper nerve cord. The third thoracic (T3) and first abdominal (A1) neuromeres of the cord are homologous structures that fuse during embryonic development. Thompson and Siegler (J. Neurosci. 13:3309, 1993) showed a difference in the number of neurons that comprise the two groups of MNB progeny, 90 in T3 and 60 in A1. In T3, the MNB arises at 29% embryogenesis and proliferates at a steady rate, adding 10 cells to the group per 5% developmental interval until shortly before the MNB dies at 78%. In A1, the MNB arises at 30% and proliferates 10 cells per 5% interval from 30% to 45%. A plateau occurs from 45% to 60%. After 60% the steady rate of proliferation resumes, until the MNB dies at 73%. In A1, a peak of cell death coincides with the plateau. We questioned whether the cell death was entirely responsible for the plateau in A1 growth or whether slowing of the MNB division rate was also a factor. Embryos (30% to 80% stages) were injected with BrdU and allowed to develop a further 5%. After processing to reveal cells of the MNB groups that incorporated BrdU, counts were made. We found no significant difference between T3 and A1 in the number of progeny labeled per 5% developmental interval. Thus, cell death, rather than a change in the proliferation rate, accounts for the plateau in A1 growth and the smaller population size. Additionally, we found that the MNB groups in A2-A7 contained 25 or fewer neurons total. Significantly fewer progeny were labeled per 5% developmental interval, consistent with an MNB division rate about half that of T3 and A1. Support: NSF IBN-9120863 & NIH KO4NS1484 (NINDS) to MVSS.

## 511.3

**DIFFERENTIATION-DEPENDENT ACTIONS OF VOLTAGE-GATED  $\text{Ca}^{2+}$  CHANNEL MODULATORS ON VSC 4.1 CELL PROLIFERATION AND APOPTOSIS.** R.G. Smith, A.H. Mohamed, S.H. Appel\*, L. Colom, D. Mosier, and W.-D. Le. Dept. of Neurology, Baylor College of Medicine, Houston, TX 77030.

Studies on the regulation of neuroblast proliferation and initiation of apoptosis in early nervous system development have suggested a prominent role for altered  $\text{Ca}^{2+}$  flux through voltage-gated calcium channels (VGCCs). Addition of the dihydropyridine L-type VGCC agonist Bay K-8644 (0.5-10  $\mu\text{M}$ ) to undifferentiated motoneuron-neuroblastoma VSC 4.1 hybrid cells produces a  $\text{Ca}^{2+}$ -dependent increase in cell proliferation rate; both dihydropyridine and non-dihydropyridine L-VGCC antagonists reduce or block VSC 4.1 cell division ( $\text{ED}_{50}$  for diltiazem, verapamil, and nifedipine = 0.05, 0.5, and 5  $\mu\text{M}$ , respectively), without affecting cell death. In contrast, addition of the peptide N-VGCC antagonist  $\omega$ -conotoxin GVIA (5-50 nM) increases cell proliferation rate.

Following cell differentiation for one week in 1mM dibutyryl cAMP, Bay K-8644 effects are lost, while nifedipine and  $\omega$ -conotoxin GVIA instead induce apoptosis, as determined by DNA laddering and blockade with 1  $\mu\text{M}$  aurintricarboxylate or 0.1 nM cycloheximide. The effect of nifedipine on cell loss is slow, is not affected by reducing extracellular  $\text{Ca}^{2+}$  with EGTA, and is significantly inhibited by prior addition of oxygen radical scavengers.  $\omega$ -Conotoxin GVIA's effects are more rapidly mediated, are prevented by reduction in extracellular  $\text{Ca}^{2+}$  with EGTA, and are partially blocked by AMPA-sensitive glutamate receptor inhibitors (GYKI-52466 and CNQX), by NOS synthetase blockers, and by NO scavengers. These data suggest that control of neuron precursor proliferation and apoptosis may be differentially regulated by modulators of different VGCCs, that differentiation-dependent changes in regulation may allow the same VGCC modulators to control different processes at different developmental stages, and that this regulation may involve indirect action of other ion channels. Supported by NIH grants NS33186 and AG08664.

## 511.5

**MAJOR SITES OF CELL DEATH IN THE FETAL CEREBRAL CORTEX ARE THE ZONES OF CELL PROLIFERATION.** A.J. Blaschke\*, K. Staley, and J.J.M. Chun. Department of Pharmacology, School of Medicine, University of California, San Diego, La Jolla, CA 92093-0636.

During development of the mammalian nervous system programmed cell death (PCD) is believed to participate in the formation of connections between neurons and their appropriate targets. The embryonic period is when most neurons are generated and initial synaptic connections are formed; PCD could thus play an important role during this time. Previous studies have documented cell death in the postnatal cerebral cortex but no thorough analyses have examined this issue in the embryo. In this study we have used *in situ* end labeling (ISEL) of fragmented DNA to show the distribution of dying cells within the murine cerebral cortex during embryonic development.

Tissue sections from Balb/c embryo cortices (E10-E18) were labeled by a modified ISEL technique and compared to adult cortex. Although few labeled cells were seen at E10 or in the adult (less than 1%), from E12-E18 many dying cells (averaging over 50% of total cells observed) were seen throughout the cerebral wall. The quantity of cell death in the cortex is significant, and indicates that PCD has an important role during mammalian neurogenesis. Even more significant, however, is the distribution of dying cells; although many are found in cortical regions where cells are postmitotic, the majority are found in the regions of cell proliferation: the primitive plexiform layer and the ventricular zone. In postmitotic zones cortical neurons are forming synapses, and cell death here can be explained by target-dependent mechanisms of PCD. However, these mechanisms cannot explain cell death in proliferative zones, where cells have not yet made synaptic connections. Our findings suggest that novel regulatory mechanisms may exist in these regions, and that neurons may undergo selection at several stages of development in order to reach maturity. ## 511.7

**NEUROTROPHINS AND bFGF DIFFERENTIALLY AFFECT THE PROLIFERATION AND DIFFERENTIATION OF CORTICAL NONPYRAMIDAL NEURONS.** I. S. Pappas, T. Sklavadias\* and J. G. Parnavelas. Dept. of Anatomy, Univ. College London, London WC1E 6BT, U.K.

A host of neurotrophic factors have now been shown to influence both the generation and differentiation of neuronal and glial progenitor cells in the nervous system. Here, we sought to investigate the role of neurotrophins and bFGF in the development of cortical cell types. Primary cultures prepared from rat embryonic cortices (E16) were infected with BAG retrovirus and then treated with neurotrophins [NGF (100 ng/ml), BDNF (10 ng/ml), NT-3 (100 ng/ml)] and bFGF (10 ng/ml) in defined medium for 7 days. The clones formed consisted either of single cells (about 30% of all clones in the control and treated cultures) or clusters of cells. Clusters varied in size according to treatment: 17-32 cells/clone in bFGF-treated cultures or 5-8 cells in untreated and NT-3-treated cultures. Treatment with NGF and BDNF resulted in clusters of a wide spectrum of sizes. These results suggest that growth factors differentially affect the proliferation of cortical progenitor cells. To further define the cortical cell types affected by the various treatments, we focused on the subpopulations of nonpyramidal neurons defined by the presence of the calcium-binding proteins calbindin (CB) and calretinin (CR). Using double-labelling techniques, we observed that clones containing CB+ cells represented 6% of the total clones in control cultures, 14% in cultures treated with bFGF, 3% with NGF, 7% with BDNF and 19% with NT-3. Clones containing CR+ neurons were only found in bFGF-treated cultures. We also established that BDNF, NT-3 and bFGF increased significantly the total number of CB+ neurons; the latter also increased the total number of CR+ neurons. This trend was confirmed by Western blot analysis. These findings suggest that neurotrophins and bFGF play a role in the proliferation, differentiation and lineage determination of CB- and CR-containing nonpyramidal neurons. **PROGRAMMED CELL DEATH IN THE FETAL CNS INVOLVES APOPTOTIC MECHANISMS.** K. Staley\*, A.J. Blaschke and J.J.M. Chun. Dept. of Pharmacology, UCSD School of Medicine, La Jolla, CA 92093-0636.

Massive cell death in both proliferative and postmitotic zones of the fetal cerebral cortex has been demonstrated by *in situ* end labeling (ISEL) of fragmented DNA. (see Soc. Neurosci. abstract Blaschke et al. 1995). To determine if this early neural cell death involves an apoptotic mechanism, we examined the developing mouse CNS for the presence of a widely accepted hallmark of apoptosis, the endogenous cleavage of genomic DNA into nucleosomal ladders. This characteristic form of DNA degradation could not be detected following the standard methods of agarose gel electrophoresis and either staining with ethidium bromide, or Southern blot hybridisation to genomic DNA. However, the use of a modified ligation-mediated polymerase chain reaction (LMPCR) enabled us to detect nucleosomal-sized DNA fragments in both the developing brain and other mammalian tissues known to undergo PCD. Amplification of nucleosomal ladders was shown to correlate directly with the extent of cell death in an established model of apoptosis, the dexamethasone treated-thymus. Since LMPCR detection of DNA fragments is dependent on the presence of blunt, 5'-phosphorylated double strand breaks, these results suggest that the endonuclease(s) responsible for DNA degradation *in vivo* generates nucleosomal ladders with these distinctive ends. A semi-quantitative analysis of nucleosomal-sized fragments detected by LMPCR in embryonic, postnatal and adult cortex showed ladder formation to correlate with the extent of cortical cell death shown previously using ISEL. This result suggests that PCD in the embryonic CNS indeed involves mechanisms of apoptosis. [supported by the Klingenstein Fund and the UC Tobacco-Related Disease Research Program]

## 511.6

**EXPRESSION OF A NEW PUTATIVE G-PROTEIN COUPLED RECEPTOR IS ENRICHED IN PROLIFERATIVE ZONES OF THE EMBRYONIC CEREBRAL CORTEX.** J. H. Hecht\*, J. A. Weiner, and J. J. M. Chun. Dept. of Pharmacology, School of Medicine, University of California, San Diego, La Jolla, CA 92093-0636.

Neurons comprising the cerebral cortex develop from histologically uniform proliferative zones. Molecules mediating cell-cell communication, such as the G-protein coupled receptor (GPR) family, may play an important role in these regions by regulating early cortical neuron development. To isolate novel GPRs expressed in the embryonic cortex, we used degenerate oligonucleotide primers in polymerase chain reaction (PCR) amplification of cDNA derived from novel murine telencephalic cell lines. A PCR product was cloned which had sequence homology to the GPR family. This clone was used as a probe to isolate a full length cDNA, termed *vzg-1*, from a mouse brain cDNA library. *Vzg-1* shares approximately 35% amino acid identity with the human and rat *edg-1* orphan receptors, and the cannabinoid and melanocortin receptors. It contains amino acid residues conserved across the GPR family and has seven predicted membrane spanning domains. Northern blot analysis shows that *vzg-1* is expressed in the embryo as early as embryonic day 13 (E13) and in the cell lines from which it was isolated. *In situ* hybridization patterns in E16 mouse embryos using riboprobes synthesized from different regions of the *vzg-1* clone show primary expression of *vzg-1* in the ventricular zone of the dorsal telencephalic wall along with expression in the marginal zone. Thus, *vzg-1* represents a new putative GPR with enriched expression in the proliferative zones of the embryonic cortex. Its expression pattern suggests that signal transduction pathways mediated by novel GPRs may be important at the earliest stages of cortical neuron development. ## 511.8

**PHENOTYPIC DIFFERENCES IN IDENTIFIED, SEGMENTALLY HOMOLOGOUS NEURONS MAY BE CAUSED BY HOMEODOMAIN GENE *LOX4*.** G. W. M. Bothe\*, V. Y. Wong and E. R. Macagno. Dept. Biol. Sci., Columbia Univ., New York NY 10027

Processes of regional differentiation in the CNS were studied in the leech, *Hirudo medicinalis*. The anteriormost pair of neurons in each midbody ganglion are segmental homologs that have three different *Lox4* expression patterns. nRMVs never express *Lox4*, RPE motoneurons express *Lox4* transiently during embryogenesis, and pRMVs express *Lox4* continually. We set out to study these neurons asking: Are there phenotypic differences between these neurons, and could those be explained by the *Lox4* expression pattern?

The interaction of RMVs and RPEs with a natural growth substrate, extracellular matrix extract, was tested *in vitro*. nRMVs grew neurites to a radius of  $80 \pm 40 \mu\text{m}$  within 1 d. The neurites of pRMVs grew to a radius of  $26 \pm 11 \mu\text{m}$ . The RPE, however, grew profusely (radius  $150 \pm 59 \mu\text{m}$ ) and had more neurite branches.

The interaction between RPE or RMV and potential targets was assayed *in vitro*. RPE axons adhered strongly on the natural target, male organ muscle cells (MOMCs). After 16 h in culture, RPEs and MOMCs could not be separated without tearing the axon apart. A short, thick, nearly unbranched neurite grew on the MOMC in 58% of the cell pairs. RPEs did not adhere strongly to body wall muscle cells and grew little. pRMV did neither adhere nor grow on MOMC.

RPE differ from nRMV and pRMV in the size and shape of their soma action potentials. RPE potentials are relatively large ( $11.5 \pm 3.9 \text{ mV}$ ), whereas nRMV potentials are small ( $3.6 \pm 0.7 \text{ mV}$ ). In addition, RPE hyperpolarize strongly after an action potential whereas nRMV and pRMV do not.

To test whether *Lox4* might be involved in establishing the above-mentioned phenotypic differences, *Lox4* mRNA was injected into adult RPEs. Preliminary results indicate that, after 2 d, injected mRNA is translated and that *Lox4*-mRNA, but not 8-gal, mRNA changes the shape of somatic action potentials of RPE neurons.

## 511.9

CHARACTERIZATION OF SEROTONIN-DEFICIENT MUTANTS IN THE NEMATODE *C. ELEGANS*. C. M. Loefer Dept. of Biology, Lafayette College, Easton, PA 18042

We are seeking to identify genes that regulate expression of neurotransmitter phenotype of serotonergic neurons in *C. elegans*. We are using two approaches: 1) isolation and characterization of serotonin-deficient mutants, some of which should identify regulatory genes, and 2) identification of marker genes used by serotonergic neurons, the genes controlled by the regulators of neurotransmitter type.

Among existing serotonin-deficient mutants is *cat-4* (*e1141*), which was first isolated as a dopamine-deficient mutant lacking formaldehyde-induced fluorescence (FIF); it was subsequently found to lack serotonin immunoreactivity as well (Sulston et al., 1975, J. Comp. Neurol. 163: 215; Desai et al., 1988, Nature 336: 638). Although *cat-4* mutant worms were previously described as serotonin hypersensitive, we have found that *cat-4* mutants are also hypersensitive to a variety of other unrelated agents. We first noticed that *cat-4* mutant worms died much more rapidly than wild type worms during routine "cleaning" of worms with bleach. Whereas wild type worms squirm in bleach for several seconds before becoming rigid, *cat-4* mutants stop moving almost instantly (< 1 sec). In addition, *cat-4* mutant carcasses seem to disappear or dissolve during this treatment, unlike those of wild type worms. We have further characterized the hypersensitivity of *cat-4* mutants to a number of agents, including SDS, levamisole and serotonin. Our observations suggest that mutation of the *cat-4* gene affects not only production of neurotransmitters, but also construction of the cuticle.

We are currently screening for additional serotonin-deficient mutants based on behavioral abnormalities, bleach hypersensitivity and serotonin immunoreactivity. We hope to identify additional genes that may be involved in expression and regulation of a serotonergic phenotype.

## 511.11

NOVEL SEPTAMER-BINDING PROTEINS MARK DIFFERENTIATION EVENTS IN THE GLIAL AND NEURONAL LINEAGE. A.L. Dobi\*, M. Palkovits\*, C.G. Palkovits, D.v. Agoston, MCN, LDN, NICHD; LCB, NIMH; NIH, Bethesda, MD 20892.

The differentiation of the multipotent neuroglial precursor requires temporally and spatially coordinated interactions between specific DNA elements and their binding proteins to restrict the expression of genes to a set that characterizes the mature phenotypes of glia or neurons. To identify these elements we used DNA methylation interference footprinting with a 5' fragment (-542, -379) of the rat enkephalin (RENK) gene and identified a truncated octamer motif (TTTGCAT=sept) that specifically binds to nuclear proteins of the embryonic rat brain. Gelshift screening with nuclear proteins derived from seven ontogenetically and phenotypically distinct brain regions between ages of embryonic day 10 (E10) and postnatal 28 (P28) showed the existence of several distinct sept-binding proteins. From E14, when neuronal and glial lineages begin to emerge we identified two very abundant proteins forming low mobility complexes. The appearance of this doublet follows the maturation of distinct brain regions as indicated by their appearance as early as at E12 in the spinal cord and the late peak of expression in the cerebellum. Because only the complex with somewhat higher mobility is present in cultures of primary cortical astrocytes and the developmental appearance of this band in ontogenetically distinct brain regions follows the temporal and spatial pattern of glia proliferation we tentatively identified this complex as glia-specific. These proteins are distinct from known octamer binding proteins because antibodies against known oct-1 or oct-2 proteins do not recognize them. The binding to the sept-motif requires phosphorylation of both proteins as treatment with phosphatases completely diminishes the formation of complexes. The expression pattern of developmental-, neuronal- and glia-specific markers in different brain regions at various developmental ages indicates that the sept-binding proteins may contribute to the early differentiation events of neuronal and glial lineages.

## 511.10

EMX1 IS EXPRESSED IN NEURONS DURING LAYERS FORMATION IN THE DEVELOPING TELEENCEPHALIC CORTEX. M. Gulisano\*, I.2, V. Broccoli\* and E. Boncinelli\* 1, 1-DIBIT-Istituto Scientifico H San Raffaele, Milan, Italy, 20132 2-Istituto di Biologia Generale, Università di Catania, Catania, Italy, 95124.

Two homeobox genes, *Emx1* and *Emx2*, have been cloned as vertebrate homologues of *empty spiracles*, a gene controlling very anterior body regions during early *Drosophila* embryogenesis. Both genes are clearly expressed during early mouse brain formation with specific patterns.

We studied in detail *Emx1* and *Emx2* expression in the developing cerebral cortex of the mouse between E12.5 and adult hood.

*Emx2* expression appears to be confined to proliferating cells in the ventricular zone, with the exclusion of both the transition field and the forming cortical plate. Between E14 and E16 *Emx2* shows a weaker expression in anterior regions than posterior regions in the cortex, suggesting a correlation of *Emx2* expression with an antero-posterior maturation gradient. Conversely at these developing stages *Emx1* is expressed in the ventricular zone, in the transitional field and in the forming cortical plate. Later in development, when cortical layers start to form, *Emx1* is expressed in differentiating cells in the cerebral cortex with exclusion of layer 1. In particular, *Emx1* seems to be specific for neuronal cells and not for glial cells. In the subplate *Emx1* expression is confined to a specific subpopulation of neurons whose function remains to be assessed.

Our data suggest that both *Emx1* and *Emx2* are involved in cerebral cortex development in the mouse. It is of interest to consider a specific role for *Emx2* in proliferating neuronal cells and for *Emx1* in neuronal cell identity in the developing cerebral cortex of the mouse.

## 511.12

THE BRAIN-SPECIFIC HELIX-LOOP-HELIX PROTEIN NEX-1: A NEURONAL ACTIVATOR OF GAP-43?

A. Bartholomä, M. Schwab, P. Gass, and K.-A. Nave\* Center for Molecular Biology (ZMBH), University of Heidelberg, D-69120 Heidelberg, Germany.

NEX-1 is a novel helix-loop-helix (HLH) protein, cloned from the adult rat brain (*Mech. Development* 48, 217-228, 1994). The rodent NEX-1 gene is expressed only in the CNS, beginning at E14, and is restricted to cells that have left the ventricular zone. Peak expression occurs in the first postnatal week, coinciding with terminal neuronal differentiation and synaptogenesis. In the adult brain, NEX-1 transcripts are most abundant in hippocampus (CA1-4), neocortex, amygdala, and cerebellum. Since HLH proteins are key developmental regulators in other systems, we have begun to address the function of NEX-1 in neuronal differentiation. A candidate target gene for NEX-1 encodes the neuronal growth-associated protein GAP-43. In the CNS, both genes display a very similar temporal and spatial pattern of expression. In undifferentiated P19 cells, the overexpression of NEX-1 and E12 activated the cloned GAP-43 promoter (kindly provided by L. Schramma). Moreover, we observed by indirect immunofluorescence that undifferentiated P19 cells became GAP-43 positive following transfection. Since control cells showed little or no immunoreactivity, this suggests that GAP-43 has been induced *de novo*. To further address the function of NEX-1 in neuronal development, we used homologous recombination to completely delete the gene in mouse embryonic stem cells. Blastocyst injections resulted in the birth of highly chimeric mice. Results of the gene targeting experiment will be discussed. (Supported by grants of BMFT and DFG to K.A.N.)

## PROCESS OUTGROWTH, GROWTH CONES, AND SPROUTING IV

## 512.1

MODIFICATION OF RETINAL AXON BRANCHING PATTERN BY THE EXPRESSION OF CONSTITUTIVELY ACTIVE CaMKII IN XENOPUS TECTAL CELLS. D.J. Zou\* and H.T. Cline, Cold Spring Harbor Laboratory, Cold Spring Harbor, NY 11724

The plasticity of developing frog retinotectal projection depends on NMDA receptor activity in tectal neurons. The possibility of that the  $Ca^{2+}$  influx through the NMDA receptor may act through a CaMKII pathway was studied by expressing the constitutively active CaMKII in tectal cells with the recombinant vaccinia virus and following the dynamic changes of the retinal axon morphology. The morphology of individual Dil labeled retinal axons was first observed *in vivo* with a confocal microscope in the stage 48 albino *Xenopus* tadpoles. Vaccinia virus containing the DNA sequences encoding the truncated CaMKII (amino acid 1-290) and a reporter  $\beta$ -galactosidase ( $\beta$ -gal) (tCaMKII virus) or  $\beta$ -gal alone ( $\beta$ -gal virus) was then injected into the ventricles of the animals. When intensive infection in the CNS occurred as indicated by the expression of  $\beta$ -gal on Day 3, the same axon's morphology was observed again. Quantitative analyses showed that the tCaMKII but not the  $\beta$ -gal axons became less complex. The branchip number decreased to  $66 \pm 4\%$ , while in the control axons it increased to  $120 \pm 7\%$ , of the Day 0 values. The branchip density decreased more than it does in the control animals,  $66 \pm 4\%$  vs.  $89 \pm 5\%$  of the initial values. The axon length did not increase ( $108 \pm 9\%$ ) as much as it does in the controls ( $142 \pm 10\%$ ). Relatively, there was a selective decrease in the branchips with high topological branch order ( $>8$ ) and short segment length (1-10  $\mu$ m). The maximal length and width of the axon arbor did not change. These results suggest that the activity of CaMKII in the tectal cells could be involved in controlling the branching pattern of retinal axons. We are studying the detailed mechanisms of these tCaMKII effects on the remodeling of retinal axon branching pattern by observing repetitively the morphology of individual axons at shorter intervals.

## 512.2

DYNAMIC GROWTH PATTERNS OF XENOPUS TECTAL CELLS AND EFFECTS OF OVEREXPRESSION OF CaMKII. Gang-Yi Wu and Holly Cline\*, Cold Spring Harbor Laboratory, Cold Spring Harbor, NY 11724

Relatively little is known about the dynamic growth patterns of dendrites and related cellular and molecular mechanisms. In order to reveal the processes of neuronal growth *in vivo*, tectal cells near the ventricular layer midway along the rostrocaudal extent of tectum were selectively labeled in *Xenopus* tadpoles between stages 46 and 49 using iontophoresis of Dil. Individual cells were imaged using time lapse confocal microscope and three-dimension reconstruction techniques. The dynamic growth of rostrally projecting cells is reported here. The development of all rostrally projecting neurons roughly followed the same time course. Data from daily observations showed that the axon was generally initiated before the dendritic elaboration. The axon was tipped with an active growth cone and navigated medially or laterally into the tectothalamic tracts. Dendrites first sprouted after the axon entered the above tracts. Once the axon reached the target area (thalamus), the dendrites dramatically increased in branch numbers and lengths. This period of fast dendritic growth lasted about 1 day and resulted in the formation an initial dendritic pattern. After this period the dendritic arbors continued to grow. No obvious regression process was detected. Observations taken at short-time intervals (5-10min) revealed that the dendritic arbor formation is a dynamic process. Addition and retraction of filopodia-like structure of dendrite growth cone and of primary branches occurred rapidly. To elucidate the functional role of CaMKII in process outgrowth, we have used the Vaccinia virus to deliver the gene for the constitutively active CaMKII (AA 1-290) into tectal neurons *in vivo*. Overexpression of CaMKII in neurons during the period of rapid dendritic growth significantly reduced the complexity and elongation of tectal cell dendrites after 2-3 days. Transfection in more mature neurons apparently did not result in such a severe reduction in dendritic arbor complexity. Therefore, our results show that the normal growth of neurons is a dynamic process. Furthermore, the data suggest that the activity-regulated enzyme CaMKII is involved in regulation of the dendritic growth of tectal neurons in *Xenopus* *in vivo*.

## 512.3

CHANGES IN INTRACELLULAR CALCIUM MAY BE PREDICTIVE OF MORPHOLOGICAL PLASTICITY IN RETINAL GANGLION CELL AXON ARBORS AND GROWTH CONES. J.A. Edwards\* and H.T. Cline. Beckman Neuroscience Center, Cold Spring Harbor Laboratory, CSH, NY 11724.

Two fundamental aspects of neuronal development are axonal navigation and the elaboration of the axon terminal within the target region. Several hypotheses, based upon data from *in vitro* model systems, attempted to relate changes in intracellular calcium ( $[Ca^{2+}]_i$ ) with morphological changes in either growth cones or complex axon arbors. To date there is no consensus opinion regarding whether changes in  $[Ca^{2+}]_i$  are required for neurite elongation and growth cone motility or to what degree these changes affect developmental morphology. Although *in vivo* recordings of  $[Ca^{2+}]_i$  have been correlated with electrical and/or mechanical stimulation of zebrafish spinal cord neurons (Fetcho and O'Malley, 1995), no direct measure of morphological plasticity and  $[Ca^{2+}]_i$  has been performed simultaneously *in vivo*. The present investigation was undertaken to study the *in vivo* relationship between  $[Ca^{2+}]_i$  and morphology in the developing visual system of albino *Xenopus laevis* tadpoles.

Calcium green-1 dextran (CaGD) was iontophoretically injected into the temporal retina of stage 43/44 tadpoles. CaGD was chosen over other available single excitation/single emission fluorescent probes on the basis of its brighter emission characteristics at lower, basal levels of  $[Ca^{2+}]_i$ . Confocal laser scanning microscopy was then used to study both changes in  $[Ca^{2+}]_i$  and morphology in single retinal ganglion cell complex axon arbors or pathfinding growth cones. Optical image planes were collected at 4  $\mu$ m intervals using a computer controlled z-motor, and imaging series were collected once every 5 minutes and analyzed using Intervention (Noran Instruments, Inc.) and VolVis (public domain) software. These studies demonstrate, for the first time, that changes in  $[Ca^{2+}]_i$  can be correlated with dynamic morphological plasticity *in vivo*. The findings from this work should aid in our understanding of the relationship between changes in  $[Ca^{2+}]_i$  and changes in axonal growth cone morphology within the developing visual system.

## 512.5

CHANGES IN  $[Ca^{2+}]_i$  PRODUCED BY DEPOLARIZATION OF GROWTH CONES FROM TONIC AND PHASIC MOTONEURONS. K. Arcaro\* and G.A. Lnenicka. Depart. of Biol. Sci., State Univ. of New York, Albany, N.Y. 12222

In a previous study, we found that prolonged depolarization with 60 mM  $K^+$  had different effects on the growth of regenerating phasic and tonic motor axons in the crayfish (*Procambarus clarkii*): axons of the tonic motoneurons continued to advance while those of the phasic motoneurons were inhibited and eventually degenerated. Experiments with calcium channel blockers indicated that this resulted from the differential effects of calcium influx. To determine whether these results were due to differences in calcium regulation or calcium sensitivity, we measured  $[Ca^{2+}]_i$  in neurites and growth cones. Regenerating motor axons were examined using ratio imaging of fura-2 fluorescence. In growth cones from tonic axons, depolarization with 60 mM  $K^+$  produced approximately a 5-fold increase in  $[Ca^{2+}]_i$ , which is maintained for the duration of the depolarization (up to 4 days). In spite of the elevated  $[Ca^{2+}]_i$ , the neurites continued to grow at normal or above normal rates. Preliminary experiments on growth cones from phasic axons indicate that similar increases in  $[Ca^{2+}]_i$  result in inhibition of growth, suggesting that phasic and tonic axon growth cones have different sensitivities to  $[Ca^{2+}]_i$ . (Supported by NSF grant IBN-9121757)

## 512.7

HETEROGENEOUS REGULATION OF NEURITE OUTGROWTH IN EMBRYONIC *XENOPUS* SPINAL NEURONS. Xiaonan Gu\* and Nicholas C. Spitzer. Dept. Biology & Center for Molecular Genetics, UCSD, La Jolla, CA.

Neurite extension is regulated by the frequency of transient  $Ca^{++}$  waves occurring naturally (8-9/h) in growth cones of embryonic *Xenopus* spinal neurons grown in culture. In  $Ca^{++}$ -free medium, stimulation of brief  $Ca^{++}$  pulses by application of 100 mM  $K^+$ /10 mM  $Ca^{++}$  mimics endogenous  $Ca^{++}$  transients in  $Ca^{++}$ -containing medium, and results in neurite outgrowth similar to that of neurons grown in the presence of calcium. From analyses of the neuronal population, both the mean neurite length and the distribution of lengths of individual neurites in stimulated cultures grown in  $Ca^{++}$ -free medium match those from cultures grown in  $Ca^{++}$ -containing medium. We have investigated the extent of differences in outgrowth of individual neurites, with the same stimulation paradigm.

We measured neurite extension between 12-15 h in culture. Between 13 and 14 h, cultures were either continuously perfused with  $Ca^{++}$ -containing medium, or perfused with  $Ca^{++}$ -free medium and stimulated at 9 h with high  $K^+$ / $Ca^{++}$ . Both treatments inhibited outgrowth in ~60% of neurites ( $n \geq 21$ ), by a mean value of 60%. Outgrowth was stimulated in 5% of neurites, and 10% of neurites exhibited no response to both treatments. Different responses to stimulation were not related to initial lengths of neurites. 25% of neurites have already stopped extension by 12 h in culture. During the process of neurite outgrowth, neurites of multipolar cells behaved similarly. As found in population analyses, neurite outgrowth was not inhibited when stimulated at the lower spontaneous frequency of propagated spikes (3/h).

These findings suggest the existence of 3 subtypes of neurons with different neurite extension machinery, since all neurites exhibit spontaneous  $Ca^{++}$  transients. Extrapolating observations from 1 h stimulation to 18 h yields an expected mean neurite length consistent with that obtained at 18 h in  $Ca^{++}$ -containing medium in previous population analyses. Thus,  $Ca^{++}$  transients regulate extension of individual neurites throughout the 18 h period. Supported by NS15918.

## 512.4

CALCIUM-DEPENDENT SIGNALING MECHANISMS GOVERN DENDRITIC OUTGROWTH AND ARBORIZATION IN DEVELOPING CEREBELLAR PURKINJE NEURONS. Andrea J. Yool\* and Raven Reistetter. Dept. of Physiology, University of Arizona College of Medicine, Tucson AZ 85724.

Purkinje neuron development in culture is characterized by the elaboration of a branched dendritic arbor during a time equivalent to postnatal development of the rat cerebellum. This structural development is accompanied by enhanced excitability and the expression of new  $Ca$  and  $K$  components of the firing pattern. Our data show that the transcription of  $K_{Ca}$  channels is developmentally regulated. The delayed  $K_{Ca}$  expression correlates with the pattern of  $K_{Ca}$  activation *in vitro* and suggests the regulatory mechanisms governing this channel are not substantially affected by the explanting process. We find a dramatic effect of chronic  $K_{Ca}$  channel blockade on neuronal development, in support of a key role for these channels in the transmembrane signaling processes that shape dendritic structure. Purkinje neuron morphology is altered by chronic treatment with 1 mM tetraethylammonium, which affects primarily the large conductance  $K_{Ca}$  channel. Control neurons show densely branched dendritic arbors; chronic TEA stimulates outgrowth over extended ranges with a generally similar branching pattern. Purkinje neurons are labeled with antibody to calbindin; structures that we have identified as dendrites by morphology are labeled appropriately by antibody to MAP2. Our hypothesis is that the calcium signals that drive outgrowth are in turn regulated by  $K_{Ca}$  channels, and that chronic blockade of  $K_{Ca}$  channels augments the calcium signals. Surprisingly, despite its importance in modulating  $Ca^{2+}$  entry,  $K_{Ca}$  has not previously attracted attention as a potentially important regulatory mechanism. Many other studies have shown that transient calcium signals are important in regulating neurite outgrowth in various cell types. In Purkinje neurons, the predominant  $Ca^{2+}$  channel is the P-type, sensitive to  $\omega$ -Aga-IVA toxin. Ongoing studies with ion channel-specific toxins will test for interactions between subtypes of  $Ca$  and  $K_{Ca}$  conductances during the maturation of the dendritic arbor.

## 512.6

NEURITE OUTGROWTH INDUCED BY LIMBIC SYSTEM-ASSOCIATED MEMBRANE PROTEIN CAN BE REGULATED BY CHANGES IN INTRACELLULAR  $Ca^{2+}$ . V. Zhukareva\*, N. Chernetskaya, M. Nowycky, and P. Levitt. Dept. Neuroscience and Cell Biology, Robert Wood Johnson Medical School - UMDNJ, Piscataway, NJ 08854 and Dept. Anatomy and Neurobiology, Med. Coll. PA, Philadelphia, PA 19129.

The limbic system-associated membrane protein (LAMP) is an Ig-superfamily member that exhibits homophilic, selective adhesive activity for specific neuronal populations. Monolayers of CHO-K1 cells transfected with full-length *lamp* cDNA (CHO<sub>L</sub> cells) show an enhanced ability to promote neurite outgrowth of fetal LAMP<sup>+</sup> neurons from perirhinal cortex and hippocampus compared to LAMP<sup>-</sup> neurons from olfactory bulb and visual cortex. The mechanism by which this specificity may be regulated has been investigated by examining the role of second messengers in mediating LAMP-induced outgrowth. Treatment of the limbic neurons with L- (20  $\mu$ M nifedipine) and N-type (1  $\mu$ M  $\omega$ -conotoxin)  $Ca$ -channel antagonists abolishes LAMP induced neurite outgrowth on the monolayer of CHO<sub>L</sub>. Limbic neurons, grown on control CHO cells treated with the same antagonist also demonstrate reduced outgrowth, although to a lesser extent. In preliminary experiments, bath application of soluble LAMP causes an increase of intracellular  $Ca^{2+}$ , which begins to decline after 40 min. of incubation. These observations indicate that LAMP may function through the activation of an intracellular signaling system involving changes in intracellular  $Ca^{2+}$  levels. Supported by MH45507 (PL) and NS22281 (MN).

## 512.8

THE EFFECT OF CALCIUM ON NEURITE OUTGROWTH IS SUBSTRATE-DEPENDENT. Jane Yiti and Carl Lagenaur\*. Dept. of Neurobiology, Univ. of Pittsburgh, Pittsburgh, PA 15261

Neurite outgrowth and growth cone shape are influenced by cellular interactions with the growth substrate. Many studies have indicated a critical role for calcium in neurite outgrowth and growth cone movement. If neurons use different signaling mechanisms for each substrate then the cells' response to extracellular calcium could differ with different substrates. Mouse cerebellar neurons were plated on four purified substrates; NCAM, L1, P84, and laminin. The cells were then grown in calcium-free media supplemented with varying concentrations of calcium ranging from 0 mM to 8 mM. Cells growing on NCAM had the longest neurites when supplemented with 1-2 mM  $Ca^{++}$ . With 8 mM  $Ca^{++}$ , the neurites were slightly shorter but the cells were still healthy. The longest neurites on L1 were observed when 1 or 2 mM  $Ca^{++}$  was added. With 4 mM  $Ca^{++}$ , cells began to die and neurites were significantly shorter. These toxic effects increased at 8 mM  $Ca^{++}$ . Cells plated on P84 did not seem to be greatly effected by differing calcium concentrations. Peak growth occurred with the addition of 4 mM  $Ca^{++}$ . At 8 mM  $Ca^{++}$ , cell viability decreased and neurites were slightly shorter. When cells are plated on laminin, neurite length, number and the amount of fasciculation increased with higher concentrations of calcium, peaking with the addition of 4 mM  $Ca^{++}$ . At 8 mM  $Ca^{++}$ , the cells were healthy with long neurites but they were defasciculated. These results identify a substrate-dependence of calcium's effects on neurite outgrowth.

## 512.9

TURNING OF NERVE GROWTH CONES INDUCED BY FOCAL ELECTRIC FIELDS IN  $\text{Ca}^{2+}$  FREE MEDIUM. S. TSUKADA, and J. FUKUDA. Department of Physiology, National Defense Medical School, Tokorozawa, Saitama, JAPAN.

Transmembrane  $\text{Ca}^{2+}$  influx and  $[\text{Ca}^{2+}]_i$  gradient at nerve growth cones has been understood as essential for turning responses of growing tips by electric currents. Here we report an opposite result that the turning responses take place in neurites growing in the absence of  $\text{Ca}^{2+}$  influx in growth cones. Dorsal root ganglia dissected from newborn rats were placed in a two chamber dish so that their neurites grew in a  $\text{Ca}$  free medium. DC current was applied to neurites through a microelectrode placed approximately 50  $\mu\text{m}$  distant from the growth cones.  $[\text{Ca}^{2+}]_i$  in neurites was measured using Calcium-green 1 under a laser scanning microscope, and  $\text{Ca}^{2+}$  stores in neurites was evaluated as a transient increase in  $[\text{Ca}^{2+}]_i$  by applying A23187 ( $\text{Ca}^{2+}$  ionophore) to neurites bathed in a  $\text{Ca}$ -free medium. Our findings are: 1) turning responses, similar to those induced in control neurites (grown in normal  $\text{Ca}^{2+}$  medium), were induced in neurites grown in  $\text{Ca}$ -free medium. 2)  $[\text{Ca}^{2+}]_i$ , which was 150 nM in control neurites, was reduced to approximately 50 nM in neurites during growth in  $\text{Ca}$ -free medium. 3) A transient increase in  $[\text{Ca}^{2+}]_i$ , that was induced in growth cones of control neurites during turning responses, was not observed in neurites grown in  $\text{Ca}$ -free medium. 4) Intracellular  $\text{Ca}^{2+}$  stores were reduced to approximately 1/3 of control level in the neurites grown in  $\text{Ca}$ -free medium. We therefore concluded that induction of turning responses were not influenced either by reduction in  $[\text{Ca}^{2+}]_i$  or by depletion of intracellular  $\text{Ca}^{2+}$  stores in rat DRG neurites.

## 512.11

EFFECTS OF INHIBITORS OF NMDA AND PI-LINKED METABOTROPIC GLUTAMATE RECEPTORS ON NEURITE DEVELOPMENT IN CULTURED RAT HIPPOCAMPAL NEURONS. G. Audesirk\*, M. Kern, and L. Cabell. Biology Department, Univ. of Colorado at Denver, Denver, CO 80217-3364.

Glutamate activates a variety of both ionotropic and metabotropic receptors. We examined the effects of inhibitors of NMDA receptors and phosphoinositide-linked metabotropic receptors on neurite development in cultured E18 rat hippocampal neurons. Receptors were activated by glutamate present in fetal bovine serum in the culture medium. After two days in culture, we measured survival, neurite initiation, axonal elongation and branching, dendrite number, and dendrite elongation and branching. Neither 200  $\mu\text{M}$  D-AP5, a competitive inhibitor of NMDA receptors, nor 10  $\mu\text{M}$  MK-801, an open-channel blocker, altered any parameter of neurite development. A second competitive inhibitor, (RS)-CPP (100  $\mu\text{M}$ ), had no effects on any parameter except axonal elongation. Several parameters of neurite development were decreased by both the active and relatively inactive enantiomers of MK-801 at 50  $\mu\text{M}$ , indicating nonspecific effects at high concentrations. These results indicate that NMDA receptors do not play an important role in the early stages of neurite development in culture. In contrast, competitive inhibitors of PI-linked metabotropic receptors, L-AP3 (100 to 500  $\mu\text{M}$ ) and (S)-4-CPG (7.5 to 10  $\mu\text{M}$ ), reduced neurite initiation and enhanced dendrite branching. D-AP3, the inactive enantiomer of L-AP3, did not alter initiation or dendrite branching. Therefore, activation of PI-linked metabotropic receptors may modulate neurite initiation and dendrite branching.

## 512.13

ENDOGENOUS NITRIC OXIDE MODULATES NEURITE GROWTH IN REGENERATING RAT SENSORY NEURONS. D.B. Wayne\* and J.H.P. Skene, Department of Neurobiology, Duke University, Durham, N.C. 27710

Application of exogenous nitric oxide (NO) to rat dorsal root ganglion (DRG) neurons in vitro can halt outgrowth of regenerating axons (Hess et al., Nature 366: 562, 1993). In DRG neurons, the enzyme nitric oxide synthase (NOS) is present during development and is upregulated during regeneration (Verge et al., PNAS 89: 11617, 1992). Therefore, we examined the role of endogenous NO in outgrowth and in particular whether NOS, a calmodulin dependent enzyme, may mediate some of the effects of calcium on outgrowth. First we confirmed that in regenerating rat DRG neurons, an increase in intracellular calcium by exposure to calcium ionophore A23187 inhibits neurite extension. We then examined the frequency and rate of DRG axon extension following treatment with the NOS inhibitor  $\text{N}^G$ -methyl-L-arginine (L-NMMA), under standard culture conditions or in the presence of A23187. Inhibition of NOS enhances outgrowth suggesting that endogenous NO may be an important modulator of axon extension. [Supported by NIH grant NS20178.]

## 512.10

DEPOLARIZATION-INDUCED CHANGES IN THE MORPHOLOGY OF GROWING NEURONS. L.M. Boulanger\* and M-m. Poo. Dept. Biol. Sci., Columbia Univ., N.Y., N.Y. 10027

Electrical activity plays a prominent role in the formation and refinement of synaptic connections in the developing nervous system as well as in regulating synaptic efficacy in the adult, but the underlying mechanisms are largely unknown. Previous studies on the effects of electrical activity and neurotransmitters in cultured neurons have shown that depolarization often leads to growth inhibition or retraction of filopodia and neurites. We have examined depolarization-induced changes in the morphology of growing *Xenopus* spinal neurons in culture. Incubation in 45 mM  $\text{K}^+$  for 2.5 min caused elevated exocytosis and rapid, long-lasting changes in neuronal morphology. Number of filopodia at the growth cone and along the neurite and apparent plasma membrane surface area were increased by depolarization. These changes were prevented when high  $\text{K}^+$  was applied in the absence of external  $\text{Ca}^{2+}$ . These depolarization-induced changes suggest a rapid,  $\text{Ca}^{2+}$ -dependent insertion of membrane material, presumably via exocytotic fusion of membrane precursor vesicles from the constitutive pathways. This possibility was further examined by visualizing membrane recycling activity in living neurons using the fluorescent dye FM1-43. Incubation with 10  $\mu\text{M}$  FM1-43 in the presence of external  $\text{Ca}^{2+}$  and high  $\text{K}^+$  caused filopodial sprouting and concomitant staining of recycling vesicles. Stained vesicles were found in clusters along the neurite and their distribution closely paralleled that of new filopodia. This is consistent with the idea that  $\text{Ca}^{2+}$ -dependent exocytosis triggers local endocytic activity, and a net gain in exocytosis over endocytosis is responsible for local filopodia protrusion and membrane growth. Thus membrane depolarization can cause rapid and sustained increases in extension and complexity of growing neurons, and  $\text{Ca}^{2+}$ -regulated membrane growth may be closely related to local membrane recycling known to be involved in the retrieval of synaptic vesicles.

## 512.12

POSSIBLE ROLE OF THE N-METHYL-D-ASPARTATE (NMDA) RECEPTOR IN THE REMODELING OF DENDRITIC ARBORIS DURING DEVELOPMENT. N.M.J. Blake\* and B.J. Claiborne\*. Program of Neuroscience, Washington Univ., St. Louis, MO 63110. \*Div. Life Sciences, Univ. Texas at San Antonio, TX 78249.

During late postnatal development, granule neurons in the rat hippocampus lose dendritic segments while their remaining branches continue to elongate: total dendritic length is conserved (Rhin and Claiborne, 1990, Dev. Brain Res. 54:115). Because synaptic activity mediated by the NMDA receptor is thought to affect the maturation of some axons in the central nervous system, we hypothesized that it may also play a role in the remodeling of granule cell dendrites.

To test this hypothesis, 3 rats were sacrificed on postnatal day (PND) 14 to provide baseline data. From PND 14 through 24, 4 littermates were injected with CPP (3-(+)-2-carboxypiperazin-4-yl-propyl-1) phosphonic acid) every 12 hrs (IP: 10 mg/Kg), and 3 were injected with saline. On PND 25, 400 $\mu\text{m}$ -thick, fixed hippocampal slices were prepared. Granule neurons were retrogradely labeled with Dil, and dendrites analyzed in 3-D.

Results indicated that granule neurons (n=16) from 14-day-old pups had 31  $\pm$  1 branches (mean  $\pm$  SEM) and total dendritic lengths of 2266  $\pm$  76 $\mu\text{m}$ . Neurons (n=18) from 25-day-old, saline treated animals exhibited significantly fewer branches (21  $\pm$  1), but similar dendritic lengths (2268  $\pm$  136 $\mu\text{m}$ ), confirming previous work. In contrast, neurons (n=17) from 25-day-old CPP-treated rats did not exhibit a significant decrease in branch number (28  $\pm$  1), but did show an increase in total dendritic length (2973  $\pm$  136 $\mu\text{m}$ ). Thus, injections of CPP reduced the branch loss normally seen in granule neurons between PNDs 14 and 24, but did not affect dendritic growth. These data suggest that synaptic activity mediated by the NMDA receptor may play a role in the remodeling of dendritic arbors during late postnatal development. (Supported by NIGMS GM 08194).

## 512.14

ROLE OF AFFERENTS IN THE DEVELOPMENT OF DENDRITIC BRANCHING AND SPINES IN CULTURED HIPPOCAMPAL NEURONS. A.H. Kossel\*, S.B. Kater. Anatomy and Neurobiology, Colorado State University, Fort Collins, CO 80523.

Presynaptic afferents likely play a major role in development and plasticity of dendritic morphology in the CNS. The present study asks how afferents can influence the morphology of neurons, and if activity and the activation of different subtypes of glutamate receptors are involved in these changes. E18 rat hippocampal neurons were grown 11-14 days on a net of axons extending from explants of entorhinal cortex, providing a constant, high density of presynaptic afferents. Synapses developed between neurons and the axonal net as determined by immunohistochemistry and EM. After 11 days, neurons on and off the axonal net were clearly different. Neurons in contact with the afferents were 4 times more branched than isolated neurons and also had a high density of spines. To assess the role of afferent activity in branch and spine formation, we grew cultures under chronic blockade of neuronal activity by TTX. Cultures treated with TTX showed a reduction in spine density, as previously reported. However, dendritic branching was not affected. In order to determine if activation of individual subtypes of glutamate receptors is involved in these postsynaptic changes, cells were grown in the presence of different glutamate receptor blockers. However, neither application of the ionotropic glutamate receptor blockers DNQX and APV, nor the metabotropic receptor-blocker MCPG led to a significant reduction in the number of spines or branches. In fact, APV treated cultures showed a transient increase in spine density around day 11. Since blockade of different glutamate receptor subtypes did not affect spine formation, neuronal activity may exert its effects on spine formation via changes in, for instance, release of cotransmitters, neurotrophins or the altered expression of synapse specific molecules. Our findings also show that neuronal afferents clearly increased dendritic branching. In conclusion our results suggest that there are several pathways by which neuronal afferents can influence neuronal structure.

## 512.15

**GAP-43 FACILITATES PEPTIDE HORMONE SECRETION IN MOUSE ANTERIOR PITUITARY AIT-20 CELLS.** C. Gamby<sup>1,2</sup>, R. G. Allent<sup>1</sup>, and L. Baizer<sup>2</sup>. <sup>1</sup>R. S. DOW Neurological Sciences Institute, Good Samaritan Hospital and Medical Center, <sup>2</sup>Dpt of Cell Biology and Anatomy and <sup>3</sup>Center for Research on Occupational and Environmental Toxicology, Oregon Health Sci. Univ., Portland, Oregon 97209.

The neuronal growth-associated protein (GAP)-43 (neuromodulin, B-50, F1), which is concentrated in the growth cones of elongating axons and in nerve terminals in restricted regions of the adult nervous system, has been implicated in the release of neurotransmitter.

To study the role of GAP-43 in evoked secretion, we transfected mouse anterior pituitary AIT-20 cells with the rat GAP-43 cDNA under control of the Rous Sarcoma Virus (RSV) promoter and derived stably transfected cell lines.

Immunoblot analysis demonstrated that GAP-43 was targeted to the membrane. Depolarization-mediated  $\beta$ -endorphin secretion was greatly enhanced in the GAP-43-expressing AIT-20 cells without a significant change in  $Ca^{2+}$  influx; in contrast, expression of GAP-43 did not alter CRF-evoked hormone secretion. The transfected cells also displayed a flattened morphology and extended processes when plated on laminin-coated substrates.

We also investigated the interaction of GAP-43 and calmodulin (CaM) in the AIT-20 cells. In the plasma membrane of cells treated with a cross-linking agent, immunoblot analysis with anti-GAP-43 antibodies shows a 70 kDa band corresponding to approximately 30 % of the total GAP-43 immunoreactivity. Immunoprecipitation with anti-GAP-43 antibodies followed by immunoblot analysis with anti-CaM antibodies shows that CaM is associated with GAP-43 in these cells.

These results suggest that AIT-20 cells are a useful model system for further investigations on the precise biological function of GAP-43.

## AXON GUIDANCE MECHANISMS AND PATHWAYS VI

## 513.1

**EXPRESSION OF A DOMINANT NEGATIVE FGF RECEPTOR IN THE DEVELOPING RETINA.** S. McFarlane\*, E. Cornel, E. Amaya, and C. E. Holt. Dept. Biology, UC San Diego, La Jolla, CA 92093-0366.

FGF signaling has been implicated in the differentiation of neurons, including retinal ganglion cells (RGCs). For instance, FGFs in culture stimulate neurite extension of RGCs and increase the expression of a differentiation marker, neurofilament protein. Our previous data shows that bFGF is expressed in the developing optic pathway of *Xenopus laevis* and that application of bFGF to the developing retinotectal projection in vivo causes retinal axons to grow around and bypass their target, the optic tectum. Our results provide further support for a role for FGF signaling in RGC differentiation. To further test the possibility that FGF signaling is important for the differentiation of RGCs in vivo we have blocked FGFR signaling by transfecting developing RGCs with a dominant negative form of the FGF receptor that lacks the intracellular kinase domains. At stage 20, a mixture of DOTAP/cDNA was injected into the proliferative neuroepithelium of the eye primordium. Embryos were injected with either a dominant negative construct (XFD, Amaya et al., 1991) or control constructs: a non-functional dominant negative (HAVNOT), Green fluorescent protein (GFP), and luciferase constructs. Embryos were allowed to develop for 48 hours until stage 41 when retinal axons have reached their target. Dominant negative and HAVNOT transfected cells were visualized with an antibody against *Xenopus* FGFR, either in cryostat or vibratome sections. GFP transfection was monitored by fluorescence and luciferase with antibody staining.

We observed RGCs expressing high levels of mutant FGFR as judged by intensity of immunostaining. These cells were located in the appropriate retinal lamina and possessed both axons and dendrites suggesting that in the absence of normal FGF signaling many aspects of RGC differentiation occur normally. We are currently investigating whether FGFRs are needed for axonal pathfinding. (Supported by NIH #NS23780, PEW Scholars Award)

## 513.3

**IN VITRO GUIDANCE OF RETINAL GANGLION CELL AXONS BY RAGS, A 95 KD TECTAL PROTEIN RELATED TO LIGANDS FOR EPH-RECEPTOR TYROSINE KINASES.** U. Drescher, C. Kremoser, G. Handwerker, J. Loschinger, H. Baier\*, M. Noda, and E. Bonhoeffer. Max-Planck-Institute for Developmental Biology, Department of Physical Biology, Spemannstr. 35, 72076 Tübingen, FRG.

Previous in vitro experiments have indicated that a glycosyl-phosphatidylinositol (GPI)-anchored protein may play an important role in guidance of retinal axons during the formation of the topographically ordered retinotectal projection. Within this projection nasal axons of retinal ganglion neurons grow to posterior tectum, temporal retina is connected to anterior tectum. In vitro, in the so-called stripe assay, retinal axons are offered the choice of growing on either anterior or posterior tectal membranes. Temporal axons are repelled by posterior membranes and grow on anterior stripes. The posterior membranes lose their repellent activity after incubation with PI-PLC, an enzyme which cleaves GPI-anchored proteins from the membrane surface. This activity can be detected only between E6 and E12, the time at which ingrowing retinal axons build up a crude scaffold of projections. Therefore, the three criteria assumed for a candidate axon guidance molecule for temporal axons are (i) GPI anchorage, (ii) expression from E6 to E12 and (iii) higher expression in posterior than in anterior tectum. Using 2D gel electrophoresis we identified a 95 kDa protein which fulfills these criteria. Cloning and sequencing of the corresponding cDNA reveals significant homologies to recently identified members of the Eph receptor tyrosine kinase ligand family. By using the stripe assay, we could demonstrate an in vitro guidance activity of this protein, in that retinal axons are repelled from stripes containing membranes derived from p25 cDNA transfected cos cells. These results indicate for the first time a specific function of a member of the Eph receptor/ligand family in processes of axon guidance. Our current investigations focus on the identification of the p25 receptor, an Eph-receptor tyrosine kinase expressed on retinal ganglion cell growth cones.

## 512.16

**NEUROTRANSMITTER RELEASE FROM GROWTH CONES OF CENTRAL CHOLINERGIC NEURONS.** H. Tatsumi<sup>1,2</sup>, S. Tsuji<sup>3</sup>, H. Soeda<sup>1</sup> and Y. Katayama<sup>1,2</sup>. <sup>1</sup>Department of Autonomic Physiology, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan. <sup>2</sup>Département de Cytologie, Institut des Neurosciences, Université Pierre et Marie Curie, Paris, France. <sup>3</sup>PRESTO JRDC Japan.

Neurons taken from the diagonal band of Broca (DBB) of new born rats (7-9 days after birth) protruded dendrites, axons and growth cones in culture. Neurons acutely isolated from the rat superior cervical ganglion (SCG) were used as a detector of the ACh release, because these cells are endowed with ACh-receptors. SCG neurons were plated on the glass coverslip, on which DBB neurons had been already cultured (2 to 7 days). Using whole-cell patch clamp technique, inward currents were recorded from SCG neurons placed close to the growth cones of DBB neurons electrically stimulated, suggesting that ACh was released from the growth cones. Rapid morphological changes of growth cones were also observed with high resolution video-microscopy at the same time.

## 513.2

**EXPRESSION AND POSSIBLE ROLE OF pp125FAK IN THE DEVELOPING XENOPUS RETINAL PROJECTION.** T. L. Worley\* and C. E. Holt. Dept. of Biology 0366, UC San Diego, La Jolla, CA 92093.

Previously we have reported that the pharmacological inhibition of protein tyrosine kinase (PTK) activity with the drugs herbimycin A and lavendustin A impairs the development of the *Xenopus* retinal projection. In addition, this treatment was found to hinder laminin-dependent retinal neurite outgrowth in culture. One inhibitor-sensitive PTK was identified as pp125FAK, which is known to become stimulated upon integrin-mediated binding in non-neuronal cells. Here we establish the presence and location of pp125FAK with immunohistochemistry in the developing *Xenopus* brain, retina and retinal growth cone. In a Western blot analysis of the same stages of brain and retina, we also show the developmentally regulated expression pattern and phosphorylation levels of pp125FAK. Finally, we observe that cytochalasin D treatment of the developing retinal projection, which in earlier studies was shown to result in aberrant pathfinding and a decrease in filopodial formation, also induces a decrease in tyrosine phosphorylation on pp125FAK. These data suggest a role for pp125FAK kinase activity in the proper establishment of the *Xenopus* retinal projection. This work was supported by NIH#NS23780 and a Pew Scholars Award.

## 513.4

**AXONAL GROWTH ON A SUBSTRATE GRADIENT OF BASAL LAMINA PROTEINS**

W. Halfter<sup>1</sup> Dept. of Neurobiology; University of Pittsburgh

In the early embryonic retina optic axons grow toward the optic disc and form a centripetal axon pattern. To see whether optic axons follow a peripheral-centrally directed substrate gradient in the retina the growth behavior of optic axons was tested on a substrate gradient of basal lamina proteins in vitro. The substrate was an extract from the inner limiting membrane from the embryonic retina. The gradients were produced by diffusion of the basal lamina proteins in a drop of PBS on a membrane filter. The slope of the gradients were determined by counting fluorescent beads in the basal lamina extract. Retinal explant stripes were placed perpendicular and parallel to the edges of the gradients and cultured for 30hrs. The growth pattern of the axons, detected by silver staining, showed that optic axons on the border of the gradients became shorter and more fasciculated. However, axons did not turn toward a higher substrate concentration indicating that the gradients were unable to guide optic axons in a particular orientation.

## 513.5

**MATURATION OF AXONAL PATHWAYS WITHIN THE BRAIN AND RETINA OF THE PRENATAL FERRET.** J.K. Johnson\*, C.L. Winslow, and N.E.J. Berman. Laboratory of Neuroscience, Dept. Anat. & Cell Biol., University of Kansas Medical Center, Kansas City, KS 66160-7400.

The distribution of GAP-43 expression was studied in the ferret (*Mustela putorius furo*) brain and retina in order to examine the ontogeny of prominent axonal pathways.

Animals between the ages of E20 and birth were used in this study. Formaldehyde-fixed brains were embedded in paraffin and serially sectioned. GAP-43 was revealed using standard immunocytochemical techniques. Reacted sections were counterstained with thionin as needed.

Strong GAP-43 immunoreactivity was present by E20, but was limited to punctate staining within the ventricular zone (VZ). No staining was observed within the marginal zone (MZ), nor were any of the central pathways present, including the optic nerve. By E28 the staining within the VZ had ended and axon outgrowth had begun throughout the brain, including the retina. By this time two separate bands of densely-stained fibers within the developing white matter (WM)/intermediate zone (IZ) had formed. Additionally, the MZ and SP had become lightly labeled, with occasional punctate staining present within the CP. Also present were strongly stained optic nerves. Most remaining major intrahemispheric central pathways expressed GAP-43 by this time (e.g., optic nerve, internal capsule). By E34 all major pathways were densely stained, including the newly formed, and densely stained, corpus callosum.

These results indicate that premigratory neurons begin to express GAP-43 while still in the VZ. Prominent central pathways form within a narrow window of time with intrahemispheric pathway development preceding formation of the corpus callosum.

Supported by grant MH 38399.

## 513.7

**PRENATAL DEVELOPMENT OF RETINOGENICULATE PROJECTIONS IN THE RAT: TARGET FINDING OF RETINOGENICULATE AXONS.** Y. Kondo<sup>\*1,2</sup>, M. Takada<sup>1</sup>, and N. Mizuno<sup>1</sup>. <sup>1</sup>Dept. Morphological Brain Science, Kyoto Univ., Kyoto 606-01, JAPAN. <sup>2</sup>Dept. Neurosciences, The Cleveland Clinic Foundation, Cleveland, OH 44195.

Employing anterograde axonal tracing with DiI, we investigated the prenatal development of retinogeniculate projections in the rat. The tracer was deposited into the retina at embryonic day (E) 16, 17, 18, 19 or 20. At E16 and E17, retinal axons were directed towards the lateral geniculate body (LG) and superior colliculus (SC), bilaterally with a clear-cut contralateral predominance. Virtually all of the axons passed through the optic tract without their penetration into the LG, although many of them reached as far as the SC by E17. At these ages, a considerable number of axons left the optic tract on the way to the LG and SC to course medially towards the third ventricle. At E18, some of the retinal axons that arrived at the SC turned to come back to the LG, and some of the retinal axons that passed through the optic tract immediately lateral to the LG brought forth axonal branches to enter the LG. These turning and budding axons for innervating the LG increased in number at E19 and E20; at these ages, medially-directed axons towards the third ventricle were no longer detected. The results indicate that retinal axons recognize the SC as the primary target and then the LG as the secondary one.

**METABOLIC LABELING OF GLYCOSAMINOGLYCANS IN THE DEVELOPING TECTUM OF THE SYRIAN HAMSTER.** Diane Hoffman-Kim\*, Arthur D. Lander, and Sonal Jhaveri. Dept. of Brain & Cognitive Sciences, MIT, Cambridge, MA 02139.

It is widely accepted that sulfated proteoglycans (PGs) influence axon development; however, the cellular and molecular mechanisms of this influence remain to be elucidated. In addition, relative contributions of protein core and glycosaminoglycan (GAG) chain(s) to PG function have yet to be clarified. We have examined the distribution of PGs in Syrian hamster tectum during the time retinotectal axons grow in and arborize. Previous immunohistochemical experiments have shown that chondroitin sulfate (CS) and keratan sulfate (KS) GAGs are concentrated primarily at the tectal midline, where retinal axons do not grow. This observation along with results of *in vitro* studies suggest a role for CSPG(s) and KSPG(s) as barriers to retinal axon growth. However, analysis of CSPG and KSPG protein cores isolated from midline and lateral tectum has suggested that similar cores are present in both areas (D. Hoffman et al., Soc. Neurosci. Abstr. 1994). We have now examined GAG production: coronal slices through developing tectum were incubated for 30 minutes in sulfate-deficient medium, cultured for 5-20 hours in medium containing 250  $\mu$ Ci/ml <sup>35</sup>S-labelled sodium sulfate and 50  $\mu$ M net sulfate, then fixed. To identify the sulfated GAG(s) produced, tissue slices were digested with either chondroitinase ABC, keratanase, heparinase, or no enzyme. Exposure of undigested slices to film indicated a concentration of radioactivity at the midline, with very little isotope present in lateral tectum. Preliminary results show that in slices treated with chondroitinase ABC, the midline radioactivity concentration decreased substantially. These results suggest that while similar PG cores are present throughout the tectum, midline cells produce more sulfated GAG (particularly CS) than lateral cells.

## 513.6

**CELLULAR LOCALIZATION OF GUIDANCE COMPONENTS IN THE ESTABLISHMENT OF RETINOTECTAL TOPOGRAPHY** R.W. Davenport\*, E. Thies, P. G. Nelson

Laboratory of Developmental Neurobiology, NICHD, NIH, Bethesda, MD 20892.

Establishment of retinotectal topography involves guidance activities expressed on the surface of tectal cell membranes. To preserve and present as many cellular guidance components to elongating retinal fibers, we designed a 3-compartment chamber to delimit areas where cultured embryonic retinal and tectal cells encounter one another. Fibers from temporal retinae of the chick (E6-E9) stopped at the edge of posterior (caudal) tectal cells, whether dissociated from chick (E5-E11) or rodent (mouse, E14; rat E17-E18). Substantial invasion by nasal axons occurred in the same culture dish and both temporal and nasal fibers grew well into regions with either chick or rodent anterior (rostral) cells. Thus, dissociated cells yielded results consistent with previous results from tectal membrane fragments: components repulsive for temporal axon extension are expressed in posterior tectal cells of both chick and rodent.

Cellular localization of guidance cues can indicate sequential processes involved in establishment of topographic projections; therefore, retinal growth cone encounters with individual tectal cells were examined with time-lapse video microscopy. Posterior tectal neurons appear selectively repulsive for temporal retinal growth cones, causing growth cone collapse and retraction. On the contrary, radial glia from all regions of the tectum attenuated retinal axon extension, without inducing sudden retraction. Nasal growth cones turned and tracked along radial glia from their natural targets, potentially indicating a second set of specific guidance cues in this system. This work was performed while RWD held a National Research Council-NICHD/NIH Research Associateship.

## 513.8

**PATHWAYS FOLLOWED BY AXONS FROM RETINAE TRANSPLANTED TO CONGENITALLY BLIND MICE.** R.D. Lund<sup>1</sup> and M.H. Hankin<sup>2</sup>. <sup>1</sup>Institute of Ophthalmology, London EC1V 9EL U.K. and <sup>2</sup>Medical College of Ohio, Toledo, OH 43614.

In order to examine the role of pre-existing pathways in providing guidance cues for optic axons, we studied the course followed by axons originating from embryonic retinae implanted in newborn *ocular retardation (or/or)* mice in which the optic nerve fails to develop. Retinae placed on the ventrolateral brainstem (apposed to the site of the optic tract) send axons dorsolaterally to innervate the ipsilateral superior colliculus and several other subcortical visual centers. Not all axons, however, follow the normal direction of the retinofugal projection: some course ventrally to cross at the level of the suprachiasmatic nucleus (or less frequently caudal to the mammillary body) to attain the position of the contralateral optic tract and grow towards visual centers on the contralateral side. Furthermore, retinae implanted in the internal capsule emit axons that follow projection fibers through the striatum to innervate the lateral geniculate and other optic nuclei.

These results show that prior existence of an optic projection is not necessary for axons derived from ectopic retinae to attain visual nuclei. While there seems to be a preference for growth along the course of the optic tract and chiasm (perhaps following molecular cues or pre-existing pathways such as the TPOC), this is not the only route that optic axons can follow in the brain. The fact that axons grow in the "wrong" direction along the course of the optic tract may argue that the orientation of growth is not conferred by the substrates over which the axons grow. Another possibility, however, is that some axons are responding selectively to cues which specify the laterality of projection.

## 513.10

**EXPRESSION OF AGGREGAN, A CHONDROITIN SULFATE PROTEOGLYCAN, IN THE DEVELOPING CHICK VISUAL PATHWAY.** B.D. McAdams\*, M. Domowicz, N. Schwartz and S.C. McLoon. Univ. of Minnesota, Minneapolis, MN 55455 and Univ. of Chicago, Chicago, IL 60637.

The growth of retinal axons through the developing retinofugal pathway involves the interaction of growth cones with a diverse set of cell surface and extracellular matrix (ECM) molecules. One class of ECM molecules, chondroitin sulfate proteoglycans, was previously identified in the path of growing retinal axons. The present study characterized the expression pattern of a chondroitin sulfate proteoglycan, aggrecan, in the developing retinofugal system using the S103L antibody. This antibody recognizes a form of aggrecan expressed in neural tissue which is not susceptible to keratanase digestion and which reacts with antibodies to 6-sulfated and unsulfated chondroitin. Aggrecan immunoreactivity was first detected in the pathway on E6 and was associated with radially-oriented cells of the peripheral retina and optic nerve head. By E7, aggrecan was found in the optic nerve, chiasm, and tract. Initially (E6-7), the aggrecan of the developing tectum was associated with radially oriented cells. In tectum from E7 to E12, aggrecan appeared progressively in a rostral to caudal sequence in the layers of long projecting axons including the retinal axon layer. During the period of retinal axon synaptogenesis, arborization, and refinement (E12-E16), aggrecan also appeared in intermediate tectal layers where these processes occur. The distribution of aggrecan in the developing visual pathway suggests that it may have a role in retinal axon growth and synaptogenesis. To test this possibility, retinal axon growth was examined in a mutant, the nanomelic chick. Nanomelic embryos express a truncated form of aggrecan that is still immunoreactive but is not secreted. Aggrecan immunostaining in the pial endfeet of radial glia as well as in the endoplasmic reticulum of other cells in the optic pathway in nanomelic embryos indicates that these cells normally synthesize aggrecan. Alteration in the timing and pattern of retinal axon growth was not evident in these mutants, which suggests that extracellular aggrecan does not have an essential role in retinal axon extension or guidance; however, the timing and distribution of aggrecan suggests a role for this proteoglycan in other developmental processes.

## 513.11

GROWTH CONE DYNAMICS OF *IN VIVO* RETINAL PATHFINDING ERRORS INDUCED BY CHONDROITIN SULFATE

A. Walz\*, C.B. Chien, C.E. Holt. Dept. of Biology, UCSD, La Jolla, CA 92093.

The axons of developing retinal ganglion cells (RGC) navigate along a defined route to reach their target, the optic tectum. Our previous studies have shown that exogenous chondroitin sulfate (CS) has a striking effect on pathfinding: retinal axons disperse widely from their normal trajectory and extend aberrantly in the telencephalon and diencephalon. In this study, we investigated the dynamic behavior of RGC axons and their growth cones in response to the application and withdrawal of CS *in vivo*.

Live time-lapse video experiments of Dil labeled RGC axons were performed on exposed brain preparations to image extending axons during the period when they grow from the base of the optic tract to the tectum (stages 33/34 to 40). Although growth in 10 mg/ml CS was slowed compared to controls, growth cone morphology was not obviously changed as the growth cones exhibited numerous filopodia and active lamellipodia. Pathfinding errors occurred mainly by wide turns in inappropriate directions. These errors could be detected usually 1 to 2 hours after CS application and were more dramatic for newly ingrowing axons than for axons that had already grown a significant distance along the tract.

We have shown previously that if CS is applied for 10 hours and then washed out for 8 hours, optic projections appear normal. We are now using the live time lapse set-up to investigate how individual axons behave during recovery to see if misrouted axons can correct their routes or are retracted.

## 513.13

EXPRESSION OF PSA-NCAM IS NOT ESSENTIAL FOR THE DEVELOPMENT OF CONGRUENT BINOCULAR MAPS IN *XENOPUS* TECTUM. Diana K. Williams\* and Susan B. Udin. Dept. of Physiology, SUNY at Buffalo, Buffalo, N.Y. 14214.

Expression of the polysialylated form of neural cell adhesion molecule (PSA-NCAM) is enhanced during development and has been correlated with expression of plasticity. Studies from this laboratory have demonstrated high levels of PSA-NCAM expression during the critical period for the establishment of binocular maps in the optic tectum of *Xenopus*. As a test of whether PSA is necessary for the alignment of axonal projections from the ipsilateral eye with axonal projections from the contralateral eye, PSA was removed from the tectum by an enzyme, endoneuraminidase (endo N), that specifically cleaves polysialic acid at an  $\alpha$ -2,8 linkage. Slices of elvax polymer impregnated with endo N were placed on the surface of the tectum immediately after metamorphosis and left in place for 1-4 months. Removal of PSA in response to endo N treatment was confirmed with western blots and tecta probed with a monoclonal antibody to PSA.

The effects of PSA removal on the morphology of isthmotectal axons were assessed from tectal wholemounts of HRP-labeled isthmotectal axons. We found no qualitative differences in the extent of ingrowth and arborization of isthmotectal axons when comparing endo N-treated tecta with control tecta. In addition, electrophysiological mappings of the binocular visual field revealed no anomalies in the alignment of ipsilateral and contralateral axonal projections in endo N-treated tecta.

These results suggest that although PSA-NCAM expression in the tectum is correlated with periods of plasticity, the PSA moiety is not crucial to the development of congruent binocular maps in otherwise normal brains.

## EFFECTS OF NEUROTROPHINS ON LAMINA-SELECTIVE BEHAVIOR OF RETINAL GANGLION CELL NEURITES IN CULTURED OPTIC TECTUM. A. Inoue\* and J.R. Sanes. Department of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.

In many parts of the central nervous system, ingrowing axons enter, arborize, and synapse in specific laminae. To study such laminar specificity, we designed a co-culture system from chick embryos, in which retinal explants are laid atop tectal slices so that retinal ganglion cell (RGC) neurites have equal, unimpeded access to all tectal laminae. Laminar specificity of RGC outgrowth, branching and arborization is conserved in this system, even when the tectal slice is chemically fixed before RGCs are added (Yamagata and Sanes, Dev. 121:189, 1995). These results implicate membrane- or matrix-bound cues as regulators of arbor formation, but studies by others suggest that soluble factors are also involved. To learn how these two classes of factors interact, we asked whether neurotrophins affect RGC outgrowth or arborization on tectal sections. Addition of BDNF to serum-free medium nearly doubled the number of neurites that branched to leave their ingrowth layer (the stratum opticum, SO) and enter the retinorecipient layers (RR). BDNF also increased the number of neurites that formed secondary branches (rudimentary arbors) in the RR. Effects were detectable at 2ng/ml and nearly maximal at 10ng/ml. Stimulation of branching occurred in the absence of significant effects on the total number or maximal length of neurites. Moreover, neither the selectivity of neurite outgrowth on the SO, nor the restriction of branches and arbors to the RR was affected by neurotrophins. NT3 and NT4/5 had similar effects, but NGF was ineffective in this assay. These results favor the idea that soluble and cell surface factors collaborate to shape axonal arbors, with the former predominantly affecting their size and the latter their position. ## ENGRAILED MISEXPRESSION PERTURBS THE TOPOGRAPHIC TARGETING OF RETINAL AXONS IN THE CHICK OPTIC TECTUM. G.C. Friedman\* and D.D.M. O'Leary. The Salk Institute, La Jolla, CA.

The targeting of retinal axons to their topographically correct termination zone (TZ) in the optic tectum is hypothesized to be controlled by guidance molecules distributed in a graded or restricted manner. The expression of these molecules is probably regulated by transcription factors and growth factors. The *engrailed* homeobox transcription factors (*En-1* and *En-2*) are two likely candidates for this function. *En* is the earliest identified molecule to be expressed in a gradient in the chick mesencephalon. In chick/quail chimeras, graded *En* expression correlates with the targeting of retinal axons in the tectum; temporal axons terminate rostrally in low *En* regions and nasal axons terminate caudally in high *En* regions (Itasaki and Nakamura, '92).

To assess more directly the role of *En* in the development of the retinotectal map, we have constructed replication competent virus (RCAS) expressing *En-1* or *En-2*. The virus ( $10^8$ - $10^9$  iu/ml) was injected into the mesencephalic luminal space of st. 10 to 12 chick embryos. Infection of cells *in vitro* and *in vivo*, as determined with an antibody to the gag viral protein, correlated with expression of the exogenous *En* genes, as determined by immunohistochemistry and *in situ* hybridization. The retinotectal projection was later analyzed after the retinotopic map is normally established by focal injections of Dil in temporal or nasal retina. In virally infected tecta, nasal axons form abnormally large and diffuse TZs, and temporal axons appear to exhibit abnormal behaviors including a failure to end in the correct TZ either due to a slowing of their growth or to retraction. These results suggest that overexpression of *En* disrupts the development of the retinotopic map. (Supported by R01 EY07025 & F32 EY06550)

## 513.14

## RETINAL GANGLION CELL PROJECTIONS ARE MODIFIED BY TRANSPLANTATION OF BDNF PRODUCING CELLS TO THE SUPERIOR COLLICULUS OF DEVELOPING RATS. J. Atkinson, M.K. Panni\* and R.D. Lund. Institute of Ophthalmology, 11-43 Bath Street, London EC1V 9EL.

Developing retinal axons must follow a stereotypical course directing them to subcortical visual centres which on arrival they must recognise. Transplantation studies suggest that local substrates close to the surface of the brainstem and diffusible factors emanating from the target region are important. We have already shown that BDNF producing fibroblasts can guide transplanted embryonic retina in the cortex. In order to test for the role of diffusible factors in the developing retino-collicular pathway, we have transplanted BDNF producing fibroblasts to the tectum of neonatal rats which have / have not had an optic axotomy. After 3-4 weeks, the resulting retinal projections were visualised by injecting the retrograde tracer HRP intravitreally and the animals perfused and stained two days later with TMB.

In the developing retino-collicular pathway of the rat, each eye distributes its connections across the whole area of both ipsilateral and contralateral superior colliculus. Most of the ipsilateral projections retract during the first ten postnatal days to produce the normal adult pattern of connections. When one eye is removed at birth this retraction fails to occur and there remains a strong ipsilateral projection. Preliminary results suggest that when BDNF producing fibroblasts are transplanted to the contralateral tectum of an optic axotomised neonatal rat, the ipsilateral projection is reduced. These results suggest that BDNF may play an important role in guiding developing retinal axons.

We would like to thank MRC and Action Research for financial support and F.H. Gage for kindly providing the BDNF cell line.

## 513.16

## AN IN VITRO ASSAY FOR STUDYING INTERACTIONS OF RETINAL AXONS WITH RADIAL GLIA OF THE OPTIC CHIASM. D.P. Sullivan and J.S.H. Taylor\*. Dept. Human Anatomy, Oxford University, South Parks Rd, Oxford. OX1 3QX UK.

At the optic chiasm retinal ganglion cell axons from the temporal part of the retina turn into the ipsilateral optic tract, whilst axons arising in the nasal part of the retina cross to the contralateral tract. It is believed that the ipsilaterally projecting axons are prevented from crossing at the chiasm by an inhibitory signal on a sub-population of radial glia in the midline. Our interest is in characterising this differential behaviour of retinal axons with midline glial cells.

We have established an *in vitro* assay to examine the behaviour of temporo-ventral and dorso-nasal retinal axons co-cultured with ependymal glia isolated from the diencephalon.

Ependymal glia can be isolated from the ventral diencephalon of E17 mouse brains by trypsinisation for one hour followed by mechanical dissociation. These cells are then cultured on a laminin substrate, or on basal lamina isolated from E7 chick retina. After 3 days in culture the glial identity of these cells has been confirmed by positive staining with  $\alpha$ -GFAP and by negative staining with neuron associated antisera (HNK-1; 3A10; 2H3). The antibody SSEA-1 that is a marker for the midline glia of the ventral diencephalon, stains a sub-population of the GFAP positive cultured glial cells, indicating that we have successfully isolated the midline glia. Explants of E13 mouse retina are taken from either the dorso-nasal or temporo-ventral retina and also grown on E7 chick retinal basement membrane. Co-cultures of retina and isolated glia have been successfully established and interactions between retinal axons and these glia studied using time-lapse video microscopy. Our preliminary observations of interactions between retinal axons and midline glial cells will be presented.

This work is supported by grants from the MRC and Wellcome Trust

## 513.17

## AXONAL, GLIAL AND PROTEOGLYCAN INTERRELATIONSHIPS IN THE DEVELOPING OPTIC PATHWAY OF FETAL FERRETS.

**B.E. Reese\*** Neuroscience Research Institute and Department of Psychology, University of California at Santa Barbara, CA 93106  
This study has examined the relationship between radial glial fibers, optic axons, and the distribution of chondroitin sulfate proteoglycans in the developing optic pathway. Standard immunohistochemical procedures were used to define the distributions of the cytostructural protein, Vimentin (Vim), and of the glycosaminoglycan, chondroitin sulfate (CS), in fetal ferrets.

On E-24, when the first pioneering optic axons have entered the optic tract, Vim-positive glial fibers extend radially from the ventricular surface to form endfeet at the ventral, pial, surface, where CS is also present. As optic axonal invasion proceeds, Vim-positive radial glial fibers become diverted to course parallel to the pial surface within the dorsal, deeper, parts of the developing pathway (Reese et al., *J. Comp. Neurol.* 349, 303); coincident with these glial fibers, the deeper parts of the tract are immunoreactive for CS on E-27 through E-33, when the sub-pial parts are relatively immunonegative. Early removal of one eye on E-25, which produces an almost entirely crossed projection from the opposite retina (Chan and Guillery, *J. Neurosci.* 13, 5277), leads to the maintenance of an exclusively radial glial architecture in the ventral diencephalon contralateral to the removed eye on E-30, where the distribution of CS remains elevated at the pial surface.

These results show that the glial architecture of the developing optic pathway is sculpted by the neuronal architecture, and suggest that the CS-bearing proteoglycans within the pathway are produced by the radial glia. This changing glial and molecular architecture may in turn influence the growth of later-arriving optic axons, since these enter the superficial, CS-free, parts of the pathway only, establishing a chronotopic ordering of axonal arrival.

## 513.19

THE ADVANCE OF AXONS THROUGH THE OPTIC CHIASM OF FETAL MICE. **S.J. Tavendale\*** and **R.W. Guillery**. Dept. of Human Anatomy, Oxford University, South Parks Road, Oxford, UK, OX1 3QX.

Previous studies of the retinofugal fibres showed growth cones distributed throughout the optic nerve but accumulated next to the pia as the nerve joins the chiasm and in the tract (Guillery and Walsh, *J. Comp. Neurol.* 265, 203-217; Colello and Guillery, *J. Comp. Neurol.* 317, 357-378). In this region the glial environment also changes from an interfascicular to a radial organisation. Reese et al. (*J. Comp. Neurol.* 349, 303-324) showed that within the chiasm itself, some of this order is lost, with growth cones also lying in a deeper position.

Electron micrographs obtained from sections spaced at 20µm intervals, cut parallel to the fibres, and extending from the prechiasmatic nerve to the origin of the optic tract in E16 and E17 mouse embryos, show that as the fibres leave the optic nerve, the growth cones move towards the ventral surface and the finer, more mature fibres, cut longitudinally, accumulate deeper in a more or less continuous field. As the fibres are traced into the chiasm, groups of fine axons and wrists course ventrally and mingle with the growth cones. These form transversely cut groups of 100-200 fibres that cross perpendicular to similar, longitudinally cut groups nearer the midline. The longitudinally cut groups dominate in the dorsal part of the midline, the transverse groups dominate ventrally. Growth cones and wrists are present throughout the dorso-ventral extent of the chiasm, but tend to be more common in ventral regions.

We conclude that growing axons become arranged in a chronotopic order before they enter the chiasm, lose some or all of this order within the chiasm as they negotiate the specialised glia of the midline, and regain a chronotopic order in the tract. The crossing in well defined bundles suggests that axons from the same eye fasciculate preferentially with each other, and that the difference between the adult chiasm of birds and eutherian mammals may be only a minor developmental one.

## 513.18

RETINAL AXON DIVERGENCE: INHIBITORY CUES FROM THE CHIASM MIDLINE DETECTED IN COLLAGEN GEL COCULTURES. **L.-C. Wang\***, **R. Rachel**, **R.C. Marcus**, and **C.A. Mason**. Dept. Path., Cntr. Neurobiol. Behav., Columbia Univ., NY, NY 10032.

During divergence of retinal axons to both sides of the brain, both crossed and uncrossed fibers travel toward the midline, and either cross the midline or turn back to the ipsilateral optic tract, respectively (Godement et al., *J. Neurosci.* 14: 7024). Recent studies in vitro have demonstrated that cells of the chiasm midline elicit differential outgrowth of crossed and uncrossed fibers, in patterns that mimic avoidance or growth across the midline (Wang et al., submitted; Wang et al., *Soc. Neurosci. Abstr.* 20: 1081). To continue to investigate how retinal growth cones detect cues for divergence, we analyzed the retinal axon growth from ventral temporal retina (source of uncrossed fibers) and from dorso-temporal, dorso- and ventronasal retina, all sources of crossed fibers. An explant of retina was positioned 200-400 microns away from an explant of the optic chiasm midline, both taken from E15 mouse embryos, and embedded in bovine or rat tail collagen. After coculture for 48 hrs, there was little evidence for either a tropic or anti-tropic effect of the chiasm on retinal neurite outgrowth, using criteria from published studies. However, chiasm explants exerted a general growth-retarding effect on retinal axons manifested as fewer and shorter neurites extending from the side of the explant nearest the chiasm. These patterns were generally not seen when the retinal explant was positioned opposite a piece of control tissue. At present, we cannot distinguish to what extent the neurite growth response depends on contact with the chiasm, and to what extent factors are released and/or are diffusible, all currently under investigation. The growth reducing effects of the chiasmatic midline on retinal axon growth are consistent with our previous studies indicating that the chiasm contains inhibitory factors that contribute to retinal axon divergence. Supported by NS 27615 to CAM.

## 514.1

## GABA EXPRESSION IN DEVELOPING SPINAL CORD NEURONS IN RAT PRIMARY CELL CULTURES.

**Johan Christenson, Sofia Kelic and Fumi Aoki\***

Department of Neuroscience, Karolinska Institute, Stockholm, Sweden.

GABA is expressed in embryonic neurons from retina (Versaux-Boiteri et al., -94) and spinal cord (Behar et al., -93). Furthermore, GABA has been shown to be released from growth cones (Taylor et al., -90) as well as to excite hippocampal neurons in the first postnatal period (Cherubini et al., -90). For these reasons GABA has been proposed to have a trophic role in early neural development. In order to study GABA's role during neural differentiation and synaptogenesis we performed an immunohistochemical study on primary cell cultures in order to establish the basis for further electrophysiological studies of neural and synaptic functions during development.

Cell cultures were prepared from embryonic rat pups (stage E14). Analysis were performed on day 1, 3, 7, 14 and 28 in culture. GABA could be detected already at day 1. The intensity of immunoreactivity (IR) as measured with ELISA increased to reach a peak at day 7. From day 7-14 the immunoreactivity gradually decreased. Immunoreactivity to neurofilament did not decrease. GABA-IR was observed in the cytoplasm at day 1-3. At day 7 the GABA-IR was strongest in the periphery of the cellbodies and in the extending processes. These findings show that GABA is expressed in a similar pattern as in intact spinal cord and that primary cell cultures can be used for studies on GABA's role during development. Experiments are now performed in order to study the effects of GABA on transmitter expression and neuronal excitability.

## 514.2

GABAERGIC PROPERTIES OF HUMAN NEURONS DERIVED FROM THE TERATOCARCINOMA CELL LINE N-TERA 2 (NT2). **S.R. Kleppner**, **M.A. Dichter**, and **V.M.-Y. Lee**. Inst. of Neurol. Sci., and Depts. of Path and Neurol., Univ. of Penn. Sch. of Med., Philadelphia PA 19104

NT2 cells are capable of generating large numbers of pure post-mitotic neuronal cells (NT2N) upon treatment with retinoic acid. The NT2N cells have previously been transplanted into nude mouse brain, and can survive for extended periods of time. Preliminary immunocytochemical studies revealed that implanted NT2N cells express the GABA biosynthetic enzyme glutamic acid decarboxylase (GAD) and further immunostaining in vitro showed that NT2N cells express GABA and one isoform of GAD, GAD67 but not GAD65. Both GABA and GAD67 levels appear to increase with time in culture. Western blot analysis confirmed the GAD immunocytochemistry. In addition, biochemical assays indicate that the NT2N cells show sodium-dependent GABA uptake. NT2N cells immunostain for synaptic densities with synaptophysin, and electron micrographs indicate the presence of synapse-like structures. Functional GABA<sub>A</sub> receptors have been electrophysiologically demonstrated on these cells although no functional inhibitory synapses have yet been observed. As there are few GABAergic cell lines available, and NT2 is a human neuronal cell line, these results suggest that the NT2N cells can be useful for studying the development and differential regulation of GABA function and inhibitory synaptogenesis in a human neuronal system. These NT2N cells may also prove useful for transplantation in situations in which GABAergic activity is reduced or where locally increased inhibition is required to dampen excess excitability. Further characterization of the GABAergic properties of these cells by HPLC, GAD activity assays and autoradiography is in progress.

## 514.3

DISTINCT EXPRESSION PATTERNS OF GABA<sub>A</sub> RECEPTOR SUBUNITS IN EMBRYONIC AND EARLY POSTNATAL RAT CNS. F. Lajouli, W. Ma, A. Da Cunha<sup>1</sup>, W. Sieghart<sup>2</sup> and J.L. Barker Lab. Neurophysiology, NINDS; <sup>1</sup>Lab. Cell biology, NIMH, NIH, Bethesda, MD 20892; <sup>2</sup>Dept. Biochemical Psychiatry, University Clinic for Psychiatry, Vienna, Austria

Although there are quite a few reports of transcript expression for GABA<sub>A</sub> receptor subunits in the developing CNS, little is known about the pre- and postnatal expression of the subunit peptides. We examined the localization of GABA<sub>A</sub> receptor  $\alpha 1$ ,  $\alpha 2$ ,  $\alpha 3$ ,  $\beta 1$ ,  $\beta 3$ ,  $\gamma 1$  and  $\gamma 2$  subunits in the developing cortex, hippocampus, thalamus and hypothalamus using immunocytochemistry with polyclonal antibodies. The  $\beta 1$  and  $\beta 3$  subunit immunoreactivity was first detected at E12 in fibers and then at E13 in cell bodies within the mantle zone of the rhombencephalon. At E14, all tested subunits, except  $\alpha 1$ , were detectable in the brain. The  $\alpha 1$  began to appear in the cortical plate and hypothalamus at E17, and in the hippocampus and thalamus during the first week postnatal. The  $\alpha 1$  increased and expanded progressively throughout brain. The  $\alpha 2$ ,  $\alpha 3$  and  $\beta 3$  subunits showed intense immunostaining throughout the four regions studied at E20, but declined dramatically in subcortical regions after the first week postnatal. The  $\gamma 2$  subunit showed a relatively constant pattern of staining. The  $\beta 1$  and  $\gamma 1$  subunits were clearly detected in the cortical ventricular zone at E17 and E20. The results are generally consistent with our findings of subunit transcript expressions and show the early emergence and age- and region-dependent expressions of the GABA<sub>A</sub> receptor subunits during embryonic and early postnatal period coincide with neurogenesis and further neuronal differentiation, suggesting that the early detected GABA<sub>A</sub> receptor subunit peptides *in vivo* may play distinctive roles in the development of the CNS

## 514.5

CELLULAR DISTRIBUTION OF TWO GLUTAMIC ACID DECARBOXYLASE ISOFORMS IN EMBRYONIC RAT HIPPOCAMPAL CELL CULTURES.

I. Chaudieu, S. Feldblum, M. J. Drian and A. Privat\*. Unité INSERM 336, U.S.T.L., 34095 Montpellier cedex 05, France.

In order to estimate the synthesis of  $\gamma$ -aminobutyric acid (GABA) in cultured GABAergic neurons, we used immunocytochemistry to study the development of the two isoforms of glutamic acid decarboxylase (GAD), GAD65 and GAD67, in hippocampal cell cultures during 28 days *in vitro* (28 DIV). The cells with GABAergic phenotype were identified using antibodies recognizing either GAD65, GAD67 or GABA. Two technical approaches were used: the immunoperoxidase and the immunofluorescence methods for single and double-staining experiments, respectively. At 21 DIV, GAD67 and GAD65 antibodies similarly stained the cell bodies and neurites of GABAergic hippocampal neurons. However the density of GAD65-immunoreactive axon terminals (punctate structures) is higher than the density of GAD67-immunoreactive axon terminals. At this stage, double-staining procedures showed a perfect colocalization of GAD65-like immunoreactive (GAD65-LI) neurons with the GAD67-LI neurons. At 7 DIV, GAD65-LI neurons accounted for 39% of the number of GABAergic neurons while GAD67-LI neurons represents 100% of the GABAergic neurons. Between 7 DIV and 28 DIV the amount of GAD65-LI neurons regularly increased to stabilize at approximately 100% of the number of GABAergic neurons. During the same period of time, the number of GAD67-LI neurons was unchanged. These results show an earlier appearance of GAD67 compared to GAD65 in GABAergic neurons in hippocampal cell cultures. The possibility that different functions could be associated to the two isoforms of GAD as previously hypothesized by Esclapez and al. (J Neurosci., 1994, 14:1834) will be discussed in light of functional data. Supported by I.N.S.E.R.M.

GABA TRANSPORTER (GATs 1-4) mRNA EXPRESSION IN EMBRYONIC AND POSTNATAL MOUSE BRAIN. J.E. Evans\*, A. Frostholt and A. Rotter, Dept. of Pharmacology and the Neuroscience Program, The Ohio State University College of Medicine, Columbus, OH 43210.

Four GABA transporter mRNAs (GATs) were examined in developing mouse brain using *in situ* hybridization with radiolabeled oligonucleotide probes. GATs 1 and 4 were densely distributed throughout the developing central nervous system. They were present over proliferating and migrating cells in subventricular zones at embryonic day 13-14 and throughout prenatal development. During postnatal development, the two signals spread throughout the brain: in adults, the highest GAT 1 signal was present in the hippocampus, olfactory bulbs, and cerebellar cortex, and GAT 4 was distributed throughout the brain stem nuclei, olfactory bulbs, spinal cord, deep cerebellar nuclei and the cerebellar granule cell layer. Unlike GATs 1 and 4, the expression of GATs 2 and 3, was largely restricted to the pia-arachnoid membrane. The GAT 2 mRNA also was expressed in proliferating and migrating cerebellar granule cells. Although GAT 1 also was present over the pia-arachnoid, it was expressed at lower levels and in a more restricted pattern within the membrane. The different developmental profiles of the four transporters may be indicative of their neurochemical roles: Although GATs 1 and 4, may subserve the classical purpose of terminating GABA transmission in neurons and glia, GATs 1, 2 and 3, also may control GABA levels in CNS vasculature. Thus, GATs in the pia-arachnoid may help to regulate the amount of GABA available to developing neurons, such as cerebellar and olfactory granule cells, which migrate along the sub-pial surface during late embryonic and early postnatal development.

## 514.4

TRANSIENT APPEARANCE OF ALTERNATIVELY-SPliced GAD<sub>67</sub> TRANSCRIPTS IN EMBRYONIC CNS AND THEIR RE-EXPRESSION IN THE TRAUMATIZED ADULT RAT SPINAL CORD

W. Ma\*, L. Chang, L. Zhang and J.L. Barker Lab. of Neurophysiology, NINDS, NIH, Bethesda MD 20892

It is known that there are at least two forms of GAD proteins (GAD<sub>65</sub> and GAD<sub>67</sub>) encoded by distinct genes. Recent studies have shown that during embryogenesis the GAD<sub>67</sub> gene undergoes developmentally-regulated alternative splicing. The translation of the spliced GAD<sub>67</sub> mRNA (EP10) may result in enzymatically active truncated GAD proteins. However, the functional significance of the truncated GAD proteins is unknown. We examined the cellular expression of GAD family mRNAs in developing and adult rat CNS using *in situ* hybridization. GAD<sub>65</sub>, GAD<sub>67</sub> and EP10 mRNAs emerged concurrently at E12 in both the germinal and mantle zones of the ventral parts of the forebrain, rhombencephalon and cervical spinal cord. During the late embryonic/early postnatal period, GAD<sub>65</sub> and GAD<sub>67</sub> mRNAs increased in density and cellular distribution throughout the CNS, while EP10 began to disappear progressively in most brain regions and spinal cord. In adult brain, EP10 remained only in the olfactory bulb, dentate gyrus of hippocampus and cerebellum in which granular cell proliferation persists. After compression of the adult male rat spinal cord, EP10 was reinduced within 3 days and persisted up to 5 weeks when rats had recovered from complete paralysis of both hind limbs to ambulatory levels of activity. Transient abundance of EP10 during neurogenesis and its recapitulation in the crushed spinal cord strongly suggest roles for truncated GAD proteins in neuronal generation and regeneration.

## 514.6

NITRIC OXIDE 'PACES' GIANT GABAERGIC ACTIVITY IN THE DEVELOPING RAT HIPPOCAMPUS THROUGH A TRANSIENTLY EXPRESSED NEURONAL STRUCTURE. F. Strata\*, M. Alzori and M. Molnar, Biophys. Lab., Int. Sch. Adv. Studies (SISSA), Via Beirut 2-4, 34013 Trieste, Italy.

The diffusible messenger Nitric Oxide (NO) has been proposed to play a role in the mechanisms underlying synaptic plasticity, development and synchronization of neural activity (Gally et al. PNAS 87, 3547-3551, 1990). We used intracellular and patch-clamp techniques to study a possible role for NO in the origin of giant GABA responses occurring at 0.02-0.2 Hz during development of the rat hippocampus. Experiments were performed on hippocampal slices obtained from neonatal rats (P1-P8) with microelectrodes filled with 3M KCl and patch pipettes filled with 146 mM KCl. Application of the NO precursor L-Arginine (0.2-2 mM) or the NO donor 3-Morpholinosydnonimine hydrochloride (SIN-1, 0.2-2.0 mM) inhibited Giant Depolarizing Potentials (GDPs). In analogy with thalamus (Pape and Mager, Neuron 9, 441-448, 1992) we tested the hypothesis of a hyperpolarization-activated 'pacemaker' current controlled by NO. Voltage-clamp experiments on hilar interneurons patched under visual control revealed the presence of a cationic inward current which was reduced by 39±15% (mean±S.E.M.) in the presence of 0.1-1 mM L-Arginine and by 64±5% by 0.3 mM Cs<sup>+</sup>. The same concentration of Cs<sup>+</sup> reversibly inhibited GDPs suggesting a role for such inward current in their generation. Biocytin injected into one hilar neuron spread throughout several hilar interneurons revealing the existence of a neural structure which was absent in the adult. The present data suggest that NO 'paces' the giant GABAergic electrical activity through a transient neuronal meshwork expressing an unusually Cs<sup>+</sup> sensitive inward rectifier current.

## 514.8

BOTH GAD65 AND GAD67 ARE PRESENT DURING CHICK EMBRYONIC BRAIN DEVELOPMENT. M.-O. Mattsson\*, A.-K. Åhman and F. Wälgberg, Dept. of Cellular and Developmental Biology, Umeå University, S-901 87 Umeå, Sweden.

We have in the present study investigated some features of GABAergic development, notably some aspects of the GABA-generating enzyme GAD and its expression, in the prosencephalon and telencephalon of the chick embryo. HPLC analysis revealed that the GABA content in the developing telencephalon increased steadily from embryonic day 3 (E3) to E17, which is due to a 20-fold increase in GAD activity. RT-PCR revealed that both GAD65 and GAD67 mRNA is present from E3 onwards. The chick specific probes that we raised indicate one major GAD65 transcript at 5.1 kb and a minor transcript at 3.9 kb on Northern blots. GAD67 mRNA has one principal band at 5.6 kb with a less intense band at 3.9 kb. Both mRNAs exhibit an increased expression during development, with a peak at E17. Immunoblot analysis confirm the presence of both GAD65 and GAD67 proteins during the investigated period. Immunoprecipitation studies are in progress to elucidate the contribution of the respective protein to GAD activity. These results will be valuable for understanding the specific role of the two GAD proteins during brain development.

## 514.9

**MOLECULAR CLONING OF MOUSE GLUTAMIC ACID DECARBOXYLASE AND GABA RELEASE FROM cDNA-TRANSFECTED CELLS.** H. Asada\*, K. Maruyama, Y. Kawamura, and K. Obata. Lab. of Neurochemistry, Natl. Inst. for Physiol. Sci., Okazaki 444, Japan.

Glutamic acid decarboxylase (GAD) catalyzes the formation of GABA from glutamic acid. There are two isoforms, GAD65 and GAD67, which are encoded by two different genes. We screened mouse brain cDNA library with cDNA probes obtained by a reverse polymerase chain reaction to obtain a full length cDNA for mouse GAD65. Sequencing of the resulting clone included an open-reading frame which encoded a 585 amino acid polypeptide that showed 97.8% identity with GAD65 from rat brain and 95.2% with that from human brain. The full length mouse GAD65 cDNA was expressed transiently in fibroblast (COS cells) and stably in neuroblastoma (Neuro-2a cells) by cDNA transfection. Both of the engineered cells produced significant amount of GABA. The GABA release into the extracellular medium was detected from the engineered COS (347±48 pmol/10<sup>6</sup> cells in 30 min.) and Neuro-2a (113±25 pmol/10<sup>6</sup> cells in 30 min.) under resting conditions, whereas control cells showed below detectable level. The treatment of high potassium (100mM) stimulation dramatically increased GABA release from Neuro-2a (360±86 pmol/10<sup>6</sup> cells in 30 min.) stably expressing GAD65 but not from COS (313±78 pmol/10<sup>6</sup> cells in 30 min.). This suggests the presence of active releasing mechanism of GABA produced by exogenously expressed GAD in Neuro-2a cells.

## 514.11

**CLOSE RELATIONSHIP OF GABA TRANSPORTERS GAT1 AND GAT4 DURING THE LATE BRAIN EMBRYOGENESIS** E. Iursky, and N. Nelson\*. Roche Institute of Molecular Biology, Roche Research Center, Nutley NJ 07110

cDNA clones representing four pharmacologically distinct GABA-transporters (GAT1 to GAT4) were previously identified in mouse brain. Two of these GAT1 and GAT4, were found to be brain specific. We studied GAT1 and GAT4 in the developing rat brain using polyclonal antibodies prepared by recombinant fusion protein strategy. Patterns of the immunoreactivity for both transporters were very similar in the embryonic and early postnatal stages. However, while GAT1 immunoreactivity was detected in distinct patterns in gray matter and growing axons, GAT4 immunoreactivity was found in subset of radial glial cell fascicles frequently oriented perpendicularly to axons expressing GAT1. Our results demonstrate a close relationship of selective GAT4 expressing radial glial elements with GAT1 expressing axons and GAT1 positive areas during the of synaptogenesis. Because the beginning of the expression for both GAT1 and GAT4 correlate with the expression of adult GABA receptor, transporters may play role in the establishment of neuronal and glial components of the GABAergic inhibitory system in the brain.

## 514.13

**CORTICAL ASTROCYTES AFFECT THE DIFFERENTIATION OF CULTURED EMBRYONIC RAT SPINAL CORD NEURONS.** Y.-X. Li<sup>1</sup>, A.E. Schaffner<sup>1</sup>, M.K. Walton<sup>2</sup>, and J.L. Barker<sup>1</sup>. <sup>1</sup>LNP, NINDS, NIH, Bethesda, MD 20892; <sup>2</sup>DCDIA, OTHR, CBER, FDA, Rockville, MD 20852

Although astrocytes(A) have been suggested to be important during CNS development, their functional roles are still not clear. Here we compared the morphological and electrical properties of spinal cord neurons cultured on poly-D-lysine(PDL) with properties of neurons cultured on A of newborn rats. Neurons were dissociated from embryonic (E) ventral spinal cord at E15 and plated on PDL or A. Differences began to appear after several hours. The processes of neurons cultured on A were thicker and longer than those of neurons cultured on PDL. Patch clamp recordings revealed that co-cultured neurons expressed higher membrane capacitance and lower input resistance at -80mV than neurons on PDL. The amplitudes of voltage-gated Na<sup>+</sup> currents recorded in co-cultured neurons were much greater than those recorded in neurons cultured on PDL. The results from gramicidin perforated-patch recordings showed that GABA-induced responses changed from de- to hyperpolarizing after 4 days in co-culture while neurons on PDL took more than two weeks to complete this process. The initial appearance and the percentage of neurons exhibiting spontaneous GABA and

## 514.10

**GABA-ERGIC DEVELOPMENT IN THE EMBRYONIC CHICK FOREBRAIN.** P. Lundgren\*, M.-O. Mattsson†, L. Johansson§ and Å. Sellström§.

† Department of Cellular and Developmental Biology, Umeå University, S-901 87 Umeå, Sweden; §Division of Experimental Medicine, National Defence Research Establishment, S-901 82 Umeå, Sweden.

We have investigated the development of the GABAergic phenotype including GABA and GAD in embryonic chick telencephali from embryonic day (E) 6 to E17, by means of *in situ* hybridization and immunohistochemical techniques. The first appearance of both GAD65 and GAD67 mRNA:s was detected in the E8 telencephalon. A weak staining with sheep antisera recognizing both forms of GAD was seen in a few cells at this stage and some GABA positive cells were also visualized. At E11 a more distinct expression of both mRNA:s were detected concomitant with an increased amount of cells staining for GAD. A bulk of GABA positive cells were observed in the paraventricular zone at this stage. The maximum expression of GAD65 and GAD67 mRNA:s and the GAD protein was reached at E14. At E17 the levels of message and protein are approximately in the same range as at E11. Co-staining with antibodies against GABA and the neuronal marker neuron-specific enolase revealed that all neurons are not GABAergic. Immuno-electron microscopy indicated that as early as E11, cells positive for both GAD and GABA exhibit processes and synapses. During all the investigated stages the message for GAD65 is less abundant than GAD67 mRNA and the antibody staining is colocalized with GAD67 mRNA. This could indicate that GAD67 is responsible for the early GABA production during the chick forebrain development.

## 514.12

**CHARACTERIZATION OF GABA<sub>A</sub> RECEPTOR COMPLEX IN GROWTH CONES.** H. Fukui<sup>1,2</sup>, M. Igarashi<sup>1</sup>, Y. Komiva<sup>1</sup>. Departments of <sup>1</sup>Molecular and Cellular Neurobiology, and <sup>2</sup>Anesthesiology and Reanimatology, Gunma Univ. Sch. of Med., Maebashi, Gunma 371, Japan.

The nerve growth cone plays a role in neurite elongation, axonal pathfinding, and accurate synaptogenesis. Intercellular calcium concentration in the growth cone is believed important for regulation of these growth cone functions. Recent studies have indicated that activation of GABA<sub>A</sub> receptors depolarizes immature neuronal membranes through Ca<sup>2+</sup> mobilization. To study ontogeny of GABA<sub>A</sub> receptor complex in growth cones, we isolated growth cone membranes (GCM) and other membrane fractions from fetal and neonatal rat forebrain, and pharmacologically characterized GABA<sub>A</sub> and benzodiazepine binding sites using [<sup>3</sup>H]-muscimol and [<sup>3</sup>H]-diazepam. Specific binding sites for [<sup>3</sup>H]-muscimol were more enriched in GCM compared to those in other membranes. Bmax values of [<sup>3</sup>H]-muscimol in GCM increased from embryonic day 17 (0.372 pmol/mg protein) through postnatal day 2 (1.44 pmol/mg protein), and then gradually decreased without any significant changes of Kd values. Specific binding sites for [<sup>3</sup>H]-diazepam were also enriched in GCM, however, no significant changes either in Kd or in Bmax values were observed during early development. We measured [Ca<sup>2+</sup>]<sub>i</sub> of the isolated growth cones by fluorescence spectrometry using Fura2/AM. GABA (100 μM) increased [Ca<sup>2+</sup>]<sub>i</sub>, and addition of phenobarbital (100 μM) enhanced this increment from 209% to 336% of the control. Elevation of [Ca<sup>2+</sup>]<sub>i</sub> by GABA plus phenobarbital was blocked by verapamil or picrotoxin. We also measured [Cl]<sub>i</sub> by fluorescence spectrometry using MQAE. GABA(100 μM) changed [Cl]<sub>i</sub> value. This change was blocked by picrotoxin; verapamil showed no effect. Our results suggest that GABA<sub>A</sub> receptor complex is enriched in GCM and that activation of GABA<sub>A</sub> receptor causes elevation of [Ca<sup>2+</sup>]<sub>i</sub> partly through L-type Ca<sup>2+</sup> channels and Cl<sup>-</sup> channels associated with GABA<sub>A</sub> receptor complex, implying that GABA<sub>A</sub> receptor in the growth cone plays some role for axonal guidance.

## 514.14

**ASTROCYTES INFLUENCE NEURONAL DEVELOPMENT IN VITRO.** A.E. Schaffner\*, Y.-X. Li and J.L. Barker. Laboratory of Neurophysiology, NINDS, NIH, Bethesda, MD 20892.

Astrocytes direct the migration and maturation of neurons *in vivo*. We compared morphological and electrophysiological properties of spinal cord (SC) and hippocampal (HPC) neurons grown on a monolayer of cortical astrocytes (A) or poly-D-lysine (PL). Within a few days *in vitro* (div), neurons on A had longer and more numerous processes than cells on PL. Synaptophysin immunoreactivity (SI) was generally confined to neuronal somata on PL at 1 div whereas neurons on A had significant process staining. At 5 div on PL, SI appeared granular and a few neurons had SI in multiple processes; SI was punctate and confined to a single process (presumably the axon) in neurons on A. Neurons grown on A exhibited spontaneous synaptic activity at earlier time points than cells grown on PL. Over a two-week period, a change from exclusively GABA- to mainly glutamate-mediated activity occurred more rapidly and in more cells grown on A versus PL. Interestingly, the number of GABA immunoreactive neurons increases during this time and plateaus at a high level (≥60% for both SC and HPC). The high % of GABA<sup>+</sup> cells in the cultures correlates with a similar % of neurons exhibiting GABA-induced spontaneous currents. There was no significant difference between the % of GABA<sup>+</sup> SC neurons grown on PL or A after 4 div. There was a significantly higher % of GABA<sup>+</sup> HPC neurons on PL relative to those on A after 4 div. We plan to determine if the time course for glutamate immunoreactivity relates to the emergence of spontaneous glutamate activity.

## 514.15

RAPID ASTROGLIAL UP-REGULATION OF GABA ACTIVATED  $\text{Cl}^-$  CURRENT IN CULTURED RAT HIPPOCAMPAL NEURONS Q.Y. Liu\*, A.E. Schaffner, V. Dunlap and J.L. Barker Lab. of Neurophysiology, NINDS, NIH, Bethesda, MD 20892.

Hippocampal neurons from rat embryos at 18 days gestation were cultured in 35 mm dishes coated with poly-D-lysine and with or without a monolayer of confluent cortical astrocytes. The modulatory effects of astrocytes on the development of GABA-activated  $\text{Cl}^-$  current were studied in neurons cultured for hours-days with whole-cell and outside-out single-channel patch clamp techniques. Drugs were applied to the recorded neuron with a fast-perfusion system. The GABA-evoked current response in these cells involves  $\text{GABA}_A$  receptors since it reverses polarity at  $E_{\text{Cl}^-}$ , has single-channel conductance and kinetics characteristic of  $\text{GABA}_A$  receptor/ $\text{Cl}^-$  channels and is completely blocked by bicuculline. Neurons grown on astrocytes have significantly more surface membrane, as indicated by visual inspection and larger whole-cell capacitance values. They exhibit greater GABA-activated  $\text{Cl}^-$  current than neurons grown on poly-D-lysine, even when normalized using membrane capacitance. GABA-activated  $\text{Cl}^-$  currents evoked in neurons cultured on poly-D-lysine and astrocytes exhibit similar dose-response curves, block by bicuculline, picrotoxin and  $\text{Zn}^{2+}$  and enhancement by diazepam. No differences were detected in the properties of  $\text{Cl}^-$  single-channels activated by GABA. Taken together, we believe that the  $\text{GABA}_A$  receptor/ $\text{Cl}^-$  channels in neurons cultured on poly-D-lysine and astrocytes are composed of similar subunits and that there are more functional  $\text{GABA}_A$  receptors per unit membrane area in neurons cultured on astrocytes than those cultured on poly-D-lysine.

## NEUROTROPHIC FACTORS: RECEPTORS AND CELLULAR MECHANISMS III

## 515.1

EXPRESSION OF TRKB PROTEIN IN NEONATAL STATUS EPILEPTICUS. G.R. Jackson, R. Baldwin, J.L. Saver, and C.G. Wasterlain, Dept. of Neurology, UCLA Sch. of Med. and Sepulveda VA Med. Center, Los Angeles, CA 90024.

Increased hippocampal expression of BDNF and its high affinity receptor, TrkB, has been demonstrated in a number of seizure models. BDNF regulates the survival and differentiation of widespread neuronal populations in the developing CNS, but its physiologic role in mature neurons is less well characterized. Although induction of *trkB* mRNA in hippocampus has been demonstrated by *in situ* hybridization, it is unclear whether this induction is matched by expression of functional receptor protein. Immunoblotting with an affinity-purified, polyclonal antibody directed against a region adjacent to the C-terminal TrkB tyrosine kinase domain identifies a major band of Mr ~150,000. We have used this technique to examine the effects of status epilepticus on TrkB expression in postnatal d4 rat pups. Animals were exposed to flurothyl every 5 min for 2 hr, a paradigm with well-characterized epileptogenic effects (Wasterlain, Neurology 26: 975). By 2 hr following the conclusion of flurothyl-induced status epilepticus, TrkB immunoreactivity was increased significantly in hippocampal extracts but not those from control regions. In the developing hippocampus, seizure-induced perturbation of BDNF-receptor interactions may underlie mossy fiber sprouting, the formation of aberrant excitatory circuits, and the development of temporal lobe epilepsy.

## 515.3

FUNCTIONAL INTERACTION OF TRKA AND TRKC NEUROTROPHIC RECEPTORS DURING DEVELOPMENT OF POSTNATAL SYMPATHETIC NEURONS. D.J. Belliveau\*, J. Kohn, D. Kaplan and F.D. Miller, Centre for Neuronal Survival, Montreal Neurological Institute, Montreal, PQ, H3A 2B4, Canada

Our laboratory has been examining the biological role of high affinity neurotrophin receptors, trkA and trkC, during development of postnatal sympathetic neurons. We have previously shown that sympathetic neurons cultured in the presence of 10 ng/ml NGF for five days respond to the addition of NT-3 with profound neurite outgrowth but when switched to NT-3 alone, do not survive. In addition to Western blotting, we performed immunocytochemistry with a trkC specific antibody directed against the intracellular domain of the receptor, revealing the presence of trkC on NGF dependent sympathetic neurons. To determine the molecular mechanisms whereby activation of trkA leads to survival and growth whereas activation of trkC in the same cells leads to growth but not survival, we are biochemically characterizing the receptors and their downstream targets in sympathetic neurons. Analysis of the autophosphorylation profiles of trkA or trkC revealed that autophosphorylation on both receptors is increased for up to 48 hours in response to constant, long term exposure to the appropriate ligand. In contrast, over the same time period, no increase in trk receptor levels was detected, either in response to NGF or NT-3. Analysis of whole cell lysates for trk phosphorylation revealed that both NGF and NT-3 led to increased phosphorylation of a number of protein whose sizes corresponded to known trk substrates. At least one of these substrates is Shc as demonstrated by immunoprecipitation. We are currently characterizing the other downstream targets of trkA versus trkC, and determining whether these two tyrosine kinases converge and/or diverge biochemically and whether this correlates with biological responsiveness. This work was supported by MRC of Canada, Network for Centres of Excellence, and Genentech Inc.

## 515.2

TRKA IS DOWN-REGULATED DURING DEVELOPMENT IN A SUBSET OF SMALL DRG NEURONS. D.C. Molliver\* and W.D. Snider, Dept. Neurology, CNSI, Washington University, St. Louis, MO 63110.

In the adult rat approximately 45% of dorsal root ganglion (DRG) neurons express TrkA. However, about 80% of DRG neurons die in the *trkA*<sup>-/-</sup> mutant mouse. We recently determined that a subset of small DRG neurons, labeled by the isolectin BSI-B4 and by antibodies to the neurofilament protein  $\alpha$ -internexin and the delta isoform of protein kinase C, does not express TrkA in the adult rat, but fails to survive in the *trkA*<sup>-/-</sup> mutant mouse. These results suggest that a population of neurons lacking TrkA in adulthood may express TrkA during development and later down-regulate TrkA. In order to determine whether this is the case, we performed immuno-cytochemistry for TrkA in the mouse hindlimb region at multiple developmental stages. TrkA-immunoreactivity (TrkA-IR) was visible in many DRG neurons at embryonic day 11 (E11), the earliest stage examined. Cell counts taken from stained sections of E13, 15, 17 and postnatal day (PND) 1 animals indicated that approximately 80% of neurons in the DRG contain TrkA up to early postnatal life. However, TrkA-IR was seen in only 63% of DRG neurons in PND7 animals, and in 40% of neurons in adult mice. These results support the hypothesis that most DRG neurons express TrkA during development, but that a subset of these neurons down-regulates TrkA postnatally. Furthermore, BSI labeling was first visible in many small DRG neurons at P7, suggesting that the down-regulation of TrkA expression may be temporally associated with the appearance of a phenotypic marker for this group of neurons. Interestingly, the postnatal down-regulation of TrkA expression appears to coincide closely with the critical period described by Mendell et al. (see TINS 1993, 16:353-59) during which small-diameter DRG neurons show functional plasticity in response to changes in the availability of NGF.

## 515.4

CHARACTERIZATION OF TRKB-MEDIATED SIGNALING PATHWAYS IN RAT CEREBELLAR GRANULE NEURONS - DIFFERENTIAL DISPLAY OF BDNF INDUCED GENES Ute Zirrgebel\*<sup>1</sup>, Yoko Ohga<sup>1</sup>, Bruce Carter<sup>2</sup>, Benedikt Berninger<sup>1</sup>, Naoyuki Inagaki<sup>1</sup>, Hans Thoenen<sup>1</sup> & Dan Lindholm<sup>1</sup> 1. Dept. Neurochemistry 2. Dept. Neurobiochemistry Max Planck Institute for Psychiatry, Am Klopferspitz 18A D-82152 Martinsried/Munich FRG

TrkB mediates the responses to BDNF and NT-4. TrkB receptors are expressed in developing cerebellar granule neurons. BDNF and NT-4 increased the survival of these neurons and induced autophosphorylation of TrkB. This resulted in phosphorylation and binding of phospholipase C $\gamma$  (PLC- $\gamma$ ) and SHC to the activated TrkB receptors. In keeping with a signaling function of PLC- $\gamma$ , we observed an increase in phosphatidyl inositol turnover and an elevated  $[\text{Ca}^{2+}]_i$  level following BDNF treatment. We show PKC activation after BDNF or TPA treatment and the blocking of the survival promoting effects of BDNF and TPA with the PKC inhibitor calphostin C. BDNF activated the ras gene product and led to a long lasting activation of MAP-kinase. These results suggest that two different pathways, the ras and the PLC- $\gamma$  pathway, are activated by TrkB receptors in primary neurons and that PKC activation is involved in the survival promoting effect of BDNF.

To study which genes are affected a *Differential Display* approach was started to isolate BDNF regulated genes in this cell culture system. We compared BDNF treated neurons with control cells performing a RT-PCR screen. We are currently analysing cloned PCR fragments.

## 515.5

FUNCTIONAL ANALYSIS OF TRK NGF RECEPTOR DOMAINS AFTER TRANSFECTION IN PRIMARY NEURONAL CULTURES. L. Aibel, P. Perez, P. Coll, D. Martin-Zanca and M. V. Chao\*. Instituto de Microbiología Bioquímica, Universidad de Salamanca, Salamanca Spain and \*Department of Cell Biology and Anatomy, Cornell University Medical College, New York, New York USA 10021

The extracellular domain of *trk* neurotrophin receptors is characterized by several common structural features, including three leucine-rich repeats, two clusters of cysteine-rich domains and two immunoglobulin-like (IgG) motifs. The intracellular domain displays a consensus catalytic tyrosine kinase domain with a short insert and cytoplasmic tail. Previous studies of chimeric cDNAs between *trkA* and *trkB* indicated that the two IgG domains were essential for NGF binding (Perez et al. *MCN*, 1995). To evaluate further the interaction between NGF and the *trkA* receptor, primary cultures of E16 rat hippocampal neurons were transfected with a  $\beta$ -galactosidase reporter gene and expression plasmids containing chimeric *trkA/trkB* cDNAs and mutated *trkA* constructs using calcium phosphate precipitation. The expression of these constructs was monitored by immunocytochemical analysis, which detected a subpopulation of neurons that are  $\beta$ -galactosidase-positive and process bearing. The level of transfection was found to be 1-2% of the total number of cells. Nearly 30% of the cells transfected with the wild type *trkA* cDNA responded to NGF with increased neurite outgrowth after 2 days of treatment. Similar values were observed with *trkA/trkB* chimeric cDNAs which contained both IgG domains of *trkA*. Other transfected constructs which contained only the cysteine-rich domains and the leucine rich repeats of *trkA* in a *trkB* backbone did not respond to NGF. These results indicate that neurotrophin signal transduction can be assessed in transfected primary neuronal cultures.

## 515.7

ANTEROGRADE TRANSPORT AND AXO-DENDRITIC TRANSFER OF NEUROTROPHINS IN THE DEVELOPING VISUAL SYSTEM. C.S. von Bartheld\*, M.R. Byers\*, R. Williams\* and M. Bothwell\*. \*Dept. of Physiology & Biophysics and \*Anesthesiology, Univ. of Washington, Seattle, WA 98195 and \*Karolinska Institute, Stockholm, Sweden.

Afferent trophic signals support neuronal survival. To test if neurotrophins can be transported anterogradely from the cell body, the eyes of E15-16 chick embryos were injected with 10-100 ng radio-iodinated neurotrophins NGF, BDNF or NT-3. Axonal transport by retinal ganglion cells (RGC) to their target, the optic tectum, was quantified 20 hrs after injection by gamma-counting and emulsion autoradiography. NT-3 was transported at a higher level (100 pg) and more consistently than BDNF, NGF, or bFGF. Transport of NT-3 appears to be receptor-mediated as it was competed by excess cold NT-3. Transport is reduced by co-injection of K252a, completely abolished by monensin, but not affected by brefeldin A or tetrodotoxin (TTX). The effect of monensin may indicate that exogenous NT-3 joins the pathway of newly synthesized proteins in the Golgi complex of RGC. More than 95% of exogenous NT-3 arrives in the tectum intact as judged by laser densitometry of SDS gels. NT-3 mRNA is expressed in the retina at E16, and *trkC* mRNA is expressed by second-order visual neurons in the tectum. High-affinity binding of BDNF and NT-3 indicates that *trk B* and *C* protein is located predominantly in dendrites rather than neuronal cell bodies. Autoradiographic analysis of NT-3 distribution in the tectum at the ultrastructural level shows that more than 30% of the transported NT-3 is transferred to second-order visual neurons and is frequently associated with vesicles. Intraocular BDNF and NT-3 can rescue tectal neurons from cell death induced by co-injection of pertussis toxin, but not by TTX. We are now testing if TTX affects the release of NT-3 at the axon terminals.

Supported by NIH grants HD 29177 and NS 30305. The neurotrophins BDNF and NT-3 were kindly provided by Regeneron.

## 515.9

NEUROTROPHIN RECEPTORS ON CHICK SYMPATHETIC NEURONS DURING THE DEVELOPMENTAL SWITCH FROM NEUROTROPHIN-3 TO NERVE GROWTH FACTOR RESPONSIVENESS. G. Dechant\*, A. Schröpel and Y.-A. Barde. Dept. of Neurobiochemistry, MPI for Psychiatry, 82152 Martinsried, Germany

Many neuronal populations switch their neurotrophic factor requirements during the time when axons first encounter their target tissues. This change in growth factor dependency might be part of a more general developmental program regulating the transition from proliferative neuroblasts to terminally differentiated neurons. We studied this phenomenon using chick sympathetic neurons as a model system. Between embryonic days 7 and 11 (E7-E11), these neurons switch from neurotrophin-3 (NT-3) to nerve growth factor (NGF) dependency. We have investigated the *in vitro* survival effects of NT-3 and NGF and asked to which extent the expression of the neurotrophin receptors *trkA*, *trkB* and *p75* reflects the changes in the biological effects of their ligands. We found that both NGF and NT-3 given at 100 ng/ml concentration support the *in vitro* survival of sympathetic neurons at all stages, indicating the maintenance of signal transducing receptors for both factors during development. The dose-response curves for NGF and NT-3 were however strongly and inversely regulated. By *in situ* hybridization we detected transcripts of the *trkA* gene as early as E4.5 in primary sympathetic chains. At all stages studied, two *trkC* transcripts were detected, one of them encoding the full-length tyrosine kinase. *p75* mRNA was upregulated between E7 and E11. In cross-linking and binding experiments, we found that *p75* on sympathetic neurons binds NT-3 with a markedly higher affinity than on recombinant cell lines. The higher binding-affinity was accompanied by an increase in ligand specificity. We suggest that the ratio between the *p75* and *trk*-tyrosine kinases regulates the neuronal responsiveness to neurotrophins during development.

## 515.6

PLACODE-DERIVED NEURONS EXPRESS TRKA mRNA BUT DO NOT RESPOND TO NGF. R. Williams\*, A. Grapin, R. Rush, N. Le Douarin and T. Ebendal. Department of Developmental Biology, Medical Nobel Institute, CMB, S-171 77 Stockholm, SWEDEN

Although it is generally considered that only neurons which are derived from the neural crest are dependent on nerve growth factor, since some neurons derived from the placodes respond to nerve growth factor *in vitro*, we have re-investigated the possibility that some of these neurons are normally dependent on nerve growth factor for survival. *In situ* hybridization was performed on serial sections taken through all the cranial ganglia of normal birds at various ages of development. Within ganglia which are exclusively derived from the epibranchial placodes, there was a subpopulation of neurons which expressed *trkA* mRNA. Within the trigeminal ganglion, which is derived from both the neural crest and the ectodermal placodes, we performed extirpations of either the placodes, the neural crest or replaced the neural crest from a chick with a quail neural crest of equivalent developmental stage. From the results of these extirpation/replacement experiments, it is clear that trigeminal neurons derived from both sources are able to express mRNA for all the high-affinity neurotrophin receptors within this ganglion. It also suggests that a subpopulation of neurons derived from the epibranchial placodes are dependent on nerve growth factor during normal embryonic development. To test this idea, purified nerve growth factor was administered to chicks between embryonic days 6 and 10 inclusive. The chicks were sacrificed at E11, the heads sectioned coronally and cell numbers within the geniculate and petrosal ganglia were counted and compared to age-matched controls. There was no significant increase in the number of neurons within either ganglion. The presence of the *trkA* receptor within neurons which do not respond to NGF suggests a mechanism of heterodimerization with other high-affinity receptors that may modulate the response of the other receptors to their ligands.

## 515.8

RETINOIC ACID AND TRKA IN DEVELOPING CHICK SYMPATHETIC NEURONS. A. Schröpel, G. Dechant and Y.-A. Barde\*. Dept. of Neurobiochemistry, MPI for Psychiatry, 82152 Martinsried, Germany

Cultured chick E7 sympathetic neurons survive for four days independently of NGF (Ernsberger et al. 1989). These neurons will eventually all die, even in the presence of NGF. However, the addition of retinoic acid (RA) to the cultures allows the responsiveness to NGF to be induced, as well as the formation of high affinity NGF receptors on these neurons (Rodriguez-Tébar et al. 1991). In the present study, we asked whether retinoic acid affects the expression of the cognate NGF receptor *trkA* in cultured sympathetic neurons. Sympathetic neurons isolated from E6.5 chicken embryos were cultured in the presence of NGF and/or RA. RNA was isolated from these cultures and analysed for *trkA* expression. Surprisingly, we found that sympathetic neurons already express *trkA* at the start of the cultures, *in vitro* as well as *in vivo*, and found no up-regulation of *trkA* mRNA upon addition of RA. To rule out the possibility that the *trkA* gene is expressed, but the mRNA not translated, we performed cross-linking experiments with iodinated NGF. Following immunoprecipitation using an antiserum directed against the C-terminus of chick *trkA*, a radioactive band of the size expected for *trkA* cross-linked with NGF was readily detected, in cultures with and without RA. Surprisingly then, the induction of NGF survival and of high affinity NGF binding cannot be explained by the *de novo* appearance or up-regulation of *trkA*, and additional mechanisms are likely to be involved.

## 515.10

BSK RECEPTOR TYROSINE KINASE IS INVOLVED IN MULTIPLE ASPECTS OF MOUSE NERVOUS SYSTEM FUNCTION DURING EMBRYONIC DEVELOPMENT. J.-H. Zhang\* and R. Zhou. Lab. for Cancer Res., College of Pharmacy, Rutgers Univ., Piscataway, NJ 08855.

Growth factor receptors and their ligands are involved in various processes during embryonic development. We have isolated recently a novel growth factor receptor termed Bsk, for brain-specific kinase (independently isolated rat and chicken homologs are named *Ehk1* and *cek7* respectively). We showed that in adult mouse, Bsk expression was limited only to the brain. Specifically, expression was found mainly in neural structures such as the hippocampus, the piriform cortex, the amygdala, and the frontal cortex, which constitute the limbic system. Analysis of Bsk expression during embryonic development by *in situ* hybridization revealed that Bsk was widely transcribed in the presumptive nervous system, including the forebrain, the midbrain, the hindbrain and the spinal cord. However, Bsk expression in the midbrain, the hindbrain and the spinal cord gradually decreased, while in the forebrain increased over time. By the time of birth, the most prominent expression of Bsk was found only in the limbic system. This high level of expression in the limbic system persisted throughout the postnatal development and remained stable in adult up to 24 months. Furthermore, Bsk expression in the developing nervous system was confined to the postmitotic neurons, since little mRNA was detected in the germinal layer where mitotic neuronal precursors are located. Our analysis of Bsk expression during embryonic development indicated that Bsk may play at least two roles in the development of mouse nervous system. The first role is in the general aspect of neuronal differentiation, since Bsk expression was found in almost all regions of the early nervous system. This function is transient. The second role is in the maintenance and survival of the limbic neurons in late embryonic and postnatal period, as suggested by the long lasting expression of Bsk in the limbic system.

**DEVELOPMENTAL EXPRESSION OF PAN TRK AND P75 RECEPTORS IN THE HUMAN BRAIN.** E.-Y. Chen\*, E.J. Mufson, J.H. Kordower, Center for Brain Repair and Dept. of Neurological Sciences, Rush Presbyterian Med. Ctr., Chicago, IL 60612.

The prenatal development of the neurons immunoreactive to the tropomyosin-related kinase (trk) and p75 nerve growth factor receptors (p75NGFr) was examined in the brain of developing humans between 13 to 34 week of gestation. In the embryonic week 13, trk-immunoreactive (trk-IR) neurons were observed in the cortical subplate zone, basal forebrain, caudate nucleus, putamen, external segment of globus pallidus, subthalamic nucleus, and substantia nigra. p75NGFr-immunoreactive (p75NGFr-IR) neurons were observed at this time point in the same structures except the caudate and substantia nigra. This pattern remained unchanged at embryonic weeks 15-16 except for the addition of the trk-IR neurons in some thalamic nuclei and in the red nucleus. By embryonic week 18, the expression of trk protein was widely distributed and seen within the cortical subplate zone, entorhinal cortical plate, basal forebrain, caudate nucleus, putamen, external segment of globus pallidus, hippocampus, subthalamic nucleus, most thalamic nuclei, lateral mammillary nucleus, some brainstem nuclei, and dentate nucleus of cerebellum. p75NGFr-IR neurons were found in cortical subplate zone, basal forebrain, putamen, external segment of globus pallidus, hippocampus, subthalamic nucleus, some brainstem nuclei, dentate nucleus and cortex of cerebellum. This staining pattern remained virtually unchanged between embryonic weeks 19-22. From embryonic week 22, the distribution of trk-IR and p75NGFr-IR neurons changed gradually. At this time, neurons in some thalamic and brainstem nuclei became progressively immunonegative for trk. These data further demonstrate an important role of neurotrophins and their receptors in the development of multiple neuronal systems in the human brain. (Supported by NS25655 and a grant from the Alzheimer's Association).

**RETROGRADE AXONAL TRANSPORT OF GDNF IN THE ADULT CENTRAL NERVOUS SYSTEM.** A. Tomac, J. Widenfalk, E. Lindqvist, L.F.H. Linf, T. Kohnot, T. Ebendal, B.J. Hoffer, and L. Olson\*. Dept. of Neuroscience, Karolinska Institute, Stockholm, Sweden; †Synergen Inc., Boulder, CO; ‡Dept. of Developmental Neuroscience, Biomedical Center, Uppsala University, Uppsala, Sweden; and §Dept. of Pharmacology, University of Colorado, Denver, CO 80262.

Glial cell line-derived neurotrophic factor (GDNF) is a distant member of the TGF $\beta$  family with potent trophic effects on dopamine neurons and  $\alpha$ -motoneurons. In situ hybridization studies suggest that GDNF may have several additional roles in the central nervous system during development and possibly in the adult. We have made stereotaxic injections of either [ $^{125}$ I]-GDNF or non-labeled GDNF into areas known from in situ hybridization to express GDNF mRNA. To the extent that such expression represents target production of trophic support, the injected GDNF species should be expected to be transported retrogradely. Using autoradiography and GDNF immunohistochemistry to detect labeled and non-labeled GDNF respectively, we found efficient transport from striatum to substantia nigra nerve cell cell bodies. Specificity was demonstrated by the absence of transport of [ $^{125}$ I]-GDNF in the presence of a 100-fold higher concentration of non-labeled GDNF. Double labeling using TH and GDNF antibodies demonstrated punctate GDNF labeling of TH-positive dopamine neurons. Injections of GDNF into several other brain areas including thalamus and cerebellum also resulted in retrograde transport. Our results suggest that specific receptor-mediated uptake and transport of GDNF can occur in several different defined areas of the central nervous system, suggesting that GDNF may act as a target-derived trophic factor for several different neuronal populations in addition to nigral dopamine neurons and spinal  $\alpha$ -motoneurons.

515.12

**DEVELOPMENTAL ALTERATIONS IN THE EXPRESSION OF THE LOW-AFFINITY NEUROTROPHIN RECEPTOR (p75) IN THE TRIGEMINAL BRAINSTEM COMPLEX (TBC) IN RAT: TRANSIENT VIBRISSAE-RELATED PATTERNING IN NUCLEUS INTERPOLARIS.** D.P. Crockett\*, Ju Wang and M.D. Egger. Dept. Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Med. Sch., Piscataway, NJ 08854-5635.

p75, expressed by neural crest-derived primary sensory neurons, binds all members of the neurotrophin family. Previously, we reported that in adult rats there is a vibrissae-related pattern of p75 immunoreactivity (IR) in the principal nucleus (PrV) of the TBC. Dense p75 IR was also observed in the superficial laminae of nucleus caudalis (SpC) and in cell bodies of the trigeminal mesencephalic nucleus. Few p75-positive fibers were detectable in nucleus interpolaris (Spl) and oralis (SpO). We now report that, in marked contrast to the adult, during the first week postpartum, dense p75 IR is present throughout the entire TBC. Within PrV, a vibrissae-related pattern of p75 IR emerges at birth (PD0) and remains a permanent feature. Within Spl, during postnatal days 4 - 7, diffuse staining is replaced by a fully formed, vibrissae-related pattern, fading during the third postnatal week. In addition, during the second and third postnatal weeks, p75 IR in SpO and in the deeper laminae of SpC gradually declines. The relative restriction in the distribution of p75 IR in the adult TBC, compared to that in the perinatal period, suggests that p75 IR plays a significant role during periods of active synaptogenesis and pattern formation.

515.14

**Characterization of GDNF binding to putative GDNF receptor.** James Treanor, Franz Hefti, Mark Siegel\*, Klaus Beck, Department of Neuroscience, Department of P-K & Metabolism, Genentech, 460 Pt San Bruno Blvd S. San Francisco CA 94080

Glial-derived neurotrophic factor (GDNF) is a distantly related member of the transforming growth factor-beta (TGF- $\beta$ ) superfamily. GDNF has been reported to support the survival and differentiation of a number of diverse neuronal cell populations including peripheral autonomic ganglia and ventral mesencephalic neurons *in vitro*. The distribution of GDNF receptor binding in adult rat brain was analyzed by receptor binding and autoradiography. In rat brain sections, [ $^{125}$ I]-labeled GDNF bound specifically to the lateral septal nucleus. GDNF binding could be induced in the area of the substantia nigra by transection of the medial forebrain bundle which severs the nigrostriatal projection. Displaceable [ $^{125}$ I]-GDNF binding was analyzed in crude homogenate and purified membrane samples prepared from adult rat septum and cortex. Only crude homogenate and membrane preparations of septal tissue showed displaceable binding.

515.16

**RETROGRADE TRANSPORT STUDY OF GLIAL CELL LINE-DERIVED NEUROTROPHIC FACTOR (GDNF) IN ADULT RAT NERVOUS SYSTEM.** Q. Yan\*, C.R. Matheson Amgen, Inc, Amgen center, Thousand Oaks, CA 91320

GDNF, a member of TGF $\beta$  superfamily, has profound neurotrophic activity on substantia nigra dopaminergic neurons and spinal and brainstem motor neurons. GDNF mRNA is made by muscle and Schwann cells in the periphery and by type I astrocytes in the CNS. Thus GDNF could be available to and act on other neuronal populations in addition to dopamine and motor neurons. In this study we used retrograde transport followed by autoradiographic techniques to examine potential neuronal populations which can bind, internalize and retrogradely transport GDNF in a receptor-mediated fashion in adult rats. In the CNS, [ $^{125}$ I]-GDNF was transported by dopaminergic neurons in the substantia nigra and VTA after injection into the striatum or ICV. In addition, we found labeling of neurons in the central linear nucleus of raphe and dorsal nucleus of raphe after both intra-striatal and ICV injection. After injection into the superior colliculus, [ $^{125}$ I]-GDNF was transported to the contralateral but not ipsilateral retinal ganglion cells. In the periphery, GDNF was transported by spinal motor neurons and DRG neurons after intra sciatic nerve injection. GDNF was not transported by superior cervical ganglia neurons after injected into the anterior eye chamber. The results of this study suggest that GDNF may have neurotrophic activity on neuronal populations which are not previously known to be GDNF responsive.

## 515.17

CHARACTERIZATION OF GDNF RECEPTORS ON PRIMARY NEURONS AND CELL LINES. M. Trupp\* and C. E. Ibáñez. Laboratory of Molecular Neurobiology, MBB, Karolinska Institute, S-17177 Stockholm, Sweden.

Glial cell line-derived neurotrophic factor (GDNF) was initially purified based upon its ability to promote the specific uptake of dopamine by rat embryonic ventral midbrain primary cultures. We have previously shown that recombinant GDNF purified from Sf21 conditioned media promotes the survival of neurons from dissociated embryonic chicken sympathetic neurons. Initially, we have characterized high affinity binding sites on these neurons by displacement of  $^{125}$ I-GDNF with unlabeled ligand. We now apply Scatchard and Hill analyses to saturation binding data to describe cooperative binding of GDNF to these neurons. In addition, a potentiation of GDNF binding was observed after addition of transforming growth factor beta (TGF $\beta$ ), resulting in a nearly seven-fold increase in the affinity of the receptor complex.

Iodinated GDNF was chemically cross-linked to receptors on neurons and various cell lines and analyzed by SDS-PAGE. Multiple GDNF binding proteins were visualized, including receptors with apparent molecular weights equivalent to the Type I, II and III receptors previously described for other members of the TGF $\beta$  superfamily. Analysis of neuronal and non-neuronal cell lines for GDNF binding indicates the existence of multiple specific binding complexes--which appear in distinct ratios providing different binding affinities.

## 515.19

REK7, AN EPH-RELATED TYROSINE KINASE RECEPTOR, IS INVOLVED IN AXON BUNDLE FORMATION IN CO-CULTURES OF CORTICAL NEURONS WITH ASTROCYTES. I.W. Caras, J. Valverde, P. Moran, Ai Shih, F. Hefli\*, J.W. Winslow, Klaus D. Beck. Genentech, Inc., S. San Francisco, CA 94080

REK7 is an EPH-related tyrosine kinase receptor expressed exclusively in the nervous system, predominantly in hippocampus and cortex. A soluble REK7-IgG fusion protein prevents axon bundling in co-cultures of cortical neurons with astrocytes, a model of late stage nervous system development and differentiation. Immunofluorescent staining of the cultures with an anti-REK7 antibody indicates that REK7 is expressed on the axon fibers of the cortical neurons, consistent with a role in axon fasciculation. We show that a ligand for REK7, AL-1, is also expressed in these co-cultures, predominantly on the surface of the astrocytes. The finding that REK7 is efficiently activated by membrane-bound AL-1 but not by soluble AL-1 suggested that soluble AL-1 might act as an antagonist of axon fasciculation. We verified this by showing that soluble AL-1 blocks axon bundling. Our findings, together with the observation that both molecules are expressed in the brain, suggest a role for REK7 and AL-1 in the formation of neuronal pathways, a feature of nervous system development and regeneration.

## 515.18

PURIFICATION, CLONING AND RECEPTOR INTERACTIONS OF AL-1, A LIGAND FOR AN EPH-RELATED RECEPTOR (REK7) INVOLVED IN AXON FASCICULATION. J. W. Winslow\*, Ai Shih, P. Moran, J. Valverde, K. D. Beck, F. Hefli, I. W. Caras. Genentech, Inc. S. San Francisco, CA 94080

REK7, also known as EHK-1 and bsk, is an EPH-related tyrosine kinase receptor expressed predominantly in the hippocampus and cortex. Cell culture studies indicate that REK7 may play a role in axon fasciculation. To study the regulation of axonal fasciculation and other neuronal activities by this receptor system, we purified by affinity chromatography a novel REK7 ligand from BT20 human carcinoma cells, and cloned it from a human embryonic brain cDNA library. This ligand, termed AL-1, is a 28 K GPI-linked protein that shares 40-50% amino acid identity with the B61, ELF-1, and EHK-1L family of EPH receptor ligands. AL-1 binds to REK7 and related receptor SEK with affinities of 1 nM and 10 nM, respectively. Membrane attachment of AL-1 appears necessary for receptor activation since endogenous REK7 receptors of cultured rat cortical neurons are efficiently autophosphorylated by transfected cells expressing GPI-linked AL-1, but not by soluble AL-1. Autophosphorylation of cortical cell REK7 can be elicited by a soluble AL-1IgG fusion protein, suggesting that dimeric or oligomeric AL-1 may be necessary for REK7 kinase activation. These results suggest that AL-1 and REK7 may interact primarily as a consequence of cell-cell contact, and support our findings from cortical neuron-astrocyte co-cultures which implicate this ligand/receptor pair in a mechanism of axonal fasciculation.

## 515.20

Localization of Al-1, a Novel Membrane-Bound Ligand, in the Mammalian CNS; Comparison with Putative Receptors Rek and Tk-7. Mark Armanini\*, Paul Moran, Ingrid Caras, Siao Ping Tsai, Arnon Rosenthal, John Winslow, Ai Shih, and Heidi Phillips. Dept. of Neuroscience, Genentech Inc., 460 Point San Bruno Blvd., S.F., CA.

A new family of membrane-bound ligands has been described which bind receptors of the Eph family. Al-1, a recently purified ligand of this family, has been demonstrated to have possible activities on cultured mammalian neurons. Based on binding-affinity studies, Eph-receptors Rek and Tk-7 have been proposed as putative receptors for Al-1.

In-situ hybridization was performed in the rat CNS to compare the expression of Al-1 with its putative receptors Rek and Tk-7 in the adult animal, as well as to compare their developmental patterns in the E15 embryo and P1 rat. In the adult rat, Al-1 expression was observed primarily in the cortex, while Rek and Tk-7 exhibited much wider distribution including the cortex, hippocampus and thalamus. Al-1 expression was much greater and more extensive earlier in development in the CNS and was observed in numerous non-neuronal embryonic tissues.

In-situ hybridization studies were also performed to localize Al-1 in regions of human and monkey forebrain. Prominent expression was seen in the cortex with no detectable expression observed in the hippocampus.

These findings suggest a developmental role for Al-1, and the adult mammalian cortex as a potential site of interaction between Al-1 with its putative receptors.

## NEURONAL DEATH VI

## 516.1

PROGRAMMED CELL DEATH IN THE DROSOPHILA CNS  
MIDLINE. Lei Zhou, Hassan Hashimi, John R. Nambu\* Biology Department, University of Massachusetts at Amherst, Amherst, MA, 01003.

During nervous system development large numbers of cells die via programmed cell death (PCD). In *Drosophila*, embryonic cell death is blocked by chromosomal deletions of the *reaper* gene, which encodes a novel protein expressed in dying cells. We have utilized a *reaper* deficiency strain, Df(3R)H99, to show that PCD is required for normal embryonic neural development. H99 mutants exhibit neural hypertrophy and defects in the projection of the segmental and intersegmental nerves. By using several  $\beta$ -galactosidase reporter genes expressed in cells of the CNS midline, we further find that prominent PCD occurs in this specific CNS structure. Ectopic 'rescued' midline cells are detected in H99 mutants from stage 12 onward and many come to reside in aberrant locations atop the nerve cord. In wild type embryos, midline cell corpses are phagocytosed by migrating macrophages. A subset of macrophages migrate posteriorly along the CNS midline and are associated with midline pores that extend through the nerve cord. Macrophage precursor cells are still present in H99 mutants and exhibit widespread migration, however they do not adopt differentiated morphologies. The ventral midline may provide cues for the migration and accumulation of macrophages. Both *tinman* and *single-minded* mutants exhibit defects in midline differentiation and macrophage distribution.

## 516.2

THE SPACEHEADS ARE A CLASS OF MUTATIONS AFFECTING NEURAL SURVIVAL IN ZEBRAFISH *DANIO RERIO*. S. Abdellah\*, J. Malicki, S. Neuhauss, Z. Rangini, A. Schier, L. Solnica-Krezel, D.Y.B. Stainier, D. Stemple, F. Zwartkruis and W. Driever. Cardiovascular Research Center, Massachusetts General Hospital and Harvard Medical School, Charlestown, MA. 02129.

We have performed a saturation mutagenesis screen for embryonic lethal mutations in zebrafish *Danio rerio*. Among the more than 700 mutations isolated, we have identified a novel class of 50 zygotic recessive mutations with characteristically altered brain morphology.

At 28 hours of development, most of the *spacehead* mutations have enlarged tectal and fourth brain ventricles. Additionally, the telencephalon appears with an anterior extension, presumably an enlargement of the second brain ventricle.

A characteristic feature of the *spaceheads* is early neural degeneration. At least two of these mutations display a visible degeneration as early as the 7-8 somite stage. In order to assess whether the observed degenerations are tissue-specific, we have employed a detection assay for apoptotic cell death on zebrafish whole-mounts using the terminal deoxynucleotidyl transferase (TdT) system. All mutations tested at 28 hours of development depict increased levels of apoptotic cell death within the entire CNS, indicating that the molecular defect affects primarily the neuroectoderm.

Future analysis of the *spaceheads* might provide a powerful tool for studying the mechanisms that lead to apoptotic cell death within the neural cell lineages.

## 516.3

## APOPTOSIS IN THE DEVELOPING ZEBRAFISH

BRAIN. L.K.Cole\*, M.E. Murray, and L.S. Ross.  
Neurobiology Program, Dept. of Biological Sciences, Ohio  
University, Athens, OH 45701.

Cell death in the nervous system is a normal developmental event which may serve to eliminate neurons failing to establish functional synapses with their targets. The term **apoptosis** is used to refer to cell death which is genetically programmed, and which occurs due to *de novo* synthesis of cytotoxic proteins by either the doomed cell itself or by other cells. Apoptosis may be caused by the lack or removal of a trophic factor when a cell fails to make a synapse with a target cell. We explored the distribution of apoptotic cells in the embryonic zebrafish brain. The fragmented DNA of apoptotic cells was marked using the ApopTag™ kit (Oncor, Gaithersburg, MD). Surprisingly low numbers of apoptotic cells were observed in the developing zebrafish brain. The highest number of apoptotic cells was seen at 24 hours postfertilization, when labeled cells in the scattered throughout the extent of the brain. In 3-day old embryos, apoptosis was confined primarily to the telencephalon. By 4 days, apoptotic cells were reduced in the telencephalon and were increased in the otocyst. In embryos beyond 4 days, the few apoptotic cells were confined mainly to the telencephalon, although occasional cells were seen in the ventral hypothalamus. These results indicate that the highest levels of apoptosis occur early in development, during the period when the major axonal tracts are being established (Ross et al., 1992, J. Neurosci. 12:467-482). Supported by NSF IBN-9222896.

## 516.5

## DEVELOPMENT OF VIRAL VECTOR-MEDIATED GENE DELIVERY SYSTEMS FOR THE RETINA. D.B. Clarke\*, T.N. Jelsma, R. Dunn, R. Slack\*, F. Miller\*, G.M. Bray and A.J. Aguayo. The Montreal General Hospital Research Institute and The Montreal Neurological Institute, McGill University, Montréal.

The intraocular administration of BDNF or NT-4 exerts potent survival effects on injured adult rodent retinal ganglion cells (Mansour-Robaey et al., PNAS 1994; Clarke et al., Soc. Neurosci. Abst., 1993). We are now exploring viral vector technology to express these molecules in retinal neurons and glia.

*In vitro*, the ability of viral vectors to direct neurotrophin expression in neuronal cells was tested using trkB-expressing PC12 cells (provided by Dr. L. Greene) that differentiate in the presence of BDNF. Cells were infected with an HSV amplicon expressing BDNF and  $\beta$ -galactosidase. Four days after infection, most cells expressing  $\beta$ -galactosidase had a morphology characteristic of differentiated PC12 cells. Furthermore, many neighbouring cells also had a differentiated morphology, suggesting that BDNF expressed from the viral vector acted on neighbouring cells.

*In vivo* observations indicate that both HSV (provided by Dr. X.O. Breakefield) and adenovirus vector systems can be used to direct the expression of a marker gene,  $\beta$ -galactosidase, to cells of the mouse retina. Delivery of neurotrophin genes to the retina will determine whether this technology can be used effectively to provide trophic support to axotomized retinal neurons.

## 516.7

## CHARACTERIZATION OF NEURONAL PROPERTIES AFTER ADENOVIRUS-MEDIATED GENE TRANSFER. D.J. Crendon\*, R.M. Easton, M. Deshmukh, J.M. Nerbonne, and E.M. Johnson, Jr., Dept. of Pharm., Washington Univ. Med. Sch., St. Louis, MO 63110.

We are interested in using molecular genetic techniques for studying neuronal cell death and the mechanism of NGF signaling. Recombinant adenovirus (Ad) has shown promise as a gene transfer vector for neurons, but there is little information on whether or not Ad vectors affect normal cellular physiology which could confound experimental results. For example, we previously found that HSV amplicon vectors caused an intractable inhibition in neuronal protein synthesis. To assess the effects of Ad vectors, superior cervical ganglion (SCG) neurons were infected with a recombinant Ad vector expressing LacZ. An moi of 40 yielded > 95% x-gal positive cells, but maximal expression was only obtained after 48 hrs. Morphologically, infected neurons were indistinguishable from controls either when they were maintained in NGF or as they underwent apoptosis after NGF deprivation. Five days after infection, protein synthesis assays showed no difference in total protein synthesis between control and infected neurons. Electrical recordings 4 days after infection revealed normal resting membrane potentials, normal Na<sup>+</sup> and K<sup>+</sup> currents in voltage clamped cells; current injection generated action potentials including repetitive spikes during prolonged current application. These results suggest that Ad vectors can provide foreign gene expression in SCG neurons for at least five days without gross cellular perturbations.

## 516.4

## THROMBIN INHIBITS NEURITE OUTGROWTH AND INDUCES CELL DEATH IN CHICK SPINAL MOTONEURON CULTURES. V.L. Proctor\*, E.D. Lloyd, &amp; L.J. Houenou. Dept. of Neurobiology &amp; Anatomy, Bowman Gray Sch. of Med., Wake Forest Univ., Winston-Salem, NC 27157, USA.

Following injury to the blood-brain barrier, neurons may be exposed to high levels of thrombin, a serine protease. Recently, we have suggested that serine proteases, including thrombin, may be involved in neuronal cell death *in vivo* (Houenou et al PNAS 92:895,1995). Furthermore, thrombin has been shown to induce apoptosis of cultured neurons and astrocytes (Soc. Neurosci. Abst. 20: 641,1994). However, whether thrombin can directly affect the development and differentiation of motoneurons is still unknown. Here we examined the effects of thrombin and its specific inhibitor, hirudin, on highly enriched cultures of spinal cord motoneurons from 5 day old-chick embryos. The results show that (1-1,000nM) thrombin significantly decreased motoneuron survival in a dose dependent fashion, when cultures were examined 2-3 days following plating. In addition, thrombin decreased the number of neurites/neuron and the number of primary branches occurring on the longest neurite. Co-treatment with hirudin or skeletal muscle extract prevented the deleterious effects of thrombin. The molecular mechanisms underlying the effects of thrombin on motoneurons are currently being examined and will also be discussed. Taken together with the fact that neurons, including motoneurons, express thrombin receptors, these results suggest that thrombin may be an important regulator of neuronal cell survival and differentiation during development and in pathology.

## 516.6

## DEPLETION OF INTERNAL CALCIUM TRIGGERS APOPTOSIS: COMPARISON WITH PROGRAMMED CELL DEATH IN SYMPATHETIC NEURONS

K. Nakayama and T. Koike\*. Graduate Program in Biological Sciences, Hokkaido University, Faculty of Science, Sapporo 060, Japan.

We have previously shown that neuronal survival under depolarizing conditions with high K<sup>+</sup> correlates well with sustained levels of cytoplasmic free calcium ([Ca<sup>2+</sup>]<sub>i</sub>) in rat superior cervical ganglion (SCG) cells and cerebellar granule neurons. This suggests that neurotrophic factors are necessary for the survival of immature neurons which otherwise die due to failure to maintain the basal [Ca<sup>2+</sup>]<sub>i</sub>. In deed, the basal level of [Ca<sup>2+</sup>]<sub>i</sub> in SCG neurons was decreased after NGF withdrawal, and when SCG neurons were deprived of NGF in the presence of the Ca<sup>2+</sup> chelator, Quin-2 AM (10-50  $\mu$ M), they were resistant to NGF deprivation (only 16 (+3) % of the neurons died at 40 hrs after NGF withdrawal in the presence of Quin-2 AM, while more than 70% died in its absence). Moreover, when cytoplasmic free Ca<sup>2+</sup> was depleted by BAPTA AM ( $\geq 50$   $\mu$ M) or Quin-2 AM, these neurons underwent apoptosis in the presence of NGF as characterized by cellular shrinkage and chromatin condensation visualized with the bis-benzimidazole stain, Hoechst 33258. This toxicity occurred in a dose-dependent manner, and was less effective when BAPTA derivatives with higher K<sub>d</sub> values were employed. Immunohistochemical study using antibodies against c-fos indicated its activation during BAPTA-mediated cell death. It is thus likely that a decrease in [Ca<sup>2+</sup>]<sub>i</sub> of SCG cells after NGF withdrawal may be involved in the cell death cascade leading to c-fos activation followed by DNA fragmentation and eventually cell death.

## EFFECTS OF INHIBITION OF CYTOSOLIC OR MITOCHONDRIAL PROTEIN SYNTHESIS ON APOPTOSIS INDUCED BY DEAFFERENTATION IN THE DEVELOPING BRAIN.

C. A. Guimarães & R. Linden\* - Instituto de Biofísica Carlos Chagas Filho, UFRJ, Rio de Janeiro 21949-900, Brazil

The superior colliculus (SC) of the neonatal rat undergoes programmed cell death (PCD) with apoptotic morphology as part of its normal development. We tested inhibitors of protein synthesis for effects on naturally-occurring and deafferentation-induced PCD in the developing SC. Neonatal rats at postnatal day 2 were injected subcutaneously with either anisomycin (ANI) or chloramphenicol (CMP), respectively a cytosolic and a mitochondrial protein synthesis inhibitor, and the left eye was removed under deep anaesthesia to produce deafferentation of the SC. Unoperated control rats received either injections of inhibitors or were untouched. Three hours after eye removal, the pups were perfused with fixatives under deep anaesthesia. Frozen sections through the brain were stained with neutral red and analyzed by light microscopy. Following deafferentation, there was an increase in the rate of cell death in the SC compared with controls. Treatment with ANI abolished this effect, indicating that the deafferentation-induced apoptosis in the neonatal SC requires cytosolic protein synthesis. Following treatment with CMP the rate of apoptosis was increased both in control and in deafferented rats. This result suggests that CMP has a general effect on PCD. Contrary to previously published results from other laboratories, the effect of inhibiting mitochondrial protein synthesis is not specific to the mechanisms of cell death induced by deafferentation. CHANGES IN CYTOPLASMIC FREE CALCIUM DURING APOPTOSIS OF PC12 CELLS FOLLOWING REMOVAL OF SERUM. C.A. Messam and R.N. Pittman. Dept. of Pharmacology, Univ. of Pennsylvania School of Medicine, Philadelphia, PA 19104.

Apoptosis is an important process in normal cellular homeostasis and development as well as cellular pathology; however, biochemical pathways involved in apoptosis have not yet been fully elucidated. Increases in intracellular  $Ca^{2+}$  are thought to play an important role in excitotoxic death of neurons as well as in apoptosis of nonneuronal cells. In addition, elevated levels of cytoplasmic  $Ca^{2+}$  have been implicated in survival of growth factor-dependent neurons; however, little information is available on dynamic changes in cytoplasmic calcium during neuronal apoptosis induced by growth factor or serum removal. To investigate the role of calcium in apoptosis of undifferentiated PC12 cells following removal of serum, the fluorescent indicator dye, fluo-3, was used to obtain multiple measurements on individual cells during the course of apoptosis. Changes in cytoplasmic free  $Ca^{2+}$  were measured 4-10 hours, 24-28 hours, or 48-52 hours after removal of serum from cells. Calcium levels were maintained at fairly constant levels at early times after serum removal; however, during the active motile phase of apoptosis, cytoplasmic free  $Ca^{2+}$  increased 3-5 fold and was sustained at these elevated levels until cells died. The initial increase in  $Ca^{2+}$  correlated with the onset of the most dynamic phase of membrane blebbing which preceded death by 1-2 hrs. Ongoing experiments are designed to investigate the source of the calcium (intracellular or extracellular), its potential role in killing these cells, and the temporal relationship between increased intracellular free calcium and changes in chromatin morphology.

MODULATION OF CELL CYCLE COMPONENTS DURING NEURAL DIFFERENTIATION AND APOPTOSIS. J.A. Erhardt, A.J. DiBenedetto, and R.N. Pittman. Dept. of Pharmacology, Univ. of Pennsylvania School of Medicine, Philadelphia, PA 19104.

PC6-3 is a subline of PC12 cells that becomes irreversibly differentiated over a period of 7-10 days in the presence of NGF (Pittman et al., 1993; J. Neurosci. 13:3669-3680). Following removal of NGF, these cells undergo a transcription-dependent cell death similar to that seen in primary cultures of sympathetic neurons. The primary focus of this study is to investigate changes occurring during apoptosis, as well as to determine specific effects of NGF on cell cycle regulators so that a clearer interpretation of subsequent changes in these proteins during cell death can be obtained. To investigate the relationship between control of the cell cycle and apoptotic cell death, changes in cell cycle components are being characterized using immunoblot analysis. Cell cycle components being investigated include cyclins A, B, D, and E; cyclin dependent kinases (Cdk) 2, 4, 5 and p34 cdc2; retinoblastoma protein (Rb); and Cdk inhibitors, p21 and p27. Changes in these proteins are being characterized at various stages of differentiation (days 3, 5, 7 and 10 of NGF treatment) and during different phases of apoptosis (4, 12, and 24 hrs following removal of NGF). Several components of the cell cycle are modulated during the period when many cells become irreversibly differentiated, and a subset of these proteins change consistently during early stages of cell death following removal of NGF. In particular, significant changes are seen in p21 and cdk2 in populations of dying cells. Potential functional roles of cell cycle regulators in cell death are being investigated by generating lines of PC6-3 cells stably transfected with sense and antisense constructs of cell cycle components under control of an inducible tetracycline transactivator.

## 516.13

DEVELOPMENTAL PATTERN OF NITRIC OXIDE SYNTHASE EXPRESSION IN *XENOPUS* SPINAL CORD WITH AN EMPHASIS ON MOTONEURON APOPTOSIS. W. L. Muhlach and E. A. Ruebke. Dept. of Zoology, Southern Illinois University, Carbondale, IL 62901.

Nitric oxide (NO) may play a role in motoneuron development (Neurosci. 57:1, '93; Neurosci. 61:719, '94; Exp. Neurol. 120:153, '93). For example, inhibitors of nitric oxide synthase (NOS) attenuate expression of a marker of motoneuron maturation (CAT-301 antigen), neonatal rat motoneurons transiently express NOS, and adult motoneurons express NOS after ventral root avulsion. Two approaches were taken to address NO's involvement in motoneuron development. First, NADPH diaphorase activity was elucidated in the lumbosacral lateral motor column (LLMC) of *Xenopus laevis* developing tadpoles before, during and shortly after motoneuron apoptosis (stages 48-50, 51-53, 54-55 respectively), prior to metamorphosis (stages 56-59 and 60-63), and in adults. Second, the sciatic nerve of adult *Xenopus* frogs was axotomized near the spinal column. At intervals of 3, 7, 14, and 21 days post-operation, animals were euthanized, and the LLMC region of the spinal cord was processed for NADPH diaphorase activity. Tissues were fixed in 4% paraformaldehyde and 40um serial x-sections were cut on a cryostat. At no time during their ontogeny, including the period of apoptosis, did the motoneurons express NOS. This implies that NOS is not induced in apoptotic motoneurons as it is in response to motoneuron injury. At stages 56-59 two populations of NOS-positive neurons, interneurons and commissural neurons, appear to synapse with the maturing motoneurons. During stages 60-63 the NOS-positive commissural neurons disappeared while the interneurons remained into adulthood. This suggests that there are NO-dependent aspects of motoneuron afferent development, and that some NO influences on motoneurons remain in the adult. Sciatic nerve axotomy did not produce positive motoneurons. Trophic factor(s) from the Schwann cells, proximal to the lesion, may have suppressed NOS expression.

## 516.10

tau PROTEIN IS DEPHOSPHORYLATED BY AN OKADAIC ACID INHIBITABLE PHOSPHATASE DURING NEURAL APOPTOSIS. J.C. Mills and R.N. Pittman. \* Grad. Group in Cell Biology and Dept. of Pharmacology, U. of Penn. Sch. of Med., Philadelphia, PA 19104.

Neural apoptosis was studied in an NGF-differentiated subline of PC12 cells. Long-term timelapse videomicroscopy has revealed that apoptosis (after withdrawal of NGF) is characterized by early beading and thinning of neurites followed closely by zeiotic membrane blebbing of cell bodies. The breakdown of neurites suggested that destabilization of microtubules might be critical to the death process and led to the hypothesis that the microtubule-stabilizing protein tau might be modified in apoptotic cells. Since death in this system -- as in most types of apoptosis -- is asynchronous, an immunocytochemical approach was developed to study tau in actively dying/blebbing cells. Apoptotic cells were identified by Hoechst 33342-stained chromatin condensation, and the state of tau in these cells was assessed by indirect fluorescent immunostaining using monoclonal antibodies (tau1, recognizing a dephosphorylated epitope; PHF1, against a phosphorylated epitope; tau49, against all forms of tau). Using this method, a substantial increase in dephosphorylated tau was detected in actively dying cells (i.e. an increase in tau1 immunoreactivity, decrease in PHF1, and little change in tau49). Of cells with apoptotic nuclei, 90±6% had substantially increased tau1 immunoreactivity, while 75±4% of the cells with increased tau1 had apoptotic nuclei; thus, it is probable that, in most cells, tau becomes dephosphorylated slightly before or at the time of chromatin condensation and remains dephosphorylated until complete nuclear fragmentation. Okadaic acid (an inhibitor of protein phosphatases 2A and 1) inhibited tau dephosphorylation significantly within 1.5 hrs at a concentration of 80 nM and within 4.5 hrs at 20 nM, suggesting that PP2A (and/or PP1) is activated in apoptotic cells at the time of morphological changes.

## 516.12

Neuronal cell death of cultured cortical neurons through apoptosis after deprivation of survival support by astroglial cells Yukio Nishizawa\*, Makoto Ohgoh, Manami Kimura, and Kouichi Katayama, Eisai Tsukuba Research Laboratories, 5-1-3 Tokodai, Tsukuba, Ibaraki 300-26, Japan  
Peripheral neurons dependent on NGF die by apoptosis after NGF deprivation. Since the dependence of central neurons on particular neurotrophic factors has been established only for small population of neurons, a convenient in vitro method for assessing the programmed cell death has not been established. On the basis of the fact that cortical neurons survive in culture for many weeks in the presence of astroglial cells, we have established an in vitro cell death model. The neurons were cultured on a cover slip on top of astroglial confluent culture and were then separated from astroglial cells. The neurons in fresh medium died within four days after separation from glial cells. This type of cell death appeared to be mediated by apoptosis, since the nuclei of dying neurons contained fragmented DNA assessed by the TUNEL method. The cell death was significantly inhibited by neurotrophic factors, NT-3, NT-4, and BDNF, but not by NGF. These results suggest that cortical neurons died after separation from glial cells through apoptosis caused by deprivation of neurotrophic factors provided by the astroglial cells.

## 516.14

SERUM DEPRIVATION-INDUCED APOPTOSIS OF THE MOTOR NEURON-LIKE NSC34 CELL LINE IS ACCOMPANIED BY p53 ACCUMULATION AND CELL CYCLE ARREST. L.T. Shaw\*, M. Bachetti & N.R. Cashman. Neuroimmunology Unit, Montréal Neurological Institute, McGill University, Montréal, Canada H3A 2B4.

We have shown that serum deprivation-induced apoptosis in the nsc34 hybrid cell line is dependent upon early generation of reactive oxygen species (ros; Shaw et al., Soc Neurosci Abs 1994). We hypothesize that *ros-dependent DNA damage induces p53-dependent apoptosis* in nsc34 cells, and in human and transgenic mouse motor neurons subjected to oxidative stress by mutation of superoxide dismutase 1 (sod 1). We now report that: 1) similar to irradiated thymocytes, apoptosing nsc34 cells exhibit accumulation of p53 protein within hours of serum deprivation, suggesting that ros-induced DNA injury and p53 accumulation are early events in our model of apoptosis. 2) The proportion of G2-M cells in serum-deprived nsc34 cultures which are *spontaneously permeabilized* (apoptosing population) is significantly less than the proportion of G2-M cells which are *experimentally permeabilized* (whole population), suggesting that cells undergoing apoptosis are arrested at G1 phase, consistent with the cell cycle checkpoint regulatory activity of p53. Our data suggests that apoptosis in motor neuron-like nsc34 cells, and perhaps motor neurons *in vivo*, is dependent upon a cascade characterized by ros generation, DNA damage and p53 accumulation. By this reasoning, ros might be regarded as both an effector mechanism in apoptosis by DNA damage, and also as a signaling mechanism by ultimately triggering p53-induced genetically regulated cell death.

## 516.15

S-ADENOSYL-L-METHIONINE PREVENTS APOPTOTIC CELL DEATH OF CEREBELLAR GRANULE NEURONS. J. Harada, N. Yoshizawa, T. Oda\* and K. Matsuda. Neuroscience Research Laboratories, Sankyo Co., Ltd., Hiromachi 1-2-58, Shinagawa-ku, Tokyo 140, Japan.

Differentiated cerebellar granule cells require depolarizing concentrations of extracellular potassium for survival in culture. Apoptotic cell death of these neurons induced by lowering potassium concentration in the culture medium, provides a good model of neuronal apoptosis in the central nervous system. Using this model system, we found that S-adenosyl-L-methionine (SAME), a naturally occurring molecule which has been reported to be neuroprotective *in vivo*, prevented the apoptotic cell death of granule cells. SAME is known to be involved following three intracellular reactions: transmethylation, glutathione biosynthesis, and polyamine biosynthesis. S-adenosyl-L-homocysteine (SAH), a potent inhibitor of transmethylation reaction mediated by SAME, did not abolish protective effect of SAME but was protective by itself. Cysteine and N-acetyl cysteine, potential glutathione precursors, also protected granule cells from cell death with similar extent. In addition, spermine strongly protected granule cells from apoptosis. The effect of spermidine was weaker than that of spermine, and putrescine showed no protective effect.  $N^1,N^{12}$ -bis(ethyl)-spermine (BESPM), an inhibitor of SAME decarboxylase, did not inhibit protective effect of SAME. BESPM also protected granule cells, suggesting that it mimics the effect of spermine.

These results suggest that SAME prevents apoptotic neuronal cell death by facilitating the production of glutathione and/or polyamines but not transmethylation reactions.

## 516.17

3',5'-TRIODO-DL-THYROXINE (T<sub>3</sub>)-INDUCED MITOCHONDRIAL PROLIFERATION AUGMENTS GENERATION OF REACTIVE OXYGEN SPECIES (ROS) IN APOPTOSIS OF THE MOTOR NEURON-LIKE NSC34 CELL LINE. N.R. Cashman\*, M. Bachetti & J.T. Shaw. Neuroimmunology Unit, Montréal Neurological Institute, McGill University, Montréal, Canada H3A 2B4.

Using electron microscopy and flow cytometry with the oxidation-sensitive fluorochrome 5,6 carboxy-2',7'-dichlorofluorescein (DCFH), we have shown that serum deprivation-induced apoptosis in the NSC34 hybrid cell line is accompanied by mitochondrial swelling and an early "burst" of ROS (Shaw *et al.*, *Soc Neurosci Abs* 1992, 1994). To ask if mitochondrial injury is a cause or consequence of observed ROS generation, we now investigate the relationship between NSC34 mitochondrial content and the kinetics of DCFH fluorescence in cells treated with the respiration inhibitor rotenone (PMS), and cells induced to undergo apoptosis by serum deprivation. Mitochondrial proliferation was induced by addition of T<sub>3</sub> to culture media (5x and 10x basal concentration). Compared to NSC34 cells cultured in basal media, T<sub>3</sub>-treated NSC34 displayed a differentiation response characterized by profuse process extension, and had increased mitochondrial content detectable by both citrate synthase activity and Southern blotting. T<sub>3</sub>-treated cells exhibited: 1) increased duration and area of the time curve of DCFH fluorescence induced by PMS treatment, presumably due to increased mitochondria available for generation of superoxide; 2) increased duration and area of the time curve of DCFH fluorescence in serum-deprived cells, suggesting that mitochondria may be an important source of ROS in this model of apoptosis; and 3) paradoxically improved survival of serum-deprived cells. As we have previously found that the rate of cell death in serum-deprived NSC34 is directly dependent upon the duration and amplitude of the early ROS "burst", our data suggest that thyroid hormones may have two opposing activities in neuronal apoptosis: 1) and *apoptosis accelerating effect* secondary to increased cellular mitochondrial content (a potential source for superoxide or cytosolic release of sequestered Ca<sup>2+</sup>); and 2) an *apoptosis inhibiting effect* perhaps due to gene transcriptional activity of this steroid receptor superfamily, as suggested by induction of NSC34 process extension in serum-fed cells.

## 516.19

A COMPARISON OF THE EFFICACY OF THE HERPES SIMPLEX VIRUS VERSUS THE ADENOVIRUS AS VECTORS TO DELIVER FOREIGN GENES INTO PRIMARY SYMPATHETIC NEURONS. Ruth S. Slack, Daniel J. Belliveau, M. Rosenberg, E. Cooper\*, R. Dunn and F.D. Miller. Centre for Neuronal Survival, Montréal Neurological Institute, 3801 University, Montréal, Quebec H3A 2B4.

In order to develop a satisfactory strategy to manipulate the genome of terminally differentiated neurons, we are exploring the possibility of using the Herpes Simplex Virus and Adenovirus as potential vectors. Viruses carrying identical expression cassettes, including the CMV promoter driving  $\beta$ -galactosidase were compared. Infectivity studies indicate that Adenovirus is more efficient at infecting primary SCG neurons than Herpes Virus. With Adenovirus at an moi of 10, greater than 80% of sympathetic neurons expressed the reporter gene with no decrease in viability. In contrast infection with Herpes virus at an moi of 10 only 25 to 30% of cell expressed  $\beta$ -galactosidase. Determinations of long-term survival following viral infection also indicate that sympathetic neurons can tolerate significantly higher titres of Adenovirus in comparison to Herpes vectors. Six days following infection at 100 moi, greater than 70% of cells infected with adenovirus survive, while less than 20% of cells infected with herpes virus remain viable. Determination of cell viability and examination of electrophysiological properties following infection will reveal the utility of these viruses as vehicles for the introduction of foreign genes into primary sympathetic neurons.

## 516.16

INCIDENCE OF APOPTOTIC NUCLEAR PROFILES IN *XENOPUS LAEVIS* CENTRAL NERVOUS SYSTEM IS INCREASED BY EXOGENOUS THYROID HORMONE EXPOSURE. M.S. Beattie\*, J.C. Bresnahan, J.N. Masters, M.J. Crowe. Neuroscience Program, Dept. of Cell Biology, Neurobiology & Anatomy, OSU Biotechnology Center, The Ohio State University, Columbus OH 43210

Metamorphosis in *Xenopus laevis* (XL) is induced and sustained by thyroid hormone (TH) which controls morphogenesis, cell death (apoptosis), and structural reorganization in many organ systems, including the CNS. Endogenous TH appears in XL tadpoles at stage (st.) 54, but larval tissues can acquire sensitivity to exogenous TH as early as st. 44. The highest concentration of TH receptor mRNAs in st. 44 tadpoles is present in the brain, spinal cord and gut epithelia. We examined the effect of exogenous TH on the incidence of nuclear fragmentation in the CNS of XL tadpoles. St. 50 and 54-56 tadpoles were exposed for 0, 12, 24, 48 h and 5 days to 100 nM TH. Tadpoles were immersion-fixed, frozen, cryostat-sectioned (20  $\mu$ m) and incubated in the nuclear stain Hoechst 33342 (10  $\mu$ g/ml) for 1 h. Sections were examined for nuclei with the condensed chromatin that is a morphological characteristic of apoptosis. No apoptosis was detected in st. 50 tadpoles exposed to TH for 0, 12 or 24 h. After 48 h, a few apoptotic nuclei were seen in the brainstem and many were present in gut epithelia. After 5 days, extensive apoptosis was present throughout the spinal cord and brain. St. 54 tadpoles demonstrated few apoptotic nuclei in the CNS exposed for 0 or 12 h. A slight increase in the number of apoptotic nuclei was seen in the CNS of 24 h exposed tadpoles and numerous apoptotic profiles were detected in both brain and spinal cord by 48 h. St. 54 tadpoles exposed for longer times became ill and often did not survive past 4 days. Numerous apoptotic nuclei were observed as well as obvious tissue damage within the spinal cord. TH appears to induce precocious apoptosis which is detectable by bisbenzimidazole staining techniques. (Support: NS10165 & NS07291)

REACTIVE CELL TYPES AROUND STAB WOUNDS IN THE AVIAN BRAIN. A. D. Székely, G. Nagy, M. Kálmán, A. Csillag and G. E. Meredith\*. 1st Dept. of Anatomy, Semmelweis Univ. Med., H-1450 Budapest, Hungary and Dept. of Anatomy, Royal Coll. of Surgeons, Dublin, Ireland.

Macrophages/microglia and reactive astroglia are the classic participants of the post-lesion demarcation and removal of damaged tissue in the vertebrate CNS. We have previously described a type of reactive glia following lesions in the chicken but not in the rat brain (Székely *et al.*, *Anat. Anz. Suppl.* 170:689, 1991). These cells displayed spontaneous peroxidase positivity (SPP) with one or two thick or thin processes running to the lesion surface. For further characterization, adult zebra finches, two-day-old chicks and adult rats were anaesthetized, placed in a stereotaxic frame and the right hemisphere was lesioned with a sterile hypodermic needle. The survival times varied between 2 and 14 days, then the animals were perfused with 4% paraformaldehyde and coronal sections were cut from the region of the lesion. In zebra finches, SPP cells were discernible and they showed NADPH-diaphorase (ND) reactivity. Also macrophages/microglia, reactive for both ND and Griffonia lectin staining, appeared close to the lesion. In young chicks, SPP cells were found in the vicinity of the stab wound and they also formed clusters around small vessels in the periphery of the lesion. Some large, vacuolar, DAB positive cells were present in these cell groups, more frequently in young birds, surrounded by lightly stained cells with an arbor of fine processes.

In rats, no similar cellular response was detected following lesions, in particular, we did not observe SPP cells or perivascular reactive cell types, apart from the appearance of macrophages/microglia and the GFAP positive astroglial cordons demarcating the lesion.

FETAL SPINAL CORD TRANSPLANTS RESCUE AXOTOMIZED RUBROSPINAL NEURONS FROM RETROGRADE CELL DEATH IN ADULT RATS.

E. Mori,<sup>1,2</sup> M. Kowada,<sup>2</sup> T. Himes,<sup>1,3</sup> Y. Itoh,<sup>2</sup> T. Sugawara,<sup>2</sup> M. Murray,<sup>1</sup> and A. Tessier,<sup>1,3\*</sup>

<sup>1</sup>Dept. of Anat. and Neurobiol., Med. Coll. of Pennsylvania and Hahnemann Univ., Philadelphia, PA 19129, U.S.A., <sup>2</sup>Dept of Neurosurg., Akita Univ. Sch. of Med., Akita 010, Japan, <sup>3</sup>Philadelphia VA Hospital.

Intraspinal transplants of fetal spinal cord (FSC) may contribute to recovery after spinal cord injury by rescuing axotomized neurons otherwise destined to die. In this study we examined whether FSC transplants can rescue axotomized Red Nucleus (RN) neurons from retrograde cell death in adult rats. RN neurons of adult female Sprague-Dawley rats were labeled by retrograde transport of Fluorogold (FG) injected bilaterally into the spinal cord at C6; 1 week later, the right-sided RN neurons were axotomized by hemisection of the left side of the C3-4 spinal cord, and either a solid piece of embryonic day (E) 14 spinal cord or gelatin was introduced into the aspirated hemisection cavity. Additional rats underwent C3-4 spinal cord hemisection with transplantation of FSC or gelatin but did not receive FG injections. 2 and 4 months after transplantation RN neurons in the caudalmost 500  $\mu$ m of the nucleus were counted and the area of the neurons measured. At both times the number of RN neurons contralateral to the hemisection was reduced by 40% in rats that received gelatin; mean cell area was also reduced by 40%. RN cell loss was ~20% in rats receiving FSC transplants, but mean cell area was reduced by 40%. FSC transplants rescue about half of the axotomized RN neurons that would otherwise die after spinal cord injury in adults and were less effective than for Clarke's nucleus where rescue is virtually complete (Himes, *et al.*, *J. Comp. Neurol.* 339: 117-131, 1994). Supported by NS 24707 and VA Research Service.

**CHARACTERIZATION OF THE KITTEN RETINOGENICULATE PATHWAY GROWN IN COCULTURE.** R.S. Erzurumlu\*, F.-S. Lo & W. Guido. Dept. of Anatomy & Neuroscience Center, LSU Medical Center, New Orleans, LA 70112.

We established a coculture model for the developing cat retinogeniculate pathway in order to study the cellular mechanisms underlying axonal and dendritic remodeling and synapse consolidation. Retinal explants and thalamic slices containing LGN from 1-day old kittens were cocultured in serum free medium. After 3-8 days, some were fixed and the lipophilic tracer DiI was placed in retina or LGN. In others, we conducted intracellular recordings with biocytin filled electrodes to obtain information about the membrane properties and synaptic responses of LGN cells receiving input from ganglion cells. Retinal ganglion cells differentiated, and had exuberant processes, growth cones and dendritic spines. Retinal axons grew into thalamic slices, and formed elaborate arbors within LGN. DiI labeling from LGN showed mostly  $\alpha$ , a few  $\gamma$ , but not any  $\beta$  cells, innervated LGN explants. Intracellular recordings indicated that LGN cells responded to small depolarizing current pulses with a train of action potentials. These responses showed rapid frequency accommodation due to the activation of a fast voltage-sensitive ( $I_f$ ), and a slow voltage-insensitive ( $I_{fHP}$ ) afterhyperpolarization. When hyperpolarized, many morphologically identified X and Y cells responded with low threshold (LT)  $Ca^{2+}$  spikes. Cells with immature morphology showed little or no LT spiking. Many LGN cells were activated synaptically by electrical stimulation of the retinal explant. EPSPs had two overlapping components, an early-fast, DNQX-sensitive (non-NMDA), and a late-slow, AP5-sensitive one (NMDA). With  $V_m$  hyperpolarization, EPSPs activated LT spikes. In some cells, increasing stimulus intensity led to multiple EPSP complexes, suggesting they receive input from more than one ganglion cell. These observations indicate that many significant cellular events characteristic of the developing cat retinogeniculate pathway can be captured in vitro. *Support by NIH NS32195 (R.S.E.) and NSF 9396270 (W.G.).*

## 517.3

**SENSORY DEAFFERENTATION AFFECTS IMMEDIATE EARLY GENE (IEG) EXPRESSION IN THE VISUAL SYSTEM OF THE ADULT CAT.** L. Arckens<sup>1,2</sup>, W. Vanduffel<sup>2</sup>, F. Zhang<sup>3</sup>, U.T. Eysel<sup>3</sup>, J.-J. Vanderhaeghen<sup>3</sup>, G.A. Orban<sup>2</sup> and F. Vandesande<sup>1</sup>. <sup>1</sup>Lab. Neuroendocrin. & Immunol. Biotechnol., <sup>2</sup>Lab. Neuro- & Psychophysiol., K.U.Leuven, B-3000 Leuven, Belgium <sup>3</sup>Lab. Neuro-pathol., U.L.Bruxelles, B-1070 Bruxelles, Belgium <sup>4</sup>Dept. Neurophysiol., Ruhr-Universität Bochum, D-44780 Bochum, Germany

In order to investigate the molecular basis of topographical reorganization occurring in adult cat visual cortex after sensory deafferentation, we have used in situ hybridization to investigate the effect of binocular central retinal lesions on the expression of four IEGs in the dLGN and in twelve visual cortical areas of the adult cat. In the deafferented region of the dLGN the amount of c-jun mRNA increased markedly, but temporarily. In contrast, deafferentation of the central portion of the dLGN resulted in decreased c-fos and junB mRNA levels. These lesion-related effects remained constant for at least one month and the dimensions of the lesioned area matched perfectly the predictions based on the retinotopic map of Sanderson (1971). At the cortical level c-jun expression increased only in layer VI of area 17 subserving central vision and only temporarily. Zif-268, c-fos and junB expression decreased not only in the region of area 17 subserving central vision but also in the corresponding regions of areas 18, 19, 21a, 21b, 7, PMLS, PLLS, VLS and DLS. These results were confirmed in immunocytochemistry using antibodies against c-fos and zif-268. Shortly after the lesion the dimensions of the lesion-affected cortical loci were twice as large in visual degrees as expected from the retinotopic maps of Rosenquist (1985). The area of cortex affected decreased over time following the lesion and the rate of shrinkage differed among areas. Our results show that many cortical areas exhibit an IEG reaction to bilateral retinal lesions. As these reactive cortical regions are larger than the deafferented area, the IEG reaction might be related both to the topographical reorganization and to the deafferentation.

## 517.5

**THE DORSAL LATERAL GENICULATE NUCLEUS OF THE VERVET MONKEY AFTER NEONATAL HEMISPHERECTOMY.** 1,3D. Boire\*, 1,2M. Herbin, 3A. Pito and 1,2,3M. Pito. <sup>1</sup>Neuropsychol. Unit and <sup>2</sup>CRSN, Université de Montréal and <sup>3</sup>MNI, McGill University, Montreal, CAN.

The effect of early hemispherectomy on the organization of the dorsal lateral geniculate nucleus (dLGN) was studied in the Vervet monkey. Retinal projections to the dLGN was studied using anterograde transport of HRP. Blocks containing the dLGN were cut in coronal sections and HRP was visualized with TMB and AHM as chromogens. Adjacent series of sections were prepared for cytochrome oxidase (CO) and acetylcholinesterase (AChE) histochemistry and neuronal cell bodies were visualized with Nissl staining. Anterograde transport of HRP following intraocular injections produced terminal labelling in a clear laminar pattern in both dLGN. Dense labelling was seen in the magnocellular layers particularly in their more lateral portion in the dLGN ipsilateral to the lesion. CO histochemistry also revealed more intense staining in the lateral portion of the magnocellular layers. Slightly less dense labelling was observed throughout the appropriate parvocellular layers. The contralateral dLGN was comparable to that of intact animals. The dLGN ipsilateral to the hemispherectomy was reduced 70% in size, distorted in shape and exhibited severe gliosis. In Nissl stained sections, laminar organization was elusive since very few neurons survived. Typical large magnocellular elements were practically absent and very dispersed parvocellular elements were observed. These results are discussed in terms of residual vision in the blind field following hemispherectomy.

**MEMBRANE PROPERTIES AND SYNAPTIC RESPONSES OF MATURE, IMMATURE, AND VISUALLY-DEPRIVED LGN CELLS.** W. Guido\*, and F.-S. Lo. Anatomy & Neuroscience Center, LSU Medical Center New Orleans, LA 70112.

Little is known about the membrane properties of LGN cells during the development and refinement of connections in the cat retinogeniculate pathway. Indeed, the functional state of immature LGN cells and the role played by visual experience has yet to be explored. Using intracellular recordings with biocytin filled electrodes in a thalamic slice preparation, we examined the membrane properties and synaptic responses of LGN cells from normal and monocularly sutured (MS) cats, and 1-day old kittens. Mature X and Y cells had many voltage-dependent properties including a low threshold (LT)  $Ca^{2+}$  conductance ( $I_T$ ) which leads to  $Ca^{2+}$  spikes and burst firing, a transient  $K^+$  conductance ( $I_A$ ) which delays the onset of action potential firing, a  $K^+$  conductance ( $I_C$ ) which contributes to firing frequency, and a mixed cation conductance ( $I_h$ ) which prevents strong hyperpolarization. EPSPs evoked by stimulation of optic tract fibers also had an NMDA component. Cells from 1-day old kittens lacked  $I_A$  and  $I_h$ . Cells resembling X and Y types, had overshooting action potentials and a single component afterhyperpolarization,  $I_T$ . LT spikes were common and some showed bursting. Other, with highly immature morphology, had wider action potentials and showed rapid frequency accommodation due to the activation of  $I_f$  and the slower  $I_{fHP}$ . Highly immature cells lacked or had very small LT spikes and these failed to give rise to bursts. Cells from 1-day old kittens had EPSPs with NMDA and nonNMDA components. In some, increasing stimulus intensity led to multiple EPSP complexes, suggesting they receive input from more than one ganglion cell. Cells recorded from deprived layers of MS cats had properties that were either similar to normal or highly immature cells. Thus prior to eye opening, LGN cells possess many important properties needed to effectively integrate retinal signals. Visual experience also plays a vital role in determining the final modeling of normal morphology and membrane properties of LGN cells. *Support by NSF 9396270 to WG.*

## 517.4

**THE EFFECT OF RETINAL LESIONS ON GAP-43 EXPRESSION IN THE VISUAL SYSTEM OF ADULT CATS.** V. Backelant<sup>1,2\*</sup>, U.T. Eysel<sup>3</sup>, G.A. Orban<sup>2</sup> and F. Vandesande<sup>1</sup>. <sup>1</sup>Lab. of Neuroendocrinology and Immunological Biotechnology, Zoological Institute, Katholieke Universiteit Leuven, <sup>2</sup>Lab. of Neuro- & Psychophysiology, Katholieke Universiteit Leuven, B-3000 Leuven, Belgium; <sup>3</sup>Lab. of Neurophysiology, Ruhr-Universität Bochum, Germany.

We have studied synaptic plasticity in the adult cat visual system after induction of small binocular central retinal lesions. GAP-43 (growth-associated protein 43) was chosen as a molecular marker for synaptic reorganization. The cats were sacrificed between 1 week and 32 weeks after induction of the retinal lesions. By means of immunohistochemical stainings we observed an increase in GAP-43 expression in the lesion-affected part of the dLGN (dorsal lateral geniculate nucleus). This increase was visible from 3 weeks after lesioning on and persisted until 32 weeks after induction of the retinal lesions. The degeneration of the retinal ganglion cell axons provoked a proliferation of reactive astrocytes in the central part of the dLGN, as visualized by GFAP (glial fibrillary acidic protein) immunostaining, which slowly subsided between 20 and 32 weeks after lesioning. In area 17, we failed to find significant changes in GAP-43 expression, despite evidence that the observed topographical reorganizations (Kaas et al., 1990, Science, 248, 229-231; Gilbert and Wiesel, 1992, Nature, 356, 150-152), are paralleled by sprouting of the long-range horizontal cortical connections (Darian-Smith and Gilbert, 1994, Nature, 368, 737-740). In conclusion, while GAP-43 expression after retinal lesions occurs in parallel with some signs of reorganization in the deafferented dLGN (Eysel et al., 1980, Brain Res., 181, 285-300), it does not accompany the topographical reorganization observed in the visual cortex. This suggests that GAP-43 expression is not necessarily associated with the recovery of visually evoked activity. We are currently examining the origin of the increased GAP-43 expression in the dLGN.

## 517.6

**INTRINSIC AS WELL AS TARGET-DERIVED FACTORS ARE INVOLVED IN THE DETERMINATION OF ANOMALOUS RETINO-THALAMIC TERMINAL MORPHOLOGIES** Changying Ling\*, Sonal Jhaveri and Gerald E. Schneider; Dept. of Brain & Cognitive Sciences, M. I. T., Cambridge, MA 02139.

In normal adult hamsters, the lateral posterior nucleus of the thalamus (LP) receives a sparse retinal input with a special distribution pattern and distinct morphological features. Neonatal tectal lesions deprive retinal axons of their major target, and at the same time massively denervate the LP, resulting in a marked increase of retinal input to the LP (Schneider, '73). In order to determine whether the terminal morphology of retinothalamic axons is dictated by the retina or by its target substrate, we subjected newborn hamsters to surgical procedures known to produce a massive retinal projection to LP. Two months later, we examined the terminal fields and the morphological features of retinal axons in LP using cholera toxin subunit B (CT-B) as an anterograde tracer. Immunolocalization of the CT-B revealed the detailed morphology of retinal terminals. Our results show that the density and termination zones of abnormal retinal projections in LP vary depending on the time of the neonatal surgery, and on the degree of the denervation caused by the tectal lesion. Several different terminal types can be recognized. In the ventromedial LP, strings of varicosities which seem to envelop proximal dendrites are similar to terminals of the tecto-LP projection. By contrast, in the dorsolateral LP, terminals resemble Type R1 and Type R2 retinogeniculate terminals (Erzurumlu et al., '88). The segregation of distinct terminal types, resembling normal tectothalamic axons or normal retinogeniculate axons, indicates roles for both target derived and intrinsic factors in the specification of terminal morphology.

## 517.7

**EMERGENCE OF CLUSTERED EYE-SPECIFIC PATTERNS IN EXPERIMENTALLY INDUCED RETINAL PROJECTIONS TO THE FERRET AUDITORY THALAMUS.** A. Angelucci\*, K.S. Cramer and M. Sur. Department of Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139.

Neonatal deafferentation of the ferret medial geniculate nucleus (MGN) produces a pattern of clustered retinal projections scattered throughout the MGN in the adult. Clusters related to the ipsilateral eye are consistently adjacent to but spatially segregated from clusters related to the contralateral eye. By analogy with lamination in the LGN, clustering and/or eye-specific segregation in the novel projection may result from the refinement of an initially more diffuse projection. To investigate this possibility, we have examined the emergence of eye-specific clustering in the novel projection to the MGN.

Following MGN deafferentation at birth, ferret kits received injections of WGA-HRP in one eye and cholera toxin subunit B in the other eye one to two days before perfusion at 3, 5, 7, 14 and 27 days post-surgery (PS). The pattern of anterograde labeling in the MGN was examined. At PS3 and PS5, labeling was diffuse and extensive throughout the medio-lateral and antero-posterior extent of MGN. Retinal axons traversing the nucleus had few branches, and inputs from the two eyes overlapped extensively. At PS7, labeling was diffuse, although a tendency to cluster was apparent in some areas. At PS14, clusters were more apparent, but overlap between projections from the two eyes was still evident. By PS27, axonal arbors were more elaborate and nearly adult-like, and clusters had become denser and further restricted.

The progressive restriction of retinal projections into eye-specific clusters in the MGN occurs over the same time period as the formation of layers and sublayers in the normal LGN. These processes may thus share similar afferent-driven mechanisms. Clustering and eye-specific segregation in the MGN occur as retinal axon arbors aggregate into specific regions. This process may involve activity-dependent interactions between axons and their targets.

## 517.9

**APP AND APLP2 LOCALIZATION IN THE DEVELOPING HAMSTER PRIMARY VISUAL PATHWAY.** A.M. Confaloni\*, A.W. Lyckman, G. Thinakaran, S.S. Sisodia and K.L. Moya. INSERM U334 and CNRS URA 1285, SHFJ, CEA, 91401 Orsay, France; Ist. Sup. Sanità, 00161 Rome, Italy; Johns Hopkins Univ. Sch. Med., Neuropath. Lab., Baltimore, MD 21205.

The amyloid precursor protein (APP) and the amyloid precursor-like protein (APLP2) are related membrane proteins arising from a multigene family. Both of these proteins undergo considerable changes in their synthesis and axonal transport during development. Here we have used polyclonal antibodies specific for APP (CT-15) and APLP2 (D2-II, CT12) to study their localization in the developing hamster retinofugal pathway.

At P0 and P1, when many retinal axons are rapidly elongating, strong APP and APLP2 immunoreactivity (IR) was observed in the optic tract (OT) over the lateral geniculate nucleus (LGN). Within the LGN we observed numerous single fibers, some studded with varicosities. In the superior colliculus (SC), APP and APLP2 IR fiber bundles were present in the stratum opticum/superficial grey. No IR cell bodies were found in any brain region.

At P11 and P12, when retinal axons are arborizing and forming numerous synapses, the OT is lightly IR for APP and APLP2. In the LGN, the APLP2 antisera revealed clusters of IR puncta that appear to correspond to early retinal axon terminal types. In the P12 SC, APLP2 IR is concentrated in cell bodies while that of APP shows only a light neuropil presence.

In the adult LGN and SC, APP and APLP2 were concentrated in cell bodies while the neuropil was very light. The OT, was devoid of APP and APLP2 IR.

These results show that the developmental localization of APP and APLP2 follows a similar pattern. The proteins are distributed along fibers during rapid axon growth and then shift to the target neuropil during synapse formation. At later stages, APP and APLP2 concentrate in cell bodies. We suggest that APP and APLP2 may be subject to similar regulatory signals during development and in the adult.

**CULTURED RAT VISUAL SYSTEM ON PLANAR ELECTRODE ARRAYS.** A. Kawana\*, H. Kamioka, P.J. Charley, E. Maeda and Y. Jimbo. NTT Basic Research Laboratories, Atsugi-shi, Kanagawa, 243-01 Japan

Electrical activity plays a major role in sculpting synaptic circuits in the nervous system. One of the best studied examples of this is the mammalian visual system. However, the changes in electrical activity during the development of the visual system remain poorly understood, because of the difficulties in carrying out multisite, non-invasive recording. We have already described multisite, non-invasive monitoring of activity in organotypic cultures of the visual cortex using the planar electrode arrays (PEA) (P. Charley et al.; Soc. for Neurosci., 1994 543.9). Here we describe the organotypic coculture of the major regions of the rat visual system on the PEA and observations on the changes in electrical activity during the development and interconnection of the networks.

64 planar electrodes embedded in the culture substrate were separated into three blocks. The distance of each block was 600  $\mu$ m. Slices (300  $\mu$ m) of visual cortex (VC) and retina were isolated from P1 rat and lateral geniculate nucleus (LGN) from E18 rat, and fixed on individual block of the substrate using coagulated chicken plasma. One day after initiating the culture, neurites grew extensively from the VC, while neurites of LGN and retinal ganglion cells grew out from the tissue at three days *in vitro* (3 DIV). Electrical activity was observed from the VC and LGN simultaneously after 5 to 6 DIV. The VC showed usually synchronized burstings from 7DIV which were observed to propagate to the LGN area and sometimes to the retinal area. As very little delay of the onset of the bursting was observed at LGN and retina, the activity in these regions may come from neurites grown out from the cortex. Activity of the cortex could not be evoked by the stimulation of the LGN. After 14 DIV, the electrical activity of VC and LGN could be evoked by the electrical stimulation from LGN and VC, respectively. These results suggest that it takes around 14 days to form functional synaptic connections between VC and LGN. The retina formed hardly any functional synaptic connections with LGN. One reason for this may be that the preferred target of the ganglion cells of the rat is not the LGN, but the superior colliculus.

## 517.8

**INHIBITION OF NITRIC OXIDE SYNTHASE DOES NOT DISRUPT FORMATION OF EYE-SPECIFIC LAYERS IN THE FERRET LATERAL GENICULATE NUCLEUS.** K.S. Cramer\*, A. Angelucci, and M. Sur. Department of Brain & Cognitive Sciences, M.I.T., Cambridge, MA 02139.

Nitric oxide (NO) may act together with NMDA receptors in activity-dependent remodeling of connections. ON/OFF sublamination in the ferret lateral geniculate nucleus (LGN) requires NMDA receptor activation (Hahm et al., Nature 351:568-570, 1991) and nitric oxide (Cramer and Sur, Soc. Neurosci. Abst. 20:1470, 1994). Segregation of eye-specific layers during the first week appears not to require activation of postsynaptic NMDA receptors (Smetters et al., Brain Res. 658:168-178, 1994). NO synthase activity becomes detectable during the first postnatal week and peaks at about four postnatal weeks (Cramer et al., J. Comp. Neurol. 353:306-316, 1995). We have examined the role of NO in the formation of eye-specific layers.

Ferret kits received N $\omega$ -nitro-L-arginine (L-NOArg) or N $\omega$ -nitro-D-arginine methyl ester (D-NAME, an inactive isomer), 20 mg/kg/day i.p., from P1 to P7. This dose of L-NOArg has been shown to reduce NO synthase activity in the brain and inhibits ON/OFF sublamination. At P7, animals received injections of WGA-HRP in one eye and cholera toxin B subunit (CTB) in the other eye. The pattern of anterograde labeling in the LGN was assessed at P8. Eye-specific segregation in L-NOArg treated animals did not differ from that of normal or control animals. In all animals, the left and right LGN had a complementary pattern of labeling, and WGA-HRP and CTB staining were complementary within each brain. Treated animals did not differ from normal or control animals in weight gain or overall brain morphology.

These results suggest that NO is not involved in the segregation of eye-specific layers in the LGN. In ferret retinogeniculate development, NO appears to be required only when NO synthase levels are high in the LGN and when NMDA receptors are required for refinement of connections.

**NMDA RECEPTOR SUBTYPES IN THE FERRET LGN DURING DEVELOPMENT.** A.S. Ramoa\*, E. Jakoi, and C. Gerwin. Dept. of Anatomy and Dept. of Neurology, Medical College of Virginia, VCU, Richmond, VA 23298.

The adult form and function of the lateral geniculate nucleus (LGN) arise after extensive modifications in circuit organization that, in the ferret, occur during the first postnatal month. We have shown recently that NMDA receptor-mediated responses of the retinogeniculate pathway change markedly during this critical period of development (J. Neurosci. 14:2098, 1994). These changes, which may be important in facilitating retinogeniculate remodeling, could result from age-related modifications in the molecular composition of the NMDA receptor. To examine this possibility, synaptic transmission and expression of mRNA in LGN neurons were studied during the first 3 postnatal months. Whole-cell recordings in the LGN slice preparation revealed that the NMDA receptor-mediated response was enhanced during the first postnatal month in both retinogeniculate and corticogeniculate pathways. Kinetic properties of the NMDA response as well as the ratio of NMDA/non-NMDA receptor-mediated response changed. Additionally, application of ifenprodil, which binds with higher affinity to heteromeric NR1/NR2B receptors than to NR1/NR2A receptors (Neuron 10:267, 1993), blocked more potently the synaptically induced NMDA response in LGN neurons during the first postnatal month than later in life.

These findings suggest that the subunit composition of the NMDA receptor changes during development and subunit NR2B is predominant at early stages. To examine the mechanisms of these changes, complementary oligonucleotide probes to NR1A, NR2A and NR2B subunits were used in Northern analysis of total RNA isolated from the LGN. Ratios of mRNA encoding NR2A and NR2B subunits were unaltered during development, suggesting that the changes in NMDA receptor response properties reflect translational and/or post-translational regulatory mechanisms. ## 517.12

**SPATIO-TEMPORAL DISTRIBUTION OF EVOKED ACTIVITY ACROSS THALAMO-CORTICAL COCULTURES: A STUDY WITH VOLTAGE-SENSITIVE DYES.** H.-P. Höpp\*, C.G. Galizia and C.M. Müller. MPI für Entwicklungsbiologie, D-72076 Tübingen, Germany.

Cocultures of visual cortex with other brain tissues have demonstrated the formation of the specific afferent and efferent connections. Physiological measurements have confirmed the organotypic organization of the cocultures. We performed fast optical recordings to determine the spatio-temporal distribution of evoked activity in thalamo-cortical cultures.

Cortical slices of 350  $\mu$ m thickness were taken from 4-6 day old rat pups and thalamic explants from E16 rat embryos. One or two thalamic explants were positioned close to the pial and/or white matter side of a visual cortical slice. Cocultures were then maintained for 7 to 42 days on Millipore culture dishes at an air-medium interface. The cultures were stained for 10-30 min with 1-50  $\mu$ M RH795 or Di-4-ANEPPS (Molecular Probes Inc.). Recordings were carried out using a 464 element photodiode array read out at 630Hz. Electrical stimuli of 50-200  $\mu$ s duration and 50-700  $\mu$ A intensity were applied via tungsten stimulation electrodes into the thalamic explants.

The optical response typically encountered in the cortex was a depolarizing transient peaking 12-16 ms after the stimulus. Across cortical layers highest amplitudes and rates of rise for this component as well as shortest delay times were frequently found in layer 4. Double components with distinct "gaps" between their individual delay times were observed over the apportion zones of the cocultured explants. Applying a paired pulse paradigm, we found depression of the second response, possibly due to the presence of feed-forward inhibitory interactions as described *in vivo*. Suppression of the transients was also demonstrated by a similar paired pulse paradigm employing 2 spatially separate stimulation electrodes and was found to depend critically on the duration of the inter-stimulus interval (ISI) used: at ISI 55 ms suppression was minute, whereas at ISI 15 ms it was almost complete. At ISI 0 ms (= coincident stimuli) positive cooperativity was observed.

Our experiments confirm and extend previous findings on the layer-specific spatio-temporal dynamics of synaptic activity in thalamo-cortical cocultures.

## 518.1

DETECTION OF VISUAL PATTERNS IN DYSTROPHIC RCS RATS FOLLOWING RPE TRANSPLANTS. P.J. Coffey<sup>1</sup>, L. Hetherington<sup>1</sup>, S.J. Whitley<sup>2</sup>, T.M. Litchfield<sup>2</sup>, R.D. Lund<sup>2</sup> AND S.R. Wright<sup>1</sup>. <sup>1</sup>Dept of Psychology, University of Sheffield, England, <sup>2</sup>Institute of Ophthalmology, London, England, <sup>3</sup>Dept. of Biomedical Sciences, University of Sheffield, England.

Recent work has shown that injections of retinal pigment epithelial cells (RPE) into the sub-retinal space of the dystrophic Royal College of Surgeon (RCS) rat can reduce the degeneration of photoreceptors seen in these animals. The goal of this procedure was to stop degeneration and improve visual performance in these animals. To date, an improvement in ERG's following this procedure has been documented, but no behavioural study has shown an improvement in visual detection or acuity. In order to assess whether this would be an appropriate clinical procedure for the related human condition of age related macular degeneration (ARMD), we examined visual pattern detection in the RCS rat after implantation of RPE cells.

Three groups of animals were used in this experiment, dystrophic RCS rats with sub-retinal RPE injections, dystrophic RCS rats and non-dystrophic RCS rats. The response of these animals to visual change in the environment were recorded in open field arenas in which a part or all of the visual environment could be altered without changing non-visual features. The rats were placed into the arenas for 5mins on two separate occasions with an interval of 5mins between each placement. The animals locomotor activity was recorded on video tape. Non-dystrophic RCS rats increased their locomotor activity when there was a change in the whole visual environment, but specifically when the change was from an unpatterned to a patterned environment. Dystrophic RCS rats locomotor activity did not change when the visual environment was altered indicating that they did not detect (i.e. see) a change in the visual environment. However, dystrophic RCS rats, which had previously received a subretinal injection of RPE cells, locomotor activity did increase following a change in the visual environment.

These preliminary results suggest that injections of RPE cells into the eye of the dystrophic RCS rat can improve visual pattern detection.

## 518.3

EXPRESSION OF SYNAPTOPHYSIN IN THE RAT RETINA FOLLOWING VARIOUS TRANSPLANTATION STRATEGIES. A.A. Vugler<sup>1</sup>, P.J. Coffey<sup>1</sup>, R.D. Lund<sup>2</sup> AND M. Vidal-Sanz<sup>3</sup>. <sup>1</sup>Dept of Psychology, University of Sheffield, <sup>2</sup>Institute of Ophthalmology, England, <sup>3</sup>Dept of Ophthalmology, University of Murcia, Spain.

Previous studies using either fetal retinal transplants on to the tectum of neonates and adults, or peripheral nerve grafts to convey regenerating retinal axons to the tectum of adults, indicate that the newly established retino-tectal connections can mediate functional responses in the host animal. Thus, it is important to understand the degree to which normal synaptic organization within these retinas is preserved. In the present study we used synaptophysin immunohistochemistry (SYN-IR) to compare patterns of synaptic organization in normal retinas to: i) retinas implanted over the tectum of neonatal and adult rats, and; ii) retinas with axons regenerating along peripheral nerve grafts.

In normal retinas, synaptophysin immunoreactivity (SYN-IR) was detected in both the inner (IPL) and outer (OPL) plexiform layers. Also, there was a third lightly stained band of variable intensity at the level of the outer limiting membrane. This pattern of expression was consistent amongst all normal retinas examined. In retinas implanted into neonates, the pattern of SYN-IR was very similar to that of the normal retina with two distinct plexiform layers positively stained. However, there was no weakly stained third band and the OPL appeared more diffuse and less intensely stained than in normals. In retinas implanted into adult rats, the pattern of SYN-IR was not as distinct as that observed either in normal retinas or in retinas implanted into neonates. Specifically, the distinction between IPL and OPL was not as clear, although some laminar organization was preserved.

The differential expression described above may reflect a number of possibilities including the age of the host recipient, placement of transplant and the reduced connectivity to host visual systems seen in adult transplants. This reduced level of synaptic organization may reflect functional differences between adult and neonatal transplants. These preliminary results might suggest a possible reduction in the synaptic organisation of transplants when placed into an adult recipient.

## 518.5

#### DISTRIBUTION OF TRANSPLANT-DERIVED RETINAL GANGLION CELLS THAT PROJECT TO THE OLIVARY PRETECTAL NUCLEUS

M.J. Young<sup>\*</sup> and R.D. Lund. Neural Transplant Program, Dept. of Pathology, Institute of Ophthalmology, Bath Street, London, U.K.

The olivary pretectal nucleus (OPN) is known to be the retinorecipient nucleus responsible for the pupillary light reflex in rats. We have recently shown that the retinal projection to the OPN arises largely from the ventral hemiretina, or superior visual field (Young et al., Soc. Neurosci. Abstr., 20, 771:1994). Here we have examined the pattern of retinal ganglion cells that project to the OPN in animals that have received intracerebral embryonic retinal transplants at birth. It is known that these grafted retinas are capable of eliciting a graft-mediated pupillary light response in the host eye, but the pattern and type of retinal ganglion cells contributing to this response have not yet been examined.

Neonatal Lister-Hooded rats received an embryonic (E13) retina over the region of the superior colliculus. The right eye was removed at the time of transplantation, which favours the innervation of the left OPN by the grafted tissue. Animals were tested at 2-3 months of age for the presence of a graft-mediated pupillary light reflex, and the left OPN of responding animals (as well as that of non-responding control animals) labelled with crystals of Di-Asp. The animals were allowed to survive for 6-7 days, and were then perfused and the host retina whole-mounted, while the injection site and grafted retinae were cut at 100 µm on a vibratome. Both host and grafted retinae were then viewed under fluorescence illumination, and the distribution of labelled retinal ganglion cells determined. It was found that, like the normal two-eyed animals, the labelled cells in the host retinae were largely distributed in the ventral retina. The labelled cells in the grafted retinae, however, showed no obvious preference for location, and were found throughout the grafted retinae. The cell types of retinal ganglion cells projecting to the OPN were found to be similar in both host and transplanted retinae.

Supported by grants from the MRC and Action Research.

## 518.2

#### SYNAPTIC BASIS OF TRANSPLANT DRIVEN PUPILLARY LIGHT REFLEX IN NEONATAL AND ADULT HOSTS

D.D.A. Lawson and R.D. Lund<sup>\*</sup>. Neural Transplant Program, Institute of Ophthalmology, Bath Street, London EC1V 9EL, UK.

Intracerebral retinal transplants have been shown to drive a pupillary light reflex (PLR) in rats (Klassen and Lund, PNAS USA 84, 6958-60: 1987), although the synaptic basis of this behaviour has yet to be examined in detail. Here we investigated the ultrastructure of the olivary pretectal nucleus (OPN), believed to be the main relay station for optic afferents in the PLR, thus enabling a comparison of host visual circuitry with that established using retinal grafts.

Embryonic (E12-E14) retinae were transplanted over the midbrain of both neonatal (P1) and immunosuppressed adult rats, the hosts surviving for a minimum of 4 months or 10 weeks respectively. Secondary tracing techniques (anterograde degeneration and/or HRP) were then employed, and the OPN studied with EM in association with control material.

Both groups displayed a transplant-driven PLR, with neonatal recipients demonstrating graft terminals throughout the entire OPN. These were involved in the intricate synaptic configurations typical of the normal optic input to the nucleus, with some sharing the same dendrites as the host projection. Adult recipients, however, had only 1/10th the number of transplant terminals by comparison, with the majority of innervation concentrated in the myelinated nuclear periphery.

These results indicate that whilst the developing CNS can accommodate complex transplant integration, both an inhibitory environment and existing neural pathways may compromise adult plasticity. It is nevertheless evident that sufficient circuit reconstruction does occur to enable behavioural adaptation, possibly via a modification of normal adult synaptic patterns.

Supported by grants from Action Research and MRC, UK.

## 518.4

ORGANIZED EMBRYONIC RETINAL TRANSPLANTS TO NORMAL OR LIGHT-DAMAGED RATS. R.B. Aramant<sup>\*</sup> and M.J. Seiler. Dept. of Ophthalmology and Dept. of Anatomy, University of Louisville School of Medicine, Louisville, KY 40292.

The aim of this study was to replace degenerated photoreceptors with embryonic retinal transplants forming parallel retinal layers like a normal retina.

Pieces of embryonic rat (E16-20) retinae were transplanted into retinas of adult normal or light-damaged Long-Evans rats. Donor retinae were labelled before transplantation with bromo-deoxy uridine (BrdU). Retinas, embedded in gelatin or collagen; or unembedded, were cut into pieces (~0.7 mm wide, up to 2 mm length). They were delivered with minimal distortion to the subretinal space by a custom-made instrument with a flat plastic nozzle, using an anterior approach.

Transplants placed with the right polarity, with their photoreceptors towards the host RPE, developed parallel layers with photoreceptor inner and outer segments. Outer segments stained intensely for rhodopsin. However, transplants placed in a reversed orientation, with their photoreceptors facing the host photoreceptors or the inner nuclear layer, did not develop outer segments. BrdU-immunoreactive donor cells could be clearly distinguished from host cells. Transplants to light-damaged retina integrated well with no glial barriers between graft and host.

In conclusion, it is possible to transplant intact pieces of fragile embryonic retina which retain the capability to develop into organized layers. In transplants with parallel layers, differentiating photoreceptors need to be in contact with host RPE to develop outer segments.

Supported by NIH grant EY08519; The Kentucky Lions Eye Foundation; The Vitreoretinal Research Foundation, Louisville, KY; and an unrestricted grant from the Research To Prevent Blindness, Inc.

## 518.6

#### CO-TRANSPLANTATION OF RETINAL PHOTORECEPTORS AND PIGMENT EPITHELIUM IN RATS. B. Juliusson<sup>1</sup>, K. Arner<sup>1</sup>, T. van Veen<sup>2</sup> and B. Ehinger<sup>1\*</sup>.

<sup>1</sup>Dept. of Ophthalmology, Univ. of Lund, S-22185 Lund, Sweden and <sup>2</sup>Dept. of Zoology, Univ. of Göteborg, S-41390 Göteborg, Sweden.

The purpose of this investigation was to combine certain dissection and transplantation techniques in order to be able to transplant a coherent sheet of photoreceptor neurons and retinal pigment epithelium to a subretinal site in rats. Whole eyes from 8-14 days old pigmented rats were incubated in enzyme solution. After enzyme treatment, the retina with adhering pigment epithelium could be dissected. The retina was then embedded in gelatin and the inner retina was removed by vibratome sectioning. From the remaining photoreceptor layer and retinal pigment epithelium, small square pieces (1.5x1.5 mm) were cut out for transplantation. These pieces were inserted in a custom made transplant carrier consisting of a flattened plastic tube with a plastic piston inside. Adult Sprague-Dawley rats were used as recipients. The transplant carrier was inserted through a window in the cornea and advanced past the lens through the zonula fibers and into the subretinal space, where the transplant was delivered. After one week, the transplants were examined by hematoxylin and eosin staining and immunocytochemistry on histological sections. The transplanted retinal pigment epithelium could be seen as a layer of cells at an appropriate location. In transplants, in which the neural retina and pigment epithelium remained appositioned, proper layering was achieved and both rods, S-cones and M-cones were found.

This method provides the possibility to transplant a coherent sheet of both photoreceptor cells and retinal pigment epithelium to the subretinal site in rat eyes.

## 518.7

FETAL SPINAL CORD TRANSPLANTS MEDIATE ANATOMICAL REORGANIZATION AND SUPPORT THE DEVELOPMENT OF TARGET REACHING AND COORDINATED POSTURAL ADJUSTMENTS AFTER CERVICAL SPINAL CORD INJURY IN NEONATAL RATS. P.S. Diener\* and B.S. Bregman, Georgetown University School of Medicine, Washington, DC 20007.

After upper cervical spinal cord overhemisection (HX) in the neonatal rat, skilled reaching fails to develop and associated postural adjustments are disrupted. The aim of this study was to determine if, in the presence of a fetal spinal cord transplant (TP), skilled forelimb movements will develop. Three day old rats received cervical spinal cord HX (C3), with (N=13) or without (N=8) a transplant of fetal cervical spinal cord (E14); unoperated pups (N=9) served as controls. All pups were examined daily from birth to one month of age using a behavioral protocol assessing reflexes, postural and forelimb motor skills. They were also trained and tested as adults for 4 weeks to perform goal-directed reaching tasks. Rats in the HX group failed to develop target-reaching and displayed poor postural control during movement. The HX + TP group developed both target-reaching and associated compensatory postural adjustments. Neuroanatomical tracing techniques were used to examine the reorganization of CNS pathways that may influence these movements. Axotomized segmental (DRG), corticospinal and brainstem spinal neurons projected axons throughout the host cord and transplant, but were dramatically reduced in the HX groups' spinal cord tissue. FluoroGold injected into the lumbar cord (L2) retrogradely labeled long propriospinal neurons located throughout the cervical (C1-C4) and brachial cord (C5-T1) in the HX + TP group. Propriospinal neuronal label was diminished in most spinal cord sections throughout C3/C4 in the HX groups, but was preserved in segments C5-T1. Acquisition of target-reaching and accompanying postural adjustments require a precise integration of segmental, intersegmental and supraspinal input to propriospinal and motor neurons over many spinal cord levels. We suggest that the transplants support the re-establishment of a more balanced input onto both propriospinal and motor neurons, permitting the development of skilled forelimb activity after neonatal spinal cord injury. Supported by NIH NINDS NS27054.

FETAL SPINAL CORD TRANSPLANTS ENHANCE HINDLIMB BEHAVIORAL FUNCTION IN SPINALLY TRANSECTED ADULT RATS. Y. Itoh\*, T. Sugawara, F. Mori, and M. Kowada, Department of Neurosurgery, Akita University School of Medicine, Akita City, Akita 010, JAPAN

Spinal cord transection in adult mammals is not only associated with paraplegia but also produces various somatic and autonomic dysfunctions which can cause death within days after lesioning. Intraspinal transplantation of embryonic CNS tissues has been used in an attempt to induce regeneration after spinal cord injury. In this study we placed embryonic spinal cord transplants in spinally transected adult rats and evaluated the extent of locomotor recovery of the hindlimbs. After a T8 laminectomy, adult Sprague-Dawley rats received intraspinal transplants of E14 spinal cord into a complete transection cavity and the dural matter was then sutured with 10-0 nylon sutures. After surgery, manual bladder expression was performed every 12 hours. One month later hindlimb behaviors on the treadmill were videotaped, videocaptured into IBM-PC, and analyzed kinematically. Bladder control became automatic by 7 days in all rats. About 70% of the transplanted rats survived 1 month after surgery. There were neither spasms nor choreoathetoid movements. Although the hindlimbs of the animals generally did not contribute to overground treadmill locomotion, some responses such as hindlimb supporting reactions and bipedal treadmill locomotion were occasionally seen. Embryonic spinal cord transplants therefore enhance recovery of some hindlimb locomotor responses after midthoracic spinal cord transection in adult rats and may provide a milieu that promotes reconstruction of interrupted spinal cord circuits.

## 518.11

MORPHOLOGICAL ASSESSMENT OF LONG-TERM FETAL BASAL FOREBRAIN ALLOGRAFTS IN FORNIX TRANSECTED CEBUS MONKEYS. Y.-T. Liu, E.J. Cochran\*, J. Martel, and J.H. Kordower, Center for Brain Repair and Department of Neurological Sciences, Rush Presbyterian Medical Center, Chicago Ill. 60612.

Grafts of cholinergic basal forebrain neurons survive and reverse memory deficits observed in animal models of Alzheimer's Disease. The present study examined the morphological properties of fetal monkey basal forebrain autografts placed in the hippocampus of Cebus monkeys. Ten young adult Cebus monkeys underwent unilateral aspirative lesions of the fornix using an open microsurgical approach. Ten-fourteen days later, monkeys received implants of solid E25-70 day Cebus monkey basal forebrain into two sites in the hippocampus. The age of the donor was determined via ultrasound and the coordinates for the implant site was determined using MRI guidance. These monkeys were sacrificed between 6 and 18 months post-transplantation. Six additional young adult Cebus monkeys underwent fornix transections but did not receive implants and served as control. Control monkeys displayed comprehensive loss of cholinergic innervation as visualized by acetylcholinesterase (AChE) staining and immunohistochemical staining for ChAT and the low affinity p75NGF receptor. Surviving grafts were found in all monkeys up to 18 months following transplantation except for those monkeys receiving implants from fetuses >55 days in gestation. Grafts from younger fetuses provided extensive cholinergic reinnervation to the hippocampus and complete homotypic reinnervation was achieved in many cases. Interestingly, the expression of all markers of cholinergic basal forebrain neurons (ChAT, AChE, p75NGF, and galanin) was similar within each case, except for the monkey sacrificed 18 months post-transplantation. In this animal, numerous AChE, p75NGF and galanin-containing neurons were observed. However, there was a paucity of ChAT-ir cells. These data indicate that cholinergic basal forebrain neurons can survive long-term in the nonhuman primate brain. (Supported by NS25655)

TRANSPLANT-MEDIATED IMPROVEMENT OF LUMBAR REFLEX EXCITABILITY FOLLOWING CHRONIC THORACIC CONTUSION SPINAL CORD INJURY IN THE RAT. Thompson\* F.J., Parmer R., Mirandi T.P., Reier P.J. Depts of Neuroscience and Neurosurgery, University of Florida Brain Institute, Gainesville, Florida 32610.

The aim of this study was to test the capacity of fetal spinal cord (FSC) transplants to improve the functional control of lumbar spinal reflex excitability following chronic contusion spinal injury of the midthoracic spinal cord. Based on the previously demonstrated robust changes in rate-modulation of the lumbar monosynaptic reflex excitability following midthoracic contusion and their relevance to the development of spasticity, analysis of these reflex measures was selected to evaluate the potential for intraspinal fetal grafts to improve the functional control of reflex excitability. The transplant treatment consisted of an intraspinal injection of E-14 FSC tissue into the cavity of the contusion lesion three months post injury. We analyzed lumbar monosynaptic reflexes in animals six months following midthoracic contusion injuries. The benefit of the treatment was determined by comparing reflex measures in animals which received treatments to those recorded in contused-untreated animals. In addition, reflex analysis was performed in normal animals and time-matched glucose-saline controls. Analysis of the tibial monosynaptic reflex in animals with midthoracic contusion injuries revealed significant alterations in rate-depression throughout the range of test frequencies. The responses observed in the graft survival group (C-180T) were markedly improved over those observed for any other injury group, particularly in the lower range of the test frequencies (i.e. 1-5 Hz). For example, at 1 Hz, a significant difference between the values observed in the transplant group were significantly more normal than observed in the contused only group (ANOVA,  $p < 0.05$ , post hoc t-test). Anatomical study revealed graft survival in 13 of 35 animals. Surviving grafts included some in which well integrated nearly full thickness restoration of the spinal cord replaced the original lesion cavities. (Sup. by SCRF-1226-01, PVA)

## 518.10

ARCuate NUCLEUS TRANSPLANTS REDUCES HYPERREACTIVITY IN THE STARTLE RESPONSE IN NEONATALLY MSG-TREATED RATS. F.J. Yang\* and M.T. Romero, Department of Psychology, State University of New York at Binghamton, Binghamton, NY. 13902

Neonatal treatment with monosodium glutamate (MSG) in rodents produces degeneration of the hypothalamic arcuate nucleus (AN) and other circumventricular areas. Hyperreactivity to environmental stimuli is also observed in these animals. In the present study 18 female rats were treated with a low dosage of MSG (0.4mg/g) or saline (SC) on postnatal days 2,4,6,8,10. On postnatal day 12, 4 of the MSG-treated animals received hypothalamic transplants containing the arcuate nucleus. The other 6 received sham surgery. Saline injected rats were also given AN grafts or sham surgery. At the end of the experiment, brains were processed for immunocytochemistry. Preliminary results indicate that neonatal MSG treatment reduced habituation rate and induced hyperreactivity in the acoustic startle response. AN grafts restored habituation and reduced hyperreactivity in MSG-treated animals to control levels. Immunocytochemical results demonstrate that all grafted tissue was viable and expressed NPY and tyrosine hydroxylase. Given that corticotropin releasing factor (CRF) seems to be involved in the modulation of the startle response, it is possible that AN grafting restructured the CRF input to the pituitary destroyed by MSG. Further studies need to address this hypothesis.

## 518.12

IMMUNOLocalization OF METHIONINE-ENKEPHALIN IN THE DEVELOPING TRANSPLANTED OLFACTORY BULB. D.L. Greene<sup>1,2\*</sup>, J.N. Kou<sup>1</sup>, and L.E. Westrum<sup>1</sup>, Dept. of Neurological Surgery<sup>1</sup>, The Univ. of WA, Seattle WA 98195; Dept. of Surgery<sup>2</sup>, The Univ. of AZ, Tucson AZ 85724.

The rat olfactory bulb (OB), with its unique architecture, connectivity, and continuously regenerating olfactory nerve (ON), has been extensively studied as a model for neuronal plasticity and transplantation. To further understand the mechanisms of transplantation, we are investigating the localization of neurotransmitters that are expressed by specific cell populations within the OB. Previously it was shown that methionine-enkephalin (Met-ENK) localizes to the periglomerular (PG) cells and fibers, and granule cells (GC) and their dendrites. These cells are all inhibitory interneurons, intrinsic to the OB, making Met-ENK a marker to follow the development and organization of TX OB neurons. Pregnant dams were injected with [<sup>3</sup>H] thymidine to label the donor OBs. Neonatal rats received a unilateral OB transplant (TX) from donor embryonic rats (15 days gestation) in the site from which the host OB had been previously removed. One, two, and greater than four weeks post-transplantation, rats were anesthetized and perfused with 4% paraformaldehyde. Cryostat sections of the TX OB were incubated with a polyclonal antibody to Met-ENK, and ultimately reacted with DAB for visualization. One week after transplantation (n=3), the TX OBs were not connected with the host forebrain, but multiple PG and GC-like cells, reactive for Met-ENK, were visible. Two weeks after transplantation (n=3), the TX OBs were connected by a small fiber bundle to the host forebrain, and the PG and GC-like cell population, reactive for Met-ENK, increased. In addition, multiple large neurons, possibly excitatory mitral/tufted-like cells, were reactive for Met-ENK. Greater than four weeks after transplantation (n=5) the TX OBs were fully connected with the host forebrain, and the level of Met-ENK reactivity was even greater with multiple PG-like cells and fibers, GC-like cells and dendrites, and mitral/tufted-like cells labeled. These results show that TX OBs contain enkephalinergic inhibitory interneurons independent of connectivity and organization; yet with increasing growth and connectivity Met-ENK levels are upregulated such that excitatory OB neurons exhibit detectable levels in addition to normally reactive inhibitory neurons. A STEREOLOGICAL STUDY OF THE SYNAPTIC ORGANIZATION OF FASCIA DENTATA TRANSPLANTS J. Zimmer\* and T. Sørensen, Dept. of Anatomy & Cell Biology, Univ. of Odense, Denmark

The synaptic differentiation of intracerebral, rat fascia dentata transplants was analyzed by the new disector stereology in order to precisely estimate, for different grafts locations, the total number of synapses and subtypes per granule cell and their dendritic distribution. Neonatal dentate tissue were grafted to 3 locations in newborn rats: the subarachnoid space (isolated grafts), the fascia dentata (homotopic grafts with host brain perforant path innervation) and the neocortex (heterotopic grafts with neocortical innervation). After 100 days the dentate grafts and the fascia dentata from normal controls were processed for EM, and semithin and ultrathin sections cut for light and electron microscopic stereological analysis of granule cell numbers, volume of dentate molecular layer and synapse numbers and types. Other grafts with corresponding locations were used to confirm the host perforant path and neocortical innervation by lesion-induced, electron dense axonal degeneration. All grafts contained the normal types of synapses found in fascia dentata. Expressed per granule cell the homotopic (n=3) and the heterotopic grafts (n=7) had a normal or near normal total number of synapses. The isolated grafts displayed a 35% decrease. A group of homotopic grafts with 50 days survival showed a slight, but not statistically significant hyperinnervation. The 50 day old homotopic grafts, the heterotopic intracortical and the isolated grafts showed immature traits by not displaying the normal increase in total synapse numbers and the normal decrease in shaft synapses from the middle to the outer third of the molecular layer. - Using disector stereology we have found that grafted dentate granule cells can become structurally and numerically almost normally innervated by neocortical afferents, and that even homotopically located dentate grafts undergo long-term synaptic reorganization along the distal dendrites.

## 518.15

PRESERVATION OF *trk* A IMMUNOREACTIVITY IN THE MEDIAL SEPTAL AREA OF FORNIX TRANSECTED RATS BY FETAL HIPPOCAMPAL GRAFTS. R. H. Baisden\*, C. C. Seymour and M. L. Woodruff, Dept. of Anatomy & Cell Biology, J. H. Quillen College of Medicine, East Tennessee State Univ., Johnson City, TN 37614

*trk* A is a specific receptor for nerve growth factor (NGF). It contains a tyrosine kinase functional element and is present in medial septal nucleus/diagonal band (MS/DB) cholinergic neurons. Lesions of the fimbria-fornix prevent transport of NGF from the hippocampus to the MS/DB and produce loss of *trk* A and choline acetyltransferase (ChAT) in these neurons. Intraventricular NGF infusion prevents this loss (Venero et al, *Neuroscience*, 59, 797-815, 1994). Kromer et al. (*Brain Res.*, 210, 153-171, 1980) demonstrated that transplants of fetal hippocampus placed into the cavity produced by surgical destruction of the fimbria-fornix will maintain ChAT and acetylcholine esterase (AChE) in medial septal neurons. The purpose of the present experiment was to determine if such transplants could sustain *trk* A receptors in MS/DB neurons in rat with fimbria-fornix lesions and, if so, the time course of the preservation. Twenty five adult male Long-Evans hooded rats were given bilateral aspiration lesions of the fimbria-fornix. Ten of these were killed by an overdose of sodium pentobarbital in pairs 6, 12, 24, 30 and 60 days after the lesion. The other 15 received transplants of E20 hippocampus. Three of these rats were killed each day on the same days as the lesion-only rats. Following perfusion with 4% paraformaldehyde the brains were removed and 40  $\mu$ m frozen sections from the anterior septum through the anterior half of the hippocampus were retained and stained with thionin or processed using the avidin-biotin immunocytochemically for *trk* A or ChAT or histochemically for AChE. Both of the enzymes and *trk* A were preserved in rats given transplants, but were lost by day 12 in rats with lesions alone. (Supported by NIH Grant ES 04070-08 to MLW and by a Research Development Grant from ETSU to RHB).

## 518.14

HOMOTOPIC AND HETEROTOPIC E17 CORTICAL TRANSPLANTS PLACED IN NEONATAL RAT ROSTRAL CORTEX MAINTAIN AXONAL PROJECTIONS APPROPRIATE TO THE HOST CORTICAL LOCALE: EVIDENCE FROM ANTEROGRADE TRACING EXPERIMENTS USING BIOTINYLATED DEXTRAN. B. Shi\* and B. B. Stanfield, Laboratory of Neurophysiology, NIMH, NIH Animal Center, Poolesville, MD 20837.

Earlier work using retrograde axonal tracers showed that both homotopic and heterotopic (occipital) E17 fetal cortical transplants placed in neonatal rat rostral cortex extend and maintain projections appropriate to the rostral cortex. This led to the notion that regional features of cortical areas are not rigidly specified at E17. Recently, a study using an anterograde tracer reported quite different results, namely that such heterotopic transplants extend projections appropriate to their region of origin and fail to project to rostral cortical targets such as the spinal cord. We have used the anterograde tracer biotinylated dextran to reexamine this issue.

Pieces of rostral or occipital E17 fetal cortex were placed into lesion cavities in the rostral cortex of newborn rats. Biotinylated dextran was iontophoretically injected into the transplants at 5 weeks of age. Only cases with injections confined to the transplants were included in the study. In both transplant types, clusters of labeled neurons are seen within the transplants and labeled axons enter the host brain. The distribution of labeled axons arising from the two types of transplants is similar: Both transplant types project to the sensorimotor thalamus, to the deep layers of the superior colliculus and to the spinal cord; and neither type projects to visual thalamus, to visual cortex or to the superficial layer of the superior colliculus. However, some differences between the projections of the two transplant types are seen. More labeled axons are seen in the spinal cord and fewer in the deep layers of the superior colliculus in cases with homotopic transplants, and the axons in the spinal cord also extend further caudal in these cases. These results confirm the earlier retrograde tracer findings and indicate that while the overall projections of the transplants are similar, there may be subtle and quantitative differences that may reflect an emerging commitment to regional fate at E17. This is consistent with behavioral differences recently found in animals with the two types of transplant.

## 518.16

ELECTROPHYSIOLOGICAL CHARACTERISTICS OF EXCITATORY SYNAPTIC CURRENTS OF PATCH-CLAMPED PURKINJE NEURONS GRAFTED ON AN ADULT CEREBELLUM. F. Tempia, M. Bravin and P. Strata\*, Dept. of Human Anatomy and Physiology, University of Torino, I-10125, Torino, Italy.

We have recently shown that Purkinje neurons (PNs) from a cerebellar primordium grafted onto the surface of an adult uninjured cerebellar cortex receive functional synapses from the three main PN input fibers. In order to evaluate the extent of maturation of the functional properties of excitatory postsynaptic currents we have investigated their electrophysiological characteristics in more detail. Whole-cell patch-clamp recordings in rat tissue slices were obtained from 20 PNs migrated from the graft into the molecular layer of the host cerebellum. In the presence of a GABA<sub>A</sub>-receptor antagonist, extracellular stimulation evoked graded and all or none currents typical of parallel and climbing fibers. With a paired stimuli protocol, graded currents showed an enhancement of the second response while all or none currents showed a depression, as described in the normal cerebellum. To investigate the nature of postsynaptic receptors, firstly we applied the AMPA/kainate receptor antagonist CNQX (10  $\mu$ M): as in normal PNs both types of postsynaptic currents were blocked. Secondly, we studied their current-voltage relationship to establish whether such receptor channels were of the linearly conducting-low Ca<sup>2+</sup>-permeable type or of the inward rectifying-highly Ca<sup>2+</sup>-permeable type expressed by cultured and probably by embryonic PNs. Both parallel and climbing fiber-mediated currents had a linear I-V relation with a reversal potential close to 0 mV, giving further support to their mature nature. In conclusion, all tested electrophysiological properties of migrated PNs were of the normal adult type. In addition, we recorded 17 PNs still located in the graft. They shared all characteristics of migrated PNs except the amplitude of climbing fiber responses, that failed to increase to normal adult values at late stages after grafting.

## MEMBRANE COMPOSITION AND CELL-SURFACE MACROMOLECULES I

## 519.1

COMPARISON OF *IN VITRO* CELL CULTURE OF RAT HIPPOCAMPAL, SPINAL CORD, AND CORTICAL NEURONS ON ARTIFICIAL SURFACES. J.J. Hickman<sup>1</sup>, K.E. Foster<sup>1</sup>, D.R. Jung<sup>1</sup>, A.E. Schaffner<sup>2</sup>, and J.L. Barker<sup>2</sup>

<sup>1</sup>Science Applications International Corporation, 1710 Goodridge Drive, McLean, VA 22102

<sup>2</sup>Laboratory of Neurophysiology, National Institute of Neurological Disorders and Stroke, National Institutes of Health, Bethesda, MD 20892

We compared the development of embryonic rat hippocampal, spinal cord, and cortical neurons on artificial surfaces, *in vitro*, in serum-containing and serum-free media. The artificial surfaces are composed of Self-Assembled Monolayers (SAMs) on glass cover slips attached via silane linkages. SAMs with a variety of functional groups were studied, including -COOH, -NH<sub>2</sub>, phenyl, -SH, and -CH<sub>3</sub>. Surface composition, both before and after culture, was determined by X-ray Photoelectron Spectroscopy (XPS). The results will be analyzed using a multivariate analysis package. In some cases, the surface greatly contributed to both initial adhesion and long term survival. Some surface effects were found to vary according to cell type.

## 519.2

CELL-SURFACE MOLECULES IMPORTANT TO THE MAINTENANCE OF RAT CEREBELLAR PURKINJE CELLS IN CULTURE. V. Dumon and M. Docherty\*, Depts. of Physiology and Pharmacology, Royal Free Hospital School of Medicine, London NW3 2PF, UK.

We are particularly interested in a GABAergic cell-surface molecule related to Glutamate Decarboxylase (GAD) which may play an important role in cellular recognition when associated with Immunoglobulin-superfamily molecules (Baekkeskov et al, *Nature* 347, 151-156, 1990). We wish to investigate the importance of this molecule and its association with Thy-1, and related proteins, using Purkinje cells prepared from the cerebella of 20 day old rats. The conditions required for isolation and maintenance of cells with tertiary dendritic trees have been established, using a total of 110 Sprague-Dawley rats. Sagittal slices (0.5mm thick, 10 per cerebellum) were cut by hand using a razor blade and incubated for 60 min at 37°C in a solution containing 20mM pipes di-potassium, 240mM sucrose, 10mM KCl, 25mM glucose, 6mM MgCl<sub>2</sub>, 1mM CaCl<sub>2</sub>, 2 mM pyruvate, gassed with 100% O<sub>2</sub>, pH 7 (sucrose buffer). Slices were then exposed to 0.2% pronase E (wt/vol sucrose buffer) for 40 min at 37°C. Extensive washing removed the enzyme before trituration. Cells were grown under a variety of conditions (different substrates, different media) and their survival monitored for more than 20 days. Immunohistochemical analysis of the Purkinje cells present in these cultures has revealed many diversities within this cell population. We have examined these subpopulations in more detail using single-cell RT-PCR. Single identified cells were removed from the culture dish using glass pipettes of internal diameter 40 $\mu$ m. After lysis of the cell, mRNA was extracted onto magnetic beads bearing oligo-dT and subjected to reverse transcription and subsequent PCR using either rTh (Promega) or Th (Boehringer Mannheim) and a variety of defined primers. PCR products were identified using Southern blotting. This culture system has allowed us to correlate the expression of Thy-1 and various forms of GAD with survival capacity.

## 519.3

EFFECT OF POTASSIUM CONCENTRATION ON (NA,K)-ATPASE IN NON-NEURONAL CELLS GROWN IN CULTURE. L.H. Farber\*, Q. Wang, D.A. Riley and D.J. Miletich. Dept. of Anesthesiology, University of Illinois at Chicago, College of Medicine, Chicago, IL 60612.

While hypokalemia (low blood potassium) is a condition of some importance to clinicians, it holds some curiosities for the basic researcher as well. Among these is the differential effect of low potassium on different organ systems in the body. Of particular interest is the fact that while hypokalemia leads to tissue levels of potassium and the enzyme (Na,K)-ATPase that are decreased in heart and skeletal muscle, these levels remain unchanged in the brain (Azuma *et al.*, Am. J. Physiol. 260:C958-C964, 1991; Albrecht and Miletich, submitted). We have endeavored to further elucidate this matter by investigating individual cell types in culture. Cells in primary cultures were switched to serum-free media containing 1 mM, 3.5 mM or 5.0 mM potassium for 36 hours. Total cellular RNA was isolated from these cells and assayed for (Na,K)-ATPase message by Northern Blot analysis. Extremely low levels of potassium led to an increased expression of the  $\alpha$ -subunit of the (Na,K)-ATPase in astrocytes. Moderate decreases in potassium levels, however, did not alter the level of expression. The results will be discussed along with their implications for the differential effects of hypokalemia in intact organisms.

## 519.5

# EFFECT OF ACUTE GANGLIOSIDE EXPOSURE ON <sup>3</sup>H-DOPAMINE ACCUMULATION & RELEASE BY SYNAPTOSOMES.

M. Medrano, R. Cabeza, D. Moss\* and L.N. Irwin. Dept. Biol. Sci., Univ. of Texas at El Paso, TX 79968

Reports in the literature suggest that gangliosides may be excitatory and that they may increase neurotransmitter release. To address the possibility that this altered excitability may affect <sup>3</sup>H-dopamine (<sup>3</sup>H-DA) storage or release, we investigated the effects of acute ganglioside exposure on <sup>3</sup>H-DA accumulation and release. Synaptosomes from rat brain striatum and cortex were prepared and exposed to 37  $\mu$ g/ml of a ganglioside mixture for 0, 30, 60 and 90 min. The accumulation of <sup>3</sup>H-DA was assessed after 30 min. of exposure to the neurotransmitter. Synaptosomes were resuspended in a normal Krebs or high potassium Krebs (35mM) solution for 15 min., to assess basal and stimulated release of <sup>3</sup>H-DA, respectively. Although our results indicate that there is no significant effect of gangliosides on accumulation, basal release or stimulated release of <sup>3</sup>H-DA, an effect on stimulated release by K<sup>+</sup> cannot totally be ruled out because the [K<sup>+</sup>] was close to maximal. Supported by RCMI Grant G12-RR-08124 from the National Center for Research Resources, NIH; and by the J. Edward and Helen M. C. Stern Endowment.

## 519.7

SHRINKING- AND SWELLING-INDUCED NEURONAL MEMBRANE DYNAMICS MONITORED BY CONFOCAL MICROSCOPY. CE Morris\*, Mills LR Loeb Institute, Ottawa Civic Hosp, Ottawa K1Y 4E9\* & Playfair Institute, Toronto Western Hosp, Toronto M5T 2S8

Subjected abruptly to shrinking stimuli, neurons internalize membrane in the form of vacuole-like dilations (VLDs) readily apparent by light microscopy. Abrupt swelling stimuli, by contrast, promote externalization of neuronal membrane (see Wan *et al* 1995 & Reuzeau *et al* 1995, both J Memb Biol 145: May issue). VLD formation and reversal are insensitive to wide variations in intracellular and extracellular ionic conditions; tension rather than chemical changes attendant on shrinking and swelling may therefore be what triggers and/or drives these membrane dynamics. Although we primarily used snail neurons, VLDs were elicited in cultured day 17 embryonic hippocampal neurons and glia and a variety of other cells. Confocal microscopy on living cells was used to study the provenance of membrane associated with VLDs.

The membrane dye, DiI, applied as an ethanol solution, partitioned almost exclusively into plasma membrane. VLDs, elicited by a shrinking stimulus immediately after DiI application, stained with DiI. When VLDs were made to reverse (via a second swelling stimulus), DiI-stained VLD membrane "everted" to the plasma membrane. In the absence of a reversing stimulus, VLDs could be seen to pinch off and become true vacuoles. These osmomechanically elicited membrane dynamics were observed repeatedly at discrete sites and were restricted to the substrate-adherent surface.

In mouse neurons, as in molluscan neurons, bath-applied rhodamine-dextran entered VLDs as they formed and was expelled during VLD reversal. Supported by NSERC Canada research grants to CEM and to LRM.

## 519.4

USE OF CERAMIDE GLYCANASE IN CELL CULTURE: EFFECT ON MYOGENESIS. K.C. Leskawa\*, M.A. Niebauer, W.I. Shaikun and L.D. Cambron. Dept. Anat. Sci. & Neurobiol., Univ. Louisville, Louisville, KY 40292

Ceramide glycanase from the leech (*Hirudo medicinalis*) has been used to liberate oligosaccharides from glycosphingolipids (GSLs), including the gangliosides, for carbohydrate structural studies. Here, we report that this enzyme can also be employed in cell culture studies to probe GSL function. Clonal skeletal muscle cells were treated with 2  $\mu$ l/ml of ceramide glycanase in complete media (containing 10% serum). Myoblast membrane fusion, which normally leads to the formation of multinucleated myotubes, was drastically inhibited. Analysis after 24 hr incubation revealed approximately 70% hydrolysis of gangliosides and 80% hydrolysis of neutral GSLs. When myoblasts were treated with ceramide glycanase for 2 days, and then transferred to control media, the ability to fuse gradually returned, myotube formation lagging 2 days behind control cultures. This suggests that during this recovery period the cells express new GSLs at the cell surface, where they play a role in the membrane fusion event. This is presently being examined directly by using surface saccharide labeling techniques.

When non-glycosylated sphingoids were studied, it was found that treatment of the myoblasts with ceramide glycanase resulted in extremely high increases in ceramide, sphingosine and sphingosine-1-phosphate. All of these compounds are believed to operate as second messengers. While our initial hypothesis is that myoblast surface glycosphingolipids are involved directly in the membrane fusion event (via recognition by surface glycosyltransferases), this new data suggest that GSL-derived second messengers could be involved in a very different signalling event during myogenesis. Supported by NINDS grant NS21057.

## 519.6

# DIFFERENTIAL MEMBRANE INTERACTIONS OF CORTISOL AND ESTRADIOL: IMPLICATIONS FOR CYTOSOLIC RECEPTOR ACTIVITY.

R.P. Mason, P.E. Mason, J. Estermyer and R.T. Rubin\*. Neurosciences Research Center, Allegheny Campus, Medical College of Pennsylvania and Hahnemann University, Pittsburgh, PA 15212.

Both cortisol and estradiol are lipophilic steroids which interact with the cell plasma membrane, in addition to binding to cytosolic receptors. To explore the interactions of these steroids with phospholipid multilamellar vesicles, we determined their membrane-based partition coefficients and their time-averaged locations within the phospholipid bilayer. In the absence of cholesterol, the (Kp(mem)) values for cortisol and estradiol were 250 and 5,000, respectively. In the presence of a physiological concentration of cholesterol (0.4:1 cholesterol/phospholipid mole ratio), the Kp(mem) values for both cortisol and estradiol were reduced by 50%. The latter is consistent with the finding of Jacobsohn *et al* (Biochim Biophys Acta 1195:131; 1994). In washout experiments, the dissociation of cortisol from the membrane was significantly greater than that of estradiol (>50% vs. <5%).

One-dimensional electron density profiles generated by small-angle x-ray diffraction (13Å resolution) indicated that these steroids occupy discrete, time-averaged locations in the lipid bilayer. Estradiol, a nonpolar steroid, was concentrated near the center of the membrane hydrocarbon core, the region with the greatest molecular volume. In contrast, cortisol, a more polar steroid, was concentrated near the phospholipid headgroups, a charged region of high molecular density.

These findings support a model of steroid partitioning to discrete locations in the cell plasma membrane prior to binding to cytosolic receptors. The membrane interactions of these steroids 1) are influenced by membrane lipid composition, particularly cholesterol content, 2) may modulate their ability to bind to and activate their specific intracellular receptors, and 3) may influence the structure-activity characteristics of membrane-bound proteins.

## 519.8

HETEROPHILIC NCAM-MEDIATED ADHESION OF TRANSFECTED CELLS TO AGRIN FROM EMBRYONIC CHICK BRAIN. B.A. Murray\*, S.D. Storms, A.S. Kim, B.-H.T. Tran and G.J. Cole†. Dept. of Developmental and Cell Biology and Developmental Biology Center, Univ. of California, Irvine, CA 92717-2300, and †Neurobiotechnology Center and Dept. of Cell Biology, Neurobiology and Anatomy, The Ohio State Univ., Columbus, OH 43210.

The neural cell adhesion molecule NCAM mediates adhesion by homophilic and heterophilic mechanisms, and heparan sulfate proteoglycans (HSPGs) have been suggested to be heterophilic NCAM ligands. The acetylcholine receptor clustering protein agrin is a heparan sulfate proteoglycan that has been shown to bind to purified NCAM. In this study, transfected mouse L cells expressing the 140 kilodalton isoform of chicken NCAM adhered to purified agrin adsorbed to a nitrocellulose substratum, and the adhesion was inhibited by a monoclonal antibody specific for chicken NCAM. Digestion experiments with heparinase and heparitinase indicated that the heparan sulfate sidechains of agrin were required for adhesion. Two brain HSPGs, agrin and the antigen recognized by the 6C4 monoclonal antibody, were detected immunologically in adhesive fractions prepared from brain membrane extracts by ion exchange chromatography, and depletion of these HSPGs with specific monoclonal antibodies inhibited the adhesion of the transfected cells to these fractions. In contrast, the HSPG perlecan was present in one of the adhesive fractions, but immune depletion using an anti-perlecan monoclonal antibody did not affect adhesion. Immune depletion and chondroitinase ABC digestion experiments suggested that chondroitin sulfates (presumably on proteoglycans) are not involved directly in adhesion, but they may modulate adhesion to HSPGs. Our experiments support the view that NCAM can mediate the adhesion of cells to agrin and that NCAM is a multivalent adhesive molecule whose function is affected both positively and negatively by interactions with several different types of extracellular matrix and cell surface molecules. (Supported by NSF grant IBN-9220156.)

## 519.9

THE DROSOPHILA NEURAL CELL ADHESION MOLECULE NEUROGLIAN INDUCES THE POLARIZED ASSEMBLY OF THE ANKYRIN CYTOSKELETON IN S2 CELLS. M. Hortsch<sup>1</sup>\*, C. Liu<sup>1</sup>, D. Homer<sup>1</sup>, G. McVicar<sup>2</sup>, S. Dissanayake<sup>2</sup> and R. Dubreuil<sup>2</sup>. <sup>1</sup>Dept. of Anatomy & Cell Biol., Univ. of Michigan, Ann Arbor, MI 48109, <sup>2</sup>Dept. of Pharm. & Physiol. Sci., Univ. of Chicago, Chicago, IL 60637

Sites of cell-cell adhesion are known to be important sites of cytoskeleton interaction with the plasma membrane. Cell adhesion molecules (CAMs) as well as cytoskeletal elements are often segregated into specialized regions of cells, such as the dendritic or axonal processes of neurons. We recently obtained evidence that Drosophila neuroglial, a member of the L1-CAM family, directly interacts with ankyrin and recruits the assembly of an ankyrin-linked membrane skeleton in S2 tissue culture cells. Ankyrin links integral membrane proteins to the actin-spectrin-based membrane skeleton in a range of different cell types and is often concentrated within restricted membrane domains. A direct protein interaction between ankyrin and neuroglial was demonstrated using the yeast two-hybrid system. In Drosophila S2 cells ankyrin is found in the cytoplasm of untransfected cells, but is specifically recruited to sites of cell-cell contact in neuroglial expressing cells. Neuroglial appears to be activated by its extracellular adhesive function so that ankyrin selectively associates with sites of cell-cell contact and not with other regions of the cell surface. These results indicate that a neural CAM can transmit positional information directly to the ankyrin-spectrin matrix. The polarization of the membrane cytoskeleton could induce the recruitment of additional signaling molecules to sites of cell-cell adhesion and might play an important role in the induction of physiological responses to cell adhesion, such as the CAM-dependent outgrowth of neurites.

## 519.11

PUTATIVE CD9-ASSOCIATED PROTEINS AND LIGAND/RECEPTOR IN S-16 SCHWANN CELLS AND PERIPHERAL NERVE MEMBRANE EXTRACTS. M. Hadjiargyrou\*, Z. Kaprielian, K.-O. Cho and P.H. Patterson. Division of Biology, California Institute of Technology, Pasadena, CA 91125

Previous work has shown that CD9 associates with various other membrane proteins in non-neural cells including the integrins GPIIb-IIIa, VLA, and  $\alpha_6\beta_1$ , small GTP-binding proteins, L1, and the diphtheria toxin receptor. To investigate whether CD9 also associates with other membrane proteins in neural cells, we used the anti-CD9 monoclonal antibody (mAb), B2C11, in immunoprecipitations with 1% CHAPS extracts of membranes from <sup>35</sup>S-methionine-labeled S-16 Schwann cells. Proteins of 130 kD and 16 kD specifically co-precipitate with CD9. If S-16 cells are extracted with 1% Brij-96, we find 30 kD and 34 kD proteins, as well as the 130 kD band, co-precipitate with CD9. De-glycosylation experiments indicate that the 130 kD protein resides on the cell surface.

We have previously shown that mAb B2C11 induces adhesion, proliferation and migration of Schwann cells. We speculate that the site recognized by B2C11 on CD9 is a functional epitope and may be a binding site of a natural ligand. To begin a search for such a ligand, we mapped the B2C11 epitope to the large extracellular domain of CD9 using fusion proteins and chimeric antibodies (CD9/IgG). Utilizing western analysis, we find that a chimeric antibody containing both CD9 extracellular domains binds a 70 kD antigen in sciatic nerve membrane extracts.

## 519.13

DEVELOPMENTAL CHARACTERIZATION OF THE CAT-315 CHONDROITIN SULFATE PROTEOGLYCAN. H.J.L. Fryer, C.E. Lander, and S. Hockfield\*. Section of Neurobiology, Yale Univ. School of Medicine, New Haven, CT 06510

Monoclonal antibody Cat-315 was produced using an immunization strategy designed to generate antibodies to molecules related to the Cat-301 proteoglycan. Like Cat-301, Cat-315 recognizes a developmentally-regulated, high molecular weight chondroitin sulfate proteoglycan (CSPG) that, in the adult, is associated with the surface of a subset of neurons in the mammalian CNS. Immunohistochemical, biochemical and cell culture experiments indicate that Cat-315 is synthesized early in development and is subsequently glycosylated and transported to the cell surface.

The pericellular Cat-315 staining is first seen at postnatal day 14; however, immunoreactivity is detected as early as embryonic day 15. At the light microscopic level, staining at embryonic and early postnatal ages appears diffuse and/or intracellular. By postnatal day 7, staining is clearly associated with neurons, but this staining is intra- rather than pericellular. In cultures of dissociated E15 rat cortex, Cat-315 stains an intracellular antigen in cells with a neuronal morphology.

On Western blots of E15 rat cortex homogenates Cat-315 recognizes a 550kD band. The apparent molecular weight of the antigen recognized by Cat-315 increases between E15 and adulthood. This increase is due to chondroitin sulfate addition, as chondroitinase ABC digestion of P0 or adult homogenates shifts the size of the immunoreactive band to the molecular weight of the antigen present in E15 cortical homogenates.

Together, these data suggest that the Cat-315 CSPG is synthesized at embryonic ages and that, as development proceeds, the antigen is glycosylated and subsequently transported to neuronal cell surfaces. Supported by EY06511.

## 519.10

IMMUNOCYTOCHEMICAL ANALYSIS OF RECEPTOR PROTEIN TYROSINE PHOSPHATASE- $\kappa$  EXPRESSION IN THE NEWBORN AND ADULT RAT CNS. G.I. Botchkina, I. Sap, T. Li, Y.-P. Jiang and J.M. Musacchio\*. Dep. of Pharmacology, NYU Medical Center, NY10016

RPTP- $\kappa$  is a recently described receptor-like protein tyrosine phosphatase, the extracellular domain of which mediates homophilic cell-cell adhesion (Sap et al., 1994, Mol. Cell Biol., 14:1). We have shown previously by in-situ hybridization analysis that the level of expression of RPTP- $\kappa$  mRNA is higher in the developing than in the adult CNS (Jiang et al., 1993, Mol. Cell Biol., 13:2942). Antiserum 116 was generated against a synthesized peptide, corresponding to residues 60 to 76, and then was affinity purified. Primary antibodies with peptide preadsorption were used as a control.

In newborn rats, the highest level of RPTP- $\kappa$  immunoreactivity was seen within the cell bodies and their processes in the ventricular and subventricular zone, choroid plexus cells and ependymal cilia. Some intensely stained migrating cells were scattered far from the ventricular zone. Both, newborns and adults, display large number of moderately immunostained cells through the brain and spinal cord gray matter.

In adults, the dot-like IR was abundant throughout the dorsal horns of the spinal cord, all rostro-caudal subdivisions of the trigeminal nucleus, and within the area postrema, gracile and cuneate nuclei. Many neurons in the dorsal root and trigeminal ganglia have moderate granular cytoplasmic immunostaining. Several neuronal populations within the brainstem, hippocampal formation and Purkinje cells in the cerebellum express moderate to low level of RPTP- $\kappa$  IR.

## 519.12

A NEURAL CHONDROITIN SULFATE PROTEOGLYCAN THAT IS SIMILAR, BUT NOT IDENTICAL, TO THE CAT-301 ANTIGEN. C.E. Lander\*, H.J.L. Fryer and S. Hockfield. Section of Neurobiology, Yale Univ. School of Medicine, New Haven, CT 06510

Monoclonal antibody Cat-301 recognizes a chondroitin sulfate proteoglycan (CSPG) associated with the surface of a subset of neurons in the mammalian CNS. Because not all neurons are labeled by Cat-301, we hypothesized that other, related molecules would be expressed with distributions different from that of Cat-301. To test this hypothesis, we used cesium chloride gradient fractions enriched in CSPGs as an immunogen for the production of new antibodies. One of the antibodies generated with this immunization strategy, Cat-315, recognizes a proteoglycan related, but not identical, to the Cat-301 CSPG.

The Cat-315 antigen co-migrates with the Cat-301 antigen and undergoes a similar shift in mobility following digestion with chondroitinase ABC. Immunodepletion experiments indicate that the antigens recognized by these antibodies represent overlapping, yet distinct, sets of CSPGs. Another difference between the antibodies is that while both antibodies recognize bovine cartilage aggrecan, only Cat-315 recognizes aggrecan purified from rat chondrosarcoma.

Histologically both Cat-315 and Cat-301 bind to the surface of subsets of neurons with a similar lattice-like pattern. The two antibodies label overlapping populations of neurons. In rat, both antibodies stain neurons in the superior colliculus and the deep cerebellar nuclei. However, Cat-301 stains many spinal cord neurons, including motor neurons, while Cat-315 labels few spinal cord neurons. Further, while Cat-301 labels very few neurons in the rat cerebral cortex, a large number of cortical neurons are labeled by Cat-315.

Thus, some neurons that lack Cat-301 on their surfaces express a similar CSPG that is recognized by Cat-315. This suggests that the antigens recognized by Cat-301 and Cat-315 belong to a family of related CSPGs which may serve similar functions for different populations of neurons. Supported by EY06511.

## 519.14

MODULATION OF DSD-1-PROTEOGLYCAN EXPRESSION BY GROWTH FACTORS O. Schnädelbach\*, C. Mandl and A. Faissner. Dept. of Neurobiology, University of Heidelberg, D-69120 Heidelberg

DSD-1-Proteoglycan (DSD-1-PG) is a chondroitin sulfate proteoglycan of 1000 kD Mr and comprises a core protein of 350-400 kD Mr which carries the DSD-1-epitope, a specialized glycosaminoglycan structure specifically recognized by monoclonal antibody (mAb) 473H.D. DSD-1-PG is produced by immature glial lineages *in vitro* and *in vivo* and, purified from postnatal mouse central nervous system (CNS), promotes neurite outgrowth of embryonic day 18 rat hippocampal neurons, suggesting that it is involved in neuron-glia interactions.

DSD-1-PG displays maximal expression perinatally and is largely downregulated in adult CNS. The CSPG is upregulated in CNS stab wounds and, in addition to its role during development, might thus contribute to CNS plasticity. In order to understand the regulatory basis of DSD-1-PG expression an ELISA based on mAb 473HD was established and used to measure proteoglycan content in cell culture systems. The glial precursor cell line Oli-neu was chosen as model system and cultivated in the presence or absence of various factors. From all growth factors tested so far, TGF- $\beta$ 1 significantly upregulated DSD-1-PG levels during a 24 hrs assay. TGF- $\beta$ 1 increased DSD-1-PG released into the culture medium by 538% and the CSPG contained in detergent extracts of the cell monolayer by 547%. In contrast, the fraction of DSD-1-positive cells remained unchanged, while their total number was reduced when compared to untreated controls.

From these data we conclude that TGF- $\beta$ 1, a growth factor which is present both in astrocytes and microglia in CNS stab wounds, might be an effector of DSD-1-PG upregulation upon CNS damage.

## 519.15

GLIAL CELLS IN THE NORMAL ADULT RAT HYPOTHALAMO-NEUROHYPOPHYSIAL SYSTEM CONTINUE TO EXPRESS THE EXTRACELLULAR GLYCOPROTEIN, TENASCIN-C. D.T. Theodosis, K. Pierre, M. A. Cadoret, M. Allard, A. Faissner<sup>1</sup> and D. A. Poulain. INSERM U 378 Univ. Bordeaux II, F33076 Bordeaux, France and <sup>1</sup>Neurobiology, Univ. Heidelberg, D-69120 Heidelberg, Germany.

Neurons and glial cells of the hypothalamo-neurohypophyseal system (HNS) undergo reversible structural changes in response to stimulation throughout life, a plasticity associated with changes in the number of synapses and the morphology of neurohypophyseal axons. The HNS continues to display several 'embryonic' features that may allow such plasticity, including the expression of adhesion molecules associated with neurohistogenesis, such as polysialylated NCAM and the F3 glycoprotein (Theodosis & Poulain 1993 Neuroscience 57,501). We here describe the expression of another glycoprotein linked to neurite outgrowth in the developing and lesioned CNS, the extracellular matrix molecule, tenascin-C (TN-C). Immunocytochemistry with antibodies specific for different parts of TN-C revealed high levels of immunoreactivity throughout the adult rat HNS. Electron microscopy of immunoperoxidase-stained sections showed that the reaction predominated in extracellular spaces and on glial surfaces; in the neurohypophysis, it was also visible on axonal surfaces. In tissues from colchicin-treated rats, the reaction filled the cytoplasm of astrocytes and tanycytes in the hypothalamus and pituitary in the neurohypophysis, indicating that, as in developing tissues, TN-C is secreted by all glial cells of the HNS. Immunoblots of tissue extracts from different regions of the system displayed immunoreactivities in the molecular weight range of 220/240 kD. No significant differences in levels of TN-C immunoreactivity were detected in relation to age, sex or physiological state, which indicates that the expression of TN-C is a permanent feature of the mammalian HNS throughout life. Whether it is implicated in the activity-dependent structural plasticity of the system remains to be determined.

## 519.17

**Identification and Characterization of the Human Extracellular Matrix Molecule Restrictin.** R.L. Ackley, R.A. Reid, R. Madison\*, J.J. Hemperly. Dept. of Molecular Biology, Becton Dickinson Research Center, P.O. Box 12016, Research Triangle Park, NC 27709 USA.

We have characterized a new protein of the human extracellular matrix that appears to be the homolog of the chicken restrictin and rat janusin matrix proteins. Within the protein coding region, the nucleotide and deduced amino acid sequences of human restrictin are 88% and 93% identical to the chicken restrictin sequence, respectively. As seen in the rat and chicken molecules, human restrictin comprises a number of epidermal growth factor-, fibronectin Type III-, and fibrinogen-like domains. DNA probes for human restrictin detect an approximately 12 kb mRNA in fetal and adult human brain but not in fetal heart, liver, lung or kidney.

Antisera were developed against a fragment of human restrictin (consisting of a portion of the fibronectin Type-III repeats) expressed in bacteria. Using this antisera, we detected 160 kD and 180 kD bands in human brain extracts by Western blotting and demonstrated fiber tract staining in human and rat brain by immunohistochemistry. Surprisingly, we also detected restrictin in Matrigel, a commercial tissue culture growth substratum, and we have found human restrictin, unlike its rat and chicken homologs, to be present in peripheral nerve.

## 519.19

**LOCALIZATION OF  $\alpha_5$  INTEGRIN-LIKE IMMUNOFLUORESCENCE IN THE ADULT RAT HIPPOCAMPUS.** L.S. Jones\* and S. Grooms, Dept. of Dev. Biol. & Anat., Univ. So. Carolina, Sch. of Med., Cola., SC 29208.

Integrins are a superfamily of adhesion molecules that link the cytoskeleton with the extracellular matrix (ECM) and/or adjacent cells. These transmembrane proteins are heterodimeric, consisting of noncovalently linked  $\alpha$  and  $\beta$  subunits. Because specific integrin subunits may be involved in synaptic remodeling that occurs during various forms of neuronal plasticity, we have used RT-PCR to verify the presence  $\alpha_5$ -integrin mRNA in rat whole-brain extracts as well as in the hippocampus. We have further demonstrated  $\alpha_5$  integrin-like immunoreactivity in the adult rat brain using confocal microscopy. 250 micron vibratome sections were immunolabeled with a primary, anti-rat  $\alpha_5$  antibody and a secondary FITC conjugated, goat anti-rabbit antibody. Dense staining was noted on choroidal and ependymal cells where  $\alpha_5$ -integrin may be localized along the basal lamina. The hippocampal pyramidal cell layer and the dentate granule cell layer were also highly immunopositive using this polyclonal  $\alpha_5$ -integrin antibody. In fact, a pronounced band of intense  $\alpha_5$  integrin-like immunoreactivity was observed at the hilar surface of the granule cell layer. The localization of the  $\alpha_5$  antibody in the apical dendrites of CA1 pyramidal neurons created a striated pattern in stratum radiatum. A sharp band of positive immunoreactivity was also noted in stratum lacunosum moleculare. The pattern of  $\alpha_5$  integrin-like immunoreactivity in regions of high synaptic density suggest that integrins may contribute to the organization of dendritic and synaptic morphology. Work supported by NINDS NS27903.

## 519.16

**AN EXTRACELLULAR MATRIX GLYCOPROTEIN ASSOCIATED WITH NEUROMUSCULAR JUNCTIONS AND PERIPHERAL NERVES** Stephanie H. Astrow\*, Minh Thuoc T. Nguyen, & Chien-Ping Ko, Dept. of Biol. Sci., Univ. of Southern California, L.A. CA 90089-2520.

The extracellular matrix (ECM) at the neuromuscular junction (NMJ) is a repository for molecules involved in synapse formation and maintenance. To identify such molecules, we generated monoclonal antibodies against *Torpedo* ECM. One of these antibodies, 6D7, recognizes the synaptic region of frog NMJs. Immunocytochemical labeling of NMJs with 6D7 is continuous with labeling of preterminal axons. Immuno-electron microscopy indicates that 6D7 labeling is localized to the ECM primarily around the terminal Schwann cells at the NMJ. The ECM surrounding peripheral nerves is also immunopositive for 6D7 with labeling found at both myelinated and nonmyelinated axons. Denervated sartorius muscles have little 6D7 immunolabeling at NMJs two weeks following injury; after reinnervation, the intensity of immunolabeling is comparable to controls. Thus, expression of the 6D7 epitope at the NMJ is innervation-dependent. In the tails of *Xenopus* tadpoles, 6D7 staining colocalizes with the chevron-like arrangement of AChRs at NMJs. On immunoblots of a detergent-soluble extract of frog peripheral nerve, 6D7 recognizes a major band of Mr. 127 kD. Treatment of this extract with N-glycanase results in greater mobility of the major immunoreactive band while treatment with O-glycanase abolishes mAb 6D7 reactivity, suggesting that the 6D7 antigen is a glycoprotein and that the epitope is an O-linked sugar moiety. Taken as a whole, the characteristics of the 6D7 antigen do not correspond to a previously identified synaptic molecule. The notion that the 6D7 antigen may be a novel component of the synaptic ECM is currently being addressed by sequence analysis.

## 519.18

**CHARACTERIZATION OF DYSTROGLYCAN-LAMININ INTERACTION IN PERIPHERAL NERVE.** H. Yamada<sup>1</sup>, A. Chiba<sup>2</sup>, T. Endo<sup>2</sup>, I. Kanazawa<sup>3</sup>, K. P. Campbell<sup>4</sup>, T. Shimizu<sup>1</sup> and K. Matsumura<sup>1,\*</sup>. <sup>1</sup>Neurology & Neuroscience, Teikyo University School of Medicine, Tokyo 173, <sup>2</sup>Glycobiology, Tokyo Metropolitan Institute of Gerontology, Tokyo 173, <sup>3</sup>Neurology, Institute of Brain Research, Tokyo University School of Medicine, Tokyo 113, <sup>4</sup>HHMI, Physiology & Biophysics, University of Iowa College of Medicine, Iowa City, IA 52242.

Two of the dystrophin-associated glycoproteins,  $\alpha$ - and  $\beta$ -dystroglycan ( $\alpha$ DG and  $\beta$ DG, respectively), are encoded by a single gene and cleaved into two proteins by posttranslational processing. The peripheral nerve isoform of  $\alpha$ DG with a molecular mass of 120 kDa binds laminin-2, the endoneurial laminin isoform comprised of the  $\alpha 2$ ,  $\beta 1$  and  $\gamma 1$  chains. In congenital muscular dystrophy and *dy* mice deficient in laminin  $\alpha 2$  chain, peripheral myelination is disturbed, suggesting a role for the dystroglycan-laminin interaction in peripheral myelogenesis. To begin to test this hypothesis, we here characterized the DG-laminin interaction in peripheral nerve.  $\alpha$ DG and  $\beta$ DG were co-localized with laminin-2 surrounding the outermost layer of myelin sheath of peripheral, but not central, nerve fibers, while Dp116 and utrophin were localized in the Schwann cell cytoplasm.  $\alpha$ DG was extracted from the peripheral nerve membranes at pH 11, while  $\beta$ DG was not extracted at pH 11 or 12.  $\beta$ DG, which did not bind laminin in blot overlay, co-purified with  $\alpha$ DG by wheat germ agglutinin and laminin affinity chromatographies. Our results indicate that  $\alpha$ DG is an extracellular peripheral membrane glycoprotein which links  $\beta$ DG in the outer membrane of Schwann cell/myelin sheath with laminin-2 in the endoneurial basal lamina. We also present data which implicate glycosylation of  $\alpha$ DG in the interaction with laminin. Based on these results, we propose a novel model of the molecular organization of the DG-laminin interaction in peripheral nerve.

## 520.1

**MOLECULAR CLONING AND CHROMOSOMAL ASSIGNMENT OF HUMAN BRAIN-TYPE PHOSPHODIESTERASE 1/NUCLEOTIDE PYROPHOSPHATASE (PD-1 $\alpha$ ) GENE.** Hirovuki Kawagoe, Osamu Soma, Junko Goji, Joji Inazawa, Hajime Nakamura, and Kimihiko Sano\*. Department of Pediatrics, Kobe University School of Medicine, Kobe 650 Japan, and <sup>8</sup>Department of Hygiene, Kyoto Prefectural Medical College, Kyoto 602 Japan

Phosphodiesterase 1/nucleotide pyrophosphatase is a widely expressed ectoenzyme. This enzyme cleaves phosphosulfate, pyrophosphate, and phosphodiester bond. Although phosphodiesterase 1/nucleotide pyrophosphatase activity was found in most of human organs and body fluids including blood, cerebrospinal fluid, bile, and seminal fluid, the physiological function of this enzyme has not been known. In a previous study, we have cloned brain-type cDNA for this enzyme from rat brain and designated PD-1 $\alpha$ . In situ hybridization analysis demonstrated that PD-1 $\alpha$  mRNA is predominantly localized in choroid plexus epithelial cells, pigment epithelial cells of the eye, and the cells in granular layer of the cerebellum. In this study we have isolated cDNA and genomic DNA encoding human PD-1 $\alpha$ . Human PD-1 $\alpha$  cDNA has a 2,589-nucleotide open reading frame encoding a polypeptide of 863 amino acids with a calculated  $M_r$  of 99,034. Northern blot analysis revealed that human PD-1 $\alpha$  transcript was present in brain, kidney, and placenta. The data-base analysis showed that human PD-1 $\alpha$  was identical with human Autotaxin (ATX), a novel tumor motility-stimulating factor, except that human PD-1 $\alpha$  lacks 156 nucleotides and 52 amino acids of human ATX. Human PD-1 $\alpha$  and human ATX are likely to be the alternative splicing products from the same gene. The 5' region of human PD-1 $\alpha$  gene contains four putative binding sites of transcription factor Sp1 without typical TATA or CAAT box and there is a potential octamer binding motif in intron 2. From the result of fluorescence in situ hybridization, human PD-1 $\alpha$  gene is located at chromosome 8q24.1. These results give a new insight into a physiological function of phosphodiesterase 1/nucleotide pyrophosphatase.

## 520.3

**POLYPEPTIDES LOCATED IN THE PLASMA MEMBRANES OF SYNAPTIC JUNCTIONS AND PUNCTA ADHAERENS JUNCTIONS IN THE RAT BRAIN MAY BE ECTO-KINASES.** R. S. Lasher\* and P. F. Erickson†. Depts. of C & S Biology and Medicine†, Univ. Colorado Med. Sch., Denver, CO 80262.

Previous work, using the monoclonal antibody (MAb) F4 and rabbit monospecific antibodies to urea-soluble polypeptides from synaptic junctions, indicated that at least four of these polypeptides are associated almost exclusively with the plasma membrane (PM) of the synaptic junction (SJ) and puncta adhaerens (PA) junctions, and that they share a common extracellularly-oriented epitope [R. S. Lasher and P. F. Erickson. 1993. *Neurosci. Abstr.* 19:701]. Characterization of these polypeptides has been expanded further by probing Western blots of 1 and 2-dimensional (D) gels of urea-soluble SJs with another MAb, 40-47:11. This MAb recognizes some portion of the peptide GTPHYLAPE, a conserved sequence in the catalytic domain of a number of protein kinases [C. H. Hagedorn, et al. 1990. *FEBS Lett.* 264:59]. In addition to this peptide, 40-47:11 reacts strongly with the catalytic subunit of cAMP-dependent protein kinase (PK) and with phosphorylase kinase, but only weakly with Ca/calmodulin-dependent PK II. Probing 1- and 2-D blots with 40-47:11 indicates that it reacts with a large number of polypeptides, including those seen to react with MAb F4 and the monospecific rabbit antibodies. Electron microscopy of Vibratome sections of rat cerebellum (ABC method), as well as unfixed and fixed synaptosomes (ABC method and immunogold), indicates that 40-47:11 recognizes an extracellularly-oriented epitope associated with PMs of SJs and PA junctions. In addition, in prefixed tissue, immunoreactivity is associated with the presynaptic dense projections, synaptic vesicles and the postsynaptic density. Both ABC and immunogold methods indicate that the epitope is also associated with filaments which bridge the synaptic cleft. These data are consistent both with the observation that ecto-kinase activity may play a role in synapse formation [Y. Kuroda et al., 1992. *Neurosci. Lett.* 135:255], and with the role of phosphorylation/dephosphorylation in the maintenance of adhaerens junctions [T. Volberg et al., 1992. *EMBO J.* 11:1733]. (Supported by NSF IBN-9320823).

## 520.5

**NT75 IS A NERVE TERMINAL PROTEIN COMPLEX.** T. C. Ritchie\* and J. D. Coulter. Dept. of Anat. & Neuroscience Program, University of Iowa, Iowa City, IA 52242.

NT75, the S-7B8 antigen, is a neuron-specific 75 kDa membrane protein concentrated in nerve terminals in the superficial spinal dorsal horn and selected synaptic regions in brain. Although virtually all neurons are capable of expressing NT75, the protein is maintained at high levels only in certain populations of neurons. NT75 expression is differentially regulated in distinct neural systems in normal adults and is modulated in a subset of spinal neurons in response to adjuvant-induced hyperalgesia. During development, expression of NT75 is tightly correlated with synaptogenesis and the onset of synaptic transmission. NT75 was purified from rat brain membranes with serial ion exchange and immunoaffinity chromatography and preparative SDS-PAGE. When highly purified NT75 is subjected to reducing SDS-PAGE, the protein resolves primarily to two bands of Mr 29 (p29) and 17 kDa (p17). Densitometry shows NT75 to be composed of p29 and p17 in a molar ratio of 2:1. Monoclonal and polyclonal antibodies to purified p29 stain NT75, p29 and two intermediate bands on Western blots. Tissue staining of rat CNS with p29 antibodies is comparable to that exhibited by the S-7B8 antibody, which is more highly reactive to the NT75 complex. Biochemical studies show purified p29 has a tendency to form disulfide linked homopolymers. Partial sequence obtained to date indicates p29 is unique. (NS23783)

## 520.2

**SURFACE PROTEIN PHOSPHORYLATION BY ECTO-PROTEIN KINASE C: ROLE IN CELLULAR HOMEOSTASIS.** E. Kornecki\*, A. Babinska, H.-A. Yang and Y.H. Ehrlich. Department of Cell Biology and Anatomy, SUNY HSC at Brooklyn, NY 11203, and CSI/IBR Center for Developmental Neuroscience, CUNY at The College of Staten Island, NY 10314.

Neurons and platelets release ATP that phosphorylates specific proteins on the cell surface. We have reported recently that this activity is catalyzed by several types of ecto-protein kinases (PKs), including enzymes with the catalytic specificity of novel and atypical isozymes of protein kinase C (Hogan et al., *J. Neurochem. in press*). Ecto-PKC with a low  $K_m$  for ATP (<1 $\mu$ M) was found to operate on the surface of nonstimulated cells, where it may play a role in cellular homeostasis. We tested this hypothesis in experiments conducted with human platelets. Normal hemostasis maintains platelets in a discoid shape and prevents them from aggregating spontaneously in the circulation. In the present study, we used a specific anti-PKC monoclonal antibody termed M.Ab.1.9. M.Ab.1.9 recognizes the catalytic domain of PKC and inhibits PKC activity without affecting other known protein kinases. Preincubation of intact human platelet suspensions with M.Ab.1.9 inhibited ecto-PKC activity. Concurrently, M.Ab.1.9 induced platelet aggregation and secretion. This platelet activation by M.Ab.1.9 was direct and did not require the addition of any known platelet agonists. We propose that constitutive ecto-PKC produces a steady-state of phosphorylation of surface proteins that plays an important role in the maintenance of homeostatic balance. Initial studies with primary neurons cultured from embryonic brain suggest that a similar mechanism plays a role in neuronal survival.

## 520.4

**SYNVEICLIN: A NOVEL 27 KD PROTEIN THAT IS A COMMON COMPONENT OF SMALL CLEAR AND LARGE DENSE-CORE REGULATED SECRETORY VESICLES.** C.-J. Jeng and E. S. Schweitzer\*. Department of Neurobiology, UCLA School of Medicine, Los Angeles, CA 90025-1763.

As part of a search to identify new components of the secretory apparatus in neuronal cells, we have isolated a monoclonal antibody that recognizes a 27 kD vesicle-specific protein in PC12 cells. This 27 kD protein is an integral membrane protein that is found in both small clear synaptic-like vesicles and large dense-core catecholaminergic vesicles. All of the 27 kD protein can be immunoprecipitated by antibodies against another vesicle protein, SV2. Immunohistochemical analysis and Western blot data indicate that the 27 kD protein is present in adrenal medullary cells but not in adrenal cortical cells, and in gray matter of the cerebral cortex but not in white matter or cerebellum. It is also present in endocrine, but not exocrine, cells in the pancreas. These data suggest that this 27 kD protein, which we have named synvesiclin, is specifically expressed in neural and endocrine cells, where it is localized to regulated secretory vesicles.

We have used the monoclonal antibody against synvesiclin to screen a  $\lambda$ gt11 expression library of PC12 cDNA, and have isolated an insert containing a partial coding sequence for a novel protein. A probe made from the insert hybridizes to both a 2.4 kb and a 3.9 kb transcript in PC12 cells RNA, but only to the 2.4 kb transcript in RNA from rat brain cortex. Using this same insert, we have re-screened the cDNA library to obtain the full-length cDNA. We are now sequencing these inserts to determine the complete primary sequence of synvesiclin.

## 520.6

**IMMUNOREACTIVITY FOR PLASMA MEMBRANE CALCIUM ATPASE IN EDINGER WESTPHAL SYNAPTIC TERMINALS.** J. L. Fujii\* & F. T. Su. Dept. of Anatomy & Cell Biology, Wayne State U. Sch. of Med., Detroit, MI 48201

The plasma membrane calcium ATPase pump (PMCA) is a high affinity calcium pump that is typically associated with the plasma membrane. Using the monoclonal antibody 5F10 (Affinity Bioreagents), we have examined PMCA expression in the neurons of the chick Edinger Westphal (EW) nucleus. Immunoreactivity for PMCA is undetectable in cell bodies located in the EW nucleus. However, PMCA immunoreactivity is clearly visible in EW synaptic terminals located in the ciliary ganglion. PMCA immunoreactivity resembles immunoreactivity for the synaptic vesicle antigen SV-2 and co-localizes with immunoreactivity for substance P and enkephalin. While PMCA immunoreactivity is most striking in EW calyciform terminals, it is also present in boutons.

The presence of PMCA immunoreactivity in EW synaptic terminals was confirmed using transmission electron microscopy. Ultrathin sections were cut of tissue stained as frozen sections using a biotinylated secondary antibody, HRP avidin complex, DAB, and silver intensification. Surprisingly, reaction product was primarily associated with clusters of synaptic vesicles rather than plasma membrane. Synaptic vesicles isolated from Torpedo electric organ also stain positive for PMCA immunoreactivity in immunodot assays. Control experiments show that Torpedo vesicles are immunoreactive for SV-2 and negative for SERCA (sarcoplasmic/endoplasmic reticulum calcium ATPase).

## 520.7

ISOLATION OF A NOVEL cDNA CLONE, mc49, FROM TORPEDO ELECTRIC ORGAN USING AN IMMUNOFLUORESCENCE-BASED EXPRESSION CLONING METHOD. M.A. Nastuk<sup>1</sup>, S. Davis<sup>2</sup>, G.D. Yancopoulos<sup>2</sup> and J.R. Fallon<sup>1</sup>. <sup>1</sup>Worcester Foundation for Experimental Biology, Shrewsbury MA 01545 and <sup>2</sup>Regeneron Pharmaceuticals, Inc., Tarrytown NY 10591.

We have identified a unique cDNA clone from a Torpedo electric organ library using modified expression cloning methodology. The procedure that we developed utilizes fluorescence immunocytochemistry to stain monolayers of transfected COS cells in an antibody- or ligand-based screening strategy. Positive COS transfectants are identified by immunofluorescent visualization of expressed epitope or ligand binding site. Positively staining cells are harvested with micropipettes; plasmid DNA is extracted, amplified, and re-transfected into fresh COS. Clonal cDNA can be obtained after two amplification rounds. Thus, this procedure is rapid as well as affording the opportunity to observe the subcellular distribution of the products of transfected genes expressed by single cells.

We applied the antibody-based version of our expression cloning method in our ongoing effort to characterize novel molecules involved in synaptic differentiation. We screened a cDNA library derived from Torpedo electric organ, a tissue rich in cholinergic synapses. Our probe was an antibody that recognizes a carbohydrate-containing epitope located on the candidate agrin receptor dystroglycan, as well as on several other synaptic proteins (Bowe et al., *Neuron* 12, 1994). We isolated and sequenced a cDNA clone encoding a polypeptide with a predicted molecular weight of approximately 49kD. The protein contains a putative signal sequence, a cysteine-enriched central region, and no apparent transmembrane domains. Database searches show that mc49 has limited homology to certain sulfotransferases. Northern blotting of various Torpedo tissues reveals that mRNA encoding mc49 is highly enriched in electric organ. Further characterization of the mc49 gene product is underway. Supported in part by NIH HD23924.

## 520.9

DISTRIBUTION OF CYTOSKELETAL PROTEINS TALIN, VINCULIN AND  $\alpha$ -ACTININ IN NORMAL AND DENERVATED RANA CUTANEOUS PECTORIS MUSCLE. R.E. LINDSEY and D. C. LINDEN.\* Department of Biology, Occidental College, Los Angeles, CA 90041.

The distribution of cytoskeletal proteins talin, vinculin and  $\alpha$ -actinin was studied in normal and denervated *Rana pipiens* cutaneous pectoris muscle using monoclonal antibodies and fluorescently labeled secondary antibodies. These proteins co-localize with clustered acetylcholine receptors (AChRs) at the neuromuscular junction (nmj) and myotendinous areas. Our goal was to study the role of these molecules in the formation of AChR clusters and organization of the synaptic extracellular matrix (possibly via integrins).

Our results at innervated nmjs show localization of talin, vinculin and  $\alpha$ -actinin within rhodamine- $\alpha$ -bungarotoxin-visualized AChR-enriched areas. In denervated muscles, there is localized staining of fluorescent rhodamine- $\alpha$ -bungarotoxin and antibodies against talin, vinculin and  $\alpha$ -actinin at regions of former nmjs. The extent of co-localization at perijunctional and extrajunctional areas in denervated muscle is being determined. We speculate that the muscle itself directs these cytoskeletal molecules to synaptic or extrajunctional cluster areas. The motor neuron is then responsible for maintaining synaptic structure. This work was supported by grants from the NSF (BIR9300299) and the California Foundation for Biochemical Research.

## 520.11

DIVALENT CATION EFFECT ON INCORPORATION OF EXOGENOUS GANGLIOSIDES INTO RAT BRAIN SYNAPTOSOMES.

M. Dittmore, R. Cabeza and L.N. Irwin\*. Department of Biological Sciences, University of Texas at El Paso, TX 79968.

Exogenous gangliosides are incorporated into brain slices *in vitro* to varying degrees as a function of the perfusing solution (Irwin and Cabeza, *Soc. Neurosci. Abstr.* 20: 708). When slices are incubated with low calcium, the amount of [<sup>3</sup>H]-gangliosides incorporated into a stable membrane compartment is changed. To further elucidate the influence of divalent cations on the distribution of incorporation we incubated synaptosomes for 30 min with [<sup>3</sup>H]-gangliosides, then exposed them for 1 h to varying calcium/magnesium ratios (0.1 mM [Ca<sup>2+</sup>]/3.6 mM [Mg<sup>2+</sup>] to 2.5 mM [Ca<sup>2+</sup>]/1.2 mM [Mg<sup>2+</sup>]). After rinsing with 10% fetal calf serum and 0.1% trypsin, synaptosomes were extracted with chloroform/methanol (2:1). Gangliosides were isolated from this lipid fraction by silicic acid chromatography and resolved by TLC into the five major mammalian brain gangliosides (M1, D1a, D1b, T1b, Q1b). Individual bands were scraped and counted by liquid scintillation. Incorporation of exogenous gangliosides was 32% less at 1.3 mM [Ca<sup>2+</sup>]/2.4 mM [Mg<sup>2+</sup>] than under normal conditions (2.5 mM [Ca<sup>2+</sup>]/1.2 mM [Mg<sup>2+</sup>]). This decrease was reversed at both higher and lower calcium/magnesium ratios, suggesting the possibility of distinct mechanisms -- one attributable to calcium, the other to magnesium. Different calcium/magnesium ratios did not differentially affect the membrane incorporation of individual gangliosides, suggesting that these mechanisms operate on all gangliosides equally. Supported by RCMJ Grant G12-RR-08124 from the National Center for Research Resources, NIH; and by the J. Edward and Helen M. C. Stern Endowment.

## 520.8

ISOLATION OF A TRANSMEMBRANE PROTEIN COMPLEX FROM THE CHOLINERGIC NERVE TERMINALS OF THE ELECTRIC ORGAN OF *N. BRASILIENSIS*. W.J. Sunderland and Steve Carlson\*. Dept. of Physiology and Biophysics, University of Washington, Seattle, Wa. 98195.

The neuromuscular junction is a highly specialized cell-cell interface. The nerve terminal shows a polarized structure with synaptic vesicles collecting at presynaptic sites directly opposite of post-synaptic clusters of nicotinic acetylcholine receptor (NACHR). The intervening synaptic basement membrane contains unique components such as acetylcholine esterase, agrin and S-laminin. It has been hypothesized that proteins in the presynaptic membrane may interact with the synaptic basement membrane to establish the nerve terminal's polarity. We have adapted a method from Miljanich (1982), for the immunopurification of nerve terminals from the electric organ of *N. Brasiliensis*. We begin with the standard synaptosomal preparation which is far from pure as indicated by the presence of NACHR, an indicator of post-synaptic contamination, and laminin and indicator of extracellular matrix. We further purify nerve terminals by immunoprecipitating with an antibody directed to an epitope of the SV2 proteoglycan that appears on the nerve terminal surface. These immunopurified membranes show greatly reduced levels of NACHR, but still contain laminin. In addition it is possible to immunoprecipitate nerve terminals with an anti-laminin antibody. We conclude that laminin is bound to the surface of our immunopurified nerve terminals. The form of laminin found on the nerve terminal stains with both an anti-S-laminin anti-sera (GP-1) and with an anti-HNK-1 antibody. If we solubilize immunopurified nerve terminals with TX-100, and immunoprecipitate with an anti-laminin antibody, we bring down the cytoskeletal protein spectrin. We conclude that our techniques have allowed us to isolate a transmembrane protein complex linking together the cytoskeleton and extracellular matrix at the site of the nerve terminal. Total staining of this protein complex reveals more than 30 proteins. We are currently looking for the transmembrane protein(s) involved in this linkage.

## 520.10

MOLECULAR AND BIOCHEMICAL CHARACTERIZATION OF SAP97 FROM RAT BRAIN AND BACTERIA EXPRESSED RECOMBINANTS S. Kuhlendahl\*, W.J. Chung, S. Reuver, C.C. Garner. Neurobiology Research Center/Department of Cell Biology, University of Alabama at Birmingham, Birmingham, Alabama 35294.

The synapse associated protein SAP97 is a member of the MAGUK family of membrane associated guanylate kinase homologs that is recruited to synaptic junctions and other sites of cell-cell contact. SAP97 exists in both a cytosolic and membrane bound form. In the latter it is highly enriched in synaptic junctional preparations. We have isolated cDNA clones encoding six different alternatively spliced isoforms of SAP97. The carboxy-terminal region of all isoforms shows high homology to soluble low molecular weight (Lwt) guanylate kinases (GK). Lwt GKs convert GMP to GDP, and are required for the synthesis of RNA and DNA, and indirectly for assembly of microtubules, protein synthesis, vesicular trafficking, *ras* mediated signal transduction pathways, and utilization of cGMP as a second messenger. Finding SAP97 at the plasma membrane suggests that membrane bound GKs may perform some novel function. To address the question whether SAP97 encodes an active GK, nucleotide binding studies and *in vitro* GK assays were performed on both recombinant bacteria expressed variants as well as on SAP97 expressed in rat brain. The *E. coli* expressed SAP97 failed to show GK activity. In contrast GK activity is found in both the soluble and membrane fractions of synaptosomes. Finding GK activity in the synaptic junctional membrane fractions, where SAP97 is highly enriched, and where Lwt GKs are absent, suggests that SAP97 may be an active membrane bound GK.

## 521.1

REGULATION OF THE HUMAN 5-HT<sub>2A</sub> RECEPTOR PROMOTER ACTIVITY BY cAMP, TPA AND DIALYZED SERUM. Q.S. Zhu\* and J.C. Shih. Dept. of Mol. Pharm. and Tox., Sch. of Pharmacy, Univ. of Southern California, 1985 Zonal Ave., Los Angeles, CA 90033.

For the human 5-HT<sub>2A</sub> receptor gene, we have identified a 0.74 kb HaeIII/PvuII promoter fragment which consisted of two sub-fragments: the 0.35 kb HaeIII/BamHI fragment, and the 0.39 kb BamHI/PvuII fragment. Both fragments exhibited promoter activity in a transient transfection assay and may be two alternative promoters for the gene. The 0.39 kb fragment contained a CRE-like sequence 5' TGAAGTCA 3'. However, 8-Br-cAMP, a PKA activator, did not have significant effect on its promoter activity (124%). TPA, an activator of PKC, increased the promoter activity of the 0.39 kb fragment slightly (160%). Since no AP-1 binding sequence has been found in this fragment, the increase may be indirect. When the HeLa cells were grown with dialyzed fetal bovine serum instead of control serum, the promoter activity was significantly increased in both the 0.35 kb (246%) and the 0.39 kb (797%) fragments, consistent with radioligand binding data. When 5 µM of 5-HT was added to the dialyzed serum, the promoter activity was not reduced to that of the control, suggesting that this increase was not due to the loss of 5-HT in the dialyzed serum. Gel retardation assay showed that binding of a nuclear protein to the 0.35 kb fragment was decreased. The significance of this DNA-binding protein will be discussed. (Supported by NIMH grants R37 MH39085 (MERIT Award), K05 MH00796 (Research Scientist Award), R01 MH37020 and Welin Professorship).

## 521.3

MODULATION OF EXPRESSION OF THE RAT BRAIN CREATINE KINASE (BCK) GENE. G.B. Molloy<sup>1</sup>, C.D. Wilson<sup>2</sup> and E.V. Kuzhikandathil<sup>3</sup> University of Delaware, Newark, DE<sup>1</sup>; Zeneca Pharmaceuticals Inc., Wilmington, DE<sup>2</sup> and University of North Carolina, Chapel Hill, N.C.<sup>3</sup>

Creatine kinases (CK) catalyze the reversible transfer of a high energy phosphate group between creatine phosphate and ADP to regenerate ATP in cell types which expend ATP rapidly. In primary rat brain cell cultures BCK mRNA levels are high in astrocytes and oligodendrocytes and low in neurons (J. Neurochem. 59: 1925-1932 [1992]). Here we asked if this pattern of BCK expression was characteristic of some established neuronal and glial cell lines and whether BCK expression could be modulated. BCK mRNA and protein were high in both the RT4 peripheral neurotumor stem cell RT4-AC36 and its glial cell derivative RT4-D6 but, conversely, were 10-fold lower in the neuronal derivative RT4-E5 and undetectable in the neuronal RT4-B8. Cell confluence increased BCK enzyme activity in RT4-D6 by 7-fold and in RT4-E5 by 4-fold; BCK protein and mRNA were also increased at high cell density. These increases were not solely due to an elevation in cAMP since forskolin and IBMX had no significant effect. Similarly, BCK mRNA was found to be extremely low in mouse neuroblastomas NS20Y and N1E-115 but 10-fold higher in NG108-15, a hybrid cell composed of a C1300 neuroblastoma and a rat C6 glioma. These results indicate that BCK expression is highest in cells displaying glial properties and may suggest BCK is expressed early during the differentiation of glial progenitor cells.

In addition, we show BCK mRNA is dramatically induced (>10-fold) by butyric acid (BA) in NIH 3T3 and Balb/c 3T3 fibroblasts. Induction is due to increased BCK transcription and not altered BCK mRNA stability. Induction is rapid (maximal in 6 hrs), does not require de novo protein synthesis and is specific since it does not occur with GABA, AABA or γ-OH-BA. This may aid the identification of the nuclear proteins responsible for repression of BCK.

## 521.5

GLUTAMATE RECEPTOR-INDUCED CREB PHOSPHORYLATION AND IMMEDIATE EARLY GENE EXPRESSION IN GLIAL CELLS OCCUR THROUGH PROTEIN KINASE C ACTIVATION. M. Pende\* and V. Gallo. Lab. Cell. Mol. Neurophysiol., NICHD, NIH, Bethesda, MD 20892.

The intracellular events leading to gene expression after non-NMDA receptor stimulation were analyzed in primary oligodendrocyte progenitor cells (O-2A). Down regulation of PKC by phorbol esters (TPA 10 nM for 24 h) and pretreatment with bisindolylmaleimide (0.5-5 µM) blocked the increase of *NGFI-A* and *c-fos* mRNA levels induced by kainate (300 µM). Incubation with kainate caused 153% increase in the specific binding of [3H]phorbol ester to intact O-2A cells, indicating a translocation of PKC to the membrane. Within 5-10 minutes after stimulation of non-NMDA receptors by kainate, the transcription factor CREB was phosphorylated on serine-133, as assessed by immunoblot analysis with an antiserum specific for the phosphorylated form of CREB. TPA (100 nM) and the muscarinic receptor agonist carbachol (100 µM) had a similar effect on CREB phosphorylation. Surprisingly, forskolin (100 µM) and growth factors PDGF and bFGF (10 ng/ml) failed to induce CREB phosphorylation in O-2A progenitor cells. Bisindolylmaleimide (5 µM) completely counteracted the effect of kainate, TPA and carbachol on CREB. The specificity of bisindolylmaleimide as PKC inhibitor was tested in PC12 cells. Bisindolylmaleimide (5 µM) was able to antagonize only TPA-induced phosphorylation of CREB in PC12 cells, whereas the effects of forskolin, NGF and ionomycin remained unaffected. Immunoblot analysis with a pan anti-PKC antibody of cellular fractions from O-2A progenitors demonstrated PKC translocation to the nucleus after phorbol esters treatment. These results define a novel pathway for CREB activation in neural cells that is dependent on PKC.

## 521.2

REGULATION OF CALRETININ GENE EXPRESSION IN PRIMARY CULTURES OF CEREBELLAR NEURONS

K.I. Strauss\*, A.M. Marini<sup>1</sup>, J. Kuznicki<sup>2</sup> & D.M. Jacobowitz<sup>3</sup> NIMH/LCS, & <sup>1</sup>Neurology Dept/USUHS, Bethesda, MD 20892 Calretinin (CR), an EF-hand calcium binding protein (homologous to calbindin D28k ~58%), is predominantly localized in discrete sets of brain neurons. Aside from binding calcium, no function has been found for this protein. CR appears early in embryonic rat, mouse, and chick cerebellum. Cerebellar granule cells (CGC), unipolar brush cells (UBC), Golgi and Lugaro (but not Purkinje) cells demonstrate intense CR staining. At postnatal day 8, rat CGC can be removed and maintained *in vitro*. In CGC cultures, CR is expressed in large (UBC or Lugaro) cells which constitute only a small proportion of the neurons in the preparation. From day 1 *in vitro* (DIV0-1), the quantity of CR mRNA rises and peaks at ~200% the initial level at DIV2-3. During DIV3-6 CR mRNA decreases to ~18% of the peak level and remains at this low level. We are using mouse CGC cultures to investigate the transcriptional regulation of the CR gene through analysis of its putative promoter region. Gel mobility shift assays will identify specific binding domains for factors in nuclear extracts, and transfected luciferase reporter vectors will detect potential neuron-specific regulatory domains for the mouse CR gene in CGC and other cultured cells.

## 521.4

REGION SPECIFIC EFFECTS OF HALOPERIDOL AND CLOZAPINE ON NEUROTENSIN AP-1 BINDING PROTEINS IN THE RAT BRAIN M.B.

Adams\* and D.M. Dorsa Depts. of Pharmacology, and Psychiatry, Univ. of WA, Seattle WA 98195 and GRECC, VAMC, Seattle WA 98108.

Our laboratory has previously demonstrated that administration of typical antipsychotic drugs (APD) lead to a dramatic increase in the transcription of the neurotensin/neuromedin N (NT/N) gene in neurons of the dorsolateral striatum (DLST) and shell sector of the nucleus accumbens (sNA). On the other hand atypical neuroleptics have little effect on NT/N mRNA levels in the DLST, but nonetheless cause a significant increase in NT/N mRNA in the sNA. To further understand these region specific effects, in the present studies we have attempted to determine which nuclear transcription factors interact with the neurotensin promoter in the DLST and sNA under both basal and stimulated conditions. The upstream promoter of the NT promoter contains several synergistically interactive response elements, including an AP-1 element. Using gel shift assays, we have determined that both DLST and sNA nuclear extracts from animals given saline injections contained little if any NT AP-1 binding activity. However, following haloperidol administration there is a significant induction of NT AP-1 binding activity in both the DLST and NA. Clozapine treatment only slightly induces protein binding to the NT AP-1 sequence in the DLST but induces a similar amount of protein binding to this element in the sNA as haloperidol. Thus, haloperidol and clozapine share the ability to influence AP-1 transcription factor expression in the sNA but not in the DLST. Since previous studies have suggested that the protein induced in the sNA is not c-fos but another fos related antigen, further studies using specific antisera will be required to identify the factors involved and whether the factors differ with acute and chronic APD treatment. Supported by the VA, NS20311 and MCBTG, T32GM07270.

## 521.6

ANTISENSE INHIBITION OF c-JUN BLOCKS NEUROTENSIN GENE INDUCTION IN PC12 CELLS. P.R. Dobner\* and R. J.

Harrison. Dept. of Mol. Genetics and Micro. and Prog. in Neurosci., Univ. of Mass. Med. Cent., Worcester, MA 01655. The tridecapeptide neurotensin (NT) likely has multiple signaling functions in the CNS, including the modulation of dopaminergic pathways. The NT promoter which contains AP-1, CRE and GRE motifs appears to integrate diverse signals resulting from stimulation by NGF, glucocorticoids, and adenylate cyclase activators in PC12 cells. Co-transfection experiments have provided evidence that c-Jun plays a key role in NT gene activation through interactions with the glucocorticoid receptor and one or more CREB/ATF factors. To examine the importance of c-Jun for NT gene induction by inducers, PC12 cells were co-transfected with either a c-Jun antisense expression vector (pCMV-NUJ) or several control plasmids together with a pNT-Luc reporter plasmid and subsequently treated with combinations of NGF, lithium, dexamethasone, and forskolin. Co-transfection of increasing amounts of pCMV-NUJ resulted in a marked dose-dependent attenuation of NT gene induction by all inducer combinations tested. The induction of pNT-Luc expression was inhibited by 60-70% at the highest input level of pCMV-NUJ tested. In contrast, neither the pCMV2 vector nor a construct driving the expression of a truncated c-Jun sense RNA (pCMV-ΔJUN) inhibited expression. Interestingly, co-transfection of a Jun B antisense construct (pCMV-NUJB) potentiated induction in a dose-dependent manner. These results provide strong evidence that c-Jun plays a key role in the activation of NT gene expression and indicate that Jun B may be involved in dampening induction.

## 521.7

**Purification and Identification of Chronically Induced Fras (Fos-Related Antigens)** B.T. Hope<sup>1</sup>, H.E. Nye<sup>2</sup>, J.-S. Chen<sup>2</sup>, N. Hiroi<sup>2</sup>, and E.J. Nestler<sup>2</sup>. <sup>1</sup>Tufts University School of Medicine, Boston, MA 02111, <sup>2</sup>Yale University School of Medicine, New Haven, CT 06508.

We and others have observed a set of putative transcription factors, called chronic Fras, which are gradually induced in rat brain specifically in those regions that are repeatedly activated by a specific drug or treatment, including cocaine, morphine, kainate and electroconvulsive seizures, tranylcypromine, haloperidol, apomorphine following 6-OHDA lesions, and these lesions alone. By 2D gel electrophoresis, we have identified four chronic Fras (MW 35-37 kDa) which are not significantly induced by acute treatment but accumulate to considerable levels with repeated treatments and then persist with a half-life of ~7 days. At least in some brain regions, chronic Fras heterodimerize with JunD to form a long-lasting AP-1 complex which we have shown to display different DNA binding characteristics compared to that of the acutely induced AP-1 complex. Thus, chronic Fras may be capable of causing long-lasting changes in gene expression that are unique to chronic, versus acute or control, conditions. Immunochromatographic analysis of the chronic Fras suggests a similarity to  $\Delta$ FosB. However, their relative time courses for induction, and their migration by 2D gel electrophoresis, show that the chronic Fras are not  $\Delta$ FosB *per se*. To positively identify the chronic Fras, we have purified these proteins to homogeneity using a combination of ion exchange chromatography and 2D gel electrophoresis. We are presently obtaining partial amino acid sequences from peptide digests of the purified proteins. Eventual identification of the corresponding cDNA sequences of the chronic Fras will allow future experiments to study a causal role for chronic Fras in biochemical and behavioral changes following chronic treatments.

## 521.9

**REGULATION OF  $\Delta$ FOSB AND CHRONIC FRAS BY ELECTROCONVULSIVE SEIZURE (ECS) AND COCAINE TREATMENTS.** J.S. Chen<sup>1</sup>, N. Hiroi<sup>1</sup>, M.B. Kelz<sup>1</sup>, B.T. Hope<sup>1</sup>, Y. Nakabeppu<sup>2</sup> and E.J. Nestler<sup>1</sup>. Laboratory of Molecular Psychiatry, Yale University School of Medicine, New Haven, CT; <sup>2</sup>Dept of Biochem., Medical Institute of Bioregulation, Kyushu University, Fukuoka 812, Japan.

Repeated administration of ECS, drugs of abuse and other agents has been shown to induce several long-lasting Fos-related antigens (Fras), named chronic Fras. The slow induction and persistent expression of the chronic Fras suggest that these proteins may mediate some long-term biochemical changes in the brain. Although there are some similarities between the chronic Fras and  $\Delta$ FosB in terms of immunoreactivity and apparent molecular weight on 1D gels, the identity of the chronic Fras is still unknown. In the present study, we analyzed the regulation of  $\Delta$ FosB expression by ECS and cocaine treatments, and characterized the chronic Fras by 2-D gel Western blotting.  $\Delta$ FosB mRNA and protein were rapidly and transiently induced in cortex by acute ECS and in striatum by acute cocaine treatment. Induction of  $\Delta$ FosB mRNA peaked at 0.5 h and returned to control levels by 12 h after a single ECS treatment.  $\Delta$ FosB protein was induced maximally at 1 h and disappeared by 24 h after the ECS treatment. This induction pattern is different from the slow and persistent induction pattern of the chronic Fras. In 2D gels,  $\Delta$ FosB and the chronic Fras migrated at different positions. Since the chronic Fras do not migrate further to the acidic end of the IEF gel than  $\Delta$ FosB, they are unlikely to be phosphorylated isoforms of  $\Delta$ FosB. Therefore, chronic Fras appear to be novel Fos-related proteins. Lack of the C-terminal antigen of FosB, which constitutes the major transactivation domain, in these chronic Fras suggests that they may be negative regulators for AP-1 mediated transcription.

## 521.11

**HSV-MEDIATED F1/GAP43 GENE TRANSFER: EVIDENCE FOR F1/GAP43-mRNA INDUCTION AND KNOCKDOWN OF KAINATE-INDUCED F1-mRNA.** A. Routtenberg<sup>1</sup>, P.A. Serrano<sup>1</sup>, R.L. Howell<sup>1</sup>, & I. Cantallero<sup>2</sup>. Cresap Neuroscience Laboratory, Northwestern Univ., Evanston, IL 60208; <sup>2</sup>Harvard Medical School and McLean Hospital, Belmont, MA 02178.

The herpes simplex virus (HSV-1) is an efficient vector for introducing foreign genes into postmitotic neurons (TINS, 1991, 14:428). Here we induce or knockdown F1/GAP-43 mRNA in rat granule cells which normally do not express this gene in the adult. We used HSV-F1/GAP43 cDNA to induce and HSV-mediated antisense to knockdown kainate-induced F1/GAP43-mRNA (see Cantallero, this meeting).

In the anesthetized rat, extracellular population responses in the dentate gyrus evoked by stimulation of perforant path fibers were used to guide the injections into the hilus for uptake by mossy fiber terminals (see Serrano, this meeting). The HSV-F1/GAP43 vector was injected unilaterally into the hilus. 24-72h post-injection the brain tissue was prepared for *in situ* hybridization using the rat antisense RNA probe corresponding to bases 779-1295 of the F1/GAP43 cDNA. The HSV-F1/GAP-43 cDNA was successfully introduced into granule cells as its mRNA was detected in both the dorsal and ventral blades 1-3d after viral injection. In adjacent granule cells no F1/GAP-43 mRNA was detected.

Kainate induces F1/GAP43 mRNA expression in granule cells peaking 24h after its application. To test the effect of the F1/GAP43 antisense on kainate-induced F1/GAP43-mRNA in granule cells, the HSV-F1/GAP43 antisense vector was injected unilaterally into the hilus 24h prior to kainate treatment administered s.c. (10mg/kg). 24h after kainate treatment, *in situ* hybridization was carried out. The anti-sense injected hippocampus showed a reduction of kainate-induced granule cell F1/GAP43 mRNA as compared to control injection of the HSV vector containing no exogenous cDNA. Control injection of the HSV vector did not alter kainate-induced F1/GAP43 mRNA levels.

Introduction of the F1/GAP43 gene or its antisense into granule cells of the adult rat may prove useful in elucidating both the sufficient and necessary roles, respectively, of F1/GAP43 in axonal growth in the *in vivo*, intact mammalian brain. Supported by grant MH25281-20 to A.R., NSF Post-doctoral grant to P.A.S., "La Caixa" Fellowship (Spain) to I.C. and HD24236 grant to R.L.N.

## 521.8

**PHARMACOLOGICAL CHARACTERIZATION OF COCAINE-INDUCED CHRONIC FRAS (FOS-RELATED ANTIGENS).**

H.E. Nye<sup>1</sup> and E.J. Nestler<sup>1</sup>. Lab of Molecular Psychiatry, Yale University School of Medicine, Dept.s of Psych. and Pharm., New Haven, CT 06508

Novel 35-37 kD Fos-like transcription factors are induced by chronic cocaine in the rat striatum (Str) and nucleus accumbens (NAC); regions implicated in many behavioral effects of this drug (*Neuron* 13:1235). In order to more completely characterize chronic Fra induction by cocaine, we examined the pharmacological aspects of this phenomenon. Chronic dose-response studies as well as manipulations of dosing intervals showed that a moderate dose of cocaine given at intermediate intervals for an intermediate period of time resulted in maximal chronic Fra induction in the Str, while the NAC tended to be more responsive to lower doses of chronic cocaine. We have also investigated the mechanism of chronic Fra induction by cocaine. Administration of the D1 antagonist, SCH 23390 (0.5mg/kg), prior to each of eight daily cocaine injections blocked chronic Fra induction in both the Str and NAC. The D2 antagonist, eticlopride (0.5 mg/kg), in the same paradigm induced chronic Fras when administered alone, but produced no further increase when combined with cocaine. Seven days of haloperidol (1 mg/kg) treatment also robustly induced chronic Fras in the striatum. Repeated co-administration of D1 (SKF 81297, 1 mg/kg) and D2 (quinpirole, 1 mg/kg) agonists, but not either agonist alone, increased chronic Fras in the Str. Finally, repeated administration of the specific dopamine uptake inhibitor, GBR-12909 (20 mg/kg), induced chronic Fras in the Str and NAC, while chronic blockade of other monoamine uptake systems (sertraline for serotonin, desipramine for norepinephrine) had no effect on these proteins. These studies provide evidence for dopaminergic mechanisms of chronic Fra induction by cocaine, and further characterize novel transcription factors that may underlie long-term changes in the brain elicited by cocaine.

**DISTINCTIVE ACTIVATION BY CHRONIC ELECTROCONVULSIVE SEIZURE TREATMENT OF TRANSCRIPTION FACTORS IN THE RAT BRAIN**

N. Hiroi<sup>1</sup>, J.-S. Chen<sup>1</sup>, E. J. Nestler<sup>1</sup>. Laboratory of Molecular Psychiatry, Yale University School of Medicine, 34 Park Street, New Haven, CT 06508

Electroconvulsive seizure (ECS) treatment is one of the most effective treatments for depression. We have previously demonstrated in the rat neocortex that chronic ECS induces transcription factors with apparent molecular weights of 35-37 kDa that were recognized as a doublet by antiserum raised against a conserved sequence of c-Fos and Fos-related antigens (FRAs) (M. Iadarola, NIH). We have now further characterized these "chronic FRAs" in various brain areas. Gel mobility shift assays showed that chronic ECS significantly induced proteins that bind to the AP-1 DNA consensus sequence in the prefrontal cortex, striatum, and amygdala and, to a lesser extent, in the hippocampus. Immunoblotting showed that the patterns of induction of c-Fos and the FRAs in the prefrontal cortex, striatum and amygdala by ECS were virtually indistinguishable. The AP-1 complex in the prefrontal cortex induced after chronic ECS was disrupted by antisera against FosB and against JunD. Preliminary immunoprecipitation studies showed that the FRAs are dimerized with Jun family member proteins in a region-specific manner. These results suggest that chronic ECS activates 35-37 kDa FRAs in many reward-related regions and that transcriptional activation of late-response genes in these brain regions by chronic FRA-Jun family heterodimers might underlie, at least partly, the therapeutic efficacy of ECS treatment.

**TRANSCRIPTION FACTORS AND SYNAPTIC PLASTICITY: PROTEIN F1/GAP-43 GENE EXPRESSION AND THE BASIC HELIX-LOOP-HELIX FAMILY.** W.R. KINNEY, R.K. MCNAMARA<sup>1</sup>, J. P. ROSENFIELD<sup>1</sup>, E. VALCOURT, AND A. ROUTTENBERG. CRESAP NEUROSCIENCE LABORATORY, NORTHWESTERN UNIV., EVANSTON, IL 60208; <sup>2</sup>UNIVERSITY OF FLORIDA, GAINESVILLE, FL 32610.

We have recently linked the induction of protein F1/GAP-43 and its mRNA in hippocampal granule cells by kainic acid (KA) to growth of their axons, the mossy fibers, in the adult rat. If this induction involves the F1 promoter/enhancer 5' flanking region, then it may be predicted that altered binding to specific recognition elements on the promoter will occur after KA administration. Analysis of recognition elements on the F1/GAP-43 gene revealed an arrangement, previously described in other genes (EMBO J., 1994, 13:3580), of multiple adjacent E-box elements, which are recognized by the basic Helix-Loop-Helix (bHLH) family of transcription factors (TFs). The presence of hippocampal TFs specifically binding to the E-box recognition element was established by selective blockade of binding both by cold competition and by an antibody to an E-box TF, MyoD1. Using a micro-dissected preparation enriched in granule cells, specific E-box binding was significantly reduced in kainate-treated animals. This was observed at 24 and 72 hr, but not before (3, 6 hr) or after (96 hr), paralleling in a general fashion the time of protein F1/GAP-43 mRNA induction by kainate. Since it is obvious that other TFs would likely be involved in F1/GAP-43 regulation, the lack of perfect parallelism is consistent with this fact.

To determine the generality of this E-box regulatory event, we studied 4 other situations where F1 expression has been increased: NGF treatment of PC12 cells, unilateral hilar lesions, long-term potentiation after 1 hr, and postnatal rat hippocampal development. In all 4 cases, decreased E-box binding preceded increased F1/GAP-43 mRNA expression. Converging evidence thus leads us to propose that E-box binding in the hippocampus act as a negative regulator of protein F1/GAP-43 gene expression. Proteins of the bHLH family would then be important for regulating axonal growth during both perinatal development as well as adult synaptic plasticity. (Supported by a Research Council of Canada Post-doctoral fellowship to R.K.M. and a NIMH grant MH25281-2 to A.R.).

## 521.13

DIFFERENCES IN RAT AND MOUSE HIPPOCAMPAL F1/GAP-43: CONSTITUTIVE mRNA EXPRESSION, KAINATE INDUCTION IN GRANULE CELLS, PROMOTER ACTIVITY IN TRANSGENIC MOUSE. U. Namgung, R. McNamara<sup>1</sup>, K.A. Paller<sup>2</sup>\*, and A. Routtenberg. Cresap Neuroscience Laboratory, <sup>1</sup>Department of Psychology, Northwestern University, Evanston, IL 60208; <sup>2</sup>University of Florida, Department of Psychiatry, Gainesville, FL 32610-0256

The induction by kainate (KA) of F1/GAP-43 mRNA observed in adult rat hippocampal granule cells (see Cantalupo et al., this meeting) was not observed in 3 different mouse strains. Though KA induced behavioral seizures similar to those in the rat, neither induction of F1/GAP-43 mRNA, nor subsequent mossy fiber sprouting observed in rat were detected in mouse.

The distribution of constitutive levels of F1/GAP-43 mRNA were noticeably different in mouse and rat. Quantitatively, F1/GAP-43 expression in rat was higher in CA3 than CA1 pyramidal cells, but equivalent in these two subfields in mouse. In CA3, F1/GAP-43 expression was significantly greater in rat than mouse, while in CA1, F1/GAP-43 expression in rat and mouse were equivalent.

These species differences may be related to F1/GAP-43 promoter activity. We studied this using a transgenic mouse (line 252) bearing a 6 kb rat F1/GAP-43 promoter/11 kb intron 1-lacZ reporter construct (J. Neurosci., 14:499, 1994). Reporter activity in hippocampal pyramidal subfields paralleled the distribution of rat F1/GAP-43 mRNA levels. No promoter activity was observed in granule cells paralleling its absence in both rat and mouse. Constitutive F1/GAP-43 expression pattern is thus determined by recognition elements present on the F1/GAP-43 promoter rather than transcription factors acting on recognition elements common to rat and mouse. But KA did not activate the rat promoter in transgenic mouse granule cells. Failure of KA to induce granule cell F1/GAP-43 expression in mouse may occur because necessary transcription factors are either absent or are not activated by KA. (Supported by MH25281-21)

## 521.15

RETINOIC ACID STIMULATES TRANSCRIPTION OF ENDOGENOUS  $\alpha$ -CaM KINASE II mRNA IN PC12 CELLS. J. Chen and P. T. Kelly\*. Department of Neurobiology and Anatomy, University of Texas Medical School, Houston, Texas 77030

Transcription of the gene encoding  $\alpha$ -CaM kinase II is very active in certain neurons in the mammalian brain.  $\alpha$ -CaM kinase II expression increases dramatically during postnatal development in hippocampus and cerebral cortex, but remains low in cerebellum. These properties indicate that its transcription is carefully regulated during brain development and in the adult CNS. We have shown that the expression of an exogenous  $\beta$ -galactosidase ( $\beta$ -gal) reporter plasmid driven by the core promoter of the  $\alpha$ -CaM kinase II gene (Olson, et al., PNAS, 92: 1659-1663, 1995) is extremely low in transfected PC12 cells under standard growth conditions. However, retinoic acid (25  $\mu$ M) stimulates cellular differentiation and significantly increases  $\alpha$ -CaM kinase II gene expression based on  $\beta$ -gal activity measurements. To further examine the regulatory effect of retinoic acid on  $\alpha$ -CaM kinase II expression, normal PC12 cells were treated with retinoic acid and changes in endogenous  $\alpha$ -mRNA levels were analyzed by RNase protection assays. retinoic acid treatment for 5 days increased transcription of endogenous  $\alpha$ -CaM kinase II mRNA by 5-fold compared to GAPDH mRNA; increases were detected only 24 hours after retinoic acid addition. These results suggest that retinoic acid may play an *in vivo* role in regulating  $\alpha$ -CaM kinase II gene expression during brain development and in the adult brain. (Supported by NIH grant NS22452.)

## 521.17

INTERLEUKIN-1 $\beta$  AND PHORBOL ESTERS SYNERGIZE TO INDUCE PROSTAGLANDIN G/H SYNTHASE-2 (CYCLOOXYGENASE-2, PGHS-2) IN PRIMARY MURINE ASTROCYTE CULTURES. M. D. Kaplan, P. D. Coleman, and M. K. O'Banion\*. University of Rochester School of Medicine and Dentistry, Depts. of Neurobiology and Anatomy and of Neurology, Rochester, NY 14642.

Cyclooxygenase is known to be important in physiologic functions such as inflammation and pain modulation. Recently, an inducible form of this enzyme, prostaglandin G/H synthase-2 (PGHS-2), was discovered. PGHS-2 is induced by inflammatory mediators such as IL-1 $\beta$ , as well as by agents known to stimulate protein kinase-C (e.g. phorbol esters like TPA), possibly through activation of the transcription factor NF- $\kappa$ B.

To better understand the mechanisms of prostaglandin production in the CNS, we have examined PGHS-2 activity and expression in primary astrocyte cultures. We demonstrate a synergistic increase in prostaglandin accumulation and PGHS-2 activity with the application of IL-1 $\beta$  and TPA, as well as similar increases in message levels for PGHS-2 as demonstrated by Northern Blot analysis. The antioxidant pyrrolidine dithiocarbamate (PDT), which is known to inhibit transcriptional activation by NF- $\kappa$ B, completely blocks prostaglandin production and PGHS enzymatic activity in IL-1 $\beta$  and TPA treated astrocytes. Despite these effects, PDT (60  $\mu$ M) did not inhibit the accumulation of PGHS-2 mRNA in treated cells. These findings suggest that PDT influences PGHS-2 activity by an as yet undefined mechanism. Further studies to identify the mode of action of PDT as well as the transcription factors that dictate PGHS-2 expression are in progress. Supported by grants from the NIA (LEAD AG09016, R01 AG01121-14 and ADC P30 AG08665), Dentist Scientist Award K16 DE00159, and the Markey Foundation.

## 521.14

CLONING AND ANALYSIS OF FOS-RELATED GENE FROM RAT HIPPOCAMPUS AFTER SYSTEMIC INJECTION OF KAINIC ACID. Z. Feng, G. Bing, Q. Qi, B. Wilson, M. K. McMillian, K. R. Pennypacker, M. Iadarola\* and J.-S. Hong. Lab. Environ. Neurosci., NIEHS/NIH, Research Triangle Park, NC; Neurobiology and Anesthesiology Branch#, NIDR/NIH, Bethesda, MD

AP-1 transcription factors play an important role in gene regulation by environmental stimuli. Systemic injection of kainic acid (KA), a glutamate receptor agonist, induced both short-term and long-term increases of AP-1 transcription factors. The acute response of AP-1 factors such as c-fos and fos-related antigen (FRA) to KA treatment has been extensively studied. However, the identity of the long-term AP-1 factors which are induced by KA is still unknown. The purpose of this study was to clone and analyze these long-term inducible transcription factors. We constructed a cDNA library from rat hippocampus three days after KA treatment and immunoscreened the new transcription factors with a FRA antibody, which was raised against the conserved M peptide region within the c-fos protein. One of fourteen positive clones, M13, from two million screened colonies was selected. Western blot analysis showed that M13 fusion protein can be recognized by FRA antibodies, but not by c-Fos, Fra-1 and Jun D antibodies. A translated M13 product is recognized by FRA antibodies *in vitro* and show 65-kDa band on SDS gel electrophoresis. The predicted peptide sequence of M13 encodes a 62-kDa protein which contains a leucine zipper domain and an octate glutamine repeat domain suggesting that this protein functions as a transcriptional factor. M13 is a unique gene based on searching Genbank. AP-1 gel shift assays with M13 translation products indicated that M13 may be involved in the stabilization of the AP-1 complex in the transcriptional regulation.

## 521.16

MECHANISMS CONTROLLING CALCIUM REGULATED GENE EXPRESSION IN NEURONS. Claire M. Johnson<sup>1</sup>, Sangeeta Chawla<sup>1</sup>, Caroline S. Hill<sup>2</sup>, Richard Treisman<sup>2</sup>, Hilmar Bading<sup>1</sup>. SPON: Brain Research Association, <sup>1</sup>MRC Laboratory of Molecular Biology, Cambridge CB2 2QH, UK, <sup>2</sup>Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX, UK.

Calcium (Ca<sup>2+</sup>) ions play a central role in the control of gene expression following electrical activation in neurons. Two major sites of Ca<sup>2+</sup> entry into hippocampal neurons are N-methyl-D-aspartate (NMDA) receptors and L-type voltage sensitive Ca<sup>2+</sup> channels. We are using primary neurons from the rat hippocampus and the rat pheochromocytoma cell line PC12 as model systems to study the mechanisms by which activation of different types of Ca<sup>2+</sup> channels are coupled to the regulation of gene transcription. One of the earliest genomic consequences of Ca<sup>2+</sup> influx into neurons is the transcriptional induction of the *c-fos* proto-oncogene. Because this transcriptional response occurs independently of the synthesis of new proteins it provides a powerful experimental system to study signalling to the nucleus.

Previous DNA transfection experiments using the wild type genomic *c-fos* gene and successive 5' promoter deletion mutants have identified a number of DNA regulatory elements important for signal-regulated transcription. These include the serum response element (SRE), the cyclic AMP response element (CRE) and the ets binding motif. However, the regulatory role of these elements in the context of the intact *c-fos* promoter is less clear. To investigate this, genomic *c-fos* DNA constructs containing mutations of specific regulatory elements placed in the natural sequence context of the entire promoter region have been transfected into PC12 cells and then tested for inducibility by Ca<sup>2+</sup> as well as growth factor pathways. Furthermore, using microinjection of oligonucleotides carrying recognition sequences for specific DNA binding proteins we analysed the contribution of individual promoter elements to the regulation of the endogenous *c-fos* gene. We demonstrate that Ca<sup>2+</sup>-activated transcription is controlled by several DNA regulatory elements. The principal target for growth factor signalling pathway in PC12 cells is the ets motif.

## 521.18

IDENTIFICATION OF A PHORBOL-ESTER-RESPONSIVE ELEMENT IN THE NEUROPEPTIDE GALANIN GENE AND SOME *trans*-ACTIVATING FACTORS. A. Rökäcs\*, K. Jiang and G. Spyrou. Lab. of Biochemistry I, MBB, Karolinska Institutet, S-171 77 Stockholm, Sweden.

The expression of the biologically active neuropeptide galanin (GAL) is elevated upon, nerve-stimulation, injury, HSV1-infection and during development, by mechanism(s) largely unknown. In the human neuroblastoma cell line (SKNSH-SY5Y), levels of GAL mRNA are elevated by phorbol myristate acetate (PMA). In an attempt to characterize the gene element(s) and the *trans*-activating factor(s) acting on the GAL-gene in response to PMA, plasmids containing  $\leq 5$  kb of the bovine GAL promoter fused to luciferase, were transfected into these cells. In doing so, we could functionally identify a PMA-responsive region in the GAL-promoter between 131 and 46 bp and by homology-sequence-search a cAMP-like responsive element (CRE-like; TGACGCGG). When an oligonucleotide harbouring this site was tested in an electrical mobility shift assay (EMSA) system, together with nuclear proteins isolated from the SY5Y-cells, two main PMA-inducible bands were observed. The binding in the main bands were reduced with unlabelled oligonucleotides in the following order of potency: CRE-consensus > CRE-like > AP1-consensus. The binding in all bands were abolished by an antibody that had been raised against rat CREB (recognizes several different proteins) and the binding in the bigger of the two main bands was reduced by antibodies against cJun and JunD. The data suggest that cJun and JunD together with members of the ATF/CREB family may be involved in the formation of these EMSA-complexes and hence these proteins may mediate increases of GAL-expression by phorbol-esters.

## 521.19

**DEVELOPMENTAL CHANGES IN ELECTROCONVULSIVE SHOCK-INDUCED EXPRESSION OF IMMEDIATE EARLY GENES IN RAT BRAIN.** S.H. Jeong, H.Y. Jung, Y.H. Joo, U.G. Kang, S.C. Cho, J.B. Park, Y.S. Kim\*, Dept. of Psychiatry & Biochemistry, Seoul National University, College of Medicine, Seoul, KOREA, 110-744

In order to study the developmental changes of the signal transduction system in the brain, we studied the changing pattern of immediate early gene (IEG) induction and cAMP Response Element Binding Protein (CREB) phosphorylation by electroconvulsive shock (ECS) in postnatal 7, 14, 21 day (p7, p14, p21) rats.

Sprague-Dawley male rats aged 7, 14, 21 days were sacrificed with appropriate time interval after single ECS, and hippocampal and cerebellar tissues were taken out. The induction of IEGs and the phosphorylation of CREB (p-CREB) were measured by Northern and Western blot respectively.

Neither *c-fos* nor *jun B* was induced in p7 rat by ECS, both in hippocampus and in cerebellum. But in p14 rats, significant inductions of *c-fos* and *jun B* were detected in both regions. In addition, IEG induction level increased further in p21 rats, so that the level was comparable with that of adult rats. In contrast, *7S8 (zif/268)* induction was significant even in p7 rats in both hippocampus and cerebellum, and reached the level of adult rats in p14 rats. But the induction level in cerebellum was far behind than that in hippocampus.

The amount of CREB measured by Western Blot was not different among rats of different age. But the amount of phosphorylated CREB (p-CREB) after ECS was gradually increased as maturation proceeds (p7<p14<p21).

We demonstrated that the response of neural cells to ECS with IEG induction undergoes gradual changes with maturation of brain tissue, and the nature of these changes vary according to each type of IEG, and each brain region. In addition we demonstrated that the phosphorylation of CREB in response to ECS also undergoes gradual changes with maturation.

## 521.20

**ESTROGEN PRODUCES DIFFERENTIAL AND GENDER-SPECIFIC REGULATION OF AP-1 DNA BINDING ACTIVITY IN RAT HYPOTHALAMUS AND PITUITARY.** Y.-S. Zhu and D.W. Pfaff\*, Lab. of Neurobiol. & Behav., Rockefeller Univ., NY 10021

It has been shown that AP-1 proteins are nuclear transcription factors that can function as a third message to regulate potential target gene expression such as for preproenkephalin (PPE). Estrogen has been shown to regulate AP-1 gene expression such as for *c-fos* in uterus. Using the electrophoretic mobility shift assay (EMSA), we have studied estrogen effects on regulation of AP-1 DNA binding activity in neuronal and non-neuronal estrogen-target tissues. Specific AP-1 binding activity in nuclear extracts was observed in hypothalamus (HYP), pituitary (PIT) and uterus of ovariectomized (OVX) female rats. This AP-1 binding was composed of at least *c-fos* and *c-jun* protein as demonstrated by supershift and immunodepletion assays. Treatment with estrogen (20 µg/rat) increased the levels of AP-1 binding in PIT and uterus of OVX females, whereas it decreased the level of AP-1 binding in HYP. These estrogen effects were visible at 15 min after treatment and were maintained for at least 72 h. These changes were not observed in striatum and cerebellum, and were much more prominent in OVX females than castrated males. Analysis of *c-fos* mRNA by slot-blot hybridization failed to show substantial changes in HYP and PIT. On the other hand, the same estrogen treatment produced rapid and significant increases in PPE mRNA in HYP of OVX females. These results show that estrogen produces differential alterations in AP-1 DNA binding in different estrogen target tissues and also suggest that changes in AP-1 DNA binding and PPE mRNA were not always correlated.

## LONG-TERM POTENTIATION: PHARMACOLOGY II

## 522.1

**TRANSGENIC MICE EXPRESSING MGLUR2 IN CA1 REGION OF HIPPOCAMPUS SHOWED DEFECTIVE LATE PHASE LTP.** L. Wang<sup>1</sup>\*, M. Mayford<sup>2</sup>, and M. Zhuo<sup>2</sup>. <sup>1</sup>Integrated Program Cell., Mol., Biochem. Studies, <sup>2</sup>HHMI, Ctr. Neurobiol. & Behav., Columbia Univ., NY, NY 10032.

Synaptic plasticity in the hippocampus is a widely used model for studying cellular and molecular mechanisms of learning and memory. Long-term potentiation (LTP) in the CA1 region of hippocampus contains two different phases: an early phase LTP (E-LTP) lasting 1-3 hours, and a late phase (L-LTP) lasting more than 3 hours. L-LTP has been shown in pharmacological experiments to be dependent on cAMP and cAMP-dependent protein kinase. To study the function of cAMP in L-LTP genetically, we have used the CaM kinase II promoter to generate transgenic mice that express the mGluR2 gene in CA1 neurons. mGluR2 is a metabotropic glutamate receptor that is negatively coupled to adenylyl cyclase. Electrophysiological studies using these transgenic mice showed that E-LTP induced by a single tetanus was not affected. However, L-LTP induced by multiple stimulus trains was significantly decreased in transgenic as compared to wild-type mice. Post-tetanic potentiation, paired-pulse facilitation, long-term depression, and depotentiation were not significantly different in transgenic as compared to wild-type mice. Biochemical studies are in progress to evaluate the inhibitory function of mGluR2 on adenylyl cyclase in the CA1 region. The mGluR2 transgene should block increases in cAMP only when the receptor is activated by its ligand glutamate. Thus, the effect of the transgene on cAMP levels should occur only during synaptic activation. The mice will also be used to probe the effects of L-LTP in learning and memory.

## 522.3

**THE mGluR ANTAGONIST MCPG AND THE CALCIUM CHANNEL BLOCKER ALUMINUM INHIBIT TEA-INDUCED LONG-TERM POTENTIATION.** B. Platt<sup>1</sup> and K. G. Reymann<sup>2</sup>. <sup>1</sup>University of Leeds, Dept. of Physiology, Leeds LS2 9NQ, UK; <sup>2</sup>Federal Institute for Neurobiology, Dept. of Neurophysiology, PSF 1860, 39008 Magdeburg, FRG.

A brief application of the K<sup>+</sup> channel blocker tetraethylammonium induces a long-lasting potentiation in the CA1 region of hippocampal slices (TEA LTP). This potentiation is assumed to be due to activation of voltage-dependent calcium channels (VDCCs) as a consequence of a strong depolarization. We investigated here the involvement of metabotropic glutamate receptors (mGluRs) and VDCCs in TEA LTP utilizing the mGluR antagonist (+)-α-methyl-4-carboxyphenyl-glycine ((+) MCPG) and the VDCC blocker aluminum (Al) on TEA LTP. Experiments were performed on rat hippocampal slices, field potentials (fEPSPs) were evoked by stimulation of the Schaffer collaterals and extracellularly recorded in the stratum radiatum of the CA1 region. TEA LTP was induced by application of 25 mM TEA for 7 min, which caused a stable potentiation. Sixty min after TEA application, the fEPSP slope was enhanced by 50%. Further control experiments revealed that TEA LTP is attenuated by the VDCC antagonist nifedipine (10 µM) but also by the N-methyl-D-aspartate (NMDA) antagonist D-2-amino-5-phosphonopentanoic acid (D-AP5; 25 µM). TEA LTP was completely blocked when Al (2.7 µg/ml ≈ 100 µM) was coapplied with TEA, i.e. only a brief and depressed potentiation occurred and the fEPSP slope declined back to baseline values within 45 min. For (+) MCPG (200 µM), a significant attenuation of TEA LTP was observed. Sixty min after TEA application the fEPSP slope was only potentiated by 18%.

Our data suggest that three components contribute to TEA LTP: one mediated by VDCCs, one dependent on NMDA activation and an additional one based on the activation of mGluRs.

## 522.2

**1S, 3R-ACPD dose-dependently induces a slow onset LTP and facilitates NMDA-dependent LTP in the dentate gyrus in vivo.** D. Manahan-Vaughan, W. Wetzel\*, and K.G. Reymann. Federal Institute for Neurobiology, Brenneckestr. 6, D-39118 Magdeburg, Germany.

1S,3R -1-aminocyclopentane 2, 3 -dicarboxylic acid (ACPD) is a selective agonist of metabotropic glutamate (mGluR) receptor. It has been shown by others that application of ACPD triggers a slow onset potentiation of the Schaffer collateral-CA1 synapse in hippocampal slices. This study examined the effect of ACPD in the dentate gyrus when applied in vivo.

Male wistar rats underwent implantation of stimulating and recording electrodes into the granule cell layer of the dentate gyrus (DG). Following 5 day recovery, the field excitatory post-synaptic potential slope function (fEPSP) and population spike amplitude (PS) was measured from freely moving animals. Drug concentrations used were 40 µM, 80 µM and 10 mM ACPD, and 200 mM (RS)-α-methyl-4-carboxyphenyl-glycine (MCPG) in an injection volume of 5 µL. Drugs were applied via a cannula implanted in the intracerebral ventricle.

Weak tetanisation produced a short-term potentiation (STP) of fEPSP and PS which decayed to baseline values by 90 min. Application of 40 µM ACPD prior to tetanus produced a similar response, whereas 80 µM ACPD facilitated STP into a LTP which lasted over 24 h. MCPG, an mGluR antagonist, completely inhibited the effect by 80 µM ACPD on LTP. 40 and 80 µM ACPD had no effect on baseline when compared with vehicle injected controls. 4 mM ACPD induced a slow onset potentiation of both fEPSP and PS which developed by 60 min and reached a plateau by 150 min. This response was maintained for over 4.5 h. MCPG applied prior to ACPD completely inhibited this effect. These results confirm that pharmacological activation of mGluRs by ACPD facilitates LTP, and indicate that under certain conditions, mGluRs can bypass the NMDA component of LTP.

## 522.4

**INDUCTION OF SYNAPTIC POTENTIATION IN THE RAT HIPPOCAMPAL SLICE BY ACTIVATION OF METABOTROPIC GLUTAMATE RECEPTORS IN THE PRESENCE OF ARACHIDONIC ACID D.R. Collins and S.N. Davies** (SPON: Brain Research Association) Department of Biomedical Sciences, Marischal College, University of Aberdeen, Aberdeen, AB9 1AS, Scotland.

We have previously shown that induction of long-term potentiation (LTP) in rat hippocampal slices from which the CA3 region has been removed requires the activation of both N-methyl-D-aspartate (NMDA) and metabotropic glutamate receptors. Here we have tested the hypothesis that this reflects a requirement for NMDA receptor mediated activation of phospholipase A<sub>2</sub> and release of arachidonic acid during activation of metabotropic receptors.

Perfusion of neither 1S,3R-aminocyclopentane-1,3-dicarboxylic acid (ACPD, 50 µM), nor arachidonic acid (10 µM), for 5 min induced any potentiation of the field EPSP recorded from 400 µm thick transverse hippocampal slices. However, co-perfusion of ACPD and arachidonic acid consistently evoked a long lasting potentiation. This potentiation was not blocked by inclusion of D-2-amino-5-phosphonopentanoate (AP5, 40 µM). Perfusion of the phospholipase A<sub>2</sub> activating peptide melittin (10 µg/ml) alone for 5 or 10 min had no long term effects, however, perfusion of ACPD immediately following melittin resulted in potentiation. The potentiation induced by co-perfusion of arachidonic acid and ACPD was prevented by the protein kinase C blocker hypericin (2 µg/ml). Docosahexanoic acid (10 µM) could not substitute for arachidonic acid in inducing potentiation.

The results indicate that activation of metabotropic glutamate receptors in the presence of either exogenously applied, or endogenously released arachidonic acid can induce synaptic potentiation, and that this potentiation relies at some stage on the activation of PKC.

## 522.5

THE REDOX STATE OF NMDA RECEPTORS DETERMINES WHETHER REPETITIVE STIMULATION EVOKES LTP OR LTD.

D.L. Tauck\*, S.D. Imahara, R.D. Kelsey, and D. Marks Department of Biology, Santa Clara University, Santa Clara, CA, 95053.

Low frequency stimulation of the Schaffer collateral/commissural input to hippocampal area CA1 elicits long-term depression (LTD) of synaptic transmission while higher frequency stimulation yields long-term potentiation (LTP). NMDA receptors mediate both forms of plasticity. Here we show that redox modulation of the NMDA receptor determines whether a particular stimulation frequency results in LTD or LTP.

Brains isolated from young male rats were sliced on a vibrating microtome and maintained in an interface chamber at 35°C. In some experiments the slices were treated with the reducing agent dithiothreitol (DTT, 100 µM) during the last 30 minutes of the one hour incubation period following slice preparation. Exposing the slices to 5,5-dithio-bis-2-nitrobenzoic acid (DTNB, 1 mM) for 30 minutes oxidized the NMDA receptors. To induce plasticity, 250 stimuli were delivered at an intensity which initially evoked a 1 mV field EPSP. NMDA receptor activity was assessed by comparing the area of the EPSP elicited by a single stimulus to that evoked after 4 conditioning stimuli at 10 Hz.

Low frequency stimulation normally produces a slight depression of synaptic transmission. However, after chemical reduction by DTT, low frequency stimulation elicits modest LTP instead of LTD. DTNB completely reverses this effect of DTT. Similarly, following oxidation of NMDA receptors in naive slices, higher frequency stimulation causes LTD instead of LTP. These results support the idea that the magnitude of NMDA receptor activity determines whether repetitive stimulation evokes LTP or LTD.

## 522.7

LONG TERM POTENTIATION IN THE PREFRONTAL CORTEX FOLLOWING MANIPULATION OF DOPAMINERGIC SYSTEMS. J.S. Bondar\*, C.A. Chapman, R.J. Racine. Dept. of Psychology, McMaster University, Hamilton, Ontario, L8S 4K1.

Neocortical long term potentiation (LTP) has been difficult to induce in chronic preparations. Recently, our lab has been able to induce potentiation reliably after 10 days of administering high frequency pulse trains. In this study, monopolar field potentials were recorded in the rat prefrontal cortex in response to test pulses (0.1 ms, 40-1259 µA) delivered to the corpus callosum. After three baseline tests, three groups were formed and each was administered drug injections (i.p.) 15 minutes prior to delivery of the pulse trains (30 trains of 8 pulses at 300Hz, 1259 µA) each day for 10 days. One group received 1.0 mg/kg apomorphine (agonist), another group received 1.0 mg/kg haloperidol (antagonist), and the control group received an equivalent volume of the sterile water vehicle. Evoked field potentials were recorded for an additional 4 week period following completion of the stimulation phase. Field potentials demonstrated two positive-going components. The early component was depressed at all intensities for the control animals 1 day after the last set of trains but had recovered to near baseline levels after 4 weeks. A similar depression has been found in our other neocortical LTP experiments, but it is correlated with increased discharge of cortical cells. A larger depression was observed in the apomorphine group that also returned to baseline by 4 weeks. The haloperidol group showed the largest depression and only partial recovery. For the second component, a small increase in amplitude was observed in the control group at 1 day post trains with a modest recovery after 4 weeks. The apomorphine group, however, demonstrated a larger enhancement that persisted 4 weeks after delivery of the pulse trains. In contrast, the haloperidol group showed a depression in this component with a return to near baseline levels after 4 weeks. These results demonstrate that long term potentiation can be induced in the prefrontal cortex, and that the potentiation can be modified by pharmacological manipulation.

## 522.9

MODULATION OF LONG-TERM POTENTIATION IN THE HIPPOCAMPAL CA1 REGION BY CHOLECYSTOKININ. D. Balschun\*, and K. G. Reymann. Department of Neurophysiology, Federal Institute for Neurobiology, Brenneckstr. 6, POB 1860, D-39008, Magdeburg, Germany.

The physiological role of sulphated cholecystokinin octapeptide (CCK-8S) in the hippocampus is not well understood. The hippocampus represents the brain region in which long-term potentiation (LTP), a model of learning and memory in higher vertebrates, is most thoroughly investigated. We examined whether (CCK-8S) may be involved in the induction and maintenance of hippocampal LTP. To address this issue, field excitatory postsynaptic potentials (fEPSP) and population spikes (PS) were recorded in the CA1 region of the rat hippocampal slice preparation and two different forms of N-methyl-D-aspartate (NMDA)-dependent LTP were employed. A weak LTP was induced by a single theta-pulse stimulation (TPS; 10 pulses at 7 Hz) and a strong LTP by a triple theta-burst stimulation (TBS; 10 bursts of 4 pulses, 100 Hz, interburst interval 200 ms, at 2 minute intervals). CCK-8S and the highly selective CCK<sub>A</sub>-receptor antagonist PD 135158 were bath-applied 40 - 50 min prior to tetanization and up to 10 min thereafter.

TPS elicited a potentiation of the fEPSP slope and the PS amplitude lasting for about 1 hour. The application of 500 nM CCK-8S led to a higher magnitude of potentiation of the fEPSP slope and the PS amplitude and a marked protraction of potentiation. PD 135158 (1 µM) decreased the potentiation of the PS amplitude but had no influence on LTP of the fEPSP slope. TBS evoked a robust LTP remaining at increased levels for at least 4 hours. Application of 1 µM PD 135158 did not change the initial potentiation of the fEPSP-slope but caused a marked impairment of the maintenance. In contrast, PD 135158 led to a higher magnitude of potentiation of the PS amplitude shortly after potentiation, but exerted no influence on the maintenance of potentiation. The results suggest that CCK-8S may modulate long-term changes in glutamatergic synaptic transmission of the hippocampus via activation of CCK<sub>A</sub>-receptors.

SELECTIVE BLOCKADE OF INHIBITORY, BUT NOT EXCITATORY, POSTSYNAPTIC POTENTIALS AND THEIR LTP IN CA1 PYRAMIDAL NEURONS. H. Grunze, D. Rainnie, E. Hearn, E. Barkai, M. Hasselmo, R. McCarley, R. Greene\* Dept. of Psychiatry, Harvard Medical School & VAMC, Brockton MA 02401, Dept. of Psychology, Harvard Univ., Cambridge MA 02138.

We previously reported that NMDA-dependent LTP of local inhibitory circuits can be elicited in hippocampal CA1 pyramidal cells (IPSP<sub>A</sub> increase of 32.5 ± 24.7% in 8/10 intracellular recordings). To further evaluate this LTP, we limited feedforward excitation and inhibition by transecting the slice, leaving only the alvear pathway intact. Tetanic stimulation of the alveus lead to an LTP of the IPSP<sub>A</sub> of 43 ± 21% in 8/12 neurons tested in agreement with our previous experiments. LTP of the IPSP was inhibited in control and transected slices by the NMDA antagonists APV, PCP, MK 801 and the endogenous substance, NAAG. A comparison of the dose-response relationship of APV for inhibiting excitatory LTP by stratum radiatum (SR) stimulation vs. inhibitory LTP by stratum oriens (SO) stimulation showed a 10-fold smaller IC<sub>50</sub> for inhibitory LTP (IC<sub>50</sub> (SR) = 5.75 ± 1.11 µM; IC<sub>50</sub> (SO) = 0.57 ± 1.13 µM; n = 6 at each concentration tested: 50-0.3 µM). A similar difference in sensitivity was observed for NAAG. The amplitude of alvear-evoked IPSP's was also sensitive to APV. At 0.4 µM APV (approximately the IC<sub>50</sub> for inhibitory LTP suppression), APV reduced the IPSP by 11 ± 3% (n=4), about 1/2 of the maximal reduction elicited by 25 µM APV of 27 ± 8.5% (n=4). We conclude that small doses of NMDA antagonists, including the endogenous partial antagonist, NAAG, are sufficient to interfere with inhibitory circuits while leaving excitation intact. Selective impairment of inhibitory circuits and their ability to undergo LTP, by low doses of antagonists, may lead to increased network activation and to specific deficits in information processing in the hippocampus, consistent with cognitive abnormalities described in PCP and ketamine induced psychosis and in schizophrenia.

## 522.8

DIFFERENTIAL EFFECTS OF PACAP ON SYNAPTIC TRANSMISSION OF RAT HIPPOCAMPAL SLICE. Teisuro Kondo\*, Takashi Tominaga, Michinori Ichikawa, and Toshio Iijima. Molecular and Cellular Neuroscience Section, Electrotechnical Laboratory, Umezono, Tsukuba, 305, Japan

Pituitary adenylyl cyclase-activating polypeptide (PACAP), a neuropeptide originally isolated from ovine hypothalamus, regulates hormone release and promotes differentiation or survival of cultured neuroblast. PACAP-38 stimulates neurite outgrowth of PC-12 cells, and increases cytosolic free calcium concentration in cultured rat hippocampal neurons. The PACAP type-I receptor, specific for PACAP, is positively coupled to adenylyl cyclase and phospholipase C. The type-II receptor, which does not discriminate between PACAP and vasoactive intestinal polypeptide, is coupled to only adenylyl cyclase. In this report we present that PACAP-38 induced long-lasting modification of synaptic transmission of rat hippocampal slice. Bath application of PACAP (1 µM) decreased both the initial slope of field e.p.s.p. at Schaffer collateral-CA1 synapses and the amplitude of population spikes of CA1 pyramidal neurons (mean percent of control: e.p.s.p., 87.6 ± 2.3%, n = 24, p < 0.005; population spikes, 88.6 ± 3.6%, n = 15, p < 0.01). In contrast, the synaptic strength in dentate gyrus was enhanced by the exposure to the same concentration of PACAP (e.p.s.p., 120.1 ± 3.5%, n = 10, p < 0.005; population spikes, 142.3 ± 7.4%, n = 8, p < 0.005, in the presence of 5 µM bicucullin). These effects were sustained more than 2 to 3 hours and the magnitude of these effects was concentration-dependent (0.1-10 µM).

## 522.10

FACILITATORY ROLE OF SOMATOSTATIN VIA MUSCARINIC CHOLINERGIC RECEPTOR IN THE GENERATION OF LONG-TERM POTENTIATION OF POPULATION SPIKES IN THE DENTATE GYRUS *IN VIVO*. N. Nishiyama\*, A. Nakata and H. Saito. Dept. of Chem. Pharmacol., Fac. of Pharmaceut. Sci., The Univ. of Tokyo, Tokyo 113, Japan.

Accumulating evidence indicate that somatostatin is involved in the cognitive function. A brief tetanic stimulation to a monosynaptic excitatory pathway in the hippocampus induces long-term potentiation (LTP) of a synaptic response both *in vivo* and *in vitro*, which is considered to be a cellular basis of learning and memory process. Recent studies revealed that somatostatin enhanced the LTP in mossy fiber-CA3 pathway of the guinea pig hippocampus *in vitro*. In the present study, we investigated whether somatostatin modulates the generation of LTP in rat perforant path-dentate gyrus synapse *in vivo*. Male Wistar rats 8-9 weeks old were anesthetized with urethane and α-chloralose. A bipolar electrode was placed in the entorhinal cortex to stimulate the medial perforant path, and the evoked potential was extracellularly recorded from the granule cell layer of the dentate gyrus. A weak tetanic stimulation (20 pulses at 60 Hz) of the perforant path induced only marginal LTP. When somatostatin (5-500 ng/rat) was injected intracerebroventricularly (i.c.v.) 20 min prior to the tetanus, the intensity of LTP increased dose-dependently. Synaptic potential evoked by a low-frequency test stimulation, however, was not altered by somatostatin. We next tested whether LTP-augmenting effect of somatostatin is mediated by cholinergic activation, because somatostatin was demonstrated to promote acetylcholine release in rat hippocampal slice. Pirenzepine (50 nmol/rat), a muscarinic M<sub>1</sub>-receptor antagonist, did not affect the weak tetanus-induced LTP by itself. But when it was coapplied with the somatostatin (50 ng/rat) 20 min before tetanus, it completely abolished the LTP-augmenting effect of somatostatin. These result suggest that somatostatin facilitates the generation of perforant path-dentate gyrus granule cell LTP via activating the muscarinic cholinergic receptor *in vivo*.

## LTP IN HIPPOCAMPUS BY HISTAMINE, C-AMP AND PKA.

O. Selbach, M.A. Pak\* and H.L. Haas Institute of Physiology II, Heinrich-Heine-University, D-40001 Düsseldorf, Germany.

The action of histamine on rat hippocampal CA1 pyramidal-cells in vitro was investigated in 0.2 mM  $\text{Ca}^{2+}/4$  mM  $\text{Mg}^{2+}$ . Histamine (HA; 5 min; 0.1-10  $\mu\text{M}$ ) caused, in 85% of the cells, a dose-dependent increase in firing rate which was characterized by a quickly rising and reversible (I), a longer lasting (II, ca. 30 min) and a later phase (III, starting after ca. 40 min). Cimetidine but not mepyramine prevented all excitations, impromidine mimicked them. Equal concentrations of histamine were more effective than impromidine. 8-Br-cAMP and the PKA-activator SP-cAMP also mimicked phases II and III. The adenylyl-cyclase-inhibitor SQ 22,536 or the PKA-inhibitor Rp-cAMP blocked them. APV significantly attenuated the late phase (III) indicating an indirect (secondary) NMDA-dependence. H1-receptor activation caused a depression of firing and seemed to potentiate H2-receptor actions. H3-receptor activation by R-alpha-methyl-histamine was ineffective on firing rate. All three phases of histaminergic excitation in the hippocampus are mediated by H2-receptors. Only the long lasting (II) and the later phase (III) depend on AC and PKA. The histaminergic system is involved in the regulation of behavioral state and can potentiate hippocampal transmission for prolonged periods of time. Supported by DFG and HFSP.

## LONG-TERM POTENTIATION: PHARMACOLOGY III

## 523.1

## ETHANOL AFFECTS HYPOTHALAMIC NEURONS PROJECTING TO THE HIPPOCAMPUS THAT INHIBIT DENTATE GRANULE CELL LTP. M.J. Wayner\*, R. Chitwood, D.L. Armstrong, and C. Phelix. Division of Life Sciences, The University of Texas at San Antonio, San Antonio, TX 78249.

In previous studies we demonstrated that ethanol inhibition of hippocampal granule cell long term potentiation (LTP) is mediated by angiotensin II (AII) and the inhibition can be blocked by losartan, a specific AII  $\text{AT}_1$  receptor antagonist (Wayner, et al. *Pharmacol. Biochem. Behav.* 45:455-464, 1993). The purpose of the present study was to demonstrate that this low dose ethanol inhibition of dentate granule cell LTP induction is mediated by lateral hypothalamic (LH) afferents that project to the granule cells. Anterograde tract tracing following horseradish peroxidase administration into the dentate granule cells revealed clearly filled neurons in the LH similar to those stained for AII (unpublished data). In urethane anesthetized rats, we have compared the effects of ethanol infusion, 6.0  $\mu\text{l}/30$  min, by means of an open ended push-pull cannula, in both the LH and the dentate gyrus, on dentate granule cell LTP. Results demonstrate a dose dependent inhibition of LTP induction when the LH is perfused, which can be blocked by losartan. Four doses of ethanol were used: 5, 10, 20, and 30 mM. There was no effect when the dentate gyrus was infused with 30 mM ethanol and normal LTP in the granule cells was observed.

## 523.3

SYNAPTIC PLASTICITY IN DISSOCIATED CHICK CEREBRAL NEURONS INDUCED BY  $\text{Mg}^{2+}$ -FREE MEDIUM. S.Kudoh\*, K.Kiyosue, M.Kasai, T.Taguchi\*. Lab of Mol Biol. Fac. of Eng.Sci. Osaka Univ., Toyonaka 560, Japan, and \* Osaka Nat'l. Res. Inst. AIST, Ikeda 563, Japan.

To analyze the molecular mechanism of long-term enhancement of synaptic transmission, we have developed a dissociated cell culture system. Using whole-cell patch clamp technique, we have demonstrated long-lasting increase of amplitude of spontaneous excitatory post synaptic currents (SEPSCs) induced by  $\text{Mg}^{2+}$ -free medium. This enhancement was inhibited by the addition of TTX, CNQX and AP5 in the  $\text{Mg}^{2+}$ -free medium, suggesting it depends on neural activity. Inhibitor of protein and RNA synthesis also inhibited the enhancement. Analysis of miniature EPSCs in the presence of TTX revealed that the enhancement accompanies the increase in frequency of miniature EPSCs. Thus, the enhancement is thought to be due to the increase of the number of transmitter release site and/or synaptic sites. Furthermore it was also demonstrated that the similar long-lasting potentiation was caused by exposing neurons to conditioned  $\text{Mg}^{2+}$ -free medium which was collected after induction of the enhancement and adjusted the  $\text{Mg}^{2+}$  concentration at the same in normal extra cellular recording solution. This result suggests that some factors which promote the potentiation of SEPSCs are released to the medium.

## 523.2

IMPAIRMENT OF CA1 HIPPOCAMPAL LTP IN MICE WITH REDUCED CALBINDIN  $\text{D}_{28\text{K}}$  EXPRESSION. A. Jouvenceau, J.M. Billard, P. Dutar\*, Y. Lamour (1), P.C. Emson (2), R. Battini, S. Molinari, L. Pozzi and S. Ferrari (3). (1) INSERM U161, 75014 Paris France; (2) Molecular Neuroscience Group, Babraham, Cambridge, U.K.; (3) Univ. di Modena, 41100 Modena, Italia.

Calbindin  $\text{D}_{28\text{K}}$  (CaBP) is strongly expressed in the CA1 pyramidal neurons of the hippocampus but the role of this calcium-binding protein is unknown. Behavioral studies have shown impaired performances of spatial learning tasks in CaBP deficient transgenic mice. Here, we report that the maintenance of long-term potentiation (LTP) is altered in hippocampal CA1 area in these mice.

Hippocampal slices were prepared from homozygous transgenic or wild-type control mice according to conventional methods. Field potentials (fEPSP) were induced by electrical stimulation of CA1 afferent fibers and recorded in stratum radiatum using extracellular electrodes. No difference in the basal properties of the fEPSPs were observed between wild and transgenic mice: amplitude and slope of control fEPSPs, paired-pulse facilitation of fEPSPs, fiber volley amplitude and the ratio of fEPSP slope to fiber volley amplitude were comparable in both populations. A robust LTP following high frequency stimulation was observed in wild-type mice. In contrast, in most homozygous mice, a potentiation of the fEPSP developed but lasted for only 20 to 30 min. These results suggest that CaBP is necessary for the maintenance but not for the induction of LTP in the CA1 area. We are now studying LTP in the CA3 region where CaBP-immunoreactivity is present presynaptically in the mossy fibers. The comparison between the results in CA1 and CA3 fields where CaBP is present post- and presynaptically respectively, will give informations on the role of CaBP with respect to its neuronal localization.

## 523.4

## A selective neuronal nitric oxide synthase inhibitor blocks LTP induction and spatial learning in the rat. C. Hölscher\*, CA Doyle, L. McGlinchey, R. Anwyl, MJ Rowan. Dept of Pharmacol. and Therap., Trinity College, Dublin 2, Ireland

Nitric oxide (NO) is a transmitter which has been suggested to play a role in memory formation. A novel selective NO synthase inhibitor, 7-nitro indazole (7-NI), has been shown to inhibit neuronal NO synthase by 85% (30mg/kg *i.p.*) while having no effect on blood pressure. 7-NI produced amnesic effects both in a water maze and in an 8-arm radial maze (30mg/kg *i.p.*, Wistar rats,  $n=16$ ). Latency as well as distance was greater in the 7-NI group in the water maze while swim speed was not affected. Latency, working memory (WM) and reference memory errors were also higher in the 7-NI group in the 8-arm maze. At the end of the second training day, no difference in performance between 7-NI and control groups was visible anymore. A change of baited arms caused a difference between groups in latency and WM errors. The quadrant analysis transfer test in the water maze showed a difference between 7-NI and control groups with a difference in the numbers of annulus crossings. Learning of a visual discrimination task was not affected. In the CA1 region of the anaesthetized rat, 7-NI (30mg/kg *i.p.*) prevented induction of LTP 30 min after injection in 6 out of 6 animals. 4 h after injection, when most of the drug is washed out, LTP was inducible again in 3 out of 3 animals. Injecting 7-NI along with L-arginine (225 mg/kg) concentrations prevented the block of LTP induction (6 out of 6). We conclude that neuronal NO synthase activity plays a role in LTP induction and in learning and memory formation in the rat.

## 523.5

## MONOAMINE DEPLETION AFFECTS SYNAPTIC PLASTICITY IN CA1 REGION OF HIPPOCAMPAL SLICE BY c-AMP-DEPENDENT MECHANISM.

N. Otmakhova\*, J. Lisman.

Biology Department, Brandeis University, Waltham, MA 02254.

In order to determine whether or not biogenic amines play a significant role in synaptic plasticity, we have compared the levels of field EPSP potentiation and depotentiation in control (C) and monoamine-depleted (D) rats. The depletion was achieved by 5 mg/kg reserpine injection 24 hours prior to experiment and by adding tyrosine hydroxylase inhibitor into the perfusion media. Depletion significantly decreased potentiation by 25-45% (40 min. after a single tetanus; 100 Hz, 1 sec). Depotentiation after low frequency stimulation (2 Hz for 10 min., 5 min. after the tetanus) was not decreased in D slices.

One role of biogenic amines is to increase c-AMP production through D1 dopaminergic or  $\beta$ -adrenergic receptors. To test the role of c-AMP, we applied water soluble derivative of adenylate cyclase activator, forskolin (10  $\mu$ M) for 5 min immediately before the tetanus to both C and D slices. Forskolin application did not affect baseline response in C or D slices. However it did significantly increase the magnitude of potentiation and decreased the level of depotentiation in D slices, resulting in values similar to control. In the C slices, on the other hand, effect of forskolin was the opposite: decrease of potentiation and increase of depotentiation levels.

This results suggest that under normal conditions, biogenic amines released during stimulation increase the magnitude of potentiation by a c-AMP-dependent mechanism.

## 523.7

## GLUTAMATE RECEPTOR STIMULATION INCREASES THE PHOSPHORYLATION OF PRE- AND POSTSYNAPTIC PKC SUBSTRATES IN HIPPOCAMPAL SLICES. G.M.J. Ramakers\*, P. Pasinelli, W.H. Gispen and P.N.E. De Graan. Rudolf Magnus Institute for Neurosciences, P.O. Box 80040, 3508 TA Utrecht, The Netherlands. (SPON: European Neuroscience Association)

Activation of protein kinase C (PKC) is thought to be an important step in long-term potentiation (LTP). Both pre- and postsynaptic PKC appear to be involved, because LTP induction in the CA1 field of the hippocampus increased the phosphorylation state of the presynaptic protein B-50 (a.k.a. GAP-43, F1) as well as that of the postsynaptic protein RC3 (a.k.a. neurogranin, BICKS) by an NMDA receptor dependent mechanism (Ramakers et al., J. Biol. Chem., in press). In this study we investigated the effect of glutamate receptor (GluR) activation on pre- and postsynaptic PKC activity, by measuring the *in situ* B-50 and RC3 phosphorylation. Rat hippocampal slices (450  $\mu$ m) were labelled with  $^{32}$ P<sub>i</sub> (100  $\mu$ Ci/ml) for 90 min at 30°C and the *in situ* phosphorylation state of B-50 and RC3 was determined after quantitative immunoprecipitation and SDS-PAGE by phosphorimaging. Treatment with Glu increased the phosphorylation of B-50 and RC3 in a concentration- and time-dependent manner. This 1 mM Glu-induced increase in B-50 and RC3 phosphorylation could be inhibited by MCPG (500  $\mu$ M), an antagonist for the metabotropic GluR (mGluR). Antagonists for the ionotropic glutamate receptors, CNQX (50  $\mu$ M), an AMPA receptor antagonist, and APV (100  $\mu$ M), an NMDA receptor antagonist, hardly affected the Glu-induced increase in RC3 and B-50 phosphorylation.

Our results show that activation of mGluR increases the phosphorylation state of both pre- and postsynaptic PKC substrates. These findings indicate an important role for mGluRs in regulating the phosphorylation state of both pre- and postsynaptic PKC substrates in the maintenance phase of LTP. (This work was supported by an ENP grant of the ESF).

## 523.9

## MODULATION OF PERTUSSIS TOXIN-SENSITIVE G-PROTEINS BY RC3/NEUROGRANIN

J.B. Watson\*, J.J. Rubino, R.W. Cohen, J.E. Margulies. Mental Retardation Research Center, UCLA, Los Angeles, CA 90095-1759, California State University at Northridge, Northridge, CA 91330, University of Hawaii at Manoa, Honolulu, HI 96822.

RC3/neurogranin is a postsynaptic, forebrain-enriched protein distinguished by an "IQ" motif containing overlapping sites for PKC phosphorylation and calmodulin-binding (in the absence of Ca<sup>2+</sup>). RC3 has also been implicated in synaptic plasticity based on its phosphorylation by PKC during NMDA receptor-mediated LTP in CA1 of hippocampus. Thus, it is essential to identify the functional consequences of RC3's phosphorylation, specifically its postsynaptic protein-protein interactions. Here we use two different experimental approaches to show that RC3 enhances pertussis toxin (PTX) effects on G-proteins. First in functional studies, RC3 increases the PTX sensitivity of serotonin-evoked IP<sub>3</sub>/Ca<sup>2+</sup>-dependent Cl<sup>-</sup> currents in *Xenopus* oocytes co-expressing 5HT<sub>2C</sub> receptors with RC3 (control 5HT<sub>2C</sub> receptor, 323±65 nA, n=5; 5HT<sub>2C</sub> receptor + PTX, 260±24.2 nA, n=4, T=0.821, P<0.4) (control 5HT<sub>2C</sub> receptor + RC3, 371±61.5 nA, n=5; 5HT<sub>2C</sub> receptor + RC3 + PTX, 135±51.4 nA, n=4, T=2.84, P<0.025). Second, biochemical studies show that a full-length RC3 synthetic peptide (RC3-78, 0.001-10  $\mu$ M), when PKC-phosphorylated, increases PTX-catalyzed ADP-ribosylation of Go/Gi in hippocampal membrane-fractions (1.4-2.5 fold). The results together suggest that RC3 interacts with Go proteins and possibly Gi proteins in dendritic spines in forebrain neurons, where it may modulate the G-protein coupling of metabotropic glutamate receptors to phospholipase C $\beta$  and IP<sub>3</sub>/Ca<sup>2+</sup> production in response to NMDA receptor activation during LTP, and potentially in learning and memory.

## 523.6

## FORSKOLIN-INDUCED POTENTIATION IN HIPPOCAMPAL DENTATE GYRUS INCREASES PHOSPHORYLATION OF CREB. J.M. Sarvey\* and P.J. Voulalas. Dept. of Pharmacology, Uniformed Services University of the Health Sciences, Bethesda, MD 20814.

A variety of stimuli activate pathways of signal transduction that utilize calcium and cAMP as their second messengers, resulting in an increase in gene expression in cultured cells. In the dentate gyrus, forskolin, which directly activates adenylate cyclase, induces a long-lasting (> 1h) increase in excitatory synaptic transmission. We have investigated the ability of forskolin to (1) potentiate dentate responses and (2) produce changes in the phosphorylation state of the cAMP-response element binding protein (CREB) in the *in vitro* hippocampal slice. Electrophysiological analyses of forskolin-treated dentate "mini" slices were accompanied by Western blot analyses of extracts of the mini slices. Forskolin (50  $\mu$ M) was bath-applied to mini slices and samples were removed 5, 10, 15 and 20 min after application of forskolin, and 20 min after wash-out of the agent. Forskolin increased the slope of the dendritic epsp to >140% of baseline levels (n=4), and increased phosphorylation of CREB above basal levels. Phosphorylation of CREB on Ser<sup>133</sup> peaked and declined within 20 min of forskolin application. This time course of activation of CREB by phosphorylation correlates with the time course observed in cultured cells and implicates CREB as a mediator of events whose signal originates at the cell membrane and culminates in transcription of genes required for long-lasting potentiation. Supported by NIH NS23865.

## 523.8

## DIFFERENTIAL EFFECTS OF DEPOLARISING STIMULI ON THE PHOSPHORYLATION STATE OF PRE- AND POSTSYNAPTIC PKC SUBSTRATES B-50 (GAP-43) AND RC3 (NEUROGRANIN). P. Pasinelli, G.M.J. Ramakers, M. van Beest, W.H. Gispen and P.N.E. De Graan\* Rudolf Magnus Institute for Neurosciences, P.O. Box 80040, 3508 TA Utrecht, The Netherlands.

RC3 (a.k.a. neurogranin, BICKS) and B-50 (a.k.a. GAP-43, neuromodulin, F1) are neuronal members of a new protein family sharing an amino acid sequence, the IQ domain, containing a PKC phosphorylation site and a calmodulin (CaM)-binding domain. Recently, we have shown that induction of LTP induced an increase in the *in situ* phosphorylation of both proteins (Ramakers et al., J. Biol. Chem., in press). In the present study we investigated the effect of various depolarising stimuli on the phosphorylation state of B-50 and RC3. Rat hippocampal slices (450  $\mu$ m) were labelled with  $^{32}$ P<sub>i</sub> (100  $\mu$ Ci/ml) for 90 min at 30°C and the *in situ* phosphorylation state of B-50 and RC3 was determined after quantitative immunoprecipitation and SDS-PAGE by phosphorimaging. Treatment of slices with K<sup>+</sup> (30 mM) or the K<sup>+</sup>-channel blocker 4-Aminopyridine (100  $\mu$ M) increased the phosphorylation state of B-50 without affecting RC3 phosphorylation. To verify that RC3 phosphorylation can be modulated under our experimental conditions, we treated slices with the phospholipase 4- $\alpha$ -phorbol 12,13 dibutyrate (PDB) or the phosphatase inhibitor okadaic acid. PDB induced a concentration- and time-dependent increase in both RC3 and B-50 phosphorylation, which could be prevented by PKC inhibitors. Okadaic acid (10<sup>-6</sup> M) increased both B-50 and RC3 phosphorylation in a time- and concentration-dependent manner, indicating that PP1 and PP2A are involved in the regulation of the *in situ* phosphorylation state of both proteins. Cyclosporin A, an inhibitor of phosphatase PP2B, had no effect on basal B-50 or RC3 phosphorylation. *In vitro* PKC phosphorylated RC3 was dephosphorylated by endogenous okadaic acid sensitive phosphatases, as well as by purified PP2B. Our data show that RC3, like B-50, is an *in situ* PKC and PP1/2A substrate. Depolarising stimuli, which increase presynaptic B-50 phosphorylation, do not affect postsynaptic RC3 phosphorylation, indicating that the phosphorylation state of these proteins is differentially regulated. (This work was supported by an ENP grant of the ESF).

## 523.10

## METABOLIC INACTIVATION OF ASTROCYTES IMPAIRS HIPPOCAMPAL LTP IN VITRO Paul H.M. Kullmann\* and Christian M. Müller. Max-Planck-Institute for Developm. Biol., 72076 Tübingen, Germany

Increasing evidence suggests intimate glia-neuronal interrelations. Thus, astrocytes respond to a variety of neurotransmitters and affect neuronal excitability, e.g. due to their role in ion, pH, and transmitter homeostasis. The functional links of these glia-neuronal interactions are still poorly understood. We therefore investigated whether astroglia are implicated in neuronal transmission and the induction or expression of long-term potentiation (LTP) in rat hippocampus. We recorded field-EPSPs to stimulation of two separate afferent pathways to the CA1 region of hippocampal slices of 4-8 week old rats. One afferent was used to monitor the capability of each slice to express stable LTP upon theta-burst stimulation (TBS, 3 bursts of 2 s applied within 20 min). Thereafter 2 mM Fluoroacetate (FA), which selectively inhibits the astroglial Krebs cycle was added to the superfusate. After at least 1 h of FA-application the second pathway was tetanized. In about 80% of the slices tested, TBS resulted only in short-term potentiation which disappeared within 1 h. However, LTP-induction by pairing low-frequency stimulation with coincident intracellular current injection showed a comparable occurrence and amplitude of potentiation in control and FA-treated slices. This indicates that metabolic inactivation of astrocytes does not interfere with the manifestation of LTP, but rather with an early step in the induction cascade. Intracellular recordings revealed no significant differences in the response-amplitudes elicited by TBS in control solution and after FA-treatment. Thus, the effect on LTP is not simply due to a transmitter depletion caused by a lack of the astroglia-derived glutamate precursor glutamine. Current studies assess the possibility that astroglial intoxication may selectively reduce NMDA-mediated responses, or enhance GABAergic response components. Both effects could account for the observed failure of TBS-induced LTP versus a successful pairing-induced LTP.

**ADHESION MOLECULES & HIPPOCAMPAL PLASTICITY: EVIDENCE THAT A SELECTIVE, DELAYED CHANGE IN NEURAL CELL ADHESION MOLECULE-180 (NCAM<sub>180</sub>) IS ASSOCIATED WITH LTP MECHANISMS.** K.B. Hoffman, B.A. Murray, & B.A. Bahr, 'Ctr. for Neurobiol. of Learning & Memory, Dept. of Developmental & Cell Biol., Univ. of Calif., Irvine, CA 92717.

The NCAM family of adhesion molecules consists of three main isoforms of 180, 140, and 120 kDa, some of which are enriched in postsynaptic densities (Persohn et al., J. Comp. Neurol. 288:92, 1989) and synaptosomal membranes (Bahr et al., Brain Res. 628:286, 1993). Interactions between NCAMs have been implicated in memory consolidation (Doyle et al., J. Neurosci. Res. 31:513, 1992) and, recently, in LTP (Lüthi et al., Nature 372:777, 1994). To determine if NCAM isoforms are modified by certain synaptic plasticity mechanisms, experiments utilized long-term hippocampal slice cultures in which NCAMs and other synaptic and structural proteins are stable for at least two months (Bahr, J. Neurosci. Res. in press, 1995).

Brief stimulation of the hippocampal slice cultures with NMDA and rapid AP5 quenching, a paradigm shown previously to produce LTP (Thibault et al., Brain Res. 476:170, 1989), generated a gradual increase in NCAM<sub>180</sub> on immunoblots. The optical density X area for the 180 kDa band was 5-50% greater than that in sister cultures treated without NMDA ( $p = 0.01$ , paired t-test,  $n=17$ ). The NMDA-induced enhancement of NCAM<sub>180</sub> immunoreactivity was more evident at 2 hours than 10 min post-stimulation, and within-sample analyses demonstrated that no corresponding change in NCAM<sub>140</sub> occurred. Moreover, the delayed increase was blocked by prior AP5 treatment, and was a transient change as evidenced by a decay phase during the 6-18 hour period post-stimulation. The NCAM modulation required a short receptor stimulation duration (10-30 sec) since extended exposures to NMDA induced a decrease instead of an increase in NCAM<sub>180</sub>, an effect that was also AP5-sensitive. These results support hypotheses which implicate reorganization of synaptic morphology in LTP, and further suggest that such mechanisms involve adhesion molecules (supported by AFOSR 89-0383 and NSF IBN-9220156).

## 523.13

**CALPAIN-MEDIATED PROTEOLYSIS AND LTP: IS CLEAVAGE OF THE SPECTRIN-BASED CYTOSKELETON DURING INDUCTION A PREREQUISITE FOR STABILIZATION?** P. Vanderklish, E. Bednarski, C.M. Gall, T.C. Saido, J. Larson, G. Lynch, 'CNLM and Dept. of Anat. & Neurobiol., Univ. of Calif., Irvine, CA 92717; Dept. of Mol. Biol., Tokyo Metro. Inst. of Med. Sci., Tokyo, 113.

The structural correlates of LTP suggest that cytoskeletal modifications are involved in LTP stabilization. Calpain 1, a  $Ca^{2+}$ -dependent protease with multiple cytoskeletal substrates, is present in dendrites and has an activation threshold within the range (low  $\mu M$ ) of  $Ca^{2+}$  concentrations achieved postsynaptically during high frequency stimulation. To investigate the potential role of calpain-mediated cytoskeletal cleavage in LTP, we sought to determine if calpain-mediated proteolysis is triggered by theta-burst stimulation (TBS), and if activation of the protease is necessary for the stable expression of potentiation. Using an antibody to the C-terminal calpain cleavage product of spectrin, we found that application of TBS to Schaffer-collateral axons in cultured hippocampal slices results in the accumulation of spectrin breakdown products (BDPs) in post-synaptic elements. Labelling occurred in the form of scattered puncta and immunostained dendritic processes in the stratum radiatum. The extent of these effects was correlated with the amount of TBS delivered using a six-point rating scheme ( $r=0.73$ ); slices receiving low frequency stimulation exhibited uniformly lower BDP staining ( $p < 0.001$ ). Cultured slices were also treated (5 days, 25  $\mu g/ml$ ) with antisense or sense oligonucleotides directed at calpain 1 mRNA. Antisense treatment reduced calpain 1 expression by approximately 50% as measured by activity and immunoblot assays. Following treatment, we attempted to induce LTP in antisense and control slices. The short-term effects of TBS ( $< 10$  min) were not different between groups. However, EPSPs measured 30 min post-TBS were significantly less potentiated in antisense slices compared to controls ( $108 \pm 3.9\%$  vs.  $133 \pm 6.3\%$  of baseline;  $p = 0.003$ ,  $n=10$  each). These results indicate that a cytoskeletal element, spectrin, is cleaved by calpain in response to LTP-inducing stimulation, and that this event may be a prerequisite for stabilizing mechanisms (supported by grants AFOSR 92-J-0307 and NIH AG00538 to G.L. and C.G.).

## POTASSIUM CHANNEL STRUCTURE, FUNCTION AND EXPRESSION III

## 524.1

**SUBSTITUTION OF G-PROTEIN BINDING DOMAINS ON THE C-TERMINUS ALTERS PORE PROPERTIES OF GIRK1:** K.M. Hurley\*, A. Kuznetsov, L. Philipson, and D. Nelson Depts. of Neurology, Medicine, and Pharmacol. & Physiol. Sci. The University of Chicago, Chicago, IL 60637.

Previously we have identified a region on the C terminus of GIRK1(C $\alpha$ ) capable of participating in the formation of coiled-coils and which we hypothesize is a G $\beta\gamma$  binding domain. To test our hypothesis, we created a chimeric channel in which C $\alpha$  was replaced by the  $\beta\gamma$  binding site from the C terminus of  $\beta$ ARK. Ile 331 was replaced by Arg and Asn 384 was replaced either by Arg or Gly. Co-expression of GIRK- $\beta$ ARK I331R/N384G with M2 yielded an inwardly rectifying Icarb 25% of wild type current amplitude. N384R produced a non-functional mutant. We observed that 4% of Icarb was sensitive to block by 100  $\mu M$  Ba $^{2+}$  in the external solution for GIRK- $\beta$ ARK I331R/N384G as opposed to the 98% block observed for GIRK-C. A significant leftward shift in the current-voltage relationship was observed for GIRK- $\beta$ ARK I331R/N384G. The current activation kinetics were also altered by substitution of the  $\beta$ ARK G $\beta\gamma$  binding domain for C $\alpha$ . The time course of current activation for GIRK1 has three components: instantaneous, fast ( $\tau_1$ ), and slow ( $\tau_2$ ). The initial instantaneous component of activation is absent in GIRK- $\beta$ ARK I331R/N384G. In addition,  $\tau_1$  is 9.4 times slower and  $\tau_2$  is 5.3 times slower than what is observed for GIRK1. The desensitization of wild-type currents typically observed with prolonged exposure to carbachol is replaced by a 200% potentiation of the carbachol induced currents in the GIRK- $\beta$ ARK chimeras. The dramatic changes observed in the biophysical properties of this chimera as compared to GIRK1 indicate that this region may not only be a G $\beta\gamma$  binding site critical for channel activation, but that it may also be part of the pore itself.

## 523.12

**ADHESION MOLECULES & HIPPOCAMPAL PLASTICITY: INTEGRIN-TYPE MATRIX RECOGNITION CONTRIBUTES TO THE STABILIZATION OF LTP, POSSIBLY INVOLVING THE RGDS-SELECTIVE MATRIX RECEPTOR F55.** B.A. Bahr, P. Xiao, E.T. Esteban & G. Lynch, The Center for the Neurobiology of Learning and Memory, University of California, Irvine, California 92717.

Synapse modulation, selection, and formation processes are frequently invoked to explain certain types of synaptic plasticity and memory encoding. Correlates of such processes are evident during neurodevelopmental events that involve at least two classes of adhesion molecules. The first is a subgroup of the immunoglobulin superfamily known as neural cell adhesion molecules (NCAMs) and which have recently been implicated in long-term potentiation (Lüthi et al., Nature 372:777, 1994). The second is the integrin family of matrix receptors whose antagonists RGDS (Staubli et al., Behav. Neural Biol. 53:1, 1990) and GRGDSP (Xiao et al., NeuroReport 2:461, 1991) inhibit LTP stabilization. Studies (Grooms et al., Exp. Neurol. 122:253, 1993) have also indicated that hippocampal synapses contain integrin-like proteins that bind RGDS peptides (e.g., F55; Bahr & Lynch, Biochem. J. 281:137, 1992).

The present study tested if integrins operate during a different LTP stage than that determined for NCAMs, and whether candidate LTP stabilizers are identified with RGDS-affinity chromatography. Hippocampal slices treated with RGDS-peptides starting 10 min after LTP induction ( $n=13$ ) exhibited control-level LTP ( $n=17$ ) for 30 min but then gradually decayed by 40% ( $p < 0.01$ ). In contrast, Lüthi et al. demonstrated that post-induction dissociation of NCAMs did not destabilize previously established potentiation. RGDS-peptides also eluted the 55-kDa F55 and faint 27 and ~120 kDa proteins from GRGDSP-sepharose; F55 was labeled by antibodies to the  $\alpha_5\beta_1$  integrin and co-migrated with synaptophysin during synaptosome isolation. Similar proteins were eluted with GAVSTA which interacts with the RGDS region of matrix proteins; correspondingly, the GAVSTA peptide also blocked stable LTP by 51% ( $p < 0.001$ ;  $n=16$ ). Thus, integrin-type matrix interactions via F55 may be involved in the functional reorganization of synaptic contacts (AFOSR 89-0383).

## 524.2

**A NOVEL INWARD RECTIFIER POTASSIUM CHANNEL EXPRESSED PREDOMINANTLY IN GLIAL CELLS.** T. Takumi, T. Ishii, Y. Horio, K. Morishige, N. Takahashi, M. Yamada, T. Yamashita, H. Kivama, K. Sohma, S. Nakanishi, and Y. Kurachi\*, Dept. of Pharmacology, Dept. of Neuroanatomy, Fac. of Med. Osaka Univ., Suita, Osaka 565 and Inst. for Immunology, Kyoto Univ. Fac. of Med., Sakyo, Kyoto 606-01, Japan.

We have isolated a novel inward rectifier K $^{+}$  channel predominantly expressed in glial cells of the central nervous system. Its amino acid sequence with a Walker type-A ATP-binding domain exhibited 53 % identity with ROMK1 and approximately 40 % identity with other inward-rectifier K $^{+}$  channels. We designate this new clone as K $_{AB}$ -2 (the second type of inward-rectifying K $^{+}$  channel with an ATP-binding domain). *Xenopus* oocytes injected with cRNA derived from this clone expressed a K $^{+}$  current which showed classical inward rectifier K $^{+}$  channel characteristics. *In situ* hybridization showed K $_{AB}$ -2 mRNA to be expressed predominantly in glial cells of the cerebellum and forebrain. Therefore, the K $_{AB}$ -2 channel is, for the first time, identified as a glial cell inward-rectifier potassium channel, which may be responsible for K $^{+}$  buffering action of glial cells in the brain.

## 524.3

CLONING AND LOCALIZATION OF TWO BRAIN-SPECIFIC INWARDLY RECTIFYING POTASSIUM CHANNELS. Noam A. Cohen\*, David S. Bredt, David J. Liss, and Solomon H. Snyder. Dept. of Neurosci., Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

Recently, a new family of genes encoding inwardly rectifying K<sup>+</sup> channels have been cloned. Utilizing a PCR based cloning strategy, with degenerate primers designed against conserved regions of the inwardly rectifying K<sup>+</sup> channels, two new members of the family have been identified in rat. Northern blot analysis of these clones demonstrates that they are localized selectively to the brain and are designated Brain Inwardly Rectifying K<sup>+</sup> (BIRK) channels. No expression is detected in kidney, spleen, liver, heart, or skeletal muscle. BIRK1 occurs in the brain at high density and is particularly enriched in the brainstem. BIRK2 is far less abundant and is most prominently expressed in the cerebral cortex, with lower levels in the corpus striatum and hippocampus. *In situ* hybridization for BIRK1 reveals neuronal distribution with highest densities of BIRK1 expression occurring in the area postrema, and lower densities in specific brain stem nuclei, including the vestibular nuclei, the motor and spinal trigeminal nuclei, and the ventral cochlear nucleus. *In situ* hybridization for BIRK2 also displays a discrete localization consistent with a neuronal distribution with highest levels in the forebrain. High levels of expression occur in the cerebral cortex with the most prominent labeling in the superficial layers. In the hippocampus, the dentate gyrus is most prominently labeled with levels in the CA-1-CA-3 regions being substantially less intense. Immunoprecipitation of BIRK1 reveals a band of approximately 70 kDa. Treatment of the immunoprecipitated protein with glycosidases increases the mobility of BIRK1 to a band of approximately 64 kDa.

## 524.5

INWARDLY RECTIFYING K<sup>+</sup> CHANNELS ARE LOCALIZED IN MICROVILLI OF SCHWANN CELLS AND MAY PARTICIPATE IN K<sup>+</sup> BUFFERING. H. Mi<sup>1</sup>, T.J. Deerinck<sup>2</sup>, M. Jones<sup>1</sup>, M.H. Ellisman<sup>2</sup>, T.L. Schwarz<sup>1\*</sup>. <sup>1</sup>Dept. of Molecular and Cellular Physiology, Stanford Univ., Stanford CA 94305 and <sup>2</sup>Dept. of Neurosciences, UCSF, La Jolla CA 92093.

The presence of K<sup>+</sup> channels in Schwann cells suggests that these cells may participate actively in action potential propagation in the peripheral nervous system. One previously suggested possibility is the buffering of extracellular K<sup>+</sup> to prevent accumulation of K<sup>+</sup> during axonal repolarization. An inwardly rectifying K<sup>+</sup> channel that could mediate this effect has been recorded in Schwann cell membranes near the node of Ranvier.

We have identified two inwardly rectifying K<sup>+</sup> channels, IRK1 and IRK3, that are expressed in adult rat Schwann cells. Immunocytochemistry with a polyclonal antibody localized these channels to nodes of Ranvier in sciatic nerve. Immunoelectron microscopy demonstrated that these K<sup>+</sup> channels are highly concentrated in microvilli (also called nodal processes) that protrude from the surface of the Schwann cell at the node and fill much of the nodal cleft. This localization is distinct from that which we had previously observed for the delayed rectifier channel Kv1.5; Kv1.5 is also concentrated near the node, but it is not abundant in the microvilli. These microvilli have a large surface area and are well situated for buffering extracellular K<sup>+</sup>. The presence within these structures of channels that are capable of permitting K<sup>+</sup> influx at resting membrane potentials lends support to the K<sup>+</sup> buffering hypothesis and indicates that IRK1 and IRK3 are likely to mediate this effect. The restricted distribution of these channels underscores how tightly channel localization is controlled in cells and how specialized the membrane domains of Schwann cells are for proper function.

## 524.7

G PROTEIN-ACTIVATED INWARDLY RECTIFYING POTASSIUM CHANNELS EXPRESSED IN *XENOPUS* OOCYTES ARE INHIBITED BY ANTISENSE cDNA. M. U. Ehrenguber, L. Byerly\*, P. Kofuji, Y. Xu, C. Lin, H. A. Lester and N. Davidson. Div. Biology, Caltech, Pasadena, CA 91125.

G protein-activated inwardly rectifying potassium channels (GIRKs) play a crucial role in determining cellular excitability. GIRK1 was originally cloned from rat atrium where it occurs as a heteromultimer with GIR2, a member of the GIRK1 gene family. The family members GIRK1, GIRK2, and GIRK3 are found in the brain. We plan to use antisense cDNA plasmids to construct recombinant adenovirus for *in vivo* suppression of GIRKs, in order to identify their role in neuronal synaptic transmission. In preparation for these experiments, GIRKs were cloned into expression plasmids, injected together with the m2 acetylcholine receptor into the nucleus of *Xenopus* oocytes, and tested functionally using the two-electrode voltage clamp technique. We also constructed plasmids carrying antisense cDNA for GIRKs. To monitor the efficiency of nuclear injection, Shaker potassium channel cDNA was coinjected. Injection of GIRK1 or GIRK2 resulted in acetylcholine-sensitive GIRK currents which strongly correlated with Shaker currents. The ratio of GIRK2 currents at -120 mV to Shaker currents at 40 mV was 0.044, while it was only 0.013 when an equal amount of antisense GIRK2 was also injected. We are now testing different sense/antisense ratios, antisense cDNA lengths, GIRKs, and GIRK combinations. Our results demonstrate that specific antisense cDNA is efficient in suppressing GIRK currents, and that nuclear injection of *Xenopus* oocytes is useful to test antisense cDNA eukaryotic expression vectors in anticipation of studies applying antisense knockout of cDNA function in neurons and other cells. Supported by the Swiss National Science Foundation, NIMH, NIGMS, and HFSP.

## 524.4

GENOMIC STRUCTURE OF THE HUMAN G PROTEIN ACTIVATED POTASSIUM CHANNEL HGIRK1. †# O. Schoots\*, ‡ T. Voskoglou and †§ H.H.M. Van Tol # Rudolf Magnus Institute, Utrecht, The Netherlands; § Dept. of Pharmacol., Univ. of Toronto; †Clarke Inst. of Psychiatry, Toronto, Ont. Canada, M5T 1R8.

HGIRK1 is a human inwardly rectifying potassium channel which is opened by free G protein  $\beta\gamma$  dimers generated through the activation of various G protein linked receptors. This activation is mediated through a membrane-delimited pathway that does not involve cytoplasmic intermediates. We studied the genomic structure of HGIRK1. Southern blot analysis of human genomic DNA with a 2.9 kb HGIRK1 cDNA as a probe indicated the presence of at least two introns. Screening of a human genomic library with this cDNA resulted in the isolation of several positively hybridizing clones. Analysis of these clones showed that the gene contained three exons and two introns. The total size of the HGIRK1 gene exceeds 65 kb. In the exons three polymorphisms were found as compared to the HGIRK1 cDNA clone. The transcription initiation site was established by rapid amplification of the 5' end of the HGIRK1 cDNA and S1 nuclease protection assays. Sequences upstream of the mRNA transcription start site were analysed for promoter activity. Promoter constructs with  $\beta$ -galactosidase and luciferase reporter genes were made and tested in various cell lines.

## 524.6

CO-INJECTION OF PORE MUTANTS WITH WILD TYPE IRK1 BLOCKS CHANNEL EXPRESSION IN *XENOPUS* OOCYTES J.L. Kugler\*, W.W. Xie, L.H. Philipson, and D.J. Nelson, University of Chicago, Chicago, IL 60637.

We have identified a critical residue in the pore region of the inward rectifier IRK1, Arg148, which when mutated to Met, Ile, Asn, His, Glu, or Ala, produces non-functional channels in *Xenopus* oocytes. To investigate the ability of these non-expressing pore mutants to act as dominant negatives, we co-injected them with wild type mRNA. When mRNA coding for the R148H and R148I mutants was injected at 1:1 with wild type mRNA, channel function was blocked. Co-injecting non-expressing C-terminally truncated channels had no effect on wild type currents. This indicates that 1) the site-directed mutants are being properly synthesized, and 2) the mutants are coassembling with the wild-type subunits and are blocking function at some point. We hypothesize that this residue may be interacting with Glu139 to form a structurally stabilizing salt bridge, possibly between adjacent subunits.

WILD-TYPE + R148I  
Currents recorded in 50 mM K<sup>+</sup> by TEVC of *Xenopus* oocytes.

## 524.8

MONITORING CHANGES IN PROTON METABOLISM ENABLES A FUNCTIONAL ANALYSIS OF INWARDLY RECTIFYING POTASSIUM CHANNELS EXPRESSED IN YEAST. K.M. Hahnenberger<sup>1</sup>, S. Kurtz<sup>2</sup>, T. Hoshi<sup>3</sup> and D.L. Miller<sup>1\*</sup>. <sup>1</sup> Molecular Devices Corporation, Sunnyvale, CA 94089. <sup>2</sup> Bristol-Myers Squibb Pharmaceutical Research Institute, Princeton, NJ 08543. <sup>3</sup> Dept. of Physiology, University of Iowa, Iowa City, IA 52242.

It has previously been shown that expression of mammalian cardiac inwardly rectifying K channels and a member of the Shaker superfamily of K channels from *Arabidopsis thaliana*, complement a defect in potassium uptake in yeast strains lacking both high and low affinity potassium transporters. In yeast, K is taken up in a 1:1 ratio with extrusion of protons. The plasma membrane H-ATPase establishes a highly negative electrical potential across the membrane, which presumably maintains the inwardly rectifying K channels in the open state.

We have utilized the tight coupling between potassium uptake and proton extrusion in yeast to analyze the function of inwardly rectifying K channels using microphysiology. The microphysiometer is a silicon sensor-based instrument which measures the rate at which cells acidify their external environment and can be used to detect small changes in proton fluxes across the plasma membrane. Exposure of yeast cells expressing a guinea pig cardiac IRK1 homologue or the *A. thaliana* KAT1 gene to channel blockers such as Cs and TEA results in a rapid and transient decrease in proton flux. Removal of the channel blockers results in a transient increase in acidification rates. The effectiveness of the channel blockers varied; the strain expressing the inward rectifying K channel exhibits a greater response to Cs while the strain expressing the plant Shaker channel was more affected by TEA. This system can be used to perform mutational analysis of ion channel function and to identify compounds which modulate ion channel activity.

## 524.9

PARTIAL CLONING AND CHARACTERIZATION OF A TWO-TRANSMEMBRANE DOMAIN K<sup>+</sup> CHANNEL IN CHICK. C.W. Lu\* and S.W. Halvorsen. Dept. of Biochem. Pharmacol., SUNY at Buffalo, Buffalo, NY 14260.

While the function of ATP-sensitive potassium channels (K<sup>+</sup>ATP) in controlling insulin release in pancreas has been described, little is known about their roles in the nervous system or muscle. Recently, K<sup>+</sup> channels (cKATP-1/CIR, uKATP-1) containing two putative transmembrane domains were cloned from rat heart. Whether they are K<sup>+</sup>ATP or muscarinic K<sup>+</sup> channel components is still unresolved. We are interested in investigating the regulation of expression and function of these channels in the developing chick heart and nervous system. Degenerate oligonucleotide primers were designed from homologous regions of the N-terminal and pore-forming regions of cKATP-1 and other two-transmembrane domain K<sup>+</sup> channels and used for RT-PCR with total RNA isolated from embryonic chick heart. A 0.44 kb product was obtained whose DNA sequence showed the encoded peptide had 90% identity with cKATP-1. This DNA fragment (C113KATP) represented 1/3 of the putative full reading frame. Northern blot analysis using <sup>32</sup>P-labeled C113KATP revealed a 2.7 kb message in ciliary ganglion, heart, leg and brain (in the lowest to highest expression order).

We are examining the regulation of this chick K<sup>+</sup> channel by electric activity, metabolic states and ligands associated with K<sup>+</sup> channel activity.

## 524.11

5-HT-INDUCED INHIBITION VIA G PROTEINS OF AN IRK CHANNEL CLONED FROM RAT BASOPHILIC LEUCEMIA CELLS. E. Wischmeyer, E. Dißmann, K.-U. Lentjes\* and A. Karschin. Max-Planck-Inst. for biophysical Chemistry, 37077 Göttingen, FRG.

The basophilic leucemia cell line RBL-2H3 exhibits a robust inwardly rectifying K<sup>+</sup> current, *I*<sub>KIR</sub>, which features steep voltage dependence and is under the inhibitory control of an as yet unidentified signaling pathway. We have isolated by PCR amplification from RBL cDNA an IRK-type channel (RBL-IRK1) which showed 94% base-pair identity to the mouse IRK1 (s. Wischmeyer et al., 1995, Eur. J. Physiol. 41:809). When transiently transfected in COS cells, the expressed 25 pS RBL-IRK1 channels gave rise to currents with single channel and macroscopic properties identical to those in RBL cells. Intracellular perfusion for 10 min with GTPγS in the whole-cell mode of patch-clamp recording suppressed *I*<sub>KIR</sub> by 50-80%. When COS cells were cotransfected with 5-HT<sub>1A</sub> receptors, application of 100 μM 5-HT (in 12/24 cells) also induced a current inhibition by 40.3±21.8% which could be mimicked by the selective 5-HT<sub>1A</sub> agonist 8-OH DPAT and antagonized by 100 μM pindolol. More consistent and more pronounced current inhibition resulted from the simultaneous administration of 5-HT and the membrane-permeable 8-bromo-cAMP. Whereas 8-bromo-cAMP (100 μM) alone did not consistently affect *I*<sub>KIR</sub>, coapplication with 50 μM 5-HT induced a block by 90.6±9.3% in 80% of the cells. The time constants of onset and relaxation from block were equally slow (τ=5 s). Thus, recombinant IRK-type channels in COS cells may be negatively controlled by a signaling process that possibly involves PKA-dependent phosphorylation.

## 524.13

MUSCARINIC MODULATION OF INWARD RECTIFIER CURRENT IN RAT SYMPATHETIC NEURONS. Hong-Sheng Wang, Jane E. Dixon and David McKinnon\*. Dept. of Neurobiology and Behavior, State University of New York, Stony Brook, NY 11794

Intracellular recordings were made from rat sympathetic neurons in isolated superior cervical ganglia (SCG), celiac ganglia (CG), and superior mesenteric ganglia (SMG). Neurons were classified as either 'phasic' or 'tonic' based on their response to a maintained depolarizing current stimulus. Inward rectifier current was differentially expressed in phasic and tonic neurons. The inward rectifier conductance was 6.4 times larger in tonic neurons than in phasic neurons. The conductance was blocked by low concentrations of external Ba<sup>2+</sup> and Cs<sup>+</sup> ions. The inward rectifier appeared to contribute to the resting membrane potential of tonic neurons.

The inward rectifier current was down-regulated by synaptic input. Repetitive stimulation of the input nerve trunk suppressed the inward rectifier conductance by 50-70%. The inhibition had a slow onset of 20-30 seconds, suggesting a second messenger mediated pathway. This synaptically mediated suppression was blocked by 1 μM atropine, and can be mimicked by bath application of muscarine. Application of 20 μM muscarine produced an average 78 ± 1.4% inhibition of the current. From dose-response curves for muscarine a mean dissociation constant of K<sub>D</sub> = 1.95 ± 0.2 μM was determined. Schild plot analysis using the competitive antagonists pirenzepine and himbacine indicated that the effect of muscarine was mediated by the M1 class of muscarinic receptors. By down-regulating the inward rectifier, synaptic input probably increases the excitability of tonic neurons.

We have examined the expression of inward rectifier potassium channel genes in the sympathetic ganglia to determine which gene product underlies this current. We have also begun to reconstruct this neuromodulatory system in *Xenopus* oocytes to determine the molecular mechanisms involved.

## 524.10

G-PROTEIN α-SUBUNIT SELECTIVITY OF A CLONED INWARDLY RECTIFYING K<sup>+</sup> CHANNEL (GIRK) EXPRESSED IN *XENOPUS* OOCYTES. G.R. Seabrook\*, N.A. Brown, D. Weinberg<sup>2</sup>, G. Milligan<sup>3</sup>, and G. McAllister. Merck Sharp & Dohme, Terlings Park, Eastwick Rd, Harlow Essex, CM20 2QR U.K. <sup>2</sup>Merck Research Laboratories, Rahway, NJ 07065 and <sup>3</sup>Univ. Glasgow, Glasgow, G12 8QQ, Scotland, U.K.

This study investigated the selectivity of G-protein α subunits for G-protein gated inwardly rectifying K<sup>+</sup> channels (GIRK) expressed in *Xenopus* oocytes using conventional two-electrode voltage-clamp recording techniques. The cDNA encoding GIRK was subcloned from a rat brain library and co-expressed with the cDNA for either G-protein α<sub>o</sub>, α<sub>i1</sub>, α<sub>i2</sub>, or α<sub>i3</sub> subunits, as well as one of a series of different G-protein linked neurotransmitter receptors. These included the human D<sub>2</sub>(short) and human NPY<sub>1</sub> receptors. Cells were voltage-clamped at -80 mV and after equilibration in high external K<sup>+</sup> (96 mM) to reverse the K<sup>+</sup> ion gradient (e.g. Dascal et al., 1993 P.N.A.S. 90, 10235-10239) the ability of receptors to activate inward currents was examined. No effects of D<sub>2</sub> or NPY<sub>1</sub> receptor agonists were observed in control experiments (GIRK + alternative receptor). Co-expression with G-protein α subunits differentially increased the efficiency of receptor mediated activation of GIRK channels depending upon the species of receptor involved. Thus it was unlikely that these variations were due to differences in efficiency of subunit expression, and most probably reflects the preferences of cloned receptors for different second messenger pathways.

## 524.12

EXPRESSION AND CELLULAR LOCALIZATION OF SIX MEMBERS OF THE GIRK AND IRK FAMILY OF INWARDLY RECTIFYING K<sup>+</sup> CHANNELS. C. Karschin, E. Dißmann<sup>1</sup>, W. Stühmer and A. Karschin<sup>1\*</sup>. MPI for Experimental Medicine and <sup>1</sup>Biophys. Chemistry, 37077 Göttingen, FRG.

The activity of inwardly rectifying K<sup>+</sup> channels is either controlled by the action of G proteins (GIRK-type) or is primarily dependent on the membrane potential (IRK-type). Molecular cloning has shown that each subfamily consists of several closely related members encoded by separate genes. In situ hybridization for 2 channels and Northern blot analysis indicate that GIRK1 and IRK2 subunits may exist in the rat brain and GIRK2, GIRK3, IRK1 and IRK3 in the mouse brain. This study provides evidence for the differential expression of all six subunits in the adult rat brain. In addition to the molecular cloning of the rat homologues from a brain cDNA library, we have performed an in situ hybridization study to evaluate the mRNA expression and cellular localization. Using specific [<sup>35</sup>S]-labeled oligonucleotide probes directed to non-conserved regions, we detected wide distribution with partly overlapping expression of the mRNAs of GIRK1,2,3 and IRK1,2,3. The distribution patterns of the GIRK subunits were very similar with high levels of expression in the cerebellum, olfactory bulb, cortex, thalamus and hippocampus. Marked differences existed in thalamic, hypothalamic and brainstem nuclei, e.g. both GIRK1 and GIRK2 were strongly expressed in the septum, where GIRK3 was absent. In contrast, IRK subunits were more differentially expressed: all mRNAs were abundant in dentate gyrus, caudate putamen, olfactory bulb and piriform cortex. IRK1 and IRK3 were restricted to these regions, but they were absent from most parts of the thalamus, cerebellum and brainstem, where IRK2 was predominantly expressed. Overlapping expression in the same cells may point to functional consequences if certain channel subunits assemble as heteromultimers, as has been evidenced recently.

## 524.14

IDENTIFICATION AND LOCALIZATION OF CA<sup>2+</sup>-ACTIVATED K<sup>+</sup> CHANNELS IN SCIATIC NERVES. R.M. Harris-Warrick<sup>1\*</sup>, H. Mi<sup>2</sup>, I. Inman<sup>2</sup>, T.J. Deerinc<sup>3</sup>, T.L. Schwarz<sup>2</sup>, M.H. Ellisman<sup>3</sup>.

<sup>1</sup>Dept. of Neurobiology and Behavior, Cornell Univ., Ithaca, NY 14853, <sup>2</sup>Dept. of Molecular and Cellular Physiology, Stanford Univ., Stanford CA 94305 and <sup>3</sup>Dept. of Neurosciences, UCSD, La Jolla CA 92093.

A large family of Ca<sup>2+</sup>-activated K<sup>+</sup> channels is encoded by the *slo* gene through alternative splicing. In order to understand the physiology of Schwann cells and myelinated nerve, we have studied the expression of this family of channels in peripheral nerve. By RT-PCR and hybridization screening of cDNA libraries of adult rat sciatic nerve, we cloned homologues of *slo* that were more than 95% identical to the murine *slo*. Though we had anticipated that this tissue might present a simpler array of gene products than the brain, we found instead that sciatic nerve RNA contained numerous alternatively spliced variants. There are three different regions in the channel that are subject to alternative splicing. Splice sites A and B were reported in both mouse and human *slo*. In rat sciatic nerve, splice site A has three forms with inserts of 0, 3, or 58 amino acids, and splice site B has two forms with either 0 or 26 amino acids. The third region, which was also seen in human *slo*, has two variants with either 0 or 4 amino acids (RSRK). We raised a polyclonal antibody against a peptide from the carboxyl terminal of the channel that is predicted to see all the forms of this channel. Immunocytochemistry revealed that the channel proteins are in Schwann cells and are associated with canaliculi that follow the outer surface of the cells. They are also relatively concentrated near the node of Ranvier in the Schwann cell outer membrane. The staining pattern is quite similar to what we previously reported for the voltage dependent K<sup>+</sup> channel Kv1.5. Electron microscopic studies are in progress to characterize the ultrastructural localization of the channels.

**Modulation of large conductance  $\text{Ca}^{2+}$ -activated  $\text{K}^+$  channel activity by charged lipids: structural requirements.** Alison L. Clarke, Steven Petrou, John V. Walsh, Jr. and Joshua J. Singer\*. Dept. Physiology, U. of Massachusetts Medical School, Worcester, MA 01655.

In a previous study carried out in toad stomach smooth muscle cells we showed that the features of the fatty acid (FA) required for its activation of a 50 pS  $\text{K}^+$  channel were both a negatively charged head group and a sufficiently hydrophobic acyl chain (Petrou *et al.*, JGP, 103:471). In the present study we investigated whether similar structural features are required for modulation of the activity of a different  $\text{K}^+$  channel; the large-conductance (270 pS)  $\text{Ca}^{2+}$ -activated  $\text{K}^+$  channel (CAK) in the smooth muscle cells from the rabbit pulmonary artery (RPA). Three classes of analogs, structurally related to short and medium chain length FAs, as well as some naturally occurring lipids (10-50  $\mu\text{M}$ ) were applied to inside-out and outside-out patches. Compounds in which the negatively charged carboxylic acid head group is replaced with a negatively charged sulphate group (alkyl sulphates) mimic the action of FAs, increasing channel activity. Palmitoyl lysophosphatidate, a negatively charged naturally occurring lipid, also increased channel activity. Alkyl amines, in which the negatively charged head group is replaced with a positively charged ammonium or trimethylammonium group and the endogenous, positively charged lipid, sphingosine, suppressed channel activity. *n*-Alkanols, like dodecanol, which possess a neutral head group had no effect on channel activity. Because the CAK channel of the rabbit pulmonary artery is gated by both voltage and  $\text{Ca}^{2+}$ , the possibility that these charged lipids may act by changing the local  $[\text{Ca}^{2+}]_i$  or the electric field within the membrane by affecting membrane surface charge needed to be addressed. FAs and FA analogs were effective in  $\text{Ca}^{2+}$  free solutions (0 mM  $\text{Ca}^{2+}$ , 5 mM or 20 mM EGTA) so that FA action via effects on local  $[\text{Ca}^{2+}]_i$  seems to be ruled out. Moreover, responses were obtained in experiments in which FAs and other analogs were applied to patches in high ionic strength (330 mM KCl) bath and pipette solutions, to "shield" surface charge. This study shows that the structural features of FAs required for activation of the toad 50 pS  $\text{K}^+$  channel are shared by the CAK channel of the RPA. The mechanism of FA action on the CAK channel appears to be direct suggesting that FAs and other naturally occurring lipids, like sphingosine and palmitoyl lysophosphatidate, may act as endogenous second messengers on this channel. NIH DK 31620.

***cslo*, A CALCIUM-ACTIVATED POTASSIUM CHANNEL GENE EXPRESSED IN CHICK'S COCHLEA.** G.-j. Jiang, M. Zidanic, C. Griguer and P.A. Fuchs\*. Dept. Physiol., U. Colorado Sch. Med., Denver, CO 80262.

Large conductance calcium-activated potassium channels (maxi- $\text{K}^+$  channels) contribute to electrical tuning of auditory hair cells in several nonmammalian vertebrate species.  $\text{I}_{\text{K(Ca)}}$  flowing through maxi- $\text{K}^+$  channels, appears late during cochlear development in chicks, coincident with a period of rapid functional maturation. We have screened a cDNA library derived from hatching chick's cochlear duct for clones with homology to *mslo*, a mouse brain homologue of the *Drosophila* gene *slowpoke* that codes for large conductance calcium-activated potassium channels (*mslo* provided by Dr. L. Salkoff, Washington U.). A full-length clone (3.9 kb) was isolated and sequenced and found to have 97% identity at the amino acid level with *mslo* over the S1-S6 transmembrane domains. In the extended carboxy terminus characteristic of slowpoke transcripts the degree of identity dropped to 93%. At the very 3' end *mslo* extends 53 amino acids further than *cslo*. *cslo* is better matched to the recently described human brain maxi- $\text{K}^+$  channel *hbr1* (Tseng-Crank *et al.*, 1994, *Neuron* 13:1315) at the 5' and 3' ends where both sequences diverge from that of *mslo*. Like *hbr1*, *cslo* contains no inserts at splice sites 1-4. It will be of interest to learn if transcription of a *cslo* variant underlies the developmental acquisition of  $\text{I}_{\text{K(Ca)}}$ . Supported by NIDCD DC 00276 and the National Organization for Hearing Research.

**DIFFERENCES IN CALCIUM SENSITIVITY OF TWO HUMAN BK CHANNEL ALTERNATIVE SPLICE VARIANTS.** S.I. Dworetzky\*, J.T. Trojnecki, M.C. McKay, C.G. Boissard, J.E. Starrett and V.K. Gribkoff. CNS Drug Discovery, Dept. 405 Bristol-Myers Squibb Co., Wallingford, CT 06492.

Several lines of physiological evidence exist for the diversity of BK channels in native cells, yet to date, only 1 gene encoding the large conductance calcium-activated potassium channel has been cloned. Alternative exon splice variants, regulatory subunits, and the existence of additional family members are some of the possibilities that could explain the differences observed in calcium sensitivities, pharmacology, single channel conductance, and channel kinetics. We have cloned several *hSlo* splice variants and report on the calcium and pharmacological sensitivities of two isoforms. There exists two splice exons at junction A, 1 at junction B, and 1 at junction C. Splice exons A1 (3 aa), B1 (27 aa) and C1 (4 aa) are identical to the *mSlo* exons. The A2 splice exon, which codes for a 29 aa insert, is only 62% homologous to the equivalent *mSlo* exon. The two variants, *hSlo* (no splice exons) and *hSloA2* (containing the A2 exon) were investigated using the two-electrode voltage clamp configuration in oocytes and inside-out single channel recordings from transiently transfected HEK 293 cells. The current-voltage relationships of oocytes expressing *hSlo* and *hSloA2* were virtually identical under control conditions, as was their response to the benzimidazole BK opener NS1619 and the specific peptidergic BK blocker iberiotoxin. The single channel conductance of the *hSlo* and *hSloA2* channels were both approximately 285 pS. However, a significant difference in their sensitivity to calcium was observed; the *hSloA2* channels were significantly more sensitive to calcium. These results demonstrate that the inclusion of the A2 exon confers an increased calcium sensitivity to the *hSlo* channel, although the functional consequences of this is not yet known.

## 524.16

**MOLECULAR GENETIC STUDIES OF THE HUMAN  $\text{Ca}^{2+}$ -ACTIVATED  $\text{K}^+$  CHANNEL  $\alpha$  AND  $\beta$  SUBUNITS.** N. Godinot<sup>1</sup>, P. Reinhart<sup>3</sup>, A. Baktha<sup>1</sup>, N. Shepherd<sup>1</sup>, S. Stinnett<sup>1</sup>, W. Kimberley<sup>1</sup>, R. Mertz<sup>2</sup>, C. D. Foster<sup>2</sup>, and J. Tseng-Crank<sup>1\*</sup>. <sup>1</sup>Dept. of Molecular Genetics and <sup>2</sup>Dept. of Cell Physiology, Glaxo Research Institute, RTP, NC 27709 and <sup>3</sup>Dept. of Neurobiology, DUMC, P.O. Box 3209, Durham, NC 27710.

The  $\text{Ca}^{2+}$ -activated  $\text{K}^+$  channels ( $\text{K}_{\text{Ca}}$ ) regulate various physiological functions such as muscle contraction and neurotransmitter secretion by direct coupling of intracellular  $\text{Ca}^{2+}$  to membrane potential. We studied tissue specificity of channel isoforms and possible linkages of channel genes to inherited diseases in order to define a role for this channel in therapeutic exploitations. We have cloned the  $\text{K}_{\text{Ca}}$  channel  $\alpha$  and  $\beta$  subunits from a human brain cDNA library and human genomic libraries. Both subunits are encoded by single genes, with multiple intron/exon structures for the  $\alpha$  subunits and at least 2 introns interrupting the coding sequences of the  $\beta$  subunit. The  $\alpha$  subunit is widely distributed, being found in virtually all tissues, while expression of the  $\beta$  subunit is restricted to smooth muscles and a few brain regions. Coexpression of both subunits may, therefore, offer functional specificity of the  $\text{K}_{\text{Ca}}$  channels in smooth muscles. We defined human chromosomal localizations by Southern hybridization to human-hamster somatic hybrid cell lines and by FISH analysis. The  $\alpha$  subunit is located at chromosome 10q22.3 and the  $\beta$  subunit is located at chromosome 5q34. We are currently characterizing suitable microsatellite markers to carry out disease linkage analysis.

Work supported in part by NIH grant #NS31253 to PHR.

## 524.18

**CLONING AND CHARACTERIZATION OF THE  $\beta$ -SUBUNIT OF A HUMAN MAXI-K CHANNEL** Kimberly Folander\* and Richard Swanson Dept. of Pharmacology, Merck Research Labs, West Point, PA 19486

Large conductance  $\text{Ca}$ -activated potassium (maxi- $\text{K}$ ) channels have been demonstrated to be composed of two subunits ( $\alpha$  and  $\beta$ ). cDNAs encoding the  $\beta$ -subunit of a human maxi- $\text{K}$  channel were isolated by screening a human aorta cDNA library and the deduced amino acid sequence is ~85% identical to the bovine protein. The gene encoding the beta subunit was mapped to human chromosome 5q34-q35 using both hybridization to DNAs derived from a panel of somatic cell hybrids and the identification of CEPH human megaYACs encoding this gene that were previously mapped to this region. Transcription of the gene was demonstrated, by Northern analysis, in a variety of human tissues with the highest levels in uterus, aorta, small intestine, colon, prostate, testis, and ovary. In most cases, the ratio of the  $\alpha$ - and  $\beta$ -subunit mRNAs detected on Northern blots was equivalent from tissue to tissue. However, in several cases, the ratio varied significantly. For example, in brain and skeletal muscle, there was a preponderance of the  $\alpha$ -subunit RNA whereas in heart, lung, and kidney, there was more  $\beta$  than  $\alpha$ . These results suggest that coassembly of the  $\alpha$ - and  $\beta$ -subunits may not be obligatory (i.e., inclusion of the  $\beta$ -subunit might represent a molecular mechanism for the generation of functional diversity in maxi- $\text{K}$  channels) or that the synthesis of functional channels in the brain, for example, may be limited by the amount of the  $\beta$ -subunit. Furthermore, the abundance of  $\beta$ -subunit mRNA in tissues such as heart suggests that this subunit might also be a structural component of other types of  $\text{K}^+$  channels.

## 525.1

CRITICAL RESIDUES FOR DETERMINING DIFFERENCES IN SINGLE CHANNEL CONDUCTANCE OF TWO CYCLIC NUCLEOTIDE-GATED ION CHANNELS. D.T. Liu, Z.-P. Sun, and S.A. Siegelbaum\*. Integrated Program in Cellular, Molecular, and Biophysical Studies, Depts. Pharmacol., & Ctr. Neuro. & Behav., HHMI, Columbia University, N.Y., NY 10032

The single channel conductance of the catfish olfactory cyclic nucleotide-gated (CNG) ion channel (OLF, 83pS) is larger than that of the bovine retinal CNG ion channel (RET, 30pS). The H5 region determines the difference in single channel conductance between RET and OLF by determining the pore diameter (Goulding et al., *Nature* 364:61-64, 1993). In the H5 region, RET and OLF differ in only three amino acid residues: RET contains a serine, leucine, and threonine at positions 350, 351, and 364, respectively, whereas OLF contains cysteine, phenylalanine, and methionine at the corresponding positions. To determine which residues are critical in determining channel conductance, each of the three residues in RET was mutated individually to the corresponding residue in OLF. Mutant cRNA were injected into *Xenopus* oocytes, and single channel recordings were then obtained. When threonine 364 was changed to a methionine, the RET single channel conductance increased from 30pS to about 43pS. When leucine 351 was changed to a phenylalanine, the single channel conductance increased from 30pS to about 48pS. Thus, each of these residues by itself was not able to fully convert the conductance of RET to OLF (83pS). Studies of the serine 350 to cysteine mutant, double mutants, and the triple mutant are presently being performed.

## 525.3

SPECIFIC INTERACTION OF VOLTAGE-GATED K<sup>+</sup> CHANNEL  $\alpha$ - AND  $\beta$ -SUBUNITS EXPRESSED IN TRANSFECTED CELLS. K. Nakahira\*, G. Shi, S. Hammond, K. J. Rhodes and J. S. Trimmer, Dept. Biochem. and Cell Biol., SUNY at Stony Brook, Stony Brook, NY 11794 and CNS Disorders, Wyeth-Ayerst Res., Pearl River, NY 10965.

To investigate the specific interaction of voltage-gated K<sup>+</sup> channel  $\alpha$ - and  $\beta$ -subunits, we have expressed the rat Kv $\beta$ 1 and Kv $\beta$ 2 K<sup>+</sup> channel  $\beta$ -subunit polypeptides either alone or in the presence of  $\alpha$ -subunits by transfection of mammalian cells. Kv $\beta$ 1 and Kv $\beta$ 2-transfected cells expressed polypeptides of molecular mass 44 kDa and 38 kDa, respectively, similar to the size predicted from the deduced primary sequence and the same size as proteins detected in rat brain by specific antibodies. Unlike Kv $\beta$ 2, immunofluorescent localization of Kv $\beta$ 1 showed intense fibrous staining of transfected cells, and Kv $\beta$ 1 was found to partition into the detergent insoluble fraction of these cells. These findings suggested a unique association of Kv $\beta$ 1 with a component of the cytoskeleton.

Co-immunoprecipitation of  $\alpha$ - and  $\beta$ -subunits expressed in co-transfected cells showed the existence of specific subunit associations. Kv $\beta$ 1 was co-immunoprecipitated with Kv1.1, Kv1.2, Kv1.3, Kv1.5 and Kv1.6, but not with Kv2.1 and Kv3.1. Kv $\beta$ 2 showed the same binding specificity. This suggested restricted association of these  $\beta$ -subunits within the *Shaker* (Kv1) family of mammalian K<sup>+</sup> channels and the existence of a conserved molecular mechanism of  $\alpha/\beta$  subunit association.

## 525.5

## RESIDUES LINING THE INTERNAL MOUTH OF Kv2.1

C. C. Shieh, J. M. Pascual<sup>1</sup>, A. M. Brown\* and G. E. Kirsch. Rammelkamp Center, Case Western Reserve University, Cleveland, OH 44109 and <sup>1</sup>College of Physicians and Surgeons, Columbia University, New York, NY 10032.

We have applied the substituted cysteine-accessibility method (SCAM) developed by Karlin and coworkers (Akabas et al., *Science* 258, 1992) to residues 369-383 in the P region of Kv2.1 (WT). Application of charged methanethiosulfonate ethyltrimethylammonium (MTSET) to the cytoplasmic surface of excised macropatches irreversibly reduced currents through channels containing the substitutions T370C, T372C, T373C and V374C. WT, I369C, M371C and other residues at the external channel mouth were unaffected by MTSET. Taken together with previous SCAM results in which residues including and beyond D378C were accessible to external MTSET (Pascual et al., *Soc. Neurosci. Abstr.* 20, 1994), we infer that the narrowest, MTSET-inaccessible part of the pore is lined by residues included in the G375-Y376-G377 triplet. Supported by NIH grants NS29473 to GEK and NS23877 and HL37044 to AMB.

\* MTSET-accessible

## 525.2

CONSTRUCTION OF A REPLICATION DEFECTIVE HERPES SIMPLEX VIRUS TYPE 1 VECTOR ENCODING A  $I_A$  POTASSIUM CHANNEL. D.R. Beers\*, L. Gui and J.L. Noebels. Dept. Neurology, Baylor Coll. Medicine, Houston, TX 77030.

The efficient introduction of genes into terminally differentiated cells is a powerful new method to study neuronal physiology. Herpes simplex virus type 1 (HSV-1) vectors can infect and persist in neurons, and therefore offer the ability to stably transfect foreign genes. Deletion of viral ribonucleotide reductase (RR) renders HSV-1 incapable of replicating in post-mitotic neurons. To modify membrane excitability by selectively overexpressing specific ion channels, an RR<sup>-</sup> HSV-1 vector was constructed that encodes a genetically engineered non-inactivating  $I_A$  K<sup>+</sup> channel subunit. The insert T7-C210, encoding the  $I_A$  K<sup>+</sup> channel subunit with a modified 5' untranslated CITE sequence and a T7 amino acid idiotype tag sequence (for the immunocytochemical localization of the expressed gene product), was excised from the plasmid pCITE-1 by *EcoRI* and *NcoI* digestion. pKHFA, containing a 10.1 kb HSV-1 fragment that removes 90% of the large subunit of RR coding region, was linearized by digestion with *BglII*. The recessed 3'-ends of both T7-C210 and pKHFA were filled in with Klenow and then blunt-end ligated forming the plasmid pK<sup>+</sup>KHFA. Orientation of the K<sup>+</sup> channel subunit was determined by *BamHI* and *HindIII* digestion. pK<sup>+</sup>KHFA was linearized with *EcoRI* and then transfected into VERO cells with lipofectamine. Following a 5 hour incubation, the transfected cells were infected with hrR3, a HSV-1 virus encoding the *lacZ* gene at the RR locus. The recombinant virus that had lost the *lacZ* sequence due to homologous recombination was detected by screening progeny virus for white plaques against a background of blue plaques in the presence of X-Gal. This vector or another constructed identically that encodes a mutant K<sup>+</sup> channel subunit and forms a dominant-negative phenotype when combined with wild-type K<sup>+</sup> channel subunits, may up- and down-regulate, respectively, K<sup>+</sup> currents and membrane excitability in transfected cells. Supported by National Multiple Sclerosis Society.

## 525.4

## CYSTEINE OXIDATION MODULATES GATING OF Kv2.1

Juan M. Pascual\* and Arthur M. Brown. College of Physicians and Surgeons, Columbia University, New York, NY 10032 and Rammelkamp Center, Case Western Reserve University, Cleveland, OH 44109.

We have superfused methylmethanethiosulfonate (MMTS) to oocytes expressing Kv2.1 channels (WT). MMTS is uncharged and reacts with cysteinyl sulfhydryls transferring a S-methyl group. MMTS caused a pronounced slowing of current activation and inactivation. This effect was absent in Kv3.1 channels. Charged MMTS analogs had no effect on Kv2.1 (Pascual et al., *Neuron* in press). To identify the MMTS target area we engineered three Kv2.1 constructs: a) a 351-amino acid C-terminal deletion that removes all 4 cysteines at the C-terminus, b) a mutant channel that combines C232A+C393S+C394S, replacing the only three cysteines in the transmembrane core region and c) a 139-amino acid N-terminal deletion that eliminates the first 6 cysteines at the cytoplasmic N-terminus. The first two constructs gated similarly to WT channels and were sensitive to MMTS. Only the N-terminal deletion produced slowly gating channels (VanDongen et al., *Neuron* 5, 1990) that were insensitive to MMTS. We propose that reduced cysteine residue(s) at the N-terminus are closely associated with the gating machinery of Kv2.1. Supported by NIH grants NS23877 and HL37044 to AMB.

## 525.6

MUTATIONS IN THE S4 REGION OF A JELLYFISH POTASSIUM CHANNEL. N. G. Grigoriev, J. D. Spafford, W. J. Gallin and A. N. Spencer\*. Dept. of Biological Sciences, University of Alberta, Edmonton, Alberta, Canada, T6G 2E9 and Bamfield Marine Station, Bamfield, B.C., Canada, V0R 1B0.

In most known *Shaker* K<sup>+</sup> channels, the putative voltage sensor (S4 segment) has seven conserved, positively charged amino-acids positioned at every third residue. However a primitive, *Shaker*-like potassium channel (*jShak1*) from the hydrozoan jellyfish, *Polyorchis penicillatus* has only six positively charged residues in the S4 segment. Mutations were made in *jShak1* to determine the functional importance of the position of an additional seventh charge, and the total length of the S4 segment. Two types of mutants were constructed. One type involved insertion of 3 residue motifs and the other involved replacement of single residues. Evidence from expressed mutants suggests that the voltage sensitivity of *jShak1* depends primarily on the position of charges on the helix and not on the total number of charges in the S4 segment. Supported by NSERC Research Grant A0419.

## 525.7

REGULATION OF VOLTAGE DEPENDENCE OF THE POTASSIUM CHANNEL. KAT1. L. Marten, D.J. Henneeger, and T. Hoshi\*. Dept. of Physiology and Biophysics, The University of Iowa, Iowa City, IA 52242.

The KAT1 channel currents are observed in response to hyperpolarization even though its structural organization is similar to those of depolarization-activated K<sup>+</sup> channels. We examined how the voltage-dependent gating of KAT1 could be manipulated by expressing the channel in *Xenopus laevis* oocytes.

When recorded in the inside-out configuration, the KAT1 channel gradually runs down. This is caused by a large shift of the voltage-dependent activity to more hyperpolarizing potentials. We searched for factors which could prevent or even reverse the rundown. Since the intracellular carboxyl segment of the channel contains several putative phosphorylation sites, we studied effects of various agents that affected the phosphorylation state of the channel. Intracellular adenosine triphosphate (ATP), but not the nonhydrolyzable ATP-analog AMP-PNP, often at least partially reversed the rundown. However, none of the agents examined alone so far reliably prevented the rundown phenomenon.

Mutations in the S4 segment, the putative voltage sensor, also affected the apparent voltage-dependent gating of KAT1. Based on the S4 sequence comparison among KAT1, *Shaker* and *eag*, we focused on S168, S180, and R176. Although the voltage dependence of the mutants shifted dramatically to a more positive direction (up to 100 mV), the mutations, however, did not markedly alter the steepness of the apparent macroscopic G(V) curve. One possible interpretation is that the KAT1 S4 domain is not coupled tightly to the voltage-dependent gating and that other channel segments are also involved in the apparent activation of KAT1. (Supported by HFSP, NIH)

## 525.9

THE PORE OF VOLTAGE-GATED POTASSIUM CHANNELS AS SEEN THROUGH THE EYES OF DENDROTOXIN. R. G. Sorensen\*. Dept. Medicine, Div. Environmental Medicine and Toxicology, Jefferson Medical College, Philadelphia, PA 19107.

$\alpha$ -Dendrotoxin is a member of a homologous family of polypeptides isolated from the venom of the green mamba, *Dendroaspis angusticeps*, that have been shown to block various voltage-dependent potassium channels of the central and peripheral nervous systems. Furthermore, the dendrotoxins are specific blockers of the Shaker-like, Kv1.x class of cloned mammalian potassium channels. Previously, I have expressed recombinant  $\alpha$ -dendrotoxin in bacteria from a synthetic gene encoding the primary sequence of the polypeptide. Using site-directed mutagenesis of the synthetic gene, mutant dendrotoxins are being prepared. These toxins are subsequently tested for the ability to block Kv1.1 that has been expressed in *Xenopus* oocytes. Changes in the affinity for block of Kv1.1 as a result of the amino acid substitution are used to identify those residues that are required for the dendrotoxin polypeptide to bind to the outer aspect of the external vestibule of the ion pore, and thereby, block voltage-dependent potassium channels. These data will be further discussed with respect to the 3-dimensional structure of dendrotoxin in order to build upon the proposed model of the external vestibule of voltage-dependent potassium channels derived from results using charybdotoxin and various other potassium channel blockers. These results will also be discussed with respect to the ability of dendrotoxin and the mutant polypeptides to block additional members of the Kv1.x class of potassium channels. (Supported by NIH grant NS31670.)

## 525.11

THE SEIZURE GENE OF *DROSOPHILA MELANOGASTER* ENCODES A POTASSIUM CHANNEL OF THE H-ERG TYPE. XinJing Wang\*, Elaine R. Reynolds, Peter Deák and Linda M. Hall. Department of Biochemical Pharmacology, SUNY at Buffalo, Buffalo, NY 14260-1200.

Mutations in the *seizure* (*sei*) locus cause a temperature-induced hyperexcitability (seizures) followed by paralysis (Jackson et al., *J. Neurosci.* 5:1144, 1985). Position cloning based on RFLP mapping has shown that the *seizure* gene product is a potassium channel subunit which is the *Drosophila* homolog of H-Erg, a member of the *eag* potassium channel family from humans (Warmke et al., *PNAS* 91:3438, 1994). Two transcript size classes produced by *sei* are expressed in a tissue and developmentally distinct fashion. Genomic sequencing of 6 mutant alleles shows that the phenotype of hyperexcitability followed paralysis is caused by the loss of, or a change in, this potassium channel subunit leading to a problem in repolarization following an action potential. Five null alleles are all recessive showing that the complete loss of one allele can be compensated by the remaining normal copy. Homozygous null alleles are viable, but hyperexcitable. At least one null allele leads to sodium channel down-regulation as measured electrophysiologically (O'Dowd & Aldrich, *J. Neurosci.* 8:3633, 1988) and by saxitoxin-binding. A missense mutation in the *sei* subunit causes a dominant phenotype suggesting that *sei* potassium channels are composed of multiple subunits and the missense form of the protein acts to "poison" channel function.

## 525.8

PROTEIN DOMAINS MEDIATING INTERACTIONS BETWEEN VOLTAGE GATED POTASSIUM CHANNELS AND MEMBRANE ASSOCIATED GUANYLATE KINASES. E. Kim\* and M. Sheng, Howard Hughes Medical Institute, and Dept. of Neurobiology, Mass General Hospital and Harvard Medical School, Boston, MA 02114

At different subcellular locations, K<sup>+</sup> channels are likely to interact with distinct intracellular cytoskeletal or signalling molecules. Using the yeast two-hybrid system, we have identified members of the *discs large* (dlg) family of membrane associated guanylate kinases as proteins that interact specifically with the shaker subfamily of voltage-gated K<sup>+</sup> channel subunits. Deletional and site-directed mutagenesis have defined a peptide sequence in the C-terminal intracellular domain of the K<sup>+</sup> channel subunit and a specific domain in the dlg-related proteins, which mediates the interaction.

## 525.10

IDENTIFICATION AND EXPRESSION OF CHARIBDOTOXIN-BINDING SITES IN CULTURED RAT SKELETAL MUSCLE. S.R. Sampson\*, A. Bak, and S. Vigdor-Alboim. Otto Meyerhoff Center, Dept. of Life Science, Bar-Ilan Univ., Ramat-Gan, Israel 52900.

High-conductance, charybdotoxin (ChTx)-sensitive K<sup>+</sup> (Maxi-K) channels are one of several types of K<sup>+</sup> channels found in excitable cells such as nerve and skeletal muscle. These channels play an important role in restoration of the membrane potential following an action potential. While much has been learned about the properties of individual channels, little is known about the factors regulating their expression in excitable cells. We have investigated the expression of ChTx-sensitive K<sup>+</sup> channels in cultured skeletal muscle by using a polyclonal antibody raised in rabbits against ChTx (Almone Labs., Jerusalem). Crude homogenates were prepared of cultures made from limb muscles of 1-2 day-old rat pups. Identification of ChTx binding sites was done with western blotting techniques. After SDS-PAGE and electrophoretic transfer of proteins to Immobilon-P membranes, the membranes were blocked by incubation in TBS containing 3% gelatin and incubated in TBST buffer containing 10 nM ChTx for 30 min. After removal of this solution and washing of the membranes, they were incubated overnight with antibody buffer containing rabbit polyclonal anti-ChTx. A distinct band of apparent molecular weight 31 kDa was observed. When membranes were incubated with ChTx and then exposed to anti-PKC $\alpha$  instead of anti-ChTx, the 31 kDa band was not seen. Similar findings were obtained when the membranes were exposed to an antibody against the KV1.5 K<sup>+</sup> channel (courtesy of Dr. J. Trimmer). Expression of the ChTx binding sites was found to increase with development of muscle cells in culture but was not dependent on fusion of individual myoblasts to multinucleated myotubes. These data suggest that the ChTx antibody recognizes ChTx bound to a site corresponding to the  $\beta$ -subunit of the ChTx-sensitive K<sup>+</sup> channel, which is also of 31 kDa apparent molecular weight. (Supported by the Harvet-Aviv Neuroscience Fund and the Ben and Effie Raber Neuroscience Research Fund.)

## 525.12

CLONING, EXPRESSION AND DISTRIBUTION OF KV4.3, A NEW MAMMALIAN SUBUNIT OF A-TYPE, LOW-VOLTAGE-ACTIVATING POTASSIUM CHANNELS. P. Seródio\*, E. Vega-Saenz de Miera and B. Rudy. Dept. Physiology & Neuroscience and Dept. Biochem., NYU Med. Ctr., N.Y. 10016

The mammalian Shal homologs (KV4 subfamily) are K<sup>+</sup> channel proteins that express transient outward currents in *Xenopus* oocytes. Antisense hybrid-arrest experiments in oocytes injected with rat brain poly (A) RNA have demonstrated that the KV4 channels are components of a 4-AP sensitive, fast-activating, fast-inactivating A-current, with a range of activation below the threshold for Na<sup>+</sup> action potential generation ("subthreshold" A-current or I<sub>SA</sub>). This same I<sub>SA</sub> is specially pronounced in oocytes injected with rat poly-A preparations from hippocampus, thalamus or cerebellum (Seródio et al. *J. Neurophysiol.* 72, p.1516-1529). Here we report the characterization of a new mammalian Shal-related protein (KV4.3) with high sequence conservation in the transmembrane portion (over 90%) as well as at the N- and C-terminals (80% and 60% respectively) to other reported members of the KV4 subfamily. Injection of KV4.3 cRNA into *Xenopus* oocytes generates a transient A-type potassium current. Consistent to the previously reported characteristics of KV4.1 and KV4.2, the currents generated by KV4.3 in oocytes can be modified to resemble whole-brain I<sub>SA</sub> by co-injection with poly (A) RNA treated with antisense oligonucleotides which arrest the expression of I<sub>SA</sub> or with a 2.4Kb rat brain poly (A) RNA fraction which does not express any detectable current on its own. Notwithstanding the high sequence and functional conservation of KV4.3 as compared to other Shal K<sup>+</sup> channels, the distribution of KV4.3 observed in rat brain by *in situ* hybridization, differs markedly from other members of this subfamily. In some brain areas KV4.2 and KV4.3 overlap but in others their distribution seems to be complementary, although the currents generated by these two cDNAs injected in oocytes are very similar.

Antibodies raised against peptides corresponding to sequences of two Shaw-related K<sup>+</sup> channel subunits (KV3.1 and KV3.2) and a component of G-protein activated inward rectifier channels (GIRK1) were used to analyze the distribution of these subunits in the brain. Each of these proteins is expressed in specific neuronal populations of the adult rat brain. KV3.1 is found in the somatic and/or axonal membrane of cerebellar granule cells, the reticular thalamic nucleus and various neuronal populations involved in the processing of auditory signals, as well as in parvalbumin-containing interneurons in the neocortex, the hippocampus and the caudate-putamen. KV3.2 proteins have an axonal distribution in some neuronal populations such as thalamic relay neurons and somatic in others such as neurons of the globus pallidus, red nucleus, deep cerebellar nuclei and a subset of neurons in the cortex and the hippocampus distinct from that expressing KV3.1. GIRK1 proteins are present in somas and dendrites of cerebellar granule cells, pyramidal cells of the hippocampus, and others. GIRK1 proteins appear to be present also in axons and terminals such as in thalamocortical projections. KV3.2 and GIRK subunits have a localization consistent with a role in the regulation of the efficacy of the thalamocortical synapse. These cellular and subcellular patterns of expression are not seen in young rats and are not fully established until about two to three weeks of postnatal development. Supported by a Grant in Aid from the American Heart Association and NIH grant NS 30989.

THE NEURAL-SPECIFIC EXPRESSION OF THE Kv3.1 POTASSIUM CHANNEL GENE IS DIRECTED BY UPSTREAM REGULATORY ELEMENTS L. Gan, S. Hahn, T.M. Perney\* and L.K. Kaczmarek. Dept. of Cellular and Molecular Physiology and Dept. of Pharmacology, Yale Univ. Sch. of Med., New Haven, CT 06510.

The Kv3.1 potassium channel gene has been shown to be largely expressed in brain, especially in neurons that are capable of firing action potentials at high frequencies in response to synaptic inputs. Many neurons in brain stem nuclei express Kv3.1 at very high level. To investigate mechanisms that lead to the specific expression pattern of the Kv3.1 gene *in vivo*, we have generated transgenic mice in which the 4.3 Kb of the 5' flanking region of the Kv3.1 gene is linked to the E. Coli lacZ reporter gene. We have shown that the overall expression pattern of the transgene is similar to that of the endogenous Kv3.1 gene. In particular, neurons in auditory brainstem and hippocampal interneurons express high levels of the transgene.

We have also studied genetic elements involved in the cell-specific expression of the Kv3.1 gene using transient transfection assays. A series of promoter fragments of the Kv3.1 gene with successive 5' deletions were linked to the chloramphenicol acetyl transferase reporter gene and transfected into various types of cell lines. Our results reveal that the Kv3.1 gene promoter is active in PC12 cells, but not in non-neuronal types of cells. Our data also suggest that both silencing and enhancing elements are involved in the neural-specific expression of this gene.

EXPRESSION OF VOLTAGE-GATED K<sup>+</sup> CHANNEL  $\beta$ -SUBUNIT mRNAs IN ADULT RAT BRAIN AND PERIPHERAL TISSUES: *IN SITU* HYBRIDIZATION AND NORTHERN ANALYSES. S.P. Nawoschik\*, N.X. Barzuzeta, K. Nakahira, L.E. Schechter, J.S. Trimmer and K.J. Rhodes. CNS Disorders, Wyeth-Ayerst Res., Pearl River, NY 10965 and Dept. Biochem. and Cell Biol., SUNY, Stony Brook, NY 11794.

Recent cloning of  $\beta$ -subunits associated with voltage-gated K<sup>+</sup> channels and their co-expression with  $\alpha$ -subunits has revealed that the gating and conductance properties of the expressed channels can be profoundly affected by the presence of a  $\beta$ -subunit polypeptide (Rettig et al., Nature 369:289, 1994). We examined the expression of two  $\beta$ -subunit polypeptides, Kv $\beta$ 1 and Kv $\beta$ 2, in rat brain and peripheral tissues using Northern and *in situ* hybridization analyses. Riboprobes directed towards unique regions of the rat Kv $\beta$ 1 and Kv $\beta$ 2 sequences were prepared by the PCR using the corresponding full length cDNAs as templates, and used to probe Northern blots of mRNA extracted from rat brain and peripheral tissues (Clontech) as well as tissue sections of fresh-frozen rat brain.

Analysis of Northern blots indicated Kv $\beta$ 1 and Kv $\beta$ 2 are predominantly expressed in brain, with lower levels of Kv $\beta$ 2 expression in spleen, heart and lung. Analysis of *in situ* autoradiograms revealed that Kv $\beta$ 1 and Kv $\beta$ 2 are widely and heterogeneously distributed in rat brain. Moreover, the relative abundance of Kv $\beta$ 1 and Kv $\beta$ 2 mRNA varied across brain regions. For example, Kv $\beta$ 1 expression was greatest within the caudate-putamen, nucleus accumbens, and CA1 pyramidal cells, with intermediate levels in Purkinje cells and brainstem motor structures. Kv $\beta$ 2 expression was greatest in neocortex, hippocampus, and entorhinal cortex, with intermediate levels in striatum, thalamic relay nuclei and the cerebellum. Comparison of  $\beta$ -subunit expression with that for *Shaker*  $\alpha$ -subunits suggested that Kv $\beta$ 1 mRNA was co-distributed predominantly with Kv1.4 mRNA, and Kv $\beta$ 2 mRNA was co-distributed predominantly with Kv1.2 mRNA.
