DEVELOPMENTAL EXPRESSION OF THE POTASSIUM CHANNEL SUBUNIT KV3.1 IN PARVALBUMIN CONTAINING INTERNEURONS OF THE RAT HIPPOCAMPUS. J. Du\*, M. Weiser\*, B. Rudy\* & C. J. McBain<sup>1</sup>. <sup>1</sup>NICHD-LCMN, NIH, Bethesda, MD 20892, and <sup>2</sup>Dept. Physiol. & Neurosci. NYU Medical Ctr. New York, NY 10016.

*In situ* hybridization has shown that the voltage-dependent K<sup>+</sup> channel subunit Kv3.1 is localized in interneurons of the hippocampus (Weiser et al. J. Neurosci. 14, 1994). Using an antibody raised against the C-terminus of Kv3.1, we have investigated the developmental expression of Kv3.1 in the hippocampus using immunostaining and Western blot techniques. Kv3.1 expression was first observed in tissue derived from P8 (12  $\mu$ m sections). The cell number per section reached a maximum by P14 (64.0  $\pm$  3.6 cells/section) and was sustained through both P20 (61.2  $\pm$  6.3) and P40 (57.8  $\pm$  4.7) (N=4 animals). The Kv3.1 protein was expressed predominantly in cells at the borders between st. pyramidal and st. oriens and st. radiatum (28.2%), in the subiculum (33.8%), and the dentate hilus (22.4%). In contrast, only a small number of immuno-positive cells were in st. oriens-alveus (8.9%) and st. radiatum-lacunosum (6.5%) (N=4 animals). Double staining of Kv3.1 and antibodies to GAD or parvalbumin showed that every Kv3.1-positive cell was both GAD and parvalbumin-positive. Approximately 80% of all parvalbumin-immunoreactive cells were Kv3.1-positive. Western blot analysis of hippocampal membrane vesicles confirmed that Kv3.1 expression started at P8. The membrane protein content of Kv3.1 increased through P10 to P40, despite the observation that the Kv3.1-positive cell number per section remained constant after P14. Electrophysiological recordings were made from cells subsequently shown to be Kv3.1-positive. These cells fired spontaneous, brief action potentials with a prominent AHP consistent with their interneuron morphology. Interestingly, parvalbumin-positive cells are resistant to damage in a number of seizure models. It is possible that Kv3.1 channels contribute to the survival of these cells by virtue of their activation at extreme depolarizing potentials occurring during seizure episodes.

## 525.16

IMMUNOHISTOCHEMICAL LOCALIZATION OF Kv1.1, Kv1.2, Kv1.4, Kv1.6, Kv $\beta$ 1 and Kv $\beta$ 2 K<sup>+</sup> CHANNEL POLYPEPTIDES IN RAT HIPPOCAMPUS. M.M. Monaghan\*, J.S. Trimmer and K.J. Rhodes. CNS Disorders, Wyeth-Ayerst Res., Pearl River, NY 10965 and Dept. Biochem. and Cell Biol., SUNY, Stony Brook, NY 11794.

In the present study we used immunohistochemical techniques to localize Shaker K<sup>+</sup> channel  $\alpha$ - and  $\beta$ -subunit polypeptides in the rat hippocampal formation. Polyclonal and monoclonal antibodies specific for the rat Kv1.1, Kv1.2, Kv1.4, Kv1.6, Kv $\beta$ 1 and Kv $\beta$ 2 subunit polypeptides were examined for specificity on immunoblots of rat brain membranes and by immunofluorescence in COS cells transiently transfected with the corresponding cDNAs. For immunohistochemistry, sections of paraformaldehyde fixed rat brain were reacted in 0.010 M NaPO<sub>4</sub> buffer containing 3% normal serum, 0.1% triton X-100, and the primary antibodies diluted 1:200-1:5000. Binding of the primary antibodies was visualized using the ABC Elite peroxidase method (Vector) and a nickel-enhanced DAB procedure.

Within the hippocampal formation, many of these K<sup>+</sup> channel subunits were concentrated within the projection fields of the perforant path. Specifically, there was a dense band of immunoreactivity for Kv1.1, Kv1.2, Kv1.4, Kv1.6, Kv $\beta$ 1 and Kv $\beta$ 2 in the middle third of the dentate molecular layer, and a similarly dense band of immunoreactivity for the four  $\alpha$ -subunits, but not Kv $\beta$ 1 or Kv $\beta$ 2, in the molecular layer of CA1-CA3. In the CA3 subfield, immunoreactivity for Kv1.1 and Kv1.4 was concentrated in the mossy fiber zone, and in the CA1 subfield, immunoreactivity for Kv1.1 and Kv $\beta$ 1 was concentrated in stratum radiatum. Interestingly, immunoreactivity for Kv $\beta$ 2, but not the  $\alpha$ -subunit polypeptides, was contained within the apical dendrites of hippocampal pyramidal cells. Taken together, these data suggest that the individual afferent, intrinsic, and efferent hippocampal projection systems express voltage-gated K<sup>+</sup> channels with varied and distinct subunit compositions and electrophysiological properties.

## 525.18

AXONAL SUBCELLULAR LOCALIZATION OF A POTASSIUM CHANNEL SUBUNIT IN RAT BRAIN: KV3.1B. C. Sekirnjak, R. Komesu, M. E. Martone, E. Bueno\*, M. Weiser\*, B. Rudy\*, and M. H. Ellisman. San Diego Microscopy and Imaging Resource, Dept. of Neuroscience, Univ. of California at San Diego, La Jolla, CA 92093-0608 and \*Dept. of Physiology and Neuroscience, New York Univ. Medical Center, New York, NY 10016.

We have analyzed the localization of the voltage gated K<sup>+</sup> channel protein Kv3.1b in rat brain at the light- and electron microscopic level, using Kv3.1b-specific antibodies. The investigation was carried out in the cerebellum, neocortex and hippocampus. We found the protein to be present in cerebellar granule cell axons (parallel fibers), in lower levels in proximal dendrites, and in cytoplasmic patches of the somata. Cell bodies and axonal terminals of a population of neocortical interneurons were found to be labeled. In the hippocampus we observed labeling in somata, processes, and synaptic terminals of certain nonpyramidal cells. Fluorescence double-labeling with parvalbumin and calbindin was used to demonstrate colocalization of Kv3.1b in cortical and hippocampal interneurons and establish the identity of these cells. Our immunocytochemical analysis is consistent with a predominantly somato-axonal localization of the protein in the areas under investigation (Weiser et al. J. Neurosci., in press). We are currently comparing this distribution with that of other members of this large family of potassium channels. Preliminary results with Kv4.2 indicate that this channel subunit colocalizes with Kv3.1b in cerebellar granule cells. However, Kv4.2 shows a somatodendritic localization, in contrast to the somato-axonal distribution of Kv3.1b.

## 525.19

THE EFFECTS OF INNervation ON THE DEVELOPMENTAL EXPRESSION OF  $Ca^{2+}$ -ACTIVATED  $K^+$  CURRENTS IN EMBRYONIC PARASYMPATHETIC NEURONS ARE NOT ACTIVITY-DEPENDENT. Priva Subramony\* and Stuart E. Dryer, Program in Neuroscience, Florida State University, Tallahassee, FL 32306.

Chick ciliary ganglion (CG) neurons that develop *in situ* in the absence of preganglionic innervation fail to express  $Ca^{2+}$ -activated  $K^+$  currents ( $I_{K[Ca]}$ ), but the mechanism of this effect is unknown (see *J. Neurosci.* 14: 3156, 1994). One possibility is that the effects of innervation are dependent upon synaptic activation of CG neurons. Alternatively, nerve terminals may secrete a differentiation factor unrelated to synaptic transmission. In the present study, chick embryos were treated chronically with mecamylamine, a potent neuronal nicotinic receptor antagonist, in order to block synaptic activation of CG neurons *in ovo*. Mecamylamine (5 mg/kg) was applied repeatedly throughout the developmental stages where functional chemical synapses are present within the CG (E6-13). With this protocol, afferent preganglionic nerve terminals are still present. As reported previously by several investigators, chronic blockade of synaptic transmission *in ovo* resulted in a large increase in naturally-occurring cell death. The resulting decrease in ganglion size was the same as that produced by complete ablation of the preganglionic nucleus early in development. However, the  $I_{K[Ca]}$  in E13 mecamylamine-treated CG neurons was indistinguishable from that of saline-treated controls. This suggests that the effects of the preganglionic afferent innervation on  $I_{K[Ca]}$  expression *in situ* are mediated by a nerve terminal-derived differentiation factor and are not dependent upon intact cholinergic synaptic transmission. NS-32748.

### ACETYLCHOLINE RECEPTOR: NICOTINIC-ACETYLCHOLINE-EFFECTS OF NICOTINE ON SPECIFIC BRAIN REGIONS

## 526.1

NICOTINIC RECEPTOR ACTIVATION POTENTIATES GLUTAMATERGIC SYNAPTIC TRANSMISSION IN CULTURED HIPPOCAMPAL NEURONS. K.A. Radcliffe and J.A. Dani\*, Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

The muscle form of the nicotinic acetylcholine receptor (nAChR) found at the neuromuscular junction is well studied, but the role of neuronal forms (nAChRs) is less well understood. Using a new quantitative approach, we recently demonstrated that the calcium influx through nAChRs is significant, suggesting that nAChRs could participate in synaptic plasticity processes (Vernino et al. (1994), *J. Neuroscience* 14: 5514-24). In the present experiments, we have used whole-cell patch clamp electrophysiology to study synaptic transmission in 15-25 day old hippocampal cell cultures. Cells were plated onto small islands of substratum to limit process outgrowth and the number of neurons contributing input to a given cell. In the presence of atropine, tetrodotoxin, and cadmium, applications of ACh (1-3mM) or nicotine (0.5mM) activated a current with rapid kinetics that caused a subsequent increase in the frequency of miniature spontaneous synaptic currents (mSSCs) at glutamatergic synapses. The mechanism for enhancement of glutamatergic mSSCs is nicotinic, not muscarinic, because atropine did not block the effect and the effect was seen with the specific agonist nicotine. In some cases, the potentiation of glutamatergic mSSC frequency was seen on islands of substratum that were extremely small, ensuring the presence of autapses. Thus, glutamatergic autapses can be potentiated if the neuron displays a current in response to nicotine application. In addition, the effect depends upon external calcium, suggesting that activation of nAChRs produces a presynaptic calcium influx that initiates the potentiation of glutamatergic mSSCs. This work was supported by NIH grant NINDS NS 21229.

## 526.3

NICOTINE STIMULATED RELEASE OF [ $^3H$ ]NOREPINEPHRINE FROM CULTURED LOCUS COERULEUS CELLS. K.A. Gallardo\*, C.G. Griffith, F.M. Leslie, Department of Pharmacology, College of Medicine, University of California, Irvine, CA 92717.

The structure and function of neuronal nicotinic acetylcholine receptors (nAChR) are of primary importance in elucidating the effect of nicotine on the central nervous system (CNS). Morphological and molecular studies of these pentameric ion channels in the adult rat brain indicate their composition to be solely  $\alpha$  and  $\beta$  subunits, of which numerous subtypes exist. Upon stimulation of central nAChRs diverse cellular responses are observed which appear to be related to the phenotype of the neuron being expressed, such that activation by nicotine can stimulate the release of various neurotransmitters with variable efficacy depending on the cell type being examined. Whether this differential release of neurotransmitter is due to receptor subunit heterogeneity is not known. There is presently conflicting evidence regarding the effect of nicotine on norepinephrine (NE) release. We have further examined this issue using primary dissociated locus coeruleus (LC) cells in culture. Cells were harvested from rostral rhombencephalon of E15 Sprague-Dawley rat embryos, cultured for 4 days, then pre-loaded with radiolabeled NE. Following a washout period, the effect of nicotine on [ $^3H$ ]NE release was examined in both calcium-containing and calcium-free media. Preliminary data indicate that nicotine stimulates NE release from embryonic LC cells in a dose-dependent manner. This nicotine effect is independent of extracellular calcium. Prior exposure of the cells to nicotine induces subsequent desensitization of the nicotinic response. These data suggest that there are nicotinic receptors on LC cells which stimulate neurotransmitter release by a novel mechanism. Ongoing studies involve a more complete pharmacological characterization of the nAChR by examining LC cell responses to various agonists and antagonists. PHS grant #19319 and 30109.

## 525.20

REGULATED EXPRESSION OF A-TYPE POTASSIUM CURRENT IN PC12 CELLS. E. A. Liles and A. L. Willard\*, Dept. of Physiology, University of North Carolina, Chapel Hill, NC 27599-7545.

Calcium influx is an important consequence of neuronal electrical activity. It is essential that excitable cells express a quantitatively appropriate balance of ion channels in order to achieve Ca influx that is right for cellular survival and function. Therefore regulation of ion channel expression is crucial. Both the duration and amplitude of action potentials are partially controlled by K currents. We have used chronic depolarization of cultured neural cells as a model for studying activity-dependent regulation of the expression of voltage-dependent ion channels.

PC12 cells were differentiated by treatment with NGF for 7-21 days prior to treatments with medium containing 25 mM KCl, which depolarizes them to -40 mV. This treatment leads to reduced Ca influx during electrical activity in at least two ways. Ca channel expression is decreased and, as we report here, expression of a rapidly activating and inactivating, 4-aminopyridine-sensitive (A-type) K current is dramatically increased following treatments with 25 mM KCl as brief as 24 hours. Confirming prior findings (Hoshi & Aldrich, 1990), almost no (1/19) untreated cells had detectable A current. In contrast, 27/37 cells treated with 25 mM KCl expressed this current. To test whether influx of external Ca is required to trigger expression of A current, we examined the effects of nifedipine, which blocks L-type Ca channels. Nifedipine reduced the expression seen after 48 hours of 25 mM KCl treatment from 75% of cells to <15% of cells.

We hypothesize that this is a novel regulatory mechanism by which excitable cells protect themselves against excess Ca influx during electrical activity. It will be interesting to examine the transduction pathways that control this change. Supported by an NIH research grant.

## 526.2

NICOTINE UPREGULATION OF NICOTINE BINDING SITES IN NGF-DIFFERENTIATED PC12 CELLS: CORRELATION WITH NICOTINE-INDUCED ACh RELEASE. R. Widstrom, J.S. Aguilar, and E.L.M. Ochoa\*, Department of Pediatrics, University of California at Davis, Davis, CA 95616 and Department of Pharmacology, University of Illinois at Chicago, Chicago, Illinois 60612.

Chronic nicotine upregulates nicotine binding sites that control neurotransmitter release from nerve terminals. We used intact PC12 cells as a model on which to test the hypothesis that nicotinic receptor upregulation coincides with desensitization of nicotinic receptor function. Cultures were: controls (C); exposed to one micromolar nicotine for one day (N); exposed to 50 ng/ml for 7 days (NGF), or NGF-treated and subsequently exposed to nicotine for one day at 1 micromolar concentration (NGF/N). Nicotine was removed prior to the assays. Nicotine increased the specific binding of [ $^3H$ ]-nicotine (54% at 80 nM drug in N with respect to C). Differentiation of PC12 cells with NGF increased binding (205%) over C. A further increase in [ $^3H$ ]-nicotine binding occurred in NGF/N (347% of C; 142% over NGF). Binding of [ $^3H$ ]-nicotine was also determined in membranes prepared from NGF, and NGF/N PC12 cells. At both 40 nM and 150 nM [ $^3H$ ]-nicotine, specific binding was increased by 36% in NGF/N as compared to NGF. To test whether desensitization of nicotinic receptor function accompanies upregulation, we measured [ $^{14}C$ ]-ACh release upon acute nicotine challenge (50 micromolar) using [ $^{14}C$ ]-choline and an extraction technique that selectively measures released ACh. In either C or N, an acute nicotine challenge did not release ACh above basal levels, contrasting with the two-fold increase in ACh release induced by nicotine in NGF. NGF/N cells had a statistically significant increase in the basal release of ACh upon nicotine challenge over NGF. However, these cells did not respond to a further nicotine challenge. Our data suggest that nicotine upregulates [ $^3H$ ]-nicotine binding sites in NGF differentiated cells and that these sites may be responsible for the elevated basal release of ACh. This may explain the nicotine-induced desensitization of ACh release seen upon nicotine challenge. This research was supported by funds provided by the Cigarette and Tobacco Surtax Fund of the State of California through the Tobacco-Related Disease Research Program of the University of California, Grant Number 3RT-0098.

## 526.4

THE EFFECTS OF ORAL NICOTINE ADMINISTRATION ON BRAIN NICOTINIC RECEPTORS AND RESPONSIVENESS TO NICOTINE. J.A. Sparks, K. Agee and J.R. Pauly\*, Dept. of Pharmacology, Medical College of Georgia, Augusta GA 30912-2300.

Our laboratory is using a mouse model to study the effects of *in utero* nicotine exposure on brain development. Since glucocorticoid hormones have been shown to regulate the number of brain nicotinic receptors as well as behavioral responsiveness to nicotine, it is important to chronically expose pregnant mice to nicotine in a non-stressful manner. We have tested whether chronic nicotine delivery via the drinking solution produces tolerance to nicotine and alterations in brain nicotinic receptors consistent with studies that have measured these parameters following other methods of nicotine delivery. Female C57BL/6 mice were given water, 2% saccharin, or nicotine in 2% saccharin (50, 100 or 200  $\mu$ g/ml) as a drinking solution for 30 days. Plasma cotinine levels were determined by ELISA and ranged between 0-200 ng/ml of plasma. Nicotine-treated animals developed dose-dependent tolerance to the locomotor depressant and hypothermic actions of nicotine. Brain nicotinic receptors, as measured by [ $^3H$ ]-cytisine and [ $^{125}I$ ]-alpha bungarotoxin autoradiography, were increased following chronic nicotine exposure. These data suggest that chronic oral nicotine exposure is appropriate for long term, non-invasive delivery of this drug. Supported by DA-08443 and the Callaway Foundation.

## 526.5

**INTRACELLULAR RECORDING OF NICOTINIC RESPONSES IN SUBSTANTIA NIGRA PARS COMPACTA (SNc) NEURONS OF THE RAT.** E.M. Sorenson\* and S.T. Kitai, Department of Anatomy and Neurobiology, University of Tennessee, College of Medicine, Memphis, TN 38163.

SNc neurons express mRNA for the  $\alpha_3$ ,  $\alpha_4$ ,  $\alpha_5$ ,  $\beta_2$ , and  $\beta_3$  subunits of the nicotinic receptor. High affinity  $^3\text{H}$ -nicotine binding in the SNc indicates that some of these subunits may be localized on neuronal cell bodies in the SNc. Furthermore, extracellular recording has shown that nicotine increases the firing rate of SNc neurons. Using intracellular recording in the brain slice, we want to determine whether dopaminergic SNc neurons directly respond to nicotinic agonists. Most neurons have responded to bath superfusion of 10-100  $\mu\text{M}$  nicotine with a depolarization and a decrease in input resistance. The depolarization was usually accompanied by an increase in cell firing. Immunocytochemical labeling of the neurons for biocytin, injected during recording, and tyrosine hydroxylase (TH), the synthetic enzyme for dopamine, revealed that of the cells localized all were TH positive. This included the cells that did not appear to respond to nicotine. We conclude that most TH neurons in the SNc depolarize in the presence of nicotine. Whether the nicotinic receptors in the SNc are pre- or postsynaptic is being further investigated as well as the possibility that some TH neurons are unresponsive due to nicotinic receptor desensitization. This work is supported by USPHS grants NS 20702 and NS 26473.

## 526.7

**EFFECTS OF BRIEF INFUSIONS OF NICOTINE ON EXPRESSION OF cFOS IN SPECIFIC POPULATIONS OF NEURONS WITHIN BRAINSTEM REGIONS.** S.G. Matta\*, J.D. Valentine, J. Pomonis and B.M. Sharp, Minneapolis Medical Research Foundation and Departments of Medicine, Hennepin County Medical Center and University of Minnesota, Minneapolis, MN 55404

Previous studies from this laboratory have shown dose-dependent induction of cFos immunoreactivity within catecholaminergic regions of the rat brainstem in response to 10-15 sec iv injections of nicotine. The present experiments were performed to identify the peptidergic neurons potentially involved in ACTH secretion that may respond to nicotine (administered at a constant infusion rate of 0.045 mg/kg/30 sec for 30 or 60 sec). Nicotine dose-dependently induced cFos in NTS-A<sub>2</sub>, NTS-C<sub>2</sub>, A<sub>1</sub> and LC, but not in C<sub>1</sub>; A<sub>2</sub> and LC showed 2.5 fold enhancements to the 30 sec infusion. These two regions and C<sub>2</sub> showed between 3.5-4 fold induction to the longer infusion. In A<sub>2</sub>, the absolute number of neurons double labeled for cFos and either activin, galanin or NPY were relatively unaffected by nicotine. In contrast, nicotine increased cFos+/NPY+ neurons in C<sub>2</sub>, and in LC both galanin and NPY neurons showed increases in double labeling; again, in both regions most of the nicotine-induced cFos expression did not occur in double (+) neurons. In summary, regionally selective expression of cFos in peptidergic neurons located in brainstem catecholaminergic regions was observed in response to nicotine. Nevertheless, most of the neurons activated to express cFos were unidentified. (Supported by DA03977)

## 526.9

**A PRESYNAPTIC MODULATORY ROLE FOR THE  $\alpha$ -BUNGAROTOXIN-SENSITIVE NICOTINIC ACETYLCHOLINE RECEPTORS (nAChRs) IN RAT OLFACTORY BULB NEURONS.** E.S. Rocha<sup>1,2</sup>, M. Alkondon<sup>1</sup>, D.R. Burt<sup>1</sup>, and E.X. Albuquerque<sup>1,2</sup>, Depts. <sup>1</sup>Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201; <sup>2</sup>Lab. Mol. Pharmacol. II, IBCCF, Univ. Fed. Rio de Janeiro, RJ, Brazil, 21944.

Functional nAChRs sensitive to blockade by  $\alpha$ -bungarotoxin ( $\alpha$ -BGT) have been characterized from both hippocampal and olfactory bulb (OB) neurons of the rat (*J. Pharmacol. Exp. Ther.* 265: 1455, 1993; *Neurosci. Lett.* 176: 152, 1994). We used the whole-cell patch-clamp technique on cultured OB neurons to investigate one of the possible physiological roles of  $\alpha$ -BGT-sensitive nAChR in the brain. ACh had differential effects on different OB cell types. In small ( $\approx 10 \mu\text{m}$ ) OB neurons, pulse (0.1-1 sec) applications of ACh, via a U-tube, elicited whole-cell currents whose peak amplitude increased as a function of the concentration of ACh (0.03 - 3 mM) and was blocked by methyllycaconitine (MLA, 1 nM). In larger (15-20  $\mu\text{m}$ ) OB neurons, application of ACh to the cells was followed by bursts of miniature excitatory postsynaptic currents (MEPSCs), even though ACh was unable to evoke whole-cell current. In a 3-sec time period following the pulse application of ACh ( $>300 \mu\text{M}$ ) to the larger neurons, MEPSCs were observed in all trials, whereas at concentrations  $<100 \mu\text{M}$  failures were observed. The MEPSCs showed a reversal potential near 0 mV and were independent of action potentials. The frequency of MEPSCs was substantially reduced by MLA (1 nM) or by the AMPA-receptor antagonist CNQX (10  $\mu\text{M}$ ). MEPSCs were not observed when ACh was applied to the neurons in a  $\text{Ca}^{2+}$ -free and  $\text{MgCl}_2$  (2 mM)-containing external solution. These findings indicate that the activation of the MLA-sensitive nAChR results in the release of glutamate which in turn activates AMPA type glutamate receptors possibly at dendro-dendritic synapses in OB neurons. (USPHS Grants NS25296, ES05730, & T32-ES07263).

## 526.6

**SELECTIVE ACTIVATION OF RAT EXTRAHYPOTHALAMIC CRH-CONTAINING NEURONS BY NICOTINE.** K.M. McAllen, S.G. Matta, J.D. Valentine, S. Nicol\*, and B.M. Sharp, Minneapolis Medical Res Fndn and Dept Medicine, Hennepin County Medical Center and Univ of Minnesota, Minneapolis, MN 55404

cFos is expressed in CRH+ neurons in the hypothalamic paraventricular nucleus (PVN) in response to iv nicotine. While PVN CRH responses are characterized, regions outside the PVN have CRH-containing neurons that may well be responsive to nicotine. To study this, immunocytochemical identification of CRH+ neurons and/or cFos+ nuclei was done in adult male rats that received saline or nicotine (0.045 mg/kg/30s or 0.09 mg/kg/60s) iv. The low dose of colchicine (7  $\mu\text{g}$ , 16 h previously) permitted some visualization of CRH in cell bodies, but minimized cFos expression. In the bed nucleus of the stria terminalis, cFos increased (3 fold) in response to both doses of nicotine, but the number of double-labeled cells was unaffected. In the central nucleus of the amygdala, cFos again showed a dose-dependent increase; in addition, the number of double-labeled neurons increased 4 fold. In contrast, in the dorsal raphe, cFos+ cells decreased dose-dependently (20 and 45%), while the number of double-labeled cells decreased (60%) only in response to the higher dose. In the locus coeruleus, only the higher dose of nicotine stimulated an increase in both cFos+ (4 fold) and cFos+/CRH+ (3 fold) neurons. In the parabrachial nucleus, cerebellum and cortex double labeling was not seen. The differential sensitivity and responsiveness of CRH neurons throughout the brain to nicotine indicate that CRH may mediate some of the CNS effects of nicotine. (Supported by DA03977)

## 526.8

**NORNICOTINE-EVOKED [ $^3\text{H}$ ]DOPAMINE RELEASE FROM RAT STRIATAL SLICES: DESENSITIZATION OF THE RESPONSE TO NORNICOTINE AFTER PRIOR EXPOSURE TO NICOTINE.** L.P. Dwoskin<sup>1</sup>, L.H. Teng<sup>2</sup>, S.T. Buxton<sup>2</sup>, and P.A. Crooks<sup>2</sup>, College of Pharmacy, University of Kentucky, Lexington, KY 40536.

Previous studies demonstrate that superfusion of rat or mouse striatal synaptosomes with low, inactive concentrations of nicotine results in desensitization of the response to a subsequent nicotine exposure (Rowell and Hillebrand, 1994; Grady et al, 1994). Nornicotine is an active nicotine metabolite and tobacco alkaloid present in brain after peripheral nicotine administration. However, its contribution to the CNS effects of tobacco smoking has not been characterized. In order to determine if nornicotine evokes dopamine (DA) release by a similar mechanism as nicotine, we determined if cross desensitization to nornicotine would occur following a pre-exposure to nicotine. In the present study, rat striatal slices preloaded with [ $^3\text{H}$ ]DA were superfused for 60 min in the absence or presence of nicotine (0.1  $\mu\text{M}$ ). During this period, nicotine-evoked [ $^3\text{H}$ ]DA release returned to basal levels. Then, both control and nicotine pre-exposed slices were superfused with nornicotine (10  $\mu\text{M}$ ) for 60 min. In control slices, nornicotine evoked [ $^3\text{H}$ ]DA release. In the nicotine pre-exposed slices, however, no response to nicotine or nornicotine was detected. Thus, nicotine pre-exposure resulted in desensitization to the response to nicotine and cross-desensitization to the response to nornicotine, suggesting that these alkaloids act via a common mechanism. (Supported by a grant from the Tobacco and Health Research Institute, Lexington, KY).

## 526.10

**EVIDENCE THAT NORNICOTINE ACTS TO RELEASE DOPAMINE FROM RAT STRIATAL SLICES BY A NICOTINIC RECEPTOR-MEDIATED MECHANISM.** L.H. Teng<sup>1</sup>, S.T. Buxton<sup>2</sup>, P.A. Crooks<sup>2</sup>, and L.P. Dwoskin<sup>2</sup>, College of Pharmacy and Graduate Center for Toxicology, University of Kentucky, Lexington, KY 40536.

Previous results demonstrate that nornicotine, an active nicotine metabolite and tobacco alkaloid, evokes the release of dopamine (DA) from rat striatal slices in a concentration- and calcium-dependent manner (Dwoskin et al, 1993). To determine if the effect of nornicotine is mediated by a nicotinic receptor, the ability of mecamylamine (MEC, a noncompetitive nicotinic receptor antagonist) and dihydro- $\beta$ -erythroidine (DH $\beta$ E, a competitive nicotinic receptor antagonist) to inhibit the effect of nornicotine was investigated. MEC (0.01-100  $\mu\text{M}$ ) and DH $\beta$ E (0.01-10  $\mu\text{M}$ ) did not evoke [ $^3\text{H}$ ]DA release themselves. However, the high concentration of DH $\beta$ E (100  $\mu\text{M}$ ) evoked [ $^3\text{H}$ ]DA release, and therefore, was not used in antagonism studies. MEC and DH $\beta$ E inhibited [ $^3\text{H}$ ]DA overflow evoked by 10  $\mu\text{M}$  nicotine. The highest concentration of MEC (100  $\mu\text{M}$ ) and of DH $\beta$ E (10  $\mu\text{M}$ ) inhibited the response to nicotine by 90% and 75%, respectively. In comparison, MEC was effective in inhibiting the response to low concentrations of nornicotine (1-10  $\mu\text{M}$ ). However, MEC was not effective against the high concentrations (100  $\mu\text{M}$  - 3 mM) of nornicotine. DH $\beta$ E (10  $\mu\text{M}$ ) inhibited 80 to 90% of the response to nornicotine (1-10  $\mu\text{M}$ ). Similarly, the effect of the high concentrations of nornicotine ( $>100 \mu\text{M}$ ) was not antagonized by DH $\beta$ E. Thus, concentrations of nornicotine less than 100  $\mu\text{M}$  activate MEC- and DH $\beta$ E-sensitive nicotinic receptors to evoke DA release from rat striatal slices. (Supported by a grant from the Tobacco and Health Research Institute, Lexington, KY).

## 526.11

REGULATION OF nAChR  $\beta 4$  SUBUNIT GENE EXPRESSION BY NERVE GROWTH FACTOR. C.B. Bigger, M. Hu, and P.D. Gardner\*. Center for Molecular Medicine, Institute of Biotechnology, Univ. of Texas Health Science Center, San Antonio, TX 78245.

Nicotinic acetylcholine receptors (nAChR) belong to a multigene family ( $\alpha 2$ - $\alpha 9$ , and  $\beta 2$ - $\beta 4$ ) that is expressed in distinct compositional, temporal and spatial patterns within the adult mammalian CNS. The functional diversity and differential expression of individual subunit genes is most likely generated by distinct molecular mechanisms. Our laboratory has focused upon the characterization of the regulatory mechanisms governing the expression of the  $\beta 4$  subunit gene during neuronal differentiation using the PC12 cell line as a model system. PC12 cells undergo differentiation into non-replicating sympathetic-like neuronal cells upon stimulation with NGF. We and others have shown that the steady-state levels of  $\beta 4$  mRNA increase approximately 5-fold upon NGF stimulation of PC12 cells as determined by Northern blot analysis. This up-regulation occurs during the late stages of neuronal differentiation and is independent of cAMP-dependent-protein kinase A activation. Transient transfection experiments and nuclear run-off assays have demonstrated that up-regulation of the  $\beta 4$  subunit gene occurs in part by transcriptional activation. Consistent with these data, inhibition of transcription with Actinomycin D (Act.D) did not result in a decrease over time in steady-state levels of  $\beta 4$  mRNA in non-stimulated versus NGF-stimulated PC12 cells, suggesting that post-transcriptional mechanisms involving  $\beta 4$  mRNA stability do not play a major role in NGF induction of  $\beta 4$  subunit gene expression. Furthermore, steady-state levels of  $\beta 4$  mRNA remained constant up to ten hours in the presence of Act. D in non-stimulated PC12 cells. Therefore, these data indicate that a major control point of  $\beta 4$  subunit gene expression during neuronal differentiation of PC12 cells occurs at the level of transcriptional activation. Further characterization of the promoter elements that confer NGF-inducibility are underway. (This work was supported by NIH grant NS30243.)

COMPARISON OF DOPAMINE RELEASE AND RUBIDIUM EFFLUX FOR ACTIVATION AND DESENSITIZATION BY NICOTINIC AGONISTS. Sharon R. Grady\*, Michael J. Marks, Scott F. Robinson, and Allan C. Collins. University of Colorado, Boulder, CO 80309.

Nicotinic agonists stimulate the release of [ $^3$ H]dopamine (DA) from striatal synaptosomes and the efflux of  $^{86}$ Rb $^{+}$  (Rb) from thalamic synaptosomes. Both responses desensitize upon long-term exposure to nicotine. The results reported here compare DA release and Rb efflux elicited by six nicotinic agonists: L-nicotine, D-nicotine, acetylcholine, carbachol, cytosine, and epibatidine. P2 fractions were prepared from C57BL/6 female mice, loaded with DA (striatum) or Rb (thalamus), and exposed to nicotinic agonists for 3-10 min. Maximal responses and desensitization rates were measured. All six agonists elicited concentration-dependent increases in DA release or Rb efflux and in the desensitization rates for both processes. Epibatidine was the most potent agonist tested ( $EC_{50}$  = 3 nM for DA and 11 nM for Rb), while carbachol was the least potent ( $EC_{50}$  = 8.8  $\mu$ M for DA and 32.5  $\mu$ M for Rb). Although it was active at low concentrations, cytosine was the least efficacious compound tested for both measures. DA release and Rb efflux differed in the relative affinities, maximal responses, and desensitization rates determined for the six agonists. Furthermore, the residual rate of DA release was substantially higher than the rate of Rb efflux observed during prolonged exposure to each agonist. Treatment with low concentrations of the agonists induced concentration-dependent decreases in subsequent responses to 10  $\mu$ M nicotine. The  $IC_{50}$  values measured for each agonist for DA release, Rb efflux and [ $^3$ H]nicotine binding were highly correlated, but not identical. The two-state model of Katz and Thesleff adequately explained the results obtained for both DA release and Rb efflux. However, the kinetic differences observed for these two functional responses suggests that the receptors mediating the responses are similar, but not identical. Supported by DA-03194 and DA-00116.

## ACETYLCHOLINE RECEPTOR: NICOTINIC EXPRESSION AND TREATMENT EFFECTS

## 527.1

GENE STRUCTURE AND cDNA MUTATION SCREENING OF  $\alpha 7$  NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR IN CONTROL AND SCHIZOPHRENIC SUBJECTS

C. Drebing\*, A. Davis, J. Hopkins, M. Barnhart, J. Logel, R. Freedman and S. Leonard. Departments of Pharmacology and Psychiatry, University of Colorado Health Sciences Center and Veterans Administration Medical Center, Denver, CO 80262.

Genomic structure of the  $\alpha 7$  nicotinic receptor was obtained by Extra Long PCR using rTth polymerase (Perkin-Elmer) and DNA purified from human postmortem brain. Sequence of the DNA in both schizophrenic and control populations showed evidence of polymorphisms. A YAC clone of  $\alpha 7$  has also been obtained; Southern blotting confirmed the presence of  $\alpha 7$  coding sequence and chromosome mapping confirmed the presence of the YAC on human chromosome 15. The cDNA sequence of  $\alpha 7$  was obtained for mutation screening from RNA purified from cycloheximide treated lymphoblast cell lines by ectopic (illegitimate) PCR. Comparison of the sequence of control and schizophrenic cDNA with that of a neuroblastoma cell line, SHSY5Y, and a clone obtained from a normal hippocampal brain library, showed conservative polymorphisms were present in both populations.

## 526.12

DIFFERENTIAL REGULATION OF THE  $\alpha$ -BUNGAROTOXIN-BINDING NICOTINIC ACETYLCHOLINE RECEPTOR SUBUNIT IN DEVELOPING NEURONAL CELLS BY K $^{+}$  DEPOLARIZATION AND NMDA RECEPTOR ACTIVATION. S.A. Berman\*, M. Didier, M. Xu, P. Almaquer and S. Bursztajn. Lab. for Molecular Neuroscience, McLean Hosp/Harvard Med. Sch. Belmont, MA 02178.

We investigated the expression of  $\alpha$ -BTX-binding nAChRs on mouse cerebellar granule cells grown under trophic conditions consisting of either chronic K $^{+}$  (30 mM) depolarization or NMDA receptor stimulation. In cerebellar cultures, 125I- $\alpha$ -BTX bound to a single saturable class of sites with a Kd identical to its binding on the immunisolated  $\alpha 7$  nAChR subunit. Combined autoradiographic and immunocytochemical studies revealed that 25-30% of glutamatergic neurons, but not glial cells, displayed a somatic and neuritic localization for these sites. The presence of the NMDA $\alpha 1$  glutamate receptor subunit was also visualized on neurons expressing this  $\alpha$ -BTX-binding. In High K $^{+}$  cultures  $\alpha$ -BTX binding exhibited a transient pattern, increasing during synaptogenesis reaching a plateau at 10-14 days in vitro and decreasing thereafter. In contrast, when cultures were maintained in a low K $^{+}$  (12.5 mM) medium, the neuronal survival was reduced and the relative amount of 125I- $\alpha$ -BTX binding decreased dramatically. Chronic NMDA treatment of cerebellar cultures in presence of low K $^{+}$  promoted long-term cell survival and maturation as well as upregulated the 125I- $\alpha$ -BTX binding during the first week in vitro as observed in high K $^{+}$  condition. However, the ontogeny of  $\alpha$ -BTX binding sites in NMDA-treated cells did not display the later transient increase which occurs in high K $^{+}$  culture conditions. This apparent upregulation of nAChRs in the presence of high K $^{+}$  appeared to be the result of an increase in the number of granule neurons binding  $\alpha$ -BTX and an elevation of the total number of  $\alpha$ -BTX binding sites per cell. To show further that the  $\alpha$ -BTX binding sites represent  $\alpha 7$  nAChRs, RNA from cerebellar granule cells was amplified by RT-PCR and this product sequenced showing a very high homology with the rat  $\alpha 7$  nAChR cDNA. Studies using specific molecular probes for the mouse  $\alpha 7$  subunit are in progress to determine whether K $^{+}$  depolarization or NMDA receptor activation regulate  $\alpha 7$  nAChR mRNA.

## 527.2

COMPARISON OF THE REGIONAL DISTRIBUTION OF  $\alpha 7$  NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR SUBUNIT mRNA AND [ $^{125}$ I]- $\alpha$ -BUNGAROTOXIN BINDING IN HUMAN POSTMORTEM BRAIN. S. Leonard\*, C. Bresse, C. Adams, J. Logel, C. Drebing, Y. Rollins, and M. Barnhart. Dept. of Pharmacology, University of Colorado Health Sciences Center and Veterans Administration Medical Center, Denver, CO 80262.

The neuronal  $\alpha 7$  nicotinic acetylcholine receptor is a member of the ligand-gated ion channel gene family and is the major  $\alpha$ -bungarotoxin ( $\alpha$ BTX) binding receptor in mammalian brain. We have determined the regional localization of  $\alpha 7$  mRNA expression and [ $^{125}$ I]- $\alpha$ -bungarotoxin binding in 40 regions dissected from human postmortem brain. Frozen tissue sections were hybridized *in situ* with a human brain  $\alpha 7$  cRNA probe, and compared with [ $^{125}$ I]- $\alpha$ BTX autoradiography in matched tissue sections. Although not abundantly expressed,  $\alpha 7$  expression was principally localized to neurons in sensory and motor nuclei, such as hippocampus, geniculate, and the reticular thalamic nucleus (RTN), but was seen at lower levels in other brain regions. [ $^{125}$ I]- $\alpha$ BTX binding was seen on neuronal processes, as well as to cell bodies. While  $\alpha 7$  mRNA expression and [ $^{125}$ I]- $\alpha$ BTX were co-localized in some of the brain regions examined, there were several regions where the localization of  $\alpha 7$  mRNA and [ $^{125}$ I]- $\alpha$ BTX binding sites did not coincide. In the hippocampus, where  $\alpha 7$  hybridization was moderately abundant, most cells were only weakly labelled with [ $^{125}$ I]- $\alpha$ BTX and only rare non-principal neurons with processes were heavily labelled. Additionally, in the RTN, there were only a few  $\alpha 7$  mRNA positive cells, but extensive [ $^{125}$ I]- $\alpha$ BTX labelling of interwoven and fused cellular processes over the entire nucleus was observed. The anatomical localization of the  $\alpha 7$  nicotinic acetylcholine receptor implicates this receptor in a number of sensory and sensory motor processes in the human brain.

## 527.3

POTENTIATION OF ACH-EVOKED CURRENTS THROUGH  $\alpha 4\beta 2$  AND  $\alpha 5\alpha 4\beta 2$  NACHRS: LOCALIZATION OF THE  $\text{Ca}^{2+}$ -REGULATORY SITE. J.A. Ramirez-Latorre and J. Role\*. Center for Neurobiol. & Behavior, Columbia University, 722W 168th St. New York, NY 10032.

To identify sequences responsible for  $\text{Ca}^{2+}$ -mediated potentiation of nAChR currents we have studied macroscopic and single-channel currents in oocytes injected with the RNA for the combinations of  $\alpha 4\beta 2$  and  $\alpha 5\alpha 4\beta 2$ . Increased  $[\text{Ca}^{2+}]_{\text{ext}}$  alters nAChR channels by i) decreasing single channel conductance, ii) increasing mean open time and iii) increasing NPo. The net effect of these changes is a potentiation of macroscopic ACh-evoked currents by  $\text{Ca}^{2+}$ . Previous experiments show that the Cys reactive reagent MTSEA interferes with  $\text{Ca}^{2+}$  regulation of both macroscopic and single nAChR channel currents. Access to the reaction site for MTSEA appears to be restricted since the larger derivatives (MTSET) have no effect. When each Cys in the N-terminal domain and two within the M1-M2 loop of  $\alpha 4$  regions were mutated to gly to examine potential MTSEA reaction sites, a single residue -Cys 243- within the M1-M2 loop was identified as crucial. We hypothesize C-243 is sufficiently close to the  $\text{Ca}^{2+}$  regulatory site that MTSEA block of  $\text{Ca}^{2+}$  regulation serves as a reporter for the molecular interactions of this site with  $\text{Ca}^{2+}$ , since the mutant is still regulated by  $\text{Ca}^{2+}$ . The sequence around C-243 is a reasonable candidate site for  $\text{Ca}^{2+}$  regulation, in view of local negative charge ( $\alpha 4$ : M1-LPSECGEK-M2). The alteration of the proposed  $\text{Ca}^{2+}$  pocket by  $\alpha 5$  is of particular interest since  $\alpha 5$  contributes another negative charge to the region. Our studies also suggest that reduction of Cys243 by MTSEA, decreases the  $\text{Ca}^{2+}$  permeability of  $\alpha 4\beta 2$  nAChRs. The  $\alpha 7$  nAChR is highly permeable to  $\text{Ca}^{2+}$  and yet the sequence in this region differs only by the substitution of a Ser for C-243. It seems likely that changes in this region are connected to  $\text{Ca}^{2+}$ -nAChR interactions. Supported by NS22061 to L.R.

## 527.5

CHRONIC NICOTINE TREATMENT UP-REGULATES  $\alpha 3$  ACHRS AND  $\alpha 7$  ACHRS EXPRESSED BY THE HUMAN NEUROBLASTOMA CELL LINE SH-SY5Y.

X. Peng\*, R. Anand, F. Wang, and J. Lindstrom. Dept. of Neuroscience, Univ. of Pennsylvania Medical School, Philadelphia, PA 19104-6074.

The human neuroblastoma cell line SH-SY5Y expresses a variety of neuronal nicotinic receptor (AChR) subunits which include  $\alpha 3$ ,  $\alpha 5$ ,  $\alpha 7$ ,  $\beta 2$ , and  $\beta 4$ . Chronic treatment with nicotine, but not d-tubocurarine or mecamylamine, induced a 600% increase in the number of  $\alpha 3$  AChRs but only a 30% increase of  $\alpha 7$  AChRs. Mecamylamine and nicotine are not synergistic in causing receptor up-regulation. The nicotine concentration dependence, time course, and extent of AChR up-regulation are different from those of  $\alpha 4\beta 2$  AChRs in M10 cells. Scatchard analysis indicated that after chronic nicotine treatment the AChRs do not change their affinity for nicotine and  $\alpha$ -bungarotoxin. Northern blot analysis showed that chronic nicotine exposure does not change the mRNA level of  $\alpha 3$  or  $\alpha 7$  subunits. These results indicate that up-regulation of  $\alpha 3$  and  $\alpha 7$  AChRs after chronic nicotine treatment occurs posttranscriptionally, as it does in M10 cells. (Supported by grants from NINDS, CSTR, CTR, and MDA).

## 527.7

Elimination of Putative Phosphorylation Sites On Nicotinic Acetylcholine Receptors Affects the Rate of Recovery From Rapid Onset Desensitization. K. Paradiso, R.W. Kulberg\*, and P. Brehm\*

Dept. of Neurobiology and Behavior, SUNY Stony Brook, Stony Brook, NY 11794 and \*Dept. of Biological Sciences, Univ. of Alaska, Anchorage, AK 99508.

Fast perfusion of acetylcholine (ACh) to excised patches from *Xenopus* oocytes injected with RNA encoding *Xenopus* muscle nicotinic acetylcholine receptors was used to study sensitivity to ACh and kinetics of desensitization. Dose-response curves place estimates of EC-50s at 4.2  $\mu\text{M}$  for the embryonic receptor type ( $\alpha\beta\gamma$ ) and 9.4  $\mu\text{M}$  for the adult receptor type ( $\alpha\beta\delta\epsilon$ ). Despite differences in EC-50, no corresponding difference was found in the onset rate of desensitization between the two receptor types. Application of 100  $\mu\text{M}$  ACh resulted in rapidly decaying inward currents which were fit by a single exponential function with an average time constant of ~60ms for both the  $\alpha\beta\gamma$  and the  $\alpha\beta\delta\epsilon$  receptors. The time-dependence of recovery for  $\alpha\beta\gamma$  receptors, measured with paired pulses, was best fit with two exponentials corresponding to a fast ( $1.7 \pm 0.5\text{s}$ , mean  $\pm$  s.d.) and a slow ( $23.4 \pm 9.2\text{s}$ ) component of recovery. To determine whether phosphorylation affects kinetics of desensitization, wild type  $\alpha\beta\gamma$  receptors were compared to receptors in which the PKA-dependent phosphorylation sites were mutated from serine to alanine on the  $\alpha$ ,  $\delta$ , and  $\gamma$  subunits. The time constants of desensitization onset were similar for both the wild type and the mutant receptors as were the time constants of recovery. However, the fast time constant of recovery accounted for only 38% of the recovery in the mutants compared to 77% in wild type  $\alpha\beta\gamma$  receptors. Thus, the overall recovery from desensitization is slower for mutant receptors supporting the proposition that receptor phosphorylation is a potential mechanism by which postsynaptic responses can be modulated. The fast onset of desensitization and slow recovery further suggests that at active synapses only a fraction of the total receptors are available for activation. Consistent with this idea, application of 2ms pulses of ACh to wild type  $\alpha\beta\gamma$  receptors, at frequencies between 10 and 40Hz, results in a progressive decrease in response ending in a steady state, as predicted by our measured onset and recovery rates.

## 527.4

COMPENSATORY CHANGES IN nAChR CHANNEL EXPRESSION FOLLOWING ANTISENSE OLIGONUCLEOTIDE-MEDIATED SUBUNIT DELETION:  $\alpha 5$  MINUS AND  $\alpha 7$  MINUS nAChR CHANNELS

C. Yu\* & L. Role. Dept. of Anat. & Cell Biol. in the Ctr for Neurobiol. & Behav. Columbia Univ. P&S, 722 W. 168th St. New York, NY 10032

Previous studies have demonstrated that  $\alpha 3$  subunit is a key component of nAChR channels in peripheral autonomic neurons (studies from Berg, Linstrom, Jacob and colleagues as well as our laboratory). Recent studies using antisense oligonucleotide-mediated deletion show that  $\alpha 5$  and  $\alpha 7$  subunits also participate in native nAChR channels (see abstracts by Yu et al., 1993, 1994). In the course of these studies we found that treatment of neurons with antisense oligonucleotides to  $\alpha 3$ ,  $\alpha 5$  or  $\alpha 7$  decreased subunit protein levels and deleted specific AChR channel subtypes, but also resulted in the expression of novel ACh-gated currents with distinct biophysical and pharmacological profiles.

The current study indicates that  $\alpha 5$  and  $\alpha 7$  may "compensate" for one another since the antisense-mediated deletion of one of these subunits results in the expression of channel subtypes with the pharmacological and/or biophysical properties of the other. Previous studies indicate that  $\alpha 5$  containing nAChRs are large  $\gamma$ , slowly desensitizing channels that are ~ 100x less sensitive to ACh (see abstract by Ramirez et al., 1993). Deletion of  $\alpha 7$  produces novel high conductance channels and results in a biphasic dose response curve. One component of the curve has an EC50 similar to that of the control, while the other component has an EC50 that is ~ 20 fold higher than that of first component. Likewise, deletion of the  $\alpha 5$  subunit results in ACh-evoked currents that are blockable by  $\alpha 7$ -bungarotoxin. Since  $\alpha 7$  is the only  $\alpha$ -BGT sensitive subunits normally expressed by these cells, this suggests that  $\alpha 7$  subunit is compensating in  $\alpha 5$ -minus neurons. Alternative interpretations, e.g., that increased expression rather than increased assembly of novel subunits are being examined (supported by NIH22061 to LR)

## 527.6

[<sup>3</sup>H]EPIBATIDINE BINDS TO NON- $\alpha 4\beta 2$  HIGH AFFINITY NICOTINIC RECEPTORS IN IMR-32 CELLS. M.L. Dávila-García\*, R.A. Houghtling and K.J. Kellar. Department of Pharmacology, Georgetown University School of Medicine, Washington, DC 20007.

IMR-32 neuroblastoma cells were established back in 1970 by Tumilowicz from human neural crest cells. These cells bind [<sup>125</sup>I]α-BTX with high affinity and [<sup>3</sup>H]ACh with low affinity. They have also been shown to express transcripts for  $\alpha 3$ ,  $\alpha 5$  and  $\beta 4$  nicotinic receptor subunits, which is consistent with their ganglionic origin. [<sup>3</sup>H]Epibatidine ([<sup>3</sup>H]EB) is a high affinity ligand for neuronal nicotinic acetylcholine receptors. We have recently demonstrated that this ligand binds two high affinity sites in adult rat forebrain with Kd values of 14.7 and 360 pM and that these sites appear to be present in nearly equimolar concentrations. One of these sites is the  $\alpha 4\beta 2$  receptor, which binds other high affinity agonist radioligands. In the present study we examined [<sup>3</sup>H]EB binding in IMR-32 cells. Since they do not appear to contain  $\alpha 4\beta 2$  receptors, [<sup>3</sup>H]EB binding in these cells could help to determine the possible identity of the second site in brain. We found that IMR-32 cells contain two high affinity sites neither of which is labelled by [<sup>3</sup>H]cytisine even at high concentrations (20nM). These two sites seem to be nicotinic in nature since nicotine competes effectively against [<sup>3</sup>H]EB for binding at both sites. Curare displaces the radioligand effectively ( $\text{IC}_{50} \approx 2\mu\text{M}$ ), but di-hydro-β-erythroidine, mecamylamine and hexamethonium are not very effective competitors. Nicotine treatment for 8 days increases the number of [<sup>3</sup>H]EB binding sites in IMR-32 cells in a dose dependent manner starting at concentrations as low as 1  $\mu\text{M}$ . Thus, we found that these cells, which do not bind [<sup>3</sup>H]cytisine and hence probably do not contain  $\alpha 4\beta 2$  nicotinic receptors, may have a third subtype of receptor which binds [<sup>3</sup>H]EB with high affinity. At least one of these non- $\alpha 4\beta 2$  nicotinic sites is regulated by nicotine.

This work was supported by NIH grants AG009973 and DA06486 to KJK and DA05417 to MIDG.

## 527.8

CLONING OF cDNA'S ENCODING PROTEINS THAT INTERACT WITH THE 43 KD PROTEIN. E.T. Fung\*, Bill, and R.L. Haganir. Department of Neurosciences, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

During development of the neuromuscular junction, the nicotinic acetylcholine receptor (nAChR) clusters in the post-synaptic membrane. While the mechanisms by which this process occur are largely unknown, some of the molecules involved in the process have been identified. One of these is the 43 kD protein, a post-synaptic membrane-associated molecule. Expression of this protein in heterologous systems leads to formation of patches of 43 kD protein at the cell surface, and co-expression with nAChR leads to the formation of patches containing both 43 kD protein and nAChR. More recently, it has been shown that 43 kD protein can cluster each of the subunits of the nAChR individually. A knowledge of the proteins with which 43 kD interacts would be critical to the understanding of the mechanisms by which it functions. Traditional approaches such as immunoprecipitation have failed to identify those proteins. As an alternative, we have turned to the yeast two-hybrid system to identify cDNA's for proteins with which 43 kD might interact. This system has proven to have a high level of sensitivity and specificity. In addition, it provides direct sequence information. Screening of a cDNA library yielded 16 positives. Sequencing and characterization of these clones is underway.

## 527.9

**DMXB, AN AGONIST SELECTIVE FOR THE  $\alpha$ -BUNGAROTOXIN BINDING SITE, TRANSIENTLY NORMALIZES AUDITORY GATING IN THE DBA/2 MOUSE.** K.E. Stevens\*, W.R. Kem, J. Strom and R. Freedman. Depts. Psychiatry and Neuroscience, Univ. Colorado Health Sciences Ctr, Denver, CO 80262 and Dept. Pharmacology and Therapeutics, Univ. Florida College of Medicine, Gainesville, FL 32610

DBA/2 mice, an inbred mouse strain with reduced numbers of hippocampal  $\alpha$ -bungarotoxin ( $\alpha$ -BTX) binding sites, consistently fail to inhibit their response to the second of 2 identical auditory stimuli, 0.5 sec apart. These mice produce hippocampal midlatency evoked potentials of similar magnitude to both clicks, unlike other strains (e.g. C3H, C57Bl, ST/b) which show a diminished response to the second stimulus. Previous studies in anesthetized rats have shown a loss of auditory gating with central administration of  $\alpha$ -BTX. We have shown that systemic nicotine injections (3 mg/kg, sc) produce a transient normalization of gating in the DBA/2 mice. Here, we report that DMXB, an agonist selective for the  $\alpha$ -BTX binding site, also produces normalization of gating in these mice. 5 min interval recordings of hippocampal auditory evoked potentials were made prior to and after a 1.0 mg/kg, sc, injection of DMXB. DMXB produced a rapid normalization of gating which was brief in duration as compared to nicotine. These data suggest that the  $\alpha$ -BTX-sensitive subtype of the nicotinic receptor modulates auditory gating in the DBA/2 mouse.

## 527.11

**NEURONAL NICOTINIC RECEPTOR mRNA ENCODING  $\alpha 4$  SUBUNIT IS DIFFERENTIALLY EXPRESSED IN RAT BRAIN.** J.J. Shacka\*, M.J. Wallace, and S.E. Robinson. Department of Pharmacology & Toxicology, Medical College of Virginia, Virginia Commonwealth University, Richmond, VA 23298-0613.

The purpose of this study was to quantitate neuronal nicotinic receptor (nNR)  $\alpha 4$  subunit mRNA in adult and three-week old Sprague-Dawley CD rat brain. 50  $\mu$ g total RNA from adult or three-week old rat hippocampus (hippocampus + septum), cortex and thalamus was size-fractionated and transferred to nitrocellulose. Northern hybridization was performed via an  $\alpha$ -32P dCTP-labelled 200 bp probe encoding the non-conserved 3' intracellular loop of nNR  $\alpha 4$ -1 subunit cDNA. Total RNA was normalized for gel loading via  $\gamma$ -32P ATP-labelled 28S rRNA. All data were quantified via Molecular Dynamics intensity units as the ratio of  $\alpha 4$  mRNA to 28S rRNA. Preliminary studies have identified three transcripts homologous to the  $\alpha 4$ -1 cDNA. The sizes of these transcripts were 8.5, 4.2 and 2.4 kb, and their quantities were similar in both age groups. All three transcripts were present in the cortex and thalamus. Virtually no 8.5 kb signal was detected in the hippocampus. The ratio of 8.5 kb mRNA to 28S was higher in the thalamus than in the cortex. The ratio of the 4.2 kb transcript to 28S was greater in the thalamus than in the cortex or hippocampus, which had similar ratios. The ratio of the 2.4 kb fragment to 28S was higher in the thalamus than in the cortex, and much lower in the hippocampus. These findings correlate well with both the putative existence of multiple transcripts encoding the  $\alpha 4$  subunit in rat brain, as well as the high abundance of  $\alpha 4$  mRNA in the thalamus and cortex in comparison to the hippocampus. The overall goal of this study is to determine the effects of prenatal nicotine exposure on the postnatal development of Sprague-Dawley CD rats, with analyses on the quantity and distribution of nNR subunits at various postnatal time points.

## 527.13

**$\alpha$ -CONOTOXIN EI: A NEW ANTAGONIST OF NICOTINIC ACETYLCHOLINE RECEPTORS.** D.R. Groebe, J.S. Martinez, B.M. Olivera, W.R. Gray, S.N. Abramson\*, and J.M. McIntosh. Department of Pharmacology, University of Pittsburgh, Pittsburgh, PA 15261; Departments of Biology and Psychiatry, University of Utah, Salt Lake City, UT 84112

$\alpha$ -Conotoxin EI was purified from milked venom of the Atlantic fish-hunting cone snail *C. ermineus* by RP-HPLC, based on its ability to produce muscle paralysis in fish and mice. The sequence was confirmed by LSI-MS and total synthesis. Disulfides were determined using partial reduction with TCEP. Although EI has a cysteine spacing analogous to  $\alpha$ -conotoxins PnIA and PnIB, and a disulfide connectivity analogous to  $\alpha$ -conotoxins MI and SI, its sequence differs significantly from all known  $\alpha$ -conotoxins. Functional effects of EI were investigated *in vivo* and *in vitro*, and compared with MI. MI is approximately 11 times more toxic to mice than EI.  $\alpha$ -Conotoxin EI displays two distinct affinities of  $11 \pm 2.4$  nM and  $350 \pm 62$  nM (32-fold difference) for the two acetylcholine-binding sites on nicotinic receptors from mouse muscle BC<sub>3</sub>H-1 cells. In contrast,  $\alpha$ -conotoxin MI displays two distinct affinities of  $0.55 \pm 0.21$  nM and  $25 \pm 5.2$   $\mu$ M (45,000-fold difference). Despite their different sequences and different affinities at the two acetylcholine-binding sites, both  $\alpha$ -conotoxin EI and MI display higher affinity for the acetylcholine-binding site near the  $\alpha/\delta$  subunit interface. The apparent affinities and site preference of  $\alpha$ -conotoxin EI for *Torpedo* nicotinic receptors were also determined.

## 527.10

**COMPARATIVE LEVELS OF NICOTINIC  $\alpha 4\beta 2$ /[<sup>3</sup>H]CYTISINE AND  $\alpha 7$ /[<sup>125</sup>I] $\alpha$ -BUNGAROTOXIN RECEPTORS IN AGED MEMORY-IMPAIRED AND MEMORY-UNIMPAIRED LONG EVANS RATS.** D. Cécère\*, H. Le Jeune, J. Aubert, W. Rowe and R. Quirion. Douglas Hospital Res. Ctr. and Dept. of Psychiatry, McGill Univ. 6875 Boul. Lasalle, Montréal, Qué., Canada, H4H 1R3.

It is now established that nicotinic receptors, likely of the  $\alpha 4\beta 2$  sub-type are markedly decreased in Alzheimer's Disease (AD) brains. Nicotine and related agonists have been shown to facilitate attentional (Rochford et al. this meeting) and cognitive behaviors in various mammals, including man. Together, this leads to pilot clinical trials with nicotinic agonists in AD. However, less is known about the  $\alpha 7$  sub-type which is also expressed in the brain and has high affinity for the toxin  $\alpha$ -bungarotoxin ( $\alpha$ -BTX). The aim of the present study was to compare the status of  $\alpha 4\beta 2$ - and  $\alpha 7$ -like nicotinic receptors in an animal model that assesses cognitive impairments, the aged memory-impaired (AI) and aged memory-unimpaired (AU) Long Evans rats (Quirion et al. J. Neurosci. 15:1455, 1995). Apparent levels of  $\alpha 4\beta 2$ - and  $\alpha 7$ -like nicotinic sites were evaluated by quantitative receptor autoradiography using [<sup>3</sup>H]cytisine (10nM) and [<sup>125</sup>I]  $\alpha$ -BTX (1.5nM) as ligand, respectively. As reported earlier in young animals (Clarke et al. J. Neurosci. 5:1307, 1985), the distribution of these two classes of nicotinic receptors is segregated and relatively complementary. No significant changes in [<sup>3</sup>H]cytisine binding levels were detected between adult (6 month old) and 24 month old AI and AU rats. Similar results were obtained for specific [<sup>125</sup>I]  $\alpha$ -BTX binding sites, except for significant increases in the CA1 subfield of the hippocampus and the accessory olfactory bulb (AOB) in the AU vs young groups, and significant decreases in the dentate gyrus and AOB of AI vs AU animals. Therefore, it appears that both  $\alpha 4\beta 2$  and  $\alpha 7$  nicotinic receptor sub-types are not markedly altered during the normal aging process. The  $\alpha 7$ /[<sup>125</sup>I]  $\alpha$ -BTX sites seem to be more sensitive to the effects of aging however, their contribution to the emergence of the cognitive deficits in the rat remains to be fully elucidated. Supported by the MRCC.

**CODISTRIBUTION OF NICOTINIC ACETYLCHOLINE RECEPTOR  $\alpha 3$  AND  $\beta 4$  SUBUNIT mRNAs DURING RAT BRAIN DEVELOPMENT** U.H. Winer-Serhan\*, F.M. Leslie. Dept. of Pharmacology, Univ. of California, Irvine CA 92717

Neuronal nicotinic acetylcholine receptors (nAChR) are pentameric ion channels, that mediate fast ligand gated currents. Whereas central [<sup>3</sup>H]nicotine binding sites consist predominantly of  $\alpha 4$  and  $\beta 2$  subunits, other subunits are also expressed in rat brain and form functional heteromeric nAChR in expression studies. In rat peripheral ganglia  $\alpha 3$  and  $\beta 4$  have been shown to form nAChR; however, this combination has not been reported in rat CNS. A previous study reported very limited expression of  $\alpha 3$  and  $\beta 4$  mRNAs during early postnatal development. We have used *in situ* hybridization with sensitive <sup>35</sup>S-labeled full-length riboprobes to further examine codistribution of  $\alpha 3$  and  $\beta 4$  mRNA in developing rat brain. Our results show, that both subunits have a distinct distribution pattern during development, with expression intensity stronger and more widespread than in the adult. Several areas showed codistribution of both mRNAs. In the telencephalon  $\alpha 3$  and  $\beta 4$  mRNAs were found in frontal, primary visual and retrosplenial cortex with peak expression during the first, second and the third postnatal week, respectively. In the CA3 region of the hippocampus, there was codistribution of  $\alpha 3$  and  $\beta 4$  mRNAs during the first and second postnatal week, with  $\alpha 3$  but not  $\beta 4$  declining thereafter. In the caudate putamen,  $\alpha 3$  and  $\beta 4$  mRNAs were found in scattered, large neurons throughout postnatal development. In the diencephalon, codistribution of  $\alpha 3$  and  $\beta 4$  mRNAs was limited to the medial habenula which had the most intense expression for both subunits in neonates and throughout development. In the mesencephalon  $\alpha 3$  and  $\beta 4$  mRNA expression was detected in the dopaminergic nuclei substantia nigra pars compacta and ventral tegmental area throughout development. However,  $\beta 4$  hybridization was weak in the SN, where several other nAChR subunits were also localized. In the pons both  $\alpha 3$  and  $\beta 4$  mRNAs were detected in the adrenergic nucleus locus coeruleus and several brain stem nuclei many of them cholinergic. The codistribution of  $\alpha 3$  and  $\beta 4$  mRNAs in different brain areas during development suggests that they form a distinct neuronal nAChR subtype which may be involved in rat brain development and neurotransmitter release. Coexpression studies are currently underway to determine whether  $\alpha 3$  and  $\beta 4$  mRNA are expressed in the same cell. Supported by PHS grant # NS30109

## 527.14

**A NEW  $\alpha$ -CONOTOXIN WHICH TARGETS  $\alpha 3\beta 2$  NICOTINIC ACETYLCHOLINE RECEPTORS.** G.E. Cartier<sup>1</sup>, D. Yoshikami<sup>1</sup>, W.R. Gray<sup>1</sup>, S. Luo<sup>1</sup>, B.M. Olivera<sup>1</sup> and J.M. McIntosh<sup>1,2</sup>. Depts. of Biology<sup>1</sup> and Psychiatry<sup>2</sup>, University of Utah, Salt Lake City, Utah, 84112.

We have isolated a 16-amino acid peptide from the venom of *Conus* (a marine snail) which potently blocks the  $\alpha 3\beta 2$  neuronal subtype of nicotinic acetylcholine receptors (nAChRs). This peptide was identified by electrophysiologically screening venom fractions against cloned nicotinic receptors expressed in *Xenopus* oocytes. The peptide's structure, which has been confirmed by mass spectrometry and total chemical synthesis, differs significantly from those of all previously isolated  $\alpha$ -conotoxins. Disulfide bridging however is conserved. The toxin blocks the response to acetylcholine in oocytes expressing  $\alpha 3\beta 2$  nAChRs with an IC<sub>50</sub> of 5-10 nM. Preliminary studies indicate that the peptide is 2 to 3 orders of magnitude less active in blocking ACh-responses of all other tested  $\alpha\beta\gamma$  nAChRs. We have recently reported the isolation and characterization of  $\alpha$ -conotoxin ImI, which selectively targets the (homomeric)  $\alpha 7$  subtype of neuronal nAChRs. Other  $\alpha$ -conotoxins selectively target the muscle subtype of nAChR. Thus, it is increasingly apparent that  $\alpha$ -conotoxins represent a significant resource for ligands with which to probe structure-function relationships of various nAChR subtypes.

## 527.15

AN *IN SITU* HYBRIDIZATION STUDY OF mRNA EXPRESSION FOR  $\alpha 5$  AND  $\alpha 6$ , PUTATIVE NICOTINIC ACETYLCHOLINE RECEPTOR SUBUNITS, DURING POSTNATAL DEVELOPMENT OF THE RAT BRAIN. **B.J. Morley and H.K. Happe**. Laboratory of Neurochemistry, Boys Town National Research Hospital, Omaha, NE 68131.

Two members of the nicotinic acetylcholine receptor subunit gene family,  $\alpha 5$  and  $\alpha 6$ , have not been demonstrated to form functional receptors when expressed in combination with other receptor subunits in oocytes. Their function in the CNS is unknown. In adults their distribution is more restricted but overlaps the distribution of  $\alpha 4$  and  $\alpha 7$  mRNAs, which encode subunit components of the high-affinity agonist receptor and the  $\alpha$ -bungarotoxin receptor, respectively. We have used *in situ* hybridization with [<sup>35</sup>S]-labeled riboprobes to examine expression patterns in developing rat brain. Expression of  $\alpha 5$  mRNA is much higher at day 10 than in adults for most brain regions. In cortex early expression of  $\alpha 5$  mRNA is apparent only in layer VI. The interpeduncular n. differs from other brain regions expressing  $\alpha 5$  as increases, rather than decreases, in mRNA expression occur during the late postnatal period. Expression of  $\alpha 6$  mRNA in medial habenulae and locus coeruleus is at near adult levels early in postnatal development while expression of  $\alpha 6$  mRNA increases 2-3 fold in ventral tegmentum and substantia nigra compacta. Our results indicate that the  $\alpha 5$  subunit, like the  $\alpha 7$  subunit, may have a role during the primary period of synaptogenesis as levels are high before day 10 and decline while synaptic interactions are being formed. For  $\alpha 6$  subunits the increase in mRNA expression occurs after other nicotinic subunits have reached adult levels and therefore may be involved in later developmental modulation of receptor properties or subunit composition.

## 527.17

DIFFERENTIAL EXPRESSION OF NEURONAL NICOTINIC RECEPTOR SUBUNIT mRNAs AMONG INDIVIDUAL INTRACARDIAC PARASYMPATHETIC NEURONS IS REVEALED BY SINGLE CELL RT-PCR. **K. Poth\*, J. Cuevas, T.J. Nutter, D.J. Adams, C.W. Luetje**, Department of Molecular and Cellular Pharmacology, University of Miami, Miami, FL, 33101.

Neuronal nAChRs are formed by various subunit combinations, each with distinct pharmacological and biophysical properties. In parasympathetic neurons cultured from rat intracardiac ganglia, 3 distinct single channel conductances have been observed (Adams and Nutter, 1992, *J. Physiol.* (Paris) 86: 67-76). Whole cell currents exhibit several different rank orders of potency for nicotinic agonists (Nutter and Adams, unpublished). Thus, individual intracardiac parasympathetic neurons may express different arrays of nAChR subunits. We have used RT-PCR to gain insight into the neuronal nAChR subunit mRNA expression patterns of these neurons. The cytoplasm of individual intracardiac parasympathetic neurons were extracted using patch pipets and subjected to RT-PCR. The nAChR subunit mRNA expression pattern differed among individual neurons, ranging from relatively simple (for example:  $\alpha 3$ ,  $\alpha 5$ ,  $\beta 4$ , or  $\alpha 3$ ,  $\alpha 5$ ,  $\beta 2$ ) to complex (for example:  $\alpha 2$ ,  $\alpha 3$ ,  $\alpha 4$ ,  $\alpha 7$ ,  $\beta 2$ ). The  $\alpha 3$  subunit was nearly always expressed, while other subunits such as  $\alpha 5$ ,  $\alpha 7$  and  $\beta 3$  were clearly expressed in some neurons and not in others. Thus, differential nAChR subunit expression may account for multiple channel classes and different pharmacological profiles observed in individual parasympathetic neurons from rat cardiac ganglia. ## ACETYLCHOLINE RECEPTOR: NICOTINIC EXPRESSION

## 528.1

PROPERTIES OF TRANSGENIC NICOTINIC ACETYLCHOLINE RECEPTORS STABLY EXPRESSED IN HUMAN CELLS AS HOMOLOGOMERS OF WILD-TYPE OR MUTANT RAT OR CHICK  $\alpha 7$  SUBUNITS. **E. Puchacz\*, J.-L. Galzi\*, B. Buisson\*, D. Bertrand\*, J.-P. Changeux\* and R.J. Lukas\***. Barrow Neurological Institute, Phoenix, AZ 85013 USA, \*Pasteur Institute, Paris, France and \*Central Medical University, Geneva, Switzerland.

Transfected cells of the SH-SY5Y human neuroblastoma or of the native nAChR-null SHEP-1 human epithelial clonal lines have been obtained that stably overexpress/express specific 125-I-labeled  $\alpha$ -bungarotoxin binding sites. The radiotoxin binding sites appear to represent nicotinic acetylcholine receptors (nAChR) formed as homooligomers of  $\alpha 7$  subunits derived from rat or chick wild-type or mutant transgenes introduced into SH-SY5Y or SHEP-1 cells. In all stably transfected cell lines expressing wild-type transgenes tested to date, functional responses are observed that are sensitive to blockade by native  $\alpha$ -bungarotoxin or methyllycaconitine and that exhibit fast kinetics for channel opening and desensitization. Transfectants are positively selected based on hygromycin resistance, and levels of expression of transgenes can be manipulated by variation of hygromycin concentration in culture medium. The efficiency of recovery of stable transfectants seems to be diminished in cells that express mutant  $\alpha 7$  transgenes that are predicted to code for proteins that form slowly-desensitizing nAChR of high  $\text{Ca}^{2+}$  permeability, perhaps suggesting that expression of mutant nAChR is cytotoxic. These stably transfected cells are ideally suited for elucidation of basic principles of ligand-gated ion channel structure and function using the simplest of all possible prototypes, a functional homooligomer. Funded in USA by NIDAL and STRC.

## 527.16

AGE-RELATED CHANGES IN THE EXPRESSION OF NICOTINIC ACETYLCHOLINE RECEPTOR SUBUNIT ALPHA-4 IN THE MOUSE BRAIN REVEALED BY IMMUNOHISTOCHEMICAL LOCALIZATION.

**R. Kulmer, L.C. Gahring, and S.W. Rogers\***. S.L.C. VA-GRECC, and Human Molecular Biology and Genetics Program, University of Utah, Salt Lake City, UT 84112.

Antibodies to neuronal nicotinic acetylcholine receptor (nAChR) subunit  $\alpha 4$  were prepared in rabbits to bacterial fusion proteins. These antibodies exhibit subunit specificity and they immunoprecipitate high affinity <sup>3</sup>H-nicotine binding sites (Rogers, et al., *J. Neurosci.* 12:4611, 1992; Flores et al., *Molec. Pharmacol.* 41:31, 1992). We have used these antibodies to localize nAChR  $\alpha 4$  staining in the mouse brain. Overall staining resembles the distribution of high affinity nicotine binding sites and nAChR  $\alpha 4$  RNA. Staining is in neuronal cell bodies, putative dendrites, and it is particularly robust in some white matter tracts such as the stria terminalis suggesting that both pre- and post-synaptic receptor localization may occur. Comparisons of the immunoreactivity pattern between brains from young (3 months, N=9) and aged (24-28 months, N=8) CBA/J mice were made. Our findings suggest that there is a marked reduction in the number of immunoreactive cells in the pyramidal layer and stratum oriens of CA1 of the hippocampus of aged mice. Furthermore, the number of dendritic arbors and axonal collaterals extending into the stratum radiatum from the pyramidal layer of these mice is diminished. These results suggest that changes in nAChR  $\alpha 4$ -related expression and distribution occur in defined subregions of the mouse brain during aging. Supported by NIH grant AG04418 and the American Federation for Aging Research.

## 528.2

FUNCTIONAL PHARMACOLOGICAL PROFILES OF DIVERSE NICOTINIC ACETYLCHOLINE RECEPTOR SUBTYPES: MECHANISMS OF ACTIVATION OR INHIBITION. **R.J. Lukas, L. Lucero\*, C.M. Eisenhour, A. Brockey, and M. Bohayets**. Division of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013.

Our previous work has shown that clonal cell lines of different derivation are excellent models for studies of fundamental properties of diverse, naturally-expressed nicotinic acetylcholine receptor (nAChR) subtypes. Here we report that agonist potencies and efficacies of agents such as nicotine, cytosine, epibatidine, and suberyldicholine vary across nAChR subtypes and to some degree across species for a given nAChR subtype based on studies testing function of human muscle-type nAChR expressed in cells of the TE671/RD clonal line or of mammalian ganglionic nAChR (probably containing  $\alpha 3$  and  $\beta 4$  subunits) expressed in cells of the IMR-32 or SH-SY5Y human neuroblastomas or the PC12 rat pheochromocytoma. Antagonistic potencies of agents such as d-tubocurarine, pancuronium, methyllycaconitine, mecamlamine, and various local anesthetics, snake toxins, or marine toxins also vary across nAChR subtypes, as do mechanisms (competitive vs. non-competitive inhibition) of nAChR block. Moreover, agents such as verapamil and dihydropyridines block nAChR subtypes with potencies that rival those for blockade of voltage-gated  $\text{Ca}^{2+}$  channels. These findings validate usefulness of clonal cells for studies of nAChR structures and functions and for elucidation of potencies and mechanisms of action of nicotinic compounds that may be clinically useful, e.g., to alter smoking habits, in cognitive enhancement, etc. Funded by NIDAL, STRC, CTR, APDA.

## 528.3

**INTERACTIONS OF TACHYKININS WITH DIVERSE NICOTINIC ACETYLCHOLINE RECEPTOR SUBTYPES.** C.M. Eisenhour and R.J. Lukas\*. Division of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013.

Substance P (SP) has been reported by several investigators to affect functional responses and/or ligand binding of some nicotinic acetylcholine receptor (nAChR) subtypes. Here we show that SP is the most potent of the tachykinins (TK) tested (SP, neurokinins A and B, eledoisin) as an acutely-acting inhibitor of function of muscle-type ( $\alpha 1\beta 1\gamma\delta$  subunit-containing) nAChR from cells of the TE671/RD human clonal line or of ganglionic ( $\alpha 3\beta 4$  subunit-containing) nAChR from cells of the SH-SY5Y human neuroblastoma or the PC12 rat pheochromocytoma. The concentrations of SP or the other TK required to affect nAChR function ( $IC_{50} \geq 1 \mu M$ ) are much lower than the concentrations shown to have little-if-any effect on radiolabeled nicotinic ligand binding to muscle-type nAChR or  $\alpha 3\beta 4$ -nAChR or to ganglionic nAChR containing  $\alpha 7$  subunits that also are found on SH-SY5Y or PC12 cells. No evidence was obtained for high (nM) affinity SP binding sites in these cells that could be coupled to second messenger production or for effects of chronic TK treatment on nAChR expression. These and other results are consistent with the conclusions of Stafford et al. (Molec. Pharm. 45: 758, 1994) that SP acts directly to affect nAChR function, probably by targeting sites on  $\beta 4$  (and  $\beta 1$ ) subunits remote from the agonist and competitive antagonist binding domains. Funded by STRC.

## 528.5

**ERBB3 AND ERBB2/NEU TRANSDUCE THE EFFECT OF HERGULIN ON ACETYLCHOLINE GENE EXPRESSION IN MUSCLE: DIFFERENTIAL EXPRESSION AT THE ENDPLATE.** N. Altiock, J.-L. Bessereau and J.-P. Changeux\*. Neurobiologie Moléculaire, Département des Biotechnologies, Institut Pasteur, 75015 Paris, France

The motor neurons modulate acetylcholine receptor (AChR) gene expression in skeletal muscle by two signalling pathways: the transmitter-evoked depolarization of muscle membrane inhibits AChR genes transcription throughout the myofiber presumably via activation of a serine/threonine kinase, while the transcription rates of AChR genes in the synaptic region are increased by nerve-derived trophic factors including AChR-inducing activity (ARIA). To gain further insight to these interactions we characterized the receptor of heregulin (HRG)/ARIA in muscle. We showed that HRG increases AChR  $\alpha$ -subunit mRNA levels via tyrosine phosphorylation of ErbB3 and ErbB2/neu in chick, rat and mouse myotubes. The protein tyrosine phosphatase inhibitor, pervanadate potentiated the responses to HRG that were in turn blocked by the tyrosine kinase inhibitor erbstatin, indicating the relevance of tyrosine phosphorylation to these events. The effects of HRG were inhibited by enhanced cellular serine/threonine phosphorylation which has been implicated in the repression of AChR genes by electrical activity. Immunocytochemical analysis of adult rat muscle revealed that while ErbB2/neu and ErbB4 are distributed in a diffuse pattern along the myofiber membrane, ErbB3 expression is exclusively restricted to the endplate suggesting its involvement in synapse-specific transcription of AChR genes by HRG/ARIA.

## 528.7

**REGULATION OF  $\alpha$ -BUNGAROTOXIN RECEPTOR EXPRESSION IN DEVELOPING NEURONS.** C. Brumwell, M.S. Levey, O.C. Ikonov and M.H. Jacob. Worcester Fdn. for Biomed. Res., Shrewsbury, MA 01545. Cellular and molecular mechanisms that regulate synapse differentiation on neurons are still largely undefined. Chick ciliary ganglion (CG) neurons express two different classes of nicotinic cholinergic receptors, acetylcholine receptors (AChRs) and  $\alpha$ -bungarotoxin receptors ( $\alpha$ -BgTRs), that are segregated into distinct domains in synaptic regions. AChRs are predominantly localized in the specialized postsynaptic membrane, whereas  $\alpha$ -BgTRs are restricted to perisynaptic regions of the neuron surface. We have recently established that the expression of AChRs is differentially regulated by innervation and target tissue interactions during synapse formation. We have now determined that these cell-cell interactions also regulate  $\alpha$ -BgTR expression.

$\alpha$ -BgTR  $\alpha 7$  subunit mRNA levels per neuron increase 3.4-fold during synapse formation and maturation, from E8 to E14, as determined by quantitative RT-PCR. Surgical removal of the preganglionic neurons or postganglionic target tissues prior to synaptogenesis causes CG  $\alpha 7$  mRNA levels to decline 1.6-fold and 2.2-fold, respectively. Interestingly, the effects of input- and target-deprivation are not additive. In contrast to  $\alpha 7$ ,  $\beta$ -tubulin mRNA levels are not affected by these manipulations. Similarly,  $\alpha$ -BgTR protein levels are specifically reduced by input- or target-deprivation as determined by histochemical labeling. Thus, innervation and target tissues regulate the expression of neurotransmitter receptors that are excluded from postsynaptic membranes. The absence of additive effects suggests input and target tissues either provide a similar factor(s), or different factors that activate a common step in the signal transduction pathway regulating  $\alpha 7$  transcript levels. Supported by NIH 21725, and the Fairlawn Foundation.

## 528.4

**SENSITIZATION OF THE MUSCLE NICOTINIC ACETYLCHOLINE RECEPTOR IN TE671 CELLS BY THE COMPETITIVE ANTAGONISTS VECURONIUM AND ROCURONIUM.** F. Van Hulzen\*, C. Sünner and D. Schaap. Organon Teknika, Bioscience Research Unit, PO Box 84, 5280 AB Bostel, The Netherlands

The TE671 cell line was used to study the desensitization and sensitization of the muscle nicotinic acetylcholine receptor (nAChR). Carbachol (CCh) stimulated the influx of  $^{86}Rb^{+}$  into the cells with an  $EC_{50}$  of  $5.5 \cdot 10^{-5} M$ . This influx was blocked by the competitive antagonists vecuronium and rocuronium with  $IC_{50}$  values of  $4 \cdot 10^{-8}$  and  $8 \cdot 10^{-7} M$ , respectively. Pre-incubation of the cells with CCh caused a time- and dose-dependent desensitization of the CCh-induced  $^{86}Rb^{+}$ -influx into the cells. After 20 min, 60% of control stimulation was left, while after 60 min only 20% was left. Binding of [ $^{125}$ ]  $\alpha$ -bungarotoxin ( $\alpha$ -BTX) was decreased with 20% after 60 min pre-incubation with 1 mM CCh. In contrast, pre-incubation with low concentrations of the competitive antagonists vecuronium bromide or rocuronium bromide caused a sensitization of the  $^{86}Rb^{+}$ -influx. One hour pre-incubation of the cells with 1  $\mu M$  vecuronium bromide or rocuronium bromide increased the control stimulation with 60% and 160%, respectively. Only a 5% increase in [ $^{125}$ ]  $\alpha$ -BTX binding was observed, which excludes receptor upregulation. It is known that the nAChR exists in equilibrium between the resting state and the desensitized state. Since competitive antagonists bind preferably to the resting state, this will shift the equilibrium in that direction and sensitize the receptor.

## 528.6

**DISSOCIATION BETWEEN ANTINOCICEPTION AND ANTI-INFLAMMATORY EFFECTS OF NICOTINE IN THE FORMALIN TEST IN RATS.** A.A. Houdi\*, M. Welch and C. Diaz. College of Pharmacy and THRI, University of Kentucky, Lexington, KY 40546.

Nicotine may selectively alter sensitivity to certain classes of pain stimuli. In this study, we examined the central and peripheral antinociceptive properties of nicotine in rats using the formalin-test. It has been suggested that the transient early phase of pain (0-5 min) after formalin is due to the direct effect on sensory receptors, whereas the tonic late phase (15-45 min) is due to an inflammatory response. In control groups, formalin solution (0.5%) injected subcutaneously (sc) into the surface of one hind paw of male Sprague-Dawley rats (300  $\pm$  30 gm, body wt.) pretreated with saline produced a characteristic biphasic pain response. Subcutaneous nicotine administration inhibited this formalin pain response in a dose-dependent (0.1-2 mg/kg) manner. Intracerebroventricularly (icv) administered nicotine inhibited formalin pain response of the first phase at lower dose (4  $\mu g$ /rat) and the first phase and partially the second phase at higher doses (20 & 40  $\mu g$ /rat). The lower dose of icv nicotine was ineffective when given sc. Nicotinic antagonist mecamylamine (0.5 mg/kg, sc) antagonized the sc nicotine effect, whereas hexamethonium (5 mg/kg, sc), a nicotinic antagonist which does not readily cross the blood brain barrier, partially blocked the response only to the second phase of nicotine's effect. Hexamethonium given icv produced analgesia to the first phase of pain only and did not affect nicotine response given centrally. Pretreatment with an opioid receptor antagonist (naloxone 1 or 2 mg/kg, sc), or nitric oxide synthase inhibitor ( $NG$ -nitro-L-arginine methyl ester, sc or icv) had no effect on the analgesic properties of subcutaneous nicotine (1 mg/kg). These results indicate that nicotine possesses analgesic activity toward two kinds of pain which may be differently modulated: a short-lived pain caused by the direct effect of formalin on sensory receptors followed by a longer lasting pain due to inflammation. This analgesic effect of nicotine is not mediated by endogenous opioids or nitric oxide systems. Supported by KTRB.

## 528.8

**A MAJOR DETERMINANT OF COMPETITIVE ANTAGONIST SENSITIVITY OF NEURONAL NICOTINIC RECEPTORS IS LOCALIZED TO RESIDUES 55-63 OF THE  $\beta 2$  SUBUNIT.** S.C. Harvey\*, C.W. Luetje. Department of Molecular and Cellular Pharmacology, University of Miami, Miami, FL 33101.

The  $\beta$  subunit contribution to the sensitivity of neuronal nAChRs to the competitive antagonist neuronal bungarotoxin (NBT) has been localized to the first 80 residues of  $\beta 2$  (Wheeler et al, 1993, *FEBS Lett.* 332:139). Determinants of sensitivity to both NBT and the structurally distinct competitive antagonist, dihydro- $\beta$ -erythroidine (DH $\beta$ E), are located within this region (Harvey and Luetje, 1994, *Soc. Neurosci. Abstr.* 20:1134). We constructed additional  $\beta$  subunit chimeras to more closely map these determinants. Receptors formed by  $\alpha 3$  and  $\beta 2$  were sensitive to 100 nM NBT (96.6  $\pm$  1.6% block), while  $\alpha 3\beta 4$  was insensitive. At an  $EC_{20}$  ACh concentration,  $\alpha 3\beta 2$  was 50 fold more sensitive to DH $\beta$ E ( $IC_{50}$ =400 nM) than  $\alpha 3\beta 4$  ( $IC_{50}$ =20  $\mu M$ ). 3  $\mu M$  DH $\beta$ E effectively blocked  $\alpha 3\beta 2$  (90.0  $\pm$  4.6% block) but had little effect on  $\alpha 3\beta 4$  (13.1  $\pm$  5.1% block). Receptors formed by  $\beta 2$ -54- $\beta 4$  were indistinguishable from  $\alpha 3\beta 4$  (5.7  $\pm$  26.0% block by NBT, 19.2  $\pm$  3.9% block by DH $\beta$ E). Receptors formed by  $\beta 2$ -63- $\beta 4$  were blocked 86.4  $\pm$  5.6% by NBT and 81.0  $\pm$  5.5% by DH $\beta$ E. Receptors formed by  $\beta 2$ -73- $\beta 4$  were blocked 89.6  $\pm$  1.4% by NBT and 90.1  $\pm$  3.1% by DH $\beta$ E. Receptors formed by  $\beta 2$ -80- $\beta 4$  were blocked 97.8  $\pm$  2.0% by NBT and 93.3  $\pm$  0.5% by DH $\beta$ E. These results show that the major determinant for both NBT and DH $\beta$ E sensitivity lies within sequence segment 55-63. Mutation experiments are in progress to identify the critical residues within this region. [Support: NIH DA-08102, AHA-FL 92GIA/849 and 92II/4].

## 528.9

**NICOTINE ENHANCES THE PEPTIDERGIC EPSC AND POTENTIATES TRANSMISSION IN BULLFROG SYMPATHETIC GANGLIA** P. Jobling\*, W.-X. Shen and J.P. Horn. Department of Neurobiology, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

Synaptic release of LHRH by preganglionic terminals excites bullfrog sympathetic neurons through suppression of M-current and activation of a second current. We have studied the effects of nicotine upon synaptic currents, responses to exogenous LHRH, and M-current, when recorded under one- and two-electrode voltage clamp. Bath application of 3  $\mu$ M nicotine evoked a steady inward current of  $0.95 \pm 0.57$  nA (n=9). Nicotine enhanced the peptidergic EPSC in 6 of 9 cells by  $55 \pm 36\%$  (x $\pm$ sd) and the inward current evoked by exogenous LHRH in 5 of 6 cells by  $54 \pm 23\%$ . M-current relaxations measured after hyperpolarizing voltage steps (-25 to -40 mV to -50 to -60 mV) were decreased by  $19 \pm 14\%$  (n=9, p<0.01), although the total current measured at the end of the voltage step increased in 3/9 cells.

Extracellular recordings of peptidergic afterdischarges from rami communicantes and simultaneous recording of membrane potential from individual B and C neurons revealed that peptidergic transmission was potentiated at nicotine concentrations of 250 nM- $\mu$ M with little associated membrane depolarization.

The results imply that activation of ligand-gated nicotinic channels can modulate synaptic events controlled by G-protein coupled receptors. Supported by NIH NS21065 and a Postdoctoral Fellowship (PJ) from the AHA, PA Affiliate.

## 528.11

**AGONIST SENSITIVITY OF NICOTINIC ACETYLCHOLINE RECEPTORS IN RAT VAGUS NERVE.** K. Eskesen and V.S. Levy. Novo Nordisk A/S, Health Care Discovery, Neuroscience, Novo Nordisk Park, DK-2760 Måløv, Denmark.

A pharmacological characterization of the ligand-gated acetylcholine receptor present in the axons of the rat vagus nerve was sought by studying the potency and efficacy of a series of nicotinic agonists on desheated vagus nerve using the "grease-gap" technique. Characteristic bell-shaped concentration response curves can be obtained from large depolarizations of the vagus nerve. The EC<sub>50</sub> values for these responses to 5 agonists when given in the rank order of potency are: epibatidine: 0.03  $\mu$ M, lobeline: 0.9  $\mu$ M, nicotine: 6  $\mu$ M, cytosine: 19  $\mu$ M and DMPP: 24  $\mu$ M. DMPP is the most and lobeline the least efficacious of the compounds tested with maximal responses of 250% and 40%, respectively, of the maximal response to nicotine. The efficacy of epibatidine, nicotine and cytosine was close to equal. There is, however, an additional component of the depolarization induced by agonists of nicotinic acetylcholine receptors. This depolarization is of lower amplitude and observed at concentrations 2-3 decades lower than the EC<sub>50</sub>-values calculated, indicating the presence of high affinity receptors. The results do not give any clear indication as to which subtype of the neuronal nicotinic receptors is present, since there is no agreement with the rank order of potency of agonists we have tested on the vagus nerve with data published for subtypes expressed in oocytes from *Xenopus laevis*. Rather it indicates that we obtain responses from more than one subtype and possibly combinations of subunits different from the ones tested in oocytes.

## 528.13

**MODULATION OF THE ACTIVITY OF THE NICOTINIC  $\alpha 3 \beta 4$  RECEPTOR SUBTYPE BY ALCOHOL.** P.J.O. Covernton, R.M. Duvoisin\*, and J.G. Connolly. Dept. of Physiology and Pharmacology, University of Strathclyde, Glasgow, G1 1XW, U.K.

Previous electrophysiological studies examining interactions between alcohol and cloned nicotinic acetylcholine receptor subunits expressed in *Xenopus* oocytes have shown that the  $\alpha 7$  receptor subtype is strongly inhibited by alcohol. In contrast, the effect of alcohol on other neuronal subtypes containing the  $\beta 2$  subunit, including  $\alpha 3 \beta 2$ , are marginal, (de Fiebre et al., 1994, P14, Abstracts, International Symposium on Nicotine, Montreal, Canada). However, in oocytes in which the  $\alpha 3 \beta 4$  combination was expressed from RNA or DNA, co-application of 30 mM ethanol with 1-10  $\mu$ M nicotine or acetylcholine resulted overall in a mean inhibition of the agonist-induced inward current of  $-2.9 \pm 5.1\%$  ( $\pm$  S.E., n=21, range = -73.4 to +23.5%; Ba<sup>++</sup> replacing Ca<sup>++</sup> in the recording solution). 100 mM ethanol potentiated the response by  $33.8 \pm 5.1\%$  (n=12, range = +0.3 to +56.7%); and 300 mM ethanol gave a potentiation of  $83.7 \pm 19.1\%$  (n=13, range = -20 to +216.4%). The varied response to alcohol, especially at lower concentrations, suggests multiple mechanisms of receptor regulation which may contribute to synaptic plasticity in brain and ganglia. The sensitivity of receptors containing  $\alpha 3$  and  $\beta 4$  subunits to clinically relevant concentrations of ethanol may also be involved in the interactive processes of addiction to alcohol and nicotine. We wish to acknowledge the support of the M.R.C. (U.K.), The Royal Society, S.H.E.R.T., the Strathclyde Molecular Biology Lab and the technical contributions of Fiona Kempson, Dr. Diane Dixon and Angela Garman.

## 528.10

**THE BINDING SITE OF RAT AND CHICK FORMS OF THE NICOTINIC RECEPTOR SUBUNIT ALPHA 7 IS DISTINGUISHED BY THE PIP SERIES OF CHOLINERGIC AGONISTS.** R.W. Vazquez, G.A. Weiland\* and R.E. Oswald. Dept. Pharmacology, Cornell Univ., Ithaca, NY 14853 USA.

A structurally related, semirigid series of cholinergic agonists were synthesized (based on 1,1-dimethyl-4-acetylpiperizinium, PIP; Carter & Oswald, *Biophys. J.* 65:840-851, 1993) and used to study activation and channel blockade of the nicotinic acetylcholine receptor (nAChR). Patch clamp experiments using BC<sub>3</sub>H1 cells expressing the mouse muscle form of the nAChR, showed that, at low concentrations (1-2  $\mu$ M), the PIP series were potent agonists, with little difference in activation properties. At high concentrations (mM), the series displays structure- and voltage-dependent noncompetitive channel blockade. Current efforts have focused on the agonist properties of the PIP series for the neuronal forms of nAChR, chick and rat  $\alpha 7$ . Using the oocyte expression system with a two-electrode voltage clamp, the PIP series displayed a discontinuous agonist profile for chick  $\alpha 7$ . Short chain derivatives activated the channel fully; however, agonist activity was lost when the chain was lengthened from PropylPIP to ButylPIP. This was found to be due most likely to the channel activation properties, rather than voltage-dependent channel blockade, as the longer chain PIP compounds failed to activate the channel at positive membrane potentials under conditions for which outward current was easily observed with ACh and shorter chain PIP derivatives (EDTA injection into the oocyte). Under identical conditions, the entire PIP series could produce currents in oocytes injected with the rat  $\alpha 7$  subunit. A related agonist (DMPP) has been shown to be a weak partial agonist of the chick  $\alpha 7$  nAChR but a full agonist for the rat  $\alpha 7$  nAChR (Gerzanich & Lindstrom, *Mol. Pharmacol.* 45:212-220, 1994). These set of experiments indicate that the PIP series can be used as sensitive probes of the nAChR binding site.

**ACTIVATION OF NICOTINIC ACETYLCHOLINE (ACh) RECEPTOR CHANNELS MOBILIZES CALCIUM FROM CAFFEINE-SENSITIVE STORES IN FURA-2 LOADED CULTURED RAT MYOBLASTS.** J. F. Fiekers\* and T.J. Heppner. Dept. Anatomy & Neurobiology, Univ. Vermont Coll. Med. Burlington, VT 05405.

Measurement of the kinetics of [Ca<sup>2+</sup>]<sub>i</sub> in response to activation of ACh receptor channels was performed using dual excitation microspectrofluorometry in fura-2-loaded rat myoblasts. Receptor-activated currents were also recorded using the whole cell configuration of the patch clamp technique. Agonist-induced currents, as well as increases in [Ca<sup>2+</sup>]<sub>i</sub>, were blocked by prior exposure of myoblasts to  $\alpha$ -bungarotoxin. Short applications of agonist (<1 sec) produced a rapid transient increase in [Ca<sup>2+</sup>]<sub>i</sub>, which usually returned to baseline levels. However, prolonged applications of agonists (>10 sec) produced a fast transient followed by a long-lasting plateau. The individual components of the [Ca<sup>2+</sup>]<sub>i</sub> signal were unrelated to activation of voltage-gated calcium channels because the responses were retained in the presence of voltage-gated calcium channel blockers. Both responses, however, were dependent on extracellular calcium. Caffeine (10mM, 10 sec) produced a rapid increase in [Ca<sup>2+</sup>]<sub>i</sub>, which initially was markedly prolonged in the presence of ryanodine. Successive applications of caffeine reduced the [Ca<sup>2+</sup>]<sub>i</sub> response in the presence of ryanodine. Plateau, but not transient, responses of ACh-activated [Ca<sup>2+</sup>]<sub>i</sub> responses were reduced following ryanodine. These results suggest that activation of ACh receptor channels plays an important role to increase [Ca<sup>2+</sup>]<sub>i</sub> by (1) influx of external calcium through the receptor-channel complex and (2) intracellular release via caffeine-sensitive stores. **Peptidyl Prolyl Isomerase Activity of Cytoplasmic Cyclophilin in the Maturation of Homo-oligomeric Receptors.** Santosh A. Helekar\* and Jim Patrick. Division of Neuroscience, Baylor College of Medicine, Houston, Texas 77030.

We have recently shown that maturation of homo-oligomeric ligand-gated ion channels,  $\alpha 7$  nicotinic and type 3 serotonin (5HT<sub>3</sub>) receptors is blocked by the widely used immunosuppressant cyclosporin A (CsA). This effect is most likely to be due to the selective blockade of a ubiquitous polypeptide called cyclophilin A (CyPA) that is present in high concentrations within neurons. The cyclophilins (CyPs) are a family of helper molecules involved in the folding of cellular proteins. They catalyze the cis-trans interconversion of prolyl peptide bonds through their peptidyl prolyl isomerase activity (PPIase), and may also serve as molecular chaperones in protein folding. Their role in CsA-induced immunosuppression is shown to be indirect through the inhibition of calcineurin.

In the present study we first provide conclusive evidence that CsA-induced blockade of homo-oligomeric receptor expression in *Xenopus* oocytes is not mediated through the indirect calcineurin-dependent mechanism. A non-immunosuppressive CsA analog SDZ211-811 that selectively blocks the PPIase activity of CyPs but does not cause inhibition of calcineurin blocked receptor expression as effectively as CsA. Second, we show that the CsA-induced reduction in receptor expression is due to the blockade of the cytoplasmic CyP. CyPA. Overexpression of CyPA but not endoplasmic reticulum resident CyP, CyPB caused a reversal of the CsA effect on receptor expression. This reversal is not simply due to the buffering of CsA by CyPA because overexpression of a mutant CyPA which is deficient in high affinity CsA binding activity also produces a reversal of the CsA effect. This mutant has a tryptophan to phenylalanine substitution at position 121 (W121F) in CyPA. This result also indicates that the ability of CyPA to bind CsA with high affinity is not important for its action in receptor maturation. A CyPA double mutant that has a histidine to glutamine change at position 126 which causes a ~200-fold reduction in the PPIase activity of CyPA also produced a reversal of the CsA effect. The latter result suggests that either the PPIase activity of CyPA is not required for the maturation of homo-oligomeric receptors or that minimal PPIase activity is sufficient to produce significant functional receptor expression. To determine which one of these two possibilities holds true for the action of CyPA we have made another CyPA mutant (CyPAR55A) that shows a ~1000-fold reduction in PPIase activity compared to the wild-type. These results enable us to clarify whether the physiological role of CyPA in oligomeric receptor maturation is that of a PPIase or that of a molecular chaperone.

## 528.15

RATE CONSTANTS IN ACETYLCHOLINE RECEPTOR DEGRADATION **Rufeng Xu and Miriam M. Salpeter\*** Department of Neurobiology and Behavior, Cornell Univ., Ithaca, NY 14850

Degradation of muscle acetylcholine receptors (AChRs) is believed to proceed via internalization, and subsequent digestion in lysosomes (Devrootes and Fambrough, Cold Spring Harbor Symp Quant Biol 40: 237, 1976; Libby et al., Cell 19: 481, 1980; Fumagalli et al., J. Neurophysiol. 41: 567, 1982). However, no detailed analysis of the rate constants involved in this internalization and exocytosis is available. We used proteinase K (PK), an enzyme previously used to cleave surface molecules (Stoorvogel et al., J. Cell Biol. 108:2137, 1989; Görne-Tschelnokow et al., EMBO J. 13:338, 1994), to determine PK-sensitive and PK-resistant AChRs in innervated mouse diaphragm muscles. The AChRs on mouse diaphragms were labeled with  $^{125}$ I- $\alpha$ -bungarotoxin *in vivo* and, at different times after labeling, the muscles were removed, washed and counted. This established that the degradation rate of the total muscle receptors had a  $t_{1/2} \sim 10.5$  days. At each post-labeling time point, the same muscle samples were digested in PK, and the PK-resistant residual radioactivity counted. After subtracting the PK-resistant counts from the total counts, a PK-sensitive compartment was established. The results were compared with a mathematical model which assumed an internalization rate constant,  $k_i$  and an exocytosis rate constant,  $k_e$ . The amount of receptors remaining in the PK-sensitive and resistant compartments at different times after labeling was consistent with a  $k_e=0.0673$  ( $t_{1/2} \sim 10.3$  days) and a  $k_i=0.693$  ( $t_{1/2} \sim 1$  day). Rate constants in denervated muscles and the effect of agents that influence degradation rate will be reported. Supported by NIH NS 09315 and 2 T32 GM07469.

IDENTIFICATION AND CHARACTERIZATION OF TYROSINE PHOSPHORYLATED PROTEINS FROM THE ELECTRIC ORGAN OF *T. CALIFORNICA*. **S. Balasubramanian and R.L. Haganir\*** Dept. of Neuroscience, Howard Hughes Med. Inst., Johns Hopkins Univ. School of Med., Baltimore, MD, 21205.

Tyrosine phosphorylation has been implicated in regulation of the synthesis, distribution and gating properties of the nicotinic acetylcholine receptor (nAChR). To better understand these processes, we are attempting to identify additional proteins which are tyrosine phosphorylated at the cholinergic synapse.

The electric organ of *T. California* is abundant in nAChR and nAChR associated proteins, and was therefore chosen as our protein source. Phosphotyrosine containing proteins were isolated by immunoaffinity chromatography using antiphosphotyrosine antibodies. Polyclonal antibodies were then generated against the tyrosine phosphorylated proteins and used to screen a  $\lambda$ gt11 expression library made from electric organ cDNA. Most of the clones identified in this manner represented the nAChR itself, which has previously been shown to be tyrosine phosphorylated (Qu et al., 1990). Of the 70 remaining clones 12 encoded type III intermediate filament from *T. California*; 11 encoded the 90 kDa heat shock protein; 9 encoded non-erythroid alpha spectrin; 39 clones were novel. We are presently characterizing the possible role of tyrosine phosphorylation in the regulation of these proteins.

## 528.19

ON MECHANISMS OF NICOTINE-INDUCED UPREGULATION AND FUNCTIONAL INACTIVATION OF DIVERSE NICOTINIC RECEPTOR SUBTYPES. **L. Ke\*, C.M. Eisenhour, M. Bencherif, E. Puchacz and R.J. Lukas** Division of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013 (\*Currently at R&D, R.J. Reynolds Tobacco Co., Winston-Salem, NC 27102).

Our previous work has shown that chronic nicotine exposure induces upregulation (increases in radioligand binding sites) of muscle-type nicotinic acetylcholine receptors (nAChR), ganglionic nAChR containing  $\alpha 3$  and  $\beta 4$  subunits or containing  $\alpha 7$  subunits, CNS nAChR containing  $\alpha 4$  and  $\beta 2$  subunits, and even transgenic nAChR in stably transfected cells lines expressing  $\alpha 7$  or  $\alpha 4$  and  $\beta 2$  nAChR subunits - all without altering nAChR subunit mRNA levels. We also have shown that chronic nicotine induces long-lasting functional inactivation (FI) of muscle-type and  $\alpha 3\beta 4$ -nAChR, but also that temporal and dose dependencies for FI differ from those for nAChR upregulation. Here we report results of pharmacological studies that further distinguish nicotine-induced upregulation from FI, that illuminate possible mechanisms involved in these processes, that identify classes of drugs (forskolin, TMB-8, pancuronium) having high value in these types of studies, that help elucidate the complex effects of treatments with drugs such as cycloheximide on nAChR expression and sensitivity to nicotine treatment, and that reveal a wide range of effects of nicotine treatment on nAChR metabolism. Results are framed within a model emphasizing post-transcriptional effects of nicotine and state transitions of diverse nAChR subtypes. Funded by NIDAL, STRC, ADCRC.

NICOTINIC RECEPTORS ACTIVATION ON CENTRAL AUTONOMIC PREGANGLIONIC NEURONES IN RAT SPINAL CORD SLICES. **C. Dominguez-Perrot\*, A. Bordey and P. Feltz** Institut de physiologie, URA 1446 CNRS, 21 rue R. Descartes 67000 Strasbourg.

Nicotinic acetylcholine receptors (nAChRs) on sympathetic preganglionic neurones (SPNs) of the region near the central canal were studied using the whole-cell patch-clamp technique in neonate rat transversal spinal cord slices (200-250  $\mu$ m). Visualization under Nomarski optics and labelling with Lucifer Yellow in the recording pipette allowed to identify recorded cells as SPNs. Central SPNs are localized in the dorsal part of the central region (CR), they are fusiform in shape, with axes ranging from (20 to 25  $\mu$ m)  $\times$  (9 to 12.5  $\mu$ m) and dendrites mediolaterally orientated. They exhibit a firing frequency ranging between 1-6 Hz which declines during the recording. Under current-clamp conditions, pressure ejection (1 mM, 100 msec) of the nicotinic receptor agonist, 1,1-dimethyl-4-phenyl-piperazinium (DMPP) induced a depolarizing response and increased the firing frequency of SPNs. Under voltage-clamp conditions, in SPNs of IML and CR, DMPP induced a small inward current ranging from -4 to -15 pA with an increase in noise. The current-voltage (IV) relationship for DMPP-induced current exhibited a reversal potential around 0 mV and a strong outward rectification. The nAChRs responses were blocked by mecamylamine, d-tubocurarine (d-TC) but were insensitive to hexamethonium, toxin F and methyllycaconitine (MLA). Moreover, superfusion of tetrodotoxin (1  $\mu$ M), CNQX (10  $\mu$ M), cadmium (100  $\mu$ M) did not abolish the DMPP-induced current which confirmed a direct effect of DMPP onto SPNs. At the peak of the current, DMPP induced the discharge of excitatory postsynaptic currents (EPSCs) or increased their discharge rate for 1-2 min following the DMPP application. These EPSCs were completely abolished by CNQX. We concluded that SPNs of the IML and CR are endowed with a functional nicotinic acetylcholine receptors. Moreover glutamate-containing terminals project onto SPNs.

## 528.18

EFFECT OF EPIDERMAL GROWTH FACTOR, INTERLEUKIN-6 AND CHOLINERGIC LIGANDS ON THE TRANSCRIPTION OF NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR SUBUNIT GENES BY HUMAN THYMIC CELLS. **Mirta Mihovilovic\*, Yun Mai and Allen D. Roses<sup>1,2</sup>** <sup>1</sup>Department of Medicine, Division of Neurology and <sup>2</sup>Department of Neurobiology, Duke University Medical Center, Durham, NC 27710.

Transcription of the  $\alpha 3$ ,  $\alpha 5$  and  $\beta 4$  subunits of nicotinic neuronal acetylcholine receptor (nAChR) genes in thymocytes and thymic epithelial cells and immunohistochemical analyses using polyclonal anti- $\alpha 3$  antibodies suggests that neuronal nAChRs similar to those expressed in ganglia are expressed in thymic cells. These receptors may be of importance in transducing signals delivered to the thymus through the autonomic nervous system.

Thymocytes express nicotinic neuronal nAChR transcripts at levels comparable to those of the thymic tissue as a whole, while epithelial cells express much lower transcripts levels. Expression of these transcripts in primary cultures of thymic epithelial cells is dependent on the presence of epidermal growth factor (EGF) and to a lesser extent on interleukin (IL-6). Thymic epithelial primary cell cultures bind monoclonal antibodies that recognize neurofilaments and in the presence of IL-6, develop thymic dendritic cell morphology that is concomitant with a decrease in keratin expression. Establishment of thymocytes in culture leads to lower levels of transcription for the  $\alpha 3$  and  $\beta 4$  nAChR subunit genes but IL-6 delays this down regulation. In addition, long term exposure to both carbamylcholine and nicotine appears to promote  $\alpha 3$  nAChR gene transcription in cultured thymic epithelial cells. These results indicate that the thymic endocrine/paracrine microenvironment is necessary to sustain nAChR subunit gene transcription by thymic cells and that cholinergic activity may modulate thymic nAChR gene transcription.

## 528.20

Target induced Changes in nAChR -Mediated currents and Subunit Gene Expression Require Membrane Associated Factor(s).

**P. Devay\*, P. Flood, C. Yu and L. Role** Departments of Anatomy and Cell Biology, The Center for Neurobiology and Behavior and Anesthesiology, Columbia Univ., P&S, 722 W. 168th St. NY, NY 10032.

Development of transmitter sensitivity in sympathetic ganglia has been charted by measuring the progressive increases in the magnitude of ACh-evoked currents and the levels of the  $\alpha 3$ ,  $\alpha 5$ ,  $\alpha 7$  and  $\beta 4$  subunit mRNAs (Moss and Role, 1992; Devay et al., 1994). These changes are induced by both preganglionic innervation and by target contact. Here we examined whether innervation of distinct sympathetic targets might differentially regulate nAChR expression. Chick sympathetic neurons, naive of preganglionic innervation or target contact (E9), were cocultured with either embryonic heart or kidney.

ACh gated macroscopic and single channel currents were assayed in neurons that appeared to innervate the target cells. The expression of  $\alpha 3$ ,  $\alpha 5$ ,  $\alpha 7$ ,  $\beta 4$  relative to actin was detected by quantitative RT-PCR. Innervation of embryonic heart by sympathetic ganglia neurons reduced the magnitude of ACh-evoked currents and increased the expression of  $\alpha 5$  and  $\alpha 7$ . Cardiac myocyte-lysate mimicked the effect of target contact on whole cell current and subunit expression. However when sympathetic neurons were cocultured with heart in a transfilter (12  $\mu$  chamber, the whole cell current decreased but mRNA levels were unchanged.

In similar experiments when embryonic kidney was used as a target, innervation of kidney explants increased ACh-evoked current and nAChR subunit expression in the sympathetic neurons. As with heart, the influence of kidney on nAChR expression could be mimicked by lysed target, but not by soluble target derived factors in the transfilter coculture assay. Supported by NS29071 to LR.

## 529.1

N-METHYL-D-ASPARTATE (NMDA)-INDUCED SEPTAL LESION PREVENTS THE RETENTION OF TOLERANCE TO ETHANOL (E) BY DESGLYCINAMIDE<sup>3</sup>-[ARG<sup>3</sup>]-VASOPRESSIN (DGAVP). P.H. Wu, J.F. Liu, A.J. Lanca, A.I. Arifuzzaman, L. Grupp<sup>1</sup> and H. Kalant. Dept. Pharmacology, Univ. of Toronto, and Addiction Research Foundation, Toronto, Canada

Tolerance to E can be maintained by DGAVP (s.c.) acting on central vasopressin V<sub>1</sub> receptors. We have identified a neurocircuit underlying the action of AVP on tolerance to E, that consists of serotonergic, vasopressinergic, cholinergic and glutamatergic projections. Other evidence implicates septal neurons that have NMDA receptors. Male Sprague Dawley rats were anesthetized and injected with saline-1 mM CaCl<sub>2</sub> (S) or NMDA (50nM in S) into the medial (M, 0.1 µl) or medial plus lateral septum (M+L, 0.3 µl) in 10 min. After 4 weeks to recover from the surgery, they were tested for their initial sensitivity to E (1.8 g/kg, i.p.) on the moving belt, and were treated chronically with E until they showed tolerance to E. Then E treatment was stopped, S or DGAVP (10 µg/rat, s.c.) treatment began, and retention of tolerance was tested 9 days later. At the end of the experiment, the rats were treated with colchicine (1.2 mg/kg, s.c., 36 h) and perfused with fixative. Brain sections were cut and stained with FITC labelled antibodies for choline acetyl transferase (CAT) and GABA. All rats showed the same initial sensitivity to E and developed tolerance to E in the same time [F(2,21)=0.08, p>0.93]. DGAVP maintained tolerance in the S group but not in the M and M+L groups [F(2,20)=3.77, p<0.04]. Nissl staining of the sections showed marked depletion of cells bodies in the M and M+L of the NMDA-treated animals. Immunocytochemistry showed that GABA immunoreactivity was markedly decreased in the lateral septum. Our results indicate that the lateral septal GABA cells with NMDA receptors may be involved in the maintenance of tolerance to E by DGAVP. Supported by NIAAA grant RO1-08212-06.

## 529.3

NMDA RECEPTOR MEDIATED BRAINSTEM LESIONS PRODUCED BY ACUTE THIAMINE DEFICIENCY IN RATS. S.X. Zhang<sup>\*</sup> and P.J. Langlais. Dept. of Psychology, San Diego State University, and VA Medical Ctr., San Diego CA 92182

An acute bout of pyridoxamine-induced thiamine deficiency (PTD) in rats produces lesions within thalamus, mammillary bodies and brainstem which resemble Wernicke's encephalopathy. Evidence suggests that thalamic lesions involve glutamate-NMDA receptor mediated excitotoxicity (Langlais, *Metabolic Brain Disease* 10: 31-44, 1995). The present study examined the role of NMDA receptors in thiamine deficiency induced neuronal loss within several brainstem nuclei. Male Sprague-Dawley rats were treated daily with a thiamine-free diet and pyridoxamine hydrobromide (0.25 mg/kg/day, i.p.). Paired controls and PTD rats were administered either MK-801 (2mg/kg/day, i.p.) or saline beginning at an early, prelesion stage (approximately day 12) and ending with the administration of thiamine, 100 mg/kg, i.p., on day 15-16. After 5 days of recovery, the brains were removed and neuronal density measured. In the PTD-saline group, neuronal loss was greatest in the inferior olivary nucleus (IOD, 77% loss) followed by the locus coeruleus (LC; 61%), lateral vestibular (LV; 58%), medial vestibular (MV; 45%), lateral superior olivary (LSO; 31%) and superior paraolivary (SPO; 22%) nuclei. MK-801 treatment was associated with a significant 20-25% increase in neuronal density in IOD, IOP, MVV, LV and LSO nuclei but had no effect on neuronal loss in LC or SPO nuclei. These observations suggest that NMDA receptors are involved in the pathogenesis of PTD-induced neuronal degeneration in some but not all brainstem nuclei. Supported by NINDS grant #NS 29481 and VA Merit Award to P.J.L.

MALONATE-INDUCED EXCITOTOXIC DEGENERATION OF THE DOPAMINERGIC NIGROSTRIATAL PATHWAY. B.P. Connop, R.J. Boegman, K. Jhamandas, R.J. Beninger and J.V. Milligan<sup>\*</sup>. Departments of Pharmacology & Toxicology, Psychology, and Physiology, Queen's University, Kingston, Ont. K7L 3N6.

Recently, inhibition of mitochondrial function has been shown to produce excitotoxic damage in the brain via a mechanism involving indirect activation of N-methyl-D-aspartate (NMDA) receptors. We have used malonic acid, an inhibitor of succinate dehydrogenase, to determine if it produces excitotoxic damage to the dopaminergic nigrostriatal pathway. In adult Sprague-Dawley rats, unilateral malonate infusions (0.5 µl) were made into the substantia nigra pars compacta and striatal tyrosine hydroxylase (TH) activity measured at 4 and 7 days post-infusion. Intrastriatal malonate, 0.25 and 0.5 µmol produced 16.2% and 62.5% decreases in striatal TH activity, respectively. A comparable decrease in striatal TH activity was seen at both 4 and 7 days post-infusion. Animals receiving malonate did not show excitation or seizures. In animals injected with 0.5 µmol malonate, systemic pretreatment with the NMDA receptor antagonist - MK801 (30 min pre- and 210 min post-infusion) - produced a 13.5% decrease in striatal TH activity. The present study shows that malonate can produce excitotoxic damage to the nigrostriatal dopamine pathway by indirect activation of NMDA receptors. (Supported by the Medical Research Council of Canada)

## 529.2

NMDA EFFECTS ON RETINAL NEUROSTEROIDS. P. Guameri<sup>\*</sup>, R. Guameri<sup>\*</sup>, C. Cascio<sup>\*</sup>, R. Monastero<sup>\*</sup>, T. Piccoli<sup>\*</sup>, F. Piccoli<sup>\*</sup>, V. Papadopoulos<sup>\*</sup>. \*IBS, CNR; \*Inst. Neuropsych., Palermo, Italy; \*Dept. Cell Biol., Georgetown Univ., Washington D.C., USA.

Neurosteroids, such as pregnenolone sulfate (P5-S), have been implicated in the NMDA-induced neuronal injury and the regulation of NMDA-gated and voltage-dependent Ca<sup>2+</sup> currents. In the present study, we examined the effects of NMDA on retinal steroidogenesis both *in vitro* and *in vivo*. Retina, a useful model in degenerative studies, has been shown to synthesize neurosteroids (J. Neurochem. 1994, 63:86). Intact retina possess P450<sub>scc</sub> enzyme, mainly located at ganglion cells, and synthesizes the novo pregnenolone (P5) and P5-S. In addition, retina neurosteroid synthesis is under control of GABA<sub>A</sub> receptors (Brain Res. 1995, in press). To study the effects of NMDA in *in vitro* P5 synthesis, retina from adult rats was incubated in Hank's buffer in the presence of 1-100 µM NMDA and P5 metabolism inhibitors. P5 synthesis was stimulated by NMDA and this effect was reversed by MK 801 and EGTA. Both cGMP content and LDH activity, measured to monitor NMDA effects, increased. This increase was potentiated by elevating the extracellular Ca<sup>2+</sup>. When NMDA was intraocularly injected, P5 and P5-S raised after 30 min. However prolonged treatments (12-16 hrs) decreased P5 levels only. In order to eliminate adrenal steroid interferences in retinal neurosteroid analysis, rats were treated with dexamethasone (DEX). Retinal P5 levels declined in DEX-treated rats compared with those of saline-treated group, whereas P5-S levels were unchanged. After prolonged exposure, when serum corticosterone levels were almost abolished, P5 levels were higher compared to those measured after short exposure, suggesting an activation of retinal P5 synthesis. DEX-treatment did not interfere with NMDA effects on P5 and P5-S. These results suggest that (i) NMDA regulates neurosteroid synthesis, maybe through stimulation of GABA release, and (ii) NMDA-stimulated P5-S formation may be involved in neurodegenerative events.

## 529.4

CELL SIZE-DEPENDENT LOSS OF RETINAL GANGLION CELLS AFTER INTRAOCULAR NMDA- AND KAINATE-INJECTIONS IN ADULT RATS. C.K. Vorwerk<sup>1</sup>, M.B. Kreutz<sup>1</sup>, M. Brosz<sup>2</sup> and B.A. Sabel<sup>1</sup>

<sup>1</sup>Otto-von-Guericke-University, Faculty of Medicine, <sup>2</sup>Institute of Medical Psychology, <sup>3</sup>Institute of Biostatistics, Leipziger St.44, Magdeburg 39120, Germany

The cell size distribution of retinal ganglion cells (RGC) surviving N-methyl-D-aspartate (NMDA) or kainate (KA) induced lesions was compared to uninjured RGCs in whole mounted rat retinae of adult rats. NMDA (20 nmoles) or KA (5 nmoles) was injected intraocularly. To determine the number and size of surviving RGC's, horseradish peroxidase (HRP) was injected into the contralateral superior colliculus 48 hours later. After an additional two days the retinae were dissected out, whole mounted, stained and analyzed for HRP-positive cells using a computer based image analysis system.

We analyzed 15,000 cells taken from uninjured controls, over 4000 NMDA treated cells and over 10,000 cells from KA treated rats. The control cell pool was divided into four size classes with equal numbers of cells in each class (3750 cells). The mean cell diameter for each class was 4.7, 8.0, 10.8, 16.2 µm. The cells from NMDA and KA treated rats were sorted into these four size classes, and this distribution compared to the expected (control) distribution. In class 3 (10.8 µm) 18% fewer cells were counted in NMDA retinae than expected when compared to controls, assuming both populations had the same distribution. Whereas 12-15% more cells were found in class 1 (4.7 µm) and class 4 (16.2 µm). A different pattern was seen in kainate treated animals, where in class 1 30% more cells were found compared to the control group. Interestingly, in class 3 and class 4 (larger cells) there were 15% fewer cells compared to control. The differential sensitivity of cell-size classes suggests that discrete subclasses of RGCs have different expression patterns of glutamate receptor subtypes and that larger RGCs are more sensitive to KA than NMDA injury.

MANIPULATION OF MEMBRANE POTENTIAL MODULATES MALONATE-INDUCED STRIATAL EXCITOTOXICITY IN VIVO. J.G. Greene<sup>\*</sup> and J.T. Greenamyre. Depts. of Neurobiology and Anatomy, Neurology, and Pharmacology, Univ. of Rochester Medical Center, Rochester, NY 14642.

Malonate is a competitive inhibitor of succinate dehydrogenase (SDH), the neurotoxicity of which is mediated indirectly by the NMDA-subtype of glutamate receptor. We have investigated the effects of pharmacological manipulation of membrane potential on the toxicity of malonate by using intrastriatal injections in rats and analysis of lesion volume. We report that a low dose of the Na-K ATPase inhibitor ouabain (0.1 nmol) that was not overtly toxic greatly exacerbated the toxicity of a low dose of malonate (0.6 µmol); this combined toxicity was blocked by the noncompetitive NMDA antagonist MK-801. Injection of a high concentration of potassium produced similar results to ouabain. The toxicity of a higher dose of ouabain (1 nmol) was largely prevented by MK-801. Co-injection of the K<sup>+</sup> channel activator minoxidil (4 nmol) attenuated the toxicity of 1 µmol of malonate by about 60%. These results indicate that membrane depolarization exacerbates malonate neurotoxicity and that membrane hyperpolarization protects against malonate-induced neuronal damage. We hypothesize that the effects of membrane potential on malonate toxicity are mediated through the NMDA receptor as a result of its combined agonist- and voltage-dependent properties.

ENHANCEMENT OF NMDA-INDUCED NEUROTOXICITY IN CULTURED HIPPOCAMPAL NEURONS FOLLOWING CHRONIC ETHANOL EXPOSURE C.T. Smothers,<sup>1</sup>\* J. Mrojek<sup>1</sup>, and D.M. Lovinger<sup>2</sup> <sup>1</sup>Dept. of Physiology, Meharry Medical College, <sup>2</sup>Dept. of Mol. Physiol. & Biophys., Vanderbilt Univ. Nashville, TN 37232.

It has been proposed that the adaptive mechanism by which ionotropic glutamate receptors cope with chronic inhibition by ethanol (EtOH) involves an increase in receptor function. This study demonstrates that chronic ethanol exposure results in an enhancement of NMDA receptor mediated neurotoxicity in cultured hippocampal neurons. In cultures of hippocampal neurons (2 wks *in vitro*), NMDA-induced neurotoxicity was examined following a 7 day chronic exposure to 100 mM EtOH (CEE) and in control cultures receiving no EtOH.

NMDA application induced cell death in dose dependent fashion in both control and CEE cultures. NMDA-induced cell death was significantly enhanced in CEE at all concentrations (50-250  $\mu$ M) versus controls ( $p < 0.003$ , ANOVA). For example, NMDA-induced cell death at 50  $\mu$ M was  $46 \pm 5\%$  in control and  $60 \pm 5\%$  in CEE cultures; while at 250  $\mu$ M NMDA cell death was  $82 \pm 2\%$  in control and  $93 \pm 2\%$  in CEE cultures. Kainic acid induced cell death was not altered as a result of CEE ( $p > 0.100$ , ANOVA). Inclusion of APV (70  $\mu$ M) during the CEE treatment paradigm prevented the enhancement of NMDA-induced cell death. Furthermore, maintenance of EtOH through NMDA application retarded NMDA-induced cell death ( $p < 0.001$ , ANOVA). No significant change in total cell numbers (live + dead) was apparent following NMDA application in control vs. CEE cultures ( $p > 0.970$ , ANOVA). These data indicate that the increased toxicity involves selective effects on NMDA receptors and may reflect withdrawal-related processes.

It has been postulated that the enhancement of NMDA-induced neurotoxicity involves an enhanced increase in intracellular calcium influx through the NMDA receptor. We are currently examining intracellular calcium transients in CEE and control cultures. Supported by NIAAA Fellowship F31-AA05361 & AA08986.

GLUTAMATE RECEPTORS MODULATE IBOGAINE NEUROTOXICITY E. O'Hearn\* and M.E. Molliver. Dept. of Neuroscience & Neurology, Johns Hopkins University School of Medicine, Baltimore, MD 21205

To test the excitotoxicity hypothesis of ibogaine-induced PKC damage we attempted to block glutamate receptors. GYKI 52466, a non-NMDA antagonist, was injected (10 or 30 mg/kg i.p.) before and twice after one dose of ibogaine (50 or 100 mg/kg i.p.). The treated rats ( $n=14$ ) exhibited substantially greater loss of PKCs and microglial activation compared to rats given ibogaine alone. After both drugs, the bands of PKC loss were much wider and the degeneration extended to both paravermis and hemispheres. We then tested the effects of an NMDA antagonist. MK-801 (1 mg/kg i.p.) administered prior to ibogaine (50 or 100 mg/kg i.p.;  $n=7$ ) markedly attenuated the degree of PKC loss caused by ibogaine alone. Neither GYKI 52466 nor MK-801 alone caused degeneration. These results demonstrate that ibogaine toxicity is profoundly modulated by glutamate antagonists. Enhancement of PKC loss after blocking non-NMDA receptors has several possible explanations. GYKI 52466 may have blocked excitation of cerebellar inhibitory neurons (basket, stellate, or Golgi cells), increasing PKC susceptibility to excitotoxic injury. Alternately, blocking non-NMDA receptors on inhibitory interneurons in brainstem may lead to increased firing in pre cerebellar neurons that activate PKCs. A third consideration (evidence lacking) is that vulnerability may increase due to an imbalance between AMPA/Kainate and metabotropic receptors. In contrast, the attenuation of PKC loss by MK-801 suggests that NMDA receptors are involved. MK-801 might reduce the activation of inferior olive by ibogaine (ibogaine binds to NMDA receptors: ref. Popik et al., 1994); alternately, excitation of other neurons (e.g., granule cells) via NMDA receptors, may normally contribute to ibogaine-induced PKC degeneration. These results suggest that neuronal connections and receptors other than those between climbing fibers and PKCs may contribute to ibogaine neurotoxicity. ## 529.11

AMPA RECEPTOR DESENSITIZATION MASKS RAPID GLUTAMATE EXCITOTOXICITY IN CULTURED MOUSE CORTICAL ASTROCYTES. J.C. David, K.A. Yamada, L.L. Dugan, J.K.J. Gabrielsen, A.M. Rosengarten, and M.P. Goldberg\*. Center for the Study of Nervous System Injury, Department of Neurology, Washington University School of Medicine, St. Louis, MO 63110.

Although cultured astrocytes express functional glutamate receptors coupled to increases in intracellular free calcium, they are generally resistant to excitotoxic cell death. One explanation is that glutamate receptor activation may be limited by rapid desensitization. To test this, we blocked AMPA receptor desensitization with a thiazide diuretic, cyclothiazide (CYZ), in cultured mouse Type I astrocytes.

In whole-cell recordings of astrocytes, brief applications of 300  $\mu$ M kainate (KA) evoked small sustained inward currents, while 300  $\mu$ M AMPA evoked small rapidly desensitizing inward currents. Both dramatically increased when desensitization was blocked by addition of 100  $\mu$ M CYZ. A few astrocytes were injured after 24 hr exposure to 500  $\mu$ M KA, but not to 500  $\mu$ M AMPA or to 500  $\mu$ M glutamate (GLU). However, with the coapplication of 10-100  $\mu$ M CYZ, each of the glutamate agonists caused widespread (60-80%) cell death, occurring even within the first few hours. This dramatic effect with CYZ, which alone was not toxic, was concentration-dependent for each of the agonists ( $EC_{50}$  30-100  $\mu$ M) and was abolished by the further addition of a competitive non-NMDA antagonist, NBQX (30  $\mu$ M). CYZ also enhanced AMPA-stimulated glutamate release into the bathing medium within 10 minutes after drug application. NMDA caused no injury even in the presence of CYZ. Concanavalin A (0.3 ng/ml), enhanced astrocyte toxicity during KA, but not AMPA, exposure and was blocked by NBQX. The AMPA receptor-mediated excitotoxicity with CYZ varied with the age of the astrocyte cultures; the maximal effect occurred around 2 weeks, but was absent by 4 weeks *in vitro*. Desensitization of astrocyte AMPA- and KA- subtypes of glutamate receptors limits excitotoxicity and may influence astrocyte and neuron vulnerability in cerebral ischemia. Supported by NIH NS32326, NS01543 (MPG), and NS01443 (KAY).

## 529.8

NMDA TOXICITY IN STRIATAL CULTURES IS POTENTIATED BY KCl-INDUCED CHRONIC DEPOLARIZATION. Q. Chen\*, D.J. Surmeier and A. Reiner. Dept. Anat. & Neurobiol., Univ. of Tennessee - Memphis, Memphis, TN 38163.

Cortical innervation plays an important role in the expression of NMDA receptor mediated excitotoxicity in striatum. Based on studies of cerebellar granule cells, it seemed possible that cortical input to striatum has this influence by chronic depolarization produced by cortical input. We therefore studied the influence of KCl depolarization on the development of NMDA receptor mediated vulnerability in striatal neurons.

Dissociated striatal neurons from E17 rat embryos were cultured for two weeks in Barrett's media containing either high (25 mM) or low (3 mM) KCl. The vulnerability of these neurons to NMDA receptor agonists including NMDA and quinolinic acid (QA) was examined by monitoring cell loss 24 hrs after 1 hr exposure. The neurons grown in high KCl had larger cell bodies and longer, thicker processes than neurons grown in low KCl. We found that 500  $\mu$ M NMDA produced significant striatal cell loss in both high and low KCl treated cultures, but QA up to 5 mM had no significant toxic effect. The striatal neuron loss produced by 500  $\mu$ M NMDA was significantly greater (47% loss) in the high KCl group than in the low KCl group (25%). In conclusion, our studies suggest that membrane depolarization produced by corticostriatal innervation could significantly potentiate NMDA receptor-mediated excitotoxicity in striatum. Chronically depolarized striatal cultures with strictly controlled glutamate content in the media may provide a more appropriate model to study the role of NMDA or other glutamate receptor subtypes in excitotoxicity in striatum. EFFECT OF CYCLOTHIAZIDE ON EXCITOTOXIC HIPPOCAMPAL INJURY IN THE IMMATURE RAT BRAIN. W. H. Trescher\* and M. V. Johnston. Kennedy Krieger Research Institute, Johns Hopkins Medical Institutions, Baltimore, MD 21205

Excitatory amino acid receptor desensitization may be a mechanism to limit glutamate neurotoxicity. Cyclothiazide blocks glutamate receptor desensitization, therefore we investigated the effects of cyclothiazide on AMPA- and kainate-induced hippocampal injury in the immature rat. Under deep anesthesia, postnatal day (PND) 7 rats received intrahippocampal injections of AMPA (2.5 nmol/0.5  $\mu$ l) or kainate (10 nmol/0.5  $\mu$ l) alone, and in combination with cyclothiazide (2.5 nmol or 25 nmol/ $\mu$ l). Additionally, cyclothiazide (25 nmol/0.5  $\mu$ l) was injected alone. Injury to the hippocampus was assessed one week later on coronal Nissl stained sections by comparison of regional cross-sectional areas of the dorsal hippocampus ipsilateral(I) and contralateral(C) to the injection site. Injury was calculated according to the formula  $100 \times (C-I)/C$  (percent damage). Cyclothiazide (25 nmol/0.5  $\mu$ l) produced a mild injury to the hippocampus ( $5.7 \pm 5.6\%$  damage). AMPA (2.5 nmol/0.5  $\mu$ l) produced  $32.5 \pm 6.7\%$  damage, but cyclothiazide (2.5 nmol and 25 nmol/0.5  $\mu$ l) coinjected with AMPA did not significantly alter the injury to the hippocampus. Kainate (10 nmol/0.5  $\mu$ l) produced  $15.7 \pm 4.5\%$  damage to the dorsal hippocampus. Coinjection of cyclothiazide increased kainate-mediated hippocampal injury (cyclothiazide 2.5 nmol,  $23.6 \pm 5.8\%$  damage; cyclothiazide 25 nmol/0.5  $\mu$ l,  $33.5 \pm 7.8\%$  damage,  $p < 0.05$ , ANOVA). The results indicate that cyclothiazide enhances excitotoxic hippocampal injury *in vivo*. Supported by NIH grant NS01482.

## 529.12

KAINATE-INDUCED DELAYED EXCITOTOXICITY IN ISOLATED RETINA. Q. Chen, J. Olney, T. Almli, M. Wax\*, M. Price and C. Romano\*. Dept. Psych. and Ophthal., Washington. U. St. Louis, MO 63110.

Delayed excitotoxic neurodegeneration occurs in response to brief periods of activation of glutamate receptors of either non-NMDA or NMDA subtype in isolated embryonic chick retina. Kainate is a powerful excitotoxin in this system, causing much more cell death (assessed by LDH release and histologically) than NMDA, AMPA, or glutamate. One mechanism for the high toxicity of kainate may be that while AMPA receptors desensitize rapidly in response to AMPA or glutamate, kainate responses are relatively non-desensitizing. Experiments were performed to test this hypothesis. First, GYKI 52466, an AMPA receptor-selective antagonist at the concentrations used, blocked kainate-induced delayed excitotoxicity, indicating that kainate toxicity was mediated through the AMPA receptor. Second, the effects of cyclothiazide, an agent that blocks desensitization, on excitotoxicity mediated by AMPA, glutamate, and kainate were determined. MK-801 was present to eliminate any NMDA receptor-mediated toxicity. Both glutamate- and AMPA-induced toxicity were greatly potentiated by cyclothiazide, whereas kainate-induced toxicity was not significantly affected. Third, co-incubation of the retina with glutamate (to desensitize AMPA receptors) and kainate decreased the toxicity of kainate. These results are consistent with the notion that the powerful toxic properties of kainate result in part from the non-desensitizing response of kainate at AMPA receptors. Desensitization does limit the neurotoxicity of the endogenous agonist glutamate and therefore this may serve as a physiological protective mechanism.

## 529.13

**THE NON-NMDA ANTAGONIST LY300168 (GYKI 53655) ATTENUATES AMPA-INDUCED EXCITOTOXICITY IN NEONATAL RAT BRAIN.** J.D.E. Barks\*, P. Wang, X.-H. Liu. Dept. of Pediatrics, Univ. of Michigan, Ann Arbor MI 48109-0646.

Susceptibility to injury mediated by the excitatory amino acids (EAAs) NMDA and AMPA peaks in immature rat brain (Brain Res 459:200; *ibid.* 583:54). NMDA toxicity is consistently attenuated by many competitive and non-competitive NMDA antagonists; reported effects of the non-NMDA antagonists NBQX and GYKI 52466 on AMPA toxicity have been less robust. We tested the effect of the putative AMPA receptor desensitization-enhancer LY300168 (GYKI 53655, E Lilly) (2.5 mg/kg/dose i.p. x 3 doses 15, 120 and 240 min post-EAA, vs. vehicle) on excitotoxic injury in postnatal day 7 (P7) rats. P7 rats were injected with (S)-AMPA (2.5 nmol, n=14) or NMDA (5 nmol, n=27) into right hippocampus (HIP). Bilateral HIP volumes were estimated by image analysis on P12. Injection of AMPA (2.5 nmol) resulted in marked right HIP atrophy with pyramidal cell loss. LY300168 (n=7; 2 died, at 2h and 48h) significantly attenuated AMPA-induced right HIP injury [right HIP volume (mm<sup>3</sup>, mean±sd): AMPA+vehicle 3.66±0.56; AMPA+LY 5.22±0.61; p=0.002, t-test]. Based on comparison with left HIP volume, 2.5 nmol AMPA resulted in 56±8% right HIP volume loss in controls, but only 43±7% after LY300168 (p<0.02, t-test). Injection of NMDA (5 nmol) resulted in moderate right HIP atrophy. LY300168 (n=14; 1 died after 48h) had no effect on NMDA-induced right HIP injury [right HIP volume (mm<sup>3</sup>, mean±sd): NMDA+ vehicle 7.58±1.08; NMDA+LY 7.30±1.71]. Mortality was not increased by LY300168 administration (3/20 vehicle-treated vs. 3/21 LY300168-treated). The data suggest that AMPA receptor desensitization modulates the response of immature brain to AMPA- but not NMDA-mediated injury, and that desensitization-enhancing strategies may be neuroprotective against EAA-mediated injury to the developing brain.

## 529.15

**AMYLOID PRECURSOR PROTEIN REGULATION BY IONOTROPIC AND METABOTROPIC GLUTAMATE RECEPTORS.** A. Valerio\*, A. Alberici, M. Paterlini, M. Grilli, P. Galli, M. Pizzi, M. Memo and P.F. Spano. Div. Pharmacol., Dept. Biomed. Sci. & Biotech., Brescia Univ. Medical School, Brescia, Italy.

The effects of the ionotropic glutamate receptor (iGluR) selective agonist N-methyl-D-aspartate (NMDA) on amyloid precursor protein (APP) levels were investigated in primary cultures of rat cerebellar granule cells. Neuron immunostaining with the anti-APP monoclonal antibody 22C11 (Boehringer Mannheim) was significantly increased 4 hours after a 15 min pulse with 100 µM NMDA. Immunoblotting of granule cell extracts using R37 antiserum, recognizing a C-terminal portion of APP, showed that all the intracellular full-length APP isoforms increased after the NMDA pulse in a dose-dependent manner. This effect was prevented by incubating the neurons in the presence of the selective metabotropic GluR (mGluR) agonist 1S,3R-ACPD. This phenomenon was related, in terms of doses and time, with the observed 1S,3R-ACPD-mediated protection on NMDA-induced granule cell death. Our results suggest that the GluR-mediated changes in APP content might participate in the control of neuronal viability. The relative abundance of different iGluR and mGluR subtypes could be of relevance in determining the neuronal response to excitatory amino acids in terms of both APP expression and survival.

The authors are grateful to Drs. T. Ishii and S. Haga (Tokyo Institute of Psychiatry, Tokyo, Japan) for the generous gift of R37 antiserum.

## 529.17

**Activation of class II of metabotropic glutamate receptors (mGluRs) inhibits the release of excitatory amino acids (EAAs) from slices and synaptosomes of rat hippocampus.** A. Poli\*, P. Di Iorio, R. Lucchi, R. Ciccarelli, G. Battaglia\*, F. Nicoletti and F. Caciagli. Dept. of Biology, Univ. of Bologna, Italy; Inst. of Pharmacology, Univ. of Chieti, Italy; Inst. of Pharmacology, Univ. of Catania, Italy; Dept. of Exp. Med., Pharmacology Section, Univ. of Perugia, Italy.

The release of EAAs seems to be modulated by mGluRs. In the hippocampus, mGluR1-5, mGluR2-3 (class II) and L-AP4-sensitive receptors have been found. We observed that the non selective mGluR agonist (1S,3R)-1-aminocyclopentane-1,3 dicarboxylic acid (1S,3R-ACPD 100 µM) reduced the electrically evoked release of endogenous EAAs from hippocampal slices. Conversely, the non selective mGluR antagonist (+)-α-methyl-4-carboxyphenylglycine (300 µM) enhanced the evoked output. Both (2S,1R,2R,4R)-(2,3-dicarboxycyclopropyl)-glycine (DCG-IV) and (2S,3S,4S)-α-(carboxycyclopropyl)-glycine (L-CCG-I), two agonists of mGluR2-3, caused a dose-dependent inhibition of EAA release from electrically triggered slices and K<sup>+</sup> stimulated synaptosomes. The inhibition was reverted by (2S,3S,4S)-2-methyl-2-(carboxycyclopropyl)-glycine, a new selective antagonist of mGluR2-3. DCG-IV and L-CCG I (1-10 µM) resulted to be 30-50 fold more potent than 1S,3R-ACPD. Surprisingly, L-AP4 did not affect EAA release from slices. In order to establish which transduction pathway is involved in the activity of the mGluR agonists we observed that 1S,3R-ACPD, DCG-IV and L-CCG-I reduced the electrically stimulated cAMP formation in the slices but, as opposed to 1S,3R-ACPD and L-CCG-I, DCG-IV did not stimulate PPI hydrolysis.

## 529.14

**MODULATION OF HYPOXIC/HYPOGLYCEMIC NEURONAL INJURY BY DIFFERENT METABOTROPIC GLUTAMATE RECEPTORS.** T. Opitz, and K. G. Reymann\*. Department of Neurophysiology, Federal Institute for Neurobiology, Brenneckestr. 6, POB 1860, D-39008, Magdeburg, Germany.

To investigate the influence of metabotropic glutamate receptors (mGluR) on neuronal injury caused by cerebral hypoxia/ischemia, we employed an *in vitro* model of hypoxia/hypoglycemia. Hippocampal slices were transiently exposed to an oxygen- and glucose-free environment which causes a pronounced drop of both ATP and creatine phosphate, an anoxic depolarization, and an incomplete recovery of synaptically evoked population spike in the CA1 region after one hour (48.5 ± 3.6 % of baseline values). This recovery was used as a measure of neuronal viability.

In this model, we applied various agonists specific for different mGluR subtypes. The specific class 1 mGluR agonists trans-azetidine-2,4-dicarboxylic acid (trans-ADA) and 3,5-dihydroxyphenylglycine (DHPG) appeared to be highly protective, but only if it was applied 20 min before the hypoxia/hypoglycemia. An activation of class 2 metabotropic glutamate receptors by (2S,1R,2R,3R)-2-(2,3-dicarboxycyclopropyl) glycine (DCG-IV), which inhibits adenylyl cyclase activity, led to a marked deterioration of the population spike recovery and even to a total prevention of the protective effect of the N-methyl-D-aspartate (NMDA) agonist D-2-amino-5-phosphonopentanoic acid.

In conclusion we could show that an activation of phospholipase C coupled (class 1) mGluRs prior to hypoxia/hypoglycemia exhibits a pronounced protective effect. In contrast to findings in NMDA toxicity in neuronal cultures we were able to demonstrate a detrimental effect by the activation of mGluRs negatively coupled to the adenylyl cyclase (class 2).

We wish to thank Drs. A. P. Kozikowski and H. Shinokazi for providing trans-ADA and DCG-IV, respectively.

**STIMULATION OF mGluR TYPES 1/5 NORMALIZE GLUTAMATE-INDUCED ALTERATION OF CALCIUM HOMEOSTASIS AND EXCITOTOXICITY IN CULTURED CEREBELLAR GRANULE CELLS.** M. Pizzi\*, P. Galli, O. Consolandi, V. Arrighi, M. Memo, P.F. Spano. Div. Pharmacol., Dept. Biomed. Sci. & Biotech., Brescia Univ. M., Brescia, Italy.

Stimulation of metabotropic glutamate receptor (mGluR) has been shown to counteract glutamate-mediated excitotoxicity in different neuronal cultures. In the present study the role of the mGluR on the control of neuronal calcium homeostasis was investigated in cerebellar granule cells. The mGluR agonist, tACPD, produced a transient increase of intracellular calcium concentration ([Ca<sup>2+</sup>]<sub>i</sub>) which showed to be developmentally regulated, being maximal at 4 days *in vitro* (DIV). Moreover, tACPD significantly reduced the [Ca<sup>2+</sup>]<sub>i</sub> rise produced by glutamate in the absence of external Mg<sup>2+</sup>. This latter effect occurred at experimental conditions superimposable to those producing neuroprotection. tACPD neither affected [Ca<sup>2+</sup>]<sub>i</sub> elevation due to depolarizing concentrations of KCl (25 mM) nor the calcium entry evoked by the calcium ionophore A 23187 (10 µM). Inhibitory effect of tACPD was insensitive to K<sup>+</sup> channel blockade operated by 2 mM tetraethylammonium (TEA). The capability of different mGluR agonists to reduce glutamate-increased [Ca<sup>2+</sup>]<sub>i</sub> rise strictly correlated with their property to elicit neuroprotection. L-AP4 (500 µM), which stimulates mGluR4/R6/R7 subtypes, was inactive in preventing glutamate-mediated both disturbance of calcium homeostasis and neurotoxicity. tACPD inhibitory modulation of glutamate-evoked [Ca<sup>2+</sup>]<sub>i</sub> rise and cell death appeared to be highly sensitive to protein kinase C blockade produced by bisindolylmaleimide (1 µM) while was weakly affected by the cyclic AMP analogue dibutyryl cyclic AMP. These data suggests that activation of mGluR1/R5 receptor subtypes reduce glutamate excitatory transmission by a mechanism involving protein kinase C activation.

## 529.18

**ACTIVATION OF CLASS I METABOTROPIC GLUTAMATE RECEPTORS (mGluRs) ENHANCES NMDA TOXICITY IN CULTURED CORTICAL CELLS.** V. Bruno\*, I. G. Battaglia<sup>1</sup>, A. Copani<sup>1</sup>, G. Casabona<sup>1</sup>, T. Knöpfel<sup>2</sup>, R. Kuhn<sup>2</sup>, P. Dell'Alba<sup>3</sup>, D.F. Condorelli<sup>3</sup> and F. Nicoletti<sup>4</sup>. <sup>1</sup>Instituto of Pharmacology and <sup>3</sup>Biochemistry, University of Catania, and <sup>4</sup>Dept. Exp. Med. Biochem. Sci., University of Perugia, Italy; <sup>2</sup>CIBA-GEIGY, Basel, Switzerland.

Mouse cortical neurons in mixed cultures express high levels of mGluR5, as indicated by both Northern analysis and immunocytochemistry. Expression of mGluR1a,b or c was low or absent. mGluR5 receptors were functionally active, as reflected by the ability of class I mGluR agonists, including quisqualate, 3,5-dihydroxyphenylglycine (DHPG) or trans-azetidine-2,4-dicarboxylic acid (t-ADA) to enhance inositol phospholipid hydrolysis. To study the influence of mGluR5 on neuronal degeneration, we have applied quisqualate, DHPG, or t-ADA either during or immediately after a toxic pulse with NMDA. In both cases, mGluR agonists increased the potency of NMDA in inducing neuronal death, although they were not toxic by themselves. Amplification of NMDA toxicity was prevented by inhibitors of protein kinase C (PKC), as well as by prolonged exposure to phorbol esters, a procedure which down regulates PKC. We conclude that activation of class I mGluRs (in particular mGluR5) in cultured cortical cells enhances excitotoxic neuronal death through a mechanism which involves PKC.

## 529.19

## METABOTROPIC RECEPTORS IN EXCITOTOXICITY: (S)-4C3HPG PROTECTS AGAINST STRIATAL QUINOLINIC ACID LESIONS

L.R. Orlando, D.G. Staandaert, J.H. Cha, J.B. Penney Jr., and A.B. Young. Dept. of Neurology, Massachusetts General Hospital, Boston, MA 02114.

Striatal quinolinic acid lesions mimic many of the neurochemical and neuropathological characteristics of Huntington's disease, including the relative loss of medium spiny neurons with sparing of interneurons. Metabotropic glutamate receptors (mGluRs) have been implicated in this toxicity. In fact, mGluR5 is heavily expressed in striatal projection neurons and not in interneurons whereas mGluR2 is confined to cholinergic interneurons. We have used two phenylglycine analogs to investigate which receptors are involved in the excitotoxic process: (S)-4-carboxy-3-hydroxyphenylglycine ((S)-4C3HPG), a selective agonist of mGluR2 and antagonist of mGluR5; and (+)-alpha-methyl-4-carboxyphenylglycine ((+)-MCPG), an antagonist of both mGluR2 and mGluR5.

(S)-4C3HPG or (+)-MCPG was injected into the striatum of male rats with 100 nmol of quinolinic acid, and 2,3,5-triphenyltetrazolium chloride (TTC) was used for lesion analysis. Doses of 1000 nmol (S)-4C3HPG or (+)-MCPG alone were not toxic. When co-injected with quinolinic acid, 500 nmol of (S)-4C3HPG reduced lesion volume by 55% ( $p < 0.01$ ) while 1000 nmol reduced lesion volume by 91% ( $p < 0.01$ ). The same doses of (+)-MCPG had no effect on lesion size. These observations confirm the important role of mGluRs in excitotoxicity. At this time it is unclear whether protection is due to antagonist effects of (S)-4C3HPG at mGluR5 or agonist effects at mGluR2.

Supported by USPHS grants NS31579 and AG11337.

## 529.20

THE METABOTROPIC GLUTAMATE RECEPTOR AGONIST, 4C3HPG, REDUCES KAINATE-INDUCED DEATH OF CORTICAL NEURONS EXPRESSING CALCIUM-PERMEABLE AMPA/KAINATE RECEPTORS. D.M. Turetsky\*, A. Buisson and D.W. Choi. Dept. of Neurology and Center for the Study of Nervous System Injury, Washington Univ. School of Medicine, St. Louis, MO 63110.

Metabotropic glutamate receptor agonists selective for the mGluR2/3 receptor subtype can reduce the overall neuronal death induced by NMDA, but not AMPA or kainate, in murine cortical cell cultures (Buisson and Choi, elsewhere this meeting; also see Bruno et al., Eur J Pharmacol 256: 109, 1994). Exposure times of several hours are required for either AMPA or kainate to destroy most cortical neurons, but a small subpopulation identified by kainate-activated cobalt uptake (a marker for AMPA or kainate receptors linked to calcium-permeable channels) exhibits heightened calcium influx and vulnerability to death induced by kainate exposures as brief as 10-60 min (Turetsky et al., Neurobiol Dis, 1:101, 1994; also unpublished data). Since kainate toxicity on these cobalt-positive neurons resembles NMDA toxicity on the general cortical neuronal population, we tested the hypothesis that the selective mGluR 2/3 agonist, S-4-carboxy-3-hydroxy-phenylglycine (4C3HPG) would indeed protect cobalt-positive neurons from kainate-induced death. 20 min exposure to 100  $\mu$ M kainate in the presence of 10  $\mu$ M MK-801 produced 73.9% ( $\pm 1.7$  SEM,  $n = 14$  cultures) loss of cobalt-positive cells, while causing little additional death in the general neuronal population. Adding 100  $\mu$ M 4C3HPG during the kainate exposure reduced cobalt-positive cell loss to 62.7% ( $\pm 2.7$  SEM) ( $n = 14$ , different at  $P < 0.01$ ). This observation supports the idea that mGluR 2/3 receptor activation can reduce excitotoxicity associated with rapid calcium entry, whether that calcium entry is mediated by NMDA or calcium-permeable AMPA/kainate receptors.

## EXCITATORY AMINO ACIDS: EXCITOTOXICITY VII

## 530.1

BRIEF EXPOSURE TO AMPA INDUCES  $Ca^{2+}$ -DEPENDENT EXCITOTOXICITY SELECTIVE TO CA1 OF ORGANOTYPIC RAT HIPPOCAMPAL SLICE CULTURE, WHILE KAINIC ACID INDUCES "SLOW" NEUROTOXICITY IN CA3. J. Chan\*. Department of Neurology, SUNY Health Science Center, Brooklyn, NY 11203.

Distinctive features of selective and delayed toxicity of the non-NMDA glutamate receptor agonists AMPA and kainic acid (KA) on subpopulations of pyramidal neurons are characterized using rat hippocampal slices, cultured from 9 day old Sprague-Dawley rats [Stoppini (1991) *J Neurosci Methods* 37, 173-182] and studied after 14-21 days in vitro. Slices were exposed to AMPA at 350C in  $Na^{+}$ -free sucrose buffer. Other slices were exposed to KA for 16 hours in serum-free growth medium. All cultures were restored to fresh culture medium for the recovery period. Some slices were pre-exposed for 15 min to one of the following antagonists: the selective, competitive AMPA receptor antagonist NBQX (10  $\mu$ M), or LY-293558 (Lilly Corp, Indianapolis, IN; 10  $\mu$ M) or the non-competitive AMPA antagonist GYKI 52466 (Lilly; 10  $\mu$ M) or the selective KA antagonist gamma-D-glutamylaminomethyl sulfonic acid (GAMS; 500  $\mu$ M). All studies included 5  $\mu$ M diiodocaine to block NMDA channels. Slices were stained with both propidium iodide 5  $\mu$ g/ml and 5  $\mu$ M SYTO 11 Live Cell Indicator (Molecular Probes, Eugene, OR). Digital images were captured microscopically using rhodamine and fluorescein filter sets.

Results:  $N = 6$  slices for each. Brief (30 min) exposure of hippocampal slice cultures to 5  $\mu$ M AMPA caused  $Ca^{2+}$ -dependent death, 24 hours later, of pyramidal neurons preferentially in CA1. In contrast, 5  $\mu$ M kainate required 16 hours of exposure and 2 days of recovery to exhibit toxicity, restricted to CA3 pyramidal neurons. AMPA or kainic acid at 1  $\mu$ M were not toxic while AMPA or kainic acid at 10  $\mu$ M caused death throughout the pyramidal cell layer ( $n = 3$ ). Agents that inhibit desensitization were not necessary to produce AMPA toxicity. Specific blockade by 3 different AMPA receptor antagonists attenuated AMPA but not kainate toxicity. Conversely, the kainate receptor antagonist GAMS (500  $\mu$ M) blocked kainate but not AMPA toxicity. Control slices, without glutamate agonist or in  $Ca^{2+}$ -free buffer showed no toxicity.

## 530.3

AMPA-INDUCED LESION OF THE RAT GLOBUS PALLIDUS: QUANTIFICATION OF THE CALCIFIED AREAS AND OF THE ASTROGLIAL AND MICROGLIAL REACTIONS. V. Petegnief, J. Saura and N. Mahy\*. U. Biochemistry, Sch. of Medicine, Univ. of Barcelona, Spain.

A dose-response study of the formation of calcium deposits and associated astroglial and microglial reactions was performed after microinjection of 0.5  $\mu$ l of a millimolar range of concentrations (0.54-21.6 mM) of AMPA in the rat ventral globus pallidus. At one month post-lesion, calcified formations were observed and quantified in the ipsilateral ventral globus pallidus, ventral pallidus, nucleus basalis of Meynert, substantia innominata, reticular thalamic nucleus and entopeduncular nucleus of the rats treated with 5.4, 10.8, 16.2 and 21.6 mM of AMPA. At the two higher doses, calcium deposits were also detected in the ipsilateral striatum at the lateral border of the globus pallidus and also in ventral nuclei of the thalamus. Calcium deposits were associated with astroglial and microglial reactions that reached statistical significance at the two higher doses. Monoamine oxidase B autoradiography, reflecting the astroglial reaction, showed a significant ( $P < 0.01$ ) increase in the enzyme in the ipsilateral globus pallidus and caudate putamen. The microglial reaction was characterized by peripheral benzodiazepine receptor (PBR) autoradiography. Ipsilateral globus pallidus and reticular thalamic nucleus showed a significant ( $P < 0.001$ ) increase in PBR radioligand binding. In conclusion, excitotoxic lesion of the rat globus pallidus with AMPA induced, in a dose-dependent manner, the formation of calcium deposits together with regionally different astroglial and microglial reactions. ## 530.2

GLUTAMATE-INDUCED CHANGES IN INTRACELLULAR FREE CALCIUM AND EXCITOTOXICITY IN CULTURED RAT CEREBELLAR GRANULE CELLS Kathleen P. Platt & David R. Bristow. SPON: Brain Research Association. School of Biological Sciences, University of Manchester, Manchester, UK.

Excitotoxicity has been implicated in the aetiology of a number of neurological disorders, however the molecular mechanisms underlying this have not been fully elucidated. In this study the susceptibility of rat cerebellar granule cells to glutamate-induced excitotoxicity was examined at 7 DIV using fluorescein diacetate/propidium iodide staining. Neurons were exposed to glutamate (1  $\mu$ M - 10 mM) for 30 minutes at 37°C and their viability was assessed 24 hours later. Glutamate induced a concentration-dependent neurotoxicity ( $ED_{50} 62 \pm 34 \mu$ M). Experiments to determine the time course of glutamate-induced excitotoxicity suggested that the majority of neuronal death occurred within 4 hours after exposure to glutamate. To examine the role of calcium in excitotoxicity, intracellular free calcium ( $[Ca^{2+}]_i$ ) levels were recorded from single cerebellar granule cells (7 - 8 DIV) loaded with fura-2/AM. The  $[Ca^{2+}]_i$  was recorded in single neurons exposed to 1 mM glutamate for 30 minutes and throughout the ensuing 4.5 hours ( $26 \pm 1^\circ$ C). In 10% (8/78) of the neurons,  $[Ca^{2+}]_i$  immediately rose to a sustained plateau ( $> 1 \mu$ M) and failed to recover. The remaining 90% (70/78) of the cells buffered the glutamate-induced  $[Ca^{2+}]_i$  load back to near basal levels after the glutamate was removed. However, in 51% of these neurons (which showed a glutamate-induced  $[Ca^{2+}]_i$  load/min of  $640 \pm 57$  nM (mean  $\pm$  SEM,  $n = 36$ )), sustained increases in  $[Ca^{2+}]_i$  were observed at various times over the next 4 hours. In contrast, the remaining 49% of these neurons (which showed glutamate-induced  $[Ca^{2+}]_i$  load/min of  $406 \pm 39$  nM (mean  $\pm$  SEM,  $n = 34$ )) maintained near basal  $[Ca^{2+}]_i$  levels for the remainder of the experiment. This delayed calcium overload correlated with neuronal cell death as determined by either loss of fura-2/AM fluorescence or by failure to respond to a subsequent glutamate stimulus. These results support a relationship between the glutamate-induced calcium load and subsequent cerebellar granule cell death ( $p < 0.01$  ANOVA with Scheffé's test).

## 530.4

RESTING AND KAINATE-INDUCED  $Ca^{2+}$  LEVELS MEASURED BY FURA-2 IMAGING OF INDIVIDUAL CA1 NEURONS AFTER GLOBAL ISCHEMIA IN THE RAT. J.A. Gorter, J.J. Petrozzino\*, D. Rosenbaum, S. Rybak, W. Pulsinelli\*, T. Nowak\*, M.V.L. Bennett, R.S. Zukin, J.A. Connor. Dept. Neurosci., Albert Einstein College of Medicine, Bronx, NY 10461. \*Roche Inst. Molecular Biology, Nutley, NJ 07110. \*Dept. Neurol., Memphis, TN 38163.

Global ischemia in the rat induces a reduction in expression of GluR2 (the subunit that limits  $Ca^{2+}$  influx via AMPA receptors) in the hippocampal CA1 region prior to neurodegeneration. We hypothesize that  $Ca^{2+}$  permeable AMPA receptors may directly mediate  $[Ca^{2+}]_i$  increases and thereby introduce  $[Ca^{2+}]_i$  loads that contribute to delayed neuronal degeneration. We measured basal and kainate evoked  $[Ca^{2+}]_i$  by optical imaging in voltage clamped CA1 pyramidal neurons in hippocampal slices. At -80 mV resting  $[Ca^{2+}]_i$  did not differ significantly in ischemic vs. control neurons ( $143 \pm 50$  nM vs.  $220 \pm 36$  nM). To eliminate the contribution of voltage- and NMDA receptor dependent  $Ca^{2+}$  influx during kainate (KA) application, which might mask changes directly due to AMPA receptors, the membrane potential was stepped from -80 to +20 mV in the presence of TTX (3  $\mu$ M), nimodipine (10  $\mu$ M), DL-APV (100  $\mu$ M) and MK-801 (10  $\mu$ M). This voltage step produced a large rise in  $[Ca^{2+}]_i$  that was similar in ischemic and control neurons. However, recovery at 10 min was more complete in control than in ischemic neurons ( $0.8 \pm 0.1 \mu$ M,  $n = 5$  vs.  $1.6 \pm 0.4 \mu$ M,  $n = 6$ ). Application of KA (300  $\mu$ M, 60 s) at +20 mV produced an outward current and elevated  $Ca^{2+}$  levels in somata and proximal dendrites of neurons from both control and ischemic rats. These effects were blocked by CNQX. In a small sample of cells no significant difference in the  $[Ca^{2+}]_i$  increase was found in 24 hrs post-ischemic vs. control neurons (41%,  $n = 2$  vs. 45%,  $n = 4$ ). Further experiments at 24 hrs and later time points are expected to shed light on the molecular mechanisms underlying delayed neuronal death after global ischemia.

## 530.5

**Ca<sup>2+</sup>-DEPENDENT NEUROTOXICITY: RELATIONSHIP BETWEEN SOURCE, INFLUX RATE AND [Ca<sup>2+</sup>]<sub>i</sub>.** HOMEOSTASIS Y.M. Lu<sup>1</sup>, H.Z. Yin<sup>1</sup>, J. Chiang and J.H. Weiss, Depts. of Neurology, U.C. Irvine, Irvine CA 92717.

Ca<sup>2+</sup>-dependent glutamate neurotoxicity results after Ca<sup>2+</sup> influx through any of three primary routes: NMDA channels, voltage sensitive Ca<sup>2+</sup> channels (VSCC) and Ca<sup>2+</sup> permeable AMPA/kainate channels (CPAK). Neurons possessing CPAK, (about 13% of neurons in cortical culture) can be identified by kainate stimulated Co<sup>2+</sup> uptake (Co<sup>2+</sup>(+) cells), and are unusually kainate vulnerable.

A close correlation was seen between Ca<sup>2+</sup> influx rate (through different routes) and resultant injury, supporting the idea that agonist triggered influx rate is a primary determinant of injury: Exposures to NMDA (20 μM with 1.8 mM Ca<sup>2+</sup> in the media) and kainate (100 μM kainate in 10 mM Ca<sup>2+</sup>) that gave similar <sup>45</sup>Ca<sup>2+</sup> influx rates, resulted after 6 hours in comparable levels of cortical neuronal injury. Also, kainate-triggered <sup>45</sup>Ca<sup>2+</sup> influx rates into highly vulnerable Co<sup>2+</sup>(+) neurons were estimated (using kainate "pre-exposures" to selectively destroy Co<sup>2+</sup>(+) neurons) to be much greater than influx into other neurons lacking CPAK.

However, imaging studies suggested a generally poor relationship between influx and [Ca<sup>2+</sup>]<sub>i</sub>. With 100 μM kainate exposures, despite the high estimated influx rate, mean [Ca<sup>2+</sup>]<sub>i</sub> responses in Co<sup>2+</sup>(+) neurons were little different from those in other neurons. Similarly, NMDA exposures (20 μM) in 1.8 mM Ca<sup>2+</sup>, despite triggering a much lower influx rate, caused [Ca<sup>2+</sup>]<sub>i</sub> responses similar to those seen with exposure in 10 mM Ca<sup>2+</sup>. These observations suggest that sequestered Ca<sup>2+</sup> (invisible to imaging) might be an important contributor to injury. However, with low (10 μM) kainate exposures Co<sup>2+</sup>(+) neurons showed significantly greater mean [Ca<sup>2+</sup>]<sub>i</sub> responses than other neurons, perhaps reflecting very low rates of Ca<sup>2+</sup> influx in cells lacking CPAK.

## 530.7

**NEUROPROTECTION IN A RAT MODEL OF EXCITOTOXICITY: NMDA ANTAGONISTS.** K.L. Brunson<sup>1</sup>, A. Khanna<sup>1</sup>, H.C. Cromwell<sup>2</sup> and R.W. Cohen<sup>1\*</sup>. <sup>1</sup>Department of Biology, California State University, Northridge, CA. 91330. <sup>2</sup>Mental Retardation Research Center, UCLA School of Medicine, Los Angeles, CA. 90024.

We are studying mutant Han-Wistar (HW) rats which develop neurodegeneration in two brain regions (hippocampus and cerebellum). Previous data suggest that the observed neuronal degeneration is the result of an alteration in glutamate receptor expression. Here, we analyze the neuroprotective effects of two NMDA antagonists, Ketamine and MK-801 using chronic and acute protocols. In the chronic study, mutants were injected weekly (in a two week interval) with either Ketamine (10 mg/Kg) or MK-801 (1 mg/Kg) starting at 30-32 days of age. Chronic MK-801-injected mutants (n=3) exhibited a longer life span (16% increase) and prolonged weight gain (14% heavier after 45 days of age) compared to saline-injected mutants (n=3). Motor skill deterioration was monitored by an open-field test for two minute sessions. After 45 days of age the MK-801-injected mutants displayed 29.5% greater motor skill activity in the open field test than the saline-injected mutants. Ketamine-injected mutants (n=8) showed minor differences compared with the saline-injected mutants (n=7). In the acute study, mutants were injected with a single, anesthetic dose of Ketamine (50 mg/Kg) at 30 days of age. Acute Ketamine-injected mutants (n=5) lived 76 days (30% increase) while acute saline-injected mutants (n=2) lived 53 days. The data show that the mutant rats derive protective effects from the NMDA antagonists, suggesting a role of glutamate-induced excitotoxicity in neuronal degeneration of our model.

## 530.9

**CYTOTOXIC EFFECTS MEDIATED THROUGH KAINATE RECEPTOR ACTIVATION.** P.-E. Mansson, J.M. Carver, J. Shu, L. Cortes-Burgos, L.-M. Zhou, J.R. Howe<sup>1</sup>, and T. Giordano<sup>2</sup>. Symphony Pharmaceuticals, Inc., Malvern, PA 19355, <sup>1</sup>Yale University School of Medicine, New Haven, CT 06520.

Exposure of neurons for prolonged periods of time or to high concentrations of excitatory amino acids (EAA), such as glutamate, results in neuronal death. The activation of glutamate receptors by EAA leads to a large influx of calcium which is thought to be responsible for the neurotoxicity. This has been well documented for two classes of glutamate receptors: the NMDA and AMPA families. However, due to the rapid desensitization of the kainate receptor family, it is not believed that EAA will elicit toxicity through this class of glutamate receptors. Exposure of cerebellar granule cells for 24 hours to 50 μM kainate results in an ~80% decrease in viability. To determine whether any of this toxicity is mediated through kainate receptors, the kainate specific antagonist, SYM2081, was added at concentrations ranging from 0.1 μM to 10 μM. No neuroprotection was observed at any concentration tested. Because of the difficulty of observing glutamate subtype specific responses in a heterogeneous population of cells expressing multiple receptor subtypes, cloned recombinant cell lines expressing either GluR6 or GluR6 and KA2 were studied for their susceptibility to toxicity through the kainate receptor. Preliminary experiments suggests that both glutamate and kainate at high concentrations (≥100 μM) are toxic to the HEK 293 cells stably transfected with either GluR6 or GluR6-KA2 subunits but not the parental cell line. Future experiments will focus on whether this toxicity can be blocked by kainate antagonists, such as SYM2081.

## 530.6

**Zn<sup>2+</sup> PERMEATES Ca<sup>2+</sup> PERMEABLE AMPA/KAINATE CHANNELS AND TRIGGERS SELECTIVE NEURODEGENERATION.** H.Z. Yin<sup>1</sup>, and J.H. Weiss, Depts. of Neurology and Psychobiology, U.C. Irvine, Irvine CA 92717.

Neurons possessing Ca<sup>2+</sup>-permeable AMPA/kainate channels can be identified by a histochemical stain based on kainate stimulated Co<sup>2+</sup> uptake (Co<sup>2+</sup>(+) cells) and are unusually vulnerable to kainate toxicity. The divalent cation, Zn<sup>2+</sup>, is synaptically released at many excitatory synapses, and may serve as a trans-synaptic messenger (it can permeate NMDA channels and voltage sensitive Ca<sup>2+</sup> channels (VSCC)). We set out to determine whether Zn<sup>2+</sup> permeates Ca<sup>2+</sup> permeable AMPA/kainate channels.

When cortical cultures are exposed for 5 min to kainate (100 μM) in the presence of Zn<sup>2+</sup> (300 μM), and the Zn<sup>2+</sup> sensitive fluorescent dye, TS-Q, Zn<sup>2+</sup> accumulation is seen in virtually all neurons. However, indicating Zn<sup>2+</sup> permeability through Ca<sup>2+</sup> permeable AMPA/kainate channels, if Na<sup>+</sup> ions are removed from the media (to prevent depolarization and activation of VSCC), TS-Q fluorescence was largely limited to the small (about 13%) subset of neurons that are Co<sup>2+</sup>(+). We next exposed cultures to kainate (for 5 min as above) in Na<sup>+</sup> containing media but with a lower Zn<sup>2+</sup> concentration (100 μM), and assessed injury 24 h later. Indicating a greater injuriousness of Zn<sup>2+</sup> entry through Ca<sup>2+</sup> permeable AMPA/kainate channels than through VSCC, these exposures selectively destroyed the Co<sup>2+</sup>(+) neurons.

We previously found that basal forebrain cholinergic (BFC) neurons are highly kainate sensitive, and are usually Co<sup>2+</sup>(+). We now report that cortical somatostatin and parvalbumin immunoreactive neurons, which are also exceptionally kainate sensitive, are also generally (over 90%) Co<sup>2+</sup>(+). Thus, direct permeation of Zn<sup>2+</sup> through Ca<sup>2+</sup> permeable AMPA/kainate channels could contribute to selective degeneration of neurons such as these in diseases like Alzheimer's, as well as subserving physiologic signaling functions.

## 530.8

**N-METHYL-D-ASPARTATE-MEDIATED TOXICITY IN CULTURED RAT CORTICAL NEURONS IS ANTAGONIZED BY FPL 15896AR.** M.A. Black, R. Tremblay, G.A.R. Mealing, R. Rav, J.P. Durkin, J.F. Whitfield, J. Blosser, and P. Morley. National Research Council of Canada, Ottawa, Ontario, Canada K1A 0R6 and Fisons Pharmaceuticals, P.O. Box 1710, Rochester, New York, 14603.

Overstimulation of glutamate receptors is believed to initiate cellular processes resulting in neuronal cell death, due in large part to the influx of Ca<sup>2+</sup> through N-methyl-D-aspartate (NMDA) receptors. While NMDA-antagonists have been shown to be neuroprotective *in vivo* and *in vitro*, their mechanism of action is not well understood. In primary cultures of rat cortical neurons, we have examined the action of a novel NMDA receptor antagonist, (S)-α-phenyl-2-pyridine-ethanamine dihydrochloride (FPL 15896AR), on glutamate- and NMDA-induced neurotoxicity as well as on two early NMDA-triggered events, namely the rise in intracellular Ca<sup>2+</sup> levels ([Ca<sup>2+</sup>]<sub>i</sub>) and the loss of membrane-associated protein kinase C (PKC) activity.

Ligand-binding assays, using a membrane fraction from rat cortical tissue, indicated that FPL 15896AR is an uncompetitive NMDA receptor antagonist (K<sub>d</sub> = 1-2 μM). To test its neuroprotective effects, 12-15 day-old cortical cultures, prepared from day 18 fetuses, were exposed to NMDA (50 μM) or glutamate (50 μM) in the presence or absence of FPL 15896AR (50 μM) for 15 minutes and viability assessed 24 h later. Exposure to NMDA or glutamate resulted in the death of ~90% of the neurons. This neurotoxicity was completely blocked by FPL 15896AR. Furthermore, FPL 15896AR (50 μM) prevented the loss of membrane-associated protein kinase C that developed 4 h following transient glutamate or NMDA exposure. The effect of FPL 15896AR on the NMDA-induced rise in [Ca<sup>2+</sup>]<sub>i</sub> was determined by microfluorimetry using the Ca<sup>2+</sup>-sensitive dye, fura-2. FPL 15896AR (25 and 50 μM) significantly (p<0.01) reduced the NMDA-triggered [Ca<sup>2+</sup>]<sub>i</sub> response by 33% and 45%, respectively.

The results show that FPL 15896AR protects against glutamate- and NMDA-mediated toxicity in primary cultures of rat cortical neurons. Whether it protects by reducing the NMDA-induced [Ca<sup>2+</sup>]<sub>i</sub> surge and/or by preventing the loss of PKC activity is not known.

## 530.10

**VISUALIZATION OF NMDA-INDUCED MITOCHONDRIAL CALCIUM UPTAKE IN STRIATAL NEURONS USING CONFOCAL MICROSCOPY.** T.-I. Peng\*, S.-S. Sheu, J.T. Greenamyre. Depts of Neurology and Pharmacology, University of Rochester, Rochester, NY 14642.

Impaired mitochondrial energy production increases neuronal vulnerability to NMDA excitotoxicity, in part, because ATP deficiency depresses Na<sup>+</sup>/K<sup>+</sup> ATPase function and leads to membrane depolarization. Membrane depolarization reduces the voltage dependent Mg<sup>2+</sup> blockade of NMDA channels and results in excessive activation of NMDA receptors. Mitochondria also serve as a Ca<sup>2+</sup> buffering system. Ca<sup>2+</sup> overloading may impair mitochondrial ATP synthesis and also cause free radical formation and lipid peroxidation. We examined whether NMDA receptor stimulation causes Ca<sup>2+</sup> sequestration in mitochondria of intact cultured striatal neurons. Mitochondrial Ca<sup>2+</sup> was monitored with the fluorescent probe, Rhod-2, and laser scanning confocal microscopy. A rapid increase of mitochondrial Ca<sup>2+</sup> was observed when the neurons were treated with 200 μM NMDA. Increased mitochondrial Ca<sup>2+</sup> was not seen in the presence of ruthenium red, an inhibitor of the mitochondrial Ca<sup>2+</sup> uniporter, or CCCP, a protonophore that breaks down the mitochondrial membrane potential necessary for Ca<sup>2+</sup> uptake. Mitochondrial Ca<sup>2+</sup> returned quickly to baseline if neurons were treated with NMDA for < 1 min; if treated for > 1 min, mitochondrial Ca<sup>2+</sup> remained somewhat elevated even after NMDA had been washed away for 10 min. The longer neurons were exposed to NMDA, the higher the residual mitochondrial Ca<sup>2+</sup> level observed. These data show directly that (i) Ca<sup>2+</sup> accumulates in mitochondria of intact neurons in response to NMDA receptor activation, and (ii) that the ability to normalize mitochondrial Ca<sup>2+</sup> decreases with the duration of receptor activation. Ca<sup>2+</sup> accumulation may play a role in mitochondrial dysfunction and render neurons more vulnerable to NMDA excitotoxicity. (Supported by a Mallinckrodt Scholar Award, a Markey Foundation Pilot Project Grant and the NPF Center of Excellence at the University of Rochester.)

**L-CYSTEINE AND DITHIOTHREITOL ENHANCE CYANIDE-INDUCED POTENTIATION OF NMDA RECEPTOR-ACTIVATED  $\text{Ca}^{2+}$  INFLUX.** P. Sun<sup>1</sup>, S.G. Rane<sup>2</sup>, P.G. Gunasekar<sup>1</sup> and G.E. Isom<sup>1</sup>. Depts. of <sup>1</sup>Pharmacol. & Toxicol. and <sup>2</sup>Biol. Sci., Purdue Univ., West Lafayette, IN 47907

In rat cerebellar granule cells, NMDA (50  $\mu\text{M}$  with 10  $\mu\text{M}$  glycine) stimulated a 4 fold increase of cytosolic free calcium ( $[\text{Ca}^{2+}]_i$ ). The NMDA response was potentiated 15-60% by NaCN at doses of 20-100  $\mu\text{M}$ , which alone had no effect on basal  $[\text{Ca}^{2+}]_i$ . The present study characterized in more detail the potentiation produced by cyanide. In whole cell patch clamp recordings, cyanide (100  $\mu\text{M}$ ) increased the amplitude and duration of NMDA-stimulated inward current (75% and 164%, respectively), suggesting a direct interaction of cyanide with the NMDA receptor. The involvement of sulfhydryl groups in cyanide's action was studied using microfluorescence to measure  $[\text{Ca}^{2+}]_i$  in fura-2 loaded neurons. Addition of the thio compound L-cysteine (100  $\mu\text{M}$ ) further enhanced the cyanide-induced potentiation from 27% to 66% above the NMDA-stimulated  $[\text{Ca}^{2+}]_i$  levels. In separate studies, the disulfide reducing agent dithiothreitol (DTT) at 2 mM slightly increased the NMDA response after 2 min incubation followed by washing. The DTT pre-treatment increased cyanide potentiation from 25% to 43% above the NMDA-stimulated  $[\text{Ca}^{2+}]_i$  levels. Pre-incubation with the sulfhydryl alkylating agent N-ethylmaleimide (NEM) (100  $\mu\text{M}$ ) for 2 min followed by washing resulted in attenuation of the cyanide potentiation from 25% to 9% above NMDA-stimulated  $[\text{Ca}^{2+}]_i$  levels. These results indicate that cyanide-induced potentiation of NMDA response can be modulated by sulfhydryl redox agents, suggesting the NMDA receptor sulfhydryl groups may be involved in cyanide's action. (Supported by NIEHS Grant No. 04140)

## 530.13

**ROLE OF INTRACELLULAR CALCIUM IN NEURONAL SURVIVAL TO EXCITATORY AMINOACID STIMULATION.** A. Novelli<sup>1</sup>, A. Torreblanca<sup>2</sup>, P. Losa-Uria<sup>1</sup> and M.T. Fernández-Sánchez<sup>1</sup>. Dept. Funct. Biol., Biochem. and Mol. Biol., Sch. of Med. and Dept. Philosophy and Psychol., Psychobiol., Univ. Oviedo, 33071 Oviedo, Spain.

We have investigated the effects of intracellular calcium concentration  $[\text{Ca}^{2+}]_i$  on cultured cerebellar neuron survival following exposure to excitatory aminoacids (EAAs). Glutamate (GLU) (40  $\mu\text{M}$ ), N-methyl-D-aspartate (NMDA) (100  $\mu\text{M}$ ) and domoate (DOM) (15  $\mu\text{M}$ ) but not  $\alpha$ -amino-3-hydroxy-5-methylisoxazole-4-propionate (AMPA) (100  $\mu\text{M}$ ), powerfully elicited  $[\text{Ca}^{2+}]_i$  increase, cGMP formation and neurotoxicity. AMPA antagonized DOM-mediated  $[\text{Ca}^{2+}]_i$  increase, cGMP formation and neurotoxicity. Reduction of extracellular  $\text{Ca}^{2+}$  concentration reduced both  $[\text{Ca}^{2+}]_i$  and cGMP increase by EAAs but not neurotoxicity. Moreover, the nitric oxide synthase inhibitor N<sup>G</sup>-monomethyl-L-Arginine (L-NMMA) (1 mM) prevented EAAs-mediated cGMP increase but was ineffective in reducing excitotoxicity. Most of DOM-mediated  $[\text{Ca}^{2+}]_i$  increase was reduced by nifedipine (NIF) (1  $\mu\text{M}$ ) which did not reduce DOM toxicity. Culture exposure to high KCl (50 mM) significantly increased  $[\text{Ca}^{2+}]_i$  and cGMP levels but did not produce neurotoxicity when MK-801 (1  $\mu\text{M}$ ) was present. Similar results were obtained following addition of the L-type voltage sensitive calcium channel agonist S(-)-BAY-K8644 (1  $\mu\text{M}$ ). Long-term (15 days) culture exposure to either high KCl or S(-)-BAY-K8644 did significantly increase glucose consumption. Such increase was abolished by reducing extracellular  $\text{Ca}^{2+}$  concentration. Long-term exposure to either high KCl or S(-)-BAY-K8644 did not significantly reduce  $[\text{Ca}^{2+}]_i$  increase in response to either GLU or DOM but significantly reduced excitotoxicity. Neuroprotection was abolished by reducing either extracellular or intracellular  $\text{Ca}^{2+}$  concentration, or by treatment with protein synthesis inhibitors. We conclude that in cultured cerebellar neurons excitotoxicity is independent of  $[\text{Ca}^{2+}]_i$  increase, and elevated  $[\text{Ca}^{2+}]_i$  may be important to the development of a protein synthesis-dependent excitoprotective mechanism. Such mechanism does not appear to involve EAA receptor desensitization, nor nitric oxide production. This work was supported by CICYT, grant SAL91-0613 & SAF94-0394

## 530.12

**CHANGES IN INTRACELLULAR FREE CALCIUM LEVELS DURING DELAYED EXCITOTOXICITY AND RESCUE IN NT2-N NEURONS.** M. Munir<sup>1</sup>, M.C. LaPlaca<sup>1</sup>, L.E. Thibault<sup>1</sup> and P. McGonigle<sup>2</sup>. Depts. of Pharmacology and Bioengineering, University of Pennsylvania, Philadelphia, PA 19104.

Using digitized videomicroscopy,  $\text{Ca}^{2+}$ -sensitive dye fura-2 and release of lactate dehydrogenase (LDH), mechanisms of  $\text{Ca}^{2+}$  regulation during the delayed phase of excitotoxicity and their relationship to cell death were examined in the NT2-N clonal line of human neurons. Exposure to 1 mM glutamate caused a rapid elevation in the  $[\text{Ca}^{2+}]_i$  which was sustained as long as glutamate was present in the media. After termination of a 15 min exposure to 1 mM glutamate  $[\text{Ca}^{2+}]_i$  declined gradually and reached near basal levels in 40-60 min. Removal of extracellular  $\text{Ca}^{2+}$  after termination of a 15 min exposure to 1 mM glutamate caused a sharp decrease in  $[\text{Ca}^{2+}]_i$  which recovered to resting levels within 10 min. Removal of extracellular  $\text{Ca}^{2+}$  for 3 hr following glutamate exposure also prevented glutamate-mediated toxicity. Blockade of NMDA receptors with dizocilpine (MK-801) or by lowering the extracellular pH, produced a faster recovery of  $[\text{Ca}^{2+}]_i$  to near basal levels similar to the one produced by removal of extracellular  $\text{Ca}^{2+}$  and also rescued the cells from excitotoxic cell death. Blockade of non-NMDA channels with 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX) or voltage-gated channels with nimodipine did not alter the time course of recovery of  $[\text{Ca}^{2+}]_i$  to basal levels and did not rescue the cells from glutamate toxicity. These observations indicate that  $\text{Ca}^{2+}$  influx occurring through the NMDA receptors during the delayed phase of rapidly triggered excitotoxicity plays a critical role in determining the final outcome of the initial glutamate insult. Influx of  $\text{Ca}^{2+}$  through non-NMDA and voltage-gated  $\text{Ca}^{2+}$  channels did not play a critical role during the delayed phase of toxicity. (Supported by NS-08803 and GM-34781)

## 530.14

**CATION DEPENDENCE OF EXCITOTOXIC GLUTAMATE-INDUCED INHIBITION OF CaM KINASE II ACTIVITY.** S.B. Churn<sup>1</sup> and R.J. DeLorenzo<sup>2</sup>. Department of Neurology, Medical College of Virginia, Richmond, VA 22298

Excitotoxic glutamate exposure results in an immediate osmotic lysis and a delayed,  $\text{Ca}^{2+}$ -dependent neuronal cell death. The  $\text{Ca}^{2+}$  dependence of delayed neuronal cell death prompted the investigation of  $\text{Ca}^{2+}$  regulated neuronal enzyme systems that may be involved in mediating delayed neuronal cell death.  $\text{Ca}^{2+}$ /calmodulin-dependent kinase II (CaM kinase II) is a neuronally enriched,  $\text{Ca}^{2+}$ -regulated effector system. CaM kinase II activity is significantly inhibited following excitotoxic glutamate exposure. The excitotoxic glutamate-induced inhibition of CaM kinase II activity has been shown to be dependent upon NMDA receptor stimulation and influx of  $\text{Ca}^{2+}$ . The present study was designed to determine whether stimulation of CaM kinase II was necessary for glutamate-induced inhibition of kinase activity. Excitotoxic glutamate exposure (500  $\mu\text{M}$ , 10 min) was performed under standard conditions (2 mM  $\text{Ca}^{2+}$ ) or with  $\text{Ca}^{2+}$  replaced by other cations. The cations were chosen for ability to enter neurons and ability to replace  $\text{Ca}^{2+}$  in calmodulin stimulation (Chao et al. 1984 Mol. Pharm. 26:75). Cations that supported calmodulin-dependent activity also supported glutamate-induced inhibition of kinase activity (e.g.  $\text{Sr}^{2+}$  69.4% control activity,  $n = 6$ , and  $\text{Mn}^{2+}$  63.9% control,  $n = 4$ ). However, replacing  $\text{Ca}^{2+}$  with cations that do not support calmodulin-dependent activity such as  $\text{Ba}^{2+}$  (94.1% control,  $n = 6$ ) or  $\text{Co}^{2+}$  (84.6% control,  $n = 4$ ), or omitting  $\text{Ca}^{2+}$  alone (99.8% control,  $n = 6$ ) protected kinase activity following glutamate exposure. A positive correlation was observed between ability to support calmodulin-dependent activity and ability to support glutamate-induced inhibition of kinase activity. The data support the conclusion that glutamate-induced inhibition of kinase activity occurs via a calmodulin-dependent process.

## GABA RECEPTORS III

## 531.1

**ALLOSTERIC MODULATORS OF THE GABA<sub>A</sub> RECEPTOR: DIFFERENTIAL INTERACTION OF BENZODIAZEPINES AND NEUROACTIVE STEROIDS WITH ETHANOL.** M. Suruki<sup>1</sup>, S. Robledo<sup>1</sup>, S. Wieland<sup>1</sup>, N.C. Lan<sup>1</sup>, K.W. Gee<sup>2</sup>, P.L. Wood<sup>1</sup> and R.B. Carter<sup>1</sup>. Dept. Pharmacology, <sup>1</sup>CoCensys and <sup>2</sup>Univ. of California, Irvine, CA 92718.

Pregnane steroids allosterically modulate GABA<sub>A</sub> receptor function in a manner similar to that of benzodiazepines, though acting at a distinct recognition site. Accordingly, neuroactive steroids exhibit pharmacologic properties similar to those of benzodiazepines, such as anticonvulsant, anxiolytic, and sedative-hypnotic activity. Inasmuch as positive allosteric modulators of GABA<sub>A</sub> receptor function exhibit profound interactions with ethanol, the effects of two endogenous neuroactive steroids, 3 $\alpha$ -OH, 5 $\alpha$ -pregnan-20-one (3 $\alpha$ ,5 $\alpha$ -P) and 3 $\alpha$ -OH, 5 $\beta$ -pregnan-20-one (3 $\alpha$ ,5 $\beta$ -P), were compared to those of two benzodiazepines, alprazolam and diazepam, on the motor function of rats when administered either alone or in combination with ethanol. Dose-dependent decreases in rotarod performance were obtained for all compounds (i.p.). Benzodiazepines (alprazolam,  $\text{TD}_{50}=3.2$ ; diazepam  $\text{TD}_{50}=7.4$ ) were more potent than neuroactive steroids (3 $\alpha$ ,5 $\alpha$ -P,  $\text{TD}_{50}=21.2$ ; 3 $\alpha$ ,5 $\beta$ -P,  $\text{TD}_{50}=22.8$ ) in this regard. When administered in combination with a subhypnotic, subataxic dose of ethanol (1.0 g/kg, i.p.), dose-response curves for the effect of the benzodiazepines on rotarod performance were shifted to the left by a factor of 10 (alprazolam,  $\text{TD}_{50}=0.3$ ; diazepam  $\text{TD}_{50}=0.8$ ). In contrast, the ataxic properties of the neuroactive steroids were unaffected by concomitant ethanol administration (3 $\alpha$ ,5 $\alpha$ -P,  $\text{TD}_{50}=29.3$ ; 3 $\alpha$ ,5 $\beta$ -P,  $\text{TD}_{50}=18.2$ ). These data indicate that positive allosteric modulators of the GABA<sub>A</sub> receptor differ with respect to their interaction with ethanol.

## 531.2

**Modulation of GABA<sub>A</sub> Receptors by Neurosteroids, Benz[e]indenes, and Their Enantiomers** L.L. Wittmer, C.F. Zorumski<sup>1</sup>, M. Kalkbrenner, A.S. Evers, Y. Hu, D.F. Covey. Depts. of Psychiatry, Anesthesiology, and Mol. Bio. & Pharmacology, Washington Univ. Sch. of Med., St. Louis, MO 63110.

Modulation of the GABA<sub>A</sub> receptor complex is thought to play a role in steroid anesthesia. We have used a series of compounds including (+) and (-) enantiomers of neurosteroids and benz[e]indenes as molecular probes for a putative steroid binding site on GABA<sub>A</sub> receptors. Compounds were assayed for their effects on GABA-mediated  $\text{Cl}^-$  currents in cultured rat hippocampal neurons and for their potency as anesthetics in a tadpole righting-reflex assay. Results indicate that (-) enantiomers are markedly less effective at potentiating the effects of GABA on GABA<sub>A</sub>  $\text{Cl}^-$  currents than the (+) enantiomers, in the most extreme case showing a 10-fold difference. Unlike the (+) enantiomers, the (-) enantiomers do not gate GABA<sub>A</sub> channels at concentrations up to 200  $\mu\text{M}$ . Both the (+) and (-) enantiomers are anesthetics in the tadpole assay; however the (-) enantiomers are strikingly less potent than the (+) enantiomers. These data provide strong evidence for the existence of an enantioselective neurosteroid binding site on GABA<sub>A</sub> receptors and suggest that direct gating of  $\text{Cl}^-$  currents by the compounds studied is not required for anesthetic effects.

## 531.3

**ANXIOLYTIC PROPERTIES OF THE NOVEL ORALLY-ACTIVE NEUROSTEROID CO 6-0549.** R.B. Carter<sup>1</sup>, S. Wieland<sup>1</sup>, N.C. Lan<sup>1</sup>, H. Xia<sup>2</sup>, J.D. Belluzzi<sup>3</sup>, L. Stein<sup>3</sup>, K.W. Gee<sup>3</sup>, and P.L. Wood<sup>1</sup>. Depts. <sup>1</sup>Pharmacol. and <sup>2</sup>Chem., CoCensys and <sup>3</sup>Dept. Pharmacol., Univ. of Calif., Irvine, CA 92718.

Neuroactive steroids are allosteric modulators of the GABA<sub>A</sub> receptor that act at a novel recognition site. Co 6-0549 is a water-soluble, orally-bioavailable neuroactive steroid prodrug, the parent of which has been demonstrated by binding and electrophysiology to be a potent modulator of the GABA<sub>A</sub> receptor. The anxiolytic-like properties of Co 6-0549 and alprazolam were characterized in the rat Geller-Seifter test. Co 6-0549 (2.0-64.0 mg/kg, p.o.) produced dose-related increases in responding under punished and unpunished components. The minimum effective dose (MED) for activity on punished responding (20-shock increase over control) was 4.8 mg/kg. Unpunished responding was suppressed to 25% of control levels at 40.1 mg/kg, yielding a therapeutic index (TI) of 8.4. In comparison alprazolam (2.0-64.0 mg/kg, p.o.) exhibited an MED of 4.1 mg/kg and a TI of 11. Neither Co 6-0549 nor alprazolam exhibited tolerance upon chronic administration (2X MED, daily, 14 days); however, whereas the maximum effects of alprazolam on punished responding required 2-3 days to develop, Co 6-0549 produced full anxiolytic-like effects following a single administration. The ataxic effects of Co 6-0549 (40.0-100.0 mg/kg, p.o.) and alprazolam (1.0-20.0 mg/kg, p.o.) were compared using the rat rotarod procedure. Whereas alprazolam impaired rotarod performance at a dose 3.2 times its MED in the Geller-Seifter (TD<sub>50</sub>=13.3), Co 6-0549 did so at a dose 16 times its MED (TD<sub>50</sub>=76.9). Moreover, inasmuch as a subhypnotic dose of ethanol (1.0 g/kg, i.p.) administered in combination, markedly potentiated alprazolam's ataxic effects (TD<sub>50</sub>=4.4), Co 6-0549 was less affected and retained a good therapeutic index (TD<sub>50</sub>=55.0; TI=11.5). These data suggest that Co 6-0549 may offer clinically-relevant advantages over current drugs.

## 531.5

**BRAIN ALLOPREGNANOLONE (AP) CONCENTRATIONS AND GABA<sub>A</sub> RECEPTOR FUNCTION IN STRESSED RATS.** M.L. Barbaccia\*, G. Roscetti, M. Trabucchi, A. Concas#, L. Dazzi#, R.H. Purdy\* and G. Biggio#. Dept. Exp. Med. Univ. of Rome "Tor Vergata"-00133 Rome-Italy, \*Dept. Psych. UCSD- San Diego, CA 92161-USA and# Dept. Exp. Biol. Univ. of Cagliari-09123 Cagliari-Italy.

Acute stress (CO<sub>2</sub> inhalation, foot shock) increased rat brain cortical steroid concentrations. Two temporal patterns were observed after CO<sub>2</sub>: a) progesterone and deoxycorticosterone were maximally increased (9 and 4 folds, respectively) 10 min following stress and decreased thereafter; b) pregnenolone and AP levels peaked (+170% and +200%, respectively) 30 min post-stress, were still high at time 60 and returned to control values by 120 min. The same stress paradigm elicited an alteration in CNS GABA<sub>A</sub> receptor function that was specular, with respect to the time course, to the changes in brain AP content. <sup>35</sup>S-TBPS binding was maximally increased, +51%, and punished responding score in the Vogel's test was decreased, -40%, 10 min after stress. The behavioral response declined more rapidly, reaching control values by 60 min, while <sup>35</sup>S-TBPS binding returned to control values by 120 min. Moreover, the immediate increase in brain cortical dopamine release evoked by foot shock (that also increased brain neurosteroids) was blunted by AP (5 ug, i.c.v.). These results suggest a physiological role for AP in the modulation of the CNS response to acute stress.

## 531.7

**BINDING CHARACTERISTICS OF [<sup>3</sup>H]ABECARNIL IN THE RAT CEREBRAL CORTEX.** A.K. Mehta\* and R.P. Shank. Drug Discovery, The R. W. Johnson Pharmaceutical Research Institute, Spring House PA 19477-0776, USA.

Abecarnil is a GABA-based anxiolytic, and is less sedating and less prone to cause motor incoordination than traditional benzodiazepine (BZ) receptor agonists. We have previously reported that abecarnil inhibits the binding of [<sup>3</sup>H]Ro 15-4513, [<sup>3</sup>H]Ro 15-1788, and [<sup>3</sup>H]flunitrazepam with a slope factor >1 in the rat cerebellum and cerebral cortex. In this study, we have characterized the binding of [<sup>3</sup>H]abecarnil (0.1-300 nM) to membranes prepared from the rat cerebral cortex. Binding reached equilibrium within 20 min at 22°C. Nonspecific binding to the biological and non-biological material accounted for ~50% of total binding. Several procedures, e.g., presoaking the filtermats with polyethylenimine, increasing the filtration washes and employing different filtration temperatures (2°C, 22°C, 37°C), were used in an attempt to reduce the nonspecific binding but there was no substantial improvement. A curve-fit analysis of saturation binding data revealed an apparent K<sub>d</sub> of 0.60 ± 0.21 nM and B<sub>max</sub> of 2.8 ± 0.7 pmol/mg protein (n = 9) at 22°C. A good fit between actual and predicted specific binding was obtained only when the equation to which the data were fitted contained a saturable site with a slope factor >1. Whether this reflects positive cooperativity in the binding of abecarnil to GABA<sub>A</sub> receptors, or an artifact arising from the high degree of nonspecific binding is unclear. The calculated K<sub>d</sub> value for abecarnil is similar to the IC<sub>50</sub> value obtained for the inhibition of [<sup>3</sup>H]Ro 15-4513 binding by unlabeled abecarnil (0.60 ± 0.21 nM vs 0.85 ± 0.24 nM). The B<sub>max</sub> value is also similar to those obtained for [<sup>3</sup>H]Ro 15-4513, [<sup>3</sup>H]Ro 15-1788 and [<sup>3</sup>H]flunitrazepam in the rat cerebral cortex (2.8 ± 0.7 vs 2.3 ± 0.6, 2.3 ± 0.5 and 2.7 ± 0.6 pmol/mg protein, respectively).

## 531.4

**DIFFERENTIAL SENSITIVITY OF SYNAPTIC GABAERGIC CURRENTS TO A NEUROACTIVE STEROID IN BRAIN SLICES FROM MALE RATS**  
E.J. Cooper, G.A.R. Johnston\*, F.A. Edwards Dept. Pharmacology, University of Sydney, N.S.W., 2006, AUSTRALIA

The concentration of the neuroactive steroid tetrahydrodeoxycorticosterone (THDOC, 5α-pregnane-3α,21-diol-20-one), in the rat brain is increased in response to conditions of mild stress. Micromolar concentrations of this steroid and other similar steroids have been reported to potentiate responses to the inhibitory neurotransmitter GABA, in isolated neurons. We have investigated the effects of more physiological levels of THDOC on synaptic GABA currents (in CNQX, 10μM and TTX, 1μM). Whole cell patch-clamp recordings were made from hippocampal dentate granule cells and cerebellar Purkinje cells in slices taken from the same animal for comparison. In all cells 1-2μM THDOC caused a rapid reversible increase in the decay time of GABA currents, with no effect on amplitude or rise time. The control currents in Purkinje cells showed a much more rapid decay (decay to half amplitude, T50% = 9.4 ± 1.1ms, n=14) than hippocampal granule cells (T50% = 21.0 ± 0.7ms, n=16). After potentiation the decay times from the two cell types were not significantly different (T50% ~ 80ms, 2μM THDOC, all groups). Thus the percentage potentiation was considerably greater in Purkinje cells (PC) than in hippocampal granule cells (HG) at these high concentrations (PC 900% vs HG 400%, 10-13 day old rats). Comparison was made between different age groups in both cell types (10-13days vs 18-21days). A significantly higher sensitivity to THDOC was found in hippocampal granule cells from the younger group than any of the other of the three groups with an increase of 29 ± 1.3% (n=6) in decay time at 50nM. This was the only group significantly affected by this low, more physiological level, of THDOC, although GABA synaptic currents in Purkinje cells from younger rats were also more sensitive to neuroactive steroids than the older group. It is suggested that the differences seen may be due to different regional and age specific distributions of GABA<sub>A</sub>-receptor subunits.

## 531.6

**NEUROSTEROID POTENTIATION OF A GABA-WITHDRAWAL SYNDROME.** E. Calixto, T. Montiel and S. Brailowsky\*. Instituto de Fisiología Celular, U.N.A.M., 04510 México D.F., MEXICO

The GABA-withdrawal syndrome (GWS) is a model of partial epilepsy which depends, for its induction, of GABA receptor activation. Paroxysmal activity appears at the intracerebral infusion site a short time after aminoacid discontinuation (min to hrs) and lasts for days. We have studied the neuromodulatory effect of the neurosteroid (NE) 3α-hydroxi-5α-pregnan-20-one (allopregnanolone) in this paradigm. In rats prepared for chronic EEG recording and intracortical microinfusions, the instillation of the NE alone or of its antagonist (a sulfate derivative), had no effects; however, when the NE was administered before or concurrently with GABA, we observed a potentiation of the GWS: shorter latency for paroxysmal discharges to appear (from 91.2 ± 2.28 min in the GABA-only group to 56.2 ± 6.1 min in the GABA+NE group) and prolonged duration (from 7.4 ± 0.2 days in the GABA-only group to 9.7 ± 0.4 days in the GABA+NE group).

These results indicate a neuromodulatory effect of allopregnanolone on GWS, which is dependent on the presence of GABA at the receptor site.

Supported in part by DGAPA-UNAM and by CONACYT, Mexico.

## 531.8

**ANDROGENIC:ANABOLIC STEROID INTERACTIONS WITH THE GABA<sub>A</sub>-BZ RECEPTOR COMPLEX** A.E.T. Masonis and M.P. McCarthy\*. CABM/RWJMS-UMDNJ, Piscataway, N.J., 08854.

We describe the complex interactions of two androgenic-anabolic steroids (AAS), 17α-methyltestosterone (17α-MT) and stanozolol, with at least three major binding sites on the γ-aminobutyric acid<sub>A</sub>-benzodiazepine receptor (GABA<sub>A</sub>-BZ receptor) complex. Interestingly, the effects of the AAS on BZ binding to synaptoneurosomes from male and female rat cortex, hippocampus, and olfactory bulb were differentially sensitive to the binding of endogenous GABA. Additionally, the magnitude of the GABA-insensitive component of the AAS effects differed between brain regions. The AAS 17α-MT had both enhancing and inhibitory effects on BZ binding, depending upon the selectivity of the BZ ligand and the brain region tested. Conversely, the AAS stanozolol acted as a potent, strict inhibitor of high affinity BZ binding. The effects of stanozolol on the binding of the GABA<sub>A</sub> receptor ligands [<sup>3</sup>H]muscimol and [<sup>3</sup>H]TBPS were also determined. Stanozolol enhanced both 25nM [<sup>3</sup>H]muscimol binding to cortical synaptoneurosomes and 5nM [<sup>35</sup>S]TBPS binding to purified cerebrocortical membranes. Stanozolol-mediated enhancement of 5nM [<sup>35</sup>S]TBPS binding was lost upon the addition of exogenous GABA. Our results are consistent with the interaction of stanozolol with a novel, GABA-sensitive stabilization site on the GABA<sub>A</sub>-BZ receptor complex.

## 531.9

ISOLATION OF AN ENDOGENOUS INHIBITOR WITH AGONISTIC ACTION ON BENZODIAZEPINE RECEPTORS. S. Fiszer de Plazas\*, M. C. Gravielle, C. Peña and L. Pignataro. Instituto de Biología Celular, Facultad de Medicina and IQUIFIB, Facultad de Farmacia y Bioquímica, Universidad de Buenos Aires, Paraguay 2155 (1121) Buenos Aires, Argentina.

In a previous work we have described the time-course of appearance of an endogenous material capable of displacing [ $^3$ H]Flunitrazepam binding from benzodiazepine (BZD) receptor sites present in the developing chick optic lobe (*NeuroReport*, 5: 1957, 1994). The aim of the present study was to purify and determine the pharmacological action of this endogenous inhibitor. The endogenous factor was isolated from synaptic membranes of chick optic lobes. The purification was performed by means of several steps of high performance liquid chromatography with C18 and C4 phase reverse columns. The effect of GABA on the inhibition of [ $^3$ H]Ro 15-1788 binding by compounds which bind to BZD receptors could predict whether their pharmacological actions would be agonistic or antagonistic to the actions of benzodiazepines (GABA "shift" test). In this work we observed that  $10^{-6}$  M GABA potentiated the inhibition of [ $^3$ H]Ro 15-1788 binding by the endogenous compound. These results demonstrated that the endogenous inhibitor possess the properties of an agonist of the BZD receptor.

## 531.11

KOJIC AMINE: A PARTIAL AGONIST OF THE GABA<sub>A</sub> RECEPTOR. Y. T. Lee, T. T. Gibbs\* and D. H. Farb. Laboratory of Molecular Neurobiology, Department of Pharmacology, Boston University School of Medicine, Boston, MA 02118.

Although benzodiazepine, barbiturate, and neurosteroid modulators of the  $\gamma$ -aminobutyric acid A receptor (GABA<sub>A</sub> R) have been characterized in detail, GABA<sub>A</sub> R agonists have been much less studied, with the exception of GABA and muscimol, both of which appear to be full agonists. Partial agonists may be useful as probes of GABA<sub>A</sub> R diversity, and may have clinical value if they produce less desensitization than full agonists. A number of drugs have been suggested to be partial GABA<sub>A</sub> R agonists, but few of these have been extensively studied electrophysiologically. Using whole cell voltage clamp recording of chick spinal cord neurons in primary tissue culture, we measured the potency and efficacy of a series of GABA<sub>A</sub> R agonists. Of these, THIP, 3-aminopropane sulfonic acid, and isoguvacine produced maximal responses smaller than that of GABA, but these drugs elicited an "off-response" upon washout. This suggests that the lower maximum response to these agonists is due to an action at a secondary inhibitory site, from which the drug dissociates more rapidly than from the agonist recognition site. This may also explain why the responses to these agonists appear to desensitize rapidly, in spite of a smaller peak amplitude. In contrast, kojic amine has characteristics expected of a partial agonist at the GABA site. The kojic amine response is inhibited by the competitive GABA<sub>A</sub> antagonist SR-95531, and the maximum response to kojic amine is about half that of GABA. When applied in combination with GABA, kojic amine inhibits the GABA response, and this inhibition may be surmounted by increasing the concentration of GABA, consistent with a competitive mechanism. We conclude that kojic amine is a partial agonist of the GABA<sub>A</sub> R of chick spinal cord neurons.

## 531.13

SELECTIVE MODULATION OF FAST AND SLOW GABA<sub>A</sub> RESPONSES IN THE RAT HIPPOCAMPUS BY VOLATILE ANESTHETICS. R. A. Pearce\*, Depts. of Anesthesiology and Anatomy, Univ. Wisconsin, Madison.

Paired-pulse depression (PPD) of the evoked population spike *in vivo* is prolonged by many anesthetics, including volatile agents such as halothane. This action is thought to be due to enhancement of GABA<sub>A</sub>-mediated feedback inhibition. Spontaneous IPSCs are prolonged by halothane, but their duration (7 ms prolonged to 20 ms) is an order of magnitude faster than PPD (70 ms prolonged to 200 ms). The present study tested the effect of two volatile anesthetics, halothane and enflurane, on fast and slow components of the evoked GABA<sub>A</sub> current, to determine if their effect on PPD could be due to prolongation of the slow component.

Evoked monosynaptic IPSCs were obtained by stimulating in the pyramidal (SP) and molecular (SL-M) layers to elicit GABA<sub>A,fast</sub> and GABA<sub>A,slow</sub>. Glutamate antagonists APV (40  $\mu$ M) and CNQX (20  $\mu$ M) were present in the perfusate, and recordings were made with 3M CsAc and 50 mM QX-314 in the electrodes. Volatile anesthetics at a concentration of 2 MAC were applied in the interface configuration.

Halothane and enflurane prolonged the decay of the slow dendritic IPSC, to approximately twice control, but did not alter the response amplitude. Halothane also prolonged the duration of the fast somatic IPSC, to over three times control, without affecting its amplitude. However, enflurane markedly reduced the amplitude of the fast somatic response, in some cases apparently eliminating the response completely, so that only a small slow component remained following SP stimulation.

It is concluded that anesthetics enhance PPD by prolonging the decay of the slow dendritic GABA<sub>A</sub> response. Furthermore, it is speculated that the pro-convulsant property of enflurane is related to its reduction of the fast somatic component of GABA<sub>A</sub> inhibition.

This work was supported by NS-01548 from NINDS.

## 531.10

3 $\alpha$ ,21-DIHYDROXY-5 $\beta$ -PREGNAN-20-ONE (5 $\beta$ -THDOC) SHARES THE SAME SITE AS 3 $\alpha$ -HYDROXY-5 $\alpha$ -PREGNAN-20-ONE (3 $\alpha$ ,5 $\alpha$ -P) IN THE MODULATION OF GABA ACTION AT THE GABA<sub>A</sub> RECEPTOR COMPLEX. B.G. Xue, R. Woodward<sup>1</sup>, C.H. Park, N.C. Lan and K.W. Gee\*, Department of Pharmacology, College of Medicine, University of California, Irvine and <sup>1</sup>Acea Pharmaceuticals, a subsidiary of CoCensys Inc., Irvine, CA 92718.

The allosteric modulation of [ $^{35}$ S]TBPS binding by the endogenous neuroactive steroids 3 $\alpha$ ,5 $\alpha$ -P and 5 $\beta$ -THDOC was studied in the rat cortex. Relative to 3 $\alpha$ ,5 $\alpha$ -P, 5 $\beta$ -THDOC has been observed to have limited efficacy as an allosteric modulator of [ $^{35}$ S]TBPS binding. Interactions between 3 $\alpha$ ,5 $\alpha$ -P and 5 $\beta$ -THDOC were examined to determine whether both neurosteroids share a common site in the modulation of [ $^{35}$ S]TBPS binding. Increasing concentrations of 5 $\beta$ -THDOC antagonized the action of 3 $\alpha$ ,5 $\alpha$ -P by shifting the concentration-response curves of 3 $\alpha$ ,5 $\alpha$ -P modulation of [ $^{35}$ S]TBPS binding to the right. Schild analysis of the data reveals that 5 $\beta$ -THDOC competitively antagonized the effect of 3 $\alpha$ ,5 $\alpha$ -P on [ $^{35}$ S]TBPS binding. 5 $\beta$ -THDOC also antagonized the potentiation of GABA-evoked chloride currents by maximally stimulating concentrations of 3 $\alpha$ ,5 $\alpha$ -P. Behavioral studies with 3 $\alpha$ ,5 $\alpha$ -P reveal the ability of 5 $\beta$ -THDOC to act as an antagonist of 3 $\alpha$ ,5 $\alpha$ -P under certain conditions. Collectively these findings support the hypothesis that 5 $\beta$ -THDOC may act as a partial agonist at the same site as 3 $\alpha$ ,5 $\alpha$ -P in the modulation of the GABA<sub>A</sub> receptor complex. (Supported by a grant from CoCensys Inc.)

## 531.12

MULTIPHASIC EFFECTS OF ALLOSTERIC MODULATORS ON GABA WHOLE-CELL CURRENTS IN ACUTELY DISSOCIATED HIPPOCAMPAL CA1 PYRAMIDAL CELLS. E.I. Tietz<sup>1,2</sup>, J. Kapur<sup>1</sup>, N. Esmail<sup>1</sup> and R.L. Macdonald<sup>1,2\*</sup>, Departments of Neurology<sup>1</sup> and Physiology<sup>2</sup>, University of Michigan, Ann Arbor, MI, 48105 and Department of Pharmacology<sup>2</sup>, Medical College of Ohio, Toledo, OH 43699.

The hippocampus contains multiple GABA<sub>A</sub> receptor (GABA<sub>A</sub>) subunit mRNAs.  $\alpha$ 1,  $\alpha$ 2,  $\alpha$ 3,  $\alpha$ 4,  $\alpha$ 5,  $\beta$ 1,  $\beta$ 2 and  $\gamma$ 2 subunit mRNAs are in high abundance.  $\alpha$ 3,  $\alpha$ 4 and  $\beta$ 2 mRNAs are moderately expressed, whereas  $\alpha$ 6 and  $\delta$  mRNAs are absent. The effects of GABA and several allosteric modulators (diazepam (DZP); zolpidem (ZOL); DMCM and lorelecrole (LOR)) on native GABA<sub>A</sub> receptors in hippocampus were studied. Whole-cell recordings were obtained from acutely dissociated CA1 pyramidal cells using standard whole-cell patch clamp techniques ( $V_h = -50$  mV). Patch pipettes contained 130 mM KCl ( $E_{Cl} = 0$  mV) and an ATP regenerating system. GABA (1  $\mu$ M-3 mM) evoked inward currents ( $EC_{50} = 10.2$   $\mu$ M; Peak current = 750 pA,  $n = 12$ ). In 20% of cells, GABA responses suggested the presence of GABA<sub>A</sub> receptors with two GABA affinities. Modulator effects on 10  $\mu$ M GABA currents were multiphasic. DZP potentiated GABA responses at two high affinity sites ( $EC_{50} = 2.3$  and 236 nM, 8 cells) by 25% and 60%. ZOL (0.3 nM-10  $\mu$ M) inhibited GABA currents at low nM concentrations and potentiated GABA<sub>A</sub> currents at higher concentrations. The inhibitory effects of ZOL, 1-100 nM, but not 1  $\mu$ M, were reversed by 1  $\mu$ M flumazenil, suggesting inverse agonist-like activity. DMCM (0.3 nM-30  $\mu$ M) inhibited GABA currents in 4/8 cells up to 55%. DMCM (0.3-100 nM & 20  $\mu$ M) potentiated GABA currents by 10-45% in 4/8 cells. LOR, which preferentially acts at recombinant GABA<sub>A</sub> receptors with  $\beta$ 2/3 subunits, potentiated GABA currents in 5 of 6 cells. The heterogeneous responses of CA1 neurons to GABA and to allosteric modulators suggests that functional GABA<sub>A</sub> receptors are assembled from those subunits with highly expressed mRNAs and that individual CA1 pyramidal cells contain GABA<sub>A</sub> receptors with  $\alpha$  subunit heteromers and/or that multiple subtypes of GABA<sub>A</sub> receptors exist in a single neuron.

## 531.14

PHARMACOLOGICALLY-DISTINCT GABA<sub>B</sub> RECEPTORS MODULATE CAMP ACCUMULATION IN A MODEL OF COINCIDENT SIGNALING. Cunningham, M.D.\* and Enna, S.J. Department of Pharmacology, Toxicology and Therapeutics, Kansas University Medical Center, Kansas City, Kansas 66160.

GABA<sub>B</sub> receptors, coupled through pertussis toxin-sensitive G proteins, modulate presynaptic neurotransmitter release, Ca<sup>2+</sup> and K<sup>+</sup> conductance, and cAMP production. GABA<sub>B</sub> receptor activation by baclofen attenuates forskolin-induced cAMP production and augments the effect of various neurotransmitters or drugs that stimulate production of cAMP through interaction with membrane-bound receptors coupled to G proteins. The dual effects of baclofen on cAMP accumulation has led to the suggestion that there exists multiple GABA<sub>B</sub> receptor subtypes. While biochemical and electrophysiological studies are generally supportive, pharmacological evidence for two GABA<sub>B</sub> receptors associated with cAMP production is lacking.

In the present study the influence of three GABA<sub>B</sub> receptor agonists and five antagonists on rat brain cAMP production was examined. While all of the agonists are equipotent with respect to inhibiting the cAMP response to forskolin and augmenting the isoproterenol-stimulated second messenger production, there is a 30-fold difference ( $P < 0.05$ ) in the potency of the antagonist CGP 52432 to inhibit the effects of baclofen in the two systems. Two other recently-synthesized GABA<sub>B</sub> antagonists, SCH 50911 and CGP 54626a, exhibited over a ten-fold difference in potency. These data support the notion that distinct GABA<sub>B</sub> receptor subtypes mediate these effects in brain.

(Supported in part by a grant from Marion Merrell Dow).

## 531.15

ANTAGONISM OF PRESYNAPTIC GABA<sub>B</sub> RECEPTORS BY CGP35348 AND CGP52432. K.M. Syd\*<sup>1</sup>, J.A. Falchetto, and A.L. Padien, Department of Pharmacology, McGill University, Montréal, Québec, H3G1Y6, CANADA

Previous work in this laboratory has identified GABA<sub>B</sub> receptor-mediated responses on primary afferent (PA) terminals in amphibian spinal cord [agonist rank order: L-baclofen, kojic amine, and GABA; hyperpolarizing - mediated by a K<sup>+</sup> permeability increase; bicuculline insensitive; poorly antagonized by phaclofen; not recorded from large myelinated axons]. Other evidence suggests that subtypes of GABA<sub>B</sub> exist in CNS both pre- and postsynaptically. The objective of this study was to examine the pharmacology of the GABA<sub>B</sub> receptors on PA using putative GABA<sub>B</sub> antagonists with presumably selective sites of action.

Experiments were done on isolated amphibian spinal cord, using sucrose gap (membrane and evoked potentials from dorsal or ventral roots, DR/VR) and intra-axonal (from single large myelinated axons) recordings in the presence of 2  $\mu$ M TTX. Concentration dependant reversible responses to 5  $\mu$ M L-baclofen were blocked 100% by CGP35348 at 30  $\mu$ M (selective for somatic GABA<sub>B</sub> receptors); and 50% by CGP52432 at 0.1  $\mu$ M (100x more potent than CGP35348, selective for autoreceptors).

The effects of the antagonists on synaptic activity were variable. CGP52432 had no effect on amplitude or duration of DR-DRP, DR-VRP, or VR-DRPs at concentrations up to 5  $\mu$ M, though CGP35348 showed a 15% increase in DR-DRP and DR-VRP amplitude at 60  $\mu$ M. The antagonists also increased the frequency of spontaneous excitatory synaptic activity.

The results demonstrate that CGP35348 and CGP52432 have different blocking properties on presynaptic GABA<sub>B</sub> receptors. The variable proconvulsant effects of the antagonists (on evoked and spontaneous synaptic activity) suggest a GABA<sub>B</sub>-mediated inhibitory pathway activated by DR stimulation. ## 531.17

THE POSTSYNAPTIC CONDUCTANCE LINKED TO GABA<sub>A</sub> RECEPTORS ACTIVATED BY ENDOGENOUSLY RELEASED TRANSMITTER. L. Mody\* and Y. De Koninck. Dept. of Neurology, UCLA Sch. of Medicine, Los Angeles, CA, and Dept. of Anesthes./Pain Mgmt. UT Southwestern Med. Ctr., Dallas, TX.

In the hippocampus, activation of postsynaptic GABA<sub>A</sub> receptors generally requires stimulation of the presynaptic terminals with a stimulus intensity greater than that necessary to elicit GABA<sub>A</sub> responses. The large stimulus intensities may be required to activate extrasynaptic GABA<sub>A</sub> receptors or to release another neurotransmitter necessary for the activation of these receptors. To establish the relative contribution of endogenously released GABA to the activation of GABA<sub>A</sub> and GABA<sub>B</sub> receptor-mediated IPSCs we depleted GABA levels through inhibition of its synthesizing enzyme, glutamic acid decarboxylase (GAD).

Isonicotinic hydrazide (isoniazid, INH; 10 mM), an inhibitor of the pyridoxine cofactor of GAD, and nipecotic acid (NIP; 2 mM), a GABA uptake blocker were perfused onto the slices. Within an hour, multiple population spikes characteristic of a diminished GABAergic inhibition appeared. The epileptic field potentials were enhanced by only <10% upon blocking postsynaptic GABA<sub>A</sub> receptors with bicuculline (100  $\mu$ M) or picrotoxin (100  $\mu$ M). Thus, reduced GAD activity and GABA uptake effectively deplete over 90% of the releasable GABA pool. We then investigated GABA<sub>A</sub> and GABA<sub>B</sub> receptor-mediated monosynaptic IPSCs in whole-cell recordings. Consistent with the above findings, INH+NIP produced a parallel reduction in the size of both types of IPSCs by 90%. This demonstrates that GABA is the endogenous transmitter responsible for the activation of both GABA<sub>A</sub> and GABA<sub>B</sub> receptor-mediated IPSCs.

The properties and the relative number of postsynaptic K<sup>+</sup> channels linked to GABA<sub>A</sub> receptors and activated by synaptically released GABA were then studied using non-stationary fluctuation analysis. We have determined that GABA<sub>A</sub> receptors are linked to outwardly rectifying small conductance (5-12 pS) K<sup>+</sup> channels. A large number (157  $\pm$  51) of these channels are activated during an average size stimulus-evoked GABA<sub>A</sub> IPSC.

## 531.19

GABA-B AGONIST BACLOFEN ENHANCES THE Gs-COUPLED RECEPTOR-INDUCED cAMP PRODUCTION VIA G-PROTEIN  $\beta\gamma$  SUBUNITS IN *XENOPUS* OOCYTES EXPRESSING RAT BRAIN POLY (A)\* RNA. Y. Uezono\*, Y. Ueda, S. Ueno, N. Yanagihara, Y. Toyohira, T. Nagatomo\*, H. Yamashita\* and F. Izumi. Depts of Pharmacol and \*1st Physiol. Univ. of Occup. & Environ. Health, School of Medicine, Kitakyushu 807, Japan.

In the CNS, GABA-B receptor is negatively coupled to adenylyl cyclase (AC) via G<sub>i/o</sub> protein followed by an inhibition of cAMP production while in some CNS region, baclofen enhances the isoproterenol- and vasoactive intestinal peptide (VIP)-induced cAMP production. Little is known about the mechanisms by which GABA-B receptor mediates an enhancement of cAMP production. We previously reported that the protein encoded by the cystic fibrosis transmembrane conductance regulator gene (CFTR), that is the Cl<sup>-</sup> channel activated by A-kinase, can be used as an electrophysiological sensor for cAMP changes in *Xenopus* oocytes. In the present study, we injected cRNA for the CFTR along with rat brain poly (A)\* RNA into oocytes and investigated the effects of baclofen on the isoproterenol-, VIP-, and putative adenylyl cyclase activating polypeptide (PACAP)-induced CFTR currents. Baclofen by itself had no effect on CFTR current, however, enhanced CFTR currents caused by isoproterenol, VIP and PACAP 2-3 fold, which were inhibited by GABA-B antagonist 2-OH baclofen. Further, the effect of baclofen is augmented by two fold after coinjection of cRNA for AC type II which is known to be activated by G $\beta\gamma$  subunits together with activated forms of G $\alpha$ s (G $\alpha$ s\*). AC type III that is not activated by G $\beta\gamma$  had no augmentation. These results suggest that the G $\beta\gamma$  subunits released by GABA-B receptor stimulation activate the isotypes of AC together with G $\alpha$ s\* in the oocytes. In the CNS baclofen may enhance the Gs-coupled receptor-induced cAMP production by an activation of the AC through G $\beta\gamma$  subunits and G $\alpha$ s\*.

## 531.16

CHANGES IN [K<sup>+</sup>]<sub>i</sub> EVOKED BY BACLOFEN IN GUINEA PIG HIPPOCAMPUS. G.V. Obrocea\* and M.E. Morris. Department of Pharmacology, University of Ottawa, Ottawa, Canada K1H 8M5.

Ion-selective microelectrodes have been used to measure changes in [K<sup>+</sup>]<sub>i</sub> and field potentials in stratum pyramidale (SP) and stratum radiatum (SR) in the CA1 region of guinea pig hippocampal slices during applications of the GABA<sub>B</sub> agonist, ( $\pm$ ) baclofen by bath perfusion (1-3000  $\mu$ M for 5 min) and pressure ejection (100  $\mu$ M, 100-900 ms). Bath application evoked dose-dependent increases in [K<sup>+</sup>]<sub>i</sub> (above resting level of 3.6  $\pm$  SE 0.23 mM) of  $\leq$  0.59  $\pm$  0.10 mM in SP (EC<sub>50</sub> = 39.7  $\mu$ M) and  $\leq$  0.65  $\pm$  0.09 mM in SR (EC<sub>50</sub> = 58.6  $\mu$ M), which were antagonized by 50  $\mu$ M CGP35348. At threshold 10  $\mu$ M baclofen produced variable changes -- either no effect or a small increase (n = 3/6) or a decrease of -0.16  $\pm$  0.40 mM in SP and -0.18  $\pm$  0.0 mM in SR (n = 3/6). With agonist concentrations  $\leq$  20  $\mu$ M the [K<sup>+</sup>]<sub>i</sub> increases usually attained an early peak, with rapid decline to a lower plateau or the resting level; higher concentrations caused changes which were sustained throughout the application.

In some experiments both bath and pressure applications of baclofen also evoked repetitive transients of [K<sup>+</sup>]<sub>i</sub> increase (2.7  $\pm$  0.03 mM, duration 5-8 s, frequency 1/12 s) which persisted throughout and after recovery, were accompanied by long-lasting field potentials and briefer, more frequent inter-ictal discharges and closely resembled the potentials observed with 4-aminopyridine (4-AP) (Morris, Obrocea & Avoli, 1993, Soc for Neurosci Abs 19: 1817).

The dose-dependent [K<sup>+</sup>]<sub>i</sub> increases evoked by baclofen are presumed to reflect a K<sup>+</sup> conductance activated by GABA<sub>B</sub> receptors. Such changes may be expected to play a role in the [K<sup>+</sup>]<sub>i</sub> accumulation evoked by GABA (especially when it is present at a high concentration) and add to that previously demonstrated for GABA<sub>A</sub> receptors (Barolet & Morris, 1991, Expl Br Res 84: 591-598).

## 531.18

GABA<sub>B</sub> ANTAGONISTS BLOCK  $\gamma$ -BUTYROLACTONE-INDUCED ABSENCE SEIZURES AND COORDINATED INDUCTION OF CRE- AND AP-1 DNA-BINDING IN MOUSE BRAIN. Y. Ito\*, K. Ishige, M. Aizawa and H. Fukuda. Dept. of Pharmacology, College of Pharmacy, Nihon University, Funabashi, Chiba 274, Japan.

We examined the effects of GABA<sub>B</sub> receptor blockade on  $\gamma$ -butyrolactone (GBL)-induced absence-like seizures and coordinated induction of nuclear cyclic AMP-responsive element (CRE)- and activator protein 1 (AP-1) DNA-binding activities. Administration of GBL induced absence-like seizures and concomitant increases in nuclear CRE- and AP-1 DNA-binding activities in whole mouse brain. GABA<sub>B</sub> antagonists such as CGP 35348 and CGP 46381 suppressed both the GBL-induced absence-like seizures and the increased nuclear CRE- and AP-1 DNA-binding activities. Gel-shift assay in various brain regions revealed that administration of GBL increased nuclear CRE- and AP-1 DNA-binding activities significantly in the midbrain and cerebral cortex but not in the cerebellum, hippocampus or pons-medulla. The region-specific increases in nuclear DNA-binding activities were also suppressed by CGP 35348. In the cerebral cortex, the increased CRE-binding activity was completely supershifted by CRE-binding protein (CREB) antibody, but not affected by c-Jun or c-Fos antibody. In addition, the AP-1 DNA-binding activity was blocked by c-Jun or c-Fos antibody and partially supershifted by CREB antibody. These results suggest that GABA<sub>B</sub> receptor-mediated synaptic responses are involved in GBL-induced absence-like seizures and that the increases in nuclear CRE- and AP-1 DNA-binding activities are correlated with the seizures. It is also suggested that CREB is involved in the CRE-binding complexes and c-Jun, c-Fos and CREB are involved in the AP-1 DNA-binding complexes.

## 531.20

D-TRYPTOPHAN-6-LUTEINIZING HORMONE-RELEASING HORMONE ANALOG (DECAPEPTYL) ADMINISTRATION DOWN-REGULATES OVARIAN PERIPHERAL-TYPE BENZODIAZEPINE RECEPTOR EXPRESSION. A. Weizman\*, I. Bachman\*, S. Leschiner\* and M. Gavish\*<sup>2,3</sup>. \*Sackler Fac. of Med., Tel Aviv Univ. 67197 Tel Aviv, and <sup>2</sup>B. Rappaport Fac. of Med. and <sup>3</sup>Rappaport Family Inst. for Res. in Med. Sci., Technion-I.I.T., 31096 Haifa, Israel.

Peripheral-type benzodiazepine receptors (PBR) are involved in the regulation of steroidogenesis, via activation of mitochondrial cholesterol transport. We previously found that hypophysectomy reduces PBR density in the adrenals and gonads. We were interested in evaluating the effect of "pharmacological" castration on PBR binding and mRNA expression in uterus, ovaries, and adrenal. In the present study, groups of female rats were "chemically" castrated by administration of decapeptyl, 50  $\mu$ g/rat/day. Half of these rats were treated with estradiol (E<sub>2</sub>), 50  $\mu$ g/rat/day. PBR density and RNA levels were compared with each other and with control rats. Decapeptyl castration resulted in reduction of [<sup>3</sup>H]PK 11195 binding in the ovaries; this effect was prevented by coadministration of E<sub>2</sub>. We are currently studying the impact of decapeptyl treatment on PBR density in other tissues, as well as measuring any difference in PBR RNA expression. Our data indicate that deprivation of pituitary gonadotropins leads to depletion of ovarian [<sup>3</sup>H]PK 11195 binding sites. This implicates E<sub>2</sub> as a necessary maintenance hormone for PBR expression in female sex organs.

## 531.21

IMPACT OF SURGICAL CASTRATION ON THE EXPRESSION OF THE PERIPHERAL-TYPE BENZODIAZEPINE RECEPTOR. M. Gavish\*,<sup>1,2</sup> C. Mazurik<sup>1</sup>, G. Weisinger<sup>1</sup> and R. Weizman<sup>3</sup>. <sup>1</sup>Bruce Rappaport Fac. of Med. and <sup>2</sup>Rappaport Family Inst. for Res. in the Med. Sciences, Technion-I.I.T., 31096 Haifa, and Sackler Fac. of Med., Tel Aviv Univ., 67197 Tel Aviv, Israel

Peripheral-type benzodiazepine receptors (PBR) have been found to play a role in steroidogenesis. Since the expression of PBR is under the control of gonadal and pituitary hormones, we undertook to study the regulation of PBR expression in the female rat genital tract axis. In the current study, groups of female rats were either castrated and treated with estradiol ( $E_2$ ; 3 mg/kg) or just castrated. [ $^3H$ ]PK 11195 binding and PBR RNA levels were measured in both groups and further compared to sham-operated rats. Castration induced a significant reduction in uterine PBR density, while  $E_2$  treatment prevented this reduction. Adrenal and renal PBR binding were not affected by castration or by  $E_2$  treatment. In contrast to the decrease in uterine [ $^3H$ ]PK 11195 binding following castration, PBR steady-state mRNA levels were found to increase. This increase was further enhanced by  $E_2$  treatment. Run-on transcription analysis indicated that these steady-state changes were not due to changes in transcription. These data indicate that hormonal regulation in the uterus affects at least two putative levels of PBR expression. These levels of control seem to be on the post-transcriptional and translational levels of PBR expression.

## 531.23

CONTROL OF PROOPiomelanocortin (POMC) mRNA LEVELS IN THE RAT ARCuate NUCLEUS BY THE POTENTIAL ENDOGENOUS BENZODIAZEPINE (BDZ) RECEPTOR LIGAND OCTADECAEUROPEPTIDE (ODN). E. Garcia de Yebenes and G. Pelletier\*. MRC Group in Molecular Endocrinology, CHUL Research Center, Laval University, Quebec, G1V 4G2 CANADA.

The neurotransmitter GABA exerts a tonic inhibitory influence on POMC neurons in the hypothalamus and melanotropic cells in the pituitary intermediate lobe. Moreover, activation of the GABA<sub>A</sub>-BDZ receptors inhibits the expression of the POMC gene. An endogenous 86 amino acid polypeptide with high affinity for the diazepam-binding sites, termed diazepam-binding-inhibitor (DBI), has been found in non-neuronal elements of the rat brain. ODN, generated from a moderate tryptic digestion of DBI (DBI[33-50]), has been shown to have the same affinity as DBI itself for the diazepam binding sites at the GABA<sub>A</sub> receptor complex. In order to investigate the influence of these endogenous peptides on the POMC gene expression at the hypothalamic level, we have studied the effects of the acute administration of ODN alone, or in combination with the GABA<sub>A</sub> antagonist picrotoxin on POMC mRNA levels as measured by *in situ* hybridization. Treatment with ODN *i.v.* at doses of 100, 200 and 400 µg/Kg produced a decrease in the hybridization signal of 11.2%, 33% and 48%, respectively. The concomitant intraperitoneal administration of picrotoxin (5 mg/Kg), completely prevented the effect of ODN. Intraventricular injection of ODN (40 µg/Kg) produced a 9.5% decrease in the POMC mRNA levels. The concomitant administration of picrotoxin not only reversed the inhibitory effect of ODN, but induced a 40% increase in the hybridization signal. In conclusion, these experiments show a negative regulation of the POMC gene expression by the endogenous peptide ODN, an effect that is reversed by the GABA<sub>A</sub> antagonist picrotoxin. We then propose that endogenous peptides with BDZ-like actions can exert an additional fine control upon the expression of neuropeptides at the hypothalamic level.

## PEPTIDE RECEPTOR STRUCTURE AND FUNCTION II

## 532.1

CLONING AND CHARACTERIZATION OF TWO ALTERNATIVE SPLICED FORMS (CRF $_{2\alpha}$  AND CRF $_{2\beta}$ ) OF A NOVEL RAT CORTICOTROPIN-RELEASING FACTOR RECEPTOR cDNA. Timothy W. Lovenberg\*, Chen Liaw, Dimitri E. Grigoriadis, Derek T. Chalmers, Changlu Liu, Errol B. De Souza. Depts. of Molecular Neurobiology and Neuroscience, Neurocrine Biosciences Inc., San Diego, CA 92121

Corticotropin releasing factor (CRF), a 41 amino acid peptide, regulates the anterior pituitary secretion of adrenocorticotropin and other proopiomelanocortin products as well as coordinates the endocrine, behavioral and autonomic responses to stress. A cDNA encoding the pituitary CRF receptor has recently been cloned (CRF $_1$  receptor). In this study, we have isolated cDNA clones for two splice forms of a putative second member of the CRF receptor family (CRF $_2$  receptor). These cDNAs were first identified using degenerate-PCR. The CRF $_{2\alpha}$  form was subsequently isolated from a rat hypothalamus cDNA library, whereas the CRF $_{2\beta}$  form was isolated from rat heart. The putative proteins encoded by these cDNAs are 411 and 431 amino acids, respectively, and have approximately 70% overall identity with the known CRF $_1$  receptor. When expressed transiently in mouse Ltk<sup>+</sup> cells, the CRF $_{2\alpha}$  and CRF $_{2\beta}$  receptors stimulate cAMP accumulation in response to known CRF-like agonists CRF, sauvagine, and urotensin I. CRF $_{2\beta}$  and CRF $_1$  receptors have nearly identical rank orders of potency for these ligands, whereas the CRF $_{2\alpha}$  receptor displays a unique profile of activation. Tissue distribution of the mRNAs by RNase protection shows expression of CRF $_{2\alpha}$  in the hypothalamus and olfactory bulb, whereas CRF $_{2\beta}$  is expressed primarily in heart and skeletal muscle, with lower levels in lung and intestine. These expression patterns are quite different from that of the CRF $_1$  receptor. *In situ* hybridization studies confirm these non-overlapping sites of expression for CRF $_{2\alpha}$  and CRF $_{2\beta}$  receptors in the CNS and periphery. Together, these results demonstrate the existence of two forms of a second CRF receptor, and suggest several directions for exploring CRF pathways as well as searching for alternate CRF-like ligands in mammals.

## 531.22

CHRONIC DENERVATION OF PARASYMPATHETIC FIBERS BLOCK THE EFFECTS OF GABA<sub>A</sub>-AGONISTS ON NEUROGENIC INFLAMMATION WITHIN THE RAT MENINGES.

V. Limmroth\*, K.I. Maynard, C. Ayata, M.A. Moskowitz, Stroke and Neurovascular Regulation, Mass. Gen. Hospital, Harvard Medical School, Charlestown, MA. 02129

We recently reported, that agents, which activate GABA<sub>A</sub>-receptors, such as valproate, muscimol or neurosteroids suppress neurogenic inflammation (NI) and substance P-induced plasma-extravasation (PE) within the meninges of rats. In this study we investigated whether the relevant GABA<sub>A</sub>-receptors were localized on sensory or parasympathetic fibers projecting to the meninges.

50 Sprague Dawley rat pups were treated neonatally with capsaicin (50mg/kg<sup>-1</sup>, s.c.) or vehicle in order to deplete small unmyelinated sensory fibers. Seven weeks later, PE (<sup>125</sup>I-albumin leakage, 50µCi kg<sup>-1</sup>) was induced within the meninges by substance P (1nmol kg<sup>-1</sup>, i.v.). In each group, 10 animals received valproate (30 and 100 mg kg<sup>-1</sup>) and 5 animals valproate (100 mg kg<sup>-1</sup>) plus bicuculline (10µg kg<sup>-1</sup>). Valproate dose-dependently reduced PE, which was reversed by bicuculline, suggesting that the involved GABA<sub>A</sub>-receptors are not expressed on capsaicin sensitive small unmyelinated fibers.

To further clarify the origin of the fibers expressing GABA<sub>A</sub>-receptors, 48 male SD rats underwent unilateral spino-palatal ganglionectomy. Ten days later NI was induced by electrical stimulation of the trigeminal ganglion (0.6mA, 5Hz, 5min). Animals were pretreated with valproate (100 mg kg<sup>-1</sup>, n=10), muscimol (100 µg kg<sup>-1</sup>, n=9), allopregnanolone (100 µg kg<sup>-1</sup>, n=5) or sumatriptan (100 µg kg<sup>-1</sup>, n=7). Only the 5HT<sub>1D</sub>-agonist sumatriptan suppressed NI in these animals.

These results suggest that a) GABA<sub>A</sub>- and 5-HT-receptors are located on different populations of nerve fibers projecting to the meninges and b) GABA<sub>A</sub>-receptors might be expressed on parasympathetic fibers projecting from the sphenopalatine ganglion to meningeal vessels.

## 531.24

IN VIVO RELEASE OF GABA WITHIN THE SPINAL CORD OF MONOARTHRITIC RATS USING MICRODIALYSIS. N.G. Bowerly\* and M. Malcangio. Dept. of Pharmacology, The School of Pharmacy, 29/39 Brunswick Square, London WC1N 1AX, U.K.

We have previously suggested that during the development of monoarthritis activation of the GABAergic system occurs to provide as an endogenous antinociceptive mechanism (Br. J. Pharmacol. 113, 1561-66, 1994). We have now evaluated *in vivo* whether the level of GABA within the spinal cord changes during chronic inflammation. For this purpose 12 Lewis rats were injected with complete Freund's adjuvant (CFA) and 10 with incomplete adjuvant (IFA). 7, 14, 21 and 28 days after inoculation, rats were anaesthetized with halothane and a microdialysis probe (200µm) was inserted into the dorsal horn of the spinal cord. Dialysates were collected at 0.5µl/min for 30 min and amino acid outflow determined by HPLC. The basal outflow of GABA was  $3.3 \pm 2.1$  pmol/15µl in IFA rats and  $1.6 \pm 0.9$  pmol/15µl in CFA rats. During perfusion with KCL (100mM in the probe) the levels of GABA in the dialysates of IFA rats were  $101 \pm 20\%$ ;  $166 \pm 37\%$ ;  $103 \pm 32\%$ ;  $229 \pm 29\%$  of basal outflow at 7, 14, 21 and 28 days respectively. By contrast the levels of GABA in dialysates of CFA rats were  $580 \pm 247\%$ ;  $543 \pm 290\%$ ;  $986 \pm 517\%$  and  $402 \pm 173\%$  of basal outflow at 7, 14, 21 and 28 days. These preliminary results would suggest that a larger amount of GABA may be available for release within the spinal cord of monoarthritis rats during development of chronic inflammation which supports previous *in vitro* data.

## 532.2

CLONING AND CHARACTERIZATION OF THE HUMAN CRF $_2$  RECEPTOR GENE AND cDNA. Chen W. Liaw, Timothy W. Lovenberg, Guy Barry, Tilman Oltersdorf\*, Dimitri E. Grigoriadis, Errol B. De Souza. Dept. of Molecular Neurobiology, Neurocrine Biosciences Inc., San Diego, CA 92121

Two CRF receptor subtypes (CRF $_1$  and CRF $_2$  receptor) with distinct brain localization and pharmacological profile have recently been cloned and characterized. For the CRF $_2$  receptor subtype, at least two splice forms, CRF $_{2\alpha}$  and CRF $_{2\beta}$  with different 5' sequences have been identified in rat. In this article, we report the genomic structure, and the corresponding cDNA sequence of the human CRF $_2$  receptor. The gene coding for human CRF $_2$  receptor consists of at least 12 exons and spans approximately 30 kb. The cDNA sequence in the protein coding region is 94% identical to that of the reported rat CRF $_{2\alpha}$  receptor. So far there is no evidence for the existence of a rat CRF $_{2\beta}$  receptor homologue in human. The encoded receptor is 411 amino acid in length and is 70% identical to the human CRF $_1$  receptor with least sequence homology in the N-terminal extracellular domain (47% identical). Cells transfected with the full length human CRF $_2$  receptor cDNA responded to rat/human CRF and sauvagine by increasing intracellular cAMP level with EC<sub>50</sub> values of ~20 nM and ~1 nM, respectively. The abundance of the CRF $_2$  receptor mRNA appears to be much lower in human than in rat in the tissues studied thus far. Therefore, CRF $_2$  receptor message may have a different regulation and/or distribution in human.

## 532.3

PHARMACOLOGICAL CHARACTERIZATION OF TWO NOVEL CORTICOTROPIN-RELEASING FACTOR RECEPTORS (CRF<sub>2α</sub> AND CRF<sub>2β</sub>) EXPRESSED IN STABLE CELL LINES.

Dimitri E. Grigoriadis\*, Timothy W. Lovenberg, Chen Liaw, Doug McGrath and Errol B. De Souza. Neurocrine Biosciences Inc., San Diego, CA 92121

Corticotropin-releasing factor (CRF) secreted by the hypothalamus is the primary regulator of the release of ACTH and other proopiomelanocortin derivatives from the anterior pituitary gland. In addition to its endocrine role, CRF has a broad extrahypothalamic distribution in brain and fulfills all of the criteria for a *bona fide* neurotransmitter. CRF<sub>1</sub> receptors and more recently two splice forms of a second member of the CRF receptor family, designated CRF<sub>2α</sub> and CRF<sub>2β</sub>, have been cloned and demonstrated to have clear and distinct patterns of distribution in rat brain and periphery. We have expressed both splice forms of the CRF<sub>2</sub> receptor subtype in stable cell lines and characterized their pharmacological and functional profiles in comparison with the CRF<sub>1</sub> receptor subtype. CRF<sub>2α</sub> and CRF<sub>2β</sub> receptors are both positively coupled to adenylate cyclase through a G-protein, however, they exhibit a different pharmacological profile between each other and CRF<sub>1</sub> receptors. The CRF-related peptides, r/hCRF, ovine CRF, bovine CRF sauvagine and Urotensin I all bind and potentially stimulate cAMP production in stable cell lines for CRF<sub>1</sub> and CRF<sub>2β</sub> receptors with approximately equal affinities. While sauvagine and Urotensin I exhibit the same affinity for CRF<sub>2α</sub> receptors as CRF<sub>1</sub> and CRF<sub>2β</sub>, r/hCRF, oCRF and bCRF, are all weaker by 10 to 100 fold for this subtype. The peptide antagonists, α-helical CRF(9-41) and d-PheCRF(12-41), both inhibit CRF- or sauvagine-stimulated cAMP production with the same potency on all receptor subtypes. The differential pharmacological profile of CRF<sub>1</sub>, CRF<sub>2α</sub> and CRF<sub>2β</sub> receptors suggests distinctive and selective functional roles for each receptor subtype. Furthermore, the stable expression of CRF receptor subtypes represents an unique opportunity for the discovery of subtype-selective non-peptide ligands which could target different aspects of CRF-mediated disorders.

## DIRECT MEASUREMENT OF CORTICOTROPIN RELEASING FACTOR-BINDING PROTEIN AND CRF-BP/CRF COMPLEX IN ALZHEIMER'S DISEASE USING TWO-SITE ELISA ASSAYS.

Dominic P. Behan\*, Xin-Jun Liu<sup>a</sup>, Nick Ling<sup>a</sup>, Birgitta Nasman<sup>b</sup>, Tommy Olsson<sup>b</sup>, Juan Troncoso<sup>c</sup> and Errol B. De Souza<sup>a</sup>. <sup>a</sup>Neurocrine Biosciences Inc., San Diego, 92121. <sup>b</sup>John Hopkins University School of Medicine, Baltimore, MD 21205

<sup>c</sup>UMEA University, Sweden.

Two-site ELISAs were developed for direct measurement of corticotropin releasing factor (CRF), CRF binding protein (CRF-BP) and the CRF-BP/CRF complex in human plasma and brain extracts. The CRF-BP ELISA had a sensitivity of 2.7 fmol/well and a broad range of detection from 0.008-8 pmol/well. Both the CRF and CRF-BP/CRF assays had a sensitivity of 0.4 fmol/well with a useful range of detection from 0.4-40 fmol/well. Plasma CRF-BP levels were  $7.1 \pm 0.64$  nmol/L in Alzheimer's patients (n=21) and  $7.5 \pm 0.35$  nmol/L in age-matched controls (n=19) with no significant differences between groups. CRF-BP levels decreased to 60% of resting levels 15 min after a bolus injection of synthetic human CRF (1 µg/kg) and gradually returned to pre-injection levels after 120 min. Conversely, bound CRF levels reciprocally increased at 15 min to  $0.58 \pm 0.03$  nmol/L in control subjects and  $0.49 \pm 0.04$  nmol/L in Alzheimer's subjects and then rapidly decreased to undetectable levels at 120 min. CRF-BP levels ranged from 5.4 - 13.5 fmol/mg of wet tissue weight in human cerebrocortical extracts with no significant differences found between controls and Alzheimer's patients. The majority (>80%) of the CRF-BP was membrane associated. Bound CRF levels were  $0.31 \pm 0.018$  and  $0.24 \pm 0.007$  fmol/mg wet tissue weight in control and Alzheimer's cerebrocortical extracts, respectively. Furthermore, bound CRF could be displaced from the binding protein using high affinity CRF-BP ligands to replenish free CRF levels to normal in the Alzheimer's extracts. These data demonstrate that CRF-BP, CRF and the CRF-BP/CRF complex can be measured by two-site ELISAs in unextracted plasma samples and brain extracts and suggest that ligand inhibitors of CRF-BP may have utility in elevating free CRF levels in disease states associated with decreased CRF.

## 532.7

## CORTICOTROPIN-RELEASING FACTOR BINDING PROTEIN LIGAND INHIBITION: A NOVEL MECHANISM FOR COGNITIVE ENHANCEMENT

S.C. Heinrichs\*, D.P. Behan, N. Ling and E.B. De Souza. Neurocrine Biosciences, Inc., 3050 Science Park Road, San Diego CA 92121.

Data from postmortem studies suggest that corticotropin-releasing factor (CRF) is a major neurotransmitter affected in Alzheimer's disease (AD). Observations that greater cognitive impairment in AD is associated with lower cerebrospinal fluid concentrations of CRF and rodent studies demonstrating CRF-induced improvement in learning and memory tasks suggest that decreases in brain CRF may contribute to cognitive impairment. The identification in brain of a high-affinity binding protein with the ability to sequester and inactivate corticotropin-releasing factor (CRF-BP) provides a novel target to modulate endogenous levels of CRF *in vivo* (see Behan et al.). Thus, central administration of selective CRF-BP ligands which dissociate CRF from CRF-BP could increase brain levels of unbound CRF. The present studies employed two behavioral measures of arousal in rats, acquisition of a learning task and exploration of an unfamiliar environment, to examine the impact on the CRF system of three distinct pharmacological tools: 1) a high affinity CRF receptor agonist, rat/human CRF (1-41), 2) selective CRF-BP ligand inhibitors, rat/human CRF (6-33) or (9-33) and 3) homologous control peptides, ovine CRF (6-33) or (9-33) which are inactive at both CRF receptors and CRF-BP. Acquisition of the Morris water maze test of spatial learning was facilitated by pre-test intracerebroventricular (icv) administration of r/hCRF (1-41), or either CRF-BP ligand inhibitor but not by either control peptide. Administration of the CRF-BP ligand inhibitor, r/hCRF (6-33) also improved performance in a visual discrimination learning paradigm. Doses of r/hCRF (1-41) which improved performance of the learning task also produced anxiogenic-like behavior in the Elevated Plus-Maze test while doses of r/hCRF (6-33) up to five fold higher than the behaviorally active dose did not modify exploration of the Plus-Maze. These data demonstrate a functional dissociation of the learning enhancement effects from emotionally-related side-effects of CRF-BP ligand inhibitors and suggest that these compounds may have therapeutic potential in treating disorders such as dementia associated with low levels of CRF in brain.

## 532.4

LOCALIZATION OF NOVEL CORTICOTROPIN-RELEASING FACTOR RECEPTOR (CRF<sub>2</sub>) mRNA EXPRESSION IN RAT BRAIN.

Derek T. Chalmers\*, Timothy W. Lovenberg, Errol B. De Souza. Dept. of Molecular Neurobiology and Neuroscience, Neurocrine Biosciences Inc., San Diego, CA 92121

Corticotropin-releasing factor (CRF) is the primary factor involved in controlling the release of ACTH from the anterior pituitary and also acts as a neurotransmitter in a variety of brain systems. The actions of CRF are mediated by G-protein coupled membrane bound receptors and a high affinity CRF receptor, CRF<sub>1</sub>, has been previously cloned and functionally characterized. We have recently isolated cDNAs encoding two splice forms of a second member of the CRF receptor family, designated CRF<sub>2α</sub> and CRF<sub>2β</sub>, which display approximately 70% homology at the nucleotide level to the CRF<sub>1</sub> receptor and exhibit distinctive pharmacological profiles. The present study utilized *in situ* hybridization histochemistry to localize the distribution of CRF<sub>2α</sub> and CRF<sub>2β</sub> receptor mRNA in rat brain and pituitary gland and compared this with the distribution of CRF<sub>1</sub> receptor expression. While CRF<sub>1</sub> receptor expression was very high in neocortical, cerebellar and sensory relay structures, CRF<sub>2α</sub> receptor expression was generally confined to sub-cortical structures. The highest levels of CRF<sub>2α</sub> receptor mRNA in brain were evident within the lateral septal nucleus and the ventromedial hypothalamic nucleus. Moderate levels of CRF<sub>2α</sub> receptor expression were evident in the olfactory bulb, amygdaloid nuclei, the paraventricular and supraoptic nuclei of the hypothalamus, the inferior colliculus and serotonin-associated raphe nuclei of the midbrain. CRF<sub>2β</sub> receptor mRNA was generally confined to non-neuronal structures, the choroid plexus and cerebral arterioles. Within the pituitary gland, CRF<sub>2</sub> receptor mRNA was detectable only at low to negligible levels in scattered cells while CRF<sub>1</sub> receptor mRNA was readily detectable in anterior and intermediate lobes. This heterogeneous distribution of CRF<sub>1</sub>, CRF<sub>2α</sub> and CRF<sub>2β</sub> receptor mRNAs suggests distinctive functional roles for each receptor in CRF-related systems.

## 532.6

## CRF BINDING PROTEIN (CRF-BP) IS EXPRESSED IN CULTURED ASTROCYTES AND NEURONS IN RESPONSE TO cAMP AND PROTEIN KINASE C STIMULATION.

Dominique Maciejewski\*, Dominic P. Behan, Derek Chalmers and Errol B. De Souza. Neurocrine Biosciences Inc., San Diego, 92121.

CRF-BP was measured in media and cell lysates of primary rat astrocytes, microglia and neurons with the use of a ligand immunoradiometric assay (LIRMA). A low basal level of CRF-BP was detected in the media but not cell lysates from primary neuronal and astrocyte cells after 48h in culture. No basal expression of CRF-BP was detected in cell lysates or media from primary microglial cultures. After forskolin, IBMX or forskolin/IBMX treatment, a robust increase in secreted CRF-BP levels in the media from astrocytes and neurons, but not microglia, was observed. Also, forskolin, IBMX and dibutyryl cAMP treatment resulted in a dose dependent increase in CRF-BP levels detected in the media from astrocytes and neurons. *In situ* hybridization analysis revealed that CRF-BP mRNA was increased in primary cultured astrocytes after IBMX/forskolin stimulation suggesting that regulation was at the level of gene transcription. Furthermore, treatment of neurons and astrocytes with specific type 3 and type 4 phosphodiesterase inhibitors also resulted in increased secretion of CRF-BP into the media. The increase in CRF-BP expression was not due to increased cell proliferation as measured by radiolabeled <sup>3</sup>H-thymidine incorporation. Treatment of astrocytes with PMA also resulted in increased CRF-BP levels in the media suggesting that the AP1 site in the human promoter may be important in CRF-BP gene regulation. Dexamethasone, hydrocortisone, dihydrocortisone, progesterone and pregnenolone inhibited forskolin/IBMX stimulated release of CRF-BP from astrocytes. These data provide evidence for the differential localization and regulation of CRF-BP in different cell types in brain and suggest that CRF-BP expression may be locally increased in disease states associated with astrogliosis.

## 532.8

## ASSESSMENT OF COMPOUND AFFINITIES AT RAT BRAIN CORTICOTROPIN RELEASING FACTOR (CRF) RECEPTORS USING A FILTRATION-BASED LIGAND BINDING ASSAY.

H. Herdon\*, J. Jerman, A. Jennings\* and M. Duckworth\*. Departments of Psychiatry Research and Medicinal Chemistry, SmithKline Beecham Pharmaceuticals, Harlow, Essex, UK.

Previous studies on [<sup>125</sup>I]-CRF binding to brain CRF receptors have generally used centrifugation-based binding assays. We have developed a simple high-throughput filtration-based binding assay and used it to assess the affinities of compounds at cortical CRF receptors. The assay measures [<sup>125</sup>I]-oCRF binding to washed homogenates of rat cerebral cortex, based on the method of De Souza (J. Neurosci. 7:88-100, 1987). Termination is by filtration through PEI-soaked GF/C filters, followed by washing with PBS containing 0.1% BSA and 0.01% Triton X-100.

Specific binding of [<sup>125</sup>I]-oCRF (defined with 1µM r/hCRF) represented 70% of total binding. Saturation analysis gave a B<sub>max</sub> value of 180 fmoles/mg protein and a K<sub>d</sub> of 5nM. Competition studies showed K<sub>i</sub> values of 6nM for r/h CRF and 9nM for oCRF. The antagonists α-helical CRF(9-41) and D-PheCRF(12-41) gave K<sub>i</sub> values of 60nM and 80nM respectively. The relative potencies of these four peptides are similar to those reported previously (Curtis et al, J. Pharm. Exp. Ther. 268:359-65, 1994; De Souza, J. Neurosci. 7:88-100, 1987), thus validating the assay. Two novel non-peptide compounds claimed as CRF receptor antagonists in recent patents from Pfizer Pharmaceuticals (Example 1 of WO 94/13643 and Example 5i of WO 94/13677) were also tested; both compounds gave K<sub>i</sub> values of 70nM. These results show that our assay can be used for the assessment of CRF agonists and both peptide and non-peptide CRF antagonists.

## 532.9

AN ANTAGONIST AT THE SOMATOSTATIN RECEPTOR SSTR5 <sup>1</sup>T. Reisine\*, <sup>1</sup>M. Tallent, <sup>1</sup>G. Liapakis, <sup>3</sup>A.-M. O'Carroll and <sup>2</sup>M. Dichter. Depts. <sup>1</sup>Pharmacology and <sup>2</sup>Neurology, Univ. of Penn. Sch. Med. and the Graduate Hospital, Philadelphia, PA 19104 and <sup>3</sup>Lab. Cell Biol. NIMH, Bethesda MD.

Somatostatin (SRIF) is a major physiological regulator of growth hormone, glucagon and insulin release. It causes biological actions by interacting with five different receptors referred to as SSTR1-5. Subtype selective agonists have been used to reveal distinct functions of these receptor subtypes. Development of antagonists would be useful in further identifying the selective biological roles of these receptors. The peptide L362,855 binds with high affinity to the cloned receptor SSTR5. At high concentrations it inhibits cAMP accumulation in cells expressing the cloned rat SSTR5. At lower concentrations it blocks SRIF inhibition of cAMP accumulation via this receptor, suggesting the peptide is a partial agonist/antagonist. The SSTR5 selective agonist BIM23052 inhibits an L-type Ca<sup>++</sup> current in the cell line AtT-20, which expresses SSTR5 mRNA. L362,855 has minimal actions on this current at low concentrations but completely blocks the electrophysiological effects of BIM23052. L362,855 does not prevent the SSTR2 selective agonist MK 678 from inhibiting Ca<sup>++</sup> currents in AtT-20 cells, suggesting that L362,855 is a selective antagonist at SSTR5. L362,855 has two phenylalanines in its structure. The analogs L363,588 and L363,587 have each individual phenylalanine converted to a tyrosine. L363,588 is a pure agonist at SSTR5 whereas L363,587 is an antagonist. Therefore, the addition of one hydroxyl group to L362,855 converts it from an antagonist to an agonist revealing an important structural determinant for the activity of this compound. L362,855 analogs may be useful in further identifying functions of SSTR5 and could serve as a foundation for the development of new SRIF antagonists with clinical uses. Supported by MH45533 and MH48518.

## 532.11

COUPLING OF THE CLONED KAPPA AND MU OPIOID RECEPTOR TO THE INWARD RECTIFIER POTASSIUM CURRENT IS DIFFERENTIALLY REGULATED. <sup>1</sup>M. Tallent\*, <sup>1,2</sup>M.A. Dichter, and <sup>1</sup>T. Reisine. <sup>1</sup>Depts. of Pharmacology and <sup>2</sup>Neurology, University of Pennsylvania School of Medicine and the Graduate Hospital, Philadelphia, PA 19104.

Three opioid receptors have recently been cloned, corresponding to the kappa, delta, and mu subtypes which had been previously characterized in endogenous tissue. These three receptor subtypes have all been shown to interact with inward rectifying potassium currents in neurons, and this appears to be an important mechanism by which the opioids mediate many of their inhibitory effects in the nervous system.

We show here that the cloned mouse kappa and rat mu opioid receptors are able to couple to an endogenously expressed inward rectifier K<sup>+</sup> current (IR) when expressed in the mouse anterior pituitary cell line AtT-20. The coupling of the kappa opioid receptor to the IR is desensitized upon pretreatment with kappa agonist. Kappa receptor desensitization appears to be homologous, as the ability of the endogenously expressed somatostatin receptor to couple to the IR is not affected by kappa receptor desensitization. The mu receptor coupling to the IR is also desensitized by pretreatment with mu agonist. However, mu receptor desensitization also causes heterologous desensitization of the endogenous somatostatin receptor. Likewise, desensitization of the somatostatin receptor causes heterologous desensitization of the mu receptor but not the kappa receptor. These results show that the cloned kappa and mu opioid receptor coupling to the IR is differentially desensitized in AtT-20 cells, with kappa receptor desensitization appearing to be homologous and mu receptor desensitization involving heterologous mechanisms. Supported by DA 08951.

## 532.13

ASSOCIATION OF THE CLONED DELTA, KAPPA AND MU OPIOID RECEPTORS WITH G PROTEINS S.F. Law\* and T. Reisine. Dept. Pharmacol., Univ. Pennsylvania Sch. Med. Philadelphia, Pa 19104

Opiates are potent analgesics and are used clinically to treat pain. They induce their biological effects by interacting with delta, kappa and mu receptors. These receptors couple to cellular effector systems via G proteins. To identify the G proteins that associate with the opiate receptors, the cloned opiate receptors were expressed in CHO cells, the receptors were solubilized with CHAPS and the receptor/G protein complexes were either uncoupled or immunoprecipitated with antisera directed against the different alpha subunits of G proteins. The mouse delta receptor predominantly associates with G<sub>i1</sub>, G<sub>i3</sub> and G<sub>o</sub>. Upon agonist binding to the receptor, G<sub>i1</sub> dissociates and G<sub>i2</sub> associates with the receptor whereas G<sub>i3</sub> and G<sub>o</sub> remain complexed with the receptor. The switch in G<sub>i</sub> subtypes may be involved in the activation of the delta receptor following agonist binding. The mouse kappa receptor also associates with G<sub>i1</sub>, G<sub>i3</sub> and G<sub>o</sub>. Following agonist binding, G<sub>i2</sub> associates with the receptor and both G<sub>i1</sub> and G<sub>i3</sub> remained coupled to the receptor. Therefore, agonist binding promotes the association of G<sub>i2</sub> with the kappa receptor. Both the delta and kappa receptor can also interact with G<sub>12</sub> and G<sub>13</sub>, which may mediate pertussis toxin insensitive actions of delta and kappa selective agonists. In contrast to the delta and kappa receptors, associations of G proteins with the cloned rat mu receptor could only be detected when agonist was bound to the receptor. Under these conditions, the mu receptor predominantly associates with G<sub>i2</sub>, G<sub>i3</sub> and G<sub>o</sub>. These studies reveal that specificity exists in the coupling of G proteins with the opiate receptors and that changes in G protein coupling occur following agonist binding which may contribute to the molecular basis of signalling via these receptors. Supported by DA08951.

## 532.10

LIGAND BINDING DOMAINS OF THE SOMATOSTATIN RECEPTOR SSTR2 G. Liapakis\*, D. Fitzpatrick, C. Codispoti, R. Vandlen and T. Reisine. Dept. Pharm., Univ. Penn. Sch. Med. Philadelphia, PA 19104 and Protein Chem. Dept., Genentech, 460 Pt. St. Bruno Blvd., S. San Francisco, CA 94080

Somatostatin (SRIF) induces its biological actions by interacting with five different receptors. The subtype SSTR2 may mediate SRIFs actions on growth hormone release. Development of SSTR2 selective drugs would be facilitated by the identification of the ligand binding domains of this receptor. To identify the ligand binding domain of SSTR2, chimeric receptors consisting of fragments of SSTR1 and SSTR2 were generated and tested for their ability to bind selective SSTR2 ligands. Chimera 282 consists of SSTR2 with the second and third extracellular loops of SSTR1. It bound native SRIFs with high affinity. The SSTR2 selective agonists NC4-28B and NC8-12 and the peptides BIM23003, MK 678 and SMS 201-995 which bind preferentially to SSTR2, bound with low affinity to 282. In contrast, they bound to the chimera 258, consisting of SSTR1 with the region spanning extracellular loops 2 and 3 of SSTR2, with high affinity indicating that ligand binding domains of SSTR2 are contained within the second and third extracellular loops. To further define determinants for ligand binding to SSTR2, the chimera 394 was generated. It consists of SSTR2 with four amino acids in the third extracellular loop exchanged for the corresponding region of SSTR1. 394 had greatly reduced affinity for the SSTR2-selective agonists NC8-12 and NC4-28B as well as the SSTR2 preferring agonist SMS 201-995 and BIM23003. These studies define a highly selective, small region of extracellular loop three as being required for the binding of constrained octa- and decapeptides to SSTR2. In contrast, the native SRIF peptides do not require this region for binding. Such information may facilitate the rational design of SSTR2 antagonists and drugs. Supported by MH45533 and MH48518.

## 532.12

AGONIST INDUCED REGULATION OF MU AND DELTA OPIOID RECEPTORS A. Blake\*, M. vonZastrow, J. Freeman and T. Reisine. Dept. Pharm., Univ. Pennsylvania, Philadelphia PA 19104 and Dept. Psych., Univ. Cal. San Francisco, San Francisco, CA 94143.

Opiates are potent analgesics used clinically to treat pain. A major side effect of chronic use of opiates is the development of tolerance. To investigate cellular mechanisms of tolerance development to opiates, the cloned mu and delta opioid receptors were epitope tagged, stably expressed in HEK 293 cells and the effects of chronic treatment of these cells with opiates on the characteristics of the opioid receptors were examined. The pharmacological characteristics of the epitope tagged mu and delta receptors are similar to those reported for mu and delta receptor expressed in the nervous system. The mu receptor selectively bound the agonist 3H-DAMGO and this binding was diminished by GTP analogs and pertussis toxin treatment, indicating the receptor coupled to G proteins. Overnight treatment of mu receptor expressing 293 cells with levorphanol or morphine decreased 3H-DAMGO binding and the binding of the antagonist 3H-diprenorphine. These results indicate that prolonged agonist treatment caused a loss in high affinity agonist binding and a down-regulation of mu receptor. The epitope tagged delta receptor selectively bound the delta agonist 3H-DSLET and this binding was sensitive to GTP analogs and pertussis toxin. Overnight treatment of delta receptor expressing 293 cells with levorphanol caused both a loss of high affinity agonist and antagonist binding indicating that the receptor was downregulated. Thus, prolonged, overnight agonist treatment of both the mu and delta receptors with agonists causes receptor downregulation, which may contribute to tolerance development to opiates. Supported by DA08951 and DA05636.

## 532.14

CLONED HUMAN SOMATOSTATIN SSTR5 RECEPTORS COUPLE TO INHIBITION OF cAMP FORMATION, STIMULATION OF PHOSPHOINOSITIDE TURNOVER, CALCIUM MOBILIZATION, ARACHIDONIC ACID RELEASE, AND CELLULAR METABOLIC RATE. J.E. Taylor\*, Biomeasure Inc., 27 Maple St., Milford, MA 01757

Somatostatin (SRIF) exhibits diverse biological effects mediated through a family of five G-protein coupled receptors (SSTR1-5). SSTR (1-5) activation has variably been shown in most native and cloned assay systems to be coupled to an inhibition of stimulated-cAMP formation, and stimulation of phosphoinositide (PI) turnover. In addition, stimulation of tyrosine phosphatase activity and inhibition of voltage-dependent Ca<sup>2+</sup> channels have been reported for the SSTR2 type. Activation of arachidonic acid (AA) release has also been reported for the SSTR4 subtype. In the present study with CHO-K1 cells stably expressing the human SSTR5 receptor, SRIF-14, SRIF-28 and SSTR5-selective ligands (BIM-23052, L-363,855) inhibited [<sup>125</sup>I-Tyr<sup>11</sup>]SRIF-14 binding with K<sub>i</sub> values of 0.38, 0.88, 0.76, and 1.2 nM, respectively. Functional analysis, showed for the first time that human SSTR5 receptors were coupled to the stimulation of AA release, in addition to cAMP inhibition and PI/Ca<sup>2+</sup> stimulation, with a rank order of potency of SRIF-28 > SRIF-14. Furthermore, employing the technique of microphysiometry to assess real-time cellular metabolism, SSTR5 specific peptides stimulated the short-term metabolism of CHO-K1 cells. These results demonstrate that human SSTR5 receptors are functionally coupled to multiple second messenger systems.

## 532.15

PHARMACOLOGICAL CHARACTERIZATION OF LY303870: A NOVEL, POTENT, AND SELECTIVE NON-PEPTIDE SUBSTANCE P RECEPTOR ANTAGONIST. B.D. Gitter<sup>a</sup>, R.F. Bruns<sup>a</sup>, J.J. Howbert<sup>a</sup>, P.W. Stengel<sup>b</sup>, D.R. Gehlert<sup>a</sup>, S. Jyengar<sup>a</sup>, D.O. Calligaris<sup>c</sup>, D. Regoli<sup>d</sup>, and P.A. Hipskind<sup>a</sup>. <sup>a</sup>Central Nervous System, <sup>b</sup>Cardiovascular, and <sup>c</sup>Biochemical Toxicology Research Divisions, Lilly Research Labs., Lilly Corp. Ctr., Indianapolis, IN 46285 and <sup>d</sup>Dept. of Pharmacol., Medical School, Univ. of Sherbrooke, Sherbrooke, Que., Canada J1H5N4

(R)-1-[N-(2-methoxybenzyl)acetyl]amino-3-(1H-indol-3-yl)-2-[N-(2-(4-(piperidin-1-yl)piperidin-1-yl)acetyl)amino]propane (LY303870) is a new, potent, and selective non-peptide neurokinin-1 (NK-1) receptor antagonist. LY303870 bound selectively and with high affinity to human peripheral ( $K_i = 0.15$  nM) and central ( $K_i = 0.10$  nM) NK-1 receptors. LY303870 inhibited [<sup>125</sup>I]SP binding to guinea pig brain homogenates with similar affinity, however, it had approximately 50 fold lesser affinity for rat NK-1 sites. The less active enantiomer, (S)-1-[N-(2-methoxybenzyl)acetyl]amino-3-(1H-indol-3-yl)-2-[N-(2-(4-(piperidin-1-yl)piperidin-1-yl)acetyl)amino]propane (LY306155), was 1,000-15,000 fold less potent in all the species examined. LY303870 antagonized *in vitro* NK-1 receptor effects as demonstrated by blockade of substance P (SP) stimulated phosphoinositide (PI) turnover in UC-11 MG human astrocytoma cells ( $K_i = 1.5$  nM) and interleukin-6 (IL-6) secretion from U-373 MG human astrocytoma cells ( $K_i = 5$  nM). In addition, LY303870 inhibited SP induced rabbit vena cava contractions ( $pA_2 = 9.4$ ) with high (50,000 fold) selectivity vs. NK-2 or NK-3 receptor-mediated responses. *In vivo*, LY303870 inhibited [Sar<sup>9</sup>,Met(O<sub>2</sub>)<sup>11</sup>]-SP induced guinea pig bronchoconstriction ( $ED_{50} = 75$  µg/kg i.v.) and pulmonary microvascular leakage in the bronchi ( $ED_{50} = 12.8$  µg/kg i.v.) and trachea ( $ED_{50} = 18.5$  µg/kg i.v.). Therefore, LY303870 is a potent and selective NK-1 receptor antagonist *in vitro* and *in vivo*. The use of LY303870 will facilitate a better understanding of NK-1 receptors in physiological processes.

## 532.17

LY303870: A CENTRALLY ACTIVE NK-1 ANTAGONIST WITH A LONG DURATION OF ACTION. R.M.A. Simmons<sup>a</sup>, B.D. Gitter<sup>a</sup>, P.A. Hipskind<sup>a</sup>, D.R. Gehlert<sup>a</sup>, C. McMillian<sup>a</sup>, R. Couture<sup>a</sup>, D. Li<sup>a</sup> and S. Jyengar<sup>a</sup>. CNS Research, Lilly Corp. Ctr., Eli Lilly and Company, Indianapolis, IN 46285.

The selective NK-1 antagonist, LY303870, has high affinity and specificity for human and guinea pig NK-1 receptors labelled with [<sup>125</sup>I]-SP ( $K_i$  of 0.10nM and 0.31nM respectively) and approximately 15- to 30-fold lower affinity for rat and mouse brain NK-1 receptors ( $K_i$  of 8.7nM and 7.5nM), consistent with previously reported species differences in the affinities of non-peptide antagonists for NK-1 receptors. *Ex-vivo* binding studies revealed that LY303870 potentially bound to central NK-1 receptors labelled by [<sup>125</sup>I]-SP over a long duration of time. *In vivo*, LY303870 blocked the characteristic nociceptive behavioral response elicited by intrathecal administration of the selective NK-1 agonist Ac-[Arg<sup>6</sup>,Sar<sup>9</sup>,Met(O<sub>2</sub>)<sup>11</sup>]-substance P 6-11 in conscious mice [est.  $ED_{50}$  0.2nmol (i.t.) and 2.5 mg/kg (i.p.) respectively]. LY303870 also selectively blocked the potentiation of the tail-flick response in the rat, elicited by intrathecally administered NK-1 agonist, [Sar<sup>9</sup>,Met(O<sub>2</sub>)<sup>11</sup>]-substance P [est.  $ED_{50}$  4 mg/kg (i.v.) and 6 mg/kg (p.o.) respectively]. LY303870 was tested in a model of persistent nociceptive activation induced by tissue injury (the formalin test). LY303870 blocked pain-related behavior in the second phase of the formalin test in a dose-dependent manner [est.  $ED_{50}$  4 mg/kg (i.p.) and 10 mg/kg (p.o.)]. Following oral administration of 10 mg/kg, the blockade of the second phase pain-related behavior was evident for at least 24 hours, consistent with *ex-vivo* binding studies to the NK-1 receptor in the brain and pharmacokinetic studies of plasma levels of LY303870. In conclusion, LY303870 blocked central NK-1 receptor-mediated nociceptive behavioral responses in both rats and mice and showed analgesic activity in the formalin test at doses that were consistent with its affinity for rodent NK-1 receptors. LY303870 is a potent, centrally active, NK-1 antagonist *in vivo*, with long lasting oral activity.

## 532.19

INTRAVENOUS SUBSTANCE P ADMINISTRATION TRANSIENTLY INCREASES RAT EAR BLOOD FLOW VIA NK-1 RECEPTOR ACTIVATION: AN *IN VIVO* NK-1 ASSAY. L.A. Phebus<sup>a</sup>, M.E. Roush<sup>a</sup>, I.H. Krushinski<sup>a</sup>, K.L. Lobb<sup>a</sup>, J.A. Nixon<sup>a</sup> and P.A. Hipskind<sup>a</sup>. The Lilly Research Laboratories, Eli Lilly & Co. Indianapolis, IN 46285.

Substance P (SP), an eleven amino acid neuropeptide, is a member of the neurokinin family which exert their effects via neurokinin (NK) receptors. SP is somewhat selective for the NK-1 receptor. Stimulation of NK-1 receptors by released neuronal SP is thought to be involved in various physiological processes including pain transmission, inflammation and vascular tone. Non-peptide NK-1 antagonists might be effective treatments for various pathophysiological conditions including persistent pain, migraine and asthma. In our search for such agents, we employed a rapid, *in vivo* test of NK-1 antagonism described here.

Male Wistar rats were anesthetized with isoflurane and placed in stereotaxic apparatus. One of the rat's ears was then gently taped, using double-sided tape, to the stereotaxic ear bar. A laser Doppler blood flow probe was positioned to measure capillary blood flow in the ear. Intravenous, bolus injections of SP (1-1000 pmol/kg) produced transient increases in ear blood flow. Using selective agonists and antagonists, this increase was documented to be mediated by NK-1 receptors. Non-peptide NK-1 antagonists were tested for their ability to shift the SP dose-response curve. In other tests, repeated low iv doses (4 pmol/kg) of SP were injected at 5 minute intervals for hours without desensitization. After a baseline was established, non-peptide NK-1 antagonists were administered and their onset, duration of action and availability by various routes of administration were examined. This method proved to be a reliable and relatively rapid *in vivo* assay of NK-1 antagonism.

## 532.16

CHARACTERIZATION OF GUINEA PIG NK-1 RECEPTORS USING THE POTENT ANTAGONIST LIGAND, [<sup>3</sup>H]-LY303870. D.R. Gehlert<sup>a</sup>, D.A. Schober<sup>a</sup>, P.A. Hipskind<sup>a</sup>, J. Nixon<sup>a</sup>, B.D. Gitter<sup>a</sup> and J.J. Howbert<sup>a</sup>. Central Nervous System Research, Lilly Research Laboratories, Eli Lilly and Co., Indianapolis, IN 46285 U.S.A.

The neuropeptide, substance P (SP), produces its biological responses by binding to NK-1 receptors found in the brain and periphery. In general, the binding properties of the NK-1 receptor have been characterized using radiolabeled SP or SP analogs. Until recently, no useful antagonist radioligands were available for the study of these receptors. [<sup>3</sup>H]-CP96,345 and the related ligand, [<sup>125</sup>I]-L-703606, have been introduced, but may interact with non-NK-1 sites. Another radioligand, [<sup>3</sup>H]-99,994 appears to bind to a single site in guinea pig striatum. Recently, another class of nonpeptide NK-1 antagonists have been discovered. In the present study, we used a radiolabeled form of the NK-1 antagonist, LY303870, for use in homogenate and autoradiographic binding studies.

[<sup>3</sup>H]-LY303870 rapidly associated with guinea pig striatal membranes and readily dissociated upon addition of unlabeled LY303870. Under equilibrium conditions, the ligand bound to a single site with a  $K_d$  of 0.22 nM and a  $B_{max}$  of 22 fmol/mg protein. (±)CP96,345, LY303870 and the related antagonist LY306740 were the most potent inhibitors of binding tested. While the nonpeptide antagonists had Hill coefficients near unity, peptide agonists were generally less potent and exhibited biphasic displacement curves. Consistent with binding to a G-protein coupled receptor, 10 µM Gpp(NH)p shifted inhibition by SP to a single, lower affinity site. The dissociation of specific [<sup>3</sup>H]-LY303870 binding was unaffected by the presence of 10 µM Gpp(NH)p.

Autoradiographic studies were conducted using sections from guinea pig forebrain and brainstem. Adjacent sections were labelled with either [<sup>3</sup>H]-LY303870 or [<sup>3</sup>H]-SP. The distribution of binding sites for these ligands was similar. The highest levels of specific binding were seen in noradrenergic areas such as the locus coeruleus and bed nucleus of the stria terminalis while lower levels were seen in areas such as the striatum and dorsal horn of the spinal cord.

In conclusion, [<sup>3</sup>H]-LY303870 binds with high affinity and selectivity to NK-1 receptors in guinea pig brain. This radioligand should provide a useful tool for the further study of mammalian NK-1 receptors.

NK-1 RECEPTORS MEDIATE A SPINAL NOCICEPTIVE REFLEX. D. Li<sup>a</sup>, R.M.A. Simmons<sup>a</sup>, R.F. Bruns<sup>a</sup>, P.A. Hipskind<sup>a</sup> and S. Jyengar<sup>a</sup>. CNS Research, Lilly Corp. Ctr., Eli Lilly and Company, Indianapolis, IN 46285.

Substance P (SP) is found in the primary afferent neurons that carry nociceptive signals to the brain. NK-1 receptors are widely distributed at spinal and supraspinal sites. The involvement of central NK-1 receptors in nociceptive behavior was tested. (1) SP, when administered intrathecally, induces a characteristic nociceptive behavioral response. Using selective agonists and antagonists, this response was further characterized in our laboratory and shown to be selectively mediated via NK-1 receptors. The selective NK-1 agonist Ac-[Arg<sup>6</sup>,Sar<sup>9</sup>,Met(O<sub>2</sub>)<sup>11</sup>]-SP 6-11, (Ac-Sar<sup>9</sup>), when administered intrathecally, mimicked the SP-elicited response described in the early studies. Selective NK-2 or NK-3 agonists did not elicit the same response. Selected Lilly NK-1 antagonists, including LY303870 and LY309809, when co-injected intrathecally (i.t.) with the agonist, blocked the Ac-Sar<sup>9</sup>-mediated nociceptive response in a dose-dependent and stereoselective manner. This response showed a structure activity relationship (SAR) that was consistent with a NK-1 receptor mediated event. Structurally unrelated NK-1 antagonists, RP67,580 and GR83224 also blocked this response, further confirming that this response was NK-1 receptor mediated. (2) CGRP, another neuropeptide found in the primary afferents, can potentiate this NK-1 receptor mediated nociceptive response when co-injected with subthreshold doses of the NK-1 agonist, while having no effect by itself. Interestingly, this potentiation was blocked by the NK-1 antagonists at doses that blocked Ac-Sar<sup>9</sup> mediated behavior alone. NK-1 antagonists (i.t.) were less potent at blocking acetic acid induced writhing. In contrast, morphine (i.t.) blocked acetic acid-induced writhing very potently, was less potent at blocking Ac-Sar<sup>9</sup> induced behavior and did not block CGRP-induced potentiation of NK-1 receptor mediated nociceptive behavior. These data suggest that NK-1 receptors may play a unique role in mediating spinal nociceptive reflexes.

## 532.20

INHIBITION OF NEUROGENIC DURAL INFLAMMATION BY LY303870, A NOVEL, NON-PEPTIDE NK-1 RECEPTOR ANTAGONIST. K.W. Johnson<sup>a</sup>, P.A. Hipskind<sup>a</sup>, K.L. Lobb<sup>a</sup>, J.A. Nixon<sup>a</sup>, P.W. Stengel<sup>a</sup> and L.A. Phebus<sup>a</sup>. Central Nervous System Research, Lilly Research Laboratories, Indianapolis, IN 46285

Neurogenic dural inflammation has been proposed as a source of pain during migraine. This inflammation is produced by the release of substance P and other inflammatory neuropeptides from sensory afferents in dural tissue. Substance P is thought to induce protein extravasation from dural postcapillary venules by activation of NK-1 receptors on the endothelium of the venules. Unilateral electrical stimulation of the trigeminal ganglion is known to induce ipsilateral release of inflammatory neuropeptides, particularly Substance P. The resulting ipsilateral dural protein extravasation from post-capillary venules and increased dural blood flow are both components of neurogenic dural inflammation. We have previously shown (Soc. for Neuroscience, 1994) that this model successfully discriminates several clinically effective and ineffective compounds for the alleviation of migraine pain. Several other groups have shown dural protein extravasation can be blocked in this model by NK-1 receptor antagonists.

We evaluated the ability of a novel, non-peptide NK-1 antagonist (LY303870) to block dural protein extravasation in guinea pigs induced by ipsilateral stimulation of the trigeminal ganglion. The compound inhibited dural extravasation in a dose dependent manner when administered by several routes. The compound was equipotent compared to sumatriptan when administered intravenously 10 minutes prior to stimulation. LY303870 was also found to be approximately 50 times more potent than sumatriptan when orally administered approximately one hour prior to stimulation. Oral doses of 1 and 100 µg/kg were found to be totally effective in blocking dural extravasation for at least 8 and 24 hours post-dose respectively. The compound was also delivered successfully as an aerosol. These effects were enantiospecific; the enantiomer, LY306155, was approximately 100 times less potent when administered intravenously. These data suggest that the inhibition of extravasation produced by LY303870 is NK-1 receptor mediated.

## 533.1

**SUPPRESSION OF CELLULAR IMMUNE FUNCTION BY DELTA OPIOID RECEPTOR ANTAGONISTS.** R. V. House\*, H. N. Bhargava, J. T. Kozak, A. S. Guy and P. T. Thomas. Life Sciences Dept., IIT Res. Inst., Chicago, IL 60616 and Dept. Pharmaceutics and Pharmacodynamics, Univ. of Illinois at Chicago, Chicago, IL 60612.

Previous studies in our laboratory have demonstrated that *in vitro* exposure to compounds acting as  $\delta$ -opioid receptor agonists results in a significant stimulation of cellular immune function. The purpose of the present studies was to assess potential immunomodulation by the peptide receptor antagonists TIPP, d-TIPP, and ICI 174864 as well as the non-peptide receptor antagonists benzydinenaltrexone (BNTX), naltrindole (NTI) and naltriben (NTB) by using a panel of *in vitro* cellular immune function assays. Murine B6C3F1 splenocytes were cultured with the compounds at concentrations between 0.00001-10  $\mu$ M. B-cell proliferation was quantitated following cellular activation, T-cell function was assessed by cytokine production following stimulation with anti-CD3 monoclonal antibody, and natural immunity was assessed by quantitating natural killer (NK) cell activity following a 24-h exposure to  $\delta$ -opioid receptor antagonists. The peptide antagonists exhibited limited activity against B-cells, exposure to BNTX and NTI suppressed B-cell proliferation, and NTB had no effect. Cytokine production by T cells was enhanced by exposure to the peptide antagonists, exposure to either BNTX or NTI resulted in suppressed cytokine production, while exposure to NTB had no significant effect. NK cell function exhibited the greatest sensitivity, with suppression observed following exposure to either peptide or non-peptide antagonists. These data suggest that  $\delta$ -opioid receptor antagonists are broadly immunosuppressive at physiological concentrations (Supported by contract No. 271-91-9201 and grant No. DA-08867 from the National Institute on Drug Abuse).

## 533.3

**SINGLE CELL RT-PCR DEMONSTRATES DIFFERENTIAL EXPRESSION OF OPIOID RECEPTOR mRNA AMONG IDENTIFIED PRIMARY AFFERENT NOCICEPTIVE NEURONS** Seth C. Silbert\*<sup>1,2</sup> and Edwin W. McCleskey.<sup>2</sup> <sup>1</sup>Washington University School of Medicine, St. Louis, MO 63110; <sup>2</sup>The Vollum Institute, Oregon Health Sciences University, Portland, OR 97201.

Opioids inhibit "2<sup>nd</sup> pain", the dull ache that persists after a noxious stimulus, while having little effect on "1<sup>st</sup> pain", the sharp initial sensation (Cooper *et al.* Pain 24:93, 1986). The lab has previously shown significant inhibition of *in vitro* Ca<sup>2+</sup> currents by  $\mu$ -opioid agonists applied to small, but not large, rat dental pulp nociceptors. We propose that selective inhibition of presynaptic Ca<sup>2+</sup> entry in small nociceptors with unmyelinated axons enables opioid analgesics to specifically interrupt 2<sup>nd</sup> pain sensations.

In the current study we apply reverse transcription, followed by competitive PCR analysis, of single neurons to address whether differential expression of opioid receptor mRNA in nociceptors underlies these selective opioid actions. Key to this approach, as an internal control against tube-to-tube variation in the efficiency of the PCR reaction, we include in each PCR sample tube a known number of competitor target molecules containing a small insertion in the native cDNA sequence. With each PCR reaction, a series of tubes containing known quantities of both the mutant and native sequence establish a standard quantitative scale against which we measure ratios of mutant and wild-type PCR product bands derived from individual nociceptor cDNA. Using this approach we have identified cells that, following reverse transcription, contain fewer than 5  $\mu$ -opioid receptor cDNA molecules, compared to others containing at least 50-150  $\mu$ -receptor cDNA molecules. We can therefore test whether those cells which lack a pharmacologic response to opioids do so because they fail to transcribe mRNA specific for this receptor.

## 533.5

**Behavioral profile induced by a novel neuropeptide acting at an opioid-like G protein-coupled receptor** Frederick J. Monsma Jr.\*, Anne Bourson, Rainer K. Reinscheid & Olivier Civelli. Hoffmann-La Roche, PRPN, CH-4002 Basel, Switzerland.

We have isolated and characterized an endogenous peptidergic ligand to a formerly "orphan" G protein-coupled receptor which has significant homology to the cloned opioid receptors. Although this peptide shares some structural similarity with the opioid peptides it does not exhibit pharmacological activity at the opioid receptors. When injected into the cerebral ventricle of rats, this peptide induced a strong decrease in locomotor activity which was dose-dependent and lasted for up to one hour. This inactivity state was accompanied by a significant loss in muscle tone but the animals were not cataleptic. No changes were seen in body temperature, heart rate, blood pressure and food intake. Our preliminary results indicate, that this novel peptide is biologically active and can induce behavioral responses different from those commonly associated with the opioid peptide system. Experiments to determine the involvement of this novel neuropeptide in analgesic responses are currently being carried out in our laboratory.

## 533.2

**ANTISENSE CONFIRMATION OF  $\mu$ - AND  $\kappa$ -OPIOID RECEPTOR MEDIATION OF MORPHINE'S EFFECTS ON BODY TEMPERATURE IN RATS.** Xiao-Hong Chen, Ellen B. Geller\*, Lee-Yuan Liu-Chen and Martin W. Adler. Department of Pharmacology, Temple University School of Medicine, Philadelphia, PA 19140

Low doses of morphine (4-16 mg/kg, s.c.) can markedly increase body temperature in the rat, but a high dose of morphine (>30 mg/kg, s.c.) can cause a profound decrease in body temperature. Based on the use of selective opioid agonists and antagonists, we postulated that these effects were due to morphine's actions on  $\mu$  and  $\kappa$  receptors, respectively. In the present study, we examined whether an antisense (AS) oligodeoxynucleotide (oligo) against cloned  $\mu$  or  $\kappa$  opioid receptors could affect morphine-induced body temperature changes. AS oligos were directed against nucleotides 1-18 of the  $\mu$  receptors and 4-21 of the  $\kappa$  receptors, respectively. Male SD rats were surgically implanted with icv cannulae. Rats received icv injections of vehicle or oligo in the animal colony room on days 1, 3 and 5. Either AS oligo or missense (MS) oligo was infused in a volume of 5  $\mu$ l over 30 sec to freely moving animals. On day 6, rats were tested. The results showed that treatment with an AS oligo against  $\mu$  opioid receptors, but not MS oligo, shifted the hyperthermia curve to the right. In addition, treatment with an AS oligo against  $\kappa$  receptors, but not MS oligo, almost completely blocked the hypothermia induced by a high dose morphine. This study confirms our earlier postulate that low doses of morphine induce an increase in body temperature primarily via  $\mu$  opioid receptors and high doses of morphine produce a decrease through  $\kappa$  opioid receptors. (NIDA Grants DA 00376 and DA 04745).

## 533.4

**Biosynthesis and regional distribution of a novel neuropeptide acting at an opioid-like G protein-coupled receptor**

Hans-Peter Nothacker\*, Rainer K. Reinscheid, Frederick J. Monsma Jr. & Olivier Civelli. Hoffmann-La Roche, PRPN, CH-4002 Basel, Switzerland.

We have identified a natural ligand of an "orphan" G protein-coupled receptor which bears high homology to the known opioid receptors. This ligand consists of a 17 amino acid peptide which also shows some sequence similarities with the opioid peptides. Consequently, we have begun to analyze the mode of biosynthesis of this novel neuropeptide. We have carried out preliminary experiments to determine the structure of the polypeptide precursor encoding this novel peptide by using molecular biological techniques. In addition, we have developed polyclonal antisera to the peptide and started to analyze the regional distribution of peptide expression by immunocytochemical methods. These analysis will be correlated with receptor autoradiography experiments and will allow us to draw a map of this novel peptidergic neuronal pathway.

## 533.6

**VARIANTS OF THE HUMAN MU OPIOID RECEPTORS: EVIDENCE FOR HETERONUCLEAR RNA FORMS.** A. Mansour\*, L.A. Bare, E. Mansson, H. Akil, and S. J. Watson. Mental Health Research Institute, University of Michigan, Ann Arbor, MI USA and Ohmeda Pharmaceuticals, NJ USA.

The recent cloning of the opioid receptors,  $\mu$ ,  $\delta$  and  $\kappa$ , suggests that they are members of the G-protein family of seven transmembrane receptors. While several lines of evidence suggest the presence of opioid receptor subtypes, there is little molecular biological data to support these findings. Recently, a variant of the  $\mu$  opioid receptor has been cloned from both the rat and human (MORIA) that differs at the 3' end. Given the variation is at an exon-intron border, it may represent an alternatively spliced form of the  $\mu$  receptor or the result of incomplete heteronuclear RNA splicing. If the  $\mu$  receptor variant is an alternatively spliced form, it should be distributed over both cytoplasmic and nuclear cellular compartments. If, on the other hand, it represents an incompletely spliced heteronuclear RNA, then it should be localized primarily in cell nuclei. *In situ* hybridization studies were performed on formaldehyde post-fixed human brain sections with cRNA probes directed either to a EcoRI-Bam HI fragment of exon 2, a Pst I-Xba I fragment of intron 1, or a Xba I -Nde 2 fragment of intron 3 of the human  $\mu$  receptor gene. The EcoI -BAM HI and PstI -Xba I fragments are "prototypical" exonic and intronic sequences, respectively, to which the XbaI-Nde 2 fragment (MORIA) may be compared. Results from emulsion-dipped sections suggest that cRNA probes directed at exon 2 of the  $\mu$  receptor produced silver grains that were distributed over cell nuclei and cytosol. In contrast, the cRNA probe to the MORIA variant showed a localization primarily in cell nuclei, similar to that seen with the intronic Pst I-Xba I cRNA probe. The results suggest that the MORIA variant is an incompletely spliced heteronuclear RNA form.

## 533.7

CHARACTERIZATION OF CLONED  $\mu$  AND  $\kappa$  OPIOID RECEPTORS IN HETEROLOGOUS SYSTEMS. A. Kouvassalis<sup>1</sup>, G. Y.K. Ng<sup>1</sup>, M. Scheidter<sup>2</sup>, M. Caron<sup>1</sup>, M. Dennis<sup>1</sup>, B.F.O'Dowd<sup>1</sup>, and S.R. George<sup>1</sup> Depart. of Pharmacol., University of Toronto and Addiction Research Foundation, Toronto, ON, <sup>2</sup>Novo Nordisk A/S, Denmark, <sup>3</sup>BioSignal, Montreal, QC.

Cloned  $\mu$  and  $\kappa$  opioid receptors have been expressed in vitro for elucidating receptor subtype-specific processes.  $\mu$  receptor expressing BHK cells showed high affinity binding for antagonists and agonists. Agonist (DAMGO) detected high affinity binding ( $K_i \sim 1$  nM) was sensitive to GTP and analogues, and mediated inhibition of adenyl cyclase. Pertussis toxin treatment resulted in the loss of agonist detected high affinity binding and the abolishment of DAMGO-mediated inhibition of adenyl cyclase activity, suggesting  $\mu$  receptor coupling to pertussis toxin-sensitive signalling pathways in the BHK cells. An alternate model was used to express cloned  $\kappa$  receptors in Sf9 cells which have been used successfully to express a number of other G protein coupled receptors for biochemical and functional studies. Expressed  $\kappa$  receptors showed saturable binding for the antagonist [<sup>3</sup>H]naloxone with a  $K_d$  of  $\sim 2$  nM in good agreement with endogenous receptors. U50488 agonist/[<sup>3</sup>H]naloxone competition binding revealed the presence of guanine nucleotide-sensitive high affinity binding sites suggesting functional coupling of expressed receptors, and is consistent with preliminary studies showing U50488-mediated inhibition of adenyl cyclase activity in the Sf9 cells. A monoclonal  $\kappa$  receptor antibody revealed the presence of a discrete  $\sim 65$  kDa immunoreactive species in membranes prepared from  $\kappa$  receptor expressing Sf9 cells not present in wild-type Sf9 membranes. Further, this antibody showed no immunoreactivity in membranes prepared from  $\mu$  receptor expressing BHK cells demonstrating the specificity of this antibody for the specific identification and purification of  $\kappa$  receptors for further biochemical studies.

## 533.9

RAPID ENDOCYTOSIS OF OPIOID RECEPTORS: DIFFERENTIAL REGULATION BY OPIOID PEPTIDE AND MORPHINE. D. Keith S. Murray, P. Zaki, P. Chu, D. Lissin, L. Kang, J. Aimi\*, C. Evans, and M. vonZastrow. Dept. Psych., UCLA, Los Angeles CA 90024, Dept Psych., Stanford Univ., Stanford CA 94305, and Dept Psych., UCSF, San Francisco CA 94143

Morphine, an important therapeutic and abused drug, activates the same receptors which are the physiological targets of endogenous opioid peptides. It is not known to what extent this molecular mimicry extends to specific mechanisms of receptor regulation. We have utilized epitope tagging and immunocytochemical techniques to study the intracellular trafficking of cloned delta and mu -subtype opioid receptors expressed in human 293 fibroblastic and mouse Neuro2 neuroblastoma cells. In the absence of receptor agonist, both subtypes of opioid receptor are localized predominantly in the plasma membrane. In the presence of enkephalin (an endogenous peptide agonist) or etorphine (an alkaloid agonist drug), both receptor subtypes undergo rapid internalization ( $t_{1/2} \sim 15$  minutes). Enkephalin and etorphine cause opioid receptors to be sorted into a rapid endocytic pathway similar to that which mediates the constitutive endocytosis of transferrin. Morphine fails to stimulate detectable rapid endocytosis of either receptor subtype, even when used at high doses which cause maximal receptor-mediated inhibition of adenyl cyclase. Furthermore, morphine inhibits the rapid endocytosis of opioid receptors when added to cells in combination with enkephalin or etorphine. These observations indicate that morphine and opioid peptide have opposing effects on a fundamental mechanism of receptor regulation.

## 533.11

EXPRESSION OF N-METHYL-D-ASPARTATE RECEPTOR (NMDAR1), DELTA OPIOID RECEPTOR (DOR) AND MU OPIOID RECEPTOR (MOR) mRNAs IN TERMINALLY DIFFERENTIATED NT2-N CELLS. J.W. Beczkowska\*, N. Gracey, V.M. Pickel, C.E. Inturrisi. Depts. of Pharmacology and Neurology and Neuroscience, Cornell U. Med. Coll., New York, NY 10021.

Retinoic acid (RA) treatment of NTera2/cl.D1 (NT2) cells, a human teratocarcinoma cell line, yields 95% pure cultures of terminally differentiated neuronal cells (NT2-N; Pleasure et al., J. Neurosci. 12:1802, 1992). Following RA-induced differentiation, NT2-N cells express functional NMDA receptors (Younkin et al., PNAS 90:2174, 1993). We compared the levels of NMDAR1, delta opioid receptor (DOR) and mu opioid receptor (MOR) mRNAs in NT2 cells, before and after treatment with RA, using a quantitative solution hybridization method (Franklin et al., Mol. Brain Res. 19:93, 1993). The level of NMDAR1 mRNA in NT2-N cells increased 10 fold, DOR mRNA increased 3 fold, and MOR mRNA increased 4 fold, as compared to NT2 cells. Northern blot analysis revealed two transcripts for NMDAR1 mRNA (4.4 and 4.2 kb) and two transcripts for DOR mRNA (7.0 and 11.0 kb). Cells were also processed for immunoperoxidase localization of NMDA and DOR antisera. In NT2-N cells the labeling for NMDA was seen within the cell bodies as well as on the processes, while it was undetectable in NT2 cells. In contrast, DOR-like immunolabeling was detected in both, NT-2 and NT2-N cells. Thus, RA differentiated NT2-N cells express increased levels for NMDAR1, DOR and MOR mRNA providing a model to study interaction between these receptor systems in human terminally differentiated neuronal cell culture. Supported by NIDA Grants DA01457, DA07274, DA00198 and DA04600.

## 533.8

TRANSCRIPTION OF MU, DELTA, AND KAPPA OPIOID RECEPTORS IN PERIPHERAL BLOOD CELLS. R. E. Rodríguez\*, A. Barrallo, M. V. Santos and R. González Sarmiento. Department of Biochemistry and Molecular Biology and Department of Medicine, Faculty of Medicine, University of Salamanca, Spain.

Several authors have observed by Northern blot analysis the lack of opioid receptor expression in mouse or rat heart, spleen, lung, liver and *vas deferens*. We have studied the transcription of mu, delta and kappa opioid receptors in adult male C57BL mice by extraction of RNA from different central and peripheral tissues using the acid guanidium thiocyanate-phenol-chloroform method. Opioid receptor fragments were generated using specific oligonucleotides for mu, delta and kappa opioid receptors by RT-PCR. Amplified cDNA from the different tissues were studied by Southern blot and hybridized with specific probes. Northern blot analysis was also done to compare results obtained by PCR and by this method. We observe opioid receptor (mu, delta, and kappa) transcription in all tissues studied by RT-PCR (brain stem, anterior brain, cerebellum, spinal cord, ileum, liver, spleen, heart, lung and kidney). These results suggest that RT-PCR is a more sensitive technique than Northern blot analysis for the determination of the transcription of these receptors. Nevertheless, RT-PCR done in peripheral blood as well as in isolated T-lymphocytes, B-lymphocytes and monocytes also show opioid receptor transcription. As a consequence we conclude that RT-PCR done on fresh tissue is not a suitable technique for the determination of opioid receptor transcription since these receptors are also expressed in peripheral blood and we can not ignore that the tissue used for the determinations is not free from blood.

## 533.10

EXPRESSION OF A KAPPA<sub>3</sub>-RELATED (KOR-3) OPIOID RECEPTOR IN A MOUSE OSTEOSARCOMA CELL LINE, MC3T3-E1

John P. Mathis\*, Kelly M. Standifer, Wendy Su and Gavril W. Pasternak, The Cotzias Laboratory of Neuro-Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY 10021.

The MC3T3-E1 mouse osteosarcoma cell line naturally expresses a kappa<sub>3</sub>-related receptor encoded by KOR-3 cDNA. The presence of this receptor has been demonstrated by Western blots and immunocytochemical staining with a monoclonal antibody (mAb 8D8). The molecular size of the band recognized on immunoblot and immunocytochemical staining patterns are similar to BE(2)-C human neuroblastoma cells. The functionality of this kappa<sub>3</sub>-related receptor has been investigated through cAMP inhibition assays. Cyclazocine and nalorphine produced inhibitory effects with EC<sub>50</sub> values of  $6600 \pm 800$  nM and  $5500 \pm 2000$  nM, respectively. Morphine, DAMGO and DPDPE did not inhibit cAMP accumulation greater than 10 %.

## 533.12

INTERNALIZATION OF FLUORESCENT OPIOID AGONISTS IN COS CELLS TRANSFECTED WITH MU AND DELTA OPIOID RECEPTORS: A CONFOCAL MICROSCOPIC STUDY. G. Gaudriault, D. Nouel<sup>1</sup>\*, J.P. Vincent and A. Beaudet<sup>1</sup>. IPMC - CNRS UPR 411, Sophia-Antipolis, 06560 Valbonne, France, <sup>1</sup> Montreal Neurol. Inst., Montreal, Canada H3A 2B4.

In order to visualize mu- and delta-opioid receptor internalization kinetics by confocal microscopy, we synthesized fluorescent derivatives of dermorphin (Bodipy-dermorphin, BDM) and deltorphin (Bodipy-deltorphin, BDLT) with high affinity (nanomolar range) and nearly complete specificity (selectivity factor of 100-1000) for mu- and delta-opioid receptors, respectively. Confocal scanning of mu- or delta-transfected COS cells incubated with 5nM BDM or BDLT for various times revealed the following: (i) dense clustering of each fluorescent ligand was initially observed on the surface of cells transfected with the appropriate receptor. This labeling was not present in non-transfected cells and was abolished by a thousand fold excess of naloxone, indicating that it was receptor dependent; it was also totally washed out by a hypertonic acid wash, confirming that it was confined to the cell surface. (ii) after longer incubation times, transfected cells incubated with the appropriate fluorescent peptides exhibited numerous, small, intensely fluorescent endosome-like particules. These were acid wash-resistant and confirmed by serial optical sectioning to be mainly intracellular. (iii) kinetic data indicated that the delta ligand was internalized considerably more efficiently than the mu one. (iv) Experiments involving COS cells cotransfected with both the mu and delta receptors showed no overlap of the two different fluorophores (green for BDM and red for BDLT) within the same endosomal compartments. These observations, combined with the kinetics data, suggest that mu- and delta-opioid receptors are internalized along two different pathways.

## 533.13

# ROLE OF THE C-TERMINAL TAIL IN CELLULAR LOCALIZATION OF THE $\mu$ OPIOID RECEPTOR MUTANTS.

V Segredo, JJ Rampil\*, Lamah and W Sadée.

Departments of Pharmacy and Pharmaceutical Chemistry  
University of California, San Francisco, CA 94143-0446.

In Human Embryonic Kidney Cells (H.E.K.) stably transfected with the  $\mu$  opioid receptor, acute morphine treatment inhibits adenylyl cyclase, indicating that the receptor is functionally expressed. The C-terminal tail of the  $\mu$  opioid receptor is rich in Ser and Thr residues which are putative sites for receptor phosphorylation. In order to assess the role of phosphorylation in agonist-induced internalization and downregulation of the  $\mu$  opioid receptor, we constructed two deletion mutants, one lacking any Ser or Thr residues in the C-terminal tail (TRUNC354), and the other maintaining the TSST region (TRUNC358). An epitope tag was added to the N-terminus of the wild type and both mutant receptors to allow immunocytochemistry with a monoclonal antibody. We found that all constructs are functional, as they inhibit adenylyl cyclase. The epitope tagged wild-type  $\mu$  receptors and TRUNC358 stably expressed in H.E.K. cells, were located at the cell surface as visualized by confocal microscopy. DAMGO, a peptide agonist, induced  $\mu$  receptor redistribution into intracellular vesicles whereas morphine treatment did not change  $\mu$  receptor localization. The TRUNC354 mutant however, was mostly localized in intracellular vesicles before any treatment. Our results suggest that the TSST region may be involved in cellular localization of the  $\mu$  opioid receptor.

Supported by NIH grant DA 04166.

## 533.15

# $\mu$ -OPIOIDS ACTIVATE TYROSINE KINASES C-SRC AND FAK.

D. Mangoura\*. The Univ. of Chicago Sch. of Med, Chicago, IL 60637.

We have previously shown that the G-protein  $\mu$ -opioid receptor is coupled to tyrosine kinase activation. We have shown that  $\mu$ M met-enkephalin caused specific increases in protein tyrosine phosphorylation. One of these proteins is pp125FAK, a focal adhesion tyrosine kinase. Both the phosphotyrosine content of FAK and the kinase activity of pp125FAK, as investigated by *in vitro* kinase assays of immunoprecipitates from control and treated cultures, were increased. In addition, these assays revealed that met-enkephalin activate tyrosine kinases, which form complexes with pp125FAK. We now report that one of them was identified as c-src (pp60<sup>src</sup>). The time curves of tyrosine phosphorylation we obtained indicate that the initial tyrosine phosphorylation (<2 min) of pp125FAK is not mediated by pp60<sup>src</sup>. Our data are consistent with a complex regulation scheme of pp125FAK, where the G-protein coupled  $\mu$ -opioid receptor activates a yet unknown tyrosine kinase, which rapidly activates pp125FAK. This kinase may be the one that initiates the rapid activation of PLD, as we have observed with  $\mu$ -opioids. The tyrosine phosphorylation of pp125FAK promotes formation of pp125FAK/pp60<sup>src</sup> complexes, which in turn facilitate tyrosine phosphorylation of pp125FAK by pp60<sup>src</sup>, detected as a second peak of pp125FAK activation. This last peak indeed coincides with the met-enkephalin-stimulated activation of pp60<sup>src</sup>. All met-enkephalin-stimulated signaling was inhibited by the antagonist naloxone. These data provide novel evidence that opioid intracellular signaling engages activation of the tyrosine kinases pp125FAK and pp60<sup>src</sup>. We propose that these protein-protein interactions may be the primary point of regulation of shape and function by opioids during brain morphogenesis (HD 09402 and BRF).

## 533.17

TRANSDUCTION SIGNALING AT DELTA OPIOID RECEPTORS IN MOUSE CORTICAL NEURONS *IN VITRO*. A. Ambrosini, L. Bresciani, G.D. Clarke\*, G. Dondio\*, V. Orlandi, F. Fidone, N. Brunello\* and G. Racagni\*. Center of Neuropharmacology, Univ. of Milan, 20133 Milan; \*SmithKline Beecham Farmaceutici, Baranzate, Milan, and \*Dept. Pharmaceutical Sciences, Univ. of Modena, Modena, (Italy).

The existence of subtypes of the delta opioid receptor is based on *in vivo* pharmacological data. No clear distinction, however, has yet been made at the molecular or cellular level. In the present study, the effects of preferential delta1 and delta2 opioid receptor agonists (DPDPE and Deltorphin II, respectively) on cAMP formation in mouse cerebral cortical neurons *in vitro* have been studied. DPDPE produced a concentration-dependent inhibition that was maximal (25%) at 1-5  $\mu$ M. The response to Deltorphin II was different, being biphasic with an initial shallow concentration-effect curve (inhibition of 30% at 0.1-1  $\mu$ M) and a second steeper phase with maximal (90%) inhibition observed at 100  $\mu$ M. A biphasic concentration-dependent reduction in cAMP levels was also observed with the novel non-peptidic selective delta agonist (-)-trans-4a-(3-hydroxyphenyl)-2-methyl-1,2,3,4,4a,5,12,12a-octahydronaphthylidene-3,4-b) acridine (SB213698B), with maximal reduction of 65% at 100  $\mu$ M.

DPDPE and deltorphin II effects were antagonized by BNTX and NTB (0.1-1  $\mu$ M), respectively, supporting the suggestion that different delta receptor subtypes are responsible for the responses observed.

Acute neuronal pretreatment with Deltorphin II (0.001-1  $\mu$ M) also reduced cGMP levels, in controls and after stimulation with glutamatergic agonist NMDA (300  $\mu$ M). This suggests that complex intracellular interactions may occur between opioid and glutamate receptor systems in cerebral cortical neurons.

## 533.14

# Delta and Mu Opioid Receptor Targeting in Madin-Darby Canine Kidney Cells.

Nakano AH\*, Wright S, Dado RJ, Arvidsson U, Riedl M, Law P, Y. Loh HH, and Elde R

Departments of Cell Biology & Neuroanatomy and Pharmacology, University of Minnesota, Minneapolis, MN 55455

Investigation of opioid peptidergic neurotransmission has been greatly facilitated with the cloning of the opioid receptors. We have been able to raise rabbit antisera to the delta and mu opioid receptors (DOR1 and MOR1, respectively). During our anatomical survey of the rat CNS using immunolocalization methods, DOR1 was found predominantly in axons, suggesting its function as a presynaptic receptor (Dado et al., *Neuroreport* 5(3): 341-4, 1993; Arvidsson et al., *J Neurosci* 15(2): 1215-1235, 1995). In contrast, our study of the MOR1 has shown predominant localization to the soma and dendrites, suggesting a postsynaptic receptor (Arvidsson et al., *J Neurosci* 15(5): 3328-3341, 1995).

Since the initial studies by Dotti and Simon (*Cell* 62(1): 63-72, 1990), it has been suggested that the axonal and soma-dendritic cell surface domains of the neuron are similar to the apical and basolateral domains of polarized epithelial cells, respectively. We have attempted to take advantage of this by transfecting Madin-Darby canine kidney cells (MDCK), a well characterized polarizable epithelial cell line, with DOR1 and MOR1. Surprisingly, our preliminary results show that both opioid receptor types appear to be targeted predominantly to the basolateral surface of MDCK cells. supported by grants from NIDA

## 533.16

BINDING PROFILES OF  $\delta$ -SPECIFIC AGONISTS IN A STABLY TRANSFECTED DOR-1 CHO CELL LINE SUGGEST THE PRESENCE OF A HIGH PROPORTION OF UNCOUPLED RECEPTORS. Babey A.M.\*; Brown G.P.; Ryan-Moro J.P.; Pasternak G.W.<sup>1,2</sup>. <sup>1</sup>The Cotzias Laboratory Molecular NeuroOncology, Memorial Sloan-Kettering Cancer Center, <sup>2</sup>Department of Neurology, Cornell Medical College, New York, N.Y., U.S.A. 10021

Transfection of cell lines with the opioid receptor clones provides a useful tool in the understanding of receptor-ligand and receptor-G protein interactions. Unfortunately, the binding profiles may differ from those of natively expressed opioid receptors in brain and cultured cell membranes. These discrepancies may be attributable to differences in processing, glycosylation or availability and abundance of G proteins in the cell line used for the transfection. We have transfected a CHO cell line with the mouse DOR-1 and find that a high proportion of the expressed delta receptors appear to be uncoupled from G proteins. Saturation binding studies using radiolabeled naltrindole (NTI), [D-Pen<sup>2</sup>, D-Pen<sup>3</sup>]-enkephalin (DPDPE), [D-Ala<sup>2</sup>, D-Leu<sup>3</sup>]-enkephalin (DADLE), and [D-Ala<sup>2</sup>, D-Glu<sup>3</sup>] deltorphin (deltorphin II) demonstrated that the high affinity agonist binding for each of the tritiated agonists did not account for more than approximately one third of the total <sup>3</sup>H-NTI binding. Affinity constants of all ligands in saturation studies were comparable to those seen in NG108-15 membranes, but the K<sub>d</sub> values as competitors of <sup>3</sup>H-NTI binding are almost 10-fold greater than would be expected. Addition of the non-hydrolyzable guanine nucleotide analogue, Gpp(NH)p, did not shift the agonist competition curves in the stably transfected cells, suggesting that these ligands are competing at uncoupled receptors. These cells will provide a useful tool in the study of receptor-ligand and receptor-G protein interactions.

## 533.18

EFFECTS OF FULL AND PARTIAL  $\mu$ -OPIOID AGONISTS ON RECEPTOR-STIMULATED [35S]GTP $\gamma$ S BINDING. Dana E. Selley\*, Laura J. Sim, Ruoyu Xiao and Steven R. Childers. Department of Physiology and Pharmacology, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27157.

The ability of full and partial  $\mu$ -opioid agonists to stimulate [35S]GTP $\gamma$ S binding was examined in rat thalamic membranes. Agonist stimulation of [35S]GTP $\gamma$ S binding required the presence of excess GDP to suppress basal labeling of G-proteins by [35S]GTP $\gamma$ S. In the presence of 30  $\mu$ M GDP, the  $\mu$ -selective agonist DAMGO stimulated [35S]GTP $\gamma$ S binding in with a maximal stimulation of 135 % and an ED<sub>50</sub> value of 214 nM. Stimulation of [35S]GTP $\gamma$ S binding by DAMGO was consistent with a  $\mu$  opioid receptor-mediated mechanism, since naloxone reversed this effect with a K<sub>d</sub> value of 1.8 nM. Comparison of DAMGO with other  $\mu$ -opioid agonists indicated that it was a full agonist in this system. Morphine was a partial agonist of relatively high efficacy, since it produced approximately 60-70% of the maximal stimulation produced by DAMGO, whereas buprenorphine was a partial agonist of low efficacy (20-30% of DAMGO-stimulation). Similar efficacy relationships among these agonists were observed in membranes from the  $\mu$ -opioid receptor-containing cell line SK-N-SH, which contained about a 10-fold lower density of [35S]GTP $\gamma$ S binding sites than rat thalamic membranes. These results indicate that the difference in efficacy for G-protein activation among  $\mu$  agonists is determined at the level of the receptor, since these efficacy differences were conserved between the two systems.

Supported by PHS grants DA-07246 and DA-02904 from NIDA.

## 533.19

ACUTE AND CHRONIC EFFECTS OF OPIOIDS ON  $[35S]$ GTP $\gamma$ S BINDING IN NG108-15 AND SK-N-SH CELLS. Christopher S. Breivogel, Dana E. Selley, and Steven R. Childers\*. Department of Physiology and Pharmacology, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27157.

The activation of inhibitory GTP-binding proteins ( $G_i$ ) by opioid agonists was measured in NG108-15 and SK-N-SH cell lines by their ability to stimulate  $[35S]$ GTP $\gamma$ S binding in membranes along with excess GDP. In NG108-15 membranes, GDP decreased total  $[35S]$ GTP $\gamma$ S binding while increasing the percent stimulation of binding by agonists; 10-20  $\mu$ M GDP optimized these parameters. In these cells, the  $\delta$ -selective agonist DSLET stimulated binding approx. two-fold with an  $ED_{50}$  of 13 nM, and the  $\delta$ -selective antagonist naltrindole (NTI) exhibited a  $K_e$  of 0.04 nM. In membranes from SK-N-SH cells, which express both  $\mu$  and  $\delta$  receptors, GDP had similar effects to decrease total  $[35S]$ GTP $\gamma$ S binding and increase agonist stimulation. In these cells, the  $\mu$  agonist DAMGO stimulated binding approx. two-fold with an  $ED_{50}$  of 0.5  $\mu$ M, while  $\delta$  agonists were much less potent. Effects of  $\mu$  and  $\delta$  antagonists were consistent with the idea that agonist stimulation of  $[35S]$ GTP $\gamma$ S binding occurred almost entirely through  $\mu$  receptors.

Chronic treatment of NG108-15 cells with DSLET (1  $\mu$ M) from 0.5 to 22 hr resulted in rapid loss of DSLET-stimulated  $[35S]$ GTP $\gamma$ S binding in membranes. Maximal agonist stimulation decreased by 80% within 0.5-1 hr, and declined even further after overnight treatment. Treatment of SK-N-SH cells with morphine (10  $\mu$ M) decreased DAMGO stimulation of binding by 60% after overnight treatment, but had little effect on DAMGO stimulation after 0.5 hr of morphine treatment.

Supported by DA-02904 from NIDA.

## 533.21

ASTROGLIAL CELLS FROM THE RAT CEREBRAL CORTEX COEXPRESS DELTA OPIOID AND GLUTAMATE RECEPTORS T. Thorlin<sup>1</sup>, P. S. Eriksson<sup>1,2</sup>, E. Hansson<sup>1,3</sup> and L. Rönnbäck<sup>1,2</sup>. Institute of Neurobiology<sup>1</sup> and Department of Neurology<sup>2</sup> University of Göteborg and Department of Cell Biology, Faculty of Health Sciences, University of Linköping<sup>3</sup>, Sweden.

Astroglial cultures from the cerebral cortex were compared with tissue from the cerebral cortex concerning the expression of delta opioid receptor mRNA. The presence of  $\delta$ -receptor mRNA in glial cultures was verified using RT-PCR and Northern blot. The level of expression was shown to be lower in glial cultures compared with brain tissue when the expression was normalized to total RNA. The amount of delta receptor mRNA was quantified using an RNase protection assay.

Cultured neurons were shown to respond with a substantial decrease in the cytoplasmic free calcium after stimulation of  $\mu$ ,  $\delta$  and  $\kappa$  receptors. On the other hand, stimulation of cultured astroglial  $\delta$  receptors resulted in a substantial increase in the cytoplasmic free calcium. Glutamate receptors were shown to be co-localized with opioid receptors on cultured astroglial cells. Corresponding results were obtained in dissociated acute preparations of astroglial cells from the cerebral cortex. Astroglial cells in culture and acute dissociated astrocytes were identified by positive immunofluorescent staining for GFAP. The results obtained in acute dissociated preparations support the *in vitro* findings. The presence of glial opioid receptors might represent a novel mechanism contributing to the depressant action of opioids on synaptic transmission via decreasing the availability of calcium necessary for presynaptic transmitter release.

## 533.20

OPIOID REGULATION OF INTRACELLULAR FREE CALCIUM IN CULTURED MOUSE DORSAL ROOT GANGLION NEURONS. Tianlai Tang and Brian M. Cox\*. Department of Pharmacology, Uniformed Services University of Health Sciences, Bethesda, MD 20814

We have examined opioid effects on intracellular free calcium concentrations ( $[Ca^{2+}]_i$ ) in cultured single mouse dorsal root ganglion (DRG) neurons using Fluo-3-based fluorimetry. Opioid agonists induced an increase in resting  $[Ca^{2+}]_i$  or an inhibition of  $K^+$ -stimulated increase in  $[Ca^{2+}]_i$  in different subsets of DRG neurons. The total neuronal population was grouped into three classes according to their somatic diameter and defined as small- (<16  $\mu$ m), intermediate- (16-25  $\mu$ m), or large- (>25  $\mu$ m) sized neurons. Substance P-like immunoreactivity was mainly detected in the small- and intermediate-sized neurons. The  $\delta$ ,  $\kappa$ , and  $\mu$  opioid receptor agonists, [D-Ser<sup>2</sup>,Leu<sup>5</sup>]enkephalin-Thr (DSLET), U69593, and [D-Ala<sup>2</sup>, MePhe<sup>4</sup>, Gly-ol<sup>5</sup>]enkephalin (DAMGO) each induced an transient increase in  $[Ca^{2+}]_i$  in a small fraction (<30%) of neurons. The increases in  $[Ca^{2+}]_i$  were blocked by the opioid antagonist, naloxone. The dihydropyridine-sensitive calcium channel blocker, nifedipine, also blocked the increase in  $[Ca^{2+}]_i$  induced by 1  $\mu$ M DSLET, indicating that the opioids induced a calcium influx through dihydropyridine-sensitive calcium channels. The rank order of potency (percentage of cells responding to each opioid agonist) was DSLET > U69593 > DAMGO. The opioid-induced increase in  $[Ca^{2+}]_i$  was mainly observed in large-sized neurons with a low incidence in the small- and intermediate-sized neurons. Opioid agonists also caused inhibition of  $K^+$  (25 mM)-stimulated increases in  $[Ca^{2+}]_i$ , which were blocked by naloxone. Greater inhibition by 1  $\mu$ M DSLET or U69593 was found in small- and intermediate-sized neurons with a less inhibition in large-sized neurons. (Supported by a grant from the National Institute on Drug Abuse).

Functional determination of opioid receptor subtypes in the hypothalamic ventromedial nucleus of the rat. Zhang, C., Kow, L. M. & Pfaff, D. W. Lab. of Neurobiology and Behavior, The Rockefeller University, 1230 York Ave., New York, NY 10021, USA.

The preproenkephalin gene is expressed in the ventromedial nucleus (VMN) of the hypothalamus and is up-regulated by estrogen in ovariectomized female rats. The major product of preproenkephalin gene, met-enkephalin (mEnk) has been suggested to play a role in reproductive and emotional behaviors, but the nature of possible mEnk effects in VMN itself and the receptor subtypes that could mediate mEnk action have not been functionally characterized. In the present study, thin (400  $\mu$ m) hypothalamic slices containing VMN were prepared from ovariectomized rats primed with estrogen. Single unit activity was recorded extracellularly with glass microelectrodes from VMN neurons, and neuronal responses to bath-applied mEnk and agonists selective for  $\mu$  (DAGO),  $\delta$  (DPDPE) and  $\kappa$  (U50,488), opioid receptors, were examined. mEnk, DAGO and DPDPE inhibited, in a dose-dependent fashion (10 nM - 10  $\mu$ M), the spontaneous firing of VMN neurons with similar potencies, while U50,488 produced a much smaller inhibition. No excitatory response was observed. The inhibition produced by mEnk was blocked by naloxone, by the  $\delta$ -selective antagonist naltrindole, and to a lesser extent by the  $\mu$ -selective antagonist  $\beta$ -funaltrexamine, while the  $\kappa$ -selective antagonist Nor-BNI had no effect on the inhibition. The antagonists had no effect of their own on the spontaneous firing of VMN neurons under the present *in vitro* conditions. These results suggest that the major opioid receptors in the rat VMN are of the  $\mu$  and  $\delta$  subtypes, and that mEnk, a potential endogenous opioid transmitter in the VMN, can exert inhibitory effects by acting on  $\delta$  and  $\mu$  receptors. Supported by: grant # HD05751.

## OPIOID RECEPTORS: DEVELOPMENT AND REGULATION

## 534.1

ATTENUATION OF MORPHINE TOLERANCE AND ACUTE DEPENDENCE BY DELTA OPIOID RECEPTOR (DOR) ANTISENSE OLIGODEOXYNUCLEOTIDE TREATMENT. B. KEST\*, C.E. Lee, G. McLemore and C.E. Inturrisi. Dept. of Pharmacology, Cornell U. Medical College, New York, NY 10021.

Studies from several laboratories indicate a modulatory role for the DOR in morphine (MOR), tolerance (TOL), and dependence (DEP). We evaluated the role of the DOR in MOR TOL and acute DEP using an *in vivo* antisense strategy in mice. Intracerebroventricular (icv) saline, antisense or mismatch (different at 4 bases) oligos (ODNs; 12.5  $\mu$ g in 5  $\mu$ l) targeting nucleotides 7-26 of the DOR-1 mRNA for 3 days did not affect MOR tail-flick analgesia. When morphine was administered along with mismatch ODN or saline on days 4, 5, and 6 the MOR  $ED_{50}$  increased 4-fold on day 7, indicating the development of MOR tolerance. In antisense treated mice, however, the MOR  $ED_{50}$  was increased only 2-fold, representing an attenuation of MOR TOL relative to saline and mismatch treated mice. Naloxone (50 mg/kg, sc) produced vertical jumping, (acute DEP), 3 h after a single dose of MOR (50 mg/kg, sc). Three days of antisense, but not mismatch, ODN reduced the incidence and magnitude of jumping. These results suggest that downregulation of the DOR affects the development of MOR TOL and acute DEP and provides new evidence for a modulatory role of the DOR in morphine pharmacodynamics. Supported by NIDA Grants DA07274, DA01457, DA00198 and Grants from the Aaron Diamond Foundation.

## 534.2

PROOPIOMELANOCORTIN AND MU OPIOID RECEPTOR mRNA EXPRESSION IN THE FEMALE GUINEA PIG HYPOTHALAMUS: EFFECTS OF CHRONIC MORPHINE TREATMENT. Y. Fang, M.J. Kelly, D.K. Grandy, O.K. Ronnekleiv\*. Dept. of Physiology, Oregon Health Sciences Univ., and ORPRC, Portland, OR 97201.

Our previous electrophysiological studies have shown that hypothalamic beta-endorphin (BE) neurons express  $\mu$ -opioid receptors, which exhibit tolerance to chronic morphine in the ovariectomized (OVX) female guinea pig (GP). To further identify the response of BE to chronic morphine treatment, female GPs were OVX and implanted (s.c.) with 4x75 mg pellets for 2 days plus 6 more pellets of either morphine or placebo for 5 days. Animals were killed between 1000 and 1100 h on day 7, the brains quickly dissected and frozen. The expression of POMC and  $\mu$ -receptor mRNAs were investigated using *in situ* hybridization with GP-specific  $^{35}S$ -labeled cRNA probes. The results from X-ray film showed that the level of POMC mRNA in the arcuate nucleus (ARC) of morphine-treated GPs (n=6) was decreased by 22% compared with the placebo controls (n=6;  $P < 0.05$ ; paired two-tailed t-test), suggesting that the activity of POMC is down-regulated due to the exposure to chronic morphine. The expression of  $\mu$ -opioid receptor mRNA was determined from emulsion-coated tissue sections. This analysis revealed that the  $\mu$ -opioid receptor mRNA was distributed in many areas of the hypothalamus including the preoptic, anterior, mediobasal (MBH), dorsomedial, posterior and mammillary regions of both placebo and morphine treated GPs. Within the MBH  $\mu$ -opioid receptor mRNA was found in the ARC. Experiments are in progress to elucidate the effects of chronic morphine on the expression of  $\mu$ -opioid receptor mRNA in the female GP. Supported by NIH grants DA07165, DA05158, and DA08562.

## 534.3

EFFECTS OF CHRONIC MORPHINE ON  $\mu$ -OPIOID RECEPTOR BINDING AND mRNA IN THE GUINEA PIG CNS. M.A. Bosch\*, M.J. Cunningham, G. Zhang, E.J. Wagner, M.J. Kelly, D.K. Grandy, O.K. Ronnekleiv. Department of Physiology, the Oregon Health Sciences University, the Vollum Institute and ORPRC, Portland, OR, 97201

To elucidate the effects of chronic morphine on the expression of  $\mu$ -opioid receptors in different regions of the guinea pig (GP) CNS, females were ovariectomized and implanted (s.c.) with 4  $\times$  75 mg pellets, followed two days later with 6 more pellets of either morphine or placebo (n=8, each). This treatment produced plasma morphine levels of 559  $\pm$  180 ng/ml as measured by HPLC. Animals were killed between 1000-1100 h on day 7 and the preoptic area (POA), mediobasal hypothalamus (MBH) and the thalamus (THAL) were microdissected. Total RNA was isolated and  $\mu$ -receptor mRNA quantified using a ribonuclease protection assay with a GP-specific cRNA probe. Morphine, compared to placebo, significantly reduced the expression of  $\mu$ -receptor mRNA in the MBH ( $p < 0.035$ ; n=8, each) but not in the POA or the THAL. To evaluate morphine's effect on  $\mu$ -opioid receptor density, saturation binding studies were performed in  $P_2$  membrane fractions using antagonist radioligand [ $^3$ H] diprenorphine. DPDP and U50488 were included in the assays to occupy  $\delta$ - and  $\kappa$ -receptors, respectively. The  $\mu$ -receptor density was significantly decreased in the MBH of morphine-treated GP ( $B_{max} = 217 \pm 9$  fmol/mg protein) vs. controls ( $B_{max} = 276 \pm 16$  fmol/mg protein), with no change in the  $K_d$  (0.38  $\pm$  0.03 nM in morph vs. 0.37  $\pm$  0.05 nM in placebo). These data suggest that chronic morphine causes a down regulation of  $\mu$ -opioid receptor binding and receptor mRNA in the MBH of the GP. Supported by NIH grants DA07165, DA05158, and DA08562.

## 534.5

OPIOID RECEPTORS ARE BASALLY PHOSPHORYLATED IN GUINEA PIG BRAIN SLICES BY PKC AND PKA. T.A. Patterson\*, S.M. Applevard and C. Chavkin. Univ. of WA. Dept of Pharmacology, Box 357280, Seattle WA 98195

Antipeptide antibodies were generated against the guinea pig kappa and rat mu opioid receptor subtypes. Specificity of the antibodies was shown by western blotting analysis, peptide block and immunoprecipitation studies. The kappa and mu antibodies precipitated proteins of approximate molecular weights 54 kD and 73 kD, respectively.

Studies were performed to determine the phosphorylation state of opioid receptors in intact neurons. Slices were made from guinea pig whole brain or forebrain for kappa and mu studies respectively. Slices were metabolically labeled with  $^{32}$ P orthophosphoric acid prior to the addition of staurosporine, H-7, RpCAMPS or R24571. Receptors were immunoprecipitated and incorporation of  $^{32}$ P was determined with scintillation counting or phosphorimaging and normalized for relative receptor concentration based on western blotting.

The kappa receptor was basally phosphorylated under these conditions. Phosphorylation of the kappa receptor was significantly decreased ( $p < 0.05$ ) in the presence of the PKC and PKA inhibitors staurosporine and H-7 and not changed in the presence of the PKA inhibitor RpCAMPS or the CAM kinase inhibitor R24571. *In vitro* back-phosphorylation studies of the solubilized kappa receptor showed it to be an excellent PKC substrate and a weaker PKA substrate, in agreement with the metabolic labeling studies. Supported by DA04123.

## 534.7

PROTEIN KINASE A (PKA) REGULATES DELTA OPIOID RECEPTOR (DOR) mRNA IN NG108-15 CELLS. S. Jenab and C. E. Inturrisi\*. Dept. of Pharmacology, Cornell U. Med. Coll., New York, NY 10021.

In NG108-15 cells forskolin (FOR) increases intracellular cAMP and cAMP-dependent protein kinases (PKA) while it decreases DOR binding (Bergsbaken et al., 1993). In contrast ethanol up-regulates DOR binding and mRNA (Charness et al., 1993; Jenab and Inturrisi, 1994). We now report that the ethanol-induced increase in DOR mRNA is blocked by FOR (10  $\mu$ M). DOR mRNA was measured using solution hybridization and Northern blot analysis. FOR alone, but not the inactive dideoxy FOR, reduced DOR mRNA by 50%. Incubation of NG108-15 cells with 200 mM ethanol increased DOR mRNA transcript levels 2 fold and FOR blocked this induction. Northern blot analysis of RNA extracts indicated that these treatments altered each of the multiple DOR transcripts proportionately so that no difference was observed in the fraction of the total hybridization signal produced by each band. Inhibition of PKA by an analogue of cAMP (cAMPS, Rp-diastereomer 50  $\mu$ M) resulted in a 2 fold increase in DOR mRNA but no further increase when combined with ethanol. These results suggest that the induction of DOR mRNA by ethanol in NG108-15 cells is related to ethanol's ability to reduce cAMP-dependent PKA activities. Furthermore, DOR gene expression can be regulated by second messengers via PKA. Supported by NIDA Grants DA01457, DA05130, DA07274 and DA00198.

## 534.4

PRENATAL MORPHINE EXPOSURE DIFFERENTIALLY ALTERS EXPRESSION OF OPIOID PEPTIDES IN STRIATUM OF NEWBORNS

A. Tempel\*, J. Yang, and R. Basheer. Department of Anesthesiology, Long Island Jewish Medical Center, New York, 11040

Chronic morphine treatment in the adult central nervous system (CNS) has produced contradictory results, ranging from no change, to an upregulation as well as a downregulation of opioid receptors. In addition, decreases in proenkephalin (PPE) and dynorphin levels in striatum and hypothalamus have been reported while peptide levels are increased following morphine treatment. In the neonate, we have demonstrated a downregulation of  $\mu$ -opioid receptors in striatum of morphine-addicted newborns. The present study was carried out to investigate the effects of prenatal morphine on the levels and expression of endogenous opioid peptides in brain regions of newborns. Dams were implanted with one morphine pellet (75mg each) or placebo one week prior to the birth of pups. Changes in mRNA levels for the opioid peptides were determined by Northern blot analysis. Alterations in opioid peptide levels were determined by radioimmunoassays (RIAs). Prenatal morphine treatment significantly increased (38%;  $p < 0.03$ ) PPE mRNA levels and decreased met-enkephalin levels (40%;  $p < 0.01$ ) in striatum of newborns. No significant alterations in dynorphin levels were observed. This data is in contrast to what is observed in the adult CNS. These data indicate that prenatal morphine treatment may increase met-enkephalin release and/or cause inhibition at the level of translation. In addition, increased transcription may be necessary to maintain equilibrium in the system when there is an increase in met-enkephalin release (supported by LJMC Faculty Research Award).

## 534.6

NOVEL EFFECTS OF FENTANYL OPIATES WITH  $\mu$ -OPIATE RECEPTORS IN A RECOMBINANT CELL LINE. C. CASEY\* AND M. TEITLER. Dept. of Pharmacology & Neuroscience, Albany Medical College, Albany, NY 12208

Previous reports have indicated that, in general, fentanyl and fentanyl-like compounds such as carfentanyl are selective  $\mu$ -opioid receptor agonists (1,2). In order to further explore the nature of novel direct molecular interactions of fentanyl derivatives with  $\mu$ -opioid receptors, and to explore possible differences in the effects of chronic fentanyl stimulation on  $\mu$ -opioid receptor function, studies were undertaken taking advantage of the recent development of recombinant cells selectively expressing the  $\mu$ -opioid receptor (3). Initial characterization indicated that there was a striking difference in the effect of GppNHP on the levels of binding of  $^3$ H-carfentanyl-labelled  $\mu$ -opioid receptors, versus  $^3$ H-DAMGO-labelled receptors. GppNHP produced a far more dramatic inhibition of the levels of  $^3$ H-carfentanyl-labelled receptors (~90% inhibition) than of  $^3$ H-DAMGO-labelled receptors (~40%). These results indicate a difference in the molecular interaction of a fentanyl-stimulated  $\mu$ -opioid receptor with a G-protein, versus a DAMGO-stimulated  $\mu$ -opioid receptor. Studies involving chronic treatments with fentanyl derivatives will be presented along with data on the initial characterization of  $^3$ H-carfentanyl binding in recombinant cells expressing  $\mu$ -opioid receptors. Mechanisms responsible for the dramatic desensitization characteristic of chronic opiate administration should be revealed by these studies.

## 534.8

DOWN REGULATION OF DELTA-OPIOID mRNA LEVELS BY INCREASED cAMP LEVELS IN DIFFERENTIATED NG108-15 CELLS. K.H. Grylvs\*, D. E. Keith, and C.I. Evans. Dept. of Psychiatry & Biobehavioral Sciences, University of California, Los Angeles CA 90024.

The second messenger cAMP has been shown to regulate adrenergic receptor mRNA (Collins et al., 1991), and the  $\mu$ -opioid promoter contains the consensus sequence for a cAMP regulatory element (Min et al., 1994). We have examined cAMP regulation of  $\delta$ -opioid mRNA in differentiated NG108-15 cells. Because the IBMX/forskolin combination is nonselective in its actions we have also used the selective PDE inhibitor rolipram and prostaglandin E<sub>2</sub> to look at cAMP regulation in NG108-15 cells differentiated with retinoic acid. Cultures were differentiated for 3 days with retinoic acid before exposure to drugs for varying lengths of time. Cells were then harvested, total RNA was isolated, and quantitative Northern analysis performed. The three agents examined: rolipram (100  $\mu$ M), IBMX/forskolin (250/5  $\mu$ M), and PGE<sub>2</sub> (10  $\mu$ M), all caused a down-regulation of  $\delta$ -opioid message to less than 10% of control levels. Maximum inhibition occurred after 8 or 24 hours of treatment. These results suggest a possible mechanism for heterologous regulation of  $\delta$ -opioid receptors.

Supported by NIDA grant # DA05010 and DA05609 and the W.M. Keck Foundation.

## 534.9

PHOSPHORYLATION OF EXPRESSED HUMAN MU OPIATE RECEPTORS J. B. Wang\*, G. Pei\* and G. R. Uhl<sup>1</sup> Dept. of Pharmaceutical Sciences, School of Pharmacy, University of Maryland at Baltimore, MD 21201, <sup>1</sup>Shanghai Institute of Cell Biology, People's Republic of China and <sup>2</sup>Molecular Neurobiology Branch, NIDA/IRP, NIH, Baltimore MD 21224

Mu opiate receptors can desensitize when agonist-induced K<sup>+</sup> channel responses are examined in expression systems including *Xenopus* oocytes. Mechanisms underlying such processes could include phosphorylation events involved in desensitizing other G-linked receptors. To explore the possible roles of phosphorylation in mu opiate receptor desensitization, we constructed mu receptors fused at N- and C- terminals to HA12CA5 epitope tags and examined their expression in COS cells. These constructions each appear to express nearly-normal affinities and B<sub>max</sub> values for [<sup>3</sup>H] DAMGO binding. These constructions expressed in COS cells were exposed to various drug treatments in the presence of <sup>32</sup>Pi, tagged proteins were immunoprecipitated with anti-HA12CA5 antibodies, resolved on SDS-PAGE gels and radiolabelled mu receptor ca. 60 kd band identified by autoradiography. mu receptor-expressing COS cells free from opiate agonists revealed no <sup>32</sup>Pi radiolabelling of the ca. 60 kd band. Cells exposed to 1 μM DAMGO for 3 min reveal apparent agonist-dependent mu receptor phosphorylation. Phorbol ester treatment for 3 min also enhanced receptor phosphorylation while forskolin failed to stimulate phosphorylation. These observations are consistent with previous suggestions of protein kinase C involvement in desensitization. Candidate sites for receptor phosphorylation are being tested by assessment of mu receptor mutants. Both mu and other G-linked receptors can alter PKC function; these mechanisms could thus be implicated in both homologous and heterologous desensitization.

## 534.11

DEVELOPMENTAL EXPRESSION OF OPIOID RECEPTOR mRNAs. R.C. Thompson\*, J. Wong, H. Akil, and S. J. Watson, Mental Health Research Institute, University of Michigan, Ann Arbor, Michigan, 48109-0720.

Endogenous opioid peptide systems have been implicated in neuronal development including putative roles as trophic factors. Binding studies of the three major classes of opioid receptors (mu (μ), delta (δ), and kappa (κ)) have demonstrated that mu and kappa receptors are detected relative early in development in the rodent (approximately E12 in rat) whereas delta receptors are not detected until postnatal time periods. Based in part on this work, much focus has been placed upon the roles of β-endorphin and dynorphin during development. However, little is known about the precise anatomical expression of the opioid receptors in the rat. In order to evaluate the potential roles of endogenous opioid peptide systems during development, we felt that it was very important to determine which opioid receptor mRNAs were expressed during specific developmental time points. The expression of mu, delta, and kappa opioid receptor mRNA was examined in rat embryos and pups by *in situ* hybridization with cRNA probes derived from the three cloned opioid receptors. Autoradiograms from these studies document several interesting findings. Mu receptor mRNA is detected as early as E12 within the developing central nervous system and in components of the peripheral nervous system at multiple developmental time points. Kappa RNA is also expressed at E12 stages. Preliminary data on delta mRNA expression suggests that it is also expressed during development but not at the same levels as kappa or mu mRNAs. Complete anatomical comparisons will be presented and discussed. This work is supported by grants DA02265 and DA 08920.

## 534.13

ONTOGENY OF THE EXPRESSION OF THE MU OPIOID RECEPTOR GENE IN RAT BRAIN: AN *IN SITU* HYBRIDIZATION STUDY. J.-G. Chabot<sup>1</sup>, Y. Tong<sup>1,2</sup>, S.-H. Shen<sup>2</sup>, B.F. O'Dowd<sup>1</sup>, S.R. George<sup>3</sup> and R. Quirion<sup>1</sup> Douglas Hosp. Res. Ctr., Dept. of Psychiatry, McGill University, Montreal, H4H 1R3. <sup>2</sup> Biotechnology Research Institute, Montreal, H4P 2R2. <sup>3</sup> Dept. of Pharmacology, Medical Sciences Building, University of Toronto, Toronto, M5S 1A8, CANADA.

The recent cloning of the μ opioid receptor has allowed the comparative localization of the receptor mRNA and its translated protein using *in situ* hybridization and quantitative receptor autoradiography (e.g., Mansour et al., *TINS*, 18, 22, 1995). The aim of the present study was to examine the developmental profile of the expression of the μ receptor mRNA in the rat brain in order to provide new insights as to the putative role of this receptor in normal brain ontogeny. The anatomical distribution of μ receptor gene expression in the developing (ED11 - PD40) and adult (PD60) rat brain was investigated using quantitative *in situ* hybridization. Eighteen μm-thick brain sections were hybridized with [<sup>32</sup>S]UTP-labeled riboprobes generated to the rat μ receptor (George et al., *BBRC* 205, 1438, 1994). μ receptor mRNA was observed to be first detectable in the neuroepithelium at ED12. In the developing CNS (ED14 - P40), transcripts were seen over numerous telencephalic, diencephalic and mesencephalic areas. For example, in the developing striatum, transcripts were detected first in the striatal anlage at ED14, increasing rapidly to reach maximal levels during the first postnatal week to then decrease to reach adult levels during the next two postnatal weeks. Hybridization signal remained diffuse in the striatum until PD6 to then began to assume the adult patchy distribution. Similar results were previously reported for μ receptor binding sites (Kent et al., *Dev. Brain Res.* 2, 487, 1982; Kornblum et al., *Brain Res.* 465, 21, 1987). In summary, endogenous opioids, μ receptor mRNA and its translated protein are present very early on in the embryonic brain and demonstrate transient increases during the critical period of neurogenesis, neuronal migration and synaptogenesis. Supported by the MRCC.

## 534.10

DIFFERENT RATE OF DESENSITIZATION IN THE MULTIPLE SIGNALING PATHWAYS OF OPIOID RECEPTOR. Shuji Kaneko\*, Nobumichi Yada<sup>1</sup>, Kei Adachi<sup>1</sup>, Akinori Akaike<sup>1</sup> and Masamichi Satoh<sup>2</sup>. Depts. of <sup>1</sup>Pharmacol. and <sup>2</sup>Mol. Pharmacol., Faculty of Pharm. Sci., Kyoto Univ., Kyoto 606-01, Japan.

RNA-injected *Xenopus* oocytes were used for studying homologous desensitization of opioid receptors to G-protein-coupled intracellular signaling pathways. In the oocytes expressing κ opioid receptor, voltage-dependent Ca<sup>2+</sup> channel α<sub>1</sub> and β subunits, the κ agonist U50488H (1 μM) inhibited Ca<sup>2+</sup> channel current in a reversible manner, and the inhibition was diminished by sustained agonist exposure (homologous desensitization). More than 30 min was required to halve the inhibition of BI- or Q-type Ca<sup>2+</sup> channels by the κ agonist, however, the t<sub>1/2</sub> for U50488H-induced inhibition of BIII- or N-type channels was only 7 ± 1 min. Moreover, in the oocytes expressing κ opioid receptor, EP<sub>4</sub> prostaglandin receptor and CFTR channel, no apparent desensitization was observed in the κ receptor-mediated potentiation of the cyclic AMP production by prostaglandin E<sub>2</sub> even when the oocytes were treated with U50488H for 2 hours or more. The time-course of desensitization of μ opioid receptor was also different in the effector molecules. These observations suggest that rate of homologous desensitization of opioid receptor is not only dependent on the receptor molecule itself but also on its intracellular signaling systems.

## 534.12

DEVELOPMENTAL EXPRESSION OF THE MU OPIOID RECEPTOR IN THE MOUSE Y. Zhu\*, B. Anton, M. Hsu, C. J. Evans, J. E. Pintar. Dept. Neurosci. & Cell Biol., UMDNJ Robert Wood Johnson Med. Sch., Piscataway, NJ 08854 and Dept. Psychiatry, UCLA Sch. of Med., Los Angeles, CA 90024.

To characterize the establishment of opioid systems during development, we have begun to examine the distribution of μ receptor mRNA at both prenatal and postnatal stages of mouse development using *in situ* hybridization. Restricted μ receptor gene expression has been detected as early as e10.5, in the VII-VIII preganglion complex. By e12.5, cells expressing μ-receptor mRNA are found in the facial (VII) and vestibulocochlear (VIII) ganglia. In the central nervous system at this age, μ-receptor mRNA expression is detected in the basal telencephalon and ventral spinal cord. At e13.5, cells expressing μ-receptor are found in the thalamus, hypothalamus and dorsal medulla with relatively high levels of μ receptor mRNA observed in caudate-putamen. At e15.5, the expression pattern of the μ receptor is similar to that at e13.5, though the intensity of the hybridization signal has increased. The mRNA expression at e15.5 has expanded to cover most of the dorsal spinal cord in addition to the ventral regions of the spinal cord seen earlier. By e17.5, μ receptor mRNA starts to appear in the mitral cell layer of olfactory bulb and in the subplate of cortex. Therefore, μ receptor expression develops earlier in many other brain regions than in the cortex. Besides caudate-putamen, strong signals are also found in the medial habenula. In the trunk, μ receptor can still only be detected in the spinal cord and the dorsal root ganglion. Our results confirm and extend results from previous ligand binding studies using whole mouse brain that showed that μ receptor binding activity can be detected as early as e12.5, and in addition, provide direct evidence for opioid receptor gene expression in the earliest stages of peripheral gangliogenesis. Supported by DA-09040 to JP.

## 534.14

THE EFFECTS OF AGING ON THE BINDING OF <sup>3</sup>H-NALTRINDOLE IN THE BRAIN AND SPINAL CORD OF F-344 RATS. D. L. Hoskins\* and T. Crisp. Department of Pharmacology, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272.

Previous studies have shown a dramatic decline in the antinociceptive efficacy of δ opioid receptor agonists with advancing age. This study was performed to ascertain whether this may be due to either a decline in the total number of receptors (B<sub>max</sub>), or a general decline in the affinity (K<sub>d</sub>) of the δ opioid receptor for its substrate. Saturation studies were performed on P2 fractions from cortex, striatum and hippocampus; while S2 fractions were used for the brainstem and spinal cord. Membranes from young (5-6 months) mature (15-16 months) and aged (25-26 months) rats were incubated with increasing concentrations of <sup>3</sup>H-naltrindole (a δ-specific opioid antagonist) for 5 hours at 25°C. Preliminary Scatchard analysis reveals no age-related decrease in either affinity or B<sub>max</sub>.

## 534.15

**THE REGULATION OF ASTROGLIAL PROENKEPHALIN AND OPIOID RECEPTOR mRNA EXPRESSION BY INTERLEUKIN-1 $\beta$ .** B.B. Ruzicka\*, R.C. Thompson, S.J. Watson and H. Akil, Mott Hilt Res Inst, University of Michigan, Ann Arbor, Michigan, 48109-0720. Opioids have been found to modulate the immune system by regulating the function of immunocompetent cells via both classical and non-classical opioid receptors. Several studies suggest that the interaction between the opioid and immune systems is not unidirectional, but rather, reciprocal, in nature. In the central nervous system (CNS), one cellular target of immune system activation is the astrocytes, glial cells which have been shown to synthesize the opioid peptide, pro-enkephalin (ENK), and, very recently, to express the  $\mu$ ,  $\delta$  and  $\kappa$  opioid receptors.

To study the potential interaction between immune factors and the astroglial opioid "system", we examined the effect of interleukin-1 $\beta$  (IL1 $\beta$ , 1 ng/ml, 24 h treatment) on the levels of ENK and  $\mu$ ,  $\delta$  and  $\kappa$  receptor mRNA expression in primary cultures of astrocytes derived from rat (postnatal day 1-2) cortex, striatum, cerebellum, hippocampus and hypothalamus. Preliminary data show that IL1 $\beta$  regulated astroglial ENK mRNA levels in a brain region-dependent manner. IL1 $\beta$  dramatically reduced (>50%) ENK mRNA levels in the hippocampus, but not in the other four astroglial cultures. The effect of IL1 $\beta$  on the opioid receptor mRNA varied both with respect to the receptor type and brain region. IL produced a significant increase (70-80%) in the  $\mu$  receptor mRNA levels in the striatal and cerebellar cultures, but had little effect on these levels in the cortical, hippocampal or hypothalamic cells. In marked contrast, IL1 $\beta$  profoundly decreased (>70%) the levels of  $\kappa$  receptor mRNA in the cortical and hypothalamic astrocytes, but had little effect on these levels in the cultures derived from other brain regions. The effects of IL1 $\beta$  on the levels of  $\delta$  receptor mRNA are currently under investigation, as are the possible intracellular signalling cascades associated with the IL1 $\beta$ -elicited effects. However, the present findings support an IL1 $\beta$ -mediated regulation of astroglial ENK and opioid receptors *in vitro*, and suggest that the glial opioid "system" may be important in the IL1 $\beta$ -initiated, coordinated response to CNS infection, trauma or injury. (Supported by the MRC of Canada and NIDA).

## 534.17

**3'-CDNA REGIONS NEGATIVELY INFLUENCE  $\mu$  OPIATE RECEPTOR EXPRESSION.** P.S. Johnson\*, J.B. Wang#, J.M. Wu#, C.E. Spivak#, G.R. Uhl#/@, C.K. Surrat#, Molecular Neurobiology Branch#, Office of the Director!, Intramural Research Program/NIDA; Dept. of Neurology and Neuroscience@, Johns Hopkins School of Medicine.

cDNA clones encoding rat and human  $\mu$  opiate receptors include products of alternative splicing that confer C-terminal receptor variant sequences, as well as lengthy stretches of 3'-untranslated sequence (3'-UTR). COS cells transiently expressing the  $\mu$ OR1 sequence with 30 bp of 3'-UTR sequence cloned into pCDNA-2 displayed [ $^3$ H]DAMGO and [ $^3$ H]naloxone binding  $B_{max}$  values 3- to 6-fold higher than those displayed by a  $\mu$ OR1 construction with 700 bp of 3'-UTR ( $\mu$ OR1-700).  $\mu$ OR1-700 expressed at levels several-fold higher than those of a  $\mu$ OR1A splice variant (Bare et al. (1994) *FEBS Lett.* 354, 213) lacking  $\mu$ OR 3'-UTR. Both  $\mu$ OR1 and  $\mu$ OR1A display similar affinities for [ $^3$ H]DAMGO and both mediate opiate-induced adenylate cyclase inhibition. Conversely, a construction lacking the 33 C-terminal  $\mu$ OR amino acids and its 3'-UTR expressed at ca. 80% of wildtype levels. 3'-Translated and untranslated sequences play significant roles in  $\mu$ OR expression levels in an *in vitro* test system. Conceivably, these sequences could function to alter mRNA stability, protein stability, and/or mRNA translation rates to regulate  $\mu$ OR expression in neurons.

## 534.16

**CHANGES IN  $\delta$ -OPIOID RECEPTOR mRNA DETECTED IN NG108-15 CELLS BY RIBONUCLEASE PROTECTION ASSAY.** E.A. Sehba, B.C. Yoburn, J.M. Carroll\*, College of Pharmacy and Allied Health Professions, St. John's University, Jamaica, N.Y. 11439

The measurement of  $\delta$ -opioid receptor (DOR) mRNA provides an important insight into the mechanism of opioid receptor regulation. Both cDNA and riboprobes can be used to assess changes in DOR mRNA. However, using Northern analysis, it was difficult to detect DOR mRNA in total RNA preparations from NG108-15 cells with a cDNA probe. Therefore, we used a ribonuclease protection assay (RPA) which afforded enhanced sensitivity. The RPA was optimized for detection of DOR, glyceraldehyde phosphate dehydrogenase (GAPDH) and actin mRNAs in total RNA from NG108-15 cells. Two riboprobes of 1116 and 450 nt were prepared from the DOR-1 plasmid (Evans et al., *Science*, 258:1952, 1992). Hybridization with either probe generated a single protected band on PAGE. Cells were treated for 24-36hr with 200mM ethanol. Ethanol produced an increase in DOR mRNA compared to controls as detected by the RPA. The change in DOR mRNA was selective since no change in actin mRNA was observed. Currently, we are investigating the temporal relationship between increased mRNA and expression of functional receptor using a binding assay. This system will be used to study the effects of various agents on DOR mRNA and receptor protein expression in NG108-15 cells. (Supported by NIDA DA 04185)

## OPIOID RECEPTORS: LOCALIZATION

## 535.1

**LOCALIZATION OF OPIOID RECEPTOR-LIKE IMMUNOREACTIVITY (OR-LI) IN PORCINE SMALL INTESTINE.** M.A. Osinski, T.R. Kowalski, M.P. Murtaugh, R.P. Elde, and D.R. Brown\*. Depts. of Vet. Pathobiology and Cell Biology & Neuroanatomy, Univ. Minnesota, St. Paul, MN 55108.

The localization of opioid receptors in the central and peripheral nervous systems has been limited to autoradiographic and *in situ* hybridization studies due to the lack of receptor-specific antisera. One of us (R.P.E.) has recently produced polyclonal antisera against unique peptide sequences of the  $\mu$  (MOR) and  $\delta$  (DOR) opioid receptors. An indirect immunofluorescence procedure was used to detect opioid receptor immunoreactivity of 10  $\mu$ m-thick cryosections of Zamboni-fixed ileum from 8-12 week old pigs of both sexes. DOR-LI was observed in the myenteric and submucosal ganglia as well as in transected axonal profiles in the circular muscle layer of the muscularis externa. Some submucosal ganglia subjacent to ileal lymphoid follicles of Peyer's patch-containing intestinal segments also exhibited DOR-LI. In the mucosa, DOR-LI was displayed by nerve fibers in the lamina propria of the villi. MOR-LI was present in the submucosal and myenteric ganglia. Immunohistochemical staining with antiserum to [Leu]enkephalin revealed a pattern of immunoreactivity similar to DOR-LI. Thus, the structural data we describe agree with previously reported pharmacological data on the role of OR neurotransmission in the control of secretory and motor function of the mammalian small intestine. Additionally, the novel finding of OR-LI near immune structures suggests a possible role for OR in intestinal neuroimmune regulation.

## 535.2

**EXPRESSION OF  $\delta$ - AND  $\kappa$ -OPIOID RECEPTOR mRNA IN THE HUMAN NEOCORTEX.** P. Schmidt<sup>1</sup>\*, A. Wevers<sup>2</sup>, K. Maderspach<sup>3</sup>, E. Cserpan<sup>3</sup>, I. Cserpan<sup>4</sup>, M. Staak<sup>1</sup>, H. Schröder<sup>2</sup>, <sup>1</sup>Inst. für Rechtsmedizin and <sup>2</sup>Inst. II für Anatomie, Univ. zu Köln, 50823 Köln, FRG, <sup>3</sup>Inst. of Biochemistry and <sup>4</sup>Genetics, Biological Research Center, Hungarian Academy of Sciences, 6701 Szeged, Hungary

The effects of opiates in the human central nervous system are mediated via at least three major classes of opioid receptors (OR):  $\mu$ ,  $\delta$  and  $\kappa$ . By means of immunohistochemistry we have previously shown the localization of the  $\kappa$ -OR protein in layers II/III, V and partly VI of the human frontal cortex.

Presently the cellular expression of the  $\delta$ - and  $\kappa$ -OR mRNA in different cortical areas (A4, A10, A17 according to Brodmann) is studied by non-isotopic *in situ* hybridization. Digoxigenin 3' endlabeled oligonucleotide probes were applied. Hybrids were visualized by alkaline phosphatase coupled anti-digoxigenin antibodies and incubation with NBT/BCIP. The mRNAs for the  $\delta$ - and  $\kappa$ -OR were expressed in all cortical areas, especially in the pyramidal cells of layer III and V as well as in the multimodal neurons of layer VI. In A4 the giant pyramidal cells and in A17 the stellate neurons stood out prominently labelled. In comparison, the transcripts of the  $\delta$ -OR seemed to be more abundant than those for the  $\kappa$ -OR. For the latter, thus, a good correlation of mRNA and protein expression sites was encountered.

The combined cellular assessment of the mRNA is intended to be compared with the expression under pathological conditions, i.e. in drug-related fatalities of heroin/morphine addicts.

Supported by DFG, grant Schr 283/13-1, and by OTKA T6374, Hungary

## 535.3

LOCALIZATION OF DOR1 AND MOR1 IMMUNOREACTIVITY IN THE MONKEY CENTRAL NERVOUS SYSTEM. M. Riedl\*, U. Arvidsson, R.J. Dado, A. Nakano, L. Vulchanova, P.-Y. Law, H.H. Loh, C.N. Honda, M.W. Wessendorf, and R. Elde. Departments of Cell Biology and Neuroanatomy and Pharmacology, University of Minnesota, Minneapolis, MN 55455.

Antisera to the cloned  $\delta$ - and  $\mu$ -opioid receptors have been raised in rabbits and extensively characterized (Dado et al., Neuroreport 1993, Arvidsson et al. J. Neurosci 1995 a, b). The distribution of DOR1- and MOR1-immunoreactivity (-ir) is generally consistent with the distribution of the receptors as ascertained by binding as well as in situ hybridization studies in the rodent brain. However, the efficacy of the antisera to recognize the receptor and the distribution of DOR1- and MOR1-ir has not been described in the primate brain. Therefore, three Maccaca mulatta monkeys (1.5 - 4 yrs.) were transcardially perfused with 4% paraformaldehyde, followed by 10% sucrose in PBS. The brain and spinal cord were blocked and 50  $\mu$  frozen sections were cut on a freezing microtome. The sections were then processed for immunohistochemistry. Prominent DOR1-ir was seen in the medial septal n., anterior hypothalamic area, globus pallidus, substantia nigra, periaqueductal gray, and spinal cord dorsal horn. Interestingly, most of the DOR1-ir was confined to axons, suggesting a presynaptic receptor. These results are similar to those reported in rat brain. Intense MOR1-ir was seen in the preoptic area of the hypothalamus, paraventricular n. of the thalamus, interpeduncular n., central linear raphe n., and spinal cord dorsal horn. In contrast to DOR1-ir, the major portion of MOR1-ir was seen in dendrites and cell bodies, suggesting a postsynaptic receptor. Supported by grants from NIDA.

## 535.5

ULTRASTRUCTURAL LOCALIZATION OF MU, DELTA AND KAPPA OPIOID RECEPTORS IN THE NUCLEUS SOLITARIUS. B.E. Maley\*<sup>1</sup>, M.G. Engle\*<sup>1</sup> and R.P. Elde\*<sup>2</sup>. <sup>1</sup>Dept. of Anatomy and Neurobiology, Univ. of Kentucky Chandler Med. Ctr., Lexington, KY 40536 and <sup>2</sup>Dept. of Cell Biology and Neuroanatomy, Univ. of Minnesota Med. Ctr., Minneapolis, MN 55455.

Opioid peptides are known to have profound effects on the cardiovascular and respiratory system. One area which is known to be involved in the synaptic circuits regulating the cardiovascular and respiratory systems is the nucleus solitarius which we have reported previously to have significant amounts of enkephalin immunoreactivity. In the present study we report the immunohistochemical demonstration at the ultrastructural level of mu, delta and kappa opioid receptors along the neuronal membrane of nucleus solitarius cells. Male Sprague-Dawley rats were perfused with 4% paraformaldehyde-0.5% glutaraldehyde in Sorenson's phosphate buffer, pH 7.4. The caudal brainstem containing the nucleus solitarius was sectioned in the coronal plane. Sections were immunostained either with the peroxidase, anti-peroxidase method for pre-embedding immunocytochemistry or with colloidal gold for the post-embedding technique. All sections were embedded in LR White resin for ultrastructural analysis. Mu and kappa opioid receptors were associated with the neuronal membrane of presynaptic terminals and postsynaptic structures at both conventional postsynaptic specializations as well as at extra-synaptic sites. In contrast, delta opioid receptors were associated with presynaptic terminals. Results of the present investigation indicate that at least the mu and kappa opioid receptors are associated with many of the same structures which we have reported to be postsynaptic to the endogenous opioid peptide, enkephalin. The presence of mu opioid receptors at extra-synaptic sites suggests that opioid peptides may exert their influence at sites other than synaptic junctions. The association of delta opioid receptors with presynaptic terminals indicates that it acts in the presynaptic regulation of those structures.

## 535.7

ULTRASTRUCTURAL LOCALIZATION OF  $\mu$ -OPIOID RECEPTOR IMMUNOREACTIVITY AND RELATIONSHIP TO ENKEPHALIN IN CERVICAL DORSAL HORN OF THE RAT SPINAL CORD. P.Y. Cheng\*<sup>1</sup>, A. Moriwaki\*<sup>2</sup>, J.B. Wang\*<sup>2</sup>, GR Uhl\*<sup>2</sup>, VM Pickel\*<sup>1</sup>. <sup>1</sup> Dept of Neurology and Neuroscience, Cornell Univ Medical College, New York, NY, 10021. <sup>2</sup> Molecular Neurobiology Branch, Intramural Research Program, NIDA and Dept of Neurology and Neuroscience, Johns Hopkins Univ School of Medicine, Baltimore, MD, 21224.

We used a polyclonal rabbit antiserum against an 18 amino acid sequence from the carboxyl terminus of the  $\mu$ -opioid receptor (MOR) to determine the potential cellular sites for the analgesic actions of opiates in the rat cervical spinal cord. By light microscopy, MOR-like immunoreactivity (MOR-LI) was most intensely localized, using either peroxidase or gold-silver labeling methods, to processes in lamina I and II of the dorsal horn. Electron microscopic examination of this region revealed prominent localization of immunogold-silver labeling for the MOR specifically along membranes of dendrites, axons and axon terminals. The majority of the gold-silver particles were associated with portions of the dendritic membrane not contacted by afferent terminals. We have also shown by dual labeling that Leu<sup>5</sup>-enkephalin (LE) was sometimes present in axon terminals which contacted the dendrites showing MOR-LI. However, the majority of the LE-labeled axon terminals did not directly appose either dendrites or axons within the plane of sections that contained MOR-LI. These results provide the first direct evidence that the MOR is preferentially localized both to non-synaptic as well as possible synaptic sites along the membrane of dendrites and axons within the superficial layers in the dorsal horn of the rat cervical spinal cord. Activation of the receptors by LE or exogenous opiates thus may produce analgesia through modulation of the postsynaptic receptivity or presynaptic release of other transmitters within superficial laminae of the spinal cord. (Supported in part by an Aaron Diamond Foundation Postdoctoral Fellowship to PYC, NIDA DA 04600 and HL 18974 to VMP and NIDA Intramural Research Program).

## 535.4

THE MU OPIOID RECEPTOR IS EXPRESSED IN THE RETINA AND RETINAL-RECIPIENT NUCLEI. N. Brecha\*, J. Johnson, R. Kui, B. Anton, D. Keith Jr., C. Evans, and C. Sternini. Depts. of Neurobiol., Med. and Psych., UCLA and VAMC-WLA, LA, CA 90073.

The purpose of this study was to determine the cellular localization of the mu opioid receptor in the rat visual system using immunohistochemistry with an affinity purified polyclonal antibody directed to the C-terminus of the mu receptor. Prominently immunostained medium to large cell bodies are found in the ganglion cell layer in all retinal regions. Immunoreactive (IR) processes are confined to the inner plexiform layer. Mu receptor-IR cells are likely to be ganglion cells. In retinal-recipient nuclei, mu receptor-IR is expressed by fibers. The highest level of mu receptor-IR is in the accessory optic nuclei (AON), and in the olivary pretectal nucleus. Moderate levels of IR are present in the superficial layers of the superior colliculus, the nucleus of the optic tract and the lateral geniculate nucleus (LGN) with stronger immunostaining in the ventral LGN and intergeniculate leaflet compared to the dorsal LGN. The lowest level of mu receptor-IR is in the suprachiasmatic nucleus. Retinal removal resulted in the elimination or reduction of mu receptor-IR in several retinal-recipient nuclei, including the LGN and the AON. These observations indicate that retinal ganglion cells give rise to the prominent mu receptor-IR fibers located in several retinal-recipient structures. These findings indicate that endogenous opioids can influence sensory processing in the visual system at mu receptors.

Supported by EY 04067, DA 05010, and VA Medical Research Funds.

## 535.6

LIGHT AND ELECTRON MICROSCOPIC LOCALIZATION OF  $\mu$ -OPIOID RECEPTOR IMMUNOREACTIVITY WITHIN THE NUCLEUS OF THE SOLITARY TRACT. TA Milner\*<sup>1</sup>, PY Cheng\*<sup>1</sup>, LY Liu-Chen\*<sup>2</sup>, C Chen\*<sup>2</sup>, VM Pickel\*<sup>1</sup>. <sup>1</sup>Dept of Neurology and Neuroscience, Cornell Univ Medical College, New York, NY, 10021. <sup>2</sup>Dept of Pharmacology, Temple Univ School of Medicine, Philadelphia, PA, 19140.

Opioids within the nucleus of the solitary tract (NTS) are involved in analgesic, cardiovascular and respiratory responses to stress. To determine the potential cellular sites for the physiological effects of the opioids within the NTS of the rat brainstem, we examined the cellular localization of the  $\mu$ -opioid receptor (MOR) using a rabbit polyclonal antiserum raised against a 17 amino acid peptide of the carboxyl terminal domain of the cloned receptor. By light microscopy, MOR-like immunoperoxidase labeling was detected throughout the rostrocaudal extent of the solitary tract and medial NTS. Electron microscopy established that varicose processes within the medial and commissural nuclei at the level of the area postrema were axon terminals. In addition, using silver-intensified immunogold, we more discretely demonstrated a preferential localization of MOR along plasma membranes of both axons and dendrites. These particles were not usually associated with synaptic specializations. Our results indicate that visceral responses to stress or pain are modulated by opioids acting non-synaptically on axons, which are most likely to be primary afferents, as well as target neurons within the NTS.

(Supported by an Aaron Diamond Foundation Postdoctoral Fellowship to PYC, NIDA DA04600 to VMP and DA04745 to LYLIC).

## 535.8

CELLULAR DISTRIBUTION OF DELTA OPIOID RECEPTORS IN THE RAT SPINAL CORD: CONFOCAL AND EM ANALYSIS WITH THREE-DIMENSIONAL RECONSTRUCTION. M. Gastard\*, P. Mailly, M. Conrath. Laboratoire de Neurobiologie des Signaux Intercellulaires, Université P. & M. Curie, 7 quai Saint-Bernard, 75252, Paris Cedex 05, France.

Using a monoclonal anti-idiotypic antibody and immunocytochemistry, we studied the distribution of delta opioid receptors in the spinal cord of rats fixed with 4% paraformaldehyde. Confocal microscopy revealed that delta opioid receptor immunoreactivity was present in many labeled axons of the superficial dorsal horn (notably lamina I) and of lamina X. EM revealed that most of immunoreactivity was associated with the plasma membrane at the interface between adjacent neurons. In lamina I, we also found membrane labeling between two axon terminals confirming the presynaptic localization of delta receptors. We found no immunolabeling at synaptic specializations.

Labeled cells bodies were found in lamina X and in ventral horn. To study the 3-D intracellular distribution of delta receptor immunoreactivity, we collected a confocal Z series of cell bodies and generated a 3-D reconstruction. Approximately 60% of total cell body immunoreactivity was found in the cytoplasm, primarily around the nucleus. EM analysis of the latter revealed immunoreactivity associated with rough ER and Golgi apparatus. About 10% of the labeling was found in the nucleus and EM analysis showed that it was associated with chromatin. This result suggests an involvement of delta receptors in long term adaptation processes as well as in dorsal horn antinociceptive mechanisms.

## 535.9

EXTRA-SYNAPTIC NEURONAL SITES FOR ENKEPHALIN ACTIVATION OF  $\mu$ -OPIOID RECEPTORS IN RAT NUCLEUS ACCUMBENS.

A.L. Svingos<sup>1</sup>, A. Moriwaki<sup>2</sup>, J.B. Wang<sup>2</sup>, G.R. Uhl<sup>2</sup> and V.M. Pickel<sup>1</sup>, Cornell Univ. Med. College, Dept. of Neurology and Neuroscience, NY, NY, 10021<sup>1</sup>, Intramural Res. Program, NIDA and Depts. of Neurology and Neuroscience, Johns Hopkins Univ., Baltimore, MD, 21224<sup>2</sup>.

The  $\mu$ -opioid receptor (MOR), and its endogenous ligands, including Leu<sup>5</sup>-enkephalin (LE), are abundantly distributed in the nucleus accumbens, a region implicated in opiate reinforcement. To determine ultrastructural sites for functions ascribed to MOR, we used an anti-MOR rabbit polyclonal antiserum raised against an 18 amino acid sequence from the C-terminal unique to MOR (Surratt et al., 1994) to examine the immunoperoxidase and immunogold-silver localization of the receptor in rat nucleus accumbens. Electron microscopy localized MOR-like immunoreactivity predominantly to extra-synaptic sites in plasma membranes of dendrites. Unmyelinated axons and axon terminals were also immunoreactive for MOR. Cytoplasmic labeling was largely associated with smooth endoplasmic reticulum in dendrites, and small clear vesicles in axons. We subsequently combined immunogold-silver labeling for MOR with immunoperoxidase detection of LE to determine potential sites for MOR activation by the endogenous ligand. LE labeled terminals formed symmetric synapses with dendrites both with and without detectable MOR-like immunoreactivity. The gold-silver MOR labeling was localized chiefly along portions of plasma membrane exclusive of the synaptic specialization. These results suggest that in rat nucleus accumbens, activation of MOR by endogenous opioid peptides or by exogenous opiates results primarily in neuronal modulation at extra-synaptic sites. This modulation most likely includes changes in the receptivity of target dendrites to other transmitters, and presynaptic modulation of transmitter release. IMMUNOHISTOCHEMICAL MAPPING OF  $\mu$ -OPIOID RECEPTOR IN THE CNS OF BOTH RAT & MOUSE B. Anton<sup>1</sup>, D.E. Keith Jr.<sup>2</sup>, J. Rogowski<sup>2</sup>, C. Yan<sup>2</sup>, X. Li<sup>2</sup>, T. To<sup>2</sup> and C.J. Evans<sup>2</sup>, Dept. of Psychiatry and Biobehavioral Sciences, UCLA, Los Angeles, California 90024.

We have generated a rabbit peptide antisera (C<sub>12</sub>-12) to the C-terminus of a murine  $\mu$ -opioid receptor recently cloned in our laboratory (Kaufman et al., *J. Biol. Chem.*, in press). Histochemistry used antigen-affinity purified C<sub>12</sub>-12 and revealed similar but not identical distribution of  $\mu$ -opioid receptor-like immunoreactivity (MOR-LI) in rat and mouse neuroaxis. Localization of MOR-LI showed a good correlation with the previously reported distribution of  $\mu$ -opioid receptor binding sites and  $\mu$ -opioid receptor mRNA in mouse and rat brain. High to very high expression of MOR-LI material was found in multiple areas of diencephalon, mesencephalon, pons-medulla, dorsalmost aspects of spinal cord and deep cerebellar nuclei. Within most of all these structures, staining was predominantly localized in long fibers, short dendritic-like processes and fine puncta. Overall, most of the telencephalic regions showed low labeling. However, notable exceptions were the olfactory areas as well as the caudate-putamen and nucleus accumbens. These two latter subcortical regions showed a characteristic patchy-like distribution of MOR-LI mostly found in neuropil. Staining in perikarya was rarely observed throughout most of the neuroaxis, although moderately labeled scattered cell bodies were observed in specific cellular layers of few brain areas such as the neocortex, ventral aspects of the nucleus accumbens and hippocampus. Our results also revealed fine anatomical differences in MOR-LI between rat and mouse brain specifically in areas such as the olfactory bulb, neocortex, hippocampus and ventral horn in spinal cord. These latter results suggest the possibility of differential circuitry modulation by MOR-specific drugs between these two rodent species.

## 535.13

REGIONAL AND TEMPORAL DIFFERENCES IN  $\mu$ ,  $\delta$ , AND  $\kappa$  OPIOID RECEPTOR EXPRESSION BY MURINE TYPE I ASTROCYTES FROM THE CEREBRAL CORTEX, HIPPOCAMPUS, CEREBELLUM, AND STRIATUM *IN VITRO*. A. Stjéne-Martin<sup>1</sup>, R.P. Elde<sup>2</sup>, and K.F. Hauser<sup>1</sup>, Dept. of Anatomy and Neurobiology<sup>1</sup>, Univ. of Kentucky Sch. of Med., Lexington, KY 40536; Dept. of Cell Biology and Neuroanatomy<sup>2</sup>, Univ. of Minnesota, Minneapolis, MN 55455.

Flat, polyhedral (type I) astrocytes from mouse forebrain express  $\mu$ ,  $\delta$ , and  $\kappa$  opioid receptors (ORs) in dissociated culture. To determine whether the heterogeneity of OR types expressed among type I astrocytes results from regional or temporal differences in the pattern of expression, primary, mixed-glial cultures were obtained from the cerebral cortex, hippocampus, cerebellum, and striatum of 1-day-old mice and examined at various days *in vitro* (DIV). OR types were identified immunocytochemically using antibodies selective for unique  $\mu$  and  $\delta$  OR epitopes. OR types were assessed functionally using fura-2-based measures of opioid-induced mobilization of free intracellular calcium ( $[Ca^{2+}]_i$ ) following activation by selective  $\kappa$ ,  $\delta$ , or  $\mu$  agonists. At 6 DIV,  $\mu$ ,  $\delta$ , and/or  $\kappa$  ORs were expressed by subpopulations of type I astrocytes in all regions, although the proportion of astrocytes expressing each OR type varied among regions. Based on immunocytochemical evidence, hippocampal astrocytes had the greatest proportion of  $\mu$ ORs (~60-75%), while astrocytes from other regions had fewer (25-40%).  $\delta$ ORs were most abundant in striatal astrocytes (60-65%), but least abundant in hippocampal astrocytes (~35%). Temporal differences were evident in opioid-induced changes in  $[Ca^{2+}]_i$ . Hippocampal and cerebral cortical astrocytes expressed ORs at 1-2 DIV, whereas astrocytes from striatum and cerebellum did not express ORs until 6 DIV. Spatio-temporal differences in the expression of particular OR types by astroglia may, in part, underlie region-specific critical periods of sensitivity to opioids during development, and may contribute to regional differences in opioid function in the adult. Supported by NIDA grant 06204.

## 535.10

ULTRASTRUCTURAL IMMUNOCYTOCHEMICAL LOCALIZATION OF MU OPIOID RECEPTORS AND LEU<sup>5</sup>-ENKEPHALIN IN PATCH COMPARTMENT OF RAT CAUDATE-PUTAMEN NUCLEUS. H. Wang<sup>1</sup>, A. Moriwaki<sup>2</sup>, J.B. Wang<sup>2</sup>, G.R. Uhl<sup>2</sup> and V.M. Pickel<sup>1</sup>, Dept. of Neurol. and Neurosci., Cornell Univ. Medical College, New York, NY 10021, and <sup>2</sup>Mol. Neurobiol. Branch, IRP, NIDA, NIH and Johns Hopkins Univ. School of Medicine, Baltimore, MD 21224.

The mu opioid receptor (MOR) is highly enriched in striatal patch zones. To determine cellular sites for MOR activation in the patch compartment, we examined the ultrastructural localization of MOR and one of its endogenous ligands, Leu<sup>5</sup>-enkephalin (LE), in rat caudate-putamen nucleus, using combined immunogold-silver and immunoperoxidase methods. The anti-MOR antibody was raised against the C-terminal 18 amino acids of the rat MOR-1 receptor (Surratt et al. (1994), JBC, 269, 20548), and shown by light microscopy to be specifically localized in the patch compartment. Electron microscopy of the patch region showed immunogold-silver particles localizing MOR like immunoreactivity (LI) mainly associated with non-synaptic plasma membranes of soma and dendrites. These were typically spiny neurons receiving abundant asymmetrical excitatory-type synapses from unlabeled axon terminals. Other axon terminals in contact with these neurons formed symmetric junctions, and were also either unlabeled or immunolabeled for LE. MORLI was infrequently found in axon terminals, some of which colocalized LE. We conclude that endogenous opioids and morphine act mainly at non-synaptic MOR reactive sites along the plasma membrane of spiny neurons in rat caudate-putamen nucleus.

## 535.12

KAPPA OPIOID RECEPTOR-LIKE IMMUNOREACTIVITY IS PRESENT IN SUBSTANCE P-CONTAINING SUBCORTICAL PROJECTIONS TO GUINEA PIG DENTATE GYRUS. C.T. Drake<sup>1</sup> and T.A. Milner<sup>2</sup>, Dept. of Neurology and Neuroscience, Cornell University Medical College, New York, NY 10021

We have previously used light and electron microscopy to demonstrate kappa opioid receptor-like immunoreactivity ( $\kappa$ -LI) in axons and terminals in the granule cell layer and inner molecular layer of the guinea pig dentate gyrus. Although several populations of neurons project to this area, the distribution and ultrastructural appearance of processes with  $\kappa$ -LI most strongly resembled previous descriptions of the substance P (SP) afferents arising from the supramammillary region of the hypothalamus (SUM). In the present study we used dual labeling electron microscopy to determine whether  $\kappa$ -LI is colocalized with SP-LI in the dentate gyrus, and unilateral fornix lesions to determine whether the processes with  $\kappa$ -LI originate extrinsically. By light microscopy, both  $\kappa$ -LI and SP-LI were present in varicose processes concentrated in the granule cell layer and supragranular region. By electron microscopy,  $\kappa$ -LI was in small unmyelinated axons and axon terminals, where it was predominantly associated with large dense-core vesicles, but was also localized to the plasmalemma and small vesicle membranes. SP-LI was found in axons and terminals with similar morphology, and rimmed small vesicles and a few dense-core vesicles. A number of terminals colocalized both  $\kappa$ -LI and SP-LI. Both single- and double-immunolabeled terminals formed predominantly asymmetric synapses with large dendrites and perikarya of granule cells. In fornix-lesioned animals, by light microscopy processes with  $\kappa$ -LI and processes with SP-LI were dramatically decreased in the supragranular region unilateral to the lesion. These findings suggest a role for  $\kappa$  receptors in presynaptic modulation of an extrinsic SP-containing projection to the dentate gyrus. Supported by DA08259, DA07274.

## 535.14

IMMUNOHISTOCHEMISTRY FOR ORL-1 IN THE RAT CNS C.J. Evans<sup>1</sup>, J. Fein<sup>2</sup>, T. To<sup>2</sup>, J. Rogowski<sup>2</sup>, X. Li<sup>2</sup>, L. Silberstein<sup>2</sup> and B. Anton<sup>1</sup>, Dept. of Psychiatry and Biobehavioral Sciences, UCLA, Los Angeles, CA 90024 & San Jose State University, San Jose, CA.

We have generated a murine IgG1 monoclonal antibody (mN18-ORL-1) to the N-terminus of the mouse ORL-1 protein using a MAPS-based synthesis of the peptide MESLFAPPFWEVLYGSHF. Localization of ORL-1-like immunoreactivity (ORL-1-LI) showed a good correlation with the neuro-anatomical distribution of ORL-1 mRNA in rat brain. High to very high labeling to ORL-1 was observed in multiple areas from the diencephalon, mesencephalon, pons/medulla and ventral and dorsal horns in the spinal cord. In the telencephalon, the pattern of expression of ORL-1-LI was more variable being very high in a dense neuropil distributed through cortical layers II-V in the neocortex, in the anterior olfactory nuclear complex, pyriform cortex, in CA1-CA4 fields and dentate gyrus in the hippocampus and in most of the septal and basal forebrain areas. In contrast, low labeling was observed in the olfactory bulb and most of the basal ganglia structures. In the cerebellum ORL-1-LI was highly expressed in the deep nuclei and no specific labeling was observed in any of the cerebellar cortical layers. ORL-1-LI was predominantly localized in long fiber processes and short dendritic-like fibers and fine puncta. Perikaryal staining was rarely observed throughout most of the stained areas, although low to moderately labeled scattered cell bodies were observed in few brain areas such as the hilus dentate in the hippocampus, caudate-putamen and cortical layers III-IV in the neocortex. Currently the endogenous ligand for ORL-1 has not been chemically identified thereby making difficult to hypothesize putative functional circuitry. However, our immunohistochemical findings enable us to anticipate a key role of the ORL-1 system in pain and analgesia, cortical olfactory processing, auditory and visual processing, hypothalamic autonomic functions, motor and sensory control, as well as a major role in learning and memory. ## 535.15

CHROMOSOMAL LOCALIZATION AND EXPRESSION PATTERN IN NERVOUS AND IMMUNE SYSTEMS OF AN OPIOID-LIKE ORPHAN RECEPTOR. H. Matthes\*, C. Gaveriaux-Ruff, K. Befort, F. Simonin, M.G. Mattei, C. Lemoine, B. Bloch and B. Kieffer. Laboratoire Protéines et Récepteurs Membranaires, C.N.R.S. UPR 9050, ESBS, Université Louis Pasteur, Bld. Sébastien Brandt, F-67400 Illkirch, France.

We have isolated an opioid like receptor cDNA from mouse brain by low stringency hybridization using a  $\mu$  mouse cDNA as a probe. Sequence analysis of this clone indicated that it contains an open reading frame encoding a 367 amino acid protein which shows high homology to all three opioid receptors,  $\delta$ ,  $\mu$  and  $\kappa$  and suggests that we have cloned the mouse counterpart of an orphan receptor cDNA isolated from rat and human by other authors during the course of this study. Expression of this cDNA in COS-7 cells did not confer opioid binding properties to the cells supposing that it does not encode an opioid receptor. Mapping studies have allowed us to assign the gene to mouse chromosome 2 region H and to the human chromosome 20 position q13.2-q13.3. *In situ* hybridization revealed that this putative receptor is highly expressed in several mouse brain areas, including the cerebral cortex, thalamus, habenula, hypothalamus, locus coeruleus and spinal cord. Using the RT-PCR technology, we have investigated the expression pattern of the transcript in human brain and found it widely represented in most tested brain structures. The transcript was also found in some immune cells.

## 536.1

EFFECTS OF INTERFERON ALPHA UPON MORPHINE INDUCED IMMUNOLOGIC CHANGES IN SPINAL CORD-INJURED RATS. N.R.S. Hall\*, J.B. Gelderd\* and Maureen P. O'Grady. Dept. of Psychiatry, Univ. of South Florida Coll. of Med., Tampa, FL 33613 and \*Dept. of Human Anatomy, Texas A&M Univ. Coll. of Med., College Station, TX 77843-1114.

Previous studies in our laboratory have revealed that the administration of morphine to spinal cord-injured rats can result in attenuation of a number of immunologic measures, including a significant reduction in spinal cord levels of IL-1. In other studies, we have confirmed that interferon alpha can bind to opioid receptors and that under certain conditions, partially attenuate the behavioral consequences of opioid withdrawal. The present study was designed to assess whether interferon alpha could reverse the immunomodulatory effects of morphine in a spinal cord transection model.

Adult male Sprague Dawley rats were anesthetized and a dorsal midline incision was made in the mid-thoracic region. A laminectomy was performed at the T5-T6 vertebral level, and the spinal cord was transected with a scalpel. A 75 mg pellet of morphine was implanted beneath the skin at the time of surgery. This resulted in plasma levels in excess of 250 ng/ml. Interferon alpha was administered at a concentration of  $300 \times 10^3$  Units per 0.1 ml via an Alzet mini-osmotic pump (model # 1003D; mean pumping rate = 1.02 microliters/hr, duration = 3 days). While morphine administration resulted in a significant reduction in thymus and spleen weight ( $p < 0.05$ ), the administration of interferon alpha failed to modulate this influence. Furthermore, there was no effect of this combination of morphine and interferon alpha upon lymphocyte blastogenesis. Thus, while interferon alpha is capable of inducing behavioral and endocrine changes associated with its opioid properties, these effects do not extend to the assessed measures of the immune system using the described protocols. These studies were supported in part by grants from NIDA (DA05723, DA072450).

## 536.3

THE SUPPRESSIVE EFFECT OF NEUROPEPTIDE Y ON FENTANYL-INDUCED MUSCULAR RIGIDITY IN THE RAT. P.W. Lui\*, S.J. Lai, L.Y. Tsen, M.J. Fu and Samuel H.H. Chan. Dept. of Anesthesiology, Veterans General Hospital-Taipei, and Institute of Pharmacology, School of Medicine, National Yang-Ming University, Taipei, Taiwan 11217, Republic of China.

The present study was to investigate the effect of centrally administered neuropeptide Y (NPY) on fentanyl-induced muscular rigidity in rats. Male Sprague-Dawley rats were anesthetized with ketamine (120 mg/kg, i.p.) and their lungs were mechanically ventilated. Intravenous administration of fentanyl (100  $\mu$ g/kg) consistently evoked a significant increase in the root mean square of the electromyographic (RMS-EMG) activity recorded from the sacrocaudal dorsalis lateralis muscle. This implied muscular rigidity was appreciably diminished by intracerebroventricular administration of NPY (4 nmol/2.5  $\mu$ l). Microinjection of NPY (40 or 160 pmol) into locus coeruleus (LC) dose-dependently inhibited the activation of RMS-EMG by fentanyl. However, LC microinjection of 160 pmol NPY plus antiserum against NPY (NPYab, 1:20), but not plus normal rabbit serum (NRS), failed to suppress fentanyl-induced EMG activation. In addition, LC microinjection of NPYab or NRS did not inhibit fentanyl-induced muscular rigidity. Our results suggest that NPY can suppress fentanyl-induced muscular rigidity at the LC, but endogenous NPY may not be involved in the modulation of this phenomenon. Supported by grant from the National Science Council (NSC-84-2331-B075-009, P.W.L.).

## 536.2

ARE ENDOGENOUS OPIATES INTEGRAL TO THE HEALING PROCESS? O.B. Ilivinsky\*, P. Shirley, J. Stray-Gundersen. Baylor/UT Southwestern Sports Science Research Center, Dallas, TX 75246

Studies performed in Russia demonstrated that opiates can stimulate nerve fiber growth in cell culture. Direct stimulation of the periaqueductal grey substance increased velocity of wound healing. Transcranial electrical stimulation (TES), used as "electroanalgesia", increased peripheral nerve regeneration and increased skin wound healing by 20% to 25%. To test the hypothesis that endogenous opiates are integral to the healing process, we created full thickness skin wounds ( $331 \pm 53 \text{ mm}^2$ ) on 172 male outbred Wistar and Sprague-Dawley rats (54-132 days). Rats were randomly separated into 5 groups over 5 experiments including TES ( $n=59$ , rats restrained, anode/behind pinnae, cathode/nasal bridge, 30-60 mins on Days 1,2,3,4 post wound, 1.2-1.5mA, 72 Hz), SHAM ( $n=32$ , restrained plus electrode placement, no current), OP ( $n=10$ , Dalargin a leu-enkephalin analog, 20ug/kg I.P. on Days 1,2,3,4), NAL+TES ( $n=12$ , same as TES plus Naloxone 2.5 mg/kg I.P. q 15 mins during TES) and CON ( $n=59$ , no treatment to wound). Each experiment had 3 treatments (Exps 1,2,3 included TES, SHAM and CON; Exp 4 TES, OP, CON; and Exp 5 TES, NAL+TES, CON). Two wound diameters were measured on Days 4, 7 and 12 post wounding by micrometer by an investigator blind to rat group. Wound photos were also taken, images digitized and areas calculated by an image analysis program. Results are presented as the differences between different group means (mean(SE)). A Multiple Cell Means analysis was performed using 5 groups, 1<sup>st</sup> or 2<sup>nd</sup> wound, younger (<63 days) or older (>63 days), and 2 strains. Significance was assigned at the  $p < 0.05$ . There were no differences between SHAM and CON or between strains. TES wounds were significantly smaller than CON on all Days (D4-5.4% (SE=2.3%), D7-7.9% (2.1%), D12-4.6% (1.1%)). OP wounds were significantly smaller than CON on Day 12 only (7.2% (2.6%)). NAL wounds were significantly larger than CON on all Days (D4 21.7% (4.9%), D7 23.7% (4.5%), D12 5.8% (2.3%)). TES made a greater difference in older rats. These results confirm the involvement of endogenous opioids in the healing process. Further, TES and OP demonstrated potential as a method to augment healing. These results are in agreement with the earlier results, however, the magnitude of the improvement from TES is much less (6% vs. 20%). The fact that TES was more effective in older rats and rats residing in Russia suggests that TES may be more effective where the healing process is suboptimal.

## 536.4

PERIPHERAL ADMINISTRATION OF MORPHINE REDUCES THE CONSEQUENCES OF INFLAMMATION PRODUCED BY TURPENTINE IN ADULT RAT URINARY BLADDER. Nicholai Y. Andreev, Natalia I. Dmitrieva, Andrew S.C. Rice\* and Stephen B. McMahon. Department of Physiology, St. Thomas's Hospital, London, SE1 7EH, U.K.

We have asked if peripheral opiate treatment can attenuate the visceral hyper-reflexia associated with experimental inflammation of the urinary bladder. In anaesthetised female Wistar rats the urinary bladder was catheterised via the urethra. Bladder motility was assessed by continuous intra-vesical pressure measurement during slow bladder filling with saline. The following were derived from the pressure recording: the micturition threshold (MT), the total time during which the bladder generated reflex contractions (TCT) and number of contractions (NC). After control determinations, the bladder was treated with 0.5 ml of 50 % turpentine for 1 hour. After this, the bladder was emptied and motility re-assessed. In all cases the inflammation produced by turpentine led to a hyper-reflexia, observed as a reduction in MT and increase in TCT and NC. The ability of morphine (0.1-0.5 mg/kg) to reverse the hyper-reflexia was then determined by either i.v. or intravesical (i.e. peripheral) administration. The threshold dose for i.v. administration was 0.25 mg/kg. When the same or smaller total amounts of morphine were administered locally, an inhibition of bladder motility was more potent. Thus, 0.1 mg/kg inhibited motility by 46%, compared to no changes after i.v. application of the same dose. All these effects of morphine were naloxone-reversible.

In separate animals the effect of morphine on plasma extravasation in rats' urinary bladder after treatment with turpentine was studied. Morphine (0.5 mg/kg) administered into the bladder significantly reduced the Evan's blue extravasation resulting from turpentine treatment.

These results suggest that opioids are capable of acting peripherally, perhaps on the terminals of bladder afferents, to reduce consequences of inflammation.

## 536.5

EFFECTS OF NOR-BINALTORPHIMINE (nBNI) AND QUATERNARY ANALOGS OF nBNI ON CI-977-INDUCED DIURESIS AND ANALGESIA. C.A. Paronis<sup>1</sup>, M. Ko<sup>2</sup>, K. Sobczyk-Kojiro<sup>3</sup>, H.L. Mosberg<sup>3</sup>, and J.H. Woods<sup>1,2</sup>, Dept. of <sup>1</sup>Pharmacology, <sup>2</sup>Psychology, and <sup>3</sup>Medicinal Chemistry, University of Michigan, Ann Arbor, MI 48109-0632.

Quaternary analogs of the selective  $\kappa$ -antagonist, nBNI, were synthesized (single quaternary - QnBNI; double quaternary - QQnBNI) and shown in binding studies to be more polar than the parent compound. We examined the  $\kappa$ -antagonist properties of nBNI, QnBNI, and QQnBNI *in vivo*, postulating that the more polar forms of nBNI would not penetrate the blood brain barrier (BBB). Diuresis, a potentially peripherally mediated response, and analgesia, a centrally mediated response, were measured in rats. The antagonists were injected either s.c. (1-32 mg/kg) or i.c. (1-100  $\mu$ g) 1 hr before the  $\kappa$ -agonist, CI-977. CI-977 (0.001-32 mg/kg) dose-dependently increased diuresis; 0.56 mg/kg CI-977 produced a maximum effect (4.7 ml/100g). The CI-977 diuresis dose-effect curve was shifted down in an orderly fashion by either s.c. or i.c. administration of nBNI, QnBNI, or QQnBNI, and no differences among the three nBNI analogs were noted. Analgesia was assessed using a warm-water tail-withdrawal procedure, the control ED<sub>50</sub> for CI-977 was 0.7 mg/kg. The CI-977 analgesia dose-response curve was shifted to the right in a similar manner after central injections of either nBNI, QnBNI, or QQnBNI (10  $\mu$ g i.c.). Likewise, systemic injections of nBNI, QnBNI, or QQnBNI (10 mg/kg s.c.) also produced similar rightward shifts of the CI-977 dose-effect curve. Our results suggest that nBNI, QnBNI, and QQnBNI do not differ their capacity to penetrate the BBB. (Supported by PHS Grants DA00254 and DA05653).

## 536.7

KAPPA OPIOID RECEPTORS IN THE GUINEA PIG HIPPOCAMPUS ARE FUNCTIONALLY COUPLED TO A 4-AP-SENSITIVE POTASSIUM CHANNEL. M.L. Simmons\* and C. Chaykin, Dept. of Pharmacology, Box 357280, Univ. of Washington, Seattle, WA 98195.

Kappa opioid receptors in the CA3 region of the hippocampus are localized on mossy fiber terminals. Activation of these receptors inhibits excitatory transmission by inhibiting excitatory amino acid release. Previous work in our lab has shown that kappa receptors in the guinea pig hippocampus are not functionally coupled to L-type or N-type calcium channels, as antagonists of these channels did not occlude the inhibitory effect of a kappa receptor agonist. We have continued these studies in CA3 pyramidal cells using whole-cell voltage-clamp recording. The kappa receptor agonist U69593 (1  $\mu$ M) produced a  $33.3 \pm 6.7\%$  (n=6) decrease the amplitude of EPSCs evoked by low-intensity stimulation of stratum granulosum. This inhibition was reversed by 100 nM norbinaltorphimine, a kappa receptor antagonist. The inhibitory effect of U69593 was not blocked by prior bath-application of 300  $\mu$ M BaCl<sub>2</sub>, suggesting that kappa receptors are not coupled to inward rectifier potassium channels. Instead, the inhibitory effect of U69593 was blocked by 100  $\mu$ M 4-aminopyridine (4-AP). These results suggest that kappa receptors on mossy fiber terminals inhibit excitatory amino acid release by increasing the potassium conductance, thereby decreasing the excitability of the presynaptic membrane. DA04123 and Merck Distinguished Scholar Fellowship (predoctoral).

## 536.9

(-)-PENTAZOCINE ANALGESIA IS MEDIATED THROUGH KAPPA<sub>1</sub> OPIOID RECEPTORS AND IS MODULATED BY AN ANTI-OPIOID SIGMA<sub>1</sub> SYSTEM. C.-C. Chien\* and G.W. Pasternak, The Cotzias Laboratory of Neuro-Oncology, Memorial Sloan-Kettering Cancer Center and Depts. of Neuroscience and Pharmacology, Cornell Univ. Medical College, New York, NY, \*Cathay General Hospital, Taipei, Taiwan

Pentazocine is a clinically useful pain killer with limited analgesic potency. In thermal antinociceptive assays, like the mouse radiant heat tailflick assay, pentazocine has a maximal analgesia effect of only 30%. When the stereoisomers of pentazocine are tested separately, only (-)-pentazocine produces analgesia. (+)-Pentazocine is inactive. Receptor binding assays show that (-)-pentazocine labels  $\mu$  and  $\kappa_1$  receptors with high affinities and  $\sigma_1$  receptors with moderate affinity whereas (+)-pentazocine potently labels  $\sigma_1$  receptors and has no significant affinity for opioid receptors. (-)-Pentazocine analgesia is antagonized both by the  $\kappa_1$ -selective antagonist norbinaltorphimine (norBNI) and by an antisense oligodeoxynucleotide directed against the cloned kappa receptor (KOR-1), implying a role for  $\kappa_1$  receptors. The  $\mu$ -selective antagonist  $\beta$ -funaltrexamine has no effect. Prior studies indicate that  $\kappa_1$  analgesia mediated by the prototypical  $\kappa_1$  analgesic U50,488H is significantly modulated by a  $\sigma_1$  anti-opioid system. (-)-Pentazocine analgesia is similarly affected. When co-administered with the  $\sigma$  antagonist haloperidol, the (-)-pentazocine dose-response curve shifts to the left with a rise in the ceiling response from 30% to 70%. The inactivity of the D<sub>2</sub> antagonist (-)-sulpiride to modulate (-)-pentazocine analgesia confirms the  $\sigma_1$  specificity of the haloperidol in this system. In conclusion, we show that  $\kappa_1$  receptors mediate (-)-pentazocine analgesia and this analgesia is modulated by an anti-opioid  $\sigma_1$  system.

## 536.6

INTERACTION BETWEEN OPIOID RECEPTOR SUBTYPES AND MIANSERIN. C.G. Pick<sup>1</sup>\*, M.M. Backer<sup>1</sup> and S. Schreiber<sup>2</sup>, <sup>1</sup>Department of Anatomy and Anthropology Sackler Sch. of Med., Tel Aviv Univ. Tel Aviv, Israel. <sup>2</sup>Department of Psychiatry Hadassah Univ. Hospital Ein-Karem, Jerusalem, Israel.

Mianserin is a tetracyclic antidepressant with potent 5-HT<sub>1</sub>, 5-HT<sub>2</sub> and 5-HT<sub>3</sub> receptor agonist. It has NE properties, due to a presynaptic  $\alpha_2$  blockade and a strong antihistamine. In this present study we have examined the analgesic effects of Mianserin alone and in conjunction with opioid subtypes. Mianserin produced analgesia in the mice hotplate assay. This analgesia was antagonized by naloxone. This sensitivity to naloxone indicated that at least some of the analgesic effect of mianserin is mediated by an opioid mechanism of action. Systemic mianserin analgesia was reversed by  $\beta$ -FNA and nor-BNI, but not nalorphine. The reversal of mianserin analgesia by  $\beta$ -FNA and nor-BNI and not by the other antagonists, indicated a possible  $\mu$  and  $\kappa_1$  mechanism and argued strongly against either  $\delta$  or  $\kappa_3$  component of analgesia.

## 536.8

EFFECTS OF CHRONIC U50,488H ADMINISTRATION ON THE  $\kappa_1$  OPIOID RESPONSE IN THE GUINEA PIG HIPPOCAMPUS. W. Jin\*, G.W. Terman and C. Chaykin, Dept. of Pharmacol., Univ. of Wash., Seattle, WA 98195

Previously studies in our laboratory demonstrated that activation of the  $\kappa_1$  opioid receptor by either exogenous or endogenous opioids inhibits dentate granule cell excitability in the guinea pig hippocampus. In the present study, we investigated whether these electrophysiological effects can be modulated by chronic administration of U50, 488H, a  $\kappa$  opioid agonist. Injection of guinea pigs with U50, 488H (s.c.) twice a day in an ascending dosage schedule (10 mg-75 mg/kg) for five days resulted in a tolerance to the drug hypothermic effects. Population spikes of dentate granule cells in the guinea pig hippocampus slice were recorded extracellularly. In naive animals, application of U69, 593, a  $\kappa_1$  agonist, produced a dose-dependent inhibition of the amplitude of the population spike. The concentration required to produce a half-maximal effect (EC<sub>50</sub>) was 11 nM. In the tolerant animals, the concentration-response curve was shifted to right (EC<sub>50</sub>=53 nM), with a decrease of maximal effect. This result suggested that a reduction in the receptor reserve may be involved in the decreasing sensitivity to U69,593. It is known that the endogenous  $\kappa$  opioids released by prolonged tetanic stimulation to the perforant path can inhibit the stimulation-induced long-term potentiation (LTP) at the perforant path-granule cell synapse. We found that the LTP induced by the prolonged tetanic stimulation was significantly enhanced in the tolerant animals, indicating the chronic U50, 488H treatment attenuated the effects of endogenous  $\kappa$  opioids. The LTP induced by a moderate tetanic stimulation (not involved in release of endogenous  $\kappa$  opioid) remained unchanged in the tolerant animals. To test the idea that the NMDA receptors are involved in the development of  $\kappa$  opioid tolerance process, we pretreated animals with MK-801 (0.10 mg/kg, 15 min prior to each injection of U50, 488H), and our preliminary result suggested that MK-801 did not prevent the development of tolerance to either the electrophysiological effect or hypothermic effect of  $\kappa_1$  opioids. These studies provided a better understanding of the mechanisms underlying  $\kappa$  opioid tolerance in the guinea pig hippocampus. Supported by DA04123.

DISSOCIATION OF THE MOTOR EFFECTS OF (+)-PENTAZOCINE FROM BINDING TO  $\sigma_1$  SITES. R.R. Matsumoto\*, A.C. Zambon, W.D. Bowen, J.M. Walker, S.L. Patrick, V.N.T. Vo, D.D. Truong, B.R. de Costa and K.C. Rice, University of California Irvine, Irvine, CA 92717; Brown University, Providence, RI 02912; NIDDK, Bethesda, MD 20892.

The purpose of this study was to determine whether a relationship existed between the motor effects produced by (+)-pentazocine (PENT) and its binding to  $\sigma_1$  sites. Scatchard analyses revealed decreased [<sup>3</sup>H]PENT binding in middle aged (5-6 months old) vs. young adult (2-3 months old) rats (P<0.001). However, there was no difference between the extent of circling behavior or dystonia produced by microinjection of PENT (9.3 nmol) into the substantia nigra or red nucleus in the two groups of animals. There was also a significant decrease in [<sup>3</sup>H]PENT binding in rats chronically treated with haloperidol (5 mg/kg, s.c., up to 20 days; P<0.05). However, despite the reduction in [<sup>3</sup>H]PENT binding, there was no difference between the extent of dystonia produced by unilateral intrastriatal microinjection of PENT into animals chronically treated with haloperidol vs. saline. The dystonic postures produced by PENT could not be attenuated with the putative  $\sigma$  antagonist BD1047 or the opiate antagonist naloxone. However, (+)-nordihydrocodeinone, partially attenuated the postural effects of PENT (P<0.03), despite its very low affinity for  $\sigma_1$ ,  $\sigma_2$ , or opiate receptors. Taken together with previous studies, the results suggest that [<sup>3</sup>H]PENT is a potent and selective probe for  $\sigma_1$  binding sites *in vitro*, but the *in vivo* effects of PENT cannot be fully attributed to actions at this site.

## 536.11

PHARMACOLOGY OF DELTA OPIOID RECEPTOR AGONISTS IN THE RAT. M. B. Weinger\*, J. S. Stuart, D. Wood, Dept. of Anesthesiology, Univ. Calif. San Diego and VAMC, San Diego, CA 92161.

The use of opiates as analgesics and anesthetics is limited by side-effects such as respiratory depression and muscle rigidity. We are investigating the role of  $\mu$ ,  $\delta$ , and  $\kappa$  opioid receptors in different opiate endpoints including antinociception (55°C tail dip), sedation (loss of righting), catalepsy, muscle rigidity (tonic EMG activity), and respiration (total body plethysmography and arterial blood gases). Intracerebroventricular (icv) administration of the  $\delta$ -preferring agonist DPDPE produced dose-dependent antinociception yet had no effect on righting or catalepsy except at very high doses. DPDPE had a biphasic respiratory effect with lower doses stimulating and higher doses modestly depressing ventilation. DPDPE alone increased hindlimb muscle tone, but partially antagonized systemic opiate rigidity. These same endpoints were investigated using the  $\delta$ -preferring agonist D-Ala<sup>2</sup>-deltorphin II (10-120 nmol icv; a gift from P. Schiller) and the non-peptide  $\delta$  agonist SNC80 (0.8-75 mg/kg subcutaneously; gift of K. Rice and S. Calderon). Coadministration of the  $\delta$  antagonist naltrindole (NTI; 2-10 nmol icv) was used to confirm the role of  $\delta$  receptors in the effects observed. NTI reversed DPDPE-induced increases in respiratory rate but did not block high-dose DPDPE ventilatory depression. Deltorphin (DELT) produced significant antinociception without catalepsy or loss of righting. DELT decreased tidal volume but did not affect respiratory rate. DELT had no effect on muscle tone or on opiate rigidity. Systemic administration of SNC80 (75 mg/kg) prominently stimulated ventilation, primarily due to increased respiratory rate. Ongoing studies will evaluate further the hypothesis that  $\delta$  agonists are effective analgesics with a favorable side-effect profile.

## 536.13

USE OF  $\delta$ -ANTISENSE OLIGO IN THE STUDY OF THE TURNOVER OF  $\delta$ -OPIOID RECEPTORS IN THE SPINAL CORD OF THE MICE. Leon F. Tseng\* and Minoru Narita, Department of Anesthesiology, Medical College of Wisconsin, Milwaukee, WI 53226.

Intrathecal (i.t.) pretreatment of male ICR mice with  $\delta$ -opioid receptor (DOR) antisense oligodeoxynucleotide (AS oligo; 163 pmol), but not mismatch (MM) oligo (163 pmol), daily for 1-3 days caused a time-dependent attenuation of antinociception induced by i.t. administered [D-Ala<sup>2</sup>]deltorphin (DT; 6.4 nmol), a DOR agonist, 24 hr after DOR AS oligo injection. Antinociception was measured by the tail-flick test. The DOR-mediated antinociception was not significantly altered after 1 day of i.t. DOR AS oligo pretreatment, but declined progressively after 2 and 3 days of treatment. The experiment was then extended to determine whether the decline in DOR activity for antinociception in the spinal cord in mice treated with DOR AS oligo is due to the stimulation of DORs by endogenously released Met-enkephalin. Concomitant i.t. treatment of mice with naltriben, which blocks DOR, together with DOR AS oligo for 24 hr prevented the attenuation of i.t. DT-induced antinociception produced by DOR AS oligo pretreatment. On the other hand, concomitant i.t. treatment of bestatin or thiorphan, which inhibits the degradation of released Met-enkephalin, with DOR AS oligo for 24 hr enhanced the attenuation of DOR antinociception induced by DOR AS oligo. Furthermore, a combination of pretreatments with DOR AS oligo given i.t. and, 10 min later,  $\beta$ -endorphin given i.c.v., which releases the Met-enkephalin in the spinal cord, dose-dependently attenuated i.t. DT-induced antinociception. These findings suggest that there is spontaneous release of endogenous Met-enkephalin, which stimulates DORs and causes a loss of DOR-mediated antinociception in mice in which the synthesis of DORs has been inhibited by DOR AS oligo (Supported by NIH grant, DA 03811).

## 536.15

INVOLVEMENT OF MET-ENKEPHALIN AND  $\delta$ -OPIOID RECEPTORS IN THE SPINAL CORD IN ANTINOCICEPTION INDUCED BY COLD WATER SWIMMING IN THE MOUSE. Hirokazu Mizoguchi\*, Minoru Narita\*, Raymond M. Quock\*, and Leon F. Tseng\*, Department of Anesthesiology, Medical College of Wisconsin, Milwaukee, WI 53226 and \*Department of Biomedical Science, College of Medicine at Rockford, University of Illinois, Rockford, IL 61107.

Mice exposed to cold water swimming (CWS; 4 °C, 3 min) produced a marked antinociception. Experiments were designed to determine whether Met-enkephalin and what types of opioid receptors in the spinal cord are involved in CWS-induced antinociception in male ICR mice. Antinociception was measured by the tail-flick test 7 min after CWS. I.t. pretreatment with antibody against Met-enkephalin, which binds the released Met-enkephalin, blocked the CWS-induced antinociception, indicating that the antinociception is mediated by release of Met-enkephalin in the spinal cord. I.t. pretreatment with naltrindole (5  $\mu$ g, 10 min) or naltriben (10  $\mu$ g, 10 min), but not 7-benzylidene naltrexone (1  $\mu$ g, 10 min), CTOP (D-Phe-Cys-Tyr-D-Trp-Orn-Thr-Phe-Thr-NH<sub>2</sub>, 50 ng, 10 min), or norbinaltorphimine (5  $\mu$ g, 24 hr), blocked the CWS-induced antinociception, indicating that the antinociception is mediated by  $\delta$ -, but not  $\delta$ -,  $\mu$ -, or  $\kappa$ -opioid receptors in the spinal cord. In  $\delta$ -opioid receptor binding experiments, suspensions of the crude synaptic membrane of the mouse spinal cord were incubated with [<sup>3</sup>H]DSLET, a  $\delta$ -opioid receptor radioligand, for 2 hr at 25 °C. DT (0.001-10  $\mu$ M), Met-enkephalin (0.1-10  $\mu$ M) dose-dependently displaced [<sup>3</sup>H]DSLET bindings, indicating that Met-enkephalin, like DT, binds to  $\delta$ -opioid receptors. It is concluded that antinociception induced by CWS is mediated by the release of Met-enkephalin acting on  $\delta$ -opioid receptor in the spinal cord (Supported by NIH grant, DA 03811).

## 536.12

AN ANTISENSE OLIGONUCLEOTIDE TO THE DELTA-OPIOID RECEPTOR (DOR1) DECREASES BOTH DELTORPHIN II SENSITIVITY AND DOR-IMMUNOREACTIVITY IN THE DORSAL HORN IN MICE. L. S. Stone,<sup>1,3\*</sup> M. Riedl,<sup>3</sup> U. Arvidsson,<sup>3</sup> L. Vulchanova,<sup>1,3</sup> K. F. Kitto,<sup>2</sup> J. Lai,<sup>4</sup> E. J. Bilksy,<sup>4</sup> F. Porreca,<sup>4</sup> P. Y. Law,<sup>1,2</sup> R. Elde,<sup>1,3</sup> H. H. Loh,<sup>1,2</sup> and G. L. Wilcox,<sup>1,2</sup> <sup>1</sup>Graduate Program in Neuroscience, Depts. of <sup>2</sup>Pharmacology and <sup>3</sup>Cell Biology & Neuroanatomy, U. of Minnesota, Minneapolis, MN 55455. <sup>4</sup>Dept. of Pharmacology, U. of Arizona, Tucson AZ 85724.

Previous reports have demonstrated that application of oligonucleotides directed against the delta-opioid receptor can decrease the analgesic potency of delta-, but not mu- or kappa- opioid receptor agonists. However, it has not been shown that the decrease in agonist sensitivity is associated with a decrease in delta-opioid receptor-immunoreactivity (DOR1-ir). We therefore sought to determine agonist effectiveness and DOR1-ir in the same experimental animals. Antisense oligonucleotide directed against DOR1, the corresponding mismatch oligonucleotide and vehicle were injected intrathecally in mice twice a day over a period of three to four days. The animals were then tested for changes in tail-flick latency after intrathecal administration of deltorphin II, transcardially perfused and processed for immunocytochemistry. Antisense-treated animals showed both a decrease in deltorphin II antinociception and a consistently lower intensity of DOR1-ir in spinal cord compared to mismatch, vehicle and naive control groups. No change was detected in the immunostaining for the mu-opioid receptor, CGRP, 5-HT or leu-enkephalin, indicating that the treatment was not toxic to primary afferent fibers or descending axons. Ongoing studies examine the effects of antisense oligonucleotides directed against the mu-receptor as well as a region common to all three receptor subtypes. This study demonstrates both the utility and selectivity of molecular lesioning by antisense oligonucleotides *in vivo*. (Supported by Grants from NIDA)

## 536.14

INHIBITION OF PROTEIN KINASE C, BUT NOT PROTEIN KINASE A, BLOCKS THE DEVELOPMENT OF ACUTE ANTINOCICEPTIVE TOLERANCE TO  $\delta$ -OPIOID RECEPTOR AGONIST IN THE MOUSE. Minoru Narita\*, Michiko Narita\*, Hirokazu Mizoguchi\*, Linda K. Vaughn\*, and Leon F. Tseng\*, Department of Anesthesiology, Medical College of Wisconsin, \*Department of Basic Sciences, Marquette University, Milwaukee, WI 53226.

Intrathecal (i.t.) treatment of male ICR mice with  $\delta$ -opioid receptor (DOR) agonist [D-Ala<sup>2</sup>]deltorphin (DT; 6.4 nmol) produced acute antinociceptive tolerance to the subsequent i.t. challenge of DT (6.4 nmol) 3 hr later. Experiments were designed to study the effects of protein kinase C (PKC) inhibitor, calphostin C (CP), and protein kinase A (PKA) inhibitor, KT5720 (KT), on development of DT-induced antinociceptive tolerance. I.t. administration of CP (1-10 ng), which injected alone had no effect on i.t. DT-induced antinociception, dose-dependently blocked the development of DT-induced antinociceptive tolerance. On the other hand, KT did not have any effect on the development of DT-induced tolerance. DOR binding experiments were designed to examine whether the DOR located in the cellular membrane is G-protein-coupled receptors and can be phosphorylated by activation of PKC. Suspensions of the crude synaptic membrane of the mouse spinal cord were incubated with [<sup>3</sup>H]DSLET for 2 hr at 25 °C. DT (0.001-10  $\mu$ M) dose-dependently displaced [<sup>3</sup>H]DSLET bindings. [<sup>3</sup>H]DSLET bindings were inhibited by GTP $\gamma$ S, a non-hydrolyzable GTP analog, indicating that DOR is G-protein coupled. [<sup>3</sup>H]DSLET bindings were decreased by phorbol 12,13-dibutyrate (PDBu, 0.01-1  $\mu$ M) dose-dependently, suggesting that phosphorylation of DOR by PKC may be involved in desensitization of DOR. It is concluded that PKC, but not PKA, plays an important role in development of DOR-mediated antinociceptive tolerance in spinal cord of the mouse (Supported by NIH grant, DA 03811).

## 536.16

TOLERANCE TO OPIOID INHIBITION OF cAMP FORMATION REQUIRES ENHANCED PKC- (BUT NOT PKA-) MEDIATED PHOSPHORYLATION. L. Wang and A.R. Gintzler\*, Dept Biochemistry, SUNY Health Science Ctr., Brooklyn, NY 11203, USA.

The evoked release of myenteric methionine-enkephalin and the stimulated formation of cAMP is regulated by a bimodal, opiate receptor-coupled mechanism. Low doses (nanomolar) enhance evoked transmitter release and second messenger formation whereas higher concentrations ( $\mu$ M) inhibit them. Excitatory opiate actions are mediated by a G<sub>i</sub>-like G protein whereas opiate inhibitory responses require a G<sub>q</sub>-like G protein. Prior, *in vivo* chronic exposure to morphine can alter the balance between opiate excitatory and inhibitory responses such that the former are predominant. In tolerant/dependent preparations, facilitation of stimulated enkephalin release and cAMP formation is observed with concentrations of opiate that are inhibitory in untreated, opiate naive tissue. The current study demonstrates, in opiate naive and 'addicted' tissue, that the phosphorylation state is a critical determinant of the direction of the opiate regulation of stimulated cAMP formation. In opiate naive preparations, negative opiate modulation of adenylyl cyclase is reversed to enhancement following inhibition of protein phosphatase or activation of PKC. In 'addicted' tissue, activation of PKC, but not PKA, (as a function of chronic *in vivo* morphine treatment) is required for the reversal of opiate inhibition to enhancement. It is proposed that tolerance to the inhibitory effects of opioids results not only from the loss of negative opiate modulation but from a qualitative change in opiate responsiveness such that excitatory responses are predominant. These changes require enhancement of PKC- (but not PKA-) mediated phosphorylation.

## 536.17

LEU-ENKEPHALIN MODULATES THE ACTIVITY OF DISTENTION-SENSITIVE NEURONS IN THE DORSAL MOTOR NUCLEUS OF THE VAGUS (DMNV). X. Zhang\*, R. Fogel and W.E. Renshan. Division of Gastroenterology, Henry Ford Hospital, Detroit, MI 48202.

It has been suggested that one consequence of the stress-related release of enkephalins is a modulation of gastrointestinal function. It is currently not clear whether the enkephalins exert this influence via a central or peripheral mechanism. Immunocytochemical studies have demonstrated, however, that 1) neurons in the DMNV have opioid receptors and 2) many of the neurons in the hypothalamus, amygdala and nodose ganglion that project to the DMNV contain enkephalins. The aim of this study was to investigate the effect of local enkephalin administration on the response of individual gut-sensitive DMNV neurons. A multibarrel pipette array was used to record each DMNV neuron's response to duodenal and gastric distention and to administer varying concentrations of Leu-enkephalin (0.1, 1.0 or 10 mM) to the pericellular environment of the recorded cell. The array's recording electrode contained 2.0% Neurobiotin in 1M KCl buffer (resistance 50-70 MΩ), allowing us to label each physiologically-characterized neuron for subsequent three-dimensional reconstruction. A total of 28 distention-sensitive DMNV neurons were characterized and labeled. As we have noted previously, most of the DMNV neurons were inhibited by the distention stimuli. Ten of the distention-sensitive neurons were inhibited by leu-enkephalin injection (6 partial reduction in firing rate, 4 complete inhibition) and 6 neurons had an increase in firing rate (though the spontaneous activity of the excited neurons was inhibited between injections). These results suggest that enkephalins may influence gastrointestinal function by directly modulating the activity of neurons in the DMNV. Supported by NS30083.

## 536.19

ENKEPHALIN SUPPRESSES SPONTANEOUS AND NMDA-INDUCED IPSPS IN SEROTONERGIC NEURONS OF THE RAT DORSAL RAPHE NUCLEUS IN VITRO.

T. Jolas\* and G.K. Aghajanian. Depts. of Psychiatry & Pharmacology, Yale School of Medicine, New Haven, CT 06508.

There is increasing evidence that opioids, in addition to their effects on the dopaminergic system, act also on the serotonergic (5-HT) system. In particular, it has been shown that intra-raphe administration of morphine increases serotonin release in the forebrain of *unanes-theized* rats (Tao and Auerbach, 1994). The purpose of the present study was to test, in dorsal raphe nucleus (DRN) slices, the effect of the opioid peptide met-enkephalin (ENK) on 5-HT neurons. Intracellularly, using KCl (2M) electrodes, these neurons were identified by standard criteria. The effects of ENK (100 μM) on spontaneous post-synaptic potentials (PSPs) and membrane potential were measured. To study the PSPs, the cells were manually held at -90mV in current clamp mode and, if the PSPs were too sparse, they were induced with NMDA (20 μM). ENK induced a slight hyperpolarization in ~30% of the 5-HT neurons and, in most cases, reduced the number of both spontaneous and NMDA-induced PSPs. ENK also reduced the number of PSPs recorded in some non-serotonergic neurons in the DRN. The PSPs were reduced by bicuculline (100 μM) and, in a few cells, by strychnine (2 μM) indicating that they are GABAergic and, possibly in some cases, glycinergic inhibitory PSPs (IPSPs). Moreover, they were blocked by TTX (2 μM) indicating their impulse-flow dependence.

In conclusion, the results of this study are consistent with the idea that opiates increase serotonin release in the forebrain through a reduction of local inhibitory tone on 5-HT neurons in the DRN.

## 536.18

ESTROGEN AND STRESS INTERACT TO REGULATE THE TRANSCRIPTIONAL ACTIVITY OF A PROENKEPHALIN PROMOTER-β-GAL FUSION GENE IN THE HYPOTHALAMUS OF TRANSGENIC MICE.

C. A. Priest\*, D. Borsook\*, S. E. Hyman\* and D. W. Pfaff. Laboratory of Neurobiology and Behavior, The Rockefeller University, New York, NY 10021; \*Harvard Medical School, Boston, MA 02114.

In the hypothalamus, proenkephalin (PE) gene expression is regulated by exposure to estrogen or stress. To examine potential interactions between these systems at the cellular level, the present study utilizes a transgenic mouse line (ENK 1.1; Mol. Endocrinol 6:1502, '92) which expresses a human PE promoter-β-gal fusion gene. Adult male mice (n = 36) were gonadally intact or castrated for 4 wks (CAST) and adult females (n = 28) were ovariectomized for 2 wks (OVX) or were 21 days postpartum. Forty-eight hrs before perfusion, CAST and OVX animals received an s.c. injection of 10 μg estradiol benzoate (EB) or oil, and 4 animals/group received no further treatment. Six hrs before perfusion, remaining animals received an i.p. injection of hypertonic (1.5 M, HYP) or isotonic (0.15 M, ISO) saline. Brains were sectioned at 25 μm and processed for X-gal histochemistry. Expression of the transgene was quantified using computer-assisted image analysis. In the VMH, levels of PE-β-gal expression were highest in gonadally intact males and postpartal dams. In CAST and OVX+EB groups, ISO increased PE-β-gal expression, as compared to uninjected animals; this did not occur in OVX or CAST+EB groups, thus demonstrating a gender-dependent interaction between EB and stress level. HYP suppressed PE-β-gal expression in all groups, as compared to expression following ISO. In the PVN, HYP induced PE-β-gal expression only in intact males and CAST+EB, indicating site-specific regulation of the transgene.

## 536.20

ENKEPHALIN SENSITIVE K<sup>+</sup> CHANNELS ON FRESHLY DISSOCIATED RAT AMYGDALA NEURONS.

Jonathan E. Freedman\*, Yong-Jian Lin and Xueguang Chen. Dept. Pharmaceutical Sciences, Northeastern Univ., Boston, MA 02115.

The amygdala is known to play a role in various opioid associated behaviors, including some subjective components of dependence and withdrawal. We are performing patch-clamp recordings from freshly dissociated rat amygdala neurons, in the presence and absence of opioid drugs. Cells were prepared from the posterior portion of the medial nucleus, or amygdalohippocampal area. Cell-attached recordings with 140 mM KCl as the main charge carrier within the patch pipette were obtained from pyramidal-shaped cells of about 30-40 μm diameter. Single channel currents with a conductance of 130 pS were observed on 8 of 11 cells tested with 10 μM met-enkephalin within the patch pipette. These channels were never observed in 14 control recordings in the absence of enkephalin ( $P < 0.001$  by a Fisher exact test). Channel currents were in the inward direction, had reversal potentials consistent with K<sup>+</sup> permeability under our recording conditions, and were inwardly rectifying. The ionic selectivity and receptor pharmacology of this channel have yet to be fully determined, but it seems probable that these channels are activated by opiate receptors. Interestingly, these 130 pS channels in the amygdala appear to be different from the 85 pS K<sup>+</sup> channel which we have previously shown to be activated by D<sub>2</sub>-like dopamine receptors in the caudate-putamen.

(Supported by MH-48545.)

## SEROTONIN RECEPTORS: EFFECTORS

## 537.1

MOUSE SEROTONIN 5-HT-5A RECEPTORS ARE NEGATIVELY COUPLED TO ADENYLATE CYCLASE E. RONKEN\*, R. van DIJK\*, M. van OOSTENBRUGGE\*, L. KODDEN\*, R. GRAILHE\*, R. HEN\*, and B. OLIVIER\* 1) CNS-Research Solvay Duphar B.V., P.O.Box 900, 1381 DA Weesp, The Netherlands; 2) Dept. of Neurobiology and Behavior, Columbia University, New York, U.S.A.

The recent cloning of serotonin 5-HT-5A and 5-HT-5B receptors has further increased the complexity of 5-HT neurotransmission. 5-HT-5A and 5-HT-5B receptors are closely related on a molecular level and expression of both receptor subtypes seems to be confined to the central nervous system. Binding properties of cloned receptors revealed high affinity towards several ergot alkaloids, notably LSD, as well as to 5-HT and 5CT. Until recently, however, no coupling of these receptors was observed to any known second messenger system. Cloned murine 5-HT-5A receptors were studied using microphysiology, a technique which measures cell metabolic activity by continuously monitoring acidification of weakly-buffered medium that is perfused over the cells. It was found that 5-HT, 5-CT and methysergide constituted partial agonists, whereas ergotamine and LSD were potent ( $EC_{50}$  LSD 18 nM; with respect to 5-CT: 230 nM) and full agonists on 5-HT-5A receptors. Potencies of compounds closely agreed with receptor binding affinity for 5-HT-5A receptors. In subsequent analysis of second messenger systems, 5-HT-5A receptors appeared to be coupled to adenylyl cyclase in an inhibitory manner. Initial experimental results were precluded due to Mycoplasma contamination, to which adenylyl cyclase appears to be extremely sensitive. After curing the cell lines, however, concentration-dependent inhibition of forskolin-stimulated formation of cAMP was found with 5-HT, 5CT, ergotamine and LSD. In conclusion, cloned mouse 5-HT-5A receptors are inhibitory coupled to adenylyl cyclase, thereby resembling more distant 5-HT receptor congeners, such as the 5-HT-type 1 family. Furthermore, the potent interaction of LSD with the 5-HT-5A receptor provides an additional mechanism through which LSD may exert its hallucinogenic properties.

## 537.2

PHARMACOLOGICAL CHARACTERIZATION OF THE RECOMBINANT HUMAN 5-HT<sub>1</sub> RECEPTOR SUBTYPE COUPLED TO ADENYLATE CYCLASE STIMULATION IN A CLONAL CELL LINE. J.M. Zgombick\*, N. Adham, J.A. Bard, P.J.-J. Vaysses, R.L. Weinshank and T.A. Branchek. Synaptic Pharmaceutical Corporation, Paramus, NJ 07652.

Functional characterization of the recombinant human 5-HT<sub>1</sub> receptor coupled to adenylyl cyclase stimulation was performed using stably transfected murine fibroblasts (LMtk<sup>+</sup> cells). The site density of the 5-HT<sub>1</sub> receptor in clonal cell membranes determined by [<sup>3</sup>H]5-HT (agonist) and [<sup>3</sup>H]LSD (antagonist) saturation studies averaged  $181 \pm 28$  and  $191 \pm 28$  fmol/mg protein, respectively, suggesting that G<sub>ai</sub> is not rate limiting and that all receptors exist in the high affinity state. In intact cells, 5-HT produced a concentration-dependent elevation of intracellular cAMP levels with an  $EC_{50}$  value of 70 nM and a maximal response of 5-fold increase above basal levels. The rank order of agonist potency in the second messenger assay paralleled their rank order of binding affinities: 5-CT > 5-HT > 5-MeOT > DPAT > sumatriptan. The potency of agonists to stimulate cAMP production was more than 10-fold lower affinity than their respective binding affinities ( $K_d$  values). These data may indicate low efficiency of receptor-effector coupling or alternatively, that the low affinity state of the receptor mediates the stimulatory response. Methiothepin and several ergot alkaloids (i.e. LSD, mesulergine) antagonized the 5-HT-mediated elevation of cAMP levels. The  $K_d$  values of the antagonists determined in the second messenger assay were in close agreement with the  $K_d$  values of these compounds in the binding assay. Pretreatment with cholera toxin abolished the 5-HT-mediated elevation in cAMP concentration, indicating that the 5-HT<sub>1</sub> subtype directly interacts with G<sub>ai</sub> protein(s) to stimulate adenylyl cyclase. No changes in inositol phosphate production or in elevation of intracellular calcium concentrations were observed after exposure of stable transfectants to 1 μM 5-HT. Clonal cell lines stably expressing the human 5-HT<sub>1</sub> receptor will serve as cellular models to study the function and regulation of the 5-HT<sub>1</sub> subtype, as well as to develop 5-HT<sub>1</sub>-selective compounds which can be employed to uncover the biological roles and potential therapeutic applications of this novel receptor subtype.

## 537.3

**SEROTONIN AFFECTS  $sK_{Ca}$  CHANNEL ACTIVITY IN RAT CORTICAL ASTROCYTES.** R.R. Margraf<sup>1</sup>, D.B. Wicht<sup>1</sup>, C.J. Charniga<sup>1</sup>, M.L. Linne<sup>2</sup>, H.K. Kimelberg<sup>1</sup>, and T.O. Jälonen<sup>1</sup>. <sup>1</sup>Division of Neurosurgery, Albany Medical College, Albany, N.Y. 12208, and <sup>2</sup>Medical School, University of Tampere, FIN-33101 Tampere, Finland.

We have found that serotonin (5-HT) in 1° astrocyte cultures increases intracellular  $Ca^{++}$ , measured with Fura-2, and inward single-channel currents. Acutely isolated astrocytes cultured for >24 hrs also respond to 5-HT. No increase in intracellular  $Ca^{++}$  is detected in astrocytes < 8 hrs following isolation. The 5-HT-induced single channel inward currents were studied using a cell-attached recording configuration. The L-type  $Ca^{++}$  channel blocker, nimodipine, reduced channel activity, but did not completely inhibit the 5-HT-induced response. A transient response to 5-HT was seen in  $Ca^{++}$  free media, indicating extracellular  $Ca^{++}$  is not necessary for onset of ion channel activity. No enhancement of channel activity was seen when 5-HT was added to cells pre-treated with 500 nM apamin, a channel blocker specific to the small-conductance  $Ca^{++}$  activated  $K^{+}$  channel ( $sK_{Ca}$ ). In the presence of U73122, a phospholipase C inhibitor, no  $K^{+}$  channel activation in response to 5-HT was observed. The 5-HT effect was inhibited by 80 nM-10  $\mu$ M ketanserin, a 5-HT<sub>2</sub> antagonist. The 5-HT<sub>1</sub> agonist 8-OH-DPAT, and the 5-HT<sub>3</sub> agonist 1-(m-phenyl)-biguanidine, did not cause ion channel activation.

In summary, we show that the majority of cultured astrocytes and a small percentage of acutely isolated astrocytes respond to 5-HT with an activation of  $sK_{Ca}$  channels which is linked to the release of intracellular  $Ca^{++}$  via the G protein and phospholipase C pathway.  $Ca^{++}$  influx through voltage-activated  $Ca^{++}$  channels may be needed for sustained channel activity. Further work is needed to establish if the absence of a response to 5-HT in most acutely isolated astrocytes results from damage to the 5-HT<sub>2A</sub> receptor during isolation which is later repaired in culture, or if the receptor is only present in a small number of cortical astrocytes *in situ*.

**AFFINITY STATES OF 5-HT<sub>1A</sub> RECEPTOR BINDING SITES ARE CHARACTERIZED ON CRYOSTAT SLICES OF RAT HIPPOCAMPUS AND DORSAL RAPHE.** S. Hunt<sup>1</sup> (1), J. Silverstein<sup>2</sup> (2), H. E. Kung<sup>3</sup> (3) and S. Maayani<sup>2</sup> (2). (1)Dept of Radiochemistry, DuPont NEN Products, Boston, MA, (2)Dept of Anesthesiology, Mount Sinai School of Medicine, NY, NY and (3)Depts. of Radiology and Pharmacology, University of Pennsylvania, Philadelphia, PA

Distinct affinity states have been proposed for a variety of G-protein coupled receptors but have not been demonstrated for naturally expressed receptors in the CNS. We report here on a comparative study of 5-HT<sub>1A</sub> receptor sites in membrane preparations and in cryostat slices of rat hippocampus and dorsal raphe. The slices were prepared on slides as for radioautography, and radioactivity bound to the slice was assayed by scintillation counting. In the slice, but not the membrane preparation, GTP analogs could induce a complete, rapid (< 10 sec) and temperature-independent loss of high affinity specific binding of the 5-HT<sub>1A</sub> agonists [<sup>3</sup>H]-DPAT and [<sup>3</sup>H]-5-CT, attributable to conversion to the low affinity state. By contrast, binding of [<sup>3</sup>H]-antagonists MPPF and WY100365 was not reduced in the presence of GTP analogs. In the absence of GTP, the density ( $B_{max}$ ) of binding sites labeled by the antagonists was significantly higher than the density of agonist-labeled sites. We have defined the high-affinity state as that labeled by agonists in the absence of GTP, and the low-affinity state as that labeled by antagonists in the presence of GTP and have determined the  $K_i$  values for 5-HT<sub>1A</sub> ligands for sites in the high affinity (KH) and low affinity (KL) states. In both brain regions  $K_L/K_H > 1$  for agonists and  $K_L/K_H \leq 1$  for antagonists (Maayani et al., this volume). We propose that the complete GTP-sensitivity in cryostat slices from rat brain renders it a system of choice for characterization of affinity states of the 5-HT<sub>1A</sub> receptor (Supported by USPHS GM 34852, MH 48125 and DA 09094)

## 537.7

**RELATIVE DRUG EFFICACY OF HALLUCINOGEN VERSUS NON-HALLUCINOGEN AGONISTS IS SIGNAL TRANSDUCTION PATHWAY DEPENDENT.** K.A. Berg<sup>1</sup>, S. Maayani<sup>2</sup>, and W. P. Clarke<sup>1</sup>. Dept. of Pharmacology<sup>1</sup>, Univ. of Texas Health Science Center, San Antonio, Texas 78284 and Dept. of Anesthesiology<sup>2</sup>, Mount Sinai School of Medicine, NY, NY 10029.

Activation of 5-HT<sub>2C</sub> receptors in CHO cells increases accumulation of inositol phosphates (IP) as well as the release of arachidonic acid (AA) via two distinct phospholipases: PLC and PLA<sub>2</sub> (Clarke et al., 1994, *Soc. Neurosci.* 20: 1158). We are studying the effects of hallucinogen (bufotenin, (±)DOI and d-LSD) vs non-hallucinogen (quipazine and TFMPP) agonists on both of these 5-HT<sub>2C</sub>-mediated pathways. CHO cells stably expressing human 5-HT<sub>2C</sub> receptors (200 fmol/mg), were pre-labeled with either [<sup>3</sup>H]-myo-inositol or [<sup>14</sup>C]-AA and IP accumulation and AA release were measured following 10 min of agonist incubation. The results of alkylating experiments with phenoxybenzamine indicated little or no receptor reserve for either response. Agonist potency was similar between the two pathways (see Table). Interestingly, the relative efficacy of the agonists differed depending upon whether activation of PLC or PLA<sub>2</sub> was measured. As shown in the table below (n = 5-9 experiments), the hallucinogens were more efficacious in eliciting AA release than IP accumulation (intrinsic activity (i.a.) ratio of AA/IP > 1) while the non-hallucinogens were more efficacious on IP accumulation (AA/IP i.a. < 1).

DRUG	IP	AA release	IP	AA release	AA/IP (i.a.)
5-HT	7.43 ± 0.1	7.34 ± 0.1	1.0	1.0	1.0
bufotenin	6.50 ± 0.1	6.33 ± 0.1	0.78 ± 0.04	1.03 ± 0.04	1.32
(±)DOI	6.72 ± 0.1	6.80 ± 0.3	0.61 ± 0.07	0.81 ± 0.08	1.33
d-LSD	7.47 ± 0.1	8.00 ± 0.3	0.17 ± 0.02	0.40 ± 0.13	2.35
quipazine	5.67 ± 0.1	5.80 ± 0.2	0.88 ± 0.14	0.61 ± 0.07	0.69
TFMPP	6.34 ± 0.1	6.21 ± 0.2	1.05 ± 0.13	0.56 ± 0.07	0.53

We suggest that the greater efficacy of hallucinogens to activate the 5-HT<sub>2C</sub>-AA pathway is due to more efficient coupling between the hallucinogen-receptor complex and the G-protein that activates PLA<sub>2</sub> than that with the G-protein that activates PLC. (supported in part by USPHS grants GM 34852 and DA 09094).

## 537.4

**5-HT<sub>1B</sub> RECEPTOR COUPLES TO CARDIAC POTASSIUM CHANNELS.**

A. Ghavami, M. Baruscotti, P. Blier<sup>+</sup>, R. B. Robinson and R. Hen. Department of Pharmacology, Columbia Univ., New York, NY 10032, USA ; <sup>+</sup>Neurobiological Psychiatry Unit, McGill Univ. Montreal, Canada.

5-HT<sub>1B</sub> receptors are expressed predominantly on axon terminals and have been shown to inhibit the release of various neurotransmitters including 5-HT and GABA. However the intracellular effectors involved in 5-HT<sub>1B</sub>-mediated inhibition of transmitter release are unknown. We decided therefore to investigate the possibility that 5-HT<sub>1B</sub> receptors might couple with ion channels. To be able to express efficiently the 5-HT<sub>1B</sub> receptor in a wide variety of cells, we constructed a recombinant adenovirus (ad-1B). This virus is replication deficient and expresses under the control of the early cytomegalovirus promoter, the 5-HT<sub>1B</sub> receptor with an hemagglutinin epitope (tag) at its amino terminal end. Using antibodies against the tag, we were able to detect 5-HT<sub>1B</sub> receptor on the membranes of various infected primary cells including neurons and myocytes. A small fraction of the neurons were expressing the 5-HT<sub>1B</sub> receptor while nearly 100% of the cardiac myocytes expressed this protein. Cardiac myocytes were used so that we could compare the 5-HT response to that of the muscarinic agonist carbachol. Neonatal rat ventricular myocytes were voltage clamped and held at -90 mV in a high K<sup>+</sup> (25mM) solution. In a control experiment, 10 non infected cells were exposed to carbachol (10  $\mu$ M). Carbachol activated an average current of 7.8 ± 3.5 pA/pF (mean ± SEM). Nine of these 10 cells were also tested for 5-HT (10  $\mu$ M) and none responded. In contrast, in 12 infected cells, an inward current was recorded in response to 5-HT; 6 of these cells were also tested for the effect of carbachol and a similar current was detected. 5-HT was tested as first drug in 8 cells and the average current amplitude recorded was 3.3 ± 0.8 pA/pF. The remaining 4 cells were first tested for carbachol and the response was 7.3 ± 2.9 pA/pF. These preliminary data indicate that, when expressed in ventricular myocytes, 5-HT<sub>1B</sub> receptors can activate an inward current. We are currently investigating the properties of this current to determine if 5-HT and carbachol are activating the same channel and if like the atrial m2 receptor, the 5-HT<sub>1B</sub> receptor can directly activate ion channels, without cytosolic second messenger intermediates.

## 537.6

**INDEPENDENT DEPRESSIVE MECHANISMS OF GABA AND 5-HT<sub>1A</sub> ON RAT SPINAL AXONS** J. Sakuma, J. Ciporen, Y. Saruhashi, J. Abrahams, and W. Young<sup>+</sup>. Department of Neurosurgery, Physiology & Biophysics, NYU Medical Center, 550 First Avenue, New York, NY 10016.

Our laboratory found two serotonergic receptor subtypes (5-HT<sub>1A</sub> and 5-HT<sub>2A</sub>) on rat spinal cord axons. One of the receptors, activated by the specific 5-HT<sub>2</sub> receptor agonist quipazine, markedly excites axons through calcium dependent mechanisms. The other receptor, activated by the specific 5-HT<sub>1A</sub> receptor agonist 8-OH-DPAT, depressed axons through yet unknown mechanisms. Our goal is to determine the characteristics and mechanisms of 8-OH-DPAT mediated depression of axonal excitability and conduction. Action potentials (AP) were activated by supramaximal constant current pulse and recorded with micropipettes inserted into the isolated rat dorsal column.

GABA and 8-OH-DPAT significantly depressed action potential amplitudes and increased latencies in cuneate-gracilis fasciculus (CGF) and corticospinal tract (CST). Preliminary results suggest that 5-HT<sub>1A</sub> receptors are present on CST axons. GABA did not significantly alter conduction velocity whereas 8-OH-DPAT significantly decreased conduction velocity. Ion-selective microelectrode recordings showed that GABA increased extracellular K<sup>+</sup> ([K<sup>+</sup>]<sub>e</sub>) while 8-OH-DPAT did not. Likewise, tetraethylammonium (TEA) did not alter 8-OH-DPAT induced depressive effects, suggesting that TEA-sensitive K<sup>+</sup> channels did not mediate the 5-HT<sub>1A</sub>-induced excitability changes. The Na/K ATPase inhibitor, ouabain, markedly enhanced the depressive effects of GABA. However, ouabain did not alter 8-OH-DPAT's depressive effects. GABA receptor antagonists had no effect on 8-OH-DPAT induced axonal depression; suggesting that the effects were not mediated by GABA release or GABA-gated Cl<sup>-</sup> channels.

These findings suggest strongly that GABA and 5-HT<sub>1A</sub> receptors depress axonal excitability through different and independent mechanisms.

## 538.1

DIFFERENTIAL EFFECTS OF 5-HT<sub>1A</sub> AND 5-HT<sub>1B</sub> RECEPTOR AGONISTS ON ESTROGENIC AND ANDROGENIC-INDUCED AGGRESSION. A. Cologer-Clifford and N.G. Simon\*, Dept. of Biological Sciences, Lehigh University, Bethlehem, PA 18015.

Male-typical aggression is facilitated by testosterone or its metabolites, while 5-HT<sub>1A</sub> and 5-HT<sub>1B</sub> receptor agonists reportedly reduce behavioral expression. We examined the interaction between these hormonal and neurochemical systems. 5-HT<sub>1A</sub> (8-OH-DPAT) and 5-HT<sub>1B</sub> (CGS12066B) agonists were administered alone or in combination to castrated CF-1 male mice subcutaneously implanted with either DES (an estrogen) or R1881 (an androgen). All of the agonist treatments reduced offensive aggression without affecting locomotor behaviors in R1881-treated animals. In DES-treated males, only DPAT and CGS+DPAT reduced aggression. Preliminary microinjection studies indicate that the medial preoptic area is an active site for 5-HT modulation of aggression in the presence of DES or R1881. These studies demonstrate a significant interaction between neuroendocrine and neurochemical regulatory systems for aggression.

## 538.3

BEHAVIORAL AND HORMONAL RESPONSES TO HALLUCINOGENS FOLLOWING CHRONIC ANTIDEPRESSANT TREATMENT IN RATS K.R. Bonson\*, J.W. Buckholz, D.L. Murphy, Laboratory of Clinical Science 10/3D41, National Institute of Mental Health, Bethesda, MD 20892-1264.

Recent studies have shown that the acute responses to self-administered hallucinogens in humans are increased following chronic administration of tricyclic antidepressants or lithium but are decreased after chronic administration of serotonin reuptake inhibitors or MAO inhibitors. Since changes in the functioning of serotonin receptor subtypes may underlie this phenomenon, the present study investigated whether the acute behavioral effects of hallucinogens with different serotonin binding profiles could be altered by the chronic administration of a variety of antidepressants in rats. Following chronic (4 week) administration of desipramine (5 mg/kg/day), clomipramine (5 mg/kg/day), fluoxetine (5 mg/kg/day), cloglyline (1 mg/kg/day), cycloserine (30 mg/kg/day) or saline, rats in each of the treatment groups were challenged with an acute dose of either DOM (25 mg/kg) as a selective 5-HT<sub>2</sub> hallucinogen, 5-MeO-DMT (5 mg/kg) as a selective 5-HT<sub>1A</sub> hallucinogen or LSD (4 mg/kg) as a non-selective 5-HT<sub>2/1A</sub> hallucinogen. Rats were then observed for emitted behaviors, with temperature measured and trunk blood collected for assessment of hormonal changes. The data indicate that, similar to human responses, the MAO inhibitor cloglyline decreased behavioral responses to all three hallucinogens in rats. Cycloserine, a partial agonist at the serine site on the NMDA receptor complex, reduced the serotonin syndrome induced by 5-MeO-DMT. Other behavioral responses to the hallucinogens were mixed following antidepressant treatment, suggesting that the behaviors observed in rats after the administration of hallucinogens at high doses may not provide a useful model of human hallucinogenic responses. Changes in plasma levels of prolactin, corticosterone and ACTH in response to hallucinogens also indicate a mixed effect of chronic antidepressant administration.

## 538.5

WAY-100635, A SILENT 5-HT<sub>1A</sub> RECEPTOR ANTAGONIST HAS ANXIOTIC EFFECTS IN RATS AND DOES NOT BLOCK STRESS-INDUCED RISES IN STRESS HORMONES. L. Groenink<sup>1</sup>, J. Mos<sup>2</sup>, J. van der Gugten<sup>1</sup>, J. Schipper<sup>2\*</sup> and B. Olivier<sup>1,2</sup>, <sup>1</sup>Dept. Psychopharmacology, Utrecht University, P.O.Box 80082, 3508 TB Utrecht and <sup>2</sup>CNS-research Solvay-Duphar B.V., Weesp, The Netherlands.

5-HT<sub>1A</sub> receptor agonists exert anxiolytic effects in both animals and humans. Moreover, these agonists enhance plasma ACTH, corticosterone and prolactin levels. We studied whether the 5-HT<sub>1A</sub> receptor antagonist WAY-100635 also affects anxiety and basal stress hormone levels in rats. Furthermore, we examined whether WAY-100635 alters stress-induced rises in plasma ACTH, corticosterone and prolactin using the adult ultrasonic vocalisation (AUV) test. In this test, rats are replaced in a cage in which they previously received inescapable shocks. WAY-100635 (0.3 mg/kg sc) significantly enhanced the number of distress vocalisations, whereas higher doses of the drug (1.0 and 3.0 mg/kg sc) did not alter the number of calls. This indicates that WAY-100635 has anxiogenic effects according to a bell-shaped dose-response. Under basal, non-stress conditions, WAY-100635 did not alter plasma ACTH and corticosterone levels. However, the highest dose of WAY-100635 significantly enhanced plasma prolactin levels. Exposure of the rats to the AUV test resulted in significant rises in plasma ACTH, corticosterone and prolactin levels. Prior administration of WAY-100635 did not alter these rises in plasma stress hormone concentrations.

Our results indicate that the supposed silent 5-HT<sub>1A</sub> receptor antagonist may have anxiogenic effects in rats. Moreover, as the stress-induced rises in plasma ACTH, corticosterone and prolactin levels are not antagonized by a blockade of the 5-HT<sub>1A</sub> receptor, this receptor is probably not of major importance in the regulation of stress-induced hormone secretion.

## 538.2

EFFECTS ON PATTERNS OF SPONTANEOUS LOCOMOTOR ACTIVITY BY SELECTIVE STIMULATION OF 5-HT<sub>1A</sub> OR 5-HT<sub>2A/C</sub> RECEPTORS IN THE RAT. V. Hillegaart, A. Estival and S. Ahlenius\*, Biochemical & Behavioral Pharmacology, Astra Arcus AB, Södertälje, Sweden.

We have previously shown that the 5-HT<sub>1A</sub> receptor agonist 8-OH-DPAT produces a specific pattern of activity, characterised by stereotyped forward locomotion in the periphery of an open-field arena. In the present study, the administration of DOI (0.05-4.0 mg kg<sup>-1</sup> sc, -20 min) or 8-OH-DPAT (6-400 µg kg<sup>-1</sup> sc, -20 min) were found to produce this pattern of locomotor activity. Such effects produced by DOI- or 8-OH-DPAT were normalised by pretreatment with the 5-HT<sub>2A/C</sub> or the 5-HT<sub>1A</sub> receptor antagonists ritanserin (2 mg kg<sup>-1</sup> sc, -30 min) and (-) pindolol (2 mg kg<sup>-1</sup> sc, -30 min), respectively. DOI-induced stereotyped locomotor activity was not antagonised by (-)pindolol pretreatment, nor was 8-OH-DPAT-induced effects antagonised by ritanserin pretreatment. Interestingly, certain aspects of the DOI-induced behavioural stimulation were significantly enhanced by the (-)pindolol treatment. Together with findings on 8-OH-DPAT/DOI interactions, as reported in the literature, this observation supports the notion of interactions between the 5-HT<sub>1</sub> and 5-HT<sub>2</sub> receptor subtypes. The precise nature of such interactions in terms of pre- and post-synaptic location of 5-HT receptors remains to be determined. **In conclusion:** Results from this study demonstrate the same stereotyped pattern of locomotor activity after stimulation of 5-HT<sub>1A</sub> or 5-HT<sub>2A/C</sub> receptors. By use of selective 5-HT receptor antagonists these effects were shown to be pharmacologically distinct.

## 538.4

EFFECTS OF CP-135,807, A POTENT 5HT<sub>1D</sub> AUTORECEPTOR AGONIST, ON SCHEDULE-CONTROLLED PERFORMANCES IN THE PIGEON. R.S. Mansbach\*, C.C. Rovetti and J.E. Macor, Pfizer Central Research, Eastern Point Road, Groton, CT 06340.

CP-135,807 binds with high affinity to central 5HT<sub>1A</sub> and 5HT<sub>1D</sub> receptors (10-fold selective for 1D), and in functional studies produces dose-dependent decreases in extracellular 5HT. These and other findings suggest that CP-135,807 may be acting as a terminal 5HT autoreceptor agonist. In an attempt to characterize the behavioral activity of selective 5HT<sub>1D</sub> ligands, adult male Carneaux pigeons were trained to discriminate i.m. injections of 0.1 mg/kg CP-135,807 from saline under a two-key, fixed ratio schedule of food-reinforced key pecking. CP-135,807 fully and dose-dependently substituted for the training dose. In contrast, little substitution was observed following administration of 8-OH-DPAT, a potent 5HT<sub>1A</sub> agonist, nor was the training stimulus blocked by WAY 100,635, a selective 5HT<sub>1A</sub> antagonist. Additional subjects were trained under a multiple schedule of food reinforcement in which responding was punished with mild electric shock in some components and not punished in other components. 8-OH-DPAT produced large increases in punished responding (>500% of control) while having little effect on unpunished responding. In contrast, CP-135,807 produced only modest increases in punished responding in a subset of animals. Taken together, these data suggest that CP-135,807 produces acute psychoactive effects in a species known to possess central 5HT<sub>1D</sub> receptors, and that these effects cannot be primarily attributed to its activity at 5HT<sub>1A</sub> sites.

## 538.6

BEHAVIORAL EFFECTS OF (±)-1-(2,5-DIMETHOXY-4-iodophenyl)-2-aminopropane, (DOI) IN THE ELEVATED PLUS-MAZE TEST. C. Bishop-Robinson<sup>1</sup>, E.S. Onaivi<sup>1\*</sup>, N.A. Darmani<sup>2</sup> and E. Sanders-Bush<sup>3</sup>, <sup>1</sup>Dept of Pharmacology, Meharry Med., College, Nashville, TN. <sup>2</sup>Dept of Pharmacology, Kirksville College of Osteopathic Medicine, Kirksville, MO. <sup>3</sup>Dept of Pharmacology, Vanderbilt Univ., Nashville, TN, 37232.

The serotonin (5-HT) system has consistently been implicated in the actions of DOI and other hallucinogens. Recent evidence suggest that the 5-HT<sub>2A/C</sub> receptor subtypes may be major targets for such drugs in the CNS. DOI-treated hooded rats (0.1-5.0 mg/kg) and DOI treated ICR mice (0.1-2.0 mg/kg), displayed aversions at lower doses and anti-aversions at higher doses to the open arms of the plus-maze. Mianserin (0.5 mg/kg) and ketanserin (0.1 mg/kg) blocked the anti-aversive behavior, but only mianserin was effective at reversing the aversions produced by the higher doses of DOI in the ICR mice. DOI produced an intense aversion in the DBA/2 and anti-aversion in the C57/BL6 mice to the open arms of the plus-maze. These opposing actions of DOI in the plus-maze may be exploited in studying the neurobehavioral effects of hallucinogens. Since flumazenil was ineffective at blocking the DOI induced changes, it was concluded that the mechanism of DOI induced anxiolysis or anxiogenesis may not involve an action at the benzodiazepine receptors. Supported by NIDA grants to E. S.-B.-DA 05781 and N. A. D.-DA07627; E.S.O.-NSF-MRCE # HRD-9255157 and RCMI grant # NIH 5G12RR0303208. C. B-R acknowledges support from MFP-American Psychological Association.

## 538.7

COMPARATIVE EFFECTS OF 5-HYDROXYTRYPTAMINE<sub>1A</sub> PARTIAL AGONISTS, FULL AGONISTS, AND ANTAGONISTS IN THE MURINE ELEVATED PLUS MAZE. D.B. Helfrich, K. Rasmussen, V. P. Rocco, J.P. Tizzano, and M.J. Kallman. Lilly Research Laboratories, Greenfield, IN 46140.

Previous studies have reported varied and often inconsistent results concerning the anxiolytic activity of 5-hydroxytryptamine<sub>1A</sub> (5-HT<sub>1A</sub>) agents on the elevated plus maze (EPM). The present set of experiments profiled the effects of the partial agonists buspirone, (+/-)-8-OH-DPAT, (-)-8-OH-DPAT, and LY315712, the full 5-HT<sub>1A</sub> agonists (+)-8-OH-DPAT and LY274600, and the selective 5-HT<sub>1A</sub> antagonist LY297996 on the murine automated EPM. Secondary pharmacology related to sedation was evaluated using home cage activity. (+/-)-DPAT (0.03-0.3 mg/kg, sc) produced dose-related increases in open arm activity with no evidence of sedation. (+)-DPAT increased open arm activity at 0.03 and 0.1 mg/kg followed by loss of effectiveness at 0.3 mg/kg with no sedation at any dose examined. In contrast, (-)-DPAT increased open arm activity at 0.03, 0.1, and 0.3 mg/kg, however, sedation was observed at all dose levels. Buspirone (0.03-3 mg/kg, sc) produced an increase in open arm activity at 0.3 mg/kg with loss of effect as doses increased (>1 mg/kg) (sedation was also noted at doses >0.3 mg/kg). The full agonist LY274600 (1-11 mg/kg, sc) also produced dose-related increases in open arm activity with sedation occurring only at doses >3 mg/kg. LY315712 (0.03-10 mg/kg, sc) produced bi-phasic effects with increased open arm activity at lower doses and loss of effect as doses increased (>1 mg/kg), with no evidence of sedation. However, the 5-HT<sub>1A</sub> antagonist LY297996 (0.03-3 mg/kg, sc) was ineffective on the maze and did not produce sedation at the doses examined. These results indicate that 5-HT<sub>1A</sub> partial and full agonists display anxiolytic activity in the murine elevated plus maze. The activity of these agents in this assay may be related to multiple factors including 5-HT<sub>1A</sub> affinity for pre- and post synaptic receptor stimulation, the degree of intrinsic activity (depending on the extent of receptor reserve), or a combination of these variables.

## 538.9

LORDOSIS BEHAVIOR AFTER CO-INFUSION OF NE AND 5-HT INTO THE VMN. S. Maswood\*, M. Caldarola-Pastuszka, and L. Uphouse. Department of Biology, Texas Woman's University, Denton, TX. 76204.

Much emphasis has been placed on the lordosis-modulating action of norepinephrine (NE) and serotonin (5-HT) in the ventromedial nucleus of the hypothalamus (VMN). In the present study, the interaction between NE and 5-HT was examined with the prediction that NE might protect against the inhibitory action of 5-HT. After a 5-10 min pretest, intact, proestrous rats were infused bilaterally into the VMN with either 1000 ng of 5-HT per bilateral site or with 1000 ng of 5-HT plus 1000 ng NE. Sexual behavior was monitored for 30 consecutive min after the infusion. When rats were infused with 5-HT alone, there was a decline in the L/M ratio by 5 min after infusion and the decline lasted an additional 10-15 min. Although NE did not prevent the decline in lordosis behavior, NE did reduce the magnitude and duration of decline in the lordosis response.

Supported by NIH RO1 HD28419.

## 538.11

NON-SELECTIVE 5-HT RECEPTOR AGONISTS AND FEMALE LORDOSIS BEHAVIOR. A. Jackson\*, A. Wolf, T. Price, A. Trevino, M. Caldarola-Pastuszka, and L. Uphouse. Department of Biology, Texas Woman's University, Denton, TX. 76204.

Activation of 5-HT<sub>1A</sub> receptors causes a decline in lordosis behavior while simultaneous activation of 5-HT<sub>2A/2C</sub> receptors attenuates this decline. In the following study, the ability of two nonselective 5-HT compounds, TFMPP and quipazine (which share agonist action at the 5-HT<sub>2C</sub> receptor), were evaluated for their ability to protect against the lordosis-inhibiting action of the 5-HT<sub>1A</sub> agonist, 8-OH-DPAT. Both TFMPP and quipazine, when infused into the ventromedial nucleus of the hypothalamus (VMN), attenuated the effect of 8-OH-DPAT. Alone, neither TFMPP nor quipazine substantially modified lordosis behavior of hormone-primed, sexually receptive rats. However, approximately 50% of hormone primed, nonreceptive rats showed increased sexual behavior following infusion of TFMPP or quipazine into the VMN. These findings support other data indicative of a complex interaction among 5-HT receptor subtypes in the control of lordosis behavior. Supported by NIH RO1 HD28419 and by NIH GM08256.

## 538.8

A SINGLE PRETREATMENT WITH 8-OH-DPAT REDUCES BEHAVIORAL INDICES OF 5-HT<sub>1A</sub> RECEPTOR ACTIVATION IN FEMALE RATS. N. Maswood, J. Hines\*, and L. Uphouse. Department of Biology, Texas Woman's University, Denton, TX. 76204.

Several studies have been designed to examine the effects of prior treatment with 5-HT<sub>1A</sub> receptor agonists on behavioral indices of receptor activation in male rats. Such studies have led to suggestions that presynaptic, but not postsynaptic, receptors readily undergo agonist modification. In few studies have the effects of prior agonist activation been examined in the female rat. Ovariectomized rats were pretreated with either 0.25 mg/kg 8-OH-DPAT or saline and 7 days later the behavioral effects of the drug were examined. This dose of the drug elicited components of the "serotonin behavioral syndrome" including flattened body posture and forepaw treading. Eating behavior and hypothermia were also present. Hypothermia, incidences of eating behavior, and the duration of flattened body posture were reduced by prior agonist activation while incidences of forepaw treading were unchanged. Thus, behavioral indices of both presynaptic autoreceptor and postsynaptic 5-HT<sub>1A</sub> receptor activation were reduced following prior agonist treatment. Supported by NIH RO1 HD28419.

## 538.10

5-HT<sub>1A</sub> RECEPTOR ACTIVATION AND FEMALE RAT LORDOSIS BEHAVIOR. L. Uphouse\*, M. Caldarola-Pastuszka, N. Maswood, and A. Jackson. Department of Biology, Texas Woman's University, Denton, TX. 76204.

In female rats, serotonin 1A (5-HT<sub>1A</sub>) receptor agonists inhibit lordosis behavior within 5-15 min following infusion into the ventromedial nucleus of the hypothalamus (VMN). When, proestrous rats received coinjections into the VMN with 200 ng 8-OH-DPAT or with 8-OH-DPAT plus the 5-HT<sub>1A</sub> receptor antagonist, (+) WAY100135, (+) WAY100135 attenuated the lordosis-inhibiting effect of the 5-HT<sub>1A</sub> agonist. Furthermore, bilateral VMN infusion with 2500 ng (+) WAY100135 facilitated lordosis behavior in suboptimally, hormone-primed ovariectomized rats. These findings strengthen the argument that activation of VMN 5-HT<sub>1A</sub> receptors is incompatible with lordosis behavior. How 5-HT<sub>1A</sub> receptor activation is translated into inhibition of lordosis behavior is unclear. However, when ovariectomized, hormone-primed rats were infused bilaterally into the VMN with a 33.3% procaine solution, lordosis behavior declined within 5-15 min. Consequently, it is possible that 5-HT<sub>1A</sub> receptor agonists inhibit lordosis behavior by reducing the firing of VMN neurons.

## 538.12

5-HT<sub>2A/2C</sub> RECEPTORS AND LORDOSIS BEHAVIOR IN FEMALE RATS. A. Wolf\*, M. Caldarola-Pastuszka, and L. Uphouse. Texas Woman's University, Department of Biology, Denton, TX. 76204.

Infusion of 2000 or 3000 ng DOI (5-HT<sub>2A/2C</sub> agonist) into the ventromedial nucleus of the hypothalamus (VMN) of non-sexually receptive, hormone-primed (0.5 µg estradiol benzoate) female rats facilitated lordosis behavior. Six of 8 rats infused with 2000 ng DOI showed facilitation while 9 of 11 rats showed facilitation following infusion with 3000 ng DOI. In sexually receptive rats, infusion of the 5-HT<sub>2A/2C</sub> antagonist, ketanserin (500 ng - 3000 ng ketanserin tartrate), produced a dose dependent reduction in lordosis behavior. However, the drug appeared to be more potent in the ovariectomized than in the intact rats. At the highest dose of ketanserin, 9 of 9 ovariectomized rats showed a reduction in lordosis behavior while only 4 of 6 intact rats showed a decline. Collectively, these findings are consistent with previous assertions that activation of 5-HT<sub>2A/2C</sub> receptors may facilitate lordosis behavior.

## 539.1

**SOMATODENDRITIC LOCALIZATION OF THE SEROTONIN 5-HT<sub>1A</sub> RECEPTOR IN ADULT RAT BRAIN.** M. Riad<sup>1</sup>, S. Garcia<sup>1</sup>, M. Hamon<sup>2</sup> and L. Descarries<sup>\*1</sup>. <sup>1</sup>Département de pathologie et CRSN, Université de Montréal, Montréal, Qc, Canada; <sup>2</sup>Neurobiologie Cellulaire et Fonctionnelle, INSERM U288, Paris, France.

An immunocytochemical protocol was developed for the light and electron microscopic visualization of 5-HT<sub>1A</sub> receptors in adult rat brain. We used specific antibodies raised against a synthetic peptide corresponding to a highly selective portion of the third intracytoplasmic loop of the rat 5-HT<sub>1A</sub> receptor [El Mestikawy et al, *Neurosci Lett*, 1990; Riad et al, *Neurochem Int*, 1991], and the peroxidase technique. Among several fixation procedures tested, perfusion with 4% paraformaldehyde yielded the best results. In the mesencephalic raphe nuclei, the immunoprecipitate was concentrated at the periphery of neuronal cell bodies and their proximal dendrites, and over small (distal) dendritic branches. In the hippocampus, a similar subcellular distribution was found, involving some interneurons as well as pyramidal and granule cells. No axonal localization (including terminals) was seen, nor any labeling of astroglia. On the basis of these ultrastructural data and light microscopic observations in other brain regions, it was concluded that the 5-HT<sub>1A</sub> receptor of adult rat CNS is essentially neuronal, and somatodendritic in both its autoreceptor (raphe nuclei) and heteroreceptor locations (e.g. hippocampus). [Supported by FCAR and MRC grant MT-3544].

## 539.3

**FURTHER STUDIES ON THE ROLE OF 5-HT<sub>1A</sub> AUTORECEPTORS IN THE EFFECT OF 5-HT REUPTAKE BLOCKADE ON EXTRACELLULAR 5-HT LEVELS IN THE RAT BRAIN.** S. Hiorth\* and S. Milano. Inst. of Physiology & Pharmacology, Dept. of Pharmacology, Univ. of Göteborg, Medicinereg. 7, S-413 90 Göteborg, SWEDEN.

The efficacy of antidepressant drugs that block serotonin (5-HT) reuptake may be restrained in the short term by the indirect activation of autoreceptors. In a continuation of our previous studies on this issue, we used *in vivo* microdialysis in anaesthetized rats to further clarify the role of 5-HT<sub>1A</sub> autoreceptors in the action of 5-HT reuptake inhibitors. Microdialysis probes were placed in the ventral hippocampus and dialysate 5-HT levels determined by HPLC-EC. Citalopram (CIT; 0.5 or 5.0 mg/kg SC) dose-dependently elevated dialysate 5-HT. The 5-HT<sub>1A</sub>/18 receptor antagonist (-)penbutolol (8 mg/kg SC, 60' after CIT, 5.0 mg/kg, SC) almost doubled 5-HT relative to CIT alone, whereas (+)penbutolol, or a combination of the  $\beta_1$ - and  $\beta_2$ -adrenoceptor blockers betaxolol and IC1118551 (lacking 5-HT<sub>1</sub> receptor affinity) failed to alter the CIT effect. This suggests that the (-)penbutolol-induced augmentation of the CIT response is not mediated by  $\beta$ -adrenoceptors. An autoreceptor dose of the 5-HT<sub>1A</sub> agonist 8-OH-DPAT (0.025 mg/kg SC) did not modify, whereas the 5-HT<sub>1A</sub> antagonist WAY100635 (0.3 mg/kg SC) strongly potentiated the CIT-induced elevation of 5-HT. The data confirm the conclusion that indirect stimulation of 5-HT<sub>1A</sub> autoreceptors – secondary to increased extracellular 5-HT in the raphe cell body areas – limits the overall 5-HT transmission-promoting action of SSRI like CIT. Indeed, recent open studies support the idea, that the clinical efficacy and onset of action of antidepressants that block 5-HT reuptake may be enhanced by concurrent 5-HT<sub>1A</sub> autoreceptor blockade.

## 539.5

**THE 5-HT<sub>1A</sub> RECEPTOR ANTAGONIST (S)-UH-301 ENHANCES BOTH THE ACUTE AND CHRONIC EFFECT OF CITALOPRAM ON CENTRAL SEROTONERGIC TRANSMISSION.** L. Arborelius\*, G.G. Nomikos, P. Hertel, P. Grillner, B. Backlund Höök, U. Hackzell and T.H. Svensson. Dept. Physiology & Pharmacology, Div. Pharmacology, Karolinska Institutet, S-171 77 Stockholm, Sweden.

The effects of (S)-UH-301 in combination with acute or chronic administration of the selective serotonin (5-HT) reuptake inhibitor citalopram (CIT) were studied on the activity of 5-HT neurons in the dorsal raphe nucleus, using single cell recording techniques, and on extracellular concentrations of 5-HT in the frontal cortex (FC) of freely moving rats, using microdialysis. Acute administration of CIT (0.3 mg/kg i.v.) significantly decreased the activity of 5-HT cells, an effect that was potentially blocked or reversed when (S)-UH-301 (0.25 and 0.5 mg/kg i.v. respectively) was administered before or after CIT. CIT (2.0 mg/kg s.c.) increased 5-HT concentrations in the FC with 186% and (S)-UH-301 (2.5 mg/kg s.c.) alone increased 5-HT by 68%. When (S)-UH-301 was injected 30 min before CIT, 5-HT concentrations increased with 425%. After treatment with CIT (20 mg/kg/day) for 14 days the baseline firing rate was not significantly different from baseline values in rats which had received saline (SAL; 1 ml/kg/day; 0.90 ± 0.12 and 1.23 ± 0.14 Hz). (S)-UH-301 (0.03-0.50 mg/kg i.v.) significantly increased the activity of 5-HT cells in CIT-treated rats, but did not affect 5-HT cells in SAL-treated rats. Biochemically, baseline concentrations of 5-HT in the FC were about 3.5 times higher in chronic CIT-treated rats (1.40 ± 0.23 fmol/min) than in SAL-treated rats (0.39 ± 0.03 fmol/min). In chronic CIT-treated rats administration of (S)-UH-301 increased 5-HT concentrations by 0.78 fmol/min, whereas in SAL-treated rats (S)-UH-301 increased 5-HT by 0.27 fmol/min. Taken together our findings show that (S)-UH-301 can augment both the acute and chronic stimulatory effect of CIT on central serotonergic transmission.

## 539.2

**EFFECTS OF THE FULL 5-HT<sub>1A</sub> AGONIST ALNESPIRONE (S 20499) ON 5-HT RELEASE IN DRN- AND MRN-INNERVATED AREAS IN RAT BRAIN**

M. Lesourd<sup>1</sup>, E. Mocaer<sup>1\*</sup>, J.M. Casanovas, F. Artigas. Dept. of Neurochemistry, C.S.I.C., Barcelona, Spain and <sup>2</sup>Institut de Recherches Internationales Servier, Paris, France

Alnespirone (S 20499) is a full agonist at pre- and post-synaptic 5-HT<sub>1A</sub> serotonergic receptors with anxiolytic properties. In vivo, alnespirone inhibits the firing of rat 5-HT dorsal raphe nucleus (DRN) neurones at low doses (ED<sub>50</sub> = 0.3 mg/kg p.o.). We have studied the effects of alnespirone on 5-HT release using microdialysis in conscious rats. These were implanted with 1.5- or 4-mm-long probes in different forebrain areas and in the DRN. 18-20 h later, the probes were perfused at 0.25 µl/min with artificial CSF containing 1 µM citalopram and 20-min fractions were collected. 5-HT and 5-HIAA were analyzed by HPLC. Basal values of dialysate 5-HT obtained in presence of 1 µM citalopram largely differed between brain regions, in accordance with the density of serotonergic fibers (e.g., basal 5-HT in the DRN was 2.5 times higher than in dorsal hippocampus). A detailed study of the dose-effect relationship has been performed in dorsal striatum, an area receiving afferents exclusively from the DRN. Alnespirone dose-dependently reduced dialysate 5-HT in the range 0.1 mg/kg - 3 mg/kg s.c. The calculated ED<sub>50</sub> was 0.26 mg/kg. The doses of 1 and 3 mg/kg induced profound and long-lasting (> 200 min) reductions of 5-HT release. The extent and duration of the maximal effect observed (-75% at 3 mg/kg) suggests full agonistic activity at 5-HT<sub>1A</sub> receptors controlling release in DRN-innervated areas, as it is comparable to other treatments (TTX, omission of Ca<sup>2+</sup> ions, etc...) that suppress firing-dependent 5-HT release. Overall, the release-reducing effects of alnespirone were more marked on neurones from the DRN than in those from the MRN, in agreement with electrophysiological data.

## 539.4

**ANTAGONISM OF SOMATODENDRITIC 5-HT<sub>1A</sub> AUTORECEPTOR ACTIVATION IN VIVO BY TWO NOVEL 5-HT<sub>1A</sub> RECEPTOR ANTAGONISTS.** R.J. Thienel\*, N.B. Fannon & A. Frazet. Dept. of Pharmacol., UTHSCSA and Audie L. Murphy Memorial Veterans Hospital, San Antonio, TX 78284.

4-(2-methoxy-phenyl)-1-[2'-(n-2"-pyridinyl)-p-iodobenzamido]-ethylpiperazine (p-MPPI) and 4-(2-methoxy-phenyl)-1-[2'-(n-2"-pyridinyl)-p-fluorobenzamido]-ethylpiperazine (p-MPPF) antagonize postsynaptic 5-HT<sub>1A</sub> receptor activation *in vivo* (Life Sci. 56:PL163, 1995). Many putative 5-HT<sub>1A</sub> receptor antagonists have been shown to be partial agonists at the somatodendritic 5-HT<sub>1A</sub> autoreceptor. We report p-MPPI and p-MPPF are antagonists at the somatodendritic 5-HT<sub>1A</sub> autoreceptor *in vivo*, as measured by 5-HT turnover. 5-HT and 5-HIAA contents in brain regions of the rat were measured by HPLC with electrochemical detection, and their ratio was used as an index of the turnover of 5-HT. Neither p-MPPI nor p-MPPF (10 mg/kg, ip) given alone significantly altered the ratio of 5-HIAA/5-HT in the hippocampus (HIP) (1.0 ± 0.2, saline; 1.1 ± 0.3, p-MPPI; 1.2 ± 0.1, p-MPPF) or striatum (STR) (1.3 ± 0.1, saline; 1.5 ± 0.1, p-MPPI; 1.6 ± 0.1, p-MPPF). The 5-HT<sub>1A</sub> agonist 8-hydroxy-2-(di-n-propylamino)tetralin (8-OH-DPAT) (0.5 mg/kg, sc) reduced the 5-HIAA/5-HT ratio in the HIP and STR by 48 and 33%, respectively (p<0.05). p-MPPI and p-MPPF were able to antagonize dose-dependently this reduction in the 5-HIAA/5-HT ratio in the HIP and STR (p<0.05) (approximate ED<sub>50</sub>'s for p-MPPI and p-MPPF, respectively: HIP: 10 and 4; STR: 2 and 4 mg/kg). Also, binding of 2 nM [<sup>3</sup>H]-p-MPPF (3 times its K<sub>d</sub>) to hippocampal membranes was unaltered by the addition of 100 µM GppNHp to the incubation medium (311 ± 35 and 338 ± 32 fmol/mg protein, in the absence and presence of GppNHp, respectively). Both p-MPPI and p-MPPF act as 5-HT<sub>1A</sub> antagonists *in vivo* at a response mediated by activation of somatodendritic 5-HT<sub>1A</sub> autoreceptors (Supported by Research Funds from the VA and USPHS Grant MH48125).

## 539.6

**REGULATION OF 5-HT RELEASE IN 5-HT<sub>1B</sub> KNOCK-OUT MICE: EXPERIMENTS IN HIPPOCAMPAL, FRONTAL CORTEX AND MIDBRAIN RAPHE SLICES.** G. Pifeyro\*, N. Castanon\*, R. Hen\* and P. Blier. Neurobiological Psychiatry Unit, McGill Univ., Montréal, Canada. \*Center for Neurobiology and Behaviour, Columbia Univ., New York, USA

5-HT<sub>1B</sub> receptors are rodent homologues of human 5-HT<sub>1D</sub> receptors. Some of these receptors are autoreceptors which negatively regulate 5-HT release in the CNS. In the present study, superfusion experiments were undertaken to assess the regulation of 5-HT release in mice genetically lacking 5-HT<sub>1B</sub> receptors. Slices were prepared from transgenic and control female mice and preloaded with [<sup>3</sup>H]-5-HT. The electrically-evoked release of 5-HT (S<sub>e</sub>) was increased by 189% in hippocampal but not in frontal cortex slices of 5-HT<sub>1B</sub> knock out mice. The selective 5-HT<sub>1B</sub> agonist CP-93129 (100 nM) inhibited evoked [<sup>3</sup>H]-5-HT release in hippocampal and cortical slices from wild-type mice but not from 5-HT<sub>1B</sub> knock-out mice. In contrast, the 5-HT<sub>1D/1B</sub> agonist sumatriptan (100 nM) did not produce a significant effect in the same projection areas in either group. The non-selective 5-HT agonist 5-carboxyamidotryptamine (5-CT; 100 nM) inhibited evoked [<sup>3</sup>H]-5-HT release by 80% in hippocampal slices and by 60% in cortical slices obtained from both, controls and mutants. These results indicate that in projection areas, 5-CT-sensitive, non-5-HT<sub>1B</sub>, non-5-HT<sub>1D</sub> receptors, negatively regulate 5-HT release in mutant mice. There was a 254% increase in S<sub>e</sub> values in mesencephalic slices (containing midbrain raphe nuclei) obtained from mutant mice. Interestingly, the 5-HT<sub>1B</sub> agonist CP-93129 (100 nM) had no effect in midbrain slices obtained from control or transgenic mice. Sumatriptan (100 nM) in contrast, inhibited [<sup>3</sup>H]-5-HT release by 60% in both groups. The latter effect was not blocked by the 5-HT<sub>1A</sub> antagonist (+)WAY 100135 in neither group of mice. These results support our previous observations indicating that 5-HT<sub>1D</sub> receptors negatively regulate 5-HT release in rodent raphe nuclei.

## 539.7

FLUOXETINE-INDUCED INCREASES IN FRONTOCORTICAL 5-HT LEVELS: A MICRODIALYSIS STUDY IN MICE LACKING 5-HT<sub>1B</sub> RECEPTORS. A.C. Trillat<sup>1</sup>, L. Malagie<sup>1</sup>, R. Searce<sup>2</sup>, C. Jacquot<sup>1</sup>, R. Hen<sup>2</sup> and A.M. Gardier<sup>1</sup>. 1-Dept. Pharmacol. JE 92-372, Fac. Pharmacie, Univ. Paris Sud, F92296 Chateau-Malabry, France. 2-Cent. Neurobiol. Behav., Columbia Univ., NY10032, USA.

5-HT<sub>1B</sub> presynaptic receptors, predominantly located on the terminals of projecting neurons, have been shown to inhibit serotonin release, when activated. This activation has already been suggested to play a role in the long-term effects of specific serotonin reuptake inhibitors (SSRI). Because there are no specific antagonists of these receptors, homozygous mutant mice lacking the gene encoding the 5-HT<sub>1B</sub> receptors in the central nervous system may represent a useful tool for elucidating further the role of these terminal autoreceptors in the SSRI mechanism of action. In the present report, we compared freely moving mutant mice and their wild-type littermates for the response to an acute injection of an SSRI fluoxetine (Flx, 10 mg/kg i.p.) on the extracellular concentrations of 5-HT as measured in the frontal cortex (FC) by *in vivo* microdialysis coupled to HPLC with amperometric detection (Saudou et al., *Science*, 265 (1994) 1875). In mutant mice, basal extracellular levels of 5-HT in FC did not differ from those of wild-type mice (in fmol/20µl: 8.51 ± 0.84 and 8.88 ± 0.83, respectively), while basal 5-HIAA efflux was significantly increased (in pmol/20µl: 1.97 ± 0.08 and 1.46 ± 0.09, P<0.001, respectively). An acute 10 mg/kg Flx dose caused similar increases in extracellular 5-HT in FC (expressed as maximal percentage of 5-HT increase over the basal values: 286 ± 50%; P<0.02 and 276 ± 74%; P<0.01, respectively). Extracellular neurotransmitter concentrations measured by *in vivo* microdialysis at nerve terminals are known to reflect a balance between transmitter release and its reuptake. As already reported in rats (Rutter and Auerbach, *J.Pharm.Exp.Ther.* 265 (1993) 1319), peripheral Flx increases extracellular 5-HT concentrations by decreasing 5-HT release and inhibiting its reuptake. Thus, the present *in vivo* study suggests that mutant mice exhibit unaltered 5-HT release and reuptake control mechanisms. Further studies (using other SSRIs at various doses) need to be performed to confirm the absence of a modulatory role of cortical 5-HT<sub>1B</sub> presynaptic receptors in the acute effects of peripheral SSRIs.

## 539.9

INHIBITION OF ADENYLYL CYCLASE ACTIVITY IN THE RAT DORSAL RAPHE REGION MEDIATED BY ACTIVATION OF 5-HT<sub>1B</sub>-LIKE RECEPTORS. W.P. Clarke<sup>1</sup>, K.A. Berg<sup>1</sup> and S. Maayani<sup>2</sup>. Dept. of Pharmacology<sup>1</sup>, Univ. of Texas Health Science Center, San Antonio, Texas 78284 and Dept. of Anesthesiology<sup>2</sup>, Mount Sinai School of Medicine, NY, NY 10029.

Regulation of the activity of serotonergic neurons, located mainly within the raphe nuclei of the brainstem, is in part due to the action of serotonin (5-HT) at somatodendritic autoreceptors which have been characterized as the 5-HT<sub>1A</sub> subtype. Serotonergic regulation of 5-HT neuronal activity has been implicated in the etiology of affective disorders such as depression and anxiety. In regions like the hippocampus, postsynaptic 5-HT<sub>1A</sub> receptor activation results in an increase in K<sup>+</sup> conductance and an inhibition of adenylyl cyclase (AC) activity. However, while it is well known that presynaptic 5-HT<sub>1A</sub> receptors in the raphe increase K<sup>+</sup> conductance, they do not appear to inhibit adenylyl cyclase. Here we report that activation of a receptor that resembles the 5-HT<sub>1B</sub> subtype inhibits AC in membranes prepared from the dorsal raphe region.

Cubes (~2 mm<sup>3</sup>) containing the dorsal raphe region from 3-8 rats (male Sprague Dawley) were pooled and homogenized. Adenylyl cyclase activity (the rate of conversion of [<sup>32</sup>P]-ATP to [<sup>32</sup>P]-cAMP) was measured in the presence of forskolin (10 µM) and various concentrations of agonists and antagonists. Selective 5-HT<sub>1A</sub> agonists (±8-OH-DPAT, (R)-8-OH-DPAT and dipropyl-5-carboxamidotryptamine did not inhibit forskolin-stimulated AC activity (FSAC). In contrast, the 5-HT<sub>1A</sub> agonist 5-carboxamidotryptamine (5-CT) produced a 10% inhibition (EC<sub>50</sub> = 25 nM) which was not affected by spiperone (3 µM), but was antagonized (10-fold shift) by methiothepin (0.3 µM). The rank order of agonist potency was 5-CT > 5-HT > RU 24969 > LSD > CP 93,129 = sumatriptan > CGS 120 66B which correlates well with that for the endogenously expressed 5-HT<sub>1B</sub>-like receptor reported in CHO cells (Berg et al., *Mol. Pharmacol.* 46: 477-484, 1994). These data suggest that in addition to 5-HT<sub>1A</sub> receptors, 5-HT<sub>1B</sub> receptors may regulate 5-HT neuronal function in the dorsal raphe. (Supported in part by USPHS grants HD 26437, MH 48125 and GM 34852)

## 539.8

THE ROLE OF TERMINAL AND SOMATODENDRITIC 5-HT<sub>1D</sub> AUTORECEPTORS IN 5-HT RELEASE. J. Sprouse\*, L. Reynolds, T. Clarke and H. Rollema. Pfizer Central Research, Groton, CT

The terminal autoreceptor which modulates 5-HT release is of the 5-HT<sub>1B</sub> or 5-HT<sub>1D</sub> subtype (depending upon species) and is inhibitory in nature such that extracellular 5-HT decreases in the presence of agonists. This system appears to be under the tonic influence of synaptic 5-HT since antagonists, when administered alone, act to increase 5-HT release (Briley and Moret, *Clin. Neuropharmacol.* 16:387, 1993). A mitigating factor in the degree of 5-HT release is thought to be the presence of somatodendritic 5-HT<sub>1D</sub> autoreceptors (Starkey and Skingle, *Neuropharmacology* 33:393, 1994), which when blocked by antagonists promote the release of 5-HT and in turn slow firing rate and reduce impulse flow to the terminals. The present study set about examining the importance of this mechanism with GR-127,935, a recently disclosed 5-HT<sub>1D</sub> antagonist.

GR-127,935 elevated extracellular 5-HT as measured with microdialysis probes located in guinea pig hypothalamus with a dose of 5 mg/kg sc resulting in a 35% increase above baseline (N = 7). Contrary to the hypothesis stated above, dorsal raphe cell firing as recorded from anesthetized guinea pigs was unaffected by doses of GR-127,935 up to 20 mg/kg iv (N = 4). In these and similar neurons, 8-OH-DPAT (10 µg/kg iv) produced the characteristic decrease in unit activity (84 ± 12 %; N = 5) expected of a 5-HT<sub>1A</sub> agonist. These data suggest that (1) unlike the terminal autoreceptors, those on cell bodies/dendrites may not be under tonic control, and/or (2) the amount of 5-HT released by this 5-HT<sub>1D</sub> antagonist at the cell body autoreceptor is not sufficient to inhibit cell firing.

## 539.10

DIFFERENTIAL ADDRESSING OF 5-HT<sub>1A</sub> AND 5-HT<sub>1B</sub> SEROTONIN RECEPTORS IN THE CNS AND IN LLC-PK1 EPIHELIAL CELLS. X. Langlois<sup>1</sup>, S. El Mestikaw<sup>1</sup>, M. Arpin<sup>2</sup>, D. Louvard<sup>2</sup>, A. Triller<sup>3\*</sup>, M. Hamon<sup>1</sup> and M. Darnon<sup>1</sup>.

<sup>1</sup>INSERM U288, <sup>2</sup>Institut Curie and <sup>3</sup>ENS-INSERM, Paris, France.

Specific antibodies raised against selective peptide sequences within the third intracellular loop of the rat 5-HT<sub>1A</sub> and 5-HT<sub>1B</sub> receptors were obtained in rabbits. Detailed mapping of the corresponding receptors in rat brain sections using immunohistochemical and immunohistochemical techniques confirmed the regional and cellular distributions previously established with specific radioligands. In particular, combined immunocytochemical investigations with these antibodies and *in situ* hybridization studies allowed the direct demonstration that both 5-HT<sub>1A</sub> and 5-HT<sub>1B</sub> receptors are synthesized by serotonergic neurons within the dorsal raphe nucleus. However, 5-HT<sub>1A</sub> receptors were exclusively found at the level of their somas and dendrites whereas 5-HT<sub>1B</sub> receptors appeared to be functionally expressed solely on their terminals. Further studies on the differential addressing of these receptors were carried out in an epithelial cell line from the pig kidney, LLC-PK1, with distinct basolateral and apical domains in the plasma membrane. These cells were transfected with constructed plasmids so as to permanently express either the rat 5-HT<sub>1A</sub> or the rat 5-HT<sub>1B</sub> receptors. Immunofluorescence experiments with specific anti-5-HT<sub>1A</sub> and anti-5-HT<sub>1B</sub> receptor antibodies and confocal microscopy examination demonstrated that 5-HT<sub>1A</sub> receptors were localized exclusively in the baso-lateral domain of the cell membrane whereas 5-HT<sub>1B</sub> receptors were confined to its apical domain. These data support the idea that the message for the differential addressing of 5-HT<sub>1A</sub> and 5-HT<sub>1B</sub> receptors is contained within the primary sequence of these receptors. Construction of chimeric receptors is under way in an attempt to identify the peptide sequence(s) responsible for the specific addressing of 5-HT<sub>1A</sub> and 5-HT<sub>1B</sub> receptors in LLC-PK1 cells.

## SEROTONIN: UPTAKE, FUNCTION

## 540.1

ANTIDEPRESSANTS INHIBIT THE NEURONAL 5-HT TRANSPORTER IN GLIAL CELLS. IN VIVO AND IN VITRO STUDIES. F. Artigas<sup>1</sup>, N. Bel G. Figueras<sup>2</sup>, C. Suñol<sup>1</sup>, M.T. Vilaró<sup>1</sup>, G. Mengod<sup>1</sup>. Dept. of Neurochemistry, C.S.I.C. Barcelona, Spain.

Rat brain astrocytes take up 5-HT with high-affinity (Dave and Kimelberg, *J Neurosci* 14:4972-4986, 1994). We have examined the sensitivity of this glial transporter to antidepressants by exposing primary cortical astrocytic cultures to 100 nM 5-HT (30 min) in presence of the uptake inhibitors citalopram, clomipramine, fluoxetine, fluvoxamine, paroxetine and sertraline. Astrocytes take up 5-HT (ca. 100 fmol/mg protein·min) and metabolize it to 5-HIAA. The addition of 1-10 µM of all uptake inhibitors reduced significantly (31-61 %) the uptake of 5-HT, as measured by the 5-HT+5-HIAA cell content at the end of the incubation period. The presence of the neuronal 5-HT transporter mRNA in cultured astrocytes was established after extraction of total RNA, reverse transcription, PCR amplification and hybridization with a probe complementary to that of the cloned 5-HT transporter.

*In vivo*, 5-HT uptake was assessed by perfusing 5-HT (0.1 - 1 µM) through a dialysis probe implanted in frontal cortex of conscious rats and measuring 5-HT at the probe outlet. Recovery of 5-HT by the tissue (uptake + diffusion) was 52 ± 4 % of the infused 5-HT in control rats. Addition of citalopram to the perfusion fluid reduced the tissue 5-HT recovery to 19 ± 2 % suggesting that most 5-HT is removed by high affinity uptake. In 5,7-DHT lesioned rats (200 µg i.c.v., 2 weeks before) the recovery of 5-HT was comparable to that in control animals or in 6-OHDA-lesioned animals (45 ± 2 % vs. 54 ± 3 % and 49 ± 2 %, respectively). Citalopram addition to the perfusion fluid reduced also the *in vivo* 5-HT uptake in 5-HT-denervated animals, thus indicating the presence of a non-neuronal uptake of 5-HT sensitive to antidepressants.

## 540.2

SPECT Imaging after Paroxetine Challenge Kate M. Bell, M.D.\* and Christopher Reist, M.D. Dept. of Psych., LBVA Hosp., Univ. Ca. Irvine Sch. of Med., Long Beach, CA 90822

Challenge paradigms coupled with SPECT imaging of cerebral blood flow (CBF) have proven useful tools in the study of many neurological and psychiatric disorders. Paroxetine, the potent and selective serotonin reuptake inhibitor, may offer greater specificity than commonly used serotonergic agents to study the function of the serotonergic system. In a pilot study, we examined the changes in CBF in 4 normal controls before and after paroxetine challenge using 99m-Tc-HMPAO SPECT. Subjects were male, right-handed and aged 32 ± 3 years. SPECT imaging was performed at rest with eyes, ears open and low ambient noise. The second scan was also obtained in the resting state 3 hours after taking 40 mg of paroxetine. Relative to the cerebellar CBF, regions of interest (ROI) before and after paroxetine challenge were compared using paired two-tailed T tests for each ROI. Significant decreases in CBF after paroxetine were seen in the temporal poles (hippocampus, medial and inferior gyri), and the right thalamus. Additional areas that showed decreases at the trend level were the right superior parietal and left superior frontal lobe. The changes are in agreement with SPECT [<sup>125</sup>I]-paroxetine binding data and would be consistent with an inhibitory role of serotonin on blood flow.

## 540.3

CHRONIC FLUOXETINE REVEALS AN INCREASE OF RENIN RELEASE BY 8-OH-DPAT: EVIDENCE AGAINST MEDIATION BY 5-HT<sub>1</sub> RECEPTORS. A. Vicentic\*, Q. Li, K. Kunimoto, W. Pinto, T.M. Cabrera, G. Battaglia and L.D. Van de Kar Dept. Pharmacol. Loyola Univ. Chicago, Sch. Med., Maywood, IL 60153.

Previous studies indicate that 5-HT<sub>1A</sub> agonists increase prolactin but not renin secretion. However, repeated injections of fluoxetine expose a stimulation of renin release by the 5-HT<sub>1A</sub> agonists 8-OH-DPAT and ipsapirone. Since chronic fluoxetine reduces the 5-HT<sub>1A</sub> receptor-mediated increases in ACTH and oxytocin, our hypothesis was that the effect of 8-OH-DPAT on renin may be due to activation of 5-HT<sub>1</sub> receptors. Male rats received either saline or fluoxetine injections (10 mg/kg, ip) once daily for 3 days. The 5-HT<sub>1</sub>/5-HT<sub>2</sub> antagonist ritanserin (0.1 mg/kg, sc) or vehicle were injected 18 hr after the last fluoxetine injection and 1.5 hr before sacrifice. Rats were challenged with saline or the 5-HT<sub>1A</sub>/5-HT<sub>2</sub> agonist 8-OH-DPAT (500 µg/kg, sc) 15 min before sacrifice. The dose of ritanserin was sufficient to inhibit both 5-HT<sub>1</sub> and 5-HT<sub>2</sub> receptor-mediated responses. The dose of 8-OH-DPAT, which has a low affinity for 5-HT<sub>1</sub> receptors, but a high affinity for 5-HT<sub>2</sub> receptors (pK<sub>i</sub> = ±7.3) was sufficient to activate both 5-HT<sub>1A</sub> and 5-HT<sub>2</sub> receptors. In fluoxetine but not in saline treated rats, 8-OH-DPAT increased renin release. Ritanserin did not inhibit this effect of 8-OH-DPAT on renin release. Also, fluoxetine potentiated the prolactin response to 8-OH-DPAT. Ritanserin did not inhibit the prolactin response to 8-OH-DPAT, regardless of whether or not the rats were treated with fluoxetine. These data suggest that induction of renin and potentiation of prolactin responses to 8-OH-DPAT, after fluoxetine exposure, are not mediated by 5-HT<sub>1</sub> receptors (supported in part by USPHS MH45812 to LVdK).

## 540.5

ORIGIN OF THE SEROTONERGIC INNERVATION TO THE DORSOLATERAL HYPOTHALAMUS IDENTIFIED BY RETROGRADE TRANSPORT AND DOUBLE IMMUNOCYTOCHEMISTRY. V. Ljubic-Thibault, A.J. Morin, E. Hamel and M. Djikic\*. Montreal Neurological Inst and Hosp, and Dept. Neurology and Neurosurgery, McGill Univ, Montréal, QC, Canada H3A 2B4

Recent observations from our laboratory suggest that the serotonergic neurons in the lateral wings of the dorsal raphe nucleus (LW-DRN) project ipsilaterally to the dorsolateral hypothalamus (DLH). Selective lesioning of DLH serotonergic terminals results in increased levels in the ipsilateral LW-DRN of the serotonin-synthesizing enzyme, tryptophan-hydroxylase (TPH) and of newly synthesized serotonin, as reflected by selective accumulation of α[<sup>3</sup>H]methyl-serotonin (α[<sup>3</sup>H]M5-HT) in this area following systemic injection of its precursor α[<sup>3</sup>H]m-tryptophan (α[<sup>3</sup>H]MTrp) (*Biochem Pharm* 49:633, 1995; and Ljubic-Thibault et al., unpublished). In order to better identify the cells of origin of these DLH serotonergic projections, we injected α[<sup>3</sup>H]MTrp (25µCi, SA 10Ci/mmol in 0.05 µl CSF) or Cholera toxin B subunit (CTb) iontophoretically at 2 µA for 30 min into the DLH (from Bregma -3.0; 1.0 lateral; 8.1 from brain surface). CTb sections were also processed for TPH immunocytochemistry. Following injection of α[<sup>3</sup>H]MTrp (10 days) or CTb (5 days), retrogradely labelled neurons were primary confined to the ipsilateral DRN. Some of the retrogradely labelled CTb neurons were also immunopositive for TPH and these were localized more specifically in the upper part of the LW-DRN. These results confirm that serotonergic neurons in the lateral aspect of the DRN project ipsilaterally to the hypothalamus (O'Hearn & Molliver, *Brain Res Bull* 13:709, 1984). Further, they show that part of the DLH serotonergic innervation originates in the lateral wings of the DRN, an area which appears particularly vulnerable to alterations in the terminal field of the DLH. Supported by MRC of Canada and NINDS-USA.

## 540.7

SEROTONIN INNERVATION IN THE RAT SUBSTANTIA NIGRA: QUANTITATIVE DATA AT THE LIGHT AND ELECTRON MICROSCOPIC LEVELS. H. Moukhsles\*, O. Bosler, J.P. Bolam, A. Vallée, D. Umbrico, M. Geffard and G. Doucet. Département de pathologie and CRSN, Université de Montréal, Montréal, Qc, Canada

To further understand the role of serotonin (5-HT) in the neural circuitry of substantia nigra (SN), we have quantified the number of 5-HT axonal varicosities, the proportion of such varicosities bearing a synaptic specialization and their repartition among potential targets in the *pars reticulata* (SNr) and *pars compacta* (SNc) of the rat. Serotonin axonal varicosities, counted at the light microscopic level following in vitro [<sup>3</sup>H]5-HT uptake/storage and radioautography, amounted to 8 x 10<sup>6</sup>/mm<sup>3</sup> in the SNr and 6 x 10<sup>6</sup>/mm<sup>3</sup> in the SNc. Their synaptic incidence, determined at the electron microscopic level following immunolabeling with a monoclonal antibody against a 5-HT-glutaraldehyde-protein conjugate, was in the order of 65-100% in the SNr and 35-50% in the SNc. The vast majority (93%) of these synapses were on dendrites. In dual labeling experiments, with the combined tyrosine hydroxylase immunolabeling of dopamine (DA) neurons, 19 % of the 5-HT synaptic contacts in the SNr were on DA dendrites and 6% were on a type of dendrites (MT) identified by its peculiarly high cytoplasmic density of microtubules. The mean diameter of the 5-HT terminals and the mean length of their synaptic contacts were smaller on DA dendrites and larger on MT dendrites than on unidentified dendrites, whereas the width of the DA dendritic targets was larger than that of unlabeled dendritic targets. The present data suggest that 1) 5-HT innervation of the SN is largely synaptic; 2) DA dendrites are among the synaptic targets, and 3) the nature of the synaptic targets is an important determinant of the dimension of 5-HT varicosities and length of synaptic contacts. (Supported by the MRC and FRSQ).

## 540.4

EFFECTS OF SEROTONIN REAGENTS ON BUFOTENINE LEVELS IN THE BRAIN OF *BUFO*. Naokuni Takeda\*,

Department of Biotechnology, Research and Development Center, COSMO Research Institute, Satte, Saitama, 340-01, Japan

Bufotenine (5-hydroxy-N, N-dimethyltryptamine: BUTN) is a methylated compound detected in urine specimens in psychiatric disorders, such as autism, epilepsy, mental retardation, depression and schizophrenia (Takeda et al., 1995; submitted). The brain of *Bufo* has been known to produce BUTN (Takeda, *Comp. Biochem. Physiol.* 107C:275, 1994; *Soc. for Neurosci.* 19:1171, 1993; 20: 1165, 1994). To get pharmacological clues to the etiology of such human psychiatric disorders, the brains of *Bufo* were used as an animal model. To examine the regulations of BUTN in the brain, serotonin reagents were injected directly into the brain by microdialysis. These were *p*-chlorophenylalanine (*p*-CPA) and ritanserin. Both *p*-CPA and ritanserin caused a decrease in the levels of BUTN, compared with sham operated controls. The level of BUTN was related to that of serotonin. The effects were greater in *p*-CPA than in ritanserin. Reduced levels of BUTN were also found in blood and urine specimens, confirming the origin of BUTN in the brain.

## 540.6

IMMUNOCYTOCHEMICAL DETECTION OF SEROTONIN AND SEROTONIN TRANSPORTER IN THE HUMAN SMALL INTESTINE. S.B. Bledsoe\*, S.K. E. Chong, and F.C. Zhou, Depts. Anatomy and Pediatrics, Indiana Univ. Sch. Med., Indianapolis, IN 46202

We previously showed that an antibody against multiple-antigenic (MAP) form peptide 315 of serotonin (5-HT) transporter (5-HTT315) can identify the 5-HT-like fibers in the brain (Bledsoe and Zhou, 1994). Currently, we report that using antibodies to 5-HT and 5-HTT315, we are able to identify 5-HT producing cells and 5-HT transporter bearing cells in the small intestines.

Human small intestine samples were obtained through biopsy and fixed in 4% paraformaldehyde for 40µm sectioning and staining. The rabbit 5-HTT315 and mouse polyclonal 5-HT (against Limulus hemocyanin conjugated 5-HT) antibodies were used for indirect immunocytochemical staining. Large columnar 5-HT-immunoreactive (im) cells were observed in the mucosal crypt or in the villi. Many 5-HT-im cells are argentaffine cell-like with apexes facing the lumens. When secretion of 5-HT occurs it should have quick access to the lumen.

The 5-HTT-im was observed in columnar cells, and located in the mucosal crypt and villi. The morphology of the 5-HTT315-im cells is similar to the 5-HT-im cells, but smaller in number. These data indicate that both 5-HT producing cells and 5-HT transporters bearing cells exist in crypts and villi of human small intestine. The existence of these two types of cells suggest that 5-HT can be produced and taken back into human small intestine. The exact role of the 5-HT in the small intestine, or the purpose of conservation or elimination of 5-HT in the GI tract is unknown. It is also unknown whether the same cells which produce the 5-HT are responsible for the uptake of the 5-HT. Study is in progress to identify the two populations of cells which produce and/or take up 5-HT (Support NIMH 50602 to Zhou).

## 540.8

PRE- AND POST-SYNAPTIC INHIBITION BY SEROTONIN IN RAT SUPRACHIASMATIC NUCLEUS (SCN) *IN VITRO*. Z.G. Jiang\*, Y.Q. Yang and C.N. Allen. Center for Research on Occupational and Environmental Toxicology and Department of Physiology, Oregon Health Sciences University, Portland, OR 97201.

Serotonergic transmission has anatomically and functionally been implicated in the SCN biological clock mechanisms in mammals, but the cellular actions of serotonin in the SCN remain largely unknown. Using a whole-cell recording technique on horizontal brain slices from circadian rhythm-monitored rats, we tested several serotonin analogs in a total of 109 cells in the ventral, VIP-positive part of the SCN. It was found that: 1) serotonin (1-100 µM), 5-CT (0.1-10 µM) or 8-OH-DPAT (1-30 µM) dose-dependently caused an outward current (5-100 pA) at -60 mV in 30 (27%) neurons throughout the 24 hr cycle. 2) The outward current was associated with an increase in input conductance, was enhanced by depolarization, reduced and reversed its polarity with hyperpolarization, and was blocked by Ba (1 mM), ritanserin (3 µM) or mesulergine (3 µM), but not by TTX (1 µM) or pindolol (3 µM). 3) The optic nerve stimulation-evoked EPSC was reduced by 10-70% (6 of 10 cells), and the focal stimulation-evoked and spontaneous IPSCs were inhibited by serotonin agonists in 20% of cells (n ≥ 10). 4) Both extrinsic glutamate-induced inward currents and GABA-induced outward currents were unaffected by serotonin (10 µM n ≥ 4). In conclusion, serotonin regulates the SCN neurons by both pre- and post-synaptic inhibition mechanisms; the latter may involve activation of 5-HT<sub>7</sub> receptors and then opening of a potassium channel. (Supported by grant AG10794)

## 540.9

## INHIBITORY ROLE OF SEROTONIN IN THE OPTIC TECTUM OF THE FROG.

A.A. Malayev\*, and E.A. Debski, School of Biological Sciences, University of Kentucky, Lexington, KY 40506

Serotonin induces membrane hyperpolarization in neurons of the optic tectum of *Rana pipiens* (Malayev & Debski, *Neurosci Abstr.* 20:1704). Using the blind patch-clamp technique in brain slices, we have examined the mechanism of this effect and its implication for tectal functioning.

External application of serotonin (100  $\mu$ M) in the presence of TTX and the absence of external  $Ca^{2+}$  induced outward current in tectal neurons clamped at -50mV. This effect could be mimicked by  $\alpha$ -methyl-serotonin (10  $\mu$ M), the mammalian 5-HT<sub>2</sub> receptor agonist. Voltage-ramp experiments showed that the activated conductance had a linear I-V curve with a reversal potential close to  $E_{K^+}$ . Including the  $Ca^{2+}$  chelator BAPTA (20 mM) in the patch-pipette did not eliminate the serotonin-activated conductance, showing that elevation of free intracellular  $Ca^{2+}$  was not necessary for current activation. However, the presence of GTP- $\gamma$ -S (500  $\mu$ M) in the pipette resulted in the irreversible activation of this conductance, suggesting the involvement of G-proteins. The effect of serotonin on tectal activity was examined by inducing synaptic current in layer 6 patch-clamped neurons by acute stimulation in layer 9, the retinorecipient layer. External application of serotonin inhibited only the delayed induced current (in 8 out of 8 cells) and did not have any effect on the monosynaptic response (in 3 out of 3 cells). This effect could again be mimicked by  $\alpha$ -methyl-serotonin (in 7 out of 7 cells). These data show that serotonin might inhibit neuronal activity in the optic tectum associated with processing of the visual signal. Supported by NSF grant IBN-9209651.

## 540.11

TOPOGRAPHIC ORGANIZATION OF THE RAT DORSAL RAPHE (DR) WITH RESPECT TO MODALITY SPECIFIC SENSORY TARGETS: A COMPUTER ASSISTED THREE DIMENSIONAL ANALYSIS M.L. Kirinides\*, D.M. Devilbiss, R.C.S. Lin and B.D. Waterhouse, Dept. of Anatomy and Neurobiology, MCP/Hahnemann Univ., Phila., PA 19102.

Previous investigations have demonstrated a crude topographic organization of the DR with respect to efferent targets in the mammalian brain. The present report describes a computer-based image analysis of the distribution and neurochemical identity of neurons within sub-regions of the DR that project to different cortical and subcortical sensory targets. Fluorescent retrograde tracers were used to identify neurons within the DR which project to sites along the ascending somatosensory trigeminal and visual pathways. Projection neurons were further identified immunohistochemically using antibodies directed against serotonin, dopamine, or GABA. Three dimensional representations of the data were created by manually or automatically scanning 40  $\mu$ m coronal brainstem sections and serially aligning arrays of retrogradely or immunohistochemically labeled cells. DR boundaries and other landmark structures with respect to a three dimensional biological coordinate system were maintained by a computer (C.A.R.P., Biographics, Inc. Winston-Salem, N.C.). Labeled cells were represented by color-coded spheres according to injection site or neurochemical identity. Thus, multiple experimental cases could be displayed simultaneously; thereby, revealing spatial relationships between functionally or chemically related subsets of DR neurons. We found that in comparison to conventional analytical procedures C.A.R.P. provided an accurate and efficient method of acquiring and manipulating a large database of neuroanatomical information. Overall, this analysis clarifies the spatial relationships between modality and neurochemical-specific clusters of cells within discrete sub-regions of the DR nucleus. (Supported by NIDA DA 05117 and NINDS 32461 to BDW)

## 540.13

## DETERMINANTS OF HUMAN PLATELET AND PLASMA SEROTONIN.

L.M. Hall\*, G.M. Anderson, and P.A. McBride, Child Study Center, Yale University School of Medicine, New Haven, CT 06510, Cornell University Medical College, N.Y., N.Y. 10121

A series of studies on the determinants of human platelet (PLT) and platelet-poor plasma (PPP) serotonin have been carried out. We have measured PLT serotonin (5HT) in patients with idiopathic thrombocytopenia (ITP), PLT and PPP 5HT in subjects receiving oral 5HT loads, and PPP 5HT in a large number of adult normal control subjects (N=21).

When measured PLT 5HT levels of ITP patients were expressed as ng/billion PLTs, an inverse relationship between level and PLT count was observed, suggesting that PLTs load 5HT throughout their circulating lifespan. No increases in PLT or PPP 5HT were observed after an oral load of 5HT (0.25 mg/kg) in normal subjects or in patients medicated with fluoxetine, suggesting that little luminal 5HT passes through the intestine into the blood stream. In addition, a meal does not appear to result in increased levels of 5HT in the general circulation, even in the presence of potent 5HT reuptake inhibitors. Finally, the mean PPP 5HT in normal subjects was  $160 \pm 80$  pg/ml, even lower than our previous estimation of 300-500 pg/ml and in agreement with the recent report of Beck et al. (BBRC, 196:260-266). The relevance of the findings to physiological models of PLT, PPP, and gut 5HT will be discussed, and the implications with respect to possible roles of 5HT in homeostasis, immune response, emesis and digestive processes will be considered.

## 540.10

## SEROTONIN MODULATES SYNAPTIC TRANSMISSION AT THE CENTRAL AMYGDALA NUCLEUS.

H. Zheng\* and M.C. Schiess, Neurology, UTMB, Galveston, TX 77555-0539

The purpose of this study was to determine the serotonin (5-HT) receptor subtypes mediating effects on postsynaptic transmission at the central amygdala nucleus (ACe) in a 500  $\mu$ M coronal *in vitro* slice preparation. Intracellular current clamp recordings from ACe neurons with stimulation (15V) of presumed amygdalo-fugal fibers within the slice typically evoked a waveform consisting of a CNQX (10  $\mu$ M) sensitive fast (f) EPSP, a bicuculline (30  $\mu$ M) sensitive f-IPSP, followed by an AP5 (50  $\mu$ M) sensitive slow (s) EPSP at -60 mV. 10  $\mu$ M 5-HT reversibly reduced the f-IPSP and s-EPSP in 26/31<sub>N</sub> neurons (84%); with no effect on synaptic transmission in 5/31<sub>N</sub> (16%). Ketanserin, 5-HT<sub>2/1C</sub> antagonist, and NAN-190, 5-HT<sub>1A</sub> antagonist, had no effect alone or in inhibiting serotonin effects on the f-IPSP and s-EPSP. The full 5-HT<sub>1A</sub> agonist, 8-OH-DPAT reduced the NMDA mediated s-EPSP 50% of the time or had no effect. 2-methyl 5-HT, 5-HT<sub>3</sub> agonist, at 10  $\mu$ M reproduced the effects of 5-HT on reducing the f-IPSP and s-EPSP. Additionally, MDL-72222, 5-HT<sub>3</sub> antagonist, blocked the effects of 5-HT on synaptic transmission. These results suggest that the identified 5-HT effects on reducing a GABA<sub>A</sub> mediated f-IPSP and an NMDA mediated s-EPSP can be partially but not solely explained by 5-HT<sub>3</sub> receptor activity. Supported by UTMB Small Grant to MCS.

## 540.12

ULTRASTRUCTURAL FEATURES OF BRAIN SEROTONIN PERIKARYA AND NERVE TERMINALS AFTER LONG TREATMENT REGIMENS WITH DEXFENFLURAMINE M. Kalia\* and N.P.O'Malley, Dept. of Neurosurgery, Jefferson Medical College of Thomas Jefferson University, Philadelphia PA 19107.

Light microscopy of immunostained serotonergic perikarya and nerve terminals reveals the presence of serotonin (5HT) but provides few morphological clues about cellular integrity. Previous studies from our laboratory have employed retrograde tracing and double immuno labeling and have demonstrated the presence of 5HT in animals treated with dexfenfluramine (DFF). In this study we examined 5HT neurons in animals treated with 16 mg/kg of DFF for 21 days. Post treatment survival periods ranged from 18 hr. to 21 days. A polyclonal serotonin antibody and standard immunocytochemical (ICC) methods were used for staining prior to embedding in plastic. Serotonergic profiles were first identified under the light microscope and serial ultra thin sections of the selected area were collected on formvar-coated grids, stained and examined on a JOEL 100CX electron microscope at an accelerating voltage of 80K. The labeling was densest in the superficial parts of the section and was visualized as an electron dense reaction product. Examination of serial sections permitted us to follow a serotonergic neuron once the labeled profile was identified. We examined the brains of 10 experimental and 10 control rats. The ultrastructure of serotonergic immunoreactive profiles was indistinguishable in the two groups. We found no ultrastructural evidence of disruption of neuronal morphology in animals treated with DFF. Since we examined transmitter identified neurons we can definitively conclude that dexfenfluramine produces no neuropathology in brain serotonergic neurons. Supported by IRIS.

## 540.14

## BURST-LIKE FIRING PATTERN IN A SUB-POPULATION OF PRESUMED 5-HT NEURONES IN THE RAT DORSAL AND MEDIAN RAPHE NUCLEI.

M. Hajós, N. Newberry\*, S.E. Gariside and T. Sharp, (SPON: European Neuroscience Association) Oxford University Department of Clinical Pharmacology, and Oxford University - SmithKline Beecham Centre for Applied Neuropsychobiology, Radcliffe Infirmary, Oxford, OX2 6HE, U.K.

It is generally accepted that 5-HT neurones in the dorsal (DRN) and median raphe nuclei (MRN) are slow firing (0.1- to 3 Hz) with a regular pattern. Here, we report the results of an *in vivo* electrophysiological study suggesting that a sub-population of raphe 5-HT neurones have additional neurophysiological characteristics. Extracellular and intracellular recordings were made in male Sprague-Dawley rats anaesthetised with chloral hydrate, Saffan, or chloral hydrate and ketamine. Extracellular or intracellular potentials were recorded with glass or metal microelectrodes using conventional electrophysiological methods. Antidromic stimulations were performed from the medial forebrain bundle (MFB).

Presumed 5-HT neurones recorded extracellularly were sorted into two categories: (i) classical 5-HT neurones firing only single spikes in a regular pattern as described previously, and (ii) neurones in which, during the otherwise regular firing pattern, some of the expected single spikes were replaced by a doublet or triplet of spikes. Spikes in this burst-like firing mode (spikes in doublets or triplets) were very close together (2.4 to 11.5 ms), and occurred with a diminishing spike amplitude. The proportion of spikes in doublets to single spikes ranged from 5 to 95% of the total spikes displayed. Burst-firing raphe neurones were detected with both glass and metal electrodes, and regardless of the type of anaesthetic used. Burst-firing neurones were inhibited by 8-OH-DPAT and were stimulated antidromically from the MFB. The bursting pattern occurred in 82 of 295 neurones recorded from the DRN, while it was much less frequent in MRN. The presence of burst-firing raphe neurones with 5-HT neurone-like properties was confirmed by *in vivo* intracellular recordings. Our findings indicate the presence of a previously unrecognised sub-population of 5-HT neurones with a burst-like firing pattern.

## 540.15

5-HT FACILITATION OF TRIGEMINAL MOTONEURONAL EXCITABILITY VIA MULTIPLE EFFECTS ON INTRINSIC MEMBRANE CONDUCTANCES. C.-F. Hsiao\*, P.R. Trueblood and S.H. Chandler. Department of Physiological Science, UCLA, Los Angeles, CA 90095

To determine the ionic mechanism(s) responsible for 5-HT facilitation of trigeminal motoneuronal (TMN) discharge during reflex and cortically induced rhythmic jaw movements in the guinea pig we investigated the effects of 5-HT application on TMN intrinsic membrane conductances in brainstem slices from guinea pigs. Bath application of 5-HT (10-30  $\mu$ M) depolarized motoneurons in current clamp and produced an inward holding current in voltage clamp mode. These effects were associated with an increase in membrane resistance and persisted in TTX, and low  $\text{Ca}^{2+}/\text{Mn}^{2+}$ -containing solutions as well as in the presence of certain  $\text{K}^{+}$  channel blockers such as 4-AP and TEA. Extrapolated instantaneous current-voltage relationships obtained before and at the peak of the 5-HT response from holding potentials between -50 and -65 mV intersected at approximately -88 mV which was slightly negative to the predicted  $\text{E}_{\text{K}}$ , suggesting that the 5-HT was partially due to a reduction in a leakage  $\text{K}^{+}$  conductance.  $\text{Ba}^{2+}$  (500  $\mu$ M) reduced the steady inward 5-HT current and increase in input resistance. However, a residual 5-HT remained. To determine if the residual 5-HT was related to the presence of a hyperpolarization-activated current  $I_{\text{h}}$ , we studied the effects of 5-HT on the cesium-sensitive  $I_{\text{h}}$ . 5-HT enhanced the peak amplitude of this current. However, in solutions containing a mixture of  $\text{Ba}^{2+}$  and  $\text{Cs}^{+}$  a residual small 5-HT was still present which was not associated with a change in input resistance. The data suggest that the previously demonstrated facilitation of TMN discharge by 5-HT during oral-motor behaviors occurs through a combination of a reduction in a leakage  $\text{K}^{+}$  current, an increase in a  $\text{Cs}^{+}$ -sensitive  $I_{\text{h}}$  and an increase in an unidentified inward current. Supported by NIH RO1 DE 06193 and DE 04166

## 540.16

SEROTONIN REDUCES AFTERHYPERPOLARIZATION IN HIPPOCAMPUS BY INHIBITING CALCIUM-INDUCED CALCIUM RELEASE. G.E. Torres\* and R. Andrade. Dept. of Pharmacological and Physiological Science, St. Louis Univ. Sch. of Med., St. Louis, MO 63104.

We have previously shown that serotonin acting on 5-H<sub>4</sub> receptors increases excitability in hippocampus by inhibiting a slow calcium-activated afterhyperpolarization (AHP). Calcium-induced calcium release (CICR) has been proposed to modulate intracellular calcium transients in hippocampus. Therefore we have now examined the role of CICR in the generation of the AHP as well as its possible regulation by serotonin.

Intracellular recordings were obtained from the CA1 region of the rat hippocampus in *in vitro* brain slices. Caffeine, but not adenosine antagonists nor the phosphodiesterase inhibitor IBMX, enhanced the AHP triggered by 1-20 action potentials. In agreement with these results, administration of the calcium release channel blockers dantrolene and ruthenium red or of the intracellular calcium pump inhibitor thapsigargin reduced the amplitude of the AHP and blocked the effect of caffeine. These results indicate that CICR plays an important role in the generation of the AHP in this area.

Interestingly, the ability of serotonin to inhibit the AHP was dramatically reduced or abolished when CICR was prevented from contributing to the AHP by using either dantrolene, ruthenium red or thapsigargin. In contrast, the ability of serotonin to reduce the AHP was increased when the contribution of CICR to the AHP was enhanced by using caffeine. These results indicate that CICR plays an important role in the generation of the AHP in the CA1 region and constitutes the specific target that is regulated by 5-HT<sub>4</sub> receptors to reduce the AHP and increase membrane excitability. Supported by MH 43985.

## INTERACTIONS BETWEEN NEUROTRANSMITTERS III

## 541.1

DOPAMINERGIC AXON TERMINALS ARE ABSOLUTELY REQUIRED FOR THE TIGHT FUNCTIONAL COUPLING BETWEEN EAA AND DA RECEPTORS

GANDOLFI O.\*, RIMONDINI R. and DALL'OLIO R.  
Dep. Pharmacology, University of Bologna, Italy

In extensively washed synaptic membrane preparations from rat frontal cortex, the *in vitro* addition of either the D<sub>1</sub> (SKF 38393) or the D<sub>2</sub> (LY 171555) specific agonists markedly decreased the apparent affinity (K<sub>d</sub>) of [<sup>3</sup>H]-MK801 specific binding. In the same membrane preparation, the concentration of L-glutamate required to produce half maximal enhancement of [<sup>3</sup>H]-MK801 binding was approximately the same both in the presence or in the absence of dopaminergic drugs.

*I.c.v.* administrations of the neurotoxin 6-OHDA resulted in a dramatic reduction of DA frontal cortex levels, whilst repeated administrations (21 consecutive days) with either the D<sub>1</sub> (SCH 23390) or the D<sub>2</sub> (YM 09151-2) antagonists failed to change amine (and metabolite) contents. Repeated administrations with D<sub>1</sub> receptor blocker selectively increased the B<sub>max</sub> values of [<sup>3</sup>H]-SCH 23390 binding while [<sup>3</sup>H]-Spiroperidol binding was increased both by repeated administrations of YM 09151-2 and by *i.c.v.* injection of 6-OHDA. Although chronic D<sub>2</sub> blockade and 6-OHDA consistently increased D<sub>2</sub> receptor number, in extensively washed synaptic plasma membranes of rats repeatedly administered with YM 09151-2 but not with 6-OHDA [<sup>3</sup>H]-MK801 binding was increased. It is concluded that the effects of NMDA receptor activation could not be directly mediated by stimulation of DA release, but are highly dependent upon the presence of DA axon terminals.

## 541.2

FAST INHIBITION OF N-METHYL-D-ASPARTATE (NMDA) RECEPTOR FUNCTION: AN ATYPICAL EFFECT OF DOPAMINE. N.G. Castro\*, Y. Aracava, & E.X. Albuquerque. Lab. Farmacol. Mol. II, IBCCF, UFRJ, RJ 21941, Brazil and Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med, Baltimore, MD 21201, USA; J.L.M. do Nascimento, M.C.F. de Mello and E.G. de Mello. Lab. Neuroquímica, IBCCF, UFRJ, RJ 21941, Brazil.

A novel, possibly non-metabotropic action of dopamine (DA) in the modulation of excitatory amino acid (EAA) function was observed in neurons isolated from the chick retina and from the rat thalamus and grown in culture. Two assays were used: EAA-mediated <sup>3</sup>H-GABA release and whole-cell patch-clamp current recordings. DA (200  $\mu$ M) inhibited <sup>3</sup>H-GABA release induced by L-GLU and NMDA, but not by kainate. This effect of DA was mimicked by (+)SKF-38393, a specific DA<sub>1</sub> receptor agonist, but not by 8-Br-cAMP (5 mM) or by forskolin (20  $\mu$ M). Also, the inhibition could not be prevented by the antagonists (+)SCH-23390 (DA<sub>1</sub>), haloperidol or spiroperidol (DA<sub>2</sub>), each at 10  $\mu$ M. The direct effects of DA and (+)SKF-38393 on NMDA-induced currents were measured using a motorized flowpipe array, fast-perfusion method. DA (100-200  $\mu$ M) and (+)SKF-38393 (50  $\mu$ M) partially blocked the current induced by NMDA (50-100  $\mu$ M with glycine 10  $\mu$ M), but not that induced by kainate. The effect was stereospecific: (-)SKF-38393 did not modulate <sup>3</sup>H-GABA release and was much less potent in blocking the NMDA-induced current. In 8 thalamic neurons, (+)SKF-38393 reduced this current by 52  $\pm$  3%; this blockade was unaffected by (+)SCH-23390 (10  $\mu$ M). The blockade developed in less than 0.5 s and reversed at a similar rate upon removal of the dopaminergic agonist. These fast kinetics are consistent with a hypothesis that a putative DA site may be closely coupled to the NMDA receptor-channel. (Supported by CNPq, CAPES, CEPEG, FAPERJ, Finep-UMAB Mol. Pharm. Train. Prog.; USPHS Grants NS25296 and ES05730).

DOPAMINE-GLUTAMATE INTERACTIONS IN THE REGULATION OF PROTEIN PHOSPHORYLATION IN THE NUCLEUS ACCUMBENS. G.L. Snyder\*, K. Albert and P. Greengard. Laboratory of Molecular & Cellular Neuroscience, The Rockefeller University, New York, NY 10021

Medium spiny neurons of the nucleus accumbens are innervated by mesolimbic dopaminergic projections from the ventral tegmental area and by glutamatergic neurons projecting from cortex and hippocampus. There is considerable evidence to indicate that the actions of dopamine and glutamate on accumbens neurons underlie many of the acute and chronic effects of various drugs of abuse. We are examining possible interactions between dopaminergic and glutamatergic systems in the regulation of protein phosphorylation in the nucleus accumbens. Neurons of the nucleus accumbens abundantly express DARPP-32, a dopamine and cAMP-regulated phosphoprotein (Mr=32kD), which is converted into a potent inhibitor of protein phosphatase-1 when phosphorylated by cAMP-dependent protein kinase (PKA). Incubation of rat nucleus accumbens slices with dopamine (DA) (100  $\mu$ M) or a D<sub>1</sub> receptor agonist (SKF 38393, 1  $\mu$ M) increases DARPP-32 phosphorylation by several-fold. DA-induced phosphorylation of DARPP-32 is inhibited by incubation with AMPA (1-100  $\mu$ M), an agonist at AMPA-type glutamate receptors. This effect is reversed by pretreatment of slices with CNQX (50  $\mu$ M), a selective antagonist. In agreement with studies in neostriatum (Halpain et al., *Nature*, 343:369), NMDA also blocks DA-induced phosphorylation of DARPP-32 in accumbens slices; this effect is reversed by the NMDA receptor antagonist, MK-801. Similar regulation of the phosphorylation of protein phosphatase inhibitor-1, another inhibitor of protein phosphatase-1, has also been observed in the nucleus accumbens. Thus, both AMPA- and NMDA-type receptors apparently participate in glutamate-mediated inhibition of DARPP-32 phosphorylation in the nucleus accumbens, most likely by mediating calcium-dependent activation of a phosphatase (calcineurin) which dephosphorylates DARPP-32. (Supported by MH40899 to P.G. and a NARSAD Young Investigator Award to G.S.)

CO-EXPRESSION OF STRIATAL DOPAMINE RECEPTOR SUBTYPES AND EXCITATORY AMINO ACID SUBUNITS. M.A. Ariano\*, E.R. Larson and K.L. Noblett. Department of Neuroscience, The Chicago Medical School, North Chicago, IL 60064.

Nigrostriatal dopamine (DA) modulates the corticostriatal glutamatergic (EAA) afferent responses. This interaction may be mediated through activation of specific DA and EAA receptor subtype combinations located predominantly on the postsynaptic medium-spiny striatal projection neuron. We examined the cellular expression patterns for D<sub>1A</sub>, D<sub>2</sub>, or D<sub>3</sub> DA receptors versus ionotropic EAA subunits; NMDA-R<sub>1</sub> and non-NMDA (GluR<sub>1</sub>, GluR<sub>2</sub>) by detection of transcript abundance, expression of encoded proteins, and analysis of binding profiles using concurrent fluorescent localization paradigms. The results demonstrate: (1) mRNA transcripts do not always reflect protein or binding patterns of the receptor, especially for the GluR<sub>1</sub> subunit, (2) all three DA receptor mRNAs are found in medium-sized striatal neurons, positive for all three encoded EAA subunit proteins, (3) GluR<sub>2/3</sub> and NMDA-R<sub>1</sub> protein containing neurons also possess viable ligand recognition sites for the D<sub>2</sub> DA receptor subfamily, (4) D<sub>2</sub> and D<sub>3</sub> protein levels are detected in neurons which bind the NMDA receptor toxin, conantokin-G. The data suggest a morphological "promiscuity" for these receptors in that all combinations of DA subtypes and EAA subunits can be co-expressed in the medium-sized striatal neuron populations. This supports physiological data (*Proc. Nat. Acad. Sci. USA* 90:9576-9580, 1993) that showed that postsynaptic responses can be predicted on the basis of co-activation of selective pairs of DA and EAA receptors in medium-sized striatal neurons. This work was supported in part by USPHS NS 23079 and NS 32277 to MAA.

## 541.5

CELLULAR ELECTROPHYSIOLOGICAL AND NEUROCHEMICAL ASSESSMENT OF HIPPOCAMPAL 5-HT AND NMDA FUNCTION FOLLOWING REPEATED FENFLURAMINE ADMINISTRATION. A. Dugar\*, K. Dowhower, and J.M. Lakoski. Departments of Pharmacology and Anesthesia, The Pennsylvania State University College of Medicine, Hershey, PA 17033

Fenfluramine, clinically used as a potent anorectic agent for treatment of obesity, stimulates the release and inhibits the reuptake of serotonin (5-HT) resulting in decreased levels of this neurotransmitter. N-methyl-D-aspartate (NMDA) antagonists have been demonstrated to protect against depletions of 5-HT produced by structurally similar substituted amphetamines. Therefore, electrophysiological and neurochemical studies of interactions between 5-HT (including the 5-HT<sub>1A</sub> subtype) and NMDA receptors may provide insight into fenfluramine-mediated responses.

Adult male Sprague-Dawley rats were injected with *d,l*-fenfluramine (FEN; 12.5 mg/kg, i.p., 2x daily for 4 days) or with vehicle (saline). At 24 hr following the last injection, *in vivo* microiontophoresis in a chloral hydrate anesthetized preparation was performed in the CA1 and CA3 hippocampal subfields using 5-HT, 8-OH-DPAT (selective 5-HT<sub>1A</sub> agonist), NMDA and MK-801 (noncompetitive NMDA antagonist). A second group was dissected, with the frontal cortex and hippocampus used for receptor binding analyses and autoradiographic localization of 5-HT<sub>1A</sub> sites ([<sup>3</sup>H]8-OH-DPAT). Electrophysiological results showed that NMDA and 5-HT exerted excitatory and inhibitory effects in the hippocampus, respectively, independent of drug treatment. In FEN treatment versus vehicle treatment groups, cells showed a supersensitivity to application of 5-HT. Binding studies suggested decreased receptor density, without a concomitant change in affinity, of 5-HT<sub>1A</sub> sites in the frontal cortex. In conclusion, repeated FEN administration results in a physiological supersensitivity to 5-HT which may be mediated, in part, by a down-regulation of 5-HT<sub>1A</sub> receptors. Using physiological and neurochemical approaches, the effects of pretreatment with MK-801 on FEN-induced responses are being evaluated to provide further insight into 5-HT and NMDA interactions.

## 541.7

INTRACORTICAL INFUSION OF NMDA RECEPTOR ANTAGONISTS: NEUROCHEMICAL EFFECTS.

P.H. Hutson\*, F. Murray and L.J. Bristow

Merck, Sharp and Dohme Research Laboratories, Neuroscience Research Centre, Terlings Park, Harlow, Essex, CM20 2QR, U.K.

Systemic administration of non competitive but not glutamate or glycine site antagonists for the NMDA receptor activate mesocorticolimbic DA pathways. However, cortical DA metabolism was increased following the local infusion of the glutamate site antagonist CPP into the medial prefrontal cortex (mPFC) (Hata et al. 1990). In the present study, rats were implanted under isoflurane anaesthesia with a unilateral guide cannula into the mPFC (A +3.7mm; L 1.0mm; H -3.0mm). 48h later infusion of CPP (1.5ug/0.5ul in 1min) increased DA metabolism (as indicated by [DOPAC]/[HVA]/[DA]) ipsilaterally in mPFC (187% of control), n. accumbens (148% of control), amygdala (146% of control), VTA (150% of control) but not striatum (110% of control) 2h later. These effects were still present 4h after CPP infusion. In contrast, infusion of the glycine/NMDA site antagonist 5,7-dichlorokynurenic acid (1.5ug/0.5ul in 1 min) at the same coordinates did not significantly increase DA or 5-HT metabolism in these brain regions at any time up to 4h. Results provide further evidence that antagonists acting at distinct sites on the NMDA receptor complex may differentially modulate mesocorticolimbic DA function. Hata, N. et al. (1990) *Neurosci. Lett.* 120, 101-104.

## 541.9

HISTAMINE SLOWS DESENSITIZATION OF NMDA RECEPTOR-MEDIATED ION CURRENT IN RAT CORTICAL NEURONS.

B. Zwart\*, T. Blank and J. Spiess. Max Planck Institute for Exp. Med., Dept. Molec. Neuroendocrinol., Hermann-Rein-Str. 3, D-37075 Goettingen, F.R.G.

Histamine may play a physiological role in modulating NMDA receptor (NMDAR) function in rat hippocampus, most likely by acting directly at an extracellular site on the NMDAR (Science 261, 104-106, 1993; Neuron 11, 1-8, 1993). The mechanism of action of histamine potentiation is not known. Glycine and spermine potentiate NMDAR-mediated ion currents by regulating agonist-induced desensitization kinetics of the receptor.

We investigated the effects of histamine on NMDAR-mediated ion currents in whole-cell voltage clamped rat cortical neurons in primary culture. In a subpopulation of the cells tested (19/33), histamine (10-100 µM) enhanced the amplitude and slowed the desensitization of the NMDA-induced responses in a concentration-dependent manner. Steady-state currents were relatively more potentiated than the initial peak currents, indicating that histamine reduces the degree of agonist-induced desensitization. The effects of histamine on steady state desensitization and rate of recovery from desensitization are currently being investigated. In another subpopulation of cortical neurons (13/33), histamine did not have any effect. In one cell, a large potentiation of the NMDA-induced inward current was observed, whereas the kinetics of desensitization remained unaffected.

The results indicate that histamine may play a physiological role in modulating NMDAR-mediated responses in a subpopulation of cortical neurons. The histamine-induced potentiation is most likely due to altered receptor desensitization properties. *Xenopus* oocyte expression studies revealed that histamine potentiation of NMDAR-mediated ion currents strongly depends on the subunits constituting the receptor (Mol. Pharmacol. 46, 531-541, 1994). The variability in effects observed may be explained by the existence of multiple isoforms of NMDARs in cortical neurons.

## 541.6

ANTAGONISTS AT THE GLYCINE MODULATORY SITE OF THE NMDA RECEPTOR REVERSE NEUROKININ<sub>1</sub> RECEPTOR AGONIST FACILITATION OF NMDA RECEPTOR EVOKED ACTIVITY IN THE RAT DORSAL HORN. P.A. Heppenstall, S.M. Fleetwood-Walker\* and T. Dickinson. Department of Preclinical Veterinary Sciences, University of Edinburgh, Edinburgh, U.K.

Evidence that substance P (SP) and glutamate coexist in fine primary afferent terminals, and that NK<sub>1</sub> and NMDA receptors interact synergistically [Randic, M. *et al.*, *J. Physiol.* 63:265-286 (1992)] suggests a potential role for these receptors in the central hyperexcitability that is brought about by sustained activity in nociceptive afferents. Indications that SP may have more than a simple direct action in acute nociception are supported by evidence that glycine is released from local inhibitory interneurons by SP [Maehara, T. *et al.*, *Regul. Peptides Suppl.* 1, S102 (1992)]. Following sustained activity, glycine might now co-activate the glycine recognition site of the NMDA receptor (Gly<sub>NMDA</sub>) and contribute to the NK<sub>1</sub> and NMDA interaction. We have investigated this hypothesis using extracellular recordings from laminae III-V dorsal horn neurons of anaesthetised rats.

Ionophoresis of the selective NMDA agonist 1-aminocyclobutane-cis-1,3-dicarboxylic acid (ACBD) produced a 945±343% increase in the firing rate. The highly selective NK<sub>1</sub> receptor agonist acetyl-[Arg<sup>6</sup>, Sar<sup>9</sup>, Met(O<sub>2</sub>)<sup>11</sup>]-SP<sub>6-11</sub> facilitated this response by 223±37%, but had no effect when applied without ACBD at the same current. In the presence of the Gly<sub>NMDA</sub> antagonists 7-chlorothiokynurenic acid or L701,252 this increment was reduced by 89±30% and 98±29% while the antagonists had no effect on ACBD evoked activity alone.

This suggests that the co-operation between NMDA and NK<sub>1</sub> receptors is mediated, in part, by the glycine site of the NMDA receptor, perhaps by means of glycine, released from an interneuron in response to substance P.

## 541.8

MODULATION OF NMDA RECEPTORS EXPRESSED IN *XENOPUS* OOCYTES BY SEROTONIN

T. Blank\*, R. Zwart and J. Spiess. Dept. Molec. Neuroendocrinology, MPI for Exp. Med., Hermann-Rein-Str. 3, 37075 Goettingen, FRG

Using *Xenopus* oocytes injected with rat brain total RNA we investigated the effect of 5-HT (5-hydroxytryptamine) on NMDA (N-methyl-D-aspartate) receptor-mediated responses. Two electrode voltage clamp recordings showed that application of 5-HT (200 nM) for 1 min caused a transient potentiation of the NMDA response. After reaching a maximum (175 ± 6.5 %, mean ± SEM, n = 7) in approximately 4 min, the current amplitude had returned to the initial control value within 28 min. Similar enhancement was obtained by application of the PKC activator phorbol 12-myristate 13-acetate (PMA, 10 nM) also for 1 min. No effect was produced by the PKA activator forskolin (20 µM). 5-HT and PMA mediated potentiation of the NMDA responses was strongly reduced by 6 min pretreatment with the PKC inhibitor sphingosine (10 µM). The 5-HT<sub>2</sub> receptor agonist, alpha-methylserotonin (200 nM), mimicked the effects of 5-HT. If 5-HT (200 nM) was coapplied with ketanserin (100 µM), a selective 5-HT<sub>2A/5-HT<sub>2C</sub></sub> receptor blocker, the potentiation of NMDA receptor-induced responses was almost completely abolished. These results demonstrate the involvement of 5-HT<sub>2</sub> receptors in serotonergic modulation of NMDA induced responses most likely via phosphoinositide (PI) hydrolysis and subsequent stimulation of PKC by its physiological activator diacylglycerol (DAG).

NMDA RECEPTOR INDUCED CURRENTS AND VOLTAGES AT NEOCORTICAL NEURONS: FACILITATION BY RECEPTORS COUPLED TO PHOSPHOLIPASE C. F.J. Kong and R.S. Neuman\*. Faculty of Medicine, Memorial University, St. John's, Newfoundland, Canada A1B 3V6.

Using sharp electrodes or whole cell recording, we have examined the actions of carbachol, 1S,3R-ACPD, 5-HT and phenylephrine on neurons, likely pyramidal cells, in slices of cortex prepared from 11-14 day old rats. Perfusion of these agonists: 1) depolarized the membrane or produced an inward current; 2) increased the amplitude and/or duration of the aspartate induced inward current/depolarization. Facilitation of the aspartate response typically appeared earlier than effects on resting membrane potential and current. The concentration-response (C-R) relationship for aspartate was examined with and without 1S,3R-ACPD as this agonist does not exhibit desensitization. 1S,3R ACPD shifted the aspartate C-R curve to the left and increased the maximum response. Facilitation of the aspartate response was observed less frequently in whole cell compared to sharp electrode recordings. However, the addition of 0.1-0.3 mM GTP to the whole cell electrode greatly increased the incidence of facilitation.

Addition of inositol triphosphate (IP<sub>3</sub>) to the whole cell electrode after recording the control aspartate responses revealed an enhancement of the aspartate induced inward current. Moreover, the carbachol induced facilitation observed with sharp electrodes was gradually eliminated following intracellular iontophoresis of heparin, an IP<sub>3</sub> receptor antagonist. In whole cell recordings perfusing the recording electrode with heparin also eliminated the carbachol facilitation.

These observations suggest that facilitation of NMDA receptor mediated response in cortical neurons results from an IP<sub>3</sub> receptor mediated release of intracellular Ca<sup>2+</sup>.

GABA REDUCES THE INITIAL PHASE OF NMDA-INDUCED ELEVATIONS IN INTRANEURONAL CALCIUM. M.L. Koenig\*, J.P. Sanders, and J.L. Meyerhoff. Div. Neuroscience, Walter Reed Army Inst. Research, Washington, DC 20307-5100.

We have investigated the hypothesis that one of the mechanisms by which GABA exerts antiepileptic effects is by reducing the excitatory effects of glutamate mediated by the NMDA receptor. Neurons derived from the forebrains of fetal (E15) rats were loaded with the fluorescent  $\text{Ca}^{2+}$  indicator indo-1-AM, and changes in intraneuronal calcium ( $[\text{Ca}]_i$ ) were monitored using the ACAS 570C confocal laser cytometer (Meridian Instr., Okemos, MI). As has been previously reported by Segal (Hippocampus 3: 229, 1993) and, more recently, by Reichling et al. (J. Physiol. 476: 411, 1994), we find that GABA itself elicits an immediate but small and transient increase in  $[\text{Ca}]_i$  in cultured fetal neurons. The increase in  $[\text{Ca}]_i$  is dose-dependent and is abolished in the absence of extracellular  $\text{Ca}^{2+}$  suggesting that GABA is promoting an influx of  $\text{Ca}^{2+}$  in these neurons. When GABA (10  $\mu\text{M}$ ) is applied two min. prior to NMDA (5  $\mu\text{M}$ ), the initial rise in  $[\text{Ca}]_i$  generated by the glutamate agonist is reduced by 50% from  $518 \pm 35 \text{ nM}$  ( $n = 31$ ) to  $223 \pm 44 \text{ nM}$  ( $n = 26$ ) ( $p < 0.001$ ). Since GABA does not appear to affect post-peak  $[\text{Ca}]_i$  levels, we are investigating the potential effectiveness, in this model, of longer acting GABAergic drugs as well as drugs which reduce the rate of catabolism of the inhibitory amino acid.

## 541.13

DOPAMINE-NMDA INTERACTIONS IN THE MODULATION OF LOCOMOTOR ACTIVITY AND ONE-TRIAL INHIBITORY AVOIDANCE RESPONSES. A. Mele\*, C. Castellano, A. Felici, S. Cabib, S. Caccia, and A. Oliverio. Dipartimento di Gen. e Biol. Mol., Università di Roma I; Istituto di Psicobiologia e Psicofarmacologia del C.N.R. and Istituto di Ricerche Farmacologiche "Mario Negri", Milano, Italy.

This study was aimed to further elucidate possible interactions between the two systems in modulating locomotor activity and memory consolidation. Systemic administrations of both DA agonists and NMDA antagonists enhance locomotor activity of NMRI mice in a dose dependent fashion. On the contrary DA agonists and NMDA antagonists have an opposite effect in the response to the one-trial inhibitory avoidance paradigm. Both D1 and D2 agonists, in fact, enhance memory consolidation, while NMDA antagonists inhibit it. We have also shown that both D1 (SKF38393) and D2 (Quinpirole) agonists, at ineffective doses, 5.0 and 0.25 mg/kg respectively, attenuate the impairing effects of NMDA antagonists in the one-trial inhibitory avoidance. Only high, sedative, doses of the D2 antagonist (sulpiride 30mg/kg), instead, are able to antagonize MK-801 induced hyperlocomotion. To further elucidate the mechanisms of interaction between the two systems we repeatedly treated the animals with DA antagonists in order to verify whether treatments that induce an increased response to DA agonists were able to elicit changes in the response to NMDA antagonists in the two behavioral assays. Repeated administrations of the D1 antagonist SCH23390 (0.5 mg/kg) were able to induce changes in the response to CPP and MK-801 in the one trial inhibitory avoidance, but not in the locomotor activity test. Repeated administrations of D2 antagonists haloperidol (4 mg/kg) or sulpiride (125 mg/kg), instead, were able to induce an enhanced response to MK-801 in both behavioral tests.

## 541.15

DOPAMINE  $\text{D}_2$  RECEPTOR ACTIVATION AND INHIBITION AFFECTS GABA AND GABA $_A$  RECEPTOR  $\beta_2/\beta_3$  SUBUNIT IMMUNOREACTIVITIES IN THE RAT PITUITARY INTERMEDIATE LOBE. S.A. Sands\*, A.L. De Blas, and B.M. Chronwall. School of Biological Sciences, University of Missouri-Kansas City, Kansas City, Missouri, 64108.

Melanotropes possess dopamine  $\text{D}_2$ , GABA $_A$  and GABA $_B$  receptors and are innervated by axons containing dopamine and GABA. Stimulation of  $\text{D}_2$  receptors decreases melanocyte proliferation, POMC mRNA levels, and calcium channel activity and protein expression. This study was conducted to test the hypothesis that dopamine receptor stimulation also regulates GABA $_A$  receptor protein in vivo. Chronic treatments with haloperidol, a dopamine  $\text{D}_2$  receptor antagonist, or bromocriptine, a receptor agonist, and immunohistochemistry for the  $\beta_2/\beta_3$  subunits of the GABA $_A$  receptor showed that receptor subunit immunoreactivity increased in overall average optical density after haloperidol treatment, whereas it decreased after bromocriptine treatment. Thus, the  $\beta_2/\beta_3$  subunit of the GABA $_A$  receptor seems to be similarly regulated to POMC and calcium channels, suggesting an interaction between the signalling pathways within the melanocyte. In a corollary experiment the presynaptic compartment was assayed by immunohistochemistry using antisera for GABA and glutamate decarboxylase (GAD). Following haloperidol treatment the number of GABA and GAD containing axons decreased. After bromocriptine treatment, GAD and GABA immunoreactive axons did not change. The mechanism of this response is, however, different from that of the postsynaptic response; it could be at the level of hypothalamic neuronal perikarya or axons and terminals.

## 541.12

N-METHYL-D-ASPARTATE-INDUCED INCREASED LEVELS OF ENDOGENOUS ADENOSINE ARE ENHANCED BY INHIBITION OF ADENOSINE DEAMINASE AND ADENOSINE TRANSPORT IN RAT STRIATUM. S. M. Delaney\* and J. D. Geiger. Dept. of Pharmacol., U. of Manitoba, Winnipeg, R3E 0W3, Canada.

Excitatory amino acid stimulation within the CNS can evoke increases in levels of endogenous adenosine which, in turn, may lead to neuroprotection. We tested whether inhibition of both adenosine metabolism and transport could potentiate such increases in adenosine. Unilateral microinjections of N-methyl-D-aspartate (NMDA) into striatum of rats subsequently killed by high-energy focused microwave irradiation (10 kW, 1.25 s) significantly increased *in vivo* levels of endogenous adenosine (data expressed as % of uninjected contralateral striatum). At a dose of 25 nmoles NMDA, levels of adenosine were  $263 \pm 16\%$ . Adenosine levels in control rats injected with vehicle (50 mM TRIS-HCl pH 7.4) were  $126 \pm 28\%$ . Inhibitors of adenosine deaminase (deoxycytidine, DCF) and nucleoside transport (diazepam, DLZP) at doses that did not affect levels of endogenous adenosine, potentiated NMDA-induced increases in adenosine levels to  $426 \pm 60\%$ . In the presence of DCF and DLZP, NMDA dose-dependently increased levels of adenosine from  $166 \pm 34\%$  at 10 nmoles to  $622 \pm 119\%$  at 100 nmoles. MK801 at a dose (4 mg/kg i.p.) that did not significantly affect levels of adenosine ( $140 \pm 18\%$ ) completely blocked NMDA-induced increases in levels of endogenous adenosine ( $110 \pm 12\%$ ). Inhibitors of adenosine metabolism and transport may provide therapeutic benefit by potentiating excitatory amino acid-induced increases in levels of endogenous adenosine. (Supported by a grant from the Medical Research Council of Canada.)

## 541.14

EFFECTS OF GABA AND DOPAMINE ON MEMBRANE PROPERTIES OF THE FIRST BASAL MOTONEURONE OF THE LOCUST. L. S. Prothero, J. C. McLelland, J. A. David and R. M. Pitman\*. University of St. Andrews, St. Andrews, Scotland, U. K. KY16 8LB.

GABA is an important inhibitory neurotransmitter in the insect nervous system, while dopamine is widely distributed in the insect CNS and can influence membrane properties of insect neurones. There is some evidence indicating that dopamine (DA) may modulate the magnitude of GABA responses. To investigate this possibility, interactions between responses mediated by these two neurotransmitter candidates have been studied on the first basilar motoneurone of the locust (*Schistocerca gregaria*) using two types of preparation. In the first, recordings were made from the motoneurone within its ganglionic environment, while in the second, recordings were made from isolated basilar motoneurone somata. GABA was focally pressure-applied to the neurone from a micropipette, while DA was added to the experimental chamber. GABA evoked a dose-dependent hyperpolarization which was accompanied with a marked increase in membrane conductance. Application of dopamine alone ( $\geq 10^{-4}\text{M}$ ) resulted in membrane depolarization which could be associated with a relatively small increase in membrane conductance. GABA responses were potentiated in the presence of DA ( $10^{-5}\text{M}$ ). The magnitude of this effect was too large to be attributed to any shift in membrane potential away from the GABA reversal potential, suggesting that dopamine has a selective modulatory effect upon responses mediated by GABA. Supported by the BBSRC, U.K..

DOPAMINE EXERTS BOTH SYNAPTIC AND NONSYNAPTIC INFLUENCES ON GABAERGIC NEURONS IN NEOSTRIATUM. L.G. Harsing, Jr.\* and M.J. Zigmond. Department of Neuroscience, University of Pittsburgh, Pittsburgh PA 15260.

Dopaminergic neurons are known to make synaptic contacts onto GABAergic neurons of the neostriatum. However, there is reason to believe that DA also exerts nonsynaptic influences on many striatal targets, and we wished to know whether this might also be true for GABAergic targets. We prepared striatal slices (350  $\mu\text{m}$ ) from rats, preloaded them with [ $^3\text{H}$ ]GABA (29 pM), superfused with standard Krebs bicarbonate buffer containing aminooxyacetic acid (0.1 mM) and nipecotic acid (0.1 mM), and measured tritium overflow during electrical stimulation (8 Hz, bipolar) an index of GABA release. The  $\text{D}_2$  receptor antagonist (-)sulpiride (0.1-10  $\mu\text{M}$ ) increased GABA release 2-fold. This effect was completely abolished by the DA synthesis inhibitor 3-iodotyrosine (2 mM), even though no decline in the tissue level of DA could be detected. This indicates an inhibitory influence of endogenous DA released from a pool with a rapid turnover. GABA release evoked by high  $\text{K}^+$  was also stimulated by sulpiride in the presence of TTX, suggesting that DA can exert an inhibitory influence on GABA via an action on GABAergic terminals. Since axoaxonic synapses are not thought to exist in this region, we assume that these effects are nonsynaptic. The  $\text{D}_1$  receptor antagonist (+)SCH-23390 (0.1-10  $\mu\text{M}$ ) failed to alter electrically-evoked GABA release when given alone, but reduced GABA efflux in the presence of sulpiride. Collectively, our findings suggest a model whereby DA exerts an excitatory influence on GABA release via  $\text{D}_1$  receptors (synaptic?), which is modulated nonsynaptically by inhibitory  $\text{D}_2$  receptors on the same neurons. (Supported in part by USPHS grant NS19608 and Fogarty International Center fellowship NS05270.)

**DOPAMINERGIC REGULATION OF EXTRACELLULAR GABA LEVELS IN THE PREFRONTAL CORTEX OF THE RAT.** A.C. Grobin\* and A.Y. Deutch. Depts. of Psychiatry and Pharmacology, Yale Univ. Sch. Medicine, New Haven, CT 06510.

Dopamine (DA) axons synapse with GABA interneurons in the prefrontal cortex (PFC) providing an anatomical basis for dopaminergic regulation of GABA function. *In vitro* studies have reported that DA agonists stimulate GABA release. We have previously shown that administration of apomorphine (APO), a mixed D<sub>1</sub>/D<sub>2</sub> agonist, augments extracellular GABA levels *in vivo*. This effect is observed when APO is given systemically or applied locally through the microdialysis probe. To further characterize this effect *in vivo*, specific D<sub>1</sub>-like and D<sub>2</sub>-like agonists were administered to male Sprague-Dawley rats and GABA levels determined in the PFC using *in vivo* microdialysis. Additionally, the D<sub>2</sub> antagonist sulpiride was infused locally prior to systemic administration of APO to explore the nature of the APO-induced increase in GABA levels. Local administration of the D<sub>1</sub> agonist SKF 38393 (0.02-2 mM) did not change extracellular GABA levels. Local administration of the D<sub>2</sub> agonist quinpirole (0.01-100  $\mu$ M) resulted in a dose-dependent increase in extracellular GABA. Local application of 20  $\mu$ M sulpiride blocked the increase in GABA levels elicited by systemic APO (0.5 mg/kg). These data suggest that DA increases GABA release in the PFC predominantly through a D<sub>2</sub>-like receptor. This report provides the first *in vivo* characterization of DA regulation of GABA release in the PFC. These studies were supported by MH-45124 and GM-07324.

**INTRASTRIATAL *c-fos* ANTISENSE OLIGONUCLEOTIDE DECREASES GABA RELEASE IN THE SUBSTANTIA NIGRA BUT NOT IN THE GLOBUS PALLIDUS. AN *IN VIVO* MICRODIALYSIS STUDY IN THE AWAKE RAT.** R. RIMONDINI<sup>1</sup>, W. SOMMER<sup>1,2</sup>, W. T. O'CONNOR<sup>2</sup>, A. HANSSON<sup>1,3</sup>, K. FUXE<sup>1</sup>, U. UNGERSTEDT<sup>2</sup>. Department of Neuroscience<sup>1</sup> and Pharmacology<sup>2</sup>, Karolinska Institutet S171-77, Sweden and The Max-Delbrück Centre for Molecular Medicine<sup>3</sup>, Berlin-Buch, Germany.

We employed the antisense phosphorothioate oligonucleotide 5'-GAACATCATGTCGT-3' to selectively "knock down" *c-fos* expression in rat striatum. *C-fos* is one of the first transcribed immediate early genes after striatal dopamine D<sub>1</sub> receptor activation. The induction of *c-fos* is believed to indicate activation of signal transduction cascades with subsequent alterations in neuronal transmission. In the present study we combined the antisense approach with *in vivo* microdialysis to investigate the effects of intrastriatal infusion of the *c-fos* antisense oligonucleotide on GABA release in the substantia nigra and the globus pallidus which represent the terminal sites of the dopamine regulated direct and indirect striatal efferent GABA pathways. Rats were implanted with an injection canula in the right striatum and one microdialysis probe (0.5mm, O.D.; 1mm membrane length) was implanted into the ipsilateral substantia nigra and another (2mm) into the ipsilateral globus pallidus. Basal dialysate GABA levels were 7.49  $\pm$  0.37nM and 9.50  $\pm$  0.7nM in the substantia nigra and globus pallidus respectively. Intrastriatal infusion of the *c-fos* antisense (1mM in 2 $\mu$ L) did not influence dialysate GABA levels in the globus pallidus but profoundly decreased (-42  $\pm$  13%) GABA levels in the ipsilateral substantia nigra within 60min compared to the sham and sense control. This finding demonstrates the importance of *c-fos* expression in the mechanism of dopamine D<sub>1</sub> receptor signal transduction in the regulation of striatonigral GABA transmission and strengthens the evidence for a differential dopamine D<sub>1</sub> and D<sub>2</sub> receptor mediated regulation of the direct and indirect striatal efferent GABA pathways.

## 541.21

**PERFUSION WITH N-METHYL-D-ASPARTATE IN RAT VENTRAL TEGMENTAL AREA BIPHASICALLY REGULATES LOCAL GABA RELEASE AND MESOSTRIATAL DOPAMINE RELEASE *IN VIVO*. A DUAL MICRODIALYSIS PROBE STUDY.** W.T. O'Connor\*, T. Wang\*, E. French\* and U. Ungerstedt. Department of Physiology and Pharmacology, Division of Pharmacology, Karolinska Institute, Stockholm S171-77, Sweden and \*Department of Pharmacology University of Arizona, College of Medicine, Tucson AZ 85724, Arizona, USA.

The effect of local perfusion with the glutamate receptor agonist N-Methyl-D-Aspartate (NMDA) in the Ventral Tegmental Area (VTA) on GABA release locally in VTA and dopamine release in the nucleus accumbens was investigated using the dual microdialysis probe approach in the halothane anaesthetized rat. One microdialysis probe was implanted in the VTA and a second probe in the ipsilateral nucleus accumbens. Local perfusion with NMDA into the VTA elicited a dose related biphasic response and a strong correlation between the ability of NMDA to increase local GABA release in the VTA and dopamine release in the nucleus accumbens was observed. Local perfusion with the 30 and 100 $\mu$ M doses of NMDA in the VTA was associated with an increase in both GABA release in the VTA and dopamine release in the nucleus accumbens. While the highest 300 $\mu$ M dose of NMDA was associated with a profound reduction in both GABA release in the VTA and dopamine release in the nucleus accumbens. In addition, the NMDA (100 $\mu$ M) induced increase in dopamine release in the nucleus accumbens was abolished following local perfusion with the noncompetitive NMDA receptor antagonist PCP (100 $\mu$ M) into the VTA. Taken together, the data suggest that NMDA receptors are located on both the A<sub>10</sub> dopamine cell body and the GABA interneuron in the VTA and that both neurons display a similar sensitivity to NMDA receptor stimulation i.e. excitation at lower doses and a depolarization blockade at higher doses of NMDA. These data strengthen the evidence for a dynamic regulation of mesolimbic GABA and dopamine transmission by cortical glutamate.

**D1- AND AMPA-MEDIATED STRIATAL AND NIGRAL GABA EFFLUX IN AWAKE RATS.** E.M. Byrnes\* and J.P. Bruno. Dept. of Psychology and Neuroscience Program, Ohio State University, Columbus, OH 43210

The mediation of striatonigral GABA efflux by D1 and AMPA receptor ligands was determined in awake rats using *in vivo* microdialysis with repeated insertions/perfusions. Intrastriatal perfusion with AMPA (100  $\mu$ M) increased striatal GABA efflux (50-175%). Intrastriatal perfusion with the full D1 agonist SKF 81297 led to bidirectional effects depending upon dose; a low dose (10  $\mu$ M) decreased striatal GABA efflux (40-60%) whereas a higher dose (100  $\mu$ M) increased GABA efflux (75-150%). Each of these effects of SKF 81297 was blocked by local perfusion with the D1 antagonist SCH 23390 (10  $\mu$ M). The bidirectional effects of the D1 agonist on striatal GABA efflux were not secondary to dose-related differences in motoric behavior. Concurrent intrastriatal perfusion of the low dose of SKF 81297 attenuated the AMPA-mediated GABA efflux whereas there was no obvious interaction between AMPA and the higher dose of SKF 81297. Intrastriatal perfusion with AMPA and/or SKF 81297 had no systematic effect on GABA efflux in substantia nigra. These results highlight the complex dose/drug modulation of striatal GABA efflux in awake animals and suggest a potential dissociation, under certain conditions, between striatal and nigra GABA efflux. The effects of ligands perfused directly into the nigra will also be presented.

## 541.20

**MUSCARINIC REDUCTION OF GABAERGIC SYNAPTIC POTENTIALS RESULTS IN DISINHIBITION OF THE EARLY-EPSP IN NEOCORTEX.** V.B. Aramakis\*, A.E. Bandrowski, E.E. Guthrie and I.H. Ashe. Depts. of Neuroscience and Psychology, Univ. of California, Riverside, CA 92521.

The ability of muscarinic actions of acetylcholine (ACh) to modulate amino acid-mediated synaptic potentials was examined in the *in vitro* rat auditory cortex, using whole-cell recording techniques. Synaptic potentials [i.e., the early-EPSP (AMPA/kainate), early-IPSP (GABA<sub>A</sub>), and late-IPSP (GABA<sub>B</sub>)] were elicited in layer III pyramidal neurons following stimulation of deep gray matter. Methacholine (MCh), a muscarinic agonist, applied by either bath (10-50  $\mu$ M) or iontophoresis (40-80 nA) produces either an increase or decrease of the amplitude of the early-EPSP. MCh-induced increase in amplitude occurs only when overt GABAergic IPSPs are also elicited (n=18/20). The magnitude of the excitatory synaptic potentials is governed by the degree of temporal overlap of IPSPs (Metherate & Ashe, *J. Physiol.*, 481, 331-348, 1994). Thus, we hypothesized that the increase in early-EPSP amplitude observed in the presence of MCh is due to disinhibition and is not a result of direct facilitation of the early-EPSP itself. This view was supported by the findings that: 1) MCh produces a decrease in the amplitude of pharmacologically isolated GABAergic IPSPs (i.e., elicited in the presence of excitatory amino acid antagonists, n=5/5) and 2) when the early-EPSP is elicited with low intensity stimulation, resulting in no apparent or a weak IPSP, its amplitude is decreased rather than increased by MCh (n=17/18). These findings suggest that fast thalamocortical transmission, via the early-EPSP, is regulated by GABA-mediated mechanisms that are susceptible to modulation by muscarinic actions of ACh. Supported by NSF (IBN 9310582).

## 542.1

**ANATOMICAL ORGANIZATION OF THE PREGANGLIONIC SYMPATHETIC NEURONS OF THE RAT SPINAL CORD.** W.J. Anderson\* and Gail Bennett. Indiana University School of Medicine, Terre Haute, IN, 47809.

In the spinal cord, it has been shown that the neurons are grouped into columns which run in a longitudinal direction. Motoneuronal cell columns are somatotopic in nature, and previous studies have demonstrated the existence between these columns. In addition to this, the main dendritic organization of Motoneuronal cell columns runs longitudinally where the formation of dendritic bundles take place. This study was performed to evaluate the anatomic and organizational similarities between motoneuronal and sympathetic neurons. Immunocytochemical techniques using antibodies to choline acetyltransferase (ChAT), 5-hydroxytryptamine (5-HT), tyrosine hydroxylase (TH), thyrotrophic Releasing Factor (TRH), neuropeptide Y, and gamma aminobutyric acid (GABA) were studied utilizing single and double immunocytochemistry. Ultrastructural studies using TME of the entire sympathetic spinal cord were studied in the horizontal and sagittal plane. The results of this study indicate a fifth column of preganglionic sympathetic groups previously described with dendritic interactions among all columns. In addition, small cholinergic interneurons interacted among all columns. Specificity of supraspinal and spinal axons innervated the intermediolateral cell column and dendrite branches between the various columns. Ultrastructurally, dendro-dendritic, dendrosomatic, and somato-somatic gap type junctions were frequent. These results support two potential functions: 1. electrotonic interactions between neuronal membranes for more efficient sympathetic coordination; 2. a dendritic substrate for spinal and supraspinal control.

## 542.3

**THE EFFECTS OF RESERPINIZATION ON MK801-INDUCED LOCOMOTION ARE TIME- AND DOSE-DEPENDANT.** R.E. Steinpreis\* and J.J. Panos. Department of Psychology, University of Wisconsin-Milwaukee, Milwaukee, WI 53211.

Depletion of catecholamines with reserpine has been reported to both increase and decrease MK801-induced locomotor activity in rats. In the present study, the effects of different doses of MK801 on locomotor activity was examined at three time periods after reserpine, using a between groups design. For each dose of MK801, groups of rats received either vehicle, MK801 without reserpine, or reserpine with MK801 administered either 6, 24 or 48 hours later. Locomotor activity was gathered by computer for 150 minutes once MK801 (or vehicle) had been administered. The effects of reserpine were dependent on the dose of MK801, such that reserpine attenuated the locomotor effects of the low dose of MK801 and enhanced MK801-induced locomotor effects at the high dose of MK801. Furthermore, the 6 hour delay after reserpine produced the largest increases in activity and the longer delays produced smaller increases, regardless of the dose of MK801. In conclusion, the directionality of reserpine's effect on MK801-induced locomotion are dependent on the dose of MK801 and the magnitude of reserpine's effects are dependent on the time lag between reserpine and subsequent administration of MK801.

## 542.5

**EFFECTS OF MORPHINE AND/OR COCAINE CO-IONTOPHORED WITH GLUTAMATE ON VENTRAL PALLIDAL NEURONAL ACTIVITY.** J. X. Liao\*, P.J. Johnson and T.C. Napier. Dept. Pharmacol., Loyola Univ. Chicago, Sch. Med., Maywood, IL 60153.

Microiontophoresis was used to investigate the possible influence of morphine and/or cocaine on glutamate-evoked responses of ventral pallidal (VP) neurons recorded extracellularly from chloral hydrate-anesthetized rats. Morphine and cocaine modulation was determined by comparing their ability to alter glutamate-induced activity ("signal") against spontaneous firing ("noise"). An ejection current-response curve (2 to 128 nA) was generated for morphine and cocaine to determine the current level which produced 50% of the maximum drug-induced response (EC<sub>50</sub>) and subthreshold current (STh), i.e. one that did not alter baseline firing rates. Of the neurons tested for drug sensitivity, 80% (12/15) were sensitive to morphine, 81% (13/16) were sensitive to cocaine, and 69% (9/13) were sensitive to both morphine and cocaine. When each drug was co-iontophoresed with glutamate, both increases and decreases in the signal-to-noise ratio were seen. These changes were independent of any drug-induced changes in spontaneous firing rate. EC<sub>50</sub> morphine altered the signal-to-noise ratio in 80% (4/5) of the neurons tested whereas EC<sub>50</sub> cocaine co-iontophoresis altered signal-to-noise ratio in 86% (6/7). STh morphine altered the signal-to-noise ratio in 83% (5/6) of tested neurons and STh cocaine altered it in 86% (6/7). Preliminary results with GABA indicate that morphine and cocaine also are able to alter GABA signal-to-noise ratios. These data suggest that morphine and cocaine regulate glutamate-evoked responses in the VP to a larger extent than the spontaneous firing rate. In addition, both drugs appear to be potent VP neuromodulators as subthreshold currents of each drug proved capable of affecting the glutamate signal. Work supported by USPHSGs DA05651 to PJJ and MH45180 to TCN.

## 542.2

**VIP AND PACAP POTENTIATE THE GLUTAMATE-EVOKED RELEASE OF ARACHIDONIC ACID FROM MOUSE CORTICAL NEURONS**

N. Stella and P.J. Magistretti\* Institut de Physiologie, Université de Lausanne, Switzerland.

Neurons containing VIP in the rodent cerebral cortex constitute a homogeneous population of bipolar, radially-oriented interneurons which can be activated by specific glutamatergic cortical afferents.

In the present study, we examined the potential interaction between VIP and glutamate on the release of arachidonic acid (AA) in primary cultures of cortical neurons. We observed that the release of AA evoked by glutamate is potentiated by VIP (EC<sub>50</sub> = 1 μM) and its analogue PACAP (EC<sub>50</sub> = 0.7 nM). This effect is mediated through PACAP I receptors and is dependent on the related formation of cAMP and PKA activation. Experiments in which the INDO-1 fluorescent dye was used show that activation of PACAP I receptors does not enhance the glutamate-evoked increase in intracellular calcium; this observation clearly indicates that the cAMP-PKA pathway potentiates the glutamate-evoked release of AA at a level downstream of the glutamate receptor-mediated increase in intracellular calcium permeability. Indeed, when intracellular calcium levels are raised in a receptor-independent manner by applying ionomycin, the ensuing AA release is still potentiated by the cAMP-PKA pathway.

Since VIP inhibits AA release evoked by glutamate in astrocytes [Stella et al. (1994) *J. Neurosci.* 14:568-575], the data reported show that VIP and glutamate interact in a synergistic and cell-specific manner on cortical neurons to increase AA release. Since AA enhances glutamatergic neurotransmission, these results suggest that VIP could amplify glutamate-mediated synaptic efficacy.

## 542.4

**DOPAMINE MODULATION OF GABA- AND GLUTAMATE-INDUCED CHANGES OF VENTRAL PALLIDAL NEURONAL ACTIVITY.** A.G. Karczmar\*, P.J. Johnson and T.C. Napier. Dept. Pharmacol., Loyola Univ. Chicago, Sch. Med., Maywood, IL 60153.

Microiontophoresis was used to investigate the possible influence of dopamine (DA) on GABA- and glutamate-induced responses of ventral pallidal (VP) neurons recorded extracellularly from chloral hydrate-anesthetized rats. DA modulation was determined by comparing its ability to alter amino acid-induced activity ("signal") against spontaneous firing ("noise"). An ejection current-response curve (5 to 100 nA) was generated for DA to determine the current level which produced 50% of the maximum DA-induced response (EC<sub>50</sub>) and subthreshold current (STh), i.e. one that did not alter baseline firing rates. When co-iontophoresed with GABA or glutamate, EC<sub>50</sub> DA altered the signal-to-noise ratio in 27 of the 34 VP neurons tested; STh DA altered signal-to-noise ratio in 33 of 45. Co-iontophoresis of DA with GABA generally diminished the inhibitory effects of GABA on VP neuronal firing as 8 of 10 neurons tested with EC<sub>50</sub> DA and 14 of 16 neurons tested with STh DA showed signal-to-noise ratio decreases (-20±8% and -26±6%, respectively). The remaining 4 neurons showed increased signal-to-noise ratios. When DA was co-iontophoresed with glutamate, 12 of 17 neurons in each of the EC<sub>50</sub> or STh DA categories showed a signal-to-noise ratio decrease (-54±33% and -102±68%, respectively) whereas the remaining neurons displayed increases (137±119% and 64±22%, respectively). These data demonstrate that when DA alters both spontaneous firing and responses evoked by GABA or glutamate, the evoked responses are affected to a larger extent. DA substantially alters GABA- and glutamate-evoked responses even at ejection currents that are below those necessary to change spontaneous firing. Thus, it appears that DA is a potent modulator of GABA and glutamate neurotransmission in the VP. Work supported by USPHSGs DA05651 to PJJ and MH45180 to TCN.

## 542.6

**GLUTAMIC ACID DECARBOXYLASE (GAD) NERVE TERMINALS INNERVATE PERIVASCULAR NEURONS AND MICROVESSELS IN THE RAT CEREBRAL CORTEX.** E. Vaucher\* and E. Hamel. Montreal Neurological Inst, McGill Univ, Montréal, Canada, H3A 2B4.

Recently, we reported that basal forebrain neurons innervate cortical microvessels in the rat frontoparietal and perirhinal cortices (Vaucher & Hamel, *Soc Neurosci Abs*, #37.4, 1994). Based on ultrastructural morphometric analyses, we suggested that not only cholinergic but also GABAergic neurons were involved in this innervation. Here, we investigated by light (LM) and electron microscopy (EM) immunocytochemistry the associations of GAD neuronal elements with local microvessels in both cortical subdivisions in the rat (n=3). We used GAD-6 monoclonal antibody (Boehringer Mannheim) which, as reported previously (Escalpez et al, 1994, *J Neurosci* 14:1834), labeled prominently nerve terminals. On 30 μm-thick sections, few GAD immunostained neurons were seen while a high density of immunoreactive puncta was observed, of which several surrounded intracortical perikarya and their apical dendrites. On 1 μm-thick semithin sections, immunoreactive punctate structures were apposed to small vessels and to numerous unlabeled (and occasionally GAD immunolabeled) cell soma contacting intraparenchymal vessels. Innervation of cell soma was confirmed at the EM level and GAD terminals were found to be highly synaptic. In both cortical areas, 20% of the perivascular GAD terminals (contained within 3 μm from the vessel wall, n=364) were very close (< 0.25 μm) to the blood vessels. In the perirhinal cortex, the terminals appeared slightly closer to vessels and smaller in size than their counterparts in the frontoparietal cortex (respectively, distance: 0.95 ± 0.07 and 1.11 ± 0.05 μm, area: 0.37 ± 0.02 and 0.46 ± 0.02 μm²). These results confirm that GAD neurons establish close relationships with cortical microvessels and suggest that GABA may have a modulatory role by acting on perivascular cell bodies which neurochemical content should be investigated. Further lesions of the substantia innominata will be performed to confirm the basal forebrain origin of these GAD fibers. Supported by the MRC of Canada and Le Ministère de la Recherche et de l'Espace, France.

## 542.7

**CALCIUM-SILENT CHOLINERGIC RECEPTORS AND BRADYKININ CO-MODULATE CYTOPLASMIC CALCIUM.** Jay S. Coggan\* and Stuart H. Thompson. Hopkins Marine Station, Department of Biological Sciences, Stanford University, Pacific Grove, CA 93950.

Intracellular Ca signals ( $Ca_i$ ) evoked by bradykinin (Bk, 10 nM) and carbachol (Cb, 1 mM) together were studied in N1E-115 neuroblastoma cells loaded with the Ca indicator fura-2. Bk and Cb both cause release of Ca from internal stores, but the Cb signal is also associated with Ca influx. When Bk and Cb were applied together, the responses were characterized by Ca release and Ca influx. The Bk and Cb-related Ca influx signal persisted in the presence of pirenzepine (200 nM) and atropine (1  $\mu$ M) but was blocked by curare (10  $\mu$ M) and pertussis toxin (0.5  $\mu$ g/ml). The Bk and Cb Ca influx was also observed in cells that do not respond to Cb alone. Calcium-silent cholinergic receptors, therefore, modulated ( $Ca_i$ ) in the presence of Bk. Marked cross desensitization of Bk receptors by Cb was also observed. The inhibition is most pronounced when the cells have been primed with a two minute dose of Cb 10 minutes before application of Bk. The cross desensitization is reversed by curare and occurs after Cb responses have fully recovered from homologous desensitization. Supported by NIH NS14519 (ST) and NS14519 (JC).

## 542.9

**ALTERATIONS OF STRIATAL AND CSF NEUROTRANSMITTER METABOLISM FOLLOWING LEVODOPA.** D.A. Loeffler\*, P.A. LeWitt, A.J. DeMaggio, P.E. Milbury, W.R. Matson, P.L. Juneau. Clinical Neuroscience Program, Sinai Hospital, Detroit, MI 48235, and ESA, Inc., Chelmsford, MA 01824-4171

Levodopa (LD) markedly improves Parkinsonism, but its long-term use is often associated with problems such as response fluctuations and dyskinesias. For these, changes in striatal dopaminergic mechanisms have been suspected, though influences on other neurotransmitter systems might be involved. We studied effects from 5 days of LD (50 mg/kg i.p. after carbidopa, 2.5 mg/kg i.p.) on dopamine (DA) and other striatal monoamine neurotransmitters in rabbit brain and foramen magnum CSF. HPLC analysis revealed the expected increases of DA and its metabolites, as well as a 2X increase of norepinephrine (NE) concentration. Though serotonin (5-HT) was unchanged, 5-hydroxytryptophan and 5-hydroxyindoleacetic acid (5-HIAA) concentrations were elevated 2X and 6X versus vehicle-treated controls. Enhanced turnover of 5-HT was suggested by an increased 5-HIAA/5-HT ratio. After LD administration, CSF showed increased DA, NE, 5-HIAA, and epinephrine concentrations. These results suggested that, in addition to its dopaminergic effects, LD therapy has influences on striatal NE and 5-HT metabolism which might contribute to outcomes of dopaminergic therapy.

## 542.11

**CCK-8 AND THE DOPAMINE D<sub>2</sub> RECEPTOR ANTAGONIST RACLOPRIDE INDUCE FOS-LIKE IMMUNOREACTIVITY IN THE SHELL PART OF THE RAT NUCLEUS ACCUMBENS VIA DIFFERENT MECHANISMS.** Xi-Ming Li, Ulla-Britt Finnman, Xiao-Jun Xu\* and Kjell Fuxe. Department of Neuroscience; \*Department of Neurophysiology at Huddinge Hospital, Karolinska Institute; Stockholm, Sweden

Induction of neuronal Fos-like immunoreactivity (IR) in the rat brain after *in vivo* treatment with cholecystokinin octapeptide (CCK-8) and the dopamine (DA) D<sub>2</sub> receptor antagonist raclopride was demonstrated. *In vivo* treatment with the neuropeptide CCK-8 (0.01, 0.1 and 1 nmol/rat, i. c. v) or the D<sub>2</sub> antagonist raclopride (0.1, 0.5 and 1 mg/kg, i. p.) alone increased the Fos-like ir profiles in a dose-dependent way in the shell part of the rat nucleus accumbens (AcbSh). Combined treatment with CCK-8 (0.1 nmol/rat) and raclopride (0.5 mg/kg) caused significant additive increases in the Fos-like ir profiles in the AcbSh. In the central caudate-putamen, the medial olfactory tubercle, and the frontal cerebral cortex where either compound alone was weakly active or inactive, the combined treatment with both compounds led to a significant induction of neuronal Fos-like ir profiles. These results suggest that the blockade of D<sub>2</sub> and activation of CCK receptor transduction lines can induce Fos-like IR and furthermore produce long-term regulation of gene expression in the striatum via different mechanisms. The observed synergistic and additive effects of CCK-8 and raclopride on the induction of neuronal Fos-like IR may be the result of an antagonistically CCK receptor regulation of D<sub>2</sub> receptors.

## 542.8

**CALCIUM RELEASE FROM INTRACELLULAR CALCIUM STORES BY ACH AND ATP RECEPTORS IN THE EMBRYONIC CHICK RETINA.** Y. Sakaki and M. Yamashita,\* Dept. Physiol., Osaka Univ. Med. Sch., Suita, Osaka 565, Japan

The signal transduction pathways from muscarinic acetylcholine (mACh) receptors and adenosine triphosphate (ATP) purinoceptors (P<sub>2</sub>) to intracellular Ca<sup>2+</sup> stores were studied in embryonic day 3 chick retinae with Ca<sup>2+</sup>-sensitive fluorescent dye Fura-2 AM.

Ca<sup>2+</sup> responses to carbamylcholine (CCh) and ATP were enhanced by the pre-treatment with LiCl (1 mM, 30 min), while pertussis toxin (PTX) treatment (250 ng/ml, 30 min) affected neither of the two responses. These results suggest the involvements of IP<sub>3</sub> and PTX-insensitive G-protein in the mACh and ATP signal transduction cascades. Thapsigargin (Tg) pre-treatment (250 nM, 12 min) completely blocked both of the responses. The ATP response was abolished after successive applications of CCh in a Ca<sup>2+</sup>-free bath solution. However, the simultaneous application of CCh and ATP induced an increase in [Ca<sup>2+</sup>]<sub>i</sub>, even when no Ca<sup>2+</sup> responses appeared after multiple applications of CCh or ATP. These interactions between CCh and ATP could suggest that the two pathways have some cross talk during the Ca<sup>2+</sup> mobilization.

An influx of extracellular Ca<sup>2+</sup> occurred after the retina was bathed in the Ca<sup>2+</sup>-free solution and this influx was enhanced by Tg (500 nM, 12 min). The addition of Zn<sup>2+</sup> or La<sup>3+</sup> to the bath solution abolished this Ca<sup>2+</sup> influx, suggesting that the embryonic retinal cell has Zn<sup>2+</sup>- and La<sup>3+</sup>-sensitive Ca<sup>2+</sup> replenishment mechanisms that can be triggered by the depletion of intracellular Ca<sup>2+</sup> stores.

## 542.10

**PURINE-DOPAMINE RELATIONSHIPS IN STRIATUM:**

**XANTHOSINE AND GUANOSINE.** P.A. LeWitt\*, D.A. Loeffler, A.J. DeMaggio, P.E. Milbury, W.R. Matson, P.L. Juneau. Clinical Neuroscience Program, Sinai Hospital, Detroit, MI 48235, and ESA, Inc., Chelmsford, MA 01824-4171.

The co-localization of striatal adenosine and dopamine (DA) receptors and their functional interactions are known links between purine and dopaminergic systems. Another relationship is suggested our findings in CSF from unmedicated Parkinson's Disease patients, that xanthine and homovanillic acid concentrations are highly correlated. Also, CSF xanthosine concentration is increased 3X as compared to controls. To explore the link between DA and purine metabolites, we produced DA depletion (with reserpine, 2 mg/kg i.p. 5 days) and DA enhancement (with levodopa, 50 mg/kg i.p. x 5 days) in rabbits. These manipulations led to 63% increase and 26% decrease, respectively, in striatal xanthosine concentrations. Both reserpine and levodopa treatments reduced striatal guanosine concentration by approximately 50%.

Xanthosine is an intermediate in the metabolism of guanosine, adenosine, and inosine nucleotides. Our observations suggest that dopaminergic stimulation regulates striatal xanthosine and, possibly, other purine metabolites. The physiological significance of these striatal purine changes and their relationship to monoaminergic neurotransmission remains to be learned.

## 542.12

**NITRIC OXIDE INDUCES RELEASE OF HYPOTHALMIC VASOPRESSIN AND CORTICOTROPIN RELEASING FACTOR *in vitro* AND *in vivo*.** T.F.W. Horn\*, E.E. Bloom and J. Raber. The Scripps Research Institute, 10666 N. Torrey Pines Rd., La Jolla, CA 92037, U.S.A.

Nitric oxide (NO) may modulate the central and peripheral release pattern of arginine-vasopressin (AVP) and corticotropin releasing factor (CRF). Therefore we investigated the direct effect of NO-containing perfusion buffer (gassed with 5% NO/95% N<sub>2</sub>) on AVP and CRF release from hypothalamic slices in an *in vitro* superfusion paradigm (samples collected at 15-min intervals). After a 90-min wash period, the first control sample was taken and the perfusion buffer switched to NO-containing medium for two consecutive sample periods followed by a final control period. This sampling procedure was repeated after 30 min. The applied NO concentration in the superfusion chambers measured by a NO-sensitive electrode reached plateau levels of approx. 3  $\mu$ M. NO induced a significant increase in AVP-release during both NO-pulses. CRF release occurred delayed and was significantly increased during the second pulse of NO only. The effect was blocked in the presence of 10 mM cobalt chloride, indicating the involvement of Ca<sup>2+</sup> or 50  $\mu$ M dantrolene, an inhibitor of intracellular calcium mobilization. Hemoglobin (100  $\mu$ g/ml) acting as a NO-scavenger abolished the effect of NO on both, AVP and CRF. The NO-induced AVP release is not required for the later changes in CRF since the same delayed effect of NO was seen in AVP-deficient Brattleboro rats. Furthermore, to confirm the results for AVP *in vivo* microdialysis with NO-containing medium within the paraventricular (PVN) and supraoptic nucleus (SON) of urethane-anesthetized rats were performed. Both, PVN- and SON- microdialysis samples (30-min) displayed increased levels of AVP during perfusion with NO-containing medium as compared to control perfusions. Our data provide the first direct evidence that NO can act locally as a positive modulator of central AVP release. By local modulation of central vasopressin release NO might also affect physiological parameters such as body temperature. We will now extend our studies to investigate the role of NO in central thermoregulation and febrile thermogenesis. (Supp. by MH47680, HFSP, DAAD)

## 542.13

**ELECTRICAL STIMULATION OF THE PREFRONTAL CORTEX INCREASES EXTRACELLULAR GLUTAMATE IN THE VENTRAL TEGMENTAL AREA.** Z.L. Rossetti\* and R.A. Wise, CSBN, Concordia University, Montréal, Québec, Canada H3G 1M8.

The ventral tegmental area (VTA) receives a major excitatory projection from the medial prefrontal cortex (PFC). Changes in this excitatory drive may underlie the response of VTA cells to drugs or external stimuli. To study the function of this excitatory pathway *in vivo*, we measured by microdialysis the extracellular concentrations of glutamate (GLU) in the VTA in response to electrical stimulation of the PFC. Following baseline stabilization, rats previously implanted with a bipolar electrode in the PFC and with a guide cannula in the VTA, were stimulated at 100  $\mu$ A (60 Hz, p.w. 0.1 msec, duration 1 sec, inter-stimulus interval 10 sec) for 10 min. Extracellular GLU was measured in 10-min samples (1  $\mu$ l/min) by HPLC with electrochemical detection, following OPA/ $\beta$ -ME derivatization. Basal dialysate concentrations of GLU were  $1.54 \pm 0.18$   $\mu$ M (mean  $\pm$  SE). Electrical stimulation elevated extracellular GLU to  $165 \pm 22\%$  ( $n=7$ ) of baseline. The stimulation-associated GLU response was no longer present when the probe was perfused with tetrodotoxin (10  $\mu$ M), suggesting that the increase in GLU was of neuronal origin. Fluorescence retrograde staining showed that cells projecting to the area of the probe originated in the vicinity of the PFC electrode. These results provide direct functional evidence of an excitatory input to the VTA from the PFC and suggest that microdialysis coupled with electrical stimulation may constitute a useful tool to study glutamatergic function *in vivo*.

**MECHANISM UNDERLYING DOPAMINE RECEPTOR MEDIATED INHIBITION OF NEUROPEPTIDE Y (NPY) RELEASE FROM PHEOCHROMOCYTOMA (PC12) CELLS.** Guihua Cao, Devin Houston\* and Thomas C. Westfall. Dept. of Pharmacol. and Physiol. Science, Saint Louis Univ. Health Sciences Center, St. Louis, MO 63104.

We have previously observed that the mixed dopamine agonist, apomorphine, inhibits the evoked release of neuropeptide Y (NPY) from both striatal slices and nerve growth factor (NGF) differentiated PC12 cells (Soc. Neurosci. Abs. 19:1173, 1993; 20:1560, 1994). In the present experiments we have carried out a further pharmacological characterization of this inhibition in PC12 cells. PC12 cells were cultured in 6-well plates and differentiated with NGF for 5 days. NPY in the release buffer and PC12 cells were measured using radioimmunoassay. Apomorphine produced a concentration-dependent ( $10^{-7}$ - $10^{-5}$  M) inhibition of potassium ( $K^+$ )-evoked (50 mM) release from PC12 cells. This effect was attenuated by pertussis toxin (50 ng/ml for 20 hr), suggesting that the involvement of a GTP-binding protein of the  $G_i$  or  $G_o$  subtype. The inhibitory effect of apomorphine was blocked by the specific dopamine  $D_2$  receptor antagonist, eticlopride, and mimicked by the dopamine  $D_2$  agonist, quinpirole. These results are consistent with the dopamine inhibitory effect being mediated by a dopamine  $D_2$  receptor. Other studies have investigated the signaling mechanisms which mediate this inhibitory effect. We have observed that the N-type calcium channel antagonist omega-conotoxin also decreases the  $K^+$ -evoked release of NPY but the effect of omega-conotoxin and apomorphine were not additive. These results are consistent with apomorphine inhibiting the release of NPY via inhibition of  $Ca^{2+}$  influx. It is concluded that the inhibitory effect of apomorphine on NPY release involves G-proteins and is mediated via dopamine  $D_2$  receptors which inhibit  $Ca^{2+}$  influx. (Supported by HL-26319 and HL-35202).

## 542.17

**NEUROMODULATORY ROLE OF ADENOSINE IN NUCLEUS ACCUMBENS-MEDIATED BEHAVIORS.** H. J. Normile\*, A. Del Villar, K. A. Martens and R. A. Barraco. Wayne State University School of Medicine, Detroit, MI 48202.

We've previously shown that bilateral microinjections of adenosine analogs into the nucleus accumbens (ACB) affects inhibitory avoidance memory and locomotor activity via activation of adenosine  $A_1$  and  $A_2a$  receptors, respectively. Numerous *in vitro* studies have suggested that the behavioral effects of adenosine and its analogs are due to a functional interaction between adenosine, its receptors and other CNS transmitter systems. The present experiment represents our initial inquiry into the CNS systems which may mediate adenosine's effects on behavior by examining the effects of adenosine  $A_1$  and  $A_2a$  receptor activation in the ACB on inhibitory avoidance memory and locomotor activity of mice pretreated IP with drugs that alter cholinergic and dopaminergic activity. Intra-ACB injections of a selective adenosine  $A_1$  receptor agonist, CPA, combined with the muscarinic receptor antagonist, scopolamine, significantly impaired inhibitory avoidance memory at doses that failed to affect performance when administered alone. Intra-ACB injections of a selective adenosine  $A_2a$  receptor agonist, CGS 21680, combined with the dopamine  $D_2/D_3$  receptor agonist quinpirole, suppressed locomotor activity at high CGS 21680 doses, whereas low doses of CGS 21680 attenuated the suppressant effects of quinpirole on locomotor activity. These findings suggest that endogenous adenosine may functionally interact with the cholinergic and dopaminergic systems in the control of ACB-mediated behaviors. (Supported in part by MBRS #RR08167 and the Joseph Young, Sr. Research Fund).

## 542.14

**INHIBITORY EFFECT OF NEUROPEPTIDE Y ON CATECHOLAMINE SYNTHESIS IN RAT PHEOCHROMOCYTOMA (PC12) CELLS.** L. A. McCullough and T. C. Westfall\*. Dept. of Pharmacol. and Physiol. Science, Saint Louis Univ. Health Sciences Center, St. Louis, MO 63104.

In rat PC12 cells differentiated with nerve growth factor (NGF), neuropeptide Y (NPY) inhibited depolarization-stimulated catecholamine synthesis as determined by *in situ* measurement of dopa production in the presence of the decarboxylase inhibitor NSD-1015. The inhibition was concentration-dependent, with 1  $\mu$ M NPY producing a 50% attenuation of the depolarization-induced increase in dopa production. The inhibitory effect of NPY was prevented by pretreatment with pertussis toxin, suggesting the involvement of a GTP-binding protein of the  $G_i$  or  $G_o$  subtype. The NPY analog [Leu<sup>31</sup>,Pro<sup>34</sup>]NPY also caused inhibition of dopa production, but was less potent than NPY itself, while NPY 13-36 and PYY had no significant effect. This pattern is most consistent with the involvement of the Y3 NPY receptor subtype. In PC12 cells differentiated to a mature chromaffin phenotype with dexamethasone, NPY also caused a concentration-dependent inhibition of dopa production with equal efficacy as in NGF-differentiated cells, although with reduced potency. PYY was again without effect in dexamethasone-differentiated cells. NPY had no effect on basal dopa production in NGF-differentiated PC12 cells or on depolarization-stimulated dopa production in undifferentiated cells. In addition, NPY was effective at inhibiting dopa production in NGF-differentiated cells following stimulation with 0.5  $\mu$ M forskolin. These results indicate that NPY, which is co-stored and co-released with catecholamines in the central and peripheral nervous systems, can modulate catecholamine synthesis by inhibiting tyrosine hydroxylation in addition to its modulatory effects on catecholamine release.

## 542.16

**ALPHA-ADRENERGIC RECEPTOR MEDIATED MODULATION OF ACTIVATION OF ADENYL CYCLASE BY VASOACTIVE INTESTINAL PEPTIDE (VIP) IN RAT CORTICAL CULTURES.** Y. Li and P. A. Rosenberg\*. Dept. of Neurol., Children's Hospital & Harvard Medical School, Boston MA 02115.

We have shown previously that catecholamines, acting through beta adrenergic receptors, and VIP, stimulate intracellular cAMP accumulation in astrocytes, release of cAMP, and extracellular hydrolysis of cAMP to adenosine (*J. Neurosci.* 14: 2953-2965; *Soc. Neurosci. Abstr.* 20: 10). Release of cAMP from astrocytes and extracellular hydrolysis to adenosine might be a general mechanism by which neuromodulators positively coupled to adenylyl cyclase might act. With this in mind, we investigated the interactions of alpha adrenergic receptors with VIP, because of the well-documented synergism between alpha1-adrenergic receptors and VIP that has been demonstrated in the cortical slice preparation (Magistretti, *Proc. Natl. Acad. Sci.* 78: 6535-6539).

Norepinephrine plus atenolol (to block activation of beta-adrenergic receptors) produced little consistent effect on VIP evoked cAMP accumulation in mixed cultures of neurons and astrocytes. In contrast, in relatively pure cultures of astrocytes, norepinephrine plus atenolol caused a large reduction in the response to VIP. This effect of norepinephrine plus atenolol could be mimicked by the alpha2-adrenergic antagonist clonidine, and could be blocked by yohimbine, establishing it as an alpha2-adrenergic receptor mediated response. We found no evidence for an alpha1-adrenergic receptor mediated effect potentiating the response to VIP. The discrepancy between the results obtained with cortical slices and with cortical cultures is unexplained, but the diminished effect of alpha2-adrenergic agonists in the mixed cultures of neurons and astrocytes suggest that the presence of neurons somehow modulates the alpha-adrenergic response in astrocytes.

Supported by a grant from NINDS (NS26830).

**SYMPATHOLYTIC ACTIVITY OF ADENOSINE AGONISTS IS DEPENDENT ON STIMULATION FREQUENCY.** C. E. Crosson\* and T. Gray. Department of Ophthalmology and Visual Sciences, Texas Tech University Health Sciences Center, Lubbock, TX 79430.

Prejunctional adenosine receptors have been identified on sympathetic nerve fibers in several systems. In this study, the effect of adenosine agonists on  $^3H$ -norepinephrine release from the isolated iris/ciliary body (ICBs) of New Zealand White rabbits was examined. Rabbits were sacrificed by an overdose of sodium pentobarbital, the eyes enucleated, and the ICBs dissected free. ICBs were loaded with  $^3H$ -norepinephrine for 60 minutes, washed, and samples collected at one minute intervals. To evoke  $^3H$ -norepinephrine release, ICBs received electrical stimulation (10 V) at 5 and 20 Hz. At 5 Hz stimulation, the addition of the relatively selective adenosine  $A_1$  agonist N<sup>6</sup>-cyclohexyladenosine (CHA) at concentrations from  $10^{-9}$  to  $10^{-6}$  M did not significantly alter the release of  $^3H$ -norepinephrine as measured by the changes in stimulus ratios. However, when tissues were stimulated at 20 Hz, the addition of CHA produced significant dose-related inhibition of norepinephrine release, with an IC<sub>50</sub> of 4.8  $\mu$ M. The adenosine  $A_2$  agonist CV-1808 did not significantly alter 20 Hz-stimulated  $^3H$ -norepinephrine release. Preincubation with the adenosine receptor antagonist 8-cyclopentyl-1,3-dimethylxanthine (CPT) reversed the suppression of  $^3H$ -norepinephrine release induced by CHA. These studies provide evidence that adenosine  $A_1$  agonists can modulate sympathetic function of the ICB. However, the expression of this response was dependent on the frequency of electrical stimulation to induce norepinephrine release. Hence, prejunctional adenosine receptors may act as circuit breakers to limit neurotransmission at high frequencies.

## 542.19

**CAFFEINE INDUCES BIPHASIC CHANGES IN BEHAVIOUR AND STRIATAL IMMEDIATE EARLY GENE EXPRESSION** Bertil B. Fredholm\*, George Nomikos and Per Svenningsson. Dept. Physiology and Pharmacology, Karolinska Institutet, Stockholm, Sweden.

Caffeine is known to increase the expression of *c-fos*, *c-jun*, and *jun B* mRNA in doses above 50 mg/kg i.p. These doses tend to depress motor behaviour, whereas lower doses (below 50 mg/kg) stimulate. Caffeine was given by i.p. injection and motor behavior recorded in an automatic activity meter. Animals were killed between 0.5 and 8 hrs after administration of caffeine. IEG expression was examined by *in situ* hybridization. At a dose (25 mg/kg) which caused increased motor behaviour caffeine decreased the expression of NGFI-A, NGFI-B and *jun B*. The effect was significant 4 and 8 hrs after caffeine injection. The decrease in NGFI-A was confined to the striatopallidal neurons. At higher doses there was an increase observed in both striatopallidal and striatonigral neurons. The effect of low dose caffeine was mimicked by the D<sub>2</sub> agonist quinpirole (1 and 3 mg/kg), but it was not blocked by the D<sub>2</sub> antagonist raclopride (2 mg/kg). The results also show that a single dose of caffeine can have diametrically opposing effects on immediate early gene expression and motor behaviour depending upon dose. The data also indicate that co-existing adenosine A<sub>2A</sub> and dopamine D<sub>2</sub> receptors have functionally important opposing actions which cannot all be explained by a direct receptor-receptor interaction.

## 542.21

**LOCALIZATION OF CHOLINERGIC AND GABAERGIC NEURONS IN THE RETICULAR NUCLEUS OF THE THALAMUS AND THEIR PROJECTIONS TO THE MEDIODORSAL NUCLEUS OF THE THALAMUS IN THE CAT.** L. Grilli\*, M. Mariotti and M. Mancía. Institute of Human Physiology II, University of Milan, I-20133 Milano, Italy.

The distribution of cholinergic and GABAergic neurons was examined in the Reticular nucleus of the thalamus (RE) of cats with a sequential immunohistochemical staining procedure using BDHC (benzidine dihydrochloride) for GAD (glutamic acid decarboxylase) after using DAB (diaminobenzidine) for ChAT (choline-acetyl-transferase). ChAT-immunoreactive cells were found among GAD-immunoreactive cells in the anterior part of the RE. ChAT+ cells were less numerous than GAD+ cells (in a ratio of 1:20). Efferent projections from the two cell types to the intermediate part of the Mediodorsal nucleus (MD) of the thalamus were examined by retrograde transport of horseradish peroxidase conjugated with wheat germ agglutinin (WGA-HRP) combined with immunohistochemical revelation of GAD and ChAT. Of the large number of cells projecting to the intermediate part of MD, GAD+ neurons represent a significant proportion (>69%) and ChAT+ neurons a very small proportion (<4.0%). More than 70% of the ChAT+ cells and less than 18% of the GAD+ cells located in the RE were retrogradely labelled. These results indicate that the cholinergic neurons lying amongst the GABAergic neurons of the anterior part of the RE may exert an influence on the neurons located in the intermediate part of the MD nucleus of the thalamus. They might also constitute, as suggested by Mancía and Otero-Costas (1973), the chemo-anatomical substrate whereby the disfacilitatory effect of the midbrain reticular formation could act on thalamo-cortical neurons.

## 542.20

**Nitric oxide mediated neuromodulation in post-hypoxic myoclonus.** D.D. Truong\*, T.Q. Vu, R.R. Matsumoto, A.G. Kanthasamy, Parkinson & Movement Disorders Laboratory, Dept. of Neurology, Univ. of California, Irvine, CA 92717.

Nitric oxide is a neuromodulator which has been implicated in excitatory amino acid mediated cellular responses. Since overactivity of excitatory amino acids has been linked to neurological consequences following hypoxia or ischemia, we evaluated the role of nitric oxide in post-hypoxic myoclonus. Following 7-10 min of cardiac arrest, rats exhibit audiogenic myoclonus, which has neurological features that resemble post-hypoxic myoclonus in humans. The nitric oxide synthase inhibitor N<sup>G</sup>-nitro-L-arginine methyl ester (L-NAME, 300mg/kg, i.p.) was administered to cardiac arrested rats and the audiogenic myoclonus was quantitated at 30 min intervals for three hrs. L-NAME significantly ( $p < 0.01$ ) attenuated audiogenic myoclonus as compared to pretreatment. The response was rapid and lasted more than three hrs. L-NAME also ameliorated seizure threshold in the post-operative period (1-3 days) of the cardiac arrest surgery. To determine the direct relationship between nitric oxide and myoclonus, the nitric oxide donor isosorbide dinitrate (ISDN, 300 mg/kg i.p.) was administered. ISDN significantly ( $p < 0.05$ ) accentuated the myoclonus score. These results suggest that nitric oxide plays a neuromodulatory role in the expression of post-hypoxic myoclonus. Experiments are in progress to identify direct/indirect neuromodulation of nitric oxide in the pathogenetic mechanism of post-hypoxic myoclonus. (Supported by Myoclonus Research Foundation).

## UPTAKE AND TRANSPORTERS: CATECHOLAMINES II

**INHIBITION OF DOPAMINE TRANSPORT BY HYDROPHOBIC CATIONS.** M.R. Rollin and J.C. Schaeffer\*. Dept. of Chemistry, California State University, Northridge, CA 91330.

Many dopamine transport inhibitors are hydrophobic cations at physiological pH and probably bind to the dopamine transporter through ion pair formation with an anionic center located in a hydrophobic region. Secondary amine derivatives of phenylethylamine and related compounds were evaluated for their ability to block <sup>3</sup>H-BTCP binding to a strong inhibitory site on the dopamine carrier in rat brain membranes and to inhibit <sup>3</sup>H-DA accumulation by synaptosomes. Secondary amines containing two large hydrophobic groups were very potent inhibitors in both assay systems. Structural changes in the hydrophobic substituents occasionally decreased inhibitor strength suggesting unfavorable steric interactions. Comparison of the inhibition curves for all the inhibitors tested in each assay system indicated the presence of normal sensitivity inhibitor and high sensitivity inhibitor classes. Simple reversible bimolecular associations can explain the normal sensitivity inhibitors, but the high sensitivity inhibitors appear to involve inhibitor/transporter interactions of greater complexity. Because assay dependent relative inhibitor potency differences, complex assay/sensitivity class patterns and both competitive and non-competitive inhibition were observed, transport inhibition by hydrophobic cations probably involves multiple transporter sites/conformations and their interactions.

## 543.2

**LONG-TERM OVARECTOMY INCREASES EXPRESSION OF THE DOPAMINE TRANSPORTER GENE IN THE RAT SUBSTANTIA NIGRA.** R. Bossé, R. Rivest and Thérèse Di Paolo\*. School of Pharmacy, Laval University, Québec, Québec G1K 7P4 and Department of Molecular Endocrinology, Laval University Medical Center, Sainte-Foy, Québec, G1V 4G2, CANADA.

Removal of dopamine (DA) from the synaptic cleft is principally done via an uptake mechanism involving the DA transporter (DAT). We have previously shown gender and sex steroid effects on rat brain DAT. We recently described decreased striatal DAT levels in ovariectomized rats. Menopause is characterized by lowered estrogen levels. Increased onset of schizophrenia and tardive dyskinesia is also observed in post-menopausal women. To further investigate the mechanisms involved in DAT regulation and their impact on CNS changes occurring at menopause, we used ovariectomy as a model of decreased gonadal function. The effect of short-term ovariectomy (ST-OVX, 2 weeks) and long-term (LT-OVX, 3 months) and its possible antagonism with a 17- $\beta$  estradiol treatment (10  $\mu$ g E<sub>2</sub>, b.i.d., 2 weeks before sacrifice) on rat substantia nigra pars compacta (SNc) and ventral tegmental area (VTA) DAT gene expression was investigated. 30 female Sprague-Dawley rats were divided into 5 groups: (1) intact rats at random stages of the estrous cycle (CTRL), (2) ST-OVX, (3) ST-OVX+E<sub>2</sub>, (4) LT-OVX and (5) LT-OVX+E<sub>2</sub>. *In situ* hybridization was used to estimate levels of the DAT mRNA. ST-OVX did not affect SNc DAT mRNA levels whereas LT-OVX led to a 36% ( $p < 0.05$ ) increase. E<sub>2</sub> treatment partially restored DAT mRNA levels toward control values in LT-OVX rats but has no effect in ST-OVX rats. Similar changes occurred in the VTA. For comparison, we recently showed that LT-OVX decreases striatal DAT density by 35%. Increased expression of the DAT was observed in the SNc and VTA following gonadal hormone withdrawal whereas the striatal DAT protein is decreased. This suggests various levels and/or mechanisms of control of this transporter. Supported by the MRC of Canada.

## 543.3

ESTROGEN MODULATION OF SYNAPTOSOMAL DOPAMINE RELEASE.  
T.L. Thompson\* and R.L. Moss. UT Southwestern Med. Ctr., Dallas, TX 75235.

We have shown previously that the ovarian steroid estrogen has short-term, presumably non-genomic, mediated membrane effects on dopaminergic activity in the nucleus accumbens (J. Neurochem. 62:1750-1756, 1994). Estrogen rapidly potentiates depolarization induced dopamine (DA) release from the nucleus accumbens in vivo and this effect is not sensitive to nomifensine (NOM) treatment. To determine whether estrogen directly interacts with the NOM sensitive-site on the DA transporter, we examined the ability of estrogen to alter 3H-DA uptake and release using a rat synaptosomal preparation. Synaptosomes prepared from ovariectomized rats were preloaded with 3H-DA in the presence or absence of NOM ( $\mu$ M-mM) and/or 17 $\beta$ -estradiol ( $\mu$ M-mM). NOM inhibited 3H-DA uptake in a dose dependent manner. Pre-exposure to 17 $\beta$ -estradiol for 15-45min. had no effect on 3H-DA uptake measured over 1 or 5 min., nor was it able to alter NOM mediated inhibition of uptake. Stimulated 3H-DA release was measured from preloaded synaptosomes in response to K<sup>+</sup> (60mM, 1 or 5min.) following exposure to buffer or 17 $\beta$ -estradiol (10-35min., pre-inc.). Basal DA release was significantly attenuated in the presence of the steroid. In addition, K<sup>+</sup>-stimulated release was consistently lower following exposure to 17 $\beta$ -estradiol. Interestingly, NOM treatment resulted in a similar attenuation of basal and K<sup>+</sup>-stimulated release. Synaptosomes which were exposed to 17 $\beta$ -estradiol and NOM responded as those treated with either agent alone. While it is apparent that 17 $\beta$ -estradiol can interact at the presynaptic membrane to modulate DA release, these preliminary data suggest it may be acting at a site distinct from the the NOM sensitive-site on the DA transporter. Experiments are currently underway to identify the precise site of steroid action. Supported by MH 47418.

## 543.5

PROTEIN KINASE ACTIVITY MODULATES DOPAMINE TRANSPORTER FUNCTION. R.A. Huff\*+, R.A. Vaughan#, M.J. Kuhar#, and G. Uhl+@. +Molec. Neurobiol. & #Nsci. Branches, IRP, NIDA, NIH; @Depts. Neurol.&Neurosci., JHUSM, Baltimore, MD 21224.

Dopaminergic neurotransmission is terminated by presynaptic reuptake of dopamine by the dopamine transporter (DAT). We have previously reported that protein kinase C (PKC) activation can alter dopamine transport Vmax in transiently-expressing COS cells (Eur. J. Pharmacol., 268, 115-119). We now report that activation of PKC with the active phorbol ester PMA in LLC-PK1 cells that stably express DAT cDNA decreases dopamine uptake Vmax values by 35%; parallel studies in transiently-expressing COS cells yield 49% decreases. No decrease in uptake was observed when either cell line was treated with the inactive phorbol ester 4 $\alpha$ -PDD. Neither PMA nor 4 $\alpha$ -PDD changed transporter number, as assayed by radioligand transporter binding. General transport process toxicities were not observed as Na<sup>+</sup>/Cl<sup>-</sup> dependent transport of alanine and the facilitated transport of leucine were unaffected in LLC-PK1 cells and only modestly altered in COS cells. Treatment with the protein kinase A inhibitor H-89 decreased dopamine transport Vmax by 80% in LLC-PK1 and 61% in COS cells, but neither effect was antagonized by 8-bromo cyclic AMP. Initial results of DAT labeling with [<sup>32</sup>P]orthophosphate followed by immunoprecipitation suggest that some of the PKC effects may result from direct transporter phosphorylation. Replication of these effects, and their absence in site-directed transporter mutants devoid of specific potential phosphorylation sites, would support a significant role for transporter phosphorylation in regulation of dopaminergic neurotransmission.

## 543.7

SPECIES-AND-BRAIN-REGION SPECIFIC DOPAMINE TRANSPORTERS: IMMUNOLOGICAL AND GLYCOSYLATION CHARACTERIZATION  
M.T. McCoy\*, V.L. Brown, R.A. Vaughan and M.J. Kuhar Neuroscience Branch, NIDA Intramural Program, Baltimore, MD 21224

Dopamine transporters from the caudate nucleus of three species (mouse, dog, and human) and from rat nucleus accumbens, frontal cortex and midbrain were analyzed for glycosylation and for cross-reactivity to antisera generated against rat dopamine transporter peptide sequences. For the immunological characterization, samples were photoaffinity labeled with [<sup>125</sup>I]DEEP and were immunoprecipitated with four different DAT anti-peptide antibodies. DATs from all species were immunoprecipitated with all four sera, although with varying effectiveness. Compared to rat DATs, precipitation of mouse DATs was most similar and precipitation of human DATs was least similar, presumably reflecting species differences in primary amino acid sequence. The transporters obtained from various brain regions of the rat were immunoprecipitated with a profile similar to the striatal DATs. Deglycosylation studies were done by immunoprecipitating photolabeled DATs followed by enzyme treatment and polyacrylamide gel electrophoresis. Samples from all species and all brain regions were sensitive to both N-glycanase and neuraminidase, and demonstrated about the same degree of M<sub>r</sub> loss as rat striatal DATs due to these enzymes. The transporters from the various species and regions displayed slightly different molecular weights, and no transporters were found with substantially lower molecular weights, indicating that if incompletely glycosylated forms are present (e.g., in the midbrain cell bodies) they do not become photolabeled. This shows that DATs from cell body regions as well as terminals are capable of ligand binding and possess mature carbohydrate structures.

## 543.4

DOPAMINE TRANSPORTER ACTIVITY IN MIDBRAIN NEURONS IS DIRECTLY CORRELATED WITH VULNERABILITY TO MPTP TOXICITY: RELATIONSHIP TO CALBINDIN-D28k. M.K. Sanghera\*, R.B. Simerly and D.C. German, Dept Psychiat, UT Southwestern Med Cntr, Dallas, TX 75235-9070, and Div Neurosci, Oregon Regional Primate Res Cntr, Beaverton, OR 97006.

The dopamine transporter (DAT) is the site at which MPP<sup>+</sup>, the neurotoxic metabolite of MPTP, gains access to dopaminergic (DA) neurons. The midbrain DA neurons in the C57BL/6 mouse that contain the calcium-binding protein, calbindin-D28k (CALB), are less vulnerable to degeneration than the DA neurons that lack CALB (Liang et al., 1995). The purpose of the present study was to examine the relationship between CALB and DAT activity in midbrain DA neurons. Male C57BL/6 mice were examined using combined *in situ* hybridization with a rat DAT cDNA riboprobe, and CALB immunohistochemistry. Four sections were examined through the midbrain DA cell complex (nuclei A8, A9 and A10). There were varying amounts of DAT mRNA activity over the CALB-containing DA neurons; some CALB-containing neurons exhibited high DAT mRNA, and some exhibited low DAT mRNA. There was a positive correlation between DAT mRNA levels and regions where cells are located that are vulnerable to MPTP-induced cell death. These data suggest that both CALB and low DAT activity are important in protecting DA neurons from MPTP-induced cell death.

## 543.6

TRANSGENIC MICE WITH DIFFERENTIAL DOPAMINE TRANSPORTER EXPRESSION: PSYCHOSTIMULANT RESPONSES AND NEUROTOXIC CONSEQUENCES. D.M. Donovan\*#, L.L. Miner#, I. Sora#, J. Mülle#, S. Prezedborski@, V. Jackson-Lewis@, S. Izenwasser\$, R. Rothman+, C. Dersch+ & G.R. Uhl!#. +Molec. Neurobiol. #, +Clin. Pharm., \$Preclin. Pharm. Branches; @Col.-Pres. Univ.; !Depts. Neurosci.&Neurol, JHUSM, Balto, MD 21224.

The dopamine transporter (DAT) has been centrally implicated in rewarding effects of cocaine and in the selective dopaminergic neurotoxicity mediated by MPP<sup>+</sup>. Transgenic mice regionally overexpressing a variant dopamine transporter in catecholaminergic neurons via the 4.8Kb tyrosine hydroxylase promoter reveal DAT overexpression in catecholaminergic cells and their processes as characterized via Northern blot analyses, immunohistochemistry, ligand binding and dopamine uptake. Sensitivity to MPP<sup>+</sup> intoxication through MPTP administration is observed in both transgenic and wild type littermate controls. The DAT transgenic animals display differences from wild type littermate controls in habituation to locomotor apparatus and in conditioned place preference mediated by both cocaine and, in initial experiments, morphine.

## 543.8

NMDA AND KAINIC ACID INCREASE THE VELOCITY OF DOPAMINE TRANSPORT IN RAT STRIATAL SUSPENSIONS AS MEASURED USING ROTATING DISK ELECTRODE VOLTAMMETRY. S. M. Welch\* and J. B. Justice, Jr., Dept. of Chemistry, Emory University, Atlanta, GA 30322.

Rotating disk electrode voltammetry is an electroanalytical technique which has been used to measure kinetics of dopamine transport in suspensions of rat striatal tissue (Meiergerd and Schenk, J. Neurochem. 63, 1683, 1994). In the present study, the technique was utilized to examine the effects of glutamate agonists on the initial velocity ( $v_0$ ) of dopamine (DA) uptake in rat striatal suspensions. DA was added to suspensions of striatal tissue obtained from male Wistar rats and the clearance of DA from the solution was monitored by a glassy carbon rotating disk electrode at an applied potential of +450 mV vs Ag/AgCl. The  $v_0$  was obtained from the slope of a linear regression performed on the first ten seconds of the clearance profile. The glutamate receptor agonists N-methyl-D-aspartic acid (NMDA) and kainic acid were found to increase initial rates of dopamine uptake. At an added DA concentration of 2  $\mu$ M, NMDA (200  $\mu$ M) increased  $v_0$  from 548  $\pm$  28 pmoles/sec/g tissue wet weight (control, n = 6) to 803  $\pm$  63 pmoles/sec/g tissue (n = 4). The increase was reversed by the competitive NMDA receptor antagonist AP5 (200  $\mu$ M). In addition, 10  $\mu$ M kainic acid increased  $v_0$  from 505  $\pm$  34 pmoles/sec/g (control, n = 6) to 702  $\pm$  71 pmoles/sec/g (n = 8). These results suggest that glutamate may play a role in regulation of the striatal dopamine transporter.

## 543.9

**NEUROPEPTIDE Y INCREASES DOPAMINE UPTAKE IN VITRO.** A. C. Thompson\* & J. B. Justice, Jr. Department of Chemistry, Emory University, Atlanta, GA 30322.

Rotating disk electrode (RDE) voltammetry was used to measure the initial velocity ( $V_0$ ) of DA uptake in nucleus accumbens suspensions (300  $\mu$ l, 37°C) prepared from male Wistar rats.  $V_0$  was calculated by linear regression on the slope of the decreasing current that followed a 2  $\mu$ M DA addition. Neuropeptide Y (NPY) at 1, 10, or 100 pM, or vehicle, was added approximately 100 s prior to the 2  $\mu$ M DA and the effect of NPY on the  $V_0$  of DA uptake into the tissue was determined.  $V_0$  was normalized to the DA concentration ( $\mu$ g/mg tissue) for data analysis.

A significant NPY dose dependent increase in the rate of DA uptake was observed ( $p < 0.002$ ). After treatment with 100 pM NPY,  $V_0$  was  $1467 \pm 260$  pmol/s/( $\mu$ g/mg) DA ( $n=9$ ) and was nearly 3-fold greater than the  $V_0$  after vehicle treatment ( $506 \pm 89$  pmol/s/( $\mu$ g/mg) DA,  $n=9$ ). Treatment with 1 pM and 10 pM NPY produced intermediate responses with  $V_0$  of  $824 \pm 123$  ( $n=10$ ) and  $1164 \pm 131$  ( $n=9$ ) pmol/s/( $\mu$ g/mg) DA, respectively.

These results suggest that NPY may regulate DA neurotransmission in the nucleus accumbens by increasing the rate of DA reuptake.

## 543.11

**NOMIFENSINE AS AN ENHANCER OF L-DOPA STIMULATED DOPAMINE RELEASE FROM SUPERFUSED STRIATAL TISSUE FRAGMENTS.** K. Xu, B. Liu, J.L. McDermott\* and D.E. Dluzen. Dept. of Anatomy, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272-0095

In this report, we examined the modulatory effects of Nomifensine (NMF), a dopamine (DA) reuptake blocker, on L-Dihydroxyphenylalanine (L-DOPA) evoked DA release from superfused corpus striatal (CS) tissue fragments of male rats. In Experiment 1, we tested the effects of L-DOPA infusions (5  $\mu$ M) in the presence of different doses of NMF upon DA release rates. We found that a statistically significant increase ( $p < 0.01$ ) in L-DOPA stimulated DA release was obtained when 1 mM of NMF was used. By contrast, 10  $\mu$ M or 100  $\mu$ M of NMF failed to alter L-DOPA evoked DA release rates. In Experiment 2, we combined NMF (1 mM) with decreasing doses of L-DOPA (5, 1, 0.1  $\mu$ M) in order to further study the effect of NMF upon DA neuronal release. Our data showed that, 50 fold reductions in L-DOPA (0.1  $\mu$ M) can be used to produce equivalent release rates in the presence of this uptake inhibitor. At the same time, with a reduction in L-DOPA, there was a corresponding decrease in 3,4-Dihydroxyphenylacetic Acid (DOPAC), which was also statistically significant ( $p < 0.01$ ). These data demonstrate that NMF, a DA uptake blocker, can be used to enhance the capacity of L-DOPA to evoke DA release from CS tissue fragments, and reduce the L-DOPA doses while maintaining equivalent L-DOPA evoked DA release rates.

## 543.13

**ANTISENSE OLIGONUCLEOTIDE INHIBITS NOREPINEPHRINE TRANSPORTER mRNA TRANSLATION IN PC12 CELLS.** Qi Xiao\* and S. M. Tejani-Butt. Dept. of Psychiatry, Univ. of Penn. Sch. of Med., Phila., PA 19104.

The norepinephrine transporter (NET) is located on NE neurons and terminals and is responsible for the reuptake of NE that is released following nerve stimulation. Since PC12 cells express NET, they are an useful *in vitro* model system for studying presynaptic NE neuronal activity. Previous studies in PC12 cells have identified two PC12 membrane proteins with a relative mass of approximately 32 kDa and 53 kDa, which may represent components of the NET. Antisense inhibition of gene expression has become a widely used strategy for regulating the expression of specific genes. The present study used sequence-specific antisense oligonucleotides (ODNs) complementary to NET mRNA, and determined whether this intervention would inhibit NET mRNA translation in PC12 cells. PC12 cells were cultured in RPMI medium 1640 and total RNA was isolated. RNA translation in  $^{35}$ S-methionine-supplemented rabbit reticulocyte lysate was performed at 30°C with 15  $\mu$ g of total RNA and 100  $\mu$ M of antisense or sense ODN for 60 min. Samples were separated on 12 % SDS-PAGE and exposed overnight to Kodak XAR film. Antisense ODNs had significant inhibitory effects on NET mRNA translation. A decrease in translation products were observed which corresponded to approximately 32 kDa and 53 kDa respectively. In contrast, 100  $\mu$ M sense ODN had no effect on NET mRNA translation. The results indicate that the antisense ODN approach may be useful for studying the regulation of NET gene expression. (Research funds from USPHS grant NS 31699).

## 543.10

**PROTEIN KINASE C ACTIVATORS DECREASE DOPAMINE UPTAKE INTO STRIATAL SYNAPTOSOMES.** B.J. Copeland\*, N.H. Neff, and M. Hadjiconstantinou. Departments of Psychiatry, Pharmacology and The Neuroscience Program, The Ohio State University College of Medicine, Columbus, Ohio, 43210

Recent evidence from cloning and transfected cell lines suggests the dopamine transporter (DAT) is modulated by second messenger-dependent pathways. To investigate this possibility, crude synaptosomes were prepared from the mouse striatum and incubated with the protein kinase C (PKC) activators phorbol 12-myristate 13-acetate (PMA; 10  $\mu$ M), or *sn*-1,2-dioctanoylglycerol (DiC<sub>8</sub>; 5  $\mu$ M) for 6 minutes at 37°C. PMA and DiC<sub>8</sub> significantly decreased the uptake of  $^3$ H-dopamine into synaptosomes. Kinetic analysis showed a decrease in the apparent  $V_{max}$  of the transporter without effect upon  $K_m$ . The inactive phorbol ester 4 $\alpha$ -PMA (10  $\mu$ M) had no effect. Washoff of PMA and DiC<sub>8</sub> failed to reverse the decrease in uptake, and no changes in  $^3$ H-mazindol binding to the DAT were observed with either compound. The addition of the protein phosphatase inhibitor, okadaic acid (OKA; 500 nM), further decreased the uptake observed with DiC<sub>8</sub>. These findings support a role for PKC in the modulation of the dopamine transporter activity, and suggest phosphorylation may be a regulatory mechanism by which transport function is altered.

## 543.12

**RAPID MEASUREMENT OF BIDIRECTIONAL NOREPINEPHRINE AND DOPAMINE TRANSPORT IN LLC-NET CELLS USING ROTATING DISK ELECTRODE VOLTAMMETRY.** W.B. Burnette\*, K.S. Danek, C.G. Trowbridge, and J.B. Justice, Jr. Department of Chemistry, Emory University, Atlanta, GA 30322.

The electrochemical technique of rotating disk electrode voltammetry (RDEV) has been applied to the measurement of the inward and outward transport of norepinephrine (NE) and dopamine (DA) in LLC-NET cells, which express the NE transporter (NET). Initial rates ( $v_0$ ) of inward transport were estimated from the first 10 seconds of data following the addition of substrate, and  $v_0$  of efflux from cells pre-loaded with 1  $\mu$ M substrate were estimated from the first 20 seconds of data following the addition of 1  $\mu$ M d-amphetamine (d-AMPH).

The kinetics of transport of DA into LLC-NET cells were studied using RDEV. The  $v_0$  of transport was measured at 30 DA concentrations ranging from 98 nM to 15.7  $\mu$ M. Estimates of  $K_m$  and  $V_{max}$  were  $1.75 \pm 0.4$   $\mu$ M and  $2.76 \pm 0.19$  fmol/min/cell, respectively (mean  $\pm$  sem). Experiments were also performed in which two additions of 1  $\mu$ M NE or DA were made to the same preparation, and either vehicle, 1  $\mu$ M d-AMPH, or 1  $\mu$ M tyramine was added in between. The ratio of the initial rates measured after each substrate addition ( $v_0 2/v_0 1$ ) was decreased from  $1.08 \pm 0.03$  to  $0.51 \pm 0.05$  for DA, and from  $0.91 \pm 0.03$  to  $0.39 \pm 0.05$  for NE in the presence of d-AMPH. A 30% increase in the  $v_0$  of inward DA transport was observed when 1  $\mu$ M tyramine was preloaded, demonstrating trans acceleration of inward DA transport. The initial rates of inward transport of 1  $\mu$ M NE and DA in control experiments were  $330 \pm 33$  and  $522 \pm 44$  amol/min/cell, respectively. The initial rates of efflux from cells preloaded with 1  $\mu$ M substrate following the addition of 1  $\mu$ M d-AMPH were  $56.6 \pm 4.8$  and  $54.6 \pm 2.0$  amol/min/cell for DA and NE, respectively. These results demonstrate the feasibility of measuring catecholamine transport in a heterologous expression system using RDEV, and further show the effects of alternative substrates for the NET on rates of bidirectional transport of NE and DA.

## 543.14

**PHENYLEPHRINE INTERACTIONS WITH NOREPINEPHRINE AND DOPAMINE TRANSPORTERS.** A.M. Elgen, G.B. Karkanas, Z. Kogen and A. Fleischmann. Depts. Neurosci. & Psychiat., Albert Einstein Coll. Med., Bronx, NY 10461

These experiments examined the influence of the  $\alpha_1$ -adrenergic agonist and sympathomimetic agent phenylephrine (PHE) on monoamine efflux and uptake in hypothalamic and striatal preparations. At 1.0  $\mu$ M, PHE promoted calcium-independent efflux of norepinephrine from hypothalamic slices. In hypothalamic synaptosomes PHE produced a concentration-dependent inhibition of  $^3$ H-norepinephrine uptake ( $IC_{50} = 90$  nM) which was neither blocked by the  $\alpha_1$ -adrenergic antagonist prazosin nor mimicked by the  $\alpha_1$  agonist methoxamine. PHE also inhibited synaptosomal uptake of  $^3$ H-dopamine ( $IC_{50} = 7$   $\mu$ M), and it promoted efflux of both norepinephrine and dopamine from synaptosomes. PHE had no effect on  $^3$ H- $\gamma$ -aminobutyric acid uptake into hypothalamic synaptosomes. To determine whether PHE can interact with the dopamine transporter we examined the ability of PHE to block  $^3$ H-dopamine uptake in synaptosomes from rat striatum. PHE produced a dose-dependent blockade of  $^3$ H-dopamine uptake in striatal synaptosomes ( $IC_{50} = 40$   $\mu$ M). To eliminate any uptake through the norepinephrine transporter we coincubated striatal synaptosomes with 100  $\mu$ M desmethylimipramine, a selective inhibitor of the norepinephrine transporter. Under these conditions PHE produced a concentration-dependent inhibition of  $^3$ H-dopamine uptake ( $IC_{50} = 30$   $\mu$ M). These findings suggest that the sympathomimetic agent PHE can act at the dopamine as well as the norepinephrine transporter. Supported by MH41414, RSDA MH00636, and T32 NS07183.

## 543.15

**INHIBITION OF VESICULAR MONOAMINE TRANSPORT BY TREATMENT OF PC12 CELLS WITH PHORBOL ESTER.** PMA N. Nakanishi\*, H. Watanabe, H. Hasegawa, T. Ueha, S. Katoh, N. Minami. Dept. of Biochem., and Dept. of Physiol., Meikai Univ. Sch. Dent., Sakado, Saitama 350-02, Japan, and Dept. of Bioscience, Nishi-Tokyo Univ., Uenohara, Yamanashi 409-01, Japan.

We reported that cAMP down-regulates cellular uptake of catecholamine by inhibiting vesicular monoamine transport process (J. Neurochem. 64, 600, 1995). This effect of cAMP was mediated by protein kinase A pathway. Since protein kinase A and protein kinase C have close relationship in the signal transduction pathway, we examine the effect of phorbol 12-myristate 13 acetate (PMA) on vesicular amine transport to clarify a role of protein kinase C in regulation of the amine transport. Activity of the vesicular amine transport was measured as 5HT uptake by digitonin-permeabilized PC12 cells. When cells were treated with PMA (1  $\mu$ M) for 30 min prior to the digitonin-permeabilization, vesicular 5HT uptake was decreased to about 50% of the control value, whereas the PMA addition into the uptake assay mixture by already permeabilized cells showed no effect. The inhibitory effect of PMA was disappeared when the intact cells were treated with both PMA and K252a, a protein kinase inhibitor. These results suggest an inhibitory effect of protein kinase C on vesicular monoamine transport.

## 543.17

**THE VESICULAR MONOAMINE TRANSPORTER, IN CONTRAST TO THE DOPAMINE TRANSPORTER, IS NOT REGULATED FOLLOWING CHRONIC COCAINE SELF-ADMINISTRATION.** J.M. Wilson\*, M.E. Carroll and S.J. Kish. Clarke Institute of Psychiatry, Toronto, Ontario and Department of Psychiatry, University of Minnesota, Minneapolis, MN.

While various neuronal markers have been used as indices of nerve terminal integrity, many are susceptible to regulatory processes which confound the quantification of nerve terminal loss. This study examined the possible regulation of the vesicular monoamine transporter (VMAT2) in rat brain. A paradigm of chronic, unlimited access to self-administration of cocaine was used. This paradigm has previously demonstrated marked up- and down-regulation of the dopamine transporter (DAT; as determined by [ $^3$ H]WIN 35,428 binding) during cocaine access and withdrawal (Wilson, et al., J. Neurosci., 14: 2966, 1994). From the same rat brain samples, sequential brain sections were retained for quantitative autoradiographic analysis of VMAT2. Following a 20 min. preincubation at 25°C in 50 mM sodium phosphate buffer (pH 7.7), brain sections were incubated for 40 min. with 5nM [ $^3$ H]TBZOH (plus 2 $\mu$ M TBZ for non-specific binding). Specific [ $^3$ H]TBZOH binding was detected in DA (striatum, nucleus accumbens, olfactory tubercle), 5-HT (dorsal raphe) and NA (hypothalamus) rich areas of control rat brain. Following chronic, unlimited access to self-administration of cocaine, no changes in [ $^3$ H]TBZOH binding to VMAT2 were detected, either on the last day of cocaine access or after 3 weeks drug withdrawal. This is in contrast to DAT which was upregulated (+65% striatum, +69% nucleus accumbens) on the last day of cocaine access and down regulated (-30% nucleus accumbens) after cocaine withdrawal. The present data support the suggestion of Vander Borgh, et al. (Neurosci, in press) that VMAT2 is not regulated by chronic perturbation of the DA system, and that consequently VMAT2 might serve as an accurate indicator of nerve terminal integrity. In addition, the lack of reduction in [ $^3$ H]TBZOH binding suggest that chronic cocaine exposure does not result in actual degeneration of DAergic nerve terminals in rat brain. (Supported by US NIDA DA 7182).

## 543.19

**PHARMACOLOGY AND DISTRIBUTION OF NOREPINEPHRINE TRANSPORTERS (NET) IN HUMAN LOCUS COERULEUS (LC) AND RAPHE NUCLEI.** G.A. Ordway\*, C.A. Stockmeier, G.W. Cason, and V. Klimek. Dept. Psychiatry & Human Behavior, University of Mississippi Med. Ctr., Jackson, MS 39126, and Dept. Psychiatry, Case Western Reserve University, Cleveland, OH, 44106.

NET are a site of action for many antidepressant drugs, e.g. tricyclic antidepressants, and drugs of abuse, e.g. cocaine. [ $^3$ H]Nisoxetine ( $^3$ H-NIS) is a unique NET ligand that does not bind to intracellular sites. The distribution of  $^3$ H-NIS binding to NET along the rostral-caudal axes of LC and dorsal and median raphe was measured autoradiographically in 7 normal human subjects post-mortem. Binding to NET was differentially distributed along the LC axis and correlated positively with numbers of neuromelanin-containing (noradrenergic) cells along the LC axis within individuals. Surprisingly, densities of NET in the dorsal and median raphe were similar to that in the LC.  $^3$ H-NIS binding to NET was observed along the entire rostral-caudal extent of the dorsal and median raphe nuclei. The possibility that  $^3$ H-NIS binds to serotonin transporters in the raphe was studied by autoradiographically assessing the inhibition of  $^3$ H-NIS binding by desipramine, imipramine or citalopram. The order of potency of these drugs for inhibition of  $^3$ H-NIS binding was identical in the LC and dorsal and median raphe nuclei, and was characteristic of binding to NET (desipramine > imipramine > citalopram). Thus, high levels of NET occurs in the LC as well as in the raphe of the human. Drugs which are selective for NET vs. serotonin transporters may achieve specificity with respect to their target proteins, but physiologically even highly selective NET drugs will bind with high capacity in the dorsal and median raphe nuclei. (Supported by MH46992 and MH45488).

## 543.16

**LOCALIZATION OF NORADRENALINE TRANSPORTER mRNA EXPRESSION IN THE HUMAN LOCUS COERULEUS.** C. Eymin<sup>1</sup>, Y. Charnay<sup>1,2</sup>, B. Greggio<sup>1</sup> and C. Bouras<sup>1,3\*</sup>. <sup>1</sup>Dpt of Psychiatry, University of Geneva, Switzerland; <sup>2</sup>CNRS, France and <sup>3</sup>Dpt of Neurobiology, Mount Sinai School of Medicine, New-York, USA.

High affinity reuptake of transmitters via selective Na<sup>+</sup>/Cl<sup>-</sup>-dependent membrane transporters are thought to play a major role in the regulation of the synaptic activity. Furthermore, there is evidence that the monoamine transporters represent the main target of certain classes of antidepressants and drugs such as cocaine. The distribution of the noradrenaline transporter mRNA was examined in the human dorsolateral pontine tegmentum, using *in situ* hybridization histochemistry. Three [ $^{35}$ S]-labeled oligonucleotide probes complementary to the nucleotide sequence encoding the amino acids 36-51, 186-197 and 579-591 of the human noradrenaline transporter mRNA were used. These sequences showed no homology with other membrane transporters or receptors sequences published in the GenBank. Analysis of film autoradiograms showed that noradrenaline transporter mRNA was expressed through the whole extent of the locus coeruleus complex. The largest population of labeled cells was seen in the nucleus locus coeruleus proper whereas few scattered labeled cells were visualized in its ventral subdivision, namely the locus subcoeruleus area. No hybridization signal was detected in the serotonergic cell groups including the median and the dorsal raphe nuclei. Thus, these anatomical findings suggest that cells expressing noradrenaline transporter mRNA in the human brainstem are predominantly, if not exclusively, concentrated within areas known to contain the largest collections of noradrenergic neurons.

## 543.18

**DISCRIMINATIVE STIMULUS EFFECTS OF ANTIDEPRESSANTS IN METHAMPHETAMINE-TRAINED SQUIRREL MONKEYS.** D.M. Grech\*, H. R.D. Speelman and J. Bergman, Harvard Medical School

New England Regional Primate Res. Center, Southborough, MA 01772-9102.

The discriminative stimulus effects of a number of clinically useful antidepressants were studied in squirrel monkeys trained to discriminate 0.30 mg/kg methamphetamine (MA) from saline using conventional drug discrimination procedures. Substitution tests were initially completed with MA (0.03-1.0 mg/kg), prior to testing a number of chemically diverse drugs such as Nomifensine (0.10-3.0 mg/kg), Bupropion (0.30-3.0 mg/kg), Trazadone (1-17.8 mg/kg), Doxepin (0.30-5.6 mg/kg), Fluoxetine (1-17.8 mg/kg), Citalopram (1-17.8 mg/kg) and Sertraline (1-10 mg/kg). For comparison purposes, a number of tricyclic antidepressants (TCA's) were also studied in these monkeys. Fluoxetine, Citalopram, Sertraline and the TCA's, drugs which primarily inhibit NE or 5-HT uptake, failed to substitute for MA. Partial substitution (>60% MA-lever responding) for MA was obtained with Nisoxetine, Trazadone and Doxepin, whereas Bupropion and Nomifensine fully substituted for MA in all subjects. These results suggest that antidepressants which function as DA uptake inhibitors share discriminative stimulus properties with MA. However, our results with Doxepin and Trazadone suggest that NE and 5-HT systems may also be involved in mediating the MA-like effects of some clinically important antidepressants. This research was supported by grants DA 03774, RR00168, DA 00499 and MH 07568.

## 543.20

**RESERPINE DECREASES NOREPINEPHRINE TRANSPORTER mRNA EXPRESSION IN THE ADRENAL MEDULLA BY AN INNervation-INDEPENDENT MECHANISM** J.F. Cubells<sup>1,3\*</sup>, J.W. Jahng<sup>2,3</sup>, H. Baker<sup>2,3</sup>, B.T. Volpe<sup>2,3</sup>, G.P. Smith<sup>1</sup>, S.S. Das<sup>3</sup> and T.H. Joh<sup>1,2,3</sup>. Depts. of <sup>1</sup>Psychiatry, <sup>2</sup>Neurology, & <sup>3</sup>Burke Med. Res. Inst., Cornell U. Med. Coll. White Plains, NY 10605.

Reserpine administration decreases levels of norepinephrine transporter (NET) mRNA and simultaneously increases levels of tyrosine hydroxylase (TH) mRNA in the adrenal medulla (AM; Cubells, et al., 1995, J. Neurochem., in press). To investigate the mechanism underlying this effect, we administered reserpine (10 mg/kg s.c., 24 h pre-mortem) or 20% ascorbic acid vehicle to rats that had undergone unilateral splanchnicotomy, and measured relative levels of NET mRNA and TH mRNA in the AM using quantitative *in situ* hybridization. Splanchnicotomy did not alter the effect of reserpine on levels of NET mRNA, but diminished the reserpine-induced increase in TH mRNA by 75%. Innervation-independent mechanisms therefore mediated the reserpine-induced decrease in NET mRNA, as well as a small component of the increase in TH mRNA. We therefore postulated that a reserpine-induced increase in levels of adrenocorticotropin (ACTH; Lowy et al., 1990, Biol. Psychiatry 27: 546) mediated the effect of reserpine on NET expression in the AM. In preliminary experiments, ACTH 1-24 (Acthar Gel, 4 U/day s.c. for 5 d) diminished NET mRNA levels in the AM of hypophysectomized rats. We hypothesize that ACTH regulates the expression of NET mRNA in the AM, presumably by stimulating adrenocortical steroid production. ## 543.21

## IBOGAINE INHIBITS BIOGENIC AMINE TRANSPORTERS.

C. Messer\* and G. Rudnick, Dept. Pharmacology, Yale University School of Medicine, New Haven, CT, 06510.

Ibogaïne, a plant indole alkaloid, has psychoactive properties and is a putative anti-addictive agent. Although several potential targets have been identified, the molecular target(s) mediating the psychoactive and possible anti-addictive properties of ibogaïne are unknown. Cells from a porcine kidney cell line (LLC-PK<sub>1</sub>) were stably transfected with transporters for each of the biogenic amines. Using [<sup>3</sup>H]dopamine as a substrate for the dopamine and norepinephrine transporters, and [<sup>3</sup>H]serotonin as a substrate for the serotonin transporter, ibogaïne was shown to specifically inhibit transport at all three biogenic amine transporters. This inhibition was significantly higher for the serotonin transporter ( $K_i = 10 \mu\text{M}$ ), than for either the norepinephrine or dopamine transporters ( $K_i = 86 \mu\text{M}$ ). The results of binding studies using a crude membrane preparation taken from the transfected LLC-PK<sub>1</sub> cells showed that ibogaïne's ability to inhibit transport is closely paralleled by its ability to inhibit the binding of 2B-carbomethoxy-3B-(4-[<sup>125</sup>I]iodophenyl)tropane, a cocaine analog, for each of the biogenic amine transporters. It has been estimated that peak brain concentrations of ibogaïne reach 100  $\mu\text{M}$  following pharmacologically effective doses in rodents (Glick, S.D. et al., Brain Res. 628:201-8.) making the biogenic amine transporters potential molecular targets for the actions of ibogaïne.

THE EFFECT OF DIABETES ON CATECHOLAMINE TRANSPORTER GENE EXPRESSION. M.D. Brot\*, P. Szot\*, A. Zavosh<sup>1,2</sup>, A.L. McCall\*, and D. Figlewicz Lattemann<sup>1,3</sup>

Divs. of Endocrin/Metab<sup>1</sup> and GRECC<sup>2</sup>, Seattle VA Medical Center, Depts. of Psychology<sup>3</sup>, and Psychiatry and Behav Sci.<sup>3</sup>, UW, Seattle, WA 98195; and Medicine Service, Portland VA Med. Center<sup>4</sup>, Portland, OR 97207.

Dopamine (DA) and norepinephrine (NE) transporters take up their respective catecholamines from the synaptic cleft, thus inactivating their signal. Exogenous insulin treatment differentially affects these transporters, increasing DA reuptake while decreasing NE uptake. There is a paucity of research on the relationship between catecholamine transporters and endogenous insulin, such as in diabetes. In the present study, we evaluated the coordinated regulation of NE and DA neuronal function by measuring gene expression for the DAT, NET, and for tyrosine hydroxylase (TH), the rate limiting enzyme for NE and DA synthesis.

Rats treated with 65 mg/kg streptozotocin became diabetic (Diabetics vs control): Glucose levels:  $538 \pm 15$  vs  $138 \pm 9$  mg/dl; Insulin levels:  $11 \pm 3$  vs  $52 \pm 5$  uU/ml. After 7 days, TH and NET mRNA were assayed in the locus coeruleus and TH and DAT mRNA were assayed in the substantia nigra compacta/ventral tegmental area by *in situ* hybridization. No difference in TH or NET mRNA was found in NE neurons. However, in DA neurons of diabetic rats, a trend ( $p=0.15$ ) for decreased levels of DAT mRNA (OD:  $0.450 \pm 0.015$  vs  $0.487 \pm 0.015$ ) and a significant ( $p<0.05$ ) decrease of TH mRNA (OD:  $0.288 \pm 0.026$  vs  $0.378 \pm 0.037$ ) were observed. These results suggest differential effects of diabetes (hypoinsulinemia) on CNS NE and DA neurons and provide molecular evidence for the altered dopaminergic function which has been observed in clinical and experimental diabetes.

## 543.22

## EFFECTS OF NERVE GROWTH FACTOR ON EXPRESSION OF VESICULAR AMINE TRANSPORTERS IN PC-12 CELLS. J.A. Near\* and C.R. Adamson, Medical Sciences Program, Indiana University School of Medicine, Bloomington, IN 47405

Tritiated dihydrotetrabenazine ([<sup>3</sup>H]TBZOH) binds with high affinity ( $K_d=2-10$  nM) to a vesicular amine transporter found in rat brain and sympathetic nerves (rVMAT<sub>2</sub>), and with much lower affinity ( $K_d = 200-500$  nM) to a similar transporter present in PC-12 cells and in normal rat adrenal (rVMAT<sub>1</sub>). PC12 cells treated with nerve growth factor (NGF) acquire a sympathetic neuron-like phenotype. The purpose of the present work was to determine if NGF treatment had any effect on the relative or absolute levels of expression of the two transporters in PC12 cells. NGF treatment led to growth of neurite-like processes in 60-85% of the cells, compared with <2% in controls. Computerized nonlinear least squares curve fitting analysis of [<sup>3</sup>H]TBZOH binding to a crude membrane fraction from control and NGF treated cells revealed that the best fit was to a two site model in all cases. Less than 5% of the total binding activity could be attributed to higher affinity sites, and the capacity of these sites (0.2 pmol/mg protein) was unaffected by NGF treatment. Lower affinity binding capacity in both treated and untreated cells increased from 15 pmol/mg protein in controls to 24 pmol/mg protein after NGF treatment. NGF treatment had no significant effect on apparent dissociation constants for either class of binding sites. We conclude from these results that NGF treatment of PC12 cells may increase the level of expression of the transporter already present in untreated cells, but that a vesicular amine transporter with higher affinity for [<sup>3</sup>H]TBZOH does not become the major form expressed after such treatment.

## 544.1

## NITRIC OXIDE INHIBITION ENHANCES PARADOXICAL SLEEP IN CATS. I. de Andrés\*, M. Garzón, B. Gomez, N. Fernandez and G. Dieguez. Dpts. Morfología and Fisiología. Universidad Autónoma. Madrid 28029, Spain.

Previous studies examining the effects of nitric oxide synthase (NOS) inhibitors on cortical evoked responses and the sleep-wakefulness states of rats and rabbits have indicated that nitric oxide may have a role in arousal and in slow wave sleep (SWS) mechanisms. In this study, we have investigated the modifications in the sleep-wakefulness states of cats after systemic administration of N<sup>o</sup>-nitro-L-arginine methyl ester (L-NAME), a NOS inhibitor. Five cats with electrodes for EEG, EMG, EOG and PGO chronic recordings were used. A 30 mg/kg dose of L-NAME was administered via i.p. in all animals; in addition, the effects of 5, 15, and 60 mg/kg were tested in three of them. The different doses, given in a randomized order, were separated by intervals of at least 15 days. Eight hour sleep recordings were obtained the day before (baseline) and in the early (days 0, 1 and 2) and late (day 10) periods after the administration of the different L-NAME doses. Comparisons among baseline and the different experimental days (Anovas for repeated measures and paired t-tests) showed that starting in the second hour after L-NAME administration, all doses effectively produced a significant increase in paradoxical sleep (PS). The PS enhancement on day 0 was similar with the different doses. However, long-lasting effects were observed with the intermediate doses (15 and 30 mg/kg) since a significant increase in PS was also detected on days 1 and 2 after L-NAME administration. The different treatments also increased SWS, but this increase only reached statistically significant values on day 0 after the 15 mg/kg dose. Sleep changes were accompanied by moderate decreases in wakefulness and/or drowsiness. These results indicate that the main effect of L-NAME in the range of doses used is to facilitate PS, thus suggesting that nitric oxide may participate in PS mechanisms.

## 544.2

## ENHANCED SPECIFIC ANORECTIC ACTIVITY OF THE NITRIC OXIDE SYNTHETASE INHIBITOR, L-NAME, IN OBESE ZUCKER RATS. A. Stricker-Krongrad\*, B. Beck and C. Burlet. INSERM U 308, 38, rue Lionnois. 54000 Nancy, France

The presence of a nitric oxide synthetase (NOS) was demonstrated in the rat brain. It has been recently shown that administration of NOS inhibitors reduces food intake in mammals. These results suggest that NO might be involved in the mechanisms controlling feeding behavior. To test this hypothesis, we administered L-NAME (L-N<sup>o</sup>-Nitro Arginine Methyl Ester) intraperitoneally (IP) and intracerebroventricularly (ICV) at dark onset in obese Zucker rats, a genetic model of hyperphagia and obesity. Lean Zucker rats served as controls. The feeding behavior was recorded via a complete automatic system. L-NAME (IP, 0, 10, 25 and 50 mg/kg) induced a dose-dependent decrease in food intake in the obese rats (MED:  $0.50 \pm 0.06$  mg/kg; ED<sub>50</sub>:  $3.50 \pm 0.46$  mg/kg), but remained ineffective in the lean rats whatever the dose used. These anorectic properties were well-translated into the picture of the microstructure of feeding behavior. L-NAME (IP) induced decreases in meal duration (-85%), in meal number (-64%) and in time spent to eat (-93%) in the obese rats. In the lean rats, decreases in meal duration (-46%), in meal number (-44%) and in time spent to eat (-65%) were balanced by an increase in meal size (+62%), leaving food intake unaffected. ICV L-NAME (10  $\mu\text{g}$ ) reproduced the same effects in the obese rats, but lean rats still remained insensitive. This study clearly demonstrates that the activity of the NOS inhibitor L-NAME is enhanced in the obese Zucker rat and that this action is most probably located into its brain. This indicates that NO could be implicated into the expression of hyperphagia.

## 544.3

MECHANISM OF ACTION OF NITRIC OXIDE (NO) DONOR-INDUCED PENILE ERECTION AND YAWNING. M.R. Melis\* & A. Argiolas. Bernard. B. Brodie Dept. Neurosci., Cagliari Univ., 09124 Cagliari, Italy.

The effect of NO donors sodium nitroprusside, hydroxylamine and isoamyl nitrite injected into a lateral ventricle (i.c.v.) or in the paraventricular nucleus of the hypothalamus (PVN) on penile erection and yawning was studied in male rats. After i.c.v. injection, only isoamyl nitrite (10-100 µg) induced these behavioral responses, while the others induced behavioral changes, i.e. motor hyperactivity and convulsions, that masked the above responses. In contrast, the NO donors (10-50 µg) induced penile erection and yawning when injected in the PVN. The NO donor responses were prevented by the guanylate cyclase inhibitors methylene blue and LY 83583 and by the oxytocin antagonist d(CH<sub>2</sub>)<sub>5</sub>-Tyr(Me)-Orn<sup>8</sup>-vasotocin given i.c.v. but not in the PVN. The NO scavenger hemoglobin was ineffective given i.c.v. or in the PVN. 8-bromo-guanosine 3':5'-cyclic monophosphate (8-Br-cGMP) (10-100 µg) did not induce penile erection and yawning when injected i.c.v. or in the PVN. These results show that NO donors induce penile erection and yawning by activating central oxytocinergic transmission in the PVN with a cGMP-independent mechanism.

## 544.5

RECIPROCAL BEHAVIORAL CROSS-SENSITIZATION BETWEEN PHENCYCLIDINE AND (-) BUT NOT (+)PENTAZOCINE. X. Xu and E.F. Domino\*. Dept. of Pharmacology, University of Michigan, Ann Arbor, MI 48109-0630 and Department of Psychology, Grand Valley State University, Allendale, MI 49401.

Phencyclidine, a noncompetitive NMDA antagonist and also a sigma ligand, produces behavioral sensitization. Our previous study suggests that phencyclidine-induced behavioral sensitization may not be mediated only by the NMDA receptor complex. The present research investigated the locomotor stimulant effects of the sigma ligand (+) and the opiate ligand (-)pentazocine, and the possibility of reciprocal cross sensitization with the two enantiomers in phencyclidine sensitized animals. Total locomotor activity and ambulation of adult female Sprague Dawley rats were assessed with an automatic photoelectric system. The acute administration of either isomer of pentazocine in doses of 10-32 mg/kg i.p. produced slight locomotor stimulation. Repeated administration of (+)pentazocine did not produce behavioral sensitization. On the other hand, repeated injections of the (-) enantiomer produced significant locomotor sensitization. (-)Pentazocine sensitized rats showed cross-sensitization to phencyclidine. Phencyclidine sensitized rats showed cross-sensitization to (-)pentazocine. This unexpected observation requires further research. (Supported in part by the Psychopharmacology Research Fund 361024.)

## 544.7

POST-TRIAL MUSCARINIC RECEPTOR BLOCKADE DOES NOT AFFECT THE RETEST PROFILE OF MICE IN THE ELEVATED PLUS-MAZE TEST OF ANXIETY. R.J. Rodgers\*, J.C. Cole, N.J.T. Johnson, C. Dewar and G.R. Kidd. Ethopharmacol. Lab., Dept. Psychology, University of Leeds, LS2 9JT, U.K.

The elevated plus-maze test is the most popular animal model of anxiety currently in use. It is based on the natural aversion of rodents for open spaces, has been validated for rats and mice and is bidirectionally sensitive to pharmacological and non-pharmacological manipulations of anxiety. One of the most intriguing aspects of this test, but one which limits its application, is the change in behavioural baseline with repeated testing. On re-exposure, mice and rats generally show an exaggerated avoidance of the open arms and a reduction in the efficacy of diazepam and similar anxiolytics. To assess the possible involvement of muscarinic receptor mechanisms in the test-retest change in behavioural baseline, mice were treated with saline, 0.1 or 1.0 mg/kg scopolamine HBr immediately after an initial 5min exposure to a standard elevated plus-maze (post-trial scopolamine). Upon 24h retest, control animals showed a retest profile comprising reductions in open arm measures and increases in aspects of risk assessment and immobility; this profile was not altered by scopolamine. The study was repeated using an initial 2 min exposure period. A very robust test-retest effect was observed using this revised procedure, while other aspects of the data confirmed that animals were acquiring considerable knowledge of the maze during the first half of a normal 5min exposure period. However, post-trial scopolamine was again ineffective in altering this effect of prior maze experience. While further research is required, these data suggest that muscarinic receptor mechanisms are not involved in the mechanisms underlying the between-trials changes in plus-maze behaviour.

## 544.4

THE NITRIC OXIDE SYNTHASE INHIBITORS N<sup>G</sup>-NITRO-L-ARGININE METHYL ESTER AND N<sup>G</sup>-NITRO-L-ARGININE ARE ANXIOLYTIC AND ARE DEVOID OF BENZODIAZEPINE SIDE-EFFECTS IN RATS.

R.W. Dunn\*, R.A. Del Vecchio and S. LaMarca. Ohmeda PPD Inc., 100 Mountain Ave., Murray Hill, NJ 07974.

N<sup>G</sup>-nitro-L-arginine methyl ester (L-NAME) and N<sup>G</sup>-nitro-L-arginine (L-NOARG) inhibited cerebellar rat neuronal nitric oxide synthase (NOS) activity with IC<sub>50</sub> values of 0.90 and 0.48 µM, respectively. Bolus iv administration of either L-NAME (54.8 and 100 mg/kg) or L-NOARG (30 mg/kg) significantly (p<0.05) disinhibited lick-shock conflict responding in water deprived rats, similar to the benzodiazepine (BZD) diazepam (0.3 and 0.5 mg/kg). The stereoisomer N<sup>G</sup>-nitro-D-arginine methyl ester (D-NAME; 100 mg/kg, iv) was inactive in the lick-shock assay. L-arginine (50 mg/kg, iv), a substrate for NOS, antagonized the anxiolytic effect of L-NAME. The BZD antagonist flumazenil (10 mg/kg, iv), which completely reversed the disinhibitory activity of diazepam, had no effect on the anxiolytic effect of L-NAME. In addition, diazepam impaired both learning in the step-down passive avoidance paradigm and motor coordination in the rotarod assay, while L-NAME and L-NOARG did not. These results show that inhibition of NOS resulted in disinhibition of conflict behavior, indicative of anxiolytic activity. Unlike diazepam, the NOS inhibitors did not produce impairments in either learning or motor coordination. Therefore, NOS inhibitors may represent a novel class of anxiolytic agents which are devoid of BZD side-effects.

## 544.6

EFFECTS OF PHENCYCLIDINE (PCP) AND MK-801 ON SENSORIMOTOR GATING IN CD-1 MICE. P. Curzon\* and M.W. Decker. Neuroscience Research, D-47W, AP-9A, Pharmaceutical Products Division, Abbott Laboratories, 100 Abbott Park Rd., Abbott Park, IL 60064-3500

Abuse of PCP, which binds in the NMDA receptor channel, or d-amphetamine, an indirect dopamine (DA) agonist, produces psychotomimetic states similar to schizophrenia. Schizophrenics have a deficit in sensorimotor gating, as measured by prepulse inhibition (PPI). In rats, compounds binding to the PCP site and DA agonists disrupt PPI of acoustic startle. In contrast to the large number of studies on the pharmacology of PPI conducted in rats, relatively little work has been done with mice. In order to develop a mouse model for testing potential antipsychotics, we tested the effects of PCP (1.1-36.0 µmol/kg) and the PCP site ligand, MK-801 (0.03-3.0 µmol/kg), on PPI in mice and determined if the neuroleptic, haloperidol, could reverse the MK-801 effect. Because PCP also binds to sigma receptors, we tested the sigma ligand (+)-3-PPP.

Male CD-1 mice (28-32 g) were tested in San Diego Instruments, SR chambers. The mice received trials in which a 120 dB (40 ms) acoustic startle stimulus was presented alone and trials in which an acoustic (20 ms) prepulse stimulus between 70 and 85 dB was given 100 ms prior to the startle stimulus. Presentation of the prepulse reduced the startle response. This PPI was analyzed by ANOVA.

Significant reductions (p<0.05) in PPI were observed following treatment with MK-801 (0.9 and 3.0 µmol/kg) or PCP (11.0 µmol/kg) i.p. Preliminary findings with mice treated with haloperidol (0.13-1.3 µmol/kg) 15 min after MK-801 (0.9 µmol/kg) revealed no significant reversal of the MK-801 disruption. In contrast to PCP, (+)-3-PPP (117.0 µmol/kg) significantly enhanced PPI (p<0.05).

The similarities of the effects of PCP and MK-801 on PPI in mice in the current study and the effects previously reported with these agents in rats suggest that a mouse model may be viable. However, further pharmacological evaluation of this mouse model with different agents needs to be carried out.

## 544.8

BEHAVIORAL EVIDENCE FOR THE MODULATION OF (+)MK-801-INDUCED HYPERLOCOMOTION BY SIGMA LIGANDS IN MONOAMINE-DEPLETED MICE.

S. Okuyama\*, Y. Imagawa and K. Tomizawa. 1st Laboratory, Medicinal Research Laboratories, Taisho Pharmaceutical Co., Ltd., 1-403 Yoshino-cho, Ohmiya, Saitama 330, Japan.

The selective non-competitive N-methyl-D-aspartate (NMDA) antagonist (+)-5-methyl-20,11-dihydro-5H-dibenzo(a,d)cyclohepten ((+)MK-801) induced a dose-dependent increase in locomotor activity in mice pretreated with a combination of reserpine and alpha-methyl-para-tyrosine (alpha-MT). A selective and potent sigma receptor "antagonist" NE-100 (N,N-dipropyl-2-[4-(methoxy-3-(2-phenylethoxy)phenyl)-ethylamine monohydrochloride]), which did not affect spontaneous locomotor activity per se, did not inhibit the locomotor stimulatory effects of (+)MK-801. Sulpiride, a dopamine D2 receptor antagonist, and clozapine, a dopamine D4 receptor antagonist, which decreased spontaneous locomotor activity, did not inhibit the locomotor stimulatory effects of (+)MK-801. The sigma receptor "agonists" (+)N-allylnormetazocine ((+)SKF10,047), (+)pentazocine and (+)-3-(3-hydroxyphenyl)-N-(1-propyl)piperidine ((+)-3-PPP), which did not affect spontaneous locomotor activity per se, dose-dependently enhanced the hyperlocomotion induced by (+)MK-801. The enhancement of (+)MK-801-induced hyperlocomotion by (+)SKF10,047, (+)pentazocine and (+)-3-PPP was completely blocked by NE-100. The enhancement of (+)MK-801-induced hyperlocomotion by (+)pentazocine was not affected by the treatment of with sulpiride and clozapine. These findings indicate that sigma ligands can markedly attenuate NMDA antagonist-induced behavior, suggesting that a major physiological role of sigma receptors might be to modulate the function of the NMDA receptor ion channel complex in vivo.

## 544.9

EFFECT OF INTRA-AMYGDALA ADMINISTRATION OF BETA ADRENERGIC AGONISTS ON THE BEHAVIOR OF RATS UNDER A DRL SCHEDULE. S. Frith, J. Wilkins, N. Leidenheimer\*, and J. M. O'Donnell, Dept. of Pharmacology, LSU Med. Ctr., Shreveport, LA.

Previous work has suggested that nuclei within the amygdaloid complex may be important in the mediation of the actions of antidepressant drugs, particularly those involving beta adrenergic receptors. In order to examine the role of these receptors in mediating antidepressant-like behavioral activity, the actions of intra-amygdala and i.c.v. infusion of the nonselective beta adrenergic agonist isoproterenol and the beta-2 selective agonist clenbuterol on differential-reinforcement-of-low-rate (DRL) behavior were determined. Doses of 10 and 30 ug of isoproterenol, administered i.c.v., produced antidepressant-like effects on DRL behavior, reducing response rate and increasing reinforcement rate. By contrast, a total dose of 60 ug (30 ug in a total volume of 1 ul, bilaterally) of isoproterenol was required to produce antidepressant-like effects when it was administered directly into the amygdala. Similarly, 30 ug clenbuterol, administered i.c.v., reduced response rate and increased reinforcement rate of rats under the DRL schedule, while a total dose of 60 ug (30 ug bilaterally) was ineffective when administered directly into the amygdala. All antidepressant-like effects of the beta adrenergic agonists were antagonized by propranolol, suggesting mediation of the agonist-induced behavioral effects by beta adrenergic receptors. The weak actions of isoproterenol and clenbuterol following intra-amygdala infusion, compared to their actions following i.c.v. administration, suggest that beta adrenergic receptors in the amygdala are not a major site of action mediating the antidepressant-like effects of beta adrenergic agonists on DRL behavior. (Supported by grants from NIMH.)

## 544.11

PROGESTERONE-BSA AND 3 $\alpha$ -ANDROSTANEDIOL-BSA CONJUGATES AFFECT ESTROUS BEHAVIOR WHEN APPLIED TO THE MBH AND POA. C.A. Frye\*, K.R. Van Keuren, P.N. Rao and M.S. Erskine, Department of Biology, Boston University, Boston, MA 02215

We investigated whether progesterone (P) and 5 $\alpha$ -androstane-3 $\alpha$ ,17 $\beta$ -diol (3 $\alpha$ -Diol) have membrane-mediated effects on lordosis behavior in the MBH and POA. Ovariectomized (ovx) rats with bilateral guide cannula over the medial basal hypothalamus (MBH) were primed with 17 $\beta$ -estradiol (E<sub>2</sub>). After a pre-test for sexual receptivity, animals received implants of 3 $\alpha$ -Diol conjugated to BSA (3 $\alpha$ -Diol:BSA), free 3 $\alpha$ -Diol diluted with BSA (3 $\alpha$ -Diol&BSA), P conjugated to BSA (P:BSA), free P diluted with BSA (P&BSA) or control BSA and were retested 5, 30, 60, 90, 120, 150, 180 and 210 min later. In contrast to control BSA, P:BSA and P&BSA implanted animals, those that received 3 $\alpha$ -Diol:BSA and 3 $\alpha$ -Diol&BSA showed facilitated lordosis. In Exp 2, additional E<sub>2</sub>-treated animals were implanted with guide cannulae aimed over the preoptic area (POA), a site implicated in the inhibition rather than the facilitation of lordosis. In contrast to control BSA, 3 $\alpha$ :BSA and 3 $\alpha$ :BSA implanted animals, receptivity increased within 5 minutes of application of P:BSA and P&BSA implants to the POA. Additional ovx animals were tested for effects of systemic hormone treatments on the efficacy of the MBH and POA implants. When P was given to E<sub>2</sub>-primed rats, 3 $\alpha$ -Diol:BSA and 3 $\alpha$ -Diol&BSA applied to the MBH or POA inhibited sexual receptivity; when 3 $\alpha$ -Diol was given s.c., 3 $\alpha$ -Diol:BSA had facilitatory effects in both areas. P:BSA and P&BSA implants in the MBH or POA of E<sub>2</sub> and P-primed rats did not further facilitate lordosis, while in E<sub>2</sub> and 3 $\alpha$ -Diol primed rats, receptivity was not facilitated by either type of P implant. 3 $\alpha$ -Diol and P may act in part at the neuronal membrane in the MBH and POA.

## 544.13

PREGNANOLONE-INDUCED HYPNOSIS AND HYPOTHERMIA ARE MEDIATED BY DIFFERENT MECHANISMS. S.-W. Chen\*, M. F. Davies and G. H. Loew, Molecular Research Institute, Palo Alto, CA 94304.

The endogenous neurosteroid-pregnanolone (5 $\beta$ -pregnan-3 $\alpha$ -ol-20-one) has anxiolytic, anticonvulsant and hyperphagic activities that are mediated by GABA<sub>A</sub> receptors. Because other modulators of the GABA<sub>A</sub> receptor system such as benzodiazepines share these activities and affect body temperature, this study examines effects of pregnanolone on body temperature and locomotor activity. After given pregnanolone (0 to 20 mg/kg) ip, the locomotor activity and body temperature were measured in male rats for 60 min. Pregnanolone dose-dependently reduced activity to a level previously observed for flunitrazepam. However, unlike flunitrazepam, pregnanolone caused minimal hypothermia. The structure-related analog, 5 $\alpha$ -pregnan-3 $\beta$ -ol-20-one (10 mg/kg), had no activity and did not reverse the sedative effect which is consistent with lack of antagonism of other known effects of pregnanolone. However, it reversed the hypothermic effect of pregnanolone. Picrotoxin, the GABA<sub>A</sub> receptor antagonist, at the dose of 0.5 mg/kg, had no effect by itself, but also reversed the hypothermic effect. These results indicate that the pregnanolone effect on body temperature may involve GABA<sub>A</sub> receptor similar to those initiating other effects, while the effect on hypnosis seems to be mediated by other mechanisms. Further investigation of other putative neurosteroid full and partial agonists will also be presented.

## 544.10

BEHAVIORAL EFFECTS OF INTRA-AMYGDALA BENZODIAZEPINES IN MICE. F.E. Lorrich and E.J. Gallaher\*, Oregon Health Sciences University and VA Medical Center, Portland OR 97201.

Benzodiazepines (BZs) have many effects: anxiolysis, hypnotic sedation, muscle relaxation, ataxia, seizure protection, and amnesia. Selective breeding has led to mice which are sensitive or resistant to some effects and not others. To determine the neurochemical bases underlying the behavioral differences, a necessary prerequisite is the identification of neuroanatomic loci contributing to each behavior. The amygdala may be involved in mediating anxiety and is currently being investigated as a locus for some of the effects of BZs.

Mice from the DHP-1 line (diazepam high performance) were prepared with bilateral guide cannulae above the basolateral nucleus of the amygdala using stereotaxic surgery. After recovery, chlordiazepoxide (CDP; 200 mM in 0.5  $\mu$ L) was infused, and the mice were examined for anxiolysis using the plus maze. Several other effects were also examined: muscle relaxation, ataxia, locomotor activation, and protection against PTZ-induced seizures. Initial results suggest that intra-amygdala CDP in mice has anxiolytic effects ( $p < 0.01$ ) in the plus maze. The percentage of open entries following vehicle infusion was  $13.6\% \pm 11$ , while following bilateral CDP infusion it was  $35.6\% \pm 7$ . No ataxic or muscle relaxant effects were found. The advantage of using mice is that there is an increasingly large database of murine genetics. These studies are currently being extended to DS and DR mice, which have been shown to differ in sensitivity to ataxia and anxiolysis.

Supported by VA Med Res Service and USPHS grant MH10317.

## 544.12

BIPHASIC EFFECTS OF ALLOPREGNANOLONE ON INTRAMALE AGGRESSION IN MICE. J.F. DeBold\*, H. Barros, S. So and K.A. Miczek, Psychology Department, Tufts University, Medford, MA 02155.

Ethanol, benzodiazepines and neuroactive steroids all have allosteric effects of neural GABA<sub>A</sub> receptors. This shared mechanism of action may be the basis for their shared behavioral effects, such as sedation and anxiolysis. In addition, benzodiazepines and ethanol both can have stimulatory effects on intramale aggression in mice. However, neuroactive steroids have not been extensively examined for their effects on aggressive behavior. The following experiment was designed to determine if a potent neuroactive steroid, 5 $\alpha$ -pregnan-3 $\alpha$ -ol, 20-one (allopregnanolone), alters aggressive behavior in male mice in the same dose response pattern as alcohol.

Adult male CFW mice were pair-housed with a female and three weeks later were observed for their behavioral response to an unfamiliar group-housed male mouse introduced into their home cage. After establishing baseline levels of aggression, the effects of allopregnanolone (1-30 mg/kg, ip) on the aggressive behavior of the male residents were measured. Mice treated with 10 mg/kg allopregnanolone showed an enhancement of aggressive behavior toward intruders, and a suppression of attack bites at the 30 mg/kg dose. Alcohol has a similar biphasic dose response effect on aggressive behavior with 1.0-1.7 g/kg, po, increasing aggression and 3.0 g/kg reducing it. Since both ethanol and allopregnanolone can have modulatory effects on the GABA<sub>A</sub> receptor complex, this suggests that their similar behavioral effects may have a similar mechanistic basis.

Supported by USPHS grant AA05122 to KAM and JFD.

## 544.14

EFFECTS OF THE DYNORPHIN-A(1-8) ANALOG E2078 IN RHESUS MONKEYS. J.A. Vivian\*, E.R. Butelman, J.H. Woods, Department of Pharmacology, University of Michigan Medical School, Ann Arbor, MI 48109-0632.

E2078 {[N-methyl-Tyr<sup>1</sup>, N-methyl-Arg<sup>7</sup>, D-Leu<sup>8</sup>]dynorphin-A(1-8)ethylamide} is a systemically active dynorphin-A analog with reported analgesic and diuretic effects in humans and rodents. The purpose of the present study was to characterize E2078 effects on food-maintained responding and diuresis in rhesus monkeys (*Macaca mulatta*). In monkeys trained to respond under a multiple-cycle FR30 schedule for food reinforcement, E2078 (0.001-0.032 mg/kg s.c.) dose-dependently decreased responding. The rate-suppressant effects were antagonized by the kappa selective antagonist nor-binaltorphimine (nor-BNI; 3.2 mg/kg s.c.). After nor-BNI administration, the potencies of both E2078 and the kappa receptor agonist U69,593 (0.001-0.1 mg/kg s.c.) were reduced for at least 5 weeks in this assay. E2078 (0.056-0.56 mg/kg s.c.) dose-dependently increased urine volume (ca. 400%). This effect was prevented by the opioid antagonist quazadocine (1.0 mg/kg s.c.) as well as nor-BNI (3.2 mg/kg). The effects of nor-BNI were again long-lasting, with the diuretic effects of E2078 and U50,488 returning to pre-nor-BNI levels after approximately 4 weeks. The results suggest that the dynorphin analog E2078 produces robust kappa-agonist effects in rhesus monkeys following systemic administration. Supported by USPHS Grants DA 00254 and DA 07268.

## 544.15

## EFFECTS OF DOPAMINE D3 RECEPTOR LIGANDS ON LOCOMOTOR ACTIVITY AND REWARD IN THE RAT

T. Kling-Petersen<sup>1</sup>, E. Ljung<sup>1</sup>, L. Wollter<sup>1</sup> and K. Svensson<sup>2</sup> <sup>1</sup>Dept. of Pharmacology, Medicinaregatan 7, 413 90 Göteborg, Sweden and <sup>2</sup>CNS Diseases Research, The Upjohn Company, Kalamazoo, MI 49001, USA.

Dopamine D3 selective agonists, like R-(+)-7-OH-DPAT produce a significant increase in reward thresholds over a wide dose range (0.094 - 96.0 nmol/kg, s.c.) while producing a decrease in locomotor activity over the same doserange in male, Spague Dawley rats. Similarly, the dopamine D3 antagonist U99194A (Haadsma-Svensson, et al. *J Med Chem* 1995, *In press*) produces an increase in locomotor activity (25.- 200 µmol/kg, s.c.) while a weak increase in reward thresholds (3.5 - 50.0 µmol/kg, s.c.) are seen in the ICSS model. U99194A is also capable of producing positive Conditioned Place Preference (12.5 - 100.0 µmol/kg, s.c.).

R-(+)-7-OH-DPAT, at doses that per se produced a increase in reward threshold, significantly enhanced d-amphetamines facilitatory effect on brain stimulation reward when administered in combination with d-amphetamine (0.25 or 1.0 mg/kg, s.c.). The same facilitatory effect is seen in the locomotor activity model. U99194A is also capable of enhancing the facilitatory effect of d-amphetamine (0.25 mg/kg, s.c. but not 1.0 mg/kg, s.c.) in the ICSS model, while U99194A produce a tendency to block the locomotor activity enhancing effects of d-amphetamine.

The present data support the hypothesis (Svensson, K. et al, *J Neural Transm*, 95, 71, 1994) that the functional D3 receptor is a postsynaptic receptor with a psychomotor inhibitory function on both behavior and reward.

## HYPOTHALAMIC-PITUITARY-ADRENAL REGULATION: OTHER I

## 545.1

LOSS OF INPUT FROM THE BED NUCLEUS OF THE STRIA TERMINALIS TO THE HYPOTHALAMIC PARAVENTRICULAR NUCLEUS AFTER ADRENALECTOMY. W.H.A.M. Mulders<sup>1</sup>, T.G.M. Hafmans<sup>1</sup>, J. Meek<sup>2</sup> Department of Anatomy and Embryology, University of Nijmegen, P.O. Box 9101, 6500 HB Nijmegen, The Netherlands.

Limbic structures, such as the hippocampus and amygdala, exert their influence on stress regulation predominantly by means of a projection to the bed nucleus of the stria terminalis (BNST), which in turn projects to the hypothalamic paraventricular nucleus (PVH). To evaluate the significance of the projection of the BNST to the PVH and in particular to the corticotropin-releasing hormone (CRH) neurons we investigated this projection in normal and adrenalectomized (ADX) Wistar rats. The latter were used for immunocytochemical detection of CRH, both on light microscopical and electron microscopical levels. The (length) density of labelled fibres and terminals in the PVH was quantified in 6 untreated and 7 ADX rats with similar injection sites in the medio-ventral BNST. Remarkably, the density was statistically significantly smaller in the whole PVH and all subdivisions of ADX rats (PVH:  $1.17 \pm 0.17 \cdot 10^3 \mu\mu^2$ ) than in untreated rats (PVH:  $2.59 \pm 0.12 \cdot 10^3 \mu\mu^2$ ;  $p < 0.004$ ). In addition, the relative density of fibers projecting to the CRH-rich part of the PVH was statistically significantly smaller in ADX rats ( $0.60 \pm 0.03$ ) than in untreated rats ( $1.10 \pm 0.0$ ;  $p < 0.01$ ) whereas the other subdivisions of the PVH showed no changes in relative density. Electron microscopical investigations showed no labelled synapses on CRH neurons and thus confirmed the absence of input from the BNST to CRH neurons after ADX. These results indicate a loss of input to the CRH neurons from the BNST following ADX and suggest a large stress-related plasticity at the level of the PVH.

## 545.3

AN INTEGRATIVE EXAMINATION OF STRESS EFFECTS ON THE HYPOTHALAMIC-PITUITARY-ADRENAL AXIS D.L. Helmreich<sup>1</sup>, M.I. Morano<sup>2</sup>, S.J. Watson<sup>3</sup> Mental Health Research Institute, Univ. of Michigan, Ann Arbor MI, 48109

Activation of the hypothalamic-pituitary-adrenal (HPA) axis by stress is a well documented response used by most mammals to maintain homeostasis after a challenge, and the impact of stress on individual components of the HPA axis has been previously characterized by us and other researchers. In the current study, we sought to determine the effects of stress on multiple components of the HPA axis, including secretagogue regulation at the level of the paraventricular nucleus of the hypothalamus (PVN) and receptor regulation at the level of hippocampus, within an individual animal in order to create an integrated view of stress effects on the HPA axis. To this end, adult male rats were subjected to either 5 days of a daily session of 1 hr of restraint stress (n=6), or 5 days of a daily session of non-habituating stressors (n=6). Unhandled animals (n=6) served as controls. On day 6, animals were euthanized via rapid decapitation; the brain, pituitary, and median eminence were quickly removed from each animal and frozen. Five days of non-habituating stress resulted in an increase in adrenal weight, and both stress paradigms resulted in a decrease in thymus weight. Preliminary results also suggest that 5 days of non-habituating stress resulted in an increase in mineralocorticoid receptor mRNA in the CA3 region of the hippocampus. Evaluation of these results, in concert with other means and ratios from individual animals, should provide a comprehensive and integrative view of the impact of stress on the HPA axis.

## 545.2

DISRUPTION OF CATECHOLAMINERGIC AFFERENTS DOES NOT ATTENUATE ACUTE FOOTSHOCK-INDUCED ACTIVATION OF STRESS-RELATED HYPOTHALAMIC NEUROSECRETORY NEURONS. H.-Y. Li<sup>1</sup>, A. Ericsson<sup>2</sup> and P.E. Sawchenko<sup>3</sup> The Salk Institute, La Jolla, Ca 92037

We showed previously that intermittent footshock induced the expression of the immediate-early gene, *c-fos*, in parvocellular CRF, and, secondarily, in magnocellular oxytocin and autonomic-related projection neurons of the paraventricular nucleus of the hypothalamus (PVH). In extrahypothalamic areas, footshock-responsive cell groups included ones associated with the limbic region of the telencephalon, somatosensory and nociceptive information processing, and brainstem catecholamine neurons. Since catecholaminergic neurons in the nucleus of the solitary tract and ventrolateral medulla comprised the dominant loci of footshock-responsive cells that were anatomically identified as projecting to the PVH, we evaluated these as a candidate afferent mediator of hypothalamic neuroendocrine responses. Using a retractable wire microknife, unilateral transections were placed in the coronal plane at the ponto-medullary junction. After 7 days' recovery, and 7 days' adaptation to the shock chamber, animals were exposed to a single footshock session (60 shocks of 1 mA current, 1 msec. duration, delivered randomly over 30 min), and sacrificed 2 hr later. Despite massive depletion of the aminergic innervation on the ipsilateral side, shock-induced Fos expression was comparable in strength and distribution in the PVH on both sides of the brain. This lesion did, however, result in a substantial reduction of Fos expression in the NTS and ventrolateral medulla on the ipsilateral side. These results contrast with those seen in response to a systemic cytokine (interleukin-1) challenge, where identical cuts ablated the Fos response in the ipsilateral PVH, but left the ipsilateral medullary induction comparable to that seen on the contralateral side. We conclude that in the footshock model, activation of medullary aminergic neurons is a secondary consequence of stress, and is mediated via a descending projection transected by our ablation. Stress-induced activation of medullary aminergic neurons does not necessarily imply an involvement of these cell groups in driving endocrine hypothalamic responses to a particular stressor.

## 545.4

GABA AND GLUTAMATERGIC LOCAL NETWORKS CONTROL CRF NEURON ACTIVITY IN ORGANOTYPIC CULTURES OF THE HYPOTHALAMIC PARAVENTRICULAR NUCLEUS. V. Bartanusz<sup>1</sup>, D. Muller<sup>2</sup>, R.C. Gaillard<sup>3</sup>, P. Sreit<sup>4</sup> and J.Z. Kiss<sup>5</sup> Department of Morphology and Department of Pharmacology, University of Geneva Medical School, Geneva Switzerland, Brain Research Institute, University of Zurich, Zurich Switzerland, Department of Endocrinology CHUV, Lausanne Switzerland

More than 60% of total synaptic connections within the paraventricular nucleus are of intrinsic (intracuclear) origin (Kiss et al. 1983). We have now investigated the role of this local circuitry in the control of CRF neuron activity. Paraventricular nuclei were microdissected from 200-400 µm thick hypothalamic slices of 5 days old rat pups and then organotypic slice cultures were prepared that retained a well preserved cytoarchitectonic organization of the CRF neuron population and its local environment in chemically defined medium for up to 5 weeks. Ultrastructural immunocytochemistry revealed that a large number of presynaptic boutons were immunoreactive with monoclonal antibodies raised against GABA or glutamate. The pharmacological block of GABA<sub>A</sub> receptor by bicucullin (20 µM) produced a robust (up to six fold) increase in CRF hormone release from the culture. This effect was completely abolished by the glutamate receptor antagonist 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX). Similarly, electrophysiological analyses of extracellular recordings from the CRF neuron subdivision showed that bicucullin markedly enhanced evoked EPSPs and resulted in the occurrence of spontaneous bursting activity. The effect of bicucullin was entirely reversed by CNQX (20 µM). We conclude that the functional activity of CRF neurons in these cultures is under a tonic inhibitory influence of an intrinsic GABA-ergic circuit. Suppression of GABA-ergic transmission appears to have a permissive role in inducing an increased activity of CRF neurons that is driven by excitatory glutamatergic synapses.

EFFECT OF MICROINJECTION OF MUSCIMOL INTO DORSOMEDIAL OR PARAVENTRICULAR HYPOTHALAMIC NUCLEUS ON STRESS-INDUCED INCREASES IN PLASMA ACTH IN RATS. S.M. Morin\*, E.H. Stoltz-Potter, and J.A. DiMicco. Dept of Pharmacol and Toxicol. and Prog. in Med. Neurobio., Indiana Univ. Sch. of Med., Indianapolis, IN 46202

Acute stress evokes large increases in heart rate (HR) and smaller increases in blood pressure (BP), and stimulates the release of adrenocorticotrophic hormone (ACTH). We have shown that microinjection of the GABA<sub>A</sub> agonist muscimol (MUS) 80 pmol into the dorsomedial hypothalamus (DMH) prior to air stress nearly abolishes these cardiovascular changes while similar injection into the paraventricular nucleus (PVN) has no effect. Here, we examined the effect of microinjection of MUS into either the PVN or the DMH on stress-induced release of ACTH which is thought to result from activation of CRF containing projections from the PVN. Rats, instrumented for the monitoring of HR and BP and for blood collection, received bilateral injection of either 80 pmol MUS or 100 nl saline vehicle (VEH) into the DMH (n=3) or the PVN (n=3) and were immediately placed in a restraining tube and subjected to 10 min of air stress. Blood samples were taken prior to microinjection and 10 min after the start of air stress. All injections were shown histologically to be in or within 200 µm of the target nucleus. As reported previously, injection of MUS into the DMH markedly attenuated stress-induced increases in HR (-71%) and BP (-88%), while injection of MUS into the PVN had no effect. Baseline plasma ACTH levels ranged from 16-84 pg/ml. Stress increased plasma ACTH levels by  $275 \pm 15$  pg/ml after injection of VEH into the DMH, but by only  $71 \pm 25$  pg/ml after injection of MUS (p=0.03; paired t-test). In rats receiving injections into the PVN, stress increased plasma ACTH levels by  $180 \pm 52$  pg/ml after VEH, and by  $117 \pm 38$  pg/ml after MUS (p>0.05; NS by paired t-test). Thus, stimulation of inhibitory GABA<sub>A</sub> receptors in the DMH suppresses both the cardiovascular and neuroendocrine effects of acute stress in rats. ## 545.7

ALTERATIONS OF NINE NEUROPEPTIDERGIC NERVE FIBERS IN THE EXTERNAL ZONE (EZ) OF THE MEDIAN EMINENCE (ME) OF THE RAT FOLLOWING SHORT TO LONG TERM ADRENALECTOMY (ADX). M. Yang\*, G. Cao, X. Zhao, K. Yang and Z. Lu. West China Univ. of Med. Sci., Chengdu, Sichuan, 610041, P.R. China.

In vivo and in vitro studies have confirmed that cholecystokinin octapeptide (CCK-8), corticotropin releasing factor (CRF), methionine-enkephalin (m-ENK), oxytocin (OT), somatostatin (SOM), substance P (SP), vasopressin (VP), and vasoactive intestinal peptides (VIP) are directly or indirectly involved in the regulation of release of ACTH during stress. The density of these neuropeptides containing nerve fibers, except CRF and VP, has not been completely studied following ADX. Using immunocytochemistry combined with Micro Image Analysis System we examined the density of nine neuropeptidergic nerve fibers in the EZ of the ME of adult male rats at 7, 21, 40, and 70 days following ADX. There was low density of the above neuropeptides containing nerve fibers in the EZ of the ME of the normal rats, except CRF and SOM containing nerve fibers that were of high density. The density of the nerve fibers containing VP increased significantly at 7 days; m-ENK and neurotensin (NT) increased significantly at 70 days after ADX. Nerve fibers containing CCK-8 and SP decreased significantly at 7 days while SOM decreased at 40 days. Nerve fibers containing CRF decreased dramatically at 7 days and returned to normal levels at 21 days after ADX; Nerve fibers containing OT and VIP were not altered. Overall, the response of these neuropeptidergic nerve fibers to ADX varied considerably. Nerve fibers containing CRF, AVP, CCK-8 and SP were altered rapidly and those fibers containing NT, m-ENK and SOM were altered slowly following ADX. The results suggest that in addition to CRF and AVP, other neuropeptides including CCK-8, NT, SOM, m-ENK, and SP are neurotransmitters/neuromodulators involved in the hypothalamo-pituitary-adrenal axis regulation, and may be involved in regulation of ACTH release during stress.

## 545.9

CHRONIC SOCIAL STRESS ALTERS BOTH HYPOTHALAMIC AND EXTRA-HYPOTHALAMIC VASOPRESSIN mRNA LEVELS IN RAT BRAIN. D.S. Albeck\*, D.C. Blanchard, R.J. Blanchard, J. Nikulina, C.R. McKittick, B.S. McEwen and R.R. Sakai. Rockefeller University, New York, NY 10021, University of Hawaii, Honolulu, HI 96822 and University of Pennsylvania, PA 19104

Dominance hierarchies are quickly established among male rats in a mixed sex colony (5 males, 2 females). The subordinate animals show physiological and behavioral effects of stress in these colonies. The subordinates can be divided into two groups, subordinate responders (SRS) and subordinate non-responders (NRS). This division is based upon the animal's ability or inability to show an increase in plasma corticosterone in response to a novel stressor (1 hr restraint stress). Using *in situ* hybridization we examined relative levels of vasopressin (AVP) mRNA levels in hypothalamic and extra-hypothalamic nuclei.

AVP mRNA levels in magnocellular regions did not vary as a function of behavioral rank. In contrast AVP mRNA expression per cell in the parvocellular region of the paraventricular nucleus was significantly greater in SRS rats than in NRS rats, while the total number of cells expressing AVP mRNA did not differ. In the medial amygdala AVP mRNA expression level per cell did not change, but the NRS rats showed significantly fewer AVP mRNA positive cells than when compared to control and dominant rats.

Paraventricular vasopressin projections to the median eminence act synergistically with corticotropin-releasing hormone as ACTH secretagogues. The current results suggest that in NRS rats this synergy is dysfunctional, possibly affecting the rats ability to show an increase in plasma corticosterone in response to a novel stressor. Behavioral consequences of disrupting vasopressin content of the medial amygdala are currently unclear although NRS rats exhibit behavioral deficits in risk assessment, overall motor activity and sexual behavior. ## 545.6

DIMINISHED "IN VIVO" HYPOTHALAMO-PITUITARY-ADRENAL (HPA) AXIS RESPONSE DURING MIDDLE AGE: EVIDENCE FOR AN ADRENAL IMPAIRMENT. M. O. Suescun, A. N. Chisari, M. E. Carino, A. Giovambattista and E. Spinedi\*. Neuroendocrine Unit, IMBICE, 1900 La Plata, Argentina.

The aim of the present work was to determine which level of the HPA axis could be mainly implicated in the decreased HPA axis function during middle-age. For this purpose, 2- and 15-month-old male mice were i.p. treated with: a) 0.1 µg ACTH, b) 0.5 µg CRH, c) 0.3 IU insulin (INS) or d) vehicle alone. Mice were then killed by decapitation at 20 min (ACTH), 30 min (CRH) or 45 min (INS) after treatment. Trunk blood was collected and plasma ACTH (IRMA) and corticosterone (B) (RIA) levels were determined. The results indicate that there were not age-related differences in basal (vehicle-injected mice, from both groups, killed at either 20, 30 or 45 min after treatment) plasma levels of both ACTH (mean  $\pm$  SEM of 10-12 mice per group:  $76.08 \pm 13.73$  vs.  $82.78 \pm 11.79$  pg/ml of plasma in 2- and 15-month-old mice, respectively) and B ( $6.07 \pm 1.05$  vs.  $4.35 \pm 1.21$  µg/dl of plasma, respectively). Plasma ACTH and B levels were significantly ( $P < 0.05$  or less) higher than the respective baseline, regardless the group, after the treatment with either stress stimulus and, we found not significant age-dependent differences in plasma ACTH concentrations after each stress treatment. Conversely, the adrenal response varied in an age-related fashion. In fact, B released in plasma after the injection of either ACTH, CRH or INS was significantly ( $P < 0.05$ ) higher in 2-month-old (mean  $\pm$  SEM, n = 8 mice per group:  $17.23 \pm 0.47$ ,  $19.94 \pm 1.75$  and  $23.86 \pm 1.01$ , respectively) than in 15-month-old mice ( $8.97 \pm 2.03$ ,  $10.27 \pm 1.59$  and  $15.31 \pm 1.49$ , respectively). Our results clearly indicate that middle-aged mice have impaired HPA axis response after the stimulation of either the hypothalamic, pituitary or adrenal level. Since full corticotrope responses were found to both INS and CRH stimuli, it remains to be determined whether adrenal ACTH receptor number or/and binding characteristics are responsible for such an impairment. (Supported by CONICET)

## 545.8

NEONATAL QUIPAZINE ADMINISTRATION DECREASES THE HYPOTHALAMIC-PITUITARY-ADRENAL (HPA) RESPONSE TO RESTRAINT STRESS IN ADULT RATS. B.M. Tannenbaum\*, S. Weaver, M.J. Meaney. \*McGill Univ., Douglas Hosp. Res. Ctr., Montreal, Canada H4H 1R3. \*Dept Animal Sci., Univ. of Alberta, Edmonton, Canada

Serotonergic input has been postulated to be involved in the upregulation of hippocampal glucocorticoid receptor (GR) levels in rats handled neonatally. Quipazine application to hippocampal cell cultures has been shown to increase GR levels (Mitchell et al., 1990, J. Neurosci. 10:1745). The increased GR levels are associated with a decreased HPA response to restraint in adult animals handled as neonates. In this study we tested whether *in vivo* quipazine application mimics the effects of neonatal handling on the response to restraint stress later in life. Male rat pups were injected either with 15 mg/kg (s.c.) quipazine dimaleate dissolved in sterile saline or saline alone from postnatal day 1-7. At 78 days of age animals were implanted with jugular catheters to obtain measures of plasma adrenocorticotrophic hormone (ACTH) before, during and following the termination of a 20 min. period of restraint. Quipazine-treated rats secreted significantly ( $p < 0.05$ ) less ACTH at 20 min. following the termination of restraint and had a trend towards lower ACTH levels at mid-restraint. Overall, integrated ACTH responses were significantly reduced in quipazine-treated animals. The results of this experiment demonstrate that neonatal quipazine administration does effect permanent changes in the response to restraint in adult rats and supports the importance of serotonergic inputs during development on the adult response to stress.

## 545.10

EXPOSURE TO STRESS EARLY IN DEVELOPMENT ALTERS HPA AXIS FUNCTIONING OF ADULT CONGENITALLY LEARNED HELPLESS (cLH) RATS. J.A. King\* and E. Edwards. \*Department of Psychiatry, Behavioral Sciences Division, University of Massachusetts Medical School, Worcester, MA 01655; \*Department of Pharmaceutical Sciences, Pharmacology & Toxicology, University of Maryland, Baltimore MD 21201.

This study examined the effects of early stressors (at postnatal day 7, day 14 and day 21) on the HPA axis functioning of cLH adult rats at baseline condition and after exposure to 40 minutes of electric footshock. Corticosterone (CORT) plasma levels were monitored in these rats exposed during development to maternal deprivation (MD) stress and to cold stress (CS). Unstressed cLH rats have CORT basal levels that were similar to controls (cNLH rats also not stressed during development). In response to early exposure to both CS and MD, there was a step-wise increase in CORT levels of cLH rats with age of presentation to either CS and MD. Day 7, 49% (1; day 14, 84% (1; and day 21, 54% (1). In response to acute footshock, adult cLH rats displayed a normal stress response if they had been exposed to CS and MD on day 7 and day 14. However, exposure to either stressor at day 21 resulted in a significant desensitization of the HPA axis (unstressed cLH rats after footshock:  $40 \mu\text{g/dl}$  CORT; day 21 CS stressed cLH rats after footshock:  $24.7 \mu\text{g/dl}$ ). These data are consistent with our findings of low baseline levels of ACTH in cLH rats stressed at day 21 with a hypersensitive ACTH response to acute stress in adulthood. Our results suggest that exposure to stress during development has long term consequences such as an altered functionality of the HPA axis in adulthood which is specially evident in response to challenge.

## 545.11

**AFFILIATIVE BEHAVIORS AND ENDOCRINE RESPONSES IN PERIADOLESCENT RATS.** E. Cirulli\*, M. L. Terranova and G. Laviola. Behav. Pathophysiology Sect., Lab. FOS, Istituto Superiore di Sanità, Viale Regina Elena 299, 00161, Rome, Italy.

Adrenal hormones have been shown to modulate social bonding in several mammalian species. In the developing rat, periadolescence [postnatal day (PND) 32-43] is characterized by elevated levels of affiliative and playful social interactions which have been suggested to underlie bond formation and the establishment of socio-sexual roles. Aim of this study was to examine the relationship between hypothalamic-pituitary-adrenal (HPA) axis activity and behavioral responses following separation and reunion of familiar and unfamiliar periadolescent rats. Sprague-Dawley rats have been kept in pairs with a same sex littermate from the time of weaning (PND 21). On PND 33 the members of each pair were separated for a 24-hr period, and randomly assigned to three groups: a) immediately sacrificed (SEP); b) reunited for 30 min with their previous cagemate (FAM); c) reunited for 30 min with an unfamiliar conspecific of the same age and sex (UNF). During the reunion both social and non-social behaviors were scored. Overall, higher levels of rough-and-tumble play were observed in encounters between UNF subjects, and this was more evident in the male group. UNF females were more involved in affiliative behaviors than in cage exploration than FAM. Blood corticosterone (CORT) levels measured at the end of the separation period did not differ from base and were higher in females than in males. Following reunion, all subjects showed increased CORT levels. Degree of familiarity did not affect hormonal changes in males, while UNF females showed a lower CORT elevation than FAM subjects. Overall, no direct relationship was found between behavioral and hormonal parameters in males, while data suggest a negative correlation between affiliative behaviors and HPA axis activation in females.

## 545.13

**ESTROGEN ALTERS NEUROENDOCRINE RESPONSES TO PSYCHOLOGICAL STRESS IN THE RAT.** E.W. Bingham\*, L.D. Van de Kar, J.M. Yracheta, Q. Li, T.S. Gray. Dept. of Cell Biol., Neurobiol., and Anatomy and Dept. of Pharmacol. and Exp. Ther., Loyola Univ. of Chicago, Maywood, IL 60153.

Circulating androgens differentially influence various neuroendocrine and behavioral responses to conditioned stress. This study tested whether estrogen modulates several important parameters of the conditioned stress response. Male and female Sprague/Dawley rats were used in this study. Female rats were ovariectomized using halothane anesthesia. These animals received either estrogen replacement (OVX+E) or a sham incision (OVX). Two weeks later, animals were subjected to a conditioned stress paradigm. On three consecutive days, experimental rats were placed in a chamber for 10 minutes and then received a 10 second footshock. On the fourth day, rats were placed in the chamber but did not receive a shock. Control rats were treated identically but were never shocked. The corticosterone ( $p < .05$ ) and prolactin ( $p < .01$ ) responses to conditioned stress were significantly potentiated in OVX+E rats compared to OVX female and intact male rats. However, the ACTH response to conditioned stress was significantly ( $p < .01$ ) higher in OVX rats compared to intact males and OVX+E females. The stress-induced increase in plasma renin concentration was potentiated ( $p < .05$ ) in OVX+E rats compared to intact males while the stress-induced increase in plasma renin activity was lower ( $p < .05$ ) in OVX rats compared to OVX + E females. This suggests differences in both renin and renin substrate. Behavioral responses to conditioned stress did not differ among males, OVX females, and OVX+E females. These data indicate that estrogen mediates several, but not all, aspects of the response to psychological stress. Supported by NIH NS20041.

## 545.15

**A LONG-TERM INCREASE IN BASAL LEVELS OF CORTICOSTERONE AND A DECREASE IN CORTICOTROPIN-BINDING GLOBULIN FOLLOWING ACUTE STRESSOR EXPOSURE.** M. Fleshner\*, T. Deak, R. L. Spencer, M. J. Laudenslager, L. R. Watkins, & S. F. Maier. Dept. Psych., Univ. CO, Boulder, CO 80309. <sup>1</sup>Dept. Psychiatry, U. CO. Health Sci. Cntr., Denver, CO.

Adrenal glucocorticoids play an important role in mediating many of the behavioral and physiological effects of exposure to stressors. Focus has been primarily on the acute stress-induced rise in glucocorticoids (corticosterone in the rat). There are reports, however, that exposure to chronic stressors can produce an increase in basal corticosterone and a decrease in corticotropin-binding globulin (CBG). These changes occur subsequent to the stress-induced rise in corticosterone. The following experiments examined whether exposure to an acute stressor (100 5-s inescapable tail shocks; IS) could also produce long-term changes in basal corticosterone (RIA) and CBG (competitive binding assay). We report that rats ( $n = 6/\text{grp}$ ) exposed to a single session of IS show increases in basal total serum corticosterone which persists 48-96 hours after IS termination. The increase is present only at the diurnal trough (AM). CBG levels are also decreased for 24-48 hours. The decrease is present at both the diurnal peak (PM) as well as trough (AM). These changes also result in an increase in the percent and amount of unbound or free corticosterone (biologically active). Thus glucocorticoid sensitive targets are exposed to high levels of free corticosterone for several days after IS termination. The long-term increase in free corticosterone reported here may play an important role in mediating some of the effects produced by IS, as well as those produced by other acute stressors. NIH-MH45045.

## 545.12

**EFFECT OF ACTH TREATMENT TO AMINOGLUTETHIMIDE TREATED RATS ON THEIR HPA AXIS RESPONSES TO STRESS.** Y.N. Wong and A.P. D'mello\*. Dept. of Pharmaceutics, Philadelphia College of Pharmacy and Science, Philadelphia, PA 19104.

The existence of stress induced facilitation has been revealed by the transient removal of corticosterone (B) response during the first stressor and the consequent sensitization of ACTH and B responses to a second stressor. Stress stimulates the secretion of a variety of ACTH and B secretagogues making it difficult to delineate the possible contribution of each factor to stress induced facilitation. The objective of the present study was to examine the specific role of ACTH in stress induced facilitation. Male Sprague-Dawley rats whose B responses to stress were transiently inhibited with aminoglutethimide (AG), were subjected either to an 1 hour physical immobilization stressor (IMM), or administered a single 50 µg/kg s.c. dose of ACTH. Twenty four hours later both groups of rats were subjected to the mild stress of a saline injection (INJ). Plasma ACTH and B were measured 15 and 30 minutes after the injection. As previously demonstrated, AG+IMM pre-treatment on day 1 caused hypersecretion of both B and ACTH to the INJ on day 2. However, the AG+ACTH pre-treatment on day 1 caused the hypersecretion of only B on day 2. The magnitude of B hypersecretion caused by both pre-treatments were similar. These results suggest that ACTH secreted during the first stressor might be responsible for stress induced facilitation of B responses to a subsequent stressor.

## 545.14

**MECHANISMS OF ACUTE STRESSOR-INDUCED CHANGES IN CORTICOSTEROID BINDING GLOBULIN (CBG).** T. Deak\*, M. Fleshner, J. L. Mariwether, L. Goehler, L. R. Watkins, R. L. Spencer & S. F. Maier. Dept. of Psychology, Univ. of Colorado, Boulder, CO 80309.

CBG is a protein responsible for the serum transport of corticosterone (CORT). Past research has demonstrated that exposure to chronic stressors or chronic high levels of glucocorticoids (GC's) causes a substantial decrease in serum levels of CBG. We have recently demonstrated that this effect can also be observed in rats exposed to a single session of inescapable shock (IS; see Fleshner et al., companion abstract). We now report that the mechanism of CBG downregulation following IS is independent of GC regulation. In all experiments, a baseline blood sample was taken from the tail vein (400 µl in <2 min), rats were exposed to 100 tail shocks (5 sec, 1.6 mA, 1 min ITI), & a second blood sample was taken 24 hours post shock. Both serum CORT & CBG were measured in each experiment (by RIA & single-point binding assay, respectively). Neither bilateral adrenalectomy (with chronic basal CORT replacement) nor i.p. RU 486 (10 mg/kg), a type II GC receptor antagonist, had any effect upon IS-induced decreases in CBG. Likewise, an injection of CORT (2.5 mg/kg i.p.) which produces stress levels of CORT was not sufficient to reduce CBG. In addition, we investigated whether autonomic innervation of the liver, the primary source of CBG, is necessary for the IS-induced decrease in CBG. Disruption of neither parasympathetic nor sympathetic innervation of the liver was able to block the IS-induced decrease in CBG. Alternative mechanisms of CBG regulation will be discussed, as well as the implications for circulating levels of corticosteroids. Supported by NIH Grant MH45045 & Undergraduate Research Opportunities Program.

## 545.16

**EFFECT OF LOCUS COERULEUS LESIONS ON THE ACTIVITY ON THE HYPOTHALAMUS-PITUITARY-ADRENAL (HPA) AXIS.** D.R. Ziegler\* and J.P. Herman. Dept. of Anatomy and Neurobiology, University of Kentucky Medical Center, Lexington, KY 40536-0084.

Recent studies have shown that activation of the HPA stress axis stimulates activity in the locus coeruleus (LC), which, in turn, leads to noradrenergic excitation of the forebrain and increased arousal. We have investigated whether this relationship is reciprocal, that is, does the LC influence the HPA axis response to stress? Naive, male Sprague-Dawley rats were microinjected in the locus coeruleus with either 6-hydroxydopamine (with ascorbic acid in saline) or vehicle. After a 7-10 day recovery period, the lesion and sham groups were further partitioned into stressed and control (handling) groups with stressed subjects undergoing a chronic variable stressor regimen applied twice a day for 2 weeks. The morning after the last day of stress/handling, all subjects were sacrificed and thymus, adrenal glands, trunk blood, and brains were collected. Data on body weight gain, adrenal hypertrophy, and thymic involution all showed a trend toward a significant difference between stressed and control subjects; however, this response was less robust than has been observed in other experiments using a 4 stress week regimen. Plasma ACTH and CORT as well as the tissue data failed to show a significant interaction between stress and lesion factors. However, it appears that LC lesions, regardless of stress or handling, elevated plasma CORT and lead to adrenal hypertrophy. Single-trial open-field behavior (immobility, ambulation, rearing, defecation) was not substantially influenced by either stress or lesion. Forthcoming data will reveal whether effects of LC lesion are exerted on central components of HPA regulation (corticotropin releasing hormone, glucocorticoid receptor and mineralocorticoid receptor protein and mRNA). Supported by MH49698.

## 545.17

CONNECTIONS BETWEEN THE AMYGDALOID CENTRAL NUCLEUS AND THE PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS: A COMBINED RETROGRADE-ANTEROGRADE TRACING STUDY. C.M. Prewitt\* and J.P. Herman. Dept. of Anatomy and Neurobiology, Univ. of Kentucky Medical Center, Lexington, KY 40536-0084.

The central nucleus of the amygdala (ACE) has been shown to affect regulation of the HPA stress axis. Bilateral lesion of ACE decreases basal CRH mRNA in paraventricular nucleus (PVN) and stress-induced release of ACTH. However, there is scant evidence to support direct projections from the ACE to the PVN region. The present studies were designed to assess potential bisynaptic forebrain circuits relaying information from the ACE to the PVN. Rats were injected with 2% fluorogold (FG) (retrograde tracer) in the PVN and with 2% PHA-L (anterograde tracer) into the ACE. Tracer distribution was revealed by immunohistochemistry. PHA-L injections were mostly confined within the lateral part of ACE; the major forebrain projection fields were primarily relegated to the juxtacapsular, ventrolateral and posterolateral subnuclei of the bed nucleus of the stria terminalis (BNST), with some labeling seen in the lateral and dorsomedial hypothalamus. No anterograde labeling was seen in the PVN. Retrograde labeling from PVN injections labeled numerous hypothalamic and preoptic nuclei and the ventromedial and posterior intermediate subdivisions of the BNST. FG labeling in the amygdala was confined to the medial division; no retrogradely labeled cells were seen in the ACE. Appositions of PHA-L fibers to FG-labeled neurons were very rare, generally being localized in the ventral region of the posterolateral BNST. No appositions were seen in hypothalamic nuclei. These data suggest that despite apparent action of the ACE on the HPA axis, connections between the ACE and PVN are unlikely to form bisynaptic connections through the BNST or hypothalamus. Supported by MH49698.

## 545.19

REVERSAL OF NEUROENDOCRINE EFFECTS OF CHRONIC STRESS BY THE TRANSCENDENTAL MEDITATION TECHNIQUE D.K. Levitsky, K.G. Walton\*, C.R.K. MacLean, N.D. C. Pugh, S.W. Wenneberg, R.H. Schneider, J.Y. Mandarino, S. Hillis<sup>2</sup>, R. Waziri<sup>1</sup>. Departments of Physiology and Chemistry, Maharishi International University, Fairfield, IA 52557 and Departments of <sup>1</sup>Psychiatry and <sup>2</sup>Statistics and Actuarial Science, University of Iowa, Iowa City, IA 52242

A previous cross-sectional study comparing long-term practitioners of Transcendental Meditation (TM) to matched controls showed highly significant differences in urinary variables reflecting neuroendocrine function. In particular, TM practitioners had decreased excretion of urinary free cortisol, aldosterone, vanillylmandelic acid, zinc, calcium and sodium, and increased excretion of dehydroepiandrosterone and nighttime 5-hydroxyindoleacetic acid (5-HIAA). In addition, TM practitioners had reduced scores on tests of anxiety and mood disturbance. These and other results suggested that the differences were due to reversal of the effects of stress by the TM program. The current prospective, random-assignment study attempted to verify this hypothesis. Healthy, Caucasian males (18-32 y) were randomly assigned to either TM or a stress education control (SEC). Before and after four months' practice of the assigned stress management program, three contiguous 8-hour urine collections were taken and psychological self-report tests sensitive to level of psychosocial stress were administered. Urine samples were analyzed for 5-HIAA by spectrophotometry, for adrenocortical steroids by RIA and for Na, K, Ca, Mg and Zn by atomic absorption spectrometry. Fourteen out of 15 key variables changed in the direction predicted for the reversal of effects of chronic stress in the TM group, whereas 7 out of the 15 changed in a direction opposite to that predicted for reversal of the effects of chronic stress in the SEC group. If changes produced by TM are cumulative over time as these and other results suggest, then the present results provide strong confirmation that TM reverses the neuroendocrine effects of chronic stress related to function of the HPA axis. Supported by NIH Research Grant #1 R15HL 40495 01A1, and NIH Grant #RR59, Clinical Research Centers Branch.

## 545.18

HPA AXIS AND ANXIETY IN ADOLESCENT PREGNANCY. A. Chicz-DeMet\*, B. Simon, T.D. Wu, H.C. Cunanen, H.A. Cornett, D. Lee, A.F. Johnson, T.D. Thai, M.S. Scott, and T. Fisher. Dept. Psychiatry & Human Behavior, UC Irvine, CA 92717.

Anxiety and stress often disturb the hypothalamic-pituitary-adrenal (HPA) axis and may contribute to poor birth outcome. Fifty-five expectant adolescents were administered the Symptom Checklist 90 Revised questionnaire during the third trimester of pregnancy to assess anxiety and stress. As expected, significant correlations were found between plasma  $\beta$ -endorphin and ACTH ( $r=0.568$ ,  $p<0.001$ ), and ACTH and cortisol ( $r=0.423$ ,  $p<0.001$ ) in expectant mothers. Prepartum anxiety scores were correlated with maternal distress indices (Global Severity Index,  $r=0.905$ ,  $p<0.001$ ); Positive Symptom Total,  $r=0.812$ ,  $p<0.001$ ), maternal infection during pregnancy ( $r=0.401$ ,  $p=0.002$ ), and fetal heart rate during labor ( $r=0.378$ ,  $p=0.004$ ). Anxiety ratings and distress indices, however, were not associated with stress hormones. Prepartum anxiety for mothers with preterm deliveries ( $N=5$ ) was 70% lower than for mothers with term births. Six month postpartum decreases in anxiety scores ( $N=38$ ) were not significant and may be attributed to the appreciably low prepartum anxiety scores. The results support a putative role of anxiety as a risk factor in pregnancy, and at labor and delivery, but fail to confirm a relationship between anxiety and stress hormone dysregulation in this small sample.

## 545.20

SPONTANEOUS VARIABILITY OF THE HUMAN WAKING EEG AND ACTH, CORTISOL AND GLUCOSE BLOOD CONCENTRATIONS W.G. Sannita\*, D. Giglioli, L. Lopez, S. Massimilla, G. Murialdo, DISM-Neurophysiopathology and DISEM. University, Genoa, Italy; Center for Cerebral Neurophysiology, CNR, Genoa, Italy; Dept. of Psychiatry, SUNY, Stony Brook, NY, USA.

Pathological unbalances and the exogenous administration of ACTH or glucocorticoids induce neuropsychological and EEG modifications congruent with the effects of substitutive hormone treatment or ACTH-fragments and with the evidence of steroid action on neurons. The spontaneous fluctuations of the quantitative (power spectral analysis) waking resting EEG and plasma ACTH, cortisol and glucose concentrations were studied in 8 male volunteers ( $24.5 \pm 1.7$  yr.) EEG recordings and blood samples (6 per subject) were obtained at pre-defined intervals during a 6-h experimental session. Glucose, cortisol and ACTH concentrations (hexokinase-G6P-DH assay or RIA) were within normal ranges, respectively  $3.37-5.6$  mmol/L,  $7.8-47.2$  nmol/L and  $3.1-17.6$  pmol/L, without pulsatile changes or correlation among variables. Systematic trend over time were not observed, with the exception of a consistent decrease of plasma cortisol. Changes in the neuropsychological status (including the visuo-spatial function) were not detected. The signal power in the  $6.5-14.0$  Hz frequency interval (corresponding to the "alpha" rhythm) of the EEG changed in phase with, and was correlated to the fluctuations of ACTH in the absence of cortisol/glucose EEG effects. Two subgroups of subjects with lower or higher EEG power values and ACTH levels respectively were identified, with cut-off between subgroups at approximately  $8-10$  pmol/L, therefore suggesting some influence of the neuro-hormonal status on the between-subject EEG variability. The correlation of ACTH and EEG appeared independent of glucose availability and not mediated through cortisol action; a role of common factors active on, and pacing the spontaneous and physiological variations in both ACTH and EEG (such as the corticotropin releasing factor) is conceivable.

## HYPOTHALAMIC-PITUITARY-ADRENAL REGULATION: CRF

## 546.1

REGULATION OF CORTICOTROPIN-RELEASING HORMONE (CRH) RECEPTOR mRNA IN THE RAT BRAIN AND PITUITARY BY GLUCOCORTICOID AND STRESS. Shinya Makino<sup>1</sup>, Jay Schulkin<sup>1</sup>, Mark A. Smith<sup>2</sup>, Karel Pacák<sup>3</sup>, Miklós Palkovits<sup>4</sup>, and Philip W. Gold<sup>1</sup>. Clinical Neuroendocrinology Branch<sup>1</sup>, Biological Psychiatry Branch<sup>2</sup> and Laboratory of Cell Biology<sup>4</sup>, NIMH, and Clinical Neuroscience Branch<sup>3</sup>, NINDS, Bethesda, MD 20892.

We used *in situ* hybridization to measure CRH receptor (CRH-R) mRNA levels in the paraventricular nucleus (PVN), anterior pituitary (AP), amygdala and bed nucleus of the stria terminalis (BNST) under several conditions. Systemic corticosterone (CORT) treatment decreased CRH-R mRNA in the PVN, AP, and lateral and basolateral nucleus of the amygdala (BLA). Acute (2 hrs) and repeated (2 hrs daily, 14 days) immobilization stress increased CRH-R mRNA in the PVN and decreased it in the AP, but did not affect CRH-R mRNA in the BLA. Adrenalectomized rats with CORT pellet replacement had higher levels of CRH-R mRNA both in the PVN and AP than sham rats following stress. Brainstem hemisection which damaged ascending catecholaminergic fibers attenuated immobilization stress-induced upregulation of CRH-R mRNA ipsilaterally in the PVN. None of the treatments affected CRH-R mRNA levels in the central and medial nucleus of the amygdala or the BNST. These results suggest that high concentrations of CORT inhibit CRH-R mRNA transcription in the PVN and AP. However, stress input can override such inhibitory effects and thus upregulate CRH-R mRNA in the PVN. The extrahypothalamic regions such as amygdala and BNST may have different sensitivities to CORT or CRH for the regulation of CRH-R mRNA.

## 546.2

MEASUREMENT OF RAT CRH mRNA EXPRESSION DURING HEMORRHAGE USING QUANTITATIVE PCR AND CAPILLARY ELECTROPHORESIS. W.J. Gdula, D.N. Darlington, J.M. Butler, B.R. McCord and D.S. Gann\*. Dept. of Surgery, Univ. of Maryland Sch. of Med., Baltimore, MD 21201 and FBI Laboratory, Forensic Science Research Unit, FBI Academy, Quantico, VA 22135.

We have developed a method to measure changes in mRNA in specific brain nuclei. This method converts extracted mRNA to cDNA by reverse-transcription and amplifies cDNA by polymerase chain reaction (PCR). To control for PCR efficiency between samples, known amounts of competitor cDNA (constructed to have the same primer hybridization sites, but of a different size) are co-amplified with the wild-type cDNA. To test this method, eight Sprague Dawley rats (300g) received a 20ml/kg hemorrhage or sham hemorrhage and the paraventricular nuclei were punched (1.5mm diameter x 2mm) at 2h. Total RNA was extracted, converted to cDNA, spiked with competitive template and amplified for 28 cycles. The products were separated by capillary electrophoresis and measured using laser induced fluorescence of intercalating dye. We found that hemorrhage elevated CRH mRNA ( $3.51\text{pg}/4\text{punches}$  vs.  $3.01\text{pg}/4\text{punches}$ ; sham). This is the first application of quantitative PCR for measuring mRNA in brain areas after hemorrhage and confirms previous findings from our laboratory. This study was supported by GM46540 and GM08414.

## 546.3

CHANGES IN CRH AND AVP mRNA AFTER ADRENALECTOMY, WATER DEPRIVATION AND HEMORRHAGE IN THE RAT. E. J. Weeks, D. N. Darlington\*, M. Tehrani and D. S. Gann. Depts. of Surg. and Physiol., U. of MD Sch. of Med., Baltimore, MD 21201.

To determine if CRH and AVP mRNA change after adrenalectomy (ADX), water deprivation (DEP) or hemorrhage (HEM), the paraventricular (PVN) and supraoptic (SON) nuclei of 48 S-D rats were punched and snap-frozen after 3days ADX, 3days DEP or 20ml/kg HEM. Total RNA was extracted, reverse transcribed to cDNA and the cDNA for CRH, AVP and the constitutively expressed glyceraldehyde phosphate dehydrogenase (GAPDH) were amplified by PCR. PCR products were measured by UV detection after HPLC and analyzed as areas under the curve. To semi-quantitatively estimate mRNA changes and to control for PCR efficiency, CRH and AVP products were expressed as ratios to the externally amplified GAPDH products. ADX led to a rise in PVN CRH mRNA ( $0.464 \pm 0.079$  vs sham  $0.178 \pm 0.083$ ). DEP led to a rise in AVP mRNA in the SON ( $1.12 \pm 0.317$  vs. Cont.  $0.573 \pm 0.114$ ) but not PVN ( $0.145 \pm 0.085$  vs. Cont.  $0.250 \pm 0.183$ ). HEM led to a rise in CRH mRNA that peaked by 4hrs and returned to normal by 8, 12 and 24hrs. AVP mRNA did not change after HEM in PVN or SON. Utilizing a highly sensitive method of detection, HEM, which increases both plasma ACTH and AVP, increases mRNA for CRH but not AVP. Supported by GM46540 and GM08414.

## 546.5

SPECIFIC IMMUNOTARGETED LESIONS OF CRF OR AVP NEURONS OF THE PVN AFFECT CORTICOTROPE FUNCTION BUT NOT LH SECRETION IN LACTATING RATS. A. Burlet\*, C-D. Walker, P. Tankosic, F.J. Tilders, D. Lavallée. INSERM U308, University of Nancy, France and McGill University, Douglas Hospital Research Center, Montreal, Canada.

Lactation in the rat is associated with elevated corticosterone (B) release, blunted adrenocortical responses to stress and inhibition of LH secretion. Since tonic activation of the adrenocortical axis might mediate LH suppression, we tested the effect of specific lesions of CRF or AVP neurons of the hypothalamic paraventricular nucleus (PVN) on 1) the inhibitory action of suckling on LH release and 2) the ACTH response to hypotensive stress during lactation. Ovariectomized females were injected over the PVN on day (d) 2 of lactation with ricin A (TX) associated to either a monoclonal anti-CRF (CRF-TX), anti-AVP (AVP-TX) antibody or to non-specific IgGs (IgG-TX). On d7, the ability of suckling to decrease LH release was measured after 24h of pup separation. On d10 and d12, ACTH and B responses to nitroprusside infusion were measured with (d10) or without (d12) pups. Hypothalamic CRF and AVP peptide and mRNA content were determined by immunocytochemistry and *in situ* hybridization, respectively. Effective PVN lesions were confirmed by a specific decrease in both peptide and mRNA levels in CRF-TX and AVP-TX groups. In AVP-TX group, CRF mRNA levels were decreased in addition to AVP mRNA, suggesting an enhanced sensitivity of a CRF/AVP-containing cell population during lactation. Suckling-induced LH decrease was not affected by either CRF or AVP lesions. However, restoration of normal ACTH responses to stress following pup separation was prevented in CRF-TX group compared to AVP-TX or IgG-TX groups, suggesting a preferential role for CRF neurons in the "reactivation" of the adrenocortical axis after lactation. The ability of PVN CRF and AVP neurons to functionally compensate for specific lesions during lactation remains to be established. (Funded by MRC Canada-CNRS).

## 546.7

CORTICOTROPIN RELEASING HORMONE (CRH) REGULATION OF ANTERIOR PITUITARY (AP) PROOPiomelanocortin (POMC) mRNA LEVELS IN FETAL SHEEP IS GESTATIONAL AGE DEPENDENT. D. A. Myers\*. Dept. Physiol., Coll. Med. Univ. of Oklahoma, Health Sci. Center, Oklahoma City, OK 73190.

AVP and CRH regulate AP ACTH secretion in fetal and adult sheep. AVP and CRH regulation of AP POMC expression in fetal sheep has not been examined with respect to development. Neither CRH nor AVP increases POMC mRNA levels in AP from adult (Endo 132:1692) or near term fetal sheep (J. Endo. 143:199). During late gestation in fetal sheep, paraventricular nuclei/ adrenocortical-dependent morphologic maturation of AP corticotropes occurs. The purpose of this study was to examine AVP and CRH modulation of POMC mRNA levels at two fetal ages: 120-122 days of gestation (dG), before the onset of fetal adrenocortical/corticotrope (A/C) maturation (n=10 fetuses), and 142-144 dG, after A/C maturation (n=4 fetuses; 147 dG-term). Fetal AP were enzymatically dispersed. After 48 hours of culture, cells were challenged (18h) with CRH, AVP or both ( $10^{-6}$  to  $10^{-10}$ M). POMC mRNA levels were also determined at dispersion, and 24 h post-dispersion for each group. At 120-122dG, CRH but not AVP increased POMC mRNA; AVP had no effect on CRH induced increase in POMC mRNA. At 142-144 dG, neither CRH nor AVP affected POMC mRNA levels, similar to reports for adult or late gestation sheep. At 120-122 dG, there was a small, but non-significant increase in POMC mRNA levels during the initial 24 h post-dispersion. At 142-144dG, POMC mRNA levels increased significantly during the initial 24 h post-dispersion. The results indicate that CRH regulation of ovine POMC gene expression may be dependent on 1) development; and 2) the level of adrenocortical activity. Supported by NIH R29 HD31127-01A1.

## 546.4

FETAL ETHANOL EFFECTS ON HYPOTHALAMIC CRF mRNA LEVELS FOLLOWING STRESS IN DEXAMETHASONE (DEX) TREATED ANIMALS. J.A. Osborn, C.K. Kim, W.K. Yu, L. Herbert, R.T. Zoeller and J. Weinberg\*. Department of Anatomy, Univ. of British Columbia, Vancouver, V6T 1Z3 Canada.

Rodents prenatally exposed to ethanol (E) demonstrate hypothalamic-pituitary-adrenal (HPA) hyperresponsiveness to stressors compared to controls. We have shown that E animals are less sensitive than controls to DEX suppression of the HPA stress response, with differential effects in males and females which are dependent on circadian rhythm. The present study investigated the possibility that hypothalamic corticotropin releasing factor (CRF) and/or vasopressin (AVP) mRNA levels may be differentially altered following stress in E males and females.

Sprague-Dawley male and female offspring from (E), pair-fed (PF), and ad lib-fed control (C) groups were tested at 80-140 days of age. Three hr post saline or DEX injection, animals were exposed to 1 min ether stress and decapitated 1 hr later. Plasma corticosterone (CORT) levels were determined. *In situ* hybridization was performed using  $^{35}$ S-labeled cDNA oligonucleotide probes for AVP and CRF in the paraventricular nucleus of the hypothalamus.

DEX injected males had significantly lower plasma CORT levels and lower CRF mRNA levels than saline injected males; there were no differences among E, PF and C males. In contrast, CRF mRNA levels were significantly higher in E than PF females and marginally higher in E than C females. DEX injected females had significantly lower plasma CORT levels than saline injected females; there were no differences among E, PF and C females. There were no differences in AVP mRNA levels among E, PF and C males or females. These data extend our previous work demonstrating a sex difference in sensitivity to DEX suppression in E animals and suggest that altered CRF biosynthesis in E animals may play a role in mediating HPA hyperresponsiveness. Supported by AA07789 NIAAA (J.W.), AA08887 NIAAA (R.T.Z.) and a Studentship, MRC of Canada (J.A.O.).

## 546.6

DIFFERENTIAL EXPRESSION OF *FOS/JUN* FAMILY IN THE PARAVENTRICULAR NUCLEUS (PVN) INDUCED BY STRESS: ITS RELATIONSHIP TO CORTICOTROPIN-RELEASING FACTOR (CRF) GENE TRANSCRIPTION. T. Imaki, T. Shibasaki, N. Chikada, S. Harada, M. Naruse, H. Demura and J. Imaki\*. Dept. of Medicine, Tokyo Women's Medical College, and Dept. of Anatomy, Nippon Medical School, Tokyo, 162, Japan

Stressful stimuli evokes the transcriptional activation of CRF gene and the *fos/jun* family. To determine a possible relationship between *fos/jun* expression and CRF gene transcription by stress, we have analyzed the expression of *fos/jun* family mRNA, and CRF heteronucleic RNA (hnRNA), which reflects gene transcription, after stress using *in situ* hybridization. Male Wistar rats were perfused transcardially 0, 5, 10, 15, 30, 60, and 120 min after beginning of 30 min-restraint. Brain sections were hybridized with  $^{35}$ S-labeled cRNA probes. Restraint stress induced rapid (within 5 min) and transient increases in *c-fos* mRNA and CRF hnRNA expressions in the PVN, with peak expression occurring at 30 min. The induction of *jun-B* was seen later than that of *c-fos* mRNA and CRF hnRNA. By contrast, *jun-D* and *c-jun*, which were constitutively expressed in the PVN, increased slightly following stress. These results suggest that differential expression of *fos/jun* gene occur in the PVN neuron following stress. None of the *fos/jun* gene studied was induced before CRF hnRNA expression, suggesting that *fos/jun* gene may not directly activate CRF gene transcription in the PVN.

## 546.8

DEVELOPMENT OF AN IMPROVED LIGAND FOR CRF RECEPTOR CHARACTERIZATION USING A RADIOLABELLED CRF ANTAGONIST M.H. Perrin, S. Sutton, J. Gulyas, D. Lovejoy\*, J.E. Rivier, and W.W. Vale. The Clayton Foundation Laboratories for Peptide Biology, The Salk Institute, La Jolla, CA 92037

In many receptor systems, labelled antagonists have advantages over agonists for the characterization of receptor structure and function. Astressin is a CRF receptor antagonist with greater potency than any previous peptide antagonist (Rivier et al., 1995 Ann. Mtg Soc. Neurosci.). The CRF receptors belong to the super-family of G-protein coupled receptors. In this super-family, the binding of agonists is usually to two sites (high and low affinity), whereas that of antagonists is mainly to one site. In our previous CRF receptor studies we have used the radiolabelled CRF agonist,  $^{125}$ I-(Nle<sup>21</sup>, Tyr<sup>32</sup>)-ovine CRF, for characterization of the natural and cloned (CRF-RA and CRF-RB) receptors. We describe here the binding of a potent CRF antagonist, Tyr<sup>12</sup>-astressin, for use as a tracer for characterizing CRF receptors. Iodinated Tyr<sup>12</sup>-astressin binds to cloned CRF-RA stably expressed in CHO cells with a K<sub>d</sub>=1.8nM; there are approximately 4x as many receptors when measured using the labelled antagonist as measured by the labelled agonist. The radiolabelled antagonist is equally well bound at 4, 18, and 37 C, reaches steady state at 20 C within 60 min and is stable for 120 min. Micromolar concentrations of guanyl nucleotides displace the labelled agonist bound to the cloned receptor but fail to displace the labelled antagonist. Both agonists and antagonists competitively displace the labelled antagonist in a dose dependent fashion in good agreement with their biological potencies. Astressin also binds with nanomolar affinity to the second cloned receptor, CRF-RB. This antagonist should prove of use for the characterization of CRF receptors and their ligands.

## 546.9

## STIMULATORY INFLUENCE OF EtOH ON ACTH SECRETION: ROLE OF VASOPRESSIN AND CORTICOTROPIN-RELEASING FACTOR.

Catherine Rivier\* and Soon Lee. The Clayton Foundation Laboratories for Peptide Biology, The Salk Institute, La Jolla, CA 92037.

The mechanisms through which EtOH stimulates ACTH secretion remain elusive. Though the primary role of the hypothalamic peptide corticotropin-releasing factor (CRF) is recognized, we do not know the level(s) at which EtOH alters CRF-dependent pathways. In addition the participation of vasopressin (VP), a peptide also released by EtOH and that regulates ACTH release, is unclear. Using an intronic probe, we measured significant increases in CRF heteronuclear RNA levels 20-40 min after injection of EtOH (3 g/kg, ip). At these times, gene expression of *c-fos* and NGFI-B was already markedly increased. CRF, CRF receptors, and VP mRNA levels were then measured 3 h after EtOH administration. Possibly because of the sizable preexisting pool of CRF mRNA in the cell body, only modest and not statistically significant increases were observed in EtOH-treated rats. On the other hand, gene expression of CRF receptors and VP was markedly elevated. To determine if the EtOH-induced stimulation of VP neurons was important in the subsequent activation of the HPA axis, we injected VP antibodies 5 min prior to EtOH administration. At doses of the antiserum that completely abolishes ACTH released by large doses of exogenous VP, the ACTH response to the acute injection of EtOH (1-3 g/kg) was significantly blunted by removing endogenous VP.

In conclusion, we have shown that acute EtOH administration up-regulates VP gene expression and CRF gene transcription in the hypothalamus, and that VP released into the portal and/or general circulation is important for the activation of the corticotrophs. These results indicate that EtOH exerts a rapid stimulatory influence on the activity of hypothalamic neurons that are important for ACTH secretion. Because hypothalamic CRF stimulates the activity of its own neurons, the appearance of CRF receptors in the hypothalamus suggests the potential presence of amplifying mechanisms through which CRF, and possibly VP, may prolong the effect of alcohol on the brain.

## 546.11

## TREADMILL-RUNNING EXERCISE ACTIVATES BRAIN TRANSCRIPTION OF CRF AND ITS TYPE 1 RECEPTOR IN THE RAT. D. Richard\*, N. Naimi, C. Roberge and S. Rivest. Department of Physiology and CHUL Research Center, Laval University, Québec, Canada, G1K 7P4

The present study was aimed at investigating the effects of treadmill-running exercise on the transcriptional activity of corticotropin-releasing factor (CRF) and its type 1 receptor (CRF<sub>1</sub> R) in the brain of male rats killed during and following a 90-minute session of exercise. Transcriptions of CRF heteronuclear (hn)RNA and CRF<sub>1</sub> R mRNA were assessed on brain sections using intronic and exonic *in situ* hybridization histochemistry. Exercise led to a rapid and transient expression of the CRF gene; 30 minutes after the onset of exercise, a positive signal for CRF hnRNA was detectable in both the parvocellular division (parvo) of the hypothalamic paraventricular nucleus (PVH) and in the inferior olivary nucleus (ION). These positive signals, which were not perceivable in resting control rats, vanished soon after the completion of exercise. Exercise also induced the transcription of the gene encoding for the CRF<sub>1</sub> R. The transcription was observed 90 and 180 minutes after the end of exercise in the parvo PVH. There was no basal expression of CRF<sub>1</sub> R mRNA during exercise or in resting control rats. The presence of CRF hnRNA in the parvo PVH and ION of exercised rats suggests that exercise can activate expression of the CRF gene in neurons involved in the control of both hypothalamic-pituitary-adrenal axis and motricity. Meanwhile, the post-exercise induction of CRF<sub>1</sub> R mRNA in the parvo PVH provides evidence that exercise may influence the CRF neuroendocrine function by acting at the CRF site of action.

## 546.13

## CASTRATION INCREASES CORTICOTROPIN RELEASING HORMONE (CRH) mRNA BUT NOT GLUCOCORTICOID RECEPTOR (GR) mRNA IN THE PARAVENTRICULAR N. OF THE HYPOTHALAMUS. R.J. Handa\*, G.J. Heina, A.H. Nagahara, J.E. Kerr. Dept. of Cell Biology, Neurobiology and Anatomy. Loyola Univ., Chicago, Stritch School of Medicine. Maywood, IL 60153.

Previous studies have demonstrated that gonadectomy (GDX) of male rats will increase the ACTH and corticosterone response to stress (Handa et al, 1994). These changes are accompanied by increases in hypothalamic CRH levels (Almeida et al, 1992; Bingaman et al, 1994). In this study, we tested the hypothesis that GDX-induced changes in hormone secretion are associated with changes in CRH mRNA or GR mRNA levels in the PVN. Male Sprague Dawley rats (3 months old) were used. Animals were GDX'd or GDX'd and implanted with two Silastic capsules containing dihydrotestosterone propionate (DHTP; 2 cm long) at the time of GDX. Control rats were left intact. Rats were sacrificed 3 weeks after GDX, and brains were removed and analyzed for CRH mRNA and GR mRNA levels. Some animals in each group were adrenalectomized (ADX'd) 4 days prior to sacrifice or ADX'd and injected daily with the specific GR agonist, RU28362 (40 ug/kg BW in sesame oil). CRH mRNA and GR mRNA were measured using *in situ* hybridization with <sup>32</sup>S labelled cRNA probes against rat CRH mRNA and GR mRNAs. Increases in CRH mRNA ( $p < 0.01$ ) were detected in GDX animals. DHTP treatment did not reduce these levels to that of the intact. There was no effect of GDX on GR mRNA levels. Furthermore, ADX increased CRH mRNA levels and RU28362 treatment of ADX rats prevented this increase. There was no interaction between ADX and GDX on CRH or GR mRNA levels. These data are consistent with GDX induced increases in hormone secretion and suggest that increases in CRH mRNA, but not alterations in GR mediated feedback regulation, are responsible for the previously observed neuroendocrine changes. ## 546.10

## POSITIVE GLUCOCORTICOID REGULATION OF CORTICOTROPIN-RELEASING HORMONE GENE EXPRESSION. A.F. Seasholtz\*, R. Regentin, and H. Guardiola-Diaz. Mental Health Research Institute and Department of Biological Chemistry, University of Michigan, Ann Arbor, MI 48109.

Corticotropin-releasing hormone (CRH) is the major hypothalamic releasing factor in the mammalian stress response. CRH is also expressed in other regions of the brain and in a variety of peripheral tissues where its role is less well understood. The endogenous CRH gene has been shown to be negatively regulated by glucocorticoids in the hypothalamus while it is positively regulated by glucocorticoids in human placental trophoblasts. In order to more systematically evaluate the role and mode of action of glucocorticoids on CRH gene expression, we have utilized CRH gene transfer experiments in cell lines. In transfected PC-12 cells, a human CRH-reporter fusion gene is positively regulated by glucocorticoids and this positive glucocorticoid regulation acts synergistically with the cAMP-mediated increase in CRH-reporter activity. The positive glucocorticoid regulation is half maximal at 5-10 nM dexamethasone and requires treatment for at least 24 hours. Studies with RU-38486 demonstrate that the glucocorticoid receptor (GR) is required. However, deletion analysis has shown that several putative GR DNA binding sites in the CRH 5' flanking DNA are not required for the positive regulation. These results suggest that positive glucocorticoid regulation of CRH-reporter expression in PC-12 cells is not mediated by DNA binding, but may involve induction of a new trans-acting protein or protein-protein interactions involving the activated GR. This work was supported by grants to A.F.S. from NARSAD and NIH DK42730.

## 546.12

## ESTROGEN POTENTIATES THE STRESS-INDUCED INCREASE OF CRH mRNA IN THE PVN. R.Y. Yukhananov\* and R.J. Handa. Department of Cell Biology, Neurobiology and Anatomy, Loyola University Medical Center, Maywood, IL 60153

Gonadal steroids, in addition to their role in the control of reproduction appear to be important regulators of the neuroendocrine stress responses. It has been shown recently that estrogen (E) may potentiate the stress-induced secretion of ACTH and corticosterone in rats and this effect is mediated at the hypothalamic level. To further clarify the mechanism of E action we have determined by *in situ* hybridization the levels of CRH mRNA in the parvocellular part of the paraventricular nucleus (PVN) following two types of stressor: injection of hyperosmotic sodium chloride (1.5 M NaCl, 10 ml/kg) and novelty (open field 15 min). Gonadectomized (GDX) male rats were implanted with silastic capsules containing E, dihydrotestosterone propionate (DHTP) or empty (placebo). CRH mRNA levels were determined by counting the number of silver grains over individual cells on slides coated with photographic emulsion. Neither E, nor DHTP pretreatment produce any changes in the levels of CRH mRNA of the home cage control. Injection of 1.5 M NaCl significantly increased the CRH mRNA levels in sham-operated, placebo- or E-treated but not DHTP-treated rats. Following novelty, however, only E-treated rats expressed significantly higher levels of CRH mRNA as compared to non-stressed control. Thus, estrogen potentiates the increase of the CRH mRNA following psychological stressor (novelty), but not following injection of hyperosmotic sodium chloride. These data suggest that estrogen potentiates neuroendocrine stress responses by influencing CRH in a stress specific fashion. The regulatory pathways mediating these effects remains to be determined. Supported by BNS 9408890 and USPHS AA08696.

## 546.14

MOLECULAR AND PHARMACOLOGICAL CHARACTERIZATION OF A CRF RECEPTOR CONSTITUTIVELY EXPRESSED BY THE HUMAN NEUROBLASTOMA CELL LINE IMR-32. L.L. Collins, M. A. Charlton<sup>1</sup>, P. M. Sweetnam\*, R. S. Duman<sup>1</sup>, W. S. Faraci. Dept. of Explor. Lead Discovery, Pfizer Central Research, Groton, CT 06340 and <sup>1</sup> Dept. of Psychiatry, Yale University School of Medicine, New Haven, CT 06508.

Radioligand binding, functional and cloning studies have revealed that the human neuroblastoma cell line, designated IMR-32, constitutively expresses a single G-coupled CRF receptor gene product. Pharmacological evaluation revealed this receptor binds [125-I]CRF in a saturable and reversible manner with an apparent dissociation constant  $K_d$  of 130 pM and a maximum binding capacity,  $B_{max}$  of 45 pmol/mg protein. In addition, it is coupled to adenylyl cyclase as determined by its ability to stimulate the formation of the second messenger cAMP and shift [125-I]CRF binding in the presence GTP analog, GMPNP. Both binding and cAMP formation were blocked by the competitive peptide antagonist, a-helical CRF. At the molecular level, these cells express only a single form of CRF receptor message RNA which appears to be homologous to a recently cloned CRF receptor (Chen et al., (1993) Proc. Natl. Acad. Sci. (USA) 90, 8967 - 8971).

## 546.15

DIVERSE SUBCELLULAR DISTRIBUTIONS OF THE CRF-BINDING PROTEIN IN RAT BRAIN AND PITUITARY. C.A. Peto, W. Vale and P.E. Sawchenko\*. The Salk Institute, La Jolla, CA 92037.

The CRF-binding protein (CRF-BP) is a 37 kDa protein, distinct from CRF receptors, that is nonetheless capable of binding the peptide with high affinity and reversibly neutralizing its biological actions. The CRF-BP has been localized in anterior pituitary, where it coexists in a subset of corticotropes, and in brain, where it shows limited overlap with cellular sites of CRF expression. Preembedding immunoperoxidase staining methods were used to permit ultrastructural analyses that might provide insight into the still obscure functions of the CRF-BP. In anterior pituitary, CRF-BP-ir was detected diffusely in the cytoplasm of cells morphologically similar to corticotropes. In these, reaction product was not detected in secretory granules, but rather was most pronounced in secondary lysosomes and multivesicular bodies. In brain, marked regional differences in the subcellular pattern of CRF-BP staining were evident. In isocortex, where colocalization of BP and peptide is rare, BP-ir was distributed in perikarya, dendrites and axons in a manner similar to that of a prototypic neuropeptide. This included nondescript reaction product deposition in cytoplasm, dendrites and axon terminals, with the latter commonly engaging in synaptic contacts with unlabeled dendritic profiles. In the oval subnucleus of the bed nucleus of the stria terminalis, a site that contains overlapping accumulations of CRF-BP-ir varicosities and CRF-ir perikarya, BP staining was restricted to vesicle-laden varicosities that only very rarely engaged in synaptic contacts. Instead, these were most commonly directly apposed to unlabeled axon varicosities and terminals. In the nucleus raphe magnus, a site at which CRF and its BP coexist extensively in perikarya, CRF-BP-ir displayed a subcellular pattern of localization much like that seen in the anterior pituitary. The results are compatible with the view that the function of the CRF-BP may vary in different cellular contexts. In cellular targets of CRF (anterior pituitary) or in neurons in which peptide and BP coexist (raphe), the CRF-BP may play a role in processing and degradation of CRF and/or ligand-receptor complexes. In some other areas of the CNS, the BP seems positioned to serve as a transmitter/modulator at conventional synapses, and in still others as a paracrine modulator of local CRF effects.

STIMULATION OF SEROTONINERGIC SYSTEM CAUSES TRANSCRIPTIONAL ACTIVATION OF CRF AND ITS RECEPTOR SELECTIVELY WITHIN THE PARAVENTRICULAR NUCLEUS (PVN) OF THE RAT HYPOTHALAMUS. S. Rivest\*, N. Laflamme, S. Boyetto, and D. Richard. Molecular Endocrinology Lab., CHUL Research Center and Dept. of Physiology, Laval University, Québec, Canada, G1V 4G2.

The present study investigated the effect of intraperitoneal (i.p.) administration of the indirect serotonergic (5-HT) agonist dexfenfluramine (FEN) on the transcriptional activity of corticotropin-releasing factor (CRF) and its receptor (CRF<sub>R</sub>) in the brains of conscious male rats via *in situ* hybridization histochemistry using both intronic and exonic probe technology. FEN induced a rapid and wide neuronal activation as indicated by the strong signal of *c-fos* mRNA in numerous structures throughout the brain 30 and 60 min after treatment. In the parvocellular division of the PVN, the large majority of CRF-immunoreactive (ir) perikarya displayed a positive signal for the mRNA encoding *c-fos*. Colocalization between CRF-ir neurons and *c-fos* positive cells was not detected in any other regions. This selective activation of PVN CRF neurons was also confirmed by the presence of CRF primary transcript; 30 min after i.p. injection of the indirect 5-HT agonist, a positive signal for CRF heteronuclear (hn)RNA was observed specifically in the parvoPVN. Moreover, transcription of the gene encoding the receptor for CRF was highly stimulated in the PVN following 5-HT activation. Although this hypothalamic nucleus exhibited a barely detectable signal under basal conditions, FEN induced a strong signal of CRF<sub>R</sub> mRNA in the parvoPVN. Interestingly, CRF-ir neurons displayed a positive signal for the mRNA encoding the CRF<sub>R</sub> 3 and 6 h after systemic treatment with the indirect 5-HT agonist. These results indicate that although FEN can generate a wide neuronal activation throughout the brain, this 5-HT agonist triggers the activity of CRF neurons selectively in the parvocellular division of the PVN, a mechanism possibly related to the activity of hypothalamic-pituitary-adrenal axis. Induction of CRF<sub>R</sub> mRNA in CRF cells of the PVN indicates that neuroendocrine CRF neurons can be targeted by CNS CRF under 5-HT stimulation.

## NEUROENDOCRINE REGULATION: HYPOTHALAMIC PEPTIDES

## 547.1

IMPACT OF INSULIN ON NEUROPEPTIDE Y (NPY) IN THE HYPOTHALAMIC ARCuate AND PARAVENTRICULAR NUCLEI IN VIVO AND IN VITRO. I. Silva, J. Wang, M. Felber, A. Akabayashi\* and S.F. Leibowitz. The Rockefeller University, New York, N. Y. 10021.

Circulating insulin has been shown to control the gene expression and synthesis of neuropeptide Y (NPY) in the hypothalamus. This peptide, in a projection from the arcuate nucleus (ARC) to the paraventricular nucleus (PVN), may have a role in energy balance, and insulin may contribute to this process via its impact on NPY. These studies examined insulin's effect on hypothalamic NPY in the rat using immunocytochemistry and radioimmunoassay. In *in vitro* studies, treatment with insulin (25-100 µg/ml) over a 4 h period dose-dependently decreased NPY release from cultures of neonatal rat hypothalamic cells (-33% at 100 µg/ml,  $p < 0.05$ ). In studies of hypothalamic fragments, insulin (100 µg/ml) markedly inhibited, by 50-85% ( $p < 0.01$ ), the release of NPY from both the hypothalamic mediodorsal region (MDH - including the paraventricular nucleus, PVN) and the hypothalamic mediobasal fragment (MBH - including the arcuate nucleus, ARC). After intracerebroventricular injection of insulin (80 mU/10 µl) in intact animals during the light (inactive) period, NPY-immunoreactive fiber densities were reliably decreased in the PVN and ARC. Insulin had no impact on NPY immunoreactivity in the dorsomedial nucleus. These results agree with other studies in showing that insulin inhibits NPY synthesis and/or release in the areas of the ARC and PVN, where NPY is believed to modulate feeding behavior.

## 547.3

BOMBESIN ACTS IN THE SUPRACHIASMATIC NUCLEUS TO AFFECT CIRCADIAN CHANGES IN TUBEROINFUNDIBULAR DOPAMINERGIC NEURON ACTIVITY AND PROLACTIN SECRETION. L.M. Mai\* and J.T. Pan. Dept. Physiol. and Anat., Natl. Yang-Ming Univ. Taipei, Taiwan, R.O.C.

We have previously shown that central administration of bombesin can block the afternoon prolactin surge (Neuroendocrinology 57:40-44, 1993). A circadian change in the activity of tuberoinfundibular dopaminergic neurons, which coincides with the onset of the prolactin surge, has also been observed (Neuroendocrinology 60:520-526, 1994). Whether bombesin acts on the tuberoinfundibular dopaminergic neuron to affect the prolactin surge and where does bombesin act in the brain were the focuses of this study. Bombesin (0.75 µg/3 µl/rat) was first injected into the lateral cerebroventricle of estrogen-primed ovariectomized rats at 1200 h through preimplanted cannulae. Both circadian changes of prolactin and tuberoinfundibular dopaminergic neuron activity were blocked by the treatment. In suprachiasmatic nuclei-lesioned rats, however, both rhythms were absent, and the injection of bombesin exhibited no significant effect either. Using microinjection of bombesin (50 ng/0.2 µl) bilaterally into either the suprachiasmatic or arcuate nuclei at 1200 h, only the former injection effectively blocked both rhythmic changes in tuberoinfundibular dopaminergic neuron activity and prolactin secretion. We conclude that bombesin may act on the rhythm generation center, the suprachiasmatic nucleus, to exert its effect to disrupt the tuberoinfundibular dopaminergic neuron activity and the prolactin surge.

## 547.2

INSULIN INHIBITS GALANIN IN THE HYPOTHALAMIC PARAVENTRICULAR NUCLEUS: IN VIVO AND IN VITRO STUDIES. J. Wang\*, D. Andrews, H. Liu and S.F. Leibowitz. The Rockefeller University, N.Y., N.Y. 10021.

Insulin controls the synthesis of neurochemicals in the brain. Recent work indicates that insulin may inhibit gene expression and production of the peptide, galanin (GAL), which potentiates feeding behavior. The present studies examined insulin's effect on hypothalamic GAL in the rat using immunocytochemistry and radioimmunoassay. In *in vitro* studies, treatment with insulin (25-100 µg/ml) over a 4 h period dose-dependently decreased GAL release from cultures of neonatal rat hypothalamic cells (-65% at 100 µg/ml,  $p < 0.05$ ). In investigations of hypothalamic fragments, insulin (100 µg/ml) inhibited, by 67% ( $p < 0.05$ ), K<sup>+</sup>-evoked release of GAL from the mediodorsal region of the hypothalamus (MDH - including paraventricular nucleus, PVN); it had no impact on GAL release from the mediobasal fragment (MBH - including arcuate nucleus, ARC). After intracerebroventricular injection of insulin (80 mU/10 µl) into intact animals during the light (inactive) period, GAL-immunoreactive fiber densities were decreased in the PVN and ARC. However, insulin had no impact on GAL-ir neurons in the dorsomedial nucleus and ARC, while in the PVN, GAL-staining neurons were not evident in either insulin-treated or control subjects. These results demonstrate a strong and site-specific inhibitory effect of insulin on GAL neurons, particularly in the mediodorsal hypothalamus or PVN area. This confirms previous results (Tang et al., Neurosci. Abstr., 1994) showing an inhibition of GAL gene expression and peptide production in the PVN.

## 547.4

DISTRIBUTION OF VASOACTIVE INTESTINAL PEPTIDE-POSITIVE FIBERS IN THE ARCuate NUCLEUS AND ITS EFFECT ON DORSOMEDIAL ARCuate NEURON ACTIVITY IN BRAIN SLICES. S.K. Huang, J.Y.H. Chan\* and J.T. Pan. Inst. Physiol., Natl. Yang-Ming Univ., Taipei, Taiwan

Vasoactive intestinal peptide (VIP) has been proposed as one of the prolactin-releasing factors, and it also acts as both central and peripheral neurotransmitter and neuromodulator. The present study investigated the distribution and action of VIP in the hypothalamus of ovariectomized Sprague-Dawley rats implanted with estrogen capsules. Using immunohistochemical staining method, VIP-positive neurons were found in the paraventricular and suprachiasmatic nuclei as previously reported by others. Dense VIP-immunoreactive fibers, however, were found in the arcuate nucleus extruding perpendicular from the border of the third ventricle, which distribution overlapped with that of the putative tuberoinfundibular dopaminergic neurons in the arcuate nucleus as doubled-labeled with tyrosine hydroxylase antibody. Using single-unit recording of dorsomedial arcuate neurons in brain slices of ovariectomized rats, VIP was shown to significantly activate the firing rates of a majority of neurons recorded (65.4%, 17/26 neurons). These results provide both anatomical and pharmacological evidence indicating that VIP may play an important role in the arcuate nucleus and in the regulation of tuberoinfundibular dopaminergic neurons.

## 547.5

ISOLATION, AND CHARACTERIZATION OF THE CHICKEN PACAP/GHRH-LIKE GENE. J.E. McRory, S.L. Krueckl, K.R. von Schalburg and N.M. Sherwood\*. Department of Biology, University of Victoria, B.C. Canada, V8W 2Y2.

In chickens the physiology of growth hormone (GH) secretion is well documented. However, a true chicken GH-releasing hormone (GHRH) has not yet been identified. We have isolated and sequenced a gene and cDNA which encodes for a precursor molecule containing two neuropeptides. One of these peptides, based on sequence identity, is pituitary adenylate cyclase activating polypeptide (PACAP). The other neuropeptide could be either GHRH or PRP (PACAP-related peptide). The chicken PACAP gene is 6145bp long and contains an intron-exon structure comparable to other members of the glucagon superfamily. Present in the chicken PACAP promoter are tentative CAAT and TATAA consensus sites 65bp upstream of a potential start site. CAAT and TATAA sites have not been reported for other PACAP genes. The role of the full length and truncated PACAP and GHRH peptides to release GH *in vivo* and *in vitro* will be presented.

## 547.7

GALANIN MESSENGER RNA AND PEPTIDE LEVELS ARE DECREASED IN RADIOHYDROECTOMY-INDUCED PITUITARY ADENOMAS. J.F. Hyde\*, K.W. Drake and J.P. Moore, Jr. Dept. of Anatomy and Neurobiology, University of Kentucky College of Medicine, Lexington, KY 40536.

We have shown that galanin gene expression is markedly increased in lactotroph (estrogen-induced) and somatotroph (GHRH-induced) adenomas. The objective of this study was to examine galanin gene expression in the development of thyrotroph adenomas. Male C57BL mice were injected with 200 µCi of iodine-131 (I-131) or saline. The development of radiothyroidectomy-induced pituitary hyperplasia/adenomas was examined at 3, 6, 9 and 12 months after I-131 injection. After 3 months, the anterior pituitaries of I-131-treated mice were 2-fold larger than control pituitaries, and plasma TSH levels were increased more than 20-fold. However, galanin peptide levels in the anterior pituitary of I-131-treated mice were decreased 80%; no changes in hypothalamic galanin peptide concentrations were detected. Treatment with estradiol increased galanin peptide concentrations in the anterior pituitaries of all mice, however, galanin peptide levels in I-131-treated mice remained 50% lower than controls. Treatment with tri-iodothyronine selectively increased pituitary galanin peptide levels in I-131-treated mice, but these levels still remained lower than controls. Plasma TSH levels and anterior pituitary size continued to increase in I-131-treated mice and were more than 100-fold and 10-fold higher, respectively, than controls by 12 months. Galanin peptide concentrations in the anterior pituitary remained depressed throughout this study. Galanin mRNA levels in the anterior pituitary were estimated by RT-PCR, and were significantly lower in I-131-treated mice. We conclude that galanin peptide concentrations are decreased in a tissue-specific manner during the onset and development of I-131-induced thyrotroph adenomas due to a decrease in galanin mRNA levels. Unlike other pituitary tumors examined, galanin does not appear to facilitate thyrotroph hyperplasia. (Supported by DK-45981 and HD-07436)

## 547.9

MODULATION OF GAP JUNCTIONAL INTERCELLULAR COMMUNICATION IN CULTURED LHRH NEURONS. D.F. Matesic\*, T. Hayashi, J.E. Trosko and J.A. Germak. Dept. of Pediatrics & Human Development, Michigan State Univ., East Lansing, MI 48824.

Rhythmic secretion of luteinizing hormone-releasing hormone (LHRH) by hypothalamic LHRH neurons controls the onset of puberty and reproduction. One potential means for coordinating LHRH secretion is via electrotonic or chemical signals transferred through gap junctions. The LHRH-secreting neuronal cell line, GT1-71, which has been shown to be dye coupled<sup>2,3</sup> and to express the gap junction protein subtype, connexin 26(Cx26)<sup>3</sup>, was used to study regulatory mechanisms of gap junctional intercellular communication. Using fluorescence recovery after photobleaching (FRAP), we found that treatment of GT1-7 neurons for 24 hr with 2µM forskolin or 100 µM dibutyryl cAMP + 100 µM IBMX increased the percentage of dye coupled cells from 12-15% in untreated cultures to 30-40%, which was maintained up to at least 48 hr. Subsequent treatment of cells with the gap junction inhibitors, octanol or dieltrin, reduced the level of coupling to below the level in untreated cells, supporting the hypothesis that the observed increase in dye coupling was mediated by gap junctions. Western blot analysis of forskolin- or dibutyryl cAMP + IBMX-treated cells showed no increase in the intensity of Cx26 protein. RT-PCR analysis showed no increase in Cx26 mRNA levels following 6, 12 or 24 hr treatment with dibutyryl cAMP + IBMX. These results suggest that increased Cx26 expression did not account for the observed increase in dye coupling. Alternative mechanisms include changes in Cx26 localization or assembly, increased numbers of cell-cell contacts, or induction of expression of other connexin subtypes. Supported by NSF IBN 94-07267 1Neuron 5: 1, 1990; 2PNAS 89: 4149, 1992; 3Neuroendocrinology 58: 485, 1993.

## 547.6

A FIXED TISSUE SLICE PREPARATION FOR EXAMINING DENDRITIC ARCHITECTURE OF NEUROENDOCRINE NEURONS IN THE RAT ARCULATE NUCLEUS. S.C. Danzer\*, N.T. McMullen and N.E. Rance. Departments of Cell Biology and Anatomy, and Pathology, University of Arizona College of Medicine, Tucson, AZ 85724.

Previous morphologic studies of dendrites in the rat arcuate nucleus have been accomplished through Golgi techniques. We have developed a technique to examine the dendritic morphology of arcuate neuroendocrine neurons by combining fluorogold labeling and intracellular injection of neurons in a fixed tissue slice preparation. Fluorogold, when injected IP, labeled arcuate neuroendocrine cells with projections to the fenestrated capillaries of the median eminence, where the blood-brain barrier is leaky. Arcuate neuroendocrine cells containing fluorogold were visualized under epifluorescent illumination in 200-500 µm tissue slices. The labeled cells were then impaled and filled, under visual control, with glass microelectrodes containing a combination of 0.5% lucifer yellow, 1% biotinylated lucifer yellow, and 2.5% biocytin. After post-fixation, the slices were processed with an ABC/DAB reaction to obtain a dark, Golgi-like fill for subsequent analysis. Preliminary results show that arcuate neuroendocrine neurons tend to be either unipolar, or multipolar with 2-4 primary dendrites. The dendritic processes are sparsely to moderately spiny, and are generally confined to the arcuate nucleus. Axons are frequently beaded and project toward the median eminence. The combination of these techniques gives reliable, complete, and permanent visualization of the morphology of hypothalamic neuroendocrine neurons in the rat arcuate nucleus. ## 547.8

INCREASED GALANIN SECRETORY ACTIVITY AND CELL NUMBER IN THE ANTERIOR PITUITARY OF hGHRH TRANSGENIC MICE. J.P. Moore, Jr.\* and J.F. Hyde. Department of Anatomy and Neurobiology, University of Kentucky College of Medicine, Lexington, KY 40536.

We recently reported that galanin mRNA and peptide levels, and immunoreactive cell numbers are increased within the anterior pituitary gland of the human growth hormone-releasing hormone (hGHRH) transgenic mouse. In order to determine if these observed increases in galanin gene expression are related to changes in peptide secretion, we employed the cell immunoblot assay (Kendall and Hymer, 1987) which allows for the detection of peptide secretion from single cells *in vitro*. Anterior pituitary glands from six month old male hGHRH transgenic and non-transgenic mice were incubated with 0.25% trypsin to prepare a dispersed cell suspension. The cell suspension was then dispensed, in a monolayer, onto an Immobilon PVDF membrane equilibrated in HEPES-buffered DMEM, and maintained at 37°C in a 95% air/5% CO<sub>2</sub> incubator for six hours. The cells were then fixed with 4% paraformaldehyde, rinsed with phosphate buffer, and stained for galanin immunoreactivity using diaminobenzidine as the chromogen. This method allows for the visualization of the secretory products from single cells as they are adsorbed onto the membranes. Utilizing an NIH Image Software system, we observed that 1) increased numbers of cells from the pituitaries of hGHRH mice secrete galanin as compared to pituitary cells from non-transgenic siblings, and 2) the amount of immunoreactive galanin peptide secreted from cells from hGHRH transgenic mice was increased as compared to non-transgenic siblings. These data show that increased galanin secretion from pituitary cells of hGHRH transgenic mice parallels the increase of galanin gene expression. Moreover, the cell immunoblot assay will allow us to determine the pituitary cell type(s) secreting galanin. (Supported by DK-45981 and HD-07436)

## 547.10

PROGESTERONE (PROG) STIMULATES THE RELEASE OF GONADOTROPIN-RELEASING HORMONE (GnRH) FROM GT1-1 NEURONS, BUT NOT VIA THE GABA<sub>A</sub> RECEPTOR AS DOES ITS METABOLITE 3α-HYDROXY-5α-PREGNAN-20-ONE (TH PROG). M. El-Etr\*, Y. Akwa, R.J. Fiddes, K. Shazand, P. Robel, E.E. Baulieu. INSERM U.33, 94276 Bicêtre, France.

We previously reported that TH PROG (10nM-10µM) stimulates within 3min the release of GnRH from immortalized hypothalamic GT1-1 neurons, through an interaction with the GABA<sub>A</sub> receptor (R) since bicuculline and picrotoxin inhibit this effect (El-Etr et al., Proc.Natl.Acad.Sci.USA, in press). Here we report that surprisingly PROG also stimulates the release of GnRH, but with a markedly different profile of action since exclusively in the micromolar range concentrations, with a six time lower potency and a lag of 20min. This effect cannot be related to the conversion of PROG to TH PROG, which can be performed by GT1-1 cells, as GABA<sub>A</sub> R antagonists do not counteract PROG action. In order to define the mechanism of action of PROG, the antagonistic effect of RU486 was tested and RT-PCR experiments were carried out to look for intracellular PROG R mRNA. The effect on GnRH release of the PROG-3-BSA conjugate, which does not cross cell membranes, was also investigated, as well as the role of calcium and sodium channels.

## 547.11

## OPIOID PEPTIDES REGULATE GnRH RELEASE IN VITRO

Y. Fan\* and M.A. Ottinger. Dept. of Poultry Science, Univ. of MD, College Park, MD 20742

Opioid peptides inhibit GnRH release in mammals. In birds, the effects of these peptides on the GnRH system is unclear. Previous experiments in our lab have shown a dose-related inhibition of cGnRH-I release in vitro with exposure to enkephalin. This study investigated effects of  $\beta$ -endorphin (END) on cGnRH-I release from hypothalamic slices in vitro. Longitudinal slices (5mm x 1mm x 3mm) spanning preoptic area to mediobasal hypothalamus (POA-MBH) taken from adult male Japanese quail (*Coturnix japonica*) were placed in chambers (Endotronics Perfusion System; slices from one brain in a chamber with a total of 6 chambers) and equilibrated in Medium 199 (Biofluids, Inc) for two hours. Baseline samples (5 min collection time) and a norepinephrine (NE;  $10^{-6}$ ; RBI) challenge were conducted during this time. END ( $10^{-7}$ ; Sigma) was added to the Medium 199 through the rest of the experiment. END exposure resulted in reduced ( $p < 0.01$ ) baseline release of cGnRH-I and in decreased ( $p < 0.01$ ) NE stimulated cGnRH-I release. In a separate experiment, a dose-response relationship was observed with END concentrations from  $10^{-8}$  to  $10^{-11}$ . Decreased cGnRH-I release was reflected in reduced pulse amplitude, with no change in frequency. These results provide evidence for inhibition of cGnRH-I release by the opioid peptide END, similar to enkephalin. Further, the reduction in NE-stimulated release of cGnRH-I also suggests a direct effect of END on both GnRH and NE neurons. Supported by USDA #88-37242-2913 and NRI#92-37203-7742 (MAO).

## 547.13

## EFFECTS OF ESTRADIOL ON LUTEINIZING HORMONE-RELEASING HORMONE IN SK-N-SH NEUROBLASTOMA CELLS.

Anna Ratka\*, Scott E. Mambourg, Mehvar Singh<sup>1</sup> Department of Pharmaceutical Sciences, College of Pharmacy, Idaho State University, Pocatello, ID 83209, <sup>1</sup>Columbia University, Department of Anatomy and Cell Biology, New York, NY 10032.

The SK-N-SH human neuroblastoma cells are investigated as a model to study the opioids-LHRH-ovarian steroids interactions at the neuronal level. Our previous study showed that the SK-N-SH cells express LHRH mRNA, and that the LHRH mRNA level and LHRH concentration decreased during neuronal differentiation induced by retinoic acid (RA,  $10 \mu\text{M}$ ). Recently we have found that the LHRH mRNA level decreased after 6-day treatment with 5 nM of estradiol (E). Quantitative densitometric analysis showed that E further potentiated the RA-induced decrease in the LHRH mRNA level ( $20.13 \text{ OD} \times \text{mm}^2$  - no treatment, 8.75 and 4.69  $\text{OD} \times \text{mm}^2$  after RA and RA+E, respectively). The concentrations of LHRH were measured after RA and/or E treatments. Marked reduction in LHRH level occurred on day 1 but was most significant on day 6 (from control value of  $4.30 \pm 1.62$  to  $0.53 \pm 0.08$  ng/mg protein after RA, to  $0.42 \pm 0.06$  ng/mg protein after E, and to  $0.61 \pm 0.18$  ng/mg protein after RA+E). Preliminary findings suggest the presence of E receptors mRNA in SK-N-SH cells; the expression of the mRNA coding for E receptors seems to be lower in cells exposed to RA. We conclude that E has a profound attenuating effect on the LHRH system in undifferentiated as well as differentiated SK-N-SH neuroblastoma cells. ## 547.15

AFFERENT SYNAPSES ON ESTROGEN RECEPTOR-IMMUNOREACTIVE NEURONS IN THE ANTEROVENTRAL PERIVENTRICULAR NUCLEUS OF THE FEMALE RAT: ELECTRON MICROSCOPY. R.E. Watson Jr., B.E. Maley, M.G. Engle, and M.C. Langub, Jr. Dept. of Anatomy and Neurobiology, University of Kentucky Med. Ctr., Lexington, KY 40536-0084.

The anteroventral periventricular nucleus (AVPv) in the female rat is critical to the steroid-mediated control of the preovulatory gonadotropin surge. It is believed that together with steroid influences, neurochemical systems including substance P (SP) and catecholamine (tyrosine hydroxylase [TH]) producing neurons play integral roles in this neuroendocrine event. We hypothesized that steroid and SP and catecholamine signals converge upon estrogen receptor-immunoreactive (ER-ir) neurons in the AVPv. Previous light level immunocytochemical data indicated that in the AVPv, SP- and TH-ir fibers are in position to synaptically contact ER-ir neurons. This study was conducted to assess the potential for such interaction at the ultrastructural level. Sections through the AVPv were immunostained sequentially for ER using monoclonal antibody H222 (Abbott Laboratories) with tetramethylbenzidine (TMB) as chromogen, and either rabbit anti-SP [1:4000] or rabbit anti-TH [1:5000; Eugene Tech] using diaminobenzidine (DAB) as chromogen. Ultrastructurally, ER-ir neurons contained intranuclear TMB crystals, while DAB reaction product was within labeled axonal terminals. The majority of DAB-labeled synaptic terminals were axodendritic; however, axosomatic contacts were present on both ER- and non-ER-ir neurons. SP-ir axosomatic synapses were upon 8.5% of ER-ir neurons and 13% of non-ER-ir neurons. Nine percent of ER-ir neurons and 9.2% of non-ER-ir neurons had TH-ir axosomatic synapses. These results provide morphological evidence for SP and catecholamine regulation of ER-ir neurons in the AVPv through axosomatic synapses and suggest a potential anatomical mechanism through which these compounds could modulate gonadotropin secretion. Supported by NIH Grant HD29050 (REW).

## 547.12

Dexamethasone Does Not Alter Basal Corticotropin-Releasing Factor (CRF) Produced by Rat Amygdaloid Neurons in Culture. JW Kasckow\*, JJ Mulchahey, <sup>†</sup>DG Parkes, CD Kilts, P Lambert, MJ Owens, ED Risby, MD Stipetic, CB Nemeroff, Emory U. Sch. Med., Dept. Psychiatry, Atlanta, GA 30322; <sup>‡</sup>Howard Florey Inst. of Exp. Physiol. and Med., U. Melbourne, Australia, 3052.

Amygdalar and hypothalamic neurons have been postulated to play a role in the stress response. Glucocorticoids negatively regulate CRF containing hypothalamic cells; however, it is not known whether similar effects on CRF containing cells in the amygdala occur. The effects of dexamethasone (DEX) on CRF in primary rat amygdalar cultures derived from E19 pups were evaluated. The amygdala was dissected bilaterally and dissociated with 0.25% trypsin. Cells were plated at a density of  $10^6$  cells/well in DMEM, 10% fetal bovine serum, 14 mM glucose, 15 mM  $\text{NaHCO}_3$ , 5 mM Hepes and pen/strep. At 17 days, triplicate sets of cells were treated 12 hours with either forskolin (3, 10, 30  $\mu\text{M}$ ) or DEX (4, 20, 100 nM). Supernatants were collected and cells were harvested with 0.1% NP-40. CRF secretion and content was measured via radioimmunoassay, expressed as mean  $\pm$  standard error, and statistical significance was determined at the  $P < 0.05$  level by Duncan's Multiple Range test. Forskolin produced significant increases in CRF intracellular content at 30  $\mu\text{M}$ :  $27.9 \pm 0.2$  vs.  $22.8 \pm 1.6$  pg/well in controls. Significant increases in CRF secretion occurred at doses as low as 3  $\mu\text{M}$ :  $17.6 \pm 0.7$  vs.  $9.1 \pm 0.2$  pg/well in controls. DEX at all three doses failed to alter secreted and intracellular levels of CRF. Intracellular content of CRF in the presence of DEX (4, 20, 100 nM) was determined in primary rat hypothalamic cultures raised under identical conditions mentioned above. A significant decrease in CRF content occurred at 100 nM:  $25.2 \pm 0.7$  vs.  $31.3 \pm 2.8$  pg/well in controls indicating that the failure of the amygdalar cultures to respond was not an artifact of the culture methods. Further characterization of these amygdalar cultures is under way in order to investigate their responsiveness to known stimulators and inhibitors of CRF involved in the stress response. Supported by NIMH MH-42088. Dr. Kasckow is a Pfizer awardee and Dr. Parkes is a CJ Martin Fellow.

FLUORESCENT ANALOGUES OF GROWTH HORMONE-RELEASING FACTOR: NEW TOOLS FOR PROBING GRF RECEPTORS.

P. Gaudreau\* and D. Langlois. Neuroendocrinology Laboratory, Notre-Dame Hospital Research Center and University of Montreal, 1560 East Sherbrooke st., Montreal, Quebec, Canada, H2L 4M1.

Highly sensitive techniques, such as flow cytometry and confocal fluorescence microscopy imaging, make possible the characterization of receptors and their cellular/subcellular localization in real time, in response to various stimuli. With this in mind, we have designed fluorescent analogues of GRF, to probe the pituitary GRF receptor. Since the side chain of Lys<sup>12</sup> and Lys<sup>21</sup> are important receptor-binding pharmacophores of GRF in this tissue, their  $\epsilon$ -amino function could not be used for fluorescein labeling. Analogues of hGRF(1-31)NH<sub>2</sub> and hGRF(1-44)NH<sub>2</sub>, bearing a Lys<sup>31</sup> were selected, because structural modifications within the segment 30-44 have less influence on GRF bioactivity. Fluorescein was also coupled to the  $\alpha$ -amino group of hGRF(1-29)NH<sub>2</sub> and hGRF(1-44)-NH<sub>2</sub>. [N<sup>6</sup>-5-carboxyfluoresceinyl-(CF)-Lys<sup>31</sup>]hGRF(1-31)NH<sub>2</sub> and [N<sup>6</sup>-5-CF-Lys<sup>31</sup>]hGRF(1-44)NH<sub>2</sub> exhibited receptor binding affinity and adenylate cyclase activity comparable to that of hGRF(1-29)NH<sub>2</sub> in rat adenohypophysis, while these parameters were decreased for [N<sup>6</sup>-fluorescein-5-thiocarbamyl(FTC)]hGRF(1-29)NH<sub>2</sub> and [N<sup>6</sup>-FTC]hGRF(1-44)NH<sub>2</sub>. The availability of high affinity fluorescent agonists of GRF receptors will be of great value to study the behavior of GRF and GRF-GRF receptor complexes in physiological and pathological conditions. LOCALIZATION OF NATRIURETIC PEPTIDE RECEPTOR mRNAs IN THE RAT BRAIN. M.C. Langub, Jr., R.E. Watson Jr., C.M. Dolgas, R. Marcinek and J.P. Herman, Dept. of Anatomy and Neurobiology, University of Kentucky Medical Center, Lexington, KY 40536-0084.

Atrial natriuretic peptide (ANP) and C-type natriuretic peptide (CNP) transduce signals primarily by high-affinity binding to the extracellular domains of membrane-bound guanylate cyclases, resulting in mobilization of cyclic GMP. The A-type natriuretic peptide receptor (NPR-A) selectively binds ANP while the B-type natriuretic peptide receptor (NPR-B) displays high selectivity for CNP. A third natriuretic peptide receptor (NPR-C) can bind both ANP and CNP but does not have the catalytic guanylate cyclase domain and has been postulated to be a "clearance" receptor. The present study employed probes designed to target the 5' extracellular ligand binding domain known to be different in all three receptor species. NPR-A and NPR-B were analyzed by *in situ* hybridization histochemistry. Strong hybridization signal for NPR-A mRNA was present only in the medial habenula, subfornical organ, area postrema, and the olfactory bulb. Notably, NPR-A mRNA was expressed also in several white matter tracts, suggestive of glial origin. In contrast, NPR-B mRNA expression appeared to be predominantly neuronal, being heavily localized in the subfornical organ, hypothalamic neuroendocrine neurons, olfactory system, and motor nuclei of cranial nerves. The distribution of NPR-C mRNA was assessed by polymerase chain reaction. This species was most abundant in cortex and hypothalamus. The results of the present study suggest the capacity for natriuretic peptide systems to exert regulatory control on a wide variety of central nervous system functions and provide the framework for biological action of the peptides in clearly defined neural circuits. Supported by the American Heart Association, Kentucky Affiliate, MH49698 and HD29050.

## 547.17

REPRODUCTIVE STATE CHANGES NADPH-DIAPHORASE IN THE PARAVENTRICULAR NUCLEUS AND THE SUPRAOPTIC NUCLEUS OF RATS **B.C. Woodside\*, B. Robinson and S. Amir**, Centre for Studies in Neurobiology, Psychology Dept., Concordia University, Montreal, Qué., Canada.

Neurons in both the paraventricular nucleus (PVN) and the supraoptic nucleus (SON) stain for NADPH-diaphorase, a histochemical marker of nitric oxide synthase. Nitric oxide itself has been implicated in the control of corticotropin releasing hormone (CRH) and oxytocin release from neurosecretory cells in the PVN and SON as well as in the neural plasticity seen in these areas. Because changes in reproductive state are associated with modulation of CRH and oxytocin release as well as morphological changes in neurons in the PVN and SON, we determined whether NADPH-diaphorase staining density would also vary as a function of reproductive state. The reproductive conditions examined were: longterm ovariectomized; Day 21 of pregnancy; Day 12 of lactation; and the diestrous and estrous days of the estrus cycle. All animals were anaesthetized with Somnotol (60mg/kg) and then perfused transcardially with saline and 4% paraformaldehyde. Brains were removed, postfixed for 18 hours, sectioned and then processed for NADPH-diaphorase histochemistry. NADPH-diaphorase staining in both the PVN and the SON was dramatically increased in late pregnant females compared with all other groups. The activity of oxytocinergic neurons is enhanced both during late pregnancy and lactation, thus it is unlikely that the increase in NADPH-diaphorase observed only in late pregnancy simply reflects an increase in neuronal activity.

## 547.18

NEURAL ENDOPEPTIDASE 24.15 COLOCALIZES TO THE NUCLEUS IN DISCRETE NEURAL POPULATIONS **Bindiya Moorjani\*, T. J. Wu, Marc J. Glucksman and James L. Roberts**, Fishberg Research Center for Neurobiology, Mount Sinai Medical Center, New York, NY 10029.

The metalloendopeptidase EC 3.4.24.15 (EP24.15) is very active in the extracellular space, where it is purported to metabolize various biologically active peptide hormones. However, it is also localized in the nucleus of neurons and glia, where its function is unknown. Preliminary studies indicated that salt-loading of rats leads to a dramatic shift in the localization of EP24.15 from the nucleus to the cytoplasm in magnocellular neurons of the hypothalamic paraventricular nucleus. To further address the distribution and cellular compartmentalization of EP24.15 in the hypothalamus we examined the localization of EP24.15 in identified neurons under various hormonal states. Female rats at various stages of the estrous cycle were transcardially perfused with 4% paraformaldehyde, and the brains post-fixed for 4 h in the same fixative. Free-floating vibratome sections were processed for single (DAB, EP24.15 only) or double labeling for EP24.15 and GnRH or Tyrosine Hydroxylase (TH). Single-labeling with EP24.15 antisera demonstrated a cellular or nuclear localization. In the double labeled sections, 50% of GnRH- or TH- positive neurons were observed to have a nuclear localization of the enzyme. The present results showing a heterogeneous nuclear localization within defined neuronal populations suggest that the location and its activity may be dependent on the neuronal status.

## NEURAL-IMMUNE INTERACTIONS: DEPRESSION AND STRESS

## 548.1

CHEMICAL INDUCED TUMORIGENESIS AND IMMUNE FUNCTION IN TRANSGENIC ANIMALS WITH IMPAIRED TYPE II GLUCOCORTICOID RECEPTOR (GR) GENE EXPRESSION. **J.M.C. Blom\*, N. Barden, D. Yiglienghi, B. Silveri and G. Racagni**, Center of Neuropsychopharmacology, Univ. of Milan, 20133 Milan, Italy, and Molecular Psychogenetics, CHUL, Québec, Canada.

Recently a transgenic animal model dealing with the neuroendocrine aspects of depression has been developed, and is characterized by partial knockout of GR gene expression, caused by GR antisense RNA expression (Pepin et al. 1992, Nature 355:725). These transgenic mice display a hyperactive hypothalamic-pituitary-adrenal (HPA) axis and dysfunctional glucocorticoid inhibitory feedback similar to that seen in 60% of depressed patients. Based on the fact that glucocorticoids affect the immune system and that both depression as well as immunosuppression play a potential important role in the onset and progress of cancer, the hypothesis was tested that dysregulation of GR gene expression, accompanied by alterations in immune functioning, may result in enhanced susceptibility to chemically induced tumorigenesis. Adult female transgenic mice and intact controls were injected s.c. with the chemical carcinogen 9,10 dimethylbenzanthracene (DMBA, 50 mg/kg) or with the vehicle (DMSO). 73% of the transgenic mice developed tumors within three weeks post-injection, while only 23% of the controls displayed tumors 8 weeks after treatment. None of the mice injected with the vehicle developed tumors. Furthermore, tumor incidence correlated positively with altered immune responsiveness, as measured by lymphocyte cell number and lymphoproliferative assays. These results indicate that suppression of the immune system enhances susceptibility to chemically-induced tumors, and that disruption of the glucocorticoid negative feedback loop and the HPA-immune axis can increase the risk of developing cancer if coincident with a carcinogenic event.

## 548.2

GLUCOCORTICOID-INDUCED PROGRAMMED-CELL DEATH (APOPTOSIS) IS INHIBITED IN TRANSGENIC MICE EXPRESSING TYPE II GLUCOCORTICOID RECEPTOR (GR) ANTISENSE RNA: DOWN-REGULATION OF Bcl-2 AND INTERLEUKIN 2 (IL-2R) RECEPTOR OVER-EXPRESSION. **M.C. Morale\*, G. Bartoloni\*, F. Italia\*, F. Gallo\*, N. Barden\* and B. Marchetti\***, Dept. Pharmacol and Pathology, Catania, IRCS Inst. Mental Retard. and Brain Aging, Troina (EN) Italy, and Mol Psychogenetics, CHUL, Québec, Canada.

A major factor in the development of thymocytes is the induction of, or the protection from, programmed cell death (apoptosis). The susceptibility of lymphocytes to glucocorticoid-induced apoptosis is part of a thymic maturational program and is known to depend on the maturation stage (immature thymocyte are particularly sensitive), the activation stage (strongly activated T-cells become resistant), local lymphokine concentration, the sex steroid hormone milieu, and most likely by other as yet undefined factors present in the thymic microenvironment. We have recently documented a number of developmental alterations and permanent effects on T-cell function in transgenic mice expressing a type II GR antisense RNA construct (Endocrinology, in press). In the present study we have investigated whether alterations in the processes involved in T-cell selection accompany the post-natal development of transgenic mice with impaired GR function. For this aim, thymus glands from intact and transgenic mice were processed at different time-intervals during post-natal ontogeny (5-60 days) and DNA fragmentation, the distribution of the oncogene bcl-2 (a candidate protein implicated in the onset of apoptosis), and two markers of T-cell proliferation (Ki67 and PCNA), were correlated to the acquisition of IL-2R inducibility. Flow cytometric and internucleosomal DNA cleavage analyses revealed a significant inhibition of apoptosis in the thymus of transgenic mice. The immunohistochemical staining pattern of Ki67 and PCNA was markedly increased in the face of a down-regulation of Bcl-2. Moreover, over expression of IL-2R accompanied the development of thymocyte responsiveness. These results provide experimental support for the concept that expression and regulation of GR at the thymus gland level constitute a crucial developmental step for the acquisition of the T-cell repertoire.

## 548.3

STRESS MAY SUPPRESS SPECIFIC IMMUNITY BY STIMULATING MACROPHAGES. **Brennan, F.X., M. Fleschner, T. Deak, L. R. Watkins, & S. F. Maier**, \*Dept Psych, Wilkes Univ., Dept. Psych, Univ. CO, Boulder, CO 80309.

Stressor exposure may activate macrophages (MØs). This activation could increase innate immunity. However, MØ activation is also suppressive of other aspects of immunity, such as T-cell proliferation to ConA or alloantigen (Fleschner et al., J. Neuroimmunology, 56, 1995). We investigated whether stress-induced MØ activation could contribute to stress-induced decreases in specific immunity, i.e., *in vivo* antibody production to KLH. Two approaches were taken: 1) Block MØ function *in vivo* prior to stress; or 2) Activate MØs *in vivo* in the absence of stress. MØ or IL-1 activity were suppressed *in vivo* with either gadolinium chloride (7.5 mg/kg; GdCl<sub>3</sub>; a phagocyte inhibitor) or IL-1 receptor antagonist (100mg/kg; IL-1RA). Rats (12/gr) were injected with either GdCl<sub>3</sub> or saline. Twenty-four hrs after injection, rats were immunized with KLH (200 µg) and exposed to either 100 5-s inescapable tail shocks (IS) or returned to their home cage. IL-1RA was administered (12/gr) after IS + KLH. MØ stimulation studies involved zymosan, LPS, or vehicle injection (12/grp) given before KLH. The Ig response to KLH was measured on days 5, 7, 10, 14 and 21 after immunization using ELISA. Preliminary results suggest that MØ blockade can inhibit IS-induced suppression of the anti-KLH Ig response, whereas MØ stimulation in the absence of IS suppresses the anti-KLH Ig response. NIH-MH45045.

## 548.4

IMPAIRED NATURAL KILLER CELL RESPONSES IN A GENETIC ANIMAL MODEL OF DEPRESSION **Elliot M. Friedman\*, Michael R. Irwin\*, and David H. Overstreet\***, (1) Department of Psychiatry, University of California, San Diego and San Diego Veterans Affairs Medical Center, San Diego, CA 92161; (2) Skipper Bowles Center for Alcoholic Studies and Department of Psychiatry, University of North Carolina, Chapel Hill, NC, 27599.

Studies examining the relationship between major depression and immune function have yielded mixed results; decreases in natural killer (NK) activity, for example, have been reported, but these changes are neither consistent nor limited to depression. Moreover, this relationship is complex, involving variables such as sleep, neuroendocrine activity, and age, and examination of the contributions of these variables to immune dysfunction in depression will require animal models.

The Flinders Sensitive Line (FSL) rat exhibits multiple behavioral and physiological abnormalities reminiscent of major depression, including sleep disturbance, reduced behavioral activity, and hypersensitivity to cholinergic agonists. We report here that these animals also exhibit reductions in NK activity.

Rats were rapidly decapitated and the spleens were removed and teased apart. Spleen NK cytotoxicity against target YAC-1 mouse lymphoma cells was determined in a standard 3-hour chromium release assay. NK number was determined by flow cytometry using a specific mouse anti-rat NK monoclonal antibody. There were no significant differences in absolute NK lytic activity among the three strains of rats, but the FSL rats had significantly more splenic NK cells than FRL rats [ $p < .05$ ]. When lytic activity was adjusted for NK cell number, the FSL rats exhibited significantly less lytic activity per cell than FRL rats [ $p < .05$ ].

Compared to control animals, the FSL rats exhibited depression-like decreases in cellular immune responses under non-stressful conditions. These results provide support for the FSL rats as a valuable model for the study of the physiological substrates of major depression.

## 548.5

DIFFERENTIAL CORTICOSTERONE RESPONSES TO VARIOUS STIMULI IN LEWIS AND FISCHER 344 RATS. T. Bienen, L. J. Grota\* and D. L. Felten. Depts. of Neurobiol. and Anat. and Psychiatry, Univ. of Rochester, NY 14642.

Lewis/N (L) and Fischer-344 (F344) rats are widely used to study the interactions between the nervous, immune, and endocrine systems. It has been reported that L rats, in comparison to F344 rats, have an attenuated hypothalamic-pituitary-adrenal (HPA) axis response to a variety of challenges. This is believed to be due to a defect in central CRH production. The purpose of this study was to investigate the responsiveness of the HPA axis in individual male L and F344 rats (200-350 grams) to a variety of treatments.

The rats were implanted with an indwelling inferior vena cava catheter and allowed to recover for 7 days. Baseline samples were taken each day before treatment. Blood samples were drawn at 15, 30, 45, 60, and 90 min. after treatment with ACTH 1-24 (500 ng/kg, day 1), stress (exposure to a new environment and ip puncture using a 26G needle, day 2), nicotine (0.01 µg/kg, day 3), and saline (day 5). After LPS treatment (60 µg/kg, day 4) samples were taken at 30 min., 1 hr, 2 hrs, 4 hrs, 6 hrs, and 24 hrs. Serum was assayed for corticosterone (CS) by RIA.

There were no significant strain differences in baseline CS levels. Both L and F344 rats responded to ACTH, stress, nicotine, and LPS with CS levels returning to baseline by the end of the sampling period. F344 rats showed significantly higher CS responses to stress at 15, 30, and 60 min., to nicotine at 15 and 30 min., and to LPS at 60 and 120 min. in comparison to L rats. We observed no significant differences between L and F344 rats in CS responses to ACTH and saline.

It is concluded that L rats are less responsive to stress and nicotine, but only slightly less responsive to LPS than F344 rats. This suggests that male L rats are capable of mounting a substantial CS response to an immunological challenge. (This work was supported by R37MH42076 and a Markey Charitable Trust Award.)

## 548.7

LABORATORY AND NATURALISTIC STRESSORS INFLUENCE IMMUNE FUNCTIONING. M.D. Zaharia, A.V. Ravindran, J. Griffiths, G.J. Remington\*, Z. Merali & H. Anisman. Dept Psychology, Carleton University & Dept of Psychiatry, Royal Ottawa Hospital, Ottawa, Ont. Canada and Neuropsychopharmacol. Res. Unit, Clarke Inst. of Psychiatry, Toronto, Ont. Canada.

Severe naturalistic and modest laboratory stressors have been shown to influence immune functioning. While the former have been associated with immunosuppression (reduced cell proliferation, natural killer cytotoxicity), the latter may provoke an immunoenhancement. In the present investigation we demonstrated that, among university students, laboratory stressors (e.g., mathematical challenge, stress interview) increased the number of NK cells without affecting either CD3, CD4, CD8 or CD19 cells. With a more profound naturalistic stressor (final academic exams), NK cell number increased to a greater extent, and an increase of CD3, CD4 and CD19 cells was also evident. In addition, the laboratory stressors provoked a marked increase of cell proliferation in response to both PHA and Con A. A still greater increase of cell proliferation was associated with the stress of the academic examination. The variations of lymphocyte numbers, as well as the stress-related alterations of cell proliferation, were unrelated to variations of plasma cortisol or ACTH. Likewise, it did not appear that the individual's previous stressor history impacted on the immune measures. However, the variations of cell numbers induced by the laboratory stressors tended to be more pronounced among dysthymic patients (i.e., chronic, low-grade depression) than in non-depressed university students. The results are related to the possibility that depressive illness and stress experiences in non-depressed subjects may be associated with activation of some aspects of the immune response.

## 548.9

DEPRESSIVE-LIKE BEHAVIOR AND INTERLEUKIN-6 (IL-6) DURING AUTOIMMUNE DISEASE. B. Sakic & H. Szechtman and JA Denburg. Depts Biomed Sci and Medicine, McMaster Univ, Hamilton, Ont, CANADA L8N 3Z5.

We suggested previously that a component of autoimmunity-associated behavioral profile (AABP) in MRL-lpr mice is depressive-like behavior. The present study examines this suggestion by employing a novel behavioral paradigm: the sucrose preference test, which had been proposed to measure decreased sensitivity to rewards, a core symptom of depression. A second aim of the study was to identify immune factors which may play a role in AABP. In 5 and 12 week old autoimmune MRL-lpr mice, the concentration-intake curve for sucrose was shifted, compared to the control MRL +/+ substrain. Pretreatment with an immunosuppressive agent obliterated the substrain difference, indicating involvement of autoimmune/inflammatory mechanisms and suggesting that autoimmune disease alters responsivity to "hedonic" stimulation. Considering that reduced sucrose intake in the MRL-lpr substrain was present before marked autoantibody production, their reduced sucrose preference is probably related to other immune factor(s). Mice with high titres of serum IL-6 showed low sucrose intake compared to mice without IL-6 bioactivity (due to immunosuppressive treatment). Results suggest that decreased sensitivity to reward precedes severe symptoms of autoimmunity, and chronic hyperproduction of IL-6 may be a factor in pathogenesis of AABP. (BS is OMHF Postdoctorate Fellow. Supported by NSERC)

## 548.6

ENHANCEMENT OF IMMUNE FUNCTION BY ACUTE STRESS.

E. S. Dhabhar\* & B. S. McEwen. Laboratory of Neuroendocrinology, The Rockefeller University, New York, NY 10021.

Immune cell trafficking is crucial to the performance of the surveillance and effector functions of the immune system. We have previously demonstrated that acute stress induces rapid, and large magnitude changes in the distribution of peripheral blood leukocytes in the rat. We have also shown that the effects of stress on leukocyte distribution are mediated by the adrenal steroid, corticosterone, acting through the Type II (glucocorticoid) receptor.

In the present series of studies we examined the skin as a target organ for the stress-induced redistribution of leukocytes. Our results suggest that acute stress induces an influx of leukocytes into the skin. In order to determine the functional immunologic consequences of these changes in leukocyte distribution, we examined the effects of acute stress on a cell-mediated immune response (delayed type hypersensitivity (DTH)) induced in the skin. Briefly, DTH was induced by challenging the dorsal surface of the right pinna of previously sensitized animals with 2,4-dinitro-1-fluorobenzene. The course of inflammation was monitored by measuring increases in pinna thickness, and by histological quantification of leukocytes infiltrating the site of challenge. We observed that the stress-induced redistribution of leukocytes to the skin was accompanied by a significant increase in the rate, magnitude, and duration of the DTH reaction observed in the skin of stressed animals compared to unstressed controls. These results suggest that under certain conditions, acute stress may enhance immune surveillance and increase the capacity of the immune system to respond to challenge. ## 548.8

MODULATION OF THE RECURRENCE OF HERPES LABIALIS BY EXPERIMENTALLY INDUCED DISGUST. A. Buske-Kirschbaum, A. Geiben, J. Guterlet, C. Wemke, K.-M. Pirke, C. Kirschbaum, H. Lehnert\* and D. H. Hellhammer. Center for Psychobiology and Psychosomatic Research, University of Trier, D-54286 Trier, Germany.

The present study was designed to determine whether emotional processes such as disgust might lead to altered immune function in patients which, as a result, is followed by manifestation of HSV symptoms. Healthy subjects (n=18) with with recurrent herpes simplex virus (HSV) infection were recruited who (1) show more than five infections/year and (2) who suffer from HSV symptoms only after experience of strong disgust due to dirty dishes (glasses, plates). They were randomly distributed to two treatment groups. The experimental group (n=9) was exposed to five slides showing dirty glasses or plates. After presenting the aversive objects visually, the volunteers were confronted with the real objects previously presented by the slides. The control group (n=9) was treated identically with the difference being that these subjects were confronted with neutral slides as well as with neutral objects. Blood samples were obtained five minutes before and 30 minutes as well as two days after stimulus presentation. Furthermore, all subjects were examined for HSV symptoms by a physician two days after the experiment. Saliva was obtained at regular intervals before and during stimulus presentation. Moreover, two additional saliva samples were collected during the medical examination two days after the treatment. Two days after presentation of the aversive objects, four experimental subjects showed HSV symptoms. No symptoms, however, could be determined in control subjects. Furthermore, elevated tumor necrosis factor (TNF-α) and suppressed cortisol concentrations were observed on day 3 in the experimental group. However, no significantly altered distribution of lymphocyte subpopulations was found after stimulus presentation after 30 minutes or two days, respectively. These data suggest that psychological processes such as the experience of disgust against specific objects can lead to alteration of immune function which might be accompanied by HSV recurrence in sensitive patients.

## 548.10

SEVERE LIFE STRESS PREDICTS EARLY HIV DISEASE PROGRESSION AND LONGITUDINAL CHANGES IN IMMUNE STATUS

JM Pettito<sup>1</sup>, J Leserman<sup>2</sup>, D Perkins<sup>2</sup>, J Folds<sup>2</sup>, B Zheng<sup>1</sup>, D Gettes<sup>1</sup>, RA Stern<sup>3</sup>, RN Golden<sup>2</sup>, DL Evans<sup>1</sup> Departments of Psychiatry, <sup>1</sup>University of Florida, Gainesville, FL, 32610, <sup>2</sup>University of North Carolina, Chapel Hill, NC, 27599, <sup>3</sup>Brown University, Providence, Rhode Island

Changes in components of immune physiology have been associated with some forms of stress in animals and humans. However, it is unknown whether stress can impact on the course of HIV disease. To test the hypothesis that life stress can influence HIV disease progression, we are conducting prospective studies in HIV-infected men. Using several different disease endpoints (e.g., CDC stage and clinical symptoms), our data reveal that severe life stress increased the likelihood of disease progression by nearly four-fold as well as the severity of early disease progression. Stress was also associated with alteration in lymphocyte subsets comprising natural killer (NK) and cytotoxic T lymphocytes (CTL). These changes were most notable in combination with co-occurring depressive symptoms. This longitudinal, prospective study provides some of the first evidence that severe life stress may influence the course of both HIV disease and immunity. Ongoing study will provide an opportunity to determine the effects of severe stress on more advanced stages of HIV disease progression.

## 548.11

IMMUNE CORRELATES IN SUBTYPES OF DEPRESSIVE DISORDER. A.V. Ravindran\*, J. Griffiths, Z. Merali and H. Anisman. Dept. of Psychiatry, Royal Ottawa Hospital, and School of Psychology, University of Ottawa, Ottawa, Ontario, Canada.

Major depressive disorder has been associated with immune alterations, including reduced mitogen-induced cell proliferation, diminished natural killer (NK) cell activity, as well as variations of several lymphocyte subsets. These immune alterations may be related to the severity of the depression or may be secondary to symptoms that characterize the disorder (e.g., anorexia, sleep disturbances, increased stress perception). In the present investigation we demonstrate that plasma endocrines and lymphocyte subsets vary across subtypes of depression (major depression, atypical depression, and dysthymia). Plasma cortisol did not differ between groups, whereas plasma ACTH levels were modestly increased in major depression. As well, analysis of platelet serotonin receptors revealed an increase of paroxetine binding sites in major depressive patients. The number of circulating NK cells was increased in all depressive groups, while in both the major and atypical depressives the total lymphocytes, CD3 (pan T), CD8 (suppressor/cytotoxic) and CD19 (pan B) cells were increased as well. Dysthymia was also associated with increased variability and levels of IL-1 $\beta$  in mitogen stimulated lymphocytes. In nondepressed patients stressors of increasing severity provoked a similar pattern of immunological change. The data are consistent with the proposition that depression may be associated with activation of some aspects of immune activity, and that such effects vary as a function of the depressive subtype. The possibility is considered that immune alterations may be related to the stress/anhedonia associated depression.

## 548.13

CORTICOTROPIN-RELEASING FACTOR TREATMENT UPREGULATES INTERLEUKIN-1 RECEPTORS IN THE MOUSE PITUITARY: REVERSAL BY DEXAMETHASONE. T. Takao\*, C. Tojo, T. Nishioka, K. Hashimoto and E. B. De Souza. Second Department of Internal Medicine, Kochi Medical School, Nankoku 783, Japan (T.T., C.T., T.N., K.H.) and Neurocrine Biosciences, Inc., San Diego, CA 92121 (E.B.D.S.).

The cytokine interleukin-1 (IL-1) alters a variety of immune, central nervous system and neuroendocrine activities characteristic of an integrator of the brain-endocrine-immune response to stress. In order to further characterize the mechanisms involved in stress-induced regulation of IL-1 receptors, we examined specific iodine-125-labeled human interleukin-1 $\alpha$  ([<sup>125</sup>I]IL-1 $\alpha$ ) binding following treatment with corticotropin-releasing factor (CRF) and dexamethasone (DEX), two major regulators of stress response. In addition, we studied plasma adrenocorticotrophic hormone (ACTH) and corticosterone levels after CRF treatment. Plasma ACTH and corticosterone were increased at 2 h after i.p. injection of rat/human CRF (40  $\mu$ g/kg/0.2 ml of saline) and returned to basal levels at 6 h after the injection. Intraperitoneal injection of r/h CRF resulted in a dramatic increase in specific [<sup>125</sup>I]IL-1 $\alpha$  binding in the pituitary at 2 and 6 h after the injection although it did not affect [<sup>125</sup>I]IL-1 $\alpha$  binding in the hippocampus, spleen and testis at any time after the injection. [<sup>125</sup>I]IL-1 $\alpha$  binding was unchanged at 2 h following DEX treatment (1 mg/kg/0.2 ml of 4% ethanol-saline) in the pituitary and the hippocampus. In contrast, DEX inhibited CRF-induced upregulation of IL-1 receptors in the pituitary at 2 h after the injection. These data demonstrate complex interactions between CRF and DEX on IL-1 receptors during stress.

## 548.15

CORTICOSTERONE AND METAPROTERENOL (BETA-ADRENERGIC AGONIST) INCREASE BREAST CANCER METASTASIS IN F344 RATS: POSSIBLE MEDIATION BY NATURAL KILLER CELLS. S. Ben-Eliyahu\*, S. Haim, G.G. Page, E. Rozen, G. Shakhari, I. Shinitz, Dept. of Psychology, Tel Aviv University, Tel Aviv 69978, Israel.

Several hormonal and immunological mechanisms have been implicated in mediating adverse effects of stress on immunity and tumor development. Specifically, corticosteroids have been shown to suppress natural killer (NK) cell activity in vitro, and similar effect of adrenalectomy were reported by some but not other investigators. Nevertheless, the in vivo effects of these hormones on NK activity and the biological significance of such suppression on tumor development is controversial. Therefore, we studied the effects of corticosterone (CORT) and metaproterenol (MP, a  $\beta$ -adrenergic agonist) in an in vivo system that is highly sensitive to NK cell activity in the context of host anti-metastatic activity. Rats were injected s.c. with either vehicle, 1, 3, or 9 mg/kg of CORT, or 1, 3, or 9 mg/kg of MP. One hour later all rats were injected intravenously with <sup>105</sup>radiolabeled MADB106 tumor cells, and 16 hr later rats were sacrificed and their lungs removed to assess tumor retention. These tumor cells metastasize only to the lungs and their lung clearance and the number of consequent lung metastases are controlled by large granular lymphocytes (LGL)/NK cells: Selective depletion of LGL/NK cells causes approximately one-hundred fold increase in these two measures, and augmentation of LGL/NK activity reduces them. Our findings indicated that both CORT and MP significantly and markedly increase lung tumor retention in a dose-dependent manner. These findings suggest that both drugs suppress LGL/NK activity in vivo. Because these drugs are known to affect adhesion and redistribution of lymphocytes, these findings should be interpreted in consideration of these process which are studied now in our laboratory.

## 548.12

CYTOKINE-INDUCED ENDOCRINE, NEUROCHEMICAL AND BEHAVIORAL ALTERATIONS. S. Lacosta\*, Z. Merali and H. Anisman. Dept. of Psychology, Carleton University & University of Ottawa, Ottawa, Ontario, Canada.

It has been hypothesized that cytokines, such as interleukin (IL)-1 $\beta$  and IL-2 may serve as a link between the immune and central nervous systems. Essentially, it is thought that cytokines secreted from activated immune cells may gain access to the brain, albeit to a limited extent, and may thus come to affect behavior. Moreover, it has been hypothesized that the brain may translate cytokine activation much as if it were a stressor. In the present investigation it was demonstrated that systemic administration of IL-1 and IL-2 (0.2-1.6  $\mu$ g) elicited different behavioral and neurochemical changes. In particular, IL-1 influenced exploratory patterns, consumption of highly palatable diets and anxiety on a plus maze. In addition, this cytokine provoked an increase of plasma corticosterone and ACTH, and altered the levels and turnover of norepinephrine (NE) and dopamine (DA) in several brain regions. In contrast, while IL-2 elicited anhedonic-like effects, acute systemic administration of this cytokine did not elicit anxiety, or increases in plasma corticosterone and ACTH. Treatment with IL-2 was, however, found to influence hypothalamic and mesolimbic catecholamine activity. It appears that in addition to hypothalamic NE and DA variations, treatment with IL-1 and IL-2 may affect monoamine activity in several mesocorticolimbic sites. While differential neurochemical and endocrine effects are elicited by the two cytokines, both induce patterns of behavior which, although not entirely congruent with one another, are typically associated with stressors.

## 548.14

ELECTROMAGNETIC FIELDS ALTER MELATONIN SYNTHESIS AND IMMUNE FUNCTION IN MAN. E.M. DeMet\*, A. Chicz-DeMet, F. Chiappelli, J.R. Anilini, S.G. Matta, A.R. Shoho, and M.A. Kung. Dept. Psychiatry & Human Behavior, UC Irvine, CA 92717, Psychiatry Service, VAMC Long Beach, CA 90822, and School of Dentistry, Lab. Human Oral & Molec. Immunol., UC Los Angeles, CA 90095.

Epidemiological surveys have linked electromagnetic field (EMF) exposure to cancer, mental illness, birth defects, and Alzheimer's disease. Animal studies indicate that EMF inhibits pineal function, but it is unclear if a similar effect occurs in man. The present paired double-blind study examined EMF effects on salivary cortisol and melatonin levels in healthy volunteers. Changes in immune function were also measured as phytohemagglutinin-stimulated interleukin-2 (IL-2) levels in T-lymphocytes. The natural earth's magnetic field was electrically balanced during sleep. No current was applied under control conditions. The applied EMF did not alter cortisol levels, but resulted in a 70% decrease in the nocturnal melatonin peak. A two-fold increase in mitogen stimulated IL-2 was also found which was not correlated with melatonin or cortisol changes. The results confirm that alterations in the earth's EMF inhibit melatonin synthesis in man. The EMF condition acts as an immuno-stressor although cortisol and melatonin may not be involved in this action.

AUTOIMMUNE MICE CAN LEARN AVOIDANCE CONDITIONING. L.M. Schrott\* and L.S. Cnics. Depts. of Psychiatry and Pediatrics, Univ. of Colorado School of Medicine, Denver, CO 80262.

Prior studies have demonstrated deficits in two-way active avoidance conditioning paradigms in autoimmune mice which are related to the degree of autoimmunity. To explore possible mechanisms of this deficit, autoimmune female NZB x NZW F1 hybrid (B/W) mice were tested in a one-way active avoidance conditioning paradigm in which there was no conflict situation and a low number of trials to minimize fatigue. B/W mice were able to learn the one-way paradigm as well as mice from the NZW control strain. No strain differences in the days to criterion or avoidance time were found. NZW mice did have more avoidances on the first test day ( $p < .02$ ), but the strains were similar on the remaining days. Since B/W mice could learn one-way avoidance, a separate group was tested in two-way avoidance which had the parameters altered to avoid fatigue, clarify contingencies, and increase cue salience. B/W mice were also able to learn this task and did not differ from NZW mice in the days to criterion or number of avoidances. B/W mice had faster avoidance times ( $p < .009$ ), as well as faster escape times on the first 2 days of testing ( $p < .04$ ). There was some evidence of poorer retention in the B/W mice, as their performance was worse on the first 10 trials of each day than on the last 10 trials ( $p < .002$ ). Thus, the two-way active avoidance deficit may be more the result of performance factors than actual cognitive problems. Recent evidence suggests that B/W display heightened anxiety and this may interfere with the learning complex tasks. Supported by MH49043, MH10643 and HD04024.

## 548.17

## INCREASED ANXIETY BEHAVIORS IN AUTOIMMUNE MICE

L.S. Cernic\* and L.M. Schrott, Depts. of Pediatrics and Psychiatry, Univ. of Colorado School of Medicine, Denver, CO 80262

The human autoimmune disorder SLE is accompanied by psychiatric symptoms including an increased incidence of anxiety. We compared the performance of autoimmune NZB x NZW F1 hybrid (B/W) mice to non-autoimmune NZW control mice on 3 measures of anxiety. B/W mice displayed an anxiety profile in the elevated plus maze as evidenced by avoidance of the open arms ( $p < .0001$  for both percent entries and time). Separate groups of mice were water deprived and tested in the open field drink test. B/W mice made fewer approaches to the water bottle which was suspended in the middle of the field ( $p < .02$ ) and spent less time drinking ( $p < .003$ ) than controls. They also had an increase in freezing behavior ( $p < .0007$ ). In a task designed to assess exploration of a novel object, B/W mice also displayed increased anxiety. They spent less time in the center portion of an open field ( $p < .004$ ), had fewer contacts with the novel object ( $p < .001$ ), and a lower contact duration ( $p < .05$ ). Since these anxiety behaviors may be modulated by over-expression of cytokines that accompany the autoimmune disease, the NZW controls were injected with the cytokine IFN- $\alpha$  and tested on the elevated plus maze. The IFN treated mice displayed an anxiety profile similar to that seen in the autoimmune mice with less time spent in open arms ( $p < .05$ ). Thus, autoimmune mice and mice exposed to the cytokine IFN- $\alpha$  display heightened anxiety which is characterized by avoidance of open and exposed places even when the motivation to explore these areas is great. This increased anxiety may interfere with learning in paradigms where aversive stimuli or conflict are present. Supported by MH49043, MH10643, and HD04024.

## 548.19

## FEMALE CHEMOSIGNALS MODULATE THE NUMBER OF

## BRAIN MAST CELLS IN MALE HAMSTERS. C.M. Novak\*

and A.A. Nunez, Dept. of Psychology & Neuroscience Program, Michigan State University, East Lansing, MI, 58824-1117. Photoperiod and age modulate the number of mast cells found in the brains of male Syrian hamsters; more mast cells are found in the brains of older animals and animals housed in a long photoperiod. Thus, reproductive status correlates with increased brain mast cell numbers. In this experiment, the influence of sexual experience or exposure to female chemosignals on brain mast cell number was investigated. Adult male hamsters were given 2 hours of exposure to (1) a receptive female hamster in a test area, (2) female hamster vaginal secretions (FHVS) in the same test area, or (3) the test area alone. Animals were perfused immediately after exposure to each condition; their brains were sectioned and stained with toluidine blue. Peri-hippocampal and thalamic mast cell numbers were counted. Significantly more mast cells were found in the brains of animals exposed to the FHVS ( $p < 0.05$ ). The animals that mated did not have more brain mast cells than control animals. It is possible that the stress associated with the presence of female chemosignals in the absence of mating is responsible for the rise in mast cell number seen here. (Supported by NSF grant IBN9209473 to A.A.N.)

## 548.18

Acquisition and Retention of Conditioned Immunosuppression of IgM Production is Mediated by the Insular Cortex. V. Ramirez-Amaya\*, B. Alvarez-Borda and F. Bermudez-Rattoni, Instituto de Fisiología Celular, UNAM, México, D.F. 04510.

Conditioned Immunosuppression is obtained by the pairing of a gustative stimulus with an immunosuppressive drug, in this case cyclophosphamide, on subsequent presentation of the gustative stimulus alone the animal shows an attenuated immune response. In previous studies it was found that insular cortex lesions disrupt the acquisition of conditioned immunosuppression, as measured by the production of antibodies to sheep red blood cells. In the present work we evaluated the effects of NMDA induced lesions in the insular cortex and the amygdala of male Wistar rats, on conditioned immunosuppression. This was measured by the production of IgM to ovalbumin. It was found that insular cortex lesions clearly disrupt both the acquisition and retention of conditioned immunosuppression, as shown by higher titer of IgM antibodies to ovalbumin compared to conditioned controls. On the other hand, amygdala lesions partially disrupt the acquisition but not retention of conditioned immunosuppression. Additionally, it was observed that both lesions did not affect the normal immune response. These results suggest that the amygdala could be important for the acquisition and that the insular cortex is essential for both acquisition and retention of the conditioned immunosuppression. This research was supported by DGAPA IN201993.

## CARDIOVASCULAR REGULATION: DETERMINANTS OF SYMPATHETIC NERVE RESPONSE

## 549.1

THE EFFECTS OF PREGNANCY AND A PROGESTERONE METABOLITE [ $3\alpha$ -OH-DIHYDROXYPROGESTERONE (DHP)] ON BAROREFLEX CONTROL OF RENAL SYMPATHETIC NERVE ACTIVITY (RSNA). S. Masilamani & C. Heesch\*, Dept. of Physiology, The Ohio State Univ., Columbus, OH 43210.

Previous experiments in anesthetized rats suggest that pregnancy (P) results in an attenuated ability to reflexly increase RSNA. Studies have shown that  $3\alpha$ -OH-DHP potentiates central GABA-ergic mechanisms and P rats have elevated levels of  $3\alpha$ -OH-DHP. The present study obtained baroreflex (BX) curves in conscious rats by recording reflex changes in RSNA due to increases and decreases in mean arterial pressure (MAP) (iv phenylephrine & nitroprusside infusions): in P rats (control), and in virgin (V) rats 1) before (control); 2) 15 min (exp 1); and 3) 30 min (exp 2) after infusion (iv) of  $3\alpha$ -OH-DHP. BX measurements are shown below.

(\* =  $P < 0.05$  vs V control).

	Baseline MAP (mmHg)	Midpoint (mmHg)	Max NA (mmHg)	NA (% increase from baseline)	Max Slope
V(control)	124 $\pm$ 6	121 $\pm$ 11	235 $\pm$ 35	135 $\pm$ 35	-3.56 $\pm$ 0.82
V (exp 1)	136 $\pm$ 7	124 $\pm$ 9	208 $\pm$ 34 *	106 $\pm$ 34 *	-2.68 $\pm$ 0.62
V (exp 2)	138 $\pm$ 9	125 $\pm$ 7	214 $\pm$ 35 *	114 $\pm$ 35 *	-2.24 $\pm$ 1.26
P (control)	103 $\pm$ 4 *	131 $\pm$ 8	121 $\pm$ 8 *	21 $\pm$ 8 *	-2.42 $\pm$ 0.47

The expected gestational hypotension was seen (decreased MAP) and the ability to increase NA (max NA & % increase from baseline NA) was virtually eliminated in P rats. In V rats, within 15 min of  $3\alpha$ -OH-DHP administration there was a diminished ability to increase NA (max NA & % increase from baseline NA) with  $3\alpha$ -OH-DHP (exp 1 & 2). These results demonstrate that pregnancy is associated with an inability to increase NA above baseline levels and that  $3\alpha$ -OH-DHP may in part participate in this diminished ability of P rats to increase NA. Supported by NIH grants RO1-HL 36245 and F32 HL 09183.

## 549.2

SUSTAINED ACTIVATION OF ARTERIAL BARORECEPTORS ALTERS THE BASIC PATTERN OF SYMPATHETIC NERVE DISCHARGE IN SPONTANEOUSLY HYPERTENSIVE (SH) RATS. M.J. Kenney\*, D.E. Claassen and T. Hirai. Dept. of Anat. and Physiol., Kansas State University, Manhattan, KS 66506

Sustained increases in arterial pressure (AP) can induce prolonged inhibition of sympathetic nerve discharge (SND) which outlasts the period of stimulation. The aim of the current study was to determine if sustained increases in AP alters the basic pattern of SND. For this purpose we used autospectral and coherence analyses to 1) characterize the frequency components in basal SND (renal, n=4; splanchnic, n=6; lumbar, n=3) and 2) determine the frequency-domain relationships between SND and AP in chloralose-anesthetized, baroreceptor-innervated SH rats before and after sustained (30 min) phenylephrine (PE)-induced increases (50 mmHg) in AP. During control before PE infusion, 40  $\pm$  3% of total power was contained in the frequency band which corresponded to the frequency of the heart rate (6-9 Hz) and the coherence value relating AP to SND was 0.90  $\pm$  0.01. After the sustained increase in AP, despite the return of AP to control levels, only 20  $\pm$  2% of total power was contained in the 6-9 Hz frequency band and the coherence value was reduced to 0.49  $\pm$  0.09. The intracerebroventricular administration of PE did not alter the basic pattern of SND (n=4). These results indicate that sustained activation of arterial baroreceptors can alter the frequency components of SND in SH rats. Supported by NIH HL48564.

## 549.3

COHERENCE OF EEG, RESPIRATION, AND HEART RATE VARIABILITY  
E.G. Lovett, J.B. Myklebust\*, M.D. Goldstein, and B.M. Myklebust.  
Laboratory of Sensory-Motor Performance, VA Medical Center, Medical  
College of Wisconsin, and Marquette University, Milwaukee, WI 53295.

Magnitude squared coherence (MSC) provides a method to evaluate the extent of a linear relationship among signals as a function of frequency. We hypothesize that, since physiologic mechanisms which govern EEG, respiration, and heart rate variations are organized at the level of the brainstem, there should be a high coherence among these signals at the respiratory frequency. We measured EEG (using standard 10-20 electrode locations), respiration (using pneumatic bellows around the chest), and heart rate variability (using ECG lead II), from normal volunteers, 22-26 years old. Subjects were supine, breathing at a self-paced regular rate with eyes closed.

Because breathing was at a regular (self-paced) rate, the power spectrum of the respiration signal routinely produced a clear peak at the respiratory frequency (0.1-0.3 Hz). A high coherence (0.8-1.0) was routinely observed between EEG and heart rate variability, EEG and respiration, and respiration and heart rate variability, at the respiratory frequency. Low coherence values ( $<0.3$ ) were computed at other frequencies. Coherence with EEG was widely distributed on the scalp. Preliminary data indicate that physiologic and behavioral manipulations can affect the level of coherence among EEG, respiration, and heart rate variability.

These data demonstrate that EEG, respiration, and heart rate variations are highly correlated at respiratory frequencies in normal subjects.

Supported by research funds from VA Rehabilitation R&D. Mr. Lovett is a Whitaker Foundation Predoctoral Fellow.

## 549.5

CENTRAL ADRENERGIC NEURONS PLAY A ROLE IN EXPRESSION OF THE 10-HZ RHYTHM IN SYMPATHETIC NERVE DISCHARGE (SND). S. Zhong\*, H.S. Ozer, S.M. Barman and G.L. Gebber. Dept. Pharmacol./Tox., Michigan State Univ., E. Lansing, MI 48824.

We tested the hypothesis that central adrenergic neurons are important for expression of the 10-Hz rhythm in SND of urethane-anesthetized, baroreceptor-denervated cats. In 15 cats in which the 10-Hz rhythm in inferior cardiac nerve activity was weak or absent, iv injection of the  $\alpha_2$ -adrenoceptor antagonists idazoxan (100  $\mu\text{g/kg}$ ) or rauwolscine (200  $\mu\text{g/kg}$ ) enhanced or induced the 10-Hz rhythm without affecting power at frequencies  $\leq 6$  Hz (demonstrated with autospectral analysis). Amphetamine (1-3 mg/kg iv) also enhanced or induced the 10-Hz rhythm without marked changes in power at frequencies  $\leq 6$  Hz ( $n = 5$ ). In six cats in which the 10-Hz rhythm was prominent, prazosin (300  $\mu\text{g/kg}$  iv), an  $\alpha_1$ -adrenoceptor antagonist eliminated the 10-Hz rhythm without changing power in SND at frequencies  $\leq 6$  Hz. These results support the view that central adrenergic neurons have a facilitatory effect on the 10-Hz rhythm. We propose that this effect is mediated through  $\alpha_1$ -adrenoceptors on their postsynaptic targets. Facilitation of the 10-Hz rhythm by idazoxan and rauwolscine may reflect enhanced activity of central adrenergic neurons perhaps by block of their  $\alpha_2$ -adreno-autoreceptors. Amphetamine is presumed to have released central catecholamines, thus facilitating the 10-Hz rhythm in SND. (Supported by NIH grants HL-33266 and HL-13187.)

## 549.7

SPINAL NETWORK CONTRIBUTE TO THE GENESIS OF LOW FREQUENCY RHYTHM PRESENT IN RR INTERVAL VARIABILITY OF ACUTE SPINAL CATS. N. Montano\*, T. Gnechchi-Ruscone, A. Porta, F. Lombardi, A. Malliani. Centro Ricerche Cardiovascolari, CNR; Medicina Interna. II, Osp. L. Sacco, University of Milan, Milan, Italy.

Spectral analysis of RR interval and arterial pressure (AP) variabilities detects two major components at low (LF; 0.04-0.15 Hz) and high (HF; 0.25 Hz) frequency. HF is related to respiration and considered a marker of vagal modulation while LF is a marker of sympathetic modulation. In decerebrate cats, spectral analysis of cardiac sympathetic efferent discharge (SND), in the range between 0 and 0.5 Hz, showed an LF oscillation, highly correlated with the LF component detectable in RR interval variability. Moreover in sino-aortic denervated cats, we have recently observed an LF component in the discharge variability of single medullary neurons, belonging to areas involved in the regulation of sympathetic outflow. To evaluate whether an LF rhythm might also originate from the spinal cord independently of brainstem, we recorded SND, ECG and AP in 18 decerebrate cats, 3 hrs after spinal section at C1 level and bilateral cervical vagotomy. In a subgroup of 5 cats recordings were also performed after a subsequent C7-T7 dorsal root section (DRS). Autoregressive spectral analysis of RR and SND variabilities revealed a major LF oscillation ( $0.07 \pm 0.02$  and  $0.09 \pm 0.01$  Hz;  $57 \pm 6$  and  $33 \pm 3$  n, respectively) and a smaller HF ventilatory-related oscillation ( $0.32 \pm 0.01$  and  $0.31 \pm 0.01$  Hz;  $27 \pm 4$  and  $22 \pm 2$  n, respectively). DRS did not significantly modify the spectral profile of both signals. These data seem to suggest that spinal structures might contribute to the genesis of the LF oscillation detectable in RR interval variability, independently of peripheral modulation of afferent sympathetic cardiovascular fibers.

## 549.4

NON-RESPIRATORY SLOW COHERENT RHYTHMS (0.2-2 Hz) IN MULTIPLE SYMPATHETIC NERVE DISCHARGES. Q.P. Yu, W.-X. Huang, M.I. Cohen\* and P.M. Gootman. Dept. of Physiol., Albert Einstein Col. Med., Bronx NY 10461.

Previous study has shown that sympathetic (symp.) nerve discharges have both fast rhythms (2-6 Hz or "3-Hz rhythm" and 7-13 Hz or "10-Hz rhythm"), and slower rhythms ( $<2$  Hz) that are presumably respiratory-related. The present study examined the possible existence of symp. non-respiratory components in these rhythms. In 31 midcollicular decerebrate, vagotomized, paralyzed cats, simultaneous recordings were taken from phrenic and 2-4 symp. nerves (cervical, splanchnic, inferior cardiac). Partial coherence analyses were used to distinguish slower symp. rhythms that were not respiratory related. All ordinary coherences (symp.-phrenic, symp.-symp., symp.-(inspiratory-tag)) had components in the range of 0.2-2 Hz, in addition to the 3 or 10 Hz peaks in symp.-symp. coherences. After partialization with the phrenic or inspiratory-tag signal, slower components in the symp.-symp. coherences were reduced but not eliminated. Further, these slower components still remained during hypocapnic apnea (abolition of normal phrenic rhythm). These results reveal for the first time that different symp. nerve discharges have coherent 0.2-2 Hz rhythms that are not related to respiration. (Supported by N.I.H. Grant HL-27300.)

## 549.6

SELECTIVE DEPRESSION OF THE 10-HZ RHYTHM IN SYMPATHETIC NERVE DISCHARGE (SND) BY CLONIDINE. H.S. Ozer\*, S. Zhong, S.M. Barman, and G.L. Gebber. Dept. Pharmacol./Tox., Michigan State Univ., E. Lansing, MI 48824.

The current study on urethane-anesthetized, baroreceptor-denervated cats is the first to show that clonidine selectively depresses the 10-Hz rhythm in SND when it co-exists with irregular 2- to 6-Hz oscillations. As revealed by autospectral analysis, power in the 10-Hz band of inferior cardiac nerve activity was dose-dependently (3-30  $\mu\text{g/kg}$  iv) reduced whereas power at frequencies  $\leq 6$  Hz was not changed. Following a cumulative dose of 30  $\mu\text{g/kg}$  iv, 10-Hz power was reduced to  $18 \pm 3\%$  of control while power at frequencies  $\leq 6$  Hz was  $97 \pm 8\%$  of control ( $n = 6$ ). These effects were reversed by iv idazoxan or rauwolscine which are  $\alpha_2$ -adrenoceptor antagonists. Inhibition of the 10-Hz rhythm by clonidine was accompanied by a reduction in mean blood pressure from  $87 \pm 7$  to  $72 \pm 7$  mm Hg. The effects of iv clonidine on SND were mimicked by microinjection of the drug into the caudal ventrolateral medulla. In contrast, microinjection into the rostral ventrolateral medulla depressed both frequency components. The power in SND at frequencies  $\leq 6$  Hz was significantly depressed by iv clonidine in 5 cats in which the 10-Hz rhythm was absent. These results imply that the 10-Hz rhythm generator exerts an inhibitory influence on the circuits responsible for 2- to 6-Hz oscillations. Depression of the 10-Hz rhythm by clonidine would release this inhibition, thereby counterbalancing the direct depressant effect of the drug on the low frequency components in SND (Supported by NIH grants HL-33266 and HL-13187.)

## 549.8

THE DISCHARGE PATTERN IN RENAL SYMPATHETIC NERVE ACTIVITY IN CONSCIOUS RATS. T. Kunitake, A. Shimokawa, M. Saita, K. Katoh, T. Hanamori and H. Kannan\*. Department of Physiology, Miyazaki Medical College, Miyazaki, 889-16, Japan

We investigated the change of discharge pattern in renal sympathetic nerve activity (RSNA) in conscious rats. Power spectrum analysis, employing a discrete Fast Fourier Transform algorithm, was used to quantify periodicities present in synchronized RSNA. In conscious rats with intact baroreceptors, RSNA was characterized by four frequency components occurring at about 0.5, 1.5, 6 and 12 Hz, which corresponded to the low-frequency fluctuation of heart rate, respiration, frequency of heart beat and its harmonics, respectively. After infusion of sodium nitroprusside (SN), the power for the component at 6 Hz which was substantially shifted with the frequency of heart beat, was significantly increased, while that for the three other components was attenuated. In sinoaortic denervated (SAD) conscious rats, all four components were abolished. We also performed the non-sequential analysis of both the peak to peak interval of RSNA and the relationship between RSNA and cardiac cycle. After detecting the peak in integrated RSNA by using the differential method, the peak to peak interval was measured. The time lag of each peak from the preceding R wave of electrocardiogram was also measured. The scatter diagram of peak to peak interval against time after R wave was made. In conscious rats with intact baroreceptors, three discrete areas that included almost all points were demonstrated on the scatter diagram. After infusion of SN, these three discrete areas persisted while their centers were slightly shifted. In SAD conscious rats, no discrete area appeared, those points were dispersed on the axis of time after the R wave. These findings suggest that 1) four frequency components exist in the synchronized RSNA of conscious rats, 2) the variation of RSNA at a frequency of heart beat is dominant during unloading of baroreceptor, and 3) arterial baroreceptors are responsible for generating the periodicity.

## 549.9

MUSCLE REFLEX INCREASES DISCHARGE OF SYMPATHETIC EFFERENTS. J.M. Hill, C.M. Adreani, C.L. Stebbins\*, M.P. Kaufman. Division of Cardiovascular Medicine, University of California, Davis, CA 95616.

Two neural mechanisms contribute to exercise-induced increases in cardiovascular and ventilatory function. The first, central command, proposes a parallel activation of central locomotor and medullary circuits controlling cardiovascular and ventilatory function. The second, the muscle reflex, proposes contraction-activated groups III and IV fibers increase cardiovascular and ventilatory function. In humans, whole nerve recordings of sympathetic discharge suggest that central command increases sympathetic outflow to skin but not to skeletal muscle and that the muscle reflex increases sympathetic outflow to skeletal muscle but not to skin. We, therefore, tested the hypothesis that the muscle reflex, but not central command, increases the discharge of single sympathetic postganglionic efferents innervating the triceps surae muscles of unanesthetized, decerebrate cats. Hexamethonium (2-20 mg/kg; iv) abolished the spontaneous and evoked activity, verifying that nerve recordings were sympathetic. The discharge of 13 efferents was increased by contraction ( $0.6 \pm 0.2$  to  $1.0 \pm 0.3$  imp/sec;  $P < 0.05$ ) but was not increased by stimulation of the mesencephalic locomotor region (MLR) ( $0.6 \pm 0.2$  to  $0.8 \pm 0.2$  imp/sec;  $P > 0.05$ ). In 9 efferents, MLR stimulation before phentolamine (2 mg/kg; iv) did not increase efferent discharge ( $0.5 \pm 0.6$  to  $1.0 \pm 0.6$  imp/sec;  $P > 0.05$ ) whereas MLR stimulation after phentolamine did ( $1.2 \pm 0.6$  to  $3.2 \pm 0.6$  imp/sec;  $P < 0.05$ ). We conclude that the muscle reflex stimulates sympathetic post-ganglionic efferents innervating the vasculature of skeletal muscle. Furthermore, baroreceptors buffer MLR-induced increases in the discharge of these efferents.

## 549.11

INDUCTION AND INHIBITION OF MEMBRANE POTENTIAL OSCILLATIONS IN RAT SYMPATHETIC PREGANGLIONIC NEURONES (SPN) BY NEUROTRANSMITTERS S.D. Logan\*, M.F. Nolan, C. Cammack, J.C. Gibson and D. Spanswick. Department of Biomedical Sciences, Marischal College, Aberdeen, AB9 1AS, UK.

We have previously described spontaneous membrane potential oscillations in a population of spinal neurones which were presumed to be SPN. These oscillations could give rise to bursting or beating patterns of spike discharge and we have suggested that they result from electrotonic coupling between neurones.

Using the whole-cell recording technique in young rat spinal cord slices 26% of sympathetic preganglionic neurones show spontaneous membrane potential oscillations. These oscillations consist of trains of biphasic waves which we have termed spikelets because of their similarity to truncated action potentials. Spikelets are composed of a brief depolarising transient followed by a longer hyperpolarising phase.

A further 35% of SPN could be made to oscillate by the application of excitatory neurotransmitters such as L-glutamate acting at both ionotropic and metabotropic receptors, by substance P (1-5  $\mu$ M) acting at NK<sub>1</sub> receptors and acetylcholine acting at nicotinic receptors. The oscillations are inhibited by GABA (250-400  $\mu$ M), muscimol (1-10  $\mu$ M) and baclofen (100  $\mu$ M), noradrenaline (5-20  $\mu$ M), carbachol (10-100  $\mu$ M) and by anaesthetics,  $\alpha$ -chloralose (100  $\mu$ M) and alphaxalone/alphadalone (5-50  $\mu$ M).

The actions of neurotransmitters in inducing oscillations means that over 60% of the SPN in this study were capable of exhibiting rhythmicogenesis. The ability of groups of electrotonically-coupled SPN to generate spontaneous discharges within the spinal cord provides a novel mechanism for the integration and synchronisation of information within the sympathetic nervous system.

MFN is in receipt of a British Heart Foundation Scholarship and CC a Glaxo R&D Studentship. This work was supported by grants from the BHF and the Wellcome Trust to SDL.

RESPONSES OF SYMPATHETIC PREGANGLIONIC NEURONES (SPNs) IN A NEONATAL RAT BRAINSTEM-SPINAL CORD PREPARATION TO APPLICATION OF ATP. Susan A. Deuchars. Royal Free Hospital School of Medicine, Rowland Hill St., London. NW3 2PF U.K.

ATP acting via P<sub>2</sub>-purinoceptors can elicit various responses while metabolism of ATP to adenosine may cause secondary effects via P<sub>1</sub>-purinoceptors (Ziganshin, Hoyle and Burnstock, Drug Dev. Res. 32, 134-146, 1994). Autoradiographic studies have indicated the presence of a relatively high density of P<sub>2</sub>-purinoceptors in the intermediate zone of the spinal cord (Bo and Burnstock, Neuroreport 5, 1601-1604, 1994). Therefore the effects of ATP (and its metabolite adenosine) on SPNs have been studied.

Neurones verified physiologically and histologically as SPNs were recorded using the whole cell patch technique (Deuchars, Morrison and Gilbey, J. Physiol. in press, 1995). Drugs were applied either by superfusion or iontophoresis in the vicinity of an SPN. A separate multibarrelled electrode was advanced close to the patch electrode until applications of glutamate caused a brisk response in an SPN. ATP was then applied and caused membrane potential changes in eight of eleven SPNs. These consisted of a slow depolarisation and a decrease in input resistance ( $n = 2$ ) or a slow depolarisation followed by a hyperpolarisation lasting up to 300s accompanied by an increase in membrane resistance ( $n = 6$ ). The later response may be elicited by adenosine derived from the metabolism of ATP since applications of adenosine caused only a slow hyperpolarisation. The receptors involved in mediating these responses are under investigation. Supported by the BHF and the Wellcome Trust

EXCITATORY AMINO ACID CONCENTRATIONS IN THE CAT SPINAL DORSAL HORN INCREASE DURING STATIC MUSCLE CONTRACTION.

G.A. Hand, G.L. Kramer, F. Petty, G.A. Ordway, and L.B. Wilson\*. The Moss Heart Center and Depts. of Physiology and Psychiatry, UT Southwestern Medical Center, Dallas, TX, 75235.

In anesthetized cats, static hindlimb muscle contraction reflexly increases mean arterial pressure (MAP) and heart rate (HR). Evidence suggests that excitatory amino acids (EAAs) are involved in the spinal transmission of this reflex. We tested the hypothesis that static contraction of the triceps surae muscle increases the extracellular concentration of glutamate (GLU) and aspartate (ASP) in the L7 dorsal horn of the spinal cord. With the exception of the L7 dorsal root, the L5 through S2 spinal roots were cut ipsilaterally to the contracting muscle. After the insertion of the microdialysis probes and a 3-hour recovery period, a 2-minute static contraction was evoked. MAP and HR increased by  $53 \pm 8$  mmHg and  $20 \pm 4$  bpm. The concentration of GLU increased  $324 \pm 59$  to  $857 \pm 80$  nM, while ASP increased  $199 \pm 57$  to  $499 \pm 113$  nM. GLU and ASP rose by similar amounts in 2 subsequent contractions. In these latter contractions, MAP and HR also increased significantly. By contrast, in cats whose L7 dorsal roots were cut after the first contraction, neither MAP, HR, GLU, nor ASP were significantly increased over baseline levels. These data demonstrate that static contraction of the hindlimb increases the extracellular concentration of GLU and ASP in the dorsal horn. Further, this study suggests that these two EAAs are involved in the spinal transmission of sensory information from the hindlimb muscle.

## 549.12

Preferential Uptake of the Binding Fragment of Tetanus Toxin (TTC) by GABAergic Terminals in the Intermediolateral Cell Column (IML). An Immuno-Electronmicroscopic Study. M.A. Ligorio\* and J.B. Cabot. Dept. of Neurobiology & Behavior, SUNY at Stony Brook, NY 11794-5230.

Tetanus is an acute infection marked not only by tonic muscle spasms, but also by potentially fatal symptoms characteristic of a hyperactive sympathetic nervous system; including, tachycardia, hypertension, and an elevated metabolic rate. Using local tetanus as an experimental model, Paar and Wellhöner (*Naunyn-Schmiedeberg's Arch. Pharmacol.* 276, 437-445, 1973) correlated an increase in sympathetic preganglionic neuron (SPN) output with a loss of inhibition in spinal polysynaptic reflexes. Tetanus toxin (a 150 kD heterodimer with a proteolytic subunit) may mediate these effects by specifically blocking the release of inhibitory neurotransmitters from axon terminals in the IML. The direct transport of TTC into the IML has previously been demonstrated (Cabot et al., *Neuroscience* 40, 805-823, 1991), but whether or not TTC is sequestered by terminals containing inhibitory neurotransmitters remains in question.

To test this hypothesis TTC was injected into the right superior cervical ganglion of male Sprague Dawley rats. After 2 days rats were perfused, and the first three thoracic spinal cord segments were processed for electron microscopy. Pre-embed immunoperoxidase and post-embed immunogold histochemistry were combined to determine if TTC and GABA colocalized in axon terminals in the IML.

Several non-overlapping photomontages of the IML were analyzed. An average of  $74\% \pm 2.8\%$  (SE) of all putative GABAergic (GABA+) terminals also contained TTC (TTC+). Contrarily, all terminals that were not GABA+ only had a  $51\% \pm 1.7\%$  (SE) chance of being TTC+. Furthermore, TTC and GABA were colocalized in a subpopulation of terminals closely apposed to identified SPN processes.

Corresponding TTC+ percentages of this subsample were statistically indistinguishable from the IML averages ( $75\% \pm 9.7\%$  (SE) for GABA+ terminals;  $47\% \pm 6.4\%$  (SE) for non GABA+ terminals). Assuming the presence of TTC in a given terminal means the same terminal would be poisoned by the native toxin in an actual case of tetanus, these results suggest that the selective uptake of tetanus toxin by GABAergic terminals is an important basis for the observed disinhibition of SPNs during tetanus. Supported by HLBI Merit award HL24103 to JBC.

METABOTROPIC GLUTAMATE RECEPTOR AGONIST, L-AP4, REDUCES MEDULLARY-STIMULUS EVOKED EPSPs IN NEONATAL RAT SYMPATHETIC PREGANGLIONIC NEURONS.

B. Bhattacharyya\* and S.F. Morrison. Dept. of Physiology, Northwestern University Medical School, Chicago, IL 60611.

The excitatory input from neurons in the rostral ventrolateral medulla (RVLM) maintains the basal discharge of spinal sympathetic preganglionic neurons (SPNs), is mediated primarily by glutamate and is important for the maintenance of resting arterial pressure. We used the *in vitro*, neonatal rat brainstem-spinal cord preparation to examine the effect of the metabotropic glutamate receptor agonist, L-AP4, on the EPSPs evoked in upper thoracic SPNs by stimulation of the RVLM (twin pulses, 0.8 ms duration, 6 ms apart, 200  $\mu$ A, 0.3 Hz). Whole-cell patch recordings of SPNs yielded resting membrane potentials with a mean of  $-47 \pm 2$  mV and RVLM stimulus-evoked EPSPs with a mean peak amplitude of  $11 \pm 3$  mV at a holding potential of  $-72 \pm 1$  mV. Bath-application of L-AP4 (10  $\mu$ M) reduced the EPSP amplitude by  $71 \pm 5\%$  ( $n=7$ ) after 5 minutes. Following a 30-minute wash, simultaneous application of the antagonist, MAP4 (200  $\mu$ M), inhibited the ability of L-AP4 (10  $\mu$ M) to depress the evoked EPSP (reduction in amplitude:  $11 \pm 6\%$ ,  $n=4$ ). These data indicate the importance of a (potentially) presynaptic metabotropic glutamate receptor in regulating the response of SPNs to their primary excitatory input from the RVLM. Supported by NIH HL-47196.

**DO SYMPATHETIC PREGANGLIONIC NEURONS RECEIVE SYNAPSES FROM INTRASPINAL CATECHOLAMINE NEURONS?** I.J. Llewellyn-Smith<sup>1</sup>, A.K. Cassam<sup>2</sup>, N.R. Krenz<sup>2</sup>, A.V. Krassioukov<sup>2</sup>, J.B. Minson<sup>1</sup>, P.M. Pilowsky<sup>1</sup>, L.F. Arnold<sup>1</sup>, J.P. Chalmers<sup>1</sup> and L.C. Weaver<sup>2</sup>.  
<sup>1</sup>Dept. of Medicine, Flinders University, Bedford Park, South Australia 5042 and <sup>2</sup>Robarts Research Institute, London, Ontario, Canada

Sympathetic preganglionic neurons (SPN) receive synapses from nerve fibers containing a variety of transmitters, including monoamines. Catecholamine synapses are thought to arise from supraspinal neurons, but dopamine synapses, which could come from intraspinal neurons, also occur in the intermediolateral cell column. To investigate whether SPN receive intraspinal catecholamine synapses, we transected the spinal cords of rats at T5. After 7-8 days, we injected cholera toxin B (CTB) into the adrenal medulla. Fourteen days after transection, the rats were perfused. Control rats received CTB injections but not transections. Sections of spinal cord from below the transection and from control segments were reacted for either tyrosine hydroxylase (TH)- and CTB-immunoreactivity simultaneously or TH-immunoreactivity alone. TH-positive fibers were present in the intermediolateral cell column below the transections, but there were fewer than in controls. SPN in both spinal and control rats received synapses from TH-immunoreactive boutons. Since degenerating nerve terminals in the intermediolateral cell column have virtually disappeared by 7 days after transection, these results suggest that some, but not all, of the catecholamine synapses on SPN come from intraspinal neurons. However, it is possible that non-catecholaminergic neurons synapsing on SPN could begin to express TH in response to the injury.

## 549.17

**CALRETININ-IMMUNOREACTIVITY IDENTIFIES A SUBPOPULATION OF ADRENAL MEDULLARY PREGANGLIONIC NEURONS IN THE CAT THAT INNERVATE ONLY NORADRENERGIC CHROMAFFIN CELLS.** S.L. Edwards, C.R. Anderson\* and R.M. McAllen\* Department of Anatomy and Cell Biology and \*The Howard Florey Institute, University of Melbourne, Parkville, Australia, 3052.

Immunohistochemistry of sections of cat adrenal gland showed that calretinin-immunoreactive (IR) nerve terminals were abundant in the medulla but had a patchy distribution. In sections stained for phenylethanolamine-N-methyl transferase (PNMT)-IR, the patches of calretinin-IR terminals were found to coincide exclusively with cords of chromaffin cells lacking PNMT-IR. Synaptophysin immunohistochemistry was used to identify the entire population of nerve terminals in the adrenal medulla. In combination with calretinin-IR, it was apparent that most, but not all, synaptophysin-IR terminals within patches of calretinin-IR terminals contained calretinin. Retrograde-labelling from the adrenal medulla using cholera toxin subunit B labelled preganglionic neurons between T4 and L1. One third of the labelled preganglionic neurons were also immunoreactive for calretinin. Although there was a major overlap, there was a clear difference in the distribution of retrogradely labelled preganglionic neurons with calretinin-IR compared to those lacking it. The distribution of the former was skewed caudally with the maximum numbers in T9 while the distribution of the latter was skewed rostrally with the maximum numbers in T7. Thus calretinin-IR marks a population of preganglionic neurons innervating noradrenergic chromaffin cells in the adrenal medulla, although calretinin is not found exclusively in these neurons as calretinin-IR was found in neurons in the intermediolateral nucleus from T1 to L5. This demonstration of separate populations of preganglionic neurons innervating the two classes of chromaffin cells provides for the first time evidence of the organisation of preganglionic neurons underlying the differential release of adrenaline and noradrenaline by the adrenal medulla in response to different physiological challenges.

## 549.19

**SERIAL SECTION ULTRASTRUCTURAL ANALYSIS OF SYNAPTIC INPUTS TO DENDRITES AND CELL BODIES OF DYE-FILLED NEURONS IN GUINEA-PIG SYMPATHETIC GANGLIA.** I.L. Gibbins\*, H. Rodgers and S. Matthew. Department of Anatomy & Histology, and Centre for Neuroscience, Flinders University, SA 5042, Australia.

Sympathetic ganglion cells receive multiple convergent synaptic inputs from spinal preganglionic neurons. Although most ganglion cells have well developed dendritic trees, little is known of the distribution of synapses along the dendrites. Therefore, we injected neurobiotin or Mini-ruby into single sympathetic ganglion cells to reveal the full extent of their dendritic trees and prepared the neurons for electron microscopy. The distribution of synapses onto the cell body and dendrites of six cells were reconstructed from runs of up to 400 serial sections. Altogether, more than 1000 µm of dendrites and most of three cell bodies were reconstructed in detail. Synapses were rare, with most of the neuronal surface being covered with Schwann cells. Synapses usually formed small clumps, most often around the origins of dendrites, but also up to 100 µm from the cell body. On average, there was about one synapse per 25 µm of dendritic length. Up to 25% of synapses were made onto the cell body or proximal dendrites within 10 µm of the cell body. Most of the synaptic boutons surrounding a cell body actually made synapses onto the dendrites of other neurons in the neighbourhood. A typical neuron with a dendritic tree of 800 - 1200 µm total length would be unlikely to receive more than 100 synapses. Since a neuron of this size would have up to 10 convergent inputs, each input must form only a small number of synapses with the target neuron. The low density of axodendritic synapses, combined with the short electrotonic lengths of the dendrites, suggests that the function of the dendrites has little to do with either providing physical space for synapses or modulating the electrical integration of postsynaptic potentials.

## 549.16

**NADPH-DIAPHORASE REACTIVE SYMPATHETIC PREGANGLIONIC NEURONS & POSSIBLE INTERACTIONS WITH CATECHOLAMINERGIC FIBERS IN HUMAN SPINAL CORD.** I.L. Smithson, K.G. Smithson\* and E.E. Benarroch. Departments of Neurology and Anesthesiology, Mayo Clinic, Rochester, MN 55905.

Sympathetic preganglionic neurons (SPN)s at T6 to T10 levels are critical for maintenance of postural normotension in humans. Depletion of these neurons produces severe orthostatic hypotension. SPNs are nicotinamide adenine dinucleotide phosphate-diaphorase (NADPH-d) reactive. We sought to determine the distribution of NADPH-d reactive SPNs in human spinal cord and their interactions with descending catecholaminergic fibers, as identified by tyrosine hydroxylase (TH) immunoreactivity. Thoracic spinal cords were obtained at autopsy from one woman and two men (age 62-93). Fixed coronal, horizontal, and sagittal 50 µm sections were obtained at T4, T8, and T10 levels. Single sections were reacted for NADPH-d, TH, or both, and examined under bright field microscopy. Abundant NADPH-d reactive SPNs were observed at all segments examined, forming clusters concentrated in the intermediolateral cell column (IML) but also present in the adjacent white and gray matter. NADPH-d SPN processes ramified both medially and rostrally, extending to adjacent SPN cell clusters. TH-immunoreactive fibers formed a loose bundle primarily located in a lateral column, adjacent to the IML. TH fibers were abundantly distributed within the NADPH-d reactive neuropil; some TH-immunoreactive varicosities appeared to directly contact NADPH-d reactive SPNs. Thus, adjacent clusters of NADPH-d SPNs appear to receive direct innervation from descending catecholaminergic innervation (presumably from C1 and A5 groups). These features may be important for mechanisms of normal maintenance of orthostatic normotension in humans and their potential involvement in clinical autonomic disorders. Supported by NIH PO1 NS32352.

## 549.18

**STELLATE GANGLIA MODULATE THE CARDIOVASCULAR (CV) RESPONSES TO CHEMICAL STIMULATION OF SENSORY RECEPTORS IN THE LEFT VENTRICLE OF PIGLETS.** Shiwei Tong, Phyllis M. Gootman\*, Isaac D. Fraser, Susan Ingenito, and Norman Gootman. Dept. of Physiol. SUNY- Health Science Center at Brooklyn, Brooklyn, NY 11203.

CV responses elicited by left ventricular (LV) injection of veratrum alkaloids (VVA) in developing piglets included bradycardia, vasodilation and hypotension; the responses were abolished following bilateral vagotomy (Gootman, et al. *Am. J. Physiol.* 1986;251:H748). However, it is unknown whether cardiac sympathetic innervation modulate these CV responses. The present study was carried out in Saffan-anesthetized, paralyzed, thoracotomized, artificially ventilated (100% O<sub>2</sub>) pigs (3-4 wks old) to determine whether left stellate ganglionectomy (LSG) or right stellate ganglionectomy (RSG) altered responses to LV injections of VVA (20 µg/kg). Aortic pressure (AoP) and left ventricular pressure (LVP) were recorded on a Grass Model 7C polygraph and on VCR tape for later analyses. Either RSG or LSG was carried out in each animal studied. At 30 min after RSG or LSG, a saline-control (0.1 ml/kg) injection was made via a catheter in the LV; 15 min later, VVA (20 µg/kg, 0.1 ml/kg) was rapidly injected (within 2-3 sec). Injections of VVA elicited greater decreases in mean AoP (15 ± 4 mmHg) and LVP (10 ± 2 mmHg) in the LSG group than in the RSG group (p<0.05). Heart rates were slower in the RSG group as compared to LSG group. These results indicate a greater role for the left stellate ganglion in modulating ventricular inotropic variables. This study provides further support of a laterality difference in postnatal development of cardiac sympathetic innervation (Tong, et al., *Lab. Animal Sci.* 1995, in press and Gootman et al., *J. Auton. Nerv. Syst.* 1992;38:191.). (Supported by NIH grant HD-28931)

## 550.1

CNS NEURONS CAPABLE OF GLOBAL CONTROL OF THE SYMPATHETIC NERVOUS SYSTEM. A.S.P. Jansen<sup>1</sup>, V. Karpitskiy, T.C. Mettenleiter<sup>2</sup>, and A.D. Loewy<sup>1</sup>. Dept. Anatomy and Neurobiology, Washington Univ. Sch. of Med., St. Louis, MO 63110 and <sup>2</sup>Fed. Research Centre for Virus Diseases of Animals, Friedrich-Loeffler Institutes, D-17498 Insel Riems, Germany.

Two different genetically engineered forms of the Bartha strain of pseudorabies virus (PRV) were used as transneuronal tracers to identify a common set of CNS neurons that regulate two different sympathetic outflow systems - one affecting the heart and the other controlling the adrenal gland. Both PRV strains contained a unique cellular marker so that they could be used together to visualize dually infected neurons by a double color fluorescence immunohistochemical staining procedure. Experiments were done in which one virus was injected unilaterally into the stellate ganglion and the other into the ipsilateral adrenal gland (or vice versa). After 4 days survival, the rats were perfused. In the brainstem, double labeled neurons were localized in the rostral ventrolateral medulla, rostral ventromedial medulla and caudal raphe nuclei. In the pons, double labeled neurons were found in the region of the A5 cell group and subcoeruleus area. A restricted part of the caudal ventrolateral periaqueductal gray matter contained double labeled neurons. In the hypothalamus, double labeled neurons were found in the paraventricular and lateral hypothalamic nuclei. This study shows that several specific areas in the brain contain neurons that are potentially able to modulate the sympathetic outflow to both adrenal gland and stellate ganglion. These neurons may cause a widespread coordinated multisystem visceral response during life-threatening situations (e.g., fight-or-flight response) or coordinate global sympathetic changes seen in the sleep-wakefulness cycle.

## 550.3

EARLY ENVIRONMENTAL INFLUENCES ON BLOOD PRESSURE RESPONSES TO STRESS IN BORDERLINE HYPERTENSIVE RATS. B.J. Sanders<sup>\*</sup> and M.J. Gray. Department of Psychology, Drake University, Des Moines IA 50311.

Several converging lines of evidence suggest that the perinatal environment can affect cardiovascular regulation in the adult rodent. Our laboratory has used the borderline hypertensive rat (BHR) to study the interaction between genetic and environmental factors in the development of hypertension. In this study, we used a cross fostering paradigm to examine maternal influence on the cardiovascular functioning of adult male BHR. All BHR were bred by mating female spontaneously hypertensive with male Wistar-Kyoto rats. On the day of birth, litters of BHR pups were assigned to one of three conditions: cross-fostered to lactating WKY dams (BHR-CF); in-fostered to another lactating SHR dam (BHR-IF), or were allowed to be reared by their natural dam (BHR-NAT). Maternal observational data revealed that the WKY dams spent significantly more time engaged in passive as contrasted with arched nursing. Also, BHR-CF pups gained significantly more weight during the weaning period. At 8-10 weeks of age systolic (SBP) and diastolic (DBP) blood pressure, and heart rate (HR) was measured directly in subjects from each group. Resting SBP, DBP and HR did not differ between the groups. However, when exposed to 10 minutes of intermittent footshock stress, BHR-CF displayed significantly lower SBP and DBP throughout the stress session compared to the BHR-IF and BHR-NAT groups. These results suggest that cardiovascular functioning may be affected by early environmental influences, some of which may be related to maternal-pup interactions.

## 550.5

EFFECTS OF TEMPERATURE ON SCIATIC NERVE LASER DOPPLER FLOW. K.C. Dines, M.C. Jorge, A.P. Mizisin and M.W. Kalichman<sup>\*</sup>. Department of Pathology, University of California, San Diego, La Jolla, CA 92093-0612.

One factor contributing to differences in nerve blood flow measurements, particularly in models of experimental diabetic neuropathy, may be differences in nerve and body temperature. Using laser Doppler flowmetry, the effects of nerve and body temperature were examined in mature female Sprague-Dawley rats (225-250g) under pentobarbital anesthesia (25mg/kg, i.p.). In the first of two studies, nerve laser Doppler flow was measured in the sciatic nerves of two groups of rats (n=6 per group) with normothermic core temperature (mean 37.2 °C) and nerve temperatures of either 30.5±0.4 °C (mean ± SEM) or 37.1±0.0 °C. In the second study, flow was measured in two groups of rats (n=6 per group) with mean nerve temperatures of 37.1 °C and a core temperature maintained either at 33.3±0.3 °C or 37.4±0.1 °C. Nerve temperature was regulated with an infrared heat lamp and core temperature was maintained with a heating pad. For all groups, Doppler flow, heart rate, blood pressure, and respiratory rate were monitored every 2 minutes for 20 minutes and averaged. In animals with core temperature maintained at 37°C, heating the sciatic nerve from room temperature to 37°C reduced nerve Doppler flux by 37.7±11.5%. This reduction was significantly greater (P<0.05) than that observed in nerves kept at room temperature (5.8±7.1%). Blood pressure tended to decrease with nerve warming, but other cardiovascular parameters were unchanged. In animals with nerve temperature at 37°C, maintaining core temperature at 37°C was associated with a reduction of 34.4±15.1% in Doppler flux from initial values. This reduction was not significantly different from that observed when core temperature was allowed to approximate room temperature (26.9±3.9%). Core hypothermia significantly depressed respiration rate and blood pressure, but not vascular resistance. These data are not consistent with the hypothesis that nerve blood flow measurements depend on core temperature, but suggest the possibility that hindlimb temperature has a role in regulation of nerve blood flow.

## 550.2

LABELING OF DIFFERENTIAL NEURONAL POPULATIONS AFTER VIRAL INFECTION OF THE DIFFERENT PARTS OF THE RAT HEART. G.J. Ter Horst<sup>\*</sup> and M.H.J. De Jongste. Dept. Biol. Psychiat. and Thoraxctr. Univ. and Acad. Hosp. Groningen. Oostersingel 59. Groningen. The Netherlands.

Our knowledge of the anatomy of cardio-vascular neuronal networks is limited. We have now characterized the locations in the brainstem and thoracic spinal cord of neurons that may modulate the functioning of the various parts of the rat heart, using the retrograde transneuronal viral labeling method. Also, the link of the neurons to the ortho- or parasympathetic heart innervation was established. To do this, Th1 transfections were performed. *Method:* Pseudorabies virus solution was deposited in the right (RV; n=10) or the left ventricular (LV; n=14) myocardium, and in the right atrium (RA; n=10). Four days after the infection the animals were fixed and sections of the brain were immuno-cytochemically studied to reveal the PRV-infected neurons. Spinalized animals (n=85) underwent the same procedure. *Results:* Bilateral, the intermediolateral cell group was infected at the levels Th1-Th11 both after RV and LV inoculation. Uni-lateral labeling in the left IML of Th1-Th6 was seen after infection of the RA. Parasympathetic preganglionic neurons were found both in the DMNX (18.2%) and the peri-ambigous area. Also, the location of the preganglionic parasympathetic neurons was related to the site of the virus injection. Higher order neurons were found in the area postrema, the solitary tract nucleus, the spinal trigeminal nuclei, the lateral reticular formation, and in the nuclei of the ventral medulla oblongata. The labeling in the latter areas, in particular the raphe pallidus, the ventromedial and the rostro-ventrolateral reticular formation was reduced or absent after the spinalization, showing the relation of these regions to the orthosympathetic heart innervation. Different neuronal populations were infected in the rostroventrolateral medulla. *Conclusion:* Viral retrograde transneuronal labeling of the heart innervating neuronal networks shows a "cardiomotopy" in the spinal cord and the brainstem.

INCREASED BLOOD PRESSURE DURING CONTEXTUAL CONDITIONED FEAR: A STUDY USING TELEMETRIC PROBES. P. Carriev<sup>\*</sup>, F. Westbrook and G. Paxinos. School of Psychology, University of New South Wales, Sydney 2052, Australia.

A rat which experiences footshock will rapidly acquire contextual fear to the environment in which it has been shocked. Contextual fear is observed upon reexposure and is characterized by a motionless posture, freezing, and signs of autonomic activation such as urination and defecation. The aim of this study was to determine the extent of the cardiovascular changes associated with this type of fear.

This study shows that simple reexposure to an expected aversive environment is associated with a marked increase in systemic blood pressure in the rat. Supported by the National Heart Foundation of Australia.

## 550.6

QUANTIFICATION OF CARDIAC NONDETERMINISM USING RECURRENCE PLOT STRATEGIES. Charles L. Webber, Jr.<sup>\*</sup> and Joseph P. Zbilut. Departments of Physiology, Loyola University of Chicago, Stritch School of Medicine, Maywood, IL 60153 and Rush Medical College, Rush-Presbyterian-Saint Luke's Medical Center, Chicago, IL 60612.

Biodynamical systems can be classified as periodic, quasi-periodic, aperiodic, or chaotic. To account for dynamical noise, simulations of deterministic oscillatory behavior can be made more realistic by including additive or multiplicative noise. An additional approach is to view biodynamical systems as nondeterministic in nature. Such systems possess discontinuous, piece-wise deterministic components (dynamical trajectories) with interposing singularities (dynamical pauses). To quantitatively gauge the level of nondeterminism present in a common physiological dynamic, electrocardiograms were recorded from normal volunteers. Each cardiac cycle was manually partitioned into deterministic (PQRST interval) and stochastic (TP interval) components. Summation of both serial segments reconstructed the complete cardiac cycle (PP interval). Coefficients of variation (covar) were computed over hundreds of values for each component. The degree of nondeterminism present scaled directly as the ratio of PP-covar to PQRST-covar (ratios > 1). Recurrence plot analysis (RPA, *J. Appl. Physiol.* 76: 965-973, 1994) was next conducted on all intervals with the finding that deterministic structuring of the dynamic decreased as the level of nondeterminism increased. It is concluded that: 1) different subjects exhibit differing levels of nondeterminism in their cardiac dynamics; 2) resident nondeterminism can be gauged by RPA without laboriously partitioning each cycle into its principle components. Other systems may likewise exhibit nondeterministic structuring including even DNA information systems with interposing deterministic exons (coding DNA) and stochastic introns (junk DNA).

## 550.7

**IDENTIFICATION OF BRAINSTEM AND DIENCEPHALIC CARDIORESPIRATORY AREAS ACTIVATED DURING EXERCISE IN AWAKE RATS.** G.A. Iwamoto\*, S.M. Wappel, G.M. Fox, K.A. Buetow and T.G. Waldrop. Depts. of Veterinary Biosciences, Physiology & Biophysics and Neuroscience Program, University of Illinois, Urbana IL 61801

Brain areas active during treadmill exercise (EX), compared to rest conditions, were identified using immunocytochemical labeling of the protein product of the proto-oncogene c-fos. Increased labeling with EX was observed in the "defence area" or "hypothalamic/subthalamic locomotor regions" including the posterior and lateral hypothalamic areas. Limited increases in labeling were also observed in the medial preoptic region. Increased labeling was also found in both colliculi, periaqueductal gray matter, cuneiform nucleus ("mesencephalic locomotor region") and in the region analogous to the A-5 catecholamine area and adjacent superior olive. Increased labeling with EX was also found in n. cuneatus and gracilis, medial portion of n. tractus solitarius, rostral and caudal ventrolateral medulla and medial structures equivalent to the raphe nuclei and adjacent ventral medulla. Conspicuous by an absence of labeling with EX were cells in thalamic areas associated with somatosensory function. Thus, areas in which labeling was increased during exercise closely correlate with brain areas which have been implicated in both autonomic and somatomotor control. These results from awake, exercising rats support those obtained previously in anesthetized animal preparations. (Supported by NIH HL06296 and NIH HL37400).

## 550.9

**ESTIMATION OF NICOTINIC RECEPTOR BINDING SITES IN THE CNS OF SPONTANEOUSLY HYPERTENSIVE (SHR) AND NORMOTENSIVE RATS BY AUTORADIOGRAPHY.** M.Gattu, S.E. Urbanawiz, J.R. Pauly and J.J. Buccafusco\*. Dept. Veterans Affairs Medical Center, and Dept. Pharmacology Toxicology, Medical College of Georgia, Augusta, GA 30912.

Central cholinergic neurons play an important role in central cardiovascular regulation and have been implicated in the pathogenesis of spontaneously hypertensive. SHR respond with exaggerated pressor responses to pharmacologic stimulation of central cholinergic muscarinic receptors compared with normotensive Wistar Kyoto rats (WKY). Less is known regarding the role of central nicotinic receptors. We estimated the number of nicotinic receptor binding sites in the brains of 12 week old SHR and WKY by using standard autoradiographic techniques. Coronal sections were exposed to saturating concentrations of [<sup>3</sup>H]-cytisine ( $\alpha_7$  subunit-containing sites) and [<sup>125</sup>I]- $\alpha$ -bungarotoxin ( $\alpha_7$  sites). In general, [<sup>3</sup>H]-cytisine binding was reduced (by up to 25%) in the brains of SHR vs. WKY. Significant reductions were observed in about 50% of the regions analyzed, including frontal cortex, caudate putamen, nucleus accumbens, medial habenula, superior colliculus and interpeduncular nucleus. SHR exhibited only regional reductions in [<sup>125</sup>I]- $\alpha$ -bungarotoxin binding sites. These were relegated to the frontal cortex and anterior olfactory nucleus (interstrain differences 29 and 32%). However, no strain differences were observed in traditional cardiovascular regulatory areas such as locus coeruleus, rostral ventrolateral medulla, parabrachial nuclei, olivary nuclei and trigeminal nuclei. Further experiments will be necessary to determine whether these alterations in the levels of nicotinic receptors in SHR are reflected in functional differences between SHR and WKY. Supported by the Dept. VA Medical Center.

## 550.11

**A WORKING HEART-BRAINSTEM PREPARATION (WH-BP) OF THE MATURE MOUSE FOR STUDYING REFLEX REGULATION OF CENTRAL CARDIO-RESPIRATORY ACTIVITY**

J.F.R. Paton\* Dept. Physiology, Univ. Bristol, Bristol, BS8 1TD, UK.

An *in vitro* wh-bp of the mouse is being developed to study medullary mechanisms controlling cardio-respiratory activity. Mice (3-4 weeks old) anaesthetised with ether were decerebrated, abdomenotomized and perfused via the descending aorta with carbogenated artificial cerebrospinal fluid containing an oncotic agent. Heart rate stabilized between 6-7 Hz and generated an end-systolic left ventricular pressure of  $100 \pm 5$  mmHg (mean  $\pm$  SD; n=21). Adequate oxygenation of the brainstem was assessed by the pattern of central respiratory activity recorded from a phrenic nerve (PN). Both the oncotic and perfusion pressures of the perfusate were adjusted so that PN discharge included a ramp-inspiratory component (300-450 ms duration), a rapid decline and post-inspiratory discharge (PI) which is comparable to that recorded from spontaneously breathing, anaesthetised mice of the same age (Paton & Richter, 1995: *Pflugers Archiv*, 430, 115-124). In the wh-bp PN discharge occurred regularly at  $24 \pm 2.4$  bursts/min and remained stable for >6 hours at 31°C. An atropine-sensitive sinus arrhythmia (coincident with the onset of the PI phase) was indicative of a central respiratory modulation of cardiac vagal motor neurones. Further, activation of either left ventricular receptors (via intra-ventricular injection of veratridine; 2  $\mu$ g) or baroreceptors (by elevating perfusion pressure) enhanced and prolonged PI activity and evoked a vagally mediated bradycardia. The findings suggest that the wh-bp may be potentially useful for studying cardio-respiratory reflex afferent regulation of cardiac vagal motor outflow at a cellular level.

British Heart Foundation funded research.

## 550.8

**THE ROLE OF ADENOSINE AND ATP METABOLISM IN A HYPOTHALAMICALLY EVOKED CARDIOVASCULAR RESPONSE.** T. Thomas, J.H. St Lambert & K.M. Spyer\*. Dept. of Physiology, Royal Free Hospital School of Medicine, Rowland Hill St, London NW3 2PF.

In  $\alpha$ -chloralose anaesthetised rats, stimulation of restricted sites in the hypothalamus elicits a characteristic cardiovascular response that is an integral component of the defence reaction. Specifically there is a biphasic increase in arterial pressure and a tachycardia. We have illustrated that adenosine is important in these changes by acting on A<sub>1</sub> receptors within the brainstem (St Lambert et al., J. Physiol. 479.P, 15P, 1994). To determine whether this adenosine is released as a result of ATP metabolism the effects of  $\alpha$ , $\beta$ -methylene ADP ( $\alpha$ , $\beta$ -meADP), an ecto-5'-nucleotidase inhibitor, on the evoked cardiovascular response were examined. Microinjections of  $\alpha$ , $\beta$ -meADP (500  $\mu$ M, 50 nL) were made at 12 sites within nucleus tractus solitarius (NTS) and 9 sites in the rostral ventrolateral medulla (RVLM). Only the initial rise in arterial pressure was reduced (32.4%,  $P < 0.01$ ) by injection of  $\alpha$ , $\beta$ -meADP at 6 sites within NTS; it had no effect when microinjected in the remaining 6 sites. On the other hand,  $\alpha$ , $\beta$ -meADP reduced only the secondary increase in arterial pressure (17.8%,  $P < 0.05$ ) when injected into all sites tested within the RVLM. The tachycardia was unaffected by microinjection of  $\alpha$ , $\beta$ -meADP into any region. These data suggest that adenosine which contributes to the cardiovascular changes associated with hypothalamic stimulation is derived from ATP metabolism. The different effects of  $\alpha$ , $\beta$ -meADP in NTS and RVLM may be explained by a difference in adenosine A<sub>1</sub> receptor density within these regions (St Lambert et al., 1994). Supported by MRC and BHF.

## 550.10

**AUTORADIOGRAPHIC DEMONSTRATION OF A<sub>1</sub> RECEPTORS IN REGIONS OF THE RAT AND CAT CNS INVOLVED IN CARDIOVASCULAR CONTROL.** J.H. St. Lambert, M. R. Dashwood, J. Muddle, C.D. Johnson\* & K.M. Spyer. Dept. Physiology, Royal Free Hospital School of Medicine, Rowland Hill St. London, NW3 2PF.

*In vivo* studies in the rat have implicated central adenosine A<sub>1</sub> receptors in the cardiovascular changes associated with the hypothalamic defence response. Here *in vitro* autoradiography has been used to study the distribution of [<sup>3</sup>H] DPCPX (an A<sub>1</sub> antagonist) binding sites in sections of the rat and cat forebrain and lower brainstem from images generated on radiation-sensitive film. Quantitative assessment of receptor density was performed and underlying tissue stained for histological examination. In both species there was a heterogeneous distribution of A<sub>1</sub> binding sites in both the forebrain and the brainstem. Specifically there was a high density of A<sub>1</sub> binding sites in the hippocampus and thalamus. In addition low levels of binding were observed in the mamillary bodies and the hypothalamus. In the brainstem, the highest density of A<sub>1</sub> binding sites was observed in the ventral lateral medulla, hypoglossal nucleus and the caudal nucleus tractus solitarius. However, receptor density was low in areas of the rostral nucleus tractus solitarius and the trigeminal tract. These results illustrate that adenosine A<sub>1</sub> receptors are localised in specific CNS regions known to be involved in central cardiovascular control. Supported by the MRC and BHF.

**THE EFFECT OF SPINAL CORD TRANSECTION ON THE NMDA RECEPTORS OF SYMPATHETIC PREGANGLIONIC NEURONS.** N.R. Krenz\* and L.C. Weaver. Neuroscience Program, The Roberts Res. Inst. and University of Western Ontario, London, Ontario, Canada N6A 5K8.

Spinal cord injury (SCI) at cervical and high thoracic levels often results in autonomic dysreflexia, which is characterized by increases in blood pressure in response to sensory stimulation. This enhanced excitability may be caused by overexpression of NMDA receptors on the sympathetic preganglionic neurons (SPNs). Intact male Wistar rats were compared to rats one and two weeks after spinal cord transection at the T<sub>7</sub> level. Antibodies to the NMDA-R1 receptor subunit, and binding of [<sup>3</sup>H] MK-801, a specific NMDA receptor antagonist, were used to assess the density of NMDA receptors in the intermediolateral cell column which contains the SPNs. One week after transection, the density of NMDA receptors was significantly reduced in the segments immediately caudal to the injury. Two weeks after SCI, there was no difference in the density of NMDA receptors between control and spinal animals at any level of the cord. Since autonomic dysreflexia is well established in rats two weeks after spinal cord transection, NMDA receptor overexpression appears not to play a role in the development of abnormal blood pressure responses. Instead, the decrease and resurgence of NMDA receptor density parallels the somal and dendritic atrophy and recovery of SPNs observed after SCI, indicating that the changes in receptor density may be a function of membrane surface area. Supported by MRC Canada.

## INTRASPINAL NEUROTRANSMITTERS POTENTIALLY INVOLVED IN AUTONOMIC DYSREFLEXIA AFTER CORD INJURY.

A.K. Cassam\* and L.C. Weaver, Neuroscience Program, John P. Roberts Res. Inst. and University of Western Ontario, London, Ont., Canada, N6A 5K8.

Autonomic dysreflexia, a condition experienced after spinal cord injury, is characterized by large increases in arterial pressure in response to visceral stimulation. Intact intraspinal inputs to sympathetic preganglionic neurons (SPNs) caudal to the injury mediate reflexes responsible for autonomic dysreflexia. Immunoreactivity (IR) for Substance P (SP), Neuropeptide Y (NPY) and the noradrenaline synthesizing enzyme dopamine beta hydroxylase (DBH) was examined to determine the presence of these transmitters in intraspinal inputs to SPNs after cord injury. The spinal cords of anesthetized male wistar rats were transected between the 4th and 5th thoracic segments and the rats were allowed to survive for 14 days. SPNs were retrogradely labelled by i.p. injection of the tracer Fluoro Gold 7 days after cord transection. Fourteen days after cord transection NPY-, SP-, and DBH-IR was present in fibres around SPNs rostral to the injury, suggesting these inputs to the SPNs are of supraspinal origin. Caudal to the transection, NPY- and DBH-IR was almost completely lost around SPNs. Occasionally very faint levels of DBH-IR were noted in a few cells in the grey matter caudal to the injury. These findings indicate that, whereas both NPY and DBH inputs to SPNs are primarily of supraspinal origin, interneuronal spinal sources of catecholamines may also exist. Conversely, SP-IR was present in numerous fibres and terminals, but not in cell bodies caudal to the transection. This observation suggests that SP inputs to SPNs may originate in afferent, or ascending spinal pathways. We anticipate that intraspinal SP and catecholamines may play a role in autonomic dysreflexia after cord injury.

## BLOOD PRESSURE DIURNAL VARIATION IN HYPERTENSIVE PATIENTS WITH SUBCLINICAL CEREBRAL ABNORMALITIES

Hing-Chung Lee, Judith A. Salerno, Gene E. Alexander, Mark B. Schapiro, Jim Stoll\*. Lab. of Neurosciences, National Institute on Aging, National Institutes of Health, Bethesda, MD 20892

**Background and Purpose** In a previous study of patients with well-treated hypertension of 10 or more year duration, anatomic imaging revealed brain atrophy. Positron emission tomography with 18FDG showed abnormal cerebral glucose metabolism. Although these patients had well-controlled office blood pressure readings, the pattern of their 24 hour ambulatory blood pressure was unknown.

**Methods** Nine hypertensive and six age-, sex- and race-matched normotensive volunteers had 24 hour ambulatory blood pressure and heart rate monitoring. Subjects were encouraged to pursue their routine activity on the day of monitoring. Every subject also had a volumetric magnetic resonance imaging of the head study.

**Results** The hypertensive patients had normal averaged 24-hour systolic and diastolic blood pressures (137/80 mm Hg). However, hourly systolic, diastolic and mean blood pressures showed no diurnal changes in the hypertensive group. Both groups had similar daytime blood pressures, but nighttime diastolic and mean blood pressures were higher in hypertensive patients. Hypertensive patients had larger cerebral lateral ventricles than normotensive controls.

**Conclusion** Treated hypertensive subjects with clinically silent brain morphometabolic abnormalities demonstrated well-controlled averaged 24 hour ambulatory blood pressure, but the pattern of diurnal blood pressure differed from normotensive controls.

## 550.14

## SPECTRAL INDICES OF ORTHOSTATIC INTOLERANCE IN POSTURAL TACHYCARDIA SYNDROME (POTS) V. Novak, P. Novak, T.L. Opfer-Gehrking and P.A. Low\*. Dept. of Neurology, Mayo Clinic, Rochester, MN 55905.

Postural tachycardia syndrome (POTS) is characterised by orthostatic tachycardia, dizziness, weakness, headache, gastrointestinal symptoms and blood pressure changes. Dynamic cardiovagal and adrenergic indices (respiratory oscillations in R-R intervals and nonrespiratory oscillations from 0.01 to 0.09 Hz in R-R intervals and blood pressure) were evaluated during head-up tilt (80°) using modified Wigner distribution. Thirty patients (28 women and 2 men) presented with a mild form of postural tachycardia <120 bpm (POTS I) and thirty patients (24 women and 6 men) had more severe form with tachycardia >120 bpm (POTS II); fifteen controls participated in the study. All patients were symptomatic during the tilt.

POTS I group was characterised by reduced respiratory oscillations in R-R intervals at rest, normal sustained decrease of spectral powers during the tilt and rapid increment up to normal values after the tilt-down ( $p < 0.001$ ). Nonrespiratory oscillations in blood pressure revealed a transient elevation during the first minute of tilt, unlike the sustained increase in the control group.

POTS II group differed from POTS I and control group by an overall loss of variability in R-R intervals. Powers at respiratory and nonrespiratory frequencies in R-R intervals at were minimal at rest, diminished even further during the tilt, and increased after the tilt-down ( $p < 0.001$ ), but never reached control values. Elevation of nonrespiratory blood pressure oscillations was transient, similarly to the POTS I group.

**CONCLUSION:** Mild signs of orthostatic intolerance as seen in POTS I group are consistent with previously reported failure of sympathetic venomotor tone resulting in an excessive venous pooling. A new finding is that the more severe form (POTS II) had cardiac autonomic denervation.

## 550.16

## CARDIOVASCULAR REGULATION IN MULTIPLE SCLEROSIS.

B. J. Diamond<sup>1,2</sup>, H. Kim<sup>1</sup>, J. DeLuca<sup>1,2</sup>, D. Cordero<sup>3</sup>, S. Kelley<sup>1</sup>, C. Egan<sup>1</sup> and V. Vilponen<sup>1</sup> Kessler Institute for Rehabilitation, Department of Research, West Orange, NJ, 07052;<sup>2</sup> Department of Physical Medicine and Rehabilitation, and <sup>3</sup>Department of Neurosciences, UMDNJ-New Jersey Medical School, Newark, NJ.

Traditional assessments of autonomic nervous system function have depended on invasive and complex procedures. Vagal power, which is the respiratory component of heart rate variability (HRV) is an alternative and non-invasive measure for indexing autonomic nervous control of the heart. The present study was conducted in order to address two primary objectives. Previous studies have assessed cardiovascular regulation in MS in terms of heart rate (i.e. interbeat intervals) or time-domain measures. Our prime objective was to examine parasympathetic and sympathetic activity during both paced and unpaced breathing in a population of clinically-definite MS patients evaluating both high frequency power (i.e. frequency-domain) and time-domain measures (i.e. heart rate). In the current study, 18 multiple sclerosis (MS) and 20 healthy subjects matched with respect to age, education and intelligence served as subjects. The MS group showed significantly lower vagal power (i.e., parasympathetic influence) during natural and paced breathing than healthy subjects. Importantly, time domain measures (i.e., heart rate) did not differ between the two groups. The impact of lower parasympathetic activity, in regard to quality of life issues and vulnerability to adverse cardiac events needs to be further evaluated. The results of this study may have implications with respect to the feasibility of using HRV as both a diagnostic and prognostic tool for evaluating parasympathetic nervous system dysfunction in MS and in providing information for developing more effective treatment and rehabilitation.

## CARDIOVASCULAR REGULATION: PHARMACOLOGY

## 551.1

## SYMPATHOLYTIC EFFECT OF DESIPRAMINE: SITE AND MECHANISM OF ACTION IN ANESTHETIZED RATS. D.Huangfu\*, Y. Hagiwara, and P.G. Guyenet, Dept. of Pharmacology, Univ. of Virginia, Charlottesville, VA 22908.

Intravenous desipramine (DMI), but not fluoxetine, dose dependently inhibited splanchnic sympathetic nerve discharge (sSND):  $-64 \pm 3\%$  after 4 mg/kg iv DMI, 172 ng/ml plasma) in urethane anesthetized debuffed rats. Inhibition by DMI was reversed or prevented by microinjection of the  $\alpha_2$ -adrenergic receptor ( $\alpha_2$ -AR) antagonist 2-methoxyidazoxan (MOI) into the rostral ventrolateral medulla (RVLM; 1 nmol/site). However, sSND inhibition by baclofen i.v. (GABA<sub>B</sub> receptor agonist) was unaffected by MOI. MOI alone raised sSND  $46 \pm 9\%$ . Microinjection of 6-hydroxydopamine into the RVLM (2  $\mu$ g/site, 10-13 days, to destroy noradrenergic terminals) did not change the effect of intravenous DMI or MOI on sSND. Slow firing presympathetic neurons of the RVLM were activated by iontophoresis of MOI and inhibited by iv DMI ( $-44 \pm 12\%$ , effect reversed by  $\alpha_2$ -AR antagonist given i.v.). Prior administration of 4 mg/kg DMI did not change the ability of i.v. clonidine (Clo) to inhibit residual sSND [ $\Delta$ SND/ $\log_2$ (clonidine dose):  $-17.6 \pm 5.7$  vs  $-16.5 \pm 3.9$  SND units/ $\log_2$ ( $\mu$ g/kg),  $p = 0.70$ ].

Interpretations: 1)  $\alpha_2$ -ARs in the RVLM are activated at rest by catecholamines probably released from C1 cells. This activation results in tonic SND inhibition. 2) DMI reduces sSND by increasing  $\alpha_2$ -AR activation in the RVLM. 3) This effect of DMI is due neither to serotonin uptake inhibition nor to blockade of norepinephrine uptake by the RVLM noradrenergic fibers. 4) DMI and Clo have simple additive inhibitory effects on SND (Grant HL-28785 to PGG).

## 551.2

## CALCIUM CHANNEL MODULATION BY PROSTAGLANDIN E2 IN CARDIOPULMONARY BARORECEPTOR NEURONS. Y. Liu\*, H.A. Browne and M. Hay, Dept. of Physiology, Univ. TX Health Sci. Ctr., San Antonio, TX 78284.

Neurotransmission of cardiopulmonary baroreceptor (CPB) neurons is modulated by glutamatergic pathways and paracrine factors such as serotonin and prostaglandin E2 (PGE2). The purpose of the present study was to begin to characterize the biophysical mechanisms underlying PGE2 inhibition of the calcium current (I<sub>Ca</sub>) in CPB neurons. The whole cell patch clamp was used to measure I<sub>Ca</sub> in cultured CPB cells which were labeled and isolated from 3 weeks old rats. The pipette solution consisted of (in mM): 124.0 CsCl, 1.0 MgCl<sub>2</sub>, 10.0 HEPES, 1.0 CaCl<sub>2</sub>, 10.0 EGTA and 250 U/ml Nystatin. The bath solution consisted of (in mM): 139.0 TEACl, 5.0 4-AP, 2.0 CaCl<sub>2</sub>, 15.0 Glucose, 15.0 HEPES. Calcium currents were activated by 10 mV depolarizing step pulses from a -80 mV holding potential. 45 CPB neurons were tested. These neurons expressed a high threshold I<sub>Ca</sub> activated near -30 mV and peaked near 0 mV. Application of PGE2 (500 nM) reversibly reduced the peak I<sub>Ca</sub> by  $25.9 \pm 12.2\%$  ( $n = 9$ ). Metabotropic glutamate receptor agonist t-ACPD at low dose alone (400  $\mu$ M) had little effect on the peak I<sub>Ca</sub>, but PGE2 plus t-ACPD at low dose inhibited the peak I<sub>Ca</sub> in the same cells by  $29.8 \pm 13.8\%$  ( $n = 10$ ). Applying high dose t-ACPD (1.6 mM) significantly suppressed the peak I<sub>Ca</sub> by  $37.6 \pm 10.0\%$  ( $n = 5$ ), while PGE2 plus t-ACPD at high dose had no further inhibition on the peak I<sub>Ca</sub> ( $37.9 \pm 6.7\%$ ). These results suggest that PGE2 inhibits the evoked calcium currents in CPB neurons and the lack of additive summation between PGE2 and t-ACPD suggests that these two ligands may share a common intracellular transduction mechanism. Supported by AHA #93G-1183, ALA and NIH #HL50304 to M. Hay.

## 551.3

DETERMINATION OF AGMATINE IN ABDOMINAL AORTA OF RATS AND GERBILS AFTER ISCHEMIA REPERFUSION INSULT (I.R.I.). G. Delbarre\*, B. Delbarre and F. Calinon, Faculté de Médecine, 37032 Tours, France.

Agmatine has been recently identified as clonidine displacing substance (CDS) and purified from rat brain. Agmatine is locally synthesized from arginine by arginine decarboxylase. Until now, agmatine has been studied in the central nervous system but none in the vessels. This is why we have determined level of agmatine in abdominal aorta of rats and gerbils by HPLC/Electrochemical method according to Xu, et al. (Xu, X., et al., *J. Liq. Chrom.*, 9:10, 1986). 24 male adult animals were used : 12 wistar rats and 12 gerbils, (6 control and 6 ischemic, ischemia of abdominal aorta : 5 min. Reperfusion : 5 min.)

	RATS	GERBILS
Control (n=6)	0.058±0.020	0.028±0.012
I.R.I. (n=6)	1.150±0.214***	0.410±0.093**
% of increase	1883	1364

Unpaired Student t test versus control group ( $p \leq 0.01^{**}$ ;  $p \leq 0.001^{***}$ ). Results of agmatine : mean±SEM ( $\mu\text{g}/\text{mg}$  of protein).

In the I.R.I. group, agmatine is significantly increased. Agmatine has been considered to be only precursor of putrescine and polyamines. Our study might show the possibility that agmatine may be a biological active molecule in its own right : in vessels, agmatine plays an important role in the vasomotricity. Because agmatine is synthesized from arginine, it is possible that drugs acting on level of agmatine are not only drugs correlated with its affinity for imidazole receptors.

## 551.5

BRAINSTEM 5-HT<sub>1A</sub> AND 5-HT<sub>1D</sub> RECEPTORS MODULATE THE CARDIORESPIRATORY RESPONSES TO UPPER AIRWAY STIMULATION IN RABBITS. A.G. Ramage\*, S. Dando & D. Jordan\*, Departments of Pharmacology and Physiology\*, Royal Free Hospital Medical School, Rowland Hill Street, London NW3 2PF, UK.

Previous studies have demonstrated that central application of buspirone, a partial agonist at 5-HT<sub>1A</sub> receptors, potentiates the bradycardia evoked by upper airway stimulation in rabbits (Futuro-Neto et al., *Brain Res.*, 629, 349-354, 1993). The present study compared the effects of 5-HT<sub>1A</sub> and 5-HT<sub>1D</sub> receptors on the cardiorespiratory responses evoked by stimulating upper airway receptors.

Studies were carried out in urethane-anesthetized, atenolol pretreated rabbits. Bi-directional tracheal cannulation allowed ventilation of the lungs and independent delivery of cigarette smoke to the upper airways. Recordings were made of baseline and reflexly-evoked changes in mean arterial blood pressure (BP), ECG, renal (RNA) and phrenic nerve activities. Buspirone (200  $\mu\text{g kg}^{-1}$  i.c., n=5) significantly decreased BP and RNA, increased phrenic rate and R-R interval, and potentiated the bradycardia evoked by a smoke challenge. These effects were abolished by pretreatment with WAY-100635 (100  $\mu\text{g kg}^{-1}$  i.v.), a 5-HT<sub>1A</sub> receptor antagonist. In contrast, following pretreatment with WAY-100635, the 5-HT<sub>1D</sub> receptor agonist sumatriptan (50  $\mu\text{g kg}^{-1}$  i.c.) significantly increased baseline BP, phrenic rate and RNA and attenuated the bradycardia, depressor response and apnoea evoked by smoke.

These data are consistent with the view that brainstem 5-HT<sub>1A</sub> and 5-HT<sub>1D</sub> receptors have modulatory roles in cardiorespiratory integration.

This work was supported by the British Heart Foundation and Wellcome Trust. We thank Wyeth Research U.K. for the gift of WAY-100635.

## 551.7

THE ANGIOTENSIN II ANTAGONIST, LOSARTAN, DECREASES RENAL SYMPATHETIC NERVE ACTIVITY AND HEART RATE IN SODIUM DEPRIVED, BUT NOT SODIUM LOADED, RATS. L. Xu and V.L. Brooks\*, Department of Physiology, Oregon Health Sciences University, Portland, OR 97201.

Angiotensin II (AII) may be involved in long term blood pressure (BP) regulation in part by supporting sympathetic nerve activity. To test this hypothesis, rats were placed on either a low salt (LS; <0.01% NaCl) diet, to increase AII levels, or a high salt (HS; 8% NaCl) diet, for 2 to 3 weeks. Experiments using conscious rats were conducted to determine if AII blockade with losartan (10 mg/kg, I.V.) suppresses renal sympathetic nerve activity (RSNA) and heart rate (HR) more in LS compared to HS rats. The experiment consisted of three periods, during which BP, RSNA, HR and central venous pressure (CVP) were recorded continuously: 30 min control, 40 min after losartan injection, and 30 min after BP was restored near to but not above control values by methoxamine infusion. Rats in the time control groups (n=5 for LS; n=6 for HS) received only vehicle (0.9% saline). In LS rats (n=6), 40 min after losartan, BP decreased from  $115 \pm 7$  to  $81 \pm 14$  mm Hg ( $p < 0.05$ ), RSNA increased from  $100 \pm 7$  to  $163 \pm 29$  % of control ( $p < 0.05$ ), but HR did not change significantly (from  $485 \pm 43$  to  $495 \pm 57$  b/min). After BP was restored to control levels ( $111 \pm 8$  mm Hg), both RSNA and HR were suppressed (RSNA:  $46 \pm 17$  %; HR:  $380 \pm 36$  b/min;  $p < 0.05$ ). In contrast, there were no significant changes in BP ( $114 \pm 4$  to  $110 \pm 7$  mm Hg), HR ( $460 \pm 9$  to  $475 \pm 15$  b/min) and RSNA ( $101 \pm 3$  to  $109 \pm 17$  %) in HS rats after losartan (n=4) or in time control rats. CVP did not change in any group. We conclude that endogenous AII supports RSNA and HR in conscious sodium deprived rats and this action can only be revealed when BP is maintained at basal levels. Supported by NIH HL 35872.

## 551.4

BLOCKADE OF ICV AII MEDIATED HYPERTENSION BY  $\alpha$ -ADRENERGIC RECEPTOR ANTAGONIST IS DEPENDENT ON DIETARY SODIUM CHLORIDE INTAKE. A.K.S. Camara, P.S. Clifford\* and J.L. Osborn, Dept of Physiol. Medical College of Wisconsin, Milwaukee, WI 53226.

We have shown that chronic intracerebroventricular ICV AII hypertension in rats is mediated by brain AT<sub>1</sub> receptors coupled with central  $\alpha$ -adrenergic neurotransmission. Experiments were conducted to determine the effect of periventricular  $\alpha$ -adrenergic blockade on ICV AII-induced hypertension in rats raised on low (5.0 mEq/kg), normal (50 mEq/kg) and high (250 mEq/kg food) sodium chloride diets from weaning. Adult rats were instrumented with femoral catheters and brain cannulae which were implanted in the lateral ventricle and the anterior ventral third ventricle (AV3V). Blockade of pressor and plasma renin activity (PRA) responses to 100 ng ICV AII injection by 25, 12.5, 6.3, 3.1 and 1.6  $\mu\text{g}$  of phentolamine was assessed in all three groups of rats. In control, ICV AII injection significantly increased ( $P < 0.05$ ) arterial pressure above control in all three groups of rats (low  $17 \pm 3$  mmHg; normal  $15 \pm 1$  mmHg; high  $16 \pm 2$  mmHg). The hypertension was abolished in all three groups of rats by pretreatment of the AV3V with 25, 12.5, and 6.3  $\mu\text{g}$  phentolamine mesylate. However, microinjection of 3.1  $\mu\text{g}$  phentolamine only blunted the pressor response to ICV AII by 53% in rats fed low but not normal or high sodium chloride diet from weaning. In contrast, 1.6  $\mu\text{g}$  phentolamine did not block the pressor response to ICV AII in any group of rats. PRA was unaltered before and after AV3V pretreatment with phentolamine and ICV AII injection. These results demonstrate that periventricular AV3V  $\alpha$ -adrenergic neurotransmission mediates ICV AII-induced hypertension which is not dependent on elevation of PRA. The interactions between the brain renin-angiotensin system and  $\alpha$ -adrenergic receptors is enhanced by low dietary sodium chloride intake but not by normal or high sodium intake. Supported by NHLBI PO1-29587.

## 551.6

SUPPRESSIVE AND FACILITATING ACTIONS OF MORPHINE ON NOCICEPTIVE REFLEX RESPONSES. I.A. Belyantseva\*, E.V. Lukoshkova, V.M. Khayutin, Dept. of Circulation Control & Biomechanics, National Cardiology Research Center, Moscow, 121552, Russia

The effects of morphine (M) on the pressor reflexes, heart rate (HR) responses and reflex discharges in sympathetic (renal nerve - RN) and somatic (n. PBST) nerves to noxious stimuli were studied in chloralose-urethane anesthetized cats. Responses were elicited by single-shock or short-train electrical stimulation of the tibial and radial A+C-afferent fibres. M given either iv (5 mg/kg) or topically, to the dorsal surface of the spinal cord L4-S2 or C6-T1 segments (0.02-0.5%), suppressed pressor reflexes, C-responses in RN and afterdischarges in n. PBST, and enhanced HR-responses. Suppressive action of the topical M was local: being applied to L4-S2 segments, it suppressed only reflex responses induced by the tibial nerve stimulation; similar responses to radial nerve stimulation were unimpaired or even enhanced. On the contrary, facilitating action of M on the HR-response was common for the reactions elicited from either of these nerves, and only a smaller increase in HR-response to tibial nerve stimulation indicated to local suppressive action of M on this reaction. An opposite relationship between all reflex changes was observed when M was delivered to C6-T1 segments. The other effects of both topical and iv (0.2-5 mg/kg) M were reduction in sympathetic tone, arterial pressure and heart rate. The first two effects could be the cause of increase in pressor reflexes from remote input after topical M and from both, radial and tibial nerves after small (0.2-2 mg/kg) doses of iv M. All described effects were concentration- (dose-) dependent and naloxone reversible. Suppressive action of iv M decreased when the number of stimuli or the stimulation frequency was increased. The results are interpreted as showing that interneuronal circuits responsible for excitatory action of nociceptive afferent volleys on sympathetic neurons exist in the spinal cord dorsal horn, and some of these circuits are common for somato-sympathetic and somato-somatic reflexes.

## 551.8

THE EFFECTS OF TAURINE AND HIGH SALT DIETS ON RENAL FUNCTION IN STROKE-PRONE SPONTANEOUSLY HYPERTENSIVE RATS (SPSHR). B.J. Jung, B. Epler, S. Liu, and B. Dawson, Jr.\*, Dept. of Pharmacodynamics, Univ. of Florida, Gainesville, FL 32610

Taurine (TAU) has been shown to lower blood pressure in several experimental models of hypertension. The present study investigated the effects of different dietary levels of TAU on the development of hypertension in SPSHR on high salt diets. SPSHR/A3N were bred from NIH stock. Male SPSHR were randomly assigned to four dietary conditions (n=6-8 per group) when they were 6 weeks old: regular chow (CON), regular chow with high salt (CON/HS), TAU deficient chow with HS (NT/HS), regular chow with HS and 1.5% TAU in the drinking water (T/HS). All other groups received tap water to drink. The HS groups were maintained initially on chow with 1% NaCl for 84 days and then switched to chow containing 3% NaCl until the end of the study at 147 days. Blood pressure (BP) was monitored by the tail cuff method biweekly. Metabolic studies were performed after 55 days on the 1% NaCl diet and after 50 days on the 3% NaCl diet. Addition of 1% NaCl to the diet produced a significant acceleration in the development of hypertension, however by day 50 on the diets the BP in the CON group was not significantly different from the HS groups. Switching to 3% NaCl did not result in a further rise in BP. The T/HS group consistently had lower BP than the other HS groups but this difference was not statistically significant. The HS diet caused ventricular hypertrophy in the CON/HS and NT/HS groups but not the T/HS group when compared to the CON. TAU also protected against renal damage over time as indexed by urinary protein excretion. HS diets had no effect on urinary TAU excretion and TAU excretion was elevated about 40-fold in the T/HS group relative to the other groups. Urinary catecholamine (NE, EPI, DA) excretion did not differ among the groups, but urinary EPI excretion was significantly elevated at 135 days compared to 55 days. HS diets did not elevate urinary DA excretion which is an adaptive response exhibited by normotensive rats.

The results of this study suggest that 1.5% TAU does not significantly lower BP in SPSHR on high salt diets but did reduce ventricular hypertrophy and renal protein excretion. SPSHR do not exhibit a salt-induced increase in renal dopamine production which may contribute to the maintenance of elevated BP, particularly in light of the marked elevation in EPI excretion. (Supported by a grant from Taisho Pharmaceutical Co., LTD.)

## 551.9

GENDER DIFFERENCES IN RESPONSE TO MELATONIN. S. Doolen, D.N. Krause and S.P. Duckles\*, Department of Pharmacology, College of Medicine, University of California, Irvine, CA, 92717.

Risk of cardiovascular disease appears to vary with gender and time of day. We have found the circadian hormone melatonin potentiates adrenergic vasoconstriction via a specific melatonin receptor in rat tail artery. Arterial ring segments from four month old male and female Fisher 344 rats were compared to investigate potential gender differences. Contractile responses to transmural nerve stimulation (TNS) were greater in male than in female rats. The circadian hormone melatonin potentiated TNS mediated vasoconstriction in both males and females. Male arteries were less sensitive to melatonin than females in estrous, metestrous, and diestrous. Sensitivity among these three cycles did not differ; however females in proestrous were less sensitive to melatonin than females in all other stages. Sensitivity to melatonin in proestrous arteries was similar to sensitivity in male arteries. Maximum potentiation was not significantly different in males compared to females in any stage of the estrous cycle. These data suggest that female sex steroids may modulate sensitivity to melatonin and influence sympathetic nerve-mediated vasoconstriction.

Supported by NIH grant R01HL50775.

## 551.11

GROWTH HORMONE REGULATES BRAIN ANGIOTENSIN II RECEPTORS IN VITRO BUT NOT IN VIVO B.D. Wyse\* and C. Sernia, Neuroendocrinology Lab., Dept of Physiology and Pharmacology, Univ. of QLD, Brisbane, Australia 4072.

Recently we reported that growth hormone (GH) upregulates peripheral angiotensin II (AT) receptors. Since the renin angiotensin system (RAS) has an important role in the regulation of cardiovascular function by the brain, we investigated the possible upregulation of brain AT by GH. AT receptor density and GH content in the brains of Dwarf (genetically GH-deficient) Lewis rats were compared with those of normal Lewis and Wistar rats. As expected, it was found that GH in the pituitary and plasma of dwarf rats (pit:  $1.4 \pm 0.8 \mu\text{g}/\text{mg}$  protein;  $15 \pm 6 \text{ ng}/\text{ml}$  plasma); was lower than in the normal Lewis (pit:  $25 \pm 7 \mu\text{g}/\text{mg}$  protein; plasma:  $153.9 \pm 21.1 \text{ ng}/\text{ml}$ ) and Wistar rats (pit:  $54.7 \pm 3.2 \mu\text{g}/\text{mg}$  protein; plasma:  $152.2 \pm 72.7 \text{ ng}/\text{ml}$ ). In addition, unexpected differences in the GH content of the hypothalamus of dwarf ( $0.08 \pm 0.03 \text{ ng}/\text{mg}$  protein), normal ( $2.03 \pm 45 \text{ ng}/\text{mg}$  protein) and Wistar ( $2.29 \pm 53 \text{ ng}/\text{mg}$  protein) rats were found. In spite of these brain GH differences, the density of hypothalamic AT receptors of the dwarf ( $74.4 \pm 16.4 \text{ fmol}/\text{mg}$  protein), normal Lewis ( $79.6 \pm 20.1 \text{ fmol}/\text{mg}$  protein) were the same. Thus *in vivo* GH upregulates AT receptors in the periphery and not the brain. This could represent true tissue specific regulation or alternatively, a dominance of non-GH regulatory mechanisms in the brain. To distinguish these two possibilities, astrocyte cultures were established from normal neonatal rat brains and the effect of  $1 \text{ ng}$  GH/ml tested at confluence. There was an upregulation of receptors, reaching a maximum increase ( $158.3 \pm 18.2\%$  of control) at 4h after the addition of GH. We conclude that GH upregulates brain astrocyte AT receptors *in vitro* and that this effect is being masked by non-GH regulatory mechanisms in the brain *in vivo*.

## 551.13

THE PRESSOR RESPONSE INDUCED BY CENTRAL INJECTION OF CARBACHOL IS BLOCKADE BY RAMIPRIL. W.A. Saad, A.C. Luiz, L.A.A. Camargo, A. Renzi and J.V. Menani, Dept. of Physiol. Sci., School Odontol., Paulista State University - UNESP, 14801-903, Araraquara, SP, Brazil.

We investigated the effects of ramipril, an angiotensin I-converting enzyme (ACE) inhibitor, on blood pressure induced by central injection of carbachol. Male Holtzman rats (250-300 g) were implanted with stainless steel cannula opening into the lateral ventricle (LV). Intracerebroventricular (ICV) injection of ramipril ( $1 \mu\text{g}/\mu\text{l}$ ) significantly blockade the pressor response after ICV injection of carbachol. The value after injection of  $\text{NaCl}$   $0.15 \text{ M}$   $\text{NaCl}$  into the LV was  $2 \pm 2 \text{ mmHg}$ . After injection of ramipril alone ICV this value was  $5 \pm 2 \text{ mmHg}$ . The injection of carbachol ( $2 \text{ nmol}/\mu\text{l}$ ) produced an increase in arterial blood pressure ( $33 \pm 6 \text{ mmHg}$ ). The injection of ramipril prior to carbachol blocked this effect ( $6 \pm 3 \text{ mmHg}$ ). This results and another obtained in our laboratory strongly support the hypothesis that the carbachol may act via angiotensinergic receptors and that the ramipril can be transformed in ramiprilat, the active drug, by the brain.

CENTRAL AND SPINAL EXCITATORY AMINO ACID RECEPTORS MEDIATE SENSORI-AUTONOMIC PROCESSING IN SHR RATS.

K.L. Youngblood, I.M. Khan, M.P. Printz\*, Dept. of Pharmacology, U. C. San Diego, La Jolla, CA 92093-0636.

Sensory stimuli, such as tactile (airpuff) startle stimuli, elicit coordinated and concurrent behavioral and autonomic (ANS) responses. Inbred spontaneously hypertensive rats (SHR<sub>1</sub>) exhibit exaggerated behavioral (motor) and autonomic (pressor and tachycardia) responses to airpuff startle stimuli relative to normotensive rats. Neural substrates and neurotransmitters involved in such sensori-autonomic processing have not yet been defined. We examined the role and subtype specificity of excitatory amino acid (EAA) receptors in sensori-motor-autonomic processing in the SHR. AP5 (NMDA receptor antagonist) or CNQX (non-NMDA receptor antagonist) were given ICV or intrathecally (IT) prior to delivery of the airpuff. AP5, ICV or IT, dose-dependently inhibited the motor response. ICV AP5 inhibited all ANS responses; however, IT AP5 unmasked a bradycardia response while inhibiting pressor and tachycardia responses. Further, with low dose of AP5 ( $12.6 \text{ nmol}$ , ICV), a dissociation was evident between inhibition of motor and ANS responses - motor was inhibited to a greater degree than pressor or tachycardia. Only a high dose ( $126 \text{ nmol}$ ) of CNQX inhibited both motor and ANS responses to a similar fashion. Our data suggest that central and/or spinal EAA receptors of the NMDA subtype may be selectively involved in the efferent limb of the sensori-motor-autonomic processing pathway while AMPA/kainate receptors are not involved in this sensory-effector pathway and the apparent inhibitory effect of CNQX on sensori-autonomic processing may be a non-selective action.

## 551.12

CARDIOVASCULAR EFFECTS ELICITED BY INTRACEREBRO-VENTRICULAR ADMINISTRATION OF CLONIDINE IN CONSCIOUS CATS. A. Ally\*, G.A. Hand and J.H. Mitchell, Moss Heart Center, UT Southwestern Medical Center, Dallas, TX 75235, and Departments of Pharmacology and Biochemistry, University of New England College of Medicine, Biddeford, ME 04005.

The cardiovascular effects of an intracerebroventricular (i.c.v.) injection of clonidine were studied using conscious cats. Administration of clonidine ( $5\text{--}10 \mu\text{g}$ ) i.c.v. decreased mean arterial pressure (MAP) and heart rate (HR) in a dose dependent manner. The highest dose of  $10 \mu\text{g}$  of clonidine decreased MAP and HR by  $39 \pm 3 \text{ mmHg}$  and  $74 \pm 20 \text{ bpm}$ , respectively ( $n=7$ ). Pretreatment with yohimbine, the  $\alpha_2$ -adrenergic antagonist ( $8 \mu\text{g}$ ; i.c.v.) blocked the cardiovascular responses to subsequent i.c.v. injection of clonidine. Furthermore, preadministration of the imidazoline and  $\text{H}_2$  histamine receptor antagonist, cimetidine ( $100 \mu\text{g}$ ; i.c.v.) prevented the cardiovascular responses of the i.c.v. injection of clonidine ( $n=4$ ). By contrast, pretreatment with the specific  $\text{I}_1$ -imidazoline receptor blocker, efaroxan ( $100 \mu\text{g}$  -  $500 \mu\text{g}$ ; i.c.v.), did not inhibit the effects of i.c.v. administration clonidine ( $n=3$ ). These results demonstrate that the effects of centrally administered clonidine on MAP and HR are not mediated by the  $\text{I}_1$  subtype of imidazoline receptors. Further, these cardiovascular responses to an i.c.v. injection of clonidine appear to result from activation of central  $\alpha_2$ -adrenergic,  $\text{H}_2$  histaminergic or the  $\text{I}_2$  subtype of imidazoline receptors.

## 551.14

SODIUM DEPRIVATION INCREASES TYROSINE HYDROXYLASE mRNA IN RAT ADRENALS AND CELIAC GANGLIA. T.L. Silliman, L. Xu, J.A. Resko\* and V.L. Brooks, Department of Physiology, Oregon Health Sciences University, Portland, OR 97201.

It is not clear whether chronic blood volume depletion produced by sodium deprivation increases sympathetic activity. Because long-term stimulation of the sympathetic nervous system is associated with elevated ganglionic tyrosine hydroxylase (TH) mRNA levels, we tested the hypothesis that sodium deprivation would increase TH mRNA in rats. TH mRNA was quantitated using a sequence-specific ribonuclease protection assay. Rats were placed on a low (LS;  $<0.01\%$  NaCl), normal (CS;  $1\%$  NaCl) or high (HS;  $8\%$  NaCl) salt diet for 23 to 25 days. At the end of this period, body weight increases were blunted ( $p<0.05$ ) in the LS ( $315 \pm 19$  to  $346 \pm 15 \text{ g}$ ;  $n=12$ ) compared to the HS ( $252 \pm 4$  to  $326 \pm 10 \text{ g}$ ;  $n=6$ ) and CS rats ( $313 \pm 16$  to  $366 \pm 12 \text{ g}$ ;  $n=13$ ). Adrenal TH mRNA was elevated ( $p<0.05$ ) in LS ( $1061 \pm 81 \text{ fg}/\mu\text{g}$  total RNA;  $n=9$ ) compared to the HS ( $732 \pm 90 \text{ fg}/\mu\text{g}$  total RNA;  $n=6$ ), but not to the CS rats ( $944 \pm 69 \text{ fg}/\mu\text{g}$  total RNA;  $n=9$ ). In addition, TH mRNA was increased ( $p<0.05$ ) in the celiac ganglia of LS rats ( $2572 \pm 102 \text{ fg}/\mu\text{g}$  total RNA;  $n=9$ ) compared to the CS rats ( $2234 \pm 67 \text{ fg}/\mu\text{g}$  total RNA;  $n=9$ ) and HS rats ( $2328 \pm 58 \text{ fg}/\mu\text{g}$  total RNA;  $n=6$ ). In contrast, TH mRNA in the superior cervical ganglia was not significantly altered by salt intake (LS,  $5249 \pm 500$ ,  $n=6$ ; HS,  $4283 \pm 223$ ,  $n=3$ ; CS,  $4560 \pm 256 \text{ fg}/\mu\text{g}$  total RNA,  $n=6$ ). In conclusion, salt deprivation increases TH mRNA in the adrenals and celiac ganglia. We speculate that the rise in TH mRNA levels is secondary to chronic blood volume depletion which increases sympathetic nerve activity. Supported by NIH HL35872.

## 551.15

## EFFECT OF NOREPINEPHRINE (NE), VASOPRESSIN (AVP), AND OXYTOCIN (OT) ON MYOCARDIAL TISSUE STRUCTURE IN VITRO

A.A. Stadnikov, I.I. Rybkin and S. Farooqui\* Dept. of Histology, Orenburg State Medical Academy, Orenburg, Russia 460014; Neuroscience Laboratory, Pennington Biomedical Research Center, Baton Rouge, LA 70808 USA

It has been shown that NE and AVP have a hypertrophic effect on the heart. We investigated the influence of AVP, NE, OT and dopamine (DA) on the structure of both cardiac muscle cells (CMC) and connective tissue cells (CTC). The relationship between CMC and connective tissue may be important for maintenance of heart tissue homeostasis. This study was completed using 6 Wistar male rats (115-125g), during spring - summer period. Pieces of myocardial tissue (approximately  $2.5 \times 105$  cells) were cultured in vials containing 199 Medium with 20% bovine fetal serum, 0.6 mg/ml each of adenosine, guanosine, uridine, cytidine, 1mg/ml glucose and 0.24 U/ml insulin for 3 days with constant rotation. There were 5 culture conditions: control, AVP (5  $\mu$ U/ml), OT (5  $\mu$ U/ml), DA (20  $\mu$ g/ml) and NE (1  $\mu$ g/ml). On day 3 tissue cultures were fixed with 2.5% glutaraldehyde in 0.1 M cacodylate buffer and embedded in Epon-Araldite resin. The average area of CMC was increased in rank order of AVP (39.26 $\pm$ 0.5), OT (43.70 $\pm$ 0.47), and NE (52.91 $\pm$ 0.58). NE treatment also increased intercellular space and number of CTC, however, we did not find clear mitosis at this stage. Therefore, despite an increase in CMC area NE decreased the ratio of CMC number to intercellular space (0.029 $\pm$ 0.001). CMC number / intercellular space was not changed in the DA, or control conditions (0.059 $\pm$ 0.003) but was slowly decreased in the VP (0.044 $\pm$ 0.0019) and was increased by OT (0.078 $\pm$ 0.0024). These results imply that hormones can influence the relationship between CMC size, area of intercellular space and number of CTC. This relationship could be important for functioning of CMC in hypertrophic myocardium.

## 551.17

## SALT LOADING INCREASES CATECHOLAMINE SECRETION AND ARTERIAL PRESSURE IN mREN-2 TRANSGENIC RATS. P. Li\*, M. F. Callahan, C. M. Ferrario, D. Ganten and M. Morris. Dept. Of Physiol. &amp; Pharmacol. and Hypertension Center, Bowman Gray Sch. of Med. of Wake Forest Univ., Winston-Salem, NC 27257.

Experiments were performed to study catecholamine (CA) secretion in mRen-2 transgenic rats (TG) after salt loading. Male TG+ and TG- rats (12 wks age) were prepared with carotid arterial catheters. Mean arterial pressure (MAP) was recorded continuously. Blood samples of rats were taken before salt loading and after four days 2% NaCl water. Basal MAP was significantly elevated in TG+ (149 $\pm$ 8.5 mmHg) as compared to TG- rats (92 $\pm$ 3.5 mmHg). After salt loading, TG+ rats significantly increased their MAP to 175 $\pm$ 10.9 mmHg while no change was observed in TG- rats. Basal levels of norepinephrine (NE) and epinephrine (EPI) were 217.9 $\pm$ 15.1 pg/ml and 98.7 $\pm$ 38.2 pg/ml in TG- rats, 249.4 $\pm$ 50.7 pg/ml and 138.0 $\pm$ 54.3 pg/ml in TG+ rats respectively. After salt loading TG+ rats increased both plasma NE and EPI approximately 3.7 fold. However, TG- rats increased plasma NE and EPI only 70% and 50% respectively. Thus TG+ rats showed an increase in MAP and CA secretion in response to high salt intake. This suggests that the increased secretion of CA may play a role in the pathogenesis of salt sensitivity in mRen-2 TG rats. (Supported by NIHHLBI-HL51952 and AHA NC 93GS15)

## UNUSUAL ADRENOCEPTORS CONTRIBUTE TO SYMPATHETIC CONSTRICTION OF SMALL CUTANEOUS ARTERIES IN THE GUINEA-PIG EAR. J.L. Morris\*. Department of Anatomy &amp; Histology, and Centre for Neuroscience, Flinders University, S.A. 5042, Australia.

Local application of norepinephrine (NE) to small arteries in guinea-pig ears produces constrictions which are partly resistant to antagonism by the  $\alpha$ -adrenoceptor antagonists prazosin, yohimbine and benextramine, but which are abolished by dihydroergotamine (Morris, Br. J. Pharmacol. 113:1105-1112, 1994). The present study set out to determine if these unusual adrenoceptors contribute to sympathetic vasoconstriction of the same arterial segments. Changes in internal diameter of arteries 80-150 $\mu$ m resting diameter in ears of guinea-pigs anaesthetized with ketamine were determined using on-line image analysis (DIAMTRAK). The cervical sympathetic nerve trunk was stimulated electrically with trains of 100 to 200 pulses delivered at 1-20Hz. Resultant constrictions were frequency-dependent, with the maximum constriction occurring at 5-10Hz. Prazosin (0.3-1 $\mu$ M) slightly reduced the magnitude of sympathetic constrictions, and consistently increased the latency of the responses. The remaining response was not reduced significantly by benextramine (1-10 $\mu$ M) or suramin (30 $\mu$ M), but was reduced dramatically by dihydroergotamine (1-10 $\mu$ M), sometimes leaving a small, slowly-developing constriction. Thus, sympathetic constriction of small cutaneous arteries can involve an initial phase mediated by  $\alpha$ -adrenoceptors, a slightly slower phase mediated by non- $\alpha$  adrenoceptors, and a much slower response probably not mediated by norepinephrine.

## PAIN MODULATION: ANATOMY AND PHYSIOLOGY—SPINAL CORD II

## 552.1

## WIND-UP OF SPINAL CORD NEURONES IS INFLUENCED BY INFLAMMATION, SPINALIZATION, ENDOGENOUS OPIOIDS AND TYPE OF STIMULATION. J. F. Herrero, P. G. de la Rubia and F. Cervero. Department of Physiology and Pharmacology, University of Alcalá de Henares, 28871 Madrid, Spain. SPON: Brain Research Association.

Frequency dependent facilitation of responses to C-fibre stimulation (wind-up) is used as a model to study central sensitisation. We have examined whether different experimental conditions influence this system. Spinal reflexes, recorded as single motor units, were elicited by percutaneous electrical stimulation in adult rats, under pentobarbitone anaesthesia. Experiments were performed in control and in carrageenan inflammatory conditions (monoarthritis), with the spinal cord intact or transected. Low and high frequency stimulation was alternated at 0.2, 0.5 and 2 ms pulse widths, using the voltage able to recruit C-fibre responses with the lowest pulse duration. Responses were challenged with i.v. naloxone 10, 100 and 1000 $\mu$ g/kg. Wind-up was observed at C-fibre latency in all conditions studied. Saturation of responses was reached earlier and at a significantly higher firing rate with longer pulse duration. During inflammation, but only in intact animals, the firing rate was increased 3 fold and the after-discharge responses 3, 4 and 5 fold for each pulse duration. The opioid antagonist naloxone induced a dose-dependent potentiation of these responses only in spinalized rats. Wind-up of A-fibre latency, however, was only observed during inflammation; similar firing rates were obtained with all pulse durations and no significant potentiation was found with naloxone. In conclusion, wind-up depends on pulse duration and spinal cord integrity, whereas inflammation alters only the firing rate. Naloxone is more effective in enhancing these responses in spinalized animals. Support: DGICYT APC-93-0102, PB-93-0491 and Química Farmacéutica BAYER S.A.

## 552.2

## ANALGESIC EFFECTS OF TRANSCUTANEOUS ELECTRICAL NERVE STIMULATION ON RENAL PAIN IN CATS. T.S. Nam, E.J. Baik, Y.U. Shin, Y. Jeong and K.S. Paik. Dept. of Physiology Yonsei Univ. College of Med., Dept. of Physiology Ajou Univ. College of Med. Dept. of Int. Med. In Ha Univ. College of Med. Seoul, Korea

Most studies concerning the antinociceptive effects of transcutaneous electrical nerve stimulation (TENS) have dealt with somatic pain. Thus, we investigated the analgesic effects of TENS on renal pain as a model of visceral pain. The renal pain was induced by acute occlusion of the ureter or renal artery. Activities of single dorsal horn neurons evoked by the renal pain-producing stimuli were monitored before and after TENS. The main results are summarized as follows: 1) The more renal C afferent inputs the dorsal horn neurons had, the greater were the responses to the stimuli that elicited the renal pain. 2) The high threshold (HT) and wide dynamic range (WDR) cells exhibited a greater responses than low threshold (LT) cells to the renal pain-producing stimuli. 3) TENS reduced the C-fiber evoked responses of dorsal horn neurons to 38.9  $\pm$  8.4% of the control value. 4) By TENS, the responses evoked by acute occlusion of the ureter or renal artery were reduced to 37.5  $\pm$  9.7% and 46.3  $\pm$  8.9% of the control value, respectively. 5) The responses elicited by squeezing the receptive fields of the skin were reduced to 40.7  $\pm$  7.9% of the control value. In conclusion, the dorsal horn neurons with renal inputs have the concomitant somatic inputs and TENS can alleviate the renal pain as well as somatic pain.

## 552.3

**INTACT FEMALE RATS ARE MORE SUSCEPTIBLE TO THE DEVELOPMENT OF NEUROPATHIC PAIN THAN OVARECTOMIZED FEMALE RATS.** D.E. Coyle\*, C.S. Schlhorst, and M.M. Behbehani. Department of Anesthesia, University of Cincinnati College of Medicine., Cincinnati, OH 45267-0531.

As previously reported, this laboratory has determined that female rats are more prone to develop neuropathic pain than male rats using the partial sciatic nerve ligation model (Coyle et al. *Neurosci. Lett.* 186:135-138, 1995). This finding correlates with the clinical observation that injury-related neuropathic pain is 2-3 times more prevalent in females than in males. In order to further characterize this gender difference, the role of ovarian hormones in predisposing female rats to the development of neuropathic pain was investigated. In a double blind randomized trial, 12 intact and 12 ovariectomized (ovexed) female rats underwent partial sciatic nerve ligation of the right rear leg. Sham operated (exposure of the nerve without ligation) and unoperated (incision through skin only) controls (ovexed and intact) were also included in the study groups. Animals were evaluated on three consecutive days for withdrawal from touch (Von Frey hairs 0.28-67g) starting on post-injury days 13, 20 and 27. The average of the minimum gram force needed to induce withdrawal was calculated and the distribution of the ovexed and intact groups compared. A significant difference was observed at post-injury day 20 and 27 between the two groups. The intact group resulted in 12/12 animals that were statistically more sensitive than controls compared to 6/12 for the ovexed group. On post-injury day 13 no statistical difference was seen between the two groups (8/12 for intact vs. 10/12 for ovexed). This study indicates that ovarian hormones, via some unknown mechanism, predispose female rats to develop neuropathic pain following injury.

## 552.5

**DORSAL ROOT REFLEXES RECORDED BILATERALLY FROM THE MEDIAL ARTICULAR NERVES IN UNILATERAL ADJUVANT ARTHRITIS.** H. Rees\*, K.A. Sluka, Y. Lu, K.N. Westlund and W.D. Willis. Marine Biomedical Inst., Univ. of Texas Medical Branch, Galveston, TX 77555-1069

Acute inflammation of the knee joint enhances the depolarization of primary afferents in the lumbar dorsal horn evoking dorsal root reflex (DRR) activity in afferent nerve fibers. The present experiments established that DRRs are present in later stages of the inflammatory process. Male rats (250-290g) were briefly anesthetized with Brevital (50 mg/kg i.p.) and one knee injected with either 75 µg or 250 µg incomplete Freund's adjuvant. Chronic unilateral inflammation developed over three days. Animals were tested daily for development of heat hyperalgesia using the paw withdrawal reflex. There was great variation in the time and degree of the development of heat hyperalgesia. The greatest effects were often recorded 6 h after the knee injection. The injected knee increased its circumference by an average of 16 mm, but little change was seen on the contralateral side. Four days following the initial injection, animals were anesthetized with sodium pentobarbital (50 mg/kg i.p.), an intravenous cannula inserted and anesthesia maintained by i.v. infusion of sodium pentobarbital (3-6 mg/kg/h). Both medial articular nerves (MAN) were dissected free and cut distally. Recordings were made of afferent activity in each cut articular nerve. DRRs were recorded in the MAN supplying the inflamed knee following mechanical stimulation of the inflamed tissue. DRRs could not be recorded from the MAN supplying the inflamed knee following mechanical stimulation of the other knee. DRRs were also evoked in the contralateral MAN, although to a lesser extent, in response to stimulation of tissue around both knee joints. The results indicate that DRRs are present bilaterally in the chronic inflammatory state. This pathophysiological phenomenon may be an important factor in the severity of inflammatory disease. (Supported by the HFSP Fellowship and NIH grants NS11255, NS09743.)

## 552.7

**THE ROLE OF G-PROTEIN AND PROTEIN KINASES IN THE SENSITIZATION OF SPINOTHALAMIC NEURONS INDUCED BY INTRADERMAL INJECTION OF CAPSAICIN IN THE PRIMATE.** K.A. Sluka, H. Rees, M. Tsuruoka\*, P.S. Chen and W.D. Willis. Marine Biomedical Institute, University of Texas Medical Branch, Galveston, TX 77555-1069

Following intradermal injection of capsaicin (3%, 100 µl) in the monkey, spinothalamic tract (STT) cells show increased 1) background discharges, 2) responses to innocuous brushing 3) responses to pressure applied to the skin. Inhibitors of second messenger systems were administered into the spinal dorsal horn by infusion through a microdialysis fiber. An inhibitor of G-proteins, GDP-γ-S (1.0mM), reversed the increased background discharges of the cell. GDP-γ-S also reversed the sensitization of the responses to brushing and pressure stimuli applied to the skin. Administration of a protein kinase inhibitor, H7 (5.0mM), had no effect on the increased background discharges of the STT cells but reversed the sensitization to brushing and pressure applied to the peripheral receptive field. The protein kinase C inhibitor, NPC15437 (10.0mM), reversed the increased background discharges of the cell and the sensitization of responses to brushing applied to the skin induced by intradermal capsaicin. Lastly, pretreatment prior to injection of capsaicin with the PKC inhibitor (NPC15437, 10mM) prevented the development of sensitization to brush stimuli applied to the receptive field without affecting background activity. Thus, G-proteins and PKC appear to be involved in the induction and maintenance of the sensitization of STT cells to mechanical stimuli. (Supported by NS09743, NS11255, Kempner Fellowship to KAS and Human Frontier Fellowship to HR).

## 552.4

**TEMPORAL SUMMATION OF C-FIBRE AFFERENT INPUTS: COMPETITION BETWEEN FACILITATORY AND INHIBITORY EFFECTS ON A C-FIBRE REFLEX IN THE INTACT RAT.** M. Gozariu, D. Le Bars\* and J.C. Willer. Lab. de Neurophysiol. Hôp. Pitié-Salpêtrière, 75013 Paris, \*INSERM U-161, 2, rue d'Alésia 75014 Paris, France.

Long-lasting facilitatory effects due to temporal summation of nociceptive inputs were repeatedly described on spinal nociceptive reflexes in spinalized non-anesthetized rats. Since noxious inputs also trigger powerful descending inhibitory controls, we investigated this question in intact, halothane-anesthetized (0.9%) rats and compared these results with those obtained in other preparations.

Electromyographic responses elicited by single-square electrical shocks (2 ms, 0.16 Hz) applied to the sural nerve territory, were recorded from the ipsilateral biceps femoris. The signal was digitized, fullwave rectified and the C-fibre responses integrated in a 100-450 ms time window. The excitability of the C-fibre reflex recorded at 1.5 times the threshold (xT) was tested following electrical conditioning stimuli (2 ms, 1 Hz, 20 s) of the sural nerve territory. In intact rats, following facilitation during the conditioning period, the reflex was inhibited in an intensity-dependent manner. Conditioning at 10 xT resulted in a maximum inhibition of  $79.9 \pm 5.1\%$  during the 2nd min of post conditioning period, with a complete recovery within 20 min. Such an inhibition was completely blocked by decerebration at obex level and was replaced by a 20 min facilitation in non-anesthetized rats (maximum during the 1st min of post conditioning period:  $152.5 \pm 14.8\%$ ). A similar facilitation was seen in non-anesthetized spinalized ( $T_8-T_{10}$ ) decerebrated rats (maximum during the 1st min of post conditioning period:  $183 \pm 25.9\%$ ).

It is concluded that following high intensity repetitive stimulation of C-fibre afferents, powerful supra-spinal mediated inhibitory mechanisms counteract, in intact rats, the increase in excitability of the flexor reflex seen in spinal animals.

## 552.6

**THE ROLE OF G-PROTEINS AND PROTEIN KINASES IN ALLODYNIA INDUCED BY INTRADERMAL INJECTION OF CAPSAICIN IN THE RAT.** W.D. Willis and K.A. Sluka\*, Marine Biomedical Institute, University of Texas Medical Branch, Galveston, TX 77555-1069

Rats were tested for responses to von Frey filaments with bending forces in the innocuous range (10 and 90mN) as a measure of allodynia before and after intradermal injection of capsaicin. Additionally, the threshold to mechanical stimulation with von Frey filaments with bending forces from 0.1-900 mN was tested before and after capsaicin. Delivery of second messenger inhibitors to the spinal cord was through a microdialysis fiber implanted into the dorsal horn of the spinal cord. Intradermal injection of capsaicin (0.1%, 100µl) resulted in allodynia and a decrease in mechanical threshold without heat hyperalgesia. The G-protein inhibitor, GDP-γ-S (0.01-1.0mM), raised the threshold to mechanical stimuli and reversed the allodynia. The general protein kinase inhibitor, H7(0.05-5.0mM), also reversed the allodynia by raising the threshold to mechanical stimulation. Specific protein kinase inhibitors of protein kinase C (NPC15437, 0.1-10.0mM), protein kinase A (H-89, 0.001-0.1mM) or protein kinase G (KT4823, 0.100-0.1mM) were equally effective in reversing the allodynia and raising the threshold to mechanical stimuli. Thus G-proteins and several protein kinases all appear to be involved in the maintenance of allodynia and mechanical hyperalgesia induced by intradermal injection of capsaicin in the rat. (Supported by NS09743, NS11255 and Kempner Fellowship to KAS).

## 552.8

**RESPONSES OF SPINAL DORSAL HORN NEURONS TO THERMAL AND MECHANICAL STIMULI BEFORE AND DURING ZYMOSAN-INDUCED INFLAMMATION OF THE RAT HINDPAW.** A. Randich\*, S.T. Meller<sup>2,3</sup>, and G.F. Gebhart<sup>1</sup>. <sup>1</sup>Dept. of Psychology, Univ. of Alabama at Birmingham, Birmingham, AL 35294, <sup>2</sup>OTC-HCTD Procter and Gamble Co., Cincinnati, OH, 45239, <sup>3</sup>Dept. of Pharmacology, Univ. of Iowa, Iowa City, IA 52242

Extracellular recordings were made of nociceptive specific (NS) and wide dynamic range (WDR) neurons in the spinal dorsal horn of the methohexital-anesthetized rat before and during zymosan-induced inflammation of the ipsilateral (left) hindpaw. Stimulus-response functions were generated for either mechanical (6.7 - 325.0 g) or thermal (36 - 50° C in 2° C increments) stimuli during a control period, and 1, 2, and 3 h after inflammation with zymosan.

The group mean thermal response threshold of all WDR neurons tested decreased significantly within 1 h of inflammation and remained at that level during the remaining 2 and 3 h test periods. In contrast, the group mean thermal response threshold of all NS neurons tested decreased in a slow and progressive manner across the entire 3 h period of testing. However, only 55 - 60% of these WDR and NS neurons showed a reduction in thermal response thresholds following inflammation, whereas 40% of both WDR and NS neurons did not change.

The group mean mechanical response threshold of all WDR neurons tested showed no change following inflammation of the hindpaw at any time. In contrast, the group mean mechanical response threshold of 80% of NS neurons showed a significant, slow and progressive reduction over the 3 h testing period. For both thermal and mechanical stimuli, the response thresholds of WDR and NS neurons were similar by 3 h.

**DIFFERENTIAL EFFECTS OF NOXIOUS HINDPAW IMMERSION ON THE RESPONSES OF IPSILATERAL AND CONTRALATERAL DORSAL HORN NEURONS IN RATS.** S. McGaughy\* and J.L. Henry. Dept. of Physiology, McGill University, Montreal, Que. H3G 1Y6.

A wealth of research demonstrates that noxious heterotopic stimulation inhibits dorsal horn neurons with both spinal and supraspinal components. However, there is conflicting evidence regarding the effects of noxious contralateral paw immersion. Single lumbar dorsal horn neurons were studied in intact rats that were either decerebrated or anesthetized with pentobarbital or ketamine and in decerebrate-spinalized rats. The afterdischarge (AD) response to an ipsilateral noxious pinch was increased by contralateral hindpaw immersion in 50°C water. This effect was seen in both intact and spinalized rats. The immersion had no effect on discharges during the pinch. Ipsilateral hindpaw immersion induced 2 types of responses - excitation or inhibition followed by an AD; this AD was inhibited by subsequent immersions. Neurons that were inhibited by ipsilateral immersion had both an excitatory and an inhibitory receptive field. Immersion, because of its wide stimulation area, may activate both the excitatory and inhibitory fields. Therefore, noxious immersion of a hindpaw may transiently activate inhibitory mechanisms which override the excitatory effects of the stimulus, and block contralateral inhibitory projections. **ULTRASTRUCTURAL DISTRIBUTION OF NADPH-DIAPHORASE IN THE RAT DORSAL HORN AND ITS RELATIONSHIP WITH PEPTIDE- AND/OR TRANSMITTER AMINO ACID-IMMUNOLABELED NERVE PROFILES.** A. Merighi\* and P. Azzar. Dipartimento di Morfofisiologia Veterinaria, University of Turin, Turin, Italy.

Nitric oxide (NO) is a recently identified neuronal messenger which is linked to excitatory amino acid receptor activation within the central nervous system. NO is synthesized by specific populations of spinal neurons, among which are comprised a number of cells of laminae II and III of the dorsal horn, and appears to be implicated in nociception, particularly in the hyperalgesia which is observed in several models of persistent pain. A number of peptides and transmitter amino acids also play a role in pain perception and are specifically localized in nerve profiles within the superficial dorsal horn. We have used pre-embedding reduced nicotinamide adenine dinucleotide phosphate (NADPH)-diaphorase histochemistry of rat spinal cord Vibratome slices in combination with post-embedding immunogold labeling for calcitonin gene-related peptide (CGRP), substance P, glutamate and  $\gamma$ -amino butyric acid (GABA) to better characterize the synaptic relationship of these neuroactive molecules in the dorsal horn. NADPH-diaphorase positivity was observed in: i) nerve cell bodies in laminae II-III; ii) dendrites in laminae I-III which received synapses of the asymmetric type from axonal endings which were generally free of dense core vesicles. These dendrites were never seen in glomerular configurations; iii) unmyelinated axons in laminae II-III. In the immunolabeled preparations, there was no co-localization with peptide positivities, but CGRP-immunoreactive nerve endings were often visible in close spatial apposition with NADPH-diaphorase containing dendrites. On the other hand, co-localization with glutamate- and, to a lesser extent, GABA-immunoreactive nerve profiles was observed in a number of nerve profiles within lamina II. These results provide morphological evidence for possible interactions between NO-, peptide- and amino acid-containing nerve processes in the superficial dorsal horn.

**ANTINOCICEPTION INDUCED BY MORPHINE IN THE CORTEX ACTS THROUGH DESCENDING INHIBITION ON SPINAL TRANSMISSION.** Serge Marchand\*, Earl Carstens, Adam Burkey, and Luc Jasmin. <sup>1</sup>Sciences de la Santé, Université du Québec, Québec, <sup>2</sup>Physiology and Behavior, University of California, Davis CA, <sup>3</sup>Neurosurgery & Cell biology, Georgetown University, Washington DC.

We previously reported that injection of morphine in the piriform cortex results in parallel inhibition of formalin induced pain behavior and *c-fos* expression in the lumbar spinal cord<sup>1</sup>. These results indicated that the cerebral cortex could be producing analgesia by an activation of the descending pain inhibitory system. In the present study, electrophysiological experiments were done to investigate the effect of morphine microinjected in this cortical analgesia site (CAS) on spinal neural responses to a nociceptive stimulus. In barbiturate-anesthetized rats, the dorsal horn neurons evoked activity to 48°C water (5 sec) was markedly suppressed during an electrical stimulation (200  $\mu$ A pulse train) or following the infusion of morphine (0.13 to 0.26 nM) in the contralateral CAS. Locally injected naloxone (0.27 nM) reversed the effect of morphine. Morphine microinjections outside of the CAS had little or no effect on neuronal response to heat. We correlated morphine microinjection sites with morphine's effect on nociceptive behavior (formalin test) and lumbar *c-fos* expression using immunocytochemistry to delimit the area of morphine sensitivity. Morphine microinjection in a sphere of approximately 1.0 mm diameter, centered in the deep piriform cortex and including adjacent piriform and ventrolateral orbital cortices, the endopiriform nucleus and the claustrum, significantly suppressed formalin behavior and numbers of *c-fos* immunoreactive spinal cells. The present results provide further evidence that morphine in a CAS induces antinociception by an inhibitory effect on spinal nociceptive neurons.

**SENSITIZATION OF DORSAL HORN NEURONS BY A SURGICAL INCISION IN THE RAT.**

T.J. Brennan\*, E. Vandermeulen, G.F. Gebhart; Depts. of Anesthesia and Pharmacology; Univ. of Iowa Hospitals and Clinics, Iowa City, IA 52242.

In previous studies, we developed an animal model for postoperative pain by placing an incision in the plantar region of the rat foot and measuring the decrease in withdrawal threshold to mechanical stimulation with von Frey filaments. Further studies on mechanical hyperalgesia were undertaken to examine the effect of a similar incision on the responses of rat dorsal horn neurons receiving input from the plantar region of the rat foot.

In halothane-anesthetized rats limited lumbar and cervical laminectomies were performed. Single lumbar dorsal horn neurons (n=43) were antidromically-activated from the cervical spinal cord, characterized as wide dynamic range (WDR), high threshold (HT), or low threshold (LT) and examined with von Frey filaments for receptive field size, threshold, and force-activity relations. All neurons were excited during the plantar incision made within the receptive field; however, 17 (15 WDR and 2 HT) of 39 neurons maintained an increased background activity 1 hour later. The average increase was from 2.9 imp/s to 5.2 imp/s. Receptive field size was expanded in 18 (17 WDR and 1 HT) of 39 indicating central sensitization. Background activity failed to remain elevated in 22 cells (13 WDR, 6 HT and 3 LT) and no receptive field expansion was observed in 21 (10 WDR, 8 HT and 3 LT). Most WDR neurons had thresholds for activation similar to the withdrawal thresholds after incisions observed in behavioral experiments.

In conclusion these studies demonstrate that central sensitization occurs following a surgical incision in rats. Sensitization of WDR neurons may result in mechanical hyperalgesia observed in behavioral studies.

## 552.12

**NALOXONE DOES NOT REVERSE TRAMADOL-INDUCED SUPPRESSION OF FORMALIN-EVOKED PAIN BEHAVIOR OR SPINAL CORD FOS EXPRESSION IN THE RAT.** K.T. Marcus, H. Wang, L. Panyacosit and A.J. Basbaum\*. Depts. Anatomy and Physiology and W.M. Keck Center for Integrative Neuroscience, UCSF, San Francisco, CA.

Tramadol is a centrally acting analgesic that produces its effect via both opioid and monoaminergic mechanisms (inhibition of noradrenaline uptake). To determine the mechanism through which tramadol is antinociceptive in a test of persistent pain, we examined the effect of oral tramadol on the behavior and fos-like immunoreactivity evoked in the formalin test. Thirty minutes prior to a hindpaw injection of 2.5% formalin (30  $\mu$ l), the rats were anesthetized with halothane and given either tramadol (30, 60, 90, or 150 mg/kg) or saline vehicle. One hour after the formalin injection, the rats were anesthetized and perfused with fixative. We performed fos immunocytochemistry on 50  $\mu$ m transverse sections of the lumbar spinal cord.

Although tramadol had little effect on Phase I behavior in the formalin test, it produced a dose-dependent inhibition of pain behavior in phase 2. We compared the pattern of fos expression in control rats and in rats that received 90 mg/kg, the lowest dose that completely blocked Phase 2. Tramadol produced significant inhibition of fos expression in the superficial dorsal horn. We also attempted to reverse the effect of tramadol by combined administration of a dose of naloxone (2.0 mg/kg, i.p.) that completely antagonizes morphine analgesia in the formalin test. Naloxone was administered 5 minutes prior to tramadol and every 30 minutes after, to maintain adequate levels of this short-half life antagonist. Naloxone was without effect on the analgesia and fos suppression produced by tramadol. These results indicate that in the formalin test of persistent pain tramadol does not produce its antinociceptive effect via interaction with opioid receptors. Activation of bulbospinal monoaminergic systems that inhibit the firing of spinal cord nociceptive neurons may be involved. This work was supported by DA08377.

**NEONATAL CAPSAICIN TREATMENT REDUCES PERSISTENT, FORMALIN-EVOKED BEHAVIORAL AND CARDIOVASCULAR RESPONSES AND C-FOS EXPRESSION IN SPINAL CORD NEURONS.** M.A. Peterson, B.K. Taylor, D.S. Rohde, C. Abbadie, W.R. McKay, S.M. Roychowdhury\* and A.J. Basbaum. Depts. Anatomy, Physiology and W.M. Keck Foundation Center for Integrative Neuroscience, UCSF, San Francisco, CA 94143-0452.

To evaluate the contribution of small diameter primary afferents to the expression of both acute and persistent pain, we measured the behavioral, cardiovascular and spinal cord dorsal horn neuronal responses evoked by noxious stimulation in neonatally-capsaicin treated animals (100 mg/kg s.c. one day postpartum). At 3-4 months of age, we placed arterial catheters into the femoral artery for chronic measurement of blood pressure and heart rate. At time of testing, baseline blood pressure and heart rate was similar between capsaicin-treated and control animals. In control animals, we found that hindpaw injection of formalin (5%, 100  $\mu$ l) produced acute (Phase 1) and persistent (Phase 2) nociceptive responses and ipsilateral activation of spinal cord dorsal horn neurons, as measured by fos-like immunoreactivity. Neonatal capsaicin treatment did not change formalin-evoked Phase 1 responses, but did significantly decrease Phase 2 behavioral and cardiovascular responses. Furthermore, neonatal capsaicin significantly reduced formalin-evoked fos expression in all laminae of the ipsilateral (but not contralateral) spinal cord. We conclude that myelinated afferents and/or small diameter afferents (not destroyed by the capsaicin pre-treatment) contribute to formalin-evoked Phase 1 responses. Our results strongly suggest that small diameter afferents contribute to the expression of persistent pain.

**SPINAL CORD SUBSTANCE P RECEPTOR IMMUNOREACTIVITY INCREASES IN BOTH INFLAMMATORY AND NERVE INJURY MODELS OF PERSISTENT PAIN.** C. Abbadie\*, J.L. Brown, P.W. Mantyh and A.J. Basbaum. Dept. of Anatomy, UCSF, San Francisco and VAMC, Minneapolis.

Numerous studies have implicated the primary afferent derived neuropeptide, substance P, (SP) which exerts its effects via the neurokinin-1/substance P receptor, (SPR) in the transmission of nociceptive messages at the level of the spinal cord. Immunocytochemical studies demonstrate that the SP receptor is concentrated in neurons of lamina I of the superficial dorsal horn. Since alterations in the number and distribution of the receptor may underlie persistent pain conditions, we have used immunocytochemistry to study the distribution of the receptor in two very different rat models of persistent pain: chronic inflammation, which is associated with increased levels of SP, and sciatic nerve section, which is associated with decreased levels of SP in the dorsal horn. Inflammation was produced by unilateral hindpaw injection of complete Freund's adjuvant.

We report that there is an upregulation of SPR immunoreactivity in the superficial laminae of the dorsal horn in both injury models. The increase was found at all time points studied (up to one week after induction of inflammation and up to two weeks after sciatic nerve section). The increase in SPR immunoreactivity was not only present in the medial part of the dorsal horn at segment L4, which is the region of input of the afferents from the hindpaw, but also in the lateral parts of the dorsal horn, and at segments rostral (L1) and caudal (S1) to the afferent input from the hindpaw. These results indicate that the regulation of the receptor is not predictable merely by the content of SP. The non-topographic upregulation of SPR in these different conditions may contribute to the central sensitization of dorsal horn nociceptors under conditions of persistent pain. To address the functional consequences of the increased SPR expression, we are evaluating the magnitude of peripheral stimulation evoked internalization of the SPR in the dorsal horn, a phenomenon that we recently described in normal rats.

## 552.17

**NOXIOUS STIMULATION EVOKES INCREASED FOS EXPRESSION IN SPINAL CORD NEURONS THAT CONTAIN GAD67 mRNA.** H. Wang, P.W. Mantyh\* and A.J. Basbaum. Depts. Anat. and Physiol. and W.M. Keck Fdn. Ctr. for Integr. Neurosci., UCSF, CA and Molec. Neurobiol. Lab., VA Med. Ctr. MN.

Hindpaw inflammation induces fos expression in large numbers of spinal cord neurons. Although many of these neurons can be double labelled by retrograde transport from supraspinal sites (Menétrey et al, 1989), the majority are presumed to be interneurons. Here we combined immunocytochemistry for the fos protein and in situ hybridization for GAD67 mRNA to identify presumed GABAergic interneurons that are activated by noxious stimulation.

Five rats (240-260 gm) were injected with 100 µl of 5% formalin into the hindpaw and were perfused with a 4% para one hour later. We performed in situ hybridization with digoxigenin to identify neurons that contain GAD67 mRNA (blue cytoplasmic staining) and followed this by fos immunohistochemistry using the ABC method, with DAB as chromogen (brown nuclear immunoreactivity). We used a camera lucida attachment to plot labelled neurons. Formalin increased the number of GAD-positive neurons in the ipsilateral cord. The numbers of labelled neurons in ipsi and contra laminae I/II were 27.5±1.6 and 19.8±2.8, respectively. The numbers in the ipsi and contra neck of the dorsal horn were 64.2±3.5 and 53.2±2.7. The percentage of fos-immunoreactive neurons that contain GAD message varied: 29.1±2.3% in laminae I/II; 41.1±5.2% in laminae III/IV; 56.4±1.6% in laminae V/VI; 77.3±6.0% in lamina VII and 89.5±4.9% in Lamina X. We did not find double labelling of fos-immunoreactive neurons in lamina VIII.

Our results confirm those of an earlier study of Todd et al (1994) that used combined GAD and fos immunocytochemistry. However, the present approach revealed significantly greater numbers of GAD positive neurons. Taken together these studies demonstrate that noxious stimulation increases both GAD message and protein, which indicates that activation of spinal cord inhibitory neural circuits is a significant component of the CNS/spinal cord response to noxious stimulation. This may serve to reduce the long term consequences of persistent noxious stimulation. Supported by NS 14627, NS 21445 and DA 08377.

## 552.19

**EXPRESSION OF CALCITONIN GENE-RELATED PEPTIDE IN PRIMARY AFFERENT NEURONS AFTER PERIPHERAL NERVE TRANSECTION.** K. Miki\*, T. Fukuoka, K. Noguchi. Dept. of Anatomy & Neuroscience, Hyogo College of Medicine, Nishinomiya, Hyogo 663, JAPAN

The expression of calcitonin gene-related peptide (CGRP) in primary afferent neurons has been shown to be down-regulated by peripheral nerve transection. However, we have recently shown that tachykinin peptide is induced in a subpopulation of DRG neurons by axotomy. This study was designed to reexamine the changes in CGRP mRNA in DRG neurons and CGRP immunoreactivity (CGRP-ir) in gracile nucleus and spinal dorsal horn after peripheral nerve transection.

Male Sprague Dawley rats (150-200g) received a unilateral injection of fluorogold into the gracile nucleus. The L-5 spinal nerve was transected 7d after fluorogold injection, and more 7d later, animals were sacrificed and L-5 DRGs were examined by *in situ* hybridization with radiolabeled CGRP probe. Control animals received a sham operation. The changes in CGRP-ir in gracile nucleus and spinal dorsal horn 1d - 28d after sciatic nerve transection were also examined using ABC method.

In control DRG, a small number of neurons labeled for fluorogold also expressed CGRP mRNA (3.7% of fluorogold-labeled cells). In contrast, axotomized DRG neurons showed a dramatic increase in the number of double-labeled neurons (19.9%). Gracile nucleus ipsilateral to the sciatic nerve transection exhibited an increased CGRP-ir compared to contralateral side. The increase in CGRP-ir was detectable a few days after axotomy and peaked at 2 weeks. However, in spinal cord, there was no lamina of dorsal horn showing an increased CGRP-ir. These results indicate that CGRP is *de novo* synthesized in a subpopulation of DRG neurons and transported to gracile nucleus, and may play a role together with tachykinin peptide in altered sensory transmission following peripheral nerve injury.

## 552.16

**CHANGES IN LUMBAR DORSAL HORN FOS-LIKE IMMUNOREACTIVITY (FLI) DURING MORPHINE WITHDRAWAL: EFFECT OF SPINAL TRANSECTION, DORSAL RHIZOTOMY OR NEONATAL CAPSAICIN TREATMENT.** D.S. Rohde\*, D.S. Chang, W.R. McKay, A.J. Basbaum, W.M. Keck Center for Integrative Neuroscience and Depts. Anatomy, Physiology and Anesthesiology, UCSF and NYU School of Medicine.

Withdrawal from morphine evokes increased fos expression in the spinal cord, particularly in laminae I and II. To determine the origin of the increased fos expression, we selectively eliminated possible sources of input and monitored FLI after naloxone-precipitated abstinence. Rats were implanted daily with 75 mg morphine or placebo pellets. On day 4, abstinence was precipitated. After one hour, the rats were anesthetized and perfused with a 10% formalin fixative. Transverse 50µm frozen sections of the spinal cord were immunoreacted with a fos polyclonal antiserum using the ABC method.

In placebo-pelleted rats, neither transection nor unilateral dorsal rhizotomy (L4-S2) induced fos expression. However, compared to unoperated rats that withdrew from morphine, both transected and rhizotomized withdrawing animals showed significant increases in FLI in laminae I/II. FLI ipsilateral to the rhizotomy was also greater than on the contralateral side. Neonatal capsaicin, which eliminates C-fibers, did not alter FLI.

We hypothesize that the increase in FLI after spinal transection results from a loss of descending inhibitory control that is activated during withdrawal (perhaps from the locus ceruleus). The increase in withdrawal-induced FLI in rhizotomized rats may have resulted from a loss of inhibitory controls exerted by large diameter primary afferents or from injury-induced reorganization in the dorsal horn. The results from rats treated neonatally with capsaicin indicate that hyperactivity of opioid receptor-laden C-fibers are not a necessary contributor to the withdrawal-induced increase in FLI in laminae I and II. We conclude that the pattern of fos expression reflects compensatory responses in local circuits intrinsic to the dorsal horn. Supported by DA08763.

**UNILATERAL MICRODIALYSIS IN THE DORSAL HORN OF AN AWAKE, BEHAVING ANIMAL AS A MODEL TO STUDY PAIN MECHANISMS *IN VIVO*.** L.E. Ross\* and B.A. Donzanti. Department of Pharmacology, Zeneca Pharmaceuticals, 1800 Concord Pike, Wilmington, DE 19850-5437.

Few methods have been successfully developed to study the *in vivo* neurochemistry of pain physiology and its modulation. Reports of techniques in awake, unrestrained animals are even more rare. Skilling et al. (1988) have used horizontal microdialysis probes which transverse both sides of the dorsal horn. Our goal here was twofold: 1) refine the method by developing a less damaging preparation and 2) collect dialysates for the analysis of aspartate, glutamate, and substance P. Rats were anesthetized and mounted in a stereotaxic frame. An anchor was cemented to the skull to allow for later attachment of tubing for infusion of artificial CSF. An incision was made over the spinal cord and muscle tissue cleared away from vertebrae T13 and L1. Small holes were drilled horizontally through the spinous processes of these two vertebrae. Pieces of #2 stainless steel suture, 1.5-2.0 cm long were passed through these holes and twisted to serve as anchors for the microdialysis probe. A hole was drilled vertically through the posterior portion of vertebra T13, slightly to the right of the midline. A 4mm microdialysis probe, coated with epoxy for the top 2mm, was slowly lowered through the hole. The probe was lowered until the top of the dialysis membrane was level with the surface of the bone. A small piece of Gelfoam was placed around the probe and cranioplastic cement applied around the probe and the two anchoring wires. After the cement hardened the incision was closed with wound clips, and the rat returned to its home cage to recover. The next day the rat was infused with artificial CSF via the probe at a rate of 5 µl/min and dialysate samples taken for analysis by HPLC for glutamate and aspartate. We are optimizing an assay for substance P, and also will use this method for analysis of changes induced by a stimulus such as formalin footpad injections.

## 552.20

**NOXIOUS STIMULI EVOKE FOS EXPRESSION EVEN IN THE SPINAL DORSAL HORN OF THE CHEMICALLY ANALGESIC RATS.** T. Honda, N. Ozaki, Y. Tonosaki, K. Nishiyama and Y. Sugiura\*. Dept. of Anatomy, Fukushima Med. Col., Fukushima, Japan, 960-12

It is well established that Fos protein is expressed by noxious stimuli in secondary neurons of the sensory pathway. In the present study, the Fos expression induced by various stimuli accompanied with or without injuries of the primary afferent fibers was examined in the spinal cord of the analgesic rats or the colchicine-treated rats.

To establish the analgesic rats, capsaicin or lidocaine hydrochloride were used. Capsaicin was systemically applied to newborn or adult rats. Lidocaine or colchicine were topically applied to the sciatic nerve of adult rats. As noxious stimuli, formalin injection into footpad or the sciatic nerve transection were performed. As painful stimuli without injuries of primary afferent fibers, electric stimulation of the sural nerve and bradykinin or histamine injection into footpad were used. Two to three hours after each stimulus, the spinal cord was removed and Fos expression was immunohistochemically examined.

All capsaicin-treated rats became analgesic and showed obvious increase of threshold to noxious thermal stimulus. In the control rats after noxious stimuli, many Fos immunoreactive (Fos-ir) cells were found in laminae I, II, III, IV, occasionally V and X of the spinal cord. Similar density and distribution of Fos-ir cells was found in the capsaicin-treated rats. By electric stimulation of the sural nerve, Fos-ir cells were detected in laminae I, II, III, IV and X. Whilst capsaicin-treatment reduced Fos expression by electric stimulation in laminae I, II, III, and IV. Bradykinin or histamine reduced Fos expression in laminae I, II, III and IV was reduced by capsaicin-treatment as well as lidocaine-treatment. Colchicine-treatment reduced formalin-induced Fos expression which was not reduced by capsaicin treatment in the spinal dorsal horn.

Our study showed that peripheral nerve injuries evoked Fos expression even in the spinal cord of chemically analgesic rats. This result strongly suggested the possibility of various signal-conduction mechanisms mediating the Fos expression in sensory processing.

## 553.1

EFFECT OF LIDOCAINE ON SCIATIC NERVE CONDUCTION IN RATS: AN *IN VIVO* SINGLE UNIT STUDY. H. Huang, J.G. Thalhammer\*, S.A. Raymond and G.R. Strichartz. Pain Research Group, Anesthesia Research Laboratories, Brigham & Women's Hospital, Harvard Medical School, Boston, MA 02115

Using an *in vivo* rat sciatic nerve preparation, with a fixed length of the nerve (22mm) exposed to lidocaine, we measured the tonic blocking concentration of lidocaine in functionally identified A $\beta$  afferents, including rapidly adapting mechanoreceptors (RA), slowly adapting mechanoreceptors (SA) and muscle spindles (MS). A total of 27 units were studied and the blocking concentrations of lidocaine ranged from 0.2 mM to 0.8 mM. Mean blocking concentrations were: RA,  $0.44 \pm 0.15$  mM, n=10; SA,  $0.40 \pm 0.15$  mM, n=11; MS,  $0.33 \pm 0.09$  mM, n=6 (NS, p=0.23). The dose-response curve from our study was compared with the data from Rosenberg and Heavner (*Acta anaesth. scand.* 24: 314-320, 1980) in which inhibition of rat sciatic A-fiber compound action potential (CAP) was studied *in vitro* (■). The median value in our single-unit study was 0.4 mM, significantly higher than the 0.19 mM EC<sub>50</sub> value from Rosenberg and Heavner. We postulate that the suppression of CAPs by low concentrations (<0.2mM) of lidocaine is not due to the abolition of impulse conduction in fibers, but instead to the slowing of impulse conduction and/or decrease in the impulse currents in single fibers. Furthermore, our results indicate that the variations in sensitivity to lidocaine among myelinated axons could not be linked to functional submodalities. (NIH USPHS GM 35647)

## 553.3

AMELIORATION OF MECHANO-SENSITIVITY IN TWO RAT MODELS OF NEUROPATHIC PAIN BY CLINICALLY EFFECTIVE ANALGESICS. M.F. Jett, J. Ravenscroft, D. Waligora, C. Kermeen, R.M. Eglen\* and J.C. Hunter. Dept. of Analgesia, Syntex Research, Palo Alto, CA 94303.

Increased mechano-sensitivity to noxious (hyperalgesia) and innocuous (allodynia) stimuli is a hallmark of neuropathic pain in humans. Drugs that are clinically effective (lidocaine, mexiletine, desipramine and amitriptyline), less effective (morphine), or ineffective (indomethacin) in the treatment of neuropathic pain were evaluated for efficacy in reducing mechano-sensitivity using the spinal nerve injury (SNL) and chronic constriction injury (CCI) models of neuropathic pain in rats. These models differ in that the SNL surgery provokes a pain response with a significant sympathetic component. Vehicle or drug was administered subcutaneously 1 h prior to evaluation of the hyperalgesia response to pin prick and the allodynia response using von Frey filaments. Lidocaine (10-60 mg/kg), mexiletine (10-100 mg/kg), desipramine (10-30 mg/kg) and amitriptyline (3-30 mg/kg) attenuated hyperalgesia and allodynia in the SNL and CCI models. The doses employed did not produce significant behavioral effects. Neither morphine (1-3 mg/kg at 30 min prior to testing) nor indomethacin (5 mg/kg) significantly reduced mechano-sensitivity in either of the models. In conclusion, drugs which are effective in reducing human neuropathic pain ameliorate mechanical hyperalgesia and allodynia in SNL and CCI models of neuropathic pain in rats.

## 553.5

INHIBITION OF NEUROPATHIC NEURAL ACTIVITY BY LIDOCAINE AND QX-314. I. Omana-Zapata\*, K.R. Bley, J.C. Hunter and D.E. Clarke. Departments of Mechanistic Pharmacology & Analgesia, Roche Biosciences, Palo Alto, CA 94305.

Neuropathic pain is correlated with persistent high-frequency nerve activity originating from peripheral nerve injury sites and the dorsal root ganglia (DRG), and is associated with long lasting changes in the responsiveness of dorsal horn (DH) neurons in the spinal cord. In order to test the sensitivity of nerve injury-induced activity to local anesthetics, we have intravenously administered lidocaine and QX-314, the quaternary derivative of lidocaine, during extracellular potential recordings from the DRG and the DH. Experiments were performed on anesthetized adult male rats whose common sciatic nerve had been transected 5 to 8 days previously. In order to monitor effects on the heart and central nervous system, EKGs and EEGs were recorded simultaneously. Lidocaine or QX-314, given i.v. at 8 min intervals, produced a dose-dependent and significant reduction of ongoing activity in the DRG and DH. ID<sub>50</sub>s (in mg/kg) for lidocaine (3.0 at DRG and 3.3 in the DH) were lower than for QX-314 (16.8 at DRG and 37.2 in the DH). The lower potency of QX-314 might be attributed to a delayed onset of effect due to slow tissue penetration. In contrast, the duration of decreased nerve activity following QX-314 infusion was much longer than for lidocaine, suggesting a persistent block of Na<sup>+</sup> channels. Consistent with a common mechanism of action, heart rate was rapidly decreased by either lidocaine (ID<sub>50</sub> ~ 27) or QX-314 (ID<sub>50</sub> ~ 51). These results suggest that QX-314 can acutely block neuronal and heart Na<sup>+</sup> channels, contrary to previous notions that it is only active following intracellular application (also see Bley *et al.*, this meeting). Whereas QX-314 does not readily penetrate the blood-brain barrier, the decrease of DH activity that followed QX-314 infusion may be secondary to the effects on the peripheral nerve or the DRG, or might be attributed to the surgical disruption of the spinal blood-brain barrier required for electrode placement.

## 553.2

THE CONTRIBUTION OF PERIPHERAL SENSORY NEURONAL INPUT TOWARDS THE MAINTENANCE OF NEUROPATHIC PAIN. J.C. Hunter\*, B. Martin, R. Lewis, L. Smith, D.J. Fontana and C. Lee. Dept. of Analgesia, Syntex Research, Palo Alto, CA 94303.

Current evidence suggests that while peripheral neural mechanisms contribute to its development, the persistence of neuropathic pain occurs predominantly through a prolonged state of central hyperexcitability and increased neural plasticity that can be maintained without further peripheral noxious input. The present study, however, investigated the possible contribution of ongoing afferent activity in the peripheral nerve to the persistence of pain following a peripheral nerve injury. QX-314, a quaternized derivative of lidocaine and inhibitor of sensory neuronal sodium channels, was tested for its analgesic potential against the cold water (0°C) allodynic response in rats following a chronic constriction injury to the common sciatic nerve. Lidocaine (10-100 mg/kg, sc), but not QX-314 (10-100 mg/kg, sc), when administered as an acute 1hr pre-treatment in rats 5 days post-surgery, produced a dose-dependent anti-allodynic effect. In contrast, QX-314, when given by chronic administration (b.i.d. at 30mg/kg, sc), exerted an almost complete anti-allodynic effect after 5, but not 1 or 3 days. The allodynia returned within 48hrs of termination of the chronic dosing schedule. *In vivo* microdialysis (icv) studies with <sup>14</sup>C-QX-314 showed that no drug entered the CNS during chronic dosing. Similarly, behavioral studies found no evidence of the locomotor effects associated with lidocaine and other local anesthetics that can readily penetrate the blood brain barrier. In conclusion, established neuropathic pain can be blocked by the sustained, but not acute, action of a peripheral local anesthetic.

## 553.4

PRE-EMPTIVE EFFECTS OF INTRATHECAL LIDOCAINE ON FORMALIN-INDUCED NOCICEPTION AND C-FOS EXPRESSION. K. Yashpal\*, P.A. Mason\*, J.E. McKenna\*, S. Sharma\*, J.L. Henry\* and T.J. Codere\*. <sup>1</sup>Pain Mechanisms Lab, Clinical Res. Instit. of Montreal, <sup>2</sup>Operational Technologies Corp., San Antonio, <sup>3</sup>Dept. of Psychol., UBC Kelowna, <sup>4</sup>Dept. of Physiol., McGill Univ.

Pretreatment with intrathecal (i.t.) lidocaine produces a prolonged antinociception during the late phase of the formalin test. We now examine whether this treatment produces a similar reduction in the formalin-induced expression of c-fos in spinal cord. Formalin pain behavior, in response to a 50  $\mu$ l injection of 2.5% formalin into the hindpaw, was assessed in rats given a lumbar i.t. injection of 50  $\mu$ l of 2.0% lidocaine, either 5 min before or 5 min after formalin injection, and compared with nociception in rats that received 50  $\mu$ l of i.t. saline 5 min before formalin. Two hours after the formalin injection, the rats were sacrificed, and spinal cords were removed and processed for c-fos (Ab-1) immunocytochemistry or immunoprecipitation.

Pain behaviors in the late phase of the formalin test were significantly reduced in rats given lidocaine 5 min before the hindpaw formalin injection, but were unaffected in rats given lidocaine 5 min after formalin. Fos protein-like immunoreactivity in response to formalin injection was restricted to the spinal cord ipsilateral to the injected hindpaw. Fos positive cells were found to be maximal in the lumbar (L2-L6) spinal cord, predominantly in the superficial layer (lamina I), as well as deeper layers (lamina V-VI). The number of Fos positive cells was significantly reduced in rats that received lidocaine before formalin, but was only slightly reduced in rats that received lidocaine after formalin. Kinetic studies on formalin-induced c-fos expression using monoclonal antibody (Ab-1) and immunoprecipitation exhibited a maximal induction at 2 hrs. with a greater enhancement in the dorsal, as opposed to the ventral, horn. C-fos expression was significantly suppressed in rats which received i.t. lidocaine before the formalin injection, confirming lidocaine's pre-emptive effect in the formalin test.

## 553.6

STRYCHNINE- AND BICUCULINE-EVOKED INCREASES IN DORSAL HORN CELL ACTIVITY ARE MODULATED BY LIDOCAINE. S. Puig\* and L.S. Sorkin. Dept. of Anesthesiology, UCSD, La Jolla, CA 92093-0818

Blockade of GABA and strychnine (STR) sensitive glycine receptors within the spinal cord results in a profound allodynia/hyperalgesia. This study examined the relative efficacy of lidocaine (LID), a local anesthetic on this enhanced neuronal activity.

Dialysis probes were placed in the lumbar dorsal horn of  $\alpha$ -chloralose anesthetized cats and extracellular recordings made from cells in close proximity. Physiological parameters were monitored and maintained. Artificial CSF was perfused through the probes and baseline responses to a range of mechanical stimuli measured. The perfusate was changed to STR (1.0 mM) or bicuculline (BIC) (0.5, 1.0 mM). An iv infusion of LID resulting in plasma levels of 1-6 mg/ml was then given. Receptive field properties were redetermined under each condition and for several LID concentrations (plasma LID concentration confirmed by gas chromatography).

Increasing plasma levels of lidocaine did not significantly reduce the STR enhanced response to low threshold stimuli until close to levels that produced conduction blockade. However, in the same cells, responses to noxious stimulation were reduced to pre-STR levels or below. BIC-enhanced responses to noxious intensities of stimulation were also preferentially modulated.

These results indicate that at the spinal level, systemic local anesthetics are better able to reduce transmission of afferent input mediated by fine myelinated or unmyelinated fibers than to reduce allodynia which is mediated by large myelinated fibers. Supported by NIH grant NS11255.

## 553.7

NOCEPTIVE AND LOW-THRESHOLD RESPONSES IN THE RAT'S THALAMUS ARE DIFFERENTIALLY AFFECTED BY HALOTHANE ANESTHESIA. C. Vahle-Hinz\*. Physiologisches Institut, Universitäts-Krankenhaus Eppendorf, D-20246 Hamburg, Germany.

The influence of varying depths of halothane anesthesia on neuronal activity and response properties was studied in single-unit recordings in the region of the ventrobasal complex. Adult rats were respired and anesthetized with 1.5% halothane and O<sub>2</sub>/N<sub>2</sub>O (30:70) for the preparations, and end-tidal CO<sub>2</sub> and heart rate were monitored continuously and kept in the physiological range. Non-noxious mechanical stimulation of fur and skin as well as noxious mechanical and thermal stimuli were applied to characterize the neuronal responses under 0.5% halothane. The halothane level then was varied between 0.5% and 1.5%. A dose-dependent reduction or suppression of the ongoing and evoked activity was seen in low-threshold mechanosensitive (LT) and wide-dynamic range nociceptive (WDR) neurons. At higher halothane levels, the LT responses changed from tonic to phasic response type, and the sensitivity as well as the receptive field sizes of the neurons were reduced. In WDR neurons, the responses to noxious stimulation changed from a sustained discharge to an on/off-response, while the afterdischarges first were reduced in frequency and duration and then were abolished. The LT responses in both kinds of neuron were more robust than the nociceptive responses in WDR neurons and were still present when all nociceptive activity was suppressed. Thus, sensory processing of information about non-noxious and noxious events may be modulated differentially at the thalamic level.

## 554.1

A MATHEMATICAL MODEL TO EVALUATE THE EFFECTS OF NEUROTRANSMITTER RESPONSES TO PROLONGED NOXIOUS STIMULATION. E. Reiner\* and B.J. Wintersen. Dept. of Physiology, University of New England College of Osteopathy, Biddeford, ME 04005

Osteopathy has long recognized somatic dysfunction, the alterations in tissue texture, range of motion and tenderness, as a body's response to prolonged changes in circulation, extracellular fluid distribution, connective tissue and neural mechanisms. Two classes of neurotransmitters (NT) may be involved; the tachykinins, e.g. Substance P (SP) and Neurokinins A (NKA), and the excitatory amino acid, glutamate (Glu). One method used to analyze these manifestations uses a prolonged noxious stimulus to induce a persistent flexion reflex as an analog to somatic dysfunction.

The specific roles of SP, NKA and Glu on the development of the persistent hindlimb flexion reflex can be evaluated using a matrix model. Noxious stimulation is delivered for 3, 30 and 300 seconds in anesthetized spinalized rats. One set is the control, while the second, third and fourth sets are given the NT receptor (NMDA, N-methyl-D-aspartate, NK<sub>1</sub> and NK<sub>2</sub>) antagonists, APV (2 amino-5-phosphonovaleric acid), CP-96,345 and SR-48,968, respectively. A matrix has been hypothesized as a mathematical model for the effects of neurotransmitter antagonists on the flexion reflex for a given stimulatory duration. The equations are expressed in terms of the flexion reflex against time, where the reflex is monitored as force, P<sub>i</sub>.

$$P_i = \sum_{j=1}^n C_{ij} + p_i(0); \quad \text{for } i=1,2,3$$

Where p<sub>i</sub>(0) is control results, i is duration and, j is antagonist.

This mathematical approach represents a novel methodology to evaluate multiple neurotransmitter and/or pharmacological effects that are overlapping but not strictly coincident. This method may have value for studying other multiple factor neuronal systems.

## 554.3

THE SPINAL RELEASE OF MET-ENKEPHALIN IS TONICALLY STIMULATED BY CHOLECYSTOKININ IN THE RAT. F. Cesselin, S. Bourgoin, A. Mauborgne, M. Hamon\* and J. J. Benoliel. INSERM U 288, 91, Boulevard de l'Hôpital, 75634 Paris cedex 13, France.

Numerous data suggest that cholecystokinin (CCK) acts as an « anti-opioid » peptide. Thus, the blockade of CCK receptors can potentiate morphine-induced analgesia and prevent tolerance to the analgesic effects of opioids. We showed that opioids, through the stimulation of a subtype of  $\delta$  receptors, can increase the release of CCK from central areas in the rat (Benoliel et al., J. Neurochem., 58 [1992] 916-922; Brain Res., 653 [1994] 81-91). This suggests that opioids could activate central CCK-ergic neurons, which act as a component of a homeostatic system tending to reduce the effects of opioids. Whether CCK (through CCK-A or CCK-B receptors) could in turn modulate the activity of a category of opioidergic neurons, i.e. the spinal met-enkephalinergic (ME) neurons, was presently investigated. For this purpose, slices of the dorsal half of the lumbar enlargement of the rat spinal cord were superfused with an artificial CSF (1 ml/4 min), and exposed to various CCK receptor ligands for assessing their possible effects on the spontaneous and K<sup>+</sup> (30 mM)-evoked release of ME-like material (MELM, determined using a specific radioimmunoassay). Compounds A 71378 and BC 264 were used as selective agonists at CCK-A and CCK-B receptors, respectively, and compounds L 364718 and L 365260, as selective antagonists at these receptors. The spontaneous outflow of MELM was affected by none of these drugs. By contrast, a significant increase in K<sup>+</sup>-evoked MELM overflow occurred upon stimulation of CCK-A receptors by A 71378 (+17% at 1  $\mu$ M, +40% at 10  $\mu$ M), whereas their blockade by L 364718 resulted in a significant decrease in the peptide outflow (-53% at 1  $\mu$ M, -70% at 10  $\mu$ M). The K<sup>+</sup>-induced release of MELM was less affected by ligands of CCK-B receptors (+25% with 10  $\mu$ M BC 264, -15% with 10  $\mu$ M L 365260). These results suggest that CCK acts preferentially at CCK-A receptors for exerting a tonic excitatory influence on spinal MELM release. Thus, CCK and ME may form a couple of mutually « antagonistic » peptides which reciprocally modulate their release in the rat spinal cord.

## 553.8

EFFECTS OF PRE- AND POST-TREATMENT WITH INTRAVENOUS ANESTHETIC AGENTS ON NOCEPTIVE BEHAVIOURS IN THE RAT FORMALIN TEST. L. Gilron<sup>1</sup> and T.J.Coderre<sup>2</sup>\*, <sup>1</sup>Department of Anaesthesia, McGill University, and <sup>2</sup>Pain Mechanisms Laboratory, Clinical Research Institute of Montreal, 110 Pine Ave. W., Montreal, PQ, CANADA H2W 1R7.

The rat formalin test has been used as a model of injury-induced central sensitization and as an animal model to study the efficacy of pre-emptive analgesia. In this study, we evaluated the nociceptive behaviour of rats from 15 to 60 min after subcutaneous hindpaw injection of 50  $\mu$ l of 1.5% formalin. In each trial, anesthetics and their respective vehicles were administered by tail-vein injection either 1 to 10 min prior to or 5 min following formalin injection.

Nociceptive scores were unaffected by pentobarbital (20 mg/kg) or propofol (10 mg/kg). Alfentanil at an anesthetic dose of 170  $\mu$ g/kg produced profound analgesia which dissipated approximately 35 min after formalin injection. The timing of alfentanil administration had no influence on its analgesic efficacy. Alphaxalone pretreatment (1.5 mg/kg) produced analgesia compared to vehicle, and resulted in significantly lower scores than post-treatment from 15 to 30 min after formalin injection. Ketamine (10 mg/kg) produced analgesia compared to vehicle when given either pre- or post-formalin. From 20 to 50 min after formalin injection, ketamine pretreatment resulted in significantly lower scores than post-treatment.

Our results show no antinociceptive effects with pentobarbital or propofol in this model, and although alfentanil did produce profound analgesia, the timing of administration did not play a role. These data do demonstrate pre-emptive analgesia with both IV alphaxalone and IV ketamine. Further studies are being conducted in our laboratory to elucidate the mechanisms of these effects.

## 554.2

THE INTERACTION BETWEEN NEUROKININ<sub>1</sub> AND METABOTROPIC GLUTAMATE RECEPTOR ANTAGONISTS IN BEHAVIOURAL NOCEPTIVE TESTS IN NORMAL AND CARRAGEENAN-TREATED RATS. M.R. Young, S.M. Fleetwood-Walker, P.J. Birch<sup>1</sup>, C. Bountra<sup>2</sup> and J. Bowers<sup>2</sup>, <sup>1</sup>Department of Preclinical Veterinary Sciences, University of Edinburgh, U.K., <sup>2</sup>Department of Molecular Science (Greenford), <sup>3</sup>Pharmacology I (Ware), Glaxo Group Research, U.K. SPON: European Brain and Behaviour Society.

Intrathecal metabotropic glutamate receptor antagonists (S)-4-carboxy-3-hydroxyphenylglycine [(S)-CHPG, (48nmol)] and L-1-amino-3-phosphopropionic acid (L-AP3, 60nmol), increase paw withdrawal latencies (PWLs) to both noxious mechanical and noxious thermal stimulation, in conscious rats. Such elevations were more profound after carrageenan-induced inflammation in the paw. However, in the same study the NK<sub>1</sub> receptor antagonist, GR82334 (3nmol), failed to alter PWLs (Young et al (1995) Br. J. Pharm. 114:316P). We have addressed the effect of combined mGlu and NK<sub>1</sub> receptor antagonists in such behavioural nociceptive tests. Lister-hooded rats (30-70g), with either normal or carrageenan-inflamed paws, received a co-injection of GR82334 and either (S)-CHPG or L-AP3 (n=16 per group), at doses equivalent to those above (in 10 $\mu$ l). Now, the increases in PWL due to mGluR antagonists were occluded when GR82334 was given simultaneously, except the (S)-CHPG-induced increase in PWL to noxious thermal stimulation in the non-inflamed paw. Statistical significance of effects (% change from pre-drug levels) was determined compared to mGluR antagonists alone, \*\* - p<0.01; \* - p<0.05 (Mann-Whitney U-test) w.r.t. the co-injection in the inflamed state:

	L-AP3	Co-injection	(S)-CHPG	Co-injection
MECHANICAL 1 min	123±47	19±8*	130±31	54±19**
THERMAL 1 min	97±6	9±9**	71±10	11±7**

These results indicate that in the state of carrageenan-induced hyperalgesia, NK<sub>1</sub> receptor antagonism appears to exert an adverse effect on the analgesia normally elicited by mGluR antagonists.

## 554.4

CAPSAICIN- AND SUBSTANCE P (SP) NH<sub>2</sub>-TERMINUS-INDUCED ANTINOCCEPTION PRECEDES THEIR INHIBITION OF SP RELEASE FROM MOUSE SPINAL CORD. V.M. Goettl\* and A.A. Larson. Graduate Program in Neuroscience, Univ. of Minnesota, St. Paul, MN 55108, U.S.A.

SP appears to be released in the spinal cord in response to a nociceptive stimulus. Capsaicin also elicits release of SP producing an initial hyperalgesia followed by antinocception. This antinocception has been attributed to the ability of capsaicin to decrease the content or release of SP associated with primary afferent C-fibers. Recently, we reported that the NH<sub>2</sub> terminus of SP may mediate the antinociceptive effect of capsaicin. To investigate the relationship between capsaicin-induced antinocception and changes in the content, release and action of SP from the spinal cord, we studied the effects of pretreatment with capsaicin and SP(1-7), an NH<sub>2</sub>-terminal metabolite of SP, in mice. Twenty-four hr after the intrathecal (i.t.) injection of capsaicin or SP(1-7), mice are antinociceptive in the acetic acid writhing, the hot plate and the formalin (second phase) assays. However, 24 hr after 0.8  $\mu$ g capsaicin or 30 nmol of SP(1-7) i.t., there was no change in SP release from perfused mouse spinal cord tissue in response to 3  $\mu$ M capsaicin (1 min) compared to vehicle injected mice. In contrast, there were significant decreases at 48 hr (p<0.02) in the amount of SP released (pg SP/mg tissue/3 min) from mice injected with capsaicin (1.73 ± 0.32) and SP(1-7) (2.49 ± 0.31) vs. vehicle (4.48 ± 0.92). There was no change in total spinal cord content of SP at either time. This indicates that, like capsaicin, SP(1-7) inhibits SP release. However, their antinociceptive effects do not appear to be mediated by changes in SP release or content. (Supported by NIDA T32 DA07234 and DA04090.)

## 554.5

INFLUENCES OF VARIOUS NEUROPEPTIDES ON EXCITATORY AMINO ACIDS RELEASE IN TRIGEMINAL SPINAL SENSORY NUCLEUS. **I.H. LEE\*, J.S. HAM, K.P. PARK and J.S. KIM** (Dept. of Oral Physiol., Coll. of Dentistry, SEOUL NAT'L UNIV., KOREA)

Many neurotransmitters, such as excitatory amino acids (EAA), substance P (SP), calcitonin gene related peptide (CGRP), play a role in pain transmission in trigeminal spinal sensory nucleus. This study was performed to elucidate the role of SP, CGRP and the role of GABAergic neurons on the release of aspartate (Asp) and glutamate (Glu) from trigeminal spinal sensory nucleus caudalis.

Push-pull perfusion (40 µl/min) was performed in trigeminal sensory nucleus of rabbits (adults either sex) and perfusate was analyzed using HPLC-FD employed o-phthalaldehyde derivatization method. The release of Asp and Glu was evoked by noxious electrical stimulation of inferior alveolar nerve with or without perfusion of SP, CGRP, GABAergic agonists and antagonists to the trigeminal sensory nucleus.

The release of EAA was increased by electrical stimulation of inferior alveolar nerve. SP and CGRP increased the release of Asp and Glu from trigeminal spinal sensory nucleus. Muscimol, GABA<sub>A</sub> agonist, significantly reduced the effects of electrical stimulation. This inhibitory effect of muscimol was antagonized by bicuculline and the release of EAA was potentiated by addition of bicuculline alone in caudal area of trigeminal sensory nucleus.

These results suggest that the EAA could be a neurotransmitter of orofacial pain transmission, and the release of EAA could be modulated by various neuropeptides.

## 554.7

SPINAL CCK<sub>B</sub> RECEPTORS MEDIATE NEUROTENSIN HYPERALGESIA FROM THE NUCLEUS RAPHE MAGNUS (RMg). **M.O. Urban\*, D.J. Smith\* and G.F. Gebhart\*** <sup>1</sup>Dept. of Pharmacology, Univ. of Iowa, Iowa City, IA 52242 and <sup>2</sup>Dept. of Anesth., WVU-HSC, Morgantown, WV 26506.

The neuropeptide neurotensin produces a hyperalgesic/antianalgesic effect on the spinal nociceptive tail-flick reflex when injected into the medullary RMg of rats. Cholecystokinin octapeptide (CCK), on the other hand, has been implicated as an antianalgesic mediator in the spinal cord. Thus, the present study was designed to determine a potential involvement of spinal CCK in mediating neurotensin hyperalgesia from the RMg. Microinjection of neurotensin (30 pmol) into the RMg of awake rats produced a facilitation of the tail-flick reflex that was completely inhibited by intrathecal (i.t.) administration of the non-selective CCK receptor antagonist proglumide (100 ng). I.t. administration of the selective CCK<sub>B</sub> receptor antagonist L-365260 dose-dependently inhibited neurotensin hyperalgesia from the RMg (ID<sub>50</sub> = 0.42 ng) at doses approximately 1000 fold less than that observed with the selective CCK<sub>A</sub> receptor antagonist L-364718 (ID<sub>50</sub> = 646 ng). Injection of CCK alone i.t. (30-100 ng) produced a hyperalgesic effect on the tail-flick reflex which was inhibited by i.t. L-365260 (ID<sub>50</sub> = 0.59 ng) at doses approximately 1000 fold less than that observed with i.t. L-364718 (ID<sub>50</sub> = 630 ng). These data indicate that spinal CCK hyperalgesia involves the CCK<sub>B</sub> receptor subtype, which is consistent with the suggestion that spinal CCK<sub>B</sub> receptors mediate neurotensin hyperalgesia from the RMg.

## 554.9

GLUTAMATE INHIBITS SUBSTANCE P RELEASE FROM TRIGEMINAL NUCLEUS CAUDALIS CAPSAICIN-SENSITIVE PRIMARY AFFERENTS. **M.C. Cuesta, H. Suarez-Roca, J.L. Arcaya, G. Gomez, G. Cano, R. Enriquez, E. Bonilla and W. Maixner\*** Sec. Neurochemistry, Instituto de Investigaciones Clinicas, Univ. of Zulia; INBIOMED-Fundacite-Zulia, Maracaibo, Venezuela and Dental Research Center, The Univ. of North Carolina at Chapel Hill, NC, 27599-7455.

Substance P (SP) and glutamate (GLU) are present in primary afferent C-fibers. These two substances play important roles in producing persistent inflammatory-evoked and neuropathic pain. Although it is clear that both of these substances are released by C-fibers, little is known about the modulatory effects of GLU on the release of SP from C-fibers. In the present study, we have examined whether GLU modulates SP release from trigeminal nucleus caudalis slices evoked by the C-fiber selective stimulant capsaicin (1 µM). Immunoreactive SP was measured in perfusates. A very low concentration of GLU (10 nM) inhibited capsaicin-evoked SP release without affecting basal release. The competitive metabotropic GLU receptor antagonist (±)-alpha-methyl-4-carboxyphenylglycine (5 µM) (±)-MCPG reversed GLU inhibition of capsaicin-evoked SP release to a facilitation. The non-competitive NMDA receptor antagonist, dizocilpine (MK-801, 0.3 µM) did not block GLU inhibitory effect. These results suggest the existence of both inhibitory and excitatory (masked) presynaptic GLU receptors on SP-containing primary afferents. (Supported by TW00305 & DE07509).

## 554.6

NOVEL NK-1 RECEPTOR ANTAGONISTS LY303870 AND LY306740 BLOCK THE RESPONSES OF CAT DORSAL HORN NEURONS TO SUBSTANCE P AND TO PERIPHERAL NOXIOUS STIMULI. **V. Radhakrishnan\* and J.L. Henry** Departments of Physiology and Psychiatry, McGill University, Montreal, Quebec.

In this study, we have tested the effects of novel substance P (NK-1) receptor antagonists LY303870 and LY306740, as well as LY306155, the enantiomer of LY303870, on the responses of nociceptive spinal dorsal horn neurons to iontophoretically applied substance P and to peripheral noxious stimuli. Extracellular recordings were obtained using multibarrel electrodes from L<sub>1</sub>-L<sub>6</sub> segments of the spinal cord in cats anesthetized with α-chloralose and spinalized at the L<sub>1</sub> level. The antagonists were given i.v. (0.5-4.0 mg/kg). Responses to substance P were significantly inhibited by LY303870 (mean % inhibition: 1 mg, 36; 2 mg, 93; 4 mg, 95; n=5-6) and by LY306740 (1.5 mg, 49; 2 mg, 81; n=5) but not by LY306155 (4 mg, 17; n=4). Responses to peripheral noxious thermal stimulation were inhibited by LY303870 (2 mg, 57; 4 mg, 69; n=6) and LY306740 (1.5 mg, 39; 2 mg, 52; n=4). Interestingly, noxious thermal responses were also inhibited by LY306155 but only at a higher dose (2 mg, 24; 4 mg, 44; n=4). Responses to noxious pinch stimuli were inhibited by LY303870 (1 mg, 26; 2 mg, 51; n=4) and LY306740 (1.5 mg, 43; 2 mg, 53; n=4). LY306155 lacked consistent effects on pinch responses. LY303870 selectively inhibited the late component of the response to stimulation of the superficial peroneal nerve with a train of high intensity electrical stimuli (1 mg, 26; 2 mg, 62; n=3). These data suggest that LY303870 and LY306740 pass from the circulation into the spinal cord where they antagonize dorsal horn neuron responses to substance P and to nociceptive inputs. (Supported by Eli Lilly and Company, Indianapolis, and the Canadian MRC).

## 554.8

NK1 RECEPTOR ON LAMINA I NEURONS OF THE SPINAL CORD: DISTRIBUTION, RELATION TO SUBSTANCE P AND RESPONSE TO PERIPHERAL STIMULATION. **J.A. Palmer, R. Mungrani, G.D. Smith\*, P.J. Birch\* and S.P. Hunt** Neurobiology Division, MRC Laboratory of Molecular Biology, Hills Road, Cambridge, CB2 2QH, UK. <sup>1</sup>Dept. of Anaesthesia, University of Cambridge, Addenbrooke's Hospital, Hills Road, Cambridge CB2 2QQ, UK. <sup>2</sup>Dept. of Molecular Science, Glaxo Research & Development Ltd, Greenford Road, Greenford, Middlesex, UB6 0HE, UK.

We have examined the distribution of the NK1 receptor in the dorsal horn of the spinal cord using immunohistochemistry with a specific antibody raised to a 15 amino acid C terminal sequence of the native protein (Vigna et al., 1994). Immunoreactivity was particularly intense on the large neurons of lamina I which in most cases were also positive for calbindin 28K-like immunoreactivity. In horizontal sections of the spinal cord the receptor protein was found to be present over the entire extent of these neurons while colocalization studies with antibodies directed against the NK1 ligand, substance P (SP), revealed that SP positive terminals were only found at certain sites on the cell surface; either the distal or proximal dendrites or less frequently over the cell body. In pentobarbital anaesthetized rats, section or crush of the sciatic nerve resulted, within 5 minutes, in the rapid internalization of NK1 immunoreactivity which recovered within 20min. This internalization was seen throughout the neuron and not restricted to areas of direct synaptic contact by SP. This strongly suggested that SP could diffuse from the presynaptic site of release and affect NK1 receptor 'at a distance' by volume transmission. We also examined these neurons 14d following adjuvant-induced inflammation of the hind paw but found no change in receptor number, cellular localization or distribution within lamina I. However, in hyperalgesia produced at 28d following loose ligation of the sciatic nerve, we were able to detect a marked increase in NK1 receptor immunoreactivity within lamina I. Vigna et al., (1994) *J. Neurosci.* 14 834-845

## 554.10

DYNORPHIN A<sub>1-17</sub> ENHANCES SUBSTANCE P RELEASE FROM TRIGEMINAL NUCLEUS CAUDALIS CAPSAICIN-SENSITIVE PRIMARY AFFERENTS. **H. Suarez-Roca\*, J.L. Arcaya, G. Gomez, M.C. Cuesta, G. Cano, and W. Maixner** Sec. Neurochemistry, Instituto de Investigaciones Clinicas, Univ. of Zulia; INBIOMED-Fundacite-Zulia, Maracaibo, Venezuela and Dental Research Center, The Univ. of North Carolina at Chapel Hill, NC 27599-7455.

The outcomes of several recent studies suggest that the endogenous opioid peptide Dynorphin A<sub>1-17</sub> (DYN) produces an anti-analgesic action in the spinal cord and may contribute to the development of persistent pain in chronic inflammatory conditions. The spinal mechanisms involved in DYN actions are not completely understood. Since substance P (SP) is a pro-nociceptive neuromodulator released by primary afferent C-fibers, we have examined whether DYN modulates SP release from trigeminal nucleus caudalis slices evoked by the C-fiber selective stimulant capsaicin (1 µM). Immunoreactive SP was measured in perfusates. A very low concentration of DYN (0.1 nM) strongly facilitated capsaicin-evoked SP release without affecting basal release. The competitive µ-opioid receptor antagonist beta-funaltrexamine (20 nM) and the non-selective opioid-receptor antagonist naloxone (100 nM) blocked the facilitatory effect of DYN. In contrast, the κ-opioid receptor antagonist, nor-binaltorphimine (3 nM) did not alter DYN's facilitatory effect. The effect of the µ<sub>1</sub>-receptor opioid receptor antagonist, naloxonazine (1 nM) is currently under investigation and will be discussed. These data suggest that DYN increases nociceptive transmission at the spinal level by increasing SP release from primary afferents following the stimulation of an opioid receptor which is sensitive to beta-funaltrexamine. It is possible that this receptor is the proposed µ<sub>1</sub>/δ-receptor complex. (Supported by TW00305 & DE07509).

## 554.11

PERIPHERAL MODULATION OF CAPSAICIN-INDUCED NEUROPEPTIDE RELEASE BY NICOTINE. S. Kilo, K.M. Hargreaves\* and C.M. Flores, Laboratory of Neuropharmacology, Univ. of Minn., Minneapolis, MN 55455

There have been conflicting reports on the ability of nicotine to stimulate neuropeptide secretion from peripheral primary afferent terminals. The purpose of the present study was to assess whether nicotine could alter capsaicin-evoked calcitonin gene-related peptide (CGRP) secretion in a newly developed rat skin superfusion model and whether such effects are receptor mediated.

Non-glabrous skin from the rat hind paw was dissected and placed in superfusion chambers bathed in normal Krebs's solution and connected by tubing to a fraction collector. After several baseline fractions, drugs were added to the buffer followed by a washout period. Fractions were subjected to radioimmunoassay using a polyclonal antiserum against CGRP.

Capsaicin alone evoked a dose-dependent, transient increase in immunoreactive CGRP (iCGRP) which peaked approximately 10 min after stimulation before returning toward baseline values. Nicotine by itself showed no effect on iCGRP release. However, when coadministered with capsaicin, nicotine displayed a dose-dependent, biphasic modulation of iCGRP release. Thus, treatment of the tissue with  $\leq 3$  mM nicotine hydrogen bitartrate resulted in potentiation of capsaicin-evoked iCGRP release. In contrast, when chambers were perfused with higher concentrations of nicotine, there was an inhibition of the iCGRP response to capsaicin. These effects were reversed by pretreatment of the tissue with the non-competitive nicotinic receptor antagonist mecamylamine. Interestingly, not only did mecamylamine by itself evoke an increase in iCGRP with a similar time course as capsaicin, but also mecamylamine potentiated capsaicin-evoked release. These data indicate that nicotine can modulate the capsaicin-evoked release of iCGRP from peripheral terminals of primary afferent neurons. The ability of mecamylamine to reverse these effects and the dose-dependence of the response indicate that nicotine may be acting either directly or indirectly through a neuronal nicotinic receptor. CYCLIC AMP MODULATES PEPTIDE RELEASE INDUCED BY ACTIVATION OF PROTEIN KINASE C IN SENSORY NEURONS. L.A. Barber\* and M.R. Vasko, Dept. of Pharmacol. and Toxicol., Indiana U. School of Medicine, Indianapolis, IN 46202

We have demonstrated that protein kinase C (PKC) activators augment resting and evoked release of neuropeptides from rat sensory neurons in culture. In addition, increasing intracellular cAMP sensitizes sensory neurons, enhancing peptide release. Because activation of PKC generates cAMP in other cell types, we examined whether PKC-mediated alterations in peptide release are modulated by an increase in cAMP.

Sensory neurons were dissociated from fetal rat dorsal root ganglia (E15-17) and grown in culture for 9-11 days. Basal release was determined by exposing neuronal cultures to HEPES buffer, whereas evoked release was obtained in buffer containing 50 nM capsaicin. Calcitonin gene-related peptide (CGRP) and cAMP content were measured by radioimmunoassay.

Exposing neurons to 10 or 100 nM phorbol 12,13-dibutyrate (PDBu) increases cellular cAMP by 50% and 200%, respectively. In contrast, the inactive analog, 4-a PDBu (100 nM) has no effect on cAMP. Treating cells with 1 nM PDBu does not alter resting release of CGRP, yet increases capsaicin-stimulated release 2-fold. Ten and 100 nM PDBu produce a 10- and 40-fold increase in peptide release above resting values, respectively. Pretreating neurons with 5 mM 9-(tetrahydro-2-furyl)adenine, an adenylyl cyclase inhibitor, significantly attenuates PDBu-induced peptide release.

These results suggest that a component of the PKC-induced peptide release from sensory neurons is dependent on the cAMP transduction pathway. This "cross-talk" among transduction cascades may be important in regulating peptide release from sensory neurons. (Supported by Amer. Heart Assn. Ind. Affil. and PHS NS 34159)

## 554.15

INVOLVEMENT OF CGRP AND SUBSTANCE P IN NEUROGENIC VASODILATION IN RAT HIND PAW. S.L. Shepherd, D.A. Cook, R.G. Hill\* & R.J. Hargreaves, Merck, Sharp and Dohme Research Laboratories, Neuroscience Research Centre, Terlings Park, Essex, CM20 2QR, U.K.

Vasodilation produced in the skin of the hind paw of the rat in response to electrical stimulation of the saphenous nerve has been shown to involve CGRP released from sensory nerve terminals. Another vasodilator, substance P, is known to be co-localised with CGRP in sensory nerve fibres. The possible interactions of these two substances in the production of neurogenic vasodilation in the rat hind paw were studied in pentobarbitone anaesthetised rats. Changes in blood flow through the skin of the hind paw were measured using a laser doppler fluxmeter. Following an injection of vehicle, the left saphenous nerve was stimulated (5 Hz, 2 ms, 10 V for 10 s) and then repeat stimulations were made at 15 min intervals after injections of the CGRP antagonist  $\alpha$ CRGP(8-37) (0.1, 0.3 & 1 mg kg<sup>-1</sup>) or the NK<sub>1</sub> receptor antagonist RP-67580 (0.1, 0.3 & 1 mg kg<sup>-1</sup>). In another series of experiments, three stimulations were made at 15 min intervals after injection of firstly vehicle, then  $\alpha$ CRGP(8-37) (1 mg kg<sup>-1</sup>) alone, then  $\alpha$ CRGP(8-37) (1 mg kg<sup>-1</sup>) plus RP-67580 (1 mg kg<sup>-1</sup>). All drugs were administered intravenously.

Stimulation of the saphenous nerve after vehicle produced an immediate increase in hind paw skin blood flow which reached a maximum by 30-60 s and returned to baseline by 15 min.  $\alpha$ CRGP(8-37) (1 mg kg<sup>-1</sup>) markedly reduced this response so that only a 'fast component' remained, i.e. a transient increase in flux reaching the same max. as that seen after vehicle but returning to baseline within 1-2 min. RP-67580 had no obvious effects on the flux response when given alone but when co-administered with  $\alpha$ CRGP(8-37) the response to electrical stimulation was almost completely abolished, i.e. RP-67580 blocked the 'fast component' revealed by administration of  $\alpha$ CRGP(8-37). These results suggest that the neurogenic vasodilation produced in the hind paw skin of the rat has two components; a 'slow component' mediated by CGRP and a 'fast component' involving substance P.

## 554.12

NEURONAL NICOTINIC RECEPTOR EXPRESSION IN THE TRIGEMINAL GANGLION OF THE RAT C.M. Flores\*, S. Kilo, R.M. DeCamp and K.M. Hargreaves, Lab. of Neuropharmacol., Univ. of Minn., Minneapolis, MN 55455.

A growing body of evidence indicates that primary afferent sensory neurons express nicotinic receptor subunit mRNAs, exhibit electrophysiological responses to nicotinic agonists and are capable of releasing neuropeptides from capsaicin-sensitive peripheral terminals following application of nicotine. The purpose of the present studies was to determine in the rat trigeminal ganglion (TGG) whether there exist high affinity neuronal nicotinic receptors, which neuronal nicotinic receptor subunit mRNAs are expressed and whether any of these are colocalized with the neuropeptides substance P (SP) or calcitonin gene-related peptide (CGRP) in individually identified neurons.

High affinity binding sites were measured in membrane homogenates using <sup>3</sup>H-cytisine in a vacuum filtration assay. Excess unlabeled nicotine (100  $\mu$ M) was used to define non-specific binding. *In situ* hybridization with antisense <sup>35</sup>S-labeled riboprobes complementary to the mRNA encoding the  $\alpha$ 2,  $\alpha$ 3,  $\alpha$ 4,  $\alpha$ 5,  $\beta$ 2 or  $\beta$ 4 subunit was performed on 20  $\mu$ m frozen sections of adult, male rat TGG. For each subunit, sense probes were used as controls. For colocalization analyses, hybridized tissue sections were subsequently subjected to immunocytochemistry using polyclonal antisera directed against either SP or CGRP.

Low but detectable specific binding of <sup>3</sup>H-cytisine in TGG was obtained. Compared with sense controls, in most of the neurons of the TGG specific hybridization was detected for each of the  $\alpha$  and  $\beta$  subunits tested with the exception of  $\alpha$ 3, which was intensely localized to an undefined subset of predominantly large, type A neurons. Colocalization studies indicated that the cellular expression of neuronal nicotinic receptor subunit mRNA included but was not restricted to neurons which contained SP and CGRP. Taken together, these findings provide a molecular and biochemical basis for the ability of nicotine to directly modulate peptide release from sensory neurons.

## 554.14

THE EFFECTS OF SELECTIVE NK<sub>1</sub> ANTAGONISTS ON SPINAL RESPONSES TO NOXIOUS PINCH IN THE ANAESTHETIZED RAT

M. J. Cumberbatch, R. G. Hill and R. J. Hargreaves SPON: Brain Research Association, Merck Sharp and Dohme, Terlings Park, Harlow, Essex CM20 2QR, UK

The effects of selective NK<sub>1</sub> receptor antagonists have been examined on responses of dorsal horn neurones to noxious mechanical stimuli. The non peptide NK<sub>1</sub> antagonists L-733,060 (rNK<sub>1</sub> receptors IC<sub>50</sub> 700 nM; hNK<sub>1</sub> receptors IC<sub>50</sub> 0.87 nM), CP-99,994 and their NK<sub>1</sub> inactive enantiomers (L-733,061 and CP-100,263), and morphine were administered i.v. Extracellular recordings of action potentials were made from single neurones in male, Sprague-Dawley rats (320-480g) anaesthetized with  $\alpha$ -chloralose. Noxious pinch stimuli were applied to the hind paw at three intensities (pinch 1, 2-3N/28mm<sup>2</sup>; pinch 2, 1.5-2N/28mm<sup>2</sup>; pinch 3, 0.8-1N/28mm<sup>2</sup>) that evoked distinct firing rates (53±10spikes/s, 33±5sp/s and 15±3sp/s respectively). Antagonist effects are expressed as percentages of the mean of three pre-drug control responses after subtraction of background activity. Significant changes (t-test) are indicated by \* (p<0.05). CP-99,994 (n=5) and CP-100,263 (n=4) had no effect at 1 or 10 mg/kg. L-733,060 and morphine reduced responses to noxious pinch similarly; lower intensity responses were depressed more than higher intensity responses.

drug	dose	pinch 1	pinch 2	pinch 3	n
L-733,060	1 mg/kg	85±8%*	88±13%	63±8%*	5
L-733,061	1 mg/kg	107±5%	106±9%	104±8%	5
L-733,060	10 mg/kg	75±4%	64±7%*	43±10%*	5
L-733,061	10 mg/kg	90±4%	85±6%	85±8%	5
morphine	1 mg/kg	81±7%	71±10%	55±13%*	6

The inactivity of L-733,061 at 1 mg/kg suggests that these effects were not due to ion channel blockade. The data indicate that spinal responses to noxious mechanical stimuli are at least, in part, mediated by NK<sub>1</sub> receptors. NK<sub>1</sub> antagonists may therefore be useful in the control of pain.

## 554.16

THE EFFECTS OF PITUITARY ADENYLATE CYCLASE ACTIVATING PEPTIDE (PACAP) ON NOCICEPTIVE BEHAVIOR EVOKED BY INJECTION OF FORMALIN.

Y.-Z. Zhang\*, A. B. Malmberg, B. Sjölund, F. Sundler, R. Håkanson, T. L. Yaksh, Dept. Anesth., Malmö Univ. Hosp., Univ. Lund, S-205 02 Malmö, Dept. Clin. Pharmacol., Sahlgren's Hosp., Gothenburg, Dept. Rehab. Lund Univ. Hosp. S-221 85 Lund, Dept. Med. Cell Res., Univ. Lund, S-223 62 Lund, Dept. Pharmacol., Univ. Lund, S-223 62 Lund, Sweden and Dept. Anesth. Univ. California, San Diego, La Jolla, CA 92093-0818, USA.

Our recent studies have suggested that PACAP may be involved in nociceptive transmission. The present study investigated the effect of intrathecal PACAP on the nociceptive behavior in the formalin test. In anesthetized male Sprague-Dawley rats (280-320g), a catheter (PE-10) was inserted through the atlanto-occipital membrane into the subarachnoid space at the level of the rostral edge of the lumbar enlargement. Seven to ten days after surgery, animals with normal motor function were selected for use in the study. PACAP-27 was administered intrathecally. Twenty minutes later, formalin solution (50 ml of 5%) was injected subcutaneously into the dorsal surface of the right hind paw. Intrathecal PACAP-27 (0.6 pmol) significantly suppressed the second phase flinching response to formalin injection. Suppression was dose-dependent. The data suggest that intrathecal injection of PACAP produces a dose-dependent depression of prolonged nociceptive behavior evoked by injection of formalin.

## 555.1

**ACTIVATION OF PERIPHERAL  $\alpha_1$ -ADRENOCEPTORS CONTRIBUTES TO PAIN INDUCED BY NORADRENALINE PLUS  $\alpha$ -METHYL-5-HT OR BY FORMALIN.** Y. Hong\* and F.V. Abbott, Dept. of Psychiatry, McGill Univ., Montreal, PQ, Canada H3A 1A1.

Peripheral adrenergic mechanisms contribute to chronic pain, hyperalgesia to pressure, and formalin-induced pain. Here we examined the effects of local injections of adrenergic receptor antagonists on pain induced by intraplantar injection of  $\alpha$ -methyl-5-HT ( $\alpha$ -m-5-HT) plus noradrenaline (NA) or PGE<sub>2</sub>, which induce behavioural responses similar to the second phase of the formalin test (Neurosci. 63, 1994, 827), and also on pain induced by formalin.

All agents were injected S.C. into the plantar surface of rats' paws, and the lifting and licking response recorded. Pain produced by  $\alpha$ -m-5-HT (10  $\mu$ g) plus NA (10  $\mu$ g) was blocked by pretreatment with the nonspecific  $\alpha$  antagonist, phentolamine (10  $\mu$ g), but not by the nonspecific  $\beta$  antagonist, timolol (10  $\mu$ g). Neither of these agents altered the pain produced by  $\alpha$ -m-5-HT plus PGE<sub>2</sub> (0.1  $\mu$ g). Pain induced by formalin (1%, 50  $\mu$ l) was biphasic, and adrenergic antagonists did not alter the first phase. The second phase was attenuated by 40% by phentolamine injected either 5 min before formalin or at the beginning of the second phase. Timolol had no effect on either phase. Pain produced by  $\alpha$ -m-5-HT plus NA or by formalin were also attenuated by the  $\alpha_1$  antagonist, prazosin (40  $\mu$ g), but not by the  $\alpha_2$  antagonist, idazoxan (40  $\mu$ g). Thus, activation of  $\alpha_1$  adrenergic activation contributes to pain associated with inflammation in some circumstances, but pain induced by  $\alpha$ -m-5-HT and PGE<sub>2</sub> is independent of adrenergic function, indicating that adrenergic function is not necessary for induction of pain by inflammatory mediators. Moreover,  $\alpha_1$  adrenergic blockade, unlike 5-HT<sub>2A</sub> blockade (Abbott et al, this meeting), attenuates pain when given after development of pain, implying that adrenergic mechanisms contribute to ongoing maintenance of pain.

## 555.3

**THE ROLE OF 5-HT<sub>2A/2C</sub> RECEPTORS IN SPINAL NOCICEPTIVE TRANSMISSION AT UPPER THORACIC SEGMENTS IN RATS.**

A. Kjørsvik, A. Tjølsen, B. Srebro\* and K. Hole, Department of Physiology, University of Bergen, N-5009 Bergen, Norway.

Aim of investigation: The role of 5-HT<sub>2A/2C</sub> receptors in regulation of nociception was investigated by using spinal administration of the 5-HT<sub>2A/2C</sub> receptor agonist ( $\pm$ )DOI-HCl. The 5-HT<sub>2A/2C</sub> receptor concentration in rats is highest at the upper thoracic segments in the spinal cord, and the injections were performed at this level.

Methods: DOI was given through intrathecal catheters. The intrathecal catheterization involved a catheter-through-needle technique in the lumbar region (L5-L6) of halothane-anesthetized rats. DOI was dissolved in 0.9% NaCl and injected in a volume of 15  $\mu$ l. Experiments were performed 1-2 days after implantation of catheters. The increasing temperature hot-plate test was performed two min after drug injection. The temperature was increased from 42 °C at a rate of 3 °C/min and a cut-off temperature of 50 °C was set to avoid tissue damage. The second time the animal licked one of the forepaws terminated the testing procedure. The temperature at this point was considered the response temperature.

Results: DOI (0.001 mM - 10 mM) injected at the upper thoracic level induced a dose-dependent decrease in the response temperature. At 100 mM DOI a considerable motor depression (hind limb abduction) was observed, and the animals seemed sedated. The rats were unaffected by the increasing temperature and showed no licking response.

Conclusion: Upper thoracic 5-HT<sub>2A/2C</sub> receptors appear to be involved in enhancement of nociception. High doses of DOI seemed to mask the pain-like behaviour.

## 555.5

**SENSITIZATION BY SEROTONIN OF FORMALIN OR PGE<sub>2</sub> INDUCED PAIN: PROPHYLACTIC BUT NOT THERAPEUTIC EFFECTS OF 5-HT<sub>2A</sub> RECEPTOR ANTAGONISTS.** F.V. Abbott\*, Y. Hong and P. Blier, Dept. of Psychiatry, McGill Univ., Montreal, PQ, Canada H3A 1A1.

We have shown that 5-HT potentiates behavioural pain responses to other inflammatory mediators, and that 5-HT<sub>2A</sub> antagonists dose-dependently block pain induced by either 5-HT plus another inflammatory mediator or by formalin (Neurosci. 63, 1994, 827; Neurosci. Abst. 20, 1994, 962). The present study examined the temporal characteristics of serotonergic sensitization of inflammatory pain.

Pain was induced by intraplantar injection of the 5-HT<sub>2</sub> receptor agonist,  $\alpha$ -methyl-5-HT ( $\alpha$ -m-5-HT), plus PGE<sub>2</sub>, or 50  $\mu$ l of 1% formalin. Simultaneous injection of  $\alpha$ -m-5-HT (10  $\mu$ g) plus PGE<sub>2</sub> (0.1  $\mu$ g) produced lifting and licking of the injected paw for a total of 10 min during 30 min of observation. When  $\alpha$ -m-5-HT was injected before PGE<sub>2</sub>, sensitization gradually decreased as the interval between  $\alpha$ -m-5-HT and PGE<sub>2</sub> was increased to 30 min. When PGE<sub>2</sub> was injected prior to  $\alpha$ -m-5-HT, sensitization persisted for more than 60 min. Pain induced by the combination of  $\alpha$ -m-5-HT and PGE<sub>2</sub> was blocked by intraplantar injection of ketanserin (5-HT<sub>2A/2C</sub> antagonist; 5  $\mu$ g) or spiperone (5-HT<sub>2A</sub> antagonist; 0.3  $\mu$ g) 5 min before the alcohols. This analgesic effect was attenuated by about 60% when the alcohols preceded the antagonist by 2 min. Formalin produced a biphasic pain response, and the second phase was selectively blocked by ketanserin (50  $\mu$ g) and spiperone (3  $\mu$ g) injected 5 min before formalin. When the antagonists were injected at the beginning of the second phase, the analgesic effect was attenuated by about 75%. Thus, 5-HT produces an irreversible sensitization of tissue to other inflammatory mediators that wanes over 30 min. The data imply that 5-HT<sub>2A</sub> antagonists prevent the evolution of pain in injured tissue, but they cannot reduce already-present pain.

## 555.2

**ACTIVATION OF 5HT<sub>2</sub> RECEPTORS POTENTIATES THE SPONTANEOUS INHIBITORY POSTSYNAPTIC CURRENTS (sIPSCs) IN TRIGEMINAL NEURONS.** K. Sugiyama, B. Haber\*, and L.-Y. M. Huang, Marine Biomedical Institute, Department of Physiology and Biophysics, The University of Texas Medical Branch, Galveston, Texas 76555-1069.

Serotonin (5HT) has been shown to inhibit the transmission of nociceptive signals in the medullary and spinal dorsal horns. One of the possible mechanisms by which 5HT exerts the analgesic action is thought to increase the release of inhibitory transmitters GABA and glycine. To test this possibility, we examined the actions of 5HT on dorsal horn neurons in the spinal trigeminal subnucleus caudalis using the whole cell patch recording technique. All the recordings were made from trigeminal neurons in thick medulla slices prepared from 15-20 day-old rats. 5HT (30-100  $\mu$ M) increased sIPSCs in 52% (29/56) of the neurons. The frequency of sIPSCs increased from 0.5 $\pm$ 0.4 Hz to 18.4 $\pm$ 8.6 Hz and the amplitude of sIPSCs increased from 25 $\pm$ 12 pA to 66 $\pm$ 42 pA (n=4). The 5HT-induced sIPSCs were completely abolished by bicuculline and strychnine. Various 5HT agonists and antagonists were used to determine the 5HT receptor subtype that mediates this 5HT action. The potentiation of sIPSCs could be mimicked by the 5HT<sub>2</sub> agonist  $\alpha$ -methyl-5HT (3-20  $\mu$ M) and be blocked by the 5HT<sub>2</sub> antagonist ketanserin (1-3  $\mu$ M). The 5HT<sub>1</sub> antagonist ICS205-905 (0.2-1  $\mu$ M) failed to inhibit the effect of 5HT on sIPSCs. In addition, we also found that the potentiation of sIPSCs was completely abolished in the presence of tetrodotoxin (0.3  $\mu$ M). These results suggest that 5HT activates 5HT<sub>2</sub> receptors on interneurons and promotes the release of GABA or glycine, thus reducing the excitability of medullary dorsal horn neurons. (Supported by NIH grants NS11255, NS30045, NS23061).

## 555.4

**THE ROLE OF THE SEROTONIN-1B RECEPTOR IN GENETIC SENSITIVITY TO OPIATE ANALGESIA IN MICE.** J.S. Mogil\*, B. Sadowski, and J.K. Belknap, Oregon Health Sciences University, Portland, OR 97201.

Morphine analgesic magnitude is a trait subject to large individual variability. A number of genetic mouse models exist that display highly divergent morphine analgesia; these include the DBA/2 and C57BL/6 inbred strains, the HAR and LAR lines selectively bred for high and low opiate analgesia, and the HA and LA lines selectively bred for high and low stress-induced analgesia. In an attempt to identify genes determining morphine analgesic magnitude in mice, we have recently performed quantitative trait locus (QTL) mapping experiments using mice derived from the DBA/2 and C57BL/6 strains (see Belknap and Crabbe, *Ann. N.Y. Acad. Sci.*, 1992). These studies have revealed two QTLs that together account for over 50% of the total genetic variance in this phenotype. One QTL, located 40 cM from the centromere on chromosome 9, shows tight linkage with the *Htr1b* gene. The *Htr1b* gene, which encodes the serotonin-1B (5HT<sub>1B</sub>) receptor subtype, is thus implicated as a candidate gene for the QTL. Serotonin receptors are known to be important in pain modulation, but the specific role of the 5HT<sub>1B</sub> receptor has remained unknown due to the lack of a specific antagonist. In the present studies, analgesic dose-response relationships (0-75 mg/kg, i.p.) of the specific 5HT<sub>1B</sub> agonist, CGS-12066A (CGS), were investigated in DBA/2, C57BL/6, HAR, LAR, HA, and LA mice. The CGS potency ratios for "high strain" (DBA/2, HAR, and HA) ED<sub>50</sub>s relative to "low strain" (C57BL/6, LAR, and LA) ED<sub>50</sub>s were found to be similar to those seen for morphine. The mixed 5HT<sub>1A/1B</sub> antagonist, (-)-pindolol (0-10 mg/kg, i.p.), was found to dose-dependently block CGS analgesia in all strains. Intriguingly, the opiate receptor antagonist, naloxone (10 mg/kg, i.p.), antagonized CGS analgesia only in high strains. These findings support a role for the 5HT<sub>1B</sub> receptor in the mediation of opiate analgesic magnitude. Supported by VA Merit Review to JKB.

## 555.6

**DIFFERENTIAL PHARMACOLOGY OF RAPHE MAGNUS STIMULATION PRODUCED ANTINOCICEPTION FOR RAT FOOT WITHDRAWAL RESPONSE EVOKED BY DIFFERENT RATES OF NOXIOUS RADIANT HEATING.** Y. Lu, H. K. Proudfoot and D. C. Yeomans\*, Dept. of Pharmacology, University of Illinois at Chicago, 60612

Electrical stimulation of neurons in the Nucleus Raphe Magnus (NRM) inhibits transmission of nociceptive information within the spinal cord. This antinociception is at least partially mediated by spinal 5-HT,  $\alpha_2$ -adrenergic and opiate receptors as indicated by the attenuation of this effect by intrathecal application of antagonists to these receptors. The purpose of this study was to determine: (1) if NRM stimulation preferentially attenuates foot withdrawal responses (FWR) evoked by high or low rates of skin heating; and (2) if 5-HT,  $\alpha_2$ , or opiate receptor antagonists preferentially attenuate the effect of NRM stimulation on high heating rate (HHR) or low heating rate (LHR) responses. To do this, we determined the NRM stimulation current thresholds to produce antinociception for FWR using high and low rates of noxious radiant heat. The  $\alpha_2$  antagonist yohimbine, the 5-HT antagonist methysergide, or the opiate antagonist naltrexone was then injected intrathecally. Fifteen minutes later, the current threshold for antinociception was remeasured. We found that NRM stimulation increases foot withdrawal latencies for both HHR and LHR, but that somewhat higher currents were necessary for HHR responses. Intrathecal application of yohimbine preferentially attenuated the antinociceptive effects of NRM stimulation on HHR responses, methysergide preferentially blocked the effect on LHR responses, and naltrexone was approximately equally effective at blocking the effects on HHR and LHR responses. We conclude that NRM stimulation differentially attenuates nociceptive responses evoked by either HHR or LHR, and that these antinociceptive effects are mediated by different neurotransmitters. Supported by PHS Grant no. DA08256.

## 555.7

**CHANGES IN ALPHA 2-ADRENERGIC RECEPTOR SUBTYPE GENE IN THE SPINAL CORD OF RATS IN AN EXPERIMENTAL MODEL OF NEUROPATHIC PAIN.** J.W. Leiphart, C.V. Dills, H.A. Duncan, H.H. Engelhardt\*, and R.M. Levy. Departments of Neurosurgery and Physiology, Northwestern University, Chicago, IL 60611.

Tying four loose ligatures around the sciatic nerve of a rat leads to neuropathic pain signs indicating spontaneous pain, allodynia and hyperalgesia (Bennett and Xie, 1988). We have demonstrated that the intrathecal administration of tizanidine, an  $\alpha_2$ -adrenergic agonist, directly to the lumbar region of the spinal cord alleviated pressure hyperalgesia in neuropathic rats while preserving normal nociceptive sensation of pressure and heat. Further characterization of the pharmacology of intrathecally administered tizanidine as an analgesic for neuropathic pain indicated that its analgesic effect was primarily mediated through the B subtype of  $\alpha_2$ -adrenergic receptor. This was surprising since  $\alpha_{2A}$  is the predominant  $\alpha_2$ -adrenergic receptor subtype in the spinal cord whereas  $\alpha_{2B}$  is only present in trace amounts.

In this study, we used the cDNA clones for the  $\alpha_{2A}$  (RG-20) and  $\alpha_{2B}$  (RNG) adrenergic receptors to determine if an increase in spinal  $\alpha_{2B}$  receptor may underlie the unique specificity and pharmacology observed in intrathecally administered tizanidine. Sciatic nerve ligation and sham surgery were performed on male Sprague-Dawley rats for comparison with unoperated rats. Seven days after the surgery, the rats were tested for signs of allodynia to cold (4°C) and pressure hyperalgesia. The rats were sacrificed, lumbar spinal cords were removed (L2-S1) and divided into left and right halves. A Northern blot of the spinal cord RNA was performed and probed with RG-20 and RNG cDNA. Preliminary data demonstrate bilateral decreases in RG-20 mRNA in both the ligated rat (40.8%  $\pm$  1.8) and the sham operated rat (22.3%  $\pm$  3.3) compared to the unoperated rat. Bilateral increases in RNG mRNA were observed in both the ligated rat (22.6%  $\pm$  4.5) and the sham operated rat (21.0%  $\pm$  11.4) compared to the unoperated rat. Our results suggest that there is a change in relative proportions of spinal  $\alpha_2$ -adrenergic receptor subtype genes in neuropathic and post-surgical pain.

## 555.9

**SPINAL ALPHA 2- NORADRENERGIC RECEPTORS DIFFER IN SUBSTRAINS OF SPRAGUE-DAWLEY (S-D) RAT.** B.A. Graham\*, D.L. Hammond\*, and H.K. Proudfoot\*. Dept. of Anesthes. & Crit. Care, Univ. of Chicago, Chicago IL 60637, \*Dept. of Pharmacol., Univ. of Illinois at Chicago, Chicago, IL 60612.

The origin of noradrenergic innervation to the dorsal horn differs in S-D rats obtained from the Sasco and Harlan vendors (Brain Res. 591:44-53, 1992). This study examined whether there were differences in the subtype of  $\alpha_2$ -noradrenergic receptors that mediate antinociception in these substrains. Male S-D rats from both vendors were fitted with intrathecal catheters and equianalgesic doses of either ST-91 (3  $\mu$ g) or dexmedetomidine (DEX; 2  $\mu$ g) were intrathecally administered in the absence or the presence of doses of idazoxan ranging from 0.03 to 30  $\mu$ g i.t.. TFLs were redetermined 10, 20, 30, 45, and 60 min later. In vehicle-treated rats, these doses of ST-91 and DEX increased TFL to approximately 10 sec. No differences were observed between Sasco and Harlan rats in the ID<sub>50</sub> of idazoxan (2  $\mu$ g) for antagonism of the antinociceptive effects of DEX. However, the ID<sub>50</sub> of idazoxan against ST-91 in Sasco rats was 0.1  $\mu$ g, whereas in Harlan rats it was 2  $\mu$ g. These findings suggest that there are functional differences in the subtypes of spinal  $\alpha_2$  noradrenergic receptors that mediate antinociception among substrains of S-D rats. This work was supported by grant DA03980 from the National Institute on Drug Abuse.

## 555.11

**CHARACTERIZATION OF THE ANTINOCICEPTIVE PROPERTIES OF CIMETIDINE AND A STRUCTURAL ANALOG.** B. Y. Li\*, J. W. Nalwalk\*, L. A. Barker\*, P. Cumming\*, M. E. Parsons\*, and L. B. Hough\*. \*Dept. of Pharmacol. and Neurosci., Albany Med. College, Albany, NY 12208; \*Dept. of Pharmacol., LSU Med. Ctr., New Orleans, LA; \*Montreal Neurological Inst., Montreal, Quebec, Canada; \*Biosci. Div., Univ. of Hertfordshire, Hatfield, Hertfordshire, UK.

Previous work has established that histamine in the brain is a mediator of analgesia and may play a role in morphine analgesic mechanisms. Although H<sub>2</sub> antagonists have been shown to block histamine analgesia, the H<sub>2</sub> antagonist cimetidine alone has been reported to induce analgesia. In the present study, the antinociceptive and pharmacological properties of cimetidine and a novel chemical congener were characterized. On both the hot plate and the tail flick nociceptive tests, cimetidine and the congener induced complete, dose-related analgesic responses when injected into the rat lateral ventricle. The congener showed strong similarities to cimetidine in analgesic efficacy, slope of dose-response curves, and chemical structure, suggesting that these compounds share a common mechanism. In contrast, histamine induced sub-maximal antinociceptive effects, and the H<sub>3</sub> antagonist thioperamide, a known histamine-releasing drug, had little or no analgesic effects. Compared with cimetidine, the congener showed very weak activity on H<sub>2</sub> receptors *in vitro* (isolated guinea-pig atrium) and *in vivo* (rat gastric secretion). In addition, the analog (100  $\mu$ M) had neither agonist nor antagonist action on guinea pig ileum H<sub>1</sub> receptors. Weak antagonism on H<sub>3</sub> receptors by the congener was also exhibited on guinea pig ileum bioassay and brain autoradiography. The compound (up to 10  $\mu$ M) also had no effect on unpurified rat brain histamine N-methyltransferase activity. These results support the hypothesis that cimetidine induces analgesia by a novel brain mechanism unrelated to H<sub>1</sub>, H<sub>2</sub>, or H<sub>3</sub> receptors (supported by DA-03186).

**EXPRESSION OF  $\alpha_1$ -ADRENERGIC RECEPTOR mRNAs IN RAT MODELS OF NEUROPATHIC PAIN.** A.L. Oaklander\*, A.J. Belzberg. Dept. Neurosurgery, Johns Hopkins Sch. Med., Baltimore, MD, 21287-7509

In certain patients with neuropathic pain, sympathectomy by intravenous  $\alpha$ -adrenoceptor antagonist, anesthetic blockade of appropriate sympathetic ganglia or surgical sympathectomy reduces pain and hyperalgesia. Rats with a spinal-nerve-ligation model of neuropathic pain also display adrenergic sensitivity, suggesting similar underlying pathophysiology to the patients'. We postulate that in these neuropathic pain states there is a change in the expression of  $\alpha$ -adrenoceptors by nociceptors or associated cells and that the release of norepinephrine from sympathetic terminals can then directly or indirectly activate nociceptors.

In these experiments, the expression of  $\alpha_1$ -adrenoceptor subtypes was examined. We used reverse-transcription Polymerase Chain Reaction to measure expression of all known  $\alpha_1$ -adrenoceptor subtypes in dorsal root ganglia (DRG) of rats with the L5-L6 spinal-nerve-ligation model (19 days-postoperative) and in the hyperalgesic skin and DRG of rats with the chronic-constriction-injury model (15 days-postoperative). mRNA was isolated from the dermis, epidermis and DRG and reverse transcribed to produce cDNA. Primer pairs specific for rat  $\alpha_{1B}$ ,  $\alpha_{1C}$ , and  $\alpha_{1A/D}$  adrenoceptor subtypes were developed and used to amplify the cDNA.

There was no substantial upregulation of  $\alpha_1$ -adrenoceptor mRNA subtype expression in experimental versus control tissues. Assuming that expression of  $\alpha_1$ -adrenoceptors is at least partly transcriptionally regulated, possible explanations for our finding are that other  $\alpha$ -adrenergic receptor types are involved or that  $\alpha_1$ -adrenoceptors may be involved at other time points or in other tissues than those studied.

## 555.10

**S 18616: A POTENT, HIGH EFFICACY AND SELECTIVE SPIROIMIDAZOLINE AGONIST AT  $\alpha_2$ -ADRENERGIC RECEPTORS (ARs).** M.J. Millan, K. Bervoets\*, S. Girardon, A. Gobert, A. Newman-Tancredi, V. Audinot, J. M. Rivet, J.-M. Lacoste and A. Cordi. Institut de Recherches de Servier, 125 Chemin de Ronde, 78290 Croissy, Paris, France.

We compared the novel  $\alpha_2$ -AR ligand, S 18616 ((S)-[7.8](2-chlorobenzo)-2-amino-1-aza-3-oxa-[4,5]spirodeca-1,7-diene) to the  $\alpha_2$ -AR agonists, dexmedetomidine (DMT) and clonidine. Affinities (K<sub>i</sub>s) were determined at  $\alpha_1$ - and  $\alpha_2$ -ARs in rat frontal cortex with [<sup>3</sup>H]-prazosin (0.1 nM) and [<sup>3</sup>H]-RX 821002 (0.2 nM), respectively. *In vivo* methods used male Wistar rats (200 - 220 g) and NMRI mice (20 - 25 g). Drugs were given s.c.. Doses are in  $\mu$ g/kg.

	Formalin	Acetic acid	STFs	Loss RR	NAD TO	$\alpha_2$	$\alpha_1$
	ID <sub>50</sub>	ID <sub>50</sub>	ID <sub>50</sub>	ED <sub>50</sub>	ID <sub>25</sub>	nM	nM
S 18616	1	1	0.5	90	2.7	0.2	120
DMT	6	4	0.9	10	2.6	2.2	NT
Clonidine	30	20	50	> 2500	4.0	46	560

Data are for inhibition of the late phase of hind-paw licking induced by formalin in mice; inhibition of writhing induced by abdominal acetic acid in mice; inhibition of spontaneous tail-flicks (STFs) elicited by the 5-HT<sub>1A</sub> agonist, 8-OH-DPAT (0.63 mg/kg, s.c.), in rats; induction of a loss of righting reflex (RR) in rats and inhibition of NAD turnover (TO) in rats. ED/ID = Effective/Inhibitory Dose. NT = not tested.

Upon i.t. administration onto lumbar cord, S 18616 (0.001) also inhibited STFs. It was active in the mouse hot-plate test upon s.c. (ED<sub>50</sub> = 66) and p.o. (100) administration. S 18616 (160) reduced NAD levels by > 90 % in frontal cortex dialysates of freely-moving rats. In conclusion, S 18616 is a potent, orally-active, selective and efficacious ligand of pre- and post-synaptic  $\alpha_2$ -ARs.

## 555.12

**EVIDENCE THAT BLOCKADE OF DOPAMINE RECEPTORS POTENTIATES VAGINOCERVICAL STIMULATION PRODUCED ANALGESIA IN RATS.** S. T. Cunningham\* and B. R. Komisaruk. Institute of Animal Behavior, Rutgers, The State University of New Jersey, Newark, NJ 07102.

Previous work from this laboratory has demonstrated that probing the vaginocervical region of the rat induces analgesia (e.g. it elevates vocalization threshold to electroshock of the tail and increases tail-flick latency to radiant heat). Several studies have implicated monoaminergic pathways in the antinociceptive effects of vaginocervical stimulation (VS). Crowley et al. (Brain Res., 137, 1977) found that dopamine (DA) receptor stimulation diminished VS-induced analgesia whereas DA D2 receptor blockade potentiated this effect. In the present experiment, we investigated the involvement of D1 receptors in VS-produced analgesia. Ovariectomized rats (N=10) were administered intraperitoneally the D1 antagonist SCH 23390 and distilled water (0, 0.0005, 0.005 and 0.05 mg/kg/1 ml distilled water) in a counterbalanced order. Ten minutes post-injection, all animals received two baseline trials followed by VS (100g and 300g) administered during two consecutive trials in (1) measures of vocalization to tail shock and (2) latency to flick tail in response to radiant heat. Experimenters were blind to drug manipulation throughout testing procedures. Results indicate that SCH 23390 dose-dependently potentiated vocalization thresholds to electroshock to the tail during VS, with no significant effects on tail-flick latency. In addition, this potentiation was most pronounced (347%) at 300 g force of VS. Taken together, these data suggest that blockade of D1 receptors markedly facilitates VS-produced analgesia. In addition, the D1 receptor modulates nociceptive pathways involved in vocalization to electroshock of the tail. Support: 5S06GM08223-11 (BRK).

## 555.13

ANTAGONISTS OF DA RECEPTOR ENHANCE ACUPUNCTURE ANALGESIA. C.B. Zhu, Y.Q. Wang, G. Wu, S.F. Xu, X.D. Cao and G.C. Wu\* Dept of Neurobio, Shanghai Med. Univ., Shanghai, 200032, P.R. China

Both 1-tetrahydropalmatine (1-THP) and droperidol (Dropl), antagonists of DA receptor, are being used as drugs with potentiating effect on acupuncture anesthesia in clinics. In the present experiments, the effects of 1-THP and Dropl on acupuncture analgesia (AA) were observed in rabbit and rat models. It was found that the pain thresholds were significantly increased in group 1-THP + AA or Dropl + AA. SKF 38393, the agonist of D1 receptor, could block the analgesia induced by acupuncture or 1-THP (icv or microinjected into N. Accumbens). By using HPLC-ECD, it was shown that 1-THP brought forth an elevation of DA in CSF with the increase of pain threshold. There was a negative correlation between changes of DA content and changes of pain threshold. Acupuncture combined with 1-THP caused a decrease in DA content significantly. Changes of different types of opioid receptor in rat brain was observed during AA potentiated by Dropl by using receptor autoradiographic technique. The results showed that the mu and delta binding sites were increased in many nuclei of the brain. Concerning the binding sites of 3H-U69593, an agonist of K receptor, however, no obvious changes were observed. Non-radioactive in situ hybridization histochemistry technique (digoxigenin) was used to observe the expression of preproenkephalin (PPE) mRNA and POMC mRNA in rat brain following the combination of Dropl with AA. Acupuncture could enhance the expression of PPE and POMC mRNA and Dropl could potentiate this action. These results suggests that antagonists of DA receptor may be achieved by blocking the DA receptor and diminishing the inhibition on opioidergic system.

## 555.14

POTENTIATION OF ANALGESIA IN DIABETIC RATS BY THE MODULATION OF THE ENDOGENOUS DOPAMINERGIC SYSTEM. L.P. Rutledge, J.M. Ngong, P.R. Cosby and M.G. Kolta\*. College of Pharmacy and Pharmaceutical Sciences, Florida A&M University, Tallahassee, FL 32307.

The present study examines the modulating role of dopamine (DA) receptors on the antinociceptive response in diabetic rats with or without insulin therapy and in non-diabetic controls (n=12/group). Diabetes was induced by streptozotocin (STZ, 45 mg/kg, IV). Insulin replacement was initiated after 6 wks of diabetes (2-3 IU/12hrs/rat, SQ) for 7 wks. Hot plate (HP) latency test was measured before diabetes induction and every three wks thereafter and at day 5, 9 and 14 of treatment with DA-ergic agents. Four rats from each group were injected with either bromocriptine (BROM, 3 mg/kg/12hrs/SQ), haloperidol (HALO, 2mg/kg/12hrs, SQ) or vehicle. The results show that HALO significantly potentiated the analgesic response in STZ-diabetic rats and significantly increased such response in the other two groups when compared with the vehicle group. BROM significantly decreased the HP response only in the STZ-diabetic rats as compared to STZ-vehicle rats. Since DA modulation is known to reciprocally alter Met-enkephalin (ME) level, therefore it is concluded from the present study that the elevated pain threshold in STZ-diabetic rats may be mediated, in part, by the endogenous ME system. (Supported by NIH/MBRS grant GM 08111 and NIH/RCMI RR 03020)

## RETINA III

## 556.1

A NOVEL TYPE OF BISTRATIFIED GABAergic AMACRINE CELL IN THE RABBIT RETINA. L.L. Wright and D.L. Vaney\*. Vision, Touch and Hearing Research Centre, The University of Queensland, Brisbane 4072, Australia.

GABA-containing amacrine cells in the mammalian retina comprise numerous distinct types, most of which have extensively overlapping dendritic trees. This study utilised Neurobiotin tracer-coupling combined with immunocytochemistry to characterise the dendritic morphology, cellular array and neurotransmitter content of a new type of GABAergic amacrine cell whose morphology differs significantly from previously characterised types. Following pentobarbitone overdose and enucleation, identified neurons in superfused DAPI-labelled retina were injected intracellularly with Neurobiotin under direct microscopic control, and then the wholemount preparations were fixed in paraformaldehyde and processed for GABA or glycine immunocytochemistry using newly developed antisera. The tracer-coupled neurons and the GABA/glycine immunoreactive neurons were visualised with Texas Red and FITC, respectively, and imaged by confocal microscopy. The bistratified cells show strong homotypic tracer-coupling and are immunopositive for GABA but immunonegative for glycine. They comprise 1.3% of the amacrine cells in the rabbit retina, with a cell density ranging from 100 cells/mm<sup>2</sup> in the peripheral retina to 350 cells/mm<sup>2</sup> in the visual streak. The soma gives rise to one or two stout primary dendrites which descend to sublamina b of the inner plexiform layer, forming a spiny dendritic tree about 150 µm wide in peripheral retina. Arising from the distal dendrites are fine varicose processes that ascend abruptly to arborise in sublamina a. Interestingly, the dendritic tree in sublamina b exhibits a high degree of territoriality, not seen in either the sublamina a arborisation or the dendritic trees of other types of GABAergic amacrine cells.

## 556.2

C38 ANTIGEN MOLECULE LOCALIZES IN RETINAL GANGLION CELLS. T. Wakabayashi<sup>1</sup>, I. Kosaka<sup>1</sup>, M. Mochii<sup>2</sup>, G. Eguchi<sup>2</sup> and Y. Fukuda<sup>1</sup>. <sup>1</sup>Dept. of Physiology, Osaka Univ. Med. Sch., Suita, Osaka, 565, JAPAN. <sup>2</sup>Div. of Morphogenesis, Natl. Inst. for Basic Biology, Okazaki, Aichi, 444, JAPAN.

We report here a new molecule which localizes in retinal ganglion cells (RGCs) in mammals. Monoclonal antibodies against RGCs were developed using an immunosuppressive method. One of these antibodies, C38 stained the somas located in the ganglion cell layer of rat and cat retinas. We verified in flatmount preparations of the rat retinas, that over 90% of retrogradely labeled cells overlapped with cells stained with C38. In optic nerve transected rat, C38 labeled only survived RGCs without erroneous labeling of glial cells which usually occurs after retrograde labeling. From these observations, we conclude that C38 is a specific marker for RGCs in flatmount preparation.

C38 recognized the antigen of deduced molecular weight of 24kDa on Western blotting. The cDNA of C38 antigen has been cloned and sequenced. By *in situ* hybridization, we were able to verify that C38 antigen was expressed in RGCs.

## 556.3

MORPHOLOGY OF CAT RETINAL GANGLION CELLS THAT PROJECT TO SUPRACHIASMATIC NUCLEUS (SCN) M. Pu<sup>1</sup>, P. Sterling<sup>1</sup>, and G. Pickard<sup>2</sup>. Departments of Neuroscience<sup>1</sup> and Psychiatry<sup>2</sup>, University of Pennsylvania, Philadelphia PA 19104

The circadian rhythms governed by the SCN are entrained by signals from retina, but which types of ganglion cell carry these signals is unknown. To identify these ganglion cells we injected rhodamine latex beads into the SCN. Following a two day survival, we placed the retina *in vitro*, identified retrogradely labeled ganglion cells by fluorescence microscopy, and injected them with Lucifer yellow and neurobiotin to visualize their full dendritic arbors. At eccentricities of 4-10mm, the dendritic trees were 600-1200µm diameter (vs 500-900µm for alpha cells in the same region). Three morphological types were observed: dense-branching, ON(40-68% of IPL); sparse-branching, OFF (2-26%); sparse-bistratified, ON/OFF(6-93%).

## 556.4

RETINAL LOCATIONS OF GANGLION CELLS WHICH PROJECT TO FROG ANTERIOR THALAMUS AND OPTIC TECTUM. E. Kicliter\* and M. Gonzalez, Dept. of Anatomy and Inst. of Neurobiol., Univ. of Puerto Rico, Med. Sci. Campus, San Juan, PR 00901.

The anterior thalamus of *Rana pipiens* receives retinal projections from both eyes. The retinal ganglion cells which terminate here are uniquely ON-type, responding to the onset of a light flash. Lesion of this region results in a loss of the *blue preference*, a positive phototaxis most easily elicited with short wavelength light. The present experiments were performed to study the retinal loci of ganglion cells which project to the anterior thalamus and compare them with those of cells which project to the optic tectum. A retrograde tracer, the B fragment of cholera toxin (CTB, 1%, 0.1-3.0 µl), was injected into either the retinal recipient neuropils of the anterior thalamus (N=5) or the tectum (N=6) of anesthetized frogs. After survival periods of 3-30 days the frogs were given a lethal dose of anesthesia and perfused transcardially with 4% paraformaldehyde. The toxin was visualized by immunocytochemical techniques in the retinas which were prepared as wholemounts. Locations of labeled cells were plotted on maps of the retinas, using a Neurolucida image analysis system. Ganglion cells labeled after anterior thalamic lesions were distributed bilaterally. In both eyes labeled cells were located in an intermediate position, with few labeled cells near the optic nerve head or in the periphery of the retina. The largest concentration of labeled cells was in the superior nasal retina. In the retinas of subjects with thalamic injections a bimodal distribution of soma sizes was observed. Smaller cells generally ranged from 6-12 µm in diameter while larger cells generally ranged from 14-20 µm. Distributions of large and small cells were overlapping. After tectal injections labeled cells were observed throughout the retina. In subjects which had received tectal injections the distribution was unimodal and soma diameters ranged from 8-23 µm. Supported, in part, by NIH Grants MH-48190 and NS-07464 and ONR Grant N00014-89-J3070.

## 556.5

**MORPHOLOGY OF RETINAL GANGLION CELLS MEDIATING THE PUPILLARY LIGHT REFLEX IN PIGEONS.** H.Y. Zhang\*, J.E. Williams and P.D.R. Gamlin. Department of Physiological Optics, University of Alabama at Birmingham, Birmingham, AL 35294.

Area pretectalis (AP), a retinorecipient pretectal nucleus, mediates the pupillary light reflex (PLR) in the pigeon (Gamlin et al., JCN, 226:523, 1984). To investigate the morphology of pupillomotor retinal ganglion cells (RGCs), we injected 0.8  $\mu$ l of either 10% fluorescein-dextran or Mini Ruby stereotactically into AP in anesthetized pigeons. After a 10-14 day survival period, animals were deeply anesthetized and perfused with 4% paraformaldehyde in 0.1M phosphate buffer. Retinae were removed and retrogradely-labeled RGCs were injected using glass micropipettes filled with a 4-5% solution of either Lucifer Yellow or Mini Ruby.

As previously reported, injections of AP result in retrograde labeling of relatively few RGCs that are distributed evenly across the retina except for an apparent paucity in the Red Field and extreme ventral retina. All AP-projecting RGCs possess very broad dendritic fields ranging from 300 to 600  $\mu$ m in diameter. In the peripheral retina, ganglion cells have extensively branched dendritic fields and soma sizes ranging from approximately 15-25  $\mu$ m. In the central and near peripheral retina, many ganglion cells have less extensively branched dendritic arbors and soma sizes ranging from approximately 8-20  $\mu$ m.

To our knowledge, this is the first report in any vertebrate class of the detailed morphology of pupillomotor RGCs. Our results demonstrate that the broad dendritic fields of pupillomotor RGCs ensure that relatively few ganglion cells can provide the retinal coverage necessary for mediating for the PLR. (Supported by EY09380 and P30 EY03039).

## 556.7

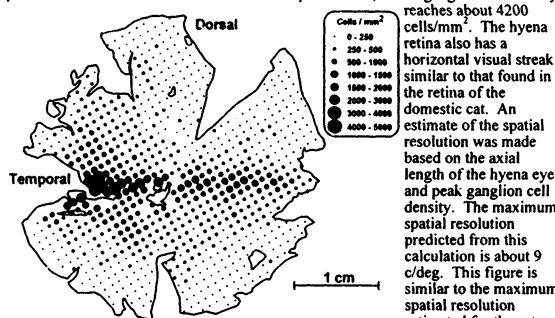

**TUBULAR EYES OF DEEPSEA FISHES: PHOTORECEPTOR AND RETINAL GANGLION CELL TOPOGRAPHY.** S.P. Collin\*, R.V. Hoskins and J.C. Partridge. Dept. of Zoology, University of Western Australia, Nedlands 6009 WA, Australia and School of Biological Sciences, University of Bristol, Bristol, United Kingdom.

The mesopelagic ichthyofauna of many of the world's deep oceans boast a number of species with asymmetric or tubular eyes. The retina consists of main and accessory components which are thought to mediate form vision and movement perception within dorsal and lateral visual space, respectively. To investigate the topography of both photoreceptor and retinal ganglion cell arrays, ten different species were collected from depths between 200 and 900 meters. Each specimen was anaesthetized by immersion with an overdose of tricaine methanesulphonate (1:2,000), fixed and wholemounted. Peak photoreceptor densities range from 97.6  $\times 10^3$  rods per  $\text{mm}^2$  in the main retina to 39.6  $\times 10^3$  rods per  $\text{mm}^2$  arranged in a tightly packed hexagonal array. Peak ganglion cell densities range from 28.1  $\times 10^3$  (*Stylophorus chordatus*) to 63.6  $\times 10^3$  cells per  $\text{mm}^2$  (*Opisthoproctus grimaldi*) in the central region of the main retina and between 0.8  $\times 10^3$  (*Argyrolepeus gigas*) and 10  $\times 10^3$  cells per  $\text{mm}^2$  (*Scopelarchus michaelisarsis*) throughout most of the accessory retina. Analysis of ganglion cell soma size shows a heterogeneous population of cells with larger cells in the accessory retina of all species. A cohort of giant alpha-like ganglion cells located in the temporal transitional zone between the main and accessory retinas of *Scopelarchus michaelisarsis* is analysed and hypothesized to represent a specialized area within the binocular visual field.

## 556.6

**RETINAL GANGLION CELL DISTRIBUTION IN THE SPOTTED HYENA, CROCUTA CROCUTA.** J.B. Calderone\*, B.E. Reese & G.H. Jacobs. Neuroscience Research Institute & Department of Psychology, University of California, Santa Barbara, CA 93106.

The spotted hyena is a member of the Superfamily Feloidae; its nearest relatives are civets, mongooses and cats. We have studied the retinal topography of this unique animal. A retina from an adult hyena was flat-mounted, stained with cresyl violet, and examined using light microscopy. Presumed retinal ganglion cells were counted at 1 mm intervals across the retina. We attempted to distinguish ganglion cells from other retinal cells (i.e., glial and displaced amacrine cells) based on their location, size, and appearance of a nucleus and substantial cytoplasm. From these measurements it was calculated that the hyena retina contains approximately 260,000 ganglion cells. A prominent area centralis was found in the temporal retina, where ganglion cell density reaches about 4200 cells/ $\text{mm}^2$ . The hyena retina also has a horizontal visual streak similar to that found in the retina of the domestic cat. An estimate of the spatial resolution was made based on the axial length of the hyena eye and peak ganglion cell density. The maximum spatial resolution predicted from this calculation is about 9 c/deg. This figure is similar to the maximum spatial resolution estimated for the cat.

## 556.8

**MORPHOLOGICAL ANALYSIS OF THE FASCICULAR PATTERN OF THE MONKEY OPTIC NERVE ACCORDING TO THE FASCICULAR SIZES.** J. Naito\*. Lab. of Animal Morphology and Function, Sch. of Agriculture, Nagoya Univ., Chikusa-ku Nagoya 464-01, Japan.

Fascicular pattern made of astrocytes' processes were analyzed in the monkey optic nerve using an image analyzer. Sectional areas of fascicles increased sharply in the distal optic nerve, and further increased gradually in the remaining part of the optic nerve. This change is mainly responsible for 'fusion' of small fascicles. Most of the fascicles were small in the distal optic nerve. Leaving the eyeball, they decreased sharply in number. In contrast, the fascicular numbers of other groups, middle-sized, large, and largest fascicles increased gradually in the distal optic nerve and become constant in the proximal optic nerve. More small and middle-sized fascicles were distributed in the central area of the optic nerve than larger fascicles. The largest fascicles were mainly distributed in the circumference of the optic nerve. Progress of the decrease in the fascicular number accurately corresponded to that of the dispersion of the optic nerve fibers. The size-distribution of fascicles seems to be related roughly to the retinotopic fiber order.

## MOTOR CORTEX: HUMAN STUDIES I

## 557.1

**MOTOR CORTEX EXCITABILITY DURING REACTION TIME.** P. Romaiguère, T. Hasbroucq, C.A. Possamaï and P. Salin\*. NBM, LNC, and LNCf, CNRS, 13402 Marseille cedex 20, France.

Changes in the motor cortex excitability before a voluntary movement were measured using transcranial magnetic stimulation (TMS) during a choice reaction time task. Because of its involvement in the execution of a movement, the motor cortex can be expected to be most likely activated in the latest part of the reaction time (RT). Three times of stimulation were thus chosen: T1, concomitant with the response signal; T3, just before the response; T2, at the mid-point between T1 and T3. The six subjects were over-trained, so that their RTs were stabilized and T3 could be determined for each of them with the best possible precision. T3 was chosen as late as possible but still ensuring that the evoked response never occurred after the onset of voluntary EMG. Changes in the evoked response size can be due to excitability changes occurring either at the cortical level or at the spinal level. To separate these changes, a second experimental session was performed, with H-reflexes evoked at T1, T2 and T3, instead of TMS responses.

The results showed that the latest the TMS, the greatest the response, while no significant change could be demonstrated in H-reflex sizes at the same times. On the other hand, TMS induced a lengthening of RTs, such that the latest the stimulation, the longest the RT; while electrical stimulations used to evoke H-reflexes induced a shortening of RTs, such that the earliest the stimulation, the shortest the RT.

We feel that these results can be replaced within the issue of continuous vs. discrete transmission of sensorimotor information.

## 557.2

**ETHANOL SUPPRESSES HUMAN MOTOR CORTEX EXCITABILITY: A TRANSCRANIAL MAGNETIC STIMULATION STUDY.** U. Ziemann\*, S. Lönnecker, W. Paulus. Dept. of Clinical Neurophysiology, University of Göttingen, D-37075 Göttingen, Germany

Transcranial magnetic stimulation (TMS) was used in six healthy volunteers to investigate the effect of ethanol on central motor system excitability. The threshold intensity for the motor evoked potential (MEP) in the resting and active abductor digiti minimi muscle, the variation of MEP amplitude with increasing stimulus intensity, the duration of the TMS induced cortical silent period (CSP), and the intracortical inhibition and facilitation after paired magnetic stimulation (interstimulus intervals 1-30 ms) were studied. In addition, the maximum M wave (Mmax) after supra-maximal electrical ulnar nerve stimulation and the peripheral silent period (PSP) were obtained. Baseline values were compared with data obtained on a mean ethanol blood concentration of 0.8 ml/l.

Resting and active motor thresholds, Mmax, MEP/Mmax ratios at various TMS intensities and the duration of the PSP were not affected by ethanol. The mean duration of the CSP was prolonged from 199 to 234 msec. The mean intracortical inhibition was enhanced, and the mean intracortical facilitation was abolished at all interstimulus intervals tested.

Our results show a suppression of motor system excitability at the cortical level by ethanol. They are compatible with data from animal experiments which have shown an attenuation of NMDA receptor-mediated synaptic currents and a potentiation of GABA currents as the main modes of action of ethanol in the central nervous system.

## 557.3

## MODIFICATION OF POST EXERCISE MEP DEPRESSION

WB McKay\*, DS Stokic, AM Sherwood, N Kharas, MR Dimitrijevic  
Division of Restorative Neurology and Human Neurobiology  
Baylor College of Medicine, Houston, Texas 77030

It has been reported that surface EMG recorded motor evoked potentials (MEPs) elicited by transcranial magnetic stimulation (TMS) of the motor cortex in human subjects are depressed following maximal voluntary contraction (MVC). Two means of modifying this post-exercise effect were examined. First, 4 subjects maintained tibialis anterior MVCs until force decreased by 50% in separate sessions, one of which included TMS delivered at 15 second intervals. Mean peak MEP amplitudes were depressed by 56% following MVC but with TMS delivered during MVC, this depression was not seen. Second, the effect of MVC duration was examined in 5 subjects during separate sessions of 5, 15 and 30 s MVCs repeated 3 times each. TMS was delivered at 5s, 30s and 1 through 5 minutes following each MVC. Depression of 1-5 minute post-exercise MEPs developed progressively over three repetitions of 5s MVCs. Following 15 or 30 second MVCs, MEPs were significantly depressed as early as 30 seconds after the first MVC and no further depression occurred with repetition. However, MEPs collected at just 5 seconds post-MVC were of significantly higher amplitude than subsequent responses. Modulation of post-exercise MEP depression, described here, results from changes in motor cortex excitability that are likely brought about by dynamic intracortical mechanisms.

This work was supported by V.L. Smith Foundation for Restorative Neurology, Houston, Tx USA.

## 557.5

LOCALIZATION OF THE CENTRAL SULCUS BY RELATIVE CORTICAL THICKNESS OF THE PRE AND POST CENTRAL GYRI ON TURBO IR MR IMAGING OF THE BRAIN J.R. Meyer, M.D., S. Roychowdhury, M.D., C. Callahan, R.T., D. Gitelman, M.D., M-M. Mesulam, M.D., T.C. Hain\* and E. J. Russell, M.D., FACR, Dept of Radiology and Center for Behavioral & Cognitive Neurology, Northwestern University, Chicago, IL 60611

To determine whether relative cortical thickness measurements of the precentral (PCG) and post-central (POCG) gyri can differentiate the central sulcus from adjacent cortical sulci. Turbo IR MR imaging (TR 2010 msec., TE 18 msec., TI 300 msec., 512 matrix, 5mm.) was performed of the entire brain with axial images parallel to the anterior commissure - posterior commissure line.

Cortical thickness was measured in each hemisphere using a jeweler's eye piece with .1mm gradations. Three measurements were obtained perpendicular to the central (CS), precentral (PCS), and superior frontal sulci (SFS), as determined by other established anatomical methods. The ratios of cortical thickness on both sides of the CS, PCS, and SFS were calculated and compared. The mean cortical thickness (MCT) ratio of PCG/POCG was 1.65 (right hemisphere = 1.53) (left hemisphere = 1.41). The MCT ratios across the PCS and SFS were 1.01 (right hemisphere = 1.03) and 1.03 (right hemisphere = 1.03), respectively. Statistical analysis using unpaired t-test yielded significant differences ( $p < .0001$ ) for PCG/POCG vs. MCT ratios across the PCS and SFS.

Cortical thickness measurements across the CS provides a new method for localizing the pre and post central gyri. The higher mean ratio of cortical thickness across the CS correlates with known cytoarchitectonic relationships.

## 557.7

NONINVASIVE LOCALIZATION OF SOMATOSENSORY CORTEX IN NEUROSURGICAL PATIENTS - A COMPARISON OF STRUCTURAL (MR) AND FUNCTIONAL (MEG) APPROACHES WITH VALIDATION BY INTRAOPERATIVE MONITORING. J. Levine\*, N. Baldwin, J. Sanders, J. Anson, A. Halliday, W. Ormon, New Mexico Institute of Neuroimaging and the Departments of Radiology, Psychology and Neurosurgery, The University of New Mexico, Albuquerque, NM.

Structural magnetic resonance imaging (MRI) and functional magnetoencephalographic (MEG) methods were used in an attempt to identify the post-central gyrus and central sulcus in 40 neurosurgical patients with mass lesions in the frontal or parietal lobe. MRI data were assessed by multiple 2D and 3D methods for identification of the central sulcus. MEG data were obtained in response to electrical stimulation of the median nerve, and dipole modelling was then used to localize the cortical source of the 20 msec component of the evoked magnetic signal, which is believed to be generated in primary somatosensory cortex. Two patients did not undergo surgery because neuroimaging data suggested that surgery would have compromised motor function. MRI alone provided confident identifications of the central sulcus in only 23 of the remaining 38 patients. In contrast, intraoperative electrocorticography confirmed the correctness of MEG-based localizations of the central sulcus in 36 of these 38 patients. The MEG data of the remaining 2 patients were obscured by artifacts that precluded central sulcus identification. For 10 patients, intraoperative stereotaxic procedures were used to specify the spatial coordinates of the hand representation of sensorimotor cortex as defined by corticography. Preoperative MEG localizations of sensorimotor cortex predicted these intraoperative MEG localizations to within 2-8 mm. It is noteworthy that for 6 patients who had localizations determined to be very poor surgical candidates, MEG demonstrated that the patient's lesion had actually displaced functional sensorimotor cortex and that surgical resection was accomplished without compromise of motor function.

## 557.4

CORTICOMOTOR REPRESENTATION OF THE STERNOMASTOID MUSCLE STUDIED WITH TRANSCRANIAL MAGNETIC STIMULATION M.L. Thompson, G.W. Thickbroom, B.J. Lockwood\* and F.L. Mastaglia. Australian Neuromuscular Research Institute and University Department of Medicine, QEII Medical Centre, Nedlands, WA 6009.

We have investigated the corticomotor representation of the sternomastoid (SM) muscle in fifteen healthy subjects using transcranial magnetic stimulation. Motor evoked potentials (MEPs) were recorded from the contralateral SM muscle via surface electrodes in all subjects, and with dual monopolar shielded needles inserted into the muscle near the motor point in one subject. A Magstim 200 with 5cm diameter figure 8 coil was used to deliver threshold-adjusted stimuli at multiple scalp sites over the motor cortex during a low-level voluntary contraction of the SM muscle. The corticomotor representation of the SM muscle was estimated by constructing maps of MEP amplitude as a function of scalp site stimulated. In 8 subjects, a response could not be evoked even with 100% stimulator output. In 5 subjects, stimulation of two separate areas of cortex gave rise to a MEP on the contralateral side, one medial and the other lateral to the hand area. In the remaining 2 subjects, the main body of the cortical representation was restricted to the region lateral to the hand area. Intramuscular recordings from the SM and platysma muscles demonstrated that the cortical representation of the SM was located in the area medial to the hand representation, and that of the platysma in the area lateral to the hand area. These findings indicate that the representation of the SM muscle forms part of the trunk representation, contrary to the conventional understanding that it is represented close to the face area (1), and that surface MEP recordings of the SM muscle include a significant contribution from the platysma muscle.

THREE DIMENSIONAL ANATOMY OF THE HUMAN CENTRAL SULCUS AND TOPOGRAPHY OF THE HAND SENSORY-MOTOR MAPS. Sastre-Janer F.A., Belin P., Mangin J.F., Frouin V., Dormont D., Masure M.C., Marsault C., Samson Y\*, Regis J. CEA-SHFJ, Orsay. Salpêtrière, Paris. La Timone, Marseille.

We analyzed the 3D morphology of the central sulcus (CS) in 17 normal subjects (10 left- and 7 right-handers), using contiguous horizontal T1-weighted 1.4 or 2 mm thick images obtained in the AC-PC plane, with a 5T or a 1.5T MR unit. A dedicated software was used to draw both CS on each horizontal section, and to visualize 3D wire-frame images of CS. The morphology was complex but two distinct elements were sharply interconnected, and could always be identified. The lower element extends in Talairach's space from  $z: +17.7 \pm 5$  to  $+49 \pm 3.5$  mm, and, viewed from above, is orthogonal to the brain surface. The upper element has a more oblique sigmoidal shape. It extends from  $+40.9 \pm 3.1$  to  $+67.1 \pm 2$  mm. It is initially connected internally, posteriorly, and orthogonal to the lower element, and reaches the surface only at high z levels. These measurements were not affected by the MR unit, the side of the CS, the gender or handedness of the subjects.

The level of the middle of the superior root ( $z: +54 \pm 2$  mm) is similar to that of previously reported spot of PET activation during fingertips vibrotactile stimulation ( $+55.9 \pm 4$  mm, Meyer et al, 91), and our preliminary PET results suggest that vibration spots may be localized vertically in the superior root, from  $64 \pm 1.3$  mm, near the surface of the brain, to  $41.8 \pm 3.8$  mm in the deep of the CS close to inferior limit of its superior root.

Taking in account the 3D anatomy of the cerebral sulci may be helpful to obtain accurate matching between structure and function in the cerebral cortex, and relevant morphometrical measurements of cortical regions.

## 557.8

MORPHOLOGICAL AND FUNCTIONAL EVIDENCE FOR TWO DIFFERENT SUBREGIONS WITHIN THE HUMAN PRIMARY MOTOR CORTEX. S. Geyer<sup>1</sup>, K. Zilles<sup>1</sup>, A. Dabringhaus<sup>1</sup>, T. Schormann<sup>1</sup> and P.E. Roland<sup>2</sup>. <sup>1</sup>Brain Research Institute, Heinrich Heine University, Düsseldorf, Germany and <sup>2</sup>Division of Human Brain Research, Dept. of Neuroscience, Karolinska Institute, Stockholm, Sweden.

In this study we describe two structurally different subregions within the primary motor cortex of man (Brodmann's area 4), which, as can be shown by positron emission tomography (PET), are functionally separate entities.

Two subregions can be defined within the primary motor cortex (an anterior one [4a] and a posterior one [4p]) due to different cell density, especially in cortical layer III and different concentrations of the muscarinic M<sub>2</sub> and serotonergic 5-HT<sub>2</sub> binding sites across all cortical layers. These two subregions were delineated in 5 normal postmortem brains which were subsequently adapted to the reference brain of a computerized brain atlas to compensate for distortions due to tissue processing and to permit the analysis of intersubject variability.

Several groups of subjects performed different types of voluntary movements of the right upper extremity during which their regional cerebral blood flow (rCBF) was measured with <sup>15</sup>O-butanol and PET. Cluster images showing significantly activated cortical fields were transferred to the same reference brain for direct comparison with the morphological data.

Fast simple movements activate both subregions. Movements guided by somatosensory information tend to recruit area 4p, whereas simple or learned responses to visual input irrespective of the speed of the response activate area 4a (Roland PE et al., Human Brain Mapping, 1995, in press).

The results suggest that the two subregions of the primary motor cortex also have different functions. Supported by the DFG (SFB 194/A6).

## 557.9

QUANTITATIVE COMPARISON OF CORTICAL ACTIVATION IN CENTRAL AND POST-CENTRAL SULCI DURING MOTOR, TACTILE AND HAPTIC TASKS, REVEALED BY FUNCTIONAL MRI. J.L. Anton, E. Guigon, H. Benali, M. Di Paola, J. Bittoun, Y. Burnod, M. Dufossé\* INSERM CREARE, UPMC, 75005 Paris, France; INSERM U66, CHU Pitié Salpêtrière, Paris, France.

We investigated the activation of the sensorimotor cortical areas during three right-hand-fingers tasks, which share information processing components: motor sequence, tactile stimulation, haptic task. Frontal MRI images were acquired around the Rolando sulcus in right-handed subjects, using a standard 1.5T Signa (GEMS) with a standard surface coil: 1/ Anatomical images were used to detect the somatomotor hand area, 2/ Angiography images allowed to detect the main veins, 3/ Functional images (gradient echo sequence) were acquired during the different behavioral conditions. The functional images were first processed to compensate the inter-frame motion due to small movements of the head and the brain. These images were then analyzed by a new statistical method based on conditioned analysis and orthogonal statistical maps, which allow to estimate the relevant part of the signal variation, free of the noise and of the unrelated signal. The highest values of the activation maps were correlated with the main veins, giving thus a rough approximation of the spatial location of the neural activity. The middle range values were correlated with the cortical ribbon on the anatomical images, revealing two main compact zones of activation, one in the central sulcus and the other one in the post-central sulcus. Quantification and comparison between tasks and subjects showed that the extent of the activated zone in the central sulcus was similar in the three tasks. This zone probably corresponds to the finger region in the Primary Motor Area (MI) and the Primary Somatosensory Area (SI). Conversely the other zone of activation in the post-central sulcus was revealed mainly for the tactile and haptic tasks, with a larger extent for the haptic task. This second region could play a role in the integration of tactile information present in both tasks and could be modulated by the active aspect of the haptic task.

## 557.11

ACTIVATION OF THE MOTOR CORTEX IN MONOZYGOTIC TWINS DETERMINED BY FUNCTIONAL MRI AT 4 TESLA. J. Ashe\*, S.G. Kim, G. Tagaris, K. Ugurbil, A.P. Georgopoulos. Brain Sciences Center, VAMC, and Center for Magnetic Resonance Research, University of Minnesota, Minneapolis, MN 55417.

There is an hemispheric asymmetry in the activation detected by functional magnetic resonance imaging (fMRI) within the motor cortex during hand movements (Kim et al., *Science* 261: 615, 1993). The right motor cortex is activated almost exclusively during movements of the contralateral hand. The left motor cortex is also activated predominantly during contralateral movements but there is significant activation during ipsilateral movements as well. The determinants of this asymmetry are not known. Among the possible explanations are (i) that the asymmetric functional activation is genetically determined, or (ii) that it is related to hand use. We have examined this issue by studying the functional activation of the motor cortex in pairs of monozygotic (MZ) twins with different handedness during performance of hand movements. Six pairs of MZ twins performed visually paced finger-thumb opposition movements with the right and left hand while their precentral gyrus was scanned using axial multislice BOLD functional imaging with a 4 Tesla system. The order of left/right movements was randomized. We tested the null hypothesis that functional activation is genetically determined and thus should be similar within twin pairs. We found that both the volume and the pattern of functional activation in the precentral gyrus differed significantly between subjects within pairs. This finding rejects the null hypothesis above and indicates that motor cortical activation during hand movements is determined by other factors (e.g. hand use) that may interact with genetic factors. (Supported by NIH grants NS32437, NS32919 and RR088079.)

## 557.13

IMPORTANCE OF EKG GATING IN FUNCTIONAL MAGNETIC RESONANCE IMAGING (fMRI) OF HUMAN MOTOR CORTEX.

K. Kuppusamy, W. Lin\*, E.M. Haacke. Mallinckrodt Institute of Radiology, Washington Univ., St. Louis, MO 63110.

We delineate the importance of EKG gating in fMRI of human motor cortex. Transaxial echo planar images covering the primary motor strip were obtained from 14 subjects (without EKG gating) and 7 subjects (with EKG gating) on a SIEMENS 1.5T VISION system using TR/TE/FA/TH=3000/66/90°/3-5mm, Number of slices=10, FOV=200mm, matrix size=64X64 (sinc interpolated to 128X128) and 60 time course images/slice. TR will be slightly altered with EKG gating depending on subject's heart rate. The time course had a repeated sequence of 5 resting and 5 activation state scans. The paradigm was "sequential finger tapping" of digits 2-5 onto digit 1 of right hand. The functional images were analyzed using cross-correlation, subtracted t-test and variance methods. The variance image was obtained using sum of the variances of the resting state images and activated state images of the entire time course data. This variance image is a primary indicator of physiological and systematic noise. The signal change increased from  $1.1 \pm 0.1\%$  (without EKG gating) to  $3.1 \pm 0.1\%$  (with EKG gating) in the contralateral primary motor cortex region. There was a considerable reduction of variance of 10–30% with EKG gating, indicating the reduction of physiological noise. This reduction of variance leads to increase in mean value of cross-correlation and hence an increase in the number of activated pixels in the contralateral primary motor cortex region. There is a very little change in total scan time with EKG gating. Our findings indicate that it is important to have EKG gating while performing any fMRI experiment.

## 557.10

RELATION OF SCALP-MEP-MAPS TO UNDERLYING CORTICAL PROFILE IN RIGHT- AND LEFT-HANDERS. J. Netz, V. Hömberg\*. Neurological Therapy Centre, Institute at the Heinrich-Heine-University, Hohensandweg 37, D-40591 Düsseldorf, Germany

In 10 normal subjects (5 right-handed, 5 left-handed) the cortical motor area of the right and left thenar was mapped by focal transcranial magnetic stimulation at a 2.5 % spacing of the respective circumferences of the 10/20 EEG-electrode positioning system. The maps were projected to the cortex profile represented in a 3D-MRI-flash-scan (128 slices) by a software developed especially for this purpose using different landmarks of the outer skull for adjustment. In 15 out of 20 cases there was a distinct single maximum but 5 maps from 4 left-handed subjects showed two distinct maxima. All maps covered at least in parts the precentral gyrus but the proportions of the maps extending onto the region anterior to the precentral gyrus ranged from 0-80 % and the proportion covering the postcentral gyrus ranged from 0-50 %.

In conclusion the cortical maps of left-handed subjects seem to differ in their spatial distribution from those of right-handed subjects. The variance of MEP-map locations in reference to the central sulcus as well as in reference to the scalp is considerable. The knowledge of the cortical profile is of limited help in predicting the exact location of MEP-maps. A further consequence of this result is, that it is problematic to average topographic data from different subjects.

## 557.12

LOCALIZATION OF FUNCTIONAL REGIONS OF HUMAN MESIAL CORTEX. T. Allison\*, G. McCarthy, M. Luby, A. Puce, and D.D. Spencer. Neuropsychology Lab., V. A. Medical Center, West Haven, CT, 06516 and Section of Neurological Surgery and Dept. of Neurology, Yale Univ. Sch. of Medicine, New Haven, CT, 06520.

We describe methods of localizing some functional regions of the mesial wall, based on 47 patients studied intraoperatively or following chronic implantation of subdural electrodes. Somatosensory evoked potentials were recorded to stimulation of posterior tibial, pudendal, median, and trigeminal nerves. Bipolar cortical stimulation was performed, and in a few cases movement-related potentials were recorded.

The genitalia are represented near the cingulate sulcus, anterior to the foot sensory area occupying the posterior paracentral lobule. These areas are posterior and inferior to the foot motor representation. In agreement with some previous studies, there is a rough somatotopic organization within the supplementary motor area (SMA), with the face represented anterior to the hand. However, there was no clear evidence of the "pre-SMA" region identified in monkeys. Complex movements involving more than one extremity were elicited by stimulation of much of the paracentral lobule. The cingulate and marginal sulci form the inferior and posterior borders of the sensorimotor areas and the SMA. The region comprising the supplementary sensory area is unclear, but may involve much of the precuneus. Movement-related potentials did not provide additional localizing information, although in some recordings focal readiness potentials were recorded from the SMA.

## 557.14

COMPARISON OF FUNCTIONAL MAGNETIC RESONANCE IMAGING (fMRI) WITH POSITRON EMISSION TOMOGRAPHY (PET) USING A QUANTITATIVE FORCE-RELATED PARADIGM.

C.Dettmers, A.Connelly, K.M.Stephan, R.Turner \*, R.S.J.Frackowiak, D.Gadian. Wellcome Department of Cognitive Neurology, Institute of Neurology, and Radiology and Physics Unit, Institute of Child Health, London, UK.

The purpose was to compare anatomical location and amplitude of signal changes in PET and fMRI using an identical force-related paradigm with each technique. 6 male subjects - 5 were identical in both studies - were asked to press repetitively a morse-key at 1Hz with their right index finger. Data were collected during 6 different conditions: at rest, at 5% of their maximum voluntary contraction (MVC), at 10%, 20%, 40% and 60%. Regional cerebral blood flow (rCBF) was determined using the  $H_2^{18}O$  bolus injection technique. fMRI data were collected with a conventional 1.5-tesla clinical MR system in one transverse section through the primary motor cortex (M1). Both data sets were subjected to the same statistical analysis (categorical and parametric analysis). Statistical parametric maps were superimposed on corresponding T1 weighted MR images for anatomical localization. Both techniques identified M1 and the posterior supplementary motor cortex in 6 out of 6 subjects. While fMRI foci were at the border of grey matter and sulci, PET foci were within the tissue 0 to 8 mm distant from the fMRI focus. While the fMRI signal increased by 4.8%, rCBF increased by 12.3% at a comparative peak force. rCBF and signal increased logarithmically in a constant ratio, suggesting that change in signal is proportional to stimulus intensity and rCBF.

## 557.15

THE DECISION TO MOVE MAY BEGIN IN THE PREFRONTAL CORTEX. G.H. Yue\*, M. Xue, T. Ng, and R.M. Enoka. Depts Biomedical Engineering and Radiology, The Cleveland Clinic Foundation, Cleveland, OH 44195

Before a voluntary movement begins, an intent to do so must arise in the brain. This intent informs the lower hierarchical motor centers of the proposed action and a muscle contraction follows. Despite numerous studies on primates and humans, it has not been possible to clearly identify the brain area(s) responsible for initiating the command to generate a motor action. The purpose of this study was to identify the brain regions involved in making the decision to move by using functional magnetic resonance brain imaging. Healthy human subjects performed various combinations of real and imagined pinches involving the index finger and thumb. These experiments were performed on a Siemens 1.5 T Vision system using a circular polarized head coil. Ten 6 mm-thick, continuous oblique-angle slices were imaged. The images were acquired with an interleaved multislice Gradient Echo pulse sequence (TR/TE = 400/40 ms, FOV = 220-230 mm, matrix size = 128 x 128). Images during rest and activity were compared with *t* test on a pixel-by-pixel basis and pixels showing significant activation were determined. The results demonstrated that tasks involved with a heightened intent to move were associated with a strong, consistent activation of the prefrontal cortex, indicating its role in generating the intent to move. Low-intent motor tasks displayed only motor cortex activity, presumably because the activity in the prefrontal cortex had already dissipated.

## 557.17

ACTIVATION OF SUPPLEMENTARY MOTOR AREA DURING SIMPLE, COMPLEX, AND BILATERAL LIMB MOVEMENTS IN HUMANS. M. Xue, T. Ng, G.H. Yue, Y.G. Comair, R.M. Enoka\*, H.O. Lüders, and M.T. Modic. The Cleveland Clinic Foundation, Cleveland, OH 44195

The supplementary motor area (SMA) in humans is thought to contribute to the programming of complex sequence of limb movements, to the coordination of independent bilateral tasks, and to the execution of simple motor actions. It has been suggested that the extent of SMA activity during a simple movement may depend on the magnitude of the subject's intent. The purpose of this study was to identify the regions of the SMA that are active during motor tasks of varying intent and complexity using functional magnetic resonance brain imaging. Healthy human subjects performed various combinations of real and imagined unilateral and bilateral finger movements. These experiments were performed on a Siemens 1.5 T Vision system using a circular polarized head coil. Ten 6 mm-thick, continuous oblique-angle slices were imaged. The images were acquired with an interleaved multislice Gradient Echo pulse sequence (TR/TE = 400/40 ms, FOV = 220-230 mm, matrix size = 128 x 128). Images during rest and activity were compared with *t* test on a pixel-by-pixel basis and pixels showing significant activity were determined. We found that independent bilateral movements of the hands were associated with the strongest SMA activity followed by a complex finger-tapping sequence. Simply pressing two fingers together continuously exhibited least SMA activation. These results suggest that the magnitude of human SMA activation depends largely on task complexity and less on intent.

## 557.16

READINESS POTENTIAL VS MOVEMENT PREPARATION

J.T. Davis\*, J.D. Lewine, K. Paulson, W.W. Orrison. Magnetic Source Imaging Facility (MSI), V.A. Medical Center, 2100 Ridgecrest Drive, Albuquerque, NM 87108, and The University of New Mexico School of Medicine, Albuquerque, NM 87131.

The goal of the study was to define the relationships between movement preparation and the readiness potential, under conditions in which the choice of movement is recalled from memory. There were either two or four possible finger movement sequences in each experiment, and these were memorized before the experiment began. Based upon a visually presented letter, the subject chose one of the previously memorized sequences of movements, and performed them. Three basic relationships were identified. 1) The reaction time and 2) the duration increased with either the number of previously memorized sequences, or with the complexity of the sequence. 3) The start of the readiness potential was time locked to the stimulus, regardless of the number of memorized sequences or the complexity of the sequences. These results indicate that the latency of the start of the readiness potential does not depend upon the time it takes to recall the sequence from memory, and thus cannot represent the cognitive activity of preparing for movement. The readiness potential may, however, represent a priming of motor or premotor cortex.

## 557.18

DISTINCT CEREBRAL ACTIVITY IN IMAGINATION AND EXECUTION OF MOVEMENT. M.-P. Deiber, V. Ibañez, R. Raman¹, N. Sadato\*, C. Toro, L. Cohen, M. Hallett. Human Motor Control Section, ¹Neuroimaging Branch, NINDS, NIH, Bethesda, MD 20892.

Regional cerebral blood flow measured by [O-15] water and PET was obtained during performance of tasks in which 10 right-handed normal volunteers responded to a first (warning) signal by imagining moving one of two right fingers (index or little finger) in one of two dimensions (abduction/elevation). According to the task, they either executed their movement or held it at the second (imperative) signal. Each trial lasted about 8 seconds, and the delay period between the warning and imperative signals varied between 2.75 and 5 seconds. Two situations were tested, one in which complete visual advance information as to finger and direction was given in the warning signal (full condition), and the other one in which the subject freely selected any of the four possible movements (free condition) (Deiber et al., Soc. Neurosci. Abstr., 20 (1), p. 443, 1994). Statistical parametric maps were generated by making planned comparisons of task and rest conditions.

When subjects imagined the movement but held their response, in both the full and the free conditions, there was an activation of the left parietal area 39/40, the left frontal area 9 and the left anterior supplementary motor area (pre-SMA). In the free condition, the cingulate cortex, right premotor area 6 and right parietal area 39/40 were also activated. When movements were actually executed after having been imagined, the right cerebellum was additionally activated in both full and free conditions. Right cerebellar activity remained when the imagination component was cancelled out by the direct comparison of tasks with imagination and execution versus tasks with imagination only. These results suggest that imagination of movement involves contralateral associative parieto-frontal areas and pre-SMA. They further suggest that the cerebellum plays a major role in processes linked to motor execution, and not to movement imagination.

## MOTOR CORTEX: HUMAN STUDIES II

## 558.1

DO GRASPING AND MATCHING OF OBJECTS INVOLVE SEPARATE VISUAL PATHWAYS? FUNCTIONAL ANATOMY WITH PET.

I. Faillenot¹, J. Decety¹\*, J. Toni¹, M.C. Grégoire², M. Jeannerod¹.

¹Inserm U94, 16 avenue du Doyen Lépine, 69500 Bron, France; ²Cermep, 59, Bld Pinet, 69003 Lyon, France.

In order to determine the neural substrate involved in grasping and in form identification respectively, task related changes in regional cerebral blood flow (rCBF) were measured in eight healthy volunteers using positron emission tomography (PET) and H<sub>2</sub><sup>15</sup>O i.v. bolus injection. Subjects were scanned during the performance of three tasks using identical stimuli, i.e. polyhedral objects of different sizes and orientations, presented at a rate of 0.3 Hz. The tasks were the following: (1) pointing with the right hand to object's center, (2) grasping objects accurately and (3) matching the form of the actual object to that of the previous one irrespective of size or orientation. Statistical analysis was performed with the 94' version of Statistical Parametric Mapping (SPM).

. During the matching task, relative to grasping task, rCBF increase was located in the left prefrontal cortex and in the right inferior temporal cortex.

. During the grasping task, relative to the matching task, rCBF increased contralaterally to the grasping hand in the inferior parietal cortex, in the occipito-parietal cortex, in the sensori-motor cortex and in the lateral premotor cortex. In addition, rCBF increased in the cerebellum as well as in the median cingulate cortex.

. During the grasping task, relative to pointing task, rCBF increase was observed in the contralateral inferior parietal cortex.

Object shape seems to be processed by different structures according to the goal of the task. These results are discussed within the framework of separate visual pathways for perception and action.

## 558.2

CORTICAL FOCI RELATED TO HAND REACHING AND GRASPING IN HUMANS EXAMINED BY REGIONAL CEREBRAL BLOOD FLOW

M. Matsumura¹, R. Kawashima², E. Naito¹, A. Ishihara¹\*, T. Satoh², T. Takahashi¹, T. Yanagisawa³ and H. Hukuda². ¹Fac. of Human Studies, Kyoto Univ., Sakyo-ku, Kyoto, 606-01. ²Dept. Nucl. Med. & Radiol., IDAC, Tohoku Univ., Aoba-ku, Sendai, 980-77. ³Dept. Radiol., Iwate Med. Sch., Uchimaru, Morioka, 020 Japan

To identify cortical foci related to reaching and grasping movements, we measured regional cerebral blood flow by PET in six right-handed normal volunteer (with written informed consent). Five cylinders with different diameters were fixed on a board in front of the subjects. In the saccade task, subjects were asked to look at a LED, embedded in the center of the each cylinder, which was lit in the random order. In the reaching task and grasping task, subjects were asked to touch the LED or grasp the cylinder with their right hand. After the anatomical standardization of the PET images by computerized brain atlas system (Roland et al. 1994), percent change of relative rCBF between two globally normalized images (reaching and saccade, also grasping and reaching), and three-dimensional t-images were calculated to find fields of activation.

In the reaching task, fields of activation were observed bilaterally in premotor areas (PMA), inter parietal sulcus areas (IPSA) and prefrontal areas, as well as in the left sensori-motor area. In the grasping task, bilateral PMA, the right IPSA, and bilateral visual areas showed significant increases in rCBF. The results indicate that human PMA and IPSA may be the key structures for both reaching and grasping movements.

## 558.3

FUNCTIONAL NEUROANATOMY OF GOAL-DIRECTED HAND AIMING MOVEMENTS: A PET STUDY. C.J. Winstein\*, P.S. Pohl, & S.T. Grafton. Motor Behavior Lab & PET Imaging Center, University of Southern California, Los Angeles, CA 90033.

The purpose of this study was to examine the effects of task complexity on the functional neuroanatomy of rapid goal-directed aiming movements. We used the PET brain imaging technique with 6 right handed young adults ( $M = 23 \pm 3.8$  yrs) while they performed reciprocal aiming in three conditions of task difficulty [Fitts' (1954) Index of Difficulty] (2.32, 4.32, 6.32) each with two target width/amplitude combinations (Type) resulting in six conditions. Six movement scans (90 s) were acquired in counterbalanced order. The path of the stylus was recorded by video (120 Hz) using 2-D kinematic techniques. Number of cycles (target to target), and kinematic features (average movement time, peak velocity, and % acceleration time) were analyzed together with the magnitude of regional cerebral blood flow (rCBF). ID, Type, cycles, and kinematic features were used as linear contrast weights in planned comparisons of rCBF means across the six movement conditions to identify regional brain activity proportionate to these effects ( $p < .005$ ). When the aiming task was easy (low ID, high cycles, high peak velocity), rCBF was greatest in the ipsilateral anterior cerebellum, contralateral posterior visual association (movement perception), and ipsilateral ventral premotor areas. Surprisingly, rCBF in the motor cortex was only mildly increased ( $p < .05$ ). With a high ID (low cycles, low velocity), rCBF was greatest in bilateral visual association, contralateral ventral and dorsal parietal, premotor, and rostral SMA areas. Difficult closed-loop aiming relies more on the dorsal parietal "stream" as well as premotor and rostral SMA cortex.

## 558.5

A NEW APPROACH TO ASSESS CORTICAL PROCESSING OF FAST REPETITIVE FINGER MOVEMENTS: STEADY-STATE MOVEMENT-RELATED CORTICAL POTENTIALS AND THEIR GENERATORS. C. Gerloff, C. Toro, L. Leocani and M. Hallett\*.

Human Motor Control Section, Medical Neurology Branch, NINDS, National Institutes of Health, Bethesda, MD 20892, U.S.A.

We investigated movement-related cortical potentials (MRCPs) and their electric sources during fast repetitive metronome- and self-paced finger extensions.

MRCPs were recorded from 6 volunteers using a 32-electrode cap (sample rate 250 Hz, upper cutoff 50 Hz, time constant DC). Subjects performed steady-state metronome-paced simultaneous extensions of their fingers II-V at 2 Hz and comparable self-paced movements. EMG-locked averaging was done offline using 500 ms time windows, each corresponding to one full cycle of the continuous 2 Hz movement. Per subject and task, 266 (mean, SD 40) movements were averaged. Brain electric source analysis (BESA) was used to model the underlying generators.

A distinct cortical potential was found in all subjects, with a parietal negative peak preceding EMG onset by about 75 ms, and a frontal negative peak following EMG onset by about 105 ms, both more pronounced contralateral to the moving side. During self-paced movements, an additional negative peak was seen at about 170 ms before EMG onset, with maximum over frontocentral midline electrodes. For both conditions, dipole modeling revealed 2 pairs of tangential sources in contralateral and ipsilateral sensorimotor cortex, one of them oriented parietally, generating the earlier parietal peak, the second pointing frontally, generating the frontal peak. For the self-paced condition, contribution of an additional source in the frontocentral midline varied across subjects. The models accounted for over 91% of grand average data and for over 89% (mean, SD 3.9%) of individual data.

Steady-state MRCPs reflect rapid changes of cortical activation during repetitive movements. We propose that their main generators are located in the pre- and post-central gyri, and show phasic, alternating activity during maintenance of this type of motor behavior.

AN EEG-BASED BRAIN-COMPUTER INTERFACE: ALTERNATIVE METHODS FOR CONTROLLING TWO-DIMENSIONAL CURSOR MOVEMENT. L. McCane\*, D.J. McFarland, T.M. Vaughan, and J.R. Wolpaw. Wadsworth Center for Laboratories and Research, NY St Dept of Health and State Univ of NY, Albany, NY 12201.

Humans can learn to control the amplitudes of specific EEG components and use them to move a cursor in one or two dimensions to a target on a video screen (Electroenceph clin Neurophysiol 78:252-259, 1991 and 90:444-449, 1994). We are trying to improve the rapidity and accuracy of two-dimensional cursor control by incorporating EEG from additional or alternative scalp locations into the algorithm that controls cursor movement.

EEG is recorded from 64 scalp locations while subjects control cursor movement. Offline analysis of these data seeks to find scalp locations and/or frequency bands that show strong correlations with target location and thus may be expected to improve online control. These parameters are then tested online.

In studies to date, two algorithms have provided significant two-dimensional cursor control. In both algorithms, vertical movement is controlled by the amplitude(s) in an alpha (i.e., 8-12 Hz) or beta (i.e., 20-25 Hz) frequency band over one (or both) sensorimotor cortices. In one of these algorithms, horizontal movement is controlled by the difference between these amplitudes over sensorimotor cortex. In the other, horizontal movement is controlled by the difference between amplitudes in an alpha or beta frequency band over right and left parietooccipital cortices.

Current studies are comparing these two algorithms to determine which is superior and are also seeking to identify further alternatives. It is likely that the optimum algorithm will be different for different subjects. (Supported by NIH grant HD30146.)

## 558.4

FUNCTIONAL MRI OF CORTICAL MOTOR AREAS DURING SEQUENTIAL TYPING MOVEMENTS. A.M. Gordon\*, D. Flament, J.-H. Lee, K. Ugurbil, S.-G. Kim and T.J. Ebner. Depts. of Physiology, Neurosurgery and Center for Magnetic Resonance Research, Univ. of Minnesota, Minneapolis, MN 55455

In the present study we examined the activation of cortical motor areas using functional MRI (4T, echo planar imaging) during the execution of a well-learned sequence of finger movements. We chose typing since it is a highly skilled task which is goal directed (i.e., requires a series of keys to be struck in a specific spatio-temporal order). Experienced typists performed several typing tasks, which varied in the spatial and temporal requirements, on a standard computer keyboard situated on their lap. They performed a repetitive movement with the right index finger (typed "J"), a repetitive sequence with the same finger (typed "JUYH"), a repetitive sequence with all four fingers of each hand (typed "JFIELSPQ"), and typed sentences which required the use of all fingers. The number of keypresses was recorded to assess motor performance. Twenty-four contiguous coronal slices (5mm each) were collected through the temporal, parietal and part of the frontal lobes. During the performance of the repetitive movements with the right index finger ("J"), a consistent activation was observed primarily in the contralateral primary motor cortex (M1). During the performance of the other tasks, which involved sequencing of movements of either the right index finger or all of the fingers, activation was also observed in the premotor cortex (PM) and supplementary motor area (SMA). In addition, for the latter tasks, parietal areas 5, 7 and 40 were activated. The results suggest a hierarchy of cortical structures involved in producing a series of finger movements, that is dependent on the degree of sequencing (PM and SMA) as well as the spatial demands of the task (parietal cortex).

## 558.6

AN EEG-BASED BRAIN-COMPUTER INTERFACE (BCI): IMPROVING PERFORMANCE BY INCREASING SPATIAL RESOLUTION. D.J. McFarland\*, L. McCane, S. David, and J.R. Wolpaw. Wadsworth Labs, NY State Dept Health and SUNY, Albany, NY 12201.

Humans can learn to control the amplitudes of specific EEG components and use them to move a cursor in one or two dimensions to a target on a video screen (Electroenceph clin Neurophysiol 78:252-259, 1991 and 90:444-449, 1994). We are trying to improve the rapidity and accuracy of cursor control by using EEG reference methods that increase spatial resolution. The present study compares four reference methods: a standard monopolar ear reference, a common average reference (CAR), and two LaPlacian derivations (nearest neighbor and next-nearest neighbor). The CAR and LaPlacians are spatial filters that accentuate EEG components of high spatial frequencies.

We analyzed 64-channel EEG data that had been gathered while four well-trained subjects controlled cursor movement. For each reference method, we defined EEG dependence on target location by computing scalp topographies of  $r^2$  (the coefficient of determination) for the frequency bands that had been used to control cursor movement online.

In all subjects, the best results (i.e., highest  $r^2$  values for the scalp locations used for cursor control online) were given by the CAR method ( $0.36(\pm 0.08SD)$ ). Values were lower for the next-nearest neighbor LaPlacian method ( $0.29(\pm 0.09)$ ) and much lower for the monopolar and nearest neighbor LaPlacian methods ( $0.19(\pm 0.09)$  and  $0.18(\pm 0.11)$  respectively).

While these results suggest that the CAR method is the best choice for a brain-computer interface (BCI) system, it is important to note that these subjects had been trained primarily with the CAR. Had they been trained with another reference, the outcome might have been different. Nevertheless, the results indicate that spatial resolution is an important factor in BCI design. (Supported by NIH grant HD30146.)

## 558.8

CHANGES IN MOTOR CORTICAL AND SUBCORTICAL ACTIVITY, DURING THE ACQUISITION OF MOTOR SKILL, INVESTIGATED USING FUNCTIONAL MRI (4T, ECHO PLANAR IMAGING). D. Flament\*, J.-H. Lee, K. Ugurbil and T.J. Ebner. Dept. Neurosurgery and Center for Magnetic Resonance Research, Univ. Minnesota, Minneapolis, MN 55455.

In an earlier study we showed that cerebellar activity is inversely related to performance, decreasing during the learning of a novel motor task. In this study we investigated whether motor cortical and subcortical areas also exhibit learning-dependent changes in activity. The reference task consisted of center-out movements to 8 targets, where a joystick was used to superimpose a cross-hair cursor onto the targets. With practice, subjects were able to do these tracking movements with a high degree of accuracy. The number of movements made and the path length of the trajectories to each target were calculated, and used to generate a performance index. The learning paradigm was a modification of this task, where the relationship between movement of the cursor and joystick was reversed. Initially, the number of errors increased, fewer accurate movements were made, and path lengths increased (performance index decreased). In 5 of 8 subjects tested, the performance gradually improved and approached or reached the performance level of the control task. We imaged 24, 5mm slices through the temporal, parietal, and part of the frontal lobes. On average, as learning progressed, the area of activation in M1, SMA and PM increased. The caudate nucleus had no change in the area of activation while the lentiform nucleus had an increased area. These findings confirm that the changes in cerebellar functional activation measured previously are not due to global hemodynamic alterations. The increased activation observed in M1, SMA and PM suggest that these areas may be directly related to the process by which skill is acquired when learning a novel motor task.

## 558.9

**VISUAL ORIENTATION DISCRIMINATION: EFFECT OF TRAINING ON BRAIN ACTIVITY. A PET STUDY.** C.Schiltz, S.Dubois, J.M. Bodart, C. Michel<sup>1</sup>, G. Orban<sup>2</sup>, and A. Roucoux\*. Lab. of Neurophysiology, U.C.L., Brussels; <sup>1</sup>PET Unit, U.C.L.; <sup>2</sup>Louvain-la-Neuve; <sup>3</sup>Lab. Neuro-<sup>4</sup>en Psychophysiology, KULeuven, Leuven, Belgium.

The aim of the present experiment was to investigate the neural mechanisms involved in visual perceptual learning. An orientation discrimination task was used as it is known to engage early visual areas (Dupont et al, PNAS, 90:10927-10931, 1993). Four male right-handed subjects were scanned before and after training (10,000 trials) in orientation identification. Three conditions were tested: Identification with right and left hand button press as response, Passive viewing and Fixation only. In each scanning (ECAT 961 HR) session, these conditions were repeated four times in random order. Statistical analysis on the rCBF brain images was performed by Statistical Parametric Mapping (Friston et al., 1994). Subtracting fixation only from identification before training revealed activations in calcarine, lingual and fusiform cortices, primary motor cortex bilaterally, cerebellum, anterior cingulate cortex and putamen. After training, the same subtraction yielded much reduced occipital activation leaving only a V1-V2 focus. There was also a decrease in primary motor activation combined with an increased activation in SMA, putamen and anterior thalamus. Similar observations were made when subtracting Passive Viewing from Discrimination. Before training, temporal, parietal and frontal regions were deactivated during discrimination. Most deactivations disappeared with training: this is probably related to the decrease in the level of difficulty after training, since the orientation difference (15 deg.) was kept constant.

## 558.11

**MENTAL SIMULATION OF MOVEMENT IN PATIENTS WITH POSTERIOR PARIETAL CORTEX LESIONS** A. Sirigu, J.-R. Duhamel, B. Pillon, L. Cohen, B. Dubois, Y. Agid\*. I.N.S.E.R.M. Unité 289, F-75013 Paris, France

The posterior parietal region has long been known to be involved in skilled arm and hand movements. Although the nature of this contribution is not fully understood, a recurring hypothesis is that the parietal cortex maintains internal models of learned limb postures and movement patterns. We recently proposed that the study of mentally simulated actions, or motor imagery, in neurological populations could provide insights into the role of different cerebral areas in movement representation (Sirigu et al., NeuroReport, vol.6, 1995).

Patients with parietal lobe lesions were compared to normal subjects and to a patient with motor cortex damage on mental simulation of finger, arm, and leg movements sequences. The goal of these tasks was to determine if the time employed to simulate a movement accurately predicts the duration of the actual movement. Normals showed consistent correlations between actual and mental movement times. This was also true for the patient with motor cortex damage in whom motor impairments of the contralesional limb could be measured just as accurately in the imagery condition as in the actual movement condition. Parietal lesions also slowed the execution of finger movement sequences, but their duration was not correlated with mental movement times: simulated movements systematically underestimated or overestimated actual movement times. One patient with a left parietal lobe lesion showed minimal slowing of actual finger movements, yet was severely impaired for all simulated hand movements. In all cases, actual and imagined movements for other body parts were well correlated, ruling out a global mental imagery impairment. While the patient with motor cortex lesions reported subjectively experiencing her motor deficit during imagery, parietal patients consistently reported difficulties in generating an image of their own hand in movement. We conclude that the posterior parietal cortex plays a critical role in activating internal representations of limb configurations and movements during mentally simulated actions.

## 558.13

**REDUCED SYNCHRONIZATION OF BIMANUAL LIMB MOVEMENT INITIATION TIMES IN AN ANTERIOR CALLOSOTOMY PATIENT FOLLOWING SURGERY.** J.C. Ellassen\* and M.S. Gazzaniga. Center for Neuroscience, Univ. of Calif., Davis, CA 95616.

The role of the anterior callosum in the synchronization of bilateral movement initiation was studied by observing pre- and post-operative performance. The patient, a 41 y.o. left-handed female with ~80 seizures/month, underwent an anterior callosotomy. Seizures fell to 10% of pre-op levels at the first post-op visit and were increasing at the second. Medication stayed constant during the experiment: 1 pre-op and 2 post-op visits (1 mo. and 3 mos.). The subject sat facing 2 electronic timers, each stopped by a separate button placed in front of the patient. The paradigm consisted of 7 blocks of 40 trials each: 1 simple left-handed reaction time (RT) block, 1 simple right RT block, 1 dual R/L RT block, and 4 blocks where the subject was instructed not to react as quickly as possible but instead to stop the clocks simultaneously to within 1 millisecond (timer accuracy). Of the 4 simultaneous stop blocks, the subject used her hands on 2, and her index fingers on 2. She was provided with full visual feedback of limbs and performance times on 2 of the blocks, 1 hand block and 1 fingertip block. Following surgery the variance of her simple and dual reaction times for each limb individually was reduced indicating overall improvement. In contrast, the variability of stop time differences between the limbs in the simultaneous stop blocks increased to statistically significant levels. Additionally, the correlation between right and left hand stop times in the dual reaction time block dropped after surgery: before surgery  $r = .9984$ , first post-op visit  $r = .7851$ , second post-op visit  $r = .9629$ . These data indicate a difficulty initiating movements of the limbs simultaneously following section of the anterior callosum. The increased correlation at the third visit suggests compensatory mechanisms are developing. Further visits will illuminate the time course of these processes. NIH/NINDS P01 NS17778-13 and McDonnell-Pew Foundation.

## 558.10

**OCULOMANUAL DYSMETRIA IN PATIENTS WITH POSTERIOR PARIETAL LESIONS.** K.R.Kessler<sup>1</sup>, S.H.Brown<sup>2</sup>, H.J.Freund<sup>1</sup>. Neurologische Klinik, Univ. Duesseldorf, FRG<sup>1</sup>, Kinesiology, Univ. Michigan, Ann Arbor, MI<sup>2</sup>.

We recently reported the effects of altered visual feedback on the initiation of coupled eye and arm movements associated with generalized parietal lobe dysfunction. These studies have been extended to patients with discrete lesions of the posterior parietal cortex which is thought to play an important role in sensorimotor integration. Using a step-tracking task, horizontal saccadic and elbow movements were examined under full visual feedback of both handle and target position and random blanking of either handle or target position. No signs of major visual field defects, optic ataxia or spatial neglect were clinically apparent at the time of testing. Eye movements were recorded using an infrared technique and arm movements were recorded by potentiometers mounted below the elbow. The contralateral arm was tested in all cases and, in one patient, both arms were tested.

The pattern of saccadic eye movement was direction dependent with multisaccades occurring in movements made away from the side of the lesion. In some cases, eye movements often resembled cerebellar saccadic dysmetria. Removal of visual information regarding target position led to an increase in the number of secondary and tertiary saccades in both movement directions. Target blanking also resulted in uncoupling of oculomanual initiation in that eye onset did not occur until after onset of arm movement. Interestingly, similar abnormalities in eye-arm tracking (delayed onset times, prolonged movement durations) occurred in the ipsilateral arm although the impairment was not as severe as in the contralateral arm.

These findings support the view that posterior parietal cortex is involved in transforming external coordinates into ocular and limb motor commands. The similarity in dysmetric eye movement patterns to that observed in cerebellar disease may reflect the functional significance of parieto-pontine-cerebellar projections in the control of eye-arm movements. **VISUAL AND MOTOR INTERACTION: SPATIOTEMPORAL PATTERNS OF INTER- AND INTRAHEMISPHERIC CORTICAL ACTIVATION** C.D. Saron\*, H.G. Vaughan Jr., G.V. Simpson, and J.J. Foxe, Depts. of Neuroscience and Neurology, Albert Einstein College of Medicine, Bronx, NY 10461.

Event-related potentials from 63 scalp sites were elicited from 5 right-handed males (23-35 yrs.) in response to checkerboard patterns presented to the left or right lower visual field quadrants in a simple reaction time (RT) task. The purpose of this experiment is to characterize the time course, regional pattern of activation and probable routes of communication between several processing stages in this basic sensorimotor task. We broadly define these stages as activation of striate, extrastriate, visuomotor, premotor and motor output regions. By examining the effects of unilateral visual stimulation and ipsimanual vs. contramanual response requirements, the timing and locations of interhemispheric transfer of both visual and motor information can be assessed. Control conditions that use stimuli without a response requirement and responses (finger lifts) without a stimulus, provide templates for subtraction from, and comparison with, the RT task conditions. Stimulus- and response-synchronized averaging optimizes measurement of early (striate and initial extrastriate) and late (premotor and motor output) activity respectively. Selection of trials for averaging from the 2nd and 3rd quartiles of each individual subject / RT condition combination sharpens the motor activity visible in the stimulus-triggered averages and the visual activity obtained in the response-triggered averages. These data are further analyzed using scalp current density (SCD) mapping and spatiotemporal dipole source modeling with correlation to individual subject brain MRIs. Between-site timing differences are measured using SCD maxima and cross-lag correlations on surface Laplacian and modeled source waveforms. The data reveal consistent initial occipital activation contralateral to the field of input followed by a delayed ipsilateral occipital response. Multiple episodes of this posterior interhemispheric transfer begin at approximately 80, 130, 230 and 400 ms post-stimulus. Activation of motor cortex contralateral to the responding hand appears to flow from ipsilateral posterior regions independent of input field. Combined SCD mapping and spatiotemporal dipole analysis disclose characteristic individual patterns of visuomotor cortical activation and interhemispheric transfer that appear to account for variations in RT. These data provide evidence for both visual and motor routes of interhemispheric interaction with inter- and intra-hemispheric activity modulated by motor demand after 80 ms post-stimulus.

## 558.14

**FUNCTIONS OF THE CORPUS CALLOSUM IN INTERHEMISPHERIC INTERACTION: TRANSFER AND INHIBITORY MODULATION.** B. Preilowski. (SPON: European Brain and Behaviour Society) Tübingen Univ., Weissenau Field Station, D-88214 Ravensburg, Germany, and Keck Center, UCSF, San Francisco, CA. 94143.

Pathological conditions as diverse as schizophrenia and dyslexia have been related to aberrations in the quality of interhemispheric interactions due to structural as well as functional abnormalities of the corpus callosum. In support of this view deficits in bimanual coordination and intermanual transfer are often cited.

Partially and completely commissurotomy patients as well as patients with pathological lesions of the corpus callosum of various etiology show different degrees of dysfunctions in coordinating both hands in novel tasks. This varies from extreme deficits with uncontrollable, independent movements and intermanual blocking to forms of coordination under visual control with evidence of intermanual coupling. Bimanual skills acquired before surgical or pathological lesions are still demonstrable and independent of the degree of deficits shown in the novel tasks. These skills also persist in patients with unilateral apraxia and alien hand syndrome. In rhesus monkeys a lack of intermanual transfer of learning despite intact commissures and evidence for such transfer despite callosotomy has been found.

These data raise doubt about simplistic models of callosal functions. Instead, it is suggested that the role of interhemispheric inhibition, the possibility of regional and state dependent changes in callosal functions and the interaction of callosal and subcortical mechanisms be given more detailed consideration. ## 559.1

**DIFFERENTIAL REGULATION OF CREB PHOSPHORYLATION BY CALCINEURIN IN DEVELOPING STRIOSOMES AND MATRIX OF ORGANOTYPIC STRIATAL CULTURES.** E.-C. Liu<sup>1</sup> and A.M. Graybiel<sup>2</sup>. Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139.

Ca<sup>2+</sup>/calmodulin-dependent protein phosphatase-2B (PP-2B or calcineurin) is one of a set of striatum-enriched signaling molecules. In the present study, we tested whether calcineurin could modulate signaling cascades in striatal neurons through dephosphorylation of the cAMP response element-binding protein (CREB), a transcription factor known to be regulated by cAMP and calcium signals. We have previously shown that activation of L-type voltage-dependent calcium channels by BAY K 8644 can induce immunodetectable Ser<sup>133</sup> phosphorylated CREB-like protein (PCREB) in organotypic cultures of neonatal striatum (Liu et al., 1994). We report here that in 1-day striatal slice cultures, processed 30 min after stimulation, the PCREB induced by BAY K 8644 is primarily in the striatal matrix: double immunostains showed that PCREB was not co-localized in DARPP-32-positive neurons of striosomes, except far medially. Pretreating such striatal cultures with the calcineurin inhibitor, FK506 (10  $\mu$ M), strikingly increased PCREB expression in striosomes: PCREB was now co-localized in DARPP-32-positive neurons of striosomes including the striatal lateral streak. This effect was not observed in slices pretreated with the FK506 control, rapamycin (10  $\mu$ M), which does not activate calcineurin. Immunostaining for calcineurin in the 1-day striatal cultures showed that calcineurin was expressed at high levels in developing striosomes relative to the matrix, except medially.

Our study suggests that activation of calcineurin by L-type voltage-dependent calcium channels could function as a Ca<sup>2+</sup> signal filter to inactivate phosphorylation of CREB-like protein primarily in the developing striosomal system, and hence may differentially regulate PCREB-mediated gene expression in striatal compartments during development. We thank Drs. D.D. Ginty and M.E. Greenberg for PCREB antiserum and Dr. I. Bekersky of Fujisawa Pharmaceuticals-USA for FK506. Supported by NIH 1 R01 HD28341, The Council for Tobacco Research-USA, and the Science Partnership at MIT.

## 559.3

**DEVELOPMENT OF INHIBITORY SYNAPSES IN RAT NEOSTRIATUM** N.A. Sharpe<sup>1</sup> and J.M. Tepper<sup>2</sup>, Aidekman Research Center, Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ USA 07102.

Excitatory input to the rat striatum increases significantly over development. Most of this increase occurs during the 3rd postnatal week due to an increase in the density of asymmetric axospinous synapses (*Soc. Neurosci. Abst.*, 18.697, 1992). In the present study we examined the postnatal development of symmetric (S) striatal synapses in the rat.

The density of S synapses in adult striatum (10.8 $\pm$ 3.7 synapses/100  $\mu$ m<sup>2</sup>) was not significantly different from that of P21 (10.8 $\pm$ 3.6/100  $\mu$ m<sup>2</sup>), P15 (10.9 $\pm$ 5.1/100  $\mu$ m<sup>2</sup>) or P10 (9.1 $\pm$ 3.4/100  $\mu$ m<sup>2</sup>). However, the postsynaptic targets of S synapses changed significantly. The density of S axodendritic synapses decreased over development (F=3.8, df=3,39, p<0.05): P10 (5.6 $\pm$ 4.4/100  $\mu$ m<sup>2</sup>), P15 (10.1 $\pm$ 5.1/100  $\mu$ m<sup>2</sup>) P21 (7.0 $\pm$ 4.1/100  $\mu$ m<sup>2</sup>), adults (3.8 $\pm$ 3.7/100  $\mu$ m<sup>2</sup>). Axospinous (necks and heads) synapses showed the opposite relationship: adults (3.2 $\pm$ 3.7/100  $\mu$ m<sup>2</sup>), P21 (3.2 $\pm$ 3.6/100  $\mu$ m<sup>2</sup>), P15 (0.8 $\pm$ 2.3/100  $\mu$ m<sup>2</sup>). At P10 no axospinous S synapses were noted. At P15 axospinous S synapses were rare, and usually terminated onto immature spines. Axospinous S synapses in adult and P21 rats typically terminated onto spine necks. Symmetric synapses terminating onto spine heads, were proximal to asymmetric synapses. Symmetric synapses in the adult were evenly distributed between axodendritic (35%) and axospinous (29%) postsynaptic targets. At P21, P15 and P10 the majority of S synapses were axodendritic (65%, 93%, and 62%, respectively). The distribution of S axospinous synapses decreased over development (30%, 7% and <1% respectively).

Thus, the number of inhibitory inputs is similar whereas their postsynaptic targets change over development. Since inhibitory input in neonates primarily terminates onto dendrites, the efficacy of each input may be greater than that of the S axospinous synapses noted in adults. Thus, these data support previous anatomic and electrophysiological studies, indicating that intrinsic inhibitory circuits develop earlier than excitatory inputs in the neonatal striatum. Supported by NS30679 and Rutgers Biomedical Research Support Grant.

## 559.5

**LOCALIZATION OF m4 RECEPTOR PROTEIN IN RAT NEOSTRIATUM.** T.M. Thomas<sup>1</sup>, H. Yi, C.-A. Gutekunst, A.J. Levey, S.M. Hersch<sup>2</sup>. Department of Neurology, Emory University School of Medicine, Atlanta, GA 30322

Muscarinic acetylcholine receptors play an important role in the modulation of striatal circuits. To further understand the role of m4 in the striatum, we performed immunoelectron microscopy on dorsal rat striatum using an m4 receptor subtype-specific antibody (Levey et al., 1991). Visualization of the antibody was achieved using either 3,3'-diaminobenzidine tetrahydrochloride or silver intensified immunogold. The immunoperoxidase technique showed m4 to be localized in the dendrites and spines of medium spiny neurons. m4 immunoreactive dendrites accounted for 53% of all dendrites counted and m4 immunoreactive spines accounted for 49% of all spines counted. Previous cell count data have shown that 44% of all striatal neurons express m4 (Hersch et al., 1994). Our data indicate that the neurons expressing m4 distribute the protein throughout their dendritic trees. m4 immunoreactive spines were found postsynaptic to asymmetric synapses. Using immunogold, m4 receptors were found to be localized in the membrane peripheral to the asymmetric active zones, suggesting that parasynaptic acetylcholine may be modulatory at these synapses. To characterize which glutamatergic synapses may be modulated by m4, we performed aspiration lesions of motor cortex. Degenerating motor corticostriatal terminals were found to synapse with m4 immunoreactive spines, suggesting that m4 receptors directly modulate motor cortical input to striatum.

## 559.2

**PSA-NCAM IN THE DEVELOPING STRIATUM: EFFECTS OF PERIPHERAL INJECTIONS OF MK-801.** A.K. Butler<sup>1</sup>, G. Rougon<sup>2</sup>, and M.F. Chesselet<sup>3</sup>. Inst. of Neurol. Sci., and Dept of Pharmacol., U. of Penn. Phila, PA19104 and U. Aix-Marseille, Luminy, France.

Polysialic acids associated with the Neural Cell Adhesion Molecule (PSA-NCAM) play a critical role in the development of the nervous system. In the visual system of *Xenopus laevis*, glutamatergic stimulation triggers a loss of synaptic plasticity and of PSA-NCAM. Little is known about the molecular mechanisms involved in the regulation of PSA-NCAM expression in mammalian brain. Previous studies in our laboratory have shown that loss of PSA-NCAM immunoreactivity in the striatum occurs after the formation of corticostriatal synapses, which use glutamate as a neurotransmitter. To determine whether glutamate is involved in the loss of striatal PSA-NCAM, Sprague Dawley rat pups were given the non-competitive NMDA antagonist MK-801 (0.25 mg/kg once daily, ip) from postnatal day 14 (P14), before corticostriatal synapse formation, until P24, after the number of corticostriatal synapses has reached the adult level. Rats were sacrificed on P25. Control animals received saline injections or were not injected. Levels of PSA-NCAM, NCAM, and synaptophysin were examined with immunohistochemistry. All MK-801 injected animals showed a loss of PSA-NCAM expression in the cortex and corpus callosum compared to controls, and 75% of these rats also had a loss of PSA-NCAM expression in the striatum. No differences were seen in the expression of NCAM or synaptophysin. In contrast, no loss of PSA-NCAM expression was observed when rats were treated for 3 days (P14 until P16) or 5 days (P14 until P18) with the same dose of MK-801. The results suggest that NMDA receptors play a role in regulating PSA-NCAM expression in the striatum after the formation of corticostriatal synapses and that PSA is down-regulated independently of NCAM and synaptophysin. ## 559.4

**EXPRESSION OF DOPAMINE RECEPTOR PROTEINS IN STRIATONIGRAL PROJECTION NEURONS.** E.S. Ince<sup>1</sup>, B.J. Ciliax<sup>2</sup>, A.J. Levey<sup>2</sup>. Dept. of Neurology, Emory Univ. Sch. of Med., Atlanta, GA 30322.

Dopamine has profound modulatory effects in the mammalian neostriatum, mediated by a heterogeneous group of dopamine receptors. A critical and unresolved question in the literature is whether D1 and D2 dopamine receptors, which together account for the vast majority of subtypes in the striatum, are expressed in the same or different striatal projection neurons. Various methods have yielded conflicting results on whether the D1 and D2 receptors are segregated to separate projection pathways or if they are co-localized in the same projection neurons. Most studies, however, have either indirectly measured the presence of the receptor proteins by mRNA analysis (e.g. *in situ* hybridization or polymerase chain reaction) or are not selective for the molecular subtypes (e.g. ligand binding). In order to address the question of segregation or co-localization of the actual receptor proteins, we have used combined immunocytochemistry and neuroanatomical tracing methods to determine if D1 and D2 proteins are expressed in striatonigral neurons in rats.

A cholera toxin-colloidal gold (Ct-Au) tracer was injected unilaterally into the substantia nigra pars reticulata and retrogradely transported to the perikarya of striatonigral neurons. Adjacent striatal sections were processed for D1 or D2 immunocytochemistry and visualized with 3,3'-diaminobenzidine tetrahydrochloride. Sections were then incubated in a silver intensification solution to visualize the Ct-Au tracer. Quantification of the neuronal perikarya indicates that 78% of the retrogradely labeled striatonigral cells were labeled with the D1 receptor antibody (n=214), but only 2% of the labeled striatonigral neurons were labeled with the D2 receptor antibody (n=340). These results indicate that at a receptor protein level, there is segregation of D1 and D2, with D1 predominantly expressed by striatonigral neurons and D2 presumably expressed mainly in striatopallidal neurons. Supported by the APDA.

**SEROTONIN AGONIST-INDUCED c-fos EXPRESSION IN THE RAT STRIATUM.** D.E. Cook<sup>1</sup>, D. Wirtshafter<sup>2</sup>. Dept. Psychology, Univ. Ill. at Chicago, Chicago, IL 60607-7143.

The current studies examined Fos-like-immunoreactivity (FLI) in the striatum following systemic injections of equimolar doses of several serotonin agonists with different profiles of receptor subtype selectivity. The selective 5HT-2 agonist DOI (6.6 mg/kg) produced a modest increase in FLI which could be markedly attenuated by pretreatment with the 5HT-2 antagonist ritanserin. DOI induced staining was most prominent in the medial, paraventricular, region of the striatum. In contrast, the 5HT-1a/5HT-1b agonist RU-24969 (5.1 mg/kg) produced a very robust increase in FLI which was unaffected by ritanserin pretreatment. RU-24969 induced FLI maximally in the dorsal half of the striatum, although patchy staining was present in the ventral half of this structure. The mixed 5HT-1/5HT-2 agonist mCPP (5 mg/kg) resulted in an intermediate amount of staining which was not significantly altered by ritanserin pretreatment.

In order to examine the role of dopamine in these responses, we examined the effects of these drugs in animals with unilateral 6-OHDA lesions. These lesions markedly reduced staining in the medial striatum following injections of RU-24969 or mCPP, but had no effect on DOI induced staining. The D1 antagonist SCH-23390 also attenuated 5HT-1 induced staining. These results suggest that striatal Fos expression can be increased by stimulation of both 5HT-1 and 5HT-2 receptors, but that these effects are produced through different mechanisms.

## 559.7

DIFFERENTIAL EFFECTS OF SCOPOLAMINE AND QUINPIR-  
OLE ON D1 AGONIST INDUCED STRIATAL *c-fos* EXPRESSION  
IN THE RAT. D. Wirtshafter, K.E. Asin and A. Nikkel. Dept.  
Psychology, Univ. Ill. at Chicago, Chicago, IL 60607 and Neuroscience  
Research, D-47U, Abbott Laboratories, Abbott Park, IL 60664.

We have reported previously that the full D1 dopamine agonist  
A77636 induces substantial Fos-like-immunoreactivity (FLI) in the  
normosensitive striatum. We here examined the ability of the antimus-  
carinic drug scopolamine (SCOP) to modify A77636 induced FLI.  
SCOP (3 mg/kg) induced little FLI by itself, but potentiated the re-  
sponse to A77636 (2.9 mg/kg) in the lateral, but not medial, striatum.  
No effects were seen in rats pretreated with SCOP methylbromide,  
which doesn't cross the blood brain barrier. In animals given A77636  
alone or in combination with SCOP, labeling was distributed in a locally  
homogeneous fashion; in contrast we have shown that combined injec-  
tions of A77636 and the D2 agonist quinpirole (QUIN) result in a  
patchy pattern of staining (Brain Res. Bull. 35:85-91, 1994). To in-  
vestigate these differences, we examined the effects of pretreatment with  
SCOP (6 mg/kg) and/or QUIN (2.5 mg/kg) on A77636 induced FLI  
using a 2 X 2 factorial design. Both drugs potentiated A77636 induced  
FLI in the lateral striatum, but statistical analysis showed that only  
QUIN pretreatment resulted in a "patchy" staining pattern. Addition-  
ally, QUIN, but not SCOP, actually reduced labeling in the medial stri-  
um. These effects of QUIN were not modified by coinjection of  
SCOP. These results suggest that the effects of QUIN on striatal FLI  
are not mediated entirely through cholinergic mechanisms.

## 559.9

LOCALIZATION OF THE NMDA RECEPTOR NR2A/2B SUBUNITS  
ON SPECIFIC STRIATAL NEURON TYPES IN RATS. A. Reiner,  
and Q. Chen. Dept. Anat. & Neurobiol., Univ. of Tennessee - Memphis,  
Memphis, TN 38163.

NMDA receptors are heteromers of diverse NMDA receptor-specific  
subunits, namely NR1 and NR2A-2D. The presence of NR2 subunits  
in the receptor significantly potentiates NMDA channel responses to ago-  
nists, and the type of NR2 subunit affects the physiological and pharma-  
cological properties of the receptor channel. Knowledge of the precise  
NR2 subunits present in the NMDA receptors of specific striatal neurons  
is critical for understanding the selective vulnerability of striatal neurons  
to NMDA excitotoxins and in putative NMDA receptor-mediated dis-  
eases, such as Huntington's disease. We therefore used an antiserum  
recognizing both NR2A and 2B subunits (the only NR2 subunits present  
in striatum) (from Chemicon) to study the expression of NR2A/B sub-  
units on specific striatal neuron types with immunofluorescence double-  
labeling methods and confocal laser scanning microscopy. Somatostatin  
(SS), cholinergic, and parvalbumin (PARV) interneurons, enkephalin  
(ENK) projection neurons and calbindin enriched matrix neurons were  
identified with specific antibodies for their defining peptide/protein; sub-  
stance P (SP) striatonigral neurons were retrogradely labeled by fluoro-  
gold injection into substantia nigra. Our results showed that the majori-  
ty of striatal cholinergic, ENK, SP, and calbindin containing matrix neu-  
rons expressed NR2A/B subunits. 56% of PARV and none of striatal  
SS interneurons possessed NR2A/B. Absence of NR2A/B subunits  
from NMDA receptors on SS striatal interneurons may confer resistance  
to NMDA receptor-mediated excitotoxicity on these neurons. NS-19620,

## 559.11

COORDINATED EXPRESSION OF DOPAMINE RECEPTORS (D1-D5) IN  
SINGLE NEOSTRIATAL NEURONS. H.R. Carter-Russell, W.J. Song, D.J. Sur-  
meier. Dept. of Anatomy and Neurobiology, College of Medicine, University of  
Tennessee, Memphis, TN 38163.

There has been a continuing debate about whether D1- and D2-class dopa-  
mine receptors are co-localized in medium spiny neurons of the neostriatum. Physi-  
ological and biochemical studies have consistently found evidence for co-local-  
ization yet anatomical techniques have not. One of the shortcomings of these  
earlier studies is that they have assumed that neostriatal neurons express little  
or no D4 or D5 (D1b) mRNA.

We have developed a procedure which enables amplification of the mRNA  
from single cells followed by specific PCR analysis to investigate the cellular  
complement of dopamine receptor mRNA's. The initial amplification provides  
sufficient material to perform approximately 50 PCR reactions. PCR based cel-  
lular profiles for D1-D5 receptor mRNA's were constructed in neurons that had  
been physiologically characterized and retrogradely labeled.

Preliminary experiments (n=22) suggest that the expression of dopamine re-  
ceptor mRNA is heterogeneous among medium spiny neurons. D1a mRNA  
was found only in retrogradely labeled striatonigral neurons. In contrast D1b  
mRNA was found in nearly half of all unlabeled (presumably striatopallidal)  
medium-sized neurons. D2 receptor mRNA was seen in less than half the stri-  
atonigral cells and most of that was the long splice variant. D4 receptor mRNA  
was present in many of those neurons lacking D2 mRNA. Both long and short  
isoforms of the D2 receptor mRNA were found in many of the unlabeled cells,  
but D4 mRNA was less abundant in this group. D3 mRNA was rarely seen in  
neurons in which RNA polymerase II had been inhibited following tissue slic-  
ing.

## 559.8

CO-LOCALIZATION OF SOMATOSTATIN, NEUROPEPTIDE Y, NEURONAL  
NITRIC OXIDE SYNTHASE AND NADPH DIAPHORASE IN STRIATAL NEU-  
RONS. G. Figueredo-Cardenas, M. Morello, G. Sancesario, G.  
Bernardini and A. Reiner. Dept. Anat. & Neurobiol., Univ. Tennessee,  
Memphis, TN 38163; †Clin. of Neurol., Univ. of Rome Tor Vergata.

The neuropeptides somatostatin (SS), neuropeptide Y (NPY), and  
the enzymes neuronal nitric oxide synthase (NOS1) and NADPH diapho-  
rase (NADPHd) are extensively colocalized in striatal interneurons,  
which has led to the widely held view that all four substances are com-  
pletely co-localized within a single class of striatal interneurons. We  
have explored the validity of this assumption in rat striatum using  
triple label immunofluorescence for SS, NPY and NOS1 combined with  
NADPHd diaphorase histochemistry. Both conventional epi-illumina-  
tion fluorescence microscopy and confocal laser scanning microscopy  
(CLSM) were used. Following image capture of the multiple-label  
fluorescence data on CLSM, sections were labeled for NADPHd for com-  
parison to the SS, NPY and NOS1 labeling. All neurons containing NOS  
in rat striatum were found to be NADPHd+, consistent with the report  
that neuronal NADPHd activity is accounted for by NOS1. We found  
similar results with epi-illumination fluorescence microscopy and  
CLSM for SS, NPY and NOS1 localization. Of those striatal neurons  
containing any combination of these, 60% contained all three, 25.5%  
contained SS and NOS, 8% contained NOS only, 6.5% contained SS only  
and none contained NPY alone or with NOS. These results indicate that  
while there is a large population of striatal neurons in which SS, NPY,  
NOS1 and NADPHd are co-localized, there appear to be smaller popu-  
lations of neurons in which SS or NOS alone or together are found.

## 559.10

COORDINATED EXPRESSION OF m1-m5 MUSCARINIC ACETYLCHOLINE  
RECEPTORS IN MEDIUM SPINY NEURONS OF THE RAT NEOSTRIATUM.  
D.J. Surmeier, Zhen Yan, Helen Carter-Russell. Dept. of Anatomy & Neurobiol-  
ogy, College of Medicine, U. of Tennessee, Memphis, TN 38163.

Previous electrophysiological studies revealed the presence of parallel  
muscarinic signaling pathways in most medium spiny neostriatal neurons  
(Howe and Surmeier, J. Neurosci., 1995). These results suggest that muscarinic  
receptors with differential coupling to intracellular signaling pathways are  
frequently co-localized. Molecular cloning studies have identified five musca-  
rinic receptors (m1-m5). Based upon their preferential coupling to second  
messenger systems, these subtypes can be grouped into two broad categories:  
m1-class (m1, m3, m5) and m4-class (m2, m4). Previous studies have sug-  
gested that m1 and m4 mRNA are frequently co-expressed by neostriatal  
neurons.

Acutely-isolated adult neostriatal neurons were patch-clamped and their  
pharmacological properties determined. The cellular contents were aspirated  
and the polyadenylated mRNA reverse transcribed. This cDNA was then  
amplified using techniques we have previously described yielding enough  
template for up to 50 PCR reactions. PCR primers specific for each muscarinic  
receptor were then used to determine how expression was coordinated.

In preliminary studies, m1 and m4 mRNA were co-localized in over three  
quarters of all medium-sized neurons. In addition, m3 and m5 mRNA were  
frequently co-expressed with m1 mRNA; m2 mRNA was never found in  
medium-sized neurons. These results confirm the inference from previous  
electrophysiological studies that medium spiny neurons have multiple,  
parallel muscarinic signaling pathways.

## 559.12

STRIATAL REGIONALIZATION AS DEMONSTRATED BY  
DIFFERENTIAL DISPLAY. W.J. Rushlow, N.S. Khoo, N.  
Rajakumar, B.A. Flumerfelt and C.C.G. Naus. Dept. of Anatomy,  
University of Western Ontario, London, Ontario, Canada, N6A 5C1.

A variety of studies have demonstrated that the caudate-  
putamen of the rat is a highly heterogeneous structure. There are  
gradients of neurochemicals across the striatum, differences in the  
topographical orientation of functionally specific projections and  
compartmentalization of the caudate-putamen into patch and matrix  
compartments. The purpose of the current study was to determine  
regional differences in gene expression in the caudate-putamen of the  
rat. This was accomplished by isolating mRNA from different regions  
of the rat striatum and using a reverse transcriptase-polymerized chain  
reaction technique referred to as differential display. The differential  
display products were run on a polyacrylamide gel in order to select  
candidate genes that are apparently expressed in one region but not  
another. These bands were excised and sequenced to determine if they  
are novel. The differential display technique yielded a large number of  
potentially differentially expressed novel genes. Several of these  
clones are currently being investigated. The results suggest that the  
striatum of the rat can be regionally subdivided based on gene  
expression. [This work was supported by the Medical Research  
Council of Canada and Huntington's Society of Canada.]

## 559.13

REGIONALLY EXPRESSED cDNA'S IN THE RAT BRAIN. B.A. Flumerfelt, W.J. Rushlow, N.S. Khoo, N. Rajakumar and C.C.G. Naus. Dept. of Anatomy, University of Western Ontario, London, Ontario, Canada, N6A 5C1.

Differential display is a powerful new technique that can be used to examine the differences between two groups of cells or regions. It is a reverse-transcriptase-polymerized chain reaction (RT-PCR) based technique that selects for poly-A adenylated cDNA's. Separation of the RT-PCR products on a polyacrylamide gel permits for direct comparison between the different samples. In the current study this technique has been applied to the striatum of the rat in order to identify genes that are regionally expressed. Using this technique, a number of candidate genes have been identified and partially sequenced. In situ hybridization studies are currently in progress to determine the anatomical distribution of these candidate genes in both the striatum and the remainder of the brain. One such candidate gene is highly expressed in the lining of the ventricles and the hippocampus but is also present in the medial portion of the caudate-putamen. These results suggest that there are a number of differences between different regions of the rat caudate-putamen. [This work supported by the Medical Research Council of Canada and the Huntington's Society of Canada.]

## 559.15

TEMPORAL CHANGES IN BASAL GANGLIA NEUROPEPTIDE mRNAs IN RESPONSE TO SEROTONIN REDUCTION BY *p*-CHLOROAMPHETAMINE. P.J. Gresch\* & P.D. Walker, Department of Anatomy & Cell Biology, Wayne State University School of Medicine, Detroit, MI. 48201

Reduced serotonin (5-HT) neurotransmission leads to a decrease in preprotachykinin (PPT) and preproenkephalin (PPE) mRNAs in the rat striatum (STR). In this study, we examined the long-term effects of lowered 5-HT on PPT and PPE mRNA levels in striatal subregions following *p*-chloroamphetamine (PCA) treatment. Adult male Sprague-Dawley rats received single ip injections of saline or PCA (10mg/kg) and were sacrificed 7 or 21 days later. Dorsomedial (DM), dorsolateral (DL), ventromedial (VM), and ventrolateral (VL) striatal subregions were assayed for monoamine and metabolite levels by HPLC-EC and mRNA levels by Northern analysis.

	7d after PCA			21d after PCA		
	5-HT	PPT mRNA	PPE mRNA	5-HT	PPT mRNA	PPE mRNA
DM-STR	-39.2	-33.1	-11.2	-24.1	58.1	-22.2
DL-STR	-60.1	23.3	5.1	-22.4	174.2	153.5
VM-STR	-47.8	-74.2*	-63.3*	-6.5	-15.0	-10.6
VL-STR	-67.0	-25.1	-25.0	-48.0	-70.6*	-40.2*

Results are expressed as % change from saline controls (n=6; \*p<0.05)

No significant mRNA changes were observed in the DM- or DL-STR. Although PPT and PPE mRNAs in the VM-STR were significantly reduced 7d after PCA, this decrease was not observed at 21d. However, lowered PPT and PPE mRNA levels were detected in the VL-STR 21d after PCA. These results demonstrate a temporal dissociation of neuropeptide mRNA levels in medial vs. lateral subregions of the ventral striatum in response to 5-HT reduction. Supported by NIH NS 30550

## 559.17

SEROTONERGIC INFLUENCE ON STRIATAL NEURONS CONTAINING NEUROPEPTIDE Y, SUBSTANCE P AND MET-ENKEPHALIN.

Compan V., Dusticier N., Nicoullon A. and Daszuta A., Cellular and Functional Neurobiology Unit, CNRS, Marseille, France.

The aim of the study was to perform a regional analysis of the serotonergic (5-HT) influence on various subsets of striatal populations such as interneurons containing neuropeptide Y (NPY) and neurons projecting either to the substantia nigra (SN) and containing substance P (SP), or to the globus pallidus (GP) containing Met-Enkephalin (M-Enk). Using immunocytochemistry and taking into account the plastic nature of the 5-HT systems, we compared the effects of incomplete and complete neurotoxic lesion obtained by injecting different volumes of 5,7-dihydroxytryptamine into the anterior raphe nuclei in rats.

Within 3 weeks after the complete lesion occurred indicated by undetectable level of 5-HT, we found a general increase in the immunoreactivity of the various peptides which was selectively expressed in different striatal regions for NPY and SP, and more homogeneously distributed in the whole structure in the case of M-Enk. Increases in the SP immunoreactivity was also differentially expressed in the SN pars compacta as compared to the pars reticulata. In contrast, incomplete lesion of the 5-HT neurons leading to about 80% decrease in 5-HT tissue levels were found to induce various responses (increase, decrease or no change) depending on the peptidergic population examined. These results indicate that the high degree of plasticity of 5-HT neurons has to be taken into consideration before to conclude for functional effects of neurotoxic lesion. Opposite changes in the responses obtained after partial and complete lesion may also be related to more or less complex 5-HT/peptides neuronal interactions. Moreover, the regional analysis points to the needs for considering the heterogeneity of the striatal organization as a main prerequisite for understanding function.

## 559.14

EFFECTS OF CHRONIC NEUROLEPTIC TREATMENT ON GENE EXPRESSION IN THE RAT STRIATUM AS REVEALED BY DIFFERENTIAL DISPLAY. N. Rajakumar, W.J. Rushlow, C.C.G. Naus, J. Stoessl and B.A. Flumerfelt. Depts. of Anatomy and Clinical Neurological Sciences, University of Western Ontario, London, Ontario, Canada, N6A 5C1.

Typical neuroleptics are a common treatment for a variety of psychotic disorders. Unfortunately, chronic neuroleptic treatment may lead to movement disorders similar to those observed with Parkinson's patients. These side effects are thought to be caused by an alteration in dopamine neurotransmission in the striatum. The goal of the current study was to determine what effect chronic treatment with the typical neuroleptic fluphenazine has on the caudate-putamen of the rat at the molecular level. In order to accomplish this, the differential display technique was used. Comparison of vehicle versus chronically fluphenazine treated rats yielded numerous candidate genes that may be fundamentally altered by the drug. Specifically, we found four candidate genes that appear to be turned off following chronic fluphenazine treatment and nine candidate genes that appear to be turned on. These results suggest that the typical neuroleptic fluphenazine causes significant alterations in striatal gene expression. [This work supported by the Medical Research Council of Canada, Ontario Mental Health and Huntington's Society of Canada.]

## 559.16

EM STUDY OF NOS+ STRIATAL TERMINALS IN RAT. M. Morello, E.J. Karle, G. Sancesari, R. Massat, G. Bernardi and A. Reiner. Dept. of Anat. & Neurobiol., Univ. of Tenn., Memphis, TN, 38163; †Clin. Neurol., II Università di Roma "Tor Vergata", Rome, ITALY, 00173.

Somatostatin, neuropeptide Y and neuronal nitric oxide synthase (NOS) have been shown to be largely contained within the same population of striatal interneurons. To help elucidate the role of these neurons in the striatum, we have used EM immunohistochemistry to study synaptic contacts of NOS+ neurons within the rat striatum. In one series of single-labeled sections, neurons were immunolabeled with diaminobenzidine (DAB) using antibodies against NOS. In a separate series of double-labeled sections, striatal parvalbumin-containing (PV+) neurons were immunolabeled with DAB, while NOS+ neurons were labeled with silver-intensified immunogold (SIG). Our single-label results showed that NOS+ perikarya and dendrites receive diverse synaptic inputs from unlabeled terminals and rarely from other NOS+ neurons. Double-label material revealed that NOS+ perikarya and dendrites receive synaptic input from PV+ terminals, as well as the unlabeled terminals and rare NOS+ terminals. In single-labeled material, the NOS+ terminals were observed to form appositions and synapses primarily with dendritic spine necks and distal dendritic shafts of unlabeled neurons, seldomly with perikarya or proximal dendritic shafts. NOS+ terminals were not observed to contact PV+ neurons in double-labeled material. Our findings suggest that NOS+ terminals frequently contact spiny projection neurons in the striatum, and only rarely contact two of the major types of striatal interneurons (i.e. NOS+ and PV+ types). These results suggest that NOS+ striatal interneurons may exert their major influence on striatal projection neurons. Supported by NS-19620 & NS-28721 (A.R.) and the Italian CNR (M.M.)

## 559.18

NALTREXONE REVERSES UNILATERAL 6-OHDA LESION-INDUCED DOPAMINE D<sub>1</sub> RECEPTOR SUPERSENSITIVITY AND ENHANCES THE LESION EFFECT ON DYNORPHIN mRNA PRODUCTION IN RAT STRIATUM. N.D. Guttenberg, B. Drukarch, H. J. Groenewegen\* and P. Voorn. Depts. of Anatomy and Neurology, Research Institute. Neurosciences, Vrije Universiteit, Amsterdam, the Netherlands.

6-OHDA lesions cause an increase in the striatal synthesis of (pre)proenkephalin (Enk). This increase results in enhanced stimulation of the mu opioid receptor subtype, for which Enk is the endogenous ligand in the striatum and globus pallidus. Previous studies have demonstrated interaction between the mu opioid and dopamine (DA) D<sub>1</sub> receptors. The present study examines the effects of antagonizing the increased mu receptor stimulation after 6-OHDA lesions on DA D<sub>1</sub> receptor sensitivity and on lesion-induced changes in Enk, substance P (SP) and dynorphin (DYN) mRNA levels in the striatum. Unilaterally 6-OHDA-lesioned rats were treated for 7 days with the selective mu opioid antagonist naltrexone (NAL) via subcutaneously implanted ALZET osmotic mini-pumps (mean pumping rate 10µl/hr, 10mg/kg). DA D<sub>1</sub> receptor-stimulated adenylyl cyclase activity was measured in superfused striatal slices of non-lesioned and lesioned striatum by calculating the conversion of [<sup>3</sup>H]ATP to [<sup>3</sup>H]cAMP. mRNA levels were measured by quantitative *in situ* hybridization. NAL treatment reversed 6-OHDA lesion-induced DA D<sub>1</sub> receptor supersensitivity to control levels. Densitometrical analysis of hybridized sections showed that NAL treatment had no significant effect on lesion-induced changes in Enk or SP mRNA levels. However, for DYN the difference between lesioned and non-lesioned striatum and the ratio of lesioned to non-lesioned striatum had increased (up 48% and up 44%, resp.). These results confirm the interaction between mu and D<sub>1</sub> receptors and suggest a possible strategy for interfering with changes in DA receptor sensitivity related to [the pharmacotherapy of] Parkinson's disease. In addition, our results suggest a direct regulatory influence of the mu receptor on DYN synthesis.

## 559.19

ROLE OF NMDA RECEPTORS IN SENSITIZATION TO DOPAMINE D1 RECEPTORS IN DOPAMINE DENERVATED RATS: STUDY OF C-FOS EXPRESSION. G. Di Chiara\*, S. Fenu, M. Morelli. Dpt. Toxicology, Univ. of Cagliari, 09100 Cagliari, Italy.

In this study we examined the effect of blockade of N-methyl-D-aspartate (NMDA) receptors on the long-term effects induced by administration of dopamine agonists, in rats with a 6-hydroxydopamine (6-OHDA) lesion of the dopaminergic nigro-striatal pathway. MK 801 potentiated the turning behavior and decreased c-fos expression induced by L-dopa or apomorphine in the 6-OHDA lesioned striatum. At the same time MK 801 blocked the sensitization (priming) induced by L-dopa or apomorphine. In these rats, in fact, administration of SKF 38393, three days after priming, did not induce any turning behavior as compared to rats primed with apomorphine or L-dopa alone; this effect was also accompanied by a reduced activation of c-fos by SKF 38393. At variance, in rats primed with SKF 38393 instead of apomorphine or L-dopa, MK 801 did not influence the activation of c-fos during the induction of priming. In these rats the turning behavior and the striatal c-fos activation induced by the subsequent administration of SKF 38393 was not reduced. The results suggest that repression of c-fos expression by MK 801 during the induction of priming might be part of the mechanisms responsible for the blockade of priming. Therefore early-genes might mediate the long-lasting changes taking place in the process of behavioral sensitization.

## BASAL GANGLIA: MOVEMENT DISORDERS AND EXPERIMENTAL MODELS

## 560.1

NEUROCHEMICAL CHANGES IN THE PRIMATE BASAL GANGLIA FOLLOWING UNILATERAL INTRACAROTID MPTP. S.B. Evans\* and S.N. Haber. Dept. of Neurobiology and Anatomy, University of Rochester School of Medicine, Rochester NY 14642.

MPTP causes a selective population of midbrain dopaminergic neurons to die. The susceptible cells are in the ventral tier of the substantia nigra (SN) and project to the sensorimotor striatum. These cells contain higher levels of message for the dopamine uptake site (DAT) and the D2 receptor (D2R) than the more resistant dorsal tier cells. Furthermore, these cells are calbindin D28-k (CABP) negative. The pattern of cell loss after MPTP treatment mimics that of Parkinson's Disease. In this study, two monkeys were given intracarotid MPTP at 0.4 mg/kg and then allowed to survive for two years. The brains were then removed, sectioned, processed for *In-situ* hybridization and immunohistochemistry, and examined by optical density analysis using NIH Image 1.52. We found that CABP expression increased significantly in the caudal putamen and GPe on the lesioned side. The pattern of CABP expression in the SN also changed from one of distinct CABP-positive and negative areas in the nonlesioned SN, to a homogenous, filled-in pattern in the lesioned SN. Enkephalin mRNA levels increased at all levels of the caudate and putamen on the lesioned side. Substance P mRNA showed decreases on the lesioned side that were not significant in all cases. DAT and D2R mRNA both showed marked decreases in the SN on the lesioned side. These results provide evidence for nigrostriatal dopamine playing a dynamic modulatory role in the striatum, for the heterogeneity of the nigrostriatal projection and for the plasticity of the primate basal ganglia. (Supported by NS22511, MH45537, and the Lucille P. Markey Charitable Trust.)

## 560.3

THE ROLE OF OPIOID PEPTIDES IN THE NEURAL MECHANISMS UNDERLYING L-DOPA-INDUCED DYSKINESIAS IN PARKINSON'S DISEASE. J.M. Brotchie\*, B. Henry, S. Duty. Division of Neuroscience, School of Biological Sciences, University of Manchester, M13 9PT, UK.

Long-term L-DOPA therapy in Parkinson's disease is plagued by debilitating dyskinesia side-effects. The neural mechanisms that underlie these dyskinesias probably involve abnormalities in GABA and EAA transmission within the basal ganglia. Striatal output neurons projecting to the external segment of the globus pallidus utilise GABA and enkephalin as co-transmitters, whilst outputs projecting to the substantia nigra and internal globus pallidus utilise GABA and dynorphin. We have recently shown that enkephalin and dynorphin serve to modulate GABA and EAA release within the basal ganglia. The aim of this study was to assess enkephalin and dynorphin transmission in striatal outputs in animal models of L-DOPA-induced dyskinesias.

We have defined the regional pattern of changes in the levels of mRNA encoding the enkephalin precursor pre-proenkephalin A and the dynorphin precursor pre-prodynorphin B, using *in situ* and Northern hybridisation with <sup>35</sup>S- and <sup>32</sup>P-labelled oligoprobes. We find that the expression of opioid peptides is significantly elevated, though shows topographical variations, in animal models of L-DOPA-induced dyskinesias. Anti-parkinsonian therapies that are associated with a lower incidence of dyskinesias e.g. lisuride or bromocriptine treatment, are not associated with such changes in opioid peptide expression. Furthermore, blockade of opioid receptors can block hyperkinetic symptoms in animal models of L-DOPA induced dyskinesias.

These findings suggest a potential role of increased enkephalin and dynorphin transmission in mediating the symptoms of dopamine-agonist-induced dyskinesias.

## 559.20

FULL DOPAMINE RECEPTOR AGONIST SKF-82958 INDUCES c-fos AND zif/268 mRNA EXPRESSION IN THE INTACT RAT STRIATUM AND MUSCARINIC CHOLINERGIC RECEPTOR ANTAGONIST SCOPOLAMINE AUGMENTS THIS INDUCTION. J.Q. Wang\* and J.F. McGinty. Dept. of Anatomy and Cell Biology, East Carolina Univ. Sch. of Med., Greenville, North Carolina 27858-4354, USA

It is generally accepted that the partial dopamine D<sub>1</sub> receptor agonist, SKF-38393, does not induce immediate early gene (IEG) expression in striatal projection neurons unless dopamine receptors are sensitized by 6-hydroxydopamine lesions or reserpine treatment. In contrast, this study demonstrates, with quantitative *in situ* hybridization, that the full D<sub>1</sub> receptor agonist, SKF-82958, induced robust expression of c-fos and zif/268 mRNAs in the intact rat striatum and cerebral cortex (particularly in cingulate, upper limb region of sensory cortex and piriform cortex) 45 min after acute injection. The induction of these 2 striatal IEGs is characterized by 1) a substantially more intense induction in the nucleus accumbens and olfactory tubercle than in the dorsal striatum; 2) induction in both patch-like and matrix compartments; 3) dose-dependent (0.02, 0.1, 0.5 and 2.0 mg/kg, s.c.) induction correlating well with dose-dependent increases in locomotor activity; and 4) blockade by the D<sub>1</sub> receptor antagonist, SCH-23390 (0.1 mg/kg, s.c.). The muscarinic cholinergic receptor antagonist, scopolamine (5 mg/kg, s.c.), which itself did not alter striatal gene expression, profoundly augmented the behaviors and expression of the 2 IEGs in the striatum induced by 0.1, 0.5 and 2.0 mg/kg SKF-82958, with greater augmentation at the lower doses. However, scopolamine attenuated basal, and SKF-82958-stimulated, expression of c-fos and zif/268 mRNA in the cortex. Scopolamine also enabled SKF-38393 (5 mg/kg, s.c.) to induce locomotor stimulation and c-fos and zif/268 mRNA expression in the intact rat striatum when SKF-38393 alone caused no such changes. These data demonstrate an ability of full D<sub>1</sub> receptor stimulation by SKF-82958 to induce IEG expression in intact rats. Furthermore, intrinsic cholinergic transmission may provide an activity-dependent inhibitory control on striatal D<sub>1</sub> receptor stimulation (Supported by DA03982).

## 560.2

REGULATION OF THE GLUR1 GLUTAMATE RECEPTOR SUBUNIT IN THE DOPAMINE-DEPLETED PRIMATE STRIATUM. J. Timothy Greenamyre\*, Richard HP Porter, Monica Garcia-Osuna & Nicole L Marmarosh. University of Rochester, Rochester, NY 14642.

After dopaminergic denervation of striatum, there is electrophysiological and biochemical evidence for polysynaptic activation of glutamatergic subthalamic and corticostriate pathways. In rats, we previously showed that there are regulatory changes in both NMDA and AMPA receptor binding in the dopamine-depleted basal ganglia. We are now beginning to study the molecular regulation of glutamate receptors in the basal ganglia of primates. Two elderly female rhesus monkeys were infused via the right carotid artery with MPTP, causing a stable hemiparkinsonian syndrome. Two years later, the monkeys were euthanized and perfused for anatomical studies. In some studies, brain sections were double-labeled immunocytochemically for tyrosine hydroxylase (TH) and GluR1, using DAB as the chromogen for TH and an [<sup>125</sup>I]-secondary antibody to localize GluR1 autoradiographically. In other studies, calbindin and GluR1 were labeled using a similar protocol. In addition, mRNA for the "flip" and "flop" splice variants of the GluR1 gene was assessed by *in situ* hybridization in free-floating, fixed sections that were later processed for TH ICC. MPTP caused a profound ipsilateral loss of TH and a striking increase in GluR1 protein in the caudate and putamen. The increase in GluR1 protein was most pronounced in patches that corresponded to calbindin-poor patches; however, there was also an increase in the matrix. Similar changes were not found in rats with 6-OHDA lesions. These results support the ideas that (i) the glutamatergic system undergoes regulatory changes after dopamine depletion; and (ii) it is not always possible to extrapolate results from 6-OHDA treated rats to MPTP treated primates. (Supported by a Mallinckrodt Scholar Award, USPHS grant NS33779 and the National Parkinson Foundation Center of Excellence at the University of Rochester.)

## 560.4

EFFECTS OF HIGH FREQUENCY STIMULATION OF THE GPI VERSUS MPTP-INDUCED PARKINSONISM IN RHESUS MONKEYS: AN ELECTROPHYSIOLOGICAL STUDY. T. Borraud\*, B. Bioulac, and Ch. Gross. CNRS URA 1200, Université de Bordeaux 2, 33076 Bordeaux Cedex France.

Parkinsonian motor symptoms are associated with an over activity of the internal part of the Globus Pallidus (GPI). Inhibition of this structure using surgical lesions (Leitinen et al., 1992), or high frequency stimulation (HFS) (Borraud et al., submitted) reduce these symptoms in parkinsonian subjects. In this study, we wanted to evaluate effect of HFS of the GPI upon neurons of the Basal Ganglia. Extracellular, unit recordings were performed upon the external part of the Globus Pallidus (GPe) and the GPI in two Macaca Mulatta under three experimental conditions: 1°) in normal animals, 2°) after MPTP injection, 3°) before and just after stimulation of the GPI. After MPTP, monkeys exhibit a stable akineto-rigid form of hemiparkinsonian syndrome and were unable to move spontaneously their parkinsonian arms. Firing rate of neurons of the GPe was decreased, with appearance of irregular bursts. In GPI, firing rate was increased with a more regular pattern. These results are similar to those obtained by other teams (Filion and Tremblay, 1991). We have implanted a bipolar stimulating electrode (Medtronic®) in the antero-medial part of the GPI using ventriculographic landmark. We recorded each cell before and just after the stimulation (130Hz, 0.6ms PW, 5 seconds train) in order to avoid artifact disturbance. During stimulation, rigidity decreased in the parkinsonian side, and monkeys were able to move their parkinsonian arms. Stimulation did not induced significant effect on the GPe. On the GPI, it induced a long lasting (20 to 130 seconds) significant decrease in firing rate ( $p < 0.001$ ) of 95% of GPI cells inside the stimulated area, and burst almost disappeared. Effect of HFS seems to be a direct unspecific depolarisation block on neurons of the GPI as already suggested for HFS of STN (Borbaud et al., 1995).

## 560.5

THE MOTOR THALAMUS IN THE PARKINSONIAN PRIMATE: ENHANCED BURST AND OSCILLATORY ACTIVITIES. Y. Kaneko<sup>\*</sup>, J.L. Vitek, Dept. of Neurology, Emory Univ. Sch. of Med., Atlanta, GA 30322.

We have previously reported an abnormal pattern of neuronal activity in the motor thalamus of parkinsonian primates. To characterize the neuronal discharge patterns in the parkinsonian state we have developed algorithms to distinguish the altered patterns of neuronal activities. We define *burst* as a period in which neuronal discharge rate is significantly higher than other periods in a spike train, while *oscillation* is defined as neuronal activity in which there is significant periodicity in its autocorrelogram. One pigtail monkey developed hemiparkinsonism following injection of 2 mg MPTP (intracarotid). The monkey was trained to sit quietly on the chair and spontaneous neuronal activities were recorded throughout the pallidum (VLo) and the cerebellar (VPLo) receiving areas of the thalamus. Burst periods were identified in 59.2% (103/174) of VLo and 36.0% (104/289) of VPLo neuronal spike trains ( $p < 0.001$ , Chi-square test). The rate for VLo was significantly higher ( $p < 0.001$ , Chi-square test) than the rate for normal monkeys' motor thalamus neurons (32.7% in 49 neurons). Intra-burst interspike interval analysis revealed a pattern similar to that found in sleep (gradual increase in interspike interval) in 46.6% of VLo neurons while 27.9% of VPLo neurons revealed such patterns ( $p < 0.001$ , Chi-square test). Oscillation was found in 19.0% of VLo and 27.0% of VPLo spike trains ( $p < 0.001$ , Chi-square test). Both were significantly ( $p < 0.001$ , Chi-square test) higher than the rate for normal monkeys (14.3%). Although the monkey did not manifest tremor, oscillation between 3-8 Hz were found in 33.3% of VLo and 19.2% of VPLo neurons. These observations suggest that the motor symptoms in parkinsonism may result from dysfunction in both pallidum- and cerebellar-thalamocortical circuits. Furthermore, given the relative difference in the pattern of neuronal activity and termination sites within the cortical motor area, these regions may have different roles in the development of parkinsonian motor symptoms.

## 560.7

ORAL DYSKINESIA INDUCED BY KAINIC ACID LESIONS OF THE SUBTHALAMIC NUCLEUS IN THE RAT. R.J.A. Banks, P.M. Brin<sup>\*</sup> and M.F. Chesselet, Univ. of Penn., Dept. of Pharmacology, Philadelphia, PA 19104.

The subthalamic nucleus (STh) has been implicated in the control of dyskinetic movements in humans, monkeys and rats. In the rat, microinjections of dopamine and serotonin agonists into the STh induce oral dyskinesia (characterised by vacuous chewing, jaw tremor and tongue protrusions). In the present study, we have assessed the effects of kainic acid-induced lesions of the STh on oral dyskinesia in the rat. Male Sprague-Dawley rats under equithesin anaesthesia were stereotactically infused with 0.9% saline or kainic acid (100 ng/100 nl) into the STh. Behaviour of the animals was recorded for a period of 20 min at time points 3 hours, 4 days and 7 days after completion of the infusion. Microinfusion of kainic acid into the STh significantly increased the duration of locomotor activity and sniffing, and the frequency of oral dyskinetic movements (characterised by transient mouth opening and closing described as gaping) in rats at time points 3 hours and 4 days surgery. In contrast, the locomotor activity, sniffing and oral dyskinetic responses returned to control levels 7 days after completion of kainic acid infusion. Lesions of areas surrounding, but not including the STh showed no significant difference from saline treated animals at any time point, suggesting the response to be specific to the STh. These data confirm and extend previous studies suggesting a role of the STh in control of oral dyskinesia. In addition, the data provide the first example of oral dyskinesia induced by loss of STh neurones in rats (as kainic acid induces complete lesions 3 days after completion of infusion). The long duration of the behavioural response (4 days) suggest this model may provide a useful tool for investigating oral dyskinesia and the role of the basal ganglia in this response. Furthermore, the changes which occur during the transition between 4 days (oral dyskinesia) and 7 days (no oral dyskinesia) are currently under investigation using biochemical and molecular biological techniques in this laboratory. Supported by PHS grants MH44894 and MH48125 and Elf Aquitaine (PMB).

## 560.9

REGULATION OF mRNA LEVELS ENCODING FOR AMPA AND NMDA GLUTAMATE RECEPTOR SUBUNITS IN THE ADULT RAT STRIATUM AFTER 6-OHDA. J.-J. Soghomonian<sup>\*</sup>, P. Salin and M. Tremblay, Centre de Recherche en Neurobiologie, Fac. Med., Univ. Laval, Quebec (QC), G1K 7P4.

Levels of mRNAs encoding for subunits of AMPA and NMDA glutamate receptors were measured in various sectors of the rat dorsal striatum two weeks after unilateral injections of 6-hydroxydopamine (6-OHDA) in the substantia nigra. The relative mRNA levels were measured on X-ray films after *in situ* hybridization with oligonucleotides labeled at their 3' end with <sup>32</sup>S-dATP and complementary to the NMDAR1, GluR1 or GluR2 subunits. The extent of dopaminergic denervation was determined on adjacent sections after <sup>3</sup>H-mazindol binding. On the side ipsilateral to the lesion, mazindol binding was decreased on average by 68% with the highest decrease found in a dorsolateral striatal sector (-85%). When compared to the contralateral striatum, NMDAR1, GluR1 and GluR2 mRNA levels were higher (+14%, 18% and 21%, respectively) in a dorsomedial sector of the striatum ipsilateral to 6-OHDA. GluR1 mRNA labeling was also significantly higher (+15%) in a ventromedial striatal sector. When compared to the saline-injected rats, higher NMDAR1 or GluR1 labeling appeared to result from an increase ipsilateral to 6-OHDA. However, higher GluR2 labeling appeared to result from an increase ipsilateral and a decrease contralateral to 6-OHDA. Changes in mRNA levels encoding for glutamate receptors may reflect a compensatory response to changes in the activity of glutamatergic afferents to the striatum in this rat experimental model of Parkinson's disease. (Supported by the Parkinson Foundation of Canada, NSERC-0155607 and FRSQ).

## 560.6

EFFECTS OF SUBTHALAMIC NUCLEUS LESIONS IN A RODENT MODEL OF TARDIVE DYSKINESIA. A.J. Stoessl<sup>\*</sup>, Clin. Neurol. Sci., Univ. of Western Ontario & Roberts Research Institute, London, ON, Canada N6A 5A5.

Current models of basal ganglia function suggest that dyskinesias result from *hypofunction* of the subthalamic nucleus (STN). It has been suggested that this mechanism would also apply to the development of tardive dyskinesia (TD) in individuals exposed to chronic neuroleptics. This view is supported by observations of reduced glucose metabolism in the STN of monkeys with neuroleptic-induced dyskinesias, but is in contrast to the model of TD recently proposed by Trugman et al. (1994), in which activity is *increased* in both the STN and the striatonigral pathway. Based on Trugman's hypothesis, as well as the recent observation (Parry et al., 1994) that intra-STN infusion of apomorphine elicits D1-dependent vacuous chewing movements (VCMs) in rats, we examined the effects of STN lesions on VCMs induced by chronic neuroleptics in the rat.

Male Sprague-Dawley rats were treated for 24 weeks with fluphenazine decanoate (FLU; 25 mg/kg i.m.) or its vehicle q 3 weeks. Bilateral STN lesions were made by stereotactic infusion of quinolinic acid (100 nmol/μl/side). FLU resulted in increased VCMs, considered analogous to TD in humans. This response was attenuated to control levels by STN lesions, which also induced increased locomotion and sniffing in vehicle-treated animals. Lesion-induced increases in these responses were suppressed by FLU. Our data indicate that neuroleptic-induced VCMs in the rat are dependent upon (D1-mediated) stimulation of the STN and suggest that current concepts of dyskinesia should be reassessed with respect to the role of this structure, in keeping with the model recently proposed by Trugman et al. (1994).

## 560.8

EFFECTS OF NMDA RECEPTOR BLOCKADE OR SUBTHALAMIC LESION ON REACTION-TIME PERFORMANCE IN A RAT MODEL OF PARKINSONISM. M. Amalric<sup>\*</sup>, C. Baunez and A. Nicoullon, Cellular and Functional Neurobiology Laboratory, CNRS, 13402 Marseille cedex 20 (France).

There is substantial evidence that excessive excitatory amino acid (EAA) activity in the striatum and in the subthalamic nucleus could account for the expression of the motor deficits resulting from alteration in dopamine function in the basal ganglia. The present study investigated the potential benefit of blocking EAA transmission at different levels in the basal ganglia in rats previously subjected to dysfunction of dopaminergic transmission and trained to perform a reaction time (RT) task. Disruption of dopamine activity induced by 6-OHDA injected in the striatum or by the D2 dopamine receptor antagonist, raclopride, impaired the performance of rats trained to release a lever as fast as possible after the occurrence of a visual stimulus. The major deficit observed was a significant lengthening of RTs. The blockade of EAA activity with either systemic or intra-striatal injection of NMDA receptor antagonists was found to reverse the motor deficits induced by the dopaminergic lesion or by raclopride treatment. In contrast, the excitotoxic lesion of the subthalamic nucleus (STN) was found to only partly alleviate the movement initiation deficits induced by the dopaminergic lesion. In addition, the lesion of the STN was found to induce other deficits expressed by an increase of premature responding, preventing the animals to recover a level of performance comparable to pre-operative values. These results suggest that the blockade of EAA transmission at the NMDA receptor subtypes might be beneficial to prevent the akinctic symptoms produced by a dopaminergic denervation of the striatum. In contrast, beside alleviating parkinsonian symptoms in our model, the STN lesion produced additional deficits, leading to question the potential therapeutic benefit of subthalamotomy in Parkinsonism.

## 560.10

DIFFERENTIAL REGULATION OF GAD65 AND GAD67 IN SUBPOPULATIONS OF STRIATAL NEURONS. N. Laprade<sup>\*</sup> and J.-J. Soghomonian, Centre de Recherche en Neurobiologie, Hôpital de l'Enfant-Jésus, Québec, Qué. Canada, G1J 1Z4.

Levels of mRNAs encoding for the two isoforms of glutamate decarboxylase (GAD65 and GAD67) are differentially regulated by dopamine receptors in rat striatum. Indeed, dopamine receptor stimulation with apomorphine or SKF-38393 increases GAD65, but not GAD67, mRNA levels while dopamine receptor blockade with haloperidol or sulpiride increases GAD67, but not GAD65, mRNA levels (Laprade and Soghomonian, Soc. Neurosci. Abs., 24 (1994) p. 988). Striatal GABAergic projection neurons are divided in two subpopulations: striatopallidal and striatonigral. Preproenkephalin (PPE) is expressed preferentially in striatopallidal neurons. In order to determine if dopamine receptors regulate each GAD isoform in PPE positive neurons or not, double *in situ* hybridization on striatal sections was performed using radioactive GAD65 or GAD67 cRNA probes labeled with <sup>32</sup>S and a PPE cRNA probe labeled with digoxigenin. mRNA levels encoding for GAD65 were increased predominantly in neurons negative for PPE following stimulation of dopamine receptors. Quantification of silver grains at single cell level revealed that the increase in GAD65 mRNA levels when compared to control animals was of 29% (448.5 ± 44.9 vs 577.9 ± 38.6) after apomorphine treatment and 23% (448.5 ± 44.9 vs 552.4 ± 37.9) after SKF-38393 treatment. On the other hand, mRNA levels encoding for GAD67 were increased mainly in neurons positive for PPE following blockade of dopamine receptors. The increase relative to controls animals was of 54% (160.9 ± 33.2 vs 247.7 ± 32.0) after haloperidol treatment and of 36% (160.9 ± 33.2 vs 218.5 ± 19.7) after sulpiride treatment. Thus, our results suggests that GAD65 and GAD67 mRNAs are differentially regulated in striatopallidal and striatonigral neurons. (Supported by the Parkinson Foundation of Canada, NSERC-0155607 and FRSQ).

## 560.11

ABNORMAL [F18]SPIPERONE BINDING IN PUTAMEN IN IDIOPATHIC DYSTONIA. J.S. Perlmuter, J. Giovanni, K.J. Black, L. McGee-Minnich, L.W. Tempel, S.M. Moerlein. Departments of Radiology, Neurology & Psychiatry, Washington University School of Medicine, St. Louis, MO 63110

Meige syndrome refers to involuntary eyelid closure associated with lower facial spasms. The eyelid squeezing can be sufficiently severe to render an individual functionally blind. Hand cramp refers to involuntary spasms of hand, forearm and arm muscles with specific actions such as writing. Both are limited forms of idiopathic dystonia with unclear pathophysiology. We measured [F18]spiperone uptake with positron emission tomography in 6 patients with Meige syndrome (4 women; mean age =  $50 \pm 4$  yrs), 3 with hand cramp (1 woman; mean age =  $46 \pm 7$  yrs) and 6 normals (5 women; mean age =  $50 \pm 16$  yrs). No patient had dystonia in other body parts and no subjects had other neurological or psychiatric abnormalities. Each subject also had a normal MRI of the brain. PET studies were done with the Siemens 953b in the 2d mode with 31 simultaneous slices (3.4 mm center-to-center slice separation). Reconstructed transverse resolution was 7 mm FWHM and axial resolution was about 4 mm. Three to 5 mCi of [F18]spiperone were injected i.v. and sequential PET scans were collected for 3 hrs. The last 30 mins of PET data were combined into a single frame and transformed into stereotactic space for subsequent data analysis. The locations of the peak concentrations of [F18] activity in left and right putamen were identified by a computerized search routine. The mean Talairach & Tournoux Stereotaxic Atlas (1988) coordinates are for the Meige subjects ( $\pm 23.0, 4.3, 5.5$ ), for the hand cramp subjects ( $\pm 25.0, 0.0, 9.3$ ) and for the normals ( $\pm 25.2, -0.7, 4.3$ ). These locations were significantly different by MANOVA ( $p < .037$ ). Descriptively the locations for the hand cramp subjects were higher than the others. The Meige subjects' peaks were more medial and posterior than normals. These data are consistent with somatotopic functional organization of dopamine receptors in putamen, and are the first in vivo demonstration of a change in dopamine receptor binding in idiopathic dystonia.

## 560.13

THE STRIATUM AND CEREBRAL NETWORKS OF VERBAL AWARENESS IN NORMAL AND HYPERKINETIC CHILDREN

Hans C. Lou, Jente Andresen, Bruce Steinberg, Thomas McLaughlin, Troels Kjaer\* and Lars Friberg. John F. Kennedy Institute, DK-2600 Glostrup, Denmark.

ADHD is a common disorder of the developing nervous system, affecting 3-6% of all school children. Striatal dysfunction is a key pathogenetic mechanism in hyperactivity which may be induced experimentally by mutations in the dopamine D1 receptor gene. To explore the role of the striatum in verbal "awareness" (attention, perception and association) we measured regional cerebral blood flow (rCBF) by single photon emission tomography in 11 normal and 16 hyperactive children during presentation of white noise or animal names. The latter increased striatal flow. Factor analysis of co-variance of rCBF identified "attentional", "linguistic", and "associative" networks. The right striatum participated in all networks in normals, but not in the stymied "associative network" in ADHD where striatal flow was generally reduced. It is concluded that the striatum is anodal structure, allowing integration of functions in verbal awareness. In ADHD striatal dysfunction disturbs such a role.

## 560.12

THE RELATIONSHIP BETWEEN STRENGTH AND RATE OF FORCE DEVELOPMENT IN PARKINSON'S DISEASE. D.M. Corcos\*, C.-M. Chen, N.P. Quinn and J.C. Rothwell. MRC Human Movement & Balance Unit and Department of Neurology, The National Hospital for Neurology & Neurosurgery, London WC1N 3BG and University of Illinois at Chicago, Chicago, IL, 60608.

This study was designed to determine the relationship between muscle strength, rate of force development, and the time to relax muscle activity or actively return force to initial resting levels. Nine patients with Parkinson's disease were tested in three movement tasks both on and off antiparkinsonian medication. In the first task, they performed maximal voluntary flexion and extension isometric contractions in order to determine their strength. In the second task, they were instructed to generate a 50% maximal voluntary contraction as fast as possible, hold the contraction for four seconds and then relax. In the third task, they were again instructed to generate a 50% maximal voluntary contraction as fast as possible, hold the contraction for four seconds and then return the force to baseline as quickly as possible. Patients were weaker off medication in both flexion and extension but this change was greater for extension. The cause of this weakness was due both to reduced agonist muscle activation and, in some patients, increased muscle coactivation. Patients took longer to generate force, relax and to return actively when off medication. Patients who became weakest when off medication also tended to develop force at reduced rates which was related to a reduction in the phasic EMG burst off medication. Removing medication resulted in an increase in all measures of contraction time but the most sensitive measure was an increase in relaxation time. These findings further our understanding of the motor deficits of Parkinson's disease in two ways. First, they suggest that one possible cause of the flexed postures adopted by patients with Parkinson's disease is a proportionately greater reduction in strength in muscle extensors. Second, the inability to relax suggests that one component of bradykinesia is related to muscle deactivation.

This study was supported by NIH grants KO4-NS01508, RO1-NS28127 and RO1-AR33189.

## REFLEX FUNCTION: ANIMAL STUDIES

## 561.1

STRETCH REFLEX MODULATION IN DECEREBRATE AND SPINAL CATS DURING TONIC AND PHASIC (LOCOMOTION) CONTRACTIONS. De Serres, S.J., Stein, R.B., Bennett, D.L., Department of Physiology and Division of Neuroscience, University of Alberta, Edmonton, Canada, T6G 2S2.

The stretch reflex was studied in the triceps surae muscle of decerebrate cats during postural tasks (tonic contractions) and, after spinalization, during locomotor activities (phasic contractions). Tonic activity was induced by stimulation of the contralateral common peroneal nerve (crossed extensor reflex) while the cats were given Naloxone and Clonidine, combined with perineal stimulation to induce locomotion. Short pulses 10 ms in duration (various amplitudes) were delivered by a motor to stretch the muscle at rest and during the contractions. With such short pulses we could cleanly separate in time the short-latency reflex force responses from the mechanical effects of the stretch. Similar recordings were also performed after deafferentation, allowing us to subtract the force changes due to the contractions. The reflex responses increase little when the amplitude is increased from 1 to 3 mm, indicating a saturation of the reflex loop. For 1 mm stretches the reflex responses are high at low levels of tonic muscle activation (decerebrate state), but gradually decrease with an increase in contraction levels. In the spinalized animals, the reflex is also high at rest (prior to locomotion), drops abruptly when locomotion starts, is small at low levels of activation (swing phase) and increases with higher levels of muscle contraction (stance phase). Thus, even in reduced preparations strong modulation of reflexes is seen which can change in opposite directions with increasing force levels during different tasks. (Research supported by MRC).

## 561.2

PLASTICITY OF THE EXTENSOR GROUP I PATHWAY CONTROLLING THE STANCE TO SWING TRANSITION IN THE CAT P. J. Whelan\*, G. W. Hiebert and K. G. Pearson. Dept. of Physiology, University of Alberta, Edmonton, AB, CANADA, T6G 2H7.

The brain possesses the capacity to reorganize itself after peripheral injury, often in a functionally meaningful way. Although much plasticity occurs at the cortical level, relatively little is known about the plasticity of spinal systems beyond the simple monosynaptic reflex. This study examines whether the efficacy of polysynaptic group I excitatory pathways to extensor motoneurons are modified after axotomy of a synergistic nerve. Previously, we have shown that stimulation of extensor nerves at group I strength can extend the stance phase and delay swing. Stimulation of the LG/S nerve prolongs stance for the duration of the stimulus train, whereas stimulation of the MG nerve moderately increases stance. We hypothesized that after axotomy of the LG/S nerve the efficacy of the MG group I input would increase. This idea was tested in 5 adult cats that had their left LG/S nerves axotomized for 3-28 days. On the experimental day we decerebrated the cats and stimulated the left (experimental) and right (control) LG/S and MG nerves during late stance. A significant increase in the efficacy of the left MG nerve occurred 5 days after axotomy of the LG/S nerve when compared to the control response. By contrast, the previously cut LG/S nerve showed a reduction in efficacy after 3 days compared to the control limb. Functionally, this plasticity may be an important mechanism by which the strength of the group I pathway is calibrated to different loads on the extensor muscles. ## 561.3

THE SIZE PRINCIPLE OF MOTOR-UNIT RECRUITMENT CROSSES MUSCLE BOUNDARIES. A.J. Sokoloff\* and T.C. Cope. Dept. Physiology, Emory University, Atlanta, GA 30322.

We are testing whether the size principle, evident in the orderly recruitment of motor units belonging to single muscles, applies to motor units belonging to different muscles. The medial and lateral gastrocnemius muscles (MG and LG, respectively) were activated in reflexes elicited in decerebrate cats ( $n=2$ ) by controlled stretch of the Achilles tendon and by punctate stimulation of the heel pad. Recruitment sequence and axonal conduction velocity (an index of motor-unit size, and a good predictor of recruitment sequence) were determined for motor-unit pairs composed of one MG and one LG unit. Recruitment was tested in multiple reflex trials, each trial eliciting EMG activity in both muscles. For the majority of pairs in which units were distinguishable by size (CV difference  $>2\text{m/s}$ ), the unit with slowest CV had the lowest recruitment threshold: 9/12 pairs in stretch reflexes, and 7/7 pairs in heel-pad reflexes. These preliminary findings demonstrate that motor units belonging to different muscles can be recruited in order by size, i.e. the size principle crosses muscle boundaries. Supported by NIH grant RO1 NS21023.

## 561.5

REGULATION OF STANCE PHASE DURATION BY FLEXOR MUSCLE AFFERENTS. G. W. Hiebert, P. J. Whelan, A. Prochazka, and K. G. Pearson\*. Dept. of Physiology, Univ. of Alberta, Edmonton, Alberta, Canada, T6G 2H7.

One proposal concerning the regulation of stance-to-swing transition during walking is that swing is initiated when the leg is extended beyond a set position. We have tested the hypothesis that the stretch-sensitive afferents in flexor muscles provide one source of afferent input to terminate the stance phase in walking cats. Decerebrate cats were made to walk on a moving treadmill belt. The hip flexor iliopsoas (IP) and the ankle flexors tibialis anterior (TA) and extensor digitorum longus (EDL) were stretched, or the nerves to TA or EDL were electrically stimulated, at various phases of the step cycle. Changes in EMG amplitude, duration and timing were monitored. Stretch of flexor muscles during stance phase reduced the duration of extensor activity and resulted in the early activation of the flexor muscles. Vibration of IP and EDL muscles, or electrical stimulation of group I afferents from EDL nerve, produced a similar resetting of the step cycle indicating that group Ia afferents from flexors can terminate extensor activity. TA vibration and electrical stimulation of TA nerve at group I strengths did not reduce extensor duration. Activation of group II afferents from TA was required to produce an effect. Activation of the flexor muscle afferents during swing phase did not consistently alter the pattern of the locomotor activity.

It is proposed that when the flexor muscles are stretched as the stance phase progresses input from muscle spindle afferents acts to inhibit the center regulating extensor activity thus leading to the initiation of swing.

## 561.7

ACTIONS FROM GROUP II MUSCLE AFFERENTS DURING FICTIVE LOCOMOTION ARE NOT MEDIATED THROUGH THE SHORT LATENCY FLEXION REFLEX PATHWAYS. M.-C. Perreault\*, P. Guertin and D.A. McCrea. Dept. of Physiology, U of Manitoba, Winnipeg, R3E 3J7, Canada.

Hindlimb flexor group II afferents exert powerful effects during MLR-evoked fictive locomotion by resetting the step cycle to extension or prolonging extension (Perreault et al. 1995, *J. Physiol.* in press). These effects contrast with the depolarizing action of the flexor afferents onto flexor motoneurons evoked at rest and are distinct from those evoked by cutaneous and joint afferents. It was thus suggested that these group II actions were mediated through reflex pathways other than those responsible for the flexion reflex. In this study we use intracellular recording from pairs of motoneurons to assess the contribution of the different pathways activated by group II strength flexor nerve stimulation (ST, 20 shocks, 100Hz) during fictive locomotion. Preliminary results show that during flexion, such stimulation hyperpolarizes flexor MNs and frequently terminates the ongoing depolarization. This hyperpolarization occurs within 60ms and is not time-locked to each stimulus pulse. Concomitantly in extensor MNs, group II stimulation resets the step cycle and evokes IPSPs that ride on top of the LDP. The latencies of these stimulus-locked IPSPs are comparable to that of the short latency FRA IPSPs seen at rest but their amplitudes are much smaller. During extension, stimulation of Sart nerve prolongs extension evoking EPSPs in extensor MNs and small amplitude IPSPs in flexor MNs; in both cases the PSPs are evoked at latency of 4-5ms. In conclusion, it is becoming increasingly evident that during the flexion phase of the locomotor cycle, there is a clear separation of group II reflexes from those considered as part of the flexion reflex system. The reorganization of the group II pathways would then consist of a replacement of the group II FRA pathways with another set of pathways that have access to the CPG interneurons. During the extension phase, the possibility that the "alternate FRA" pathways are responsible for the effects remains open. Supported by the MRC and the Rick Hansen Legacy Fund.

## 561.4

THE CUTANEOUS REGULATION OF ANKLE EXTENSOR GAMMA MOTONEURONE DISCHARGE IN THE CAT. P.H. Ellaway\*, N.J. Davey, & M. Ljubisavljevic. Department of Physiology, Charing Cross and Westminster Medical School, London W6 8RF, United Kingdom.

Cutaneous afferents regulate the discharge of fusimotor neurones via oligosynaptic spinal pathways (Davey & Ellaway 1989 *J. Physiol.* 411 97-114). This work examines the effect of skin input from the heel on  $\gamma$ -motoneurons to muscle spindles of the gastrocnemius soleus (GS) muscles in the decerebrate, spinal (T9) cat.

We have stimulated discrete areas of skin within the sural nerve field using an electromagnetic vibrator pulsed at 10 Hz. Cross correlation and coherence analysis have been used to reveal the connectivity between sensory input and  $\gamma$ -motoneurons. Peristimulus time histograms (psth) showed that, although most  $\gamma$ -motoneurons were excited at short latency, a substantial minority were inhibited by skin stimulation. On the lateral, dorsal edge of the sural field, skin stimulation could evoke inhibition of the discharge of  $\gamma$ -motoneurons excited from elsewhere in the sural field. All recordings showed significant peaks of coherence (at 10 Hz) between stimuli and  $\gamma$ -discharge. Psth responses and coherence at 10 Hz were abolished or attenuated by section of the sural nerve. Both types of analysis revealed that excitatory and inhibitory influences had a topographic organization. The most powerful excitatory effects came from skin over the lateral aspect of the calcaneum. Inhibition had its strongest representation more lateral and dorsal to the calcaneum.

Sinusoidal stretch of GS muscles and recordings from muscle spindle afferents (Ellaway et al 1994 *J. Physiol.* 479 30P) suggested that the dominant effect of skin stimulation tends to be excitation of static  $\gamma$ -motoneurons which may be accompanied by either excitation or inhibition of dynamic  $\gamma$ -motoneurons.

We conclude that cutaneous input may have a role in the regulation of the different types of fusimotor action during movements involving stretch of the skin about the ankle joint. Supported by the Medical Research Council, U.K.

## 561.6

Ia AFFERENTS AND LOCOMOTION: RESETTING THE RECORD M.J. Angel\*, P. Guertin & D.A. McCrea. Dept. Physiology, U. of Manitoba, Winnipeg, R3E 3J7, CANADA.

Stimulation of ankle extensor group I afferents during feline locomotion can either enhance ongoing extensor activity or reset the step cycle to extension. This extensor activation replaces the group I non-reciprocal reflex inhibition of synergists seen in non-locomoting preparations. Other labs have claimed that activation of Ia muscle spindle afferents is without strong effect on the locomotor pattern. This observation along with direct evidence for the involvement of Golgi tendon organ (Ib) afferents in resetting has resulted in the notion that it is mainly Ib reflexes that are reorganized during locomotion. This claim is refuted by recent data from our lab. We have shown that Achilles' tendon vibration activating only triceps surae and plantaris (TSPI) Ia afferents enhances locomotor extension as powerfully as electrical stimulation of individual ankle extensor nerves. Ia activation can also delay the onset of flexion and reset the step cycle. Intracellular recordings from extensor motoneurons show that selective activation of Ia afferents from TSPI evokes both powerful disynaptic and longer latency EPSPs in ankle, knee and hip extensor motoneurons during extension. We argue that Ia afferents also access the locomotor CPG resulting in prolongation of extension and a delay in the onset of flexion. To set the record straight, it appears that activation of Ia and Ib afferents results in similar reflex actions during fictive locomotion. These effects, perhaps via common interneurons, provide a positive length/force feedback system to aid in extension and forward propulsion during locomotion. Supported by MRC & Rick Hansen Legacy Fund.

## 561.8

COMBINED ACTIONS OF INTERNEURONS AND MOTONEURONS PRODUCE EXTENSION ENHANCEMENT DURING FICTIVE LOCOMOTION. D.A. McCrea\*, P. Guertin, M.J. Angel and M.-C. Perreault. Dept. of Physiology, U of Manitoba, Canada.

Stimulation of extensor group I afferents can modulate the locomotor step cycle by increasing the duration and intensity of extensor activity throughout the ipsilateral hindlimb. While group I afferents partly exert their actions during locomotion through CPG circuitry, little is known about the possible contribution of intrinsic plateau-like potentials of motoneurons to their increased depolarization during extension enhancement. In the present study, intracellular recording during group I afferent evoked extension enhancement was used to compare the ability of group I stimulation to evoke plateau-like potentials of close synergist and other extensor motoneurons during MLR evoked fictive locomotion in cats. In close synergist motoneurons, ankle extensor group I stimulation evoked large monosynaptic and short latency excitation and often plateau-like potentials during extension enhancement. On the other hand in hip and knee extensor motoneurons, the smaller short latency depolarizations produced by ankle extensor afferents rarely evoked plateau-like potentials during extension enhancement. Thus the relative contribution of CPG evoked effects and intrinsic motoneuron properties to extension enhancement may depend upon of the amount of short-latency depolarization evoked by group I afferent stimulation in each motoneuron species. This suggests that group I afferents modulate motor output during fictive locomotion through a combination of intrinsic motoneuron properties and pre-motoneuronal pathways. Supported by the MRC and the Rick Hansen Legacy Fund.

## 561.9

**SPATIAL ORGANIZATION OF CUTANEOUS POSTSYNAPTIC POTENTIALS IN MOTONEURONS OF ANKLE MUSCLES IN THE CAT.** T.M. Hamm\*, Z.-S. Han, M.L. McCurdy, and V. Turkin. Div. of Neurobiology, Barrow Neurological Inst., Phoenix, AZ 85013.

We have investigated the possibility that cutaneous stimulation of the paw might assist in the control of posture and locomotion by means of spatially organized pathways to motoneurons that innervate muscles with actions at the ankle, a group having diverse mechanical actions and patterns of use. Postsynaptic potentials were produced by brief taps and electrical stimulation applied to the surfaces of the paw and recorded in motoneurons of ankle muscles in decerebrate cats. The taps were applied to the dorsal and ventral surfaces of the paw, plantar cushion, and dorsal surface over the metatarsal-phalangeal joint with 1 cm discs attached to miniature air pistons. Forces of 2-3 N were applied in 30 ms pulses while recordings were made from motoneurons of the following pools: medial (MG) and lateral gastrocnemius (LG), tibialis anterior (TA) and extensor digitorum longus (EDL), flexor digitorum longus (FDL) and flexor hallucis longus (FHL), and peroneus longus (PL) and brevis (PB). Although variability was found in the postsynaptic responses, an overall pattern emerged for the responses to stimulation of most cutaneous sites in each of the motoneuron species. With the exception of peroneus brevis, in which excitation was the dominant pattern from all stimulation sites, the responses in each motoneuron species differed between stimulation sites. Moreover, comparison of responses to stimulation of each site in different motoneuron species revealed different patterns of postsynaptic potentials. Differences were evident in responses from stimulation of at least one site in comparison of LG and MG, PB and PL, FDL and FHL, and TA and EDL. Our results demonstrate a spatial organization of cutaneous pathways to motoneurons that differentiates between motor pools with different functions, suggesting the utility of these pathways in the control of locomotion and posture.

## 561.11

**FACILITATION OF STARTLE BY ELECTRICAL STIMULATION OF AMYGDALA EFFERENTS: TIMING RELATIONSHIPS AND CIRCUITRY.** P.W. Frankland\*, R.A.M. Brown and J.S. Yeomans. Dept. of Psychology, University of Toronto, Toronto, Canada M5S 1A1.

Electrical stimulation of the caudal ventral amygdalofugal (VAF) pathway facilitates acoustic startle responses when the electrical and acoustic stimuli are presented close together in time (Rosen & Davis, 1990). Here we deliver a 0.1 ms pulse at currents below those required to evoke an unconditioned startle response together with stimulation of the acoustic startle pathway, either electrically (two 0.1 ms pulses) or acoustically (4 ms noise burst). Then we test which intervals between the startle-eliciting stimulus and the facilitation pulse evoke the strongest startle responses. Resulting curves were fitted with normal distributions to estimate the center and range of enhancement. For acoustic stimuli, the enhancement curves for stimulation of the VAF or lateral midbrain were centered on intervals of 3-4 ms. Stimulation of the ventral cochlear nucleus was enhanced by VAF stimulation at intervals centered on 1-2 ms. Stimulation of the medial longitudinal fasciculus in the medulla was enhanced by VAF stimulation at intervals centered on -1 to 0 ms. Therefore, 1) the transmission time from the VAF to the midbrain is less than 1 ms; 2) transmission times through the primary startle circuit are 2-3 ms from the speaker to the cochlear nucleus, and about 1 ms from the cochlear nucleus to the medulla; 3) the enhancement of startle by medulla stimulation suggests that integration can occur downstream from the RPC at the level of the spinal cord.

## 561.13

**EMG RESPONSE OF PINNAE MUSCLES TO AZIMUTHAL VARIATIONS OF FREE-FIELD SOUNDS IN DECEREbrate RATS.** B.J. Frost and L. Li\*. Visual and Auditory Neurosciences Lab., Psychology Dept., Queen's Univ., Kingston, Ontario, Canada, K7L 3N6

Electromyographic (EMG) recordings from the cervicoauricular muscle (CAM) group to free-field sounds were made in decerebrate and unanesthetized rats. The rat was pre-anesthetized deeply with sodium pentobarbital (60 mg/kg, i.p.). The brainstem was transected at the precollicular level. Very fine flexible EMG insulated wire electrodes were inserted into the CAM to record multi-unit activity. All the wounds were then sutured and anesthesia was discontinued. After the rat recovered from anesthesia, wide-band noise pulses (60 ms in duration with 5 ms rise and decay times) were presented and speaker positions were varied in azimuth. Sound-levels were set at 5 or 10 dB above empirically determined threshold for an EMG response to a sound from the extreme ipsilateral azimuth. Short latency transient EMGs were produced and in some cases varied in spike rate with sound source location. At least two major classes of the CAM EMG response were identified: omnidirectional and directionally sensitive. The omnidirectional CAM EMG exhibited a flat azimuth function or gradual decline only at extreme contralateral azimuths. For the directionally sensitive CAM EMG, the maximum activity was displayed at extreme ipsilateral azimuths, but as speaker was moved toward the extreme contralateral azimuth, the sound-evoked activity declined systematically. This study suggests that auditory spatial tuning curves can be measured in the pinnae motor system.

## 561.10

**MODULATION BY CUTANEOUS AFFERENTS OF THE POSITIVE FEEDBACK OF MUSCLE CONTRACTION IN CAT PERONEAL MOTONEURONS.** J.-F. Perrier, D. Zytnicki\*, B. Lamotte d'Incamps, N. Kouchtir, L. Jami. URA CNRS 1448, UFR des Saints-Pères, 75006 Paris, France.

In a previous work (1), it was established that afferent inputs generated during sustained isometric contraction of Peroneus Brevis (PB) elicit excitatory potentials in peroneal motoneurons. The aim of the present work was to investigate whether cutaneous inputs, known to occur during movements, could interfere with this positive feedback of muscle contraction. Motoneurons supplying peroneal muscles were recorded intracellularly in anesthetized cats in which a hindlimb had been denervated except for PB muscle and the skin territory supplied by Peroneus Superficialis (PS) nerve. Mechanical stimulation of the skin was elicited by ramp-and-hold indentations applied on PS territory with a servo-controlled length actuator. Complex excitatory and inhibitory responses were recorded in peroneal motoneurons mainly during the dynamic phases of the ramps. In most cases, ramps of 1-3 mm amplitudes evoked excitatory potentials in motoneurons. Inhibitory potentials and/or further excitation appeared during 4-5 mm ramps. These observations are consistent with the pattern of responses observed in peroneal motoneurons during graded electrical stimulations of PS nerve: excitatory potentials appeared for stimulations at 1.1-1.6T and inhibitory potentials appeared, in some but not all motoneurons, for stimulation above 2T.

When mechanical skin stimulation was applied during PB contraction, simple summation of effects elicited by cutaneous and muscular inputs occurred in most peroneal motoneurons. The net result was either an enhancement or a reduction of the positive contraction-feedback.

**DOPAMINE D<sub>2</sub> RECEPTOR AGONISTS ALTER GAP MODULATION OF STARTLE AMPLITUDE.** D. S. Leitner\* and E. M. Gitten. Department of Psychology, Saint Joseph's University, Philadelphia, PA 19131-1395.

Dopamine agonists have been demonstrated to disrupt the ability of innocuous sensory events (prestimuli) to reduce the amplitude of a subsequently elicited acoustic startle reflex (ASR). Pulses of pure tones or noise have typically been used as prestimuli. The present series of experiments used brief silent periods in otherwise continuous noise (gaps) to investigate how administration of D<sub>1</sub> and D<sub>2</sub> dopamine receptor agonists would affect gap's modulation of the rat's ASR amplitude.

The first and second experiments investigated the abilities of the D<sub>2</sub> receptor agonist (-)-quinpirole hydrochloride (.1 to 1.6 mg/kg) and the D<sub>1</sub> receptor agonist (±)SKF-38393 (.1 to 5.0 mg/kg), respectively, to alter gap startle modulation. The third experiment investigated the effects of a single high dose of quinpirole (5.0 mg/kg) on gap startle modulation. The fourth experiment examined the ability of the dopamine receptor blocker haloperidol (.2 mg/kg) to reverse quinpirole's effects. The final experiment investigated whether simultaneous administration of quinpirole and SKF-38393 would produce a synergistic effect on gap startle modulation.

Quinpirole had a biphasic effect, with the lowest doses enhancing and the higher doses decreasing the ability of a gap to reduce startle amplitude. SKF-38393 had no reliable effect on gap detection at any dose used. At high doses quinpirole blocked gap inhibition of startle amplitude. The fourth experiment showed that haloperidol blocked the effects of quinpirole. The fifth experiment showed that ineffective doses of SKF-38393 interacted with quinpirole. These data suggest a commonality of mechanism supporting the abilities of gaps and pulses of pure tones and noise to modulate startle amplitude. All of these effects were very sensitive to the exact stimulus parameters used, suggesting differential neural processing of long and short gaps presented at long and short interstimulus intervals.

## 562.1

**POWER DENSITY SPECTRUM OF SURFACE ELECTROMYOGRAM DURING DYNAMIC ISOMETRIC CONTRACTIONS.** C. Maioli\* and C. Orizio. Dip. di Scienze Biomediche, Univ. di Brescia, 25123 Italy.

It is well established that frequencies of the power density spectrum (PDS) of the surface electromyogram (SEMG) are related to the overall conduction velocity of the active motor units (MU) in the muscle, thus providing some insight on the underlying MU recruitment strategy. Accordingly, it has been reported that the high-frequency content of the PDS increases with force magnitude during static isometric contractions. By contrast, scanty information is available on the changes of the SEMG spectrum associated with dynamic variations of isometric force.

We recorded the bipolar SEMG (1 cm inter-electrode distance) from the biceps brachii of healthy males 22-40 years old. Subjects were required to match a visual target with a feedback signal proportional to the elbow flexion force. Three different time courses of the force target were used: 1) constant levels (3 s duration) from 10 to 80% of maximal voluntary contraction (MVC); 2) ramps from 0 to 80% MVC in 10 s; 3) steps from 10 to 40% MVC as a reaction-time response to an acoustic signal. Time-varying PDS was estimated by means of the application of an autoregressive model of order 20 to the SEMG signal sampled at 1024 Hz.

SEMG spectrum was found to be multi-modal with three distinct power peaks centered at about 40, 70 and 100 Hz. At constant force levels, the power ratio between the first and the second peak decreases with force magnitude, being the second peak almost absent at 10-20% MVC and as large as the first peak at 80% MVC. By contrast, during slow ramps the ratio of the first two peaks tends to be constant and close to 1 from 20-30% up to 80% MVC, in most subjects. In both motor tasks, the magnitude of the third peak was not consistently correlated with the level of force. Finally, in the dynamic phase of the force step trials the SEMG spectrum was characterized by the appearance of a sharp peak around 100 Hz. Its amplitude was usually larger than the amplitude of the third peak observed during the trials with constant or ramp force profiles.

## 562.3

**AN EXPERIMENTAL SIMULATION METHOD FOR EVALUATION OF THE EFFECTS OF CENTRAL MOTOR UNIT ACTIVATION STRATEGIES ON EMG.** M. Hulliger\*, S.J. Day, W.M. Morrow and B. Kacmar. Dept. of Clinical Neurosciences, Univ. of Calgary, Alberta, Canada T2N 4N1.

The EMG is a complex interference signal resulting from the summation of trains of motor unit (MU) action potentials (MUAP). Its features are determined by peripheral (MUAP shape) and central (MU firing) parameters. However, during voluntary contractions the relative contributions of these parameters to EMG characteristics cannot be determined from EMG recordings alone. To complement and evaluate computer simulations of EMG (e.g. J. Neurophysiol. 70, 2470-88, 1993) an experimental EMG simulation technique has been developed, which is based on multi-channel independent stimulation of single MUs (SMUs) in a cat nerve-muscle preparation.

Currently up to 40-56 SMUs (master-set) of a hindlimb muscle are isolated in ventral roots. Successively, four subsets (10-14) of SMUs are stimulated independently using customized stimulator and electrode arrays and pre-edited computer-generated pulse trains (up to 56 individual patterns), with added Gaussian noise imitating physiological firing variability. Special software permits ready simulation of a range of central MU pool activation strategies, featuring e.g. varying degrees of recruitment, rate modulation and MU synchronization. Master-set EMG and force signals are obtained off-line by linearly summing raw EMG and force signals recorded during MU-subset stimulation.

Strictly simultaneous stimulation of substantially more than 10-15 MUs is unrealistic for various technical reasons. Therefore the above technique of successive stimulation of different subsets of MUs was adopted. This still permits activation of each MU with a unique pattern. Moreover, control experiments demonstrated that multi-MU EMG signals result from strictly linear summation of SMUAP trains, and that the intermediate forces (150-250 g, as generated by MU subset activation) also sum linearly.

The technique is used to evaluate EMG-force relations (Day et al., this volume) and effects of MU synchronization on EMG. It will also be applied in a study of the role of central MU control strategies on EMG characteristics during muscle fatigue. Supported by AHFMR and MRC.

## 562.5

**SELECTIVE RECRUITMENT WITHIN TRICEPS SURAE MUSCLES OF THE DECEREBRATE CAT ALTERS KNEE TORQUE TRAJECTORIES.** S.J. Bonasera\*, J.H. Lawrence III†, C.M.J.I. Price, and T.R. Nichols. Department of Physiology, Emory University, Atlanta, GA 30322, and † Center for Biomedical Engineering, University of Kentucky, Lexington, KY 40506.

Differential activity of the two major heads of feline gastrocnemius (G) generate distinct ankle torque trajectories differing in the relative proportion of abduction to plantarflexion torques (Nichols et al., *Exp. Brain Res.* 97:366, 1993). These data suggested that the CNS both represented and exploited the complex biomechanical insertion of lateral gastrocnemius (LG) and medial gastrocnemius (MG) onto calcaneus to produce functionally different ankle movements.

The muscle origins of MG and LG at the knee also suggest that differential activation of G may evoke different knee torques. MG attaches at the femoral medial condyle, and thus may produce knee flexion and adduction; conversely, LG attaches at the femoral lateral condyle, and thus may produce knee flexion and abduction. To test this hypothesis, we used a three-dimensional force transducer to calculate knee joint torques in unanesthetized decerebrate cats in response to peripheral nerve stimulation evoking crossed-extension (XER) or caudal cutaneous sural nerve (SNR) reflexes. Both SNR and XER evoked strong flexion at the knee. In agreement with biomechanical predictions, torque trajectories evoked by SNR consistently adducted the knee, while torque trajectories evoked by XER consistently abducted the knee. This study further emphasizes the unique role of multi-articular muscles in the specification of whole limb mechanical properties, and demonstrates that functional roles of multi-articular muscles must be evaluated in the context of their mechanical actions at each spanned joint. (Supported by NIH Grant NS20855).

## 562.2

**DECOMPOSITION OF COMPOUND MUSCLE ACTION POTENTIALS (CMAP) FROM ABDUCTOR POLLICIS BREVIS MUSCLE (APB) WITH FEED-FORWARD NEURAL NETWORK.** J. Fang, B. T. Shahani\*, D. Graupe. Rehab. Med & Restorative Med. Sci., Univ. of Ill. at Chicago, Chicago, IL 60612

A feed-forward neural network was implemented to decompose the surface CMAP based on spatial and temporal summations of the templates of motor unit potentials. The motor unit templates for slow and fast types of motor units were collected by the low level voluntary contraction of the muscle, and near threshold stimulation of the median nerve at the wrist, respectively. The surface CMAPs from normal APB muscle corresponding to 100%, 50%, and 10% of the maximal stimulus intensities were obtained by electrical stimulation of median nerve at the wrist. The estimate of the number of motor units in the muscle was 157. Our study also showed that at 50% of maximal stimulus intensity, 30.9% of slow motor units had been recruited compared to 52.5% of fast motor units. Whereas, at 10% of maximal stimulus intensity, only 1% of slow motor units had been recruited compared to 24.2% of fast motor units. We believe that this technique is simple and non-invasive, and can be applied to electro-physiological examination of patients with neuromuscular disorders to obtain more information with regard to: 1) the number of motor units recruited; 2) the type of motor units and their distribution in the motor neuron pool; 3) the way different types of motor units are recruited; and 4) the conduction delay among individual motor units of different types.

## 562.4

**THE EFFECTS OF VARIOUS ACTIVATION STRATEGIES ON THE ISOMETRIC EMG-FORCE RELATION: AN EXPERIMENTAL SIMULATION STUDY.** S.J. Day, M. Hulliger, K.A. Scheepstra and R.G. Lee\*. Dept. of Clinical Neurosciences, Univ. of Calgary, Alberta, Canada T2N 4N1.

While different motor unit (MU) pool activation strategies have been identified for various human muscles (J. Physiol. 308, 103-14, 1980), the relative effects of recruitment (Rc) and rate modulation (RM) on the EMG-force relation during asynchronous MU pool activation remain controversial. For single MUs force saturates with increasing rate of activation, whereas EMG magnitude increases linearly; in contrast, during increasing asynchronous stimulation of the MU pool, the EMG signal also demonstrates saturation, largely due to increasing signal cancellation (Soc. Neurosci. Abstr. 19, 405.03, 1993). Consequently, as motor drive increases, the relative degrees of saturation of EMG and force will determine the shape of the EMG-force relationship. In the present study a wide range of MU pool activation strategies were explored using a cat nerve-muscle preparation.

The L7 and S1 ventral roots were divided into filaments containing either 3-30 soleus MUs (multi-MU simulations) or a single MU. In either case, 10 filaments were activated independently and asynchronously at fixed length. Various 10 channel constellations of stimulation patterns initiated different central activation strategies, including pure Rc, pure rate RM and intermediate designs with varying contributions from each. For single-MU simulations raw EMG and force signals were summed for four 10 channel sets to simulate activation of a substantial proportion of the MU pool (Hulliger et al., this volume).

For both multi-MU and single-MU simulations pure Rc produced greater force increases than EMG (gain compression), while pure RM caused significantly larger increases in EMG than force (gain expansion). Combined activation strategies gave intermediate, mostly similar EMG-force relations, suggesting that for likely physiological MU activation strategies EMG-force characteristics are much less variable. Individual 10 channel constellations of single-MUs revealed substantially less EMG saturation than multiple 10 channel constellations, indicating that cancellation-related EMG saturation can be very pronounced, when sufficient numbers of MUs are activated at physiological rates. Supported by AHFMR and MRC.

## 562.6

**AGE AND PRACTICE EFFECTS ON MOTOR UNIT DISCHARGE RATE VARIABILITY.** C. Patten, J.R. Burke\*, G. Kamen, D. Rowland. Motor Control Laboratory, Department of Physical Therapy, Boston University, Boston, MA 02215.

One possible explanation for the observation that older adults demonstrate greater motor performance variability than younger individuals lies in the underlying variability in motor unit discharge rates. The present study was conducted in an effort to measure discharge rate variability in young and older adults. Six young (21-30 yrs) and six older (65-82 yrs) subjects were studied on each of two days while performing 50% MVC and 100% MVC isometric contractions using fifth digit abduction. During the 50% MVC task subjects performed a ramp contraction for 15 seconds. Motor unit recordings were obtained from the abductor digiti minimi muscle using a four-wire needle electrode. Spike recognition software was used to obtain individual motor unit discharge occurrences. The results demonstrated that measures of discharge rate variability, including standard deviation (SD) and coefficient of variation (CV), were similar for both groups. For the 50% MVC condition maximal discharge rate standard deviation was 0.040 for the young subjects and 0.045 for the older adults ( $p > .05$ ), and CV's demonstrated a similar effect ( $Y = 2.12$ ,  $O = 2.16$ ;  $p > .05$ ). SD's were greater on day one than day two (0.070 day one vs. 0.015 day two;  $p < .01$ ), and these results were mirrored by the results for CV (3.96 day one vs. 0.40 day two;  $p < .01$ ). There were no statistically significant group x day interactions ( $p > .05$ ). These results indicate that: 1) discharge rate variability appears to be similar in young and older adults, and 2) repeated practice reduces the variability of motor unit discharge rates.

MOTOR UNIT SYNCHRONIZATION AND FORCE TREMOR ARE REDUCED IN SKILL- COMPARED TO STRENGTH-TRAINED SUBJECTS. J.G. Semmler and M.A. Nordstrom\*. Department of Physiology, University of Adelaide, Adelaide 5005, Australia.

We have recently shown in right-handed subjects that motor unit (MU) synchronization in first dorsal interosseus (FDI) muscle is weaker in the dominant (skilled) hand than the non-dominant hand (Semmler & Nordstrom, *Exp. Brain Res.*, in press, 1995). MU synchrony reveals information about corticomotoneuron (CM cell) activity and the distribution of their direct projections to motoneurons (Datta *et al.*, *J. Physiol.* 432:401-425, 1991). Our results suggest that preferential use of the hand may influence these features of cortical control of FDI. To assess the importance of muscle usage patterns on MU synchrony, we have studied 5 skill-trained (ST) musicians, 5 strength-trained (WT) weightlifters and 6 untrained (UT) subjects. Mean MU synchrony during index finger abduction (expressed as frequency of extra synchronous discharges above chance) was significantly lower in ST ( $0.22 \pm 0.02 \text{ s}^{-1}$ , 162 MU pairs) than UT subjects ( $0.32 \pm 0.02 \text{ s}^{-1}$ , 199 pairs,  $P < 0.05$ ) and WT subjects ( $0.44 \pm 0.03 \text{ s}^{-1}$ , 183 pairs,  $P < 0.01$ ). Differences in MU synchrony for UT and WT subjects were also significant ( $P < 0.01$ ). Duration of synchronous peaks was similar for each group. Force tremor was quantified during isometric abduction of FDI at 0.5 N and 3.5 N. Tremor RMS amplitude was significantly lower ( $P < 0.01$ ) in ST vs. WT subjects. However, there were no significant correlations between mean MU synchrony in a muscle and tremor amplitude (*cf.* Semmler & Nordstrom, *Exp. Brain Res.*, in press, 1995). Therefore, differences in MU synchronization are not responsible for the differences in force tremor between groups. Weaker FDI MU synchrony in ST subjects may reflect a more restricted distribution of direct projections from CM cells to FDI motoneurons, or a reduced excitability of CM cells during the task. Our data suggest that skill- and strength-training are associated with opposite adaptations in these features of the cortical control of FDI.

## 562.9

"PREFLEXES" - PROGRAMMABLE, HIGH-GAIN, ZERO-DELAY INTRINSIC RESPONSES OF PERTURBED MUSCULOSKELETAL SYSTEMS. I.E. Brown, S.H. Scott\* and G.E. Loeb. Dept. Physiology, Queen's Univ., Kingston, ON K7L 3N6.

Motor physiologists have often viewed the ensemble of muscles and bones in a limb as undesirably complex and redundant for the performance of simple tasks such as reaching and walking. These complexities and redundancies can, however, be used by the nervous system to achieve much better performance in the face of external and internal perturbations than could be achieved by reflex control alone in mechanically simple systems. We hypothesize that the nervous system uses the "redundant" aspects of limb posture and muscle activation patterns to create a general mechanical impedance to perturbations, as originally proposed by Hogan (1984, IEEE AC-29:681). This generalized impedance typically includes "stiffness" terms related to the force-length relationships for muscle and connective tissues, "viscosity" terms related to the force-velocity relationships, and inertial terms related to skeletal posture. Using a new set of experimental data and equations that more broadly and accurately describe the mechanical properties of muscles and tendons, we have simulated the behavior of various model systems of muscles and skeletal linkages in response to typical perturbations. The results suggest that the nervous system could use these intrinsic properties (particularly the interaction between the force-velocity relationship and the series compliance of various muscle architectures) to achieve a broad and useful range of programmable responses to perturbations, in agreement with recent experimental evidence that it actually does so (Gottlieb, 1994, *Exp. Br. Res.* 97:545). In addition to high effective gain, these responses occur at zero time delay, hence the suggested term "preflexes." Thus, preflexes are particularly effective at reducing the instability inherent in relying exclusively on neurally mediated reflexes with high gains.

## 562.11

DECORRELATION WITHIN AND CORRELATION BETWEEN ANTAGONIST MOTOR NUCLEI BY RECURRENT INHIBITION. M.G. Maltenfort\*, C.J. Heckman, R.E. Druzinsky and W.Z. Rymer. Dept. of Physiology, Northwestern Univ. Med. Sch., Chicago, IL 60611

A functionally realistic computer model of motor pools with recurrent inhibition and force output was constructed. Synaptic connectivity was matched to physiology. Agonist-antagonist pairs were linked by inhibition between the two Renshaw cell (RC) populations. Stochastic inputs were used to simultaneously control stiffness and position.

Within a motoneuron pool, correlations between single units and population firing were both positive and negative along a range centered at zero. RC feedback narrows this range ( $p < 0.01$ ), so that individual motoneurons are more likely to be uncorrelated. This decorrelation abolishes discrete peaks in the power spectra of force at the mean rate of motoneuron firing (15-35 Hz, depending on pool activity).

Simulations of the linked pools demonstrate that mutual inhibition between antagonist RCs can correlate unfused and partially fused motor unit twitches across the two pools. Coherence between pools is 0.4 - 0.5 at the frequencies of motoneuron firing. Coherence of position vs. its control signal declined the same amount at the same frequencies, as synchronous units contracting with opposite actions canceled.

The net effect of both phenomena is to abolish 'microtremor' at the joint which could adversely interact with stretch receptors.

## 562.8

INHIBITION OF THE LONG-LATENCY STRETCH REFLEX DURING RAPID STEP-TRACKING WRIST MOVEMENTS IN HUMANS AND MONKEYS. J.W. Mink\*, R.J. Bateman, and W.T. Thach. Depts of Neurology and Anatomy & Neurobiology, and The McDonnell Center for Higher Brain Function, Washington Univ. Med. School, St. Louis, MO 63110.

The long latency stretch reflex (LLSR) involves a multi-synaptic, transcortical mechanism that is active to maintain posture against external perturbations. Previous studies have shown that the LLSR can be gated in response to instruction. We have previously hypothesized that posture holding mechanisms are inhibited by the basal ganglia inhibited during voluntary movement so as not to interfere with the desired movement (Mink and Thach, 1991). This study sought to determine if the LLSR in the wrist flexor muscles is inhibited during wrist movement.

Six healthy human volunteers and two rhesus monkeys performed a visually guided hold-step-hold wrist movement task. They performed the task by placing their hand in a wedge-shaped manipulandum that was controlled by flexing or extending the wrist in the horizontal plane. The task was performed with constant torque loads opposing or assisting the wrist movement. EMG was recorded from surface electrodes overlying the wrist flexor and extensor muscles. To elicit the LLSR, torque pulses (50 - 100 msec) or steps (1 sec) of several different magnitudes were superimposed on the static load in order to stretch the wrist flexor muscles.

In the maintained hold prior to movement, the LLSR occurred with a mean latency of 50 msec in humans and 26 msec in monkeys. The magnitude of the LLSR correlated with the magnitude of the preload and with the velocity of the imposed stretch. During rapid wrist movement, the LLSR was suppressed by 10 - 30% when the movement was made by contracting the loaded flexors and by 50 - 80% when the movement was made by relaxing the loaded flexors. These results show that the LLSR is active during maintained wrist posture and is inhibited during voluntary wrist movement. ## 562.10

REALISTIC NEURAL CONTROL FOR REAL MUSCULOSKELETAL TASKS.

G.E. Loeb\*, Bio-Medical Engineering Unit, Queen's Univ., Kingston, ON K7L 3N6.

All motor tasks can be divided into a nominal trajectory (input motor signals U and output sensory signals S) and a set of perturbation trajectories ( $\Delta U$  and  $\Delta S$ ) that would occur in response to a set of perturbations ( $\Delta x$ ; e.g. external loads or internal computational noise) that the subject expects to encounter. The motor program controls  $\Delta S(t)$  through two separate mechanisms: "preflexes" (see adjacent poster) that arise from the mechanical impedance (Z) presented by the skeletal posture and intrinsic properties of active muscles (M), and reflexes that arise from the spinal regulator gain (K) that generates  $\Delta U$  in response to  $\Delta S$ . The job of the descending control system is to find a set of commands (C) to the spinal interneurons that simultaneously produces both K and the desired nominal output U when combined with nominal sensory feedback S. The brain presumably uses adaptive control (e.g. neural networks) to learn to produce C according to performance criteria associated with a given task and based on responses to the set of perturbations that have been experienced previously. This learning requires computation of an error signal (E) from the weighted (W) summed differences between the sensory signals received ( $S + \Delta S$ ) and the desired trajectory ( $S^*$ ).

This schematization divides motor control into three very different but complementary functions and incorporates concisely and explicitly important aspects of the control problem (e.g. perturbations, impedance and performance criteria) that are often omitted or implicit.

## 562.12

PRESYNAPTIC INHIBITION AND POSTSYNAPTIC GAIN RECRUITMENT MECHANISM DURING AN ISOMETRIC ANKLE JOINT RAMP CONTRACTION IN MAN - A SIMULATION STUDY.

T. Sinkjaer\* and R.J. H. Wilmink. Center for Sensory-Motor Interaction (SMI), Dept. of Medical Informatics and Image Analysis, Aalborg University, Fredrik Bajersvej 7D, DK-9220 Aalborg, DENMARK.

In this study we are applying a model which can describe some of the neural mechanisms underlying the facilitation of the H-reflex as it is observed during dynamic muscle contractions. Healthy subjects were asked to make a voluntarily isometric ramp-and-hold plantar-flexion around the ankle joint with a maximum force level of 15Nm, while getting visual force feedback. The ramp lasted for 0.5s followed by a 1s hold. During this we elicited H-reflexes with a 100ms interval before and during the active movement. The experiments showed an increase in the size of the H-reflex prior to the onset of the ramp-contraction and a slow decrease towards the end of the hold-contraction. The motoneuron model used to simulate the experimental observations was based on a dynamic pool with 200 alpha motoneurons. Each motoneuron had cell properties like excitability, firing rate dynamics and pre- and post-synaptic interactions. The output from the pool was translated into a soleus EMG signal from which the H-reflex was simulated. The pool itself was modelled as a continuum with a distributed excitability from the smallest (slowest) unit to the largest (fastest) unit (Slot, P., Sinkjaer, T. Biological Cybernetics. 70:351-358, 1994). We simulated the experimental results using either a presynaptic inhibition or a postsynaptic gain recruitment mechanism. Both mechanisms were able to model the experimental outcome.

## 562.13

DO CONTRALATERAL INFLUENCES ONTO SOLEUS H REFLEXES REQUIRE COMPLEX SPINAL MECHANISMS? J.E. Misiaszek\*, J. Cheng, J.D. Brooke and W.R. Staines. Human Biology Dept., University of Guelph, Guelph, ON, Canada, N1G 2W1.

Passive movements of a single leg phasically modulate soleus H reflexes of that leg. Reflexes of the opposite leg are also attenuated, however, phasing to the movement has not yet been demonstrated. Presently, H reflexes of the stationary leg were sampled from twelve subjects while the other leg was A) passively cycled at 20 and 40 rpm and B) stationary. Eight points across the cycle were tested. H reflex gain displayed a rate dependent reduction across the cycle ( $p < 0.01$ ). No phasing was detected. We hypothesized the lack of phasing could be attributed to sensory drive originating in biarticular muscles. Passive movements of the hip or knee were isolated in eight subjects to eliminate biphasic stretching of these muscles. Reflexes were sampled for four positions in the cycle (0, 25, 50 and 75% of the cycle) at 20 and 40 rpm and while stationary. Reflex gain in the leg contralateral to the movement was reduced across the cycle during hip movement at 40 rpm ( $p < 0.05$ ). Phasing was not evident. Similar results arose from knee movements. The ipsilateral influences of isolated joint movements displayed both a strong rate ( $p < 0.05$ ) and phase ( $p < 0.05$ ) effect. Phasic afferent discharging has been invoked to explain the ipsilateral influences, however, the results suggest a more complex system is required for the crossed effects. Supported by NSERC (Canada).

## 562.15

ACTIVITY OF SPINAL INTERNEURONS DURING "FICTIVE" BEHAVIORS IN THE FROG SPINAL CORD-HINDLIMB PREPARATION. Piron, L. and Schottland, J.\* Dept. Brain and Cog. Sci., M.I.T., Cambridge, MA 02139

Spinal interneuronal networks have been implicated in the coordination of reflex behaviors and equilibrium postures (Bizzi et al. 1991). We sought to investigate the contribution of a wide range of spinal interneurons to the set of reflex behaviors that corresponds to microstimulation-induced equilibrium postures (Giszter et al. 1993) by using the *in vitro* frog spinal cord-hindlimb preparation.

The frog spinal cord and hindlimb were placed in separate chambers, connected only by the spinal nerves. We implanted electrode wires in four muscles that discriminate among the reflexes. We recorded interneuronal activity extracellularly using 10-15 MOhm NaCl-filled pipettes. Interneurons were identified by their response to stimulation of descending pathways via a suction electrode positioned on the lateral white matter at the rostral end of the hemisectioned spinal cord, and by their lack of antidromic response to stimulation of the main nerve trunk to the hindlimb. Reflex behaviors, including wipe, flexion withdrawal, and extension, were elicited by touching or pinching the skin of the hindlimb, which was fixed by pins at the hip.

Interneurons were recorded at depths ranging from 5-730  $\mu$ m from ten animals. As reported by Berkowitz and Stein (1994) in the turtle spinal cord, twelve interneurons were active during more than one different reflex behavior. In contrast to the turtle, however, interneurons in our paradigm exhibited a much broader range of activity patterns. Six interneurons were selectively activated during particular movement sequences. Eleven were activated during muscle contraction, even though no movement occurred. In some cases the activity closely matched the period of muscle contraction, while in others it could be considerably shorter, or could outlast the period of muscle activity. The activity of four interneurons could not be related to any obvious features of the experimental paradigm and six interneurons did not participate in the generation of any reflex behaviors.

## 562.14

MOTOR UNIT ACTIVITY PATTERNS IN AN AMPLITUDE-SCALED ISOTONIC TASK IN THE PIGEON. R. Panteón and P. Zeigler\* Hunter College (CUNY), New York, NY 10021.

Eating and drinking in pigeons are stereotyped behaviors, differing primarily in jaw movement topography. Eating is an episodic response in which the jaw exhibits gape amplitudes scaled to the size of the food object. Drinking is rhythmic, with a relatively constant jaw opening amplitude. Both are produced by the same mechanical arrangement of bones and muscles, and common motoneuron pools. To examine motor control mechanisms of scaling and pattern generation, conditioning procedures were used to bring jaw-movements under experimental control in a fixed-head preparation. Displacements of the upper and lower beaks were monitored and correlated with EMG activity from lower jaw muscles. Jaw muscle activity was sampled at 10kHz to isolate individual motor units and a spike train analysis carried out. Relations between variations in movement amplitude and motor unit properties (threshold, frequency) were examined to assess the manner in which these properties are modulated during amplitude scaling. The results suggest both the operation of the "size principle" and the existence of individual motor units reflecting different functional task groups. ## MUSCLE: BIOMECHANICS

## 563.1

BIOMECHANICAL AND MUSCULAR LINKS BETWEEN THE SCAPULA AND HEAD-NECK SYSTEM. T. Liinamaa, R.J. Runciman and F.J.R. Richmond\*. MRC Group in Sensory-Motor Physiology, Queen's University, Kingston, ON, Canada, K7L 3N6

Most studies of head movement in cats view the head and cervical column as if it were a self-contained motor system. However, biomechanical analyses suggest an important role for the scapula, both as a site at which forelimb loading forces are transmitted to the axial skeleton, and as an attachment for neck muscles. In the sitting cat, ground reaction forces transmitted through the forelimbs exert a parasagittally-directed torque on the scapula that tends to rotate its dorsal margin caudally. This force is presumably counterbalanced by the tonic contractions of muscles running rostrally to the head and neck. Electromyographic analyses of shoulder muscles are consistent with this premise. The rostralmost heads of rhomboideus that attach onto the skull (occipitoscapularis) and cervical vertebrae (rhomboideus minor) are active tonically in quietly sitting cats. These muscle regions are also richer in slow fibers than other parts of rhomboideus or of adjacent levator scapulae, which is active during horizontal turns. Results suggest that the biomechanical and neural mechanisms responsible for maintaining stable head posture may not be characterized completely unless consideration is given to the role of the scapula and forelimbs (and perhaps also the trunk) which convey ground-reaction forces to the head-neck complex. (Supported by MRC of Canada)

## 563.2

UNUSUAL MUSCLE SARCOMERE LENGTHENING AND SHORTENING WITH ELBOW JOINT FLEXION R.L. Lieber\* and J. Fridén Depts. of Orthopaedics and Bioengineering, UCSD, La Jolla, CA 92093 and Hand Surgery Unit, Göteborg University, Sweden.

Sarcomere length (SL) was measured in extensor carpi radialis brevis (ECRB) muscles during elbow flexion in 13 individuals undergoing surgical lengthening of the muscle for lateral epicondylitis (tennis elbow). As an adjunct to our previous study of the wrist (*J. Neurophysiol.* 71: 874-881, 1994), we measured sarcomere length changes during elbow joint flexion at 30° intervals. Unexpectedly, sarcomere length demonstrated a biphasic response to continuous elbow flexion from 3.49±0.11  $\mu$ m in the extended position increasing to 3.68±0.09  $\mu$ m, then decreasing to 3.34±0.09  $\mu$ m, then increasing to 3.81±0.12  $\mu$ m and then decreasing again to 3.45±0.16  $\mu$ m. Such a response would be expected to have profound mechanical consequences with elbow flexion since the muscle would go through two active lengthening cycles which are known to cause muscle injury and high stresses. This unusual sarcomere behavior may underlie some of the ECRB pathology as in tennis elbow. Anatomical dissections of cadaveric specimens failed to provide an obvious underlying structural basis for the observed results. Our provisional hypothesis is that the ECRB origin which overlies the lateral epicondyle is able to "flip" back and forth during elbow rotation, thus crossing the elbow axis of rotation.

## 563.3

IS MUSCLE A GOOD MECHANICAL DAMPER? D.C. Lin\* and W.Z. Rymer, Depts of Biomedical Eng. and Physiology, Northwestern Univ., Chicago, IL 60611.

Force-velocity properties of muscle are often cited as having beneficial damping characteristics. Yet these properties are usually determined with steady-state activation and under unphysiological loading conditions. The purpose of this study is to determine how much damping is actually done by a muscle in a situation where damping is needed: specifically, we chose to simulate the action of the antagonist muscle in a rapid single-joint movement during which a brief burst of activation is used to generate the decelerating force acting on a load.

Experimental data were collected from the cat soleus muscle in an anesthetized preparation. Inertial loads were simulated using force feedback to a length servo. The protocol was to provide the load with an initial velocity to stretch the muscle and then apply an electrical stimulus for a brief period of time (100 ms). Electrical stimulation was applied at the ventral roots, making it possible to grade muscle force output. Muscle length and force were recorded. Both the initial velocity and magnitude of the inertial load were varied.

The most general method to quantify damping is to consider it as an energy dissipating process. Thus the loss of kinetic energy from the mass due to the opposing force generated by the muscle was computed. The data showed that the amount of energy dissipated by the muscle increased with both increasing inertia and initial velocity. However this result may have just been a consequence of the kinematics associated with varying the inertial load. In order to investigate this possibility, mechanical models of different linear actuators were tested under the identical loading conditions as the experiment. It was determined that only a minimal amount of viscoelasticity was necessary to replicate the energy dissipation characteristics of muscle. This result indicates muscle under these conditions acts similar to a force generator with limited mechanical properties rather than a passive mechanical element.

Robustness to variations in inertial load, which is improved by damping properties, was determined by examining the resulting kinematics (final velocity and maximum length excursion) at the end of the muscle activation period. The robustness of the muscle was comparable to an actuator with only modest damping properties, in agreement with the previous result.

## 563.5

THE EFFECT OF VARIABLE FREQUENCY TRAIN VERSUS CONSTANT FREQUENCY TRAIN STIMULATION ON THE HUMAN PARALYZED SOLEUS MUSCLE. Y.J. Chang, R.K. Shields\* Physical Therapy Graduate Program, University of Iowa, Iowa City, IA 52242.

Muscle force generation depends not only on the frequency of stimulation but also on the pattern of stimulation (Stein and Parnigiani 1979 Brain Res). Under fatigued conditions, doublets (6 ms ipi's) have been shown to enhance torque in paralyzed muscle (Shields and Shields 1994 Soc Neuro Abstr). Less certain are whether the enhanced torques are sustained using a variable frequency train and whether the "potentiated state of the muscle" influences this response. We compared the effect of a variable frequency train (VFT) to a constant frequency train (CFT) before, immediately after, and every 5 minutes for 20 minutes after a Burke-like fatigue protocol. Ten chronically paralyzed legs (> 1 year) had the soleus muscle activated via the tibial nerve with either 6 CFT trains (20 Hz, 10 pulses) or 6 VFT trains (1st ipi = 6 ms, train = 50 ms, 12 pulses). All CFT or VFT trains were separated by 1 s. Next, the soleus muscle was fatigued by activating the tibial nerve with a 20 Hz train every s for .333 s for two minutes. Following fatigue the same VFT or CFT protocol was repeated. The VFT or CFT was selected at random initially then all subjects returned 7 days later to receive the alternate protocol (CFT/VFT). The maximum torque (MT), mean torque (MNT), and rate of torque development (RTD) was normalized to a pre-fatigue 15 Hz contraction so that the CFT and VFT could be compared at each time period tested. The VFT caused a significant increase in RTD before and at all time periods after fatigue as compared to the CFT. The VFT MNT was not different than the CFT before fatigue but was significantly greater at all time periods after fatigue. The VFT MT was also not significantly different from the CFT before fatigue, but was significantly greater after fatigue. Although the magnitude of the difference was reduced when the muscle was further potentiated, all measurements (PT, MNT, RTD) for the VFT remained significantly greater than the CFT. Mechanisms contributing to these findings will be discussed.

## 563.7

FORCE-FREQUENCY AND FATIGUE PROPERTIES IN HUMAN LONG FINGER-FLEXOR MOTOR UNITS. A.J. Fuglevand\*, V.G. Macfield, and B. Bigland-Ritchie. John B. Pierce Laboratory, 290 Congress Ave., New Haven, CT 06519.

Adaptation in motoneuron firing rate during fatigue may serve to optimize force output as the mechanical function of the muscle units change (Bigland-Ritchie et al. *J. Physiol.* 340: 335, 1983). The generality of this hypothesis rests in part on a fundamental question: how do the mechanical properties of different motor-unit types change during various fatigue tasks? To address this question, intraneural stimulation was used to elicit twitch and force-frequency responses before and after intermittent stimulation with a standard fatigue protocol (40 Hz train for 330 ms, 1 train per s, 2 min) in single motor units ( $n = 13$ ) of human long finger-flexor muscles. Before fatigue, two distinct groups (Group 1,  $n = 8$ ; Group 2,  $n = 5$ ) of units could be identified based on the stimulus frequency needed for half-maximum force; Group 1 required (mean  $\pm$  SD)  $9.5 \pm 0.7$  Hz while Group 2 required  $15.5 \pm 1.1$  Hz. Twitch contraction times between the two groups were not statistically different (Group 1 =  $56.4 \pm 15.5$  ms; Group 2 =  $46.4 \pm 5.1$  ms). For all units tested, one was fatigue-sensitive (fatigue index, FI < 0.25), 3 were fatigue-resistant (FI > 0.75) and the remainder were of intermediate fatigability ( $0.25 \leq FI \leq 0.75$ ). The fatigue index of Group 1 was not significantly different than that of Group 2 ( $0.62 \pm 0.26$  vs.  $0.455 \pm 0.27$ ). After intermittent stimulation, the force-frequency curves in the five most fatigable units (FI < 0.5) shifted rightward, exhibiting low-frequency fatigue which persisted after 10 min of recovery. These results suggest that force loss in fatigue-susceptible units would be exacerbated if firing rate declined during this type of task. Supported by USPHS NS 14576 & HL 30062.

## 563.4

NONLINEAR SUMMATION OF FORCE IN CAT SOLEUS DURING DYNAMIC CHANGES IN STIMULUS RATE OR MUSCLE LENGTH. T.G. Sandercock\* and C.J. Heckman, Department of Physiology, Northwestern Univ. Sch. of Med., Chicago, IL 60611

Forces from different motor units within a muscle are often assumed to sum linearly. Yet, even in muscles with the simplest architecture, the fibers exert their force through tendons and aponeuroses that are crosslinked and therefore partially shared. This mechanical interaction may result in substantial nonlinear summation. The purpose of this study was to measure nonlinear summation in cat soleus during dynamic contractions most likely to produce nonlinear summation via shared series elastic elements. In 5 anesthetized cats the soleus was attached to a servomechanism to control muscle length and record force. The ventral roots were divided into two bundles so each innervated approximately half of the soleus. Nonlinear summation was measured by subtracting the force when each part was stimulated alone from the force when both parts were stimulated together. Two experiments were performed: 1) During continuous stimulation of one part of muscle the stimulation of the other part was either abruptly started or terminated; and 2) During stimulation of one or both parts, the muscle was moved with quick ramp stretches or releases. Both experiments resulted in small but measurable nonlinear summation (less than 5% of maximum tetanic tension). To test the hypotheses that stretch of the common series elastic elements can account for the nonlinear summation, tendon stretch during stimulation of both parts of the muscle was estimated. The servomechanism was then programmed to mimic that tendon stretch during stimulation of a single part of the muscle. Most (70%) of the nonlinear summation could be accounted for by tendon stretch.

## 563.6

EFFECTS OF MODE OF STIMULATION OF PARALYZED HUMAN MUSCLE ON FORCE AND FATIGUE CHARACTERISTICS. Y.M. Kots, S.J. Harkema, N.L. Banks, M.N. Bieschke, E. Eldred\*, B.H. Dobkin, V.R. Edgerton, Departments of Neurology and Physiological Sciences, University of California, Los Angeles, 90095.

The mode and level of current needed to stimulate human muscle is related to an array of factors such as safety, skin irritability, maximum evoked force, comfort level, muscle fatigue, as well as initiation of reflexes and co-activation of non-stimulated muscles. To address these issues a tendonometer technique was developed to measure the isometric force generated by the tibialis anterior in response to sinusoidal currents at carrier frequencies (CF) of 1000, 2500 and 5000 Hz, with and without a 100-Hz full amplitude modulation, in 4 spinal cord injured (SCI) subjects and 4 control subjects. Current amplitude to muscle force ratios (A:F) were computed from the muscle's response to 3 sec stimulation elicited every 30 sec while increasing the current amplitude until a force plateau or the subject's tolerance level was reached. At a modulated CF of 2500 Hz the maximum force (MF) was similar to the MF produced with a 100-Hz rectangular pulse stimulation. At the lower CF, the A:F decreased and the MF increased. Modulation of the CF also increased the MF and decreased the A:F. This effect of modulation was most prominent at 2500 and 5000 Hz. Subjects perceived the modulation stimulation as more comfortable than the unmodulated one at each of the CF's. Muscle fatigue during 15 evoked contractions (4 or 5 sec duration, every 12 or 15 sec) was higher in SCI subjects than control subjects. In SCI subjects, the fatigue was lower at the higher CF's. As well, for equal CF's, the unmodulated CF produced a lower level of fatigue than the modulated CF. These data demonstrate that the identification of optimal modes of electrical muscle stimulation for subject's comfort as well as for determining maximum force and resistance to fatigue of a specific muscle group is feasible. (Supported by NIH grants NS 16333 and NRSA HD 07416).

## 563.8

CAT LATERAL RECTUS MOTOR UNITS EXHIBIT SUBMAXIMAL POWER IN RESPONSE TO A PULSE-STEP STIMULATION PARADIGM. K.E. Wilson, M.S. Shall, T. Ramoa and S.J. Goldberg\*, Depts. of Anat. and Phys. Ther., P.O. Box 980709, Med. Coll. Va.-VCU, Richmond, VA 23298-709.

Motor unit physiologists typically examine contractile characteristics such as tetanic tension and fusion frequency in response to motoneuron (MN) activation with a range of briefly applied (200 ms) monotonic stimulation frequencies. In this study we also used a 2 sec MN stimulation protocol which included a high frequency pulse lasting 25 ms followed by a constant frequency. The first 10 ms of stimulation (4 pulses) was at 350 Hz followed by 15 ms (3 pulses) at 250 Hz followed by 1975 ms at a constant frequency ranging from 40-200 Hz. This pulse-step stimulation paradigm mimics MN firing patterns observed during "real" saccades and fixation. The resultant range of tensions produced during the steady state phase of the pulse-step stimulation paradigm was compared to tensions evoked monotonically at similar frequencies.

We observed 63 twitch plus 6 non-twitch units. Both contraction speed and fatigue data were collected on 40 twitch units so they could be type classified as FF, FR, SF, and S ( $n=20, n=4, n=13$ , and  $n=3$  respectively). All classes of twitch, as well as non-twitch, motor units demonstrated weaker maximum tetanic tensions in response to pulse-step stimulation as compared to monotonic stimulation at similar frequencies. And these tension differences were generally greater in FF motor units.

A wide range (~50 to ~200 Hz) of monotonic stimulation frequencies evoked linear tension increments in all units. But a much narrower range (~50 to ~120 Hz) of frequencies evoked linear tension increments following the pulse phase of our 2 sec stimulation paradigm. Indeed, no unit demonstrated a maximum tension greater than that attained during the pulse phase of stimulation. The pulse phase, then, created a tension "ceiling" that the units never exceeded. This tension was usually less than the maximum tension the units could reach during the strictly monotonic stimulation paradigm.

Supported by an A.D. Williams grant from VCU and EY07924.

## 563.9

**CONTRACTILE PROPERTIES OF THE MG MUSCLE AND ITS TWO REGIONS IN THE ADULT RAT OF DIFFERENT AGES.** S. Vanden Noven\*, K.L. Seburn, and P.F. Gardiner. Sch. of Physical & Occup. Therapy, McGill Univ. (H3G 1Y5), & Sciences de l'Activité Physique, Univ. de Montreal, Montreal, QC.

To determine if the two regions (i.e., an oxidative/deep region and a low-oxidative/superficial region) of the medial gastrocnemius (MG) muscle with differing contractile properties are maintained in aging, contractile properties were compared in the Sprague-Dawley (Harlan) rat at three age periods: 2-3 mo (n=3), 6-7 mo (n=7) and 24-25 mo (50% survival age: n=4). These two regions have been shown to be supported, in part, by the two extramuscular nerve branches (NBr: proximal or distal; Vanden Noven et al., 1994). Isometric contractile properties were measured *in situ*, first with stimulation of the whole MG nerve followed by stimulation of either NBr. Tetanic force output, normalized to the ratio of muscle weight/body weight, was compared between the 3 groups. MG in animals at the 50% survival age showed the characteristics of 'aged' muscle: decreased mass, decreased force output and slowed contraction times. Furthermore, the region innervated by the proximal NBr of the MG nerve was more fatigue resistant than that innervated by the distal NBr. The differential contractile properties of the two muscle regions in the adult, identified by the extramuscular NBr innervation, are maintained or enhanced in animals at the 50% survival age (Funded: NSERC Canada).

## 563.11

**MECHANICAL PROPERTIES OF PHYSIOLOGICALLY RECRUITED TRICEPS SURAE MUSCLES OF THE CAT.** Clotilde M. J. I. Price\*, Timothy C. Cope and T. Richard Nichols. Dept. of Physiology, Emory University, Atlanta, GA 30329, USA.

Mechanical responses of active muscles result from the intrinsic properties of the muscle and the effects of proprioceptive feedback. This interaction is poorly understood for natural movements and especially for muscles of heterogeneous fiber type composition during natural recruitment. Following self-reinnervation of the triceps surae muscles, those muscles lack functional proprioceptive feedback (Cope et al., *J. Neurophysiol.* 71:817-820, 1994) but recover normal motor innervation. To evaluate the intrinsic mechanical properties of naturally recruited muscles and the contributions of component fiber types, velocity of stretch and contractile history, we studied the responses to lengthening of reinnervated whole muscles and type-identified single muscle fibers. When stretch was preceded by an isometric contraction, as in the case of a postural perturbation, the responses of whole muscles varied systematically with force in a manner consistent with the fiber type composition of motor units active at the onset of the stretch. However, at higher forces the short range stiffness did not appear to be velocity dependent as was expected from the single fiber data. When we preceded the stretch by a shortening, as occurs just before the stance phase of locomotion, stiffness was reduced and was no longer amplitude dependent. These results illustrate that the specialized dynamic properties of different fiber types are expressed at the corresponding force levels and that these properties adapt appropriately to the ongoing behavioral task. (Supported by NS 20855)

## 563.13

**CHRONIC LEAD TREATMENT ALTERS STRUCTURE AND FUNCTION OF MOUSE FLEXOR MUSCLE.** M.A. Fahim\*, A.H. Al Dhaheri<sup>1</sup> and F. El-Sabban. Faculty of Medicine, U.A.E. University and Ministry of Health<sup>1</sup>, P.O. Box 17666, Al Ain, United Arab Emirates.

The effect of chronic exposure to divalent cations on skeletal muscle was investigated. Two treatment levels of lead acetate (low 0.1 and high 1 mg/kg) were made by subcutaneous injections for 7 days. Comparative analyses of *in situ* muscle isometric contractile characteristics were studied in urethane-anesthetized (2 mg/g, i.p.) control and lead-exposed male mice. Control muscle twitch tension reached  $1.81 \pm 0.2$  g. Chronic lead treatments did not affect muscle contractile speed, but significantly reduced the twitch tension in both high and low doses. This effect was in a dose-dependent manner;  $1.21 \pm 0.07$  g for low dose and  $0.9 \pm 0.05$  g for high dose. Chronic lead treatments accelerated muscle fatigue after 200 stimuli in both doses equally. However, marked elevation in tetanic (25Hz) specific tension were observed in the high-dose treated animals, indicating changes in contractile apparatus function. The high dose of lead treatment induced ultrastructural changes in the intramuscular axons and neuromuscular junctions. The observed morphological changes could alter physiological responses attained; however, such a level of exposure to lead would be required to manifest these changes. These results suggest that lead exposure at a low concentration can compromise *in situ* skeletal muscle isometric contraction.

## 563.10

**CONTRACTILE PROPERTIES OF SKELETAL MUSCLE IN SHAKER RATS.** J.S. Fisher, M. Brown, B.R. Clark, S.D. Minor\*. Program in Physical Therapy, Washington Univ. School of Med., St. Louis, MO 63108.

Gait deficits in the Shaker (SH) rat, a Sprague-Dawley mutant strain with progressive loss of cerebellar Purkinje cells, suggest possible muscle weakness. Accordingly, contractile characteristics of Shaker soleus (SOL), plantaris (PLA), peroneus longus (PER), and extensor digitorum longus (EDL) were compared to muscles of control Sprague-Dawley rats.

Muscle weight to body weight ratios for control and SH were not different, indicating that atrophy was not present. Peak tetanic tension ( $P_o$ ), when expressed as the ratio of  $P_o$  to muscle mass, was comparable for controls and Shakers for all 4 muscles studied. Observed gait deficits, therefore, are not a result of distal muscle weakness. The possibility of hip and/or trunk weakness cannot be discounted, however.

Time to peak twitch tension (TTP) was significantly faster in the Shaker SOL, PLA, and PER compared to controls. The decline in  $P_o$  in response to a 5 min fatigue protocol was greater (30 vs. 14%,  $p < .05$ ) in SH SOL, but there was no difference in fatigue for the EDL. TTP and fatigue characteristics suggest a shift of muscle fiber type distribution from slow toward fast. Histological examination of SH soleus did not reveal a greater proportion of fast fibers than in controls. The faster SH TTP may be related to altered expression of fast and slow myosin or related to altered properties of the sarcoplasmic reticulum, characteristics that are undetectable with ATPase staining. The findings observed could be explained by altered neural drive secondary to abnormal cerebellar output. (Funding provided by NIH-AG00585 and the Program in Physical Therapy).

**PRELIMINARY STUDIES OF MOTOR UNITS IN THE SUPERFICIAL MASSETER MUSCLE IN RATS.** R. E. Druzinsky\* and L. E. Wineski. Dept. of Physiology, Northwestern Univ., Chicago, IL 60611, and Dept. of Anatomy, Morehouse Sch. Med., Atlanta, GA 30310.

Little is known about the mechanical properties of individual motor units (MUs) of jaw adductor muscles. We have begun a program to study MUs in the superficial masseter muscle in rats, using neurophysiological, enzyme histochemical, and immunocytochemical methods. Preliminary data suggest that the superficial masseter is composed largely of type IIB fibers, with smaller populations of types I, IIA, and others which we presume to be IIX/IID. All fibers exhibit positive NADH reactions, suggesting that fatigue resistance is high, even in IIB MUs. Unlike the rabbit masseter, there are no positive cardiac alpha fibers in the rat SM.

We have developed a new experimental protocol which allows stable penetrations of axons of the trigeminal nerve in rats. The rat is mounted in a stereotaxic frame and a large craniotomy is made on one side of the skull. The tendon of origin of the superficial masseter muscle is freed from the zygomatic arch and clamped in series with a load cell, and the mandible is rigidly fixed using a clamp that grasps the mandibular body. Glass micropipette electrodes filled with a solution of 3M KCl (12 - 20 MΩ) are driven into the nerve as it runs along the floor of the cranial cavity, while passing small current pulses (4-6 nA) through the electrode. Axons are identified as superficial masseter motor axons by the presence of visible contractions of the superficial masseter, by all or none twitch forces recorded at the tendon, and by unitary action potentials recorded from EMG electrodes inserted into the muscle.

Stable penetrations have been maintained for as long as 45 minutes. Preliminary studies have shown that twitch tensions of motor units with peak tensions as small as 159mg (1.6 mN) can easily be isolated in superficial masseter muscles that can generate 20 grams of twitch force. To our knowledge these are the first measurements of single MU forces measured directly from the tendon of a whole jaw adductor muscle.

Supported by NIH DE05562, NS528076, and GM08248.

RECURRENT EXCITATORY CONNECTIONS IN CA1 MINI-SLICES  
MEDIATE CARBACHOL INDUCED OSCILLATIONS A. M. Borroni\* & W.B. Levy University of Virginia Health Sciences Center, Dept. of Neurosurgery Charlottesville, VA 22908.

A prominent feature of hippocampal activity is a 4-10 Hz oscillation that requires activation of muscarinic receptors. This oscillation is referred to as rhythmic slow activity (RSA), or theta rhythm, and is generally associated with exploratory behavior but can be seen under other circumstances (Reviewed in Bland & Colom, '93). The activation of muscarinic receptors *in vitro* induces oscillations of similar frequency to those seen *in vivo*. Such experiments (Konopacki et al., '87; '92) demonstrate that entorhinal and septal inputs are not necessary for the generation of oscillations in the hippocampus. Here we report a carbachol induced oscillation (2-3 Hz) in disinhibited CA1 mini-slices. These oscillations have a similar laminar profile to theta rhythms recorded *in vivo* and are atropine sensitive. Oscillations were inhibited by CNQX but not by APV or by high concentrations of bicuculline ( $> 80 \mu\text{M}$ ). In addition, baclofen and higher concentrations of carbachol, manipulations that decrease excitatory transmission through a presynaptic mechanism, also suppressed oscillatory activity. Cell firing recorded in stratum pyramidale (SP) was associated with the negative phase of the oscillation recorded in SP. These results suggest that carbachol induced oscillations in CA1 mini-slices arise from rhythmic activation of excitatory currents at the soma and/or proximal basilar dendrites. These currents are most likely due to glutamatergic connections between CA1 cells that are suppressable by carbachol and baclofen. *In vivo*, it is likely that this intrinsic CA1 system interacts with inputs from CA3 and the entorhinal cortex to produce oscillations of higher frequency. Supported by NIH NS 15488, MH00622 to WBL and NIH 5-T32-NS07199 to AMB.

## 564.3

EXCITATORY AND INHIBITORY POSTSYNAPTIC CURRENTS EVOKED IN CA1 INTERNEURON SUBTYPES IN RAT HIPPOCAMPAL SLICES. F. Morin\*, C. Beaulieu and J.-C. Lacaille. Center for Research in Neurological Sciences and Depts. of Physiology and Pathology, Univ. of Montreal, Montreal, Canada, H3C 3J7.

Excitatory and inhibitory synaptic mechanisms in hippocampal interneurons are mediated by glutamate and GABA. The aim of the present study was to characterize pharmacologically isolated non-NMDA, NMDA, and GABA<sub>A</sub> postsynaptic currents evoked in morphologically identified pyramidal cells (PC; n=16) and subtypes of interneurons (INT; n=47) in (1) str. oriens near the alveus (O/A), (2) near str. pyramidale (PYR), and (3) at the str. radiatum and lacunosum-moleculare border (L-M), using voltage clamp recordings in hippocampal slices of young rats. Patch electrodes were filled with (in mM) 120 CH<sub>3</sub>O<sub>2</sub>SCs, 20 QX-314, 8 NaCl, 1 MgCl<sub>2</sub>, 10 HEPES, 1 EGTA, 2 ATP-tris, 0.4 GTP-tris, and biocytin (0.1%). Non-NMDA EPSCs were isolated in AP5 and bicuculline (BIC) and antagonized by CNQX. They were similar in all cell types, had linear I-V relations and reversed near 5 mV. Rise time and decay time constant of non-NMDA EPSCs were slower at depolarized membrane potentials. NMDA EPSCs, isolated in CNQX and BIC and antagonized by AP5, were generally similar in all cell types, except for a slower rise time in INT of O/A. NMDA EPSCs had a region of negative slope between -80 and -20 mV and reversed near 7 mV. They displayed faster rise time and slower decay time constant at depolarized potentials. GABA<sub>A</sub> IPSCs, isolated in AP5 and CNQX and antagonized by BIC, were similar in all cell types, with linear I-V relations and E<sub>rev</sub> of -32 mV. Rise time of GABA<sub>A</sub> IPSCs was not voltage sensitive but decay time constant was slower at depolarized potentials. In conclusion, morphologically distinct classes of interneurons and pyramidal cells display similar non-NMDA and GABA<sub>A</sub> postsynaptic currents, however the kinetics of their NMDA currents may differ, being slower in interneurons of O/A.

## 564.5

IMAGING OF Ca<sup>2+</sup> RESPONSES ELICITED BY GLUTAMATE IN CA1 INTERNEURONS OF RAT HIPPOCAMPAL SLICES. L. Carman\*, M. Ouardouz, R. Robitaille, J.-C. Lacaille. Center for Research in Neurological Sciences and Depts. of Physiology and Pediatrics, University of Montreal, Montreal (Qc), Canada H3C 3J7.

Glutamate excitation of hippocampal interneurons is mediated by ionotropic and metabotropic receptors heterogeneously expressed in different subtypes of interneurons. The aim of this study was to characterize Ca<sup>2+</sup> responses evoked by glutamate in different populations of interneurons in rat hippocampal slices (P14-17). Interneurons were loaded with the fluorescent Ca<sup>2+</sup> indicator fluo 3-AM by incubating slices for 60 minutes at 35°C in ACSF saturated with O<sub>2</sub>/CO<sub>2</sub> containing 10  $\mu\text{M}$  fluo 3-AM and 0.02% pluronic acid. Changes in fluorescence were observed using a BioRad 600 confocal microscope and expressed as percentage change from resting level. Local application of glutamate (500  $\mu\text{M}$ ) evoked responses in 75% of cells in str. oriens (OR; n=21/28) and in 83% in str. radiatum/lacunosum-moleculare (LM; n=15/18). Three types of Ca<sup>2+</sup> responses were observed. First, a transient Ca<sup>2+</sup> rise of 59.1 $\pm$ 7.7% was present in 76% of OR cells and 53% of LM cells. In 7 cells, the onset of this response was 12.0 $\pm$ 4.8 s and the duration was 24.7 $\pm$ 3.6 s. Second, an oscillatory Ca<sup>2+</sup> response was seen 24% of OR interneurons. It consisted of 3-4 peaks with an initial Ca<sup>2+</sup> rise of 107.5 $\pm$ 26.6% (onset 8.5 $\pm$ 2.6 s; total duration 174 $\pm$ 31 s; n=3). Third, a prolonged response was found in 47% of LM interneurons that consisted of an initial Ca<sup>2+</sup> peak of 118.3 $\pm$ 19.3% followed by a prolonged secondary peak (onset 26.1 $\pm$ 13.9 s; total duration 218 $\pm$ 32 s; n=2). Preliminary results show that CNQX and AP-5 reversibly blocked Ca<sup>2+</sup> responses in 4 of 11 OR cells but responses were still present in 3 cells. Responses were reversibly blocked in 2 of 5 LM cells and no responses were seen in the others. In conclusion, Ca<sup>2+</sup> responses in hippocampal interneurons may involve different mechanisms mediated by ionotropic and metabotropic glutamate receptors. These mechanisms may be selectively expressed in specific subtypes of interneurons. (Supported by the MRC, FRSC, FCAR, Sloan Foundation and Savoy Foundation)

## 564.2

COMPARISON OF INTRINSIC PROPERTIES IN DIFFERENT SUBTYPES OF CA1 INTERNEURONS USING WHOLE CELL RECORDINGS IN RAT HIPPOCAMPAL SLICES. J.-C. Lacaille\*, F. Morin and C. Beaulieu. Center for Research in Neurological Sciences and Departments of Physiology and Pathology, University of Montreal, Montreal, Canada, H3C 3J7.

Physiological classes of local circuit cells have been identified in the hippocampus of adult animals based on their distinctive intrinsic membrane properties. The aim of the present study was to compare the intrinsic properties of morphologically identified CA1 pyramidal cells (PC; n=9) and interneurons (INT; n=15) located in (1) str. oriens/alveus (O/A), (2) near str. pyramidale (PYR), and (3) at the str. radiatum and lacunosum-moleculare border (L-M), in hippocampal slices of young rats (14-22 days) using whole cell current-clamp recordings. Patch electrodes were filled with (in mM) 140 K-gluconate, 5 NaCl, 2 MgCl<sub>2</sub>, 10 HEPES, 0.5 EGTA, 2 ATP-tris, 0.4 GTP-tris, and biocytin (0.1%). Significant differences were found between properties of INT and PC, but not between INT subtypes. Action potentials were smaller in amplitude (82 mV) and shorter in duration (1.9 ms) in INT than PC (95 mV, 3.0 ms, respectively). R<sub>in</sub> was greater (236.1 M $\Omega$ ) and  $\tau_m$  faster (28.9 ms) in INT than PC (135.6 M $\Omega$ , 46.0 ms, respectively). Afterhyperpolarizations (AHPs) were biphasic but fast and medium duration components were larger in amplitude in INT (-13.2 and -5.4 mV, respectively) than in PC (-0.1 and 1.1 mV, respectively). Depolarizing current pulses evoked regular firing in all INT and burst firing in 50% of PC. During hyperpolarizing current pulses, responses in all cell types displayed inward rectification, followed by anodal break excitation. Thus, significant differences were observed with whole cell recordings between membrane properties of INT and PC. However, these membrane characteristics were similar across all INT subtypes. The maturation of distinctive membrane properties of interneurons in L-M may therefore not yet be completed in young animals.

## 564.4

UNITARY IPSCs EVOKED IN CA1 PYRAMIDAL CELLS BY ACTIVATION OF SINGLE INTERNEURONS IN RAT HIPPOCAMPAL SLICES. M. Ouardouz\* and J.-C. Lacaille. Centre de Recherche en Sciences Neurologiques et Département de Physiologie, Université de Montréal, Montréal (Qc), Canada, H3C 3J7.

Although GABAergic synaptic mechanisms are well understood in the hippocampus, little is known about the inhibition produced by individual interneurons. The aim of the present study was to characterize unitary IPSCs (uIPSCs) elicited in CA1 pyramidal cells by stimulation of single interneurons of different subtypes located in stratum (str.) oriens (OR-uIPSCs), near str. pyramidale (PYR-uIPSCs) and near str. lacunosum-moleculare (LM-uIPSCs). Specific cell types were visually identified in hippocampal slices of young rats (14-21 days) and whole cell voltage clamp recordings were obtained from pyramidal cells with K-gluconate or CH<sub>3</sub>O<sub>2</sub>SCs containing patch electrodes. Individual interneurons were stimulated (0.5-7  $\mu\text{A}$ , 1 ms) with a loose cell-attached patch electrode containing ACSF, in AP-5 and CNQX. At +20 mV, uIPSCs fluctuated in amplitude. Averaged LM-uIPSCs had significantly ( $p<0.05$ ) smaller amplitude (mean  $\pm$  sem: 39.9  $\pm$  6.9 pA, n=14), slower rise time (12.0  $\pm$  1.8 ms) and slower decay time constant (69.7  $\pm$  11.8 ms) than OR-uIPSCs (76.3  $\pm$  15.5 pA, 4.1  $\pm$  0.8 ms, 54.4  $\pm$  7.0 ms, respectively; n=14) and PYR-uIPSCs (108.6  $\pm$  17.0 pA, 4.1  $\pm$  0.8 ms, 43.4  $\pm$  3.4 ms, respectively; n=16). Mean E<sub>rev</sub> of averaged IPSCs was -53.1  $\pm$  2.1 mV with K-gluconate (n=9) and -58.5  $\pm$  2.6 mV with CH<sub>3</sub>O<sub>2</sub>SCs (n=13). uIPSCs were reversibly blocked by 25  $\mu\text{M}$  bicuculline to 2.8  $\pm$  2.1% of control amplitude (n=19: 5 LM, 6 OR and 8 PYR). uIPSCs from all cell types were enhanced by the GABA<sub>A</sub> receptor antagonist CGP55845A (5  $\mu\text{M}$ ) to 141.6  $\pm$  12.8% of control amplitude (n=10). In 9 cells examined, averaged uIPSCs did not show paired-pulse inhibition at intervals of 100 ms. These results suggest that specific subtypes of interneurons may generate Cl<sup>-</sup>-mediated GABA<sub>A</sub> IPSCs, which have different kinetics. These unitary IPSCs may be tonically modulated by GABA<sub>B</sub> receptors but may not show paired-pulse inhibition.

## 564.6

CHARACTERIZATION OF MOSSY FIBER-EVOKED RESPONSES IN THE CA3 SUBFIELD OF THE HIPPOCAMPUS, *in vivo* M.F. Yeckel\* and T.W. Berger. Dept. of Biomedical Engineering, and Program in Neuroscience, University of Southern California, Los Angeles, CA 90089-1451.

The fundamental characteristics of mossy fiber innervation of CA3 pyramidal cells has been a topic of considerable debate. To date, most investigations have used sharp electrode and whole-cell recording techniques, and have focused on identifying biophysical properties of mossy fiber activation. Despite numerous studies examining changes in presumed mossy fiber-evoked field responses, a comprehensive characterization of mossy-evoked CA3 field responses has yet to be performed. Several properties of this pathway make characterization of mossy fiber-evoked responses in CA3 difficult: i) the projection is spatially restricted, and requires precise placement of the stimulating electrode, ii) the proximity of the soma region to synaptic innervation results in a considerable overlap between synaptically generated current sinks and current sinks generated by cellular discharge, and iii) due to convergence of several synaptic inputs, isolation of mossy fiber-evoked responses has proven to be problematic. In this study, we present a series of experiments in which we address these issues and characterize mossy fiber-evoked responses in the CA3c subfield, *in vivo*.

Stimulating electrodes were placed into the hilus of the dentate gyrus of halothane-anesthetized rabbits. Criteria used to identify mossy fiber-evoked monosynaptic responses of CA3 pyramidal cells, include: 1) short-latency, orthodromic activation of unitary discharges in s. pyramidale of CA3, while antidromically exciting the dentate, 2) current-source density analyses (CSD) identifying a short-latency current sink in s. lucidum of CA3 and, 3) the induction of NMDA-independent LTP. Relevant to the debate on mossy fiber excitation, CSD data show a narrow range along CA3 pyramidal dendrites ( $\sim 100 \mu\text{m}$ ) where field responses can accurately be interpreted as monosynaptically-evoked pop. EPSPs. In general, contamination by both CA3 pop. spikes, and disynaptic excitation of CA3 via recurrent collaterals, severely limits the evaluation of CA3 field responses. ## 564.7

## USE OF A VOLTERRA FUNCTIONAL POWER SERIES TO CHARACTERIZE NONLINEARITIES IN RESPONSES OF NEURAL SYSTEMS TO PULSE TRAIN STIMULATION.

W.A. Scaringe\*, V.Z. Marmarelis, and T.W. Berger.

Dept. of Biomedical Engineering and Program in Neuroscience, University of Southern California, Los Angeles, CA 90089-1451.

Volterra (1930) developed a general functional power series (FPS) representation for dynamic nonlinear systems such that the kernels of the series have a simple and useful interpretation. For neural systems stimulated with a train of pulses, the Volterra series characterizes the dynamic nonlinearities of the system in terms of the synergistic effects of multiple pulses on the system response. The first order kernel specifies the response to a single stimulus pulse, the second order kernel specifies the change in the response due to the synergistic effects of pairs of pulses, etc. Thus, the Volterra series is a useful nonlinear system characterization tool and a useful predictive model.

In this work, we investigate the crosscorrelation technique for estimating the full waveform kernels of the Volterra series for neural systems. The procedure uses response data measured while stimulating the system with a Poisson random sequence of pulses. Krausz (1975) developed an orthogonal FPS model for this Poisson test input and showed how to estimate the kernels of the series using output-input crosscorrelations. We show that these kernels are different from the Volterra kernels in that they contain components involving any higher order nonlinearity in the system. However, the difference between the two sets of kernels only becomes significant if the system is stimulated at a high stimulus rate and the area under the higher order kernels is large. Thus, crosscorrelation is a useful method for full waveform kernel estimation. We describe practical techniques for estimating the Volterra kernels using crosscorrelation and we demonstrate these techniques using simulated data (for which the actual kernels are known) and experimental data from the rabbit hippocampus.

## HIPPOCAMPAL EVOKED POTENTIALS FROM CONTRALATERAL SCHAEFFER'S COLLATERAL STIMULATION SHOW DISCRETE ACTIVITY PATTERN IMAGES. D.M. Rector\*, G.R. Poe, M.P. Kristensen, and R.M. Harper.

Department of Anatomy and Cell Biology and the Interdepartmental Neuroscience Program, UCLA School of Medicine, Los Angeles, CA, 90095-1763.

We assessed images of reflected light from the surface of the cat dorsal hippocampus together with evoked electrical potentials to determine the spatial organization of neural activation during crossed Schaeffer's collateral stimulation. Cats were anesthetized with sodium pentobarbital, eight stimulating electrodes were inserted in the right hippocampus, and an optic probe coupled to a CCD video camera was lowered to the surface of the contralateral dorsal hippocampus. The camera detected spatial patterns of reflected light intensity through the optic probe. A bipolar electrode, attached to the anterior side of the optic probe, recorded hippocampal commissural potentials evoked by contralateral stimulation.

Evoked electrical potentials and reflected light images were digitized simultaneously, and stored continuously during 20 to 100 single biphasic pulse stimuli at 0.5ms duration, 0.1Hz, 200µA current. Stimuli were directed to each of the eight stimulating electrodes in random order. Optical and electrical responses from stimulation were averaged across trials. Stimuli elicited a complex population synaptic potential lasting 500msec. Image sequences revealed discrete regions of increased and decreased activation, which depended on the position of the stimulating electrode. Activation of the dorsal hippocampal surface shows a distinct topographical organization of contralateral Schaeffer's collateral projections.

## ELECTROPHYSIOLOGICAL CHARACTERISTICS OF MORPHOLOGICALLY-IDENTIFIED PYRAMIDAL "BASKET" CELLS OF RAT DENTATE GYRUS RECORDED IN HIPPOCAMPAL SLICES. H.E. Scharfman\*, Neurology Res. Ctr., Helen Hayes Hospital, W.Haverstraw, NY 10993, and Depts. Pharmacology &amp; Neurology, Columbia Univ., College of Physicians &amp; Surgeons, NY, NY.

Pyramidal-shaped cells located at the base of the granule cell layer are one of the most common types of inhibitory interneurons in the dentate gyrus. They are often assumed to be basket cells and play a critical role in inhibition of granule cells. However, little is known about their physiology. Therefore, membrane properties and synaptic responses were recorded from these cells, which were identified as pyramidal by intracellular injection of Neurobiotin (n=15). The morphology of these cells revealed that they are not necessarily basket cells, because a basket-like plexus was rare and axon collaterals in other layers were common. Antidromic action potentials could often be evoked by weak stimulation of the hilus or molecular layers. Membrane properties were similar to fast-spiking cells (putative interneurons) that have been described elsewhere. For example, input resistance was high (mean 95.4 megohms), time constant was short (mean 7.4 msec) and there was a large afterhyperpolarization following single action potentials. However, action potential duration was usually longer (mean 1.1 msec total duration) and spike frequency adaptation was usually stronger than classic interneurons. Responses to molecular layer stimulation evoked EPSPs primarily; IPSPs were absent or not robust. EPSPs could be surprisingly small (less than 2 mV amplitude, 30 msec duration at threshold) in light of the large dendritic tree in the molecular layer. Even when EPSPs were large, suprathreshold stimuli rarely evoked more than one action potential at resting potential. This may be one of the reasons why they are relatively resistant to prolonged perforant path stimulation. Supported by NINDS grant 30831.

## 564.8

## ANALOG VLSI IMPLEMENTATION OF A NONLINEAR MODEL OF HIPPOCAMPUS. T.W. Berger\*, B.J. Sheu, R. Tsai, and M. Saglam. Depts. of Biomedical Engineering, Electrical Engineering, Center for Neural Engineering, and Program in Neuroscience, University of Southern California, Los Angeles, CA 90089.

We have demonstrated that a nonlinear systems analytic approach can be used to develop an experimentally-based model in the form of the kernels of a functional power series of the dynamics of single neurons in the hippocampus. The kernels include the contribution of all possible sources of nonlinearities and represent the cell's response to the present input in the context of a "sliding window" of the input history. We used the kernel models of dentate granule cells and inhibitory interneurons to implement a hardware representation of the dentate gyrus. A unique hybrid analog/digital design was used which includes the following: i) the input is a series of impulses that can be arbitrarily specified, with a sample of the recent history of input events stored in a set of shift registers; ii) the kernel functions are represented in analog, using capacitors charged to different voltage levels depending on the kernel value: the first order kernel,  $h_1(t)$ , is stored as a single value; the second order kernel,  $h_2(t, \Delta)$ , is stored as an array of values; the third order kernel,  $h_3(t, \Delta_1, \Delta_2)$ , is stored as a matrix of values; iii) the charges on the capacitors are "refreshed" periodically from an off-chip source; the design maintains total independence between the refresh functions and the computation functions; iv) with each input event, an output current is generated from the  $h_1(t)$  memory cell; additional currents are generated by the subset of  $h_2(t, \Delta)$  and  $h_3(t, \Delta_1, \Delta_2)$  values addressed according to the pattern of previous input events stored in the shift registers; v) summation of the currents from the  $h_1(t)$ ,  $h_2(t, \Delta)$  and  $h_3(t, \Delta_1, \Delta_2)$  sets of memory cells determines the "neuron" output. The above design has been incorporated into a 3x3 architecture for a locally interconnected network of 9 neurons. A prototype has been fabricated through MOSIS using 2 µm technology. Supported by the ONR, NIH, and NIMH.

## 564.10

COMPARISON OF GRANULE CELL IPSPs PRODUCED BY ORTHODROMIC AND ANTIDROMIC STIMULATION OF THE DENTATE GYRUS. J.S. Fitzpatrick<sup>1</sup>, H.E. Scharfman<sup>2</sup>, and T.W. Berger<sup>2</sup>.<sup>1,2</sup>Program in Neurobiology and <sup>2</sup>Dept. of Biomedical Engineering, Univ. of Southern California, Los Angeles, CA 90089 and <sup>3</sup>Neurology Research Center, Helen Hayes Hospital, West Haverstraw, NY 10993 and Columbia University, NY, NY.

The local circuitry of the dentate gyrus contains multiple inhibitory pathways, including complex feedforward and feedback systems which terminate on granule cells, the output cells of the dentate gyrus. The two inhibitory systems may exert different effects on the activity of granule cells. We have begun a comparison of the effects of feedforward and feedback inhibition on granule cells and in our initial studies have characterized the IPSPs produced by orthodromic and antidromic stimulation of granule cells.

Simultaneous intracellular and extracellular recordings were made from granule cells in transverse hippocampal slices from rabbits. Both feedforward and feedback systems were activated by suprathereshold s. molecular stimulation. The feedback system, including pathways activated by area CA3 neurons, was activated by suprathereshold stimulation of s. lucidum of area CA3c. Stimulation of either pathway evoked biphasic IPSPs that were blocked by the GABA<sub>A</sub> antagonist bicuculline (early IPSP) and GABA<sub>B</sub> antagonist saclofen (late IPSP). Orthodromically-elicited IPSPs were always larger than antidromically-elicited IPSPs, indicating that simultaneous activation of both feedforward and feedback systems from perforant path stimulation results in greater inhibition of granule cells than activation of feedback systems alone from s. lucidum stimulation. In future studies we will dissect the components of the feedforward and feedback pathways and use nonlinear systems analysis techniques to evaluate the behavior of the pathways at different frequencies of stimulation. Supported by an NIDSEG Fellowship to JSF; grants from ONR, NIMH, NIH, and Biomedical Simulations Resource to TWB; and NINDS 30831 to HES.

## 564.12

## OLFACTORY BULB, PIRIFORM AND LATERAL ENTORHINAL PROJECTIONS TO THE HIPPOCAMPUS: A CURRENT SOURCE DENSITY STUDY. K.J. Canning\*, V.R. Heale and L.S. Leung. Dept. Physiology, Univ. Western Ontario, London, Ontario, Canada N6A 5C1.

Current source density was used to evaluate inputs to the hippocampus provided by the olfactory bulb, piriform cortex, lateral entorhinal cortex and lateral perforant path (LPP) in the urethane anesthetized rat. Field potentials were recorded at 50 µm depth intervals in tracks through CA1 and dentate gyrus (DG) of the dorsal hippocampus. Cathodal stimulation of the olfactory bulb, piriform cortex, lateral entorhinal cortex and LPP resulted in a current sink at the outer molecular layer (OML) of the dorsal blade of the DG with an onset latency of 20, 13, 7 and 4 ms respectively. Stimulation of the LPP but not olfactory bulb, piriform cortex or lateral entorhinal cortex resulted in a larger and earlier sink at the dorsal than the ventral blade of the DG. Paired pulse facilitation (PPF) (50 ms interpulse interval) at the DG was facilitated by more than 100% following olfactory bulb and piriform stimulation but only approximately 5% following LPP stimulation. LPP also resulted in a short latency (<6 ms) CA1 stratum lacunosum moleculare (SLM) sink, likely provided by excitatory currents at the distal apical dendrites of CA1. The SLM sink is independent of the OML sink because, 1) the SLM sink is later than the DG sink and 2) it has large PPF (~50%) while the OML sink has small PPF (~5%). In conclusion, it is postulated that the olfactory bulb and piriform projections to the DG OML were mediated through the lateral entorhinal cortex generating an excitatory synaptic current sink at the distal dendrites of DG granule cells (OML), and most of the PPF of inputs to the DG occurs at or prior to the entorhinal cortex. Physiological inputs from the olfactory bulb and piriform cortex probably result in equal and simultaneous involvement of the dorsal and ventral blades of the DG, even though LPP stimulation resulted in larger and earlier dorsal than ventral activation. Supported by Human Frontier Science Program.

## 564.13

## CHARACTERIZATION OF HIPPOCAMPAL INTERNEURONS INHIBITED BY OPIOID PEPTIDES

J. Brunton, L. Bernheim\* and S. Chrapak. Dept of Physiology, University Medical center, 1211 Geneva 4, Switzerland.

In the hippocampus, opioid peptides induce a disinhibition of pyramidal cells that results from a reduction in firing of unidentified inhibitory interneurons as well as from a reduction of GABA release directly at the level of the terminal. Since interneurons form a heterogeneous population, we combined the whole cell recording technique with biocytin injections to characterize the CA3 interneurons sensitive to opioids in brain slices of young rats. Of 50 cells located in the stratum lucidum and radiatum, 18 were inhibited by DAMGO (2.5  $\mu$ M), 2 by DPDPE (2.5  $\mu$ M) and none by U50469 (2.5  $\mu$ M), respective agonists for  $\mu$ ,  $\delta$  and  $\kappa$ -opioid receptors. The response to DAMGO was antagonized by CTOP and persisted in the presence of tetrodotoxin. It proved difficult to classify DAMGO sensitive cells: 8 were localized in the stratum lucidum and 7 in the stratum radiatum; most had a fusiform shape with an axis either parallel or perpendicular to the pyramidal layer; all cells presented an  $I_H$  current with variable kinetics, 2 cells presented a prominent  $I_A$  current; finally 2 cells exhibited subthreshold oscillations underlying clusters of 30-40 Hz activity. Our preliminary results suggest that opioid peptides depress the activity of a very diverse population of CA3 interneurons.

## OPEN LOOP CIRCUIT ANALYSIS OF RAT ENTORHINAL CORTEX USING CURRENT SOURCE DENSITY MEASUREMENTS OF EVOKED POTENTIALS. K. F. Ahrens\* and W. J. Freeman. Dept. of Molecular and Cell Biology, University of California, Berkeley, CA 94720.

The limbic system receives olfactory input via the lateral olfactory tract (LOT) at synapses on the apical dendrites of layer II and III pyramidal cells in the entorhinal cortex (EC). The primary input to the hippocampus, the perforant path (PP), originates in the superficial layers of the EC, as well. In order to map out the functional circuitry by which olfactory information is processed in the EC, we recorded simultaneous field potentials in anesthetized Sprague Dawley rats using a 16 channel silicon microelectrode. Using one dimensional current source density (CSD) analysis on the evoked potentials resulting from electrical stimulation of the LOT and the PP, we have observed the distribution of current sinks and sources corresponding to synaptic currents and passive return currents as a function of depth in the EC. By blocking polysynaptic activation within the entorhinal cortex with deep pentobarbital sodium anesthesia, we see only the current sources and sinks due to monosynaptic inputs. Furthermore, the elimination of recurrent excitation and inhibition yields the "open loop" state, which is useful for modeling the dynamics of olfactory-entorhinal interactions.

## SIMULTANEOUS RECORDING OF MULTIPLE CELLS IN THE MEDIAL SEPTUM OF FREELY MOVING RATS. C. King, M. Recce\* Dept. of Anatomy, University College London, Gower St., London WC1E 6BT, U.K.

Cells of the medial septum and diagonal band of Broca act as a pacemaker for the generation of the 6-8 Hz theta rhythm in the hippocampus (Bland and Bland, Br. Res. 375:102-116, 1986). These cells have been studied extensively in urethane-anesthetized animals (Alonso et al. Br. Res. 413:135-146, 1987), in which cell firing activity was found to be phase-locked to the hippocampal theta rhythm. Furthermore, reversible inactivation of activity in the medial septum leads to loss of the hippocampal theta rhythm as well as causing an increase in the number of errors made in a working memory task on a radial maze (Mizumori et al. J. Neurosci. 9:3915-3928, 1989).

We recorded from medial septal cells using chronic implantation of tetrodes, allowing the examination of multiple cells simultaneously. The rats were allowed to move freely and were trained to run from end to end of a linear track. The autocorrelation function of approximately 30% of the cells showed an 8 Hz rhythm of varying strength, and, in certain cases, these cells also demonstrated phase-locking to the hippocampal theta rhythm. The firing behaviours of these cells were similar to those found in anaesthetized rats (Alonso et al. *ibid*).

Those cells that were most clearly phase-locked with the theta rhythm also showed an increase in frequency of burst firing corresponding to an increase in the rat's running speed. Occasionally rhythmic interactions could be observed between cells recorded simultaneously, in which cross-correlation plots showed clearer oscillations over a narrow time period than the autocorrelation plots. Cells were also found whose rhythmic firing depended on the spatial orientation of the linear track and the direction of motion of the rat.

This work was supported by the Wellcome Trust and the MRC (UK).

## 564.14

## CALCIUM CURRENTS IN SAO INTERNEURONS OF THE RAT HIPPOCAMPUS. G.C.Faas\* and W.J.Wadman. Inst. for Neurobiology, Univ. of Amsterdam, 1098 SM Amsterdam, The Netherlands.

Interneurons were located in stratum Alveus / Oriens (sAO) of 225  $\mu$ m thick rat hippocampal slices using infrared microscopy. The surface of the slice was cleaned and the in-situ patch-clamp technique was used to gain voltage control over the cell. Sodium and potassium currents were blocked with the appropriate intra- and extracellular solutions. In this way isolated calcium currents were recorded as has been described before. A transient low voltage activated (LVA) calcium current was evoked by depolarization from -130 mV to -50 mV (threshold > -70 mV). Depolarization from -65 mV to -10 mV evoked a sustained high voltage activated (HVA) component, which was larger and more transient when evoked from -130 mV.

The pipette solution contained Lucifer Yellow and Biocytin which allowed a morphological identification of the patched neurons after the electrophysiological measurements. More than 18 sAO interneurons were investigated. Of this group 6 had a clear stellate morphology and 11 a polar morphology. All neurons contained the HVA calcium currents with a mean amplitude of 134 pA, but a large variation from neuron to neuron. The non-stellate cells contained a LVA current (135 pA) that was significantly larger than the LVA current in the stellate cells (38 pA).

The sAO interneurons are strategically placed in the local hippocampal network to participate in recurrent inhibition. Their excitability will in part be determined by on the types and location of calcium currents presence

## 564.16

## ACTION OF CENTRAL OXYTOCIN IN THE BED NUCLEI OF THE STRIA TERMINALIS (BST) IN THE PRE-PARTUM PERIOD AND AFTER STEROID TREATMENT. S.J. Housham, M.G. Terenzi and C.D. Ingram\*. Neuroendocrine Research Group, Department of Anatomy, University of Bristol, Bristol BS8 1TD, UK.

During lactation i.c.v. administration of oxytocin (OT) has a facilitatory effect on the bursting of hypothalamic OT neurones which is mediated via OT-sensitive neurones in the BST (Ingram et al. J. Neuroendocr. 1995: 7, 1-13). There is an increase in both the facilitatory effect of OT (Hughes et al. Neuroendocr. Lett. 1993: 15, 363-367) and the density of OT receptors in the BST (Insel, J. Neuroendocr. 1990: 2, 539-545) during the peri-partum period. This study examined the changing responses of BST neurones to central OT in the pre-partum period and their possible steroid regulation.

Studies were performed on Wistar rats on days 19 or 22 of gestation. Animals were anaesthetised (urethane 1.25 g/kg i.p.), cannulated for measurement of intramammary pressure responses to increasing doses OT i.v. (0.2, 0.5, 1.1, 2.2 ng) and prepared for electrophysiological recording. Mammary glands of day 22 animals were more sensitive to OT i.v. than those of day 19 (response to 0.5 ng: 6/6 vs. 1/6) consistent with receptor up-regulation. Responses of BST neurones in day 22 animals were also larger both in the proportion of responsive neurones (42 vs. 33%) and magnitude (mean peak  $8.4 \pm 1.1$  vs.  $6.5 \pm 1.6$  sp/s) but were characterised by a significantly delayed onset (mean onset  $14.0 \pm 0.5$  min). To investigate steroid regulation, a second group of animals underwent hysterectomy and bilateral ovariectomy on day 19 of pregnancy followed by 3 daily injections of either 10  $\mu$ g oestradiol ( $E_2$ ) or 5 mg progesterone (P). Mammary glands of all  $E_2$ -treated animals responded 2.2 ng OT but only 60% P-treated did so, although those which did respond showed no difference in sensitivity. BST cells from  $E_2$ -treated animals showed a higher baseline firing (1.9 Hz) than P-treated animals (0.8 Hz) and a higher proportion of neurones responding to 1.1 ng OT i.c.v. (55% for  $E_2$  and 25% for P), consistent with increased OT receptor expression. These data demonstrate dynamic pre-partum changes in responses of limbic neurones to i.c.v. OT and suggest the importance of the changing steroid environment for the regulation of OT receptors.

## 564.18

## TEMPORARY SUPPRESSION OF MEDIAL SEPTAL ACTIVITY GREATLY REDUCES THE ACTIVITY OF CA1 PLACE CELLS. E. Brazhnik\*, R.U. Muller and S.E. Fox. Dept. of Physiol., SUNY Health Sci. Ctr., Brooklyn, NY 11203

Septohippocampal neurons have well known influences on hippocampal activity. We sought to clarify such influences on the spatial firing properties of pyramids (place cells) and theta-related firing of interneurons (theta cells).

Preliminary results of tetracaine inactivations of MS/DB done as rats chased food pellets in a 76 cm dia. cylinder indicate that the location-specific firing of CA1 place cells is greatly reduced. In 16 min sessions shortly after tetracaine injections (1  $\mu$ l, 2%), the average in-field and overall firing rate of 19 cells decreased by about 80%; some cells ceased firing for large parts of the session. The effect on firing rate is considerably greater than reported by Mizumori et al. (J. Neurosci. 9: 3915-3928, 1989) for CA1 place cells but comparable to what they reported for CA3c/hilar place cells. Mizumori et al. also reported that positional firing specificity was preserved for CA1 units. We observed residual firing within the region of the field, but the rate was usually too low to conclude that spatial specificity was preserved.

To help test if tetracaine acts by suppressing discharge of MS/NB neurons or fibers of passage, injections of the GABA-A agonist muscimol (0.1-0.3 mg) were made into MS/DB. Muscimol reduced the in-field firing rate of 15 CA1 place cells by about 90%; overall rate was also reduced. Muscimol action persisted for more than 3 hr whereas firing rates mostly recovered 30 min after tetracaine. The result suggests that profound reduction of place cell discharge can occur when only the input from MS/NB neurons is decreased; additional effects of tetracaine on fibers of passage are not necessary to explain the effect.

Both muscimol and tetracaine abolished theta rhythm recorded at the fissure and reduced the firing rates of theta cells (interneurons). The recovery of location-specific firing followed the same time course as the recovery of theta rhythm, corroborating the notion that activity of MS/DB neurons plays a critical role for both hippocampal EEG and place cell activity. (Supported by NIH NS 17095 and NS 20686.)

## 564.19

THE ANTIDEPRESSANT EFFECT ON DEGENERATIVE PROCESS IN THE SUPRAOPTICAL AND PARAVENTRICULAR HYPOTHALAMIC NUCLEI INDUCED BY BILATERAL OLFACTORY BULB ABLATION IN C57BL/6J MICE. N.V. Bobkova, I.V. Nesterova, E.V. Gurevich, I. Aleksandrova, N.A. Otmakhova, Int. of Cell Biophysics, 142292 Pushchino, Moscow Region, Russia

Bilateral bulbectomy in rats and mice induces behavioral, hormonal, a neurochemical changes, counteracted by chronic antidepressant treatment. In this study we examined morphological changes in the neurosecretory neurons in the supraoptical (SO) and paraventricular (PV) nuclei of the hypothalamus resulted from bulbectomy in C57BL/6j mice. SO and PV are known to receive projections from the raphe nuclei and locus coeruleus as well as from the olfactory bulbs. The brains (28 days after surgery) were fixed and embedded in paraffin. Serial 5µm sections were stained according to Gomory-Gabou method and counterstained by Gaidengainu method. 1000 cells were counted in each mouse in each nucleus. Bulbectomy caused increase in the number of picnomorphic cells (4.5 times in SO and 3 times in PV,  $p=0.001$ ), while the proportion of normal neurons decreased by 45.6 and 60%, respectively. The proportion of neurons with low secretory activity increased 2.5 times in SO and 5.5 times in PV. Antidepressant trazodone (20 mg/kg, for 14 days starting 14 days after surgery) counteracted the degenerative process in both nuclei. Bulbectomized mice treated with trazodone did not differ from sham-operated mice in the proportion of picnomorphic and normal neurons in either nucleus. However, the proportion of the neurons with decreased secretory activity was higher in both nuclei in the trazodone-treated mice comparing to sham-operated control. The same treatment with amitriptyline counteracted the effect of bulbectomy in SO only. Trazodone is a 5-HT<sub>2</sub> receptor antagonist and has been shown to down-regulate 5-HT<sub>2</sub> serotonin receptors increased by bulbectomy as well as alleviate degenerative process in the dorsal raphe nucleus induced by bulbectomy. It seems possible that trazodone counteracts bulbectomy-induced degeneration by preserving serotonergic input into both nuclei.

## 564.20

SLEEP, MONOAMINES, AND EFFECT OF IMIPRAMINE (Imip) ON MOTOR ACTIVITY IN OLFACTORY BULBECTOMIZED RATS. H.H. Webster<sup>1</sup>, K.M. Dewar<sup>1\*</sup>, R. Godbout<sup>1</sup>, D. Perry<sup>1</sup>, and M. Vézina<sup>2</sup>. Depts. Psychiat.<sup>1</sup> & Pharmacol.<sup>2</sup> Univ. of Montréal, (Qué) Canada H3C 3J7.

Altered behavioral and physiological characteristics in rats following bilateral olfactory bulb ablation (OBX) are known collectively as the OBX syndrome, which is analogous to depression in humans. In the present study we investigated the effect of OBX on paradoxical sleep (PS) latency and on levels of serotonin (5-HT), noradrenaline (NA), dopamine (DA), and of their metabolites in the raphe, hippocampus and amygdala. Motor activity before and after imipramine was also investigated. Sleep was recorded for periods of 24 h using EEG, EMG and eye movements before and weekly up to 56 days postOBX (lights on from 6am. to 6pm). Analysis of baseline and postOBX day 21 data for 3 rats showed that PS latency was reduced by 36% from 4am to 4pm. HPLC analysis showed that 5-HT was decreased in the hippocampus on postOBX day 21. NA declined in the raphe on day 21 and in the amygdala on days 14 and 21. 5-HIAA was increased in the raphe on days 14 and 21 and in the hippocampus on days 7, 14, and 21; and decreased in the amygdala on day 7. No change was found in DA, DOPAC, or HVA. Imip administration in 10 rats (5mg/kg/day s.c.) with minipumps began 7 days post-OBX and lasted 21 days. Compared to untreated sham-operated rats, motor activity was increased both in untreated OBX rats and in OBX rats treated subchronically (<14 days) with Imip. Motor activity in OBX rats treated chronically (> 14 days) with Imip was normalized to the level of untreated sham-operated rats. We conclude that a reduced PS latency is part of the OBX syndrome, that MAs are affected in specific ways in some structures, and that hyperactivity responds to chronic but not acute Imip. Supported by MRC Canada and CAFIR, Univ. Montréal.

## LEARNING AND MEMORY: SYSTEMS AND FUNCTIONS VII

## 565.1

COMPARISON OF MOTOR SKILL LEARNING IN ELDERLY AND YOUNG HUMAN SUBJECTS. D. B. Willingham<sup>\*</sup>, and E. Winter. Dept. Psychology, Univ. of Virginia, Charlottesville, VA 22903. Elsewhere we have suggested that different types of motor skill learning are subserved by different neural circuits: specifically, motor sequencing by the basal ganglia and supplementary motor area, and learning new perceptual-motor mappings by the cerebellum, parietal cortex and premotor cortex. Because these areas are not implicated in normal aging, we predicted healthy elderly subjects should not be impaired in these types of motor skill learning tasks. Healthy elderly subjects (mean = 76 years) and young subjects (mean = 20 years) were compared on two sequence-learning tasks and two perceptual-motor mapping tasks. The sequencing tasks included the serial response time (RT) task, in which a repeating sequence is embedded in a four-choice RT task and a stepping-stone maze in which subjects responded using a button board. Previous work has shown that part of the learning is sequence-specific. The perceptual-motor mapping tasks were a four-choice RT task in which subjects must learn a new mapping between stimuli and responses (press one key to the right) and; the stepping-stone maze task, but subjects responded with a mouse. Previous work has shown that in this task subjects primarily learn the mapping between cursor movement and mouse movement. As predicted, elderly subjects showed learning equivalent to that of young subjects on all tasks.

## 565.2

NETWORK ANALYSIS OF RECOGNITION OF FAMILIAR AND NOVEL PICTURES. R. Cabeza<sup>\*</sup>, A. R. McIntosh, E. Tulving. Rotman Research Institute, North York, ONT M6A 2E1.

In Tulving et al. (Neuroreport, 1994, 5, 2525-2528), subjects saw colored pictures of scenes and landscapes, and 24 hr later they distinguished between seen and unseen pictures, while undergoing rCBF PET scans. During the scan window, pictures were all familiar (OLD scans) or all novel (NEW scans). Familiarity activations (OLD-NEW) were found in the prefrontal cortex and anterior cingulate, whereas novelty activations (NEW-OLD) were observed on the right hippocampal gyrus, medial prefrontal and orbitofrontal, and left temporoccipital cortex.

Network analysis (McIntosh AR, Gonzalez-Lima F. Human Brain Mapp., 1994, 2: 2-22) of these data yielded an elaborate pattern of interactions involving a number of brain regions. In both OLD and NEW scans, activity in prefrontal areas was positively correlated with activity in temporal and cingulate areas, and negatively correlated with activity in occipital and hippocampal areas. We interpret this pattern to reflect a functional network involved in recognition attempt, irrespective of the familiarity of the stimuli. The main difference between OLD and NEW conditions was a negative correlation, stronger in the NEW than in the OLD condition, between hippocampus and contralateral prefrontal cortex, especially between the left hippocampus and right prefrontal. We interpret this correlation to reflect an opposing relation between the left hippocampus and right prefrontal cortex for novel items, an idea consistent with the assumed role of this latter area in retrieval of familiar items (Tulving et al., Proc. Natl. Acad. Sci. USA, 1994, 91, 2016-2020).

## 565.3

PET, MULTIVARIATE STATISTICS, AND THE NEURAL SYSTEMS INVOLVED IN IMPLICIT AND EXPLICIT MEMORY FOR VISUAL OBJECTS. K. Chen, A. Uecker, P. Jones, E. Reiman, L. Yun, D. Schacter, L. Cooper, and R. Lansing<sup>\*</sup>. ARL Division of Neural Systems, Memory and Aging and the Dept. of Psychiatry, Univ. of Arizona; Dept. of Psychology, Harvard Univ.; Dept. of Psychology, Columbia Univ., and the Samaritan PET Center, Good Samaritan Regional Medical Center, Phoenix, AZ, USA.

Positron emission tomography (PET), <sup>15</sup>O-water, and the Statistical Parametric Mapping (SPM) were used to characterize regions of the brain that participate in implicit memory, explicit memory, and the structural representation of visual objects.

In contrast to object decisions about previously studied structurally impossible objects, object decisions about previously studied structurally possible objects were associated with priming, postulated blood flow increases in the vicinity of inferior temporal and fusiform gyri, and blood flow increases in several other regions. In contrast to recognition decisions about previously studied structurally impossible objects, recognition decisions about previously studied structurally possible object were associated with better recognition memory, a postulated blood flow increase in the vicinity of the right hippocampal formation, and blood flow increases in several other regions.

Four multivariate statistical techniques (principal components analysis, multidimensional scaling, cluster analysis, and structural equations modeling) were used post hoc to investigate interactions among the implicated brain regions, consider the potentially complementary role of multivariate statistics in the analysis of brain mapping studies, and provide a better understanding of the neural systems involved in implicit and explicit memory for visual objects. Supported by the Flinn Foundation.

## 565.4

NEUROANATOMICAL CORRELATES OF VISUAL WORD RECOGNITION. R. Habib<sup>\*</sup>, L. Nyberg, E. Tulving, R. Cabeza, L.-G. Nilsson, S. Kapur, S. Houle, and A. R. McIntosh. Rotman Research Institute of Baycrest Centre, 3560 Bathurst Street, North York Ont, Canada. M6A 2E1.

Brain regions involved in episodic memory retrieval (visual word recognition) were studied using positron emission tomography. Prior to scanning, subjects were auditorily presented with two lists of words. In one list, the subjects' attention was focused on verbal, semantic aspects of the stimuli; in the other on nonverbal, nonsemantic aspects. Each subject underwent 8 scans; 2 word reading scans and 6 recognition scans (in 2 recognition scans, nonstudied words were shown; in another 2, words from the nonsemantic encoding condition, and in still another 2, words from the semantic encoding condition).

A region in the right prefrontal cortex was significantly activated during word recognition compared to word reading. Activation patterns across the recognition conditions showed that a high memory performance (following semantic processing) was associated with increased activation in the left middle/superior temporal gyrus. Retrieval following semantic processing involved increased activation in the left prefrontal cortex. Retrieval following nonsemantic processing was associated with increased activation in regions in the right hemisphere, including the parahippocampal gyrus.

It is concluded that activation in the right prefrontal cortex during episodic retrieval is independent of retrieval success and that it may be related to effortful search processes implicated in episodic retrieval attempt. Moreover, it is suggested that retrieval of information partly activates brain regions engaged during the acquisition of the same information.

## 565.5

DIFFERENT ASPECTS OF WORKING MEMORY SHOW SELECTIVE CHANGES WITH AGE. A. Wingfield\*, K.C. Lindfield, P.A. Tun, K.S. Richards, & M.J. Rosen. Department of Psychology and Vollen National Center for Complex Systems, Brandeis University, Waltham, MA 02254.

Working memory is usually defined as involving components of memory storage and processing of information, operating in a limited work space (Baddeley, 1986). However, the ways in which working memory have been defined operationally in the neuroscience literature have been varied. In this experiment we tested a battery of measures believed to involve important aspects of working memory (Carpenter, Miyake, & Just, 1994). These included: (1) holding and storage capacity (as measured by simple memory span tests that require only passive storage of words or digits), (2) computational work space (as measured by span tests that require both storage and manipulation of information), (3) processing speed (as measured by a speeded test requiring transposition of digits and symbols), and (4) inhibitory processes (as measured by a modified version of the Stroop color-word test).

In this study we probed the contribution of these various aspects of working memory by comparing young adults with elderly adults, who are often selectively compromised in certain cognitive capacities. Twenty young (mean age = 18.8 years) and 20 elderly (mean age = 72.4 years) normal functioning adults participated in the battery of tests. Results showed larger age differences for tests tapping computational space and speeded processes than for those measuring simple memory storage. This dissociation stresses the importance of a careful specification of the features of working memory being examined from one experiment to another.

## 565.7

CEREBRAL ACTIVATION BY A WORKING MEMORY TASK: A HUMAN FMRI STUDY. A.S. Bloom\*, S.M. Rao, J.A. Bobholz, T.A. Hammeke, S.A. Fuller, J.R. Binder, R.C. Cox, J. Pankiewicz, H.H. Harsch, J.-K. Cho, M. Rossing and E.A. Stein. Departments of Pharmacology, Psychiatry, Neurology and Biophysics Research Institute, Medical College of Wisconsin, Milwaukee, WI 53226.

Brain systems involved in human working memory are not well described. A recent PET study by Jonides et al. (1993) reported that a visuospatial working memory task activated right frontal, parietal, occipital and premotor cortex. We have used a very similar task in a whole-brain functional MRI study. While undergoing FMRI, young right-handed subjects were presented with spatial working memory and perceptual control tasks. Imaging was conducted using a 1.5T GE Signa scanner equipped with a 3-axis local gradient coil and an endcapped quadrature birdcage RF coil, using a blipped gradient-echo echo-planar pulse sequence. Sixteen contiguous 7 mm sagittal slices covering the entire brain were collected with a TR=4 s producing 64 images per series. Functional images were generated for each slice using a cross-correlational method then warped into stereotaxic space. Activation by the perceptual control task was subtracted from that produced by the working memory task. The results of this study are in good agreement with the PET study of Jonides. Both studies observed activation in the right prefrontal and occipital cortex and bilateral activation in superior parietal and premotor regions. In addition, we observed activation in right thalamus, left anterior cingulate and bilateral insular regions. The results of this study demonstrate that multiple brain systems subserve working memory in humans and that whole-brain FMRI is an effective method for the investigation of these systems. (Supported by DA09465.)

## 565.9

RIGHT PREFRONTAL PET ACTIVATION DURING SEMANTIC MONITORING A.K. MacLeod\*, R.L. Buckner, S.E. Petersen, and M.E. Raichle. Washington Univ. Sch. of Med., Box 8225, St. Louis, MO 63110.

Areas of the normal human brain used for semantic monitoring were identified using positron emission tomography (PET). For a series of tasks, subjects (N=12) viewed a list of animal names and decided whether the names represented "dangerous" animals. Surface characteristics of the task such as stimulus rate, number of targets, and mode of monitoring were varied across multiple conditions within- and between-subjects. Common to all of these conditions was the semantic monitoring requirement. A passive word viewing condition was used as the control. A subset of these data has been previously analyzed in a limited fashion and revealed activation in left prefrontal cortex, anterior cingulate, and visual extrastriate cortex (Petersen 1989, *J. Cog Neuro.*; 1993 in *Brain Mechanisms of Perception and Memory*, Oxford). In the current analysis, more subjects were included and the entire brain was surveyed for activation. Using a replication approach, reliable activations were identified in anterior and dorsal right prefrontal cortex (mean x,y,z = 25,57,10 and 11,35,46 both p<.01). The locations of these areas are similar to areas that have been activated during several memory recall tasks (Buckner 1995 *J. Neurosci.*; companion abstract). Importantly, the right prefrontal activations in the current experiment demonstrate that participation of these areas is not limited to recall of recently learned information or for information associated with a unique temporal event (episodic memory retrieval). Perhaps these areas of right prefrontal cortex facilitate the maintenance of a task dependent context, or template, for matching. During episodic memory retrieval tasks, the context is supplied by the specific source in which the information was learned. In the present experiment, the context is semantic information about characteristics and qualities of dangerous animals.

## 565.6

WHERE IS WORKING MEMORY WORKING? C.M. Cowey, C. Polkey\*, B. Meldrum\*, R. Morris. Institute of Psychiatry, University of London, U.K. \*Maudsley Hospital, London, U.K.

The aim of this study is to demonstrate the neuro-anatomical substrate of the Central Executive: a component of a theoretical cognitive model of short-term memory: Working Memory. The Central Executive allocates attentional capacity to "slave-systems" which process visual and verbal material in the execution of short-term memory tasks. A dissociation between attentional capacity for single, and that for dual-tasks has been demonstrated in work involving patients with Alzheimer's disease, with dual-task performance selectively declining as a function of the progression of the disease. From this exploration a suggested frontal lobe site for the division of attention has emerged. The present study tested this hypothesis with an investigation of patients with highly localised neural atrophy. Individuals with epilepsy and either lesions of the frontal lobe or hippocampus were required to perform tests of attention and memory, in single and concurrent trials. Subjects tracked a moving target across a touch-sensitive computer screen. Against this baseline a second task was introduced. Preliminary results suggest that individuals with frontal lobe lesions display the greatest decrement over single and concurrent trials. It is argued that this Janusian ability is mediated by the frontal lobes.

## 565.8

PET STUDIES OF THE RECALL OF PICTURES AND WORDS FROM MEMORY R.L. Buckner\*, M.E. Raichle, E.M. Miezin, and S.E. Petersen. Washington Univ. Sch. of Med., Box 8111, St. Louis, MO 63110.

Recent neuroimaging studies have demonstrated activation in areas of prefrontal cortex during memory retrieval (Buckner and Tulving, 1995 *Handbook of Neuropsychology*, Elsevier). Two new PET studies were conducted to determine if, during the retrieval of pictorial information, prefrontal brain areas would again be activated in addition to brain areas related to picture processing. In study one, 10 subjects were scanned during the naming and viewing of pictures. Compared to analogous conditions using word stimuli, visual areas were activated including a right fusiform area that has been previously observed during face processing and attention to stimulus shape (Haxby 1994, Corbetta 1991 both *J. Neurosci.*). In study two, 14 subjects learned picture-word and word-word pairs before PET scans. During PET scans, subjects either recalled the names (labels) of the pictures or the words. For both conditions, recall was auditorily cued with word members of the pairs. There was no differential activation between picture and auditory recall for any of the visual areas activated during picture processing (study one). Moreover, comparison of picture recall to another task (auditory word repetition) also did not reveal differential activity in visual cortex. However, robust activations in frontal cortex were reliably observed in both the picture and auditory recall conditions as compared to repetition. These frontal activations were in bilateral anterior insular cortex and in anterior right prefrontal cortex. Medial and lateral parietal, anterior cingulate, SMA, and cerebellum were also activated. PET-MRI coregistration was used to localize the responses within several of the individual subjects. The right prefrontal activations were closely localized (mean x,y,z = 27,49,16) to similar areas activated during the stem-cued recall of words (32,50,6; Buckner 1995 *J. Neurosci.*).

## 565.10

GENERALIZATION OF PRACTICE-RELATED EFFECTS IN MOTOR LEARNING USING THE DOMINANT AND NON-DOMINANT HAND MEASURED BY PET. H. van Mier\*, L.W. Tempel, J.S. Perlmutter, M.E. Raichle and S.E. Petersen. Washington Univ. Sch. of Med., Box 8111, St. Louis, MO 63110.

Using PET, functional effects of practice on motor performance have been examined in 32 normal right handed subjects. In a study presented last year 16 subjects practiced moving a pen with their dominant right hand continuously in a clockwise direction through a cut-out maze and square pattern as fast and accurately as possible with their eyes closed. Several control conditions were used to distinguish practice related from motor performance changes (e.g. changes in movement velocity). Some areas, including left primary motor cortex, showed changes in activation which could be attributed to motor performance. Decreases in activity attributable to practice were found in right premotor and parietal areas, cingulate cortex and left cerebellum, while practice-related increases were found in supplementary motor area (SMA).

Because of the surprising lateralization of the practice-related effects, a second group of 16 normal right handed subjects was scanned while performing the same tasks, but using the non-dominant left hand. As would be expected areas relating directly to motor performance shifted lateralization (e.g., primary motor cortex activity was now seen in the right hemisphere). The practice-related changes, however, were seen in the same hemisphere and areas as those found with right hand performance (e.g. right premotor and parietal regions and left cerebellum). These results clearly suggest that processes related to this motor learning task activate right cortical and left cerebellar areas independent from the hand used, and thus must be coding information abstract from the motor performance of the task itself.

## 565.11

FUNCTIONAL MRI OF THE PREFRONTAL CORTEX DURING SEMANTIC ENCODING. A.M. Golub<sup>1</sup>\*, P. Erhard<sup>2</sup>, J.P. Strupp<sup>2</sup>, P. Andersen<sup>2</sup>, G. Adriany<sup>2</sup>, X. Hu<sup>2</sup>, K. Ugurbil<sup>2</sup>. Department of Psychology, California State University, Sacramento, CA 95864<sup>1</sup> and Center for Magnetic Resonance Research, University of Minnesota Medical School, Minneapolis, MN 55455<sup>2</sup>.

The left prefrontal cortex has been implicated in memory and attention. We used functional MRI to investigate neuroanatomical correlates of the depth of processing effect. Our goal was to replicate and extend, using fMRI at 4 Tesla, recent PET reports of left inferior prefrontal cortex activation during a semantic information processing task. Seven normal volunteer subjects viewed two types of word lists in an ABABA design. Subjects made non-semantic judgments (Task A) or semantic judgments (Task B). Each word was presented only once and subjects indicated a yes/no decision by pressing one of two buttons on a joystick. Experiments were conducted on a 4 Tesla SISCO/Siemens system using a quadrature birdcage coil and a head gradient set (30 mT/m). Following acquisition of anatomic images, a total of 160 consecutive multislice (12 slices) T2\* weighted EPI images were acquired with a 64x64 matrix, a FOV of 20x20cm and a slice thickness of 10 mm. Both hemispheres were covered (A-a-1 to A-d-10 to F/G-a-1 to F/G-d-10 in Talairach coordinates). Data were zero padded to 128x128 before Fourier transformation. The delay due to hemodynamic response was estimated by searching for the maximal cross correlation with a sliding reference function and was used to define two t-tests, which compared each activation period with both neighboring periods, i.e., with each ABA. Only pixels significant on both t-tests ( $p = 0.001$ ) and part of an activated cluster of at least 16 pixels were used for the activation time course. Significant activation was observed in the left prefrontal cortex in Brodmann's areas 10, 9, 45 and possibly 11. These activations are consistent with other recent fMRI reports and with PET findings and may reflect a hemispheric encoding asymmetry, activation of novelty detectors, or an asymmetry in prefrontal cortex activation associated with other aspects of the task. Supported by NIH Grant RR08079 and a CSUS SFS grant.

## 565.13

RETRIEVAL OF REMOTE KNOWLEDGE VERSUS LEARNING OF NEW KNOWLEDGE: PET EVIDENCE FOR DISTINCT NEURAL SYSTEMS. R.D. Jones\*, T. Grabowski, D. Tranel. Dept. of Neurology, Division of Cog. Neuroscience, Univ. of Iowa College of Medicine, Iowa City, IA 52242 USA

Lesion studies have suggested that retrieval of old, factual, concrete knowledge and learning of new, factual, concrete knowledge depend on distinct systems in temporal lobe. Here we report a positron emission tomography (PET) study which supports this notion.

A right-handed 70 year old woman with limbic encephalitis caused by thymoma was evaluated four months after diagnosis. Severe multimodal anterograde and retrograde memory defects were found. An (18F) fluorodeoxyglucose (FDG) PET scan showed thalamic and diffuse cortical, but especially bilateral mesial and right anterolateral temporal hypometabolism. Two years later there was marked resolution of the remote memory defect, with persistent anterograde memory impairment. Retrieval of nonunique knowledge and other neuropsychological functions were normal. A second FDG PET then showed increased metabolism in the thalamus and most cortical regions, including the lateral right temporal lobe. Metabolism in the right temporal pole and orbital cortex were unimproved, whereas metabolism in the left temporal pole and in both mesial temporal regions declined markedly. Recovery of retrograde memory occurred despite reduction in mesial temporal metabolism. These findings provide further support for the implication of non-mesial temporal lobe structures in the retrieval of remote factual knowledge.

BRAIN MECHANISMS IN HUMAN CLASSICAL CONDITIONING: A PET BLOOD-FLOW STUDY.

Kenneth Hugdahl<sup>1</sup>, Anna Berardi<sup>2</sup>, William L. Thompson<sup>2</sup>, Stephen M. Kosslyn<sup>3</sup>, Robert Macy<sup>2</sup>, David P. Baker<sup>2</sup>, Nathaniel M. Alpert<sup>1</sup>, and Joseph E. LeDoux<sup>4</sup>. <sup>1</sup>Department of Biological and Medical Psychology, University of Bergen, Norway <sup>2</sup>Department of Psychology, Harvard University, Cambridge, MA. <sup>3</sup>Department of Radiology, Massachusetts General Hospital, Boston, MA. <sup>4</sup>Center for Neural Science, New York University, New York, N.Y. (SPON: European Brain and Behaviour Society).

Five healthy male subjects participated in a classical conditioning experiment, and positron emission tomography (PET) was used to compare regional cerebral blood flow before and after conditioning. The subjects participated in three different experimental phases. In the first (habituation) phase they listened to 24 repetitions of a tone with random intervals. In the second (acquisition) phase, the tone was paired with a brief shock to the hand whenever it occurred. In the third (extinction) phase, the tone was presented alone again. 15-O PET scans were taken during the habituation and extinction phases. Because the habituation and extinction phases were identical, any difference in blood flow to the tones presented during extinction should be due to conditioning that occurred during the acquisition phase. Statistical parametric mapping (SPM) analysis of the PET data showed increased activation in frontal and temporal regions of the brain during extinction, particularly in the right hemisphere. The results are interpreted as evidence for the involvement of cortical areas in human classical conditioning.

## 565.12

AN FMRI ANALYSIS OF MEDIAL TEMPORAL LOBE ACTIVATION IN MEMORY ENCODING. M.P. McAndrews\*, S. Taylor, A.P. Crawley, M. Wood and D.J. Mikulis. The Toronto Hospital, Western Division, Toronto, Ontario, M5T 2S8, Canada.

Several recent studies using PET and fMRI have shown activation of medial temporal structures in memory tasks during the presentation of novel stimuli in comparison with previously studied or more familiar stimuli. The present research examined the difference in activation patterns to visual presentation of orthographically regular non-words (Study 1) and word pairs (Study 2). In the novel conditions, a unique stimulus was presented for study at the rate of 1 per second (non-words) or 1 per 2 seconds (word pairs). In the familiar conditions, a small set of items that had been studied prior to scanning were presented repeatedly throughout image acquisition at the same rates as novel stimuli. Six young volunteers were scanned using a conventional 1.5 Tesla magnet (gradient echo, 256x128 matrix, TE=40, TR=68, FOV=48). Functional images comprised a single 4 mm oblique axial slice, oriented through the longitudinal axis of the body of the hippocampus. For each subject, a statistical t-map was generated by comparing activation in the novel versus familiar conditions.

Results for the non-word task indicated small (1-3%) but significant activation in the posterior medial temporal lobe regions in all subjects. This effect was considerably weaker, appearing in only 3 of 6 subjects, for the word pair task. We are currently collecting three-dimensional isotropic voxel scans to permit more precise anatomical localization of the activated regions in a new group of subjects. These findings are consistent with other data indicating the activation of the hippocampal formation in response to novelty, presumably reflecting the operations involved in encoding new information in memory.

## 565.14

NEURAL REPRESENTATIONS FOR CONCRETE, ABSTRACT, AND EMOTIONAL WORD LEXICA: A POSITRON EMISSION TOMOGRAPHY STUDY.

M. Beauregard\*, H. Chertkow, S. Murtha, R. Dixon, A. Evans. Centre Hospitalier Côte-des-Neiges; Lady Davis Institute, Jewish General Hospital; Montreal Neurological Institute, Montréal.

Evidence from cognitive neuropsychology suggests that there is a permanent representation for the visual form of known words in the brain. Neuropsychological and functional imaging studies have suggested that this representation, termed the orthographic lexicon, is localized either in the left occipital lobe or, alternatively, in the left temporal lobe. In order to localize the brain regions involved in the representations for concrete, abstract, and emotional word lexica, we have carried out a H<sub>2</sub><sup>15</sup>O PET study on 10 normal right-handed male subjects whose age ranged between 18 and 28 years. A series of scans were performed during different cognitive tasks. In each of the conditions, subjects were told to simply relax and passively look at the material presented on the screen, either flashing Plus Signs (baseline), random letters, concrete words, abstract words, or emotionally-laden words. Results were analyzed for the following subtraction pairs: Random letters minus Plus Sign baseline; Concrete words minus Plus Sign baseline; Abstract words minus Plus Sign baseline; and Emotional words minus Plus Sign baseline. Each of these last three subtractions produced peaks of significantly increased cerebral blood flow (CBF) in the left inferior and middle temporal gyri, and in the left (and right occipital lobe, for Abstract and Emotional words) occipital lobe. In addition, the Emotional minus Plus Sign baseline subtraction produced peaks of increased CBF in the left orbital frontal region and in the midline superior frontal gyrus area. These results suggest that the left temporal lobe region is involved in the neuroanatomic substrate for the orthographic lexicon and that additional regions of the frontal cortex are implicated in the processing of affective information.

## 565.16

LONG-TERM RETENTION OF EYELID CONDITIONING AND SKILL ACQUISITION IN AMNESIA. J. Daum, M. M. Schugens, F. M. Eblen\* and N. Birbaumer. Institute of Medical Psychology and Department of Neurology, University of Tübingen, 72074 Tübingen, Germany.

Nondeclarative learning, as indicated by classical conditioning or skill acquisition, has been shown to be intact in amnesia, but so far little is known about the long-term retention of these abilities across weeks or months. In the present study, classical eyelid conditioning (tone-airpuff pairings) and tracking performance were assessed in a baseline session, 10 days and 2 months after initial learning in patients with an amnesic syndrome and matched control subjects.

Amnesic patients acquired classically conditioned eyelid responses as readily as control subjects and showed significant savings at both intervals testing retention. The amount of savings was similar to that of controls. None of the patients remembered the previous testing sessions or recognized equipment or stimuli. Despite a lack of awareness of stimulus contingencies, amnesic patients showed significant cortical negativities in the interval between conditioned and unconditioned stimulus. In the motor skill acquisition task the amnesic patients also showed significant learning and savings of the acquired skill over the 10 day and 2 month intervals, without remembering any previous experience with the task.

In summary, the results indicate that amnesic patients are able to retain newly learned motor behavior over an extended period of time to a degree similar to control subjects. It is interesting to note that although EEG recordings indicate cortical processing of stimulus contingencies in the conditioning task, amnesic patients fail to become aware of them.

## 565.17

TEMPORAL FACTORS IN MEMORY FOR NONOBJECTIVE IMAGES VERSUS WORDS. Andreas E. Savakis, Robert W. Doty\* and Ruiming Fei, Department of Physiology, University of Rochester School of Medicine, Rochester, New York 14642.

From among several hundred multicolored, abstract, nonverbalizable images and over 1100 four-letter, nonoffensive words, test items were chosen at random. In 5 sessions, 3 for images and 2 for words, at weekly intervals, 8 subjects were shown 240 targets on a computer monitor and were asked to identify rapidly and accurately whether a target was being presented for the first time, "new", or was a repetition, "old". Repetitions occurred after 1, 2, 4, 8, 16, or 32 presentations, randomly placed throughout a session. In session 1, images were viewed for 2 sec each, with a 3-sec intertrial interval; while for session 2, with different images, viewing time was 200 msec followed by a 2-sec colored mask. For the 3rd week, 60 randomly selected images each from weeks 1 and 2 were "old" to be discriminated from 120 entirely "new" images, with 2-sec viewing time. In week 4, words were displayed for 200 msec, followed by the 2-sec mask; and in week 5, "old" words from week 4 were to be distinguished from "new" words. In week 1 recognition was 81.8% ( $d' = 1.82$ ) vs 73.5% ( $d' = 1.26$ ) for week 2; while week 4 (words) was at 93.6% ( $d' = 2.97$ ). Long-term memory was strikingly different: 65.2% ( $d' = 0.65$ ) for week-1 images, twice viewed for 2 sec 2 weeks earlier, vs 55% ( $d' = 0.39$ ) for 200-msec views a week previously; and 67% ( $d' = 0.89$ ) for words after 1 week. Reaction times (RTs) were shorter for shorter exposures, averaging 850 and 800 msec for weeks 2 and 4, vs 1 sec in week 1; and were relatively flat throughout a session. However, RT consistently incremented, and accuracy decremented, as a function of number of intervening images yet, surprisingly, showed no significant indication of interference from the inevitably increasing mnemonic load as the session progressed. Thus, a linkage of specific image or word pairs can be deduced, such that it takes longer to identify a previously perceived item the longer it has been in memory. Whether this is purely an effect of time (unlikely given weeks 3 and 5), or a mixture of time and interference, remains a puzzle.

## 565.19

LEARNING OF VISUOMOTOR COORDINATION WITH ROTATED VISUAL FEEDBACK E.A. Kagerer\*, J. Bloedel\*, G. Stelmach, Motor Control Lab, Arizona State University, Tempe AZ, 85287-0404 \*Barrow Neurological Institute, Phoenix, AZ 85013

The purpose of this experiment was to investigate learning and transfer in a point-to-point aiming task. The task required subjects to make horizontal movements to three target locations on a digitizer board that were also displayed on a monitor. The visual feedback displayed on the monitor was either normal or rotated by 90°. Without vision of their arm, subjects connected the targets by moving the pen between the target locations. After practicing the task under normal and 90° rotated conditions, subjects transferred to a different set of three target locations which required a novel movement pattern. Group 1 (n=8) learned and transferred in the same workspace, which was located in front of the ipsilateral shoulder. Group 2 (n=8) learned in one workspace and transferred to a workspace located just to the opposite side of the subjects' midline. 20 trials were given during baseline (with normal visual feedback), and 60 during learning/transfer. Transfer was assessed based on a statistical comparison of the mean movement times during the first five trials for the learning and transfer conditions in each group. The findings indicate that subjects in Group 1 showed significant positive transfer. In contrast, when learning and transfer were carried out in a different workspace, no significant transfer occurred. These data suggest that when a new sequential visuo-motor task is learned, transfer related to the acquisition of a new pattern can occur, providing the workspace remains the same. Supported by Flinn Foundation.

USING COMPUTER PROGRAMS AND BRAIN PUZZLES FOR DETECTION OF READING IMPAIRMENT IN CHILDREN I. Zarco de Coronado\*, J.G. Coronado Zarco and E. Montes de Oca. Dpto. de Fisiología, Fac de Medicina, Universidad Nacional Autónoma de México A. P. 70250; CP 04510 and Instituto Nacional de la Comunicación Humana (National Institute of Human Communication). Mexico.

Some of the learning problems are related to neurophysiological alterations of the students. Previous studies in our laboratory indicate that computer programs are effective to test visuo spatial abilities in children. It is well known that initial reading requires auditory, visual and associative components. The advanced skills in reading need also visual coordination, extraction of the conceptual content in the phonological structure of the language in order to build the semantic networks. *Objective.* This study was conducted in order to examine Mexican children abilities for reading learning as revealed by using computer games with traditional prehispanic illustrations and schematic brain representations. *Methods.* Computers were carried to suburban communities and hearing children were instructed to use the programs. Data recording about the number of essays to complete the game was automatically recorded. The velocity of the reading was also determined. *Results.* About 40% of the examined children were slow readers and half of them showed visuo motor deficiency. This work suggests that normal children are most of the time good readers. Half of the slow readers showed visuo-motor disabilities and the rest of the children probably need better individualized or tutorial educational programs.

## 565.18

INTENSITY DISCRIMINATION OF VIBRATORY STIMULI CAN BE IMPROVED BY TRAINING. S.J. Bolanowski, K.L. Hall, J.C. Makous\* and M.M. Merzenich Inst. for Sensory Res., Syracuse Univ. Syracuse, NY 13244 and Keck Center for Integrative Neurosci. UCSF, San Francisco, CA 94143.

While it is generally accepted that the magnitude of sensation is related to the physical intensity of the stimulus, the exact form of this relationship and its neural basis have been debated since the time of Weber. Fechner, using the ability of observers to discriminate stimulus intensities (Differenz Limen, DL) and integrating along the intensity domain, proposed a logarithmic relationship between perceived magnitude and stimulus intensity, but this notion has been supplanted by the still controversial power law of Stevens. Because the perception of sensation magnitudes and their differences must be reflected in the DLs, their possible modification should permit studies to access the largely unknown mechanisms underlying intensity perception. We report that the DLs for vibratory stimuli can be transiently modified with training on a DL task (2AFC, gated pedestal). Specifically, DLs were found to decrease by approximately 50% during training (23 daily sessions), and after 3 months post-training, approached pre-training levels. Although no change in threshold sensitivity occurred, DLs for the homologous, contralateral, untrained site were also affected, but in a complicated way that may be channel- (Pacianian, P, versus non-Pacianian, NP) and intensity-specific. Training in the vibratory-DL task also appeared to produce changes in spatial discrimination as assessed by two-point thresholds. This vibratory-based spatial effect, and the bilateral and stimulus-specific effects, may implicate cortical neural-plasticity and suggest that the perception of sensation magnitude comes about through complex (learned?), spatio-temporal mechanisms. ## 565.20

SELF-GENERATED ERRORS IN PROSE RECALL IN AN AFRICAN-AMERICAN POPULATION WITH UNILATERAL BRAIN LESIONS N. Winrow\*, L. H. Hicks, A. Campbell, Jr. Howard University, Washington, DC 20059; J. Grafman, NIH NINDS/MNB; COGNITIVE NEUROSCIENCE SECTION, BETHESDA, MD.

Webster et al (1992) reported a greater incidence of self-generated errors (SGE) on a memory task in patients with right hemisphere damage than in patients with left hemisphere damage or normal controls. The present study analyzed whether these errors occur more often in specific quadrants of the brain. SGEs were defined as distortions or additions by the subjects to the themes or plots of the story. Results revealed that there were no differences between brain injured patients and non-neurological controls in SGE production. Subjects in each group produced more dependent SGEs (misinterpretations caused by words or phrases with ambiguous meaning) than the other two types of SGE.

The results indicate that this present study did not replicate the findings of Webster (1992). The reason behind comparable performance among groups and disparate results between this present investigation and that of Webster et al is that in our study, non-neurological subjects' errors frequently represented a misinterpretation in what was portrayed by the characters in the story, rather than a failure to remember what the tester said. This finding indicates that the stories of the Logical Memory Subtest may contain words and phrases that are ambiguous to subjects from minority cultures.

## 566.1

**PAIN WITH A STRONG AFFECTIVE DIMENSION REPRODUCED BY STIMULATION OF THE HUMAN SOMATOSENSORY THALAMUS.** F.A. Lenz<sup>1</sup>, R.H. Gracely, A.J. Romanoski, E.J. Hope, L.H. Rowland, P.M. Dougherty. Depts. Neurosurg, Psych, Card & Neurosci, Hopkins Hosp, Baltimore, and NAB-NIDR-NIH, Bethesda, MD.

The thalamic substrate of both the affective-motivational aspect of pain and memory for pain has been poorly understood. We report results of studies carried out in the region of the thalamic principal somatosensory nucleus (ventralis caudalis - Vc) prior to thalamotomy for tremor in a patient with a diagnosis of panic disorder. Cells located in the 14mm lateral plane had cutaneous receptive fields on the hand. Microstimulation in the region posterior to Vc evoked sharp chest pain, including the affective dimension, almost identical to atypical chest pain occurring during his panic attacks. His pains were not associated with any change in cardiac function. As measured using a questionnaire, the description of stimulation-associated pain was more similar ( $P < 10^{-7}$ ) to that of atypical chest pain than would be expected by random selection so that the two were rated 'almost identical' by the patient. In a retrospective review, stimulation-associated pain with a strong affective dimension only occurred in patients who had experienced such pain spontaneously. Sharp chest pains without an affective dimension were evoked by stimulation at 3 sites in patients (n=100) without prior experience of sharp chest pain with a strong affective dimension.

The region posterior to Vc is connected to SII, parasympathetic and insular structures which may be involved in corticolimbic circuits subserving somatosensory memory. Therefore thalamic stimulation in this patient may have activated corticolimbic circuits involved in somatosensory memory that are conditioned by prior experience of pain. (Supported by Lilly and the NIH - NS28598, K08 NS01384, P01 NS32386).

## 566.3

**ALZHEIMER'S DISEASE PATIENTS SHOW IMPLICIT LEARNING OF NOVEL PATTERNS.** S. Corkin<sup>1</sup>, B.R. Postle<sup>1</sup>, and J.H. Growdon<sup>1,2</sup>. <sup>1</sup>Department of Brain and Cognitive Sciences and the Clinical Research Center, Massachusetts Institute of Technology, Cambridge, MA 02139; <sup>2</sup>Department of Neurology, Massachusetts General Hospital, Boston, MA 02114.

Priming is a kind of implicit learning (learning without awareness) that does not depend upon the medial temporal-lobe system. For example, the amnesic patient H.M., who underwent bilateral medial temporal-lobe resection, shows intact priming with novel patterns (Gabrieli et al., 1990), suggesting that perceptual priming with nonverbal material does not depend upon areas critical for explicit memory. A logical candidate for the neural substrate that supports this kind of priming is perirhinal cortex, an area that is relatively spared in AD (Arnold et al., 1990). We therefore predicted that AD subjects would be unimpaired on pattern priming. Subjects copied each of six target figures onto dot patterns. After performing a 3-minute distracter task, they were given the same dot patterns (without lines) and asked to draw the first figure that came to mind by connecting the dots with straight lines. In a test of recognition (explicit) memory, subjects viewed each of the six patterns of dots that they had copied previously and were asked to indicate which of four possible completions corresponded to the figure that they had copied 3 minutes earlier. The AD and NCS groups both achieved a mean priming score of 13.1%. In contrast, the recognition score for NCS was higher (mean = 58%) than that for AD subjects (mean = 43.2%). Our finding of intact pattern priming in AD suggests that nonverbal perceptual priming depends upon perirhinal cortex. This finding is consistent with previous studies from our laboratory in which AD subjects showed intact perceptual identification priming with words and pseudowords (Keane et al., 1991; 1994).

## 566.5

**Involvement of the Human Amygdaloid Complex in Emotional Memory.** L. Cahill<sup>1</sup>, R. Babinsky<sup>2</sup>, H. Markowitz<sup>2</sup> and J.L. McGaugh<sup>1</sup>. <sup>1</sup>Center for the Neurobiology of Learning and Memory, and Department of Psychobiology, University of California, Irvine, CA 92717-3800; <sup>2</sup>Department of Physiological Psychology, University of Bielefeld, D-33501, Bielefeld, Germany.

Considerable evidence from studies of infra-human, and to a lesser extent human, subjects suggests that the Amygdaloid Complex (AC) is particularly involved with memory during emotionally arousing learning situations. We have begun to test this hypothesis in a patient (B.P.) with bilateral, circumscribed amygdala damage (resulting from Urbach-Wiethe disease) using a paradigm previously shown to be sensitive to beta-adrenergic blockade (Cahill et al., 1994). Subjects viewed a brief slide, narrated slide show in which emotional events are introduced in the middle phase of the story. Immediately after, subjects rated their emotional reaction to the story. Retention of the story was assessed one week later. Control subjects demonstrated superior memory for the emotional story phase compared to the non-emotional phase. In contrast, B.P. exhibited normal retention of the non-emotional story phase, but showed no evidence of enhanced retention for the emotional story phase. Further, B.P.'s self-described emotional reaction to the story was normal. These results support the view that AC function in humans underlies, at least part, enhanced memory associated with emotional arousal.

## 566.2

**DISSOCIATION BETWEEN INTERHEMISPHERIC INTEGRATION OF PROCEDURAL AND DECLARATIVE LEARNING OF A VISUOMOTOR SKILL IN CALLOSAL AGENESIS.** E. de Guise<sup>1</sup>, M. Lassonde<sup>1</sup> and L. Richer<sup>2</sup>. 1- Groupe de Recherche en Neuropsychologie Expérimentale, Univ. de Montréal Qué., Canada. and 2- Univ. du Québec à Chicoutimi, Canada.

Acallosal subjects show impairments on simple tasks requiring bilateral interdependent motor control. However, few studies have assessed the ability of these subjects to learn a skill that would require the simultaneous contribution of each hemisphere in its acquisition. The present study thus examined whether acallosal subjects could learn a visuomotor skill that involved a motor control from either both or only one hemisphere. The performance of five acallosal subjects aged 20 to 35 years was compared to that of five control subjects, matched for age and I.Q. on a modified version of the serial reaction time task developed by Nissen and Bullemer (1987). On each trial a light appeared at one of four locations. Subjects were instructed to press the one key, out of a set of four keys, that was directly below the light. For the bimanual (interhemispheric) condition, subjects rested the middle and index fingers of both hands on the four keys. In the unimanual (intrahemispheric) condition, subjects rested the index, middle, third and little fingers of the dominant hand on the four keys. In each condition, the subjects received 16 blocks of 100 trials. Each block comprised 10 repetitions of a 10-trial sequence. Following the training, subjects received one block of trials in a self-generated sequence task in order to evaluate their declarative knowledge of the repeated sequence. Results indicated that acallosals learned the visuomotor skill on the unimanual condition as well as their controls. However, they did not learn the sequence in the bimanual condition despite the fact that they knew the sequence explicitly. This finding indicates first, that the corpus callosum is important for procedural learning of a visuomotor skill that requires interhemispheric integration and second, that the development of knowledge in the declarative memory system does not affect knowledge, or performance, in the procedural system.

## 566.4

**EMOTIONAL MODULATION OF COVERT SPATIAL CUEING OF ATTENTION: A CLASSICAL CONDITIONING STUDY.**

Kjell M. Stormark<sup>1</sup>, Kenneth Hugdahl<sup>1</sup> and Michael J. Posner<sup>2</sup>.

<sup>1</sup>Department of Biological and Medical Psychology, University of Bergen, Norway and <sup>2</sup>Department of Psychology, University of Oregon, USA. (SPON: European Brain and Behaviour Society).

Spatial cuing of attentional shifts were investigated when the cue had acquired emotional significance through a classical conditioning procedure. In the conditioning phase, half of the subjects (Conditioning group) received an aversive white noise tone (UCS) contingent upon presentation of a frame-lit rectangle, which was thus turned into a conditioned stimulus (CS+). The Control group received equal number of noise presentations, but they were never paired with the rectangle. During the attentional cuing phase, both groups participated in the covert attentional shift task where the location of the frame-lit rectangle validly or invalidly cued attention to the location a response-target would appear in. The Conditioning group tended to show overall faster reaction times, with no difference between invalid and valid trials, while the Control group showed the predicted delayed RTs on invalid trials. The N1-component of the Event-related Potential to the cue was also larger in the Conditioning group. The emotional salience the cue attracted through the conditioning procedure thus facilitated rapid attentional shifts from the cued to the uncued location on invalid trials.

## 566.6

**CEREBELLAR SIZE CORRELATES WITH MEMORY FUNCTIONS IN YOUNG NORMAL HUMANS.** Paradiso S., Robinson R.G., O'Leary D., Arndt S., Woodworth C.H., Andreasen N.C. Univ. of Iowa Dept. of Psychiatry, Iowa City, IA 52242.

Cerebellar and total brain size were estimated through automatic, atlas-based volume measurements using MR images obtained with a T1 weighted 3-D SPGR sequence on a 1.5-T GE Signa scanner (Andreasen et al., JAMA 272, 1994) and locally developed software (Andreasen et al., JNCN 5, 1993). Sample consisted of 83 healthy subjects (46 males;  $24.8 \pm 4.5$  years of age;  $14.7 \pm 1.7$  years of education). Full Scale (FS) IQ was  $113 \pm 12.2$  (mean and SD); Verbal IQ,  $109 \pm 12.8$ ; Performance IQ,  $113 \pm 2.3$ ). The study evaluated the relationship between *in vivo* volume of the cerebellum (CV) and intelligence (WAIS-R V&P FSIQ), motor dexterity (WAIS-R Finger Tapping), attention (WAIS-R Digit Span), verbal production (MAE Controlled Oral Word Association), verbal (% ret., WMS Logical Memory), and visual (% ret., Rey-Osterrieth Figure) memory. One-tailed Pearson partial correlation coefficients were calculated using volume of cerebrum as a covariate. For each significant correlation between neuropsychological function and total CV, correlations with left and right cerebellar hemisphere were determined as replications. CV correlated significantly with motor dexterity (left hand  $r = .218$   $p = .045$ , right hand  $r = .211$   $p = .050$ ) and logical memory ( $r = .27$   $p = .017$ ). Motor dexterity correlation with left (right hand  $r = .22$ ,  $p = .04$ ; left hand  $r = .24$ ,  $p = .03$ ) and right hemisphere ( $r$  hand  $r = .18$ ,  $p = .07$ ; l hand  $r = .15$   $p = .11$ ) did not show a clear lateralization effect. Logical memory correlated with right and left hemispheres (rhem  $r = .28$ ,  $p = .012$ , C.I. = .472-.064; lhem  $r = .22$ ,  $p = .034$ , C.I. = .416-.0). These results show that structural/functional relationships exist between cerebellum and effortful memory, and timed motor dexterity.

## 566.7

**SELECTIVE DISRUPTION OF EYEBLINK CLASSICAL CONDITIONING BY CONCURRENT TAPPING: EVIDENCE FOR CEREBELLAR PROCESSING.** M. Pakk<sup>1</sup>, R. B. Ivry<sup>2</sup>, & D. S. Woodruff-Pak<sup>1</sup>. Lab of Cognitive Neuroscience, Phila. Geriatric Cntr. & Temple Univ., Phila., PA 19122<sup>1</sup>, Univ. of California, Berkeley, CA 94720<sup>2</sup>.

The purpose of this study was to test the hypothesis that memory systems may be distinguished on the basis of their neurobiological substrates. A total of 140 young, normal adults participated in one of seven conditions. Eighty subjects were simultaneously engaged in EBCC and either a tapping task, a recognition task, a choice reaction time task, or the viewing of a video. Sixty control subjects were simultaneously engaged in the explicitly unpaired control paradigm and either the tapping, recognition, or choice reaction time task. The presumed critical neurobiological substrate for both EBCC and the tapping task was the cerebellum, and the presumed critical substrate for the recognition task was the hippocampus. Choice reaction time and video viewing were chosen as control tasks. The results revealed a selective disruption of eyeblink classical conditioning (EBCC) when it was performed concurrently with tapping. Subjects who simultaneously performed EBCC and tapping were impaired in EBCC compared to both control subjects and subjects who simultaneously performed the recognition task. The groups did not differ in unconditioned response control measures or in their awareness of testing procedures and learning. Tapping, recognition, and choice reaction time performance was comparable for subjects in the paired and unpaired control groups, although subjects in the paired group sometimes showed slower reaction times on the choice reaction task. The results provide evidence for the existence of neurobiologically distinct memory systems, and suggest that the selective disruption of EBCC, when concurrently performed with tapping, may be attributed to cerebellar involvement in both tasks. Supported by NIA 1 R01 AG09752 to DSW-P and NINDS 1R29 NS30256 to RBL.

## 566.9

**MOTOR SKILL ACQUISITION IN PATIENTS WITH PARKINSON'S DISEASE OR CEREBELLAR DAMAGE.** M. M. Schugens, I. Daum, H. Ackermann, and H. Topka<sup>1</sup>. Institute of Medical Psychology and Department of Neurology, University of Tübingen, 72074 Tübingen, Germany.

Models of multiple memory systems discuss the role of different brain structures in the acquisition of declarative and nondeclarative memory. The cerebellum as well as the basal ganglia have been implicated in the acquisition of motor skills. In the present study a group of patients with selective cerebellar damage and a group of patients suffering from Parkinson's disease were investigated on two versions of a computerized tracking task. The first task involved the tracking of a small target on a computer screen with a pointer controlled by a joystick. The horizontal movement of the target was regular whereas the vertical movement of the target was irregular. In the second task both directions of target movement were irregular; the movement of the joystick and the target in the horizontal direction were reversed.

Patients with damage of the cerebellum displayed less learning than the respective control group in task 1 where a regular movement of the target allowed automation of the tracking movement whereas no such deficit was observed in the mirror reversed task (task 2). The patients suffering from Parkinson's disease acquired the task with the regular component as well as the control group, but learning deficits were observed in task 2 when the joystick movement was reversed and the target moved irregularly.

The results indicate that damage to the cerebellum impairs the acquisition of motor skills that involve the preprogramming of movement whereas damage of the basal ganglia circuitry is detrimental to the learning of motor skills that put higher demands on hand-eye coordination.

**TEMPORAL OCCIPITAL LESIONS IMPAIR PRIMING DURING WORD STEM COMPLETION.** L. Nielsen-Bohman, \* D. Swick, M.

Ciranni, R. T. Knight & A. P. Shimamura, Dept. Neurology & Center for Neuroscience, UC Davis & Dept. Psychology, UC Berkeley. Posterior cortical involvement in priming processes is supported by deficits in word priming in Alzheimer's dementia and PET studies of word priming. We examined word stem completion priming in five patients with unilateral temporal-occipital vascular lesions (3 left with hippocampal involvement, 2 right with hippocampal sparing) identified from CT or MRI scans (average lesion volume 33cc) and eight age-matched control subjects. The patients scored within the normal range on the WAIS-R and were variably impaired on the WMS-R. The Warrington Recognition Memory Test showed that while left hemisphere lesion patients showed impaired word recognition, possibly related to their hippocampal lesion or syndrome of alexia without agraphia, all lesion patients had normal recognition for faces. In the study phase, subjects were sequentially shown 10 words (e.g. MOTEL) and asked to rate the pleasantness of each word (i.e., incidental learning). Immediately following word presentation, twenty word stems (eg. MOT) were presented, and subjects were asked to complete the stems with the first words that came to mind. Study words could be used to complete 10 stems, and the other stems were used to assess baseline guessing rates. Lesion patients and control subjects showed comparable baseline word generation rates (control=8%, patient=12%). However, patients completed fewer word stems with previously presented words (control=43% patient=22%,  $p=0.064$ ), showing impairment of word priming. No difference was seen between left and right lesion groups. These data suggest that word priming is mediated by inferior temporal and occipital cortex.

## 566.8

**A RELATIONSHIP BETWEEN COGNITIVE PROCESSING AND PERCEPTION OF TEMPORAL DURATION IN PATIENTS WITH FRONTAL LOBE OR CEREBELLAR LESIONS.** J. A. Mangels\*, R. B. Ivry, & N. Shimizu, Dept. of Psychology, University of California, Berkeley, CA 94720.

Both the frontal lobes and cerebellum have been associated with deficits in temporal information processing. Patients with frontal lobe lesions often exhibit deficits on tests of temporal order. Lesions to the cerebellum can impair timing functions. Recent studies indicate a neuroanatomical connection between the cerebellum and frontal lobes. Thus, temporal processing deficits of patients with frontal lobe lesions may extend to timing abilities, such as perception of duration.

In a previous study, we found that patients with frontal lobe lesions were impaired on perceptual judgments of long durations (4000 msec). These patients were not impaired relative to control subjects on perception of short durations (400 msec) or a non-timing control task (frequency perception). Given that temporal processing of long durations (>1000 msec) may be cognitively mediated, the present study explores whether timing deficits exhibited by patients with frontal lobe lesions are related to cognitive deficits in attention and strategic processing.

Patients with dorsolateral prefrontal lesions and control subjects were tested on a series of five long duration (4000 msec) perception tasks in which sustained attention (open vs. subdivided intervals) and strategy (no strategy vs. experimenter-provided strategy) were manipulated. Across all tasks, subjects judged whether a standard interval was longer or shorter than a comparison interval of varying duration. Frontal patients and control subjects did not differ on perception of open durations. Frontal patients were impaired relative to control subjects when the standard interval was subdivided into 400 msec intervals and no strategy was provided. Yet, these groups performed comparably on the subdivided condition when the experimenter provided a counting strategy. These findings suggest that impairments of frontal patients on tasks of temporal perception result from deficits in cognitive processes, rather than deficits in perception of duration. Performance of patients with frontal lobe lesions will be compared to patients with cerebellar lesions, who may have primary deficits in time perception.

## 566.10

**CONTRIBUTION OF THE STRIATUM AND CEREBELLUM TO THE AUTOMATIZATION OF A VISUOMOTOR SKILL ASSESSED WITH A DUAL-TASK PARADIGM.** J. Doyon\*, 1,2,3, R. Laforce Jr., 1,2, D. Gaudreau, 1,2, J.-P. Bouchard<sup>2,3</sup>, and P. J. Bédard<sup>2,3</sup>. <sup>1</sup>Ecole de Psychologie, <sup>2</sup>Centre de Recherche en Neurobiologie, Québec, Canada, G1K 7P4, Université Laval, et <sup>3</sup>Département des Sciences Neurologiques, Hôpital de l'Enfant-Jésus, Qc, Canada, G1J 1Z4.

Research from our laboratory has recently demonstrated that the disruption of either the striatal or the cerebellar circuitry in patient populations may adversely affect the implicit learning of a repeated visuomotor sequence late in the acquisition process. The present study examined whether this impairment was due to a lack of automatization of the skill using a dual-task paradigm. To this end, the performance of nine Parkinson's disease patients (PD) (Stage 1, n=6, Stages 2-3, n=3) and of 11 cerebellar patients (CER) was compared to that of groups of normal subjects (n=9 and n=12, respectively) on the Repeated Sequence Test, while subjects were performing the Brooks Matrices presented auditorily as a secondary task in both early and late phases of learning. Subjects were required to complete 8 matrices concomitantly with 8 separate blocks of three embedded sequences after having received either 40 (Session 1), or 240 (Session 6) presentations of the sequence. As expected, a dual-task interference was observed in both Sessions 1 and 6, although the groups never differed significantly in their pattern of results on the primary task. By contrast, an impairment on the Brooks Matrices was observed only in the patient groups that had already shown a learning deficit in our previous studies (ie. PD[2-3] and CER), hence suggesting that the latter subjects did not have access to the same level of residual cognitive resources to complete the matrices compared to controls. Such findings are consistent with the notion that both the striatum and the cerebellum play an important role in the automatization of a visuomotor skill.

## 566.12

**SELECTIVE LOSS OF MEMORY FOR MUSIC AFTER BILATERAL DAMAGE TO THE AUDITORY CORTEX.** I. Peretz\*, G.R.E.N.E., Univ. of Montreal, Montreal (Qué), H3C 3J7, Canada.

C.N. is a 40-year old right-handed nurse who suffered from a severe auditory agnosia limited to music after bilateral damage to the auditory cortex. C.N., whose cognitive and speech functions are otherwise normal, is totally unable to identify or to experience a sense of familiarity with musical excerpts that were once highly familiar to her. However, she can recognize the lyrics that usually accompany the songs. She can also identify familiar sounds, such as animal cries. Thus, her agnosia appears highly specific to music (Peretz, Kolinsky, Tramo et al., *Brain*, 1994). A follow-up study shows that C.N. has now recovered most perceptual skills for music. This recovery is not accompanied by any signs of improvement in music recognition, which remains extremely poor. She is still markedly impaired at naming a tune and at judging its familiarity, as well as at memorizing familiar as well as novel music. This deficit is found to be not only modality-specific but music-specific as well. The findings suggest the existence of a perceptual memory that is specialized for music and that can be selectively damaged so as to prevent most forms of recognition ability.

## 566.13

**ARENAMAZE - A VIRTUAL 'WATERMAZE' FOR HUMANS** I.C. Reid, N.F. Wright and L.J. Whalley\* Aberdeen Univ., Dept. of Mental Health, Aberdeen, UK.

The Morris Open Field Watermaze has become a widely used test of spatial learning in the rat. Few spatial tests used with human subjects capture the navigational aspects of the watermaze in a convenient way. Previous attempts have generally used real world solutions, such as the large radial maze painted out on a field by Glassman et al (Brain Res. Bull. 34:151-159, 1994). Such tests are expensive and unwieldy. Virtual space, modelled on a computer, may be more convenient, reliable and cheaper.

We used a modification of the popular computer game "DOOM" (ID software) running on a conventional 486PC to create a "virtual" open field maze for humans. "DOOM" can be edited using a shareware package (DEU2) to create the 2-D illusion of a 3-D arena surrounded by "virtual" extra-maze cues and containing a fixed "hidden" goal escape platform viewed as if from a first person perspective. Using features available in the regular game, subjects can be "teleported" to random start locations within the arena from which to search for a hidden goal area using a trackball mouse. Escape latency measures (and probe trials to measure spatial bias in the absence of the goal platform) can easily be recorded in a manner analogous to those used in the rat Watermaze. The apparent dimensions of the environment were scaled up from the rodent version of the task.

The performance of 7 amnesic (Korsakoff) patients was compared on the task with 6 control subjects. Following a non-spatial practice session, each group was given 9 trials in the spatial task in a single session, followed by a probe trial. The Korsakoff group showed significantly elevated latencies across trials and reduced spatial bias. Further modifications of the program permitted us to develop control non-spatial tasks and a "virtual" radial maze. While this work is clearly at a preliminary stage (and the use of dedicated 3-D modelling software may produce a more professional-looking interface) our findings demonstrate the potential value of simple and inexpensive "VR-like" approaches to testing cognitive function.

## 566.15

**INTACT IMPLICIT MEMORY FOR NEWLY-FORMED VERBAL ASSOCIATIONS IN AMNESIC PATIENTS.** Y. Goshen-Gottstein, Dept. of Psychology, Tel-Aviv University, and Morris Moscovitch\*, Rotman Institute of Baycrest Centre and Erindale College, University of Toronto, Mississauga, Ontario, L5L 1C6, Canada.

Implicit and explicit memory for newly-formed associations between two random words was tested in ten amnesic patients with various etiologies. At study, subjects saw two simultaneously-presented words on a screen (120 pairs in all) and formed a sentence containing both words. At test, subjects saw 40 of the same old pairs, 40 recombined pairs in which a word from one pair was recombined with a word from another and 80 pairs containing new words which had not been studied. In the implicit test, subjects saw two letter strings and had to determine whether both formed words. In the explicit test, subject had to determine whether both words had appeared at study. Despite being severely impaired on the explicit test, amnesic patients performed like control subjects on the implicit test: responses were fastest to old pairs, intermediate to recombined pairs, and slowest to new pairs. Contrary to many theories, the results indicate that amnesic patients, even those with bilateral medial temporal-lobe damage, can form and retain new associations. Evidence indicates that these associations are perceptually based.

## 566.17

**EFFECTS OF LESIONS OF EITHER THE AMYGDALA OR ANTERIOR RHINAL CORTEX ON CROSSMODAL DNMS IN RHESUS MACAQUES.** S. Goulet\* and E.A. Murray. Lab of Neuropsychology, NIMH, NIH, Bethesda, MD 20892, U.S.A.

Naive rhesus monkeys were trained preoperatively on both visual and tactual versions of delayed nonmatching-to-sample (DNMS) using a set of 40 objects. Each day, the 40 objects were randomly assigned anew to 20 pairs, to be used for the 20 trials comprising a test session. Ten seconds intervened between sample presentation and choice. Monkeys were trained until they scored 90 correct responses in 100 trials, first in vision then in touch. Next, they were confronted with the crossmodal version of the task, which used a sample presentation in the dark but a choice test in the light. After reaching the same performance criterion as in the intramodal phases or completing 1000 trials of training, monkeys received either bilateral aspiration lesions of the anterior rhinal (i.e. entorhinal plus perirhinal) cortex (AntRh, N=2), bilateral excitotoxic lesions of the amygdala (A, N=2) based on magnetic resonance images from those animals, or were retained as unoperated controls (CON, N=2). Following surgery or rest, we assessed each monkey's retention of the crossmodal task by calculating its deficit score (mean percent correct over last 100 trials pre-op or pre-rest minus mean percent correct over first 300 trials post-op or post-rest). Group A was not impaired relative to Group CON. These preliminary results argue against the idea that the amygdala is critical for crossmodal associations. By contrast, Group AntRh was impaired relative to Group CON (deficit score of 22 versus 9). Moreover, neither of the AntRh subjects reattained the criterion within the 1000-trial training limit, whereas all subjects in Groups A and CON did. These data suggest that the anterior rhinal cortex mediates retention of tactual-to-visual crossmodal associations.

## 566.14

**SPATIAL-ARRAY LEARNING BY PATIENTS WITH FOCAL TEMPORAL-LOBE EXCISIONS.** J. Crane, B. Milner\*, & G. Leonard, McGill University, Montreal, Quebec, Canada, H3A 2B4.

Smith and Milner (1989) demonstrated a role for the right hippocampal region in delayed but not in immediate recall of object locations. Because all these patients' removals included lateral temporal neocortex, a combined-lesion effect could not be ruled out. We examined this question directly by testing patients who had undergone selective amygdalo-hippocampectomy (AH), or anterior temporal-lobectomy (TL). The paradigm involved learning supra-span spatial arrays over successive trials. Included were 18 AH patients [7 left (LAH) and 11 right (RAH)], and 31 TL patients (15 L and 16 R) who were categorized further based on extensive (11 LTH and 8 RTH) or minimal (5 LTH and 7 RTH) hippocampal encroachment. Fourteen age- and education-matched normal control subjects (NC) were also tested. No group differences were found in recall immediately after the first presentation (Trial 1), but ANOVA revealed a strong group effect for number of trials to criterion. Post hoc tests confirmed that both the LTH and NC groups required fewer trials than the RTH and RAH groups. In addition, the LTH group was superior to the RTH group. Our findings suggest that right medial temporal-lobe structures are critically involved in the learning but not in the encoding of object-location information.

## 566.16

**PERIRHINAL CORTEX IN HUMAN AND MONKEY: TOPOGRAPHY, NEUROCHEMISTRY AND PATHOLOGY IN ALZHEIMER'S DISEASE.** A. Solodkin\*, C. Dennison, J. Townsend and G.W. Van Hoesen. Anatomy and Neurology. University of Iowa College of Medicine. Iowa City, IA 52242.

The perirhinal cortex (area 35) is a classic isocortex located "around" the rhinal sulcus in mammals. It is bordered medially by the entorhinal cortex (area 28) and laterally by the inferior temporal cortex (area 36), however, it has not been easy to establish its limits with these areas. Our findings in monkey and human temporal cortex, based on multiple methods, were aimed to precisely delimit area 35.

Fixed tissue from monkey and human temporal cortex was stained for calcium-binding proteins, non-phosphorylated neurofilament protein, AChE, NADPH-d and in AD with Thioflavine-S and Alz-50.

Results in the monkey using calbindin-D28 and SMI-32 revealed that the perirhinal cortex, lies along the lateral bank of the rhinal sulcus, and is formed at least by two sub-areas. These can be segregated clearly from areas 28 and 36.

In the human, area 35 has a columnar organization which can be highlighted by parvalbumin, AChE staining and in AD pathology. This columnarity, conveniently marks the anterior-posterior extent of this cortex, and reveals that area 35 in anterior areas, can occupy both banks of the rhinal sulcus, whereas in posterior parts, it is located along the medial bank of the collateral sulcus. Additionally, at least two sub-areas, were noted.

In summary: (1) good markers exist to locate area 35; (2) there are differences in area 35 among primates, with humans having evidence for a columnar or vertical organization; (3) the perirhinal cortex is greatly expanded in the human brain and segregated into modular units. These are affected early in AD and may be linked to its early memory impairments. Supported by NS 14944 and PO NS 19632.

## 566.18

**EARLY LESIONS OF THE HIPPOCAMPAL FORMATION IN PRIMATES IMPAIR CONTEXT-DEPENDENT RECOGNITION MEMORY.** Q. Pascalis and J. Rachevalier.\* Dept. Neurobiology & Anatomy, Univ. Texas Sch. Med. Houston Tx, 77225.

Both early and late lesions of the hippocampal formation in primates are known to yield few if any effects on visual recognition memory (Mishkin & Murray, 1994 Curr. Op. Neurobiol., 200, 4). However, this lack of impairment may not reflect intact recognition memory, but rather it might indicate that the experimental parameters were not appropriate to detect the impairment. To test this possibility, 3 normal adult monkeys (N) and 3 with neonatal lesions of the hippocampal formation (H), including the hippocampus proper and parahippocampal gyrus, were trained in a modified version of a paired-comparison task. In this task, the animals were familiarized with a picture of an object presented over a background for a cumulative 20-sec period. After a 10-sec delay, the same object was paired with a novel one for two retention trials of 5-sec each. In these retention trials, the familiar and novel objects were presented in six different conditions. In three conditions, the familiar object was over the same background used during the familiarization period and in the other three, it was over a new background. Animals in Group N showed a preference for the novel objects in all conditions (average 63%), whereas those in Group H showed a preference for the novel objects only when the familiar objects were presented over their original backgrounds (average 63% vs 49%). These results suggest that neonatal lesions of the hippocampal formation impair recognition memory when the context in which an object is learned has been changed, and strengthen the proposal that the hippocampal formation may be critical for contextual and/or relational memory (Eichenbaum, et al., 1994, Beh. & Brain Sci., 17, 3). Supported by NIMH grant MH49728, the John D. and Catherine T. MacArthur Foundation and a Fellowship from the Fondation Fyssen to OP.

## 566.19

DIFFERENTIAL CHOLINERGIC DYNAMICS ASSOCIATED WITH PERFORMANCE ON DELAYED NON-MATCHING TO SAMPLE AND DELAYED RESPONSE TASKS: AN *IN VIVO* MICRODIALYSIS STUDY IN NON-HUMAN PRIMATES. T.D. Smith\*, R.C. Saunders and D.R. Weinberger. Clinical Brain Disorders Branch, NIMH, Bethesda, MD 20892.

*In vivo* microdialysis was used to monitor extracellular levels of acetylcholine (ACh) in hippocampus (HC) and prefrontal cortex (PFC) in alert rhesus monkeys. Previously we demonstrated that substantial increases in extracellular PFC and HC ACh levels are associated with performance on control motor tasks, as well as on memory tasks. Because no difference was seen between tasks, the present study was undertaken in order to determine whether or not differential ACh overflow is associated with task difficulty. ACh was monitored in HC and PFC while monkeys performed delayed response (DR) (retention intervals of 1 and 10 s), a spatial working memory task, or delayed non-matching to sample (DNMS) (list length of 1, 10, or 20 items), a visual recognition memory task. Microdialysis probes placed into HC and PFC were perfused with artificial CSF at a rate of 1.1  $\mu$ l/min. Samples were collected every ten minutes and assayed for ACh using HPLC with electrochemical detection. After a stable ACh baseline was established, monkeys performed a task for 20 min and then sat quietly during recovery of neurochemicals back to baseline. This same protocol was then repeated with another task. As previously demonstrated, an increase in extracellular PFC and HC ACh levels was associated with performance on both tasks, with peak overflow occurring after completion of the tasks. Enhanced ACh levels could be abolished by tetrodotoxin infusion. Preliminary results from one monkey, but with several replications, suggests a double dissociation in ACh overflow related to task difficulty and the region sampled. Thus, in PFC a greater ACh overflow was associated with a 10 s delay during performance on DR as compared to a 1 s delay (peak 35% vs 15%, respectively). In contrast, HC ACh overflow was similar at both delays. Conversely, differential levels of HC ACh overflow (35% and 15%) were related to increased list length (1 and 20, respectively) during performance on DNMS, while PFC ACh overflow was not differentiated. These preliminary results suggest that ACh may be differentially involved in PFC and HC during cognitive activation.

## 566.21

INCREASED METABOLIC ACTIVITY IN THE ENTORHINAL AND PERIRHINAL CORTICES AND SUBICULUM IN MONKEYS PERFORMING WORKING MEMORY TASKS AS REVEALED BY THE 2-DEOXYGLUCOSE METHOD.

Dayachi, L.\*, Friedman, H.R. and Goldman-Rakic, P.S., Yale School of Medicine, Section of Neurobiology, New Haven, Connecticut, 06510, U.S.A.

As a continuation of our investigation on the role of the hippocampal formation and adjacent cortices in memory function, we have most recently analyzed metabolic activity in the entorhinal and perirhinal cortices as well as the subicular complex of the hippocampus in monkeys performing working memory or control tasks. Rhesus monkeys were trained in a Wisconsin General Test Apparatus to perform a manual delayed spatial alternation (DA), delayed object alternation (DOA) or a control task. Local cerebral glucose utilization (LCGU) during the performance of these tasks was then measured and quantified using a single label ( $^{14}$ C) 2-deoxyglucose paradigm. LCGU was significantly elevated ( $p < .05$ ) in the medial and lateral entorhinal regions (17.9% and 21.2% higher, respectively), rostral perirhinal area 35 (19.3%), caudal perirhinal area 36 (19.6%) and the subiculum (25.6% increase) of monkeys performing working memory tasks (DA and DOA) compared to those performing control tasks. As a measure of individual differences in blood flow, the LCGU of the medial geniculate body was analyzed in all animals because each was exposed to the same white noise during the experiment. This analysis revealed no significant difference between groups. The finding that the entorhinal and perirhinal cortices are more active during working memory tasks than control tasks is consistent with lesion data in monkeys, demonstrating a memory impairment in delayed match-to-sample tasks after rhinal cortex lesions with sparing of concurrent object discrimination and other tests of associative (long term) memory (Gaffan, D. and Murray, E.A., 1992, Behavioral Neuroscience, 106, 30-38). Not only do these data provide further evidence of medial temporal structure involvement in working memory, they also provide a functional analysis of the anatomical network connecting the prefrontal cortex to the hippocampal formation (Goldman-Rakic, P. S. et al., 1984, Neuroscience, 12, 719-743). Supported by ONR grant N00014-91-J-1251.

## 566.23

A NOVEL TEST OF SPATIAL WORKING MEMORY IN PRIMATES: CONTRASTING EFFECTS OF EXCITOTOXIC LESIONS AND DOPAMINE DEPLETION OF THE PREFRONTAL CORTEX IN THE MARMOSET. P. Collins, B. J. Everitt, T.W. Robbins and A.C. Roberts, Department of Experimental Psychology, University of Cambridge, Cambridge, CB2 3EB U.K. (SPON:European Brain and Behaviour Society)

Patients with frontal lobe damage or Parkinson's disease (PD) are impaired on a self-ordered searching task designed to measure spatial working memory. We have previously described the development of a primate analogue of this task, in which on any given trial, a computer presents a pre-defined number of identical blue squares at random sites across a touch-sensitive screen. The monkeys task is to touch each square once, and once only, in a self determined sequence to obtain reward. In control animals performance declined from 90% correct on sequences of 2 squares to 30% correct on sequences of 5 squares and was correlated with the development of a spatial searching strategy. The present experiments assessed the contribution of the prefrontal cortex and its dopamine input to the performance of this task. Excitotoxic lesions of prefrontal cortex produced a marked impairment in task performance which was associated with profound perseveration. In stark contrast, selective lesions of the mesocortical dopamine input to the prefrontal cortex, which degenerates in PD, did not effect task performance. However, both lesion groups were impaired on a manual spatial delayed-response task, a classical measure of spatial working memory in which strategies are not necessary for successful performance. Since the utilisation of a spatial strategy is a key constituent of the self-ordered searching task, it may be that this cognitive function protects spatial working memory from the effects of prefrontal dopamine depletion in tasks in which strategies aid performance. These data suggest that the dopamine dependent deficit seen in PD may be due to striatal dopamine depletion and will be discussed in the light of the effect of these lesions on alternative tests of frontal lobe function in monkey and man.

## 566.20

INCREASE IN CEREBRAL ACETYLCHOLINE ASSOCIATED WITH BEHAVIORAL PERFORMANCE IN MONKEYS: AN *IN VIVO* MICRODIALYSIS STUDY. Y. Tang\* and T. G. Aigner. Laboratory of Neuropsychology, National Institute of Mental Health, Bethesda, MD 20892-4415

Previous lesion studies in monkeys suggest that rhinal cortex, temporal cortex, and hippocampus are involved in recognition memory. In addition, pharmacological studies have identified the neuromodulator acetylcholine (ACh) as playing a significant role in mnemonic processes. In the present study, extracellular levels of ACh and choline in perirhinal cortex (PR), inferior temporal cortex (IT), and dentate gyrus (DG) of the hippocampus in 2 awake, behaving rhesus monkeys (*macaca mulatta*) were monitored using *in vivo* microdialysis. Animals were trained to perform an automated version of a recognition memory task, delayed nonmatching-to-sample (DNMS) with lists of 10 symbols, and a non-memory control task, plus-symbol-touching (PST). Magnetic resonance imaging scans were used as a guide to place microdialysis probes into PR, IT, and DG. Probes were perfused with lactated Ringer's solution containing 10  $\mu$ M neostigmine at the rate of 1.0  $\mu$ l/min; samples were collected every 20 min beginning 1 hr after probe placement and analyzed for ACh and choline concentrations by HPLC coupled with electrochemical detection. Performance on DNMS was associated with 41%, 26%, and 24% increases in ACh overflow in PR, IT, and DG, respectively. During performance of the PST task, ACh overflow increased 34%, 24%, and 7% above baseline in PR, IT, and DG, respectively, then returned to baseline levels when the monkey again sat quietly. The increases of ACh overflow are statistically significant ( $p < 0.05$ ,  $n = 9$ , vs the levels of ACh while the monkeys sat quietly). By contrast, choline levels decreased without any relation to performance on the behavioral tasks. The results indicate that cholinergic activity in PR, IT, and DG increases during processes of memory, attention, and arousal in nonhuman primates.

## 566.22

AFFECTIVE AND ATTENTIONAL SHIFTING: A FUNCTIONAL DISSOCIATION BETWEEN THE DORSOLATERAL AND ORBITAL PREFRONTAL CORTICES OF THE MONKEY.

R. Dias, T.W. Robbins and A.C. Roberts\*, Department of Experimental Psychology, University of Cambridge, Cambridge, CB2 3EB, UK.

Perseverative responding on visual discrimination reversal tasks has been reported widely following lesions of orbital prefrontal cortex (pfc) in monkeys. This has been likened to the perseverative responding described in patients with frontal lobe damage on the Wisconsin Card Sort Test, a test of set-shifting ability. However, in man, dorsolateral pfc, and not orbital pfc, has been identified as the critical locus for the deficit. This discrepancy between the monkey and human literature may be misleading as there are fundamental differences in the cognitive processes underlying performance of these two types of task. To reconcile this discrepancy, the present study investigated the effects of excitotoxic lesions of dorsolateral and orbital regions of the prefrontal cortex in the marmoset on both attentional set-shifting and visual discrimination reversal learning within the same paradigm.

The results demonstrate that dorsolateral pfc, and not orbital pfc, is the critical locus for attentional set-shifting. In contrast the orbital pfc, and not the dorsolateral pfc, is the critical locus for visual discrimination reversal learning. This double dissociation would suggest that the dorsolateral pfc provides flexibility at the level of attentional selection whilst the orbital pfc provides flexibility at the level of affective processing. These results have implications for how we analyse the cognitive and affective changes associated with neuropsychiatric disorders including schizophrenia and depression.

## 567.1

## HEMIDECONTORTION AND REVERSAL LEARNING IN THE RAT: HEMISPHERIC ASYMMETRY FOR TENDENCY TO PERSEVERATE.

M. Noonan\* &amp; S. Axelrod. Canisius College and SUNY at Buffalo.

Noonan and Axelrod (1992) reported a consistent hemispheric asymmetry in rats for the ability to master the second task of a two-task sequence. In the present experiment we tested the hypothesis that this effect was due to an asymmetrical representation of the tendency to perseverate.

Rats were taught a left-right response differentiation in a water-maze, and, based on their turning biases during acquisition, were categorized as either left-turners or right-turners. Rats from both groups were then subjected to either left- or right-hemidecortication, and tested six weeks later on a reversal of the initial task. Scores on the reversal task revealed significant hemispheric differences which were in opposite directions for the turning groups.

The results are taken as compatible with the hypothesis that the tendency to perseverate is asymmetrically represented in the rat. The data suggest that, for each group, the more perseverative hemisphere is contralateral to the turning bias shown during acquisition of the initial learning.

## 567.3

## THE EFFECTS OF MEDIAL FRONTAL LESIONS ON OBJECT DISCRIMINATION AND REVERSAL TASKS USING A NEW COMPUTER-AUTOMATED TOUCHSCREEN TESTING PROCEDURE FOR THE RAT.

J.L. Muir\*, T.J. Bussey, B.J. Everitt and T.W. Robbins. Dept. of Experimental Psychology, University of Cambridge, Cambridge CB2 3EB and \*School of Psychology, University of Wales College of Cardiff, Cardiff CF1 3YG, U.K.

Recently it has been reported that lesions of the anterior cingulate cortex in the rat produce a variety of behavioural impairments. For example, while such lesions fail to affect simple visual discrimination learning, they do impair the acquisition of an 8-pair concurrent visual discrimination task (Muir et al., *Soc. Neurosci. Abstr.* 20:1211, 1994). Furthermore, rats with lesions of the anterior cingulate cortex are able to learn a conditional visual discrimination task at a faster rate than control animals (Bussey et al., *Soc. Neurosci. Abstr.* 19: 1233, 1993). In attempting to provide an explanation for these results, we have suggested that the anterior cingulate cortex may be involved in the acquisition of stimulus-reinforcement associations.

However, the connections between the rostral medial frontal area (MF) and structures such as the nucleus accumbens suggest that this region may also be important in the acquisition of stimulus-reinforcement learning. In addition, Petrides (*Behav. Brain Res.* 16: 95-101, 1985) has suggested that anterior frontal cortex in the primate is important for conditional learning. It remains to be demonstrated whether the anterior cingulate and medial frontal cortices in the rat are functionally dissociable. Thus, in the present study, following excitotoxic lesions of the pre-genu MF cortex, rats were tested on tasks previously shown to be sensitive to cingulate cortex damage including 8-pair concurrent and conditional discrimination learning. Somewhat surprisingly, lesions of the MF cortex had no effect on any of these tasks but did produce a significant impairment on reversal of a simple discrimination, even though acquisition of this simple visual discrimination was unimpaired. Together with our earlier findings, these results suggest that the anterior cingulate cortex may mediate stimulus-reinforcement learning while the medial frontal cortex in the rat may be important for the inhibition of prepotent responding.

## 567.5

THE RELATIONSHIP BETWEEN TACTILE DISCRIMINATION LEARNING AND ACETYLCHOLINE RELEASE IN FRONTAL AND SOMATOSENSORY CORTICES: AN *IN VIVO* MICRODIALYSIS STUDY IN FREELY-MOVING RATS. A.E. Butt\* & R.W. Dykes. Département de Physiologie, Université de Montréal, Québec, Canada H3C 3J7.

We examined the relationship between cortical acetylcholine (ACh) release and tactile discrimination learning in rats. After microdialysis probe guides were implanted in the frontal cortex and in the vibrissae field of the somatosensory (SI) cortex, animals were pre-trained to enter either of two chambers from a common starting location for food reinforcement. Microdialysis probes (3 mm) were then inserted and animals underwent five daily sessions (30-trials) of either tactile discrimination training or control procedures. Microdialysis samples were collected from frontal and SI cortices for 1 hr in the home cage prior to testing and for the duration of testing each day by perfusing the probes with Ringer solution and neostigmine (2 nM). Based on reports of enhanced ACh release in response to appetitive reinforcement-based conditioning procedures (Ingalls, Day, & Fibiger, 1994; Sarter & Bruno, 1994), it was hypothesized that ACh release in the frontal cortex in both groups would be greater during testing, compared to baseline release in the home cage. And as demonstrated by Ingalls et al. (1994), it was expected that ACh release in frontal cortex would increase with training in both groups. It was further hypothesized that ACh release in the SI cortex would be greater in the discrimination-trained animals than in controls, and that SI ACh release would increase over the course of training in the tactile discrimination group in parallel with increased discrimination performance accuracy. Results confirmed the hypothesis that appetitively reinforced conditioning procedures would cause a progressive enhancement in the release of ACh in frontal cortex in both groups. Moreover, the pattern of ACh release in frontal and SI cortices differed between discrimination-trained and control animals; during the task, discrimination-trained animals showed greater ACh release in SI cortex than controls, and the extent of this release was related to degree of discrimination training. ## CLASSICALLY CONDITIONED JAW MOVEMENT AND HEART RATE RESPONSES IN RABBITS WITH MEDIAL PREFRONTAL LESIONS. Joselyn McLaughlin and D.A. Powell.\* VA Medical Center and University of South Carolina, Columbia, SC 29208.

Damage to the medial prefrontal cortex (mPFC) prevents acquisition of classically conditioned heart rate (HR) decreases during aversive conditioning. This experiment focused on whether similar effects would be observed during appetitive conditioning. Rabbits with bilateral (mPFC) lesions were compared to sham lesioned rabbits in an appetitive conditioning experiment in which tones were CSs and an intraoral injection of sweetened water was the US. A third group of sham rabbits received unpaired tone and water presentations. Significant jaw movement conditioning occurred in the sham and lesioned animals compared to the unpaired sham control group. However it was accompanied by tone-evoked HR decelerations early during training but only in the sham-paired group. All animals showed accelerative HR CRs during later sessions; moreover, animals with mPFC lesions showed greater conditioned accelerations than the unpaired or sham-paired group. These findings suggest that the lesion prevented normal parasympathetic inhibitory control of the heart, resulting in greater sympathetic activation.

## THE EFFECTS OF CINGULATE CORTEX LESIONS IN THE RAT ON THE ACQUISITION OF SIMPLE AND CONDITIONAL VISUAL DISCRIMINATION OF COMPUTER GRAPHIC STIMULI IN A TOUCHSCREEN TESTING APPARATUS. T.J. Bussey\*, J.L. Muir\*, B.J. Everitt and T.W. Robbins. Dept. of Experimental Psychology, University of Cambridge, Cambridge CB2 3EB and \*School of Psychology, Univ. of Wales College of Cardiff, Cardiff CF1 3YG, U.K.

It is becoming increasingly clear that the cingulate cortex in the rat can be subdivided into anterior and posterior components which are functionally dissociable. For example, we have recently reported that anterior cingulate lesions produce enhanced learning of a conditional visual discrimination task carried out in a Skinner box, whereas posterior cingulate lesions produce an impairment (Bussey et al., *Soc. Neurosci. Abstr.* 19:1233, 1993). Furthermore, using a new automated touchscreen testing procedure involving the presentation of computer-graphic stimuli, we have shown that on an 8-pair concurrent discrimination task, the opposite pattern of results is obtained with these lesions (Muir et al., *Soc. Neurosci. Abstr.* 20:1211, 1994).

In the present study, we employed the touchscreen testing method to determine whether the pattern of effects obtained on the conditional task would be obtained using a touchscreen version of this task, in which the opportunity for stimulus sampling and the position of the animal prior to responding were tightly controlled. In the touchscreen task, a discriminative stimulus was presented in the central of three response windows. The rat was required to nose-poke this stimulus, the identity of which provided a cue as to which of two responses (nose-poke right or left) would result in reward. Posterior cingulate lesioned animals were impaired in acquisition during the late stages of learning, thus replicating our findings using the Skinner box version of this task. Anterior cingulate lesions had no effect. There was also no effect of either anterior or posterior cingulate cortex lesions on acquisition of a simple visual discrimination or reversal, suggesting that the effects obtained on the conditional tasks were not due to perceptual factors. This pattern of results will be discussed in terms of our recent proposal that anterior and posterior cingulate cortices may be involved in the acquisition of stimulus-reinforcer and stimulus-response associations respectively.

## PRETEST INFUSION OF LIDOCAINE INTO THE INSULAR OR MEDIAL PREFRONTAL CORTEX IMPAIRS RETRIEVAL OF REMOTE MEMORY IN AN INHIBITORY AVOIDANCE TASK. K. C. Liang\* &amp; W.-L. Liao. Psychology, Natl. Taiwan Univ. &amp; Neuroscience, Natl. Yang-Ming Univ., Taipei, Taiwan, R.O.C.

Extensive evidence implicates the amygdala in formation of affective memory. Our previous findings further indicate that in an inhibitory avoidance task, inactivation of the amygdala impaired retrieval of a recent (1-day) but not a remote (21-day) memory. The cerebral cortex is implicated in long-term storage of memory. In search of the neural circuitry critically involved in expression of a remote memory, this study examined the roles of three cortical regions receiving amygdala projections in retrieving memory formed 1 or 21 days ago in an inhibitory avoidance task.

Male Wistar rats received surgery to implant cannulae bilaterally into the insular, medial prefrontal or perirhinal cortex. Rats were trained on a one-trial step-through inhibitory avoidance task with a 1.14 mA/1 s footshock. Five minutes prior to the retention test given 1 or 21 days after training, rats received intra-cortical infusion of vehicle or 2% lidocaine. Results indicated that in the 1-day retention test, independent or conjoint inactivation of the insular and medial prefrontal cortices had no effect on retention. In contrast, such treatments given in the 21-day test severely impaired memory expression. Pretest infusion of lidocaine into the perirhinal cortex, while did not impair retention in the 1-day test, would impair memory expression in the 21-day test only if the rats had previously been tested on a 1-day test.

These data, taken along with previous ones, suggested that the amygdala and its associated cortices, at least the insular or medial prefrontal cortex, play important roles in retrieving, respectively, recent and remote memory of affective experience. They are consistent with a notion that the long-term storage of affective memory might involve cortical circuits.

MEMORY FOR OBJECT-OBJECT PAIRED ASSOCIATES: ROLE OF THE PREFRONTAL CORTEX. N. Kurzina\*, M. Granholm and R.P. Kesner. Dept. of Psychology, University of Utah, Salt Lake City, UT 84112

It has been shown previously that infralimbic-prelimbic (IPL) cortex lesions impair working memory for visual object information. In order to test whether this working memory deficit would also contribute to paired associate learning for visual objects, the role of the IPL of the rat frontal cortex was investigated in an object-object paired associate task.

Based on a successive discrimination go/no-go paradigm, rats were trained to remember that two pairs of objects (AB and CD as well as BA and DC) resulted in reinforcement (positive trial). All other combinations of the same objects (AD, BD, DB, etc.) were non-reinforced (negative trials) and were considered to be mispairs.

After animals learned this task to a criterion of at least a two second difference between positive and negative trials during two consecutive weeks (200 trials), the animals received under Nembutal anesthesia either electrolytic lesions of the IPL or served as sham-operated controls. After a one week recovery period they were tested for retention of the task for 3 sets of 200 trials each.

The results indicate that rats with damage of the IPL areas did not have a severe deficit in performance of this task compared to presurgery level and sham-operated rats. It is likely that the IPL of the rat frontal neocortex is not critical for object-object relationship performance, even though IPL cortex is involved in working memory for visual object information.

IDENTIFICATION OF VISUAL TARGETS BY SPATIAL CONTEXT IN THE GERBIL: THE EFFECTS OF CORTICAL LESIONS.

M. G. Bigel\*, I. Sharma and C. G. Ellard, Department of Psychology, University of Waterloo, Waterloo, ON, N2L 3G1

Mongolian gerbils (*Meriones unguiculatus*) use retinal image size (RIS) to calibrate distance in a jumping task. The RIS algorithm depends on correlation of image size with target distance. When gerbils are trained to jump to targets of varying size, the use of RIS relies upon target identification. Our goals were to determine whether gerbils use local features or spatial context to identify targets and to assess the effects of cortical lesions on target identification in a jumping task. Sham controls and gerbils with either parietal or temporal lesions were trained to jump across a gap of randomly varying size to either a wide or narrow target. Targets had distinctive local features and were associated with unique spatial contexts. Test sessions were identical with training sessions but included probe trials using an intermediate sized target. The probe was presented with local features and spatial context that either matched or mismatched those seen during training. If gerbils were using RIS, they would over-jump when the probe target was narrower than the training target and underjump when it was wider. Results showed that normal and temporal gerbils could use spatial context but not local features to identify targets and parietal gerbils could use neither cue. We conclude that, for purposes of object identification, spatial context takes precedence over local features and that parietal lesions impair the ability to identify spatial contexts.

## 567.11

DISCRIMINATORY CHANGES IN NUCLEUS ACCUMBENS DOPAMINERGIC ACTIVITY IN RATS AS ASSOCIATED WITH SOCIAL BEHAVIOR HABITUATION-DISHABITUATION RESPONSES. Y. Shang, B. Liu, and D.E. Dluzen\*. Department of Anatomy, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272.

The *in vivo* activity of the nucleus accumbens (N. Acc.) dopaminergic system was evaluated in adult male rats, who were subjected to either a two-time, 5-min exposure to the same (A-A) or different (A-B) ovariectomized (OVX) rats with an inter-trial interval of 25 min. Extracellular DOPAC release was measured at 5 min intervals throughout these social behavior habituation-dishabituation trials. In the A-A condition ( $n = 5$ ), no changes in DOPAC release between the first and second social stimulus exposure ( $t = 0.57$ , N.S.) were obtained. Associated with these neurochemical responses were reductions in behavioral investigation ( $t = 2.27$ ,  $p < 0.05$ ). In contrast, for the A-B condition ( $n = 6$ ), DOPAC release significantly increased to the second stimulus exposure ( $t = 2.89$ ,  $p < 0.05$ ) which was associated with increased social investigation ( $t = 2.89$ ,  $p < 0.05$ ). These results demonstrate discriminatory responsiveness of the N. Acc. dopaminergic system as a function of exposure to the same or different social stimulus and suggest a role for this system in the mediation of memory/recognition processes to social stimuli.

## 567.8

A NEURAL SYSTEM ANALYSIS OF SPATIAL RECOGNITION MEMORY: ROLE OF THE PREFRONTAL CORTEX. T. Janis, R.P. Kesner\*. Dept. of Psychology, University of Utah, Salt Lake City, UT 84112

Based on prior research implicating the ventral lateral orbital cortex (VLO) and prelimbic and infralimbic cortex (IPL) as part of the prefrontal cortex in processing spatial information, the role of VLO and IPL in mediating working memory for spatial information was investigated using a continuous recognition spatial memory task. Rats were each allowed access to 12 arms of a 12 arm maze from a central platform. Access required that the rat orient to a cue on a clear Plexiglas door of the designated arm; upon orientation, the door was opened and latency to reach the end of each arm was measured. Of the 12 presentations per trial, three or four of the arms were repeated, but did not contain reinforcement. Repeated arms were presented with lags ranging from 0 to 6 (from 0 to 6 different arm presentations between the first and the repeated presentation). The dependent variable consisted of the difference in latencies between the first and the second (repeated) presentation of an arm. Rats were trained to a criterion of a grand mean (all lags) 3 second difference between the first presentation and the repetition based on 16 trials (one per day) for a total of 8 presentations per lag. After they reached criterion, the rats received under Nembutal anesthesia electrolytic lesions of the VLO, IPL or served as sham operated controls. One week after recovery they were retested for 32 trials. Results indicated that, relative to controls, rats with IPL lesions, but not VLO lesions, were impaired in continuous recognition memory performance. These results indicate that IPL cortex, but not VLO, may be part of a working memory for spatial information circuit.

## 567.10

INVOLVEMENT OF THE MEDIAL PREFRONTAL CORTEX CHOLINERGIC SYSTEM IN PRECLINICAL MODELS OF WORKING MEMORY IN THE RAT. A.H.J. Herremans, J.A.D.M. Tonnaer\*. Dept. of psychopharmacology, Faculty of Pharmacy, Utrecht University, Sorbonnelaan 16, 3584 CA, Utrecht, The Netherlands.

The involvement of the medial Prefrontal Cortex (mPFC) cholinergic system in working memory (WM) was investigated by assessing the effects of bilateral infusion into the mPFC of scopolamine on performance in a Delayed Matching to Position (DMTP) task and a Delayed Conditional Discrimination task (DCD) in rats. In the DMTP-task scopolamine infusions dose dependently disrupted performance independent of delay, indicating no specific role of the mPFC cholinergic system in WM. Moreover, rats trained on a DMTP-task displayed mediating behavior during delays in 50% of the trials to solve the task which seriously affects the validity of the DMTP-task as a model for WM. Furthermore, a time sampling method indicated that scopolamine infusions into the mPFC disrupted mediating behavior during the task. In a post-hoc analysis scopolamine was found to impair discriminability in a delay-dependent manner only in animals that used mediating behavior in the majority of the trials instead of using WM. Rats that displayed little mediating behavior, and as a consequence used WM showed no delay dependent effect. We developed a DCD task that better prevents mediating behavior. Bilateral infusion of scopolamine into the mPFC dose-dependently impaired DCD-performance. No delay dependent effect was found indicating that scopolamine did not specifically affect WM. This result agrees with the result of the rats using little mediating behavior in the DMTP task suggesting no specific involvement of the mPFC cholinergic system in WM.

REVERSIBLE LESIONS OF STRIATUM, AMYGDALA, AND SUBSTANTIA NIGRA AFTER INHIBITORY AVOIDANCE: DIFFERENTIAL EFFECTS OF HIGH AND LOW FOOTSHOCK INTENSITY. R. Salado Castillo, M. Sánchez-Alavez, G. L. Ouirarte, and R. A. Prado-Alcalá\*. Fac. Med. Natl. Univ. of México, México, D.F. 04510.

Interference with synaptic activity of the striatum (STR), amygdala (AMY), and substantia nigra (SN) produces marked memory deficits of inhibitory avoidance trained with relatively low intensities of footshock. It has been reported that when high intensities are used, amnesic treatments administered intrastratially become totally ineffective; given to the amygdala a partial protective effect against amnesia is obtained. To further characterize this protective effect, and its possible generalization to another structure, rats were trained in inhibitory avoidance with 1.0, 2.0 or 3.0 mA and then injected into the STR, AMY or SN with lidocaine; retention of the task was measured 24 hr later. A significant amnesic state was found after training with 1.0 mA, about 50% reponding after training with 2.0 mA, and no deficits after 3.0 mA. These results support the hypothesis that after an enhanced learning experience there is a functional rearrangement in those structures involved in memory functions.

INVESTIGATION OF THE EFFECTS OF COOLING THE PARABRACHIAL NUCLEUS, MEDIAL PREOPTIC AREA, AND CAUDATE PUTAMEN IN RATS. Y. Wang, D. G. Lavond, K. C. Chambers\*, Department of Psychology, University of Southern California, Los Angeles, CA 90089-1061.

Permanent lesions of the area postrema (AP) produce a constellation of symptoms which includes learned aversions to novel diets. When temporary lesioning of the AP by cooling is paired with consumption of a sucrose solution, a learned aversion to the sucrose solution occurs. Three experiments were conducted to determine whether this effect of cooling is limited to the AP or whether cooling other brain areas also can induce a CTA. Three brain areas were selected to be cooled, the parabrachial nucleus, which is involved in the mediation of CTAs, the medial preoptic area, which is thought to be involved in the modulation of CTAs, and the caudate putamen, which is not known to be involved in CTAs. For each brain area, two groups were tested: Cooling and No-Cooling. On acquisition day, after all of the rats had access to a sucrose solution for 1 hour, the selected brain area of the rats assigned to the Cooling group was cooled for 60 minutes. For each brain area, the Cooling group displayed a significant decrease in sucrose solution consumption on the first test day after acquisition while the No-Cooling group did not show any change in consumption. This suggests that the CTA induced by cooling of the AP is not specific to this brain region but is due to a more general effect of cooling on brain regions. Supported by USC FRIF

RADIAL ARM MAZE PERFORMANCE AND OPEN FIELD ACTIVITY IN STRIATAL KAINIC ACID-LESIONED RATS. Y. Ichitani\* and T. Iwasaki, Inst. of Psychology, Univ. of Tsukuba, Tsukuba, Ibaraki 305, Japan.

Striatal kainic acid (KA) lesions, which induce neuronal cell loss in the striatum without affecting fibers and terminals passing through it, are used to make an animal model of Huntington's disease. In this study we investigated whether these animals show any impairment of radial arm maze (RAM) performance and any changes of activity level in the open field test. Female adult Wistar rats were trained to run down all 8 arms rapidly to obtain reward pellets in an elevated RAM. One or two days after reaching the criterion, they were injected with KA (0.5 or 1.0  $\mu\text{g}/1.0 \mu\text{l}$  / each side) or 0.02M phosphate buffer (PB) into the striatum bilaterally. After recovery from operation, they were retrained in the RAM task until they reached the criterion (maximum 15 trials). Then the open field test (90 x 90 x 30cm) was conducted 5 min a day for 3 consecutive days (26-28 days after KA or PB injection). In postoperative RAM test, although control animals could reach the criterion immediately, the number of trials to reach the criterion was increased dose-dependently in KA-lesioned rats and most rats injected with KA 1.0  $\mu\text{g}$  could not relearn the task after 15 trials. In the openfield test, KA-lesioned rats showed more ambulation than control rats. Results indicate that animals with lesions of striatal neurons had difficulty in performing RAM task and this impairment could not be attributable to motor impairment. Thus our results suggest that striatal neurons play an important role in performance of this kind of spatial or working memory task.

## 567.17

LEARNING-INDUCED CYTOGENESIS IN THE BRAIN OF FOOD-STORING MARSH-TITS (*Parus palustris*). S.N. Patel, N.S. Clayton, & J.R. Krebs, (SPON: Brain Research Association), The University of Oxford, Depts of Zoology and Pharmacology, South Parks Road, Oxford, OX1 3PS, U.K.

Food-storing species of passerine birds have a larger hippocampal region relative to the rest of the telencephalon, than do non-storing species. Experience of storing and retrieving results in an increase in hippocampal volume and in neurone number (Clayton and Krebs, 1994, *PNAS*, 91: 7410-7414). In juvenile hand-raised marsh tits, there is an increase in the intensity of food-storing on day 44. Here we sought to determine whether hippocampal neurogenesis occurs as a result of food storing behaviour (thereby accounting for the increase in hippocampal neuronal number), and whether cytogenesis occurs prior to the increase in food storing intensity seen at day 44.

Hand-raised marsh tits were divided into experienced and control groups. Experienced birds were allowed to store and retrieve seeds in an experimental arena every third day from nutritional independence (day 35) while age-matched controls were prevented from storing and retrieving by providing them with powdered seeds while they were in the arena. Three experienced birds and three controls were sacrificed at day 41, 47 and 56. Three 35 day old birds served as pre-experimental controls. All birds received a single injection of 0.05  $\mu\text{Ci}$  of  $^3\text{H}$ -thymidine i.p. one hour before intracardiac perfusion with saline flush and 4% paraformaldehyde fixative. The rate of cytogenesis was measured by examining the percentage of cells labelled (by autoradiography) in the ventricular zone in 6  $\mu\text{m}$  thick paraffin embedded sections.

The results of 5 experienced and 7 control birds show that the rate of cytogenesis is significantly greater in experienced birds compared to controls in the ventricular zones of the hippocampus and the hyperstriatum ventrale (HV), but not the neostriatum, irrespective of the amount of experience. The results show that the HV as well as the hippocampus is involved in some aspect of food storing behaviour which involves the induction of cytogenesis in these regions.

## 567.14

COMPETITIVE "PLACE-CUE" RETENTION IN THE WATER MAZE: MEDIAL VERSUS LATERAL CAUDATE-PUTAMEN. B.D. Devan\*, R.J. McDonald & N.M. White, Department of Psychology, McGill University, Montreal, Quebec, Canada.

This study investigated functional differences between the medial and lateral parts of the caudate-putamen (dorsal striatum) in the acquisition and performance of water maze behaviors guided by either complex spatial or simple cues. Rats with dorsomedial (DM) or dorsolateral (DL) caudate-putamen lesions and sham-operated controls were initially trained on the standard hidden platform task. Rats with DM lesions, but not DL lesions, took longer to escape to the hidden platform and spent significantly more time swimming in the peripheral portion of the maze (i.e., thigmotaxis navigation). However, the DM group eventually achieved control levels of performance, and exhibited a significant bias for swimming in the training quadrant and crossing the location of the platform even when it was removed from the pool. In the second phase of the experiment, the three groups were given visible platform training in a different room/maze with the platform moved to a new location each day. Rats with DM lesions returned to thigmotaxis on the first visible trial block, but thereafter did not differ from controls. In the third phase of the experiment, the rats were brought back to the original room/maze. Following 4 invisible platform trials they were given a competitive "place-cue" retention test consisting of 4 trials from two start points that were equidistant from the invisible platform, located in its original position, and the visible platform, which was now positioned in the center of the diagonally opposite quadrant. The following results are expressed as the percentage of escapes to the visible versus invisible platform: Controls (61/39); DM (89/11) and DL (44/56). These results suggest that the DM caudate-putamen, by virtue of its connections with limbic and prefrontal cortical regions, may mediate responses based on spatial (S-S) information processing. In contrast, the DL region, by virtue of its direct sensory input from cortex and thalamus and its output to high level motor control systems, may mediate simple stimulus-response learning.

## 567.16

EFFECTS OF UNILATERAL DORSO-STRIATAL LESION ON THE PERFORMANCE ON A LATERALISED REACTION TIME TASK.

Dobrössy, M.D. and Dunnett, S.B.\*, MRC Cambridge Centre for Brain Repair and Department of Experimental Psychology, University of Cambridge, England.

The effects of various doses of systematically administered amphetamine and unilateral dorso-striatal lesions on the performance on a Skinner box adaptation of a visual reaction/movement time task were separately investigated. Food deprived rats were trained to hold the central perplex panel for a variable delay after which a visual stimulus was presented on either side of the animal. The rats were rewarded following a lateralised movement toward, and a press on, the previously extended lever above which the stimulus appeared. In the amphetamine study the pattern of responses reflected a dose dependent state in nearly all of the measured variables. The reaction and movement time also decreased with the low and the middle amphetamine doses. The delay dependent decrease in reaction time observed with the saline treated animals essentially disappeared as a consequence of the amphetamine. This data suggests an enhanced motor readiness exacerbating the increased anticipation of cue presentation as the delay progresses, potentially mediated by dopamine surplus in the striatum. Unilateral dorso-striatal lesions resulted in the increase of error trials, while not differing from the controls in the total number of trials attempted. The lesioned animals showed a bias to respond towards their ipsilateral side, a tendency which is mirrored in the decreased accuracy to respond to contralateral visual stimuli. The overall mean reaction time to contralateral stimuli, was retarded compared to their pre-lesion performance. The results of the lesion study suggest that the lateralised effects are rooted in executive and not in sensory or attentional processes. Contralateral visual cues did instigate responses. The anticipation of the stimulus, directly related to response execution, which shortened the reaction time the longer the required panel hold, was less apparent on the contralateral side following the lesion.

## 567.18

MORPHOLOGICAL AND ELECTROPHYSIOLOGICAL CHARACTERISATION OF NEURONS IN THE IMHV OF THE CHICK BRAIN. P.M. Bradley, B.D. Burns, T.M. King & A.C. Webb, Department of Neurobiology, Medical School, Newcastle upon Tyne, UK. (SPON: Brain Research Association).

The IMHV has been shown to be essential for learning in the chick. As a consequence of this learning there are changes in the morphological and electrophysiological characteristics of neurons in the IMHV. In order to be able to understand the neuronal circuitry that underlies these learning related changes we have attempted to correlate the electrophysiological characteristics of IMHV neurons with their morphology.

Biocytin filled intracellular electrodes were used to record the properties of a total of 26 neurons in the IMHV. The cells were then visualised, measured and classified as small or medium non-spiny neurons or as small, medium or large spiny neurons. Neurons were also classified according to their response to external stimulation. Type 1 cells displayed an EPSP sometimes with a spike. Type 2 cells showed prolonged depolarisation accompanied by a train of spikes. Type 3 cells showed an EPSP followed by a late hyperpolarisation.

In both spiny and non-spiny neurons the cells with the most extensive dendrites showed lower (more positive) resting membrane potentials and higher passive membrane resistance. Spiny cells were significantly larger than non-spiny cells and had a significantly lower incidence of spontaneous activity and a lower passive membrane resistance. Type 2 cells were smaller than other neurons, were spontaneously active and displayed significantly larger spontaneous EPSP's. Type 1 cells displayed a shorter time constant and a larger evoked EPSP than type 3 cells.

These results suggest a link between structure and function in the IMHV and provide a basis for modelling neuronal circuitry in the IMHV.

## 567.19

**APV PREVENTS SPINE ELIMINATION DURING AUDITORY IMPRINTING OF DOMESTIC CHICKS.** J. Bock and K. Braun\*. Fed. Inst. Neurobiol., 39118 Magdeburg, Germany.

Previous studies using Golgi impregnation techniques revealed in the medio-rostral neostriatum/hyperstriatum ventrale (MNH) of imprinted chicks an up to 45% reduction of spine frequency on type I neurons compared to naive controls (Scheich, 1987, *J. Comp. Physiol. A* 161: 605-619). Type I neurons develop LTP-like potentiation after tetanic stimulation of thalamic inputs, which can be blocked by the selective NMDA-antagonist DL-2-amino-5-phosphono valeric acid (APV) (Wang et al., 1994, *Neurosci.* 3: 689-699.). In behavioral experiments APV prevents imprinting in a dose dependent manner (Bock et al., 1993, *Europ. J. Neurosci., Suppl.* 5: 221). These observations suggest that NMDA-dependent potentiation of synapses is one of the mechanisms which underlie this learning process and we speculate that it may also be causally related to the observed morphological changes. To test this hypothesis we compared the spine frequencies in Golgi-Cox impregnated brains from APV-treated trained but not imprinted chicks, imprinted chicks and naive untreated chicks. Spine frequencies of type I neurons were calculated using the Neurolucida system (MicroBrightField, Inc.), which allows quantitative 3D analysis of microscopic images. The spine frequencies of type I neurons of APV-treated chicks and unimprinted controls were similar and both groups showed significant higher spine frequencies (about 35%) than imprinted subjects ( $p < 0.001$ , Kruskal-Wallis). Thus, APV-treatment not only blocks the induction of LTP and impairs auditory imprinting but also prevents the elimination of dendritic spines. This suggests an involvement of NMDA-receptor activation in the synaptic selection process during imprinting. The imprinting stimulus may activate a subset of synaptic connections in the MNH, which subsequently are potentiated and thereby stabilized and this potentiation may induce elimination of non-activated synapses. Supported by DFG Schn 505/2-1 and BMBF (GSF 07 NBL 06)

## 567.21

**SICKNESS-CONDITIONED LEARNING IN DAY-OLD CHICKS: MEMORY FORMATION DEPENDS ON TIME OF LITHIUM CHLORIDE INJECTION.** T.A. Barber\*, M.F. Pearlman, and K.E. Patrick. Psychology Department, Dickinson College, Carlisle, PA 17013-2896.

In the sickness-conditioned learning paradigm, the chick pecks a dry bead and is injected 30 min later with lithium chloride (LiCl). When tested 4 hours later, the chick avoids the "training" bead but pecks novel beads. Memory can be disrupted by injecting glycoprotein synthesis inhibitors around the time of "training", suggesting that memory formation concerning the bead begins well before any consequences have occurred.

The current experiment examined learning in this task following different times between presentation of the training bead and LiCl injection. Chicks injected with LiCl 5 or 10 min after training pecked the bead at test; they did not form an association between the bead and the sickness. In contrast, chicks injected with LiCl 15, 20, 30 or 45 min after training avoided the bead, evidence of memory formation for the association. These results suggest that the chick cannot learn the association unless the "memory" for pecking the bead is at least 15 min old.

Lesions of the intermediate medial hyperstriatum ventrale (IMHV) produce amnesia in passive avoidance learning in the chick, suggesting that the IMHV is involved in associating visual characteristics of the stimuli and consequences of pecking. Experiments in progress are examining the role of the IMHV in the sickness-conditioned learning paradigm.

## 568.1

**VOCAL-ACOUSTIC PATHWAYS IN SYNODONTID AND ARIID CATFISH.** F. Ladich, M. A. Marchaterre\*, L. Goldstein and A.H. Bass. Section of Neurobiology & Behavior, Cornell Univ., Ithaca, NY; Inst. of Zoology, Univ. of Vienna, Althanstrasse 14, A-1090 Vienna, Austria.

Several families of catfish, including Synodontidae and Ariidae, utilize swimbladder "drumming" and pectoral spine stridulation to generate vocal communication signals. Biotin compounds were used as retrograde and transneuronal tracers to identify the positions of motor and premotor neurons associated with the vocal/sonic muscles (see Bass et al., *J. Neurosci.*, 14: 4025, 1994). Dextran-biotin revealed the positions of ipsilateral vocal motoneurons: paired nuclei, located in the caudal medulla and rostral spinal cord, are located on the midline between the central canal and the medial longitudinal fasciculus (MLF) in synodontids, but lateral to the MLF in ariids. Pectoral spine motoneurons were labeled within the ventrolateral motor column in both families. Biotin transport also identified motoneurons in both families, and premotor neurons only in synodontids where labelled fibers and small somata were found bilaterally in the vocal motor nuclei. Biotin-filled neurons were also located within the ventrolateral medulla, rostral to motoneurons, and gave rise to commissural and lateral brainstem bundles linking the vocal motor circuitry to rostral regions of the brainstem considered to be acoustic. Vocal-acoustic pathways have been identified in other distantly related teleosts (Bass et al., 1994), suggesting that such links are a widespread trait shared by diverse groups of aquatic and terrestrial vertebrates that vocalize. Research support from US National Science Foundation and Austrian Science Foundation.

**INFLUENCE OF THE EXTRACELLULAR MATRIX PROTEIN TENASCIN ON AUDITORY FILIAL IMPRINTING IN THE DOMESTIC CHICK.** M. Metzger\*, J. Wang, K. Braun and M. Schachner. Federal Institute for Neurobiology, POB 1860, 39008 Magdeburg, FRG & Swiss Federal Institute of Technology, Hönggerberg, 8093 Zürich, Switzerland

The extracellular matrix protein tenascin (Tn) has been implicated in a variety of morphogenetic events such as neurite outgrowth and pattern formation. In a forebrain area of the domestic chick, the medio-rostral neostriatum/hyperstriatum ventrale (MNH), we found proliferative as well as regressive changes of synaptic connections during different stages of auditory filial imprinting, hence we speculate that recognition molecules such as Tn may be essential for these events. In order to test this hypothesis we blocked different Tn epitopes by intracranial injections of different monoclonal antibodies against Tn and subsequently we tested the imprinting success in behavioral tests. 15 min prior to each behavioral test newly hatched chicks were injected bilaterally into the MNH by the aid of a specially designed headholder either with 2µl of the monoclonal antibody Tn 68 or monoclonal antibody 578, both of which recognize different epitopes of the Tn molecule. In the Tn 68 injected group there was a significant decrease of imprinting success compared to the control group (PBS) and the 578 injected group. Single- and double labelling immunohistochemistry revealed that (i.) the diffusion of the injected Tn antibodies was restricted to the MNH, (ii.) the general distribution of Tn in the juvenile chick forebrain is widespread and (iii.) Tn is particularly accumulated around neuronal somata containing the Ca-binding protein parvalbumin. This Tn staining pattern is reminiscent of perineuronal nets. Since, in the MNH, a subpopulation of the PV+ neurons is GABAergic we are currently testing the hypothesis that Tn may influence GABAergic mechanisms. (Supported by the Deutsche Volkswagenstiftung)

## 568.2

**SOUND PRODUCING MECHANISM, HANDEDNESS, AND DEVELOPMENTAL CHANGES IN CHANNEL CATFISH SOUND PRODUCTION.** M.L. Fine\*, D. McElroy, J. Rafi, C.B. King, K. Loesser and S. Newton. Depts. of Biology, Va. Commonwealth University, Mary Washington College, and Va. State University.

The first pectoral spine of the channel catfish (*Ictalurus punctatus*) functions in swimming, defensive locking and stridulatory sound production. In this study we examined the mechanism of sound production and developmental changes in the sound producing organ and in acoustic parameters of threat sounds. Stridulation was typically produced by pectoral fin abduction when a convex ridged spinal process was rubbed against a rough but relatively featureless concave surface in the glenoid channel of the pectoral girdle. Typical sounds consisted of a series of 7-15 pulses per fin sweep of 56-177 ms, and we suggest that each pulse is produced by an individual ridge, successively contacting channel bone. Approximately half of the fish had a fin preference, and most of these were right handed. The spine and the girdle grew continuously, and the ridges became worn, with minimal remodeling, and grew further apart. Sound pressure level increased and central frequency decreased with fish size. Although sweep and pulse duration increased with fish size, the number of pulses remained constant, and the pulse repetition rate decreased, correlating with the greater distance between ridges and longer sweep time. Supported by NIH DC01083.

## 568.3

ULTRAVIOLET AND POLARIZED-LIGHT SENSITIVITY IN REPRODUCTIVE TROUT OF TWO SPECIES. D. C. Parkyn\* Dept. of Biology, University of Victoria, Victoria, Canada. V8W 2Y2.

The principal objective of the study was to examine differences in spectral and polarization (E-vector) sensitivity of non-reproductive and reproductive adult brook char (*Salvelinus fontinalis*) and rainbow trout (*Oncorhynchus mykiss*). Spectral and (E-vector) sensitivity were characterized using multiunit-recording from axons of retinal-ganglion cells in the optic nerve. In contrast to non-reproductive adults (as based on gonad development), ultraviolet (UV) and vertical e-vector sensitive mechanisms were identified in reproductive individuals. Both UV sensitivity and vertical E-vector sensitivity are mediated by UV cones. However, this UV mechanism is not present in non-reproductive adults in either species. Therefore, spectral and polarized-light sensitivity of the reproductive adults was more similar to that found in juvenile salmonids (i.e. four classes of cone photoreceptors, and two classes of polarization-sensitive mechanisms). These observations concur with studies showing the presence of putative UV-cones in the retinae of fish treated with thyroxine and histological studies of returning migratory salmonids (see Hawryshyn, Beaudet, and Novales F.). This supports the hypothesis that UV and polarization sensitivity are used by salmonids during their migration to natal streams for reproduction. To assess the functional role of UV-polarization sensitivity, I measured behavioral orientation using a video-image tracking system. My results revealed that some reproductive *O. mykiss* innately-orient relative to the plane of polarized light. This research was supported by an operating grant from the Natural Sciences and Engineering Research Council of Canada (C.W. Hawryshyn) and the University of Victoria (CWH and DCP).

## 568.5

FEEDING NEUROECOLOGY OF THE MECHANOSENSORY LATERAL LINE IN THE ATLANTIC STINGRAY, *DASYATIS SABINA*. K.P. Maruska and T.C. Tricas\*. Department of Biological Sciences, Florida Institute of Technology, Melbourne, FL 32901-6988.

The Atlantic stingray, *D. sabina*, feeds almost exclusively on small benthic invertebrates that it excavates from the sand substrate. This study examined the anatomy, spatial organization and innervation patterns of mechanoreceptors to predict the sequential function of each lateralis sub-system in prey detection, positioning, and capture. Superficial neuromasts extend only on the dorsal surface in bilateral rows along the midline from the spiracle to the tip of the tail. Dorsal hyomandibular canals have long radial neuromast-free tubules that project to the pectoral fin margins. The peripheral ventral canals have a similar arrangement of pores along the rostral margin but are displaced medially on the posterior disk surface. An extensive, confluent, and compliant ventral inner canal system lacks surface pores and extends rostrally from the pelvic region to the head where it expands between the mouth and disk margin. Vesicles of Savi are aligned in bilateral rows on the ventral midline of the snout. The mandibular canal spans the lower jaw and terminates in a single pore at each corner of the mouth. Ventral canal neuromast abundance ( $\bar{x} = 1028$ ) is approximately twice that of the dorsal ( $\bar{x} = 532$ ) system. Across size classes (22 - 32 cm disk width,  $n = 10$ ) the number of neuromasts increases only in the mandibular canal and total number of axons innervating each canal group does not change. We suggest that pore-bearing peripheral canals function in predation as detectors of water movement made by prey near the rostral margin and caudal underside of the disk. The extensive complex of inner canals on the ventrum that lack pores is hypothesized to 1) reduce noise caused by water movement across the skin during prey excavation, and 2) function as modified touch receptors for the guidance of exposed prey to the vesicles of Savi and mouth. Final positioning of prey immediately before capture is facilitated by the mandibular canal on the lower jaw.

## 568.7

CONTRIBUTIONS OF CANAL AND SUPERFICIAL NEUROMAST SENSORY CELLS TO THE ELECTROPHYSIOLOGICAL ACTIVITIES OF THE LATERAL LINE SYSTEM OF A CICHLID FISH (*Astronotus ocellatus*). H. Y. Yan\* School of Biological Sciences, University of Kentucky, Lexington, KY 40506-0225

It was demonstrated (Song, Yan and Popper, 1995: Hearing Research, In press) recently that by exposing a cichlid fish, oscar (*Astronotus ocellatus*) to the aminoglycoside antibiotic, gentamicin sulfate, selective damages occurred to one class of sensory hair cells (canal neuromasts) of the lateral line system but no morphological damages could be found in the other class of the sensory hair cells, superficial neuromasts. This study was undertaken to examine electrophysiological changes to the lateral line nerves of oscar after direct exposures to gentamicin sulfate solution (20 ppm) for 1, 2, 3, 4, 8, and 12 days. Extracellular recording techniques were used to measure the changes due to the damage of canal neuromasts. Recovery of the electrophysiological activities was also investigated when damaged neuromasts were allowed to regenerate after four days of exposure to gentamicin sulfate. By using this unique selective damage protocol, contributions of each class of neuromasts in the electrophysiological activities of the lateral line of fish can be assessed.

## 568.4

WHAT THE FLOUNDER'S EYE TELLS THE FLOUNDER'S SKIN. V. S. Ramachandran\*, R. L. Gregory, C. W. Tyler, D. Rogers-Ramachandran, S. Duensing, C. Pillsbury, and C. Ramachandran. UCSD, Brain and Perception Lab, Psychology, 0109, La Jolla, CA 92093-0109

Until recently, it was widely believed that flounders had a remarkable ability to match the pattern on their skin with the background (Sumner, 1911). This claim was recently challenged by Sidel (1977) who suggested that the "blending" was done mainly by the beholder, not the flounder. We placed 5 specimens of the tropical flounder *Bothus ocellatus* on 3 background patterns -- a coarse checkerboard, a fine checkerboard, a uniform grey of the same mean luminance. (The fish were placed for 5 minutes on each pattern and videotaped.) They were able to match the background pattern with surprising fidelity in just 6-8 seconds. A principal components analysis of the radial (Fourier) power spectrum of the fish versus the background showed, objectively, that there were 3 predominant channels of independent information about the background texture being expressed as camouflage patterns on the flounder. When the fish were placed on a sparse polka-dot pattern, each animal became pale and developed two small, but prominent black spots as if to mimic the polka-dots! We conclude that flounders do indeed have a remarkable capacity for rapid adaptive camouflage. We suggest that there are "feature detecting" neurons in the fish tectum that respond to different spatial frequencies and exert direct neural control over corresponding sets of melanophores in the skin.

## 568.6

APPROACH STRATEGIES USED BY MOTTLED SCULPIN IN LOCALIZING DIPOLE SOURCES. S. Coombs and R.A. Conley. Parml Hearing Institute, Loyola University of Chicago.

Mottled sculpin respond to the sinusoidal vibration of a small sphere with an initial orientation towards the source followed by a stepwise approach to the source that culminates in a strike. The x,y coordinates of the fish's position at each step in the pathway were digitized from a frame-by-frame videotape analysis and mapped into a computational matrix (Matlab) that used the dipole flow field equations to compute pressure gradients and flow angles at each position. Results from over 300 pathways (6 fish) to a 50 Hz suprathreshold source (varying in start distance (0.5 - 10 cm) and angular (0 - 360°) relationship to the fish) show that paths vary. A common approach is one in which fish maintain a < 45° angle to the source and flowline, but alternate between being to the left and right of the source. The total number of left and rightward positions was nearly equal for all but two fish, one of which had roughly twice as many leftward responses and the other which had twice as many rightward responses. Pressure gradients along the fish's head increased from below 10 Pa for start positions, to 10-100 Pa for pre-strike positions, and to 100-1000 Pa for strike positions. Those across the fish's head remained below 10 Pa for all positions. Taken together, these results suggest that fish find the source by minimizing the pressure gradient across the head and maximizing it along the head.

## 568.8

PROCESSING OF HYDRODYNAMIC INFORMATION BY NEURONS IN THE MEDULLA OF THE GOLDFISH. J. Mogdans\* and H. Bleckmann, Zoologisches Institut, Universität Bonn, Poppelsdorfer Schloß, D-53115 Bonn, Germany.

Fishes use a special sensory system, the lateral line, to detect weak water movements. To investigate central processing of hydrodynamic stimuli, we recorded single unit activity of neurons in the medulla of the goldfish while stimulating the lateral line with a small object moving in the water. Unit responses to various object speeds, object distances, and object sizes were measured. Responses were characterized by unit firing patterns and quantified by the discharge rate during stimulus presentation.

Spontaneous activity of mechanosensory lateral line units in the goldfish medulla was low (mean 2.5 spikes/sec, range 0-16 spikes/sec,  $n=35$ ). On the basis of temporal discharge patterns, four different response types were distinguished. Twentyfive units responded to moving objects with increases in discharge rate. Five units exhibited oscillating increases and decreases in discharge rate. One unit responded to moving objects with a decrease in neural activity. In general, discharge rates were independent of the direction of object movement. In two units, however, the pattern of the response reversed when movement direction was reversed. For all units tested, discharge rate decreased with decreasing object speed and increasing distance between object and fish. Discharge rates were comparable for object sizes between 1 cm and 2 cm but decreased when object size was reduced to 0.5-0.25 cm. We are currently studying whether medullary lateral line units respond differentially to objects that are accelerated or moved at a constant speed along the side of the fish.

The results indicate that in the goldfish medulla, different lateral line neuron populations may be responsible for the processing of different aspects of hydrodynamic stimuli. Moreover, the data suggest neuronal interaction at the level of the medulla, possibly through lateral inhibition. Lateral inhibition may establish direction and space sensitivity.

## VISUAL PRIMING OF MAUTHNER INITIATED ESCAPE RESPONSES TRIGGERED BY SOUND IN THE GOLDFISH.

R. C. Eaton\*, M. M. Walli, A. L. Guzik and J. L. Casagrand. Center for Neuroscience, University of Colorado, Boulder CO 80309-0334.

The Mauthner cell initiates escape from aversive auditory stimuli such as those generated by a predatory strike or an object falling into the water. We previously observed that if the escape path was blocked, the animal turned *toward* the aversive stimulus, a ball dropped into the water. This suggested that visual information could override the directionality of the responses triggered by auditory stimuli. In this experiment we dropped two balls into the water, one in front and one behind the fish. The ball drops were separated by 50 ms. The ball that hit the water first always triggered the response, but the ball that was most in the field of view primed the directionality. In cases when the trigger stimulus was behind the fish, the fish turned away from the priming stimulus and toward the trigger stimulus. This apparent tactical error occurred in 70.5% of such trials, compared to a rate of 12.5% with a single ball where there was no conflicting visual priming ( $p < 0.005$ ,  $X^2$ ). Further, in the paradigm with two balls, a blind control fish escaped away from the direction of the trigger stimulus. Thus visual components of the stimulus can control the direction of an escape triggered by sound. [Supported by the ONR].

## SENSORY GUIDANCE OF MAUTHNER-MEDIATED STARTLE IN GOLDFISH AND CICHLIDS. J.G. Canfield\* and C.I. Rose, Department of Biology, University of Utah, Salt Lake City, UT 84112

Acoustically-evoked escape behaviors were compared between goldfish (*Carassius auratus*), a hearing specialist, and the cichlid *Haplochromis burtoni*, a hearing nonspecialist. When unilateral sound stimuli were presented alone, both species avoided the direction of either a compressive or rarefying stimulus. If a light preceded and was contralateral to the sound pulse, goldfish avoided the sound source, whereas cichlids avoided the visual cue and turned toward the sound. Thus, for goldfish, acoustic cues predominate in both initiating and directing the response by activating the Mauthner cell ipsilaterally to the sound source. For cichlids sound is the releasing stimulus, but response direction is determined by visual cues; the Mauthner cell contralateral to the sound source presumably is activated in these conditions. Chronic recordings from the goldfish Mauthner cell indicate that only the initial rising phase (1.6 msec) of the stimulus is required to direct the response. After a 24 hour exposure to a 0.1 mmol/l cobalt solution (a treatment thought to inhibit lateral line function), goldfish escape performance improved but cichlids would not startle. Activating both speakers simultaneously with opposite polarity directly accelerates the fish's ears and reduces lateral line and pressure cues. When the speakers are not precisely matched for rate of rise, goldfish integrate sound pressure and particle motion aurally, while cichlids preferentially use lateral line cues to detect the direction of the startling sound source. With matched speakers, both species avoid the direction of the initially compressive sound source. This suggests a primitive mechanism for aurally detecting and avoiding the sounds associated with ram-type predators. [NIMH RO3MH50269]

## 568.10

## THE ROLE OF MAUTHNER CELLS IN FAST STARTLE RESPONSES. S.J.

Zottoli\*, B.C. Newman, H.I. Rieff and D.C. Winters. Dept. of Biology and Neurosci. Prog., Williams College, Williamstown, MA 12617.

Goldfish respond to an abrupt acoustic stimulus with a rapid, C-type startle response (C-start). A C-start is preceded by Mauthner cell (M-cell) activity in the goldfish, *Carassius auratus*. M-cells appear to initiate C-starts with other reticulospinal neurons contributing to the overall response. To further investigate the role of M-cells in C-start responses, either both M-cells were selectively ablated or their axons were selectively axotomized. M-cells were ablated in 8 goldfish by locating their axon cap, moving the microelectrode 50  $\mu$ m lateral to the cap, penetrating the M-cell soma and mechanically killing the cell. In 6 sham-operated control animals the axon caps were located but the somata were not damaged. Both M-axons were selectively axotomized just caudal to the facial lobe in 7 goldfish by penetrating the axons with a microelectrode and mechanically disrupting them. In 6 control animals the microelectrode was lowered close to the M-axon without damaging it. The probability of eliciting C-start responses and a series of kinematic parameters (i.e., latency, angle, velocity) were compared between experimental and control animals 3 hrs postoperatively. The success of both operations was confirmed morphologically at the end of the experiment. Fish with double ablations or double axotomies demonstrated a decrease in the probability of C-start responses ( $p < .0001$ ) when compared to their respective control groups. This reduced probability suggests that the M-cells may not only initiate C-starts but also contribute to the excitation of other reticulospinal neurons involved in this type of startle response. (Supported in part by an Essei Foundation grant to Williams College).

## INVERTEBRATE LEARNING AND BEHAVIOR III

## 569.1

ASSOCIATIVE LEARNING AND MEMORY IN *C. ELEGANS*. G.E. Morrison\*, N. Kumar, J.Y.M. Wen, S. Runciman, H. Negandhi and D. van der Kooy. Neurobiology Research Group, Dept. of Anatomy, University of Toronto, Toronto, ON, Canada, M5S 1A8.

We have developed a discriminative classical conditioning assay for *Caenorhabditis elegans* based on the chemoattractive properties of the conditioning stimuli (CS), Na<sup>+</sup> (NaCH<sub>3</sub>COO) and Cl<sup>-</sup> (NH<sub>4</sub>Cl). The CS ions are equally preferred under naive conditions. After exposure to one of the CS ions (CS+) in the presence of the US (*E. coli*, a food source), counterbalanced by an equal exposure to the alternate ion (CS-) in the absence of the US, the worms demonstrate a significant preference for the CS+ ion on testing. To ask about the differences between the worms that chose correctly (the CS+ ion) on testing and those that did not (chose the CS- ion), animals were separated into two groups following testing (those that chose the CS+ and those that chose the CS-) and then immediately retested without any further conditioning. On retest, both groups, in significant numbers, chose the CS+ ion over the CS- ion, suggesting that the assay may measure the probability of making a correct response (learning) in individual animals. Preferences for the CS+ ion could be easily reversed by replacing the appetitive *E. coli* food suspension with an aversive garlic extract. Conditioning with garlic as the US caused the worms to significantly avoid the garlic paired ion (CS+ ion) and approach the unpaired ion (CS- ion). US only tests with garlic did not affect the equal ion preference of otherwise naive worms on testing. These learning assays allowed for the isolation and behavioural characterization of two mutant *C. elegans* lines impaired in associative learning, designated *ltn-1* and *ltn-2*. Both lines show no short- or long-term associative learning, but appear normal in tests of non-associative learning and sensorimotor function. Complementation studies demonstrate that the two mutations are different. Outcrossing the two mutant lines indicates that they are both recessive. Using the sequence tagged site strategy for *C. elegans* and multiplex PCR techniques, we have begun mapping the two mutations through the generation of Bergerac/mutant (N2) hybrids.

## 569.2

ASSOCIATIVE LEARNING IN *C. ELEGANS* USING OLFACTORY CONDITIONING. Hiten Negandhi\*, Joseph Y.M. Wen, Glenn Morrison, Sue Runciman and Derek van der Kooy. Neurobiology Research Group, University of Toronto, Toronto, Canada, M5S 1A8.

*C. elegans*, a soil dwelling nematode, is an attractive organism for the reductionist study of learning and memory due to its excellent genetics and well defined neuroanatomy. We have previously isolated two learning mutants, *ltn-1* and *ltn-2*, which were impaired in an associative taste learning paradigm based on chemotaxis to Na<sup>+</sup> (NaCH<sub>3</sub>COO) and Cl<sup>-</sup> (NH<sub>4</sub>Cl). These mutants did not demonstrate any impairments in non-associative learning or sensorimotor function. We have developed a new associative learning paradigm, this time based on the olfactory ability of *C. elegans* to track certain volatile chemicals. In the unconditioned state the nematode is attracted to diacetyl, the conditioned stimulus (CS), and displays an unmistakable tracking response. Acetic acid, which the animal finds aversive, is used as the unconditioned stimulus (US). Training involves placing a population of worms onto a mesh filter and subsequently exposing them to diacetyl, followed by a brief submersion in acetic acid. After six such rounds of conditioning individual worms are tested for their response to a small drop of the CS. After conditioning, a significant proportion of wild type worms no longer track the CS, suggesting that they have learned the association. Several controls including CS only, US only, explicitly unpaired, and pseudo-random conditioning rule out non-associative effects. The *ltn-1* and *ltn-2* mutants isolated in our previous paradigm are also impaired in this new olfactory associative learning paradigm. This suggests that the associative learning impairment in these mutants extends across conditioning with various sensory modalities. A habituation/dishabituation (non-associative) paradigm has been designed using the same diacetyl smell employed in associative conditioning. We plan to test the *ltn-1* and *ltn-2* associative learning mutants on this paradigm to determine if they show any deficits in non-associative learning.

## 569.3

RECOVERY FROM HABITUATION AND HABITUATION OF SPONTANEOUS BEHAVIOR IN *C. ELEGANS*: DEPENDENCE ON CIRCUIT CHARACTERISTICS. S. B. Wicks\* and C. H. Rankin. Dept. of Psychology, Univ. of British Columbia, Vancouver, BC CANADA V6T 1Z4.

The nematode tap withdrawal reflex demonstrates various forms of non-associative learning. The circuitry which supports this reflex has been identified and consists of seven sensory neurons and nine interneurons. It has been shown that recovery from habituation in *C. elegans* possesses an interstimulus interval (ISI) dependence. However, it is not generally clear whether this dependence is on the ISI *per se* or whether it is on the morphology of the habituation produced at that ISI. It is possible to dissociate these possibilities by producing lesions in the circuitry which supports the plasticity such that the morphology of habituation is manipulated independent of the ISI. Habituation of animals at a 10s ISI—as compared to a 60s ISI—results in a faster rate and deeper asymptotic level of habituation. In addition, animals trained at a 10s ISI show recovery within 5 minutes; animals trained at a 60s ISI do not. PLM- animals which were trained at a 10s ISI habituated like 60s ISI control animals—both in terms of rate and asymptotic levels of habituation. Recovery in these animals resembled recovery of the 10s ISI controls rather than the 60s ISI controls. Thus recovery dynamics are dictated by the ISI rather than by the morphology of the habituation curve.

As a first step in localizing the site of behavioral plasticity in the tap withdrawal circuit we analyzed habituation of spontaneous behavior. Animals reverse both in response to tap and spontaneously. The tap evoked reversals are mediated by the mechanosensory neurons of the tap withdrawal circuit; the spontaneous reversals may not be mediated by these cells. We determined that the spontaneous reversals of animals that had undergone habituation of the tap withdrawal response were not also habituated. This suggests that habituation of the tap withdrawal reflex may be localized to the sensory neurons and their terminals and is not due to intrinsic changes in the interneurons which drive locomotion.

## 569.5

LONG-LASTING ALTERATIONS IN RESPONSIVENESS AFTER REPEATED BLOCKS OF TRAINING AT DIFFERENT TIMES DURING DEVELOPMENT IN *CAENORHABDITIS ELEGANS*. C. D. O. Beck\*, H. Aulakh and C. H. Rankin. Dept. of Psychology, Univ. of British Columbia, Vancouver, BC CANADA V6T 1Z4.

Previously, we demonstrated that during adulthood *C. elegans* is capable of long-term memory (over 24 h) for repeated blocks of stimulation in the locomotory response to a vibrational stimulus, tap. We have now developed a method of examining the long-term memory for repeated blocks of stimulation during early development and at maturity.

*C. elegans* has a reproductive cycle of 3.5 days, and during development passes through four larval stages, L1-4, each ended by a molt of the cuticle. The development of worms was synchronized by bleaching gravid adults, killing larval and adult worms but leaving eggs intact. Within 3 to 5 h, the hatched L1 larval worms were separated into control and experimental groups. Controls received no stimulation, while experimental worms received 100 trains of taps in 5 blocks of 20 stimuli. Within each block, stimuli were given at a 60-s ISI, and between blocks there was a 1-h rest interval. Testing was done individually with 10 stimuli at a 60-s ISI. Worms were trained together in a large group at one developmental stage (i.e. L1 or young adult) and tested individually 46 and 50 h after the beginning of training. Preliminary results suggest that while the responsiveness of worms trained as adults was not altered, the responsiveness of worms trained early in development at L1 was enhanced. These results are of interest in light of the knowledge that the tap withdrawal circuit undergoes rewiring during development as new neurons arise and are incorporated. It is possible that early stimulation may influence the course of development. Further research into this finding is underway.

## 569.7

SIGNAL PROPAGATION IN THE NERVE RING OF THE NEMATODE *C. ELEGANS*. S. R. Lockery\* and D. H. Hall. Inst. of Neuroscience, Univ. of Oregon, Eugene, OR 97403 and Dept. of Neuroscience, Albert Einstein College of Med., New York, NY 10461.

Voltage clamp recordings from neurons in the nerve ring, the major site of synaptic integration in *C. elegans*, indicate that most neurons do not have regenerative potentials. This suggests that signal propagation is largely passive. We tested this idea by constructing compartmental models representing the main types of neurons in the ring: (1) RMD, a short monopolar ring interneuron, (2) AWC, a bipolar sensory neuron, and (3) AVH, a long monopolar interneuron. Membrane resistivity ( $R_m$ ) was estimated from single channel currents in cell-attached patches from L1 larvae. This was possible because the input resistance of *C. elegans* neurons is so high that the membrane capacitance charges and discharges as the channel opens and shuts. We first estimated the membrane time constant ( $\tau_m$ ) by fitting sums of exponentials to the time course of the discharge current, then calculated  $R_m$  by dividing  $\tau_m$  by the specific membrane capacitance.  $R_m$  ranged from 0.5 - 2.6 K $\Omega$  cm<sup>2</sup>. Axial resistivity ( $R_i$ ) was assumed to be 400  $\Omega$  cm. Cell dimensions were determined from electron micrographs of L1 larvae. Signal propagation was studied by measuring the decrement in voltage from a synapse near the soma to the point furthest away in the nerve ring. Decrements ranged from 56% for RMD to 76% for AVH. Actual decrements are probably smaller, however, because we underestimated  $R_m$  and overestimated  $R_i$  and process length in the ring. Thus, regenerative potentials are not necessary for signal propagation in the nerve ring in *C. elegans*.

## 569.4

A DEVELOPMENTAL STUDY OF HABITUATION OF ACCELERATIONS IN *C. ELEGANS*. T. N. Gannon\* and C. H. Rankin. Dept. of Psychol., Univ. of British Columbia, Vancouver, BC, CANADA V6T 1Z4.

We have demonstrated that the tap withdrawal reflex of *C. elegans* displays habituation, dishabituation and sensitization. Through the use of laser ablation techniques, the neural circuit underlying this tap withdrawal response has been elucidated. To study learning in the tap withdrawal reflex throughout the course of development in *C. elegans*, we must first address the problem that, unlike adults, the larval animals do not consistently reverse to tap, but rather accelerate about one-half of the time. We circumvent this problem by selectively laser ablating either the tail-touch neurons (PLML and PLMR) that transduce stimuli that produce the accelerations, or the head-touch neurons (ALML and ALMR) that transduce stimuli that produce the reversals: With PLML and PLMR ablated, worms of all ages consistently reverse to tap; with ALML and ALMR ablated, adult worms consistently accelerate to tap. When the above neurons are ablated in adult worms the reversal and acceleration responses appear to habituate at different rates. In a previous study we examined habituation in the reversal response over the course of development. The results showed that although animals of all developmental stages did demonstrate habituation, there were some developmental differences among the stages.

In this study we are examining the time-course and magnitude of habituation of the acceleration response across developmental stages. We are examining the time-course and magnitude of habituation and recovery from habituation of accelerations at two different inter-stimulus intervals (10 and 60 seconds) for twenty different animals tested at each of the six major developmental stages in *C. elegans*. Preliminary results indicate that even the youngest animals tested accelerate to tap when ALML and ALMR are ablated, and that this response does seem to habituate.

## 569.6

A MUTATIONAL APPROACH TO THE ANALYSIS OF HABITUATION IN THE NEMATODE *C. ELEGANS*. C. H. Rankin\*. Dept. of Psychology, Univ. of British Columbia, Vancouver B.C. CANADA V6T 1Z4.

The nematode *Caenorhabditis elegans* is capable of a number of forms of behavioral plasticity. In my laboratory we have focused on the factors influencing both short- and long-term habituation and recovery from habituation. We have investigated the role of a number of behavioral parameters including number of stimuli and interstimulus interval (ISI) on habituation. In addition, we have carried out a circuit analysis and determined the contributions of a number of identified neurons to the rate and degree of habituation in intact animals. With this knowledge about the behavioral and neural characteristics of habituation in *C. elegans* we are now ready to carry out a mutational analysis of habituation in this organism. To do this we have used two approaches. In the first approach we have examined habituation and recovery from habituation in individual worms from a variety of mutant strains identified by other research laboratories. These include mutants missing specific neurons (e.g. *egl-5*; missing a pair of sensory neurons), specific neurotransmitters (e.g. *cat-1* missing catecholamines), and a number of mutants that showed behavioral abnormalities in other tests of plasticity in other laboratories. Mutants missing neurons that play a role in producing the response to tap confirmed our laser ablation studies. Worms that show abnormal thermotactic behaviors (supplied by I. Mori) showed some interesting variations in habituation patterns. Several mutations appear to affect probability of responding to tap without affecting habituation, while one mutant appears to show the initial rapid drop in habituation followed by recovery while stimulation continues. We continue to follow up on this approach. In the second approach we have used computer-assisted tracking to observe large numbers of worms at a time. With this system we have begun a mutational analysis of habituation using the mutagen EMS. This approach will allow us to complete a genetic dissection of the components and processes contributing to habituation and influencing short and long term memory for habituation.

## 569.8

CYCLIC AMP, A SIGNAL MOLECULE INVOLVED IN THE BEHAVIORAL SEX-PEPTIDE RESPONSE IN *DROSOPHILA MELANOGASTER* FEMALES? J. Fleischmann<sup>1</sup>, B. Dauwalder<sup>2</sup>, T. Chapman<sup>3</sup>, B. Cotton<sup>1</sup>, M. Schlump<sup>1</sup> and E. Kubli<sup>1</sup>. <sup>1</sup>University of Zurich, 8057 Zurich, Switzerland. <sup>2</sup>UT MD Anderson Cancer Center, Houston, USA. <sup>3</sup>University College London, London, UK.

Mating elicits several well defined responses in the female of *Drosophila melanogaster*: Ovulation and oviposition are increased, the remating rate (measured as percentage of females copulating within a given time period = receptivity) is low and the female shows rejection behavior towards courting males by extruding her ovipositor. Central to the control of these responses is the sex-peptide (SP), a 36 amino acid long peptide, synthesized in the male accessory glands. During copulation it is transferred into the female. Injected into virgin females, or ectopically expressed, SP induces the same reactions as observed after normal copulation. From work with gynandromorphs it is known that performance of sex-specific behaviors depends on the sex of certain parts of the brain. This finding and the complex behavioral changes induced by SP imply that the nervous system is involved in the females' reaction to SP.

*dunce* is known to be a learning and memory mutant. The *dunce* gene product is expressed predominantly in the mushroom bodies, a brain structure thought to be involved in these processes. *dunce* females remate more frequently than the wild type. We tested the mating response of SP-injected *dunce* females. They do not respond to the SP with reduction of receptivity. We used transgenic *dunce* females carrying a heat-inducible *dunce*\* rescue construct to test whether the *dunce* gene product is physiologically required for induction of the SP response at the time of injection. We observed a partial rescue of the SP response in heat-induced *dunce* transgenic females injected with SP. Since the *dunce* gene codes for a cAMP-phosphodiesterase and the cAMP level in *dunce* mutant flies is elevated, we conclude that the cAMP level might be crucial for the behavioral SP-response.

**MOLECULAR CHARACTERIZATION OF THE MUSHROOM BODY DERANGED LOCUS OF DROSOPHILA MELANOGASTER.** K. Miyamoto, M. Gasser and K. Furukubo-Tokunaga\*. Zoologisches Institut der Universität Basel, CH-4051 Basel, Switzerland.

Mushroom bodies are a pair of neuropil structures that are essential for various higher order behaviors in *Drosophila* such as olfactory learning and courtship. Negatively reinforced olfactory learning is completely abolished in the mutant *mushroom body deranged*, in which the axons of mushroom bodies fail to find the right path leading to abnormally enlarged calyces with degeneration of peduncles and lobes (Heisenberg et al., 1985. J. Neurogenet. 2: 1-30.). By genetic deficiency mapping, we have delimited the *mbd* locus at 17B3-6 on the X chromosome and completed DNA walk that covers the region 17A-C. Molecular mapping of the chromosomal break points of the deficiency lines have defined the *mbd* locus at a region of 30 kb in the distal vicinity of the *wint-3* gene. Three of the mushroom body specific enhancer-trap lines (isolated in the R.L. Davis lab) have also been mapped on the DNA walk in the proximal vicinity of the *mbd* locus. A putative *mbd* transcriptional unit, which is transcribed at various developmental stages, has been identified and isolated as a cDNA clone. The structure and the expression pattern of this transcriptional unit will be presented (supported by the Swiss NSF).

## 569.11

**INHIBITION OF NO-SYNTHASE SPECIFICALLY IMPAIRS LONG-TERM MEMORY IN THE HONEYBEE, *Apis mellifera*.** U. Müller\*. Institut für Neurobiologie FU-Berlin, 14195 Berlin, Germany.

NO-synthase (NOS) in the bee brain has similar properties as the corresponding vertebrate enzyme. The localization of NOS in the antennal lobes and the lip of the mushroom body calyces, sites of associative learning, suggests a role of the NO system in the processing of chemosensory information and in mechanisms of olfactory learning and memory. Inhibition of the NOS during the associative olfactory conditioning (CS-US pairing) specifically interferes with the formation of long-term memory as measured at 24 h (LTM), while inhibition before or after associative CS-US pairing has no effect on LTM formation. Blocking of NOS does not interfere with acquisition or memory retrieval. Interestingly, inhibition of the NOS during a single CS-US pairing, does not affect conditioned response up to 24 h after conditioning, indicating that this form of LTM requires multiple learning trials. Although the molecular target of NO action, mediating LTM is as yet unknown, a likely effector of NO is the soluble guanylate cyclase. We have shown that the cGMP produced via activation of the NOS modulates different components of the cAMP cascade. Therefore, it is conceivable that the specific loss of the LTM indicates a requirement of NO mediated mechanisms during CS-US pairing, possibly a NO dependent modulation of the cAMP cascade in the Kenyon cells.

**A SINGLE CEREBRAL INTERNEURON INITIATES DIFFERENT ELEMENTS OF FEEDING BEHAVIOR IN THE MOLLUSC, *CLIONE LIMACINA*.** T.P. Norekian\* and R.A. Satterlie. Dept. Zoology, ASU, Tempe, AZ 85287 and FHL, Univ. of Washington, WA 98250.

*Clione limacina* is a specialized predator that feeds on actively swimming pteropods of the genus *Limacina*. To seize the prey, *Clione* rapidly everts 6 tentacle-like oral appendages, called buccal cones, which surround and hold the *Limacina* shell. Then, the radula and specialized chitinous hooks are used to pull the *Limacina* body from its shell, to be swallowed whole. Feeding behavior is also characterized by acceleration of swimming and depression of all defensive withdrawal reactions. Several groups of neurons which control different components of feeding, withdrawal and swimming behaviors in *Clione* have been previously identified. However, the question of their coordinated activity, necessary for developing feeding behavior, still remains open. We describe here a pair of cerebral interneurons which have widespread excitatory and inhibitory effects on a number of neurons in the cerebral and pedal ganglia, directed toward the initiation of feeding behavior in *Clione*. This bilaterally symmetrical neuron, designated Cr-PC (Cerebral neuron initiating Prey Capture), produced monosynaptic activation of Cr-A motoneurons which control buccal cone extrusion, and inhibition of Cr-B and Cr-L motoneurons whose spike activity maintains buccal cones in a continuous withdrawn position inside the head in non-feeding animals. Cr-PC neuron also produced monosynaptic activation of a number of swim motoneurons in the pedal ganglia and pedal serotonergic Pd-SW neurons involved in peripheral modulation of swimming. Cr-PC neuron in *Clione* functions much like the C-PR which was suggested to evoke a feeding arousal in *Aplysia*.

## 569.10

**THE EFFECT OF MUSHROOM BODY ABLATION ON LEARNING AND MEMORY IN COURTSHIP BEHAVIOR IN *DROSOPHILA*.** S.M. McBride, G. Baker and K.K. Siwicki\*. Biology Department, Swarthmore College, Swarthmore, PA 19081.

Evidence that the neural structures called mushroom bodies (MB) are related to learning in *Drosophila* includes recent experiments in which the MBs were specifically ablated by treatments with the DNA synthesis inhibitor Hydroxyurea (HU). MB-ablated flies were unable to learn to associate shock and odor in a classical conditioning paradigm (deBelle & Heisenberg, 1994, *Science* 263, 692). Using the same ablation technique, we tested the role of the MBs in a behavioral learning paradigm, experience-dependent courtship. Experience-dependent courtship occurs when a virgin male is placed with a fertilized female for 60 minutes and as a result displays less vigorous courtship towards a virgin female (Siegel & Hall, 1979, *PNAS* 76, 3430). The effects of MB ablation on learning in this paradigm were tested in males immediately after training, while the effects on memory were tested 30 and 60 minutes after training. Results indicated that the HU-induced MB ablations had no effect on learning in the experience-dependent courtship paradigm: both MB-ablated and control males learned to reduce their courtship behavior as a result of experience with a fertilized female. In control males the learned behavior persisted for at least 60 minutes after training; MB-ablated males, however, exhibited significantly less memory retention than controls at 30 and 60 minutes after training. Our results implicate the MBs in the process of memory retention, but not in the initial learning of preconditioned courtship behavior.

## 569.12

**NITRIC OXIDE IS IMPLICATED IN OLFACTORY LEARNING IN *HELI* BUT NOT IN OLFACTORY ORIENTATION PER SE.**

T. Teyke\*. Inst. Zoologie (III), Joh. Gutenberg-University, 55099 Mainz, Germany.

Nitric oxide (NO) has been implicated in learning in vertebrates and invertebrates. In *Helix*, nitric oxide has been localized in the central ganglia and might also be present in peripheral olfactory sensory neurons. Therefore, the role of NO in olfactory learning (food-attraction conditioning) is contrasted to that in olfactory orientation. Food-attraction conditioning is an olfactory learning phenomenon in which snails, by feeding on a food, acquire the ability to locate this particular food. Prior to feeding, naive snails are unable to detect the food; in control runs only 8% of the experimental animals [n=50] located the food. After these tests, NO synthesis was inhibited by injection of selective NO-synthase inhibitor L-NAME (75 mg/kg) into the haemolymph; a control group received injections of vehicle. Snails were fed 1 hour after injection, and the effect of feeding (food conditioning) was assessed the next day by the animals' ability to locate the conditioned food.

Inhibition of NOS significantly reduced food finding ability. While 72% of the saline injected snails located the food, snails injected with L-NAME showed reduced food finding ability, and only 44% of the animals were able to locate the food. This is a highly significant reduction from the performance of saline injected controls, indicating that some aspects of food-attraction learning require the functional enzyme NOS. Complete abolishment of the learning, however, was not observed, and increasing the dosage to 150 mg/kg had effects that were similar to those caused by the lower dosage.

Olfactory orientation *per se* remained unaffected. When food-conditioned animals (fed 24 hrs before) were injected with L-NAME, their food finding ability was indistinguishable from that of saline injected controls when tested 1 hour or 1 day after injection (83% and 62% of the snails located the food, respectively).

These results suggest that NO is involved in the acquisition of food-attraction learning, and that the inhibitory effect of L-NAME on olfactory learning is not due to impeded olfactory functioning.

## 569.14

**TWO-PHASE MECHANISM OF AVERSIVE ASSOCIATIVE LEARNING IN *IN-VITRO* BREEDING EMBRYOS AND ADULTS OF THE POND SNAIL, *LYMNAEA STAGNALIS*.** M. Yamanaka, S. Kojima, Y. Fujito\* and E. Ito\*. Lab. Animal Behavior & Intelligence, Div. Biol. Sci., Grad. Sch. Sci., Hokkaido Univ., Sapporo 060, Japan and \*Dept. Physiol., Sch. Med., Sapporo Med. Univ., Sapporo 060, Japan.

A method for the building-up of an associative learning with an aversive unconditioned stimulus (UCS) in *in-vitro* breeding embryos of the pond snail, *Lymnaea stagnalis*, was established. The embryos were maintained in the individual holes of micro assay plates and covered with extract from the egg cocoons and then with tap water. To train the embryos for the associative learnings, they were settled upside down in the individual small holes of silicon dishes and perfused continuously with Jockusch solution (B. Jockusch, 1968). The conditioned stimulus (CS, sucrose) and the UCS (KCl) were associated 5 times. The feeding responses of the embryos in some later developmental stages, in which the assembly of ganglia had already begun, were successfully terminated by a sucrose application as a test, and their acquired behavior was maintained until adulthood.

Although an aversive associative learning is always built up in both embryos and adults of *Lymnaea*, a favorite learning was also sometimes possible. As previously proposed (S. Kojima et al., 1995) to explain this difference, we have examined the neuromodulation mechanisms in their interneurons. For the aversive learning, it was observed that an excited UCS interneuron inhibited that for the CS for a long time. Namely, the sucrose application (CS) failed to start the feeding response in the behavioral experiments. After many training sessions, the excited CS interneuron eventually activated that for the UCS, and thus the CS caused the shrinkage or the withdrawal of the associative behavior. For the aversive associative learning, however, the first phase was enough and, therefore, it was easily built up. With regards to the favorite learning, the CS interneuron had to directly activate that for the UCS. This meant that the first phase like that in the aversive learning must have been skipped and only the second one was required. Such activation and the CS-induced aversive response were difficult to observe.

## 569.15

AN OPTICAL AND ELECTROPHYSIOLOGICAL STUDY OF MODULATION OF NEURONAL ACTIVITY IN SLUG CEREBRAL GANGLIA. S. Kawahara\*, S. Toda, and Y. Kirino. Faculty of Pharmaceutical Sciences, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113, JAPAN

The terrestrial slug *Limax marginatus* has a high ability in odor-taste associative learning. When a slug is exposed to an odor of a food followed by a solution of quinidine sulfate, the slug shows an aversive response to that odor the next time. The locus at which the learning takes place is thought to be the cerebral ganglia, where inputs from the olfactory (tentacle) and gustatory (lip) nerves are integrated.

We attempted to find a cellular correlate of learning and memory in the form of plasticity in the cerebral ganglia, using electrophysiological and optical techniques. The cerebral ganglia with tentacle and lip nerves attached were isolated from the slug. A local field potential was measured from the procerebral (PC) lobe of the cerebral ganglia. An electrical stimulation of the tentacle nerve evoked a negative potential in the neuropil of the PC lobe. The evoked potential was decreased by addition of 0.1 mM NiCl<sub>2</sub> to the medium or by replacement of CaCl<sub>2</sub> with MgCl<sub>2</sub>. This implies that the evoked potential reflects the postsynaptic potential of PC neurons. After a tetanus stimulation was applied to the tentacle nerve and the cell mass of the PC lobe, the amplitude of the evoked potential increased. The potentiation lasted for about 15 min after the shock. This potentiation was mimicked by bath-application of serotonin (10  $\mu$ M). These results suggest that input from the tentacle nerve to the PC neuron can be modulated. Optical measurement of neural activity in the PC lobe using a voltage-sensitive dye and 128 x 128 MOS-FET camera gave results consistent with this idea.

## INVERTEBRATE LEARNING AND BEHAVIOR IV

## 570.1

LONG-TERM POTENTIATION OF *APLYSIA* SENSORY NEURON SYNAPSES AFTER TAIL PINCH: EFFECTS OF POSTSYNAPTIC HYPERPOLARIZATION AND BAPTA INJECTION. M. Cui\* and E.T. Walters. Department of Integrative Biology, University of Texas - Houston Medical School, TX 77030.

Recently we found that LTP produced by intracellularly firing tail sensory neurons (SNs) was reduced by postsynaptic hyperpolarization or BAPTA injection into the postsynaptic motor neuron (MN) (Cui & Walters, *Soc. Neurosci. Abstr.* 20:1071, 1994). To test contributions of voltage- and Ca-dependent postsynaptic induction signals during noxious stimulation of the SNs' receptive fields, we activated the SNs peripherally, using 10 intense pinches to the tail at 5 sec intervals. Intracellular test stimuli were applied to an SN every 5 min while recording from 2 MNs. Hyperpolarization of one MN soma to -120 mV or more failed to significantly reduce tail-pinch-induced potentiation at 1 min (mean EPSP amplitude 262% of baseline vs. 278% in concurrently recorded, non-hyperpolarized control MNs) or 30 min (mean EPSP 170% vs 172% in controls, n=5 animals), perhaps because the injected current could not hyperpolarize the postsynaptic membrane sufficiently during massive MN depolarization. In contrast, injection of BAPTA into one MN reduced 1 min potentiation in 5 of 6 animals (mean EPSP 306% vs 341%) and reduced 30 min potentiation in 4 of 6 animals (mean EPSP 112% vs. 130%). Injection of BAPTA had an even stronger effect on potentiation produced by relatively weak tail shock, reducing both the 1 min and 30 min potentiation in 5 of 5 animals (mean EPSPs 153% and 212%, and 98% and 139%, respectively). These results suggest that postsynaptic induction signals contribute at least partially to LTP underlying site-specific sensitization of the tail-withdrawal reflex.

## 570.3

GLUTAMATE INDUCES A CHANGE FROM SYNAPTIC SHORT-TERM DEPRESSION TO SHORT-TERM FACILITATION IN *HELIIX POMATIA*. G.R.J. Christoffersen\* and T.S.S. Schilhab (SPON: European Neuroscience Association). Neuroscience Centre for Cognition and Memory, August Krogh Inst., Univ. of Copenhagen, Copenhagen, Denmark, 2100.

EPSPs in neuron RPa3 in *Helix pomatia* display short-term depression when repeatedly activated by stimulation of an afferent nerve at a low, constant strength near threshold value. In contrast to this, a series of EPSPs activated at a higher, constant strength not only begins at a higher amplitude, but displays short-term facilitation. Presently, we tested the ability of glutamate to induce the shift from depression to facilitation at a constant stimulus strength.

Experiments began by a series of EPSPs, activated by stimulation of the right pallial nerve (1/10 Hz) at a constant strength of less than 1.5 times threshold value. Following that, the ganglia were exposed 4 times for 2 min. at 20 min. intervals to constant concentrations of Na-glutamate (ranging in different experiments from 0.5  $\mu$ M to 10  $\mu$ M). 10 min. after the last exposure, a second series of EPSPs were elicited using the same stimulus strength and frequency as before.

The results showed, that glutamate had induced two changes. 1) The amplitude of the first EPSP in the second series had increased by an average factor of  $6.4 \pm 1.7$  S.E.M. compared to the first EPSP of the first series. 2) While the first series displayed short-term depression, the potentiated EPSPs in the second series displayed short-term facilitation. Control experiments in normal saline showed a reduced initial EPSP in the second series and short-term depression of the subsequent EPSPs of that series. The effects of glutamate had not decayed 60 min. after the last exposure.

In conclusion, glutamate induced a long-term EPSP enhancement on top of which, a normal short-term depressing capacity was replaced by short-term facilitation. This change is different from heterosynaptic facilitation in for instance *Aplysia*. Here, the amplitude of depressed EPSPs are also increased, but continued EPSP activation after the facilitation leads to short-term depression - in contrast to the presently observed short-term facilitation.

## 570.2

DYNAMICS OF INDUCTION AND EXPRESSION OF LONG-TERM SYNAPTIC FACILITATION IN *APLYSIA*. J. Mauelshagen, G.R. Parker, & T.J. Carew\*. Dept. of Psychology, Yale University, New Haven, CT, 06520.

In the tail sensory-motor synapses in *Aplysia*, multiple applications of serotonin (5HT) induce both short-term and long-term synaptic facilitation (STF and LTF) (Emptage & Carew, 1993). In the present study, we examined the temporal dynamics of these two forms of synaptic plasticity.

We first examined the expression of STF and LTF. Five applications (6 min each) of 10  $\mu$ M 5HT were delivered to isolated pleural-pedal ganglia. EPSP amplitudes were recorded before and immediately after the first 5HT application, and again at either 3, 10, 15, or 20 hrs after the last 5HT application. Data are expressed as % baseline. STF was induced after the first 5HT application ( $\bar{x}$ =198%;  $p<.001$ ;  $n=34$ ), and decayed to baseline by 3 hrs ( $\bar{x}$ =94%;  $n=12$ ). At the 10-hr test no significant LTF was observed ( $\bar{x}$ =135%;  $n=8$ ); however, LTF was clearly expressed at both the 15-hr test ( $\bar{x}$ =199%;  $p<.02$ ;  $n=6$ ), and at the 20-hr test ( $\bar{x}$ =130%;  $p<.02$ ;  $n=9$ ). These data show that STF completely decays several hours before the expression of LTF.

We next characterized the induction of LTF by exposing different preparations to a specific number (1 to 5) of 5 min 50  $\mu$ M 5HT applications. Tests were made: (1) at baseline; (2) immediately after the first application; (3) immediately after the last application; and (4) every 15 min thereafter for up to 3 hrs. The amount of facilitation progressively and significantly declined with additional 5HT applications (1st:  $\bar{x}$ =207%,  $n=19$ ; 2nd:  $\bar{x}$ =182%,  $n=4$ ; 3rd:  $\bar{x}$ =139%,  $n=4$ ; 4th:  $\bar{x}$ =159%,  $n=5$ ; 5th:  $\bar{x}$ =82%;  $n=4$ ; Comparing 1st and 5th application:  $\bar{x}$  reduction=125%;  $p<.003$ ). Moreover, in 6 preparations a second phase of facilitation appeared within one hour after the last 5HT application and subsequently decayed to baseline. These preliminary results may reflect a separate mechanistic component in the induction of LTF (Ghirardi et al., 1995). They further suggest that the induction and expression of LTF may be composed of multiple phases of facilitation that can be temporally dissociated in this system.

## 570.4

MODULATION OF NEURONAL ACTIVITY IN THE HEAD GANGLIA OF *APLYSIA* BY BAG CELL PEPTIDES.

Samuel K. Moore, Valerie L. Begnoche, Yiwen Liu, Z. Z. Pan\* and Earl Mayeri  
Dept. of Physiology, University of California, San Francisco, CA 94143-0444 USA.

Egg laying hormone (ELH) and other bag cell peptides are released from the bag cells and other cells of the ELH neural system at the initiation of egg laying. In the abdominal ganglion they modulate activity of target neurons for up to several hours. To identify sites of action and possible neurotransmitter or neurohormonal roles for these peptides in the head ganglia, the effects of application of peptides to the head ganglia were compared to the effects of endogenous release of the peptides during bag cell burst discharges. In an isolated CNS or a reduced CNS preparation, ELH application for 6-15 min inhibited ongoing fictive locomotion, as recorded extracellularly from the parapedal commissure. Subsequent washing out of the peptide produced an excitation lasting 7-45 min. A bag cell burst discharge produced similar inhibition followed by excitation. Using intracellular recordings, we also found cells in the cerebral ganglion that are responsive to ELH and  $\alpha$ -BCP. The results support the idea that aspects of reproductive behavior are controlled by neuromodulation of circuits in the head ganglia by these neuropeptides. (Supported by NIH grants NS16490 and NS16033.)

## 570.5

**FMRFAMIDE SUPPRESSES THE DEVELOPMENT OF SENSITIZATION-INDUCED INCREASE IN HEART RATE IN APLYSIA CALIFORNICA**  
J.K. Krontiris-Litowitz\*. Dept. of Biological Sciences, Youngstown State University, Youngstown, OH 44555

Previous studies in this laboratory have shown that sensitizing stimulation applied to the tail body wall will produce an increase in heart rate lasting for several hours. Billy and Walters (1989) have demonstrated that tail mechanoreceptors are less responsive when exposed to FMRFamide. This study investigates whether FMRFamide applied to tail mechanoreceptors can alter the development or maintenance of sensitization-induced increases in heart rate.

Heart rate was monitored in an *in vitro* preparation using a cannula implanted in the anterior aorta. FMRFamide ( $10^{-6}$ M) was perfused to the lateral body wall while sensitizing shocks were delivered to the same location via implanted electrodes. When FMRFamide was applied concurrent with sensitizing stimulation, there was no increase in heart rate. At 30 min post-training, heart rate was 80.8% (SEM 5.3) of prestimulation values and at 90 min after stimulation, heart rate was 78.9% (SEM 5.9)(N=8). Thus FMRFamide appears to act peripherally at tail mechanoreceptors to suppress sensitization-induced increases in heart rate.

## 570.7

**HETEROSYNAPTIC MODULATION OF APLYSIA SENSORIMOTOR SYNAPSES DEPRESSED BY LOW FREQUENCY HOMOSYNAPTIC ACTIVITY EMERGES LATE DURING SYNAPSE FORMATION IN VITRO.**  
Z.-Y. Sun\* and S. Schacher. *Ctr. Neurobiol. & Behav., Columbia Univ. College of P & S, NYSP, New York, NY 10032.*

Previous studies indicate that multiple processes mediated by at least two second messenger pathways, PKA and PKC, contribute to 5-HT facilitation of *Aplysia* sensorimotor synapses. The contributions of each of the second messenger pathways in evoking changes in synaptic efficacy may be dependent on the previous stimulus history of the sensory neuron (SN). To explore the contributions of the second messenger systems in mediating short- and long-term synaptic facilitation evoked by 5-HT, we used cell culture to examine the time course for the expression of 5-HT facilitation of SN-L7 synapses first depressed by low frequency (30 sec intervals) stimulation of the SN, and 5-HT facilitation of nondepressed synapses. Cultures were tested on days 1, 2, and 4. Despite the large increase in synaptic efficacy over time (2-3 fold), the kinetics of homosynaptic depression (HSD) were unchanged between day 1 and day 4. In addition, there was no difference over time in the level of facilitation by 5-HT in nondepressed synapses. By contrast, 5-HT facilitation of depressed synapses was significantly lower in day 1 cultures. These early cultures also responded differently to low frequency stimulation in the presence of 5-HT. On day 4, the kinetics of HSD is altered significantly by 5-HT. However, the kinetics of HSD on day 1 in the presence of 5-HT were identical to controls, despite the initial facilitation produced by 5-HT. Preliminary data suggest that the altered kinetics of HSD evoked by 5-HT on day 4 is mediated primarily via an interaction between HSD and the increase in PKC activity evoked by 5-HT. The results are consistent with previous studies suggesting that activation of the PKC pathway contributes significantly to facilitation of depressed synapses. Moreover, they suggest that the PKA pathway triggered by 5-HT is present early, while components of the PKC pathway activated by 5-HT develop over time in culture.

## 570.9

**A COMPUTATIONAL MODEL OF ACTIVITY-DEPENDENT POTENTIATION AND ITS EXTERNAL MODULATION AT L30 INHIBITORY SYNAPSES IN APLYSIA.** S.A. Fisher\*, T.M. Fischer and T.J. Carew. Yale Univ., Dept. of Psych., New Haven, CT 06520.

In *Aplysia*, activity-dependent synaptic potentiation from inhibitory interneurons (L30s) is induced by tactile stimulation, providing dynamic gain control in the siphon-withdrawal reflex (SWR) (Fischer & Carew, 1993, 1995). In addition, tail shock (TS) selectively inhibits specific components of L30 potentiation; these TS effects are mimicked by 5-HT and by reduced external  $Ca^{2+}$  ([ $Ca^{2+}$ ]<sub>o</sub>) (Fischer & Carew, 1994). To examine the role of L30 potentiation and its modulation in the SWR, we constructed a computational model that included both the L30s and the L29s, excitatory interneurons which are reciprocally connected to the L30s.

The model was built using the software package NEURON and incorporated empirically derived biophysical and synaptic features of the L29-L30 circuit. L30 potentiation was modeled with two processes: frequency facilitation (FF) and post-tetanic potentiation (PTP). In our simulations, the frequency of steady-state L30 activation (1.5 to 6 Hz) was varied to mimic activation by different levels of ambient tactile stimulation. Based on cellular data (Fischer & Carew, 1994) FF and PTP were differentially dependent upon [ $Ca^{2+}$ ]<sub>o</sub>, so that only PTP was suppressed by a 50% reduction in [ $Ca^{2+}$ ]<sub>o</sub>.

The model revealed that at low frequencies synaptic enhancement is mainly driven by FF, which saturates quickly, providing minimal temporal integration. At higher frequencies, the build up of PTP is more prevalent and extends the temporal integration underlying synaptic enhancement. With reduced [ $Ca^{2+}$ ]<sub>o</sub> (suppressing PTP), L30 potentiation is primarily regulated by FF across all frequencies, which provides less steady-state synaptic enhancement and less temporal integration, thus changing the fundamental integrative properties of the circuit. These data suggest different functional roles for FF and PTP in the dynamic regulation of this reflex circuit.

## 570.6

**PROTEIN PHOSPHATASE INHIBITOR OKADAIC ACID AFFECTS SHORT- AND LONG-TERM DEPRESSION OF APLYSIA SENSORIMOTOR SYNAPSES EVOKED BY FMRFAMIDE.** H. Zhu\*, Z.-Y. Sun and S. Schacher. *Ctr. Neurobiol. & Behav., Columbia Univ. College of P & S, NYSP, New York, NY 10032.*

The sensorimotor synapse of *Aplysia* can be depressed for short and long durations by the neuropeptide FMRFamide. Many of the short- and long-term actions of FMRFamide are mediated by metabolites of arachidonic acid. FMRFamide also activates several protein phosphatases including those blocked by okadaic acid. We therefore examined the actions of FMRFamide on the efficacy of the sensorimotor synapse formed in culture in the presence of 200 nM okadaic acid, a concentration that did not evoke excitability changes in the sensory or motor cells. Short-term depression was measured by testing the efficacy of the connections following bath applying 1  $\mu$ M FMRFamide after the sensory cells were first given 5 stimuli (30 sec intervals) to stabilize the EPSP amplitude. Okadaic acid had no effect on the kinetics of homosynaptic depression. The expression of long-term depression was measured 24 hr following 4 repeated applications of FMRFamide. Okadaic acid did not affect the initial level of synaptic depression, but affected the time course of short-term depression. The amplitude of the EPSP was reduced by 58% and 66% 30 sec following application of FMRFamide in controls and okadaic acid, respectively. After 2 min, controls recovered by only 7% (N=9) while the okadaic acid-treated cultures recovered by 35% (N=13). Okadaic acid also altered long-term depression. Whereas FMRFamide reduced EPSP amplitudes by -23% (N=8) compared to an increase of 1.5% for controls (N=7), application of FMRFamide in the presence of okadaic acid (N=10) evoked only a -8% change. Interestingly, okadaic acid alone (N=13) affected the cultures by evoking a decline in the EPSP amplitude of -22%. All cultures expressed similar levels of short-term depression 24 hr after treatment (from -57% to -61%). The results suggest that protein phosphatases may contribute to the maintenance phase of short- and long-term depression evoked by FMRFamide.

## 570.8

**NEUROPEPTIDE EXPRESSION IN VARICOSITIES OF APLYSIA SENSORY NEURONS IS REGULATED BY THE TARGET AND NEUROMODULATORS EVOKING LONG-TERM SYNAPTIC PLASTICITY.**  
L. Santorelli, P.G. Montarolo and S. Schacher\*. *Ctr. Neurobiol. & Behav., Columbia Univ. College of P & S, NYSP, New York, NY 10032.*

The synapses of mechanosensory neurons (SNs) of *Aplysia* undergo long-term functional and structural modulation with behavioral training. Similar changes are evoked in connections established in cell culture by specific neuromodulators. Since the number of SN varicosities can be modulated both up and down for long durations, we examined whether the expression of synapse-specific molecules such as sensorin, the SN-specific neuropeptide (Brunet et al., 1991), are also modulated 24 hr following either 5-HT applications that evoke long-term facilitation, or FMRFamide applications that evoke long-term depression. We measured a) changes in the amplitude of the EPSP, b) changes in the number of sensory varicosities with fluorescent dye fills of each SN before and after treatment, and c) the expression of sensorin in varicosities by immunocytochemical staining with standard methods. Both 5-HT and FMRFamide evoked functional and structural changes in the sensorimotor connections established after 5 days in culture compared to control treatment. Consistent with previous studies indicating that varicosities contacting the major axons of L7 contained transmitter release sites, the expression of sensorin was highest in sensory varicosities contacting the proximal motor axons; 54% of the varicosities were sensorin-positive, compared to 22% of varicosities contacting distal neurites or the substrate. Following treatment with 5-HT, 73% of the pre-existing varicosities and 59% of the new varicosities were sensorin-positive. By contrast, only 31% of pre-existing SN varicosities were sensorin-positive following treatment with FMRFamide compared to 52% in another group of controls. These results suggest that neuromodulators not only regulate overall structure but also regulate both up and down the expression of SN peptide at putative synaptic sites either by modulating synthesis or peptide processing, or by changing turnover.

**DEVELOPMENTAL EMERGENCE OF IDENTIFIED SIPHON MOTOR NEURONS COINCIDES WITH THE BEHAVIORAL EXPRESSION OF THEIR UNIQUE SIPHON MOVEMENT IN APLYSIA.** T.M. Fischer\*, K. Lin, and T.J. Carew. Yale University, Department of Psychology, New Haven, CT 06520.

The number of neurons in the CNS of *Aplysia* increases markedly during the final stage of juvenile development, Stage 12 (Cash & Carew, 1989). This coincides with the expression of behavioral sensitization of the siphon withdrawal response (SWR) (Rankin & Carew, 1988). To examine whether new neurons may contribute to the emergence of sensitization, we have combined cell birthdating techniques with behavioral observations to track the emergence of a specific class of siphon motor neurons (MNs), the LFS-B cells (4 total), which have been implicated in SWR sensitization (Frost et al., 1988).

Stage 12 was partitioned into two sub-stages: Early 12 (E12: 9-13 mm) and Late 12 (L12: 18-25 mm). The approximate birthdates of LFS-B neurons was determined through the use of BrdU and standard double-label immunocytochemical techniques. Animals were first chronically exposed to 1  $\mu$ M BrdU for the duration of E12 or L12, then reared to adulthood (>10 cm). LFS-B MNs were then positively identified physiologically by monitoring siphon movements induced by intracellular activation, after which the cells were injected with 2% Neurobiotin. Of the LFS-B MNs identified in L12-exposed animals, 45% (10 of 22) were BrdU positive, whereas only 24% (4 of 17) of MNs identified in E12-exposed animals were BrdU positive.

In adults, LFS-B MNs mediate a unique siphon response (flaring) which is elicited by tail stimulation. Studies examining the development of flaring in E12, L12, and adult animals (using suprathreshold tail stimulation) revealed that flaring first becomes apparent only in Stage L12. Collectively, our results suggest that the LFS-B MNs are born and are integrated into a functional neural circuit relatively late in development, raising the possibility that their emergence may contribute to the expression of sensitization in this same developmental stage.

## MODULATION OF CURRENTS IN DROSOPHILA LARVAL AND ADULT CNS NEURONS BY SEROTONIN.

N.J.D. Wright\* and Y. Zhong.

Center for Learning and Memory, Cold Spring Harbor Laboratory, 1 Bungtown Road, Cold Spring Harbor, NY 11724.

In order to understand the neural contribution to defective learning and memory in *Drosophila* mutants we are analyzing how neurotransmitter-induced responses are altered in these mutants. In this study we examine the effects of serotonin. Serotonin has been shown to modulate certain ionic currents by activating secondary messenger cascades. Some of these effects have been implicated in regulating neuronal excitability and synaptic transmission and may be involved in learning and memory. Three distinct serotonin receptors have been cloned from *Drosophila*. We show by whole-cell patch-clamping that serotonin can affect two distinct currents in both larval and adult *Drosophila* neurons in acute culture. One of the components is the slowly inactivating, voltage-activated potassium current ( $K_v$ ) which is reversibly inhibited. The other is a "leakage" current which is activated constantly but can be inhibited by serotonin. This "leakage" current is gated by cation channels which have a reversal potential of around +10mV and have a conductance of between 20-30pS. Its amplitude varies between neurons from 5 to 50pA when clamped at -80mV. Inhibition of this current appears to exert a profound effect on membrane potential: hyperpolarizing neurons from -50mV to as much as -100mV. We have examined over 200 neurons, 70 of which were from adult *Drosophila* brains, and over 35% respond to serotonin. A study of whether and how these responses are altered in learning and memory mutants is currently in progress.

## 570.13

## SEROTONIN ENHANCES CALCIUM CURRENT IN ISOLATED SOMATA OF APLYSIA PARAPODIAL MOTOR NEURONS. G.N. Gamkrelidze\*, P.J. Laurienti and J.E. Blankenship. Marine Biomedical Inst., Univ. Tx. Med. Br., Galveston, TX 77555-1069.

The pedal ganglia of *Aplysia brasiliana* contain identified motor neurons (MN's) and serotonergic modulatory cells (POP cells) which innervate parapodial muscles and fire rhythmically during swimming. With each parapodial opening during swimming, POP cell activity enhances motoneuron-induced junction potentials and muscle contractions and relaxation rates. We have shown using current clamp that POP cells or exogenously applied 5-HT modulates a  $Ca^{2+}$  component of MN action potentials to facilitate neuromuscular transmission while having no effect on motoneuron action potential width. We are now investigating the membrane ion currents in isolated somata of parapodial MN's using single electrode voltage-clamp in order to identify the mechanism whereby 5-HT causes an increase in transmitter release. The head-ganglia were removed from the animal with the parapodia still attached via the parapodial nerves. Pedal ganglia were desheathed and then treated with 0.5% Pronase E (40 min) followed by 1% collagenase (120 min). After the enzymes were washed out, putative MN's were identified by their ability to cause parapodial contractions and then isolated from the pedal ganglion by gently pulling the impaled cell away from the ganglion using the penetrating electrode. The stretched axon was then severed near the soma, and the cell was transferred to a solution of artificial sea water (ASW) containing 50mM TEA, 1  $\mu$ M TTX and 10mM 4AP. Experiments were performed on isolated somata with resting membrane potentials near -50 mV. Depolarizing voltage steps activated an inward current that was entirely blocked in 0  $Ca^{2+}$  ( $Co^{2+}$ ) ASW. Part of this current was blocked by 10 $\mu$ M nifedipine. Application of 5  $\mu$ M 5-HT increased the peak inward current by an average of 40% ( $n=3$ ), suggesting that 5-HT may mediate the facilitatory effect of POP cells on neuromuscular transmission by directly enhancing  $Ca^{2+}$  current.

## 570.15

## PLASTICITY IN APLYSIA GILL-WITHDRAWAL BEHAVIOR: A NEURAL NETWORK MODEL. J.L. Leonard\*, Mark O. Hatfield Marine Science Center, Newport, OR 97365.

Studies of behavioral plasticity in the *Aplysia* gill-withdrawal response (GWR) show that even habituation involves changes at multiple sites and the much-studied changes at the identified synapses between LE sensory cells and central gill motor neurons (GMNs) do not account for plasticity in the behavior. There are at least three parallel but interacting pathways which will mediate habituation and facilitation of the GWR: the peripheral nervous system (PNS) (Peretz et al. 1976, the Interneuron II pacemaker system (Int II) (Pinsker 1982-3), and the identified direct CNS system (many authors). Here I propose that plasticity in the GWR is the result of parallel-distributed processing with the three pathways representing subnets in a Nowlan-Jacobs system of mini-nets. In the simplest configuration, both the PNS and Interneuron II systems represent mini-nets, with the direct CNS system acting as a "referee" to choose the "correct" mini-net. The six GMNs, along with some as yet unidentified inhibitory gill motor neurons, act as an output layer of the referee network, serving to determine the response of the periphery. Novel phenomena predicted by the model include a) the as yet unidentified sensory neurons to the GMNs also provide input to the Int II cells (R25/L25); b) the neuromodulators known to change weights in the direct CNS system have no direct effect on Int II; and 3) siphon PNS sensory cells provide input to both CNS and PNS networks.

## 570.12

## IONIC CURRENTS IN DISSOCIATED APLYSIA BRASILIANA PARAPODIAL MUSCLE FIBERS. P.J. Laurienti\*, G.N. Gamkrelidze and J.E. Blankenship. Marine Biomedical Inst., Univ. Tx. Med. Br., Galveston, TX 77555-1069.

Transmission at the parapodial neuromuscular junction in *Aplysia brasiliana* is enhanced by serotonin (5-HT) and provides a useful model for studying synaptic plasticity. Previous work in our laboratory has demonstrated that 5-HT enhances the calcium component of motoneuron action potentials, indicating that a portion of the serotonergic facilitation occurs at the presynaptic terminal. However, the possibility that 5-HT has a direct effect on parapodial muscle remains. We have used a dissociated muscle preparation to study membrane ion currents under voltage-clamp conditions. Initial surveys of total membrane current utilized voltage ramps to produce I-V curves. All cells had outwardly rectified I-V curves with membrane resistance increasing upon hyperpolarization and decreasing with depolarization. The I-V curves provide evidence that these muscle fibers lack an inwardly rectifying  $K^+$  current. Analysis of membrane currents activated by depolarizing voltage steps revealed two populations of muscle fibers. Type I fibers have two main depolarization-activated currents: a TEA-sensitive, outward  $K^+$  current and a  $Co^{2+}$ -sensitive, inward  $Ca^{2+}$  current which may have several components. Type II fibers not only express the  $K^+$  and  $Ca^{2+}$  currents found in Type I fibers, but also have a transient, outward current and a non-inactivating, outward current. These currents are reduced in 250mM  $K^+$  SW and blocked in 15% Cl<sup>-</sup> (isethionate-substituted) SW. Both currents are sensitive to TEA and 4-AP and blocked in 0  $Ca^{2+}$  seawater. This work is the first description of the membrane currents in *Aplysia* parapodial muscle. Experiments are currently underway to investigate the effect of 5-HT on these muscle membrane currents.

## 570.14

## DYNAMIC REPRESENTATION OF LEARNED INFORMATION IN A DISTRIBUTED MEMORY IN APLYSIA. J.R. Lieb Jr.\* and W.N. Frost, Dept. of Neurobiology and Anatomy, Univ. of Texas Medical School, Houston, Texas, 77225.

In the *Aplysia* siphon-withdrawal reflex circuit, the memory for sensitization is represented as a distributed set of circuit modifications (Frost et al., J. Neurobiol., 1988). Our previous use of a realistic computer simulation of this circuit indicated that these sites of plasticity store separate and distinct aspects of the information encoded in sensitization. Specifically, plasticity at the sensory neuron (LE) to motor neuron (LFS) connection encodes changes in the frequency of firing of the phasic motor neuron firing response, which is related to reflex amplitude. Plasticity within the interneuronal population encodes changes in the long-lasting component of the motor neuron firing response, which is related to reflex duration (Lieb and Frost, Soc. Neurosci. Abstr. 1992).

In our present work we find that the information stored by these sites is expressed differently depending upon the intensity of the test stimulus. First, weak inputs are amplified much more than strong inputs following sensitization. Thus the circuit acts to bias motor neuron firing responses toward a uniform level in the sensitized state, independent of stimulus intensity. Second, the quantitative contribution of individual sites of plasticity to the sensitized circuit output also depends on stimulus intensity. For example, with weak stimuli, enhanced interneuronal recruitment by plasticity at sensory neuron to interneuron synapses contributes more importantly than the interneuronal sites of plasticity. With stronger input, however, this relationship reverses. This phenomenon is also observed when the interneuronal sites of plasticity themselves are dissected; the relative contribution made by the L29 and L30 circuit modifications reverses with increasing stimulus intensity.

These results suggest that while the sites of plasticity encoding memory are fixed, the information represented by these sites can be dynamic, shifting in anatomical location with changes in the intensity of the test stimulus.

## 570.16

## PREDICTING AGE IN APLYSIA CALIFORNICA FROM SHELL AREA, GANGLIA AREA, AND WEIGHT. J. Thomas, C. Hong†\*, T. Capot, V. Chandhoke, and J.M. Flinn. George Mason Univ., Fairfax, VA. 22030. †NIH ‡University of Miami-FL

Shell and ganglia areas and weight were examined across age groups in 115 *A. californica* from the Aplysia Resource Center Miami, Florida. The post-hatch ages of the animals studied were 4 (n=8), 4.5 (n=13), 5.5 (n=28), 7 (n=24), 9 (n=9), 10 (n=25), and 12 (n=8) months. Using a dissecting microscope, we measured both the abdominal ganglia and the shell of each animal. Previous studies (e.g. Peretz & Adkins, 1982) have suggested that age can be determined by shell size. Consequently, we examined age(A) as a function of weight(W), shell area(S), and ganglia area(G), individually. Best-fit equations showed: 66% of the variability in age can be predicted from its relation with weight,  $A = 4.78 + .03(W) + 4.50e-05(W)^2$ ; 64% can be predicted from shell area,  $A = 4.71 + .17(S)$ ; and, 63% can be predicted from ganglia area,  $A = 4.30 + 1.07(G)$ . Both ganglia and shell areas were predominantly linear with age, unlike weight. Age was then analyzed as a function of both weight and ganglia area and weight and shell area. 69% of the variability in age can be predicted from both weight and ganglia area,  $A = 3.71 + .02(W) + 3.21e-05(W)^2 + 1.54(G) + .41(G) + .04(G)^2$ . 71% can be predicted from weight and shell area,  $A = 3.92 + .09(W) + 2.13e-05(W)^2 + .26(S) + .01(S)^2 + 8.68e-05(S)^2$ . A combination of shell area and weight appear to be the most reliable predictors of age, with  $r = .84 (\sqrt{.71})$ , for this set of animals.

EFFECTS OF CROWDING ON THE SEROTONERGIC AND DOPAMINERGIC SYSTEMS IN APLYSIA CALIFORNICA. S. Shirazi, J.M. Flinn\* and V. Chandhoke. George Mason University, Fairfax, Virginia 22030.

The effects of crowding were assessed in 105 *A. californica* raised in crowded or uncrowded conditions (C or U), subdivided into tanks with or without a protein skimmer, which removed organics such as pheromones, (S or N). Animals were reared from 82 to 171 days (post-hatch). Mean weights were significantly affected by both skimming and crowding, but neurochemical data suggested that pheromonal levels regulated growth more significantly than tactile stimuli; see Table 1. Metabolic pathways were examined for serotonin (5-HT) and dopamine (DA) using HPLC. Both tryptophan and 5-HT were significantly reduced in the unskimmered groups. The availability of tryptophan and constancy in conversion rates for tryptophan to 5-HT in all groups (22%) except the US (29%) suggests that the 5-HT differences were metabolically driven. Previous experiments indicated that crowding reduced learning which could be due to reduced levels of 5-HT. The function of DA within *A. californica* is not as well understood. DA concentrations were higher in the crowded vs. uncrowded groups; however, concentrations were significantly higher in groups with a protein skimmer. Crowding can have an effect via increased tactile or chemical concentrations. These data suggest that the pheromonal effects are more important.

Group Means	US	CS	UN	CN	p(SK)	p(CR)

## INGESTIVE BEHAVIOR V

## 571.1

INVOLVEMENT OF 5-HT<sub>2C</sub> RECEPTORS IN THE HYPOPHAGIC EFFECTS OF SIBUTRAMINE AND D-FENFLURAMINE IN RATS H.C. Jackson, S.C. Cheetham, L.J. Hutchins, S.E. Mazurkiewicz, D.J. Heal and W.R. Buckett (SPON: Brain Research Association). Knoll Pharmaceuticals Research Department, Nottingham, NG2 3AA, U.K.

The novel 5-HT and NA reuptake inhibitor, sibutramine, reduces food intake in rats. This response is attenuated by non-selective 5-HT antagonists and the  $\beta$ 1-adrenoceptor antagonist metoprolol (A. Stricker-Krongrad, personal communication). This study uses the 5-HT<sub>2C</sub> receptor antagonist, SB200646, to investigate whether these receptors are involved in the hypophagic effects of sibutramine. The 5-HT releaser, d-fenfluramine, was examined for comparison. Male Sprague-Dawley rats (350-500g, n=6-8) were maintained on reversed phase lighting (lights off 09.00-17.00h) with free access to powdered diet and water. Feeding jars and water bottles were weighed at the time of p.o. drug administration (09.00h) and after 2-8h. Sibutramine (3, 10 mg/kg) and d-fenfluramine (1-10 mg/kg) produced dose-related decreases in food and water intake over the dark period. SB200646 (10-40 mg/kg) had no effect on food and water intake. Concurrent administration of SB200646 partially antagonised the decrease in mean food intake (g/kg rat weight $\pm$ sem) induced by sibutramine (vehicle 34.0 $\pm$ 3.4; sib 10 mg/kg 0.9 $\pm$ 0.3\*; sib+SB 20 mg/kg 10.1 $\pm$ 4.1\*; sib+SB 40 mg/kg 10.4 $\pm$ 1.6\*; \*P<0.05 vs. vehicle, \$P<0.05 vs. sib) and d-fenfluramine (vehicle 36.5 $\pm$ 1.2; d-fen 10 mg/kg 2.5 $\pm$ 1.3\*; d-fen+SB 20 mg/kg 8.1 $\pm$ 2.7\*; d-fen+SB 40 mg/kg 10.4 $\pm$ 2.2\*; \$P<0.05 vs. d-fen) over the 8h dark period. The inhibitory effects of SB200646 on d-fenfluramine (but not sibutramine) hypophagia were apparent by 2h. SB200646 also partially inhibited the decrease in water intake induced by sibutramine and d-fenfluramine. These results implicate 5-HT<sub>2C</sub> receptors in the hypophagia induced by sibutramine and d-fenfluramine although clearly other mechanisms contribute to these effects.

## 571.3

CONGENITAL SEROTONIN ABNORMALITIES ALTER THE ADVERSE EFFECTS OF EXERCISE STRESS. P.F. Aravich, T. Hsu, W. Walker, H.A. Funk & T.S. Rieg. Eastern Virginia Med. School, Norfolk, VA 23501; Vets. Aff. Med. Ctr., Hampton, VA 23667; Governor's School for Sci. & Tech., Hampton, VA 23666; Hampton Univ., Hampton, VA 23668; Christopher Newport Univ., Newport News, VA 23606.

There is growing interest in the adverse effects of exercise stress and caloric restriction in the rat. This is relevant to exercise and weight control in normal people and to anorexia nervosa, which is highly correlated with hyperactivity. Our previous data suggest that brain serotonin mitigates the adverse effects of the exercise-stress syndrome. This investigation determined if congenital serotonin abnormalities affect it. Adult female Fawn-Hooded (FH) rats (n=8) and Wistar strain controls (n=9) were the subjects. FH rats have normal 5HT content and turnover but region-specific 5HT<sub>1A</sub> reductions and 5HT<sub>2A</sub> increases. These receptors are linked to, e.g., food intake, locomotor behavior, thermoregulation and/or anorexia nervosa. All animals were subjected to the exercise-stress syndrome (1.5 h/day free access to food; 22.5 h/day free access to activity running wheels). FH rats were reliably sub-sensitive to the wheel running effect of the paradigm and ate less than Wistar controls. Both groups lost weight at the same rate despite reliably higher food-to-running ratios in the FH rats. The "morphological stress triad" (relative adrenal hypertrophy; immune organ atrophy) was reliably worse in FH rats. It is concluded that congenital 5HT<sub>1A</sub>/5HT<sub>2A</sub> abnormalities exacerbate the adverse effects of the exercise stress syndrome on immune organ atrophy but not weight loss.

## 571.2

SEROTONERGIC MECHANISMS OF THE LATERAL PARABRACHIAL NUCLEUS INHIBIT SODIUM INTAKE IN RATS. J. V. Menani\*, R. L. Thunhorst and A. K. Johnson. Departments of Psychology and Pharmacology and the Cardiovascular Center, University of Iowa, Iowa City, IA 52242, USA, and Department of Physiology, School of Dentistry, UNESP, Araraquara, SP 14800, Brazil.

In this study we investigated the role of the serotonergic pathways of the lateral parabrachial nucleus (LPBN) in the control of NaCl intake in rats. Bilateral injection of the serotonergic 5HT<sub>1</sub>/5HT<sub>2</sub> receptor antagonist, methysergide (4  $\mu$ g/0.2  $\mu$ l) into the LPBN produced a marked increase in 0.3 M NaCl intake induced by angiotensin II (ANG II, 50 ng/1  $\mu$ l) injected intracerebroventricularly (13.5 $\pm$ 3.8 vs. 3.5 $\pm$ 1.0 ml in 1 h with vehicle into LPBN) or by treatment with furosemide (FURO, 10 mg/kg) + captopril (CAP, 5 mg/kg) injected subcutaneously (18.3 $\pm$ 2.9 vs. 4.1 $\pm$ 0.9 ml in 2 h with vehicle into LPBN). Injection of the serotonergic 5HT<sub>2A</sub>/5HT<sub>2C</sub> receptor agonist, DOI (5  $\mu$ g/0.2  $\mu$ l) bilaterally into the LPBN reduced the 0.3 M NaCl intake after FURO + CAP (2.1 $\pm$ 0.8 ml in 2 h). The water intake observed simultaneously with salt intake was not changed by these treatments into LPBN. The results suggest that a serotonergic mechanism associated with the LPBN has strong inhibitory influence on sodium intake in rats.

Supported by FAPESP 93/0167-7; NHLBI HL-14338 and HL-44546.

## 571.4

DIURNAL RHYTHMS OF EXTRACELLULAR SEROTONIN WITHIN RAT HYPOTHALAMIC PARAVENTRICULAR NUCLEUS. L. McMahon, R. Thiagarajan, T. Green, and P.J. Wellman\*. Dept. of Psychology, Texas A&M University, College Station, TX 77843-4235.

Serotonin-releasing neurons within the rat hypothalamic paraventricular nucleus (PVN) are presumed to suppress carbohydrate intake at the beginning of the dark cycle. A previous microdialysis study revealed a peak in extracellular levels of the 5-HT metabolite 5-HIAA within the PVN at the onset of the dark cycle, but no study to date has assessed potential rhythms of extracellular 5-HT within the PVN across the diurnal cycle. Adult male (n=6) albino rats were prepared with concentric 2 mm microdialysis probes aimed at the PVN. A series of 60 minute dialysate samples (1  $\mu$ l/min) were collected every hour over a 24 hour period, with half of the rats starting collection at 0700 hrs, and the remainder starting at 1900 hrs. Across the light cycle, there was observed a gradual decline in extracellular 5-HT levels that reached a nadir (1.1 pg) at 1800 hrs. In contrast, extracellular 5-HT gradually increased over the dark cycle reaching a peak (2.1 pg) at 0400 hrs. Extracellular levels of PVN 5-HIAA exhibited a peak at 1800 hrs during the light cycle and then increased in a pattern similar to that of 5-HT with a second peak evident later in the dark cycle. The observed increase in 5-HT evident later in the dark cycle may play a role in the modulation of feeding.

This project was supported by funds from the Thompson Medical Company and by funds from the Program for Scholarly and Creative Activities.

## 571.5

**SEROTONERGIC MECHANISMS OF THE LATERAL PARABRACHIAL NUCLEUS (LPBN) AND AT<sub>1</sub> RECEPTORS OF THE SUBFORNICAL ORGAN (SFO) ON THE INTAKE OF NaCl AND WATER.** D.S.A. Colombari\*, J.V. Menani, T.G. Beltz, and A.K. Johnson. Depts. of Psychol. and Pharmacol. and the Cardio. Center, Univ. of Iowa, Iowa City, IA 52242.

Serotonergic mechanisms of the LPBN play an inhibitory role in the dipsogenic response induced by intracerebroventricular angiotensin II (ANG II). In this study we investigated the effects of a serotonergic receptor antagonist (methysergide) injected into the LPBN, and of an angiotensinergic AT<sub>1</sub> receptor antagonist (losartan) injected into the SFO on the intake of water and 0.3 M NaCl induced by ANG II injected into the SFO. Rats had stainless steel cannulas implanted bilaterally in the LPBN and another in the SFO. When only water was available, the injection of ANG II (20 ng/200 nL) into the SFO induced water intake (6.5±1.1 mL/1 h) which was not changed after bilateral injection of methysergide (4 µg/200 nL) into the LPBN (10.3±2.3 mL/1 h). When both water and 0.3 M NaCl were available, ANG II into the SFO induced significant intake of water (7.2±1.4 mL/1 h) but not 0.3 M NaCl (1.0±0.5 mL/1 h). Pretreatment with bilateral injection of methysergide into the LPBN increased 0.3 M NaCl intake induced by ANG II into the SFO (10.5±3.6 mL/1 h) and the water intake associated with the NaCl intake (12.7±2.0 mL/1 h). These responses induced by ANG II after methysergide into the LPBN were blocked by pretreatment with losartan (1 µg/200 nL) injected into the SFO (0.7±0.5 and 0.9±0.7 mL/1 h, for NaCl and water, respectively). The results suggest that serotonergic mechanisms associated to the LPBN may be involved with an inhibitory mechanism controlling salt intake induced by ANG II into the SFO. In addition, they also show that the water and NaCl intake induced by ANG II into the SFO is mediated by AT<sub>1</sub> receptors. Support: FAPESP, NIH-HLBI

## 571.7

**ATROPINE DECREASES DRINKING BUT NOT FEEDING IN DIABETIC RATS.** E. Murzi\*, P. Rada and L. Hernandez. Laboratory of Behavioral Physiology, Medical School, Los Andes University, Merida 5101, Venezuela.

Diabetic rats exhibit polydipsia and polyphagia. Lateral intrahypothalamic injections of acetylcholine (ACh) or carbachol evoke vigorous drinking which is abolished by ip. injections of atropine sulfate (1), a cholinergic blocker, in normal rats. We evaluated the effect of ip. atropine sulfate on food and water intake and monitored by microdialysis the hypothalamic levels of ACh in streptozotocin-diabetic male rats individually housed with food and water ad libitum. Water and food intake were measured by weighing the drinkers and the spillage proof feeders. The animals received four doses of atropine sulfate (0.0, 1.0, 2.5, 5 mg/Kg) and food and water intake was measured 2h, 5h, 8h, and 24h after drug injection. Water intake but not food intake linearly decreased for the first 8h after atropine sulfate injection (the regression coefficient was highly significant: R=0.96). This decrease of drinking is not due to malaise since feeding was not affected. In preliminary experiments with brain microdialysis, variations of lateral hypothalamic ACh levels were observed in diabetic rats after ip. administration of atropine sulfate. These results suggest that an increased activity of the cholinergic neurons in the lateral hypothalamus could induce the polydipsia observed in diabetic rats.

## 571.9

**THE INVOLVEMENT OF AMYGDALA GABA RECEPTORS IN THE RAPID AROUSAL OF SALT INTAKE IN RATS.** L.Y. Ma\*, D.M. Zhang, S.J. Fluharty and R.R. Sakai. Depts. of Animal Biology, Pharmacology and Institute of Neurological Sciences, University of Pennsylvania, Philadelphia, PA 19104.

We have previously reported that certain adrenal steroids or their tetrahydro (TH) derivatives implanted in the amygdala arouse sodium intake in rat. The data suggested that the rapid injection of saline immediately after implants in the amygdala may be acting through the GABA/benzodiazepine receptor system. In the present study, we have extended these observations to examine the effect of implants of various adrenal steroids and GABA receptor agonists or antagonists on salt intake.

All rats (n=6-8/group) were fitted with bilateral guide cannula which allowed implantation of agents directly into the medial nucleus of the amygdala. They were given ad libitum food and water but access to 0.25 M NaCl for only 2 hours each day. On the test day, they were injected with aldosterone (ALDO), deoxycorticosterone acetate (DOCA), their tetrahydro (TH) derivatives, flunitrazepam  $\beta$ -carboline or cholesterol (200 ng) and their 2 hour intake of 0.25 M NaCl recorded. The results demonstrated that 1) TH-DOCA and TH-ALDO markedly increased 0.25 M NaCl intake as compared to blank or cholesterol treatment; 2) this salt intake was further facilitated by  $\beta$ -carboline pretreatment and was not inhibited by the adrenal steroid receptor agonists RU-28318 or RU-486; and 3) the salt intake induced by TH-DOCA and flunitrazepam was inhibited by the GABA antagonist RU15-4513, while 10% sucrose intake was not affected by either treatment. Together, these data confirm and extend our previous studies by suggesting a novel mechanism for steroid induction of sodium intake involving a non-genomic action in the amygdala. ## 571.6

**REDUCTION OF FOOD INTAKE AND ALTERATION OF LICKING DISTRIBUTION BY THE 5-HT<sub>1A</sub> AGONIST CP-94,253 IN RATS.** M. Lee and K. J. Simansky\*, Dept. Pharmacology, Med. Coll. Pennsylvania and Hahnemann University, Philadelphia, PA 19129.

Pharmacological studies have implicated 5-HT<sub>1A</sub> receptors in central serotonergic inhibitory control of feeding. We analyzed the ability of the pyrrolopyridine CP-94,253, a selective 1B agonist that penetrates the blood-brain barrier (Koe et al., 1992), to reduce food intake in rats. Given i.p. 30 min before the tests, doses ranging from 5-40 µmol/kg decreased 30-min intake of sweetened milk after 18-h deprivation, of pellets in rats maintained on a fixed amount of food per day (ca. 28 g) and of 10% sucrose after 2-h deprivation. Doses of 10, 28 and 20 µmol/kg produced approximately 50% reductions of pellets, milk and sucrose, respectively. Thus, CP-94,253 appeared to be more potent in reducing consumption of a solid, less palatable diet. Time-sampling analysis of the 20 µmol/kg dose in the pellet and sucrose tests revealed that CP-94,253 reduced the frequency of feeding and increased the incidence of standing but not resting. Meal duration was shortened. Analysis of the distribution of licking during the test with sucrose established that 20 µmol/kg reduced the total number of licks, and the size and frequency of bursts of licks (licks occurring with ILI < 250 msec) without altering the efficiency of licking. By comparison with these results, the peripherally acting 5-HT<sub>1A</sub> (1A,1B,1D,1-Like) agonist, 5-carboxamidotryptamine (5-CT) is >100-fold more potent than CP-94,253 in the pellet and milk tests. Furthermore, CP-94,253 and 5-CT differed in their behavioral profiles in the sucrose test. Overall, the results suggest that CP-94,253 may be a useful probe for central serotonergic mechanisms in feeding. Further analyses are in progress to determine the sites and establish the receptor mechanism for anorectic actions of CP-94,253. Supported by MH 41987 to KJS.

## 571.8

**OPIOID-INDUCED FEEDING BY MORPHINE MICROINJECTIONS INTO THE PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS AND THE NUCLEUS ACCUMBENS IS MEDIATED BY AN ENHANCEMENT OF TASTE PALATABILITY.** Peciña, S\* and Berridge K.C. Psychology Department, University of Michigan, Ann Arbor, MI 48104.

The enhancement in food intake produced by opioid agonists (i.e. morphine) administration, both systemically and intracranially, has now been repeatedly demonstrated. But what are the psychological processes that mediate this effect? Based on observations that opioid agonists selectively increase the intake of highly palatable food much more than the intake of regular chow in rats, it has been proposed that opioid-induced increase in food intake is at least partly mediated by an enhancement of taste palatability. This hypothesis has been supported by recent findings that opioid agonists increase hedonic taste reactivity patterns (e.g., tongue protrusions, etc.) in response to a sucrose solution in rats. But can opioid hedonic enhancement be elicited from the specific brain structures in which microinjections of opioid agonists evoke feeding? We investigated the effects of microinjections of morphine into the paraventricular nucleus of the hypothalamus (PVN; 0, 1, 5, 10, 25, 50 µg), and of bilateral microinjections of morphine into the nucleus accumbens (NAcc; 0, 1, 5, 10, 25 µg) on feeding and on taste reactivity patterns. Morphine microinjections in these two structures significantly enhance: food intake and taste palatability. These results demonstrate the opioid-induced feeding enhancement into the PVN and the NAcc is mediated by an enhancement of taste palatability.

## 571.10

**EFFECTS OF THE BENZODIAZEPINE RECEPTOR INVERSE AGONIST Ro 15-4513 ON CONSUMPTION OF SUCROSE AND SACCHARIN SOLUTIONS ANALYSED USING A LICKING MICROSTRUCTURE APPROACH.** S.J. Cooper\* and S. Higgs Department of Psychology, University of Durham, Science Laboratories, South Road, Durham, DH1 3LE, England.

The increase in ingestive behaviour observed following administration of benzodiazepine receptor (BZR) agonists is a well known phenomenon, but the anorectic action of BZR inverse agonists is less well characterised. Therefore, in the present studies we aimed to examine in great detail the decrease in ingestive behaviour brought about by the BZR partial inverse agonist Ro 15-4513 (1-10mg/kg). In a 20 min test session rats had access either to a 1% sucrose solution or a 0.1% saccharin solution. We videotaped the animals licking behaviour during this period and then performed a microstructural analysis of the data. Ro 15-4513 was found to dose dependently reduce consumption of both the sucrose and saccharin solutions. In the case of sucrose drinking the reduction in intake was due to a decrease in both the number of bouts and the mean bout duration. The total duration of drinking, total number of licks and duration of the first bout of drinking were also reduced. There was no effect of the drug on intra-bout lick rate, latency to engage in drinking or the post-bout drinking time. The effect of Ro 15-4513 on saccharin drinking was very similar but in this case the reduction in intake was mainly due to a reduction in the number of bouts. The results are discussed with reference to the effects of benzodiazepines on palatability.

## 571.11

NOREPINEPHRINE INFLUENCES GABA RESPONSE TO GLUCOPRIVATION IN VENTROMEDIAL HYPOTHALAMUS OF RATS. J.L. Beverly<sup>1</sup>, M. Beverly<sup>1</sup>, M. D'Souza<sup>1</sup>, J. Roberts<sup>1</sup>, M. Shutt<sup>1</sup>, R. van Husen<sup>1</sup>, and N.F. Shay<sup>2</sup>. Dept. Nutrition, Texas Tech Univ., Lubbock, TX 79409 <sup>2</sup>Univ. Illinois, Champaign, IL 61801

In response to glucoprivic episode, extracellular GABA is increased in the ventromedial hypothalamus (VMH) in a bimodal fashion. Norepinephrine (NE) turnover in the VMH may also be increased in response to glucoprivation. To determine if NE influences the GABA response to glucoprivation male Sprague-Dawley rats were fitted with guide cannulae to the VMH (n=8) or lateral hypothalamus (LH; n=8) and chronic jugular vein catheters. After a 7-10 d recovery, a 1 mm microdialysis probe was placed in the VMH or LH and continuously perfused with Krebs Ringers Buffer (KRB) at 2  $\mu$ l/min. Three hr after placement of probes, baseline GABA was determined in 3 consecutive 10 min samples. Dialysate was changed to KRB+NE (10  $\mu$ M) and 3 consecutive 10 min samples collected before administering a single dose of 2-deoxyglucose (2-DG; 200 mg/kg i.v.). Samples were collected at 10 min intervals for 60 min after 2-DG. GABA was analyzed by HPLC-EC. GABA concentrations in the VMH increased (44%, p<0.05) as a single peak with the addition of NE to dialysate. In response to 2-DG, GABA concentration in the VMH increased as a single broad peak (43% increase, p<0.05). GABA concentrations recovered from the LH were not altered by the addition of NE to dialysate or in response to 2-DG. Increased NE activity in the VMH may mediate the increase in GABA concentration after a glucoprivic challenge. Supported by Whitchall Foundation, Inc.

HYPOTHALAMIC HISTAMINE MODULATES INGESTIVE BEHAVIOR AND THERMOGENESIS INDUCED BY INTERLEUKIN-1 $\beta$ . T. Sakata\*, H. Yoshimatsu and M. Kurokawa. Dept. of Internal Medicine, School of Medicine, Oita Medical University, Oita, 879-55 Japan.

Homeostatic involvement of hypothalamic neuronal histamine in adaptive behavior and thermogenesis was investigated when interleukin-1 $\beta$  (IL-1 $\beta$ ), an endogenous pyrogen, was infused peripherally in rats. IL-1 $\beta$  decreased food and water intake, and elevated body temperature. Depletion of neuronal histamine in the hypothalamus induced by  $\alpha$ -fluoromethylhistidine, a suicide inhibitor of the histamine synthesizing enzyme histidine decarboxylase (HDC), attenuated the suppressive effect of IL-1 $\beta$  on food intake, facilitated the inhibitory effect on water intake, and enhanced its thermogenic effect. Simultaneously IL-1 $\beta$  increased activity of HDC, and histamine-N-methyltransferase, a neuronal histamine catabolizing enzyme. Pretreatment with indomethacin completely blocked those increase in turnover of neuronal histamine induced by IL-1 $\beta$ . Hypothalamic prostaglandin E2 (PGE2) activated by peripheral IL-1 $\beta$ , but not peripheral PGE2, increased both activities of HDC and HMT. Ginsenoside Rg1, a major component of panax ginseng, modulated the suppressive effects of IL-1 $\beta$  on ingestive behavior, resulting in a lowering of body temperature. The findings suggest that the effects of IL-1 $\beta$  on ingestive behavior and thermogenesis may be modulated by dynamics of hypothalamic neuronal histamine through activation of hypothalamic PGE2 which is elevated by peripheral IL-1 $\beta$ .

## 571.15

POSSIBLE INVOLVEMENT OF NITRIC OXIDE IN CHLORDIAZEPOXIDE-INDUCED FEEDING IN THE MOUSE. D.A. Czech\*, Department of Psychology, Marquette University, Milwaukee, WI 53233

Chlordiazepoxide (CP) and other benzodiazepine receptor ligands reliably stimulate feeding behavior in a number of animal species. Most recently, it has also been reported that the vasodilating gas, nitric oxide (NO), can have a modulating effect on both feeding and drinking behavior. The current study investigates a possible modulatory effect of NO on CP-induced feeding in mice.

In expt.1, male ICR mice were injected s.c. with several doses of the nitric oxide synthase (NOS) inhibitor L-N<sup>G</sup>-nitro arginine (L-NOARG) or 0.9% NaCl vehicle (Veh). Fifteen min later, 10 mg/kg of chlordiazepoxide-HCl (CP) or Veh was administered s.c. Five groups were thus formed: Veh/Veh (baseline feeding control), Veh/CP and three groups given doses of L-NOARG (10, 25 or 50 mg/kg) along with CP. Thirty min later, mice were placed in a polyethylene cage containing a preweighed rodent chow pellet for a 1-hr feeding test. Water was unavailable during testing. Amount of food (g) ingested was evaluated separately at 30 and 60 min with randomized one-way ANOVAs, along with Student's and Dunnett's t-tests; alpha level was set at p<0.05. A CP-induced hyperphagia was partially reversed in a dose-related manner, reaching significance at all doses of L-NOARG at 30 min and by the two higher doses at 60 min.

In expt.2, mice were injected s.c. with 25 mg/kg of L-NOARG, along with 500 mg/kg i.p. of the natural NOS substrate, L-arginine (L-arg) or the inactive isomer, D-arginine (D-arg). A challenge dose of 10 mg/kg CP, or Veh, was injected s.c. 15 min later. Subsequent food intake tests were conducted as in expt.1. Data were evaluated with Student's t-tests, again at 30 and 60 min. L-arg partially, but significantly, reversed the attenuation by L-NOARG of CP-induced hyperphagia; D-arg was ineffective, hence revealing a stereospecific effect.

These data are consistent with previous research reporting effects of L-NOARG in deprivation-induced feeding, thus suggesting NO involvement in CP-induced feeding as well.

## 571.12

GENE EXPRESSION OF TYROSINE HYDROXYLASE (TH) IN THE PARAVENTRICULAR (PVN) AND SUPRAOPTIC (SON) NUCLEI OF STREPTOZOTOCIN DIABETIC (STZ-D) RATS: RELATIONSHIP TO CO-EXISTING NEUROPEPTIDES. L.F. Pardo, G. Brennan\*, S.E. Bachus, and M. Jhanwar-Uniyal. The Rockefeller Univ. NY, NY 10021 and St. Elizabeths at NIMH, Washington D.C. 20032.

Dopamine (DA) synthesizing neurons in the PVN also synthesize neuropeptides, such as cholecystokinin (CCK), galanin (GAL) oxytocin (OT) and vasopressin (VP), all known to regulate various endocrine functions. In this study, we induced diabetes in male SD rats by administering the pancreatic  $\beta$ -catalytic agent STZ (60 mg/kg BW, IP). Rats were sacrificed 21 days post-injection when 20% loss in body weight, decrease in insulin and increase in glucose was achieved. *In situ* hybridization histochemistry was used to measure mRNA for TH, the rate-limiting enzyme in DA biosynthesis, and other co-existing neuropeptides.

The results show: 1) TH mRNA increased dramatically in PVN (p=0.008) and SON (p=0.009) of STZ-D rats; 2) PVN TH mRNA was correlated negatively with VP mRNA in controls (r=-0.91; p<0.05) but positively in STZ-D (r=0.85; p<0.05) rats; 3) PVN TH mRNA was strongly correlated with CCK (r=0.87; p<0.05) and GAL (r=0.82; p<0.05) mRNA in STZ-D rats; 4) SON TH mRNA was positively correlated only with OT (r=0.83; p<0.05) mRNA in STZ-D rats. These results suggest anatomical specificity in activated DA in VP neurons in PVN and SON. Co-activation of DA with VP, CCK and GAL indicates a complex interaction occurring in the hypothalamo-pituitary axis in diabetes.

## 571.14

NITROUS OXIDE-ENHANCED INTAKE OF A PALATABLE FLUID IN WATER-DEPRIVED RATS IS REVERSED BY AN OPIOID RECEPTOR BLOCKER. K.D. Guidinger, D.A. Czech, A.C. Faching, J.F. Headrick and J.C. Brooks\*. Department of Psychology and School of Dentistry - Basic Sciences, Marquette University, Milwaukee, WI 53233

Our laboratory recently observed that subanesthetic concentrations of nitrous oxide (N<sub>2</sub>O) can stimulate food intake in rats in a concentration-related manner, and that this effect is attenuated with an opioid receptor blocker. We now report a N<sub>2</sub>O-induced enhancement of consumption of a palatable fluid, which is very sensitive to antagonism by naltrexone, using within-subjects designs.

In expt.1, 16-20 hr (overnight) water-deprived male Long-Evans hooded rats were exposed to three concentrations of a N<sub>2</sub>O and O<sub>2</sub> mixture (10, 20 & 30% N<sub>2</sub>O) and to compressed room air (RA) control circulated through an enclosed environment. Following an initial acclimation to gases, rats were given access to a 0.15% saccharin-Na solution from a sipper tube in the same environment and intake was monitored electronically at 1-min intervals over a 40 min test period. Food was unavailable during testing, and tests were separated by 3-4 days. Cumulative intakes were analyzed at selected times from access to saccharin solution and from first drinking bout with repeated measures ANOVAs, and Dunnett's or Student's t-tests; alpha level was set at p<0.05. Relative to RA controls, intake increased significantly at both 20% and 30% N<sub>2</sub>O, with 20% N<sub>2</sub>O exhibiting a more pronounced shift.

In expt.2, similarly water-deprived rats were pretreated with several doses of naltrexone-HCl (Ntx) (0.01-3.0 mg/kg s.c.) or 0.9% NaCl vehicle prior to being exposed to a challenge concentration of 20% N<sub>2</sub>O; subsequent procedures were the same as in expt.1. Significant attenuation of a 20% N<sub>2</sub>O-induced increase in intake occurred at the relatively low dose of 0.03 mg/kg Ntx.

These data are consistent with the previously observed N<sub>2</sub>O-induced stimulation of solid food intake in the rat, and also implicate an opioid mechanism.

## 571.16

DEFECTIVE SYMPATHETIC ACTIVATION AND INSULIN RELEASE DURING PVN INFUSIONS OF NOREPINEPHRINE IN OBESITY-PRONE RATS. B.E. Levin\*. Neurology Svc., VA Medical Ctr., East Orange, NJ 07018.

Male Sprague-Dawley rats gain weight homogeneously when fed chow. But when fed a diet high in energy, fat and sucrose, half develop diet-induced obesity; the rest are diet-resistant. Although both chow-fed, obesity-prone (OP) and resistant (OR) rats weigh the same, OP rats have higher 24h urine norepinephrine (NE) levels and widespread decreases in forebrain  $\alpha_2$ -adrenoceptor binding including the hypothalamic paraventricular n. (PVN). Here, a functional test of this receptor deficit was made with bilateral indwelling PVN cannulae in OP (urine NE: 1.86 $\pm$ 0.11ng/24h) and OR (0.88 $\pm$ 0.08ng/24h; P=0.01) rats. Correct cannula placement was established by induction of eating in satiated rats following bolus injection of NE (20nmol). At baseline, fasted OP rats had 32% higher plasma insulin (p=0.05) and 9% higher glucose (P=0.001) levels than OR rats. Bilateral 20min PVN NE infusions (150pmol/min) increased plasma NE levels by 96% (P=0.05) and insulin by 32% (P=0.05) compared to carrier infusions in fasted OR rats but produced no change in OP rats. PVN NE infusions altered neither plasma glucose nor epinephrine levels nor motor activity in either phenotype. Thus, the defective sympathetic activation and insulin release shown by OP rats during NE stimulation of the PVN is in keeping with their reduced PVN  $\alpha_2$ -adrenoceptor binding. This finding may be important in the pathogenesis of obesity.

Supported by the NIDDK and VA Medical Research.

## 571.17

AMANTADINE DOES NOT PREVENT NEUROLEPTIC-INDUCED OBESITY IN RATS. L. Teneud\*, M.E. López, Q. Contreras, T. Alastre, L. Hernández, E. Musseo, M. Altemus, S. Weiss and T. Baptista. Laboratory of Behavioral Physiology, Medical School, Universidad de Los Andes, Mérida, VENEZUELA, and Biological Psychiatry Branch, NIH, Bethesda, MD.

The efficacy of the antiviral agent Amantadine (AM) to prevent neuroleptic-induced obesity was assessed in a model of sulpiride-induced weight gain in adult female rats. The effects of AM (5,10,20,50 and 100 mg/kg/sc. or ip.) on body weight and food intake were tested in drug-free animals and rats under a chronic regimen of Sulpiride (SUL) administration (20 mg/kg/ip for 21 days). In drug-free rats, acute administration of AM/ip. displayed a dose dependent anorectic effect:  $r=0.99$ ,  $F(1,4) = 213$ ,  $p < 0.001$ . However, chronic administration of AM significantly decreased body weight gain in drug-free rats only at the dose of 100 mg/kg/sc. Similarly, SUL-induced obesity was prevented by AM only at the dose of 100 mg/kg. AM did not prevent SUL-induced disruption of the vaginal cycle at any dosage. In addition, SUL-induced hyperprolactinemia was not counteracted by AM at the dose of 50 or 100 mg/kg. Finally, as assessed by brain microdialysis, systemic administration of AM (50 and 100 mg/kg) induced a slight and non-significant increase in dopamine overflow in the lateral hypothalamus, a putative brain area involved in the anorectic effect of the drug. The results suggest that AM displays a weak antagonistic effect on SUL-induced obesity in rats. This contrasts with anecdotal reports of prevention of neuroleptic-induced weight gain and hyperprolactinemia in patients with mental disorders.

## HORMONAL CONTROL OF REPRODUCTIVE BEHAVIOR: BEHAVIORAL MEASURES

## 572.1

MICROINJECTION OF OXYTOCIN (OXT) INTO THE MEDIAL PREOPTIC-ANTERIOR HYPOTHALAMUS (MPOA-AH) AND VENTROMEDIAL HYPOTHALAMUS (VMH) OVERRIDES THE INHIBITORY EFFECTS OF PROGESTERONE (P) ON LORDOSIS IN SYRIAN HAMSTERS. D. Carol Whitman\* and H. Elliott Albers. Lab. Neuroendocrinol. & Behav., Depts. Biol. and Psychol., Georgia State Univ., Atlanta, Ga.

The levels of lordosis induced by injection of OXT into the MPOA-AH and the VMH of ovariectomized estradiol (EB)-primed hamsters mimics that observed on estrus or following administration of EB and P. Injection of an OXT antagonist into the same brain areas inhibits EB and P induced-lordosis in hamsters. To further investigate the relationship between the effects of OXT and P on lordosis we examined whether the inhibitory effects of P could block the ability of OXT to induce lordosis. OVX hamsters were given EB (10 $\mu$ g, s.c.) followed 44 hrs later by P (500  $\mu$ g, s.c.) and 68 hrs by a second P injection. Three hrs later each hamster received a microinjection of OXT or saline (counterbalanced) and was tested with a male for lordosis duration (sec). Following the second P (500 $\mu$ g, s.c.) injection, OXT induced a significantly longer duration of lordosis (472.0 $\pm$ 63.8 sec) than did saline (48.3 $\pm$ 48.3). These data indicate that OXT can override the mechanisms that inhibit lordosis in response to P.

Supported by NSF IBN 9222099.

## 572.3

ESTROGEN INCREASES THE STRENGTH OF A MEDULLARY-LUMBOSACRAL MOTONEURONAL PROJECTION, POSSIBLY INVOLVED IN LORDOSIS BEHAVIOR IN THE CAT.

V.G.J.M. VanderHorst\*, H. de Weerd and G. Holstege. Department of Anatomy, University of Groningen, Oostersingel 69, 9713 EZ, The Netherlands

The nucleus retroambiguus (NRA) is a compact group of interneurons located in the caudal medullary tegmentum. The NRA forms a relay between the periaqueductal gray (PAG) and motoneuronal cellgroups involved in vocalization and possibly lordosis behavior. NRA interneurons have recently been shown to project directly to distinct motoneuronal cellgroups in the lumbosacral cord innervating hindlimb muscles such as iliopsoas, adductor and hamstring muscles, as well as proximal tail and pelvic floor muscles. This set of muscles is involved in lordosis behavior in the cat, which is typically displayed in the presence of elevated levels of estrogen. Estrogen is known to induce plastic changes in hypothalamic pathways which play a role in lordosis behavior. The question arises whether estrogen induced changes are also present in the NRA-motoneuronal pathway. Therefore, the density of the NRA-lumbosacral projection was studied in six estrous and eleven non-estrous cats at the light and electron microscopical level. The NRA was injected with WGA-HRP and light microscopically, the density and arborization pattern of anterogradely labeled axons in their target motoneuronal cell columns was studied. At the ultrastructural level, the number of labeled terminals was counted in the semimembranosus motoneuronal cell group and their synaptic morphology was studied. The results show marked differences in the NRA-lumbosacral projection in estrous versus non-estrous cats. Light microscopically, the density of labeled NRA axons was much higher in estrous than in non-estrous cats. At the ultrastructural level, the number of labeled NRA terminals increased significantly in estrous cats. The results suggest that estrogen induces axonal outgrowth and synapse formation in the NRA-lumbosacral motoneuronal pathway. Periodical, estrogen related changes in the density of the NRA-lumbosacral motoneuronal pathway might be one of the factors responsible for lordosis to occur.

## 572.2

MEASURING INTENSITY OF SEXUAL BEHAVIOR IN FEMALE CATTLE. Frank, J.C.M. van Eerdenburg\* and Jan H. van Vliet. Dept. Herd Health & Reproduction, Faculty of Veterinary Sciences, 3584 CL Utrecht, The Netherlands.

Estrus detection on dairy farms is usually done by watching for female sexual behavior. A six weeks long, dayround, behavioral survey revealed that only 37% of the modern dairy cows stood to be mounted, a behavior comparable to lordosis in rodents, which has always been the key in estrus detection. However, other, less specific, components of female sexual behavior were performed by the cows. Although showing these also in diestrus, the frequency is higher during estrus. We calculated a scoring scale (Table 1) for these behaviors in order to be able to compare the intensity of estrous behavior between individual animals and herds in neuro-endocrine and -anatomical studies regarding the regulation of female sexual behavior in cattle.

Table 1: Scoring scale for estrous behavior in cattle:	
mucous vaginal discharge	3 points
cajoling	3 points
restlessness	5 points
being mounted but not standing	10 points
sniffing on vagina of other cow	10 points
resting with chin on other cow	15 points
mounting (or attempting) other cows	35 points
mounting headside of other cow	45 points
standing heat	100 points

This scoring system is cumulative during a 24 hour period and can also be used for estrus detection.

## 572.4

BEHAVIORAL EFFECTS OF 3 $\alpha$ -ANDROSTANEDIOL: HYPOTHALAMIC AND PREOPTIC AREA ACTIONS VIA A GABAERGIC MECHANISM.

M. S. Erskine\* and C. A. Frye. Department of Biology, Boston University, Boston, MA 02215.

We investigated whether 5 $\alpha$ -androstane-3 $\alpha$ ,17 $\beta$ -diol (3 $\alpha$ -androstenediol; 3 $\alpha$ -Diol), a neurosteroid whose effects are primarily inhibitory to lordosis behavior, may act through interactions with  $\gamma$ -aminobutyric acid (GABA) receptor complexes (GBRs) in the medial basal hypothalamus (MBH) and the preoptic area (POA). In Exp. 1, ovariectomized (ovx) rats were implanted with bilateral guide cannulae aimed above the MBH and were later treated with estradiol-17 $\beta$  (E<sub>2</sub>, 2 injections of 1  $\mu$ g/0.2 ml in 10% ethanol) and either 3 $\alpha$ -Diol (3.0 mg/kg sc) or vehicle. Progesterone (0.5 mg sc) was given 24 hrs after the first E<sub>2</sub> injection and a pre-test for lordosis responsiveness was carried out 4 hrs later. The GABA<sub>A</sub> agonist, muscimol (50 ng), then was infused into the MBH and rats were tested 10, 30 and 60 min later. Muscimol infusion facilitated lordosis in vehicle-treated controls, but 3 $\alpha$ -Diol-treated animals failed to show this facilitation. To ascertain whether 3 $\alpha$ -Diol would also prevent muscimol's action in the POA, a site in which muscimol inhibits, rather than facilitates, sexual receptivity, ovx animals in Exp. 2 were implanted with bilateral guide cannulae aimed above the POA and were treated with E<sub>2</sub>, 3 $\alpha$ -Diol, and P and infused and tested as in Exp. 1. Muscimol and 3 $\alpha$ -Diol each significantly inhibited lordosis; when they were combined, the inhibition was more pronounced. In Exp. 3, POA infusions of the GABA<sub>A</sub> antagonist, bicuculline, counteracted the inhibition of lordosis by both muscimol and 3 $\alpha$ -Diol. In Exp. 4, *in vitro* treatment of POA and MBH membrane fractions with 3 $\alpha$ -Diol (30  $\mu$ M) enhanced maximal [<sup>3</sup>H]-muscimol binding without altering the affinity of the binding sites for the agonist. These data suggest that 3 $\alpha$ -Diol inhibits E<sub>2</sub> and progesterin-induced lordosis behavior via actions at GBRs in both the MBH and POA. Supported by grants from Eli Lilly Co. and HD21802 to MSE and NRSA MH10744 to CAF.

## 572.5

**SEXUAL BEHAVIOR REGULATED (PACE) BY THE FEMALE INDUCES A REWARD STATE.** Araceli Alonso and Raúl G. Paredes\*. Psychology Department, Universidad Anáhuac, México D.F. 11000.

The possibility that female coital behavior induces a reward state of a duration sufficiently long, and an intensity sufficiently high, to allow association between that state and environmental cues was evaluated in the present experiment. Female rats were ovariectomized (OVX) and treated with estradiol benzoate (EB) or EB plus progesterone (P). In these 2 groups the females were not able to control their coital contacts. Another group of OVX females was treated with EB plus P and were allowed to control (pace) her sexual interactions with males. Two additional groups of OVX females were included, one treated with saline and the other with morphine (1 mg/kg). The initial preference for a white or black compartment was determined in a 10 min session. The animals were then paired to a reinforcing event (copulation or morphine injection) followed 24 hrs later by a pairing to the non reinforcing situation (injection of vehicle). After 3 pairings to each event their preference was tested again. Females that were allowed to pace their sexual contacts with males showed a place preference similar to that induced by morphine treatment. The groups of females in the nonpaced situation did not modified their preference after mating. The results indicate that sexual interaction in females induces a reward state when they are able to pace their sexual contacts.

## 572.7

**EFFECTS OF TESTOSTERONE (T), PROGESTERONE (P), AND DI-HYDROTESTOSTERONE (DHT) ON THE INHIBITION OF LORDOTIC BEHAVIOR IN THE MALE RAT.** P.C. BUTLER, S.E. HUBER, AND G.J. BLOCH\*. Dept. of Psychology, BYU, Provo, UT 84602.

In a brief report, Dohanich et al (Horm. Beh. 17, '83) reported that T lowered the incidence of lordosis in EB primed male rats, but we found no inhibitory effect of T on lordosis quotients (LQ), or the incidence of lordosis (Bloch et al, Neurosci 20, '94). P is produced in large quantities by the adrenals and testes, so we tested for its effects on lordosis with and without T. Adult gonadectomized EB primed and non-primed male rats were given blank (Bk), T, P, or T&P-filled Silastic capsules. Four behavioral tests for lordosis were spaced one week apart. Repeated measures ANOVA revealed that EB primed males given T&P together showed significantly less lordosis than EB primed males that received Bk, T or P alone (For example, fourth week LQ means $\pm$ SEM: T&P= 36.2 $\pm$ 10.5 vs. 76.7 $\pm$ 5.0, 68.9 $\pm$ 7.5, 67.5 $\pm$ 8.0, for Bk, T, and P treatments, p's from 0.002 to 0.01). Although LQ scores were very low in males not primed with EB, the incidence of lordosis was significantly lower after treatment with T&P than with T alone (2 out of 12, vs. 6 out of 12, p<0.04). In an additional study, EB primed gonadectomized and adrenalectomized male rats treated with Bk, T, P, T&P, DHT, and DHT&P showed similar results (LQ: Bk=80.0 $\pm$ 3.3, T=71.0 $\pm$ 7.8, P=72.7 $\pm$ 5.6 vs. T&P=22.8 $\pm$ 7.7; DHT=52.7 $\pm$ 10.5, DHT&P=49.4 $\pm$ 7.5). DHT was inhibitory as has been reported previously (Baum, Science 182, '73), but DHT&P together did not further reduce LQ's. Thus, P acts synergistically with T, but not with DHT, to inhibit lordosis in the male rat. Supported by HD 27334.

**DAMAGE TO THE TELENCEPHALIC NUCLEUS TAENIAE DISRUPTS SEXUAL APPROACH BEHAVIOR IN MALE JAPANESE QUAIL.** R. Thompson\*, J. Goodson, M. Ruscio, and E. Adkins-Regan, Cornell University, Psychology Dept., Ithaca, NY 14853.

Nucleus taeniae (nTN) is a prominent cell group of the avian archistriatum proposed to be homologous with the mammalian amygdala. Because nTN appears to be similar to the medial nucleus of the mammalian amygdala with respect to sex-steroid binding sites (Watson & Adkins-Regan, 1989), we designed an experiment to see if it plays some role in sexual behavior toward female conspecifics. Adult, sexually experienced male Japanese quail housed under short-day photoperiodic conditions and given exogenous testosterone propionate received either bilateral, electrolytic ablations of nTN (n=8) or a sham surgical procedure (n=14). Ablations were confirmed with histological analysis. Birds with nTN damage were slower to approach a female housed behind clear plexiglass at the other end of a runway apparatus (mean of the means for individual birds over 4 test sessions: 1.39 min $\pm$ .32 SEM, experimental group; .66 min $\pm$ .27 SEM, sham group, F = 6.22, p<0.05) and spent less time in proximity to the female stimulus during a 5 minute testing session when physical contact was not allowed, although this difference did not reach significance (mean of the means for individual birds over 4 test sessions: 3.78 min $\pm$ .23 SEM, experimental group; 4.31 min $\pm$ .26 SEM, sham group, F = 3.02, p=.09). Copulatory behavior itself appeared unaffected. These results have implications for the potential homology of nTN with the medial nucleus.

## 572.6

**FACTORS AFFECTING THE FEMALE POSTEJACULATORY REFRACTORY PERIOD IN RATS.** L.Y. Yang\* and L.G. Clemens. Neuroscience Program and Department of Zoology, Michigan State University, East Lansing, MI 48824

When the female rat is tested in a situation that allows her to escape from the male during copulation, she "paces" her sexual contact with the male. It has been reported that different numbers of intromissions prior to ejaculation affect the female rat's postejaculatory refractory period (PER) (Yang and Clemens, 1994). The objective of the present study was to investigate the effect of other male related stimuli on the temporal aspects of female copulatory behavior. In Experiment I, we examined the effect of the seminal plug, the penile cup and prostate secretions on the female rat's pacing behavior. Results showed that neither the seminal plug, the penile cup nor prostate secretions contributed to female's PER. Experiment II investigated the relation of male's ejaculation duration to the female's PER. Results indicated that the female's PER increased in length as the ejaculation duration increased. In addition, the number of intromissions preceding ejaculation was positively correlated with the duration of the ejaculatory reflex.

**ALTERED SEXUAL PARTNER PREFERENCE IN MALE FERRETS GIVEN EXCITOTOXIC LESIONS OF THE PREOPTIC AREA/ANTERIOR HYPOTHALAMUS.** M.J. Baum\* and R.G. Paredes. Dept. of Biology, Boston University Boston, MA 02215

In Experiment 1 prepubertal male and female ferrets were gonadectomized, treated daily with estradiol benzoate (EB), and tested in a T-maze for approach to a stud male versus an estrous female. Males given bilateral infusions of the NMDA excitotoxin, quinolinic acid aimed at the dorsomedial POA/AH, preferred to approach a stimulus male significantly more often than control males which received either a sham- or a unilateral mPOA/AH lesion or bilateral infusions of quinolinic acid which produced no detectable excitotoxic damage to the mPOA/AH. Males with bilateral mPOA/AH lesions also neck gripped the stimulus female on significantly fewer trials. EB-treated female subjects with bilateral mPOA/AH lesions, like control females, preferred to approach the stimulus male. The males used in Experiment 1 had never experienced circulating levels of testosterone (T) characteristic of the breeding season. In Experiment 2 prepubertally gonadectomized males and females were treated with a high dose of T propionate and tested several times with a receptive female prior to brain surgery. Males which received bilateral excitotoxic lesions of the mPOA/AH neck gripped and mounted stimulus females significantly less than control males. Again, when given EB followed by T-maze tests of partner preference, males with bilateral mPOA/AH lesions, like sham-operated female controls, preferred to approach the sexually active stimulus male significantly more often than control males, which preferred to approach the stimulus female. Our results suggest that neurons in the mPOA/AH play an important role in the integration of sensory cues which determine heterosexual partner preference in the male ferret, in addition to facilitating masculine coital performance. ## 572.10

**ANABOLIC-ANDROGENIC STEROIDS AND SEXUAL BEHAVIOR IN INTACT MALE RATS.** A.S. Clark\* and A.S. Fast. Dept. of Psychology, Dartmouth College, Hanover, NH 03755.

Anabolic-androgenic steroids (AAS) are synthetic androgen-like substances frequently abused by athletes. Very little is known regarding the impact of chronic AAS use on male reproductive function. The present study compared the effects of long-term treatment with three popular AAS on the display of male sexual behavior in gonadally intact male Long-Evans rats. The three AAS selected for study were methyltestosterone, methandrostenedione and nandrolone decanoate. Doses of each AAS comparable to human abuse dose ranges were administered to sexually active male rats daily for 12 weeks. Sexual behavior was quantified each week by an observer blind to the treatment conditions.

Treatment with methyltestosterone proved the most disruptive to male sexual behavior: 50% of the rats treated with the high dose of this AAS failed to complete an ejaculatory sequence by the end of the testing period. Treatment with the high dose of methandrostenedione resulted in a modest increase in ejaculation latency by the end of the testing period, while treatment with the medium dose of nandrolone decanoate produced subtle but persistent changes in several components of male sexual behavior. These results indicate that individual AAS compounds have unique effects on the components of male sexual behavior. These characteristics may reflect the efficacy of specific AAS compounds at androgen receptors.

## 572.11

**THE INFLUENCE OF ANABOLIC-ANDROGENIC STEROIDS ON THE ESTROUS CYCLE IN RATS.**

M.E. Blasberg\*, C.J. Langan and A.S. Clark, Dept. of Psychology, Dartmouth College, Hanover, NH 03755.

Anabolic-androgenic steroids (AAS) are synthetic androgen-like substances that have been abused by both male and female athletes with the goal of increasing physical strength and athletic abilities. Because other androgens have been shown to interfere with the estrous cycle of female rats, the ability of two AAS to disrupt specific components of the estrous cycle was examined in two separate groups of adult female Long-Evans rats. Female sexual behavior and vaginal cytology were monitored daily over a baseline period, a two-week drug treatment period, and a recovery period. The AAS selected for this study were methyltestosterone and methandrostenolone, AAS compounds frequently abused by athletes. Animals received either the high, medium or low dose of the AAS or the oil vehicle. The number of days of sexual receptivity and vaginal estrus were compared between groups.

Treatment with methyltestosterone significantly reduced receptive behavior and days of vaginal estrus during drug treatment period in a dose-dependent manner. Treatment with methandrostenolone produced no significant disruption in sexual behavior or vaginal cytology as compared to controls. The unique chemical structures or metabolic products of methyltestosterone and methandrostenolone may underlie their distinct effects on female reproductive function. Supported by NIDA-08574.

## 572.13

**INTEGRATION OF CHEMOSENSORY AND HORMONAL CUES IS ESSENTIAL FOR MALE SEXUAL BEHAVIOR IN THE SYRIAN HAMSTER: ROLE OF THE MEDIAL AMYGDALOID NUCLEUS.** R.L. WOOD\*, Dep't of Ob/Gyn, Yale University, New Haven, CT 06520

Mating behavior in the male hamster is dependent upon both chemosensory and hormonal cues, and copulation is abolished if either signal is interrupted. Through reciprocal interaction of these signals, chemosensory stimuli increase circulating testosterone, and steroid hormones enhance chemoinvestigation. Furthermore, these cues are transmitted through parallel pathways in separate subdivisions of the medial amygdaloid nucleus (Me), bed nucleus of the stria terminalis (BNST) and medial preoptic area (MPOA). Previously, we demonstrated that a single testosterone implant in Me can increase mounting in castrate males, and that integration of chemosensory stimuli with steroid signals in BNST/MPOA is essential for mating. The present studies determined if Me is likewise capable of chemosensory and hormonal integration. The approach was to place an intracerebral implant of testosterone in Me, combined with removal of a single olfactory bulb (UBx), ipsilateral or contralateral to the steroid implant. Ipsilateral UBx blocks communication between chemosensory and hormonal circuits. Sexually-experienced males were used (n=10 each). 12 weeks after castration, a single olfactory bulb was removed, and each male received a testosterone-filled cannula (23 ga). 2 weeks later, there was no effect on sexual behavior in ipsilateral or contralateral UBx males. To determine if steroid stimulation of mating behavior in Me requires bilateral chemo-sensory input, a second study separated implantation and UBx. Contralateral UBx abolished behavioral stimulation in 7 males with an implant in Me. These results confirm that integration of hormonal and chemosensory cues is required for mating behavior. Moreover, steroid facilitation of sexual behavior in Me requires bilateral chemosensory input. (Supported by HD 32669).

## 572.15

**DIFFERENTIAL ROLE OF RAT MEDIAL AMYGDALA IN THE REGULATION OF ERECTION IN THREE CONTEXTS.** Y. Kondo\*, B.D. Sachs<sup>1</sup>, and Y. Sakuma, Dept. Physiology, Nippon Medical School, Tokyo 113, Japan, and <sup>1</sup>Dept. of Physiology, Univ. of Connecticut, Storrs, CT 06269-1020, U.S.A.

We studied erection in rats during (a) copulation, (b) somesthetic stimulation of the penis (reflexive erection), and (c) proximity to inaccessible estrous females (noncontact erection, NCE). Tests were conducted 7-10 days after the rats received radiofrequency lesions of the medial amygdala (MAL, n=8) or sham operations (Sham, n=10). During copulation tests, 6/8 MAL rats achieved intromission, but because of their slower copulatory rate, 0/6 males ejaculated within the 20-min limit after the first intromission, compared with 9/10 Sham males (p<.001). The mean intromission ratio [I/(M+1), in part a measure of erectile function] was similar in the two groups (MAL=0.47; Sham=0.60, p=.25), implying no significant erectile dysfunction in copulating MAL rats. The groups also did not differ reliably on any measure of reflexive erection in response to touch/pressure. However, 0/8 MAL rats displayed NCE, compared with 8/10 Sham rats (p<.01). The data suggest an important role for the rat MA in NCE, but not for erection in the other two contexts. The MA has been implicated in chemosensory processing. However, since bedding from estrous rats does not provoke erection (Sachs et al, *Physiol. Behav.* 55:1073; 1994), NCE may be mediated by a non-olfactory function of the MA.

## 572.12

**MATING IN MALE MICE LACKING THE GENE FOR NEURAL NITRIC OXIDE (nNOS) SYNTHASE.** S.L. Klein<sup>1</sup>, G.E. Demas<sup>1</sup>, L.J. Kriegsfeld<sup>1</sup>, R.J. Nelson<sup>1</sup>, A.L. Burnett<sup>2</sup>, P.J. Huang<sup>3</sup>, M.C. Fishman<sup>4</sup>, V.L. Dawson<sup>2</sup>, T.M. Dawson<sup>2</sup>, and S.H. Snyder<sup>1</sup>. <sup>1</sup>Dept of Psychology, <sup>2</sup>Dept. of Urology, <sup>3</sup>Dept of Neuroscience, Johns Hopkins Univ., Baltimore, MD 21218, <sup>4</sup>Cardiovascular Research Center, Massachusetts General Hospital, Boston, MA 02129.

To determine the specific role of nNOS in male mating behavior and penile erection, homologous recombination was used to create mutant mice with targeted disruption of the nNOS gene (nNOS-). nNOS- and wild-type (WT) males were paired with estrous WT females for 30 min mating tests. There were no significant differences between nNOS- and WT males in the latency to the first mount, number of mounts, latency to first intromission, inter-intromission interval, number of intromissions, or percentage of animals ejaculating with WT females. WT and nNOS- mice produced equivalent numbers of young when bred to WT females. In addition, bilateral stimulation of the cavernous nerves resulted in penile erection in nNOS- animals. In another mating test, nNOS- and WT males were paired with nonestrous WT females for 8 h. Initially, wild-type and nNOS- males mounted females to the same extent, indicative of a normal male response to a novel female. This behavior diminished rapidly in WT males, but only a modest non-significant decrease in the number of mounts was seen in the nNOS- males after the first hour. nNOS- mice continued to attempt to mount nonestrous females at a significantly higher rate than WT males throughout the 8 h test. Plasma testosterone values did not differ significantly between WT and nNOS- mice either before or after the behavioral observations. nNOS- mice did not display any significant impairments on any other behavioral assessments. These findings provide the first evidence for a role of central nNOS neurons in mating behavior.

## 572.14

**DIFFERENTIAL ROLE OF THREE BRAIN REGIONS (MPOA, PVH, AND NPGi) IN RAT ERECTILE FUNCTION.** Y.-C. Liu\*, J.D. Salamone, and B.D. Sachs, Dept. of Psychology, Univ. of Connecticut, Storrs, CT 06269-1020.

Three brain regions, the medial preoptic area (MPOA), paraventricular nucleus of the hypothalamus (PVH) and nucleus paragigantocellularis (NPGi), received radiofrequency or sham lesions to compare their roles in penile erection in three contexts: copulation, reflexive erection, and noncontact erection (NCE; i.e., while in proximity to inaccessible estrous females). In two weekly post-op tests, NCEs were displayed by 3/7 & 5/7 MPOAx males vs. 6/10 & 9/10 Sham males (ns). In copulation tests 1-2 days after each NCE test, 1/7 & 1/7 MPOAx males ejaculated vs. 9/10 & 10/10 Sham males (each p<.01). These results support the view that MPOAx rats are aroused autonomically and motorically by estrous females, but unable to translate their sexual arousal into copulatory behavior. PVHx males had smaller intromission ratios (IR, p<.03) and longer ejaculation latencies (p<.02). In supine tests, 2/8 PVHx males vs. 8/10 Sham males displayed reflexive erection (p<.05). The groups were similar in proportion of males showing NCE in two post-op tests, but PVHx males had longer latencies than Sham rats in the second test (p<.01). Thus, PVH lesions impaired erectile function in all three contexts. NPGix males had fewer mounts (p<.03) and intromissions (p<.02) prior to ejaculation than Sham rats, but the IR was unaffected. Reflexive erections were displayed by 9/10 NPGix males vs. 3/8 Sham males (p<.05) and vs. 3/10 NPGi males before lesion (p<.02). In NCE, tests the groups did not differ reliably. These data support the hypothetical inhibitory role for the NPGi in erectile and/or ejaculatory function during copulation and reflexive erection, but not NCE. Collectively, these data and those from other investigators support the view that brain regions participate differentially in erectile function, depending in part on the context in which erection is evoked. (HD08933)

## 572.16

**MOUNTING BEHAVIOR PREDICTS FERTILITY OF MALE TRANSGENIC MICE OVEREXPRESSING HUMAN GROWTH HORMONE (GH) GENE.** C.J. Meliska\* and A. Bartke, Southern Illinois University School of Medicine, Carbondale, IL 62901-6512.

Male transgenic (T) mice overexpressing the human placental GH variant gene (mMT-hGH.V) exhibit reproductive deficits in spite of normal testosterone levels and normal sperm counts (*J. Reprod. Fert.* 95:109, 1992). To evaluate the relationship of copulatory behavior to fertility, we first measured mount, intromission, and ejaculation indices in 2-5 month-old mice (10 T and 10 non-T litter mate controls) during 1-hr tests with ovariectomized, estrogen and progesterone primed females. After 8 tests, each male was housed with 3 intact females for 27 days. Females were checked daily for vaginal plugs and sacrificed 14 days after insemination to determine numbers of corpora lutea, live, and dead fetuses. Relative to non-T controls, T mice displayed shorter latencies to intromit after the initial mount (311 vs. 28 s, P = 0.013); made more pre-ejaculation intromissions (18.2 vs. 61.1, P = 0.043); plugged fewer (3.0 vs. 1.8, P = 0.01), and took longer to plug intact females (3.6 vs. 11.0 days, P = 0.008); and sired fewer live fetuses per insemination (9.0 vs. 2.6, P = 0.017) than non-T controls. Among both T and non-T mice, mount rate (mounts/min) between first mount and first intromission in the copulation tests was inversely correlated with number of live fetuses (r = -.66, P = 0.027), suggesting that reduced fertility is associated with altered male copulatory behavior, including a rapid rate of mounting the female prior to the first intromission. (Supported by NIH Grant HD20001.)

## 573.1

ENHANCED STIMULANT EFFECTS FOLLOWING CHRONIC ANABOLIC STEROID ADMINISTRATION. J.W. Boja\*. Dept. Of Pharmacology, NEOUCOM, Rootstown, OH 44272.

The abuse of anabolic steroids has dramatically increased not only by adult body-builders and athletes but also by adolescents as well. It has been estimated that 250,000 high school students have either tried or are currently using anabolic steroids. A recent study reported that 4.7% of male and 2.9% of female ninth grades were using anabolic steroids. In addition, the subjects were more likely to engage in risky behaviors such as needle sharing and co-administration of other illicit drugs such as cocaine. Chronic stimulant administration has been reported to lead to higher feelings of aggression, mania, depression and other behavioral disturbances. These symptoms may be enhanced with the concurrent use of other powerful psychoactive substances like amphetamine or cocaine. In order to study the co-abuse liability of anabolic steroids and stimulant use, juvenile male Sprague-Dawley rats (50-60g) were injected IM once a week with 200 mg/kg nandrolone decanoate or the corn oil vehicle for six weeks. Two days after the last injection, the animals were placed into an activity chamber for 30 minutes prior to injection of 10 mg/kg amphetamine sulfate. While there were no differences in baseline activity, amphetamine-stimulated activity was significantly higher in the steroid treated than in the vehicle treated controls. In addition the anabolic steroid treated animals displayed heightened aggression towards resident intruders compared to controls. These results indicate that a significant co-abuse liability between anabolic steroids and stimulants may exist.

## 573.3

SEX DIFFERENCES IN OPEN-FIELD BEHAVIOR BEFORE AND AFTER AMPHETAMINE: COMPARISON OF NEONATALLY GONAECTOMIZED (NEOGX) AND ADULT-GX RATS. R.H. MILLS\*, J.G. KOHLERT, L.W. JOHNSON, T. SLADE AND G.I. BLOCH. Dept. of Psychology, BYU, Provo, UT 84602.

Adult-Gx male rats show a lower locomotor response to D-amphetamine sulfate (AMPH) than adult-Gx females (Forgie & Stewart, '93). To further explore this issue, males and females were Gx or sham-Gx at 6-30 hr after birth and at 75-80 days of age. Animals were acclimated on days 6-8 after adult-Gx, then received 2.0mg/kg AMPH i.p. on day 9. Locomotor behavior was analyzed by ranking the behavior by its position on an inverted U-shaped curve based on scores of both ambulatory (beam-breaks) and stereotyped behaviors; this method is unambiguous, giving a clear, positive relation between rankings and AMPH dosage (Kohlert & Bloch, '94). Adult-Gx females showed significantly greater levels of basal locomotor activity than the other groups during the first acclimation session and during the first 6 min of all 3 acclimation sessions (p's .01 to .04, Newman-Keuls); a similar result was reported by Stewart & Cygan ('80) using 3-minute tests. Adult-Gx males responded significantly less to AMPH than animals in the other groups (p's .05 to .005, Mann-Whitney tests). We saw no difference in the acute AMPH response among NeoGx males, NeoGx females, and adult-Gx females. Forgie & Stewart ('94) reported lower total activity scores in NeoGx than adult-Gx females, but results were ambiguous because NeoGx females also had higher levels of stereotypy. No difference in basal and AMPH-stimulated activities in NeoGx males vs. NeoGx females suggests that prenatal testosterone is not responsible for the sex difference in Gx animals. However, estrogen during the post-neonatal period appears to increase basal open-field activities in adult-Gx rats, while testosterone during this period appears to reduce the AMPH-stimulated response in adult-Gx rats. Supported by HD27334.

## 573.5

CHARACTERIZATION OF AMPHETAMINE SENSITIZATION IN MALE AND FEMALE RHESUS MONKEYS: IS IT RELATED TO BEHAVIORAL AND HORMONAL INDICES OF STRESS? S. A. Casner\* and P. S. Goldman-Rakic. Yale University School of Medicine, Section of Neurobiology, 333 Cedar Street, New Haven, Connecticut, 06510.

Sensitization to amphetamine (AMPH) has been proposed as one model of AMPH psychosis. In rats, there are sex, individual and strain differences in the response to both acute and chronic AMPH administration. To our knowledge, an in depth characterization of AMPH sensitization in male and female non-human primates has not been described.

For these experiments, young adult male and female rhesus monkeys were assigned to either AMPH or saline groups. Assignment was based on the incidence of ritualistic and stereotypic behaviors exhibited in the home cage over months of baseline behavioral observations. Behaviors, such as stereotypic pacing and self-biting, are considered indicative of a stressful response to single-unit housing and/or early social deprivation. For the AMPH group, both acute and chronic responses to AMPH will be explored via daily behavioral analysis, serum analysis of prolactin, AMPH and cortisol, and in vivo SPECT imaging of dopamine and serotonin receptors. Saline controls will undergo the same procedures to control for possible effects of daily injections and anesthesia. We hypothesize that the baseline behavioral categorization of an animal (stressed vs. non-stressed) will be predictive of either a high or low response to subsequent AMPH administration, respectively.

Preliminary findings indicate that a high incidence of stereotypic pacing in the home cage is reflected in a basal serum cortisol level that is significantly higher than that of animals which do not exhibit any signs of ritualistic or stereotypic behaviors in the home cage environment. Initial findings of AMPH concentrations in serum post-injection (0.1 mg/kg; i.m.) are higher in stressed compared to non-stressed animals. These results are being replicated at higher doses of AMPH. Sensitization data will be reported at the meeting. [Supported by the Stanley Foundation and MH44866]

## 573.2

GLUCOCORTICOID RECEPTOR MRNA IS DOWN-REGULATED IN THE HIPPOCAMPUS OF RATS BEHAVIORALLY SENSITIZED TO AMPHETAMINE. P.D. Shilling\*, J.R. Kelsoe, D.S. Segal. Dept of Psychiatry and Neurosciences Program, Univ. Calif., San Diego, CA 92093.

Repeated administration of amphetamine-like stimulants to adult rats results in enhanced behavioral responsiveness to subsequent administration of these drugs. The mechanisms underlying these behavioral changes may have important implications for stimulant abuse as well as for various forms of psychopathology. Recent evidence suggests corticosterone may play a role in the development of sensitization (Rivet et al. Brain Res. 198:149;1989), perhaps through the down-regulation of glucocorticoid receptor (GR) (Reul et al. Mol. Endocrinol. 3(10):1674;1989). To test this hypothesis we examined the effects of 5 daily injections of amphetamine (AMPH) (2.5mg/kg) on GR mRNA of adult Sprague Dawley rats. This treatment has been shown to produce pronounced sensitization characterized by a progressively more rapid onset and intensification of stereotypy and enhanced post-stereotypy hyperactivity. Two other groups received saline for 4 days and then either saline or AMPH on the fifth day. All animals were sacrificed 24 hours after the last treatment and *in situ* hybridization was performed with an antisense mRNA GR probe. Message was detected by film autoradiography. Quantification of hippocampal GR mRNA was accomplished by computer analysis of digitized images of CA1 and dentate gyrus using Image 1.55. Acute AMPH did not alter GR mRNA. In contrast repeated exposure to AMPH resulted in significant down-regulation in CA1 (P<.04) and a nonsignificant trend towards down-regulation in dentate gyrus. Further studies will be performed to determine if down-regulation of GR mRNA is critical for the development of behavioral sensitization.

## 573.4

MK-801 AND HALOPERIDOL FAIL TO BLOCK AMPHETAMINE SENSITIZATION INDUCED BY CHRONIC IMMOBILIZATION STRESS. L. Ho, B.K. Tolliver, and S.P. Berger\*. University of California, San Francisco and SFVAMC, San Francisco CA 94121.

Although the cross-sensitization which develops with repeated exposure to stress or amphetamine is well established, the mechanisms which underlie these processes remain incompletely understood. The present study examined the abilities of MK-801 and haloperidol pretreatment to block the development of amphetamine sensitization induced by repeated immobilization stress in male Sprague-Dawley rats. Fifteen minutes before each of ten 30 minute restraint sessions, rats were administered saline, MK-801 (0.01, 0.10 or 0.25 mg/kg i.p.) or haloperidol (0.10 or 0.25 mg/kg i.p.). Control rats received the same injection regimen without restraint. Four days after the final treatment, rats were tested for locomotor response to novelty, saline and d-amphetamine (1.5 mg/kg i.p.). Exposure to stress significantly enhanced the locomotor response to amphetamine (p<0.003) but not to saline (p=0.46) in each of the drug groups, with no stress X drug interactions present. Secondary analysis of dose effects in each drug group revealed that at 0.25 mg/kg, repeated MK-801 induced amphetamine sensitization in control rats and potentiated stress-induced sensitization in restrained rats (p<0.05). In contrast, while pretreatment with 0.10 mg/kg haloperidol enhanced the locomotor response to novelty (p<0.05), neither dose of haloperidol affected the locomotor response to saline or amphetamine in control or stressed rats. In the context of previous reports of blockade of amphetamine-induced sensitization by both MK-801 and haloperidol at doses used in the present studies, these results suggest that amphetamine- and stress-induced behavioral sensitization may proceed through divergent mechanisms. (Supported by USPHS grant DA07376-04)

## 573.6

ACUTE EFFECTS OF METHYLPHENIDATE ON OPERANT BEHAVIOR IN THE RHESUS MONKEY. P. Morris, M.P. Gillam, C. McCarty, D.L. Frederick\* and M.G. Paule. Division Of Neurotoxicology, NCTR, FDA, Jefferson, AR 72079-9502.

In the present study, the stimulant methylphenidate (MPH) was administered to male adult rhesus monkeys (N=7) previously trained on the five food-reinforced tasks of the NCTR non-human primate Operant Test Battery (OTB). Each task is designed to model a different aspect of brain function, including motivation (M), time estimation (TE), learning (L), color & position discrimination (CPD) and short-term memory (STM). When tested 15 minutes after acute MPH challenges (0.03 to 1.75 mg/kg, i.v.), operant performance was differentially affected, as indicated by the minimum dose required for a significant disruption of behavior in each of the tasks (0.3 mg/kg: M, TE, STM; 1.0 mg/kg: L, CPD). Decreased numbers of reinforcements were earned in all affected tasks. In some tasks (M, L) both response accuracy and response rate were decreased, but in other tasks neither were affected (CPD, STM); for the TE task response accuracy was affected, but not response rate. It was concluded that the distinctive profile of behavioral effects observed for MPH, when considered together with those for previously tested stimulants such as amphetamine and cocaine, continues to underscore the varied sensitivities of each OTB task to pharmacological manipulation.

## 573.7

**EFFECTS OF AMPHETAMINE ANALOGUES ON THE PERFORMANCE OF A DISCRIMINATION IN RATS.** Z. Zhang, J.M. Moerschbaecher and P.J. Winsauer\*. Department of Pharmacology, LSU Medical Center, New Orleans, LA 70112.

A fixed-ratio discrimination procedure was used as a baseline to characterize the effects of four amphetamine analogues on complex behavior. In the presence of a light above the center lever, rats were required to complete one of two fixed-ratios (FR 8 or FR 16). Completion of the ratio turned off the center light and produced a light above each of two side levers. If an FR 16 was completed, a response on the left lever produced a food pellet. If an FR 8 was completed, a response on the right lever produced food. Errors produced a brief timeout. Methamphetamine, fenfluramine, 3,4-methylenedioxy-amphetamine (MDA), and 3,4-methylenedioxymethamphetamine (MDMA) decreased response rate in a dose-related manner. Methamphetamine (1-3.2 mg/kg) disrupted the accuracy of responding. In contrast, fenfluramine, MDMA, and MDA had no effect on accuracy. Fenfluramine (0.56 mg/kg) administered in combination with methamphetamine shifted the methamphetamine dose-response curve for percent errors to the left. Fenfluramine did not alter the dose-response curve for MDMA or MDA. The data suggest that various amphetamine analogues may interact differently with serotonergic systems in terms of their effects on the performance of a discrimination. ## 573.9

**PSYCHOSTIMULANT-INDUCED CONDITIONED ACTIVITY DOES NOT APPEAR TO OBEY TO THE RULES GOVERNING THE FORMATION OF A PAVLOVIAN CONDITIONED BEHAVIOR.** S.H. Ahmed, L. Stinus and M. Cador\*. Lab. Neuropsychobiologie des désadaptations, Université Bordeaux II, INSERM U.259, Domaine de Carrière, Rue Camille Saint-Saëns, 33077 Bordeaux Cedex, France.

Recently, we have developed a within-subject design in order to study the hypothetical associative basis of psychostimulant-induced conditioned activity. In this design, conditioned activity was evidenced when the activity of a same group of rats following a vehicle challenge was greater in an amphetamine-paired environment (CS+) than in a vehicle-paired environment (CS-). Here, we report that: a) conditioned activity developed readily even when rats were exposed to the CS+ following a delay as long as 50 min between the injection of amphetamine (1.25 mg/kg) and the onset of exposure to the CS+ (temporal contiguity); b) the development of conditioned activity was not diminished by increasing the probability of occurrence of the amphetamine effects in the absence of the CS+ relatively to the probability of their occurrence in the presence of the CS+ (contingency); c) the development of conditioned activity seemed to be unaffected by repeated preexposures (0, 5 or 10 preexposures) to the amphetamine effects in the experimental context before the start of the drug-pairing phase (US preexposure). Taken together, these findings did not fit well with what would be expected if conditioned activity was a true Pavlovian conditioned behavior. At least, these results suggest that the amphetamine event seems not to be processed by rats in a manner similar to conventional US events. Thus, future works should emphasize the differences rather than the similarities with Pavlovian US events in order to describe how drug effects are processed and represented by rats. These studies have important implications to our understanding of how stimuli paired with drug effects may influence the relapse of drug taking behaviors.

## 573.11

**EFFECT OF CHRONIC PSYCHOSTIMULANT AND OPIATE TREATMENT ON SUBSEQUENT LONG-TERM APPETITIVE BEHAVIORS FOR DRUG, SEXUAL AND FOOD REWARD: INTERACTION WITH ENVIRONMENTAL VARIABLES.** C. Nocjar\*, J. Panksepp, & R.L. Conner. Dept. of Psychology, Bowling Green State University, Bowling Green, OH 43403.

It has been hypothesized that sensitization phenomena may play a role in long-term appetitive behaviors to seek drugs (Robinson & Berridge, 1993). This study therefore assessed whether chronic amphetamine, cocaine or morphine pretreatment would affect amphetamine reward-seeking behaviors following long-term drug abstinence, and, whether these effects would generalize to more natural rewards as well. Since environmental variables do appear to affect the development of sensitization phenomena (Einat & Szechtman, 1993), the drug-paired environment was manipulated as well. Rats received 10 days treatment with amphetamine (1 or 5 mg/kg), cocaine (5 mg/kg), morphine (2 or 10 mg/kg), or saline in a runway (run for injection), shuttle-box, or homecage environment. Following 1 or 14 days drug abstinence, appetitive testing for food reward, sexual reward and low-dose amphetamine place-conditioning was conducted. Rats that received chronic psychostimulant pretreatment in a runway apparatus showed long-term enhanced appetitive behaviors for food and drug reward. Sexual pursuit was also enhanced in these animals when testing began 24 hours following drug cessation. However, if the chronic psychostimulant pretreatment was non-contingently administered in a shuttle-box or home-cage environment, amphetamine place-conditioning was depressed. These results show that repetitive use of addictive drugs produce lasting enhancements in appetitive behaviors for drug reward and more natural rewards as well. Furthermore, expected response contingencies to attain drug reward can enhance the development of sensitized incentive to seek rewards.

## 573.8

**THE EFFECTS OF DIFFERENTIAL REARING ON THE PSYCHOSTIMULANT EFFECT OF AMPHETAMINE AND THE DOPAMINE TRANSPORTER.** J.M. Valone\*, A.P. Williamson, R.A. Bevins, W.B. Shaw, L.P. Dwoskin and M.T. Bardo. Department of Psychology, University of Kentucky, Lexington, KY 40506.

The present study assessed the locomotor and rewarding effects of amphetamine (AMPH) in rats raised in either an enriched condition (EC) or impoverished condition (IC). Since AMPH may evoke dopamine (DA) release by reversing the DA transporter, we also assessed the kinetics of [<sup>3</sup>H] DA uptake (0.1-10  $\mu$ M) in the striatum of EC and IC rats. To assess the behavioral effects of AMPH, a single-trial conditioned place preference (CPP) procedure was used. Rats were surgically implanted with an intravenous (IV) jugular catheter for drug delivery. Conditioning consisted of injecting rats with AMPH (1 mg/kg) at the beginning of a 30-min placement into one compartment of the CPP apparatus. On a separate day, animals also received a 30-min exposure to the other compartment following saline. Sham controls were exposed to both compartments without drug. On Day 3, rats received a 15-min preference test. Results showed that AMPH increased locomotor activity more on the conditioning day in EC rats than IC rats, but did not differ in AMPH-induced CPP. There were no differences between EC and IC rats in striatal [<sup>3</sup>H] DA uptake as quantified by  $K_m$  or  $V_{max}$ , nor were there any differences in cocaine (0.0001-100  $\mu$ M) inhibition of [<sup>3</sup>H] DA uptake. Thus, the enhanced sensitivity to the locomotor stimulant effect of IV AMPH observed in EC rats relative to IC rats was not accompanied by any difference in the striatal DA transporter. (Supported by USPHS Grants DA-05312 and DA-07746).

## 573.10

**EFFECT OF PRIOR SENSITIZATION OF STEREOTYPY ON THE ACQUISITION AND RETENTION OF TOLERANCE TO AMPHETAMINE HYPOPHAGIA.** K.M. Hughes\* and D.L. Wolgin. Dept. of Psychology, Florida Atlantic Univ., Boca Raton, FL 33431.

We previously found that prior sensitization of stereotypy did not retard the subsequent development of tolerance to the hypophagic effect of amphetamine (Wolgin and Kinney 1992). Since this result was unexpected, a systematic replication of that study was undertaken. Rats were given intermittent injections of either amphetamine (2.5 mg/kg, ip) to induce sensitization of stereotypy, or saline as a control. Following sensitization, subgroups from each group received daily injections of either amphetamine (2 mg/kg) or saline 20 min before a 30 min milk test. Dose-response (DR) curves conducted before and after the chronic phase showed that both sensitized and nonsensitized groups were tolerant to drug-induced hypophagia. Tolerance was accompanied by a suppression of stereotyped movements. The rats were then given milk tests for 3 wk without injections. A final DR curve revealed the loss of tolerance. These results confirm that prior sensitization of stereotypy does not retard the subsequent development of tolerance and show that tolerance can be extinguished by giving repeated milk tests without injections.

## 573.12

**MORPHINE POTENTIATES AMPHETAMINE- AND COCAINE-INDUCED ROTATIONAL BEHAVIOR IN THE RAT.** H.L. Kimmel\* and S.G. Holtzman. Dept. of Pharmacology, Emory Univ. School of Medicine, Atlanta, GA 30322.

Rats with unilateral 6-hydroxydopamine-induced lesions of the nigrostriatal tract respond to dopaminergic drugs by circling. Amphetamine (AMPH) and cocaine (COC), which act presynaptically to elevate synaptic levels of dopamine, induce turning ipsilaterally to the lesion. Morphine (MOR) also elevates synaptic dopamine levels, but induces little turning. The present study determined if MOR would enhance turning induced by AMPH and COC as an approach to assessing possible opioid modulation of brain dopamine systems. Adult male Sprague-Dawley rats given unilateral lesions with 6-hydroxydopamine were injected with MOR (0.03-10 mg/kg, SC) and either AMPH (0.1-1.0 mg/kg, SC) or COC (1.0-10 mg/kg, IP). Beginning immediately after the injections, full and partial ipsilateral turns and direction changes were recorded every 15 min for 4 hr. By itself, MOR had little effect, but it dose-dependently increased the magnitude and duration of full and partial ipsilateral turning induced by COC and AMPH, with a peak effect at 3.0 mg/kg. The opioid antagonist, naltrexone (0.1 mg/kg, SC), which had no effect on rotational behavior alone or in combination with AMPH, blocked potentiation of the effects of 1.0 mg/kg AMPH by 3.0 mg/kg MOR; thus the potentiating effect of MOR involves opioid receptors. These data provide further evidence for opioid modulation of the behavioral effects of stimulant drugs mediated by dopamine in the nigrostriatal tract. [Supported, in part, by Grant DA00541 and by K05 DA00008, both from NIDA.]

## 573.13

EFFECTS OF DYNORPHIN A-(1-13) ON METHAMPHETAMINE-INDUCED BEHAVIORAL SENSITIZATION IN MICE. M. Ukai\*, T. Toyoshi and T. Kameyama. Department of Chemical Pharmacology, Faculty of Pharmaceutical Sciences, Meijo University, Nagoya 468, Japan.

Dynorphin A-(1-13), a  $\kappa$ -opioid receptor agonist, has been reported to modulate the behavioral effects of dopamine receptor agonists. The response to the indirect dopamine receptor agonist methamphetamine (MAP) is sensitized with repeated administrations. The purpose of the present study was to determine the effects of intracerebroventricular administration of dynorphin A-(1-13) on the MAP (2 mg/kg)-induced behavioral sensitization in mice by using multidimensional behavioral analyzer which can simultaneously record four different kinds of behavioral responses such as linear locomotion, circling, rearing and grooming. Male ddY mice received MAP (2 mg/kg) or its vehicle combined with dynorphin A-(1-13) (3 and 12.5  $\mu$ g) 6 times at 3- to 4-day intervals. Behavior was also repeatedly measured after drug administrations. The repeated administrations of MAP (2 mg/kg) markedly sensitized behavioral responses such as linear locomotion and circling but not grooming. The MAP (2 mg/kg)-induced behavioral sensitization remained evident even after withdrawal for 3 weeks. Dynorphin A-(1-13) (3 and 12.5  $\mu$ g) significantly inhibited the behavioral sensitization induced by MAP (2 mg/kg). These results suggest that the MAP-induced behavioral sensitization is evident in linear locomotion and circling, and  $\kappa$ -opioid receptor agonists inhibit the sensitization.

## 573.15

MDL 100,907 EFFECTS ON AMPHETAMINE-INDUCED FACILITATION OF SELF-STIMULATION THRESHOLD AND LOCOMOTOR ACTIVITY IN RATS. V.L. Tsibulsky\*, S.R. Grocki, S.L. Fledderjohann, D. Wallace, and R.A. Frank. Brain Stimulation Lab, University of Cincinnati, Cincinnati, OH 45221-0376.

There is a common opinion that repeated injections of amphetamine in rats result in sensitization to motor stimulant effects but not to facilitation effects on self-stimulation behavior. In addition, the role for 5-HT<sub>2</sub> receptors has been shown in locomotor effects of amphetamine but not in latter. This experiment was designed to test both locomotion measured by stabilimeter platforms and self-stimulation threshold in the course of subchronic 10 day injections of 1 mg/kg amphetamine alone or in combination with 2 mg/kg MDL 100,907, a specific 5-HT<sub>2</sub> antagonist, in the same rats. The self-stimulation facilitation effect of amphetamine as well as the locomotor hyperactivity reached the maximal level in the first 30 min after injection and decreased by 50-60% at the end of the 2 h test period. There was no alteration in pharmacodynamics of this effect in the course of subchronic 10 day injections. MDL 100,907 attenuated the effect of amphetamine only on locomotion and only on the first day of injection, but not on the following days. In conclusion, there was no tolerance, sensitization or aftereffects of amphetamine alone or in combination with MDL 100,907 on self-stimulation threshold or locomotion.

This project was supported by NIDA grant DA04483, R.A. Frank, PI.

## 573.17

INDIVIDUAL DIFFERENCES IN PSYCHOSTIMULANT-INDUCED FACILITATION OF BRAIN STIMULATION REWARD. S.R. Grocki\*, V.L. Tsibulsky, R.A. Frank. University of Cincinnati, OH 45221-0376.

Substantial individual differences in susceptibility to substance abuse have been documented in the human clinical literature. These differences may reflect variation in the central neurochemistry associated with the incentive properties of drugs. We have used stimulant-induced facilitation of brain stimulation reward to evaluate individual differences in the euphoric effects of drugs in rats.

Twenty four Sprague-Dawley rats were implanted with bipolar stainless steel electrodes into the ventral tegmental area (VTA) and were trained to nose poke for stimulation. The number of pulses delivered in each train of stimulation was varied from 0 to 15 to determine self-stimulation threshold using a modified version of the method of constant stimuli. Once the rats achieved stable thresholds, they were injected with amphetamine (0.33, 0.66, 1.0 mg/kg) and cocaine (7.5, 15.0, 30.0 mg/kg). A significant correlation ( $r = .78$ ) was found between amphetamine and cocaine-induced facilitation of brain reward stimulation. It is hypothesized that the individual differences noted in this study reflect differences in the psychostimulants' effects on brain reward systems.

## 573.14

IBOGAINE EFFECTS ON SWEET PREFERENCE AND AMPHETAMINE-INDUCED LOCOMOTION: IMPLICATIONS FOR ADDICTION. J.R. Blackburn\* and K.K. Szumlanski. Dept. of Psychology, McMaster University, Hamilton, Ont, L9S 4K1.

Ibogaine is reputedly efficacious in the treatment of addiction to stimulants, opiates, nicotine, and alcohol. The neural basis of such effects is unclear. One possibility is that ibogaine interferes with the shared capacity of these addictive agents to increase dopamine activity, but reports of ibogaine effects on dopamine activity have been inconsistent. Our study suggests those inconsistencies may result from variations in prior drug exposure.

If ibogaine blocks dopamine activity, then it should, like dopamine blockers, decrease preference for natural rewards such as sweet solutions. However, 20 or 40 mg/kg ibogaine did not decrease preference for a glucose-saccharin solution when it was administered to male Long Evans rats 24 hr prior to test. Nor did these doses of ibogaine attenuate conditioned preference for a neutral flavour previously paired with sweet taste.

Effects of 40 mg/kg ibogaine on amphetamine-induced locomotion were investigated in drug naive and drug experienced (4 prior doses of 1.5 mg/kg amphetamine) rats. Locomotion was significantly lower in those ibogaine-treated rats that had previously been exposed to amphetamine than in those that had not. Thus, ibogaine may serve to decrease induced levels of dopamine activity in drug-experienced animals or humans from elevated, sensitized levels back to baseline levels. This could lead to reduced sensitized drug craving in addiction.

## 573.16

EFFECTS OF THE 5-HT<sub>2A</sub> ANTAGONIST, MDL 28,133A, ON APOMORPHINE-INDUCED STEREOTYPED BEHAVIOR IN RATS. D.J. Feldman\*, R.A. Frank\*, R. Flannery\*, G. Byrd\*, G. Metcalf\*, and J.H. Kehne. Department of Psychology, University of Cincinnati, Cincinnati, Ohio, 45220-0376, and Marion Merrell Dow Research Institute, 2110 E. Galbraith Road, Cincinnati, Ohio 45215.

Hyperactive dopamine (DA) systems may contribute to conditions such as schizophrenia and stimulant drug abuse. 5HT<sub>2A</sub> receptors modulate some, but not all, of these effects. DA overactivation induced by amphetamine lowers the threshold for brain stimulation reward (BSR). This effect is reduced by a D<sub>2</sub> (haloperidol), a D<sub>2</sub>/5HT<sub>2A</sub> (MDL 28,133A), but not a selective 5HT<sub>2A</sub> (MDL 100,907) receptor antagonist. The present study evaluated the role of D<sub>2</sub> receptors in the actions of MDL 28,133A by measuring its ability to antagonize stereotyped behaviors produced by direct postsynaptic D<sub>2</sub> receptor stimulation with 0.4 mg/kg apomorphine. Effects on stereotypies produced by indirect stimulation of postsynaptic D<sub>2</sub> receptors with 4.0 mg/kg d-amphetamine were also assessed. The main finding of this study was that haloperidol and MDL 28,133A, but not MDL 100,907, reduced apomorphine-induced stereotypies, and these effects occurred in the dose ranges that were active in the BSR paradigm. These data support the conclusion that a D<sub>2</sub> antagonist action accounts for the ability of MDL 28,133A to reduce d-amphetamine lowering of BSR threshold. Furthermore, given that apomorphine-induced stereotypies are mediated by stimulation of striatal D<sub>2</sub> receptors, these data provide additional support for the conclusion that MDL 100,907, a putative antipsychotic, is devoid of extrapyramidal side effect liability. This research was supported by grants from Marion Merrell Dow and NIDA (DA04483) to R.A. Frank.

## 573.18

NOVELTY-INDUCED LOCOMOTION AND GABA<sub>A</sub> RECEPTOR BINDING. R.J. Gruen\*, M. Selim, K. Wenberg, A.J. Friedhoff, and G.W. Bradberry. New York Univ., NY, NY 10016, Yale Univ., New Haven, CT 06510.

The results of recent studies suggest that novelty-induced locomotion (NL) may represent a reliable correlate of vulnerability to drug self-administration. Given that ligands which bind to the GABA<sub>A</sub> receptor complex regulate the activity of dopamine (DA) (Gruen et al., 1992), and the DA system has been shown to play an important role in locomotor behavior, we examined the relationship between NL and GABA<sub>A</sub> receptor binding in the adult rat using the GABA<sub>A</sub> antagonist [<sup>3</sup>H]SR 95531. NL and amphetamine-induced (1.5 mg/kg; i.p.) locomotion was assessed by placing animals in a circular corridor equipped with photocell beams. [<sup>3</sup>H]SR 95531 binding was conducted according to the method of McCabe et al. (1988). NL was significantly correlated with amphetamine-induced locomotion ( $r = .95$ ;  $p \leq .01$ ). In addition, we found that there were significant correlations between NL and [<sup>3</sup>H]SR 95531 binding in the cingulate cortex ( $r = .91$ ;  $p \leq .01$ ), prefrontal cortex ( $r = .85$ ;  $p \leq .01$ ), and ventral pallidum ( $r = .85$ ;  $p \leq .01$ ). These findings suggest that individual differences in GABA<sub>A</sub> receptor binding may play an important role in NL and drug self-administration. Supported by DA-08073 (CWB) and MH-08618 (AJF).

## 573.19

**Effects of Concurrent Administration of Ethanol and Methamphetamine on D1 and D2 Binding Sites and Locomotor Activity.** Allean O. Fouse and M.A. Blackshear\* Department of Biological Sciences, Tennessee State University, Nashville, TN 37209-1561.

The acute and chronic effects of concurrent administration of ethanol and methamphetamine (MAP) on brain dopamine D1 and D2 binding sites and locomotor activity were studied. Male Sprague-Dawley mice (26-30 gm) were divided into four treatment groups: Group I - saline and water, Group II - MAP and water; Group III - saline and ethanol; Group IV - MAP and ethanol. Ethanol treated mice received 10% ethanol in the drinking water, while mice receiving only MAP or ethanol had free access to water. In acute studies, the mice received a single dose of 0.5 mg/kg of MAP or physiological saline. Locomotor activity was monitored in 15 minute intervals for 75 minutes. For chronic studies, 0.5 mg/kg of MAP was injected daily for 7 days. Locomotor activity was measured on day 9 and again on day 20 after the last injection, after a challenge dose of 0.125 mg/kg of MAP was given. While locomotor activity was higher in MAP treated mice, it was highest in mice receiving both MAP and ethanol in both acute and chronic studies. Maximal stimulation occurred at 45 minutes post MAP treatment. Despite the marked changes that were observed in locomotor activity in animals treated with both MAP and ethanol, no significant changes were observed in D1 binding sites in the striatum. However, a small but significant increase in D2 binding sites was observed in the limbic area. In view of recent studies which demonstrate that MAP and ethanol interactions in humans can cause psychoses and sudden death in humans, these results will provide additional information their combined behavioral and biochemical effects.

## 573.20

**Neural network aided behavioral analysis of amphetamine and apomorphine sensitization.**

Peter Laudrup\* & Lane J. Wallace, College of Pharmacy, Ohio State University, 500 W 12th Ave, Columbus OH-43210. E-mail: laudrup@osu.edu.

The purpose of this study was to evaluate a method which can predict the drug and its dose based on a description of drug-elicited behaviors integrating locomotor activity and stereotypic movements. Naive rats were treated with various doses of either amphetamine, cocaine, or apomorphine. Every fifteen minutes during two hours each animal was monitored for ten seconds for the appearances of well defined behavioral patterns (locomoting, rearing, sniffing in the air, sniffing at the cage floor, or grooming). These data were presented to a neural network designed to match the behavior with the dose and drug that induced it. The network is a three-layer backpropagation network trained with random input noise and momentum.

The network trained successfully to discriminate amphetamine and apomorphine behaviors, but failed to discriminate between amphetamine and cocaine. Interestingly, the network revealed that apomorphine sensitized rats challenged with a low dose of amphetamine elicit a behavior similar to a high dose of apomorphine - a sensitized response. In contrast, rats sensitized with amphetamine and challenged with a low apomorphine dose elicit low apomorphine-like behavior - no cross-sensitization.

These results indicate that sensitization induced by the postsynaptic agonist apomorphine implements changes that are manifested when amphetamine induces dopamine release from the presynaptic site. In contrast, the changes responsible for amphetamine sensitization have to be located somewhere upstream from the apomorphine action site. (Supported by DA07722 and DA06776)

## DRUGS OF ABUSE: AMPHETAMINES AND OTHER STIMULANTS IV

## 574.1

**DIFFERENTIAL DISPLAY PCR DETECTS NOVEL CLONES RELATING TO METHAMPHETAMINE-INDUCED REVERSE TOLERANCE.** I. Umekage\*, S. Sugita and Y. Watanabe. Department of Pharmacology, National Defense Medical College, Tokorozawa 359, Japan

Dramatic behavioral changes occur after exposure to psychomotor stimulator such as methamphetamine (MAP). It is known that repeated administration of MAP induces reverse tolerance to ambulatory activity in rodents. The molecular mechanism in the drug-specific responses is still unknown. In order to understand the molecular nature of reverse tolerance, we have used the Differential Display PCR (D.D.PCR) technique to identify genes that are differentially expressed after single or repeated administration of MAP. Reverse tolerance was induced in seven-week-old ddy mice by repeated administration of MAP (2mg/kg, s.c.) at three or four-day intervals. Four weeks later, total RNA was extracted from the whole brain five or twenty or sixty minutes after another administration of MAP. Using D.D.PCR technique, we obtained twelve clones that have unique expression patterns. These patterns were different from those of the clones from single administration of MAP. Among the sequences of these cDNA, no significant identifications with EMBL sequence were observed. Present results suggest gene expression may be associated with the induction and maintenance of reverse tolerance.

## 574.2

**p53 TUMOR SUPPRESSOR GENE IS A MEDIATOR OF METHAMPHETAMINE-INDUCED NEUROTOXICITY IN MICE.** J.L. Cadet\*, and H. Hirata. Neuroscience Branch, Molecular Neuropsychiatry Section, NIH, NIDA, IRP, Baltimore, MD 21224

p53-knockout transgenic mice provide a useful toxicity model because p53 has been shown to be involved in the development of apoptosis in a number of cell lines. In order to assess if p53 is involved in the neurotoxicity caused by methamphetamine (METH) on the dopaminergic systems, we have evaluated the effects of this drug in male wild-type as well as heterozygous and homozygous p53-knockout mice. The status of dopaminergic terminals was determined after the administration of 3 different doses of METH (2.5, 5.0, and 10 mg/kg were given 2 hours apart for a total of 4 injections in one day). In wild-type mice, METH caused dose-dependent decreases in DA uptake sites in both the striatum and nucleus accumbens. The percentage of decrease was greater in the striatum. In p53-knockout mice, the depletion caused by METH was attenuated in a strain-dependent fashion, with the homozygous mice showing the greatest protection. These results provide evidence for a role of p53 in the neurotoxic effects of METH on the dopaminergic system. They also suggest a role for p53 in the development of neurodegenerative disorders such as Parkinson's disease.

## 574.3

**ISOLATION OF A NOVEL GENE FROM THE FOREBRAIN OF A RAT TRAINED TO SELF-ADMINISTER AMPHETAMINE INTO THE NUCLEUS ACCUMBENS VIA A MICRODIALYSIS PROBE.** S.A. Brooks\*, R.R. Rule\*, Q.R. Javid\*, P.H. Janak\* and J.L. Martinez, Jr. Dept. of Int. Bio., \*Dept. of Psych., Univ. of California, Berkeley, 94720; \*Dept. of Public Health, Johns Hopkins Univ., Baltimore, MD, 21205; \*Dept. of Phys. and Pharm., Wake Forest Univ., Winston-Salem, N.C. 27157; \*Div. Life. Sci., Univ. Texas, San Antonio, 78249.

We have isolated a 2.8 kb clone from a subtracted library generated from the forebrain of rats trained to self-administer amphetamine via microdialysis probe (SNA 1994 vol. 20, part 2, p. 1030) and sequenced 1.5 kb of this clone. Searches of the NCBI database with this sequence revealed no consensus matches in the database. The 1.5 kb of sequence contains 3 putative open reading frames and searches of the NCBI Database with the putative proteins from these open reading frames revealed one that demonstrated a 59% homology to rat succinyl-CoA ligase. The other two open reading frames did not demonstrate significant homology to protein sequences in the database. Since the entire clone has not been sequenced, it is possible that we do not yet have the actual coding open reading frame. Screening of a Rat Multi-Tissue Northern blot (Clontech) revealed a 4.4 kb band and a 2 kb band present in all the tissues on the blot. The 4.4 kb band had the strongest binding in heart and the 2 kb band had the strongest binding in lung; brain showed moderate binding of both bands. Additionally, liver showed binding of a small, less than 1 kb, band that was not present in any of the other lanes. Screening of a Genomic DNA Zoo-Blot (Clontech) revealed binding in all lanes. Further analysis will include sequencing the remainder of the clone and screening a rat brain library for full length clones, Northern blot and RPA analysis, and *in situ* hybridization using the brains of both amphetamine self-administration animals and controls. Supported by NSF 94-11564.

## 574.4

**CHANGES IN TRANSCRIPTIONAL FACTOR AP-1 BINDING ACTIVITIES IN THE RAT BRAIN AFTER SUBCHRONIC METHAMPHETAMINE ADMINISTRATION.**

T. Ishihara, K. Akiyama\*, K. Kashihara\*, H. Ujike, T. Hamamura and S. Kuroda. Dept. of Neuropsychiatry and Neurology\*, Okayama University Medical School, 2-5-1 Shikata-cho, Okayama 700, JAPAN.

The present study examined the effect of acute and subchronic administration of methamphetamine (MAP) on transcriptional factor AP-1 binding protein in the rat brain using gel mobility shift assay. A single MAP administration (4 mg/kg) induced robust increase in AP-1 binding in the striatum, nucleus accumbens and cingulate cortex with the maximal level being observed at 3 hours. AP-1 binding increased significantly in the three brain regions at one-week abstinence following cessation of subchronic MAP administration (4 mg/kg for 14 days), whereas it decreased significantly in the cingulate cortex, but did not change in the striatum or nucleus accumbens at four-week abstinence. After an abstinence of 4 weeks, a MAP challenge (4 mg/kg) induced increase in AP-1 binding which was attenuated as compared to that occurred after an acute administration to naive rats. A supershift assay using antibodies raised against Fos/Jun revealed that the increase in AP-1 binding protein that occurred after the acute MAP and at one-week abstinence following cessation of the subchronic MAP administration corresponded to induction of Fos/Jun and lasting elevation of Jun, respectively. A MAP challenge after an abstinence of 4 weeks induced Fos in the three brain regions, and Jun in the nucleus accumbens and cingulate cortex. It is concluded that AP-1 binding undergoes quantitative and qualitative changes after subchronic MAP administration.

## 574.5

## CHANGES IN G PROTEIN MESSENGER RNAs AFTER THE BEHAVIORAL SENSITIZATION TO METHAMPHETAMINE.

H. Ujike\*, K. Akiyama, S. Kuroda, Dept. of Neuropsychiatry, Okayama Univ. Med. Sch., Okayama 700, Japan

A possible role of G proteins in the behavioral sensitization to methamphetamine was investigated using *in situ* hybridization to mRNAs of  $\alpha$  subunits encoding  $G_s$ ,  $G_{i2}$ , and  $G_o$  proteins. Rats received 4 mg/kg of methamphetamine for 14 consecutive days. Four hours after the last injection,  $G_{o\alpha}$  mRNA showed an increase of 16.6-31.6% in CA1, CA3 and dentate gyrus regions of the sensitized hippocampus.  $G_{i\alpha}$  mRNA also increased by 24.2% in CA1, while  $G_{s\alpha}$  mRNA was unaffected. These changes of  $G_{o\alpha}$  and  $G_{i\alpha}$  mRNA recovered to normal levels after 48-hour abstinence. No other brain regions, such as substantia nigra, ventral tegmentum area, striatum, accumbens and cortices, were affected in the expression of any G protein mRNA. The present study suggests that the increase in the expression of  $G_o$  and  $G_i$ , not  $G_s$  mRNA of hippocampus after sensitization to methamphetamine may alter neurotransmission between some receptors and their second messengers and result in adaptation of neural function related to behavioral sensitization.

## 574.7

PRE-EXPOSURE TO STRESS ENHANCES AMPHETAMINE-INDUCED SENSITIZATION: EXPRESSION OF THE IMMEDIATELY EARLY GENE *c-fos*. T. Hamamura\*, Y. Ichimaru and H.C. Fibiger, Division of Neurological Sciences, Department of Psychiatry, University of British Columbia, Vancouver, B.C., Canada V6T 1Z3

Amphetamine (AMPH) abuse results in psychosis that resembles paranoid schizophrenia. Moreover, stressful experience is supposed to increase vulnerability for AMPH-induced psychosis. To investigate the neuroanatomical basis of this phenomenon, this study examined the effects of pre-exposure to stress on AMPH sensitization by brain mapping using Fos immunohistochemistry. Rats received footshock or sham-shock for 3 days. Three days after the last session, rats received repeated injections of AMPH (4 mg/kg i.p., 8 times in total) or saline. After a 14 day drug abstinent period, rats were challenged with 2 mg/kg AMPH. By itself, the AMPH sensitization procedure enhanced subsequent AMPH-induced Fos expression in only one structure, the medial part of lateral habenula (LHbm). In contrast, when animals were pre-exposed to footshock stress, the AMPH sensitization procedure resulted in significantly enhanced AMPH-induced Fos expression in four additional structures, those being agranular insular cortex, piriform cortex, nucleus accumbens and medial caudate putamen. These results indicate that there are significant interactions between pre-exposure to footshock stress and AMPH sensitization in terms of the subsequent ability of AMPH to enhance regional Fos expression.

## 574.9

## DISTAL FOS INDUCTION BY PCP INJECTIONS INTO A NUCLEUS ACCUMBENS REWARD SITE. C. Marcangione, W. A. Carlezon, Jr., R. A. Wise\*, and J. G. Pfaus, Center For Studies in Behavioral Neurobiology and Department of Psychology, Concordia Univ., Montréal, Que, CANADA H3G 1M8.

Rats learn to lever-press for phencyclidine (PCP) injections into ventro-medial (shell) but not the dorso-lateral (core) region of nucleus accumbens (NAS)<sup>1</sup>. PCP has several actions of possible relevance; it is a dopamine uptake inhibitor, and NMDA channel blocker that also binds to  $\sigma$  receptors. To identify efferent projections from PCP reward sites in NAS, we determined Fos expression after a series of rewarding PCP injections. The rats received 26 unilateral infusions of PCP (12 nmol per 120 nl infusion) or vehicle into the ventro-medial (shell) region of NAS; each animal's injections were "yoked" to the rate and pattern of administration of a rat previously trained to lever-press for similar injections. The rats were sacrificed for histological analysis of Fos immunoreactivity 90 min after the first infusion of PCP. Serial coronal sections were taken from the area of the medial prefrontal cortex (mPFC) through the pedunculo-pontine tegmental nucleus of the midbrain. PCP induced Fos expression at several sites distal to the NAS injection sites; dramatic expression was seen in the rostral pole of the ventral tegmental area and in the ventral premammillary nucleus. The injections also appeared to induce Fos in the mPFC, dorsal striatum, lateral preoptic area, lateral septum, central nucleus of the amygdala, and ventral premammillary nuclei. Our observations will be quantified and will be the basis for hypotheses as to the efferent pathways involved in PCP reward.

EFFECTS OF SELECTIVE ADENOSINE A1 AND A2a AGONISTS ON AMPHETAMINE-INDUCED LOCOMOTION AND *c-fos* INDUCTION IN STRIATUM AND NUCLEUS ACCUMBENS. S.M. Turgeon\*, A.E. Pollack, L. Sushiem and J.S. Fink, Molecular Neurobiology Laboratory, Massachusetts General Hospital, and Dept. of Neurology, Harvard Medical School, Boston, MA 02114

Adenosine receptors and dopamine receptors have been shown to interact at both behavioral and cellular levels. Adenosine A1 and A2a and dopamine D2 receptors are present in the striatum. While the cellular localization of A1 receptors in striatum is unknown, A2a and D2 receptors have been shown to be colocalized to striatopallidal neurons. Low doses of amphetamine produce locomotion which is dependent on release of dopamine in the anteromedial striatum and nucleus accumbens. The effects of selective A1 and A2a adenosine receptor agonists on locomotion and *c-fos* induction following a low dose of amphetamine were assessed in rats. Pretreatment with the A1 adenosine receptor agonist CHA or the A2a adenosine receptor agonist APEC inhibited locomotion following an injection of amphetamine (1.5 mg/kg). This dose of amphetamine induced *c-fos*-like immunoreactivity in an antero-dorsomedial distribution in the caudate-putamen and uniformly in the core and shell of the nucleus accumbens. Pretreatment with the A2a agonist APEC, but not the A1 agonist CHA, attenuated *c-fos* induction in caudate-putamen and nucleus accumbens by amphetamine. These findings indicate that amphetamine-induced behavior is subject to modulation by adenosine receptors through mechanisms which are both related to and independent of *c-fos* induction.

## 574.8

## METHYLENEDIOXYMETHAMPHETAMINE (MDMA, ECSTASY) CAUSES INCREASES IN C-FOS EXPRESSION IN CU/ZN SUPEROXIDE DISMUTASE TRANSGENIC MICE. B.N. Ladenheim, E.E. Ladenheim\*, C.J. Epstein and J.L. Cadet, Molecular Neuropsychiatry Section, NIH/NIDA, IRP, Baltimore, Maryland 21224.

MDMA is a psychoactive drug of abuse commonly known as Ecstasy. MDMA causes dopamine (DA) depletion in striatum of mice. The toxic effects of this agent seem to involve superoxide radicals since Cu/Zn superoxide dismutase (SOD) transgenic (Tg) mice that express the human gene are protected against the deleterious effects of the drug. In the present study, we tested the possibility that MDMA might cause changes in *c-Fos* immunoreactivity in mouse brain. In addition, we tested the idea that superoxide radicals might be involved by comparing the effects of MDMA in non-transgenic (Non-Tg) and SOD-Tg mice. MDMA elicited a dose-related activation of *c-Fos*-like immunoreactivity in both NON-Tg and SOD-Tg mice. MDMA-induced labeling was more intense in brain regions associated with the limbic system. These include the piriform, perirhinal and entorhinal cortices, islands of Calleja, olfactory tubercle, amygdala and hippocampal CA-1 regions. These results suggest that administration of Ecstasy is associated with stimulation of limbic structures and are consistent with the known psychotropic effects of this drug. These results also indicate that *c-fos* regulation by MDMA might not be dependent on oxidative mechanisms.

## 574.10

CHANGES IN *c-fos*, NGFI-A, AND NEUROTENSIN mRNA EXPRESSION IN RATS SENSITIZED TO AMPHETAMINE. D.L. Evans\*, L.M. Figur, M.P. Stone, K.A. Svensson and K.M. Merchant, CNS Diseases Research, The Upjohn Company, Kalamazoo, MI 49001

Neural mechanisms underlying the phenomenon of stimulant sensitization have relevance for not only abuse potential of drugs but also emotional and therapeutic drug responses in psychotic disorders. In order to identify neurochemical/neuroanatomical correlates of this sensitization phenomenon, we examined the expression of two immediate early genes, *c-fos* and NGFI-A, and a neuropeptide, neurotensin, in rat forebrain regions. Rats were treated with 2 mg/kg s.c. of amphetamine or vehicle once daily for 5 days (priming treatment), withdrawn from the drug for 7 days, and then acutely challenged with amphetamine or vehicle. Immediately after the acute treatment, locomotor behavior was monitored for 1 h, after which rats were sacrificed and brains used for *in situ* hybridization of *c-fos*, NGFI-A and neurotensin (NT/N) mRNA. As expected, acute amphetamine challenges to amphetamine-primed rats produced a greater locomotor activation than that seen in the saline-primed animals. In contrast, the responses of NGFI-A, *c-fos* and NT/N mRNA to an acute amphetamine challenge were attenuated in rats sensitized to amphetamine in a regionally-specific manner. Greatest attenuation was observed in the expression of NGFI-A mRNA in the medial prefrontal cortex and the neostriatum and NT/N mRNA in the nucleus accumbens. Interestingly, in the neostriatum, NGFI-A mRNA was reduced more in the extrastriosomal matrix as compared to the striosomes. The role of the specific dopamine receptor subtype in the amphetamine sensitization phenomenon is being investigated.

OVERNIGHT WITHDRAWAL FROM NICOTINE REDUCES LYMPHOCYTE C-FOS EXPRESSION IN HUMAN SMOKERS *IN VIVO*.

Andrew B. Norman\*, Michael Tabet, John Ganim. Division of Neuroscience, Department of Psychiatry, University of Cincinnati College of Medicine, Cincinnati, Ohio 45267

Changes in the expression of immediate-early response genes, such as c-fos, in response to stimulants may mediate the long-term neurochemical adaptations leading to dependence. We have previously found that the administration of Nicorette® gum to nicotine-naïve human subjects produced a rapid transient increase in lymphocyte fos protein levels *in vivo*. We investigated whether changes in c-fos expression occurred in cells from nicotine dependent individuals as a result of smoking and during withdrawal. Subjects fasted and refrained from smoking on the morning prior to and during the study. An 8 ml blood sample was obtained at 8 a.m. and additional samples were obtained 30, 90, 150 and 270 minutes later. Lymphocytes were rapidly separated, washed, homogenized and frozen. The fos protein levels were determined by quantitative immunoblotting using [<sup>3</sup>H]fos protein as a standard. After 4 to 8 weeks, smokers returned and repeated the study with the exception that they smoked ad libitum. There was a marked decrease in lymphocyte fos protein levels in all smokers undergoing overnight withdrawal relative to the same individuals not undergoing withdrawal and relative to nicotine-naïve individuals. Lymphocyte fos levels may provide a quantitative biological measure of withdrawal severity. (Supported by the Smokeless Tobacco Research Council, Inc.)

## 574.13

## EFFECT OF ABSTINENCE SYNDROME ON DOPAMINE RELEASE IN THE MESOLIMBIC SYSTEM OF NICOTINE DEPENDENT RATS. A MICRODIALYSIS STUDY. E. Carboni\*, C. Giua and G. Di Chiara. Dept. of Toxicology, University of Cagliari, Viale Diaz 182, 09126 Cagliari, Italy.

Drugs of abuse like morphine, nicotine and alcohol share the common feature of increasing dopamine levels in the nucleus accumbens when administered acutely. A decrease of mesolimbic dopamine release follows the withdrawal of morphine in chronically treated rats. In nicotine dependent rats an abstinence syndrome can be precipitated by both the nicotinic antagonist mecamylamine and by naloxone suggesting the existence of an endogenous opioid component in nicotine dependence and abstinence syndrome. The aim of the present study was to investigate the changes of dopamine release induced by mecamylamine, naloxone or withdrawal in rats treated chronically with nicotine and correlate the results with the appearance of the abstinence syndrome. Male Sprague Dawley rats (260 g) were implanted with an Alzet osmotic minipump that delivers 9 mg/Kg/day of nicotine tartrate. Nine days after rats were implanted with a dialysis probe in the nucleus accumbens and 24 hour later dopamine was measured. Basal dopamine levels were increased in nicotine dependent rats by 44 % Mecamylamine at the dose of 1 and 2 mg/Kg s.c. decreased by about 40 % dopamine release in nicotine dependent rats while did not affect dopamine in controls. Naloxone (4.5 mg/Kg s.c. decreased dopamine release controls but not in nicotine dependent rats. Nicotine 0.2 mg/Kg s.c. increased by about 50 % dopamine release in control rats and only by 10 % in nicotine dependent rats. Our data indicate that chronic nicotine treatment induces an increase in dopamine release. Blockade of nicotine receptors by mecamylamine causes the precipitation of the abstinence syndrome and a decrease of dopamine release. Naloxone, although is able to precipitate the abstinence syndrome in nicotine dependent rats, caused a decrease in dopamine release in controls but not in nicotine dependent rats suggesting that, the fall in dopamine release might not be associated with nicotine abstinence syndrome.

## NICOTINE SELF-ADMINISTRATION IN RATS E.C. Donny, A.R. Caggiula\*, S. Knopf Dept. of Psychology, University of Pittsburgh, Pittsburgh, PA. 15260 and Pittsburgh Cancer Institute

Animal models of drug self-administration have greatly contributed to current knowledge of the factors which influence drug-maintained behavior. To date, however, research into the neuropharmacological and behavioral effects of nicotine in rodents has been based almost entirely on designs in which the experimenter administers the drug. While such designs have considerably expanded our understanding of nicotine's effects, a self-administration model would provide a valuable tool for further characterizing nicotine-maintained behavior. To date, however, other laboratories have had difficulty in obtaining reliable self-administration using iv nicotine in rats.

We have recently replicated Corrigan and Coen's (1989) model of iv nicotine self-administration. Male Sprague-Dawley rats maintained stable responding (18 infusions/1 hr session) on an FR5 to .03mg/kg/infusion. Responding was partially extinguished by substituting saline, and reacquired after nicotine was reintroduced. Responding decreased at .003mg/kg but was unchanged at .06 mg/kg and total intake increased at the higher dose. We are now investigating some of the basic effects of self-administered nicotine and comparing them to those resulting from experimenter-administered drug. Supported by DA07546

## NICOTINE INJECTIONS IN THE VENTRAL TEGMENTAL AREA INCREASE LOCOMOTION AND C-FOS EXPRESSION IN THE LIMBIC FOREBRAIN OF THE RAT. G.G. Nomikos\*, A. Malmerfelt, G. Panagis, K. Chergui, M. Nisell and T.H. Svensson. Dept. of Physiology and Pharmacology, Div. of Pharmacology, Karolinska Institutet, S-17177 Stockholm, Sweden.

Results of recent studies have suggested that nicotinic receptors in the ventral tegmental area (VTA) may be of primary importance for the locomotor-activating and reinforcing actions of nicotine. Here we examined the effects of acute injections of nicotine in the VTA on locomotor activity and on Fos immunoreactivity in the limbic forebrain and the basal ganglia. We also studied the effects of repeated nicotine injections in the VTA on locomotor activity to determine whether sensitization of locomotion would develop. Bilateral intrategmental injections of nicotine (0.02, 0.2, 2.0 and 8.0 ug/0.5ul/side) dose-dependently increased all parameters of locomotor activity-with the exception of rearing-in an open field. Nicotine (8.0 ug/0.5ul/side) injection in the VTA increased c-fos expression in the nucleus accumbens and the medial prefrontal cortex, but not in the dorsolateral striatum. Similar results on Fos immunoreactivity were observed following acute systemic injections of nicotine (0.5-2.0 mg/kg, s.c.). Pretreatment (30 min) with the nicotinic receptor antagonist mecamylamine (1.0 mg/kg, s.c.) prevented nicotine-induced hyperlocomotion and reduced the increased number of Fos-positive nuclei in the limbic forebrain. Repeated VTA injections of nicotine (2.0 ug/0.5ul/side; total of six injections at a rate of one injection every 48 hr) progressively increased locomotion across test days. These findings directly support the notion that VTA represents the critical neural substrate mediating the behavior-activating, sensitizing and consequently the dependence-producing actions of nicotine. ## 574.14

## CONDITION-INDEPENDENT SENSITIZATION OF LOCOMOTOR STIMULATION AND MESOCORTICAL DOPAMINE RELEASE FOLLOWING CHRONIC NICOTINE TREATMENT IN THE RAT. M. Nisell\*, G.G. Nomikos, P. Hertel, G. Panagis and T.H. Svensson. Dept. of Physiology &amp; Pharmacology, Div. of Pharmacology, Karolinska Institutet, S-171 77 Stockholm, Sweden.

Chronic nicotine (NIC) treatment augments NIC-induced locomotion, an effect that seems critically dependent on activation of brain dopamine (DA) systems. In this study the effects of chronic, intermittent NIC treatment on locomotor activity and brain dopaminergic activity were examined. Male rats received 12 daily injections in their home cage of saline (SAL) or NIC (0.5 mg/kg, s.c.). Twenty-four hr after the last injection, the locomotor activity was measured. Furthermore, microdialysis experiments were performed in awake animals, measuring extracellular concentrations of DA in the prefrontal cortex (PFC) and the nucleus accumbens (NAC). Also, extracellular single cell recordings from DA neurons in the ventral tegmental area (VTA) were performed in anesthetized animals. Nicotine (0.5 mg/kg, s.c.) increased locomotor activity to a greater extent in NIC-pretreated than in SAL-pretreated animals. Nicotine (0.5 mg/kg, s.c.) also increased DA release in the PFC and in the NAC. After NIC-pretreatment, the NIC-induced DA release was enhanced in the PFC, but unaffected in the NAC. Intravenously administered NIC dose-dependently increased burst activity, starting at 12 µg/kg in SAL-pretreated animals and at 6 µg/kg in NIC-pretreated animals, and also dose-dependently increased firing rate in SAL- as well as NIC-pretreated animals, starting at 25 µg/kg. These results demonstrate that behavioral sensitization after chronic NIC treatment is accompanied by an enhanced DA release specifically within the PFC. This phenomenon may be highly significant for the dependence-producing effects of NIC.

## 574.16

## SELECTIVE CENTRAL OR PERIPHERAL NICOTINIC ANTAGONISM BY CHLORISONDAMINE S. Knopf\*, A.R. Caggiula, A.F. Sved, A.M. Schreihofer and C.G. McAllister. University of Pittsburgh and Pittsburgh Cancer Institute, Pittsburgh, PA 15260.

Chlorisondamine (CHLOR) is a potent nicotinic receptor blocker which does not readily cross the blood-brain barrier due to its bisquaternary structure. However, its usefulness as a tool for distinguishing central vs peripheral sites of nicotine's action depends on establishing dose/time parameters which produce exclusively peripheral or central blockade when administered either systemically or centrally. In Sprague-Dawley rats, CHLOR (0.1 mg/kg, s.c.) given 20 min earlier significantly attenuated the increase in mean arterial blood pressure (MAP) induced by either nicotine (NIC) (40 µg i.v.) or the specific peripheral nicotinic agonist dimethylphenylpiperazinium iodide (DMPP) (10 µg i.v.), indicating effective ganglionic blockade, but had no effect on the NIC (1.33 mg/kg s.c.)-induced increases in plasma adrenocorticotrophic hormone (ACTH) and vasopressin, indicating that central receptors were unaffected.

Using the same measures, it was found that 5 µg CHLOR administered into the lateral ventricle 5 hr earlier significantly attenuated the NIC (1.33 mg/kg s.c.)-induced increase in plasma ACTH, but had no effect on DMPP-induced increase in MAP. Therefore, using these doses and times, it is possible to produce selective central or peripheral nicotinic antagonism with chlorisondamine. Supported by DA07546 and DA08505.

## 574.17

BEHAVIORAL MANIFESTATIONS OF THE NICOTINE ABSTINENCE SYNDROME IN RATS. B.E. Hildebrand, G.G. Nomikos, C. Bondiers, M. Nisell, S.E. Kraljic and T.H. Svensson, Dept. of Physiology & Pharmacology, Div. of Pharmacology, Karolinska Institutet, S-171 77 Stockholm, Sweden.

There are very few behavioral models in use for the nicotine abstinence syndrome. This study has used a somewhat modified model of the opiate abstinence syndrome. Male Wistar rats were infused for 7 days with 9 mg/kg/day nicotine tartrate via subcutaneously implanted Alzet 2ML1 osmotic micropumps. Rats were observed for 30 minutes in a plexiglass box before, during and after infusion (at 16 and 40 hrs after explantation of the pumps). The signs observed as behavioral measures of spontaneous nicotine withdrawal were: gasps, genital licks, ptosis, teeth chatters, wet shakes, yawns and changes in locomotor activity as compared to baseline session and to sham operated controls. Statistical evaluation revealed a significant increase in overall abstinence signs both at 16 and 40 hrs, ( $p < 0.05$ ) as compared to baseline and ( $p < 0.01$ ) to controls. Moreover, there was a significant reduction in locomotor activity ( $p < 0.01$ ) at both withdrawal sessions. Another group were injected with the centrally acting nicotinic receptor antagonist mecamylamine, 1mg/kg s.c., on the seventh day of infusion. This treatment precipitated the abstinence syndrome, characterized by an even higher increase in overall abstinence signs as compared to all other groups ( $p < 0.001$ ), while there was no significant change in locomotor activity. Preliminary results from this laboratory show that a low dose of nicotine (0.15mg/kg s.c.) administered to spontaneously abstinent rats extinguishes the withdrawal syndrome. Moreover, administration of the peripherally acting nicotinic receptor antagonist chlorisondamine, 1mg/kg s.c., seems to elicit at least some components of the withdrawal syndrome, as described in the above model. This model of nicotine abstinence may prove useful in examining further the underlying mechanisms of nicotine dependence and withdrawal. (Supported by the Council for Tobacco Research Inc., U.S.A.)

## 574.19

EFFECT OF NICOTINE (NIC) ON DOPAMINE (DA) RELEASE FROM TERMINAL REGIONS OF THREE DOPAMINERGIC PATHWAYS. D.L. Marshall\*, P.H. Redfern and S. Wonnacott, Sch. Pharmacy & Pharmacol. and Sch. Biol. & Biochem., Univ. Bath, Bath BA2 7AY, U.K.

The ability of NIC to enhance DA release in the mesolimbic DA pathway is thought to underlie NIC's reinforcing properties [1]. Systemically administered NIC results in greater DA release from accumbens than from striatum of frontal cortex [2, 3]. Why the mesolimbic system is more sensitive, and the precise site of action of nicotine remain unclear. Here we have compared the release of DA by NIC from the terminal regions of the 3 DA pathways in adult male Sprague-Dawley rats using *in vivo* microdialysis. NIC was delivered to the terminals via the dialysis probe.

NIC produced an immediate, dose-dependent increase in DA release ( $n=6-8$ ). At a high NIC concentration ( $3 \times 10^{-1} M$ ) peak DA release was increased to  $265 \pm 119$  fold of basal (striatum),  $101 \pm 51$  fold (accumbens) and  $21 \pm 12$  fold (cortex); release was not inhibited by prior addition of  $10^{-3} M$  mecamylamine (MEC) suggesting a non-specific mechanism of action. At a lower NIC concentration ( $3 \times 10^{-2} M$ ) peak DA release was  $3.3 \pm 1.1$  fold of basal (striatum),  $3.2 \pm 1.1$  fold (accumbens) and  $1.1 \pm 0.1$  fold (cortex); release was inhibited by MEC suggesting NIC acts via stimulation of nAChRs. The estimated  $EC_{50}$  for specific DA release by NIC was  $3.5 \times 10^{-3} M$  for the striatum and accumbens, and  $5 \times 10^{-3} M$  for the cortex. The effective *in vivo* recovery for NIC in the striatum was 0.5%, giving  $EC_{50}$  values in the low micromolar range. These data suggest there is no difference in the sensitivity of the terminal regions of the different ascending DA pathways to the specific effects of NIC.

## 574.21

ALTERATIONS IN CORTICOSTERONE BINDING SITES FOLLOWING CHRONIC NICOTINE ADMINISTRATION IN RATS. M. Shoaib, V.K. Patchev\*, and O.F.X. Almeida, Neuroadaptations Group, Department of Neuroendocrinology, Max-Planck Institute of Psychiatry, Clinical Institute, Kraepelinstrasse 2, 80804 Munich, GERMANY.

The mechanisms underlying the adaptive responses following chronic exposure to nicotine are not known. While increases in nicotinic binding sites are evident after chronic administration of nicotine, there are studies implicating corticosteroids in nicotine tolerance. The present experiment was conducted to examine the influence of repeated nicotine treatment on corticosterone receptor binding. To confirm the nature of the chronic treatments, behavioural tests were conducted on locomotor activity one day prior to sacrifice. Male Sprague Dawley rats were injected chronically twice daily for 7 or 28 days with nicotine (0.6 mg/kg SC) or saline in their home cages. The next day, the rats were challenged with nicotine (0.6 mg/kg SC) or saline and locomotor activity was monitored. The rats were then adrenalectomised and the following day, the hippocampus and hypothalamus were dissected. Cytosol preparations were assayed using  $^3H$ -corticosterone as the radioligand, and dexamethasone was used to displace binding. In saline-pretreated rats, a nicotine challenge produced robust depression of locomotor activity. Both nicotine pretreated groups of rats displayed tolerance to this depressant response, and over the second half of the 2 hr test, sensitisation was apparent to the activating effects of nicotine. In both nicotine-treated groups, corticosterone binding sites ( $B_{max}$ ) and binding affinities ( $K_d$ ) decreased in both the hippocampus and hypothalamus. These results suggest that glucocorticoids may be involved in the adaptive responses to chronic nicotine treatment. Furthermore, changes in binding to corticosterone suggest altered physiological drive of the hypothalamic pituitary adrenal axis, which may account for the tolerance observed to the behavioural effects of nicotine.

## 574.18

A TIME-COURSE ANALYSIS OF BEHAVIOURAL SENSITIZATION TO NICOTINE IN THE RAT. D.H. Johnson\*, J.A. Engel and B. Söderpalm, Inst. of Physiol. and Pharmacol., Dept. of Pharmacol., Göteborg University, Sweden.

Nicotine, amphetamine, cocaine, opiates and ethanol share the ability to induce behavioural and neuronal sensitization in laboratory animals. These phenomena have been implicated in the development of psychic dependence to drugs of abuse. Behavioural sensitization to nicotine has been documented as an enhancement of nicotine-induced locomotor activity (LMA; measured over 30' to 60' without any detailed time-resolution) after 5 - 15 daily injections, as compared to nicotine-induced LMA day 1.

The purpose of the present experiments was to obtain more detailed information regarding the time-course (over five-minute intervals) of the LMA response to nicotine throughout chronic intermittent nicotine treatment, the maximal sensitized response and the duration of an established sensitization.

Adult male S-D rats received nicotine daily (0.4 mg/kg, s.c.) and LMA (30' habituation followed by drug injection and recording for another 30') was recorded on days 1, 6, 9 and 14. On day 6, the LMA response during the first 10-minute period after injection (early phase) was sensitized ( $p < 0.001$ ), whereas LMA during the last 20-minute period (late phase) was not sensitized until on day 14, and then only weakly. The total LMA response (30') was sensitized from day 9 ( $p < 0.001$ ). Some animals received further nicotine treatment and were tested on days 16, 20, 29, 31, 38 and 44. The maximal sensitized response (200 % of the day 1 response, both regarding the early and late LMA phase) was obtained from day 29. Nicotine treatment was then interrupted and 1, 3 and 5 months later the animals were again challenged with nicotine. The early phase LMA response remained significantly sensitized at all time-points (approx. 150 % after 5 months), whereas the late phase response was further enhanced after 1 month (250 %) and sharply declined after 5 months (68 %).

These results indicate that behavioural sensitization to nicotine may involve two processes affecting the early and late phase LMA after nicotine injection differently. Sensitization to the early phase response appears rapidly induced, robust and long-lasting, while that to the late phase develops slowly, appears boosted after interruption of nicotine administration, but is not as long-lasting as the early phase sensitization.

## 574.20

ACUTE TOLERANCE TO THE DOPAMINE RESPONSE TO NICOTINE. I.M. Maisonneuve\*, C.R. Deibel and S.D. Glick, Department of Pharmacology and Neuroscience, Albany Medical College, Albany, NY 12208.

There is increasing evidence that the rewarding effect of nicotine is mediated by the dopamine mesolimbic system. Acute tolerance to the subjective effects of nicotine in novice smokers has been hypothesized to be the basis for the subsequent increase in drug intake. This phenomenon has been observed in *in vitro* paradigms, but not yet reported *in vivo* in naive animals. Using *in vivo* microdialysis in awake and freely moving male Sprague Dawley rats, we investigated the acute dopamine response to two 5 minute i.v. infusions of nicotine, administered one hour apart, in the shell area of the nucleus accumbens. I.v. nicotine infusions (0.16 mg/kg/5min or 0.32 mg/kg/5min) produced increases in extracellular dopamine levels as well as in DOPAC and HVA, the two main dopamine metabolites. The magnitude of the dopamine increases was dose dependent (dose effect,  $F_{(1,10)} = 5.34$ ,  $p < 0.043$ ). For both doses, the response decreased with the second infusion (infusion effect,  $F_{(1,10)} = 6.98$ ,  $p < 0.024$ ). Pretreatment, 30 minutes before the first nicotine infusion, with the selective nicotinic receptor antagonist mecamylamine (5mg/kg, i.p.) abolished the dopamine increases. On-going experiments are determining the duration of the observed acute desensitization.

(Supported by DA03817 and by the Aaron Diamond Foundation).

## 575.1

**SELECTIVE AREAS ARE DAMAGED IN THE AMYGDALOID COMPLEX AFTER SEIZURES INDUCED BY SYSTEMIC INJECTION OF KAINIC ACID.** J. Tuunanen<sup>1</sup>, T. Halonen<sup>1</sup>, A. Pitkanen<sup>2</sup>. <sup>1</sup>Dept. of Neurology and <sup>2</sup>A.I. Virtanen Institute, Univ. of Kuopio, P.O. Box 1627, FIN-70211 Kuopio, Finland.

Neuronal damage in the hippocampus is a common finding in patients with temporal lobe epilepsy and in experimental epilepsy. Much less attention has been paid on the damage in the other regions of the temporal lobe such as in the amygdala. We used the systemic injection of kainic acid (9mg/kg) to produce status epilepticus in rats. Two weeks after the induction of seizures the animals were intracardially perfused and the distribution and severity of neuronal damage in different nuclei of the amygdaloid complex was analyzed from sections stained with thionin and Gallyas silver impregnation. The number of GABA- and somatostatin-immunoreactive (SOM-ir) interneurons were analyzed in the lateral and basal nuclei of the amygdaloid complex. The severity of neuronal damage varied between different amygdaloid nuclei and between the nuclear divisions. For example, in the lateral nucleus, the dorsolateral division was well preserved, whereas the ventrolateral and medial divisions were heavily damaged. In the basal nucleus, the magnocellular and intermediate divisions were well preserved compared to the parvocellular division that was severely damaged. In the lateral nucleus, the number of GABA-ir neurons was 49% and the number of SOM-ir neurons 46% of that in controls. In the basal nucleus, the number of GABA-ir neurons was 24% and the number of SOM-ir neurons 34% of that in controls. These data indicate that like in the hippocampus also in the amygdaloid complex there are selective areas which are vulnerable to seizures. In addition we found GABAergic inhibitory interneurons to be severely damaged in the amygdaloid complex in this model of epilepsy.

## 575.3

**MOSSY FIBER SPROUTING FOLLOWING TRANSECTION OF SUBCORTICAL AND CORTICAL AFFERENTS TO THE HIPPOCAMPUS IN RATS TREATED WITH KAINIC ACID.** J. Jolkkonen\*, E. Jolkkonen and A. Pitkanen. Departments of Neurology and A.I. Virtanen Institute, University of Kuopio, Kuopio, Finland.

Administration of kainic acid induces prolonged seizures that are accompanied with a neuronal loss and mossy fiber sprouting in the dentate gyrus. Mechanisms that regulate initiation of plastic response and guidance of mossy fibers to a new target area (i.e. the supragranular area and the inner molecular layer) are poorly understood. In the present study, we investigated whether the major afferent pathways to the hippocampus could modify a slowly occurring synaptic reorganization induced by an epileptic insult. Thus, the perforant pathway or the fimbria-fornix were bilaterally transected 2 days following generalized seizures induced by systemic administration of kainic acid (9 mg/kg). Two months later, aberrant mossy fiber sprouting was estimated from Timm-stained horizontal sections throughout the hippocampus. The severity of sprouting was scored from 0 (no sprouting) to 7 (most severe sprouting). Somatostatin immunohistochemistry was used to estimate the neuronal loss in the dentate hilus. In sham-operated rats, mossy fiber sprouting to a new target area was increased (212-1420%) following kainic acid treatment compared to that in saline treated rats. The number of somatostatin neurons in the dentate hilus decreased by 50-84% and, in particular, the temporal end of the hippocampus was severely affected. In perforant pathway transected rats treated with kainic acid, Timm staining in the supragranular area and the inner molecular layer was also increased (146-1612%), but the decrease in the number of hilar somatostatin neurons was less significant (34-51%). In fimbria-fornix transected rats treated with kainic acid, aberrant mossy fiber sprouting was significantly lower (227-314%) compared to that in sham-operated rats. In these rats, somatostatin neurons in the dentate hilus were better preserved in the septal end of the hippocampus than in the temporal end. These results suggest that in this particular model of epilepsy, aberrant synaptic reorganization may partly be modulated by mechanism(s) dependent on the subcortical afferents to the hippocampus.

## 575.5

**IN VIVO INTRACELLULAR RECORDING AND LABELING OF GRANULE CELLS IN THE DENTATE GYRUS OF EPILEPTIC KAINATE-TREATED RATS.** P.S. Buckmaster\* and F.E. Dudek. Dept. of Anatomy and Neurobiology, Colorado State University, Fort Collins, CO 80523.

*In vivo* intracellular recording and labeling techniques were used to examine dentate granule cells in rats that had been treated with kainic acid and, months later, were observed having spontaneous, recurrent seizures. Urethane-anesthetized animals were placed in a stereotaxic apparatus. Granule cells were impaled and synaptic responses to perforant path stimulation were obtained. In some epileptic rats, granule cells displayed a brief EPSP followed by a large-amplitude, high-conductance, biphasic IPSP. In other epileptic animals, a delayed depolarization was superimposed on the IPSP. In an extreme case, a single, low-intensity stimulus evoked repetitive bursts of action potentials with no evidence of synaptic inhibition. Individual granule cells were labeled with biocytin, and their complete axon arbors were reconstructed. Granule cells in epileptic rats consistently showed axon collaterals that projected into the inner molecular layer. Most of the molecular layer axons remained close to the parent cell. However, in some cases, axons crossed the hilus and projected to the molecular layer of the opposite blade of granule cells and spanned over 750  $\mu$ m, or 15% of the total septotemporal length of the hippocampus. These data suggest that strong synaptic inhibition is present in granule cells of most epileptic kainate-treated rats. Axon projections to the molecular layer and late synaptic depolarizations suggest the existence of a functional recurrent excitatory circuit.

## 575.2

**SEIZURE FREQUENCY AND SUPRAGRANULAR SPROUTING IN 3 DIFFERENT MODELS OF CHRONIC SPONTANEOUS SEIZURES.** R.L.M. Rivero\*, C.M. Kohmann, A.P. Simão, P.R. Penna, A. Borin and L.E.A.M. Mello. Depto. de Fisiologia, Escola Paulista de Medicina-UNIFESP, 04023-900 São Paulo, Brazil.

Sprouting of hippocampal dentate gyrus mossy fibers onto the supragranular layer has been described in both human tissue and experimental models of epilepsy. However it is still controversial as to whether it is adaptive (leading to blockade of seizures) or mal-adaptive (contributing to seizure generation or expression). Here we have induced chronic recurrent seizures and mossy fiber sprouting in 3 different models: intrahippocampal injection of kainic acid (KA) (1.25  $\mu$ g, unilateral); intraperitoneal (i.p.) injection of KA (10 mg/kg); and i.p. injection of pilocarpine (Pilo) (320 mg/kg). Behavioral observations for the assessment of spontaneous recurrent seizures were performed thereafter for a period of 40 weeks, 3-8 h/day, 5 days/week. After 40 weeks the animals were deeply anesthetized and their brains histologically processed according the Neo-Timm method. Frequency of SRS was highest for Pilo-injected animals (2.3 SRS/rat/week), followed by systemically-injected KA (1.5 SRS/rat/week) and intrahippocampal KA (0.4 SRS/rat/week). Similarly, intensity of the supragranular mossy fiber sprouting was highest for the Pilo animals, followed by systemic-KA and intrahippocampal KA. We suggest that the different seizure patterns among these models might be in part related to the amount of the mossy fiber sprouting. The simplest hypothesis for such possible link is that mossy fiber sprouting contributes to seizure generation or expression.

## 575.4

**KAINIC ACID-INDUCED MOSSY FIBER SPROUTING AND SYNAPSE FORMATION IN THE RAT DENTATE GYRUS.** H.J. Wenzel\*, C.S. Woolley and P.A. Schwartzkroin. Dept. of Neurological Surgery, University of Washington, Seattle, WA 98195-6470.

In an experimental model of temporal lobe epilepsy, kainic acid (KA) administration in rats evokes seizures which are accompanied by hippocampal and hilar neuronal death and synapse degeneration. KA treatment has been shown to result in sprouting of dentate gyrus granule cell axons (mossy fibers) to aberrant sites in the inner molecular layer. It has been hypothesized that these aberrant mossy fibers form synapses with granule cells at sites normally innervated by hilar mossy cells, which have been lost as a result of KA treatment. In order to determine the postsynaptic targets of these aberrant mossy fibers, we have performed light and electron microscopic analysis of electrophysiologically identified granule cells injected with biocytin in hippocampal slices taken from adult rats 2-5 months following injection of KA (12 mg/kg s.c.); Timm staining was performed on sections from the same brains in order to document the overall degree of sprouting for each animal. Examination of Timm stained tissue indicated 1) a progressive growth of mossy fibers in the inner molecular layer and 2) high interanimal variability in the degree of sprouting. Light microscopic examination of biocytin-filled mossy fiber collaterals in KA-treated animals revealed increased collateralization of mossy fibers in the hilus compared to controls as well as mossy fiber growth into the stratum granulosum; sprouted mossy fiber collaterals crossed the s. granulosum and branched in the inner molecular layer. Electron microscopic examination of serially reconstructed biocytin-filled mossy fiber collaterals in the molecular layer revealed mossy fiber boutons that formed asymmetrical synapses with dendritic spines and shafts of granule cells (including autapses on the parent dendrites of a biocytin-filled granule cell). These results support the view that KA-induced synaptic reorganization could provide a basis for recurrent excitation of dentate gyrus granule cells.

## 575.6

**CHANGES IN N-ACETYLASPARTATE, N-ACETYLSPARTYLGLUTAMATE AND LACTATE IN KAINATE-INDUCED EPILEPSY.** T. Nimura, F.C. Cheng, S.H. Graham, R.A. Swanson and P.R. Weinstein\* Dept. of Neurological surgery, Univ. of Calif., San Francisco and VA medical center, SF 94121.

We examine the hypothesis that N-acetylaspertate (NAA), N-acetylspartylglutamine (NAAG) and lactate have a good correlation with spectroscopic contents in kainate-induced epilepsy. Epilepsy was induced by the injection of kainic acids (10mg/kg) subcutaneously. Animals were sacrificed by microwave at 3, 12, 24, 72 h after injection. Control animals were injected same dose saline. The brains were removed and dissected hippocampus (H), amygdala (A), piriform cortex (PC) and frontal cortex (FC). The contents of NAA and NAAG were measured by HPLC and lactate were determined by fluorimetric assay. NAA decreased at 12 h, 24 h and 72 h significantly ( $p < 0.05$  or  $p < 0.01$ ) in H and A. In PC, NAA at 24 h and 72 h ( $p < 0.05$  or  $p < 0.01$ ) was much lower than control. The concentration of NAA in FC didn't change significantly. NAAG increased at 12 and 24 h ( $p < 0.05$ ) in H and at 12 h in A ( $p < 0.05$ ). However, NAAG reduced after 12h significantly in PC ( $p < 0.01$  or  $p < 0.05$ ). Lactate were significantly higher than control in every lesion at 12 h ( $p < 0.00001$ ), but not at 3 h. Lactate decreased at 24 h in everywhere near the control level, but went up at 72 h except FC ( $p < 0.05$ ). These data showed that spectroscopic measurements didn't necessarily reflect true concentrations during the acute phase in kainate-induced epilepsy. This observation suggests that this discrepancy may be overestimated changes in NAA and lactate contents by changes in NAA and lactate relaxation time.

## 575.7

**ACTIVATION OF CRF-EXPRESSING NEURONS IN EXTRAHYPOTHALAMIC SITES FOLLOWING SEIZURES.** D.T. Piekut\* and B. Phipps. Dept. of Neurobiology and Anatomy, University of Rochester, Rochester, NY 14642.

We have previously reported FOS expression in hypothalamic CRF neurons following the elicitation in rats of fully generalized seizures by kainic acid (KA). This finding suggests that seizure induction activates the hypothalamic-pituitary-adrenal axis. Effects of seizures on extrahypothalamic CRF are virtually unknown.

In this study, Sprague-Dawley rats were administered KA (18 mg/kg, ip), and animals typically responded with a fully generalized seizure syndrome. Control animals were injected with saline. Animals were allowed to survive from 5-48 hours following KA. Animals were perfused and brains were processed for CRF immunocytochemistry. Preliminary findings show a significant increase from 5-48 hours following KA injection in CRF immunoreactivity. Immunolabeled cell bodies and fibers are found in extrahypothalamic sites that typically demonstrate little or no CRF in controls. Marked increases in the number of neuronal perikarya are observed in deep layers of piriform cortex along with thick and beaded neuronal processes. Other sites of increased labeling of CRF perikarya and fibers include lateral septum, dorsal endopiriform nucleus, fundus striati, and nucleus of the lateral olfactory tract. Additionally, CRF labeled cell bodies are found typically in the basolateral and lateral amygdaloid nuclei. In hippocampus, labeling of pyramidal cell bodies is observed, and cells are labeled in the polymorphic layer of dentate gyrus. Many of the aforementioned areas exhibiting increased CRF immunoreactivity are areas of brain exhibiting degenerative changes following kainate elicited seizures. Although it is not entirely clear what function CRF may play at these extrahypothalamic sites, its presence in vulnerable areas suggests a neuroprotective or neurodegenerative role. Supported by NIH grant NS18626

## 575.9

**ALTERED EXPRESSION OF PLASMA MEMBRANE CALCIUM ATPASE mRNAs WITHIN THE HIPPOCAMPUS FOLLOWING KAINATE-INDUCED SEIZURES.** M.L. Garcia\*, K.D. Murray, E.E. Strehler, P.J. Isackson. Department of Molecular Neuroscience, Jacksonville, FL 32224

Calcium, a ubiquitous second messenger, has been linked to several pathological conditions. The plasma membrane calcium ATPase (PMCA) is one of the primary methods of translocating calcium. As an initial assessment of the possible involvement of PMCA in kainate (KA)-induced neurodegeneration, we have determined the effect of KA-induced seizures upon PMCA mRNA expression. In situ hybridization was performed on tissue from adult male Sprague-Dawley rats sacrificed at various time points following intraperitoneal injection of KA. KA altered the expression within the hippocampal subfields for mRNAs of all isoforms. PMCA 1, 2, and 3 mRNAs exhibited hybridization below control levels 12 to 48 hours post-injection within CA1 and CA3. Within the dentate gyrus, PMCA 2 mRNA hybridized below control levels 4 hours post-injection and exceeded control levels at 48 and 96 hours post-injection. These observations provide evidence that KA-induced seizures alter the expression of the PMCA at the mRNA level suggesting a possible role for the PMCA in the neuronal degeneration within CA1 and CA3 pyramidal cell layers inherent to this paradigm.

## 575.11

**INCREASED FASCIA DENTATA POSTSYNAPTIC AMPA AND GABA RECEPTORS PRECEDE AXON SPROUTING AFTER INTRAHIPPOCAMPAL KAINATE.** J.P. Leite\*, T.L. Babb, G.W. Mathem, A.C. Chu, C.R. Rosales, K.M. Yeoman, P.A. Kuhlman and J.K. Pretorius. UCLA School of Medicine, Los Angeles, CA, 90024.

Recent studies indicate that receptor changes are associated with axonal sprouting in the epileptic sclerotic fascia dentata (FD), however it is unknown if these receptors increase independently or in response to the ingrowth of the aberrant axons. Intrahippocampal kainic acid (KA) reproduces many behavioral, electroencephalographic and pathological features of hippocampal epilepsy. We correlated the time course of AMPA and GABA postsynaptic receptor changes in KA-treated rats to the axonal reorganizations of mossy fibers (MFs) and GABAergic fibers. KA (0.4µg/0.2µl) was injected unilaterally in the right hippocampus; while the contralateral side received a saline injection. Animals were sacrificed at post-injection days (PIDs) 2, 5, 10, 15, 22 and 30 and their brains processed for Nissl, Neo-Timm (MFs), and immunocytochemistry (ICC) for GAD, GABA-A $\delta$ , GluR1 and GluR2/3 receptors. Increased receptor-ICC staining for GluR1 and GluR2/3 occurred as early as PID 2; however more staining occurred at PID 5 and was maintained out to PID 30 ( $p < 0.05$ ). Timm positive terminals were detected in the molecular layer only after PID 10. GABA-A $\delta$  receptors were also increased at PID 2-5 and maintained above control in all subsequent groups ( $P < 0.03$ ), before GAD positive sprouting was observed. Transitory axonal and postsynaptic receptor changes were observed in the contralateral side, but the staining returned to control levels after PID 22. Our results indicate that following KA damage, upregulation of postsynaptic AMPA and GABA receptors precede the ingrowth of MF and GABA reinnervation of the FD. This supports the hypothesis that early changes in the reinnervated target neuron receptors are based on molecular mechanisms that are temporally-independent of those that promote axon sprouting to the FD molecular layer. ## 575.8

**AGE-RELATED CHANGES IN PARVALBUMIN IMMUNOREACTIVITY FOLLOWING KAINIC ACID SEIZURE.** E.F. Sperber\*, K.K. Weireter, H. Kubova and M.T. Romero. Depts of Neurology, Albert Einstein College of Medicine, NYC, NY 10461 and Psychology, SUNY Binghamton, NY 13902.

Studies indicate normal cell function is dependent on intracellular calcium homeostasis. An accumulation of calcium in the cell has been linked to neuronal damage and cell death in several pathological states including status epilepticus. It has been shown that proteins as PV (parvalbumin) which sequester calcium may have a protective role.

We have repeatedly demonstrated that immature rat is more resistant to status epilepticus induced hippocampal damage in comparison to adult rat. The purpose of the present study was to determine whether the calcium binding protein, PV, was differentially altered following kainic acid induced status epilepticus with age. Fourteen day old and adult rats were treated with kainic acid. Four days post-seizure, animals were sacrificed and sections prepared for PV immunocytochemistry. Results indicated age-related differences in the distribution and number of PV positive expressed cells. In the adult hippocampus there were only a small number of intact positively PV stained cells and extensive degenerating profiles were observed. In contrast, the kainic acid treated immature hippocampus had extensive positive staining of cells that were similar in distribution, density and morphology to age-matched controls. Results suggest that the presence of parvalbumin may have age-related functional differences.

## 575.10

**EXPRESSION OF THE INDUCIBLE 70-kDa HEAT SHOCK PROTEIN FOLLOWING KAINIC ACID-INDUCED STATUS EPILEPTICUS IN RAT.** J.N. Armstrong\*, J.C.L. Plumier, H.A. Robertson, and R.W. Currie. Laboratory of Molecular Neurobiology, Depts. of Pharmacology, Anatomy and Neurobiology, Dalhousie University, Halifax, N.S., Canada, B3H 4H7.

Using both immunohistochemistry and *in situ* hybridization, we examined the rat brain for the expression of the inducible 70-kDa heat shock protein (HSP70) at 1, 3, 6, 12, and 24 hrs after kainic acid-induced status epilepticus (12 mg/kg i.p.). No HSP70 protein was found at 1 or 3 hrs following administration of kainic acid. However, HSP70 immunoreactivity (HSP70-IR) was observed in a small population of neurons in the hilar region of the hippocampus at 6 hrs post-injection. No other immuno-positive cells could be detected in the brain at this time point. Substantial HSP70-IR was observed in neurons of the dentate hilus as well as in hippocampal CA1 and CA3c neurons 12 hrs after kainic acid administration. Other areas including the basolateral, medial and central amygdala, the ventral portion of the perirhinal cortex and layer II of the pyriform cortex demonstrated HSP70-IR at this time. At 24 hrs, HSP70-IR was observed throughout CA3 and the perirhinal cortex. Other small populations of cells were observed to be immuno-positive for HSP70 protein including a small portion of dentate granule cells, the mediodorsal thalamus, the amygdala, layer V pyramidal cells and some deep layer VI cells in the neocortex. HSP70 immunoreactive astrocytes were also observed in the dentate hilus and the molecular layer of CA1 24 hrs after injection of kainic acid. Cresyl violet staining of adjacent sections revealed pyknotic cells in the areas that HSP70 immunoreactive astrocytes were observed. *In situ* hybridization for HSP70 mRNA at 3 and 6 hrs after the injection of kainic acid revealed a similar pattern of expression to that observed at 12 and 24 hrs using immunohistochemistry for HSP70 protein. Work is currently underway to identify the population of dentate hilar neurons that express HSP70 protein at 6 hrs after the administration of kainic acid. (Supported by MRC and SmithKline Beecham Pharmaceuticals)

## 575.12

**EFFECTS OF MELATONIN ON KAINATE-INDUCED NEUROTOXICITY.** M. Lipartiti, D. Franceschini, E. Aromataris, N. Schiavo, M. Gusella and P. Giusti\*. Department of Pharmacology, L.go Meneghetti, 2. 35131 Padova (Italy)

It has been suggested that free radical formation may play a significant role in non-NMDA mediated excitatory aminoacid neurotoxicity (H.S. Chow, J.J. Lynch, K. Rose and D.W. Choi, *Brain Res.* 639, 102, 1994). To test this hypothesis, the neuroprotective effects of melatonin, a potent endogenous hydroxyl radical scavenger (D.F. Tan, L.D. Chen, B. Poeggeler, L.C. Manchester, and R.J. Reiter, *Endocrine Journal* 1, 57, 1993), were evaluated against kainate-induced neurotoxicity both *in vitro* and *in vivo*. Seven-day-old primary cultures of rat cerebellar granule neurons were employed in the *in vitro* study. Cells were exposed to different doses of kainate for 30 min in the absence or presence of melatonin (500 µM), and viability was assessed 24 h later by means of MTT technique. Melatonin blocked the neurotoxic effect of kainate. A similar effect was observed after melatonin administration *in vivo* (2.5 mg/kg i.p., 4 times) in kainate (10 mg/kg i.p.) treated rats. Melatonin administration reduced kainate-induced mortality, body weight loss, and also neurodegeneration. Melatonin's protection against the neurotoxic effects of kainate, could be explained, at least in part, by its anti-scavenger profile.

## 575.13

**DIFFERENCES IN ACOUSTICALLY-EVOKED NEURONAL RESPONSE IN EXTERNAL NUCLEUS OF INFERIOR COLLICULUS (IC) OF NORMAL AND GENETICALLY EPILEPSY-PRONE RATS: RESPONSE CHANGES PRODUCED BY MICROINJECTION OF NMDA INTO IC CENTRAL NUCLEUS.** D.N.Chakravarty\* and C.L.Faingold. Dept. Pharmacology, Southern Illinois University School of Medicine, Springfield, IL 62794.

Anatomical studies have demonstrated neuronal connections between IC central nucleus (ICc) and external nuclei (ICx) of IC. In the audiogenic seizure (AGS) network of the genetically epilepsy-prone rat (GEPR), this intracollicular pathway is a potential trajectory for generation of seizure activity, after AGS initiation in ICc. The ICx connection may be a critical pathway, since the ICc unlike the ICx, lacks connections to nuclei with motor outputs, required for behavioral manifestations of AGS. The present study examined acoustically-evoked neuronal responses in ICx of the GEPR and normal animals and examined changes after contralateral infusion of NMDA into ICc (10 nmol/0.5 µl, 2 min). Anesthetized (ketamine-xylazine 85/3mg/kg) GEPR and normal rats were used. Response patterns of ICx neurons to 50 presentations of tone bursts at characteristic frequency (10 dB SPL above threshold) were subject to poststimulus time histogram analysis. NMDA was then infused into the contralateral ICc and changes in ICx response pattern changes were evaluated. Tonic response patterns were observed in 24% of normal ICx cells (5/21), which was significantly lower than the incidence of tonic firing in GEPR ICx cells (71%, 15/21) (Chi square  $p < 0.01$ ), pre-NMDA. Mean neuronal firing in the GEPR was also significantly higher than normal ( $p < 0.001$ , ANOVA). This increased incidence of tonic firing and mean firing increase in ICx neurons in the GEPR indicate an increased ICx excitability in the GEPR, further supporting involvement of the ICx in the AGS network. Following NMDA infusion, 60% (9/15) of normal cells displayed excitation (mean increase, 36%), reversibly. NMDA doses, similar to those that result in increased ICx neuronal responses in the present study, also produce AGS susceptibility in normal animals. This suggests a critical mechanism subserving the role of ICx in the AGS network. (Support NIH NINDS NS 21281)

## 575.15

**NEUROBEHAVIORAL ASSESSMENT OF THE EFFECTS OF SUB-CONVULSIVE DOSES OF A POTENT CONVULSANT (TMPP) IN THREE RAT STRAINS.** J. Rossi III\*, C. Nocjar\*, M.Y. Vaningan\*, T.J. Moore, C.Y. Ademujo\*, G.D. Ritchie\* and J. Panksepp\*. Tri-Service Toxicology Consortium: Naval Medical Research Institute Detachment (Toxicology) and Geo-Centers, Inc<sup>1</sup>, Wright-Patterson Air Force Base, OH and Dept. of Psychology<sup>2</sup>, Bowling Green State University, Bowling Green, OH.

Clinical seizures induced by neuroconvulsants is a topic of extensive study; however, there is little information (with the exception of behavioral kindling) available concerning short- and long-term neurobehavioral consequences of exposure to sub-clinical doses of convulsants. Trimethylolpropane phosphate (TMPP), a neuro-convulsant 100 times more potent than PTZ, was reliably shown in this study to disrupt performance of a well-trained operant task in a time frame consistent with brain uptake of the drug and appearance of EEG paroxysms. In an eight-arm radial maze test, TMPP administration increased latency to find food in the first trial, yet significantly reduced time to find and consume food (compared to controls) during the second trial in which previously unbaited arms contained food. In a plus maze, sub-clinical doses of TMPP were also shown to increase timidity significantly in adult rats, and decrease play solicitation (dorsal pins) in juvenile rats. Repeated administration of low doses of TMPP (0.0125-0.2 mg/kg) sensitized both locomotor response to amphetamine challenge and audiogenic seizure sensitivity in rats tested 30-60 days later. This finding is consistent with the previous research in the laboratory showing long-term kindling of EEG paroxysms but not behavioral seizures. Finally, it was shown that repeated TMPP administration neither increased nor decreased place preference as tested in a shuttlebox.

## 575.14

**CHARACTERIZATION OF TRIMETHYLOLPROPANE PHOSPHATE (TMPP), A CHEMICAL MODEL FOR ABSENCE EPILEPSY.** G.D. Ritchie\*, T.K. Narayanan<sup>1</sup>, A. Jung<sup>1</sup> and J. Rossi III. Tri-Service Toxicology Consortium: Naval Medical Research Institute Detachment (Toxicology) and Geo-Centers, Inc<sup>1</sup>, Wright-Patterson AFB, OH 45433-7903.

Sub-convulsive doses of TMPP, a convulsant 100 times more potent than PTZ, have been shown both to increase EEG paroxysms in rats for up to 6 hours post-injection, and kindle long-term increases in abnormal EEG activity but not behavioral seizures. TMPP administration in sub-clinical doses reliably disrupted performance of a well-trained operant task requiring attention, although no behavioral seizure activity was observed. The present study characterized the uptake, distribution, disposition, clearance and ligand binding of TMPP. TMPP was shown to cross the blood-brain barrier 6-10 min. post-injection, distribute in highest concentrations in the cerebellum, striatum and hippocampus, and clear from brain tissues 60%+ within 3 hours and 95%+ in 24 hours. A significant increase in blood serum concentration of TMPP was observed 3-6 hours post-administration, perhaps consistent with changes in blood-brain barrier permeability and/or kidney clearance rate. Repeated administration of TMPP for five days did not result in accumulation of the drug in any tissues, including fat, questioning the mechanism of TMPP-induced CNS sensitization. Ligand binding studies indicated possible interference with the GABA/GABA<sub>A</sub> inhibitory mechanism, with the interesting additional observation of TMPP-induced enhancement of bicuculline binding.

## 575.16

**SIMULTANEOUS MICRODIALYSIS, EEG AND BEHAVIORAL ASSESSMENT OF EFFECTS OF SUB-CONVULSIVE DOSES OF TRIMETHYLOLPROPANE PHOSPHATE (TMPP) IN SPRAGUE-DAWLEY RATS.** J.W. Lindsey, S. Prues\*, C. Alva, G.D. Ritchie\*, J. Rossi III and H.N. Davis\*. Tri-Service Toxicology Consortium: Naval Medical Research Institute Detachment (Toxicology), Geo-Centers, Inc<sup>1</sup>, Wright-Patterson Air Force Base, OH and Department of Psychology, Wright State University, Dayton, OH<sup>2</sup>

Administration (i.p.) of TMPP [1.5 µg/kg-0.4 mg/kg] has been shown to reliably induce EEG paroxysms and sub-clinical and clinical seizures in rats in a dose-related manner. The consistent observation of TMPP-induced sub-clinical behavioral seizures (*i.e.*, twitches, *etc.*) that are temporally correlated with EEG paroxysms motivated an effort to temporally correlate behavioral seizure activity, EEG paroxysms and changes in neurotransmitter (and major metabolite) levels in nuclei thought to be associated with seizure induction or recruitment. Rats implanted with both EEG electrodes and microdialysis cannulas were injected with TMPP. A video editing system was used to correlate sub-clinical behavioral seizures with EEG paroxysms and changes in five transmitters/metabolites: dopamine, DOPAC, 5-HIAA, 5-HT, and HVA, as measured by microdialysis. Microdialysis probes in the nucleus accumbens recorded gradual changes in dopamine and serotonin levels, then return to baseline levels, correlating with onset and termination of TMPP-induced behavioral seizures and EEG paroxysms. Integrated behavioral responses to TMPP administration, including activated sniffing, were reliably correlated with occurrence of specific EEG paroxysms.

## EPILEPSY: BASIC MECHANISMS IV

## 576.1

**CHANGES IN GENE EXPRESSION IN A HIPPOCAMPAL NEURONAL CULTURE MODEL OF RECURRENT SPONTANEOUS SEIZURES.** R.E. Blair\*, S. Sombati and R.J. DeLorenzo. Department of Pharmacology and Toxicology and Department of Neurology, Medical College of Virginia, Richmond, VA 23298.

Brief exposure of hippocampal neuronal cultures to a Mg<sup>2+</sup>-free media results in long lasting recurrent spontaneous seizure activity as recorded by whole cell patch-clamp. This "epileptic" phenomenon persists for the life of the hippocampal culture, and is a potential tool for understanding the molecular mechanisms that underlie seizure discharges (Sombati and DeLorenzo, J. Neurophys., in press). Hippocampal neuronal cultures were exposed to a Mg<sup>2+</sup>-free media, and at 1, 3, and 6 days post-exposure cultures were harvested for RNA isolation and analyzed by whole-cell patch-clamp studies. Epileptiform activity and seizure discharges were observed at all time points following Mg<sup>2+</sup>-free exposure. Molecular probes complementary to NMDA receptor subunits (NR2A, NR2B, and NR2C), AMPA/K<sub>A</sub> receptor subunit (GluR-A) and GABA<sub>A</sub> receptor subunits (GABA<sub>A</sub>-1-α and GABA<sub>A</sub>-2-α) were used to study mRNA expression. Furthermore, molecular probes complementary to γ-actin, c-fos, and ligand, a membrane bound protein, were also used to measure mRNA expression. At 24 hours post-treatment, GluR-A, GABA<sub>A</sub>-2-α, and ligand mRNA showed significant decreases of 46.3%, 20.4%, and 17.5%, respectively. γ-actin mRNA levels showed a significant decrease of 36.5% and 31.6% at 0.0 and 24 hours, respectively. At 3 and 6 days post-exposure, mRNA levels for GluR-A and GABA<sub>A</sub>-2-α remained significantly down. mRNA levels for NR2A, NR2B, NR2C, GABA<sub>A</sub>-1-α, and c-fos showed no significant changes following the Mg<sup>2+</sup>-free exposure. These findings demonstrate that Mg<sup>2+</sup>-free exposure results in selective long lasting changes in mRNA levels, and suggest that these enduring alterations in genetic expression may underlie the recurrent spontaneous seizure activity observed in this model.

## 576.2

**INDUCTION OF HYPEREXCITABILITY BY KNOCK-DOWN OF GABA-A-α2 RECEPTOR SUBUNIT IN CULTURED HIPPOCAMPAL NEURONS.** S. Sombati\*, L. Severt, E. Jakoi and R. DeLorenzo. Dept. of Neurology, Medical College of VA, VCU, Richmond, VA 23298.

Loss of GABA-mediated inhibition has been proposed to underlie seizure initiation and duration [Lothman, et al., Progress in Neurobiology 37(1):1-82, 1991]. Nonetheless, the regulatory role of the GABA receptor and its specific isoform in hyperexcitability remains unclear. We are interested in the possible role of the GABA-A-α2 receptor in neuronal hyperexcitability.

Neonatal hippocampal neurons were cultured at high density and used for experiments after 2 weeks in culture. Antisense strategy was employed by applying antisense oligodeoxynucleotides (1µM, ODN) daily for 3 days to the cultures. Control cultures (n=11 plates) were treated with matching missense oligodeoxynucleotides (n=9 plates). The effects of such treatments on neuronal excitability were examined using whole-cell voltage-clamp intracellular recordings. In normal bath solution (containing 1mM Mg<sup>2+</sup>) antisense-treated neurons exhibited long-duration epileptiform bursts (1-4sec) and each burst exhibited a large depolarization (30-45 mV) containing 10-20 spikes. "Seizure" activity of 3-10 Hz was often observed in the cultures. Both epileptiform burst and spike frequencies increased dramatically when Mg<sup>2+</sup> in the bath was lowered to .7 mM. Moreover, paired recordings revealed the activity to be synchronous. These effects were not observed in control neurons unless GABA receptor antagonist bicucullin was included in the bath.

The results indicate that selective down-regulation of GABA-A-α2 receptor subunits by gene knock-down techniques induced neuronal hyperexcitability and seizure discharge. Reduction of the GABA receptor through decreased genetic expression may be a mechanism underlying the generation and maintenance of seizure activity. Supported by NIH grant NS-23350.

## 576.3

**DECREASED EXPRESSION OF THE  $\alpha 5$  SUBUNIT OF THE GABA-A RECEPTOR IN A MODEL OF TEMPORAL LOBE EPILEPSY.** C.R. Houser<sup>\*1</sup>, M. Esclapez<sup>1</sup>, J.M. Fritschy<sup>2</sup>, and H. Mohler<sup>2</sup>. Brain Research Institute<sup>1</sup>, UCLA, Los Angeles, CA 90095, and Institute of Pharmacology<sup>2</sup>, University of Zurich, Zurich, Switzerland.

The presence of multiple GABA-A receptor subunit-subtypes raises the possibility that specific subtypes could be differentially regulated in disorders such as epilepsy. We have focused our initial studies on the expression of the  $\alpha 5$  subunit in the hippocampus of chronic pilocarpine-treated rats with recurrent seizures. In normal animals, immunoreactivity for the  $\alpha 5$  subunit is particularly strong in dendritic layers of CA1 and CA2; moderate levels of labeling are present in CA3; and very low levels of labeling are found in the dentate gyrus. However, in rats with recurrent seizures (3-4 months after pilocarpine injections), immunohistochemical labeling for the  $\alpha 5$  subunit is substantially decreased in CA1 and is virtually absent in CA2. Expression of  $\alpha 5$  mRNA is also significantly decreased in stratum pyramidale of CA1 and CA2. The decreases in receptor and mRNA labeling do not appear to be related to the loss of pyramidal neurons since these neurons are generally preserved in this model. No comparable changes in  $\alpha 1$  and  $\alpha 2$  subunits were detected. These findings indicate that the  $\alpha 5$  subunit of the GABA-A receptor is capable of substantial and prolonged alterations in an *in vivo* model of chronic epilepsy. Supported by NS29231 and NS21908.

**DEVELOPMENT OF RAPID HIPPOCAMPAL KINDLING: RELATION TO GAP-43 AND NEUROTROPHIN GENE EXPRESSION**

E. Elmér, M. Kokaia, J. Ferenec, Z. Kokaia and O. Lindvall<sup>\*</sup>  
Restorative Neurology Unit, Department of Neurology, University Hospital, S-221 85 Lund, Sweden.

In rapid kindling (RK), suprathreshold electrical stimulations every 5 min with low intratrain frequency lead to the development of severe limbic seizures within a few hours. The temporal evolution of the increased seizure susceptibility after RK is not known in detail. We have studied the development of excitability and explored a possible role of neurotrophins and other growth related factors after RK. Rats were given 40 electrical stimulations in the hippocampus according to the RK paradigm (400  $\mu$ A, 10 Hz, 1 ms square wave pulses for 10 s). To assess excitability, 5 test kindling stimulations were then performed with 5 min interval in separate groups at 6, 12 and 24 h, 5 days and 2 and 4 weeks after RK. We found increased seizure susceptibility already during the first 24 h but that the behavioral seizures in response to test stimulations became progressively more severe up to 4 weeks following RK. Neurotrophin and GAP-43 mRNA expression was analysed using *in situ* hybridization at 2 h up to 4 weeks after RK. BDNF mRNA levels were markedly increased at 2 h in the hippocampus (420% in dentate gyrus, 310% in CA1, 240% in CA3), piriform cortex (400%) and amygdala (200%), compared to non-stimulated controls. TrkB mRNA levels were also elevated at the same timepoint in the dentate gyrus (420%). Both BDNF and trkB mRNAs had returned to basal levels at 12h and no changes were detected at later time-points. Transient increases of GAP-43 mRNA levels were detected at 12 and 24 h after RK (410% in dentate gyrus, 175% in CA1, 160% in CA3, 170% in amygdala and 220% in piriform cortex at 24 h). We hypothesize that the first, acute phase of increased seizure susceptibility after cessation of RK stimulations might be related to modulation of glutamatergic synaptic transmission, possibly caused by alterations in BDNF levels, while the second, long-term phase of kindled state maintenance could be attributed to structural synaptic reorganization triggered by transient increases in BDNF, TrkB and GAP-43 expression.

## 576.7

**INDUCTION OF NF- $\kappa$ B IN RAT BRAIN FOLLOWING KAINIC ACID INDUCED SEIZURES AND LPS ADMINISTRATION.** A.V. Prasad<sup>\*</sup>, W.H. Pilcher and S.A. Joseph. Neurosurgery, Box 670, Univ. of Rochester Med. Ctr., Rochester, NY 14623.

Nuclear factor- $\kappa$ B (NF- $\kappa$ B) is a regulatory transcription factor controlling the expression of numerous genes including cytokines which are associated with cell death. We have previously shown that NF- $\kappa$ B is present in rat brain and its activation by metrazole induced seizures was via a nitric oxide signaling pathway. In these studies, we have extended the knowledge of NF- $\kappa$ B induction mechanisms in rat brain tissue following 1) kainic acid (KA) induced seizures in which correlates were made with the onset of neuronal cell death and 2) lipopolysaccharide (LPS), a bacterial endotoxin administered rats in a developmental study. In the first experiment, our results indicate that the induction of NF- $\kappa$ B preceded apparent cell death due to the seizures by several hours. In second experiment involving rat pups (Ages 3 - 38 days post partum), the DNA binding activity of NF- $\kappa$ B was analyzed in brain at 24 h post injections. The data revealed a high level of constitutive NF- $\kappa$ B until day 21 at which time the rats reach their sexual maturity and the density levels are inversely proportional to the increase in age until day 21. After day 21 the DNA binding activity could be induced by LPS. The data on NF- $\kappa$ B subunit proteins, p50 and p65 in both KA and LPS administered rat brains correlate to their corresponding DNA binding activities as determined by the western immunoblotting analysis. The apparent refractory age related mechanisms of transcription factor induction is further investigation. Supported by NIH grant NS21323.

## 576.4

**NMDAR1 mRNA SPLICED VARIANTS AT THE C-TERMINAL BUT NOT AT THE N-TERMINAL DOMAIN ARE ALTERED IN THE KINDLED HIPPOCAMPUS.** A. Vezzani<sup>1\*</sup>, C. Speciale, F. Della Vedova, M. Tamburin and L. Benatti. Istituto di Ricerche Farmacologiche Mario Negri, Milano, Pharmacia R&D CNS, 20014 Nerviano, Italy.

A lasting enhancement of the NMDA receptor function has been suggested to play a significant role in the chronic hyperexcitability of the hippocampus after kindling epileptogenesis. We have investigated whether hippocampal kindling induces alterations in the expression of NMDAR1(NR1) splice variants, at exon5 which confers different sensitivity to polyamine, and exon21 which encodes a 37-amino acid insert containing the major phosphorylation sites for PKC. One week after stage 5 of kindling in rats, the relative abundance of two alternatively spliced forms at the C-terminal domain, respectively containing (+) or lacking (-) exon21, was reversed compared to controls, in the dorsal hippocampus ipsilateral and contralateral to the electrical stimulation (exon21<sup>+</sup>/exon21<sup>-</sup> mRNA ratio, mean $\pm$ SE, controls, 1.3 $\pm$ 0.04; kindled ipsi, 0.64 $\pm$ 0.05, p<0.05; kindled contra, 0.48 $\pm$ 0.07, p<0.01). Similar bilateral effects were observed in the ventral hippocampus (temporal pole). No changes were found after induction of a single afterdischarge. No significant alterations were induced by kindling in the relative abundance of the spliced variants containing or lacking exon5.

Our findings show selective and lasting changes in the alternative splicing of the NR1 gene after repeated application of an epileptogenic stimulus. This may generate receptors with different functional properties possibly underlying the increased sensitivity to NMDA observed in kindled animals.

## 576.6

**C-FOS MAPPING AFTER HYPERBARIC OXYGEN SEIZURES: COMPARISON WITH PENTYLENETETRAZOLE AND MAXIMAL ELECTROSHOCK SEIZURES.** C.R. Auer<sup>\*</sup>, S.T. Ahlers, W. Koller, D. Glerup. Naval Medical Research Institute, Bethesda, MD 20889-5607.

Exposure to hyperbaric oxygen (HBO) causes seizures by an unknown mechanism. To help identify the brain structures involved we mapped c-fos protein distribution in rat brains after HBO seizures and compared it to the distribution seen after seizures induced by either pentylene tetrazole (PTZ) or maximal electroshock (MES). We also characterized the motor activity seen in HBO seizures compared with PTZ and MES seizures. Seizures were elicited in 21 male, Long-Evans, hooded rats by exposure to either HBO (100% O<sub>2</sub>, 6 ATA, N=6), PTZ (50 mg/kg ip, N=8) or MES (ear clips, 99 mA, 100 Hz, 1 s, N=7). Rats were anesthetized and perfused fixed and their brains removed either 1, 2, or 3 h post-seizure. Brain sections were prepared and stained immunohistochemically for c-fos activity using the ABC technique (Oncogene polyclonal primary antibody, Vectastain kits). Behaviorally, HBO motor seizures were characterized primarily by facial/forelimb clonus, "kangaroo" rearing postures, and occasional generalized clonic activity; running/bouncing was never observed. PTZ seizures were similar to HBO seizures, except several rats exhibited running/bouncing activity. MES seizures were tonic extensor followed by limb clonus. HBO seizures induced c-fos staining in more cerebral structures than either PTZ or MES seizures, most prominently in hippocampus, entorhinal cortex, pyriform cortex, amygdala, olfactory bulbs, and other cortex. Staining was prominent at 1 h, peaked at 2 h, and was nearly absent by 3 h post-seizure. PTZ seizures induced c-fos staining most prominently in pyriform and entorhinal cortex; staining peaked at 2 h, but was generally less intense than HBO at 1 h and more intense than HBO at 3 h. Following MES seizures the most prominent staining was at 1 h in hippocampus, entorhinal cortex, and ventromedial hypothalamus; less so in amygdala, olfactory bulbs, and pyriform cortex. Staining was decreased at 2 h and nearly absent by 3 h. Behaviorally, HBO seizures were more similar to PTZ seizures than MES seizures and can be categorized as "limbic". The pattern of c-fos labeling of rat brains following HBO seizures is anatomically and temporally distinct from patterns seen after PTZ or MES seizures. (Support: NIMHDC WU 62233N 343P30.004-1519)

## 576.8

**PLATELET-ACTIVATING FACTOR IS A MESSENGER IN KAINATE EPILEPTOGENESIS-ENHANCED MITOGEN ACTIVATED PROTEIN KINASE ACTIVITY IN HIPPOCAMPUS.** P. Mukherje, M. A. DeCoster, and N. G. Bazan<sup>\*</sup>. LSU Medical Center, Neuroscience Center, New Orleans, LA 70112-2234.

Cellular kinases such as mitogen activated protein (MAP) kinase serve as transducers of both normal and pathological second messenger signalling. In the present study we investigated the activity of MAP kinase in both *in vivo* and *in vitro* models of kainic acid (KA)-induced epileptogenesis and neuronal injury. *In vivo*, treatment of rats by intraperitoneal injection of 10mg/kg body weight of KA caused an induction of MAP kinase activity in hippocampus starting at 4 hours, with maximal activity detected at 3 days, and persisting to 7 days posttreatment. This induction was also found to occur in primary cultures of rat hippocampal neurons, with 100  $\mu$ M KA treatment for 45 minutes leading to a 3-4 fold increase in activity. Because of the involvement of the potent lipid activator platelet-activating factor (PAF) in both epileptic and ischemic brain injury, we evaluated the role of PAF as a mediator in KA-induced MAP kinase activation. In hippocampal neurons it was found that PAF (100 nM) increased MAP kinase activity 3-fold. This increase in activity was inhibited by 65-70% when the cultures were pretreated 45 minutes with the intracellular PAF antagonist BN 50730 (100 nM). We found that BN 50730 (1  $\mu$ M) was also effective in inhibiting MAP kinase activity stimulated by 100  $\mu$ M KA treatment of the hippocampal neurons. This response to KA may include the early signalling events of cell death, since using the release of lactate dehydrogenase as a marker, we found that 100  $\mu$ M KA treatment resulted in significant cell loss (150% of controls) one day after KA addition. These results indicate that PAF may be a mediator in early signalling events following epileptogenesis and neurotrauma, specifically, at the level of cellular kinase activity (Supported by NS 23002).

# Kainic Acid Induced Seizures Reduces Inositol 1,4,5-Trisphosphate 3-Kinase mRNA Expression in Rat Dentate Gyrus

Hyun Kim\*, Im-Joo Rhyu, \*Yong-Sik Kim, Seung-Hoon Han, Chang-Mi Kim and Young-Suk Suh

Department of Anatomy, Korea University College of Medicine; \*Department of Psychiatry, Seoul National University College of Medicine, Seoul, Korea

It has been reported that convulsion increases phosphatidylinositol 4,5-bisphosphate breakdown and inositol 1,4,5-trisphosphate(IP<sub>3</sub>) accumulation. To understand further the role of convulsion in IP<sub>3</sub> metabolism, it seems reasonable to investigate the effect of convulsion on the expression of IP<sub>3</sub>-kinase, which mediates turnover of IP<sub>3</sub> to inositol 1,3,4,5-tetrakisphosphate. In the present study we demonstrate the effect of kainic acid(KA) induced seizures on the expression of IP<sub>3</sub> kinase gene using *in situ* hybridization histochemistry. The pattern of expression of IP<sub>3</sub>-kinase mRNA was not changed until 2 h after KA injection. However, at 3 h after KA injection, clear reduction in the expression of the mRNA was observed in the dentate gyrus of hippocampus. At 6 h after injection, IP<sub>3</sub>-kinase mRNA level in the dentate gyrus was returned to basal level. We could not detect any apparent changes in the expression of IP<sub>3</sub>-kinase mRNA in the CA1-CA3 areas of hippocampus, the striatum, and the cerebral cortex at any time point examined. In the temporal pattern, the reduction of the expression in the dentate gyrus was preceded by the induction of *c-fos* after KA induced seizures. These observations suggest that the IP<sub>3</sub>-kinase might be one of the genes whose expression can be altered by KA induced seizures.

## 576.11

# NEURONAL AND ASTROCYTIC CONNEXIN mRNA EXPRESSION IN TETANUS TOXIN INDUCED EPILEPTOGENICITY. K. Elisevich\*, S. Rempel, S. Dodd, K. Ellis, B. Smith, K. Hirst. Epilepsy Research Unit, Henry Ford Hospital, Detroit, MI, 48202.

The mRNA of two connexins, Cx32 in neurons and Cx43 in astrocytes, was studied by Northern blot following injection of tetanus toxin (2-4 µg; 3 MLD<sub>50</sub>) into the basolateral nucleus of the amygdala. Animals were monitored electrographically at weekly intervals with electrodes implanted in both amygdalae. Cohorts of 3 animals were sacrificed at week 1, 2, 3, 4, 6, 8 and 10 following injection and the region of the right and left amygdala was collected, frozen and later pooled for Northern blot. Generation of spiking electrographically was manifest in all animals during the first 4 weeks followed by variable attenuation and cessation by 10 weeks. Regression analysis was performed for each connexin with pairing of left (injected)-right values. Over the first 4 weeks, Cx32 mRNA expression showed a significant ( $p < 0.05$ ) increasing trend in both left and right amygdalae. Astrocytic Cx43 mRNA showed a significant ( $p < 0.05$ ) increasing trend for the left amygdala and a nonsignificant decreasing trend for the right. There was a tendency for both Cx32 and Cx43 mRNA expression to plateau or return to baseline beyond 4 weeks. Injection of tetanus toxin significantly ( $p < 0.05$ ) diminished Cx32 and Cx43 mRNA expression when compared to implantation of the electrode alone in the left amygdala. This effect diminished beyond the 4 week point with decline in expression for the noninjected cohort. Regression analysis for Cx32 and Cx43 mRNA expression in the left amygdala in the injected animals however showed no significant trends whatsoever.

These findings provide no convincing evidence of a correlation between Cx32 and Cx43 mRNA expression and the development of epileptogenicity using low titres of tetanus toxin injected into the amygdala. (Supported by the Epilepsy Foundation of America)

# INCREASED EMOTIONALITY AFTER AMYGDALA KINDLING IN RATS MAY BE RELATED TO RECEPTOR REGULATION I. GABA<sub>A</sub> AND BENZODIAZEPINES. L.E. Kalynchuk\*, J.C. McEachern, K.N. Barr, J.P.J. Pinel, & C.A. Shaw. Depts. of Psychology, Physiology and Ophthalmology, Univ. of British Columbia, Vancouver, B.C., V6T 1Z4.

We have previously reported that amygdala kindling in rats results in increased emotional behavior, which depends on both the site of stimulation (Pinel et al., this meeting) and the number of kindling stimulations (Kalynchuk et al., 1995). However, the physiological correlates of this emotionality have not been identified. In this experiment, we investigated the relation between long-term amygdala kindling, emotional behavior, and GABA<sub>A</sub> and BZ receptor plasticity. Bipolar electrodes were implanted in the basolateral amygdala of 15 male, Long-Evans rats. The rats then received either 99 convulsive (kindled,  $n=10$ ) or sham (control,  $n=5$ ) stimulations. One day after its last stimulation, each rat was first tested on an elevated-plus maze, then placed in an open field, and finally scored for its resistance to capture from the open field. The next day the rats were killed and their brains immediately frozen. GABA<sub>A</sub> and BZ receptors were detected by <sup>3</sup>H-SR 95531 and <sup>3</sup>H-flunitrazepam binding respectively. These ligands were then visualized by autoradiography and the differences in binding in several brain regions were quantified. The kindled rats engaged in more escape behavior from the elevated-plus maze and were more resistant to capture from the open field than the control rats were. They also had more GABA<sub>A</sub> and BZ ligand binding in the dentate gyrus and less ligand binding in the cortex compared to the control rats. These results suggest that long-term amygdala kindling results in a site-specific regulation of inhibitory receptors. This pattern of receptor regulation may contribute to the increased emotionality in these rats and may be important in understanding the behavioral disturbances often experienced by temporal lobe epileptics. (supported by NSERC grants to J.P.J.P. & C.A.S. and by M.R.C. scholarships to L.E.K. & J.C.M.)

## 576.10

# EFFECT OF NMDA RECEPTOR ANTAGONIST ON AUDIOGENIC SEIZURE AND SEIZURE INDUCED *c-fos* mRNA EXPRESSION OF MATURE RATS AFTER NEONATAL EXPOSURE TO PROPYLTHIOURACIL (PTU). N. Ishida, T. Nishimura, H. Kanai, A. Higashiyama, M. Sadamatsu, N. Kato\*, Y. Kuroda, and B.S., McEwen. Dept. of Psychiat. Shiga Univ. Med. Sci. Otsu, 520-21, Japan. Lab. of Neuroendocrinol., Rockefeller Univ., New York, NY 10021-6399.

Mature PTU rats, which exposed to 0.02% PTU through the mother's milk at 0 to 19 post natal days, show running fits followed by generalized tonic-clonic seizure (GTCS) by acoustic stimulation. Kato et al. reported the specific expression of *c-fos* mRNA after GTCS in PTU rats (Soc. Neurosci. Abst. 20:406, 1994). It has been reported that NMDA receptors contribute to audiogenic seizure responses in genetically epilepsy prone rats. We used *in situ* hybridization for *c-fos* mRNA determination in the brain of PTU rats and the effect of NMDA receptor antagonist on audiogenic seizure and *c-fos* mRNA expression were examined. NMDA receptor antagonist, dizocilpine at a dose of 0.01, 0.05 and 0.5 mg/kg were administered intraperitoneally to 35 PTU rats 30 min prior to acoustic stimulation. Control rats received vehicle before acoustic stimulation. Dizocilpine inhibited audiogenic seizure of PTU rats in a dose-dependent manner. There was a significant difference of *c-fos* mRNA expression after acoustic stimulation between PTU rats and control rats in septal nucl., bed nucl., dorsomedial hypothalamic nucl., arcuate nucl., central gray, superior colliculus, peripuncular nucl. and inferior colliculus (IC). In IC, a marked *c-fos* mRNA expression was observed in the external nucl. and not in the central nucl. When high dose of dizocilpine was applied, PTU rats showed neither behavioral GTCS nor expression of *c-fos* mRNA in external nucl. of IC. These results suggested that NMDA receptors in IC contribute to the audiogenic seizure in PTU rats.

## 576.12

# INDUCTION OF AP-1 DNA-BINDING ACTIVITY IN THE RAT HIPPOCAMPUS FOLLOWING AMYGDALA KINDLED SEIZURES. K. Kashihara, K. Sato, K. Akiyama, T. Ishihara<sup>1</sup> & T. Shomori.<sup>1</sup> Department of Neurology & Neuropsychiatry, Okayama University Medical School, Okayama 700, <sup>2</sup>Clinical Research Institute, National Sanatorium Minamiokayama Hospital, Okayama 701-03, Japan.

In order to elucidate the role of transcription factor in the plastic changes in the central nervous system associated with the development of kindling, we determined the temporal pattern of AP-1 induction and its component proteins in the rat hippocampus following kindled seizures. Male Sprague-Dawley rats had once daily electrical stimulations from the left amygdala. After reaching stage 5 (Racine) generalized seizures, rats were decapitated 0, 30min, 1, 2, 4, 8, 24 hr after the final seizure. The hippocampi were dissected, and nuclear protein extracts were prepared. AP-1 DNA-binding activities were determined by using gel-mobility shift assay with <sup>32</sup>P-labeled AP-1 probe. In order to determine the component proteins raised against AP-1, antibodies for Fos and Jun family proteins were added to supershift the DNA-protein complex. Autoradiogram of the specific AP-1 bands revealed that AP-1 DNA-binding activity was enhanced, peaked at 2hr after the seizure and returned to the control level within 24 hr. Supershift analysis revealed that Jun B plus JunD and c-Fos were the main component proteins for seizure-induced AP-1. AP-1 may be involved in the development of long-lasting seizure susceptibility associated with kindling.

## 576.14

# INCREASED EMOTIONALITY AFTER AMYGDALA KINDLING IN RATS MAY BE RELATED TO RECEPTOR REGULATION II. AMPA, KAINATE, AND ACETYLCHOLINE. J.C. McEachern, L.E. Kalynchuk, H.C. Fibiger\*, J.P.J. Pinel, & C.A. Shaw. Depts. of Psychology, Physiology, and Neuroscience, U.B.C., Vancouver, B.C., V6T 1Z4.

We have previously reported that long-term amygdala kindling in rats results in increased emotional behavior. However, the potential contribution of excitatory receptor regulation to the development of this emotionality has not been studied. In this experiment, we investigated the relation between long-term amygdala kindling, emotional behavior, and AMPA, KA, and ACH receptor plasticity. Bipolar electrodes were implanted in the basolateral amygdala of 15 male, Long-Evans rats. The rats then received either 99 convulsive (kindled,  $n=10$ ) or sham (control,  $n=5$ ) stimulations. One day after its last stimulation, each rat was first tested on an elevated-plus maze, then placed in an open field and finally scored for its resistance to capture from the open field. The next day the rats were killed and their brains immediately frozen. The AMPA, KA, and ACH receptors were detected by <sup>3</sup>H-CNQX, <sup>3</sup>H-KA, and <sup>3</sup>H-QNB binding respectively. They were then visualized by autoradiography and the resulting film quantified using a densitometer. The kindled rats engaged in more escape behavior from the elevated-plus maze and were more resistant to capture from the open field than the control rats were. They also had less CNQX binding in hippocampal CA1, dentate gyrus, and amygdala, and less KA binding in hippocampal CA3 compared to the control rats. QNB binding was lower in hippocampal CA1 and higher in the dentate gyrus and cortex relative to controls. These findings, combined with our report of increased inhibitory ligand binding (Kalynchuk et al., this meeting), suggest that a reciprocal regulation of inhibitory and excitatory receptors occurs after long-term amygdala kindling. This pattern of receptor regulation may be related to the permanent kindled state and to the increased emotionality and defensiveness in these rats.

## 576.15

ANTICONVULSANT ACTION OF THE STRYCHNINE-SENSITIVE GLYCINE SITE IN THE NUCLEUS RETICULARIS PONTIS ORALIS. S.L. Peterson\*. Department of Medical Pharmacology and Toxicology, Texas A&M University Health Science Center, College Station, Texas 77843.

Previous studies in this laboratory have demonstrated that local microinfusion of the strychnine-insensitive glycine site partial agonist D-cycloserine into the n. reticularis pontis oralis (RPO) inhibits the tonic hindlimb extension (THE) component of maximal electroshock (MES). The purpose of the present study was to characterize further the role of the strychnine-insensitive glycine site in the RPO in inhibiting THE.

Bilateral RPO microinfusion of 100 nmol D-cycloserine inhibited THE in all rats tested. 100 nmol L-cycloserine had no effect on THE. RPO microinfusion of the agonists glycine and D-serine (1-100 nmol) had no effect on THE. RPO microinfusion of the antagonist 5,7-dichlorokynurenic acid (1-20 nmol) significantly reduced the incidence of THE. Neither the partial agonists (+)HA-966 and ACPC (50-200 nmol) nor strychnine (1-20 nmol) altered the MES response.

These results support a hypothesis for subtypes of the strychnine-insensitive glycine site and indicate that antagonist activity at that site regulates anticonvulsant mechanisms in the RPO. (Supported by NIH grant 32626)

## 576.16

THE RELATION OF THE [<sup>3</sup>H]  $\gamma$ -HYDROXYBUTYRIC ACID BINDING SITE TO THE GABA<sub>A</sub> RECEPTOR. O. Carter Snead III\* Div. Neurol. Childrens Hospital Los Angeles, Dept. Neurol. Univ. Southern California, Sch. Med. Los Angeles, CA 90027

$\gamma$ -Hydroxybutyric acid (GHB) is a naturally occurring compound which has the ability to induce generalized absence seizures when given to animals. GHB has been hypothesized to induce this effect via the postsynaptic GABA<sub>A</sub> receptor (Bernasconi et al, J Neur. Trans. 1992;35(Suppl):155). We sought to test this hypothesis by examining the affinity of GABA<sub>A</sub> agonists and antagonists for the [<sup>3</sup>H]GHB binding site, the affinity of GHB and a GHB antagonist for the [<sup>3</sup>H]GABA<sub>A</sub> binding site, and the effect of guanylate nucleotides and pertussis toxin on both, using autoradiographic binding assays.

GHB and its antagonist, NCS 382, did not compete for [<sup>3</sup>H]GABA<sub>A</sub> binding; nor did (-) baclofen or the [<sup>3</sup>H]GABA<sub>A</sub> antagonists, CGP 35348 or SCH 50911, compete for [<sup>3</sup>H]GHB binding; however, the [<sup>3</sup>H]GABA<sub>A</sub> antagonists phaclofen and 2-OH saclofen did show an affinity for [<sup>3</sup>H]GHB binding in frontal cortex with an IC<sub>50</sub> of 300 mM and 400 mM respectively.

Guanylate nucleotides and pertussis toxin depressed [<sup>3</sup>H]GABA<sub>A</sub> binding throughout the brain, attenuated [<sup>3</sup>H]GHB binding only in frontal cortex and thalamus, those regions involved in GHB-induced absence seizures, and reversed the affinity of phaclofen and 2-OH saclofen for [<sup>3</sup>H]GHB binding.

These data raise the possibility that the [<sup>3</sup>H]GHB binding site may be an important part of the presynaptic GABA<sub>A</sub> receptor.

## 576.16

IN VIVO ANTICONVULSANT MODULATION OF SEIZURE-INDUCED CHANGES IN HIPPOCAMPAL GABA AND GLUTAMATE LEVELS. H.L. Rowley, K.F. Martin<sup>1</sup>, J. Rabii\* and C.A. Marsden Department of Physiology and Pharmacology, Queen's Medical Centre, Nottingham, NG7 2UH and <sup>1</sup>Knoll Pharmaceuticals Research Department, Nottingham, NG2 3AA U.K.

We have previously used the maximal electroshock (MES) model to demonstrate generalised seizure-induced functional changes in GABA and glutamate (GLU) levels *in vivo* (Rowley et al., Br. J. Pharmacol. in press, 1995). Here we report the effects of pre-treatment with phenytoin or sodium valproate (Na-VPA), on these changes.

A concentric microdialysis probe was implanted into the ventral hippocampus of male, Lister hooded rats (250-350g), under Equithesin anaesthesia. 24 hr later, basal samples (5 min collections), were collected prior to MES administration via ear-clip electrodes to conscious animals. Stimulus parameters were 200V for 2 sec which induced tonic hind-limb extensions (HLE). Amino acids were analysed by HPLC with EC detection (Rowley et al., J. Neurosci. Meth., 57, 93-99, 1995).

In saline-treated controls (n=6) following MES, there was a significant (p<0.001; ANOVA) immediate increase in basal GABA (0.21 ± 0.01 pmol/20µl) and GLU (0.58 ± 0.02 pmol) levels of 112 ± 28% and 30 ± 8% respectively. Subsequently, GABA levels were reduced to 0.11 ± 0.01 pmol for the remainder of the experiment whereas GLU levels were reduced to 0.52 ± 0.02 pmol over the next 15 min period before a transient increase at 20 min post-ictally. Phenytoin (20mg/kg i.p.), 60 min prior to MES, prevented HLE (n=6) and attenuated the immediate increase in GLU levels by 46 ± 9% (p<0.01). No effects were observed on GABA release or on the secondary increase in glutamate. Na-VPA (400mg/kg i.p.), also prevented HLE (n=6) and increased basal GABA levels to 0.31 ± 0.01 pmol (p<0.01). Following MES, the initial increase in GABA and GLU was unaffected but the secondary changes in both amino acids were prevented.

These results suggest that phenytoin is an effective anticonvulsant in this model by preventing the stimulated release of GLU, whereas Na-VPA is effective by enhancing GABA-mediated inhibition. This work was supported by BBSRC and Knoll Pharmaceuticals.

## BETA-AMYLOID: NEUROPATHOLOGY I

## 577.1

EXPRESSION OF AMYLOID PRECURSOR PROTEIN IN SUBSTANTIA NIGRA AFTER A UNILATERAL 6-HYDROXYDOPAMINE LESION IN RATS. M. Eriksdotter-Jönhagen\*, R. Cowburn, L. Holmberg, B. Wiehager, E. Sundström, Dept. Clinical Neuroscience and Family Medicine, Division of Geriatric Medicine, Huddinge Hospital, 141 86 Huddinge, Sweden.

The  $\beta$ -amyloid peptide forms part of four precursor polypeptides constituting the amyloid precursor protein (APP). APP may play a role in Alzheimer's disease and other neurodegenerative processes. Changes in APP expression have been reported following a number of experimental lesioning paradigms. However, the role of APP in degenerative and regenerative processes remains unclear. To further investigate the role of APP we have used the morphologically and pharmacologically well characterized unilateral 6-hydroxydopamine lesion model to study APP expression in a defined subset of neurons within the substantia nigra (SN). APP-immunoreactivity was determined using the monoclonal antibody 22C11. This antibody recognized the same full length APP isoforms in control and lesioned animals as determined by Western blotting. Two days after the lesion, an increased APP-immunoreactivity was seen in a small number of neurons in the medial, ventral part of the ipsilateral SN while many more neurons in this area were swollen and showed increased tyrosine hydroxylase (TH)-immunoreactivity. After 13 days there was no difference in APP expression between lesioned and non-lesioned sides but with time a decreasing number of TH-immunoreactive neurons was found throughout the SN on the lesioned side. After a 6-hydroxydopamine lesion, it appears that changes in APP-immunoreactivity occur in a small subpopulation of SN neurons. These changes are transient, as compared to the permanent changes in TH-immunoreactivity.

## 577.2

SOLUBLE A $\beta$  OLIGOMERS IN NORMAL AND ALZHEIMER DISEASE BRAINS. Y.-M. Kuo,<sup>1</sup> M.R. Emmerling<sup>2\*</sup>, C. Vigo-Pelfrey<sup>3</sup>, T.C. Kasunic<sup>1</sup>, J.B. Kirkpatrick<sup>4</sup>, M.J. Ball<sup>5</sup> & A.E. Roher<sup>1</sup> <sup>1</sup>Department of Anatomy and Cell Biology, Wayne State University School of Medicine, Detroit, MI 48201; <sup>2</sup>Parke Davis, Ann Arbor, MI 48106; <sup>3</sup>Athena Neurosciences, Inc., South San Francisco, CA 94080; <sup>4</sup>Department of Pathology, Baylor College of Medicine, Houston, TX 77030; <sup>5</sup>Departments of Pathology and Neurology, Oregon Health Sciences University, Portland, OR 97201.

Water soluble oligomers of A $\beta$  N-40 and N-42 present in normal and Alzheimer disease (AD) cerebral cortex were quantified by a sensitive sandwich ELISA. The soluble peptides were isolated from brain homogenates by ultracentrifugation (220,000 and 435,000 g) and by graded membrane filtration (<10, 10-30, 30-100, >100 kDa). Our results indicated a continuous distribution of soluble monomers and oligomers of A $\beta$ . AD brains contained 6 times more soluble A $\beta$  oligomers than control brains. Most of the soluble A $\beta$  peptides in AD brains were of the N-42 type, which on average amounted to 12 times the values observed in control brains. The amount of insoluble A $\beta$  in the cerebral cortex of AD patients was about 100 times more than that found in control brains. Interestingly, the quantity of A $\beta$  N-42 measured in AD cortex was about 50 times greater than that present in the CSF of AD patients, using the same ELISA technique. This disparity may result from the integrity of the physical barriers separating the two extracellular spaces. Our data implicates the increased pool of soluble oligomeric A $\beta$  in the pathogenesis of AD, since this fraction is toxic to some cells in culture. In addition, soluble A $\beta$  has been found capable of generating cation channels in membranes *in vitro*, thus, providing a potential mechanism for cellular injury in AD.

CLEARANCE OF AMYLOID BETA-PEPTIDE FROM CEREBROSPINAL FLUID AND BRAIN. <sup>1</sup>N. Strazielle, <sup>2</sup>J.-F. Ghersi-Egna, <sup>3</sup>J. Ghiso, <sup>4</sup>M. P. Dehouck, <sup>5</sup>C. Patlak, <sup>6</sup>B. Frangione, <sup>7</sup>P. Gorevic, and <sup>8</sup>J. Fenstermacher. <sup>1</sup>Depts. Medicine and <sup>2</sup>Surgery, SUNY Stony Brook, NY 11794; <sup>3</sup>INSERM U325 and Institut Pasteur, Lille, France; <sup>4</sup>Dept. Pathology, NYU, New York, NY 10016, and <sup>5</sup>Dept. Anesthesiology, Henry Ford Hosp., Detroit, MI 48202.

Soluble forms of amyloid beta-peptide (sA $\beta$ ) are normal metabolites of amyloid precursor protein (APP) and are found at very low concentrations in normal cerebrospinal fluid (CSF) and plasma and in extracts of Alzheimer's disease (AD) brain but are not detectable in control, amyloid-free brain. Insoluble forms of A $\beta$  are the major peptide fragments of senile plaques and cerebrovascular amyloid deposits in AD. The distribution of the predominant sA $\beta$  in CSF, sA $\beta_{1-40}$ , was studied in the CSF-brain-blood system: 1) *in vivo* by stereotactically infusing 1.0  $\mu$ l of CSF containing <sup>125</sup>I-sA $\beta_{1-40}$  at physiological concentration into one lateral ventricle of the rat for 60 sec and 2) *in vitro* by introducing <sup>125</sup>I-sA $\beta_{1-40}$  on either side of a coculture model of the blood-brain barrier (BBB) consisting of a monolayer of bovine brain capillary endothelial cells grown on a collagen-coated filter in the presence of glial cells. <sup>14</sup>C-PEG 4000 was used as an inert compound of similar molecular weight as sA $\beta_{1-40}$ . The autoradiographic and gel electrophoretic data from the *in vivo* study indicated that sA $\beta_{1-40}$ : 1) was more rapidly cleared from CSF and brain than PEG; 2) penetrated less into brain tissue than PEG; and 3) was significantly bound to larger CSF proteins. The flux of sA $\beta_{1-40}$  in both directions across the *in vitro* BBB model was about 40% larger than that of PEG and was not altered when sA $\beta_{1-40}$  concentration was raised from 30 nM to 1.8  $\mu$ M. *In vitro* the larger flux across the BBB of sA $\beta_{1-40}$  vis-a-vis PEG may be related to its greater lipid solubility and transcellular diffusion and not to a specific transporter for sA $\beta_{1-40}$ , whereas *in vivo* the rapid clearance of sA $\beta_{1-40}$  from CSF and brain may involve some BBB transporter for CSF protein-sA $\beta_{1-40}$  complexes.

CARBOXYL- AND AMINO-TERMINAL PROPERTIES OF DEPOSITED A $\beta$  IN ALZHEIMER AND DOWN'S SYNDROME BRAINS.

Takeshi Iwatsubo\*, Takaomi C. Saido<sup>§</sup>, David M. Mann<sup>¶</sup>, Hiroaki Fukumoto<sup>¶</sup>, Asano Asami-Odaka\*, Nobuhiro Suzuki<sup>¶</sup>, Yasuo Ihara<sup>†</sup> Depts. of Neuropathol. and Neurosci.\*, Neuropathol. <sup>†</sup>, Univ. of Tokyo, Tokyo Metropol. Inst. of Med. Sci. <sup>§</sup>, Takeda Chemical Industries <sup>¶</sup>, Japan, Dept. of Pathol. Sci. <sup>¶</sup>, Univ. of Manchester, UK

To investigate the tissue distribution and chronological relationships in the deposition of A $\beta$  molecules with different carboxyl(C)- and amino(N)-termini, we examined by immunocytochemistry different morphological types of A $\beta$  deposits in Alzheimer's disease (AD) brains, and Down's syndrome (DS) brains over a wide range of ages. Consecutive sections from formalin-fixed paraffin-embedded frontal and cerebellar cortices of AD and DS brains were immunostained with the following A $\beta$  antibodies: BC05(A $\beta$  42(43)-specific), BA27 (A $\beta$  40), Ab9204(A $\beta$  L-Asp1), BAN50, BAN52(A $\beta$  1-16, L-Asp1,7>isoAsp), anti-A $\beta$  3pE (3pyroGlu), anti-A $\beta$  11pE (11pyroGlu), anti-p3N(17Leu). BC05 stained virtually all senile plaques (SP) of both diffuse (DP) and mature type. BA27 stained only a subset of SP, especially mature ones, and cerebral amyloid angiopathy (CAA). Amino-terminal A $\beta$  antibodies, especially Ab9204, preferentially immunolabeled mature SP and CAA in a similar pattern to BA27, suggesting that A $\beta$  1-40 is present in these A $\beta$  deposits. A $\beta$  3pE and 11pE were more widely distributed than A $\beta$  N1- and A $\beta$  40-immunoreactivities in mature SP, especially in core portions, as well as in a proportion of DP. Anti-p3N preferentially stained mature SP and CAA but few DP. Early DP in young DS brains, as well as cerebellar DP, were BC05-positive, but only occasionally positive for A $\beta$  N1, 3pE, 11pE and p3N, and not reactive with BA27. Mature SP in older DS brains acquired A $\beta$  N1, 3pE, 11pE, p3N and BA27 immunoreactivities. These results suggest that A $\beta$  species ending at the 42nd(43rd) residue, with N-terminus other than L-Asp1, initially accumulate in AD and DS brains; deposition of A $\beta$  species with truncated N-termini and A $\beta$  1-40 occurs at later stages of plaque evolution.

IN VIVO MODIFICATIONS OF  $\beta$ -AMYLOID PEPTIDE PROVIDING PROTECTION FROM MAJOR AMINOPEPTIDASES

T.C. Saido\*, T. Iwatsubo, H. Shimada, Y. Ihara, S. Kawashima, Department of Molecular Biology, Tokyo Metropolitan Institute of Medical Science; Faculty of Pharmaceutical Sciences, University of Tokyo; Department of Pathology, Tokyo Medical College; Institute for Brain Research, University of Tokyo, Tokyo, JAPAN.

Deposition of  $\beta$ -amyloid (A $\beta$ ) generating senile plaques in brain is critically involved in the development of Alzheimer's disease, making it essential to clarify the mechanism by which the A $\beta$  peptides form aggregates. One structural factor of A $\beta$  associated with depositability and thus with pathogenicity is a variation in the carboxyl terminal length, i.e. A $\beta$  40 versus A $\beta$  42, whereas information on the amino terminal heterogeneity is yet limited. To assess the possible pathological role of amino terminal modifications in plaque formation, we quantitated A $\beta$  species possessing normal L-aspartate, isoaspartate, D-aspartate, or pyroglutamate at the amino terminus, using anti-A $\beta$  antibodies that distinguish one from another. The majority of A $\beta$  extracted from brains with various degrees of senile plaque deposition possessed nonstandard amino-termini, the ratios of which to the standard L-aspartate form correlated with the ratio of A $\beta$  42 to A $\beta$  40, indicating that A $\beta$  peptides with modified amino termini were initially deposited. Because these modifications render A $\beta$  resistant to major aminopeptidases, our observation suggests that proteolysis of A $\beta$  from its amino terminus is a rate-limiting step in normal A $\beta$  catabolism.

IMMUNOLocalization OF RECEPTORS FOR THE GLOBULAR AND COLLAGEN REGION OF THE COMPLEMENT COMPONENT C1q IN ALZHEIMER DISEASE BRAIN. R. Veerhuis<sup>1</sup>, B. Ghebrehewet<sup>2</sup>, T.H. Hogan<sup>3\*</sup> and G.M. Pasinetti<sup>3</sup>. <sup>1</sup>Dept. of Pathology and Psychiatry, Free University, Amsterdam, The Netherlands; <sup>2</sup>Dept. of Medicine and Pathology, State University of New York, Stony Brook, NY 11794; <sup>3</sup>Division of Neurogerontology, Andrus Gerontology Center, USC, Los Angeles, CA 90089.

Activated complement (C) components are selectively associated with senile plaques in Alzheimer disease (AD) brain. The role of C components in the AD plaques is little understood and might be pertinent to the recruitment and activation of inflammatory cells. C1q, a subcomponent of C1, is found in complex with amyloid  $\beta$ -peptides (A $\beta$ ) of the AD plaques and there is evidence that A $\beta$  might control the activation state of C1. In this study we explored the presence of C1q receptors (C1qR) in temporal cortex specimens of AD (n=10) and non-demented age matched controls (n=4). We used polyclonal antisera specific for both the 60 kDa low affinity C1qR for the collagen region of C1q (cC1qR), and for the 33 kDa high affinity receptor for the globular heads of C1q (gC1qR) (Ghebrehewet et al, 1994). We found that in AD brains both the cC1qR and the gC1qR immunolocalized with neuritic A $\beta$  plaques, which are associated with activated microglia and dystrophic neurites. No C1qR's immunoreactivity was found in A $\beta$  plaques of the diffuse type in brains of non-demented controls. Intense immunostaining of both cC1qR and gC1qR was found in microglia of the white matter in both AD and non-demented control brains. The cellular immunolocalization of C1qR (c and g) in AD neuritic plaques is unresolved. These observations support a possible role for C1q in C mediated inflammatory responses in AD. Ongoing *in situ* hybridization studies will clarify the cell type expression of C1qR's in amyloid plaques at the mRNA level. Supported by the Nathan W. & Margaret T. Shock Aging Research Foundation to GMP.

## 577.8

THE AMYLOID BURDEN OF THE CEREBRAL CORTEX IN NON-DEMENTED OLD AGE. A. Guillozet<sup>1</sup>, J.F. Smiley<sup>1</sup>, D.C. Mash<sup>2</sup> and M.M. Mesulam<sup>1</sup>. <sup>1</sup>Northwestern University, Chicago, IL and <sup>2</sup>University of Miami School of Medicine, Miami, FL

The A $\beta$  amyloid burden in the cerebral cortex of patients with Alzheimer's disease and age-matched controls has usually been assessed by counting the number of neuropil plaques. Since plaques have widely different sizes, this approach may be misleading. We used computerized densitometry to calculate the proportional cortical area covered by immunocytochemically detected A $\beta$  in the cerebral cortex of non-demented elderly specimens. Cortical areas and laminae were delineated in matching sections stained with cresyl violet.

Major inter-individual differences were noted. All cortical areas in all specimens contained A $\beta$  deposits with microscopic features of neuropil plaques. In general, the amyloid burden (proportional area covered by A $\beta$ ) was lowest in primary motor cortex and in somatosensory koniocortex (<5%). The results were more variable in visual and auditory koniocortex where the amyloid burden ranged from <1% to 12%. In some specimens, the amyloid burden of paralimbic and association cortices (areas 24,19,21,22) reached levels that were regionally as high as 15-25%. Most cortical areas had distinct laminar patterns of A $\beta$  deposits. In general, layers I-IV contained a greater amyloid burden than the deeper cortical layers.

These results indicate that A $\beta$  deposits in non-demented elderly individuals may be very substantial. The regional and laminar variations in the distribution of these deposits may shed light on the nature of age-related changes of neural function and the differential regional vulnerabilities to Alzheimer's disease.

SELECTIVE ALTERATIONS OF AMYLOID PRECURSOR PROTEIN ISOFORM LEVELS IN HUMAN HEAD INJURY. K. Horsburgh\*, M. Roberts, J.A.R. Nicoll, D.I. Graham. Wellcome Surgical Institute and Department of Neuropathology\*, University of Glasgow, Glasgow, G61, U.K.

In experimental animal models, expression of amyloid precursor protein (APP) can be altered in response to various forms of injury. There is minimal information regarding APP in human brain following trauma despite the detection of  $\beta$ -amyloid deposition in at least 30% of head-injury cases. The present study sought to determine whether levels of APP are altered in human cortex following head injury.

Brain tissue from nine head-injury cases and eight cases without neurological disease were obtained post-mortem. APP levels were examined in the left and right superior temporal cortex using western immunoblot analysis with a monoclonal antibody to APP (clone 2C11). APP isoforms were visualised at 135, 130 and 120kDa and the relative levels of each APP was measured using an image analysis system. In the head injury group, levels of the 135kDa APP isoform were significantly reduced from control levels by at least 25% ( $P < 0.005$ ) in the cortex of both cerebral hemispheres. Similarly cortical levels of 130kDa APP isoform were reduced compared to control levels but these did not reach statistical significance. In contrast, the levels of the 120kDa APP isoform exhibited a trend towards an increase in head injury cortex compared to control levels. There was no relation between the levels of each APP isoform to post-mortem interval and age of the patients in the groups of post-mortem control or head injury brains. In the head injury group, the length of survival following the initial insult was not related to APP levels.

Thus, APP isoform levels are selectively altered in cortex after head injury. These alterations in APP may be pertinent to the pathology observed in post-mortem human head injury.

CARBOXYL TERMINAL  $\beta$ -AMYLOID DEPOSITS IN AGED HUMAN, CANINE, AND POLAR BEAR BRAINS. T. L. TEKIRIAN, G. M. COLE\*, M. J. RUSSELL, F. YANG\*, D. R. WEKSTEIN, E. PATEL, D. A. SNOWDON, W. R. MARKESBERY, J. W. GEDDES\*. Sanders-Brown Center on Aging, University of Kentucky, Lexington, Kentucky 40536; \*Geriatrics, Sepulveda VA Hospital, Sepulveda, CA 91343; †Anesthesiology, School of Medicine, University of California, Davis, CA 95616

C-terminal  $\beta$ -amyloid peptide residues A $\beta$ 40 and A $\beta$ 42 were immunocytochemically analyzed to compare plaque and cerebrovascular (CVA) deposits of aged animals with those observed in human brain. Aged beagle dogs (ages 14-17) solely acquire diffuse-type plaques and lack neurofibrillary tangles (NFTs). Aged polar bear brains (ages 35-36) contain diffuse plaques as well as PHF-1 positive NFTs. Diffuse plaques predominate in non-demented, elderly, individuals. Alzheimer's disease (AD) cases had both diffuse & mature (cored) neuritic plaques. In all cases, diffuse plaques were positively immunostained with anti-A $\beta$ 42 antibody. Anti-A $\beta$ 40 strongly immunolabeled CVA deposits in all species, however, some CVA was preferentially labeled with A $\beta$ 42. The shift from A $\beta$ 42 to A $\beta$ 40 was more rapid in CVA in contrast to the same transition in plaques. A $\beta$ 40 selectively stained a subset of mature AD plaques; A $\beta$ 40-positive immunostaining was not evident in any of the non-AD plaques. The aged dog, polar bear, as well as the human, displayed A $\beta$  deposition at the outer molecular layer of the dentate gyrus (DGOML). This region may be one of the earliest sites of A $\beta$  deposition. Plaque maturation appeared to correlate with subject age, starting as a diffuse cloud (aged dog), progressing to a more aggregated state (polar bear) and diffuse (non-demented human) vs extremely compacted plaques seen within the AD DGOML. These cross-species data indicate that A $\beta$  deposition in aged mammals is similar to the earliest stages observed in human brain.

## 577.13

AMYLOID PRECURSOR-LIKE PROTEIN 2 IS ASSOCIATED WITH SENILE PLAQUES IN ALZHEIMER'S DISEASE. M. T. Webster<sup>1</sup>, C. P. L. H., Chen<sup>2</sup>, P. T., Francis<sup>1</sup>, F. E. Sherriff<sup>1,2</sup>, R. C. A. Pearson<sup>1\*</sup>, D. M. Bowen<sup>1</sup>. Institute of Neurology, London<sup>1</sup>, Department of Neuropathology, Oxford University<sup>2</sup>, Department of Biomedical Science, University of Sheffield<sup>3</sup>, U.K.

Several antibodies, including the commercially available 22C11, raised against amyloid precursor protein (APP) epitopes fail to discriminate APP from amyloid precursor-like protein (APLP2). We have raised and characterised a novel monoclonal antibody (3B11) to a peptide sequence in APLP2 not present in APP (Webster *et al*, 1995, Biochemical Journal, *in press*). With this antibody, APLP2 was detected by Western blotting in rat and human brain, lumbar and ventricular cerebrospinal fluid, as well as lysate and conditioned media from cell lines including PC12, SH-SY-5Y and cortical and cerebellar granule cells. Using immunocytochemistry, strong labelling by 3B11 was found surrounding plaques in AD brain. The pattern of APLP2 labelling therefore resembles that of APP. More detailed studies in normal and AD brain are underway to verify this. In rat brain, preliminary studies of regional and cellular distribution of APLP2 and APP indicate differences, this was particularly apparent in the brainstem. Localisation of APLP2 is an important step towards understanding the relationship of this protein with APP and its relevance in AD pathogenesis.

## 577.10

$\beta$ -AMYLOID (A $\beta$ ) PEPTIDES IN DIVERSE NEURODEGENERATIVE DISEASES (ND), ALZHEIMER'S DISEASE (AD) AND AGED INDIVIDUALS. J. A. Schneider, M. Gearing, H. Mori, and S. S. Mirra\*, Dept. of Pathology and Laboratory Medicine, VA Medical Center & Emory University School of Medicine, Atlanta, GA 30322; Tokyo Institute of Psychiatry, Tokyo, Japan.

In AD, A $\beta$ 42 is the predominant species in senile plaques, thought to precede A $\beta$ 40 deposition (Iwatsubo, *et al*. Neuron 1994;13:45). We sought to determine whether a similar pattern of peptide deposition occurs in neocortical plaques in ND patients and elderly nondemented individuals. Since apolipoprotein E  $\epsilon$ 4 allele dosage is correlated with A $\beta$  deposition, we also investigated the influence of  $\epsilon$ 4 genotype on A $\beta$  peptide pattern. We examined 54 brains with neocortical A $\beta$  deposition: 32 cases of AD, 18 of diverse ND (progressive supranuclear palsy, Pick's disease, corticobasal degeneration, Parkinson's disease, and multisystem degeneration), and those of 4 elderly nondemented individuals. Nine of the 18 ND cases also met neuropathologic criteria for AD. Immunohistochemistry using C-terminal-specific antibodies revealed that, in virtually all cases, A $\beta$ 42-positive plaques outnumbered A $\beta$ 40-positive plaques. The ratio of A $\beta$ 40:A $\beta$ 42 plaques was 0.37 in AD and 0.40 in ND cases with coexistent AD pathology. In ND cases without coexistent AD, and in elderly nondemented individuals, however, this ratio dropped to 0.25 and 0.26, respectively. Interestingly, in AD cases and ND cases with coexistent AD pathology, the ratio of A $\beta$ 40:A $\beta$ 42 was higher in cases with an  $\epsilon$ 4 allele (0.42 vs. 0.27 in cases without an  $\epsilon$ 4 allele). Although a genotype effect was not observed in the 9 ND cases without AD and the 4 elderly individuals, the number of cases is small. Our results suggest that the pattern of A $\beta$ 40 and A $\beta$ 42 deposition in ND and elderly individuals is similar to that of AD; A $\beta$ 40-positive neocortical plaques are more frequent, however, in cases meeting neuropathologic criteria for AD. Furthermore, ApoE genotype may influence the proportion of plaques that are A $\beta$ 40-positive in AD. Supported by AG10130 and VA Merit Award.

## 577.12

DIFFERENTIAL PATTERN OF  $\beta$ -AMYLOID A4, AMYLOID PRECURSOR PROTEIN AND APOLIPOPROTEIN E DEPOSITION IN PLAQUES IN ALZHEIMER'S DISEASE. D. R. Thal<sup>1,2</sup>, A. Dietrich<sup>1</sup>, W. Härtig<sup>3</sup>, R. Schober<sup>1</sup>. Departments of Neuropathology, University of Leipzig, 04103 Leipzig. <sup>2</sup>Department of Neuropathology, University of Frankfurt a. M., 60528 Frankfurt a. M. <sup>3</sup>Department of Neurochemistry, University of Leipzig, 04109 Leipzig, Germany

In Alzheimer's disease  $\beta$ -amyloid A4 ( $\beta$ -A4), amyloid precursor protein (APP) and apolipoprotein E (Apo E) have been well demonstrated to be components of both senile plaques and blood vessels affected by amyloid angiopathy. Quantitative regional and stage dependent differences of  $\beta$ -A4, APP and/or Apo E positive plaques have been largely neglected so far, although they may be of pathological relevance. Therefore, we investigated 20 cases of Alzheimer's disease by semiquantitative immunohistochemistry. The cases were staged according to Braak and Braak (Acta Neuropathol. 82: 239-259; 1991). The density of  $\beta$ -A4 (DAKO, 6F/3D), amyloid precursor protein APP 695 (Boehringer, 22C11) and Apo E (Boehringer, 2E1) positive plaques was examined in the Ammon's horn, the entorhinal cortex, and the occipital and temporal isocortex. The results showed the highest frequency of  $\beta$ -A4 positive plaques in the entorhinal cortex and the temporal isocortex through all stages with increasing density in severe stages. In contrast, the frequency of APP and Apo E positive plaques was pronounced in sector CA 1. The occipital cortex showed a differential staining pattern similar to the temporal isocortex in that the number of  $\beta$ -A4 positive plaques was larger than the number of APP and Apo E positive plaques. This difference was seen throughout all stages investigated but was most pronounced in stages 3 and 4. In conclusion, the immunoreactivity of APP in plaques seems to be pronounced in the region CA 1 of the hippocampus. Possible explanations are either pathological inputs from the entorhinal cortex affect by neurofibrillary changes and / or stage dependent factors in plaque formation.

## 577.14

REACTIVE ASTROCYTES AND APP-IMMUNOREACTIVE DYSTROPHIC NEURITES ARE INDEPENDENTLY ASSOCIATED WITH AMYLOID PLAQUES. S. L. Weinstein\*, C. J. Pike, B. J. Cummings and C. W. Cotman. Institute for Brain Aging and Dementia, University of California, Irvine, CA 92717 USA

The fibrillar  $\beta$ -amyloid protein (A $\beta$ ) plaques of Alzheimer's disease (AD) are associated with reactive astrocytes and dystrophic neurites. Previously we reported that in hippocampal sections of AD brains, reactive astrocytes appear to colocalize with plaques during the relatively early stages of AD, and that this association may occur prior to and independent of the presence of PHF-1 immunoreactive dystrophic neurites. We also found plaque types associated with reactive astrocytes but not dystrophic neurites, and plaques associated with dystrophic neurites but not reactive astrocytes. To determine the generalizability of these trends, we extended our examination of cellular colocalization with plaques to include earlier markers of dystrophic neurites, additional brain regions, and Down's syndrome (DS) brains. Fifty  $\mu$ m sections of frontal cortex and hippocampus from 4 DS and 10 AD brains, ranging in neuropathology from mild to severe, were triple immunolabeled with antibodies recognizing A $\beta$ , reactive astrocytes (GFAP), and dystrophic neurites (PHF-1, APP). In agreement with our previous observations in AD hippocampus, we report the presence of plaques with the following immunoreactivities in DS and other AD brain regions: GFAP(+)/PHF(+), GFAP(-)/PHF(+), GFAP(+)/PHF(-). In addition, we report similar patterns using APP, a marker of earlier neuritic dystrophy than PHF-1. These data reveal that reactive astrocytes can associate with plaques in the absence of early stage dystrophic neurites, suggesting that plaque-associated reactive astrocytosis may occur in response to specific plaque components (e.g., A $\beta$ ) rather than solely in response to degenerating neurites.

## 577.15

**SOLUBLE AMYLOID BETA IN DOWN'S SYNDROME BRAINS.** J.K. Teller, C. Russo, L.M. DeBusk, D.M.A. Mann\*, M. Tabaton\*, and P. Gambetti. Division of Neuropathology, Institute of Pathology, Case Western Reserve University, Cleveland, OH 44106, U.S.A., \*Department of Pathological Sciences, University of Manchester, Manchester M13 9PT, U.K., and \*Institute of Anatomy, University of Genova, Genova, Italy.

We report a quantitative assessment of the presence of the soluble form of amyloid beta (A $\beta$ ) peptide in Down's syndrome (DS) and age-matched control brains. Soluble, buffer-extractable A $\beta$  (Tabaton et al., BBRC, 200, 1598-1603, 1994) has been detected in DS brains from individuals of ages ranging from 4 days to 61 years, that included cases lacking amyloid plaques. A $\beta$  peptides were detected in all DS cases regardless of age and plaque presence. The amount of free A $\beta$  increased exponentially concurrently with the appearance of amyloid plaques. In control individuals no soluble A $\beta$  could be detected by using our extraction procedure. The results suggest that soluble A $\beta$  is constitutively present at elevated concentration in DS brain many years before any deposits are detectable. A mechanism is likely to keep the level of soluble A $\beta$  sufficiently low to inhibit the formation of deposits before the critical age of plaque formation. Once plaques are formed the amount of extractable A $\beta$  rises exponentially, most probably representing a mixture of free and loosely bound, aggregated peptide. Supported by NIA grants AG0812, AGNS08155, AG08992, the Britton Fund, and grants from NATO and Telethon (E126).

## 577.17

**INDOMETHACIN REVERSES  $\beta$ -AMYLOID INDUCED GLIOSIS.** B.A. Tate\*, E. Netland and R.E. Majoie. Dept of Psychiatry and Human Behavior, Miriam Hospital and Brown University, Providence, RI 02906.

Oral indomethacin treatment has been shown to improve cognitive test performance in mild to moderately impaired Alzheimer's patients (Rogers et al., 1993), possibly through effects on glia or its anti-inflammatory actions. Neuropathological evaluations of rats receiving chronic intracranial infusion of  $\beta$ -amyloid peptide indicate gliosis and macrophage infiltration results from  $\beta$ -amyloid exposure. Therefore, the effects of indomethacin in this animal model were evaluated. Indomethacin (2.5 mg/ml in 2% DMSO) or vehicle was concurrently administered via intra-ventricular infusion into rats receiving  $\beta$ -amyloid or 5% glucose vehicle. In amyloid-infused animals, immunopositive amyloid deposits were found in cortical and hippocampal tissue adjacent to the ventricles. Double immunostaining procedures demonstrated co-localization of  $\beta$ -amyloid deposits and GFAP positive cells. Indomethacin treatment dramatically reduced GFAP staining, but not amyloid staining. Therefore, centrally administered indomethacin can reduce  $\beta$ -amyloid induced gliosis.

## 577.19

**BAP LEVELS DECREASE IN THE CSF FOLLOWING CHOLINERGIC LESIONING OF THE FIMBRIA FORNIX.** D.M. Tummolo, A.B. Brown, J.S. Jacobsen, K. Rhodes, J. Sonnenberg-Reines\*. Department of Central Nervous System Biological Research, Wyeth-Ayerst Res, A Division of American Home Products Corporation, Pearl River, N.Y. 10965.

Haroutunian has shown that infusions into the nucleus basalis of Meynert with N-methyl-D-aspartate induced cholinergic deficits (Brain Res., 1989 487:200-203) and amyloid precursor protein (APP) expression in the cortex of the rat (Mol Brain Res., 1991 10: 173) and that this induction results in the constant release of APP into the cerebrospinal fluid (CSF). Increased levels of soluble APP were also present in the CSF collected from lesioned aged rats relative to sham operated controls or lesioned younger rats. (Neurosci. Abstract, 1994, # 435.11).

In the current series of experiments we made bilateral fornix lesions in rabbits (N=8) by transecting the fornix bilaterally using a Scouten wire knife. After 24-96 hours of survival, operated animals and unoperated controls were sacrificed by pentobarbital overdose. The CSF was immediately collected and the brains removed, dissected and rapidly frozen on dry ice. In CSF the levels of BAP were measured by ELISA and Western analysis, and PNII by Western analysis. One hemisphere from each animal was cut into 25  $\mu$ m horizontal sections and processed histochemically for visualization of AChE and immunocytochemically for visualization of APP metabolites. The other hemisphere was used to measure APP, BAP and C-terminal fragment levels by Western analysis and immunoprecipitation. We found, a transient increase in soluble APP levels in the CSF, while BAP levels decrease. When hippocampus or frontal cortex tissue was analyzed by Western analysis or immunoprecipitation techniques the levels of BAP or APP were unaffected by lesioning. Immunocytochemistry of tissue samples reveals similar results.

The development of a cholinergic animal model may provide a convenient means to assess the utility of novel therapeutic strategies designed to slow the rate of the progression of AD.

**SOLUBLE AMYLOID BETA IN FETAL BRAINS WITH TRISOMY 21.** M. Tabaton, G. Angelini\*, C. Russo\*, D. Zaccheo, F. Dagna\*, P. Scartezzini\*, J.K. Teller\*, P. Gambetti\*. (SPON: Society of Neuroscientists of Africa) Institute of Anatomy, University of Genova, \*Advanced Biotechnology Center, and \*Hospital Galliera, Genova, Italy, and \*Division of Neuropathology, Case Western Reserve University, Cleveland, OH 44106.

Soluble amyloid beta peptide (sA $\beta$ ) has been detected in brain tissue from Alzheimer's disease (AD) and Down's syndrome subjects. The same form of sA $\beta$  is normally undetectable in the brain from healthy subjects. Therefore, abnormal accumulation of sA $\beta$  might be a primary event in amyloidogenesis. We analyzed sA $\beta$  in fetal brains from trisomy 21 cases (20-22 week-old), and in control fetal brains with trisomies 13 and 18, and in cases without chromosomal abnormalities. sA $\beta$  was immunoprecipitated from cerebral cortex extracts with an anti-A $\beta$  antiserum, electrophoresed, Western-blotted, and detected with anti-A $\beta$  monoclonal antibodies. Two sA $\beta$  peptides were detected with 6E10 antibody (anti-A $\beta$  1-17) in five out of nine trisomy 21 brains, and none in the control cases. The peptides identical to sA $\beta$  peptides extracted from AD brains. There was no difference in A $\beta$  precursor protein mRNA between trisomy 21 brains positive or negative for sA $\beta$ . The findings indicate that sA $\beta$  accumulates very early in brains of individuals with trisomy 21, most likely due to the presence of an additional copy of the A $\beta$  precursor gene. Supported by NIA grants AG0812, AGNS08155, AG08992, the Britton Fund, and grants from NATO and Telethon (E126).

## 577.18

**ANALYSES OF AMYLOID  $\beta$  PROTEIN SPECIES IN AD BRAINS BY ELISA** A. Tamaoka\*(1), T. Kondo(2), N. Sawamura(1), A. Odaka(3), N. Suzuki(3), N. Sahara(2), K. Ozawa(2), S. Shoji(1), and H. Mori(2). Department of Neurology, University of Tsukuba, Tsukuba, Ibaraki 305(1); Department of Molecular Biology, Tokyo Institute for Psychiatry, Setagaya, Tokyo 156(2); Discovery Research Division, Takeda Chemical Industries, Ltd., Tsukuba, Ibaraki 300-42, Japan(3).

Alzheimer's disease (AD) is characterized by the accumulation of amyloid  $\beta$  protein (A $\beta$ ) in senile plaques and amyloid angiopathy. The production of A $\beta$  from its precursor protein (APP) is known to be a physiological reaction from the finding of soluble A $\beta$  in cerebrospinal fluids as well as cell culture media. Since amyloid deposition is believed to be insoluble and highly specific in AD etiology, a pathogenic reaction could occur leading to conversion of A $\beta$  from a soluble form to an insoluble one. To clarify the mechanism involved in such pathogenic conversion of A $\beta$ , we measured the amounts of total A $\beta$ , A $\beta$ 1-40 and A $\beta$ 1-42/43 in brain cortices of patients with sporadic AD using the ELISA systems, which could differentiate two types of A $\beta$ (A $\beta$ 1-40 and A $\beta$ 1-42/43), and found that the amounts of insoluble A $\beta$ 1-42/43 and A $\beta$ 1-40 were linearly related to the total amount of A $\beta$  deposits at their lower and higher concentrations, respectively. We also performed 5 consecutive washes of the insoluble precipitates of AD brains with buffered saline. Both species of A $\beta$  were found in all 5 supernatant fractions and their amounts were gradually decreased. The ratio of A $\beta$ 1-42/43 to A $\beta$ 1-40 was increased with the number of washes, indicating that A $\beta$ 1-40 existed in an exposed manner as compared to A $\beta$ 1-42/43. These findings taken together with the hypothesis that A $\beta$ 1-42/43 functions as a "seed" that increases the kinetics of amyloid fibril formation, we conclude that A $\beta$ 1-42/43 is the predominant species of initial amyloid formation, A $\beta$ 1-40 mainly associated with amyloid deposits in their growth phases.

## 578.1

## APP on the surface of cultured rat cortical neurons.

E. Storey<sup>†</sup>, M. Katz<sup>†</sup>, K. Beyreuther<sup>#</sup>, C.L. Masters<sup>†</sup>.<sup>†</sup> Department of Pathology, The University of Melbourne, Parkville, Australia 3052; and <sup>#</sup> Center for Molecular Biology, University of Heidelberg, Heidelberg, Germany.

We have previously shown that APP is co-localized with markers of adhesion patches on neurites, but is not present on the surface of growth cones. These results are at first sight surprising in view of the reported short half-life of APP in PC12 cells (20-30 min). Here we provide further evidence that the APP in these segments is actually on the neurite surface, and that the half-life of this surface pool is considerably longer than that of the general cellular pool. Segmentally-distributed APP can be visualised on the surface of unfixed neurons immunostained at 4°C in the presence of azide. Enzymatic treatment of unfixed neurons with calpain 1 substantially removed these segments as judged by immunofluorescence. Confocal laser microscopy shows the segments to be hollow. Metabolic labelling followed by surface biotinylation and two-stage precipitation shows that the labelled, biotinylated pool has a half-life of 3.5-5.5 hours, and is susceptible to surface trypsinization. Other labelled but non-biotinylated APP species are not susceptible to such digestion, and presumably represent the intracellular pool. The reason for the surface pool's stability is unclear: it is not C-terminally truncated (*i.e.* does not lack the clathrin recognition sequence), and does not seem to consist predominantly of Kunitz protease inhibitor-containing isoforms of APP.

## 578.3

IMMUNOCHEMICAL STUDY OF AD BRAIN USING MONOCLONAL ANTIBODY AGAINST APP717 SITE. N. Nukina<sup>\*</sup>, K. Keiko, I. Kanazawa

Department of Neurology, University of Tokyo, Tokyo, Japan 113  
The amyloid core in senile plaques of Alzheimer's disease is composed of beta protein. Recent discovery of familial Alzheimer's diseases which are linked to APP mutations suggests that the beta protein accumulation is a primary pathology. It is important to clarify how the processing of APP in those cases with the mutation is different from the processing in other cases. To determine whether APP717 site accumulates in amyloid plaques, we raised monoclonal antibodies against the synthetic peptides around APP717.

Monoclonal antibody was raised against APP712-719 with mutation (Val/Ile) or without mutation. Antibodies were screened by ELISA with the synthetic peptide used for antigen and synthetic peptide APP715-723. We obtained several monoclonal antibodies which react with both peptide, suggesting that those antibodies react with APP715-719. One of the antibody called APP63-21 was used in this study.

Tris Saline insoluble fraction were examined by ECL western blot kit (Amersham) using the antibody. The antibody reacts with APP C terminal fragments. Immunoreaction was relatively stronger in AD samples than in normal samples. The result was compatible with the previous study showing increased APP C terminal immunoreactivity in ADs. This antibody also stained senile plaques, suggesting that APP accumulating in senile plaque includes APP717 site.

## 578.5

HIGH-RESOLUTION IMAGING OF A $\beta$  ATTACHMENT TO NERVE CELL SURFACES AND DOWNSTREAM CYTOARCHITECTURAL CONSEQUENCES. W.L. Klein<sup>\*</sup>, Barber, K., Bodovitz, S., Stevens, G., Kraft, G., MacDonald, R., and Mala, R. Dept. Neurobiol. & Physiol., Northwestern University, Evanston, IL

Amyloid  $\beta$  proteins in their aggregated state trigger deterioration of SH-SY5Y human neuroblastoma cells (Lambert et al, 1994, J. Neurosci. Res. 39:377). Deterioration is differentiation-dependent, as retinoic acid-induced cells die, but their proliferating precursors are unscathed. Cell death correlates with an evoked upregulation of FAK Tyr(P) (Zhang et al, 1994, J. Biol. Chem. 269:25247). FAK is an unusual protein tyrosine kinase coupled by integrins and other cell surface receptors to cytoskeletal regulation. The current study of SH-SY5Y cells was designed to obtain high resolution images of the cytoskeletal-surface membrane-A $\beta$  relationship and its response to differentiation. Cells were exposed to A $\beta$  1-42 aggregates and examined by whole mount transmission electron microscopy (WMTM; Tsui et al, 1983, PNAS 80:5779); because it omits embedding and sectioning, WMTM concomitantly provides high contrast images of extracellular, cell surface, and intracellular compartments, making it highly suited to the current work. Association of aggregates with the cell surface was clearly evident in both differentiated and undifferentiated cells, but a local degenerative response occurred only in differentiated cells. Aggregates comprised structurally heterogeneous forms, including flocculant and fibrillar subtypes. The subtype associated with cell surfaces was clearly fibrillar. Surfaces of differentiated neurites stretched out upon the fibrils, which appeared to meld with the cell surface, making it difficult to discern where the aggregate stopped and the cell began. At points of contact, surface integrity was weakened, membranous organelles were less abundant, and microfilaments were withdrawn. Experiments are in progress to monitor cytoskeletal responses in real time using confocal microscopy. To simplify sampling, we have developed cationic liposomes as a new means to deliver specific probes to the interiors of living cells.

## 578.2

THE DEVELOPMENTAL EXPRESSION OF THE BETA-AMYLOID PRECURSOR PROTEIN IN RAT BRAIN: A PRELIMINARY REPORT. C. Nall, D.K. Lahiri, K. Sambamurti<sup>#</sup>, M. Zaphiriou and J.I. Numburger<sup>\*</sup>. Lab. of Molecular Neurogenetics, Institute of Psychiatric Research, Indiana Univ. Sch. of Med., 791 Union Drive Indianapolis, IN 46202 and <sup>#</sup>Dept. of Pathology, Univ. of Texas Health Sci. Cent., Houston, TX-77030

Alzheimer's disease (AD) is characterized by depositions of amyloid  $\beta$ -protein (A $\beta$ ) in the brain in the form of extracellular plaques and cerebrovascular amyloid. A $\beta$  is derived from a family of large  $\beta$ -amyloid precursor proteins (BAPP) which are integral membrane glycoproteins. To understand the biological function we examined the protein expression profile during the early stages of rat development. We extended this study to understand the effects of genetic predisposition to alcoholism on the expression and processing of BAPP. For this study, we compared the gel patterns of BAPP immunoreactive proteins between alcohol-preferring (P) and non-alcohol-preferring (NP) rats.

Rat brains from 7 different age groups (4d, 7d, 14d, 21d, 36d, 43d and 78d) were divided into the following four sections: cerebral hemispheres, cerebellum, brain stem and olfactory bulb. Extracts from each region were subjected to western blotting with mAb22C11 which detected proteins in the range of 110-140 kDa normally observed for BAPP and BAPP-like proteins. The levels of BAPP in all regions of the brain, except the olfactory bulb, were significantly higher in earlier days (7d) than in the other days studied. The levels in the olfactory bulb were lower than other areas and remained constant throughout the development. No significant differences were observed between the levels of BAPP expression in extracts from P- vs. NP-rats. Our preliminary results suggest that BAPP expression is high during early development of rats and may therefore play a significant role during this period. Supported by a N.I.H. grant R01 AG10297 to D.K. Lahiri.

## 578.4

AMYLOID  $\beta$  AND AMYLOID ASSOCIATED PROTEINS ARE INVOLVED IN RIMMED VACUOLES IN CHLOROQUINE-INDUCED MYOPATHY.K. Tsuzuki<sup>1</sup>, R. Fukatsu<sup>2</sup>, Y. Takamaru<sup>3</sup>, T. Yoshida<sup>4</sup>, K. Kobayashi<sup>1</sup>, N. Fujii<sup>1</sup>, and N. Takahata<sup>2</sup>. <sup>1</sup>Dept. of Microbiology, <sup>2</sup>Dept. of Neuropsychiatry, Sapporo Med. Univ. Sch. of Med., <sup>3</sup>Sapporo Municipal General Hospital, <sup>4</sup>Dept. of Pediatrics, Hokkaido Univ. Sch. of Med., Sapporo 060, Japan.

Deposition of amyloid is the pathological characteristic in Alzheimer's disease (AD). Amyloids are known to be composed of amyloid  $\beta$  (A $\beta$ ) and a variety of additional proteins, designated as amyloid associated proteins, which are considered to play an important role in A $\beta$  deposition or amyloid formation. To the present, their significance in the pathogenesis of AD remains unclear. Recently, we demonstrated immunohistochemical evidence that A $\beta$  and cathepsin D accumulate in vacuolated muscle fibers in chloroquine-induced myopathy in rats.

In this study, we examine immunopathologically whether or not A $\beta$ , N-, C-terminals of amyloid precursor protein (APP), a number of amyloid associated proteins, apolipoprotein E (apoE), SP-40,40,  $\alpha_1$ -antichymotrypsin ( $\alpha_1$ -ACT), and ubiquitin immunoreactivities are present in rimmed vacuoles (RVs) of affected muscle in experimental chloroquine myopathy. Denervated soleus muscle from rats 14 days after chloroquine treatment, were studied. By day 14, RVs were most notable. Transverse serial paraffin sections obtained from affected soleus muscle, were stained using the standard streptavidin-biotin peroxidase technique. Immunopathological studies demonstrated that the A $\beta$ , N-, C- terminal of APP, apoE, SP-40,40,  $\alpha_1$ -ACT, ubiquitin, and cathepsin D were present in the RVs.

Further studies are needed to understand the significance of amyloid associated proteins in the formation of RVs in this chloroquine myopathy. This in turn could provide a useful model for insight into the mechanism underlying the expression and regulation of amyloid associated proteins, in addition to APP in the amyloidogenesis and pathogenesis of AD.

## 578.6

INTRACELLULAR LOCALIZATION OF  $\beta$  AMYLOID PRECURSOR PROTEIN IMMUNOREACTIVITY. A. Dranovsky<sup>1</sup>, S. Lyubsky<sup>2</sup>, D. Goldgaber<sup>2</sup>.M.S.T.P. Program, Depts. of <sup>1</sup>Psychiatry and <sup>2</sup>Pathology, School of Medicine, State Univ. of New York at Stony Brook, Stony Brook, NY 11794.

$\beta$  amyloid precursor protein (APP) has been implicated in cytoskeletal abnormalities associated with neuronal degeneration of Alzheimer's Disease. Although APP is also present in cells of nonneuronal origin, its intracellular function has not been elucidated. Intracellular immuno-localization of APP was investigated by confocal immunofluorescence microscopy on human epithelial (Hep-2) cells. A fibrillar, intermediate filament like, distribution of APP was observed with antibodies (Ab) to synthetic peptides corresponding to the C and N termini of APP but not with preadsorbed controls. Dual label laser confocal microscopy demonstrated colocalization of APP immunoreactivity with vimentin immunoreactivity, partial colocalization with keratin, and a slight overlap with tubulin. Differences between APP C and APP N immunoreactivities were observed.

## 579.1

ENGRAFTMENT OF P19 CELLS OVER EXPRESSING hAPP751 INTO RAT ENTORHINAL CORTEX. S.M. Grant\*, M. Szyf, A.C. Cuello, Dept. of Pharmacology & Therapeutics, McGill University, Montreal, Quebec, Canada, H3G 1Y6.

The aim of this work is to investigate the effect of focal over expression of APP751 on an area of cortex known to be affected early in the evolution of Alzheimer's disease-type pathology in patients with Down's syndrome or Alzheimer's disease. The mouse embryonal carcinoma cell line P19, which is capable of terminal differentiation to a CNS phenotype, was transfected with the full cDNA for the human amyloid precursor protein (APP) 751 isoform. Several stable clones were isolated and verified by Southern blotting. Western analysis of cell lysates and conditioned medium confirmed the over expression of APP and production of the amyloid peptide. For grafting, APP-expressing cells or control (neo<sup>+</sup>vector-only) cells were placed stereotactically into the right entorhinal cortex of mature Sprague Dawley rats. The rats were maintained under cyclosporin A 10 mg/kg immunosuppression for various survival times. After perfusion with 4% paraformaldehyde in 0.1M phosphate buffer, pH 7.4, the brains were post-fixed and cryoprotected, then processed for immunocytochemistry and Nissl stained to localize the graft and to reveal epitopes of interest. Work is ongoing to analyse integration of the grafted cells into the host cortex and to examine host brain responses and the potential for amyloid deposition. In addition to their use in grafting studies, it is expected that these clones will yield information on the interaction between aberrant APP expression, cell differentiation and viability of different lineages. This work is supported by the Alzheimer Society of Canada and the MRC of Canada.

THIAMINE DEFICIENCY LEADS TO NOVEL PLAQUE-LIKE ACCUMULATIONS OF AMYLOID PRECURSOR PROTEIN-LIKE IMMUNOREACTIVITY IN DAMAGED BRAIN REGIONS. N.Y. Calingasan\*, S.E. Gandy\*, H. Baker\*, K.F. R. Sheu\*, J.D. Smith\*, J.L. Breslow\*, B.T. Lamb\*, J.D. Gearhart\*, D.J. Selkoe\*, D.L. Price\*, S.S. Sisodia\* and G.E. Gibson\*. <sup>1</sup>Cornell Univ. Med. Coll. at Burke Med. Res. Inst., White Plains, NY 10605; <sup>2</sup>Cornell Univ. Med. Coll., New York, NY 10021; <sup>3</sup>Rockefeller Univ., New York, NY 10021; <sup>4</sup>Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205; <sup>5</sup>Brigham and Women's Hospital, Boston, MA 02115.

Experimental thiamine deficiency (TD) is a classical model of a nutritional deficit associated with a generalized impairment of oxidative metabolism and selective cell loss in the brain. In rats, TD-induced cell degeneration is associated with accumulation of amyloid precursor protein (APP)-like immunoreactivity in swollen, abnormal neurites and perikarya. Prompted by these data and our previous findings of a genetic variation in the development of the symptoms of TD, we extended our studies to mice. C57BL/6, ApoE knockout and APP YAC transgenic mice received thiamine-deficient diet *ad libitum* and daily injections of the thiamine antagonist pyridoxamine. Immunocytochemistry employed antiserum against human APP<sup>645-694</sup>. Eleven days of TD produced pathological lesions in the thalamus, mamillary body and inferior colliculus. Unlike rats, APP-like immunoreactive neurites in all strains of mice were sparsely scattered and did not delimit the thalamic lesions. In addition, abnormal clusters of intensely immunoreactive materials occurred only in areas of cell damage. These clusters appeared as either "rosettes" or clumps with an unstained central core. While these clusters strikingly resembled Alzheimer amyloid plaques morphologically, immunostaining using an antiserum to synthetic A $\beta_{1-40}$  and thioflavine S histochemistry failed to show positive reactivity. These clusters were not observed in thiamine-deficient rats. Our results demonstrate species differences in the response to central nervous system injury. Although the relevance of these clusters to TD-induced neurodegeneration is still unclear, this is the first report that chronic oxidative deficits can lead to this novel pathology. (Supported by Grant MH48325)

## 579.5

EXPRESSION OF HUMAN APP770 IN RATS DISRUPTS PLACE, BUT NOT CUE OR MOTOR, MEMORY. D.P. Binsack\*, M. Montoya-Zavala\*, and C.A. Marotta\*, Depts. of Psychiatry and Human Behavior<sup>1,3</sup> and Neuroscience<sup>2</sup>, Brown University, Providence, R.I. 02912; and Alteon, Inc.<sup>2</sup>, Ramsey, NJ 07446.

The most common symptom of Alzheimer's Disease (AD) is memory loss, however the relationship between the clinical disorder and the accumulation of extracellular senile plaques containing beta amyloid is unclear. To examine this issue transgenic rats were made and examined behaviorally. A metallothionein promoter linked to the human APP 770 cDNA followed by an SV40 late poly(A) region was used. A pUC19 vector was used as a backbone for this construct. The construct was microinjected into fertilized embryos from a Sprague-Dawley rat. The embryos were placed into a foster mother and allowed to come to term. After birth and weaning, DNA was isolated from a tail biopsy and the presence of the transgene was confirmed via PCR in the F2 generation. Male rats (6-8 m/o), [APP<sup>+</sup>: n = 10; controls: n = 15], were trained in a multi-component water maze task in which each rat served as its own control. The task simultaneously assessed long-term (LT) and short-term (ST) place memory, cue memory and motor memory. Amyloid rats exhibited severe deficits in LT and ST place memory but not in cue or motor memory. Further, the deficits were not attributable to visual, attentional, or motivational factors. Preliminary neuropathological examinations suggest that widespread accumulation of plaques were not a prerequisite for the observed specific behavioral disruption.

## 579.2

CANINE LEPTOMENINGEAL ORGAN CULTURE: A MODEL FOR STUDYING THE PATHOGENESIS OF  $\beta$ -AMYLOID FORMATION. G. Pavlakovic\*, D. D'Urso, R. Frank, I. Prikulis and R. Prior, Dept. of Neurology, University of Dusseldorf, D-40225 Dusseldorf, Germany

Cerebral amyloid angiopathy (CAA) is characterized by the deposition of amyloid  $\beta$  protein (A $\beta$ ) in the cortical and leptomeningeal vessel walls. CAA is the major cause of non-hypertensive cerebral hemorrhage in the elderly and is a neuropathological feature of Alzheimer's disease and Down's syndrome. It is likely that common pathogenetic factors promote A $\beta$  deposition in the cortical senile plaques of Alzheimer's disease and in the vascular amyloid. Since dogs are one of the few species which develop age-associated A $\beta$  deposits in the cerebral vasculature, we attempted to use old dog leptomeninges as a model for  $\beta$ -amyloid formation. Leptomeninges were dissected from euthanized old dogs and kept in culture up to 8 weeks. Histological evaluation of paraffin sections showed good tissue preservation with a high number of leptomeningeal arterioles which are the vessel type primarily affected by CAA. Viability of the leptomeningeal vessels was demonstrated by staining with fluorescein diacetate and propidium iodide. Immunofluorescence microscopy of leptomeningeal cryosections stained with antibodies against A $\beta$ , amyloid precursor protein (APP), apolipoprotein E, smooth muscle actin and fibronectin, demonstrated the presence of all these antigens in the leptomeningeal vessel walls even after 4 weeks of culture. Immunoprecipitation of metabolically (<sup>35</sup>S-Methionin) labeled APP showed that the cultured leptomeninges continue to produce different isoforms of full-length APP, which may represent a source of A $\beta$  needed for the development of cerebrovascular amyloid. Hence, the canine leptomeningeal organ culture may be a suitable model to study A $\beta$  deposition and  $\beta$ -amyloid formation. (Supported by DFG)

## 579.4

Establishment of APP-targeted mice with a humanized A $\beta$  sequence and the Swedish FAD mutations. A.G. Reaume, S.P. Trusko, D.S. Howland\*, D.M. Lang and R.W. Scott, Cephalon, Inc., 145 Brandywine Pk, West Chester, PA 19380.

To create an animal model for examining the role of human A $\beta$  in the development of AD-related neuropathology we have utilized a gene-targeting approach to humanize the mouse A $\beta$  gene sequence and simultaneously introduce the K670N/M671L mutations linked to familial AD (FAD) in a Swedish kindred. This was accomplished by site-specific mutagenesis of exon 16 of the mouse APP gene using a gene replacement strategy in embryonic stem cells. The positive selection marker, PGKneo, used to enrich for homologous recombinants was excised from intron 15 of the APP-targeted allele in ES cells by means of a site-specific recombination system. Mouse lines carrying the APP-targeted locus in which the neo selectable marker was (neo-) and was not (neo+) removed have been established. In mice created by this strategy, normal processing of mouse APP should result in production of human A $\beta$  in the absence of mouse A $\beta$ . Spatial and temporal patterns of A $\beta$  production are expected to be normal. Furthermore, incorporation of the Swedish FAD mutations should enhance A $\beta$  production while APP levels remain normal. This will eliminate potential complication of APP overexpression associated with conventional APP transgenic approaches on the development of any AD-related neuropathologies. Expression of humanized APP has been verified in the mutant ES cells and mouse lines using antisera specific for the humanized APP domain. An accompanying abstract (Howland et al.) describes the characterization of APP processing and A $\beta$  production in the APP-targeted mice.

## 579.6

DOPAMINE RECEPTOR AUTORADIOGRAPHY IN TRANSGENIC MOUSE MODELS OF ALZHEIMER'S DISEASE. M.D. Roberson, C.A. Singer, A. Horita\*, R.C. LeBoeuf, K. Fukuchi, D.M. Dorsa and A.S. Unis, Dept. of Psychiatry & Beh. Sci., Box 356560, Univ. of Washington, Seattle, WA 98195-6560.

Disruption of dopaminergic neuronal pathways in Alzheimer's disease (AD) has been proposed and is supported by clinical observations of psychotic symptoms early in the course of the illness. Since the degenerative processes seen in AD are hypothesized to result from the toxic effects of accumulated  $\beta$ -amyloid (A $\beta$ ), mitigated or worsened by apolipoprotein E (ApoE) isoforms, we examined dopamine receptors using tissue slice autoradiography in two C57BL/6 transgenic mouse strains in which either A $\beta$  or ApoE expression was modified. In the first strain, A $\beta$  was over-expressed using a construct containing amino- and carboxy- regions of the amyloid precursor protein (APP) linked to the chicken  $\beta$  actin promoter. In the second strain, ApoE expression was knocked out using gene targeting to replace the endogenous gene with a dysfunctional construct. Receptor autoradiography was conducted using <sup>125</sup>I-labeled antagonists for D<sub>1</sub>-like (SCH 23382) and D<sub>2</sub>-like receptors (epidepride) in frozen brain sections from the striatum and hippocampus.

Preliminary analysis of relative optical density of autoradiograms derived from brain sections revealed strain-specific alterations in striatal dopamine receptor antagonist binding. Specifically, <sup>125</sup>I-SCH 23382 specific binding was elevated (137% of the control C57BL/6 mouse strain) in the caudate-putamen (CPu) of the A $\beta$  overexpressor strain while no change was observed in the ApoE knockout strain. In contrast, <sup>125</sup>I-epidepride specific binding was significantly reduced (to 25% of controls) in the CPu of the ApoE knockout strain with no differences observed in the A $\beta$  overexpressor strain. Experiments are underway to better characterize these strain-related differences in binding. Nevertheless, these data suggest that altered expression of A $\beta$  or ApoE, two major constituents of the neuritic plaques seen in AD, may contribute to the disruption of dopaminergic neuronal systems.

## 579.7

**Herpes virus-mediated transfer of genetic components implicated in Alzheimer's Disease into the mouse brain.** M.E. Fotaki, R.J. Pink, G. Huber\*, J. Mous. Pharmaceutical Research, F. Hoffmann-La Roche Ltd., CH-4002 Basel, Switzerland.

Our goal is to study the phenotypic response of neuronal cells of the normal or transgenic murine brain after introduction of genes involved in Alzheimer's disease such as mutant forms of the amyloid precursor protein gene (APP) and the  $\epsilon 4$  allele of the apolipoprotein E gene (ApoE4). For these gene transfer experiments we used an amplicon type expression vector, pHerpes-L, which carries the  $\beta$ -galactosidase reporter gene under the control of SV40 promoter and can be packaged into Herpes viral particles in the presence of replication deficient helper virus.

Two mutated forms of the APP have been cloned into pHerpes-L amplicon under the CMV promoter, creating: 1) pHLAD37 with the APP695 gene carrying a single mutation (Val642 to Ile) and 2) pHLAD40 with the same gene with a double mutation (Lys595 to Asn and Met596 to Leu). Expression from these constructs has been confirmed by Western blot of transiently transformed Vero derived cells. The ApoE cDNA has been cloned from a human liver cDNA library and the mutation generating the  $\epsilon 4$  allele has been introduced.

Injections of the mouse brain with 5  $\mu$ l of the HLAD40 viral stock in the hippocampus region showed no gross tissue damage in the injection site although immunostaining detected increased number of astrocytes and microglia as a result of the injection. Under the conditions used only limited number of cells were infected with the amplicon vector and currently we are working on improving the viral stock to obtain higher efficiency of gene transfer.

## 579.9

**SEX-DEPENDENT COGNITIVE IMPAIRMENTS IN TRANSGENIC MICE THAT OVEREXPRESS THE CARBOXY-TERMINAL FRAGMENT OF THE AMYLOID PRECURSOR PEPTIDE (APP-C100)** J. Arters, D. McPhie, R.L. Neve\* and J. Berger-Sweeney\* Dept. Biological Sciences, Wellesley College, Wellesley, MA 02181 and \*Mailman Research Center, McLean Hospital, Belmont, MA 02178.

The cause of the degeneration of neurons in Alzheimer's disease (AD) is not fully understood. We hypothesize that abnormal processing of amyloid precursor peptide (APP) results in the generation of a carboxy-terminal peptide fragment (C-100) which is responsible for the characteristic neurodegeneration and subsequent cognitive impairments in AD patients. The current study examined the effects of overexpression of this C-100 fragment on cognitive function in mice. Three lines of C-100 transgenic mice (C57BL/6J x SJL/J hybrids) were generated using the dystrophin brain promoter. At one year of age, 44 transgenics and non-transgenic littermates were tested on cued, spatial and reversal tasks in the Morris swim maze. The most consistent finding in the three lines was that transgenic females exhibited a severe impairment on the reversal task as compared to transgenic males and controls; while transgenic males performed either equal to, or better than, controls. In one transgenic line, the transgenic females also exhibited a slight cued, and a more pronounced spatial deficit with respect to transgenic males and controls. Furthermore, there were no significant differences among the groups in locomotor activity or swim speed which could account for the impaired performance of the transgenic females. These results suggest that overexpression of C-100 differentially affects cognitive performance in the two sexes. Interestingly, gender differences in cognitive performance have also been noted in patients with AD.

## 579.8

**Comparison of Neuritic Dystrophy and Amyloid Plaques in APP Transgenic Mice and Alzheimer's Disease.** E. Masliah\*, A. Sisk\*, M. Mallory\*, L. Mucke† and D. Games§. #Depts. of Neurosciences and Pathology, University of California San Diego, La Jolla, CA 92093, †Dept. of Neuropharmacology, Scripps Research Institute, La Jolla, CA 92037 and §Athena Neurosciences, Inc., South San Francisco, CA 94080.

Overexpression of mutated human amyloid precursor protein (hAPP) under the control of platelet derived growth factor promoter (PDAPP minigene) in transgenic (tg) mice results in neurodegenerative changes similar to Alzheimer's disease (AD) (Nature 373:523,1995). We examined the neuritic component of amyloid plaques in this model and compared these abnormalities with other hAPP tg mice (Brain Res 666:151,1994) and AD. Serial reconstructions were performed on images derived using laser confocal and electron microscopy. Amyloid fibrils 9-11 nm in diameter were abundant in the PDAPP tg and were strikingly similar to those observed in AD. In both cases, the amyloid was surrounded by interdigitating membranes and associated with dense core vesicles. Neurons were associated with plaques in both PDAPP tg mice and AD. In PDAPP tg mice, distal neuronal processes contained amyloid fibrils and electron dense material, less evident in AD. Dystrophic neurites were also observed in high expressors NSE-hAPP695 (717 V->I) tg mice, but were much less abundant than in PDAPP tg mice. Dystrophic neurites formed occasional synapses and contained many dense multilaminar bodies and neurofilaments (10nm); no paired helical filaments have yet been observed. Low expressor hAPP tg mice did not develop dystrophic neurites. In the PDAPP tg mice, synaptic alterations were most prominent in the periplaque region. The above results indicate that  $\beta$ -amyloid can occur within neuritic processes and that such neuritic alterations may contribute to plaque formation in AD. This work was funded in part by Athena Neurosciences, Inc., NIH AG5131, AG10689, AG11385 and the State of California Department of Health Services.

## ALZHEIMER'S DISEASE: ApoE

## 580.1

**APOJ BUT NOT APOE RETARDS APOPTOSIS IN PC12 CELLS.** G.E. Maestre<sup>1,2</sup>, C.Y.I. Yan<sup>1</sup> and M.L. Shelanski<sup>1</sup>. Dept. of Pathology, Columbia University, New York, N.Y. 10032 U.S.A.<sup>1</sup> and I.I.B., Universidad del Zulia, Apdo.526, Maracaibo Venezuela<sup>2</sup>

This study examines the survival of PC12 cells after serum and growth factor deprivation in the presence of ApoE or ApoJ. PC12 cells were grown for 10 days in the presence of 15% serum (naive) or in a NGF-containing-serum free medium (primed). After extensive rinsing, cells were replated in serum and NGF-free medium, and treated with ApoJ or one of the 3 isoforms of ApoE. Purified human ApoJ (Quidel) was used at concentrations of 0.16, 16 and 160  $\mu$ g/ml, while recombinant ApoE (Panvera Corp.) was used at concentrations of 16 and 32  $\mu$ g/ml. At 24 hours of treatment with ApoJ, the number of cells alive was significantly increased (70% vs. 40% in untreated cells). By day 4 all control cells were dead, while 10% of the ApoJ treated cells remained viable. Treatment with ApoE had no effect on cell survival. No significant difference was detected between naive and primed cells.

These results suggest that ApoJ may trigger a protective mechanism in response to deprivation of trophic factors, leading to a retardation of apoptotic cell death.

## 580.2

**APOLIPOPROTEIN E MODULATES THE ACTIVITIES OF SECRETED  $\beta$ APP IN AN ISOFORM-SPECIFIC MANNER.** S.W. Barger\* and M.P. Mattson. Sanders-Brown Center on Aging and Department of Anatomy & Neurobiology, University of Kentucky, Lexington, KY.

Specific alleles of both apolipoprotein E (ApoE) and  $\beta$ -amyloid precursor protein ( $\beta$ APP) are genetically linked to Alzheimer's disease. Rare mutations in  $\beta$ APP appear to be sufficient to cause AD, implicating an abnormality in the function of  $\beta$ APP or one of its proteolytically derived fragments. With respect to ApoE, polymorphisms common in humans are linked in a rank order to the age of onset of AD: ApoE4 < ApoE3 < ApoE2. We have investigated possible molecular interactions between these proteins that would explain their relationship to the disease. Secreted forms of  $\beta$ APP (sAPP) protect primary neurons from metabolic and excitotoxic insults and modulate their electrophysiological excitability (Furukawa et al., this meeting). Therefore, we reasoned that ApoE might interfere with these activities in a manner consistent with their rank in predisposing for AD. Surprisingly, we found that ApoE actually enhanced the ability of sAPP to acutely depress rest calcium levels and ameliorate excitotoxicity in primary neurons, with the E3 isoform being more potent than E4. A second activity of sAPP which appears to result from a different region of the molecule, the elevation of inositol phosphate generation, was inhibited by ApoE. These effects depended on a direct molecular interaction between ApoE and sAPP as they were dependent on time and concentration of incubation of the two proteins; furthermore, the proteins were coprecipitated from mixtures. These data suggest that ApoEs bind with isoform-specific affinity to a specific region of sAPP and modulate the bioactivity of individual sAPP domains. Supported by the Alzheimer's Association, NINDS, and French Foundation.

## 580.3

AMYLOID P COMPONENT AND APOLIPOPROTEIN E IN ALZHEIMER'S DISEASE. T. Duong\*, P. J. Acton and E. J. Chaney. Terre Haute Center, Indiana Univ. Sch. of Med., Terre Haute, IN 47809.

Amyloid P component (APC) and apolipoprotein E (Apo E) have been localized previously to the lesions of Alzheimer's disease (AD): the senile plaques (SP) and the neurofibrillary tangles (NFT). In this study, the distribution of APC and Apo E in the lesions of AD have been compared by immunohistochemistry in a set of 10 AD patients staged histopathologically for the degree of disease severity (H. Braak and E. Braak, Acta Neuropathol. 82, 239-259, 1991). The patients were grouped into transentorhinal (I-II), limbic (III-IV) and isocortical (V-VI) stages. Tissue blocks from the hippocampus CA1 region and entorhinal cortex were fixed in phosphate-buffered 4% paraformaldehyde and cut on a cryostat (40 µm section thickness). Adjacent sections were processed free-floating using a monoclonal antibody to APC (Sigma; 1:1000) or a polyclonal antibody to Apo E (Midland Bioproducts; 1:3000). The number of SP and NFT labeled by APC or Apo E were determined and expressed as a density (number/mm<sup>2</sup>). The results show that in stages I-IV, the density of APC- and Apo E-immunoreactive SP in both brain regions studied were similar but in later stages (V-VI), the density of Apo E-immunoreactive SP was higher compared to APC. The density of NFT immunoreactive to APC or Apo E were similar at all stages in both brain regions although the density of APC-immunoreactive NFT was slightly higher in the hippocampus CA1 region in stages V-VI. **These results suggest that, in our patients, both APC and Apo E accumulate at the same rate in AD lesions in early stages of the disease; but, in late stages, there may be a greater deposition of Apo E in SP or APC in NFT.** This work was supported by NIH NINDS grant NS31524

## 580.5

THE DISTRIBUTION OF APOLIPOPROTEIN AND APOLIPOPROTEIN RECEPTOR mRNAs IN THE RAT FOREBRAIN. Keith Page\* and Bradley Hyman. Neurology Research, Harvard Medical School, Massachusetts General Hospital, Boston 02114, USA.

In order to map the distributions of Alzheimer pathology related apolipoproteins and their receptors in the rat CNS, *in situ* hybridizations were performed. Serial 16µm sections were examined using 45mer oligonucleotide probes to apolipoproteins E<sub>J</sub> and A1 mRNAs, low density lipoprotein receptor (LDLR), very low density lipoprotein receptor (VLDLR), low density lipoprotein receptor related protein (LRP) and the LDL receptor-associated protein (RAP) mRNAs. Non-specific hybridizations were assessed using the appropriate sense probes and a 45mer probe of random sequence which produced no hybridization signal. Apolipoprotein E, J and A1 mRNAs were abundant in rat forebrain; ApoE and ApoA1 mRNAs were expressed diffusely across all brain regions studied with particularly high expression in the CA-subfields and dentate gyrus, while ApoJ mRNA was also strongly expressed in neocortex and choroid plexus. Emulsion dipped sections revealed that ApoE and ApoJ mRNA expression was largely restricted to non-neuronal elements while ApoA1 mRNA appeared to be localised to neurons. The distributions of LRP and RAP mRNA were nearly identical, both were located in neurons and densely expressed in the hippocampus, both LRP and RAP mRNA were present in choroid plexus. VLDLR and LDLR mRNA were diffusely expressed, indicating their likely glial localisation. These data show a differential distribution of apolipoproteins and different ApoE receptors in various cell populations in the rat CNS.

## 580.7

EFFECTS OF APOE3 AND APOE4 ON THE PHOSPHORYLATION OF TAU PROTEINS. D. Kapkov\*, Christine Guenzi, John C. Lehmann. Dept. Neurosurgery MS 407, Medical College of Pennsylvania and Hahnemann University, Philadelphia PA 19102-1192.

Both ApoE3 and ApoE4 significantly reduced [32P] incorporation into tau by protein kinases CK1 and CK2, but the effect was more robust for ApoE3. When ApoE3 was added to tau together with protein kinases, it almost completely prevented phosphorylation of tau by CK1 or CK2 added separately. Preincubation of ApoE3 with tau reduced this effect, in contrast to ApoE4, whose effect was generally independent of preincubation with tau. Such an insensitivity of ApoE4 in comparison with ApoE3 to starting conditions suggests the importance of a dimer structure, which is much more stable for ApoE3.

Antibody recognition of AD-specific sites of tau protein failed to correlate as predicted by the level of phosphorylation in the presence and absence of ApoE. Remarkably, when ribosome-free brain extract was used as a source of total protein kinase activity, ApoE3 and ApoE4 did not reduce the level of phosphorylation of tau. But if ApoE4 was preincubated with tau at pH 7.7, the phosphorylation by brain extract protein kinases was significantly increased. These results suggest that ApoE4 and ApoE3 have differential effects on the phosphorylation of tau protein, which may be pertinent to the relatively early development of AD pathology in patients homozygous for ApoE4.

## 580.4

APOLIPOPROTEIN E (APOE) ISOFORMS BIND DIFFERENTIALLY TO TAU AND OTHER CYTOSKELETAL PROTEINS. G.V.W. Johnson<sup>1</sup>, L.M. Fleming<sup>1</sup>, W.J. Strittmatter<sup>2</sup> and K.H. Weisgraber<sup>3</sup>. <sup>1</sup>Dept. of Psychiatry, Univ. of Alabama at Birmingham, Birmingham, AL 35294-0017. <sup>2</sup>Dept. of Neurology, Duke Univ. Med. Ctr., Durham, NC 27710 and <sup>3</sup>Gladstone Institute, Univ. of California, San Francisco, CA 94140-9100.

The frequency of the ε4 allele of apoE is significantly increased in late-onset familial and sporadic Alzheimer's disease. In *vitro* apoE3, but not apoE4, binds to the microtubule-associated proteins (MAPs) tau and MAP-2C, as evidenced by the presence of apoE/MAP complexes on SDS-polyacrylamide gels run under non-reducing conditions. In this study the associations of apoE2, E3 and E4 with several cytoskeletal proteins were examined using both gel shift and overlay assays. The association of the longest isoform of human recombinant tau (T4L) and the shortest isoform (T3), with the different isoforms of apoE were examined under non-reducing conditions on SDS-polyacrylamide gels. As expected, apoE3 formed SDS-resistant complexes with T4L and T3. ApoE2, however, did not form detectable complexes with T4L, although apoE2 did bind to T3. ApoE4 did not bind to either T3 or T4L as determined by the gel shift assay. ApoE3 also formed SDS-stable complexes with bovine tau and neurofilament proteins, but not with actin. The association of apoE3 and apoE4 with T4L, actin or tubulin was further examined in an overlay assay with known amounts of the proteins slot-blotted onto nitrocellulose. The resulting blots were incubated with 5 µg/ml of apoE3 or apoE4, rinsed thoroughly and then probed with an apoE antibody. The results indicated apoE3 and apoE4 bound T4L and tubulin equally well. In contrast, apoE3 bound actin significantly better than apoE4. In addition, apoE3 bound tubulin to a significantly greater extent than T4L. These results indicate that apoE isoforms interact with cytoskeletal proteins with at least two different binding affinities. The stronger interaction which results in the formation of complexes which are SDS-stable only occurs with apoE3, while the other interactions between apoE and cytoskeletal proteins are apparently not isoform specific.

## 580.6

NEUROTOXIC EFFECTS OF APOLIPOPROTEIN E SYNTHETIC PEPTIDES AND PROTECTION BY HEPARIN AND HEPARAN SULFATE. M. Tolar\*, M. A. Marques, J. A. K. Harmony<sup>1</sup> and K. A. Cutcher. Dept. of Neurosurgery and Dept. of Pharmacology and Cell Biophysics<sup>2</sup>, University of Cincinnati, Cincinnati, OH 45267-0515

Apolipoprotein E (ApoE) is localized to amyloid plaques and neurofibrillary tangles in Alzheimer's disease (AD) brains and its ε4 isoform is implicated in familial and sporadic AD. However, the specific role that apoE may play in the etiology of AD is unknown. ApoE-related peptides have been found to cause extensive degeneration *in vitro* when applied to explant cultures of chick sympathetic ganglia (Exp. Neurol. 130: 120-126; 1994). These findings have been extended in the present study of dissociated chick sympathetic neurons, and undifferentiated and nerve growth factor-differentiated PC12 cells, as well as testing agents that might be expected to block toxicity. ApoE can be internalized by the low density lipoprotein (LDL) receptor, or the LDL receptor-related protein, and all toxic apoE peptides include the receptor-binding domain of apoE, as well as the overlapping heparin-binding site.

Dose-response curves of apoE peptides were found to be similar for both sympathetic neurons and PC12 cells. Half-maximal effective concentrations of toxic peptides in the various cell culture systems ranged from 2-4 µM. To determine the site of action and neurotoxic mechanism of the apoE peptides, we undertook blockage studies designed to interfere with their anticipated interaction with cell-surface receptors. The peptides were applied at half-maximal effective concentrations and protective effects of heparin and heparan sulfate (HS) were tested. A 10 min preincubation of any of the apoE peptides with either heparin or HS abolished their neurotoxic effects in a dose-dependent manner in all cell-culture systems studied. Complete abolition was achieved at 2-4 µM. These results suggest that the toxicity of apoE peptides is mediated by the cell interaction with either receptor- or heparin-binding site of the peptides and provide evidence that the heparin-binding site located on apoE peptides is functional. (Supported by a Res. Challenge Grant and NIH grants NS31410 and HL 27333.)

## 580.8

APO E EXPRESSION IN PLAQUE TYPES IN ALZHEIMER'S DISEASE. W.S.T. Griffin\*, J.G. Sheng, and R.E. Mrak. Ark. Child. Hosp. Res. Inst., Univ. Ark. Med. Sci., Dept. Vet. Aff. Med. Ctr., Little Rock, AR 72202.

β-Amyloid-containing plaques are a salient histopathologic feature of Alzheimer's disease. These plaques have been shown to contain apolipoprotein E (Apo E), and a potential pathogenic role for Apo E in neuritic plaque formation has been suggested. This predicts that Apo E should be present in early (diffuse, non-neuritic) amyloid deposits. To examine this possibility, we used immunohistochemical double labelling of temporal lobe tissue sections from 12 Alzheimer patients, age 66-88. Amyloid-immunopositive plaques were classified into four types according to the pattern of amyloid distribution (diffuse vs dense core) and the presence or absence of β-amyloid precursor protein-immunoreactive dystrophic neurites. Only 6% of diffuse non-neuritic plaques contained Apo E, and these had very low immunoreactivity. In contrast, 83% of diffuse neuritic plaques and 86% of dense-core neuritic plaques were highly immunoreactive for Apo E. Only 6% of dense core non-neuritic ("burnt out") plaques showed Apo E immunoreactivity. In each case, the area of Apo E immunoreactivity completely overlapped with that of β-amyloid. These results suggest that Apo E deposition occurs concomitant with, or following, but does not precede dystrophic neurite formation in amyloid plaques. These findings, together with the previous demonstration of Apo E immunoreactivity in the non-progressing diffuse amyloid deposits in cerebellum in Alzheimer's disease, suggest that plaque-associated Apo E is not the critical initiating factor in dystrophic neurite formation in amyloid deposits in Alzheimer's disease. This work was supported in part by NIH AG10208, NS 27414, and AG12411.

## 580.9

**DOES THE APOLIPOPROTEIN E  $\epsilon 4$  ALLELE ACCELERATE THE FORMATION OF HIPPOCAMPAL NEURITIC PLAQUES?** J.M. Olichnev, L. Hansen, D. Galasko, T. Saitoh, C.R. Hofstetter, D. Connor\*, R. Katzman, L.J. Thal. Dept. of Neurosciences, University of California, San Diego, CA 92093.

**Objective:** To test if the apolipoprotein E (APOE)  $\epsilon 4$  genotype increases the proportion of neuritic plaques (NP) versus diffuse plaques (DP) present in the hippocampus of autopsied Alzheimer's disease (AD) and Lewy Body Variant (LBV) cases. **Methods:** Thioflavin-S stained sections of the posterior hippocampus (CA1 region of the pyramidal cell layer, including what previously has been called the prosubiculum) were examined for NP and DP counts in 92 cases of AD (n=56) and LBV (n=36). Effects of APOE genotype, age and duration of clinical symptoms upon NP and DP were analyzed. **Results:** For AD and LBV combined, cases without any  $\epsilon 4$  alleles had a mean number of 6 NP per 1.6 mm<sup>2</sup> (comprising 66% of the total plaques). For cases with one  $\epsilon 4$  allele, the mean NP count was 8 (70% of total plaques). For cases with two  $\epsilon 4$  alleles, the mean NP count was 10 (84% of total plaques). Differential effects of APOE genotype upon the NP/DP proportion was seen between the AD and LBV groups. **Conclusions:** The APOE  $\epsilon 4$  allele may favor the transformation of diffuse plaques into neuritic plaques.

## 580.11

**INCREASED EXPRESSION OF APOLIPOPROTEIN D IN OLIGODENDROGLIA IN ALZHEIMER BRAIN**

S.C. Patel\*, M.L. Grunnet, S. Suresh, W. McConathy, R.C. Patel\*, Y.C. Patel\*, and K. Asotra. <sup>1</sup>UNTHSC, Fort Worth, TX; <sup>2</sup>Clarkson Univ., Potsdam, NY; <sup>3</sup>McGill Univ., Montreal, QB; <sup>4</sup>VAMC, Newington & UCONN Health Center, Farmington, CT.

Apolipoprotein D (apo D), a 27-32 kDa glycoprotein component of human high density lipoproteins (HDL) and a member of the lipocalin-calycin superfamily of small hydrophobic ligand carrier proteins, has been implicated in the transport of cholesterol, progesterone, bilirubin and a variety of similar ligands. Apo D is widely expressed in many tissues including the nervous system. In the crushed rat sciatic nerve, levels of apo D increase by 500-fold as the nerve regenerates, suggesting a role for the protein in the repair of neural tissues after injury. In the current studies, we investigated apo D expression in the normal human brain and in brains from select neurodegenerative disorders. Using an affinity purified antibody to human apo D and biotin-streptavidin enhanced immunocytochemistry, we observed that in the normal human brain there was little apo D expression which was restricted to scattered astrocytes and to perivascular fibroblasts. In contrast, apo D was readily detected in the brains of three individuals with histopathologically confirmed Alzheimer's disease. Most of the apo D immunoreactivity in AD brain was found in oligodendroglia; lower levels of apo D expression were found in reactive astrocytes and in microglia. No immunoreactivity was observed in neurons. A similar pattern of immunoreactivity, but of much lesser intensity was found in a patient with ALS-dementia. In general, the intensity of apo D immunoreactivity in the three AD brains paralleled the occurrence of established neuropathological features of AD, including amyloid plaques and neurofibrillary tangles. Our results suggest that induction of apo D in oligodendroglia may play a role in Alzheimer and other human neurodegenerative disorders.

## 580.13

**INFLUENCE OF APOLIPOPROTEIN E GENOTYPE ON DIFFUSE PLAQUE FORMATION IN CORTEX OF NONDEMENTED ELDERLY.** J.S. Bains, S.S. Bou, T. Fung, D. Hoffinger, C.L. White III, A.W. Clark\*, U. of Calgary, Alberta T2N 4N1 Canada; and U. of Texas Southwestern Medical School, Dallas, TX 75235 USA.

Apolipoprotein E (ApoE), a facilitator of lipid metabolism, is encoded by a gene on chromosome 19. The most common alleles are epsilon 2, 3, and 4. Previous evidence suggests that the epsilon 4 allele predisposes to sporadic and familial Alzheimer's disease (AD). The pathogenetic point of entry for ApoE in AD-type degeneration is not known. In neocortex, the earliest stage of AD-type degeneration is formation of diffuse plaques (DP), seen to varying extent in nondemented elderly subjects. We have initiated a study to determine whether ApoE genotype influences this stage. Postmortem samples of neocortex from nondemented subjects (ages 60-99 years) are studied with a Steiner silver stain highly sensitive and specific for DP. Each subject is thus assigned a DP score from 0 (normal) to 5 (extensive DP, similar to AD but without other AD pathology). ApoE restriction isotyping is then done on DNA from each case, PCR-amplified with selected oligonucleotide primers. For cases studied to date, analysis of covariance was used to compare the 3/3 and 3/4 genotype groups, with the DP score as the dependent variable and age as the covariate. Those of genotype 3/3 (n=25) and 3/4 (n=16) yielded age-adjusted DP scores of 1.07 and 2.00, respectively. The difference was significant (p=0.019). Sample sizes from other genotype groups (n=7) were too small for analysis. Our findings support an influence of the ApoE epsilon 4 allele in formation of DP in neocortex of nondemented elderly, a very early stage of AD-type degeneration.

## 580.10

**EXPRESSION OF HUMAN APOLIPOPROTEIN E4 BLOCKS NEURITE OUTGROWTH FROM MURINE NEUROBLASTOMA CELLS.** S. Bellista, B.P. Nathan, R.W. Mahley,† and R.E. Pitas.\*† Gladstone Institute of Cardiovascular Disease, Cardiovascular Research Institute, Departments of †Medicine and ‡Pathology, University of California, San Francisco, CA 94141-9100.

We have previously shown that, in the presence of a source of lipid, apolipoprotein (apo) E4, a protein associated with late-onset familial and sporadic Alzheimer's disease (AD), inhibits neurite outgrowth from cultured dorsal root ganglion neurons, whereas apoE3 stimulates outgrowth. In the current studies, murine neuroblastoma cells (Neuro-2a) were stably transfected with human apoE3 or apoE4 cDNA, and the effect on neurite outgrowth was examined. The transfected cells secreted 44 to 89 ng of apoE per mg of cell protein in 48 h. In the absence of a source of lipid, neurite outgrowth was the same in the apoE3- and apoE4-secreting cells. Incubation of the cells with  $\beta$ -migrating very low density lipoproteins ( $\beta$ -VLDL) or with very low density lipoproteins (VLDL) resulted in inhibition of neurite extension from the apoE4-secreting cells and an increase in neurite extension from the apoE3-secreting cells. Similar effects were observed when cells were incubated with lipid emulsions containing only phosphatidylcholine and triolein (1:4 ratio). Incubation of the cells with apo HDL<sub>2</sub>, a specific type of high density lipoprotein that is similar to the HDL in cerebrospinal fluid, resulted in a moderate isoform-specific effect, which was not as dramatic as that observed with  $\beta$ -VLDL and VLDL. Low density lipoproteins did not produce a differential effect on neurite outgrowth in the apoE3- and apoE4-secreting cells. Whether the lipid particle serves only as a vehicle to deliver apoE to the cells or if specific lipids are required for the differential effects remains to be determined. These data suggest that apoE4 in the brain together with lipoproteins, which are known to occur in the central nervous system, may inhibit neurite extension *in vivo*, thus contributing to the progression of AD.

## 580.12

**CHARACTERIZATION OF APOLIPOPROTEIN E FRAGMENTS FROM ALZHEIMER'S DISEASE AND CONTROL TISSUE.** M.A. Marques, M. Tolar, J.A.K. Harmony\* and K.A. Crutcher\*. Dept. of Neurosurgery and Dept. of Pharmacology and Cell Biophysics\*, Univ. of Cincinnati, Cincinnati, OH-45267-0515.

The role of apolipoprotein E (apoE) in the nervous system is unknown. The lipid-binding function of apoE has led to the hypothesis that this protein plays a role in peripheral nerve regeneration by recycling lipids, especially cholesterol, thereby providing membrane components to regenerating axons. Furthermore, the striking association between inheritance of the allele for the E4 isoform of the protein and the risk of developing Alzheimer's disease (AD) suggests a role for this protein in this disease, perhaps through its association with beta amyloid or tau proteins. However, the exact role played by apoE has not been determined yet.

We have found that apoE synthetic peptides are toxic to chick sympathetic and cortical neurons, as well as to PC-12 cells *in vitro* (Exp. Neurol. 130:120-126; 1994, and Tolar et al., this meeting). These results suggest the possibility that peptides generated from apoE play a role in neurodegeneration in AD. As an initial approach to test this hypothesis, we have studied post-mortem tissue from AD and age-matched control patients to determine whether apoE peptide fragments are present. Two different biochemical approaches were used: immunoprecipitation and heparin-sepharose chromatography column followed by ion-exchange chromatography, reverse phase HPLC, SDS-PAGE and electroimmunoblot analysis. CSF samples from both AD and control patients were found to contain apoE fragments in size from 22 kDa to 5 kDa. Brain tissue homogenates contained three distinct apoE fragments: 22kDa, 16kDa and 10 kDa. (Supported by Research Challenge Grant and NS 31410.)

## 580.14

**APOLIPOPROTEIN E GENOTYPE AND NEUROPATHOLOGICAL PHENOTYPE IN SPORADIC ALZHEIMER'S DISEASE.**

R. Egensperger, S. Kösel, P. Mehraein and M.B. Graeber\*. Molecular Neuropathology Laboratory, Institute of Neuropathology, Ludwig-Maximilians-University, 80337 Munich, Germany

Several studies have demonstrated an association between apolipoprotein E (APOE) allele  $\epsilon 4$  and Alzheimer's disease (AD). As interactions between APOE gene products and the BA4 peptide are considered to play an important role in the pathogenesis of AD, we have studied the relationship between APOE genotypes and quantitative aspects of AD neuropathology. For genotyping of APOE, a new polymerase chain reaction (PCR) assay was developed which allows analysis of formalin-fixed and paraffin-embedded brain tissue (Egensperger et al., in press). Quantitative evaluation of histological phenotypes was performed by counting the number of amyloid plaques with  $\tau$ -positive neurites, measuring the tissue area covered by cortical BA4-immunoreactive deposits and counting the number of  $\tau$ -positive neurons using a computer-assisted image analysis system. The frequency of the APOE allele  $\epsilon 4$  in 19 clinically characterized and neuropathologically verified cases of AD was 39% (9  $\epsilon 3/\epsilon 4$ -heterozygotes, 3  $\epsilon 4/\epsilon 4$ -homozygotes). Detailed correlations between histological phenotypes and APOE genotypes are currently being carried out. Preliminary results suggest that not only the severity of AD lesions but also the extent of perivascular amyloid deposition is positively correlated to the number of APOE  $\epsilon 4$  alleles. In addition, the extent of microglial activation as indicated by increased expression of major histocompatibility complex class II molecules appeared to be highest in APOE  $\epsilon 4$  homozygotes.

## 580.15

PSYCHOMETRIC PERFORMANCE AND APOE4 IN SUBJECTS WITH DEMENTIA OF THE ALZHEIMER TYPE (DAT). K. Mann Koepke<sup>1</sup>, A. Goate, M. Storandt, C. Talbot, E. Grant. Departments of Neurology, Psychiatry, Psychology & Biostatistics, Washington University, St. Louis, MO 63110.

The presence of at least one apolipoprotein E4 allele (APOE4) has been demonstrated to significantly increase the risk for the development of dementia of the Alzheimer type (DAT) and to lower the age of onset in these individuals. That APOE4 may directly and substantially contribute to the etiology of DAT in these patients has been hypothesized but not yet confirmed. This hypothesis would suggest that at any stage of dementia, subjects with at least one APOE4 allele should perform less well or have a different distribution of decline on tests of cognitive function than age- and stage-matched non-APOE4 subjects. Reed et al (Arch Neurol 1994;51:1189-1192.) tested this hypothesis in "normal" male fraternal twin pairs discordant for APOE4 and found poorer mean performance on cognitive tests in the E4-positive twins.

Subjects with a Clinical Dementia Rating (CDR) of 0 (no dementia), 0.5 (very mild), or 1.0 (mild dementia) and recruited for study by the Washington University Memory and Aging Project were evaluated for cognitive function using the Washington University ADRC Psychometric Battery and genotyped for APOE using PCR methods. Grouped by APOE4 genotype (i.e., no, one, or two APOE4 alleles), controlling for age (inverse relationship found between E4 dosage and age at time of testing) and CDR (i.e., CDR=0, 0.5, or 1), no group differences were found in performance on any of the 15 psychometric variables assessed ( $F=1.44$ ,  $df=19/187$ ,  $p=0.12$ ). These results fail to support the conclusions of Reed and colleagues of poorer psychometric performance in APOE4 positive individuals.

## 580.17

APOE IS EXPRESSED IN SKNSH-SY 5Y NEUROBLASTOMA CELLS. C. Soulié<sup>1</sup>, J. Wallois-Dupont<sup>1</sup>, J. Perez-Tur<sup>1</sup>, M.C. Chartier-Harlin<sup>1</sup>, J. L'Epagnol<sup>2</sup>, A. Delacourte<sup>1</sup> and M.L. Cailliet-Boudin<sup>1\*</sup>. 1: Inserm U422, 59045 Lille, France.

2: Institut de Recherches SERVIER, 78290 Croissy sur Seine, France.

In human brain, apoE is synthesized and secreted by astrocytes, and is generally reported to be absent in neurons. In Alzheimer brain, apolipoprotein E is present within senile plaques and neurofibrillary tangles, suggesting that apoE may be involved in this disorder. In the present study, apoE was found in the neuroblastoma cell line, SKNSH-SY 5Y.

Presence of apoE was demonstrated by both immunochemical analysis and reverse transcription polymerase chain reaction. Using a monoclonal antibody against apoE, apoE immunoreactivity was found in the cytoplasm and neurites of neuroblastoma cells SY 5Y. ApoE distribution varied during NGF-differentiation time. SY 5Y cells were genotyped E3/E3.

ApoE synthesis in SY 5Y cells is an important finding because these cells were used as a model of Alzheimer-type neurodegeneration. After okadaic acid treatment, SY 5Y express hyperphosphorylated Tau proteins, Tau 55 and Tau 64, with Alzheimer-type epitopes. These results suggest that neurons could express apoE, and SY 5Y may be used to study apoE-Tau interactions.

## 580.19

SPECIFIC TAU PROFILE IN THE BRAIN FROM PATIENTS WITH MYOTONIC DYSTROPHY. P. Vermersch<sup>1,3\*</sup>, N. Sergeant<sup>1</sup>, M.M. Ruchoux<sup>2</sup>, Ch. Daems<sup>3</sup>, H. Petit<sup>3</sup>, Ph. Dewailly<sup>4</sup>, A. Delacourte<sup>1</sup>. 1)INSERM U422, Place de Verdun, Departments of 2)Pathology, 3)Neurology and 4)Geriatrics and Internal Medicine, University of Lille, 59045 France.

Pathological Tau proteins (PTP) are immunodetected in SDS brain extracts from patients with Alzheimer's disease (AD) or progressive supranuclear palsy. These PTP, which are the basic components of neurofibrillary lesions (NFL), are different from normal Tau proteins which are soluble and rapidly dephosphorylated after death. It has been reported that NFL are present in the brain from patients with myotonic dystrophy (MyD). Using AD2, a specific monoclonal antibody against PTP, we performed a mono and two dimensional immunoblotting and immunohistological studies of the brain of two MyD cases, aged 53 and 61 at death and compared the Tau profile with those obtained in AD. In both cases, we found NFL in the superficial layers of the limbic and temporal lobes. No amyloid deposits were found. PTP were immunodetected in the same areas and in the amygdala. The densitometric data showed different Tau profiles in MyD and AD. We found a low amount of the Tau 69 isoform in MyD and in most of the cortical areas, Tau 55 were in higher amounts compared with AD homogenates. This study shows evidence for a specific Tau pathology in MyD, probably due to the overexpression of the myotonic protein kinase in the brain of these patients.

## 580.16

EXPRESSION OF APOLIPOPROTEIN E ALLELES IN ALZHEIMER'S DISEASE BRAINS. J. PÉREZ-TUR<sup>1,\*</sup>, J.C. LAMBERT<sup>1</sup>, J.P. DAVID<sup>2</sup>, C. DIMENZA<sup>2</sup>, P. VERMERSCH<sup>1</sup>, A. DELACOURTE<sup>1</sup>, M.C. CHARTIER-HARLIN<sup>1</sup>. 1)INSERM-Unité 422, Place de Verdun, F59045 LILLE cedex (France). 2)Centre Hospitalier Emile Roux, 1 av Verdun, F94456 Limeil-Brevannes (France).

Several studies had demonstrated that the apolipoprotein E (apoE) is one of the most important risk factors for the development of either familial or sporadic late-onset (LO) Alzheimer's disease (AD). This genetic association, found by a number of groups, has been reinforced by the finding that apoE may bind both Aβ and tau proteins in a isoform-specific fashion. This has led to the proposal of a hypothesis by which the binding of the E4 isoform to the Aβ-peptide should enhance its rate of deposition and then increase the risk for developing AD. But an important number of people producing the E4 isoform are not affected by the disease, even in their 9th or 10th decades, so other factors than the APOE genotype should be involved.

In 1991, Diederich and colleagues, showed an increased expression of the APOE gene in the brain of Alzheimer's disease patients. Then, the isoform-specific effects of this protein in AD should be due not only to the differences in sequence, but also to differences in the expression of each allele.

In the present work, we study the amount of mRNA for each allele present in 5 AD brains and in control brains. We performed a RT-PCR on RNA obtained from brains with a post-mortem delay ranging from 2-8 h. After restriction enzyme digestion, the samples were loaded on a polyacrylamide gel, subjected to electrophoresis and then stained in a ethidium bromide bath. The gel was photographed and the image was scanned and analysed with a computer program.

The relative data obtained for each of the three heterozygote genotypes are presented.

3: Image Project, Hospital Côtes des Neiges, H3W 1W5, Montreal, Canada.

AD2 is a phosphorylation-dependant IgG mAb raised against Alzheimer PHF. Its epitope is located on the C terminal part of Tau. AD2 is able to specifically detect pathological Tau proteins in brain homogenates, in less than 10 µl of homogenate (1W/10V), on western blots and at a mAb concentration of 0.2 µg/ml. AD2 detects a Tau triplet (Tau 55, 64, 69) in Alzheimer's disease, which is different from the biopsy-derived normal "hyperphosphorylated" Tau triplet. For PSP as well as Corticobasal Degeneration, AD2 immunodetects Tau 64 and 69, which provides a biochemical signature for PSP-type lesions. In the same way, we were able to characterize Pick's Disease and a subtype of Frontal Lobe Degeneration.

## 581.1

INCREASED RISK OF DEMENTIA IN MOTHERS OF ALZHEIMER'S DISEASE CASES: EVIDENCE FOR MATERNAL INHERITANCE. S. D. Edland, J. Silverman, E. R. Peskind\*, D. Tsuang, E. Wijsman, J. C. Morris. Department of Environmental Health, Univ. of Washington, Seattle, WA 98195-4709.

Duara et al. [Neurol, 43:1377-1384] found a 3.6:1 mother to father ratio among affected parents of familial Alzheimer's disease (AD) subjects. This observation is consistent with several speculative hypotheses regarding the etiology of AD. The present study tested the hypothesis of maternal inheritance in 118 AD subjects from the Consortium to Establish a Registry for Alzheimer's Disease (CERAD) cohort. Age adjusted relative risk was calculated using the Cox proportional hazards model. 24 dementia cases were ascertained in the parental generation. Among these, the age adjusted mother:father relative risk was 2.9 (95% CIs 1.1 to 7.7). Among a subset of 10 families with one parent and at least two siblings affected, the ratio of affected mothers to fathers was 9:1. These findings are consistent with the hypothesis of maternal inheritance in AD. Confirmation with a larger sample or by genetic investigations of families with maternal inheritance patterns is required.

## 581.3

CYSTATIN C: HCHWA-ICELANDIC-LIKE MUTATION IN SQUIRREL MONKEYS WITH CEREBRAL AMYLOID ANGIOPATHY. L. Wei, J.C. Walker and E. Levy\*. Depts. Pharmacology and Pathology, New York University Med. Center, New York, NY 10016; Neuropathology Lab. The Johns Hopkins University Sch. Med. Baltimore, MD and Dept. Neurology, University of Greifswald, Germany.

The primary histological locus of cerebral amyloid deposition varies in aged humans and in different species of non-human primates. In aged rhesus monkeys (*Macaca mulatta*), amyloid deposition occurs most frequently in senile plaques, whereas in aged squirrel monkeys (*Saimiri sciureus*) the cerebral blood vessels are most affected. Cerebral amyloid angiopathy (CAA) can occur as a sporadic disorder in aged humans, as a frequent component of Alzheimer's disease, or in hereditary cerebral hemorrhage with amyloidosis (HCHWA). Immunohistochemical studies have demonstrated dual staining of the vascular amyloid of CAA patients with antibodies to amyloid  $\beta$ -protein (A $\beta$ ) and to cystatin C, a cysteine protease inhibitor.

We found that in aged squirrel monkeys the amyloid, previously shown to be immunoreactive with anti-A $\beta$  antibodies, reacts also with antibodies to cystatin C. The cystatin C cDNA was sequenced to determine if CAA in these monkeys is related to a species-specific amino acid change. While the predicted amino acid sequence in rhesus monkeys differs from the human sequence by four residues, that of the squirrel monkeys has seven additional amino acid substitutions, one of which is Leu68Met. The amyloid protein isolated from the leptomeninges of Icelandic patients with HCHWA-I is composed of cystatin C containing a single amino acid substitution, Leu68Gln. We propose that specific amino acid substitutions in cystatin C may modulate amyloid deposition in the walls of cerebral blood vessels. Supported by NIH grants AG11481, AG05146 and NS20471.

KYNURENIC ACID AND KYNURENINE AMINOTRANSFERASES KAT I AND KAT II IN THE BRAINS OF PATIENTS WITH DOWN SYNDROME AND ALZHEIMER'S DISEASE. H. Baran, N. Cairns, N. Singewald and G. Lubec. Dept. of Pediatrics, Univ. of Vienna, Austria, \* Brain Bank, Dept. of Neuropathology, Institute of Psychiatry, London, England, \*\*Dept. of Pharmacology and Toxicology, Univ. of Innsbruck, Austria.

The present study was designed to examine the biosynthetic machinery of the excitatory amino acid receptor antagonist kynurenic acid (KYNA) in frontal cortex of patients with DOWN syndrome (DS) and Alzheimer's disease (AD). We measured the content of KYNA, determined by HPLC and activities of enzymes synthesizing KYNA, kynurenine aminotransferases I and II (KAT I and KAT II) in the presence of the 1 mM co-substrates 2-oxoglutarate, 2-oxoisocaproate and pyruvate at their pH optima of 10.0 for KAT I and 7.4 for KAT II. KYNA content was normal in frontal cortex from AD patients (0.28  $\pm$  0.05 pmol/mg tissue) and increased in DS (205 %) as compared with control (0.22  $\pm$  0.05 pmol/mg tissue). In DS and AD the activities of KAT's were remarkably altered. KAT I was significantly reduced (75-86 %) in the presence of all three 2-oxo acids in both diseases. Significantly lowered KAT II activity was observed only in the presence of 2-oxoglutarate (34 %) in frontal cortex from AD. Reduction of KAT I and KAT II activities in frontal cortex did not correlate with the decline of choline acetyltransferase in frontal cortex from both diseases. Measurement of amino acids revealed no changes in the levels of  $\gamma$ -aminobutyric acid, taurine, glycine, aspartate, glutamate and arginine in frontal cortex from DS and AD patients. Our data demonstrated changes in the parameters of kynurenine metabolism and suggest the involvement of KAT's deficit in the brain in DS and AD patients. As KYNA antagonizes competitively the N-methyl-D-aspartate (NMDA) receptors, a system responsible for memory, learning and cognitive functions, our present data may suggest a link to the neuronal degeneration mediated by overstimulation of NMDA receptors. Supported by grants from Red Bull and Austria Science Research Fund (No H0043-MED to H.B.)

ANALYSIS OF THE 19Q13.2 CHROMOSOMAL REGION IN ALZHEIMER'S DISEASE. S.E. Poduslo\*, M.R. Neal, J.D. Schwankhaus. Department of Neurology, Texas Tech University Health Sciences Center, Lubbock, TX 79430.

Alzheimer's Disease is characterized by progressive dementia with cortical neuronal loss associated with  $\beta$ -amyloid plaques and neurofibrillary tangles. The disease is heterogeneous. There is strong evidence for a genetic component due to multiple affecteds in large families. The gene for apolipoprotein E, located on chromosome 19, has an  $\epsilon 4$  allele which has been implicated in late onset Alzheimer's Disease. In our studies of 163 probable Alzheimer's patients from Texas, we found that the late onset patients had a frequency 0.412 for the  $\epsilon 4$  allele while the early onset patients had a frequency of 0.537. Spouses, used as the control group, had a frequency of 0.087 for the  $\epsilon 4$  allele. We examined markers and genes surrounding ApoE for associations with the disease. These included BCL3, LIPE, D19S47, D19S178, ApoCII, and ApoCI. We found no association of the disease with BCL3, LIPE, or D19S47. There may be a weak association with ApoCI and D19S178 as described by Chartier-Harlin et al. *Human Mol Genet* 3:569, 1994, and Schellenberg et al. *Ann Neurol* 31:223, 1992. We found a strong association of the  $\epsilon 4$  allele with a restriction site in ApoCI. Of the Alzheimer's patients homozygous for the  $\epsilon 4$  allele, over 90% had the CI restriction site. However, CEPH family members homozygous for the  $\epsilon 4$  allele also had the CI restriction site. Taylor's group found a tight linkage of ApoE and ApoCI as well as a common regulatory element between the 2 genes (Lauer et al. *J Biol Chem* 263:7277, 1988; Simonet et al. *J Biol Chem* 266:8651, 1991). We are sequencing this area of the chromosome to further delineate this association.

PREPARATION AND TESTING OF YAC-DNA FOR THE GENERATION OF TRANSGENIC RODENTS Ulrich Kosciessa and Claus Braestrup\*, Schering AG Research Laboratories, Müllerstr. 170-178, 13353 Berlin, Germany

The principal advantage of Yeast artificial chromosomes (YACs) as transgenes compared to cDNAs is essentially the copy number dependent and integration site independent expression. YACs contain gene loci which are not influenced by flanking expression regulators (enhancers/silencers). They guarantee protein expression and because they represent intact genomic loci they also produce splice variants. The YAC transgenes are controlled by their natural promoters and 3'UTRs.

A major disadvantage of YACs is their size. They are very sensitive to shearing forces which occur during preparation and microinjection. We overcame these problems by avoiding concentrations by centrifugation during DNA preparation as this leads to significant degradation of the YAC. In our procedure the YAC is purified and concentrated in two pulsed field gel electrophoresis (PFGE) runs. In a conventional first PFGE the YAC is separated from other Yeast DNA. In a second PFGE (high percentage of agarose) with the slice (first PFGE) containing the purified YAC the DNA is concentrated while entering the second gel with higher agarose concentration. The excised concentrated YAC band can now be stored for several month until usage or eluted by conventional agarasing.

Because of their sensitivity against shearing forces the YACs need to be tested for integrity after passage through the microinjection needle. For this we agarose the concentrated YAC slice in a polyamines containing buffer. After removal of residual agarose we microinject the YAC into the same buffer. Yeast strains deficient for the selection marker located on the YAC are then transformed with the injected YAC. Resulting transformants obtained by plating on selection agar are further analysed by PFGE.

## 581.6

PROSPECTIVE CLINICAL-PATHOLOGIC INVESTIGATION OF PARKINSONISM IN ALZHEIMER'S DISEASE (AD). D.A. Bennett\*, D.W. Gilley, R.S. Joglekar, E.J. Cochran. Rush Alzheimer's Disease Center, Chicago, IL 60612

We evaluated 25 consecutive patients with clinical and pathologic diagnoses of AD and a brain autopsy within 12 months of the last examination. Parkinsonism was assessed with the Unified Parkinson's Disease Rating Scale. Cortical neuritic plaques and neurofibrillary tangles, and substantia nigra neuronal loss (SNloss) and Lewy bodies were quantified on 5-micron thick paraffin-embedded sections stained with modified Bielschowsky and hematoxylin-eosin as recommended by CERAD. Average age at death was 77.5 years and average mini-mental state examination (MMSE) was 9.2. Four persons had one parkinsonian domain, 6 had two, 4 had three, and 2 had all four. Nine persons had at least mild neuronal loss, 4 with Lewy bodies. Age at death, SNloss and MMSE were all related to parkinsonism; after adjusting, only SNloss and age at death remained independent correlates. These data support the view that extranigral, age-related changes contribute to parkinsonism among persons with AD.

**MICROTUBULE-ASSOCIATED PROTEIN TAU IN CEREBROSPINAL FLUID: IMPLICATIONS FOR A POTENTIAL DIAGNOSTIC MARKER IN ALZHEIMER'S DISEASE.** H. Arai<sup>1</sup>, M. Terajima<sup>1</sup>, M. Miura<sup>2</sup>, S. Higuchi<sup>3</sup>, S. Takase<sup>4</sup>, C. Clark<sup>5</sup>, V. M.-Y. Lee<sup>6</sup>, J. Q. Trojanowski<sup>6</sup>, and H. Sasaki<sup>1</sup>. 1. Department of Geriatric Medicine, Tohoku University School of Medicine, Sendai 980, Japan, 2. Research and Development Department, Mitsubishi Kagaku Bio-clinical Laboratories, Itabashi-ku, Tokyo 174, Japan, 3. National Institute of Alcoholism, Kurihama National Hospital, Kanagawa 239, Japan, 4. Department of Neurology, Kohnan Hospital, Sendai 980, Japan, 5. Department of Neurology, The Graduate Hosp. Philadelphia, PA 19146, U.S.A. 6. Division of Anatomic Pathology, Department of Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia PA 19104, U.S.A.

Cerebrospinal fluids (CSFs) from 67 patients with Alzheimer's disease (AD) and 94 patients with non-AD neurological diseases as well as 19 normal subjects were surveyed by sandwich enzyme-linked immunodorbent assay (ELISA) to quantitate levels of the microtubule-associated protein tau in CSF (CSF-tau). The CSF-tau level was significantly increased ( $P < 0.001$ ) in AD patients ( $80.7 \pm 46.6$  pg/ml) as compared with that in patients with non-AD neurological diseases ( $21.4 \pm 32.3$  pg/ml) and controls ( $9.0 \pm 4.5$  pg/ml). In AD, the significant increase was found irrespective of age at onset, apolipoprotein E genotype and clinical stage. Western blots of AD CSF proteins revealed two to three tau immunoreactive bands with apparent molecular weight between 50 and 65 kDa consistent with phosphorylated CSF-tau. Taken together, our results suggest that CSF-tau might reflect the accumulation of altered tau due to the progressive death of neurons in the AD brain, and that the assay of CSF-tau by ELISA may prove to be a reliable and early diagnostic test in AD.

## 581.9

**EVIDENCE OF BLOOD-CEREBROSPINAL-FLUID-BARRIER IMPAIRMENT FOR HIGH MOLECULAR WEIGHT PROTEINS IN A SUBGROUP OF ELDERLY PATIENTS WITH MAJOR DEPRESSION AND ALZHEIMER'S DISEASE** H. Hampel<sup>\*</sup>, C. Hock, A. Haberl, C. Berger, M. Ackenheil, F. Müller-Spahn and H.-J. Möller. Department of Psychiatry, University of Munich, 80336 Munich, Germany and Department of Psychiatry, University of Basle, 4025 Basle, Switzerland

Serum and cerebrospinal fluid (CSF) from 44 patients with clinical probable Alzheimer's disease (AD) (subdivided into two groups with 18 early onset [EO] and 26 late onset [LO] cases) and 24 patients with Major Depression (MD) were assayed for concentrations of albumin and IgG. The severity of dementia was assessed with the Mini Mental State Examination (MMSE). The CSF/serum ratio for albumin and IgG as well as the IgG-index were used to evaluate blood-CSF barrier (BCB) function. Various patients showed signs of BCB dysfunction for high molecular weight proteins like albumin more pregnant in the MD than in the AD group. This was significantly correlated to the total CSF protein content. The permeability of the BCB and the total CSF protein content were not correlated to measures of dementia severity. Our data indicate a BCB leakage in a subgroup of 16 % demented and more pregnant in 21% of the depressed patients. Whether BCB impairment, in a possible yet undefined neurobiological subgroup of patients with MD and AD, plays a role in the pathophysiology of the diseases or is only an epiphenomenon, remains to be investigated. In total BCB impairment is unspecific either for AD or MD.

## 581.11

**A STUDY OF SENSORY MOTOR COORDINATION IN ALZHEIMER'S DISEASE.** P. Demers<sup>1,2</sup>, M. Lassonde<sup>1\*</sup> and A. Robillard<sup>2</sup>. <sup>1</sup> Hôpital Maisonneuve-Rosemont <sup>2</sup> Département de psychologie, Université de Montréal, Montréal, CANADA.

This study examined movement accuracy and movement time in 11 subjects with probable Alzheimer's disease and in 8 normal elderly controls. Subjects had to point to targets (red light emitting diodes), randomly presented on a board. This board was covered with an isotropic resistant surface that measures terminal movement accuracy in two dimensions. The task was executed under two conditions: with visual control and without vision of the arm. Results indicate that subjects with dementia of the Alzheimer type were as accurate as normal controls only in the experimental condition where both proprioception and vision were available. The measurement of variable error and constant error revealed significant differences between groups but only in the no-visual feedback condition. Indeed, demented subjects had more variations in their performance and a larger constant error in that condition. Undershooting was present in all subjects as revealed by the direction of the constant error. However, the magnitude of the undershooting movement was more important in AD subjects than in controls in the absence of visual feedback. Finally, movement time was significantly longer in demented subjects than in normal controls. This effect was especially evident with the non-dominant hand in the absence of visual feedback. Longer movement time did not result in an increased movement accuracy in the group with dementia. These findings suggest that DAT subjects need to rely on more than one source of afference to accurately execute a fine motor movement. They also support the idea that movement disturbance, other than limb apraxia, may be present in Alzheimer's disease.

## 581.8

**ANTEMORTEM CSF TAU IS RELATED TO NEURONAL PATHOLOGY AT AUTOPSY IN ALZHEIMER'S DISEASE.** D. Galasko<sup>\*</sup>, L. Hansen, C. Vigo-Pelfrey, D. Schenk, P. Seubert. Dept. of Neurosciences, University of California, San Diego, CA 92093 and Athena Neurosciences, South San Francisco, CA 94080.

Antemortem biological markers of Alzheimer's disease (AD) such as cerebrospinal fluid (CSF) levels of tau, APP and amyloid beta protein have been proposed. For example, CSF tau is increased in many AD patients, even very early in the course of their dementia. Comparison between CSF measures and autopsy data allows the relationship between CSF markers and brain lesions to be clarified.

We have measured CSF tau in patients with clinical probable AD, using a sensitive 2-site sandwich ELISA. From this cohort, 9 patients have come to autopsy, from 3 - 8 years after the CSF was obtained. Brains were examined histologically in a standard protocol, that included counts of neurofibrillary tangles and senile and neuritic plaques.

CSF tau ranged from 148 - 538 pg/ml. Of the 4 patients with the lowest tau levels, 3 had pathology of Lewy body variant of AD, with cortical and subcortical Lewy bodies, and one had "plaque only" AD; NFT were exceedingly rare in these 4 patients, while plaque counts met criteria for AD. The remaining 5 patients had abundant NFT in the hippocampus and neocortex. The 2 patients with tau levels over 500 pg/ml had the highest NFT counts, especially striking in the hippocampus. In patients with AD, CSF tau levels therefore appear to be related to the extent of neurofibrillary pathology; this damage presumably releases soluble tau that can diffuse into CSF.

## 581.10

**CEREBRAL BLOOD FLOW CHANGES IN RESPONSE TO VISUAL STIMULATION IN DEMENTED PATIENTS**

H.A. Buchtel<sup>\*</sup>, R.A. Koeppel, J. Mountz, N.L. Foster, S. Berent, B. Giordani and D.E. Kuhl. VA Medical Center, Ann Arbor and University of Michigan Departments of Psychiatry, Internal Medicine, Division of Nuclear Medicine, Neurology, and Psychology.

The visual-spatial disorders that are commonly seen in dementia are usually attributed to a disturbance of higher-order mechanisms rather than to reduced responsiveness of the visual system. However, EEG evoked potentials are slowed or reduced in amplitude in patients with Alzheimer's Disease (AD) and Parkinson's Disease (PD) with dementia. To test the possibility that visual-spatial deficits seen in dementia may be secondary to reduced input to higher cortical centers, we carried out [O-15]-water activation PET scans with two groups of demented patients (PD with dementia, N=5; probable AD; N=5), and two control groups (normal control subjects, N=7; and cognitively intact patients with PD, N=4). Overall metabolic values were lower for the patient groups compared to normals, and stimulation effects were significantly lower in association cortices for the demented patients compared to the non-demented individuals. We are uncertain if the effect observed would entirely account for the behavioral findings in visual-spatial tasks, and plan to study these phenomena further. We do feel that responsiveness in the visual system should not be excluded as one of the factors contributing to cognitive deficits in demented patients.

**SPARING OF PRIMARY SENSORY AND MOTOR ABILITIES IN INTERMEDIATE STAGES OF ALZHEIMER'S DISEASE.**

Y. Lakmache<sup>1</sup>, S. Gauthier<sup>2\*</sup>, F. Lepore<sup>1</sup>, and M. Lassonde<sup>1</sup>.

<sup>1</sup>Psychology Dept, Uni. of Montreal and <sup>2</sup>McGill Center Qc., Canada.

Higher-order cognitive functions have been extensively investigated in patients with probable Alzheimer's disease (AD). Additionally, modality-specific elementary sensory-motor integration remains under-reported. The aim of this study was to evaluate visual, somesthetic and motor performance in early AD's patients using six screening tasks. Ten probable AD's patients (stages III & IV on the Reisberg Scale) were compared to 10 age and sex matched controls. Visual acuity was measured with the Rosenbaum test and visual field integrity (confrontation) was also assessed. The Face-hand test, digital agnosia and single and double finger localisation were used to assess somesthetic function. Finally, the Purdue Pegboard was administered in order to verify unimanual and bimanual dexterity. Results showed that there were no differences in visual, somesthetic and motor modalities in all subjects tested irrespective of the stage of illness. However, a difference was noted in the face-hand test. Thus, stage IV patients showed deficits when crossed and uncrossed distal-proximal stimulation was applied. The findings of this study suggest that, in spite of higher order cognitive deficits in probable AD, less elaborated motor and sensory (visual and somesthetic) functions are preserved even in intermediate stages of the illness. Furthermore, these observations confirm that the primary sensory and motor areas are dysfunctional only late in AD and concord well with neuroanatomical findings demonstrating that these areas are not affected in the early stages of the illness.

## 581.13

PREHENSILE ADAPTABILITY IN DEMENTIA OF THE ALZHEIMER TYPE. V. Buckles\*, J.C. Morris, J. Duchek, L. Hunt. Alzheimer's Disease Research Center, Washington University School of Medicine, St. Louis, MO 63110.

Global cognitive loss in dementia of the Alzheimer type (DAT) is associated with reduced functional abilities, e.g. driving. Previous studies have rarely controlled for dementia severity, particularly the mildest stages of DAT. Our purpose was to examine a simple but overlearned movement in subjects in the earliest stages of DAT. In this experiment, three task characteristics of prehension were manipulated to study movement adaptations made by DAT subjects compared to elderly controls: object size (cylinder size: 5cm vs 2.5cm), movement direction (straight vs left), and speed/accuracy directions (fast but accurate vs fast). DAT subjects were staged in 2 groups according to dementia severity: very mild (n=8) and mild (n=8). Controls (n=8) and DAT subjects were asked to grasp a cylinder 20cm from the starting hand position, lift and place it on a target 20cm from the cylinder's original location when they heard a 'go' tone. Except for the 'fast' condition, subjects were instructed to 'move as quickly and accurately as possible.' **Results:** Mildly demented subjects had longer reaction times and movement times, used lower peak velocities, and spent a greater proportion of time in deceleration than controls. An interesting question is how well did DAT subjects adapt to changes in the task characteristics compared to controls. Only time to peak aperture showed a group X condition interaction, where the mildly demented subjects reached peak aperture (opening of the fingers to grasp) later in fast and left movements compared to other groups. DAT subjects adapted similarly to controls. The ability to adapt overlearned skills to meet task demands appears preserved in very mild and mildly demented subjects, and may have implications for more complex motor skills such as driving. Support: NIH AG10145.

## 581.15

DISCRIMINATION OF ALZHEIMER'S AND PARKINSON'S DISEASE BY ANALYSIS OF REGIONAL CSF PROFILES USING QUANTITATIVE CT BRAIN IMAGING. D.H. Mathalon, E.V. Sullivan, P.K. Shear, K.O. Lim\*, H.J. Sagar, J.A. Yesavage, J.R. Tinklenberg, and A. Pfefferbaum. Dept. of Psychiatry and Behavioral Sciences, Stanford University School of Medicine and DVAMC, Palo Alto, CA 94304; Dept. of Clinical Neurology, University of Sheffield, England.

The primary pathology of Alzheimer's disease (AD) is cortical whereas that of Parkinson's disease (PD) is nigrostriatal; yet, cortical atrophy has been observed in PD. We used CT measures of CSF volumes to compare the regional pattern of brain atrophy in AD and PD across 6 regions of interest (ROI; frontal, parieto-occipital, temporal sulci, Sylvian fissures, lateral and 3rd ventricles). Subjects were 31 normal controls (NC; 62±11y), 117 AD (69±8y), and 54 PD (62±8y). Data were expressed as age- and head size-corrected Z-scores (standardized to controls; NC ROI mean=0±1sd). A MANOVA revealed group differences across the ROIs, with AD and PD showing greater CSF volumes than NC in every ROI except the lateral ventricles, which were not abnormally enlarged in PD. Moreover, AD showed more severe atrophy than PD in every ROI except the parieto-occipital sulci, where the groups did not differ. A discriminant analysis of AD vs. PD using the 6 ROIs as discriminators correctly classified 81.2% of AD and 83.3% of PD. However, this discriminative power may have simply reflected the overall CSF volume profile elevation of AD relative to PD. Accordingly, we performed a multivariate profile analysis to compare the relative distributions of regional atrophy in the two diseases, independent of the overall difference in profile elevations. AD and PD exhibited different patterns of regional brain atrophy; a discriminant function using only within-subject differences between ROIs as discriminators correctly classified 82.1% of AD and 83.3% of PD. In AD, the lateral ventricles, Sylvian fissures, and temporal sulci were equally abnormal and more enlarged than the frontal, parieto-occipital, and 3rd ventricle. By contrast, in PD, the cortical and 3rd ventricle ROIs were atrophic relative to the lateral ventricles, with Sylvian and temporal atrophy comparable to that in the other cortical ROIs. Thus, AD and PD are distinguishable by their regional profiles of brain atrophy as measured with CT. [Funded by MH 40041, MH 30854, AA 05965, DVA]

<sup>2)</sup> Dep. of Neurology, Sapporo Med. Univ. Sch. of Med., Sapporo, Japan 060

It is known that object recognition is impossible under conditions where miniature eye movements do not occur due to anesthesia. Also, as it has been suggested that miniature eye movements are chaotic (Yoshimatsu et al, 1993), we carried out fractal analysis of the miniature eye movements. The results showed that abnormal findings are characteristic of dementia patients with a frontal lobe deficit, suggesting a close relationship between the attention function and miniature eye movements (Fujii et al, 1994). Using an eye movement analyzer (Takei Co. LTD.), we applied bandpass filter to the data of miniature eye movements of both eyes from the results of tests carried out on Alzheimer's disease patients, vascular dementia patients and healthy subjects, and obtained the drift component. We then carried out mathematical analysis using a newly developed analytical software program. Analysis was carried out to obtain the following: correlation coefficient, pseudo topographical space, topographical space in time series, and waveform in time series.

The results of these analyses were different for Alzheimer's disease patients compared to healthy subjects and vascular dementia patients. Although the clinical significance of these analytical results is not clear, the results of this mathematical analysis did show that vascular dementia patients and elderly healthy subjects were similar, and we were also able to obtain characteristic findings for Alzheimer's disease patients. Thus, the results of this analysis are thought to be useful in the differential diagnosis of vascular dementia and Alzheimer's disease. It is thought that the difference in the analytical results for these two diseases may also reflect the difference in the nature of the recognition deficit between vascular dementia and Alzheimer's disease.

## NEUROMUSCULAR DISEASES

## 582.1

RUBRAL, VESTIBULAR, AND RETICULAR PROJECTIONS TO SPINAL CORD IN THE MUTANT *MDX* MOUSE. D. Minciacchi\*, D. Carretta, M. Santarelli, B. Carrai, F. Pinto, A. Sbriccoli, and A. Granato. Dept. of Neurol. and Psychiat. Sci., Univ. of Florence, Italy, and §Lab. of Exp. Neurol. and §Inst. of Anat., Catholic Univ., Rome, Italy.

The mutant *mdx* mouse is acknowledged model of the human disease Duchenne Muscular Dystrophy. Previous investigations from our laboratory demonstrated that the cortico-spinal system of *mdx* is altered impressively (Minciacchi et al., Soc. Neurosci. Abstr., Vol. 20, p3, 1994).

In the present study we analyzed, in *mdx* mice, the spinal projections of the red nucleus (RN), and the medial and lateral vestibular (MVe and LVe), gigantocellular reticular (Gi), and raphe magnus (RMg) nuclei. Injections of aqueous solutions of horseradish peroxidase were performed into the cervical spinal cord of *mdx* and normal mice, and retrogradely labeled neurons were studied in the brainstem.

Populations of labeled neurons are present in RN, MVe, LVe, Gi, and RMg of both normal and *mdx* mice. In contrast to normal animals, spinal projecting neurons in the RN of *mdx* mice are reduced of about 40% and the difference is significant (p<0.05). Conversely, in MVe, LVe, Gi, and RMg, the cell populations projecting to spinal cord are quantitatively matching; in no case the difference between *mdx* and normal animals is significant. No major comparative variation was observed in the morphology and size of spinal projecting cell populations in RN, MVe, LVe, Gi, and RMg.

The present data show that the structural alterations of the cortico-spinal system we observed previously in *mdx* mice are not unique since the rubro-spinal system is altered as well. The damages of the central nervous system in *mdx* selectively involve structures implicated in the control of motor behaviour. The fact that only a part of supra-spinal motor centers is affected represents an information of pivotal interest and opens the possibility to reconsider the pathogenetic hypotheses of Duchenne Muscular Dystrophy.

## 582.2

MEMBRANE ELECTRICAL PROPERTIES OF SKELETAL MUSCLE FIBERS OF DYSTROPHIC (MDX) MICE DURING AGING. A. De Luca\*, S. Piemo, A. Roselli, F. Natuzzi, and D. Conte Camerino. Unit of Pharmacology, Dept. of Pharmacobiology, Faculty of Pharmacy, University of Bari, Italy.

*Mdx* mouse is genetically homolog with human Duchenne muscular dystrophy (Engel et al., in *Myology*, 1133, 1994). We previously recorded a transient increase of macroscopic chloride conductance (GCl) in extensor digitorum longus (EDL) muscle from *mdx* mice during the 2nd month of age, a period characterized by a successful regeneration of the hind limb muscles. On the contrary a decrease of this parameter has been observed in the non-regenerating diaphragm (DIA) muscle of the same strain (De Luca et al., *Biophys. J.* 68: A274, 1995; Engel et al., 1994). To better evaluate the relationship between the changes of GCl and the regeneration and degeneration events, the component conductances to chloride and potassium (GK) ions of EDL and DIA muscles were recorded *in vitro* by means of computerized intracellular microelectrode technique from *mdx* mice undergoing aging (14 month-old), a spontaneous degenerative event characterized by a decrease of GCl and an increase of GK (De Luca et al., *J. Pharmacol. Exp. Ther.* 269: 948, 1994). The EDL muscles from aged control mice (C57BL/10) were characterized by a significant decrease of GCl from the adult value of 2248±96µS/cm² (n=60) to 1860±100µS/cm² (n=20) and by a 20% increase of GK. Conversely, the GCl value of EDL muscle from aged *mdx* mice was not significantly different with respect to adult value (2021±96µS/cm²; n=86), being 2108±125µS/cm² (n=28). Also GK was unaffected being 429±44 µS/cm² (n=27) vs. 404±50µS/cm² (n=24) of adult *mdx* EDL muscles. In the control mice, the GCl of DIA was 2186±143µS/cm² (n=16) in adult and 1095±115µS/cm² (n=11) in aged and GK was 30% higher in the aged animals. In the DIA muscle from aged *mdx* mice GCl was dramatically low being 660±94µS/cm² (n=13) vs. 1755±136µS/cm² (n=12) of adult *mdx* DIA. Thus, the EDL muscle from *mdx* mice has a high regenerative potential, which has in GCl a sensitive target, that allows the muscle to counteract degenerative conditions such as aging. On the contrary a non-regenerating *mdx* muscle, such as DIA, is more sensitive to the progression of aging-induced degeneration (Telethon-Italy project n° 322).

## 582.3

NITRIC OXIDE SYNTHASE IS COMPLEXED WITH DYSTROPHIN IN SKELETAL MUSCLE AND ABSENT FROM SARCOLEMMMA IN DUCHENNE MUSCULAR DYSTROPHY. J.E. Brenman, D.S. Chao, H. Xia, D. Copenhagen\*, and D.S. Bredt. Dept. of Physiology, UCSF, CA 94143.

Nitric oxide (NO) is synthesized in skeletal muscle by neuronal NO synthase (nNOS), which is localized beneath the sarcolemma of fast twitch muscle fibers. We now show that nNOS associates with both microsomal and cytoskeletal fractions of skeletal muscle. This subcellular localization is mediated by anchoring of nNOS to dystrophin, the protein product of the gene mutated in Duchenne and Becker muscular dystrophy. Specificity of binding is demonstrated by copurification of nNOS and dystrophin by both succinylated wheat germ agglutinin and 2' 5'-ADP affinity chromatography procedures. Dystrophin interacts with the amino-terminal domain of nNOS which contains a 66 amino acid motif that is shared by a family of cytoskeletal associated proteins including syntrophin, a known binding partner of dystrophin. *mdx* mice and humans with Duchenne muscular dystrophy (DMD) evince a selective loss of nNOS protein and catalytic activity from membrane and cytoskeletal fractions and an accumulation of nNOS in muscle cytosol. These data demonstrate a novel role for dystrophin in localizing a signaling enzyme to the myotube plasma membrane. Aberrant regulation of nNOS in dystrophic fast twitch muscle fibers may contribute to selective degeneration of this fiber type in DMD.

Ca<sup>2+</sup> CURRENT RECORDINGS FROM MYOCYTES TREATED WITH LES SERUM. K.D. García\*, M. Mylneff\*, and K.G. Beam#. Depts. of Anatomy and Neurobiology\* and Physiology#, Colorado State Univ., Fort Collins, CO 80523, and Dept. of Biology\*, Marquette Univ., Milwaukee, WI 53233.

Lambert-Eaton Myasthenic Syndrome (LES) is a human autoimmune disorder characterized by decreased quantal content at the neuromuscular junction. LES antibodies do not appear to specifically react with one type of Ca<sup>2+</sup> channel since they decrease both the LVA and the HVA components of Ca<sup>2+</sup> current in dorsal root ganglion cells (DRGs) and neuroblastoma cells. Past research has concluded that LES antibodies do not react with myocytes since they do not alter the strength of muscle contraction elicited by direct stimulation. However, no one has recorded Ca<sup>2+</sup> currents in myocytes treated with LES serum. In the present study we examine the possible effects of LES serum on murine cardiac and skeletal myocytes. Serum from three patients previously tested on DRGs was used. Serum from patients I and II, who were definitively diagnosed as having LES, decreased both HVA and LVA components of Ca<sup>2+</sup> current in DRGs. Serum from patient III, who was diagnosed as having myasthenia gravis and some characteristics of LES, did not decrease DRG Ca<sup>2+</sup> currents. Cells were maintained in culture for 3-10 days. Serum from normal individuals or one of the three patients was added to the culture medium 24 h before currents were recorded. Ca<sup>2+</sup> currents were measured with the whole-cell variant of the patch clamp method (10mM Ca<sup>2+</sup> as charge carrier). Currents were evoked by 300-ms depolarizations applied from a holding potential of -80 mV. In myocytes, sera from patients I and II did not decrease Ca<sup>2+</sup> currents while serum from patient III decreased the HVA component of Ca<sup>2+</sup> current. These results suggest that LES antibodies do not react with Ca<sup>2+</sup> channels in myocytes and that muscle inflammation in myasthenia gravis may result in production of antibodies to muscle type Ca<sup>2+</sup> channels. Supported by NIH grant NS 26416 to Kurt Beam.

## 582.7

CALCIUM OVERLOAD AND POSTSYNAPTIC VACUOLATION IN TRANSGENIC MICE AS A FUNCTION OF CHOLINERGIC RECEPTOR ION CHANNEL KINETICS. C. M. Gomez, R. Maselli, J. W. Day\*, and R.W. Wollmann, Univ. of Minn., Minneapolis, MN 55455.

Changes in acetylcholine receptor (AChR) channel kinetics occur in neuromuscular junction (NMJ) development and underlie some congenital myasthenic syndromes (CMS). To assess the role of such changes on NMJ calcium (Ca<sup>2+</sup>) overload and NMJ integrity we created transgenic (TG) mice expressing mutant AChRs with a range of ion channel abnormalities. Muscle was studied in vitro using voltage-clamp and patch-clamp single-channel analysis, using a histochemical stain for ionized Ca<sup>2+</sup>, glyoxal bis-hydroxanil, and by electron microscopy (EM). Mice expressing AChRs with the mutation,  $\delta$ S262T (open times prolonged 3-fold) had no evidence of Ca<sup>2+</sup> overload and normal motor endplates by EM. Mice expressing AChRs with the mutations,  $\alpha$ C418W (open times prolonged 5-fold) or  $\alpha$ L251T (open-times prolonged 10-fold) had histochemical evidence of Ca<sup>2+</sup> overload at a mean of 1% of NMJ when studied at rest. This proportion increased ten-fold (10% of NMJ) after exercise or nerve stimulation. Ca<sup>2+</sup> overload was totally prevented in the gastrocnemius of exercised mice by prior sciatic nerve ligation. NMJ of  $\alpha$ C418W-TG mice appeared normal by EM. In contrast, in forelimb flexor muscle of exercised  $\alpha$ L251T-TG mice the junctional sarcoplasm was filled with membrane-bound vacuoles between and beneath the secondary synaptic clefts in multiple NMJ examined. Mitochondria in the region were morphologically normal. These findings suggest that increased AChR channel open time interferes with Ca<sup>2+</sup> homeostasis at the NMJ and is responsible for the pathologic changes seen in many CMS. Supported by NIH-CIDA# K08NS01540 and the Muscular Dystrophy Association.

## 582.4

A POSSIBLE FUNCTIONAL CORE REGION OF DYSTROPHIN. Cheng Zhang\*, Youmei Xie\*, Genbin Shi, Zhoulun Liu, Jianhua Chai. Dept. of Neurology, First Hospital, Sun Yat-sen Univ. of Med. Sci., Guangzhou, 510080 and Dept. of Obstetric and Gynecology<sup>1</sup>, West China Univ. of Med. Sci., Chengdu, 610041, P. R. China.

Dystrophin is the protein product of DMD gene. The observation that abnormalities of dystrophin result in different phenotypes (DMD and BMD) suggests the possibility that mutations in different critical functional regions of the DMD gene might result in different phenotypes. Hydrophobicity and hydrophilicity plots of the 3685 amino acid sequence of dystrophin were analyzed using Genepro software (window 56). Our results demonstrated that dystrophin contains four hydrophobic regions located in dystrophin amino acid domains 95-120, 1990-2010, 2438-2493, and 3150-3300, respectively. Among the four regions, the hydrophobicity in the third one (amino acids 2438-2493) is the strongest. We have named the third hydrophobic region the Deletion Hot Spot Hydrophobic Peptide (DHSHP) of dystrophin because the amino acids belonging to this region are coded by the deletion hot spot exon 51 of the dystrophin gene. In order to assess the relationship between deletions in DHSHP and phenotype, we collected 189 cases of DMD and BMD with DNA in-frame deletions of the dystrophin gene from nine published papers. Among the 189 cases, 70 were DMD and 119 were BMD. Of the DMD patients, 55.7% (39) had deletions in the DHSHP. Of the BMD patients Only 3.4%(4) had deletion in the DHSHP (Chi-square test, P<0.01). This result suggests that the presence or absence of the DHSHP region is one significant determinant of DMD/BMD phenotype.

## 582.6

A  $\beta$  SUBUNIT MUTATION IN THE PUTATIVE GATE OF THE ACETYLCHOLINE RECEPTOR (ACHR) CHANNEL CAUSES A CONGENITAL MYASTHENIC SYNDROME (CMS). Jason Gammack, Ricardo Maselli, Cesar Labarca, Christopher Gomez\*, Univ. of Minn., Minneapolis, MN 55455.

A number of CMS are due to kinetic disorders of the muscle AChR. In some, mutations have been found in the gene encoding the  $\epsilon$  subunit of the AChR. We used intracellular and extracellular microelectrode studies to detect a kinetic disorder of AChRs in a patient with a severe CMS. One population of channels had open times of approximately 6-8 ms. We screened for single strand conformation polymorphisms in DNA amplified from the ion channel-(M2) coding regions of the patient's four AChR genes. We found an abnormal conformer in the  $\beta$  subunit M2 domain that was present in the patient, but not in his asymptomatic parents or siblings. By allele-specific sequence analysis we identified a C-to-A transversion in the  $\beta$  subunit gene. This mutation codes for the substitution of a methionine residue for leucine263, a highly conserved residue that is believed to participate with homologous leucine residues to form the ion channel gate. Only the wild type sequence was present in the  $\beta$  subunit M2 regions amplified from the patient's parents and siblings. To confirm the role of this mutation in the pathogenesis of his disease we generated the homologous mouse mutation in cloned mouse  $\beta$  subunit cDNA and compared ACh-induced currents induced in oocytes expressing AChRs with the  $\beta$ L263M mutation to those with wild type AChRs. We found that AChRs with this mutation had ten-fold greater sensitivity to ACh, as judged by EC50, than do wild type AChRs. We conclude that a spontaneous mutation in codon 263 of the  $\beta$  subunit gene is responsible for this patient's CMS. Supported by NIH# R01 NS33202-01A1.

## 582.8

ELECTRON MICROSCOPIC INVESTIGATION OF MUSCLE MITOCHONDRIA IN CHRONIC FATIGUE SYNDROME. A.V. Plioplys\*, S. Plioplys, Chronic Fatigue Syndrome Center, Mercy Hospital, Stevenson Expwy at King Drive, Chicago, IL 60616.

Chronic Fatigue Syndrome (CFS) patients suffer from disabling physical and mental fatigue. Abnormalities in mitochondrial function can lead to fatigue and weakness. Other researchers have reported ultrastructural mitochondrial abnormalities in CFS patients (W.M.H. Behan, J Pathol 1992; 166: 213-214).

We obtained percutaneous needle muscle biopsies from 15 CFS patients and 15 age and sex-matched controls. We investigated previously reported ultrastructural abnormalities in CFS: subsarcolemmal mitochondrial aggregates, intermyofibrillar mitochondrial aggregates, mitochondrial circumference, area, pleomorphism and the presence of compartmentalization of the inner mitochondrial membrane. All of the steps of tissue processing, electron microscopy and data abstracting and analysis were performed in a totally blinded fashion. All of our data was rigorously quantified and statistically analyzed. We studied over 2,500 mitochondria.

We observed all of the previously reported abnormalities of mitochondrial ultrastructure in our CFS patients. However, in all of the parameters studied the results obtained from the controls were identical to those of the CFS patients.

Although there is no ultrastructural mitochondrial abnormality in CFS patients, other lines of evidence suggest the presence of a possible functional mitochondrial abnormality. This study was supported by the Chronic Fatigue Syndrome Association of Minnesota and by Sigma-Tau Pharmaceutical Company.

CHARACTERISTICS AND FUNCTIONAL CORRELATION OF THE EMG AND TORQUE OF THE STRETCH REFLEX IN SPASTICITY. F. Lin and M. Sabbahi<sup>1</sup>. School of Physical Therapy, Texas Woman's University, Houston, TX 77030.

The purpose of this study was to evaluate the contribution of stretch reflexes in the volitional and functional wrist performance in spasticity. The stretch reflexes of wrist flexors, evoked by ramp-and hold stretches, were recorded at four different stretch velocities and four levels of background muscle contraction in ten spastic stroke patients. The reflexive EMG (flexor carpi radialis) and wrist flexion torque responses were recorded. When compared with ten age-matched healthy subjects, the reflex gain and amplitude of the EMG short-latency response in spasticity, but not the torque response, were significantly higher than normal. The EMG to torque ratio of the stretch reflex response was also significantly higher in spastic patients. Unlike normal, the EMG short-latency reflex in spasticity was independent of the background muscle contraction. Three patterns of EMG long-latency response were recorded among spastic patients. Patients of pattern A (n=3, prolonged and enlarged long-latency reflex) tended to have lower spasticity and higher functional level. Patients of pattern B (n=2, reduced or absent long-latency reflex) tended to have higher spasticity and lower functional level. Patients of pattern C (n=5, delayed and enlarged long-latency reflex) were a mixed group. In average, the EMG long-latency reflex in spasticity was not higher than normal, which suggested that the long-latency reflex response has little contribution to spasticity. The reduced long-latency reflex response in pattern B was probably a result of inhibition from the preceding short-latency reflex. The degree of clinical spasticity (measured by the Ashworth scale) showed strong reverse correlation with the volitional (active range of motion, grip strength) and functional (Fugl-Meyer tests, Box & Blocks Test) movement performance and moderate correlation with the EMG response of the stretch reflex. No correlation was found between the degree of spasticity and the torque response of the stretch reflex. (This study was funded by training grant #40341 from NIDRR.)

## 582.11

HYDROCORTISONE (HC) INCREASES MEROSIN AND CAUSES ITS AGGREGATION IN ANEURALLY CULTURED HUMAN MUSCLE. L. McFerrin, V. Askanas<sup>\*</sup> and W.K. Engel. USC Neuromuscular Center, Los Angeles, CA 90017-1969.

Merosin, a laminin isoform, is a newly-discovered component of the basal lamina of striated muscle and peripheral nerve. Merosin deficiency has been described as a cause of certain congenital myopathies (CM). Previously we demonstrated in aneurally cultured human muscle that glucocorticoids increase amounts of dystrophin and acetylcholine receptors (AChRs), and causes aggregation of dystrophin, AChRs, and utrophin. Aggregates of all three co-localize with each other.

Now we have studied the influence of HC on the distribution and amount of merosin in aneurally cultured human muscle. In 7 experiments, each from a different normal muscle biopsy, human muscle cultures were established from the satellite cells. Treatment with 20 uM HC was initiated after myoblast fusion was completed (approximately 8 days after cultures were established) and it was continued for 1, 2, and 3 weeks. In both HC-treated and control cultures, increase of merosin was developmentally regulated. As compared to controls, in the HC-treated cultures the merosin was: a) increased approximately 2-fold; and b) localized along the surface of the fiber in very pronounced irregular aggregates, in distinct contrast to a uniform distribution in the controls. Unlike dystrophin and utrophin, merosin aggregation did not co-localize with AChRs. Our study demonstrates for the first time that treatment with glucocorticoid increases merosin and influences its localization. These results suggest that treatment with glucocorticoid may benefit some CM patients.

## 582.13

T Cell Receptor V $\beta$ 15 Gene Usage in Guillain-Barré Syndrome A. Khalil-Shirazi<sup>1</sup>, N.A. Gregson<sup>2</sup>, M.A. Hall<sup>3</sup>, R.A.C. Hughes<sup>1</sup>, P. Doherty<sup>4</sup>, J.S. Lanchbury<sup>3</sup>. Departments of Neurology<sup>1</sup>, Anatomy & Cell Biology<sup>2</sup>, Molecular Immunogenetics<sup>3</sup>, Experimental Pathology<sup>4</sup>, UMDS, Guy's Campus, London SE1 9RT, UK.

We set out to determine whether the T cell receptor (Tcr) V $\beta$  gene usage in acute inflammatory demyelinating polyradiculoneuropathy (AIDP) is restricted. We separated activated from non-activated peripheral blood T cells with anti-IL2 receptor (anti-CD25) antibody-labelled magnetic beads from four AIDP patients and 4 normal control (NC) subjects. The Tcr V $\beta$  gene usage of circulating activated and non-activated T cells was heterogeneous in all the patients and controls, but the activated T cells of all 4 of the AIDP patients showed a more limited usage of V $\beta$  genes and enhanced V $\beta$ 15 usage, as compared to the unactivated T cells. This was not seen in the healthy controls. The activated and non-activated T cells from a patient with acute motor and sensory axonal neuropathy (AMSAN) showed a similar V $\beta$  gene usage to that of the controls. From a further patient with AIDP, we studied the V $\beta$  gene usage of short-term T cell lines reactive to the peripheral nerve myelin proteins P<sub>2</sub>, P<sub>0</sub> and the P<sub>0</sub> peptide amino acid sequence 184-208. The V $\beta$  gene usage of the lines was heterogeneous, but the cell line responsive to the P<sub>0</sub> peptide showed prominent usage of V $\beta$ 15. We conclude that T cells activated during the immune response associated with AIDP preferentially use V $\beta$  15. The limited Tcr usage of activated T cells may indicate a restricted response to a common antigen, or a role for an as yet undefined superantigen in the pathogenesis of AIDP.

## 582.10

THE EXPRESSION OF C-FOS AND C-JUN FOLLOWING DENERVATION AND REINNERVATION OF MUSCLE. H.D. Soares<sup>\*</sup>, S.-C. Chen, T. Curran, and J.I. Morgan. Roche Inst of Molec. Biol, Nutley, NJ 07110

Previous studies in our laboratory have demonstrated prolonged increases of *c-fos* and *c-jun* mRNA in chronically denervated muscle suggesting a regulatory role for these two cellular immediate early genes during muscle fiber atrophy. We compared muscle fiber *c-fos* and *c-jun* expression following either sciatic nerve transection (chronic denervation atrophy) or sciatic nerve crush (reinnervation) in transgenic mice harboring either *c-fos-lacZ* or *c-jun-lacZ* transgenes. Sciatic nerve transection resulted in prolonged elevations of both *c-fos* and *c-jun* mRNA in denervated muscle for up to four weeks after trauma. However, sciatic nerve crush elicited only transient increases in *c-fos* and *c-jun* mRNA with levels returning to baseline values by two weeks post injury. Although increased *c-fos* levels were associated with nuclear Fos protein expression, elevated *c-jun* message was not accompanied by concomitant increases of nuclear Jun protein expression in denervated muscle. Interestingly, Fos-lacZ induction appeared first in muscle fiber nuclei adjacent to the motor endplates 24 hours following either sciatic nerve transection or crush. However, Fos-lacZ expression spread to adjoining muscle fibers at 2 and 4 weeks after sciatic transection while Fos-lacZ expression following crush injury was absent in muscle at later timepoints. In summary, these results suggest that *c-fos* expression is dependent upon the innervation status of muscle and may participate in the responses that contribute to degenerative muscle diseases elicited by muscle denervation.

## 582.12

EXPRESSION OF INTERLEUKIN 10-MRNA IN WALLERIAN DEGENERATION AND DEMYELINATION OF THE RAT PNS G. Stoll<sup>\*</sup>, S. Jander, J. Pohl and C. Gillen. Dept. of Neurology, Heinrich-Heine-Universität, 40225 Düsseldorf, Germany

Interleukin 10 (IL10) is a potent immunosuppressant which blocks macrophages and TH1 cell mediated immune responses. In this study we localized mRNA for IL10 in the rat PNS by *in situ* hybridization using a digoxigenin-labeled riboprobe specific for rat IL10. In normal sciatic nerves some Schwann cells (SC) expressed IL10-mRNA. After nerve transection the number of IL10-mRNA positive cells dramatically increased at days 2 and 4. Most IL10-mRNA positive cells could be identified as S100 positive SC by immunocytochemistry while ED1 positive macrophages were IL10-mRNA negative. By day 14 only occasional cells were IL10-mRNA positive. In immune-mediated demyelination induced by active immunization with peripheral nerve myelin macrophages transiently expressed IL10-mRNA. In conclusion our data suggest that SC provide an immunosuppressant system in the PNS that is activated after nerve transection. Moreover, IL10-mRNA is differentially regulated in macrophages in response to axotomy and during immune-mediated demyelination.

## 582.14

EXPERIMENTAL MONONEUROPATHY: MICROENVIRONMENTAL MECHANISMS OF SENSITIZATION. H. Sasaki, M. Kihara, K. K. Nickander, P. J. Zollman, I. L. Smithson, J. D. Schmelzer<sup>\*</sup>, E. E. Benarroch and P. A. Low. Department of Neurology, Mayo Clinic, Rochester, MN 55905.

The application of 4 loose ligatures to sciatic nerve results in spontaneous nerve activity and a reduction in thermal and mechanoreceptor thresholds. Fiber degeneration occurs, but the mechanism of fiber degeneration and sensitization is unknown. We evaluated nerve blood flow (NBF), morphometric alterations, norepinephrine, and neuropeptides at the lesion and the ipsilateral L5 dorsal root ganglia (DRG). Tissues were evaluated from days 2 to 45 in Sprague-Dawley male rats. NBF was measured using microelectrode H<sub>2</sub>-polarography and was significantly increased within the lesion but reduced by >70% at the lesion edge. Norepinephrine (NE), measured by HPLC/electrochemical detection showed a large increase (x6) within the ligatures at day 5, x2 above the lesion and normal distal to the ligature. By day 14, there was a mild (40%) reduction in NE distal to the ligatures. Glyoxylic acid fluorescence confirmed increased noradrenergic fluorescence within the ligatures. Morphometric analysis showed that >75% fibers had undergone axonal degeneration at the lesion. We postulate that the ligatures create a dam where vasoactive agents (NE, CGRP, NPY) accumulate, increasing NBF and nociceptor sensitization. Ischemia occurs at the lesion edge, causing degeneration of myelinated fibers with relative sparing of unmyelinated fibers. A second site of sensitization occurs at the DRG (see Zollman et al. abstract), involving  $\alpha$ -adrenoreceptors and changes in neuropeptide expression.

## 582.15

PERIPHERAL NEUROPEPTIDE PLASTICITY IN A QUADRUPLE LIGATURE MODEL OF PAINFUL NEUROPATHY. P. J. Zollman, E. E. Benarroch\*, D. A. Wittrock, I. L. Smithson, L. M. Ivanjack, J. D. Schmelzer and P. A. Low. Department of Neurology, Mayo Clinic, Rochester, MN 55905.

Peripheral axotomy produces plastic changes in neuropeptide expression in the dorsal root ganglion (DRG) (Hokfelt et al., TINS 17:22-30, 1994). We sought to determine whether changes in concentration and distribution of neuropeptide Y (NPY), and calcitonin gene-related peptide (CGRP) in the DRG, sciatic nerve (ScN), and lumbar sympathetic ganglion (LSG) occur in the neuropathy model produced by application of 4 loose ligatures in the ScN. Male Sprague-Dawley rats underwent quadruple ligation on the left ScN; controls underwent ScN sham manipulation. Rats were sacrificed (pentobarbital) at 2 to 45 days thereafter. Bilateral ScN, DRG and LSG (L4-L5 levels) were harvested and processed either for radioimmunoassay or immunocytochemistry. There was a significant increase in the levels of NPY and CGRP in both the DRG and ScN, ipsilateral to the ligation. These changes correlated with behavioral indices and were most marked at 14 days. For NPY (n=6), DRG  $12.5 \pm 2$  vs.  $1.5 \pm 1$  pg/ml;  $p=0.0005$ , and ScN  $20 \pm 1$  vs.  $9.5 \pm 2$  pg/ml;  $n=6$ ;  $p=0.0015$ ). NPY was expressed in large DRG neurons on the ligation side. Increase of CGRP (n=6) was less dramatic in the DRG ( $30 \pm 2$  vs.  $20 \pm 2$ ;  $p=0.001$ ) than in ScN ( $39 \pm 3$  vs.  $17 \pm 1$  pg/ml;  $p=0.0001$ ). Thus, in the 4 ligation model of sciatic neuropathy, there is up-regulation of NPY expression in the corresponding DRG neurons. Local increases in CGRP may contribute to increased ScN blood flow within the lesion.

Mitochondrial myopathy, encephalopathy, lactic acidosis, and stroke-like episode (MELAS) is recognized as a distinctive clinical entity in mitochondrial diseases. Recent advances indicated that genetic abnormality in mitochondrial DNA is responsible for mitochondrial respiratory enzyme complexes. But it is still unanswered whether or not this genetic deficit is involved in pathogenesis, and distribution of lesions in the CNS and systemic organs.

Case: 24 year old Japanese female. She had a mild delay in psychomotor development, and experienced generalized convulsive seizure at age 17. After recurrent episodes of right hemiplegia, hemi anopsia, she began to show difficulty in understanding and expressing speech and repetitive behaviors. MRI (T2) revealed high signal areas in bi-temporal and occipital lobes. Elevated level of lactic acid and pyruvate in serum and CSF was notable. She became mutistic and terminated in Kluver-Bucy like state, and died from intractable paralytic ileus.

Neuropathological findings were consistent with those of reported cases. Multiple necrotic foci accentuated in the parietal and occipital lobes. Ragged-red fibers seen in skeletal muscle, and cardiomyopathy. Extended mitochondria were found in GI tracts. Heteroplasmy of wild type and mutant DNA were examined using PCR and Apa I digestion. The results suggest that there is a tendency in correlation between heteroplasmy and distribution of the lesion.

Present case was considered to be a typical case of MELAS both clinically and pathologically. Further studies are needed to understand the characteristic distribution.

OXPHOS PROTEIN DEFECTS IN ALZHEIMER'S DISEASE, IN PARKINSON'S DISEASE AND IN MITOCHONDRIAL ENCEPHALOMYOPATHIES REVEALED BY BLUE NATIVE ELECTROPHORESIS. H. Schägger<sup>1</sup>, S. Diekmann<sup>2,3</sup>, and T.G. Ohm<sup>1,2</sup>. <sup>1</sup>Zentrum der Biologischen Chemie, <sup>2</sup>Morphologie, Universitätsklinikum, Frankfurt am Main, <sup>3</sup>Institut Anatomy, Charité, Berlin, Germany.

Blue native electrophoresis is a novel method for near-quantitative isolation of native membrane protein complexes from biological membranes and for molecular mass determination of native protein complexes (H. Schägger & G. von Jagow (1991) Anal. Biochem. 199, 223-231; H. Schägger et al. (1994) Anal. Biochem. 217, 220-230). Combined with Tricine-SDS-PAGE in the second dimension a two-dimensional micro-scale technique was elaborated for the quantification of OXPHOS enzymes from 10-20 mg specimens from skeletal muscle, heart, liver and brain (H. Schägger (1995) Meth. Enzymol. 260, in press).

In Alzheimer's disease complex V amounts in hippocampus were selectively reduced to 50% of the controls. Energy shortage might be a reason for cell degeneration.

In Parkinson's disease the amounts of complex I proteins in substantia nigra were found to be normal, whereas catalytic activities were reduced. This favors models implicating endogenous or exogenous inhibitors like MPP<sup>+</sup>.

The 2D-electrophoretic technique proved to be a highly sensitive method for the detection of single and multiple OXPHOS defects in mitochondrial encephalomyopathies. The effects of point mutations in mitochondrial DNA were demonstrated for the first time directly at the protein level. The protein analysis is rather independent of the post mortem delay in contrast to the analysis of mRNA levels.

SYMPOSIUM: THE ROLE OF THE CEREBELLUM IN COGNITION. T. Thach, Washington Univ. Med. Sch. (Chairperson); J. Fiez, Univ. Iowa; R. Ivry, Univ. Calif. at Berkeley; P. Strick, VA Medical Center and SUNY-Health Science Center at Syracuse.

**Does the cerebellum contribute to mental activity?** Julie Fiez will describe mental task performances that activate the cerebellum during functional imaging studies and aspects that are impaired by cerebellar ablation. These tasks and aspects include producing verbs in response to nouns, the Tower of Toronto game, the detection of performance errors, and the improvement in performance with repeated performance. Richard Ivry will discuss the idea that the cerebellum can be conceptualized as an internal timing mechanism. He will argue that this hypothesis can account for the deficits observed in motor performance, certain perceptual tasks, and sensorimotor learning.

**How might the cerebellum control mental activities?** Peter Strick will discuss the new findings that the primate cerebellum projects via thalamus to areas 6, 8, 9, 46 in the frontal lobe cortex. These areas are active in certain mental operations, and these pathways provide a means whereby the cerebellum can influence them.

**What specifically might the cerebellum contribute?** Tom Thach will summarize the principles thought by Marr and Albus to underlie the cerebellar role in movement coordination and motor learning, and the favorable evidence. These principles will then be extended to include mental operations carried on by the above areas of cerebral cortex as influenced by their cerebellar inputs. The suggestion is that many of the mental operations may be related to mental movement, which in turn is supported by these cortical areas. A specific cerebellar contribution may be the linkage of elements within these cortical areas together through trial and error learning into a synergic combination, and its linkage to a behavioral context, whose occurrence can then automatically trigger the combined response.

## 584

SYMPOSIUM: LIGAND-GATED ION CHANNEL SUPERFAMILY FEUD. R.J. Lukas, Barrow Neurological Inst. (Chairperson); J. Lindstrom, Univ. of Pennsylvania; R.W. Olsen, UCLA; S.F. Heinemann, Salk Inst.; David J. Julius, UCSF.

Members of the ligand-gated ion channel (LGIC) subset of neurotransmitter receptors are multi-component, cell surface complexes that directly regulate transmembrane ionic permeability and cellular electrical excitation/inhibition throughout the nervous system. These features distinguish LGIC from the metabotropic subset of monomeric/second messenger signaling-coupled neurotransmitter receptors, from voltage-gated ion channels, and from ion channels in the plasma membrane or on microsomes that respond to intracellular ligands. Recent advances have shown that LGIC exist as a much more extended and structurally diverse group of macromolecules than heretofore realized. This session will review genetic/epi-genetic bases and functional manifestations of this receptor diversity.

**Ronald J. Lukas** will provide a fundamental introduction to the field and will briefly discuss use of stably transfected cell lines in studies of homooligomeric nicotinic acetylcholine receptor (nAChR) subtypes. **Jon Lindstrom** will discuss the genetic basis of nAChR subunit diversity, structural and functional manifestations of variations in nAChR subunit composition, and physiological and pathological roles of different nAChR. Similarly, **Richard W. Olsen** will describe the structurally and functionally diverse family of ionotropic GABA receptors (GABA-R) and their roles in nervous system function. The presentation by **Stephen F. Heinemann** will concern the biology of ionotropic glutamate receptors (GluR), some of their roles in learning and disease, and the placement of GluR subunits into a gene superfamily distinct from that containing GABA-R, nAChR, and glycine receptor subunit genes. **David J. Julius** will discuss how identification of ionotropic receptors for ATP establishes yet another neurotransmitter receptor gene superfamily, why ionotropic serotonin receptors belong in the GABA/glycine/nicotine receptor superfamily, and roles of ionotropic serotonin or ATP receptors in neurotransmission and behavior.

## 586.1

## NEURONAL RESPONSES RELATED TO MEMORY RETRIEVAL IN THE PRIMATE INFEROTEMPORAL CORTEX.

Y. Naya, K. Sakai\* and Y. Miyashita. Dept. of Physiol., Sch. of Med., Univ. of Tokyo, Tokyo 113, Japan.

Visual long-term memory has been assessed by the pair-association (PA) task, in which a subject retrieves and chooses the paired associate of a cue picture. Our previous report on pair-recall neurons suggests that the anterior inferotemporal (AIT) cortex is involved in the processes of memory retrieval (Sakai & Miyashita, *Nature* 354, 152). To test the possibility that the response of pair-recall neurons is triggered by the initiation of memory retrieval, we devised the pair-association with color switch (PACS) task. Twelve pairs of Fourier descriptors were used as visual stimuli, each pair containing a green picture and a cyan picture. In the PACS task, the necessity for memory retrieval and its initiation time were controlled by a color switch in the middle of the delay period. A control task, in which there is no color switch, corresponds to the conventional delayed matching-to-sample (DMS) task where the monkey chooses the same picture as the cue. After two macaque monkeys were trained in both tasks, extracellular discharges of single neurons were recorded from the AIT cortex. We found that pair-recall neurons started to respond just after the color switch in the PACS task, when the cue-optimal picture's associate was presented as a cue. However, they showed no response change in the DMS task. This effect was statistically significant among picture-responsive delay neurons ( $n = 29$ ) including pair-recall neurons ( $n = 12$ ). We confirmed that this effect is not due to the visual response to colors. Furthermore, when the cue-optimal picture was presented as a cue, these neurons showed suppression after the color switch in the PACS task, whereas they showed sustained activation in the DMS task. These results demonstrate that the response of AIT neurons can be selectively triggered by the retrieval of paired associates from long-term memory store.

## 586.3

## DIFFERENT BEHAVIORAL EFFECTS OF DAMAGE TO VISUAL AREA TE AND PERIRHINAL CORTEX. E.A. Buffalo\*, S.J. Ramus, S. Zola-Morgan, and L.R. Squire. Depts. of Philosophy, Psychiatry, and Neurosciences, UCSD, La Jolla CA 92093, and VAMC, San Diego, CA 92161.

Previous lesion studies of visual association area TE have reported marked impairment on tests of visual perception and visual memory. However, most previous TE lesions included damage to what is now known to be perirhinal (PR) cortex, a component of the medial temporal lobe memory system important for memory. It is possible that in previous studies of TE lesions, the inclusion of PR cortex contributed to the behavioral impairment. We compared the performance of 5 monkeys with TE lesions, 5 monkeys with PR lesions, and 7 normal monkeys (N). Both the TE and PR groups were similarly impaired on the trial-unique delayed nonmatching to sample task (percent correct averaged across delays of 15 sec, 60 sec, 10 min, and 40 min: TE=74.9, PR=75.2, N=81.0; TE or PR vs N,  $p < .05$ ). Monkeys with TE lesions were impaired on the 8-pair concurrent discrimination task (TE=933 trials, N=469 trials,  $p < .05$ ) but were unimpaired on retaining single object discriminations (TE=89% correct, N=86% correct,  $p > .10$ ). By contrast, monkeys with PR lesions showed an opposite pattern (concurrent score = 639 trials, object score = 82%). Analysis of variance (using standardized scores) revealed a significant group by task interaction ( $p < .05$ ). The findings provide the first evidence that within the visual domain, the deficit following TE lesions is different from the deficit following PR lesions. This conclusion is tempered by the fact that on the concurrent task, two of the PR monkeys performed within the range of the monkeys with TE lesions.

## 586.5

## IMPAIRED PROBABILISTIC CLASSIFICATION LEARNING IN HUNTINGTON'S DISEASE. B.J. Knowlton\*, J.S. Paulsen, and L.R. Squire. Depts. of Psychiatry and Neurosciences, UCSD, and VA Med Center, San Diego, 92161

Damage to the hippocampus and related areas results in impaired declarative memory, while sparing a variety of other memory abilities in a range of species. An area that may be important for nondeclarative memory is the caudate nucleus. Double dissociations have been found in experimental animals between the effects on memory of hippocampal lesions and caudate lesions. Tasks largely dependent on the hippocampus and related areas include win-shift learning problems and delayed nonmatching to sample tasks. Tasks largely dependent on the caudate nucleus include win-stay learning problems and pattern discrimination tasks, or what has been termed habit learning. A difficulty in extending the dissociation between habit learning and declarative learning to humans is that many tasks learned gradually as habits by experimental animals can be acquired by humans using a declarative (memorizing) strategy in just a few trials. Recently, amnesic patients were found to perform normally on a probabilistic classification task that is analogous to a habit learning task in that information must be learned gradually across many trials. There were 4 pattern cues, each probabilistically associated with one of two outcomes. On each trial, subjects were presented with 1, 2, or 3 of these cues, and after selecting one of the 2 outcomes, they received feedback as to whether their response was correct. Patients with Huntington's disease (HD,  $n=12$ ) were tested on this task because they have prominent pathology in the caudate nucleus. Unlike amnesic patients, HD patients exhibited no learning across 50 training trials, and they performed significantly worse than a matched control group ( $n=12$ ). These results are consistent with the idea that probabilistic classification learning in humans is analogous to habit learning and, like habit learning, it depends on the integrity of the caudate nucleus.

## 586.2

## EFFECTS OF SELECTIVE ABLATIONS OF INFERIOR TEMPORAL CORTEX OF SQUIRREL MONKEYS ON VISUAL PERCEPTION AND MEMORY. R.E. Weller\*, M. S. LeDoux, L. M. Toll, M. K. Viikinsalo, and R. A. Hicks. Dept. of Psychology, Univ. of Alabama at Birmingham, Birmingham, AL 35294.

Anatomical studies have suggested that inferior temporal (IT) cortex of squirrel monkeys consists of caudal (ITC), intermediate (ITI), and rostral (ITR) areas, with ITC containing dorsal (ITCd) and ventral (ITCv) subdivisions. We have hypothesized that ITCv is homologous to area TEO of macaque monkeys, and ITI and ITR are homologous to posterior and anterior TE of macaques (Weller and Steele, 1992; Steele and Weller, 1993). The present study compared visual memory and pattern discrimination learning in squirrel monkeys with bilateral ablations of ITCv ( $n=4$ ), ITI and ITR ( $n=4$ ), or ITI and ITR plus ventrally adjacent cortex in the region of perirhinal cortex ("ITR+",  $n=3$ ), with unoperated animals serving as controls ( $n=3$ ). Animals were tested in a reduced WGTA on two visual memory tasks, delayed non-matching to sample (DNMS) with trial-unique objects and concurrent object discriminations, and five pairs of two-dimensional pattern discriminations. Only the ITR+ animals were significantly impaired compared to the controls on difficult variations of DNMS and the concurrent object discriminations. Although all lesioned groups were significantly worse than the controls learning three of the pattern discriminations, the ITCv animals showed the greatest deficits. Thus, the behavioral results support the suggested homologies between subdivisions of IT cortex in squirrel and macaque monkeys. These results also help to define the relative contributions of rostral IT cortex and perirhinal cortex to vision.

## 586.4

## IMPORTANCE OF THE HIPPOCAMPAL REGION AND ENTORHINAL CORTEX IN HUMAN MEMORY: NEUROPSYCHOLOGICAL AND NEUROPATHOLOGICAL FINDINGS FROM A NEW PATIENT N.L. Rempel-Clower\*, S. Zola-Morgan, L.R. Squire, D.G. Amaral, VAMC, San Diego, CA 92161, Depts. of Psychiatry and Neurosciences, UCSD, La Jolla, CA 92093, Center for Behavioral Neuroscience, SUNY Stony Brook, NY 11794

Following an ischemic episode that resulted in a circumscribed, bilateral lesion of the entire CA1 field of the hippocampus, patient RB exhibited a moderately severe anterograde memory deficit. Last year we reported neuropsychological and postmortem neuropathological findings from two additional cases of amnesia resulting from ischemia or anoxia, i.e., patients GD and LM (Rempel-Clower et al., *SN Abstr.*, 1994, 20:1075). Patient GD had damage limited primarily to the CA1 field of the hippocampus and, like RB, had moderately severe anterograde amnesia and little detectable retrograde amnesia. Patient LM had more extensive damage to the hippocampal region, including all the CA fields and the dentate gyrus. He also sustained slight cell loss in entorhinal cortex, likely due to retrograde degeneration. The severity of LM's anterograde amnesia was similar to that of the other patients, but he had severe, temporally graded retrograde amnesia. We now report findings from an additional patient, WH, whose amnesia resulted from a probable ischemic event and who had more severe anterograde amnesia than patients RB, GD, or LM. Patient WH, like LM, had severe, temporally graded retrograde amnesia. Postmortem analyses revealed that patient WH had cell loss in all CA fields of the hippocampus, the dentate gyrus, and the subiculum. There was also substantial cell loss bilaterally in layers III, V, and VI of entorhinal cortex. The findings from all four patients suggest that damage limited to the hippocampal region is sufficient to produce moderately severe anterograde amnesia. More extensive damage to the hippocampal region, possibly together with damage to entorhinal cortex produces severe, temporally graded retrograde amnesia.

## 586.6

## DIFFERENCES IN THE FLEXIBILITY OF DECLARATIVE AND NONDECLARATIVE MEMORY. P.J. Reber\*, B.J. Knowlton and L.R. Squire. Department of Psychiatry, UCSD and VA Medical Center, San Diego, 92161.

Declarative memory is dependent on medial temporal lobe/diencephalic brain structures. In an effort to develop a property list for declarative memory, we tested the hypothesis that declarative memory is more flexible than nondeclarative memory. Amnesic patients ( $n=8$ ) and control subjects ( $n=16$ ) completed a probabilistic classification task (presented as weather prediction) previously shown to be intact in amnesia and impaired in patients with Huntington's disease. In this task, four cues were each probabilistically associated with one of two outcomes (rain or shine). On each of 50 training trials, subjects saw 1, 2, or 3 of the cues, they predicted the outcome, and they received feedback. Subjects were then given a 13-item test that asked about their task knowledge in ways that required, to a varying extent, flexible application of what they had learned. For example, subjects were asked to select the one cue most associated with a given outcome. Amnesic patients and control subjects exhibited equivalent, gradual learning of the task. On the test that followed, amnesic patients were impaired on some items, e.g. they had difficulty giving a numerical rating for cues that were weakly associated with the outcome in question. In a second experiment, new control subjects completed the classification task and the follow-up 13-item test, and they were additionally asked to rate to what extent each question required indirect, flexible use of task knowledge. Those items rated as requiring the most flexible use of knowledge tended to be the same items on which amnesic patients exhibited the greatest impairment. The flexibility exhibited by control subjects most likely reflects the concomitant acquisition of declarative knowledge about the task, which was epiphenomenal to acquisition performance. The performance of the amnesic patients suggests that knowledge acquired implicitly is less flexible than declarative (explicit) knowledge and is used less effectively in situations that are dissimilar to the original learning conditions.

## 586.7

CONSERVATION OF A PROCESS FOR SPATIAL REPRESENTATION AND REORIENTATION ACROSS HUMAN ADULTS, CHILDREN, AND ADULT RATS. L. Hermer, E. Spelke, and L. Nadel.\* Department of Psychology, Cornell University, Ithaca, NY 14853

A wealth of behavioral and physiological evidence suggests that spatial representations for navigation are only formed with reference to spatial orientation and that spatial orientation is calibrated by spatial representations of the environment (e.g. see McNaughton et al., 1995). Adult rats can reorient themselves using representations of the shape of the environment with only minimal exposure to the fixed positions of cues within it (Cheng, 1986; Margules & Gallistel, 1988; Biegler & Morris, 1993, ex. 2), and they fail to reorient by nongeometric information such as distinctive odors, visual patterns, or brightnesses unless they have extensive associative training (Knierim et al., 1994). We have previously shown that children aged 18-24 mos., like adult rats, reorient in a novel rectangular environment exclusively in accord with environmental shape, even when other information is perceived, is remembered, and can be used after the same exposure to solve other memory tasks (Hermer & Spelke, 1994, 1995). In contrast, human adults readily use nonspatial information (e.g. wallcolor) or conjunctions of spatial and nonspatial information to solve these reorientation tasks. We used a series of concurrent tasks designed to interfere with specific cognitive processes to probe in adults whether the geometric and nongeometric processes were separable and whether the child's geometric reorientation process was conserved in adults. Here we report that adults engaged in a verbal interference task lose their distinctive ability to use nonspatial information in reorientation tasks, and instead rely exclusively on the shape of the environment. However, adults engaged in the same interference task were able to use surface color and pattern to retrieve a movable hidden object, showing that they like young children had encoded and could use this information in another context. These results suggest biological conservation across adult rats, young children, and human adults of a process for representing the shape of the environment and for using it to recalibrate compass sense. This process appears to be relatively independent of language and attention, unlike the nongeometric process that distinguishes human adult performance in these tasks from that of young children and other adult mammals. The results are discussed with respect to psychological and physiological models of spatial information processing in these species.

## 586.9

MAMILLARY BODY LESIONS IN RHESUS MONKEYS IMPAIR OBJECT-IN-PLACE MEMORY AND LEAVE THE FORNIX WITHOUT FUNCTION. D. Gaffan\*, A. Parker and S. A. Guitnikov. Exp Psychology, Oxford University, Oxford OX1 3UD, U.K.

Six monkeys were trained pre-operatively in an automated object-in-place memory task in which they learned 20 new scenes in each daily session. Three of the six monkeys then received stereotactically guided mamillary body lesions, leaving the fornix intact, while the other three received a control operation. Postoperatively the control animals' rate of learning new scenes was unchanged but the animals with mamillary body lesions showed a severe impairment, equal to that seen in previous experiments after fornix transection. All six animals were then given fornix transection, in addition to the existing mamillary or control lesion. The control group now showed, after fornix transection, an impairment equal to that of the animals with mamillary body lesions alone. But the animals with mamillary body lesions did not show any additional impairment following fornix transection. We conclude that (1) the role of the mamillary bodies in a model of human episodic memory is as important as the role of the fornix (2) the fornix and mamillary bodies form a single functional memory system, since the effect of lesions in both parts is no more severe than the effects of a lesion in one of the parts alone (3) the idea that the functional effects of fornix transection result from cholinergic deafferentation of the hippocampus receives no support from the present results; rather, they support the idea that in primates the fornix and mamillary bodies, together with connected structures including the subiculum, mamillothalamic tract and cingulate bundle, form a cortico-cortical association pathway for episodic memory.

## 586.11

NECESSARY ROLE OF HIPPOCAMPUS PLUS SUBJACENT CORTEX BUT NOT AMYGDALA IN CONDITIONAL MOTOR LEARNING. E. A. Murray\* and S. P. Wise. Labs. of Neuropsychology and Systems Neuroscience, NIMH, NIH, Bethesda, MD 20892

We investigated whether either the amygdala plus subjacent cortex or the hippocampus plus subjacent cortex was necessary for conditional visuomotor learning. On each behavioral trial, rhesus monkeys were presented with a single visual stimulus in the center of a videomonitor screen. The stimulus remained on the screen until the monkey responded by making one of three possible joystick movements: left, right, and down. For each stimulus, one and only one response was scored correct and reinforced. Monkeys were required to learn a total of 24 new visuomotor conditional associations (problems) in 400 trials; 8 sets of 3 novel problems each were administered for 50 trials apiece. After the monkeys had learned the task, they received bilateral aspiration lesions of either the amygdala plus subjacent cortex (N=2) or hippocampus plus subjacent cortex (N=4). To measure the effect on learning of new visuomotor conditional problems, we examined the mean percent error obtained in the last 5 days of preoperative learning with the last 5 (of 15) postoperative days. Removal of the amygdala plus subjacent cortex (N=2) had no significant effect on the rate of learning. This finding falsifies the hypothesis that the amygdala is necessary for reward-mediated learning, in general. By contrast, removal of the hippocampus plus subjacent cortex (N=4) had a substantial effect on learning in each subject (mean percent error of 37.0 compared with 11.6). We conclude that the hippocampal formation plus subjacent cortex is necessary for the efficient association of arbitrary visual stimuli with spatially-directed movements.

## 586.8

MONKEYS WITH EARLY HIPPOCAMPAL FORMATION LESIONS ARE IMPAIRED ON THE TRANSVERSE PATTERNING PROBLEM. M. C. Alvarado\*, A. A. Wright & J. Bachevalier. Department of Neurobiology & Anatomy, U. T. Medical School, Houston, TX 77225

The transverse patterning problem (A+ vs. B; B+ vs. C; C+ vs. A-) is a task that requires subjects to use configural associations and is sensitive to hippocampal formation damage in rodents [Alvarado & Rudy, 1995, Beh. Neurosci., 109(2):204-211]. To determine whether the hippocampal region in non-human primates is also important for performance on this task, we trained five adult rhesus macaques (*Macaca mulatta*) on an object-discrimination version of transverse patterning (TP). Three monkeys were normal (N) and 2 had neonatal aspiration lesions of the hippocampal region, including parahippocampal gyrus (H). Because all subjects had extensive training on nonmatching-to-sample paradigms, the TP task was designed to discourage subjects from erroneously using the nonmatching strategy. Thus, animals were trained on two sets of TP discriminations, members of which were presented on alternate trials such that a given trial contained no objects from the preceding trial. Six objects (A-F) were used to form two sets: Set 1- A+ vs. B; B+ vs. C- and C+ vs. A; Set 2- D+ vs. E; E+ vs. F- and F+ vs. E-. Animals received five trials of each problem daily (total: 30 trials). Training continued until animals reached a criterion of 27/30 correct for 60 consecutive trials on each problem set, or a maximum of 1000 trials on each set. Group N solved both sets in an average of 325 trials whereas Group H did not reach criterion on either set. To assess whether their impairment was due to an inability to solve six discriminations under conditions of high interference, we altered the task slightly by adding a new object to each problem set so that the task could be solved without the use of configural associations. The problems were constructed as follows: Set 1- A+ vs. B; B+ vs. C- and C+ vs. X; Set 2- D+ vs. E; E+ vs. F- and F+ vs. Y. Animals in Group H reached criterion on both sets in five sessions. These results suggest that the hippocampal region in primates is important for configural or relational memory.

## 586.10

THE REPRESENTATION OF SPACE IN THE PRIMATE HIPPOCAMPUS. E.T. Rolls\*, R.G. Robertson and P. Georges-Francois.

Univ. Oxford, Dept. Exptl. Psychol., Oxford OX1 3UD, England.

It has recently been possible to extend the analysis of hippocampal function in spatial and memory functions in primates (Rolls and O'Mara, 1993; O'Mara et al., 1994; Treves and Rolls, 1994) by making recordings in monkeys actively walking in the laboratory, so that the activity of monkey hippocampal neurons can be analysed during active spatial exploration in environments similar to those in which "place" cells are found in rats. In a sample of 250 cells recorded in this situation, no "place" cells have so far been found. Instead, we have found a considerable population of "view" cells tuned to respond when the monkey looks at small parts of the environment. We have been able to demonstrate (1) that these hippocampal neurons respond to a view of space 'out there', not to the place where the monkey is; (2) that the responses depend on where the monkey is looking, by measuring eye position; (3) that the responses in some cases depend on the location of particular cues in the environment; (4) that the responses in some cases are not affected if the view details are obscured with curtains; and (5) that the cells retain part of their "space" tuning even in complete darkness, for several minutes. These findings lead to a reconceptualization of what is represented in the primate hippocampus, and of how it functions in memory and spatial processing.

## 586.12

THE ISSUE OF PARAHIPPOCAMPAL CORTEX IN THE RAT R.D. Burwell\* and D.G. Amaral. Center for Behavioral Neuroscience, State University of New York at Stony Brook, Stony Brook, NY 11794-2575.

Neuropsychological studies of amnesic patients and experimental lesion studies in monkeys indicate that the perirhinal and parahippocampal cortices are important components of the medial temporal lobe memory system. Studies of the cortical connectivity of these regions in the monkey show that they receive distinctly different complements of cortical inputs suggesting that each uniquely contributes to memory function. In support of this notion, experimental lesions of the monkey perirhinal cortex, but not the parahippocampal cortex, impair visual object recognition memory (Ramus, S.J., Zola-Morgan, S. and L.R. Squire, *Soc. Neurosci. Abstracts* 20(2): 1047, 1994). Within the framework of these studies in the monkey, it is of interest to determine whether there are distinct cortical regions in the rat that are homologous to the perirhinal and parahippocampal cortices in the monkey. Our neuroanatomical studies of perirhinal cortex (areas 35 and 36) in the rat indicate that the rostral and caudal portions exhibit distinctly different cytoarchitectonic and histochemical characteristics. Different enough, in fact, to be considered separate cytoarchitectonic regions. Moreover, these rostral and caudal portions of perirhinal cortex demonstrate different patterns of cortical and subcortical connectivity. Thus, we use the term perirhinal to encompass rostral areas 35 and 36 and the term postrhinal to designate caudal areas 35 and 36 in the rat. The connectivity of these regions suggests that the postrhinal cortex in the rat shares a number of connectional characteristics with the parahippocampal cortex in the monkey. For example, like the parahippocampal cortex in the monkey, the postrhinal cortex, but not the perirhinal cortex, in the rat receives a strong input from the retrosplenial cortex. Cytoarchitectonic and connectional characteristics of the perirhinal and postrhinal cortices in the rat will be discussed.

## 587.1

INVOLVEMENT OF THE HYPOTHALAMUS IN AFRICAN TRYPANOSOMIASIS: MICROGLIA INVASION AND EFFECTS OF INTERFERON- $\gamma$  AND MELATONIN. M. Bentivoglio<sup>1</sup>, G. Grassi-Zucconi<sup>2</sup>, Z.-C. Peng<sup>1</sup>, K. Kristensson<sup>3</sup>. <sup>1</sup>Inst. Anat., Univ. Verona, <sup>2</sup>Dept. Cell Biol., Univ. Perugia, Italy; and <sup>3</sup>Dept. Neurosci., Karolinska Inst., Stockholm, Sweden

Previous experimental evidence pointed out the involvement of the hypothalamus in the experimental infection in rats with the parasite *Trypanosoma brucei* (Tb), which causes sleeping sickness in humans. Interferon- $\gamma$  (IFN- $\gamma$ ), which is promptly induced during the infection in both experimental rats and humans, plays a crucial role in trypanosomiasis by promoting Tb proliferation. Three experimental paradigms were adopted in the present investigation. A) Recombinant IFN- $\gamma$  was intracerebroventricularly administered in normal rats, and the induction of the immediate early gene *c-fos* was used as a tool to detect neuronal activation in the brain, exploiting Fos-immunocytochemistry. After IFN- $\gamma$  injection, Fos-immunoreactive (ir) neurons were selectively concentrated in the hypothalamic suprachiasmatic nucleus (SCN), which plays a role of circadian pacemaker. B) In advanced stages of Tb infection in rats, glial cells were immunocytochemically investigated in the brain using anti-GFAP and anti-OX-42 antibodies. The most consistent finding was represented by a proliferation of OX-42-ir microglial cells in the hypothalamus of the infected rats. These findings suggest that IFN- $\gamma$  can exert both a direct and glial-mediated effect on the hypothalamus during Tb infection. C) Previous data indicated that the infected rats display a striking sleep fragmentation, with a considerable reduction of synchronized sleep (SS). Melatonin (3 mg/kg s.c. in 50% DMSO) was acutely administered to rats in advanced stages of Tb infection. This treatment resulted in a significant increase of the length of SS episodes in the infected rats in respect to the vehicle-exposed ones. Thus, exogenous melatonin, whose receptors are normally concentrated in the SCN, restored a normal sleep pattern during the infection.

REGIONAL CEREBRAL BLOOD FLOW CHANGES DURING DIFFERENT STAGES OF SLEEP IN HUMANS STUDIED BY POSITRON EMISSION TOMOGRAPHY. N. Hoffe, D. Reutens, P. Fiset, A. Alonso\*, J. Gotman, A. Evans and B.E. Jones. Montreal Neurological Institute, McGill University, Montreal, Quebec, Canada H3A 2B4.

The present study was undertaken to examine the regional cerebral blood flow (rCBF) changes that occur during different stages of sleep in humans in order to determine if specific regions are activated or inactivated in association with spindling and delta EEG activity. PET scans were performed at night on 5 normal subjects using bolus injections of  $H_2^{18}O$ , in association with on-line computer EEG recording and sleep stage determination for 1) relaxed wakefulness with eyes closed, marked by alpha activity (8.5-11.5 Hz) in the EEG, 2) stage 2 sleep, marked by spindles (12-15 Hz), and 3) stage 3-4 sleep, marked by delta waves (1.0-4 Hz). Resulting PET images were co-registered with high resolution MRI scans. A marked and significant decrease in rCBF occurred in the thalamus during both stage 2 sleep in association with spindles ( $t = -8.76$ ) and stage 3-4 sleep in association with delta waves ( $t = -8.17$ ), as compared by averaged image subtraction to relaxed wakefulness with alpha activity. The decrease was centered in the dorsomedial nuclei and extended out to the peripheral edge of the dorsal and ventral, lateral nuclei through the anterior to posterior extent of the dorsal thalamus. These results indicate that the dorsal thalamus, which represents the afferent gateway to the cerebral cortex, is markedly inactivated in association with both spindle and delta activity during sleep. The inactivation of the dorsal thalamus, which could result from inhibition by surrounding reticularis GABAergic neurons, may represent the primary substrate for the loss of consciousness that occurs in humans during slow wave sleep. ## 587.5

THE SUPRACHIASMATIC NUCLEUS (SCN) INFLUENCES CIRCADIAN BODY TEMPERATURE AND CIRCAANNUAL RHYTHMS IN GROUND SQUIRRELS. N.F. Ruby<sup>1</sup>\*, J. Dark<sup>2</sup>, H.C. Heller<sup>1</sup>, and I. Zucker<sup>2</sup>. <sup>1</sup>Dept. of Biological Sciences, Stanford Univ., Stanford, CA 94305; <sup>2</sup>Dept. of Psychology, Univ. of California, Berkeley, CA 94720.

Circadian and circannual rhythms were monitored in female ground squirrels over a 6 year interval. Animals were weighed weekly, underwent SCN ablation or a sham operation, and were monitored for 1-3 additional years ( $T_a = 22^\circ C$ ). Squirrels were then implanted with transmitters, transferred to a cold room ( $T_a = 6^\circ C$ ), and Tb was measured telemetrically at 10 min intervals for 2 1/2 more years.

Circadian Tb rhythms were present in sham-operated squirrels ( $n=6$ ) during normothermia ( $T_b = 37^\circ C$ ) and deep torpor ( $T_b = 7^\circ C$ ), but were eliminated at both  $T_b$ s in animals with complete bilateral SCN ablation (SCNx;  $n=8$ ). SCNx squirrels spent twice as much time torpid and had 3 times as many torpor bouts as intact animals, but their individual bouts were 40% shorter in duration. Seasonal patterns of hibernation and body mass changes were eliminated in 4 SCNx animals; the interval between torpor bouts never exceeded 10 days during a 2 year interval. Circannual rhythms were attenuated in the remaining SCNx and partial SCNx squirrels.

The SCN likely generates circadian Tb rhythms during hibernation and may control individual torpor bout duration, as well as hibernation season duration. Circannual rhythms of body mass and hibernation may be mediated by the SCN in squirrels maintained at low  $T_a$ s.

## 587.2

LOCAL RATES OF CEREBRAL PROTEIN SYNTHESIS MEASURED IN SLEEPING MONKEYS ARE POSITIVELY CORRELATED WITH PERCENT TIME IN DEEP SLEEP. C. Beebe Smith\*, T. Dang, M. Ito, K. Mori, H. Nakanishi, R.K. Nakamura, H. Namba, F. Storch, S. Suda, Y. Sun, C. Gillin, W. Mendelson, M. Mishkin, C. Kennedy, and L. Sokoloff. NIMH, Bethesda, MD 20892.

Regional rates of cerebral protein synthesis (ICPS<sub>reg</sub>) were determined with the autoradiographic L-[1- $^{14}C$ ]leucine method (Smith et al., *PNAS* 85:9341, 1988) in 7 awake and 7 asleep rhesus monkeys. Monkeys were previously prepared to permit monitoring of behavioral state and conditioned to sleep in a restraining chair in a darkened, ventilated chamber. Prior to injection of [ $^{14}C$ ]leucine all animals slept until their first REM period (sleep duration of 1-3 h). Controls were then awakened and remained awake. Stages of sleep in experimental animals were scored by analysis of EEG, EOG and EMG. This indicated that NREM sleep occupied 71 to 99% of the experimental period, the time spent in deep sleep (stage IV) varying from 0 to 84%. Compared to awake controls, mean values for ICPS<sub>reg</sub> were higher in all 57 regions in the sleeping animals, but the differences reached statistical significance in only four regions. However, in all regions, ICPS<sub>reg</sub> was positively correlated with percent time in deep sleep, weighted for the integrated specific activity of leucine in gray matter during the periods of deep sleep. The correlation coefficient reached statistical significance in 18 of the 57 regions ( $p < 0.05$ ) and approached this level of significance in an additional 16 regions ( $0.05 < p < 0.1$ ). Regions in hypothalamus, brain stem, and basal ganglia were predominantly involved. These results suggest that, in the sleeping monkey, deep sleep is accompanied by widespread increases in rates of cerebral protein synthesis.

## 587.4

RE-ENTRAINMENT OF SCN CIRCADIAN RHYTHMS FOLLOWING A 12 HOUR LIGHT-DARK CYCLE PHASE SHIFT: AN EX VIVO STUDY IN THE RAT. Valentin K. Grikoff, Rick L. Pieschl, and Frank D. Yocca. Central Nervous System Drug Discovery, Bristol-Myers Squibb Pharmaceutical Research Institute, 5 Research Parkway, Wallingford, CT 06492.

Rat suprachiasmatic nucleus (SCN) neurons *in vitro* discharge in a pattern that may have a relationship to circadian rhythms in behavior observed *in vivo*. We have examined the issue of whether SCN rhythms *in vitro* reflect the behavioral history of the animal in the period prior to sacrifice by investigating (ex vivo) the re-entrainment of SCN rhythms of rats subjected to a 12 hr shift in the 12/12 light/dark (L/D) cycle. Previous studies have shown that behavioral rhythms require about 7 days to re-entrain following a 12 hr shift in the L/D cycle produced by coupling 2 light periods. Slices including the SCN were obtained from adult male Long-Evans rats at 1-14 days after the 12 hr phase shift and the SCN multiple-unit activity recorded for up to 72 hrs following sacrifice. The peak firing rate for unshifted control animals was observed at CT 5.8 $\pm$ 0.3, while shifted animals phase-delayed (relative to control) by 3.2 $\pm$ 0.5, 5.0 $\pm$ 0.7, 8.6 $\pm$ 0.4, 11.5 $\pm$ 0.5, and 11.1 $\pm$ 0.8 hrs on days 1, 2, 4, 7 and 14, respectively, suggesting that the SCN activity *in vitro* reflected the behavioral and physiological status of the animal prior to sacrifice, and 2.) was fully re-entrained to the phase shift by day 7. The pineal hormone melatonin (MEL) was given (s.c., 1 mg/kg) to animals exposed to an identical 12 hr L/D phase shift and its effects on re-entrainment were observed at days 1-4. MEL-treated animals phase delayed 5.6 $\pm$ 1.2, 7.6 $\pm$ 0.8, and 9.8 $\pm$ 0.4 hrs on days 1, 2 and 4, respectively, a significant decrease in the time required to re-entrain SCN circadian rhythms. There was no significant effect of MEL on control multiple-unit SCN circadian rhythms.

## 587.6

SEROTONERGIC MECHANISMS IN THE AMYGDALA AND REM SLEEP REGULATION. L. D. Sanford\*, S. M. Tejani-Butt, R. J. Ross, and A. R. Morrison. Lab. for Study of the Brain in Sleep. Sch. of Vet. Med. and Dept. of Psychiatry, Univ. of Penna., Philadelphia, PA 19104.

Serotonin (5-HT) has an inhibitory role in REM, presumably via direct input from the dorsal raphe nucleus (DRN) into pontine regions involved in the generation of REM. DRN also projects to the amygdala, which in turn projects massively to many of these same pontine regions. We examined the effect on REM of microinjecting 5-HT into the amygdala, and we measured the density of 5-HT transport binding sites in four amygdaloid nuclei. Rats ( $N=7$ ) were implanted with cannulae aimed into the amygdala and with electrodes for recording EEG, EMG and PGO waves. Saline or 5-HT (1.5 mM) was microinjected in NREM or REM. During REM, 5-HT significantly decreased ( $p < .001$ ) the mean latency to a change of state to either waking or NREM (59.2  $\pm$  25.8 sec) compared to saline (131.9  $\pm$  15.5 sec). Seventy percent of microinjections of 5-HT during REM resulted in short latency arousals (mean latency 40.9  $\pm$  43.4 sec), and 57 percent resulted in a change of state to either waking or NREM within 35 sec (mean latency 17.11  $\pm$  11.0 sec). In contrast, microinjections of saline did not appear to affect behavioral state. Microinjections of 5-HT during NREM rarely produced arousal and did not prevent the entrance into REM. Quantitative autoradiographic analysis of [ $^3H$ ]cynanipramine binding to 5-HT transporter sites indicated moderate 5-HT innervation in the central and medial nuclei of the amygdala. Relatively greater density of 5-HT transporter sites was seen in the basolateral and lateral nuclei of the amygdala suggesting possible sites of action for the microinjections of 5-HT. The present results demonstrate a role for serotonergic mechanisms in the amygdala in the control of arousal state. SEROTONIN-LIGHT INTERACTIONS DURING THE DEAD ZONE OF THE PHOTIC PHASE RESPONSE CURVE. P. D. Penev\*, P. C. Zee and F. W. Turek. Dept. Neurobiology and Physiology, Northwestern University, Evanston, IL 60208.

Rapidly accumulating evidence indicates the ability of serotonin to modify the responsiveness of the rodent circadian pacemaker to light. However, the interactions between serotonergic and photic stimuli in the circadian system have been studied exclusively during the subjective night. In the present study the circadian phase-resetting properties of the 5-HT agonist, 8-OH-DPAT, were used as an endpoint to examine the potential interactions between serotonergic and photic stimuli during the subjective day.

Male golden hamsters, kept in constant darkness, were exposed to combined treatments with 8(OH)DPAT (1.0 mg/kg i.p.) and light (120 min, 500-700 lux) or activity restriction (120 min restraint procedure). Vehicle treatment at CT 7 alone ( $-0.8 \pm 3$  min,  $n=6$ ) or in combination with a 2-hour light pulse ( $5 \pm 2$  min,  $n=8$ ) did not affect the phase of the hamster circadian pacemaker. However, the same photic stimulus, significantly attenuated the phase resetting properties of 8(OH)DPAT at CT 7 ( $19 \pm 6$  min,  $p < 0.01$ ) in hamsters that showed consistent phase shifts following treatment with the 5-HT agonist alone ( $56 \pm 4$  min,  $n=8$ ). In contrast, the 2-hour restraint procedure had no significant effect ( $p > 0.1$ ) on the magnitude of 8(OH)DPAT-induced phase shifts in a similarly selected group of animals ( $45 \pm 9$  min vs.  $60 \pm 4$  min,  $n=6$ ). These results indicate that in the presence of increased serotonergic activity, exposure to light during the dead zone of the photic PRC can play an important role in circadian phase control. The existence of such widespread interactions between retinal and raphe inputs may underlie the integration of environmental and behavioral time-giving cues in the mammalian circadian system.

## 587.9

ASTROCYTE GFAP EXPRESSION IN SUPRACHIASMATIC NUCLEI IS ENHANCED IN TAU MUTANT HAMSTER. J. Lu\*, M. Menaker. Department of Biology, NSF Center for Biological Timing, Gilmer Hall, University of Virginia, Charlottesville, VA 22903

Astrocyte glial fibrillary acidic protein immunoreactivity (GFAP-IR) exhibits circadian variation in the suprachiasmatic nuclei (SCN) of hamsters kept in constant darkness (DD), suggesting that astrocyte may be involved in circadian rhythm generation (Lavialle and Saviere 1993). A single gene mutations (tau) in the hamster causes a shortening of circadian period from 24 hrs in the wild type to 20 hrs in homozygous mutants. The present study pursues if GFAP-IR differs between tau mutants and wild type hamsters. Homozygous tau mutants, heterozygous mutants and wild type hamsters were produced by breeding heterozygous mutants. The genotypes were determined by free running period of wheel-running activity in constant darkness (DD). The average periods of homozygous, heterozygous and wild type hamster were 20 hr, 22 hr and 24 hr respectively. At one month of DD, 4-5 animals of each genotype were anesthetized and perfused at circadian time (CT) 04, CT10, CT16 and CT22. The brains were removed and sectioned at 25  $\mu$ m through SCN. The sections were immunostained for GFAP. The density of GFAP-IR was determined using Quantex image analysis system. The results show that GFAP-IR exhibits a circadian rhythm with peak at CT10 and trough at CT22 in all three genotypes. GFAP-IR amplitude was the highest in homozygous, moderate in heterozygous mutants and the lowest in wild type hamsters. At CT22, there is no significant difference in GFAP-IR among three genotypes. These results suggest that SCN astrocytes are either involved in generating circadian rhythms or that GFAP levels are affected by the clock. Supported by NIH Training Grant T32-HD07382 (JL) and Air Force Office of Scientific Research (MM).

## 587.11

DEFINING THE PHOTIC LIGHT INPUT PATHWAY TO THE SUPRACHIASMATIC NUCLEUS. H.M. Cooper\*, R.G. Foster, J.K. Bowmaker, A. Szol, E. Nevo, J. Negróni, and A. Attar. *CERVEAU et VISION*, INSERM U-371, 69675 Bron, FRANCE; Imperial College, London, UNITED KINGDOM; Inst. of Ophthalmology, London, UNITED KINGDOM; Univ. Semmelweis, Budapest, HUNGARY; Inst. of Evolution, Haifa, ISRAEL.

We have used molecular approaches, opsin immunohistochemistry, microspectrophotometry (MSP), retrograde tracing and viral tract tracing methods to dissect out the photic pathway regulating circadian physiology in mammals. In all species examined (sheep, primate, mouse, gerbil, mole-rat) the retinal ganglion cells (RGC) projecting to the suprachiasmatic nucleus are morphologically similar and resemble the gamma class of RGCs. The cell soma is small to medium sized (9-15  $\mu$ m diameter) and has 2-3 long, sparsely branched, primary dendrites with an asymmetrical spatial organization. Retinohypothalamic RGCs constitute a minority (< 1%) of the total ganglion cell population in all species, except for the mole-rat in which the majority of cells projects to the SCN. RGCs are distributed over the entire surface of the retina in nocturnal species, but in the dorso-nasal region in diurnal species. RT-PCR analysis of the retina in blind mammals (*rd* mice, mole-rat) which conserve circadian responses reveals that rods are not required for circadian photoreception, but that a pigment homologous to that of the mouse/human green cone opsin (spectral absorbance  $\approx 505$ -6 nm) is involved. This is confirmed by use of anti-opsin immunohistochemistry and *in situ* MSP measures of photoreceptor cells. Modelling this organization illustrates how retinal and optical constraints are combined to increase the efficiency of this system for the detection of diffuse, ambient light levels.

## 587.8

INDUCTION OF A CYCLIC AMP RESPONSE ELEMENT MODULATOR (CREM) SPLICE VARIANT, ICER mRNA (INDUCIBLE CYCLIC AMP EARLY REPRESSOR), IN THE RAT SUPRACHIASMATIC NUCLEUS (SCN) AFTER PHOTIC AND PHARMACOLOGICAL STIMULI.

Jens D. Mikkelsen\*, Kelly C. Morgan and Philip J. Larsen. Dept. Anat., Univ. Copenhagen, Blegdamsvej 3, 2200 N, Denmark

The mechanisms through which photic and pharmacological stimuli entrain the circadian clock located in the SCN are poorly understood. Within neurons of the SCN, photic stimuli induce a number of transcriptional factors belonging to the fos- and jun-families, which heteromerize and bind to AP-1 binding sites in the promoter region of unidentified genes. This mechanism is considered to be important in photic entrainment. Recently another transcriptional factor, ICER, which is one of many splice variants of the CREM gene, was cloned from the rat pineal gland. Although ICER has been associated with clock function in the pinealocyte, no basal expression has been detected in the SCN. Adult male rats kept under a DD cycle were given a 20 min light pulse at CT5 or CT19, and sacrificed 60 min after the pulse. Serial sections of the SCN were hybridized for ICER, *c-fos*, and *junB* mRNA. At CT19 light induces increases of ICER, *c-fos*, and *junB* mRNA expression, while much smaller increases were observed at CT5. Even though the relative rise of transcription was rather similar for all of the transcriptional factors examined, the maximal expression of ICER mRNA observed after light was about 10-fold lower than *c-fos* mRNA. In another experiment, we administered the dopamine-1 receptor agonist, SKF 38393 into pregnant rats at E19, to determine whether SCN expression of *c-fos* mRNA associated with fetal entrainment of the clock is accompanied by induction of ICER mRNA expression. In this case, a very prominent induction of both *c-fos*, *junB*, and ICER was observed in the SCN. These data indicate that ICER, which is a strong repressor of *c-fos* transcription plays a role in entrainment of both the fetal and adult SCN.

## 587.10

DIFFERENTIAL DISPLAY REVEALS NEW MRNAS THAT ARE REGULATED BY A CIRCADIAN CLOCK IN XENOPUS RETINA. C. B. Green and J. C. Besharse\*. Dept. of Anatomy and Cell Biology, The University of Kansas Medical Center, Kansas City, KS 66160.

We have shown that a circadian clock is present within photoreceptors of the *Xenopus laevis* retina (Cahill and Besharse, 1993, *Neuron*, 10: 573). This clock controls multiple aspects of retinal physiology, including transcription of the tryptophan hydroxylase gene (Green and Besharse, 1994, *J. Neurochem.* 62: 2420). To elucidate molecular mechanisms of clock control, we have conducted a screen to identify clock-regulated mRNAs. *Xenopus* eye cups were cultured in constant darkness and at 6 hour intervals for 2 days, retinas and medium samples were removed. Melatonin measurement was used as a control to insure rhythmicity in the cultures, and retinal RNA was used for differential display (Liang and Pardee, 1992, *Science*, 257: 967). This permitted comparison of sub-populations of mRNA from different time points. Using the criterion of rhythmic peaks on two consecutive days, the majority of mRNAs in the retina (>99%) were not rhythmic. Lack of rhythmicity was also seen in Northern analysis of rod opsin, interphotoreceptor retinoid binding protein, actin and *c-fos*. In contrast, a small number of displayed bands exhibited a high amplitude rhythmic pattern. Northern analysis of one of these revealed two bands (named RM1) at about 2 and 3.9 Kb. These bands had the same high amplitude rhythm seen in the display. The differential display product was used to screen a *Xenopus* retinal cDNA library resulting in isolation of 4 cDNA clones. Preliminary analysis of RM1 clones indicates that both messages are represented and may be products of differential splicing. In addition, *in situ* hybridization reveals that RM1 is localized to photoreceptor inner segments. Further analysis of RM1 and other rhythmic mRNAs revealed in this screen should provide insight into the molecular mechanisms of clock control.

## 587.12

ORGANIZATION OF THE PREGENICULATE NUCLEUS IN PRIMATES WITH SPECIAL REFERENCE TO THE INTERGENICULATE LEAFLET.

N. Chevassus Au Louis\* and H.M. Cooper. INSERM U 371, Cerveau et vision, 69 675 Bron, FRANCE.

The mammalian ventral lateral geniculate (vLGN) nucleus is classically divided into three main parts: an external division, an internal division and the intergeniculate leaflet (IGL). The internal and external divisions are involved in visual sensory and visuomotor functions whereas the IGL plays a specific role in circadian regulation through feedback connections with the suprachiasmatic nucleus. The organization of the primate homologue of the vLGN, the pregeniculate nucleus (PGN) has received less attention. The purpose of our study was to determine the general organization of the primate PGN by assessing the anatomical and immunohistochemical specificities of this structure in the three main primate lineages: prosimians (*Microcebus*), New World primates (*Callithrix*) and Old World primates (*Macaca*).

The distribution of calcium binding proteins, parvalbumin and calbindin, or acetylcholinesterase and cytochrome oxidase activities constitute reliable tools for identifying the PGN and for distinguishing different subdivisions within this structure. The homologue of the internal division lies adjacent to the reticular nucleus and contains few neuropeptide containing cells or fibres. The external subdivision is juxtaposed to the dorsal geniculate nucleus (dLGN) and contains fibres immunoreactive to NPY, SP and ENK. Neurons immunoreactive to NPY and ENK as well as SP fibres are present in the IGL. Both the IGL and the external division of the PGN receive a robust serotonergic innervation. The change in position of the PGN and its subdivisions compared to that in other mammals results from the significant expansion of the dLGN and cerebral peduncle.

## 587.13

## CHARACTERIZATION OF THE NEURONAL CONTROL OF THE RAT PINEAL GLAND USING VIRAL TRANSNEURONAL TRACING

P.J. Larsen\* L.W. Enquist† and J.P. Card† Dept. Anat., Univ. Copenhagen, Denmark, †Dept. Mol. Biol., Princeton Univ. Princeton, N.J., †Dept. Neurosci., Univ. Pittsburgh, Pittsburgh, PA, USA

Multisynaptic pathways through which the CNS modulates the activity of the rat pineal gland were characterized using a neurotrophic swine  $\alpha$ -herpesvirus ( $\alpha$ -HSV) that replicates within synaptically linked neurons. Following injection of an attenuated strain of swine  $\alpha$ -HSV into the superficial pineal, the spatiotemporal passage of virus through the neuraxis was determined using specific antibodies recognizing PRV and other markers of viral infection. Immunohistochemical analysis revealed productive infection in spatially and temporally separated populations of neurons initially visible in the superior cervical ganglion (SCG) and subsequently apparent in the intermediolateral column (IML) of the upper thoracic spinal cord, the dorsal paraventricular subdivision of the hypothalamic paraventricular nucleus (PVN), and the suprachiasmatic nucleus (SCN). Other infected CNS cell groups known to give rise to descending projections to the IML also became infected. The multisynaptic passage of swine  $\alpha$ -HSV through the PVN reproducibly involved subpopulations of neurons in both areas. Infected neurons first emerged in the dorsal paraventricular subdivision of the PVN followed by neurons in the lateral and medial paraventricular subdivisions. Infection of these neurons preceded the appearance of infected neurons in the dorsomedial SCN. Removal of the superior cervical ganglion (SCGX) prior to viral infection eliminated infection within the aforementioned CNS circuits and revealed an additional parasympathetic projection through the sphenopalatine ganglion that ultimately led to infection of neurons in the superior salivatory nucleus. The present data provide a morphological substrate for CNS control of the rhythmic secretion of melatonin from the pineal gland.

## 588.1

DETERMINATION OF CRITICAL BRAIN REGIONS FOR OBJECT RECOGNITION IN THE HUMAN VISUAL SYSTEM. J. Hart, Jr.\* M. Kraut, N. E. Crone, B. Soher, J. Sieracki, R.N. Bryan, & B. Gordon. Depts. of Neurology, Radiology, Biomedical Engineering, Cognitive Science, and the Zanvyl Krieger Mind/Brain Institute, The Johns Hopkins University, Baltimore, MD 21287

An important issue in both cognitive and in clinical neurosciences is whether behavioral functions are critically dependent upon the operations of focal cerebral regions, or merely associated with those operations. A patient who was being evaluated for seizure focus extirpation provided a unique opportunity to address this issue. Implanted subdural electrode arrays covered his right occipital, temporal, and parietal lobes. Behavioral testing, done across all the investigative techniques discussed here, consisted of a visual object/nonobject shape recognition task. Regional involvement was assessed using direct cortical recording and functional MRI (fMRI). Direct cortical recording showed activation of the right TPO and inferior TO regions in association with performance of the task. However, direct electrical cortical interference testing in this region failed to impair the behavior. Nor did surgical resection of this region, done for purposes of extirpation of the epileptic focus. Moreover, post-resection fMRI (10 mm thick coronal sections, imaging parameters TR/TE/ $\alpha$ =60/60/40°) showed activation only in the left posterior middle or inferior temporal gyrus.

These findings can best be explained by: a) the left posterior middle or inferior temporal gyrus being involved in the immediate recovery of the function of object recognition after resection of the right temporo-occipital region, or more likely, b) both regions are involved in object recognition, with only the presence of one, or specifically the left middle or inferior temporal gyrus, being critically necessary to perform object recognition.

Regardless of these possibilities, these data show that regional functional activation is not necessarily a guide to whether the region is critically involved with performance of a function (either in the normal state, or following resection).

## 588.3

## REPEATED PRESENTATION OF OBJECTS REDUCES ACTIVITY IN VENTRAL OCCIPITOTEMPORAL CORTEX: A fMRI STUDY OF REPETITION PRIMING

A. Martin\*, F.M. Lalonde, C.L. Wiggs, J. Weisberg, L.G. Ungerleider, and J.V. Haxby. National Institute of Mental Health, NIH, Bethesda, MD, 20892

Changes in neural activity as a function of stimulus repetition were investigated with functional MRI. Line drawings of objects were presented at fixation for 180 msec, at a rate of 1 item every 2 sec, for silent naming. Subjects viewed 6 alternating blocks of objects and noise patterns (10 items per block). For 4 subjects, the same objects, in a different order, were presented on the first and second blocks, followed by a block of novel (i.e., not previously presented) objects (A, A', B), while 4 subjects viewed blocks composed of novel objects only (A, B, C). Voice on-set time data from 21 normal subjects confirmed that naming was significantly faster for blocks of repeated, compared to blocks of novel, objects (repetition priming).

Analyses of the fMRI data (echo planar imaging; TR = 3000 msec, TE = 40 msec), recorded from the posterior left hemisphere (6 contiguous 5 mm thick coronal slices) revealed an area of increased signal intensity in the ventral occipitotemporal cortex for objects relative to noise patterns. Moreover, this activity was modulated by experience. Specifically, object repetition produced a significant decrease in signal intensity that returned to its initial level when novel objects were re-introduced (A, A', B), whereas intensity in this region remained constant for subjects who viewed only novel objects (A, B, C). These data are consistent with single unit recordings from the inferior temporal lobe of monkeys (EK Miller, L. Li, & R. Desimone (1991). *Science* 254:1377) and suggest that increased efficiency in object processing may be mediated, at least in part, by decreased neural activity in discrete cortical regions.

## 588.2

OBJECT SHAPE RECOGNITION IN THE HUMAN VISUAL SYSTEM AS SHOWN BY fMRI. M. Kraut, B. Soher, J. Sieracki, R.N. Bryan, B. Gordon\*, and J. Hart, Jr. Depts. of Neurology, Radiology, Biomedical Engineering, Cognitive Science and the Zanvyl Krieger Mind/Brain Institute, The Johns Hopkins University, Baltimore, MD 21287.

We have used functional magnetic resonance imaging (fMRI) to help determine what cortical regions are activated during processing of visual object shape in humans.

We studied 8 normal young adults, 5 men and 3 women using a behavioral paradigm with a baseline condition of visual detection and an activated condition of object/nonobject shape discrimination decision. fMRI data were gathered using 10 mm thick coronally oriented sections ranging from the occipital pole to the anterior hippocampus. Scanning parameters were TR/TE/ $\alpha$ =60/60/40°. Regions of activation in each section were detected by cross correlation analysis (Bandettini et al, J. Magn. Res. Med. 30:161), and were superimposed upon collocated T1 weighted anatomic images.

Six of the eight subjects studied exhibited significant signal changes. 4/6 showed changes in the inferior temporal gyri (3 bilateral, 1 right only), 3/6 in the occipitotemporal gyri (1 bilateral, 1 left only, 1 right only) and 2/6 at the TPO junction (1 bilateral, 1 right only). Both these last subjects also showed activation in either the inferior temporal or occipitotemporal gyri bilaterally.

These data strongly suggest that processing of object shape information in humans activates discrete cortical regions bilaterally. The cortical regions involved correspond with those regions purported to participate in the "ventral" pathway of visual object processing described in subhuman primates and are consistent with lesion studies of visual agnosia in humans.

## 588.4

SEPARATE CONCEPTS ARE RETRIEVED FROM SEPARATE NEURAL SYSTEMS: NEUROANATOMICAL AND NEUROPSYCHOLOGICAL DOUBLE DISSOCIATIONS. D. Tranel\*, H. Damasio, A.R. Damasio and J.P. Brandt. Div. of Cognitive Neuroscience, Dept. of Neurology, Univ. of Iowa, Iowa City, IA 52242.

Both clinical reports and systematic neuropsychological studies have shown that patients with damage in certain brain sites develop defects in the visual recognition of non-unique concrete entities, such as animals or tools and utensils, and we have hypothesized that there are different neural systems dedicated to different domains of knowledge. In this study, we report a double dissociation relative to type of entity and site of lesion. We studied 160 subjects with focal lesions to various sectors of the telencephalon, and 150 age- and education-matched controls. All subjects performed a visual recognition task in which they had to identify entities from varied conceptual categories, including animals (n=90), fruits/vegetables (n=67), and tools/utensils (n=104). Controls performed close to 90% correct in all categories. Fourteen brain-damaged subjects had severely impaired recognition of animals (X=69.4%) and normal recognition of tools/utensils (X=93.9%); fruits/vegetables were intermediate (X=81.7%). Three brain-damaged subjects had the reverse pattern: recognition of tools/utensils was defective (X=79.3%) and recognition of animals was normal (X=91.0%); fruits/vegetables were normal (X=90.0%). Neuroanatomical analysis revealed systematic differences in the lesions of the two groups. In the animal-defective group, lesions were centered in the occipital or occipitotemporal region, unilaterally right or left, or bilaterally. In the tool/utensil-defective group, lesions were centered in the lateral aspect of the left occipitotemporal region. The findings suggest that different neural systems are indeed related to the reconstruction of concepts concerning different types of entities.

**SEPARATE LEXICAL CATEGORIES ARE RETRIEVED FROM SEPARATE SYSTEMS: A PET ACTIVATION STUDY.** A.R. Damasio,\* T.J. Grabowski, H. Damasio, D. Tranel, R.J. Frank, J. Spradling, L.L.B. Ponto, G.L. Watkins & R.D. Hichwa. Div. Cognitive Neurosci., Dept. Neurology & PET Imaging Ctr., Univ. of Iowa, Iowa City, IA 52242.

The study of subjects with lesions in left inferotemporal cortex (IT) and left temporal pole (TP) has suggested the existence of separate neural substrates for the retrieval of word forms for unique and nonunique entities. Access to proper nouns depends on the TP, whereas access to common nouns depends on IT. We have now investigated this hypothesis framework in normal subjects using positron emission tomography (PET).

Nine normal, right-handed subjects were studied with quantitative [ $^{15}\text{O}$ ]H<sub>2</sub>O PET. Subjects performed three naming tasks and a control task, twice each. Stimuli were black-and-white photos of (1) familiar (famous) faces, (2) animals, and (3) tools and utensils. In the control task, subjects decided whether unfamiliar faces were presented upside down or rightside up. Oral responses were required for all tasks, and performance data were collected. The search for significant activation was directed *a priori* to TP and IT (bilaterally), defined by interactive analysis of coregistered 3D magnetic resonance images of the brains of participating subjects. PET data were analyzed with a pixelwise general linear model (Friston, 1991).

Relative to the control task, the naming tasks produced activation in left IT and both TPs. Face naming activated both TPs, but not left IT. Naming animals and tools activated left posterior IT and also left TP (but more weakly than for naming faces). Activation by naming tools was posterior and lateral to that produced by naming animals.

These data are consistent with the findings from lesion studies and further support the notion that knowledge systems are regionalized.

**EVENT-RELATED POTENTIALS AND GAMMA-BAND RESPONSES (30 HZ) DISTINGUISH NOUNS FROM VERBS.** F. Pulvermüller\*, H. Preißl, W. Lutzenberger & N. Birbaumer.

Department of Med. Psychology and Behav. Neurobiology, University of Tübingen, 72074 Tübingen, Germany

Lesion evidence strongly suggests that the cortical counterparts of nouns and verbs are localized in different brain areas. In this study, different electrocortical responses to nouns and verbs were recorded non-invasively from the skull of healthy individuals. Differences in electrocortical responses were most pronounced close to the primary motor and visual cortices. A positive component peaking around 200 ms post stimulus onset was larger over motor cortices after verbs compared to nouns. Over visual cortices, however, nouns evoke more pronounced positivities than verbs. Analysis of spectral responses in the lower gamma-range (25-35 Hz) revealed essentially the same picture: 30-Hz responses to nouns were stronger over visual cortices and those to verbs were stronger over motor areas. Behavioral testing revealed stronger visual associations for nouns and stronger motor associations for verbs. The results are explained in the framework of a neurobiological model of language based on Hebb's concept of cell assemblies.

**NEURAL SYSTEMS FOR PERCEPTION AND WORKING MEMORY ARE MORE STRONGLY COUPLED FOR LOCATIONS THAN FOR FACES** Susan M. Courtney\*, Leslie G. Ungerleider, Katrina Keil, James V. Haxby. National Institute of Mental Health, Bethesda MD 20892-1366.

Face and location working memory activate distinct regions in extrastriate and prefrontal cortex (Courtney et al., Soc. Neurosci. Abstr., 20:6, 1994). To dissociate the roles of these regions in perception and working memory, we measured regional cerebral blood flow (rCBF) in 10 healthy volunteers using positron emission tomography (PET) while the subjects performed sensorimotor control and working memory tasks. Working memory tasks involved retention of the identity or location of a single face over intervals of 1, 5, or 9 sec. Stimuli for face and location working memory tasks were identical. For face working memory, striate and ventral occipitotemporal extrastriate areas showed a decline in rCBF with longer retention intervals, indicating these areas participate principally in perceptual and encoding operations performed during visual stimulation. By contrast, inferior and orbital frontal areas activated by the face working memory tasks showed more sustained rCBF increases over longer retention intervals, indicating greater participation in maintaining a working memory representation when visual stimuli are absent. For location working memory, however, this dissociation between extrastriate and prefrontal areas was not observed. Activations in inferior and superior parietal cortex, as well as nonsignificant increases in rCBF in superior frontal cortex, all demonstrated a tendency to increase with longer delay intervals. In contrast to the results for face working memory, these findings indicate that extrastriate areas used for the perception of spatial location are also involved in maintaining an active representation of a particular location in working memory.

**DIFFERENT NEURAL SYSTEMS FOR THE RECOGNITION OF ANIMALS AND MAN-MADE TOOLS.**

D. Perani\*, S. F. Cappa, V. Bettinardi, S. Bressi, M. Gorno-Tempini, M. Matarrese, F. Fazio. INB-CNR, Scientific Institute H S Raffaele, Universities of Milan and Brescia, ITALY

Several lines of evidence, ranging from anthropology through developmental psychology to clinical observation in neurological patients, suggest that human semantic knowledge of living entities is represented separately from knowledge of man-made tools. Using positron emission tomography (PET), we mapped rCBF increases in normal volunteers during the recognition of visual stimuli representing living (animals) and non-living (artefacts) entities. The subjects had to decide whether pairs of visual stimuli were different representations of the same object, or different objects: 1. animal discrimination: same-different judgement of animal pictures (same: two different pictures of the same animal, different: two pictures of different animals); 2. artefacts discrimination: same-different judgement of object pictures (same: two different pictures of the same object, different: two pictures of different objects). Two combined control conditions were used to account for the apperceptive stages of visual recognition: 1. visual texture discrimination; 2. shape discrimination: same-different judgement of meaningless shapes (modified Vanderplas figures). PET data were analysed using SPM package (MRC-CU, London). The combined control conditions were compared to each of the experimental conditions. Activations significant at  $p < 0.001$  were considered. Animal recognition was associated with activations in the inferior temporo-occipital areas, bilaterally, whereas artefact recognition engaged a predominantly left hemispheric network, involving also the left dorsolateral frontal cortex. These findings provide *in vivo* evidence for a fractionation of the neural substrates of semantic knowledge in man. Different processing requirements, preferential access to structural knowledge for living stimuli and to functional information for objects, or separate representational systems may account for this anatomical fractionation.

## 588.8

**OBJECT AND SPATIAL WORKING MEMORY ACTIVATES DORSOLATERAL PREFRONTAL CORTEX: A FUNCTIONAL MRI STUDY.** M. D'Esposito\*, R.K. Shin, J.A. Detre, S. Incedon, D. Annis, G.K. Aguirre, M. Grossman, D.C. Alsop. Departments of Neurology & Radiology, University of Pennsylvania, Philadelphia, PA 19104.

Primate studies have demonstrated that distinct neuronal populations within dorsolateral prefrontal cortex subserve working memory for objects/patterns vs spatial locations. We tested the hypothesis that a similar anatomical dissociation exists in humans by performing functional MRI studies in 8 normal subjects during tasks designed to probe object vs spatial working memory. In the memory condition, subjects attended to serially presented stimuli and determined if each stimulus or location was the same as that presented two stimuli back. In the control condition, subjects were asked to identify a single predetermined stimulus or location. Each subject was presented with up to four different stimulus sets: letters, symbols, faces and spatially-arrayed squares. Echoplanar MRI was performed at 1.5 T in 16 contiguous 5mm axial slices and regions of activation were identified by correlation with the task. Activation during the working memory condition was reliably found in dorsolateral middle frontal gyrus (Brodmann's areas 9 & 46) in all stimulus conditions. Bilateral frontal activation was seen in 7/8 subjects in all conditions, but activation was greater on the right in the spatial condition in 6/8 subjects. Thus, a similar region within dorsolateral prefrontal cortex was activated during this paradigm regardless of the type of information held in working memory (object or location). One possible explanation for this finding may be that functional MRI lacks the spatial resolution to distinguish separate neuronal populations that are dedicated to different domains of working memory. Alternatively, performance on this paradigm may require a single executive control process that functions independently of the type of information being temporarily stored.

## 588.10

**FUNCTIONAL MRI STUDY OF MENTAL IMAGE GENERATION.** M.J. Farah\*, M.D'Esposito, R.K. Shin, M. Stallcup, G.K. Aguirre, D.C. Alsop, M. Grossman, L.J. Tippet, J.A. Detre. Departments of Psychology, Neurology & Radiology, University of Pennsylvania, Philadelphia, PA 19104.

In mental imagery, or "seeing with the mind's eye", visual representations are activated by an internal image generation mechanism, rather than by external stimuli. This study addressed two issues regarding mental imagery: the involvement of occipital cortex in imagery and the localization of the image generation mechanism. Subjects listened to two classes of words under alternating conditions: abstract (non-imagable) and concrete words. Subjects were instructed to listen passively to the abstract words and were told to actively generate images of presented concrete words. Echoplanar fMRI was performed in 16 contiguous 5mm axial slices. Volumes of activation were identified by correlation with task above a threshold  $r$  value. For each subject, total volume of activation within predefined volumes of interest was measured. Although area 17 was not reliably activated by imagery, area 19 of occipital cortex was activated in two out of five subjects. Four out of five subjects showed activation of area 37, which was significantly greater on the left side ( $p < 0.05$ ). The activation of area 19 during visual images evoked by auditory stimuli suggests a role for occipital association cortex in visual imagery. Left inferior temporal activity accords well with previous localizations for image generation inferred from cases of loss of mental image generation following brain damage.

## 588.11

LATENCY OF THE VISUAL MEMORY POTENTIAL IS RELATED TO RECOGNITION TIME FOR IDENTIFYING FACES. H. Begleiter\*, B. Porjesz and A. Litke. SUNY HSCB, Dept. Psychiatry, 450 Clarkson Ave., Brooklyn, NY 11203, USA.

A number of human studies have identified an event-related potential (ERP) which appears to index memory processes involved in object recognition, including faces. These neuroelectric phenomena in humans are rather similar to single cell studies in the inferotemporal cortex of monkeys. In order to determine the coupling of recognition time and this visual memory potential (VMP) we used a delayed matching to sample paradigm with half of the S2 faces presented in an inverted position. Our results indicate that as response time increases to inverted faces so does the latency of the VMP component of the ERP. These data provide support for the coupling of VMP and behavioral recognition.

## 588.12

COULD TIME-SERIES PREDICTION ASSIST VISUAL PROCESSING? W. Softky\* MRB/NIDDK/NIH, BSA Bldg. #350, Bethesda, MD 20892

When a brain constructs a model of the environment from its sensory input, it might need to verify the model's accuracy. One method of verification is multivariate time-series prediction: a good model could predict the near-future activity of its sensory input fibers, much as a good scientific theory predicts future data. Such a predicting model would require copious top-down connections to compare the predictions with the input. That feedback could improve the model's performance in two ways: by biasing internal activity toward expected patterns, and by generating specific error signals if the predictions fail.

I constructed an event-driven, computationally efficient network to make such predictions in a simple dynamic visual environment. Although designed to predict accurately rather than to seem biological, the network appears similar to cortex in several respects. It uses over 8000 irregularly spiking units in three layers; over 200,000 variable-delay excitatory synapses of two types—brief and prolonged—whose effects multiply; sparse, specific, local connectivity, almost all excitatory; implicit local inhibition (winner-take-all); massive feedback signals which bias lower units' activity toward predictions; local "binding" by precisely coincident spikes; and "surprise" units, driven by mismatches between predicted and actual input activity, which detect discontinuities in the stimulus. Units in the upper layer are the most coarsely tuned in space and time, but the most stimulus-specific; in principle they could both drive, and receive feedback signals from, yet higher layers. Given as training inputs a grid of noisy spike trains driven pixel-wise by a single drifting bar at various orientations, unsupervised learning produced units tuned to bar orientation, straight or curved motion, and contour discontinuity (end-stopping). The network's generality may allow it to learn more specific and abstract responses in other stimulus environments, or modalities.

## BETA-AMYLOID: NEUROPATHOLOGY II

## 589.1

MOLECULAR MECHANISMS OF AMYLOID  $\beta$  PEPTIDE INDUCED HUMAN NEURONAL DEATH. LeBlanc, A.C.\*. William Chu, Cynthia Goodyer, Hélène Douillard. Depts. Neurol. & Neurosurg. and Pediatrics, McGill U. and Bloomfield Centre for Research in Aging, LDI, JGH, Montréal, Quebec, H3T1E2

Apoptosis has been proposed as the mechanism of amyloid  $\beta$  peptide (A $\beta$ ) neurotoxicity. However, little is known about the molecular mechanisms of A $\beta$ -induced neuronal cell death. We have established a highly purified foetal human primary neuron culture. These neurons express high levels of amyloid precursor protein (APP) mostly of the APP<sub>695</sub> type. Metabolism through the secretory pathway accounts for approximately 40% of newly synthesized APP. In addition, five C-terminal peptides arising from the endosomal lysosomal pathway are similar to those previously observed in human brain. APP metabolism through the 4 kDa A $\beta$ -producing pathway is higher than in rat neurons. To evaluate the molecular mechanisms involved in the neurotoxicity of A $\beta$ <sub>1-40</sub> and A $\beta$ <sub>1-42</sub> versus a control reverse A $\beta$ <sub>40-1</sub> peptide, these neuron cultures are treated at various times with physiological concentrations of each A $\beta$  peptide. Total cell death is evaluated by trypan blue exclusion and Molecular Probe's live/dead cell assay. Cell death by apoptosis is assessed by the detection of condensed chromatin with Hoechst or propidium iodide staining. We are presently evaluating the expression of immediate early genes, c-fos, jun-b and c-jun by RT-PCR, immunocytochemistry and immunoblots. The results will be compared to those obtained from serum deprivation induced neuronal apoptosis. Supported by grants from NIH, Fond de Recherche en Santé du Québec and Canadian Society of Alzheimer to AL.

INTERACTIONS OF GLIAL CELLS WITH ALZHEIMER SENILE PLAQUE CORES *IN VITRO* D.A. DeWitt\*, G. Perry, C. Doller, S.L. Siedlak, and J. Silver. Dept. of Neuroscience, Case Western Reserve University, Cleveland, OH 44106

Senile plaques (SP) are molecularly complex structures. Reactive astrocytes and activated microglia are an invariable feature in neuritic SPs. Previous models have demonstrated that synthetic A $\beta$ , the major protein found in SPs can induce reactive gliosis and activate microglia. However, many other proteins are also present in the SP. Our goal was to develop a model which mimicked the SP in as many aspects as possible. Isolated SP cores were bound to glass coverslips and presented to cells in culture. Rat cortical astrocytes do not phagocytose SP cores, but become reactive and surround the SP with processes. Astrocytes which were in contact with SP cores showed increased GFAP immunoreactivity, consistent with a reactive state. This response is similar to that seen in AD brain. In contrast, microglial cells could phagocytose whole SP cores (10  $\mu$ m). Phagocytosis of SP cores occurred as soon as 2 hours, with >90% of cores internalized by seven days. Subsequently, A $\beta$  immunogenic material could be seen within many small vesicles. The total number of intact SP cores decreased exponentially through 30 days in culture with microglia. These results suggest that SP material can be phagocytosed and broken down by microglial cells. Cocultures with astrocytes and incubation with proteoglycans will be used to determine if SP core phagocytosis and removal can be altered. Supported by NIH grants AG 07552, and NS 25713.

## 589.3

OXIDATIVE STRESS, POSTTRANSLATIONAL PROTEIN MODIFICATIONS AND ALZHEIMER DISEASE M.A. Smith, P.L. Richey, P. Mulvihill, L.M. Sayre and George Perry (SPON: Society of Neuroscientists of Africa) Departments of Pathology and Chemistry, Case Western Reserve University, Cleveland, Ohio 44106, USA

Alzheimer disease (AD) is characterized by deposits of insoluble proteins that form two main distinctive lesions called senile plaques (SP) and neurofibrillary tangles (NFT). Here we propose that one mechanism by which normally soluble proteins are accumulated as insoluble aggregates of proteins in SP and NFT could be related to oxidative posttranslational protein modifications. In previous studies we have shown SP and NFT have modification by the carbonyl-related modifications known as advanced glycation end products. In this study we amplified these results by determining the presence of free carbonyl groups in NFT and PHF- $\tau$ . We chemically demonstrate carbonyl-related modifications in the several protein components of NFT using 2,4 dinitrophenyl hydrazine (DNPH), a reagent that reacts with protein-bound carbonyl moieties.

The *in vivo* occurrence of modifications in NFT suggests that carbonyl-modification is associated with a generalized cytoskeletal abnormality that may be critical in the pathogenesis of neurofibrillary pathology. Importantly, we also found that chemical modification of  $\tau$  by carbonyl reagents renders the same solubility characteristics found in the protein components of isolated NFT further supporting the idea that extensive oxidative stress-related posttranslational modifications, through the formation of crosslinks, might account for the biochemical properties of NFT and their resistance to degradation *in vivo*. Supported by NIH grant AG09287.

## 589.4

$\tau$ /BPP INTERACTION: THE PATHOGENIC PATHWAY OF ALZHEIMER DISEASE? G. Perry\*, S.L. Siedlak, P.L. Richey, P. Mulvihill, D. Praprotnik, R.N. Kalaria and M.A. Smith. Institute of Pathology and Department of Neurology, Case Western Reserve University, Cleveland, Ohio, USA

The main protein components of neurofibrillary tangles and senile plaques,  $\tau$  and amyloid- $\beta$  protein, respectively, are well characterized, however the molecular mechanisms responsible for their deposition are, as yet, unknown.

The present study demonstrates by several independent techniques that  $\tau$  directly interacts with a conformation-dependent membrane spanning domain of the amyloid- $\beta$  protein precursor (BPP) that includes the BPP<sub>717</sub> mutation site associated with familial forms of AD. First, using a dot-blot assay we found that  $\tau$  only bound to C-terminal BPP peptides sharing residues BPP<sub>714-723</sub>. Second, steric hindrance of potential  $\tau$ -binding sites in AD brain with sequence-specific BPP peptide antisera was only effective with antibodies against those BPP peptides containing BPP<sub>714-723</sub>. Third, in quantitative competition experiments only those BPP peptides encompassing the BPP<sub>714-723</sub> sequence were able to completely block  $\tau$  binding. Fourth, using an *in vitro* solid phase binding assay, we showed that iodinated  $\tau$  bound in a saturable manner with high affinity to immobilized BPP<sub>714-733</sub> with a calculated  $K_D$  of 9.6nM.

Our findings provide clear evidence for a direct interaction between  $\tau$  and BPP and suggest that neurofibrillary tangles and senile plaques, often considered separate entities, may contribute towards each others formation.

Supported by NIH grant AG07752.

## 589.5

CSF LEVELS OF A $\beta$ 42 AND TAU ARE ALTERED IN ALZHEIMER'S DISEASE. C. Vigo-Pelfrey<sup>1</sup>, R. Motter<sup>1</sup>, D. Kholodenko<sup>1</sup>, R. Barbour<sup>1</sup>, K. Johnson-Wood<sup>1</sup>, D. Galasko<sup>2</sup>, L. Chang<sup>3</sup>, B. Miller<sup>3</sup>, C. Clarke<sup>4</sup>, R. Green<sup>5</sup>, D. Olson<sup>6</sup>, P. Southwick<sup>6</sup>, R. Wolfert<sup>6</sup>, B. Munroe<sup>6</sup>, F. Coria<sup>7</sup>, I. Lieberburg<sup>1</sup>, P. Seubert<sup>1</sup>, D. Schenk<sup>1\*</sup>. <sup>1</sup>Athena Neurosciences, South San Francisco, CA 94080; <sup>2</sup>UCSD, San Diego, CA 92161; <sup>3</sup>UCLA, Torrance, CA 90509; <sup>4</sup>University of Pennsylvania, Philadelphia, PA 19146; <sup>5</sup>Emory University, Atlanta, Georgia 30329; <sup>6</sup>Hybritech, Inc, San Diego, CA 92126; <sup>7</sup>Segovia Hospital, Segovia, Spain.

The CSF levels of A $\beta$ 42 and tau were measured in a well characterized group of Alzheimer's disease (AD; n=37), other neurological disease (ND, n=32) and normal control (NC; n=20) subjects. Despite the large amount of A $\beta$ 42 present in AD brain, levels in AD CSF were significantly lower than that in the other groups (p<0.0001) suggesting that clearance of this protein may be impaired in AD. As previously reported, tau levels are significantly elevated in AD (p<0.001). SDS-PAGE characterization of the tau from AD and control CSF did not show obvious differences in either the MW or phosphorylation state. Combining these measures identifies populations with either elevated tau and low A $\beta$ 42 (96% AD), low tau and elevated A $\beta$ 42 (100% non-AD) or low tau and low A $\beta$ 42 (a mixture of the 3 groups accounting for 41% of the subjects).

(mean $\pm$ SD, pg/ml)	AD	ND	NC
A $\beta$ 42	383 $\pm$ 76**	543 $\pm$ 177	632 $\pm$ 156
Tau	407 $\pm$ 241*	168 $\pm$ 63	212 $\pm$ 102

\*p<.001 AD vs. either control group

\*\*p<.001 AD vs. either control group

## 589.7

**$\beta$ -AMYLOID ACCUMULATION WITHIN ENTORHINAL CORTEX PREDICTS SEVERITY OF DEMENTIA IN ALZHEIMER'S DISEASE.** B.J. Cummings\*, C.J. Pike, and C.W. Cotman. Brain Aging and Dementia Institute, University of California, Irvine, CA 92717-4550

Many have argued that  $\beta$ -amyloid accumulation in Alzheimer's disease (AD) is a secondary event, in part because plaque number does not correlate strongly with cognitive dysfunction. However, several conditions are necessary to adequately address this issue: i) AD tissue from a broad range of cognitively affected individuals must be included in the analysis; ii) There must be a short interval between neuropsychological testing and death; iii) A sensitive and reproducible assay for  $\beta$ -amyloid must be used; and iv) The area occupied by  $\beta$ -amyloid and not simply plaque number must be measured. We have recently shown that in the aged canine, an animal model which lacks neurofibrillary tangles, the extent of  $\beta$ -amyloid accumulation appears to correlate with their ability to recall previously learned information (Cummings *et al.*, 1995). For the current study of  $\beta$ -amyloid deposition in AD, we selected 20 individuals from mildly impaired to severely demented based on Mini-Mental Status Exam scores (MMSE) obtained, on average, 10 months prior to death. Using formic acid enhanced immunostaining for  $\beta$ -amyloid and computer based image analysis of cross sectional area ("load") rather than manual counts of plaque number, we found a strong relationship between  $\beta$ -amyloid "load" in entorhinal cortex and cognitive deficits in AD patients ( $r = -0.83$ ). We also quantified plaque number ( $r = -0.73$ ) and tangle number ( $r = -0.64$ ) in the same cases. Post-mortem  $\beta$ -amyloid load in entorhinal cortex accurately predicts the severity of global dementia, and thus A $\beta$  likely represents an important factor in the clinical manifestation of AD, since  $\beta$ -amyloid deposition precedes NFT formation, and  $\beta$ -amyloid correlates with cognitive deficits in the absence of NFTs in the canine.

## 589.9

**THE INHIBITORY EFFECTS OF BAFILOMYCIN A<sub>1</sub> ON  $\beta$ -SECRETASE ACTIVITY DIFFER AMONG CELL TYPES.** B.D. Greenberg\*, S. Mistretta, J.T. Durkin, S. Murthy, M. Savage and R. Siman. Cephalon, Inc., 145 Brandwine Parkway, West Chester, PA 19380.

The macrolide antibiotic bafilomycin A<sub>1</sub> (bafA<sub>1</sub>) is a potent inhibitor of the vacuolar H<sup>+</sup>-ATPase, the activity of which neutralizes certain acidic subcellular compartments. BafA<sub>1</sub> also inhibits the production of secreted APP derivatives generated by the so-called  $\beta$ -secretase (Knops *et al.*, J. Biol. Chem. 270:2419-2422, 1995; Haass *et al.*, J. Biol. Chem. 270:6186-6192, 1995). In these studies, levels of A $\beta$  and the NH<sub>2</sub>-terminal  $\beta$ -secretase fragment (here termed "APP $\beta$ ") were reduced by bafA<sub>1</sub> in HEK293 cells transfected with the Swedish mutant APP cDNA, and in fibroblasts obtained from patients harboring this mutation. No inhibition of A $\beta$  or APP $\beta$  production were observed in media conditioned by wild-type fibroblasts or HEK293 cells transfected with wild-type APP. On the other hand, bafA<sub>1</sub> did inhibit formation of these APP derivatives in human mixed brain cultures (HMBC) and HS683 neuroglioma cells transfected with wild-type APP (Knops *et al.*). Here we report results of similar experiments utilizing M17 neuroblastoma cells transfected with Swedish mutant APP<sub>695</sub>. Using a pool of stable transfectants that expresses roughly equivalent levels of wild-type and mutant APP, we employed ELISAs that distinguish these two APP $\beta$  forms to show that bafA<sub>1</sub> inhibits  $\beta$ -secretase activity with an IC<sub>50</sub> of ~2nM only on the wild-type substrate. Hence, as with HMBC and HS683 cells, the effect of bafA<sub>1</sub> on  $\beta$ -secretase cleavage of mutant and wild-type substrates was reversed relative to HEK293 cells. Together, these results suggest that two distinct  $\beta$ -secretases may exist that act on either the wild-type or mutant substrates, with a cell type-specificity. Alternatively, cleavage of these substrates by a single enzyme may occur in distinct subcellular compartments that are differentially sensitive to the effects of bafA<sub>1</sub>, in which case the subcellular trafficking of these two APP forms would likely differ among cell types.

## 589.6

**CHOLINERGIC FIBRE LOSS ASSOCIATED WITH DIFFUSE PLAQUES IN THE NON-DEMENTED ELDERLY.** T.G. Beach<sup>1\*</sup> and W.G. Honer<sup>2</sup>. <sup>1</sup>Departments of Pathology (Neuropathology) and <sup>2</sup>Psychiatry, The University of British Columbia, Vancouver, British Columbia, Canada. Consecutive cases without a history of significant neurological illness were collected at autopsy. 14 cases were  $\geq$  60 yrs of age; 10 were younger. Of the 14 over age 60, 9 had diffuse amyloid plaques in both inferior temporal gyrus (ITG) and entorhinal cortex (ECx), as detected with immunohistochemistry (IHC) for  $\beta$ -amyloid peptide ( $\beta$ -AP) while 5 did not. All 14 of the over-60 cases were mildly affected with neuropil threads and/or neurofibrillary tangles, as assessed with IHC using the Alz-50 antibody and Bielschowsky silver staining; these changes were mainly confined to the parahippocampal gyrus (Braak stages I or II). Neuritic plaques were present in only four cases (all also  $\beta$ -AP +ve) but were few in number and poorly developed (CERAD criteria for AD not fulfilled). Synaptic antigen density, examined with quantitative IHC using the EP10 and SP15 monoclonal antibodies, did not differ amongst groups (under-60 vs over-60, over-60/ $\beta$ -AP +ve vs over-60/ $\beta$ -AP-ve) in either ITG or ECx. Cholinergic (ACh) fibre densities were estimated in sections stained with acetylcholinesterase enzyme histochemistry by manually counting their intersections with an ocular reticule. Mean ACh fibre density was decreased in both ITG and ECx (30% and 40% depletion respectively) in the over-60/ $\beta$ -AP +ve group compared to the over-60/ $\beta$ -AP-ve group; this was statistically significant only in ECx (t-test; p=0.03). These results suggest that: 1) ACh fibre loss is an early, preclinical event in AD 2) Diffuse plaques are associated with a significant decrease in ACh fibre density. Supported by the British Columbia Health Research Foundation

**DECREASED CEREBROSPINAL FLUID  $\alpha$ -SECRETASE CLEAVED AMYLOID PRECURSOR PROTEIN (APP) SEPARATES ALZHEIMER PATIENTS WITH THE SWEDISH APP<sub>670/671</sub> MUTATION FROM NON-MUTATION CARRIERS** L. Lannfelt\*, H. Basun, L.-O. Wahlund, B. A. Rowe, S. L. Wagner. Karolinska Institute, Department of Clinical Neuroscience (Geriatric Medicine), Huddinge University Hospital, S-141 48 Huddinge, Sweden

The Salk Institute Biotechnology/Industrial Associates, Inc. (SIBIA), 505 Coast Blvd, So, La Jolla, CA 92037

A constituent of senile plaques in Alzheimer's disease (AD) is  $\beta$ -amyloid, a proteolytic fragment of the amyloid precursor protein (APP). APP can be metabolised by at least two pathways, of which one involves generation of soluble APP by an unidentified enzyme named  $\alpha$ -secretase. This cleavage generates soluble  $\alpha$ -secretase cleaved APP ( $\alpha$ -sAPP), which was measured by a new enzyme-linked immunosorbent assay in cerebrospinal fluid from members of a Swedish AD family with a pathogenic mutation at APP<sub>670/671</sub>. Mutation-carriers with AD had low levels of  $\alpha$ -sAPP (160 $\pm$ 48 ng/ml), with no overlap compared to non-carriers (257 $\pm$ 48 ng/ml). Presymptomatic mutation-carriers showed intermediate  $\alpha$ -sAPP levels. There was a strong correlation between decreased  $\alpha$ -sAPP and age in the mutation-carriers ( $R=0.94$ ;  $p=0.005$ ). Today there exists no antemortem marker in AD with sufficient sensitivity and specificity. Measurement of  $\alpha$ -sAPP represents a promising diagnostic marker of AD.

**FIBROBLASTS FROM CARRIERS OF FAMILIAL AD LINKED TO CHROMOSOME 14 SHOW INCREASED A $\beta$  PRODUCTION.** D. Scheuner<sup>1\*</sup>, T. Bird<sup>2</sup>, M. Citron<sup>3</sup>, L. Lannfelt<sup>4</sup>, G. Schellenberg<sup>2</sup>, D. Selkoe<sup>3</sup>, M. Vitanen<sup>4</sup>, and S. G. Younkin<sup>1,5</sup>. <sup>1</sup>Case Western Reserve Univ., Cleveland, OH; <sup>2</sup>Univ. of Washington, Seattle, WA; <sup>3</sup>Harvard Univ., Boston, MA; <sup>4</sup>Karolinska Institute, Stockholm, Sweden; <sup>5</sup>Mayo Clinic Jacksonville, Jacksonville, FL.

To evaluate amyloid  $\beta$  protein precursor (BAPP) processing in familial AD linked to chromosome 14, we obtained fibroblast lines from known carriers in 4 separate families (18 lines: 5, 7, 2, and 4 from the 4 families) and from appropriate controls (15 lines). BAPP synthesis was evaluated by pulse labeling for 20 minutes and quantitating newly synthesized BAPP by phosphorimaging after immunoprecipitation and SDS/PAGE. Medium from sister cultures maintained for 5 days was analyzed for A $\beta$ 1-40 on days 2-5 and for A $\beta$  ending at A $\beta$ 42(43) on day 5. The amount of BAPP synthesized in 20 min was not significantly different in the AD and control lines. In 5 separate experiments, we assessed [A $\beta$ 1-40]/BAPP synthesis rate and [A $\beta$ 42(43)]/BAPP synthesis rate and compared the control fibroblasts with groups of fibroblasts representing the 4 families. In each of over 50 comparisons made between the AD families and controls, the values measured in the AD families exceeded those in the controls. Of the 18 lines analyzed, 4 were from one Swedish family. The increases in the Swedish lines were small compared to those in lines from the other 3 families. By themselves, these small increases were not significant, but the fibroblasts from all 4 families showed a qualitatively similar shift with A $\beta$ 42(43) increasing more than A $\beta$ 1-40. Analysis of the 5 day data from all 4 families showed that [A $\beta$ 1-40]/BAPP synthesis rate in the 18 AD lines was 2.1 times that in the 15 controls (p<0.003) and that [A $\beta$ 42(43)]/BAPP synthesis rate in the AD lines was ~8.9 times that in controls (p<0.0003). These data and our similar results on plasma samples (Song *et al.*, these meetings) indicate that in FAD linked to chromosome 14 as previously shown in FAD linked to the BAPP717 and ANL mutations, BAPP processing is altered in a way that fosters amyloid deposition.

## 589.11

PLASMA AMYLOID  $\beta$  PROTEIN (A $\beta$ ) ENDING AT A842(43) IS INCREASED IN CARRIERS OF FAMILIAL AD (FAD) LINKED TO CHROMOSOME 14. X-H Song<sup>1</sup>\*, N. Suzuki<sup>2</sup>, T. Bird<sup>3</sup>, E. Peskind<sup>3</sup>, G. Schellenberg<sup>3</sup>, and S. G. Younkin<sup>1,4</sup>. <sup>1</sup>Case Western Reserve Univ., Cleveland, OH; <sup>2</sup>Discovery Research Division, Takeda Chemical Industries Ltd., Wadai 10, Tsukuba, Ibaraki, 300-42 Japan; <sup>3</sup>Univ. of Washington, Seattle, WA; <sup>4</sup>Mayo Clinic Jacksonville, Jacksonville, FL.

A $\beta$ 1-40 and A $\beta$ 1-42(43) both increase significantly in the plasma of patients with the FAD-linked BAPP $\Delta$ NL mutation (Jensen et al., this meeting). To determine whether plasma A $\beta$  increases in FAD linked to chromosome 14, we obtained plasma samples from 3 families [family 1: 6 carriers (4 affected, 1 possibly affected, 1 unaffected), 7 non-carriers; family 2: 1 affected carrier; family 3: 1 affected carrier, 1 non-carrier]. In addition, we obtained plasma from 1 affected patient with the FAD-linked BAPP717 $\Delta$ ile mutation and their unaffected spouse. All samples were analyzed for A $\beta$ 1-40 (BAN-50/BA-27 ELISA) and A $\beta$ 1-42(43) (BAN-50/BC-05 ELISA). In addition, we used a BC-05/4G8 ELISA that detects not only A $\beta$ 1-42(43) but also amino-terminally truncated A $\beta$ s (e.g. A $\beta$ 17-42). In the plasma of the 8 chromosome 14-linked FAD carriers, A $\beta$ 1-42(43) showed a highly significant ( $p < 0.0003$ ) increase to 2.17 times that observed in the 9 non-carriers, and 7 of the 8 carriers had A $\beta$ 1-42 concentrations that were higher than any of the 9 non-carriers. The concentration of A $\beta$ 1-42 in the carriers (BC-05/4G8 ELISA) also increased significantly ( $p < 0.02$ ) to 1.36 times that observed in the non-carriers, and the concentration of A $\beta$ 1-40 increased non-significantly to 1.12 times that in the non-carriers. As expected from our previous studies of transfected cells, plasma A $\beta$ 1-42 in the patient with the  $\Delta$ ile mutation was selectively elevated to 1.6 times the mean control value (20% higher than any of the controls) whereas A $\beta$ 1-40 fell in the middle of the control range. These data on plasma and our data on fibroblasts (Scheuner et al., this meeting) indicate that in chromosome 14-linked FAD as in FAD linked to BAPP717 or  $\Delta$ NL mutations, A $\beta$  concentration is elevated in a way that fosters amyloid deposition.

## 589.13

HETEROGENEITY OF CALCIUM RESPONSE IN EARLY-ONSET FAMILIAL ALZHEIMER FIBROBLASTS. <sup>1,2</sup> Y. Tatebayashi\*, <sup>3</sup>M. Takeda, <sup>3</sup>K. Kamino, <sup>2</sup>T. Kudo, <sup>1</sup>I. Yoshida and <sup>2</sup>T. Nishimura. <sup>1</sup>Dept. Neuropsychiatry, Nissei Hosp. Osaka, Japan, <sup>2</sup>Dept. Neuropsychiatry, Osaka Univ. Medical Sch. Osaka, Japan, and <sup>3</sup>Dept. Geriatric Medicine, Osaka Univ. Medical Sch. Osaka, Japan.

Changes in calcium response were studied to clarify the pathological process of Alzheimer's disease (AD). Cultured fibroblasts from patients with early-onset familial AD (FAD; n=6; 3 families; OS-1, 2 and 3), sporadic AD (SAD; n=4), and age-matched healthy control subjects (n=4) were studied with ACAS Interactive Laser Cytometer. Fibroblasts from two independent families with FAD (OS-1 and 2) showed a suppressed calcium response after stimulation by 100nM bradykinin in Ca<sup>2+</sup>-free condition compared with OS-3, SAD, and control fibroblasts when they were arrested only in S phase. Since OS-1 families has APP717:Val-Ile mutation, abnormal APP processing in S phase might be responsible for the abnormal calcium response. Microsatellite DNA polymorphisms on chromosome 14q24.3 revealed that OS-2 and -3 families were different in genotype of D14S43 and the former had more possibility to be linked with the chromosome 14 rather than the latter. These results support the existence of heterogeneity in the calcium response and may suggest that the candidate gene located on the chromosome 14 affects the APP processing and results in the cell-cycle dependent abnormal calcium response.

## 589.12

THE BAPP<sup>670/671</sup> ALZHEIMER MUTATION (SWEDISH) INCREASES PLASMA AMYLOID  $\beta$  PROTEIN CONCENTRATION. M. Jensen<sup>1</sup>\*, X-H Song<sup>2</sup>, N. Suzuki<sup>3</sup>, L. Lannfelt<sup>1</sup> and S. G. Younkin<sup>2</sup>. <sup>1</sup>Karolinska Institute, Dept. of Clinical Neuroscience and Family Medicine, Huddinge University Hospital, S- 141 86 Huddinge, Sweden. <sup>2</sup>Division of Neuropathology, Institute of Pathology, Case Western Reserve University, Cleveland, OH 44106. <sup>3</sup>Discovery Research Division, Takeda Chemical Industries Ltd., Wadai 10, Tsukuba, Ibaraki, 300-42 Japan.

The ~4 kD amyloid  $\beta$  protein, which is a cleavage product of the amyloid  $\beta$  protein precursor (BAPP), forms insoluble fibrils in brains and vessels of patients with Alzheimer's disease. Using enzyme-linked immunosorbent assays (ELISAs), we developed a method for measuring A $\beta$  1-40 and A $\beta$  1-42(43) in human plasma. We have used the method for analyzing plasma from a large Swedish Alzheimer family in which a double mutation at codon 670/671 of the APP gene converts lysine-methionine to asparagine-leucine. A group of 12 mutation carriers (5 symptomatic, 55-68 years old, 7 pre-symptomatic, 28-51 years old) and 31 non-carriers (20-74 years old) was investigated. The carriers showed a 2.8-fold increase of A $\beta$  1-40 concentration compared to non-carriers ( $p < 0.0001$ ), with a total separation between the groups. A similar 2.1-fold increase of A $\beta$  1-42(43) concentration ( $p < 0.0001$ ) was seen, with only a slight overlap between the groups. No difference in A $\beta$  levels was seen between symptomatic and pre-symptomatic carriers, which shows that the increase of A $\beta$  levels is a very early event in the disease. It also indicates the importance of plasma A $\beta$  as an early marker for identifying individuals who will develop AD because of elevated A $\beta$  concentration.

## NEURAL-IMMUNE INTERACTIONS: OTHER

## 590.1

CALCITONIN GENE RELATED PEPTIDE (CGRP) RELEASE IN THE HIPPOCAMPAL FORMATION (HF) OF ADRENALECTOMIZED (ADX) RATS MAY SUPPRESS INFLAMMATORY IMMUNE RESPONSES TO DYING GRANULE CELL NEURONS. K. Bulloch<sup>1</sup>\*, T.A. Milner<sup>2</sup>, and B.S. McEwen<sup>1</sup>. Lab. of Neuroend. The Rockefeller University (1), and Cornell University, Medical Col. Dept. of Neurol. and Neurosci., N. Y., New York 10021 (2).

ADX results in cell death in granule cells of the dentate gyrus (DG). Cell death occurs via apoptosis, thereby preventing the HF from undergoing massive neuronal damage due to cytokine release and a consequent inflammatory immune response. Studies now show that CGRP is increased in the HF after several types of insult, and also has an effect on such HF functions as long term potentiation (LTP) and learning. CGRP also contains cellular immune responses in specific organs such as the thymus, by inducing apoptosis in thymocytes, suppresses cell-mediated immunity and blocking macrophages from presenting antigen. Given the immunological and behavioral effects of this peptide, we have begun to characterize the distribution of CGRP in the HF of ADX rats. Light microscopic analysis shows CGRP-immunoreactivity (CGRP-ir) is distributed diffusely in the inner third molecular layer (ITML) of the DG and in DG hilar and in CA3c neurons. In ADX rats, CGRP-ir is far more intense. Electron microscopic analysis of the DG shows that CGRP-ir is primarily found in large, dense core vesicles (100-120 nm) contained in axons and in small axon terminals which form asymmetrical synapses with dendritic spines in the ITML and a few cells within the granule cell layer. Fornix lesions did not reduce CGRP-ir in the HF of ADX rats indicating that the CGRP is mostly derived from intrinsic neurons rather than the subcortical pathway. Future studies may elucidate the role CGRP plays in regulating immune responses in the HF and lead to a clearer understanding of pathological and psychological effects of CNS trauma. ## 590.2

IMMUNIZATION-INDUCED INFLAMMATORY INFILTRATION OF THE CNS IN TRANSGENIC MICE EXPRESSING A MICROBIAL ANTIGEN IN ASTROCYTES. P. Borrow\*, J.L. Cornell, M.D. Rupprecht, and L. Mucke. Department of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

Transgenic mice expressing a defined microbial antigen from central nervous system (CNS) cell type-specific promoters can be utilized to investigate the consequences of induction of peripheral immune responses to foreign antigens produced by different CNS cell types. Following peripheral immunization with  $\beta$ -galactosidase ( $\beta$ -gal) in complete Freund's adjuvant, transgenic mice expressing this target antigen under control of the glial fibrillary acidic protein promoter in astrocytes of the CNS mounted strong  $\beta$ -gal-specific T and B cell responses, and developed massive mononuclear cell infiltration of the CNS. The infiltrating cells, principally CD4<sup>+</sup> T lymphocytes and monocyte/macrophages, with some CD8<sup>+</sup> T cells and very few B cells, were found both perivascularly and intraparenchymally, and were located predominantly in the hippocampal formation and cerebellum, the areas of highest  $\beta$ -gal expression. Resident CNS cells were activated in response to this inflammatory infiltration of the brain, as astrogliosis, microgliosis, and upregulation of MHC class I and II antigen expression were observed. These CNS changes were accompanied by a generalized increase in blood-brain barrier permeability. The resemblance of these pathologic changes to aspects of human immune inflammatory disorders, e.g., multiple sclerosis, suggest that an initiating step in such diseases could be the induction of a peripheral immune response to microbial or autoantigens expressed in astrocytes.

## 590.3

INDUCIBLE NITRIC OXIDE SYNTHASE mRNA LEVELS IN RAT BRAIN ARE UPREGULATED BY PERIPHERAL LIPOPOLYSACCHARIDE ADMINISTRATION. J. Licinio\*, P.W. Gold, and M.-L. Wong, Clinical Neuroendocrinology Branch, National Institute of Mental Health, NIH, Bethesda, MD 20892-1284.

Nitric oxide is an important informational substance synthesized from L-arginine by the enzyme nitric oxide synthase (NOS). There are at least two forms of NOS, constitutive and inducible. The constitutive form is present in endothelium (eNOS), and in central and peripheral nervous system (nNOS). Inducible NOS (iNOS) is present in kidney, liver, macrophages, and endothelium. An iNOS was recently cloned from rat astrocytes (Galea *et al.* J. Neurosci. Res. 1994;37:406-414). We conducted an *in situ* hybridization histochemistry study using a <sup>35</sup>S-labeled antisense riboprobe to determine whether the expression of the gene encoding the astrocyte-derived iNOS isoform in brain was affected by peripheral immune mediators. Virus and antibody-free male Sprague-Dawley rats (250g) were studied 24 h after saline or high-dose intraperitoneal (ip) lipopolysaccharide (LPS) administration. We found induction of iNOS mRNA in various brain regions 24 h after ip LPS. These data indicate that peripheral immune mediators can upregulate iNOS mRNA in rat brain and provide additional evidence that nitric oxide may participate in the complex communication pathway between the immune system and the brain. Abnormalities in that pathway are known to cause susceptibility to inflammatory disease. The elements involved in communicating signals between the immune system and the brain include cytokines, the hypothalamic-pituitary-adrenal axis, and possibly nitric oxide.

## 590.5

PROSTAGLANDIN E<sub>2</sub> INDUCES EXCITATION OF MYENTERIC NEURONS IN THE GUINEA PIG ILEUM. J.A.J.M. Dekkers, A.B.A. Kroese\* and L.M.A. Akkermans, Department of Human and Animal Physiology, Agricultural University, Haarweg 10, 6709 PJ Wageningen, The Netherlands.

The mode of action of the inflammatory mediator prostaglandin E<sub>2</sub> (PGE<sub>2</sub>) on myenteric neurons was investigated by intracellular recordings in a conventional plexus preparation. Bath application (3-6 min) of PGE<sub>2</sub> (1-1000 nM) evoked a concentration dependent and reversible slow (>5 min) depolarization in 23 of 26 AH and 12 of 13 S neurons. The slow depolarization evoked by PGE<sub>2</sub> was TTX-insensitive. The amplitude ranged from 4±1 mV at 1 nM to 13±3 mV at 1 µM in both types of neuron. S and AH neurons showed augmentation of excitability by PGE<sub>2</sub>, as was observed by the occurrence of spontaneous action potentials and an increase in the number of action potentials evoked by depolarizing current pulses. In AH neurons, the PGE<sub>2</sub> induced depolarization was accompanied by an increase in membrane resistance (control 114±13 MΩ), which ranged from 8±3 MΩ at 1 nM to 73±27 MΩ at 1 µM. In AH neurons, PGE<sub>2</sub> (1 µM) reduced the amplitude (7±1 mV) and the duration (8±1 s) of the post-spike afterhyperpolarization by 50%. In S neurons, PGE<sub>2</sub> evoked either an increase (n=6) or a decrease (n=6) in membrane resistance. Moreover, PGE<sub>2</sub> evoked bursts of fEPSPs in S neurons, indicative for cyclical activity in the myenteric plexus.

The results show that PGE<sub>2</sub> in the nM concentration range induces excitation of myenteric neurons. It is concluded that the inflammatory mediator PGE<sub>2</sub> can modulate gastrointestinal motility by a direct action on neurons in the myenteric plexus.

## 590.7

ASSOCIATION BETWEEN INCREASED SERUM SOLUBLE INTERLEUKIN-2 RECEPTORS AND DISTURBANCE IN THE CONTROL OF MOTOR MUSCLE FORCE IN SCHIZOPHRENIC PATIENTS. M.H. Rapaport, M.P. Caligiuri\*, J.B. Lohr, Dept. of Psychiatry, Univ. of CA, San Diego, School of Medicine, Psychiatric Service, San Diego Veteran's Affairs Med. Ctr., La Jolla, CA 92037

It has previously been shown that serum soluble interleukin-2 receptors (SIL-2Rs), a sign of immune activation, are increased in approximately 30% of schizophrenic subjects, and that serum SIL-2Rs are particularly elevated in schizophrenic subjects with tardive dyskinesia. In this paper we extend our previous work by investigating the relationship between motor force instability and SIL-2Rs receptors in 35 schizophrenic patients. We were particularly interested in investigating this relationship because increases in muscle force instability seem to precede the development of tardive dyskinesia and also because measurement of muscle force instability may be a more accurate way of reproducibly measuring involuntary movements. We hypothesized that there would be a positive correlation between increased levels of SIL-2Rs and muscle motor force instability. Serum SIL-2Rs and muscle force instability were positively correlated (r=0.5, p<.001), and this correlation held even for a small subset of neuroleptic naive patients (r=.53, df 9, p=.008). Further, when we dichotomized patients into high and low serum SIL-2R groups, high serum SIL-2R schizophrenics had significantly more muscle force instability than the low serum SIL-2R receptor group (U=73.0, Z=-2.64, p<.008). These findings suggest that there is an important clinical correlation between immune activation and muscle force instability.

## 590.4

THE VAGUS MEDIATES CYTOKINE STIMULATION OF PLASMA ADRENO-CORTICOTROPIN PRODUCED BY INTRAPERITONEAL INTERLEUKIN-1β AND ENDOTOXIN/LIPOPOLYSACCHARIDE. L. P. Kapcala\*, J. R. He, Y. Gao, J. Q. Pieper, and L. J. DeTolla, Endocrine Div. and Prog. of Comp. Med., Univ. of Maryland Sch. of Med., Baltimore, MD 21201

Although interleukin (IL)-1β or endotoxin/lipopolysaccharide (LPS), which stimulates cytokines, activates the hypothalamic-pituitary-adrenal axis (HPAA), the mechanism(s) by which peripheral IL-1β or LPS stimulates is not clear. Recently, the vagus has been implicated in mediating peripheral cytokine signalling of brain. To investigate a possible mechanism of peripheral cytokine stimulation of the brain, we tested the hypothesis that the vagus mediates immune activation of the HPAA by determining the effect of vagotomy on plasma adreno-corticotropin (ACTH) in rats after intraperitoneal (ip) IL-1β and LPS. Adult male Sprague-Dawley rats underwent subdiaphragmatic vagotomy or sham surgery 1 wk prior to study. Rats were sacrificed 2 hrs after ip saline, IL-1β (20 µg/kg) or LPS (4 mg/kg).

	Control	IL-1β	LPS
Sham Vagot. (PI ACTH)	26 ± 5	178 ± 52*	437 ± 58*
Vagotomy (mean±SEM)	25 ± 6	59 ± 20	304 ± 47*

Vagotomy abolished IL-1β stimulation of plasma ACTH and attenuated (~30% decrease) the LPS stimulation of plasma ACTH.

**CONCLUSION:** The vagus plays a critically important role in mediating peripheral (ip) activation of the HPAA by IL-1β and at least a partial role in mediating ip HPAA activation by LPS.

## 590.6

PRIMARY DEMYELINATION AND MOTOR DISEASE INDUCED BY THE CNS PRODUCTION OF INTERLEUKIN-3 (IL-3) IN TRANSGENIC MICE. I. L. Campbell\*, C.-S. Chiang, H.C. Powell\*, A. J. Roberts and L.H. Gold, Department of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037. \*VA Research Service, VAMC and University of California San Diego, La Jolla, CA 92093.

Macrophage/microglia (MM) may play an important role in mediating tissue injury in a variety of CNS disorders. To examine this possibility, transgenic (tg) mice were developed in which the expression of the MM activation factor, IL-3, was targeted to astrocytes using a GFAP-IL3 fusion gene construct. Tg mice with low levels of IL-3 expression developed from 5 mo of age a progressive and eventually fatal motor disorder (gait abnormality, tremor, ataxia then quadruplegia). Examination of motor performance using a rotarod apparatus revealed impairment in the tg mice just prior to the onset of visible motor changes. Neurohistologic and electron microscopic analysis in symptomatic tg mice, revealed multi-focal plaque-like, white matter lesions in cerebellum and brain stem. Lesions showed extensive primary demyelination and remyelination in association with the accumulation of large numbers of MM, many of which contained numerous lipid rich vacuoles and/or crystalline 'pole-shaped' inclusions. Lymphocytes were rarely, if at all present. In addition to recruitment from the periphery and possibly other brain areas, significant proliferation of the MM cells in the white matter was also observed. Lesion-associated MM cells were shown to be activated with markedly increased expression of the complement C3 receptor and MHC class II (Ia) molecules. As with clinical signs, white matter disease in the tg mice was progressive commencing at approx. 4 mo age. Prior to this age, increased IL-3 expression by perivascular MM cells was the earliest detectable change in the CNS, implicating these cells in the later development of white matter disease. In conclusion, tg mice with low levels of cerebral IL-3 expression develop a progressive motor disorder as a result of a vigorous T-cell independent MM-associated demyelination process. Many of the clinicopathologic manifestations of this disorder resemble those observed in acute MS indicating the GFAP-IL3 tg mouse represents a significant new model to study the role of MM in the pathogenesis of CNS demyelinating disease. Supported by USPHS grant MH50426.

## 590.8

EPINEPHRINE STIMULATES INCREASED IL-6 BLOOD LEVELS IN HEALTHY HUMAN SUBJECTS. G.H. Pelton\*, L.H. Price, G.R. Heninger, Dept of Psychiatry, Yale Univ. School of Med., 34 Park St., New Haven, CT 06519

Both physiologic and psychologic challenges activate several stress responsive systems, including: 1) the Sympathetic Nervous System (SNS) (eg. incr. plasma catecholamine levels), 2) the hypothalamic-pituitary-adrenal (HPA) axis (eg. incr. serum cortisol), and 3) the immune system (eg. incr. levels of cytokines including IL-6). In order to assess the specificity of the SNS in humans on IL-6 release and the HPA axis, several doses of Epinephrine (E) were administered to healthy human subjects and changes in plasma IL-6, cortisol and SNS variables (Heart Rate (HR) and Blood Pressure (BP)) were measured. **METHODS:** Placebo or single subcutaneous (SQ) E doses (0.25mg/subject, or 0.5mg/subject) or a 60 min. continuous IV E infusion at one of three doses (0.05 ug/kg/min, 0.1ug/kg/min or 0.15ug/kg/min), were admin. in a double blind randomly designed manner to healthy human subjects. Before and after the E or placebo administration, IL-6, cortisol, plasma E and norepinephrine (NE), BP and HR, and subjective mood and anxiety measures were obtained. **RESULTS:** IL-6 levels peaked at 90 minutes after SQ E or initiating the IV infusion, with mean peak IL-6 levels of 1.5pg/ml for the placebo, 1.7pg/ml and 2.8pg/ml for the SQ, and 1.4pg/ml, 2.9pg/ml, and 6.0pg/ml for the IV, in respective stepwise increasing doses. Changes in cortisol blood levels were inconsistent. Plasma E but not NE increased in a dose related stepwise manner. BP and HR demonstrated a clear dose response relationship with a maximal mean BP of 142/70 and mean HR of 102 at the 0.15ug/kg/min dose. Changes in IL-6 positively correlated to changes in HR. No consistent increases in anxiety or mood states were observed. **DISCUSSION:** This is the first demonstration that E produces a dose-dependent increase in plasma IL-6 levels in humans. The E induced increase in IL-6 occurred without changes in plasma cortisol indicating that the CNS can affect the immune system during stress directly through E release, without involvement of the HPA axis. Since E is released during both psychological and physical stress, peripheral E levels can be an important and specific mediator of the effects of stress on the immune system. This has implications for the role of stress in the dysregulation of the immune system in illness.

## 590.9

**EFFECTS OF SURGICAL STRESS AND PHARMACOLOGIC STIMULATION OF THE HPA AXIS ON INTERLEUKIN-6 IN HUMANS.** G. Heninger<sup>1</sup>, F. Sevarino, S. Southwick, L. Karper, D. Charney and J. Krystal, Depts. of Psychiatry and Anesthesiology, Yale Univ., New Haven, Ct 06510

In rats, stress from footshock, restraint, or a conditioned aversive stimulus produces large (over 5-10 fold) increases in plasma ACTH, corticosterone and interleukin-6 (IL-6). In humans, large increases in cortisol (C) and IL-6 have been reported following surgery and myocardial infarction, but the relative role of the HPA axis and the SNS on IL-6 release is not clear. **METHODS:** To compare the effects of increased plasma catecholamines to the effects of HPA axis stimulation on plasma IL-6 and C in humans, IL-6 and C were repeatedly measured before and following IV infusion of placebo and 3 drugs known to increase C levels: yohimbine (Y) (.4mg/kg), M-chlorophenylpiperazine (M) (.1 mg/kg), and ketamine (K) (.9mg/kg) and before and after open heart surgery which markedly increases plasma catecholamines. IL-6 was measured with an ELISA and C with RIA. **RESULTS:** In comparison to placebo, all drugs produced C increases averaging near 10 ug/dL, but the IL-6 response to Y, M and K did not differ from placebo. In contrast, surgery produced mean increases of: IL-6, 40 pg/ml; epinephrine (E), 531 pg/ml; norepinephrine (NE), 187 pg/ml; and C, 1 ug/dL. Increases in IL-6 correlated to changes in E ( $r = .86$ ) but not NE or C. **CONCLUSION:** Changes in plasma IL-6 do relate to changes in plasma E levels, but not to HPA axis stimulation. This is validated by a recent study (Pelton, et al., this meeting) where E infusions have been shown to increase IL-6. Supported by: The Stanley Foundation and VA Awards.

## 590.11

**AGE-DEPENDENT PHENOTYPIC SWITCHING OF MAST CELLS IN NGF-TRANSGENIC MICE.** M.L. Getchell<sup>1,2,4</sup>, A. Kulkarni-Narla<sup>2</sup>, S. Takami<sup>2</sup>, K.M. Albers<sup>3</sup>, and T.V. Getchell<sup>2,4</sup>, Depts. of <sup>1</sup>Surgery, <sup>2</sup>Physiology, and <sup>3</sup>Pathology; <sup>4</sup>Sanders-Brown Center on Aging, Univ. of Kentucky Coll. of Med., Lexington, KY 40536.

Mast cells (MCs) are effector cells that are prominently involved in the immune response to allergy and inflammation. MC phenotype and numbers were compared in the nasal and oral mucosae and skin of 3- and 6-week old transgenic mice in which NGF expression in epithelial basal cells was driven by the keratin-14 promoter, and in their nontransgenic littermates. Histochemistry with Alcian blue/safranin and berberine sulfate, which stain heparin present in connective tissue MCs but not chondroitin sulfate present in mucosal MCs, was used to distinguish between MC phenotypes. All MCs in 3-week old mice were of the mucosal phenotype except in the tongue of the transgenics, where MCs exhibited primarily mixed or connective tissue phenotypes. MC numbers in the transgenics were increased an average of 3.6X over those in the nontransgenics. In 6-week old transgenics, NGF overexpression resulted in the mucosal phenotype in tissues that contained MCs of the connective tissue or mixed phenotype in nontransgenics. MC numbers in the transgenics were increased an average of 2.5X over those in the nontransgenics. These results suggest that NGF overexpression affects the synthesis of molecular markers of MC phenotype.

**DIFFERENTIAL T CELL RESPONSE TO STRESS IN PUBERTAL COMPARED TO ADULT FEMALE MONKEYS** C.J. Rogers, C.S. Brissette-Storkus, L.A. Hayes, W.H. Chambers and J.L. Cameron\* Depts of Cell Biology & Physiology, Pathology, Psychiatry, and Neuroscience, and the Pittsburgh Cancer Institute. University of Pittsburgh, Pittsburgh, PA 15261.

We have previously shown in adult female monkeys that exposure to acute stress decreases the level of expression of the adhesion molecule, CD2, on a subpopulation of cytolytic T cells. Specifically, in adults, cytolytic T cells (i.e. CD8<sup>+</sup> cells) can be divided into two populations, one that expresses more CD2 (CD2<sup>bright</sup> cells) than the second (CD2<sup>dim</sup> cells). Acute stress exposure causes a selective loss of CD2 from the CD2<sup>bright</sup> population, which may impair cytolytic activity of these cells. The goal of the present study was to determine if the T cell response to stress is influenced by age or pubertal status. Blood samples were collected from 23 pubertal monkeys (19-33 months old), before and after exposure to acute stress (placement in a novel room with repetitive blood sample collection) at 3 month intervals during pubertal development. When the pubertal animals were first studied, 20 monkeys had a single level of expression of CD2 on T cells that was between the levels found in the CD2<sup>dim</sup> and CD2<sup>bright</sup> populations of adults. In these animals the level of CD2 expression was unresponsive to acute stress. However, three of the eldest pubertal monkeys demonstrated an adult-like expression of CD2 with a stress-induced loss of CD2 from the CD2<sup>bright</sup> population. These results indicate that both the basal expression of CD2 on T cells and the stress-responsive loss in CD2 expression are associated with pubertal development. We are currently investigating whether these developmental changes in CD2 expression are linked to developmental changes in cytolytic activity of T cells.

**MAST CELLS EXPRESS A FUNCTIONAL PERIPHERAL CANNABINOID RECEPTOR CB2: DIFFERENTIAL SENSITIVITY TO ARACHIDONYLETHANOLAMIDE AND PALMITOYLETHANOLAMIDE.** L. Facci, R. Dal Toso\*, S. Romanello, A. Buriani, L. Petrelli, S.D. Skaper and A. Leon. Research/ife S.c.p.A., 31033 Castelfranco Veneto, Italy.

Mast cells (MCs) are bone marrow-derived cells of immune lineage found in mucosal and connective tissues and in the nervous system, where they have important roles in inflammation and in neuroimmune interactions. Little is known about endogenous molecules and mechanisms capable of modulating MC activation. Palmitoylethanolamide (PEA) is found in numerous tissues, including brain, and has been proposed to behave as a local autacoid capable of down-regulating MC activation and inflammation. A cognate N-acylamide, arachidonylethanolamide (anandamide), is synthesized in brain and is a candidate endogenous agonist for the central cannabinoid receptor (CB1). As a second cannabinoid receptor (CB2) has been described in the periphery, the possible presence of CB2 on MCs and their interaction with N-acylamides was investigated. Here we report that MCs express the gene for CB2. Further, MCs have a functional CB2 receptor protein with negative regulatory effects on their activation. PEA and anandamide bind CB2, but only the former down-modulated MC activation *in vitro*. The functional effect of PEA, as well as that of active cannabinimetic compounds, was antagonized by anandamide. These results strongly suggest that CB2 receptors exert, upon agonist binding, a negative regulatory effect on MC activation and therefore inflammation. The demonstration that PEA, unlike anandamide, displays agonistic activity on CB2 suggests that such naturally occurring long-chain saturated fatty acid amides are potential endogenous functional ligands for CB2. Modulatory activities on MCs exerted by these molecules strengthen a proposed autacoid local inflammation antagonism (ALIA) mechanism. PEA and its derivatives ("ALIAMides") may thus provide new antiinflammatory therapeutic strategies specifically targeted to MCs, including those of an autoimmune origin like multiple sclerosis.

**SHAPING OF RECEPTIVE FIELD PROPERTIES IN DEVELOPING RETINAL GANGLION CELLS IN THE ABSENCE OF EARLY CHOLINERGIC SPONTANEOUS ACTIVITY.** E. Sernagor\* and N.M. Grzywacz. Smith-Kettlewell Eye Research Institute, San Francisco, CA 94115.

The maturation of receptive field (RF) properties of turtle retinal ganglion cells (GCs) occurs at 2-4 weeks post-hatching (PH), and is temporally correlated to the disappearance of spontaneous bursts of activity expressed by these cells when they are immature (Sernagor & Grzywacz, *J. Neurophysiol.*, 1995).

To study the role of these bursts in shaping mature RF properties, we have investigated their development during chronic blockade of the bursts. We have used curare, a cholinergic nicotinic blocker, because it eliminates the bursts *in vitro* (Sernagor & Grzywacz, *ARVO*, 1994). Curare (1 mM) was mixed to the slow-release polymer Elvax 40W. Pieces of Elvax were implanted intraocularly at different developmental stages, and extracellular recordings of light responses were obtained at 1 month PH. Both RF areas and the incidence of GCs with concentric RFs were significantly smaller in curarized retinas than in normal ones. The earlier curare was applied, the more pronounced the effects were. When curare was applied at hatching and turtles were dark-reared, RF areas did not expand as in non-curarized dark-reared turtles (Sernagor & Grzywacz, *Neurosci. Abstr.*, 1994). The curarized dark-reared RFs resembled those of curarized GCs raised in the light. The incidence of concentric RFs was similar in curarized retinas that developed either in normal light or in the dark, and in non-curarized dark-reared retinas. We have previously reported that the incidence of orientation selectivity is lower in dark-reared retinas. However, curare had no effect on that property.

These results demonstrate that early acetylcholine-dependent spontaneous bursts, but not light, control the development of RF areas. As GCs develop more specialized functional properties, light becomes more involved in their maturation. Both spontaneous bursts and light-driven activity are required for the maturation of concentric RFs. Finally, maturation of orientation selectivity depends primarily on visual experience. **OPTIC NERVE STIMULATION ELICITS EVOKED RESPONSES IN SUPERIOR COLLICULUS OF EMBRYONIC RATS *IN VITRO*.** L.J. Reece\* and C.H. Lim. Developmental Neurobiology Group, Research School of Biological Sciences, The Australian National University, Canberra, ACT 2601

Recent experiments *in vivo* indicate there is no optic nerve conduction in the rat until P0 and no response to visual stimuli in the colliculus until P10, close to the time of eye opening (1). Our recent *in vitro* findings of early capacity for synaptic function in the superior colliculus of the wallaby well before the onset of eye opening have led us to examine similar questions in the visual system of the rat.

Evoked responses were examined in the superior colliculus of late embryonic and early postnatal rat pups (E14 - P6) in a standard perfusion chamber. The preparation consisted of a hemi-mesencephalic/diencephalic preparation with the contralateral optic nerve intact. Responses were robust, long-lasting and could be elicited with relatively low voltage low frequency bipolar stimulation. Evoked potentials were seen as early as E18; these potentials were blocked by cobalt (a calcium blocker) and by kynurenic acid (a glutamatergic antagonist). In addition, several potentials reversed with depth, another indication of synaptic activity. Replacement of sodium by choline completely blocked the responses, indicating that sodium, not calcium, is the primary ionic carrier for axonal conduction. Responses were detected in caudal colliculus as early as E18, and conduction velocity averaged around 0.1 m/s. Application of gamma-aminobutyric acid (GABA) blocked the potential in a dose-dependent manner as early as E18; this action was itself blocked by bicuculline methiodide (BMI), a GABA-A antagonist. Our studies show there is clearly conduction in the optic nerve plus a capacity for synaptic function in the colliculus at early ages in an *in vitro* preparation; we are pursuing the question of why the *in vitro* and *in vivo* results differ dramatically.

## 591.3

SPONTANEOUS BURSTING OF GANGLION CELLS IN THE DEVELOPING RETINA REQUIRES SYNAPTIC INPUT. M.B. Feller\*, D.P. Wellis, F.S. Werblin, C.J. Shatz. HHMI and Dept. of Molecular and Cell Biology, University of California, Berkeley, CA 94720.

Ganglion cells in the neonatal ferret retina spontaneously fire bursts of action potentials in the form of excitatory waves that propagate across the retina. Ganglion and amacrine cells also undergo periodic spontaneous increases in intracellular calcium concentration in a correlated fashion (Wong et al., Nature 374:716 1995). How is this activity generated at these ages, when the photoreceptors and bipolar cells are immature and not yet functional?

Combined optical imaging of fura-2 stained neonatal retinas (P0-P12) and whole cell voltage clamp recordings reveal that the periodic bursts of activity recorded in the ganglion cell layer are generated synaptically. Cells undergo a barrage of inward synaptic currents that reverse near 0 mV with a period ranging from 2-4 minutes. The synaptic currents in an individual ganglion cell, as well as the correlated waves of activity in many ganglion cells, were blocked by bath application of 100µM d-tubocurarine, a nicotinic acetylcholine receptor antagonist, or 10µM nicotine, an agonist whose tonic exposure desensitizes the receptor. Propagating waves were evoked experimentally by locally puffing potassium or nicotine at ganglion and amacrine cell processes.

Since the only known cholinergic cell type in the mammalian retina is a subset of amacrine cells, these results suggest that a requirement for the spontaneous correlated activity in ganglion cells is synaptic input from cholinergic amacrine cells.

## 591.5

SPONTANEOUS RETINAL INPUTS DRIVE POSTSYNAPTIC ACTION POTENTIALS IN THE LGN. A. A. Penn\*, R. Gallego, R. Mooney, and C.J. Shatz. HHMI & Dept. Molec. & Cell Biol., UC, Berkeley, CA 94720.

Correlated spontaneous activity coming from the retina during early development is thought to play a key role in guiding the formation of highly ordered connections in the visual system. But is this activity transmitted to the LGN?

We developed an *in vitro* preparation in neonatal mice in which both retinas, the retinogeniculate pathway and the LGN neurons are intact. With extracellular microelectrodes placed in the LGN, we obtained multiunit and single unit recordings of periodic bursts of spikes with an interburst periodicity resembling that of the retinal signal (30s-90s). Individual units showed repetitive, signature spiking patterns, but there was a wide range of spike patterns between individual units. To demonstrate that we were recording the postsynaptic activity of the LGN neurons, we used the fact that the retinogeniculate synapse is glutamatergic, but the spontaneous activity of the RGCs is not affected by the glutamate blockade. Application of 10µM CNQX blocked all spike activity when the electrode was in the LGN, but periodic bursting activity was maintained in the optic tract. The similarity of the periodicity of the bursts to the synaptic currents which have been recorded in the postsynaptic neurons in the same preparation (R. Mooney et al., Soc. Neurosci. Ab., '95) is further evidence that the postsynaptic neurons are driven to spike by retinal inputs. These results lend strong support to the hypothesis that correlated retinal activity can drive activity-dependent synaptic reorganization within the LGN. Moreover, because LGN neurons receive sufficiently strong inputs to generate bursts of action potentials, it is possible that even at very early times in development, information from the retina is relayed all the way to the visual cortex.

## 591.7

A LOCAL CORTICAL SOURCE OF NEUROTROPHIN RESCUES LATERAL GENICULATE NEURONS FROM THE EFFECTS OF MONOCULAR DEPRIVATION. D.R. Riddle\* and L.C. Katz, Department of Neurobiology, Duke University Medical Center, Durham, NC 27710.

Monocular deprivation during the critical period leads to marked shrinkage of neurons in the deprived-eye layers of the lateral geniculate nucleus (LGN). This atrophy may result from a decreased ability of less active LGN neurons to compete for some neurotrophin. We tested this possibility directly using a novel method for *in vivo* delivery of neurotrophins. Fluorescent latex microspheres were coated with NT-4, NT-3 or BDNF. Small adjacent injections of control and neurotrophin-coated microspheres were placed in the visual cortex of ferrets (P38-P45) and the contralateral eye was sutured closed. Since microspheres are retrogradely transported, it was possible to determine precisely which neurons in the LGN were exposed to, bound and internalized the neurotrophin. After four days, 250-700 cells labeled with NT-4-coated microspheres and a similar number of cells containing control microspheres were measured in coded sections of the ipsilateral LGN of each animal. Neurons containing control microspheres were 17% smaller in the closed-eye layer than in the open-eye layer ( $199 \pm 9$  vs  $241 \pm 8 \mu m^2$ , mean  $\pm$  sem,  $N=6$  animals,  $p<0.001$  by paired t-test). Cells in the closed-eye layer that contained NT-4-coated microspheres, however, showed no such shrinkage ( $239 \pm 11$  vs  $241 \pm 8 \mu m^2$ ,  $p>0.3$ ). Neurons in the open-eye layer that contained NT-4-coated microspheres were no larger than control neurons ( $246 \pm 7$  vs  $241 \pm 8 \mu m^2$ ,  $p>0.01$ ). Thus, the data reflect specific rescue of cells in the closed-eye layer from the presumed effects of a competitive imbalance, rather than a general growth promoting effect. Preliminary evidence indicates that neither NT-3 nor BDNF has a similar rescue effect. These results, taken together with evidence that exogenous NT-4 blocks normal development of ocular dominance columns (Cabelli et al., 1995, *Science* 267:1662), provide evidence for a link between activity-dependent competitive interactions and the control of neuronal growth and connectivity by neurotrophins. Supported by EY06617 (DRR) and EY07690 (LCK). We thank Regeneron Pharmaceuticals Inc. for the generous gift of the neurotrophins.

## 591.4

PERIODIC SYNAPTIC CURRENTS IN THE NEONATAL LGN ARE GENERATED BY RETINAL ACTIVITY. R. Mooney\*, A. A. Penn, and C. J. Shatz. HHMI & Dept. Molec. & Cell Biol. UC, Berkeley, CA 94720.

Electrophysiological and optical recording techniques show that in neonatal ferrets, rats and mice, before the onset of photoreceptor function, retinal ganglion cells generate high frequency periodic bursts of action potentials that propagate in waves across the retina. Are these patterns of retinal ganglion cell activity detectable within the LGN and, if so, what effect do they have on the electrical activity of LGN neurons?

To address these questions, we developed an *in vitro* preparation of the neonatal mouse brain containing both retinas connected to the LGN. In P0-P4 mice, highly periodic barrages of postsynaptic currents (PSCs) were observed when whole cell voltage clamp techniques were used to record synaptic currents from individual LGN neurons. These PSCs had a periodicity like the bursts exhibited by the retinal ganglion cells themselves (ca. every 30-90 seconds), were glutamatergic, and were reversibly blocked by applying lidocaine to the optic nerve, indicating that they were the result of the periodic retinal activity. Although the average PSC amplitude recorded in the LGN was quite small (ca. 5-10 pA), these PSCs could strongly depolarize the postsynaptic membrane. When the postsynaptic cell was taken out of voltage clamp, the periodic barrage of synaptic activity caused the cell to undergo a prolonged depolarization, which could drive the cell to generate bursts of action potentials. Therefore, periodic waves of retinal activity strongly influence the electrical behavior of LGN neurons, and could function in activity-dependent synaptic reorganization within the LGN.

Supported by NSF IBN 93-19539, March of Dimes, NIMH 48108 to C.J.S., H.H. Whitney to R.M., & M.S.T.P. Trainee GM 07365 to A.A.P.

## 591.6

EARLY DEVELOPMENT OF RETINOGENICULATE PROJECTIONS IN THE FETAL PRIMATE. C. Meissire\* and L.M. Chalupa, Dept. of Neurobiology, Sect. of Neurobiology, Physiology and Behavior, University of California, Davis, CA 95616.

A hallmark of the primate visual system is the unique segregation of the magno- and parvocellular pathways from the retina to the cortex. Since little is known about the prenatal development of such pathways we have investigated the target specificity of retinofugal projections in the developing rhesus monkey. Two carbocyanine dyes, dil and diA, were implanted in the optic nerve, or optic tract, of fixed specimens, ranging in age from embryonic (E) day 48 to E78 (gestation 165 $\pm$ 2 days). After an appropriate storage time at 37°C coronal sections were cut with a vibratome and anterograde labeling was examined using confocal microscopy. By E48, the first retinal axons were seen to navigate through the inner part of the dLGN to their distal midbrain targets. At this age, the more numerous crossed contingent of retinal fibers establishes a few collaterals at the level of the pregeniculate and dLGN, whereas the uncrossed contingent remains unbranched. By E53, the density of collaterals increases in the contralateral pregeniculate and dLGN. Remarkably, these branches are exclusively located in the medial part of the dLGN (the presumed parvocellular anlage) and avoid its lateral counterpart, where the magnocellular layers will emerge. By E65 a dense ramification of axonal branches is still strictly confined to the inner part of the dLGN in the prospective parvocellular layers. The magnocellular layers are not innervated until E 78, some 3 weeks after retinal fibers first invade the dLGN anlage. These observations suggest that the retinogeniculate parvocellular pathway is formed much earlier than the magnocellular pathway. (Supported by NIH EY08763 and RR00169. CM supported by M.R.E.)

## 591.8

PRENATAL DEVELOPMENT OF THE HUMAN RETINOGENICULATE PROJECTION STUDIED WITH DIL. B.F. Heyner\*, Dept. of Pathology (Neuropathology), Stanford Univ. Med. Ctr., Stanford, CA 94305-5324.

The adult mammalian lateral geniculate nucleus (LGN) is divided into histologic laminae which receive monocular afferent inputs from either the left or right retina. During fetal development, the LGN initially appears as a homogeneous cell mass, with lamination occurring later in gestation. Previous studies in animals have shown that left and right eye inputs to the developing LGN initially overlap, and are subsequently segregated into eye-specific layers which correspond to the histologic laminae of the LGN. Shatz (J. Neurosci. 3:482-499, 1983) has shown that afferent segregation occurs prior to histologic lamination of the LGN, by about 2 weeks in cats.

In the developing human LGN, early histologic lamination is observed at about 22 weeks gestational age (GA). To determine if the segregation of left and right eye afferents precedes histologic lamination in the human LGN, the lipophilic tracer dil was injected into one optic nerve ( $n=2$ ) or optic tract ( $n=4$ ) of normal 20-22 weeks GA human fetal brains, which were obtained at post mortem examination and fixed in paraformaldehyde. After 6-10 months diffusion, sections through the LGN were cut in the coronal plane on the freezing sliding microtome, counterstained with DAPI, and examined by fluorescence microscopy. Following optic nerve injections, dil fluorescence in the LGN was localized to distinct alternating bands, presumed to be the precursors of histologic laminae. In contrast, optic tract injections labeled the entire LGN diffusely (except for cell-sparse zones between developing histologic laminae in 22 weeks GA brains). In all cases, fluorescence was strictly localized to the developing retinogeniculate pathway, without labeling of adjacent nuclei or tracts.

These results indicate that the segregation of left and right eye afferents in the human LGN begins prior to 20 weeks GA, and precedes histologic lamination by at least 2 weeks.

## 591.9

**TRANSIENT TENASCIN-IMMUNOREACTIVE BOUNDARIES DURING THE DEVELOPMENT OF FUNCTIONAL LAYERS IN FERRET LATERAL GENICULATE NUCLEUS** C.M. Müller<sup>1</sup>\*, A. Faissner<sup>2</sup> and S. Altrögge<sup>3</sup>. \*Max-Planck-Institute for Developmental Biology, 72076 Tübingen, Germany; <sup>2</sup>Dept. Neurobiol., University Heidelberg, 69120 Heidelberg, Germany.

The thalamic dorsal lateral geniculate nucleus (dLGN) of the adult ferret visual pathway reveals distinct anatomical layers receiving selective input from the contralateral (A) and ipsilateral (A1) eye, respectively. These layers are further subdivided into sublaminae innervated by "on"- and "off"-center ganglion cells. In ferret, the parcellation of these functional units occurs postnatally under the influence of retinal activity by axonal remodeling. The astroglia derived matrix molecule tenascin has been shown to influence axonal growth and is transiently expressed at developing functional boundaries in the CNS, e.g. around the somatosensory barrels in rodent cortex (Steindler et al., *Dev. Biol.* 131:243,1989). Using immunocytochemistry we investigated the spatio-temporal expression of tenascin in the dLGN. Our data show that strong tenascin immunoreactivity (TN-IR) is uniformly distributed in the dLGN during the first postnatal week. A prominent band of TN-IR is present at the boundary between the dLGN and the perigeniculate nucleus at P7. In the second postnatal week TN-IR in dLGN becomes strongest in the region of the future interlaminar zone between A and A1. This pattern is due to a reduction of tenascin-IR within the future layers and coincides with the time of segregation of the ipsi- and contralateral retinothalamic projections. A further distinct TN immunoreactive band occurs within lamina A during the third postnatal week, spatio-temporally coincident with the segregation of "on"- and "off"-laminae. We propose that tenascin plays a role in the formation of the functional subdivisions of the dLGN, most probably by restricting axonal growth to individual sublaminae during the process of activity-dependent reorganization of retino-thalamic projections. ## 591.10

**SELF-ORGANIZING SENSORY MAP FORMATION ACHIEVED WITH A PURELY LOCAL LEARNING RULE MAXIMIZING INFORMATION-THEORETIC ENTROPY** Marc M. Van Hulle<sup>\*</sup> Laboratorium voor Neuro- en Psychofysiologie, K.U.Leuven, Faculteit Geneeskunde, Campus Gasthuisberg, Herestraat, B-3000 Leuven, Belgium.

Models accounting for the formation of sensory maps from simple principles of self-organization abound in the literature. One of the most successful models in this respect is the Kohonen rule and its many variations. A key feature of this unsupervised competitive learning rule is the neighborhood connection kernel whose range shrinks over time. There are several problems with this procedure: If the neighborhood kernel shrinks too fast, then several topological defects may occur that will not be resolved. Moreover, as long as the neighborhood is present, the correct criterion (error potential) is not minimized. Furthermore, when the neighborhood kernel has disappeared, the resulting map will undersample high probability regions and oversample low probability regions of the afferent input space. However, the biological evidence shows that the central representation simply follows the peripheral sensor density: it is not necessary to postulate an additional magnification in the lateral geniculate nucleus or the primary visual cortex (Wässle et al., *Nature*, 1989). In addition, in the Kohonen rule, global communication between all neurons is needed to determine the unique "winner" neuron, which again is biologically implausible. We will show that it is possible to achieve sensory maps with an unsupervised learning rule performing local weight updates only, and thus without requiring shrinking neighborhood kernels and global connection kernels: the rule requires only communication among immediate neighbors. The rule maximizes the information transfer (information-theoretic entropy) of the map. Its convergence and speed of convergence can be shown formally. We will apply the rule to retinotopic map formation and verify that it approximates the magnification factor found in the visual cortex.

The author is a senior research associate of the National Fund for Scientific Research (Belgium).

## VISUAL CORTEX: STRIATE V

## 592.1

**SPATIOTEMPORAL ANALYSIS OF JOINT FIRING OF NEURONS IN MONKEY V1** K.P. Purpura<sup>\*</sup>, E. Katz and J.D. Victor. Dept. Neurol. & Neurosci., Cornell Univ. Med. College, New York, N.Y. 10021.

We have developed a new method for analyzing the joint firing of visually-driven neural activity. This method departs from conventional methods of crosscorrelation analysis in that details of receptive field structure and dynamics are preserved in a spatiotemporal map of the joint firing. Multi- and single electrode pair recordings were made in the striate cortex of anesthetized/paralyzed macaque monkeys. Stimuli consisted of arrays of luminance checks or oriented bars driven by multi-input pseudorandom binary M-sequences. A data set consisted of the responses elicited from 16 presentations of a given M-sequence, with every other run an inverted repeat. Standard techniques were used to calculate the 1st- and 2nd-order spatiotemporal kernels. To estimate the joint firing between two channels of activity the time of occurrence of a spike on one channel (binned to 4 ms) was used as the center point for a temporal window onto the other channel. If a spike occurred in the latter channel within the temporal window a spike was added to the measure of joint firing at the time point in the M-sequence corresponding to the occurrence of the spike in the first channel. The joint firing activity was crosscorrelated against the M-sequence to produce binary spatiotemporal kernels just as was done with the individual channels. Joint activity typically appeared in regions of receptive field overlap. These maps of joint firing, however, could not determine if the joint activity was due merely to common driving by the stimulus or to interactions between the channels. To resolve the origin of joint firing a "shuffled" measure was produced by taking one channel of activity from one M-sequence presentation and the other channel from one of the other repeats of the sequence. Many of the maps of joint V1 activity produced by the shuffle closely resembled those of the unshuffled maps indicating that many neural pairs were driven independently by the stimulus. However, we did find several pairs for which a large part of the joint firing arose from neural interactions. The magnitude, spatial distribution and time course of these interactions will be discussed.

## 592.3

**SHORT AND LONG-RANGE RESPONSE SYNCHRONIZATION IN MACAQUE STRIATE CORTEX** S.R. Friedman-Hill<sup>\*</sup>, P.E. Maldonado and C.M. Gray. Center For Neuroscience, University of California, Davis, CA 95616

We investigated the incidence and stimulus-dependence of local and distant temporal correlations in areas V1 and V2 of the awake macaque. For single units recorded from the same site, 36% exhibited significant local synchrony. The cross correlation functions (CCF) were characterized by semi-periodic oscillation with a mean frequency of 49±6 Hz, in 92% of pairs. For the group of pairs with oscillatory CCFs, 64% had periodic ACFs for both units and 36% had periodic ACFs for one member of the pair. We also examined the incidence of cross correlations between single units recorded at sites separated by 3-5mm. Only one pair demonstrated significant CCFs. However, our present sample contains only one instance where both units have rhythmic ACFs.

Cross-correlation analysis of multiunit activity (MUA) recorded at two sites separated by 3-5mm yielded significant correlations in 38% of the pairs, with a mean frequency of 49±6 Hz. In 91% of these pairs, the ACFs of the MUA at both sites showed significant oscillations. Shared orientation preference did not appear to play a strong role in determining whether two sites exhibited synchrony. Although there were no instances of correlations between sites with orientation preference more than 67° apart, there were equivalent rates of synchrony (~50%) for sites with tuning differences of 0°, 22°, and 45°.

Oscillatory activity is a strong predictor of short and long-range cross correlation. Although there were instances of non-significant CCFs when one or both members of a pair had rhythmic ACFs, we found no instances of significant CCFs when both sites had non-rhythmic ACFs.

## 592.2

**STIMULUS-DEPENDENT NEURONAL OSCILLATIONS IN AREAS V1 AND V2 OF THE ALERT MACAQUE MONKEY** C.M. Gray<sup>\*</sup>, S.R. Friedman-Hill and P.E. Maldonado. Center for Neuroscience, Univ. of Calif., Davis, CA 95616.

Although abundant in the cat, studies of the occurrence and properties of stimulus-dependent neuronal oscillations in the visual cortex of the monkey have led to conflicting results. In an effort to resolve these differences we have performed multiunit and single unit recordings in areas V1 and V2 in two macaque monkeys trained to perform a visual fixation task. Cells were activated by drifting and stationary light bars and spatial frequency gratings. The occurrence of oscillations was evaluated using correlation and spectral analyses. In V1 48% of multiunit recordings and 30% of single unit recordings exhibited statistically significant oscillatory firing. The mean frequency was 52±7 Hz and 50±7 Hz, respectively. In V2 34% of multiunit recordings were oscillatory, having a mean frequency of 49±8 Hz. In no instance did we observe significant oscillations in trial-shuffled correlograms (i.e. the shift predictor), nor were any significant spectral peaks encountered at 80 Hz, the refresh rate of our video monitor. These data exclude the possibility that the oscillations were driven, in a time-locked fashion, by the visual stimulus. The oscillatory modulation was greatest for the preferred stimulus and decreased at stimulus directions, spatial frequencies and luminance values away from the optimum. Little or no oscillatory modulation was present in the spontaneous activity of oscillatory cells. Stationary stimuli evoked oscillatory responses of equal magnitude, but lower frequency, than those evoked by moving stimuli (moving freq=56±5 Hz, static freq=42±9 Hz, p<0.003). Finally, the oscillatory firing of single cells typically consisted of repetitive sequences of high frequency bursts of action potentials "chattering". The similarity of incidence, magnitude, frequency and stimulus dependence of oscillatory activity in cat and monkey suggest that this phenomenon is a general property of mammalian visual cortex. Supported by NEI (EY08686-06) and the Klingenstein Foundation.

## 592.4

**TIME COURSE AND FREQUENCY DISTRIBUTION OF OSCILLATORY FIRING PATTERNS IN THE MACAQUE PRIMARY VISUAL CORTEX** P.E. Maldonado<sup>\*</sup>, S.R. Friedman-Hill and C.M. Gray. Center for Neuroscience, University of California, Davis, CA 95616.

We have demonstrated the presence of stimulus-dependent oscillatory firing patterns in single and multiunit recordings from the primary visual cortex of alert macaque, while performing a simple visual fixation task. We examined whether the frequency distribution for oscillatory firing patterns across the sample (40 - 65 Hz), was similar to that of the responses of single units across consecutive presentations of the same square-wave drifting grating. For 35 single units studied, we found that the frequency distribution across 20 to 30 trials was statistically similar (P < 0.01) to that across cells. This suggests that single cells do not exhibit a constant oscillation frequency, but rather fluctuate from trial to trial, within a broad range.

The typical response of oscillating single units to a square-wave drifting grating consists of an initial transient ON response of 50 msec duration, followed by a less intense, sustained response that continues as long as the stimulus is presented in the visual field. Correlation and spectral analysis of the temporal firing patterns of 25 single neurons during the ON and the sustained response revealed that during the ON response there were no significant oscillations, whereas significant oscillations are detected during the extent of the sustained response. Thus, oscillatory firing patterns do not arise immediately upon the stimulus onset, but they develop during the subsequent sustained response. A similar analysis performed in 20 cell pairs that exhibited short range synchronous oscillations resulted in a similar temporal pattern. These results suggest that adjacent cells that are located in the same minicolumn, initially exhibit asynchronous firing that becomes synchronized at longer latencies. Supported by NEI EY08686-06 and the Klingenstein Foundation.

## 592.5

**WHY NEURONS MAKE BAD COINCIDENCE DETECTORS BUT GOOD PERIODICITY DETECTORS** B. Mel, Dept. Biomed. Engin., USC 1451, Los Angeles, CA 90089, E. Niebur, D. W. Croft & F. Gabbiani, CNS, Caltech 139-74, Pasadena, CA 91125.

It has been suggested that the visual system and other sensory systems use temporal codes. We study how neurons respond to temporal structure in their inputs using simulations of (1) a 164-compartment pyramidal cell with passive or active dendrites, and NMDA or non-NMDA type synaptic input, and (2) a single-compartment integrate-and-fire neuron. In each run, 100 randomly placed excitatory synapses were activated at 100 Hz and the cell's mean output firing rate was recorded. In different runs, and over a range of peak excitatory synaptic conductances, the temporal structures of input spike trains was varied along 2 continuous dimensions: synchronicity (S) and periodicity (P).  $S=0$  meant complete asynchrony and  $S=1$  complete synchrony among trains;  $P=0$  meant Poisson and  $P=1$  periodic trains. Surprisingly, only modest increases in output firing rate were seen as S increased from 0 to 1, and only for the smallest peak synaptic conductances studied. In these cases, input coincidences were required for the cell to reach firing threshold. More surprisingly, the output firing rate was dependent on P over essentially the entire range of peak synaptic conductances studied; 3-fold increases in output firing rate were common as P increased from 0 to 1. This is explained by the fact that increases in P reduced synaptic saturation (i.e. loss of driving force) due to accidental temporal overlap of EPSPs within individual input trains.

**EEG COHERENCE IN POST-LSD PERSISTING PERCEPTUAL DISORDER.** H.D. Abraham, F.H. Duffy. Neurophysiology Lab., Children's Hospital, Boston, MA 02115.

LSD, a potent hallucinogenic drug, is capable of causing apparently permanent hallucinations and pseudohallucinations in certain vulnerable individuals. This disorder, hallucinogen persisting perceptual disorder (HPPD), has been related to disinhibition of the visual apparatus of the CNS by studies of visual psychophysics, including CFF and dark adaptation studies, and quantified electroencephalography. In the latter, we found that visual hallucinators had decreased latencies for the P200 visually evoked potential waveform, and faster alpha frequencies. Accordingly, we studied the direction, degree and regionalization of cortical EEG coherence in 38 subjects with post-LSD visual disorder and 88 LSD naive controls. We found statistical increases in regional cortical coupling in the HPPD subjects involving the primary visual, temporal and posterior parietal cortices, and decreases bifrontally. Coherence was negatively associated with P200 latency, and positively associated with alpha frequency. These data suggest that in HPPD visual disinhibition is positively associated with increases in neuronal coherence in regions of the cerebrum serving visual function. The ramifications of this finding in light of recent neurobiological models of attention are discussed.

**CORTICAL AND THALAMIC CORRELATES OF INDUCED BRIGHTNESS** A.F. Rossi\*, C.D. Rittenhouse, and M.A. Paradiso Department of Neuroscience, Brown University, Providence, RI, 02912

Brightness changes can be induced in a static field by modulating the luminance of surrounding areas. We used this induction phenomenon to investigate the neural representation of brightness. Extracellular recordings were made from neurons in striate cortex and LGN of anesthetized cats using stimuli that produced brightness induction. While a cell's classical receptive field (CRF) was covered by a uniform gray field, the luminance of rectangular flanking regions was modulated sinusoidally in time, inducing brightness modulation in the CRF roughly in antiphase to the luminance modulation of the flanks. While some neurons were unaffected by the flanking stimuli, many others responded in a phase-locked manner at the temporal frequency of the flank modulation. In two important respects the response of the modulated neurons was correlated with perceived brightness. First, for many neurons the response modulation induced by the flanks was phase shifted by 180 deg. compared with the response to luminance modulation in the CRF. This is consistent with the phase shift in perceived brightness seen in the central field. Second, the luminance modulation rates that produced neural modulation were similar to those that perceptually produced brightness induction. Perceptually, brightness changes can only be induced at surprisingly low temporal frequencies (below about 3 Hz), whereas brightness changes resulting from direct luminance modulation occur up to the flicker fusion rate (30-60 Hz). We found that the responses of neurons significantly decreased when the luminance modulation of the flanks was 2 Hz or higher. Importantly, this reduced response to higher frequency luminance modulation was not observed in conditions where the luminance was modulated within the CRF. These findings suggest that brightness information is explicitly represented in the responses of neurons at early stages in the visual system. **PHYSIOLOGICALLY IDENTIFIED CELL GROUPS HAVE DISTINCT RECEPTIVE FIELD AND MORPHOLOGICAL PROPERTIES IN CAT STRIATE CORTEX.** D.A. McCormick\* and C.M. Gray\*. \*Yale Univ. Med. Sch. 333 Cedar St. New Haven CT 06510 and #Center for Neurosci., Univ. Cal., Davis, CA 95616

Neurons of the visual cortex have been characterized according to their morphology, intrinsic membrane properties, and receptive field responses, while the relationships between these features have been only partially defined. Here we performed intracellular recordings from neurons in cat striate cortex with biocytin-filled microelectrodes and correlated the morphology and receptive field properties of neurons with identified intrinsic membrane properties. Four distinct electrophysiological groups were noted: 1) Regular spiking; 2) Intrinsic Burst-generating; 3) Fast Spiking; and 4) Chattering. Regular spiking neurons formed a heterogeneous group of cells, both morphologically and in visual response properties, and were typically pyramidal cells in layers II, III, V or VI exhibiting simple or complex receptive fields. Intrinsic burst-generating neurons generated single bursts of 3-5 action potentials as well as tonic, single spike activity, were large layer V pyramidal cells, and exhibited complex receptive fields. Fast spiking neurons exhibited short duration (< 1 msec) action potentials, could generate high frequency (> 350 Hz) discharges, and were local interneurons. Chattering neurons, characterized by the generation of short duration (< 1 msec duration) action potentials in high frequency (>350 Hz) bursts, were layer II-III spiny neurons, had simple receptive fields, were the most visually responsive of the 4 classes, and generated rhythmic bursts of action potentials at 20-60 Hz upon delivery of an optimal visual stimulus or with the injection of a constant current pulse. Autocorrelograms revealed that 20-60 Hz oscillations in the visual response were typical only for chattering cells, suggesting that these neurons are the pacemakers for the generation of cortical 20-60 Hz synchronized oscillations. These results indicate that distinct cell types in the primary visual cortex perform unique tasks in local circuit activity that is dependent upon their intrinsic membrane properties as well as their anatomical connections.
